`text2list` splits a character string into a list of substrings, using the strings in the list `separators` as delimiters. `text2list` returns a list containing the substrings.

Without the option `Cyclic`, the text is split as follows. The first occurrence of one of the delimiters in `separators` is located in `text`. If no delimiter is found, the full text is returned as the only substring. Otherwise, the substring up to the delimiter defines the first substring. The delimiter is the second substring. The remaining text is processed as above until there are no more characters left.

Without `Cyclic`, the result does not depend on the order of the delimiters.

With the option `Cyclic`, the first delimiter in `separators` is used to identify the first substring. The delimiter itself is the second substring. Then the second delimiter in `separators` is used to identify the third substring etc.

After using the last delimiter of the list, the first one is used again, until the whole text is processed or until the current delimiter is not found in the remaining text.

With `Cyclic`, the result depends on the order of the delimiters.

`text2list` is a function of the system kernel.

Examples

Example 1

The following example demonstrates the difference in calling `text2list` with and without the option `Cyclic`:

```
text2list("This is a simple example!", ["is", "mp"])
```

```
["Th", "is", " ", "is", " a si", "mp", "le exa", "mp", "le!"]
```

```
text2list("This is a simple example!", ["is", "mp"], Cyclic)
```

```
["Th", "is", " is a si", "mp", "le example!"]
```

Example 2

The following example demonstrates the difference in calling `text2tbl` with and without the option `Cyclic`:

```
text2tbl("This is a simple example!", ["is", "mp"])
```

1	"Th"
2	"is"
3	" "
4	"is"
5	" a si"
6	"mp"
7	"le exa"
8	"mp"
9	"le!"

```
text2tbl("This is a simple example!", ["is", "mp"], Cyclic)
```

1	"Th"
2	"is"
3	" is a si"
4	"mp"
5	"le example!"

Parameters

`text`

The text to be analyzed: a character string

separators

Delimiters: a list of character strings. The empty string `""` is not accepted as a delimiter.

Options

Cyclic

The delimiter list is used cyclicly

Return Values

List, respectively a table, of character strings.

See Also

MuPAD Functions

`coerce` | `expr2text` | `int2text` | `tbl2text` | `text2expr` | `text2int` | `text2tbl`

text2tbl

Split a character string into a table of substrings

Syntax

```
text2tbl(text, separators, <Cyclic>)
```

Description

`text2tbl` splits a character string into a table of substrings, using the strings in the list `separators` as delimiters. `text2tbl` returns a table, using the indices `1`, `2`, `3` etc.

Without the option `Cyclic`, the text is split as follows. The first occurrence of one of the delimiters in `separators` is located in `text`. If no delimiter is found, the full text is returned as the only substring. Otherwise, the substring up to the delimiter defines the first substring. The delimiter is the second substring. The remaining text is processed as above until there are no more characters left.

Without `Cyclic`, the result does not depend on the order of the delimiters.

With the option `Cyclic`, the first delimiter in `separators` is used to identify the first substring. The delimiter itself is the second substring. Then the second delimiter in `separators` is used to identify the third substring etc.

After using the last delimiter of the list, the first one is used again, until the whole text is processed or until the current delimiter is not found in the remaining text.

With `Cyclic`, the result depends on the order of the delimiters.

`tbl2text` restores strings split by `text2tbl`.

`text2tbl` is a function of the system kernel.

Examples

Example 1

The following example demonstrates the difference in calling `text2list` with and without the option `Cyclic`:

```
text2list("This is a simple example!", ["is", "mp"])
```

```
["Th", "is", " ", "is", " a si", "mp", "le exa", "mp", "le!"]
```

```
text2list("This is a simple example!", ["is", "mp"], Cyclic)
```

```
["Th", "is", " is a si", "mp", "le example!"]
```

Example 2

The following example demonstrates the difference in calling `text2tbl` with and without the option `Cyclic`:

```
text2tbl("This is a simple example!", ["is", "mp"])
```

1	"Th"
2	"is"
3	" "
4	"is"
5	" a si"
6	"mp"
7	"le exa"
8	"mp"
9	"le!"

```
text2tbl("This is a simple example!", ["is", "mp"], Cyclic)
```

1	"Th"
2	"is"
3	" is a si"
4	"mp"
5	"le example!"

Parameters

`text`

The text to be analyzed: a character string

`separators`

Delimiters: a list of character strings. The empty string `""` is not accepted as a delimiter.

Options

`Cyclic`

The delimiter list is used cyclicly

Return Values

List, respectively a table, of character strings.

textinput

Interactive input of text

Syntax

```
textinput(<prompt1>)
```

```
textinput(<prompt1>, x1, <prompt2>, x2, …)
```

Description

`textinput` allows interactive input of text.

`textinput()` displays the prompt "`Please enter text:`" and waits for input by the user. The input is converted to a character string, which is returned as the function's return value.

`textinput(prompt1)` uses the character string `prompt1` instead of the default prompt "`Please enter text:`".

`textinput( prompt1 x1)` converts the input to a character string and assigns this string to the identifier or local variable `x1`. The default prompt is used, if no prompt string is specified.

Several input values can be read with a single `textinput` command. Each identifier in the sequence of arguments makes `textinput` return a prompt, waiting for input to be assigned to the identifier or variable. A character string preceeding the identifier or variable in the argument sequence replaces the default prompt. Cf. "Example 3" on page 1-2109. Arguments that are neither prompt strings nor identifiers or variables are ignored.

The input may extend over several lines. In the output string, MuPAD uses the character `\n` (carriage return) to separate lines.

Input characters with a leading `\` are not interpreted as control characters, but as two separate characters.

The identifiers or variables `x1` etc. may have values. These are overwritten by `textinput`.

Examples

Example 1

The default prompt is displayed, the input is converted to a character string and returned:

```
textinput()
```

```
Please enter text input: << myinput >>
```

```
     "myinput"
```

Example 2

A user-defined prompt is used, the input is assigned to the identifier `x`:

```
textinput("enter your name: ", x)
```

```
enter your name: << Turing >>
```

```
     "Turing"
```

```
x
```

```
     "Turing"
```

```
delete x:
```

Example 3

If several values are to be read, separate prompts can be defined for each value:

```
textinput("She: ", hername, "He:  ", hisname)
```

```
She: << Bonnie >> He:  <<
Clyde >>
```

```
     "Clyde"
```

```
hername, hisname
```

```
     "Bonnie", "Clyde"
```

```
delete hername, hisname:
```

Parameters

`prompt1, prompt2, …`

Input prompts: character strings

`x1, x2, …`

identifiers or local variables

Return Values

Last input, converted to a character string.

TEXTWIDTH

Maximum number of characters in an output line

Description

The environment variable TEXTWIDTH determines the maximum number of characters in one line of screen output.

Possible values: Positive integer smaller than 2^{31}.

Output is broken into several lines if it needs more than TEXTWIDTH characters per line.

Deletion via the statement "`delete TEXTWIDTH`" resets TEXTWIDTH to its default value. Executing the function `reset` also restores the default value.

The minimal value of TEXTWIDTH is 10.

TEXTWIDTH is set to its maximum value 2^{31} - 1 when printing to a text file using `fprint`. Thus, no additional line breaks occur in the output.

TEXTWIDTH does not influence the typesetting of expressions which is available for some user interfaces of MuPAD.

TEXTWIDTH is set to the new number of available columns every time the console is resized.

Examples

Example 1

Set the maximum number of characters in one line of screen output to 15:

```
TEXTWIDTH := 15:
```

Restore TEXTWIDTH to its default value:

```
delete TEXTWIDTH
```

Example 2

The following procedure adds empty characters to produce output that is flushed right:

```
myprint := proc(x) local l; begin
             if domtype(x) <> DOM_STRING then
                x := expr2text(x);
             end_if;
             l := length(x);
             print(Unquoted, _concat(" " $ TEXTWIDTH - l, x))
           end_proc:

myprint("hello world"):  myprint(30!):  myprint("bye bye"):
```

```
                                                          hello world

                                    265252859812191058636308480000000

                                                            bye bye
```

```
delete myprint:
```

See Also

MuPAD Functions

`fprint` | `PRETTYPRINT` | `print`

theta

Theta series

Syntax

```
theta(x)
```

Description

`theta(x)` represents the value of the theta series $\sum_{n=-\infty}^{\infty} e^{-\pi x n^2}$.

The theta series converges for all complex numbers `x` with positive real part.

Floating-point results are computed for floating-point arguments. For other arguments, the function returns symbolically with the imaginary part of complex numbers normalized to lie between zero and 2.

Environment Interactions

When called with a floating-point argument, the function is sensitive to the environment variable `DIGITS` which determines the numerical working precision.

Examples

Example 1

The theta series takes on large values for small positive arguments. Small values are taken on near *I*:

```
theta(0.001), theta(0.001 + I)
```

$$31.6227766,\ 5.092623095\ 10^{-340}$$

Example 2

Since the theta series is (2 i)-periodic, the imaginary part of complex arguments may be reduced:

```
theta(7 + 5*I)
```

$$\text{theta}(7 + i)$$

For exact or symbolic arguments, a symbolic call is returned:

```
theta(3), theta(x)
```

$$\text{theta}(3), \text{theta}(x)$$

Parameters

x

An arithmetical expression

Return Values

Arithmetical expression

See Also

MuPAD Functions
`dedekindEta` | `zeta`

rtime

Measure real time

Syntax

```
rtime()
```

```
rtime(a1, a2, …)
```

Description

`rtime()` returns the real time in milliseconds that elapsed since the start of the current MuPAD session.

`rtime(a1, a2, ...)` returns the real time needed to evaluate all arguments.

The result of `rtime` is the real time. Thus, `rtime` can be used to measure the total time spent by the MuPAD process as well as by external processes spawned from inside the MuPAD session. Note that an interactive call of `rtime()` is not very useful, since the idle time of the user is included. However, `rtime(a1, a2, ...)` often yields a useful and more realistic timing than `time(a1, a2, ...)` if the evaluation of the arguments spawns external processes. Such a situation may arise in a numerical computation because some routines of the `numeric` library call external numerical tools using hardware floats. Cf. “Example 4” on page 7-93.

If no external process besides MuPAD are running, the timings returned by `rtime(a1, a2, ...)` and `time(a1, a2, ...)` roughly coincide.

On computers without “time-sharing”, such as the Macintosh computer, real time and CPU time roughly coincide.

`rtime` is a function of the system kernel.

Examples

Example 1

This example shows how to do a time measurement and assign the computed value to an identifier at the same time. Note that the assignment needs extra parenthesis when passed as argument:

```
time((a := int(exp(x)*sin(x), x)))
```

464.029

```
a
```

$$-\frac{e^x\,(\cos(x)-\sin(x))}{2}$$

```
delete a:
```

Alternatively, one may time groups of statements in the following way:

```
t0 := time():
command1
command2
...
time() - t0
```

Example 2

Here we use `rtime` to compute the elapsed hours, minutes and seconds since this session was started:

```
t := rtime()/1000:
h := trunc(t/3600):
m := trunc(t/60 - h*60):
s := trunc(t - m*60 - h*3600):

print(Unquoted, "This session is running for " .
                h . " hours, " .
```

```
                m . " minutes and " .
                s . " seconds.")
```

```
This
session is running for 0 hours, 0 minutes and 10 seconds.
```

```
delete t, h, m, s:
```

Example 3

To obtain a nicer output, the measured time can be multiplied with the appropriate time unit:

```
time(isprime(2^1000000000 - 1))*unit::msec
```

```
                    280.018 msec
```

Alternatively, use `stringlib::formatTime`:

```
stringlib::formatTime(time(isprime(2^1000000000 - 1)))
```

```
                  "0.280017 seconds"
```

Parameters

`a1, a2, …`

Arbitrary MuPAD objects

Return Values

Nonnegative integer giving the elapsed time in milliseconds.

See Also

MuPAD Functions

`prog::profile` | `time`

More About

- “Measure Time”

time

Measure CPU time

Syntax

```
time()
```

```
time(a1, a2, …)
```

Description

`time()` returns the total CPU time in milliseconds that was spent by the current MuPAD process.

`time(a1, a2, ...)` returns the CPU time needed by the current MuPAD process to evaluate all arguments.

The result of `time()` comprises all the computation time spent by the MuPAD process. This includes the time for system initialization and reading input (parsing). However, it excludes the time spent by other external processes, even if they were spawned from inside the MuPAD session or if they were started by a `system` command. Further, in an interactive session, the idle time between the execution of MuPAD commands is excluded.

If no external process besides MuPAD are running, the timings returned by `rtime(a1, a2, ...)` and `time(a1, a2, ...)` roughly coincide.

The time returned by `time` is computed in a system-dependent way, usually counting the number of clock ticks of the system clock. Hence, the result is a multiple of the system's time unit and cannot be more precise than 1 such unit. E.g., the time unit is 10 milliseconds for many UNIX systems.

On computers without “time-sharing”, such as the Macintosh computer, real time and CPU time roughly coincide.

`time` is a function of the system kernel.

Examples

Example 1

This example shows how to do a time measurement and assign the computed value to an identifier at the same time. Note that the assignment needs extra parenthesis when passed as argument:

```
time((a := int(exp(x)*sin(x), x)))
```

464.029

```
a
```

$$-\frac{e^x\,(\cos(x)-\sin(x))}{2}$$

```
delete a:
```

Alternatively, one may time groups of statements in the following way:

```
t0 := time():
command1
command2
...
time() - t0
```

Example 2

Here we use `rtime` to compute the elapsed hours, minutes and seconds since this session was started:

```
t := rtime()/1000:
h := trunc(t/3600):
m := trunc(t/60 - h*60):
s := trunc(t - m*60 - h*3600):

print(Unquoted, "This session is running for " .
                h . " hours, " .
```

```
                m . " minutes and " .
                s . " seconds.")
```

```
This
session is running for 0 hours, 0 minutes and 10 seconds.
```

```
delete t, h, m, s:
```

Example 3

To obtain a nicer output, the measured time can be multiplied with the appropriate time unit:

```
time(isprime(2^1000000000 - 1))*unit::msec
```

```
                    280.018 msec
```

Alternatively, use `stringlib::formatTime`:

```
stringlib::formatTime(time(isprime(2^1000000000 - 1)))
```

```
                  "0.280017 seconds"
```

Parameters

`a1, a2, …`

Arbitrary MuPAD objects

Return Values

Nonnegative integer giving the elapsed time in milliseconds.

More About

- “Measure Time”

transpose

Transpose of a matrix

Syntax

```
transpose(A)
```

Description

`transpose(A)` returns the transpose A^t of the matrix A.

The transpose of the $m \times n$ matrix A is the $n \times m$ matrix B with $B_{i,j} = A_{j,i}$.

If the input is a matrix of category `Cat::Matrix`, then `linalg::transpose` is called to compute the result. In contrast to the linalg routines, the function `transpose` also operates on `array`s and `hfarray`s.

If the argument does not evaluate to a matrix of one of the types mentioned above, symbolic call `transpose(A)` is returned.

Examples

Example 1

The following matrix is real. Thus, the Hermitian transpose coincides with the transpose:

```
A := array(1..2, 1..2, [[1, 2], [3, PI]])
```

$$\begin{pmatrix} 1 & 2 \\ 3 & \pi \end{pmatrix}$$

```
transpose(A) = htranspose(A)
```

$$\begin{pmatrix} 1 & 3 \\ 2 & \pi \end{pmatrix} = \begin{pmatrix} 1 & 3 \\ 2 & \pi \end{pmatrix}$$

In general, this does not hold for complex matrices:

```
A := hfarray(1..2, 1..3, [[1, I, 3 + I], [PI*I, 4, 5]])
```

$$\begin{pmatrix} 1.0 & 1.0\,i & 3.0+1.0\,i \\ 3.141592654\,i & 4.0 & 5.0 \end{pmatrix}$$

```
transpose(A) <> htranspose(A)
```

$$\begin{pmatrix} 1.0 & 3.141592654\,i \\ 1.0\,i & 4.0 \\ 3.0+1.0\,i & 5.0 \end{pmatrix} \neq \begin{pmatrix} 1.0 & -3.141592654\,i \\ -1.0\,i & 4.0 \\ 3.0-1.0\,i & 5.0 \end{pmatrix}$$

```
delete A:
```

Example 2

We compute the product $A^H A$ of a matrix given by a `hardware float array`. This data type allows matrix multiplication using the operator `*`:

```
A := hfarray(1..2, 1..3, [[1, I, 3], [PI*I, 4, 5 + I]])
```

$$\begin{pmatrix} 1.0 & 1.0\,i & 3.0 \\ 3.141592654\,i & 4.0 & 5.0+1.0\,i \end{pmatrix}$$

```
AH:= htranspose(A)
```

$$\begin{pmatrix} 1.0 & -3.141592654\,i \\ -1.0\,i & 4.0 \\ 3.0 & 5.0-1.0\,i \end{pmatrix}$$

The product $A^H A$ is Hermitian:

```
AH*A = htranspose(AH*A)
```

$$\begin{pmatrix} 10.8696044 & -11.56637061\,i & 6.141592654 - 15.70796327\,i \\ 11.56637061\,i & 17.0 & 20.0 + 1.0\,i \\ 6.141592654 + 15.70796327\,i & 20.0 - 1.0\,i & 35.0 \end{pmatrix} =$$

$$\begin{pmatrix} 10.8696044 & -11.56637061\,i & 6.141592654 - 15.70796327\,i \\ 11.56637061\,i & 17.0 & 20.0 + 1.0\,i \\ 6.141592654 + 15.70796327\,i & 20.0 - 1.0\,i & 35.0 \end{pmatrix}$$

```
delete A, AH:
```

Example 3

If the input does not evaluate to a matrix, then symbolic calls are returned:

```
delete A, B:
transpose(A) + 2*htranspose(B)
```

$$2\,\overline{B}^{t} + A^{t}$$

Parameters

A

A matrix: either a 2-dimensional `array`, a 2-dimensional `hfarray`, or an object of the category `Cat::Matrix`

Return Values

Matrix of the same domain type as A.

Overloaded By

A

See Also

MuPAD Functions

`htranspose` | `linalg::htranspose` | `linalg::transpose`

More About

- "Transpose Matrices"

htranspose

The Hermitian transpose of a matrix

Syntax

```
htranspose(A)
```

Description

`htranspose(A)` returns the Hermitian transpose A^H of the matrix A (the complex conjugate of the transpose of A).

The Hermitian transpose of the $m \times n$ matrix A is the $n \times m$ matrix B with $B_{i,j} = \overline{A_{j,i}}$.

If the input is a matrix of category `Cat::Matrix`, then `linalg::htranspose` is called to compute the result. In contrast to the linalg routines, the function `htranspose` also operates on `array`s and `hfarray`s.

If the argument does not evaluate to a matrix of one of the types mentioned above, symbolic call `htranspose(A)` is returned.

Examples

Example 1

The following matrix is real. Thus, the Hermitian transpose coincides with the transpose:

```
A := array(1..2, 1..2, [[1, 2], [3, PI]])
```

$$\begin{pmatrix} 1 & 2 \\ 3 & \pi \end{pmatrix}$$

```
transpose(A) = htranspose(A)
```

$$\begin{pmatrix} 1 & 3 \\ 2 & \pi \end{pmatrix} = \begin{pmatrix} 1 & 3 \\ 2 & \pi \end{pmatrix}$$

In general, this does not hold for complex matrices:

```
A := hfarray(1..2, 1..3, [[1, I, 3 + I], [PI*I, 4, 5]])
```

$$\begin{pmatrix} 1.0 & 1.0\,i & 3.0+1.0\,i \\ 3.141592654\,i & 4.0 & 5.0 \end{pmatrix}$$

```
transpose(A) <> htranspose(A)
```

$$\begin{pmatrix} 1.0 & 3.141592654\,i \\ 1.0\,i & 4.0 \\ 3.0+1.0\,i & 5.0 \end{pmatrix} \neq \begin{pmatrix} 1.0 & -3.141592654\,i \\ -1.0\,i & 4.0 \\ 3.0-1.0\,i & 5.0 \end{pmatrix}$$

```
delete A:
```

Example 2

We compute the product $A^H A$ of a matrix given by a `hardware float array`. This data type allows matrix multiplication using the operator `*`:

```
A := hfarray(1..2, 1..3, [[1, I, 3], [PI*I, 4, 5 + I]])
```

$$\begin{pmatrix} 1.0 & 1.0\,i & 3.0 \\ 3.141592654\,i & 4.0 & 5.0+1.0\,i \end{pmatrix}$$

```
AH:= htranspose(A)
```

$$\begin{pmatrix} 1.0 & -3.141592654\,i \\ -1.0\,i & 4.0 \\ 3.0 & 5.0-1.0\,i \end{pmatrix}$$

The product $A^H A$ is Hermitian:

```
AH*A = htranspose(AH*A)
```

$$\begin{pmatrix} 10.8696044 & -11.56637061\,i & 6.141592654 - 15.70796327\,i \\ 11.56637061\,i & 17.0 & 20.0 + 1.0\,i \\ 6.141592654 + 15.70796327\,i & 20.0 - 1.0\,i & 35.0 \end{pmatrix} =$$

$$\begin{pmatrix} 10.8696044 & -11.56637061\,i & 6.141592654 - 15.70796327\,i \\ 11.56637061\,i & 17.0 & 20.0 + 1.0\,i \\ 6.141592654 + 15.70796327\,i & 20.0 - 1.0\,i & 35.0 \end{pmatrix}$$

```
delete A, AH:
```

Example 3

If the input does not evaluate to a matrix, then symbolic calls are returned:

```
delete A, B:
transpose(A) + 2*htranspose(B)
```

$$2\,\overline{B}^{t} + A^{t}$$

Parameters

A

A matrix: either a 2-dimensional `array`, a 2-dimensional `hfarray`, or an object of the category `Cat::Matrix`

- "Transpose Matrices"

traperror

Trap errors

Syntax

```
traperror(object)
```

```
traperror(object, t)
```

```
traperror(object, MaxSteps = s)
```

Description

`traperror(object)` traps errors produced by the evaluation of `object`.

`traperror(object, t)` does the same. Moreover, it stops the evaluation if it is not finished after a real time of `t` seconds.

`traperror` traps errors caused by the evaluation of the object. Syntactical errors, i.e., errors on parsing the object, cannot be caught. The same holds true for fatal errors causing the termination of MuPAD.

`traperror` returns the error code `0` if no error happened. The error code is `1320` if the given time limit `t` is exceeded ("`Execution time exceeded`") and `1321` if the given number of "execution steps" is exceeded. The error code is `1028` if the error was raised by the command `error`.

If `traperror` is called with a numerical second argument, this number is taken as a time limit, measured in seconds, of "process time" (see the documentation of the `time` function for a discussion of this term).

When using the option `MaxSteps = s`, the caller sets a time limit which is not system-dependent, but rather measured in terms of MuPAD evaluation steps.

The number `s` does *not* refer directly to evaluation steps, but rather to a fixed (large) number of steps which may change from one MuPAD release to the next, but is fixed within one release. The number `s` is twice the number of outputs caused by `Pref::report(9)` for a calculation using the maximum time allowed.

If traperror has no time limit set and an "Execution time exceeded" error is raised by an enclosing traperror(..., t) command, then this error is not trapped by the inner traperror. It is trapped by the traperror call that has set the time limit. Cf. "Example 5" on page 1-2134.

The object can be an assignment which, for syntactical reasons, must be enclosed in additional brackets. The following code fragment demonstrates a typical application of traperror:

```
if traperror((x := SomeErrorProneFunction())) = 0 then
     DoSomethingWith(x);
else RespondToTheError();
end_if;
```

Use lasterror to reproduce the trapped error.

Examples

Example 1

Errors that happen during the execution of kernel functions have various error codes, depending on the problem. E.g., "Division by zero" produces the error code 1025:

```
y := 1/x: traperror(subs(y, x = 0))
```

```
     1025
```

```
lasterror()
```

```
Error: Division by zero. [_power]
```

Example 2

All errors raised using the function error have the error code 1028. Errors during the execution of library functions are of this kind:

```
traperror(error("My error!"))
```

```
     1028

lasterror()

Error: My error!
```

Example 3

We try to factor a polynomial, but give up after ten seconds:

```
traperror(factor(x^1000 + 4*x + 1), 10)

     1320

lasterror()

 Error: Execution time exceeded;   Evaluating:
faclib::univ_mod_gcd
```

Example 4

For use inside other routines, it is preferable to use `MaxSteps` instead of a time limit, to achieve consistent results across slower and faster machines:

```
traperror(factor(x^1000 + 4*x + 1), MaxSteps=10)

     1321

lasterror()

 Error: Execution MaxSteps exceeded [traperror];
  Evaluating: faclib::ddf
```

Note that evaluation steps may take vastly different amounts of time, so even on the same machine, different expressions evaluated with the same value of `MaxSteps` may be terminated after very different lengths of time:

```
time(traperror(factor(x^1000 + 4*x + 1), MaxSteps=1));
time(traperror(while TRUE do 1 end_while, MaxSteps=1));
```

```
time(traperror(int(1/sqrt(1/r-1/r0), r=0..r0), MaxSteps=1))
```

```
                                2204
```

```
                                40
```

```
                                468
```

Example 5

Here we have two nested `traperror` calls. The inner call contains an unterminated loop and the outer call has a time limit of `2` seconds. When the execution time is exceeded, this special error is not trapped by the inner `traperror` call. Because of the error, `print(1)` is never executed:

```
traperror((traperror((while TRUE do 1 end)); print(1)), 2)
```

```
                                1320
```

```
lasterror()
```

```
Error: Execution time is exceeded.
```

Parameters

`object`

Any MuPAD object

`t`

The time limit: a positive integer

`s`

The execution limit: a positive integer

Return Values

Nonnegative integer.

triangularPulse

Triangular pulse function

Syntax

```
triangularPulse(a, b, c, x)
```

```
triangularPulse(a, c, x)
```

Description

`triangularPulse(a, b, c, x)` represents the triangular function.

`triangularPulse(a, c, x)` is a shortcut for `triangularPulse(a, (a + c)/2, c, x)`.

`triangularPulse(x)` is a shortcut for `triangularPulse(-1, 0, 1, x)`.

`triangularPulse` represents the triangular pulse function. This function is also called the triangle function, hat function, tent function, or sawtooth function.

If `a`, `b`, and `c` are variables or expressions with variables, `triangularPulse` assumes that `a <= b <= c`. If `a`, `b`, and `c` are numerical values that do not satisfy this condition, `triangularPulse` throws an error.

If `a < x < b`, the triangular function equals `(x - a)/(b - a)`. If `b < x < c`, the triangular function equals `(c - x)/(c - b)`. Otherwise, it equals 0. See "Example 1" on page 1-2137 and "Example 2" on page 1-2137.

If `a = b` or `b = c`, the triangular function can be expressed in terms of the rectangular function. See "Example 3" on page 1-2137.

If `a = b = c`, `triangularPulse` returns 0. See "Example 4" on page 1-2138.

`triangularPulse(x)` is equivalent to `triangularPulse(-1, 0, 1, x)`. See "Example 5" on page 1-2138.

`triangularPulse(a, c, x)` is equivalent to `triangularPulse(a, (a + c)/2, c, x)`. See "Example 6" on page 1-2138.

`triangularPulse` also accepts infinities as its arguments. See “Example 9” on page 1-2140.

`triangularPulse` and `tripulse` are equivalent.

Examples

Example 1

Compute the triangular pulse function for these input arguments:

```
[triangularPulse(-2, 0, 2, -3),
 triangularPulse(-2, 0, 2, -1/2),
 triangularPulse(-2, 0, 2, 0),
 triangularPulse(-2, 0, 2, 3/2),
 triangularPulse(-2, 0, 2, 3)]
```

$$\left[0, \frac{3}{4}, 1, \frac{1}{4}, 0\right]$$

Example 2

Compute the triangular pulse function for `a < x < b`:

```
triangularPulse(a, b, c, x) assuming a < x < b
```

$$\frac{a-x}{a-b}$$

Compute the triangular pulse function for `b < x < c`:

```
triangularPulse(a, b, c, x) assuming b < x < c
```

$$-\frac{c-x}{b-c}$$

Example 3

Compute the triangular pulse function for `a = b` and `c = b`:

```
triangularPulse(b, b, c, x) assuming b < c
```

$$\_\ \frac{(c-x)\ \text{rectangularPulse}(b, c, x)}{b-c}$$

```
triangularPulse(a, b, b, x) assuming a < b
```

$$\frac{(a-x)\ \text{rectangularPulse}(a, b, x)}{a-b}$$

Example 4

For `a = b = c`, the triangular pulse function returns 0:

```
triangularPulse(a, a, a, x)
```

$$0$$

Example 5

Use `triangularPulse` with one input argument as a shortcut for computing `triangularPulse(-1, 0, 1, x)`:

```
triangularPulse(x)
```

$$\text{triangularPulse}(-1, 0, 1, x)$$

```
[triangularPulse(-10),
 triangularPulse(-3/4),
 triangularPulse(0),
 triangularPulse(2/3),
 triangularPulse(1)]
```

$$\left[0, \frac{1}{4}, 1, \frac{1}{3}, 0\right]$$

Example 6

Use `triangularPulse` with three input arguments as a shortcut for computing `triangularPulse(a, (a + c)/2, c, x)`:

```
triangularPulse(a, c, x)
```

$$\text{triangularPulse}\left(a, \frac{a}{2}+\frac{c}{2}, c, x\right)$$

```
[triangularPulse(-10, 10, 3),
 triangularPulse(-1/2, -1/4, -2/3),
 triangularPulse(2, 4, 3),
 triangularPulse(2, 4, 6),
 triangularPulse(-1, 4, 0)]
```

$$\left[\frac{7}{10}, 0, 1, 0, \frac{2}{5}\right]$$

Example 7

Rewrite the triangular pulse function in terms of the Heaviside step function:

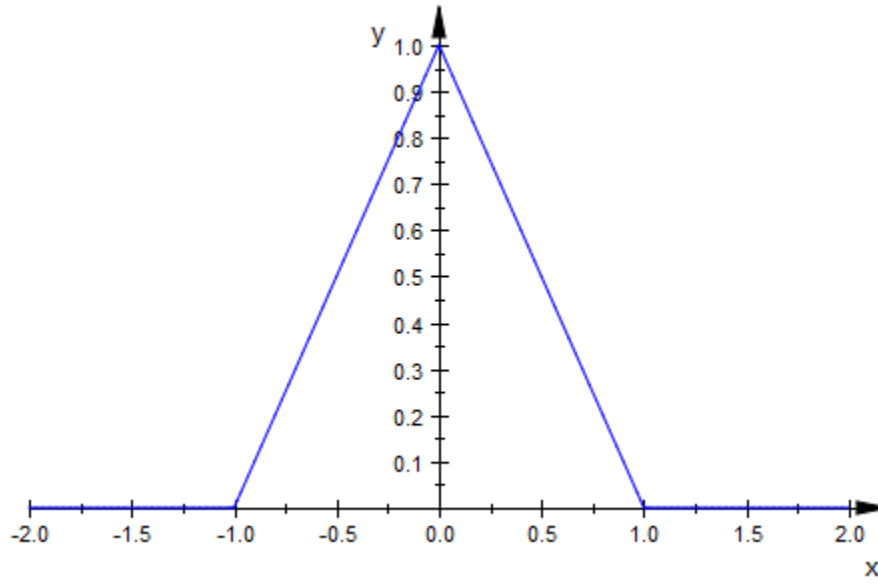
```
rewrite(triangularPulse(a, b, c, x), heaviside)
```

$$\frac{\text{heaviside}(x-a)\,(a-x)}{a-b} - \frac{\text{heaviside}(x-b)\,(a-x)}{a-b} - \frac{\text{heaviside}(x-b)\,(c-x)}{b-c} + \frac{\text{heaviside}(x-c)\,(c-x)}{b-c}$$

Example 8

Plot the triangular pulse function:

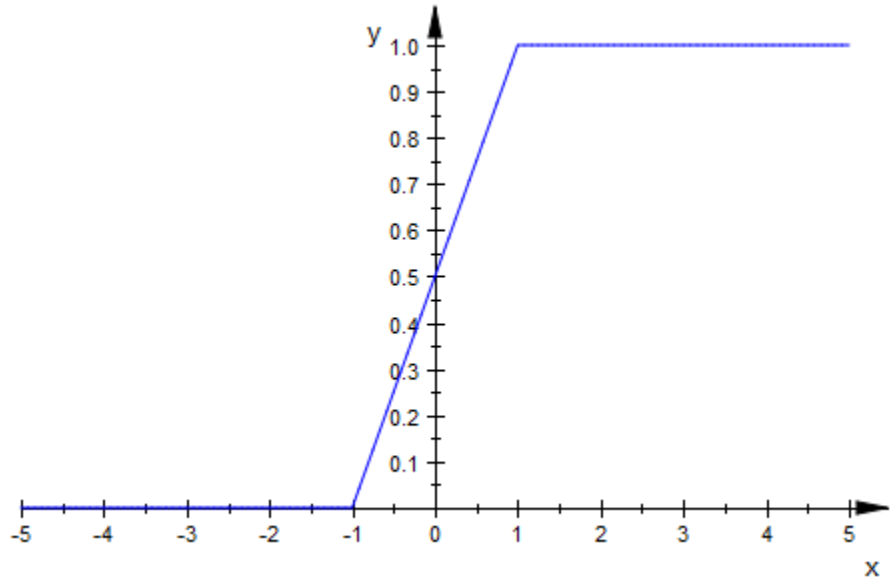
```
plot(triangularPulse(x), x = -2..2)
```



Example 9

Plot the triangular pulse function for which the argument `c` is a positive infinity:

```
plot(triangularPulse(-1, 1, infinity, x))
```



Parameters

a, b, c, x

Arithmetical expressions.

Return Values

Arithmetical expression.

Overloaded By

x

MuPAD Functions
`heaviside` | `piecewise` | `rectangularPulse`

tripulse

Triangular pulse function

Syntax

```
tripulse(a, b, c, x)
```

```
tripulse(a, c, x)
```

Description

`tripulse(a, b, c, x)` represents the triangular function.

`tripulse(a, c, x)` is a shortcut for `tripulse(a, (a + c)/2, c, x)`.

`tripulse(x)` is a shortcut for `tripulse(-1, 0, 1, x)`.

`tripulse` and `triangularPulse` are equivalent. These functions represent the triangular pulse function. For details and examples, see `triangularPulse`.

Parameters

`a`, `b`, `c`, `x`

Arithmetical expressions.

Return Values

Arithmetical expression.

Overloaded By

x

MuPAD Functions
`heaviside` | `piecewise` | `rectangularPulse` | `triangularPulse`

TRUE

Boolean constant TRUE

Description

MuPAD uses a three state logic with the Boolean constants `TRUE`, `FALSE`, and `UNKNOWN`.

The Boolean constants `TRUE`, `FALSE`, `UNKNOWN` are of domain type `DOM_BOOL`.

See and, or, not for the logical rules of the MuPAD three state logic.

Boolean constants are returned by system functions such as `bool` and `is`. These functions evaluate Boolean expressions such as equations and inequalities.

Examples

Example 1

The Boolean constants may be combined via `and`, `or`, and `not`:

```
(TRUE and (not FALSE)) or UNKNOWN
```

```
TRUE
```

Example 2

The function `bool` serves for reducing Boolean expressions such as equations or inequalities to one of the Boolean constants:

```
bool(x = x and 2 < 3 and 3 <> 4 or UNKNOWN)
```

```
TRUE
```

The function `is` evaluates symbolic Boolean expressions with properties:

```
assume(x > 2): is(x^2 > 4), is(x^3 < 0), is(x^4 > 17)
```

```
TRUE, FALSE, UNKNOWN
```

```
unassume(x):
```

Example 3

Boolean constants occur in the conditional part of program control structures such as `if`, `repeat`, or `while` statements. The following loop searches for the smallest Mersenne prime larger than 500 (see `numlib::mersenne` for details). The function `isprime` returns `TRUE` if its argument is a prime, and `FALSE` otherwise. Once a Mersenne prime is found, the `while`-loop is interrupted by the `break` statement:

```
p := 500:
while TRUE do
  p := nextprime(p + 1):
  if isprime(2^p - 1) then
     print(p);
     break;
  end_if;
end_while:
```

```
    521
```

Note that the conditional part of `if`, `repeat`, and `while` statements must evaluate to `TRUE` or `FALSE`. Any other value leads to an error:

```
if UNKNOWN then "true" else "false" end_if
```

```
Error: Cannot evaluate to Boolean. [if]
```

```
delete p:
```

FALSE

Boolean constant FALSE

Description

MuPAD uses a three state logic with the Boolean constants TRUE, FALSE, and UNKNOWN.

The Boolean constants TRUE, FALSE, UNKNOWN are of domain type DOM_BOOL.

See and, or, not for the logical rules of the MuPAD three state logic.

Boolean constants are returned by system functions such as bool and is. These functions evaluate Boolean expressions such as equations and inequalities.

Examples

Example 1

The Boolean constants may be combined via and, or, and not:

```
(TRUE and (not FALSE)) or UNKNOWN
```

```
TRUE
```

Example 2

The function bool serves for reducing Boolean expressions such as equations or inequalities to one of the Boolean constants:

```
bool(x = x and 2 < 3 and 3 <> 4 or UNKNOWN)
```

```
TRUE
```

The function is evaluates symbolic Boolean expressions with properties:

```
assume(x > 2): is(x^2 > 4), is(x^3 < 0), is(x^4 > 17)
```

```
TRUE, FALSE, UNKNOWN
```

```
unassume(x):
```

Example 3

Boolean constants occur in the conditional part of program control structures such as `if`, `repeat`, or `while` statements. The following loop searches for the smallest Mersenne prime larger than 500 (see `numlib::mersenne` for details). The function `isprime` returns `TRUE` if its argument is a prime, and `FALSE` otherwise. Once a Mersenne prime is found, the `while`-loop is interrupted by the `break` statement:

```
p := 500:
while TRUE do
  p := nextprime(p + 1):
  if isprime(2^p - 1) then
     print(p);
     break;
  end_if;
end_while:
```

```
    521
```

Note that the conditional part of `if`, `repeat`, and `while` statements must evaluate to `TRUE` or `FALSE`. Any other value leads to an error:

```
if UNKNOWN then "true" else "false" end_if
```

```
Error: Cannot evaluate to Boolean. [if]
```

```
delete p:
```

UNKNOWN

Boolean constant UNKNOWN

Description

MuPAD uses a three state logic with the Boolean constants `TRUE`, `FALSE`, and `UNKNOWN`.

The Boolean constants `TRUE`, `FALSE`, `UNKNOWN` are of domain type `DOM_BOOL`.

See and, or, not for the logical rules of the MuPAD three state logic.

Boolean constants are returned by system functions such as `bool` and `is`. These functions evaluate Boolean expressions such as equations and inequalities.

Examples

Example 1

The Boolean constants may be combined via `and`, `or`, and `not`:

```
(TRUE and (not FALSE)) or UNKNOWN
```

```
TRUE
```

Example 2

```
bool(x = x and 2 < 3 and 3 <> 4 or UNKNOWN)
```

```
TRUE
```

The function `is` evaluates symbolic Boolean expressions with properties:

```
assume(x > 2): is(x^2 > 4), is(x^3 < 0), is(x^4 > 17)
```

```
TRUE, FALSE, UNKNOWN
```

```
unassume(x):
```

Example 3

Boolean constants occur in the conditional part of program control structures such as `if`, `repeat`, or `while` statements. The following loop searches for the smallest Mersenne prime larger than 500 (see `numlib::mersenne` for details). The function `isprime` returns `TRUE` if its argument is a prime, and `FALSE` otherwise. Once a Mersenne prime is found, the `while`-loop is interrupted by the `break` statement:

```
p := 500:
while TRUE do
  p := nextprime(p + 1):
  if isprime(2^p - 1) then
     print(p);
     break;
  end_if;
end_while:
```

```
    521
```

Note that the conditional part of `if`, `repeat`, and `while` statements must evaluate to `TRUE` or `FALSE`. Any other value leads to an error:

```
if UNKNOWN then "true" else "false" end_if
```

```
Error: Cannot evaluate to Boolean. [if]
```

```
delete p:
```

type

Type of an object

Syntax

```
type(object)
```

Description

`type(object)` returns the type of the object.

If `object` is not an expression of domain type `DOM_EXPR`, then `type(object)` is equivalent to `domtype(object)`, i.e., `type` returns the domain type of the object.

If `object` is an expression of domain type `DOM_EXPR`, then its type is determined by its 0-th operand (the "operator"). If the operator has a `"type"` slot, then `type` returns this value, which usually is a string. If the operator has no `"type"` slot, then `type` returns the string `"function"`.

In contrast to most other functions, `type` does not flatten arguments that are expression sequences. Cf. "Example 4" on page 1-2152.

Examples

Example 1

If an object is not an expression, its type equals its domain type:

```
type(3)
```

```
DOM_INT
```

Example 2

The operator of a sum is `_plus`; the type slot of that operator is `"_plus"`:

```
type(x + y*z)
```

```
"_plus"
```

`type` evaluates its argument: thereby, the difference of `x` and `y` becomes the sum of `x` and `(-1)*y`. Its type is not `"_subtract"`, but `"_plus"`:

```
type(x - y)
```

```
"_plus"
```

Example 3

If the operator of an expression is not a function environment having a type slot, the expression is of type `"function"`:

```
type(f(2))
```

```
"function"
```

Example 4

The following call to `type` is *not* regarded as a call with two arguments, because expression sequences in the argument are not flattened:

```
type((2, 3))
```

```
"_exprseq"
```

Parameters

`object`

Any MuPAD object

Return Values

Domain type of type `DOM_DOMAIN` or a character string.

Overloaded By

object

See Also

MuPAD Functions
`coerce` | `domtype` | `hastype` | `testtype`

unassume

Delete the properties of an identifier

Syntax

```
unassume(x)
```

Description

`unassume(x)` deletes the properties of the identifier `x`.

`unassume` serves for deleting properties of identifiers set via `assume`. See "Properties" for a description of the property mechanism.

If `x` is a list or a set of identifiers, then the properties of all specified identifiers are deleted.

The command `delete x` deletes the value and the properties of the identifier `x`.

Examples

Example 1

Properties are attached to the identifiers `x` and `y`:

```
assume(x > 0): assume(y < 0): getprop(x), getprop(y)
```

$$(0, \infty), (-\infty, 0)$$

```
sign(x), sign(y)
```

$$1, -1$$

`unassume` or `delete` deletes the properties:

```
unassume(x): delete y: getprop(x), getprop(y)
```

$$\mathbb{C},\ \mathbb{C}$$

```
sign(x), sign(y)
```

$$\mathrm{sign}(x),\ \mathrm{sign}(y)$$

The properties of several identifiers can be deleted simultaneously by passing a list or a set to `unassume`:

```
assume(x > y): unassume([x, y]): getprop(x), getprop(y)
```

$$\mathbb{C},\ \mathbb{C}$$

Parameters

x

An identifier or a list or a set of identifiers

Return Values

Void object `null()`.

See Also

MuPAD Functions

`assume` | `delete` | `getprop` | `is`

undefined

Undefined value

Description

`undefined` indicates results of mathematically undefined operations.

MuPAD uses the special value `undefined` to indicate the results of operations that are not defined in mathematics.

You can use the `undefined` value as an input. Arithmetical operations involving `undefined` also return `undefined`. Multiplying infinities by 0 returns `undefined`.

For floating-point intervals, MuPAD uses the special value `RD_NAN` instead of `undefined`. If you use typeset mode, MuPAD displays `RD_NAN` as `NaN` in output regions. Multiplying infinities `RD_INF` and `RD_NINF` by 0 returns `RD_NAN`.

Examples

Example 1

Perform the following operations with infinities. MuPAD returns the `undefined` value for these operations:

```
0*infinity, infinity - infinity, infinity/infinity
```

```
undefined, undefined, undefined
```

Example 2

Compute the limit of the sine function at infinity. Since this limit does not exist (is not mathematically defined), MuPAD returns `undefined`:

```
limit(sin(x), x = infinity)
```

```
undefined
```

Example 3

Multiply infinities by 0:

```
infinity*0, -infinity*0
```

```
undefined, undefined
```

```
RD_INF*0, RD_NINF*0
```

```
NaN, NaN
```

More About

- “Mathematical Constants Available in MuPAD”

unit

Physical units

Syntax

```
unit::nam
```

Description

Objects such as `unit::m`, `unit::kg`, `unit::sec` etc. represent the physical units "meters", "kilograms", "seconds" etc.

`unit` domain provides some methods for simplifying and converting arithmetical expressions involving such units.

`unit` objects such as `unit::m` or `unit::kg` serve for representing physical units. They are domain objects of domain type `unit`.

These objects behave like symbolic names (identifiers) and can be used to build arithmetical expressions involving numbers and symbols such as `3*unit::m^2` or `a*unit::cm + b*unit::inch^2/unit::mm`. Units must be used consistently in expressions, and should be specified for unknown variables so that the variables themselves are dimensionless. In calls to `solve`, you should always solve for dimensionless variables by specifying the dimensions. Cf. "Example 3" on page 1-2167.

Expressions such as `20*unit::cm + 0.3*unit::m` involving several units of the same type ('length,' 'mass,' 'time' etc.) are *not* simplified automatically. Use `unit::convert`, `unit::simplify`, `simplify`, or `Simplify` to convert all subexpressions to common units. These routines are described further down below.

On input, use the prefix `unit::` as in `unit::mm`, `unit::km` for millimeters, kilometers etc. On the screen, this prefix is stripped off. For example, `1.23*unit::mm` is displayed as `1.23 mm`.

The available units are listed further down below.

Note that some units such as `unit::mm`, `unit::millimeter` and `unit::millimeters` represent the same physical unit. Use an interactive command such as `info(unit::oz)`

to find information on `unit::oz` including all the alternative names that can be used in MuPAD. Cf. “Example 7” on page 1-2170.

Note: Beware: If you mix different MuPAD units representing the same physical unit, *no automatic simplifications* are done! Use `simplify` to simplify an expression such as `2*unit::m + 3*unit::meter` to `5*unit::m`.

Expressions such as `unit::kg*(unit::m/unit::s)^2` can be used to represent a composite unit. You can convert them to other units such as `unit::Joule` via `unit::convert`.

Some of the conversion factors between the various units are given by exact rational numbers (e.g., `unit::inch = 127/50*unit::cm`), while others are linked by floating-point factors (e.g., `unit::cal = 4.1868*unit::Joule`). Use `float` to approximate exact values by floats. Use `numeric::rationalize` to approximate floats by rational numbers.

Most system functions such as `diff`, `factor`, `normal` etc. accept expressions containing units, treating the units like symbolic identifiers. See “Example 9” on page 1-2171.

The available units are listed below. If the required unit is not available, you can use `unit::newUnit` to add your own unit to the `unit` domain. See “Example 4” on page 1-2167.

- mcF (= mcFarad = mcfarad = microF = microFarad = microfarad)
- mF (= mFarad = mfarad), cF, dF, F (= Farad = farad), daF, hF
- kF (= kFarad = kfarad) , MF, GF, TF, PF, EF

Electric Conductance:

- S (= Siemens = siemens)

Magnetic Inductance:

- H (= Henry = henry)

Magnetic Flux Density, Magnetic Inductivity:

- T (= Tesla = tesla), G (= Gauss = gauss)

Magnetic Flux:

- Wb (= Weber = weber), M (= Maxwell = maxwell)

Magnetic Field Strength:

- Oe (= Oersted = oersted)

Magnetomotive Force (= Electric Current):

- Gb (= Gilbert = gilbert)

Luminous Intensity:

- `fcd`, `acd`, `pcd`, `ncd`, `mccd`, `mcd`, `ccd`, `dcd`, `cd` (= `candela` = `Candela`), `dacd`, `hcd`
- `kcd`, `Mcd`, `Gcd`, `Tcd`, `Pcd`, `Ecd`, `HK`, `IK`

Luminance:

- `sb` (= `stilb`), `asb` (= `apostilb`)

Luminous Flux:

- `lm` (= `lumen`)

Illuminance:

- `lx` (= `lux`), `ph` (= `phot`), `nx`

Radiation:

- `langley`

Radioactivity:

- `aBq`, `fBq`, `pBq`, `nBq`, `mcBq`, `mBq`, `cBq`, `dBq`, `Bq` (= `Becquerel` = `becquerel`), `daBq`
- `hBq`, `kBq`, `MBq`, `GBq`, `TBq`, `PBq`, `EBq`, `Ci` (= `Curie`)

Equivalent Dosage:

- `aSv`, `fSv`, `pSv`, `nSv`, `mcSv`, `mSv`, `cSv`, `dSv`
- `Sv` (= `Sievert` = `sievert`), `daSv`, `hSv`, `kSv`, `MSv`, `GSv`, `TSv`, `PSv`, `ESv`
- `arem`, `frem`, `prem`, `nrem`, `mcrem`, `mrem`, `crem`, `drem`
- `rem` (= `Rem`), `darem`, `hrem`, `krem`, `Mrem`, `Grem`, `Trem`, `Prem`, `Erem`

Absorbed Dosage:

- `aGy`,`fGy`,`pGy`,`nGy`,`mcGy`,`mGy`,`cGy`,`dGy`, `Gy` (= `Gray` = `gray`), `daGy`,`hGy`,`kGy`, `MGy`, `GGy`
- `TGy`,`PGy`,`EGy`, `rd`

Ionising Dosage:

- `R` (= `Roentgen`)

Lens Power:

- `dpt` (= `diopter` = `dioptre`)

Dynamic Viscosity:

- `P` (= `Poise`)

Kinematic Viscosity:

- `St` (= `Stokes`)

Mass Per Length:

- `tex`, `den` (= `denier`)

Examples

Example 1

Units not convertible are left alone by `unit::convert`:

```
unit::convert(1.23*unit::kg*unit::inch^2/unit::mm, unit::cm)
```

$$79.35468\ \text{cm kg}$$

```
unit::convert(unit::km/unit::hour, unit::m/unit::sec)
```

$$\frac{5\ \frac{m}{sec}}{18}$$

Example 2

`unit::simplify` favors kg over pounds:

```
unit::simplify(1.23*unit::kg^2/unit::pound*unit::inch^2/unit::mm)
```

$$68.87681995\ \text{inch kg}$$

Example 3

Specify units for unknown variables so that the variables you solve for are dimensionless. If you apply units inconsistently, you get incorrect results.

Demonstrate this by omitting the unit for an unknown variable in an equation and solving the equation. The `solve` function cannot solve the equation.

```
L := 1*unit::m:
y := 0.1*unit::m:
f := y - x*cos(L/x):
solve(f,x)
```

$$\varnothing$$

Solve the equation for the unknown variable by specifying the correct unit for the variable.

```
f := y - x*unit::m*cos(L/(x*unit::m)):
solve(f,x)
```

$$\{0.1898572041\}$$

Example 4

We add new velocity units to the `unit` domain:

```
unit::newUnit(SpeedOfLight = 300000*unit::km/unit::sec)
```

$$\text{SpeedOfLight}$$

Now, the unit `unit::SpeedOfLight` exists and can be used like any other unit in the `unit` domain. We use it to define yet another velocity unit:

```
unit::newUnit(Warp9 = 1.516*unit::SpeedOfLight)
```

$$\text{Warp9}$$

We convert the velocity of 123.4 miles per hour into the new speed units:

```
unit::convert(123.4*unit::mile/unit::hour, unit::SpeedOfLight)
```

$$0.0000001838824533\ \text{SpeedOfLight}$$

```
unit::convert(123.4*unit::mile/unit::hour, unit::Warp9)
```

$$0.0000001212944943\ \text{Warp9}$$

We verify the new units:

```
unit::convert(unit::SpeedOfLight, unit::km/unit::sec)
```

$$300000\ \frac{\text{km}}{\text{sec}}$$

```
unit::convert(unit::Warp9, unit::SpeedOfLight)
```

$$1.516\ \text{SpeedOfLight}$$

```
unit::convert(unit::Warp9, unit::km/unit::sec)
```

$$454800.0\ \frac{\text{km}}{\text{sec}}$$

Example 5

We create a symbolic expression involving different units of type 'length':

```
27*unit::cm + 30*unit::mm
```

$$27\ \text{cm} + 30\ \text{mm}$$

This expression is not simplified automatically. We apply `simplify`:

```
simplify(%)
```

$$30\ \text{cm}$$

We convert this length to inch:

```
unit::convert(%, unit::inch)
```

$$\frac{1500\ \text{inch}}{127}$$

```
float(%)
```

$$11.81102362\ \text{inch}$$

Here is another example for simplification and conversion:

```
1234*unit::g + 1.234*unit::kg*unit::m^2/unit::inch^2
```

$$1234\ g + 1.234\ \frac{\text{kg}\ m^2}{\text{inch}^2}$$

```
simplify(%)
```

$$1913937.825\ g$$

```
unit::convert(%, unit::ounce)
```

$$67512.17003\ \text{ounce}$$

The target unit in `unit::convert` may be an expression:

```
unit::convert(unit::pound*unit::km/unit::hour,
              unit::kg*unit::m/unit::s)
```

$$\frac{45359237\ \frac{\text{kg}\ m}{s}}{360000000}$$

Example 6

The probably most interesting method of the `unit` domain is the conversion routine `unit::convert`. Given any expression involving units, you can specify a target unit which is to be used to express the units:

```
unit::convert(unit::ounce, unit::kilogram)
```

$$\frac{45359237\ \text{kilogram}}{1600000000}$$

The target unit needs not be of the same physical type as the expression that is to be rewritten. In the following example, we wish to rewrite a torque (given in "Newton meters") in terms of units involving the power unit "Watt." Note that a torque is an energy, i.e., "power" multiplied by "time":

```
unit::convert(1.23*unit::Nm, unit::W)
```

$$1.23\ W\ s$$

We wish to rewrite "Newton meters" in terms of units involving "centimeters":

```
unit::convert(unit::Nm, unit::cm)
```

$$10000\ \frac{\text{cm}^2\ \text{kg}}{s^2}$$

The target unit may be a composite expression. We wish to rewrite "Newton meters" in terms of "grams," "centimeters," and "milliseconds":

```
unit::convert(unit::Nm, unit::g*unit::cm^2/unit::msec^2)
```

$$10\ \frac{\text{cm}^2\ g}{\text{msec}^2}$$

Example 7

The `info` command provides information on units. In particular, it lists alternative names that can be used in MuPAD:

```
info(unit::nm)
```

```
nanometer: a length unit

Alternative names: unit::nanom, unit::nanometer, unit::nanometers, unit::nm
```

```
info(unit::Joule)
```

```
joule: a unit of energy

Alternative names: unit::J, unit::Joule, unit::Newtonmeter, unit::Nm, unit::Ws, unit::
```

Example 8

We use `unit::convert2SIunits` to convert a mass expressed in non-metric units to SI base units:

```
mass := 2*unit::cal*unit::msec^2/unit::inch^2 - 45*unit::carat
```

$$2\,\frac{\mathrm{cal}\,\mathrm{msec}^2}{\mathrm{inch}^2} - 45\ \mathrm{carat}$$

```
unit::convert2SIunits(mass)
```

$$0.003979105958\ \mathrm{kg}$$

```
delete mass:
```

Example 9

Most system functions such as `diff`, `factor`, `normal` etc. treat units like ordinary symbolic identifiers:

```
diff(x/unit::m*exp(-x^2/unit::m^2), x)
```

$$e^{-x^2\,\frac{1}{m^2}}\,\frac{1}{m} - \left(2\,x^2\,e^{-x^2\,\frac{1}{m^2}}\right)\,\frac{1}{m^3}$$

```
factor(%)
```

$$-\frac{2\,x^2 - m^2}{e^{\frac{x^2}{m^2}}}\,\frac{1}{m^3}$$

```
normal((4*unit::m^2 - a^2*unit::m^2)/(2*unit::m - a*unit::m))
```

$$2\,m + a\,m$$

Parameters

`nam`

The name of the physical unit, see the list below. Some units such as `unit::mm` and `unit::millimeter` represent the same physical unit.

Methods

`convert` — Convert an expression to other units

`convert(x, targetunit)` converts all units in the arithmetical expression x to multiples of the targetunit if possible. The targetunit may be one of the unit objects of type 'length,' 'mass' etc. It may also be an arithmetical expression such as `unit::km/unit::sec`. In this case, x is rewritten in terms of the units found in targetunit.

`convert2SIunits` — Rewrite to SI units

`convert2SIunits(x)` rewrites all units in the arithmetical expression x in terms of corresponding SI base units.

`simplify` — Combine like units in an expression

`unit:: simplify(x)` converts all units in the arithmetical expression x to some basic unit found in x, i.e., all length units are expressed by the same length unit, all mass units are expressed by the same mass unit, all time units are expressed by the same time unit etc.

`newUnit` — Define a new unit

```
newUnit(newname = expression)
```

`unit::newUnit(newname = f*oldunit)` creates a new unit that may be addressed by `unit::newname`. Its name newname must be an identifier. It is declared as the `f`-fold of

some unit `oldunit` that must be an expression such as `unit::mm/unit::sec` involving units provided by the unit domain. The conversion factor f must be an arithmetical expression (typically, a numerical conversion factor).

`display` — Format for output

`display(x)` formats the screen output of the arithmetical expression x such that the units appear as a separate factor at the end of each term.

`findUnits` — Find all units in expression

`findUnits(x)` returns a set of all units found in the arithmetical expression x.

`Celsius2Fahrenheit` — Convert degrees Celsius to degrees Fahrenheit

`unit::Celsius2Fahrenheit(x)` converts a numerical value x representing a temperature in degrees Celsius into a numerical value representing this temperature in degrees Fahrenheit.

`Celsius2Kelvin` — Convert degrees Celsius to Kelvin

`unit::Celsius2Kelvin(x)` converts a numerical value x representing a temperature in degrees Celsius into a numerical value representing this temperature in degrees Kelvin.

`Celsius2Rankine` — Convert degrees Celsius to degrees Rankine

`unit::Celsius2Rankine(x)` converts a numerical value x representing a temperature in degrees Celsius into a numerical value representing this temperature in degrees Rankine.

`Celsius2Reaumur` — Convert degrees Celsius to degrees Reaumur

`unit::Celsius2Reaumur(x)` converts a numerical value x representing a temperature in degrees Celsius into a numerical value representing this temperature in degrees Reaumur.

`Fahrenheit2Celsius` — Convert degrees Fahrenheit to degrees Celsius

`unit::Fahrenheit2Celsius(x)` converts a numerical value x representing a temperature in degrees Fahrenheit into a numerical value representing this temperature in degrees Celsius.

`Fahrenheit2Kelvin` — Convert degrees Fahrenheit to Kelvin

`unit::Fahrenheit2Kelvin(x)` converts a numerical value x representing a temperature in degrees Fahrenheit into a numerical value representing this temperature in degrees Kelvin.

`Fahrenheit2Rankine` — Convert degrees Fahrenheit to degrees Rankine

`unit::Fahrenheit2Rankine(x)` converts a numerical value x representing a temperature in degrees Fahrenheit into a numerical value representing this temperature in degrees Rankine.

`Fahrenheit2Reaumur` — Convert degrees Fahrenheit to degrees Reaumur

`unit::Fahrenheit2Reaumur(x)` converts a numerical value x representing a temperature in degrees Fahrenheit into a numerical value representing this temperature in degrees Reaumur.

`Kelvin2Fahrenheit` — Convert Kelvin to degrees Fahrenheit

`unit::Kelvin2Fahrenheit(x)` converts a numerical value x representing a temperature in degrees Kelvin into a numerical value representing this temperature in degrees Fahrenheit.

`Kelvin2Celsius` — Convert Kelvin to degrees Celsius

`unit::Kelvin2Celsius(x)` converts a numerical value x representing a temperature in degrees Kelvin into a numerical value representing this temperature in degrees Celsius.

`Kelvin2Rankine` — Convert Kelvin to degrees Rankine

`unit::Kelvin2Rankine(x)` converts a numerical value x representing a temperature in degrees Kelvin into a numerical value representing this temperature in degrees Rankine.

`Kelvin2Reaumur` — Convert Kelvin to degrees Reaumur

`unit::Kelvin2Reaumur(x)` converts a numerical value x representing a temperature in degrees Kelvin into a numerical value representing this temperature in degrees Reaumur.

`Rankine2Fahrenheit` — Convert degrees Rankine to degrees Fahrenheit

`unit::Rankine2Fahrenheit(x)` converts a numerical value x representing a temperature in degrees Rankine into a numerical value representing this temperature in degrees Fahrenheit.

`Rankine2Kelvin` — Convert degrees Rankine to Kelvin

`unit::Rankine2Kelvin(x)` converts a numerical value x representing a temperature in degrees Rankine into a numerical value representing this temperature in degrees Kelvin.

`Rankine2Celsius` — Convert degrees Rankine to degrees Celsius

`unit::Rankine2Celsius(x)` converts a numerical value x representing a temperature in degrees Rankine into a numerical value representing this temperature in degrees Celsius.

`Rankine2Reaumur` — Convert degrees Rankine to degrees Reaumur

`unit::Rankine2Reaumur(x)` converts a numerical value x representing a temperature in degrees Rankine into a numerical value representing this temperature in degrees Reaumur.

`Reaumur2Fahrenheit` — Convert degrees Reaumur to degrees Fahrenheit

`unit::Reaumur2Fahrenheit(x)` converts a numerical value x representing a temperature in degrees Reaumur into a numerical value representing this temperature in degrees Fahrenheit.

`Reaumur2Kelvin` — Convert degrees Reaumur to Kelvin

`unit::Reaumur2Kelvin(x)` converts a numerical value x representing a temperature in degrees Reaumur into a numerical value representing this temperature in degrees Kelvin.

`Reaumur2Rankine` — Convert degrees Reaumur to degrees Rankine

`unit::Reaumur2Rankine(x)` converts a numerical value x representing a temperature in degrees Reaumur into a numerical value representing this temperature in degrees Rankine.

`Reaumur2Celsius` — Convert degrees Reaumur to degrees Celsius

`unit::Reaumur2Celsius(x)` converts a numerical value x representing a temperature in degrees Reaumur into a numerical value representing this temperature in degrees Celsius.

universe

Set-theoretical universe

Description

`universe` represents the set-theoretical universe of all objects.

`universe` is the only element of the domain `stdlib::Universe`.

The standard set operations such as union, intersection and subtraction can be used with `universe`.

Examples

Example 1

We show some basic set operations involving `universe`:

```
universe union {a}
```

$$\text{universe}$$

```
universe intersect {a}
```

$$\{a\}$$

```
{a} minus universe
```

$$\varnothing$$

See Also

MuPAD Domains
DOM_SET

MuPAD Functions
`intersect | minus | union`

unprotect

Remove protection of identifiers

Syntax

```
unprotect(x)
```

Description

`unprotect(x)` removes any write protection of the identifier `x`.

`unprotect(x)` is equivalent to `protect(x, ProtectLevelNone)`.

`unprotect` does not evaluate its argument. Cf. “Example 2” on page 1-2179.

Examples

Example 1

`unprotect` allows to assign values to system functions:

```
unprotect(sign): sign(x) := 1
```

```
    1
```

However, we strongly advise not to change identifiers protected by the system. We undo the previous assignment:

```
delete sign(x): protect(sign, ProtectLevelError):
```

Example 2

`unprotect` does not evaluate its argument. Here the identifier `x` is unprotected and not its value `y`:

```
x := y:  protect(y): unprotect(x): y := 1
```

```
Warning: The protected variable 'y' is overwritten. [_assign]

     1

 Warning: Protected variable
'y' overwritten. [_assign]

     1

unprotect(y): delete x, y:
```

Example 3

The identifier a is protected with various levels. `unprotect` returns the previous protection level:

```
protect(a):
unprotect(a)

     ProtectLevelWarning

protect(a, ProtectLevelError):
unprotect(a)

     ProtectLevelError
```

At this place, a is not protected:

```
unprotect(a)

     ProtectLevelNone
```

Parameters

x

An identifier

Return Values

Previous protection level of `x`: either `ProtectLevelError` or `ProtectLevelWarning` or `ProtectLevelNone` (see `protect`).

See Also

MuPAD Functions
`protect`

use

Use library functions by a short name

Syntax

```
use(L, <Alias>, f1, f2, …)
use(L, <Alias>)
```

Description

`use(L, f)` 'exports' the public function `L::f` of the library `L` to the global namespace such that it can be accessed as `f` without the prefix `L`.

`use(L)` exports all public functions of the library `L`.

A library contains *public* functions which may be called by the user. The collection of these functions forms the *interface* of the library. (There may be other, private, functions, too, which are not intended to be called by the user directly, and are not documented.) The standard way of accessing the public function `f` from the library `L` is via `L::f`. When the function `f` is *exported*, it can be accessed more briefly as `f`. Technically, exporting means that the global identifier `f` is assigned the value `L::f`. Alternatively, when the option `Alias` is used, an `alias` is created.

Unexporting the library function `f` means that the value of the global identifier `f` is deleted. Afterwards, the library function is available only as `L::f`.

`use(L, f1, f2, ...)` exports the given functions `f1, f2, ...` of `L`. However, if one of the identifiers already has a value, the corresponding function is not exported. A warning is printed instead. An error is returned if one of the identifiers is not the name of a public library function.

`use(L)` exports all public functions of `L`.

A function that is already exported will not be exported twice.

`use` evaluates its first argument `L`, but it does not evaluate the remaining arguments `f1, f2, ...`, if any.

The function `info` displays the interface functions and the exported functions of a library.

Some libraries have functions that are always exported. These functions cannot be unexported. The function `append` from the library `listlib` is such an example.

Environment Interactions

When a function is exported, it is assigned to the corresponding global identifier. When it is unexported, the corresponding identifier is deleted.

Examples

Example 1

Export the function `invphi` of the library numlib, and then undo the export:

```
numlib::invphi(4!)
```

```
      [35, 39, 45, 52, 56, 70, 72, 78, 84, 90]
```

```
use(numlib, invphi):
invphi(4!)
```

```
      [35, 39, 45, 52, 56, 70, 72, 78, 84, 90]
```

```
unuse(numlib, invphi):
invphi(4!)
```

```
      invphi(24)
```

Export all functions of the library numlib:

```
use(numlib):
```

```
invphi(100)
```

```
Warning: Identifier 'divisors' already has a value. It is not exported. [use]
```

```
Warning: Identifier 'contfrac' already has a value. It is not exported. [use]
```

$$[101, 125, 202, 250]$$

Here, `use` issues warnings because `contfrac` and `divisors` are already available as global functions. For example, there is the global `contfrac` function that uses `numlib::contfrac` for numerical arguments. Undo the export of the `numlib` functions.

```
unuse(numlib):
invphi(100)
```

$$\text{invphi}(100)$$

Example 2

`use` issues a warning if a function cannot be exported since the corresponding identifier already has a value:

```
invphi := 17:
use(numlib, invphi)
```

```
Warning: Identifier 'invphi' already has a value. It is not exported. [use]
```

Parameters

`L`

The library: a domain

`f1, f2, …`

Public functions of `L`: identifiers

Options

`Alias`

Use `alias(f = L::f)` to create an alias `f` for `L::f` rather than exporting `L::f` by the assignment `f:= L::f`.

Return Values

Void object `null()` of type `DOM_NULL`.

Algorithms

The names of the public functions of a library `L` are stored in the set `L::interface`. This set is used by the function `info` and for exporting.

The names of functions exported from a library `L` are stored in the set `L::_exported`.

See Also

MuPAD Functions

`:=` | `alias` | `delete` | `info` | `unuse`

unuse

Undo the use command

Syntax

```
unuse(L, f1, f2, …)
unuse(L)
```

Description

`unuse(L, f)` undoes the export of the public function `L::f` of the library `L` such that it is no longer available as `f`.

`unuse(L)` undoes the export of all previously exported public functions of the library `L`.

A library contains *public* functions which may be called by the user. The collection of these functions forms the *interface* of the library. (There may be other, private, functions, too, which are not intended to be called by the user directly, and are not documented.) The standard way of accessing the public function `f` from the library `L` is via `L::f`. When the function `f` is *exported*, it can be accessed more briefly as `f`. Technically, exporting means that the global identifier `f` is assigned the value `L::f`. Alternatively, when the option `Alias` is used, an `alias` is created.

Unexporting the library function `f` means that the value of the global identifier `f` is deleted. Afterwards, the library function is available only as `L::f`.

`unuse(L, f1, f2, ...)` unexports all given functions of `L`. Note that `unuse` does not evaluate the identifiers. Thus, it is not necessary to use `hold` to protect them from being evaluated.

`unuse(L)` unexports all public functions of the library `L`.

`unuse` evaluates its first argument `L`, but it does not evaluate the remaining arguments `f1, f2, ...`, if any.

The function `info` displays the interface functions and the exported functions of a library.

Some libraries have functions that are always exported. These functions cannot be unexported. The function `append` from the library `listlib` is such an example.

Environment Interactions

When a function is exported, it is assigned to the corresponding global identifier. When it is unexported, the corresponding identifier is deleted.

Examples

Example 1

Export the function `invphi` of the library numlib, and then undo the export:

```
numlib::invphi(4!)
```

```
[35, 39, 45, 52, 56, 70, 72, 78, 84, 90]
```

```
use(numlib, invphi):
invphi(4!)
```

```
[35, 39, 45, 52, 56, 70, 72, 78, 84, 90]
```

```
unuse(numlib, invphi):
invphi(4!)
```

```
invphi(24)
```

Export all functions of the library numlib:

```
use(numlib):
invphi(100)
```

```
Warning: Identifier 'divisors' already has a value. It is not exported. [use]
```

```
Warning: Identifier 'contfrac' already has a value. It is not exported. [use]
```

```
[101, 125, 202, 250]
```

Here, `use` issues warnings because `contfrac` and `divisors` are already available as global functions. For example, there is the global `contfrac` function that uses `numlib::contfrac` for numerical arguments. Undo the export of the `numlib` functions.

```
unuse(numlib):
invphi(100)
```

```
invphi(100)
```

Example 2

`use` issues a warning if a function cannot be exported since the corresponding identifier already has a value:

```
invphi := 17:
use(numlib, invphi)
```

```
Warning: Identifier 'invphi' already has a value. It is not exported. [use]
```

Parameters

`L`

The library: a domain

`f1, f2, …`

Public functions of `L`: identifiers

Options

`Alias`

Use `alias(f = L::f)` to create an alias `f` for `L::f` rather than exporting `L::f` by the assignment `f:= L::f`.

Return Values

Void object `null()` of type `DOM_NULL`.

Algorithms

The names of the public functions of a library `L` are stored in the set `L::interface`. This set is used by the function `info` and for exporting.

The names of functions exported from a library `L` are stored in the set `L::_exported`.

More About

- "Use the MuPAD Libraries"

val

Value of an object

Syntax

```
val(object)
```

Description

`val(object)` replaces every identifier in `object` by its value.

`val` does not perform any simplification of the result.

If the result of `val` is a set, duplicate elements are removed from that set.

`val` does not work recursively, i.e., if the value of an identifier in turn contains identifiers, then these are not replaced by their values. See “Example 3” on page 1-2191.

`val` does not flatten its argument. Hence, an expression sequence is accepted as argument. Cf. “Example 2” on page 1-2191.

Examples

Example 1

`val` replaces identifiers by their values, but does not call arithmetical functions such as `_plus`:

```
a := 0: val(a*b + 4 + 0)
```

$$0\,b + 4 + 0$$

Duplicate elements in sets are removed:

```
a := b: val({a, b, a*0})
```

$\{b, 0\ b\}$

```
delete a:
```

Example 2

`val` does not flatten its argument, nor does it remove void objects of type `DOM_NULL`:

```
a := null(): val((a, null()))
```

```
 null(), null()
```

However, it is not legal to pass several arguments:

```
val(a, null())
```

```
Error: The number of arguments is incorrect. [val]
```

```
delete a:
```

Example 3

`val` does not recursively substitute values for the identifiers:

```
delete a, b: a := b: b := c: val(a)
```

b

Parameters

`object`

Any MuPAD object

Return Values

“evaluated” object.

See Also

MuPAD Functions
`eval` | `hold` | `LEVEL` | `level` | `MAXLEVEL`

vectorPotential

Vector potential of a three-dimensional vector field

Syntax

```
vectorPotential(j, [x1, x2, x3], <Test>)
```

Description

`vectorPotential(j, x)` returns the vector potential of the vector field $\vec{j}(\vec{x})$ with respect to $\vec{x}$. This is a vector field $\vec{v}$ with $\mathrm{curl}_{\vec{v}}(\vec{x}) = \vec{j}$.

The vector potential of a vector function `j` exists if and only if the divergence of `j` is zero. It is uniquely determined.

If the vector potential of `j` does not exist, then `vectorPotential` returns `FALSE`.

If `j` is a vector then the component ring of `j` must be a field (i.e., a domain of category `Cat::Field`) for which definite integration can be performed.

If `j` is given as a list of three arithmetical expressions, then `vectorPotential` returns a vector of the domain `Dom::Matrix()`.

Examples

Example 1

We check if the vector function $\vec{j}(x, y, z) = \left(x^2\, y,\ -\frac{y^2\, x}{2},\ -x\, y\, z\right)$ has a vector potential:

```
delete x, y, z:
vectorPotential(
  [x^2*y, -1/2*y^2*x, -x*y*z], [x, y, z], Test
)
```

```
TRUE
```

The answer is yes, so let us compute the vector potential of $\vec{j}$:

```
vectorPotential(
  [x^2*y, -1/2*y^2*x, -x*y*z], [x, y, z]
)
```

$$\begin{pmatrix} -\frac{x\,y^2\,z}{2} \\ -x^2\,y\,z \\ 0 \end{pmatrix}$$

We check the result:

```
curl(%, [x, y, z])
```

$$\begin{pmatrix} x^2\,y \\ -\frac{x\,y^2}{2} \\ -x\,y\,z \end{pmatrix}$$

Example 2

The vector function $\vec{j} = (x^2, 2\,y, z)$ does not have a vector potential:

```
vectorPotential([x^2, 2*y, z], [x, y, z])
```

```
FALSE
```

Parameters

j

A list of three arithmetical expressions, or a 3-dimensional vector (i.e., a 3×1 or 1 ×3 matrix of a domain of category `Cat::Matrix`)

x_1, x_2, x_3

(indexed) identifiers

Options

`Test`

Check whether the vector field `j` has a vector potential and return `TRUE` or `FALSE`, respectively.

Return Values

Vector with three components, i.e., an 3×1 or $1 \times n$ matrix of a domain of category `Cat::Matrix`, or a boolean value.

MuPAD Functions

`curl` | `divergence` | `gradient` | `laplacian` | `potential`

version

Version number of the MuPAD library

Syntax

```
version()
```

Description

`version()` returns the version number of the installed MuPAD library.

The call `Pref::kernel()` returns the version number of the installed MuPAD kernel.

The version numbers of the kernel and the library may differ: `version` refers to the library, whereas the call `Pref::kernel()` returns the version number of the kernel.

Examples

Example 1

The version of this MuPAD library is:

```
version()
```

```
[6, 2, 0]
```

Return Values

Version number: a list of three nonnegative integers.

See Also

MuPAD Functions

`buildnumber` | `Pref::kernel`

warning

Print a warning message

Syntax

```
warning(message)
```

Description

`warning(message)` prints the message with the prefix "`Warning:`".

`warning` may be used to print information about potential problems in an algorithm. E.g., it is used in `limit` to provide hints.

Examples

Example 1

A warning:

```
warning("You should not do this!"):
```

```
Warning: You should not do this!
```

Example 2

This example shows a simple procedure which divides two numbers. If the second argument is omitted, a warning is printed and the computation continues:

```
mydivide := proc(x, y)
begin
  if args(0) < 2 then
    warning("Denominator not given, using 1.");
    y := 1;
  end_if:
```

```
  x/y
end_proc:
mydivide(10)

Warning: Denominator not given, using 1. [mydivide]

     10
```

Parameters

`message`

A character string

Return Values

Void object of type `DOM_NULL`.

See Also

MuPAD Functions

`error` | `print`

whittakerM

The Whittaker M function

Syntax

```
whittakerM(a, b, z)
```

Description

The `whittakerM` function $M_{a,\,b}(z)$ is related to the confluent hypergeometric function ${}_pF_q(a,\,b,\,z) = \Phi(a,\,b,\,z)$ by the formula:

$$M_{a,\,b}(z) = \mathrm{e}^{-\frac{z}{2}}\, z^{\frac{1}{2}+b}\, \Phi\left(\frac{1}{2}+b-a,\,1+2\,b,\,z\right),$$

The WhittakerM function is defined for complex arguments a, b, and z.

For most of the values of the parameters, an unevaluated function call is returned. Cf. “Example 1” on page 1-2200.

Explicit symbolic expressions are returned for some particular values of the parameters. Cf. “Example 2” on page 1-2200.

Note: MuPAD defines ${}_1F_1(a,\,a,\,z) = \mathrm{e}^z$ for all complex numbers a. As a consequence, the MuPAD `whittakerM` differs from the corresponding function in M. Abramowitz and I. A. Stegun, “Handbook of Mathematical Functions” when $\frac{1}{2}+b-a$ and $1 + 2\,b$ are negative integers and $\frac{1}{2}+b-a \geq 1+2\,b$. Some of the formulas in Chapter 13 of the “Handbook of Mathematical Functions” do not hold for the MuPAD `whittakerM` with such arguments. Cf. “Example 4” on page 1-2201.

Environment Interactions

When called with floating-point arguments, these functions are sensitive to the environment variable `DIGITS` which determines the numerical working precision.

Examples

Example 1

Unevaluated calls are returned for exact or symbolic arguments:

```
whittakerM(a, b, x), whittakerW(-3/2, 1/2, 1)
```

$$\mathrm{M}_{a,b}(x),\ \mathrm{W}_{-\frac{3}{2},\frac{1}{2}}(1)$$

Floating point values are returned for floating-point arguments:

```
whittakerM(-2, 0.5, -50), whittakerW(-3/2, 1/2, 0.0)
```

$$0.00000001666553264,\ 0.7522527781$$

Example 2

Explicit expressions are returned for some specific values of the parameters:

```
whittakerM(0, b, x), whittakerW(0, b, x), whittakerW(-3/2, 1/2, 0),
whittakerM(-3/2, 0 ,x), whittakerW(a, -a + 1/2, x)
```

$$4^b\sqrt{x}\,\Gamma(b+1)\,\mathrm{I}_b\left(\frac{x}{2}\right),\ \frac{x^{b+\frac{1}{2}}\,\mathrm{K}_b\left(\frac{x}{2}\right)}{\sqrt{\pi}\,x^b},\ \frac{4}{3\sqrt{\pi}},\ \sqrt{x}\,\mathrm{e}^{\frac{x}{2}}\,(x+1),\ x^{1-a}\,x^{2a-1}\,\mathrm{e}^{-\frac{x}{2}}$$

Example 3

The functions `diff`, `float`, `limit`, and `series` handle expressions involving the Whittaker functions

```
diff(whittakerM(a,b,z),z), float(whittakerW(-3/2,1/2,0))
```

$$\frac{M_{a+1,b}(z)\left(a+b+\frac{1}{2}\right)}{z}-\left(\frac{a}{z}-\frac{1}{2}\right)M_{a,b}(z),\ 0.7522527781$$

```
series(whittakerW(-3/2,1/2,x),x,3)
```

$$\frac{4}{3\sqrt{\pi}}+x\left(\frac{2\sigma_1}{\sqrt{\pi}}-\frac{2}{3\sqrt{\pi}}\right)+x^2\left(\frac{2\left(\frac{5\,\mathrm{EULER}}{4}-\frac{5\ln(2)}{2}+\frac{5\ln(x)}{4}+\frac{17}{24}\right)}{\sqrt{\pi}}-\frac{\sigma_1}{\sqrt{\pi}}+\frac{1}{6\sqrt{\pi}}\right)+O(x^3)$$

where

$$\sigma_1=\mathrm{EULER}-2\ln(2)+\ln(x)+\frac{5}{3}$$

Example 4

For some values of the input parameters, recurrence and differential relations in Chapter 13 of M. Abramowitz and I. A. Stegun, "Handbook of Mathematical Functions" may not hold for the MuPAD `whittakerM` functions. For example, Formula 13.4.32

$$z\frac{\partial}{\partial z}M_{a,b}(z)=\left(\frac{z}{2}-a\right)M_{a,b}(z)+\left(a+b+\frac{1}{2}\right)M_{a+1,b}(z)$$

is not satisfied for $a = 0$ and $b=-\frac{3}{2}$:

```
expand(x*diff(whittakerM(0, -3/2, x), x) <>
x/2*whittakerM(0, -3/2, x) - whittakerM(1, -3/2, x))
```

$$-\frac{e^{-\frac{x}{2}}}{2}-\frac{x\,e^{-\frac{x}{2}}}{4}-\frac{e^{-\frac{x}{2}}}{x}\neq\frac{e^{-\frac{x}{2}}}{2}+\frac{x\,e^{-\frac{x}{2}}}{4}-\frac{e^{\frac{x}{2}}}{x}$$

Parameters

a, b, z

arithmetical expressions

Return Values

Arithmetical expression.

Overloaded By

z

Algorithms

$M_{a,\,b}(z)$ and $W_{a,\,b}(z)$ satisfy Whittaker's differential equation:

$$\frac{\partial^2}{\partial z^2}\,y+\left(-\frac{1}{4}+\frac{a}{z}+\frac{\frac{1}{4}-b^2}{z^2}\right)y=0$$

.

See Also

MuPAD Functions

`hypergeom` | `kummerU` | `whittakerW`

whittakerW

The Whittaker W function

Syntax

```
whittakerW(a, b, z)
```

Description

The `whittakerW` function $W_{a,b}(z)$ is related to the confluent hypergeometric function $kummerU(a, b, z) = U(a, b, z)$ by the formula:

$$W_{a,b}(z) = e^{-\frac{z}{2}} z^{\frac{1}{2}+b} U\left(\frac{1}{2}+b-a, 1+2b, z\right).$$

The WhittakerW function is defined for complex arguments a, b, and z.

For most of the values of the parameters, an unevaluated function call is returned. Cf. "Example 1" on page 1-2203.

Explicit symbolic expressions are returned for some particular values of the parameters. Cf. "Example 2" on page 1-2204.

Environment Interactions

When called with floating-point arguments, these functions are sensitive to the environment variable `DIGITS` which determines the numerical working precision.

Examples

Example 1

Unevaluated calls are returned for exact or symbolic arguments:

```
whittakerM(a, b, x), whittakerW(-3/2, 1/2, 1)
```

$$M_{a,b}(x),\ W_{-\frac{3}{2},\frac{1}{2}}(1)$$

Floating point values are returned for floating-point arguments:

```
whittakerM(-2, 0.5, -50), whittakerW(-3/2, 1/2, 0.0)
```

$$0.00000001666553264,\ 0.7522527781$$

Example 2

Explicit expressions are returned for some specific values of the parameters:

```
whittakerM(0, b, x), whittakerW(0, b, x), whittakerW(-3/2, 1/2, 0),
whittakerM(-3/2, 0 ,x), whittakerW(a, -a + 1/2, x)
```

$$4^b \sqrt{x}\,\Gamma(b+1)\,I_b\left(\frac{x}{2}\right),\ \frac{x^{b+\frac{1}{2}}\,K_b\left(\frac{x}{2}\right)}{\sqrt{\pi}\,x^b},\ \frac{4}{3\sqrt{\pi}},\ \sqrt{x}\,e^{\frac{x}{2}}\,(x+1),\ x^{1-a}\,x^{2a-1}\,e^{-\frac{x}{2}}$$

Example 3

The functions `diff`, `float`, `limit`, and `series` handle expressions involving the Whittaker functions

```
diff(whittakerM(a,b,z),z), float(whittakerW(-3/2,1/2,0))
```

$$\frac{M_{a+1,b}(z)\left(a+b+\frac{1}{2}\right)}{z}-\left(\frac{a}{z}-\frac{1}{2}\right)M_{a,b}(z),\ 0.7522527781$$

```
series(whittakerW(-3/2,1/2,x),x,3)
```

$$\frac{4}{3\sqrt{\pi}} + x\left(\frac{2\sigma_1}{\sqrt{\pi}} - \frac{2}{3\sqrt{\pi}}\right) + x^2\left(\frac{2\left(\frac{5\,\mathrm{EULER}}{4} - \frac{5\ln(2)}{2} + \frac{5\ln(x)}{4} + \frac{17}{24}\right)}{\sqrt{\pi}} - \frac{\sigma_1}{\sqrt{\pi}} + \frac{1}{6\sqrt{\pi}}\right) + O(x^3)$$

where

$$\sigma_1 = \mathrm{EULER} - 2\ln(2) + \ln(x) + \frac{5}{3}$$

Example 4

For some values of the input parameters, recurrence and differential relations in Chapter 13 of M. Abramowitz and I. A. Stegun, "Handbook of Mathematical Functions" may not hold for the MuPAD `whittakerM` functions. For example, Formula 13.4.32

$$z\frac{\partial}{\partial z}M_{a,b}(z) = \left(\frac{z}{2} - a\right)M_{a,b}(z) + \left(a + b + \frac{1}{2}\right)M_{a+1,b}(z)$$

is not satisfied for $a = 0$ and $b = -\frac{3}{2}$:

```
expand(x*diff(whittakerM(0, -3/2, x), x) <>
x/2*whittakerM(0, -3/2, x) - whittakerM(1, -3/2, x))
```

$$-\frac{e^{-\frac{x}{2}}}{2} - \frac{x\,e^{-\frac{x}{2}}}{4} - \frac{e^{-\frac{x}{2}}}{x} \neq \frac{e^{-\frac{x}{2}}}{2} + \frac{x\,e^{-\frac{x}{2}}}{4} - \frac{e^{\frac{x}{2}}}{x}$$

Parameters

a, b, z

arithmetical expressions

Return Values

Arithmetical expression.

Overloaded By

z

Algorithms

$M_{a,\,b}(z)$ and $W_{a,\,b}(z)$ satisfy Whittaker's differential equation:

$$\frac{\partial^2}{\partial z^2}\,y + \left(-\frac{1}{4} + \frac{a}{z} + \frac{\frac{1}{4} - b^2}{z^2}\right) y = 0$$

.

See Also

MuPAD Functions

`hypergeom` | `kummerU` | `whittakerM`

wrightOmega

The Wright ω function

Syntax

```
wrightOmega(x)
```

Description

$\omega(x)$ is defined in terms of Lambert's W function as $\omega(x) = \mathrm{W}_{\left\lceil \frac{\Im(x)-\pi}{2\pi} \right\rceil}(e^x)$.

For $x \neq t$ - i π with $t \leq$ - 1, $y = \omega(x)$ is a solution of the equation $y + ln(y) = x$. The complete solution set of this equation is

$$y = \begin{cases} \varnothing & \text{if } \Re(x) \leq -1 \wedge \Im(x) = -\pi \\ \{\omega(x),\ \omega(x - 2\pi i)\} & \text{if } \Re(x) \leq -1 \wedge \Im(x) = \pi \\ \{\omega(x)\} & \text{otherwise} \end{cases}.$$

A floating-point value is computed if the argument is a floating point value. Unevaluated symbolic calls are returned for most exact arguments. For some special cases explicit symbolic representations are returned.

Environment Interactions

When called with a floating-point argument, the function is sensitive to the environment variable `DIGITS` which determines the numerical working precision.

Examples

Example 1

Most calls with exact arguments return themselves unevaluated:

```
wrightOmega(1/2); wrightOmega(I*PI);
```

$$\omega\left(\frac{1}{2}\right)$$

$$\omega(\pi\, i)$$

Some special arguments return explicit symbolic representations:

```
wrightOmega(-1+I*PI); wrightOmega(ln(2)+6*PI*I);
```

$$-1$$

$$W_3(2)$$

If the argument is a floating-point value, then a floating-point result will be returned:

```
wrightOmega(0.5)
```

$$0.7662486082$$

Parameters

x

An arithmetical expression, the “argument”

Return Values

Arithmetical expression

See Also

MuPAD Functions
`lambertW`

write

Write values of variables into file

Syntax

```
write(<Bin | Text>, <Encoding = "encodingValue">, filename, <x1, x2, …>)
```

```
write(<Encoding = "encodingValue">, n, <x1, x2, …>)
```

Description

`write` serves for storing information from the current MuPAD session in a file. The file contains the values of identifiers of the current session. These identifiers are assigned the stored values when this file is read into another MuPAD session via the function `read`.

`write(filename, x1, x2, ...)` stores the current values of the identifiers x_1, x_2 etc. to the file filename.

`write(filename)` stores the values of all identifiers defined in the current session to the file filename.

`write(n)` and `write(n, x1, x2, ...)` store the data in the file associated with the file descriptor `n`.

`write(..., Encoding = "encodingValue", ...)` stores the current values of identifiers in the specified encoding only when writing in `Text` mode. For the supported encodings, see “Options” on page 1-2215. You can use this option with any of the previously specified syntaxes.

If the file is specified by its name, `write` creates a new file or overwrites an existing file; `write` opens and closes the file automatically.

If `WRITEPATH` does not have a value, `write` interprets the file name as a pathname relative to the “working folder”.

Note that the meaning of “working folder” depends on the operating system. On Microsoft Windows systems and on Mac OS X systems, the “working folder” is the folder

whereMATLAB is installed. On UNIX systems, it is the current working folder in which MATLAB was started. When started from a menu or desktop item, this is typically the user's home folder.

Also absolute path names are processed by `write`.

Instead of a file name, also a file descriptor of a file opened via `fopen` can be used. See “Example 2” on page 1-2212. In this case, the data written by `write` are appended to the corresponding file. The file is not closed automatically by `write` and must be closed by a subsequent call to `fclose`.

Note that `fopen(filename)` opens the file in read-only mode. A subsequent `write` command to this file causes an error. Use the `Write` or `Append` option of `fopen` to open the file for writing.

The file descriptor 0 represents the screen.

`write` stores procedures with the option `noExpose` in encrypted format.

Note: `write` stores the *values* of the given identifiers, not *their full evaluation*! See “Example 3” on page 1-2213.

Environment Interactions

The function is sensitive to the environment variable `WRITEPATH`. If this variable has a value, the file is created in the corresponding folder. Otherwise, the file is created in the “working folder.”

Examples

Example 1

The variable `a` and its value `b + 1` are stored in a file named `test`:

```
a := b + 1:
fid := fopen(TempFile, Write, Text):
write(fid, a):
```

Use `fname` to return the name of the temporary file you created:

```
file := fname(fid):
```

The content of this file is displayed via `ftextinput`:

```
ftextinput(file)
```

```
"a := hold(_plus)(hold(b), 1):"
```

Delete the value of `a`. Reading the file `test` restores the previous value:

```
delete a:
read(file):
a
```

$$b + 1$$

For identifiers that have no value, `write` writes a `delete` command to the file:

```
delete a:
write(Text, 0, a):

delete a:
```

Example 2

The file `test` is opened for writing using the MuPAD binary format:

```
fid := fopen(TempFile):
file := fname(fid):
n := fopen(file, Write)
```

```
17
```

This number is the descriptor of the file and can be used in a write command:

```
a := b + 1:
write(n, a):
fclose(n):

delete a:
```

```
read(file):
a
```

$$b + 1$$

Clean up:

```
delete n, a:
```

Example 3

The value `b + 1` is assigned to the identifier `a`. After assigning the value `2` to `b`, complete evaluation of `a` yields `3`:

```
a := b + 1:
b := 2:
a
```

$$3$$

Note, however, that the value of `a` is the expression `b + 1`. This value is stored by a `write` command:

```
fid := fopen(TempFile, Write, Text):
write(fid, a):
file := fname(fid):
ftextinput(file)
```

"a := hold(_plus)(hold(b), 1):"

Consequently, this value is restored after reading the file into a MuPAD session:

```
delete a, b:
read(file):
a
```

$$b + 1$$

```
delete a:
```

Example 4

`write`, when writing binary format, can store procedures with the option `noExpose` set. They are encrypted before writing:

```
f := proc(a)
  option noExpose;
begin
  print(a, a^2, a*a);
end_proc:

write("hidden_proc.mb", f):

delete f:

read("hidden_proc.mb"):

f(-2...3);
expose(f)
```

$$-2.0 \ldots 3.0,\ 0.0 \ldots 9.0,\ -6.0 \ldots 9.0$$

```
proc(a)
  name f;
  option noDebug, noExpose;
begin
  /* Hidden */
end_proc
```

This is the intention behind option `noExpose`: You can develop code you wish not to publish, then include `option noExpose` in your sources, rerun your tests, use `write` to write a binary version of your library and distribute that.

Example 5

To specify the encoding to write data, use Encoding. The Encoding option applies only to text files that are opened using a file name and not a file descriptor. Write the value of the identifier `a:="abcäöü"` into a temporary file in the encoding “`UTF-8`”:

```
a:="abcäöü":
write(Text,Encoding="UTF-8","write_test",a):
```

Specify the correct encoding to read the file:

```
read("write_test", Encoding="UTF-8")
```

```
"abcäöü"
```

If you do not specify an encoding, the default system encoding is used. Thus, your output might vary from that shown next. Characters unrecognized by the default system encoding are replaced by the default substitution character for that encoding:

```
a:="abcäöü":
write(Text, "write_test", a):
read("write_test")
```

```
"abc"
```

Parameters

`filename`

The name of a file: a character string

x_1, x_2, …

identifiers

`n`

A file descriptor provided by `fopen`: a nonnegative integer

Options

`Bin`, `Text`

With `Bin`, the data are stored in the MuPAD binary format. With `Text`, standard ASCII format is used. The default is `Bin`.

In ASCII format, assignments of the form `identifier := hold(value):` or `delete identifier:` are written into the file. See “Example 1” on page 1-2211.

Encoding

This option lets you specify the character encoding to use. The allowed encodings are:

"Big5"	"ISO-8859-1"	"windows-932"
"EUC-JP"	"ISO-8859-2"	"windows-936"
"GBK"	"ISO-8859-3"	"windows-949"
"KSC_5601"	"ISO-8859-4"	"windows-950"
"Macintosh"	"ISO-8859-9"	"windows-1250"
"Shift_JIS"x	"ISO-8859-13"	"windows-1251"
"US-ASCII"	"ISO-8859-15"	"windows-1252"
"UTF-8"		"windows-1253"
		"windows-1254"
		"windows-1257"

The default encoding is system dependent. If you specify the encoding incorrectly, characters might read incorrectly. Characters unrecognized by the encoding are replaced by the default substitution character for the specified encoding.

Encodings not listed here can be specified but might not produce correct results.

Return Values

Void object of type DOM_NULL.

zeta

The Riemann zeta function

Syntax

```
zeta(z)
zeta(z, n)
```

Description

`zeta(z)` represents the Riemann zeta function $\zeta(z) = \sum_{k=1}^{\infty} \frac{1}{k^z}$.

`zeta(z, n)` represents the n-th derivative $\sum_{k=1}^{\infty} \frac{(-\ln(k))^n}{k^z}$ of the zeta function.

The series converge only if the real part of `z` is greater than 1. The definition of the zeta function is extended to the entire complex plane, except for a simple pole `z = 1`, by analytic continuation.

The calls `zeta(z)` and `zeta(z, 0)` are equivalent.

A floating-point result is returned for floating-point arguments *z*.

The following special exact values are implemented:

$\zeta(0) = -\frac{1}{2}$, $\zeta(0, 1) = -\frac{\ln(\pi)}{2} - \frac{\ln(2)}{2}$,

$\zeta(z) = 0$ for even integers $z < 0$,

$\zeta(z) = -\frac{\text{bernoulli}(1-z)}{1-z}$ for odd integers z satisfying - *Pref*::*autoExpansionLimit*() $\le z < 0$,

$\zeta(z) = \frac{(2\pi)^z \,|\text{bernoulli}(z)|}{2\,z!}$ for even integers z satisfying $0 \le z \le$ *Pref*::*autoExpansionLimit*(),

$\zeta(\infty) = 1$, $\zeta(\infty, n) = 0$ for $n > 0$.

`zeta` returns a symbolic function call, if the argument does not evaluate to one of the above numbers.

Note: Floating point evaluation is rather slow for large values of n. Further, for large n, evaluation for $\Re(z) < 0$ is much slower than the evaluation for $\Re(z) \geq 0$.

Environment Interactions

When called with a floating-point argument z, the function is sensitive to the environment variable `DIGITS` which determines the numerical working precision.

Examples

Example 1

We demonstrate some calls with exact and symbolic input data:

```
zeta(-6), zeta(-5), zeta(-4), zeta(-3), zeta(-2), zeta(-1)
```

$$0,\ -\frac{1}{252},\ 0,\ \frac{1}{120},\ 0,\ -\frac{1}{12}$$

```
zeta(0), zeta(2), zeta(3), zeta(4), zeta(5), zeta(6), zeta(7)
```

$$-\frac{1}{2},\ \frac{\pi^2}{6},\ \zeta(3),\ \frac{\pi^4}{90},\ \zeta(5),\ \frac{\pi^6}{945},\ \zeta(7)$$

```
zeta(1/2), zeta(1 + I, 1), zeta(z^2 -I, 2)
```

$$\zeta\left(\frac{1}{2}\right),\ \zeta'(1+i),\ \zeta''(z^2-i)$$

Here are some values of the derivative of the zeta function:

```
zeta(0, 1), zeta(infinity, 1)
```

$$-\frac{\ln(2)}{2}-\frac{\ln(\pi)}{2},\ 0$$

Floating point values are computed for floating-point arguments:

```
zeta(-1001.0), zeta(12.3, 1), zeta(0.5 + 14.13472514*I, 2)
```

$$-1.348590824\,10^{1771},\ -0.0001389996909,\ -0.614409794-0.2297836439\,i$$

`zeta` has a pole at the point $z = 1$:

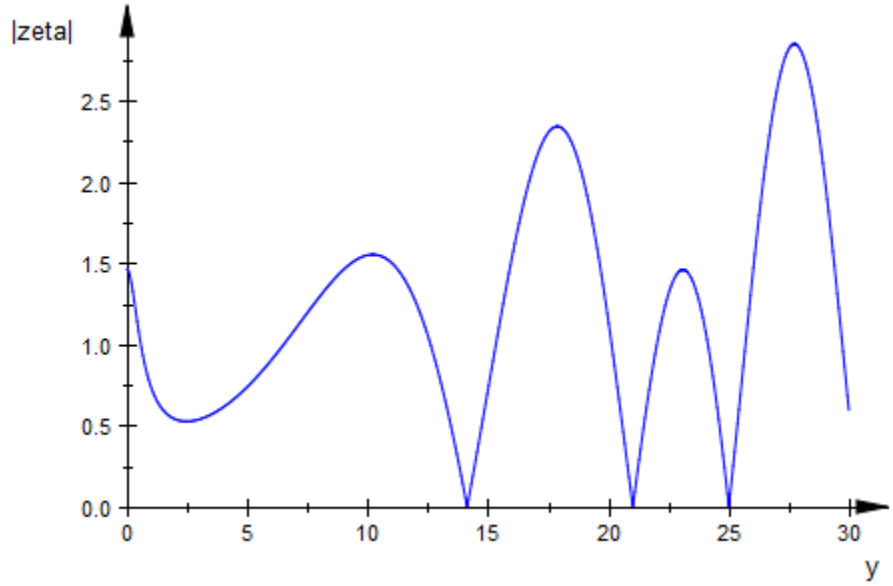
```
zeta(1)
```

```
Error: Singularity. [zeta]
```

Example 2

Looking for nontrivial roots of the Zeta function, we plot the function $f(z) = |\zeta(z)|$ along the "critical line" of complex numbers with real part $\frac{1}{2}$:

```
plotfunc2d(abs(zeta(1/2 + y*I)), y = 0..30,
                                 Mesh = 500,
                                 AxesTitles = ["y", "|zeta|"])
```



The following calls search for numerical roots along the critical line:

```
numeric::solve(zeta(1/2 + I*y), y = 10..20),
numeric::solve(zeta(1/2 + I*y), y = 20..22),
numeric::solve(zeta(1/2 + I*y), y = 22..26)
```

$$\{14.13472514\}, \{21.02203964\}, \{25.01085758\}$$

Parameters

z

An arithmetical expression

n

An arithmetical expression representing a nonnegative integer

Return Values

Arithmetical expression.

Overloaded By

z

MuPAD Functions

`bernoulli`

zip

Combine lists

Syntax

```
zip(list1, list2, f)
```

```
zip(list1, list2, f, default)
```

Description

`zip(list1, list2, f)` combines two lists via a function `f`. It returns a list whose i-th entry is `f(list1[i], list2[i])`. Its length is the minimum of the lengths of the two input lists.

`zip(list1, list2, f, default)` returns a list whose length is the maximum of the lengths of the two input lists. The shorter list is padded with the `default` value.

If `f` produces the void object of type `DOM_NULL`, then this element is removed from the resulting list.

`zip` is recommended for fast manipulation of lists. It is a function of the system kernel.

Examples

Example 1

The fastest way of adding the entries of two lists is to 'zip' them via the function `_plus`:

```
zip([a, b, c, d], [1, 2, 3, 4], _plus)
```

$$[a+1,\ b+2,\ c+3,\ d+4]$$

If the input lists have different lengths, then the shorter list determines the length of the returned list:

```
zip([a, b, c, d], [1, 2], _plus)
```

$$[a+1,\ b+2]$$

The longer list determines the length of the returned list if a value for padding the shorter list is provided:

```
zip([a, b, c, d], [1, 2], _plus, 17)
```

$$[a+1,\ b+2,\ c+17,\ d+17]$$

Parameters

`list1, list2`

lists of arbitrary MuPAD objects

`f`

Any MuPAD object. Typically, a function of two arguments.

`default`

Any MuPAD object

Return Values

List.

Overloaded By

list1, list2

MuPAD Functions

`map` | `op` | `select` | `split`

ztrans

Z transform

Syntax

```
ztrans(f, k, z)
```

Description

`ztrans(f, k, z)` computes the Z transform of the expression `f = f(k)` with respect to the index `k` at the point `z`.

The Z transform `F(z)` of the function `f(k)` is defined as follows:

$$F(z) = \sum_{k=0}^{\infty} \frac{f(k)}{z^k}$$

If `ztrans` cannot find an explicit representation of the transform, it returns an unevaluated function call. See “Example 4” on page 1-2225.

If `f` is a matrix, `ztrans` applies the Z transform to all components of the matrix.

To compute the inverse Z transform, use `iztrans`.

Examples

Example 1

Compute the Z transform of these expressions:

```
ztrans(1/k!, k, z)
```

$$e^{\frac{1}{z}}$$

```
ztrans(sin(k), k, z)
```

$$\frac{z \sin(1)}{z^2 - 2\cos(1)\, z + 1}$$

Example 2

Compute the Z transform of this expression and then simplify the result:

```
ztrans(cos(a*k + b), k, z)
```

$$\frac{z \cos(b)\,(z - \cos(a))}{z^2 - 2\cos(a)\, z + 1} - \frac{z \sin(a) \sin(b)}{z^2 - 2\cos(a)\, z + 1}$$

```
Simplify(%)
```

$$-\frac{z\,(\cos(a - b) - z\cos(b))}{z^2 - 2\cos(a)\, z + 1}$$

Example 3

Compute the Z transform of this expression with respect to the variable `k`:

```
F := ztrans(2*k + 3, k, z)
```

$$\frac{3z}{z-1} + \frac{2z}{(z-1)^2}$$

Evaluate the Z transform of the expression at the points $z = 2a + 3$ and $z = 1 + i$. You can evaluate the resulting expression `F` using `|` (or its functional form `evalAt`):

```
F | z = 2*a + 3
```

$$\frac{3\,(2a+3)}{2a+2} + \frac{2\,(2a+3)}{(2a+2)^2}$$

Also, you can evaluate the Z transform at a particular point directly:

```
ztrans(2*k + 3, k, 1 + I)
```

$$1 - 5\,i$$

Example 4

If `ztrans` cannot find an explicit representation of the transform, it returns an unevaluated call:

```
ztrans(f(k), k, z)
```

$$\text{ztrans}(f(k), k, z)$$

`iztrans` returns the original expression:

```
iztrans(%, z, k)
```

$$f(k)$$

Example 5

Compute the following Z transforms that involve Kronecker's Delta function and the Heaviside function:

```
ztrans(f(k)*kroneckerDelta(k, 1) +
       g(k)*kroneckerDelta(k, -5), k, z)
```

$$\frac{f(1)}{z}$$

```
ztrans(binomial(k, 2)*heaviside(5 - k), k, z)
```

$$\frac{z}{(z-1)^3} + \frac{5}{z^5} + \frac{6\,z - \frac{z^6}{(z-1)^3} + 3\,z^2 + z^3}{z^5}$$

Simplify the last expression using `simplify`:

```
simplify(%)
```

$$\frac{z^3 + 3\,z^2 + 6\,z + 5}{z^5}$$

Example 6

Compute the Z transforms of this expression that involves the Heaviside function:

```
ztrans(heaviside(k - 3), k, z)
```

$$\frac{\frac{1}{z-1} + \frac{1}{2}}{z^3}$$

Note that MuPAD uses the value `heaviside(0) = 1/2`. You can define a different value for `heaviside(0)`:

```
unprotect(heaviside):
heaviside(0) := 1:
```

For better performance, MuPAD remembers the previously computed value of the Z transform. To force the system to recalculate the transform, clear its remember table:

```
ztrans(Remember, Clear):
```

For details about the remember mechanism, see Remember Mechanism.

Defining a different value for `heaviside(0)` produces a different value of the Z transform:

```
ztrans(heaviside(k - 3), k, z)
```

$$\frac{\frac{1}{z-1} + 1}{z^3}$$

For further computations, restore the original value:

```
heaviside(0):= 1/2:
protect(heaviside):
```

Example 7

Compute the Z tranforms of these expressions:

```
ztrans(k*f(k), k, z)
```

$$-z\,\frac{\partial}{\partial z}\,\mathrm{ztrans}(f(k),\,k,\,z)$$

```
ztrans(f(k + 1), k, z)
```

$$z\,\mathrm{ztrans}(f(k),\,k,\,z) - z\,f(0)$$

Parameters

f

Arithmetical expression or matrix of such expressions

k

Identifier or indexed identifier

z

Arithmetical expression representing the evaluation point

Return Values

Arithmetical expression or unevaluated function call of type `ztrans`. An explicit result can be a `piecewise` object. If the first argument is a matrix, the result is returned as a matrix.

MuPAD Functions

`iztrans` | `iztrans::addpattern` | `ztrans::addpattern`

ztrans::addpattern

Add patterns for the Z transform

Syntax

```
ztrans::addpattern(pat, k, z, res, <vars, <conds>>)
```

Description

`ztrans::addpattern(pat, k, z, res)` teaches `ztrans` to return $\text{ztrans}(\text{pat}, k, z) = \sum_{k=0}^{\infty} \frac{\text{pat}}{z^k} = \text{res}$.

The `ztrans` function uses a set of patterns for computing Z transforms. You can extend the set by adding your own patterns. To add a new pattern to the pattern matcher, use `ztrans::addpattern`. MuPAD does not save custom patterns permanently. The new patterns are available in the *current* MuPAD session only.

Variable names that you use when calling `ztrans::addpattern` can differ from the names that you use when calling `ztrans`. See “Example 2” on page 1-2230.

You can include a list of free parameters and a list of conditions on these parameters. These conditions and the result are protected from premature evaluation. This means that you can use `not iszero(a^2 - b)` instead of `hold( _not @ iszero )(a^2 - b)`.

The following conditions treat assumptions on identifiers differently:

- `a^2 - b <> 0` takes into account assumptions on identifiers.
- `not iszero(a^2 - b)` disregards assumptions on identifiers.

See “Example 3” on page 1-2231.

Environment Interactions

Calling `ztrans::addpattern` changes the expressions returned by future calls to `ztrans`.

Examples

Example 1

Compute the Z transform of the function `foo`. By default, MuPAD does not have a pattern for this function:

```
ztrans(foo(k), k, z)
```

$$\text{ztrans}(\text{foo}(k), k, z)$$

Add a pattern for the Z transform of `foo` using `ztrans::addpattern`:

```
ztrans::addpattern(foo(k), k, z, bar(z)):
```

Now `ztrans` returns the Z transform of `foo`:

```
ztrans(foo(k), k, z)
```

$$\text{bar}(z)$$

After you add a new transform pattern, MuPAD can use that pattern indirectly:

```
ztrans(foo(k + 3), k, z)
```

$$z^3\,\text{bar}(z) - z\,\text{foo}(2) - z^2\,\text{foo}(1) - z^3\,\text{foo}(0)$$

Example 2

Define the Z transform of `foo(x)` using the variables `x` and `y` as parameters:

```
ztrans::addpattern(x, x, y, y/(y^2-2*y+1)):
```

The `ztrans` function recognizes the added pattern even if you use other variables as parameters:

```
ztrans(s, s, t)
```

$$\frac{t}{t^2 - 2\,t + 1}$$

Example 3

Use assumptions when adding this pattern for the Z transform:

```
ztrans::addpattern(FOO(x*k), k, z, sin(1/(x - 1/2))*BAR(z),
                                    [x], [abs(x) < 1]):
ztrans(FOO(x*k), k, z) assuming -1 < x < 1
```

$$\sin\left(\frac{1}{x-\frac{1}{2}}\right)\,\mathrm{BAR}(z)$$

If $|x| \geq 1$, you cannot apply this pattern:

```
ztrans(FOO(x*k), k, z) assuming x >= 1
```

$$\mathrm{ztrans}(\mathrm{FOO}(k\,x),\,k,\,z)$$

If MuPAD cannot determine whether the conditions are satisfied, it returns a `piecewise` object:

```
ztrans(FOO(x*k), k, z)
```

$$\begin{cases} \sin\left(\frac{1}{x-\frac{1}{2}}\right)\,\mathrm{BAR}(z) & \text{if } |x| < 1 \end{cases}$$

Note that the resulting expression defining the Z transform of `FOO(x*k)` implicitly assumes that the value of `x` is not 1/2. A strict definition of the pattern is:

```
ztrans::addpattern(BAR(x*k), k, z, sin(1/(x - 1/2))*FOO(z),
                   [x], [abs(x) < 1, x <> 1/2]):
```

If either the conditions are not satisfied or substituting the values into the result gives an error, `ztrans` ignores the pattern. For this particular pattern, you can omit specifying the assumption `x <> 1/2`. If `x = 1/2`, MuPAD throws an internal "Division by zero." error and ignores the pattern:

```
ztrans(FOO(s/2),s,t)
```

$$\mathrm{ztrans}\left(\mathrm{FOO}\left(\frac{s}{2}\right),\,s,\,t\right)$$

Parameters

pat

Arithmetical expression in the variable k representing the pattern to match

k

Identifier or indexed identifier used as a variable in the pattern

z

Identifier or indexed identifier used as a variable in the result

res

Arithmetical expression in the variable k representing the pattern for the result of the transformation

vars

List of identifiers or indexed identifiers used as "pattern variables" (placeholders in pat and res). You can use pattern variables as placeholders for almost arbitrary MuPAD expressions not containing k or z. You can restrict them by conditions given in the optional parameter conds.

conds

List of conditions on the pattern variables

Return Values

Object of type DOM_NULL

See Also

MuPAD Functions

iztrans | iztrans::addpattern | ztrans

2

adt – Abstract Datatypes

adt::Heap
adt::Queue
adt::Stack
adt::Tree

adt::Heap

Abstract data type “Heap”

Syntax

```
adt::Heap()
```

Description

`adt::Heap` implements the abstract data type “Heap”.

A “heap” or “priority queue” is a data type that stores a collection of elements. Elements can be compared and the minimal element can be read and deleted from the heap.

In `adt::Heap`, each element is associated with a comparison key, typically a real number. The keys must be comparable with one another using `<`.

To get access to the largest element in an `adt::Heap`, you can simply negate the comparison keys.

`adt::Heap` returns a function environment. This object has slots `"insert"`, `"nops"`, `"min_pair"`, `"min_element"`, and `"delete_min"` which allow operations on the heap. See the examples.

`adt::Heap` does not allow access to other elements than the minimal one.

Examples

Example 1

`adt::Heap()` creates an empty heap:

```
h := adt::Heap()
```

```
adt::Heap(...)
```

The slot `"nops"` of `h` shows the number of elements in the heap:

```
h::nops()
```

```
     0
```

`h::insert` is the method to insert new elements. It expects two arguments: the comparison key and the data. For now, we simply insert some numbers, so we repeat the number in both arguments:

```
h::insert(3,3):
h::insert(1,1):
h::insert(2,2):

h::nops()
```

```
     3
```

When retrieving the elements with `h::delete_min`, we see that they are returned in increasing order:

```
h::delete_min(), h::delete_min(), h::delete_min()
```

```
     1, 2, 3
```

The heap is now empty:

```
h::nops()
```

```
     0
```

Calling `delete_min` on an empty heap returns `FAIL`:

```
h::delete_min()
```

```
     FAIL
```

Algorithms

`adt::Heap` uses a complete binary tree stored in a list. Insertions operate in expected constant time, with a worst case time logarithmic in the number of elements in the heap. For `"delete_min"`, both the average and the worst-case running time are $O(\log n)$, with n the size of the heap.

See Also

MuPAD Functions

`adt::Queue` | `adt::Stack` | `adt::Tree`

adt::Queue

Abstract data type “Queue”

Syntax

```
adt::Queue(queue)
```

Description

`adt::Queue` implements the abstract data type “Queue”. To create a queue, an expression sequence of any MuPAD objects can be given to initialize the queue, otherwise an empty queue is built.

Note: The methods of all abstract data types must be called especially and will result changing the object itself as side effect.

With `Q := adt::Queue()` an empty queue is built and assigned to the variable `Q`.

Every queue will be displayed as `Queue` followed by a number. This name is generated by `genident`.

Note: *All following methods changes the value of `Q` itself.* A new assignment to the variable (in this example `Q`) is not necessary, in contrast to all other MuPAD functions and data types.

The methods `clear`, `dequeue`, `empty`, `enqueue`, `front`, `length`, `reverse` are available for handling with queues.

Examples

Example 1

Create a new queue with strings as arguments.

```
Q := adt::Queue("1", "2", "3", "4")
```

```
Queue1
```

Show the length of the queue.

```
Q::length()
```

```
4
```

Fill up the queue with a new element. The queue will be changed by the method, no new assignment to `Q` is necessary!

```
Q::enqueue("5")
```

```
"5"
```

Show the front of the queue. This method does not change the queue.

```
Q::front(), Q::front()
```

```
"1", "1"
```

After twice getting an element of the queue, the third element is the new front of the queue, and the length is `3`.

```
Q::dequeue(), Q::dequeue(), Q::front(), Q::length()
```

```
"1", "2", "3", 3
```

Now revert the queue. The last element will be the first element.

```
Q::reverse(): Q::front()
```

```
"5"
```

Enlarge the queue with `"2"`.

```
Q::enqueue("2"):
Q::empty()
```

```
FALSE
```

Finally collect all elements of the queue in the list assigned to ARGS, until the queue is empty.

```
ARGS := []:
while not Q::empty() do ARGS := append(ARGS, Q::dequeue()) end:
ARGS
```

```
["5", "4", "3", "2"]
```

Parameters

queue

An expression sequence of objects to initialize the queue

Methods

clear — Clear the queue

```
clear()
```

dequeue — Get an element from the queue

```
dequeue()
```

empty — I the queue empty

```
empty()
```

enqueue — Fill up the queue

```
enqueue(x)
```

front — Front of the queue

```
front()
```

`length` — Length of the queue

```
length()
```

`reverse` — Revert the queue

```
reverse()
```

adt::Stack

Abstract datatype “Stack”

Syntax

```
adt::Stack(stack)
```

Description

`adt::Stack` implements the abstract data type “Stack.” To create a stack, an expression sequence of any MuPAD objects can be given to initialize the stack, otherwise an empty stack is built.

Note: The methods `adt::Stack`, like those of all abstract data types, change their argument as a side effect.

With `S := adt::Stack()` an empty stack is built and assigned to the variable `S`.

Note: *All following methods change the value of S itself*. A new assignment to the variable (in this example `S`) is not necessary, in contrast to most other MuPAD functions and data types.

The stacks created in a session are named `Stack1, Stack2,...` and printed as such.

Examples

Example 1

We create an empty stack, and fill it with some values:

```
S := adt::Stack();
S::push(a): S::push(b): S::push(c):
```

```
Stack1
```

The stack now contains 3 elements:

```
S::nops()
```

```
3
```

The top of the stack is the last valued pushed:

```
S::top()
```

```
c
```

Now, we fetch successively the values contains in S; they come back in reversed order:

```
S::pop();
S::pop();
S::pop()
```

```
c
```

```
b
```

```
a
```

Now, the stack is empty. Trying to pop again an element from it results in a FAIL value being returned:

```
S::pop()
```

```
FAIL
```

Parameters

`stack`

An expression sequence of objects to initialize the stack

Return Values

Object of the domain `adt::Stack`

Methods

`S::empty` — I the stack empty

```
S::empty()
```

`S::nops` — Size of the stack

```
S::nops()
```

`S::depth` — Depth of the stack

```
S::depth()
```

`S::top` — Top element of the stack

```
S::top()
```

`S::push` — Push an element on the stack

```
S::push(x)
```

`S::pop` — Pop an element from the stack

```
S::pop()
```

`S::reverse` — Revert the stack

```
S::reverse()
```

`S::copy` — Copy of the stack

```
S::copy()
```

adt::Tree

Abstract data type “Tree”

Syntax

```
adt::Tree(tree)
```

Description

`adt::Tree` implements the abstract data type “Tree”.

A tree must be given as a special MuPAD list. The first object of the list is the root of the tree. All further objects are leaves or subtrees of the tree. A subtree is again a special list (as described), and any other MuPAD object will be interpreted as leaf of the tree (see “Example 1” on page 2-13).

A tree can be used to display data in tree structure using the function `output::tree` (or the method `"print"` of a tree). The nodes and leaves of the tree will be printed by MuPAD when the tree will be displayed.

A tree can also be used as datatype to keep and handle any MuPAD data.

Note: The methods of all abstract data types must be called especially and will result changing the object itself as side effect.

`T := adt::Tree([_plus, 3, 4, [_mult, 5, 3], 1])` builds a tree and assigns it to the variable `T`.

Every tree will be displayed as `Tree` followed by a number. This name is generated by `genident`.

To display the content of a tree, the function `expose` or the method `"print"` of the tree itself must be used.

Note: *All following methods changes the value of T itself.* A new assignment to the variable (in this example T) is not necessary, in contrast to all other MuPAD functions and data types.

The methods `nops`, `op`, `expr`, `print`, `indent`, `chars` are now available for handling with trees.

Examples

Example 1

Creating a simple tree with only two leaves. To access and display a tree it must be assigned to a variable:

```
T := adt::Tree(["ROOT", "LEFT", "RIGHT"])
```

```
     Tree1
```

The tree will only be printed by its name. To display the tree, the function `expose` or the method `"print"` of the tree must be used:

```
T::print()
```

```
ROOT
|
+-- LEFT
|
`-- RIGHT
```

```
expose(T)
```

```
ROOT
|
+-- LEFT
|
`-- RIGHT
```

The next tree contains two subtrees as leaves:

```
T := adt::Tree(["ROOT", ["LROOT", "LLEFT", "LRIGHT"],
                        ["RROOT", "RLEFT", "RRIGHT"]]):
T::print()
```

```
ROOT
|
+-- LROOT
|   |
|   +-- LLEFT
|   |
|   `-- LRIGHT
|
`-- RROOT
    |
    +-- RLEFT
    |
    `-- RRIGHT
```

Example 2

Get the operands of a tree: Also a subtree can be an operand:

```
T := adt::Tree(["ROOT", ["LROOT", "LLEFT", "LRIGHT"],
                        "MIDDLE",
                        ["RROOT", "RLEFT", "RRIGHT"]]):
T::op()
```

```
Tree4, "MIDDLE", Tree5
```

Use `expose` to display subtrees:

```
map(%, expose)
```

```
LROOT                  RROOT
|                      |
+-- LLEFT , "MIDDLE", +-- RLEFT
|                      |
`-- LRIGHT             `-- RRIGHT
```

Get all operands including the root:

```
T::op(0..T::nops())
```

"ROOT", Tree6, "MIDDLE", Tree7

Access to various operands:

```
T::op(0);
T::op(2..3);
T::op([1, 2])
```

"ROOT"

"MIDDLE", Tree9

"LRIGHT"

Example 3

The default characters are `["|", "+", "-", „", " "]`:

```
T := adt::Tree(["ROOT", ["LROOT", "LLEFT", "LRIGHT"],
                        ["RROOT", "RLEFT", "RRIGHT"]]):
T::print()
```

```
ROOT
|
+-- LROOT
|   |
|   +-- LLEFT
|   |
|   `-- LRIGHT
|
`-- RROOT
    |
    +-- RLEFT
    |
    `-- RRIGHT
```

The characters can be changed:

```
T::chars(["|", "|", "_", "|", " "]):
T::print()
```

```
ROOT
|
|__ LROOT
|   |
|   |__ LLEFT
|   |
|   |__ LRIGHT
|
|__ RROOT
    |
    |__ RLEFT
    |
    |__ RRIGHT
```

Example 4

A tree visualizes the structure of an expression:

```
T:= adt::Tree([_plus, [_power, [sin, x], 2], [_power, [cos, x], 2]]):
T::print()
```

```
_plus
|
+-- _power
|   |
|   +-- sin
|   |   |
|   |   `-- x
|   |
|   `-- 2
|
`-- _power
    |
    +-- cos
    |   |
    |   `-- x
    |
    `-- 2
```

A tree can be converted to a MuPAD expression:

```
T::expr(), simplify(T::expr())
```

$$\cos(x)^2 + \sin(x)^2,\ 1$$

Parameters

`tree`

The tree, given as a special list (see details)

Methods

`nops` — Number of operands

```
nops()
```

In this example `T` has `4` operands, the numbers `3`, `4`, `1` and the subtree `adt::Tree([_mult, 5, 3])`.

`op` — Operand of a tree

```
op(<n>)
```

`T::op(n)` returns the specified operands of the tree. `n` can be a number between `0` and `T::nops()` (`0` gives the root of the tree), a sequence `i..j` (to return the *i*th to *j*th operand), or a list to specify operands of subtrees (exactly as for the kernel function `op`). `T::op()` returns all operands except the `0`-th as expression sequence. See “Example 2” on page 2-14.

`expr` — Convert a tree to an expression

```
expr()
```

`print` — Display a tree

```
print()
```

`indent` — Indent width of each operand

```
indent(<n>)
```

`chars` — Indent width of each operand

```
chars(<list>)
```

Ax – Axioms

Ax::canonicalOrder
Ax::canonicalRep
Ax::canonicalUnitNormal
Ax::closedUnitNormals
Ax::efficientOperation
Ax::indetElements
Ax::normalRep
Ax::noZeroDivisors
Ax::systemRep

Ax::canonicalOrder

Axiom of canonically ordered sets

Description

`Ax::canonicalOrder` states that a domain has an order < (`_less`) which is defined by the canonical order of the MuPAD expressions.

This implies that the order of two elements is defined by the system function `_less`.

Ax::canonicalRep

Axiom of canonical representation

Description

`Ax::canonicalRep` states that domain elements are canonically represented, i.e. that each element of the domain has only one unique expression which represents it.

This axiom implies that for an abelian monoid the axiom `Ax::normalRep` also holds. This is not enforced by the category but must be stated by the implementor of a domain.

Ax::canonicalUnitNormal

Axiom of canonical unit normals

Description

`Ax::canonicalUnitNormal` states that the method `"unitNormal"` of an integral domain (category `Cat::IntegralDomain`) returns a unique unit normal.

This means that for each non-zero element `x` of the integral domain there exists an unique associate among the associate class of `x`, i.e. for any `x` and `y` of a domain `dom` of category `Cat::IntegralDomain` where `dom::associates(x, y)` returns `TRUE` the equation `dom::equal(dom::unitNormal(x), dom::unitNormal(y)) = TRUE` must hold.

Note that this axiom does not imply that the unit normals are canonically represented. The unit normals of `x` and `y` must be mathematically equal in the sense of the method `"equal"`, they need not be structurally equal as MuPAD objects.

Ax::closedUnitNormals

Axiom of closed unit normals

Description

`Ax::closedUnitNormals` states that the unit normals of an integral domain are closed under multiplication, i.e., that `dom::equal(x, dom::unitNormal(a) * dom::unitNormal(b)) = TRUE` implies `dom::equal(x, dom::unitNormal(x)) = TRUE` for all elements `x`, `a` and `b` of the domain `dom`.

This axiom may be used only in conjunction with the axiom `Ax::canonicalUnitNormal`. If an integral domain has no unique unit normals, this axiom may not be stated.

Ax::efficientOperation

Axiom of efficient operations

Syntax

```
Ax::efficientOperation(oper)
```

Description

`Ax::efficientOperation(oper)` states that operation `oper` can be performed efficiently.

The string `oper` must be the name of the operation's slot in the domain stating the axiom. Examples are `"_mult"`, `"_invert"` or `"_divide"`.

Parameters

`oper`

A string which defines the efficient operation.

Ax::indetElements

Axiom that indeterminates may be elements

Description

`Ax::indetElements` states that there exist domain elements that may also be regarded as being transcendental over the domain.

`Ax::indetElements` has no mathematical meaning: elements of a ring are always algebraic (of degree 1) over the ring. However, since there are domains in MuPAD that comprise all MuPAD identifiers, insisting on this viewpoint would mean that polynomials over such domains could not be constructed. Hence MuPAD allows the user to regard an identifier as being transcendental over the set of all identifiers.

Ax::normalRep

Axiom of normal representation

Description

`Ax::normalRep` states that an abelian monoid has a canonical representation of its zero element, i.e., that there is only one unique expression to represent zero.

If the axiom `Ax::normalRep` holds for a domain `dom`, one may test for zero by comparing an element with `dom::zero` using the system function `_equal`.

Ax::noZeroDivisors

Axiom of rings with no zero divisor

Description

`Ax::noZeroDivisors` states that a ring without a unit has no zero divisors, i.e., that the product of two non-zero elements is never zero.

Note that an integral domain implicitly has no zero divisors.

Ax::systemRep

Axiom of façade domains

Description

`Ax::systemRep` states that domain elements are represented by elements of built-in domains.

There are principally two ways to represent the elements of a domain: On the one hand the elements may be created explicitly by the system function `new`, on the other hand one may use the built-in (or basic) domains of MuPAD (like `DOM_INT`) to represent the elements.

Domains which don't create elements of their own but use elements of basic domains instead are called *façade domains*.

The usage of basic domains for the representation has the advantage that system functions may be used directly as methods of the domain without the overhead caused by overloading and procedure calls. But it has some severe limitations, see the domain `Dom::Expression` for details.

The axiom `Ax::systemRep` is used to state that the elements of a domain are represented by basic domains and are not created by `new`.

Cat::BaseCategory

Base category

Description

`Cat::BaseCategory` is the most general super-category of all categories defined by the Cat package. Any domain in the Dom package is of this category.

The methods defined by `Cat::BaseCategory` are related to type conversion and equality testing, they are not related to an algebraic structure.

Methods

Basic Methods

`convert` — Convert into this domain

```
convert(x)
```

`convert_to` — Convert to certain type

```
convert_to(x, T)
```

`equal` — Test for equality

```
equal(x, y)
```

Note that this method does *not* overload the function `_equal`, i.e. the = operator. The function `_equal` cannot be overloaded.

`expr` — Convert into expression

```
expr(x)
```

Conversion Methods

`coerce` — Coerce into this domain

```
coerce(x)
```

The implementation provided tries to convert `x` into an element of this domain by first calling `dom::convert(x)` and then, if this fails, `x::dom::convert_to(x, dom)`; it retuns `FAIL` if both methods fail.

`equiv` — Test for equivalence

```
equiv(x, y)
```

The implementation provided tries to convert `x` and `y` into elements of this domain and then calls `dom::equal` with these elements. It returns `FAIL` if the conversion fails or the equality test returns `UNKNOWN`.

`new` — Create element of this domain

```
new(x)
```

Given a domain `D`, an expression of the form `D(x,...)` results in a call of the form `D::new(x,...)`.

The implementation provided here tries to convert `x` by calling `dom::convert(x)` and returns the result. It raises an error if `dom::convert` returns `FAIL`.

`print` — Return expression to print an element

```
print(x)
```

Please do *not* print directly in this method by calling the function `print` for example!

The implementation provided here is `dom::expr`.

`testtype` — Test type of object

```
testtype(x, T)
```

This method must return `TRUE` if it can decide that `x` is of type `T`, `FALSE` if it can decide that `x` is not of type `T` and `FAIL` if it can not decide the test.

This method is called in three different situations: Either if the argument `x` is of this domain, or if `T` is this domain, or if `T` is an element of this domain. Thus the following three situations can arise:

- `x` is an element of the current domain.

  In this case it must be tested if `x` may be regarded as an element of the type `T`, which may either be a domain or type expression. By default, this is only true if the domain type of `x` is `T`, or if `T` is a domain constructor for which `x::dom::hasProp(x, T)` is `TRUE`. In particular, `x` is, by default, not of type `T` if `T` is a type of the Type library.
- `T` is the current domain.

  In this case it must be tested if `x` may be regarded as an element of this domain. By the default implementation provided, this is `TRUE` only if the domain type of `x` is `dom`.
- `T` is an element of the current domain.

  In this case `T` is regarded as a type expression. The default implementation provided returns `TRUE` if the domain type of `x` is `T`, and `FAIL` if not. A special rule holds if `T` is a façade domain: in that case, `coerce(x,T)` is called, if this is successful `TRUE` is returned and `FAIL` if not.

Technical Methods

`new_extelement` — Create element of kernel or façade domain

```
new_extelement(x, …)
```

When an expression `new(D,x,...)` is evaluated and `D` is a domain with method `"new_extelement"`, then `D::new_extelement(D,x,...)` is evaluated and returned as result.

Kernel or façade domains must define this method because otherwise the function `new` would return a “container” element of `D` rather than a “raw” element as intended.

The implementation provided here returns the result of `D::new(x,...)`.

Cat::AbelianGroup

Category of Abelian groups

Description

`Cat::AbelianGroup` represents the category of Abelian groups.

A `Cat::AbelianGroup` is an Abelian monoid with cancellation law where the operation + is invertible.

Categories

`Cat::CancellationAbelianMonoid`

Methods

Basic Methods

`_negate` — Return opposite

```
_negate(x)
```

Mathematical Methods

`equal` — Test for equality

```
equal(x, y)
```

`intmult` — Return integer multiple

```
intmult(x, n)
```

_subtract — Subtract two elements

```
_subtract(x, y)
```

Cat::AbelianMonoid

Category of Abelian monoids

Description

`Cat::AbelianMonoid` represents an Abelian monoid.

An `Cat::AbelianMonoid` is an Abelian semi-group with a neutral element `dom::zero` according to the operation + (`_plus`).

Use the axiom `Ax::normalRep` to state that zero is always represented in a unique way (i.e. canonically).

If an Abelian monoid has not the axion `Ax::normalRep` then `dom::zero` is only one possible representation of the neutral element. An Abelian semi-group must at least have the method `"iszero"` to test for zero in such a case.

Axioms

If the domain has `Ax::canonicalRep`, then `Ax::normalRep`.

Categories

`Cat::AbelianSemiGroup`

Entries

"zero"	Must hold the neutral element according to the operation +.

Methods

Mathematical Methods

`intmult` — Return integer multiple

```
intmult(x, n)
```

`iszero` — Test if element is zero

```
iszero(x)
```

Cat::AbelianSemiGroup

Category of Abelian semi-groups

Description

`Cat::AbelianSemiGroup` represents the category of Abelian semi-groups where the operation is written as addition. Hence an `Cat::AbelianSemiGroup` is a set with an associative and commutative operation + (`_plus`).

Note that non-Abelian semi-groups with operation `*` have category `Cat::SemiGroup`.

Categories

`Cat::BaseCategory`

Methods

Basic Methods

`_plus` — Return the sum of its arguments

```
_plus(x, …)
```

Mathematical Methods

`intmult` — Return integer multiple

```
intmult(x, n)
```

Cat::Algebra

Category of associative algebras

Syntax

```
Cat::Algebra(R)
```

Description

`Cat::Algebra(R)` represents the category of associative algebras over the commutative ring `R`.

A `Cat::Algebra(R)` is a module over a commutative ring `R` which also is a ring.

Categories

`Cat::Ring`, `Cat::Module`(R)

Parameters

R

A domain which is a commutative ring. The algebra will be an algebra over this ring.

Cat::CancellationAbelianMonoid

Category of abelian monoids with cancellation

Description

`Cat::CancellationAbelianMonoid` represents the category of Abelian monoids with cancellation.

A `Cat::CancellationAbelianMonoid` is an Abelian monoid where the cancellation law holds according to the operation +, i.e. $a + b = a + c$ implies $b = c$.

Categories

`Cat::AbelianMonoid`

Methods

Basic Methods

`_subtract` — Subtract two elements

```
_subtract(x, y)
```

Mathematical Methods

`equal` — Test for equality

```
equal(x, y)
```

The method `"iszero"` is used to test for zero.

`_negate` — Negate element

```
_negate(x)
```

`intmult` — Return integer multiple

```
intmult(x, n)
```

Cat::CommutativeRing

Category of commutative rings

Description

`Cat::CommutativeRing` represents the category of commutative rings.

A `Cat::CommutativeRing` is a ring with unit `dom::one` where the multiplication `*` (`_mult`) is commutative. It is also a right module over itself.

This implementation additionally assumes that the elements are always constant with respect to differentiation and derivates. One must re-implement the methods `"diff"` and `"D"` if this assumption is false.

Categories

`Cat::Ring`, `Cat::RightModule(dom)`

Methods

Mathematical Methods

`diff` — Differentiate element

```
diff(x, <v, …>)
```

`D` — Return derivative

```
D(l, x)
```

Cat::DifferentialRing

Category of ordinary differential rings

Description

`Cat::DifferentialRing` represents the category of ordinary differential rings.

A `Cat::DifferentialRing` is a commutative ring with a single derivation operator `D`.

A derivation is a linear operator with product rule, i.e. $(f\ g)' = f'\ g + f\ g'$ holds for all f and g.

Categories

`Cat::PartialDifferentialRing`

Methods

Basic Methods

`D` — Return derivative

```
D(f)
```

`diff` — Differentiation with respect to a variable

```
diff(f, x)
```

Cat::EntireRing

Category of entire rings

Description

`Cat::EntireRing` represents the category of entire rings.

An `Cat::EntireRing` is a ring with unit `"one"` which has no zero divisors: Given non-zero ring elements a and b the product a times b is never zero.

Axioms

`Ax::noZeroDivisors`

Categories

`Cat::Ring`, `Cat::RightModule(dom)`

Cat::EuclideanDomain

Category of Euclidean domains

Description

`Cat::EuclideanDomain` represents the category of Euclidean domains.

A `Cat::EuclideanDomain` is a principal ideal domain with an "Euclidean degree" function `"euclideanDegree"` and operations `"quo"` and `"rem"` computing the Euclidean quotient and Euclidean remainder.

The Euclidean degree returns nonnegative integers such that for each non-zero x and y there exist s and r such that $x = y\,s + r$ and either the Euclidean degree of r is less than that of s or r is zero.

In addition s is equal to `quo(x,y)` and r is equal to `rem(x,y)`.

Categories

`Cat::PrincipalIdealDomain`

Methods

Basic Methods

`euclideanDegree` — Return Euclidean degree

```
euclideanDegree(x)
```

`divide` — Division with remainder

```
divide(x, y)
```

Mathematical Methods

`_divide` — Exact division

```
_divide(x, y)
```

`gcd` — Greatest common divisor

```
gcd(x, …)
```

`gcdex` — Extended greatest common divisor

```
gcdex(x, y)
```

`idealGenerator` — Generator of finitely generated ideal

```
idealGenerator(x, …)
```

`quo` — Euclidean quotient

```
quo(x, y)
```

The default implementation provided here uses the basic method `"divide"`.

`rem` — Euclidean remainder

```
rem(x, y)
```

The default implementation provided here uses the basic method `"divide"`.

Cat::FactorialDomain

Category of factorial domains

Description

`Cat::FactorialDomain` represents the category of factorial domains (i.e., unique factorization domains).

A `Cat::FactorialDomain` is an integral domain with gcd where an unique factorization can be computed.

The factorization methods are named `"factor"` and `"sqrfree"` and must return elements of the domain `Factored` over this domain.

Categories

`Cat::GcdDomain`

Methods

Basic Methods

`factor` — Unique factorization

```
factor(x)
```

See `Factored` for details about the representation of the factorization.

Mathematical Methods

`irreducible` — Test if element is irreducible

```
irreducible(x)
```

sqrfree — Square-free factorization

```
sqrfree(x)
```

See `Factored` for details about the representation of the factorization.

The default implementation provided here uses the method `"factor"` and therefore may be very inefficient.

Cat::Field

Category of fields

Description

`Cat::Field` represents the category of fields.

A `Cat::Field` is a factorial domain, an Euclidean domain and a skew field. As a Euclidean domain, it has a commutative multiplication `*` (`_mult`) and as a skew field, the multiplication is invertible.

Many of the methods defined for factorial and Euclidean domains are trivial for a field.

Axioms

`Ax::canonicalUnitNormal`, `Ax::closedUnitNormals`

Categories

`Cat::EuclideanDomain`, `Cat::FactorialDomain`, `Cat::SkewField`

Methods

Mathematical Methods

`associates` — Test for associate elements

```
associates(x, y)
```

`_divide` — Exact division

```
_divide(x, y)
```

divide — Division with remainder

```
divide(x, y)
```

divides — Test if division is exact

```
divides(x, y)
```

euclideanDegree — Return Euclidean degree

```
euclideanDegree(x)
```

factor — Unique factorization

```
factor(x)
```

gcd — Greatest common divisor

```
gcd(x, …)
```

irreducible — Test if element is irreducible

```
irreducible(x)
```

isUnit — Test if element is an unit

```
isUnit(x)
```

quo — Return Euclidean quotient

```
quo(x, y)
```

rem — Return Euclidean remainder

```
rem(x, y)
```

sqrfree — Square-free factorization

```
sqrfree(x)
```

unitNormal — Unit normal form

```
unitNormal(x)
```

`unitNormalRep` — Unit normal representation

```
unitNormalRep(x)
```

Cat::FiniteCollection

Category of finite collections

Description

`Cat::FiniteCollection` represents the category of finite collections, i.e., the category of "universal" bags.

A finite collection is a data structure where each element represents a finite bag of "things" of any type.

The elements are numbered `1,...,nops(c)`, where `nops(c)` is the number of elements in the bag.

Categories

`Cat::BaseCategory`

Methods

Basic Methods

`_index` — Return element given its index

```
_index(x, i)
```

`map` — Map function on elements

```
map(x, f, <a, …>)
```

`nops` — Return number of elements

```
nops(x)
```

`op` — Return certain elements

```
op(x)

op(x, i)
```

Must return the `i`-th element of `x` or `FAIL` if an element with the given index does not exist.

Operand ranges or paths need not be handled by this method because they are handled directly by `op`.

`set_index` — Change element with given index

```
set_index(x, i, v)
```

Overloads the function `_assign` with an `_index` expression on the left hand side. The result is assigned to `x`.

`subs` — Substitute in elements

```
subs(x, e = f)
```

`subsop` — Substitute operands

```
subsop(x, i = v)
```

Technical Methods

`mapCanFail` — Map function on elements

```
mapCanFail(x, f, <a, …>)
```

`testEach` — Test each element with a predicate

```
testEach(x, f, <a, …>)
```

`testOne` — Test if element exists fulfilling a predicate

```
testOne(x, f, <a, …>)
```

Cat::GcdDomain

Category of integral domains with gcd

Description

`Cat::GcdDomain` represents the category of integral domains with a gcd.

A `Cat::GcdDomain` is an integral domain where the greatest common divisor of two elements can be computed by the method `"gcd"`.

Categories

`Cat::IntegralDomain`

Methods

Basic Methods

`gcd` — Greatest common divisor

`gcd(x, …)`

The method must satisfy the following conditions:

1. `x` and `y` must divide `dom::gcd(x,y)`,
2. if `z` divides both `x` and `y`, then `z` must divide `dom::gcd(x,y)`,
3. if a domain has the axiom `Ax::canonicalUnitNormal` then `dom::gcd(x,y)` must be equal to `dom::unitNormal(dom::gcd(x,y))`.

Remember that `x` divides `y` if `_divide(x,y)` does not return `FAIL`.

Mathematical Methods

`lcm` — Least common multiple

```
lcm(x, …)
```

Cat::Group

Category of groups

Description

`Cat::Group` represents the category of groups.

A `Cat::Group` is a (potentially non-Abelian) monoid where the group operation `*` (`_mult`) is invertible.

Categories

`Cat::Monoid`

Methods

Mathematical Methods

`_divide` — Return quotient

```
_divide(x, y)
```

Cat::HomogeneousFiniteCollection

Category of homogeneous finite collections

Syntax

```
Cat::HomogeneousFiniteCollection(T)
```

Description

`Cat::HomogeneousFiniteCollection(T)` represents the category of homogeneous finite collections (i.e. bags) of elements of the domain `T`.

A `Cat::HomogeneousFiniteCollection` is a finite collection where each element of the collection must be from the same domain T.

Categories

`Cat::FiniteCollection`

If T is a `Cat::OrderedSet`, then `Cat::OrderedSet`.

Parameters

`T`

A domain which must be from the category `Cat::BaseCategory`. Only elements of this domain may be contained in the collection.

Entries

"elemDom"	The parameter domain T.

Methods

Mathematical Methods

`_less` — Compare two elements

```
_less(x, y)
```

Returns `TRUE` if `x` is less than `y`.

The collections `x` and `y` are ordered by the lexical ordering of their elements.

Cat::HomogeneousFiniteProduct

Category of homogeneous finite products

Syntax

```
Cat::HomogeneousFiniteProduct(T)
```

Description

`Cat::HomogeneousFiniteProduct(T)` represents the category of homogeneous finite products of elements of the domain `T`.

A `Cat::HomogeneousFiniteProduct(T)` is a homogeneous finite collection where each collection has the same number of elements of the domain `T`.

The number of elements must be given by the entry `"card"`, which must be defined by domains of this category. It is not given as a category parameter simply because it is not needed. Thus no unnecessary instances of the category are created.

One could principally implement all the algebraic operations here, but they will be slow if the methods `"_index"` and `"set_index"` are slow, which most often will be the case. So we avoid the work and let the domain implementors do it.

Categories

`Cat::HomogeneousFiniteCollection`(T)

If `T` is a `Cat::DifferentialRing`, then `Cat::DifferentialRing`.

If `T` is a `Cat::PartialDifferentialRing`, then `Cat::PartialDifferentialRing`.

If `T` is a `Cat::CommutativeRing`, then `Cat::CommutativeRing`.

If `T` is a `Cat::SkewField`, then `Cat::SkewField`.

If `T` is a `Cat::Ring`, then `Cat::Ring`.

If T is a Cat::Rng, then Cat::Rng.

If T is a Cat::AbelianGroup, then Cat::AbelianGroup.

If T is a Cat::CancellationAbelianMonoid, then Cat::CancellationAbelianMonoid.

If T is a Cat::AbelianMonoid, then Cat::AbelianMonoid.

If T is a Cat::AbelianSemiGroup, then Cat::AbelianSemiGroup.

If T is a Cat::Group, then Cat::Group.

If T is a Cat::Monoid, then Cat::Monoid.

If T is a Cat::SemiGroup, then Cat::SemiGroup.

If T is a Cat::CommutativeRing, then Cat::Algebra(T).

If T is a Cat::Ring, then Cat::LeftModule(T).

If T is a Cat::Ring, then Cat::RightModule(T).

Parameters

T

A domain which must be from the category Cat::BaseCategory. This defines the domain of the products elements.

Entries

"card"	Must hold the number of elements of a collection.
"characteristic"	Defined if T is a ring: In this case the characteristic of the product domain is the same as that of T.

Methods

Basic Methods

`zip` — Combine elements

```
zip(x, y, f)
```

`zipCanFail` — Combine elements, may fail

```
zipCanFail(x, y, f)
```

Access Methods

`nops` — Return number of elements

```
nops(x)
```

Cat::IntegralDomain

Category of integral domains

Description

`Cat::IntegralDomain` represents the category of integral domains.

A `Cat::IntegralDomain` is a commutative and entire ring which has a "partial" division method `"_divide"`: If `b` divides `a` then `dom::_divide(a,b)` must return the quotient, otherwise `FAIL`. The result of the method `"_divide"` must be unique.

Use the axiom `Ax::canonicalUnitNormal` to state in addition that there exists a canonical unit normal form for each element of the ring. If a ring has the axiom `Ax::canonicalUnitNormal` the method `"unitNormal"` must return the unique unit normal for a ring element. If the axiom is not valid the method may return any associate.

Use the axiom `Ax::closedUnitNormals` in addition to state that the unit normals which are computed by the method `"unitNormal"` are closed under multiplication, i.e. that the product of two unit normals returns a unit normal.

These two axioms are not implicitly valid for an `Cat::IntegralDomain` because there are integral domains for which one can't compute a canonical unit normal for each element.

Categories

`Cat::EntireRing`, `Cat::CommutativeRing`, `Cat::Algebra(dom)`

Methods

Basic Methods

`_divide` — Return quotient

```
_divide(x, y)
```

The result must be unique:

1. the product `y * dom::_divide(x,y)` must be equal to `x` provided that `y` is not zero and `y` divides `x`,
2. if `x` is equal to `y * z` then `y` must divide `x`.

It is an error if `y` is zero.

`isUnit` — Test if element is a unit

```
isUnit(x)
```

`unitNormal` — Return an associate

```
unitNormal(x)
```

If the ring has the axiom `Ax::canonicalUnitNormal` the method must return the unique unit normal of `x`.

An implementation is provided if the ring has *not* the axiom `Ax::canonicalUnitNormal`: In this case simply `x` is returned.

Mathematical Methods

`associates` — Test if elements are associates

```
associates(x, y)
```

`divides` — Test if elements divides another

```
divides(x, y)
```

`unitNormalRep` — Return the unit normal representation

```
unitNormalRep(x)
```

If the ring has the axiom `Ax::canonicalUnitNormal` the method must return the unique unit normal of `x`. The default implementation uses the method `"unitNormal"` to compute the unit normal `n` in this case.

If the ring dos not have the axiom `Ax::canonicalUnitNormal` the method simply returns `[x, dom::one, dom::one]`.

Cat::LeftModule

Category of left R -modules

Syntax

```
Cat::LeftModule(R)
```

Description

`Cat::LeftModule(R)` represents the category of left `R`-modules.

A `Cat::LeftModule(R)` is an Abelian group together with a rng `R` (a ring without unit) and a left multiplication `*` (`_mult`).

The left multiplication is an operation taking an element of rng `R` and a module element and returning a module element.

Given ring elements a, b and module elements x, y the following 3 distibutive laws must hold:

1. $(a\,b)\,x = a\,(b\,x)$,
2. $(a + b)\,x = a\,x + b\,x$,
3. $a\,(x + y) = a\,x + a\,y$.

Beware: The operation of a non-Abelian semi-group is also written as `*` (`_mult`). The method `"_mult"` must handle the situation if a left module is also a non-Abelian semi-group. In such a case it must both implement the group operation and the left multiplication by elements of the rng.

Categories

`Cat::AbelianGroup`

Parameters

R

A domain which must be from the category `Cat::Rng`.

Methods

Basic Methods

`_mult` — Left multiplication by a rng element

```
_mult(r, x)
```

Cat::Matrix

Category of matrices

Syntax

```
Cat::Matrix(R)
```

Description

`Cat::Matrix(R)` represents the category of matrices over the rng `R`.

A `Cat::Matrix(R)` is a matrix of arbitrary dimension over a component ring `R`.

In the following description of the methods, we use the following notations for a matrix *A* from a domain of category `Cat::Matrix(R)`:

nrows(*A*) denotes the number of rows and *ncols*(*A*) the number of columns of *A*.

Further on, a *row index* is an integer ranges from 1 to *nrows*(*A*), and a *column index* is an integer ranges from 1 to *ncols*(*A*).

Categories

`Cat::BaseCategory`

Parameters

`R`

A domain which must be from the category `Cat::Rng` (a ring without unit).

Entries

"coeffRing"	is set to `R`.

Methods

Basic Methods

`_index` — Matrix indexing

```
_index(A, i, j)
```

`matdim` — Matrix dimension

```
matdim(A)
```

`new` — Matrix definition

```
new(m, n)
```

Of course, this method may implement further possibilites to create matrices (for example, see the method `"new"` of the domain constructor `Dom::Matrix`).

`set_index` — Setting matrix components

```
set_index(A, i, j, x)
```

Mathematical Methods

`_negate` — Negate a matrix

```
_negate(A)
```

`_plus` — Add matrices

```
_plus(A1, A2, …)
```

The matrices must be of the same domain type, otherwise `FAIL` is returned.

`_subtract` — Subtract two matrices

```
_subtract(A, B)
```

`equal` — Test on equality of matrices

```
equal(A, B)
```

`identity` — Identity matrix

```
identity(n)
```

It only exists if `R` is of category `Cat::Ring`, i.e., a ring with unit.

`iszero` — Test on zero matrices

```
iszero(A)
```

Note that there may be more than one representation of the zero matrix of a given dimension if `R` does not have the axiom `Ax::canonicalRep`.

`transpose` — Transpose of a matrix

```
transpose(A)
```

Access Methods

`col` — Extracting columns

```
col(A, c)
```

`concatMatrix` — Horizontal concatenation of matrices

```
concatMatrix(A, B)
```

An error message is issued if the two matrices do not have the same number of rows.

`delCol` — Deleting columns

```
delCol(A, c)
```

If `A` only consists of one column then `NIL` is returned.

`delRow` — Deleting rows

```
delRow(A, r)
```

If A only consists of one row then NIL is returned.

row — Extracting rows

```
row(A, r)
```

setCol — Replacing columns

```
setCol(A, c, v)
```

setRow — Replacing rows

```
setRow(A, r, v)
```

stackMatrix — Appending of matrices vertically

```
stackMatrix(A, B)
```

An error message is issued if the two matrices do not have the same number of columns.

swapCol — Swapping matrix columns

```
swapCol(A, c1, c2)
```

swapRow — Swapping matrix rows

```
swapRow(A, r1, r2)
```

Cat::Module

Category of R-modules

Syntax

```
Cat::Module(R)
```

Description

`Cat::Module(R)` represents the category of `R`-modules.

A `Cat::Module(R)` is a left and right `R`-module over a commutative ring `R`.

Right and left multiplications must be both implemented by the method `"_mult"`.

Categories

`Cat::LeftModule(R)`, `Cat::RightModule(R)`

Parameters

`R`

A domain which must be from the category `Cat::CommutativeRing`.

Cat::Monoid

Category of monoids

Description

`Cat::Monoid` represents the category of monoids.

`Cat::Monoid` is a non-Abelian semi-group with a neutral element one (`dom::one`) according to the group operation `*` (`_mult`).

Categories

`Cat::SemiGroup`

Entries

"one"	Must hold the neutral element according to the operation `*`.

Methods

Basic Methods

`_invert` — Return inverse

```
_invert(x)
```

Mathematical Methods

`isone` — Test if element is one

```
isone(x)
```

_power — Raise to the nth power

```
_power(x, n)
```

This implementation does “repeated squaring”.

Cat::OrderedSet

Category of ordered sets

Description

`Cat::OrderedSet` represents the category of ordered sets.

An `Cat::OrderedSet` is a set with a (complete) order relation < (`_less`).

Use the axiom `Ax::canonicalOrder` to state that elements of a domain are canonically ordered as MuPAD expressions (i.e. ordered with respect to the kernel function `_less`).

Categories

`Cat::BaseCategory`

Methods

Basic Methods

`_less` — Compare if element is less

```
_less(x, y)
```

An implementation is provided if this domain has axiom `Ax::canonicalOrder`.

Mathematical Methods

`_leequal` — Compare if element is less or equal

```
_leequal(x, y)
```

The implementation provided uses the methods `"_less"` and `"equal"`.

`max` — Return maximum

```
max(x, …)
```

`min` — Return minimum

```
min(x, …)
```

`sort` — Sort list of elements

```
sort(l)
```

Cat::PartialDifferentialRing

Category of partial differential rings

Description

`Cat::PartialDifferentialRing` represents the category of partial differential rings.

A `Cat::PartialDifferentialRing` is a commutative ring with a finite set of derivation operators `D_i`.

A derivation is a linear operator with product rule, i.e. `D_i(f * g)` equals `D_i(f) * g + f * D_i(g)` for all `f` and `g`.

For many partial differential rings the derivations are differentiations with respect to some indeterminates. Thus in order to support a natural notion it is also supposed that a method `"diff"` exists, such that `diff(f, x)` returns the partial derivation of `f` with respect to the indeterminate `x`.

Categories

`Cat::CommutativeRing`

Methods

Basic Methods

`D` — Return derivative

```
D(l, x)
```

`diff` — Return partial derivative

```
diff(x, <v, …>)
```

Cat::Polynomial

Category of multivariate polynomials

Syntax

```
Cat::Polynomial(R)
```

Description

`Cat::Polynomial(R)` represents the category of multivariate polynomials over `R`.

A `Cat::Polynomial(R)` is a multivariate polynomial ring over a commutative coefficient ring `R`.

Axioms

If `R` has `Ax::canonicalUnitNormal`, then `Ax::canonicalUnitNormal`.

If `R` has `Ax::closedUnitNormals`, then `Ax::closedUnitNormals`.

Categories

`Cat::PartialDifferentialRing`, `Cat::Algebra(R)`

If `R` is a `Cat::FactorialDomain`, then `Cat::FactorialDomain`.

If `R` is a `Cat::GcdDomain`, then `Cat::GcdDomain`.

If `R` is a `Cat::IntegralDomain`, then `Cat::IntegralDomain`.

Parameters

`R`

A domain which must be from the category `Cat::CommutativeRing`.

Entries

"coeffRing"	The coefficient ring R.
"characteristic"	The characteristic of this domain, which is the same as that of the ring R.

Methods

Basic Methods

coeff — Return coefficients

```
coeff(p)
```

```
coeff(p, x, n)
```

```
coeff(p, n)
```

Must return the coefficient of x^n of p, which is a polynomial in the remaining indeterminates.

Must return the coefficient of x^n of p, where x is the main variable of p.

degree — Return total degree

```
degree(p)
```

```
degree(p, x)
```

Must return the degree of p with respect to the indeterminate x.

degreevec — Return degree vector

```
degreevec(p)
```

evalp — Evaluate at a point

```
evalp(p, x = v, …)
```

More than one evaluation point may be given. The result must be a polynomial in the remaining indeterminates or an element of R.

`indets` — Return indeterminates

```
indets(p)
```

`lcoeff` — Return leading coefficient

```
lcoeff(p)
```

`lmonomial` — Return leading monomial

```
lmonomial(p)
```

`lterm` — Return leading term

```
lterm(p)
```

`mainvar` — Return main variable

```
mainvar(p)
```

`mapcoeffs` — Map coefficients

```
mapcoeffs(p, f, <a, …>)
```

`multcoeffs` — Multiply coefficients

```
multcoeffs(p, c)
```

`nterms` — Return number of terms

```
nterms(p)
```

`nthcoeff` — Return n-th coefficient

```
nthcoeff(p, n)
```

`nthmonomial` — Return n-th monomial

```
nthmonomial(p, n)
```

`nthterm` — Return n-th term

```
nthterm(p, n)
```

`tcoeff` — Return trailing coefficient

```
tcoeff(p)
```

`unitNormal` — Return unit normal

```
unitNormal(p)
```

An implementation is provided if `R` has the axiom `Ax::canonicalUnitNormal`: In this case `p` is multiplied by an unit of `R` such that the leading coefficient has unit normal representation in `R`.

`unitNormalRep` — Return unit normal representation

```
unitNormalRep(p)
```

An implementation is provided if `R` has the axiom `Ax::canonicalUnitNormal`.

Mathematical Methods

`content` — Return content

```
content(p)
```

`isUnit` — Test if element is a unit

```
isUnit(p)
```

`primpart` — Return primitive part

```
primpart(p)
```

`poly2list` — Convert into a list

```
poly2list(p)
```

`solve` — Solve polynomial equation

```
solve(p, x, <opt, …>)
```

```
solve(p, x = T, <opt, …>)

solve(p)
```

Solves the polynomial equation `p = 0` with respect to `x` over the domain `T`. See the function `solve` for details about the optional arguments `opt, ...`

The polynomial `p` must be univariate. Solves the polynomial equation `p = 0` with respect to the indeterminate of `p` over the domain `R`.

Cat::PrincipalIdealDomain

Category of principal ideal domains

Description

`Cat::PrincipalIdealDomain` represents the category of principal ideal domains.

A `Cat::PrincipalIdealDomain` is an integral domain with gcd where each ideal is principal. Note that the method `"idealGenerator"` has to find generators for finitely generated ideals only.

Categories

`Cat::GcdDomain`

Methods

Basic Methods

`idealGenerator` — Return generator of ideal

```
idealGenerator(x, …)
```

Cat::QuotientField

Category of quotient fields

Syntax

```
Cat::QuotientField(R)
```

Description

`Cat::QuotientField(R)` represents the category of quotient fields over `R`.

A `Cat::QuotientField` is the field of fractions over the integral domain `R`.

Categories

`Cat::Field`, `Cat::Algebra(R)`

If `R` has `Cat::OrderedSet`, then `Cat::OrderedSet`.

Parameters

`R`

A domain which must be from the category `Cat::IntegralDomain`.

Entries

"characteristic"	The characteristic of this domain, which is the same as that of `R`.

Methods

Basic Methods

`denom` — Return denominator

```
denom(x)
```

`numer` — Return numerator

```
numer(x)
```

Mathematical Methods

`equal` — Test for equality

```
equal(x, y)
```

`iszero` — Test for zero

```
iszero(x)
```

`_less` — Test if element is less

```
_less(x, y)
```

`retract` — Return retracted element

```
retract(x)
```

The default implementation uses the method "`_divide`" to divide numerator and denominator.

Cat::RightModule

Category of right R-modules

Syntax

```
Cat::RightModule(R)
```

Description

`Cat::RightModule(R)` represents the caregory of right `R`-modules.

A `Cat::RightModule` is an Abelian group together with a ring `R` and a right multiplication `*` (`_mult`).

The right multiplication is an operation taking an element of ring `R` and a module element and returning a module element.

Given ring elements a, b and module elements x, y the following 3 distributive laws must hold:

1. $x\,(a\,b) = (x\,a)\,b$,
2. $x\,(a + b) = x\,a + x\,b$,
3. $(x + y)\,a = x\,a + y\,a$.

Beware: The operation of a non-Abelian semi-group is also written as `*` (`_mult`). The method `"_mult"` must handle the situation if a right module is also a non-Abelian semi-group. In such a case it must both implement the group operation and the right multiplication by elements of the ring.

Categories

`Cat::AbelianGroup`

Parameters

R

A domain which must be from the category `Cat::Ring`.

Methods

Basic Methods

`_mult` — Right multiplication by a ring element

```
_mult(x, r)
```

Cat::Ring

Category of rings

Description

`Cat::Ring` represents the category of rings.

A `Cat::Ring` is a ring with a unit `dom::one`, i.e., an Abelian group according to the operation `+` (`_plus`) and a non-Abelian monoid according to the operation `*` (`_mult`) where in addition the two distributive laws $a\,(b + c) = a\,b + a\,c$ and $(a + b)\,c = a\,c + b\,c$ hold.

A `Cat::Ring` is also a left module over itself. The left multiplication of the module is also written as `*` (`_mult`).

Note that a ring without unit is a `Cat::Rng`.

Categories

`Cat::Rng`, `Cat::Monoid`, `Cat::LeftModule(dom)`

Entries

"characteristic"	Must hold the characteristic of this ring.

Cat::Rng

Category of rings without unit

Description

`Cat::Rng` represents the category of rings without unit.

A `Cat::Rng` is a ring without a unit, i.e. an Abelian group according to the operation `+` (`_plus`) and a non-Abelian semi-group according to the operation `*` (`_mult`) where in addition the two distributive laws $a\,(b + c) = a\,b + a\,c$ and $(a + b)\,c = a\,c + b\,c$ hold.

Use the axiom `Ax::noZeroDivisors` to state that there are no zero divisors according to `*`, i.e. that the product of non-zero elements never is zero.

Categories

`Cat::AbelianGroup`, `Cat::SemiGroup`

Cat::SemiGroup

Category of semi-groups

Description

`Cat::SemiGroup` represents the category of semi-groups.

A `Cat::SemiGroup` represents the category of non-Abelian semi-groups, where the group operation is written as multiplication. Hence a `Cat::SemiGroup` is a set with an associative operation `*` (`_mult`).

Note that Abelian semi-groups with operation + have category `Cat::AbelianSemiGroup`.

Categories

`Cat::BaseCategory`

Methods

Basic Methods

`_mult` — Return product

```
_mult(x, …)
```

Mathematical Methods

`_power` — Return integer power

```
_power(x, n)
```

Cat::Set

Category of sets of complex numbers

Description

`Cat::Set` represents the category of subsets of the complex numbers.

Sets of this category allow set-theoretic operations as well as pointwise arithmetical operations.

The main feature of `Cat::Set` is a particular overloading mechanism. It provides `n`-ary operators that can handle operands from different domains of category `Cat::Set`, as well as mixed input where some operands are of types not belonging to `Cat::Set`. *Hence, in the methods of* `Cat::Set`*, operands of arbitrary type are allowed.*

There are three kinds of operators: `n`-ary (associative and commutative), binary (not assumed to be commutative), and unary (mapping a function). `Cat::Set` provides generic methods for generating these kinds of operators, and uses them to define default methods overloading the common set-theoretic and arithmetical functions.

By default, any operation of sets is defined, but returns unevaluated since the arithmetical or set-theoretic expression cannot be simplified. Each domain of type `Cat::Set` must provide particular slots and tables in order to achieve simplifications in certain special cases.

Arithmetical operations are defined pointwise. It is not an error if some operation is not defined for all elements of a set.

`Cat::Set` is mainly used by domains of sets returned by `solve`.

Categories

`Cat::BaseCategory`

Methods

Mathematical Methods

commassop — Return an n-ary commutative and associative operator for sets

```
commassop(operatorname)
```

The returned procedure first sorts its operands (which it may do because of commutativity). Those operands not belonging to a domain of category `Cat::Set` are handled by the usual overloading mechanism, i.e. by the slot `operatorname` of one of their domains. Out of the others, several operands belonging to the same domain are handled by the slot `"homog".operatorname` of that domain. Finally, the returned method tries to combine each possible pair of operands. If they are from the same domain, `"bin".operatorname` is called for them. The following is done if the operands are from different domains: let `T1` and `T2` be their types; then their `"inhomog".operatorname` slots are used. If such a slot exists in the domain `T1`, it must contain a table indexed by possible types `T2`, and the entry at that index must be a procedure that carries out the operation for exactly two arguments, the first being a `T1`, the second being a `T2`. Conversely, if such a slot exists in the domain `T2`, it must contain a table indexed by possible types `T1`, and the entry at that index must be a procedure that carries out the operation for exactly two arguments, the first being a `T2`, the second being a `T1`.

The slot `"homog".operatorname`, or a table entry in the slot `"inhomog".operatorname`, may return `FAIL` in order to indicate that it could not simplify its input; if they are missing, this indicates that a simplification is generally not possible for input of this type. In these cases, the returned procedure proceeds by trying to combine another two of the given arguments.

A slot `"bin".operatorname` usually won't exist, except for the case that there is no `"homog".operatorname`; usually the latter can also take care for the case of exactly two operands.

The whole process is repeated over and over until no new simplifications occur or only one operand is left. If no more simplifications occur, an unevaluated call to the operator is returned, the arguments being all remaining operands that could not be combined further.

`binop` — Return a binary operator for sets

```
binop(operatorname)
```

The returned procedure uses the slot `"bin".operatorname` of its first argument if both arguments are of the same type. Otherwise it uses the slot `"inhomogleft".operatorname` of its first argument; if that fails, it uses the slot `"inhomogright".operatorname` of its second argument; each of these slots, if it exists, must contain tables, indexed by the type of the other argument, such that `slot(T1, "inhomogleft".operatorname)[T2]` and `slot(T2, "inhomogright".operatorname)[T1]` carry out the operation for objects of type `T1` and `T2`, in this order.

No commutativity of the operation is assumed.

If the slots or table entries do not exist or return `FAIL`, an unevaluated call to the operator is returned.

`homogassop` — Return an n-ary operator for sets belonging to the same domain

```
homogassop(operatorname)
```

`_union` — Union of sets

```
_union(S1, …)
```

`_intersect` — Intersection of sets

```
_intersect(S1, …)
```

`_plus` — Set of sums of set elements

```
_plus(S1, …)
```

The sum of sets is computed by the commutative-associative operator generated by `"commassop"`, using the slots `"homog_plus"` and `"inhomog_plus"` of the domains of its operands.

`_mult` — Set of product of set elements

```
_mult(S1, …)
```

The product of sets is computed by the commutative-associative operator generated by `"commassop"`, using the slots `"homog_mult"` and `"inhomog_mult` of the domains of its operands.

`_minus` — Set of subtractions

`_minus(`S_1`, `S_2`)`

`_power` — Pointwise power

`_power(`S_1`, `S_2`)`

The power of sets is computed by the binary operator generated by `"binop"`, using the slots `"homog_power"`, `"inhomogleft_power"`, and `"inhomogright_power"` of its operands.

`map` — Map an operation to a set

`map(S, f)`

By overloading this method in a particular domain, the behavior of sets changes whenever a special function is applied to them.

Cat::SkewField

Category of skew fields

Description

`Cat::SkewField` represents the category of skew fields (division rings).

A `Cat::SkewField` represents a ring with unit where each non-zero element is invertible. This structure is also called division ring in the literature.

Categories

`Cat::Ring`

Cat::SquareMatrix

Category of square matrices

Syntax

```
Cat::SquareMatrix(R)
```

Description

`Cat::SquareMatrix(R)` represents the category of square matrices over the rng `R`.

A `Cat::SquareMatrix(R)` represents the rng (ring without unit) of square matrices over the coefficient domain `R`.

Categories

`Cat::Rng`, `Cat::Matrix(R)`

If `R` has `Cat::Ring`, then `Cat::Ring`.

Parameters

`R`

A domain which must be from the category `Cat::Rng`.

Entries

"characteristic"	Defined if `R` is a ring: In this case the characteristic of the matrix domain is the same as that of `R`.

Cat::UnivariatePolynomial

Category of univariate polynomials

Syntax

```
Cat::UnivariatePolynomial(R)
```

Description

`Cat::UnivariatePolynomial(R)` represents the category of univariate polynomials over `R`.

A `Cat::UnivariatePolynomial(R)` is a univariate polynomial over the commutative ring `R`.

Categories

`Cat::Polynomial(R)`, `Cat::DifferentialRing`

If `R` has `Cat::Field`, then `Cat::EuclideanDomain`.

Parameters

`R`

A domain which must be from the category `Cat::CommutativeRing`.

Methods

Basic Methods

`pdivide` — Pseudo-divide polynomials

```
pdivide(p, q)
```

Must return a sequence `(b, s, r)` of a ring element `b` and polynomials `s` and `r` such that $multcoeffs(p, b) = s\,q + r$ holds with $b = lcoeff(q)^{degree(p) - degree(q) + 1}$.

`pquo` — Return pseudo-quotient

```
pquo(p, q)
```

`prem` — Return pseudo-remainder

```
prem(p, q)
```

Cat::VectorSpace

Category of vector spaces

Syntax

```
Cat::VectorSpace(F)
```

Description

`Cat::VectorSpace(F)` represents the category of vector spaces over the field `F`.

A vector space is an Abelian group with an operation + (`_plus`).

The scalar product has to be implemented via the method `"_mult"`. Other kinds of multiplication are not defined.

Categories

`Cat::Module(F)`

Parameters

`F`

A domain which must be from the category `Cat::Field`.

Methods

Basic Methods

`_mult` — Return scalar product

```
_mult(c, x)
```

`_mult(x, c)`

Must return the scalar product of `x` and `c`.

combinat – Combinatorics

combinat::bell
combinat::cartesianProduct
combinat::catalan
combinat::choose
combinat::compositions
combinat::modStirling
combinat::partitions
combinat::permute
combinat::powerset
combinat::stirling1
combinat::stirling2
combinat::subwords

combinat::bell

Bell numbers

Syntax

```
combinat::bell(n)
```

```
combinat::bell(expression)
```

Description

`combinat::bell(n)` computes the n-th Bell number.

The n-th Bell number is defined by the exponential generating function:

$$e^{e^x-1} = \sum_{n=0}^{\infty} \frac{\mathrm{bell}(n)}{n!} x^n$$

Often another definition is used. The n-th Bell number is the number of different ways of partitioning the set {1, 2, …, *n*} into disjoint nonempty subsets, and *bell*(0) is defined to be 1.

Bell numbers are computed using the formula:

- *bell*(0) = 1

  $\mathrm{bell}(n+1) = \sum_{i=0}^{n} \binom{n}{i} \mathrm{bell}(i)$ for $n > 0$

Examples

Example 1

The third Bell number is 5:

```
combinat::bell(3)
```

$$5$$

This means that you can partition the set {1, 2, 3} into disjoint subsets in 5 different ways. These are {{1, 2, 3}}, {{1}, {2, 3}}, {{2}, {1, 3}}, {{3}, {1, 2}}, and {{1}, {2}, {3}}. Or, that you can write 105 = 3 5 7 as 5 different products. These are 105 = 3 35 = 5 21 = 7 15 = 3 5 7.

Example 2

If one uses a wrong argument, an error message is returned.

```
combinat::bell(3.4)
```

```
Error: A nonnegative integer is expected. [combinat::bell]
```

Example 3

It can be useful to return the unevaluated function call.

```
a := combinat::bell(x);
x := 4;
a ;
delete(a);
```

$$\text{combinat::bell}(x)$$

$$4$$

$$15$$

Parameters

n

Nonnegative integer

`expression`

An expression of type `Type::Arithmetical` which must be a nonnegative integer if it is a number.

Return Values

Positive integer value if `n` was a nonnegative integer. Otherwise `combinat::bell` returns the unevaluated function call.

combinat::cartesianProduct

Cartesian product

Syntax

```
combinat::cartesianProduct(S1, …)
```

Description

`combinat::cartesianProduct(S1, ...)` returns the cartesian product of the sets or lists *S1*, … as a list of lists.

The cartesian product of S_1 through S_n consists of all lists of length n whose i-th entry is an operand of the set or list S_i, for $1 \le i \le n$.

Any integer k among the arguments is identified with the set of the first k positive integers.

The ordering of the output is unspecified.

Examples

Example 1

The following calls are equivalent:

```
combinat::cartesianProduct({1, 2}, {a, b}),
combinat::cartesianProduct(2, [b, a])
```

$$[[1, a], [2, a], [1, b], [2, b]], [[1, b], [2, b], [1, a], [2, a]]$$

Parameters

S1

Set, list, or nonnegative integer

Return Values

List of lists, each of them having as many operands as there were arguments passed to `combinat::cartesianProduct`.

combinat::catalan

Catalan numbers

Syntax

```
combinat::catalan(n)
```

Description

`combinat::catalan`(n) returns the `n`-th Catalan number.

The Catalan numbers are ubiquitous in combinatorics. For example, `combinat::catalan(n)` counts the Dyck words of size `n`, the ordered trees with `n` nodes, the binary trees with `n+1` nodes, the complete binary trees with `2n+1` nodes, the standard tableaux with two rows of size `n`, the triangulations of a regular `n+2`-gone, or the non-crossing partitions of {1, 2, …, *n*}.

`combinat::catalan(n)` is calculated using the formula

$$\text{catalan}(n) = \frac{1}{n+1}\binom{2n}{n}.$$

Examples

Example 1

We compute the first Catalan numbers:

```
combinat::catalan(n) $ n = 0..6
```

$$1, 1, 2, 5, 14, 42, 132$$

Example 2

If one uses a wrong argument, an error message is returned

```
combinat::catalan(-1)
```

```
Error: The object '-1' is incorrect. The type of argument number 1 must be 'Type::NonNe
  Evaluating: combinat::catalan
```

Parameters

n

Nonnegative integer

Return Values

Positive integer.

combinat::choose

Subsets of a given size

Syntax

```
combinat::choose(S, k)
```

Description

`combinat::choose(S, k)` returns all subsets of `S` that have exactly `k` elements.

If `S` is an integer, it represents the set of the first `S` positive integers.

Examples

Example 1

There are three subsets of a three-element set that have exactly two elements:

```
combinat::choose({a, b, c}, 2)
```

$$\{a, b\}, \{a, c\}, \{b, c\}$$

Parameters

S

Set or nonnegative integer

k

Nonnegative integer

Return Values

Sequence of sets.

combinat::compositions

Compositions of an integer

Syntax

```
combinat::compositions(n, <MinPart = k>, <MaxPart = l>, <Length = m>)
```

Description

`combinat::compositions(n)` returns all compositions of the nonnegative integer `n`.

A *composition* of a nonnegative integer `n` is a list of positive integers with total sum `n`.

Examples

Example 1

We output all compositions of the integer 4:

```
combinat::compositions(4)
```

```
[[4], [3, 1], [2, 2], [2, 1, 1], [1, 3], [1, 2, 1], [1, 1, 2], [1, 1, 1, 1]]
```

Example 2

It is possible to output only the compositions of a certain length:

```
combinat::compositions(4, Length=2)
```

```
[[3, 1], [2, 2], [1, 3]]
```

Example 3

The options `MinPart` and `MaxPart` can be used to set constraints on the sizes of all parts. Using `MaxPart`, you can select compositions having only small entries. This is the list of the compositions of 4 with all parts at most 2:

```
combinat::compositions(4, MaxPart=2)
```

```
[[2, 2], [2, 1, 1], [1, 2, 1], [1, 1, 2], [1, 1, 1, 1]]
```

`MinPart` is complementary to `MaxPart` and selects compositions having only large parts (it takes a non-negative value). This is the list of the compositions of 4 with all parts at least 2:

```
combinat::compositions(4, MinPart=2)
```

```
[[4], [2, 2]]
```

By default, the parts of a composition have to be positive. This can be changed using the option `MinPart`. In the following example, the options `Length` and `MinPart` are combined together to obtain the list of the compositions of 4 with 3 nonnegative parts:

```
combinat::compositions(4, Length=3, MinPart=0)
```

```
[[4, 0, 0], [3, 1, 0], [3, 0, 1], [2, 2, 0], [2, 1, 1], [2, 0, 2], [1, 3, 0], [1, 2, 1], [1, 1, 2], [1, 0, 3],
  [0, 4, 0], [0, 3, 1], [0, 2, 2], [0, 1, 3], [0, 0, 4]]
```

If no length is given, `MinPart=0` is not allowed.

Parameters

`n`

Nonnegative integer

Options

`MinPart`

Option, specified as `MinPart = k`

Return only compositions consisting of integers greater or equal than `k`. The option `MinPart = 0` is only allowed if also the option `Length` is given. Default is 1.

`MaxPart`

Option, specified as `MaxPart = l`

Return only compositions consisting of integers less or equal than `l`.

`Length`

Option, specified as `Length = m`

Return only compositions consisting of exactly `m` integers.

combinat::modStirling

Modified Stirling numbers

Syntax

```
combinat::modStirling(q, n, k)
```

Description

`combinat::modStirling` computes the modified Stirling numbers.

`combinat::modStirling(q,n,k)` takes the elementary symmetric polynomial in `n` variables of degree `k` and evaluates it for the values $q + 1, \ldots, q + n$. Note that `k` must not be greater than `n`.

Examples

Example 1

```
combinat::modStirling(2,4,2)
```

```
     119
```

Parameters

q

The argument: an integer

n

The number of variables: a nonnegative integer

k

The degree: a nonnegative integer

Return Values

Positive integer.

combinat::partitions

Partitions of an integer

Syntax

```
combinat::partitions(n)
```

Description

`cominat::partitions(n)` returns the number of partitions of the integer `n`.

A *partition* of a nonnegative integer `n` is a non-increasing list of positive integers with total sum `n`.

Examples

Example 1

There are 5 partitions of 4:

```
combinat::partitions(4)
```

```
    5
```

Parameters

`n`

Nonnegative integer

Algorithms

Counting is done efficiently with Euler's pentagonal formula for small values of n and Hardy-Ramanujan-Rademacher's formula otherwise.

combinat::permute

Permutations of a list

Syntax

```
combinat::permute(l, <Duplicate>)
```

```
combinat::permute(n, <Duplicate>)
```

Description

For a list `l`, the call `combinat::permute(l)` returns all permutations of `l`.

For an integer `n`, the call `combinat::permute(n)` returns all permutations of the list `[1, ..., n]`.

A permutation of a list is a list that contains the same elements, and each of them the same number of times, as the original list.

Equivalently, a permutation of a list `l` of n elements is any `f(l)` where `f` is an element of the symmetric group `Dom::SymmetricGroup(n)`. Different `f` may produce the same `f(l)`; with the option `Duplicate`, every permutation is listed as many times as it occurs in that way; without that option, every permutation is listed only once.

Examples

Example 1

There are six permutations of three letters:

```
combinat::permute([a, b, c])
```

$$[[b, c, a], [c, b, a], [a, c, b], [c, a, b], [a, b, c], [b, a, c]]$$

To permute the first three integers, the following syntax is also possible:

```
combinat::permute(3)
```

```
[[2, 3, 1], [3, 2, 1], [1, 3, 2], [3, 1, 2], [1, 2, 3], [2, 1, 3]]
```

If some list entry occurs several times, the number of permutations decreases:

```
combinat::permute([a, a, b])
```

```
[[a, b, a], [b, a, a], [a, a, b]]
```

However, the same permutation is listed as often as it can be obtained by applying different elements of the symmetric group S_3 if the option `Duplicate` is given.

```
combinat::permute([a, a, b], Duplicate)
```

```
[[a, b, a], [b, a, a], [a, b, a], [b, a, a], [a, a, b], [a, a, b]]
```

We could have achieved the same by permuting three different symbols and then setting two of them equal:

```
subs(combinat::permute([a, b, c]), c=a)
```

```
[[b, a, a], [a, b, a], [a, a, b], [a, a, b], [a, b, a], [b, a, a]]
```

Parameters

`l`

List

`n`

Positive integer

Options

`Duplicate`

List every permutation as often as it can be produced in different ways by applying some bijective mapping (element of the symmetric group) to the original list.

combinat::powerset

Subsets of a set

Syntax

```
combinat::powerset(S)
```

Description

If `S` is a set, `combinat::powerset(S)` returns the set of all subsets of `S`. If `l` is a list, `combinat::powerset(l)` returns the set of all sublists of `l`.

The powerset of a list `l` is the set of all lists that can be obtained by deleting some elements of `l` and leaving the others in order.

`combinat::powerset` has been overloaded for multisets of type `Dom::Multiset`. The powerset of a multiset `S` consists of all multisets that contain only elements occurring also in `S`, each of them at most as many times as it occurs in `S`.

Examples

Example 1

Given a finite set, `combinat::powerset` returns the powerset (set of all subsets) of the input:

```
combinat::powerset({a, b, c})
```

$$\{\varnothing, \{c\}, \{a\}, \{b\}, \{b, c\}, \{a, b\}, \{a, c\}, \{a, b, c\}\}$$

The same works for multisets:

```
combinat::powerset(Dom::Multiset(a, a, b))
```

$$\{\varnothing, \{[a, 1]\}, \{[a, 2]\}, \{[b, 1]\}, \{[a, 1], [b, 1]\}, \{[a, 2], [b, 1]\}\}$$

Example 2

The powerset of a list `l` of pairwise different elements is the same as the powerset of the set of these elements, except that it consists of lists in which the order of elements is the same as in `l`:

```
combinat::powerset([c, a, b])
```

$$\{[], [a], [b], [c], [a, b], [c, a], [c, b], [c, a, b]\}$$

In general, the powerset of a list `l` is the same as the powerset of the multiset of its elements, except that it consists of lists in which the original order is preserved:

```
combinat::powerset([a, b, a])
```

$$\{[], [a], [b], [a, a], [a, b], [b, a], [a, b, a]\}$$

Parameters

s

Set

l

List

combinat::stirling1

Stirling numbers of the first kind

Syntax

```
combinat::stirling1(n, k)
```

Description

`combinat::stirling1(n,k)` computes the Stirling numbers of the first kind.

Let $S(n, k)$ be the number of permutations of `n` symbols that have exactly `k` cycles. Then `combinat::stirling1(n,k)` computes $(-1)^{(n+k)} S(n, k)$.

Let $S_1(n, k)$ be the Stirling number of the first kind, then we have:

$$\sum_{k=0}^{n} S_1(n, k)\, x^k = x(x-1)\cdots(x-n+1)$$

.

Examples

Example 1

Let us have a look what's the result of $x\,(x-1)\,(x-2)\,(x-3)\,(x-4)\,(x-5)$ written as a sum.

```
expand(x*(x-1)*(x-2)*(x-3)*(x-4)*(x-5))
```

$$x^6 - 15\,x^5 + 85\,x^4 - 225\,x^3 + 274\,x^2 - 120\,x$$

Now let us "prove" the formula mentioned in the "Details" section by calculating the proper Stirling numbers:

```
combinat::stirling1(6,1);
```

```
combinat::stirling1(6,2);
combinat::stirling1(6,3);
combinat::stirling1(6,4);
combinat::stirling1(6,5);
combinat::stirling1(6,6)
```

$$-120$$

$$274$$

$$-225$$

$$85$$

$$-15$$

$$1$$

Example 2

```
combinat::stirling1(3,-1)
```

```
Error: Nonnegative integers are expected. [combinat::stirling1]
```

Parameters

n, k

Nonnegative integers

Return Values

Integer.

References

J.J. Rotman, An Introduction to the Theory of Groups, 3rd Edition, Wm. C. Brown Publishers, Dubuque, 1988

combinat::stirling2

Stirling numbers of the second kind

Syntax

```
combinat::stirling2(n, k)
```

Description

`combinat::stirling2(n,k)` computes the number of ways of partitioning a set of `n` elements into `k` non-empty subsets.

`combinat::stirling2(n,k)` is calculated using the formula

$$\text{stirling2}(n, k) = \frac{1}{k!}\left(\sum_{j=0}^{k}(-1)^{k-j}\binom{k}{j}j^{n}\right).$$

Examples

Example 1

One can partition the set {1, 2, 3} into {1, 2, 3} = {1, 2} ∪ {3} = {1, 3} ∪ {2} = {2, 3} ∪ {1}

```
combinat::stirling2(3,2)
```

```
    3
```

Example 2

```
combinat::stirling2(3)
```

```
Error: Two arguments are expected. [combinat::stirling2]
```

Parameters

n, k

Nonnegative integers

Return Values

Nonnegative integer.

combinat::subwords

Subwords of a word

Syntax

```
combinat::subwords(w)
```

Description

The function `combinat::subwords(w)` returns a list of all subwords (sublists) of the list `w`.

A subword of a word w is a word obtained by deleting the letters at some of the positions in w. A subword is generated as many times as it appears in the word.

To obtain each subword only once, `combinat::powerset` should be used.

Examples

Example 1

There are 8 subwords of the word `[a, b, c]`:

```
combinat::subwords([a, b, c])
```

$$[[], [a], [b], [a, b], [c], [a, c], [b, c], [a, b, c]]$$

Parameters

`w`

List

6

daetools – Analyze and Reduce Differential Algebraic Equations (DAEs)

daetools::findDecoupledBlocks
daetools::incidenceMatrix
daetools::isLowIndexDAE
daetools::massMatrixForm
daetools::reduceDAEIndex
daetools::reduceDAEToODE
daetools::reduceDifferentialOrder
daetools::reduceRedundancies

daetools::findDecoupledBlocks

Search for decoupled blocks in systems of equations

Syntax

```
[eqsBlocks,varsBlocks] := daetools::findDecoupledBlocks(eqs,vars)
```

Description

`[eqsBlocks,varsBlocks] := daetools::findDecoupledBlocks(eqs,vars)` identifies subsets (blocks) of equations that can be used to define subsets of variables. The number of variables `vars` must coincide with the number of equations `eqs`.

The `i`th block is the set of equations determining the variables in `vars[varsBlocks[i]]`. The variables in `vars[varsBlocks[1],...,varsBlocks[i-1]]` are determined recursively by the previous blocks of equations. After you solve the first block of equations for the first block of variables, the second block of equations, given by `eqs[eqsBlocks[2]]`, defines a decoupled subset of equations containing only the subset of variables given by the second block of variables `vars[varsBlock[2]]`, plus the variables from the first block (these variables are known at this time). Thus, if a nontrivial block decomposition is possible, you can split the solution process for a large system of equations involving many variables into several steps, where each step involves a smaller subsystem.

The number of blocks is `nops(eqsBlocks)`. It coincides with `nops(varsBlocks)`. If `nops(eqsBlocks) = nops(varsBlocks) = 1`, then a nontrivial block decomposition of the equations is not possible.

The implemented algorithm requires that for each variable in `vars` there must be at least one matching equation in `eqs` involving this variable. The same equation cannot also be matched to another variable. If the system does not satisfy this condition, then `daetools::findDecoupledBlocks` throws an error. In particular, `daetools::findDecoupledBlocks` requires that `nops(eqs) = nops(vars)`.

Examples

Example 1

Compute a block lower triangular decomposition of a symbolic system of differential algebraic equations (DAEs).

Create the following system of four differential algebraic equations. Here, the expressions `x1(t)`, `x2(t)`, `x3(t)`, and `x4(t)` represent the state variables of the system. The system also contains symbolic parameters `c1`, `c2`, `c3`, `c4`, and the expressions `f(t,x,y)` and `g(t,x,y)`.

```
eqs := [c1*diff(x1(t),t) + c2*diff(x3(t),t) = c3*f(t,x1(t),x3(t)),
        c2*diff(x1(t),t) + c1*diff(x3(t),t) = c4*g(t,x3(t),x4(t)),
        x1(t) = g(t,x1(t),x3(t)),
        x2(t) = f(t,x3(t),x4(t))]:
vars:= [x1(t), x2(t), x3(t), x4(t)]:
```

Use `daetools::findDecoupledBlocks` to find the block structure of the system.

```
[eqsBlocks, varsBlocks] := daetools::findDecoupledBlocks(eqs, vars)
```

$$[[[1, 3], [2], [4]], [[1, 3], [4], [2]]]$$

The first block contains two equations in two variables.

```
eqs[eqsBlocks[1]]
```

$$\left[c1\,\frac{\partial}{\partial t}\,x1(t) + c2\,\frac{\partial}{\partial t}\,x3(t) = c3\,f(t, x1(t), x3(t)),\ x1(t) = g(t, x1(t), x3(t))\right]$$

```
vars[varsBlocks[1]]
```

$$[x1(t), x3(t)]$$

After you solve this block for the state variables `x1(t)`, `x3(t)`, you can solve the next block of equations. This block consists of one equation.

```
eqs[eqsBlocks[2]]
```

$$\left[c2\ \frac{\partial}{\partial t}\,x1(t) + c1\ \frac{\partial}{\partial t}\,x3(t) = c4\ g(t, x3(t), x4(t))\right]$$

This block involves one variable.

```
vars[varsBlocks[2]]
```

$$[x4(t)]$$

After you solve the equation from block 2 for the state variable `x4(t)`, the remaining block of equations `eqs[eqsBlocks[3]]` defines the remaining variable `vars[varsBlocks[3]]`.

```
eqs[eqsBlocks[3]];
vars[varsBlocks[3]]
```

$$[x2(t) = f(t, x3(t), x4(t))]$$

$$[x2(t)]$$

Find the permutations that convert the system to a block lower triangular form.

```
eqsPerm := [op(eqsBlocks[i]) $ i = 1..nops(eqsBlocks)];
varsPerm := [op(varsBlocks[i]) $ i = 1..nops(varsBlocks)]
```

$$[1, 3, 2, 4]$$

$$[1, 3, 4, 2]$$

Convert the system to a block lower triangular system of equations.

```
eqs := eqs[eqsPerm];
vars := vars[varsPerm]
```

$$\left[\mathrm{c1}\,\frac{\partial}{\partial t}\,\mathrm{x1}(t)+\mathrm{c2}\,\frac{\partial}{\partial t}\,\mathrm{x3}(t)=\mathrm{c3}\,f(t,\,\mathrm{x1}(t),\,\mathrm{x3}(t)),\right.$$

$$\mathrm{x1}(t)=g(t,\,\mathrm{x1}(t),\,\mathrm{x3}(t)),\;\mathrm{c2}\,\frac{\partial}{\partial t}\,\mathrm{x1}(t)+\mathrm{c1}\,\frac{\partial}{\partial t}\,\mathrm{x3}(t)=\mathrm{c4}\,g(t,\,\mathrm{x3}(t),\,\mathrm{x4}(t)),$$

$$\left.\mathrm{x2}(t)=f(t,\,\mathrm{x3}(t),\,\mathrm{x4}(t))\right]$$

$$[\mathrm{x1}(t),\,\mathrm{x3}(t),\,\mathrm{x4}(t),\,\mathrm{x2}(t)]$$

Find the incidence matrix of the resulting system. The incidence matrix shows that the system of permuted equations has three diagonal blocks of size 2-by-2, 1-by-1, and 1-by-1.

```
daetools::incidenceMatrix(eqs, vars)
```

$$\begin{pmatrix}1&1&0&0\\1&1&0&0\\1&1&1&0\\0&1&1&1\end{pmatrix}$$

Parameters

eqs

A list or a vector of equations or expressions in the state variables `vars` and their derivatives. Expressions represent equations with `0` right side.

vars

A list or a vector of identifiers or expressions, such as `[x1(t),x2(t)]`.

Return Values

A nested list of integers representing permutations required to convert the original system `eqs,vars` to a block lower triangular form.

`daetools::incidenceMatrix` | `daetools::isLowIndexDAE` | `daetools::massMatrixForm` | `daetools::reduceDAEIndex` | `daetools::reduceDAEToODE` | `daetools::reduceDifferentialOrder` | `daetools::reduceRedundancies`

Introduced in R2014b

daetools::incidenceMatrix

Find incidence matrix of system of equations

Syntax

```
A := daetools::incidenceMatrix(eqs,vars)
```

Description

`A := daetools::incidenceMatrix(eqs,vars)` for `m` equations `eqs` and `n` variables `vars` returns an `m`-by-`n` matrix `A`, where `A[i,j] = 1` if `eqs[i]` contains `vars[j]` or any derivative of `vars[j]`. All other elements of `A` are `0`s.

Examples

Example 1

Find the incidence matrix of a system of five equations in five variables.

Create the following vector `eqs` containing five symbolic differential equations.

```
eqs := [diff(y1(t),t) = y2(t),
        diff(y2(t),t) = c1*y1(t) + c3*y3(t),
        diff(y3(t),t) = y2(t) + y4(t),
        diff(y4(t),t) = y3(t) + y5(t),
        diff(y5(t),t) = y4(t)]:
```

Create the vector of variables. Here, `c1` and `c3` are symbolic parameters (not variables) of the system.

```
vars := [y1(t), y2(t), y3(t), y4(t), y5(t)]:
```

Find the incidence matrix `A` for the equations `eqs` with respect to the variables `vars`.

```
A := daetools::incidenceMatrix(eqs, vars)
```

Parameters

`eqs`

A list or a vector of equations or expressions in the state variables `vars` and their derivatives. Expressions represent equations with `0` right side.

`vars`

A list or a vector of identifiers or expressions, such as `[x1(t), x2(t)]`.

Return Values

A matrix of `1`s and `0`s.

Introduced in R2014b

daetools::isLowIndexDAE

Check if differential index of system equations is lower than 2

Syntax

```
daetools::isLowIndexDAE(eqs,vars)
```

Description

`daetools::isLowIndexDAE(eqs,vars)` checks if the system `eqs` of first-order semilinear differential algebraic equations (DAEs) has a low differential index. If the differential index of the system is `0` or `1`, `isLowIndexDAE` returns `TRUE`. If the differential index of `eqs` is higher than `1`, then `daetools::isLowIndexDAE` returns `FALSE`.

The number of equations `eqs` must match the number of variables `vars`.

Examples

Example 1

Check if a system of first-order semilinear DAEs has a low (`0` or `1`) differential index.

Create the following system of two differential algebraic equations. Here, `x(t)` and `y(t)` are the state variables of the system.

```
eqs := [diff(x(t),t) = x(t) + y(t), x(t)^2 + y(t)^2 = 1];
vars := [x(t), y(t)]
```

$$\left[\frac{\partial}{\partial t} x(t) = x(t) + y(t),\ x(t)^2 + y(t)^2 = 1\right]$$

$$[x(t),\ y(t)]$$

Use `daetools::isLowIndexDAE` to check the differential order of the system. The differential order of this system is `1`. For systems of index `0` and `1`, `daetools::isLowIndexDAE` returns `TRUE`.

```
daetools::isLowIndexDAE(eqs, vars)
```

```
TRUE
```

Example 2

Check if the following DAE system has a low or high differential index. If the index is higher than `1`, then use `daetools::reduceDAEIndex` to reduce it.

Create the following system of two differential algebraic equations. Here, `x(t)`, `y(t)`, and `z(t)` are the state variables of the system.

```
eqs := [diff(x(t),t) = x(t) + z(t),
        diff(y(t),t) = f(t),
        x(t) = y(t)];

vars := [x(t), y(t), z(t)]
```

$$\left[\frac{\partial}{\partial t}x(t) = x(t) + z(t),\ \frac{\partial}{\partial t}y(t) = f(t),\ x(t) = y(t)\right]$$

$$[x(t),\ y(t),\ z(t)]$$

Use `daetools::isLowIndexDAE` to check the differential index of the system. For this system, `daetools::isLowIndexDAE` returns `FALSE`. This means that the differential index of the system is `2` or higher.

```
daetools::isLowIndexDAE(eqs, vars)
```

```
FALSE
```

Use `daetools::reduceDAEIndex` to rewrite the system so that the differential index is `1`. The new system has one additional state variable, `Dyt(t)`.

```
[newEqs, newVars, transform, oldIndex] :=
```

```
daetools::reduceDAEIndex(eqs, vars):

newEqs;
newVars
```

$$[x'(t) - x(t) - z(t),\ \mathrm{Dyt}(t) - f(t),\ x(t) - y(t),\ x'(t) - \mathrm{Dyt}(t)]$$

$$[x(t),\ y(t),\ z(t),\ \mathrm{Dyt}(t)]$$

`daetools::reduceDAEIndex` also returns the differential index of the original system.

```
oldIndex
```

$$2$$

Check if the differential order of the new system is lower than 2.

```
daetools::isLowIndexDAE(newEqs, newVars)
```

$$\mathrm{TRUE}$$

Parameters

`eqs`

A list or a vector of equations or expressions in the state variables `vars` and their derivatives. Expressions represent equations with 0 right side.

`vars`

A list or a vector of identifiers or expressions, such as `[x1(t), x2(t)]`.

Return Values

TRUE or FALSE.

Introduced in R2014b

daetools::massMatrixForm

Extract mass matrix and right side of semilinear system of differential algebraic equations

Syntax

```
MF := daetools::massMatrixForm(eqs,vars)
```

Description

`MF := daetools::massMatrixForm(eqs,vars)` returns a list containing the mass matrix `M` and the right side of equations `F` of a semilinear system of first-order differential algebraic equations (DAEs). Algebraic equations in `eqs` that do not contain any derivatives of the variables in `vars` correspond to empty rows of the mass matrix `M`.

The mass matrix `M` and the right side of equations `F` refer to the form `M(t,x(t)x'(t)) = F(t,x(t))`.

Examples

Example 1

Convert a semilinear system of differential algebraic equations to mass matrix form.

Create the following system of differential algebraic equations. Here, `x1(t)` and `x2(t)` represent state variables of the system. The system also contains symbolic parameters `r` and `m`, and the parameter `f(t, x1(t), x2(t))`.

```
eqs :=
 [m*x2(t)*diff(x1(t), t) + m*t*diff(x2(t), t) = f(t, x1(t), x2(t)),
  x1(t)^2 + x2(t)^2 = r^2];

vars := [x1(t), x2(t)];
```

$$\left[m\,t\,\frac{\partial}{\partial t}\,\mathrm{x2}(t)+m\,\mathrm{x2}(t)\,\frac{\partial}{\partial t}\,\mathrm{x1}(t)=f(t,\mathrm{x1}(t),\mathrm{x2}(t)),\ \mathrm{x1}(t)^2+\mathrm{x2}(t)^2=r^2\right]$$

$$[\mathrm{x1}(t), \mathrm{x2}(t)]$$

Find the mass matrix form of this system.

```
MF := daetools::massMatrixForm(eqs, vars):
M := MF[1];
F := MF[2]
```

$$\begin{pmatrix} m\,\mathrm{x2}(t) & m\,t \\ 0 & 0 \end{pmatrix}$$

$$\begin{pmatrix} f(t, \mathrm{x1}(t), \mathrm{x2}(t)) \\ r^2 - \mathrm{x1}(t)^2 - \mathrm{x2}(t)^2 \end{pmatrix}$$

Parameters

`eqs`

A list or a vector of equations or expressions in the state variables `vars` and their derivatives. Expressions represent equations with `0` right side.

`vars`

A list or a vector of identifiers or expressions, such as `[x1(t), x2(t)]`.

Return Values

A list of two matrices. The first entry is the mass matrix. The number of rows is the number of equations in `eqs`, and the number of columns is the number of variables in `vars`. The second entry is an `n`-by-`1` matrix of the right side of equations, where `n` is the number of equations `eqs`.

Introduced in R2014b

daetools::reduceDAEIndex

Convert system of first-order differential algebraic equations to equivalent system of differential index 1

Syntax

```
[newEqs,newVars,R,oldIndex] := daetools::reduceDAEIndex(eqs,vars)
```

Description

`[newEqs,newVars,R,oldIndex] := daetools::reduceDAEIndex(eqs,vars)` converts a high-index system of first-order differential algebraic equations `eqs` to an equivalent system `newEqs` of differential index `1`. The `daetools::reduceDAEIndex` function keeps the original equations and variables and introduces new variables and equations. It also returns the matrix R that expresses the new variables in newVars as derivatives of the original variables vars and the differential index oldIndex of the original system of DAEs, eqs.

After conversion, `daetools::reduceDAEIndex` checks the differential index of the new system by calling `daetools::isLowIndexDAE`. If the index of newEqs is `2` or higher, then `daetools::reduceDAEIndex` issues a warning.

The implementation of `daetools::reduceDAEIndex` uses the Pantelides algorithm. This algorithm reduces higher-index systems to lower-index systems by selectively adding differentiated forms of the original equations. The Pantelides algorithm can underestimate the differential index of a new system, and therefore, can fail to reduce the differential index to `1`. In this case, `daetools::reduceDAEIndex` issues a warning and returns the value of oldIndex as `UNKNOWN`. The `daetools::reduceDAEToODE` function uses more reliable, but slower Gaussian elimination. Note that `daetools::reduceDAEToODE` requires the DAE system to be semilinear.

Examples

Example 1

Reduce the differential index of a system that contains two second-order differential algebraic equations. Because the equations are second-order equations, first use `reduceDifferentialOrder` to rewrite the system to a system of first-order DAEs.

Create the following system of two second-order DAEs. Here, `x(t)`, `y(t)`, and `F(t)` are state variables of the system.

```
eqs := [diff(x(t), t, t) = -F(t)*x(t),
        diff(y(t), t, t) = -F(t)*y(t) - g,
        x(t)^2 + y(t)^2 = r^2];
vars := [x(t), y(t), F(t)]
```

$$\left[\frac{\partial^2}{\partial t^2}x(t) = -F(t)\,x(t),\ \frac{\partial^2}{\partial t^2}y(t) = -g - F(t)\,y(t),\ x(t)^2 + y(t)^2 = r^2\right]$$

$$[x(t),\ y(t),\ F(t)]$$

Rewrite this system so that all equations become first-order differential equations. The `daetools::reduceDifferentialOrder` function replaces the second-order DAE by two first-order expressions by introducing the new variables `Dxt(t)` and `Dyt(t)`.

```
[eqs, vars, R] := daetools::reduceDifferentialOrder(eqs, vars):
newEquations = eqs;
newVariables = vars;
relations = R
```

$$\text{newEquations} = [\text{Dxt}'(t) + F(t)\,x(t),\ \text{Dyt}'(t) + g + F(t)\,y(t),\ -r^2 + x(t)^2 + y(t)^2,\ \text{Dxt}(t) - x'(t),\ \text{Dyt}(t) - y'(t)]$$

$$\text{newVariables} = [x(t),\ y(t),\ F(t),\ \text{Dxt}(t),\ \text{Dyt}(t)]$$

$$\text{relations} = [\text{Dxt}(t) = x'(t),\ \text{Dyt}(t) = y'(t)]$$

Use `daetools::reduceDAEIndex` to rewrite the system so that the differential index is 1.

```
[eqs,vars,R,originalIndex] := daetools::reduceDAEIndex(eqs,vars):
newEquations = eqs;
newVariables = vars;
relations = R;
originalDAEIndex = originalIndex
```

$$\text{newEquations} = [\text{Dxtt}(t) + F(t)\,x(t),\ g + \text{Dytt}(t) + F(t)\,y(t),\ -r^2 + x(t)^2 + y(t)^2,$$
$$\text{Dxt}(t) - \text{Dxt1}(t),\ \text{Dyt}(t) - \text{Dyt1}(t),\ 2\,\text{Dxt1}(t)\,x(t) + 2\,\text{Dyt1}(t)\,y(t),$$
$$2\,y(t)\,\text{Dyt1}'(t) + 2\,\text{Dyt1}(t)^2 + 2\,\text{Dxt1}(t)^2 + 2\,\text{Dxt1t}(t)\,x(t),\ \text{Dxtt}(t) - \text{Dxt1t}(t),$$
$$\text{Dytt}(t) - \text{Dyt1}'(t),\ \text{Dyt1}(t) - y'(t)]$$

$$\text{newVariables} = [x(t),\ y(t),\ F(t),\ \text{Dxt}(t),\ \text{Dyt}(t),\ \text{Dytt}(t),\ \text{Dxtt}(t),\ \text{Dxt1}(t),\ \text{Dyt1}(t),\ \text{Dxt1t}(t)]$$

$$\text{relations} = [\text{Dytt}(t) = \text{Dyt}'(t),\ \text{Dxtt}(t) = \text{Dxt}'(t),\ \text{Dxt1}(t) = x'(t),\ \text{Dyt1}(t) = y'(t),\ \text{Dxt1t}(t) = x''(t)]$$

$$\text{originalDAEIndex} = 3$$

Use `daetools::reduceRedundancies` to shorten the system.

```
[eqs, vars, solvedEquations,
 constantVariables,
 replacedVariables,
 otherEquations] := daetools::reduceRedundancies(eqs, vars):
newEquations = eqs;
newVariables = vars;
```

$$\text{newEquations} = [\text{Dxtt}(t) + F(t)\,x(t),\ g + \text{Dytt}(t) + F(t)\,y(t),\ -r^2 + x(t)^2 + y(t)^2,$$
$$2\,\text{Dxt}(t)\,x(t) + 2\,\text{Dyt}(t)\,y(t),\ 2\,y(t)\,\text{Dyt}'(t) + 2\,\text{Dyt}(t)^2 + 2\,\text{Dxt}(t)^2 + 2\,\text{Dxtt}(t)\,x(t),$$
$$\text{Dytt}(t) - \text{Dyt}'(t),\ \text{Dyt}(t) - y'(t)]$$

$$\text{newVariables} = [x(t),\ y(t),\ F(t),\ \text{Dxt}(t),\ \text{Dyt}(t),\ \text{Dytt}(t),\ \text{Dxtt}(t)]$$

Parameters

`eqs`

A list or a vector of equations or expressions in the state variables `vars` and their derivatives. Expressions represent equations with `0` right side.

`vars`

A list or a vector of identifiers or expressions, such as `[x1(t), x2(t)]`.

Return Values

A nested list containing the following four lists: a list of new equations, a list of new variables, a list of relations between new and original variables, and the differential index of the original DAE system. If `daetools::reduceDAEIndex` fails to reduce the differential index to `1`, then it issues a warning and returns `UNKNOWN` instead of the differential index of the original DAE system.

`daetools::findDecoupledBlocks` | `daetools::incidenceMatrix` | `daetools::isLowIndexDAE` | `daetools::massMatrixForm` | `daetools::reduceDAEToODE` | `daetools::reduceDifferentialOrder` | `daetools::reduceRedundancies`

Introduced in R2014b

daetools::reduceDAEToODE

Convert system of first-order quasilinear differential algebraic equations to equivalent system of differential index 0

Syntax

```
[newEqs,constraintEqs,oldIndex] = daetools::reduceDAEToODE(eqs,vars)
```

Description

`[newEqs,constraintEqs,oldIndex] := daetools::reduceDAEToODE(eqs,vars)` converts a high-index system of first-order semilinear algebraic equations `eqs` to an equivalent system of ordinary differential equations, `newEqs`. It also returns a vector of constraint equations and the differential index oldIndex of the original system of semilinear DAEs, eqs.

The differential index of the new system is `0`, that is, the Jacobian of `newEqs` with respect to the derivatives of the variables in `vars` is invertible.

The implementation of `daetools::reduceDAEToODE` is based on Gaussian elimination. This algorithm is more reliable than the Pantelides algorithm used by `daetools::reduceDAEIndex`, but it can be much slower.

The number of equations `eqs` must coincide with the number of variables `vars`.

Examples

Example 1

Check if a DAE system has a low (`0` or `1`) or high (`>1`) differential index. If the index is higher than `1`, then first try to reduce the index by using `daetools::reduceDAEIndex` and then by using `daetools::reduceDAEToODE`.

Create the following system of differential algebraic equations. Here, `x1(t)`, `x2(t)`, and `x3(t)` represent state variables of the system. The system also contains the expressions `q1(t)`, `q2(t)`, and `q3(t)` that do not represent state variables.

```
eqs := [diff(x2(t),t) = q1(t) - x1(t),
        diff(x3(t),t) = q2(t) - 2*x2(t) - t*(q1(t)-x1(t)),
        q3(t) - t*x2(t) - x3(t) = 0];
vars := [x1(t), x2(t), x3(t)]
```

$$\left[\frac{\partial}{\partial t}\,\mathrm{x2}(t) = \mathrm{q1}(t) - \mathrm{x1}(t),\ \frac{\partial}{\partial t}\,\mathrm{x3}(t) = \mathrm{q2}(t) - 2\,\mathrm{x2}(t) - t\,(\mathrm{q1}(t) - \mathrm{x1}(t)),\ \mathrm{q3}(t) - \mathrm{x3}(t) - t\,\mathrm{x2}(t) = 0\right]$$

$$[\mathrm{x1}(t),\ \mathrm{x2}(t),\ \mathrm{x3}(t)]$$

Use `daetools::isLowIndexDAE` to check the differential index of the system. For this system, `daetools::isLowIndexDAE` returns `FALSE`. This means that the differential index of the system is `2` or higher.

```
daetools::isLowIndexDAE(eqs, vars)
```

$$\mathrm{FALSE}$$

Use `daetools::reduceDAEIndex` as your first attempt to rewrite the system so that the differential index is `1`. For this system, `daetools::reduceDAEIndex` issues a warning because it cannot reduce the differential index of the system to `0` or `1`.

```
[newEqs, newVars, R, oldIndex] :=
    daetools::reduceDAEIndex(eqs, vars):

newEquations = newEqs;
newVariables = newVars;
relations = R;
originalIndex = oldIndex
```

```
Warning: The index of the reduced DAEs is larger than 1. [daetools::reduceDAEIndex]
```

$$\mathrm{newEquations} = [\mathrm{x2}'(t) - \mathrm{q1}(t) + \mathrm{x1}(t),\ \mathrm{Dx3t}(t) - \mathrm{q2}(t) + 2\,\mathrm{x2}(t) + t\,(\mathrm{q1}(t) - \mathrm{x1}(t)),\ \mathrm{q3}(t) - \mathrm{x3}(t) - t\,\mathrm{x2}(t),\ \mathrm{q3}'(t) - t\,\mathrm{x2}'(t) - \mathrm{x2}(t) - \mathrm{Dx3t}(t)]$$

$$\text{newVariables} = [\text{x1}(t), \text{x2}(t), \text{x3}(t), \text{Dx3t}(t)]$$

$$\text{relations} = [\text{Dx3t}(t) = \text{x3}'(t)]$$

$$\text{originalIndex} = \text{UNKNOWN}$$

If `daetools::reduceDAEIndex` cannot reduce the semilinear system so that the index is `0` or `1`, try using `daetools::reduceDAEToODE`. This function can be much slower, therefore it is not recommended as a first choice.

```
[newEqs, constraintEqs, oldIndex] :=
    daetools::reduceDAEToODE(eqs, vars):

ODEs = eqs;
constraintEquations = constraintEqs;
originalIndex = oldIndex
```

$$\text{ODEs} = \left[\frac{\partial}{\partial t}\,\text{x2}(t) = \text{q1}(t) - \text{x1}(t),\ \frac{\partial}{\partial t}\,\text{x3}(t) = \text{q2}(t) - 2\,\text{x2}(t) - t\,(\text{q1}(t) - \text{x1}(t)),\right.$$
$$\left.\text{q3}(t) - \text{x3}(t) - t\,\text{x2}(t) = 0\right]$$

$$\text{constraintEquations} = [\text{q2}'(t) - \text{q3}''(t) - \text{q1}(t) + \text{x1}(t),\ \text{x3}(t) - \text{q3}(t) + t\,\text{x2}(t),$$
$$\text{q3}'(t) - \text{q2}(t) + \text{x2}(t)]$$

$$\text{originalIndex} = 3$$

Parameters

eqs

A list or a vector of equations or expressions in the state variables `vars` and their derivatives. Expressions represent equations with `0` right side.

`vars`

A list or a vector of identifiers or expressions, such as `[x1(t), x2(t)]`.

Return Values

A nested list containing the following three lists: a list of ordinary differential equations, a list of constraint equations encountered during system reduction, and the differential index of the original DAE system.

`daetools::findDecoupledBlocks` | `daetools::incidenceMatrix` | `daetools::isLowIndexDAE` | `daetools::massMatrixForm` | `daetools::reduceDAEIndex` | `daetools::reduceDifferentialOrder` | `daetools::reduceRedundancies`

Introduced in R2014b

daetools::reduceDifferentialOrder

Reduce systems of higher-order differential equations to systems of first-order differential equations

Syntax

```
[newEqs,newVars,R] := daetools::reduceDifferentialOrder(eqs,vars)
```

Description

`[newEqs,newVars,R] := daetools::reduceDifferentialOrder(eqs,vars)` rewrites a system of higher-order differential equations eqs as a system of first-order differential equations `newEqs` by substituting derivatives in `eqs` with new variables. It also returns the matrix `R` that expresses the new variables in `newVars` as derivatives of the original variables `vars`. Here, `newVars` consists of the original variables `vars` augmented with these new variables.

Examples

Example 1

Reduce a system containing a second- and a third-order expression to a system containing only first-order DAEs, and return a matrix that expresses the variables generated by `daetools::reduceDifferentialOrder` via the original variables of this system.

Create the following system of differential equations, which includes a second- and a third-order expression. Here, `x(t)` and `y(t)` are state variables of the system.

```
eqs := [diff(x(t),t,t) = diff(f(t),t,t,t),
        diff(y(t),t,t,t) = diff(f(t),t,t)];
vars := [x(t), y(t)]
```

$$\left[\frac{\partial^2}{\partial t^2}x(t) = \frac{\partial^3}{\partial t^3}f(t),\ \frac{\partial^3}{\partial t^3}y(t) = \frac{\partial^2}{\partial t^2}f(t)\right]$$

$$[x(t),\ y(t)]$$

Rewrite this system so that all equations become first-order differential equations. The `daetools::reduceDifferentialOrder` function replaces the higher-order DAE with first-order equations by introducing the new variables `Dxt(t)`, `Dyt(t)`, and `Dytt(t)`. This function returns a nested list containing the following three lists: a list of new equations, a list of new variables, and a list of relations between the new and the original variables. Display `newEqs`, `newVars`, and `R` separately.

```
[newEqs, newVars, R] :=
    daetools::reduceDifferentialOrder(eqs, vars):

newEqs;
newVars;
R
```

$$[\mathrm{Dxt}'(t) - f''''(t),\ \mathrm{Dytt}'(t) - f'''(t),\ \mathrm{Dxt}(t) - x'(t),\ \mathrm{Dyt}(t) - y'(t),\ \mathrm{Dytt}(t) - \mathrm{Dyt}'(t)]$$

$$[x(t),\ y(t),\ \mathrm{Dxt}(t),\ \mathrm{Dyt}(t),\ \mathrm{Dytt}(t)]$$

$$[\mathrm{Dxt}(t) = x'(t),\ \mathrm{Dyt}(t) = y'(t),\ \mathrm{Dytt}(t) = y''(t)]$$

Parameters

eqs

A list or a vector of equations or expressions in the state variables `vars` and their derivatives. Expressions represent equations with `0` right side.

vars

A list or a vector of identifiers or expressions, such as `[x1(t), x2(t)]`.

Return Values

A nested list containing the following three lists: a list of new equations, a list of new variables, and a list of relations between the new and the original variables.

daetools::reduceRedundancies

Simplify system of first-order differential algebraic equations by eliminating redundant equations and variables

Syntax

```
[newEqs,
 newVars,
 solvedEquations,
 constantVariables,
 replacedVariables,
 otherEquations
] := daetools::reduceRedundancies(eqs, vars)
```

Description

`[newEqs, newVars, solvedEquations, constantVariables, replacedVariables, otherEquations] := daetools::reduceRedundancies(eqs, vars)` eliminates simple equations from the system of first-order differential algebraic equations `eqs`. It returns a list of remaining equations, a list of remaining variables, and four more lists containing information on the eliminated equations and variables. For details, see “Return Values” on page 6-29.

Examples

Example 1

Use `daetools::reduceRedundancies` to simplify a system of five differential algebraic equations in four variables to a system of two equations in two variables.

Create the following system of five differential algebraic equations for four state variables: `x1(t)`, `x2(t)`, `x3(t)`, and `x4(t)`. This system also contains symbolic parameters `a1`, `a2`, `a3`, `a4`, `b`, `c`, and a parameter function `f(t)` that is not a state variable.

```
eqs := [a1*diff(x1(t),t)+a2*diff(x2(t),t) = b*x4(t),
```

```
        a3*diff(x2(t),t)+a4*diff(x3(t),t) = c*x4(t),
        x1(t) = 2*x2(t),
        x4(t) = f(t),
        f(t) = sin(t)];
vars := [x1(t), x2(t), x3(t), x4(t)]
```

$$\left[a1\ \frac{\partial}{\partial t}\,x1(t) + a2\ \frac{\partial}{\partial t}\,x2(t) = b\ x4(t),\ a3\ \frac{\partial}{\partial t}\,x2(t) + a4\ \frac{\partial}{\partial t}\,x3(t) = c\ x4(t),\ x1(t) = 2\ x2(t),\right.$$

$$\left.x4(t) = f(t),\ f(t) = \sin(t)\right]$$

$$[x1(t),\ x2(t),\ x3(t),\ x4(t)]$$

Use `daetools::reduceRedundancies` to eliminate redundant equations and corresponding state variables.

```
[newEqs, newVars,
 solvedEquations,
 constantVariables,
 replacedVariables,
 otherEquations
] := daetools::reduceRedundancies(eqs, vars):
```

Display the new equations and new variables.

```
newEqs;
newVars
```

$$\left[a1\ x1'(t) - b\ f(t) + \frac{a2\ x1'(t)}{2},\ \frac{a3\ x1'(t)}{2} + a4\ x3'(t) - c\ f(t)\right]$$

$$[x1(t),\ x3(t)]$$

Display the equations that `daetools::reduceRedundancies` used to replace those state variables from `vars` that do not appear in `newEqs`.

```
solvedEquations
```

$$[x1(t) - 2\,x2(t),\ x4(t) - f(t)]$$

Display those state variables from `vars` that `daetools::reduceRedundancies` replaced by constant values.

```
constantVariables
```

$$[x4(t) = f(t)]$$

Display those state variables from `vars` that `daetools::reduceRedundancies` replaced by expressions in terms of other variables.

```
replacedVariables
```

$$\left[x2(t) = \frac{x1(t)}{2}\right]$$

Display those equations from `eqs` that do not contain any of the state variables `vars`.

```
otherEquations
```

$$[f(t) - \sin(t)]$$

Parameters

`eqs`

A list or a vector of equations or expressions in the state variables `vars` and their derivatives. Expressions represent equations with `0` right side.

`vars`

A list or a vector of identifiers or expressions, such as `[x1(t), x2(t)]`.

Return Values

A nested list containing the following lists:

- A list of new equations
- A list of those variables that remain in the new DAE system
- A list of equations that do not appear in `newEqs`
- A list of equations `[y1 = value1(t), y2 = value2(t),...]` defining those of the variables `[y1,y2,...]` (contained in the original equations `eqs` and the original `vars`) that were eliminated from `eqs`. In `newEqs`, they are replaced by the values.
- A list of equations `[y1 = Y1(t,x,diff(x,t),...), y2 = Y2(t,x,diff(x,t),...),...]` defining those of the variables `]y1,y2,...]` (in the original `vars`) that were eliminated in terms of the variables that are still in `newVars`. (Typically, equations involving only two variables are used to eliminate one of the variables.)
- A list of equations that do not contain any of the variables. These equations do not appear in `newEqs`.

DOM_ARRAY

(symbolic, multidimensional) arrays

Description

DOM_ARRAY is a multidimensional container type, storing arbitrary MuPAD objects at integer indices.

Arrays are a fundamental data type in many programming languages: For a fixed number of indices ("dimensions"), for each index an integer from a fixed range, an array provides space to store an arbitrary piece of data at this combination.

Function Calls

Using an array as a function symbol creates the list obtained by using each array entry as a function symbol for the operands used, i.e., `array(1..2, [f, g])(x, y)` results in `array(1..2, [f(x, y), g(x, y)])`.

Operations

As with any container, the most important operation on an array is reading and writing its entries, which is performed by indexed access, as in `A[1, 2]` or `B[1, 3, 2] := exp(x)`. Trying to access an element outside the boundaries of an array raises an error.

The function `map` applies some function or transformation to each element of an array, returning an array of the same format as its input, with the results of the calls as its entries.

If `A` is an array, `nops(A)` returns the number of elements in `A`.

Operands

If `A` is an array, the 0th operand of `A`, `op(A, 0)`, will be the sequence starting with the number of dimensions (an integer n) followed by n ranges of integers, which denote the

acceptable ranges of indices for each dimension, including both numbers listed in the range.

For $1 \le i \le nops(A)$, the ith operand of A is the ith entry of A, in the lexicographic order of indices.

Uninitialized entries of arrays will be displayed symbolically while still in the array. When being accessed by `op` or indexed access, `NIL` is returned.

Output

One-dimensional arrays are displayed as row vectors, two-dimensional arrays as matrices. Higher-dimensional arrays are written in functional form, using the `index = value` notation, and do not have a typesetting version. This also causes typesetting to be disabled for any surrounding expression in the same output.

Element Creation

The primary way of creating arrays is the function `array`. Beside that, obviously, `coerce` can convert a number of data types, such as matrices into arrays and a number of MuPAD functions, especially in the `numeric` library, return arrays.

MuPAD Functions
`array` | `matrix`

DOM_BOOL

Boolean constants

Description

DOM_BOOL is the data type of the truth values TRUE, FALSE, and UNKNOWN.

MuPAD uses a three-valued logic system, with these values (constants) TRUE, FALSE, and UNKNOWN.

Function Calls

Using a Boolean constant as a function returns that constant unchanged. The arguments of the call are *not* evaluated.

Operations

The most important operations on Boolean values are the logical operators `and`, `not`, `or`, `xor`, `==>`, `<=>`, and using them in conditions of `if` or `piecewise`.

Operands

Boolean constants are atomic.

Output

TRUE is displayed as *TRUE*, FALSE is displayed as *FALSE*, and UNKNOWN is shown as *UNKNOWN*.

Element Creation

The three constants can be types in as shown above. Additionally, many MuPAD functions returns Boolean values, the most generic/prominent two being `bool` and `is`.

See Also

MuPAD Functions
`bool` | `if` | `is`

DOM_COMPLEX

(Simple) Complex Numbers

Description

DOM_COMPLEX is the type of complex numbers with integer, rational, or floating-point components.

Complex numbers of type DOM_COMPLEX have two operands, their real and imaginary part. These are objects of type DOM_FLOAT, DOM_INT, or DOM_RAT. Complex numbers with other components (such as $\sqrt{2} + i\,\pi$) are not of domain type DOM_COMPLEX, but DOM_EXPR.

Function Calls

Calling a complex number as a function returns that number unchanged. The arguments of the call are *not* evaluated.

Operations

Most MuPAD functions operate on complex numbers. Use Re and Im to access the real and imaginary part, respectively.

Operands

Every object of type DOM_COMPLEX has two operands, the real and the imaginary part.

Output

Objects of type DOM_COMPLEX are essentially written as expressions in rectangular form. The imaginary unit is displayed as *I*.

Element Creation

Complex numbers can be constructed by typing in the corresponding expression, such as `3+4*I`. The keyword for typing the imaginary unit I is `I` (a capital letter i).

`DOM_FLOAT` | `DOM_INT` | `DOM_RAT`

DOM_DOMAIN

Data type of data types

Description

`DOM_DOMAIN` is the data type of datatypes.

Each MuPAD object has a unique data type. Since a data type is a MuPAD object, too, it must itself have a data type; the data type comprising all data types (including itself) is `DOM_DOMAIN`.

There are two kinds of elements of `DOM_DOMAIN`: data types of the kernel, and data types defined in the library or by the user (*domains*). Objects that have a data type of the latter kind are called *domain elements*.

A data type has the same internal structure as a table; its entries are called slots. One particular slot is the *key*; no two different data types can have the same key. Most of the other slots determine how arguments of that data type are handled by functions.

Once a user-defined domain has been constructed, it cannot be destroyed.

Examples

Example 1

Our first example stems from ethnology: some languages in Polynesia do not have words for numbers greater than three; every integer greater than three is denoted by the word “many”. Hence two plus two does not equal four but “many”. We are going to implement a domain for this kind of integers; in other words, we are going to implement a data type for the finite set {1, 2, 3, *many*}.

```
S := newDomain("Polynesian integer")
```

```
Polynesian integer
```

At this point, we have defined a new data type: a MuPAD object can be a Polynesian integer now. No operations are available yet; the domain consists of its key only:

```
op(S)
```

```
"key" = "Polynesian integer"
```

Even though there are no methods for input and output of domain elements yet, Polynesian integers can be entered and displayed right now. You have to use the function `new` for defining domain elements:

```
x := new(S, 5)
```

```
new(Polynesian integer, 5)
```

Now, `x` is a Polynesian integer:

```
type(x)
```

```
Polynesian integer
```

Of course, MuPAD cannot know what meaning a Polynesian integer has and what its internal structure should be. The arguments of the call to the function `new` are just stored as the zeroth, first, etc. operand of the domain element, without checking them. You may call `new` with as many arguments as you want:

```
new(S, 1, 2, 3, 4); op(%)
```

```
new(Polynesian integer, 1, 2, 3, 4)
```

```
1, 2, 3, 4
```

`new` cannot know that Polynesian integers should have exactly one operand and that we want `5` to be replaced by `many`. To achieve this, we implement our own method `"new"`; this also allows us to check the argument. We have one more problem: domain methods should refer to the domain; but they should not depend on the fact that the domain is currently stored in `S`. For this purpose, MuPAD has a special local variable `dom` that always refers to the domain a procedure belongs to:

```
S::new :=
proc(i : Type::PosInt)
begin
```

```
  if args(0) <> 1 then
    error("There must be exactly one argument")
  end_if;
  if i > 3 then
    new(dom, hold(many))
  else
    new(dom, i)
  end_if
end_proc:
```

A function call to the domain such as `S(5)` now implicitly calls the `"new"` method:

```
S(5)
```

```
new(Polynesian integer, many)
```

```
S("nonsense")
```

```
Error: The object '"nonsense"' is incorrect. The type of argument number 1 must be 'Ty
  Evaluating: S::new
```

In the next step, we define our own output method. A Polynesian integer `i`, say, shall not be printed as `new(Polynesian integer, i)`, only its internal value `1`, `2`, `3`, or `many` shall appear on the screen. Note that this value is the first operand of the data structure:

```
S::print :=
proc(x)
begin
  op(x, 1)
end_proc:
S(1), S(2), S(3), S(4), S(5)
```

```
1, 2, 3, many, many
```

By now, the input and output of elements of `S` have been defined. It remains to define how the functions and operators of MuPAD should react to Polynesian integers. This is done by *overloading* them. However, it is not necessary to overload each of the thousands of functions of MuPAD; for some of them, the default behavior is acceptable. For example, expression manipulation functions leave domain elements unaltered:

```
x := S(5): expand(x), simplify(x), combine(x); delete x:
```

```
many, many, many
```

Arithmetical operations handle domain elements like identifiers; they automatically apply the associative and commutative law for addition and multiplication:

```
(S(3) + S(2)) + S(4)
```

```
2 + 3 + many
```

In our case, this is not what we want. So we have to overload the operator +. Operators are overloaded by overloading the corresponding "underline-functions"; hence, we have to write a method `"_plus"`:

```
S::_plus :=
proc()
local argv;
begin
  argv := map([args()], op, 1);
  if has(argv, hold(many)) then
     new(dom, hold(many))
  else
     dom(_plus(op(argv)))
  end_if
end_proc:
```

Now, the sum of Polynesian integers calls this slot:

```
S(1) + S(2), S(2) + S(3) + S(7)
```

```
3, many
```

Deleting the identifier `S` does not destroy our domain. It can still be reconstructed using `newDomain`.

```
delete S:
op(newDomain("Polynesian integer"))
```

```
"key" = "Polynesian integer", "new" = proc S::new(i) ... end, "print" = proc S::print(x) ... end,
  "_plus" = proc S::_plus() ... end
```

Example 2

We could now give a similar example for more advanced Polynesian mathematics with numbers up to ten, say. This leads to the question whether it is necessary to enter all the code again and again whenever we decide to count a bit farther. It is not; this is one of the advantages of *domain constructors*. A domain constructor may be regarded as a function that returns a domain depending on some input parameters. It has several additional features. Firstly, the additional keywords `category` and `axiom` are available for specifying the mathematical structure of the domain; in our case, we have the structure of a commutative semigroup where different domain elements have different mathematical meanings (we call this a domain with a canonical representation). Secondly, an initialization part may be defined that is executed exactly once for every domain returned by the constructor; it should at least check the parameters passed to the constructor. Each domain created in such a way may inherit methods from other domains, and it must at least inherit the methods of `Dom::BaseDomain`.

```
domain CountingUpTo(n : Type::PosInt)
  inherits Dom::BaseDomain;
  category Cat::AbelianSemiGroup;
  axiom Ax::canonicalRep;

  new := proc(x : Type::PosInt)
  begin
    if args(0) <> 1 then
      error("There must be exactly one argument")
    end_if;
    if x > n then
      new(dom, hold(many))
    else
      new(dom, x)
    end_if
  end_proc;

  print := proc(x) begin op(x, 1) end_proc;

  _plus := proc() local argv;
  begin
    argv:= map([args()], op, 1);
    if has(argv, hold(many)) then
       new(dom, hold(many))
    else
       dom(_plus(op(argv)))
    end_if
```

```
  end_proc;

// initialization part
begin
  if args(0) <> 1 then
    error("Wrong number of arguments")
  end_if;
end:
```

Now, `CountingUpTo` is a domain constructor:

```
type(CountingUpTo)
```

DomainConstructor

We have defined the domain constructor `CountingUpTo`, but we have not created a domain yet. This is done by calling the constructor:

```
CountingUpToNine := CountingUpTo(9);
CountingUpToTen := CountingUpTo(10)
```

CountingUpTo(9)

CountingUpTo(10)

We are now able to create, output, and manipulate domain elements as in the previous example:

```
x := CountingUpToNine(3): y := CountingUpToNine(7):
x, x + x, y, x + y, y + y
```

3, 6, 7, many, many

```
x := CountingUpToTen(3): y := CountingUpToTen(7):
x, x + x, y, x + y, y + y
```

3, 6, 7, 10, many

```
delete CountingUpToNine, CountingUpToTen, CountingUpTo, x, y:
```

No domain constructor with the same name may be used again during the same session.

Example 3

Suppose that your domain does not really depend on a parameter, but that you need some of the other features of domain constructors. Then you may define a domain constructor `dc`, say, that is called without parameters. From such a domain constructor, you can construct exactly one domain `dc()`. Instead of defining the constructor via `domain dc() ... end` first and then using `d := dc()` to construct the domain `d`, say, you may directly enter `domain d ... end`, thereby saving some work.

Continuing the previous examples, suppose that we want to count up to three, knowing that we never want to count farther. However, we want to declare our domain to be an Abelian semigroup with a canonical representation of the elements. This is not possible with a construction of the domain using `newDomain` as in "Example 1" on page 7-9: we have to use the keyword domain. You will notice at once that the following source code is almost identical to the one in the previous example—we just removed the dependence on the parameter `n`.

```
domain CountingUpToThree

inherits Dom::BaseDomain;
category Cat::AbelianSemiGroup;
axiom Ax::canonicalRep;

new := proc(x : Type::PosInt)
begin
  if args(0) <> 1 then
    error("There must be exactly one argument")
  end_if;
  if x > 3 then
    new(dom, hold(many))
  else
    new(dom, x)
  end_if
end_proc;

print := proc(x) begin op(x, 1) end_proc;

_plus := proc() local argv;
begin
  argv:= map([args()], op, 1);
  if has(argv, hold(many)) then
     new(dom, hold(many))
  else
```

```
    dom(_plus(op(argv)))
  end_if
end_proc;

end:
```

Now, `CountingUpToThree` is a domain and not a domain contructor:

```
type(CountingUpToThree)
```

```
DOM_DOMAIN
```

You may use this domain in the same way as `CountingUpTo(3)` in "Example 2" on page 7-13.

Function Calls

When called as a function, the data type creates a new object of this data type out of the arguments of the call. E.g., the call `DOM_LIST(1, 2, x)` generates the list `[1, 2, x]` of domain type `DOM_LIST` (although, in this case, you probably prefer to type in `[1, 2, x]` directly which results in the same object). It depends on the particular type which arguments are admitted here.

In the case of a domain, the `"new"` method of that domain is called.

Operations

You can obtain the slots of a domain using `slot`. The function `slot` can also be used on the left hand side of an assignment to define new slots, or to re-define existing slots. Use `delete` to delete slots.

Operands

A data type consists of an arbitrary number of equations (objects of type `"equal"`). If `a = b` is among these equations, we say that the *slot*`a` of the data type equals `b`. By convention, `a` is usually a string. Each domain has at least one slot indexed by `"key"`.

Element Creation

The names of the data types provided by the MuPAD kernel are of the form `DOM_XXX`, such us `DOM_ARRAY`, `DOM_HFARRAY`, `DOM_IDENT`, `DOM_INT`, `DOM_LIST`, `DOM_TABLE` etc.

You can create further data types using the function `newDomain` (cf. “Example 1” on page 7-9) or via the keyword domain (cf. “Example 3” on page 7-15).

You can also create new data types by calling a *domain constructor*. Various pre-defined domain constructors can be found in the library Dom. You can also define your own domain constructors using the keyword domain. Cf. “Example 2” on page 7-13.

The domain type (data type) of any MuPAD object can be queried by the function `domtype`.

Algorithms

Only one domain with a given key may exist. If it is stored in two variables `S` and `T`, say, assigning or deleting a slot `slot(S, a)` implicitly also changes `slot(T, a)` (reference effect). This also holds if `a = "key"`.

Note: You get no warning even if `T` is protected.

DOM_EXEC

Kernel functions

Description

Objects of type DOM_EXEC represent kernel functions implemented in C++.

Unlike functions defined at the library level (which are stored in objects of type DOM_PROC), functions defined in C++ in the MuPAD kernel are represented by objects of type DOM_EXEC.

Users normally need not care about DOM_EXECs except for the cases where explicitly testing the domtype of arguments; in those cases, DOM_EXEC should often be treated identically to DOM_PROC.

Most kernel functions are actually stored inside function environments of type DOM_FUNC_ENV, and therefore, you can see DOM_EXEC only when explicitly accessing the first or second operand of those function environments.

Function Calls

An object of type DOM_EXEC essentially represents a function; using it in this way calls the corresponding function.

Operands

The operands of a DOM_EXEC are used internally, may change at any time and remain undocumented.

See Also

MuPAD Domains
DOM_FUNC_ENV | DOM_PROC

DOM_EXPR

Type of “general expressions”

Description

DOM_EXPR is the data type of symbolic function calls. This includes expressions such as $a + b$ which is internally stored as `_plus(a, b)`.

In MuPAD, non-atomic symbolic expressions which are not elements of special domains have type DOM_EXPR.

Objects of type DOM_EXPR have a 0th operand which contains the functor (the function symbol, the f in $f(x)$). This operand is not counted in the result of nops. The subsequent operands can be of arbitrary type (although most functions will limit the number and type of operands when evaluated).

The 0th operand of a DOM_EXPR will be a procedure or function environment only in exceptional circumstances. In usual circumstances, expressions only have expressions, domain elements, or identifiers as their 0th operands.

Examples

Example 1

Function calls are of type DOM_EXPR:

```
domtype(sin(x))
```

```
DOM_EXPR
```

The 0th operand of a function call is the function symbol:

```
op(sin(x), 0)
```

```
sin
```

This operand is taken into account neither by nops nor by op if called with one argument:

```
nops(sin(x)), op(sin(x))
```

$$1, x$$

Function Calls

The effect of using an expression of type DOM_EXPR as a function to call depends on the 0th operand of the expression. For many system functions, the result is that of using all operands of the expression as functions, passing the *unevaluated* arguments. (These functions may in turn evaluate their arguments.)

Operations

Most MuPAD functions (documented as accepting "arithmetical expressions") are built to work on elements of type DOM_EXPR.

Often, the operands of an expression will be expressions themselves. This creates a so-called "expression tree" which can be visualized using `prog::exprtree`.

Operands

All expressions are internally represented as function calls. The 0th operand is the function symbol of this call.

Evaluation

Evaluating an expression results in calling the 0th operand as a function. For library functions without `option hold`, the operands are evaluated first.

See Also

MuPAD Functions
`prog::exprtree`

DOM_FLOAT

Real Floating Point Numbers

Description

DOM_FLOAT is the type of (arbitrary precision) real floating-point numbers.

Apart from exact symbolic calculations, MuPAD can also compute numerical approximations with arbitrary precision.

MuPAD uses the values RD_INF and RD_NINF for real positive and negative infinities in floating-point intervals.

MuPAD uses the value RD_NAN to indicate undefined values in floating-point intervals. If you use typeset mode, MuPAD displays this value as NaN in output regions.

Function Calls

Calling a floating-point number as a function returns the number unchanged. The arguments of the call are *not* evaluated.

Operations

Just about any arithmetical operation can be performed with floating-point numbers.

Operands

DOM_FLOATs are atomic.

Output

The output format of DOM_FLOAT depends on the setting of Pref::floatFormat and is documented there.

Element Creation

Floating point numbers are typed in with an optional sign (an arbitrary number of `+` and `-` signs), an optional integer part (consisting of digits), a decimal point (irrespective of locale settings of the operating system, MuPAD always expects a decimal point), a fractional part (one or more decimal digits) and optionally a decimal shift, written as the letter `e` followed by an optionally signed integer.

The decimal shift is interpreted as a power of ten, i.e., `6.022e23` is the Avogadro number $6.022\ 10^{23}$.

Additionally, the function `float` and most calls to functions of the `numeric` library create floating-point numbers as well.

See Also

`DOM_COMPLEX` | `DOM_INTERVAL` | `DOM_RAT`

MuPAD Functions
`DIGITS` | `float`

DOM_FUNC_ENV

Data type of function environments

Description

DOM_FUNC_ENV is the data type of function environments.

MuPAD uses function environments (domain type DOM_FUNC_ENV) to integrate functions into the system. All MuPAD library functions and most kernel functions are implemented as function environments.

A function environment stores special function attributes (slots) in an internal table. When an overloadable system function, such as `diff`, `expand`, or `float`, encounters an object of type DOM_FUNC_ENV, it searches the function environment for a corresponding slot.

Operands

A function environment consists of three operands. The first operand is a procedure that computes the return value of a function call. The second operand is a procedure for printing a symbolic function call on the screen. The third operand is a table that specifies how the system functions handle symbolic function calls.

Element Creation

`funcenv` and `fp::unapply` (or its equivalent `-->`) create function environments of type DOM_FUNC_ENV.

See Also

MuPAD Domains
DOM_EXEC | DOM_PROC

MuPAD Functions
`fp::unapply` | `funcenv`

DOM_HFARRAY

Hardware floating-point arrays

Description

DOM_HFARRAY is a multidimensional container type, storing hardware floating-point numbers at integer indices.

Unlike generic arrays, objects of type DOM_HFARRAY are containers of hardware floating-point numbers, real or complex. They take up considerably less space than the corresponding arrays of software floats (DOM_FLOAT) would, but the range of hardware floating-point numbers is much more limited.

Function Calls

Using an hf-array as the symbol of a function call returns that hf-array unchanged. The arguments of the call are not evaluated.

Operations

Read and write access to an hf-array is performed using indexed access, as in A[1], which automatically converts between hardware and software floats. Trying to write a value which cannot be converted into a hardware float into an hf-array causes an error to be raised, as does accessing an element out of bounds.

The function map applies some function or transformation to each element of an hf-array, returning an hf-array of the same format as its input, with the results of the calls as its entries. If a result cannot be converted to a hardware float, an error is raised.

If A is an hf-array, nops(A) returns the number of elements in A.

Basic arithmetic works on hf-arrays: Addition and subtraction of hf-arrays of identical format combines the containers element-wise, addition and subtraction of constants is applied to the main diagonal. For two-dimensional hf-arrays, multiplication performs matrix multiplication. Division is possible for completeness, but should be avoided, as it

numerically inverts the dividend first, and this is hardly ever the algorithmically “right” way to handle a numerical problem.

Operands

If A is an hf-array, the 0th operand of A, `op(A, 0)`, will be the sequence starting with the number of dimensions (an integer n) followed by n ranges of integers, which denote the acceptable ranges of indices for each dimension, including both numbers listed in the range.

For $1 \le i \le nops(A)$, the ith operand of A is the ith entry of A, in the lexicographic order of indices.

Output

One-dimensional hf-arrays are displayed as row vectors, two-dimensional hf-arrays as matrices. Higher-dimensional hf-arrays are written in functional form, writing the entries as a flat list, and do not have a typesetting version. This also causes typesetting to be disabled for any surrounding expression in the same output.

Element Creation

The primary way of creating hf-arrays is the function `hfarray`. Other important functions (optionally) returning hardware float arrays include several functions of the `numeric` library and `import::readbitmap`.

MuPAD Functions
`float | hfarray`

DOM_IDENT

Symbolic Identifiers

Description

`DOM_IDENT` is the data type of symbolic identifiers, used for example for indeterminates.

To perform symbolic computations, it is often necessary to represent indeterminates, which may or may not carry assumptions. These indeterminates (which in some contexts may also be bound identifers and which may also be assigned specific values) are called “identifiers” in MuPAD and have the domain type `DOM_IDENT`.

Function Calls

Calling a `DOM_IDENT` as a function creates a `DOM_EXPR`. If the identifier has a value, the evaluation of that `DOM_EXPR` may result in an arbitrary value.

Operations

Identifiers are valid arithmetical expressions, so most MuPAD functions happily accept identifiers.

To get and analyze the name of an identifier, you can use `coerce(identifier, DOM_STRING )` and look at the resulting string. (The call `""."identifier"` returns the same string and is shorter to type.)

Operands

Identifiers are atomic.

Output

Identifiers are displayed with their names, with the following special cases in typesetting:

- Underscores (_) in the middle of identifiers cause subscripting: `x_2` is displayed as x_2.
- Certain constructs of the form `` `&...;` `` in identifiers are replaced by special typeset characters. For example, `` `&alpha;&rarr;` `` is displayed as $\vec{\alpha}$. To generate these identifiers, we suggest using the Symbol library, which would use `Symbol::accentRightArrow(Symbol::alpha)` for the example above.

Element Creation

A sequence of characters, underscores and digits which does not start with a digit is considered an identifier. Examples: `x`, `x0`, `t_0`.

Additionally, an arbitrary string of characters enclosed in 'backticks' `` ` `` is also an identifier. Examples: `` `x+y` ``, `` `a plus 1` ``. If the string of characters between the back ticks is a valid identifier already, this input form creates the same identifier as the one without the backticks.

DOM_INT

Integers

Description

DOM_INT is the domain of integer constants such as 42 or - 56412564156717653. The size of integers is limited to $2^{2^{21}} - 1$ in absolute value.

Function Calls

Calling an integer as a function returns that integer unchanged. The arguments are *not* evaluated.

Operations

Integers are arithmetical expressions and thus accepted by almost every MuPAD function.

To represent an integer in a basis different from 10, please use `int2text`.

Operands

Integers are atomic.

Element Creation

Integers are given by an optional sign (an arbitrarily long string of + and - signs) and a sequence of decimal digits. Apart from this direct input method, many MuPAD commands such as `text2int` return integers.

MuPAD Domains
DOM_FLOAT | DOM_RAT

DOM_INTERVAL

Floating point intervals

Description

Object of type DOM_INTERVAL represents an interval of complex numbers. Either border may be *infinity* or - ∞. The borders are represented by floating point numbers (DOM_FLOAT).

Objects of type DOM_INTERVAL represent numerical enclosures of rectangles in the complex plane or finite unions thereof. Numerical enclosures of real intervals are an important special case.

Because an element of type DOM_INTERVAL contains floating-point numbers of type DOM_FLOAT, its exact value depends on the value of the environment variable DIGITS at the time of creation.

The result of all arithmetical operations on elements of type DOM_INTERVAL is rounded outwards, that is, the resulting (union of) rectangle(s) is *guaranteed* to contain the exact result. If the result interval is purely real, the lower bound of the result is guaranteed to be no larger than the exact value of the exact result, while the upper value of the result is guaranteed to be no smaller than the exact value. The exact values may not be representable as floating-point numbers. In this case, the result of a single operation such as + or * is the smallest representable interval containing the exact result. In other words, operations on DOM_INTERVAL are locally optimal.

Note that the representation of an element of DOM_INTERVAL on the screen is generated with outward rounding, too. This may lead to "apparent overestimation," as you can see in "Example 1" on page 7-31.

For generating matrix or polynomial rings over floating-point intervals, use the façade domain Dom::FloatIV.

Examples

Example 1

An interval of type `DOM_INTERVAL` can only hold floating-point numbers, which are internally stored as binary numbers. For this reason, it cannot hold symbolic expressions as its operands:

```
iv := hull(PI)
```

$$3.141592653 \ldots 3.141592654$$

This intervals certainly does contain π. However, the value printed on the screen does not accurately describe the interval generated, as you can see when you print the same interval with a larger value of `DIGITS`:

```
DIGITS := 15: iv; delete DIGITS:
```

$$3.14159265358979 \ldots 3.1415926535898$$

In the first output, it looked as if the difference between the two borders (the width of the interval) was 10^{-8}, while in the latter output we can see that it is at most 10^{-13}. Actually, the difference is even smaller:

```
op(iv,2) - op(iv,1)
```

$$6.938893904\ 10^{-18}$$

This rounding does not take place for symbolic values which can be represented exactly in both the internal (binary) and the on-screen (decimal) format:

```
iv := hull(1); op(iv,2) - op(iv,1)
```

$$1.0 \ldots 1.0$$

$$0.0$$

However, floating-point values in the input are assumed to be approximations up to the current computing precision:

```
iv := hull(1.0); op(iv,2) - op(iv,1)
```

$$0.9999999999 \ldots 1.000000001$$

$$5.204170428\ 10^{-18}$$

Example 2

If you convert `infinity` or `-infinity` into an interval of type `DOM_INTERVAL`, the resulting interval will contain the corresponding floating-point infinity, which are displayed as `RD_INF` or `RD_NINF`, respectively:

```
hull(infinity), hull(-infinity)
```

$$2.098578716\ 10^{323228496} \ldots \text{RD\_INF},\ \text{RD\_NINF} \ldots -2.098578716\ 10^{323228496}$$

Since the range of floating-point numbers is limited, also conversion of finite values may generate floating-point infinities. The exact limit of floating-point numbers may change from one MuPAD version to the next. Currently, the following command exceeds the representable range::

```
hull(exp(10^9))
```

$$2.098578716\ 10^{323228496} \ldots \text{RD\_INF}$$

As for calculating with intervals with infinities as their borders, note that any multiplication where one factor is exactly zero and the other factor contains either infinity results in the interval encompassing the whole real axis:

```
(0...0) * (1e30...infinity)
```

$$\text{RD\_NINF} \ldots \text{RD\_INF}$$

Example 3

Objects of type DOM_INTERVAL represent rectangular subsets of the complex plane with the sides parallel to the coordinate axes or unions of such rectangles. In the following example, the exact result would be a rotated rectangle. Interval arithmetics returns the smallest non-rotated rectangle enclosing the precise result:

```
(1...2+I)*(1+I)
```

$$0.0 \ldots 2.0 + 1.0 \ldots 3.0\,i$$

Example 4

When computing with floating-point numbers, you can easily run into cancellation and round-off errors without noticing:

```
(1+1e-18) - 1.0
```

$$0.0$$

```
sin(1e42)
```

$$0.4587729978$$

The fundamental problem of numerical computations is that there is no indication to these errors. Of course, you can get around most problems of this type by increasing the number of significant digits, if you know that problems are lurking:

```
DIGITS:=50:
(1+1e-18) - 1.0,
sin(1e42)
```

$$9.9999999999999999999999999999999999994337442995\ 10^{-19},$$

$$-0.79299795477606144587030822830754387995851407627768$$

Interval calculations, amongst other things, provide a way to be notified of cancellation since the result of an operation over DOM_INTERVAL is certain to contain the exact result:

```
DIGITS:=10:
(1+1e-18) - hull(1.0)
```

$$-5.204170428\ 10^{-18} \ldots 5.204170428\ 10^{-18}$$

```
sin(hull(1e42))
```

$$-1.0 \ldots 1.0$$

```
DIGITS:=50:
sin(hull(1e42))
```

$$-0.79299795477606165563526882849270558686988301102149 \ldots -0.79299795477606111453539571969660597818990980366 84$$

So, in the latter case we know that the first 17 digits are correct and that the 18th digit is 3, 4, or 5.

Function Calls

The result of a call to an interval is the interval itself, regardless of the arguments. The arguments are not evaluated.

Operations

You can access the borders of an interval using `op`. See below for the details.

Intervals can be viewed as sets, and the corresponding functions `union`, `intersect`, and `minus` work on intervals, too.

As of version 2.5, MuPAD implements the following operations on elements of type `DOM_INTERVAL`:

- The basic arithmetical operations: `+`, `-`, `*`, `/`, `^`, `sqrt`.
- The trigonometric functions and their inverses: `sin`, `cos`, `tan`, `sec`, `csc`, `cot`, `arcsin`, `arccos`, `arctan`, `arccsc`, `arccot`.

- The exponential function and the logarithm.
- The hyperbolic functions and their inverses: `sinh`, `cosh`, `tanh`, `sech`, `csch`, `coth`, `arcsinh`, `arccosh`, `arctanh`, `arccsch`, `arccoth`.
- The functions `Re`, `Im` (real- and imaginary part), `abs`, `sign` and `arg` (the `argument' = polar angle of a complex number).
- For real intervals, `gamma` and `beta`.
- `ceil`, `floor`, `trunc`, `round`.

For legal combinations of arguments, all computations are carried out in interval arithmetics, see “Example 4” on page 7-33.

Operands

The operands of an interval depend on its value:

- An interval of type `DOM_INTERVAL` may be a union of rectangles in the complex plane. In this case, the 0th operand is the identifier `union`, while the remaining operands are the corresponding rectangles, which are of type `DOM_INTERVAL`.
- Rectangles with non-zero imaginary part, which are not unions, have two operands of type `DOM_INTERVAL`: Their real and imaginary parts, both of which are real intervals.
- Real intervals, i.e., non-union rectangles with vanishing imaginary part, have two operands, their left and right borders.

Output

A real interval is displayed in the form “left `...` right”, where “left” and “right” are the borders of the interval, printed as floating-point numbers.

A complex interval is displayed as “(real part) + (imaginary part) * I”, with the real and imaginary part displayed as real intervals.

A union of rectangles is displayed as “interval union interval”, with the intervals inside written as specified above.

The output of an interval depends on the environment variable `DIGITS` as well as on the preference settings `Pref::floatFormat` and `Pref::trailingZeroes`.

Note that the borders are rounded outwards for printing. “Example 1” on page 7-31 shows how this effects the output.

Element Creation

Elements of type DOM_INTERVAL can be constructed in the following ways:

- With the function hull:

```
hull(PI, -3, 1/2), hull(1/3)
```

$$-3.0 \ldots 3.141592654,\ 0.3333333333 \ldots 0.3333333334$$

- With the operator ... (which in turn calls hull):

```
1 ... 4+I
```

$$1.0 \ldots 4.0 + 0.0 \ldots 1.0\,i$$

- The function interval creates elements of type DOM_INTERVAL as well, but may return expressions:

```
interval(x^2+sin(1))
```

$$x^2 + 0.8414709848 \ldots 0.8414709849$$

Note that floating-point values in the input of hull or interval are considered to be approximations, even if the value displayed in the decimal system can be represented exactly in the internal binary format. This is because hull cannot decide whether, for example, 0.25 has actually been typed in as such or if it should have been some 0.25 + ϵ. If you want zero-width intervals, use a rational number as input which can be represented exactly in binary:

Algorithms

Intervals of type DOM_INTERVAL are always interpreted as *closed* intervals, i.e., the endpoints belong to the set. It is reasonable not to have open intervals included, since most operations will enlarge the resulting interval anyway (although only marginally so).

DOM_LIST

Lists of Objects

Description

Lists (of domain type `DOM_LIST`) are ordered collections of an arbitrary number of arbitrary MuPAD objects, except for sequences and the null object.

In MuPAD, the mathematical construct of an n-tuple is implemented as the data type `DOM_LIST`. Lists consist of an arbitrary (finite) number of arbitrary objects, with the exception of expression sequences, which are split into their operands when placed into a list.

Unlike sets, lists can contain multiple copies of the same element. The order of elements in a list is preserved.

Lists can be empty.

Examples

Example 1

To create a list for our first example, we use the operator `$`:

```
L := [x_.i $ i=1..10]
```

$$[x_1, x_2, x_3, x_4, x_5, x_6, x_7, x_8, x_9, x_10]$$

This list contains 10 elements:

```
nops(L)
```

$$10$$

The fifth element of the list is x_5 and the list of elements from x_3 through x_6 can also be accessed very easily:

```
L[5], L[3..6]
```

$$x_5,\ [x_3, x_4, x_5, x_6]$$

To change an element of the list, we use the indexed form on the left hand side of an assignment:

```
L[5] := 5
```

$$5$$

```
L
```

$$[x_1, x_2, x_3, x_4, 5, x_6, x_7, x_8, x_9, x_10]$$

Note that this assignment only changes `L`, not x_5:

```
x_5
```

$$x_5$$

Likewise, we can change a sublist by assigning another list to it. This may change the length of the list:

```
L[3..6] := [1, 2]
```

$$[1, 2]$$

```
nops(L), L
```

$$8,\ [x_1, x_2, 1, 2, x_7, x_8, x_9, x_10]$$

Function Calls

Using a list as a function symbol creates the list obtained by using each list element as a function symbol for the operands used, i.e., `[f, g](x, y)` results in `[f(x, y), g(x, y)]`.

Operations

Assuming that `L` is a list, the number of elements in `L` can be determined by calling `nops(L)`.

Individual elements of the list are accessed in the form `L[1]`, `L[2]` etc. when counting from the beginning or `L[-1]`, `L[-2]` etc. when counting from the end. Trying to access an element "outside" the list or `L[0]` raises an error.

Continuous sub-lists can be extracted by using a range in an indexed access: `L[2..4]` returns the list `[L[2], L[3], L[4]]`; `L[2..-2]` returns the list `L` without its first and last element.

Both forms of indexed access can also be used as the left hand side of an assignment, cf. "Example 1" on page 7-37.

Lists can be concatenated with the dot operator, as in `L1 . L2` or its functional form, `_concat`.

The function `contains` finds the first occurrence of a given MuPAD object in a list. `select` and `split` can be used to extract those elements from a list fulfilling an arbitrary predicate.

Lists can be sorted with `sort` or `prog::sort`.

The function `map` applies a function to all elements of a list, returning the list of results. To combine two lists element-wise with some function, use `zip`.

Assigning a list to a list of identifiers is possible and results in a simultaneous assignment, cf. `?_assign`.

Operands

The operands of a list are its elements.

Element Creation

The most direct way of creating a list is to place a sequence of MuPAD objects (separated by commas) between rectangular brackets, as in `[1, 2, 3]`.

DOM_PROC

Data type of procedures

Description

DOM_PROC is the data type of procedures.

MuPAD procedures belong to the kernel domain DOM_PROC.

You can enclose procedures of type DOM_PROC into function environments of type DOM_FUNC_ENV.

Element Creation

proc and its equivalent -> create procedures of type DOM_PROC.

See Also

MuPAD Domains
DOM_PROC_ENV

MuPAD Functions
funcenv | proc

DOM_PROC_ENV

Data type of procedure environments

Description

Procedure environments are mostly ephemeral objects and are only rarely seen by the user (and even more rarely useful to examine). A procedure environment represents a procedure that is currently being executed: formal parameters and local variables have values.

Procedure environments do rarely become visible, and you do not need to manipulate them directly. They serve only one purpose: if a procedure is generated inside another procedure, variable names in the body of the inner procedure that are not declared local there refer to names in the outer procedure, provided they are declared local in the outer procedure. (See the Programming Manual for more information on the scoping rules for MuPAD.) Consequently, the inner procedure must contain information on the current values of local variables of the outer procedure. Hence, the status of the outer procedure is encoded into an object of type `DOM_PROC_ENV`, and that object is stored in the returned procedure as its twelfth operand.

You never need to generate objects of this type. There are no operations available.

Examples

Example 1

The only occasion on which you should come across a procedure environment is the following: an outer procedure returns an inner procedure depending on formal parameters or local variables of the outer procedure:

```
outer :=
proc(x)
option escape;
begin
  /* inner procedure to return : */
  y -> x + y
end_proc:
```

```
add5 := outer(5)
```

$$y \to x + y$$

In spite of the (slightly confusing) output, `x` has a special meaning here: it points to the parameter `x` of `outer`. That parameter currently has the value `5` and won't be changed any more. To be able to access that value, the particular instance of `outer` in the status of being executed has to be stored in `add5`:

```
expr2text(op(add5, 12))
```

```
"DOM_PROC_ENV(0x1f9d904)"
```

Operands

The number of operands of a procedure environment depends on the number of local and saved variables of the outer procedure. Details about the operands remain undocumented.

Algorithms

The integers appearing in the output of objects of type `DOM_PROC_ENV` have no mathematical meaning; they denote positions in memory.

DOM_RAT

Rational Numbers

Description

DOM_RAT is the data type of rational numbers.

Examples

Example 1

The operands of a rational number are its numerator and denominator:

```
op(2/3)
```

$$2, 3$$

When substituting an operand, the resulting DOM_RAT is again normalized:

```
subsop(2/3, 2=6)
```

$$\frac{1}{3}$$

Function Calls

Using a rational number as a function returns that number unchanged. The function arguments are *not* evaluated.

Operations

Rational numbers are arithmetical expressions and therefore valid inputs to most MuPAD functions.

The numerator and denominator of a rational number can be accessed using `numer` and `denom` or by using `op` directly.

Elements of `DOM_RAT` are always normalized, cf. “Example 1” on page 7-44.

Operands

A rational number has two operands, which are integers: Its numerator and its denominator.

Element Creation

The division of two integers results in an integer or a rational number.

See Also

MuPAD Domains

`Dom::Rational` | `DOM_COMPLEX` | `DOM_FLOAT` | `DOM_INT`

DOM_SET

Sets of Objects

Description

Set of type `DOM_SET` can store an arbitrary finite number of arbitrary MuPAD objects, except for sequences and the null object.

In MuPAD, finite sets are implemented with the data type `DOM_SET`. Sets are unordered collections of arbitrary objects, with identical objects appearing only once. Sequences (objects separated by commas) are "flattened" when put into a set, i.e., instead of the sequence, its elements are placed into the set. The null object is treated as the empty sequence, i.e., it does not result in an element in the set.

Sets can be empty. The empty set is displayed as ∅.

Function Calls

Using a set as a function symbol creates the set obtained by using each element as a function symbol for the operands used, i.e., `{f, g}(x, y)` results in `{f(x, y), g(x, y)}`.

Operations

Assuming that S is a set, the number of elements in S can be obtained by calling `nops(S)`.

Individual elements of the set can be obtained in two subtly different ways:

1 Using an indexed access, as in `S[2]`, returns the n-th element of the set, counted in the order as the set appears on the screen. This is a potentially slow operation, since it requires determining that order for each access, i.e., sorting the set.

  Negative indices are accepted, counting from the end of the sequence of elements. Trying to access an element "outside" the set or `S[0]` raises an error.

2 Using `op`, as in `op(S, 2)`, returns the n-th element of the set, counted in the internal order. This is a fast operation ($O(n)$ to get the n-th element, irrespective of the size of S), but the internal order of two mathematically identical sets can be completely different and almost any operation changing a set can completely change its internal order, so no assumptions should be made.

Both of these ways also accept ranges as indices. `S[2..4]` returns the set `{S[2], S[3], S[4]}`, while `op(S, 2..4)` returns the sequence `op(S, 2), op(S, 3), op(S, 4)`.

To iterate over all elements of a set in no particular order, using `map` or the `$` operator is highly superior to using a `for`-loop with either of the above element access methods. If a `for`-loop is required, you should use the form `for s in S`, which has linear complexity as well.

The usual set operations are provided as infix operations: `union`, `minus`, `intersect`.

To change an element of a set, the preferred method is to remove it using `minus` and adding a new one using `union`. It is also possible to replace an element with `subsop`; replacing an element with `null()` deletes it from the set. (Note that `subsop` does not do a side-effect assignment.)

The function `contains` checks for occurrence of a given MuPAD object in a set; see also the `in` operator for the same purpose, but with different evaluation semantics. `select` and `split` can be used to extract those elements from a set fulfilling an arbitrary predicate.

To get a list of the elements of a set, use `coerce`. To get such a list with the elements ordered in the same way as printed on the screen, use `DOM_SET::sort(S)`.

Operands

The operands of a set are its elements, in the internal order. (See above for details.)

Output

Sets are ordered for the output.

Element Creation

The most direct way of creating a set is to place a sequence of MuPAD objects (separated by commas) between curly brackets, as in {1, 2, 3}.

MuPAD Domains
`Dom::ImageSet` | `Dom::Multiset` | `DOM_LIST`

DOM_STRING

Texts (character strings)

Description

Texts (which are not really “mathematical objects”, but useful to the programmer) in MuPAD are of domain type `DOM_STRING`.

MuPAD can manipulate texts (strings of characters). These are primarily used for output and data input.

Examples

Example 1

As far as `op` is concerned, a string cannot be dissected:

```
s := "this is a string":
op(s, 1), op(s, 2)
```

```
"this is a string", FAIL
```

To access individual characters or substrings, use indexed access:

```
s[1], s[6..7]
```

```
"t", "is"
```

Assigning to a substring may change the length of a string:

```
s[6..7] := "changes";
s
```

```
"changes"
```

```
"this changes a string"
```

Function Calls

Using a string as a function returns the string unchanged. The arguments are *not* evaluated.

Operations

Strings can be concatenated using the dot operator or its functional equivalent, `_concat`.

The length of a string can be obtained using `length`.

Substrings and individual characters (which are strings of length 1) can be accessed using `substring` or indexed access, with indices starting at 1 and negative indices counting from the end of the string: `s[1]`, `s[3..-2]`. It is also possible to perform an indexed assignment to a string, cf. “Example 1” on page 7-49.

To convert a string into the MuPAD expression that would be obtained by using the string as an input, use `text2expr`. For simple MuPAD expressions, it is possible to get a string that evaluates to that expression using `expr2text`. Expressions that are not convertible in this way include all expressions containing local variables set with `option escape`. Also, expressions involving floating point numbers usually will change when being converted to strings and back.

Operands

Strings are atomic, i.e., they have exactly one operand, the string itself.

Output

The output form of strings is very similar to their input form. When typesetting, spaces at the beginning and the end of strings are ignored and multiple adjacent blanks as well as newlines are collapsed to a single space.

Element Creation

A string is created by enclosing characters in a pair of typewriter quotes: `"this is a string"`. The following special sequences are supported (but see below for the typeset output; these are useful only for non-typeset output):

- `"\n"` denotes an end-of-line character.
- `"\b"` is almost identical to `"\n"`, except that for "pretty-printing" it encodes the baseline of the current object.
- `"\t"` is a tabulator.
- `"\\"` encodes a backslash.

See the documentation of `print` for details.

DOM_VAR

Local Variables in Procedures

Description

Local variables (variables in the programming sense, with “lexical scoping”) are of domain type `DOM_VAR`.

When writing MuPAD functions, often intermediate results need to be stored and retrieved. Like most programming languages, MuPAD offers “local variables” for this purpose. These local variables do not conflict with global identifiers of the same name nor with other local variables of the same name used at other places.

Local variables use “lexical scoping”, i.e., they can be used in all program code that is written inside the body of the procedure declaring the local variable. Note that returning anything with a reference to a local variable requires the use of `option escape` in the procedure definition.

Operations

Local variables can be assigned values and these values can later be retrieved.

Element Creation

Local variables are created by using either the special names `dom` or `procname` or one of the names declared with the keyword `local` inside a procedure definition.

Dom::AlgebraicExtension

Simple algebraic field extensions

Syntax

Domain Creation

```
Dom::AlgebraicExtension(F, f)
Dom::AlgebraicExtension(F, f, x)
Dom::AlgebraicExtension(F, f1 = f2)
Dom::AlgebraicExtension(F, f1 = f2, x)
```

Element Creation

```
Dom::AlgebraicExtension(F,f)(g)
Dom::AlgebraicExtension(F, f)(rat)
```

Description

Domain Creation

For a given field *F* and a polynomial $f \in F[x]$, `Dom::AlgebraicExtension(F, f, x)` creates the residue class field *F[x]/<f>*.

`Dom::AlgebraicExtension(F, f1=f2, x)` does the same for $f = f_1 - f_2$.

`Dom::AlgebraicExtension(F, f, x)` creates the field *F[x]/<f>* of residue classes of polynomials modulo *f*. This field can also be written as *F[x]/<f>*, the field of residue classes of rational functions modulo *f*.

The parameter `x` may be omitted if `f` is a univariate polynomial or a polynomial expression that contains exactly one indeterminate; it is then taken to be the indeterminate occurring in `f`.

The field `F` must have normal representation.

`f` must not be a constant polynomial.

`f` must be irreducible; this is *not* checked.

`f` may be a polynomial over a coefficient ring different from `F`, or multivariate; however, it must be possible to convert it to a univariate polynomial over `F`. See "Example 2" on page 7-55.

Element Creation

`Dom::AlgebraicExtension(F, f)(g)` creates the residue class of `g` modulo `f`.

If `rat` has numerator and denominator `p` and `q`, respectively, then `Dom::AlgebraicExtension(F,f)(rat)` equals `Dom::AlgebraicExtension(F,f)(p)` divided by `Dom::AlgebraicExtension(F,f)(q)`.

Superdomain

`Dom::BaseDomain`

Axioms

If F has `Ax::canonicalRep`, then `Ax::canonicalRep`.

Categories

`Cat::Field`, `Cat::Algebra(F)`, `Cat::VectorSpace(F)`

If F is a `Cat::DifferentialRing`, then `Cat::DifferentialRing`.

If F is a `Cat::PartialDifferentialRing`, then `Cat::PartialDifferentialRing`.

Examples

Example 1

We adjoin a cubic root `alpha` of `2` to the rationals.

```
G := Dom::AlgebraicExtension(Dom::Rational, alpha^3 = 2)
```

$$\text{Dom::AlgebraicExtension}(\text{Dom::Rational}, \text{alpha}^3 - 2 = 0, \text{alpha})$$

The third power of a cubic root of `2` equals `2`, of course.

```
G(alpha)^3
```

$$2$$

The trace of α is zero:

```
G::conjTrace(G(alpha))
```

$$0$$

You can also create random elements:

```
G::random()
```

$$2 - 814\ \text{alpha}^2 - 65\ \text{alpha} + 824$$

Example 2

The ground field may be an algebraic extension itself. In this way, it is possible to construct a tower of fields. In the following example, an algebraic extension is defined using a primitive element `alpha`, and the primitive element `beta` of a further extension is defined in terms of `alpha`. In such cases, when a minimal equation contains more than one identifier, a third argument to `Dom::AlgebraicExtension` must be explicitly given.

```
F := Dom::AlgebraicExtension(Dom::Rational, alpha^2 = 2):
G := Dom::AlgebraicExtension(F, bet^2 + bet = alpha, bet)
```

$$\text{Dom::AlgebraicExtension}(\text{Dom::AlgebraicExtension}(\text{Dom::Rational}, \text{alpha}^2 - 2 = 0, \text{alpha}), -\text{alpha} + \text{bet} + \text{bet}^2 = 0, \text{bet})$$

Example 3

We want to define an extension of the field of fractions of the ring of bivariate polynomials over the rationals.

```
P:= Dom::DistributedPolynomial([x, y], Dom::Rational):
F:= Dom::Fraction(P):
K:= Dom::AlgebraicExtension(F, alpha^2 = x, alpha)
```

```
Dom::AlgebraicExtension(Dom::Fraction(Dom::DistributedPolynomial([x,
  y], Dom::Rational, LexOrder)), -x + alpha^2 = 0, alpha)
```

Now $K = Q[\sqrt{x}, y]$. Of course, the square root function has the usual derivative; note that $\frac{1}{\sqrt{x}}$ can be expressed as $\frac{\alpha}{x}$:

```
diff(K(alpha), x)
```

$$\frac{\text{alpha}}{2\,x}$$

On the other hand, the derivative of $\sqrt{x}$ with respect to y is zero, of course:

```
diff(K(alpha), y)
```

$$0$$

We must not use `D` here. This works only if we start our construction with a ring of univariate polynomials:

```
P:= Dom::DistributedPolynomial([x], Dom::Rational):
F:= Dom::Fraction(P):
K:= Dom::AlgebraicExtension(F, alpha^2 = x, alpha):
D(K(alpha))
```

$$\frac{\text{alpha}}{2\,x}$$

Parameters

`F`

The ground field: a domain of category `Cat::Field`

`f, f1, f2`

Polynomials or polynomial expressions

`x`

Identifier

`g`

Element of the residue class to be defined: polynomial over `F` in the variable `x`, or any object convertible to such.

`rat`

Rational function that belongs to the residue class to be defined: expression whose numerator and denominator can be converted to polynomials over `F` in the variable `x`. The denominator must not be a multiple of `f`.

Entries

"zero"	the zero element of the field extension
"one"	the unit element of the field extension
"groundField"	the ground field of the extension
"minpoly"	the minimal polynomial `f`
"deg"	the degree of the extension, i.e., of `f`
"variable"	the unknown of the minimal polynomial `f`
"characteristic"	the characteristic, which always equals the characteristic of the ground field. This entry only exists if the characteristic of the ground field is known.

"degreeOverPrimeField"	the dimension of the field when viewed as a vector space over the prime field. This entry only exists if the ground field is a prime field, or its degree over its prime field is known.

Methods

Mathematical Methods

`_plus` — Sum of field elements

```
_plus(a, …)
```

This method overloads the function `_plus` of the system kernel.

`_mult` — Product of field elements

```
_mult(a, …)
```

This method overloads the function `_mult` of the system kernel.

`_power` — Raise to the nth power

Inherited from `Cat::Monoid`.

`_negate` — Negate a field element

```
_negate(a)
```

This method overloads the function `_negate` of the system kernel.

`_subtract` — Difference of field elements

```
_subtract(a, b)
```

This method overloads the function `_subtract` of the system kernel.

`equal` — Test for mathematical equality

Inherited from `Dom::BaseDomain`.

`equiv` — Test for equivalence

Inherited from `Cat::BaseCategory`.

`iszero` — Test whether a field element is zero.

```
iszero(a)
```

This method overloads the function `iszero`.

`isone` — Test if element is one

Inherited from `Cat::Monoid`.

`isUnit` — Test if element is an unit

Inherited from `Cat::Field`.

`intmult` — Multiply a field element by an integer

```
intmult(a, b)
```

This method is more efficient than `"_mult"` in this special case.

`_invert` — Inverse of a field element

```
_invert(a)
```

This method overloads the function `_invert`.

`_divide` — Exact division

Inherited from `Cat::Field`.

`divide` — Division with remainder

Inherited from `Cat::Field`.

`quo` — Return Euclidean quotient

Inherited from `Cat::Field`.

`rem` — Return Euclidean remainder

Inherited from `Cat::Field`.

`euclideanDegree` — Return Euclidean degree

Inherited from `Cat::Field`.

`idealGenerator` — Generator of finitely generated ideal

Inherited from `Cat::EuclideanDomain`.

`divides` — Test if division is exact

Inherited from `Cat::Field`.

`gcd` — Gcd of field elements

`gcd(a, …)`

This method overloads the function `gcd`.

`gcdex` — Extended greatest common divisor

Inherited from `Cat::EuclideanDomain`.

`associates` — Test for associate elements

Inherited from `Cat::Field`.

`unitNormal` — Unit normal form

Inherited from `Cat::Field`.

`unitNormalRep` — Unit normal representation

Inherited from `Cat::Field`.

`lcm` — Least common multiple

Inherited from `Cat::GcdDomain`.

`sqrfree` — Square-free factorization

Inherited from `Cat::Field`.

`irreducible` — Test if element is irreducible

Inherited from `Cat::Field`.

`factor` — Unique factorization

Inherited from `Cat::Field`.

`conjNorm` — Norm of an element

```
conjNorm(a)
```

`conjTrace` — Trace of an element

```
conjTrace(a)
```

`minimalPolynomial` — Minimal polynomial of an element

```
minimalPolynomial(a)
```

`D` — Differential operator

```
D(a)
```

This method overloads the function `D`.

This method must not be called for inseparable extensions; note that MuPAD cannot check whether an extension is separable.

See “Example 3” on page 7-56.

`diff` — Partial differentiation

```
diff(a, x1, …)
```

Differentiation is defined to be the continuation of differentiation of the ground field; this method exists only if the ground field has a method `"diff"`, too.

Differentiation is not possible in inseparable extensions.

This method overloads the function `diff`.

This method must not be called for inseparable extensions; note that MuPAD cannot check whether an extension is separable.

See “Example 3” on page 7-56.

`random` — Random element of the field

```
random()
```

The `random` method of the ground field is used to generate coefficients of a random polynomial of the ground field; the residue class of that polynomial is the return value. Hence the probability distribution of the elements returned depends on that of the `random` method of the ground field.

Conversion Methods

`convert` — Convert into a field element

```
convert(x)
```

If the conversion fails, then `FAIL` is returned.

`convert_to` — Convert a field element into another type

```
convert_to(a, T)
```

Field elements can be converted to polynomials or expressions. Field elements represented by constant polynomials can also be converted to the same types as the elements of the ground field; in particular, they can be converted to elements of the ground field.

`coerce` — Coerce into this domain

Inherited from `Cat::BaseCategory`.

`new` — Create element of this domain

Inherited from `Cat::BaseCategory`.

`expr` — Convert an element of the field into an expression

```
expr(a)
```

This method overloads the function `expr`.

`subs` — Avoid substitution

Inherited from `Dom::BaseDomain`.

`subsex` — Avoid extended substitution

Inherited from `Dom::BaseDomain`.

`testtype` — Test type of object

Inherited from `Cat::BaseCategory`.

`print` — Return expression to print an element

Inherited from `Cat::BaseCategory`.

`printMethods` — Print out methods

Inherited from `Dom::BaseDomain`.

`TeX` — Generate TeX output

Inherited from `Dom::BaseDomain`.

`hasProp` — Test for a certain property

Inherited from `Dom::BaseDomain`.

`whichEntry` — Return the domain or category implementing an entry

Inherited from `Dom::BaseDomain`.

`allEntries` — Return the names of all entries

Inherited from `Dom::BaseDomain`.

`undefinedEntries` — Return missing entries

Inherited from `Dom::BaseDomain`.

`getAxioms` — Return axioms stated in the constructor

Inherited from `Dom::BaseDomain`.

`getSuperDomain` — Return super-domain stated in the constructor

Inherited from `Dom::BaseDomain`.

`allSuperDomains` — Return all super-domains

Inherited from `Dom::BaseDomain`.

`getCategories` — Return categories stated in the constructor

Inherited from `Dom::BaseDomain`.

`allAxioms` — Return all axioms

Inherited from `Dom::BaseDomain`.

`allCategories` — Return all categories

Inherited from `Dom::BaseDomain`.

MuPAD Domains
`Dom::GaloisField`

Dom::ArithmeticalExpression

Domains of arithmetical expressions

Syntax

```
Dom::ArithmeticalExpression(x)
```

Description

`Dom::ArithmeticalExpression` is a façade domain of arithmetical expressions built up by the system functions and operators like `+` and `*`.

This domain has almost no algebraic structure because unqualified expressions have no normal form. (For example, there are rational expressions for zero which are not normalized to `0`.) The main purpose of `Dom::ArithmeticalExpression` is to provide implementations for methods used by façade sub-domains like `Dom::Integer` which are represented by a subset of the arithmetical expressions.

Elements of `Dom::ArithmeticalExpression` are usually not created explicitly. However, if one creates elements using the usual syntax, the input is converted to an expression using `expr`, then it is checked whether the result is an arithmetical expression.

Superdomain

`Dom::Expression`

Axioms

`Ax::systemRep`

Categories

`Cat::BaseCategory`

Examples

Example 1

For brevity, we will use `AE` as a shorthand notation for `Dom::ArithmeticalExpression`:

```
AE := Dom::ArithmeticalExpression
```

Dom::ArithmeticalExpression

An element of this domain can *not* be created as follows:

```
e := AE(2*sin(x) + f(x)/y)
```

$$2\sin(x) + \frac{f(x)}{y}$$

Since `Dom::ArithmeticalExpression` is a façade domain, `e` is not a domain element, but an expression:

```
domtype(e)
```

DOM_EXPR

The fact that no error was returned yields the information that `e` is an arithmetical expression. This can also be checked as follows:

```
testtype(e,AE)
```

TRUE

In contrast to its super-domain `Dom::Expression`, this domain only allows elements which are valid arguments for the arithmetical functions, thus the following yields an error:

```
AE([a, b])
```

```
Error: The arguments are invalid. [Dom::ArithmeticalExpression::new]
```

Parameters

x

An arithmetical expression

Entries

"key"	The name of this domain.
"one"	The neutral element w.r.t. `"_mult"`: the constant `1`.
"zero"	The neutral element w.r.t. `"_plus"`: the constant `0`.

Methods

Mathematical Methods

`_divide` — Divide arithmetical expressions

```
_divide(f, g)
```

This method overloads the function `_divide`.

For details, please see `_divide`.

`_invert` — Invert an arithmetical expression

```
_invert(f)
```

This method overloads the function `_invert`.

For details, please see `_invert`.

`_mult` — Multiplie arithmetical expressions

```
_mult(<f, g, …>)
```

This method overloads the function `_mult`.

For details, please see `_mult`.

`_negate` — Negate an arithmetical expression

```
_negate(f)
```

This method overloads the function `_negate`.

For details, please see `_negate`.

`_plus` — Add arithmetical expressions

```
_plus(<f, g, …>)
```

This method overloads the function `_plus`.

For details, please see `_plus`.

`_power` — Power operator

```
_power(f, g)
```

This method overloads the function `_power`.

For details, please see `_power`.

`_subtract` — Subtract an arithmetical expression

```
_subtract(f, g)
```

For details, please see `_subtract`.

`D` — Differential operator for functions

```
D(f)
```

`D([c1, …], f)`

This method overloads the function `D`.

For details, please see `D`.

`diff` — Differentiate an arithmetical expression

`diff(f, <x, …>)`

This method overloads the function `diff`.

For details, please see `diff`.

`equiv` — Test for equivalence

Inherited from `Cat::BaseCategory`.

`intmult` — Multiply an arithmetical expression with an integer

`intmult(f, n)`

This method overloads the function `_mult`.

For details, please see `_mult`.

`iszero` — Test for zero

`iszero(f)`

This method overloads the function `iszero`.

For details, please see `iszero`.

`max` — Maximum of numbers

`max(x, <y, …>)`

All numerical arguments must be real.

This method overloads the function `max`.

For details, please see `max`.

`min` — Minimum of numbers

```
min(x, <y, …>)
```

All numerical arguments must be real.

This method overloads the function `min`.

For details, please see `min`.

`norm` — Norm of an arithmetical expression

```
norm(f)
```

This method overloads the function `abs`.

For details, please see `abs`.

`random` — Create random expression

Inherited from `Dom::Expression`.

Access Methods

`subs` — Substitution

Inherited from `Dom::Expression`.

`subsex` — Extended substitution

Inherited from `Dom::Expression`.

Conversion Methods

`coerce` — Coerce into this domain

Inherited from `Cat::BaseCategory`.

`convert` — Check for being an arithmetical expression

```
convert(x)
```

`convert_to` — Conversion to other domains

Inherited from `Dom::Expression`.

`expr` — Just return the argument

Inherited from `Dom::Expression`.

`float` — Convert numbers to floats

Inherited from `Dom::Expression`.

Technical Methods

`allAxioms` — Return all axioms

Inherited from `Dom::BaseDomain`.

`allCategories` — Return all categories

Inherited from `Dom::BaseDomain`.

`allEntries` — Return the names of all entries

Inherited from `Dom::BaseDomain`.

`allSuperDomains` — Return all super-domains

Inherited from `Dom::BaseDomain`.

`testtype` — Test type of object

Inherited from `Cat::BaseCategory`.

`undefinedEntries` — Return missing entries

Inherited from `Dom::BaseDomain`.

`whichEntry` — Return the domain or category implementing an entry

Inherited from `Dom::BaseDomain`.

`getAxioms` — Return axioms stated in the constructor

Inherited from `Dom::BaseDomain`.

`getCategories` — Return categories stated in the constructor

Inherited from `Dom::BaseDomain`.

`getSuperDomain` — Return super-domain stated in the constructor

Inherited from `Dom::BaseDomain`.

`hasProp` — Test for a certain property

Inherited from `Dom::BaseDomain`.

`info` — Print short information about this domain

Inherited from `Dom::BaseDomain`.

`new` — Create element of this domain

Inherited from `Cat::BaseCategory`.

`print` — Return expression to print an element

Inherited from `Cat::BaseCategory`.

`printMethods` — Print out methods

Inherited from `Dom::BaseDomain`.

`testtype` — Test whether its argument is an expression

Inherited from `Dom::Expression`.

`undefinedEntries` — Return missing entries

Inherited from `Dom::BaseDomain`.

`whichEntry` — Return the domain or category implementing an entry

Inherited from `Dom::BaseDomain`.

MuPAD Domains
`Dom::Expression`

Dom::BaseDomain

Root of the domain hierarchy

Description

`Dom::BaseDomain` is the root of the domain hierarchy as defined by the Dom package. Every domain of the package inherits from it.

The only purpose of `Dom::BaseDomain` is to supply all domains of the package with some basic methods like `"hasProp"`. Elements of `Dom::BaseDomain` cannot be created.

Unlike other super-domains this domain does not impose any restrictions on the representation of the elements of its sub-domains. Thus it may be a super-domain for any domain created by a domain constructor.

Categories

`Cat::BaseCategory`

Entries

"create_dom"	This domain entry is used to revive the domain when it is read from a binary MCode stream. If this entry is present it is written to the MCode stream instead of the contents of the domain. When the stream is read it is used to create the domain. If this entry does not exist all entries of the domain are written to the stream and read in later to create the domain. `Dom::BaseDomain` defines `"create_dom"` to have the same value as the key of the

domain, as stored in the entry `"key"`. All domains of the Dom package inherit this entry, thus they must be created by the reader of the MCode stream by evaluating the expression stored in the key.

Methods

Mathematical Methods

`equal` — Test for mathematical equality

```
equal(x, y)
```

If this domain has the axiom `Ax::canonicalRep`, which implies that two domain elements are mathematically equal if and only if they are structurally equal, the kernel function `_equal` is used to decide the equality. In this case `UNKNOWN` is never returned.

If the axiom `Ax::canonicalRep` does not hold the method will return `TRUE` if `x` and `y` are structurally equal (in the sense of the function `_equal`) and `UNKNOWN` otherwise.

Conversion Methods

`convert_to` — Convert element

```
convert_to(x, T)
```

The implementation provided here can convert `x` to an element of this domain (the trivial case) or to an element of `Dom::Expression` (by using the method `"expr"`, see `Cat::BaseCategory`).

`TeX` — Generate TeX output

```
TeX(x)
```

The default implementation provided here converts `x` into an expression using the method `"expr"` and then uses the function `generate::TeX` to convert the expression.

Access Methods

`allAxioms` — Return all axioms

```
allAxioms()
```

`allCategories` — Return all categories

```
allCategories()
```

`allEntries` — Return the names of all entries

```
allEntries()
```

`allSuperDomains` — Return all super-domains

```
allSuperDomains()
```

The last, most general, super-domain of all domains of the Dom package is `Dom::BaseDomain`.

`getAxioms` — Return axioms stated in the constructor

```
getAxioms()
```

`getCategories` — Return categories stated in the constructor

```
getCategories()
```

`getSuperDomain` — Return super-domain stated in the constructor

```
getSuperDomain()
```

`hasProp` — Test for a certain property

```
hasProp(d)
```

```
hasProp(dc)
```

```
hasProp(a)
```

```
hasProp(ac)
```

`hasProp(c)`

`hasProp(cc)`

`hasProp(dc)` tests if this domain or a super-domain of it was defined by the domain constructor `dc`.

`hasProp(a)` tests if this domain has the axiom `a`.

`hasProp(ac)` tests if an axiom of this domain was defined by the axiom constructor `ac`.

`hasProp(c)` tests if this domain has the category `c`.

`hasProp(cc)` tests if a category of this domain was defined by the category constructor `cc`.

`info` — Print short information about this domain

`info()`

It prints out the super-domains, categories, axioms and entry names of this domain.

If an entry `"info_str"`, which must be a string, is defined for this domain it is used to print the header line.

`printMethods` — Print out methods

`printMethods(<sort>, <Table>)`

`printMethods(<sort>, Tree)`

If no sorting function is given, `sort` is used as default.

Similar as above, using `Tree` provides only that the names of the entries are inserted into a tree, an element of the domain `adt::Tree`. The tree is both printed out and returned by the method.

Using neither `Table` nor `Tree` the function does the same as `dom::printMethods(sort, Table)`.

`subs` — Avoid substitution

`subs(x, , …)`

Sub-domains should provide a new implementation of this method with sensible semantics if possible.

`subsex` — Avoid extended substitution

```
subsex(x, , …)
```

Sub-domains should provide a new implementation of this method with sensible semantics if possible.

`undefinedEntries` — Return missing entries

```
undefinedEntries()
```

An entry is missing if it should have a definition according to a category of the domain, but the definition is not present.

`whichEntry` — Return the domain or category implementing an entry

```
whichEntry(e)
```

`FAIL` is returned if no entry with the given name is defined for this domain.

Dom::Complex

Field of complex numbers

Syntax

```
Dom::Complex(x)
```

Description

`Dom::Complex` is the domain of complex constants represented by expressions of type `DOM_INT`, `DOM_RAT`, `DOM_FLOAT` or `DOM_COMPLEX`. An expression of type `DOM_EXPR` is considered a complex number if it is of type `Type::Arithmetical` and if it contains only indeterminates which are of type `Type::ConstantIdents` or if it contains no indeterminates, cf. “Example 2” on page 7-80.

`Dom::Complex` is of category `Cat::Field` due to pragmatism. This domain actually is not a field because `bool(1.0 = float(3) / float(3))` returns `FALSE`, for example.

Elements of `Dom::Complex` are usually not created explicitly. However, if one creates elements using the usual syntax, it is checked whether the input expression can be converted to a number. This means `Dom::Complex` is a facade domain which creates elements of domain type `DOM_INT`, `DOM_RAT`, `DOM_FLOAT`, `DOM_COMPLEX` or `DOM_EXPR`.

`Dom::Complex` has no normal representation, because `0` and `0.0` both represent the zero.

Viewed as a differential ring, `Dom::Complex` is trivial. It only contains constants.

`Dom::Complex` has the domain `Dom::BaseDomain` as its super domain, i.e., it inherits each method which is defined by `Dom::BaseDomain` and not re-implemented by `Dom::Complex`. Methods described below are re-implemented by `Dom::Complex`.

Superdomain

`Dom::ArithmeticalExpression`

Axioms

`Ax::systemRep`, `Ax::efficientOperation("_divide")`, `Ax::efficientOperation("_mult")`, `Ax::efficientOperation("_invert")`

Categories

`Cat::DifferentialRing`, `Cat::Field`

Examples

Example 1

Creating some complex numbers using `Dom::Complex`:

```
Dom::Complex(2/3)
```

$$\frac{2}{3}$$

```
Dom::Complex(2/3 + 4*I)
```

$$\frac{2}{3} + 4\,i$$

Example 2

It's also possible to use expressions or constants for creating an element of `Dom::Complex`:

```
Dom::Complex(PI)
```

$$\pi$$

```
Dom::Complex(sin(2))
```

$$\sin(2)$$

```
Dom::Complex(sin(2/3*I) + 3)
```

$$3 + \sinh\left(\frac{2}{3}\right) i$$

If the expression cannot be converted to an element of `Dom::Complex` we will get an error message:

```
Dom::Complex(sin(x))
```

```
Error: The arguments are invalid. [Dom::Complex::new]
```

Parameters

x

An expression of type `DOM_INT`, `DOM_RAT`, `DOM_FLOAT`, `DOM_COMPLEX`. An expression of type `DOM_EXPR` is also possible if it is of type `Type::Arithmetical` and if it contains only indeterminates which are of type `Type::ConstantIdents` or if it contains no indeterminates.

Entries

"characteristic"	the characteristic of this field is 0.
"one"	the unit element; it equals `1`.
"zero"	The zero element; it equals `0`.

Methods

Mathematical Methods

`_divide` — Divide numbers

```
_divide(x, y)
```

`_invert` — Invert numbers

```
_invert(x)
```

`_mult` — Multiplie numbers

```
_mult(x, y, …)
```

`_negate` — Negate numbers

```
_negate(x)
```

`_plus` — Add numbers

```
_plus(x, y, …)
```

`_power` — Power operator

```
_power(x, y)
```

`_unequal` — Inequalities

```
_unequal(x, y)
```

`conjugate` — Conversion to a basic type

```
conjugate(x)
```

`D` — Differential operator

```
D(x)
```

`diff` — Differentiates

```
diff(z, <x, …>)
```

`equal` — Equations

```
equal(x, y)
```

`expr` — Conversion to a basic type

```
expr(x)
```

`iszero` — Zero test

```
iszero(x)
```

`norm` — Absolute value of a number

```
norm(x)
```

`random` — Random number generation

```
random()
```

```
random(n)
```

```
random(m .. n)
```

`random(n)` returns a random number generator which creates complex random numbers where the real parts and the imaginary parts are positive integers between 0 and n - 1.

`random(m..n)` returns a random number generator which creates complex random numbers where the real parts and the imaginary parts are positive integers between m and n.

`unequal` — Inequalities

```
unequal(x, y)
```

Conversion Methods

`convert` — Conversion into this domain

```
convert(x)
```

An arithmetical expression can be converted if it only contains subexpression of the types just mentioned.

If the conversion fails, `FAIL` is returned.

`convert_to` — Conversion to other domains

```
convert_to(x, T)
```

If the conversion fails, FAIL is returned.

The following domains are allowed for T: DOM_INT, Dom::Integer, DOM_RAT, Dom::Rational, DOM_FLOAT, Dom::Float, Dom::Numerical, DOM_COMPLEX and DOM_EXPR.

normal — Normal form of objects

```
normal(x)
```

Dom::DenseMatrix(R)(m, n, List, Banded)

Dom::DenseMatrix(R)(1, n, List)

Dom::DenseMatrix(R)(m, 1, List)
```

Description

Domain Creation

`Dom::DenseMatrix(R)` creates domains of matrices over a component domain `R` of category `Cat::Rng` (a ring, possibly without unit).

If the optional parameter `R` is not given, the domain `Dom::ExpressionField()` is used.

A vector with n entries is either an $n \times 1$ matrix (a column vector), or a $1 \times n$ matrix (a row vector).

Arithmetical operations with matrices can be performed by using the standard arithmetical operators of MuPAD.

E.g., if `A` and `B` are two matrices defined by `Dom::DenseMatrix(R)`, `A + B` computes the sum, and `A * B` computes the product of the two matrices, provided that the dimensions are correct.

Similarly, `A^(-1)` or `1/A` computes the inverse of a square matrix `A` if it exists, and returns `FAIL` otherwise. See “Example 1” on page 7-89.

Many system functions have been overloaded for matrices, such as `map`, `subs`, `has`, `zip`, `conjugate` to compute the complex conjugate of a matrix, `norm` to compute matrix norms, or `exp` to compute the exponential of a matrix.

Most of the functions in the MuPAD linear algebra package `linalg` work with matrices. For example, the command `linalg::gaussJordan(A)` performs Gauss-Jordan elimination on `A` to transform `A` to its reduced row echelon form.

The domain `Dom::DenseMatrix(R)` represents matrices over `R` of arbitrary size, and it therefore does not have any algebraic structure (other than being a *set* of matrices).

The domain `Dom::SquareMatrix(n, R)` represents the *ring* of $n \times n$ matrices over R. The domain `Dom::MatrixGroup(m, n, R)` represents the *Abelian group* of $m \times n$ matrices over R.

We use the following notations for a matrix A (an element of `Dom::DenseMatrix(R)`):

- *nrows*(A) denotes the number of rows of A.
- *ncols*(A) denotes the number of columns of A.

- A *row index* is an integer in the range from 1 to *nrows*(*A*).
- A *column index* is an integer in the range from 1 to *ncols*(*A*).

Note: The components of a matrix are no longer evaluated after the creation of the matrix, i.e., if they contain free identifiers they will not be replaced by their values.

Element Creation

`Dom::DenseMatrix(R)(Array)` and `Dom::DenseMatrix(R)(Matrix)` create a new matrix with the dimension and the components of `Array` and `Matrix`, respectively.

The components of `Array` or `Matrix` are converted into elements of the domain `R`. An error message is issued if one of these conversions fails.

`Dom::DenseMatrix(R)(List)` creates an $m \times 1$ column vector with components taken from the nonempty list, where m is the number of entries of `List`.

`Dom::DenseMatrix(R)(ListOfRows)` creates an $m \times n$ matrix with components taken from the nested list `ListOfRows`, where m is the number of inner lists of `ListOfRows`, and n is the maximal number of elements of an inner list. Each inner list corresponds to a row of the matrix. Both m and n must be non-zero.

If an inner list has less than n entries, then the remaining components in the corresponding row of the matrix are set to zero.

The entries of the inner lists are converted into elements of the domain `R`. An error message is issued if one of these conversions fails.

It might be a good idea first to create a two-dimensional array from that list before calling `Dom::DenseMatrix(R)`. This is due to the fact that creating a matrix from an array is the fastest way one can achieve. However, in this case the sublists must have the same number of elements.

The call `Dom::DenseMatrix(R)(m, n)` returns the $m \times n$ zero matrix.

Use the method `"identity"` to create the $n \times n$ identity matrix.

The call `Dom::DenseMatrix(R)(m, n, Array)` creates an $m \times n$ matrix with components taken from `Array`, which must be an array or an hfarray. `Array` must have $m\,n$ operands. The first m operands define the first row, the next m operands define the

second row, etc. The formatting of the array is irrelevant. E.g., any array with 6 elements can be used to create a matrix of dimension 1 ×6, or 2×3, or 3×2, or 6 ×1.

The call `Dom::DenseMatrix(R)(m, n, List)` creates an $m \times n$ matrix with components taken from the list `List` with $m\,n$ elements. The first m elements of the list define the first row, the next m elements of the list define the second row, etc.

The call `Dom::DenseMatrix(R)(m, n, ListOfRows)` creates an $m \times n$ matrix with components taken from the list`ListOfRows`.

If $m \geq 2$ and $n \geq 2$, then `ListOfRows` must consist of at most `m` inner lists, each having at most `n` entries. The inner lists correspond to the rows of the returned matrix.

If an inner list has less than `n` entries, then the remaining components of the corresponding row of the matrix are set to zero. If there are less than `m` inner lists, then the remaining lower rows of the matrix are filled with zeroes.

`Dom::DenseMatrix(R)(m, n, f)` returns the matrix whose (i, j)th component is the value of the function call `f(i,j)`. The row index i ranges from 1 to m and the column index j from 1 to n.

The function values are converted into elements of the domain `R`. An error message is issued if one of these conversions fails.

`Dom::DenseMatrix(R)(1, n, List)` returns the 1 ×n row vector with components taken from `List`. The list `List` must have at most `n` entries. If there are fewer entries, then the remaining vector components are set to zero.

The entries of the list are converted into elements of the domain `R`. An error message is issued if one of these conversions fails.

`Dom::DenseMatrix(R)(m, 1, List)` returns the $m \times 1$ column vector with components taken from `List`. The list `List` must have at most `m` entries. If there are fewer entries, then the remaining vector components are set to zero.

The entries of the list are converted into elements of the domain `R`. An error message is issued if one of these conversions fails.

Superdomain

`Dom::BaseDomain`

Axioms

If R has `Ax::canonicalRep`, then `Ax::canonicalRep`.

Categories

`Cat::Matrix(R)`.

Examples

Example 1

First we create the domain of matrices over the field of rational numbers:

```
MatQ := Dom::DenseMatrix(Dom::Rational)
```

```
Dom::DenseMatrix(Dom::Rational)
```

We assigned this domain to the identifier `MatQ`. Next we define the 2×2 matrix

$$\begin{pmatrix} 1 & 5 \\ 2 & 3 \end{pmatrix}$$

by a list of two rows, where each row is a list of two elements:

```
A := MatQ([[1, 5], [2, 3]])
```

$$\begin{pmatrix} 1 & 5 \\ 2 & 3 \end{pmatrix}$$

In the same way we define the following 2 ×3 matrix:

```
B := MatQ([[-1, 5/2, 3], [1/3, 0, 2/5]])
```

$$\begin{pmatrix} -1 & \frac{5}{2} & 3 \\ \frac{1}{3} & 0 & \frac{2}{5} \end{pmatrix}$$

and perform matrix arithmetic using the standard arithmetical operators of MuPAD, e.g., the matrix product $A\,B$, the 4th power of A as well as the scalar multiplication of A times $\frac{1}{3}$:

```
A * B, A ^ 4, 1/3 * A
```

$$\begin{pmatrix} \frac{2}{3} & \frac{5}{2} & 5 \\ -1 & 5 & \frac{36}{5} \end{pmatrix}, \begin{pmatrix} 281 & 600 \\ 240 & 521 \end{pmatrix}, \begin{pmatrix} \frac{1}{3} & \frac{5}{3} \\ \frac{2}{3} & 1 \end{pmatrix}$$

The matrices A and B have different dimensions, and therefore the sum of A and B is not defined. MuPAD issues an error message:

```
A + B
```

```
Error: The dimensions do not match. [(Dom::DenseMatrix(Dom::Rational))::_plus]
```

To compute the inverse of A, just enter:

```
1/A
```

$$\begin{pmatrix} -\frac{3}{7} & \frac{5}{7} \\ \frac{2}{7} & -\frac{1}{7} \end{pmatrix}$$

If a matrix is not invertible, `FAIL` is the result of this operation. For example, the matrix:

```
C := densematrix(2, 2, [[2]])
```

$$\begin{pmatrix} 2 & 0 \\ 0 & 0 \end{pmatrix}$$

is not invertible, hence:

```
C^(-1)
```

FAIL

Example 2

We create the domain of matrices over the reals:

```
MatR := Dom::DenseMatrix(Dom::Real)
```

$$\text{Dom::DenseMatrix}(\text{Dom::Real})$$

Beside standard matrix arithmetic, the library `linalg` offers a lot of functions dealing with matrices. For example, if one wants to compute the rank of a matrix, use `linalg::rank`:

```
A := MatR([[1, 2], [2, 4]])
```

$$\begin{pmatrix} 1 & 2 \\ 2 & 4 \end{pmatrix}$$

```
linalg::rank(A)
```

$$1$$

Use `linalg::eigenvectors` to compute eigenvalues and eigenvectors of the matrix *A*:

```
linalg::eigenvectors(A)
```

$$\left[\left[0,\ 1,\ \left[\begin{pmatrix} -2 \\ 1 \end{pmatrix}\right]\right],\ \left[5,\ 1,\ \left[\begin{pmatrix} \frac{1}{2} \\ 1 \end{pmatrix}\right]\right]\right]$$

Try `info(linalg)` for a list of available functions, or enter `help(linalg)` for details about the library `linalg`.

Some of the functions in the `linalg` package simply serve as "interface" functions for methods of a matrix domain described above. For example, `linalg::transpose` uses the method `"transpose"` to get the transposed matrix. The function `linalg::gaussElim` applies Gaussian elimination to a matrix, such as:

```
linalg::gaussElim(A)
```

$$\begin{pmatrix} 1 & 2 \\ 0 & 0 \end{pmatrix}$$

The computation is performed by the method `"gaussElim"` as described above. Such functions of the `linalg` packages, in contrast to the corresponding methods of the domain `Dom::DenseMatrix(R)`, check their incoming parameters, and some of them offer extended functionalities.

Example 3

In this example, we use the default matrix domain which is created by `Dom::DenseMatrix()`. This domain represents matrices whose components can be arbitrary arithmetical expressions (i.e., the component ring is the domain `Dom::ExpressionField()`).

This domain is already known to MuPAD by the name `matrix`:

```
A := densematrix(
  [[1, 2, 3, 4], [2, 0, 4, 1], [-1, 0, 5, 2]]
)
```

$$\begin{pmatrix} 1 & 2 & 3 & 4 \\ 2 & 0 & 4 & 1 \\ -1 & 0 & 5 & 2 \end{pmatrix}$$

```
domtype(A)
```

Dom::DenseMatrix()

Matrix components can be extracted by the index operator `[]`:

```
A[2, 1] * A[1, 2] - A[3, 1] * A[1, 3]
```

7

If one of the indices is not in its valid range, an error message is issued. Assignments to matrix components are performed similarly:

```
delete a:
```

```
A[1, 2] := a^2: A
```

$$\begin{pmatrix} 1 & a^2 & 3 & 4 \\ 2 & 0 & 4 & 1 \\ -1 & 0 & 5 & 2 \end{pmatrix}$$

Beside the usual indexing of matrix components, it is also possible to extract submatrices from a given matrix. The following call creates the submatrix of A which consists of the rows 2 to 3 and columns 1 to 3 of A:

```
A[2..3, 1..3]
```

$$\begin{pmatrix} 2 & 0 & 4 \\ -1 & 0 & 5 \end{pmatrix}$$

The index operator does not allow to insert submatrices into a given matrix. This is implemented by the function `linalg::substitute`.

Example 4

In the following examples, we demonstrate the different ways of creating matrices. We work with matrices defined over the field $\mathbb{Z}_{19}$, i.e., the field of integers modulo 19. This component ring can be created with the domain constructor `Dom::IntegerMod`.

We start by giving a list of rows, where each row is a list of row entries:

```
MatZ19 := Dom::DenseMatrix(Dom::IntegerMod(19)):
MatZ19([[1, 2], [2]])
```

$$\begin{pmatrix} 1 \bmod 19 & 2 \bmod 19 \\ 2 \bmod 19 & 0 \bmod 19 \end{pmatrix}$$

The elements of the two inner lists, the row entries, were converted into elements of the domain `Dom::IntegerMod(19)`.

The number of rows is the number of sublists of the argument, i.e., $m = 2$. The number of columns is determined by the length of the inner list with the most entries, which is

the first inner list with two entries. Missing entries in the other inner lists are treated as zero components. The call:

```
MatZ19(4, 4, [[1, 2], [2]])
```

$$\begin{pmatrix} 1 \bmod 19 & 2 \bmod 19 & 0 \bmod 19 & 0 \bmod 19 \\ 2 \bmod 19 & 0 \bmod 19 & 0 \bmod 19 & 0 \bmod 19 \\ 0 \bmod 19 & 0 \bmod 19 & 0 \bmod 19 & 0 \bmod 19 \\ 0 \bmod 19 & 0 \bmod 19 & 0 \bmod 19 & 0 \bmod 19 \end{pmatrix}$$

fixes the dimension of the matrix. Missing entries and inner lists are treated as zero components and zero rows, respectively.

An error message is issued if one of the given entries cannot be converted into an element over $\mathbb{Z}_{19}$:

```
MatZ19([[2, 3], [-1, I]])
```

```
Error: Cannot define a matrix over 'Dom::IntegerMod(19)'. [(Dom::DenseMatrix(Dom::Integ
```

Example 5

This example illustrates how to create a matrix with components given as values of an index function. First we create the 2 ×2 Hilbert matrix (see also the functions `linalg::hilbert` and `linalg::invhilbert`):

```
densematrix(2, 2, (i, j) -> 1/(i + j - 1))
```

$$\begin{pmatrix} 1 & \frac{1}{2} \\ \frac{1}{2} & \frac{1}{3} \end{pmatrix}$$

Note the difference when working with expressions and functions. If you give an expression it is treated as a function in the row and column indices:

```
delete x:
densematrix(2, 2, x), densematrix(2, 2, (i, j) -> x)
```

$$\begin{pmatrix} x(1,1) & x(1,2) \\ x(2,1) & x(2,2) \end{pmatrix}, \begin{pmatrix} x & x \\ x & x \end{pmatrix}$$

Example 6

Diagonal matrices can be created with the option `Diagonal` and a list of diagonal components:

```
MatC := Dom::DenseMatrix(Dom::Complex):
MatC(3, 4, [1, 2, 3], Diagonal)
```

$$\begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 2 & 0 & 0 \\ 0 & 0 & 3 & 0 \end{pmatrix}$$

Hence, to define the $n \times n$ identity matrix, you can enter:

```
MatC(3, 3, [1 $ 3], Diagonal)
```

$$\begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}$$

or even call:

```
MatC(3, 3, x -> 1, Diagonal)
```

$$\begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}$$

The easiest way to create the identity matrix, however, is to use the method `"identity"`:

```
MatC::identity(3)
```

$$\begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}$$

Example 7

Toeplitz matrices can be defined with the option `Banded`. The following call defines a three-banded matrix with the component 2 on the main diagonal and the component - 1 on the first subdiagonals:

```
densematrix(4, 4, [-1, 2, -1], Banded)
```

$$\begin{pmatrix} 2 & -1 & 0 & 0 \\ -1 & 2 & -1 & 0 \\ 0 & -1 & 2 & -1 \\ 0 & 0 & -1 & 2 \end{pmatrix}$$

Example 8

Some system functions can be applied to matrices, such as `norm`, `expand`, `diff`, `conjugate`, or `exp`.

For example, to expand the components of the matrix:

```
delete a, b:
A := densematrix(
  [[(a - b)^2, a^2 + b^2], [a^2 + b^2, (a - b)*(a + b)]]
)
```

$$\begin{pmatrix} (a-b)^2 & a^2+b^2 \\ a^2+b^2 & (a+b)\,(a-b) \end{pmatrix}$$

enter:

```
expand(A)
```

$$\begin{pmatrix} a^2-2\,a\,b+b^2 & a^2+b^2 \\ a^2+b^2 & a^2-b^2 \end{pmatrix}$$

If you want to differentiate the matrix components, then call for example:

```
diff(A, a)
```

$$\begin{pmatrix} 2a-2b & 2a \\ 2a & 2a \end{pmatrix}$$

To substitute matrix components by some values, enter:

```
subs(A, a = 1, b = -1)
```

$$\begin{pmatrix} 4 & 2 \\ 2 & 0 \end{pmatrix}$$

The function `zip` can also be applied to matrices. The following call combines two matrices A and B by dividing each component of A by the corresponding component of B:

```
A := densematrix([[4, 2], [9, 3]]):
B := densematrix([[2, 1], [3,-1]]):
zip(A, B, `/`)
```

$$\begin{pmatrix} 2 & 2 \\ 3 & -3 \end{pmatrix}$$

The quoted character `` `/` `` is another notation for the function `_divide`, the functional form of the division operator `/`.

If one needs to apply a function to the components of a matrix, then use the function `map`. For example, to simplify the components of the matrix:

```
C := densematrix(
  [[sin(x)^2 + cos(x)^2, cos(x)*tan(x)],
  [(a^2 - b^2)/(a + b), 1]]
)
```

$$\begin{pmatrix} \cos(x)^2+\sin(x)^2 & \cos(x)\tan(x) \\ \frac{a^2-b^2}{a+b} & 1 \end{pmatrix}$$

call:

```
map(C, Simplify)
```

$$\begin{pmatrix} 1 & \sin(x) \\ a-b & 1 \end{pmatrix}$$

Example 9

However, there may appear some unexpected results using the function `diff` in the context of matrices. The derivative of the following unspecified function `f` of a matrix is computed due to the chain rule:

```
diff(f(densematrix([[a*x^2, b], [c, d]])), x)
```

$$\begin{pmatrix} 2\,a\,x\,f'\left(\begin{pmatrix} a\,x^2 & b \\ c & d \end{pmatrix}\right) & 0 \\ 0 & 0 \end{pmatrix}$$

Usually, the function `f` would implicitly be assumed to be scalar. Hence, the derivative of `f` should be scalar as well. In the above situation the chain rule is applied for differentiation: the inner function is the matrix containing the symbolic components `a*x^2`, `b`, `c` and `d`. Its derivative is computed by simply applying `diff` to each component of the matrix:

```
diff(densematrix([[a*x^2, b], [c, d]]), x)
```

$$\begin{pmatrix} 2\,a\,x & 0 \\ 0 & 0 \end{pmatrix}$$

Finally, the exterior unspecified function `f` is implicitly assumed to be scalar, such that each component of the derivative of the inner function is multiplied by the exterior differentiation.

Example 10

A column vector is represented as a 2×1 matrix:

```
MatR := Dom::DenseMatrix(Dom::Real):
v := MatR(2, 1, [1, 2])
```

$$\begin{pmatrix} 1 \\ 2 \end{pmatrix}$$

The dimension of this vector is:

```
MatR::matdim(v)
```

$$[2, 1]$$

Use `linalg::vecdim`, or even call `nops(v)` to get the length of a vector:

```
linalg::vecdim(v)
```

$$2$$

The *i*th component of this vector can be extracted in two ways: either by `v[i,1]` or by `v[i]`:

```
v[1], v[2]
```

$$1, 2$$

We get the 2-norm of `v` by the following call:

```
norm(v, 2)
```

$$\sqrt{5}$$

Parameters

R

A ring, i.e., a domain of category `Cat::Rng`; default is `Dom::ExpressionField()`

`Array`

A one- or two-dimensional `array` or `hfarray`

`Matrix`

A matrix, i.e., an element of a domain of category `Cat::Matrix`

`m, n`

Matrix dimension (positive integers)

`List`

A list of matrix components

`ListOfRows`

A list of at most `m` rows; each row given as a list of at most `n` matrix components

`f`

A function or a functional expression with two parameters (the row and column index)

`g`

A function or a functional expression with one parameter (the row index)

Options

`Diagonal`

Create a diagonal matrix

With the option `Diagonal`, diagonal matrices can be created with diagonal elements taken from a list, or computed by a function or a functional expression.

`Dom::DenseMatrix(R)(m, n, List, Diagonal)` creates the $m \times n$ diagonal matrix whose diagonal elements are the entries of `List`.

`List` must have at most $min(m, n)$ entries. If it has fewer elements, the remaining diagonal elements are set to zero.

The entries of `List` are converted into elements of the domain `R`. An error message is issued if one of these conversions fails.

`Dom::DenseMatrix(R)(m, n, g, Diagonal)` returns the matrix whose ith diagonal element is `g(i, i)`, where the index i runs from 1 to $min(m, n)$.

The function values are converted into elements of the domain `R`. An error message is issued if one of these conversions fails.

`Banded`

Create a banded Toeplitz matrix

`Dom::DenseMatrix(R)(m, n, List, Banded)` creates an $m \times n$ banded Toeplitz matrix with the elements of `List` as entries. The number of entries of `List` must be odd, say $2h + 1$, and must not exceed `n`. The resulting matrix has bandwidth at most $2h + 1$.

A Toeplitz matrix is a matrix where the elements of each band are identical. See also "Example 7" on page 7-96.

All elements of the main diagonal of the created matrix are initialized with the middle element of `List`. All elements of the ith subdiagonal are initialized with the $(h + 1 - i)$th element of `List`. All elements of the ith superdiagonal are initialized with the $(h + 1 + i)$th element of `List`. All entries on the remaining sub- and superdiagonals are set to zero.

The entries of `List` are converted into elements of the domain `R`. An error message is issued if one of these conversions fails.

Entries

"isSparse"	is always `FALSE`, as elements of `Dom::DenseMatrix(R)` use a dense representation of their matrix components.
"randomDimen"	is set to `[10,10]`. See the method `"random"` below for details.

Methods

Mathematical Methods

_divide — Divide matrices

```
_divide(A, B)
```

An error message is issued if the dimensions of A and B do not match.

This method only exists if R is a commutative ring with a unit, i.e., a domain of category Cat::Ring.

This method overloads the function _divide for matrices, i.e., one may use it in the form A / B, or in functional notation: _divide(A, B).

_invert — Compute the inverse of a matrix

```
_invert(A, Normal = b)
```

If the component ring R is the domain Dom::Float, a floating-point approximation of the inverse matrix is computed by the function numeric::inverse.

This method only exists if R is a domain of category Cat::Ring.

This method overloads the function _invert for matrices, i.e., one may use it in the form 1/A or A^(-1), or in functional notation: _invert(A).

If Normal = TRUE, then the matrix inverse is always returned in a normalized form. For details about normalization, see normal. If Normal = FALSE, then the matrix inverse can appear in a normalized form, but normalization is not guaranteed. By default Normal = TRUE.

Normal affects the results only if a matrix contains variables or exact expressions, such as sqrt(5) or sin(PI/7).

_mod — Map the modulo operator to a matrix

```
_mod(A, n)
```

n must be non-zero, and a mod n must be defined for every entry a of A.

This method overloads the function `mod` for matrices; one may use it in the form `A mod n`, or in functional notation: `_mod(A, n)`.

`_mult` — Multiplie matrices by matrices, vectors and scalars

```
_mult(x, y)
```

```
_mult(x, y)
```

If `y` is of the domain type `R` or can be converted into such an element, the corresponding scalar multiplication is computed.

Otherwise, `y` is converted into a matrix of the domain type of `x`. If this conversion fails, then this method calls the method `"_mult"` of the domain of `y` giving all arguments in the same order.

If `x` is a matrix of the same domain type as `y`, then the matrix product $x\,y$ is computed. An error message is issued if the dimensions of the matrices do not match.

If `x` is of the domain type `R` or can be converted into such an element, the corresponding scalar multiplication is computed.

Otherwise, `x` is converted into a matrix of the domain type of `y`. If this conversion fails, then `FAIL` is returned.

This method handles more than two arguments by calling itself recursively with the first half of all arguments and the last half of all arguments. Then the product of these two results is computed with the system function `_mult`.

This method overloads the function `_mult` for matrices, i.e., one may use it in the form `x * y`, or in functional notation: `_mult(x, y)`.

`_negate` — Negate a matrix

```
_negate(A)
```

This method overloads the function `_negate` for matrices, i.e., one may use it in the form `-A`, or in functional notation: `_negate(A)`.

`_plus` — Add matrices

```
_plus(A, B, …)
```

The arguments `A, B , ...` are converted into matrices of the domain type `Dom::DenseMatrix(R)`. `FAIL` is returned if one of these conversions fails.

This method overloads the function `_plus` for matrices, i.e., one may use it in the form `A + B`, or in functional notation: `_plus(A, B)`.

`_power` — Integer power of a matrix

```
_power(A, n)
```

If the power `n` is a negative integer then `A` must be nonsingular and `R` must be a domain of category `Cat::IntegralDomain`. Otherwise `FAIL` is returned.

If `n` is zero and the component ring `R` is a ring with no unit (i.e., of category `Cat::Rng`, but not of category `Cat::Ring`), `FAIL` is returned.

This method overloads the function `_power` for matrices, i.e., one may use it in the form `A^n`, or in functional notation: `_power(A, n)`.

`conjugate` — Complex conjugate of a matrix

```
conjugate(A)
```

This method only exists if `R` implements the method `"conjugate"`, which computes the complex conjugate of an element of the domain `R`.

This method overloads the function `conjugate` for matrices, i.e., one may use it in the form `conjugate(A)`.

`cos` — Cosine of a matrix

```
cos(A)
```

If `A` is not square, an error message is issued. If the component domain of `A` does not allow the computation of `cos(elem)` for an arbitrary element `elem` of the component ring, `FAIL` is returned.

This method uses the function `numeric::expMatrix` for a floating-point approximation of the exponential of `A` if `A` is defined over the domain `Dom::Float`.

If some eigenvalues of `A` do not exist in `R` or cannot be computed, then `FAIL` is returned.

In the symbolic case the functions `exp` and `linalg::jordanForm` are called. The latter may not be able to compute the Jordan form of `A`. In this case `FAIL` is returned.

This method only exists if `R` is a domain of category `Cat::Field`.

This method overloads the function `cos` for matrices, i.e., one may use it in the form `cos(A)`.

`diff` — Differentiation of matrix components

```
diff(A, …)
```

This method only exists if `R` implements the method `"diff"`.

This method overloads the function `diff` for matrices, i.e., one may use it in the form `diff(A, ...)`. See “Example 8” on page 7-96 and “Example 9” on page 7-98.

`equal` — Equality test of matrices

```
equal(A, B)
```

Note that if `R` has the axiom `Ax::systemRep` then `normal` is used to simplify the components of `A` and `B` before testing their equality.

`exp` — Exponential of a matrix

```
exp(A, <t>)
```

If `A` is not square, an error message is issued. If the component domain of `A` does not allow the computation of `exp(elem)` for an arbitrary element `elem` of the component ring, `FAIL` is returned.

This method uses the function `numeric::expMatrix` for a floating-point approximation of the exponential of `A` if `A` is defined over the domain `Dom::Float` and if $t = 1$.

If some eigenvalues of `A` do not exist in `R` or cannot be computed, then `FAIL` is returned.

In the symbolic case the function `linalg::jordanForm` is called, which may not be able to compute the Jordan form of `A`. In this case `FAIL` is returned.

This method only exists if `R` is a domain of category `Cat::Field`.

This method overloads the function `exp` for matrices, i.e., one may use it in the form `exp(A, ...)`.

expand — Expand matrix components

```
expand(A)
```

This method only exists if R implements the method "expand", or if R has the axiom Ax::systemRep (in this case, the system function expand is used).

This method overloads the function expand for matrices, i.e., one may use it in the form expand(A).

factor — Scalar-matrix factorization

```
factor(A)
```

The factor s is the gcd of all components of the matrix A. Hence, this method only exists if R is of category Cat::GcdDomain.

This method overloads the function factor for matrices, i.e., one may use it in the form factor(A).

float — Floating-point approximation of the matrix components

```
float(A)
```

This method only exists if R implements the method "float".

Note: Usually the floating-point approximations are not elements of R! For example, Dom::Integer implements such a method, but the floating-point approximation of an integer cannot be re-converted into an integer.

This method checks whether the resulting matrix can be converted into the domain type of A only if testargs returns TRUE (e.g., if one calls this method from the interactive level of MuPAD).

Otherwise, one has to take care that the matrix returned is compatible to its component ring.

---

gaussElim — Gaussian elimination

```
gaussElim(A)
```

If the matrix is not square, i.e., the determinant of A is not defined, then the third entry of the list returned is the value FAIL.

This method only exists if the component ring R is an integral domain, i.e., a domain of category Cat::IntegralDomain.

If R has the method "pivotSize", then the pivot element of smallest size is chosen at every pivoting step, whereby pivotSize must return a positive integer representing the "size" of an element.

If no such method is defined, Gaussian elimination without a pivot strategy is applied to A.

If R has the axiom Ax::efficientOperation("_invert") and is of category Cat::Field, then ordinary Gaussian elimination is used. Otherwise, fraction-free elimination is performed on A.

If R implements the method "normal", it is used to simplify subsequent computations of the Gaussian elimination process.

Note that if R does not implement the method "normal", but the elements of R are represented by kernel domains, i.e., R has the axiom Ax::systemRep, the system function normal is used instead.

identity — Identity matrix

```
identity(n)
```

This method only exists if the component ring R is of category Cat::Ring, i.e., a ring with unit.

int — Integration of matrix components

```
int(A, …)
```

This method only exists if R implements the method "int".

This method overloads the system function int for matrices, i.e., one may use it in the form int(A, ...).

iszero — Test for zero matrices

```
iszero(A)
```

Note that there may exist more than one representation of the zero matrix of a given dimension if R does not have Ax::canonicalRep.

If R implements the method "normal", it is used to simplify the components of A for the zero-test.

Note that if R does not implement such a method, but the elements of R are represented by kernel domains, i.e., R has the axiom Ax::systemRep, the system function normal is used instead.

This method overloads the function iszero for matrices, i.e., one may use it in the form iszero(A).

matdim — Matrix dimension

```
matdim(A)
```

norm — Norm of matrices and vectors

```
norm(A, Infinity)

norm(A, Maximum)

norm(v, Infinity)

norm(v, Maximum)

norm(A, Frobenius)

norm(A, 1)

norm(v, Euclidean)

norm(v, k)
```

norm(A, Maximum) computes the maximum norm of the matrix A, which is the maximum row sum (the row sum is the sum of norms of each component in a row).

If the domain R does not implement the methods "max" and "norm", FAIL is returned.

Using norm(v, Infinity) for a vector v the maximum norm of all elements is returned.

If the domain R does not implement the methods "max" and "norm", FAIL is returned.

Using `norm(v, Maximum)` for a vector `v` the maximum norm of all elements is returned.

If the domain `R` does not implement the methods `"max"` and `"norm"`, `FAIL` is returned.

`norm(A, Frobenius)` computes the Frobenius norm of `A`, which is the square root of the sum of the squares of the norms of each component.

If the result is no longer an element of the domain `R`, or if `R` does not implement the method `"norm"`, `FAIL` is returned.

`norm(A, 1)` computes the 1-norm of the matrix `A`, which is the maximum sum of the norms of the elements of each column. If `R` does not implement the methods `"max"` and `"norm"`, `FAIL` is returned.

`norm(v, Euclidean)` computes the Euclidean norm (2-norm) of the vector `v`, which is defined to be the square root of the sum of the norms of the elements of `v` raised to the square.

`FAIL` is returned if the result is no longer an element of the domain `R`. The function `linalg::scalarProduct` is used to compute the Euclidean norm of the vector `v`.

If `R` does not implement the method `"norm"`, `FAIL` is returned.

`norm(v, k)` computes the k-norm of the vector `v`, which is defined to be the kth root of the sum of the norms of the elements of `v` raised to the kth power.

`FAIL` is returned if the result is no longer an element of the domain `R`. For $k = 2$, the function `linalg::scalarProduct` is used to compute the 2-norm of `v`.

If `R` does not implement the method `"norm"`, `FAIL` is returned.

The method `norm` overloads the function `norm` for matrices, i.e., one may use it in the form `norm(A k )`, where `k` is either `Infinity`, `Frobenius`, or a positive integer. The default value of `k` is `Infinity`.

`normal` — Simplification of matrix components

`normal(A)`

If `R` does not implement the method `"normal"`, but the elements of `R` are represented by kernel domains, i.e., `R` has the axiom `Ax::systemRep`, then the system function `normal` is applied to the components of `A`. Otherwise `normal(A)` returns `A` without any changes.

This method overloads the function `normal` for matrices, i.e., one may use it in the form `normal(A)`.

`nonZeros` — Number of non-zero components of a matrix

```
nonZeros(A)
```

`nonZeroes` — Number of non-zero components of a matrix

```
nonZeroes(A)
```

`nonZeroOperands` — Return a sequence of all non-zero operands

```
nonZeroOperands(A)
```

This method is useful for retrieving information on the non-zero entries. For example, to find out the types of the entries in the matrix, one should not consider all operands `op(A)`, because this would also involve the zero entries. For large matrices with few entries, it is much more efficient to use this method to extract the entries.

`random` — Random matrix generation

```
random()
```

This method only exists if `R` implements the method `"random"`.

The dimension of the matrix is also chosen randomly, but it is limited by the values given in `"randomDimen"` (see “Entries” above).

To change the value of the entry `"randomDimen"` for a domain `MatR` created with `Dom::DenseMatrix`, one must first unprotect the domain `Dom` (see `unprotect` for details).

`sin` — Sine of a matrix

```
sin(A)
```

If `A` is not square, an error message is issued. If the component domain of `A` does not allow the computation of `sin(elem)` for an arbitrary element `elem` of the component ring, `FAIL` is returned.

This method uses the function `numeric::expMatrix` for a floating-point approximation of the exponential of `A` if `A` is defined over the domain `Dom::Float`.

If some eigenvalues of A do not exist in R or cannot be computed, then FAIL is returned.

In the symbolic case the functions exp and linalg::jordanForm are called. The latter may not be able to compute the Jordan form of A. In this case FAIL is returned.

This method only exists if R is a domain of category Cat::Field.

This method overloads the function sin for matrices, i.e., one may use it in the form sin(A).

sqrt — Square root of a matrix

```
sqrt(A, <sqrtfunc>)
```

Returned is a matrix B with $B^2 = A$ such that the eigenvalues of B are the square roots of the eigenvalues of A or FAIL if the square root of the matrix does not exist. For computing the square roots of the eigenvalues a function satisfying $sqrtfunc(a)^2 = a$ for every element a of the coefficient ring of A can be given as optional second argument.

For details we refer to the help page of the function linalg::sqrtMatrix.

testeq — Testing for equality of two matrices

```
testeq(A, B)
```

tr — Trace of a square matrix

```
tr(A)
```

If A is not square, then an error message is issued.

transpose — Transpose of a matrix

```
transpose(A)
```

Access Methods

_concat — Horizontal concatenation of matrices

```
_concat(A, B, …)
```

An error message is issued if the given matrices do not have the same number of rows.

This method overloads the function `_concat` for matrices, i.e., one may use it in the form `A . B . ...`, or in functional notation: `_concat(A, B, ...)`.

`_index` — Matrix indexing

```
_index(A, i, j)

_index(A, r1 .. r2, c1 .. c2)

_index(v, i)

_index(v, i1 .. i2)
```

If `i` and `j` are not integers, then the call of this method returns in its symbolic form (of type `"_index"`) with evaluated arguments.

Otherwise an error message is given, if `i` and `j` are not valid row and column indices, respectively.

Note: Note that this method uses the system function `context` to evaluate the entry in the context of the calling environment.

`_index(A,r1..r2,c1..c2)` returns the submatrix of `A` created by the rows of `A` with indices from `r1` to `r2` and the columns of `A` with indices from `c1` to `c2`.

`_index(v,i)` returns the *i*th entry of the vector `v`.

An error message is issued if `v` is not a vector.

If `i` is not an integer, then the call of this method returns in its symbolic form (of type `"_index"`) with evaluated arguments.

Otherwise an error message is given, if `i` is less than one or greater than the dimension of `v`.

Note: Note that this method uses the system function `context` to evaluate the entry in the context of the calling environment.

`_index(v,i1..i2)` returns the subvector of `v`, formed by the entries with index `i1` to `i2`. See also the method `"op"`.

An error message is issued if `v` is not a vector.

This method overloads the function `_index` for matrices, i.e., one may use it in the form `A[i, j]`, `A[r1..r2, c1..c2]`, `v[i]` and `v[i1..i2]`, respectively, or in functional notation: `_index(A, ...)`.

`concatMatrix` — Horizontal concatenation of matrices

```
concatMatrix(A, B, …)
```

`col` — Extracting a column

```
col(A, c)
```

An error message is issued if `c` is less than one or greater than the number of columns of `A`.

`delCol` — Deleting a column

```
delCol(A, c)
```

`NIL` is returned if `A` consists of only one column.

An error message is issued if `c` is less than one or greater than the number of columns of `A`.

`delRow` — Deleting a row

```
delRow(A, r)
```

`NIL` is returned if `A` consists of only one row.

An error message is issued if `r` is less than one or greater than the number of rows of `A`.

`evalp` — Evaluating matrices of polynomials at a certain point

```
evalp(A, x = a, …)
```

This method is only defined if `R` is a polynomial ring of category `Cat::Polynomial`.

This method overloads the function `evalp` for matrices, i.e., one may use it in the form `evalp(A, x = a)`.

`length` — Length of a matrix

```
length(A)
```

This method overloads the function `length` for matrices, i.e., one may use it in the form `length(A)`.

`map` — Apply a function to matrix components

```
map(A, func, <expr, …>)
```

Note: Note that the function values are converted into elements of the domain `R` only if `testargs` returns `TRUE` (e.g., if one calls this method from the interactive level of MuPAD).

If `testargs` returns `FALSE`, then one must guarantee that the function calls return elements of the domain type `R`, otherwise the resulting matrix, which is of domain type `Dom::DenseMatrix(R)`, would have components which are not elements of the domain `R`!

This method overloads the function `map` for matrices, i.e., one may use it in the form `map(A, func, ...)`.

`mapNonZeroes` — Apply a function to the non-zero components of a matrix

```
mapNonZeroes(A, f, <p1, p2, …>)
```

`nops` — Number of components of a matrix

```
nops(A)
```

This method overloads the function `nops` for matrices, i.e., one may use it in the form `nops(A)`.

`op` — Component of a matrix

```
op(A, i)
```

```
op(A)
```

This method returns an expression sequence of all components of A.

See also the method "_index".

This method overloads the function op for matrices, i.e., one may use it in the form op(A, i) and op(A), respectively.

row — Extracting a row

```
row(A, r)
```

An error message is issued if r is less than one or greater than the number of rows of A.

setCol — Replacing a column

```
setCol(A, c, v)
```

An error message is issued if c is less than one or greater than the number of rows of A.

setRow — Replacing a row

```
setRow(A, r, v)
```

An error message is issued if r is less than one or greater than the number of rows of A.

stackMatrix — Vertical concatenation of matrices

```
stackMatrix(A, B, …)
```

An error message is issued if the given matrices do not have the same number of columns.

subs — Substitution of matrix components

```
subs(A, …)
```

Note: Note that the function values are converted into elements of the domain R only if testargs returns TRUE (e.g., if one calls this method from the interactive level of MuPAD).

If testargs returns FALSE, then one must guarantee that the function calls return elements of the domain type R, otherwise the resulting matrix, which is of domain type

`Dom::DenseMatrix(R)`, would have components which are not elements of the domain `R`!

This method overloads the function `subs` for matrices, i.e., one may use it in the form `subs(A, ...)`.

subsex — Extended substitution of matrix components

`subsex(A, …)`

Note: Note that the results of the substitutions are converted into elements of the domain `R` only if `testargs` returns `TRUE` (e.g., if one calls this method from the interactive level of MuPAD).

If `testargs` returns `FALSE`, then one must guarantee that the results of the substitutions are of the domain type `R`, otherwise the resulting matrix, which is of domain type `Dom::DenseMatrix(R)`, would have components which are not elements of the domain `R`!

This method overloads the function `subsex` for matrices, i.e., one may use it in the form `subsex(A, ...)`.

subsop — Operand substitution of matrix components

`subsop(A, i = x, …)`

Note: Note that `x` is converted into the domain `R` only if `testargs` returns `TRUE` (e.g., if one calls this method from the interactive level of MuPAD).

If `testargs` returns `FALSE`, then `x` must be an element of `R`, otherwise the resulting matrix, which is of domain type `Dom::DenseMatrix(R)`, would have components which are not elements of the domain `R`!

See also the method `"set_index"`.

This method overloads the function `subsop` for matrices, i.e., one may use it in the form `subsop(A, ...)`.

swapCol — Swapping matrix columns

```
swapCol(A, c1, c2)
```

```
swapCol(A, c1, c2, r1 .. r2)
```

An error message is issued if one of the column indices is less than one or greater than the number of columns of `A`.

`swapCol(A,c1,c2,r1..r2)` swaps the column with index `c1` and the column with index `c2` of `A`, but by taking only those column components which lie in the rows with indices `r1` to `r2`.

An error message is issued if one of the column indices is less than one or greater than the number of columns of `A`, or if one of the row indices is less than one or greater than the number of rows of `A`.

swapRow — Swapping matrix rows

```
swapRow(A, r1, r2)
```

```
swapRow(A, r1, r2, c1 .. c2)
```

An error message is issued if one of the row indices is less than one or greater than the number of rows of `A`.

`swapCol(A,r1,r2,c1..c2)` swaps the row with index `r1` and the row with index `r2` of `A`, but by taking only those row components which lie in the columns with indices `c1` to `c2`.

An error message is issued if one of the row indices is less than one or greater than the number of rows of `A`, or if one of the column indices is less than one or greater than the number of columns of `A`.

set_index — Setting matrix components

```
set_index(A, i, j, x)
```

```
set_index(v, i, x)
```

Note: Note that `x` is converted into an element of the domain `R` only if `testargs` returns `TRUE` and `i` and `j` are integers (e.g., if one calls this method from the interactive level of

MuPAD). If x is a matrix of the same type as A or can be converted into a matrix of the same type as A and the indices i or j are ranges corresponding to a submatrix of A, then x replaces the corresponding submatrix in A.

Otherwise one has to take care that x is of domain type R.

See also the method "subsop".

set_index(v,i,x) replaces the *i*th entry of the vector v by x.

set_index on vectors overloads the function set_index for matrices, i.e., one may use it in the form A[i, j] := x and v[i] := x, respectively, or in functional notation: A := set_index(A, i, j, x) or v := set_index(v, i, x).

zip — Combine matrices component-wise

zip(A, B, func, <expr, …>)

The row number of the matrix returned is the minimum of the row numbers of A and B, and its column number is the minimum of the column numbers of A and B.

Note: Note that the function values are converted into elements of the domain R only if testargs returns TRUE (e.g., if one calls this method from the interactive level of MuPAD).

If testargs returns FALSE, then one must guarantee that the function calls return elements of the domain type R, otherwise the resulting matrix, which is of domain type Dom::DenseMatrix(R), would have components which are not elements of the domain R!

This method overloads the function zip for matrices, i.e., one may use it in the form zip(A, B, ...).

Conversion Methods

convert — Conversion to a matrix

convert(x)

FAIL is returned if the conversion fails.

x may either be an array, a matrix, or a list (of sublists, see the parameter ListOfRows in "Creating Elements" above). Their entries must then be convertible into elements of the domain R.

convert_to — Matrix conversion

```
convert_to(A, T)
```

T may either be DOM_ARRAY, DOM_LIST, or a domain constructed by Dom::DenseMatrix or Dom::SquareMatrix. The elements of A must be convertible into elements of the domain R.

Use the function expr to convert A into an object of a kernel domain (see below).

create — Defining matrices without component conversions

```
create(x, …)
```

This method works more efficient than if one creates matrices by calling the method "new" of the domain, because it avoids any conversion of the components. One must guarantee that the components have the correct domain type, otherwise run-time errors can be caused.

If x is a list of sublists, it might be a good idea first to create a two-dimensional array from that list before calling this method. This is due to the fact that creating a matrix from an array is the fastest way one can achieve.

Please note that when creating a two-dimensional array from a list of sublists, the sublists must have the same number of elements.

expr — Matrix conversion into an object of a kernel domain

```
expr(A)
```

The result is an array representing the matrix A where each entry is an object of a kernel domain.

This method overloads the function expr for matrices, i.e., one may use it in the form expr(A).

`expr2text` — Matrix conversion to a string

```
expr2text(A)
```

This method overloads the function `expr2text` for matrices, i.e., one may use it in the form `expr2text(A)`.

`TeX` — TeX formatting of a matrix

```
TeX(A)
```

Note that in the case of very large matrices the output will not be useful. For printing large matrices use the function `"doprint"`.

The method `"TeX"` of the component ring `R` is used to get the TeX-representation of each component of `A`.

This method is used by the function `generate::TeX`.

Technical Methods

`assignElements` — Multiple assignment to matrices

```
assignElements(A, …)
```

The assigned components must have the domain type `R`, an implicit conversion of the components into elements of domain type `R` is not performed.

This method overloads the function `assignElements` for matrices, i.e., one may use it in the form `assignElements(A, ...)`.

`mkDense` — Conversion of a matrix to an array

```
mkDense(Array)
```

```
mkDense(List)
```

```
mkDense(r, c, List)
```

`mkDense(List)` tries to convert the list `List` into an array `a`. The result is either `FAIL` if this is not possible, or the list `[r, c, a]`, where the positive integers `r` and `c` give the

dimension of `a`. See the parameters `List` and `ListOfRows` in "Creating Elements" above for admissible formats of `List`.

The array `a` has dimension one if `r` or `c` is equal to one. The entries of `a` have been converted into elements of the domain `R`.

`mkDense(r,c,List)` tries to convert the list `List` into an array `a` of the dimension `r` times `c`.

The result is either `FAIL` if this is not possible, or the list `[r, c, a]`.

The array `a` has dimension one if `r` or `c` is equal to one. The entries of `a` have been converted into elements of the domain `R`.

`print` — Printing matrices

```
print(A)
```

Note: Note that in general it is not useful to print very large matrices. Hence, a warning message is be displayed if the size of the matrix oversteps a certain dimension – printing such matrices can be done by using the function `"doprint"`.

`doprint` — Printing very large matrices

```
doprint(A)
```

`unapply` — Create a procedure from a matrix

```
unapply(A, <x, …>)
```

This method overloads the function `fp::unapply` for matrices, i.e., one may use it in the form `fp::unapply(A)`.

MuPAD Domains
`Dom::Matrix` | `Dom::MatrixGroup` | `Dom::SquareMatrix`

Dom::DihedralGroup

Dihedral groups

Syntax

Domain Creation

```
Dom::DihedralGroup(n)
```

Element Creation

```
Dom::DihedralGroupn(l)
```

Description

Domain Creation

`Dom::DihedralGroup(n)` creates the dihedral group of size n, i.e., the group of symmetries of a regular polygon with n edges.

`Dom::DihedralGroup(n)` creates the group of all congruent mappings of the plane that induce a bijective mapping of the set of corners of a regular n-angle to itself.

Element Creation

`Dom::DihedralGroup(n)([a,b])` represents the group element "t^a carried out after r^b", where r is a rotation that maps each corner to its left neighbor, and t is a reflection w.r.t. some fixed central diagonal.

Superdomain

`Dom::BaseDomain`

Axioms

`Ax::canonicalRep`

Categories

`Cat::Group`

Examples

Example 1

Define the group D_6, i.e., the group of congruence mappings of the hexagon:

```
G := Dom::DihedralGroup(6)
```

```
Dom::DihedralGroup(6)
```

Then elements may be created as follows:

```
a := G([7, 19]);
```

```
[1, 1]
```

This means that 19 rotations—mapping each corner to its left neighbor—and 7 reflections have the same effect as one operation of either type.

Parameters

n

Positive integer

`l`

List or array of two integers

Entries

"size"	the number of elements, which equals $2n$.
"one"	the mapping leaving each point fixed.

Methods

Mathematical Methods

`_mult` — Functional composition of elements

```
_mult(a, …)
```

This method overloads the kernel function `_mult`.

`_invert` — Inverse of an element

```
_invert(a)
```

This method overloads the kernel function `_invert`.

`_power` — Power of an element

```
_power(a, n)
```

It overloads the kernel function `_power`.

`order` — Order of a group element

```
order(a)
```

`random` — Random element

```
random()
```

Conversion Methods

`expr` — Convert group element to list

```
expr(a)
```

`TeX` — TeX output of a group element

```
TeX(a)
```

`equiv` — Test for equivalence

Inherited from `Cat::BaseCategory`.

`new` — Create element of this domain

Inherited from `Cat::BaseCategory`.

`coerce` — Coerce into this domain

Inherited from `Cat::BaseCategory`.

`hasProp` — Test for a certain property

Inherited from `Dom::BaseDomain`.

`whichEntry` — Return the domain or category implementing an entry

Inherited from `Dom::BaseDomain`.

`isone` — Test if element is one

Inherited from `Cat::Monoid`.

`printMethods` — Print out methods

Inherited from `Dom::BaseDomain`.

`info` — Print short information about this domain

Inherited from `Dom::BaseDomain`.

`_divide` — Return quotient

Inherited from `Cat::Group`.

`getAxioms` — Return axioms stated in the constructor

Inherited from `Dom::BaseDomain`.

`getCategories` — Return categories stated in the constructor

Inherited from `Dom::BaseDomain`.

`equal` — Test for mathematical equality

Inherited from `Dom::BaseDomain`.

`allAxioms` — Return all axioms

Inherited from `Dom::BaseDomain`.

`undefinedEntries` — Return missing entries

Inherited from `Dom::BaseDomain`.

`allCategories` — Return all categories

Inherited from `Dom::BaseDomain`.

`testtype` — Test type of object

Inherited from `Cat::BaseCategory`.

`allEntries` — Return the names of all entries

Inherited from `Dom::BaseDomain`.

`getSuperDomain` — Return super-domain stated in the constructor

Inherited from `Dom::BaseDomain`.

`subs` — Avoid substitution

Inherited from `Dom::BaseDomain`.

`allSuperDomains` — Return all super-domains

Inherited from `Dom::BaseDomain`.

subsex — Avoid extended substitution

Inherited from `Dom::BaseDomain`.

Dom::DistributedPolynomial

Domains of distributed polynomials

Syntax

Domain Creation

```
Dom::DistributedPolynomial(<Vars, <R, <Order>>>)
```

Element Creation

```
Dom::DistributedPolynomial(Vars, R, Order)(p)
```

```
Dom::DistributedPolynomial(Vars, R, Order)(lm)
```

```
Dom::DistributedPolynomial(Vars, R, Order)(lm, v)
```

Description

`Dom::DistributedPolynomial(Vars, R, ..)` creates the domain of polynomials in the variables of the list `Vars` over the commutative ring `R` in distributed representation.

`Dom::DistributedPolynomial(Vars, R, Order)` creates a domain of polynomials in the variables of the list `Vars` over a domain of category `Cat::CommutativeRing` in sparse distributed representation with respect to the monomial ordering `Order`.

If `Dom::DistributedPolynomial` is called without any argument, a polynomial domain in arbitrarily many indeterminates over the domain `Dom::ExpressionField(normal)` with respect to the lexicographic monomial ordering is created.

If `Dom::DistributedPolynomial` is called only with the variable list `Vars` as argument, the polynomial domain in the variable list `Vars` over the domain `Dom::ExpressionField(normal)` with respect to the lexicographic monomial ordering is created.

Note: Only commutative coefficient rings of type `DOM_DOMAIN` are allowed which inherit from `Dom::BaseDomain`. If `R` is of type `DOM_DOMAIN` but does not inherit from `Dom::BaseDomain`, the domain `Dom::ExpressionField(normal)` will be used instead.

`Dom::DistributedPolynomial` accepts expressions as indeterminates, similar to the kernel domain `DOM_POLY`. Hence, for example, `[x,cos(x)]` is a valid variable list.

If the variable list `Vars` is the empty list (`[]`), a polynomial domain in arbitrarily many indeterminates is created. In this case, when creating new elements from polynomials or polynomial expressions, the system function `indets` is first called to get the variables and then the polynomial is created with respect to these variables. Hence, in this case only identifiers can be valid indeterminates, because `indets` returns only identifiers.

It is not allowed to create polynomial domains in arbitrarily many indeterminates over another polynomial domain of category `Cat::Polynomial`, but it is possible to create multivariate polynomial domains with a given list of variables over any polynomial domain.

`Dom::DistributedPolynomial` represents polynomials over arbitrary commutative rings. It is intended as a basic domain for distributed polynomials from which it is easy to create new distributed polynomial domains.

All usual algebraic and arithmetical polynomial operations are implemented, including Gröbner basis computation.

Note: It is highly recommended to use only coefficient rings with unique zero representation. Otherwise it can happen that, e.g., a polynomial division will not terminate or a wrong degree will be returned.

Please note that for reasons of efficiency not all methods check their arguments, not even at the interactive level. In particular this is true for many access methods, converting methods and technical methods.

Superdomain

`Dom::BaseDomain`

Axioms

If R has `Ax::normalRep`, then `Ax::normalRep`.

If R has `Ax::canonicalRep`, then `Ax::canonicalRep`.

Categories

If Vars has exactly one variable, then `Cat::UnivariatePolynomial(R)`, else `Cat::Polynomial(R)`.

Examples

Example 1

The following call creates a polynomial domain in x, y and z.

```
DP := Dom::DistributedPolynomial([x, y, z])
```

Dom::DistributedPolynomial([x, y, z], Dom::ExpressionField(normal, iszero ∘ normal), LexOrder)

Since neither the coefficient ring nor the monomial ordering was specified, this domain is created with the default values for these parameters.

It is rather easy to create elements of this domain, as e.g.

```
a := DP(x + 2*y*z + 3)
```

$$x + 2\,y\,z + 3$$

```
b := DP(z^4 - 2*y^2*x^2)
```

$$-2\,x^2\,y^2 + z^4$$

In contrast to expressions all elements of this domain have a representation which is fixed by the chosen `Order`, the representation of the coefficient ring `R` and the way of representing monomials.

With these elements one can now perform usual arithmetic operations as, e.g., (scalar) multiplication, multiplication with integers and adding polynomials and ring elements:

```
4*b^2 + a/3 + 1/2
```

$$16\,x^4\,y^4 - 16\,x^2\,y^2\,z^4 + \frac{x}{3} + \frac{2\,y\,z}{3} + 4\,z^8 + \frac{3}{2}$$

There are a lot of methods for manipulating polynomials and to get access to all parts of a polynomial. For example one has access to the leading monomial of a as follows:

```
lmonomial(a)
```

$$x$$

The leading monomial of a polynomial depends on the monomial ordering, so with respect to the degree order one gets a different result:

```
lmonomial(a, DegreeOrder)
```

$$2\,y\,z$$

To get a minus its leading monomial one may call:

```
DP::reductum(a)
```

$$2\,y\,z + 3$$

Obviously the following identity holds:

```
a - lmonomial(a) - DP::reductum(a)
```

$$0$$

There are also methods for converting elements of this domain into other domains, like a basic polynomial domain or the domain of arbitrary expressions:

```
poly(a), domtype(poly(a))
```

$$\text{poly}(x + 2\,y\,z + 3,\ [x,\ y,\ z],\ \text{Dom::ExpressionField}(\text{normal},\ \text{iszero} \circ \text{normal})),\ \text{DOM\_POLY}$$

```
expr(b), domtype(expr(b))
```

$$z^4 - 2\,x^2\,y^2,\ \text{DOM\_EXPR}$$

Parameters

`Vars`

A list of indeterminates. Default is `[]` (the empty list, indicating "arbitrary indeterminates").

`R`

A commutative ring, i.e., a domain of category `Cat::CommutativeRing`. Default is `Dom::ExpressionField(normal)`.

`Order`

A monomial ordering, i.e., one of the predefined orderings `LexOrder`, `DegreeOrder` or `DegInvLexOrder` or any object of type `Dom::MonomOrdering`. Default is `LexOrder`.

`p`

A polynomial or a polynomial expression.

`lm`

List of monomials, which are represented as lists containing the coefficients together with the exponents or exponent vectors.

`v`

List of indeterminates. This parameter is only valid for `Vars = []`.

Entries

"characteristic"	The characteristic of this domain.
"coeffRing"	The coefficient ring of this domain as defined by the parameter `R`.
"key"	The name of the created domain.
"one"	The neutral element w.r.t. `"_mult"`.

"ordering"	The monomial order as defined by the parameter `Order`.
"variables"	The list of variables as defined by the parameter `Vars`.
"zero"	The neutral element w.r.t. `"_plus"`.

Methods

Mathematical Methods

`_divide` — Exact polynomial division

```
_divide(a, b)
```

```
_divide(a, b)
```

```
_divide(a, b)
```

It overloads the function `_divide` for polynomials, i.e., one may use it either in the form `a / b`, or in functional form `_divide(a, b)`.

Note: This method only exists if `R` is an integral domain, i.e., a domain of category `Cat::IntegralDomain`.

`_invert` — Inverse of an element

```
_invert(a)
```

`_mult` — Multiplie polynomials and coefficient ring elements

```
_mult(<a, b, …>)
```

This method overloads the function `_mult` for polynomials, i.e., one may use it either in the form `a * b * ...` or in functional notation `_mult(a, b, ...)`.

`_negate` — Negate a polynomial

```
_negate(a)
```

This method overloads the function `_negate` for polynomials, i.e., one may use it either in the form `-a` or in functional notation `_negate(a)`.

`_plus` — Add polynomials and coefficent ring elements

```
_plus(<a, b, …>)
```

This method overloads the function `_plus` for polynomials, i.e., one may use it either in the form `a + b + ...` or in functional notation `_plus(a, b, ...)`.

`_power` — Nth power of a polynomial

```
_power(a, n)
```

This method overloads the function `_power` for polynomials, i.e., one may use it either in the form `a^n` or in functional notation `_power(a,n)`.

`_subtract` — Subtract a polynomial or a coefficient ring element

```
_subtract(a, b)
```

This method overloads the function `_subtract` for polynomials, i.e., one may use it either in the form `a - b` or in functional notation `_subtract(a, b)`.

`associates` — Test if elements are associates

Inherited from `Cat::IntegralDomain`.

`content` — Content of a polynomial

```
content(a)
```

Note: This method only exists if `R` is a domain of category `Cat::GcdDomain`.

`D` — Differential operator for polynomials

```
D(a)
```

```
D(l, a)
```

`Dpoly` — Differential operator for polynomials

```
Dpoly(a)
```

```
Dpoly(l, a)
```

`Dpoly(l,a)` computes the partial derivative of `a` with respect to `l`. For details see `polylib::Dpoly`.

This method overloads the function `polylib::Dpoly` for polynomials.

`decompose` — Functional decomposition of a polynomial

```
decompose(a, <var>)
```

If `a` is a polynomial in only one variable, the second argument is not necessary.

This method overloads the function `polylib::decompose` for polynomials.

`diff` — Differentiate a polynomial

```
diff(a, varseq)
```

If `varseq` is an empty sequence, `a` is returned unchanged.

If in `varseq` an expression occurs which is not a variable of `a`, the zero polynomial is returned.

This method overloads the function `diff` for polynomials.

`dimension` — Dimension of affine variety

```
dimension(ais, <ord>)
```

```
dimension(ais, <ord>)
```

This method is merely an interface for the function `groebner::dimension`.

Note: This method only exists if `R` is a field, i.e., a domain of category `Cat::Field` and `Vars` is not the empty list.

`divide` — Divide polynomials

```
divide(a, b, <Quo | Rem | Exact>)
```

```
divide(a, b, var, <Quo | Rem | Exact>)
```

If no option is given, the quotient `s` and the remainder `r` are computed such that `a = s*b + r` and the degree of `r` in the relevant indeterminate is smaller than that of `b`. The sequence consisting of `s, r` is returned, otherwise `FAIL`.

If the option `Quo` is given, only the quotient `s` is returned.

If the option `Rem` is given, only the remainder `r` is returned.

If the option `Exact` is given, only the quotient `s` is returned, in case the remainder is zero, otherwise `FAIL`.

`divide(a,b,Exact)` divides the multivariate polynomial `a` by `b`. If `a` cannot be divided by `b`, the method returns `FAIL`.

This method overloads the function `divide` for polynomials.

Note: This method only exists if `R` is a field, i.e., a domain of category `Cat::Field` and either this domain is of category `Cat::UnivariatePolynomial(R)` or `R` has characteristic zero (`R::characteristic = 0`). If the first pair of conditions is true then the first call is valid otherwise the second one.

`divides` — Test if elements divides another

Inherited from `Cat::IntegralDomain`.

`equal` — Test for mathematical equality

Inherited from `Dom::BaseDomain`.

`equiv` — Test for equivalence

Inherited from `Cat::BaseCategory`.

`evalp` — Evaluate a polynomial

```
evalp(a, var = e)
```

This method overloads the function `evalp` for polynomials.

`factor` — Factor a polynomial

```
factor(a)
```

This method overloads the function `factor` for polynomials.

Note: This method only exists if `R` is a domain of category `Cat::Field` or if `R` is the domain `Dom::Integer`.

`func_call` — Applie expressions to a polynomial

```
func_call(a, e1, …, en, <Expr>)
```

```
func_call(a, e1, …, en, <Expr>)
```

```
func_call(a, e1, …, en, <Expr>)
```

`a(e1,...,en)` applies the sequence `e1,...,en` of either elements of this domain or elements of `R` with respect to `Vars` (where `n` is the number of variables) to the polynomial `a`. An element of this domain or an element of the coefficient ring respectively is returned.

`a(e1,...,en, Expr)` applies the sequence of expressions or of elements of this domain or of elements of `R` to the polynomial `a`. With this call `a` is first converted into an expression. Afterwards `e1,...,en` is substituted into this expression with respect to `Vars`. The return value may be any object.

The number of variables must be equal to the number of applied expressions.

Note: This method only exists if `Vars` has at least one indeterminate.

`gcd` — Greatest common divisor of polynomials

```
gcd(a, b, …)
```

This method overloads the function `gcd` for polynomials.

Note: This method only exists if `R` is a domain of category `Cat::GcdDomain`.

---

gcdex — Extended Euclidean algorithm for polynomials

```
gcdex(a, b)
```

This method overloads the function `gcdex` for polynomials. Especially, it only works for coefficient rings described there.

Note: This method only exists if `R` is a domain of category `Cat::GcdDomain`.

---

groebner — Reduced Gröbner basis

```
groebner(ais, <ord>, <Reorder>)
```

```
groebner(ais, <ord>, <Reorder>)
```

If the option `Reorder` is given, the lexicographical order of variables may change to another one that is likely to decrease the running time.

Note: Note that this may also cause a change of the returned list, which may now have polynomials over the same coefficient ring `R` but with a possibly re-ordered variable list. Thus, it may contain elements *not* belonging to this domain.

This method is merely an interface for the function `groebner::gbasis`.

Note: This method only exists if `R` is a field, i.e., a domain of category `Cat::Field`, and `Vars` is not the empty list.

---

idealGenerator — Generator of finitely generated ideal

Inherited from `Cat::EuclideanDomain`.

int — Definite and indefinite integration of a polynomial

```
int(a, <x>)
```

```
int(a, <x = x0 .. x1>)
```

`int(a,x=x0..x1)` returns the definite integral $\int_{x0}^{x1} a \, dx$ or `FAIL`, if the result is not an element of this domain or an element of a polynomial domain over `Dom::Fraction(R)`.

This method overloads the function `int` for polynomials.

`intmult` — Multiplie a polynomial with an integer

```
intmult(a, z)
```

This method is more efficient than using polynomial multiplication and is, e.g., necessary for the method `"Dpoly"`.

`irreducible` — Test if element is irreducible

Inherited from `Cat::FactorialDomain`.

`isUnit` — Test if element is a unit

Inherited from `Cat::Polynomial`.

`isone` — Test for one

```
isone(a)
```

Note: The result can only be valid if the coefficients of `a` are in normal form (i.e., if zero has a unique representation in `R`). Thus, `R` should have at least `Ax::normalRep`.

`iszero` — Test for zero

```
iszero(a)
```

Note: The result can only be valid, if the coefficients of `a` are in normal form (i.e., if zero has a unique representation in `R`). Thus, the coefficient ring `R` should have at least `Ax::normalRep`.

`lcm` — Least common multiple of polynomials

```
lcm(a, b, …)
```

This method overloads the function `lcm` for polynomials.

Note: This method only exists if R is a domain of category Cat::GcdDomain.

makeIntegral — Make the coefficients fraction free

```
makeIntegral(a)
```

Note: This method only exists if R is a domain of category Cat::GcdDomain and R has the method "denom".

monic — Normalize a polynomial

```
monic(a)
```

The zero polynomial returns itself.

Note: This method only exists if R is a field, i.e., a domain of category Cat::Field.

normalForm — Complete reduction modulo an ideal

```
normalForm(a, ais, <ord>)
```

```
normalForm(a, ais, <ord>)
```

This method is merely an interface for the function groebner::normalf.

Note: This method only exists if R is a field, i.e., a domain of category Cat::Field, and Vars is not the empty list.

pdioe — Solve polynomial Diophantine equations

```
pdioe(a, b, c)
```

This method overloads the function solvelib::pdioe.

Note: This method only exists if R is a field, i.e., a domain of category Cat::Field and Vars consists of a single variable.

pdivide — Pseudo-division of polynomials

```
pdivide(a, b, <Quo | Rem>)
```

If the option `Quo` is given, only the pseudo-quotient `q` is returned.

If the option `Rem` is given, only the pseudo-remainder `r` is returned.

This method overloads the function `pdivide` for polynomials.

Note: This method only exists if `Vars` consists of a single variable.

---

pquo — Pseudo-quotient of polynomials

```
pquo(a, b)
```

Note: This method only exists if `Vars` consists of a single variable.

---

prem — Pseudo-remainder of polynomials

```
prem(a, b)
```

Note: This method only exists if `Vars` consists of a single variable.

---

primpart — Return primitive part

Inherited from `Cat::Polynomial`.

quo — Euclidean quotient

Inherited from `Cat::EuclideanDomain`.

random — Create a random polynomial

```
random()
```

With every call the global variable `SEED` is changed by a call of `random()`. Thus it is hard to create the same random sequence twice, see `random`.

If the parameter `Vars` is the empty list, first a list of 1 to 4 variables is generated randomly and the random polynomial is generated in these indeterminates afterwards.

This method overloads the function `polylib::randpoly` for polynomials.

`rem` — Euclidean remainder

Inherited from `Cat::EuclideanDomain`.

`resultant` — Resultant of two polynomials

```
resultant(a, b, <var>)
```

`resultant(a, b, var)` returns the resultant of `a` and `b` with respect to the variable `var`.

The value returned is a polynomial of this domain or `FAIL`.

This method overloads the function `polylib::resultant` for polynomials.

Note: This method only exists if `R` has the method `"_divide"`.

`ringmult` — Multiplie a polynomial with a coefficient ring element

```
ringmult(a, c)
```

`solve` — Zero of polynomials

```
solve(a, <var>, <options>)
```

```
solve(a, <vars>, <options>)
```

```
solve(ais, <var>, <options>)
```

```
solve(ais, <vars>, <options>)
```

`solve(ais, ..)` tries to find the zeros of the polynomial system `ais`. The exact behavior depends on further arguments.

For a detailed description of possible return values and options see function `solve`.

This method overloads the function `solve`.

`SPolynomial` — Compute the S-polynomial of two polynomials

```
SPolynomial(a, b, <ord>)
```

This method is merely an interface for the function `groebner::spoly`.

Note: This method only exists if `R` is a field, i.e., a domain of category `Cat::Field`, and `Vars` is not the empty list.

`sqrfree` — Square-free factorization of polynomials

```
sqrfree(a)
```

The `ai` are primitive and pairwise different square-free divisors of `a` and represented as elements of this domain. `u` is a unit of the coefficient ring and represented as an element of this domain. The `ei` are integers.

This method overloads the function `polylib::sqrfree` for polynomials.

Note: This method only exists if `R` is a field, i.e., a domain of category `Cat::Field`, or if `R` is `Dom::Integer`.

`unitNormal` — Return unit normal

Inherited from `Cat::Polynomial`.

`unitNormalRep` — Return unit normal representation

Inherited from `Cat::Polynomial`.

Access Methods

`coeff` — Coefficient of a polynomial

```
coeff(a)
```

```
coeff(a, var, n)
```

```
coeff(a, n)
```

`coeff(a,var,n)` returns the coefficient of the term `var^n`—as an element of this domain if it is of category `Cat::Polynomial(R)`, or as an element of the coefficient ring `R` if it is of `Cat::UnivariatePolynomial(R)`, where `a` is considered as a univariate polynomial in a valid variable `var`.

`coeff(a,n)` returns the coefficient of the term `var^n`—as an element of this domain if it is of category `Cat::Polynomial(R)`, or as an element of the coefficient ring `R` if it is of `Cat::UnivariatePolynomial(R)`, where `a` is considered as a univariate polynomial in `var` and `var` is the main variable of `a`, i.e., the variable returned by `dom::mainvar(a)`.

This method overloads the function `coeff` for polynomials.

`degree` — Degree of a polynomial

```
degree(a)
```

```
degree(a, var)
```

`degree(a, var)` returns the degree of `a` with respect to `var`.

The degree of the zero polynomial is defined as zero.

This method overloads the function `degree` for polynomials.

`degreevec` — Vector of exponents of the leading term of a polynomial

```
degreevec(a, <ord>)
```

The degree vector of the zero polynomial is defined as a list of zeros.

This method overloads the function `degreevec` for polynomials.

`euclideanDegree` — Euclidean degree function

```
euclideanDegree(a)
```

Note: This method only exists if `Vars` consists of a single variable.

`ground` — Ground term of a polynomial

```
ground(a)
```

This method overloads the function `ground` for polynomials.

`has` — Existence of an object in a polynomial

```
has(a, obj)
```

This method overloads the function `has`.

`indets` — Indeterminate of a polynomial

```
indets(<a>)
```

In case `Vars` is not the empty list, `indets` can be called without argument.

Since this domain allows expressions as indeterminates, the returned set may contain expressions, too.

This method overloads the function `indets` for polynomials.

`lcoeff` — Leading coefficient of a polynomial

```
lcoeff(a)
```

```
lcoeff(a, <vars>, <ord>)
```

`lcoeff(a, ord)` returns the leading coefficient of `a` with respect to the monomial ordering `ord` as an element of the coefficient ring `R`.

`lcoeff(a, vars, ord)` returns the leading coefficient of `a` with respect to the variable list `vars` and the monomial ordering `ord` as an element of this domain if it is of category `Cat::Polynomial(R)`, or as an element of the coefficient ring `R` if it is of `Cat::UnivariatePolynomial(R)`.

- If `ord` is not explicitly given, the lexicographical order `LexOrder` will be used instead.
- It tries to convert `a` into a polynomial in the specified list of indeterminates `vars` over the coefficient ring `R` and returns `FAIL` if this conversions fails.

This method overloads the function `lcoeff` for polynomials.

ldegree — Lowest degree of a polynomial

```
ldegree(a)
```

```
ldegree(a, x)
```

`ldegree(a, x)` returns the lowest degree of the variable `x` in `a`.

This method overloads the function `ldegree` for polynomials.

lmonomial — Leading monomial of a polynomial

```
lmonomial(a, <ord>)
```

```
lmonomial(a, <vars>, <ord>, <Rem>)
```

`lmonomial(a, vars, ord)` returns the leading monomial of `a` with respect to the variable list `vars` and the monomial ordering `ord` as an element of this domain.

- If `ord` is not explicitly given, the lexicographical order `LexOrder` will be used instead.
- It tries to convert `a` into a polynomial in the specified list of indeterminates `vars` over the coefficient ring `R` and returns `FAIL` if this conversions fails.

`lmonomial(a, vars, ord, Rem)` returns the list consisting of the leading monomial and the reductum of `a` with respect to the variable list `vars` and the monomial ordering `ord` as a list of elements of this domain.

- If `ord` is not explicitly given, the lexicographical order `LexOrder` will be used instead.
- It tries to convert `a` into a polynomial in the specified list of indeterminates `vars` over the coefficient ring `R` and returns `FAIL` if this conversions fails.

Note: In MuPAD a monomial denotes a coefficient together with a power product as, e.g., $3\,x^2$.

This method overloads the function `lmonomial` for polynomials.

lterm — Leading term of a polynomial

```
lterm(a)
```

```
lterm(a, <vars>, <ord>)
```

`lterm(a, ord)` returns the leading coefficient of `a` with respect to the monomial ordering `ord` as an element of this domain.

`lterm(a, vars, ord)` returns the leading term of `a` with respect to the variable list `vars` and the monomial ordering `ord` as an element of this domain.

- If `ord` is not explicitly given, the lexicographical order `LexOrder` will be used instead.
- It tries to convert `a` into a polynomial in the specified list of indeterminates `vars` over the coefficient ring `R` and returns `FAIL` if this conversions fails.

Note: In MuPAD a term denotes a power product without a coefficient as, e.g., $x^2 y^3 z$.

This method overloads the function `lterm` for polynomials.

`mainvar` — Main variable of a polynomial

```
mainvar(<a>)
```

If `Vars` is not the empty list, `mainvar` can be called without argument.

`mapcoeffs` — Applie a function to the coefficients of a polynomial

```
mapcoeffs(a, f, <e1, …>)
```

This method overloads the function `mapcoeffs` for polynomials.

`multcoeffs` — Multiplie the coefficients of a polynomial with a factor

```
multcoeffs(a, c)
```

This method overloads the function `multcoeffs` for polynomials.

`nterms` — Number of terms of a polynomial

```
nterms(a)
```

This method overloads the function `nterms` for polynomials.

`nthcoeff` — N-th coefficient of a polynomial

```
nthcoeff(a, n, <ord>)
```

If n is larger than the number of monomials of the polynomial then the function returns FAIL.

The zero polynomial has no monomials. nthcoeff returns FAIL when invoked on the zero polynomial.

This method overloads the function nthcoeff for polynomials.

nthmonomial — N-th monomial of a polynomial

```
nthmonomial(a, n, <ord>)
```

If n is larger than the number of monomials of the polynomial then the function returns FAIL.

The zero polynomial has no monomials. nthmonomial returns FAIL for the zero polynomial.

This method overloads the function nthmonomial for polynomials.

nthterm — N-th term of a polynomial

```
nthterm(a, n, <ord>)
```

If n is larger than the number of monomials of the polynomial then the function returns FAIL.

The zero polynomial has no monomials. nthterm returns FAIL when called with the zero polynomial.

This method overloads the function nthterm for polynomials.

orderedVariableList — Ordered list of indeterminates of a polynomial

```
orderedVariableList(<a>)
```

In case Vars is not the empty list, orderedVariableList can be called without an argument.

pivotSize — Size of a pivot element

```
pivotSize(a)
```

This method is called if this domain is used as the component ring of a matrix domain to perform Gaussian elimination.

`reductum` — Reductum of a polynomial

```
reductum(a, <ord>)
```

`subs` — Avoid substitution

Inherited from `Dom::BaseDomain`.

`subsex` — Avoid extended substitution

Inherited from `Dom::BaseDomain`.

`tcoeff` — Lowest coefficient of a polynomial

```
tcoeff(a, <ord>)
```

This method overloads the function `tcoeff` for polynomials.

Conversion Methods

`coerce` — Coerce into this domain

Inherited from `Cat::BaseCategory`.

`convert` — Conversion to a polynomial

```
convert(p)
```

`convert_to` — Convert element

Inherited from `Dom::BaseDomain`.

`expr` — Conversion to a basic type

```
expr(a)
```

This method overloads the function `expr`.

poly — Convert to a basic polynomial domain

```
poly(a)
```

This method overloads the function `poly`.

TeX — TeX formatting of a polynomial

```
TeX(a)
```

TeXCoeff — TeX formatting of a polynomial coefficient

```
TeXCoeff(c)
```

TeXident — TeX formatting of a polynomial indeterminate

```
TeXident(var)
```

TeXTerm — TeX formatting of a polynomial term

```
TeXTerm(t)
```

Technical Methods

adaptIndets — Convert polynomials to common indeterminates

```
adaptIndets(<a, b, …>)
```

Note: This method only exists if the parameter `Vars` is the empty list (`[]`).

---

allAxioms — Return all axioms

Inherited from `Dom::BaseDomain`.

allCategories — Return all categories

Inherited from `Dom::BaseDomain`.

allEntries — Return the names of all entries

Inherited from `Dom::BaseDomain`.

`allSuperDomains` — Return all super-domains

Inherited from `Dom::BaseDomain`.

`getAxioms` — Return axioms stated in the constructor

Inherited from `Dom::BaseDomain`.

`getCategories` — Return categories stated in the constructor

Inherited from `Dom::BaseDomain`.

`getSuperDomain` — Return super-domain stated in the constructor

Inherited from `Dom::BaseDomain`.

`hasProp` — Test for a certain property

Inherited from `Dom::BaseDomain`.

`info` — Print short information about this domain

Inherited from `Dom::BaseDomain`.

`isNeg` — Test on leading output token

```
isNeg(a)
```

`mult` — Multiplie polynomials

```
mult(a, b, …)
```

`new` — Create a new element

```
new(p)
```

```
new(lm)
```

```
new(lm, v)
```

`dom(p)` creates an element of this domain from a polynomial or a polynomial expression `p` and returns that element. If this is not possible, an error message is given.

If `Vars` is chosen as the empty list (`[]`) then in creating new elements from a polynomial or polynomial expression the function `indets` is first called to get the identifiers.

Afterwards the element is created with this list of identifiers. For creating an element from a constant the dummy variable `_dummy` is introduced. The drawback of this approach is that two mathematically equal polynomials may have variable lists which differ by the dummy variable.

`dom(lm)` creates, if `Vars` is not the empty list `[]`, a polynomial from the list `lm` of the form `[[c1, [e11,... e1n]],... [cm,[em1,... emn]]]` where the `ci` are coefficients and the `eij` are the exponents with respect to `Vars`. For a univariate polynomial this list can be simplified to `[[c1,e1],... [cm,em]]`.

`dom(lm,v)` creates, if `Vars = []`, a polynomial from the list `lm` of the form `[[c1, [e11,... e1n]],... [cm,[em1,... emn]]]` where the `ci` are coefficients and the `eij` are the exponents with respect to `v`. For a univariate polynomial this list can be simplified to `[[c1,e1],... [cm,em]]`. The list of indeterminates `v` must contain valid indeterminates.

`plus` — Add polynomials

```
plus(a, b, …)
```

`print` — Print polynomials

```
print(a)
```

This method overloads the function `print`.

`printMethods` — Print out methods

Inherited from `Dom::BaseDomain`.

`printMonomial` — Print a monomial in defined order

```
printMonomial(c, d, v)
```

`printTerm` — Print a term in defined order

```
printTerm(d)
```

```
printTerm(d, v)
```

`printTerm(d,v)` returns an ordered sequence of the indeterminates together with their powers as given in the variable list `v` and the degree vector `d` respectively.

Note that this call is only valid if `nops(v)=nops(d)`.

`Rep` — Data representation of a polynomial

```
Rep(a)
```

`sign` — Leading sign of a polynomial

```
sign(a)
```

Note: this method does not have the meaning of a mathematical sign function!

`testtype` — Test type of object

Inherited from `Cat::BaseCategory`.

`undefinedEntries` — Return missing entries

Inherited from `Dom::BaseDomain`.

`whichEntry` — Return the domain or category implementing an entry

Inherited from `Dom::BaseDomain`.

See Also

MuPAD Domains

`Dom::MultivariatePolynomial` | `Dom::Polynomial` | `Dom::UnivariatePolynomial`

Dom::Expression

Domain of all objects of basic type

Syntax

```
Dom::Expression(x)
```

Description

`Dom::Expression` comprises all objects only consisting of operands of built-in types.

`Dom::Expression` is a façade domain: it has no domain elements, but uses system representation.

Unlike `Dom::ExpressionField`, `Dom::Expression` does not belong to any arithmetical category, and its elements need not be arithmetical expressions.

`Dom::Expression` mainly serves as a super-domain to `Dom::ArithmeticalExpression`; it rarely makes sense to use it directly.

Superdomain

`Dom::BaseDomain`

Axioms

`Ax::systemRep`, `Ax::efficientOperation("_divide")`, `Ax::efficientOperation("_mult")`, `Ax::efficientOperation("_invert")`

Categories

`Cat::BaseCategory`

Examples

Example 1

Almost every MuPAD object can be converted to an expression. Objects of basic type *are* expressions.

```
Dom::Expression([3, array(1..2), rectform(exp(I))])
```

$$[3,\ (\ \mathrm{NIL}\ \ \mathrm{NIL}\ ),\ \cos(1)+\sin(1)\,i]$$

The `convert` method flattens its argument: hence expression sequences are *not* allowed.

```
Dom::Expression((3, x))
```

```
Error: The number of arguments is incorrect. [expr]
  Evaluating: Dom::Expression::new
```

Parameters

x

An object of basic type consisting only of operands of built-in types, or any other object convertible to such using `expr`.

Entries

"randomIdent"	an identifier used for creating random elements

Methods

Conversion Methods

`convert` — Conversion of objects

```
convert(x)
```

`convert_to` — Conversion to other domains

```
convert_to(x, T)
```

`expr` — Just return the argument

```
expr(x)
```

`testtype` — Test whether its argument is an expression

```
testtype(x, Dom::Expression)
```

This method overloads `testtype`; since `Dom::Expression` has no domain elements, the overloading can only be caused by the second argument.

`float` — Convert numbers to floats

```
float(x)
```

Technical Methods

`subs` — Substitution

```
subs(x, s, …)
```

`subsex` — Extended substitution

```
subsex(x, s, …)
```

`random` — Create random expression

```
random()
```

MuPAD Domains
`Dom::ExpressionField`

Dom::ExpressionField

Domains of expressions forming a field

Syntax

Domain Creation

```
Dom::ExpressionField(<Normal, <IsZero>>)
```

Element Creation

```
Dom::ExpressionField(Normal, IsZero)(e)
```

Description

Domain Creation

`Dom::ExpressionField(Normal, IsZero)` creates a domain of expressions forming a field, where the functions `Normal` and `IsZero` are used to normalize expressions and test for zero.

The function `Normal` is used to normalize the expressions representing the elements, the function `IsZero` is used to test the expressions for zero. It is assumed that the field has characteristic 0.

The domain cannot decide if the element expressions—given the normalizing function and zero test—actually form a field. It is up to the user to choose correct functions for normalizing and zero test and to enter only valid expressions as domains elements.

One should view this domain constructor as a pragmatic way to create a field of characteristic 0 in an ad-hoc fashion. Note that the default of using `id` and `iszero` does not yield a field really, but it is often convenient and sensible to use the resulting structure as a field.

`Normal` must be a function which takes an expression representing a domain element and returns the normalized expression. `Normal` should return `FAIL` if the expression is not valid.

If `Normal` is not given, then the system function `id` is used, i.e., only the kernel simplifier is used to normalize expressions.

If a normalizing function other than `id` is given, it is assumed that this functions returns a normal form where the zero element is uniquely represented by the constant `0`.

`IsZero` must be a function which takes an expression representing a domain element and returns `TRUE` if the expression represents zero and `FALSE` otherwise.

If `IsZero` is not given, then `iszero @ Normal` is used for zero testing. If `Normal` is equal to `id` this functional expression is simplified to `iszero`.

If `Normal` is equal to `id` and `IsZero` is equal to `iszero`, a façade domain is created, i.e., the domain elements are simply expressions and are not explicitly created by `new`.

Otherwise the elements of the domain are explicitly created by `new`. Each such element has one operand, which is the expression representing the domain element. The element expressions are normalized after each operation using the function `Normal`.

Element Creation

`Dom::ExpressionField(Normal, IsZero)(e)` creates a field element represented by the expression `e`. The expression is normalized using the function `Normal`.

If `Normal` returns `FAIL`, it is assumed that the expression does not represent a valid field element. If this test is not fully implemented the domain cannot decide if the expression represents a valid field element. In this case it is up to the user to enter only valid expressions as field elements.

If `Normal` is equal to `id` and `IsZero` is equal to `iszero`, the domain is only a façade domain. In this case the expression `e` is returned after being simplified by the built-in kernel simplifier.

Superdomain

If `Normal = id` and `IsZero = iszero`, then `Dom::ArithmeticalExpression`, else `Dom::BaseDomain`.

Axioms

`Ax::indetElements`

If `Normal = id` and `IsZero = iszero`, then `Ax::efficientOperation ("_divide"), Ax::efficientOperation ("_mult"), Ax::efficientOperation("_invert")`, else `Ax::normalRep`.

If `Normal = id` and `IsZero = iszero` and `IsZero = iszero`, then `Ax::systemRep`.

Categories

`Cat::Field`, `Cat::DifferentialRing`

Examples

Example 1

`Dom::ExpressionField(normal)` creates a field of rational expressions over the rationals. The expressions representing the field elements are allways normalized by `normal`:

```
Fn := Dom::ExpressionField(normal):
a := Fn((x^2 - 1)/(x - 1))
```

$$x + 1$$

The field elements are explicit elements of the domain:

```
domtype(a)
```

Dom::ExpressionField(normal, iszero ∘ normal)

Example 2

In the domain `Dom::ExpressionField(id, iszero@normal)` the expressions representing the elements are normalized by the kernel simplifier only:

```
Fi := Dom::ExpressionField(id, iszero@normal):
a := Fi((x^2 - 1)/(x - 1))
```

$$\frac{x^2-1}{x-1}$$

The elements of this domain are not normalized (when viewed as rational expressions over the rationals), thus the domain does not have the axiom `Ax::normalRep`:

```
b := a/Fi(x + 1) - Fi(1)
```

$$\frac{x^2-1}{(x-1)\,(x+1)}-1$$

But nevertheless this domain also represents the field of rational expressions over the rationals, because zero is detected correctly by the function `iszero @ normal`:

```
iszero(b)
```

TRUE

Parameters

`Normal`

A function used to normalize the expressions of the domain; default is `id`.

`IsZero`

A function used to test the expressions of the domain for zero; default is `iszero @ Normal`.

`e`

An expression representing a field element.

Entries

"characteristic"	The characteristic of the fields created by this constructor is assumed to be `0`.
"one"	The element represented by the expression `1` is assumed to be a neutral element w.r.t. `"_mult"`.
"zero"	The element represented by the expression `0` is assumed to be a neutral element w.r.t. `"_plus"`.

Methods

Mathematical Methods

`abs` — Absolute value

```
abs(x)
```

Overloads the function `abs`, thus may be called via `abs(x)`.

`combine` — Combine terms of the same algebraic structure

```
combine(x, <a>)
```

Overloads the function `combine`, thus may be called via `combine(x,...)`.

`conjugate` — Complex conjugate

```
conjugate(x)
```

Overloads the function `conjugate`, thus may be called via `conjugate(x)`.

`D` — Differential operator

```
D(<l>, x)
```

Overloads the function `D`, thus may be called via `D(x)` or `D(l, x)`.

`denom` — Denominator

```
denom(x)
```

Overloads the function `denom`, thus may be called via `denom(x)`.

`diff` — Differentiate an element

```
diff(x, <v, , …>)
```

Overloads the function `diff`, thus may be called via `diff(x,...)`.

`_divide` — Divide elements

```
_divide(x, y)
```

Overloads the function `_divide`, thus may be called via `x/y` or `_divide(x, y)`.

`equal` — Test for mathematical equality

```
equal(x, y)
```

`expand` — Expand an element

```
expand(x)
```

Overloads the function `expand`, thus may be called via `expand(x)`.

`factor` — Factorize an element

```
factor(x)
```

Overloads the function `factor`, thus may be called via `factor(x)`.

`float` — Floating-point approximation

```
float(x)
```

Overloads the function `float`, thus may be called via `float(x)`.

`gcd` — Greatest common divisor

```
gcd(x, …)
```

Overloads the function `gcd`, thus may be called via `gcd(x,...)`.

`Im` — Imaginary part of an element

```
Im(x)
```

Overloads the function `Im`, thus may be called via `Im(x)`.

`int` — Definite and indefinite integration

```
int(x, <v>)
```

Overloads the function `int`, thus may be called via `int(x,...)`.

`intmult` — Integer mutiple

```
intmult(x, n)
```

`_invert` — Invert an element

```
_invert(x)
```

Overloads the function `_invert`, thus may be called via `1/x` or `_invert(x)`.

`iszero` — Test for zero

```
iszero(x)
```

Overloads the function `iszero`, thus may be called via `iszero(x)`.

`lcm` — Least common multiple

```
lcm(x, …)
```

Overloads the function `lcm`, thus may be called via `lcm(x, ...)`.

`_leequal` — Test if less or equal

```
_leequal(x, y)
```

Please note that the function `_leequal` can only test numbers (in a syntactical sense), but not constant expressions like PI or `sqrt(2)`.

Overloads the function `_leequal`, thus may be called via `x <= y`, `y >= x` or `_leequal(x, y)`.

`_less` — Test if element is less

```
_less(x, y)
```

Please note that the function `_less` can only test numbers (in a syntactical sense), but not constant expressions like PI or `sqrt(2)`.

Overloads the function `_less`, thus may be called via `x < y`, `y > x` or `_less(x, y)`.

`limit` — Limit computation

```
limit(x, <v, …>)
```

Overloads the function `limit`, thus may be called via `limit(x,...)`.

`max` — Maximum of arguments

```
max(x, …)
```

Overloads the function `max`, thus may be called via `max(x,...)`.

`min` — Minimum of arguments

```
min(x, …)
```

Overloads the function `min`, thus may be called via `min(x,...)`.

`_mult` — Multiplie elements

```
_mult(x, …)
```

If all arguments are of this domain or can be coerced to this domain (using the method `coerce`), the product of the expressions representing the arguments is calculated using the function `_mult`.

If one of the arguments cannot be coerced, the arguments up to the offending one are multiplied and then the method `"_mult"` of the domain of the offending argument is called to multiply the remaining arguments.

Overloads the function `_mult`, thus may be called via `x*...` or `_mult(x,...)`.

`_negate` — Negate an element

```
_negate(x)
```

Overloads the function `_negate`, thus may be called via `-x` or `_negate(x)`.

`norm` — Norm of an element

```
norm(x)
```

Overloads the function `norm`, thus may be called via `norm(x)`.

Please note that the system function `norm`, applied to an expression, computes the norm of that expression interpreted as a polynomial expression and *not* the absolute value of the expression. This may be regarded as an inconsistency.

`normal` — Normal form

```
normal(x)
```

Overloads the function `normal`, thus may be called via `normal(x)`.

`numer` — Numerator

```
numer(x)
```

Overloads the function `numer`, thus may be called via `numer(x)`.

`_plus` — Add elements

```
_plus(x, …)
```

If all arguments are of this domain or can be coerced to this domain (using the method `coerce`) the sum of the expressions representing the arguments is calculated using the function `_plus`.

If one of the arguments cannot be coerced the arguments up to the offending one are added and then the method `"_plus"` of the domain of the offending argument is called to add the remaining arguments.

Overloads the function `_plus`, thus may be called via `x+...` or `_plus(x,...)`.

`_power` — Exponentiate arguments

```
_power(x, y)
```

```
_power(x, y)
```

If both arguments are of this domain the power is calculated by mapping the function `_power` to the expressions representing the arguments.

If one of the arguments is not of this domain it is coerced to this domain, then the power is computed. If the coercion fails an error is raised.

Note that it is assumed that at least one of the arguments is of this domain.

Overloads the function `_power`, thus may be called via `x^y` or `_power(x, y)`.

`radsimp` — Simplifie radicals

```
radsimp(x)
```

Overloads the function `radsimp`, thus may be called via `radsimp(x)`.

`random` — Create a random element

```
random()
```

See `polylib::randpoly` for details about creating random polynomials.

`Re` — Real part of an element

```
Re(x)
```

Overloads the function `Re`, thus may be called via `Re(x)`.

`sign` — Sign of an element

```
sign(x)
```

Overloads the function `sign`, thus may be called via `sign(x)`.

`simplify` — General simplification of an element

```
simplify(x, <a>)
```

Overloads the function `simplify`, thus may be called via `simplify(x,...)`.

`solve` — Solve an equation

```
solve(x, <a, …>)
```

Note that this method will never return an element of this domain. See `solve` for details about results and optional additional arguments.

Overloads the function `solve`, thus may be called via `solve(x,...)`.

`sqrfree` — Square-free factorization

```
sqrfree(x)
```

Overloads the function `polylib::sqrfree`, thus may be called via `polylib::sqrfree(x)`.

`_subtract` — Subtract elements

```
_subtract(x, y)
```

Overloads the function `_subtract`, thus may be called via `x-y` or `_subtract(x, y)`.

Conversion Methods

`convert` — Convert to this domain

```
convert(x)
```

`convert_to` — Convert to other domain

```
convert_to(x, T)
```

`expr` — Convert to basic type

```
expr(x)
```

This method is called by the function `expr` if a subexpression of the argument is an element of this domain.

`new` — Creating an element

```
new(x)
```

Overloads the function call operator for this domain, thus may be called via `F(x)` where `F` is this domain.

Access Methods

nops — Number of operands

```
nops(x)
```

Overloads the function `nops`, thus may be called via `nops(x)`.

op — Get operands

```
op(x)
```

```
op(x, i)
```

Returns the operand with index `i` of the expression representing `x`. If `i` is `0` then the operator of the expression is returned, which usually is not an element of this domain. The other operands are converted to elements of this domain.

This method is called by the function `op` when an element of this domain is contained, as a subexpression, in the first argument of `op`. Operand ranges and paths are handled by `op` and need not be handled by this method. See `op` for details.

subs — Substitute subexpressions

```
subs(x, e, …)
```

Maps `subs` to the expression representing `x`. The resulting expression is converted to an element of this domain.

This method is called by the function `subs` when an element of this domain is contained, as a subexpression, in the first argument of `subs`. See `subs` for details.

subsex — Extended substitution

```
subsex(x, e, , …)
```

Maps `subsex` to the expression representing `x`. The resulting expression is converted to an element of this domain.

This method is called by the function `subsex` when an element of this domain is contained, as a subexpression, in the first argument of `subsex`. See `subsex` for details.

`subsop` — Substitute operand

```
subsop(x, e, , …)
```

This method is called by the function `subsop` when an element of this domain is contained, as a subexpression, in the first argument of `subsop`. Operand ranges and paths are handled by `subsop` and need not be handled by this method. See `subsop` for details.

Technical Methods

`indets` — Identifier of an element

```
indets(x, <optionName>)
```

Overloads the function `indets`, thus may be called via `indets(x)` and `indets(x, optionName)`, respectively.

`length` — Size of an element

```
length(x)
```

Overloads the function `length`, thus may be called via `length(x)`.

`map` — Applie function to operands

```
map(x, f, <a, …>)
```

Overloads the function `map`, thus may be called via `map(x, f,...)`.

`rationalize` — Approximate floating-point numbers by rationals

```
rationalize(x, <a, …>)
```

Note that this method does *not* overload the function `rationalize` from the standard library package, but the function `numeric::rationalize` from the `numeric` package instead. Thus the method may be called via `numeric::rationalize(x,...)`.

`pivotSize` — Pivot size

```
pivotSize(x)
```

Dom::Float

Real floating-point numbers

Syntax

```
Dom::Float(x)
```

Description

`Dom::Float` is the set of real floating-point numbers represented by elements of the domain `DOM_FLOAT`.

`Dom::Float` is the domain of real floating point numbers represented by expressions of type `DOM_FLOAT`.

`Dom::Float` has category `Cat::Field` out of pragmatism. This domain actually is not a field because `bool(1.0 = float(3) / float(3))` returns `FALSE` for example.

Elements of `Dom::Float` are usually not created explicitly. However, if one creates elements using the usual syntax, it is checked whether the input expression may be converted to a floating point number. This means `Dom::Float` is a facade domain which creates elements of domain type `DOM_FLOAT`.

Viewed as a differential ring `Dom::Float` is trivial, it contains constants only.

`Dom::Float` has the domain `Dom::Numerical` as its super domain, i.e., it inherits each method which is defined by `Dom::Numerical` and not implemented by `Dom::Float`. Methods described below are re-implemented by `Dom::Float`.

Superdomain

`Dom::Numerical`

Axioms

`Ax::canonicalRep`, `Ax::systemRep`, `Ax::canonicalOrder`, `Ax::efficientOperation("_divide")`, `Ax::efficientOperation("_mult")`, `Ax::efficientOperation("_invert")`

Categories

`Cat::DifferentialRing`, `Cat::Field`, `Cat::OrderedSet`

Examples

Example 1

Creating some floating-point numbers using `Dom::Float`. This example also shows that `Dom::Float` is a facade domain.

```
Dom::Float(2.3); domtype(%)
```

```
    2.3

    DOM_FLOAT
```

```
Dom::Float(sin(2/3*PI) + 3)
```

```
    3.866025404
```

```
Dom::Float(sin(x))
```

```
Error: The arguments are invalid. [Dom::Float::new]
```

Example 2

By tracing the method `Dom::Float::testtypeDom` we can see the interaction between `testtype` and `Dom::Float::testtypeDom`.

```
prog::trace(Dom::Float::testtypeDom):
delete x:
testtype(x, Dom::Float);
testtype(3.4, Dom::Float);
prog::untrace(Dom::Float::testtypeDom):

enter Dom::Float::testtypeDom(x, Dom::Float)
computed FAIL

    FALSE

enter Dom::Float::testtypeDom(3.4, Dom::Float)
computed TRUE

    TRUE
```

Parameters

x

An expression which can be converted to a `DOM_FLOAT` by the function `float`.

Entries

"one"	the unit element; it equals `1.0`.
"zero"	The zero element; it equals `0.0`.

Methods

Mathematical Methods

`pivotSize` — Size of a pivot element

`pivotSize(x)`

This method is called if this domain is used as the component ring of a matrix domain to perform Gaussian elimination.

`random` — Random number generation

```
random()
```

Conversion Methods

`convert` — Conversion of objects

```
convert(x)
```

In general, if `float(x)` evaluates to a real floating-point number of type `DOM_FLOAT`, this number is the result of the conversion.

`convert_to` — Conversion to other domains

```
convert_to(x, T)
```

The following domains are allowed for `T`: `DOM_FLOAT`, `Dom::Float` and `Dom::Numerical`.

`testtype` — Type checking

```
testtype(x, T)
```

In general this method is called from the function `testtype` and not directly by the user. “Example 2” on page 7-171 demonstrates this behavior.

Dom::FloatIV

The “field” of Floating Point Intervals

Syntax

```
Dom::FloatIV(x, …)
```

Description

`Dom::FloatIV` is the inclusion algebra of (finite unions of) rectangular intervals in the complex plane.

`Dom::FloatIV` is the domain of kernel intervals of type `DOM_INTERVAL`.

`Dom::FloatIV` has category `Cat::Field` out of pragmatism. This domain actually is not a field because, for example, there is no additive inverse of `1...2`.

Elements of `Dom::FloatIV` are usually not created explicitly. The syntax given above is equivalent to an `interval` call, with no check to ensure that the result is in fact an interval, it could, for example, also be an expression with all numerical coefficients replaced by intervals. Apart from this behavior of the constructor and the `"convert"` slot, `Dom::FloatIV` is a façade domain for elements of domain type `DOM_INTERVAL`.

Viewed as a differential ring `Dom::FloatIV` is trivial, it contains constants only.

`Dom::FloatIV` has the domain `Dom::Numerical` as its super domain, i.e., it inherits each method which is defined by `Dom::Numerical` and not re-implemented by `Dom::FloatIV`. Methods described below are those implemented by `Dom::FloatIV`.

Superdomain

`Dom::Complex` | `Dom::Float` | `Dom::Integer` | `Dom::Interval` | `Dom::Numerical` | `Dom::Rational` | `Dom::Real`

Dom::Fraction

Field of fractions of an integral domain

Syntax

Domain Creation

```
Dom::Fraction(R)
```

Element Creation

```
Dom::Fraction(R)(r)
```

Description

Domain Creation

`Dom::Fraction(R)` creates a domain which represents the field of fractions $F = \left\{ \frac{x}{y} \middle| x \in \mathbb{R}, y \in \mathbb{R} \setminus \{0\} \right\}$ of the integral domain R.

An element of the domain `Dom::Fraction(R)` has two operands, the numerator and denominator.

If `Dom::Fraction(R)` has the axiom `Ax::canonicalRep` (see below), the denominators have unit normal form and the gcds of numerators and denominators cancel.

The domain `Dom::Fraction(Dom::Integer)` represents the field of rational numbers. But the created domain is not the domain `Dom::Rational`, because it uses a different representation of its elements. Arithmetic in `Dom::Rational` is much more efficient than it is in `Dom::Fraction(Dom::Integer)`.

Element Creation

If `r` is a rational expression, then an element of the field of fractions `Dom::Fraction(R)` is created by going through the operands of `r` and converting each operand into an

element of `R`. The result of this process is `r` in the form $\frac{x}{y}$, where x and y are elements of `R`. If `R` has `Cat::GcdDomain`, then x and y are coprime.

If one of the operands can not be converted into the domain `R`, an error message is issued.

Superdomain

`Dom::BaseDomain`

Axioms

`Ax::normalRep`

Categories

`Cat::QuotientField(R)`

Examples

Example 1

We define the field of rational functions over the rationals:

```
F := Dom::Fraction(Dom::Polynomial(Dom::Rational))
```

$$\text{Dom::Fraction(Dom::Polynomial(Dom::Rational, LexOrder))}$$

and create an element of `F`:

```
a := F(y/(x - 1) + 1/(x + 1))
```

$$\frac{x + y + x\,y - 1}{x^2 - 1}$$

To calculate with such elements use the standard arithmetical operators:

```
2*a, 1/a, a*a
```

$$\frac{2x+2y+2xy-2}{x^2-1}, \frac{x^2-1}{x+y+xy-1}, \frac{x^2y^2+2x^2y+x^2+2xy^2-2x+y^2-2y+1}{x^4-2x^2+1}$$

Some system functions are overloaded for elements of domains generated by `Dom::Fraction`, such as `diff`, `numer` or `denom` (see the description of the corresponding methods `"diff"`, `"numer"` and `"denom"` above).

For example, to differentiate the fraction `a` with respect to `x` enter:

```
diff(a, x)
```

$$-\frac{y-2x+2xy+x^2y+x^2+1}{x^4-2x^2+1}$$

If one knows the variables in advance, then using the domain `Dom::DistributedPolynomial` yields a more efficient arithmetic of rational functions:

```
Fxy := Dom::Fraction(
  Dom::DistributedPolynomial([x, y], Dom::Rational)
)
```

Dom::Fraction(Dom::DistributedPolynomial([x, y], Dom::Rational, LexOrder))

```
b := Fxy(y/(x - 1) + 1/(x + 1)):
b^3
```

$$(x^3y^3+3x^3y^2+3x^3y+x^3+3x^2y^3+3x^2y^2-3x^2y-3x^2+3xy^3-3xy^2-3xy+3x+y^3-3y^2+3y-1)/(x^6-3x^4+3x^2-1)$$

Example 2

We create the field of rational numbers as the field of fractions of the integers, i.e., $\mathbb{Q} = \left\{ \frac{x}{y} \;\middle|\; x \in \mathbb{Z}, y \in \mathbb{Z} \setminus \{0\} \right\}$:

```
Q := Dom::Fraction(Dom::Integer):
Q(1/3)
```

$$\frac{1}{3}$$

```
domtype(%)
```

Dom::Fraction(Dom::Integer)

Another representation of $\mathbb{Q}$ in MuPAD is the domain `Dom::Rational` where the rationals are of the kernel domains `DOM_INT` and `DOM_RAT`. Therefore it is much more efficient to work with `Dom::Rational` than with `Dom::Fraction(Dom::Integer)`.

Parameters

`R`

An integral domain, i.e., a domain of category `Cat::IntegralDomain`

`r`

A rational expression, or an element of `R`

Entries

"characteristic"	is the characteristic of `R`.
"coeffRing"	is the integral domain `R`.
"one"	is the one of the field of fractions of `R`, i.e., the fraction 1.
"zero"	is the zero of the field of fractions of `R`, i.e., the fraction 0.

Methods

Mathematical Methods

_divide — Divide two fractions

```
_divide(x, y)
```

This method overloads the function `_divide` for fractions, i.e., one may use it in the form `x / y` or in functional notation: `_divide(x, y)`.

_invert — Invert a fraction

```
_invert(r)
```

This method overloads the function `_invert` for fractions, i.e., one may use it in the form `1/r` or `r^(-1)`, or in functional notation: `_invert(r)`.

_less — Less-than relation

```
_less(q, r)
```

An implementation is provided only if `R` is an ordered set, i.e., a domain of category `Cat::OrderedSet`.

This method overloads the function `_less` for fractions, i.e., one may use it in the form `q < r`, or in functional notation: `_less(q, r)`.

_mult — Multiplie fractions by fractions or rational expressions

```
_mult(q, r)
```

If `q` is not of the domain type `Dom::Fraction(R)`, it is considered as a rational expression which is converted into a fraction over `R` and multiplied with `q`. If the conversion fails, `FAIL` is returned.

The same applies to `r`.

This method also handles more than two arguments. In this case, the argument list is splitted into two parts of the same length which both are multiplied with the function `_mult`. The two results are multiplied again with `_mult` whose result then is returned.

This method overloads the function `_mult` for fractions, i.e., one may use it in the form `q * r` or in functional notation: `_mult(q, r)`.

`_negate` — Negate a fraction

```
_negate(r)
```

This method overloads the function `_negate` for fractions, i.e., one may use it in the form `-r` or in functional notation: `_negate(r)`.

`_power` — Integer power of a fraction

```
_power(r, n)
```

This method overloads the function `_power` for fractions, i.e., one may use it in the form `r^n` or in functional notation: `_power(r, n)`.

`_plus` — Add fractions

```
_plus(q, r, …)
```

If one of the arguments is not of the domain type `Dom::Fraction(R)`, then `FAIL` is returned.

This method overloads the function `_plus` for fractions, i.e., one may use it in the form `q + r` or in functional notation: `_plus(q, r)`.

`D` — Differential operator

```
D(r)
```

An implementation is provided only if `R` is a partial differential ring, i.e., a domain of category `Cat::PartialDifferentialRing`.

This method overloads the operator `D` for fractions, i.e., one may use it in the form `D(r)`.

`denom` — Denominator of a fraction

```
denom(r)
```

This method overloads the function `denom` for fractions, i.e., one may use it in the form `denom(r)`.

`diff` — Differentiation of fractions

```
diff(r, u)
```

This method overloads the function `diff` for fractions, i.e., one may use it in the form `diff(r, u)`.

An implementation is provided only if `R` is a partial differential ring, i.e., a domain of category `Cat::PartialDifferentialRing`.

`equal` — Test on equality of fractions

```
equal(q, r)
```

`factor` — Factorize the numerator and denominator of a fraction

```
factor(r)
```

The factors u, r_1, ..., r_n are fractions of type `Dom::Fraction(R)`, the exponents e_1, ..., e_n are integers.

The system function `factor` is used to perform the factorization of the numerator and denominator of `r`.

This method overloads the function `factor` for fractions, i.e., one may use it in the form `factor(r)`.

`intmult` — Integer multiple of a fraction

```
intmult(r, n)
```

`iszero` — Test for zero

```
iszero(r)
```

An element of the field `Dom::Fraction(R)` is zero if its numerator is the zero element of `R`. Note that there may be more than one representation of the zero element if `R` does not have `Ax::canonicalRep`.

This method overloads the function `iszero` for fractions, i.e., one may use it in the form `iszero(r)`.

`numer` — Numerator of a fraction

```
numer(r)
```

This method overloads the function `numer` for fractions, i.e., one may use it in the form `numer(r)`.

`random` — Random fraction generation

```
random()
```

The returning fraction is normalized (see the methods `"normalize"` and `"normalizePrime"`.

Conversion Methods

`convert_to` — Fraction conversion

```
convert_to(r, T)
```

If the conversion fails, `FAIL` is returned.

The conversion succeeds if `T` is one of the following domains: `Dom::Expression` or `Dom::ArithmeticalExpression`.

Use the function `expr` to convert `r` into an object of a kernel domain (see below).

`expr` — Convert a fraction into an object of a kernel domain

```
expr(r)
```

The result is an object of a kernel domain (e.g., `DOM_RAT` or `DOM_EXPR`).

This method overloads the function `expr` for fractions, i.e., one may use it in the form `expr(r)`.

`TeX` — TeX formatting of a fraction

```
TeX(r)
```

The method `TeX` of the component ring `R` is used to get the TeX-representations of the numerator and denominator of `r`, respectively.

`retract` — Retraction to base domain

```
retract(r)
```

Technical Methods

`normalize` — Normalizing fractions

```
normalize(x, y)
```

Normalization means to remove the gcd of `x` and `y`. Hence, `R` needs to be of category `Cat::GcdDomain`. Otherwise, normalization cannot be performed and the result of this method is the fraction $\frac{x}{y}$.

`normalizePrime` — Normalizing fractions over integral domains with a gcd

```
normalizePrime(x, y)
```

In rings of category `Cat::GcdDomain`, elements are assumed to be relatively prime. Hence, there is no need to normalize the fraction $\frac{x}{y}$.

In rings not of category `Cat::GcdDomain`, normalization of elements can not be performed and the result of this method is the fraction $\frac{x}{y}$.

MuPAD Domains
`Dom::Rational`

Dom::GaloisField

Finite fields

Syntax

Domain Creation

```
Dom::GaloisField(q)
Dom::GaloisField(p, n)
Dom::GaloisField(p, n, f)
Dom::GaloisField(F, n)
Dom::GaloisField(F, n, f)
```

Element Creation

```
Dom::GaloisField(p, n, f)(g)
```

Description

Domain Creation

`Dom::GaloisField(p, n, f)` creates the residue class field Z_p[X]/<f>, a finite field with p^n elements. If `f` is not given, it is chosen at random among all irreducible polynomials of degree n.

`Dom::GaloisField(q)` (where $q = p^n$) is equivalent to `Dom::GaloisField(p,n)`.

`Dom::GaloisField(F, n, f)` creates the residue class field *F[X]/<f>*, a finite field with $|F|^n$ elements.

If `f` is not given, a random irreducible polynomial of appropriate degree is used; some free identifier is chosen as its variable, and this one must also be used when creating domain elements.

Although $n = 1$ is allowed, `Dom::IntegerMod` should be used for representing prime fields.

If `F` is of type `Dom::GaloisField`, consisting of residue classes of polynomials, the variable of these polynomials must be distinct from the variable of `f`. If a tower several of Galois fields is constructed, the variable used in the uppermost Galois field must not equal any of those used in the tower. A special entry `"VariablesInUse"` serves to keep track of all variables appearing somewhere in the tower.

Element Creation

`Dom::GaloisField(p,n,f)(g)` (or, respectively, `Dom::GaloisField(F,n,f)(g)`) creates the residue class of `g` modulo `f`. It is represented by the unique polynomial in that class that has smaller degree than `f`.

Superdomain

`Dom::AlgebraicExtension(Dom::IntegerMod(p), f)`

Axioms

`Ax::canonicalRep`

Categories

`Cat::Field`, `Cat::Algebra(F)`, `Cat::VectorSpace(F)`

Examples

Example 1

We define `L` to be the field with 4 elements. Then $a^4 = a$ for every $a \in L$, by a well-known theorem.

```
L:=Dom::GaloisField(2, 2, u^2+u+1): L(u+1)^4
```

$$u+1$$

Parameters

q

Prime power

p

Prime

n

Positive integer

f

Univariate irreducible polynomial over `Dom::IntegerMod(p)` or `F`, or polynomial expression convertible to such

F

Finite field of type `Dom::IntegerMod` or `Dom::GaloisField`.

g

Univariate polynomial over the ground field in the same variable as `f`, or polynomial expression convertible to such

Entries

"zero"	the zero element of the field
"one"	the unit element of the field
"characteristic"	the characteristic of the field

"size"	the number of elements of the field
"PrimeField"	the prime field, which equals `Dom::IntegerMod(p)`.
"Variable"	the variable of the polynomial `f`.
"VariablesInUse"	a list consisting of `"Variable"` and the variables used by the ground field.

Methods

Mathematical Methods

`iszero` — Test for zero

```
iszero(a)
```

It overloads the function `iszero`.

`_power` — Integer power of an element

```
_power(a, n)
```

It overloads `_power`.

`frobenius` — Frobeniu map

```
frobenius(a)
```

`conjugates` — Conjugate of an element

```
conjugates(a)
```

`order` — Order of an element

```
order(a)
```

`isSquare` — Test whether an element is a square

```
isSquare(a)
```

`ln` — Discrete logarithm

```
ln(a, b)
```

`elementNumber` — Enumerate field elements

```
elementNumber(a)
```

The inverse of this mapping has not been implemented.

`companionMatrix` — Companion matrix of the Galois field over its ground field

```
companionMatrix()
```

`companionPowers` — Power of the companion matrix

```
companionPowers()
```

`matrixRepresentation` — Isomorphism to the algebra generated by the companion matrix

```
matrixRepresentation(a)
```

If A is the companion matrix, the image of $\sum_i a_i X^i$ is $\sum_i a_i A^i$.

`randomPrimitive` — Choose a primitive element at random

```
randomPrimitive()
```

`isBasis` — Test elements for being a basis over the ground field

```
isBasis(l)
```

`isNormal` — Test whether a given field element is normal

```
isNormal(a)
```

`randomNormal` — Choose normal element at random

```
randomNormal()
```

`isPrimitivePolynomial` — Test whether a polynomial over the field is primitive

```
isPrimitivePolynomial(h)
```

Conversion Methods

`convert` — Conversion from other types

```
convert(a)
```

`convert_to` — Conversion to other types

```
convert_to(a, T)
```

MuPAD Domains
`Dom::AlgebraicExtension` | `Dom::IntegerMod`

Dom::ImageSet

Domain of images of sets under mappings

Syntax

Domain Creation

```
Dom::ImageSet()
```

Element Creation

```
Dom::ImageSet(f, x, S)
```

```
Dom::ImageSet(f, [x1, …], [S1, …])
```

Description

Domain Creation

`Dom::ImageSet` is the domain of all sets of complex numbers that can be written as the set of all values taken on by some mapping, i.e., sets of the form $\{f(x_1, \ldots, x_n) \mid x_i \in S_i\}$ for some function f and some sets S_1, …, S_n.

Image sets are mainly used by `solve` to express sets like $\{k\,\pi \mid k \in \mathbb{Z}\}$.

`Dom::ImageSet` belongs to the category `Cat::Set`—arithmetical and set-theoretic operations are inherited from there.

Element Creation

`Dom::ImageSet(f, x, S)` represents the set of all values that can be obtained by substituting some element of `S` for `x` in the expression `f`.

`Dom::ImageSet(f, [x1, ...], [S1, ...])` represents the set of all values that can be obtained by substituting, for each i, the identifier x_i by some element of S_i in the expression `f`.

`Dom::ImageSet(f, x, S)` represents the set $\{f \mid x \in S\}$. `Dom::ImageSet(f, [x1, ..., xn], [S1, ..., Sn])` represents the set $\{f \mid x_i \in S_i\}$, $i = 1 \ldots n$.

`f` need not contain `x`; on the other hand, it may contain other identifiers (free variables).

If a list of several identifiers is given, the identifiers must be distinct.

`S` must be a set; see `solve` for an overview of the different kinds of sets in MuPAD.

`Dom::ImageSet` carries out some automatical simplifications that may produce a result of a type different from `Dom::ImageSet`.

`Dom::ImageSet` renames the variables `x1, ..., xn`, in order to avoid naming conflicts as well as producing a nicer output.

Superdomain

`Dom::BaseDomain`

Categories

`Cat::Set`

Examples

Example 1

We define S to be the set of all integer multiples of π.

```
S:= Dom::ImageSet(ugly*PI, ugly, Z_)
```

$$\{\pi\, k \mid k \in \mathbb{Z}\}$$

Our ugly variable name has been replaced by a nicer one which suggests that it represents an integer.

We may now apply the usual set-theoretic operations.

```
S intersect Dom::Interval(3..7)
```

$$\{\pi, 2\,\pi\}$$

Example 2

An element of an image set may be obtained by substituting all parameters by some values:

```
S:= Dom::ImageSet(a^7 + b^3 + C, [a, b], [Z_, Z_])
```

$$\{k^7 + l^3 + C \mid k \in \mathbb{Z}, l \in \mathbb{Z}\}$$

On calling the `evalParam` method, we have to take care that the variable names have been replaced.

```
Dom::ImageSet::evalParam(S, k = 3, l = 5)
```

$$C + 2312$$

The same may be achieved using the index operator:

```
S[3, 5]
```

$$C + 2312$$

Substituting only for one parameter, we obtain an image set in the other parameter:

```
Dom::ImageSet::evalParam(S, k = 3)
```

$$\{l^3 + C + 2187 \mid l \in \mathbb{Z}\}$$

A parameter may be substituted by itself, meaning that it becomes a free variable:

```
Dom::ImageSet::evalParam(S, k = k)
```

$$\{k^7 + l^3 + C \mid l \in \mathbb{Z}\}$$

The `evalParam` method cannot be used to substitute a free variable:

```
Dom::ImageSet::evalParam(S, C = 3)
```

$$\{k^7 + l^3 + C \mid k \in \mathbb{Z}, l \in \mathbb{Z}\}$$

```
delete S:
```

Parameters

`f`

Arithmetical expression

`x`

Identifier or indexed identifier

`S`

Set of any type

Methods

Mathematical Methods

`changevar` — Change the name of a variable

```
changevar(A, oldvar, newvar)
```

The new variable `newvar` must not equal any element of the list of variables; this is not checked!

`setvar` — Set the name of the variable

```
setvar(A, newvar)
```

```
setvar(A, newvar)
```

For an argument A that is not an image set, the method "setvar" is applied to all image sets contained in the expression A. A might be, for example, a union, intersection, etc. of image sets and other sets.

homogpointwise — Define an n-ary pointwise operator for image sets

```
homogpointwise(Op)
```

Op must accept arithmetical expressions as arguments.

isEmpty — Test whether a set is empty

```
isEmpty(A)
```

substituteBySet — Substitute an ImageSet for a variable

```
substituteBySet(a, x, A)
```

freeIndets — Free parameters of a set

```
freeIndets(A)
```

If $A = \{f(x_1, \ldots, x_n, y_1, \ldots y_k) \mid x_i \in S_i\}$, the x_i are called bound and the y_i are called free parameters.

Use the slot "variables" to obtain the bound parameters.

evalParam — Insert values for bound parameters

```
evalParam(A(x = value, …))
```

If x is not a parameter, but a free variable of A, it is not substituted by value.

value may be an identifier or contain identifiers; in particular, it may contain x and/or some of the remaining parameters. This may be used to convert parameters into free variables.

Several parameters may be replaced in a single call.

See “Example 2” on page 7-197.

`_index` — Extract element by inserting values for bound parameters

```
_index(A, value1, …)
```

The number of values passed must match the number of variables of `A`.

It is not checked whether for each i, the value for the ith parameter belongs to the ith set.

See "Example 2" on page 7-197.

Access Methods

`expr` — Defining mapping as an expression

```
expr(A)
```

This method overloads the function `expr`.

`variables` — List of variables

```
variables(A)
```

The free parameters (identifiers appearing in f other than the x_i) can be obtained using the `"freeIndets"` slot.

`nvars` — Number of variables

```
nvars(A)
```

`sets` — List of sets

```
sets(A)
```

Technical Methods

`print` — Print image set

```
print(A)
```

Dom::Integer

Ring of integer numbers

Syntax

```
Dom::Integer(x)
```

Description

`Dom::Integer` is the ring of integer numbers represented by elements of the domain `DOM_INT`.

Elements of `Dom::Integer` are usually not created explicitly. However, if one creates elements using the usual syntax, it is checked whether the input is an integer number. This means that `Dom::Integer` is a façade domain which creates elements of domain type `DOM_INT`.

Viewed as a differential ring `Dom::Integer` is trivial, it contains constants only.

`Dom::Integer` has the domain `Dom::Numerical` as its super domain, i.e., it inherits each method which is defined by `Dom::Numerical` and not re-implemented by `Dom::Integer`. Methods described below are those implemented by `Dom::Integer`.

Superdomain

`Dom::Numerical`

Axioms

`Ax::canonicalRep`, `Ax::systemRep`, `Ax::canonicalOrder`, `Ax::canonicalUnitNormal`, `Ax::closedUnitNormals`, `Ax::efficientOperation("_divide")`, `Ax::efficientOperation("_mult")`

Categories

`Cat::EuclideanDomain`, `Cat::FactorialDomain`, `Cat::DifferentialRing`, `Cat::OrderedSet`

Examples

Example 1

Creating some integer numbers using `Dom::Integer`. This example also shows that `Dom::Integer` is a façade domain.

```
Dom::Integer(2); domtype(%)
```

```
    2

    DOM_INT
```

```
Dom::Integer(2/3)
```

```
Error: The arguments are invalid. [Dom::Integer::new]
```

Example 2

By tracing the method `Dom::Integer::testtypeDom` we can see the interaction between `testtype` and `Dom::Integer::testtypeDom`.

```
prog::trace(Dom::Integer::testtypeDom):
delete x:
testtype(x, Dom::Integer);
testtype(3, Dom::Integer);
prog::untrace(Dom::Integer::testtypeDom):
```

```
enter Dom::Integer::testtypeDom(x, Dom::Integer)
computed FALSE

    FALSE
```

```
enter Dom::Integer::testtypeDom(3, Dom::Integer)
computed TRUE

    TRUE
```

Parameters

x

An integer

Methods

Mathematical Methods

`associates` — Associate elements

```
associates(x, y)
```

`_divide` — Division of two objects

```
_divide(x, y)
```

`_divides` — Decide if a number divides another one

```
_divides(x, y)
```

`euclideanDegree` — Euclidean degree

```
euclideanDegree(x)
```

`factor` — Factorization

```
factor(x)
```

gcd — Gcd computation

```
gcd(x1, x2, …)
```

gcdex — Applie the extended Euclidean algorithm

```
gcdex(x, y)
```

_invert — Inverse of an element

```
_invert(x)
```

irreducible — Prime number test

```
irreducible(x)
```

isUnit — Test if an element is a unit

```
isUnit(x)
```

lcm — Compute the lcm

```
lcm(x1, x2, …)
```

quo — Compute the euclidean quotient

```
quo(x, y)
```

random — Random number generation

```
random()
```

```
random(n)
```

```
random(m .. n)
```

This methods returns a random number between 0 and n - 1.

This methods returns a random number between `m` and `n`.

rem — Compute the Euclidean reminder

```
rem(x, y)
```

`unitNormal` — Unit normal part

```
unitNormal(x)
```

`unitNormalRep` — Unit normal representation

```
unitNormalRep(x)
```

Conversion Methods

`convert` — Conversion of objects

```
convert(x)
```

`convert_to` — Conversion to other domains

```
convert_to(x, T)
```

The following domains are allowed for `T`: `DOM_INT`, `Dom::Integer`, `Dom::Rational`, `DOM_FLOAT`, `Dom::Float` and `Dom::Numerical`.

`testtype` — Type checking

```
testtype(x, T)
```

Usually, this method is called from the function `testtype` and not directly by the user. “Example 2” on page 7-202 demonstrates this behavior.

Dom::IntegerMod

Residue class rings modulo integers

Syntax

Domain Creation

```
Dom::IntegerMod(n)
```

Element Creation

```
Dom::IntegerMod(n)(a)
```

Description

Domain Creation

`Dom::IntegerMod(n)` creates the residue class ring of integers modulo `n`.

`Dom::IntegerMod(n)` creates the integer residue class rings $\mathbb{Z}/n\mathbb{Z}$.

Element Creation

`Dom::IntegerMod(n)(a)` creates the residue class of `a` modulo `n`.

Superdomain

`Dom::BaseDomain`

Axioms

`Ax::normalRep`, `Ax::canonicalRep`, `Ax::noZeroDivisors`, `Ax::closedUnitNormals`, `Ax::canonicalUnitNormal`,

`Ax::efficientOperation("_invert")`, `Ax::efficientOperation("_divide")`, `Ax::efficientOperation("_mult")`

Categories

If n is prime, then `Cat::Field`, else `Cat::CommutativeRing`.

Examples

Example 1

We define the residue class ring of the integers `mod 7`:

```
Z7:= Dom::IntegerMod(7)
```

```
Dom::IntegerMod(7)
```

Next, we create some elements:

```
a:= Z7(1); b:= Z7(2); c:= Z7(3)
```

```
1 mod 7
```

```
2 mod 7
```

```
3 mod 7
```

We may use infix notation for arithmetical operations since the operators have been overloaded:

```
a + b, a*b*c, 1/c, b/c/a/c
```

```
3 mod 7, 6 mod 7, 5 mod 7, 1 mod 7
```

`a` and `b` are squares while `c` is not:

```
Z7::isSquare(a), Z7::isSquare(b), Z7::isSquare(c)
```

```
TRUE, TRUE, FALSE
```

Indeed, `c` is a generator of the group of units:

```
Z7::order(a), Z7::order(b), Z7::order(c)
```

```
1, 3, 6
```

Parameters

`n`

Positive integer greater than 1

`a`

Any integer or a rational number whose denominator is coprime to `n`

Entries

"characteristic"	the characteristic of the residue class ring, `n`
"one"	the unit element, `1 mod n`
"zero"	the zero element, `0 mod n`

Methods

Mathematical Methods

`_divide` — Division of two elements

```
_divide(element1, element2)
```

`_invert` — Invert elements

```
_invert(element)
```

`_mult` — Multiply elements

```
_mult(element, …)
```

`_negate` — Negate elements

```
_negate(element)
```

`_plus` — Add elements

```
_plus(element, …)
```

`_power` — Power of elements

```
_power(element, power)
```

`_subtract` — Subtraction of two elements

```
_subtract(element1, element2)
```

`D` — Return derivative

Inherited from `Cat::CommutativeRing`.

`associates` — Test for associate elements

Inherited from `Cat::Field`.

`coerce` — Coerce into this domain

Inherited from `Cat::BaseCategory`.

`diff` — Differentiate element

Inherited from `Cat::CommutativeRing`.

`divide` — Division with remainder

Inherited from `Cat::Field`.

`divides` — Test if division is exact

Inherited from `Cat::Field`.

`equal` — Test for mathematical equality

Inherited from `Dom::BaseDomain`.

`equiv` — Test for equivalence

Inherited from `Cat::BaseCategory`.

`euclideanDegree` — Return Euclidean degree

Inherited from `Cat::Field`.

`factor` — Unique factorization

Inherited from `Cat::Field`.

`gcd` — Greatest common divisor

Inherited from `Cat::Field`.

`gcdex` — Extended greatest common divisor

Inherited from `Cat::EuclideanDomain`.

`idealGenerator` — Generator of finitely generated ideal

Inherited from `Cat::EuclideanDomain`.

`irreducible` — Test if element is irreducible

Inherited from `Cat::Field`.

`isUnit` — Test if element is an unit

Inherited from `Cat::Field`.

`isone` — Test if element is one

Inherited from `Cat::Monoid`.

`lcm` — Least common multiple

Inherited from `Cat::GcdDomain`.

quo — Return Euclidean quotient

Inherited from `Cat::Field`.

rem — Return Euclidean remainder

Inherited from `Cat::Field`.

sqrfree — Square-free factorization

Inherited from `Cat::Field`.

testtype — Test type of object

Inherited from `Cat::BaseCategory`.

isSquare — Test for being a square

```
isSquare(element)
```

iszero — Zero test

```
iszero(element)
```

ln — Discrete logarithm

```
ln(element, base)
```

The result is `infinity` if `element` is not in the subgroup generated by `base`.

The result is `FAIL` if `base` is not a unit.

order — Order

```
order(element)
```

The result is `FAIL` if `element` is not a unit.

Access Methods

subs — Avoid substitution

Inherited from `Dom::BaseDomain`.

subsex — Avoid extended substitution

Inherited from `Dom::BaseDomain`.

Conversion Methods

TeX — TeX output

```
TeX(element)
```

convert — Conversion

```
convert(number)
```

The conversion fails if the denominator of `number` and the modulus `n` are not relatively prime.

convert_to — Conversion

```
convert_to(element, d)
```

expr — Convert an element to an expression

```
expr(element)
```

Technical Methods

allAxioms — Return all axioms

Inherited from `Dom::BaseDomain`.

allCategories — Return all categories

Inherited from `Dom::BaseDomain`.

allEntries — Return the names of all entries

Inherited from `Dom::BaseDomain`.

allSuperDomains — Return all super-domains

Inherited from `Dom::BaseDomain`.

`getAxioms` — Return axioms stated in the constructor

Inherited from `Dom::BaseDomain`.

`getCategories` — Return categories stated in the constructor

Inherited from `Dom::BaseDomain`.

`getSuperDomain` — Return super-domain stated in the constructor

Inherited from `Dom::BaseDomain`.

`hasProp` — Test for a certain property

Inherited from `Dom::BaseDomain`.

`info` — Print short information about this domain

Inherited from `Dom::BaseDomain`.

`new` — Create element of this domain

Inherited from `Cat::BaseCategory`.

`print` — Printing elements

```
print(element)
```

`printMethods` — Print out methods

Inherited from `Dom::BaseDomain`.

`random` — Random element

```
random()
```

`undefinedEntries` — Return missing entries

Inherited from `Dom::BaseDomain`.

`unitNormal` — Unit normal form

Inherited from `Cat::Field`.

`unitNormalRep` — Unit normal representation

Inherited from `Cat::Field`.

`whichEntry` — Return the domain or category implementing an entry

Inherited from `Dom::BaseDomain`.

Dom::Interval

Intervals of real numbers

Syntax

```
Dom::Interval(l, r)

Dom::Interval([l], r)

Dom::Interval(l, [r])

Dom::Interval([l], [r])

Dom::Interval([l, r])
```

Description

`Dom::Interval` represents the set of all intervals of real numbers.

`Dom::Interval(l, r)` creates the interval of all real numbers between `l` and `r`. If a border is given as a list with `l` or `r` as the sole element, this border will be regarded as a closed border, otherwise the interval does not contain `l` and `r`.

A border can be any arithmetical expression that could represent a real number, e.g., `sqrt(2*x)` and `a + I`. Properties are ignored.

The domain `Dom::Interval` provides fundamental operations to combine intervals with intervals and other mathematical objects.

The return value can be either an interval of type `Dom::Interval` or the empty set of type `DOM_SET`, if the interval is empty.

Most mathematical operations are overloaded to work with intervals (such as `sin`). If f is a function of n real variables, its extension to intervals is defined to be $f(J_1, \ldots, J_n) = \{f(j_1, \ldots, j_n) \mid j_i \in J_i\}$. The return value of such an operation is in most cases an interval, a union of intervals, a `Dom::ImageSet` or a set. For example,

the sine of an interval `[a, b]` is the interval `{sin(x), x in [a, b]}` that contains all sine values of the given interval. In general, you should expect the return value to be an interval larger than strictly necessary. Also note that, when using the same interval twice in one formula, the uses are regarded as independent, so `interval1/interval1` does not return the interval `[1, 1]` as you might expect.

The functions overloaded in this way are:

- `_mult`, `_divide`, `_invert`, `_power`
- `_plus`, `_negate`, `_subtract`
- `abs`
- `cos`, `arccos`, `cosh`, `arccosh`, `cot`, `arccot`, `coth`, `arccoth`, `csc`, `arccsc`, `csch`, `arccsch`, `sec`, `arcsec`, `sech`, `arcsech`, `sin`, `arcsin`, `sinh`, `arcsinh`, `tan`, `arctan`, `tanh`, `arctanh`
- `dirac`, `heaviside`
- `exp`, `ln`
- `sign`

Furthermore, an interval is a special type of set. This is reflected by `Dom::Interval` having the category `Cat::Set`. Among the methods inherited from `Cat::Set`, the following are especially important: `intersect`, `minus` and `union`.

An interval can be open or closed. If one border is given as a list with one element `[x]`, then this element `x` is taken as border and the interval will be created as closed at this side. If the interval should be closed at both sides, one list with the both borders as arguments can be given.

Superdomain

`Dom::BaseDomain`

Categories

`Cat::Set`, `Cat::AbelianMonoid`

Examples

Example 1

First create a closed interval between 0 and 1.

```
A:= Dom::Interval([0], [1])
```

$$[0, 1]$$

Now another open interval between -1 and 1.

```
B:= Dom::Interval(-1, 1)
```

$$(-1, 1)$$

Intervals can be handled like other objects.

```
A + B, A - B, A*B, A/B
```

$$(-1, 2), (-1, 2), (-1, 1), \mathbb{R}$$

```
2*A, 1 - A, (A - 1)^2
```

$$[0, 2], [0, 1], [0, 1]$$

Example 2

Standard functions are overloaded to work with intervals.

```
sin(B), float(sin(B))
```

$$(-\sin(1), \sin(1)), (-0.8414709848, 0.8414709848)$$

Example 3

The next examples shows some technical methods to access and manipulate intervals.

Get the borders and open/closed information about intervals.

```
A:= Dom::Interval([0], [1]):
Dom::Interval::left(A), Dom::Interval::leftB(A)
```

$$0, [0]$$

```
Dom::Interval::isleftopen(A), Dom::Interval::subsleft(A, -1)
```

$$\mathrm{FALSE}, [-1, 1]$$

Parameters

`l`

The left border. If given as a list of one element (the left border), the interval will be created as left closed.

`r`

The right border. If given as a list of one element (the right border), the interval will be created as right closed.

Entries

"one"	the unit element; it equals the one-point interval [1, 1].
"zero"	the zero element; it equals the one-point interval [0, 0].

Methods

Mathematical Methods

`Im` — Imaginary part of an interval (this always equals zero)

```
Im(interval)
```

`Re` — Real part of an interval (this is the interval)

```
Re(interval)
```

`_divide` — Divide intervals

```
_divide(interval1, interval2)
```

`_intersect` — Intersection of sets

Inherited from `Cat::Set`.

`_invert` — Invert intervals

```
_invert(interval)
```

`_minus` — Set of subtractions

Inherited from `Cat::Set`.

`_mult` — Set of product of set elements

Inherited from `Cat::Set`.

`_negate` — Negate intervals

```
_negate(interval)
```

`_plus` — Set of sums of set elements

Inherited from `Cat::Set`.

`_power` — Pointwise power

Inherited from `Cat::Set`.

`_union` — Union of sets

Inherited from `Cat::Set`.

`abs` — Absolute value of intervals

```
abs(interval)
```

arccos — Inverse cosine of intervals

```
arccos(interval)
```

arccosh — Area cosine of intervals

```
arccosh(interval)
```

arccot — Inverse cotangent of intervals

```
arccot(interval)
```

arccoth — Area cotangent of intervals

```
arccoth(interval)
```

arcsin — Inverse sine of intervals

```
arcsin(interval)
```

arcsinh — Area sine of intervals

```
arcsinh(interval)
```

arctan — Inverse tangent of intervals

```
arctan(interval)
```

arctanh — Area tangent of intervals

```
arctanh(interval)
```

coerce — Coerce into this domain

Inherited from `Cat::BaseCategory`.

contains — Containing an element

```
contains(interval, element)
```

cos — Cosinu of intervals

```
cos(interval)
```

`cosh` — Hyperbolic cosinus of intervals

```
cosh(interval)
```

`cot` — Cotangent of intervals

```
cot(interval)
```

`coth` — Hyperbolic cotangent of intervals

```
coth(interval)
```

`dirac` — Dirac distribution of an interval

```
dirac(interval)
```

`equiv` — Test for equivalence

Inherited from `Cat::BaseCategory`.

`exp` — Exponential function of an interval

```
exp(interval)
```

`heaviside` — Heaviside function

```
heaviside(interval)
```

`intmult` — Return integer multiple

Inherited from `Cat::AbelianMonoid`.

`ln` — Natural logarithm of an interval

```
ln(interval)
```

`max` — Maximum of an interval

```
max(interval, …)
```

The maximum of intervals is the set of all possible results of the function `max` when applied to a sequence of arguments consisting of exactly one element of each interval.

min — Minimum of an interval

```
min(interval, …)
```

The minimum of intervals is defined analogously to their maximum.

new — Create an interval

```
new(left, right)
```

```
new([left], right)
```

```
new(left, [right])
```

```
new([left], [right])
```

sign — Signum of an interval

```
sign(interval)
```

sin — Sine of intervals

```
sin(interval)
```

sinh — Hyperbolic sine of intervals

```
sinh(interval)
```

tan — Tangent of intervals

```
tan(interval)
```

tanh — Hyperbolic tangent of intervals

```
tanh(interval)
```

Access Methods

borders — Border of an interval

```
borders(interval)
```

`left` — Left border of an interval

```
left(interval)
```

`leftB` — Left border of an interval

```
leftB(interval)
```

`isleftopen` — Left open interval

```
isleftopen(interval)
```

`isrightopen` — Right open interval

```
isrightopen(interval)
```

`iszero` — Null interval

```
iszero(interval)
```

`op` — Operand (borders) of an interval

```
op(interval)
```

`subs` — Substitution in intervals

```
subs(Interval, equation, …)
```

`subsex` — Avoid extended substitution

Inherited from `Dom::BaseDomain`.

`subsleft` — Substitute left border

```
subsleft(interval, left)
```

`subsright` — Substitute right border

```
subsright(interval, right)
```

`subsvals` — Substitute both borders

```
subsvals(interval, left, right)
```

Conversion Methods

`convert` — Converting objects to intervals

```
convert(object)
```

If the conversion fails, `FAIL` is returned.

`convert_to` — Convert element

Inherited from `Dom::BaseDomain`.

`float` — Convert to floating-point interval

```
float(interval)
```

`getElement` — One element of an interval

```
getElement(interval)
```

`simplify` — Simplify intervals

```
simplify(interval)
```

`testtype` — Test type of object

Inherited from `Cat::BaseCategory`.

`TeX` — Generate TeX output

Inherited from `Dom::BaseDomain`.

Technical Methods

`allAxioms` — Return all axioms

Inherited from `Dom::BaseDomain`.

`allCategories` — Return all categories

Inherited from `Dom::BaseDomain`.

`allEntries` — Return the names of all entries

Inherited from `Dom::BaseDomain`.

`allSuperDomains` — Return all super-domains

Inherited from `Dom::BaseDomain`.

`emptycheck` — Check intervals

```
emptycheck(interval)
```

`equal` — Comparison of intervals

```
equal(interval, interval)
```

`getAxioms` — Return axioms stated in the constructor

Inherited from `Dom::BaseDomain`.

`getCategories` — Return categories stated in the constructor

Inherited from `Dom::BaseDomain`.

`getSuperDomain` — Return super-domain stated in the constructor

Inherited from `Dom::BaseDomain`.

`hasProp` — Test for a certain property

Inherited from `Dom::BaseDomain`.

`info` — Print short information about this domain

Inherited from `Dom::BaseDomain`.

`map` — Apply functions to intervals

```
map(interval, function, <argument, …>)
```

`mapBorders` — Apply functions to the borders of an interval

```
mapBorders(interval, function, <argument, …>)
```

`print` — Printing intervals

```
print(interval)
```

`printMethods` — Print out methods

Inherited from `Dom::BaseDomain`.

`random` — Random interval

```
random()
```

`undefinedEntries` — Return missing entries

Inherited from `Dom::BaseDomain`.

`whichEntry` — Return the domain or category implementing an entry

Inherited from `Dom::BaseDomain`.

`zip` — Combine intervals

```
zip(interval, interval, function)
```

Algorithms

The operand of an object of `Dom::Interval` is an object of the domain `property::IVnat`, which realizes the basic interval arithmetic. This domain is not documented.

Dom::LinearOrdinaryDifferentialOperator

Domain of linear ordinary differential operators

Syntax

Domain Creation

```
Dom::LinearOrdinaryDifferentialOperator(<Var, <DVar, <Ring>>>)
```

Element Creation

```
Dom::LinearOrdinaryDifferentialOperator(Var, DVar, Ring)(p)
```

```
Dom::LinearOrdinaryDifferentialOperator(Var, DVar, Ring)(l)
```

```
Dom::LinearOrdinaryDifferentialOperator(Var, DVar, Ring)(eq, yx)
```

Description

`Dom::LinearOrdinaryDifferentialOperator(Var, DVar, Ring)` creates the domain of linear ordinary differential operators with coefficients in the differential ring `Ring` and with derivation `Var` where `DVar` is the differential indeterminate. Elements of this domain are also called Ore polynomials and the multiplication of two elements is completely determined by the prescribed rule $\mathrm{Var}\ r = r\ \mathrm{Var} + \frac{\partial}{\partial \mathrm{DVar}}\ r$ for every element `r` in `Ring`. And so `Dom::LinearOrdinaryDifferentialOperator` is a noncommutative ring.

Note: Nevertheless, for some reasons, for every element `r` in `Ring`, `Var*r` is automatically rewritten as `r*Var`. See “Example 1” on page 7-228.

If `Dom::LinearOrdinaryDifferentialOperator` is called without any argument, a domain with coefficients in `Dom::ExpressionField(normal)` with derivation `Df` and differential indeterminate `x` is created.

Note: Only commutative differential rings of type `DOM_DOMAIN` are allowed which inherit from `Dom::BaseDomain`. If `Ring` is of type `DOM_DOMAIN` but does not inherit from `Dom::BaseDomain`, the domain `Dom::ExpressionField(normal)` will be used instead.

Note: It is highly recommend to use only coefficient rings with unique zero representation. Otherwise it can happen that, e.g., a polynomial division will not terminate or a wrong degree will be returned.

Examples

Example 1

First we create the domain of linear ordinary differential operators:

```
lodo := Dom::LinearOrdinaryDifferentialOperator()
```

Dom::LinearOrdinaryDifferentialOperator(Df, x, Dom::ExpressionField(normal, iszero ∘ normal))

by default the above domain has coefficients in the field `Dom::ExpressionField(normal)` with derivation `Df` and differential indeterminate `x`.

We can create elements of `lodo` in 3 ways: polynomials in `Df`, list of elements of `Dom::ExpressionField` and with a linear ordinary homogeneous differential equation:

```
lodo(Df^2 + (x + 1)*Df + 2*x), lodo([2*x, x + 1, 1]),
lodo(diff(y(x),x,x) + (x + 1)*diff(y(x),x) + 2*x*y(x), y(x))
```

$$\mathrm{Df}^2 + (x+1)\,\mathrm{Df} + 2\,x,\ \mathrm{Df}^2 + (x+1)\,\mathrm{Df} + 2\,x,\ \mathrm{Df}^2 + (x+1)\,\mathrm{Df} + 2\,x$$

It's easy to obtain the linear differential equation associated to a linear differential operator:

```
L := lodo((x + x^3)*Df^3 + (6*x^2 + 3)*Df^2 - 12):
L(y(x))
```

$$6\,x^2\,\frac{\partial^2}{\partial x^2}\,y(x) - 12\,y(x) + x\,\frac{\partial^3}{\partial x^3}\,y(x) + x^3\,\frac{\partial^3}{\partial x^3}\,y(x) + 3\,\frac{\partial^2}{\partial x^2}\,y(x)$$

and one can also evaluates a differential operator at an expression:

```
L(2*x^2 + 1), L(ln(x)), L(ln(x), Unsimplified)
```

$$0,\ -\frac{12\,x^2\ln(x)+4\,x^2+1}{x^2},\ \frac{2\,(x^3+x)}{x^3}-\frac{6\,x^2+3}{x^2}-12\ln(x)$$

Multiplication of elements of `lodo` is noncommutative but for every element `r` of the coefficients ring one has `Df*r = r*Df`:

```
lodo(x^2*Df), lodo(Df*x^2), lodo(Df)*lodo(x^2)
```

$$x^2\,\mathrm{Df},\ x^2\,\mathrm{Df},\ x^2\,\mathrm{Df}+2\,x$$

Example 2

`Dom::LinearOrdinaryDifferentialOperator` is a domain where the Euclidean division exists but one has to precise if the multiplication of 2 elements of this domain is made on the right or on the left side:

```
L1 := lodo(x*Df^3 + (x^2 - 3)*Df^2 + 4*x*Df + 2):
lodo::leftDivide(L1,lodo(x*Df + 1))
```

quotient	$\mathrm{Df}^2+\frac{\mathrm{Df}\,\left(x^2-4\right)}{x}+2$
remainder	0

```
lodo(x*Df + 1) * %[quotient] = L1
```

$$x\,\mathrm{Df}^3+(x^2-3)\,\mathrm{Df}^2+(4\,x)\,\mathrm{Df}+2=x\,\mathrm{Df}^3+(x^2-3)\,\mathrm{Df}^2+(4\,x)\,\mathrm{Df}+2$$

Hence one has the notions of greatest common divisor, least common multiple on the right and on the left, and a modified version of the extended Euclidean algorithm:

```
L2 := lodo(x*Df + 1):
```

```
ree := lodo::rightExtendedEuclid(L1,L2)
```

$$\left[\left[-\frac{12}{x^2},\ 1,\ -\mathrm{Df}^2-\frac{x^2-6}{x}\,\mathrm{Df}-\frac{2\,(x^2+6)}{x^2}\right],\right.$$
$$\left.\left[\frac{x^3}{12}\,\mathrm{Df}+\frac{x^2}{4},\ -\frac{x^3}{12}\,\mathrm{Df}^3+\left(\frac{x^2}{4}-\frac{x^4}{12}\right)\mathrm{Df}^2-\frac{x^3}{2}\,\mathrm{Df}-\frac{x^2}{2}\right]\right]$$

The right greatest common divisor and the left least common multiple can be read from the above list:

```
iszero(lodo::rightGcd(L1,L2) - ree[1][1]),
iszero(ree[1][1] - (ree[1][2]*L1 + ree[1][3]*L2)),
iszero(lodo::leftLcm(L1,L2) - (-ree[2][1]*L1)),
iszero(-ree[2][1]*L1 - ree[2][2]*L2)
```

TRUE, TRUE, TRUE, TRUE

Example 3

One can compute polynomial, rational and exponential zeros of linear differential operators of any degree provided the ring `Ring` is the field of rational functions of `x`

```
L3 := lodo((x^2 + 1)*x*Df^3 + 3*(2*x^2 + 1)*Df^2 - 12):
lodo::rationalZeros(L3), lodo::exponentialZeros(L3)
```

$$\left\{x^2+\frac{1}{2}\right\},\ \left\{x^2+\frac{1}{2},\ x\sqrt{x^2+1}\right\}$$

even when the operator contains some parameters rationally:

```
lodo::exponentialZeros(
lodo(Df^4 + (b*l - 2*a^2 - a*l*x)*Df^2 + a^4-a^2*b*l + a^3*l*x))
```

$$\left\{e^{a\,x},\ e^{-a\,x}\right\}$$

Example 4

One can factorize linear differential operators into irreducible factors when the ring `Ring` is the field of rational functions of `x`. Nevertheless, the algorithm is complete only for operators of degree at most 3; for higher degree only left and right factors of degree 1 are found:

```
factor(lodo((x^2 + 1)*x*Df^3 + 3*(2*x^2 + 1)*Df^2 - 12)),
factor(lodo(Df^3 + a*x*Df + a + b^3 + a*b*x))
```

$$((x\,(x^2+1))\,\mathrm{Df}+5\,x^2+3)\left(\mathrm{Df}+\frac{x\,(6\,x^2+5)}{(x^2+1)\,(2\,x^2+1)}\right)\left(\mathrm{Df}-\frac{4\,x}{2\,x^2+1}\right),$$

$$(\mathrm{Df}+b)\,(\mathrm{Df}^2-b\,\mathrm{Df}+a\,x+b^2)$$

Here the operator factors into two factors of degree 2 which cannot be found by MuPAD:

```
factor(lodo(Df^2 + x^3 + 1/x^3) * lodo(Df^2 + x^2 - 1/x^3))
```

$$\mathrm{Df}^4+(x^2+x^3)\,\mathrm{Df}^2+\frac{2\,(2\,x^5+3)}{x^4}\,\mathrm{Df}+\frac{-12\,x+x^5+x^6+x^{11}-1}{x^6}$$

Example 5

Solving linear differential operators using the command `solve` is also possible:

```
solve(lodo(Df^2 + (3 - x)/(16*x^2)))
```

$$\left\{x^{1/4}\,e^{-\frac{\sqrt{x}}{2}},\ x^{1/4}\,e^{\frac{\sqrt{x}}{2}}\right\}$$

For certain cases, where the groups associated to the dfferential operators are finite primitive groups of degree 2, a polynomial is returned corresponding to the minimal polynomial of all zeros of the differential operator (they are algebraic over the base field):

```
solve(lodo(Df^2 +
```

```
(-27*x + 32*x^2 + 27)/(144*x^2 - 288*x^3 + 144*x^4)))
```

$$\left\{\text{RootOf}\left({}_Y1^{24} + \left(-4320\,x^2\,(x-1)^3\right)\,{}_Y1^{16} + \left(\left(51840\,\sqrt{3}\,i\right)x^3\,(x-2)\,(x-1)^4\right)\,{}_Y1^{12} + \left(-2799360\,x^4\,(x-1)^6\right)\,{}_Y1^{8} + \left(\left(4478976\,\sqrt{3}\,i\right)x^5\,(x-2)\,(x-1)^7\right)\,{}_Y1^{4} + 2985984\,x^8\,(x-1)^8,\ {}_Y1\right)\right\}$$

For linear differential operators of degree greater than 3 only exponential zeros will be found:

```
solve(lodo(x*Df^4 + (-x + 4)*Df^3 - 3*Df^2 - x^2*Df - x + x^2))
```

$$\left\{\frac{e^x}{x}\right\}$$

Certain second degree linear differential operator can be solved in terms of some special functions (nonliouvillian functions) such as `airyAi`, `besselI` and `whittakerM`:

```
solve(lodo(Df^2 - (x + 1)/(x - 1)^5))
```

$$\left\{\text{airyAi}\left(\sigma_1,\ 0\right)\,(x-1),\ \text{airyBi}\left(\sigma_1,\ 0\right)\,(x-1)\right\}$$

where

$$\sigma_1 = -\frac{2\,2^{1/3}\,\sqrt{3}\,i + 2\,2^{1/3}\,x + 2\,2^{1/3} + 2\,2^{1/3}\,\sqrt{3}\,x\,i}{8\,x - 8}$$

```
solve(lodo(Df^2 - (243 + 4*x^8 + 162*x^2 + 19*x^4)/
                  36/x^2/(x^2 + 3)^2))
```

$$\left\{\frac{\text{M}_{\frac{1}{2},\,-\frac{2}{3}\left(\frac{x^2}{3}+1\right)}}{\sqrt{x}},\ \frac{\text{W}_{\frac{1}{2},\,-\frac{2}{3}\left(\frac{x^2}{3}+1\right)}}{\sqrt{x}}\right\}$$

Parameters

`Var`

An indeterminate of type `DOM_IDENT`. Default is `Df`.

`DVar`

A differential indeterminate of type `DOM_IDENT`. Default is `x`.

`Ring`

An arbitrary commutative differential ring of characteristic zero. Default is `Dom::ExpressionField(normal)`.

`p`

A polynomial expression in `Var`.

`l`

A list corresponding to the coefficients of the differential operator. If n is the length of `l` then the result returned is `l[1] + l[2]*Var + ... + l[n]*Var^(n-1)`.

`eq`

A linear homogeneous differential equation.

`yx`

A function of `DVar` representing the dependent variable of the above linear differential equation.

Methods

Mathematical Methods

`_mult` — Multiplie linear differential operators

```
_mult(<a, b, …>)
```

This method overloads the function `_mult` of the system kernel, i.e. one may use it either in the form `a * b * ...` or in functional notation `_mult(a, b, ...)`.

`_negate` — Negate a linear differential operator

```
_negate(a)
```

This method overloads the function `_negate` of the system kernel, i.e. one may use it either in the form `-a` or in functional notation `_negate(a)`.

`_plus` — Add linear differential operators and coefficient ring elements

```
_plus(<a, b, …>)
```

This method overloads the function `_plus` of the system kernel, i.e. one may use it either in the form `a + b + ...` or in functional notation `_plus(a, b, ...)`.

`_power` — Nth power of a linear differential operator

```
_power(a, n)
```

This method overloads the function `_power` of the system kernel, i.e., one may use it either in the form `a^n` or in functional notation `_power(a,n)`.

`_subtract` — Subtract a linear differential operator

```
_subtract(a, b)
```

This method overloads the function `_subtract` of the system kernel, i.e. one may use it either in the form `a - b` or in functional notation `_subtract(a, b)`.

`adjoint` — Adjoint of a linear differential operator

```
adjoint(a)
```

`companionSystem` — Companion matrix of a linear differential operator

```
companionSystem(a)
```

If `a` is not of positive degree, an error message is issued.

`D` — Derivative of a linear differential operator

```
D(<l>, a)
```

`Dpoly` — Derivative of a linear differential operator

```
Dpoly(<l>, a)
```

`Dpoly(l,a)` computes the partial derivative of `a` with respect to `l`. If `l = [1,...,1]` with `length(l) = n` then the method computes the `n`-th derivative `a`. If `l = []` then the result returned is `a`.

`evalLODO` — Applie an expression to a linear differential operator

```
evalLODO(a, f)
```

This method may be used either in the form `a(f)` or in functional notation `evalLODO(a,f)`.

`exponentialZeros` — Exponential zeros of a linear differential operator

```
exponentialZeros(a)
```

Note: This method only works when `Ring` is the field of rational functions in `DVar`.

`factor` — Factor a linear differential operator

```
factor(a)
```

Note: This method is only available when the base field `Ring` is the field of rational functions in `DVar`. If `a` is of degree greater than or equal to 4 then only left and right factors of degree 1 of `a` will be found. Otherwise, a complete factorization is returned.

This method overloads the function `factor` of the system kernel.

`factors` — List of irreducible factors of a linear differential operator

```
factors(a)
```

`func_call` — Applie an expression to a linear differential operator

```
func_call(a, f, <Unsimplified>)
```

This method may be used either in the form `a(f)` or in functional notation `func_call(a,f)`.

`leftDivide` — Left division of 2 linear differential operators

```
leftDivide(a, b)
```

`leftExtendedEuclid` — Left extended Euclidean algorithm for linear differential operators

```
leftExtendedEuclid(a, b)
```

`leftExtendedGcd` — Coefficient in the left extended Euclidean algorithm

```
leftExtendedGcd(a, b)
```

`leftGcd` — Left greatest common divisor of linear differential operators

```
leftGcd(a, b)
```

`leftLcm` — Left least common multiple of linear differential operators

```
leftLcm(a, b)
```

`leftQuotient` — Left quotient of linear differential operators

```
leftQuotient(a, b)
```

`leftRemainder` — Left remainder of linear differential operators

```
leftRemainder(a, b)
```

`makeIntegral` — Integral form of a linear differential operator

```
makeIntegral(a)
```

`monic` — Normalize a linear differential operator

```
monic(a)
```

`polynomialZeros` — Polynomial zeros of a linear differential operator

```
polynomialZeros(a)
```

Note: This method only works when `Ring` is the field of rational functions in `DVar`.

`rationalZeros` — Rational zeros of a linear differential operator

```
rationalZeros(a)
```

Note: This method only works when `Ring` is the field of rational functions in `DVar`.

`rightDivide` — Right division of 2 linear differential operators

```
rightDivide(a, b)
```

`rightExtendedEuclid` — Right extended Euclidean algorithm for linear differential operators

```
rightExtendedEuclid(a, b)
```

`rightExtendedGcd` — Coefficient in the right extended Euclidean algorithm

```
rightExtendedGcd(a, b)
```

`rightGcd` — Right greatest common divisor of linear differential operators

```
rightGcd(a, b)
```

`rightLcm` — Right least common multiple of linear differential operators

```
rightLcm(a, b)
```

`rightQuotient` — Right quotient of linear differential operators

```
rightQuotient(a, b)
```

`rightRemainder` — Right remainder of linear differential operators

```
rightRemainder(a, b)
```

`solve` — Zero of a linear differential operator

```
solve(a, <Transform>, <Irreducible>)
```

The algorithm for finding liouvillian solutions is complete for operators of degree at most 2 and enables to solve partially operators of higher degree (i.e. it finds all exponential solutions). The algorithm for finding solutions in terms of special functions (nonliouvillian solutions) is not complete even for the degree 2.

When option `Transform` is given the unimodular transformation is performed unconditionally and when option `Irreducible` is given, `a` is assumed to be irreducible.

Note: This method only works when `Ring` is the field of rational functions in `DVar`.

This method overloads the function `solve` of the system kernel.

`symmetricPower` — Symmetric power of a linear differential operator

```
symmetricPower(a, m)
```

`unimodular` — Unimodular transformation of a linear differential operator

```
unimodular(a, <Transform>)
```

If the option `Transform` is given then `a` is transformed unconditionally even if `a` has yet a unimodular Galois group.

Access Methods

`coeff` — Coefficient of a linear differential operator

```
coeff(a)
```

```
coeff(a, Var, n)
```

```
coeff(a, n)
```

`coeff(a,Var,n)` returns the coefficient of the term `Var^n` as an element of the coefficient ring `Ring`, where `a` is a linear differential operator in the variable `Var`.

`coeff(a,n)` returns the coefficient of the term `Var^n` as an element of the coefficient ring `Ring`, where `a` is a linear differential operator in the variable `Var`.

This method overloads the function `coeff` of the system kernel.

`degree` — Degree of a linear differential operator

```
degree(a)
```

The degree of the zero polynomial is defined as zero.

This method overloads the function `degree` for polynomials.

`vectorize` — List of coefficients of a linear differential operator

```
vectorize(a)
```

Conversion Methods

`convert` — Conversion to a linear differential operator

```
convert(a)
```

`FAIL` is returned if the conversion fails.

`expr` — Conversion into an object of a kernel domain

```
expr(a)
```

This method overloads the function `expr` of the system kernel.

`TeX` — TeX formatting of a linear differential operator

```
TeX(a)
```

This method is used by the function `generate::TeX`.

Description

Domain Creation

`Dom::Matrix(R)` creates domains of matrices over a component domain `R` of category `Cat::Rng` (a ring, possibly without unit).

If the optional parameter `R` is not given, `Dom::ExpressionField()` is used as component domain. Matrices of this type accept arbitrary MuPAD expressions (numbers, symbols etc.) as entries. The name `matrix` is an alias for this default matrix domain `Dom::Matrix()`.

A vector with n entries is either an $n \times 1$ matrix (a column vector), or a $1 \times n$ matrix (a row vector).

Arithmetical operations with matrices can be performed by using the standard arithmetical operators of MuPAD.

E.g., if `A` and `B` are two matrices defined by `Dom::Matrix(R)`, `A + B` computes the sum, and `A * B` computes the product of the two matrices, provided that the dimensions are appropriate.

Similarly, `A^(-1)` or `1/A` computes the inverse of a square matrix `A` if it exists. Otherwise, `FAIL` is returned. See “Example 1” on page 7-246.

Many system functions are overloaded for matrices, such as `map`, `subs`, `has`, `zip`, E.g., use `conjugate` to compute the complex conjugate of a matrix, `norm` to compute matrix norms, or `exp` to compute the exponential of a matrix.

Most of the functions in the MuPAD linear algebra package linalg work with matrices. For example, the command `linalg::gaussJordan(A)` performs Gauss-Jordan elimination on `A` to transform `A` to its reduced row echelon form.

See the documentation of linalg for a list of available functions of this package.

The domain `Dom::Matrix(R)` represents matrices over `R` of arbitrary size. Therefore, it does not have any algebraic structure (other than being a *set* of matrices).

In this help page, we use the following notations for a matrix A (an element of `Dom::Matrix(R)`):

- *nrows*(A) denotes the number of rows of A.
- *ncols*(A) denotes the number of columns of A.
- A *row index* is an integer in the range from 1 to *nrows*(A).
- A *column index* is an integer in the range from 1 to *ncols*(A).

Note: The number of rows and columns, respectively, of a matrix must be less than 2^{31}.

Note: The components of a matrix are no longer evaluated after the creation of the matrix, i.e., if they contain free identifiers they will not be replaced by their values.

Element Creation

`Dom::Matrix(R)(Array)` and `Dom::Matrix(R)(Matrix)` create a new matrix with the dimension and the components of `Array` and `Matrix`, respectively.

The components of `Array` or `Matrix` are converted to elements of the domain `R`. An error message is issued if one of these conversions fails.

The creation of (sparse) matrices via arrays is useful for matrices of moderate size. Note that indexed assignments to arrays are much faster than the corresponding indexed assignments to matrices. However, since all elements of the array (including the zeroes) need to be filled in before conversion to a (sparse) matrix, memory is wasted for very large and very sparse matrices. In such a situation, one should define a table containing only the non-zero elements and convert the table to a matrix (see below).

`Dom::Matrix(R)(List)` creates an $m \times 1$ column vector with components taken from the nonempty list, where m is the number of entries of `List`.

One may also use a list of equations to create an object of `Dom::Matrix`. In this case the entries of the list must be of the form `(i, j) = value`, where `i` and `j` denote the row

and column index and `value` the coefficient of the matrix. `i` and `j` need to be positive integers.

`Dom::Matrix(R)(ListOfRows)` creates an $m \times n$ matrix with components taken from the nested list `ListOfRows`, where m is the number of inner lists of `ListOfRows`, and n is the maximal number of elements of an inner list. Each inner list corresponds to a row of the matrix. Both m and n must be non-zero.

If an inner list has less than n entries, the remaining components in the corresponding row of the matrix are set to zero.

The entries of the inner lists are converted to elements of the domain `R`. An error message is issued if one of these conversions fails.

The call `Dom::Matrix(R)(m, n)` returns the $m \times n$ zero matrix.

Use the method `"identity"` to create the $n \times n$ identity matrix.

The call `Dom::Matrix(R)(m, n, Array)` creates an $m \times n$ matrix with components taken from `Array`, which must be an array or an hfarray. `Array` must have $m\,n$ operands. The first m operands define the first row, the next m operands define the second row, etc. The formatting of the array is irrelevant. E.g., any array with 6 elements can be used to create a matrix of dimension 1×6, or 2×3, or 3×2, or 6×1.

`Dom::Matrix(R)(m, n, List)` creates an $m \times n$ matrix with components taken row after row from the non-empty list. The list must contain $m\,n$ entries.

`Dom::Matrix(R)(m, n, ListOfRows)` creates an $m \times n$ matrix with components taken from the list `ListOfRows`.

If $m \geq 2$ and $n \geq 2$, then `ListOfRows` must consist of at most `m` inner lists, each having at most `n` entries. The inner lists correspond to the rows of the returned matrix.

If an inner list has less than `n` entries, the remaining components of the corresponding row of the matrix are set to zero. If there are less than `m` inner lists, the remaining lower rows of the matrix are filled with zeroes.

`Dom::Matrix(R)(m, n, Table)` creates an $m \times n$ matrix with components taken from the table `Table`.

By defining the entries of the table first, one can easily create large and sparse matrices. The entry `Table[i, j]` of the table will be the entry in the `i`-th row and the `j`-th

column of the matrix. Therefore, the table needs to be indexed by positive integers `i` and `j`.

`Dom::Matrix(R)(m, n, [(i1, j1) = value1, (i2, j2) = value2, ...])` is a further way to create a matrix specifying only the non-zero entries `A[i1, j1] = value1`, `A[i2, j2] = value2` etc. The ordering of the entries in the input list is irrelevant.

`Dom::Matrix(R)(m, n, f)` returns the matrix whose (i, j)-th component is the value of the function call `f(i, j)`. The row index i ranges from 1 to m and the column index j from 1 to n.

The function values are converted to elements of the domain `R`. An error message is issued if one of these conversions fails.

`Dom::Matrix(R)(1, n, Array)` returns the $1 \times n$ row vector with components taken from `Array`. The `array` or `hfarray` `Array` must have `n` entries.

The entries of the array are converted to elements of the domain `R`. An error message is issued if one of these conversions fails.

`Dom::Matrix(R)(1, n, List)` returns the $1 \times n$ row vector with components taken from `List`. The list `List` must have at most `n` entries. If there are fewer entries, the remaining vector components are set to zero.

The entries of the list are converted to elements of the domain `R`. An error message is issued if one of these conversions fails.

`Dom::Matrix(R)(1, n, Table)` returns the $1 \times n$ row vector with components taken from `Table`. The table `Table` must not have more than `n` entries. If there are fewer entries, the remaining vector components are regarded as zero.

`Dom::Matrix(R)(m, 1, Array)` returns the $m \times 1$ column vector with components taken from `Array`. The `array` or `hfarray` `Array` must have `m` entries.

The entries of the array are converted to elements of the domain `R`. An error message is issued if one of these conversions fails.

`Dom::Matrix(R)(m, 1, List)` returns the $m \times 1$ column vector with components taken from `List`. The list `List` must have at most `m` entries. If there are fewer entries, the remaining vector components are set to zero.

The entries of the list are converted to elements of the domain `R`. An error message is issued if one of these conversions fails.

`Dom::Matrix(R)(m, 1, Table)` returns the $m \times 1$ column vector with components taken from `Table`. The table `Table` must have no more than `m` entries. If there are fewer entries, the remaining vector components are regarded as zero.

Examples

Example 1

Whenever possible, one should use `Dom::ExpressionField()` as the coefficient domain of matrices – therefore `Dom::ExpressionField()` is the default coefficient domain of matrices.

The components of matrices over `Dom::ExpressionField()` can be arbitrary arithmetical expressions. Consider

```
Mat := Dom::Matrix()
```

```
Dom::Matrix()
```

We assigned the domain to the identifier `Mat` and now we can define a matrix A of two rows, where each row is a list of two elements by the following line:

```
A := Mat([[1, 5], [2, 3]])
```

$$\begin{pmatrix} 1 & 5 \\ 2 & 3 \end{pmatrix}$$

In the same way, we define the following 2 ×3 matrix:

```
B := Mat([[-1, 5/2, 3], [1/3, 0, 2/5]])
```

$$\begin{pmatrix} -1 & \frac{5}{2} & 3 \\ \frac{1}{3} & 0 & \frac{2}{5} \end{pmatrix}$$

and perform matrix arithmetic using the standard arithmetical operators of MuPAD, e.g., the matrix product $A\,B$, the fourth power of A as well as the scalar multiplication of A times $\frac{1}{3}$:

```
A * B, A ^ 4, 1/3 * A
```

$$\begin{pmatrix} \frac{2}{3} & \frac{5}{2} & 5 \\ -1 & 5 & \frac{36}{5} \end{pmatrix}, \begin{pmatrix} 281 & 600 \\ 240 & 521 \end{pmatrix}, \begin{pmatrix} \frac{1}{3} & \frac{5}{3} \\ \frac{2}{3} & 1 \end{pmatrix}$$

The matrices A and B have different dimensions, and therefore the sum of A and B is not defined. MuPAD issues an error message:

```
A + B
```

```
Error: The dimensions do not match. [(Dom::Matrix(Dom::ExpressionField()))::_plus]
```

To compute the inverse of A, just enter:

```
1/A
```

$$\begin{pmatrix} -\frac{3}{7} & \frac{5}{7} \\ \frac{2}{7} & -\frac{1}{7} \end{pmatrix}$$

If a matrix is not invertible, `FAIL` is the result of this operation. For example, the matrix:

```
C := Mat(2, 2, [[2]])
```

$$\begin{pmatrix} 2 & 0 \\ 0 & 0 \end{pmatrix}$$

is not invertible, hence:

```
C^(-1)
```

FAIL

```
delete A, B, C:
```

Example 2

We create the domain of matrices over the coeffcient ring `Dom::ExpressionField()`:

```
Mat := Dom::Matrix()
```

Dom::Matrix()

Beside standard matrix arithmetic, the library linalg offers many functions dealing with matrices. For example, if one wants to compute the rank of a matrix, use `linalg::rank`:

```
A := Mat([[1, 2], [2, 4]])
```

$$\begin{pmatrix} 1 & 2 \\ 2 & 4 \end{pmatrix}$$

```
linalg::rank(A)
```

1

Use `linalg::eigenvectors` to compute eigenvalues and eigenvectors of the matrix A:

```
linalg::eigenvectors(A)
```

$$\left[\left[0,\ 1,\ \left[\begin{pmatrix} -2 \\ 1 \end{pmatrix}\right]\right],\ \left[5,\ 1,\ \left[\begin{pmatrix} \frac{1}{2} \\ 1 \end{pmatrix}\right]\right]\right]$$

Try `info(linalg)` for a list of available functions, or enter `help(linalg)` for details about the library linalg.

Some of the functions in the `linalg` package simply serve as "interface" functions for methods of a matrix domain described above. For example, `linalg::transpose` uses the method `"transpose"` to get the transposed matrix. The function `linalg::gaussElim` applies Gaussian elimination to a matrix by calling the method `"gaussElim"`:

```
linalg::gaussElim(A) = A::dom::gaussElim(A)[1]
```

$$\begin{pmatrix} 1 & 2 \\ 0 & 0 \end{pmatrix} = \begin{pmatrix} 1 & 2 \\ 0 & 0 \end{pmatrix}$$

In contrast to the methods of the domain `Dom::Matrix(R)`, the corresponding functions of the `linalg` packages do extended checking of their input parameters. Note that there might be minor differences in the functionality of the `linalg` functions and the matrix methods. E.g., the option `ColumnElimination` is not available in `linalg::gaussElim`, but only in the `"gaussElim"` method of the matrix domain:

```
A::dom::gaussElim(A, ColumnElimination)
```

$$\left[\begin{pmatrix} 1 & 0 \\ 2 & 0 \end{pmatrix}, 1, 0, \{1\}\right]$$

```
delete A:
```

Example 3

We create the default matrix domain `Dom::Matrix()`. As a shortcut, this domain can also be created via `matrix`:

```
A := matrix([[ 1, 2, 3, 4],
             [ 2, 0, 4, 1],
             [-1, 0, 5, 2]])
```

$$\begin{pmatrix} 1 & 2 & 3 & 4 \\ 2 & 0 & 4 & 1 \\ -1 & 0 & 5 & 2 \end{pmatrix}$$

```
domtype(A)
```

```
Dom::Matrix()
```

Matrix components can be extracted by the index operator `[]`:

```
A[2, 1] * A[1, 2] - A[3, 1] * A[1, 3]
```

```
7
```

If one of the indices is not in its valid range, an error message is issued. Assignments to matrix components are performed similarly:

```
delete a:
A[1, 2] := a^2: A
```

$$\begin{pmatrix} 1 & a^2 & 3 & 4 \\ 2 & 0 & 4 & 1 \\ -1 & 0 & 5 & 2 \end{pmatrix}$$

Beside the usual indexing of matrix components, it is also possible to extract submatrices from a given matrix. The following call creates the submatrix of A which consists of the rows 2 to 3 and columns 1 to 3 of A:

```
A[2..3, 1..3]
```

$$\begin{pmatrix} 2 & 0 & 4 \\ -1 & 0 & 5 \end{pmatrix}$$

The index operator does not allow to insert submatrices into a given matrix. This is implemented by the function `linalg::substitute`.

```
delete A:
```

Example 4

In the following examples, we demonstrate the different ways of creating matrices. We work with matrices defined over the field $\mathbb{Z}_{19}$, i.e., the field of integers modulo 19. This component ring can be created with the domain constructor `Dom::IntegerMod`.

We start by giving a list of rows, where each row is a list of row entries:

```
MatZ19 := Dom::Matrix(Dom::IntegerMod(19)):
MatZ19([[1, 2], [2]])
```

$$\begin{pmatrix} 1 \bmod 19 & 2 \bmod 19 \\ 2 \bmod 19 & 0 \bmod 19 \end{pmatrix}$$

The elements of the two inner lists, the row entries, were converted to elements of the domain `Dom::IntegerMod(19)`.

The number of rows is the number of sublists of the argument, i.e., $m = 2$. The number of columns is determined by the length of the inner list with the most entries, which is the first inner list with two entries. Missing entries in the other inner lists are treated as zero components. The call:

```
MatZ19(4, 4, [[1, 2], [2]])
```

$$\begin{pmatrix} 1 \bmod 19 & 2 \bmod 19 & 0 \bmod 19 & 0 \bmod 19 \\ 2 \bmod 19 & 0 \bmod 19 & 0 \bmod 19 & 0 \bmod 19 \\ 0 \bmod 19 & 0 \bmod 19 & 0 \bmod 19 & 0 \bmod 19 \\ 0 \bmod 19 & 0 \bmod 19 & 0 \bmod 19 & 0 \bmod 19 \end{pmatrix}$$

fixes the dimension of the matrix. Missing entries and inner lists are treated as zero components and zero rows, respectively.

An error message is issued if one of the given entries cannot be converted to an element over $\mathbb{Z}_{19}$:

```
MatZ19([[2, 3], [-1, I]])
```

```
Error: Cannot define a matrix over 'Dom::IntegerMod(19)'. [(Dom::Matrix(Dom::IntegerMod
```

```
delete MatZ19:
```

Example 5

This example illustrates how to create a matrix with components given as values of an index function. First we create the 2 ×2 Hilbert matrix (see also the functions `linalg::hilbert` and `linalg::invhilbert`):

```
Dom::Matrix()(2, 2, (i, j) -> 1/(i + j - 1))
```

$$\begin{pmatrix} 1 & \frac{1}{2} \\ \frac{1}{2} & \frac{1}{3} \end{pmatrix}$$

Note the difference when working with expressions and functions. If you give an expression it is treated as a function in the row and column indices:

```
delete x:
Dom::Matrix()(2, 2, x), Dom::Matrix()(2, 2, (i, j) -> x)
```

$$\begin{pmatrix} x(1,1) & x(1,2) \\ x(2,1) & x(2,2) \end{pmatrix}, \begin{pmatrix} x & x \\ x & x \end{pmatrix}$$

Example 6

Diagonal matrices can be created with the option `Diagonal` and a list of diagonal components:

```
Mat := Dom::Matrix():
Mat(3, 4, [1, 2, 3], Diagonal)
```

$$\begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 2 & 0 & 0 \\ 0 & 0 & 3 & 0 \end{pmatrix}$$

Hence, to define the $n \times n$ identity matrix, you can enter:

```
Mat(3, 3, [1 $ 3], Diagonal)
```

$$\begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}$$

or call:

```
Mat(3, 3, x -> 1, Diagonal)
```

$$\begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}$$

The easiest way to create the identity matrix, however, is to use the method `"identity"`:

```
Mat::identity(3)
```

$$\begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}$$

```
delete Mat:
```

Example 7

Toeplitz matrices can be defined with the option `Banded`. The following call defines a three-banded matrix with the component 2 on the main diagonal and the component - 1 on the first subdiagonal and superdiagonal:

```
Dom::Matrix()(4, 4, [-1, 2, -1], Banded)
```

$$\begin{pmatrix} 2 & -1 & 0 & 0 \\ -1 & 2 & -1 & 0 \\ 0 & -1 & 2 & -1 \\ 0 & 0 & -1 & 2 \end{pmatrix}$$

Example 8

Some system functions can be applied to matrices, such as `norm`, `expand`, `diff`, `conjugate`, or `exp`.

For example, to expand the components of the matrix:

```
delete a, b:
A := Dom::Matrix()(
  [[(a - b)^2, a^2 + b^2], [a^2 + b^2, (a - b)*(a + b)]]
```

```
)
```

$$\begin{pmatrix} (a-b)^2 & a^2+b^2 \\ a^2+b^2 & (a+b)\,(a-b) \end{pmatrix}$$

enter:

```
expand(A)
```

$$\begin{pmatrix} a^2-2\,a\,b+b^2 & a^2+b^2 \\ a^2+b^2 & a^2-b^2 \end{pmatrix}$$

If you want to differentiate the matrix components, then call for example:

```
diff(A, a)
```

$$\begin{pmatrix} 2\,a-2\,b & 2\,a \\ 2\,a & 2\,a \end{pmatrix}$$

To substitute matrix components by some values, enter:

```
subs(A, a = 1, b = -1)
```

$$\begin{pmatrix} 4 & 2 \\ 2 & 0 \end{pmatrix}$$

The function `zip` can also be applied to matrices. The following call combines two matrices *A* and *B* by dividing each component of *A* by the corresponding component of *B*:

```
A := Dom::Matrix()([[4, 2], [9, 3]]):
B := Dom::Matrix()([[2, 1], [3,-1]]):
zip(A, B, `/`)
```

$$\begin{pmatrix} 2 & 2 \\ 3 & -3 \end{pmatrix}$$

The quoted character `` `/` `` is another notation for the function `_divide`, the functional form of the division operator `/`.

If one needs to apply a function to the components of a matrix, then use the function `map`. For example, to simplify the components of the matrix:

```
C := Dom::Matrix()(
  [[sin(x)^2 + cos(x)^2, cos(x)*tan(x)],
  [(a^2 - b^2)/(a + b), 1]]
)
```

$$\begin{pmatrix} \cos(x)^2+\sin(x)^2 & \cos(x)\tan(x) \\ \frac{a^2-b^2}{a+b} & 1 \end{pmatrix}$$

call:

```
map(C, Simplify)
```

$$\begin{pmatrix} 1 & \sin(x) \\ a-b & 1 \end{pmatrix}$$

```
delete A, B, C:
```

Example 9

However, there may appear some unexpected results using the function `diff` in the context of matrices. The derivative of the following unspecified function `f` of a matrix is computed due to the chain rule:

```
diff(f(matrix([[a*x^2, b], [c, d]])), x)
```

$$\begin{pmatrix} 2\,a\,x\,f'\left(\begin{pmatrix} a\,x^2 & b \\ c & d \end{pmatrix}\right) & 0 \\ 0 & 0 \end{pmatrix}$$

Usually, the function `f` would implicitly be assumed to be scalar. Hence, the derivative of `f` should be scalar as well. In the above situation the chain rule is applied for differentiation: the inner function is the matrix containing the symbolic components

`a*x^2`, `b`, `c` and `d`. Its derivative is computed by simply applying `diff` to each component of the matrix:

```
diff(matrix([[a*x^2, b], [c, d]]), x)
```

$$\begin{pmatrix} 2\,a\,x & 0 \\ 0 & 0 \end{pmatrix}$$

Finally, the exterior unspecified function `f` is implicitly assumed to be scalar, such that each component of the derivative of the inner function is multiplied by the exterior differentiation.

Example 10

A column vector is represented by a 2×1 matrix:

```
Mat := Dom::Matrix():
v := Mat(2, 1, [1, 2])
```

$$\begin{pmatrix} 1 \\ 2 \end{pmatrix}$$

The dimension of this vector is:

```
Mat::matdim(v)
```

$$[2, 1]$$

The length of a vector may also be queried by `linalg::vecdim` or `nops(v)`:

```
linalg::vecdim(v)
```

$$2$$

The *i*th component of this vector can be extracted in two ways: either by `v[i, 1]` or by `v[i]`:

```
v[1], v[2]
```

$$1, 2$$

We compute the 2-norm of `v` by the following call:

```
norm(v, 2)
```

$$\sqrt{5}$$

```
delete Mat, v:
```

Example 11

We create random matrices over the field of the rational numbers. Consider a random matrix `A1` with 3 rows and 3 columns:

```
Mat := Dom::Matrix(Dom::Rational):
A1 := Mat::random(3, 3)
```

$$\begin{pmatrix} -\frac{65}{824} & \frac{221}{72} & -\frac{245}{597} \\ \frac{741}{814} & \frac{229}{220} & \frac{747}{79} \\ \frac{764}{979} & -\frac{535}{617} & -\frac{535}{477} \end{pmatrix}$$

A second matrix `A2` should contain at most 2 non-zero entries. We can create such a matrix by using 2 as the third argument for `random`:

```
A2 := Mat::random(3, 3, 2)
```

$$\begin{pmatrix} 0 & 0 & \frac{905}{906} \\ 0 & 0 & 0 \\ 0 & \frac{4}{133} & 0 \end{pmatrix}$$

The product of these matrices is given by

```
C := A1 * A2
```

$$\begin{pmatrix} 0 & -\frac{140}{11343} & -\frac{58825}{746544} \\ 0 & \frac{2988}{10507} & \frac{223535}{245828} \\ 0 & -\frac{2140}{63441} & \frac{345710}{443487} \end{pmatrix}$$

By default, matrices are displayed like 'dense' arrays with zeroes in the empty places. For sparse matrices of large column and/or row dimension, such a 'dense' print mode is not appropriate: formatting of the print output would be very time consuming. Further, a 'dense' print output is not very informative for sparse matrices. For this reason, the `"doprint"` method provides a sparse output mode printing only the non-zero entries:

```
C::dom::doprint(C)
```

```
Dom::Matrix(Dom::Rational)(3, 3, [(1, 2) = -140/11343, (1, 3) = -58825/746544, (2, 2) = 2988/10507\
, (2, 3) = 223535/245828, (3, 2) = -2140/63441, (3, 3) = 345710/443487])
```

With this method, one can also print large sparse matrices. We create a random sparse matrix with 100 rows, 200 columns and at most 6 non-zero entries:

```
X := Mat::random(100, 200, 6):  print(X)
```

```
Warning: This matrix is too large for display. To see all nonzero entries of a matrix A
```

```
Dom::Matrix(Dom::Rational)(100, 200, ["..."])
```

```
 Warning: This matrix is too large for display.
If you want to see all nonzero entries of a matrix, say A, then call
'A::dom::doprint(A)'. [(Dom::Matrix(Dom::Rational))::print]
```

```
 Warning: This matrix is too large for display.
If you want to see all nonzero entries of a matrix, say A, then call
'A::dom::doprint(A)'. [(Dom::Matrix(Dom::Rational))::print]
```

```
Dom::Matrix(Dom::Rational)(100, 200, ["..."])
```

The warning speaks for itself. `X` is regarded as 'too large for display' since, with the default 'dense' output mode, the sparse matrix would be printed as a huge array-like

structure of dimension 100×200 with (integer) zeroes in the empty places. The sparse print mode should be used:

```
X::dom::doprint(X)
```

```
Dom::Matrix(Dom::Rational)(100, 200, [(16, 64) = 448/765, (19, 4) = -61/702, (27, 126) = 343/304, \
  (46, 42) = 433/49, (68, 176) = 451/483, (100, 97) = -235/174])
```

For convenience, there is a function `doprint` that calls this method by just entering:

```
doprint(X)
```

```
Dom::Matrix(Dom::Rational)(100, 200, [(16, 64) = 448/765, (19, 4) = -61/702, (27, 126) = 343/304, \
  (46, 42) = 433/49, (68, 176) = 451/483, (100, 97) = -235/174])
```

```
delete Mat, A1, A2, C, X:
```

Parameters

`R`

A ring, i.e., a domain of category `Cat::Rng`. The default ring is `Dom::ExpressionField()`.

`Array`

A one- or two-dimensional `array` or `hfarray`

`Matrix`

A matrix, i.e., an element of a domain of category `Cat::Matrix`

`m, n`

Matrix dimension (positive integers)

`List`

A list of matrix components

`ListOfRows`

A list of at most `m` rows; each row given as a list of at most `n` matrix components

`Table`

A table of coefficients of the matrix for sparse input

`f`

A function or a functional expression with two parameters (the row and column index)

`g`

A function or a functional expression with one parameter (the row index)

Options

`Diagonal`

Create a diagonal matrix

With the option `Diagonal`, diagonal matrices can be created with diagonal elements taken from a list, or computed by a function or a functional expression.

`Dom::Matrix(R)(m, n, List, Diagonal)` creates the $m \times n$ diagonal matrix, whose diagonal elements are the entries of `List`.

`List` must have at most $min(m, n)$ entries. If it has fewer elements, the remaining diagonal elements are set to zero.

The entries of `List` are converted to elements of the domain `R`. An error message is issued if one of these conversions fails.

`Dom::Matrix(R)(m, n, g, Diagonal)` returns the sparse matrix whose ith diagonal element is `g(i, i)`, where the index i runs from 1 to $min(m, n)$.

The function values are converted to elements of the domain `R`. An error message is issued if one of these conversions fails.

`Banded`

Create a Toeplitz matrix

`Dom::Matrix(R)(m, n, List, Banded)` creates an $m \times n$ Toeplitz matrix with the elements of `List` as entries. The number of entries of `List` must be odd, say $2h + 1$, and must not exceed $2\,min(m, n) - 1$. The bandwidth of the resulting matrix is at most $2h + 1$.

A Toeplitz matrix is a matrix where the elements of each band are identical. See also "Example 7" on page 7-253.

All elements of the main diagonal of the created matrix are initialized with the middle element of `List`. All elements of the i-th subdiagonal are initialized with the $(h + 1 - i)$-th element of `List`. All elements of the i-th superdiagonal are initialized with the $(h + 1 + i)$-th element of `List`. All entries on the remaining sub- and superdiagonals are set to zero.

The entries of `List` are converted to elements of the domain `R`. An error message is issued if one of these conversions fails.

Entries

"isSparse"	is always `TRUE`.
"randomDimen"	is set to `[10, 10]`. See the method `"random"` below for details.

Methods

Mathematical Methods

`_divide` — Divide matrices

`_divide(A, B)`

An error message is issued if the dimensions of `A` and `B` do not match.

This method only exists if `R` is a commutative ring with a unit, i.e., a domain of category `Cat::Ring`.

This method overloads the system function `_divide` for matrices, i.e., one may use it in the form `A / B`, or in functional notation: `_divide(A, B)`.

_invert — Compute the inverse of a matrix

```
_invert(A, Normal = b)
```

This method only exists if R is a domain of category Cat::Ring.

This method overloads the system function _invert for matrices, i.e., one may use it in the form 1/A or A^(-1), or in functional notation: _invert(A).

If Normal = TRUE, then the matrix inverse is always returned in a normalized form. For details about normalization, see normal. If Normal = FALSE, then the matrix inverse can appear in a normalized form, but normalization is not guaranteed. By default Normal = TRUE.

Normal affects the results only if a matrix contains variables or exact expressions, such as sqrt(5) or sin(PI/7).

_mod — Map the modulo operator to the elements of a matrix

```
_mod(A, n)
```

n must be non-zero, and a mod n must be defined for every entry a of A.

This method overloads the function _mod for matrices; one may use it in the form A mod n, or in functional notation: _mod(A, n).

_mult — Multiplie matrices by matrices, vectors and scalars

```
_mult(x, y)
```

```
_mult(x, y)
```

If y is of the domain type R or can be converted to such an element, the corresponding scalar multiplication is computed.

Otherwise, y is converted to a matrix of the domain type of x. If this conversion fails, this method calls the method "_mult" of the domain of y giving all arguments in the same order.

If x is a matrix of the same domain type as y, the matrix product $x\,y$ is computed. An error message is issued if the dimensions of the matrices do not match.

If x is of the domain type R or can be converted to such an element, the corresponding scalar multiplication is computed.

Otherwise, `x` is converted to a matrix of the domain type of `y`. If this conversion fails, `FAIL` is returned.

This method handles more than two arguments by calling itself recursively with the first half of all arguments and the last half of all arguments. Then the product of these two results is computed with the system function `_mult`.

This method overloads the system function `_mult` for matrices, i.e., one may use it in the form `x * y`, or in functional notation: `_mult(x, y)`.

`_negate` — Negate a matrix

```
_negate(A)
```

This method overloads the system function `_negate` for matrices, i.e., one may use it in the form `-A`, or in functional notation: `_negate(A)`.

`_plus` — Add matrices

```
_plus(A, B, …)
```

The arguments `A, B , ...` are converted to matrices of the domain type `Dom::Matrix(R)`. `FAIL` is returned if one of these conversions fails.

This method overloads the system function `_plus` for matrices, i.e., one may use it in the form `A + B`, or in functional notation: `_plus(A, B)`.

`_power` — Integer power of a matrix

```
_power(A, n)
```

If the power `n` is a negative integer then `A` must be nonsingular and `R` must be a domain of category `Cat::IntegralDomain`. Otherwise `FAIL` is returned.

If `n` is zero and the component ring `R` is a ring with no unit (i.e., of category `Cat::Rng`, but not of category `Cat::Ring`), `FAIL` is returned.

This method overloads the system function `_power` for matrices, i.e., one may use it in the form `A^n`, or in functional notation: `_power(A, n)`.

`conjugate` — Complex conjugate of a matrix

```
conjugate(A)
```

This method only exists if R implements the method "conjugate", which computes the complex conjugate of an element of the domain R.

This method overloads the system function conjugate for matrices, i.e., one may use it in the form conjugate(A).

cos — Cosine of a matrix

```
cos(A)
```

If A is not square, an error message is issued. If the component domain of A does not allow the computation of cos(elem) for an arbitrary element elem of the component ring, FAIL is returned.

This method uses the function numeric::expMatrix for a floating-point approximation of the exponential of A if A is defined over the domain Dom::Float.

If some eigenvalues of A do not exist in R or cannot be computed, then FAIL is returned.

In the symbolic case the functions exp and linalg::jordanForm are called. The latter may not be able to compute the Jordan form of A. In this case FAIL is returned.

This method only exists if R is a domain of category Cat::Field.

This method overloads the function cos for matrices, i.e., one may use it in the form cos(A).

diff — Differentiation of matrix components

```
diff(A, …)
```

This method only exists if R implements the method "diff".

This method overloads the system function diff for matrices, i.e., one may use it in the form diff(A, ...). See “Example 8” on page 7-253 and “Example 9” on page 7-255.

equal — Equality test of matrices

```
equal(A, B)
```

Note that if R has the axiom Ax::systemRep then normal is used to simplify the components of A and B before testing their equality.

exp — Exponential of a matrix

```
exp(A, <t>)
```

If A is not square, an error message is issued. If the component domain of A does not allow the computation of `exp(elem)` for an arbitrary element `elem` of the component ring, `FAIL` is returned.

This method uses the function `numeric::expMatrix` for a floating-point approximation of the exponential of A if `A*t` contains at least one floating-point number and all entries can be converted to floating-point numbers.

If some eigenvalues of A do not exist in R or cannot be computed, then `FAIL` is returned.

In the symbolic case, the function `linalg::jordanForm` is called, which may not be able to compute the Jordan form of A. In this case `FAIL` is returned.

This method only exists if R is a domain of category `Cat::Field`.

This method overloads the system function `exp` for matrices, i.e., one may use it in the form `exp(A, ...)`.

expand — Expand matrix components

```
expand(A)
```

This method only exists if R implements the method `"expand"`, or if R has the axiom `Ax::systemRep` (in this case, the system function `expand` is used).

This method overloads the system function `expand` for matrices, i.e., one may use it in the form `expand(A)`.

factor — Scalar-matrix factorization

```
factor(A)
```

The factor s is the gcd of all components of the matrix A. Hence, this method only exists if R is of category `Cat::GcdDomain`.

This method overloads the system function `factor` for matrices, i.e., one may use it in the form `factor(A)`.

`float` — Floating-point approximation of the matrix components

```
float(A)
```

This method only exists if `R` implements the method `"float"`.

Note: Usually the floating-point approximations are not elements of `R`! For example, `Dom::Integer` implements such a method, but the floating-point approximation of an integer cannot be re-converted to an integer.

This method checks whether the resulting matrix can be converted to the domain type of `A` only if `testargs()` returns `TRUE` (e.g., if one calls this method from the interactive level of MuPAD).

Otherwise, one has to take care that the matrix returned is compatible with its component ring.

`fourier` — Fourier transform of the matrix components

```
fourier(A, t, s)
```

This method overloads the function `fourier` for matrices.

`gaussElim` — Gaussian elimination for matrices

```
gaussElim(A, <ColumnElimination>)
```

With the option `ColumnElimination`, the matrix A is reduced to a lower triangular echelon form via elementary *column* operations (without `ColumnElimination`, the Gauss algorithm uses elementray *row* operations to obtain the upper echelon form). The following relation holds: `transpose(gaussElim(A, ColumnElimination)[1]) = gaussElim(transpose(A))[1]`. With `ColumnElimination`, the last entry of the returned list is the set of characteristic *column* indices of A.

For very large $m \times n$ matrices A with m much greater n, the column elimination is faster than the row elimination.

If the matrix is not square, i.e., the determinant of `A` is not defined, then the third entry of the returned list is the value `FAIL`.

This method only exists if the component ring `R` is an integral domain, i.e., a domain of category `Cat::IntegralDomain`.

If `R` has the method `"pivotSize"`, the pivot element of smallest size is chosen at every pivoting step, whereby `pivotSize` must return a positive integer representing the "size" of an element.

If no such method is defined, Gaussian elimination without a pivot strategy is applied to `A`.

If `R` has the axiom `Ax::efficientOperation("_invert")` and is of category `Cat::Field`, ordinary Gaussian elimination is used. Otherwise, fraction-free elimination is performed on `A`.

If `R` implements the method `"normal"`, it is used to simplify subsequent computations of the Gaussian elimination process.

Note that if `R` does not implement the method `"normal"`, but the elements of `R` are represented by kernel domains, i.e., `R` has the axiom `Ax::systemRep`, the system function `normal` is used instead.

`identity` — Identity matrix

```
identity(n)
```

This method only exists if the component ring `R` is of category `Cat::Ring`, i.e., a ring with unit.

`int` — Integration of matrix components

```
int(A, …)
```

This method only exists if `R` implements the method `"int"`.

This method overloads the system function `int` for matrices, i.e., one may use it in the form `int(A, ...)`.

`ifourier` — Inverse Fourier transform of the matrix components

```
ifourier(A, s, t)
```

This method overloads the function `ifourier` for matrices.

`ilaplace` — Inverse Laplace transform of the matrix components

```
ilaplace(A, s, t)
```

This method overloads the function `ilaplace` for matrices.

`iszero` — Test for zero matrices

```
iszero(A)
```

Note that there may exist more than one representation of the zero matrix of a given dimension if `R` does not have `Ax::canonicalRep`.

If `R` implements the method `"normal"`, it is used to simplify the components of `A` for the zero-test.

Note that if `R` does not implement such a method, but the elements of `R` are represented by kernel domains, i.e., `R` has the axiom `Ax::systemRep`, the system function `normal` is used instead.

This method overloads the system function `iszero` for matrices, i.e., one may use it in the form `iszero(A)`.

`laplace` — Laplace transform of the matrix components

```
laplace(A, t, s)
```

This method overloads the function `laplace` for matrices.

`matdim` — Matrix dimension

```
matdim(A)
```

`norm` — Norm of matrices and vectors

```
norm(A, Infinity)

norm(A, Maximum)

norm(v, Infinity)

norm(v, Maximum)
```

```
norm(A, Frobenius)
```

```
norm(A, 1)
```

```
norm(v, Euclidean)
```

```
norm(v, k)
```

`norm(A, Maximum)` computes the maximum norm of the matrix `A`, which is the maximum row sum (the row sum is the sum of norms of each component in a row).

If the domain `R` does not implement the methods `"max"` and `"norm"`, `FAIL` is returned.

Using `norm(v, Infinity)` for a vector `v` the maximum norm of all elements is returned.

If the domain `R` does not implement the methods `"max"` and `"norm"`, `FAIL` is returned.

Using `norm(v, Maximum)` for a vector `v` the maximum norm of all elements is returned.

If the domain `R` does not implement the methods `"max"` and `"norm"`, `FAIL` is returned.

`norm(A, Frobenius)` computes the Frobenius norm of `A`, which is the square root of the sum of the squares of the norms of each component.

If the result is no longer an element of the domain `R`, or if `R` does not implement the method `"norm"`, `FAIL` is returned.

`norm(A, 1)` computes the 1-norm of the matrix `A`, which is the maximum sum of the norms of the elements of each column. If `R` does not implement the methods `"max"` and `"norm"`, `FAIL` is returned.

`norm(v, Euclidean)` computes the Euclidean norm (2-norm) of the vector `v`, which is defined to be the square root of the sum of the norms of the elements of `v` raised to the square.

`FAIL` is returned if the result is no longer an element of the domain `R`. The function `linalg::scalarProduct` is used to compute the Euclidean norm of the vector `v`.

If `R` does not implement the method `"norm"`, `FAIL` is returned.

`norm(v, k)` computes the k-norm of the vector `v`, which is defined to be the kth root of the sum of the norms of the elements of `v` raised to the kth power.

FAIL is returned if the result is no longer an element of the domain R. For $k = 2$, the function linalg::scalarProduct is used to compute the 2-norm of v.

If R does not implement the method "norm", FAIL is returned.

The method norm overloads the function norm for matrices, i.e., one may use it in the form norm(A k), where k is either Infinity, Frobenius, or a positive integer. The default value of k is Infinity.

normal — Simplification of matrix components

```
normal(A)
```

If R does not implement the method "normal", but the elements of R are represented by kernel domains, i.e., R has the axiom Ax::systemRep, the system function normal is applied to the components of A. Otherwise normal(A) returns A without any changes.

This method overloads the system function normal for matrices, i.e., one may use it in the form normal(A).

nonZeros — Number of non-zero components of a matrix

```
nonZeros(A)
```

nonZeroes — Number of non-zero components of a matrix

```
nonZeroes(A)
```

nonZeroOperands — Return a sequence of all non-zero operands

```
nonZeroOperands(A)
```

This method is useful for retrieving information on the non-zero entries. For example, to find out the types of the entries in the matrix, one should not consider all operands op(A), because this would also involve the zero entries. For large matrices with few entries, it is much more efficient to use this method to extract the entries.

random — Random matrix generation

```
random()

random(g)
```

```
random(m, n)

random(m, n, g)

random(m, n, p)

random(m, n, p, g)
```

The dimension of the matrix is also chosen randomly. The matrix size is limited by the values `"randomDimen"` (see "Entries" above). To change the value of the entry `"randomDimen"`, one must first unprotect the domain `Dom` (see `unprotect` for details).

When calling the `"random"` method with one parameter `g`, this parameter is regarded as a random generator. The matrix entries are created by the calls `g()` which must return elements of the coefficient ring `R`.

The dimension of the matrix is chosen randomly as above.

When calling the `"random"` method with two positive integers `m` and `n`, a random matrix with `m` rows and `n` columns is created. Its elements are generated by the method `"random"` of the component ring `R`. If `R::random` does not exist, `FAIL` is returned.

`random(m,n,g)` creates a matrix with `m` rows and `n` columns. The third parameter `g` is regarded as a random generator. The matrix entries are created by the calls `g()` which must return elements of the coefficient ring `R`.

When calling the `"random"` method with positive integers `m`, `n` and a nonnegative integer `p`, a sparse matrix with `m` rows, `n` columns and at most `p` non-zero entries is created. These entries are generated by the function `"random"` of the component ring `R`. If `R::random` does not exist, `FAIL` is returned.

The integer `p` must satisfy $0 \le p \le m\,n$.

When calling the `"random"` method with four parameters, a sparse matrix with `m` rows, `n` columns and at most `p` non-zero entries is created. The fourth parameter `g` is regarded as a random generator. The matrix entries are created by the calls `g()` which must return elements of the coefficient ring `R`.

The integer `p` must satisfy $0 \le p \le m\,n$.

`sin` — Sine of a matrix

```
sin(A)
```

If A is not square, an error message is issued. If the component domain of A does not allow the computation of `sin(elem)` for an arbitrary element `elem` of the component ring, `FAIL` is returned.

This method uses the function `numeric::expMatrix` for a floating-point approximation of the exponential of A if A is defined over the domain `Dom::Float`.

If some eigenvalues of A do not exist in R or cannot be computed, then `FAIL` is returned.

In the symbolic case the functions `exp` and `linalg::jordanForm` are called. The latter may not be able to compute the Jordan form of A. In this case `FAIL` is returned.

This method only exists if R is a domain of category `Cat::Field`.

This method overloads the function `sin` for matrices, i.e., one may use it in the form `sin(A)`.

`sqrt` — Square root of a matrix

```
sqrt(A, <sqrtfunc>)
```

Returned is a matrix B with $B^2 = A$ such that the eigenvalues of B are the square roots of the eigenvalues of A or `FAIL` if the square root of the matrix does not exist. For computing the square roots of the eigenvalues a function satisfying $sqrtfunc(a)^2 = a$ for every element a of the coefficient ring of A can be given as optional second argument.

For details we refer to the help page of the function `linalg::sqrtMatrix`.

`testeq` — Testing for equality of two matrices

```
testeq(A, B)
```

`tr` — Trace of a square matrix

```
tr(A)
```

If A is not square, an error message is issued.

`transpose` — Transpose of a matrix

```
transpose(A)
```

Access Methods

`_concat` — Horizontal concatenation of matrices

```
_concat(A, B, …)
```

This method overloads the system function `_concat` for matrices, i.e., one may use it in the form `A . B . ...`, or in functional notation: `_concat(A, B, ...)`.

`_index` — Matrix indexing

```
_index(A, i, j)

_index(A, r1 .. r2, c1 .. c2)

_index(v, i)

_index(v, i1 .. i2)
```

If `i` and `j` are not integers, the call of this method returns in its symbolic form (of type `"_index"`) with evaluated arguments.

Otherwise an error message is given, if `i` and `j` are not valid row and column indices, respectively.

Note: Note that this method uses the system function `context` to evaluate the entry in the context of the calling environment.

`_index(A,r1..r2,c1..c2)` returns the submatrix of `A` created by the rows of `A` with indices from `r1` to `r2` and the columns of `A` with indices from `c1` to `c2`.

This method returns the *i*th entry of the vector `v`.

An error message is issued if `v` is not a vector.

If `i` is not an integer, the call of `_index(v,i)` returns in its symbolic form (of type `"_index"`) with evaluated arguments.

Otherwise an error message is given, if `i` is less than one or greater than the dimension of `v`.

Note: Note that this method uses the system function `context` to evaluate the entry in the context of the calling environment.

`_index(v,i1..i2)` returns the subvector of `v`, formed by the entries with index `i1` to `i2`. See also the method `"op"`.

An error message is issued if `v` is not a vector.

`_index` overloads the system function `_index` for matrices, i.e., one may use it in the form `A[i, j]`, `A[r1..r2, c1..c2]`, `v[i]` and `v[i1..i2]`, respectively, or in functional notation: `_index(A, ...)`.

`addCol` — Addition of a multiple of one column to the multiple of another column

```
addCol(A, i, j, f, <g>)
```

`i` and `j` must be positive integers smaller than or equal to the number of columns of the matrix `A`.

If `f` and `g` are not elements of the coefficient domain `R` of the matrix `A` and cannot be converted to `R`, `FAIL` is returned.

`addRow` — Addition of a multiple of one row to the multiple of another row

```
addRow(A, i, j, f, g)
```

`i` and `j` must be positive integers smaller than or equal to the number of rows of the matrix `A`.

If `f` and `g` are not elements of the coefficient domain `R` of the matrix `A` and cannot be converted to `R`, `FAIL` is returned.

`concatMatrix` — Horizontal concatenation of matrices

```
concatMatrix(A, B, …)
```

`col` — Extracting a column of a matrix

```
col(A, c)
```

An error message is issued if `c` is less than one or greater than the number of columns of `A`.

`delCol` — Deleting a column of a matrix

```
delCol(A, c)
```

`NIL` is returned if `A` consists of only one column.

An error message is issued if `c` is less than one or greater than the number of columns of `A`.

`delRow` — Deleting a row of a matrix

```
delRow(A, r)
```

`NIL` is returned if `A` consists of only one row.

An error message is issued if `r` is less than one or greater than the number of rows of `A`.

`evalp` — Evaluating matrices of polynomials at a certain point

```
evalp(A, x = a, …)
```

This method is only defined if `R` is a polynomial ring of category `Cat::Polynomial`.

This method overloads the system function `evalp` for matrices, i.e., one may use it in the form `evalp(A, x = a)`.

`length` — Length of a matrix

```
length(A)
```

This method overloads the system function `length` for matrices, i.e., one may use it in the form `length(A)`.

`map` — Apply a function to matrix components

```
map(A, f, <p1, p2, …>)
```

Note: Note that values returned by `f` are converted to elements of the domain `R` only if `testargs()` returns `TRUE` (i.e., if one calls this method from the interactive level of MuPAD).

If `testargs()` returns `FALSE`, one must guarantee that `f` returns elements of the domain type `R`. Otherwise, the resulting matrix will have components which are not elements of the component ring `R`!

Note: If the function `f` does not map the zero element of the component ring to the zero element, a sparse matrix will change into a dense matrix. This may lead to memory problems when dealing with very large (sparse) matrices.

Note that there is the method `"mapNonZeroes"` which maps a function to the non-zero entries of the matrix only.

This method overloads the system function `map` for matrices, i.e., one may use it in the form `map(A, f p1 , p2 , , …)`.

`mapNonZeroes` — Apply a function to the non-zero components of a (sparse) matrix

```
mapNonZeroes(A, f, <p1, p2, …>)
```

`multCol` — Multiplication of one column by a scalar factor

```
multCol(A, i, f)
```

`i` must be a positive integer smaller than or equal to the number of columns of the matrix `A`.

If `f` is not an element of the coefficient domain `R` of the matrix `A` and cannot be converted to `R`, `FAIL` is returned.

`multRow` — Multiplication of one row by a scalar factor

```
multRow(A, i, f)
```

`i` must be a positive integer smaller than or equal to the number of rows of the matrix `A`.

If `f` is not an element of the coefficient domain `R` of the matrix `A` and cannot be converted to `R`, `FAIL` is returned.

`nops` — Number of components of a matrix

```
nops(A)
```

This method overloads the system function `nops` for matrices, i.e., one may use it in the form `nops(A)`.

`op` — Component of a matrix

```
op(A, i)
```

```
op(A)
```

This method returns an expression sequence of all components of A.

See also the method "_index".

This method overloads the system function op for matrices, i.e., one may use it in the form op(A, i) and op(A), respectively.

row — Extracting a row from a matrix

```
row(A, r)
```

An error message is issued if r is less than one or greater than the number of rows of A.

setCol — Replacing a column of a matrix

```
setCol(A, c, v)
```

An error message is issued if c is less than one or greater than the number of rows of A.

setRow — Replacing a row of a matrix

```
setRow(A, r, v)
```

An error message is issued if r is less than one or greater than the number of rows of A.

stackMatrix — Vertical concatenation of matrices

```
stackMatrix(A, B, …)
```

An error message is issued if the given matrices do not have the same number of columns.

subs — Substitution of matrix components

```
subs(A, …)
```

Note: Note that the function values are converted to elements of the domain R only if testargs() returns TRUE (e.g., if one calls this method from the interactive level of MuPAD).

If `testargs()` returns `FALSE`, one must guarantee that `f` returns elements of the domain type `R`. Otherwise, the resulting matrix, which is of domain type `Dom::Matrix(R)`, would have components which are not elements of the domain `R`!

This method overloads the system function `subs` for matrices, i.e., one may use it in the form `subs(A, ...)`.

subsex — Extended substitution of matrix components

```
subsex(A, …)
```

Note: Note that the results of the substitutions are converted to elements of the domain `R` only if `testargs()` returns `TRUE` (e.g., if one calls this method from the interactive level of MuPAD).

If `testargs()` returns `FALSE`, one must guarantee that the results of the substitutions are of the domain type `R`, otherwise the resulting matrix, which is of domain type `Dom::Matrix(R)`, would have components which are not elements of the domain `R`!

This method overloads the system function `subsex` for matrices, i.e., one may use it in the form `subsex(A, ...)`.

subsop — Operand substitution of matrix components

```
subsop(A, i = x, …)
```

Note: Note that `x` is converted to the domain `R` only if `testargs()` returns `TRUE` (e.g., if one calls this method from the interactive level of MuPAD).

If `testargs()` returns `FALSE`, `x` must be an element of `R`, otherwise the resulting matrix, which is of domain type `Dom::Matrix(R)`, would have components which are not elements of the domain `R`!

See also the method `"set_index"`.

This method overloads the system function `subsop` for matrices, i.e., one may use it in the form `subsop(A, ...)`.

swapCol — Swapping matrix columns

```
swapCol(A, c1, c2)
```

```
swapCol(A, c1, c2, r1 .. r2)
```

An error message is issued if one of the column indices is less than one or greater than the number of columns of `A`.

`swapCol(A,c1,c2,r1..r2)` swaps the column with index `c1` and the column with index `c2` of `A`, but by taking only those column components which lie in the rows with indices `r1` to `r2`.

An error message is issued if one of the column indices is less than one or greater than the number of columns of `A`, or if one of the row indices is less than one or greater than the number of rows of `A`.

swapRow — Swapping matrix rows

```
swapRow(A, r1, r2)
```

```
swapRow(A, r1, r2, c1 .. c2)
```

An error message is issued if one of the row indices is less than one or greater than the number of rows of `A`.

`swapCol(A,r1,r2,c1..c2)` swaps the row with index `r1` and the row with index `r2` of `A`, but by taking only those row components which lie in the columns with indices `c1` to `c2`.

An error message is issued if one of the row indices is less than one or greater than the number of rows of `A`, or if one of the column indices is less than one or greater than the number of columns of `A`.

set_index — Setting matrix components

```
set_index(A, i, j, x)
```

```
set_index(v, i, x)
```

Note: Note that `x` is converted into an element of the domain `R` only if `testargs` returns `TRUE` and `i` and `j` are integers (e.g., if one calls this method from the interactive level of

MuPAD). If x is a matrix of the same type as A or can be converted into a matrix of the same type as A and the indices i or j are ranges corresponding to a submatrix of A, then x replaces the corresponding submatrix in A.

Otherwise one has to take care that x is of domain type R.

See also the method "subsop".

set_index(v,i,x) replaces the *i*th entry of the vector v by x.

set_index on vectors overloads the function set_index for matrices, i.e., one may use it in the form A[i, j] := x and v[i] := x, respectively, or in functional notation: A := set_index(A, i, j, x) or v := set_index(v, i, x).

zip — Combine matrices component-wise

zip(A, B, f, <p1, p2, …>)

The row number of the matrix returned is the minimum of the row numbers of A and B. Its column number is the minimum of the column numbers of A and B.

Note: Note that the values returned by f are converted to elements of the domain R only if testargs() returns TRUE (i.e., if one calls this method from the interactive level of MuPAD).

If testargs() returns FALSE, one must guarantee that f returns elements of the domain type R. Otherwise, the resulting matrix will have components which are not elements of the component ring R!

This method overloads the system function zip for matrices, i.e., one may use it in the form zip(A, B, f p1 , p2 , , …).

Conversion Methods

convert — Conversion to a matrix

convert(x)

FAIL is returned if the conversion fails.

x may either be an array, a matrix, or a list (of sublists, see the parameter ListOfRows in "Creating Elements" above). Their entries must then be convertible into elements of the domain R.

convert_to — Matrix conversion

```
convert_to(A, T)
```

T may either be DOM_ARRAY, DOM_LIST, or a domain constructed by Dom::Matrix or Dom::SquareMatrix. The elements of A must be convertible into elements of the domain R.

Use the function expr to convert A into an object of a kernel domain (see below).

create — Defining matrices without component conversions

```
create(x, …)
```

This method works more efficiently than if one creates matrices by calling the method "new" of the domain, because it avoids any conversion of the components. One must guarantee that the components have the correct domain type, otherwise run-time errors can be caused.

expr — Conversion of a matrix to an object of a kernel domain

```
expr(A)
```

The result is an array representing the matrix A where each entry is an object of a kernel domain.

This method overloads the system function expr for matrices, i.e., one may use it in the form expr(A).

expr2text — Conversion of a mtrix to a string

```
expr2text(A)
```

This method overloads the system function expr2text for matrices, i.e., one may use it in the form expr2text(A).

TeX — TeX formatting of a matrix

```
TeX(A)
```

Note that in the case of very large matrices the output will not be useful. For printing large matrices use the function "doprint" to obtain a sparse matrix output displaying all non-zero entries. Alternatively, use the matrix slot "setPrintMaxSize" to set the maximal size of matrices that will be printed like "dense" arrays with zero entries displayed as the integer 0.

The method "TeX" of the component ring R is used to get the TeX-representation of each component of A.

This method is used by the function generate::TeX.

Technical Methods

assignElements — Multiple assignment to matrices

```
assignElements(A, …)
```

The assigned components must have the domain type R, an implicit conversion of the components into elements of domain type R is not performed.

This method overloads the system function assignElements for matrices, i.e., one may use it in the form assignElements(A, ...).

mkSparse — Conversion of an array or a list of lists to a sparse structure

```
mkSparse(Array)
```

```
mkSparse(List)
```

```
mkSparse(r, c, List)
```

The 'sparse structure' s is a list of c univariate polynomials that is used to store the non-trivial elements of the columns of matrices.

mkSparse(List) tries to convert the list List into a a sparse structure. The result is either FAIL if this is not possible, or the list [s, [r, c]], where the positive integers r and c are the dimension of the corresponding matrix. The 'sparse structure' s is a list

of univariate polynomials that is used to store the non-trivial elements of the columns of matrices.

See the parameters `List` and `ListOfRows` in “Creating Elements” above for admissible formats of `List`.

The matrix is regarded as a column or a row vector, if `r` or `c` is equal to one. T

`mkSparse(r,c,List)` tries to convert the list `List` into a sparse structure representing a matrix of dimension `r` times `c`.

The result is either `FAIL` if this is not possible, or the list `[s, [r, c]]`. The 'sparse structure' `s` is a list of univariate polynomials that is used to store the non-trivial elements of the columns of matrices.

The matrix is regarded as a column or a row vector, if `r` or `c` is equal to one. T

`print` — Printing matrices

```
print(A)
```

Note: Note that it will not be useful to print very large sparse matrices with lots of zero coefficients in this way – printing such matrices can be done by using the function `"doprint"`.

Use the matrix slot `"setPrintMaxSize"` to set the maximal size of matrices that will be printed like “dense” arrays with zero entries displayed as the integer 0.

`doprint` — Printing large sparse matrices

```
doprint(A)
```

`setPrintMaxSize` — Set the maximal size of matrices that will be printed like “dense” arrays

```
setPrintMaxSize(printMaxSize)
```

The value of the parameter `printMaxSize` may also be `infinity`. In this case, matrices of arbitrary size are printed like “dense” arrays.

This method returns the previous value of `printMaxSize`.

The default value is `printMaxSize` = 500.

`unapply` — Create a procedure from a matrix

```
unapply(A, <x, …>)
```

This method overloads the system function `fp::unapply` for matrices, i.e., one may use it in the form `fp::unapply(A)`.

Dom::MatrixGroup(m, n, R)(<m, n>, g, <Diagonal>)

Dom::MatrixGroup(m, n, R)(<m, n>, List, <Banded>)
```

Description

Domain Creation

`Dom::MatrixGroup(m, n, R)` creates a domain which represents the Abelian group of $m \times n$ matrices over the component ring `R`, i.e., it is a domain of category `Cat::AbelianGroup`.

The domain `Dom::ExpressionField()` is used as the component ring for the matrices if the optional parameter `R` is not given.

For matrices of a domain created by `Dom::MatrixGroup(m, n, R)`, matrix arithmetic is implemented by overloading the standard arithmetical operators `+, -, *, /` and `^`. All functions of the linalg package dealing with matrices can be applied.

`Dom::MatrixGroup(m, n, R)` has the domain `Dom::Matrix(R)` as its super domain, i.e., it inherits each method which is defined by `Dom::Matrix(R)` and not re-implemented by `Dom::MatrixGroup(m, n, R)`.

Methods described below are implemented by `Dom::MatrixGroup`.

The domain `Dom::Matrix(R)` represents matrices over `R` of arbitrary size, and it therefore does not have any algebraic structure (except of being a *set* of matrices).

The domain `Dom::SquareMatrix(n, R)` represents the *ring* of $n \times n$ matrices over R.

Element Creation

`Dom::MatrixGroup(m, n, R)(Array)` and `Dom::MatrixGroup(m, n, R)(Matrix)` create a new matrix formed by the entries of `Array` and `Matrix`, respectively.

The components of `Array` and `Matrix`, respectively, are converted into elements of the domain `R`. An error message is issued if one of these conversions fails.

The call `Dom::MatrixGroup(m, n, R)( m , n )` returns the $m \times n$ zero matrix. Note that the $m \times n$ zero matrix can also be found in the entry `"zero"` (see below).

`Dom::MatrixGroup(m, n, R)( m , n List)` creates an $m \times n$ matrix with components taken from the list `List`.

This call is only allowed for $m \times 1$ or $1 \times n$ matrices, i.e., if either `m` or `n` is equal to one.

If the list has too few entries, the remaining components of the matrix are set to zero.

The entries of the list are converted into elements of the domain `R`. An error message is issued if one of these conversions fails.

`Dom::MatrixGroup(m, n, R)( m , n ListOfRows)` creates an $m \times n$ matrix with components taken from the nested list `ListOfRows`. Each inner list corresponds to a row of the matrix.

If an inner list has less than `n` entries, the remaining components in the corresponding row of the matrix are set to zero. If there are less than `m` inner lists, the remaining lower rows of the matrix are filled with zeroes.

The entries of the inner lists are coerced into elements of the domain `R`. An error message is issued if one of these conversions fails.

It might be a good idea first to create a two-dimensional array from that list before calling `Dom::MatrixGroup(m, n, R)`. This is due to the fact that creating a matrix from an array is the fastest way one can achieve. However, in this case the sublists must have the same number of elements.

`Dom::MatrixGroup(m, n, R)( m , n f)` returns the matrix whose (i, j)th component is the value of the function call `f(i, j)`. The row index i ranges from 1 to `m` and the column index j from 1 to `n`.

The function values are coerced into elements of the domain `R`. An error message is issued if one of these conversions fails.

Superdomain

`Dom::Matrix(R)`

Axioms

If R has `Ax::canonicalRep`, then `Ax::canonicalRep`.

Categories

`Cat::Matrix(R)`, `Cat::AbelianGroup`

Examples

Example 1

A lot of examples can be found on the help page of the domain constructor `Dom::Matrix`, and most of them are also examples for working with domains created

by `Dom::MatrixGroup`. This example only highlights some differences with respect to working with matrices of the domain `Dom::Matrix(R)`.

The following command defines the abelian group of 3 ×4 matrices over the rationals:

```
MatGQ := Dom::MatrixGroup(3, 4, Dom::Rational)
```

Dom::MatrixGroup(3, 4, Dom::Rational)

```
MatGQ::hasProp(Cat::AbelianGroup), MatGQ::hasProp(Cat::Ring)
```

TRUE, FALSE

`MatGQ` is a commutative group with respect to the addition of matrices. The unit of this group is the 3 ×4 zero matrix:

```
MatGQ::zero
```

$$\begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}$$

Note that some operations defined by the domain `MatGQ` return matrices which are no longer elements of the matrix group. They return matrices of the domain `Dom::Matrix(Dom::Rational)`, the super-domain of `MatGQ`.

For example, if we define the matrix:

```
A := MatGQ([[1, 2, 1, 2], [-5, 3], [2, 1/3, 0, 1]])
```

$$\begin{pmatrix} 1 & 2 & 1 & 2 \\ -5 & 3 & 0 & 0 \\ 2 & \frac{1}{3} & 0 & 1 \end{pmatrix}$$

and delete its third column, we get the matrix:

```
MatGQ::delCol(A, 3)
```

$$\begin{pmatrix} 1 & 2 & 2 \\ -5 & 3 & 0 \\ 2 & \frac{1}{3} & 1 \end{pmatrix}$$

which is of the domain type:

```
domtype(%)
```

$$\text{Dom::Matrix(Dom::Rational)}$$

As another example we create the 3×3 identity matrix using the method `"identity"` of our domain:

```
E3 := MatGQ::identity(3)
```

$$\begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}$$

This is also a matrix of the domain `Dom::Matrix(Dom::Rational)`:

```
domtype(E3)
```

$$\text{Dom::Matrix(Dom::Rational)}$$

If we concatenate `E3` to the right of the matrix `A` defined above, we get the 3 ×7 matrix:

```
B := A . E3
```

$$\begin{pmatrix} 1 & 2 & 1 & 2 & 1 & 0 & 0 \\ -5 & 3 & 0 & 0 & 0 & 1 & 0 \\ 2 & \frac{1}{3} & 0 & 1 & 0 & 0 & 1 \end{pmatrix}$$

which is of the domain type `Dom::Matrix(Dom::Rational)`:

```
domtype(B)
```

$$\text{Dom::Matrix(Dom::Rational)}$$

Example 2

We can convert a matrix from a domain created with `Dom::MatrixGroup` into or from another matrix domain, as shown next:

```
MatGR := Dom::MatrixGroup(2, 3, Dom::Real):
MatC := Dom::Matrix(Dom::Complex):

A := MatGR((i, j) -> i*j)
```

$$\begin{pmatrix} 1 & 2 & 3 \\ 2 & 4 & 6 \end{pmatrix}$$

To convert `A` into a matrix of the domain `MatC`, enter:

```
coerce(A, MatC)
```

$$\begin{pmatrix} 1 & 2 & 3 \\ 2 & 4 & 6 \end{pmatrix}$$

```
domtype(%)
```

$$\text{Dom::Matrix(Dom::Complex)}$$

The conversion is done component-wise. For example, we define the following matrix:

```
B := MatC([[0, 1, 0], [exp(I), 0, 1]])
```

$$\begin{pmatrix} 0 & 1 & 0 \\ e^{i} & 0 & 1 \end{pmatrix}$$

The matrix B has one complex component and therefore cannot be converted into the domain `MatGR`:

```
coerce(B, MatGR)
```

```
      FAIL
```

Note: The system function `coerce` uses the methods `"convert"` and `"convert_to"` implemented by any domain created with `Dom::MatrixGroup` and `Dom::Matrix`.

Parameters

`m, n`

Positive integers (matrix dimension)

`R`

A commutative ring, i.e., a domain of category `Cat::CommutativeRing`; the default is `Dom::ExpressionField()`

`Array`

An $m \times n$ array

`Matrix`

An $m \times n$ matrix, i.e., an element of a domain of category `Cat::Matrix`

`List`

A list of matrix components

`ListOfRows`

A list of at most `m` rows; each row is a list of at most `n` matrix components

`f`

A function or a functional expression with two parameters (the row and column index)

`g`

A function or a functional expression with one parameter (the row index)

Options

`Diagonal`

Create a diagonal matrix

With the option `Diagonal`, diagonal matrices can be created with diagonal elements taken from a list, or computed by a function.

`Dom::MatrixGroup(m, n, R)( m , n List, Diagonal)` creates the $m \times n$ diagonal matrix whose diagonal elements are the entries of `List`.

`List` must have at most $min(m, n)$ entries. If it has fewer elements, then the remaining diagonal elements are set to zero.

The entries of `List` are coerced into elements of the domain `R`. An error message is issued if one of these conversions fails.

`Dom::MatrixGroup(m, n, R)( m , n g, Diagonal)` returns the matrix whose ith diagonal element is `g(i, i)`, where the index i runs from 1 to $min(m, n)$.

The function values are coerced into elements of the domain `R`. An error message is issued if one of these conversions fails.

`Banded`

Create a banded Toeplitz matrix

With the option `Banded`, banded matrices can be created.

A *banded matrix* has all entries zero outside the main diagonal and some of the adjacent sub- and superdiagonals.

`Dom::MatrixGroup(m, n, R)( m , n List, Banded)` creates an $m \times n$ banded Toeplitz matrix with the elements of `List` as entries. The number of entries of `List` must be odd, say $2h + 1$, and must not exceed `n`. The resulting matrix has bandwidth at most $2h + 1$.

All elements of the main diagonal of the created matrix are initialized with the middle element of `List`. All elements of the *i*th subdiagonal are initialized with the (*h* + 1 - *i*)th element of `List`. All elements of the *i*th superdiagonal are initialized with the (*h* + 1 + *i*)th element of `List`. All entries on the remaining sub- and superdiagonals are set to zero.

The entries of `List` are converted into elements of the domain `R`. An error message is issued if one of these conversions fails.

Entries

"one"	is only defined if `m` is equal to `n`; in that case it defines the $n \times n$ identity matrix.
"randomDimen"	is set to `[m, n]`.
"zero"	is the $m \times n$ zero matrix.

Methods

Mathematical Methods

`evalp` — Evaluating matrices of polynomials at a certain point

```
evalp(A, x = a, …)
```

This method is only defined if `R` is a polynomial ring of category `Cat::Polynomial`.

This method overloads the function `evalp` for matrices, i.e., one may use it in the form `evalp(A, x = a)`.

`identity` — Identity matrix

```
identity(k)
```

Note: The matrix returned is of the domain `Dom::Matrix(R)`, if $m \neq n$ or if $k \neq n$.

`matdim` — Matrix dimension

```
matdim(A)
```

`random` — Random matrix generation

```
random()
```

The components of the random matrix are randomly generated with the method `"random"` of the component ring `R`.

Access Methods

`_concat` — Horizontally concatenation of matrices

```
_concat(A, B, …)
```

An error message is issued if the given matrices do not have the same number of rows.

Note: The returned matrix is of the domain `Dom::Matrix(R)`.

This method overloads the function `_concat` for matrices, i.e., one may use it in the form `A . B . ...`, or in functional notation: `_concat(A, B, ...)`.

`_index` — Matrix indexing

```
_index(A, i, j)
```

```
_index(A, r1 .. r2, c1 .. c2)
```

```
_index(A, i)
```

```
_index(A, i1 .. i2)
```

If `i` and `j` are not integers, then the call of this method returns in its symbolic form (of type `"_index"`) with evaluated arguments.

Otherwise an error message is given, if `i` and `j` are not valid row and column indices, respectively.

Note: Note that the system function `context` is used to evaluate the entry in the context of the calling environment.

This method overloads the function `_index` for matrices, i.e., one may use it in the form `A[i, j]` or in functional notation: `_index(A, i, j)`.

Returns the submatrix of `A`, created by the rows of `A` with indices from `r1` to `r2` and the columns of `A` with indices from `c1` to `c2`.

Note: The submatrix is of the domain `Dom::Matrix(R)`.

This method returns the *i*th entry of `A`.

If `i` is not an integer, then the call of this method returns in its symbolic form (of type `"_index"`) with evaluated arguments.

Otherwise an error message is given, if `i` is less than one or greater than the dimension of `v`.

This call is only allowed for $1 \times n$ or $m \times 1$ matrices, i.e., either `m` or `n` must be equal to one. Otherwise an error message is issued.

Note: Note that the system function `context` is used to evaluate the entry in the context of the calling environment.

This method returns the subvector of `A`, formed by the entries with index `i1` to `i2` (see also the method `"op"`).

This call is only allowed for $1 \times n$ or $m \times 1$ matrices, i.e., either `m` or `n` must be equal to one. Otherwise an error message is issued.

This method overloads the function `_index` for matrices, i.e., one may use it in the form `A[i,j]`, `A[r1..r2,c1..c2]`, `A[i]` or `A[i1..i2]`, respectively, or in functional notation: `_index(A, ...)`.

`concatMatrix` — Horizontally concatenation of matrices

```
concatMatrix(A, B, …)
```

col — Extracting a column

```
col(A, c)
```

An error message is issued if `c` is less than one or greater than `n`.

delCol — Deleting a column

```
delCol(A, c)
```

`NIL` is returned if `A` only consists of one column.

Note: The returned matrix is of the domain `Dom::Matrix(R)`.

An error message is issued if `c` is less than one or greater than `n`.

delRow — Deleting a row

```
delRow(A, r)
```

`NIL` is returned if `A` only consists of one row.

Note: The returned matrix is of the domain `Dom::Matrix(R)`.

An error message is issued if `r` is less than one or greater than `m`.

row — Extracting a row

```
row(A, r)
```

An error message is issued if `r` is less than one or greater than `m`.

stackMatrix — Concatenating of matrices vertically

```
stackMatrix(A, B, …)
```

An error message is issued if the given matrices do not have the same number of columns.

Note: The matrix returned is of the domain `Dom::Matrix(R)`.

Conversion Methods

`convert` — Conversion into a matrix

```
convert(x)
```

`FAIL` is returned if the conversion fails.

`x` may either be an $m \times n$ array, or an $m \times n$ matrix of category `Cat::Matrix`.

`x` can also be a list. See the parameter `List` and `ListOfRows` in "Creating Elements" above for admissible values of `x`.

The entries of `x` must be convertable into elements of the domain `R`, otherwise `FAIL` is returned.

```

```
Dom::MonomOrdering(Matrix(params))
```

Description

`Dom::MonomOrdering` represents the set of all possible monomial orderings. A monomial ordering is a well-ordering of the set of all k-tuples of nonnegative integers for some k.

In MuPAD, a monomial ordering is implemented as a function that, when applied to two lists of nonnegative integers, returns `-1`, `0`, or `1` if the first list is respectively smaller than, equal to, or greater than the second list. Each ordering can only compare lists of one fixed length, called its its *order length*. Since the lists under consideration will be exponent vectors in most cases, their length is also referred to as the number of indeterminates.

Monomial orderings are used in algebraic geometry for comparing terms $\prod_{i=1}^{n} X_i^{\alpha_i}$ and $\prod_{i=1}^{n} X_i^{\beta_i}$ in a polynomial ring. Since `Dom::MonomOrdering` works on the exponent vectors $[\alpha_1, \ldots, \alpha_n]$ and $[\beta_1, \ldots, \beta_n]$, `degreevec` must be applied to the terms to be compared before applying `Dom::MonomOrdering`.

Elements of `Dom::MonomOrdering` can be used as arguments for `lcoeff`, `lmonomial`, `lterm`, and `tcoeff` as well as for the functions of the groebner package in order to specify the monomial ordering to be considered.

Monomial orderings are created by calling `Dom::MonomOrdering(someIdentifier(parameters))`, where `someIdentifier` is one of a certain set of predefined identifiers, as stated below. Converting `someIdentifier` into a string gives the *order type* of the monomial ordering.

`Dom::MonomOrdering(Lex(n))` creates the lexicographical order on n indeterminates.

`Dom::MonomOrdering(RevLex(n))` creates the reverse lexicographical order on n indeterminates, i.e., `Dom::MonomOrdering(RevLex(n))([a1,...,an])= Dom::MonomOrdering(Lex(n))([an,...,a1])`.

`Dom::MonomOrdering(DegLex(n))` creates the degree order on n indeterminates with the lexicographical order used for tie-break.

`Dom::MonomOrdering(DegRevLex(n))` creates the degree order on n indeterminates with the reverse lexicographical order used for tie-break .

`Dom::MonomOrdering(DegInvLex(n))` creates the degree order on n indeterminates, with the tie break being the opposite to the lexicographical order.

`Dom::MonomOrdering(Weighted...(w1,...,wn))` returns a weighted degree order with weights w_1 through w_n. The word following the word `Weighted` specifies the tie-break used. Note that MuPAD uses the ordinary degree order as the first tie-break.

`Dom::MonomOrdering(Matrix(params))` creates a matrix order, with the order matrix defined by `Dom::Matrix()(params)`.

`Dom::MonomOrdering(Block(o1, ..., on))` or, equivalently, `Dom::MonomOrdering([o1, ..., on])`, creates a block order such that `Dom::MonomOrdering(o1)` is used on the first indeterminates, then `Dom::MonomOrdering(o2)` is used as a tie-break on the following indeterminates etc.

Block orders may be nested, i.e., the blocks may be block orders, too.

Weight vectors with negative entries and order matrices do not define well-orderings in general. You may enter such orderings, but it may cause trouble, e.g., to use them with the groebner package.

Categories

`Cat::BaseCategory`

Examples

Example 1

We define `ORD` by prescribing that lists $[a, b, c]$ are ordered according to their weighted degrees $5\,a + 2\,b + \pi\,c$. For lists with equal weighted degree, the non-weighted degree $a + b + c$ is used as a tie-break. Finally, the lexicographical order decides (in fact, this last step is not necessary because π is irrational).

```
ORD:=Dom::MonomOrdering(WeightedDegLex(5, 2, PI))
```

$$\text{WeightedDegLex}(5, 2, \pi)$$

With respect to `ORD`, `[1, 6, 1]` is smaller than `[2, 1, 3]`:

```
ORD([1,6,1], [2,1,3])
```

$$-1$$

Parameters

`n`

Positive integer

$w_1, \ldots$

Numerical expressions

$o_1, \ldots$

Valid arguments to `Dom::MonomOrdering`

`params`

A sequence valid as the sequence of arguments to `Dom::Matrix()`.

Methods

Mathematical Methods

`func_call` — Compare two lists of integers

```
func_call(o, l1, l2)
```

The lengths of `l1` and `l2` must not exceed the order length of `o`. If `l1` or `l2` is too short, the necessary number of zeroes is appended.

Access Methods

`ordertype` — Return the type of an order

```
ordertype(o)
```

If `o` equals `Dom::MonomOrdering(someIdentifier(params))`, then converting `someIdentifier` into a string gives the order type of `o`.

`orderlength` — Return the length of an order

```
orderlength(o)
```

`nops` — Number of blocks

```
nops(o)
```

`block` — Get a particular block

```
block(o, i)
```

`blocktype` — Get the order type of a particular block

```
blocktype(o, i)
```

`blocklength` — Get the order length of a particular block

```
blocklength(o, i)
```

Conversion Methods

`expr` — Return an expression from which the order can be restored

```
expr(o)
```

Dom::Multiset

Multisets

Syntax

```
Dom::Multiset(<s1, s2, …>)
```

Description

`Dom::Multiset` is the domain of multisets, i.e., sets with possibly multiple identical elements.

A multiset is represented by a set of lists of the form [*s*, *m*], where *s* is an element of the multiset and *m* its multiplicity.

Multisets can be returned by the system solver `solve`. For example, the input `solve(x^3 - 4*x^2 + 5*x - 2, x, Multiple)` gives all roots of the polynomial $x^3 - 4x^2 + 5x - 2$ in form of the multiset `{[1, 2], [2, 1]}`.

The standard set operations such as union, intersection and subtraction of sets have been extended to deal with multisets.

These operations can handle different types of sets, such as sets of type `DOM_SET` and multisets. One may, for example, compute the union of the multiset `{[a, 2], [b, 1]}` and the set `{c}`, which results in the multiset `{[a, 2], [b, 1], [c, 1]}`.

The elements of the multiset are sorted at the time where the multiset is created. The system function `sort` is used in order to guarantee that exactly one representation exists for a multiset, independent of the sequence in which the arguments appear.

`Dom::Multiset(s1, s2, ...)` creates the multiset consisting of the elements `s1, s2, ...`

Multiple identical elements in `s1, s2`, ... are collected. For example, the call `Dom::Multiset(a, b, a, c)` creates a multiset with the elements `a, b, c`. The element `a` has multiplicity two, the other two elements `b` and `c` both have multiplicity one.

Superdomain

`Dom::BaseDomain`

Categories

`Cat::Set`

Examples

Example 1

The multiset $\{a, a, b\}$ consists of the two different elements a and b, where a has multiplicity two and b has multiplicity one:

```
delete a, b, c:
set1 := Dom::Multiset(a, a, b)
```

$$\{[a, 2], [b, 1]\}$$

We create another multiset:

```
set2 := Dom::Multiset(a, c, c)
```

$$\{[a, 1], [c, 2]\}$$

Standard set operations such as disjoint union, intersection or subtraction are implemented for multisets and can be performed using the standard set operators of MuPAD:

```
set1 union set2
```

$$\{[a, 3], [b, 1], [c, 2]\}$$

```
set1 intersect set2
```

$$\{[a, 1]\}$$

```
contains(set1, a), contains(set1, d)
```

$$\text{TRUE, FALSE}$$

Example 2

Some system functions were overloaded for multisets, such as `expand`, `normal` or `split`.

If we apply `expand` to a multiset, for example, we get an expression sequence of all elements of the multiset (appearing in correspondence to their multiplicity):

```
delete a, b, c, d, e:
set := Dom::Multiset(a, b, c, a, c, d, c, e, c)
```

$$\{[a, 2], [b, 1], [c, 4], [d, 1], [e, 1]\}$$

```
expand(set)
```

$$a, a, b, c, c, c, c, d, e$$

If you want to convert a multiset into an ordinary set of the domain type `DOM_SET`, use `coerce`:

```
coerce(set, DOM_SET)
```

$$\{a, b, c, d, e\}$$

Note: The system function `coerce` uses the methods `"convert"` and `"convert_to"` of the domain `Dom::Multiset`.

Compare the last result with the return value of the function `expr`, when it is applied for multisets:

```
expr(set)
```

$$\{[a, 2], [b, 1], [c, 4], [d, 1], [e, 1]\}$$

The result is a set of the domain type DOM_SET, consisting of lists of the domain type DOM_LIST with two entries, an element of the multiset and the corresponding multiplicity of that element.

Parameters

s1, s2, …

Objects of any type

Entries

"isFinite"	is TRUE because Dom::Multiset represents finite sets.
"inhomog_intersect"	a table of the form T = Proc(multiset, setoftypeT). This entry is used internally by the implementation, and thus should not be touched.
"inhomog_union"	a table of the form T = Proc(multiset, setoftypeT). This entry is used internally by the implementation, and thus should not be touched.

Methods

Mathematical Methods

normal — Normalization of multisets

```
normal(set)
```

This method overloads the function normal for multisets, i.e., one may use it in the form normal(set).

`powerset` — Power set of a multiset

```
powerset(set)
```

The power set of `set` is returned as a set of multisets.

`random` — Random multiset generation

```
random()
```

The number of elements created, including their multiplicities, is restricted to 20.

Access Methods

`_index` — Multiset indexing

```
_index(set, i)
```

See the method `"op"`.

This method overloads the function `_index` for multisets, i.e., one may use it in the form `set[i]`, or in functional notation: `_index(set, i)`.

`contains` — Check on existence of set elements

```
contains(set, s)
```

This method overloads the function `contains` for multisets, i.e., one may use it in the form `contains(set, s)`.

`equal` — Test on equality of multisets

```
equal(set1, set2)
```

The system function `_equal` is used for the test.

`expand` — Expand a multiset to a sequence of its elements

```
expand(set)
```

This method overloads the function `expand` for multisets, i.e., one may use it in the form `expand(set)`.

`getElement` — Extract one element from a multiset

```
getElement(set)
```

Note that the elements of the multiset are sorted with the use of the system function `sort`, and thus the order of a multiset depends on the sorting criteria specified by this function.

This method overloads the function `solvelib::getElement`, i.e., one may use it in the form `solvelib::getElement(set)`.

`has` — Check on existence of (sub-)expressions

```
has(set, expr)
```

To check whether `expr` is contained as an element of `set` and not as a subexpression of the elements of `set`, the function `contains` must be used.

This method overloads the function `has` for multisets, i.e., one may use it in the form `has(set, expr)`.

`map` — Apply a function to multiset elements

```
map(set, func, <expr, …>)
```

It overloads the function `map` for multisets, i.e., one may use it in the form `map(set, func, ...)`.

`multiplicity` — Multiplicity of an element

```
multiplicity(set, s)
```

Elements which are not contained in `set` have multiplicity zero.

`card` — Number of elements in a multiset

```
card(set)
```

This method overloads the function `card`.

`nops` — Number of different elements in a multiset

```
nops(set)
```

This method overloads the function `nops` for multisets, i.e., one may use it in the form `nops(set)`.

`op` — Element of a multiset

```
op(set)

op(set, i)
```

Returns the *i*-th element *s* of the multiset `set` and its multiplicity *m* in form of the list [*s*, *m*].

See also the method `"_index"`.

Note that the elements of the multiset are sorted with the use of the system function `sort`, and thus the order of a multiset depends on the sorting criteria specified by this function.

This method overloads the function `op` for multisets, i.e., one may use it in the form `op(s, i)`.

`select` — Selecting of multiset elements

```
select(set, func, <expr, …>)
```

This method overloads the function `select` for multisets, i.e., one may use it in the form `select(set, func, ...)`. See `select` for details.

`split` — Splitting a multiset

```
split(set, func, <expr, …>)
```

This method overloads the function `split` for multisets, i.e., one may use it in the form `split(set, func, ...)`. See `split` for details.

`subs` — Substitution of elements in multisets

```
subs(set, …)
```

This method overloads the function `subs` for multisets, i.e., one may use it in the form `subs(set, ...)`.

Conversion Methods

convert — Conversion into a multiset

```
convert(x)
```

FAIL is returned if the conversion fails.

Currently only sets of type DOM_SET can be converted into multisets.

convert_to — Multiset conversion

```
convert_to(set, T)
```

FAIL is returned if the conversion fails.

Currently T may either be DOM_SET to convert the multiset set into a set (loosing the multiplicities and the order of the elements of set), or DOM_EXPR or "_exprseq" to convert set into an expression sequence (see the method "expand" for details).

See also the method "expr".

expr — Multiset conversion into an object of a kernel domain

```
expr(set)
```

This method overloads the function expr for multisets, i.e., one may use it in the form expr(set).

sort — Sorting of multisets

```
sort(set)
```

This method overloads the function sort for multisets, i.e., one may use it in the form sort(set).

Technical Methods

bin_intersect — Intersection of two multisets

```
bin_intersect(set1, set2)
```

This method is called from routines defined in the category `Cat::Set`, which implements among others the overloading of the function `intersect` for multisets. One may intersect two multisets directly by `set1 intersect set2`, or in functional notation by `_intersect(set1, set2)`.

`bin_minus` — Subtraction of two multisets

```
bin_minus(set1, set2)
```

This method is called from routines defined in the category `Cat::Set`, which implements among others the overloading of the function `minus` for multisets. One may subtract two multisets directly by `set1 minus set2`, or in functional notation by `_minus(set1, set2)`.

`homog_union` — Union of multisets

```
homog_union(set, …)
```

This method is called from routines defined in the category `Cat::Set`, which implements among others the overloading of the function `union` for multisets. One may compute the union of two multisets directly by `set1 union set2`, or in functional notation by `_union(set1, set2)`.

`nested_union` — Union of nested sets

```
nested_union(setofsets)
```

This method is called from routines defined in the category `Cat::Set`, which implements among others the overloading of the function `union` for multisets and sets. One may compute the union of multisets and sets directly by `set1 union set2`, or in functional notation by `_union(set1, set2)`.

Dom::MultivariatePolynomial

Domains of multivariate polynomials

Syntax

Domain Creation

```
Dom::MultivariatePolynomial(<Vars, <R, <Order>>>)
```

Element Creation

```
Dom::MultivariatePolynomial(Vars, R, Order)(p)
```

```
Dom::MultivariatePolynomial(Vars, R, Order)(lm)
```

Description

`Dom::MultivariatePolynomial(Vars, R, ..)` creates the domain of multivariate polynomials in the variable list `Vars` over the commutative ring `R` in distributed representation.

`Dom::MultivariatePolynomial` represents multivariate polynomials over arbitrary commutative rings.

All usual algebraic and arithmetical polynomial operations are implemented, including Gröbner basis computation and some classical construction tools used in invariant theory.

Note: It is highly recommend to use only coefficient rings with unique zero representation. Otherwise it may happen that, e.g., a polynomial division will not terminate or a wrong degree will be returned.

`Dom::MultivariatePolynomial(Vars, R, Order)` creates a domain of multivariate polynomials in the variable list `Vars` over a domain `R` of category `Cat::CommutativeRing` in sparse distributed representation with respect to the monomial ordering `Order`.

`Dom::MultivariatePolynomial()` creates a polynomial domain in the variable list `[x,y,z]` over the domain `Dom::ExpressionField(normal)` with respect to the lexicographic monomial ordering.

`Dom::MultivariatePolynomial(Vars)` generates the polynomial domain in the variable list `Vars` over the domain `Dom::ExpressionField(normal)` with respect to the lexicographic monomial ordering is created.

Note: Only commutative coefficient rings of type `DOM_DOMAIN` which inherit from `Dom::BaseDomain` are allowed. If `R` is of type `DOM_DOMAIN` but does not inherit from `Dom::BaseDomain`, the domain `Dom::ExpressionField(normal)` will be used instead.

In contrast to the domain `Dom::DistributedPolynomial`, `Dom::MultivariatePolynomial` accepts only identifiers (`DOM_IDENT`) as indeterminates. This restriction enables some further methods described below.

Please note: For reasons of efficiency not all methods check their arguments, not even at the interactive level. In particular this is true for many access methods, converting methods and technical methods. This may cause strange error messages.

Superdomain

`Dom::DistributedPolynomial`

Axioms

If R has `Ax::normalRep`, then `Ax::normalRep`.

If R has `Ax::canonicalRep`, then `Ax::canonicalRep`.

Categories

If Vars has a single variable, then `Cat::UnivariatePolynomial(R)`, else `Cat::Polynomial(R)`.

Examples

Example 1

To create the ring of multivariate polynomials in x, y and z over the rationals one may define

```
MP := Dom::MultivariatePolynomial([x, y, z], Dom::Rational)
```

$$\text{Dom::MultivariatePolynomial}([x, y, z], \text{Dom::Rational}, \text{LexOrder})$$

The elementary symmetric polynomials of this domain are

```
s1 := MP(x + y + z)
```

$$x + y + z$$

```
s2 := MP(x*y + x*z + y*z)
```

$$x\,y + x\,z + y\,z$$

```
s3:=MP(x*y*z)
```

$$x\,y\,z$$

A polynomial is called symmetric if it remains unchanged under every possible permutation of variables as, e.g.:

```
s3=s3(MP(y), MP(z), MP(x))
```

$$x\,y\,z = x\,y\,z$$

These polynomials arise naturally in studying the roots of a polynomial. To show this, we first have to create an univariate polynomial, e.g., in U over MP, and generate a polynomial in U with roots in x, y and z.

```
UP:=Dom::UnivariatePolynomial(U, MP)
```

Dom::UnivariatePolynomial(*U*, Dom::MultivariatePolynomial([*x*, *y*, *z*], Dom::Rational, LexOrder), LexOrder)

```
f := UP((U - x)*(U - y)*(U - z))
```

$$U^3 + (-x - y - z)\,U^2 + (x\,y + x\,z + y\,z)\,U - x\,y\,z$$

```
UP(U^3)-s1*UP(U^2)+s2*UP(U)+(-1)^3*s3
```

$$U^3 + (-x - y - z)\,U^2 + (x\,y + x\,z + y\,z)\,U - x\,y\,z$$

This exemplifies that the coefficients of `f` are (elementary) symmetric polynomials in its roots.

From the fundamental theorem of symmetric polynomials we know that every symmetric polynomial can be written uniquely as a polynomial in the elementary symmetric polynomials. Thus we can rewrite the following symmetric polynomial `s` in the elementary symmetric polynomials `s1`, `s2` and `s3`,

```
s:=MP(x^3*y+x^3*z+x*y^3+x*z^3+y^3*z+y*z^3)
```

$$x^3\,y + x^3\,z + x\,y^3 + x\,z^3 + y^3\,z + y\,z^3$$

```
S:=MP::rewritePoly(s,[s1=S1,s2=S2,s3=S3])
```

$$S1^2\,S2 - S1\,S3 - 2\,S2^2$$

where these polynomials are represented by the three new variables `S1`, `S2` and `S3` respectively. To see that this new polynomial `S` in the new variables indeed represents the old original polynomial `s`, we simply have to plug in the three elementary symmetric polynomials into `S`:

```
poly(S, Expr)(s1,s2,s3)
```

$$x^3\,y + x^3\,z + x\,y^3 + x\,z^3 + y^3\,z + y\,z^3$$

When one has a given list of polynomials, e.g., like:

```
l:=[3*s1,2*s1,s1,s3]
```

$$[3x+3y+3z,\ 2x+2y+2z,\ x+y+z,\ xyz]$$

and one wants to sort them in an appropriate order, one may use one of the following two methods.

```
MP::sortList(l,Dom::MonomOrdering(DegLex(3)))
```

$$[xyz,\ 2x+2y+2z,\ x+y+z,\ 3x+3y+3z]$$

```
MP::stableSort(l,Dom::MonomOrdering(DegLex(3)))
```

$$[xyz,\ 3x+3y+3z,\ 2x+2y+2z,\ x+y+z]$$

In the first sorted list the order of the three polynomials of the same degree has changed, while with the second method this order remains stable.

Example 2

Let $G \subset \mathrm{GL}(n, k)$ be a finite (matrix) subgroup of the general linear group. Then a polynomial $f \in k[x_1, \ldots, x_n]$ is called *invariant under* G, if for all $A \in G$

$$f(x) = f(A\,x)$$

where $x = (x_1 \ \cdots \ x_n)$. The symmetric polynomials `s1`, `s2` and `s3` from the previous example are invariants under the symmetric group S_3. In fact, these three fundamental invariants yet generate the whole ring of invariants of S_3.

Now let us examine the invariants of the famous icosahedral group. One may find a representation of this group on page 73 of H. F. Blichfeldt: Finite collineation groups, University of Chicago Press, 1917.

$$S' = \begin{pmatrix} \varepsilon^3 & 0 \\ 0 & \varepsilon^2 \end{pmatrix},\ U' = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix},\ T' = \begin{pmatrix} \alpha & \beta \\ \beta & -\alpha \end{pmatrix},\ \varepsilon^5 = 1,\ \alpha = \frac{\varepsilon^4 - \varepsilon}{\sqrt{5}},\ \beta = \frac{\varepsilon^2 - \varepsilon^3}{\sqrt{5}}$$

The group is generated from these three matrices, has 120 elements and is thus a finite subgroup, even of the special linear group $SL(2, \mathbb{Q}(\varepsilon))$. It is also well known that

$$i_1 = x_1 x_2^{11} - x_1^6 x_2^6 - x_1^{11} x_2$$

is a fundamental invariant of degree 12 of this group. To declare i_1 in MuPAD one has first to define the polynomial domain.

```
MP:=Dom::MultivariatePolynomial([x1,x2],Dom::Rational)
```

$$\text{Dom::MultivariatePolynomial}([x1, x2], \text{Dom::Rational}, \text{LexOrder})$$

```
i1:=MP(x1*x2^(11)-11*x1^6*x2^6-x1^(11)*x2)
```

$$-x1^{11}\,x2 - 11\,x1^6\,x2^6 + x1\,x2^{11}$$

From the invariant i_1 one can compute a further fundamental invariant i_2 with

```
i2:=MP::hessianDet(i1)
```

$$-121\,x1^{20} + 27588\,x1^{15}\,x2^5 - 59774\,x1^{10}\,x2^{10} - 27588\,x1^5\,x2^{15} - 121\,x2^{20}$$

But to get more simple coefficients we choose i_2 as

```
i2:=-1/121*MP::hessianDet(i1)
```

$$x1^{20} - 228\,x1^{15}\,x2^5 + 494\,x1^{10}\,x2^{10} + 228\,x1^5\,x2^{15} + x2^{20}$$

instead. Similar we obtain a third fundamental invariant i_3 with

```
i3:=1/20*MP::jacobianDet([i1,i2])
```

$$x1^{30} + 522\,x1^{25}\,x2^5 - 10005\,x1^{20}\,x2^{10} - 10005\,x1^{10}\,x2^{20} - 522\,x1^5\,x2^{25} + x2^{30}$$

In contrast to the symmetric groups, where all invariants can be uniquely represented by the fundamental invariants, the fundamental invariants of this group have an algebraic relation, a so-called syzygy between them. It is possible to represent i_3^2 in two ways:

```
MP::rewritePoly(i3^2,[i1=I1,i2=I2,i3=I3])
```

$$-1728\,I1^5 + I2^3$$

```
MP::rewritePoly(i3^2,[i1=I1,i2=I2,i3=I3],Unsorted)
```

$$I3^2$$

And hence we get the syzygy:

```
MP::rewritePoly(i3^2,[i1=I1,i2=I2,i3=I3],Unsorted)-
MP::rewritePoly(i3^2,[i1=I1,i2=I2,i3=I3]) = 0
```

$$1728\,I1^5 - I2^3 + I3^2 = 0$$

Parameters

`Vars`

A list of indeterminates. Default: `[x,y,z]`.

`R`

A commutative ring, i.e., a domain of category `Cat::CommutativeRing`. Default: `Dom::ExpressionField(normal)`.

`Order`

A monomial ordering, i.e., one of the predefined orderings `LexOrder`, `DegreeOrder`, or `DegInvLexOrder` or any object of type `Dom::MonomOrdering`. Default: `LexOrder`.

`p`

A polynomial or a polynomial expression.

`lm`

List of monomials, which are represented as lists containing the coefficients together with the exponents or exponent vectors.

Entries

"characteristic"	The characteristic of this domain.
"coeffRing"	The coefficient ring of this domain as defined by the parameter `R`.
"key"	The name of the domain created.
"one"	The neutral element w.r.t. `"_mult"`.
"ordering"	The monomial ordering defined by the parameter `Order`.
"variables"	The list of variables defined by the parameter `Vars`.
"zero"	The neutral element w.r.t. `"_plus"`.

Methods

Mathematical Methods

`D` — Differential operator for polynomials

Inherited from `Dom::DistributedPolynomial`.

`Dpoly` — Differential operator for polynomials

Inherited from `Dom::DistributedPolynomial`.

`SPolynomial` — Compute the S-polynomial of two polynomials

Inherited from `Dom::DistributedPolynomial`.

`_divide` — Exact polynomial division

Inherited from `Dom::DistributedPolynomial`.

`_invert` — Inverse of an element

Inherited from `Dom::DistributedPolynomial`.

_mult — Multiplie polynomials and coefficient ring elements

Inherited from `Dom::DistributedPolynomial`.

_negate — Negate a polynomial

Inherited from `Dom::DistributedPolynomial`.

_plus — Add polynomials and coefficent ring elements

Inherited from `Dom::DistributedPolynomial`.

_power — Nth power of a polynomial

Inherited from `Dom::DistributedPolynomial`.

_subtract — Subtract a polynomial or a coefficient ring element

Inherited from `Dom::DistributedPolynomial`.

associates — Test if elements are associates

Inherited from `Cat::IntegralDomain`.

borderedHessianDet — Bordered Hessian determinant of a polynomial

```
borderedHessianDet(a, b, <v>)
```

borderedHessianMat — Bordered Hessian matrix of a polynomial

```
borderedHessianMat(a, b, <v>)
```

content — Content of a polynomial

Inherited from `Dom::DistributedPolynomial`.

decompose — Functional decomposition of a polynomial

Inherited from `Dom::DistributedPolynomial`.

degLex — Compare two polynomials w.r.t. the graded lexicographical order

```
degLex(a, b)
```

`degRevLex` — Compare two polynomials w.r.t. the graded reverse lexicographical order

```
degRevLex(a, b)
```

`diff` — Differentiate a polynomial

Inherited from `Dom::DistributedPolynomial`.

`dimension` — Dimension of affine variety

Inherited from `Dom::DistributedPolynomial`.

`divide` — Divide polynomials

Inherited from `Dom::DistributedPolynomial`.

`divides` — Test if elements divides another

Inherited from `Cat::IntegralDomain`.

`equal` — Test for mathematical equality

Inherited from `Dom::BaseDomain`.

`equiv` — Test for equivalence

Inherited from `Cat::BaseCategory`.

`evalp` — Evaluate a polynomial

Inherited from `Dom::DistributedPolynomial`.

`factor` — Factor a polynomial

Inherited from `Dom::DistributedPolynomial`.

`func_call` — Applie expressions to a polynomial

Inherited from `Dom::DistributedPolynomial`.

`gcd` — Greatest common divisor of polynomials

Inherited from `Dom::DistributedPolynomial`.

`gcdex` — Extended Euclidean algorithm for polynomials

Inherited from `Dom::DistributedPolynomial`.

`groebner` — Reduced Gröbner basis

Inherited from `Dom::DistributedPolynomial`.

`hessianDet` — Hessian determinant of a polynomial

```
hessianDet(a, <v>)
```

`hessianMat` — Hessian matrix of a polynomial

```
hessianMat(a, <v>)
```

`homogeneousComponents` — List of homogeneous components of a polynomial

```
homogeneousComponents(a)
```

`idealGenerator` — Generator of finitely generated ideal

Inherited from `Cat::EuclideanDomain`.

`int` — Definite and indefinite integration of a polynomial

Inherited from `Dom::DistributedPolynomial`.

`intmult` — Multiplie a polynomial with an integer

Inherited from `Dom::DistributedPolynomial`.

`irreducible` — Test if element is irreducible

Inherited from `Cat::FactorialDomain`.

`isHomogeneous` — Test if a polynomial is homogeneous

```
isHomogeneous(a)
```

`isUnit` — Test if element is a unit

Inherited from `Cat::Polynomial`.

`isone` — Test for one

Inherited from `Dom::DistributedPolynomial`.

`iszero` — Test for zero

Inherited from `Dom::DistributedPolynomial`.

`jacobianDet` — Jacobian determinant of a polynomial

```
jacobianDet(ais, <v>)
```

`jacobianMat` — Jacobian matrix of a polynomial

```
jacobianMat(ais, <v>)
```

`lcm` — Least common multiple of polynomials

Inherited from `Dom::DistributedPolynomial`.

`makeIntegral` — Make the coefficients fraction free

Inherited from `Dom::DistributedPolynomial`.

`monic` — Normalize a polynomial

Inherited from `Dom::DistributedPolynomial`.

`normalForm` — Complete reduction modulo an ideal

Inherited from `Dom::DistributedPolynomial`.

`pdioe` — Solve polynomial Diophantine equations

Inherited from `Dom::DistributedPolynomial`.

`pdivide` — Pseudo-division of polynomials

Inherited from `Dom::DistributedPolynomial`.

`pquo` — Pseudo-quotient of polynomials

Inherited from `Dom::DistributedPolynomial`.

prem — Pseudo-remainder of polynomials

Inherited from `Dom::DistributedPolynomial`.

primpart — Return primitive part

Inherited from `Cat::Polynomial`.

quo — Euclidean quotient

Inherited from `Cat::EuclideanDomain`.

random — Create a random polynomial

Inherited from `Dom::DistributedPolynomial`.

rem — Euclidean remainder

Inherited from `Cat::EuclideanDomain`.

resultant — Resultant of two polynomials

Inherited from `Dom::DistributedPolynomial`.

rewriteHomPoly — Rewrite a polynomial in terms of other polynomials

```
rewriteHomPoly(a, ais, v)
```

All the polynomials `a` and `ais` must be homogeneous.

The variables of `v` should be new variables.

rewritePoly — Rewrite a polynomial in terms of other polynomials

```
rewritePoly(a, [ai = vi], <Unsorted>)
```

This method can be used for representing a polynomial with respect to a given polynomial basis.

When option `Unsorted` is given, the list `[ai=vi]` is not sorted. Otherwise, in a precomputation step this list will be sorted in the `ai`'s w.r.t. the graded lexicographical order (`"degLex"`).

Please note: the algorithm depends on the order of `Vars` and `ais`.

All the polynomials `ai` must be homogeneous.

The variables of `vi` should be new variables.

`ringmult` — Multiplie a polynomial with a coefficient ring element

Inherited from `Dom::DistributedPolynomial`.

`solve` — Zero of polynomials

Inherited from `Dom::DistributedPolynomial`.

`sqrfree` — Square-free factorization of polynomials

Inherited from `Dom::DistributedPolynomial`.

`unitNormal` — Return unit normal

Inherited from `Cat::Polynomial`.

`unitNormalRep` — Return unit normal representation

Inherited from `Cat::Polynomial`.

Access Methods

`coeff` — Coefficient of a polynomial

Inherited from `Dom::DistributedPolynomial`.

`degree` — Degree of a polynomial

Inherited from `Dom::DistributedPolynomial`.

`degreevec` — Vector of exponents of the leading term of a polynomial

Inherited from `Dom::DistributedPolynomial`.

`euclideanDegree` — Euclidean degree function

Inherited from `Dom::DistributedPolynomial`.

`ground` — Ground term of a polynomial

Inherited from `Dom::DistributedPolynomial`.

`has` — Existence of an object in a polynomial

Inherited from `Dom::DistributedPolynomial`.

`indets` — Indeterminate of a polynomial

Inherited from `Dom::DistributedPolynomial`.

`lcoeff` — Leading coefficient of a polynomial

Inherited from `Dom::DistributedPolynomial`.

`ldegree` — Lowest degree of a polynomial

Inherited from `Dom::DistributedPolynomial`.

`lmonomial` — Leading monomial of a polynomial

Inherited from `Dom::DistributedPolynomial`.

`lterm` — Leading term of a polynomial

Inherited from `Dom::DistributedPolynomial`.

`mainvar` — Main variable of a polynomial

Inherited from `Dom::DistributedPolynomial`.

`mapcoeffs` — Applie a function to the coefficients of a polynomial

Inherited from `Dom::DistributedPolynomial`.

`multcoeffs` — Multiplie the coefficients of a polynomial with a factor

Inherited from `Dom::DistributedPolynomial`.

`nterms` — Number of terms of a polynomial

Inherited from `Dom::DistributedPolynomial`.

`nthcoeff` — N-th coefficient of a polynomial

Inherited from `Dom::DistributedPolynomial`.

`nthmonomial` — N-th monomial of a polynomial

Inherited from `Dom::DistributedPolynomial`.

`nthterm` — N-th term of a polynomial

Inherited from `Dom::DistributedPolynomial`.

`order` — Compare two polynomials w.r.t. a given order

```
order(a, b, o)
```

`orderedVariableList` — Ordered list of indeterminates of a polynomial

Inherited from `Dom::DistributedPolynomial`.

`pivotSize` — Size of a pivot element

Inherited from `Dom::DistributedPolynomial`.

`reductum` — Reductum of a polynomial

Inherited from `Dom::DistributedPolynomial`.

`sortList` — Sort a list of polynomials w.r.t. a given order

```
sortList(ais, o)
```

This sorting method may be not stable if `o` is not a total order.

`stableSort` — Sort a list of polynomials w.r.t. a given order

```
stableSort(ais, o)
```

This sorting method is stable, even if `o` is not a total order.

`subs` — Avoid substitution

Inherited from `Dom::BaseDomain`.

`subsex` — Avoid extended substitution

Inherited from `Dom::BaseDomain`.

`tcoeff` — Lowest coefficient of a polynomial

Inherited from `Dom::DistributedPolynomial`.

MuPAD Domains

`Dom::DistributedPolynomial` | `Dom::Polynomial` | `Dom::UnivariatePolynomial`

Dom::Natural

Semi-ring of natural integer numbers

Syntax

```
Dom::Natural(x)
```

Description

`Dom::Natural` is the semi-ring of integer numbers represented by elements of the domain `DOM_INT`.

`Dom::Natural` is the domain of natural integer numbers represented by expressions of type `DOM_INT`.

Elements of `Dom::Natural` are usually not created explicitly. However, if one creates elements using the usual syntax, it is checked whether the input is an integer number. This means that `Dom::Natural` is a façade domain which creates elements of domain type `DOM_INT`.

Viewed as a differential ring `Dom::Natural` is trivial, it contains constants only.

`Dom::Natural` has the domain `Dom::Numerical` as its super domain, i.e., it inherits each method which is defined by `Dom::Numerical` and not re-implemented by `Dom::Natural`. Methods described below are those implemented by `Dom::Natural`.

Superdomain

`Dom::Numerical`

Axioms

`Ax::canonicalRep`, `Ax::systemRep`, `Ax::canonicalOrder`, `Ax::canonicalUnitNormal`, `Ax::closedUnitNormals`, `Ax::efficientOperation("_divide")`, `Ax::efficientOperation("_mult")`

Categories

`Cat::EuclideanDomain`, `Cat::FactorialDomain`, `Cat::DifferentialRing`, `Cat::OrderedSet`

Examples

Example 1

Creating some integer numbers using `Dom::Natural`. This example also shows that `Dom::Natural` is a façade domain.

```
Dom::Natural(2); domtype(%)
```

```
    2

    DOM_INT
```

```
Dom::Natural(2/3)
```

```
Error: The arguments are invalid. [Dom::Natural::new]
```

Example 2

By tracing the method `Dom::Natural::testtypeDom` we can see the interaction between `testtype` and `Dom::Natural::testtypeDom`.

```
prog::trace(Dom::Natural::testtypeDom):
delete x:
testtype(x, Dom::Natural);
testtype(3, Dom::Natural);
prog::untrace(Dom::Natural::testtypeDom):
```

```
enter Dom::Natural::testtypeDom(x, Dom::Natural)
computed FAIL

    FALSE
```

```
enter Dom::Natural::testtypeDom(3, Dom::Natural)
computed TRUE

    TRUE
```

Parameters

x

An integer

Methods

Mathematical Methods

`_divide` — Division of two objects

```
_divide(x, y)
```

`_divides` — Decide if a number divides another one

```
_divides(x, y)
```

`euclideanDegree` — Euclidean degree

```
euclideanDegree(x)
```

`factor` — Factorization

```
factor(x)
```

`gcd` — Gcd computation

```
gcd(x1, x2, …)
```

`gcdex` — Applie the extended Euclidean algorithm

```
gcdex(x, y)
```

`_invert` — Inverse of an element

```
_invert(x)
```

`irreducible` — Prime number test

```
irreducible(x)
```

`isUnit` — Test if an element is a unit

```
isUnit(x)
```

`lcm` — Compute the lcm

```
lcm(x1, x2, …)
```

`quo` — Compute the euclidean quotient

```
quo(x, y)
```

`random` — Random number generation

```
random()
```

```
random(n)
```

```
random(m, …, n)
```

This methods returns a random number between 0 and n - 1.

This methods returns a random number between `m` and `n`.

`rem` — Compute the Euclidean reminder

```
rem(x, y)
```

`unitNormal` — Unit normal part

```
unitNormal(x)
```

`unitNormalRep` — Unit normal representation

```
unitNormalRep(x)
```

Conversion Methods

`convert` — Conversion of objects

```
convert(x)
```

`convert_to` — Conversion to other domains

```
convert_to(x, T)
```

The following domains are allowed for for `T`: `DOM_INT`, `Dom::Natural`, `Dom::Rational`, `DOM_FLOAT`, `Dom::Float` and `Dom::Numerical`.

`testtype` — Type checking

```
testtype(x, T)
```

Usually, this method is called from the function `testtype` and not directly by the user. “Example 2” on page 7-330 demonstrates this behavior.

Dom::Numerical

Field of numbers

Syntax

```
Dom::Numerical(x)
```

Description

`Dom::Numerical` is the field of numbers.

`Dom::Numerical` is the domain of numbers represented by one of the kernel domains `DOM_INT`, `DOM_RAT`, `DOM_FLOAT`, or `DOM_COMPLEX`.

`Dom::Numerical` is of category `Cat::Field` due to pragmatism. This domain actually is not a field because `bool(1.0 = float(3) / float(3))` returns `FALSE`, for example.

Elements of `Dom::Numerical` are usually not created explicitly. However, if one creates elements using the usual syntax, it is checked whether the input expression can be converted into a number (see below).

This means that `Dom::Numerical` is a façade domain which creates elements of domain type `DOM_INT`, `DOM_RAT`, `DOM_FLOAT` or `DOM_COMPLEX`. Every system function dealing with numbers can be applied, and computations in this domain are performed efficiently.

`Dom::Numerical` has no normal representation, because `0` and `0.0` both represent zero.

Viewed as a differential ring, `Dom::Numerical` is trivial. It only contains constants.

If `x` is a constant arithmetical expression such as `sin(2)` or `PI + 2`, the system function `float` is applied to convert `x` into a floating-point approximation.

An error message is issued if the result of this conversion is not of domain type `DOM_FLOAT` or `DOM_COMPLEX`.

Superdomain

`Dom::ArithmeticalExpression`

Axioms

`Ax::canonicalRep`, `Ax::systemRep`, `Ax::efficientOperation("_divide")`, `Ax::efficientOperation("_mult")`, `Ax::efficientOperation("_invert")`

Categories

`Cat::DifferentialRing`, `Cat::Field`

Examples

Example 1

`Dom::Numerical` contains numbers of the domains `DOM_INT`, `DOM_RAT`, `DOM_FLOAT` and `DOM_COMPLEX`:

```
Dom::Numerical(2), Dom::Numerical(2/3),
Dom::Numerical(3.141), Dom::Numerical(2 + 3*I)
```

$$2,\ \frac{2}{3},\ 3.141,\ 2+3\,i$$

Constant arithmetical expressions are converted into a real and complex floating-point number, respectively, i.e., into an element of the domain `DOM_FLOAT` or `DOM_COMPLEX` (see the function `float` for details):

```
Dom::Numerical(exp(5)), Dom::Numerical(sin(2/3*I) + 3)
```

$$148.4131591,\ 3.0+0.717158461\,i$$

Note that the elements of this domain are elements of kernel domains, there are no elements of the domain type `Dom::Numerical`!

An error message is issued for non-constant arithmetical expressions:

```
Dom::Numerical(sin(x))
```

```
Error: The arguments are invalid. [Dom::Numerical::new]
```

Example 2

`Dom::Numerical` is regarded as a field, and it therefore can be used as a coefficient ring of polynomials or as a component ring of matrices, for example.

We create the domain of matrices of arbitrary size (see `Dom::Matrix`) with numerical components:

```
MatN := Dom::Matrix(Dom::Numerical)
```

$$\text{Dom::Matrix(Dom::Numerical)}$$

Next we create a banded matrix, such as:

```
A := MatN(4, 4, [-PI, 0, PI], Banded)
```

$$\begin{pmatrix} 0 & 3.141592654 & 0 & 0 \\ -3.141592654 & 0 & 3.141592654 & 0 \\ 0 & -3.141592654 & 0 & 3.141592654 \\ 0 & 0 & -3.141592654 & 0 \end{pmatrix}$$

and a row vector with four components as a 1 ×4 matrix:

```
v := MatN([[2, 3, -1, 0]])
```

$$\begin{pmatrix} 2 & 3 & -1 & 0 \end{pmatrix}$$

Vector-matrix multiplication can be performed with the standard operator `*` for multiplication:

```
v * A
```

$$\begin{pmatrix} -9.424777961 & 9.424777961 & 9.424777961 & -3.141592654 \end{pmatrix}$$

Finally we compute the determinant of the matrix A, using the function `det`:

```
det(A)
```

```
97.40909103
```

Parameters

x

An arithmetical expression

Entries

"characteristic" is zero.

Methods

Mathematical Methods

D — Differential operator for numbers

```
D(a)
```

See the function D for details and further calling sequences.

diff — Differentiation of numbers

```
diff(a, x)
```

See the function `diff` for details and further calling sequences.

norm — Absolute value of numbers

```
norm(a)
```

`random` — Random number generation

```
random()
```

Conversion Methods

`convert` — Conversion of objects into numbers

```
convert(x)
```

If `x` is of the domain type `DOM_INT`, `DOM_RAT`, `DOM_FLOAT` or `DOM_COMPLEX`, `x` is returned.

Otherwise `float(x)` is computed and the result is returned, if it is of the domain type `DOM_FLOAT` or `DOM_COMPLEX`. If it is not, `FAIL` is returned.

`convert_to` — Conversion into other domains

```
convert_to(a, T)
```

If the conversion fails, `FAIL` is returned.

It currently handles the following domains for `T`: `DOM_INT`, `Dom::Integer`, `DOM_RAT`, `Dom::Rational`, `DOM_FLOAT`, `Dom::Float` and `DOM_COMPLEX`.

`testtype` — Type checking

```
testtype(a, T)
```

This method is called from the function `testtype`.

Dom::Polynomial

Domains of polynomials in arbitrarily many indeterminates

Syntax

Domain Creation

```
Dom::Polynomial(<R, <Order>>)
```

Element Creation

```
Dom::PolynomialRorder(p)
```

```
Dom::PolynomialRorder(lm, v)
```

Description

`Dom::Polynomial(R, ..)` creates the domain of polynomials in arbitrarily many indeterminates over the commutative ring `R` in distributed representation.

`Dom::Polynomial` represents polynomials in arbitrarily many indeterminates over arbitrary commutative rings.

It is simply a front end to the domain `Dom::DistributedPolynomial([],R,Order)` and thus all usual algebraic and arithmetical polynomial operations are implemented. Please see the documentation for `Dom::DistributedPolynomial` for a list of methods.

`Dom::Polynomial(R, Order)` creates a domain of polynomials in arbitrarily many indeterminates over a domain of category `Cat::CommutativeRing` in sparse distributed representation with respect to the monomial ordering `Order`.

If `Dom::Polynomial` is called without any argument, a polynomial domain over the domain `Dom::ExpressionField(normal)` with respect to the lexicographic monomial ordering is created.

Note: Only commutative coefficient rings of type `DOM_DOMAIN` which inherit from `Dom::BaseDomain` are allowed. If `R` is of type `DOM_DOMAIN` but does not inherit from

`Dom::BaseDomain`, the domain `Dom::ExpressionField(normal)` will be used instead.

Only identifiers should be used as polynomial indeterminates, since when creating a new element from a polynomial or a polynomial expression the function `indets` is first called to get the identifiers and then the polynomial is created with respect to these identifiers.

Note: It is highly recommend to use only coefficient rings with unique zero representation. Otherwise it may happen that, e.g., a polynomial division will not terminate or a wrong degree will be returned.

Please note that for reasons of efficiency not all methods check their arguments, not even at the interactive level. In particular, this is true for many access methods, converting methods and technical methods. Thus, improper use of these methods may result in confusing error messages.

Superdomain

`Dom::DistributedPolynomial`

Axioms

`Ax::indetElements`

Categories

`Cat::Polynomial(R)`

Examples

Example 1

The following call creates the polynomial domain over the rationals.

```
PR:=Dom::Polynomial(Dom::Rational)
```

Dom::Polynomial(Dom::Rational, LexOrder)

Since the monomial ordering was not specified, this domain is created with the default value for this parameter.

It is rather easy to create elements of this domain, as, e.g.,

```
a := PR(x*(2*x + y^3) - 7/2)
```

$$2x^2 + x y^3 - \frac{7}{2}$$

```
b := PR(x*(2*t + z^3) - 6)
```

$$2tx + x z^3 - 6$$

```
c := a^2-b/3+3
```

$$-\frac{2tx}{3} + 4x^4 + 4x^3 y^3 + x^2 y^6 - 14x^2 - 7x y^3 - \frac{x z^3}{3} + \frac{69}{4}$$

Parameters

R

A commutative ring, i.e., a domain of category `Cat::CommutativeRing`. Default: `Dom::ExpressionField(normal)`.

Order

A monomial ordering, i.e., one of the predefined orderings `LexOrder`, `DegreeOrder`, or `DegInvLexOrder` or an element of the domain `Dom::MonomOrdering`. Default: `LexOrder`.

p

A polynomial or a polynomial expression.

`lm`

List of monomials, which are represented as lists containing the coefficients together with the exponents or exponent vectors.

`v`

List of indeterminates.

Entries

"characteristic"	The characteristic of this domain, which is the characteristic of `R`.
"coeffRing"	The coefficient ring of this domain as defined by the parameter `R`.
"key"	The name of the domain created.
"one"	The neutral element w.r.t. `"_mult"`, which is `R::one`.
"ordering"	The monomial order as defined by the parameter `Order`.
"zero"	The neutral element w.r.t. `"_plus"`, which is `R::zero`.

Algorithms

To create polynomials from expressions with no suitable indeterminates the dummy variable `_dummy` is introduced. With this variable it is possible to create elements from constants which otherwise would fail. The drawback of this approach is that two mathematically equal polynomials may have variable lists which differ by this dummy variable.

MuPAD Domains

`Dom::DistributedPolynomial` | `Dom::MultivariatePolynomial` | `Dom::UnivariatePolynomial`

Dom::Product

Homogeneous direct products

Syntax

Domain Creation

```
Dom::Product(Set, <n>)
```

```
Dom::ProductSetn(e1, e2, …, en)
```

```
Dom::ProductSetn(List)
```

Description

`Dom::Product(Set, n)` is an `n`-fold direct product of the domain *Set*.

`Dom::Product(Set, n)(e1, e2, ..., en)` creates the `n`-tuple (e_1, e_2, …, e_n).

The objects `e1`, `e2`, ..., `en` must be convertible into elements of the domain `Set`, otherwise an error message is issued.

`Dom::Product(Set, n)(List)` creates the `n`-tuple (l_1, l_2, …, l_n).

The `n` elements l_i of `List` must be convertible into elements of the domain `Set`, otherwise an error message is issued.

The list must consist of exactly `n` elements, otherwise an error message is issued.

Following to the definition of a direct product many of the methods such as `"D"` and `"_negate"` just map the operation to all the components of the tuple.

Most `n`-ary methods like `"_plus"` and `"_mult"` apply the operation component-wise to the tuples.

Superdomain

`Dom::BaseDomain`

Axioms

If Set has `Ax::canonicalRep`, then `Ax::canonicalRep`.

If Set has `Cat::AbelianMonoid`, then `Ax::normalRep`.

Categories

`Cat::HomogeneousFiniteProduct(Set)`

Examples

Example 1

Define the 3-fold direct product of the rational numbers:

```
P3 := Dom::Product(Dom::Rational, 3)
```

$$\text{Dom::Product}(\text{Dom::Rational}, 3)$$

and create elements:

```
a := P3([1, 2/3, 0])
```

$$\left[1, \frac{2}{3}, 0\right]$$

```
b := P3(2/3, 4, 1/2)
```

$$\left[\frac{2}{3}, 4, \frac{1}{2}\right]$$

We use the standard arithmetical operators to calculate with such tuples:

```
a + b, a*b, 2*a
```

$$\left[\frac{5}{3}, \frac{14}{3}, \frac{1}{2}\right], \left[\frac{2}{3}, \frac{8}{3}, 0\right], \left[2, \frac{4}{3}, 0\right]$$

Some system functions were overloaded for such elements, such as `diff`, `map` or `zip` (see the description of the corresponding methods `"diff"`, `"map"` and `"zip"` above).

For example, to divide each component of `a` by 2 we enter:

```
map(a, `/`, 2)
```

$$\left[\frac{1}{2}, \frac{1}{3}, 0\right]$$

The quoted character `` `/` `` is another notation for the function `_divide`, the functional form of the division operator `/`.

Be careful that the mapping function returns elements of the domain the product is defined over. This is not checked by the function `map` (for efficiency reasons) and may lead to "invalid" tuples. For example:

```
b := map(a, sin); domtype(b)
```

$$\left[\sin(1), \sin\left(\frac{2}{3}\right), 0\right]$$

$$\text{Dom::Product}(\text{Dom::Rational}, 3)$$

But the components of `b` are no longer rational numbers!

Parameters

`Set`

An arbitrary domain of elements, i.e., a domain of category `Cat::BaseCategory`

`n`

The dimension of the product (a positive integer); default is `1`

`e1e2, en, …`

Elements of `Set` or objects convertible into such

`List`

A list of `n` elements of `Set` or objects convertible into such

Entries

"dimen"	is the dimension of `Dom::Product(Set, n)`, which is equal to `n`.
"coeffRing"	is the domain `S`.
"one"	is the `n`-tuple `(Set::one, Set::one, ..., Set::one)`. This entry only exists if `Set` is a monoid, i.e., a domain of category `Cat::Monoid`.
"zero"	is the `n`-tuple `(Set::zero, Set::zero, ..., Set::zero)`. This entry only exists if `Set` is an Abelian group, i.e., a domain of category `Cat::AbelianGroup`.

Methods

Mathematical Methods

`_divide` — Divide tuples

```
_divide(x, y)
```

This method only exists if `Set` is a (multiplicative) group, i.e., a domain of category `Cat::Group`.

This method overloads the function `_divide` for `n`-tuples, i.e., one may use it in the form `x / y`, or in functional notation: `_divide(x, y)`.

`_invert` — Compute the inverse of a tuple

```
_invert(x)
```

This method only exists if `Set` is a (multiplicative) group, i.e., a domain of category `Cat::Group`.

This method overloads the function `_invert` for `n`-tuples, i.e., one may use it in the form `1/x` or `x^(-1)`, or in functional notation: `_inverse(x)`.

`_less` — Less-than relation

```
_less(x, y)
```

An implementation is provided only if `Set` is an ordered set, i.e., a domain of category `Cat::OrderedSet`.

This method overloads the function `_less` for `n`-tuples, i.e., one may use it in the form `x < y`, or in functional notation: `_less(x, y)`.

`_mult` — Multiplie tuples by tuples and scalars

```
_mult(x, y, …)
```

If `x` is not of the type `Dom::Product(Set,n)`, it is considered as a scalar which is multiplied to each component of the `n`-tuple `y` (and vice versa).

This method only exists if `Set` is a semigroup, i.e., a domain of category `Cat::SemiGroup`.

This method also handles more than two arguments. In this case, the argument list is split into two parts of the same length which both are multiplied with the function `_mult`. These two result are multiplied again with `_mult` whose result then is returned.

This method overloads the function `_mult` for `n`-tuples, i.e., one may use it in the form `x * y`, or in functional notation: `_mult(x, y)`.

`_negate` — Negate an n-tuple

```
_negate(x)
```

This method overloads the function `_negate` for `n`-tuples, i.e., one may use it in the form `-x`, or in functional notation: `_negate(x)`.

`_power` — ith power of a tuple

```
_power(x, i)
```

An implementation is provided only if `Set` is a semigroup, i.e., a domain of category `Cat::SemiGroup`.

This method overloads the function `_power` for `n`-tuples, i.e., one may use it in the form `x^i`, or in functional notation: `_power(x, i)`.

`_plus` — Add tuples

```
_plus(x, y, …)
```

The sum of two `n`-tuples x and y is defined component-wise as $(x_1 + y_1, \ldots, x_n + y_n)$.

This method overloads the function `_plus` for `n`-tuples, i.e., one may use it in the form `x + y`, or in functional notation: `_plus(x, y)`.

`D` — Differential operator

```
D(x)
```

An implementation is provided only if `Set` is a partial differential ring, i.e., a domain of category `Cat::PartialDifferentialRing`.

This method overloads the operator `D` for `n`-tuples, i.e., one may use it in the form `D(x)`.

`diff` — Differentiation of n-tuples

```
diff(a, x)
```

This method overloads the function `diff` for `n`-tuples, i.e., one may use it in the form `diff(a, x)`.

An implementation is provided only if `Set` is a partial differential ring, i.e., a domain of category `Cat::PartialDifferentialRing`.

`equal` — Test on equality of n-tuples

```
equal(x, y)
```

`intmult` — Multiple of a tuple

```
intmult(x, k)
```

An implementation is provided only if `Set` is an Abelian semigroup, i.e., a domain of category `Cat::AbelianSemiGroup`.

`iszero` — Test on zero

```
iszero(x)
```

Note that there may be more than one representation of the zero `n`-tuple if `R` does not have `Ax::canonicalRep`.

This method overloads the function `iszero` for `n`-tuples, i.e., one may use it in the form `iszero(x)`.

`random` — Random tuple generation

```
random()
```

Access Methods

`_index` — Tuple indexing

```
_index(x, i)
```

See also the method `"op"`.

This method overloads the function `_index` for `n`-tuples, i.e., one may use it in the form `x[i]`, or in functional notation: `_index(x, i)`.

`map` — Apply a function to tuple components

```
map(x, func, <expr, …>)
```

Note: Note that the function values will *not* be implicitly converted into elements of the domain `Set`. One has to take care that the function calls return elements of the domain type `Set`.

This method overloads the function `map` for `n`-tuples, i.e., one may use it in the form `map(x, func, ...)`.

`mapCanFail` — Apply a function to tuple components

```
mapCanFail(x, func, <expr, …>)
```

op — Component of a tuple

```
op(x, i)
```

```
op(x)
```

See also the method "_index".

This method overloads the function op for n-tuples, i.e., one may use it in the form op(x, i).

Returns a sequence of all components of x.

set_index — Assigning tuple components

```
set_index(x, i, e)
```

See also the method "subsop".

Note: This method does not check whether e has the correct type.

This method overloads the indexed assignment _assign for n-tuples, i.e., one may use it in the form x[i] := e, or in functional notation: _assign(x[i], e).

sort — Sorting the components of a tuple

```
sort(x)
```

This method overloads function sort for tuples, i.e. one may use it in the form sort(x).

subs — Substitution of tuple components

```
subs(x, …)
```

Note: The objects obtained by the substitutions will not be implicitly converted into elements of the domain Set. One has to take care that the substitutions return elements of the domain Set.

This method overloads the function subs for n-tuples, i.e., one may use it in the form subs(x, ...). See subs for details and calling sequences.

`testEach` — Check every component for a certain condition

```
testEach(x, func, <expr, …>)
```

`func` must return either `TRUE` or `FALSE`, otherwise a runtime error is raised.

`testOne` — Check an component for a certain condition

```
testOne(x, func, <expr, …>)
```

`func` must return either `TRUE` or `FALSE`, otherwise a runtime error is raised.

`zip` — Combine tuples component-wise

```
zip(x, y, func, <expr, …>)
```

Note: The function values will not be implicitly converted into elements of the domain `Set`. One has to take care that the function calls return elements of the domain `Set`.

This method overloads the function `zip` for `n`-tuples, i.e., one may use it in the form `zip(x, y, func, ...)`.

`zipCanFail` — Combine tuples component-wise

```
zipCanFail(x, y, func, <expr, …>)
```

Conversion Methods

`convert` — Conversion into an n-tuple

```
convert(List)
```

```
convert(e1, <e2, …>)
```

`FAIL` is returned if this conversion fails.

Tries to convert the arguments into an element of the domain `Dom::Product(Set, n)`. This can be done if exactly `n` arguments are given where each argument can be converted into an element of the domain `Set`.

FAIL is returned if this conversion fails.

expr — Conversion into an object of a kernel domain

```
expr(x)
```

This method overloads the function expr for n-tuples, i.e., one may use it in the form expr(x).

Dom::Quaternion

Skew field of quaternions

Syntax

```
Dom::Quaternion(listi)
```

```
Dom::Quaternion(ex)
```

```
Dom::Quaternion(M)
```

Description

Domain `Dom::Quaternion` represents the skew field of quaternions.

Quaternions are usually defined to be complex 2 ×2 matrices of the special form

$$\begin{pmatrix} a+b\,\mathrm{i} & -c-d\,\mathrm{i} \\ c-d\,\mathrm{i} & a-b\,\mathrm{i} \end{pmatrix},$$

where a, b, c, d are real numbers. Another usual notation is $a + bi + cj + dk$; the subfield of those quaternions for which $c = d = 0$ is isomorphic to the field of complex numbers.

The domain `Dom::Quaternion` regards these fields as being identical, and it allows both notations that have been mentioned, as well as simply `[a,b,c,d]`.

If you enter a quaternion as an arithmetical expression `ex`, the identifiers `i`, `j`, and `k` are understood in the way mentioned above; `I`, `J`, and `K` may be used alternatively, and you may also mix small and capital letters. Every subexpression of `ex` not containing one of these must be real and constant.

Note: Be sure that you have not assigned a value to one of the identifiers mentioned.

`Dom::Quaternion` has the domain `Dom::BaseDomain` as its super domain, i.e., it inherits each method which is defined by `Dom::BaseDomain` and not re-

implemented by `Dom::Quaternion`. Methods described below are re-implemented by `Dom::Quaternion`.

Superdomain

`Dom::BaseDomain`

Axioms

`Ax::canonicalRep`

Categories

`Cat::SkewField`

Examples

Example 1

Creating some quaternions.

```
Dom::Quaternion([1,2,3,4]),
Dom::Quaternion(11+12*i+13*j+14*k);
M := Dom::Matrix(Dom::Complex)([[3+4*I,-6-2*I],[6-2*I,3-4*I]]):
M, Dom::Quaternion(M)
```

$$1+2\,\mathrm{i}+3\,j+4\,k,\ 11+12\,\mathrm{i}+13\,j+14\,k$$

$$\begin{pmatrix} 3+4\,\mathrm{i} & -6-2\,\mathrm{i} \\ 6-2\,\mathrm{i} & 3-4\,\mathrm{i} \end{pmatrix},\ 3+4\,\mathrm{i}+6\,j+2\,k$$

Example 2

Doing some standard arithmetic.

```
a:=Dom::Quaternion([1,2,3,4]):
b:=Dom::Quaternion([11,2,33.3,2/3]):
a*b, a+b, a^2/3, b^3;
```

$$-95.56666667 - 107.2\,\mathrm{i} + 72.96666667\,j + 105.2666667\,k,\ 12 + 4\,\mathrm{i} + 36.3\,j + \frac{14\,k}{3},$$

$$-\frac{28}{3} + \frac{4\,\mathrm{i}}{3} + 2\,j + \frac{8\,k}{3},\ -35409.03667 - 1500.668889\,\mathrm{i} - 24986.137\,j - 500.222963\,k$$

Example 3

More mathematical operations:

```
a:=Dom::Quaternion([1,2,3,4]):
b:=Dom::Quaternion([11,2,33.3,2/3]):
Dom::Quaternion::nthroot(b,3);
abs(a), sign(b)
```

$$2.993953193 + 0.07959236197\,\mathrm{i} + 1.325212827\,j + 0.02653078732\,k$$

$$\sqrt{30},\ 0.3130950929 + 0.05692638053\,\mathrm{i} + 0.9478242358\,j + 0.01897546018\,k$$

Example 4

Some miscellaneous operations.

```
a:=Dom::Quaternion([1,2,3,4]):
Dom::Quaternion::matrixform(a);
map(a, sqrt), map(a, _plus, 1);
```

$$\begin{pmatrix} 1+2\,\mathrm{i} & -3-4\,\mathrm{i} \\ 3-4\,\mathrm{i} & 1-2\,\mathrm{i} \end{pmatrix}$$

$$1 + \sqrt{2}\,\mathrm{i} + \sqrt{3}\,j + 2\,k,\ 2 + 3\,\mathrm{i} + 4\,j + 5\,k$$

Parameters

`listi`

A list containing four elements of type `Type::Real`

`ex`

Arithmetical expression

`M`

A matrix of type `Dom::Matrix(Dom::Complex)`. It has to be of a special form described in the Details section.

Entries

"characteristic"	the characteristic of this domain is 0
"one"	the unit element; it equals `Dom::Quaternion([1,0,0,0])`.
"size"	the number of quaternions is `infinity`.
"zero"	The zero element; it equals `Dom::Quaternion([0,0,0,0])`.

Methods

Mathematical Methods

`_mult` — Multiplie quaternions

```
_mult(x, y, …)
```

`_plus` — Add quaternions

```
_plus(x, y, …)
```

`_power` — n-th power of a quaternion

```
_power(x, n)
```

`Im` — Return the imaginary (vectorial) part of a quaternion.

```
Im(x)
```

The result is still a quaternion.

`Re` — Return the real part of a quaternion.

```
Re(x)
```

The result is of type `Type::Real`.

`abs` — Absolute value of a quaternion

```
abs(x)
```

The result is of type `Type::Real`.

`conjugate` — Conjugate element

```
conjugate(x)
```

`intpower` — Multiplie quaternions

```
intpower(x, {DOM_INT})
```

The implementation uses “repeated squaring”.

`Dom::Quaternion` is used by `"_power"`.

`nthroot` — N-th root of a quaternion

```
nthroot(x, n)
```

The implementation uses “repeated squaring”.

`Dom::Quaternion` is used by `"_power"`.

`norm` — Norm of a quaternion

```
norm(x)
```

The result is of type `Type::Real`.

`random` — Random number generation

```
random()
```

`scalarmult` — Scalar multiplication

```
scalarmult(s, x)
```

`scalarprod` — Inner product

```
scalarprod(x, y)
```

`sign` — Sign of a quaternion

```
sign(x)
```

The result is of type `Type::Real`.

Conversion Methods

`convert` — Conversion of objects

```
convert(x)
```

`convert_to` — Conversion to other domains

```
convert_to(x, T)
```

It currently handles the following domains for `T`: `DOM_EXPR`, `DOM_LIST`, `Dom::Matrix(Dom::Complex)`.

`expr` — Convert a quaternion to an object of a kernel domain

```
expr(x)
```

The result is an object of the kernel domain `DOM_EXPR`.

This method overloads the function `expr` for quaternions, i.e., you may use it in the form `expr(x)`.

`matrixform` — Convert a quaternion to a 2 x 2 matrix with complex entries.

```
matrixform(x)
```

The result is an object of the domain `Dom::Matrix(Dom::Complex)`.

Technical Methods

`TeX` — Generate TeX-formatted string

```
TeX(x)
```

`map` — Apply a function to all components of a quaternion

```
map(x, f, arg, …)
```

If optional arguments are present, then each component `co` of `x` is replaced by f(co, arg...). So for the quaternion $x := a + bi + cj + dk$, `Dom::Quaternion(x, f, arg, ...)` returns the quaternion $f(a, arg, \ldots) + f(b, arg, \ldots)\, i + f(c, arg, \ldots)\, j + f(d, arg, \ldots)\, k$.

`simplify` — Simplification of a quaternion

```
simplify(x)
```

MuPAD Domains
`Dom::Complex`

Dom::Rational

Field of rational numbers

Syntax

```
Dom::Rational(x)
```

Description

`Dom::Rational` is the domain of rational numbers represented by elements of the domains `DOM_INT` or `DOM_RAT`. `Dom::Rational` represents the field of rational numbers.

Elements of `Dom::Rational` are usually not created explicitly. However, if one creates elements using the usual syntax, it is checked whether the input is of type `DOM_INT` or `DOM_RAT`. This means `Dom::Rational` is a façade domain which creates elements of domain type `DOM_INT` or `DOM_RAT`.

Viewed as a differential ring `Dom::Rational` is trivial, it contains constants only.

`Dom::Rational` has the domain `Dom::Numerical` as its super domain, i.e., it inherits each method which is defined by `Dom::Numerical` and not re-implemented by `Dom::Rational`. Methods described below are re-implemented by `Dom::Rational`.

Superdomain

`Dom::Numerical`

Axioms

`Ax::canonicalRep`, `Ax::systemRep`, `Ax::canonicalOrder`, `Ax::efficientOperation("_divide")`, `Ax::efficientOperation("_mult")`, `Ax::efficientOperation("_invert")`

Categories

`Cat::QuotientField(Dom::Integer)`, `Cat::DifferentialRing`, `Cat::OrderedSet`

Examples

Example 1

Creating some rational numbers using `Dom::Rational`. This example also shows that `Dom::Rational` is a façade domain.

```
Dom::Rational(2/3) ; domtype(%)
```

$$\frac{2}{3}$$

DOM_RAT

```
Dom::Rational(2.0)
```

```
Error: The arguments are invalid. [Dom::Rational::new]
```

Example 2

By tracing the method `Dom::Rational::testtypeDom` we can see the interaction between `testtype` and `Dom::Rational::testtypeDom`.

```
prog::trace(Dom::Rational::testtypeDom):
delete x:
testtype(x, Dom::Rational);
testtype(3/4, Dom::Rational);
prog::untrace(Dom::Rational::testtypeDom):
```

```
enter Dom::Rational::testtypeDom(x, Dom::Rational)
computed FAIL
```

FALSE

```
enter Dom::Rational::testtypeDom(3/4, Dom::Rational)
computed TRUE

    TRUE
```

Parameters

x

An integer or a rational number

Methods

Mathematical Methods

`denom` — Denominator of a rational number

```
denom(x)
```

`diff` — Differentiates

```
diff(z, <x, …>)
```

`numer` — Numerator of the rational number

```
numer(x)
```

`random` — Random number generation

```
random()
```

`retract` — Retract to an integer element

```
retract(x)
```

Conversion Methods

`convert` — Conversion of objects

```
convert(x)
```

`convert_to` — Conversion to other domains

```
convert_to(x, T)
```

The following domains are allowed for `T`: `DOM_INT`, `Dom::Integer`, `Dom::Rational`, `DOM_RAT`, `DOM_FLOAT`, `Dom::Float` and `Dom::Numerical`.

`testtype` — Type checking

```
testtype(x, T)
```

In general this method is called from the function `testtype` and not directly by the user. “Example 2” on page 7-361 demonstrates this behaviour.

MuPAD Domains

`Dom::Complex` | `Dom::Float` | `Dom::Numerical` | `Dom::Rational` | `Dom::Real`

Dom::Real

Field of real numbers

Syntax

```
Dom::Real(x)
```

Description

`Dom::Real` is the field of real numbers represented by elements of the kernel domains `DOM_INT`, `DOM_RAT`, `DOM_FLOAT`, and `DOM_EXPR`.

`Dom::Real` is the domain of real numbers represented by expressions of type `DOM_INT`, `DOM_RAT` or `DOM_FLOAT`. An expression of type `DOM_EXPR` is considered as a real number if it is of type `Type::Arithmetical` and if it contains no indeterminates which are not of type `Type::ConstantIdents` and if it contains no imaginary part. See "Example 2" on page 7-365.

`Dom::Real` has category `Cat::Field` due to practical reasons. This domain actually is not a field because `bool(1.0 = 1e100 + 1.0 - 1e100)` returns `FALSE` for example.

Elements may not have an unique representation, for example `bool(0 = sin(2)^2 + cos(2)^2 - 1)` returns `FALSE`.

Elements of `Dom::Real` are usually not created explicitly. However, if one creates elements using the usual syntax, it is checked whether the input expression can be converted to a number. This means `Dom::Real` is a façade domain which creates elements of domain type `DOM_INT`, `DOM_RAT`, `DOM_FLOAT`, or `DOM_EXPR`.

`Dom::Real` has no normal representation, because `0` and `0.0` both represent zero.

Viewed as a differential ring, `Dom::Real` is trivial, it contains constants only.

`Dom::Real` has the domain `Dom::Complex` as its super domain, i.e., it inherits each method which is defined by `Dom::Complex` and not re-implemented by `Dom::Real`. Methods described below are re-implemented by `Dom::Real`.

Superdomain

`Dom::Complex`

Axioms

`Ax::systemRep`, `Ax::canonicalOrder`, `Ax::efficientOperation("_divide")`, `Ax::efficientOperation("_mult")`, `Ax::efficientOperation("_invert")`

Categories

`Cat::DifferentialRing`, `Cat::Field`, `Cat::OrderedSet`

Examples

Example 1

The following lines demonstrate how to generate elements of `Dom::Real`. The rational and the floating-point numbers are elements of the real numbers:

```
Dom::Real(2/3)
```

$$\frac{2}{3}$$

```
Dom::Real(0.5666)
```

$$0.5666$$

Example 2

The numbers `PI` and `sin(2)` are real numbers whereas `sin(2/3 * I) + 3` and `sin(x)` for general symbolic `x` are not real numbers. If we try to create the elements

`Dom::Real(sin(2/3 * I) + 3)` and `Dom::Real(sin(x))` an error message is produced.

```
Dom::Real(PI)
```

$$\pi$$

```
Dom::Real(sin(2))
```

$$\sin(2)$$

```
Dom::Real(sin(2/3 * I) + 3)

Error: The arguments are invalid. [Dom::Real::new]
Dom::Real(sin(x))

Error: The arguments are invalid. [Dom::Real::new]
```

Parameters

x

An expression of type `DOM_INT`, `DOM_RAT`, or `DOM_FLOAT`. An expression of type `DOM_EXPR` is also allowed if it is of type `Type::Arithmetical` and if it contains no indeterminates which are not of type `Type::ConstantIdents` and if it contains no imaginary part.

Methods

Mathematical Methods

`_less` — Boolean operator "less"

```
_less(x, y)
```

`_leequal` — Boolean operator "less or equal"

```
_leequal(x, y)
```

`_power` — Power operator

```
_power(z, n)
```

`conjugate` — Complex conjugate

```
conjugate(x)
```

`Im` — Imaginary part of a real number

```
Im(x)
```

`random` — Random number generation

```
random()
```

```
random(n)
```

```
random(m .. n)
```

This method returns a random number generator which creates positive integer between 0 and n - 1.

This method returns a random number generator which creates positive integer between m and n.

`Re` — Real part of a real number

```
Re(x)
```

Conversion Methods

`convert` — Conversion of objects

```
convert(x)
```

`convert_to` — Conversion to other domains

```
convert_to(x, T)
```

The following domains are allowed for T: DOM_INT, Dom::Integer, DOM_RAT, Dom::Rational, DOM_FLOAT, Dom::Float, Dom::Numerical, Dom::ArithmeticalExpression, Dom::Complex.

Dom::SquareMatrix(n, R)(<n, n>, List, <Diagonal>)

Dom::SquareMatrix(n, R)(<n, n>, g, <Diagonal>)

Dom::SquareMatrix(n, R)(<n, n>, List, <Banded>)
```

Description

Domain Creation

`Dom::SquareMatrix(n, R)` creates a domain which represents the ring of $n \times n$ matrices over a component domain `R`. The domain `R` must be of category `Cat::Rng` (a ring, possibly without unit).

If the optional parameter `R` is not given, the domain `Dom::ExpressionField()` is used as the component ring for the square matrices.

For matrices of a domain created by `Dom::SquareMatrix(n, R)`, standard matrix arithmetic is implemented by overloading the standard arithmetical operators `+, -, *, /` and `^`. All functions of the `linalg` package dealing with matrices can also be applied.

`Dom::SquareMatrix(n, R)` has the domain `Dom::Matrix(R)` as its super domain, i.e., it inherits each method which is defined by `Dom::Matrix(R)` and not re-implemented by `Dom::SquareMatrix(n, R)`.

Methods described below are re-implemented by `Dom::SquareMatrix`.

The domain `Dom::Matrix(R)` represents matrices over `R` of arbitrary size, and it therefore does not have any algebraic structure (except of being a *set* of matrices).

The domain `Dom::MatrixGroup(m, n, R)` represents the Abelian group of $m \times n$ matrices over R.

Element Creation

`Dom::SquareMatrix(n, R)(Array)` and `Dom::SquareMatrix(n, R)(Matrix)` create a new matrix formed by the entries of `Array` and `Matrix`, respectively.

The components of `Array` and `Matrix`, respectively, are converted into elements of the domain `R`. An error message is issued if one of these conversions fails.

The call `Dom::SquareMatrix(n, R)( n , n )` returns the $n \times n$ zero matrix. Note that the $n \times n$ zero matrix is also defined by the entry `"zero"` (see below).

`Dom::SquareMatrix(n, R)( n , n ListOfRows)` creates an $n \times n$ matrix with components taken from the nested list `ListOfRows`. Each inner list corresponds to a row of the matrix.

If an inner list has less than `n` entries, the remaining components in the corresponding row of the matrix are set to zero. If there are less than `n` inner lists, the remaining lower rows of the matrix are filled with zeroes.

The entries of the inner lists are converted into elements of the domain `R`. An error message is issued if one of these conversions fails.

It might be a good idea first to create a two-dimensional array from that list before calling `Dom::SquareMatrix(n, R)`. This is due to the fact that creating a matrix from

an array is the fastest way one can achieve. However, in this case the sublists must have the same number of elements.

`Dom::SquareMatrix(n, R)( n , n f)` returns the matrix whose (i, j)th component is the value of the function call `f(i, j)`. The row and column indices i and j range from 1 to `n`.

The function values are converted into elements of the domain `R`. An error message is issued if one of these conversions fails.

Superdomain

`Dom::Matrix(R)`

Axioms

If R has `Ax::canonicalRep`, then `Ax::canonicalRep`.

Categories

`Cat::SquareMatrix(R)`

Examples

Example 1

A lot of examples can be found on the help page of the domain constructor `Dom::Matrix`, and most of them are also examples for working with domains created by `Dom::SquareMatrix`.

These examples only concentrate on some differences with respect to working with matrices of the domain `Dom::Matrix(R)`.

The following command defines the ring of two-dimensional matrices over the rationals:

```
SqMatQ := Dom::SquareMatrix(2, Dom::Rational)
```

$$\text{Dom::SquareMatrix}(2, \text{Dom::Rational})$$

```
SqMatQ::hasProp(Cat::Ring)
```

$$\text{TRUE}$$

The unit is defined by the entry `"one"`, which is the 2×2 identity matrix:

```
SqMatQ::one
```

$$\begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}$$

Note that some operations defined by the domain `SqMatQ` return matrices which are no longer square. They return therefore matrices of the domain `Dom::Matrix(Dom::Rational)`, the super-domain of `SqMatQ`. For example, if we delete the first row of the matrix:

```
A := SqMatQ([[1, 2], [-5, 3]])
```

$$\begin{pmatrix} 1 & 2 \\ -5 & 3 \end{pmatrix}$$

we get the matrix:

```
SqMatQ::delRow(A, 1)
```

$$\begin{pmatrix} -5 & 3 \end{pmatrix}$$

which is of the domain type:

```
domtype(%)
```

$$\text{Dom::Matrix}(\text{Dom::Rational})$$

Example 2

We can convert a square matrix into or from another matrix domain, as shown next:

```
SqMatR := Dom::SquareMatrix(3, Dom::Real):
MatC := Dom::Matrix(Dom::Complex):

A := SqMatR((i, j) -> sin(i*j))
```

$$\begin{pmatrix} \sin(1) & \sin(2) & \sin(3) \\ \sin(2) & \sin(4) & \sin(6) \\ \sin(3) & \sin(6) & \sin(9) \end{pmatrix}$$

To convert `A` into a matrix of the domain `MatC`, enter:

```
coerce(A, MatC)
```

$$\begin{pmatrix} \sin(1) & \sin(2) & \sin(3) \\ \sin(2) & \sin(4) & \sin(6) \\ \sin(3) & \sin(6) & \sin(9) \end{pmatrix}$$

```
domtype(%)
```

$$\mathrm{Dom::Matrix(Dom::Complex)}$$

The conversion is done component-wise, as the following examples shows:

```
B := MatC([[0, 1], [exp(I), 0]])
```

$$\begin{pmatrix} 0 & 1 \\ e^{i} & 0 \end{pmatrix}$$

The matrix B is square but has one complex component and therefore cannot be converted into the domain `SqMatR`:

```
coerce(B, SqMatR)
```

FAIL

Parameters

`n`

A positive integer

`R`

A ring, i.e., a domain of category `Cat::Rng`; default is `Dom::ExpressionField()`

`Array`

An $n \times n$ array

`Matrix`

An $n \times n$ matrix, i.e., an element of a domain of category `Cat::Matrix`

`List`

A list of matrix components

`ListOfRows`

A list of at most `n` rows; each row is a list of at most `n` matrix components

`f`

A function or a functional expression with two parameters (the row and column index)

`g`

A function or a functional expression with one parameter (the row index)

Options

`Diagonal`

Create a diagonal matrix

With the option `Diagonal`, diagonal matrices can be created with diagonal elements taken from a list, or computed by a function.

`Dom::SquareMatrix(n, R)( n , n List, Diagonal)` creates the $n \times n$ diagonal matrix whose diagonal elements are the entries of `List`.

`List` must have at most `n` entries. If it has fewer elements, the remaining diagonal elements are set to zero.

The entries of `List` are converted into elements of the domain `R`. An error message is issued if one of these conversions fails.

`Dom::SquareMatrix(n, R)( n , n g, Diagonal)` returns the matrix whose ith diagonal element is `g(i)`, where the index i runs from 1 to `n`.

The function values are converted into elements of the domain `R`. An error message is issued if one of these conversions fails.

`Banded`

Create a banded Toeplitz matrix

`Dom::SquareMatrix(n, R)( n , n List, Banded)` creates an $n \times n$ banded Toeplitz matrix with the elements of `List` as entries. The number of entries of `List` must be odd, say $2h + 1$, and must not exceed `n`. The resulting matrix has bandwidth at most $2h + 1$.

All elements of the main diagonal of the created matrix are initialized with the middle element of `List`. All elements of the ith subdiagonal are initialized with the $(h + 1 - i)$th element of `List`. All elements of the ith superdiagonal are initialized with the $(h + 1 + i)$th element of `List`. All entries on the remaining sub- and superdiagonals are set to zero.

The entries of `List` are converted into elements of the domain `R`. An error message is issued if one of these conversions fails.

Entries

"one"	is the $n \times n$ identity matrix. This entry exists if the component ring `R` is a domain of category `Cat::Ring`, i.e., a ring with unit.

"randomDimen"	is set to `[n, n]`.
"zero"	is the $n \times n$ zero matrix.

Methods

Mathematical Methods

`evalp` — Evaluating matrices of polynomials at a certain point

```
evalp(A, x = a, …)
```

This method is only defined if `R` is a polynomial ring of category `Cat::Polynomial`.

This method overloads the function `evalp` for matrices, i.e., one may use it in the form `evalp(A, x = a)`.

`identity` — Identity matrix

```
identity(k)
```

Note: The matrix returned is of the domain `Dom::Matrix(R)` if $k \neq n$.

This method only exists if the component ring `R` is of category `Cat::Ring`, i.e., a ring with unit.

`matdim` — Matrix dimension

```
matdim(A)
```

`random` — Random matrix generation

```
random()
```

The components of the random matrix are generated with the method `"random"` of the component ring `R`.

Access Methods

`_concat` — Horizontal concatenation of matrices

```
_concat(A, B, …)
```

An error message is issued if the given matrices do not have the same number of rows.

Note: The matrix returned is of the domain `Dom::Matrix(R)`!

This method overloads the function `_concat` for matrices, i.e., one may use it in the form `A . B . ...`, or in functional notation: `_concat(A, B, ...)`.

`_index` — Matrix indexing

```
_index(A, i, j)
```

```
_index(A, r1 .. r2, c1 .. c2)
```

If `i` and `j` are not integers, then the call of this method returns in its symbolic form (of type `"_index"`) with evaluated arguments.

Otherwise an error message is given, if `i` and `j` are not valid row and column indices, respectively.

Note: Note that the system function `context` is used to evaluate the entry in the context of the calling environment.

Returns the submatrix of `A`, created by the rows of `A` with indices from `r1` to `r2` and the columns of `A` with indices from `c1` to `c2`.

Note: The submatrix returned is of the domain `Dom::Matrix(R)`!

This method overloads the function `_index` for matrices, i.e., one may use it in the form `A[i, j]` and `A[r1..r2, c1..c2]`, respectively, or in functional notation: `_index(A, ...)`.

concatMatrix — Horizontal concatenation of matrices

```
concatMatrix(A, B, …)
```

col — Extracting a column

```
col(A, c)
```

An error message is issued if `c` is less than one or greater than `n`.

delCol — Deleting a column

```
delCol(A, c)
```

`NIL` is returned if `A` only consists of one column.

Note: The matrix returned is of the domain `Dom::Matrix(R)`.

An error message is issued if `c` is less than one or greater than `n`.

delRow — Deleting a row

```
delRow(A, r)
```

`NIL` is returned if `A` only consists of one row.

Note: The matrix returned is of the domain `Dom::Matrix(R)`.

An error message is issued if `r` is less than one or greater than `n`.

row — Extracting a row

```
row(A, r)
```

An error message is issued if `r` is less than one or greater than `n`.

stackMatrix — Vertical concatenation of matrices

```
stackMatrix(A, B, …)
```

An error message is issued if the given matrices do not have the same number of columns.

Note: The matrix returned is of the domain `Dom::Matrix(R)`!

Conversion Methods

`create` — Defining matrices without component conversions

```
create(x, …)
```

This method should be used if the elements of the parameters `x`, ... are elements of the domain type `R`. This is often the case if a matrix is to be created whose components come from preceding matrix and scalar operations.

MuPAD Domains
`Dom::Matrix` | `Dom::MatrixGroup`

Dom::SymmetricGroup

Symmetric groups

Syntax

```
Dom::SymmetricGroup(n)
```

```
Dom::SymmetricGroup(n)(l)
```

Description

`Dom::SymmetricGroup(n)` creates the symmetric group of order n, that is, the domain of all the permutations of $\{1, \ldots, n\}$ elements.

A permutation of n elements is a bijective mapping of the set $\{1, \ldots, n\}$ onto itself.

The domain element `Dom::SymmetricGroup(n)(l)` represents the bijective mapping of the first n positive integers that maps the integer i to `l[i]`, for $1 \le i \le n$.

Superdomain

`Dom::BaseDomain`

Axioms

`Ax::canonicalRep`

Categories

`Cat::Group`

Examples

Example 1

Consider the group of permutations of the first seven positive integers:

```
G := Dom::SymmetricGroup(7)
```

```
Dom::SymmetricGroup(7)
```

We create an element of `G` by providing the image of 1, 2, etc.:

```
a:=G([2,4,6,1,3,5,7])
```

```
[2, 4, 6, 1, 3, 5, 7]
```

```
a(3)
```

```
6
```

Parameters

`n`

Positive integer

`1`

List or array consisting of the first n integers in some order.

Entries

"one"	the identical mapping of the set {1, …, n} to itself.

Methods

Mathematical Methods

`_mult` — Product of permutations

```
_mult(a1, …)
```

This method overloads the function `_mult`.

`_invert` — Inverse of a permutation

```
_invert(a)
```

This method overloads the function `_invert`.

`func_call` — Function value of a permutation at a point

```
func_call(a, i)
```

It computes the function value of `a` at `i`, i.e., the integer that `i` is mapped to by the permutation `a`; `i` must be an integer between 1 and n.

`cycles` — Cycle representation of a permutation

```
cycles(a)
```

`order` — Order of a permutation

```
order(a)
```

`inversions` — Number of inversions

```
inversions(a)
```

`sign` — Sign of a permutation

```
sign(a)
```

`random` — Random permutation

```
random()
```

Access Methods

`allElements` — Return all elements of the group

```
allElements()
```

`size` — Return the size of the group

```
size()
```

Conversion Methods

`convert` — Conversion of an object into a permutation

```
convert(x)
```

`convert_to` — Conversion of a permutation into another type

```
convert_to(a, T)
```

`expr` — Convert a permutation into a list

```
expr(a)
```

Dom::UnivariatePolynomial

Domains of univariate polynomials

Syntax

Domain Creation

```
Dom::UnivariatePolynomial(<Var, <R, <Order>>>)
```

Element Creation

```
Dom::UnivariatePolynomial(Var, R, Order)(p)
```

```
Dom::UnivariatePolynomial(Var, R, Order)(lm)
```

Description

`Dom::UnivariatePolynomial(Var, R, ..)` creates the domain of univariate polynomials in the variable `Var` over the commutative ring `R`.

`Dom::UnivariatePolynomial` represents univariate polynomials over arbitrary commutative rings.

All usual algebraic and arithmetical polynomial operations are implemented, including Gröbner basis computations.

`Dom::UnivariatePolynomial(Var, R, Order)` creates a domain of univariate polynomials in the variable `Var` over a domain of category `Cat::CommutativeRing` in sparse representation with respect to the monomial ordering `Order`.

`Dom::UnivariatePolynomial()` creates the univariate polynomial domain in the variable `x` over the domain `Dom::ExpressionField(normal)` with respect to the lexicographic monomial ordering.

`Dom::UnivariatePolynomial(Var)` creates the univariate polynomial domain in the variable `Var` over the domain `Dom::ExpressionField(normal)` with respect to the lexicographic monomial ordering.

Note: Only commutative coefficient rings of type `DOM_DOMAIN` which inherit from `Dom::BaseDomain` are allowed. If `R` is of type `DOM_DOMAIN` but inherits not from `Dom::BaseDomain`, the domain `Dom::ExpressionField(normal)` will be used instead.

For this domain only identifiers are valid variables.

Note: It is highly recommend to use only coefficient rings with unique zero representation. Otherwise it may happen that, e.g., a polynomial division will not terminate or a wrong degree will be returned.

Please note that for reasons of efficiency not all methods check their arguments, not even at the interactive level. In particular this is true for many access methods, converting methods and technical methods. Therefore, using these methods inappropriately may result in strange error messages.

Superdomain

`Dom::MultivariatePolynomial`

Axioms

If R has `Ax::normalRep`, then `Ax::normalRep`.

If R has `Ax::canonicalRep`, then `Ax::canonicalRep`.

Categories

`Cat::UnivariatePolynomial(R)`

Examples

Example 1

To create the ring of univariate polynomials in x over the integers one may define

```
UP:=Dom::UnivariatePolynomial(x,Dom::Integer)
```

$$\text{Dom::UnivariatePolynomial}(x, \text{Dom::Integer}, \text{LexOrder})$$

Now, let us create two univariate polynomials.

```
a:=UP((2*x-1)^2*(3*x+1))
```

$$12\,x^3 - 8\,x^2 - x + 1$$

```
b:=UP(((2*x-1)*(3*x+1))^2)
```

$$36\,x^4 - 12\,x^3 - 11\,x^2 + 2\,x + 1$$

The usual arithmetical operations for polynomials are available:

```
a^2+a*b
```

$$432\,x^7 - 288\,x^6 - 264\,x^5 + 200\,x^4 + 35\,x^3 - 36\,x^2 - x + 2$$

The leading coefficient, leading term, leading monomial and reductum of a are

```
lcoeff(a),lterm(a),lmonomial(a),UP::reductum(a)
```

$$12,\ x^3,\ 12\,x^3,\ -8\,x^2 - x + 1$$

and a is of degree

```
degree(a)
```

$$3$$

The method `gcd` computes the greatest common divisor of two polynomials

```
gcd(a,b)
```

$$12\,x^3 - 8\,x^2 - x + 1$$

and `lcm` the least common multiple:

```
lcm(a,b)
```

$$36\,x^4 - 12\,x^3 - 11\,x^2 + 2\,x + 1$$

Computing the definite and indefinite integral of a polynomial is also possible,

```
int(a)
```

$$3\,x^4 - \frac{8\,x^3}{3} - \frac{x^2}{2} + x$$

which is in the case of indefinite integration simply the antiderivative of the polynomial.

```
D(int(a)), domtype(D(int(a)))
```

$$12\,x^3 - 8\,x^2 - x + 1,\ \text{Dom::UnivariatePolynomial}(x,\ \text{Dom::Fraction}(\text{Dom::Integer}),\ \text{LexOrder})$$

But, since for representing the indefinite integral of `a` the coefficient ring chosen as the integers is not appropriate, the polynomial ring over its quotient field is used instead.

Furthermore, interpreting the polynomials as polynomial functions is also allowed in applying coefficient ring elements, polynomials of this domain or arbitrary expressions with option `Expr` to them:

```
a(5)
```

$$1296$$

```
a(b)
```

$$559872\,x^{12} - 559872\,x^{11} - 326592\,x^{10} + 414720\,x^9 + 73872\,x^8 - 123120\,x^7 - 9924\,x^6 + 18408\,x^5 + 1144\,x^4 - 1364\,x^3 - 97\,x^2 + 38\,x + 4$$

```
a(sin(x),Expr)
```

$$12\,\sin(x)^3 - 8\,\sin(x)^2 - \sin(x) + 1$$

To get a vector of coefficients of a polynomial, which gives the dense representation of it, one may use the method `vectorize`.

```
UP::vectorize(a), UP::vectorize(a,6)
```

$$[1, -1, -8, 12], [1, -1, -8, 12, 0, 0]$$

Parameters

`Var`

An indeterminate given by an identifier; default is `x`.

`R`

A commutative ring, i.e. a domain of category `Cat::CommutativeRing`; default is `Dom::ExpressionField(normal)`.

`Order`

A monomial ordering, i.e. one of the predefined orderings `LexOrder`, `DegreeOrder` or `DegInvLexOrder` or an element of domain `Dom::MonomOrdering`; default is `LexOrder`.

`p`

A polynomial or a polynomial expression.

`lm`

List of monomials, which are represented as lists containing the coefficients together with the exponents or exponent vectors.

Entries

"characteristic"	The characteristic of this domain.
"coeffRing"	The coefficient ring of this domain as defined by the parameter `R`.
"key"	The name of the domain created.
"one"	The neutral element w.r.t. `"_mult"`.
"ordering"	The monomial order as defined by the parameter `Order`.
"variables"	The list of the variable as defined by the parameter `Var`.
"zero"	The neutral element w.r.t. `"_plus"`.

Methods

Access Methods

`coeff` — Coefficient of a polynomial

```
coeff(a)
```

```
coeff(a, Var, n)
```

```
coeff(a, n)
```

`coeff(a, Var, n)` returns the coefficient of the term `Var^n` as an element of `R`.

`coeff(a, n)` returns the coefficient of the term `Var^n` as an element of `R`.

This method overloads the function `coeff` for polynomials.

`degree` — Degree of a polynomial

Inherited from `Dom::DistributedPolynomial`.

`degreevec` — Vector of exponents of the leading term of a polynomial

Inherited from `Dom::DistributedPolynomial`.

`euclideanDegree` — Euclidean degree function

Inherited from `Dom::DistributedPolynomial`.

`ground` — Ground term of a polynomial

Inherited from `Dom::DistributedPolynomial`.

`has` — Existence of an object in a polynomial

Inherited from `Dom::DistributedPolynomial`.

`indets` — Indeterminate of a polynomial

Inherited from `Dom::DistributedPolynomial`.

`lcoeff` — Leading coefficient of a polynomial

Inherited from `Dom::DistributedPolynomial`.

`ldegree` — Lowest degree of a polynomial

Inherited from `Dom::DistributedPolynomial`.

`lmonomial` — Leading monomial of a polynomial

Inherited from `Dom::DistributedPolynomial`.

`lterm` — Leading term of a polynomial

Inherited from `Dom::DistributedPolynomial`.

`mainvar` — Main variable of a polynomial

Inherited from `Dom::DistributedPolynomial`.

`mapcoeffs` — Applie a function to the coefficients of a polynomial

Inherited from `Dom::DistributedPolynomial`.

`multcoeffs` — Multiplie the coefficients of a polynomial with a factor

Inherited from `Dom::DistributedPolynomial`.

`nterms` — Number of terms of a polynomial

Inherited from `Dom::DistributedPolynomial`.

`nthcoeff` — N-th coefficient of a polynomial

Inherited from `Dom::DistributedPolynomial`.

`nthmonomial` — N-th monomial of a polynomial

Inherited from `Dom::DistributedPolynomial`.

`nthterm` — N-th term of a polynomial

Inherited from `Dom::DistributedPolynomial`.

`order` — Compare two polynomials w.r.t. a given order

Inherited from `Dom::MultivariatePolynomial`.

`orderedVariableList` — Ordered list of indeterminates of a polynomial

Inherited from `Dom::DistributedPolynomial`.

`pivotSize` — Size of a pivot element

Inherited from `Dom::DistributedPolynomial`.

`reductum` — Reductum of a polynomial

Inherited from `Dom::DistributedPolynomial`.

`sortList` — Sort a list of polynomials w.r.t. a given order

Inherited from `Dom::MultivariatePolynomial`.

`stableSort` — Sort a list of polynomials w.r.t. a given order

Inherited from `Dom::MultivariatePolynomial`.

`subs` — Avoid substitution

Inherited from `Dom::BaseDomain`.

`subsex` — Avoid extended substitution

Inherited from `Dom::BaseDomain`.

`tcoeff` — Lowest coefficient of a polynomial

Inherited from `Dom::DistributedPolynomial`.

`vectorize` — Vectorized form of a polynomial

```
vectorize(a, <n>)
```

Factored

Objects kept in factored form

Syntax

```
Factored(list, <type>, <ring>)
```

```
Factored(f, <type>, <ring>)
```

Description

`Factored` is the domain of objects kept in factored form, such as prime factorization of integers, square-free factorization of polynomials, or the factorization of polynomials in irreducible factors.

The argument `list` must be a list of odd length and of the form `[u, f1, e1, f2, e2, ..., fr, er]`, where the entries u and f_i are elements of the domain `ring`, or can be converted into such elements. The e_i must be integers. Here, i ranges from 1 to r.

See section “Operands” below for the meaning of the entries of that list.

An error message is reported, if one of the list entries is of wrong type.

An arithmetical expression `f` given as the first argument is the same as giving the list `[ring::one, f, 1]`.

See section “Operands” below for the meaning of the entries of that list.

`f` must be an element of the domain `ring`, or must be convertible into such an element, otherwise an error message would be given.

The argument `type` indicates what is known about the factorization. Currently, the following types are known:

- `"unknown"` – nothing is known about the factorization.
- `"irreducible"` – the f_i are irreducible over the domain `ring`.

- `"squarefree"` – the f_i are square-free over the domain `ring`.

If this argument is missing, then the type of the created factored object is set to `"unknown"`.

The type of factorization is known to any element of `Factored`. Use the methods `"getType"` and `"setType"` (see below) to read and set the type of factorization of a given factored object.

The argument `ring` is the ring of factorization. It must be an integral domain, i.e., a domain of category `Cat::IntegralDomain`.

If this argument is missing, then the domain `Dom::ExpressionField()` is used.

The ring of factorization is known to any element of `Factored`. Use the methods `"getRing"` and `"setRing"` (see below) to read and set the ring of factorization of a given factored object.

You can use the index operator `[ ]` to extract the factors of an element `f` of the domain `Factored`. E.g., for $f = u\, f_1^{e_1} f_2^{e_2} \ldots$, you have $f[1] = u$, $f[2] = f_1^{e_1}$, $f[3] = f_2^{e_2}$ etc.

You can also use the methods `"factors"` and `"exponents"` (see below) to access the operands, i.e., the call `Factored::factors(f)` returns a list of the factors f_i, and `Factored::exponents(g)` returns a list of the exponents e_i ($1 \le i \le r$).

The system functions `ifactor`, `factor` and `polylib::sqrfree` are the main application of this domain, they return their result in form of such factored objects (see their help pages for information about the type and ring of factorization).

There may be no need to explicitly create factored objects, but to work with the results of the mentioned system functions.

Note that an element of `Factored` is printed like an expression and behaves like that. As an example, the result of `f := factor(x^2 + 2*x + 1)` is an element of `Factored` and printed as `(x + 1)^2`. The call `type(f)` returns `"_power"` as the expression type of `f`.

For an element `f` of `Factored`, the call `Factored::convert(f, DOM_LIST)` gives a list of all operands of `f`.

Examples

Example 1

The following computes the prime factorization of the integer 20:

```
f := ifactor(20)
```

$$2^2\,5$$

The result is an element of the domain `Factored`:

```
domtype(f)
```

Factored

which consists of the following five operands:

```
op(f)
```

1, 2, 2, 5, 1

They represent the integer 20 in the following form: $20 = 1\,2^2\,5$. The factors are prime numbers and can be extracted via `Factor::factors`:

```
Factored::factors(f)
```

[2, 5]

`ifactor` kept the information that the factorization ring is the ring of integers (represented by the domain `Dom::Integer`), and that the factors of `f` are prime (and therefore irreducible, because $\mathbb{Z}$ is an integral domain):

```
Factored::getRing(f), Factored::getType(f)
```

Dom::Integer, "irreducible"

We can convert such an object into different forms, such as into a list of its operands:

```
Factored::convert_to(f, DOM_LIST)
```

$$[1, 2, 2, 5, 1]$$

or into an unevaluated expression, keeping the factored form:

```
Factored::convert_to(f, DOM_EXPR)
```

$$2^2\,5$$

or back into an integer:

```
Factored::convert_to(f, Dom::Integer)
```

$$20$$

You may also use the system function `coerce` here, which has the same effect.

Example 2

We compute the factorization of the integers 108 and 512:

```
n1 := ifactor(108); n2 := ifactor(512)
```

$$2^2\,3^3$$

$$2^9$$

The multiplication of these two integers gives the prime factorization of 55296 = 108 512:

```
n1*n2
```

$$2^{11}\,3^3$$

Note that the most operations on such objects lead to an un-factored form, such as adding these two integers:

```
n1 + n2
```

$$620$$

You may apply the function `ifactor` to the result, if you are interested in its prime factorization:

```
ifactor(%)
```

$$2^2\ 5\ 31$$

You an apply (almost) each function to factored objects, functions that mainly expect arithmetical expressions as their input. Note that, before the operation is applied, the factored object is converted into an arithmetical expression in un-factored form:

```
Re(n1)
```

$$108$$

Example 3

The second system function which deals with elements of `Factored`, is `factor`, which computes all irreducible factors of a polynomial.

For example, if we define the following polynomial of $\mathbb{Z}_{101}$:

```
p := poly(x^12 + x + 1, [x], Dom::IntegerMod(101)):
```

and compute its factorization into irreducible factors, we get:

```
f := factor(p)
```

$$\text{poly}(x^2 + 73\,x + 29, [x], \text{Dom::IntegerMod}(101))$$

$$\text{poly}(x^5 + 62\,x^4 + 64\,x^3 + 63\,x^2 + 58\,x + 100, [x], \text{Dom::IntegerMod}(101))$$

$$\text{poly}(x^5 + 67\,x^4 + 72\,x^3 + 100\,x^2 + 33\,x + 94, [x], \text{Dom::IntegerMod}(101))$$

If we multiply the factored object with an element that can be converted into an element of the ring of factorization, then we get a new factored object, which then is of the factorization type `"unknown"`:

```
x*f
```

$$\text{poly}(x^2 + 73\,x + 29,\ [x],\ \text{Dom::IntegerMod}(101))$$

$$\text{poly}(x^5 + 62\,x^4 + 64\,x^3 + 63\,x^2 + 58\,x + 100,\ [x],\ \text{Dom::IntegerMod}(101))$$

$$\text{poly}(x^5 + 67\,x^4 + 72\,x^3 + 100\,x^2 + 33\,x + 94,\ [x],\ \text{Dom::IntegerMod}(101))\ x$$

```
Factored::getType(%)
```

"unknown"

You may use the function `expand` which returns the factored object in expanded form as an element of the factorization ring:

```
expand(f)
```

$$\text{poly}(x^{12} + x + 1,\ [x],\ \text{Dom::IntegerMod}(101))$$

Example 4

The third system function which return elements of `Factored` is `polylib::sqrfree`, which computes the square-free factorization of polynomials. For example:

```
f := polylib::sqrfree(x^2 + 2*x + 1)
```

$$(x + 1)^2$$

The factorization type, of course, is `"squarefree"`:

```
Factored::getType(f)
```

"squarefree"

Parameters

`list`

A list of odd length

`f`

An arithmetical expression

`type`

A string (default: `"unknown"`)

`ring`

A domain of category `Cat::IntegralDomain` (default: `Dom::ExpressionField()`)

Function Calls

Calling a factored object as a function yields the object itself, regardless of the arguments. The arguments are *not* evaluated.

Operations

You can apply (almost) every function to factored objects, functions that mainly expect arithmetical expressions as their input.

For example, one may add or multiply those objects, or apply functions such as `expand` and `diff` to them. But the result of such an operation then is usually not any longer of the domain `Factored`, as the factored form could be lost due to the operation (see examples below).

Call `expr(f)` to convert the factored object `f` into an arithmetical expression (as an element of a kernel domain).

The call `coerce(f, DOM_LIST)` returns a list of operands of the factored object `f` (see method `"convert_to"` below).

Operands

An element f of `Factored` consists of the $r + 1$ operands u, f_1, e_1, f_2, e_2, …, f_r, e_r, such that $f = u\, f_1^{e_1} f_2^{e_2} \ldots f_r^{e_r}$.

The first operand u and the factors f_i are elements of the domain `ring`. The exponents e_i are integers.

Methods

Mathematical Methods

`_mult` — Multiply factored objects

```
_mult(f, g, …)
```

Suppose that `g` is an element of the domain `ring` (or can be converted into such an element).

If `g` is a unit of `ring` or a factor of `f`, then the result is a factored object of the same factorization type as `f`. Otherwise, the result is an element of `Factored` with the factorization type `"unknown"`.

If both `f` and `g` are factored objects with factorization type `"irreducible"`, then the result is again a factored object of this type, i.e., the result is still in factored form.

Otherwise, the factored form of `f` is lost, and the result of this method is an element of `ring`.

This method overloads the function `_mult` for factored objects, i.e., one may use it in the form `f*g*...`, or in functional notation: `_mult(f, g, ...)`.

`_power` — Raise a factored object to a certain power

```
_power(f, n)
```

If `n` is a positive integer and `f` a factored object with factorization type `"irreducible"` or `"squarefree"`, then the result is still a factored object of this type.

Otherwise, the factored form of `f` is lost, and the result of this method is an element of `ring`.

This method overloads the function `_power` for factored objects, i.e., one may use it in the form `f^n`, or in functional notation: `_power(f, n)`.

`expand` — Expand a factored object

```
expand(f)
```

`exponents` — Get the exponents of a factored object

```
exponents(f)
```

`factor` — Factor a factored object

```
factor(f)
```

If `f` already is of the factorization type `"irreducible"`, then this method just return `f`.

Otherwise, this method converts `f` into an element of the domain `ring` and calls the method `"factor"` of `ring`.

This method returns a factored object of the domain `Factored` with factorization type `"irreducible"`, if the factorization of `f` can be computed (otherwise, `FAIL` is returned).

This method overloads the function `factor` for factored objects, i.e., one may use it in the form `factor(f)`.

`factors` — Get the factors of a factored object

```
factors(f)
```

`irreducible` — Test if a factored object is irreducible

```
irreducible(f)
```

The test on irreducible is trivial, if `f` has the factorization type `"irreducible"`.

Otherwise, this method converts `f` into an element of `ring` and calls the method `"irreducible"` of `ring`. The value `FAIL` is returned, if the domain `ring` cannot test if `f` is irreducible.

`iszero` — Test on zero for factored objects

```
iszero(f)
```

This method overloads the function `iszero` for factored objects, i.e., one may use it in the form `iszero(f)`.

`sqrfree` — Compute a square-free factorization of a factored object

```
sqrfree(f)
```

If `f` already is of the factorization type `"squarefree"`, then this method just return `f`.

Otherwise, this method converts `f` into an element of the domain `ring` and calls the method `"squarefree"` of `ring`.

This method returns a factored object of the domain `Factored` with factorization type `"squarefree"`, if the square-free factorization of `f` can be computed (otherwise, `FAIL` is returned).

This method overloads the function `polylib::sqrfree` for factored objects, i.e., one may use it in the form `polylib::sqrfree(f)`.

Access Methods

`_index` — Extract a term of a factored object

```
_index(f, i)
```

Responds with an error message, if `i` is greater than the number of terms of `f`.

This method overloads the index operator `[ ]` for factored objects, i.e., one may use it in the form `f[i]`.

`getRing` — Get the ring of factorization

```
getRing(f)
```

`getType` — Get the type of factorization

```
getType(f)
```

`has` — Existence of an object in a factored object

```
has(f, x, …)
```

This method overloads the function `has` for factored objects, i.e., one may use it in the form `has(f, x, ...)`.

`map` — Map a function to the operands of factored objects

```
map(f, func, …)
```

See the system function `map` for details.

This method overloads the function `map` for factored objects, i.e., one may use it in the form `map(f, func, ...)`.

`nops` — Number of operands of a factored object

```
nops(f)
```

This method overloads the function `nops` for factored objects, i.e., one may use it in the form `nops(f)`.

`op` — Extract an operand of a factored object

```
op(f, i)
```

Returns `FAIL`, if `i` is greater than the number of operands of `f`.

This method overloads the function `op` for factored objects, i.e., one may use it in the form `op(f, i)`.

`select` — Select operands of a factored object

```
select(f, func, …)
```

This method overloads the function `select` for factored objects, i.e., one may use it in the form `select(f, func, ...)`.

`set_index` — Set/change a term of a factored object

```
set_index(f, i, x)
```

Responds with an error message, if `i` is greater than the number of terms of `f`.

Note: Make sure that `x` either is an element of the domain `ring`, or an integer.

This method overloads the index operator `[ ]` for factored objects, i.e., one may use it in the form `f[i] := x`.

`setRing` — Set the ring of factorization

```
setRing(f, ring)
```

Note: Use this method with caution! Make sure that the factorization of `f` is still valid over the new ring, and that the operands of `f` have the correct domain type.

`ring` must be a domain of category `Cat::IntegralDomain`, which is not checked by this method.

`setType` — Set the type of factorization

```
setType(f, type)
```

Note: Use this method with caution! Make sure that the factorization type corresponds with the factorization of `f`.

`subs` — Substitute subexpressions in the operands of a factored object

```
subs(f, x = a, …)
```

This method overloads the function `subs` for factored objects, i.e., one may use it in the form `subs(f, x = a, ...)`.

`subsop` — Substitute operands of a factored object

```
subsop(f, i = a, …)
```

This method overloads the function `subsop` for factored objects, i.e., one may use it in the form `subsop(f, i = a, ...)`.

`type` — Expression type of factored objects

```
type(f)
```

Conversion Methods

`convert` — Convert an object into a factored object

```
convert(x)
```

If the conversion fails, then `FAIL` is returned.

`x` may either be a list of the form `[u, f1, e1, ..., fr, er]` of odd length (where `u, f1, ..., fr` are of the domain type `ring`, or can be converted into such elements, and `e1, ..., er` are integers), or an element that can be converted into the domain `ring`. The latter case corresponds to the list `[ring::one,x,1]`.

`convert_to` — Convert factored objects into other domains

```
convert_to(f, T)
```

If the conversion fails, then `FAIL` is returned.

If `T` is the domain `DOM_LIST`, then the list of operands of `f` is returned.

If `T` is the domain `DOM_EXPR`, then the unevaluated expression `u*f1^e1*f2^e2*...*fr^er` is returned, where `u, f1, e1, ...` are the operands of `f`.

Otherwise, the method `"convert"` of the domain `T` is called to convert `f` into an element of the domain `T` (which could return `FAIL`).

Use the function `expr` to convert `f` into an object of a kernel domain (see below).

`create` — Create simple and fast a factored objects

```
create(list)
```

```
create(x)
```

This method creates a new factored object with the operands `ring::one, x, 1`.

expr — Convert a factored object into a kernel domain

```
expr(f)
```

Note: Note that the factored form of `f` may be lost due to this conversion.

expr2text — Convert a factored object into a string

```
expr2text(f)
```

testtype — Type testing for factored objects

```
testtype(f, T)
```

This method is called from the system function `testtype`.

TeX — LaTeX formatting of a factored object

```
TeX(f)
```

The method `"TeX"` of the domain `ring` is used to get the LaTeX-representation of the corresponding operands of `f`.

This method is called from the system function `generate::TeX`.

Technical Methods

_concat — Concatenate operands of factored objects

```
_concat(f, g)
```

`f` and `g` must have the same factorization type and factorization ring, otherwise an error message is given.

maprec — Allow recursive mapping for factored objects

```
maprec(f, x, …)
```

First `f` is converted into the unevaluated expression `u*f1^e1*f2^e2*...*fr^er`, where `u, f1, e1, ...` are the operands of `f`. Then the function `misc::maprec` is called with this expression as its first parameter.

Note that the result of this method is not longer an object of `Factored`!

`print` — Pretty-print routine for factored objects

```
print(f)
```

`unapply` — Create a procedure from a factored object

```
unapply(f, <x>)
```

This method overloads the function `fp::unapply` for factored objects, i.e., one may use it in the form `fp::unapply(f)`. See `fp::unapply` for details.

Series::Puiseux

Truncated Puiseux series expansions

Syntax

```
Series::Puiseux(f, x, <order>, <dir>)
```

```
Series::Puiseux(f, x = x0, <order>, <dir>)
```

Description

`Series::Puiseux` is a domain for truncated series expansions. Elements of this domain represent initial segments of Taylor, Laurent, or Puiseux series expansions, as well as slightly more general types of series expansions.

The system function `series` is the main application of this domain. It tries to compute a Taylor, Laurent, or Puiseux series or a more general series expansion of a given arithmetical expression, and the result is returned as an element of `Series::Puiseux` or, possibly, of the more general domain `Series::gseries`.

There is usually no need for you to explicitly create elements of this domain. The methods described on this help page apply if you want to process a result returned by `series` further.

Note: If you create elements explicitly as described above, then any special mathematical function, such as `sin` or `exp`, involving the series variable is considered as a coefficient. Use `series` to expand such functions as well, and use the constructor only if `f` does not contain any special mathematical functions. Cf. “Example 1” on page 7-409.

Use the type specifier `Type::Series` to determine for an element of this domain, which kind of series expansion it is.

Note: The coefficients are allowed to depend sublinearly on the variable of the series expansion. For example, logarithmic terms in the series variable may appear as

coefficients. Be aware that this is no Puiseux series in the mathematical sense. Cf. “Example 4” on page 7-417 and the help page for `series`.

Environment Interactions

The function is sensitive to the global variable `ORDER`, which determines the default number of terms of the expansion.

Examples

Example 1

You can create objects of `Series::Puiseux` in various ways. The standard method is to use the constructor. The second argument specifies the series variable and the expansion point, with default 0 if omitted:

```
Series::Puiseux(x/(1 - x), x);
Series::Puiseux(x/(1 - x), x = 2);
Series::Puiseux(x/(1 - x), x = complexInfinity);
```

$$x + x^2 + x^3 + x^4 + x^5 + x^6 + O(x^7)$$

$$-2 + x - 2 - (x-2)^2 + (x-2)^3 - (x-2)^4 + (x-2)^5 + O((x-2)^6)$$

$$-1 - \frac{1}{x} - \frac{1}{x^2} - \frac{1}{x^3} - \frac{1}{x^4} - \frac{1}{x^5} + O\left(\frac{1}{x^6}\right)$$

The third argument, if present, specifies the desired number of terms. If it is omitted, the value of the environment variable `ORDER` is used:

```
Series::Puiseux(x/(1 - x), x = 2, 4);
ORDER := 2:
Series::Puiseux(x/(1 - x), x);
delete ORDER:
```

$$-2 + x - 2 - (x-2)^2 + (x-2)^3 + O((x-2)^4)$$

$$x + x^2 + O(x^3)$$

The methods `const`, `one`, and `zero` provide shortcuts for creating series expansions with only a constant term or no non-zero term at all. Specifying the order of the error term is mandatory:

```
Series::Puiseux::const(PI, x, 4);
Series::Puiseux::one(x = 2, 3);
Series::Puiseux::zero(x = 0, 3/2);
Series::Puiseux::zero(x = complexInfinity, 5);
```

$$\pi + O(x^4)$$

$$1 + O((x-2)^3)$$

$$O\left(x^{3/2}\right)$$

$$O\left(\frac{1}{x^5}\right)$$

Note that, e.g., `O(x^(3/2))` is not an element of `Series::Puiseux`, but can be converted by the constructor:

```
f := O(x^(3/2));
g := Series::Puiseux(f, x);
domtype(f), domtype(g)
```

$$O\left(x^{3/2}\right)$$

$$O\left(x^{3/2}\right)$$

$$O, \text{Series::Puiseux}$$

Both the constructor `Series::Puiseux` and the method `const` regard special mathematical functions, such as `exp` or `sin`, as coefficients:

```
Series::Puiseux(sin(x)/(1 - x), x, 4);
Series::Puiseux::const(cos(x), x = 1, 3);
```

$$\sin(x) + x\sin(x) + x^2\sin(x) + x^3\sin(x) + O(x^4)$$

$$\cos(x) + O((x-1)^3)$$

Use the system function `series` if you want to have special functions expanded as well:

```
series(sin(x)/(1 - x), x, 4);
```

$$x + x^2 + \frac{5x^3}{6} + \frac{5x^4}{6} + O(x^5)$$

The constructor returns `FAIL`, if it cannot convert the input into an element of `Series::Puiseux`. Then `series` may be able to produce a more general expansion:

```
delete a:
Series::Puiseux(x^a/(1 - x), x);
f := series(x^a/(1 - x), x);
domtype(f);
```

FAIL

$$x^a + x\,x^a + x^a\,x^2 + x^a\,x^3 + x^a\,x^4 + x^a\,x^5 + O(x^a\,x^6)$$

Series::gseries

The method `create` is a purely syntactical constructor, where the operands are specified explicitly. The sixth and seventh arguments are optional and default to 0 and `Undirected`, respectively:

```
Series::Puiseux::create(3, 1, 5, [1/2, 5], x) =
Series::Puiseux::create(3, 1, 5, [1/2, 5], x, 0, Undirected)
```

$$\frac{x^{1/3}}{2} + 5\,x^{2/3} + O\left(x^{5/3}\right) = \frac{x^{1/3}}{2} + 5\,x^{2/3} + O\left(x^{5/3}\right)$$

```
Series::Puiseux::create(1, -2, 1, [ln(x), 0, 3], x, complexInfinity);
```

$$x^2 \ln(x) + 3 + O\left(\frac{1}{x}\right)$$

Example 2

We demonstrate the internal structure of objects of type `Series::Puiseux`:

```
f := series(exp(x), x = 1);
g := series(sin(sqrt(1/x)), x = infinity);
h := series(sin(sqrt(-x))/x, x = 0)
```

$$e + e\,(x-1) + \frac{e\,(x-1)^2}{2} + \frac{e\,(x-1)^3}{6} + \frac{e\,(x-1)^4}{24} + \frac{e\,(x-1)^5}{120} + O((x-1)^6)$$

$$\frac{1}{\sqrt{x}} - \frac{1}{6\,x^{3/2}} + \frac{1}{120\,x^{5/2}} + O\left(\frac{1}{x^{7/2}}\right)$$

$$-\frac{1}{\sqrt{-x}} + \frac{\sqrt{-x}}{6} - \frac{(-x)^{3/2}}{120} + O\left(x^{5/2}\right)$$

```
op(f);
op(g);
op(h)
```

$$0,\ 1,\ 0,\ 6,\ \left[e,\ e,\ \frac{e}{2},\ \frac{e}{6},\ \frac{e}{24},\ \frac{e}{120}\right],\ x = 1,\ \text{Undirected}$$

$$0,\ 2,\ 1,\ 7,\ \left[1,\ 0,\ -\frac{1}{6},\ 0,\ \frac{1}{120}\right],\ x = \text{complexInfinity},\ \text{Left}$$

$$1,\ 2,\ -1,\ 5,\ \left[-\frac{1}{\sqrt{-x}},\ 0,\ \frac{\sqrt{-x}}{6},\ 0,\ -\frac{(-x)^{3/2}}{120}\right],\ x = 0,\ \text{Undirected}$$

The series `f` and `g` are of type 0, while `h` is of type `1`:

```
op(f, 1), op(g, 1), op(h, 1)
```

$$0,\ 0,\ 1$$

The branching order of `f` is 1, and the branching order of both `g` and `h` is 2:

```
op(f, 2), op(g, 2), op(h, 2)
```

$$1,\ 2,\ 2$$

The third and the fourth operand determine the order of the leading term and the error term, respectively:

```
ldegree(f) = op(f, 3)/op(f, 2),
ldegree(g) = op(g, 3)/op(g, 2),
ldegree(h) = op(h, 3)/op(h, 2);
Series::Puiseux::order(f) = op(f, 4)/op(f, 2),
Series::Puiseux::order(g) = op(g, 4)/op(g, 2),
Series::Puiseux::order(h) = op(h, 4)/op(h, 2);
```

$$0 = 0,\ \frac{1}{2} = \frac{1}{2},\ -\frac{1}{2} = -\frac{1}{2}$$

$$6 = 6,\ \frac{7}{2} = \frac{7}{2},\ \frac{5}{2} = \frac{5}{2}$$

For series expansions of type 0, the fifth operand contains the coefficients of the expansion:

```
op(f, 5) = [coeff(f)];
op(g, 5) = [coeff(g)];
```

$$\left[e,\ e,\ \frac{e}{2},\ \frac{e}{6},\ \frac{e}{24},\ \frac{e}{120}\right] = \left[e,\ e,\ \frac{e}{2},\ \frac{e}{6},\ \frac{e}{24},\ \frac{e}{120}\right]$$

$$\left[1,\ 0,\ -\frac{1}{6},\ 0,\ \frac{1}{120}\right] = \left[1,\ 0,\ -\frac{1}{6},\ 0,\ \frac{1}{120}\right]$$

However, `h` is an expansion of type 1, and then the fifth operand stores the summands:

```
op(h, 5);
[coeff(h)];
```

$$\left[-\frac{1}{\sqrt{-x}},\ 0,\ \frac{\sqrt{-x}}{6},\ 0,\ -\frac{(-x)^{3/2}}{120}\right]$$

$$\left[-\frac{\sqrt{x}}{\sqrt{-x}},\ 0,\ \frac{\sqrt{-x}}{6\sqrt{x}},\ 0,\ -\frac{(-x)^{3/2}}{120\,x^{3/2}}\right]$$

The sixth operand contains the series variable and the expansion point:

```
op(f, 6), Series::Puiseux::indet(f), Series::Puiseux::point(f);
op(g, 6), Series::Puiseux::indet(g), Series::Puiseux::point(g);
op(h, 6), Series::Puiseux::indet(h), Series::Puiseux::point(h);
```

$$x = 1,\ x,\ 1$$

$$x = \text{complexInfinity},\ x,\ \text{complexInfinity}$$

$$x = 0,\ x,\ 0$$

The expansions `f` and `h` are undirected, while `g` is a directed expansion from the left along the real line to the positive infinity:

```
op(f, 7) = Series::Puiseux::direction(f),
op(g, 7) = Series::Puiseux::direction(g),
op(h, 7) = Series::Puiseux::direction(h);
```

$$\text{Undirected} = \text{Undirected},\ \text{Left} = \text{Left},\ \text{Undirected} = \text{Undirected}$$

Note: Since the internal structure may be subject to changes, accessing the operands of and element of `Series::Puiseux` via `op` should be avoided. Use the corresponding access methods instead.

Example 3

Around branch points, the series expansions of type 1 can approximate a function in a wider range than those of type 0:

```
f := x -> arcsin(x + 1):
g := series(f(x), x, 2);
h := series(f(x), x, 2, Right);
```

$$\frac{\pi}{2} - \sqrt{2}\,\sqrt{-x} - \frac{\sqrt{2}\,(-x)^{3/2}}{12} + O\left(x^{5/2}\right)$$

$$\frac{\pi}{2} - \sqrt{2}\,\sqrt{x}\,\mathrm{i} + \frac{\sqrt{2}\,x^{3/2}\,\mathrm{i}}{12} + O\left(x^{5/2}\right)$$

The expansion `g`, of type 1, approximates `f` well in an open disc centered at the origin. However, the expansion `h`, of type 0, was requested for positive real values of `x` only, and in fact it does not approximate `f` on the negative real axis and in the upper half plane:

```
op(g);
op(h);
```

$$1,\ 2,\ 0,\ 5,\ \left[\frac{\pi}{2},\ -\sqrt{2}\,\sqrt{-x},\ 0,\ -\frac{\sqrt{2}\,(-x)^{3/2}}{12}\right],\ x = 0,\ \text{Undirected}$$

$$0,\ 2,\ 0,\ 5,\ \left[\frac{\pi}{2},\ -\sqrt{2}\,\mathrm{i},\ 0,\ \frac{\sqrt{2}\,\mathrm{i}}{12}\right],\ x = 0,\ \text{Right}$$

```
DIGITS := 4:
[f(0.01), f(0.01*I), f(-0.01), f(-0.01*I)];
map([g(0.01), g(0.01*I), g(-0.01), g(-0.01*I)], float);
map([h(0.01), h(0.01*I), h(-0.01), h(-0.01*I)], float);
```

```
delete DIGITS:
```

$$[1.571 - 0.1413\,i,\ 1.471 + 0.1001\,i,\ 1.429,\ 1.471 - 0.1001\,i]$$

$$[1.571 - 0.1413\,i,\ 1.471 + 0.1001\,i,\ 1.429,\ 1.471 - 0.1001\,i]$$

$$[1.571 - 0.1413\,i,\ 1.671 - 0.1001\,i,\ 1.712,\ 1.471 - 0.1001\,i]$$

The method `convert01` converts a series expansion of type 0 into one of type 1:

```
h1 := Series::Puiseux::convert01(h);
op(h1);
```

$$\frac{\pi}{2} - \sqrt{2}\,\sqrt{x}\,i + \frac{\sqrt{2}\,x^{3/2}\,i}{12} + O\left(x^{5/2}\right)$$

$$1,\ 2,\ 0,\ 5,\ \left[\frac{\pi}{2},\ -\sqrt{2}\,\sqrt{x}\,i,\ 0,\ \frac{\sqrt{2}\,x^{3/2}\,i}{12}\right],\ x = 0,\ \text{Right}$$

The reverse conversion, using the method `convert10`, is in not always possible:

```
op(Series::Puiseux::convert10(h1));
op(Series::Puiseux::convert10(g));
```

$$0,\ 2,\ 0,\ 5,\ \left[\frac{\pi}{2},\ -\sqrt{2}\,i,\ 0,\ \frac{\sqrt{2}\,i}{12}\right],\ x = 0,\ \text{Right}$$

$$1,\ 2,\ 0,\ 5,\ \left[\frac{\pi}{2},\ -\sqrt{2}\,\sqrt{-x},\ 0,\ -\frac{\sqrt{2}\,(-x)^{3/2}}{12}\right],\ x = 0,\ \text{Undirected}$$

You can enforce a conversion by using properties:

```
assume(x > 0):
op(Series::Puiseux::convert10(g));
```

```
unassume(x):
```

$$0,\ 2,\ 0,\ 5,\ \left[\frac{\pi}{2},\ -\sqrt{2}\,i,\ 0,\ \frac{\sqrt{2}\,i}{12}\right],\ x = 0,\ \text{Undirected}$$

Example 4

Despite the name, elements of `Series::Puiseux` may contain coefficient functions depending on the series variable:

```
f := series(psi(x), x = infinity, 4);
domtype(f), coeff(f, 0)
```

$$\ln(x) - \frac{1}{2\,x} - \frac{1}{12\,x^2} + O\left(\frac{1}{x^4}\right)$$

$$\text{Series::Puiseux},\ \ln(x)$$

With respect to differentiation, integration, and composition, such expansions behave like functions of the series variable and not like formal series:

```
diff(f, x) = series(diff(psi(x), x), x = infinity, 4)
```

$$\frac{1}{x} + \frac{1}{2\,x^2} + \frac{1}{6\,x^3} + O\left(\frac{1}{x^5}\right) = \frac{1}{x} + \frac{1}{2\,x^2} + \frac{1}{6\,x^3} + O\left(\frac{1}{x^5}\right)$$

```
int(f, x) = series(int(psi(x), x), x = infinity, 4)
```

$$x\,(\ln(x) - 1) - \frac{\ln(x)}{2} + \frac{1}{12\,x} + O\left(\frac{1}{x^3}\right) = x\,(\ln(x) - 1) + \frac{\ln(2)}{2} + \frac{\ln(\pi)}{2} - \frac{\ln(x)}{2} + \frac{1}{12\,x} + O\left(\frac{1}{x^3}\right)$$

```
f @ series(2*x, x = infinity) = series(psi(2*x), x = infinity, 4)
```

$$\ln(2) + \ln(x) - \frac{1}{4\,x} - \frac{1}{48\,x^2} + O\left(\frac{1}{x^4}\right) = \ln(2) + \ln(x) - \frac{1}{4\,x} - \frac{1}{48\,x^2} + O\left(\frac{1}{x^4}\right)$$

Example 5

The basic arithmetical operations are implemented for elements of `Series::Puiseux`:

```
f := series(exp(x), x, 4);
g := series(sqrt(x)/(1 - x), x, 4);
h := series(cot(x), x, 4);
```

$$1 + x + \frac{x^2}{2} + \frac{x^3}{6} + O(x^4)$$

$$\sqrt{x} + x^{3/2} + x^{5/2} + x^{7/2} + O\left(x^{9/2}\right)$$

$$\frac{1}{x} - \frac{x}{3} + O(x^3)$$

```
f + g + h;
_plus(f, g, h)
```

$$\frac{1}{x} + 1 + \sqrt{x} + \frac{2x}{3} + x^{3/2} + \frac{x^2}{2} + x^{5/2} + O(x^3)$$

$$\frac{1}{x} + 1 + \sqrt{x} + \frac{2x}{3} + x^{3/2} + \frac{x^2}{2} + x^{5/2} + O(x^3)$$

```
f - h = _subtract(f, h);
-g = _negate(g);
```

$$-\frac{1}{x} + 1 + \frac{4x}{3} + \frac{x^2}{2} + O(x^3) = -\frac{1}{x} + 1 + \frac{4x}{3} + \frac{x^2}{2} + O(x^3)$$

$$-\sqrt{x} - x^{3/2} - x^{5/2} - x^{7/2} + O\left(x^{9/2}\right) = -\sqrt{x} - x^{3/2} - x^{5/2} - x^{7/2} + O\left(x^{9/2}\right)$$

```
f*g*h;
```

```
_mult(f, g, h)
```

$$\frac{1}{\sqrt{x}} + 2\sqrt{x} + \frac{13\,x^{3/2}}{6} + 2\,x^{5/2} + O\left(x^{7/2}\right)$$

$$\frac{1}{\sqrt{x}} + 2\sqrt{x} + \frac{13\,x^{3/2}}{6} + 2\,x^{5/2} + O\left(x^{7/2}\right)$$

```
f/g = _divide(f, g);
1/h = _invert(h);
```

$$\frac{1}{\sqrt{x}} - \frac{x^{3/2}}{2} - \frac{x^{5/2}}{3} + O\left(x^{7/2}\right) = \frac{1}{\sqrt{x}} - \frac{x^{3/2}}{2} - \frac{x^{5/2}}{3} + O\left(x^{7/2}\right)$$

$$x + \frac{x^3}{3} + O(x^5) = x + \frac{x^3}{3} + O(x^5)$$

Operands that are not of type `Series::Puiseux` are implicitly converted into series expansions with the same expansion point via the constructor before the arithmetical operation is performed:

```
f - 1 - x;
h * (sin(x) + x);
```

$$\frac{x^2}{2} + \frac{x^3}{6} + O(x^4)$$

$$\frac{\sin(x)}{x} + 1 - \frac{x\,\sin(x)}{3} - \frac{x^2}{3} + O(x^3)$$

An error occurs when the expansion points differ or the directions of expansion are incompatible:

```
f := series(arccot(x), x = 0, Left);
g := series(sqrt(sin(x)), x = 0, Right);
f + g
```

$$-\frac{\pi}{2}-x+\frac{x^3}{3}-\frac{x^5}{5}+O(x^7)$$

$$\sqrt{x}-\frac{x^{5/2}}{12}+\frac{x^{9/2}}{1440}+O\left(x^{13/2}\right)$$

```
Error: Inconsistent direction. [Series::Puiseux::plus]
```

```
h := series(1/x, x = 2, 4);
f * h
```

$$\frac{1}{2}-\frac{x-2}{4}+\frac{(x-2)^2}{8}-\frac{(x-2)^3}{16}+O((x-2)^4)$$

```
Error: Both series must use the same variables and expansion points. [Series::Puiseux:
```

If the directions are compatible, then the direction of the result specifies the minimal range where all operands are defined:

```
s := series(tanh(x), x, Real);
```

$$x-\frac{x^3}{3}+\frac{2\,x^5}{15}+O(x^7)$$

```
f + s;
Series::Puiseux::direction(%)
```

$$-\frac{\pi}{2}-\frac{x^5}{15}+O(x^7)$$

Left

Example 6

The method `scalmult` implements multiplication by a constant or a single term:

```
f := series(1 + 2*x^3, x);
Series::Puiseux::scalmult(f, 5) = 5*f;
Series::Puiseux::scalmult(f, 5, 3) = 5*x^3*f;
```

$$1 + 2\,x^3 + O(x^6)$$

$$5 + 10\,x^3 + O(x^6) = 5 + 10\,x^3 + O(x^6)$$

$$5\,x^3 + 10\,x^6 + O(x^9) = 5\,x^3 + 10\,x^6 + O(x^9)$$

```
g := series(1 + 2*x^3, x = 2, 3);
Series::Puiseux::scalmult(g, 1, 3) = (x - 2)^3*g
```

$$17 + 24\,(x-2) + 12\,(x-2)^2 + O((x-2)^3)$$

$$17\,(x-2)^3 + 24\,(x-2)^4 + 12\,(x-2)^5 + O((x-2)^6) =$$

$$17\,(x-2)^3 + 24\,(x-2)^4 + 12\,(x-2)^5 + O((x-2)^6)$$

```
h := series(1 + 2*x^3, x = complexInfinity);
Series::Puiseux::scalmult(h, 1, 1/2) = x^(-1/2)*h
```

$$2\,x^3 + 1 + O\left(\frac{1}{x^3}\right)$$

$$2\,x^{5/2} + \frac{1}{\sqrt{x}} + O\left(\frac{1}{x^{7/2}}\right) = 2\,x^{5/2} + \frac{1}{\sqrt{x}} + O\left(\frac{1}{x^{7/2}}\right)$$

Example 7

Exponentiation is implemented for integral and rational exponents:

```
f := series(exp(x), x, 3);
```

```
f^2 = _power(f, 2);
f^(1/3) = _power(f, 1/3)
```

$$1 + x + \frac{x^2}{2} + O(x^3)$$

$$1 + 2\,x + 2\,x^2 + O(x^3) = 1 + 2\,x + 2\,x^2 + O(x^3)$$

$$1 + \frac{x}{3} + \frac{x^2}{18} + O(x^3) = 1 + \frac{x}{3} + \frac{x^2}{18} + O(x^3)$$

Exponents are allowed to be non-rational, if the series expansion starts with a constant summand independent of the series variable:

```
f^I = series(exp(I*x), x, 3);
```

$$1 + x\,\mathrm{i} - \frac{x^2}{2} + O(x^3) = 1 + x\,\mathrm{i} - \frac{x^2}{2} + O(x^3)$$

```
g := series(sin(-x), x);
g^I
```

$$-x + \frac{x^3}{6} - \frac{x^5}{120} + O(x^7)$$

```
Error: The exponent must be a rational number. [Series::Puiseux::_power]
```

If the exponent contains the series variable, then an error occurs:

```
f^x
```

```
Error: The exponent must not contain the series variable. [Series::Puiseux::_power]
```

For undirected expansions and rational exponents that are not integral, the result has type 1 in general:

```
g^(1/2);
```

```
op(%, 1);
```

$$\sqrt{-x} - \frac{(-x)^{5/2}}{12} + \frac{(-x)^{9/2}}{1440} + O\left(x^{13/2}\right)$$

$$1$$

The result simplifies when you specify one of the directions `Left` or `Right`:

```
g := series(sin(-x), x, Left):
g^(1/2);
op(%, 1);
```

$$-\sqrt{x}\,\mathrm{i} + \frac{x^{5/2}\,\mathrm{i}}{12} - \frac{x^{9/2}\,\mathrm{i}}{1440} + O\left(x^{13/2}\right)$$

$$0$$

```
g := series(sin(-x), x, Right):
g^(1/2);
```

$$\sqrt{x}\,\mathrm{i} - \frac{x^{5/2}\,\mathrm{i}}{12} + \frac{x^{9/2}\,\mathrm{i}}{1440} + O\left(x^{13/2}\right)$$

Example 8

Functional composition of elements of `Series::Puiseux` is implemented by the method `_fconcat`:

```
f := series(ln(x), x = 1, 4);
g := series(cos(y), y = 0);
f@g = _fconcat(f, g);
series(ln(cos(y)), y = 0, 4);
```

$$x - 1 - \frac{(x-1)^2}{2} + \frac{(x-1)^3}{3} - \frac{(x-1)^4}{4} + O\left((x-1)^5\right)$$

$$1 - \frac{y^2}{2} + \frac{y^4}{24} + O(y^6)$$

$$-\frac{y^2}{2} - \frac{y^4}{12} + O(y^6) = -\frac{y^2}{2} - \frac{y^4}{12} + O(y^6)$$

$$-\frac{y^2}{2} - \frac{y^4}{12} + O(y^6)$$

If the left argument is not of type `Series::Puiseux`, it is implicitly expanded around the limit point of the right argument before the composition:

```
f := series(sin(-x), x = 0);
sqrt(y) @ f = Series::Puiseux(sqrt(y), y) @ f;
```

$$-x + \frac{x^3}{6} - \frac{x^5}{120} + O(x^7)$$

$$\sqrt{-x} - \frac{(-x)^{5/2}}{12} + \frac{(-x)^{9/2}}{1440} + O\left(x^{13/2}\right) = \sqrt{-x} - \frac{(-x)^{5/2}}{12} + \frac{(-x)^{9/2}}{1440} + O\left(x^{13/2}\right)$$

If the right argument is not of type `Series::Puiseux`, it is implicitly expanded around the origin via the constructor before the composition:

```
f @ sqrt(y) = f @ Series::Puiseux(sqrt(y), y)
```

$$-\sqrt{y} + \frac{y^{3/2}}{6} - \frac{y^{5/2}}{120} + O\left(y^{7/2}\right) = -\sqrt{y} + \frac{y^{3/2}}{6} - \frac{y^{5/2}}{120} + O\left(y^{7/2}\right)$$

This may not work if the argument to be converted contains special mathematical functions, but you can explicitly expand it into a series via `series` in this case:

```
f @ tan(y)
```

FAIL

```
f @ series(tan(y), y = 0)
```

$$-y-\frac{y^3}{6}+\frac{y^5}{40}+O(y^7)$$

Mathematically, the composition of series expansions is not defined if the limit point of the right argument is not the expansion point of the left argument:

```
g := series(y^2 - 1, y = 0);
f @ g
```

$$-1+y^2+O(y^6)$$

FAIL

```
f @ (y^2 - 1)
```

FAIL

```
f @ series(y^2 - 1, y = 1, 4)
```

$$-2\,(y-1)-(y-1)^2+\frac{4\,(y-1)^3}{3}+2\,(y-1)^4+O((y-1)^5)$$

The method `revert` computes the inverse of a truncated series expansion with respect to composition. The expansion point of the inverse is the limit point of the input and vice versa:

```
f := series(ln(x), x = 1, 4);
revert(f) = series(exp(x), x = 0, 5)
```

$$x-1-\frac{(x-1)^2}{2}+\frac{(x-1)^3}{3}-\frac{(x-1)^4}{4}+O((x-1)^5)$$

$$1+x+\frac{x^2}{2}+\frac{x^3}{6}+\frac{x^4}{24}+O(x^5)=1+x+\frac{x^2}{2}+\frac{x^3}{6}+\frac{x^4}{24}+O(x^5)$$

```
f := series(cot(x), x = 0);
revert(f) = series(arccot(x), x = complexInfinity);
```

$$\frac{1}{x} - \frac{x}{3} - \frac{x^3}{45} + O(x^5)$$

$$\frac{1}{x} - \frac{1}{3\,x^3} + \frac{1}{5\,x^5} + O\left(\frac{1}{x^7}\right) = \frac{1}{x} - \frac{1}{3\,x^3} + \frac{1}{5\,x^5} + O\left(\frac{1}{x^7}\right)$$

```
f @ revert(f), revert(f) @ f
```

$$x + O\left(\frac{1}{x^5}\right), x + O(x^7)$$

If the series variable occurs in the coefficients or the type flag is 1, an error occurs:

```
f := series(ln(sin(x)), x);
g := series(arcsin(x + 1), x, 2);
```

$$\ln(x) - \frac{x^2}{6} - \frac{x^4}{180} + O(x^6)$$

$$\frac{\pi}{2} - \sqrt{2}\,\sqrt{-x} - \frac{\sqrt{2}\,(-x)^{3/2}}{12} + O\left(x^{5/2}\right)$$

```
revert(f)
```

```
Error: Cannot compute the functional inverse. [Series::Puiseux::revert]
```

```
revert(g)
```

```
Error: Cannot compute the functional inverse. [Series::Puiseux::revert]
```

Example 9

The methods `diff` and `int` implement term-by-term differentiation and integration:

```
f := series(ln(x), x = 1, 4);
g := diff(f, x);
series(1/x, x = 1, 4);
int(g, x);
```

$$x - 1 - \frac{(x-1)^2}{2} + \frac{(x-1)^3}{3} - \frac{(x-1)^4}{4} + O((x-1)^5)$$

$$1 - (x-1) + (x-1)^2 - (x-1)^3 + O((x-1)^4)$$

$$1 - (x-1) + (x-1)^2 - (x-1)^3 + O((x-1)^4)$$

$$x - 1 - \frac{(x-1)^2}{2} + \frac{(x-1)^3}{3} - \frac{(x-1)^4}{4} + O((x-1)^5)$$

If you specify a range of integration, then the result is an arithmetical expression plus a symbolic definite integral of the *O*-term:

```
int(f, x = 1..2);
```

$$\int_1^2 O((x-1)^5, x = 1)\, \mathrm{d}x + \frac{11}{30}$$

Example 10

Most special mathematical functions are overloaded for `Series::Puiseux`:

```
f := series(x/(1 - x), x, 4);
exp(f) = series(exp(x/(1 - x)), x, 4);
ln(f) = series(ln(x/(1 - x)), x, 4);
```

$$x + x^2 + x^3 + x^4 + O(x^5)$$

$$1 + x + \frac{3\,x^2}{2} + \frac{13\,x^3}{6} + O(x^4) = 1 + x + \frac{3\,x^2}{2} + \frac{13\,x^3}{6} + O(x^4)$$

$$\ln(x) + x + \frac{x^2}{2} + \frac{x^3}{3} + O(x^4) = \ln(x) + x + \frac{x^2}{2} + \frac{x^3}{3} + O(x^4)$$

If the system is unable to compute the composition, it returns a symbolic function call with evaluated arguments:

```
delete g:
g(f)
```

$$g(x + x^2 + x^3 + x^4 + O(x^5))$$

```
exp(series(x + 1/x, x = infinity, 5))
```

$$e^{x + \frac{1}{x} + O\left(\frac{1}{x^4}\right)}$$

In this case, you can try `series` to compute the composition:

```
series(exp(x + 1/x), x = infinity, 5)
```

$$e^x + \frac{e^x}{x} + \frac{e^x}{2\,x^2} + \frac{e^x}{6\,x^3} + \frac{e^x}{24\,x^4} + O\left(\frac{e^x}{x^5}\right)$$

Example 11

The system functions `Re`, `Im`, and `conjugate` work for all real series expansions:

```
f := series(exp(I*x), x, Real);
Re(f) = series(cos(x), x, Real);
Im(f) = series(sin(x), x, Real) + O(x^6);
conjugate(f) = series(exp(-I*x), x, Real);
```

$$1 + x\,\mathrm{i} - \frac{x^2}{2} - \frac{x^3\,\mathrm{i}}{6} + \frac{x^4}{24} + \frac{x^5\,\mathrm{i}}{120} + O(x^6)$$

$$1 - \frac{x^2}{2} + \frac{x^4}{24} + O(x^6) = 1 - \frac{x^2}{2} + \frac{x^4}{24} + O(x^6)$$

$$x - \frac{x^3}{6} + \frac{x^5}{120} + O(x^6) = x - \frac{x^3}{6} + \frac{x^5}{120} + O(x^6)$$

$$1 - x\,i - \frac{x^2}{2} + \frac{x^3\,i}{6} + \frac{x^4}{24} - \frac{x^5\,i}{120} + O(x^6) = 1 - x\,i - \frac{x^2}{2} + \frac{x^3\,i}{6} + \frac{x^4}{24} - \frac{x^5\,i}{120} + O(x^6)$$

Except in trivial cases, a symbolic function call is returned for an undirected expansion:

```
Re(series(PI, x));
Re(series(exp(I*x), x));
```

$$\pi + O(x^6)$$

$$\Re\left(1 + x\,i - \frac{x^2}{2} - \frac{x^3\,i}{6} + \frac{x^4}{24} + \frac{x^5\,i}{120} + O(x^6)\right)$$

Example 12

The method `contfrac` converts a series expansion into a continued fraction:

```
f := series(exp(x), x, 10);
contfrac(f);
```

$$1 + x + \frac{x^2}{2} + \frac{x^3}{6} + \frac{x^4}{24} + \frac{x^5}{120} + \frac{x^6}{720} + \frac{x^7}{5040} + \frac{x^8}{40320} + \frac{x^9}{362880} + O(x^{10})$$

$$1 + \cfrac{x}{1 + \cfrac{x}{-2 + \cfrac{x}{-3 + \cfrac{x}{2 + \cfrac{x}{5 + \cfrac{x}{-2 + \cfrac{x}{-7 + \cfrac{x}{2 + \cfrac{x}{9 + O(x)}}}}}}}}}$$

```
g := series(tan(x), x = PI, 10);
contfrac(g);
```

$$x - \pi - \frac{(\pi - x)^3}{3} - \frac{2\,(\pi - x)^5}{15} - \frac{17\,(\pi - x)^7}{315} - \frac{62\,(\pi - x)^9}{2835} + O(-(\pi - x)^{11})$$

$$\cfrac{-\pi + x}{1 + \cfrac{(\pi - x)^2}{-3 + \cfrac{(\pi - x)^2}{5 + \cfrac{(\pi - x)^2}{-7 + \cfrac{(\pi - x)^2}{9 + O\left((\pi - x)^2\right)}}}}}$$

If the coefficients of a series expansion depend on the series variable, then so do the coefficients of the corresponding continued fraction:

```
h := series(ln(x + 1/x), x = infinity);
contfrac(h)
```

$$\ln(x) + \frac{1}{x^2} - \frac{1}{2\,x^4} + O\left(\frac{1}{x^6}\right)$$

$$\ln(x) + \cfrac{x^{-2}}{1 + \cfrac{x^{-2}}{2 + O\left(x^{-2}\right)}}$$

Example 13

For series expansions around the origin, the method `laplace`, overloading `laplace`, computes the Laplace transform term by term, if the second argument is the series variable. The result is a series expansion around infinity:

```
delete s:
f := series(exp(x), x);
g := laplace(f, x, s);
series(laplace(exp(x), x, s), s = infinity);
```

$$1 + x + \frac{x^2}{2} + \frac{x^3}{6} + \frac{x^4}{24} + \frac{x^5}{120} + O(x^6)$$

$$\frac{1}{s} + \frac{1}{s^2} + \frac{1}{s^3} + \frac{1}{s^4} + \frac{1}{s^5} + \frac{1}{s^6} + O\left(\frac{1}{s^7}\right)$$

$$\frac{1}{s}+\frac{1}{s^2}+\frac{1}{s^3}+\frac{1}{s^4}+\frac{1}{s^5}+\frac{1}{s^6}+O\left(\frac{1}{s^7}\right)$$

Similarly, the method `ilaplace` computes the inverse Laplace transform term by term for series expansions around infinity, if the second argument is the series variable. The result is a series expansion around 0:

```
ilaplace(g, s, x)
```

$$1+x+\frac{x^2}{2}+\frac{x^3}{6}+\frac{x^4}{24}+\frac{x^5}{120}+O(x^6)$$

The Laplace transform and the inverse Laplace transform, respectively, of a series do not make sense for expansion points other than 0 or infinity, respectively, and in these cases a symbolic function call is returned:

```
laplace(series(ln(x), x = 1, 2), x, s);
```

$$\text{laplace}\left(x-1-\frac{(x-1)^2}{2}+O((x-1)^3), x, s\right)$$

If the second argument is not the series variable, then the coefficients are transformed:

```
h := series(sin(x*y), x = 1, 2);
laplace(h, y, s);
```

$$\sin(y)+y\cos(y)\,(x-1)+O((x-1)^2)$$

$$\frac{1}{s^2+1}-\left(\frac{1}{s^2+1}-\frac{2\,s^2}{(s^2+1)^2}\right)(x-1)+O((x-1)^2)$$

Example 14

When called with one argument, the method `coeff` returns the sequence of all coefficients of a series expansion:

```
f := series(tan(x), x);
```

```
coeff(f)
```

$$x + \frac{x^3}{3} + \frac{2\,x^5}{15} + O(x^7)$$

$$1,\ 0,\ \frac{1}{3},\ 0,\ \frac{2}{15}$$

```
g := series(1/(x - 1)^2, x = infinity);
coeff(g)
```

$$\frac{1}{x^2} + \frac{2}{x^3} + \frac{3}{x^4} + \frac{4}{x^5} + \frac{5}{x^6} + \frac{6}{x^7} + O\left(\frac{1}{x^8}\right)$$

$$1,\ 2,\ 3,\ 4,\ 5,\ 6$$

When called with two arguments, `coeff` returns an individual coefficient:

```
coeff(f, -1), coeff(f, 1), coeff(f, 2), coeff(f, 13/2);
```

$$0,\ 1,\ 0,\ 0$$

If the second argument exceeds the order of the error term, `coeff` returns `FAIL`:

```
coeff(f, 10)
```

$$\text{FAIL}$$

When the expansion point is `complexInfinity`, `coeff(s, n)` returns the coefficient of $\frac{1}{x^n}$, where `x` is the series variable of `s`:

```
coeff(g, 2), coeff(g, -3), coeff(g, -15/2)
```

$$0,\ 2,\ 0$$

Specifying the series variable as second or third argument, respectively, is optional:

```
coeff(f) = coeff(f, x);
```

```
coeff(f, 3) = coeff(f, x, 3)
```

$$\left(1,\ 0,\ \frac{1}{3},\ 0,\ \frac{2}{15}\right) = \left(1,\ 0,\ \frac{1}{3},\ 0,\ \frac{2}{15}\right)$$

$$\frac{1}{3} = \frac{1}{3}$$

For series expansions of type 1, the "coefficients" in general involve the series variable:

```
h := series(sin(sqrt(-x)), x);
coeff(h);
coeff(h, 3/2);
```

$$\sqrt{-x} - \frac{(-x)^{3/2}}{6} + \frac{(-x)^{5/2}}{120} + O\left(x^{7/2}\right)$$

$$\frac{\sqrt{-x}}{\sqrt{x}},\ 0,\ -\frac{(-x)^{3/2}}{6\,x^{3/2}},\ 0,\ \frac{(-x)^{5/2}}{120\,x^{5/2}}$$

$$-\frac{(-x)^{3/2}}{6\,x^{3/2}}$$

Example 15

The method `ldegree` returns the order of the leading term of a series expansion. When the expansion point is `complexInfinity` and the leading term is $\frac{1}{x^n}$, then this is n:

```
f := series(x*sin(sqrt(-x)), x);
g := series(cot(x), x = PI);
h := series(2*arccot(x), x = infinity);
```

$$-(-x)^{3/2} + \frac{(-x)^{5/2}}{6} - \frac{(-x)^{7/2}}{120} + O\left(x^{9/2}\right)$$

$$-\frac{1}{\pi - x} - \frac{x - \pi}{3} + \frac{(\pi - x)^3}{45} + O\left(-(\pi - x)^5\right)$$

$$\frac{2}{x} - \frac{2}{3\,x^3} + \frac{2}{5\,x^5} + O\left(\frac{1}{x^7}\right)$$

```
ldegree(f), ldegree(g), ldegree(h)
```

$$\frac{3}{2},\ -1,\ 1$$

The method `lcoeff` returns the coefficient of the leading term. For an expansion of type 1, it generally involves the series variable:

```
lcoeff(f), lcoeff(g), lcoeff(h)
```

$$-\frac{(-x)^{3/2}}{x^{3/2}},\ 1,\ 2$$

The method `lterm` returns the leading term itself:

```
lterm(f), lterm(g), lterm(h)
```

$$x^{3/2},\ -\frac{1}{\pi - x},\ \frac{1}{x}$$

Finally, the method `lmonomial` returns the whole summand:

```
lmonomial(f) = lcoeff(f)*lterm(f);
lmonomial(g) = lcoeff(g)*lterm(g);
lmonomial(h) = lcoeff(h)*lterm(h);
```

$$-(-x)^{3/2} = -(-x)^{3/2}$$

$$-\frac{1}{\pi - x} = -\frac{1}{\pi - x}$$

$$\frac{2}{x} = \frac{2}{x}$$

If the series expansion consists only of an O-term, all four methods return `FAIL`:

```
s := Series::Puiseux::zero(x, 6);
ldegree(s), lcoeff(s), lterm(s), lmonomial(s)
```

$$O(x^6)$$

$$\text{FAIL}, \text{FAIL}, \text{FAIL}, \text{FAIL}$$

Example 16

The methods `nthcoeff`, `nthmonomial`, and `nthterm` return the nth non-zero coefficient, monomial, or term, respectively, of a series expansion. In contrast to polynomials, they count from the term of lowest order on, i.e., the ordering is ascending by exponent for finite expansion points and descending by exponent when the expansion point is `complexInfinity`:

```
f := series(x*sin(sqrt(-x)), x);
g := series(cot(x), x = PI);
h := series(2*arccot(x), x = infinity);
```

$$-(-x)^{3/2} + \frac{(-x)^{5/2}}{6} - \frac{(-x)^{7/2}}{120} + O\left(x^{9/2}\right)$$

$$-\frac{1}{\pi - x} - \frac{x - \pi}{3} + \frac{(\pi - x)^3}{45} + O\left(-(\pi - x)^5\right)$$

$$\frac{2}{x} - \frac{2}{3\,x^3} + \frac{2}{5\,x^5} + O\left(\frac{1}{x^7}\right)$$

```
nthcoeff(f, 1) = lcoeff(f);
nthmonomial(g, 1) = lmonomial(g);
nthterm(h, 1) = lterm(h);
```

$$-\frac{(-x)^{3/2}}{x^{3/2}} = -\frac{(-x)^{3/2}}{x^{3/2}}$$

$$-\frac{1}{\pi - x} = -\frac{1}{\pi - x}$$

$$\frac{1}{x} = \frac{1}{x}$$

```
nthcoeff(f, 3), nthmonomial(f, 3), nthterm(f, 3);
nthcoeff(g, 3), nthmonomial(g, 3), nthterm(g, 3);
nthcoeff(h, 3), nthmonomial(h, 3), nthterm(h, 3);
```

$$-\frac{(-x)^{7/2}}{120\,x^{7/2}}, -\frac{(-x)^{7/2}}{120}, x^{7/2}$$

$$-\frac{1}{45}, \frac{(\pi - x)^3}{45}, -(\pi - x)^3$$

$$\frac{2}{5}, \frac{2}{5\,x^5}, \frac{1}{x^5}$$

If the second argument is not positive or exceeds the number of non-zero summands, all three methods return `FAIL`:

```
nthcoeff(f, -4), nthterm(g, 0), nthmonomial(h, 4)
```

FAIL, FAIL, FAIL

Example 17

We illustrate the difference between the ordering of terms in polynomials and series expansions. The ordering of the terms in a polynomial agrees with the ordering of the terms in a series expansion with expansion point `complexInfinity`:

```
f := poly(2*(x^2 + x)^3);
g := series(f, x = complexInfinity);
[lcoeff(f), lmonomial(f), lterm(f)];
[lcoeff(g), lmonomial(g), lterm(g)];
```

$$\mathrm{poly}(2\,x^6 + 6\,x^5 + 6\,x^4 + 2\,x^3, [x])$$

$$2\,x^6 + 6\,x^5 + 6\,x^4 + 2\,x^3 + O(1)$$

$$[2, \mathrm{poly}(2\,x^6, [x]), \mathrm{poly}(x^6, [x])]$$

$$[2, 2\,x^6, x^6]$$

```
[nthcoeff(f, 2), nthmonomial(f, 3), nthterm(f, 4)];
[nthcoeff(g, 2), nthmonomial(g, 3), nthterm(g, 4)];
```

$$[6, \mathrm{poly}(6\,x^4, [x]), \mathrm{poly}(x^3, [x])]$$

$$[6, 6\,x^4, x^3]$$

For finite expansion points, however, the ordering of the terms in a series expansion is the reverse of the ordering of the terms in the corresponding polynomial:

```
h := series(f, x = 0);
[lcoeff(h), lmonomial(h), lterm(h)];
[nthcoeff(h, 2), nthmonomial(h, 3), nthterm(h, 4)];
```

$$2\,x^3 + 6\,x^4 + 6\,x^5 + 2\,x^6 + O(x^9)$$

$$[2, 2\,x^3, x^3]$$

$$[6, 6\,x^5, x^6]$$

Example 18

The method `iszero` checks whether a series expansion has no non-zero summands apart from the *O*-term:

```
f := series(exp(x), x);
g := Series::Puiseux(0, x = 2, 4);
iszero(f), iszero(g)
```

$$1 + x + \frac{x^2}{2} + \frac{x^3}{6} + \frac{x^4}{24} + \frac{x^5}{120} + O(x^6)$$

$$O((x-2)^4)$$

FALSE, TRUE

Example 19

The methods `convert` tries to convert an arbitrary object into an element of `Series::Puiseux`. If the input does not suggest an expansion point, `convert` uses the origin:

```
f := asympt(1/(x + 1), x = infinity);
g := sin(x)/(1 - x);
h := poly((x + 1)^10);
u := O((x - 1)^3, x = 1);
```

$$\frac{1}{x} - \frac{1}{x^2} + \frac{1}{x^3} - \frac{1}{x^4} + \frac{1}{x^5} - \frac{1}{x^6} + O\left(\frac{1}{x^7}\right)$$

$$-\frac{\sin(x)}{x-1}$$

$$\text{poly}(x^{10} + 10\,x^9 + 45\,x^8 + 120\,x^7 + 210\,x^6 + 252\,x^5 + 210\,x^4 + 120\,x^3 + 45\,x^2 + 10\,x + 1, [x])$$

$$O((x-1)^3, x = 1)$$

```
domtype(f), domtype(g), domtype(h), domtype(u)
```

Series::gseries, DOM_EXPR, DOM_POLY, O

```
F := Series::Puiseux::convert(f);
G := Series::Puiseux::convert(g);
H := Series::Puiseux::convert(h);
U := Series::Puiseux::convert(u);
```

$$\frac{1}{x} - \frac{1}{x^2} + \frac{1}{x^3} - \frac{1}{x^4} + \frac{1}{x^5} - \frac{1}{x^6} + O\left(\frac{1}{x^7}\right)$$

$$\sin(x) + x\sin(x) + x^2\sin(x) + x^3\sin(x) + x^4\sin(x) + x^5\sin(x) + O(x^6)$$

$$1 + 10x + 45x^2 + 120x^3 + 210x^4 + 252x^5 + 210x^6 + 120x^7 + 45x^8 + 10x^9 + x^{10} + O(x^{16})$$

$$O((x-1)^3)$$

`convert` returns `FAIL`, if it is unable to convert the input, e.g., because the input contains no or more than one indeterminate:

```
Series::Puiseux::convert(sin(1)),
Series::Puiseux::convert([1, y, 3])
```

FAIL, FAIL

The method `convert_to` tries to convert an element of `Series::Puiseux` into a specified type:

```
Series::Puiseux::convert_to(F, Series::gseries);
Series::Puiseux::convert_to(F, contfrac);
Series::Puiseux::convert_to(G, DOM_EXPR);
Series::Puiseux::convert_to(H, DOM_POLY);
Series::Puiseux::convert_to(H, O);
Series::Puiseux::convert_to(U, O);
```

$$\frac{1}{x} - \frac{1}{x^2} + \frac{1}{x^3} - \frac{1}{x^4} + \frac{1}{x^5} - \frac{1}{x^6} + O\left(\frac{1}{x^7}\right)$$

$$\frac{x^{-1}}{1+\frac{x^{-1}}{1+O\left(x^{-5}\right)}}$$

$$\sin(x)+x^2\sin(x)+x^3\sin(x)+x^4\sin(x)+x^5\sin(x)+x\sin(x)$$

$$\mathrm{poly}(x^{10}+10x^9+45x^8+120x^7+210x^6+252x^5+210x^4+120x^3+45x^2+10x+1,\ [x])$$

$$O(1)$$

$$O((x-1)^3,\ x=1)$$

`convert_to` returns `FAIL`, if it is unable to perform the requested conversion:

```
Series::Puiseux::convert_to(F, 0),
Series::Puiseux::convert_to(F, DOM_LIST)
```

$$\mathrm{FAIL},\ \mathrm{FAIL}$$

Example 20

The method `expr` converts an element of `Series::Puiseux` into an arithmetical expression, discarding the *O*-term. In general, the ordering of the summands is not preserved:

```
f := series(exp(x*y), x);
g := series(ln(x), x = 1, 3);
```

$$1+x\,y+\frac{x^2\,y^2}{2}+\frac{x^3\,y^3}{6}+\frac{x^4\,y^4}{24}+\frac{x^5\,y^5}{120}+O(x^6)$$

$$x-1-\frac{(x-1)^2}{2}+\frac{(x-1)^3}{3}+O((x-1)^4)$$

```
expr(f);
expr(g);
```

$$\frac{x^5\,y^5}{120}+\frac{x^4\,y^4}{24}+\frac{x^3\,y^3}{6}+\frac{x^2\,y^2}{2}+x\,y+1$$

$$x-\frac{(x-1)^2}{2}+\frac{(x-1)^3}{3}-1$$

The method `float` applies the system function `float` to all coefficients:

```
float(f);
float(g);
```

$$1.0+x\,y+0.5\,x^2\,y^2+0.1666666667\,x^3\,y^3+0.04166666667\,x^4\,y^4+0.008333333333\,x^5\,y^5+O(x^6)$$

$$1.0\,(x-1)-0.5\,(x-1)^2+0.3333333333\,(x-1)^3+O((x-1)^4)$$

Example 21

The methods `combine`, `expand`, and `normal` apply the corresponding system functions to all coefficients:

```
delete a, y:
f := series(y/(x + y^a), x, 4);
g := combine(f);
expand(g);
```

$$\frac{y}{y^a}-\frac{x\,y}{y^{2\,a}}+\frac{x^2\,y}{y^{3\,a}}-\frac{x^3\,y}{y^{4\,a}}+O(x^4)$$

$$y^{1-a}-x\,y^{1-2\,a}+x^2\,y^{1-3\,a}-x^3\,y^{1-4\,a}+O(x^4)$$

$$\frac{y}{y^a} - \frac{x\,y}{y^{2\,a}} + \frac{x^2\,y}{y^{3\,a}} - \frac{x^3\,y}{y^{4\,a}} + O(x^4)$$

For efficiency reasons, the arithmetical methods of `Series::Puiseux` usually do not perform any symbolic simplifications. Use `expand` or `normal` to simplify the results:

```
h := series(exp(x), x, 4)^a;
expand(h);
normal(h);
```

$$1 + a\,x + x^2\left(\frac{a}{2} + \frac{a\,(a-1)}{2}\right) + x^3\left(\frac{a}{6} + \frac{\left(\frac{a}{2} + \frac{a\,(a-1)}{2}\right)(a-2)}{3} + \frac{a\,(2\,a-1)}{6}\right) + O(x^4)$$

$$1 + a\,x + \frac{a^2\,x^2}{2} + \frac{a^3\,x^3}{6} + O(x^4)$$

$$1 + a\,x + \frac{a^2\,x^2}{2} + \frac{a^3\,x^3}{6} + O(x^4)$$

```
u := series(arctanh(x + y), x, 4);
normal(u);
```

$$\operatorname{arctanh}(y) - \frac{x\,\mathrm{i}}{y^2\,\mathrm{i} - \mathrm{i}} + \frac{x^2\,y}{(y^2-1)^2} - \frac{x^3\,(3\,y^2+1)}{3\,(y^2-1)^3} + O(x^4)$$

$$\operatorname{arctanh}(y) - \frac{x}{y^2-1} + \frac{x^2\,y}{(y^2-1)^2} - \frac{x^3\,(3\,y^2+1)}{3\,(y^2-1)^3} + O(x^4)$$

Besides normalizing the coefficients, the method `normal` also removes leading and trailing zeroes from the coefficient list:

```
v := Series::Puiseux::create(1, 3, 10,
                             [0, 1/2, 0, 5, 0, 0], x, 2);
coeff(v);
normal(v);
```

```
coeff(%);
```

$$\frac{(x-2)^4}{2} + 5\,(x-2)^6 + O((x-2)^{10})$$

$$0,\ \frac{1}{2},\ 0,\ 5,\ 0,\ 0$$

$$\frac{(x-2)^4}{2} + 5\,(x-2)^6 + O((x-2)^{10})$$

$$\frac{1}{2},\ 0,\ 5$$

The method `map` applies a given function to all coefficients. E.g., the system function `factor` is not overloaded for `Series::Puiseux`, but you can use `map` to express all coefficients in factored form:

```
map(u, factor);
```

$$\operatorname{arctanh}(y) - \frac{x}{(y-1)\,(y+1)} + \frac{y\,x^2}{(y-1)^2\,(y+1)^2} - \frac{(3\,y^2+1)\,x^3}{3\,(y-1)^3\,(y+1)^3} + O(x^4)$$

In the next example, we use `map` to multiply all coefficients of a series expansion by a constant:

```
w := series(exp(x), x, 3);
map(w, _mult, PI) = PI*w
```

$$1 + x + \frac{x^2}{2} + O(x^3)$$

$$\pi + \pi\,x + \frac{\pi\,x^2}{2} + O(x^3) = \pi + \pi\,x + \frac{\pi\,x^2}{2} + O(x^3)$$

For series expansions of type 1, `map` applies the function to all non-zero coefficients as returned by `coeff`:

```
z := series(sin(sqrt(-x)), x);
coeff(z);
map(z, cos);
```

$$\sqrt{-x} - \frac{(-x)^{3/2}}{6} + \frac{(-x)^{5/2}}{120} + O\left(x^{7/2}\right)$$

$$\frac{\sqrt{-x}}{\sqrt{x}},\ 0,\ -\frac{(-x)^{3/2}}{6\,x^{3/2}},\ 0,\ \frac{(-x)^{5/2}}{120\,x^{5/2}}$$

$$\sqrt{x}\,\cos\left(\frac{\sqrt{-x}}{\sqrt{x}}\right) + x^{3/2}\cos\left(\frac{(-x)^{3/2}}{6\,x^{3/2}}\right) + x^{5/2}\cos\left(\frac{(-x)^{5/2}}{120\,x^{5/2}}\right) + O\left(x^{7/2}\right)$$

Example 22

Three different methods can be used to substitute for the series variable: `_fconcat`, `func_call`, and `subs`. Suppose `f` is an element of `Series::Puiseux` and we want to substitute an expression `t` for the series variable `x`. Then `_fconcat` converts `t` into a series expansion around the origin via the constructor, computes the functional composition, and returns the result as an element of `Series::Puiseux`:

```
f := series(exp(x), x = 0, 5);
Series::Puiseux::_fconcat(f, y) = f @ y;
f @ (y^2 + y);
```

$$1 + x + \frac{x^2}{2} + \frac{x^3}{6} + \frac{x^4}{24} + O(x^5)$$

$$1 + y + \frac{y^2}{2} + \frac{y^3}{6} + \frac{y^4}{24} + O(y^5) = 1 + y + \frac{y^2}{2} + \frac{y^3}{6} + \frac{y^4}{24} + O(y^5)$$

$$1 + y + \frac{3\,y^2}{2} + \frac{7\,y^3}{6} + \frac{25\,y^4}{24} + O(y^5)$$

The composition may fail if the limit point of `t` around the origin differs from the expansion point of `f` or if `t` contains special mathematical functions:

```
f @ (y + 1);
```

FAIL

```
f @ sin(y);
```

FAIL

Moreover, the composition does not work if the expression `t` is constant or contains more than one indeterminate:

```
f @ PI;
```

```
Error: Cannot compute composition. [Series::Puiseux::_fconcat]
```

```
f @ (x + y);
```

```
Error: Cannot compute composition. [Series::Puiseux::_fconcat]
```

You can enforce the composition by explicitly converting `t` into a series:

```
f @ series(y + 1, y = -1);
f @ series(sin(y), y = 0);
f @ series(x + y, x = -y);
```

$$1 + y + 1 + \frac{(y+1)^2}{2} + \frac{(y+1)^3}{6} + \frac{(y+1)^4}{24} + O((y+1)^5)$$

$$1 + y + \frac{y^2}{2} - \frac{y^4}{8} + O(y^5)$$

$$1 + x + y + \frac{(x+y)^2}{2} + \frac{(x+y)^3}{6} + \frac{(x+y)^4}{24} + O((x+y)^5)$$

Substitution with `func_call` always works. It discards the error term, `t` is substituted literally, and the result is an expression and not an object of type `Series::Puiseux`:

```
f(5) = Series::Puiseux::func_call(f, 5);
f(y) = Series::Puiseux::func_call(f, y);
```

$$\frac{523}{8} = \frac{523}{8}$$

$$\frac{y^4}{24} + \frac{y^3}{6} + \frac{y^2}{2} + y + 1 = \frac{y^4}{24} + \frac{y^3}{6} + \frac{y^2}{2} + y + 1$$

```
f(y^2 + y);
f(y + 1);
f(sin(y));
f(PI);
f(x + y);
```

$$y + \frac{(y^2+y)^2}{2} + \frac{(y^2+y)^3}{6} + \frac{(y^2+y)^4}{24} + y^2 + 1$$

$$y + \frac{(y+1)^2}{2} + \frac{(y+1)^3}{6} + \frac{(y+1)^4}{24} + 2$$

$$\frac{\sin(y)^4}{24} + \frac{\sin(y)^3}{6} + \frac{\sin(y)^2}{2} + \sin(y) + 1$$

$$\pi + \frac{\pi^2}{2} + \frac{\pi^3}{6} + \frac{\pi^4}{24} + 1$$

$$x + y + \frac{(x+y)^2}{2} + \frac{(x+y)^3}{6} + \frac{(x+y)^4}{24} + 1$$

Finally, if `subs` is used to substitute for the series variable, only very special substitutions are allowed (see the description of `subs` above for more details). Then a change of variable is performed, and the result is again of type `Series::Puiseux`:

```
subs(f, x = y^2 + y)
```

```
Error: Invalid substitution. [Series::Puiseux::subs]
```

```
subs(f, x = y + 1)
```

$$1 + y + 1 + \frac{(y+1)^2}{2} + \frac{(y+1)^3}{6} + \frac{(y+1)^4}{24} + O((y+1)^5)$$

```
subs(f, x = sin(y))
```

```
Error: Invalid substitution. [Series::Puiseux::subs]
```

```
subs(f, x = PI)
```

```
Error: The substitution is invalid. Exactly one indeterminate is expected. [Series::Pui
```

```
subs(f, x = x + y)
```

```
Error: The substitution is invalid. Exactly one indeterminate is expected. [Series::Pui
```

All three methods can handle the case where the series variable occurs in the coefficients:

```
s := series(ln(x^2 + x), x);
s @ (2*y);
s(2*y);
subs(s, x = 2*y);
```

$$\ln(x) + x - \frac{x^2}{2} + \frac{x^3}{3} - \frac{x^4}{4} + \frac{x^5}{5} + O(x^6)$$

$$\ln(2) + \ln(y) + 2\,y - 2\,y^2 + \frac{8\,y^3}{3} - 4\,y^4 + \frac{32\,y^5}{5} + O(y^6)$$

$$2\,y + \ln(2\,y) - 2\,y^2 + \frac{8\,y^3}{3} - 4\,y^4 + \frac{32\,y^5}{5}$$

$$\ln(2\,y) + 2\,y - 2\,y^2 + \frac{8\,y^3}{3} - 4\,y^4 + \frac{32\,y^5}{5} + O(y^6)$$

Of course, `subs` can also be used to substitute for other objects than the series variable in the coefficients and in the expansion point:

```
g := series(cos(x + y), x, 4);
h := series(1/x, x = y, 4);
```

$$\cos(y) - x\sin(y) - \frac{x^2\cos(y)}{2} + \frac{x^3\sin(y)}{6} + O(x^4)$$

$$\frac{1}{y} - \frac{x-y}{y^2} + \frac{(x-y)^2}{y^3} - \frac{(x-y)^3}{y^4} + O((x-y)^4)$$

```
subs(g, y = PI) = series(cos(x + PI), x, 4);
subs(h, y = 2) = series(1/x, x = 2, 4);
```

$$-1 + \frac{x^2}{2} + O(x^4) = -1 + \frac{x^2}{2} + O(x^4)$$

$$\frac{1}{2} - \frac{x-2}{4} + \frac{(x-2)^2}{8} - \frac{(x-2)^3}{16} + O((x-2)^4) = \frac{1}{2} - \frac{x-2}{4} + \frac{(x-2)^2}{8} - \frac{(x-2)^3}{16} + O((x-2)^4)$$

Even simultaneous substitutions are possible in the coefficients:

```
subs(g, [hold(sin) = cos, hold(cos) = sin, y = 2])
```

$$\sin(2) - x\cos(2) - \frac{x^2\sin(2)}{2} + \frac{x^3\cos(2)}{6} + O(x^4)$$

An error occurs, if the right hand side contains the series variable:

```
subs(h, y = x)
```

```
Error: The substitution is invalid. The right side must not contain the series variable
```

Example 23

The method `has` checks, whether an object occurs syntactically in the coefficients, the series variable, the expansion point, or the direction of an element of `Series::Puiseux`:

```
f := series(sin(x + 2*y), x = PI, 2);
has(f, x), has(f, y), has(f, PI), has(f, 2), has(f, Undirected);
has(f, hold(sin)), has(f, 3), has(f, sin(2*y)), has(f, x - PI);
```

$$-\sin(2\,y)+\cos(2\,y)\,(\pi-x)+O((\pi-x)^2)$$

TRUE, TRUE, TRUE, TRUE, TRUE

TRUE, FALSE, TRUE, FALSE

The last call returns `FALSE` since the expression `x - PI` occurs only in the screen output, but not in the internal representation of `f`.

```
g := series(sign(x), x, Right);
has(g, Right), has(g, Undirected);
```

$$1+O(x^6)$$

TRUE, FALSE

Example 24

The method `truncate` discards summands up to the given order:

```
f := series(x*sin(sqrt(x)), x);
Series::Puiseux::truncate(f, 10);
Series::Puiseux::truncate(f, 9/2);
Series::Puiseux::truncate(f, 7/2);
Series::Puiseux::truncate(f, 3);
Series::Puiseux::truncate(f, 3/2);
Series::Puiseux::truncate(f, 1);
```

$$x^{3/2} - \frac{x^{5/2}}{6} + \frac{x^{7/2}}{120} + O\left(x^{9/2}\right)$$

$$x^{3/2} - \frac{x^{5/2}}{6} + \frac{x^{7/2}}{120} + O\left(x^{9/2}\right)$$

$$x^{3/2} - \frac{x^{5/2}}{6} + \frac{x^{7/2}}{120} + O\left(x^{9/2}\right)$$

$$x^{3/2} - \frac{x^{5/2}}{6} + O\left(x^{7/2}\right)$$

$$x^{3/2} - \frac{x^{5/2}}{6} + O\left(x^{7/2}\right)$$

$$O\left(x^{3/2}\right)$$

$$O\left(x^{3/2}\right)$$

Parameters

f

An arithmetical expression representing a function in x

x

An identifier

x_0

The expansion point: an arithmetical expression. If not specified, the default expansion point 0 is used.

`order`

The number of terms to be computed: a nonnegative integer. The default order is given by the environment variable `ORDER` (default value 6).

`dir`

Either `Left`, `Right`, `Real`, or `Undirected`. This optional argument can be used to specify that the resulting expansion is possibly valid along the real line only. The default is `Undirected`, which means that the expansion is valid in a neighborhood of the expansion point in the complex plane.

Return Values

an object of domain type `Series::Puiseux`, or the value `FAIL`, if the `f` cannot be converted, e.g., if powers with non-rational exponents occur in `f`.

Function Calls

Calling an element of `Series::Puiseux` as a function discards the error term and substitutes the first argument for the series variable. See the description of the method `"func_call"` and “Example 22” on page 7-444.

Operations

`Series::Puiseux` implements the basic arithmetic of truncated series expansions. Use the ordinary arithmetical operators `+, -, *, /, ^`, and `@` for composition.

The arithmetical methods of `Series::Puiseux` usually do not perform any symbolic simplifications. Use `combine`, `expand`, or `normal` to request such simplifications explicitly.

See “Example 5” on page 7-418 and “Example 21” on page 7-441.

Special mathematical functions, such as `exp` or `sin`, are overloaded for elements of `Series::Puiseux`; cf. “Example 10” on page 7-427.

The system functions `coeff`, `lcoeff`, `nthcoeff`, `ldegree`, `lmonomial`, `nthmonomial`, `lterm`, and `nthterm` work on truncated series expansions. Note that in contrast to polynomials, coefficients, monomials, and terms are counted from the term of lowest order term on. Cf. “Example 17” on page 7-436.

Use the function `expr` to convert a series expansion to an arithmetical expression (as an element of a kernel domain).

Operands

A series of the domain type `Series::Puiseux` has the following seven operands:

1. a *type flag* $t \in \{0, 1\}$,
2. the *branching order* b, a positive integer,
3. an integer v such that $\frac{v}{b}$ is the order of the leading term,
4. an integer $e \geq v$ such that $\frac{e}{b}$ is the order of the error term,
5. a list of coefficients $l_1, \ldots, l_n$,
6. the *series variable* x and the *expansion point* x_0 in form of an equation $x = x_0$; the expansion point x_0 may be `complexInfinity` as well,
7. a *direction*, `Undirected`, `Real`, `Left`, or `Right`.

The type flag distinguishes between two different internal representations.

If $t = 0$, then the operands above represent the truncated series expansion

$$\sum_{1 \leq i \leq n} \left(l_i (x - x_0)^{\frac{(v+i-1)}{b}} + O\left((x - x_0)^{e/b} \right) \right)$$

.

If the expansion point x_0 is `complexInfinity`, then the operands represent the truncated expansion

$$\sum_{1 \leq i \leq n} \left(\frac{l_i}{x^{\frac{(i+v-1)}{b}}} + O\left(\frac{1}{x^{\frac{e}{b}}} \right) \right)$$

.

- A summand $l_i(x-x_0)^{\frac{(v+i-1)}{b}}$ (or $\frac{l_i}{x^{\frac{(i+v-1)}{b}}}$, respectively) is called a *monomial* of the expansion,
- the power $(x-x_0)^{\frac{(v+i-1)}{b}}$ (or $\frac{1}{x^{\frac{(v+i-1)}{b}}}$, respectively) is called a *term*,
- l_i is the corresponding *coefficient*, and
- the exponent $\frac{(v+i-1)}{b}$ is the *order* of the corresponding term or monomial.

If $t = 1$, then the operands above represent the expansion

$$\sum_{1 \le i \le n} \left(l_i + O\left((x-x_0)^{e/b}\right)\right)$$

.

In this case, the powers of x - x_0 are explicitly stored in the list, and l_i contains only terms of growth order $O\left((x-x_0)^{\frac{(v+i-1)}{b}}\right)$. The corresponding expansion for `x0 = complexInfinity` is

$$\sum_{1 \le i \le n} \left(l_i + O\left(\frac{1}{x^{\frac{e}{b}}}\right)\right)$$

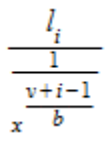
,

and l_i contains only terms of growth order $O\left(\frac{1}{x^{\frac{(v+i-1)}{b}}}\right)$.

The notions term and order are the same as for $t = 0$, a summand l_i is called a monomial, and the corresponding coefficient is

$$\frac{l_i}{(x-x_0)^{\frac{v+i-1}{b}}}$$

(or



,

respectively).

The latter type of representation serves for correct expansions around branch points. For example, if we want to expand $f(x) = \sqrt{x}$ around $x = 0$, then the truncated Puiseux series $\sqrt{-1}\,\sqrt{x} + O\left(x^{13/2}\right)$ does not approximate $f(x)$ in the lower half of the complex plane. With $t = 1$, the expansion $\sqrt{(-x)} + O\left(x^{13/2}\right)$, which approximates $f(x)$ also in the lower part of the complex plane near the origin, can be represented as an object of domain type `Series::Puiseux`.

The direction d has the same meaning as the parameter `dir` of the constructor. If d = *Undirected*, the operands above represent an expansion valid in some neighborhood of the expansion point in the complex plane. Usually, this is an open disc centered at `x0`. If $d \neq$ *Undirected* and x_0 represents a real number, this means that the expansion is valid for real values of x only. If d = *Left* or d = *Right*, then the expansion is valid for $x < x_0$ or $x > x_0$, respectively.

In the case `x_0 = complexInfinity`, and if d = *Undirected*, we have an expansion valid in the neighborhood of the north pole of the Riemann sphere, i.e., for all $x \in \mathbb{C}$ of sufficiently large absolute value. If d = *Left*, we have an expansion around the positive real infinity valid for sufficiently large real values of x. Similarly, if d = *Right*, we have an expansion around the negative real infinity valid for sufficiently large negative real values of x. Finally, if d = *Real*, the expansion is valid both around *infinity* and around $-\infty$.

Cf. “Example 2” on page 7-412.

Element Creation

Typically, objects of type `Series::Puiseux` are generated by calls to `series` or `taylor`.

Methods

Mathematical Methods

`conjugate` — Complex conjugation

```
conjugate(s)
```

This method overloads the system function `conjugate`. Cf. “Example 11” on page 7-428.

`contfrac` — Conversion into a continued fraction

```
contfrac(s)
```

This method overloads the system function `contfrac`. Cf. “Example 12” on page 7-429.

`diff` — Differentiation

```
diff(s, t)
```

This method overloads the system function `diff`. Cf. “Example 9” on page 7-426.

`_divide` — Division

```
_divide(s, t)
```

`_fconcat` — Functional composition

```
_fconcat(s, t)
```

If both `s` and `t` are of type `Series::Puiseux`, then the functional composition can only be defined if the limit point of t for values close to its expansion point is equal to the expansion point of s. Otherwise, an error occurs.

At least one of the arguments must be of type `Series::Puiseux`. If one of the arguments is not of this type, then it is converted into an element of `Series::Puiseux` via the constructor. If s is not of type `Series::Puiseux`, then it is converted into a

series expansion around the limit point of t. If t is not of type `Series::Puiseux`, then it is converted into a series expansion around 0. The implicit conversion is performed only if the corresponding expression contains exactly one free variable.

This method overloads the system function `_fconcat` for series expansions, i.e., you may use it in the form `s@t`. See "Example 8" on page 7-423 and "Example 22" on page 7-444.

`Im` — Imaginary part

```
Im(s)
```

This method overloads the system function `Im`. Cf. "Example 11" on page 7-428.

`int` — Integration

```
int(s, t | t = a .. b)
```

This method overloads the system function `int`. Cf. "Example 9" on page 7-426, and the help page of `int` for a description of further optional arguments.

`_invert` — Reciprocal of a series

```
_invert(s)
```

This method overloads the system function `_invert`, i.e., you may use it in the form `1/s`.

`ilaplace` — Inverse Laplace transform

```
ilaplace(s, u, v)
```

If `u` is not the series variable of `s`, then the coefficients of `s` are transformed, but not the expansion point. Otherwise, the expansion point of `s` must be infinity, `v` must be an identifier, and `s` is transformed term by term. The result is then a series expansion around $v = 0$.

This method overloads the function `ilaplace` for series expansions. Cf. "Example 13" on page 7-430.

`laplace` — Laplace transform

```
laplace(s, u, v)
```

If `u` is not the series variable of `s`, then the coefficients of `s` are transformed, but not the expansion point. Otherwise, the expansion point of `s` must be 0, the order of the leading term of `s` must be nonnegative, `v` must be an identifier, and `s` is transformed term by term. The result is then a series expansion around $v = \infty$.

This method overloads the function `laplace` for series expansions. Cf. "Example 13" on page 7-430.

`_mult` — Multiplication

```
_mult(s, t, , …)
```

Use the method `Series::Puiseux::scalmult` to multiply a series expansion `s` by a constant or a power of $x - x_0$.

This method overloads the system function `_mult` for series expansions, i.e., you may use it in the form `s*t*...`. Cf. "Example 5" on page 7-418.

`_negate` — Negation

```
_negate(s)
```

This method overloads the system function `_negate`, i.e., you may use it in the form `-s`.

`_plus` — Addition

```
_plus(s, t, , …)
```

This method overloads the system function `_plus` for series expansions, i.e., you may use it in the form `s+t+...`. Cf. "Example 5" on page 7-418.

`_power` — Exponentiation

```
_power(s, n)
```

If n is a rational number, the direction of `s` is `Undirected` or `Real`, and the leading coefficient of `s` is not positive, then the type flag of the result is 1 in general.

If n is not a rational number, then the leading summand of s must not contain the series variable. Otherwise, an error occurs.

This method overloads the system function `_power` for series expansions, i.e., you may use it in the form `s^n`. Cf. "Example 7" on page 7-421.

Re — Real part

```
Re(s)
```

This method overloads the system function `Re`. Cf. “Example 11” on page 7-428.

revert — Functional inversion

```
revert(s)
```

The expansion point of the inverse is the limit point of `s`.

This method overloads the system function `revert`. Cf. “Example 8” on page 7-423.

scalmult — Multiplication by a single monomial

```
Series::Puiseux::scalmult(s, a, k)
```

series — Serie expansion

```
series(s, y | y = y0, <order>, <dir>)
```

This method overloads the system function `series`.

_subtract — Subtraction

```
_subtract(s, t)
```

Access Methods

coeff — Extract coefficients

```
coeff(s, <x>, n)
```

```
coeff(s, <x>)
```

The second call returns the sequence of all coefficients of `s`, starting with the coefficient of lowest order. (This is the coefficient of the term with the highest exponent if x_0=`complexInfinity`.)

Specifying the variable `x` is optional; if it is present, it must coincide with the series variable of `s`.

This method overloads the system function `coeff`. Cf. “Example 14” on page 7-431.

`direction` — Direction of expansion

```
Series::Puiseux::direction(s)
```

`indet` — Serie variable

```
Series::Puiseux::indet(s)
```

`iszero` — Zero test

```
iszero(s)
```

This method overloads the system function `iszero`. Cf. “Example 18” on page 7-438.

`lcoeff` — Leading coefficient (of lowest order)

```
lcoeff(s)
```

This method overloads the system function `lcoeff`. See “Example 15” on page 7-433 and “Example 17” on page 7-436.

`ldegree` — Leading degree

```
ldegree(s)
```

This method overloads the system function `ldegree`. See “Example 2” on page 7-412 and “Example 15” on page 7-433.

`lmonomial` — Leading monomial (of lowest order)

```
lmonomial(s)
```

This method overloads the system function `lmonomial`. See “Example 15” on page 7-433 and “Example 17” on page 7-436.

`lterm` — Leading term (of lowest order)

```
lterm(s)
```

This method overloads the system function `lterm`. See “Example 15” on page 7-433 and “Example 17” on page 7-436.

`nthcoeff` — Extract coefficients

```
nthcoeff(s, n)
```

This method overloads the system function `nthcoeff`. See “Example 16” on page 7-435 and “Example 17” on page 7-436

`nthmonomial` — Extract monomials

```
nthmonomial(s, n)
```

This method overloads the system function `nthmonomial`. See “Example 16” on page 7-435 and “Example 17” on page 7-436.

`nthterm` — Extract terms

```
nthterm(s, n)
```

This method overloads the system function `nthterm`. See “Example 16” on page 7-435 and “Example 17” on page 7-436.

`order` — Order of the error term

```
Series::Puiseux::order(s)
```

`point` — Expansion point

```
Series::Puiseux::point(s)
```

Conversion Methods

`convert` — Convert any object into a series expansion

```
convert(f)
```

If no expansion point can be determined from `f`, the origin is used. Cf. “Example 19” on page 7-438.

`convert_to` — Convert a series expansion into another domain

```
convert_to(s, T)
```

Use the function `expr` to convert `s` into an object of a kernel domain.

`convert01` — Convert into a series expansion of type 1

```
Series::Puiseux::convert01(s)
```

`convert10` — Try to convert into a series expansion of type 0

```
Series::Puiseux::convert10(s)
```

For undirected expansions, the conversion is not possible in general, and then `s` is returned. However, you can enforce a conversion (with a not necessarily equivalent result) by using properties. Cf. “Example 3” on page 7-415.

`expr` — Convert a series expansion into an element of a kernel domain

```
expr(s)
```

This method overloads the system function `expr`. Cf. “Example 20” on page 7-440.

`float` — Convert numeric parts of the coefficients into floats

```
float(s)
```

This method overloads the system function `float`. Cf. “Example 20” on page 7-440.

Technical Methods

`combine` — Combine coefficients

```
combine(s)
```

This method overloads the system function `combine`; see the corresponding help page for further optional arguments. Cf. “Example 21” on page 7-441.

`const` — Convert a constant expression into a truncated series

```
Series::Puiseux::const(f, x | x = x0, n, <d>)
```

If the expansion point `x0` is omitted, `x0 = 0` is assumed. If the direction `d` is omitted, `d = Undirected` is assumed.

Use with care, since this function does not perform type checking. Cf. “Example 1” on page 7-409.

`create` — Syntactical constructor

```
Series::Puiseux::create(b, v, e, l, x, <x0>, <d>)
```

If the expansion point `x0` is omitted, `x0 = 0` is assumed. If the direction `d` is omitted, `d = Undirected` is assumed.

Use with care, since this function does not perform type checking. Cf. “Example 1” on page 7-409.

`expand` — Expand coefficients

```
expand(s)
```

This method overloads the system function `expand`; see the corresponding help page for further optional arguments. Cf. “Example 21” on page 7-441.

`func_call` — Evaluation at a point

```
Series::Puiseux::func_call(s, t)
```

You may also use this method in the form `s(t)`. Cf. “Example 22” on page 7-444.

`has` — Check whether an object occurs syntactically

```
has(s, t)
```

This method overloads the system function `has`. Cf. “Example 23” on page 7-449.

`map` — Apply a function to all non-zero coefficients

```
map(s, f, <arg1, , …>)
```

This method overloads the system function `map`. Cf. “Example 21” on page 7-441.

`normal` — Normal form

```
normal(s)
```

This method overloads the system function `normal`. Cf. “Example 21” on page 7-441.

one — Create a truncated series with constant term 1

```
Series::Puiseux::one(x, <x0>, n, <d>)
```

If the expansion point `x0` is omitted, `x0 = 0` is assumed. If the direction `d` is omitted, `d = Undirected` is assumed.

Use with care, since this function does not perform type checking. Cf. "Example 1" on page 7-409.

print — Pretty-print routine

```
print(s)
```

truncate — Truncate a series expansion

```
Series::Puiseux::truncate(s, n)
```

Cf. "Example 24" on page 7-449.

subs — Replace subexpressions

```
subs(s, old = new)
```

```
subs(s, [old1 = new1, old2 = new2, …])
```

If the series variable `x` of `s` does not occur in the left hand sides `old, old1, old2, ...`, then the substitution takes place in the coefficients and in the expansion point of `s`. The series variable must not occur in the right hand sides `new, new1, new2, ...`.

Note: In contrast to the usual behavior of `subs`, the result of the substitution is subjected to an additional evaluation.

In the second call, the series variable `x` of `s` must not occur anywhere in the substitution equations. In the first call, `x` is allowed to occur in `old` only if `old` equals `x`. In this case, a change of variable is performed, and `new` must be of the form

```
x0 + a*(b*y - c)^k
```

if `x0 <> complexInfinity` and

```
a*(b*y - c)^k
```

if `x0 = complexInfinity`, where

- `x0` is the expansion point of `s`
- `k` is a non-zero rational number
- `y` is an identifier, which may well be equal to `x`, and otherwise `y` must not occur in the coefficients of `s`.
- `a, b, c` are arithmetical expressions not involving `y`, with `a, b` being non-zero. If the direction of `s` is not `Undirected`, then `a` and `b` must represent real numbers.
- `c` is zero if either `x0 <> complexInfinity` and `k` is positive or `x0 = complexInfinity` and `k` is negative. In this case, the result of the substitution has expansion point `complexInfinity`.
- If `c` is non-zero, then the result of the substitution has expansion point `c/b`.

Use one of the methods `"_fconcat"` or `"func_call"` for more general substitutions for the series variable.

This method overloads the system function `subs`; Cf. “Example 22” on page 7-444.

`zero` — Create a truncated series with an error term only

```
Series::Puiseux::zero(x, <x0>, n, <d>)
```

If the expansion point `x0` is omitted, `x0 = 0` is assumed. If the direction `d` is omitted, `d = Undirected` is assumed.

Note: Although `Series::Puiseux::zero(x, n)` and `O(x^n)` are mathematically equivalent and are printed in the same way, they are different MuPAD objects. The former is an element of type `Series::Puiseux`, while the latter is an element of type `O`.

Use with care, since this function does not perform type checking. Cf. “Example 1” on page 7-409.

MuPAD Functions

`asympt` | `series`

MuPAD Domains
`Series::gseries`

Series::gseries

Generalized series expansions

Syntax

```
Series::gseries(f, x, <order>, <Left | Right>)
```

```
Series::gseries(f, x = a, <order>, <Left | Right>)
```

Description

`Series::gseries` is the domain of series expansions generalizing Taylor, Laurent and Puiseux expansions.

The call `Series::gseries(f, x)` computes a series expansion at the right hand side of $x = 0$.

The system functions `series` and `asympt` are the main application of this domain. The latter function only returns elements of this domain, whereas `series` can return an element of `Series::gseries` in cases, where a Puiseux series expansion does not exist.

There may be no need to explicitly create elements of this domain, but to work with the results of the mentioned system functions.

See the help page of the system function `asympt` for a detailed description of the parameters and examples for working with elements of the domain `Series::gseries`.

Note: Note that elements of `Series::gseries` only represents *directional* (real) series expansions.

Environment Interactions

The function is sensitive to the global variable `ORDER`, which determines the default number of terms of the expansion.

Parameters

`f`

An arithmetical expression

`x`

The series variable: an identifier

`a`

The expansion point: an arithmetical expression or ±`infinity`

`order`

The truncation order: a nonnegative integer

Options

`Left`

Compute a series expansion that is valid for real x smaller than a.

`Right`

Compute a series expansion that is valid for real x larger than a (the default case).

Return Values

Object of domain type `Series::gseries`, or the value `FAIL`.

Function Calls

Calling an element of `Series::gseries` as a function yields the object itself, regardless of the arguments. The arguments are *not* evaluated.

Operations

`Series::gseries` implements standard arithmetic of generalized series expansions. Use the ordinary arithmetical operators `+`, `-`, `*`, `/`, and `^`.

The system functions `coeff`, `lcoeff`, `nthcoeff`, `lterm`, `nthterm`, `lmonomial`, `nthmonomial`, and `ldegree` work on generalized series expansions. See the corresponding help pages of these functions for calling parameters. See the description of these methods below for further details.

The method `"indet"` returns the series variable of the series expansion, i.e., if `s` is an object of the domain `Series::gseries`, then `s::dom::indet(s)` returns the series variable.

The method `"point"` returns the expansion point of the series.

Use the function `expr` to convert a generalized series expansion into an arithmetical expression (as an element of a kernel domain).

Operands

A series of the domain type `Series::gseries` consists of four operands:

1. A list of pairs $[c_i, f_i]$. Each pair represents a *monomial* $c_i f_i$ of the series expansion, where the c_i are the *coefficients* and f_i the *terms* of `s`. The coefficients do not contain the series variable.

   This list can be empty, if the order of the expansion is zero.
2. An arithmetical expression `g` representing the *error term* of the form $O(g)$. It may be the integer 0, in which case the expansion is exact.
3. The *series variable* `x`.
4. The *expansion point* `a`.

Methods

Mathematical Methods

`_divide` — Divide two series expansions

```
_divide(s, t)
```

If the arguments are not of domain type `Series::gseries`, then they are converted into such objects. `FAIL` is returned, if one of these conversions fails.

This method overloads the function `_divide` for elements of `Series::gseries`, i.e., you may use it in the form `s/t`.

`_invert` — Multiplicative inverse of a series expansion

```
_invert(s)
```

This method overloads the function `_invert` for elements of `Series::gseries`, i.e., you may use it in the form `1/s`.

`_mult` — Multiply series expansions

```
_mult(s, t, …)
```

If both `s` and `t` are series expansions of the domain `Series::gseries`, then the result is a series expansion of the domain `Series::gseries`, too. Both series expansions must have the same series variable and expansion point, otherwise `FAIL` is returned.

If `s` or `t` is a series expansion of the domain `Series::Puiseux`, then it is converted into an object of `Series::gseries`. If this fails, then `FAIL` is returned. Otherwise, the product is computed and returned as an object of the domain `Series::gseries`.

If `s` is a series expansion and `t` is an arithmetical expression, then `t` is converted into a series expansion via the constructor `Series::gseries` (and vice versa).

Each argument of this method that is not of the domain type `Series::gseries` is converted into such an element, i.e., a generalized series expansion is computed. If this fails, then `FAIL` is returned.

This method overloads the function _mult for elements of Series::gseries, i.e., you may use it in the form s*t*....

_negate — Negative of a series expansion

```
_negate(s)
```

This method overloads the function _negate for elements of Series::gseries, i.e., you may use it in the form -s.

_plus — Add series expansions

```
_plus(s, t, …)
```

If both s and t are series expansions of the domain Series::gseries, then the result is a series expansion of the domain Series::gseries, too. Both series expansions must have the same series variable and expansion point, otherwise FAIL is returned.

If s or t is a series expansion of the domain Series::Puiseux, then it is converted into an object of Series::gseries. If this fails, then FAIL is returned. Otherwise, the sum is computed and returned as an object of the domain Series::gseries.

If s is a series expansion and t is an arithmetical expression, then t is converted into a series expansion via the constructor Series::gseries (and vice versa).

Each argument of this method that is not of the domain type Series::gseries is converted into such an element, i.e., a generalized series expansion is computed. If this fails, then FAIL is returned.

This method overloads the function _plus for elements of Series::gseries, i.e., you may use it in the form s+t+ ....

_power — Exponentiation of a series expansion

```
_power(s, n)
```

The exponent n must not involve the series variable of s. Otherwise, an error occurs.

If n is a positive integer, then repeated squaring is used for computing the nth power of s. Otherwise, the binomial theorem is applied after factoring out the leading monomial.

This method overloads the function _power for elements of Series::gseries, i.e., you may use it in the form s^n.

`_subtract` — Subtract two series expansions

```
_subtract(s, t)
```

If the arguments are not of domain type `Series::gseries`, then they are converted into such objects. `FAIL` is returned, if one of these conversions fails.

This method overloads the function `_subtract` for elements of `Series::gseries`, i.e., you may use it in the form `s-t`.

Access Methods

`coeff` — Extract coefficients

```
coeff(s, <n>)
```

This method overloads the function `coeff` for elements of `Series::gseries`.

`indet` — Serie variable

```
Series::gseries::indet(s)
```

Use the method `"point"` to get the expansion point of `s`.

`iszero` — Zero test

```
iszero(s)
```

This method overloads the function `iszero` for elements of `Series::gseries`.

`lcoeff` — Leading coefficient

```
lcoeff(s)
```

This method overloads the function `lcoeff` for elements of `Series::gseries`.

`ldegree` — Leading degree

```
ldegree(s)
```

This method overloads the function `ldegree` for elements of `Series::gseries`.

`lmonomial` — Leading monomial

```
lmonomial(s)
```

This method overloads the function `lmonomial` for elements of `Series::gseries`.

`lterm` — Leading term

```
lterm(s)
```

This method overloads the function `lterm` for elements of `Series::gseries`.

`nthcoeff` — Extract a coefficient

```
nthcoeff(s, n)
```

This method overloads the function `nthcoeff` for elements of `Series::gseries`.

`nthmonomial` — Extract a monomial

```
nthmonomial(s, n)
```

This method overloads the function `nthmonomial` for elements of `Series::gseries`.

`nthterm` — Extract a term

```
nthterm(s, n)
```

This method overloads the function `nthterm` for elements of `Series::gseries`.

`point` — Expansion point

```
Series::gseries::point(s)
```

Use the method `"indet"` to get the series variable of `s`.

Conversion Methods

`convert` — Convert an object into a generalized series expansion

```
Series::gseries::convert(x)
```

`convert_to` — Convert a generalized series expansion into other domains

```
Series::gseries::convert_to(s, T)
```

`T` might be the domain `DOM_POLY`, where the sum of monomials is considered as a polynomial in the indeterminates of the third operand of `s`.

If `T` is the domain `DOM_EXPR`, then the conversion is the same as implemented by the method `"expr"` (see below).

If `T` is the domain `Series::Puiseux`, then the system tries to convert `s` into a Puiseux series. If the conversion is not possible, `FAIL` is returned.

Use the function `expr` to convert `s` into an object of a kernel domain.

`create` — Create simple and fast a generalized series expansion

```
Series::gseries::create(list, errorTerm, x = a)
```

Note: This method should be used with caution, because no argument checking is performed. Use it to *create*, not to compute elements of `Series::gseries`.

`expr` — Convert a generalized series expansion into an element of a kernel domain

```
expr(s)
```

This method overloads the function `expr` for elements of `Series::gseries`.

`series` — Apply the function `series` to a generalized series expansion

```
series(s, x | x = x0, <order>, <dir>)
```

This method overloads the function `series` for elements of `Series::gseries`. See the corresponding help page for a description of the possible arguments.

Technical Methods

`combine` — Apply the function `combine` to all terms

```
combine(s, <target>)
```

This method overloads the system function `combine`. See the corresponding help page for a description of the optional argument `target`.

`has` — Check whether an object occurs syntactically

```
has(s, t)
```

This method overloads the system function `has`.

`map` — Map a function to the coefficients

```
map(s, func, …)
```

This method overloads the function `map` for elements of `Series::gseries`.

`print` — Pretty-print routine

```
print(s)
```

`subs` — Substitute into a generalized series expansion

```
subs(s, x = a, …)
```

This method overloads the function `subs` for elements of `Series::gseries`.

`TeX` — LaTeX formatting

```
Series::gseries::TeX(s)
```

This method is called by the system function `generate::TeX`.

export – Export Data

export::stl

export::stl

Export STL data

Syntax

```
export::stl(filename, [x, y, z], u = u_min .. u_max, v = v_min .. v_max, options)

export::stl(n, [x, y, z], u = u_min .. u_max, v = v_min .. v_max, options)

export::stl(filename, object_1, <object_2, …>, options)

export::stl(n, object_1, <object_2, …>, options)
```

Description

`export::stl` is used to create a triangulation of a parametrized surface and write the triangulation data in STL format to an external file.

STL files contain triangulation data of 3D surfaces. Each triangle is stored as a unit normal and three vertices. The normal and the vertices are specified by three coordinates each, so there is a total of 12 numbers stored for each triangle. Read the "Background" section of this help page for further details.

If the surface is closed, it is regarded as the boundary of a 3D solid. The normals of the triangles written into the STL file should point from the inside of the body to the outside.

Note: Note that the direction of the normals that `export::stl` writes into the STL file depend on the parametrization $x(u, v)$, $y(u, v)$, $z(u, v)$!

If `p1 = (x(u, v), y(u, v), z(u, v))`, `p2 = (x(u + du, v), y(u + du, v), z(u + du, v))`, `p3 = (x(u, v + dv), y(u, v + dv), z(u, v + dv))` are the corners of a triangle, the normal associated with this triangle is the cross product of the side `p2 - p1` times the side `p3 - p2`. The routine `export::stl` chooses neighboring values of the surface parameters with `du = (`u_{max}` - `u_{min}`)/(n_u - 1)` and `dv = (`v_{max}` - `v_{min}`)/(n_v - 1)`, respectively.

Note: Thus, if your parametrization is such that the cross product of the vectors $p_2 - p_1$ and $p_3 - p_2$ does not point to the outside of your body, you just need to let one of the parameters (u, say) run from u_{max} to u_{min} instead of from u_{min} to u_{max}. Just replace your call

```
export::stl(filename, [x,y,z], u = `u_{min}` .. `u_{max}`, v =
`v_{min}` .. `v_{max}`)
```

by

```
export::stl(filename, [x,y,z], u = `u_{max}` .. `u_{min}`, v =
`v_{min}` .. `v_{max}`).
```

Up to the irrelevant ordering in the STL file, the triangles generated by these calls are the same apart from the direction of the normal associated with each triangle.

If the file is specified by a character string, the corresponding file is opened and closed, automatically.

As an alternative to specifying the file by a string, the user may open the file herself via `fopen` in `Write` mode and pass the file descriptor returned by `fopen` to `export::stl`. If binary data are to be written to the file, make sure that it is opened with the `Raw`, i.e., call `fopen(filename, Write, Raw)`.

Note: Note that `export::stl` does not close the file automatically if it is specified by a file descriptor. It remains open after `export::stl` has finished its job. The file needs to be closed explicitly by the user using `fclose`.

If the file is specified by a character string, the name may correspond to an absolute or a relative path name. In particular, the environment variable `WRITEPATH` is taken into account. The details on the help page of `fopen` hold for `export::stl`, too.

Note: With the option `Append`, the file is first opened for reading and, after reading of the data in the file, opened for writing. If no absolute pathname is used to specify the file, make sure that the environment variables `READPATH` and `WRITEPATH` point to the same folder. Alternatively, it is a good idea to place the file in the same folder as the MuPAD notebook which you are currently using. If this notebook is saved on

the disk of your computer, the absolute path is available as the environment variable NOTEBOOKPATH. Thus, specifying a file named "myfile.stl", say, by the absolute path name NOTEBOOKPATH."myfile.stl" ensures that the file is found in the same folder as your notebook.

Text files generated with the option Text or the equivalent Ascii can be opened and read with any text editor. However, binary files generated with the option Bin or the equivalent options Binary or Raw are faster to create and to process.

The file generated by export::stl can be read and visualized in MuPAD using the plot primitive plot::SurfaceSTL.

If the file name given ends in ".gz", export::stl writes a compressed file which can be read by any program supporting gzip compression.

Environment Interactions

The function is sensitive to the environment variable DIGITS which determines the numerical working precision. The current value of DIGITS determines the number of significant decimal digits with which the STL data are written to the specified file. (This holds for text files. In binary STL files all numerical values have a precision of about 7 decimal digits.) For the internal computation of the data by MuPAD, the value of DIGITS is temporarily increased by 10 to minimize round-off effects.

The STL data generated by export::stl are written to the specified file.

Examples

Example 1

We generate a sphere given by the following parametrization:

```
x:= cos(u)*sin(v):
y:= sin(u)*sin(v):
z:= cos(v):
```

We call export::stl to generate the STL data and write them into a file named "sphere.stl". The file is to be generated in the same directory as the current MuPAD

notebook that we are using. Hence, we specify an absolute path name for the file using the path of the current notebook. If this notebook was saved to the disk of your computer, this path is available in the environment variable NOTEBOOKPATH:

```
filename:= NOTEBOOKPATH."sphere.stl":
export::stl(filename, [x, y, z], u = 0 .. 2*PI, v = 0 .. PI, Text)
```

Since the file was created in Text format, it can be opened with any text editor. It should look like this:

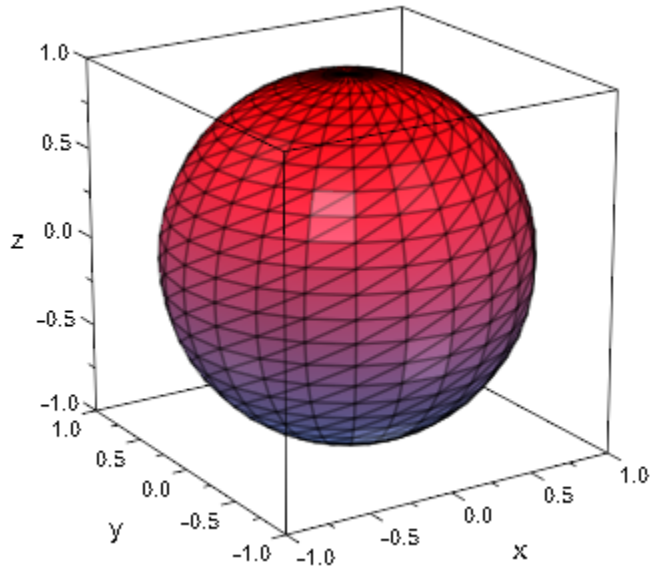
```
solid MuPADtoSTL1
 facet normal -0.06540070486 -0.008610166138 -0.9978219344
  outer loop
   vertex 100.0 100.0 300.0
   vertex 112.607862 103.3782664 298.7167292
   vertex 113.0526192 100.0 298.7167292
  endloop
 endfacet
 facet normal -0.1950260058 -0.02567566076 -0.9804619409
  outer loop
   vertex 113.0526192 100.0 298.7167292
   vertex 112.607862 103.3782664 298.7167292
   vertex 125.0 106.6987298 294.8888739
  endloop
 endfacet

 ...

endsolid MuPADtoSTL1
```

We reimport the STL data and visualize the surface using plot::SurfaceSTL:

```
plot(plot::SurfaceSTL(filename, MeshVisible))
```



We reduce the number of significant output digits to a reasonable size. Further, we specify a mesh size and request a specific output box:

```
DIGITS:= 7:
export::stl(filename, [x, y, z], u = 0..2*PI, v = 0..PI,
            Mesh = [10, 10],
            OutputBox = [-100..100, -100..100, -100..100],
            Text):
```

The file now should look like this:

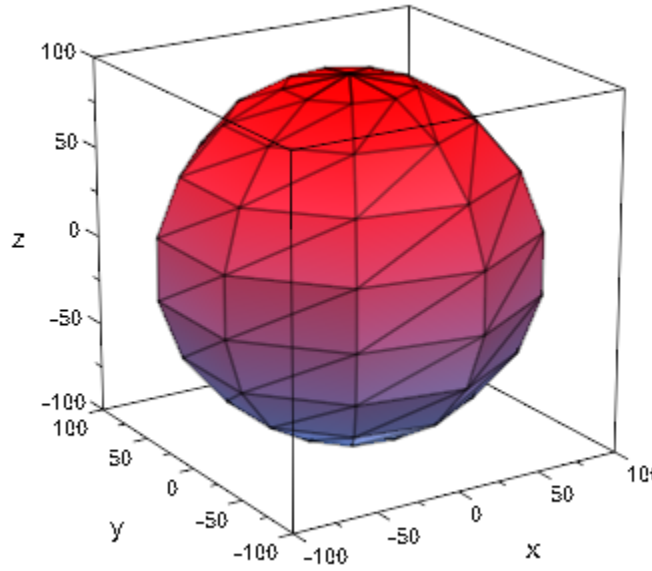
```
solid MuPADtoSTL2
 facet normal -0.1733024 -0.06307691 -0.9828467
  outer loop
   vertex -3.10912 0.000000002143114 100.0
   vertex 24.32249 22.66816 93.96926
   vertex 32.7003 0.000000002143114 93.96926
  endloop
 endfacet

 ...
```

```
endsolid MuPADtoSTL2
```

We visualize the new content of the file:

```
plot(plot::SurfaceSTL(filename, MeshVisible))
```



```
delete x, y, z, filename, DIGITS:
```

Example 2

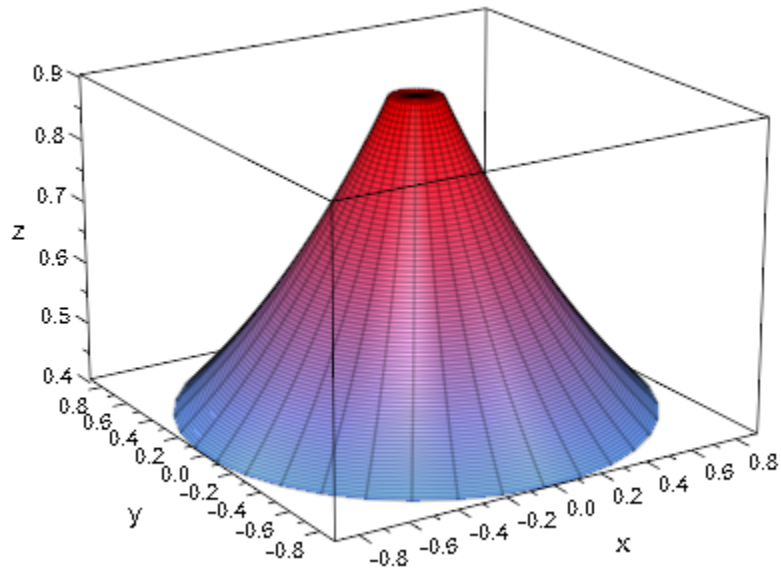
We specify the parametrization of the surface by a mixture of expressions and procedures:

```
x:= piecewise([0.1 < u < 0.9, u*cos(v)], [Otherwise, 0]):
y:= (u, v) -> piecewise([0.1 < u < 0.9, u*sin(v)], [Otherwise, 0]):
z:= (u, v) -> if u <= 0.1 then exp(-0.1)
              elif u < 0.9 then exp(-u)
              else exp(-0.9)
```

```
                end_if:
```

This is the surface that we wish to export to STL:

```
plot(plot::Surface([x, y, z], u = 0..1, v = 0..2*PI,
                                    Mesh = [100, 36])):
```

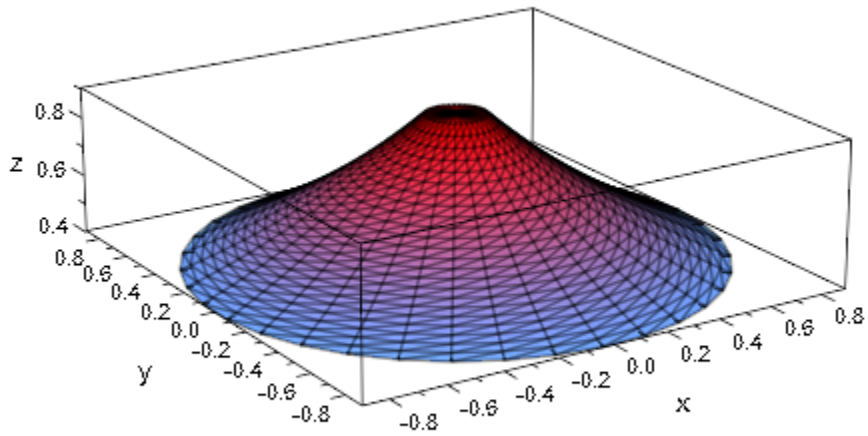


We assume that there is no external file “sample.stl”. We create it by opening it in `Write` mode in the same directory as the current MuPAD notebook that we are using. Hence, we specify an absolute path name for the file using the path of the current notebook. If this notebook was saved to the disk drive of your computer, this path is available in the environment variable `NOTEBOOKPATH`. The file descriptor `n` returned by `fopen` is passed to `export::stl`:

```
filename:= NOTEBOOKPATH."sample.stl":
DIGITS:= 7:
export::stl(filename, [x, y, z], u = 0..1, v = 0..2*PI,
                                        Mesh = [30, 36])
```

We reimport the STL data and visualize the surface using `plot::SurfaceSTL`:

```
plot(plot::SurfaceSTL(filename, MeshVisible))
```

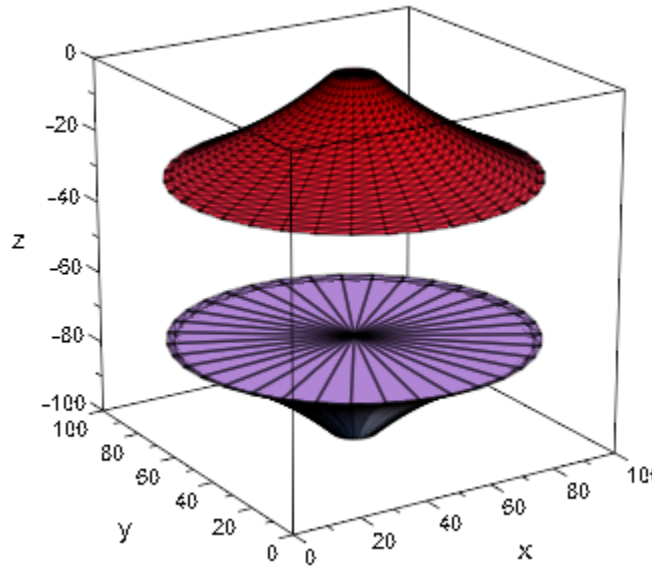


We can append a further surface to the file using the option `Append`:

```
export::stl(filename, [x, y, -z], u = 0..1, v = 0..2*PI,
            Mesh = [30, 36],
            OutputBox = [0..100, 0..100, -100..0],
            Append)
```

We visualize the new content of the file via `plot::SurfaceSTL`:

```
plot(plot::SurfaceSTL(filename, MeshVisible))
```



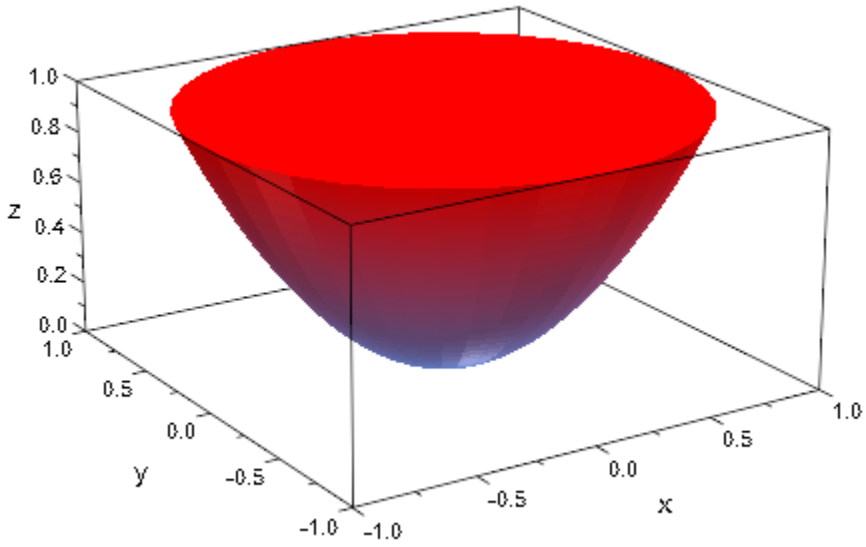
```
delete x, y, z, filename, DIGITS:
```

Example 3

We wish to create a closed surface consisting of a “bowl” with a “lid”.

```
bowl:= [u*cos(v), u*sin(v), u^2], u = 0 .. 1, v = 0 .. 2*PI:
lid:=  [u*cos(v), u*sin(v),  1 ], u = 0 .. 1, v = 0 .. 2*PI:

filename:= NOTEBOOKPATH."sample.stl":
DIGITS:= 7:
export::stl(filename, bowl, Mesh = [30, 36]):
export::stl(filename, lid, Mesh = [30, 36], Append):
plot(plot::SurfaceSTL(filename), Scaling = Constrained):
```



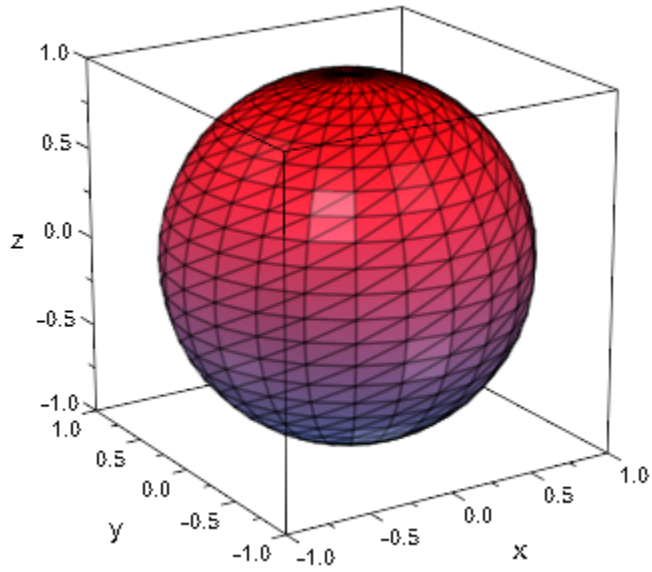
```
delete filename, DIGITS:
```

Example 4

We demonstrate the options `Scaling` = `Constrained` and `Scaling` = `Unconstrained`. With `Scaling` = `Constrained`, the coordinates given by the parametrization `x, y, z` are scaled by the same factor to fit the surface into the output box. Here, we create a sphere of radius 1. The output box is not a cube: the range for the `z` coordinate is notably larger than for `x` and `y`. Nevertheless, the sphere stays a sphere when using `Scaling` = `Constrained`. However, the output box is not completely filled by the sphere:

```
x:= cos(u)*sin(v):
y:= sin(u)*sin(v):
z:= cos(v):
DIGITS:= 7:
filename:= NOTEBOOKPATH."sphere.stl":
export::stl(filename, [x, y, z], u = 0 .. 2*PI, v = 0 .. PI,
            OutputBox = [-1 .. 1, -1 .. 1, -3 .. 3],
            Scaling = Constrained):
```

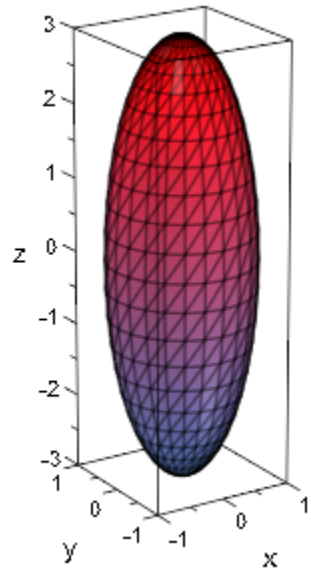
```
plot(plot::SurfaceSTL(filename,
                      Scaling = Constrained,
                      MeshVisible))
```



With `Scaling` = `Unconstrained`, the sphere is deformed to an ellipsoid filling the output box:

```
export::stl(filename, [x, y, z], u = 0..2*PI, v = 0..PI,
            OutputBox = [-1..1, -1..1, -3..3],
            Scaling = Unconstrained):

plot(plot::SurfaceSTL(filename,
                      Scaling = Constrained,
                      MeshVisible))
```



```
delete x, y, z, filename, DIGITS:
```

Parameters

`filename`

A file name: a non-empty character string

`n`

A file descriptor provided by `fopen`: a positive integer

$\texttt{object}_1$, $\texttt{object}_2$, …

3D graphical objects of the `plot` library

`x, y, z`

The coordinate functions: arithmetical expressions or `piecewise` objects depending on the surface parameters u and v. Alternatively, procedures that accept 2 input parameters u, v and return a numerical value when the input parameters are numerical.

u

The first surface parameter: an identifier or an indexed identifier.

u_{min} .. u_{max}

The range for the parameter u: u_{min}, u_{max} must be numerical real values.

v

The second surface parameter: an identifier or an indexed identifier.

v_{min} .. v_{max}

The range for the parameter v: v_{min}, v_{max} must be numerical real values.

Options

Mesh

Option, specified as `Mesh = [nu, nv]`

Sets the mesh size: the integer n_u determines, how many equidistant points in the `u` direction are used to sample the parametrization `x, y, z` numerically. Correspondingly, the integer n_v determines, how many equidistant points in the `v` direction are used. Thus, a regular mesh of (n_u - 1) (n_v - 1) rectangles is used. Each rectangle is split into 2 triangles, resulting in a triangulation consisting of 2 (n_u - 1) (n_v - 1) triangles. The default is `Mesh = [25, 25]`.

OutputBox

Option, specified as `OutputBox = [xmin .. xmax, ymin .. ymax, zmin .. zmax]`

By default, the coordinates of the mesh points defining the STL object are written into the file as provided by the parametrization of the surface. Thus, if several objects are written into the file via the option `Append`, the position of the objects in space is transparent and can be controlled by the user via a suitable parametrization. However, many devices such as Rapid Prototyping tools with which the STL file shall be processed, impose severe restrictions on the data in the STL file. E.g., the original STL specification requires that the x, y, z coordinates of the mesh points are positive. Many devices require

that the coordinates must lie in a prescribed range (between 0 and 100, say). The option `OutputBox` provides a simple mean to shift and scale the coordinates given by the parametrization to a prescribed range.

The option `OutputBox = [ xmin.. xmax, ymin.. ymax, zmin.. zmax]` sets the output box defined by numerical values `xmin, …, zmax`. The mathematical coordinates `x(u, v), y(u, v), z(u, v)` with `u`, `v` ranging from `umin` to `umax` and from `vmin` to `vmax`, respectively, are shifted and scaled such that the output coordinates written to the STL file range between the values `xmin` and `xmax`, `ymin` and `ymax`, `zmin` and `zmax`.

Note: If several objects are written to the file via the option `Append`, only the very last call of `export::stl` should bear the option `OutputBox`!

This last call shifts and scales all coordinates of all surfaces inside the file such that the entire scene of objects fits into the output box. The relative size and positions of the objects are preserved.

See “Example 3” on page 8-10.

This option is rather expensive since all data in the STL file need to be modified!

This option is not available if the file was opened outside `export::stl` and passed by a file descriptor `n`.

`Scaling`

Option, specified as `Scaling = Unconstrained` or `Scaling = Constrained`

With `Scaling = Unconstrained`, the surface is scaled by different factors in the x, y, and z direction, such that it fills the output box set by the option `OutputBox - [`x_{min}` .. `x_{max}`, `y_{min}` .. `y_{max}`, `z_{min}` .. `z_{max}`]` . Thus, the output coordinates of a sphere define an ellipsoid with diameters given by the side lengths of the output box. This is the default setting.

With `Scaling = Constrained`, the surface is scaled by the same factor in the x, y, and z direction such that it fits into the output box set by the option `OutputBox = [`x_{min}` .. `x_{max}`, `y_{min}` .. `y_{max}`, `z_{min}` .. `z_{max}`]` . A sphere will remain a sphere even if the sides of the output box have different lengths.

This option is ignored if not used in conjunction with the `OutputBox` option.

`Ascii`, `Bin`, `Binary`, `Raw`, `Text`

With the synonymous flags `Bin`, `Binary`, or `Raw`, respectively, the STL file is created as a binary file. If a binary file is specified by a file descriptor `n`, make sure that is was opened by the command `n:= fopen(filename, Write, Raw)`. With the synonymous flags `Text` and `Ascii`, repectively, the STL file is created as a text file. The default is `Bin`.

`Append`

With this flag, the STL data of the surface are appended to an existing STL file named "filename". If no such file exists, it is created and processed as without `Append`. This option is not available if the file was opened outside `export::stl` and passed by a file descriptor `n`.

Return Values

`null()` object.

Algorithms

There are two storage formats available for STL files, which are ASCII and BINARY. ASCII files are human-readable while BINARY files are smaller and faster to process. Both ASCII as well as BINARY files can be generated by `export::stl`. A typical ASCII STL file looks like this:

```
solid sample
 facet normal -4.470293E-02 7.003503E-01 -7.123981E-01
  outer loop
   vertex -2.812284E+00 2.298693E+01 0.000000E+00
   vertex -2.812284E+00 2.296699E+01 -1.960784E-02
   vertex -3.124760E+00 2.296699E+01 0.000000E+00
  endloop
 endfacet
 ...
endsolid sample
```

STL BINARY files have the following format:

```
Bytes  Type   Description
80     ASCII  header, no data significance
4      uint   number of facets in file

4      float  normal  x - start of facet
4      float  normal  y
4      float  normal  z
4      float  vertex1 x
4      float  vertex1 y
4      float  vertex1 z
4      float  vertex2 x
4      float  vertex2 y
4      float  vertex2 z
4      float  vertex3 x
4      float  vertex3 y
4      float  vertex3 z
2      byte   not used  - end of facet
       ...
```

Facet orientation: The facets define the surface of a 3D object. As such, each facet is part of the boundary between the interior and the exterior of the object. The orientation of the facets (which way is "out" and which way is "in") is specified redundantly in two ways which should be consistent. First, the direction of the normal is outward. Second, which is most commonly used nowadays, the facet vertices are listed in counter-clockwise order when looking at the object from the outside (right-hand rule).

Vertex-to-vertex rule: Each triangle must share two vertices with each of its adjacent triangles. In other words, a vertex of one triangle cannot lie on the side of another.

Axes: The format specifies that all vertex coordinates must be strictly positive numbers. However, it seems that – with a few exceptions – most software used today (MuPAD included) allow negative coordinates as well.

Units: The STL file does not contain any scale information; the coordinates may be interpreted in arbitrary units.

Further details about the STL file format are available in the web, e.g., at:

- www.ennex.com/fabbers/StL.asp,
- www.math.iastate.edu/burkardt/data/stl/stl.html and
- rpdrc.ic.polyu.edu.hk/content/stl/stl_introduction.htm.

Collections of STL sample files can be found in the web, e.g., at:

- www.wohlersassociates.com/Software-for-Rapid-Prototyping.html and
- www.cs.duke.edu/~edels/Tubes.

Information about rapid prototyping technologies is available in the web, e.g., at:

www.cs.hut.fi/~ado/rp/rp.html.

MuPAD Graphical Primitives
`plot::SurfaceSTL`

fp – Functional Programming

fp::apply
fp::bottom
fp::curry
fp::expr_unapply
fp::fixargs
fp::fixedpt
fp::fold
fp::nest
fp::nestvals
fp::unapply

fp::apply

Apply function to arguments

Syntax

```
fp::apply(f, <e, …>)
```

Description

`fp::apply(f,a)` returns `f(a)`.

`fp::apply` applies the function `f` to the arguments given by `e`, ...

Environment Interactions

Same side effects as when calling `f(e,...)` directly.

Examples

Example 1

Apply the function `f` to `x` and `y`:

```
fp::apply(f, x, y)
```

$$f(x, y)$$

Example 2

Apply the functions of the first list to the arguments given by the second list:

```
zip([sin, cos], [x, y], fp::apply)
```

$[\sin(x), \cos(y)]$

Parameters

`f`

Function

`e`

Object used as argument

Return Values

Result of the function call `f(e,...)`.

fp::bottom

Function that never returns

Syntax

```
fp::bottom()
```

Description

`fp::bottom()` never returns because it raises an error.

Environment Interactions

Raises an error in any case.

Examples

Example 1

Calling `fp::bottom` is equivalent to calling `error` with a fixed error string:

```
fp::bottom()
```

```
Error: The bottom is reached. [fp::bottom]
```

`fp::bottom` is used to indicate the bottom of a recursion inside a `traperror` call. In most cases, programs not using `fp::bottom` will be more readable.

Return Values

This function never returns.

fp::curry

Curry an n-ary function

Syntax

```
fp::curry(f, <n>)
```

Description

`fp::curry(f)` returns the higher-order function $x \to (y \to f(x, y))$.

`fp::curry` returns the curried version of the `n`-ary function `f`. If no arity `n` is given, then the function is assumend to be binary.

If `n` is smaller than 2 then `f` is returned. Otherwise, given a n-ary function f, `fp::curry` returns the function $x_1 \to ((x_2, \ldots, x_n) \to f(x_1, \ldots, x_n))$

Examples

Example 1

Create curried versions of binary and 3-nary functions:

```
cf := fp::curry(f):
cf(x)(y)
```

$$f(x, y)$$

```
cg := fp::curry(g, 3):
cg(x)(y)(z)
```

$$g(x, y, z)$$

Example 2

A curried version of `_plus` may be used to create a function which increments its argument by `1`:

```
inc := fp::curry(_plus)(1):
inc(x)
```

$$x + 1$$

Parameters

`f`

n-ary function

`n`

Nonnegative integer

Return Values

Unary higher-order function.

fp::expr_unapply

Create a functional expression from an expression

Syntax

```
fp::expr_unapply(e, <x, …>)
```

Description

`fp::expr_unapply(e,x)` tries to interpret the expression `e` as a function in `x` and to return a functional expression computing that function.

`fp::expr_unapply` views the expression `e` as a function in the indeterminates `x,...` and tries to return a functional expression computing that function. If `fp::expr_unapply` cannot find a functional expression `FAIL` is returned.

If no indeterminates are given, any indeterminates of `e` found by `indets` are used.

Examples

Example 1

Get the functional expression computing `sin(x)`:

```
fp::expr_unapply(sin(x), x)
```

```
     sin
```

```
fp::expr_unapply(sin(x[1]), x[1])
```

```
     sin
```

Example 2

Get the functional expression computing `sin(x)^2+cos(x)^2`:

```
fp::expr_unapply(sin(x)^2 + cos(x)^2)
```

$$\sin^2 + \cos^2$$

Parameters

e

Expression

x

Identifier or indexed identifier

Return Values

Functional expression or `FAIL`.

See Also

MuPAD Functions
`fp::unapply`

fp::fixargs

Create function by fixing all but one argument

Syntax

```
fp::fixargs(f, n, <e, …>)
```

Description

`fp::fixargs(f,1,y)` returns the function $x \to f(x, y)$.

`fp::fixargs` returns an unary function, defined by fixing all but the `n`-th argument of the function `f` to the values given by `e...`.

Thus, given a m-ary function f and m - 1 values e_1, …, e_{m-1}, `fp::fixargs` returns the function

$$x \to f\left(e_1, \ldots, e_{n-1}, x, e_n, \ldots, e_{m-1}\right)$$

Examples

Example 1

Fix the first and third argument of `f` to `x1` and `x3`:

```
fp::fixargs(f, 2, x1, x3)(y)
```

$$f(\mathrm{x1}, y, \mathrm{x3})$$

Example 2

Create a function which increments its argument by one:

```
inc := fp::fixargs(_plus, 1, 1):
inc(x)
```

$$x+1$$

Example 3

Create a function which tests the identifier `x` for a type:

```
type_of_x := fp::fixargs(testtype, 2, x):
map([DOM_INT, DOM_IDENT], type_of_x)
```

$$[\text{FALSE}, \text{TRUE}]$$

Parameters

`f`

Function

`n`

Positive integer defining free argument

`e`

Object used as fixed argument

Return Values

Unary function.

fp::fixedpt

Returns fixed point of a function

Syntax

```
fp::fixedpt(f)
```

Description

`fp::fixedpt(f)` returns the fixed point of the unary function `f`.

`fp::fixedpt` is implemented as the *Y* combinator which is defined as follows:

$$Y: f \to g(f)(g(f))$$

where the function *g* is defined as

$$g: f \to h \to x \to f(h(h))(x)$$

Examples

Example 1

A function computing the Fibonacci numbers is created as a fixed point:

```
fb2 := (f,n) -> if n <= 2 then 1 else f(n-1) + f(n-2) end:
fib := fp::fixedpt(fp::curry(fb2)):
fib(i) $ i=1..9
```

```
1, 1, 2, 3, 5, 8, 13, 21, 34
```

Parameters

f

Unary function

Return Values

Unary function.

fp::fold

Create function which iterates over sequences

Syntax

```
fp::fold(f, <e, …>)
```

Description

`fp::fold` returns a function which repeatedly applies `f` to sequences of arguments, where the expressions `e...` are used as starting values.

Thus, given the function f and the starting values e_1, …, e_n, `fp::fold` returns the function which is defined by

$$(x_1, x_2, \ldots, x_m) \to f(x_m, \ldots f(x_2, f(x_1, e_1, \ldots, e_n))\ldots)$$

for any positive integer m. If the argument sequence is void (i.e. $m = 0$) the function simply returns the sequence (e_1, …, e_n).

Examples

Example 1

A call to `fp::fold` returns a function, which accepts an arbitrary number of arguments:

```
fp::fold(f, x)(y1, y2, y3)
```

$$f(\text{y3}, f(\text{y2}, f(\text{y1}, x)))$$

Example 2

The function `pset` returns the power set of the set given by its arguments:

```
addelem := (x,y) -> y union map(y, _union, {x}):
pset := fp::fold(addelem, {{}}):
pset(a,b,c)
```

$$\{\emptyset, \{c\}, \{a\}, \{b\}, \{b, c\}, \{a, b\}, \{a, c\}, \{a, b, c\}\}$$

Parameters

f

Function

e

Object used as starting value

Return Values

Function.

fp::nest

Repeated composition of function

Syntax

```
fp::nest(f, n)
```

Description

`fp::nest(f,n)` returns the `n`-fold repeated composition of the function `f`.

Thus, given the function `f`, `fp::nest` returns the identity function `id` if `n` is 0 and otherwise the function

$$f(f(\ldots f(x)\ldots))$$

`n`-fold repeated.

Note that `fp::nest` is obsolete, one should use the `@@` operator or its functional form `_fnest` instead. It is only supported for compatibility with former versions of MuPAD.

Examples

Example 1

Apply the 3-fold repeated composition of `f` to `x`:

```
fp::nest(f, 3)(x)
```

$$f(f(f(x)))$$

Example 2

Numerically finding a fixed point of the function `cos` by repeated application:

```
p :=fp::nest(cos, 100)(1.0):
p, cos(p)
```

```
0.7390851332, 0.7390851332
```

Parameters

f

Function

n

Nonnegative integer

Return Values

Function.

See Also

MuPAD Functions

`_fconcat` | `_fnest` | `fp::nestvals`

fp::nestvals

Repeated composition returning intermediate values

Syntax

```
fp::nestvals(f, n)
```

Description

`fp::nestvals(f, n)` returns a function which applies the function `fn`-fold repeatedly to its argument and returns the intermediate $n + 1$ values as a list.

Thus `fp::nestvals` returns the function $[x, f(x), \ldots, f(f(\ldots f(x)\ldots))]$

The function returned is equivalent to `[_fnest(f,i) $i=0..n]`, but more efficient.

Examples

Example 1

Apply `f` 3 times nested to `x`:

```
fp::nestvals(f, 3)(x)
```

$$[x, f(x), f(f(x)), f(f(f(x)))]$$

Example 2

Apply `cos` 4 times nested to `1.0` and return the result and intermediate values:

```
fp::nestvals(cos, 4)(1.0)
```

$$[1.0, 0.5403023059, 0.8575532158, 0.6542897905, 0.7934803587]$$

Parameters

f

Function

n

Nonnegative integer

Return Values

Function.

See Also

MuPAD Functions
`_fconcat` | `_fnest`

fp::unapply

Create a procedure from an expression

Syntax

```
fp::unapply(e, <x, …>)
```

Description

`fp::unapply` views the expression `e` as a function in the indeterminates `x,...` and returns a procedure computing that function.

If no indeterminates are given, any indeterminates of `e` found by `indets` are used.

Examples

Example 1

Get the procedure computing `sin(x)^2+cos(y)^2`:

```
s := fp::unapply(sin(x)^2 + cos(y)^2, x, y)
```

$$(x, y) \to \cos(y)^2 + \sin(x)^2$$

Parameters

e

Expression

x

Identifier or indexed identifier

Return Values

Procedure.

Overloaded By

e

generate – Generate Input to Other Programs

generate::C
generate::fortran
generate::MATLAB
generate::MathML
generate::optimize
generate::Simscape
generate::TeX

generate::C

Generate C formatted string

Syntax

```
generate::C(e, <NoWarning>)
```

Description

`generate::C(e)` generates C code for the MuPAD expression `e`.

`generate::C` returns a C formatted string representing an expression, equation, list of equations or a matrix.

An equation represents an assignment in C code. The type of the assignment is `double`.

When generating C code for a matrix, the generator assigns only nonzero elements. See “Example 3” on page 10-3.

To print an output string to a file, use the `fprint` function. Use the printing option `Unquoted` to remove quotation marks and to expand special characters like line breaks and tabs.

Use the `generate::optimize` function to optimize the MuPAD code before converting it to C code. See “Example 5” on page 10-4.

The `NoWarning` option lets you suppress warnings. See “Example 6” on page 10-4.

Examples

Example 1

The code generator converts a list of equations to a sequence of assignments:

```
generate::C([x1 = y2^2*(y1 + sin(z)), x2 = tan(x1^4)]):
```

```
print(Unquoted, %)
```

```
  x1 = (y2*y2)*(y1+sin(z));
  x2 = tan(x1*x1*x1*x1);
```

Example 2

MuPAD matrix and array indexing differs from C array indexing. By default, MuPAD array indices start with 1, and C array indices start with 0. To create the code compatible with the default indexing in C, the `generate::C` function decrements each index by one:

```
A:= matrix([[1,2],[3,4]]):
generate::C(A)."\n".
  generate::C(hold(Determinante = A[1,1]*A[2,2] - A[1,2]*A[2,1])):
print(Unquoted, %)
```

```
  A[0][0] = 1.0;
  A[0][1] = 2.0;
  A[1][0] = 3.0;
  A[1][1] = 4.0;

  Determinante = A[0][0]*A[1][1]-A[0][1]*A[1][0];
```

Example 3

Generated C code does not include assignments for zero elements of a matrix:

```
A:= matrix([[1, 0, 0],[0, 0, 1]]):
print(Unquoted, generate::C(A))
```

```
  A[0][0] = 1.0;
  A[1][2] = 1.0;
```

Example 4

If the first index of an array is not 1, the `generate::C` function issues a warning:

```
A:= array(1..2, 2..3, [[1,2],[3,4]]):
print(Unquoted, generate::C(A))
```

```
Warning: The array index 'A[1..2, 2..3]' is out of range 1..n. [DOM_ARRAY::CF]

  A[0][1] = 1.0;
  A[0][2] = 2.0;
  A[1][1] = 3.0;
  A[1][2] = 4.0;
```

Example 5

The `generate::C` function does not optimize your code:

```
print(Unquoted,
      generate::C([x = a + b, y = (a + b)^2])):

  x = a+b;
  y = pow(a+b,2.0);
```

You can use the `generate::optimize` function before converting your MuPAD expression to C code. For example, this function can reduce the number of operations by finding common subexpressions:

```
print(Unquoted,
      generate::C(
          generate::optimize([x = a + b, y = (a + b)^2])
      )):

  x = a+b;
  y = x*x;
```

Example 6

By default, the `generate::C` function can issue warnings:

```
print(Unquoted, generate::C(f(x)))

Warning: Function 'f' is not verified to be a valid C function.

  t0 = f(x);
```

If you started using `generate::C` recently, the warnings can help you identify the potential issues in the converted code. If you want to suppress warnings, use the `NoWarning` option:

```
print(Unquoted, generate::C(f(x), NoWarning))
```

```
  t0 = f(x);
```

Parameters

e

An expression, equation, list of equations, or a matrix

Options

`NoWarning`

Suppress warnings.

Return Values

`generate::C` returns a string containing C code.

See Also

MuPAD Functions

`fprint` | `generate::optimize` | `print`

generate::fortran

Generate Fortran formatted string

Syntax

```
generate::fortran(e, <NoWarning>, <Version = "versionName">)
```

Description

`generate::fortran(e)` generates Fortran code for the MuPAD expression `e`.

`generate::fortran` returns a Fortran formatted string representing an expression, equation, list of equations, or a matrix.

An equation represents an assignment in Fortran code. The type of the assignment is `double`.

When generating Fortran code for a matrix, the generator assigns only nonzero elements. See “Example 2” on page 10-7.

To print an output string to a file, use the `fprint` function. To remove quotation marks and to expand special characters like line breaks and tabs, use the printing option `Unquoted`.

Use the `generate::optimize` function to optimize the MuPAD code before converting it to Fortran code. See “Example 4” on page 10-7.

The `NoWarning` option lets you suppress warnings. See “Example 5” on page 10-8.

The `Version` option specifies the target version of the Fortran compiler that `generate::fortran` uses to generate code. The options are `Fortran77` (default), `Fortran90`, and `Fortran95`. See “Example 6” on page 10-9.

Examples

Example 1

The code generator converts a list of equations to a sequence of assignments.

```
generate::fortran([x[1] = y[2 + i]^2*(y[1] + sin(z)),
                   x[2] = tan(x[1]^4)]):
print(Unquoted,%)
```

```
      x(1) = (sin(z)+y(1))*y(i+2)**2
      x(2) = tan(x(1)**4)
```

Example 2

Generated Fortran code does not include assignments for zero elements of a matrix.

```
A:= matrix([[1, 0, 0],[0, 0, 1]]):
print(Unquoted, generate::fortran(A))
```

```
      A(1,1) = 1.0D0
      A(2,3) = 1.0D0
```

Example 3

If the first index of an array is not 1, then the `generate::fortran` function issues a warning.

```
A:= array(1..2, 2..3, [[1,2],[3,4]]):
print(Unquoted, generate::fortran(A))
```

```
Warning: The array index 'A[1..2, 2..3]' is out of range 1..n. [DOM_ARRAY::CF]
```

```
      A(1,2) = 1.0D0
      A(1,3) = 2.0D0
      A(2,2) = 3.0D0
      A(2,3) = 4.0D0
```

Example 4

The `generate::fortran` function does not optimize your code.

```
print(Unquoted,
      generate::fortran([x = a + b, y = (a + b)^2])):
```

```
      x = a+b
      y = (a+b)**2
```

You can use the `generate::optimize` function before converting your MuPAD expression to Fortran code. For example, this function can reduce the number of operations by finding common subexpressions.

```
print(Unquoted,
      generate::fortran(
          generate::optimize([x = a + b, y = (a + b)^2])
      )):

      x = a+b
      y = x**2
```

Example 5

By default, the `generate::fortran` function can issue warnings.

```
print(Unquoted, generate::fortran(gamma(x)))

Warning: Function 'gamma' requires a Fortran2008 compiler.

      t0 = gamma(x)
```

Warnings help identify potential issues in converted code. To suppress warnings, use the `NoWarning` option.

```
print(Unquoted, generate::fortran(gamma(x), NoWarning))

      t0 = gamma(x)
```

If the warning specifies that the compiler required is either Fortran90 or Fortran95, then you can suppress the warning by specifying the correct compiler version using `Version`. For example, the `ceiling` function requires Fortran90 instead of the default Fortran77.

```
generate::fortran(ceil(x))
```

```
Warning: Function 'ceiling' requires a Fortran90 compiler.
```

```
"    t0 = ceiling(x) "
```

Specify `Version` as `Fortran90`. The `generate::fortran` function does not issue a warning.

```
generate::fortran(ceil(x), Version = "Fortran90")
```

```
"    t0 = ceiling(x) "
```

Example 6

By default, the `generate::fortran` function uses the target Fortran version `Fortran77` to generate code. To specify `Fortran90` or `Fortran95` as the target version, use the `Version` option.

Generate output for the Fortran90 compiler by specifying the `Version` option as `Fortran90`.

```
f := expand((x+1)^20):
fcode90 := generate::fortran(f, Version = "Fortran90"):
print(Unquoted, fcode90)
```

```
      t0 = x*2.0D1+x**2*1.9D2+x**3*1.14D3+x**4*4.845D3+x**5*1.5504D4+x**&
     &6*3.876D4+x**7*7.752D4+x**8*1.2597D5+x**9*1.6796D5+x**10*1.84756D5&
     &+x**11*1.6796D5+x**12*1.2597D5+x**13*7.752D4+x**14*3.876D4+x**15*1&
     &.5504D4+x**16*4.845D3+x**17*1.14D3+x**18*1.9D2+x**19*2.0D1+x**20+1&
     &.0D0
```

The code formatting for multiline statements in `Fortran90` differs from the formatting in the default target of `Fortran77`.

Parameters

e

An expression, equation, list of equations, or a matrix

Options

`NoWarning`

Suppress warnings.

`Version`

Specify the Fortran compiler version. The default version is `Fortran77`. The `Version` values are `Fortran77`, `Fortran90`, and `Fortran95`. For example, `generate::fortran(..., Version = "Fortran90")` uses compiler version `Fortran90`.

Return Values

`generate::fortran` returns a string containing Fortran code.

See Also

MuPAD Functions
`fprint` | `generate::optimize` | `print`

generate::MATLAB

Generate MATLAB formatted string

Syntax

```
generate::MATLAB(e, <NoWarning>)
```

Description

`generate::MATLAB(e)` generates MATLAB code for the MuPAD expression `e`.

`generate::MATLAB` returns a MATLAB formatted string representing an expression, equation, list of equations or a matrix.

`generate::MATLAB` assumes that the type of converted data is `double`. See “Example 1” on page 10-12.

An equation represents an assignment in MATLAB code. See “Example 4” on page 10-13.

When generating MATLAB code for a matrix, the generator produces a matrix of zeros, and then it substitutes nonzero elements. See “Example 2” on page 10-12.

Use the `generate::optimize` function to optimize the MuPAD code before converting it to the MATLAB syntax. See “Example 5” on page 10-13.

To display generated MATLAB code on screen, use the `print` function. Use the printing option `Unquoted` to remove quotation marks and to expand special characters like line breaks and tabs. If a generated code line is longer than the `TEXTWIDTH` setting, the `print` function breaks that line into several shorter lines. The inserted line continuation character (\) is not valid in MATLAB. To avoid inserting line continuation characters, increase the `TEXTWIDTH` setting or use the `fprint` function to write generated code to a file.

`generate::MATLAB` does not create a MATLAB function. You can print an output string to a file using the `fprint` function with the `Unquoted` option. See “Example 6” on page 10-14.

Working from the MATLAB workspace you can create a MATLAB function containing your expression. To call the MuPAD expression from the MATLAB workspace, use `evalin` or `feval` functions. See “Create MATLAB Functions from MuPAD Expressions”.

If you work with the Simulink® products, you can copy the generated code and paste it into a Simulink block. Also, you can call the MuPAD expression from the MATLAB workspace using `evalin` or `feval` functions. Working from the MATLAB workspace you can automatically create a Simulink block containing your expression. See “Create MATLAB Function Blocks from MuPAD Expressions”.

The `NoWarning` option lets you suppress warnings. See “Example 7” on page 10-14.

Examples

Example 1

By default, MATLAB stores all numeric values as double-precision floating-point. In accordance with the default MATLAB data type, `generate::MATLAB` converts the elements of expressions, equations, and matrices to the `double` format:

```
print(Unquoted, generate::MATLAB(x^2 + y/3 + 1/6))
```

```
  t0 = y*(1.0/3.0)+x^2+1.0/6.0;
```

Example 2

The generator produces a matrix of zeros, and then it replaces nonzero elements:

```
A:= matrix([[1, 0, 0],[0, 0, 1]]):
print(Unquoted, generate::MATLAB(A))
```

```
  A = zeros(2,3);
  A(1,1) = 1.0;
  A(2,3) = 1.0;
```

Example 3

If the first index of an array is not 1, the `generate::MATLAB` function issues a warning:

```
A:= array(1..2, 2..3, [[1,2],[3,4]]):
print(Unquoted, generate::MATLAB(A))
```

```
Warning: The array index 'A[1..2, 2..3]' is out of range 1..n. [DOM_ARRAY::CF]
```

```
  A = zeros(2,2);
  A(1,2) = 1.0;
  A(1,3) = 2.0;
  A(2,2) = 3.0;
  A(2,3) = 4.0;
```

Example 4

When generating MATLAB code from equations, you get assignments instead of equations. For example, generate MATLAB code for the following list of equations:

```
f := generate::MATLAB([x = exp(t*s), y = sin(t)*cos(s)]):
print(Unquoted, f)
```

```
  x = exp(s*t);
  y = cos(s)*sin(t);
```

Example 5

The `generate::MATLAB` function does not optimize your code:

```
print(Unquoted,
      generate::MATLAB([x = a + b, y = (a + b)^2])):
```

```
  x = a+b;
  y = (a+b)^2;
```

You can use the `generate::optimize` function before converting your MuPAD code to MATLAB syntax. For example, this function can reduce the number of operations by finding common subexpressions:

```
f := generate::optimize([x = a + b, y = (a + b)^2]):
print(Unquoted,
      generate::MATLAB(f)):
```

```
  x = a+b;
  y = x^2;
```

Example 6

To create a file with a MATLAB formatted string representing a symbolic expression, use the `fprint` function:

```
A:= matrix([[1, 0, 0],[0, 0, 1]]):
fprint(Unquoted, Text, "matrixA.m", generate::MATLAB(A))
```

If the file matrixA.m already exists, `fprint` replaces the existing MATLAB code with the converted symbolic expression. You can open and edit the resulting file.

Example 7

By default, the `generate::MATLAB` function can issue warnings:

```
print(Unquoted, generate::MATLAB(g(x)))
```

```
Warning: Function 'g' is not verified to be a valid MATLAB function.
```

```
  t0 = g(x);
```

If you started using `generate::MATLAB` recently, the warnings can help you identify the potential issues in the converted code. If you want to suppress warnings, use the `NoWarning` option:

```
print(Unquoted, generate::MATLAB(g(x), NoWarning))
```

```
  t0 = g(x);
```

Parameters

e

An expression, equation, list of equations, or a matrix

Options

`NoWarning`

Suppress warnings.

Return Values

`generate::MATLAB` returns a string containing MATLAB code.

generate::MathML

Generate MathML from expressions

Syntax

```
generate::MathML(expr, options)
```

Description

`generate::MathML(expr)` returns the MathML code representing `expr`. To print this code to a file, use `fprint`.

Examples

Example 1

Generate the MathML code from the following expression. Use `hold` to prevent evaluation of the integral. By default, `generate::MathML` returns both Presentation and Content MathML, and includes annotations.

```
generate::MathML(hold(int)(exp(x^2)/x, x))
```

```
<math xmlns='http://www.w3.org/1998/Math/MathML'>
  <semantics>
    <mrow>
      <mo form='prefix'>&Integral;</mo>
      <mrow/>
      <mfrac>
        <msup>
          <mo>&ee;</mo>

```

Example 3

Generate MathML code from the following expression and write the result to `filename.mathml` by using `fprint`.

```
fprint(Text, "filename.mathml",
       generate::MathML(hold(int)(exp(x^2)/x, x))):
```

Parameters

`expr`

Arithmetical expression

Options

`Annotation`

Option, specified as `Annotation = FALSE`.

Suppresses the output of annotations.

`Content`

Option, specified as `Content = FALSE`.

Suppresses the MathML Content part of the output.

`Presentation`

Option, specified as `Presentation = FALSE`.

Suppresses the MathML Presentation part of the output.

Return Values

`generate::MathML` returns an object containing MathML code.

Overloaded By

expr

MuPAD Functions
`fprint` | `print`

generate::optimize

Generate optimized code

Syntax

```
generate::optimize(r)
```

Description

`generate::optimize(r)` returns a sequence of equations representing an "optimized computation sequence" for the input expression r. Each equation in the sequence corresponds to an assignment of a subexpression of the input expression to a "temporary variable." Common subexpressions are computed only once, thus reducing the total operation count.

The number of operations, namely additions (or subtractions), multiplications (or divisions) and in particular functions calls of the output is usually lower than the number of such operations of the input. This facility is useful for code generation.

Examples

Example 1

In this first example, we show the effects of optimization for a simple expression:

```
generate::optimize(cos(x^2) + x^2*sin(x^2) + x^4)
```

$$[t2 = x^2,\ t1 = \cos(t2) + t2\ \sin(t2) + t2^2]$$

The "blind" computation of the input expression requires 7 multiplications, 2 additions and 2 function calls. The optimized version introduces a "temporary variable" `t2` storing the subexpression `x^2` that is used to compute the final result `t1`. This reduces the total cost to 3 multiplications, 2 additions and 2 function calls, albeit using 1 extra assignment to the temporary variable `t2`.

Example 2

Here we repeat the exercise of the first example but with an array of expressions:

```
generate::optimize(array(1..2, 1..2, [[x^3, x^2],[x^2, x^4]]))
```

$$\left[t2 = x^2,\ t1 = \begin{pmatrix} t2\,x & t2 \\ t2 & t2^2 \end{pmatrix}\right]$$

The original input requires 6 multiplications. The optimized version needs only 3 multiplications and 1 extra assignment.

Example 3

We optimize a list of equations representing a computation sequence for 3 variables `t`, `C[1]`, `C[2]`:

```
generate::optimize([t = u, C[1] = t*(u - w)^2, C[2] = 2*(u - w)^3])
```

$$\left[t = u,\ t1 = u - w,\ t2 = t1^2,\ C_1 = t\,t2,\ C_2 = 2\,t1\,t2\right]$$

The original computation requires 5 multiplications and 2 subtractions. The optimized version needs 4 multiplications and 1 subtraction.

Note that since these examples involve small expressions, the computational savings are slight. In the case of very large expressions, optimization can yield a considerable dividend.

Parameters

r

An expression, array or list of equations

Return Values

List of equations.

Algorithms

A number of FORTRAN compilers provide optimizers. However, they use algorithms of complexity $O(n^2)$ and $O(n^3)$ where n is the size of the input expressions. For large amounts of code, these algorithms may "break." MuPAD provides a reasonably good scalar (as in non-vectorized and non-parallelized) optimizer which is limited to common subexpression optimization and using binary powering for integer powers. It uses hashing of expressions so that given a sub-expression, it can determine in constant time if this subexpression has already occurred. This results in an overall efficiency which is of lower complexity namely, $O(n)$ i.e. linear in the size of the input expressions to be optimized, Hence overall efficiency is not compromised by very large expressions. This does mean that not all possible optimizations are made but nonetheless a number of reductions including the exploitation of some symmetries are possible.

It should be understood that "optimization" is meant in the sense of compiler optimization. The end-result rarely corresponds to the absolute irreducible minimum number of operations – or as in the case of FORTRAN code generation, the absolute minimum of floating-point operations (FLOPS). Achieving this limit can be extremely difficult if not impossible especially for large computational sequences. Nonetheless, in a number of real-life instances, the MuPAD optimizer can yield a very useful result. Additionally, MuPAD provides symbolic manipulation tools such as `factor` which can yield additional reduction in operation costs.

In many cases of optimization, it is most often a matter of how best to pose the problem so as to fully exploit every possible symmetry or useful natural property of the given problem.

generate::Simscape

Generate Simscape equation

Syntax

```
generate::Simscape(e, <NoWarning>)
```

Description

`generate::Simscape(e)` generates Simscape™ code for the MuPAD expression `e`.

Simscape software extends the Simulink product line with tools for modeling and simulating multidomain physical systems, such as those with mechanical, hydraulic, pneumatic, thermal, and electrical components. Unlike other Simulink blocks, which represent mathematical operations or operate on signals, Simscape blocks represent physical components or relationships directly. With Simscape blocks, you build a model of a system just as you would assemble a physical system. For more information about Simscape software, see “Simscape”.

You can extend the Simscape modeling environment by creating custom components. When you define a component, use the equation section of the component file to establish the mathematical relationships among a component's variables, parameters, inputs, outputs, time, and the time derivatives of each of these entities. MuPAD and Simscape software let you perform symbolic computations and use the results of these computations in the equation section. The `generate::Simscape` function translates the results of symbolic computations to Simscape language equations.

`generate::Simscape` returns a Simscape formatted string representing an expression, equation, list of expressions or equations, or a matrix.

`generate::Simscape` converts the identifier `t` to the variable `time` in the resulting Simscape code. However, the name `t` of a function call does not change during conversion. See “Example 1” on page 10-27 and “Example 2” on page 10-27.

`generate::Simscape` converts any derivative with respect to the variable `t` to the Simscape notation `x.der`, where `x` is the time-dependent variable. See “Example 3” on page 10-28.

`generate::Simscape` assumes that the type of converted data is `double`. See “Example 4” on page 10-28.

When generating Simscape code for a matrix, the generator produces a dense matrix. See “Example 5” on page 10-28.

Use the `generate::optimize` function to optimize the MuPAD code before converting it to the Simscape syntax. See “Example 6” on page 10-29.

`generate::Simscape` converts piecewise expressions to Simscape code by using the `if` statements. See “Example 7” on page 10-29.

The equation section of a Simscape component file supports a limited number of functions. For details and the list of supported functions, see Simscape equations. If a symbolic equation contains the functions that are not available in the equation section of a Simscape component file, `generate::Simscape` cannot correctly convert these equations to Simscape equations. Such expressions do not trigger an error. The following types of expressions are prone to invalid conversion:

- Expressions with infinities
- Expressions that contain programming structures, such as loops, coditional statements (except for the `if` statement), and `map` function calls
- Expressions that contain intervals, sets, and lists

To display generated Simscape code on screen, use the `print` function. To remove quotation marks and to expand special characters like line breaks and tabs, use the printing option `Unquoted`. If a generated code line is longer than the `TEXTWIDTH` setting, the `print` function breaks that line into several shorter lines. The inserted line continuation character (\) is not valid in Simscape. To avoid inserting line continuation characters, increase the `TEXTWIDTH` setting or use the `fprint` function to write generated code to a file.

To write generated Simscape code to a file, use the `fprint` function with the `Unquoted` option. See “Example 8” on page 10-30.

The `NoWarning` option lets you suppress warnings. See “Example 2” on page 10-27.

Examples

Example 1

The `generate::Simscape` function replaces all instances of the MuPAD identifier `t` with the variable `time`. For example, convert the following equation to the Simscape equation:

```
e := A*sin(w*t) + B*cos(w*t) = 0:
print(Unquoted, generate::Simscape(e))
```

```
  B*cos(time*w)+A*sin(time*w) == 0.0;
```

Example 2

The `generate::Simscape` function does not change the function name `t` in function calls:

```
print(Unquoted, generate::Simscape([t(), t(0), t(x)]))
```

```
Warning: Function 't' is not verified to be a valid Simscape function.

Warning: Function 't' is not verified to be a valid Simscape function.

Warning: Function 't' is not verified to be a valid Simscape function.

  t();
  t(0.0);
  t(x);
```

This example produces a few identical warnings. If you started using `generate::Simscape` recently, warnings can help you identify potential issues in the converted code. If you want to suppress warnings, use the `NoWarning` option:

```
print(Unquoted, generate::Simscape([t(), t(0), t(x)], NoWarning))
```

```
t();
t(0.0);
t(x);
```

Example 3

When generating Simscape code, the `generate::Simscape` function converts the derivatives with respect to the variable `t` to the Simscape notation `x.der`. Here `x` is the time-dependent variable. For example, generate the Simscape code for the equation `e` that has two time-dependent variables:

```
e := x'(t) + diff(y(t), t) + 2*x + 5 = 0:
print(Unquoted, generate::Simscape(e))
```

```
x*2.0+x.der+y.der+5.0 == 0.0;
```

Example 4

By default, Simscape stores all numeric values as double-precision floating-point values. In accordance with this default data type, `generate::Simscape` converts the elements of expressions, equations, and matrices to the double format:

```
print(Unquoted, generate::Simscape(x^2 + y/3 + 1/6))
```

```
y*(1.0/3.0)+x^2+1.0/6.0;
```

Example 5

`generate::Simscape` can generate Simscape code for a MuPAD matrix. In contrast to `generate::MATLAB` (which produces sparse matrices), the Simscape code generator produces dense matrices:

```
A:= matrix([[1, 0, 0],[0, 0, 1]]):
print(Unquoted, generate::Simscape(A))
```

```
[
1.0 0.0 0.0
0.0 0.0 1.0
];
```

Example 6

The `generate::Simscape` function does not optimize your code:

```
print(Unquoted,
      generate::Simscape([x = a + b, y = (a + b)^2])):
```

```
  x == a+b;
  y == (a+b)^2;
```

You can use the `generate::optimize` function before converting your MuPAD code to Simscape syntax. For example, this function can reduce the number of operations by finding common subexpressions:

```
print(Unquoted,
      generate::Simscape(
          generate::optimize([x = a + b, y = (a + b)^2])
      )):
```

```
  x == a+b;
  y == x^2;
```

Example 7

The `generate::Simscape` function also accepts piecewise expressions. The function uses `if` statements when generating Simscape code for piecewise expressions. For example, the Fourier transform of the following expression is a piecewise function:

```
FT := fourier(exp(-abs(x)*abs(t))*sin(t)/t, t, s)
```

$$\begin{cases} \arctan\left(\frac{s+1}{|x|}\right) - \arctan\left(\frac{s-1}{|x|}\right) & \text{if } x \neq 0 \end{cases}$$

`generate::Simscape` converts this result to a valid Simscape expression:

```
print(Unquoted, generate::Simscape(FT))
```

```
  if (x ~= 0.0)
    -atan((s-1.0)/abs(x))+atan((s+1.0)/abs(x));
```

```
else
  NaN;
end
```

Example 8

To create a text file with a Simscape formatted string representing a symbolic expression, use the `fprint` command:

```
e := x'(t) + 2*x + 5 = 0:
fprint(Unquoted, Text, "eqn.txt", generate::Simscape(e))
```

If the file `eqn.txt` already exists, `fprint` replaces the existing Simscape code with the converted symbolic expression. You can open and edit the resulting text file.

Parameters

`e`

An expression, equation, list of equations, or a matrix

Options

`NoWarning`

Suppress warnings.

Return Values

`generate::Simscape` returns a `string` containing Simscape code. In case of invalid conversion, the returned value is an arbitrary string.

See Also

MuPAD Functions

`fprint` | `generate::MATLAB` | `generate::optimize` | `print`

generate::TeX

Generate formatted string from expressions

Syntax

```
generate::TeX(e)
```

Description

`generate::TeX(e)` returns a TeX formatted string representing `e`. This string may be printed to a file using `fprint`. Use the printing option `Unquoted` to remove quotes and to expand special characters like newlines and tabs.

The output string may be used in the math-mode of TeX. Note that `generate::TeX` doesn't break large formulas into smaller ones.

Examples

Example 1

`generate::TeX` generates a string containing the TeX code:

```
generate::TeX(hold(int)(exp(x^2)/x, x))
```

```
"\int \frac{\mathrm{e}^{x^2}}{x} \,\mathrm{d} x"
```

Use `print` with option `Unquoted` to get a more readable output:

```
print(Unquoted, generate::TeX(hold(int)(exp(x^2)/x, x)))
```

```
\int \frac{\mathrm{e}^{x^2}}{x} \,\mathrm{d} x
```

Example 2

This example shows how to write a `"TeX"`-method for a domain. The domain elements represent open intervals. The `"TeX"`-method makes recursive use of `generate::TeX` in order to TeX-format its operands and concatenates the resulting strings to a new string containing the TeX output of the interval.

```
Interval := newDomain("Interval"):
Interval::TeX :=
  e -> "\\left]".generate::TeX(extop(e, 1)).
       ", ".generate::TeX(extop(e, 2))."\\right[":
print(Unquoted,
      generate::TeX(new(Interval, 1, x^(a+2)))):
```

```
\left]1, x^{a + 2}\right[
```

Parameters

e

An arithmetical expression

Return Values

`generate::TeX` returns a string containing TeX code.

Overloaded By

e

Algorithms

The TeX packages amsmath and amssymb are needed.

A domain overloading `generate::TeX` has to provide a function as its `"TeX"`-slot which translates its elements into a TeX formatted string. This function may use `generate::TeX` recursively. See “Example 2” on page 10-32.

Graph::addEdges

Adds one or several edges to a graph

Syntax

```
Graph::addEdges(G, Edge)

Graph::addEdges(G, Edge, <EdgeWeights = ew>, <EdgeCosts = ec>, <EdgeDescriptions = ed>)
```

Description

`Graph::addEdges` adds one or several edges to an already existing Graph. An edge is represented by a list containing two vertices of the graph. A warning is raised if one of the specified edges does already exist in the graph.

`Graph::addEdges(G,Edge)` adds the edge(s) `Edge` to the graph `G`. The two vertices of each edge must be vertices in the given graph. Otherwise an error is raised. If an edge is specified that already exists, a warning will be printed that this edge is not used.

With `Graph::addEdges(G, Edge,EdgeWeights=ew,EdgeCosts=ec, EdgeDescriptions=ed)` the weight, cost and description of each edge can be set to every edge additionally. If these specifications are missing, the default value `0(=None)` is assumed. If a specification is used it has to hold exactly the same number of values as there are edges. Otherwise an error will be raised.

Note: The value `None` can be used in the specification lists for every edge that is not to be specified explicitly.

Examples

Example 1

First, an undirected graph with two vertices and no edges is created. Then two edges are added:

```
G := Graph([a, b, c, d], []):
Graph::printEdgeInformation(G):
G := Graph::addEdges(G, [[a, b], [c, d]]):
Graph::printEdgeInformation(G)
```

```
No edges.
```

```
Edges existing in the graph:
----------------------------
[a, b], [c, d], [b, a], [d, c]
```

As you can see, `[b,a]` and `[d,c]` were inserted automatically.

```
G2 := Graph::addEdges(G, [[a,d]]):Graph::getEdges(G2)
```

$$[[a, d], [d, a], [a, b], [c, d], [b, a], [d, c]]$$

Now, what happens if an edge is inserted that already exists in the graph?

```
G := Graph::addEdges(G, [[d, c]])
```

```
Warning: The following edges were not used for operation: [[d, c]]. [Graph::selectEdge
```

$$\text{Graph}(\ldots)$$

Suppose, we try to insert an edge with a vertex not existing in the graph:

```
G := Graph::addEdges(G, [[a, 5]])
```

```
Error: One or more edges contain vertices that are not in list '[5]'. [Graph::addEdges
```

Now let's see what happens when a directed graph is created:

```
G := Graph([a, b, c, d], [], Directed):
G := Graph::addEdges(G, [[a, b], [b, c], [c, d]],
                     EdgeWeights = [2/8, -5, PI],
                     EdgeCosts = [30, -40, None]):
Graph::printGraphInformation(G)
```

```
Vertices: [a, b, c, d]
```

```
Edges: [[a, b], [b, c], [c, d]]
Vertex weights: no vertex weights.
Edge descriptions: no edge descriptions.
Edge weights: [a, b] = 1/4, [b, c] = -5, [c, d] = PI (other existing edges\
 have no weight)
Edge costs: [a, b] = 30, [b, c] = -40 (other existing edges have costs zer\
o)
Adjacency list (out): a = [b], b = [c], c = [d], d = []
Adjacency list (in): a = [], b = [a], c = [b], d = [c]
Graph is directed.
```

Have a close look at the Edge costs line. The edge `[c,d]` is not mentioned explicitly due to the value `None`:

```
G2 := Graph::addEdges(G, [[a, b], [a, d]], EdgeWeights=[10, 20],
                      EdgeCosts = [80, 90],
                      EdgeDescriptions = ["First way", "Second way"]):
Graph::printGraphInformation(G2)
```

```
Warning: The following edges were not used for operation: [[a, b]]. [Graph::selectEdge]
```

```
Vertices: [a, b, c, d]
Edges: [[a, d], [a, b], [b, c], [c, d]]
Vertex weights: no vertex weights.
Edge descriptions: [a, d] = "Second way"
Edge weights: [a, b] = 1/4, [b, c] = -5, [c, d] = PI, [a, d] = 20 (other e\
xisting edges have no weight)
Edge costs: [a, b] = 30, [b, c] = -40, [a, d] = 90 (other existing edges h\
ave costs zero)
Adjacency list (out): a = [b, d], b = [c], c = [d], d = []
Adjacency list (in): a = [], b = [a], c = [b], d = [a, c]
Graph is directed.
```

If an edge has specifications, but exist already in the graph, the specifications will not change. (see Information for edge `[a, b]` above)

Parameters

G

`Graph`

`Edge`

List of one or more edges

`ew, ec`

Lists of numbers

`ed`

List of texts

`b`

Boolean value

Options

`EdgeWeights`

The weight(s) of the new edge(s). Default is 0.

`EdgeCosts`

The cost(s) of the new edge(s). Default is 0.

`EdgeDescriptions`

The description(s) for the new edge(s). Default is no text.

Return Values

`Graph` with the correct edges inserted.

Graph::addVertices

Adds one or several vertices to a graph

Syntax

```
Graph::addVertices(G, Vertex, <VertexWeights = vw>)
```

Description

`Graph::addVertices` adds one or several vertices to an already existing graph. A vertex is represented by an arbitrary expression. A warning is raised if one of the specified vertices does already exist in the graph.

`Graph::addVertices(G, Vertex)` adds the vertices in `Vertex` to the graph `G`. If a vertex is specified that already exists, a warning will be printed that this vertex (and it's vertex weight) is not used.

With `Graph::addVertices(G, Vertex,VertexWeights=vw)` the weight can be set to every vertex additionally. If these specifications are missing, the default value `0(=None)` is assumed. If a specification is used it has to hold exactly the same number of values as there are vertices. Otherwise an error will be raised.

Note: The value `None` can be used in the specification lists for every edge that is not to be specified explicitly.

Examples

Example 1

First, an undirected graph with two vertices and no edges is created. Then two vertices are added:

```
G := Graph([a, b, c, d], []):
Graph::printVertexInformation(G):
```

```
G := Graph::addVertices(G, [e, f]):
Graph::printVertexInformation(G)
```

```
Vertices existing in the graph:
------------------------------
Vertex a has weight None
Vertex b has weight None
Vertex c has weight None
Vertex d has weight None
```

```
Vertices existing in the graph:
------------------------------
Vertex a has weight None
Vertex b has weight None
Vertex c has weight None
Vertex d has weight None
Vertex e has weight None
Vertex f has weight None
```

No weights were specified, so every vertex has weight `None`. In the algorithms default-values will be used accordingly.

Now, what happens if a vertex is inserted that already exists in the graph?

```
G2 := Graph::addVertices(G, [a, g], VertexWeights=[10, 100]):
Graph::printVertexInformation(G2)
```

```
Warning: The following vertices already exist: [a]. [Graph::selectVertex]
```

```
Vertices existing in the graph:
------------------------------
Vertex a has weight None
Vertex b has weight None
Vertex c has weight None
Vertex d has weight None
Vertex e has weight None
Vertex f has weight None
Vertex g has weight 100
```

If a vertex weight is specified for a vertex already existing, it will not be changed (see Vertex `a` above)

Parameters

`G`

`Graph`

`Vertex`

List of one or more vertices

`vw`

Lists of numbers

Options

`VertexWeights`

The weight(s) of the new vertex/vertices. Default is 0.

Return Values

`Graph` with the correct vertices inserted.

Graph::admissibleFlow

Checks a flow for admissibility in a Graph

Syntax

```
Graph::admissibleFlow(G, f)
```

Description

`Graph::admissibleFlow(G, f)` checks if the flow `f` is admissible in the Graph `G` according to its vertices and their capacities.

`Graph::admissibleFlow` checks whether a given flow is an admissible flow in the specified graph. A flow in a graph is a table `t`, where `t[[i,j]]` gives the number of units flowing from vertex `i` to vertex `j`. `Graph::admissibleFlow` returns `TRUE` if the flow is admissible. Otherwise `FALSE` is returned.

`Graph::admissibleFlow` does not check whether the flow is admissible, if a flow from vertex `i` to vertex `j` is allowed to pass through other vertices. See “Example 2” on page 11-11.

Examples

Example 1

In a cyclic graph with default capacities (1), the flow with one unit flowing from each vertex to its successor is certainly admissible:

```
G1 := Graph::createCircleGraph([v1, v2, v3, v4]):
Graph::admissibleFlow(G1, table([v1, v2] = 1,
                                [v2, v3] = 1,
                                [v3, v4] = 1,
                                [v4, v1] = 1))
```

```
    TRUE
```

Example 2

The flow must be specified in whole. `Graph::admissibleFlow` does not include “hops”, like skipping vertices in the path:

```
Graph::admissibleFlow(Graph::createCircleGraph([v1, v2, v3]),
                                    table([v1, v3] = 1))
```

```
    FALSE
```

Parameters

`G`

Graph

`f`

The flow, specified in a table

Return Values

Either TRUE or FALSE

Graph::bipartite

Finds out if a graph is bipartite.

Syntax

```
Graph::bipartite(G, <Bool | Lists>)
```

Description

`Graph::bipartite(G)` finds out whether G is bipartite or not.

`Graph::bipartite(G, Sets)`: If G is bipartite, then a list containing two lists will be returned. Each of the lists contains the vertices belonging to the set. If G is not bipartite, then `FAIL` will be returned instead of any list.

`Graph::bipartite(G, Bool)` offers the same result as `Graph::bipartite(G)`. If G is bipartite, then `TRUE` will be returned, otherwise `FALSE`.

Examples

Example 1

A small graph containing 3 vertices with 2 edges connecting them is created:

```
G := Graph([a, b, c], [[a, b], [b, c]]):
Graph::bipartite(G, Lists);
Graph::bipartite(G, Bool)
```

$$[[b], [a, c]]$$

$$\text{TRUE}$$

Two lists with vertices are shown. Another word for bipartite is two-colorable. This means that the graph above can be colored with only two colors so that no two vertices

have the same color if connected with an edge. The bottom output could also be accomplished without using the parameter `Bool`:

```
Graph::bipartite(G)
```

```
    TRUE
```

The following example shows what happens when a graph is not bipartite (an edge is added to connect the vertices a and c):

```
G2 := Graph::addEdges(G, [[a, c]]):
Graph::bipartite(G2, Lists);
Graph::bipartite(G2, Bool)
```

```
    FAIL
```

```
    FALSE
```

Parameters

`G`

`Graph`

Options

`Lists`

If Lists is stated the return value will be a list of two lists containing the (sorted) vertices belonging to each set, or `FAIL`.

`Bool`

If Bool is stated the return value will be either `TRUE` or `FALSE`. This is the default.

Return Values

Depending on the options either a boolean value or list-sets will be returned.

Graph::breadthFirstSearch

Makes a breadth first Search in a graph.

Syntax

```
Graph::breadthFirstSearch(G, <StartVertex = v>)
```

Description

`Graph::breadthFirstSearch` traverses through a graph via breadth first search. The output shows the first time of identification and the predecessor of each vertex. If a vertex is a single vertex with no predecessor its predecessor is *infinity*.

`Graph::breadthFirstSearch(G, StartVertex = v)` traverses through a graph via breadth first search starting from vertex `v`. The output shows the first time of identification and the predecessor of each vertex. If a vertex is a single vertex with no predecessor its predecessor is *infinity*.

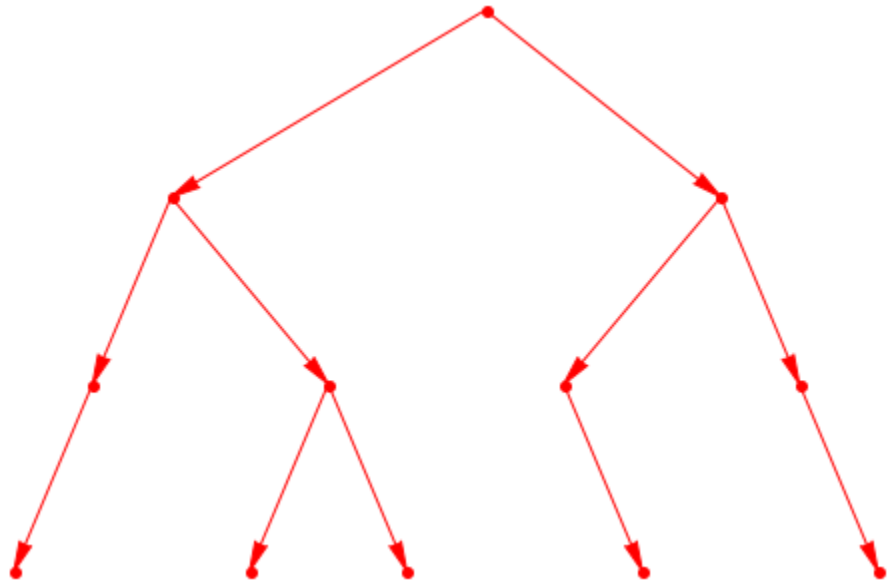
Examples

Example 1

A typical tree is created and drawn for a better understanding of the algorithm:

```
G := Graph([a, b, c, d, e, f, g, h, i, j, k, l],
           [[a, b], [a, c], [b, d], [b, e], [c, f], [c, g],
            [d, h], [e, i], [e, j], [f, k], [g, l]],
           Directed):
plot(
  Graph::plotGridGraph(G, VerticesPerLine = [12, 12, 12, 12],
    VertexOrder = [
  None, None, None, None, None, None,
  a,    None, None, None, None, None,
  None, None, b,    None, None, None,
  None, None, None, c,    None, None,
  None, d,    None, None, e,    None,
  None, f,    None, None, g,    None,
```

```
  h,    None, None, i,    None, j,
  None, None, k,    None, None, l
    ]
  )
)
```



Now we call breadthFirstSearch to find out the starting times and predecessors

```
Graph::breadthFirstSearch(G)
```

a	1	a	0	a	a
b	2	b	1	b	a
c	3	c	1	c	a
d	4	d	2	d	b
e	5	e	2	e	b
f	6	f	2	f	c
g	7	g	2	g	c
h	8	h	3	h	d
i	9	i	3	i	e
j	10	j	3	j	e
k	11	k	3	k	f
l	12	l	3	l	g

Vertex `a` is dicovered first, then vertex b and so on. The right table shows the predecessor of every vertex. The backtracking from a single vertex is therefore really simple. `a` as the first vertex discovered in its component can not be backtracked any further. The distance of each vertex in its component can be read in the middle table. Root-vertices always have the value `0` (they `are` the roots).

Example 2

What happens now, if there exist a vertex that has no connection to any other vertex. The upper example is taken and a single vertex is added without changing anything else. Then a breadth first search is invoked on the graph:

```
G := Graph([a, b, c, d, e, f, g, h, i, j, k, l],
           [[a, b], [a, c], [b, d], [b, e], [c, f], [c, g],
            [d, h], [e, i], [e, j], [f, k], [g, l]],
           Directed):

G2 := Graph::addVertices(G, [m]):
Graph::breadthFirstSearch(G2, StartVertex = [a])
```

a	1	a	0	a	a
b	2	b	1	b	a
c	3	c	1	c	a
d	4	d	2	d	b
e	5	e	2	e	b
f	6	f	2	f	c
g	7	g	2	g	c
h	8	h	3	h	d
i	9	i	3	i	e
j	10	j	3	j	e
k	11	k	3	k	f
l	12	l	3	l	g
m	13	m	0	m	∞

The newly inserted vertex `m` has no predecessor. The predecessor therefore holds the value *infinity*.

Example 3

If we start somewhere in the graph without knowing the root of the DAG, the results are of course different:

```
G := Graph([a, b, c, d, e, f, g, h, i, j, k, l],
           [[a, b], [a, c], [b, d], [b, e], [c, f], [c, g],
            [d, h], [e, i], [e, j], [f, k], [g, l]],
           Directed):

Graph::breadthFirstSearch(G, StartVertex = [c])
```

$$\begin{bmatrix} a & 6 \\ b & 7 \\ c & 1 \\ d & 8 \\ e & 9 \\ f & 2 \\ g & 3 \\ h & 10 \\ i & 11 \\ j & 12 \\ k & 4 \\ l & 5 \end{bmatrix}, \begin{bmatrix} a & 0 \\ b & 1 \\ c & 0 \\ d & 2 \\ e & 2 \\ f & 1 \\ g & 1 \\ h & 3 \\ i & 3 \\ j & 3 \\ k & 2 \\ l & 2 \end{bmatrix}, \begin{bmatrix} a & a \\ b & a \\ c & c \\ d & b \\ e & b \\ f & c \\ g & c \\ h & d \\ i & e \\ j & e \\ k & f \\ l & g \end{bmatrix}$$

The predecessor of `c` is `c`, but if we look at the graph it should be `a`. This is nevertheless not quite correct. Breadth first search takes the given vertex and uses this as the root of the graph (no in-vertices!). This explains also why the next call shows a *infinity* as predecessor to l.

Parameters

`G`

`Graph`

`v`

List containing one vertex.

Options

`StartVertex`

Defines a vertex from which to start the breadth first traversal.

Return Values

List containing three tables. The first table holds the timestamp of the discovery. The second the distance to the root-vertex. The last table holds the predecessor vertices.

Graph::checkForVertices

Checks if all vertices in edges really exist.

Syntax

```
Graph::checkForVertices(Edge, Vertex)
```

Description

`Graph::checkForVertices(Edge, Vertex)` checks if all vertices out of Edge are in Vertex.

Examples

Example 1

What vertices are within the stated edges, but not in the vertex list?

```
Graph::checkForVertices([[a, b], [1, 2]], [a, 2])
```

$$[b, 1]$$

Neither b nor 1 were in the second list. a was in the first edge and 2 in the second.

Example 2

A more complex example. The second list contains a vertex that does not exist in the graph at all. For the checking it does not matter though. Every vertex NOT in the second list is to be returned. In the end it does not matter if the vertex-list contains vertices that are not existent, because only existing vertices are returned.

```
G := Graph::createCompleteGraph(10):
Graph::checkForVertices(Graph::getEdges(G), [1, 2, 3, 11])
```

```
[4, 5, 6, 7, 8, 9, 10]
```

Parameters

`Edge`

List of one or more Edges

`Vertex`

List of one or more vertices

Return Values

List with the vertices out of the Edges that were not stated in Vertex.

Graph::chromaticNumber

Chromatic number of a graph

Syntax

```
Graph::chromaticNumber(G)
```

Description

`Graph::chromaticNumber(G)` returns the chromatic number of the graph `G`. The chromatic number of a graph is defined to be the number of colors necessary to color it such that no two adjacent vertices have the same color.

Examples

Example 1

We compute the chromatic number of the complete graph with 5 vertices; it must be 5 since any two vertices are adjacent:

```
Graph::chromaticNumber(Graph::createCompleteGraph(5))
```

```
    5
```

Parameters

`G`

An undirected graph

Return Values

Positive integer

Algorithms

Internally, the chromatic polynomial is used to compute the chromatic number.

See Also

MuPAD Functions

`Graph::chromaticPolynomial`

Graph::chromaticPolynomial

Calculates a chromatic polynomial

Syntax

```
Graph::chromaticPolynomial(G, x)
```

Description

`Graph::chromaticPolynomial(G, x)` returns the chromatic polynomial of the graph `G`. Evaluating the result at $x = n$, for any integer n, gives the number of possible ways to color the graph `G` using n colors such that no two adjacent vertices have the same color.

`G` must be an undirected graph: if an edge goes from a to$b$, another edge must go from b to a, for any two vertices$a$, b.

Examples

Example 1

We compute the chromatic polynomial of the complete graph with 5 vertices:

```
f:= Graph::chromaticPolynomial(Graph::createCompleteGraph(5), x)
```

$$\mathrm{poly}(x^5 - 10\,x^4 + 35\,x^3 - 50\,x^2 + 24\,x, [x])$$

There are 240 ways to color a complete graph with 5 vertices, since this is the number of bijective mappings between the set of colors and the set of vertices:

```
f(5)
```

$$120$$

```
delete f:
```

Example 2

Now let us delete one edge from a complete graph:

```
G:= Graph::createCompleteGraph(5):
G:= Graph::removeEdge(G, [[2, 3]]):
G:= Graph::removeEdge(G, [[3, 2]])
```

```
Graph(...)
```

Now there are some additional possible colourings: vertices 2 and 3 may now have the same color, in five different ways; in each case, there must be one of the four remaining colors that does not occur at all. In each of the 20 cases, we are left with 3 vertices that form a complete graph and 3 colors, such that there are 6 colourings. Altogether this gives us 120 additional colourings:

```
Graph::chromaticPolynomial(G, x)(5)
```

```
240
```

Parameters

G

An undirected graph

x

An identifier

Return Values

polynomial

Algorithms

Computing the chromatic polynomial of a graph with n vertices reduces to computing two chromatic polynomials of graphs with n - 1 vertices. The running time is hence roughly 2^n.

See Birkhoff and Lewis, *Chromatic Polynomials*, Trans. AMS, Vol. 60, p.355–451, 1946.

Graph::contract

Contracts vertices

Syntax

```
Graph::contract(G, VertexTable)
```

Description

`Graph::contract(G, VertexTable)` contracts the vertices for each entry in the table.

Note: The graph to be contracted must not have edge weights, costs or descriptions. If it has, an error will be raised.

Note: If `VertexTable` contains vertices not in `G`, these will be skipped.

Examples

Example 1

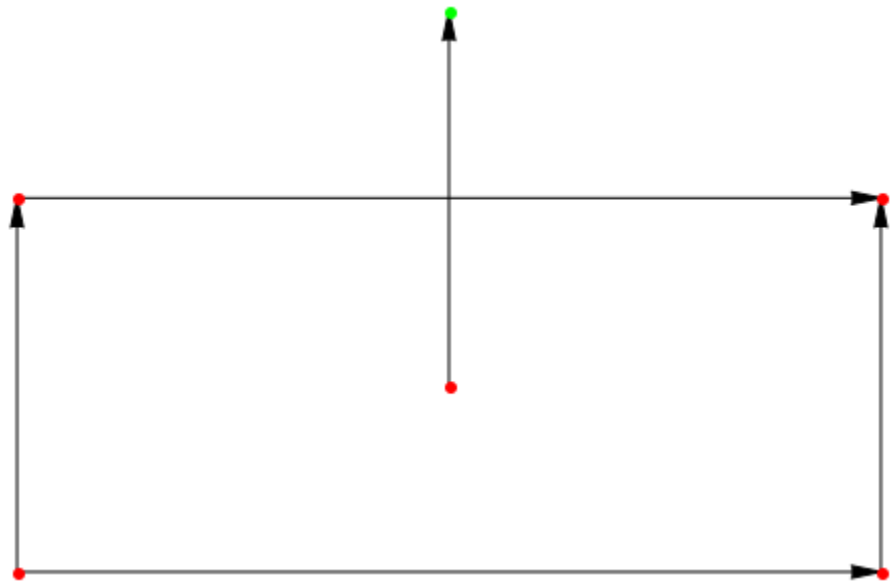
A simple example to see how a contraction is done.

```
ConG := Graph([a, b, c, d, e, f],
              [[a, c], [d, a], [f, c], [d, f], [e, b]],
              Directed):
Graph::printGraphInformation(ConG)
```

```
Vertices: [a, b, c, d, e, f]
Edges: [[a, c], [d, a], [d, f], [e, b], [f, c]]
Vertex weights: no vertex weights.
Edge descriptions: no edge descriptions.
Edge weights: no edge weights.
Edge costs: no edge costs.
```

```
Adjacency list (out): a = [c], b = [], c = [], d = [a, f], e = [b], f = [c]
Adjacency list (in): a = [d], b = [e], c = [a, f], d = [], e = [], f = [d]
Graph is directed.
```

```
plot(
  Graph::plotGridGraph(ConG,
       VerticesPerLine = 3,
       VertexOrder = [None, b,    None,
                      a,    None, c,
                      None, e,    None,
                      d,    None, f],
       EdgeColor = RGB::Black))
```



```
t := table(A = [a, b, c],
           B = [d, f])
```

A	$[a, b, c]$
B	$[d, f]$

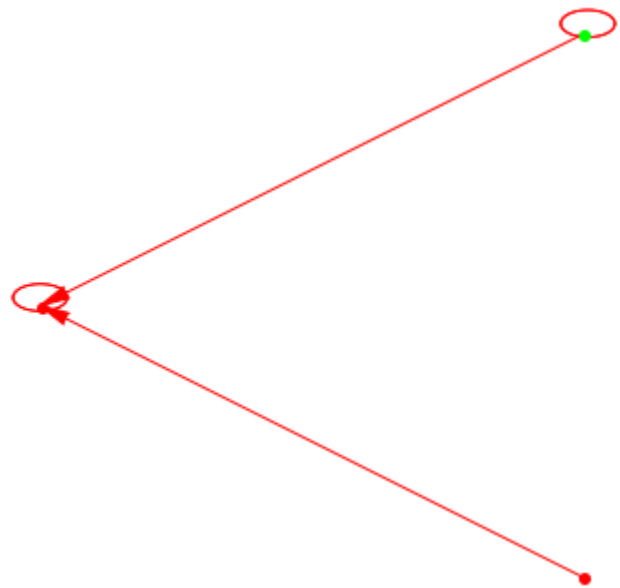
```
newG := Graph::contract(ConG, t):
```

```
Graph::printGraphInformation(newG)
```

```
Vertices: [A, B, e]
Edges: [[A, A], [B, A], [B, B], [e, A]]
Vertex weights: no vertex weights.
Edge descriptions: no edge descriptions.
Edge weights: no edge weights.
Edge costs: no edge costs.
Adjacency list (out): e = [A], A = [A], B = [A, B]
Adjacency list (in): e = [], A = [A, B, e], B = [B]
Graph is directed.
```

Since vertices *a*, *b*, *c* were contracted to vertex *A*, edge [a,c] was removed and edge [A, A] was created. Vertices *d*, *f* took care of the deletion of edges [*d*, *a*], [*d*, *f*], [*f*, *c*]. Instead edges [*B*, *A*] and[*B*, *B*] were created. In the end edge [*e*, *b*] was changed to [*e*, *A*] since vertex *b* does not exist any longer because it was replaced by *A*.

```
plot(Graph::plotGridGraph(newG,
          VerticesPerLine = 2,
          VertexOrder = [None, B,
                         A,    None,
                         None, e]))
```



Example 2

`Graph::contract` ignores vertices not in the graph:

```
Con2 := Graph([], []):
t := table(A = [a, b, c], B = [d, f]):
Graph::printGraphInformation(Graph::contract(Con2, t))
```

```
Vertices: no vertices.
Edges: []
Adjacency list (out): no edges.
Adjacency list (in): no edges.
Graph is undirected.
```

Parameters

`G`

`Graph`

`VertexTable`

A table with the name of the new vertex on the left side and a list of vertices to contract on the right side.

Return Values

`Graph` consisting of the new vertices and edges.

Graph::convertSSQ

Converts a Graph into a single source single sink Graph

Syntax

```
Graph::convertSSQ(G, q, s)
```

Description

`Graph::convertSSQ(G, q, s)` converts the graph `G` into a directed single source single sink graph. The specified vertices `q` and `s` are added to the graph. It is an error if they are already predefined. Otherwise they are connected to the other vertices of the graph in the following way:

A new edge `[q,i]` is added for every vertex `i` with a positive weight. A new edge `[i,s]` is added for every vertex `i` with a negative weight. The capacities of these edges are in each case the weight of node `i`. The edge weights are zero.

Examples

Example 1

A testexample to show the transformation.

```
V  := [1, 2, 3, 4]:
Vw := [4, 0, 0, -4]:
Ed := [[1, 2], [1, 3], [2, 3], [2, 4], [3, 4]]:
Ec := [2, 2, 1, 3, 1]:
Ew := [4, 2, 2, 3, 5]:
G1 := Graph(V, Ed, VertexWeights = Vw,
            EdgeWeights = Ew,EdgeCosts = Ec):
G2 := Graph::convertSSQ(G1, [q], [s]):
Graph::printGraphInformation(G2)
```

```
Vertices: [1, 2, 3, 4, q, s]
Edges: [[1, 2], [1, 3], [2, 1], [2, 3], [2, 4], [3, 1], [3, 2], [3, 4], [4\
, 2], [4, 3], [4, s], [q, 1]]
Vertex weights: 1 = 0, 2 = 0, 3 = 0, 4 = 0, q = 4, s = -4 (other existing \
vertices have no weight)
Edge descriptions: no edge descriptions.
Edge weights: [1, 2] = 4, [1, 3] = 2, [2, 3] = 2, [2, 4] = 3, [3, 4] = 5, \
[2, 1] = 4, [3, 1] = 2, [3, 2] = 2, [4, 2] = 3, [4, 3] = 5, [q, 1] = 4, [4\
, s] = 4 (other existing edges have no weight)
Edge costs: [1, 2] = 2, [1, 3] = 2, [2, 3] = 1, [2, 4] = 3, [3, 4] = 1, [2\
, 1] = 2, [3, 1] = 2, [3, 2] = 1, [4, 2] = 3, [4, 3] = 1, [q, 1] = 0, [4, \
s] = 0 (other existing edges have costs zero)
Adjacency list (out): 1 = [2, 3], 2 = [1, 3, 4], 3 = [1, 2, 4], 4 = [2, 3,\
 s], q = [1], s = []
Adjacency list (in): 1 = [2, 3, q], 2 = [1, 3, 4], 3 = [1, 2, 4], 4 = [2, \
3], q = [], s = [4]
Graph is directed.
```

The former undirected graph was transformed into a directed one!

Parameters

q, s

Vertices not predefined in the Graph

G

A Graph

Return Values

Directed augmented Graph

Algorithms

Both, Bellman and Dijkstra expect a Graph without negative circles. Only Dijkstra may return erroneous results when negative edges (either weights or costs) are specified.

The Bellman algorithm originated from: Ahuja, Magnanti, Orlin: Dom::Graph Flows, Prentice-Hall, 1993 Section 5.4

Graph::createCircleGraph

Generates a circle Graph

Syntax

```
Graph::createCircleGraph(L, <Directed | Undirected>)
```

```
Graph::createCircleGraph(N, <Directed | Undirected>)
```

Description

`Graph::createCircleGraph(L)` generates a circle Graph

`Graph::createCircleGraph([v1,...,vn])` generates a new graph which is the cycle `[v1,v2]`, `[v2,v3]`, ..., `[vn,v1]`. The values for the edge weights, edge costs and vertex weights can be set manually via `Graph::setEdgeWeights`, `Graph::setEdgeCosts` and `Graph::setVertexWeights`

`Graph::createCircleGraph(3)` generates a new graph which is the cycle `[1,2]`, `[2,3]`, `[3,1]`. The values for the edge weights, edge capacities and vertex weights can be set manually via `Graph::setEdgeWeights`, `Graph::setEdgeCosts` and `Graph::setVertexWeights`

`Graph::createCircleGraph(3, Undirected)` generates a new graph which includes the vertices `[1,2]`, `[2,3]`, `[3,1][2,1]`, `[3,2]`, `[1,3]`.

Examples

Example 1

A (directed) circle graph with four vertices:

```
G1 := Graph::createCircleGraph(4):
Graph::printGraphInformation(G1)
```

```
Vertices: [1, 2, 3, 4]
Edges: [[1, 2], [2, 3], [3, 4], [4, 1]]
Vertex weights: no vertex weights.
Edge descriptions: no edge descriptions.
Edge weights: no edge weights.
Edge costs: no edge costs.
Adjacency list (out): 1 = [2], 2 = [3], 3 = [4], 4 = [1]
Adjacency list (in): 1 = [4], 2 = [1], 3 = [2], 4 = [3]
Graph is directed.
```

Example 2

The same graph but this time with parameter `Undirected`:

```
G2 := Graph::createCircleGraph(4, Undirected):
Graph::printGraphInformation(G2)
```

```
Vertices: [1, 2, 3, 4]
Edges: [[1, 2], [1, 4], [2, 1], [2, 3], [3, 2], [3, 4], [4, 1], [4, 3]]
Vertex weights: no vertex weights.
Edge descriptions: no edge descriptions.
Edge weights: no edge weights.
Edge costs: no edge costs.
Adjacency list (out): 1 = [2, 4], 2 = [1, 3], 3 = [2, 4], 4 = [1, 3]
Adjacency list (in): 1 = [2, 4], 2 = [1, 3], 3 = [2, 4], 4 = [1, 3]
Graph is undirected.
```

Example 3

The circle graph with predefined vertices:

```
G3 := Graph::createCircleGraph([a, b, c, d, 4, 5, 6]):
Graph::printGraphInformation(G3)
```

```
Vertices: [4, 5, 6, a, b, c, d]
Edges: [[4, 5], [5, 6], [6, a], [a, b], [b, c], [c, d], [d, 4]]
Vertex weights: no vertex weights.
Edge descriptions: no edge descriptions.
Edge weights: no edge weights.
Edge costs: no edge costs.
Adjacency list (out): a = [b], b = [c], c = [d], d = [4], 4 = [5], 5 = [6]\
```

```
, 6 = [a]
Adjacency list (in): a = [6], b = [a], c = [b], d = [c], 4 = [d], 5 = [4],\
 6 = [5]
Graph is directed.
```

Parameters

`L`

List of vertices

`N`

A positive Integer

Options

`Directed`

The Graph is created as a directed graph. `Default`.

`Undirected`

The Graph is created as an undirected graph.

Return Values

Graph

Graph::createCompleteGraph

Generates a complete graph

Syntax

```
Graph::createCompleteGraph(n)
```

Description

`Graph::createCompleteGraph(n)` generates the complete Graph with `n` vertices. A complete graph has a connection between each pair of vertices (except to itself).

The vertices of the generated graph are labeled with the numbers `1` to `n`.

Examples

Example 1

The complete Graph with three vertices has 3 2 = 6 edges:

```
G := Graph::createCompleteGraph(3):
Graph::printGraphInformation(G)
```

```
Vertices: [1, 2, 3]
Edges: [[1, 2], [1, 3], [2, 1], [2, 3], [3, 1], [3, 2]]
Vertex weights: no vertex weights.
Edge descriptions: no edge descriptions.
Edge weights: no edge weights.
Edge costs: no edge costs.
Adjacency list (out): 1 = [2, 3], 2 = [1, 3], 3 = [1, 2]
Adjacency list (in): 1 = [2, 3], 2 = [1, 3], 3 = [1, 2]
Graph is undirected.
```

Parameters

n

A positive integer

Return Values

Graph

Graph::createGraphFromMatrix

Transfers a squared matrix into a directed graph

Syntax

```
Graph::createGraphFromMatrix(M)
```

Description

`Graph::createGraphFromMatrix(M)` generates a directed Graph where each $m_{i,j}$ in the matrix defines an edge from$i$ to j. The value of the cell defines the weight of the resulting edge.

The vertices of the generated graph are labeled with the numbers `1` to `n`, where n defines the column/row-dimension of the matrix. Since the matrix has to be squared, n stays the same.

Examples

Example 1

A matrix is defined and the resulting squared matrix is transfered into a Graph.

```
a := matrix([[3, 2, 4], [2, 3, 6], [4, 8, 3]]);
G := Graph::createGraphFromMatrix(a):
Graph::printGraphInformation(G)
```

$$\begin{pmatrix} 3 & 2 & 4 \\ 2 & 3 & 6 \\ 4 & 8 & 3 \end{pmatrix}$$

```
Vertices: [1, 2, 3]
Edges: [[1, 1], [1, 2], [1, 3], [2, 1], [2, 2], [2, 3], [3, 1], [3, 2], [3\
, 3]]
```

```
Vertex weights: no vertex weights.
Edge descriptions: no edge descriptions.
Edge weights: [1, 1] = 3, [1, 2] = 2, [1, 3] = 4, [2, 1] = 2, [2, 2] = 3, \
[2, 3] = 6, [3, 1] = 4, [3, 2] = 8, [3, 3] = 3 (other existing edges have \
no weight)
Edge costs: no edge costs.
Adjacency list (out): 1 = [1, 2, 3], 2 = [1, 2, 3], 3 = [1, 2, 3]
Adjacency list (in): 1 = [1, 2, 3], 2 = [1, 2, 3], 3 = [1, 2, 3]
Graph is directed.
```

Parameters

M

A matrix

Return Values

Graph

Graph::createRandomEdgeWeights

Sets random weights to edges

Syntax

```
Graph::createRandomEdgeWeights(G, r, <Dom::Integer | Dom::Real>)
```

Description

`Graph::createRandomEdgeWeights(G, x..y)` creates random integer edge weights within the range `x..y`.

`Graph::createRandomEdgeWeights(G, x..y, Dom::Integer)` does exactly the same.

`Graph::createRandomEdgeWeights(G, x..y, Dom::Real)` creates random real edge weights within the range `x..y`.

Note: Already existing edge weights will be changed, too!

Examples

Example 1

Creating edge weights for a small cyclic graph. First, it has no specified weights:

```
G1 := Graph::createCircleGraph(5):
Graph::printGraphInformation(G1)
```

```
Vertices: [1, 2, 3, 4, 5]
Edges: [[1, 2], [2, 3], [3, 4], [4, 5], [5, 1]]
Vertex weights: no vertex weights.
Edge descriptions: no edge descriptions.
Edge weights: no edge weights.
Edge costs: no edge costs.
Adjacency list (out): 1 = [2], 2 = [3], 3 = [4], 4 = [5], 5 = [1]
```

```
Adjacency list (in): 1 = [5], 2 = [1], 3 = [2], 4 = [3], 5 = [4]
Graph is directed.
```

Now the weights are set within the range `-100..50` (your output may differ due random assignment):

```
G2 := Graph::createRandomEdgeWeights(G1, -100..50):
Graph::printGraphInformation(G2)
```

```
Vertices: [1, 2, 3, 4, 5]
Edges: [[1, 2], [2, 3], [3, 4], [4, 5], [5, 1]]
Vertex weights: no vertex weights.
Edge descriptions: no edge descriptions.
Edge weights: [1, 2] = 47, [2, 3] = -12, [3, 4] = 28, [4, 5] = 1, [5, 1] =\
 -36 (other existing edges have no weight)
Edge costs: no edge costs.
Adjacency list (out): 1 = [2], 2 = [3], 3 = [4], 4 = [5], 5 = [1]
Adjacency list (in): 1 = [5], 2 = [1], 3 = [2], 4 = [3], 5 = [4]
Graph is directed.
```

If the weights should be of type Real it can be set optionally:

```
G2 := Graph::createRandomEdgeWeights(G1, -100..50, Dom::Real):
Graph::printGraphInformation(G2)
```

```
Vertices: [1, 2, 3, 4, 5]
Edges: [[1, 2], [2, 3], [3, 4], [4, 5], [5, 1]]
Vertex weights: no vertex weights.
Edge descriptions: no edge descriptions.
Edge weights: [1, 2] = -67.72964183, [2, 3] = -10.16896282, [3, 4] = -72.8\
4684348, [4, 5] = -61.00518722, [5, 1] = 18.2662729 (other existing edges \
have no weight)
Edge costs: no edge costs.
Adjacency list (out): 1 = [2], 2 = [3], 3 = [4], 4 = [5], 5 = [1]
Adjacency list (in): 1 = [5], 2 = [1], 3 = [2], 4 = [3], 5 = [4]
Graph is directed.
```

Parameters

G

A graph

r

A range

Return Values

Graph

Graph::createRandomEdgeCosts

Sets random costs to edges

Syntax

```
Graph::createRandomEdgeCosts(G, r, <Dom::Integer | Dom::Real>)
```

Description

`Graph::createRandomEdgeCosts(G, x..y)` creates random edge weights of type Integer within the range `x..y`.

`Graph::createRandomEdgeCosts(G, x..y, Dom::Integer)` does exactly the same.

`Graph::createRandomEdgeCosts(G, x..y, Dom::Real)` creates random edge weights of type Real within the range x..y.

Note: Already existing edge costs will be changed, too!

Examples

Example 1

Creating edge weights for a small cyclic graph. First, it has no specified weights:

```
G1 := Graph::createCircleGraph(5):
Graph::printGraphInformation(G1)
```

```
Vertices: [1, 2, 3, 4, 5]
Edges: [[1, 2], [2, 3], [3, 4], [4, 5], [5, 1]]
Vertex weights: no vertex weights.
Edge descriptions: no edge descriptions.
Edge weights: no edge weights.
Edge costs: no edge costs.
Adjacency list (out): 1 = [2], 2 = [3], 3 = [4], 4 = [5], 5 = [1]
```

```
Adjacency list (in): 1 = [5], 2 = [1], 3 = [2], 4 = [3], 5 = [4]
Graph is directed.
```

Now the costss are set within the range `-100..50` (your output may differ due random assignment):

```
G2 := Graph::createRandomEdgeCosts(G1, -100..50):
Graph::printGraphInformation(G2)
```

```
Vertices: [1, 2, 3, 4, 5]
Edges: [[1, 2], [2, 3], [3, 4], [4, 5], [5, 1]]
Vertex weights: no vertex weights.
Edge descriptions: no edge descriptions.
Edge weights: no edge weights.
Edge costs: [1, 2] = 47, [2, 3] = -12, [3, 4] = 28, [4, 5] = 1, [5, 1] = -\
36 (other existing edges have costs zero)
Adjacency list (out): 1 = [2], 2 = [3], 3 = [4], 4 = [5], 5 = [1]
Adjacency list (in): 1 = [5], 2 = [1], 3 = [2], 4 = [3], 5 = [4]
Graph is directed.
```

If the costs should be of type Real it can be set optionally:

```
G2 := Graph::createRandomEdgeCosts(G1, -100..50, Dom::Real):
Graph::printGraphInformation(G2)
```

```
Vertices: [1, 2, 3, 4, 5]
Edges: [[1, 2], [2, 3], [3, 4], [4, 5], [5, 1]]
Vertex weights: no vertex weights.
Edge descriptions: no edge descriptions.
Edge weights: no edge weights.
Edge costs: [1, 2] = -67.72964183, [2, 3] = -10.16896282, [3, 4] = -72.846\
84348, [4, 5] = -61.00518722, [5, 1] = 18.2662729 (other existing edges ha\
ve costs zero)
Adjacency list (out): 1 = [2], 2 = [3], 3 = [4], 4 = [5], 5 = [1]
Adjacency list (in): 1 = [5], 2 = [1], 3 = [2], 4 = [3], 5 = [4]
Graph is directed.
```

Parameters

G

A graph

r

A range

Return Values

Graph

Graph::createRandomGraph

Generates a random graph.

Syntax

```
Graph::createRandomGraph(VertexNr, EdgeNr, <Directed | Undirected>)
```

Description

`Graph::createRandomGraph` generates a random graph.

`Graph::createRandomGraph(VertexNr, EdgeNr)` generates a random graph with VertexNr vertices and EdgeNr edges.

Note: If the number EdgeNr is too great (i.e. $\text{EdgeNr} \geq \frac{\text{VertexNr}\,(\text{VertexNr}-1)}{2}$), a complete graph will be created.

`Graph::createRandomGraph(VertexNr, EdgeNr, Undirected)` generates a random graph with VertexNr vertices and 2 *EdgeNr* edges is created. This is due to the fact that no odd number of undirected edges could be created otherwise.

Examples

Example 1

The following graph was created `randomly`, meaning that your results will most probably differ:

```
G := Graph::createRandomGraph(5,6):
Graph::printGraphInformation(G)
```

```
Vertices: [1, 2, 3, 4, 5]
```

```
Edges: [[1, 4], [2, 1], [2, 4], [2, 5], [3, 1], [3, 4]]
Vertex weights: no vertex weights.
Edge descriptions: no edge descriptions.
Edge weights: no edge weights.
Edge costs: no edge costs.
Adjacency list (out): 1 = [4], 2 = [1, 4, 5], 3 = [1, 4], 4 = [], 5 = []
Adjacency list (in): 1 = [2, 3], 2 = [], 3 = [], 4 = [1, 2, 3], 5 = [2]
Graph is directed.
```

Example 2

The same number of vertices, but this time the edges are undirected (and therefore the number of Edges is (2 *EdgeNr*)). As you can clearly see, the edges differ from the edges created above:

```
G := Graph::createRandomGraph(5, 6, Undirected):
Graph::printGraphInformation(G)
```

```
Vertices: [1, 2, 3, 4, 5]
Edges: [[1, 4], [1, 5], [2, 3], [2, 4], [2, 5], [3, 2], [4, 1], [4, 2], [4\
, 5], [5, 1], [5, 2], [5, 4]]
Vertex weights: no vertex weights.
Edge descriptions: no edge descriptions.
Edge weights: no edge weights.
Edge costs: no edge costs.
Adjacency list (out): 1 = [4, 5], 2 = [3, 4, 5], 3 = [2], 4 = [1, 2, 5], 5\
 = [1, 2, 4]
Adjacency list (in): 1 = [4, 5], 2 = [3, 4, 5], 3 = [2], 4 = [1, 2, 5], 5 \
= [1, 2, 4]
Graph is undirected.
```

Example 3

If the number of edges to be created extends the possible limit ($\frac{\text{vertices}\,(\text{vertices}-1)}{2}$), a complete graph will be returned:

```
G := Graph::createRandomGraph(3, 6, Undirected):
Graph::printGraphInformation(G)
```

```
Warning: Cannot produce the required number of edges. Creating a complete graph instead
```

```
Vertices: [1, 2, 3]
Edges: [[1, 2], [1, 3], [2, 1], [2, 3], [3, 1], [3, 2]]
Vertex weights: no vertex weights.
Edge descriptions: no edge descriptions.
Edge weights: no edge weights.
Edge costs: no edge costs.
Adjacency list (out): 1 = [2, 3], 2 = [1, 3], 3 = [1, 2]
Adjacency list (in): 1 = [2, 3], 2 = [1, 3], 3 = [1, 2]
Graph is undirected.
```

Parameters

`VertexNr`

Positive integer

`EdgeNr`

Positive integer

Options

`Directed`

If `Directed` is stated, a directed Graph is created `Default`

`Undirected`

If `Undirected` is stated, an undirected Graph is created.

Return Values

`Graph`

Graph::createRandomVertexWeights

Sets random weights to vertices

Syntax

```
Graph::createRandomVertexWeights(G, r, <Int | Real>)
```

Description

`Graph::createRandomVertexWeights(G, x..y)` creates random vertex weights of type Integer within the range x..y.

`Graph::createRandomVertexWeights(G, x..y, Real)` creates random vertex weights of type Real within the range x..y.

Note: Already existing vertex weights will be changed, too!

Examples

Example 1

Creating vertex weights for a small cyclic graph. First, it has no specified weights:

```
G1 := Graph::createCircleGraph(5):
Graph::printGraphInformation(G1)
```

```
Vertices: [1, 2, 3, 4, 5]
Edges: [[1, 2], [2, 3], [3, 4], [4, 5], [5, 1]]
Vertex weights: no vertex weights.
Edge descriptions: no edge descriptions.
Edge weights: no edge weights.
Edge costs: no edge costs.
Adjacency list (out): 1 = [2], 2 = [3], 3 = [4], 4 = [5], 5 = [1]
```

```
Adjacency list (in): 1 = [5], 2 = [1], 3 = [2], 4 = [3], 5 = [4]
Graph is directed.
```

Now the weights are set within the range `-100..50` (your output may differ due random assignment):

```
G2 := Graph::createRandomVertexWeights(G1, -100..50):
Graph::printGraphInformation(G2)
```

```
Vertices: [1, 2, 3, 4, 5]
Edges: [[1, 2], [2, 3], [3, 4], [4, 5], [5, 1]]
Vertex weights: 1 = 47, 2 = -12, 3 = 28, 4 = 1, 5 = -36 (other existing ve\
rtices have no weight)
Edge descriptions: no edge descriptions.
Edge weights: no edge weights.
Edge costs: no edge costs.
Adjacency list (out): 1 = [2], 2 = [3], 3 = [4], 4 = [5], 5 = [1]
Adjacency list (in): 1 = [5], 2 = [1], 3 = [2], 4 = [3], 5 = [4]
Graph is directed.
```

If the weights should be of type Real it can be set optionally:

```
G2 := Graph::createRandomVertexWeights(G1, -100..50, Real):
Graph::printGraphInformation(G2)
```

```
Vertices: [1, 2, 3, 4, 5]
Edges: [[1, 2], [2, 3], [3, 4], [4, 5], [5, 1]]
Vertex weights: 1 = -67.72964183, 2 = -10.16896282, 3 = -72.84684348, 4 = \
-61.00518722, 5 = 18.2662729 (other existing vertices have no weight)
Edge descriptions: no edge descriptions.
Edge weights: no edge weights.
Edge costs: no edge costs.
Adjacency list (out): 1 = [2], 2 = [3], 3 = [4], 4 = [5], 5 = [1]
Adjacency list (in): 1 = [5], 2 = [1], 3 = [2], 4 = [3], 5 = [4]
Graph is directed.
```

Parameters

G

A graph

`r`

A range

Options

`Int`

If stated, the weights are only of type integer. (Default)

`Real`

If stated, the weights are only of type real.

Return Values

Graph

Graph::depthFirstSearch

Makes a depth first Search in a graph.

Syntax

```
Graph::depthFirstSearch(G, <StartVertex = v>)
```

Description

`Graph::depthFirstSearch` traverses through a graph via depth first search. The output shows the first time of identification, the finishing time and the predecessor of each vertex. If a vertex is a single vertex with no predecessor its predecessor is *infinity*.

`Graph::depthFirstSearch(G, StartVertex=v)` traverses through a graph via depth first search starting from vertex `v`. The output shows the first time of identification, the finishing time and the predecessor of each vertex. If a vertex is a single vertex with no predecessor its predecessor is *infinity*.

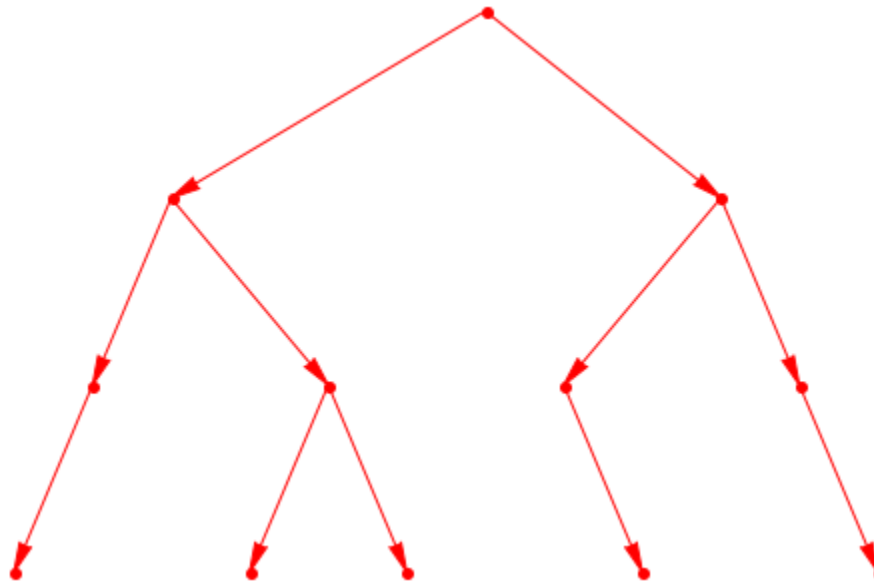
Examples

Example 1

A typical tree is created and drawn for a better understanding of the algorithm.

```
G := Graph([a, b, c, d, e, f, g, h, i, j, k, l],
           [[a, b], [a, c], [b, d], [b, e], [c, f], [c, g],
            [d, h], [e, i], [e, j], [f, k], [g, l]],
           Directed):
plot(
  Graph::plotGridGraph(G, VerticesPerLine = [12, 12, 12, 12],
    VertexOrder = [
  None, None, None, None, None, None,
  a,    None, None, None, None, None,
  None, None, b,    None, None, None,
```

```
  None, None, None, c,    None, None,
  None, d,    None, None, e,    None,
  None, f,    None, None, g,    None,
  h,    None, None, i,    None, j,
  None, None, k,    None, None, l
    ]
  )
)
```



Now we call `Graph::depthFirstSearch` to find out the starting times, the finishing times and the predecessors of each vertex:

```
Graph::depthFirstSearch(G)
```

a	1	a	24	a	a
b	2	b	13	b	a
c	14	c	23	c	a
d	3	d	6	d	b
e	7	e	12	e	b
f	15,	f	18,	f	c
g	19	g	22	g	c
h	4	h	5	h	d
i	8	i	9	i	e
j	10	j	11	j	e
k	16	k	17	k	f
l	20	l	21	l	g

Vertex a is dicovered first, then vertex b and so on. The table in the middle shows the finishing times. h for example has the finishing time of 5, meaning that vertices a, b, c, d and h itself were visited before it was recognized that h is a leaf (finishing time = starting time + 1). The right table shows the predecessor of every vertex. The backtacking from a single vertex is therefore really simple. a as the first vertex discovered in its component can not be backtracked any further.

Example 2

What happens now, if there exist a vertex that has no connection to any other vertex. The upper example is taken and a single vertex is added without changing anything else. Then a depth first search is invoked on the graph:

```
G := Graph([a, b, c, d, e, f, g, h, i, j, k, l],
           [[a, b], [a, c], [b, d], [b, e], [c, f], [c, g],
            [d, h], [e, i], [e, j], [f, k], [g, l]],
           Directed):

G2 := Graph::addVertices(G, [m]):
Graph::depthFirstSearch(G2, StartVertex = [a])
```

a	1	a	24	a	a
b	2	b	13	b	a
c	14	c	23	c	a
d	3	d	6	d	b
e	7	e	12	e	b
f	15	f	18	f	c
g	19	g	22	g	c
h	4	h	5	h	d
i	8	i	9	i	e
j	10	j	11	j	e
k	16	k	17	k	f
l	20	l	21	l	g
m	25	m	26	m	∞

The newly inserted vertex `m` has no predecessor. The predecessor holds therefore the value *infinity*.

Example 3

If we start somewhere in the graph without knowing the root of the DAG, the results are of course different:

```
G := Graph([a, b, c, d, e, f, g, h, i, j, k, l],
           [[a, b], [a, c], [b, d], [b, e], [c, f], [c, g],
            [d, h], [e, i], [e, j], [f, k], [g, l]],
           Directed):

Graph::depthFirstSearch(G, StartVertex = [c])
```

a	11	a	24	a	a
b	12	b	23	b	a
c	1	c	10	c	c
d	13	d	16	d	b
e	17	e	22	e	b
f	2	f	5	f	c
g	6	g	9	g	c
h	14	h	15	h	d
i	18	i	19	i	e
j	20	j	21	j	e
k	3	k	4	k	f
l	7	l	8	l	g

The predecessor of `c` is `c`, but if we look at the graph it should be `a`. This is nevertheless not quite correct. Breadth first search takes the given vertex and uses this as the root of the graph (no in-vertices!). This explains also why the next call shows a *infinity* as predecessor to l:

```
Graph::depthFirstSearch(G, StartVertex = [l])
```

a	3	a	24	a	a
b	4	b	15	b	a
c	16	c	23	c	a
d	5	d	8	d	b
e	9	e	14	e	b
f	17,	f	20,	f	c
g	21	g	22	g	c
h	6	h	7	h	d
i	10	i	11	i	e
j	12	j	13	j	e
k	18	k	19	k	f
l	1	l	2	l	∞

Parameters

`G`

`Graph`

`v`

List containing one vertex.

Options

`StartVertex`

Defines a vertex from which to start the depth first traversal.

Return Values

List containing three tables. The first table holds the first identification timestamp of each vertex, the second the finishing timestamp and the third the predecessor vertex.

Graph::getAdjacentEdgesEntering

Returns the incident edges.

Syntax

```
Graph::getAdjacentEdgesEntering(G, Vertex)
```

Description

`Graph::getAdjacentEdgesEntering(G, Vertex)` returns a list with vertices `v1..vn`, where `[v1, Vertex] .. [vn, Vertex]` are incident (incoming) Edges to `Vertex`.

Examples

Example 1

First, a complete graph is defined:

```
G1 := Graph::createCompleteGraph(5):
Graph::printGraphInformation(G1)
```

```
Vertices: [1, 2, 3, 4, 5]
Edges: [[1, 2], [1, 3], [1, 4], [1, 5], [2, 1], [2, 3], [2, 4], [2, 5], [3\
, 1], [3, 2], [3, 4], [3, 5], [4, 1], [4, 2], [4, 3], [4, 5], [5, 1], [5, \
2], [5, 3], [5, 4]]
Vertex weights: no vertex weights.
Edge descriptions: no edge descriptions.
Edge weights: no edge weights.
Edge costs: no edge costs.
Adjacency list (out): 1 = [2, 3, 4, 5], 2 = [1, 3, 4, 5], 3 = [1, 2, 4, 5]\
, 4 = [1, 2, 3, 5], 5 = [1, 2, 3, 4]
Adjacency list (in): 1 = [2, 3, 4, 5], 2 = [1, 3, 4, 5], 3 = [1, 2, 4, 5],\
 4 = [1, 2, 3, 5], 5 = [1, 2, 3, 4]
Graph is undirected.
```

Now we get the vertices that form all incident edges `[2, 1] .. [5, 1]`:

```
Graph::getAdjacentEdgesEntering(G1, [1])
```

```
[2, 3, 4, 5]
```

Now we get the vertices that form all incident edges `[1, 5] .. [4, 5]`:

```
Graph::getAdjacentEdgesEntering(G1, [5])
```

```
[1, 2, 3, 4]
```

Parameters

`G`

A graph

`Vertex`

One vertex of `G`.

Return Values

List

Graph::getAdjacentEdgesLeaving

Returns the adjacent edges.

Syntax

```
Graph::getAdjacentEdgesLeaving(G, Vertex)
```

Description

`Graph::getAdjacentEdgesLeaving(G, Vertex)` returns a list with vertices `v1..vn`, where `[Vertex, v1] .. [Vertex, vn]` are adjacent (outgoing) Edges to `Vertex`.

Examples

Example 1

First, a complete graph is defined:

```
G1 := Graph::createCompleteGraph(5):
Graph::printGraphInformation(G1)
```

```
Vertices: [1, 2, 3, 4, 5]
Edges: [[1, 2], [1, 3], [1, 4], [1, 5], [2, 1], [2, 3], [2, 4], [2, 5], [3\
, 1], [3, 2], [3, 4], [3, 5], [4, 1], [4, 2], [4, 3], [4, 5], [5, 1], [5, \
2], [5, 3], [5, 4]]
Vertex weights: no vertex weights.
Edge descriptions: no edge descriptions.
Edge weights: no edge weights.
Edge costs: no edge costs.
Adjacency list (out): 1 = [2, 3, 4, 5], 2 = [1, 3, 4, 5], 3 = [1, 2, 4, 5]\
, 4 = [1, 2, 3, 5], 5 = [1, 2, 3, 4]
Adjacency list (in): 1 = [2, 3, 4, 5], 2 = [1, 3, 4, 5], 3 = [1, 2, 4, 5],\
 4 = [1, 2, 3, 5], 5 = [1, 2, 3, 4]
Graph is undirected.
```

Now we get the vertices that form all adjacent edges `[1, 2] .. [1, 5]`:

```
Graph::getAdjacentEdgesLeaving(G1, [1])
```

```
[2, 3, 4, 5]
```

Now we get the vertices that form all adjacent edges `[2, 1] .. [2, 5]`:

```
Graph::getAdjacentEdgesLeaving(G1, [2])
```

```
[1, 3, 4, 5]
```

Parameters

`G`

A graph

`Vertex`

One vertex of `G`.

Return Values

List

Graph::getBestAdjacentEdge

Returns the "best" incident edges.

Syntax

```
Graph::getBestAdjacentEdge(G, Vertex, Vertices, <Min | Max>, <Weights | Costs>)
```

Description

`Graph::getBestAdjacentEdge(G, Vertex)` returns the best incident edge according to specified attributes.

`Graph::getBestAdjacentEdge(G, Vertex, Vertices)` returns a vertex `v` out of `Vertices`. The best edge is (Vertex, v) according to the specifications.

Examples

Example 1

Let us create a graph and find out the edge with the least weight:

```
G1 := Graph([1, a, 3, 4], [[1, a], [1, 3], [1, 4]],
            EdgeWeights = [10, 20, 30],
            EdgeCosts = [30, 20, 10]):
Graph::getBestAdjacentEdge(G1, [1], Graph::getVertices(G1)),
Graph::getBestAdjacentEdge(G1, [1], Graph::getVertices(G1),
                                              Min, Weights)
```

$$a, a$$

The result shows that edge [1, a] has the least weight. It also shows that `Min` and `Weights` are the defaults if omitted. Next, we want to know the edge with maximum weight:

```
Graph::getBestAdjacentEdge(G1, [1], Graph::getVertices(G1), Max)
```

```
    4
```

The vertex with maximum weight is edge [1,4]. Now we have a look at the costs. The minimum cost edge can be found with:

```
Graph::getBestAdjacentEdge(G1, [1], Graph::getVertices(G1), Costs)
```

```
    4
```

So the vertex with maximum weight is also the edge with minimum costs. Finally let us search for the edge with maximum costs:

```
Graph::getBestAdjacentEdge(G1, [1], Graph::getVertices(G1),
                                                  Costs, Max)
```

```
    a
```

Parameters

`G`

A graph

`Vertex`

One vertex of `G`.

`Vertices`

Vertices in `G`.

Options

`Min`

If stated, the edge with the minimum attribute will be found. (Default)

`Max`

If stated, the edge with the maximum attribute will be found.

`Weights`

If stated, edge weights will be used for comparison. (Default)

`Costs`

If stated, edge costs will be used for comparison.

Return Values

Vertex

Graph::getEdgeCosts

Returns a table with the edge costs.

Syntax

```
Graph::getEdgeCosts(G)
```

Description

`Graph::getEdgeCosts(G)` returns a table with the edge costs of the graph `G`. Thus `Graph::getEdgeCosts(G)` returns the costs of all edges in `G`.

Note: Costs will most probably only be defined, if transportation problems occur.

Note: If FAIL is returned, no costs werde defined (this way both, network and graph algorithms handle this situation correct.)

Examples

Example 1

First lets define a graph without edge costs:

```
G1 := Graph::createCircleGraph(3):
Graph::getEdgeCosts(G1)
```

```
    FAIL
```

`FAIL` was returned, because no edge costs were defined.

```
Graph::getEdges(G1);
G1 := Graph::setEdgeCosts(G1, [[1, 2], [3, 1]], [5, 1/2]):
Graph::getEdgeCosts(G1)
```

```
[[1, 2], [2, 3], [3, 1]]
```

[1, 2]	5
[3, 1]	$\frac{1}{2}$

The first output shows all the edges and the second one the assigned edge costs.

Parameters

G

A graph

Return Values

Table

Graph::getEdgeDescriptions

Returns a table with the edge descriptions.

Syntax

```
Graph::getEdgeDescriptions(G)
```

Description

`Graph::getEdgeDescriptions(G)` returns a table with the edge descriptions of the graph `G`. Thus `Graph::getEdgeDescriptions(G)` returns the weight of all edges in `G`.

Note: Descriptions will most probably only be defined, if transportation problems occur.

Note: If FAIL is returned, no descriptions were defined (this way both, network and graph algorithms handle this situation correct.)

Examples

Example 1

First lets define a graph without edge descriptions:

```
G1 := Graph::createCircleGraph(3):
Graph::getEdgeDescriptions(G1)
```

```
    FAIL
```

`FAIL` was returned, because no edge descriptions were defined.

```
Graph::getEdges(G1);
G1 := Graph::setEdgeDescriptions(G1, [[1, 2], [3, 1]],
                                 ["Shortcut", "Highway 66"]):
```

```
Graph::getEdgeDescriptions(G1)
```

```
[[1, 2], [2, 3], [3, 1]]
```

[1, 2]	"Shortcut"
[3, 1]	"Highway 66"

The first output shows all the edges and the second one the assigned edge descriptions.

Parameters

G

A graph

Return Values

Table

Graph::getEdges

Returns a list with all edges

Syntax

```
Graph::getEdges(G)
```

Description

`Graph::getEdges(G)` returns a list containing all edges of the graph `G`. Each edge is represented by a list containing the two connected vertices.

Examples

Example 1

`Graph::getEdges` only returns the edges, without their capacities:

```
G1 := Graph::createCircleGraph([v1, v2, v3, v4]):
Graph::getEdges(G1)
```

```
[[v1, v2], [v2, v3], [v3, v4], [v4, v1]]
```

```
G2 := Graph::createCompleteGraph(3):
Graph::getEdges(G2)
```

```
[[1, 2], [1, 3], [2, 1], [2, 3], [3, 1], [3, 2]]
```

Parameters

`G`

A Graph

Return Values

List of all edges, a list of lists

Graph::getEdgesEntering

Returns the incoming edges

Syntax

```
Graph::getEdgesEntering(G)
```

Description

`Graph::getEdgesEntering(G)` returns a table with the adjacency lists for incident (incoming) edges. Thus `Graph::getEdgesEntering(G)` returns a table containing all those vertices `w` for which there is an edge `[w, v]` in `G`.

Examples

Example 1

A small directed graph is created to show the incoming (incident) edges:

```
V := [1, 2, 3, 4, 5]:
Ed := [[1, 2], [1, 3], [2, 3], [2, 4], [3, 4], [3, 5], [4, 5]]:
G1 := Graph(V, Ed, Directed):
Graph::getEdgesEntering(G1)
```

1	[]
2	[1]
3	[1, 2]
4	[2, 3]
5	[3, 4]

In an undirected graph the output could look like this:

```
G1 := Graph::createCompleteGraph(5):
```

```
Graph::getEdgesEntering(G1)
```

1	[2, 3, 4, 5]
2	[1, 3, 4, 5]
3	[1, 2, 4, 5]
4	[1, 2, 3, 5]
5	[1, 2, 3, 4]

Parameters

G

A graph

Return Values

Table

Graph::getEdgesLeaving

Returns the outgoing edges

Syntax

```
Graph::getEdgesLeaving(G)
```

Description

`Graph::getEdgesLeaving(G)` returns a table with the adjacency lists for adjacent (outgoing) edges. Thus `Graph::getEdgesLeaving(G)` returns a table containing all those vertices `w` for which there is an edge `[v,w]` in `G`.

Examples

Example 1

A small directed graph is created to show the outgoing (adjacent) edges:

```
V := [1, 2, 3, 4, 5]:
Ed := [[1, 2], [1, 3], [2, 3], [2, 4], [3, 4], [3, 5], [4, 5]]:
G1 := Graph(V, Ed, Directed):
Graph::getEdgesLeaving(G1)
```

1	[2, 3]
2	[3, 4]
3	[4, 5]
4	[5]
5	[]

In an undirected graph the output could look like this:

```
G1 := Graph::createCompleteGraph(5):
```

```
Graph::getEdgesLeaving(G1)
```

1	[2, 3, 4, 5]
2	[1, 3, 4, 5]
3	[1, 2, 4, 5]
4	[1, 2, 3, 5]
5	[1, 2, 3, 4]

Parameters

G

A graph

Return Values

Table

Graph::getEdgeNumber

Returns the number of edges.

Syntax

```
Graph::getEdgeNumber(G)
```

Description

`Graph::getEdgeNumber(G)` returns a number representing the number of edges in `G`.

Examples

Example 1

Let us create a graph and find out the number of edges:

```
G1 := Graph([1, a, 3, 4], [[1, a], [1, 3], [1, 4]]):
Graph::getEdgeNumber(G1)
```

```
6
```

We know that a complete graph consists of $|Vertices|^2 - |Vertices|$ edges:

```
G2 := Graph::createCompleteGraph(4):
Graph::getEdgeNumber(G2)
```

```
12
```

Parameters

`G`

A graph

Return Values

Number

Graph::getEdgeWeights

Returns a table with the edge weights.

Syntax

```
Graph::getEdgeWeights(G)
```

Description

`Graph::getEdgeWeights(G)` returns a table with the edge weights of the graph `G`. Thus `Graph::getEdgeWeights(G)` returns the weight of all edges in `G`.

Note: Weights will most probably only be defined, if transportation problems occur.

Note: If FAIL is returned, no weights were defined (this way both, network and graph algorithms handle this situation correct.)

Examples

Example 1

First lets define a graph without edge weights:

```
G1 := Graph::createCircleGraph(3):
Graph::getEdgeWeights(G1)
```

```
    FAIL
```

`FAIL` was returned, because no edge weights were defined.

```
Graph::getEdges(G1);
G1 := Graph::setEdgeWeights(G1, [[1, 2], [3, 1]], [5, 1/2]):
Graph::getEdgeWeights(G1)
```

```
[[1, 2], [2, 3], [3, 1]]
```

[1, 2]	5
[3, 1]	$\frac{1}{2}$

The first output shows all the edges and the second one the assigned edge weights.

Parameters

G

A graph

Return Values

Table

Graph::getSubGraph

Returns a subgraph.

Syntax

```
Graph::getSubGraph(G, Vertex)
```

Description

`Graph::getSubGraph(G, Vertex)` returns a subgraph according to the specified vertices.

`Graph::getSubGraph(G)` returns a graph that only holds the specified vertices and the belonging edges.

Examples

Example 1

First, a complete graph is defined with some additional settings:

```
G1 := Graph::createCompleteGraph(5):
G1 := Graph::setEdgeWeights(G1, [[1,2]], [20]):
G1 := Graph::setEdgeCosts(G1, [[1, 2]], [20]):
G1 := Graph::setEdgeDescriptions(G1, [[1, 2]], ["Shortcut"]):
Graph::printGraphInformation(G1)
```

```
Vertices: [1, 2, 3, 4, 5]
Edges: [[1, 2], [1, 3], [1, 4], [1, 5], [2, 1], [2, 3], [2, 4], [2, 5], [3\
, 1], [3, 2], [3, 4], [3, 5], [4, 1], [4, 2], [4, 3], [4, 5], [5, 1], [5, \
2], [5, 3], [5, 4]]
Vertex weights: no vertex weights.
Edge descriptions: [1, 2] = "Shortcut", [2, 1] = "Shortcut"
Edge weights: [1, 2] = 20, [2, 1] = 20 (other existing edges have no weigh\
t)
Edge costs: [1, 2] = 20, [2, 1] = 20 (other existing edges have costs zero)
```

```
Adjacency list (out): 1 = [2, 3, 4, 5], 2 = [1, 3, 4, 5], 3 = [1, 2, 4, 5]\
, 4 = [1, 2, 3, 5], 5 = [1, 2, 3, 4]
Adjacency list (in): 1 = [2, 3, 4, 5], 2 = [1, 3, 4, 5], 3 = [1, 2, 4, 5],\
 4 = [1, 2, 3, 5], 5 = [1, 2, 3, 4]
Graph is undirected.
```

Now we get the subgraph for the vertices `1,2,4`:

```
G2 := Graph::getSubGraph(G1, [1, 2, 4]):
Graph::printGraphInformation(G2)
```

```
Vertices: [1, 2, 4]
Edges: [[1, 2], [1, 4], [2, 1], [2, 4], [4, 1], [4, 2]]
Vertex weights: no vertex weights.
Edge descriptions: [1, 2] = "Shortcut", [2, 1] = "Shortcut"
Edge weights: [1, 2] = 20, [2, 1] = 20 (other existing edges have no weigh\
t)
Edge costs: [1, 2] = 20, [2, 1] = 20 (other existing edges have costs zero)
Adjacency list (out): 1 = [2, 4], 2 = [1, 4], 4 = [1, 2]
Adjacency list (in): 1 = [2, 4], 2 = [1, 4], 4 = [1, 2]
Graph is undirected.
```

The subgraph for the vertices `1,3,4` looks like:

```
G2 := Graph::getSubGraph(G1, [1, 3, 4]):
Graph::printGraphInformation(G2)
```

```
Vertices: [1, 3, 4]
Edges: [[1, 3], [1, 4], [3, 1], [3, 4], [4, 1], [4, 3]]
Vertex weights: no vertex weights.
Edge descriptions: no edge descriptions.
Edge weights: no edge weights.
Edge costs: no edge costs.
Adjacency list (out): 1 = [3, 4], 3 = [1, 4], 4 = [1, 3]
Adjacency list (in): 1 = [3, 4], 3 = [1, 4], 4 = [1, 3]
Graph is undirected.
```

Parameters

`G`

A graph

`Vertex`

A list containing one or more vertices of `G`.

Return Values

Graph

Graph::getVertexNumber

Returns the number of vertices.

Syntax

```
Graph::getVertexNumber(G)
```

Description

`Graph::getVertexNumber(G)` returns a number representing the number of vertices in `G`.

Examples

Example 1

An example with 100 vertices:

```
G1 := Graph::createCompleteGraph(100):
Graph::getVertexNumber(G1)
```

```
      100
```

Parameters

`G`

A graph

Return Values

Number

Graph::getVertexWeights

Returns a table with the vertex weights.

Syntax

```
Graph::getVertexWeights(G)
```

Description

`Graph::getVertexWeights(G)` returns a table with the vertex weights of the graph `G`. Thus `Graph::getVertexWeights(G)` returns the weight of all vertices in `G`.

Note: If FAIL is returned, no weights were defined (this way both, network and graph algorithms handle this situation correct.)

Examples

Example 1

First lets define a graph without vertex weights:

```
G1 := Graph::createCircleGraph(3):
Graph::getVertexWeights(G1)
```

```
FAIL
```

`FAIL` was returned, because no vertex weights were defined.

```
Graph::getVertices(G1);
G1 := Graph::setVertexWeights(G1, [1, 3], [5, 1/2]):
Graph::getVertexWeights(G1)
```

```
[1, 2, 3]
```

1	5
3	$\frac{1}{2}$

The first output shows all the vertices and the second one the assigned vertex weights.

Parameters

G

A graph

Return Values

Table

Graph::getVertices

Returns a list with all vertices

Syntax

```
Graph::getVertices(G)
```

Description

`Graph::getVertices(G)` returns the list of all vertices of the Graph `G`.

Examples

Example 1

A small creation of two different graphs and the output `getVertices` generates:

```
G1 := Graph::createCompleteGraph(10):
Graph::getVertices(G1)
```

$$[1, 2, 3, 4, 5, 6, 7, 8, 9, 10]$$

```
G2 := Graph::createCircleGraph([x.i $ i = 1..12]):
Graph::getVertices(G2)
```

$$[x1, x2, x3, x4, x5, x6, x7, x8, x9, x10, x11, x12]$$

Parameters

`G`

A graph

Return Values

List

Graph::inDegree

Returns the indegree of one or more vertices.

Syntax

```
Graph::inDegree(G, <Vertex>)
```

Description

`Graph::inDegree(G, Vertex)` returns the indegree of the vertex `Vertex` in the Graph `G`, i.e., the number of edges `[u,Vertex]`.

`Graph::inDegree(G, [v1, v2, ..., vn])` returns a table in which the keys are `v1, v2, ..., vn` and the corresponding values are the indegrees.

`Graph::inDegree(G)` returns a table in which each node of `G` is mapped to its indegree. `Graph::inDegree(G)` is equivalent to `Graph::inDegree(G, Graph::getVertices(G))`.

Examples

Example 1

In a complete graph of n vertices, each vertex has indegree n - 1:

```
G := Graph::createCompleteGraph(5):
Graph::inDegree(G, [2, 4, 5]), Graph::inDegree(G),
Graph::inDegree(G, Graph::getVertices(G))
```

2 | 4	1 | 4
4 | 4	2 | 4
5 | 4	3 | 4
	4 | 4
	5 | 4

1 | 4
2 | 4
3 | 4
4 | 4
5 | 4

The first table shows what happens, if some vertices are specified. The second and third table return all indegrees, but with two different calls (the second is redundant).

Example 2

Remember that also only one vertex needs to be specified as a list!

```
G := Graph::createCompleteGraph(5):
Graph::inDegree(G, [2])
```

2	4

Parameters

`G`

A Graph

`Vertex`

A list containing one or more vertices.

Return Values

Table containing all the indegrees of the specified vertices.

Graph::isConnected

Finds out if the graph is connected

Syntax

```
Graph::isConnected(G)
```

Description

`Graph::isConnected(G)` returns `TRUE` if `G` is connected, `FALSE` otherwise.

Examples

Example 1

A circle graph is made to create a connected Graph:

```
G1 := Graph::createCircleGraph(3):
Graph::isConnected(G1)
```

```
    TRUE
```

After adding a single vertex to the graph, it is not connected any more:

```
G2 := Graph::addVertices(G1, [4]):
Graph::isConnected(G2)
```

```
    FALSE
```

Parameters

`G`

A graph

Return Values

TRUE or FALSE

Graph::isDirected

Finds out if the graph is directed

Syntax

```
Graph::isDirected(G)
```

Description

`Graph::isDirected(G)` returns `TRUE` if `G` is directed, `FALSE` otherwise.

Examples

Example 1

A circle graph is made to create a directed Graph:

```
G1 := Graph::createCircleGraph(3):
Graph::isDirected(G1)
```

```
TRUE
```

Example 2

Now a complete graph is created in order to get an undirected graph:

```
G1 := Graph::createCompleteGraph(3):
Graph::isDirected(G1)
```

```
FALSE
```

Parameters

G

A graph

Return Values

TRUE or FALSE

Graph::isEdge

Finds out if the edges exists

Syntax

```
Graph::isEdge(G, Edge)
```

Description

`Graph::isEdge(G)` returns `TRUE` if `ALL` specified edges exist in `G`, `FALSE` otherwise.

Examples

Example 1

A circle graph is made to create a directed Graph:

```
G1 := Graph::createCircleGraph(3):
Graph::printGraphInformation(G1)
```

```
Vertices: [1, 2, 3]
Edges: [[1, 2], [2, 3], [3, 1]]
Vertex weights: no vertex weights.
Edge descriptions: no edge descriptions.
Edge weights: no edge weights.
Edge costs: no edge costs.
Adjacency list (out): 1 = [2], 2 = [3], 3 = [1]
Adjacency list (in): 1 = [3], 2 = [1], 3 = [2]
Graph is directed.
```

First let us check for an existing single edge:

```
Graph::isEdge(G1, [[1, 2]] )
```

```
    TRUE
```

Now we check if several edges exist:

```
Graph::isEdge(G1, [[1, 2], [2, 3]] )
```

```
    TRUE
```

What about a non existing edge?

```
Graph::isEdge(G1, [[3, 2]] )
```

```
    FALSE
```

Finally a list of some existing and non existing edges is checked:

```
Graph::isEdge(G1, [[1, 2], [2, 3], [3, 2]])
```

```
    FALSE
```

Parameters

`G`

A graph

`Edge`

A list containing one or more edges

Return Values

TRUE or FALSE

Graph::isVertex

Finds out if special vertices exist in the Graph

Syntax

```
Graph::isVertex(G, Vertex)
```

Description

`Graph::isVertex(G)` returns `TRUE` if `ALL` specified vertices exist in `G`, `FALSE` otherwise.

Examples

Example 1

A circle graph is made to create a directed Graph:

```
G1 := Graph::createCircleGraph(3):
Graph::printGraphInformation(G1)
```

```
Vertices: [1, 2, 3]
Edges: [[1, 2], [2, 3], [3, 1]]
Vertex weights: no vertex weights.
Edge descriptions: no edge descriptions.
Edge weights: no edge weights.
Edge costs: no edge costs.
Adjacency list (out): 1 = [2], 2 = [3], 3 = [1]
Adjacency list (in): 1 = [3], 2 = [1], 3 = [2]
Graph is directed.
```

First, let us check for an existing vertex:

```
Graph::isVertex(G1, [1])
```

```
TRUE
```

Now we check if several vertices exist:

```
Graph::isVertex(G1, [1, 2])
```

```
    TRUE
```

What about a non existing vertex?

```
Graph::isVertex(G1, [4])
```

```
    FALSE
```

Finally a list of some existing and non existing vertices is checked:

```
Graph::isVertex(G1, [1, 2, 4])
```

```
    FALSE
```

Parameters

`G`

A graph

`Vertex`

A list containing one or more vertices

Return Values

TRUE or FALSE

Graph::longestPath

Longest paths from one single node

Syntax

```
Graph::longestPath(G, v, <w>, <Length>, <Path>)
```

Description

`Graph::longestPath(G, v)` returns a table with the length of longest paths from `v` to all other nodes in the Graph with respect to the edge weight.

`Graph::longestPath(G, v, w)` returns the length of a longest path from `v` to `w`.

If the optional argument `Path` is given, a table with longest paths is returned. If both `Length` and `Path` are given, then both the length of the longest paths and the paths are returned. Paths are given as lists of nodes in reverse order.

If `Path` is not given, the option `Length` has no effect.

Note: The Graph `G` must be directed and should not contain cycles.

Examples

Example 1

We construct a Graph and try a few calls to `Graph::longestPath`:

```
V  := [1, 2, 3, 4, 5]:
Ed := [[1, 2], [1, 3], [2, 3], [2, 4], [3, 4], [3, 5], [4, 5]]:
Ew := [7, 6, 5, 4, 2, 2, 1]:
G  := Graph(V, Ed, EdgeWeights = Ew, Directed):
Graph::longestPath(G, 1)
```

1	0
2	7
3	12
4	14
5	15

```
Graph::longestPath(G, 1, Path)
```

2	[2, 1]
3	[3, 2, 1]
4	[4, 3, 2, 1]
5	[5, 4, 3, 2, 1]

Parameters

`G`

A Graph

`v, w`

Vertices in `G`

Options

`Length`

Return a table with the lengths of shortest paths

`Path`

Return a table with the paths themselves

Return Values

Table, an integer or a list of nodes

Algorithms

The implemented algorithm is a variation of the algorithm of Bellman.

Graph::maxFlow

Computes a maximal flow through a graph

Syntax

```
Graph::maxFlow(G, s, t)
```

Description

`Graph::maxFlow(G,s,t)` computes a maximal flow from `s` to `t` in `G` with respect to the edge capacities. `s` and `t` must be nodes in `G`.

`Graph::maxFlow(G,s,t)` returns a sequence containing the flow value, that is the inflow of `s`, which equals the outflow of `s`, and the flow itself in form of table `tbl` with the flow from vertex `v` to vertex `w` is `tbl[[v,w]]`.

Examples

Example 1

In the complete Graph with four vertices and default capacities of 1, the maximum flow from one vertex to another one consists of sending one unit through each of the remaining vertices and one directly, which makes three units altogether:

```
G1 := Graph::createCompleteGraph(4):
Graph::maxFlow(G1, [1], [4])
```

	[1, 2]	1
	[2, 1]	0
	[1, 3]	1
	[3, 1]	0
	[1, 4]	1
3,	[2, 3]	0
	[3, 2]	0
	[4, 1]	0
	[2, 4]	1
	[4, 2]	0
	[3, 4]	1
	[4, 3]	0

Example 2

As a more complex example, the following graph shows that this function also finds flows through multiple edges, unlike `Graph::admissibleFlow`, which only works on completely described flows:

```
V := [1, 2, 3, s, t]:
Edge := [[s, 1], [t, 2], [1, 2], [1, 3], [2, 3], [3, t]]:
up := [5, 5, 2, 6, 6, 1]:
G2 := Graph(V, Edge, EdgeCosts = up, Directed):
Graph::maxFlow(G2, [s], [t])
```

	[1, 2]	0
	[1, 3]	1
1,	[2, 3]	0
	[*s*, 1]	1
	[*t*, 2]	0
	[3, *t*]	1

Parameters

`G`

Graph

`s, t`

Expressions (vertices in `G`)

Return Values

List, containing a number and a table

Algorithms

The implemented algorithm is the preflow-push algorithm of Goldberg &Tarjan with the FIFO selection strategy and an exact distance labeling ("A new approach to the maximum-flow problem", Journal of the ACM 35(4), 1988).

The running time is $O(n^3)$, where n is the number of vertices in the Graph.

Graph::minCost

Computes a minimal cost flow

Syntax

```
Graph::minCost(G)
```

Description

`Graph::minCost(G)` computes a minimal cost flow in `G` with respect to the edge capacities, the edge weights and the vertex weights of `G`.

The vertex weights are interpreted as supply and demand. The edge weights give restrictions for the flow on every edge. The edge costs are the cost for one unit flow over an edge.

The algorithm computes a flow, if there is any, which is possible and satisfactory, i.e., it is within the supply and demand range, which respects the capacities and which has minimal cost.

Examples

Example 1

We construct a Graph with five vertices and seven edges. One of the vertices is a pure source (1), another one is a pure sink (5). No other vertices supply or demand any goods, they only serve as transportation junctions:

```
V  := [1, 2, 3, 4, 5]:
Vw := [25, 0, 0, 0, -25]:
edges := [[1, 2], [1, 3], [2, 3], [2, 4], [3, 4], [3, 5], [4, 5]]:
Ec := [7, 6, 5, 4, 2, 2, 1]:
Ew := [30, 20, 25, 10, 20, 25, 20]:
G1 := Graph(V, edges, EdgeCosts = Ec, EdgeWeights = Ew,
            VertexWeights = Vw, Directed):
Graph::minCost(G1)
```

[1, 2]	5
[1, 3]	20
[2, 3]	0
[2, 4]	5
[3, 4]	0
[3, 5]	20
[4, 5]	5

,

[1, 2]	35
[1, 3]	120
[2, 3]	0
[2, 4]	20
[3, 4]	0
[3, 5]	40
[4, 5]	5

, 220,

1	12
2	5
3	2
4	1
5	0

All 25 units could be transported from vertex 1 to vertex 5, for a total cost of 220. The cost for each edge can be found in the first table, the accumulated costs in the second and the last table holds the dual prices. For example 6 units flow over edge [1, 3] since 6 20 = 120 and 7 units flow over edge [1, 2] since 7 5 = 35.

Parameters

G

Graph

Return Values

Sequence, consisting of three tables and a number. The first table holds the amount flowing over the edge, the second the accumulated costs for each used edge and the number is the sum of all edge-costs for the flow. The last table holds the dual prices for each vertex.

Algorithms

The implemented algorithm is the relaxation algorithm due to Bertsekas (taken from Bertsekas, “Linear Network Optimization”, MIT Press, Cambridge(Mass.)-London, 1991) which is known to be one of the fastest algorithms in practice.

Graph::minCut

Computes a minimal cut

Syntax

```
Graph::minCut(G, q, s)
```

Description

`Graph::minCut(G,q,s)` computes a minimal cut in `G` that separates `q` from `s`, i.e., a subset `T` of the set `S` of edges of `G` such that every path from `q` to`s` contains at least one edge in `T`. The cut is minimal with respect to the capacities of the edges.

`Graph::minCut(G,q,s)` returns a sequence consisting of the cut value (the sum of the edge weights of the cut edges) and a list with the edges of the cut.

Note that `q` is separated from `s`, not vice versa.

Examples

Example 1

In a complete graph, a vertex can be separated from another one only by cutting all edges starting at the first vertex:

```
G1 := Graph::createCompleteGraph(4):
Graph::minCut(G1, [1], [4])
```

```
3, [[1, 2], [1, 3], [1, 4]]
```

Example 2

In the following example, the edge from vertex `q` to vertex `1` could have been used as well, but its edge capacity is higher than that of the edge used, so the minimality condition precludes this choice:

```
V := [1, 2, 3, q, s]:
Edge := [[q, 1], [1, 2], [1, 3], [2, 3], [3, s]]:
up := [5, 2, 6, 6, 1]:
G2 := Graph(V, Edge, EdgeWeights = up, Directed):
Graph::minCut(G2, [q], [s])
```

$$1, [[3, s]]$$

There is no path from vertex `s` to vertex `q` (or any other vertex of the Graph), so no cut is necessary to separate `s` from `q`:

```
Graph::minCut(G2, [s], [q])
```

$$0, []$$

Parameters

`q, s`

Vertices that have to be defined within G

`G`

Graph

Return Values

Sequence, consisting of the “cut value” and a list of edges cut

Graph::minimumSpanningTree

Creates a MST

Syntax

```
Graph::minimumSpanningTree(G, <SearchFor = Weights | Costs>, <ReturnAsTable>)
```

Description

`Graph::minimumSpanningTree(G)` creates a minimum spanning tree of `Graph` `G` according to the weights of the edges and returns a Graph consisting only of them. The same result would be achieved using `Graph::minimumSpanningTree(G, SearchFor = Weights)`

`Graph::minimumSpanningTree(G, SearchFor = Costs)` creates a minimum spanning tree according to the costs of the edges and returns a Graph consisting only of them.

`Graph::minimumSpanningTree(G, ReturnAsTable)` creates a minimum spanning tree according to the weights of the edges and returns a list with two objects. The first is a table consisting of the used edges and their weights. The second object is a number containing the sum of all the edge weights.(The same result can be achieved using: `Graph::minimumSpanningTree(G, SearchFor=Weights, ReturnAsTable)`.)

`Graph::minimumSpanningTree(G, SearchFor=Costs, ReturnAsTable)` creates a minimum spanning tree according to the costs of the edges and returns a list with two objects. The first is a table consisting of the used edges and their costs. The second object is a number containing the sum of all the edge costs.

Examples

Example 1

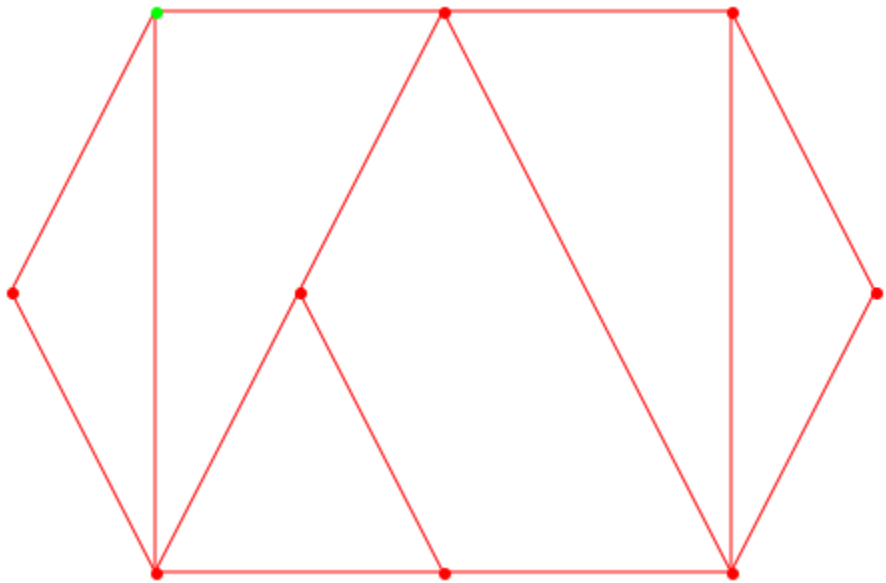
The following graph `G` will be used throughout all the examples. For details on the format of `G`, see `Graph`. (Have a look at the edge [*c*, *f*]. This edge is responsible for the different outputs whether `Costs` or `Weights` was chosen.)

```
G := Graph([a, b, c, d, e, f, g, h, i],
           [[a, b], [a, h], [b, h], [b, c], [c, d], [d, f], [d, e],
            [f, e], [h, g], [g, f], [c, i], [h, i], [g, i], [c, f]],
         EdgeWeights = [4, 8, 11, 8, 7, 14, 9, 10, 1, 2, 2, 7, 6,  4],
         EdgeCosts   = [4, 8, 11, 8, 7, 14, 9, 10, 1, 2, 2, 7, 6, 12]):
```

We will plot this graph and all graphs derived from it using `Graph::plotGridGraph` with the following options:

```
plotOptions :=
  VerticesPerLine=7,
  VertexOrder = [
     None, b,    None, c,    None, d,    None,
     a,    None, i,    None, None, None, e,
     None, h,    None, g,    None, f,    None]:

plot(Graph::plotGridGraph(G, plotOptions))
```



Now we use this Graph to create a minimum spanning tree according to the weights of the edges and have a look which edges were used:

```
Graph::minimumSpanningTree(G, SearchFor = Weights, ReturnAsTable),
```

```
Graph::minimumSpanningTree(G, ReturnAsTable)
```

σ_1, σ_1

where

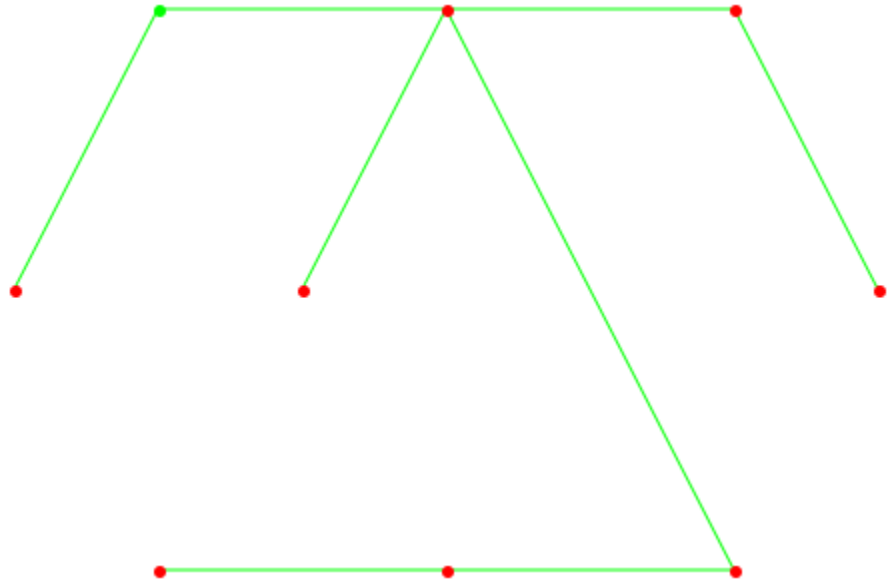
$\sigma_1 =$

$[a, b]$	4
$[b, a]$	4
$[b, c]$	8
$[c, b]$	8
$[c, d]$	7
$[d, c]$	7
$[c, f]$	4
$[d, e]$	9, 37
$[e, d]$	9
$[f, c]$	4
$[c, i]$	2
$[i, c]$	2
$[f, g]$	2
$[g, f]$	2
$[g, h]$	1
$[h, g]$	1

Both calls return exactly the same tables. That was expected and just to show that it is of no importance if the additional `SearchFor=Weights` is omitted.

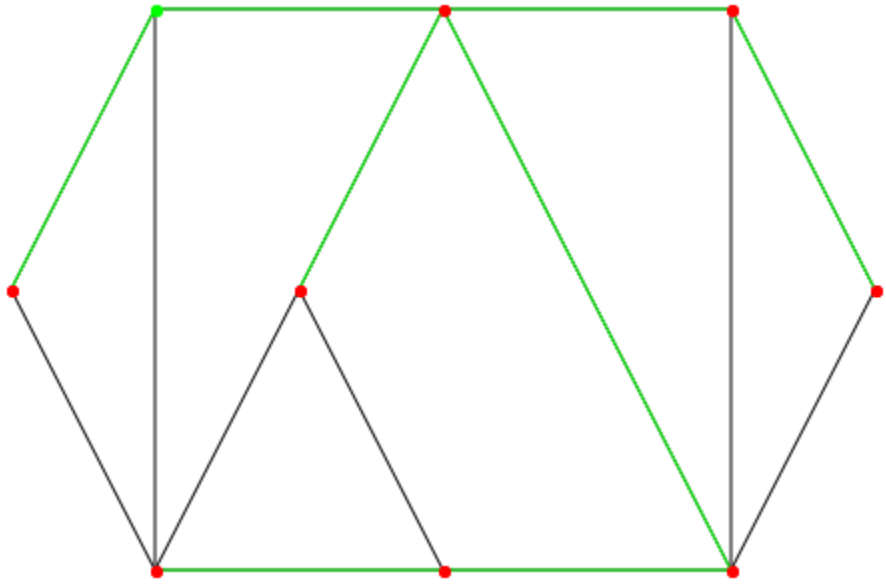
Now we want to get the minimum spanning tree returned as a Graph so we can have a look how it looks like

```
weightMST := Graph::minimumSpanningTree(G):
plot(Graph::plotGridGraph(weightMST, plotOptions,
                          EdgeColor = RGB::Green))
```

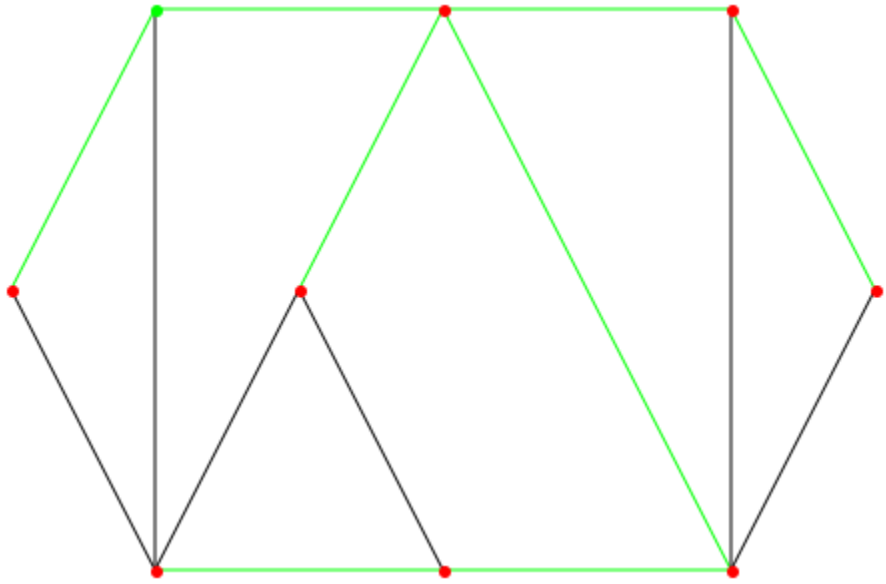


There are two ways of displaying both graphs at the same time:

```
plot(
  Graph::plotGridGraph(G, plotOptions, EdgeColor = RGB::Black),
  Graph::plotGridGraph(weightMST, plotOptions,
                       EdgeColor = RGB::Green)
)
```



```
edgesWeightMST := Graph::getEdges(weightMST):
plot(Graph::plotGridGraph(G, plotOptions,
         EdgeColor = RGB::Black,
         SpecialEdges = edgesWeightMST,
         SpecialEdgeColor = RGB::Green))
```



Example 2

Maybe instead of the weights there is an interest in getting the MST for the costs of the edges.

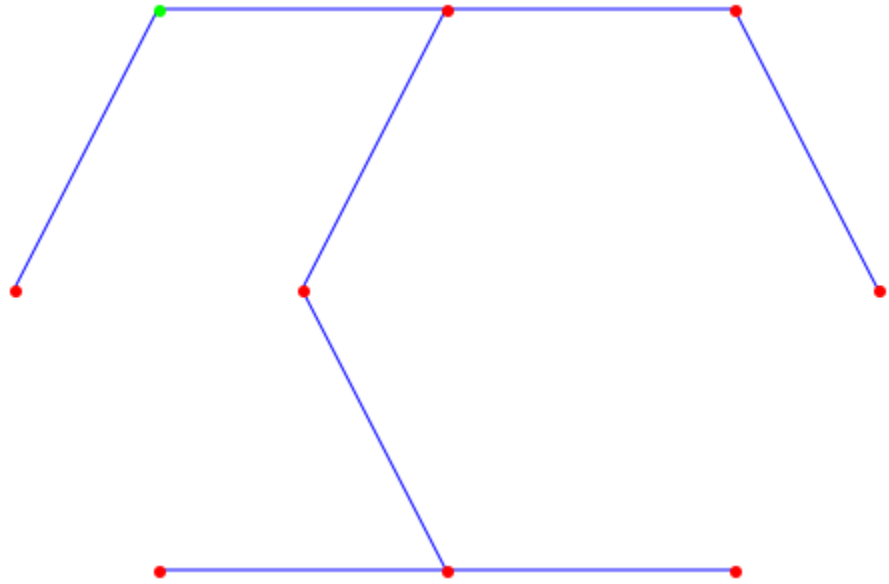
```
G := Graph([a, b, c, d, e, f, g, h, i],
           [[a, b], [a, h], [b, h], [b, c], [c, d], [d, f], [d, e],
            [f, e], [h, g], [g, f], [c, i], [h, i], [g, i], [c, f]],
         EdgeWeights = [4, 8, 11, 8, 7, 14, 9, 10, 1, 2, 2, 7, 6,  4],
         EdgeCosts   = [4, 8, 11, 8, 7, 14, 9, 10, 1, 2, 2, 7, 6, 12]):

Graph::minimumSpanningTree(G, SearchFor = Costs, ReturnAsTable)
```

[a, b]	4
[b, a]	4
[b, c]	8
[c, b]	8
[c, d]	7
[d, c]	7
[d, e]	9
[e, d]	9, 39
[c, i]	2
[i, c]	2
[f, g]	2
[g, f]	2
[g, h]	1
[h, g]	1
[g, i]	6
[i, g]	6

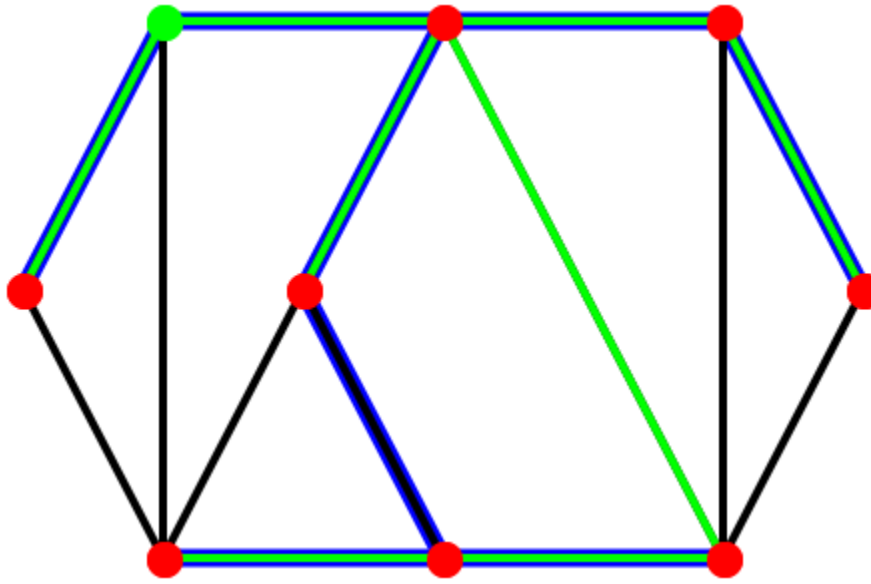
Plotting this spanning tree is just as easy as above:

```
costMST := Graph::minimumSpanningTree(G, SearchFor = Costs):
plot(Graph::plotGridGraph(costMST, plotOptions,
                          EdgeColor = RGB::Blue))
```



To combine both spanning trees, we use different line widths, to avoid one graph being completely covered by the other:

```
plot(
  plot::Group2d(
    Graph::plotGridGraph(costMST, plotOptions,
                         EdgeColor = RGB::Blue),
    LineWidth = 2.5
  ),
  plot::Group2d(
    Graph::plotGridGraph(G, plotOptions,
                EdgeColor = RGB::Black),
    Graph::plotGridGraph(weightMST, plotOptions,
                          EdgeColor = RGB::Green),
    PointSize = 5,
    LineWidth = 1
  )
)
```



Parameters

`G`

`Graph`

Options

`SearchFor`

Can either be `Costs` or `Weights`. Default is `Weights`

`ReturnAsTable`

If omitted, a Graph is returned, otherwise a list containing a table and the sum of the edge weights/costs.

Return Values

Graph consisting of the MST. Only if `ReturnAsTable` was specified, a list containing a table and a number are returned. The table holds the edges with either the weights or costs of each edge and the number is the sum of all edges.

Graph

Creates new graph

Syntax

```
Graph(V, E, <VertexWeights = vw>, <EdgeDescriptions = ed>, <EdgeWeights = ew>, <EdgeCos
```

Description

`Graph(V, E)` creates a graph.

`Graph([v1,...,vn],[e1,...,em])` generates a new undirected graph with n vertices and m edges.

`Graph([1,a,3], [[1,a],[1,3]], Directed)` generates a new directed graph with the vertices `1`, `a`, `3` and the edges `[1,a]`, `[1,3]`.

`Graph([a,b,3], [[a,b],[b,3]], VertexWeights = [1,2,3], EdgeWeights = [4,5])` generates a new directed graph where the vertices have the values `a=1`, `b=2`, `3=3` and the edges `[a,b]=4`, `[b,3]=5`.

`Graph([a,b,3], [[a,b],[b,3]], VertexWeights = [1,None,3], EdgeWeights = [4, None])` generates a new directed graph where the vertices have the values `a=1`, `3=3` and the edges `[a,b]=4`. The difference to the example directly above is that the keyword `None` can be used to not assign a value to a vertex or edge.

Examples

Example 1

An (undirected) graph with four vertices:

```
G1 := Graph([1,a,3], [[1,a],[1,3]]):
Graph::printGraphInformation(G1)
```

```
Vertices: [1, 3, a]
Edges: [[1, 3], [1, a], [3, 1], [a, 1]]
Vertex weights: no vertex weights.
Edge descriptions: no edge descriptions.
Edge weights: no edge weights.
Edge costs: no edge costs.
Adjacency list (out): 1 = [3, a], a = [1], 3 = [1]
Adjacency list (in): 1 = [3, a], a = [1], 3 = [1]
Graph is undirected.
```

Example 2

The same graph but this time with parameter `Directed`:

```
G1 := Graph([1,a,3], [[1,a],[1,3]], Directed):
Graph::printGraphInformation(G1)
```

```
Vertices: [1, 3, a]
Edges: [[1, 3], [1, a]]
Vertex weights: no vertex weights.
Edge descriptions: no edge descriptions.
Edge weights: no edge weights.
Edge costs: no edge costs.
Adjacency list (out): 1 = [3, a], a = [], 3 = []
Adjacency list (in): 1 = [], a = [1], 3 = [1]
Graph is directed.
```

Example 3

The circle graph with predefined vertices:

```
G3 := Graph([a,b,3], [[a,b],[b,3]],
           VertexWeights = [1,2,3],
               EdgeWeights = [4,5]):
Graph::printGraphInformation(G3)
```

```
Vertices: [3, a, b]
Edges: [[3, b], [a, b], [b, 3], [b, a]]
Vertex weights: a = 1, b = 2, 3 = 3 (other existing vertices have no weigh\
t)
Edge descriptions: no edge descriptions.
```

```
Edge weights: [a, b] = 4, [b, 3] = 5, [b, a] = 4, [3, b] = 5 (other existi\
ng edges have no weight)
Edge costs: no edge costs.
Adjacency list (out): a = [b], b = [3, a], 3 = [b]
Adjacency list (in): a = [b], b = [3, a], 3 = [b]
Graph is undirected.
```

Example 4

The circle graph with predefined vertices:

```
G3 := Graph([a,b,3,7], [[a,b],[b,3],[3,7]],
VertexWeights = [1,2,3,4], EdgeWeights = [-1,-2,-5],
EdgeDescriptions = ["Small", None, "Smallest"]):
Graph::printGraphInformation(G3)
```

```
Vertices: [3, 7, a, b]
Edges: [[3, 7], [3, b], [7, 3], [a, b], [b, 3], [b, a]]
Vertex weights: a = 1, b = 2, 3 = 3, 7 = 4 (other existing vertices have n\
o weight)
Edge descriptions: [a, b] = "Small", [3, 7] = "Smallest", [b, a] = "Small"\
, [7, 3] = "Smallest"
Edge weights: [a, b] = -1, [b, 3] = -2, [3, 7] = -5, [b, a] = -1, [3, b] =\
 -2, [7, 3] = -5 (other existing edges have no weight)
Edge costs: no edge costs.
Adjacency list (out): a = [b], b = [3, a], 3 = [7, b], 7 = [3]
Adjacency list (in): a = [b], b = [3, a], 3 = [7, b], 7 = [3]
Graph is undirected.
```

If you look at the edge descriptions, the keyword `None` can be used for every edge which is not supposed to have a description.

Parameters

V

List of vertices

E

List of edges

`vw`, `ew`, `ec`

List of numbers

`ed`

List of strings

Options

`Directed`

The Graph is created as a directed graph.

`Undirected`

The Graph is created as an undirected graph. `Default`.

Graph::outDegree

Returns the outdegree of one or more vertices.

Syntax

```
Graph::outDegree(G, <Vertex>)
```

Description

`Graph::outDegree(G)` returns the number of edges leaving each vertex `Vertex` of the Graph `G`.

`Graph::outDegree(G, Vertex)` returns the outdegree of the vertex `Vertex` in the Graph `G`, i.e., the number of edges `[Vertex, u]`.

`Graph::outDegree(G, [v1, v2, ..., vn])` returns a table in which the keys are `v1, v2, ..., vn` and the corresponding values are the outdegrees.

`Graph::outDegree(G)` returns a table in which each node of `G` is mapped to its outdegree. `Graph::outDegree(G)` is equivalent to `Graph::outDegree(G, Graph::getVertices(G))`.

Examples

Example 1

In a complete graph of n vertices, each vertex has outdegree n - 1:

```
G := Graph::createCompleteGraph(5):
Graph::outDegree(G, [2, 4, 5]), Graph::outDegree(G),
Graph::outDegree(G, Graph::getVertices(G))
```

		1	4	1	4
2	4	2	4	2	4
4	4^2	3	4^2	3	4
5	4	4	4	4	4
		5	4	5	4

The first table shows what happens, if some vertices are specified. The second and third table return all indegrees, but with two different calls (the second is redundant).

Example 2

Remember that also only one vertex needs to be specified as a list !

```
G := Graph::createCompleteGraph(5):
```

```
Graph::outDegree(G, [2])
```

2	4

Parameters

G

A Graph

Options

Vertex

A list containing one or more vertices.

Return Values

Table containing all the outdegrees of the specified vertices.

Graph::plotBipartiteGraph

Plots a Graph in a bipartite layout

Syntax

```
Graph::plotBipartiteGraph(G, <PointSize = n>, <SpecialVertices = [v1, …,vn]>, <SpecialE
```

Description

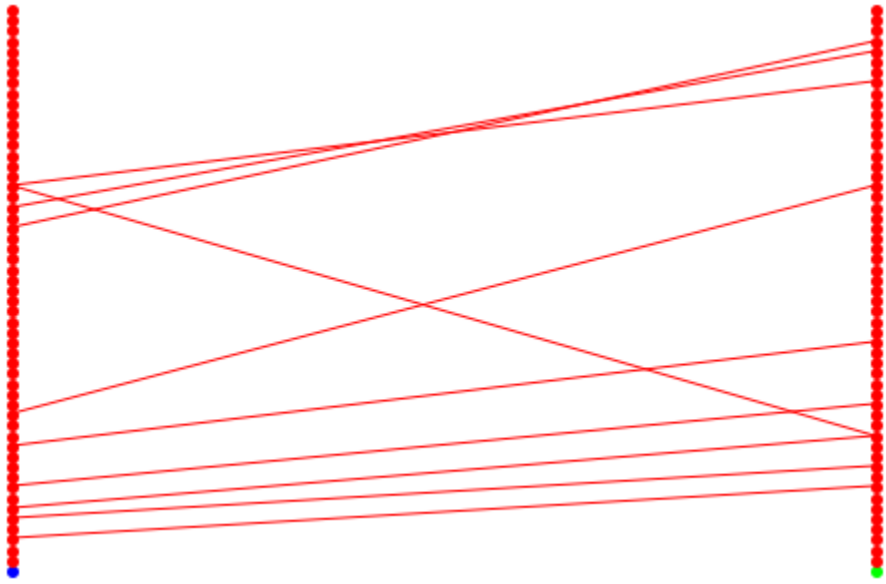
`Graph::plotBipartiteGraph(G)` returns a `plot::Group2d` object in which the vertices are ordered in two rows (from bottom to top). The first vertex in the left row is drawn in blue and the second (the first vertex in the right row) in green. All other vertices are drawn in red. The width of the points is predefined with 40.

Examples

Example 1

A random graph is created and plotted (your output may differ due to random creation):

```
G1 := Graph::createRandomGraph(110, 10, Undirected):
plot(Graph::plotBipartiteGraph(G1)):
```



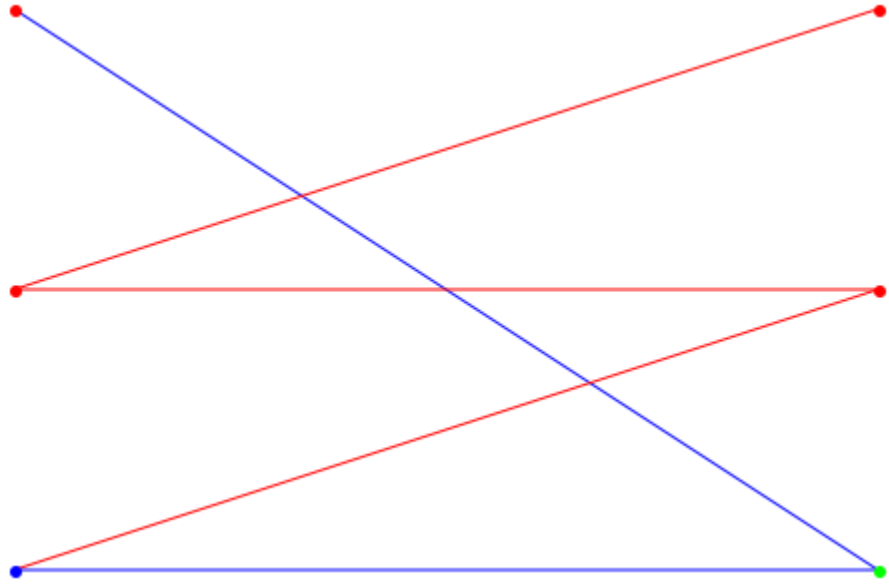
Example 2

If some edges are to be emphasized they can be drawn in a special color:

```
G2 := Graph([1, 2, 3, 4, 5, 6],
            [[1, 2], [2, 3], [3, 4], [4, 5], [1, 6]]):
Graph::bipartite(G2, Lists)
```

$$[[2, 4, 6], [1, 3, 5]]$$

```
edges := [[6, 1], [1, 2]]:
plot(Graph::plotBipartiteGraph(G2, SpecialEdges = edges,
                               SpecialEdgeColor = RGB::Blue))
```



Parameters

G

Graph

n

a positive integer

[v_1, …,v_n]

a list of vertices

[e_1, …,e_n]

a list of edges

Options

`PointSize`

Defines the thickness in which the points are drawn. Default is 40.

`SpecialVertices`

Defines a set of vertices. This option makes only sense if used with the option `SpecialVertexColor`.

`SpecialEdges`

Defines a set of edges. This option makes only sense if used with the option `SpecialEdgeColor`.

`EdgeColor`

Defines a color with which to draw the edges. Default is `RGB ::Red`.

`SpecialEdgeColor`

Defines a color to be used to draw the set of edges specified. This option makes only sense if used with the option `SpecialEdges`.

`VertexColor`

Defines a color with which to draw the vertices. If this option is specified, the first two vertices are set to this color, too. They can be given different colors via `Vertex1Color` and `Vertex2Color`. Default is `RGB::Red`.

`SpecialVertexColor`

Defines a color to be used to draw the set of vertices specified. This option makes only sense if used with the option `SpecialVertices`.

`Vertex1Color`

Defines a color with which to draw the first vertex with (the starting vertex at the bottom of the first set). Default is `RGB::Blue`.

`Vertex2Color`

Defines a color with which to draw the second vertex with (the starting vertex at the bottom of the second set). Default is `RGB::Green`.

Return Values

`plot::Group2d`

Graph::plotCircleGraph

Plots a Graph in a circle layout

Syntax

```
Graph::plotCircleGraph(G, <PointSize = n>, <SpecialVertices = [v1, …,vn]>, <SpecialEdge
```

Description

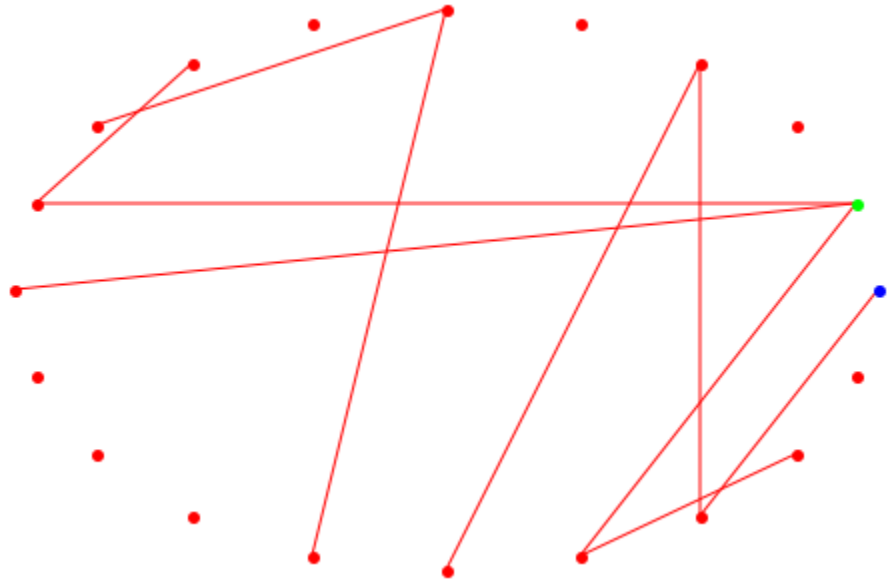
`Graph::plotCircleGraph(G)` returns a `plot::Group2d` object in which the vertices are ordered in a circle (rightmost position upwards). The first vertex is drawn in blue and the second in green. All other vertices are drawn in red. The edges are drawn in red. The width of the points is predefined with 40. If a vertex points to itself it will be drawn outside

Examples

Example 1

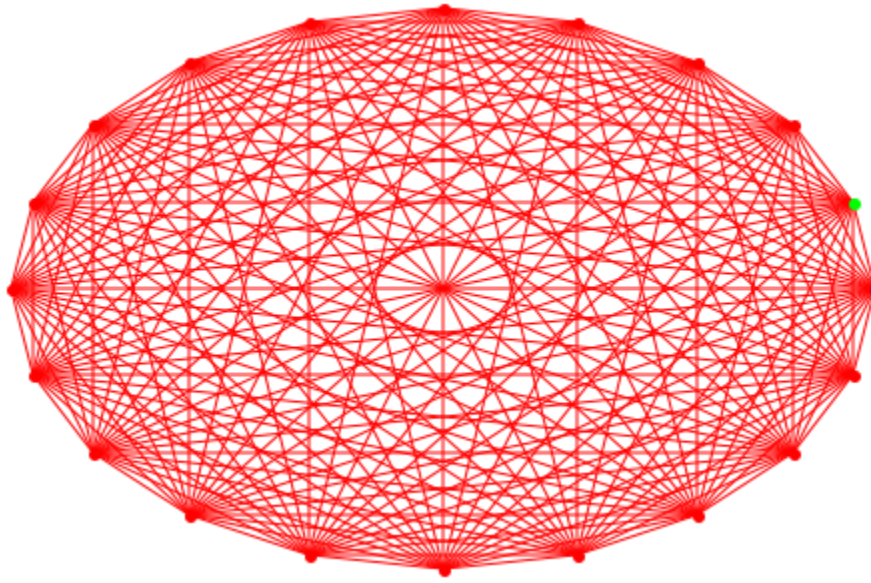
A random graph is created and plotted (your output may differ due random creation):

```
G1 := Graph::createRandomGraph(20, 10, Undirected):
plot(Graph::plotCircleGraph(G1))
```



Next, a complete graph will be plotted.

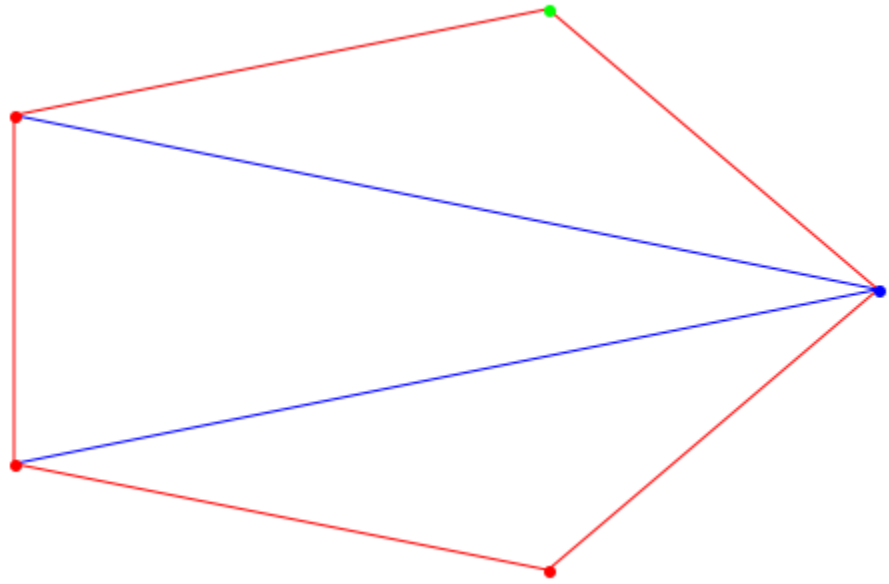
```
G1 := Graph::createCompleteGraph(20):
plot(Graph::plotCircleGraph(G1))
```



Example 2

If some edges are to be emphasized they can be drawn in a special color:

```
G2 := Graph([1, 2, 3, 4, 5],
            [[1, 2], [2, 3], [3, 4], [4, 5],
             [1, 3], [1, 4], [1, 5]]):
edges := [[1, 3], [1, 4]]:
plot(Graph::plotCircleGraph(G2,
                SpecialEdges = edges, SpecialEdgeColor = RGB::Blue))
```



Parameters

G

Graph

n

a positive integer

[v_1, …,v_n]

a list of vertices

[e_1, …,e_n]

a list of edges

Options

`PointSize`

Defines the thickness in which the points are drawn. Default is 40.

`SpecialVertices`

Defines a set of vertices. This option makes only sense if used with the option `SpecialVertexColor`.

`SpecialEdges`

Defines a set of edges. This option makes only sense if used with the option `SpecialEdgeColor`.

`EdgeColor`

Defines a color with which to draw the edges. Default is RGB::Red

`SpecialEdgeColor`

Defines a color to be used to draw the set of edges specified. This option makes only sense if used with the option `SpecialEdges`

`VertexColor`

Defines a color with which to draw the vertices. If this option is specified, the first two vertices are set to this color, too. They must be specified via `Vertex1Color` and `Vertex2Color` to distinct them again. Default is RGB::Red

`SpecialVertexColor`

Defines a color to be used to draw the set of vertices specified. This option makes only sense if used with the option `SpecialVertices`

`Vertex1Color`

Defines a color with which to draw the uppermost left (first) vertex with (the starting vertex). Default is RGB::Blue

`Vertex2Color`

Defines a color with which to draw the second vertex with. Default is RGB::Green

Return Values

`plot::Group2d`

Graph::plotGridGraph

Plots a Graph in a grid layout

Syntax

```
Graph::plotGridGraph(G, <PointSize = n>, <VerticesPerLine = n>, <VertexOrder = [n1, …,n
```

Description

`Graph::plotGridGraph(G)` returns a plot::Scene object in which the vertices are square ordered (topmost left to downmost right). The number of vertices per line is the floor of the squareroot of the number of the vertices. The first vertex is drawn in RGB::Blue and the second in RGB::Green. All other vertices are drawn in RGB::Red. The edges are drawn in RBG::Red. The width of the points is predefined with 40. If the last line contains only one vertex, it will be drawn centered in the middle of the line.

`Graph::plotGridGraph(G, VerticesPerLine=n)` returns a plot::Scene object like described above with one exception. In every line there are exactly `n` vertices. They appear in sorted order depending on their name. If the last row consists of only one vertex, this one will be centered.

`Graph::plotGridGraph(G, VerticesPerLine=[v1..vn])` returns a plot::Scene object like described above with one exception. In line 1 there are exactly `v1` vertices placed. In line 2 there are `v2` vertices and so on. The last line contains `vn` vertices. They appear in sorted order depending on their name. The sum of the numbers specified in VerticesPerLine must equal the number of vertices in the graph.

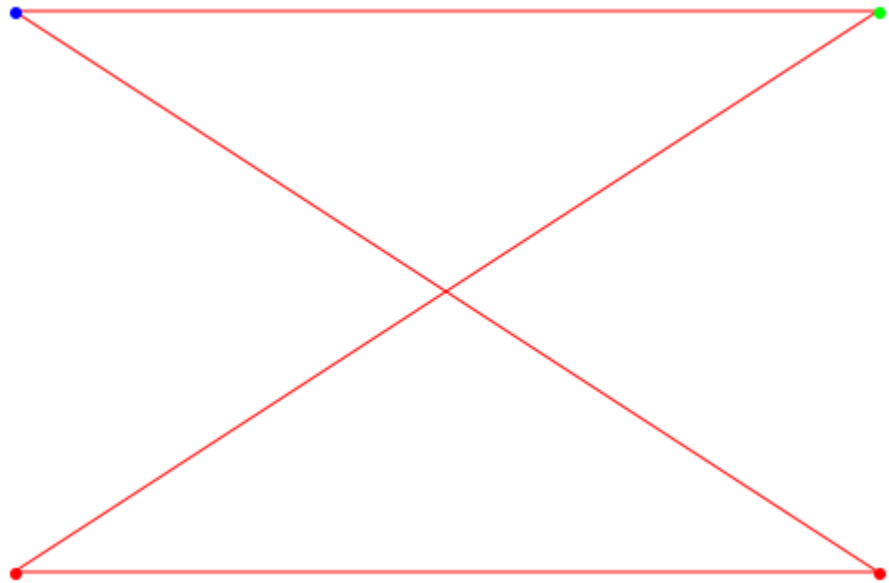
`Graph::plotGridGraph(G, VerticesPerLine=n, VertexOrder=[v1..vn])` returns a plot::Scene object like described above with one exception. In every line there are exactly `n` vertices. They appear in sorted order depending on the order that was specified in VertexOrder. `vi` can consist of any vertex defined as well as the substitute `None`. Nevertheless the number of vertices in `G` must not exceed the number of VerticesPerLine. If the last line holds only one vertex, it will be centered.

Examples

Example 1

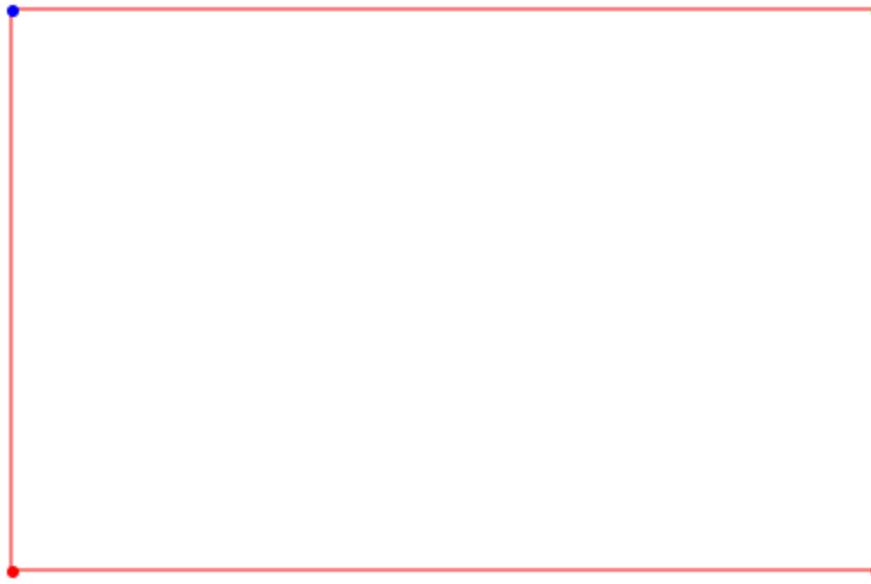
First, a small graph is created and plotted with the default values:

```
G := Graph([a, b, c, d], [[a, b], [b, c], [c, d], [d, a]]):
plot(Graph::plotGridGraph(G))
```



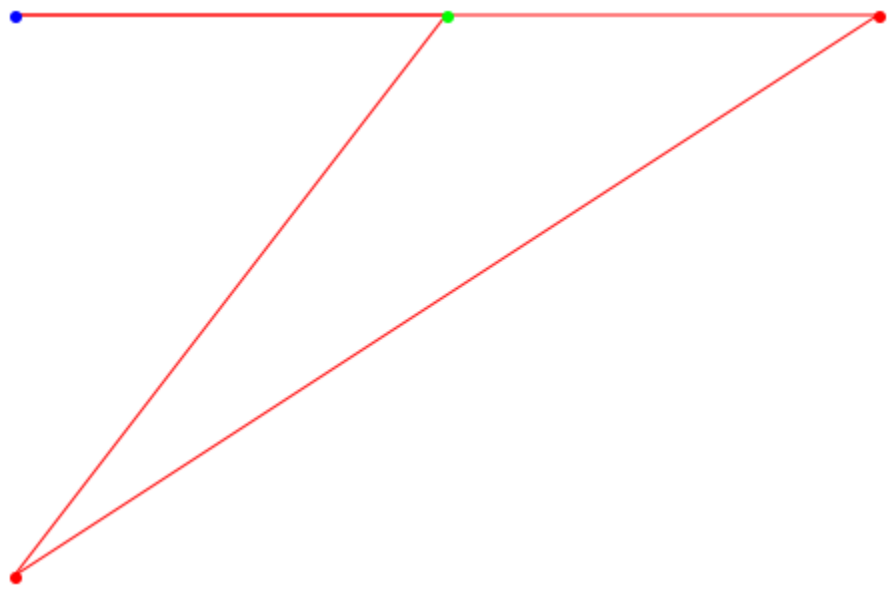
Now, we exchange the two vertices `c` and `d`. The order given above was `[a, b, c, d]`:

```
plot(Graph::plotGridGraph(G, VertexOrder = [a, b, d, c]))
```



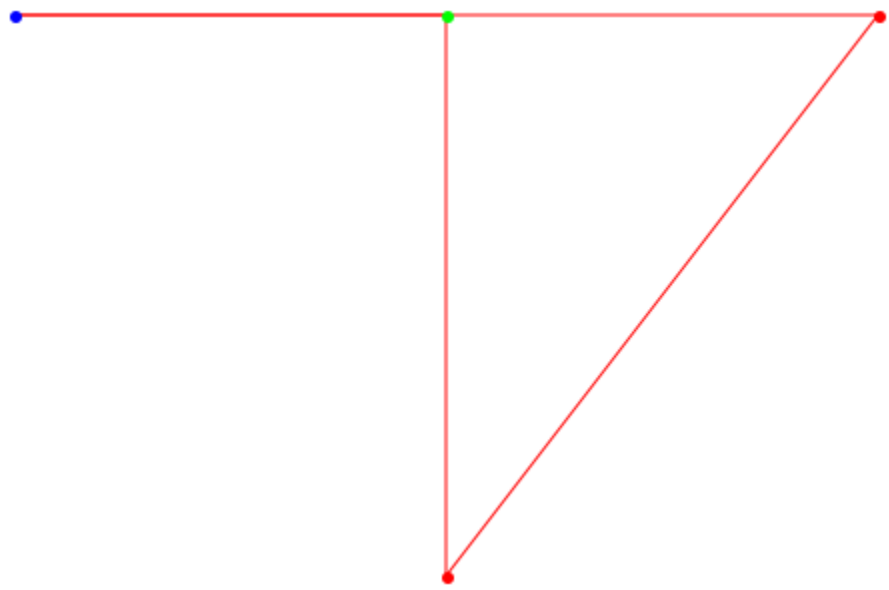
If only one vertex is placed in the last line, it will be centered:

```
plot(Graph::plotGridGraph(G, VertexOrder = [a, b, d, c],
                          VerticesPerLine = 3))
```



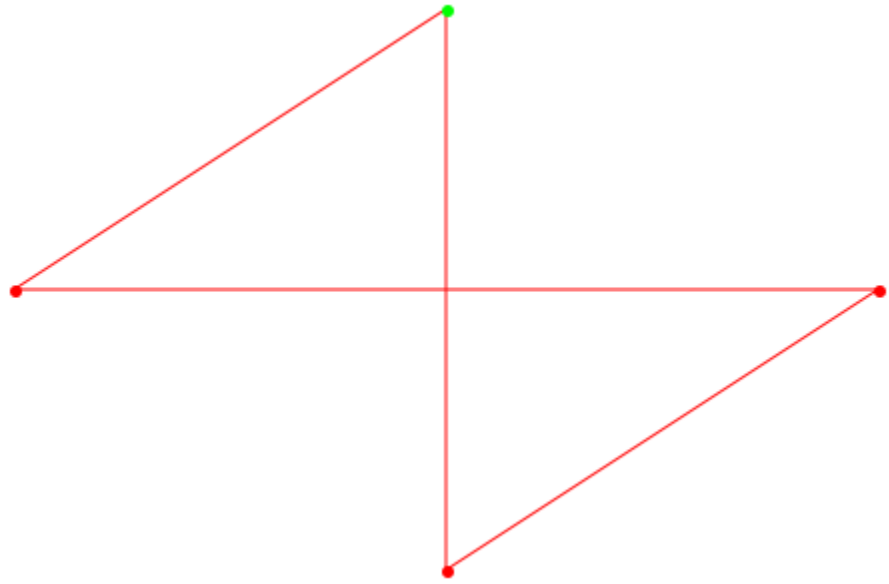
The same result can be gained by defining the Vertices per line specifically (in this case the number of vertices must be no less than the number of vertices in the graph):

```
plot(Graph::plotGridGraph(G, VertexOrder = [a, b, d, c],
                          VerticesPerLine = [3, 1]))
```



Now we get to the point, why the plot routine got the name Grid. The substitute `None` can be used whenever a place should be skipped. Think of some drawing paper with caskets. The layout is exactly the same. In this case it would consist of 3 caskets in each row. None leaves it blank, while a vertex from the Graph is drawn. Because the first casket is empty, the first color is omitted, too. The vertex `a` which is placed in the second casket is drawn as predefined in `Vertex2Color` (`RGB::Green`):

```
plot(Graph::plotGridGraph(G,
       VertexOrder = [None, a,    None,
                      b,    None, c,
                      None, d,    None],
       VerticesPerLine = 3))
```



Example 2

With the knowledge obtained so far, it is possible to get deeper into the art of creating objects. One of the most usefull outputs is that of a tree. Thus a Graph is created to be used for the tree output:

```
TreeGraph := Graph([a, b, c, d, e, f, g, h, i, j, k, l],
             [[a, b], [a, c], [b, d], [b, e], [c, f], [c, g],
              [d, h], [e, i], [e, j], [f, k], [g, l]], Directed):
```

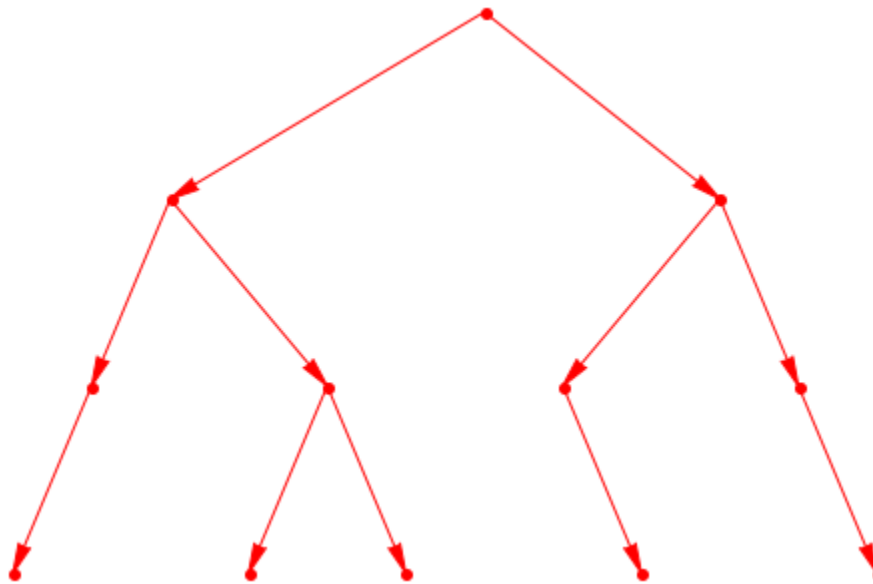
Next we define a special vertex order, because the vertices are not drawn the way they were defined:

```
vOrder :=
[None, None, None, None, None, None,
 a,    None, None, None, None, None,
 None, None, b,    None, None, None,
 None, None, None, c,    None, None,
 None, d,    None, None, e,    None,
 None, f,    None, None, g,    None,
 h,    None, None, i,    None, j,
```

```
 None, None, k,    None, None, l    ]:
```

Now it is time to have a look at how the tree looks:

```
plot(Graph::plotGridGraph(TreeGraph,
              VerticesPerLine = 12, VertexOrder = vOrder))
```

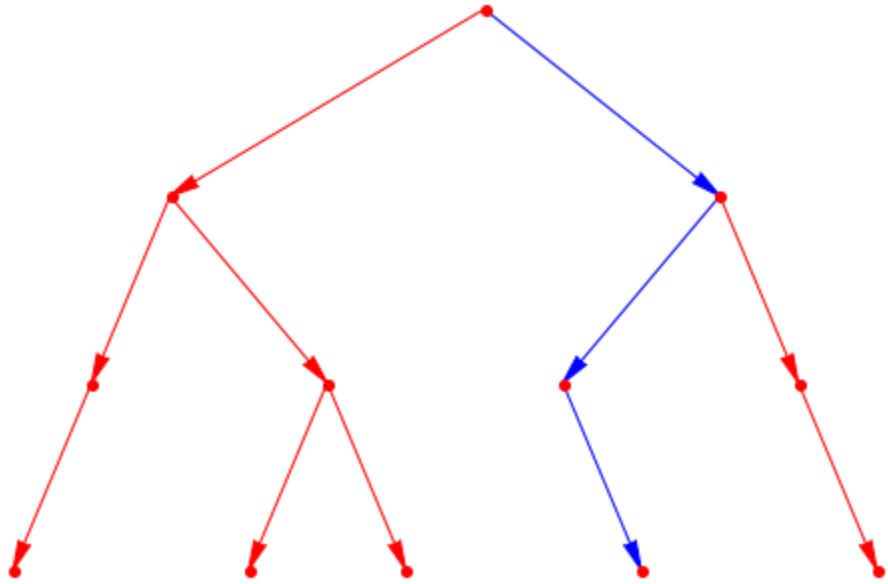


Now we want to see the path from vertex `a` to Vertexb. For this example it will be given explicitly. For bigger graphs one of the `shortestPath` procedures is recommended:

```
specialPath := [[a, c], [c, f], [f, k]]:
```

Finally we draw the path inside the Graph and have a good overview about the path it takes:

```
plot(Graph::plotGridGraph(TreeGraph,
         VerticesPerLine = 12, VertexOrder = vOrder,
         SpecialEdges = specialPath, SpecialEdgeColor = RGB::Blue))
```

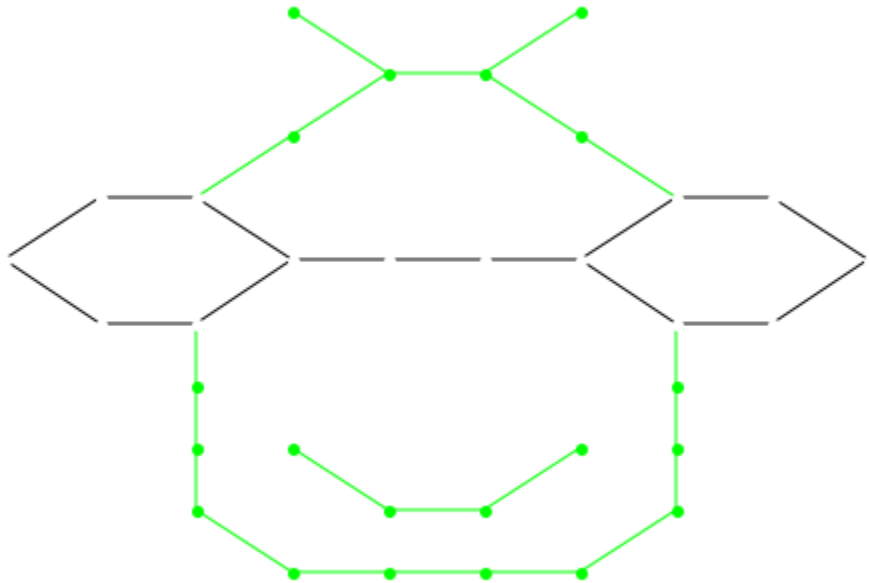


Example 3

To show what can be done with more detailed and complex examples a small outer face is being drawn (have a close look ath the Vertices which are not drawn, because the color is set to RBG::White and thus equals the background-color). Additionaly, the “eyes” have been colored differently, so the usage of `SpecialVertexColor` could be presented:

```
Smile := Graph([1,2,4,5,7,8,9,10,11,12,13,14,15,16,17,18,19,20,
                21,22,23,24,25,26,27,28,29,30,31,32,33,34,35,36],
          [[1,4],[2,5],[4,5],[7,4],[5,8],[7,10],[9,10],[10,14],[9,13],
           [13,19],[19,20],[20,14],[14,15],[15,16],[16,17],[17,11],
           [ 8,11],[11,12],[12,18],[18,22],[22,21],[21,17],[21,24],
           [24,28],[28,32],[32,36],[36,35],[35,34],[34,33],[33,29],
           [29,25],[25,23],[23,20],[26,30],[30,31],[31,27]]):
plot(
  Graph::plotGridGraph(Smile, VerticesPerLine = 10,
     VertexOrder = [
       None,None,None,   1,None,None,   2,None,None,None,
       None,None,None,None,   4,   5,None,None,None,None,
       None,None,None,   7,None,None,   8,None,None,None,
       None,   9,  10,None,None,None,None,  11,  12,None,
```

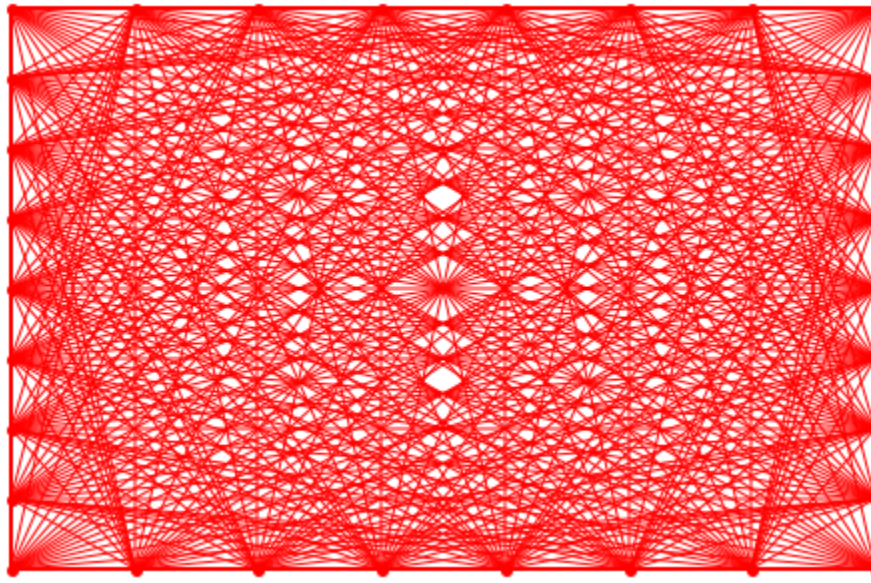
```
        13,None,None,  14,  15,  16,  17,None,None,  18,
      None,  19,  20,None,None,None,None,  21,  22,None,
      None,None,  23,None,None,None,None,  24,None,None,
      None,None,  25,  26,None,None,  27,  28,None,None,
      None,None,  29,None,  30,  31,None,  32,None,None,
      None,None,None,  33,  34,  35,  36,None,None,None],
    SpecialEdges = [[13,9],[9,10],[10,14],[14,20],[20,19],[19,13],
      [14,15],[15,16],[16,17],[17,21],[21,22],[22,18],[18,12],[12,11],
      [11,17]],
    SpecialVertices = [1,2,4,5,7,8,23,24,25,26,27,28,29,30,31,
      32,33,34,35,36],
    VertexColor = RGB::White,
    SpecialVertexColor = RGB::Green, EdgeColor = RGB::Green,
    SpecialEdgeColor = RGB::Black)
)
```



Example 4

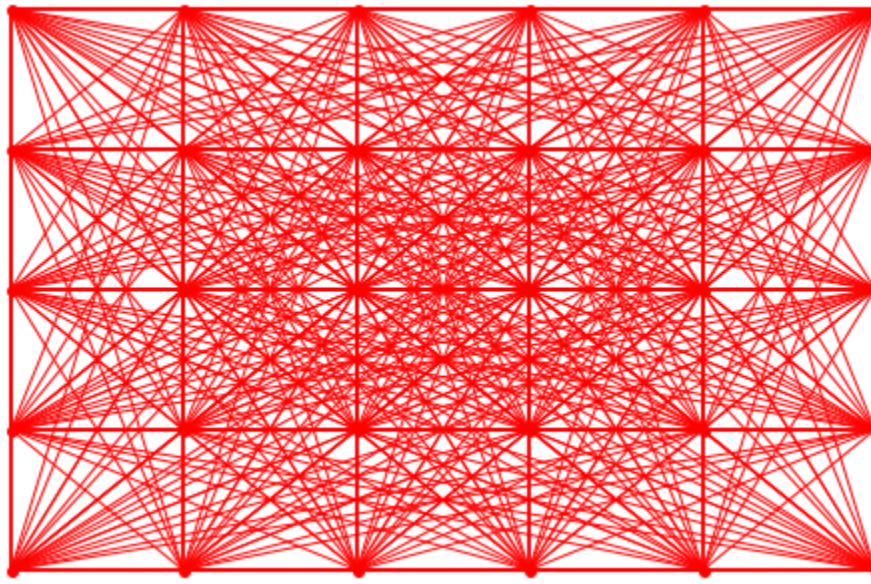
The next example is a complete graph drawn with the vertices ordered in a square so that all vertices can be connected inside the square:

```
CG := Graph::createCompleteGraph(30):
plot(Graph::plotGridGraph(CG,
       VerticesPerLine = [8, 2, 2, 2, 2, 2, 2, 8],
       Vertex1Color = RGB::Red, Vertex2Color = RGB::Red))
```



Using the default values in every line vertices are drawn and the graph looks not as "dense" as the above one:

```
plot(Graph::plotGridGraph(CG, Vertex1Color = RGB::Red,
                          Vertex2Color = RGB::Red))
```

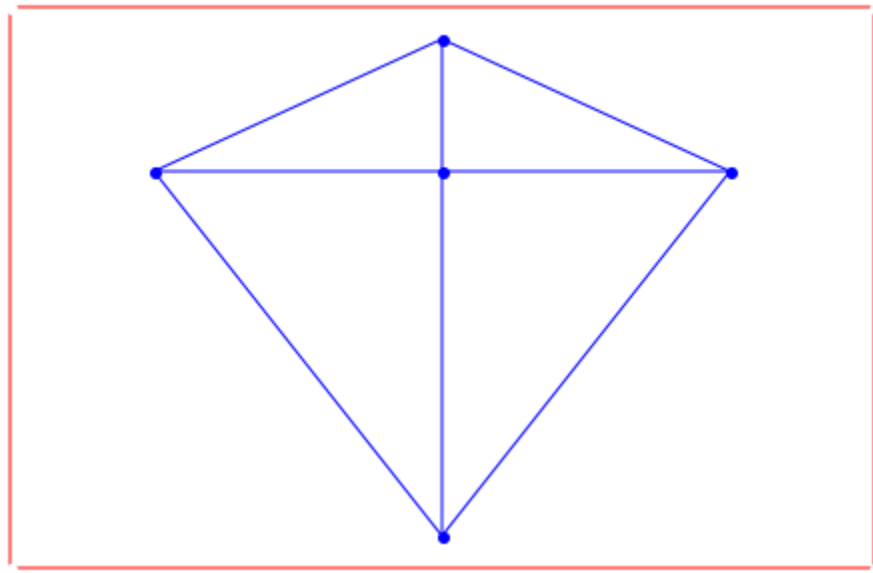


Example 5

The last example shows a small kite inside a frame:

```
Shield := Graph([1, 2, 3, 4, 5, 6, 7, 8, 9],
          [[1, 2], [1, 8], [2, 9], [8, 9], [3, 5], [4, 5],
           [5, 6], [5, 7], [3, 6], [6, 7], [3, 4], [4, 7]]):
plot(Graph::plotGridGraph(Shield, Vertex1Color = RGB::White,
       Vertex2Color = RGB::White, VertexColor = RGB::White,
       VerticesPerLine = 7,
       VertexOrder = [
           1,None,None,None,None,None,   2,
        None,None,None,   3,None,None,None,
        None,None,None,None,None,None,None,
        None,None,None,None,None,None,None,
        None,None,None,None,None,None,None,
        None,   4,None,   5,None,   6,None,
        None,None,None,None,None,None,None,
        None,None,None,None,None,None,None,
        None,None,None,None,None,None,None,
        None,None,None,None,None,None,None,
```

```
 None,None,None,None,None,None,None,
 None,None,None,None,None,None,None,
 None,None,None,None,None,None,None,
 None,None,None,None,None,None,None,
 None,None,None,None,None,None,None,
 None,None,None,None,None,None,None,
 None,None,None,   7,None,None,None,
    8,None,None,None,None,None,   9],
SpecialVertices = [3, 4, 5, 6, 7],
SpecialVertexColor = RGB::Blue,
SpecialEdges = [[3, 5], [4, 5], [5, 6], [5, 7],
                [3, 6], [6, 7], [3, 4], [4, 7]],
SpecialEdgeColor = RGB::Blue))
```



Parameters

G

Graph

n

a positive integer

[n_1, …,n_m]

a list of positive integers

[v_1, …,v_n]

a list of vertices

[e_1, …,e_n]

a list of edges

Options

PointSize

Defines the thickness in which the points are drawn. Default is 40.

VerticesPerLine

If specified as single number, this many vertices are placed in every row. If specified as list, the number of vertices per line are read out of the list. If the vertices are specified as list, the number of vertices must match either the number of vertices defined in the graph, or, if specified, the number defined in `VertexOrder`.

VertexOrder

Defines an order in which the vertices are to be placed. It starts in the upper left and ends in the lower right. The number of specified vertices must match the number of vertices defined in the graph or the sum of the vertices specified in VerticesPerLine.

SpecialVertices

Defines a set of vertices. This option makes only sense if used with the option `SpecialVertexColor`.

`SpecialEdges`

Defines a set of edges. This option makes only sense if used with the option `SpecialEdgeColor`.

`EdgeColor`

Defines a color with which to draw the edges. Default is RGB::Red

`SpecialEdgeColor`

Defines a color to be used to draw the set of edges specified. This option makes only sense if used with the option `SpecialEdges`

`VertexColor`

Defines a color with which to draw the vertices. If this option is specified, the first two vertices are set to this color, too. They must be specified via `Vertex1Color` and `Vertex2Color` to distinct them again. Default is RGB::Red

`SpecialVertexColor`

Defines a color to be used to draw the set of vertices specified. This option makes only sense if used with the option `SpecialVertices`

`Vertex1Color`

Defines a color with which to draw the uppermost left (first) vertex with (the starting vertex). If `VertexOrder` holds a `None` for this vertex, it will be skipped. Default is RGB::Blue

`Vertex2Color`

Defines a color with which to draw the second vertex with. If `VertexOrder` holds a `None` for this vertex, it will be skipped. Default is RGB::Green

Return Values

Plot::Scene.

Graph::printEdgeCostInformation

Prints the edge costs of a graph

Syntax

```
Graph::printEdgeCostInformation(G)
```

Description

`Graph::printEdgeCostInformation` prints the edge costs of a graph.

`Graph::printEdgeCostInformation(G)` prints the edge costs of the graph G

Examples

Example 1

A circle graph is created and the edge costs of it printed to screen:

```
G := Graph::createCircleGraph(3):
Graph::printEdgeCostInformation(G)
```

```
No edge costs defined.
```

```
G := Graph::setEdgeCosts(G, [[1, 2], [2, 3], [3, 1]], [10, 20, 30]):
Graph::printEdgeCostInformation(G)
```

```
Edge costs existing in the graph:
----------------------------------------
Edge [1, 2] has cost 10
Edge [2, 3] has cost 20
Edge [3, 1] has cost 30
```

Parameters

G

`Graph`

Return Values

Text containing information about the edge costs of a graph.

Graph::printEdgeDescInformation

Prints the edge descriptions of a graph

Syntax

```
Graph::printEdgeDescInformation(G)
```

Description

`Graph::printEdgeDescInformation` prints the edge descriptions of a graph.

`Graph::printEdgeDescInformation(G)` prints the edge descriptions of the graph *G*

Examples

Example 1

A circle graph is created and the edge descriptions of it printed to screen:

```
G := Graph::createCircleGraph(3):
Graph::printEdgeDescInformation(G)
```

```
No edge descriptions defined.
```

```
G := Graph::setEdgeDescriptions(G, [[1, 2], [2, 3], [3, 1]],
                                   ["Shortcut","Highway","Speedup"]):
Graph::printEdgeDescInformation(G)
```

```
Edge descriptions existing in the graph:
----------------------------------------
Edge [1, 2] = "Shortcut"
Edge [2, 3] = "Highway"
Edge [3, 1] = "Speedup"
```

Parameters

G

Graph

Return Values

Text containing information about the edge descriptions of a graph.

Graph::printEdgeInformation

Prints the edges of a graph

Syntax

```
Graph::printEdgeInformation(G)
```

Description

`Graph::printEdgeInformation` prints the edges of a graph.

`Graph::printEdgeInformation(G)` prints the edges used in the graph *G*.

Examples

Example 1

A circle graph is created and the edges of it printed to screen:

```
G := Graph::createCircleGraph(3):
Graph::printEdgeInformation(G)
```

```
Edges existing in the graph:
----------------------------
[1, 2], [2, 3], [3, 1]
```

Example 2

A complete graph is created and the edges of it printed to screen:

```
G := Graph::createCompleteGraph(3):
Graph::printEdgeInformation(G)
```

```
Edges existing in the graph:
```

```
----------------------------
[1, 2], [1, 3], [2, 1], [2, 3], [3, 1], [3, 2]
```

Parameters

G

Graph

Return Values

Text containing information about the edges of a graph.

Graph::printEdgeWeightInformation

Prints the edge weights of a graph

Syntax

```
Graph::printEdgeWeightInformation(G)
```

Description

`Graph::printEdgeWeightInformation` prints the edge weights of a graph.

`Graph::printEdgeWeightInformation(G)` prints the edge weights of the graph *G*

Examples

Example 1

A circle graph is created and the edge weights of it printed to screen:

```
G := Graph::createCircleGraph(3):
Graph::printEdgeWeightInformation(G)
```

```
No edge weights defined.
```

```
G := Graph::setEdgeWeights(G, [[1, 2], [2, 3], [3, 1]], [10, 20, 30]):
Graph::printEdgeWeightInformation(G)
```

```
Edge weights existing in the graph:
----------------------------------------
Edge [1, 2] has weight 10
Edge [2, 3] has weight 20
Edge [3, 1] has weight 30
```

Parameters

G

Graph

Return Values

Text containing information about the edge weights of a graph.

Graph::printGraphInformation

Prints the edges of a graph

Syntax

```
Graph::printGraphInformation(G)
```

Description

`Graph::printGraphInformation` prints a summary of various information about a graph.

`Graph::printGraphInformation(G)` prints a summary of the graph *G*

Examples

Example 1

A circle graph is created and a summary of it printed to screen:

```
G := Graph::createCircleGraph(3):
Graph::printGraphInformation(G)
```

```
Vertices: [1, 2, 3]
Edges: [[1, 2], [2, 3], [3, 1]]
Vertex weights: no vertex weights.
Edge descriptions: no edge descriptions.
Edge weights: no edge weights.
Edge costs: no edge costs.
Adjacency list (out): 1 = [2], 2 = [3], 3 = [1]
Adjacency list (in): 1 = [3], 2 = [1], 3 = [2]
Graph is directed.
```

Example 2

A complete graph is created and a summary of it printed to screen:

```
G := Graph::createCompleteGraph(3):
Graph::printGraphInformation(G)
```

```
Vertices: [1, 2, 3]
Edges: [[1, 2], [1, 3], [2, 1], [2, 3], [3, 1], [3, 2]]
Vertex weights: no vertex weights.
Edge descriptions: no edge descriptions.
Edge weights: no edge weights.
Edge costs: no edge costs.
Adjacency list (out): 1 = [2, 3], 2 = [1, 3], 3 = [1, 2]
Adjacency list (in): 1 = [2, 3], 2 = [1, 3], 3 = [1, 2]
Graph is undirected.
```

Parameters

G

Graph

Return Values

Text containing information about the graph.

Graph::printVertexInformation

Prints vertex information of a graph

Syntax

```
Graph::printVertexInformation(G)
```

Description

`Graph::printVertexInformation` prints the edges of a graph.

`Graph::printVertexInformation(G)` prints the edges of the graph G

Examples

Example 1

A circle graph is created and information of the vertices printed to screen:

```
G := Graph::createCircleGraph(3):
Graph::printVertexInformation(G)
```

```
Vertices existing in the graph:
------------------------------
Vertex 1 has weight None
Vertex 2 has weight None
Vertex 3 has weight None
```

Example 2

A complete graph is created and information of the vertices printed to screen:

```
G := Graph::createCompleteGraph(3):
Graph::printVertexInformation(G)
```

```
Vertices existing in the graph:
-------------------------------
Vertex 1 has weight None
Vertex 2 has weight None
Vertex 3 has weight None
```

Parameters

G

Graph

Return Values

Text containing information about the vertices of a graph.

Graph::removeEdge

Removes one or several edges from a graph

Syntax

```
Graph::removeEdge(G, e)
```

```
Graph::removeEdge(G, l)
```

Description

`Graph::removeEdge(G, [e1, ..., en])` removes edges `e1...en` from graph `G`.

`Graph::removeEdge` deletes one or several edges from a graph. An edge is represented by a list containing two vertices of the graph. A warning is printed if the specified edge is not contained in the graph.

`Graph::removeEdge(G, e)` removes the edge `e` from the graph `G`.

`Graph::removeEdge(G, l)` removes all edges in list `l` from graph `G`.

Examples

Example 1

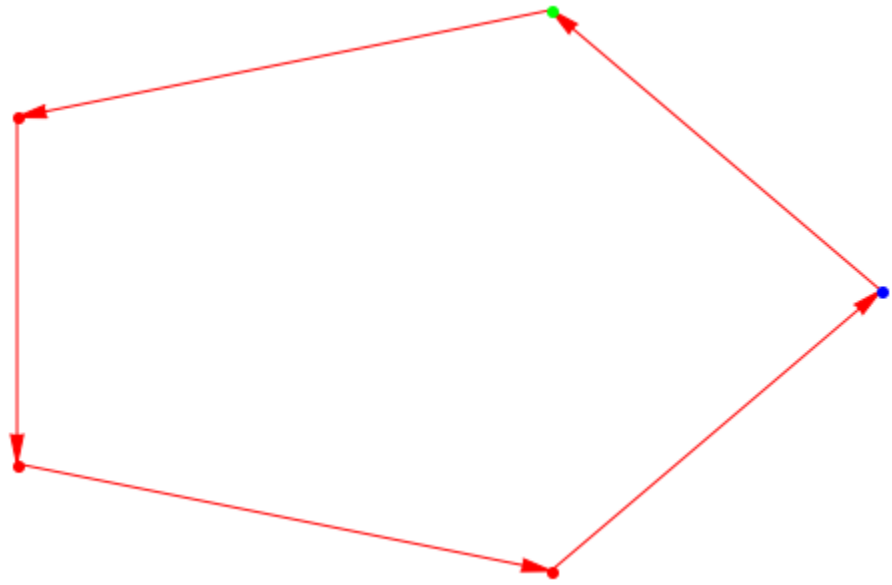
Removing an edge from a cyclic graph results in a (degenerated) tree:

```
G1 := Graph::createCircleGraph(5):
Graph::printGraphInformation(G1)
```

```
Vertices: [1, 2, 3, 4, 5]
Edges: [[1, 2], [2, 3], [3, 4], [4, 5], [5, 1]]
Vertex weights: no vertex weights.
```

```
Edge descriptions: no edge descriptions.
Edge weights: no edge weights.
Edge costs: no edge costs.
Adjacency list (out): 1 = [2], 2 = [3], 3 = [4], 4 = [5], 5 = [1]
Adjacency list (in): 1 = [5], 2 = [1], 3 = [2], 4 = [3], 5 = [4]
Graph is directed.
```

```
plot(Graph::plotCircleGraph(G1))
```

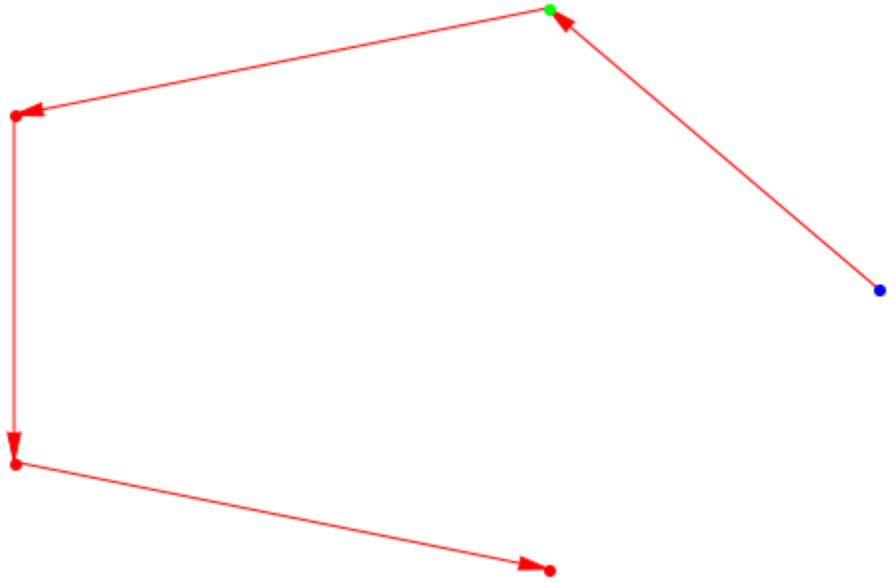


```
G2 := Graph::removeEdge(G1, [[5, 1]]):
Graph::printGraphInformation(G2)
```

```
Vertices: [1, 2, 3, 4, 5]
Edges: [[1, 2], [2, 3], [3, 4], [4, 5]]
Vertex weights: no vertex weights.
Edge descriptions: no edge descriptions.
Edge weights: no edge weights.
Edge costs: no edge costs.
Adjacency list (out): 1 = [2], 2 = [3], 3 = [4], 4 = [5], 5 = []
Adjacency list (in): 1 = [], 2 = [1], 3 = [2], 4 = [3], 5 = [4]
```

```
Graph is directed.

plot(Graph::plotCircleGraph(G2))
```

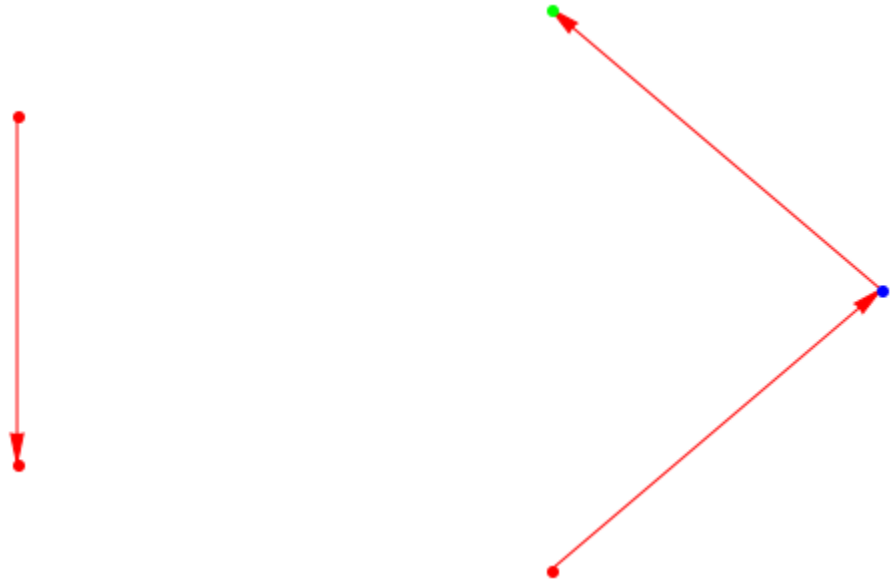


If more than one edge is to be removed they must also be specified in a list:

```
edges := [[2, 3], [4, 5]]:
G3 := Graph::removeEdge(G1, edges):
Graph::printGraphInformation(G3)
```

```
Vertices: [1, 2, 3, 4, 5]
Edges: [[1, 2], [3, 4], [5, 1]]
Vertex weights: no vertex weights.
Edge descriptions: no edge descriptions.
Edge weights: no edge weights.
Edge costs: no edge costs.
Adjacency list (out): 1 = [2], 2 = [], 3 = [4], 4 = [], 5 = [1]
Adjacency list (in): 1 = [5], 2 = [1], 3 = [], 4 = [3], 5 = []
Graph is directed.

plot(Graph::plotCircleGraph(G3))
```



Parameters

`l`

A list of edges

`e`

An edge

`G`

A graph

Return Values

Graph

Graph::removeVertex

Removes one or several vertices from a graph

Syntax

```
Graph::removeVertex(G, v)
```

```
Graph::removeVertex(G, l)
```

Description

`Graph::removeVertex(G, v)` removes vertex `v` from graph `G`.

`Graph::removeVertex(G, [v1, ..., vn])` removes vertices `v1...vn` from graph `G`.

`Graph::removeVertex` deletes one or several vertices from a graph. A warning is printed if the specified vertex is not contained in the graph.

Note: If a vertex is connected to other vertices with edges, they will be removed from the graph, too!

`Graph::removeVertex(G, v)` removes the vertex `v` from the graph `G`.

`Graph::removeVertex(G, l)` removes all vertices in list `l` from graph `G`.

Examples

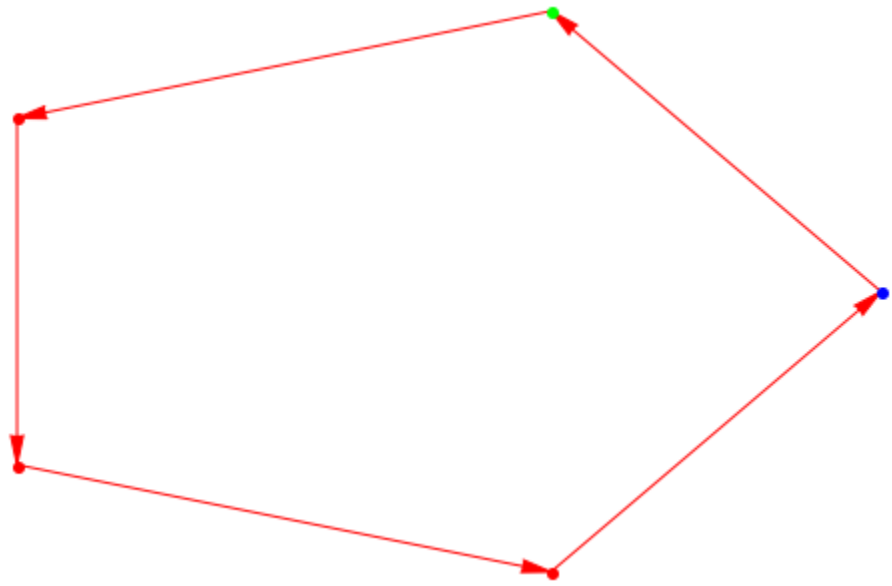
Example 1

Removing a vertex from a cyclic graph removes also two edges:

```
G1 := Graph::createCircleGraph(5):
Graph::printGraphInformation(G1)
```

```
Vertices: [1, 2, 3, 4, 5]
Edges: [[1, 2], [2, 3], [3, 4], [4, 5], [5, 1]]
Vertex weights: no vertex weights.
Edge descriptions: no edge descriptions.
Edge weights: no edge weights.
Edge costs: no edge costs.
Adjacency list (out): 1 = [2], 2 = [3], 3 = [4], 4 = [5], 5 = [1]
Adjacency list (in): 1 = [5], 2 = [1], 3 = [2], 4 = [3], 5 = [4]
Graph is directed.
```

```
plot(Graph::plotCircleGraph(G1))
```

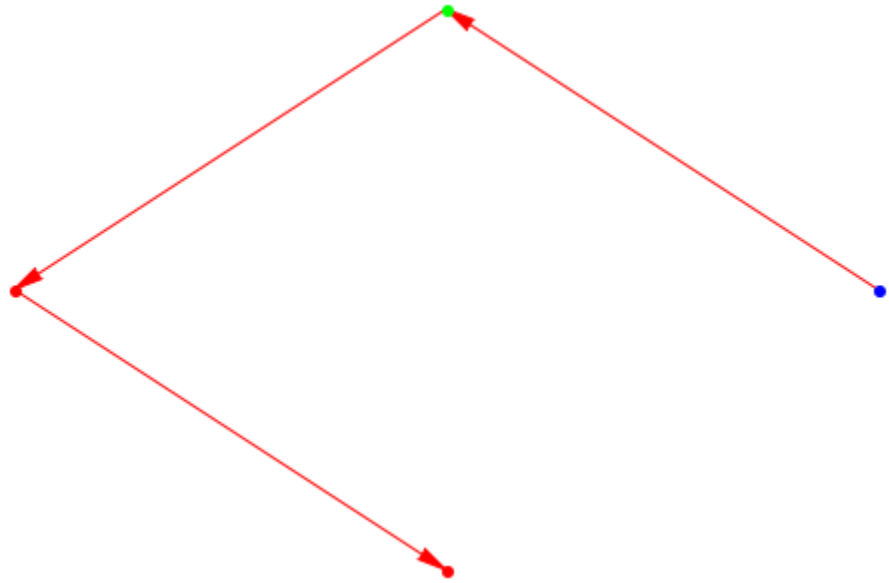


```
G2 := Graph::removeVertex(G1, [1]):
Graph::printGraphInformation(G2)
```

```
Vertices: [2, 3, 4, 5]
Edges: [[2, 3], [3, 4], [4, 5]]
Vertex weights: no vertex weights.
Edge descriptions: no edge descriptions.
Edge weights: no edge weights.
Edge costs: no edge costs.
Adjacency list (out): 2 = [3], 3 = [4], 4 = [5], 5 = []
```

```
Adjacency list (in): 2 = [], 3 = [2], 4 = [3], 5 = [4]
Graph is directed.
```

```
plot(Graph::plotCircleGraph(G2))
```

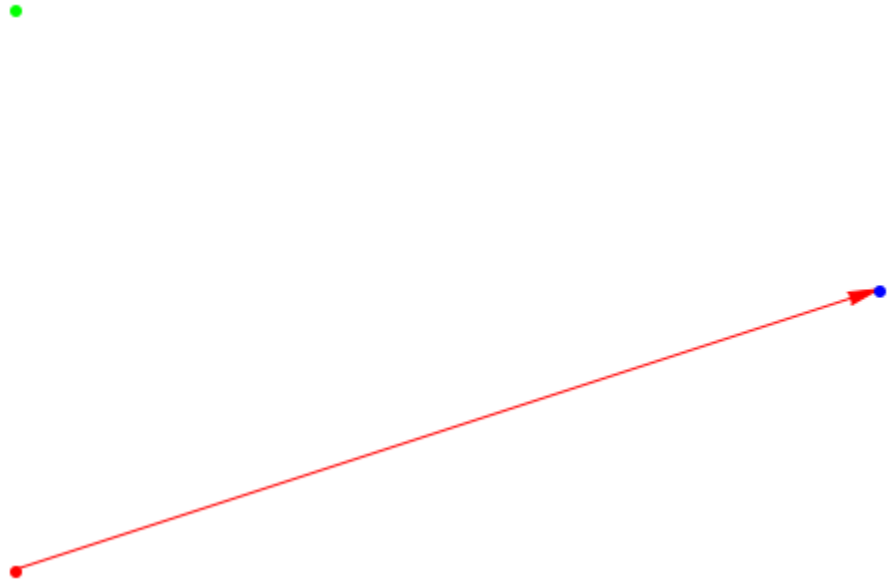


If more than one vertex is to be removed they must also be specified in a list:

```
vertices := [2, 4]:
G3 := Graph::removeVertex(G1, vertices):
Graph::printGraphInformation(G3)
```

```
Vertices: [1, 3, 5]
Edges: [[5, 1]]
Vertex weights: no vertex weights.
Edge descriptions: no edge descriptions.
Edge weights: no edge weights.
Edge costs: no edge costs.
Adjacency list (out): 1 = [], 2 = [], 3 = [], 5 = [1]
Adjacency list (in): 1 = [5], 2 = [], 3 = [], 5 = []
Graph is directed.
```

```
plot(Graph::plotCircleGraph(G3))
```



Parameters

`l`

A list of vertices

`v`

A vertex

`G`

A graph

Return Values

Graph

Graph::residualGraph

Computes the residual graph

Syntax

```
Graph::residualGraph(G, f, <Extended>)
```

Description

`Graph::residualGraph(G, flow)` computes the residual of the graph `G` with respect to the flow `flow`, meaning the graph that remains when the flow `flow` is "subtracted" from `G`.

`Graph::residualGraph` computes the residual graph with respect to a given flow. A flow in a Graph is a table `tbl`, where `tbl[[i,j]]` gives the number of units flowing from vertex `i` to vertex `j`.

If the optional argument `Extended` is given, then also those edges with a zero residual capacity are considered, otherwise these edges are omitted.

Examples

Example 1

In the following call, `G2` is the graph consisting of the remaining transport capacities after a given flow:

```
G1 := Graph::createCompleteGraph(3):
G2 := Graph::residualGraph(G1,
     table( [1, 2] = 1, [2, 1] = 1/2,
            [1, 3] = 0, [3, 1] = 0.5,
            [2, 3] = 1, [3, 2] = 0 ) ):
Graph::getEdgeWeights(G2)
```

[2, 1]	$\frac{1}{2}$
[1, 3]	1
[3, 1]	0.5
[3, 2]	1

The algorithm detects the lack of edge weights and edge costs and sets all edge weights and costs to default values of 1.

Example 2

The resulting graph depends on whether the option `Extended` is used:

```
V := [1, 2, 3, q, s]:
Edge := [[q, 1], [1, 2], [1, 3], [2, 3], [3, s]]:
up := [5, 4, 4, 2, 5]:
G := Graph(V,Edge,EdgeWeights = up, Directed):
flow := table([q, 1] = 5, [3, s] = 5, [1, 2] = 1,
              [1, 3] = 4, [2, 3] = 1):
G1 := Graph::residualGraph(G, flow):
Graph::printGraphInformation(G1);
```

```
Vertices: [1, 2, 3, q, s]
Edges: [[2, 1], [3, 1], [3, 2], [s, 3], [1, q], [1, 2], [2, 3]]
Vertex weights: no vertex weights.
Edge descriptions: no edge descriptions.
Edge weights: [1, 2] = 3, [2, 3] = 1, [2, 1] = 1, [3, 1] = 4, [3, 2] = 1, \
[s, 3] = 5, [1, q] = 5 (other existing edges have no weight)
Edge costs: [1, 2] = 1, [2, 3] = 1, [2, 1] = -3, [3, 1] = 0, [3, 2] = -1, \
[s, 3] = 0, [1, q] = 0 (other existing edges have costs zero)
Adjacency list (out): 1 = [2, q], 2 = [1, 3], 3 = [1, 2], q = [], s = [3]
Adjacency list (in): 1 = [2, 3], 2 = [1, 3], 3 = [2, s], q = [1], s = []
Graph is directed.
```

Edge Weights contain the residual graph with all the flows. Edge Costs show the flow that was substracted or added. For example edge [1, 2] had weight 4. After a flow of 3 was sent over it, the residual edge [2, 1] contains the flow of -3 and the residual edge [1, 2] contains the flow of 1. Since the negative flow of the reverted edge plus the flow of the

edge in the residual graph have to sum up to the flow it shows that the flow is calculated correctly. (- (- 3) + 1 = 4)

```
G1 := Graph::residualGraph(G, flow, Extended):
Graph::printGraphInformation(G1);
```

```
Vertices: [1, 2, 3, q, s]
Edges: [[2, 1], [3, 1], [3, 2], [s, 3], [1, q], [1, 2], [1, 3], [2, 3], [3\
, s], [q, 1]]
Vertex weights: no vertex weights.
Edge descriptions: no edge descriptions.
Edge weights: [q, 1] = 5, [1, 2] = 4, [1, 3] = 4, [2, 3] = 2, [3, s] = 5, \
[2, 1] = -4, [3, 1] = -4, [3, 2] = -2, [s, 3] = -5, [1, q] = -5 (other exi\
sting edges have no weight)
Edge costs: [1, 2] = 3, [1, 3] = 0, [2, 3] = 1, [3, s] = 0, [q, 1] = 0, [2\
, 1] = 1, [3, 1] = 4, [3, 2] = 1, [s, 3] = 5, [1, q] = 5 (other existing e\
dges have costs zero)
Adjacency list (out): 1 = [2, 3, q], 2 = [1, 3], 3 = [1, 2, s], q = [1], s\
 = [3]
Adjacency list (in): 1 = [2, 3, q], 2 = [1, 3], 3 = [1, 2, s], q = [1], s \
= [3]
Graph is directed.
```

Parameters

`G`

Graph

`flow`

The predefined flow

Options

`Extended`

Include edges with zero capacities

Return Values

`Graph`

Graph::revert

Reverts the edges of a graph.

Syntax

```
Graph::revert(G)
```

Description

`Graph::revert(G)` returns a graph in which all edges [u, v] and their properties belong to edges [v, u].

`Graph::revert` overloads the system function `revert`.

Examples

Example 1

First, a circle graph is defined with some additional settings:

```
G1 := Graph::createCircleGraph(3):
G1 := Graph::setEdgeWeights(G1, [[1, 2]], [20]):
G1 := Graph::setEdgeCosts(G1, [[1, 2]], [20]):
G1 := Graph::setEdgeDescriptions(G1, [[1, 2]], ["Shortcut"]):
Graph::printGraphInformation(G1)
```

```
Vertices: [1, 2, 3]
Edges: [[1, 2], [2, 3], [3, 1]]
Vertex weights: no vertex weights.
Edge descriptions: [1, 2] = "Shortcut"
Edge weights: [1, 2] = 20 (other existing edges have no weight)
Edge costs: [1, 2] = 20 (other existing edges have costs zero)
Adjacency list (out): 1 = [2], 2 = [3], 3 = [1]
Adjacency list (in): 1 = [3], 2 = [1], 3 = [2]
Graph is directed.
```

Now we revert the graph:

```
G2 := revert(G1):
Graph::printGraphInformation(G2)
```

```
Vertices: [1, 2, 3]
Edges: [[1, 3], [2, 1], [3, 2]]
Vertex weights: no vertex weights.
Edge descriptions: [2, 1] = "Shortcut"
Edge weights: [2, 1] = 20 (other existing edges have no weight)
Edge costs: [2, 1] = 20 (other existing edges have costs zero)
Adjacency list (out): 1 = [3], 2 = [1], 3 = [2]
Adjacency list (in): 1 = [2], 2 = [3], 3 = [1]
Graph is directed.
```

Parameters

G

A graph

Return Values

Graph

Graph::setEdgeCosts

Assigns edge costs to edges.

Syntax

```
Graph::setEdgeCosts(G, Edge, EdgeCosts, <OnlySpecifiedEdges>)
```

Description

`Graph::setEdgeCosts(G, Edges, EdgeCosts)` returns a graph where `Edges` have the edge costs `EdgeCosts`.

Note: If *OnlySpecifiedEdges* is stated and an undirected graph is to be changed, only the edges specified are used and not the inverted ones. For example if a call `Graph::setEdgeCosts(G, [[u,v]], [1])` is invoked, only the edge [*u*, *v*] gets 1. The edge [*v*, *u*] will not be changed.

Note: The substitute `None` can be used when a specified edge should not get the assigned costs.

Examples

Example 1

First lets define a graph without edge costs:

```
G1 := Graph::createCircleGraph(3):
Graph::getEdgeCosts(G1)
```

```
FAIL
```

`FAIL` was returned, because no edge costs werde defined.

```
Graph::getEdges(G1);
G1 := Graph::setEdgeCosts(G1, [[1, 2], [3, 1]], [5, 1/2]):
Graph::getEdgeCosts(G1)
```

$$[[1, 2], [2, 3], [3, 1]]$$

[1, 2]	5
[3, 1]	$\frac{1}{2}$

The first output shows all the edges and the second one the assigned edge costs.

```
G1 := Graph::setEdgeCosts(G1, [[2, 3]], [infinity]):
Graph::getEdgeCosts(G1)
```

[1, 2]	5
[3, 1]	$\frac{1}{2}$
[2, 3]	∞

It is easy to see that only the edge cost of `[2,3]` was changed.

Example 2

First lets define a graph without edge costs:

```
G1 := Graph::createCompleteGraph(3):
Graph::getEdgeCosts(G1)
```

FAIL

`FAIL` was returned, because no edge costs werde defined.

```
Graph::getEdges(G1);
G2 := Graph::setEdgeCosts(G1, [[1, 2], [3, 1]], [5, 1/2]):
Graph::getEdgeCosts(G2)
```

[[1, 2], [1, 3], [2, 1], [2, 3], [3, 1], [3, 2]]

[1, 2]	5
[2, 1]	5
[1, 3]	$\frac{1}{2}$
[3, 1]	$\frac{1}{2}$

The first output shows all the edges (the graph is undirected !) and the second one the assigned edge costs. Not only the specified edges were set, but also the reverted edges.

```
Graph::getEdges(G1);
G2 := Graph::setEdgeCosts(G1, [[1, 2], [3, 1]], [5, 1/2],
                          OnlySpecifiedEdges):
Graph::getEdgeCosts(G2)
```

[[1, 2], [1, 3], [2, 1], [2, 3], [3, 1], [3, 2]]

[1, 2]	5
[3, 1]	$\frac{1}{2}$

It is easy to see that only the specified edge costs were changed and not the reverted edges, too.

Example 3

There exist also the possibility to set the costs via a table instead of a list.

```
tbl := table([1, 2] = 15, [1, 3] = 20):
G2 := Graph::createCompleteGraph(3):

G2 := Graph::setEdgeCosts(G2, [[1, 2], [3, 1]], tbl):
Graph::getEdgeCosts(G2)
```

[1, 2]	15
[2, 1]	15
[1, 3]	20
[3, 1]	20

And again, but this time only the specified edges:

```
tbl := table([1, 2] = 15, [1, 3] = 20):
G2 := Graph::createCompleteGraph(3):

G2 := Graph::setEdgeCosts(G2, [[1, 2], [3, 1]], tbl,
                          OnlySpecifiedEdges):
Graph::getEdgeCosts(G2)
```

[1, 2]	15
[3, 1]	20

Parameters

`G`

A graph

`Edge`

A list of one or more edges

`EdgeCosts`

A list of one or more numbers, or a table consisting of the edges with their costs.

Options

`OnlySpecifiedEdges`

Only the edges specified in `Edge` will be set.

Return Values

New graph with the corrected edge costs.

Graph::setEdgeDescriptions

Assigns edge Descriptions to edges.

Syntax

```
Graph::setEdgeDescriptions(G, Edge, EdgeDescriptions, <OnlySpecifiedEdges>)
```

Description

`Graph::setEdgeDescriptions(G, Edges, EdgeDescriptions)` returns a graph where `Edges` have the edge descriptions `EdgeDescriptions`.

Note: If *OnlySpecifiedEdges* is stated and an undirected graph is to be changed, only the edges specified are used and not the inverted ones. For example if a call `Graph::setEdgeDescriptions(G, [[u,v]], [1])` is invoked, only the edge [u, v] gets 1. The edge [v, u] will not be changed.

Note: The substitute `None` can be used when a specified edge should not get the assigned description.

Examples

Example 1

First lets define a graph without edge descriptions:

```
G1 := Graph::createCircleGraph(3):
Graph::getEdgeDescriptions(G1)
```

```
FAIL
```

`FAIL` was returned, because no edge descriptions werde defined.

```
Graph::getEdges(G1);
G1 := Graph::setEdgeDescriptions(G1, [[1, 2],[3, 1]],
                                 ["Route 66", "Speedway"]):
Graph::getEdgeDescriptions(G1)
```

```
[[1, 2], [2, 3], [3, 1]]
```

[1, 2]	"Route 66"
[3, 1]	"Speedway"

The first output shows all the edges and the second one the assigned edge descriptions.

```
G1 := Graph::setEdgeDescriptions(G1, [[2, 3]], ["Shortcut"]):
Graph::getEdgeDescriptions(G1)
```

[1, 2]	"Route 66"
[3, 1]	"Speedway"
[2, 3]	"Shortcut"

It is easy to see that only the edge description of `[2,3]` was changed.

Example 2

First lets define a graph without edge Descriptions:

```
G1 := Graph::createCompleteGraph(3):
Graph::getEdgeDescriptions(G1)
```

```
FAIL
```

`FAIL` was returned, because no edge descriptions werde defined.

```
Graph::getEdges(G1);
G2 := Graph::setEdgeDescriptions(G1, [[1, 2], [3, 1]],
                                 ["Route 66", "Speedway"]):
```

```
Graph::getEdgeDescriptions(G2)
```

```
[[1, 2], [1, 3], [2, 1], [2, 3], [3, 1], [3, 2]]
```

[1, 2]	"Route 66"
[2, 1]	"Route 66"
[1, 3]	"Speedway"
[3, 1]	"Speedway"

The first output shows all the edges (the graph is undirected !) and the second one the assigned edge Descriptions. Not only the specified edges were set, but also the reverted edges.

```
Graph::getEdges(G1);
G2 := Graph::setEdgeDescriptions(G1, [[1, 2], [3, 1]],
                                 ["Route 66", "Speedway"],
                                 OnlySpecifiedEdges):
Graph::getEdgeDescriptions(G2)
```

```
[[1, 2], [1, 3], [2, 1], [2, 3], [3, 1], [3, 2]]
```

[1, 2]	"Route 66"
[3, 1]	"Speedway"

It is easy to see that only the specified edge Descriptions were changed and not the reverted edges, too.

Example 3

There exist also the possibility to set the Descriptions via a table instead of a list.

```
tbl := table([1, 2] = "Highway", [1, 3] = "Road to nowhere"):
G2 := Graph::createCompleteGraph(3):
Graph::getEdgeDescriptions(G2):

G2 := Graph::setEdgeDescriptions(G2, [[1, 2], [3, 1]], tbl):
Graph::getEdgeDescriptions(G2)
```

[1, 2]	"Highway"
[2, 1]	"Highway"
[1, 3]	"Road to nowhere"
[3, 1]	"Road to nowhere"

And again, but this time only the specified edges:

```
tbl := table([1, 2] = "Highway", [1, 3] = "Road to nowhere"):
G2 := Graph::createCompleteGraph(3):
Graph::getEdgeDescriptions(G2):
G2 := Graph::setEdgeDescriptions(G2, [[1, 2], [3, 1]], tbl,
                                 OnlySpecifiedEdges):
Graph::getEdgeDescriptions(G2)
```

[1, 2]	"Highway"
[3, 1]	"Road to nowhere"

Parameters

`G`

A graph

`Edge`

A list of one or more edges

`EdgeDescriptions`

A list of one or more numbers, or a table consisting of the edges with their descriptions.

Options

`OnlySpecifiedEdges`

Only the edges specified in `Edge` will be set.

Return Values

New graph with the corrected edge Descriptions.

Graph::setEdgeWeights

Assigns edge weights to edges.

Syntax

```
Graph::setEdgeWeights(G, Edge, EdgeWeights, <OnlySpecifiedEdges>)
```

Description

`Graph::setEdgeWeights(G, Edges, EdgeWeights)` returns a graph where `Edges` have the edge weights `EdgeWeights`.

Note: If *OnlySpecifiedEdges* is stated and an undirected graph is to be changed, only the edges specified are used and not the inverted ones. For example if a call `Graph::setEdgeWeights(G, [[u,v]], [1])` is invoked, only the edge [*u*, *v*] gets 1. The edge [*v*, *u*] will not be changed.

Note: The substitute `None` can be used when a specified edge should not get the assigned weights.

Examples

Example 1

How to set edge weights with a list:

```
G1 := Graph::createCircleGraph(3):
Graph::getEdgeWeights(G1)
```

```
FAIL
```

`FAIL` was returned, because no edge weights were defined.

```
Graph::getEdges(G1);
G1 := Graph::setEdgeWeights(G1, [[1, 2], [3, 1]], [5, 1/2]):
Graph::getEdgeWeights(G1)
```

$$[[1, 2], [2, 3], [3, 1]]$$

[1, 2]	5
[3, 1]	$\frac{1}{2}$

The first output shows all the edges and the second one the assigned edge weights.

```
G1 := Graph::setEdgeWeights(G1, [[2, 3]], [infinity]):
Graph::getEdgeWeights(G1)
```

[1, 2]	5
[3, 1]	$\frac{1}{2}$
[2, 3]	∞

It is easy to see that only the edge weight of `[2, 3]` was changed.

Example 2

How to set edge weights with a table:

```
G1 := Graph::createCompleteGraph(3):
Graph::getEdgeWeights(G1)
```

FAIL

`FAIL` was returned, because no edge weights were defined.

```
Graph::getEdges(G1);
G2 := Graph::setEdgeWeights(G1, [[1, 2], [3, 1]], [5, 1/2]):
Graph::getEdgeWeights(G2)
```

[[1, 2], [1, 3], [2, 1], [2, 3], [3, 1], [3, 2]]

[1, 2]	5
[2, 1]	5
[1, 3]	$\frac{1}{2}$
[3, 1]	$\frac{1}{2}$

The first output shows all the edges (the graph is undirected !) and the second one the assigned edge weights. Not only the specified edges were set, but also the reverted edges.

```
Graph::getEdges(G1);
G2 := Graph::setEdgeWeights(G1, [[1, 2], [3, 1]], [5, 1/2],
                            OnlySpecifiedEdges):
Graph::getEdgeWeights(G2)
```

[[1, 2], [1, 3], [2, 1], [2, 3], [3, 1], [3, 2]]

[1, 2]	5
[3, 1]	$\frac{1}{2}$

It is easy to see that only the specified edge Weights were changed and not the reverted edges, too.

Example 3

There exist also the possibility to set the weights via a table instead of a list.

```
tbl := table([1, 2] = 15, [1, 3] = 20):
G2 := Graph::createCompleteGraph(3):

G2 := Graph::setEdgeWeights(G2, [[1, 2], [3, 1]], tbl):
Graph::getEdgeWeights(G2)
```

[1, 2]	15
[2, 1]	15
[1, 3]	20
[3, 1]	20

And again, but this time only the specified edges:

```
tbl := table([1, 2] = 15, [1, 3] = 20):
G2 := Graph::createCompleteGraph(3):

G2 := Graph::setEdgeWeights(G2, [[1, 2], [3, 1]], tbl,
                            OnlySpecifiedEdges):
Graph::getEdgeWeights(G2)
```

[1, 2]	15
[3, 1]	20

Parameters

`G`

A graph

`Edge`

A list of one or more edges

`EdgeWeights`

A list of one or more numbers, or a table consisting of the edges with their weights.

Options

`OnlySpecifiedEdges`

Only the edges specified in `Edge` will be set.

Return Values

New graph with the corrected edge weights.

Graph::setVertexWeights

Assigns vertex weights to vertices.

Syntax

```
Graph::setVertexWeights(G, Vertex, VertexWeights)
```

Description

`Graph::setVertexWeights(G, Vertex, VertexWeights)` returns a graph where the vertices in `Vertex` have the vertex weights `VertexWeights`.

Note: The substitute `None` can be used when a specified edge should not get the assigned weights.

Examples

Example 1

How to set vertex weights with a list:

```
G1 := Graph::createCircleGraph(3):
Graph::getVertexWeights(G1)
```

```
FAIL
```

`FAIL` was returned, because no vertex weights were defined.

```
Graph::getVertices(G1);
G1 := Graph::setVertexWeights(G1, [1, 3], [5, 1/2]):
Graph::getVertexWeights(G1)
```

```
[1, 2, 3]
```

1	5
3	$\frac{1}{2}$

The first output shows all vertices and the second the assigned vertex weights.

Example 2

How to set vertex weights with a table:

```
G1 := Graph::createCompleteGraph(3):
Graph::getVertexWeights(G1)
```

FAIL

FAIL was returned, because no vertex weights were defined.

```
G2 := Graph::createCompleteGraph(3):
tbl := table(1 = 15, 3 = 20):
G2 := Graph::setVertexWeights(G2, [1, 3], tbl):
Graph::getVertexWeights(G2)
```

1	15
3	20

Parameters

G

A graph

Vertex

A list of one or more vertices

VertexWeights

A list of one or more numbers, or a table consisting of the vertices with their weights.

Return Values

New graph with the corrected vertex weights.

Graph::shortestPathAllPairs

Shortest paths from and to all vertices

Syntax

```
Graph::shortestPathAllPairs(G, <SearchFor = Weights | Costs>)
```

Description

`Graph::shortestPathAllPairs(G)` returns a table with all paths between all vertices.

`Graph::shortestPathAllPairs(G, SearchFor=Costs)` returns a `table` with all paths according to the edge costs.

`Graph::shortestPathAllPairs(G, SearchFor=Weights)` returns a `table` with all paths according to the edge weights. (Default)

Examples

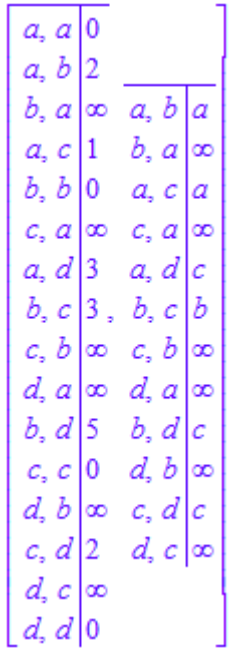
Example 1

A small graph to be used for the algorithms:

```
G := Graph([a, b, c, d], [[a, b], [a, c], [b, c], [c, d]],
           EdgeWeights = [2, 1, 3, 2],
           EdgeCosts = [1, 3,1, 2],
           Directed):
```

Now the shortest path between all vertices is found according to the edge weights, because no specification was given and defaults are used.

```
Graph::shortestPathAllPairs(G)
```



a, a	0
a, b	2
b, a	∞
a, c	1
b, b	0
c, a	∞
a, d	3
b, c	3 ,
c, b	∞
d, a	∞
b, d	5
c, c	0
d, b	∞
c, d	2
d, c	∞
d, d	0

a, b	a
b, a	∞
a, c	a
c, a	∞
a, d	c
b, c	b
c, b	∞
d, a	∞
b, d	c
d, b	∞
c, d	c
d, c	∞

The interpretation of the table is as follows:

The first table holds each path: (FromVertex, ToVertex) = weight/cost. The second table is a bit more tricky. The left hand side again is the path itself. On the right hand side though, the vertex that was found before the final vertex was reached is stated. If for example the path from `a` to `d` is to be found with all vertices that are used within this path it is done in the following way: First take the path itself `(a, d)`. The predecessor is `c`. Now have a look for the path `(a, c)`. It's predecessor is `a`. Since the predecessor equals the first vertex in the path to be found, the search is over and the path `a -> c -> d` is found. To search the graph for costs the option `SearchFor=Costs` has to be added.

```
Graph::shortestPathAllPairs(G, SearchFor = Costs)
```

a, a	0
a, b	1
b, a	∞
a, c	2
b, b	0
c, a	∞
a, d	4
b, c	1 ,
c, b	∞
d, a	∞
b, d	3
c, c	0
d, b	∞
c, d	2
d, c	∞
d, d	0

a, b	a
b, a	∞
a, c	b
c, a	∞
a, d	c
b, c	b
c, b	∞
d, a	∞
b, d	c
d, b	∞
c, d	c
d, c	∞

Example 2

Now the weights of the graph are changed, so that negative edge weights are assigned. You will see that this does not influence the correctness of the results the algorithm returns (like for example Dijkstra).

```
G := Graph([a, b, c, d], [[a, b], [a, c], [b, c], [c, d]],
           EdgeWeights = [2, 1, 3, 2],
           EdgeCosts = [1, 3,1, 2],
           Directed):

G := Graph::setEdgeWeights(G, Graph::getEdges(G), [2, 1, -3, 2]):

Graph::shortestPathAllPairs(G)
```

a, a	0			
a, b	2			
b, a	∞	a, b	a	
a, c	−1	b, a	∞	
b, b	0	a, c	b	
c, a	∞	c, a	∞	
a, d	1	a, d	c	
b, c	−3,	b, c	b	
c, b	∞	c, b	∞	
d, a	∞	d, a	∞	
b, d	−1	b, d	c	
c, c	0	d, b	∞	
d, b	∞	c, d	c	
c, d	2	d, c	∞	
d, c	∞			
d, d	0			

Parameters

G

Graph

Options

SearchFor

Defines whether the weights of the graph are considered or the costs. Default is `Weights`.

Return Values

List consisting of two tables. The first table holds the sum of the path weights or costs and the second the predecessors for every path (to find the complete path).

Algorithms

The algorithm is also known as Floyd-Warshall or Roy-Warshall algorithm. The idea behind it is to solve the problem by continuous matrix multiplication. he only difference is that Floyd uses the assignment $a_{i,j} := min(a_{i,j}, a_{i,k} + a_{k,j})$.

Graph::shortestPathSingleSource

Shortest paths from one single vertex

Syntax

```
Graph::shortestPathSingleSource(G, StartVertex, <EndVertex = v>, <SearchWith = Dijkstra
```

Description

`Graph::shortestPathSingleSource(G, StartVertex=vertex)` gives the length of a shortest path from `StartVertex` to every other vertex in `G`.

`Graph::shortestPathSingleSource(G, StartVertex=sv)` returns a table with all paths from *sv* to any other.

`Graph::shortestPathSingleSource(G, StartVertex=sv, ReturnAsGraph)` returns a `table` with all paths from *sv* to any other because EndVertex has to be set in order to get a Graph as return value.

With `Graph::shortestPathSingleSource(G, StartVertex=sv, EndVertex=ev, SearchWith=Dijkstra, SearchFor=Costs)` returns a `table` from vertex *sv* to vertex *ev* according to Dijkstra which used the edge-costs for its algorithm.

Note: Using Dijkstra for shortest path can be erroneus if the graph contains negative edges.

Note: If `ReturnAsGraph` is stated and `EndVertex` omitted, a table is returned nevertheless.

Examples

Example 1

A small graph to be used for the algorithms:

```
G := Graph([a, b, c, d], [[a, b], [a, c], [b, c], [c, d]],
           EdgeWeights = [2, 1, 3, 2],
           EdgeCosts = [1, 3, 1, 2], Directed):
```

Now the shortest path is found according to Bellman using edge weights, because no specification was given and defaults are used:

```
Graph::shortestPathSingleSource(G, StartVertex = [a])
```

$$\left[\begin{array}{c|c} a & 0 \\ b & 2 \\ c & 1 \\ d & 3 \end{array}, \begin{array}{c|c} b & a \\ c & a \\ d & c \end{array}\right]$$

To search the graph with Bellman for costs the option `SearchFor=Costs` has to be added:

```
Graph::shortestPathSingleSource(G, StartVertex = [a],
                                SearchFor=Costs)
```

$$\left[\begin{array}{c|c} a & 0 \\ b & 1 \\ c & 2 \\ d & 4 \end{array}, \begin{array}{c|c} b & a \\ c & b \\ d & c \end{array}\right]$$

Example 2

Now the weights of the graph are changed, so that negative edge weights are assigned. After this the procedure is called again with Bellman and afterwards with Dijkstra to compare the results:

```
G := Graph([a, b, c, d], [[a, b], [a, c], [b, c], [c, d]],
           EdgeWeights = [2, 1, 3, 2],
           EdgeCosts = [1, 3, 1, 2], Directed):

G := Graph::setEdgeWeights(G, Graph::getEdges(G),
                           [2, 1, -3, 2]):

Graph::shortestPathSingleSource(G, StartVertex = [a],
```

```
                                    SearchWith = Bellman),
Graph::shortestPathSingleSource(G, StartVertex = [a],
                                    SearchWith = Dijkstra)
```

$$\left[\begin{array}{c|c} a & 0 \\ b & 2 \\ c & -1 \\ d & 1 \end{array}, \begin{array}{c|c} b & a \\ c & b \\ d & c \end{array}\right], \left[\begin{array}{c|c} a & 0 \\ b & 2 \\ c & -1 \\ d & 3 \end{array}, \begin{array}{c|c} b & a \\ c & a \\ d & c \end{array}\right]$$

This is a typical example where Dijkstra can make a mistake because he does not correct earlier solutions (a so called greedy strategy). Although vertex `c` gets the correct value `-1`, at the time `d` got the value `3`, vertex `c` still held the value `1`. This happens because Dijkstra first searches the best solutions (a->c = 1) then traverses further (c->d = 1 + 2 = 3). In spite of changing the value of vertex `c` the value for d is never to be changed again (because no other path ever reaches it again):

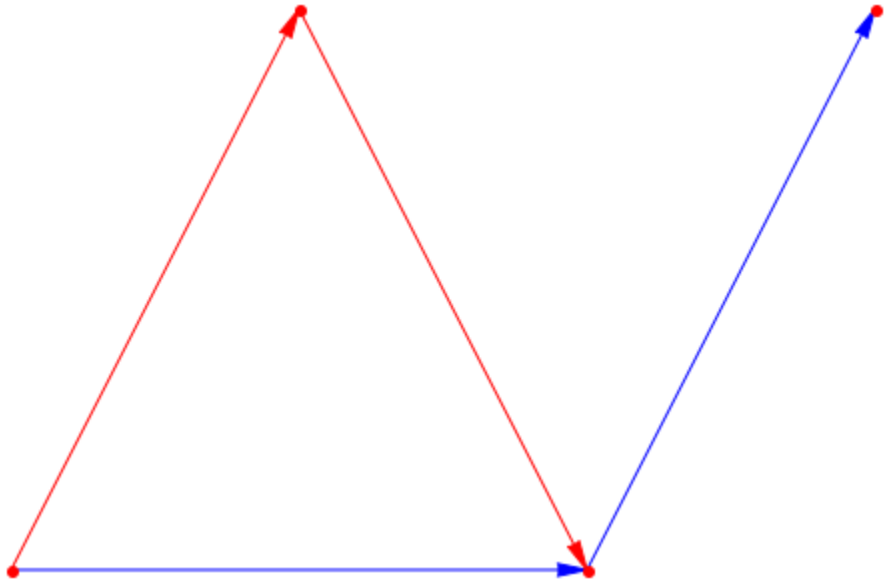
It might be interesting to see a shortest path inside the graph. Here are two steps that accomplish this task:

Fist step (creation of a shortest path graph [in this case with Dijkstra]):

```
dijk := Graph::shortestPathSingleSource(G, StartVertex = [a],
                                        EndVertex = [d],
                                        SearchWith = Dijkstra,
                                        ReturnAsGraph):
```

Second step (combination of the graphs using `plotGridGraph`):

```
plot(Graph::plotGridGraph(G, VerticesPerLine = 4,
       VertexOrder = [None, b, None, d, a, None, c, None],
       VertexColor = RGB::Red,
       SpecialEdges = Graph::getEdges(dijk),
       SpecialEdgeColor = RGB::Blue))
```



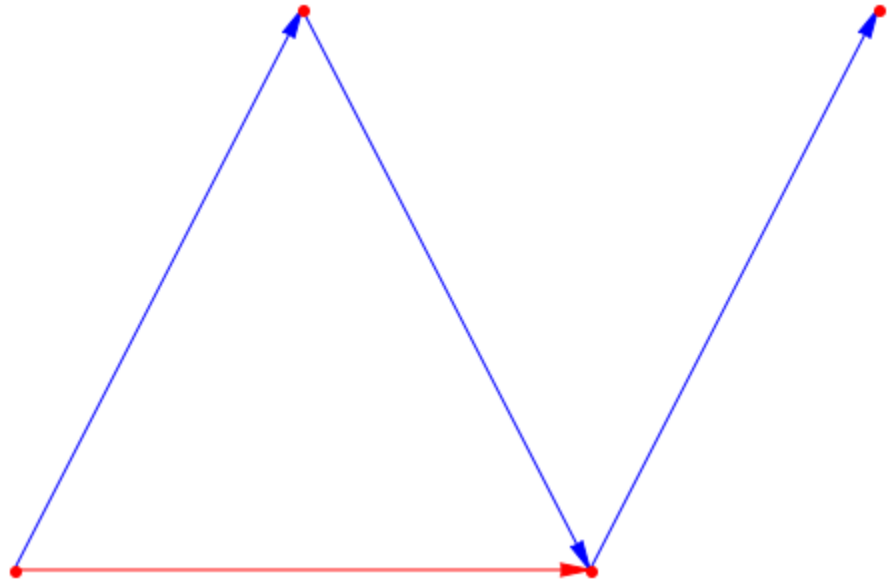
The same with Bellman to show the differences:

Fist step (creation of a shortest path graph [in this case with Dijkstra]):

```
bellm := Graph::shortestPathSingleSource(G, StartVertex = [a],
                                         EndVertex = [d],
                                         SearchWith = Bellman,
                                         ReturnAsGraph):
```

Second step (combination of the graphs using `plotGridGraph`):

```
plot(Graph::plotGridGraph(G, VerticesPerLine = 4,
       VertexOrder = [None, b, None, d, a, None, c, None],
       VertexColor = RGB::Red,
       SpecialEdges = Graph::getEdges(bellm),
       SpecialEdgeColor = RGB::Blue))
```



Parameters

`G`

Graph

`vertex`

A vertex in G

Options

`EndVertex`

Specifies a single vertex to which the shortest path is to be found.

`SearchWith`

Defines the algorithm to use. Dijkstra can be erroneus if the graph consists of negative edges. Default is `Bellman`

`SearchFor`

Defines whether the weights of the graph are considered or the costs. Default is `Weights`.

`ReturnAsGraph`

If stated and EndVertex is set, the path is returned as a Graph. If stated and EndVertex is not set, this option is omitted.

Return Values

Either a list consisting of two tables or a Graph. The first table holds the weights or cost for each vertex and the second the predecessors for every vertex (to find the path)

Algorithms

Both, Bellman and Dijkstra expect a Graph without negative circles. Only Dijkstra may return erroneous results when negative edges (either weights or costs) are specified.

The Bellman algorithm originated from: Ahuja, Magnanti, Orlin: Graph Flows, Prentice-Hall, 1993 Section 5.4

Graph::stronglyConnectedComponents

Finds the strongly connected components

Syntax

```
Graph::stronglyConnectedComponents(G)
```

Description

`Graph::stronglyConnectedComponents(G)` finds the strongly connected components of `G`

`Graph::stronglyConnectedComponents` returns all the strongly connected components of a graph. Single vertices form a component of themselves.

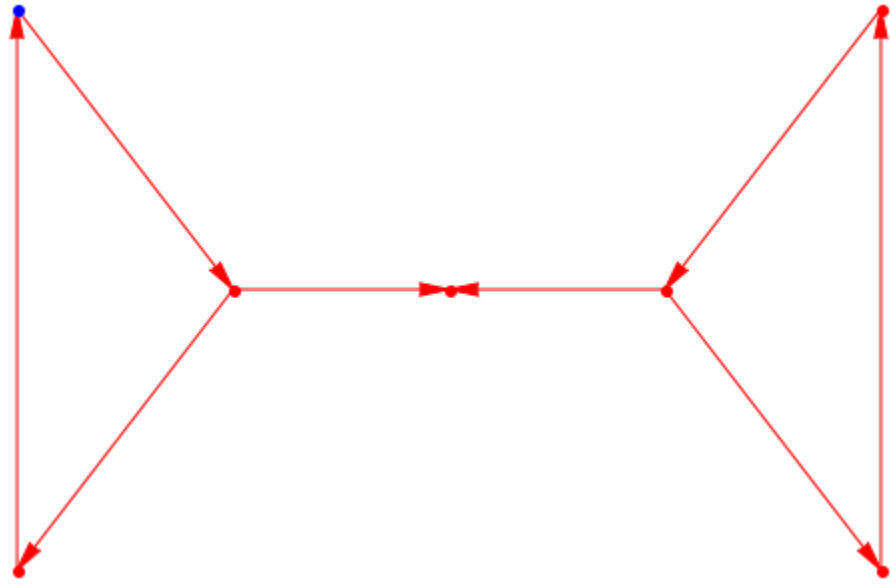
Examples

Example 1

Two obvious components pointing to a single vertex:

```
G1 := Graph([a, b, c, d, e, f, g],
            [[a, b], [b, g], [g, a], [b, c],
             [d, c], [e, d], [d, f], [f, e]], Directed):

plot(Graph::plotGridGraph(G1,
       VertexOrder = [a,    None, None, None, e,
                      None, b,    c,    d,    None,
                      g,    None, None, None, f],
       VerticesPerLine=5))
```



The graphical output reveals the two "big" components `[a, b, g]` and `[d, e, f]`. The single vertex `[c]` forms a component of itself:

```
G2 := Graph::stronglyConnectedComponents(G1)
```

$$[\text{Graph}(\ldots), \text{Graph}(\ldots), \text{Graph}(\ldots)]$$

A list containing three Graphs is returned. Now we find out which vertices belong to each component:

```
Graph::getVertices(op(G2, 1))
```

$$[d, e, f]$$

```
Graph::getVertices(op(G2, 2))
```

$$[a, b, g]$$

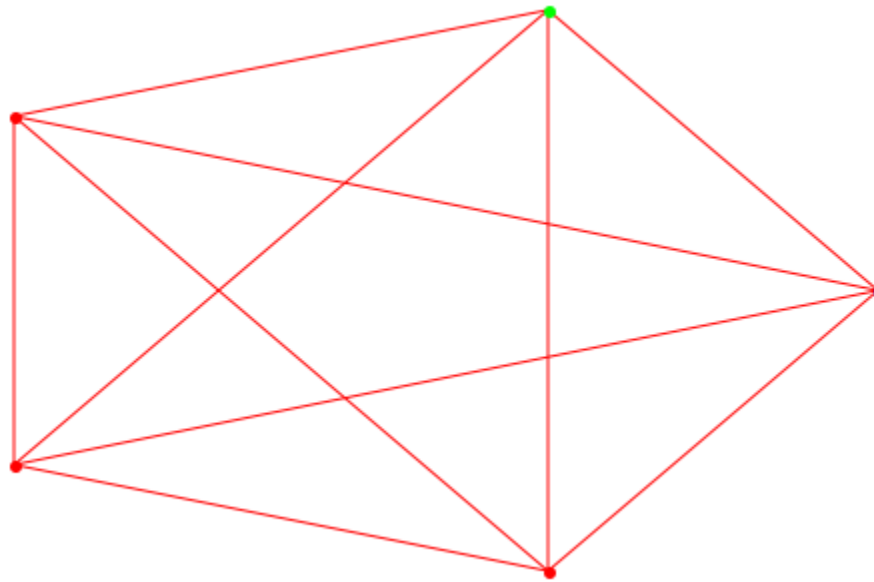
```
Graph::getVertices(op(G2, 3))
```

$$[c]$$

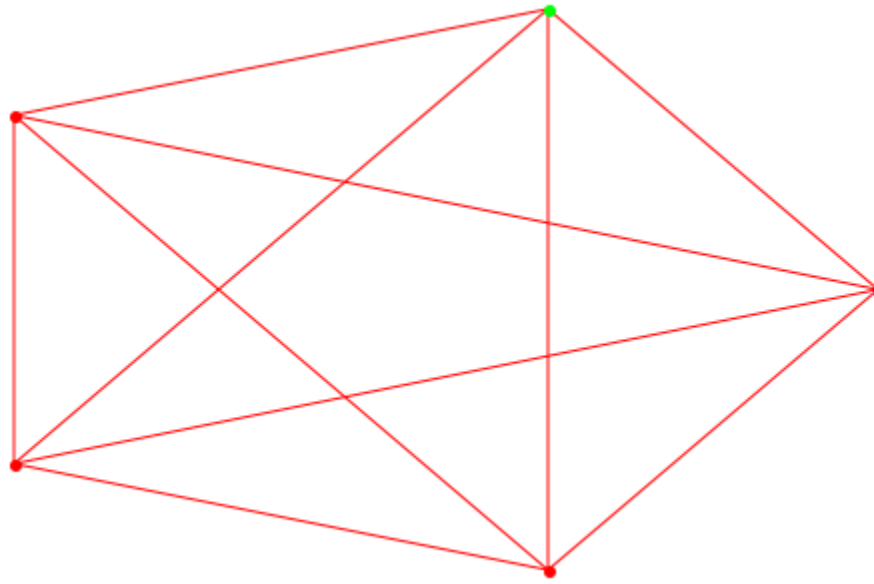
Example 2

A complete graph is returned as a single component:

```
G3 := Graph::createCompleteGraph(5):
plot(Graph::plotCircleGraph(G3))
```



```
G4 := Graph::stronglyConnectedComponents(G3):
plot(Graph::plotCircleGraph(op(G4)))
```



It was necessary to use op(G4), because G4 is a list containing a graph!

Parameters

G

A graph

Return Values

List of graphs containing the strongly connected components.

Graph::topSort

Topological sorting of the vertices

Syntax

```
Graph::topSort(G)
```

Description

`Graph::topSort(G)` computes a topological sorting of the graph `G`, i.e., a numbering T of the vertices, such that $T_i < T_j$ whenever there is an edge $[i, j]$ in the graph. Single vertices are positioned at the beginning.

`Graph::topSort` returns a list containing two tables. The first table holds the ordering of the vertices. The second table shows the predecessors of each vertex. If several vertex u_i precede a vertex v, the first vertex in the ordering of u_i is the predecessor of v. If no predecessor exist, the value will be *infinity*.

Note: If `G` contains any cycle then a topological sorting does not exist and the call of `Graph::topSort` results in an error.

Examples

Example 1

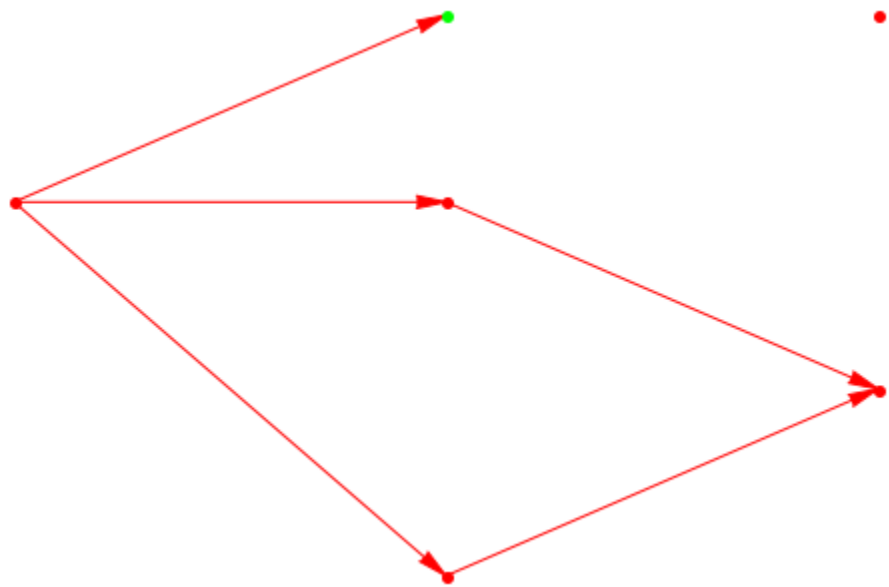
A "butterfly" graph that is decomposed in three strongly connected components:

```
G1 := Graph([a, b, c, d, e, f],
            [[a, b], [a, c], [a, d], [c, e], [d, e]],
            Directed):
Graph::topSort(G1)
```

$$\begin{bmatrix} 1 & f \\ 2 & a \\ 3 & b \\ 4 & c \\ 5 & d \\ 6 & e \end{bmatrix}, \quad \begin{bmatrix} a & a \\ b & a \\ c & a \\ d & a \\ e & c \\ f & \infty \end{bmatrix}$$

The first table shows the ordering of the vertices. The left side holds the order for each vertex, whereas the right side holds the name of the vertex. The second table shows the predecessors of each vertex. If no predecessor exist, the right side holds *infinity*. Otherwise the right side holds the vertex that is the direct predecessor of the vertex on the left side. To see how the graph looks a graphical plotting helps:

```
plot(Graph::plotGridGraph(G1,
         VertexOrder = [None, b,    f,
                        a,    c,    None,
                        None, None, e,
                        None, d,    None],
         VerticesPerLine=3))
```



Parameters

G

A graph

Return Values

List containing two tables.

groebner – Gröbner bases

groebner::dimension
groebner::eliminate
groebner::gbasis
groebner::normalf
groebner::spoly
groebner::stronglyIndependentSets

groebner::dimension

Dimension of the affine variety generated by polynomials

Syntax

```
groebner::dimension(polys, <order>)
```

Description

`groebner::dimension(polys)` computes the dimension of the affine variety generated by the polynomials in the set or list `polys`.

The rules laid down in the introduction to the groebner package concerning the polynomial types and the ordering apply.

The polynomials in the list `polys` must all be of the same type. In particular, do not mix polynomials created via `poly` and polynomial expressions!

Examples

Example 1

An example from the book of Cox, Little and O'Shea (see below):

```
groebner::dimension([y^2*z^3, x^5*z^4, x^2*y*z^2])
```

```
2
```

Parameters

`polys`

A list or set of polynomials or polynomial expressions of the same type. The coefficients in these polynomials and polynomial expressions can be arbitrary arithmetical expressions.

`order`

One of the identifiers `DegInvLexOrder`, `DegreeOrder`, and `LexOrder`, or a user-defined term ordering of type `Dom::MonomOrdering`. The default ordering is `DegInvLexOrder`.

Return Values

Nonnegative integer

Algorithms

First, the Gröbner basis of the given polynomials with respect to the given monomial ordering is computed using `groebner::gbasis`. This Gröbner basis is then used to compute the dimension of the affine variety generated by the polynomials.

References

The implemented algorithm is described in Cox, Little, O'Shea: “Ideals, Varieties and Algorithms”, Springer, 1992, Chapter 9.

MuPAD Functions

`groebner::gbasis` | `poly`

groebner::eliminate

Eliminate variables

Syntax

```
groebner::eliminate(sys, vars)
```

Description

`groebner::eliminate(sys, vars)` returns a list of polynomial expressions obtained by eliminating the elements of `vars` from `sys`. In other words, the return value does not contain the variables in `vars`, every zero of the original system `sys` must be a zero of the return value, and every tuple of numbers that makes the return value zero can be extended to a solution of `sys`.

Examples

Example 1

Suppose that $x^2 + y = 0$ and $x + y = 0$, what does this imply for y?

```
groebner::eliminate({x^2 +y, y+x}, {x})
```

$$[y^2 + y]$$

We infer that for every pair (x, y) solving the system, y must satisfy $y^2 + y = 0$, that is, $y = 0$ or $y = -1$. Indeed:

```
solve({x^2 +y, y+x}, {x, y})
```

$$\{[x = 0, y = 0], [x = 1, y = -1]\}$$

Parameters

`sys`

A set or list of polynomial expressions. The coefficients in these polynomial expressions can be arbitrary arithmetical expressions.

`vars`

A set or list of identifiers

Return Values

List of polynomial expressions

Algorithms

`groebner::eliminate` proceeds by computing a lexical-order Gröbner basis. Hence the computation complexity grows fast when increasing the number of variables.

See Also

MuPAD Functions
`groebner::gbasis`

groebner::gbasis

Computation of a reduced Gröbner basis

Syntax

```
groebner::gbasis(polys, <order>, options)
```

Description

`groebner::gbasis(polys)` computes a reduced Gröbner basis of the ideal generated by the polynomials in the list `polys`.

The rules laid down in the introduction to the groebner package concerning the polynomial types and the ordering apply.

The polynomials in the list `polys` must all be of the same type. In particular, do not mix polynomials created via `poly` and polynomial expressions!

The ordering strategy indicated by `Reorder` is used automatically when polynomial expressions are used.

Examples

Example 1

We demonstrate the effect of various input formats. First, we use polynomial expressions to define the polynomial ideal. The Gröbner basis is returned as a list of polynomial expressions:

```
groebner::gbasis([x^2 - y^2, x^2 + y], LexOrder)
```

$$[x^2 + y,\ x^4 - x^2]$$

Next, the same polynomials are defined via `poly`. Note that `poly` fixes the ordering of the variables.

```
groebner::gbasis([poly(x^2 - y^2, [x, y]),
                  poly(x^2 + y, [x, y])], LexOrder)
```

$$[\mathrm{poly}(x^2+y,[x,y]),\ \mathrm{poly}(y^2+y,[x,y])]$$

Changing the ordering of the variables in `poly` changes the lexicographical ordering. This results in a different basis:

```
groebner::gbasis([poly(x^2 - y^2, [y, x]),
                  poly(x^2 + y, [y, x])], LexOrder)
```

$$[\mathrm{poly}(y+x^2,[y,x]),\ \mathrm{poly}(x^4-x^2,[y,x])]$$

With `Reorder` the ordering of the variables may be changed internally:

```
groebner::gbasis([poly(x^2 - y^2, [x, y]),
                  poly(x^2 + y, [x, y])], LexOrder, Reorder)
```

$$[\mathrm{poly}(y+x^2,[y,x]),\ \mathrm{poly}(x^4-x^2,[y,x])]$$

Example 2

Polynomials over arbitrary fields are allowed. In particular, you can use the field of rational functions in some given variable(s):

```
F := Dom::Fraction(Dom::DistributedPolynomial([y])):
F::Name := "Q(y)":
groebner::gbasis(
[poly(y*z^2 + 1, [x, z], F),
poly((y^2 + 1)*x^2 - y - z^3, [x, z], F)])
```

$$\left[\mathrm{poly}\left(x^2+\frac{z}{y+y^3}-\frac{y}{y^2+1},[x,z],\mathrm{Q(y)}\right),\ \mathrm{poly}\left(z^2+\frac{1}{y},[x,z],\mathrm{Q(y)}\right)\right]$$

```
delete F:
```

Parameters

`polys`

A list or set of polynomials or polynomial expressions of the same type. The coefficients in these polynomials and polynomial expressions can be arbitrary arithmetical expressions. If `polys` are polynomials over an arbitrary domain, then their coefficients must be domain elements and the domain must be a field.

`order`

One of the identifiers `DegInvLexOrder`, `DegreeOrder`, and `LexOrder`, or a user-defined term ordering of type `Dom::MonomOrdering`. The default ordering is `DegInvLexOrder`.

Options

`Factor`

With this option, `groebner::gbasis` returns a set of lists, such that each list is the Gröbner basis of an ideal. The union of these ideals is a superset of the ideal given as input, and a subset of the radical of that ideal. In other words, it has the same variety (only the multiplicity of points can change).

`IgnoreSpecialCases`

With this option, `groebner::gbasis` handles all coefficients in all intermediate results as nonzero unless these coefficients are equal to zero for all parameter values. In other words, if the coefficients are rational functions of the free parameters, then results are correct on all of the parameter space except on an algebraic variety of lower dimension.

`Reorder`

With this option `groebner::gbasis` internally may change the lexicographical ordering of variables to decrease running time.

With this option the variables are sorted internally such that they have a “heuristic optimal” ordering. Consequently, the ordering of the variables in the output polynomials may differ from their ordering in the input polynomials. For details on the ordering strategy, see W. Boege, R. Gebauer und H. Kredel: “Some Examples for Solving Systems

of Algebraic Equations by Calculating Groebner Bases" im J. Symbolic Comp. (1986) Vol. 1, 83-98.

Re-ordering is always applied when polynomial expressions are used for input.

`Monic`

Option, specified as `Monic = N`

This option sets the normalizing routine to `N`. For every polynomial `f` in the polynomial ring, `N(f, o)` must return some associate of `f`, where `o` is the chosen order.

The method `N` should be chosen such that it produces simple output.

By default, `polylib::primpart` is used for polynomials with integer coefficients; other polynomials are divided by their leading coefficient.

`Order`

Option, specified as `Order = order`

This option is equivalent to passing `order` as an argument.

Return Values

List of polynomials. The output polynomials have the same type as the polynomials of the input list.

Algorithms

In most cases, `groebner::gbasis` computes the basis via the Buchberger algorithm with the "sugar" selection strategy being used.

References

For general information, see T. Becker and V. Weispfenning: "Gröbner Bases", Springer (1993). For details on the sugar selection strategy, see A. Giovini, T. Mora, G. Niesi,

L. Robbiano, C. Traverso: “One sugar cube, please — or Selection strategies in the Buchberger algorithm”, Proc. ISSAC '91, Bonn, 49-54 (1991).

MuPAD Functions

`poly`

groebner::normalf

Complete reduction modulo a polynomial ideal

Syntax

```
groebner::normalf(p, polys, <order>)
```

Description

`groebner::normalf(p, polys)` computes a normal form of the polynomial `p` by complete reduction modulo all polynomials in the list `polys`.

The rules laid down in the introduction to the groebner package concerning the polynomial types and the ordering apply.

The polynomials in the list `polys` must all be of the same type as `p`. In particular, do not mix polynomials created via `poly` and polynomial expressions.

Examples

Example 1

We consider the ideal generated by the following polynomials:

```
p1 := poly(x^2 - x + 2*y^2, [x,y]):
p2 := poly(x + 2*y - 1, [x,y]):
```

We compute the normal form of the following polynomial `p` modulo the ideal generated by `p1`, `p2` with respect to lexicographical ordering:

```
p :=  poly(x^2*y - 2*x*y + 1, [x,y]):
groebner::normalf(p, [p1, p2], LexOrder);
```

$$\mathrm{poly}(-2y^3+2y^2-y+1, [x, y])$$

Note that p1, p2 do not form a Gröbner basis. The corresponding Gröbner basis leads to a different normal form of p:

```
groebner::normalf(p, groebner::gbasis([p1, p2]), LexOrder)
```

$$\mathrm{poly}\left(-\frac{5\,y}{9}+1,\,[x,\,y]\right)$$

```
delete p1, p2, p:
```

Parameters

p

A polynomial or a polynomial expression. The coefficients in this polynomial and polynomial expression can be arbitrary arithmetical expressions.

polys

A list of polynomials of the same type as p. In particular, if p is a polynomial expression, polys must be a list of polynomial expressions.

order

One of the identifiers DegInvLexOrder, DegreeOrder, and LexOrder, or a user-defined term ordering of type Dom::MonomOrdering. The default ordering is DegInvLexOrder.

Return Values

Polynomial of the same type as the input polynomials. If polynomial expressions are used as input, then a polynomial expression is returned.

Algorithms

A polynomial g is a reduced form of a polynomial p modulo a list of polynomials p_1, …, p_n, if $g \equiv p$ and none of the leading terms of the p_i divides the leading term of p, or

if — for some i — g is a reduced form of p - $q\,p_i$, where q is the quotient of the leading monomial of p and the leading monomial of p_i. A reduced form always exists, but need not be unique. It is unique, if the p_i form a Gröbner basis.

In the implementation of `groebner::normalf`, reduction modulo some p_i of largest possible total degree is preferred, if reduction modulo several p_i is possible.

MuPAD Functions

`groebner::gbasis` | `poly`

groebner::spoly

The S-polynomial of two polynomials

Syntax

`groebner::spoly(`p_1`, `p_2`, <order>)`

Description

`groebner::spoly(p1, p2)` computes the S-polynomial of the polynomials `p1` and `p2`.

The rules laid down in the introduction to groebner concerning the polynomial types and the ordering apply.

The polynomials must be of the same type. In particular, do not mix polynomials created via `poly` and polynomial expressions!

Examples

Example 1

The polynomials

```
p1 := poly(x^2 - x + 2*y^2, [x, y]):
p2 := poly(x + 2*y - 1, [x, y]):
```

generate the following S-polynomial with respect to lexicographical ordering:

```
groebner::spoly(p1, p2, LexOrder)
```

$$\mathrm{poly}(-2\,x\,y+2\,y^2,\,[x,\,y])$$

```
delete p1, p2:
```

Parameters

p_1, p_2

A list or set of polynomials or polynomial expressions of the same type. The coefficients in these polynomials and polynomial expressions can be arbitrary arithmetical expressions.

`order`

One of the identifiers `DegInvLexOrder`, `DegreeOrder`, and `LexOrder`, or a user-defined term ordering of type `Dom::MonomOrdering`. The default ordering is `DegInvLexOrder`.

Return Values

Polynomial of the same type as the input polynomials. If polynomial expressions are used as input, then a polynomial expression is returned.

Algorithms

The S-polynomial of two polynomials p_1, p_2 is defined to be

$$\frac{\mathrm{lcm}(\mathrm{lterm}(p_1), \mathrm{lterm}(p_2))}{\mathrm{lmonomial}(p_1)}\, p_1 - \frac{\mathrm{lcm}(\mathrm{lterm}(p_1), \mathrm{lterm}(p_2))}{\mathrm{lmonomial}(p_2)}\, p_2,$$

where `lterm` and `lmonomial` are used in the same sense as the MuPAD functions of the same name. This formula is constructed such that the leading terms of the two summands cancel.

See Also

MuPAD Functions
`poly`

groebner::stronglyIndependentSets

Strongly independent set of variables

Syntax

```
groebner::stronglyIndependentSets(G)
```

Description

`groebner::stronglyIndependentSets(G)` computes a strongly independent set of variables modulo the ideal generated by `G`.

A set of variables S is strongly independent modulo an ideal I if no leading term of an element of the Gröbner basis of I consists entirely of elements of S. A set is maximally strongly independent if no proper superset of it is strongly independent. Two maximally strongly independent set may be of different size.

`groebner::stronglyIndependentSets` accepts Gröbner bases in the format returned by `groebner::gbasis`.

Examples

Example 1

The following example has been given by Moeller and Mora in 1983.

```
G:=map([X0^8*X2, X0*X3, X1^8*X3, X1^7*X3^2, X1^6*X3^3,
  X1^5*X3^4, X1^4*X3^5, X1^3*X3^6, X1^2*X3^7, X1*X3^8],
  poly, [X3, X2, X1, X0]):
groebner::stronglyIndependentSets(G)
```

```
[2, {X0, X1}, {{X2, X3}, {X0, X1}, {X1, X2}}]
```

```
delete G:
```

Parameters

G

The Gröbner basis of an ideal: a list.

Return Values

List of the form `[d, S, M]`, where `d` is an integer equal to the dimension of the ideal generated by `G`, `S` is the greatest strongly independent set of variables, and `M` is a set consisting of all maximal strongly independent sets of variables or a piecewise consisting of such lists.

MuPAD Functions

`groebner::gbasis`

import – Import Data

import::csv
import::readbitmap
import::readdata
import::readlisp

import::csv

Read CSV data from an ASCII file

Syntax

```
import::csv(filename, <separator>, <NonNested>, <Trim>, <DecimalComma>)
import::csv(n, <separator>, <NonNested>, <Trim>, <DecimalComma>)
```

Description

`import::csv` is used to read CSV ("Comma Separated Values" or "Character Separated Values") data files produced by external programs, like Microsoft Excel®. CSV is an ASCII based tabular data file format, formally defined in RfC 4180, that has fields separated by the comma character.

Note: Some localized versions of Microsoft Excel use semicolons instead of commas! Set the parameter `separator` to change the default separator.

`import::csv(filename)` reads the data in the file `filename`. File data separated by a comma are regarded as different data elements. The result is a list of lists, each sublist representing one line of the file.

`import::csv(filename, separator)` reads the data in the file `filename`. File data separated by the character `separator` are regarded as different data elements. The result is a list of lists, each sublist representing one line of the file.

`import::csv(filename, separator, NonNested)` reads the data in the file `filename` as a single data record. File data separated by the character `separator` are regarded as different data elements. The result is a plain non-nested list containing the data of all lines of the file.

In contrast to `finput`, the data must not be ended by a colon or semicolon. Data separated by `separator` are interpreted as single data items. The default separator is a comma.

Empty lines are ignored.

All data elements in the file that cannot be converted to valid MuPAD numbers are imported as MuPAD strings.

`import::csv` tries to convert a number contained in the CSV file to a valid MuPAD number. For example: 1,234.56 or 1 234.56 are converted to the MuPAD number 1234.56. Many countries use a comma to separate the integral and fractional part instead of the dot used in England and the US. For example: 1234,56 or 1.234,56 are converted to 1234.56. `import::csv` expects this number format if the option `DecimalComma` is given.

Note: A comma as CSV separator doesn't make sense if the comma is used to separate thousands in a number or the decimal comma is used. In most cases, the CSV file uses a semicolon to separate data. So, a semicolon should be used as separator.

Note: All numbers contained in the CSV file must use the same radix separator, mixed formats cannot be converted.

With `NonNested`, the result will be a list containing all data. Otherwise, the result is a list of list, each "inner" list representing a line of the CSV file.

With `Trim`, leading and trailing blanks in strings are removed.

If the file is specified by a string, the corresponding file is opened and closed, automatically. If the user has opened a text file in `Read` mode and passes the file descriptor to import::readdata, the file remains open and needs to be closed by the user.

Files compressed with `gzip` or in a compatible format, whose names end in "`.gz`", are automatically decompressed while being read by `import::csv`.

`import::csv(filename)` searches for the file in various directories:

- First, the name is interpreted as a relative file name: `filename` is concatenated to each directory given by the environment variable `READPATH`.
- Then the file name is interpreted as an absolute path name.
- Then the file name is interpreted relative to the "working directory".
- Last, the file name is concatenated to the directory path.

If a file can be opened with one of this names, then the file is read.

Note that the meaning of "working directory" depends on the operating system. On Microsoft Windows systems and on Apple Mac OS X systems, the "working directory" is the folder where MuPAD is installed. On UNIX systems, it is the current working directory in which MuPAD was started; when started from a menu or desktop item, this is typically the user's home directory.

A path separator ("/") is inserted as necessary when concatenating a given path and `filename`.

If a file is specified by a file name, there is no need to open or close the file via `fopen` and `fclose`, respectively. This is done automatically by `import::readdata`.

Instead of a file name, also a file descriptor of a file opened via `fopen` can be used. Note that the file must have been opened in `Read` mode by `fopen`. If a file descriptor is used, the corresponding file is not closed automatically but must be closed by the user via `fclose`.

Examples

Example 1

We wish to read CSV data into a MuPAD session. Assume that the file "`datafile.csv`" contains the following two columns of ASCII data:

```
a ,12.5
  a-b   ,1234.56
```

`import::csv` returns the following list representing the data in the file:

```
data := import::csv("datafile.csv")
```

```
     [["a ", 12.5], [" a-b  ", 1234.56]]
```

```
data := import::csv("datafile.csv", Trim)
```

```
     [["a", 12.5], ["a-b", 1234.56]]
```

```
data := import::csv("datafile.csv", NonNested)
```

```
["a ", 12.5, " a-b  ", 1234.56]
```

Example 2

Let us assume that the file "`datafile.csv`" contains the following ASCII data:

```
a ;12.5
a-b;1,234.56
a b; -12345.6789E-02
```

We specify the data separator `";"` for reading the data:

```
import::csv("datafile.csv", ";")
```

```
[["a ", 12.5], ["a-b", 1234.56], ["a b", -123.456789]]
```

Example 3

Let us assume that the file "`datafile.csv`" contains the following ASCII data:

```
abc;12,5
a-b;1.234,56
a b; -12345.6789E-02
```

We specify the data separator `";"` and the option `DecimalComma` for reading the data:

```
import::csv("datafile.csv", ";", DecimalComma)
```

```
[["a ", 12.5], ["a-b", 1234.56], ["a b", -123.456789]]
```

Parameters

`filename`

The file name: a non-empty character string

n

A file descriptor provided by `fopen`: a positive integer

separator

The separator between data elements: a character string of length 1 (a single character). The default separator is a comma (the single character string `","`).

Options

NonNested

Return all file data as a single data record in a non-nested list. The data of all lines are ordered sequentially in this list.

Trim

Leading and trailing blanks in strings are removed.

DecimalComma

A decimal comma instead of a decimal point is used as the radix separator in the CSV file.

Return Values

Nested list of lists. The sublists contain the data of the individual lines. With the option `NonNested`, a plain list containing all data elements from every line in the file.

MuPAD Functions

`FILEPATH` | `fopen` | `import::readdata` | `readbytes` | `READPATH`

import::readbitmap

Read bitmap data

Syntax

```
import::readbitmap(filename, <ReturnType = DOM_HFARRAY | DOM_ARRAY | DOM_LIST>)
```

Description

`import::readbitmap` is used for reading ASCII or binary data files storing bitmap images of pictures. The following standard graphical formats can be read: BMP, DCX, DDS, WAD, GIF, ICO, JPG, LIF, MDL, PCD, PCX, PIC, PIX, PNG, PNM, PSD, PSP, PXR, RAW, SGI, TGA, TIF, WAL, XPM. The format of the pixel data is determined automatically from the contents of the file. The return value `[w, h, colordata]` provides the pixel height `h`, the pixel width `w`, and the color data of the bitmap image.

Either the complete return value or just the third element, `colordata`, can be passed to the function `plot::Raster` to generate a plot object that can be used in a MuPAD graphics. E.g., the command

```
plot(plot::Raster(import::readbitmap("mypicture.jpeg")))
```

creates a MuPAD graphics of the bitmap stored in the JPG file "`mypicture.jpeg`".

Note: Most of the standard graphical formats store the pixel data row by row in the usual reading order starting with the upper left corner of the image. The pixel data in the returned array `colordata` (if requesting `ReturnType = DOM_ARRAY`), however, are to be interpreted as follows:

`colordata[1, 1]` is the RGB color of the lower left corner.

`colordata[h, 1]` is the RGB color of the upper left corner.

`colordata[1, w]` is the RGB color of the lower right corner.

`colordata[h, w]` is the RGB color of the upper right corner.

The interpretation of the other return types is analogous, see below for details on the return types.

This is consistent with the interpretation of a color array by `plot::Raster`.

`import::readbitmap(filename)` searches for the file in various directories:

- First, the name is interpreted as a relative file name: `filename` is concatenated to each directory given by the environment variable `READPATH`.
- Then the file name is interpreted as an absolute path name.
- Then the file name is interpreted relative to the "working directory."
- Last, the file name is concatenated to the directory path.

If a file can be opened with one of this names, then the file is read.

Note that the meaning of "working directory" depends on the operating system. On Microsoft Windows systems and on Apple Mac OS X systems, the "working directory" is the folder where MuPAD is installed. On UNIX systems, it is the current working directory in which MuPAD was started; when started from a menu or desktop item, this is typically the user's home directory.

A path separator ("/") is inserted as necessary when concatenating a given path and `filename`.

`import::readbitmap` does not accept file handles returned by `fopen`. Nor can it handle files which have been compressed by `gzip`, but since most bitmap formats employ high quality compression in any case, there is little reason to try compressing them again in any case.

Examples

Example 1

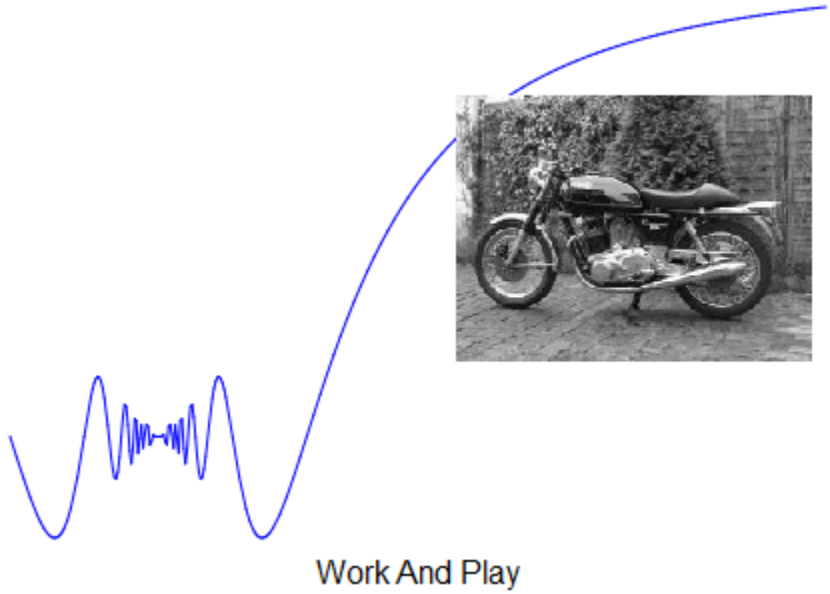
We import a PGM (portable graymap) picture:

```
[w, h, Norton] := import::readbitmap("Norton.pgm"):
```

The bitmap image is to be embedded in a MuPAD graphics. We use the width `w` and the height `h` to place the bitmap in a rectangle whose sides have the same ratio as the

original bitmap. With `Scaling = Constrained` we make sure that this aspect ratio is also used in the final graphics:

```
xmin := 2: xmax := xmin + w/100:
ymin := 0.5: ymax := ymin + h/100:
plot(plot::Function2d(x*sin(PI/x), x = -1..4.5, AdaptiveMesh = 2),
     plot::Raster(Norton, x = xmin ..xmax, y = ymin .. ymax),
     Scaling = Constrained, Footer = "Work And Play"):
```



Parameters

`filename`

The file name: a non-empty character string

Options

`ReturnType`

Option, specified as `ReturnType = DOM_HFARRAY | DOM_ARRAY | DOM_LIST`

Set the type of the actual color data returned as `colordata`.

If set to `DOM_LIST`, `colordata` is a nested list, the outermost list containing `h` lists, each of which represents one row of image data and contains `w` lists of three floating-point numbers, each of which represents an "RGB Colors" color.

If set to `DOM_ARRAY`, `colordata` is an array containing lists with color information, as in `array(2, 1..h, 1..w, [color`$_1$`, color`$_2$`, …] )`. The interpretation is analogous to the nested lists described above.

If set to `DOM_HFARRAY`, which is the default setting, `colordata` is a `DOM_HFARRAY` of dimensions `hfarray(3, 1..h, 1..w, 1..3, [actual data])`. The interpretation of these floating-point values is as described above for the `DOM_LIST` case.

Return Values

list`[w, h, colordata]`. The integer `w` is the pixel width of the bitmap. The integer `h` is the pixel height of the bitmap. `colordata` provides the `RGB` colors of the bitmap. Its type depends on the setting of the option `ReturnType`.

MuPAD Functions

`import::readdata` | `readbytes` | `READPATH`

MuPAD Graphical Primitives

`plot::Raster`

import::readdata

Read data from an ASCII file

Syntax

```
import::readdata(filename | n, <separator>, <NonNested>)
```

Description

`import::readdata(filename)` reads the data in the file `filename`. File data separated by whitespace are regarded as different data elements. The result is a list of lists, each sublist representing one line of the file.

`import::readdata(filename, separator)` reads the data in the file `filename`. File data separated by the character `separator` are regarded as different data elements. The result is a list of lists, each sublist representing one line of the file.

`import::readdata(filename, separator, NonNested)` reads the data in the file `filename` as a single data record. File data separated by the character `separator` are regarded as different data elements. The result is a plain non-nested list containing the data of all lines of the file.

`import::readdata(filename)` searches for the file in various directories:

- First, the name is interpreted as a relative file name: `filename` is concatenated to each directory given by the environment variable `READPATH`.
- Then the file name is interpreted as an absolute path name.
- Then the file name is interpreted relative to the “working directory.”
- Last, the file name is concatenated to the library directory.

If a file can be opened with one of this names, then the file is read.

Note that the meaning of “working directory” depends on the operating system. On Microsoft Windows systems and on Apple Mac OS X systems, the “working directory”

is the folder where MuPAD is installed. On UNIX systems, it is the current working directory in which MuPAD was started; when started from a menu or desktop item, this is typically the user's home directory.

A path separator ("/") is inserted as necessary when concatenating a given path and `filename`.

If a file is specified by a file name, there is no need to open or close the file via `fopen` and `fclose`, respectively. This is done automatically by `import::readdata`.

Instead of a file name, also a file descriptor of a file opened via `fopen` can be used. Note that the file must have been opened in `Read` mode by `fopen`. If a file descriptor is used, the corresponding file is not closed automatically but must be closed by the user via `fclose`.

Files compressed by `gzip` or a compatible program (having a name ending in "`.gz`") are decompressed automatically upon reading.

All data elements in the file are interpreted as MuPAD objects. If a data element cannot be interpreted as a MuPAD object, it is imported as a MuPAD string. Otherwise, the corresponding MuPAD object is inserted into the list returned by `import::readdata`.

Note: Note that the MuPAD objects corresponding to the data elements are evaluated after reading. E.g., the data element "sin(0)" in the file is evaluated and imported as the MuPAD integer 0. Beware: the characters "`;`" and "`:`" have a specific meaning if not specified as separators in `import::readdata`: they separate MuPAD commands. Hence, if a read data element contains one of this characters, MuPAD interprets this data element as a sequence of statements and, upon evaluation, returns the value of the *last* statement as the MuPAD object corresponding to the data element. Cf. "Example 3" on page 13-14.

In contrast to `finput`, the data elements in the file do not have to be ended by a colon or a semicolon.

Empty lines in the file are ignored.

Examples

Example 1

We wish to read statistical data into a MuPAD session to test the correlation of two data samples. Assume that the file "`datafile`" contains the following two columns of ASCII data (each column representing a data sample):

```
 0.12    0.2534
 2.324   5.72
 1.02    2.2232
 4.02    7.321
 7.4    14.9
-7.4   -15.1
```

`import::readdata` returns the following list representing the data in the file:

```
data := import::readdata("datafile")
```

$$[[0.12, 0.2534], [2.324, 5.72], [1.02, 2.2232], [4.02, 7.321], [7.4, 14.9], [-7.4, -15.1]]$$

The data structure `stats::sample` converts this nested list into two data columns:

```
s := stats::sample(data)
```

```
 0.12  0.2534
2.324    5.72
 1.02  2.2232
 4.02   7.321
  7.4    14.9
 -7.4   -15.1
```

The following computation shows that there is a very strong correlation between the data in the first column and the data in the second column:

```
stats::correlation(s, 1, 2)
```

$$0.9982703003$$

If the data in the file are supposed to represent a single sample (data record), we may ignore the fact that the numbers are arranged on several lines. With `NonNested`, the data are read as a single sample:

```
data := import::readdata("datafile", NonNested)
```

$$[0.12, 0.2534, 2.324, 5.72, 1.02, 2.2232, 4.02, 7.321, 7.4, 14.9, -7.4, -15.1]$$

Mean and standard deviation of the data are:

```
stats::mean(data), stats::stdev(data)
```

$$1.900133333, 7.568789783$$

```
delete data, s:
```

Example 2

Let us assume that the file "`datafile`" contains the following ASCII data:

```
1 | 2   | 3

4| 5 | 6.65786
7| 8 |9| 5 | "ahfjd" | ab100|-23
```

We specify the data separator `"|"` for reading the data:

```
import::readdata("datafile", "|")
```

$$[[1, 2, 3], [4, 5, 6.65786], [7, 8, 9, 5, "ahfjd", ab100, -23]]$$

Note that whitespace inside the data elements as well as the empty line in the file are ignored.

Example 3

We first create the ASCII data files that will be used in this example. We recall that x degrees Celsius are $\frac{9x}{5} + 32$ degrees Fahrenheit. First, two data files are created

containing the matching temperatures from - 5 degrees Celsius to 30 degrees Celsius in steps of 5 degrees Celsius:

```
n1 := fopen(Text, "data1", Write):
n2 := fopen(Text, "data2", Write):
for celsius from -5 to 20 step 5 do
  fahrenheit := 9/5*celsius + 32:
  fprint(Unquoted, n1, celsius, " ", fahrenheit):
  fprint(n2, celsius, fahrenheit):
end_for:
fclose(n1):
fclose(n2):
```

The file "`data1`" now contains the following data:

```
-5 23
0 32
5 41
10 50
15 59
20 68
```

The file "`data2`" contains the following data:

```
-5:23:
0:32:
5:41:
10:50:
15:59:
20:68:
```

Now, we import the data:

```
import::readdata("data1")
```

$$[[-5, 23], [0, 32], [5, 41], [10, 50], [15, 59], [20, 68]]$$

Reading data from the file "`data2`" yields an unexpected result:

```
import::readdata("data2")
```

$$[[23], [32], [41], [50], [59], [68]]$$

What went wrong? Remember that the default data separator is whitespace. Consequently, MuPAD reads the expression `-5:23:` as the only data element in the first line. When MuPAD evaluates this data element, it interprets it as a sequence of two MuPAD statements. The result of the statement sequence is the result of the last of the two statements, i.e., the number 23. This is the first datum in the resulting list. For getting the data as desired, an appropriate separator must be specified. The file "`data2`" should be read as follows:

```
import::readdata("data2", ":")
```

$$[[-5, 23], [0, 32], [5, 41], [10, 50], [15, 59], [20, 68]]$$

We use the option `NonNested` to get a plain list containing all data elements without putting each record (line) in a sublist of its own:

```
import::readdata("data2", ":", NonNested)
```

$$[-5, 23, 0, 32, 5, 41, 10, 50, 15, 59, 20, 68]$$

```
delete n1, n2:
```

Example 4

Here we can see that the data are evaluated after reading. First, we create the data file:

```
n1 := fopen(Text, "data3", Write) :
fprint(Unquoted, n1, a, " 12 ", b):
fclose(n1):
```

Now, the data are read:

```
import::readdata("data3")
```

$$[[a, 12, b]]$$

If `a` and `b` have values, we get:

```
a := 3:  b := 34:  import::readdata("data3")
```

$$[[3, 12, 34]]$$

```
delete n1, a, b:
```

Example 5

First, we create a data file with random floating-point data that a separated by blank characters:

```
n := fopen(Text, "data4", Write):
for i from 1 to 3 do
    fprint(Unquoted, n, (frandom(), " ") $ j = 1..4);
end_for;
fclose(n):
```

This file is reopened for reading with `fopen`:

```
n := fopen(Text, "data4", Read)
```

```
     64
```

The file descriptor `n` returned by `fopen` can be passed to `import::readdata`:

```
import::readdata(n)
```

```
[[0.2703567032, 0.8142678572, 0.1145977439, 0.247668289],
  [0.436855213, 0.7507294917, 0.5143284818, 0.47002619],
  [0.06956333824, 0.5063265159, 0.4145331467, 0.365909575]]
```

Note, however, that the file was opened explicitly by the user with `fopen` and is not closed automatically by `import::readdata`. Consequently, the user is supposed to close the file explicitly via `fclose`:

```
fclose(n):
delete i, n:
```

Parameters

`filename`

The file name: a non-empty character string

n

A file descriptor provided by `fopen`: a positive integer

separator

The separator between data elements: a character string of length 1 (a single character). The default separator is whitespace.

Options

NonNested

Return all file data as a single data record in a non-nested list. The data of all lines are ordered sequentially in this list.

Return Values

Nested list of lists. The sublists contain the data of the indiviual lines. With the option `NonNested`, a plain list containing all data elements from every line in the file.

import::readlisp

Parse Lisp-formatted string

Syntax

```
import::readlisp(s)
```

Description

`import::readlisp(s)` parses the Lisp-formatted string `s` and returns the corresponding MuPAD expression.

`import::readlisp` returns the constructed MuPAD expression as an unevaluated call. So the result of `import::readlisp` is in every case of type `DOM_EXPR`.

If the parsed string `s` contains only white spaces, then the unevaluated `null()` expression is returned.

Examples

Example 1

A first example:

```
import::readlisp("(INTEGRATE (EXPT X -1) X)")
```

$$\int \frac{1}{X}\,\mathrm{d}X$$

```
import::readlisp("(EXP 2.0)")
```

$$e^{2.0}$$

Example 2

In “Example 1” on page 13-19 above we can see that the corresponding MuPAD expression is not evaluated. Let us have a closer look at this behavior:

```
domtype(import::readlisp("(INTEGRATE (EXPT X -1) X)")),
eval(import::readlisp("(INTEGRATE (EXPT X -1) X)")),
domtype(import::readlisp("(EXP 2.0)")),
eval(import::readlisp("(EXP 2.0)"))
```

DOM_EXPR, $\ln(X)$, DOM_EXPR, 7.389056099

Example 3

Another example demonstrating that `import::readlisp` returns an unevaluated call:

```
x := 2:  import::readlisp("(* x (/ 2 y))")
```

$x\,\frac{2}{y}$

```
eval(import::readlisp("(* x (/ 2 y))"))
```

$\frac{4}{y}$

Example 4

An empty string is converted into an unevaluated call of `null()`:

```
type(import::readlisp(""))
```

"null"

We try to convert an illegal Lisp string:

```
import::readlisp("(* 2(EXP 3)")
```

```
Error: The closing parenthesis is missing. [import::parseLambda]
```

Parameters

s

A string

Return Values

MuPAD expression of type `DOM_EXPR`

intlib – Integration Utilities

intlib::byparts
intlib::changevar
intlib::intOverSet
intlib::printWarnings

intlib::byparts

Integration by parts

Syntax

```
intlib::byparts(integral, du)
```

Description

`intlib::byparts(integral, du)` performs on `integral` the integration by parts, where `du` is the part to be integrated and returns an expression containing the unevaluated partial integral.

Mathematically, the rule of integration by parts is formally defined for indefinite integrals as

$$\int u'(x)\, v(x)\, \mathrm{d}x = u(x)\, v(x) - \int u(x)\, v'(x)\, \mathrm{d}x$$

and for definite integrals as

$$\int_a^b u'(x)\, v(x)\, \mathrm{d}x = u(b)\, v(b) - u(a)\, v(a) - \int_a^b u(x)\, v'(x)\, \mathrm{d}x$$

.

`intlib::byparts` works for indefinite as well as for definite integrals.

If MuPAD cannot solve the integral for `du` in case of definite integration, the function call is returned unevaluated.

The first argument should contain a symbolic integral of type `"int"`. Such an expression can be obtained with `hold` or `freeze` (cf. “Example 1” on page 14-3).

The second argument `du` should typically be a partial expression of the integrand in `integral`.

Examples

Example 1

As a first example we apply the rule of integration by parts to the integral $\int_a^b x\,e^x\,dx$. By using the function `hold` we ensure that the first argument is of type `"int"`:

```
intlib::byparts(hold(int)(x*exp(x), x = a..b), exp(x))
```

$$b\,e^b - a\,e^a - \int_a^b e^x\,dx$$

In this case the ansatz is chosen as $u'(x) = e^x$ and thus $v(x) = x$.

Example 2

In the following we give a more advanced example using the method of integration by parts for solving the integral $\int e^{a\,x}\sin(b\,x)\,dx$. For this we have to prevent that the integrator already evaluates the integrals. Thus we first inactivate the requested integral with the function `freeze`

```
F := freeze(int)(exp(a*x)*sin(b*x), x)
```

$$\int e^{a\,x}\sin(b\,x)\,dx$$

and apply afterwards partial integration with $u'(x) = e^{a\,x}$:

```
F1 := intlib::byparts(F, exp(a*x))
```

$$\frac{e^{a\,x}\sin(b\,x)}{a} - \int \frac{b\,e^{a\,x}\cos(b\,x)}{a}\,dx$$

This result contains another symbolic integral, which MuPAD can solve directly:

```
eval(F1)
```

$$\frac{e^{a\,x}\sin(b\,x)}{a} - \frac{b\,e^{a\,x}\,(a\cos(b\,x)+b\sin(b\,x))}{a\,(a^2+b^2)}$$

Example 3

Here we demonstrate the difference between indefinite and definite integration by parts. If in the indefinite case the partial part cannot be solved, simply the unevaluated integral is plugged into the integration rule:

```
intlib::byparts(hold(int)(x*f(x), x),f(x))
```

$$x\int f(x)\,dx - \int\int f(x)\,dx\,dx$$

This is no longer true for the definite case:

```
intlib::printWarnings(TRUE):
intlib::byparts(hold(int)(x*f(x), x=a..b),f(x))
```

```
Warning: No closed form for 'int(f(x), x)' is found. [intlib::byparts]
```

$$\text{intlib::byparts}\left(\int_a^b x\,f(x)\,dx,\ f(x)\right)$$

Parameters

`integral`

Integral: an arithmetical expression containing a symbolic `"int"` call of the form `int(du*v, x)` or `int(du*v, x = a..b)`

`du`

The part to be integrated: an arithmetical expression

Return Values

Arithmetical expression.

See Also

MuPAD Functions

`intlib::changevar` | `subs`

intlib::changevar

Change of variable

Syntax

```
intlib::changevar(integral, eq, <var>)
```

Description

`intlib::changevar(integral, eq)` performs a change of variable for indefinite and definite integrals.

Mathematically, the substitution rule is formally defined for indefinite integrals as

$$\int f(g(x))\, g'(x)\, \mathrm{d}x = \left(\left(\int f(t)\, \mathrm{d}t \right) \Big|_{t = g(x)} \right)$$

and for definite integrals as

$$\int_a^b f(g(x))\, g'(x)\, \mathrm{d}x = \int_{g(a)}^{g(b)} f(t)\, \mathrm{d}t$$

`intlib::changevar(integral, eq)` performs in `integral` the change of variable defined by `eq` and returns an unevaluated new integral. You can use the `eval` command to find the closed form of this new integral providing that the closed form exists.

`intlib::changevar` works for indefinite as well as for definite integrals.

The first argument should contain a symbolic integral of type `"int"`. Such an expression can be obtained with `hold` or `freeze`. See “Example 1” on page 14-7.

If more than two variables occur in `eq`, the new variable must be given as third argument.

If MuPAD cannot solve the given equation `eq` an error will occur.

Examples

Example 1

As a first example we perform a change of variable for the integral $\int_a^b f(x+c)\,\mathrm{d}x$. By using the `hold` function we ensure that the first argument is of type `"int"`:

```
intlib::changevar(hold(int)(f(x + c), x = a..b),
                  t = x + c, t)
```

$$\int_{a+c}^{b+c} f(t)\,\mathrm{d}t$$

Note that in this case the substitution equation has two further variables besides x. Thus it is necessary to specify the new integration variable as third argument.

Example 2

In the following example we use the change of variable method for solving the integral $\int\cos(\ln(x))\,\mathrm{d}x$. First we perform the transformation $t = ln(x)$:

```
f1 := intlib::changevar(hold(int)(cos(ln(x)), x),
                        t = ln(x), t)
```

$$\int e^t \cos(t)\,\mathrm{d}t$$

Now we can evaluate the integral with the MuPAD integrator:

```
f2:=eval(f1)
```

$$\frac{e^t\,(\cos(t)+\sin(t))}{2}$$

Finally we change the variable t back to x and get the result:

```
F := simplify(f2 | t = ln(x))
```

$$\frac{\sqrt{2}\, x \sin\left(\frac{\pi}{4}+\ln(x)\right)}{2}$$

We can also verify the solution of the integral:

```
simplify(diff(F,x) - cos(ln(x)))
```

$$0$$

Parameters

`integral`

The integral: an arithmetical expression containing a symbolic `"int"` call

`eq`

Equation defining the new integration variable in terms of the old one: an equation

`var`

The new integration variable: an identifier

Return Values

Arithmetical expression.

See Also

MuPAD Functions

`intlib::byparts` | `subs`

intlib::intOverSet

Integration over a set

Syntax

```
intlib::intOverSet(f, x, S)
```

Description

`intlib::intOverSet(f, x, S)` computes the integral $\int_{-\infty}^{\infty} f(x)\, i_S(x)\, \mathrm{d}x$ where $i_S(x)$ is the indicator function of the set S.

If S is an interval (a, b) with $a \le b$, the call is equivalent to `int(f, x=a..b)`. However, by definition, interchanging the borders to `int(f, x=b..a)` just reverses the sign of the latter while (b, a) is empty and any integral over the empty set is zero.

The function may return unevaluated if the integral could not be computed.

Examples

Example 1

For intervals, calling `intlib::intOverSet` is just equivalent to calling definite integration:

```
int(1/x, x=1..2), intlib::intOverSet(1/x, x, Dom::Interval(1, 2))
```

$$\ln(2), \ln(2)$$

If the lower border is greater than the upper, this does not hold anymore:

```
int(1/x, x=2..1), intlib::intOverSet(1/x, x, Dom::Interval(2, 1))
```

$$-\ln(2), 0$$

Example 2

In more complex cases, the function returns unevaluated:

```
intlib::intOverSet(1/x^2, x, solve(t > sin(t), t))
```

$$\int_{x \in \mathrm{solve}(\sin(t) < t,\, t)} \frac{1}{x^2}\, dx$$

Parameters

f

Arithmetical expression

x

Identifier

S

Set-theoretic expression

Return Values

Arithmetical expression.

MuPAD Functions
`int`

intlib::printWarnings

Enable or disable warnings

Syntax

```
intlib::printWarnings(TRUE)
```

```
intlib::printWarnings(FALSE)
```

```
intlib::printWarnings()
```

Description

`intlib::printWarnings` lets you enable or disable warnings.

By default, MuPAD does not display warnings during integration. To enable warnings, use the `intlib::printWarnings(TRUE)` function call. If later you want to disable warnings, use the `intlib::printWarnings(FALSE)` function call. See “Example 1” on page 14-11.

The `intlib::printWarnings()` function call shows whether warnings are enabled or disabled. See “Example 1” on page 14-11.

The output of `intlib::printWarnings` displays the previous setting. You can save this previous setting and switch to a new setting in a single function call. See “Example 2” on page 14-12.

Examples

Example 1

Enable the warnings by setting the value of `intlib::printWarnings` to `TRUE`:

```
intlib::printWarnings(TRUE):
```

Compute the integral of $|x|$ under the assumption that `x` is an integer. MuPAD cannot integrate the expression over a discrete subset of the real numbers. The system issues a warning and integrates over the set $\mathbb{R}$ of real numbers:

```
int(abs(x), x) assuming x in Z_
```

```
Warning: Cannot integrate when 'x' has property 'Z_'. The assumption that 'x' has the p
```

$$\frac{x^2\,\mathrm{sign}(x)}{2}$$

If you evaluate the same integral again, MuPAD does not recalculate the integral. The system remembers the previous result and returns it, skipping the warning:

```
int(abs(x), x) assuming x in Z_
```

$$\frac{x^2\,\mathrm{sign}(x)}{2}$$

To check whether the warnings are enabled or disabled, use the `intlib::printWarnings()` function call:

```
intlib::printWarnings()
```

TRUE

Disable the warnings for further computations:

```
intlib::printWarnings(FALSE):
```

Example 2

Enable the warnings and save the previous setting in a single function call:

```
old := intlib::printWarnings(TRUE):
```

Assume that `x` is positive. Then, integrate `x` over the interval [- 2, 1]. In this case, the system issues a warning, temporarily disregards the assumption `x > 0`, and integrates over the interval [- 2, 1]:

```
assume(x > 0):
int(x, x = -2..1)
```

```
Warning: The assumption that 'x' has property 'Dom::Interval([-2], [1])' instead of giv
```

$$-\frac{3}{2}$$

Restore the setting of `intlib::printWarnings`:

```
intlib::printWarnings(old):
```

The warnings are disabled now:

```
intlib::printWarnings()
```

FALSE

For further computations, clear the assumption on the variable `x`:

```
unassume(x):
```

Return Values

Previously set value TRUE or FALSE

linalg::addCol

Linear combination of matrix columns

Syntax

`linalg::addCol(A, c1, c2, s1)`

`linalg::addCol(A, c1, c2, s1, s2)`

Description

`linalg::addCol(A, c1, c2, s1)` adds s_1 times column c_1 to column c_2, in the matrix A.

`linalg::addCol(A, c1, c2, s)` returns a copy of the matrix A in which column c_2 of A is replaced by $s\,col(A, c_1) + col(A, c_2)$.

`linalg::addCol(A, c1, c2, s1, s2)` returns a copy of the matrix A in which column c_2 of A is replaced by $s_1\,col(A, c_1) + s_2\,col(A, c_2)$.

Examples

Example 1

The following defines a 3×3 matrix over the integers:

```
A := Dom::Matrix(Dom::Integer)(
  [[1, 2, 3], [4, 5, 6], [7, 8, 9]]
)
```

$$\begin{pmatrix} 1 & 2 & 3 \\ 4 & 5 & 6 \\ 7 & 8 & 9 \end{pmatrix}$$

We replace the 2nd column by - *col*(*A*, 1) + *col*(*A*, 2), i.e., we subtract the first column from the second:

```
linalg::addCol(A, 1, 2, -1)
```

$$\begin{pmatrix} 1 & 1 & 3 \\ 4 & 1 & 6 \\ 7 & 1 & 9 \end{pmatrix}$$

Example 2

The following defines a 2×3 matrix over the reals:

```
B := Dom::Matrix(Dom::Real)(
  [[sin(2), 0, 1], [1, PI, 0]]
)
```

$$\begin{pmatrix} \sin(2) & 0 & 1 \\ 1 & \pi & 0 \end{pmatrix}$$

If `s` is an expression that does not represent a real number then an error message is reported. The following tries to replace the 1st column by *x* *col*(*B*, 3) + *col*(*B*, 1), where *x* is an identifier which cannot be converted to the component ring `Dom::Real` of *B*:

```
delete x: linalg::addCol(B, 3, 1, x)
```

```
Error: Cannot convert 'x'. [linalg::addCol]
```

Example 3

If symbolic expressions are involved, then one may define matrices over a component ring created by `Dom::ExpressionField`. The following example defines a matrix over this default component ring:

```
delete a11, a12, a21, a22, x:
C := matrix([[a11, a12], [a21, a22]])
```

$$\begin{pmatrix} a11 & a12 \\ a21 & a22 \end{pmatrix}$$

We retry the input from the previous example:

```
linalg::addCol(C, 2, 1, x)
```

$$\begin{pmatrix} a11 + a12\,x & a12 \\ a21 + a22\,x & a22 \end{pmatrix}$$

Parameters

A

An $m \times n$ matrix of a domain of category `Cat::Matrix`

c_1, c_2

The column indices: positive integers less or equal to n

s_1, s_2

Expressions that can be converted to the component ring of A

Return Values

Matrix of the same domain type as A.

See Also

MuPAD Domains
`Dom::Matrix`

MuPAD Functions
`linalg::addRow` | `linalg::col` | `linalg::multCol` | `linalg::multRow`

linalg::addRow

Linear combination of matrix rows

Syntax

```
linalg::addRow(A, r₁, r₂, s)
```

```
linalg::addRow(A, r₁, r₂, s₁, s₂)
```

Description

`linalg::addRow(A, r₁, r₂, s₁)` adds s_1 times row r_1 to row r_2, in the matrix `A`.

`linalg::addRow(A, r₁, r₂, s)` returns a copy of the matrix A in which row r_2 of A is replaced by $s\,row(A, r_1) + row(A, r_2)$.

`linalg::addRow(A, r₁, r₂, s₁, s₂)` returns a copy of the matrix A in which row r_2 of A is replaced by $s_1\,row(A, r_1) + s_2\,row(A, r_2)$.

Examples

Example 1

The following defines a 3×3 matrix over the integers:

```
A := Dom::Matrix(Dom::Integer)(
  [[1, 2, 3], [4, 5, 6], [7, 8, 9]]
)
```

$$\begin{pmatrix} 1 & 2 & 3 \\ 4 & 5 & 6 \\ 7 & 8 & 9 \end{pmatrix}$$

We replace the 2nd row by - $row(A, 1) + row(A, 2)$, i.e., we subtract the first row from the second:

```
linalg::addRow(A, 1, 2, -1)
```

$$\begin{pmatrix} 1 & 2 & 3 \\ 3 & 3 & 3 \\ 7 & 8 & 9 \end{pmatrix}$$

Example 2

The following defines a 2×3 matrix over the reals:

```
B := Dom::Matrix(Dom::Real)(
  [[sin(2), 0, 1], [1, PI, 0]]
)
```

$$\begin{pmatrix} \sin(2) & 0 & 1 \\ 1 & \pi & 0 \end{pmatrix}$$

If `s` is an expression that does not represent a real number then an error message is reported. The following tries to replace the 1st row by $x\,row(B, 2) + row(B, 1)$, where x is an identifier which cannot be converted to the component ring `Dom::Real` of B:

```
delete x: linalg::addRow(B, 2, 1, x)
```

```
Error: Cannot convert 'x'. [linalg::addRow]
```

Example 3

If symbolic expressions are involved, then one may define matrices over the component ring created by `Dom::ExpressionField`. The following example defines a matrix over this default component ring:

```
delete a11, a12, a21, a22, x:
C := matrix([[a11, a12], [a21, a22]])
```

$$\begin{pmatrix} a11 & a12 \\ a21 & a22 \end{pmatrix}$$

We retry the input from the previous example:

```
linalg::addRow(C, 2, 1, x)
```

$$\begin{pmatrix} a11 + a21\,x & a12 + a22\,x \\ a21 & a22 \end{pmatrix}$$

Parameters

A

An $m \times n$ matrix of a domain of category `Cat::Matrix`

r_1, r_2

The row indices: positive integers less or equal to m

s, s_1, s_2

Expressions that can be converted to the component ring of A

Return Values

Matrix of the same domain type as A.

See Also

MuPAD Functions

`linalg::addCol` | `linalg::multCol` | `linalg::multRow` | `linalg::row`

linalg::adjoint

Adjoint of a matrix

Syntax

```
linalg::adjoint(A)
```

Description

`linalg::adjoint(A)` computes the adjoint $Adj(A)$ of the $n \times n$ matrix A. The adjoint matrix satisfies the equation $A\ \mathrm{Adj}(A) = \det A\ I_n$, where I_n is the $n \times n$ identity matrix.

The component ring of `A` must be of category `Cat::CommutativeRing`.

Examples

Example 1

We define a matrix over the rationals:

```
MatQ := Dom::Matrix(Dom::Rational):
A := MatQ([[0, 2, 1], [2, 1, 0], [1, 0, 2]])
```

$$\begin{pmatrix} 0 & 2 & 1 \\ 2 & 1 & 0 \\ 1 & 0 & 2 \end{pmatrix}$$

Then the adjoint matrix of `A` is given by:

```
Ad := linalg::adjoint(A)
```

$$\begin{pmatrix} 2 & -4 & -1 \\ -4 & -1 & 2 \\ -1 & 2 & -4 \end{pmatrix}$$

We check the property of the adjoint matrix Ad mentioned above:

```
A * Ad = det(A)*MatQ::identity(3)
```

$$\begin{pmatrix} -9 & 0 & 0 \\ 0 & -9 & 0 \\ 0 & 0 & -9 \end{pmatrix} = \begin{pmatrix} -9 & 0 & 0 \\ 0 & -9 & 0 \\ 0 & 0 & -9 \end{pmatrix}$$

Parameters

A

A square matrix of a domain of category `Cat::Matrix`

Return Values

Matrix of the same domain type as A.

Algorithms

The adjoint of a square matrix A is the matrix whose (i, j)-th entry is the (j, i)-th cofactor of A.

The (j, i)-th *cofactor* of A is defined by $\alpha'_{ji} = (-1)^{i+j} \det\left(A_{ij}\right)$, where A_{ij} is the submatrix of A obtained from A by deleting the i-th row and j-th column.

See Also

MuPAD Functions

`det`

linalg::angle

Angle between two vectors

Syntax

```
linalg::angle(u, v)
```

Description

`linalg::angle(u,v)` computes the angle φ between the two vectors `u` and `v`, defined by

$$\varphi = \mathrm{acos}\left(\frac{\langle \vec{u}, \vec{v}\rangle}{\|\vec{u}\|_2 \, \|\vec{v}\|_2}\right),$$

where $\langle \vec{u}, \vec{v}\rangle$ denotes the scalar product of two vectors given by `linalg::scalarProduct`, and $\|\cdot\|_2$ the 2-norm of a vector, i.e., $\|\vec{u}\|_2 = \sqrt{\langle \vec{u}, \vec{u}\rangle}$.

`linalg::angle` does not check if the computation is defined in the corresponding component ring. This can lead to an error message, as shown in “Example 2” on page 15-13.

The following relationship between the angle between $\vec{u}$ and $\vec{v}$ and the angle between $\vec{u}$ and $-\vec{v}$ holds: $\varphi(\vec{u}, \vec{v}) = \pi - \varphi(\vec{u}, \vec{v})$.

An error message is returned if the vectors are not defined over the same component ring.

Examples

Example 1

We compute the angle between the two vectors $\begin{pmatrix} 2 \\ 5 \end{pmatrix}$ and $\begin{pmatrix} -3 \\ 3 \end{pmatrix}$:

```
phi := linalg::angle(
  matrix([2, 5]), matrix([-3, 3])
)
```

$$\arccos\left(\frac{\sqrt{18}\,\sqrt{29}}{58}\right)$$

We use the function `float` to get a floating-point approximation of this number:

```
float(phi)
```

$$1.165904541$$

We give two further examples:

```
linalg::angle(
  matrix([1, -1]), matrix([1, 1])
)
```

$$\frac{\pi}{2}$$

```
linalg::angle(
  matrix([1, 1]), matrix([-1, -1])
)
```

$$\pi$$

Example 2

`linalg::angle` does not check whether the term $\frac{\langle \vec{u}, \vec{v} \rangle}{\|\vec{u}\|_2 \, \|\vec{v}\|_2}$ is defined in the corresponding component ring.

As an example, we try to compute the angle between two vectors with components in $\mathbb{Z}_7$:

```
MatZ7 := Dom::Matrix(Dom::IntegerMod(7))
```

$$\text{Dom::Matrix}(\text{Dom::IntegerMod}(7))$$

The following call leads to an error because the 2-norm cannot be computed:

```
linalg::angle(MatZ7([1, 1]), MatZ7([-1, -1]))
```

```
Error: An integer exponent is expected. [(Dom::IntegerMod(7))::_power]
```

Note that the domain `Dom::IntegerMod(7)` does not implement the square root of an element, therefore in MuPAD you cannot compute the angle of any two vectors over $\mathbb{Z}_7$.

Parameters

u, v

Vectors of the same dimension; a vector is a $n \times 1$ or $1 \times n$ matrix of a domain of category `Cat::Matrix`

Return Values

Arithmetical expression.

See Also

MuPAD Functions

`arccos` | `linalg::scalarProduct` | `linalg::vecdim`

linalg::basis

Basis for a vector space

Syntax

```
linalg::basis(S)
```

Description

`linalg::basis(S)` returns a basis for the vector space spanned by the vectors in the set or list *S*.

`linalg::basis(S)` removes those vectors in `S` that are linearly dependent on other vectors in `S`. The result is a basis for the vector space spanned by the vectors in `S`.

For an ordered basis of vectors, `S` should be a list of vectors.

The vectors in `S` must be defined over the same component ring.

The component ring of the vectors in `S` must be a field, i.e., it must be of category `Cat::Field`.

Examples

Example 1

We define the domain of matrices over $\mathbb{Q}$:

```
MatQ := Dom::Matrix(Dom::Rational):
```

and compute a basis for the vector space spanned by the vectors $\begin{pmatrix} 3 \\ -2 \end{pmatrix}$, $\begin{pmatrix} 1 \\ 0 \end{pmatrix}$ and $\begin{pmatrix} 5 \\ -3 \end{pmatrix}$:

```
v1 := MatQ([3, -2]):
v2 := MatQ([1, 0]):
v3 := MatQ([5, -3]):
linalg::basis([v1, v2, v3])
```

$$\left[\begin{pmatrix} 3 \\ -2 \end{pmatrix}, \begin{pmatrix} 1 \\ 0 \end{pmatrix}\right]$$

If not a list but a set of vectors is given, then the basis returned may not consist of the same vectors as above. The order of the vectors in the set depends on the internal order (see `sysorder` and `DOM_SET`), i.e., the order of the vectors appears to be random:

```
b := linalg::basis({v1, v2, v3}):
op(b, 1)
```

$$\begin{pmatrix} 3 \\ -2 \end{pmatrix}$$

Parameters

S

A set or list of n-dimensional vectors; a vector is a $n \times 1$ or $1 \times n$ matrix of a domain of category `Cat::Matrix`

Return Values

Set or a list of vectors, respectively.

See Also

MuPAD Functions

`linalg::intBasis` | `linalg::sumBasis` | `lllint`

linalg::charmat

Characteristic matrix

Syntax

```
linalg::charmat(A, x)
```

Description

`linalg::charmat(A, x)` returns the characteristic matrix $x\,I_n$ - A of the $n \times n$ matrix A, where I_n denotes the $n \times n$ identity matrix.

The component ring of `A` must be a commutative ring, i.e., a domain of category `Cat::CommutativeRing`.

The characteristic matrix $M = x\,I_n - A$ of A can be evaluated at a point $x = u$ via `evalp(M, x = u)`. See "Example 2" on page 15-18.

Examples

Example 1

We define a matrix over the rational numbers:

```
A := Dom::Matrix(Dom::Rational)([[1, 2], [3, 4]])
```

$$\begin{pmatrix} 1 & 2 \\ 3 & 4 \end{pmatrix}$$

and compute the characteristic matrix of A in the variable x:

```
MA := linalg::charmat(A, x)
```

$$\begin{pmatrix} x-1 & -2 \\ -3 & x-4 \end{pmatrix}$$

The determinant of the matrix MA is a polynomial in x, the characteristic polynomial of the matrix A:

```
pA := det(MA)
```

$$x^2 - 5\,x - 2$$

```
domtype(pA)
```

Dom::DistributedPolynomial([x], Dom::Rational, LexOrder)

Of course, we can compute the characteristic polynomial of A directly via `linalg::charpoly`:

```
linalg::charpoly(A, x)
```

$$x^2 - 5\,x - 2$$

The result is of the same domain type as the polynomial pA.

Example 2

We define a matrix over the complex numbers:

```
B := Dom::Matrix(Dom::Complex)([[1 + I, 1], [1, 1 - I]])
```

$$\begin{pmatrix} 1+i & 1 \\ 1 & 1-i \end{pmatrix}$$

The characteristic matrix of B in the variable z is:

```
MB := linalg::charmat(B, z)
```

$$\begin{pmatrix} z-1-i & -1 \\ -1 & z-1+i \end{pmatrix}$$

We evaluate MB at $z = i$ and get the matrix:

```
evalp(MB, z = I)
```

$$\begin{pmatrix} -1 & -1 \\ -1 & -1+2\,i \end{pmatrix}$$

Note that this is a matrix of the domain type `Dom::Matrix(Dom::Complex)`:

```
domtype(%)
```

Dom::Matrix(Dom::Complex)

Parameters

A

A square matrix of a domain of category `Cat::Matrix`

x

An identifier

Return Values

Matrix of the domain `Dom::Matrix(Dom::DistributedPolynomial([x], R))` or of `Dom::DenseMatrix(Dom::DistributedPolynomial([x], R))`, where `R` is the component ring of `A`.

See Also

MuPAD Functions

`linalg::charpoly`

linalg::charpoly

Characteristic polynomial of a matrix

Syntax

```
linalg::charpoly(A, x)
```

Description

`linalg::charpoly(A, x)` computes the characteristic polynomial of the matrix A. The characteristic polynomial of a $n \times n$ matrix is defined by $p_A(x) := \det\left(x\, I_n - A\right)$, where I_n denotes the $n \times n$ identity matrix.

The component ring of `A` must be a commutative ring, i.e., a domain of category `Cat::CommutativeRing`.

Examples

Example 1

We define a matrix over the rational numbers:

```
A := Dom::Matrix(Dom::Rational)([[1, 2], [3, 4]])
```

$$\begin{pmatrix} 1 & 2 \\ 3 & 4 \end{pmatrix}$$

Then the characteristic polynomial $p_A(x)$ is given by:

```
linalg::charpoly(A, x)
```

$$x^2 - 5\,x - 2$$

It is of the domain type:

```
domtype(%)
```

$$\text{Dom::DistributedPolynomial}([x], \text{Dom::Rational}, \text{LexOrder})$$

Example 2

We define a matrix over $\mathbb{Z}_7$:

```
B := Dom::Matrix(Dom::IntegerMod(7))([[1, 2], [3, 0]])
```

$$\begin{pmatrix} 1 \bmod 7 & 2 \bmod 7 \\ 3 \bmod 7 & 0 \bmod 7 \end{pmatrix}$$

The characteristic polynomial $p_B(x)$ of `B` is given by:

```
p := linalg::charpoly(B, x)
```

$$(1 \bmod 7)\, x^2 + (6 \bmod 7)\, x + (1 \bmod 7)$$

We compute the zeros of $p_B(x)$, i.e., the eigenvalues of the matrix `B`:

```
solve(p)
```

$$\{[x = 3 \bmod 7],\ [x = 5 \bmod 7]\}$$

Parameters

A

A square matrix of a domain of category `Cat::Matrix`

x

An identifier

Return Values

Polynomial of the domain `Dom::DistributedPolynomial([x],R)`, where `R` is the component ring of `A`.

Algorithms

`linalg::charpoly` implements Hessenberg's algorithm to compute the characteristic polynomial of a square matrix A. See: Henri Cohen: *A Course in Computational Algebraic Number Theory*, GTM 138, Springer Verlag.

This algorithm works for any field and requires only $O(n^3)$ field operations, in contrast to $O(n^4)$ when computing the determinant of the characteristic matrix of A.

Since the size of the components of A in intermediate computations of Hessenberg's algorithm can swell extremely, it is only applied for matrices over `Dom::Float` and `Dom::IntegerMod`.

For any other component ring, the characteristic polynomial is computed using the Berkowitz algorithm.

References

Reference: Jounaidi Abdeljaoued, *The Berkowitz Algorithm, Maple and Computing the Characteristic Polynomial in an Arbitrary Commutative Ring*, MapleTech Vol 4 No 3, pp 21-32, Birkhäuser, 1997.

MuPAD Functions

`det` | `linalg::charmat` | `linalg::hessenberg` | `linalg::minpoly`

linalg::col

Extract columns of a matrix

Syntax

```
linalg::col(A, c)
```

```
linalg::col(A, c1 .. c2)
```

```
linalg::col(A, list)
```

Description

`linalg::col(A, c)` extracts the *c*-th column vector of the matrix *A*.

`linalg::col(A, c1.. c2)` returns a list of column vectors whose indices are in the range `c1.. c2`. If `c2< c1` then the empty list `[]` is returned.

`linalg::col(A, list)` returns a list of column vectors whose indices are contained in `list` (in the same order).

Examples

Example 1

We define a matrix over $\mathbb{Q}$:

```
A := Dom::Matrix(Dom::Rational)(
  [[1, 1/5, 2], [-3/2, 0, 5]]
)
```

$$\begin{pmatrix} 1 & \frac{1}{5} & 2 \\ -\frac{3}{2} & 0 & 5 \end{pmatrix}$$

and illustrate the three different input formats for `linalg::col`:

```
linalg::col(A, 2)
```

$$\begin{pmatrix} \frac{1}{5} \\ 0 \end{pmatrix}$$

```
linalg::col(A, [2, 1, 3])
```

$$\left[\begin{pmatrix} \frac{1}{5} \\ 0 \end{pmatrix}, \begin{pmatrix} 1 \\ -\frac{3}{2} \end{pmatrix}, \begin{pmatrix} 2 \\ 5 \end{pmatrix}\right]$$

```
linalg::col(A, 2..3)
```

$$\left[\begin{pmatrix} \frac{1}{5} \\ 0 \end{pmatrix}, \begin{pmatrix} 2 \\ 5 \end{pmatrix}\right]$$

Parameters

`A`

An $m \times n$ matrix of a domain of category `Cat::Matrix`

`c`

The column index: a positive integer less or equal to n

c_1 `..` c_2

A range of column indices (positive integers less or equal to n)

`list`

A list of column indices (positive integers less or equal to n)

Return Values

Single column vector or a list of column vectors; a column vector is an $m \times 1$ matrix of category `Cat::Matrix(R)`, where R is the component ring of `A`.

See Also

MuPAD Functions

`linalg::delCol` | `linalg::delRow` | `linalg::row` | `linalg::setCol` | `linalg::setRow`

linalg::companion

Companion matrix of a univariate polynomial

Syntax

```
linalg::companion(p, <x>)
```

Description

`linalg::companion(p)` returns the companion matrix associated with the polynomial *p*.

`p` must be monic and of degree one at least.

If `p` is a polynomial, i.e., an object of type `DOM_POLY`, then specifying `x` has no effect.

If `p` is a polynomial, then the component ring of the returned matrix is the coefficient ring of `p`, except in two cases for built-in coefficient rings: if the coefficient ring of `p` is `Expr` then the domain `Dom::ExpressionField()` is the component ring of the companion matrix. If it is `IntMod(m)` then the companion matrix is defined over the ring `Dom::IntegerMod(m)` (see “Example 2” on page 15-27).

If `p` is a polynomial expression, then the companion matrix is defined over `Dom::ExpressionField()`.

If `p` is a polynomial expression containing several symbolic indeterminates then `x` must be specified and distinguishes the indeterminate `x` from the other symbolic parameters.

Examples

Example 1

We start with the following polynomial expression:

```
delete a_0, a_1, a_2, a_3:
p := x^4 + a_3*x^3 + a_2*x^2 + a_1*x + a_0
```

$$x^4 + a_3 x^3 + a_2 x^2 + a_1 x + a_0$$

To compute the companion matrix of p with respect to x we must specify the second parameter x, because the expression `p` contains the indeterminates a_0, a_1, a_2, a_3 and x:

```
linalg::companion(p)
```

```
Error: The polynomial expression is multivariate. Specify the indeterminate as second a
```

```
linalg::companion(p, x)
```

$$\begin{pmatrix} 0 & 0 & 0 & -a_0 \\ 1 & 0 & 0 & -a_1 \\ 0 & 1 & 0 & -a_2 \\ 0 & 0 & 1 & -a_3 \end{pmatrix}$$

Of course, we can compute the companion matrix of p with respect to a_0 as well:

```
linalg::companion(p, a_0)
```

$$\left(-x^4 - a_3 x^3 - a_2 x^2 - a_1 x \right)$$

The following fails with an error message, because the polynomial p is not monic with respect to a_1:

```
linalg::companion(p, a_1)
```

```
Error: Polynomial is not monic. [linalg::companion]
```

Example 2

If we enter a polynomial over the built-in coefficient domain `Expr`, then the companion matrix is defined over the standard component ring for matrices (the domain `Dom::ExpressionField()`):

```
C := linalg::companion(poly(x^2 + 10*x + PI, [x]))
```

$$\begin{pmatrix} 0 & -\pi \\ 1 & -10 \end{pmatrix}$$

```
domtype(C)
```

Dom::Matrix()

If we define a polynomial over the build-in coefficient domain `IntMod(m)`, then the companion matrix is defined over the corresponding component ring `Dom::IntegerMod(m)`, as shown in the next example:

```
p := poly(x^2 + 10*x + 7, [x], IntMod(3))
```

$\mathrm{poly}(x^2 + x + 1, [x], \mathrm{IntMod}(3))$

```
C := linalg::companion(p)
```

$$\begin{pmatrix} 0 \bmod 3 & 2 \bmod 3 \\ 1 \bmod 3 & 2 \bmod 3 \end{pmatrix}$$

```
domtype(C)
```

Dom::Matrix(Dom::IntegerMod(3))

Parameters

p

An univariate polynomial, or a polynomial expression

x

An identifier

Return Values

Matrix of the domain `Dom::Matrix(R)`.

Algorithms

The companion matrix of the polynomial $x^n + a_{n_1} x^{n-1} + \ldots + a_1 x + a_0$ is the matrix:

$$C = \begin{pmatrix} 0 & \cdots & 0 & -a_0 \\ 1 & \ddots & & -a_1 \\ & \ddots & & \vdots \\ & & 0 & -a_{n-1} \\ & & 1 & -a_n \end{pmatrix}.$$

The companion matrix of a univariate polynomial p of degree n is an $n \times n$ matrix C with $p_C = p$, where p_C is the characteristic polynomial of C.

linalg::concatMatrix

Join matrices horizontally

Syntax

`linalg::concatMatrix(A, B1, <B2, …>)`

Description

`linalg::concatMatrix(A, B1, B2, dots )` returns the matrix formed by joining the matrices A, B_1, B_2, … horizontally.

The matrices `B1, B2, dots` are converted into the matrix domain `Dom::Matrix(R)`, where `R` is the component ring of `A`.

An error message is raised if one of these conversions fails, or if the matrices do not have the same number of rows as the matrix `A`.

A short form of `linalg::concatMatrix` is available through the dot operator `.`, i.e., instead of `linalg::concatMatrix(A, B)` one may use the short form `A . B`.

Examples

Example 1

We define the matrix:

```
A := matrix([[sin(x), x], [-x, cos(x)]])
```

$$\begin{pmatrix} \sin(x) & x \\ -x & \cos(x) \end{pmatrix}$$

and append the 2×2 identity matrix to the right of `A`:

```
I2 := matrix::identity(2):
linalg::concatMatrix(A, I2)
```

$$\begin{pmatrix} \sin(x) & x & 1 & 0 \\ -x & \cos(x) & 0 & 1 \end{pmatrix}$$

The short form for this operation is:

```
A . I2
```

$$\begin{pmatrix} \sin(x) & x & 1 & 0 \\ -x & \cos(x) & 0 & 1 \end{pmatrix}$$

Example 2

We define a matrix from the ring of 2×2 square matrices:

```
SqMatQ := Dom::SquareMatrix(2, Dom::Rational):
A := SqMatQ([[1, 2], [3, 4]])
```

$$\begin{pmatrix} 1 & 2 \\ 3 & 4 \end{pmatrix}$$

Note the following operation:

```
AA := A . A
```

$$\begin{pmatrix} 1 & 2 & 1 & 2 \\ 3 & 4 & 3 & 4 \end{pmatrix}$$

returns a matrix of a different domain type as the input matrix:

```
domtype(AA)
```

$$\text{Dom::Matrix(Dom::Rational)}$$

Parameters

A, B_1, B_2, ...

Matrices of a domain of category `Cat::Matrix`

Return Values

Matrix of the domain type `Dom::Matrix(R)`, where `R` is the component ring of `A`.

See Also

MuPAD Functions
`linalg::stackMatrix`

linalg::cond

Condition number of a matrix

Syntax

```
linalg::cond(M, <1 | 2 | Spectral | Infinity | Frobenius>)
```

Description

`linalg::cond(M)` computes the condition number of a matrix, defined by $\|M\|_\infty \left\|\frac{1}{M}\right\|_\infty$. By default the matrix norm Infinity is used by `linalg::cond`.

`linalg::cond(M)` is the short form of `linalg::cond(M, Infinity)`.

`linalg::cond(M, k)` computes the condition number of the matrix M, defined by $\|M\|_k \left\|\frac{1}{M}\right\|_k$.

For further details see the help page of `norm`.

Examples

Example 1

We define the 3×3 matrix A.

```
A := matrix(3,3, [[1,0,3],[-4,2,0],[0,3,-2]])
```

$$\begin{pmatrix} 1 & 0 & 3 \\ -4 & 2 & 0 \\ 0 & 3 & -2 \end{pmatrix}$$

Now we calculate the condition number of A for some matrix norms.

```
linalg::cond(A)
```

$$\frac{33}{10}$$

```
linalg::cond(A, Infinity)
```

$$\frac{33}{10}$$

```
linalg::cond(A, 1)
```

$$3$$

```
linalg::cond(A, Frobenius)
```

$$\frac{\sqrt{2}\,\sqrt{43}\,\sqrt{251}}{40}$$

The result for the spectral norm is too complex, so we want the floating valuation. The tiny imaginary part is a rounding artifact:

```
linalg::cond(A, 2);
float(%)
```

$$\sqrt{\frac{343}{9\,\sigma_1}+\sigma_1+\frac{43}{3}}\,\sqrt{\frac{11401}{5760000\,\sigma_2}+\sigma_2+\frac{251}{2400}}$$

where

$$\sigma_1=\left(\frac{3970}{27}+\frac{\sqrt{27}\,\sqrt{910841}\,i}{27}\right)^{1/3}$$

$$\sigma_2=\left(\frac{705851}{13824000000}+\frac{\sqrt{910841}\,\sqrt{176947200000000}\,i}{176947200000000}\right)^{1/3}$$

$$2.223147175+1.386849201\,10^{-18}\,i$$

If *A* contains at least one floating-point number, the result will be computed numerically.

```
B := A:
B[1,1] := float(B[1,1]):
linalg::cond(B, 2)
```

$$2.223147175$$

Example 2

We define the 2×2 matrix C.

```
C := matrix([[1,-2],[3,-4]])
```

$$\begin{pmatrix} 1 & -2 \\ 3 & -4 \end{pmatrix}$$

Now we calculate the condition number of C for some matrix norms.

```
linalg::cond(C,1)
```

$$21$$

```
linalg::cond(C,Infinity)
```

$$21$$

```
linalg::cond(C,Frobenius); Simplify(%);
```

$$\frac{\sqrt{2}\,\sqrt{15}\,\sqrt{30}}{2}$$

$$15$$

Example 3

Hilbert matrices are very ill-conditioned:

```
linalg::cond( linalg::hilbert(3) )
```

$$748$$

```
linalg::cond( linalg::hilbert(5) )
```

$$943656$$

```
linalg::cond( linalg::hilbert(7) )
```

$$\frac{1970389773}{2}$$

Parameters

M

Square matrix of domain type `Dom::Matrix`

Options

`Frobenius`, **`Infinity`**, **`Spectral`**

The index of the matrix norm.

Return Values

Arithmetical expression.

See Also

MuPAD Functions
`norm`

linalg::crossProduct

Cross product of three-dimensional vectors

Syntax

```
linalg::crossProduct(u, v)
```

Description

`linalg::crossProduct(u, v)` computes the cross product of the three-dimensional vectors $\vec{u}$ and $\vec{v}$. This is the vector

$$\vec{u} \times \vec{v} = \begin{pmatrix} u_2\, v_3 - u_3\, v_2 \\ u_3\, v_1 - u_1\, v_3 \\ u_1\, v_2 - u_2\, v_1 \end{pmatrix}.$$

The vectors must be defined over the same component ring.

Examples

Example 1

We define two vectors:

```
a := matrix([[1, 2, 3]]);
b := matrix([[-1, 0, 1]])
```

$$\begin{pmatrix} 1 & 2 & 3 \end{pmatrix}$$

$$\begin{pmatrix} -1 & 0 & 1 \end{pmatrix}$$

The cross product of these two vectors is a vector $\vec{c}$ which is orthogonal to $\vec{a}$ and $\vec{b}$:

```
c:= linalg::crossProduct(a, b)
```

$$(2 \quad -4 \quad 2)$$

```
linalg::scalarProduct(a, c), linalg::scalarProduct(b, c)
```

$$0, 0$$

Parameters

u, v

3-dimensional vectors, i.e., either two 3 ×1 or two 1 ×3 matrices of a domain of category `Cat::Matrix`

Return Values

Vector of the same domain type as `u`.

See Also

MuPAD Functions

`linalg::scalarProduct`

linalg::delCol

Delete matrix columns

Syntax

```
linalg::delCol(A, c)
```

```
linalg::delCol(A, c1 .. c2)
```

```
linalg::delCol(A, list)
```

Description

`linalg::delCol(A, c)` returns a copy of the matrix *A* in which the column with index *c* is deleted.

`linalg::delCol(A, c1.. c2)` deletes those columns whose indices are in the range `c1.. c2`. If `c2< c1` then the input matrix `A` is returned.

`linalg::delCol(A, list)` deletes those columns whose indices are contained in `list`.

If all columns are deleted then `NIL` is returned.

Examples

Example 1

We define the following matrix:

```
A := matrix([[1, 2, 3, 4], [5, 6, 7, 8]])
```

$$\begin{pmatrix} 1 & 2 & 3 & 4 \\ 5 & 6 & 7 & 8 \end{pmatrix}$$

and demonstrate the three different input formats for `linalg::delCol`:

```
linalg::delCol(A, 2)
```

$$\begin{pmatrix} 1 & 3 & 4 \\ 5 & 7 & 8 \end{pmatrix}$$

```
linalg::delCol(A, [1, 3])
```

$$\begin{pmatrix} 2 & 4 \\ 6 & 8 \end{pmatrix}$$

```
linalg::delCol(A, 2..4)
```

$$\begin{pmatrix} 1 \\ 5 \end{pmatrix}$$

Example 2

We compute the inverse of the 2×2 matrix:

```
MatQ := Dom::Matrix(Dom::Rational):
A := MatQ([[3, 2], [5, -4]])
```

$$\begin{pmatrix} 3 & 2 \\ 5 & -4 \end{pmatrix}$$

by appending the 2×2 identity matrix to the right side of A and applying the Gauss-Jordan algorithm provided by the function `linalg::gaussJordan`:

```
B := linalg::gaussJordan(A . MatQ::identity(2))
```

$$\begin{pmatrix} 1 & 0 & \frac{2}{11} & \frac{1}{11} \\ 0 & 1 & \frac{5}{22} & -\frac{3}{22} \end{pmatrix}$$

We get the inverse of `A` by deleting the first two columns of the matrix `B`:

```
AI := linalg::delCol(B, 1..2)
```

$$\begin{pmatrix} \frac{2}{11} & \frac{1}{11} \\ \frac{5}{22} & -\frac{3}{22} \end{pmatrix}$$

Finally, we check the result:

```
A * AI, AI * A
```

$$\begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}, \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}$$

Note: The inverse of `A` can be computed directly by entering `1/A`.

Parameters

`A`

An $m \times n$ matrix of a domain of category `Cat::Matrix`

`c`

The column index: a positive integer less or equal to n

c_1 `..` c_2

A range of column indices (positive integers less or equal to n)

`list`

A list of column indices (positive integers less or equal to n)

Return Values

Matrix of a domain of category `Cat::Matrix(R)`, where `R` is the component ring of `A`, or `NIL`.

More About

- "Swap and Delete Rows and Columns"

linalg::delRow

Delete matrix rows

Syntax

```
linalg::delRow(A, r)
```

```
linalg::delRow(A, r1 .. r2)
```

```
linalg::delRow(A, list)
```

Description

`linalg::delRow(A, r)` returns a copy of the matrix A in which the row with index r is deleted.

`linalg::delRow(A, r1.. r2)` deletes those rows whose indices are in the range `r1.. r2`. If `r2< r1` then the input matrix `A` is returned.

`linalg::delRow(A, list)` deletes those rows whose indices are contained in `list`.

If all rows are deleted then `NIL` is returned.

Examples

Example 1

We define the following matrix:

```
A := matrix([[1, 2], [3, 4], [5, 6], [7, 8]])
```

$$\begin{pmatrix} 1 & 2 \\ 3 & 4 \\ 5 & 6 \\ 7 & 8 \end{pmatrix}$$

and illustrate the three different input formats for `linalg::delRow`:

```
linalg::delRow(A, 2)
```

$$\begin{pmatrix} 1 & 2 \\ 5 & 6 \\ 7 & 8 \end{pmatrix}$$

```
linalg::delRow(A, [1, 4])
```

$$\begin{pmatrix} 3 & 4 \\ 5 & 6 \end{pmatrix}$$

```
linalg::delRow(A, 2..4)
```

$$\begin{pmatrix} 1 & 2 \end{pmatrix}$$

Parameters

`A`

An $m \times n$ matrix of a domain of category `Cat::Matrix`

`r`

The row index: a positive integer less or equal to m

r_1 `..` r_2

A range of row indices (positive integers less or equal to m)

`list`

A list of row indices (positive integers less or equal to m)

Return Values

Matrix of a domain of category `Cat::Matrix(R)`, where `R` is the component ring of `A` or `NIL`.

More About

- "Swap and Delete Rows and Columns"

linalg::eigenvalues

Eigenvalues of a matrix

Syntax

```
linalg::eigenvalues(A, <Multiple>)
```

Description

`linalg::eigenvalues(A)` returns a list of the eigenvalues of the matrix A.

A floating-point approximation of the eigenvalues is computed with `numeric::eigenvalues`, if the matrix `A` is defined over the component ring `Dom::Float` (see "Example 1" on page 15-46). In this case it is recommended to call `numeric::eigenvalues` directly for a better efficiency.

The eigenvalues are obtained by computing the zeros of the characteristic polynomial of `A`. The solver `solve` must be able to compute the roots of the characteristic polynomial over the component ring of `A`.

Examples

Example 1

We compute the eigenvalues of the matrix

$$A = \begin{pmatrix} 1 & 4 & 2 \\ 1 & 4 & 2 \\ 2 & 5 & 3 \end{pmatrix}.$$

```
A := matrix([[1, 4, 2], [1, 4, 2], [2, 5, 3]]):
linalg::eigenvalues(A)
```

$$\{0, 4 - \sqrt{15}, \sqrt{15} + 4\}$$

If we consider the matrix over the domain `Dom::Float`, then the call of `linalg::eigenvalues(A)` results in a numerical computation of the eigenvalues of `A` via `numeric::eigenvalues`:

```
B := Dom::Matrix(Dom::Float)(A):
linalg::eigenvalues(B)
```

$$\left\{-1.370431546\ 10^{-15},\ 0.1270166538,\ 7.872983346\right\}$$

Example 2

With the option `Multiple` we get the information about the algebraic multiplicity of each eigenvalue:

```
C := Dom::Matrix(Dom::Rational)(4, 4, [[-3], [0, 6]])
```

$$\begin{pmatrix} -3 & 0 & 0 & 0 \\ 0 & 6 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}$$

```
linalg::eigenvalues(C, Multiple)
```

$$[[-3,\ 1],\ [0,\ 2],\ [6,\ 1]]$$

Parameters

A

A square matrix of a domain of category `Cat::Matrix`

Options

Multiple

Returns a list of sublists, where each sublist contains an eigenvalue of `A` and its algebraic multiplicity. Note that due to rounding errors, this may lead to wrong results in cases where multiple eigenvalues exist and `numeric::eigenvalues` is used.

Return Values

Set of the eigenvalues of A, or a list of inner lists when the option `Multiple` is given (see below).

See Also

MuPAD Functions

`linalg::charpoly` | `linalg::eigenvectors` | `numeric::eigenvalues` | `solve`

linalg::eigenvectors

Eigenvectors of a matrix

Syntax

```
linalg::eigenvectors(A)
```

Description

`linalg::eigenvectors(A)` computes the eigenvalues and eigenvectors of the matrix A.

A floating-point approximation of the eigenvalues and the eigenvectors is computed using `numeric::eigenvectors`, if the matrix `A` is defined over the component ring `Dom::Float` (see "Example 1" on page 15-50). In this case it is recommended to call `numeric::eigenvalues` directly for a better efficiency.

`linalg::eigenvectors` works as follows: For each eigenvalue λ of the $n \times n$ matrix `A`, a basis for the kernel of ($\lambda\, I_n$ - A), the eigenspace of `A` with respect to the eigenvalue λ, is computed using the Gauss-Jordan algorithm (see `linalg::gaussJordan`). Here, I_n denotes the $n \times n$ identity matrix.

The eigenvectors are of the domain `Dom::Matrix(R)`, where `R` is the component ring of `A`.

The component ring of the matrix `A` must be a field, i.e., a domain of category `Cat::Field`, for which the solver `solve` is able to compute the zeros of a polynomial.

It can happen that a basis for the eigenspace of `A` with respect to a certain eigenvalue cannot be computed (e.g., if the component ring does not have a canonical representation of the zero element). In this case `linalg::eigenvectors` answers with a warning message and returns `FAIL`.

Examples

Example 1

We compute the eigenvalues and the eigenvectors of the matrix

$$A = \begin{pmatrix} 1 & -3 & 3 \\ 6 & -10 & 6 \\ 6 & 6 & 4 \end{pmatrix}$$:

```
A := Dom::Matrix(Dom::Rational)(
  [[1, -3, 3], [6, -10, 6], [6, 6, 4]]
):
Ev:= linalg::eigenvectors(A)
```

$$\left[\left[-11,\ 1,\ \left[\begin{pmatrix} -\frac{7}{10} \\ -\frac{9}{5} \\ 1 \end{pmatrix}\right]\right],\ \left[-2,\ 1,\ \left[\begin{pmatrix} -1 \\ 0 \\ 1 \end{pmatrix}\right]\right],\ \left[8,\ 1,\ \left[\begin{pmatrix} \frac{1}{4} \\ \frac{5}{12} \\ 1 \end{pmatrix}\right]\right]\right]$$

The matrix A is diagonalizable. Hence, we extract the eigenvectors and combine them to a matrix P such that P^-1 * A * P is the diagonal matrix whose diagonal entries are given by the corresponding eigenvalues:

```
Eigenvectors:= Ev[1][3][1], Ev[2][3][1], Ev[3][3][1]
```

$$\begin{pmatrix} -\frac{7}{10} \\ -\frac{9}{5} \\ 1 \end{pmatrix},\ \begin{pmatrix} -1 \\ 0 \\ 1 \end{pmatrix},\ \begin{pmatrix} \frac{1}{4} \\ \frac{5}{12} \\ 1 \end{pmatrix}$$

```
P:= Eigenvectors[1].Eigenvectors[2].Eigenvectors[3]
```

$$\begin{pmatrix} -\frac{7}{10} & -1 & \frac{1}{4} \\ -\frac{9}{5} & 0 & \frac{5}{12} \\ 1 & 1 & 1 \end{pmatrix}$$

```
P^-1 * A * P
```

$$\begin{pmatrix} -11 & 0 & 0 \\ 0 & -2 & 0 \\ 0 & 0 & 8 \end{pmatrix}$$

A more skillful way of extracting the above eigenvectors from the output generated by `linalg::eigenvectors` is the following:

```
map(Ev, op@op, 3)
```

$$\left[\begin{pmatrix} -\frac{7}{10} \\ -\frac{9}{5} \\ 1 \end{pmatrix}, \begin{pmatrix} -1 \\ 0 \\ 1 \end{pmatrix}, \begin{pmatrix} \frac{1}{4} \\ \frac{5}{12} \\ 1 \end{pmatrix}\right]$$

If we consider the matrix `A` over the domain `Dom::Float`, the call of `linalg::eigenvectors(A)` results in a numerical computation of the eigenvalues and the eigenvectors of `A` via the function `numeric::eigenvectors`:

```
B := Dom::Matrix(Dom::Float)(A):
linalg::eigenvectors(B)
```

$$\left[\left[8.0,\ 1,\ \left[\begin{pmatrix} 0.2248595067 \\ 0.3747658445 \\ 0.8994380268 \end{pmatrix}\right]\right], \left[-2.0,\ 1,\ \left[\begin{pmatrix} 0.7071067812 \\ 0.0 \\ -0.7071067812 \end{pmatrix}\right]\right],\right.$$
$$\left.\left[-11.0,\ 1,\ \left[\begin{pmatrix} 0.3218603429 \\ 0.8276408818 \\ -0.4598004899 \end{pmatrix}\right]\right]\right]$$

Parameters

A

A square matrix of a domain of category `Cat::Matrix`

Return Values

List of sublists, where each sublist consists of an eigenvalue λ of A, its algebraic multiplicity and a basis for the eigenspace of λ. If a basis of an eigenspace cannot be computed, FAIL is returned.

See Also

MuPAD Functions

`linalg::eigenvalues` | `linalg::nullspace` | `numeric::eigenvectors`

linalg::expr2Matrix

Construct a matrix from equations

Syntax

```
linalg::expr2Matrix(eqns, <vars, R>, <Include>)
```

Description

`linalg::expr2Matrix(eqns, vars)` constructs the extended coefficient matrix $\left(A, \vec{b}\right)$ of the system of m linear equations in `eqns` with respect to the n indeterminates in `vars`. The vector $\vec{b}$ is the right-hand side of this system.

`linalg::expr2Matrix` returns the extended coefficient matrix $M = \left(A, \vec{b}\right)$. The right-hand side vector $\vec{b}$ can be extracted from the matrix M by `linalg::col(M, n + 1)`.

The coefficient matrix A can be extracted by `linalg::delCol(M, n + 1)`.

Arithmetical expressions in `eqns` are considered as equations with right hand-sides zero.

If no variables are given, then the indeterminates of the equations are determined with the function `indets` and the option `PolyExpr`, i.e., the left-hand sides of the equations are considered as polynomial expressions.

If no component ring `R` is given then the standard domain `Dom::ExpressionField()` is chosen as the component ring of the extended coefficient matrix.

The coefficients of the linear equations are converted into elements of the component ring `R`. An error message is returned if this is not possible.

Examples

Example 1

The extended coefficient matrix of the system $x + y + z = 1$, $2\,y - z + 5 = 0$ of linear equations in the variables x, y, z is the following 2×4 matrix:

```
delete x, y, z:
Ab := linalg::expr2Matrix(
  [x + y + z = 1, 2*y - z + 5], [x, y, z], Dom::Real
)
```

$$\begin{pmatrix} 1 & 1 & 1 & 1 \\ 0 & 2 & -1 & -5 \end{pmatrix}$$

We use `linalg::matlinsolve` to compute the general solution of this system:

```
linalg::matlinsolve(Ab)
```

$$\left[\begin{pmatrix} \frac{7}{2} \\ -\frac{5}{2} \\ 0 \end{pmatrix}, \left[\begin{pmatrix} -\frac{3}{2} \\ \frac{1}{2} \\ 1 \end{pmatrix}\right]\right]$$

The coefficient matrix or the right-hand side vector can be be extracted from the matrix `Ab` in the following way:

```
A := linalg::delCol(Ab, 4); b := linalg::col(Ab, 4)
```

$$\begin{pmatrix} 1 & 1 & 1 \\ 0 & 2 & -1 \end{pmatrix}$$

$$\begin{pmatrix} 1 \\ -5 \end{pmatrix}$$

Example 2

The following two inputs lead to different linear systems:

```
delete x, y, z:
linalg::expr2Matrix([x + y + z = 1, 2*y - z + 5 = x]),
linalg::expr2Matrix([x + y + z = 1, 2*y - z + 5 = x], [x, y])
```

$$\begin{pmatrix} 1 & 1 & 1 & 1 \\ -1 & 2 & -1 & -5 \end{pmatrix}, \begin{pmatrix} 1 & 1 & 1-z \\ -1 & 2 & z-5 \end{pmatrix}$$

Example 3

Note the difference between calling `linalg::expr2Matrix` with and without option `Include`:

```
delete x, y:
linalg::expr2Matrix([x + y = 1, 2*x - y = 3], [x, y])
```

$$\begin{pmatrix} 1 & 1 & 1 \\ 2 & -1 & 3 \end{pmatrix}$$

```
linalg::expr2Matrix([x + y = 1, 2*x - y = 3], [x, y], Include)
```

$$\begin{pmatrix} 1 & 1 & -1 \\ 2 & -1 & -3 \end{pmatrix}$$

Parameters

`eqns`

The system of linear equations, i.e. a set or list of expressions of type `"_equal"`

`vars`

A set or list of indeterminates

`R`

A commutative ring, i.e., a domain of category `Cat::CommutativeRing`

Options

`Include`

Appends the negative of the right-hand side vector $\vec{b}$ to the coefficient matrix A of the given system of linear equations. The result is the $m \times (n+1)$ matrix $\left(A, -\vec{b}\right)$.

Return Values

$m \times (n+1)$ matrix of the domain `Dom::Matrix(R)`.

See Also

MuPAD Functions

`indets` | `linalg::matlinsolve` | `linsolve`

linalg::factorCholesky

The Cholesky decomposition of a matrix

Syntax

```
linalg::factorCholesky(A, <NoCheck>, <Real>)
```

Description

`linalg::factorCholesky(A)` computes the Cholesky factorization of a Hermitian positive definite matrix A and returns a lower triangular matrix L, such that $L\,L^H = A$. Here, L^H is the Hermitian conjugate of L (the complex conjugate of the transpose).

The component ring of `A` must be a field (a domain of category `Cat::Field`).

If A is not a Hermitian positive definite matrix, then `linalg::factorCholesky` throws an error. If you use `NoCheck`, `linalg::factorCholesky` does not check whether the matrix is Hermitian positive definite. See "Example 2" on page 15-58.

If you use `Real`, then `linalg::factorCholesky` assumes that `A` is real and symmetric and, therefore, does not apply complex conjugate in the course of the algorithm.

`linalg::factorCholesky` returns `FAIL` if it fails to compute the matrix L over the component ring of `A`. (The algorithm requires the computation of square roots of some elements in L).

Environment Interactions

Properties of identifiers are taken into account.

Examples

Example 1

Define matrix `S` as follows:

```
S := Dom::Matrix(Dom::Rational)(
  [[4, -2, 4, 2], [-2, 10, -2, -7], [4, -2, 8, 4], [2, -7, 4, 7]]
)
```

$$\begin{pmatrix} 4 & -2 & 4 & 2 \\ -2 & 10 & -2 & -7 \\ 4 & -2 & 8 & 4 \\ 2 & -7 & 4 & 7 \end{pmatrix}$$

Compute the Cholesky factorization of S:

```
L := linalg::factorCholesky(S)
```

$$\begin{pmatrix} 2 & 0 & 0 & 0 \\ -1 & 3 & 0 & 0 \\ 2 & 0 & 2 & 0 \\ 1 & -2 & 1 & 1 \end{pmatrix}$$

Verify the result:

```
is(L * htranspose(L) = S)
```

$$\text{TRUE}$$

Example 2

Define matrix H as follows:

```
H := matrix([[a, b], [b, a]])
```

$$\begin{pmatrix} a & b \\ b & a \end{pmatrix}$$

`linalg::factorCholesky` cannot compute the Cholesky factorization because it cannot prove that H is a Hermitian matrix:

```
linalg::factorCholesky(H)
```

```
Error: A Hermitian matrix is expected. [linalg::factorCholesky]
```

If you assume that `a` and `b` are real, then matrix `H` is Hermitian. Still, `linalg::factorCholesky` cannot compute the Cholesky factorization:

```
linalg::factorCholesky(H) assuming a in R_ and b in R_
```

```
Error: Cannot check whether the matrix component is positive. [linalg::factorCholesky]
```

Use the `NoCheck` option to skip checking whether this matrix is Hermitian positive definite. Now, `linalg::factorCholesky` computes the factorization:

```
L := linalg::factorCholesky(H, NoCheck)
```

$$\begin{pmatrix} \sqrt{a} & 0 \\ \frac{b}{\sqrt{a}} & \frac{\sqrt{a\,|a| - |b|^2}}{\sqrt{|a|}} \end{pmatrix}$$

This result is not generally valid:

```
L*htranspose(L) = H
```

$$\begin{pmatrix} \sqrt{a}\,\overline{\sqrt{a}} & \frac{\sqrt{a}\,\overline{b}}{\overline{\sqrt{a}}} \\ \frac{b\,\overline{\sqrt{a}}}{\sqrt{a}} & \frac{\overline{\sqrt{a\,|a| - |b|^2}}\,\sqrt{a\,|a| - |b|^2}}{|a|} + \frac{b\,\overline{b}}{\sqrt{a}\,\overline{\sqrt{a}}} \end{pmatrix} = \begin{pmatrix} a & b \\ b & a \end{pmatrix}$$

It is valid for `0 < a < b`:

```
simplify(L*htranspose(L) = H) assuming 0 < b < a
```

$$\begin{pmatrix} a & b \\ b & a \end{pmatrix} = \begin{pmatrix} a & b \\ b & a \end{pmatrix}$$

Example 3

Compute the Cholesky factorization of matrix `H` using `NoCheck` to skip checking whether it is Hermitian positive definite. By default, `linalg::factorCholesky` computes a Hermitian factorization $A = L\,L^H$. Thus, the result contains complex conjugates (implied by $|a| = a^*\bar{a}$).

```
H := matrix([[a, b], [b, a]]):
L := linalg::factorCholesky(H, NoCheck)
```

$$\begin{pmatrix} \sqrt{a} & 0 \\ \frac{b}{\sqrt{a}} & \frac{\sqrt{a\,|a| - |b|^2}}{\sqrt{|a|}} \end{pmatrix}$$

To avoid complex conjugates in the result, use `Real`:

```
L := linalg::factorCholesky(H, NoCheck, Real)
```

$$\begin{pmatrix} \sqrt{a} & 0 \\ \frac{b}{\sqrt{a}} & \sqrt{\frac{a^2 - b^2}{a}} \end{pmatrix}$$

With this option, `linalg::factorCholesky` computes a symmetric factorization $A = L\,L^t$ instead of a Hermitian factorization $A = L\,L^H$:

```
simplify(L*transpose(L) = H)
```

$$\begin{pmatrix} a & b \\ b & a \end{pmatrix} = \begin{pmatrix} a & b \\ b & a \end{pmatrix}$$

Parameters

A

Square matrix of a domain of category `Cat::Matrix`.

Options

NoCheck

Skip checking whether A is Hermitian positive definite. When you use this option, the identity $L\,L^H = A$ is guaranteed to hold only if A is a Hermitian positive definite matrix.

`Real`

Compute the Cholesky factorization assuming that matrix A is symmetric and all its symbolic parameters are real. In this case, the transpose of the matrix is its Hermitian transpose. Use this option if A contains symbolic parameters, and you want to avoid complex conjugates. When using this option, the identity $L\,L^T = A$ is guaranteed to hold.

Return Values

Matrix of the same domain type as `A`, or the value `FAIL`.

Algorithms

The Cholesky factorization of a Hermitian positive definite $n \times n$ matrix A is a decomposition of A in a product $L\,L^H = A$, such that L is a lower triangular matrix with positive entries on the main diagonal. L is called the "Cholesky factor" of A.

If $L = (l_{i,j})$, where $1 \le i \le n$, $1 \le j \le n$, is the Cholesky factor of A, then $\det A = \left(\prod_{i=1}^{n} l_{ii}\right)^2$.

See Also

MuPAD Functions

`linalg::isHermitian` | `linalg::isPosDef`

linalg::factorLU

LU-decomposition of a matrix

Syntax

```
linalg::factorLU(A)
```

Description

`linalg::factorLU(A)` computes an LU-decomposition of an $m \times n$ matrix A, i.e., a decomposition of the A into an $m \times m$ lower triangular matrix L and an $m \times n$ upper triangular matrix U such that $PA = LU$, where P is a permutation matrix.

The diagonal entries of the lower triangular matrix L are equal to one (*Doolittle*-decomposition). The diagonal entries of U are the pivot elements used during the computation.

The matrices L and U are unique.

`pivindex` is a list `[ r1, r2, ...]` representing the row exchanges of A in the pivoting steps, i.e., $B = PA = LU$, where $b_{ij} = a_{r_i, j}$.

A floating-point approximation of the decomposition is computed using `numeric::factorLU`, if the matrix `A` is defined over the component ring `Dom::Float`. In this case it is recommended to call `numeric::factorLU` directly for a better efficiency.

The algorithm also works for singular A. In this case either L or U is singular.

L and U are nonsingular if and only if A is nonsingular.

The component ring of the matrix `A` must be a field, i.e., a domain of category `Cat::Field`.

Examples

Example 1

We compute an LU-decomposition of the real matrix:

```
A := Dom::Matrix(Dom::Real)(
  [[2, -3, -1], [1, 1, -1], [0, 1, -1]]
)
```

$$\begin{pmatrix} 2 & -3 & -1 \\ 1 & 1 & -1 \\ 0 & 1 & -1 \end{pmatrix}$$

```
[L, U, pivlist] := linalg::factorLU(A)
```

$$\left[\begin{pmatrix} 1 & 0 & 0 \\ \frac{1}{2} & 1 & 0 \\ 0 & \frac{2}{5} & 1 \end{pmatrix}, \begin{pmatrix} 2 & -3 & -1 \\ 0 & \frac{5}{2} & -\frac{1}{2} \\ 0 & 0 & -\frac{4}{5} \end{pmatrix}, [1, 2, 3]\right]$$

The lower triangular matrix L is the first element und the upper triangular matrix U is the second element of the list LU. The product of these two matrices is equal to the input matrix A:

```
L * U
```

$$\begin{pmatrix} 2 & -3 & -1 \\ 1 & 1 & -1 \\ 0 & 1 & -1 \end{pmatrix}$$

Example 2

An LU-decomposition of the 3×2 matrix:

```
A := Dom::Matrix(Dom::Real)([[2, -3], [1, 2], [2, 3]])
```

$$\begin{pmatrix} 2 & -3 \\ 1 & 2 \\ 2 & 3 \end{pmatrix}$$

gives a 3×3 lower triangular matrix and a 3×2 upper triangular matrix:

```
[L, U, pivlist] := linalg::factorLU(A)
```

$$\left[\begin{pmatrix} 1 & 0 & 0 \\ \frac{1}{2} & 1 & 0 \\ 1 & \frac{12}{7} & 1 \end{pmatrix}, \begin{pmatrix} 2 & -3 \\ 0 & \frac{7}{2} \\ 0 & 0 \end{pmatrix}, [1, 2, 3]\right]$$

```
L * U
```

$$\begin{pmatrix} 2 & -3 \\ 1 & 2 \\ 2 & 3 \end{pmatrix}$$

Example 3

To compute the LU-decomposition of the matrix:

```
A := matrix([[1, 2, -1], [0, 0, 3], [0, 2, -1]])
```

$$\begin{pmatrix} 1 & 2 & -1 \\ 0 & 0 & 3 \\ 0 & 2 & -1 \end{pmatrix}$$

one row interchange is needed, and we therefore get a non-trivial permutation list:

```
[L, U, pivlist] := linalg::factorLU(A)
```

$$\left[\begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}, \begin{pmatrix} 1 & 2 & -1 \\ 0 & 2 & -1 \\ 0 & 0 & 3 \end{pmatrix}, [1, 3, 2]\right]$$

The corresponding permutation matrix is the following:

```
P := linalg::swapRow(matrix::identity(3), 3, 2)
```

$$\begin{pmatrix} 1 & 0 & 0 \\ 0 & 0 & 1 \\ 0 & 1 & 0 \end{pmatrix}$$

Hence, we have a decomposition of A into the product of the three matrices $\frac{1}{P}$, L and U as follows:

```
P^(-1) * L * U
```

$$\begin{pmatrix} 1 & 2 & -1 \\ 0 & 0 & 3 \\ 0 & 2 & -1 \end{pmatrix}$$

Example 4

You may compute an LU-decomposition of a matrix with symbolic components, such as:

```
delete a, b, c, d:
A := matrix([[a, b], [c, d]])
```

$$\begin{pmatrix} a & b \\ c & d \end{pmatrix}$$

The diagonal entries of the matrix U are the pivot elements used during the computation. They must be non-zero, if the inverse of U is needed:

```
[L, U, pivlist] := linalg::factorLU(A)
```

$$\left[\begin{pmatrix} 1 & 0 \\ \frac{c}{a} & 1 \end{pmatrix}, \begin{pmatrix} a & b \\ 0 & d - \frac{b\,c}{a} \end{pmatrix}, [1, 2]\right]$$

For example, if we use this decomposition to solve the linear system $A\,\vec{x} = \vec{b}$ for arbitrary vectors $\vec{b} = (b_1, b_2)^t$, then the following result is only correct for $a \neq 0$ and $d - \frac{b\,c}{a} \neq 0$:

```
delete b1, b2:
linalg::matlinsolveLU(L, U, matrix([b1, b2]))
```

$$\begin{pmatrix} \dfrac{b1 - \dfrac{b\,(a\,b2 - b1\,c)}{a\,d - b\,c}}{a} \\ \dfrac{a\,b2 - b1\,c}{a\,d - b\,c} \end{pmatrix}$$

Parameters

A

A matrix of a domain of category `Cat::Matrix`

Return Values

List `[L, U, pivindex]` with the two matrices L and U of the domain `Dom::Matrix(R)` and a list `pivindex` of positive integers. `R` is the component ring of `A`.

Algorithms

The following algorithm for solving the system $A\,\vec{x} = \vec{b}$ with a nonsingular matrix A uses LU-decomposition:

1. Compute a LU-decomposition of A: $A = L\,U$.
2. Solve $\vec{y} = \dfrac{\vec{b}}{L}$ by forward substitution.
3. Solve $\vec{x} = \dfrac{\vec{y}}{R}$ by backward substitution.

The LU-decomposition of a matrix A is useful for solving several systems of linear equations $A\,\vec{x} = \vec{b}$ with the same coefficient matrix A and several right-hand side vectors $\vec{b}$, because then step one of the algorithm above needs to be done only once.

MuPAD Functions

`linalg::factorCholesky` | `linalg::factorQR` | `linalg::inverseLU` | `linalg::matlinsolveLU` | `lllint` | `numeric::factorLU`

linalg::factorQR

QR-decomposition of a matrix

Syntax

```
linalg::factorQR(A)
```

Description

`linalg::factorQR(A)` computes an QR-decomposition of an $m \times n$ matrix A, i.e., a decomposition of A into an $m \times m$ unitary matrix Q and an $m \times n$ upper triangular matrix R such that $Q\,R = A$.

`linalg::factorQR` uses Gram-Schmidt orthonormalization to compute the decomposition.

For a singular or non-square matrix `A` the QR-decomposition of `A` is not unique.

The columns of Q form an orthonormal basis with respect to the scalar product of two vectors, defined by `linalg::scalarProduct`, and the 2-norm of two vectors (see the method `"norm"` of the domain constructor `Dom::Matrix`).

If the component ring of `A` does not define the method `"conjugate"`, then the factor Q is orthogonal instead of unitary.

If the columns of `A` cannot be orthonormalized then `FAIL` is returned.

If `A` is a matrix over the domain `Dom::Float` and the computations are based on the standard scalar product, then the use of the corresponding function from the numeric library (`numeric::factorQR`) is recommended.

Even if `A` is defined over the real or the complex numbers the call of `numeric::factorQR` with the option `Symbolic` is recommended for better efficiency.

The component ring of the matrix `A` must be a field, i.e., a domain of category `Cat::Field`.

Examples

Example 1

We compute the QR-decomposition of a real matrix:

```
A := Dom::Matrix(Dom::Real)(
  [[2, -3, -1], [1, 1, -1], [0, 1, -1]]
)
```

$$\begin{pmatrix} 2 & -3 & -1 \\ 1 & 1 & -1 \\ 0 & 1 & -1 \end{pmatrix}$$

```
QR := linalg::factorQR(A)
```

$$\left[\begin{pmatrix} \frac{2\sqrt{5}}{5} & -\frac{\sqrt{6}}{6} & -\frac{\sqrt{2}\sqrt{15}}{30} \\ \frac{\sqrt{5}}{5} & \frac{\sqrt{6}}{3} & \frac{\sqrt{2}\sqrt{15}}{15} \\ 0 & \frac{\sqrt{6}}{6} & -\frac{\sqrt{2}\sqrt{15}}{6} \end{pmatrix}, \begin{pmatrix} \sqrt{5} & -\sqrt{5} & -\frac{3\sqrt{5}}{5} \\ 0 & \sqrt{6} & -\frac{\sqrt{6}}{3} \\ 0 & 0 & \frac{2\sqrt{2}\sqrt{15}}{15} \end{pmatrix} \right]$$

The orthogonal matrix Q is the first element und the upper triangular matrix R is the second element of the list `QR`. The product of these two matrices is equal to the input matrix `A`:

```
QR[1] * QR[2]
```

$$\begin{pmatrix} 2 & -3 & -1 \\ 1 & 1 & -1 \\ 0 & 1 & -1 \end{pmatrix}$$

Example 2

The QR-decomposition of the 3×2 matrix:

```
B := Dom::Matrix(Dom::Real)(
  [[2, -3], [1, 2], [2, 3]]
)
```

$$\begin{pmatrix} 2 & -3 \\ 1 & 2 \\ 2 & 3 \end{pmatrix}$$

yields a 3×3 orthogonal matrix and a 3×2 upper triangular matrix:

```
QR := linalg::factorQR(B)
```

$$\left[\begin{pmatrix} \frac{2}{3} & -\frac{31\sqrt{194}}{582} & \frac{\sqrt{194}}{194} \\ \frac{1}{3} & \frac{8\sqrt{194}}{291} & \frac{6\sqrt{194}}{97} \\ \frac{2}{3} & \frac{23\sqrt{194}}{582} & -\frac{7\sqrt{194}}{194} \end{pmatrix}, \begin{pmatrix} 3 & \frac{2}{3} \\ 0 & \frac{\sqrt{194}}{3} \\ 0 & 0 \end{pmatrix}\right]$$

```
QR[1] * QR[2]
```

$$\begin{pmatrix} 2 & -3 \\ 1 & 2 \\ 2 & 3 \end{pmatrix}$$

For this example we may call `numeric::factorQR(B, Symbolic)` instead, which in general is faster than `linalg::factorQR`:

```
QR := numeric::factorQR(B, Symbolic)
```

$$\left[\begin{pmatrix} \frac{2}{3} & -\frac{31\sqrt{194}}{582} & \frac{\sqrt{194}}{194} \\ \frac{1}{3} & \frac{8\sqrt{194}}{291} & \frac{6\sqrt{194}}{97} \\ \frac{2}{3} & \frac{23\sqrt{194}}{582} & -\frac{7\sqrt{194}}{194} \end{pmatrix}, \begin{pmatrix} 3 & \frac{2}{3} \\ 0 & \frac{\sqrt{194}}{3} \\ 0 & 0 \end{pmatrix}\right]$$

Parameters

A

A matrix of a domain of category `Cat::Matrix`

Return Values

List `[Q, R]` of the two matrices Q and R (of the same domain type as `A`), or the value `FAIL`.

Algorithms

The QR-decomposition can be used to generate a least square solution to an overdetermined system of linear equations. If $A\,\vec{x} = \vec{b}$, then $R\,\vec{x} = Q^t\,\vec{b}$ can be solved via backward substitution.

MuPAD Functions

`linalg::factorCholesky` | `linalg::factorLU` | `lllint` | `numeric::factorQR`

linalg::frobeniusForm

Frobenius form of a matrix

Syntax

```
linalg::frobeniusForm(A, <All>)
```

Description

`linalg::frobeniusForm(A)` returns the Frobenius form of the matrix A, also called the Rational Canonical form of A.

`linalg::frobeniusForm(A, All)` computes the Frobenius form R of `A` and a transformation matrix P such that PRP^{-1}.

The Frobenius form as computed by `linalg::frobeniusForm` is unique (see below).

The component ring of `A` must be a field, i.e., a domain of category `Cat::Field`.

Examples

Example 1

The Frobenius form of the following matrix over $\mathbb{C}$:

```
A := Dom::Matrix(Dom::Complex)(
  [[1, 2, 3], [4, 5, 6], [7, 8, 9]]
)
```

$$\begin{pmatrix} 1 & 2 & 3 \\ 4 & 5 & 6 \\ 7 & 8 & 9 \end{pmatrix}$$

is the matrix:

```
R := linalg::frobeniusForm(A)
```

$$\begin{pmatrix} 0 & 0 & 0 \\ 1 & 0 & 18 \\ 0 & 1 & 15 \end{pmatrix}$$

The transformation matrix P can be selected from the list `[R, P]`, which is the result of `linalg::frobeniusForm` with option `All`:

```
P := linalg::frobeniusForm(A, All)[2]
```

$$\begin{pmatrix} 1 & 1 & 30 \\ 0 & 4 & 66 \\ 0 & 7 & 102 \end{pmatrix}$$

We check the result:

```
P * R * P^(-1)
```

$$\begin{pmatrix} 1 & 2 & 3 \\ 4 & 5 & 6 \\ 7 & 8 & 9 \end{pmatrix}$$

Parameters

A

A square matrix of a domain of category `Cat::Matrix`

Options

All

Returns the list `[R, P]` with the Frobenius form R of `A` and a transformation matrix P such that $A = P\,R\,P^{-1}$.

Return Values

Matrix of the same domain type as `A`, or the list `[R, P]` when the option `All` is given.

Algorithms

The Frobenius form of a square matrix A is the matrix

$$R = \begin{pmatrix} R_1 & & \\ & \ddots & \\ & & R_r \end{pmatrix},$$

where $R_1, \ldots, R_r$ are known as companion matrices and have the form:

$$R_i = \begin{pmatrix} 0 & \cdots & 0 & -a_0 \\ 1 & & & -a_1 \\ & \ddots & & \vdots \\ & & 0 & \vdots \\ & & 1 & -a_{n_i-1} \end{pmatrix}, \; i = 1, \ldots, r$$

.

In the last column of the companion matrix R_i, you see the coefficients of its minimal polynomial in ascending order, i.e., the polynomial $m_i := X^{n_i} + a_{n_i-1} X^{n_i-1} + \ldots + a_1 X + a_0$ is the minimal polynomial of the matrix R_i.

For these polynomials the following holds: m_{i+1} divides m_i for $i = 1, \ldots, r - 1$, and the product of all m_i for $i = 1, \ldots, r$ gives a factorization of the characteristic polynomial of the matrix A. The Frobenius form defined in this way is unique.

linalg::gaussElim

Gaussian elimination

Syntax

```
linalg::gaussElim(A, <All>)
```

Description

`linalg::gaussElim(A)` performs Gaussian elimination on the matrix A to reduce A to a similar matrix in upper row echelon form.

A row echelon form of `A` returned by `linalg::gaussElim` is not unique. See `linalg::gaussJordan` for computing the *reduced* row echelon form.

The component ring R of `A` must be an integral domain, i.e., a domain of category `Cat::IntegralDomain`.

If R is a field, i.e., a domain of category `Cat::Field`, ordinary Gaussian elimination is used. Otherwise, `linalg::gaussElim` applies fraction-free Gaussian elimination to `A`.

`linalg::gaussElim` serves as an interface function for the method `"gaussElim"` of the matrix domain of `A`, i.e., one may call `A::dom::gaussElim(A)` directly instead of `linalg::gaussElim(A, All)`

Refer to the help page of `Dom::Matrix` for details about the computation strategy of `linalg::gaussElim`.

Examples

Example 1

We apply Gaussian elimination to the following matrix:

```
A := Dom::Matrix(Dom::Rational)(
```

```
  [[1, 2, 3, 4], [-1, 0, 1, 0], [3, 5, 6, 9]]
)
```

$$\begin{pmatrix} 1 & 2 & 3 & 4 \\ -1 & 0 & 1 & 0 \\ 3 & 5 & 6 & 9 \end{pmatrix}$$

which reduces A to the following row echelon form:

```
linalg::gaussElim(A)
```

$$\begin{pmatrix} 1 & 2 & 3 & 4 \\ 0 & 2 & 4 & 4 \\ 0 & 0 & -1 & -1 \end{pmatrix}$$

Example 2

We apply Gaussian elimination to the matrix:

```
B := Dom::Matrix(Dom::Integer)(
  [[1, 2, -1], [1, 0, 1], [2, -1, 4]]
)
```

$$\begin{pmatrix} 1 & 2 & -1 \\ 1 & 0 & 1 \\ 2 & -1 & 4 \end{pmatrix}$$

and get the following result:

```
linalg::gaussElim(B, All)
```

$$\left[\begin{pmatrix} 1 & 2 & -1 \\ 0 & -2 & 2 \\ 0 & 0 & -2 \end{pmatrix}, 3, -2, \{1, 2, 3\}\right]$$

We see that $rank(B) = 3$ and $\det B = -2$.

Parameters

A

A matrix of a domain of category `Cat::Matrix`

Options

All

Returns a list $[T, \text{rank}(A), \det A, \{j_1, \ldots, j_r\}]$ where T is a row echelon form of A and $\{j_1, \ldots, j_r\}$ is the set of characteristic column indices of T.

If A is not square, then the value `FAIL` is given instead of $\det A$.

Return Values

a matrix of the same domain type as A, or the list `[T, rank(A), det(A), {j_1,dots,j_r}]` when the option `All` is given (see below).

Algorithms

Let $T = (t_{i,j})_{1 \le i \le m,\, 1 \le j \le n}$ be an $m \times n$ matrix. Then T is a matrix in an upper *row echelon form*, if $r \in \{0, 1, \ldots, n\}$ and indices $j_1, j_2, \ldots, j_r \in \{1, \ldots, n\}$ exist with:

1. $j_1 < j_2 < \cdots < j_r$.
2. For each $i \in \{1, \ldots, r\}$: $t_{i,1} = t_{i,2} = \cdots = t_{i,j_i - 1} = 0$.
3. For each $i \in \{r + 1, \ldots, m\}$: $t_{i,j} = 0$ for each $j \in \{1, \ldots, n\}$.

The indices $j_1, j_2, \ldots, j_r$ are the *characteristic column indices* of the matrix T.

See Also

MuPAD Functions

`linalg::gaussJordan` | `lllint`

linalg::gaussJordan

Gauss-Jordan elimination

Syntax

```
linalg::gaussJordan(A, <All>)
```

Description

`linalg::gaussJordan(A)` performs Gauss-Jordan elimination on the matrix A, i.e., it returns the reduced row echelon form of A.

The component ring R of `A` must be an integral domain, i.e., a domain of category `Cat::IntegralDomain`.

If R is a field, i.e., a domain of category `Cat::Field`, then the leading entries of the matrix T in reduced row echelon form are equal to one.

If R is a ring providing the method `"gcd"`, then the components of each row of T do not have a non-trivial common divisor.

If the component ring of `A` is a field, then the reduced row echelon form is unique.

Examples

Example 1

We apply Gauss-Jordan elimination to the following matrix:

```
A := Dom::Matrix(Dom::Rational)(
  [[1, 2, 3, 4], [-5, 0, 3, 0], [3, 5, 6, 9]]
)
```

$$\begin{pmatrix} 1 & 2 & 3 & 4 \\ -5 & 0 & 3 & 0 \\ 3 & 5 & 6 & 9 \end{pmatrix}$$

```
linalg::gaussJordan(A, All)
```

$$\left[\begin{pmatrix} 1 & 0 & 0 & \frac{1}{2} \\ 0 & 1 & 0 & \frac{1}{2} \\ 0 & 0 & 1 & \frac{5}{6} \end{pmatrix}, 3, \text{FAIL}, \{1, 2, 3\}\right]$$

We see that $rank(B) = 3$. Because the determinant of a matrix is only defined for square matrices, the third element of the returned list is the value `FAIL`.

Example 2

If we consider the matrix from "Example 1" on page 15-79 as an integer matrix and apply the Gauss-Jordan elimination we get the following matrix:

```
B := Dom::Matrix(Dom::Integer)(
  [[1, 2, 3, 4], [-5, 0, 3, 0], [3, 5, 6, 9]]
):
linalg::gaussJordan(B)
```

$$\begin{pmatrix} 2 & 0 & 0 & 1 \\ 0 & -2 & 0 & -1 \\ 0 & 0 & -6 & -5 \end{pmatrix}$$

Parameters

A

A matrix of a domain of category `Cat::Matrix`

Options

All

Returns a list $[T, \text{rank}(A), \det A, \{j_1, \ldots, j_r\}]$ where T is the reduced row echelon form of `A` and $\{j_1, \ldots, j_r\}$ is the set of characteristic column indices of `T`.

If A is not square, then the value FAIL is given instead of $\det A$.

Return Values

a matrix of the same domain type as A, or the list `[T, rank(A), det(A), {j_1,dots,j_r}]` when the option `All` is given (see below).

Algorithms

Let $T = (t_{i,j})_{1 \le i \le m,\, 1 \le j \le n}$ be an $m \times n$ matrix. Then T is a matrix in *reduced row echelon form*, if $r \in \{0, 1, \ldots, n\}$ and indices $j_1, j_2, \ldots, j_r \in \{1, \ldots, n\}$ exist with:

1. $j_1 < j_2 < \cdots < j_r$.
2. For each $i \in \{1, \ldots, r\}$: $t_{i,1} = t_{i,2} = \cdots = t_{i,j_i - 1} = 0$. In addition, if A is defined over a field: $t_{i,j_i} = 1$.
3. For each $i \in \{r + 1, \ldots, m\}$: $t_{i,j} = 0$ for each $j \in \{1, \ldots, n\}$.
4. For each $i \in \{1, \ldots, r\}$: $t_{k,j_i} = 0$ for each $k \in \{1, \ldots, i - 1\}$.

The indices $j_1, j_2, \ldots, j_r$ are the *characteristic column indices* of the matrix T.

MuPAD Functions

`linalg::gaussElim`

linalg::hermiteForm

Hermite normal form of a matrix

Syntax

```
linalg::hermiteForm(A, <All>)
```

Description

`linalg::hermiteForm(A)` computes the Hermite normal form of a non-singular integer square matrix A. This is an upper-triangular matrix H such that $H_{jj} \geq 0$ and $-\frac{H_{jj}}{2} < H_{ij} \leq \frac{H_{jj}}{2}$ for $j > i$. In the case, A is not a square matrix or a singular matrix, the matrix H is simply an upper-triangular matrix.

If the matrix `A` is not of the domain `Dom::Matrix(Dom::Integer)` then `A` is converted into a matrix of this domain for intermediate computations.

If this conversion fails, then an error message is returned.

`linalg::hermiteForm(A, All)` computes a transformation matrix U and a matrix H such that $H = UA$.

Examples

Example 1

We compute the Hermite normal form of the matrix:

```
A := Dom::Matrix(Dom::Rational)(
   [[9, -36, 30], [-36, 192, -180], [30, -180, 180]]
)
```

$$\begin{pmatrix} 9 & -36 & 30 \\ -36 & 192 & -180 \\ 30 & -180 & 180 \end{pmatrix}$$

```
linalg::hermiteForm(A)
```

$$\begin{pmatrix} 3 & 0 & 30 \\ 0 & 12 & 0 \\ 0 & 0 & 60 \end{pmatrix}$$

We may also compute the transformation matrix by giving the option `All`:

```
linalg::hermiteForm(A, All)
```

$$\left[\begin{pmatrix} 3 & 0 & 30 \\ 0 & 12 & 0 \\ 0 & 0 & 60 \end{pmatrix}, \begin{pmatrix} 13 & 9 & 7 \\ 6 & 4 & 3 \\ 20 & 15 & 12 \end{pmatrix}\right]$$

Let us check the result:

```
U := linalg::hermiteForm(A, All)[2]:
```

```
U * A
```

$$\begin{pmatrix} 3 & 0 & 30 \\ 0 & 12 & 0 \\ 0 & 0 & 60 \end{pmatrix}$$

Parameters

`A`

An integer matrix of category `Cat::Matrix`

Options

`All`

Returns the list `[H, U]` with the hermite normal form H of `A` and the corresponding transformation matrix U

Return Values

Either a matrix of the same domain type as `A` or the list `[H, U]` when the option `All` is given.

Algorithms

Let A be an $n \times n$ matrix with coefficients in $\mathbb{Z}$. Then there exists an $n \times n$ matrix $H = (h_{ij})$ in Hermite normal form such that $H = AU$ with $|U| = \pm 1$.

Note that H is unique, if A has full row rank. The matrix U is not unique. U may be computed by using the option `All`.

If A is a square matrix, then the product of the diagonal elements of its Hermite normal form is, up to the sign, the determinant of A.

`linalg::frobeniusForm` | `linalg::jordanForm` | `linalg::smithForm` | `lllint`

linalg::hessenberg

Hessenberg matrix

Syntax

```
linalg::hessenberg(A, <All>)
```

Description

`linalg::hessenberg(A)` returns an (upper) Hessenberg matrix H.

`linalg::hessenberg` uses Gaussian elimination without pivoting. There is no special implementation for matrices with floating-point components.

The component ring of `A` must be a field, i.e., a domain of category `Cat::Field`.

Examples

Example 1

Consider the matrix:

```
A := Dom::Matrix(Dom::Rational)(
  [[0, 1, 0, -1], [-4/3, 2/3, 5/3, -1/3],
   [-1, 2, 0, 0], [-5/3, 4/3, 1/3, 1/3]]
)
```

$$\begin{pmatrix} 0 & 1 & 0 & -1 \\ -\frac{4}{3} & \frac{2}{3} & \frac{5}{3} & -\frac{1}{3} \\ -1 & 2 & 0 & 0 \\ -\frac{5}{3} & \frac{4}{3} & \frac{1}{3} & \frac{1}{3} \end{pmatrix}$$

The following Hessenberg matrix is similar to A:

```
H := linalg::hessenberg(A)
```

$$\begin{pmatrix} 0 & -\frac{1}{4} & -\frac{1}{7} & -1 \\ -\frac{4}{3} & \frac{3}{2} & \frac{34}{21} & -\frac{1}{3} \\ 0 & \frac{7}{8} & -\frac{17}{14} & \frac{1}{4} \\ 0 & 0 & -\frac{72}{49} & \frac{5}{7} \end{pmatrix}$$

If the corresponding transformation matrix is needed as well, call `linalg::hessenberg` with option `All`:

```
[H, P] := linalg::hessenberg(A, All)
```

$$\left[\begin{pmatrix} 0 & -\frac{1}{4} & -\frac{1}{7} & -1 \\ -\frac{4}{3} & \frac{3}{2} & \frac{34}{21} & -\frac{1}{3} \\ 0 & \frac{7}{8} & -\frac{17}{14} & \frac{1}{4} \\ 0 & 0 & -\frac{72}{49} & \frac{5}{7} \end{pmatrix}, \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & -\frac{3}{4} & 1 & 0 \\ 0 & -\frac{8}{7} & -\frac{1}{7} & 1 \end{pmatrix}\right]$$

Then P is a nonsingular matrix such that the product PAP^{-1} is equal to H:

```
P * A * P^(-1)
```

$$\begin{pmatrix} 0 & -\frac{1}{4} & -\frac{1}{7} & -1 \\ -\frac{4}{3} & \frac{3}{2} & \frac{34}{21} & -\frac{1}{3} \\ 0 & \frac{7}{8} & -\frac{17}{14} & \frac{1}{4} \\ 0 & 0 & -\frac{72}{49} & \frac{5}{7} \end{pmatrix}$$

Parameters

A

A square matrix of a domain of category `Cat::Matrix`

Options

All

Returns the list `[H, P]` with a Hessenberg matrix H similar to `A` and the corresponding nonsingular transformation matrix P such that $H = PAP^{-1}$.

Return Values

Matrix of the same domain type as `A`, or the list `[H, P]` when the option `All` is given.

Algorithms

An $n \times n$ matrix $A = (a_{i,j})_{1 \le i \le n,\ 1 \le j \le n}$ is called an (upper) *Hessenberg matrix*, if the following holds: $a_{i,j} = 0$ for all $i, j \in \{1, \ldots, n\}$ with $i > j$.

For each square matrix A over a field there exists a Hessenberg matrix similar to A. In general, the upper Hessenberg matrix is not unique.

MuPAD Functions

`linalg::charpoly`

linalg::hilbert

Hilbert matrix

Syntax

```
linalg::hilbert(n, <R>)
```

Description

`linalg::hilbert(n)` returns the $n \times n$ Hilbert matrix $H = (h_{i,j})_{1 \le i \le m,\ 1 \le j \le n}$ defined by $h_{i,j} = \frac{1}{(i+j-1)}$.

The entries of Hilbert matrices are rational numbers. Note, however, that the returned matrix is not defined over the component domain `Dom::Rational`, but over the standard component domain `Dom::ExpressionField()`. Thus, no conversion is necessary when working with other functions that expect or return matrices over that component domain.

Use `linalg::hilbert(n, Dom::Rational)` to define the $n \times n$ Hilbert matrix over the field of rational numbers.

Examples

Example 1

We construct the 3×3 Hilbert matrix:

```
H := linalg::hilbert(3)
```

$$\begin{pmatrix} 1 & \frac{1}{2} & \frac{1}{3} \\ \frac{1}{2} & \frac{1}{3} & \frac{1}{4} \\ \frac{1}{3} & \frac{1}{4} & \frac{1}{5} \end{pmatrix}$$

This is a matrix of the domain `Dom::Matrix()`.

If you prefer a different component ring, the matrix may be converted to the desired domain after construction (see `coerce`, for example). Alternatively, one can specify the component ring when creating the Hilbert matrix. For example, specification of the domain `Dom::Float` generates floating-point entries:

```
H := linalg::hilbert(3, Dom::Float)
```

$$\begin{pmatrix} 1.0 & 0.5 & 0.3333333333 \\ 0.5 & 0.3333333333 & 0.25 \\ 0.3333333333 & 0.25 & 0.2 \end{pmatrix}$$

```
domtype( H )
```

Dom::Matrix(Dom::Float)

Parameters

`n`

The dimension of the matrix: a positive integer

`R`

The component ring: a domain of category `Cat::Rng`; default: `Dom::ExpressionField()`

Return Values

$n \times n$ matrix of the domain `Dom::Matrix(R)`.

Algorithms

Hilbert matrices are symmetric and positive definite.

Hilbert matrices of large dimension are notoriously ill-conditioned challenging any numerical inversion scheme. However, their inverse can also be computed by a closed formula (see `linalg::invhilbert`).

linalg::htranspose

Hermitian transpose of a matrix

Syntax

```
linalg::htranspose(M)
```

Description

`linalg::htranspose(M)` computes the Hermitian transpose of the matrix *M*.

The Hermitian transpose of *M* is computed. The result is an $n \times m$ matrix.

The [i, j]th element of the result is equal to the conjugate of the [j, i]th element of M.

Examples

Example 1

We define a 3×4 matrix:

```
A := matrix([[1, 2, 3, 4], [-I, 0, 1+I, 0], [3, 5, 6, 9]])
```

$$\begin{pmatrix} 1 & 2 & 3 & 4 \\ -i & 0 & 1+i & 0 \\ 3 & 5 & 6 & 9 \end{pmatrix}$$

Then the Hermitian transpose of A is the 4 ×3 matrix:

```
linalg::htranspose(A)
```

$$\begin{pmatrix} 1 & i & 3 \\ 2 & 0 & 5 \\ 3 & 1-i & 6 \\ 4 & 0 & 9 \end{pmatrix}$$

Parameters

M

$m \times n$ matrix of domain `Dom::Matrix`

Return Values

$n \times m$ matrix of domain `Dom::Matrix`.

Overloaded By

M

Algorithms

Let $A = (a_{i,j})_{1 \le i \le m,\ 1 \le j \le n}$ be an $m \times n$ matrix. Then the Hermitian transpose of A is the $n \times m$ matrix:

$$A^t = \begin{pmatrix} \overline{a_{1,1}} & \overline{a_{1,2}} & \cdots & \overline{a_{m,1}} \\ \overline{a_{1,2}} & \overline{a_{2,2}} & \cdots & \overline{a_{m,2}} \\ \vdots & \vdots & \cdots & \vdots \\ \overline{a_{1,n}} & \overline{a_{1,n}} & \cdots & \overline{a_{m,n}} \end{pmatrix}.$$

MuPAD Functions

`conjugate` | `linalg::transpose`

linalg::intBasis

Basis for the intersection of vector spaces

Syntax

`linalg::intBasis(`S_1`, `S_2`, …)`

Description

`linalg::intBasis( `S_1`, `S_2`, ...)` returns a basis for the intersection of the vector spaces spanned by the vectors in S_1, S_2, ….

The domain type of the vectors of the returned set is the domain type of the first parameter S_1.

A basis for the zero-dimensional space is the empty set or empty list, respectively.

The given vectors must be defined over the same component ring which must be a field, i.e., a domain of category `Cat::Field`.

Examples

Example 1

We define three vectors $\vec{v}_1, \vec{v}_2, \vec{v}_3$ in $\mathbb{Q}^2$:

```
MatQ := Dom::Matrix(Dom::Rational):
v1 := MatQ([[3, -2]]); v2 := MatQ([[1, 0]]); v3 := MatQ([[5, -3]])
```

$$\begin{pmatrix} 3 & -2 \end{pmatrix}$$

$$\begin{pmatrix} 1 & 0 \end{pmatrix}$$

$$\begin{pmatrix} 5 & -3 \end{pmatrix}$$

A basis for the vector space $V_1 \cap V_2 \cap V_3$ with

- V_1 generated by $\vec{v}_1, \vec{v}_2, \vec{v}_3$
- V_2 generated by $\vec{v}_1, \vec{v}_3$
- V_3 generated by $\vec{v}_1 + \vec{v}_2, \vec{v}_2, \vec{v}_1 + \vec{v}_3$

is:

```
linalg::intBasis([v1, v2, v3], [v1, v3], [v1 + v2, v2, v1 + v3])
```

$$[(4\ \ -2),(1\ \ 0)]$$

Example 2

The intersection of the two vector spaces spanned by the vectors in S_1 and S_2, respectively:

```
S1 := {matrix([[1, 0, 1, 0]]), matrix([[0, 1, 0, 1]])};
S2 := {matrix([[1, 2, 1, 1]]), matrix([[-1, -2, 1, 0]])}
```

$$\{(0\ 1\ 0\ 1),(1\ 0\ 1\ 0)\}$$

$$\{(-1\ -2\ 1\ 0),(1\ 2\ 1\ 1)\}$$

is the zero-dimensional space:

```
linalg::intBasis(S1, S2)
```

$$\varnothing$$

Parameters

`S1, S2, ...`

Either sets or lists of n-dimensional vectors (a vector is an $n \times 1$ or $1 \times n$ matrix of a domain of category `Cat::Matrix`)

Return Values

Set or a list of vectors, according to the domain type of the parameter S_1.

See Also

MuPAD Functions

`linalg::basis` | `linalg::sumBasis`

linalg::inverseLU

Computing the inverse of a matrix using LU-decomposition

Syntax

```
linalg::inverseLU(A)
```

```
linalg::inverseLU(L, U, pivindex)
```

Description

`linalg::inverseLU(A)` computes the inverse $\frac{1}{A}$ of the square matrix A using LU-decomposition.

`linalg::inverseLU(L, U, pivindex)` computes the inverse of the matrix $A = P^{-1} L U$ where `L`, `U` and `pivindex` are the result of an LU-deomposition of the (nonsingular) Matrix A, as computed by `linalg::factorLU`.

The matrix `A` must be nonsingular.

`pivindex` is a list `[r[1], r[2], ...]` representing a permutation matrix P such that $B = PA = LU$, where $b_{ij} = a_{r_i, j}$.

It is not checked whether `pivindex` has such a form.

The component ring of the input matrices must be a field, i.e., a domain of category `Cat::Field`.

Examples

Example 1

We compute the inverse of the matrix:

```
A := Dom::Matrix(Dom::Real)(
```

```
  [[2, -3, -1], [1, 1, -1], [0, 1, -1]]
)
```

$$\begin{pmatrix} 2 & -3 & -1 \\ 1 & 1 & -1 \\ 0 & 1 & -1 \end{pmatrix}$$

using LU-decomposition:

```
Ai := linalg::inverseLU(A)
```

$$\begin{pmatrix} 0 & 1 & -1 \\ -\frac{1}{4} & \frac{1}{2} & -\frac{1}{4} \\ -\frac{1}{4} & \frac{1}{2} & -\frac{5}{4} \end{pmatrix}$$

We check the result:

```
A * Ai, Ai * A
```

$$\begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}, \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}$$

We can also compute the inverse of A in the usual way:

```
1/A
```

$$\begin{pmatrix} 0 & 1 & -1 \\ -\frac{1}{4} & \frac{1}{2} & -\frac{1}{4} \\ -\frac{1}{4} & \frac{1}{2} & -\frac{5}{4} \end{pmatrix}$$

`linalg::inverseLU` should be used for efficiency reasons in the case where an LU decomposition of a matrix already is computed, as the next example illustrates.

Example 2

If we already have an LU decomposition of a (nonsingular) matrix, we can compute the inverse of the matrix $A = P^{1} L U$ as follows:

```
LU := linalg::factorLU(linalg::hilbert(3))
```

$$\left[\begin{pmatrix} 1 & 0 & 0 \\ \frac{1}{2} & 1 & 0 \\ \frac{1}{3} & 1 & 1 \end{pmatrix}, \begin{pmatrix} 1 & \frac{1}{2} & \frac{1}{3} \\ 0 & \frac{1}{12} & \frac{1}{12} \\ 0 & 0 & \frac{1}{180} \end{pmatrix}, [1, 2, 3]\right]$$

```
linalg::inverseLU(op(LU))
```

$$\begin{pmatrix} 9 & -36 & 30 \\ -36 & 192 & -180 \\ 30 & -180 & 180 \end{pmatrix}$$

`linalg::inverseLU` then only needs to perform forward and backward substitution to compute the inverse matrix (see also `linalg::matlinsolveLU`).

Parameters

`A, L, U`

A square matrix of a domain of category `Cat::Matrix`

`pivindex`

A list of positive integers

Return Values

Matrix of the same domain type as `A` or `L`, respectively.

See Also

MuPAD Functions

`_invert` | `linalg::factorLU` | `linalg::matlinsolveLU`

linalg::invhilbert

Inverse of a Hilbert matrix

Syntax

```
linalg::invhilbert(n, <R>)
```

Description

`linalg::invhilbert(n)` returns the inverse of the $n \times n$ Hilbert matrix H. The $n \times n$ Hilbert matrix $H = (h_{i,j})_{1 \le i \le m,\, 1 \le j \le n}$ is defined by $h_{i,j} = \frac{1}{(i+j-1)}$.

`linalg::invhilbert` uses an explicit formula for the inverse.

Note that the entries of the inverse of a Hilbert matrix are integers. But the returned matrix is defined over the standard component domain `Dom::ExpressionField()` so that no conversion is necessary when working with other functions that expect or return matrices over that component domain.

`linalg::invhilbert(n,Dom::Integer)` returns the inverse of the $n \times n$ Hilbert matrix defined over the integers.

Examples

Example 1

We compute the inverse of the 3×3 Hilbert matrix:

```
A := linalg::invhilbert(3)
```

$$\begin{pmatrix} 9 & -36 & 30 \\ -36 & 192 & -180 \\ 30 & -180 & 180 \end{pmatrix}$$

This is a matrix of the domain `Dom::Matrix()`.

If you prefer a different component ring, the matrix may be converted into the desired domain afterwards (see `coerce`, for example). Alternatively, one can specify the component ring when calling `linalg::invhilbert`, for example the domain `Dom::Float`:

```
A := linalg::invhilbert(3, Dom::Float)
```

$$\begin{pmatrix} 9.0 & -36.0 & 30.0 \\ -36.0 & 192.0 & -180.0 \\ 30.0 & -180.0 & 180.0 \end{pmatrix}$$

```
domtype( A )
```

Dom::Matrix(Dom::Float)

Parameters

n

The dimension of the matrix: a positive integer

R

The component ring: a domain of category `Cat::Rng`; default: `Dom::ExpressionField()`

Return Values

$n \times n$ matrix of the domain `Dom::Matrix(R)`.

Algorithms

Hilbert matrices of large dimension are notoriously ill-conditioned, challenging any numerical inversion scheme.

`linalg::invhilbert` uses the formula

$$\left(\frac{1}{H}\right)_{i,j} = \frac{(-1)^{i+j}\left(c_i\, c_j\right)}{i+j-1}$$

where

$$c_i = \frac{(n+i-1)!}{(n-i)!\,((i-1)!)^2}$$

for the inverse of the $n \times n$ Hilbert matrix H. All entries of $\frac{1}{H}$ are integers.

linalg::invpascal

Inverse of a Pascal matrix

Syntax

```
linalg::invpascal(n, <R>)
```

Description

`linalg::invpascal(n)` returns the inverse of the $n \times n$ Pascal matrix.

The entries of inverse Pascal matrices are integer numbers. Note, however, that the returned matrix is not defined over the component domain `Dom::Integer`, but over the standard component domain `Dom::ExpressionField()`. Thus, no conversion is necessary when working with other functions that expect or return matrices over that component domain.

The runtime to compute the inverse $n \times n$ Pascal matrix via `linalg::invpascal` is $O(n^2)$. This is much faster than inverting the Pascal matrix by a generic inversion algorithm.

The Pascal matrices are provided by `linalg::pascal`.

Examples

Example 1

We construct the inverse 3×3 Pascal matrix:

```
linalg::invpascal(3)
```

$$\begin{pmatrix} 3 & -3 & 1 \\ -3 & 5 & -2 \\ 1 & -2 & 1 \end{pmatrix}$$

This is a matrix of the domain `Dom::Matrix()`.

If you prefer a different component ring, the matrix may be converted to the desired domain after construction (see `coerce`, for example). Alternatively, one can specify the component ring when creating the inverse Pascal matrix. For example, specification of the domain `Dom::Float` generates floating-point entries:

```
linalg::invpascal(3, Dom::Float)
```

$$\begin{pmatrix} 3.0 & -3.0 & 1.0 \\ -3.0 & 5.0 & -2.0 \\ 1.0 & -2.0 & 1.0 \end{pmatrix}$$

```
domtype(%)
```

Dom::Matrix(Dom::Float)

Parameters

`n`

The dimension of the matrix: a positive integer

`R`

The component ring: a domain of category `Cat::Rng`; default: `Dom::ExpressionField()`

Return Values

$n \times n$ matrix of the domain `Dom::Matrix(R)`.

Algorithms

Pascal matrices and their inverses are symmetric and positive definite.

The determinant of a Pascal matrix and its inverse is 1.

The inverse of a Pascal matrix has integer entries.

If λ is an eigenvalue of a Pascal matrix/inverse Pascal matrix, then $\frac{1}{\lambda}$ is also an eigenvalue of the matrix.

The entries Q_{ij} of the inverse $n \times n$ Pascal matrix Q satisfy the linear relation

$$Q_{i,j} = Q_{i,j+1} + Q_{i+1,j} + (-1)^{i+j} \binom{n}{i} \binom{n}{j}.$$

This relation is used by `linalg::invpascal` to compute the matrix.

linalg::isHermitian

Checks whether a matrix is Hermitian

Syntax

```
linalg::isHermitian(A)
```

Description

`linalg::isHermitian(A)` determines whether the matrix A is Hermitian, i.e., whether $A = \overline{A}^t$, where $\overline{A}$ denotes the conjugate matrix.

If the component ring of the matrix `A` does not provide the method `"conjugate"`, then `A` is tested for symmetry, i.e., `linalg::isHermitian` returns `TRUE` if and only if `A` satisfies the equation $A = A^t$.

Examples

Example 1

Here is an example of a Hermitian matrix:

```
A := Dom::Matrix(Dom::Complex)([[1, I], [-I, 1]])
```

$$\begin{pmatrix} 1 & i \\ -i & 1 \end{pmatrix}$$

```
linalg::isHermitian(A)
```

TRUE

The following matrix is not Hermitian:

```
B := Dom::Matrix(Dom::Complex)([[1, -I], [-I, 1]])
```

$$\begin{pmatrix} 1 & -i \\ -i & 1 \end{pmatrix}$$

```
linalg::isHermitian(B)
```

FALSE

The reason is the following:

```
linalg::transpose(conjugate(B)) <> B
```

$$\begin{pmatrix} 1 & i \\ i & 1 \end{pmatrix} \neq \begin{pmatrix} 1 & -i \\ -i & 1 \end{pmatrix}$$

Example 2

Here is an example of a symmetric matrix over the integers:

```
C := Dom::Matrix(Dom::Integer)([[1, 2], [2, -1]])
```

$$\begin{pmatrix} 1 & 2 \\ 2 & -1 \end{pmatrix}$$

```
linalg::isHermitian(C)
```

TRUE

Parameters

A

A square matrix of a domain of category `Cat::Matrix`

Return Values

Either TRUE or FALSE.

See Also

MuPAD Functions
`linalg::isPosDef`

linalg::isPosDef

Test a matrix for positive definiteness

Syntax

```
linalg::isPosDef(A)
```

Description

`linalg::isPosDef(A)` checks whether the matrix A is positive definite, so that $\vec{x}^t A \vec{x} > 0$ for arbitrary vectors $\vec{x} \neq \vec{0}$.

The component ring of `A` must be a field, i.e., a domain of category `Cat::Field`.

An error message is returned, if a result of an intermediate computation cannot be checked for being positive (which could happen, for example, if components of `A` are symbolic).

Environment Interactions

Properties of identifiers are taken into account.

Examples

Example 1

Here is an example of a positive definite matrix:

```
MatR := Dom::Matrix( Dom::Real ):
A := MatR([[14, 6, 9], [6, 17, -4], [9, -4, 13]])
```

$$\begin{pmatrix} 14 & 6 & 9 \\ 6 & 17 & -4 \\ 9 & -4 & 13 \end{pmatrix}$$

```
linalg::isPosDef(A)
```

TRUE

The following matrix is not positive definite:

```
B := MatR([[1, 2, 3], [2, 3, 4], [5, 6, 7]])
```

$$\begin{pmatrix} 1 & 2 & 3 \\ 2 & 3 & 4 \\ 5 & 6 & 7 \end{pmatrix}$$

```
linalg::isPosDef(B)
```

FALSE

Example 2

`linalg::isPosDef` in general does not work for matrices with symbolic entries. It may respond with an error message (because the system in general cannot decide whether a symbolic component is positive), such as for the following matrix:

```
delete a, b:
C := matrix([[a, b], [b, a]])
```

$$\begin{pmatrix} a & b \\ b & a \end{pmatrix}$$

```
linalg::isPosDef(C)
```

```
Error: Cannot check whether the matrix component is positive. [linalg::factorCholesky]
```

However, properties of identifiers are taken into account, so that, for example, `linalg::isPosDef` is able to perform the test correctly for the following matrix:

```
assume(a > 1): C := matrix([[a, 1], [1, a]]):
linalg::isPosDef(C)
```

```
TRUE
```

Note that such computations depend on the power of the underlying property mechanism implemented in the `property` library.

Parameters

A

A matrix of a domain of category `Cat::Matrix`

Return Values

Either TRUE or FALSE.

See Also

MuPAD Functions

`linalg::factorCholesky` | `linalg::isHermitian`

linalg::isUnitary

Test whether a matrix is unitary

Syntax

```
linalg::isUnitary(A)
```

Description

`linalg::isUnitary` tests whether the matrix A is a unitary matrix. An $n \times n$ matrix A is unitary, if $A\,\overline{A}^t = I_n$, where I_n is the $n \times n$ identity matrix.

The square matrix `A` is a unitary matrix, if and only if the columns of `A` form an orthonormal basis with respect to the scalar product `linalg::scalarProduct` of two vectors.

The correctness of the result `FALSE` of `linalg::isUnitary` can only be guaranteed if the elements of the component ring R of the matrix `A` are canonically represented, i.e., if each element of R has only one unique representation.

The axiom `Ax::canonicalRep` states that a domain has this property. Hence, `linalg::isUnitary` returns `FALSE` or `UNKNOWN`, respectively, depending on whether the component ring of `A` has the axiom `Ax::canonicalRep`.

If the component ring of `A` does not define the method `"conjugate"` then it is checked whether `A` is an orthogonal matrix such that $A\,A^t = E_n$, where E_n is the $n \times n$ identity matrix.

Examples

Example 1

The following matrix is unitary:

```
A := 1/sqrt(5) * matrix([[1, 2], [2, -1]])
```

$$\begin{pmatrix} \frac{\sqrt{5}}{5} & \frac{2\sqrt{5}}{5} \\ \frac{2\sqrt{5}}{5} & -\frac{\sqrt{5}}{5} \end{pmatrix}$$

```
linalg::isUnitary(A)
```

TRUE

Parameters

A

A square matrix of a domain of category `Cat::Matrix`

Return Values

Either `TRUE`, `FALSE`, or `UNKNOWN`.

See Also

MuPAD Functions

`linalg::orthog` | `linalg::scalarProduct`

linalg::jordanForm

Jordan normal form of a matrix

Syntax

```
linalg::jordanForm(A, <All>)
```

Description

`linalg::jordanForm(A)` returns the Jordan normal form J of the matrix A.

`linalg::jordanForm` computes a nonsingular transformation matrix P and a matrix J such that $A = P\,J\,P^{-1}$ with $J = diag(J_1, \ldots, J_r)$ and Jordan matrices $J_1, \ldots, J_r$.

The Jordan normal form of a square matrix A over a field F exists if the characteristic polynomial of A splits over F into linear factors. If this is not the case for the matrix `A`, then `linalg::jordanForm` returns `FAIL`.

The Jordan normal form is unique up to permutations of the Jordan matrices $J_1, \ldots, J_r$.

The implemented method computes the eigenvalues of `A`. It returns `FAIL` if this is not possible (see `linalg::eigenvalues`).

The component ring of `A` must be a field, i.e., a domain of category `Cat::Field`.

Examples

Example 1

The Jordan normal form of the matrix:

```
A := Dom::Matrix(Dom::Complex)([[1, 2], [4, 5]])
```

$$\begin{pmatrix} 1 & 2 \\ 4 & 5 \end{pmatrix}$$

is the following matrix:

```
J := linalg::jordanForm(A)
```

$$\begin{pmatrix} -2\sqrt{3}+3 & 0 \\ 0 & 2\sqrt{3}+3 \end{pmatrix}$$

The corresponding transformation matrix P can be obtained from the result `[J, P]` of `linalg::jordanForm` with the option `All`:

```
P := linalg::jordanForm(A, All)[2]
```

$$\begin{pmatrix} -\frac{\sqrt{3}}{2}-\frac{1}{2} & \frac{\sqrt{3}}{2}-\frac{1}{2} \\ 1 & 1 \end{pmatrix}$$

We check the result:

```
map(P * J * P^(-1), radsimp)
```

$$\begin{pmatrix} 1 & 2 \\ 4 & 5 \end{pmatrix}$$

To get this result we must apply the function `radsimp` to each component of the matrix that is returned by the matrix product PJP^{-1}.

Parameters

`A`

A square matrix of a domain of category `Cat::Matrix`

Options

`All`

Returns the list `[J, P]` with the Jordan normal form J of `A` and the corresponding transformation matrix P such that $A = PJP^{-1}$.

Return Values

Either a matrix of the same domain type as A, the list `[J, P]` when the option `All` is given, or the value `FAIL`.

linalg::kroneckerProduct

Kronecker product of matrices

Syntax

```
linalg::kroneckerProduct(A, <B, …>)
```

Description

`linalg::kroneckerProduct(A, B)` computes the Kronecker product of two matrices A and B.

The Kronecker product (direct matrix product) of an $m \times n$ matrix A and a $p \times q$ matrix B is the $(m\,p) \times (n\,q)$ matrix $A \otimes B$ given in block form as

$$A \otimes B = \begin{pmatrix} a_{1,1}\,B & \dots & a_{1,n}\,B \\ \vdots & & \vdots \\ a_{m,1}\,B & \dots & a_{m,n}\,B \end{pmatrix}.$$

Componentwise: $A \otimes B_{I,J} = A_{i,j}\,B_{k,l}$ with $I = p\,(i - 1) + k$, $J = q\,(j - 1) + l$.

If A and B are matrices of the same matrix domain with the same component ring, the result is a matrix of the same type as A and B. If the domains or the component rings of A and B differ, `linalg::kroneckerProduct` tries to convert B into the domain type of A by `A::dom::coerce`. If this fails, conversion of A to the domain type of B is attempted. If no conversion is possible, an error is raised.

Note: Note that the Kronecker product is only implemented for matrices over the domains `Dom::Matrix`, `Dom::SquareMatrix` or `Dom::MatrixGroup`. In particular, this includes matrices created by `matrix`.

A call with more than two arguments produces `linalg::kroneckerProduct(A, B, C) = linalg::kroneckerProduct(linalg::kroneckerProduct(A, B), C)` etc.

A call with only one argument is possible. It returns the input matrix.

Examples

Example 1

We consider two matrices A and B with symbolic components:

```
A:= matrix([[a11, a12], [a21, a22]]);
B:= matrix([[b11, b12, b13], [b21, b22, b23]]);
```

$$\begin{pmatrix} a11 & a12 \\ a21 & a22 \end{pmatrix}$$

$$\begin{pmatrix} b11 & b12 & b13 \\ b21 & b22 & b23 \end{pmatrix}$$

The Kronecker product of A and B is computed by multiplying the matrix B with each of the components of the matrix A. The resulting block matrix is returned as a matrix of larger dimension:

```
linalg::kroneckerProduct(A, B);
```

$$\begin{pmatrix} a11\,b11 & a11\,b12 & a11\,b13 & a12\,b11 & a12\,b12 & a12\,b13 \\ a11\,b21 & a11\,b22 & a11\,b23 & a12\,b21 & a12\,b22 & a12\,b23 \\ a21\,b11 & a21\,b12 & a21\,b13 & a22\,b11 & a22\,b12 & a22\,b13 \\ a21\,b21 & a21\,b22 & a21\,b23 & a22\,b21 & a22\,b22 & a22\,b23 \end{pmatrix}$$

```
delete A, B:
```

Example 2

An $n \times n$ matrix H with components in {- 1, 1} is called a *Hadamard matrix* if H multiplied with its transpose equals n times the $n \times n$ identity matrix. The matrix H defined below is a Hadamard matrix:

```
H:= matrix([[1, 1], [1, -1]]);
H * linalg::transpose(H) = 2 * matrix::identity(2);
```

$$\begin{pmatrix} 1 & 1 \\ 1 & -1 \end{pmatrix}$$

$$\begin{pmatrix} 2 & 0 \\ 0 & 2 \end{pmatrix} = \begin{pmatrix} 2 & 0 \\ 0 & 2 \end{pmatrix}$$

Hadamard matrices play a role in the field of error correcting codes. A basic property of this type of matrices is that the Kronecker product of two Hadamard matrices is again a Hadamard matrix. We verify this statement for the matrix `H`:

```
H2:= linalg::kroneckerProduct(H, H);
```

$$\begin{pmatrix} 1 & 1 & 1 & 1 \\ 1 & -1 & 1 & -1 \\ 1 & 1 & -1 & -1 \\ 1 & -1 & -1 & 1 \end{pmatrix}$$

Indeed, the matrix `H2` is a again a Hadamard matrix:

```
H2 * linalg::transpose(H2) = 4 * matrix::identity(4);
```

$$\begin{pmatrix} 4 & 0 & 0 & 0 \\ 0 & 4 & 0 & 0 \\ 0 & 0 & 4 & 0 \\ 0 & 0 & 0 & 4 \end{pmatrix} = \begin{pmatrix} 4 & 0 & 0 & 0 \\ 0 & 4 & 0 & 0 \\ 0 & 0 & 4 & 0 \\ 0 & 0 & 0 & 4 \end{pmatrix}$$

```
delete H, H2:
```

Parameters

`A, B, …`

Matrices of the domains `Dom::Matrix`, `Dom::SquareMatrix` or `Dom::MatrixGroup`

Return Values

Matrix of the same type as A or B.

linalg::matdim

Dimension of a matrix

Syntax

```
linalg::matdim(A)
```

Description

`linalg::matdim(A)` returns the dimension of the matrix *A*, i.e., the number of rows and columns of *A*.

`linalg::matdim` is an interface function for the method `"matdim"` of the matrix domain of `A`, i.e., instead of `linalg::matdim(A)` one may call `A::dom::matdim(A)` directly.

Examples

Example 1

The dimension of the matrix:

```
A := matrix([[1, 2, 3, 4], [3, 1, 4], [5, 6]])
```

$$\begin{pmatrix} 1 & 2 & 3 & 4 \\ 3 & 1 & 4 & 0 \\ 5 & 6 & 0 & 0 \end{pmatrix}$$

can be determined by:

```
linalg::matdim(A)
```

$$[3, 4]$$

Parameters

A

An $m \times n$ matrix of a domain of category `Cat::Matrix`

Return Values

List `[m, n]`, where `m` is the number of rows and `n` is the number of columns of `A`.

See Also

MuPAD Functions

`linalg::ncols` | `linalg::nrows` | `linalg::vecdim`

linalg::matlinsolve

Solving systems of linear equations

Syntax

```
linalg::matlinsolve(A, b, <list>, options)
linalg::matlinsolve(A, B, options)
linalg::matlinsolve(A, options)
```

Description

`linalg::matlinsolve(A, b)` computes the general solution of the equation $A\,\vec{x} = \vec{b}$.

`linalg::matlinsolve(A, b)` returns the solution vector $\vec{x}$ of the system $A\,\vec{x} = \vec{b}$ if it is a unique solution.

`linalg::matlinsolve(A, b)` returns a list $\left[\vec{w}, \left[\vec{v}_1, \ldots, \vec{v}_r\right]\right]$ if the system $A\,\vec{x} = \vec{b}$ has more than one solution, where $\vec{w}$ is one particular solution, i.e., $A\,\vec{w} = \vec{b}$ and $\vec{v}_1, \ldots, \vec{v}_r$ form a basis of the kernel of A, i.e., the solution space of the homogenous system $A\,\vec{x} = (\vec{0})$.

Each solution $\vec{x}$ has the form $\vec{x}_s + s_1\,\vec{v}_1 + \ldots + s_r\,\vec{v}_r (r \le n)$ with certain scalars $s_1, \ldots, s_r$.

A list of n scalars $[s_1, \ldots, s_n]$ may be passed as the additional parameter `list`. This extracts the solution $\vec{x}_s + s_{i_1}\,\vec{v}_1 + \ldots + s_{i_r}\,\vec{v}_r$ with $\{i_1, \ldots, i_r\} = \{1, \ldots, n\} \setminus \{j_1, \ldots, j_l\}$ from the solution space of the system $A\,\vec{x} = \vec{b}$, where $j_1, \ldots, j_l$ are the characteristic column indices of A (see `linalg::gaussJordan`).

The entries of `list` are converted to elements of the component ring of A (an error message is returned if this is not possible).

Note: This option should only be used for exact and symbolic computations. In the case that A or b contains floating-point entries, it should not be used.

If the system $A\vec{x} = \vec{b}$ has no solution, then the empty list `[]` is returned.

`linalg::matlinsolve(A)` solves the matrix equation $C\vec{x} = \vec{b}$, where $\vec{b}$ is the last column of A and C is A with the last column deleted.

`linalg::matlinsolve(A, B)` returns the solution X of the matrix equation $AX = B$, if it has exactly one solution. Otherwise the empty list `[]` is returned.

The vector b and the matrix B respectively, are converted into the domain `Dom::Matrix(R)`, where R is the component ring of A. Solution vectors also belong to this domain.

The component ring of A must be an integral domain, i.e., a domain of category `Cat::IntegralDomain`.

`linalg::matlinsolve` can compute the general solution for systems with more than one solution only over fields, i.e., component rings of category `Cat::Field`. If in this case the component ring of A does not have a canonical representation of the zero element, then it may happen that `linalg::matlinsolve` does not find a basis for the null space. In such a case, a wrong result is returned.

`linalg::matlinsolve` does exploit a sparse structure of A. (A matrix is *sparse* if it has many zero components). See “Example 5” on page 15-130.

Use the function `numeric::matlinsolve` to solve a linear system numerically.

Examples

Example 1

Solve the linear system:

$$\begin{pmatrix} 1 & 2 \\ -1 & 2 \end{pmatrix} \vec{x} = \begin{pmatrix} 1 \\ -1 \end{pmatrix}$$

over the reals. First, enter the coefficient matrix and the right side:

```
MatR := Dom::Matrix(Dom::Real):
A := MatR([[1, 2], [-1, 2]]); b := MatR([1, -1])
```

$$\begin{pmatrix} 1 & 2 \\ -1 & 2 \end{pmatrix}$$

$$\begin{pmatrix} 1 \\ -1 \end{pmatrix}$$

Next, call `linalg::matlinsolve` to solve the system:

```
x := linalg::matlinsolve(A, b)
```

$$\begin{pmatrix} 1 \\ 0 \end{pmatrix}$$

The system has exactly one solution. The vector `x` satisfies the matrix equation given above:

```
A * x
```

$$\begin{pmatrix} 1 \\ -1 \end{pmatrix}$$

Example 2

The system:

$$\begin{pmatrix} 1 & 2 \\ -1 & -2 \end{pmatrix} \vec{x} = \begin{pmatrix} 1 \end{pmatrix}$$

does not have a solution over $\mathbb{R}$ (in fact, over no component domain):

```
MatR := Dom::Matrix(Dom::Real):
A := MatR([[1, 2], [-1, -2]]): b := MatR([1, 0]):
```

```
linalg::matlinsolve(A, b)
```

```
[]
```

Example 3

Solve the linear system:

$$\begin{pmatrix} 1 & 1 & -4 & -7 & -6 \\ & 1 & -3 & -5 & -7 \end{pmatrix} \vec{x} = \begin{pmatrix} 30 \\ 17 \end{pmatrix}$$

over the rational numbers. First, enter the coefficient matrix and the right side:

```
MatQ := Dom::Matrix(Dom::Rational):
A := MatQ([[1, 1, -4, -7, -6], [0, 1, -3, -5, -7]]);
b := MatQ([30, 17])
```

$$\begin{pmatrix} 1 & 1 & -4 & -7 & -6 \\ 0 & 1 & -3 & -5 & -7 \end{pmatrix}$$

$$\begin{pmatrix} 30 \\ 17 \end{pmatrix}$$

Next, call `linalg::matlinsolve` to solve the system:

```
sol:= linalg::matlinsolve(A, b)
```

$$\left[\begin{pmatrix} 13 \\ 17 \\ 0 \\ 0 \\ 0 \end{pmatrix}, \left[\begin{pmatrix} 1 \\ 3 \\ 1 \\ 0 \\ 0 \end{pmatrix}, \begin{pmatrix} 2 \\ 5 \\ 0 \\ 1 \\ 0 \end{pmatrix}, \begin{pmatrix} -1 \\ 7 \\ 0 \\ 0 \\ 1 \end{pmatrix} \right] \right]$$

The result is to be interpreted as follows: The first vector of the list `sol` is a particular solution of the linear system:

```
A * sol[1]
```

$$\begin{pmatrix} 30 \\ 17 \end{pmatrix}$$

The second entry of the list contains a basis for the null space of A, i.e., the solution space of the corresponding homogenous system $A\,\vec{x} = (\vec{0})$ (the kernel of A). The basis returned is given as a list of vectors.

The following input checks this fact by computing the product $A\,\vec{x}$ for each vector $\vec{x}$ of the list `sol[2]`:

```
map(sol[2], x -> A * x)
```

$$\left[\begin{pmatrix} 0 \\ 0 \end{pmatrix}, \begin{pmatrix} 0 \\ 0 \end{pmatrix}, \begin{pmatrix} 0 \\ 0 \end{pmatrix}\right]$$

Any solution of the linear system can be represented as a sum of a particular solution (here: `sol[1]`) and a linear combination of the basis vectors of the kernel of A. Hence the input system has an infinite number of solutions.

For example, another solution of the system is given by:

```
x := sol[1] + 1*sol[2][1] + 1/2*sol[2][2] - 2*sol[2][3]
```

$$\begin{pmatrix} 17 \\ \frac{17}{2} \\ 1 \\ \frac{1}{2} \\ -2 \end{pmatrix}$$

```
A * x
```

$$\begin{pmatrix} 30 \\ 17 \end{pmatrix}$$

If you identify the columns of the coefficient matrix A of the linear system with the variables x_1, x_2, x_3, x_4, x_5, then you see from the general solution that the variables x_3,

x_4, x_5 act as free parameters. They can be assigned arbitrary rational values to obtain a unique solution.

By giving a list of values for these variables as a third parameter to `linalg::matlinsolve`, you can select a certain vector from the set of all solutions of the linear system. For example, to select the same vector `x` as chosen in the previous input, enter:

```
linalg::matlinsolve(A, b, [0, 0, 1, 1/2, -2])
```

$$\begin{pmatrix} 17 \\ \frac{17}{2} \\ 1 \\ \frac{1}{2} \\ -2 \end{pmatrix}$$

If you are only interested in a particular solution and do not need the general solution of the linear system, enter:

```
linalg::matlinsolve(A, b, Special)
```

$$\begin{pmatrix} 13 \\ 17 \\ 0 \\ 0 \\ 0 \end{pmatrix}$$

This call suppresses the computation of the kernel of A.

Example 4

If the linear system is given in the form of equations the function `linalg::expr2Matrix` can be used to form the corresponding matrix equation:

```
delete x, y, z:
Ab := linalg::expr2Matrix(
  [x + y + z = 6, 2*x + y + 2*z = 10, x + 3*y + z = 10]
```

```
)
```

$$\begin{pmatrix} 1 & 1 & 1 & 6 \\ 2 & 1 & 2 & 10 \\ 1 & 3 & 1 & 10 \end{pmatrix}$$

The result here is the extended coefficient matrix of the input system, that is, the right side vector $\vec{b}$ is the 4th column vector of the matrix `Ab`. Since you did not specify a component ring for this matrix, the standard component ring for matrices, the domain `Dom::ExpressionField()`, was chosen.

To solve the linear system, call:

```
linalg::matlinsolve(Ab)
```

$$\left[\begin{pmatrix} 4 \\ 2 \\ 0 \end{pmatrix}, \left[\begin{pmatrix} -1 \\ 0 \\ 1 \end{pmatrix}\right]\right]$$

The system has an infinite number of solutions. The third variable z acts as a free parameter and therefore can have any (complex) value.

To get the general solution in parameter form, you can use parameters for the variables x, y, z of the input system:

```
delete u, v, w:
sol := linalg::matlinsolve(Ab, [u, v, w])
```

$$\begin{pmatrix} 4-w \\ 2 \\ w \end{pmatrix}$$

This is possible here because you perform the matrix computations over `Dom::ExpressionField()` which lets you compute with symbolical (arithmetical) expressions.

To select a certain vector from the set of solutions, for example, the solution for $w = 1$, enter:

```
x := subs(sol, w = 1)
```

$$\begin{pmatrix} 3 \\ 2 \\ 1 \end{pmatrix}$$

Example 5

Consider a system of linear equations with a sparse structure, that is, the coefficient matrix has many zero components:

```
eqs := {x1 + x5 = 0, x2 - x4 = 1, x3 + 2*x5 = 2, x4 - x5 = -1}:
Ab := linalg::expr2Matrix(eqs, [x1, x2, x3, x4, x5])
```

$$\begin{pmatrix} 1 & 0 & 0 & 0 & 1 & 0 \\ 0 & 1 & 0 & -1 & 0 & 1 \\ 0 & 0 & 1 & 0 & 2 & 2 \\ 0 & 0 & 0 & 1 & -1 & -1 \end{pmatrix}$$

`linalg::matlinsolve` exploits the sparsity of the coefficient matrix if it is passed as a matrix of type `Dom::Matrix`. Alternatively, you can use the function `linsolve` which allows sparse input and output via symbolic equations:

```
linsolve(eqs)
```

$$[x1 = -x5,\ x2 = x5,\ x3 = 2 - 2\,x5,\ x4 = x5 - 1]$$

You also can use the function `numeric::matlinsolve` with the option `Symbolic` instead of `linalg::matlinsolve`:

```
A := linalg::delCol(Ab, 6):
b := linalg::col(Ab, 6):
numeric::matlinsolve(A, b, Symbolic)
```

$$\left[\begin{pmatrix} 0 \\ 0 \\ 2 \\ -1 \\ 0 \end{pmatrix}, \begin{pmatrix} -1 \\ 1 \\ -2 \\ 1 \\ 1 \end{pmatrix}\right]$$

Note that the function `numeric::matlinsolve` always works over a subfield of the complex numbers and does not let you specify the domain of computation. Without the option `Symbolic`, `numeric::matlinsolve` converts input data to floating-point numbers.

Example 6

Check whether the matrix equation

$$\begin{pmatrix} 1 & 2 \\ -2 & 3 \end{pmatrix} \vec{x} = \begin{pmatrix} 4 & 2 \\ 6 & 3 \end{pmatrix}$$

has a unique solution over the integers.

Start by entering the coefficient matrix and the right side matrix:

```
MatZ := Dom::Matrix(Dom::Integer):
A := MatZ([[1, 2], [-2, 3]]); B := MatZ([[4, 2], [6, 3]])
```

$$\begin{pmatrix} 1 & 2 \\ -2 & 3 \end{pmatrix}$$

$$\begin{pmatrix} 4 & 2 \\ 6 & 3 \end{pmatrix}$$

Next, solve the matrix equation:

```
X := linalg::matlinsolve(A, B)
```

$$\begin{pmatrix} 0 & 0 \\ 2 & 1 \end{pmatrix}$$

The equation indeed has a unique solution (otherwise the answer of `linalg::matlinsolve` would be the empty list `[]`). Check the result:

```
A * X
```

$$\begin{pmatrix} 4 & 2 \\ 6 & 3 \end{pmatrix}$$

Example 7

If you use the `Normal` option, `linalg::matlinsolve` calls the `normal` function for final results. This call ensures that `linalg::matlinsolve` returns results in normalized form:

```
A := matrix([[1, s], [t, -1]]):
b := matrix([s + 1, t - 1]):
x := linalg::matlinsolve(A, b)
```

$$\begin{pmatrix} 1 \\ 1 \end{pmatrix}$$

If you specify `Normal = FALSE`, `linalg::matlinsolve` does not call `normal` for the final result:

```
x := linalg::matlinsolve(A, b, Normal = FALSE)
```

$$\begin{pmatrix} s - \frac{s\,(t\,(s+1)-t+1)}{s\,t+1} + 1 \\ \frac{t\,(s+1)-t+1}{s\,t+1} \end{pmatrix}$$

Example 8

Solve this system:

```
A := matrix([[1, s], [1, t]]):
b := matrix([1, 1]):

linalg::matlinsolve(A, b)
```

$$\begin{pmatrix} 1 \\ 0 \end{pmatrix}$$

Note that more solutions exist for `t = s`. `linalg::matlinsolve` omits these solutions because it makes some additional assumptions on symbolic parameters of this system. To see the assumptions that `linalg::matlinsolve` made while solving this system, use the `ShowAssumptions` option:

```
linalg::matlinsolve(A, b, ShowAssumptions)
```

$$\left[\begin{pmatrix}1\\0\end{pmatrix}, [], [], [t-s\neq 0]\right]$$

Parameters

A

$m\times n$ matrix of a domain of category `Cat::Matrix`

B

$m\times k$ matrix of a domain of category `Cat::Matrix`

b

m-dimensional column vector, i.e., a $m\times 1$ matrix of a domain of category `Cat::Matrix`

list

List of n elements of the component ring of `A`

Options

Normal

Option, specified as `Normal = b`

Return normalized results. The value `b` must be `TRUE` or `FALSE`. By default, `Normal = TRUE`, meaning that `linalg::matlinsolve` guarantees normalization of the returned results. Normalizing results can be computationally expensive.

By default, `linalg::matlinsolve` calls `normal` before returning results. This additional internal call ensures that the final result is normalized. This call can be computationally expensive. This option affects the output only if the solution contains variables or exact expressions, such as `sqrt(5)` or `sin(PI/7)`.

To avoid this additional call, specify `Normal = FALSE`. In this case, `linalg::matlinsolve` also can return normalized results, but does not guarantee such normalization. See “Example 7” on page 15-132.

ShowAssumptions

Return information about internal assumptions that `linalg::matlinsolve` made on symbolic parameters in `eqs`.

With `ShowAssumptions`, `linalg::matlinsolve` returns a list `[S, KernelBasis, Constraints, Pivots]`. The lists `Constraints` and `Pivots` contain equations and inequalities involving symbolic parameters in `A` and `b` (or `B`). Internally, these were assumed to hold true when solving the system. See “Example 8” on page 15-132.

When Gaussian elimination produces an equation `0 = c` with nonzero `c`, `linalg::matlinsolve` without `ShowAssumptions` returns `[]`. If `c` involves symbolic parameters, try using `linalg::matlinsolve` with `ShowAssumptions` to solve such systems. If the system is solvable, you will get the solution. In this case, an equation `0 = c` is returned in the `Constraints` list. If the system is not solvable, `linalg::matlinsolve` with `ShowAssumptions` returns `[[], [], [], []]`.

Special

Only one particular solution `w` of the system $A\vec{x} = \vec{b}$ is returned. This supresses the computation of a basis for the kernel of `A`.

Unique

Checks whether the system has a unique solution and returns it. The return value `NIL` means that the system has more than one solution.

Return Values

Without `ShowAssumptions`, `linalg::matlinsolve` can return a vector or a list `[S, KernelBasis]` (possibly empty), where `S` is a solution vector and `KernelBasis` is a list of basis vectors for the kernel of `A`. It also can return a matrix or the value `NIL`.

The matrix and the vectors, respectively, are of the domain type `Dom::Matrix(R)`, where `R` is the component ring of `A`.

With `ShowAssumptions`, `linalg::matlinsolve` returns a list `[S, KernelBasis, Constraints, Pivots]`. The lists `Constraints` and `Pivots` contain equations and inequalities involving symbolic parameters in `A` and `b` (or `B`). Internally, these

were assumed to hold true when solving the system. If the system is not solvable, `linalg::matlinsolve` with `ShowAssumptions` returns `[[], [], [], []]`.

Algorithms

Let A be an $m \times n$ matrix with components from a field F and $\vec{b}$ an m-dimensional vector over F. Let $\left(A, \vec{b}\right)$ be the extended coefficient matrix of the linear system $A\,\vec{x} = \vec{b}$.

Then the following holds:

- The linear system $A\,\vec{x} = \vec{b}$ has a solution, if and only if $\mathrm{rank}\left(A, \vec{b}\right) = \mathrm{rank}(A)$.
- It has exactly one solution, if and only if $\mathrm{rank}\left(A, \vec{b}\right) = \mathrm{rank}(A) = n$.
- If $\vec{x}_s$ is a solution of the system $A\,\vec{x} = \vec{b}$ and $\left\{\vec{v}_1, \ldots, \vec{v}_r\right\}$ a basis of the kernel of A, then

  $$L\left(A, \vec{b}\right) = \left\{\vec{w} + \lambda_1\,\vec{v}_1 + \lambda_2\,\vec{v}_2 + \cdots + \lambda_r\,\vec{v}_r \;\middle|\; \lambda_1, \ldots, \lambda_r \in K\right\}$$

  is the set of all solutions of the linear system $A\,\vec{x} = \vec{b}$, the *general solution* of the (inhomogeneus) linear system.

The *kernel of the matrixA* is defined as:

$$\ker(A) = \left\{\vec{w} \;\middle|\; A\,\vec{w} = \vec{0}\right\}.$$

The kernel of A is a vector space over F of dimension n - *rank*(A).

More About

- "Solve Algebraic Systems"

linalg::matlinsolveLU

Solving the linear system given by an LU decomposition

Syntax

```
linalg::matlinsolveLU(L, U, b)
```

```
linalg::matlinsolveLU(L, U, B)
```

Description

`linalg::matlinsolveLU(L, U, b)` solves the linear system $L\,U\,\vec{x} = \vec{b}$, where the matrices L and U form an LU-decomposition, as computed by `linalg::factorLU`.

If the third parameter is an $n \times k$ matrix `B` then the result is an $n \times k$ matrix X satisfying the matrix equation $L\,U\,X = B$.

The system to be solved always has a unique solution.

The diagonal entries of the lower diagonal matrix `L` must be equal to one (*Doolittle*-decomposition, see `linalg::factorLU`).

`linalg::matlinsolveLU` expects `L` and `U` to be nonsingular.

`linalg::matlinsolveLU` does not check on any of the required properties of `L` and `U`.

The component ring of the matrices `L` and `U` must be a field, i.e., a domain of category `Cat::Field`.

The parameters must be defined over the same component ring.

Examples

Example 1

We solve the system

$$\begin{pmatrix} 2 & -3 & -1 \\ 1 & 1 & -1 \\ & 1 & -1 \end{pmatrix} X = \begin{pmatrix} 1 & & \\ & 1 & \\ & & 1 \end{pmatrix}$$:

```
MatR := Dom::Matrix(Dom::Real):
A  := MatR([[2, -3, -1], [1, 1, -1], [0, 1, -1]]);
I3 := MatR::identity(3)
```

$$\begin{pmatrix} 2 & -3 & -1 \\ 1 & 1 & -1 \\ 0 & 1 & -1 \end{pmatrix}$$

$$\begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}$$

We start by computing an LU-decomposition of A:

```
LU := linalg::factorLU(A)
```

$$\left[\begin{pmatrix} 1 & 0 & 0 \\ \frac{1}{2} & 1 & 0 \\ 0 & \frac{2}{5} & 1 \end{pmatrix}, \begin{pmatrix} 2 & -3 & -1 \\ 0 & \frac{5}{2} & -\frac{1}{2} \\ 0 & 0 & -\frac{4}{5} \end{pmatrix}, [1, 2, 3] \right]$$

Now we solve the system $A\,X = I_3$, which gives us the inverse of A:

```
Ai := linalg::matlinsolveLU(LU[1], LU[2], I3)
```

$$\begin{pmatrix} 0 & 1 & -1 \\ -\frac{1}{4} & \frac{1}{2} & -\frac{1}{4} \\ -\frac{1}{4} & \frac{1}{2} & -\frac{5}{4} \end{pmatrix}$$

```
A * Ai, Ai * A
```

$$\begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}, \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}$$

Parameters

L

An $n \times n$ lower triangular matrix of a domain of category `Cat::Matrix`

U

An $n \times n$ upper triangular form matrix of the same domain as `L`

B

An $n \times k$ matrix of a domain of category `Cat::Matrix`

b

An n-dimensional column vector, i.e., an $n \times 1$ matrix of a domain of category `Cat::Matrix`

Return Values

n-dimensional solution vector or $n \times k$ dimensional solution matrix, respectively, of the domain type `Dom::Matrix(R)`, where `R` is the component ring of `A`.

MuPAD Functions

`linalg::factorLU` | `linalg::inverseLU` | `linalg::matlinsolve`

linalg::minpoly

Minimal polynomial of a matrix

Syntax

```
linalg::minpoly(A, x)
```

Description

`linalg::minpoly(A, x)` computes the minimal polynomial of the square matrix A in x, i.e., the monic polynomial of lowest degree annihilating the matrix A.

The minimal polynomial of `A` divides the characteristic polynomial of `A`, by Cayley-Hamilton theorem.

If the matrix is defined over `Dom::Float`, then due to numerical errors the computed polynomial can have a degree higher than the dimension of the matrix. In such cases, `linalg::minpoly` returns the value `FAIL`. See "Example 3" on page 15-142.

The component ring of `A` must be a field, i.e., a domain of category `Cat::Field`.

Examples

Example 1

We define the following matrix over the rational numbers:

```
A := Dom::Matrix(Dom::Rational)(
  [[0, 2, 0], [0, 0, 2], [2, 0, 0]]
)
```

$$\begin{pmatrix} 0 & 2 & 0 \\ 0 & 0 & 2 \\ 2 & 0 & 0 \end{pmatrix}$$

The minimal polynomial of the matrix A in the variable x is then given by:

```
delete x:  linalg::minpoly(A, x)
```

$$x^3 - 8$$

In this case, the minimal polynomial is in fact equal to the characteristic polynomial of A:

```
linalg::charpoly(A, x)
```

$$x^3 - 8$$

Example 2

The minimal polynomial of the matrix:

```
B := matrix([[0, 1, 0], [0, 0, 0], [0, 0, 0]])
```

$$\begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}$$

is a polynomial of degree 2:

```
m := linalg::minpoly(B, x)
```

$$x^2$$

The characteristic polynomial of B has degree 3 and is divided by the minimal polynomial of B:

```
p := linalg::charpoly(B, x)
```

$$x^3$$

```
p / m
```

$$x$$

Example 3

For the following example, MuPAD is not able to compute the minimal polynomial, and thus `FAIL` is returned:

```
C := Dom::Matrix(Dom::Float)([
   [7, 0, 0, 0, 0], [1, 0, 0, 0, 0], [1, 2, 0, 0, 0],
   [1, 2, 3, 0, 0], [1, 2, 3, 4, 7]
])
```

$$\begin{pmatrix} 7.0 & 0.0 & 0.0 & 0.0 & 0.0 \\ 1.0 & 0.0 & 0.0 & 0.0 & 0.0 \\ 1.0 & 2.0 & 0.0 & 0.0 & 0.0 \\ 1.0 & 2.0 & 3.0 & 0.0 & 0.0 \\ 1.0 & 2.0 & 3.0 & 4.0 & 7.0 \end{pmatrix}$$

```
delete x:  linalg::minpoly(C, x)
```

```
Warning: Cannot compute the minimal polynomial. [linalg::minpoly]
```

FAIL

In fact, for this example MuPAD is not able to check for zero equivalence during Gaussian elimination and therefore chose a wrong pivot element.

If you perform the computation over the coefficient domain`Dom::ExpressionField(normal)` instead, then in most cases the minimal polynomial can be computed:

```
C := matrix([
   [7, 0, 0, 0, 0], [1, 0, 0, 0, 0], [1, 2, 0, 0, 0],
   [1, 2, 3, 0, 0], [1, 2, 3, 4, 7]
])
```

$$\begin{pmatrix} 7 & 0 & 0 & 0 & 0 \\ 1 & 0 & 0 & 0 & 0 \\ 1 & 2 & 0 & 0 & 0 \\ 1 & 2 & 3 & 0 & 0 \\ 1 & 2 & 3 & 4 & 7 \end{pmatrix}$$

```
linalg::minpoly(C, x)
```

$$x^5 - 14\,x^4 + 49\,x^3$$

However, in general this problem regarding zero recognition cannot be avoided.

Parameters

A

A square matrix of a domain of category `Cat::Matrix`

x

An indeterminate

Return Values

Polynomial of the domain `Dom::DistributedPolynomial([x],R)`, where `R` is the component ring of `A`, or the value `FAIL`.

MuPAD Functions

`linalg::charpoly` | `linalg::frobeniusForm`

linalg::multCol

Multiply columns with a scalar

Syntax

```
linalg::multCol(A, c, s)
```

```
linalg::multCol(A, c1 .. c2, s)
```

```
linalg::multCol(A, list, s)
```

Description

`linalg::multCol(A, c, s)` returns a copy of the matrix A resulting from A by multiplying the c-th column of A with the scalar s.

`linalg::multCol(A, c1.. c2, s)` returns a copy of the matrix `A` obtained from `A` by multiplying those columns whose indices are in the range `c1.. c2` with the scalar `s`.

`linalg::multCol(A, list, s)` returns a copy of the matrix `A` obtained from matrix `A` by multiplying those columns whose indices are contained in `list` with the scalar `s`.

The scalar `s` is converted into an element of the component ring of the matrix `A`. An error message is returned if the conversion fails.

Examples

Example 1

We define the following matrix:

```
A := matrix([[1, 2, 3], [4, 5, 6], [7, 8, 9]])
```

$$\begin{pmatrix} 1 & 2 & 3 \\ 4 & 5 & 6 \\ 7 & 8 & 9 \end{pmatrix}$$

and illustrate the three different input formats for `linalg::multCol`:

```
linalg::multCol(A, 2, -1)
```

$$\begin{pmatrix} 1 & -2 & 3 \\ 4 & -5 & 6 \\ 7 & -8 & 9 \end{pmatrix}$$

```
linalg::multCol(A, 1..2, 2)
```

$$\begin{pmatrix} 2 & 4 & 3 \\ 8 & 10 & 6 \\ 14 & 16 & 9 \end{pmatrix}$$

```
linalg::multCol(A, [3, 1], 0)
```

$$\begin{pmatrix} 0 & 2 & 0 \\ 0 & 5 & 0 \\ 0 & 8 & 0 \end{pmatrix}$$

Parameters

A

An $m \times n$ matrix of a domain of category `Cat::Matrix`

c

The column index: a positive integer less or equal to n

c_1 .. c_2

A range of column indices (positive integers less or equal to n)

list

A list of column indices (positive integers less or equal to n)

Return Values

Matrix of the same domain type as A.

See Also

MuPAD Functions

`linalg::addCol` | `linalg::addRow` | `linalg::multRow`

linalg::multRow

Multiply rows with a scalar

Syntax

```
linalg::multRow(A, r, s)
```

```
linalg::multRow(A, r1 .. r2, s)
```

```
linalg::multRow(A, list, s)
```

Description

`linalg::multRow(A, r, s)` returns a copy of the matrix *A* resulting from *A* by multiplying the *r*-th row of *A* with the scalar *s*.

`linalg::multRow(A, r1.. r2, s)` returns a copy of the matrix `A` obtained from `A` by multiplying those rows whose indices are in the range $r_1 .. r_2$ with the scalar `s`.

`linalg::multRow(A, list, s)` returns a copy of the matrix `A` obtained from matrix `A` by multiplying those rows whose indices are contained in `list` with the scalar `s`.

The scalar `s` is converted into an element of the component ring of the matrix `A`. An error message is returned if the conversion fails.

Examples

Example 1

We define the following matrix:

```
A := matrix([[1, 2, 3], [4, 5, 6], [7, 8, 9]])
```

$$\begin{pmatrix} 1 & 2 & 3 \\ 4 & 5 & 6 \\ 7 & 8 & 9 \end{pmatrix}$$

and illustrate the three different input formats for `linalg::multRow`:

```
linalg::multRow(A, 2, -1)
```

$$\begin{pmatrix} 1 & 2 & 3 \\ -4 & -5 & -6 \\ 7 & 8 & 9 \end{pmatrix}$$

```
linalg::multRow(A, 1..2, 2)
```

$$\begin{pmatrix} 2 & 4 & 6 \\ 8 & 10 & 12 \\ 7 & 8 & 9 \end{pmatrix}$$

```
linalg::multRow(A, [3, 1], 0)
```

$$\begin{pmatrix} 0 & 0 & 0 \\ 4 & 5 & 6 \\ 0 & 0 & 0 \end{pmatrix}$$

Parameters

`A`

An $m \times n$ matrix of a domain of category `Cat::Matrix`

`r`

The row index: a positive integer less or equal to m

r_1 `..` r_2

A range of row indices (positive integers less or equal to m)

`list`

A list of row indices (positive integers less or equal to m)

Return Values

Matrix of the same domain type as A.

MuPAD Functions

`linalg::addCol` | `linalg::addRow` | `linalg::multCol`

linalg::ncols

Number of columns of a matrix

Syntax

```
linalg::ncols(A)
```

Description

`linalg::ncols(A)` returns the number of columns of the matrix *A*.

Examples

Example 1

The matrix:

```
A:= matrix([[1, 2, 3, 4], [3, 1, 4], [5, 6]])
```

$$\begin{pmatrix} 1 & 2 & 3 & 4 \\ 3 & 1 & 4 & 0 \\ 5 & 6 & 0 & 0 \end{pmatrix}$$

has four columns:

```
linalg::ncols(A)
```

$$4$$

Parameters

A

A matrix of a domain of category `Cat::Matrix`

Return Values

Positive integer.

See Also

MuPAD Functions

`linalg::matdim` | `linalg::nrows` | `linalg::vecdim`

linalg::nonZeros

Number of non-zero elements of a matrix

Syntax

```
linalg::nonZeros(A)
```

Description

`linalg::nonZeros(A)` returns the number of non-zero components of the matrix *A*.

Examples

Example 1

The matrix

```
MZ7 := Dom::Matrix(Dom::IntegerMod(7)):
A := MZ7([[18, -1], [4, 81]])
```

$$\begin{pmatrix} 4 \bmod 7 & 6 \bmod 7 \\ 4 \bmod 7 & 4 \bmod 7 \end{pmatrix}$$

has four non-zero entries:

```
linalg::nonZeros(A)
```

$$4$$

The matrix:

```
B := MZ7([[21, 2], [-1, 14]])
```

$$\begin{pmatrix} 0 \bmod 7 & 2 \bmod 7 \\ 6 \bmod 7 & 0 \bmod 7 \end{pmatrix}$$

has only two non-zero entries:

```
linalg::nonZeros(B)
```

$$2$$

Parameters

A

A matrix of a domain of category `Cat::Matrix`

Return Values

Nonnegative integer

linalg::normalize

Normalize a vector

Syntax

```
linalg::normalize(v)
```

Description

`linalg::normalize(v)` normalizes the vector $\vec{v}$ with respect to the 2-norm ($\|\vec{v}\|_2 = \sqrt{\langle \vec{v}, \vec{v} \rangle}$).

The result of `linalg::normalize(v)` is a vector that has norm 1 and the same direction as `v`.

The scalar product $\langle \vec{v}, \vec{v} \rangle$ for a vector $\vec{v}$ is implemented by the function `linalg::scalarProduct`.

The norm of a vector is computed with the function `norm`, which is overloaded for vectors. See the method `"norm"` of the domain constructor `Dom::Matrix` for details.

If the norm is an object that cannot be converted into an element of the component ring of `v`, then an error occurs (see “Example 2” on page 15-155).

Examples

Example 1

We define the following vector:

```
u := matrix([[1, 2]])
```

$$\begin{pmatrix} 1 & 2 \end{pmatrix}$$

Then the vector of norm 1 with the same direction as u is given by:

```
linalg::normalize(u)
```

$$\left(\frac{\sqrt{5}}{5}\ \frac{2\sqrt{5}}{5}\right)$$

Example 2

The following computation fails because the vector (1, 2) cannot be normalized over the rationals:

```
v := Dom::Matrix(Dom::Rational)([[1, 2]]):
linalg::normalize(v)
```

```
Error: Cannot normalize the given vector over its component ring. [linalg::normalize]
```

If we define v over the real numbers, then we get the normalized vector of v as follows:

```
w := Dom::Matrix(Dom::Real)(v): linalg::normalize(w)
```

$$\left(\frac{\sqrt{5}}{5}\ \frac{2\sqrt{5}}{5}\right)$$

Parameters

v

A vector, i.e., an $n\times 1$ or $1\times n$ matrix of a domain of category `Cat::Matrix`

Return Values

Vector of the same domain type as v.

See Also

MuPAD Functions

`linalg::scalarProduct` | `norm`

linalg::nrows

Number of rows of a matrix

Syntax

```
linalg::nrows(A)
```

Description

`linalg::nrows(A)` returns the number of rows of the matrix *A*.

Examples

Example 1

The matrix:

```
A := matrix([[1, 2, 3, 4], [3, 1, 4], [5, 6]])
```

$$\begin{pmatrix} 1 & 2 & 3 & 4 \\ 3 & 1 & 4 & 0 \\ 5 & 6 & 0 & 0 \end{pmatrix}$$

has three rows:

```
linalg::nrows(A)
```

$$3$$

Parameters

A

A matrix of a domain of category `Cat::Matrix`

Return Values

Positive integer.

See Also

MuPAD Functions

`linalg::matdim` | `linalg::ncols` | `linalg::vecdim`

linalg::nullspace

Basis for the null space of a matrix

Syntax

```
linalg::nullspace(A)
```

Description

`linalg::nullspace(A)` returns a basis for the null space of the matrix A, i.e., a list B of linearly independent vectors such that $A\,\vec{x} = \vec{0}$ if and only if $\vec{x}$ is a linear combination of the vectors in B.

The component ring of the matrix `A` must be a field, i.e., a domain of category `Cat::Field`.

If the component ring of `A` does not have a canonical representation of the zero element, it can happen that `linalg::nullspace` does not find a basis for the null space. In such a case, a wrong result is returned.

Examples

Example 1

The kernel of the matrix:

```
A := Dom::Matrix(Dom::Real)(
  [[3^(1/2)*2 - 2, 2], [4, 3^(1/2)*2 + 2]]
)
```

$$\begin{pmatrix} 2\sqrt{3}-2 & 2 \\ 4 & 2\sqrt{3}+2 \end{pmatrix}$$

is one-dimensional, and a basis is $\left\{ \begin{pmatrix} -\frac{1}{\sqrt{3}-1} \\ 1 \end{pmatrix} \right\}$:

```
linalg::nullspace(A)
```

$$\left[\begin{pmatrix} -\frac{1}{\sqrt{3}-1} \\ 1 \end{pmatrix} \right]$$

Parameters

A

A matrix of a domain of category `Cat::Matrix`

Return Values

List of (column) vectors of the domain `Dom::Matrix(R)`, where `R` is the component ring of `A`.

`linalg::basis` | `linalg::matlinsolve` | `linsolve` | `numeric::matlinsolve`

linalg::ogCoordTab

Table of orthogonal coordinate transformations

Syntax

```
linalg::ogCoordTab[ogName](u1, u2, u3, <c>)

linalg::ogCoordTab[ogName,
  Transformation](u1, u2, u3, <c>)

linalg::ogCoordTab[ogName,
  InverseTransformation](u1, u2, u3, <c>)

linalg::ogCoordTab[ogName,
  UnitVectors](u1, u2, u3, <c>)

linalg::ogCoordTab[ogName,
  Scales](u1, u2, u3, <c>)

linalg::ogCoordTab[ogName, Ranges](<c>)

linalg::ogCoordTab[ ogName , Dimension]
```

Description

`linalg::ogCoordTab` is a table of predefined orthogonal coordinate transformations in $\mathbb{R}^3$.

The entry associated with `ogName` defines a coordinate transformation $\vec{x} = \vec{x}(\vec{u})$ which maps the orthogonal parameters $\vec{u} = (u_1, u_2, u_3)$ to a vector $\vec{x} = (x_1, x_2, x_3)$ in Cartesian coordinates.

The coordinate systems `EllipticCylindrical` and `Torus` are defined with a constant parameter `c` which has to be passed as an additional argument. See “Example 2” on page 15-164.

The following coordinate transformations are stored in `linalg::ogCoordTab`. They are invertible for the indicated parameter values:

- `Cartesian`:

$u_1 \in \mathbb{R}$, $u_2 \in \mathbb{R}$, $u_3 \in \mathbb{R}$:

$$x_1 = u_1,\ x_2 = u_2,\ x_3 = u_3$$

- `Spherical` and its equivalent `Spherical[RightHanded]`:

  $0 < u_1 < \infty$, $0 \le u_2 \le \pi$, $0 \le u_3 < 2\pi$:

  $$x_1 = u_1 \sin(u_2) \cos(u_3),\ x_2 = u_1 \sin(u_2) \sin(u_3),\ x_3 = u_1 \cos(u_2)$$

- `Spherical[LeftHanded]`:

  $0 < u_1 < \infty$, $0 \le u_2 < 2\pi$, $0 \le u_3 \le \pi$:

  $$x_1 = u_1 \cos(u_2) \sin(u_3),\ x_2 = u_1 \sin(u_2) \sin(u_3),\ x_3 = u_1 \cos(u_3)$$

- `Cylindrical`:

  $0 < u_1 < \infty$, $0 \le u_2 < 2\pi$, $u_3 \in \mathbb{R}$:

  $$x_1 = u_1 \cos(u_2),\ x_2 = u_1 \sin(u_2),\ x_3 = u_3$$

- `EllipticCylindrical`:

  $0 < u_1 < \infty$, $0 \le u_2 < 2\pi$, $u_3 \in \mathbb{R}$ (with a real constant c):

  $$x_1 = c \cos(u_1) \cos(u_2),\ x_2 = c \sinh(u_1) \sin(u_2),\ x_3 = u_3$$

- `ParabolicCylindrical`:

  $0 < u_1 < \infty$, $u_2 \in \mathbb{R}$, $u_3 \in \mathbb{R}$:

  $$x_1 = \frac{\left({u_1}^2 - {u_2}^2\right)}{2},\ x_2 = u_1\, u_2,\ x_3 = u_3$$

- `RotationParabolic`:

  $0 < u_1 < \infty$, $0 < u_2 < \infty$, $0 \le u_3 < 2\pi$:

$$x_1 = u_1\, u_2 \cos(u_3),\ x_2 = u_1\, u_2 \sin(u_3),\ x_3 = \frac{\left(u_1{}^2 - u_2{}^2\right)}{2}$$

- `Torus`:

  $0 < u_1 < c$, $0 \le u_2 < 2\,\pi$, $0 \le u_3 < 2\,\pi$ (with a positive constant c):

$$x_1 = \left(c - u_1 \cos(u_2)\right) \cos(u_3),\ x_2 = \left(c - u_1 \cos(u_2)\right) \sin(u_3),\ x_3 = u_1 \sin(u_2)$$

`linalg::ogCoordTab` is used by functions such as `curl`, `divergence`, `gradient`, and `laplacian` to perform computations in non-Cartesian coordinates.

Examples

Example 1

The following call returns the Cartesian vector $\vec{x} = [x, y, z]$ in terms of the right-handed spherical coordinates $\vec{u} = [u_1, u_2, u_3]$:

```
linalg::ogCoordTab[Spherical[RightHanded],
                           Transformation](u1, u2, u3)
```

$$[u1 \cos(u3) \sin(u2),\ u1 \sin(u2) \sin(u3),\ u1 \cos(u2)]$$

The spherical coordinates expressed by the Cartesian coordinates:

```
linalg::ogCoordTab[Spherical[RightHanded],
                    InverseTransformation](x, y, z)
```

$$\left[\sqrt{x^2 + y^2 + z^2},\ \arccos\left(\frac{z}{\sqrt{x^2 + y^2 + z^2}}\right),\ \arccos\left(\frac{x}{\sqrt{x^2 + y^2}}\right)\right.$$

$$\left. + \operatorname{sign}(y)\,(\operatorname{sign}(y) - 1)\left(\pi - \arccos\left(\frac{x}{\sqrt{x^2 + y^2}}\right)\right)\right]$$

Note the `sign(y)` in the expression for u_3. This ensures that the correct angle is returned for any value of y:

```
assume(y > 0):
linalg::ogCoordTab[Spherical[RightHanded],
                   InverseTransformation](x, y, z)
```

$$\left[\sqrt{x^2+y^2+z^2},\ \arccos\left(\frac{z}{\sqrt{x^2+y^2+z^2}}\right),\ \arccos\left(\frac{x}{\sqrt{x^2+y^2}}\right)\right]$$

```
linalg::ogCoordTab[Spherical[RightHanded],
                   InverseTransformation](1, 1, 0),
linalg::ogCoordTab[Spherical[RightHanded],
                   InverseTransformation](-1, 0, 1),
linalg::ogCoordTab[Spherical[RightHanded],
                   InverseTransformation](1, 0, 2),
linalg::ogCoordTab[Spherical[RightHanded],
                   InverseTransformation](1, -1, 3)
```

$$\left[\sqrt{2},\ \frac{\pi}{2},\ \frac{\pi}{4}\right],\ \left[\sqrt{2},\ \frac{\pi}{4},\ \pi\right],\ \left[\sqrt{5},\ \arccos\left(\frac{2\sqrt{5}}{5}\right),\ 0\right],\ \left[\sqrt{11},\ \arccos\left(\frac{3\sqrt{11}}{11}\right),\ \frac{7\pi}{4}\right]$$

These parameter values are from the following ranges:

```
linalg::ogCoordTab[Spherical[RightHanded], Ranges]()
```

$$[0..\infty,\ 0..\pi,\ 0..2\,\pi]$$

The following orthonormal vectors are tangent to the spherical parameter lines:

```
linalg::ogCoordTab[Spherical[RightHanded], UnitVectors](u1, u2, u3)
```

$$[[\cos(u3)\sin(u2),\ \sin(u2)\sin(u3),\ \cos(u2)],\ [\cos(u2)\cos(u3),\ \cos(u2)\sin(u3),\ -\sin(u2)],\ [-\sin(u3),\ \cos(u3),\ 0]]$$

The `scaling factors' are:

```
linalg::ogCoordTab[Spherical[RightHanded],Scales](u1, u2, u3)
```

$$[1, u1, u1 \sin(u2)]$$

There is the following relationship between the Jacobian of the transformation $\vec{u} \to \vec{x}$ from the orthogonal coordinates to the Cartesian coordinates:

```
xyz:= linalg::ogCoordTab[Spherical[RightHanded],
                                  Transformation](u1, u2, u3):
unitvectors:= linalg::ogCoordTab[Spherical[RightHanded],
                                     UnitVectors](u1, u2, u3):
scales:= linalg::ogCoordTab[Spherical[RightHanded],
                                        Scales](u1, u2, u3):

linalg::transpose(jacobian(xyz, [u1, u2, u3])) =
  matrix(3, 3, scales, Diagonal)* matrix(unitvectors)
```

$$\sigma_1 = \sigma_1$$

where

$$\sigma_1 = \begin{pmatrix} \cos(u3)\sin(u2) & \sin(u2)\sin(u3) & \cos(u2) \\ u1\cos(u2)\cos(u3) & u1\cos(u2)\sin(u3) & -u1\sin(u2) \\ -u1\sin(u2)\sin(u3) & u1\cos(u3)\sin(u2) & 0 \end{pmatrix}$$

```
delete y, xyz, unitvectors, scales:
```

Example 2

The following call returns the Cartesian vector $\vec{x} = [x, y, z]$ in terms of elliptic cylindrical coordinates $\vec{u} = [u, v, w]$ involving a parameter c:

```
linalg::ogCoordTab[EllipticCylindrical, Transformation](u, v, z, c)
```

$$[c\cosh(u)\cos(v),\ c\sinh(u)\sin(v),\ z]$$

We compute the gradient of the function $f(u, v, w) = x(u, v, w)$ in elliptic cylindrical coordinates $\vec{u} = [u, v, w]$.

```
f:= (c*cos(v)*cosh(u))^2:
```

For computing the components of the gradient with respect to an orthogonal system, it is sufficient to know the 'scale parameters':

```
linalg::ogCoordTab[EllipticCylindrical, Scales](u, v, w, c)
```

$$\left[c\sqrt{\cosh(u)^2-\cos(v)^2},\ c\sqrt{\cosh(u)^2-\cos(v)^2},\ 1\right]$$

```
gradf := gradient(f, [u, v, w], %)
```

$$\begin{pmatrix} \frac{2\,c\cosh(u)\cos(v)^2\sinh(u)}{\sqrt{\cosh(u)^2-\cos(v)^2}} \\ -\frac{2\,c\cosh(u)^2\cos(v)\sin(v)}{\sqrt{\cosh(u)^2-\cos(v)^2}} \\ 0 \end{pmatrix}$$

These are the coefficients of the gradient with respect to the orthonormal basis $\vec{e}_u, \vec{e}_v, \vec{e}_w$ returned via the option `UnitVectors`:

```
[e_u, e_v, e_w] :=
linalg::ogCoordTab[EllipticCylindrical, UnitVectors](u, v, w, c)
```

$$[[\sigma_1, \sigma_2, 0], [-\sigma_2, \sigma_1, 0], [0, 0, 1]]$$

where

$$\sigma_1 = \frac{\cos(v)\sinh(u)}{\sqrt{\cosh(u)^2-\cos(v)^2}}$$

$$\sigma_2 = \frac{\cosh(u)\sin(v)}{\sqrt{\cosh(u)^2-\cos(v)^2}}$$

We convert the lists `e_u`, `e_v`, `e_w` into column vectors via `matrix`. Thus, in the standard basis of $\mathbb{R}^3$, the gradient vector field is:

```
G :=   gradf[1]*matrix(e_u)
     + gradf[2]*matrix(e_v)
     + gradf[3]*matrix(e_w)
```

$$\begin{pmatrix} \frac{2\,c\,\cosh(u)\,\cos(v)^3\,\sinh(u)^2}{\cosh(u)^2-\cos(v)^2} + \frac{2\,c\,\cosh(u)^3\,\cos(v)\,\sin(v)^2}{\cosh(u)^2-\cos(v)^2} \\ 0 \\ 0 \end{pmatrix}$$

$$\begin{pmatrix} \frac{2\,c\,\cosh(u)\,\cos(v)^3\,\sinh(u)^2}{\cosh(u)^2-\cos(v)^2} + \frac{2\,c\,\cosh(u)^3\,\cos(v)\,\sin(v)^2}{\cosh(u)^2-\cos(v)^2} \\ 0 \\ 0 \end{pmatrix}$$

$$\begin{pmatrix} \frac{2\,c\,\cosh(u)\,\cos(v)^3\,\sinh(u)^2}{\cosh(u)^2-\cos(v)^2} + \frac{2\,c\,\cosh(u)^3\,\cos(v)\,\sin(v)^2}{\cosh(u)^2-\cos(v)^2} \\ 0 \\ 0 \end{pmatrix}$$

We simplify this expression using the identities $sin^2(v) = 1 - cos^2(v)$, $sinh^2(u) = cosh^2(u) - 1$:

```
normal(subs(G, sin(v)^2 = 1 - cos(v)^2,
               sinh(u)^2 = cosh(u)^2 - 1))
```

$$\begin{pmatrix} 2\,c\,\cosh(u)\,\cos(v) \\ 0 \\ 0 \end{pmatrix}$$

This is the gradient of the function $f(x, y, z) = x^2$ with x expressed by elliptic cylindrical coordinates:

```
G := gradient(x^2, [x, y, z])
```

$$\begin{pmatrix} 2\,x \\ 0 \\ 0 \end{pmatrix}$$

```
[x, y, z] :=
linalg::ogCoordTab[EllipticCylindrical, Transformation](u, v, w, c)
```

$$[c\,\cosh(u)\,\cos(v),\ c\,\sinh(u)\,\sin(v),\ w]$$

```
map(G, eval)
```

$$\begin{pmatrix} 2\,c\,\cosh(u)\,\cos(v) \\ 0 \\ 0 \end{pmatrix}$$

```
delete f, gradf, e_u, e_v, e_w, G, x, y, z:
```

Parameters

`ogName`

The name of a predefined coordinate system. The following 3 dimensional coordinate systems are available: `Cartesian`, `Spherical` (equivalent to `Spherical[RightHanded]`), `Spherical[LeftHanded]`, `Cylindrical`, `EllipticCylindrical`, `ParabolicCylindrical`, `RotationParabolic`, `Torus`.

u_1, u_2, u_3

The coordinates of the orthogonal system: identifiers, indexed identifiers, or arithmetical expressions.

x_1, x_2, x_3

Cartesian coordinates: identifiers, indexed identifiers, or arithmetical expressions.

`c`

An arithmetical expression. The default value is `c` = 1.

Options

Transformation

`linalg::ogCoordTab [ogName, Transformation]( u1, u2, u3, c )` returns a list of arithmetical expressions `[ x1( u1, u2, u3), x2( u1, u2, u3), x3( u1, u2, u3)]` defining the transformation from the orthogonal coordinates u_i to the Cartesian coordinates x_j. The transformation is invertible if the coordinates u_i are from the range $a_i < u_i < b_i$ where `[a1..b1, a2..b2, a3..b3]` = `linalg::ogCoordTab [ogName, Ranges](c)`.

InverseTransformation

`linalg::ogCoordTab [ogName, InverseTransformation]( x1, x2, x3, c )` returns a list of arithmetical expressions `[ u1( x1, x2, x3), u2( x1, x2, x3), u3( x1, x2, x3)]` defining the inverse transformation. The inverse transformation produces parameter values u_i in the range $a_i \le u_i \le b_i$ given by `[a1..b1, a2..b2, a3..b3]` = `linalg::ogCoordTab [ogName, Ranges](c)`.

UnitVectors

`linalg::ogCoordTab [ogName, UnitVectors]( u1, u2, u3, c )` returns a list of orthonormal vectors $\left[\vec{e}_1, \vec{e}_2, \vec{e}_3\right]$, where each vector is represented by a list of three arithmetical expressions. These vectors $\vec{e}_i = \frac{1}{s_i}\frac{\partial}{\partial u_i}\vec{x}$ with $s_i = \left|\frac{\partial}{\partial u_i}\vec{x}\right|$ are the unit vectors tangent to the parameter lines `u`$_i$.

Scales

`linalg::ogCoordTab [ogName, Scales]( u1, u2, u3, c )` returns a list `[ s1, s2, s3]` of "scaling factors" of the transformation $\vec{u} \to \vec{x}$. The "scales" are the Euclidean lengths $s_i = \left|\frac{\partial}{\partial u_i}\vec{x}\right|$ of the vectors $\frac{\partial}{\partial u_i}\vec{x}$ tangent to the parameter lines `u`$_i$.

Return Values

Most of the entries in `linalg::ogCoordTab` are functions:

`linalg::ogCoordTab [ogName, Transformation]( u1, u2, u3, c )` returns a list of arithmetical expressions `[ x1( u1, u2, u3), x2( u1, u2, u3), x3( u1, u2, u3)]` defining the transformation from the orthogonal coordinates u_i to the Cartesian coordinates x_j.

`linalg::ogCoordTab [ogName, InverseTransformation]( x1, x2, x3, c )` returns a list of arithmetical expressions `[ u1( x1, x2, x3), u2( x1, x2, x3), u3( x1, x2, x3)]` defining the inverse transformation.

`linalg::ogCoordTab [ogName, UnitVectors]( u1, u2, u3, c )` returns a list of orthogonal unit "vectors." The "vectors" are given as lists of arithmetical expressions.

`linalg::ogCoordTab [ogName, Scales]( u1, u2, u3, c )` returns a list of arithmetical expressions.

`linalg::ogCoordTab [ogName, Ranges]( c )` returns a list of ranges `[ a1.. b1, a2.. b2, a3.. b3]`. The transformation is invertible for parameter values $a_i < u_i < b_i$.

`linalg::ogCoordTab [ogName, Dimension]` yields the dimension of the space parametrized by the orthogonal coordinates. Presently, all predefined systems parametrize $\mathbb{R}^3$, i.e., the dimension is 3 in all cases.

The call `linalg::ogCoordTab [ogName]( u1, u2, u3, c )` is identical to the call `linalg::ogCoordTab [ogName, UnitVectors]( u1, u2, u3, c )`.

linalg::orthog

Orthogonalization of vectors

Syntax

```
linalg::orthog(S, <Real>)
```

Description

`linalg::orthog(S)` orthogonalizes the vectors in S using the Gram-Schmidt orthogonalization algorithm.

The vectors in `S` are orthogonalized with respect to the scalar product `linalg::scalarProduct`.

If O is the returned set, then the vectors of O span the same subspace as the vectors in `S`, and they are pairwise orthogonal, i.e.: $\vec{v}\,\vec{w} = 0$ for all $\vec{v}, \vec{w} \in O$ with $\vec{v} \neq \vec{w}$.

The vectors returned are not normalized. To normalize them use `map(O, linalg::normalize)`.

For an ordered set of orthogonal vectors, `S` should be a list.

The vectors in `S` must be defined over the same component ring.

The component ring of the vectors in `S` must be a field, i.e., a domain of category `Cat::Field`.

If you use the `Real` option, `linalg::orthog` computes an orthogonal basis using a real scalar product in the orthogonalization process.

Examples

Example 1

The following list of vectors is a basis of the vector space $\mathbb{R}^3$:

```
MatR := Dom::Matrix(Dom::Real):
S := [MatR([2, 1, 0]), MatR([-3, 1, 1]), MatR([-1, -1, -1])]
```

$$\left[\begin{pmatrix}2\\1\\0\end{pmatrix}, \begin{pmatrix}-3\\1\\1\end{pmatrix}, \begin{pmatrix}-1\\-1\\-1\end{pmatrix}\right]$$

The Gram-Schmidt algorithm then returns an orthogonal basis for $\mathbb{R}^3$. We get an orthonormal basis with the following input:

```
ON:= linalg::orthog(S)
```

$$\left[\begin{pmatrix}2\\1\\0\end{pmatrix}, \begin{pmatrix}-1\\2\\1\end{pmatrix}, \begin{pmatrix}-\frac{2}{15}\\\frac{4}{15}\\-\frac{2}{3}\end{pmatrix}\right]$$

The vectors can be normalized using `linalg::normalize`:

```
map(ON, linalg::normalize)
```

$$\left[\begin{pmatrix}\frac{2\sqrt{5}}{5}\\\frac{\sqrt{5}}{5}\\0\end{pmatrix}, \begin{pmatrix}-\frac{\sqrt{6}}{6}\\\frac{\sqrt{6}}{3}\\\frac{\sqrt{6}}{6}\end{pmatrix}, \begin{pmatrix}-\frac{\sqrt{2}\sqrt{15}}{30}\\\frac{\sqrt{2}\sqrt{15}}{15}\\-\frac{\sqrt{2}\sqrt{15}}{6}\end{pmatrix}\right]$$

We may also build a matrix from the vectors in `S` an apply `linalg::orthog` to this matrix. The result is the matrix whose columns are given by the above elements of the list `ON`:

```
A:= S[1].S[2].S[3]
```

$$\begin{pmatrix}2 & -3 & -1\\1 & 1 & -1\\0 & 1 & -1\end{pmatrix}$$

```
linalg::orthog(A)
```

$$\begin{pmatrix} 2 & -1 & -\frac{2}{15} \\ 1 & 2 & \frac{4}{15} \\ 0 & 1 & -\frac{2}{3} \end{pmatrix}$$

Example 2

The orthogonalization of the vectors:

```
T := {matrix([[-2, 5, 3]]), matrix([[0, 2, 1]])}
```

$$\{(0\ 2\ 1), (-2\ 5\ 3)\}$$

gives:

```
linalg::orthog(T)
```

$$\left\{(0\ 2\ 1), \left(-2\ -\frac{1}{5}\ \frac{2}{5}\right)\right\}$$

Example 3

The result of `linalg::orthog` is a list or set of linearly independent vectors, even if the input contains linearly dependent vectors:

```
MatQ := Dom::Matrix(Dom::Rational):
S := [MatQ([2, 1]), MatQ([3, 4]), MatQ([-1, 1])]
```

$$\left[\begin{pmatrix} 2 \\ 1 \end{pmatrix}, \begin{pmatrix} 3 \\ 4 \end{pmatrix}, \begin{pmatrix} -1 \\ 1 \end{pmatrix}\right]$$

```
linalg::orthog(S)
```

$$\left[\begin{pmatrix} 2 \\ 1 \end{pmatrix}, \begin{pmatrix} -1 \\ 2 \end{pmatrix}\right]$$

Example 4

Compute an orthogonal basis of this matrix:

```
A := matrix([[a, 1], [1, a]]):
linalg::orthog(A)
```

$$\begin{pmatrix} a & -\frac{a^2-1}{a\,\overline{a}+1} \\ 1 & -\frac{\overline{a}-a^2\,\overline{a}}{a\,\overline{a}+1} \end{pmatrix}$$

To avoid complex conjugates, use the `Real` option:

```
linalg::orthog(A, Real)
```

$$\begin{pmatrix} a & -\frac{a^2-1}{a^2+1} \\ 1 & \frac{a\left(a^2-1\right)}{a^2+1} \end{pmatrix}$$

Parameters

`S`

A set or list of vectors of the same dimension (a vector is an $n \times 1$ or $1 \times n$ matrix of a domain of category `Cat::Matrix`) or a matrix

Options

`Real`

Avoid using a complex scalar product in the orthogonalization process.

Return Values

Set or a list of vectors, respectively.

linalg::pascal

Pascal matrix

Syntax

```
linalg::pascal(n, <R>)
```

Description

`linalg::pascal(n)` returns the $n \times n$ Pascal matrix P given by $P_{i,j} = \binom{i+j-2}{i-1}$, $1 \le i, j \le n$.

The entries of Pascal matrices are integer numbers. Note, however, that the returned matrix is not defined over the component domain `Dom::Integer`, but over the standard component domain `Dom::ExpressionField()`. Thus, no conversion is necessary when working with other functions that expect or return matrices over that component domain.

Use `linalg::pascal(n, Dom::Integer)` to define the $n \times n$ Pascal matrix over the ring of integer numbers.

Inverse Pascal matrices are provided by `linalg::invpascal`.

Examples

Example 1

We construct the 3×3 Pascal matrix:

```
linalg::pascal(3)
```

$$\begin{pmatrix} 1 & 1 & 1 \\ 1 & 2 & 3 \\ 1 & 3 & 6 \end{pmatrix}$$

This is a matrix of the domain `Dom::Matrix()`.

If you prefer a different component ring, the matrix may be converted to the desired domain after construction (see `coerce`, for example). Alternatively, one can specify the component ring when creating the Pascal matrix. For example, specification of the domain `Dom::Float` generates floating-point entries:

```
linalg::pascal(3, Dom::Float)
```

$$\begin{pmatrix} 1.0 & 1.0 & 1.0 \\ 1.0 & 2.0 & 3.0 \\ 1.0 & 3.0 & 6.0 \end{pmatrix}$$

```
domtype(%)
```

Dom::Matrix(Dom::Float)

Example 2

The Cholesky factor of a Pascal matrix consists of the elements of Pascal's triangle:

```
linalg::factorCholesky(linalg::pascal(4))
```

$$\begin{pmatrix} 1 & 0 & 0 & 0 \\ 1 & 1 & 0 & 0 \\ 1 & 2 & 1 & 0 \\ 1 & 3 & 3 & 1 \end{pmatrix}$$

Parameters

`n`

The dimension of the matrix: a positive integer

`R`

The component ring: a domain of category `Cat::Rng`; default: `Dom::ExpressionField()`

Return Values

$n \times n$ matrix of the domain `Dom::Matrix(R)`.

Algorithms

Pascal matrices are symmetric and positive definite.

The determinant of a Pascal matrix is 1.

The inverse of a Pascal matrix has integer entries.

If λ is an eigenvalue of a Pascal matrix, then $\frac{1}{\lambda}$ is also an eigenvalue of the matrix.

`linalg::hilbert` | `linalg::invhilbert` | `linalg::invpascal` | `linalg::invvandermonde` | `linalg::toeplitz` | `linalg::toeplitzSolve` | `linalg::vandermonde` | `linalg::vandermondeSolve`

linalg::permanent

Permanent of a matrix

Syntax

```
linalg::permanent(A)
```

Description

`linalg::permanent(A)` computes the permanent of the square matrix A.

The component ring of the matrix `A` must be a commutative ring, i.e., a domain of category `Cat::CommutativeRing`.

Examples

Example 1

We compute the permanent of the following matrix:

```
delete a11, a12, a21, a22:
A := matrix([[a11, a12], [a21, a22]])
```

$$\begin{pmatrix} a11 & a12 \\ a21 & a22 \end{pmatrix}$$

which gives us the general formula for the permanent of an arbitrary 2 ×2 matrix:

```
linalg::permanent(A)
```

$$a11\ a22 + a12\ a21$$

Example 2

The permanent of a matrix can be computed over arbitrary commutative rings. Let us create a random matrix defined over the ring $\mathbb{Z}_6$, the integers modulo 6:

```
B := linalg::randomMatrix(5, 5, Dom::IntegerMod(6))
```

$$\begin{pmatrix} 3 \bmod 6 & 2 \bmod 6 & 3 \bmod 6 & 5 \bmod 6 & 4 \bmod 6 \\ 2 \bmod 6 & 5 \bmod 6 & 2 \bmod 6 & 1 \bmod 6 & 1 \bmod 6 \\ 1 \bmod 6 & 3 \bmod 6 & 3 \bmod 6 & 2 \bmod 6 & 2 \bmod 6 \\ 1 \bmod 6 & 0 \bmod 6 & 3 \bmod 6 & 3 \bmod 6 & 5 \bmod 6 \\ 0 \bmod 6 & 0 \bmod 6 & 0 \bmod 6 & 1 \bmod 6 & 3 \bmod 6 \end{pmatrix}$$

The permanent of this matrix is:

```
linalg::permanent(B)
```

$$4 \bmod 6$$

Its determinant is:

```
det(B)
```

$$0 \bmod 6$$

Parameters

A

A square matrix of a domain of category `Cat::Matrix`

Return Values

Element of the component ring of A.

Algorithms

The permanent of an $n \times n$ matrix $A = (a_{i,j})_{1 \le i \le n,\ 1 \le j \le n}$ is defined similary as the determinant of A, only the signs of the permutations do not enter the definition:

$$\mathrm{perm}(A) := \sum_{\sigma \in S_n} \prod_{j=1}^{n} a_{\sigma(j),\,j}$$

.

(S_n is the symmetric group of all permutations of {1, …, n}.)

In contrast to the computation of the determinant, the computation of the permanent takes time $O(n^2\,2^n)$.

See Also

MuPAD Functions

`det`

linalg::pseudoInverse

Moore-Penrose inverse of a matrix

Syntax

```
linalg::pseudoInverse(A)
```

Description

`linalg::pseudoInverse(A)` computes the Moore-Penrose inverse of A.

If the Moore-Penrose inverse of `A` does not exist, then `FAIL` is returned.

The component ring of the matrix `A` must be a field, i.e., a domain of category `Cat::Field`.

Examples

Example 1

The Moore-Penrose inverse of the 2×3 matrix:

```
A := Dom::Matrix(Dom::Complex)([[1, I, 3], [1, 3, 2]])
```

$$\begin{pmatrix} 1 & i & 3 \\ 1 & 3 & 2 \end{pmatrix}$$

is the 3×2 matrix:

```
Astar := linalg::pseudoInverse(A)
```

$$\begin{pmatrix} \frac{7}{96} + \frac{1}{32} i & \frac{1}{24} - \frac{1}{32} i \\ -\frac{7}{32} - \frac{5}{96} i & \frac{5}{16} + \frac{7}{96} i \\ \frac{7}{24} + \frac{1}{16} i & \frac{1}{96} - \frac{3}{32} i \end{pmatrix}$$

Note that in this example, only:

```
A * Astar
```

$$\begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}$$

yields the identity matrix, but not (see “Backgrounds” below):

```
Astar * A
```

$$\begin{pmatrix} \frac{11}{96} & \frac{3}{32} - \frac{1}{48}\,i & \frac{29}{96} + \frac{1}{32}\,i \\ \frac{3}{32} + \frac{1}{48}\,i & \frac{95}{96} & -\frac{1}{32} - \frac{1}{96}\,i \\ \frac{29}{96} - \frac{1}{32}\,i & -\frac{1}{32} + \frac{1}{96}\,i & \frac{43}{48} \end{pmatrix}$$

Parameters

A

A matrix of category `Cat::Matrix`

Return Values

Matrix of the same domain type as `A`, or the value `FAIL`.

Algorithms

For an invertible matrix A, the Moore-Penrose inverse A^* of A coincides with the inverse of A. In general, only $A\,A^*\,A = A$ and $A^*\,A\,A^* = A^*$ holds.

If A is of dimension $m \times n$, then A^* is of dimension $n \times m$.

The computation of the Moore-Penrose inverse requires the existence of a scalar product on the vector space K^n, where K is the coefficient field of the matrix A. This is only the

case for some fields K in theory, but `linalg::scalarProduct` works also for vectors over other fields (e.g. finite fields). The computation of a Moore-Penrose inverse may fail in such cases.

See Also

MuPAD Functions

`_invert`

linalg::randomMatrix

Generate a random matrix

Syntax

```
linalg::randomMatrix(m, n, <R>, <bound>, <Diagonal | Unimodular>)
```

Description

The call `linalg::randomMatrix(m, n)` returns a random $m \times n$ matrix over the default component ring for matrices, i.e., over the domain `Dom::ExpressionField()`.

The matrix components are generated by the method `"random"` of the domain `R` (see “Example 2” on page 15-185).

The parameter `bound` is given as a parameter to the method `"random"` of the domain `R` in order to bound the size of the components of the random matrix. The correct type of `bound` is determined by the method `"random"`. The parameter has no effect if the slot `"random"` does not have a size argument.

Examples

Example 1

We create a random square matrix over the integers. Because the matrix is random the created matrix can vary:

```
linalg::randomMatrix(2, 2, Dom::Integer)
```

$$\begin{pmatrix} 824 & -65 \\ -814 & -741 \end{pmatrix}$$

If you want to bound the size of its components, say between -2 and 2, enter:

```
linalg::randomMatrix(2, 2, Dom::Integer, -2..2)
```

$$\begin{pmatrix} -1 & 1 \\ -2 & 1 \end{pmatrix}$$

Example 2

The following input creates a random vector over the component ring `Dom::FloatIV` of floating-point intervals. Because the vector is random the created vector can vary:

```
v := linalg::randomMatrix(1, 4, Dom::FloatIV)
```

```
[[0.2703581654 ... 0.831037179, 0.1531565158 ... 0.9948127811, 0.1801642274 ... 0.2662729024,
  0.4520830547 ... 0.6787819565]]
```

```
domtype(v)
```

```
Dom::Matrix(Dom::FloatIV)
```

The components of this matrix are random floating-point intervals created by the `"random"` method of the domain constructor `Dom::FloatIV`.

Example 3

To create a random diagonal matrix over the rationals we enter, for example:

```
linalg::randomMatrix(3, 3, Dom::Rational, Diagonal)
```

$$\begin{pmatrix} \frac{229}{220} & 0 & 0 \\ 0 & -\frac{535}{617} & 0 \\ 0 & 0 & -\frac{245}{597} \end{pmatrix}$$

Example 4

The following command creates a random unimodular matrix over the integers so that its determinant is either 1 or -1:

```
A := linalg::randomMatrix(3, 3, Dom::Integer, Unimodular)
```

$$\begin{pmatrix} -1 & -8 & 4 \\ 4 & 0 & -5 \\ -3 & 5 & 2 \end{pmatrix}$$

```
det(A)
```

$$-1$$

We can bound the size of the components. The following input returns a unimodular matrix $A = (a_{ij})$ with $|a_{ij}| \leq 2$ for $i, j = 1, 2, 3$:

```
A := linalg::randomMatrix(3, 3, 2, Unimodular)
```

$$\begin{pmatrix} 0 & -1 & 0 \\ 1 & 0 & 2 \\ 1 & 0 & 1 \end{pmatrix}$$

Since we did not specifiy the component ring, the matrix is defined over the standard component ring for matrices (the domain `Dom::ExpressionField()`):

```
domtype(A)
```

$$\text{Dom::Matrix()}$$

Parameters

`m, n`

Positive integers

`R`

The component ring, i.e., a domain of category `Cat::Rng`; default: `Dom::ExpressionField()`

`bound`

An arithmetical expression

Options

`Diagonal`

Creates a random $m \times n$ diagonal matrix over `R`.

`Unimodular`

Creates a random $m \times m$ unimodular matrix over `R`, so that its determinant is a unit in `R`.

Note: Note that this option is only available for square matrices.

The norm of each component of the matrix returned does not exceed `bound`, which must be a positive integer, if specified. The default value of `bound` is 10.

Return Values

Matrix of the domain `Dom::Matrix(R)`.

References

For generating random unimodular matrices, see Jürgen Hansen: *Generating Problems in Linear Algebra*, MapleTech, Volume 1, No.2, 1994.

linalg::rank

Rank of a matrix

Syntax

```
linalg::rank(A)
```

```
linalg::rank(S)
```

Description

`linalg::rank(A)` computes the rank of the matrix A.

`linalg::rank(S)` computes the rank of the matrix whose columns are the vectors in S.

The row rank of a matrix is the maximal number of linearly independent row vectors of that matrix. The column rank of a matrix is the maximal number of linearly independent column vectors of that matrix. For each matrix, its row rank is equal to its column rank. This number is called the rank of a matrix.

The component ring of `A` or of the vectors given in `S` must be an integral domain (a domain of category `Cat::IntegralDomain`).

`linalg::rank` replaces symbolic elements of a matrix by random integer numbers between 1 and 10^{10}. Then the function computes the rank of the resulting numeric matrix by Gaussian elimination (see `linalg::gaussElim`). This approach introduces a tiny chance of getting a wrong result.

Note: `linalg::rank` does not simplify special functions and algebraic numbers. For some matrices, this approach leads to wrong results. See “Example 3” on page 15-189.

Examples

Example 1

Define the following matrix `A` over $\mathbb{Z}$:

```
MatZ := Dom::Matrix(Dom::Integer):
A := MatZ([[1, 2, 3, 4], [-1, 0, 1, 0], [3, 5, 6, 9]])
```

$$\begin{pmatrix} 1 & 2 & 3 & 4 \\ -1 & 0 & 1 & 0 \\ 3 & 5 & 6 & 9 \end{pmatrix}$$

Compute the rank of the matrix A:

```
linalg::rank(A)
```

$$3$$

Example 2

Use the three vectors $\begin{pmatrix} 0 \\ 1 \\ 1 \end{pmatrix}, \begin{pmatrix} 0 \\ 1 \\ 0 \end{pmatrix}, \begin{pmatrix} 0 \\ 0 \\ 1 \end{pmatrix}$ to define the columns of the matrix A. Compute the rank of A:

```
MatZ := Dom::Matrix(Dom::Integer):
S:= { MatZ([0,1,1]), MatZ([0,1,0]), MatZ([0,0,1]) }:
linalg::rank(S)
```

$$2$$

Example 3

The `linalg::rank` function does not use any simplification rules for special functions, algebraic numbers (radicals), and so on. If `linalg::rank` computes intermediate expressions that can be simplified to zero, the function can return incorrect results. For example, create the following matrices:

```
A := matrix([[exp(x + y), exp(x)], [exp(y), 1]]);
B := matrix([[sin(x)^2 + cos(x)^2, 1], [1, 1]]);
C := matrix([[sqrt(6), sqrt(2)], [sqrt(3), 1]])
```

$$\begin{pmatrix} e^{x+y} & e^{x} \\ e^{y} & 1 \end{pmatrix}$$

$$\begin{pmatrix} \cos(x)^2 + \sin(x)^2 & 1 \\ 1 & 1 \end{pmatrix}$$

$$\begin{pmatrix} \sqrt{6} & \sqrt{2} \\ \sqrt{3} & 1 \end{pmatrix}$$

There is only one independent row in each of these matrices. The rank of the matrices `A`, `B`, and `C` is 1. The `linalg::rank` function returns 2 because it does not simplify the expressions $e^{x+y} - e^x e^y$, $sin^2 + cos^2$ - 1, and $\sqrt{2}\sqrt{3} - \sqrt{6}$:

```
linalg::rank(A), linalg::rank(B), linalg::rank(C)
```

$$2, 2, 2$$

Parameters

A

A matrix of a domain of category `Cat::Matrix`

S

A list or set of column vectors of the same dimension (a column vector is an $n \times 1$ matrix of a domain of category `Cat::Matrix`)

Return Values

Nonnegative integer

See Also

MuPAD Functions

`det` | `linalg::gaussElim`

linalg::row

Extract rows of a matrix

Syntax

```
linalg::row(A, r)
```

```
linalg::row(A, r1 .. r2)
```

```
linalg::row(A, list)
```

Description

`linalg::row(A, r)` extracts the *r*-th row vector of the matrix *A*.

`linalg::row(A, r1.. r2)` returns a list of row vectors whose indices are in the range `r1.. r2`. If `r2< r1` then the empty list `[]` is returned.

`linalg::row(A, list)` returns a list of row vectors whose indices are contained in `list` (in the same order).

Examples

Example 1

We define a matrix over $\mathbb{Q}$:

```
A := Dom::Matrix(Dom::Rational)(
  [[1, 1/5], [-3/2, 5], [2, -3]]
)
```

$$\begin{pmatrix} 1 & \frac{1}{5} \\ -\frac{3}{2} & 5 \\ 2 & -3 \end{pmatrix}$$

and illustrate the three different input formats for the function `linalg::row`:

```
linalg::row(A, 2)
```

$$\left(-\frac{3}{2}\ 5\right)$$

```
linalg::row(A, [2, 1, 3])
```

$$\left[\left(-\frac{3}{2}\ 5\right), \left(1\ \frac{1}{5}\right), (2\ -3)\right]$$

```
linalg::row(A, 2..3)
```

$$\left[\left(-\frac{3}{2}\ 5\right), (2\ -3)\right]$$

Parameters

`A`

An $m \times n$ matrix of a domain of category `Cat::Matrix`

`r`

The row index: a positive integer less or equal to m

r_1 `..` r_2

A range of row indices (positive integers less or equal to m)

`list`

A list of row indices (positive integers less or equal to m)

Return Values

Single row vector or a list of row vectors; a row vector is a $1 \times n$ matrix of category `Cat::Matrix(R)`, where R is the component ring of `A`.

MuPAD Functions

`linalg::col` | `linalg::delCol` | `linalg::delRow` | `linalg::setCol` | `linalg::setRow`

linalg::scalarProduct

Scalar product of vectors

Syntax

```
linalg::scalarProduct(u, v, <Real>)
```

Description

`linalg::scalarProduct(u, v)` computes the scalar product of the vectors $\vec{u} = (u_1, \ldots, u_n)$ and $\vec{v} = (v_1, \ldots, v_n)$ with respect to the standard basis, i.e., the sum $u_1 \overline{v_1} + \ldots + u_n \overline{v_n}$.

The scalar product is also called “inner product” or “dot product”.

If the component ring of the vectors `u` and `v` does not define the entry `"conjugate"` or if the option `Real` is specified, then `linalg::scalarProduct` uses the definition $u_1 v_1 + \ldots + u_n v_n$ of the scalar product.

The vectors `u` and `v` must be defined over the same component ring.

`linalg::scalarProduct` can be redefined to a different scalar product. This also affects the behaviour of functions such as `linalg::angle`, `linalg::factorQR`, `linalg::isUnitary`, `norm` (for vectors and matrices), `linalg::orthog` and `linalg::pseudoInverse` depend on the definition of `linalg::scalarProduct`. See “Example 3” on page 15-196.

Environment Interactions

Properties of identifiers are taken into account.

Examples

Example 1

We compute the scalar product of the vectors (i, 1) and (1, - i):

```
MatC := Dom::Matrix(Dom::Complex):
u := MatC([I, 1]): v := MatC([1, -I]):
linalg::scalarProduct(u, v)
```

$$2\,i$$

Example 2

We compute the scalar product of the vectors $\vec{u} = (u_1, u_2)$ and $\vec{v} = (v_1, v_2)$ with the symbolic entries u_1, u_2, v_1, v_2 over the standard component ring for matrices:

```
delete u1, u2, v1, v2:
u := matrix([u1, u2]): v := matrix([v1, v2]):
linalg::scalarProduct(u, v)
```

$$u1\,\overline{v1} + u2\,\overline{v2}$$

You can use `assume` to tell the system that the symbolic components are to represent real numbers:

```
assume([u1, u2, v1, v2], Type::Real):
```

Then the scalar product of $\vec{u}$ and $\vec{v}$ simplifies to:

```
linalg::scalarProduct(u, v)
```

$$u1\,v1 + u2\,v2$$

Alternatively, the option `Real` can be specified:

```
unassume(u1, u2, v1, v2):
```

```
linalg::scalarProduct(u, v, Real)
```

$$u1\ v1 + u2\ v2$$

Example 3

One particular scalar product in the real vector space of continuous functions on the interval [0, 1] is defined by

$$(f, g) = \int_0^1 f(t)\, g(t)\, \mathrm{d}t$$

.

To compute an orthogonal basis corresponding to the polynomial basis 1, t, t^2, t^3, ... with respect to this scalar product, we replace the standard scalar product by the following procedure:

```
standardScalarProduct := linalg::scalarProduct:
unprotect(linalg):
linalg::scalarProduct := proc(u, v)
    local F, f, t;
begin
    // (0)
    f := expr(u[1] * v[1]);

     // (1)
    t := indets(f);
    if t = {} then t := genident("t") else t := op(t, 1) end_if;

     // (2)
    F := int(f, t = 0..1);

     // (3)
    u::dom::coeffRing::coerce(F)
end:
```

We start with step `(0)` to convert $f(t)\, g(t)$ to an expression of a basic domain type, such that the system function `int` in step `(2)` can handle its input (this is not necessary if the elements of the component ring of the vectors are already represented by elements of basic domains).

Step `(1)` extracts the indeterminate of the polynomials, step `(2)` computes the scalar product as defined above and step `(3)` converts the result back to an element of the component ring of vectors `u` and `v`.

Note that we need to unprotect the write protected identifier `linalg`, otherwise the assignment would lead to an error message.

We next create the matrix which consists of the first five of the above polynomials:

```
P := matrix([[1, t, t^2, t^3, t^4]])
```

$$\begin{pmatrix} 1 & t & t^2 & t^3 & t^4 \end{pmatrix}$$

If we now perform the Gram-Schmidt orthogonalization procedure on the columns of `P` with the function `linalg::orthog`, we get:

```
S := linalg::orthog(linalg::col(P, 1..4))
```

$$\left[(1), \left(t - \frac{1}{2}\right), \left(t^2 - t + \frac{1}{6}\right), \left(t^3 - \frac{3\,t^2}{2} + \frac{3\,t}{5} - \frac{1}{20}\right)\right]$$

Each vector in `S` is orthogonal to the other vectors in `S` with respect to the modified scalar product. We check this for the first vector:

```
linalg::scalarProduct(S[1], S[j]) $ j = 2..nops(S)
```

$$0, 0, 0$$

Finally, we undo the redefinition of the scalar product, so as not to run into trouble with subsequent computations:

```
linalg::scalarProduct := standardScalarProduct:
protect(linalg, Error):
```

Parameters

`u, v`

Vectors of the same dimension (a vector is an $n \times 1$ or $1 \times n$ matrix of a domain of category `Cat::Matrix`)

Options

`Real`

Use $u_1 v_1 + \ldots + u_n v_n$ as the definition of the scalar product, i.e., suppress the use of `conjugate`.

Return Values

Element of the component ring of `u` and `v`.

See Also

MuPAD Functions

`linalg::angle` | `linalg::crossProduct` | `linalg::factorQR` | `linalg::isUnitary` | `linalg::orthog` | `norm`

linalg::setCol

Change a column of a matrix

Syntax

```
linalg::setCol(A, p, c)
```

Description

`linalg::setCol(A, p, c)` returns a copy of matrix A with the p-th column replaced by the column vector $\vec{c}$.

If `c` is a list with at most m elements, then `c` is converted into a column vector. An error message is returned if the conversion is not possible (e.g., if an element of the list cannot be converted into an object of the component ring of `A`; see "Example 2" on page 15-200).

Examples

Example 1

We define a matrix over the rationals:

```
MatQ := Dom::Matrix(Dom::Rational):
A := MatQ([[1, 2], [3, 2]])
```

$$\begin{pmatrix} 1 & 2 \\ 3 & 2 \end{pmatrix}$$

and replace the 2nd column by the 2×1 zero vector:

```
linalg::setCol(A, 2, MatQ([0, 0]))
```

$$\begin{pmatrix} 1 & 0 \\ 3 & 0 \end{pmatrix}$$

Example 2

We create the 2×2 zero matrix over $\mathbb{Z}_6$:

```
B := Dom::Matrix(Dom::IntegerMod(6))(2, 2)
```

$$\begin{pmatrix} 0 \bmod 6 & 0 \bmod 6 \\ 0 \bmod 6 & 0 \bmod 6 \end{pmatrix}$$

and replace the 2nd column by the vector $\begin{pmatrix} 1 \\ -1 \end{pmatrix}$. We give the column vector in form of a list. Its elements are converted implicitly into objects of the component ring of `B`:

```
linalg::setCol(B, 2, [1, -1])
```

$$\begin{pmatrix} 0 \bmod 6 & 1 \bmod 6 \\ 0 \bmod 6 & 5 \bmod 6 \end{pmatrix}$$

The following input leads to an error message because the number `1/3` can not be converted into an object of type `Dom::IntegerMod(6)`:

```
linalg::setCol(B, 1, [1/3, 0])
```

```
Error: The column vector is invalid. [linalg::setCol]
```

Parameters

A

An $m \times n$ matrix of a domain of category `Cat::Matrix`

c

A column vector, or a list that can be converted into a column vector of the domain `Dom::Matrix(R)`, where `R` is the component ring of `A` (a column vector is an $m \times 1$ matrix)

Return Values

Matrix of the same domain type as A.

See Also

MuPAD Functions

`linalg::col` | `linalg::delCol` | `linalg::delRow` | `linalg::row` | `linalg::setRow`

linalg::setRow

Change a row of a matrix

Syntax

```
linalg::setRow(A, p, r)
```

Description

`linalg::setRow(A, p, r)` returns a copy of the matrix A with the p-th row replaced by the row vector $\vec{r}$.

If `r` is a list with at most n elements, then `r` is converted into a row vector. An error message is returned if the conversion is not possible (e.g., if an element of the list cannot be converted into an object of the component ring of `A`; see "Example 2" on page 15-203).

Examples

Example 1

We define a matrix over the rationals:

```
MatQ := Dom::Matrix(Dom::Rational):
A := MatQ([[1, 2], [3, 2]])
```

$$\begin{pmatrix} 1 & 2 \\ 3 & 2 \end{pmatrix}$$

and replace the 2nd row by the 1×2 zero vector:

```
linalg::setRow(A, 2, MatQ(1, 2, [0, 0]))
```

$$\begin{pmatrix} 1 & 2 \\ 0 & 0 \end{pmatrix}$$

Example 2

We create the 2×4 zero matrix over $\mathbb{Z}_6$:

```
B := Dom::Matrix(Dom::IntegerMod(6))(2, 4)
```

$$\begin{pmatrix} 0 \bmod 6 & 0 \bmod 6 & 0 \bmod 6 & 0 \bmod 6 \\ 0 \bmod 6 & 0 \bmod 6 & 0 \bmod 6 & 0 \bmod 6 \end{pmatrix}$$

and replace the 2nd row by the vector (1, - 1, 1, - 1). We give the row vector in form of a list. Its elements are converted implicitly into objects of the component ring of `B`:

```
linalg::setRow(B, 2, [1, -1, 1, -1])
```

$$\begin{pmatrix} 0 \bmod 6 & 0 \bmod 6 & 0 \bmod 6 & 0 \bmod 6 \\ 1 \bmod 6 & 5 \bmod 6 & 1 \bmod 6 & 5 \bmod 6 \end{pmatrix}$$

The following input leads to an error message because the number $\frac{1}{3}$ can not be converted into an object of type `Dom::IntegerMod(6)`:

```
linalg::setRow(B, 1, [1/3, 0, 1, 0])
```

```
Error: The row vector is invalid. [linalg::setRow]
```

Parameters

`A`

An $m \times n$ matrix of a domain of category `Cat::Matrix`

`r`

A row vector or a list that can be converted into a row vector the domain `Dom::Matrix(R)`, where `R` is the component ring of `A` (a row vector is a $1 \times n$ matrix)

Return Values

Matrix of the same domain type as `A`.

See Also

MuPAD Functions

`linalg::col` | `linalg::delCol` | `linalg::delRow` | `linalg::row` | `linalg::setCol`

linalg::smithForm

Smith canonical form of a matrix

Syntax

```
linalg::smithForm(A)
```

Description

`linalg::smithForm(A)` computes the Smith canonical form of the n-dimensional square matrix A, i.e., an $n \times n$ diagonal matrix S such that $S_{i-1,i-1}$ divides $S_{i,i}$ for $i = 2, \ldots, n$.

The Smith canonical form of a matrix A is unique.

The component ring of A must be a Euclidean ring, i.e., a domain of category `Cat::EuclideanDomain`.

Examples

Example 1

We define a matrix over the integers:

```
MatZ := Dom::Matrix(Dom::Integer):
A := MatZ([[9, -36, 30], [-36, 192, -180], [30, -180, 180]])
```

$$\begin{pmatrix} 9 & -36 & 30 \\ -36 & 192 & -180 \\ 30 & -180 & 180 \end{pmatrix}$$

The Smith canonical form of A is then given by:

```
linalg::smithForm(A)
```

$$\begin{pmatrix} 3 & 0 & 0 \\ 0 & 12 & 0 \\ 0 & 0 & 60 \end{pmatrix}$$

Example 2

We compute the Smith canonical form of a matrix over a ring of polynomials:

```
MatPoly := Dom::Matrix(Dom::DistributedPolynomial([x], Dom::Rational)):
B := MatPoly(
  [[-(x - 3)^2*(x - 2),(x - 3)*(x - 2)*(x - 4)],
   [(x - 3)*(x - 2)*(x - 4),-(x - 3)^2*(x - 4)]
])
```

$$\begin{pmatrix} -x^3+8x^2-21x+18 & x^3-9x^2+26x-24 \\ x^3-9x^2+26x-24 & -x^3+10x^2-33x+36 \end{pmatrix}$$

The Smith canonical form of the matrix `B` is the following matrix:

```
linalg::smithForm(B)
```

$$\begin{pmatrix} x-3 & 0 \\ 0 & x^3-9x^2+26x-24 \end{pmatrix}$$

Parameters

A

A square matrix of a domain of category `Cat::Matrix`

Return Values

Matrix of the same domain type as `A`.

Algorithms

An $n \times n$ matrix $S = (s_{ij})$ with coefficients in a Euclidean ring is said to be in Smith canonical form if S is a diagonal matrix (with nonnegative coefficients in case of the ring $\mathbb{Z}$) such that $s_{i,\,i}$ divides $s_{i+1,\,i+1}$ for all $i < n$.

See Also

MuPAD Functions

`linalg::frobeniusForm` | `linalg::hermiteForm` | `linalg::jordanForm`

linalg::sqrtMatrix

Square root of a matrix

Syntax

```
linalg::sqrtMatrix(A, <sqrtfunc>)
```

Description

`linalg::sqrtMatrix(A)` returns the square root of the matrix A.

If A has an eigenvalue 0 of algebraic multiplicity larger than its geometric multiplicity, then the square root of A does not exist.

Examples

Example 1

A square root of a diagonal matrix is given by the diagonal matrix, whose diagonal entries are just the square roots of the original matrix.

Compute the square root of the matrix

$$A = \begin{pmatrix} 4 & 0 & 0 \\ 0 & 2 & 0 \\ 0 & 0 & -1 \end{pmatrix}.$$

```
A := matrix([[4, 0, 0], [0, 2, 0], [0, 0, -1]]):
S := linalg::sqrtMatrix(A)
```

$$\begin{pmatrix} 2 & 0 & 0 \\ 0 & \sqrt{2} & 0 \\ 0 & 0 & i \end{pmatrix}$$

Check the correctness of the result:

```
S^2
```

$$\begin{pmatrix} 4 & 0 & 0 \\ 0 & 2 & 0 \\ 0 & 0 & -1 \end{pmatrix}$$

Example 2

Compute the square root of the matrix

$$A = \begin{pmatrix} 2 & -2 & 0 \\ -1 & 3 & 0 \\ -\frac{1}{3} & \frac{5}{3} & 2 \end{pmatrix}:$$

```
A := matrix([[2, -2, 0], [-1, 3, 0], [-1/3, 5/3, 2]]):
S := linalg::sqrtMatrix(A)
```

$$\begin{pmatrix} \frac{4}{3} & -\frac{2}{3} & 0 \\ -\frac{1}{3} & \frac{5}{3} & 0 \\ \frac{2\sqrt{2}}{3} - 1 & 1 - \frac{\sqrt{2}}{3} & \sqrt{2} \end{pmatrix}$$

If you compute the square of the matrix S and simplify the result, you obtain the matrix A:

```
simplify(S^2)
```

$$\begin{pmatrix} 2 & -2 & 0 \\ -1 & 3 & 0 \\ -\frac{1}{3} & \frac{5}{3} & 2 \end{pmatrix}$$

Using the function `x -> -sqrt(x)` as second argument for the computation of the square root of the matrix `A`, obtain a different matrix, whose components are just the negative components of the original square root computed above:

```
S:= linalg::sqrtMatrix(A, x -> -sqrt(x)):
S, simplify(S^2);
```

$$\begin{pmatrix} -\frac{4}{3} & \frac{2}{3} & 0 \\ \frac{1}{3} & -\frac{5}{3} & 0 \\ 1-\frac{2\sqrt{2}}{3} & \frac{\sqrt{2}}{3}-1 & -\sqrt{2} \end{pmatrix}, \begin{pmatrix} 2 & -2 & 0 \\ -1 & 3 & 0 \\ -\frac{1}{3} & \frac{5}{3} & 2 \end{pmatrix}$$

Parameters

A

A square matrix of a domain of category `Cat::Matrix`

sqrtfunc

A function satisfying $sqrtfunc(a)^2 = a$ for every element a of the coefficient ring of A (i.e. the square root function of the coefficient domain of A).

Return Values

Matrix B with $B^2 = A$ such that the eigenvalues of B are the square roots of the eigenvalues of A or `FAIL` if the square root of the matrix does not exist

See Also

MuPAD Functions

`funm` | `linalg::eigenvalues` | `linalg::eigenvectors` | `linalg::jordanForm` | `numeric::eigenvalues` | `numeric::eigenvectors` | `numeric::expMatrix` | `numeric::fMatrix` | `solve`

linalg::stackMatrix

Join matrices vertically

Syntax

```
linalg::stackMatrix(A, <B1, B2, …>)
```

Description

`linalg::stackMatrix(A, B1, B2, ...)` returns the matrix formed by joining the matrices `A, B1, B2, ...` vertically.

The matrices `B1, B2, ...` are converted into the matrix domain `Dom::Matrix(R)`, where `R` is the component ring of `A`.

An error message is raised if one of these conversions fails, or if the matrices do not have the same number of columns as the matrix `A`.

Examples

Example 1

We define a matrix:

```
A:= matrix( [[sin(x),x], [-x,cos(x)]] )
```

$$\begin{pmatrix} \sin(x) & x \\ -x & \cos(x) \end{pmatrix}$$

and append the 2×2 identity matrix to the lower end of the matrix `A`:

```
linalg::stackMatrix(A, matrix::identity(2))
```

$$\begin{pmatrix} \sin(x) & x \\ -x & \cos(x) \\ 1 & 0 \\ 0 & 1 \end{pmatrix}$$

Example 2

We define a matrix from the ring of 2×2 square matrices:

```
SqMatQ := Dom::SquareMatrix(2,Dom::Rational):
A := SqMatQ([[1, 2], [3, 4]])
```

$$\begin{pmatrix} 1 & 2 \\ 3 & 4 \end{pmatrix}$$

Note that the following operation:

```
AA := linalg::stackMatrix(A, A)
```

$$\begin{pmatrix} 1 & 2 \\ 3 & 4 \\ 1 & 2 \\ 3 & 4 \end{pmatrix}$$

returns a matrix of a different domain type as the input matrix:

```
domtype(AA)
```

Dom::Matrix(Dom::Rational)

Parameters

A, <B_1, B_2, …>

Matrices of a domain of category `Cat::Matrix`

Return Values

Matrix of the domain type `Dom::Matrix(R)`, where `R` is the component ring of `A`.

See Also

MuPAD Functions

`linalg::concatMatrix`

linalg::submatrix

Extract a submatrix or a subvector from a matrix or a vector, respectively

Syntax

```
linalg::submatrix(A, r1 .. r2, c1 .. c2)

linalg::submatrix(A, rlist, clist)

linalg::submatrix(v, i1 .. i2)

linalg::submatrix(v, list)
```

Description

`linalg::submatrix(A, r1.. r2, c1.. c2)` returns a copy of the submatrix of the matrix A obtained by selecting the rows r_1, $r_1 + 1$, …, r_2 and the columns c_1, $c_1 + 1$, …, c_2.

`linalg::submatrix(v, i1.. i2)` returns a copy of the subvector of the vector $\vec{v}$ obtained by selecting the components with indices i_1, $i_1 + 1$, …, i_2.

The index notation `A[ r1.. r2, c1.. c2]` and `v[ i1.. i2]`, respectively, can be used instead of `linalg::submatrix(A, r1.. r2, c1.. c2)` and `linalg::submatrix(v, i1.. i2)`.

`linalg::submatrix(A,rlist,clist)` returns the submatrix of the matrix `A` whose (i, j)-th component is $a_{rlist_i,\, clist_j}$.

`linalg::submatrix(v,list)` returns the subvector of the vector `v` whose i-th component is v_{list_i}.

If `v` is a row vector or a column vector, then `linalg::submatrix(v, 1..1, i1.. i2)` and `linalg::submatrix(v, i1.. i2, 1..1)`, respectively, are valid inputs, and they both are equivalent to the call `linalg::submatrix(v, i1.. i2)`.

Examples

Example 1

We define the following matrix:

```
A := matrix([[1, x, 0], [0, x^2, 1]])
```

$$\begin{pmatrix} 1 & x & 0 \\ 0 & x^2 & 1 \end{pmatrix}$$

The submatrix $(a_{1,j})_{1 \le j \le 2}$ of A is given by:

```
linalg::submatrix(A, 1..1, 1..2)
```

$$\begin{pmatrix} 1 & x \end{pmatrix}$$

Equivalent to the use of the index operator we obtain:

```
A[1..1, 1..2]
```

$$\begin{pmatrix} 1 & x \end{pmatrix}$$

We extract the first and the third column of A and get the 2×2 identity matrix:

```
linalg::submatrix(A, [1, 2], [1, 3])
```

$$\begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}$$

Example 2

Vector components can be accessed by a single index or a range of indices. For example, to extract the first two components of the following vector:

```
v := matrix([1, 2, 3])
```

$$\begin{pmatrix} 1 \\ 2 \\ 3 \end{pmatrix}$$

just enter the command:

```
v[1..2]
```

$$\begin{pmatrix} 1 \\ 2 \end{pmatrix}$$

Of course, the same subvector can be extracted with the command `linalg::submatrix(v, 1..2)`.

The following input returns the vector comprising the first and the third component of `v`:

```
linalg::submatrix(v, [1, 3])
```

$$\begin{pmatrix} 1 \\ 3 \end{pmatrix}$$

Parameters

`A`

An $m \times n$ matrix of a domain of category `Cat::Matrix`

`v`

A vector with k components, i.e., a $k \times 1$ or $1 \times k$ matrix of a domain of category `Cat::Matrix`

r_1 `..` r_2, c_1 `..` c_2

Ranges of row/column indices: positive integers less or equal to m and n, respectively

`rlist`, `clist`

Lists of row/column indices: positive integers less or equal to m and n, respectively

i_1 `..` i_2

A range of vector indices: positive integers less or equal to k

`list`

A list of vector indices: positive integers less or equal to k

Return Values

Matrix of the same domain type as A or a vector of the same domain type as v, respectively.

See Also

MuPAD Functions

`linalg::col` | `linalg::row` | `linalg::substitute`

linalg::substitute

Replace a part of a matrix by another matrix

Syntax

```
linalg::substitute(B, A, m, n)
```

Description

`linalg::substitute(B, A, m, n)` returns a copy of the matrix `B`, where entries starting at position $[m, n]$ are replaced by the entries of the matrix `A`, i.e., B_{mn} is A_{11}.

If the matrices are defined over different component domains, then the entries of `A` are converted into elements of the component domain of the matrix `B`. If one of these conversions fails, then an error message is returned.

Examples

Example 1

We define the following matrix:

```
B := matrix(
  [[1, 2, 3, 4], [5, 6, 7, 8],
   [9, 10, 11, 12], [13, 14, 15, 16]]
)
```

$$\begin{pmatrix} 1 & 2 & 3 & 4 \\ 5 & 6 & 7 & 8 \\ 9 & 10 & 11 & 12 \\ 13 & 14 & 15 & 16 \end{pmatrix}$$

and copy the 2×2 zero matrix into the matrix `B`, beginning at position [3, 3]:

```
A := matrix(2, 2):
```

```
linalg::substitute(B, A, 3, 3)
```

$$\begin{pmatrix} 1 & 2 & 3 & 4 \\ 5 & 6 & 7 & 8 \\ 9 & 10 & 0 & 0 \\ 13 & 14 & 0 & 0 \end{pmatrix}$$

Matrix entries out of range are ignored:

```
linalg::substitute(B, A, 4, 4)
```

$$\begin{pmatrix} 1 & 2 & 3 & 4 \\ 5 & 6 & 7 & 8 \\ 9 & 10 & 11 & 12 \\ 13 & 14 & 15 & 0 \end{pmatrix}$$

Parameters

A, B

Matrices of a domain of category `Cat::Matrix`

m, n

Positive integers

Return Values

Matrix of the same domain type as `B`.

See Also

MuPAD Functions

`linalg::concatMatrix` | `linalg::setCol` | `linalg::setRow` | `linalg::stackMatrix` | `linalg::submatrix`

linalg::sumBasis

Basis for the sum of vector spaces

Syntax

`linalg::sumBasis(`S_1`, `S_2`, …)`

Description

`linalg::sumBasis( `S_1`, `S_2`, ...)` returns a basis of the vector space $V_1 + V_2 + \ldots$, where V_i denotes the vector space spanned by the vectors in S_i.

To obtain an ordered basis, ``S_1`, `S_2`, ...` should be given as lists of vectors.

A basis of the zero-dimensional space is the empty set or list, respectively.

The given vectors must be defined over the same component ring, which must be a field, i.e., a domain of category `Cat::Field`.

Examples

Example 1

We define three vectors $\vec{v}_1, \vec{v}_2, \vec{v}_3$ over $\mathbb{Q}$:

```
MatQ := Dom::Matrix(Dom::Rational):
v1 := MatQ([[3, -2]]); v2 := MatQ([[1, 0]]); v3 := MatQ([[5, -3]])
```

$$\begin{pmatrix} 3 & -2 \end{pmatrix}$$

$$\begin{pmatrix} 1 & 0 \end{pmatrix}$$

$$\begin{pmatrix} 5 & -3 \end{pmatrix}$$

A basis of the vector space $V_1 + V_2 + V_3$ with

- V_1 generated by $\vec{v}_1, \vec{v}_2, \vec{v}_3$
- V_2 generated by $\vec{v}_1, \vec{v}_3$
- V_3 generated by $\vec{v}_1 + \vec{v}_2, \vec{v}_2, \vec{v}_1 + \vec{v}_3$

is:

```
linalg::sumBasis([v1, v2, v3], [v1, v3], [v1 + v2, v2, v1 + v3])
```

$$[(3\ \ -2),(1\ \ 0)]$$

Example 2

The following set of two vectors:

```
MatQ := Dom::Matrix(Dom::Rational):
S1 := {MatQ([1, 2, 3]), MatQ([-1, 0, 2])}
```

$$\left\{\begin{pmatrix}-1\\0\\2\end{pmatrix},\begin{pmatrix}1\\2\\3\end{pmatrix}\right\}$$

is a basis of a two-dimensional subspace of $\mathbb{Q}^3$:

```
linalg::rank(S1)
```

$$2$$

The same holds for the following set:

```
S2 := {MatQ([0, 2, 3]), MatQ([2, 4, 6])};
linalg::rank(S2)
```

$$\left\{\begin{pmatrix}0\\2\\3\end{pmatrix},\begin{pmatrix}2\\4\\6\end{pmatrix}\right\}$$

$$2$$

The sum of the corresponding two subspaces is the vector space $\mathbb{Q}^3$:

```
Q3 := linalg::sumBasis(S1, S2)
```

$$\left\{\begin{pmatrix}-1\\0\\2\end{pmatrix}, \begin{pmatrix}0\\2\\3\end{pmatrix}, \begin{pmatrix}1\\2\\3\end{pmatrix}\right\}$$

Parameters

S_1, S_2, …

A set or list of vectors of the same dimension (a vector is a $n\times1$ or $1\times n$ matrix of a domain of category `Cat::Matrix`)

Return Values

Set or a list of vectors, according to the domain type of the parameter S_1.

See Also

MuPAD Functions

`linalg::basis` | `linalg::intBasis` | `linalg::rank`

linalg::swapCol

Swap two columns in a matrix

Syntax

`linalg::swapCol(A, c1, c2)`

`linalg::swapCol(A, c1, c2, r1 .. r2)`

Description

`linalg::swapCol(A, c1, c2)` returns a copy of the matrix *A* with the columns with indices c_1 and c_2 interchanged.

The effect of `linalg::swapCol(A, c1, c2, r1.. r2)` is that only the components from row r_1 to row r_2 of column c_1 are interchanged with the corresponding components of column c_2.

Examples

Example 1

We consider the following matrix:

```
A := matrix(3, 3, (i, j) -> 3*(i - 1) + j)
```

$$\begin{pmatrix} 1 & 2 & 3 \\ 4 & 5 & 6 \\ 7 & 8 & 9 \end{pmatrix}$$

The following command interchanges the first and the second column of A. The result is the following matrix:

```
linalg::swapCol(A, 1, 2)
```

$$\begin{pmatrix} 2 & 1 & 3 \\ 5 & 4 & 6 \\ 8 & 7 & 9 \end{pmatrix}$$

If only the components in the first two rows should be affected, we enter:

```
linalg::swapCol(A, 1, 2, 1..2)
```

$$\begin{pmatrix} 2 & 1 & 3 \\ 5 & 4 & 6 \\ 7 & 8 & 9 \end{pmatrix}$$

The third row remains unchanged.

Parameters

A

An $m \times n$ matrix of a domain of category `Cat::Matrix`

c_1, c_2

The column indices: positive integers less or equal to n

r_1 .. r_2

A range of row indices (positive integers less or equal to m)

Return Values

Matrix of the same domain type as A.

linalg::swapRow

Swap two rows in a matrix

Syntax

`linalg::swapRow(A, r1, r2)`

`linalg::swapRow(A, r1, r2, c1 .. c2)`

Description

`linalg::swapRow(A, r1, r2)` returns a copy of the matrix *A* with the rows with indices r_1 and r_2 interchanged.

The effect of `linalg::swapRow(A, r1, r2, c1.. c2)` is that only the components from column c_1 to column c_2 of row r_1 are interchanged with the corresponding components of row r_2.

Examples

Example 1

We consider the following matrix:

```
A := matrix(3, 3, (i, j) -> 3*(i - 1) + j)
```

$$\begin{pmatrix} 1 & 2 & 3 \\ 4 & 5 & 6 \\ 7 & 8 & 9 \end{pmatrix}$$

The following command interchanges the first and the second row of A. The result is the following matrix:

```
linalg::swapRow(A, 1, 2)
```

$$\begin{pmatrix} 4 & 5 & 6 \\ 1 & 2 & 3 \\ 7 & 8 & 9 \end{pmatrix}$$

If only the components in the first two columns should be affected, we enter:

```
linalg::swapRow(A, 1, 2, 1..2)
```

$$\begin{pmatrix} 4 & 5 & 3 \\ 1 & 2 & 6 \\ 7 & 8 & 9 \end{pmatrix}$$

The third column remains unchanged.

Parameters

A

An $m \times n$ matrix of a domain of category `Cat::Matrix`

r_1, r_2

The row indices: positive integers less or equal to m

c_1 .. c_2

A range of column indices (positive integers less or equal to n)

Return Values

Matrix of the same domain type as A.

linalg::sylvester

Sylvester matrix of two polynomials

Syntax

```
linalg::sylvester(p, q)
```

```
linalg::sylvester(f, g, x)
```

Description

`linalg::sylvester(p, q)` returns the Sylvester matrix of the two polynomials p and q.

If no variable is specified, then the polynomials `p` and `q` must be either of the domain `DOM_POLY` or from a domain of category `Cat::Polynomial`. Polynomial expressions are not allowed.

If the polynomials `p` and `q` are of the domain `DOM_POLY`, then they must be univariate polynomials. The component ring of the Sylvester matrix is the common coefficient ring R of `p` and `q`, except in the following two cases for built-in coefficient rings: If R is `Expr` then the domain `Dom::ExpressionField()` is the component ring of the Sylvester matrix. If R is `IntMod(m)`, then the Sylvester matrix is defined over the ring `Dom::IntegerMod(m)` (see “Example 2” on page 15-230).

Otherwise, if the polynomials `p` and `q` are from a domain of category `Cat::Polynomial`, then the Sylvester matrix is computed with respect to the main variable of `p` and `q` (see the method `"mainvar"` of the category `Cat::Polynomial`). In the case of univariate polynomials the Sylvester matrix is defined over the common coefficient ring of `p` and `q`. In the case of multivariate polynomials, the Sylvester matrix is defined over the component ring `Dom::DistributedPolynomial(ind, R)`, where `ind` is the list of all variables of `p` and `q` except `x`, and `R` is the common coefficient ring of the polynomials.

If `f` and `g` are polynomial expressions or multivariate polynomials of type `DOM_POLY`, then you must specifiy the variable `x`.

In the case of polynomial expressions, the component ring of the Sylvester matrix is the domain `Dom::ExpressionField()` (see “Example 3” on page 15-231).

In the case of multivariate polynomials the Sylvester matrix is defined over the component ring `Dom::DistributedPolynomial(ind, R)`, where `ind` is the list of all variables of `f` and `g` except `x`, and `R` is the common coefficient ring of the polynomials (see "Example 4" on page 15-231).

At least one of the input polynomials must have positive degree with respect to the main variable or `x`, respectively, but it is not necessary that both of them have positive degree.

Examples

Example 1

The Sylvester matrix of the two polynomials $p = x^2 + 2x - 1$ and $q = x^4 + 1$ over $\mathbb{Z}$ is the following 6×6 matrix:

```
delete x: Z := Dom::Integer:
S := linalg::sylvester(poly(x^2 + 2*x - 1, Z), poly(x^4 + 1, Z))
```

$$\begin{pmatrix} 1 & 2 & -1 & 0 & 0 & 0 \\ 0 & 1 & 2 & -1 & 0 & 0 \\ 0 & 0 & 1 & 2 & -1 & 0 \\ 0 & 0 & 0 & 1 & 2 & -1 \\ 1 & 0 & 0 & 0 & 1 & 0 \\ 0 & 1 & 0 & 0 & 0 & 1 \end{pmatrix}$$

Example 2

If the polynomials have the built-in coefficient ring `IntMod(m)`, then the Sylvester matrix is defined over the domain `Dom::IntegerMod(m)`:

```
delete x:
S:= linalg::sylvester(
  poly(x + 1, IntMod(7)), poly(x^2 - 2*x + 2, IntMod(7))
)
```

$$\begin{pmatrix} 1 \bmod 7 & 1 \bmod 7 & 0 \bmod 7 \\ 0 \bmod 7 & 1 \bmod 7 & 1 \bmod 7 \\ 1 \bmod 7 & 5 \bmod 7 & 2 \bmod 7 \end{pmatrix}$$

```
domtype(S)
```

```
Dom::Matrix(Dom::IntegerMod(7))
```

Example 3

The Sylvester matrix of the following two polynomial expressions with respect to the variable x is:

```
delete x, y:
S := linalg::sylvester(x + y^2, 2*x^3 - 1, x)
```

$$\begin{pmatrix} 1 & y^2 & 0 & 0 \\ 0 & 1 & y^2 & 0 \\ 0 & 0 & 1 & y^2 \\ 2 & 0 & 0 & -1 \end{pmatrix}$$

```
domtype(S)
```

```
Dom::Matrix()
```

The Sylvester matrix of these two polynomials with respect to y is the following 2×2 matrix:

```
linalg::sylvester(x + y^2, 2*x^3 - 1, y)
```

$$\begin{pmatrix} 2x^3 - 1 & 0 \\ 0 & 2x^3 - 1 \end{pmatrix}$$

Example 4

Here is an example for computing the Sylvester matrix of multivariate polynomials:

```
delete x, y: Q := Dom::Rational:
T := linalg::sylvester(poly(x^2 - x + y, Q), poly(x + 2, Q), x)
```

$$\begin{pmatrix} 1 & -1 & y \\ 1 & 2 & 0 \\ 0 & 1 & 2 \end{pmatrix}$$

```
domtype( T )
```

$$\text{Dom::Matrix}(\text{Dom::DistributedPolynomial}([y], \text{Dom::Rational}, \text{LexOrder}))$$

The Sylvester matrix of these two multivariate polynomials with respect to `y` is:

```
linalg::sylvester(poly(x^2 - x + y, Q), poly(x + 2, Q), y)
```

$$\begin{pmatrix} x+2 \end{pmatrix}$$

Parameters

`p, q`

Polynomials

`f, g`

Polynomials or polynomial expressions of positive degree

`x`

A variable

Return Values

Matrix of the domain `Dom::Matrix(R)`, where `R` is the coefficient domain of the polynomials (see below).

See Also

MuPAD Functions

`polylib::discrim` | `polylib::resultant`

linalg::tr

Trace of a matrix

Syntax

```
linalg::tr(A)
```

Description

`linalg::tr(A)` returns the trace of the square matrix A, i.e., the sum of the diagonal elements of A.

Examples

Example 1

We compute the trace of the following matrix:

```
A := Dom::Matrix(Dom::Integer)
  (3, 3, (i, j) -> 3*(i - 1) + j)
```

$$\begin{pmatrix} 1 & 2 & 3 \\ 4 & 5 & 6 \\ 7 & 8 & 9 \end{pmatrix}$$

```
linalg::tr(A)
```

$$15$$

Parameters

A

A square matrix of a domain of category `Cat::Matrix`

Return Values

Element of the component ring of A.

See Also

MuPAD Functions
`det`

More About

- “Compute Determinants and Traces of Square Matrices”

linalg::toeplitz

Toeplitz matrix

Syntax

```
linalg::toeplitz(m, n, [t_-k, …,t_k], <R>)
linalg::toeplitz(n, [t_-k, …,t_k], <R>)
linalg::toeplitz(c, r)
linalg::toeplitz(r)
```

Description

`linalg::toeplitz(m, n, [t_-k, ..., t_-1, t_0, t_1, ..., t_k])` returns the $m \times n$ Toeplitz matrix

$$\begin{pmatrix} t_0 & t_1 & t_2 & \cdot & \cdot & \cdot & \cdot & \cdot & t_k \\ t_{-1} & t_0 & t_1 & t_2 & \cdot & \cdot & \cdot & \cdot & t_{k-1} \\ t_{-2} & t_{-1} & t_0 & t_1 & t_2 & \cdot & \cdot & \cdot & t_{k-2} \\ \cdot & & \cdot & \cdot & \cdot & & & & \cdot \\ \cdot & & & \cdot & \cdot & \cdot & & & \cdot \\ \cdot & & & & \cdot & t_0 & t_1 & t_2 & \\ \cdot & & & & \cdot & t_{-1} & t_0 & t_1 & \\ t_{-k} & \cdot & \cdot & \cdot & \cdot & \cdot & t_{-2} & t_{-1} & t_0 \end{pmatrix}.$$

`linalg::toeplitz(n, [t_-k, ..., t_k])` returns the square Toeplitz matrix of dimension $n \times n$.

A number of entries $[t_{-k}, \ldots, t_k]$ must be an odd number $2k + 1$. There must be at least k diagonal bands above the diagonal and k diagonal bands below the diagonal: k must satisfy $k \le min(m, n) - 1$. Entries with matrix indices (i, j) satisfying $|i - j| > k$ are set to 0.

Toeplitz matrices of dimension $n \times n$ can be inverted with $O(n^2)$ operations. See `linalg::toeplitzSolve`.

`linalg::toeplitz(c, r)` generates a nonsymmetric Toeplitz matrix having `c` as its first column and `r` as its first row. If the first elements of `c` and `r` differ, `toeplitz` issues a warning and uses the first element of the column.

`linalg::toeplitz(r)` generates a symmetric Toeplitz matrix if `r` is real. If `r` is complex, but its first element is real, then this syntax generates the Hermitian Toeplitz matrix formed from `r`. If the first element of `r` is complex, then the resulting matrix is Hermitian off the main diagonal, meaning that T_{ij} = conjugate(T_{ji}) for $i \neq j$.

When you use matrices in MuPAD computations, both computational efficiency and memory use can depend on whether the matrix is sparse or dense. The first two syntaxes are optimized for generating sparse matrices and, therefore, these syntaxes are preferable. For details about improving performance when working with matrices, see "Use Sparse and Dense Matrices".

Examples

Example 1

Construct a 4×4 Toeplitz matrix with three bands:

```
linalg::toeplitz(4, [-1, 2, 1])
```

$$\begin{pmatrix} 2 & 1 & 0 & 0 \\ -1 & 2 & 1 & 0 \\ 0 & -1 & 2 & 1 \\ 0 & 0 & -1 & 2 \end{pmatrix}$$

Construct a 3×5 Toeplitz matrix with symbolic entries:

```
linalg::toeplitz(3, 5, [a, b, c])
```

$$\begin{pmatrix} b & c & 0 & 0 & 0 \\ a & b & c & 0 & 0 \\ 0 & a & b & c & 0 \end{pmatrix}$$

Example 2

Construct a Toeplitz matrix by using a vector to specify its first row. For a real vector, the resulting matrix is symmetric:

```
r := matrix([1, 2, 3]):
linalg::toeplitz(r)
```

$$\begin{pmatrix} 1 & 2 & 3 \\ 2 & 1 & 2 \\ 3 & 2 & 1 \end{pmatrix}$$

For a complex vector, the resulting matrix is Hermitian off the main diagonal:

```
r := matrix([1 + I, 2 + I, 3 + I]):
T := linalg::toeplitz(r);
htranspose(T)
```

$$\begin{pmatrix} 1+i & 2+i & 3+i \\ 2-i & 1+i & 2+i \\ 3-i & 2-i & 1+i \end{pmatrix}$$

$$\begin{pmatrix} 1-i & 2+i & 3+i \\ 2-i & 1-i & 2+i \\ 3-i & 2-i & 1-i \end{pmatrix}$$

Example 3

Construct a Toeplitz matrix by using two vectors to specify its first column and first row:

```
c := matrix([1, a/2, b/2]):
r := [1, a, b]:
linalg::toeplitz(c, r)
```

$$\begin{pmatrix} 1 & \frac{a}{2} & \frac{b}{2} \\ a & 1 & \frac{a}{2} \\ b & a & 1 \end{pmatrix}$$

If the first elements of the vectors differ, `linalg::toeplitz` issues a warning and uses the first element of the column:

```
c := matrix([1, a/2, b/2]):
r := [2, a, b]:
linalg::toeplitz(c, r)
```

```
Warning: First element of input column does not match first element of input row. Colu
```

$$\begin{pmatrix} 2 & \frac{a}{2} & \frac{b}{2} \\ a & 2 & \frac{a}{2} \\ b & a & 2 \end{pmatrix}$$

Parameters

`m, n`

Row and column dimensions of the matrix: positive integers.

$t_{-k}, \ldots, t_k$

Arithmetical expressions or elements of the component ring `R`.

`R`

Component ring: a domain of category `Cat::Rng`. The default ring is `Dom::ExpressionField()`.

`c`

Vector specifying the first column of a Toeplitz matrix.

`r`

Vector specifying the first row of a Toeplitz matrix.

Return Values

Matrix of the domain `Dom::Matrix(R)`.

See Also

MuPAD Functions

`linalg::hilbert` | `linalg::invhilbert` | `linalg::invpascal` | `linalg::invvandermonde` | `linalg::pascal` | `linalg::toeplitzSolve` | `linalg::vandermonde` | `linalg::vandermondeSolve`

linalg::toeplitzSolve

Solve a linear Toeplitz system

Syntax

```
linalg::toeplitzSolve(t, y)
```

Description

`linalg::toeplitzSolve(t, y)` returns the solution $\vec{x}$ of the linear Toeplitz system $\sum_{j=1}^{n} t_{i-j}\, x_j = y_i$ with $i = 1, \ldots, n$.

`linalg::toeplitzSolve(t, y)` with `t` = $[t_k, \ldots, t_0, \ldots, t_{-k}]$ and `y` = $[y_1, \ldots, y_n]$ solves the $n \times n$ Toeplitz system

$$\begin{pmatrix} t_0 & t_{-1} & \cdot & \cdot & \cdot & t_{-k} & & \\ t_1 & t_0 & t_{-1} & \cdot & \cdot & t_{-k} & & \\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & & \\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & & \\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & & \\ t_k & t_{k-1} & \cdot & \cdot & \cdot & t_{-k} & & \\ & t_k & t_{k-1} & \cdot & \cdot & \cdot & t_{-k} & \\ & & t_k & t_{k-1} & \cdot & \cdot & \cdot & t_{-k} \\ & & & & \cdot & \cdot & \cdot & \cdot \\ & & & & \cdot & \cdot & \cdot & \cdot \\ & & & & \cdot & \cdot & \cdot & \cdot \end{pmatrix} \begin{pmatrix} x_1 \\ x_2 \\ \vdots \\ x_n \end{pmatrix} = \begin{pmatrix} y_1 \\ y_2 \\ \vdots \\ y_n \end{pmatrix}$$

with $2k + 1$ bands.

`linalg::toeplitzSolve` implements the Levinson algorithm. It uses $O(n^2)$ elementary operations to solve the Toeplitz system. The memory requirements are

$O(n)$. For dense Toeplitz systems, it is faster than the general solver `solve` and the linear solvers `linsolve`, `numeric::linsolve`, `linalg::matlinsolve` and `numeric::matlinsolve`.

Note: Note that the Levinson algorithm requires that all principal minors

$$t_0, \begin{pmatrix} t_0 & t_{-1} \\ t_1 & t_0 \end{pmatrix}, \begin{pmatrix} t_0 & t_{-1} & t_{-2} \\ t_1 & t_0 & t_{-1} \\ t_2 & t_1 & t_0 \end{pmatrix}, \text{etc}$$

are non-singular.

If `linalg::toeplitzSolve` does not manage to find the solution due to this limitation, or if the system is very sparse with k smaller than $\sqrt{n}$, we recommend to generate the corresponding Toeplitz matrix via `linalg::toeplitz` and compute the solution via `linalg::matlinsolve` or `numeric::matlinsolve`, respectively. Cf. “Example 2” on page 15-242

`linalg::toeplitzSolve` can solve Toeplitz systems over arbitrary coefficient rings. Just make sure that both the Toeplitz entries t as well as the components of the 'right hand side' y are elements of the desired coefficient ring. Cf. “Example 3” on page 15-243.

Examples

Example 1

The Toeplitz entries t and the right hand side y of the linear system are entered as row vectors:

```
t := matrix([4, 2, 1, 3, 5]):
y := matrix([y1, y2, y3]):
```

The solution of the Toeplitz system is returned as a vector of the same type as the input vector y:

```
x := linalg::toeplitzSolve(t, y): x, domtype(x)
```

$$\begin{pmatrix} \frac{7\,y2}{25} - \frac{y1}{5} + \frac{4\,y3}{25} \\ \frac{2\,y1}{5} - \frac{19\,y2}{25} + \frac{7\,y3}{25} \\ \frac{2\,y2}{5} - \frac{y3}{5} \end{pmatrix}, \text{Dom::Matrix}()$$

If the input vector is a list, the output is a list, too:

```
x := linalg::toeplitzSolve(t, [y1, y2, y3]): x, domtype(x)
```

$$\left[\frac{7\,y2}{25} - \frac{y1}{5} + \frac{4\,y3}{25},\ \frac{2\,y1}{5} - \frac{19\,y2}{25} + \frac{7\,y3}{25},\ \frac{2\,y2}{5} - \frac{y3}{5}\right], \text{DOM\_LIST}$$

```
delete t, y, x:
```

Example 2

The Levinson algorithm cannot solve the following Toeplitz system because the first principal minor of the Toeplitz matrix (the central element of the Toeplitz entries) vanishes:

```
linalg::toeplitzSolve([1, 0, 1], [y1, y2, y3, y4])
```

FAIL

This does not necessarily imply that the Toeplitz system is not solvable. We generate the corresponding Toeplitz matrix and use a generic linear solver such as `linalg::matlinsolve`:

```
T := linalg::toeplitz(4, 4, [1, 0, 1])
```

$$\begin{pmatrix} 0 & 1 & 0 & 0 \\ 1 & 0 & 1 & 0 \\ 0 & 1 & 0 & 1 \\ 0 & 0 & 1 & 0 \end{pmatrix}$$

```
linalg::matlinsolve(T, matrix([y1, y2, y3, y4]))
```

$$\begin{pmatrix} y2 - y4 \\ y1 \\ y4 \\ y3 - y1 \end{pmatrix}$$

Example 3

We solve a Toeplitz system over the field $\mathbb{Z}_7$ (the integers modulo 7) represented by the domain `Dom::IntegerMod(7)`:

```
R := Dom::IntegerMod(7):
t := [R(5), R(3), R(2), R(5), R(1)]:
y := [R(1), R(2), R(3)]:
linalg::toeplitzSolve(t, y)
```

$$[1 \bmod 7,\ 5 \bmod 7,\ 2 \bmod 7]$$

```
delete R, t, y:
```

Parameters

`t`

A vector or a list with $2k + 1$ elements. (A vector is a $(2k + 1)\times 1$ or a $1 \times (2k + 1)$ matrix of category `Cat::Matrix`).

`y`

A vector or a list with n elements

Return Values

Vector or list with n elements of the same domain type as the elements of `y`. `FAIL` is returned if the algorithm does not succeed in finding a solution.

linalg::transpose

Transpose of a matrix

Syntax

```
linalg::transpose(A)
```

Description

`linalg::transpose(A)` returns the transpose A^t of the matrix A.

`linalg::transpose` is an interface function for the method `"transpose"` of the matrix domain of `A`, i.e., instead of `linalg::transpose(A)` one may call `A::dom::transpose(A)` directly.

Examples

Example 1

We define a 3×4 matrix:

```
A := matrix([[1, 2, 3, 4], [-1, 0, 1, 0], [3, 5, 6, 9]])
```

$$\begin{pmatrix} 1 & 2 & 3 & 4 \\ -1 & 0 & 1 & 0 \\ 3 & 5 & 6 & 9 \end{pmatrix}$$

Then the transpose of `A` is the 4 ×3 matrix:

```
linalg::transpose(A)
```

$$\begin{pmatrix} 1 & -1 & 3 \\ 2 & 0 & 5 \\ 3 & 1 & 6 \\ 4 & 0 & 9 \end{pmatrix}$$

Parameters

A

A matrix of a domain of category `Cat::Matrix`

Return Values

Matrix of the same domain type as A.

Algorithms

Let $A = (a_{i,j})_{1 \le i \le m,\ 1 \le j \le n}$ be an $m \times n$ matrix. Then the transpose of A is the $n \times m$ matrix:

$$A^t = \begin{pmatrix} a_{1,1} & a_{1,2} & \cdots & a_{m,1} \\ a_{1,2} & a_{2,2} & \cdots & a_{m,2} \\ \vdots & \vdots & \cdots & \vdots \\ \vdots & \vdots & \cdots & \vdots \\ \vdots & \vdots & \cdots & \vdots \\ a_{1,n} & a_{1,n} & \cdots & a_{m,n} \end{pmatrix}.$$

linalg::vandermonde

Vandermonde matrices and their inverses

Syntax

```
linalg::vandermonde([v1, v2, …], <R>)
```

Description

`linalg::vandermonde( v1, v2, ... , vn)` returns the $n \times n$ Vandermonde matrix V with entries $V_{ij} = v_i^{j-1}$.

Use `linalg::vandermonde([ v1, ..., vn], R)` to define the $n \times n$ Vandermonde matrix over the field `R`. Note that the Vandermonde nodes v_i must be elements of `R` or must be convertible to elements of `R`. The same holds true for the inverse Vandermonde matrix.

Vandermonde matrices of dimension $n \times n$ can be inverted with $O(n^2)$ operations. Linear equations with a Vandermonde coefficient matrix can be solved via `linalg::vandermondeSolve`.

Examples

Example 1

We construct a 3×3 Vandermonde matrix:

```
V := linalg::vandermonde([v1, v2, v3])
```

$$\begin{pmatrix} 1 & v1 & v1^2 \\ 1 & v2 & v2^2 \\ 1 & v3 & v3^2 \end{pmatrix}$$

The inverse of this matrix is:

```
linalg::invvandermonde([v1, v2, v3])
```

$$\begin{pmatrix} \frac{v2\,v3}{\sigma_3} & -\frac{v1\,v3}{\sigma_2} & \frac{v1\,v2}{\sigma_1} \\ -\frac{v2+v3}{\sigma_3} & \frac{v1+v3}{\sigma_2} & -\frac{v1+v2}{\sigma_1} \\ \frac{1}{\sigma_3} & -\frac{1}{\sigma_2} & \frac{1}{\sigma_1} \end{pmatrix}$$

where

$$\sigma_1 = (v1 - v3)\,(v2 - v3)$$

$$\sigma_2 = (v1 - v2)\,(v2 - v3)$$

$$\sigma_3 = (v1 - v2)\,(v1 - v3)$$

`V` and its inverse are matrices of the domain `Dom::Matrix()`. One can specify a special component ring for the matrices, provided the nodes can be converted to elements of the ring. For example, specification of the domain `Dom::Float` generates floating-point entries:

```
V := linalg::vandermonde([2, PI, 1/3], Dom::Float)
```

$$\begin{pmatrix} 1.0 & 2.0 & 4.0 \\ 1.0 & 3.141592654 & 9.869604401 \\ 1.0 & 0.3333333333 & 0.1111111111 \end{pmatrix}$$

```
domtype(V)
```

Dom::Matrix(Dom::Float)

It is faster to compute the inverse via `linalg::invvandermonde` than inverting the Vandermonde matrix by a generic inversion algorithm (as implemented by `V^(-1)`):

```
V^(-1) = linalg::invvandermonde([2, PI, 1/3], Dom::Float)
```

$$\begin{pmatrix} -0.5503876788 & 0.2079506905 & 1.342436988 \\ 1.826356876 & -0.7278274166 & -1.098529459 \\ -0.5255815182 & 0.3119260357 & 0.2136554825 \end{pmatrix} =$$

$$\begin{pmatrix} -0.5503876788 & 0.2079506905 & 1.342436988 \\ 1.826356876 & -0.7278274166 & -1.098529459 \\ -0.5255815182 & 0.3119260357 & 0.2136554825 \end{pmatrix}$$

```
delete V:
```

Parameters

v_1, v_2, …

The Vandermonde nodes: arithmetical expressions

R

The component ring: a domain of category `Cat::Rng`; default: `Dom::ExpressionField()`

Return Values

$n \times n$ matrix of the domain `Dom::Matrix(R)`.

Algorithms

Vandermonde matrices are notoriously ill-conditioned. The inverses of large floating-point Vandermonde matrices are subject to severe round-off effects.

linalg::invvandermonde

Vandermonde matrices and their inverses

Syntax

```
linalg::invvandermonde([v1, v2, …], <R>)
```

Description

`linalg::invvandermonde( v1, v2, ... , vn)` returns the inverse of the Vandermonde matrix with nodes v_i.

Use `linalg::vandermonde([ v1, ..., vn], R)` to define the $n \times n$ Vandermonde matrix over the field `R`. Note that the Vandermonde nodes v_i must be elements of `R` or must be convertible to elements of `R`. The same holds true for the inverse Vandermonde matrix.

Vandermonde matrices of dimension $n \times n$ can be inverted with $O(n^2)$ operations. Linear equations with a Vandermonde coefficient matrix can be solved via `linalg::vandermondeSolve`.

Examples

Example 1

We construct a 3×3 Vandermonde matrix:

```
V := linalg::vandermonde([v1, v2, v3])
```

$$\begin{pmatrix} 1 & v1 & v1^2 \\ 1 & v2 & v2^2 \\ 1 & v3 & v3^2 \end{pmatrix}$$

The inverse of this matrix is:

```
linalg::invvandermonde([v1, v2, v3])
```

$$\begin{pmatrix} \frac{v2\,v3}{\sigma_3} & -\frac{v1\,v3}{\sigma_2} & \frac{v1\,v2}{\sigma_1} \\ -\frac{v2+v3}{\sigma_3} & \frac{v1+v3}{\sigma_2} & -\frac{v1+v2}{\sigma_1} \\ \frac{1}{\sigma_3} & -\frac{1}{\sigma_2} & \frac{1}{\sigma_1} \end{pmatrix}$$

where

$$\sigma_1 = (v1 - v3)\,(v2 - v3)$$

$$\sigma_2 = (v1 - v2)\,(v2 - v3)$$

$$\sigma_3 = (v1 - v2)\,(v1 - v3)$$

`V` and its inverse are matrices of the domain `Dom::Matrix()`. One can specify a special component ring for the matrices, provided the nodes can be converted to elements of the ring. For example, specification of the domain `Dom::Float` generates floating-point entries:

```
V := linalg::vandermonde([2, PI, 1/3], Dom::Float)
```

$$\begin{pmatrix} 1.0 & 2.0 & 4.0 \\ 1.0 & 3.141592654 & 9.869604401 \\ 1.0 & 0.3333333333 & 0.1111111111 \end{pmatrix}$$

```
domtype(V)
```

Dom::Matrix(Dom::Float)

It is faster to compute the inverse via `linalg::invvandermonde` than inverting the Vandermonde matrix by a generic inversion algorithm (as implemented by `V^(-1)`):

```
V^(-1) = linalg::invvandermonde([2, PI, 1/3], Dom::Float)
```

$$\begin{pmatrix} -0.5503876788 & 0.2079506905 & 1.342436988 \\ 1.826356876 & -0.7278274166 & -1.098529459 \\ -0.5255815182 & 0.3119260357 & 0.2136554825 \end{pmatrix} =$$

$$\begin{pmatrix} -0.5503876788 & 0.2079506905 & 1.342436988 \\ 1.826356876 & -0.7278274166 & -1.098529459 \\ -0.5255815182 & 0.3119260357 & 0.2136554825 \end{pmatrix}$$

```
delete V:
```

Parameters

v_1, v_2, …

The Vandermonde nodes: arithmetical expressions

R

The component ring: a domain of category `Cat::Rng`; default: `Dom::ExpressionField()`

Return Values

$n \times n$ matrix of the domain `Dom::Matrix(R)`.

Algorithms

Vandermonde matrices are notoriously ill-conditioned. The inverses of large floating-point Vandermonde matrices are subject to severe round-off effects.

linalg::vandermondeSolve

Solve a linear Vandermonde system

Syntax

```
linalg::vandermondeSolve(v, y, <Transposed>)
```

Description

`linalg::vandermondeSolve(v, y)` returns the solution $\vec{x}$ of the linear Vandermonde system $\sum_{j=1}^{n} v_i^{j-1} x_j = y_i$ with $i = 1, \ldots, n$.

`linalg::vandermondeSolve` uses $O(n^2)$ elementary operations to solve the Vandermonde system. It is faster than the general solver `solve` and the linear solvers `linsolve`, `numeric::linsolve`, `linalg::matlinsolve` and `numeric::matlinsolve`.

The solution $\vec{x} = (x_1, \ldots, x_n)$ returned by `linalg::vandermondeSolve([v[i] $ i=1..n], [y[i] $ i=1..n])` yields the coefficients of the polynomial $p(v) = x_1 + x_2\, v + \cdots + x_n\, v^{n-1}$ interpolating the data table $(v_1, y_1), \ldots, (v_n, y_n)$, i.e.,

$$p(v_1) = y_1, \ldots, p(v_n) = y_n .$$

See “Example 1” on page 15-255.

Examples

Example 1

The Vandermonde points v and the right hand side y of the linear system are entered as vectors:

```
delete y0, y1, y2:
v := matrix([[0, 1, 2]]);
y := matrix([[y0, y1, y2]])
```

$$\begin{pmatrix} 0 & 1 & 2 \end{pmatrix}$$

$$\begin{pmatrix} y0 & y1 & y2 \end{pmatrix}$$

The solution vector is:

```
x := linalg::vandermondeSolve(v, y)
```

$$\left(y0 \quad 2\,y1 - \frac{3\,y0}{2} - \frac{y2}{2} \quad \frac{y0}{2} - y1 + \frac{y2}{2} \right)$$

The solution yields the coefficients of the interpolating polynomial:

```
P := v -> _plus(x[i+1]*v^i $ i=0..2):
```

through the points $(0, y_0)$, $(1, y_1)$, $(2, y_2)$:

```
P(v[1]), P(v[2]), P(v[3])
```

$$y0,\ y1,\ y2$$

With the optional argument `Transposed`, the linear system with the transposed Vandermonde matrix corresponding to `v` is solved:

```
linalg::vandermondeSolve(v, y, Transposed)
```

$$\left(y0 - \frac{3\,y1}{2} + \frac{y2}{2} \quad 2\,y1 - y2 \quad \frac{y2}{2} - \frac{y1}{2} \right)$$

```
delete v, y, x, P:
```

Example 2

The Vandermonde points v and the right hand side y of the linear system are entered as 2×1 matrices:

```
Mat := Dom::Matrix(Dom::ExpressionField(normal)):

delete v1, v2, y1, y2:
v := Mat([v1, v2]):
y := Mat([y1, y2]):
```

We define the vectors over the domain `Dom::ExpressionField(normal)` in order to simplify intermediate computations.

Next, we compute the solution of the corresponding Vandermonde system:

```
x := linalg::vandermondeSolve(v, y)
```

$$\begin{pmatrix} \frac{v1\,y2 - v2\,y1}{v1 - v2} \\ \frac{y1 - y2}{v1 - v2} \end{pmatrix}$$

We construct the Vandermonde matrix `V` and verify the result:

```
V := Mat([[1, v[1]], [1, v[2]]])
```

$$\begin{pmatrix} 1 & v1 \\ 1 & v2 \end{pmatrix}$$

```
V * x
```

$$\begin{pmatrix} y1 \\ y2 \end{pmatrix}$$

```
delete Mat, v, y, x, V:
```

Example 3

We solve a Vandermonde system over the field $\mathbb{Z}_7$ (the integers modulo 7) represented by the domain `Dom::IntegerMod(7)`:

```
MatZ7 := Dom::Matrix(Dom::IntegerMod(7)):
v := MatZ7([1, 2, 3]): y := MatZ7([0, 1, 2]):
```

```
linalg::vandermondeSolve(v, y)
```

$$\begin{pmatrix} 6 \bmod 7 \\ 1 \bmod 7 \\ 0 \bmod 7 \end{pmatrix}$$

```
delete MatZ7, v, y:
```

Parameters

v

A vector with distinct elements (a vector is an $n \times 1$ or $1 \times n$ matrix of category `Cat::Matrix`). Alternatively, a list with n distinct elements is also accepted.

y

A vector of the same dimension and domain type as `v`. Alternatively, a list with n elements is also accepted.

Options

`Transposed`

Returns the solution $\vec{x}$ of the transposed system $\sum_{j=1}^{n} v_j^{\,i-1} x_j = y_i$ with $i = 1, \ldots, n$.

Return Values

Vector of the same domain type as `y`.

Algorithms

The Vandermonde matrix

$$V = \begin{pmatrix} 1 & v_1 & v_1^2 & \dots & v_1^{n-1} \\ 1 & v_2 & v_2^2 & \dots & v_2^{n-1} \\ . & . & . & . & . \\ . & . & . & . & . \\ . & . & . & . & . \\ 1 & v_n & v_n^2 & \dots & v_n^{n-1} \end{pmatrix}$$

generated by $v = [v_1, \ldots, v_n]$ is invertible if and only if the v_i are distinct.

The vector $\vec{x}$ returned by `linalg::vandermondeSolve(x, y)` is the unique solution of $V\,\vec{x} = \vec{y}$.

The vector x returned by `linalg::vandermondeSolve(x, y, Transposed)` is the unique solution of $V^t\,\vec{x} = \vec{y}$.

linalg::vecdim

Number of components of a vector

Syntax

```
linalg::vecdim(v)
```

Description

`linalg::vecdim(v)` returns the number of elements of the vector $\vec{v}$.

Examples

Example 1

We define a column vector with two elements and a row vector with four elements:

```
v1 := matrix([1, 0]); v2 := matrix([[1, 2, 3, 4]])
```

$$\begin{pmatrix} 1 \\ 0 \end{pmatrix}$$

$$(1\ 2\ 3\ 4)$$

`linalg::vecdim` gives us the number of elements, i.e., the dimension of these vectors:

```
linalg::vecdim(v1), linalg::vecdim(v2)
```

$$2, 4$$

In contrast, the function `linalg::matdim` returns the number of rows and columns of these vectors:

```
linalg::matdim(v1), linalg::matdim(v2)
```

```
[2, 1], [1, 4]
```

Parameters

v

A vector, i.e., an $n \times 1$ or $1 \times n$ matrix of a domain of category `Cat::Matrix`

Return Values

Positive integer.

See Also

MuPAD Functions

`linalg::matdim` | `linalg::ncols` | `linalg::nrows`

linalg::vectorOf

Type specifier for vectors

Syntax

```
linalg::vectorOf(R)
```

```
linalg::vectorOf(R, n)
```

Description

`linalg::vectorOf(R)` is a type specifier representing all objects of a domain of category `Cat::Matrix` with component ring `R` and number of rows or number of columns equal to one.

`linalg::vectorOf(R,n)` is a type specifier representing all objects of a domain of category `Cat::Matrix` with component ring `R` and number of rows equal to `n` and number of columns equal to one, or vice versa.

`linalg::vectorOf(Type::AnyType,n)` is a type specifier representing all objects of a domain of category `Cat::Matrix` with an arbitrary component ring `R` and number of rows equal to `n` and number of columns equal to one, or vice versa.

Examples

Example 1

`linalg::vectorOf` can be used together with `testtype` to check whether a MuPAD object is a vector:

```
MatZ := Dom::Matrix(Dom::Integer):
v := MatZ([1, 0, -1])
```

$$\begin{pmatrix} 1 \\ 0 \\ -1 \end{pmatrix}$$

The following yields FALSE because v is 3-dimensional vector:

```
testtype(v, linalg::vectorOf(Dom::Integer, 4))
```

```
    FALSE
```

The following yields FALSE because v is defined over the integers:

```
testtype(v, linalg::vectorOf(Dom::Rational))
```

```
    FALSE
```

Of course, v can be converted into a vector over the rationals, as shown by the following call:

```
bool(coerce(v, Dom::Matrix(Dom::Rational)) <> FAIL)
```

```
    TRUE
```

This shows that `testtype` in conjunction with `linalg::vectorOf(R)` does not check whether an object can be converted into a vector over the specified component ring R. It checks only if the object is a vector whose component ring is R.

The following test returns TRUE because v is a 3-dimensional vector:

```
testtype(v, linalg::vectorOf(Type::AnyType, 3))
```

```
    TRUE
```

Example 2

`linalg::vectorOf` can also be used for checking parameters of procedures. The following procedure computes the orthogonal complement of a 2-dimensional vector:

```
orth := proc(v:linalg::vectorOf(Type::AnyType, 2))
begin
    [v[1], v[2]] := [-v[2],v[1]];
    return(v)
end:
```

```
u := matrix([[1, 2]]); u_ := orth(u)
```

$$\begin{pmatrix} 1 & 2 \end{pmatrix}$$

$$\begin{pmatrix} -2 & 1 \end{pmatrix}$$

Calling the procedure `orth` with an invalid parameter leads to an error message:

```
orth([1, 2])
```

```
Error: The object '[1, 2]' is incorrect. The type of argument number 1 must be 'slot(Ty
  Evaluating: orth
```

Parameters

R

The component ring: a library domain

n

A positive integer

Return Values

Type expression of the domain type Type.

See Also

MuPAD Functions

`testtype`

linalg::wiedemann

Solving linear systems by Wiedemann's algorithm

Syntax

```
linalg::wiedemann(A, b, <mult>, <prob>)
```

Description

`linalg::wiedemann(A, b, mult, ...)` tries to find a vector $\vec{x}$ that satisfies the equation $A\,\vec{x} = \vec{b}$ by using Wiedemann's algorithm.

The parameter `mult` must be a function such that the result of `mult(A,y)` equals $A\,\vec{y}$ for every n-dimensional column vector $\vec{y}$. The parameter `y` is of the same domain type as `A`. The argument `mult` does not need to handle other types of parameters, nor does it need to handle other matrices than `A`.

`linalg::wiedemann` uses a probabilistic algorithm. For a deterministic variant enter `FALSE` for the optional parameter `prob`.

If the system $A\,\vec{x} = \vec{b}$ does not have a solution, then `linalg::wiedemann` returns `FAIL`.

If the system $A\,\vec{x} = \vec{b}$ has more than one solution, then a random one is returned.

Due to the probabilistic nature of Wiedemann's algorithm, the computation may fail with small probability. In this case `FAIL` is returned. If the deterministic variant is chosen, then the algorithm may be slower for a small number of matrices.

The vector `b` must be defined over the component ring of `A`.

The coefficient ring of `A` must be a field, i.e., a domain of category `Cat::Field`.

It is recommended to use `linalg::wiedemann` only if `mult` uses significantly less than $O(n^2)$ field operations.

Examples

Example 1

We define a matrix and a column vector over the finite field with 29 elements:

```
MatZ29 := Dom::Matrix(Dom::IntegerMod(29)):
A := MatZ29([[1, 2, 3], [4, 7, 8], [9, 12, 17]]);
b := MatZ29([1, 2, 3])
```

$$\begin{pmatrix} 1 \bmod 29 & 2 \bmod 29 & 3 \bmod 29 \\ 4 \bmod 29 & 7 \bmod 29 & 8 \bmod 29 \\ 9 \bmod 29 & 12 \bmod 29 & 17 \bmod 29 \end{pmatrix}$$

$$\begin{pmatrix} 1 \bmod 29 \\ 2 \bmod 29 \\ 3 \bmod 29 \end{pmatrix}$$

Since `A` does not have a special form that would allow a fast matrix-vector multiplication, we simply use `_mult`. Wiedemann's algorithm works in this case, although it is less efficient than Gaussian elimination:

```
linalg::wiedemann(A, b, _mult)
```

$$\left[\begin{pmatrix} 24 \bmod 29 \\ 21 \bmod 29 \\ 17 \bmod 29 \end{pmatrix}, \text{TRUE} \right]$$

Example 2

Now let us define another matrix that has a special form:

```
MatZ29 := Dom::Matrix(Dom::IntegerMod(29)):
A := MatZ29([[1, 0, 0], [0, 1, 2], [0, 0, 1]]);
```

```
b := MatZ29(3, 1, [1, 2, 3]):
```

$$\begin{pmatrix} 1 \bmod 29 & 0 \bmod 29 & 0 \bmod 29 \\ 0 \bmod 29 & 1 \bmod 29 & 2 \bmod 29 \\ 0 \bmod 29 & 0 \bmod 29 & 1 \bmod 29 \end{pmatrix}$$

For this particular matrix, it is easy to define an efficient multiplication method:

```
mult := proc(dummy, y)
begin
    y[2]:=y[2]+2*y[3];
    y
end:
linalg::wiedemann(A, b, mult)
```

$$\left[\begin{pmatrix} 1 \bmod 29 \\ 25 \bmod 29 \\ 3 \bmod 29 \end{pmatrix}, \text{TRUE} \right]$$

Parameters

A

An $n \times n$ matrix of a domain of category `Cat::Matrix`

b

An n-dimensional column vector, i.e., an $n \times 1$ matrix of a domain of category `Cat::Matrix`

mult

A matrix-vector multiplication method: function or functional expression; default: `_mult`

prob

TRUE or FALSE (default: TRUE)

Return Values

Either the list `[x, TRUE]` if a solution for the system $A\,\vec{x} = \vec{b}$ has been found, or the list `[x, FALSE]` if a non-zero solution for the corresponding homogeneous system $A\,\vec{x} = \vec{0}$ has been found, or the value `FAIL` (see below).

Algorithms

The expected running time for the probabilistic algorithm is $O(n^2 + n\,M)$, and the running time for the deterministic variant is $O(n^2\,M)$ in the worst case, but only $O(n^2 + n\,M)$ on average. Here, M is the number of field operations that the matrix-vector multiplication routine `mult` uses.

The basic idea of the algorithm is to solve a linear system $A\,\vec{x} = \vec{b}$ by finding the minimal polynomial $f(y)$ that solves $f(A)\,\vec{b} = \vec{0}$. If the constant coefficient $c = f(0)$ is non-zero and $g(y) := f(y) - c$, the equality $g(A)\,\vec{b} = -c\,\vec{b}$ implies that $\vec{x} = -\frac{1}{c}\left(\frac{g}{y}\right)(A)$ is the solution.

The polynomial f is found by looking for the minimal polynomial h satisfying $\vec{u}\,h(A)\,\vec{b} = \vec{0}$ for some randomly chosen row vector $\vec{u}$. This may yield $h \neq f$ in unlucky cases, but in general the probability for this is small.

linopt::corners

Return the feasible corners of a linear program

Syntax

```
linopt::corners([constr, obj], vars, <All>, <Logic>)

linopt::corners([constr, obj, <NonNegative>, <seti>], vars, <All>, <Logic>)

linopt::corners([constr, obj, <NonNegative>, <All>], vars, <All>, <Logic>)

linopt::corners([constr, obj, <setn>, <seti>], vars, <All>, <Logic>)

linopt::corners([constr, obj, <setn>, <All>], vars, <All>, <Logic>)
```

Description

`linopt::corners([constr, obj], vars)` returns all valid corners of the linear program.

`linopt::corners([constr, obj], vars, All)` returns all corners of the linear program.

[`constr`, `obj`] is a linear program of the same structure like in `linopt::maximize`. The second parameter `vars` specifies the order in which the components of the corners found are printed; if e.g. {x=1, y=2} is a corner and [x,y] was entered, [1,2] will be returned.

As options, for finding the corners, one may use `All` and/or `Logic`. `All` causes the output of non-feasible corners, too, `Logic` allows the algorithm to search for corners in planes like x=0, too, although $x \geq 0$ is not part of the input. This guarantees that for all non-empty feasible regions a corner will be found.

As the result of `linopt::corners` a triple consisting of the set of corners, the maximal objective function value found and the corner associated to it is returned. If there is no feasible corner found, only the empty set is returned.

Examples

Example 1

We compute all valid corners of a small linear program:

```
k := [{4 <= 2*x + 2*y, -2 <= 4*y - 2*x, -8 <= y - 2*x,
       y - 2*x <= -2, y <= 6}, x + y]:
linopt::corners(k, [x, y])
```

$$\left[\left\{\left[\frac{4}{3}, \frac{2}{3}\right], \left[\frac{5}{3}, \frac{1}{3}\right], [4, 6], [5, 2], [7, 6]\right\}, 13, [7, 6]\right]$$

Now we compute all corners, also the ones which are not valid. We see that we now get e.g. also the corner which is given by the cut of $-2x + 4y = 2$ and $-2x + y \leq -2$. Here we see that the invalid corner (13,6) has the maximal objective function value 19:

```
k := [{4 <= 2*x + 2*y, -2 <= 4*y - 2*x, -8 <= y - 2*x,
       y - 2*x <= -2, y <= 6}, x + y]:
linopt::corners(k, [x, y], All)
```

$$\left[\left\{[-4, 6], [1, 0], \left[\frac{4}{3}, \frac{2}{3}\right], \left[\frac{5}{3}, \frac{1}{3}\right], \left[\frac{10}{3}, -\frac{4}{3}\right], [4, 6], [5, 2], [7, 6], [13, 6]\right\}, 19, [13, 6]\right]$$

```
delete k:
```

Example 2

As one can see the linear program given by the constraints $x + y \geq -1$ and $x + y \leq 3$ and the linear objective function $x + 2y$ has no corners:

```
l := [{-1 <= x + y, x + y <= 3}, x + 2*y]:
linopt::corners(l,[x,y]), linopt::corners(l,[x,y], All)
```

$$\varnothing, \varnothing$$

If one also assumes a cut with a coordinate plane as a corner, some corners exist. One can use `linopt::plot_data` to visualize this problem:

```
linopt::corners(l, [x,y], Logic)
```

```
[{[-1, 0], [0, 0], [0, -1], [0, 3], [3, 0]}, 6, [0, 3]]
```

```
delete l:
```

Parameters

`constr`

A set or list of linear constraints

`obj`

A linear expression

`seti`

A set which contains identifiers interpreted as indeterminants

`setn`

A set which contains identifiers interpreted as indeterminants

`vars`

A list containing the variables of the linear program described by `constr` and `obj` and the existing options

Options

`All`

This option can appear at two different places in the call of `linopt::corners`. If it is part of the linear program it means that all variables are constrained to be integers. If it appears as the third or forth argument of the call it means that all corners, not only the valid ones should be computed by `linopt::corners`.

`NonNegative`

All variables are constrained to be nonnegative

Logic

This allows the algorithm to search for corners in planes like x=0 too, although $x \geq 0$ is not part of the linear program.

Return Values

Set or a list with 3 elements.

MuPAD Functions

`linopt::maximize` | `linopt::minimize` | `linopt::plot_data`

linopt::maximize

Maximize a linear or mixed-integer program

Syntax

```
linopt::maximize([constr, obj], <DualPrices>)

linopt::maximize([constr, obj, <NonNegative>, <seti>])

linopt::maximize([constr, obj, <NonNegative>, <All>])

linopt::maximize([constr, obj, <setn>, <seti>])

linopt::maximize([constr, obj, <setn>, <All>])

linopt::maximize([constr, obj, <NonNegative>], DualPrices)

linopt::maximize([constr, obj, <set>], DualPrices)
```

Description

`linopt::maximize([constr, obj])` returns the solution of the linear or mixed-integer program given by the constraints `constr` and the linear objective function `obj` which should be maximized.

The expression `obj` is the linear objective function to be maximized subject to the linear constraints `constr`. The function `linopt::maximize` returns a triple consisting of the state of the output, `OPTIMAL`, `EMPTY` or `UNBOUNDED`, a set of equations which describes the optimal solution of the specified linear program, which is empty or depends on a free variable Φ subject to the state, and finally the maximal objective function value, which can be either a number, `-infinity` or a linear function in Φ.

The states `OPTIMAL`, `EMPTY` or `UNBOUNDED` have the following meanings. `OPTIMAL` means an optimal solution for the linear program was found. If the state is `EMPTY` no optimal solution was found and if it is `UNBOUNDED` then the solution has no upper bound.

If the option `NonNegative` is used all variables are constrained to be nonnegative. If instead of `NonNegative` a set `setn` is given then only the variables from `setn` are constrained to be nonnegative.

If the option `All` is used all variables are constrained to be integers. If instead of `All` a set `seti` is given, then only the variables from `seti` are constrained to be integers.

As a second parameter for `linopt::maximize` the option `DualPrices` is provided for the linear case (the first parameter therefore must not have more than three elements). This option causes the output of the dual-prices in addition to the solution-tripel. In this case the result of `linopt::maximize` is a sequence of a list containing the solution-tripel and a set containing the dual prices. See “Example 4” on page 16-8.

Examples

Example 1

We try to solve the linear program

$$2\,c_1 \le 1$$

$$2\,c_2 \le 1$$

with the linear objective function $c_1 + 2\,c_2$:

```
linopt::maximize([{2*c1 <= 1, 2*c2 <= 1}, c1 + 2*c2])
```

$$\left[\text{OPTIMAL},\ \left\{c1 = \frac{1}{2},\ c2 = \frac{1}{2}\right\},\ \frac{3}{2}\right]$$

Example 2

Now let's have a look at the linear program

$$\begin{aligned} 3\,x + 4\,y - 3\,z &\le 23 \\ 5\,x - 4\,y - 3\,z &\le 10 \\ 7\,x + 4\,y + 11\,z &\le 30 \end{aligned}$$

with the linear objective function $-x + y + 2\,z$. If we make no restriction to the variables the result is unbounded:

```
c := [{3*x + 4*y - 3*z <= 23, 5*x - 4*y - 3*z <= 10,
       7*x + 4*y + 11*z <= 30}, -x + y + 2*z]:
linopt::maximize(c)
```

$$\left[\text{UNBOUNDED}, \left\{x = -\text{PHI1}, y = 0, z = \frac{7\,\text{PHI1}}{11} + \frac{30}{11}\right\}, \frac{25\,\text{PHI1}}{11} + \frac{60}{11}\right]$$

But if all variables are constrained to be nonnegative, we get a result. That's also the case if only x and y are constrained to be nonnegative:

```
linopt::maximize(append(c, NonNegative));
linopt::maximize(append(c, {x, y}))
```

$$\left[\text{OPTIMAL}, \left\{x = 0, y = \frac{49}{8}, z = \frac{1}{2}\right\}, \frac{57}{8}\right]$$

$$\left[\text{OPTIMAL}, \left\{x = 0, y = \frac{49}{8}, z = \frac{1}{2}\right\}, \frac{57}{8}\right]$$

```
delete c:
```

Example 3

The following linear program do not have a solution:

```
linopt::maximize([{x <= -1, x >= 0}, x])
```

$$[\text{EMPTY}, \varnothing, -\infty]$$

Example 4

The output of the dual prices can be enforced with the option `DualPrices`:

```
linopt::maximize([{2*c1 <= 1, 2*c2 <= 1},c1 + 2*c2],
                 DualPrices)
```

$$\left[\text{OPTIMAL}, \left\{\text{c1} = \frac{1}{2}, \text{c2} = \frac{1}{2}\right\}, \frac{3}{2}\right], \left\{\left[\text{c1} \le \frac{1}{2}, 1\right], \left[\text{c2} \le \frac{1}{2}, 2\right]\right\}$$

Example 5

We have a look at the knapsack problem with *x1*, *x2*, *x3*, *x4* ∈ {0, 1}:

```
c := {20*x1 + 15*x2 + 20*x3 + 5*x4 <= 25}:
c := c union {x1 <= 1, x2 <= 1, x3 <= 1, x4 <= 1}:
f := 10*x1 + 15*x2 + 16*x3 + x4:
linopt::maximize([c, f, NonNegative, All])
```

$$[\text{OPTIMAL}, \{x1 = 0, x2 = 0, x3 = 1, x4 = 1\}, 17]$$

```
delete c, f:
```

Parameters

`constr`

A set or list of linear constraints

`obj`

A linear expression

`seti`

A set which contains identifiers interpreted as indeterminates

`setn`

A set which contains identifiers interpreted as indeterminates

Options

`All`

All variables are constrained to be integers

`NonNegative`

All variables are constrained to be nonnegative

`DualPrices`

This option is only available in the linear case. It causes the output of the dual-prices in addition to the solution-triple.

Return Values

List or a sequence of a list and a set containing the solution of the linear or mixed-integer program.

linopt::minimize

Minimize a linear or mixed-integer program

Syntax

```
linopt::minimize([constr, obj], <DualPrices>)

linopt::minimize([constr, obj, <NonNegative>, <seti>])

linopt::minimize([constr, obj, <NonNegative>, <All>])

linopt::minimize([constr, obj, <setn>, <seti>])

linopt::minimize([constr, obj, <setn>, <All>])

linopt::minimize([constr, obj, <NonNegative>], DualPrices)

linopt::minimize([constr, obj, <set>], DualPrices)
```

Description

`linopt::minimize([constr, obj])` returns the solution of the linear or mixed-integer program given by the constraints `constr` and the linear objective function `obj` which should be minimized.

The expression `obj` is the linear objective function to be minimized subject to the linear constraints `constr`. The function `linopt::minimize` returns a triple consisting of the state of the output, `OPTIMAL`, `EMPTY` or `UNBOUNDED`, a set of equations which describes the optimal solution of the specified linear program, which is empty or depends on a free variable Φ subject to the state, and finally the minimal objective function value, which can be either a number, `infinity` or a linear function in Φ.

The states `OPTIMAL`, `EMPTY` or `UNBOUNDED` have the following meanings. `OPTIMAL` means an optimal solution for the linear program was found. If the state is `EMPTY` no optimal solution was found and if it is `UNBOUNDED` then the solution has no upper bound.

If the option `NonNegative` is used all variables are constrained to be nonnegative. If instead of `NonNegative` a set `setn` is given then only the variables from `setn` are constrained to be nonnegative.

If the option `All` is used all variables are constrained to be integers. If instead of `All` a set `seti` is given, then only the variables from `seti` are constrained to be integers.

As a second parameter for `linopt::minimize` the option `DualPrices` is provided for the linear case (the first parameter therefore must not have more than three elements). This option causes the output of the dual-prices in addition to the solution-tripel. In this case the result of `linopt::minimize` is a sequence of a list containing the solution-tripel and a set containing the dual prices. See “Example 4” on page 16-13.

Examples

Example 1

We try to solve the linear program

$$\begin{aligned} c_1 + c_2 &\le 3 \\ c_2 &\le 9 \end{aligned}$$

with the linear objective function - c_1 - c_2:

```
linopt::minimize([{c1 + c2 <= 3, c2 <= 9}, -c1 - c2])
```

$$[\text{OPTIMAL}, \{c1 = 0, c2 = 3\}, -3]$$

Example 2

Now let's have a look at the linear program

$$\begin{aligned} 3x + 4y - 3z &\le 23 \\ 5x - 4y - 3z &\le 10 \\ 7x + 4y + 11z &\le 30 \end{aligned}$$

with the linear objective function - $x + y + 2z$. If we make no restriction to the variables the result is unbounded:

```
c := [{3*x + 4*y - 3*z <= 23, 5*x - 4*y - 3*z <= 10,
       7*x + 4*y + 11*z <= 30}, -x + y + 2*z]:
linopt::minimize(c)
```

$$\left[\text{UNBOUNDED}, \left\{y = -\text{PHI1}, x = -4\,\text{PHI1} - \frac{13}{2}, z = -\frac{16\,\text{PHI1}}{3} - \frac{85}{6}\right\}, -\frac{23\,\text{PHI1}}{3} - \frac{131}{6}\right]$$

But if all variables are constrained to be nonnegative, we get a result. That's also the case if only x and y are constrained to be nonnegative:

```
linopt::minimize(append(c, NonNegative));
linopt::minimize(append(c, {x, y}))
```

$$[\text{OPTIMAL}, \{x = 2, y = 0, z = 0\}, -2]$$

$$\left[\text{OPTIMAL}, \left\{x = 0, y = \frac{13}{8}, z = -\frac{11}{2}\right\}, -\frac{75}{8}\right]$$

```
delete c:
```

Example 3

The following linear program does not have a solution:

```
linopt::minimize([{x <= -1, x >= 0}, x])
```

$$[\text{EMPTY}, \varnothing, \infty]$$

Example 4

The output of the dual prices can be enforced with the option `DualPrices`:

```
linopt::minimize([{c1 + c2 <= 3, c2 <= 9}, -c1 - c2],
                 DualPrices)
```

$$[\text{OPTIMAL}, \{c1 = 0, c2 = 3\}, -3], \{[c1 + c2 \le 3, 1], [c2 \le 9, 0]\}$$

Parameters

`constr`

A set or list of linear constraints

`obj`

A linear expression

`seti`

S set which contains identifiers interpreted as indeterminates

`setn`

A set which contains identifiers interpreted as indeterminates

Options

`All`

All variables are constrained to be integer

`NonNegative`

All variables are constrained to be nonnegative

`DualPrices`

This option is only available in the linear case. It causes the output of the dual-prices in addition to the solution-tripel.

Return Values

List or a sequence of a list and a set containing the solution of the linear or mixed-integer program.

See Also

MuPAD Functions

`linopt::corners` | `linopt::maximize` | `linopt::plot_data`

linopt::plot_data

Plot the feasible region of a linear program

Syntax

```
linopt::plot_data([constr, obj, <NonNegative>, <seti>], vars)
```

```
linopt::plot_data([constr, obj, <NonNegative>, <All>], vars)
```

```
linopt::plot_data([constr, obj, <setn>, <seti>], vars)
```

```
linopt::plot_data([constr, obj, <setn>, <All>], vars)
```

Description

`linopt::plot_data([constr, obj], vars)` returns a graphical description of the feasible region of the linear program [constr, obj], and the line vertical to the objective function vector through the corner with the maximal objective function value found.

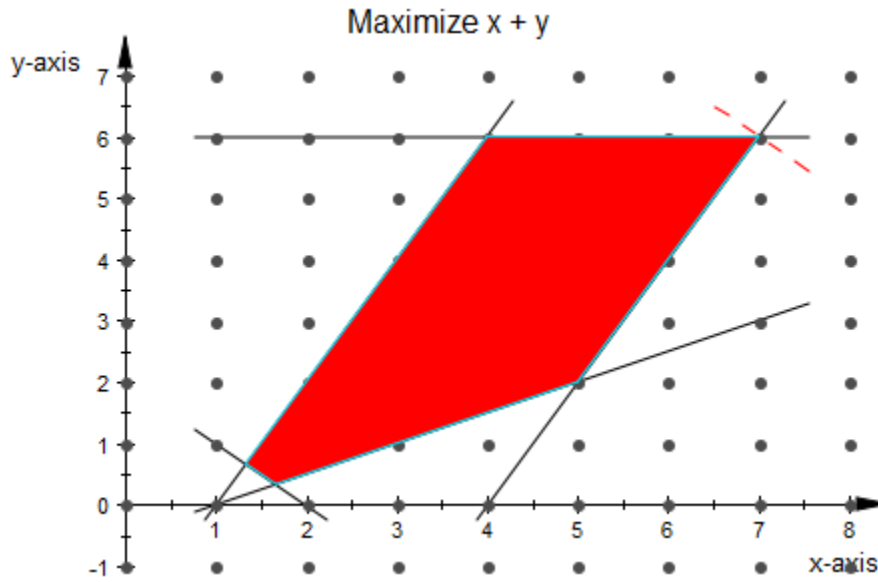
[`constr`, `obj`] is a linear program with exactly two variables. The problem has the same structure like in `linopt::maximize`. The second parameter `vars` specifies which variable belongs to the horizontal and vertical axis.

Examples

Example 1

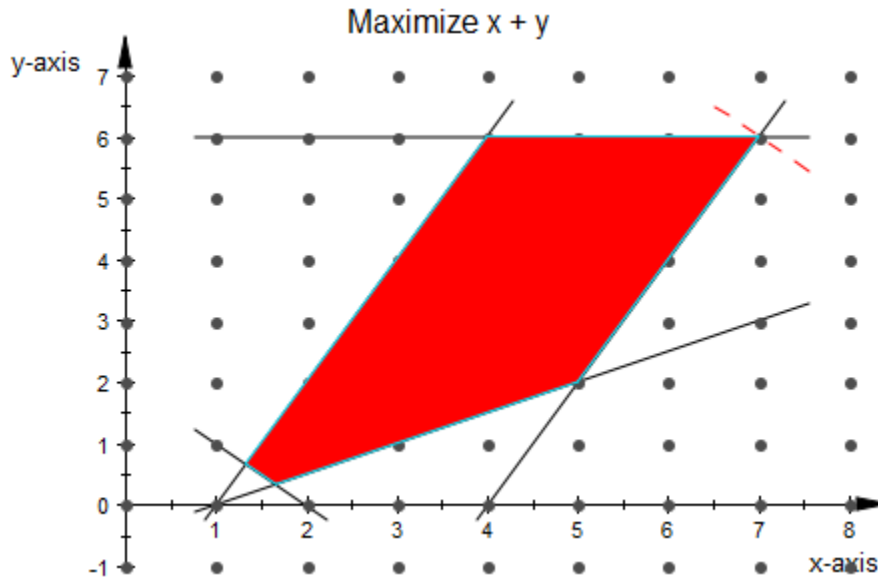
We plot the feasible region of the given linear program. Here the valid corners of the linear program are easy to see:

```
k := [{2*x + 2*y >= 4, -2*x + 4*y >= -2, -2*x + y >= -8,
       -2*x + y <= -2, y <= 6}, x + y, NonNegative]:
g := linopt::plot_data(k, [x, y]):
plot(g):
```



In this example there is no difference if the Option `NonNegative` is given for the linear program or not:

```
k := [{2*x + 2*y >= 4, -2*x + 4*y >= -2, -2*x + y >= -8,
       -2*x + y <= -2, y <= 6}, x + y]:
g := linopt::plot_data(k, [x, y]):
plot(g):
```

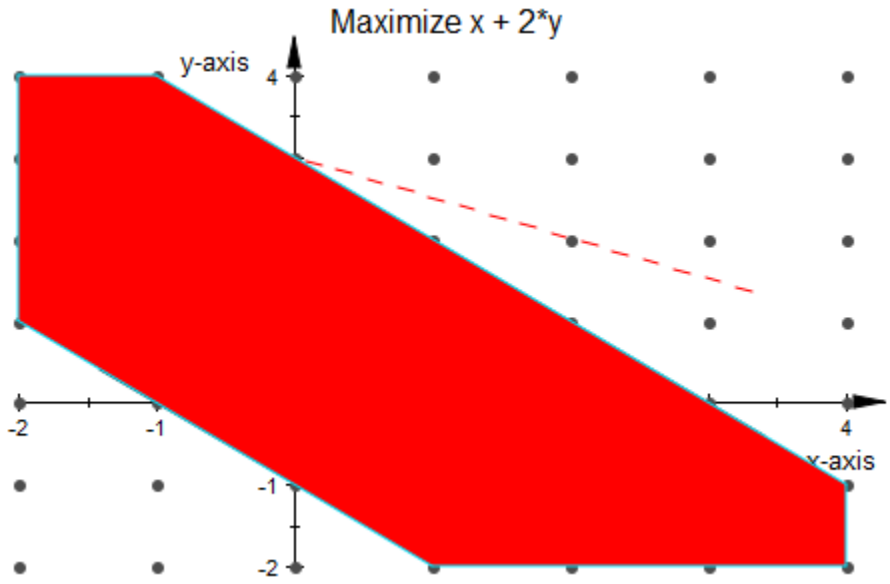


```
delete k, g:
```

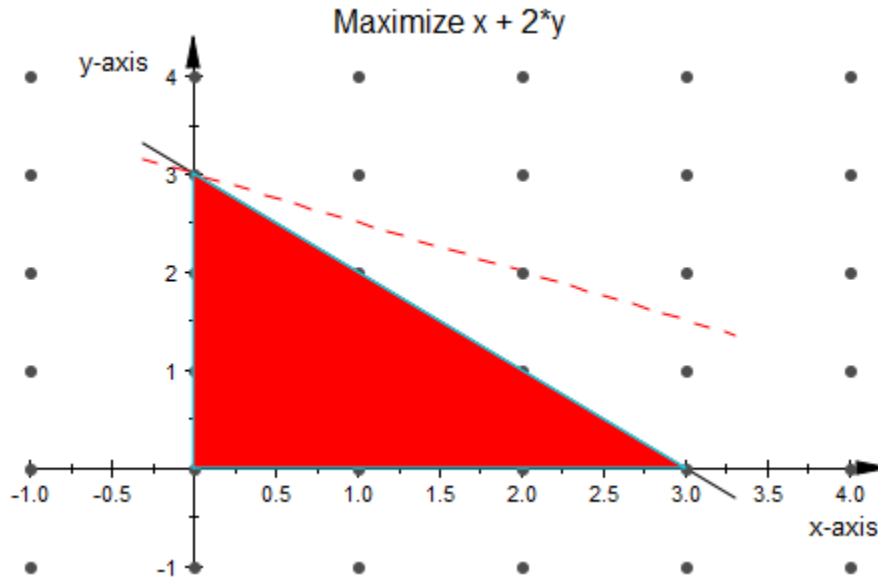
Example 2

Now we give an example where one can see a difference if the variables are constrained to be nonnegative:

```
k := [{x + y >= -1, x + y <= 3}, x + 2*y]:
g := linopt::plot_data(k, [x, y]):
plot(g):
```



```
k := [{x + y >= -1, x + y <= 3}, x + 2*y, NonNegative]:
g := linopt::plot_data(k, [x, y]):
plot(g):
```



```
delete k, g:
```

Parameters

`constr`

A set or list of linear constraints

`obj`

A linear expression

`seti`

A set which contains identifiers interpreted as indeterminates

`setn`

A set which contains identifiers interpreted as indeterminates

vars

A list containing the two variables of the linear program described by `constr` and `obj` and the existing options

Options

All

All variables are constrained to be integer

NonNegative

All variables are constrained to be nonnegative

Return Values

Expression describing a graphical object which can be used by `plot`.

See Also

MuPAD Functions

`linopt::corners` | `linopt::maximize` | `linopt::minimize`

linopt::Transparent

Return the ordinary simplex tableau of a linear program

Syntax

```
linopt::Transparent([constr, obj, <NonNegative>, <seti>])

linopt::Transparent([constr, obj, <NonNegative>, <All>])

linopt::Transparent([constr, obj, <setn>, <seti>])

linopt::Transparent([constr, obj, <setn>, <All>])
```

Description

`linopt::Transparent([constr, obj])` returns the ordinary simplex tableau of the given linear program given by the constraints `constr` and the linear objective function `obj`.

[`constr`, `obj`] is a Linear Optimization Problem of the same structure like in `linopt::maximize`. As the result the ordinary simplex tableau of the given problem is returned; this means that equations will be replaced by two unequations and unbounded variables will be replaced by two new variables.

Internally the tableau returned consists of more information than viewable on the screen. Therefore `linopt::Transparent::convert` is provided to perform the transduction into the structure of the screen-tableau. (This can be necessary if the returned tableau shall serve as an input-parameter for another function — e.g. a user defined procedure for the selection of pivot elements.) If an ordinary simplex with two phases is wished, the next step should be the call of `linopt::Transparent::phaseI_tableau`.

All functions of the linopt library using the tableau returned by `linopt::Transparent` try to minimize the problem! Therefore it can be necessary to multiply the objective function with -1 first.

In the simplex tableau returned a special notation is used. "linopt" stands for the tableau them self, "obj" describes the linear objective function, "restr" stands for the vector of restrictions, slk[1], slk[2], ... are the slack variables and the names of the other variables

stand for themselves. Variables which are given as row labels indicate that they are part of the base.

Examples

Example 1

First a small example, returning the ordinary simplex tableau of the given linear program. One can see that the slack variables are forming the basis:

```
k := [{x + y >= -1, x + y <= 3}, x + 2*y, NonNegative]:
linopt::Transparent(k)
```

"linopt"	"restr"	slk_1	slk_2	y	x
"obj"	0	0	0	2	1
slk_1	1	1	0	−1	−1
slk_2	3	0	1	1	1

It follows a little bit larger example:

```
k := [{3*x + 4*y - 3*z <= 23, 5*x - 4*y - 3*z <= 10,
       7*x + 4*y + 11*z <= 30}, -x + y + 2*z, NonNegative]:
linopt::Transparent(k)
```

"linopt"	"restr"	slk_1	slk_2	slk_3	y	x	z
"obj"	0	0	0	0	1	−1	2
slk_1	23	1	0	0	4	3	−3
slk_2	10	0	1	0	−4	5	−3
slk_3	30	0	0	1	4	7	11

The result of `linopt::Transparent` is of domain type `linopt::Transparent`. So it can be used as input for other `linopt::Transparent::*` function, e.g. for `linopt::Transparent::suggest`:

```
k := [{x + y >= -1, x + y <= 3}, x + 2*y, NonNegative]:
t := linopt::Transparent(k):
domtype(t), linopt::Transparent::suggest(t)
```

linopt::Transparent, OPTIMAL

```
delete k, t:
```

Parameters

`constr`

A set or list of linear constraints

`obj`

A linear expression

`seti`

A set which contains identifiers interpreted as indeterminates

`setn`

A set which contains identifiers interpreted as indeterminates

Options

`All`

All variables are constrained to be integer

`NonNegative`

All variables are constrained to be nonnegative

Return Values

Simplex tableau of domain type `linopt::Transparent`.

MuPAD Functions

`linopt::Transparent::autostep` | `linopt::Transparent::convert` | `linopt::Transparent::dual_prices` | `linopt::Transparent::phaseI_tableau` | `linopt::Transparent::phaseII_tableau` | `linopt::Transparent::result` | `linopt::Transparent::simplex` | `linopt::Transparent::suggest` | `linopt::Transparent::userstep`

linopt::Transparent::autostep

Perform the next simplex step

Syntax

```
linopt::Transparent::autostep(tableau)
```

Description

`linopt::Transparent::autostep(tableau)` performs the next step of the simplex algorithm. This is the same step that `linopt::Transparent::suggest` would suggest for the given simplex tableau `tableau`.

Normally `linopt::Transparent::autostep` returns the next simplex tableau. If the calculation of the simplex algorithm is finished `linopt::Transparent::autostep` returns a set containing a solution of the given linear program described by `tableau`.

Examples

Example 1

The ordinary simplex tableau of a given linear program is created:

```
k := [{x + y >= 2}, x, NonNegative]:
t := linopt::Transparent(k)
```

$$\begin{pmatrix} \text{"linopt"} & \text{"restr"} & \text{slk}_1 & y & x \\ \text{"obj"} & 0 & 0 & 0 & 1 \\ \text{slk}_1 & -2 & 1 & -1 & -1 \end{pmatrix}$$

The next two steps of the simplex algorithm are executed for the given simplex tableau:

```
linopt::Transparent::autostep(t);
```

```
linopt::Transparent::autostep(%)
```

$$\begin{pmatrix} \text{"linopt"} & \text{"restr"} & \text{slk}_1 & y & x \\ \text{"obj"} & -2 & 1 & -1 & 0 \\ x & 2 & -1 & 1 & 1 \end{pmatrix}$$

$$\begin{pmatrix} \text{"linopt"} & \text{"restr"} & \text{slk}_1 & y & x \\ \text{"obj"} & 0 & 0 & 0 & 1 \\ y & 2 & -1 & 1 & 1 \end{pmatrix}$$

```
delete k, t:
```

Example 2

The ordinary simplex tableau of a given linear program is created:

```
k := [{x + y >= -1, x + y <= 3}, x + 2*y, NonNegative]:
t := linopt::Transparent(k)
```

$$\begin{pmatrix} \text{"linopt"} & \text{"restr"} & \text{slk}_1 & \text{slk}_2 & y & x \\ \text{"obj"} & 0 & 0 & 0 & 2 & 1 \\ \text{slk}_1 & 1 & 1 & 0 & -1 & -1 \\ \text{slk}_2 & 3 & 0 & 1 & 1 & 1 \end{pmatrix}$$

If the end of the simplex algorithm is reached, `linopt::Transparent::autostep` returns a solution of the given linear program:

```
linopt::Transparent::suggest(t),
linopt::Transparent::autostep(t)
```

$$\text{OPTIMAL}, \{x = 0, y = 0\}$$

```
delete k, t:
```

Parameters

`tableau`

A simplex tableau of domain type `linopt::Transparent`

Return Values

Simplex tableau of domain type `linopt::Transparent` or a set which contains the solution of the linear program.

`linopt::Transparent` | `linopt::Transparent::convert` | `linopt::Transparent::dual_prices` |

```
linopt::Transparent::phaseI_tableau | linopt::Transparent::result
| linopt::Transparent::simplex | linopt::Transparent::suggest |
linopt::Transparent::userstep
```

linopt::Transparent::clean_basis

Delete all slack variables of the first phase from the basis

Syntax

```
linopt::Transparent::clean_basis(tableau)
```

Description

`linopt::Transparent::clean_basis(tableau)` removes the additional slack variables of the phase one of the simplex algorithm from the optimal basic (described by `tableau`) calculated by `linopt::Transparent::phaseI_tableau` and `linopt::Transparent::simplex`.

At the end of the phase one of the 2-phase simplex algorithm, explicitly started by using `linopt::Transparent::phaseI_tableau`, it is necessary to eliminate all artificial variables from the optimal basis before phase two can be started by using `linopt::Transparent::phaseII_tableau`. `linopt::Transparent::clean_basis` performs some pivot steps until all phase one slack variables do not occur in the basis any longer.

Examples

Example 1

In this example we first compute an optimal basis for the first phase of the simplex algorithm:

```
t := linopt::Transparent([{x <= 1,y <= 1,x + y >= 2},
                          0,NonNegative]):
t := linopt::Transparent::phaseI_tableau(t):
t := linopt::Transparent::simplex(t)
```

"linopt"	"restr"	slk_4	slk_5	slk_6	slk_1	slk_2	slk_3	y	x
"obj"	0	2	2	0	1	1	1	0	0
x	1	1	0	0	1	0	0	0	1
y	1	0	1	0	0	1	0	1	0
slk_6	0	−1	−1	1	−1	−1	−1	0	0

As we can see the artificial slack variable slk[6] is an element of the optimal basis. An error message is returned if we apply `linopt::Transparent::phaseII_tableau` or `linopt::Transparent::simplex` to this simplex tableau:

```
linopt::Transparent::phaseII_tableau(t);
```

```
Error: Clean the basis from phase I slack variables first. [linopt::Transparent::phase
```

So we have to use `linopt::Transparent::clean_basis` before continuing with the appropriate function:

```
t := linopt::Transparent::clean_basis(t);
linopt::Transparent::phaseII_tableau(t)
```

"linopt"	"restr"	slk_4	slk_5	slk_6	slk_1	slk_2	slk_3	y	x
"obj"	0	1	1	1	0	0	0	0	0
x	1	0	−1	1	0	−1	−1	0	1
y	1	0	1	0	0	1	0	1	0
slk_1	0	1	1	−1	1	1	1	0	0

"linopt"	"restr"	slk_1	slk_2	slk_3	y	x
"obj"	0	0	0	0	0	0
x	1	0	−1	−1	0	1
y	1	0	1	0	1	0
slk_1	0	1	1	1	0	0

```
delete t:
```

Parameters

`tableau`

A simplex tableau of domain type `linopt::Transparent`

Return Values

Simplex tableau of domain type `linopt::Transparent`.

linopt::Transparent::convert

Transform the given tableau into a structure printable on screen

Syntax

```
linopt::Transparent::convert(tableau)
```

Description

`linopt::Transparent::convert` converts `tableau` into a two dimensional array which corresponds with the screen-tableau. One can now access the element in the *i*-th row and *j*-th column of the simplex tableau by accessing the corresponding element of the array.

Internally the given `tableau` of domain type `linopt::Transparent` contains a lot of more information than the simplex tableau which is printed by some functions of the `linopt` library, e.g. `linopt::Transparent::simplex`, and which is visible on the screen. Furthermore it is not possible to access the element in the *i*-th row and *j*-th column of `tableau` to get the corresponding element from the simplex tableau which is visible on the screen.

While the internal structure of `tableau` is not known the structure of the two dimensional array is well defined. So it can be easily used in own procedures. See “Example 2” on page 16-36.

Examples

Example 1

We convert a simplex tableau of domain type `linopt::Transparent` into a two dimensional array:

```
k := [{x + y >= 2}, x, NonNegative]:
t := linopt::Transparent(k):
a := linopt::Transparent::convert(t):
t, domtype(t);
```

```
a, domtype(a)
```

$$\begin{pmatrix} \text{"linopt"} & \text{"restr"} & \text{slk}_1 & y & x \\ \text{"obj"} & 0 & 0 & 0 & 1 \\ \text{slk}_1 & -2 & 1 & -1 & -1 \end{pmatrix}, \text{linopt::Transparent}$$

$$\begin{pmatrix} \text{"linopt"} & \text{"restr"} & \text{slk}_1 & y & x \\ \text{"obj"} & 0 & 0 & 0 & 1 \\ \text{slk}_1 & -2 & 1 & -1 & -1 \end{pmatrix}, \text{DOM\_ARRAY}$$

```
delete a, k, t:
```

Example 2

We will write another simplex routine `mysimplex` for solving a linear program. For this we define the function `eigenpivot` for finding the pivot element of a given simplex tableau. `eigenpivot` assumes that the simplex tableau is given as a two dimensional array.

Here is the procedure `eigenpivot`, which is not coded in every detail, e.g., the error checking isn't implemented completely:

```
eigenpivot := proc(T: DOM_ARRAY)
   local i,j,m,n,k,l,mini;
   begin
     m := op(T,[0,2,2]):
     n := op(T,[0,3,2]):
     k := 0:
     l := 0:
     mini := unbesetzt:

      for j from 3 to n do
       if T[2,j] < 0 then
         l := j:
         break
       end_if:
     end_for:
     if l=0 then return(OPTIMAL) end_if:
     for i from 3 to m do
```

```
      if T[i,l] > 0 and (mini=unbesetzt or T[i,2]/T[i,l] < mini) then
        k := i:
        mini := T[k,2]/T[k,l]
      end_if
    end_for:
    if k=0 then return(UNBOUNDED) end_if:
    return(T[k,1],T[1,l]):
end_proc:
```

This is the new simplex algorithm `mysimplex` which uses `eigenpivot` and some function from the `linopt` library:

```
mysimplex := proc(P)
   local T;
   begin
     T := linopt::Transparent(P):
     T := linopt::Transparent::phaseI_tableau(T):
     piv := eigenpivot(linopt::Transparent::convert(T)):
     while piv <> OPTIMAL and piv <> UNBOUNDED do
       T := linopt::Transparent::userstep(T,piv):
       piv := eigenpivot(linopt::Transparent::convert(T))
     end_while:

      if piv = UNBOUNDED then
       error(" Phase I unbounded ?!?")
     end_if:
     if T[2,2] <> 0
        then return(EMPTY)
     end_if:
     T := linopt::Transparent::clean_basis(T):

      T := linopt::Transparent::phaseII_tableau(T):
     piv := eigenpivot(linopt::Transparent::convert(T)):
     while piv <> OPTIMAL and piv <> UNBOUNDED do
       T := linopt::Transparent::userstep(T,piv):
       piv := eigenpivot(linopt::Transparent::convert(T))
     end_while:

      if piv = OPTIMAL
       then return(linopt::Transparent::result(T))
       else return(UNBOUNDED)
     end_if
end_proc:
```

We now apply `mysimplex` to a linear program:

```
k := [{2*x + 2*y >= 4, -2*x + 4*y >= -2, -2*x + y>= -8,
       -2*x + y <= -2, y <= 6}, -x - y]:
k := append(k, NonNegative):
mysimplex(k);
```

$$\{x = 7, y = 6\}$$

```
delete k, eigenpivot, mysimplex:
```

Parameters

`tableau`

A simplex tableau of domain type

Return Values

Two dimensional array, representing the given simplex tableau `tableau`.

linopt::Transparent::dual_prices

Get the dual solution belonging to the given tableau

Syntax

```
linopt::Transparent::dual_prices(tableau)
```

Description

`linopt::Transparent::dual_prices(tableau)` returns the dual solution of the linear optimization problem given by `tableau`.

This procedure returns the dual solution belonging to the given tableau in form of a set of lists containing two elements, the first one is a restriction and the second one is the value belonging to the slack variable connected to the restriction in the dual solution.

Examples

Example 1

Here it is demonstrated that the dual solution of the final tableau is similar to the second element of the result of `linopt::minimize` using the option `DualPrices`:

First we compute the final tableau of the simplex algorithm:

```
k := [{x <= 2, y <= 2, x + 2*y >= 4}, - x + y, NonNegative]:
t := linopt::Transparent(k):
t := linopt::Transparent::simplex(t)
```

$$\begin{pmatrix} \text{"linopt"} & \text{"restr"} & \text{slk}_1 & \text{slk}_2 & \text{slk}_3 & y & x \\ \text{"obj"} & 1 & \frac{3}{2} & 0 & \frac{1}{2} & 0 & 0 \\ x & 2 & 1 & 0 & 0 & 0 & 1 \\ \text{slk}_2 & 1 & \frac{1}{2} & 1 & \frac{1}{2} & 0 & 0 \\ y & 1 & -\frac{1}{2} & 0 & -\frac{1}{2} & 1 & 0 \end{pmatrix}$$

Now we compute the solutions:

```
linopt::Transparent::dual_prices(t);
linopt::minimize(k, DualPrices)[2]
```

$$\left\{\left[4 \le x+2\,y,\ \frac{1}{2}\right],\ [0 \le x,\ 0],\ \left[x \le 2,\ \frac{3}{2}\right],\ [0 \le y,\ 0],\ [y \le 2,\ 0]\right\}$$

$$\left\{\left[4 \le x+2\,y,\ \frac{1}{2}\right],\ [0 \le x,\ 0],\ \left[x \le 2,\ \frac{3}{2}\right],\ [0 \le y,\ 0],\ [y \le 2,\ 0]\right\}$$

```
delete k, t:
```

Example 2

We compute the dual solution of another linear program:

```
k := [{x <= 2, y <= 2, x + 2*y >= 4}, -x + y, NonNegative]:
t := linopt::Transparent(k);
linopt::Transparent::dual_prices(t)
```

$$\begin{pmatrix} \text{"linopt"} & \text{"restr"} & \text{slk}_1 & \text{slk}_2 & \text{slk}_3 & y & x \\ \text{"obj"} & 0 & 0 & 0 & 0 & 1 & -1 \\ \text{slk}_1 & 2 & 1 & 0 & 0 & 0 & 1 \\ \text{slk}_2 & 2 & 0 & 1 & 0 & 1 & 0 \\ \text{slk}_3 & -4 & 0 & 0 & 1 & -2 & -1 \end{pmatrix}$$

$$\{[4 \le x + 2\,y,\ 0],\ [0 \le x,\ -1],\ [x \le 2,\ 0],\ [0 \le y,\ 1],\ [y \le 2,\ 0]\}$$

```
delete k, t:
```

Parameters

`tableau`

A simplex tableau of domain type `linopt::Transparent`

Return Values

Set of lists, each containing 2 elements.

MuPAD Functions

`linopt::Transparent` | `linopt::Transparent::result`

linopt::Transparent::phaseI_tableau

Start an ordinary phase one of a 2-phase simplex algorithm

Syntax

```
linopt::Transparent::phaseI_tableau(tableau)
```

Description

`linopt::Transparent::phaseI_tableau` explicitly starts an (ordinary) phase one of the simplex algorithm , i.e. rows associated with infeasible basic variables are multiplied with -1 and another identity matrix with new slack variables is added to the given tableau. As soon as an optimal tableau with relative costs 0 is found the calculation can be continued with `linopt::Transparent::clean_basis` and the second phase of the simplex algorithm (`linopt::Transparent::phaseII_tableau`).

Examples

Example 1

The first simplex tableau is created and the first phase of the simplex algorithm is started:

```
t := linopt::Transparent([{x + y >= 2}, x, NonNegative]);
t := linopt::Transparent::phaseI_tableau(t)
```

$$\begin{pmatrix} \text{"linopt"} & \text{"restr"} & \text{slk}_1 & y & x \\ \text{"obj"} & 0 & 0 & 0 & 1 \\ \text{slk}_1 & -2 & 1 & -1 & -1 \end{pmatrix}$$

$$\begin{pmatrix} \text{"linopt"} & \text{"restr"} & \text{slk}_2 & \text{slk}_1 & y & x \\ \text{"obj"} & -2 & 0 & 1 & -1 & -1 \\ \text{slk}_2 & 2 & 1 & -1 & 1 & 1 \end{pmatrix}$$

We can see that a new slack variable, slk_2, was added to the tableau. And if we now execute `linopt::Transparent::simplex` we can see that we have just finished the first phase of the simplex algorithm:

```
linopt::Transparent::suggest(t);
t := linopt::Transparent::simplex(t):
linopt::Transparent::suggest(t)
```

$$\text{slk}_2,\ y$$

"linopt::Transparent::phaseII_tableau"

We continue the simplex algorithm by executing `linopt::Transparent::clean_basis`, `linopt::Transparent::phaseII_tableau` and `linopt::Transparent::simplex`. Observe in this special case `linopt::Transparent::clean_basis` is not necessary:

```
t := linopt::Transparent::clean_basis(t):
t := linopt::Transparent::phaseII_tableau(t):
t := linopt::Transparent::simplex(t);
linopt::Transparent::suggest(t)
```

$$\begin{pmatrix} \text{"linopt"} & \text{"restr"} & \text{slk}_1 & y & x \\ \text{"obj"} & 0 & 0 & 0 & 1 \\ y & 2 & -1 & 1 & 1 \end{pmatrix}$$

OPTIMAL

```
delete t:
```

Parameters

tableau

A simplex tableau of domain type `linopt::Transparent`

Return Values

Simplex tableau of domain type `linopt::Transparent`.

MuPAD Functions

`linopt::Transparent` | `linopt::Transparent::autostep` | `linopt::Transparent::clean_basis` | `linopt::Transparent::convert` | `linopt::Transparent::dual_prices` |

linopt::Transparent::phaseII_tableau | linopt::Transparent::result | linopt::Transparent::simplex | linopt::Transparent::suggest | linopt::Transparent::userstep

linopt::Transparent::phaseII_tableau

Start phase two of a 2-phase simplex algorithm

Syntax

```
linopt::Transparent::phaseII_tableau(tableau)
```

Description

`linopt::Transparent::phaseII_tableau(tableau)` starts the second phase of the simplex algorithm on the given simplex tableau `tableau`.

After the explicitly started first phase of the simplex algorithm (see `linopt::Transparent::phaseI_tableau`) terminated with an optimal tableau with associated costs 0 and no phase one slack variables in the basis (see `linopt::Transparent::clean_basis`) this procedure can be used to start phase II. The procedure eliminates all artificial variables of phase I and their associated columns and reenters the old objective function modified for the new basis.

Examples

Example 1

The first simplex tableau is created and the first phase of the simplex algorithm is finished:

```
t := linopt::Transparent([{x + y >= 2}, x, NonNegative]):
t := linopt::Transparent::simplex(
        linopt::Transparent::phaseI_tableau(t))
```

$$\begin{pmatrix} \text{"linopt"} & \text{"restr"} & \text{slk}_2 & \text{slk}_1 & y & x \\ \text{"obj"} & 0 & 1 & 0 & 0 & 0 \\ y & 2 & 1 & -1 & 1 & 1 \end{pmatrix}$$

One sees that the artificial slack variable slk[2] of the first phase is removed by `linopt::Transparent::phaseII_tableau`. In this example it is not necessary to use `linopt::Transparent::clean_basis` for cleaning the basis:

```
linopt::Transparent::phaseII_tableau(t)
```

$$\begin{pmatrix} \text{"linopt"} & \text{"restr"} & \text{slk}_1 & y & x \\ \text{"obj"} & 0 & 0 & 0 & 1 \\ y & 2 & -1 & 1 & 1 \end{pmatrix}$$

```
delete t:
```

Example 2

Again the first simplex tableau is created and the first phase of the simplex algorithm is finished:

```
t := linopt::Transparent([{x <= 1, y <= 1, x + y >= 2},
                          0, NonNegative]):
t := linopt::Transparent::phaseI_tableau(t):
t := linopt::Transparent::simplex(t)
```

$$\begin{pmatrix} \text{"linopt"} & \text{"restr"} & \text{slk}_4 & \text{slk}_5 & \text{slk}_6 & \text{slk}_1 & \text{slk}_2 & \text{slk}_3 & y & x \\ \text{"obj"} & 0 & 2 & 2 & 0 & 1 & 1 & 1 & 0 & 0 \\ x & 1 & 1 & 0 & 0 & 1 & 0 & 0 & 0 & 1 \\ y & 1 & 0 & 1 & 0 & 0 & 1 & 0 & 1 & 0 \\ \text{slk}_6 & 0 & -1 & -1 & 1 & -1 & -1 & -1 & 0 & 0 \end{pmatrix}$$

In this example the artificial slack variable `slk[6]` is an element of the optimal basis. So we have to use `linopt::Transparent::clean_basis` before continuing with `linopt::Transparent::phaseII_tableau`, otherwise we will get an error message:

```
linopt::Transparent::phaseII_tableau(t)
```

```
Error: Clean the basis from phase I slack variables first. [linopt::Transparent::phase
```

```
t := linopt::Transparent::clean_basis(t):
linopt::Transparent::phaseII_tableau(t)
```

$$\begin{pmatrix} \text{"linopt"} & \text{"restr"} & \text{slk}_1 & \text{slk}_2 & \text{slk}_3 & y & x \\ \text{"obj"} & 0 & 0 & 0 & 0 & 0 & 0 \\ x & 1 & 0 & -1 & -1 & 0 & 1 \\ y & 1 & 0 & 1 & 0 & 1 & 0 \\ \text{slk}_1 & 0 & 1 & 1 & 1 & 0 & 0 \end{pmatrix}$$

```
delete t:
```

Parameters

`tableau`

A simplex tableau of domain type `linopt::Transparent`

Return Values

Simplex tableau of domain type `linopt::Transparent`.

linopt::Transparent::result

Get the basic feasible solution belonging to the given simplex tableau

Syntax

```
linopt::Transparent::result(tableau)
```

Description

`linopt::Transparent::result(tableau)` returns the basic feasible solution belonging to the given simplex tableau `tableau`.

Only the user defined variables are taken into account - the dual prices can be achieved by use of `linopt::Transparent::dual_prices`.

Examples

Example 1

We first compute an edge for an initial simplex tableau:

```
k := [{x <= 1, y <= 1, x + y >= 2}, 0, NonNegative]:
t := linopt::Transparent(k):
linopt::Transparent::result(t)
```

$$\{x = 0, y = 0\}$$

Now we compute the edge for the final tableau, which is identical to the optimal solution of the linear program given by `k`. We get the final simplex tableau by using `linopt::Transparent::simplex`:

```
t := linopt::Transparent(k):
t := linopt::Transparent::simplex(t):
linopt::Transparent::result(t)
```

$$\{x = 1, y = 1\}$$

```
linopt::minimize(k)
```

$$[\text{OPTIMAL}, \{x = 1, y = 1\}, 0]$$

```
delete k, t:
```

Parameters

`tableau`

A simplex tableau of domain type `linopt::Transparent`

Return Values

Set containing the values of the user defined variables for the feasible solution.

MuPAD Functions

`linopt::Transparent` | `linopt::Transparent::dual_prices`

linopt::Transparent::simplex

Finish the current phase of the 2-phase simplex algorithm

Syntax

```
linopt::Transparent::simplex(tableau)
```

Description

`linopt::Transparent::simplex` runs the current phase of the 2-phase simplex algorithm until the end, i.e. if phase I was explicitly started (see `linopt::Transparent::phaseI_tableau`) the first phase will lead the optimal tableau. Sometimes it can be necessary to eliminate some slack variables of phase one by using `linopt::Transparent::clean_basis`.

If there was no phase I started by the user, `(linopt::Transparent)::simplex` returns the last optimal tableau or the empty set if there was no feasible solution found.

Examples

Example 1

We apply `linopt::Transparent::simplex` to an ordinary simplex tableau of a linear program and we get the optimal tableau:

```
k := [{x + y >= 2}, x, NonNegative]:
t := linopt::Transparent(k);
t := linopt::Transparent::simplex(t)
```

$$\begin{pmatrix} \text{"linopt"} & \text{"restr"} & \text{slk}_1 & y & x \\ \text{"obj"} & 0 & 0 & 0 & 1 \\ \text{slk}_1 & -2 & 1 & -1 & -1 \end{pmatrix}$$

$$\begin{pmatrix} \text{"linopt"} & \text{"restr"} & \text{slk}_1 & y & x \\ \text{"obj"} & 0 & 0 & 0 & 1 \\ y & 2 & -1 & 1 & 1 \end{pmatrix}$$

Let us proof the obtained result:

```
linopt::Transparent::suggest(t)
```

OPTIMAL

```
delete k, t:
```

Example 2

If the first phase of the simplex algorithm was started explicitly,`linopt::Transparent::simplex` returns only the optimal tableau of the first phase:

```
k := [{x + y >= 2}, y, NonNegative]:
t := linopt::Transparent(k):
t := linopt::Transparent::phaseI_tableau(t);
t := linopt::Transparent::simplex(t)
```

$$\begin{pmatrix} \text{"linopt"} & \text{"restr"} & \text{slk}_2 & \text{slk}_1 & y & x \\ \text{"obj"} & -2 & 0 & 1 & -1 & -1 \\ \text{slk}_2 & 2 & 1 & -1 & 1 & 1 \end{pmatrix}$$

$$\begin{pmatrix} \text{"linopt"} & \text{"restr"} & \text{slk}_2 & \text{slk}_1 & y & x \\ \text{"obj"} & 0 & 1 & 0 & 0 & 0 \\ y & 2 & 1 & -1 & 1 & 1 \end{pmatrix}$$

The next step of the simplex algorithm is computed:

```
linopt::Transparent::suggest(t)
```

"linopt::Transparent::phaseII_tableau"

With `linopt::Transparent::autostep` we execute the first step of the second phase of the simplex algorithm. One can see that the simplex algorithm is not finished yet:

```
t := linopt::Transparent::autostep(t):
linopt::Transparent::suggest(t);
```

$$y, x$$

If we then apply `linopt::Transparent::simplex` again we get the optimal solution. Here we don't had to use `linopt::Transparent::clean_basis`, before using `linopt::Transparent::autostep`, because there are no artificial variables in the basis computed by the first `linopt::Transparent::simplex` call above:

```
t := linopt::Transparent::simplex(t);
linopt::Transparent::suggest(t)
```

$$\begin{pmatrix} \text{"linopt"} & \text{"restr"} & \text{slk}_1 & y & x \\ \text{"obj"} & 0 & 0 & 1 & 0 \\ x & 2 & -1 & 1 & 1 \end{pmatrix}$$

OPTIMAL

```
delete k, t:
```

Parameters

`tableau`

A simplex tableau of domain type `linopt::Transparent`

Return Values

Simplex tableau of domain type `linopt::Transparent` or the empty set if there was no feasible solution found.

linopt::Transparent::suggest

Suggest the next step in the simplex algorithm

Syntax

```
linopt::Transparent::suggest(tableau)
```

Description

`linopt::Transparent::suggest(tableau)` suggests the next step in the simplex algorithm for the given simplex tableau `tableau`.

Normally this suggestion will be a pivot element, i.e. a sequence of a basic and a non-basic variable. If a phase I of the 2-phase simplex algorithm was started explicitly (see `linopt::Transparent::phaseI_tableau`) and the current tableau belongs to a feasible solution the suggestion will be the string `"linopt::Transparent::phaseII_tableau"`. At the end of the calculation the 'suggestion' is the identifier `OPTIMAL`.

The result of `linopt::Transparent::suggest` can be influenced if the global identifier `OPTIMAL` has a value. For this reason the identifier `OPTIMAL` is protected.

Examples

Example 1

We have a look at a linear program where the ordinary simplex tableau of the given problem is not the last tableau during the computation of the simplex algorithm. Looking at the ordinary simplex tableau we see that the element of the slk[2]-labeled row and the x-labeled column is a pivot element:

```
k := [{3*x + 4*y - 3*z <= 23, 5*x - 4*y - 3*z <= 10,
       7*x + 4*y + 11*z <= 30}, -x + y + 2*z, NonNegative]:
t := linopt::Transparent(k);
```

```
linopt::Transparent::suggest(t)
```

$$\begin{pmatrix} \text{"linopt"} & \text{"restr"} & \text{slk}_1 & \text{slk}_2 & \text{slk}_3 & y & x & z \\ \text{"obj"} & 0 & 0 & 0 & 0 & 1 & -1 & 2 \\ \text{slk}_1 & 23 & 1 & 0 & 0 & 4 & 3 & -3 \\ \text{slk}_2 & 10 & 0 & 1 & 0 & -4 & 5 & -3 \\ \text{slk}_3 & 30 & 0 & 0 & 1 & 4 & 7 & 11 \end{pmatrix}$$

$$\text{slk}_2,\ x$$

```
delete k, t:
```

Example 2

Here the ordinary simplex tableau still contains the solution of the linear program if the linear objective function is to minimize (see `linopt::Transparent` for more information):

```
k := [{x+y>=-1, x+y<=3}, x+2*y, NonNegative]:
t := linopt::Transparent(k);
linopt::Transparent::suggest(t)
```

$$\begin{pmatrix} \text{"linopt"} & \text{"restr"} & \text{slk}_1 & \text{slk}_2 & y & x \\ \text{"obj"} & 0 & 0 & 0 & 2 & 1 \\ \text{slk}_1 & 1 & 1 & 0 & -1 & -1 \\ \text{slk}_2 & 3 & 0 & 1 & 1 & 1 \end{pmatrix}$$

$$\text{OPTIMAL}$$

```
delete k, t:
```

Example 3

Here we explicitly start the first phase of the simplex algorithm. If we want a solution of the original linear program we have to apply the second phase of the simplex algorithm:

```
k := [{3*x + 4*y - 3*z <= 23, 5*x -4*y -3*z <= 10,
       7*x + 4*y + 11*z <= 30}, -x + y + 2*z, NonNegative]:
t := linopt::Transparent(k):
t := linopt::Transparent::phaseI_tableau(t):
t := linopt::Transparent::simplex(t):
linopt::Transparent::suggest(t)
```

```
"linopt::Transparent::phaseII_tableau"
```

```
delete k, t:
```

Parameters

`tableau`

A simplex tableau of domain type `linopt::Transparent`

Return Values

Sequence of 2 identifiers, the identifier `OPTIMAL` or the string `"linopt::Transparent::phaseII_tableau"`.

linopt::Transparent::userstep

Perform a user defined simplex step

Syntax

```
linopt::Transparent::userstep(tableau, basvar, nonbasbar)
```

Description

`linopt::Transparent::userstep(tableau, basvar, nonbasbar)` performs a user defined simplex step in the `tableau` with the pivot element defined by `basvar` and `nonbasvar`.

Examples

Example 1

We execute the simplex step given by the pivot element `(slk[1],x)`:

```
k := [{x + y >= 2}, x, NonNegative]:
t:= linopt::Transparent(k);
linopt::Transparent::userstep(t, slk[1], x)
```

$$\begin{pmatrix} \text{"linopt"} & \text{"restr"} & \text{slk}_1 & y & x \\ \text{"obj"} & 0 & 0 & 0 & 1 \\ \text{slk}_1 & -2 & 1 & -1 & -1 \end{pmatrix}$$

$$\begin{pmatrix} \text{"linopt"} & \text{"restr"} & \text{slk}_1 & y & x \\ \text{"obj"} & -2 & 1 & -1 & 0 \\ x & 2 & -1 & 1 & 1 \end{pmatrix}$$

Example 2

If we specify a wrong pivot element, we will get an error message:

```
k := [{3*x + 4*y - 3*z <= 23, 5*x - 4*y - 3*z <= 10,
       7*x + 4*y + 11*z <= 30}, -x + y + 2*z, NonNegative]:
t:= linopt::Transparent(k);
linopt::Transparent::userstep(t, x, y)
```

"linopt"	"restr"	slk_1	slk_2	slk_3	y	x	z
"obj"	0	0	0	0	1	−1	2
slk_1	23	1	0	0	4	3	−3
slk_2	10	0	1	0	−4	5	−3
slk_3	30	0	0	1	4	7	11

```
Error: The pivot element is not specified or specified incorrectly. [linopt::Transparer

delete k, t:
```

Parameters

`tableau`

A simplex tableau of domain type `linopt::Transparent`

`basvar`

A basic variable represented by an identifier that has to leave the basis

`nonbasvar`

A non-basic variable represented by an identifier that has to enter the basis

Return Values

Simplex tableau of domain type `linopt::Transparent`.

listlib – Manipulating Lists

listlib::insert
listlib::insertAt
listlib::merge
listlib::removeDuplicates
listlib::removeDupSorted
listlib::setDifference
listlib::singleMerge
listlib::sublist

listlib::insert

Insert an element into a list

Syntax

```
listlib::insert(list, element, <function>)
```

Description

`listlib::insert(list, element)` inserts `element` into `list`.

With the function `listlib::insert` any element can be inserted into any list.

With the third optional argument a function can be given that compare the elements of the list with the element to insert and therewith determines the position, the element is inserted. The given function is called with two elements and have to return `TRUE`, if the two elements are in the right order, otherwise `FALSE` (see next paragraph).

The given function is called step by step with an element of the list as first argument and the given element as second argument, until it returns `FALSE`. Then the given element is inserted into the list in *front* of the last proved element (see “Example 2” on page 17-3).

Note: The list must be ordered with regard to the order function, otherwise the element could be inserted at the wrong place.

If no third argument is given the function `_less` is used. If no order of the elements with regard to `_less` is defined, a function must be given, otherwise an error appears. The system function `sysorder` always can be used.

Examples

Example 1

Insert 3 into the given ordered list:

```
listlib::insert([1, 2, 4, 5, 6], 3)
```

$$[1, 2, 3, 4, 5, 6]$$

Insert 3 into the given descending ordered list. The insert function represents and preserves the order of the list:

```
listlib::insert([6, 5, 4, 2, 1], 3, _not@_less)
```

$$[6, 5, 4, 3, 2, 1]$$

Because identifiers cannot be ordered by `_less`, another function must be given, e.g., the function that represents the systems internal order:

```
listlib::insert([a, b, d, e, f], c, sysorder)
```

$$[a, b, c, d, e, f]$$

Example 2

Because no function is given as third argument, the function `_less` is used. `_less` is called: `_less(1, 3)`, `_less(2, 3)`, `_less(4, 3)` and then 3 is inserted in front of 4:

```
listlib::insert([1, 2, 4], 3)
```

$$[1, 2, 3, 4]$$

If the list is not ordered right, then the insert position could be wrong:

```
listlib::insert([4, 1, 2], 3)
```

$$[3, 4, 1, 2]$$

Example 3

The following example shows, how expressions can be ordered by a user defined priority. This order is given by the function named `priority`, which returns a smaller number, when the expression has a type with higher priority:

```
priority := X -> contains(["_power", "_mult", "_plus"], type(X)):
priority(x^2), priority(x + 2)
```

$$1, 3$$

The function `sortfunc` returns `TRUE`, if the both given arguments are in the right order, i.e., the first argument has a higher (or equal) priority than the second argument:

```
sortfunc := (X, Y) -> bool(priority(Y) > priority(X)):
sortfunc(x^2, x + 2), sortfunc(x + 2, x*2)
```

$$\text{TRUE}, \text{FALSE}$$

Now the expression `x*2` is inserted at the "right" place in the list:

```
listlib::insert([x^y, x^2, x*y, -y, x + y], x*2, sortfunc)
```

$$[x^y, x^2, 2\,x, x\,y, -y, x+y]$$

Parameters

`list`

MuPAD list

`element`

MuPAD expression to insert

`function`

Function that determines the insert position

Return Values

Given list enlarged with the inserted element

See Also

MuPAD Functions

`_concat` | `append` | `listlib::insertAt`

listlib::insertAt

Insert an element into a list at a given position

Syntax

```
listlib::insertAt(list, element, <pos>)
```

Description

`listlib::insertAt(list, element, pos)` inserts `element` into `list` at position `pos`.

With the function `listlib::insertAt` any element can be inserted into any list at a specified place.

The third argument (the "insert index") determines the place to insert the element into the given list.

If the insert index is less than `1` the element is inserted in front of the list. If the insertion index is greater than `nops(list)` the element is appended to the list. To append an element to a list the kernel function `append` is faster.

If no third argument is given, the given element is inserted in front of the list.

If the argument `element` is a list too, the elements of this list will be inserted (or appended) instead of the whole list by preserving the order.

Examples

Example 1

Insertion `2` at the third place of the given list:

```
listlib::insertAt([1, 1, 1], 2, 3)
```

```
[1, 1, 2, 1]
```

Insertion of an element in front of a list. The third argument is optional in this case:

```
listlib::insertAt([1, 1, 3, 1], 2, 0), listlib::insertAt([1, 1, 3, 1], 2)
```

$$[2, 1, 1, 3, 1], [2, 1, 1, 3, 1]$$

Appending of an element. This could be done faster with `append`:

```
listlib::insertAt([1, 2, 3], 4, 1000), append([1, 2, 3], 4)
```

$$[1, 2, 3, 4], [1, 2, 3, 4]$$

Parameters

`list`

A list

`element`

Any MuPAD object

`pos`

Any integer

Return Values

Given list enlarged with the inserted element

See Also

MuPAD Functions

`_concat` | `append` | `listlib::insert`

listlib::merge

Merging two ordered lists

Syntax

```
listlib::merge(list1, list2, <function>)
```

Description

`listlib::merge(list1, list2)` merges both lists into one list.

With the third optional argument a function can be given that compare the elements of the lists and therewith determines the order of the elements. The given function is called with two elements and have to return `TRUE`, if the two elements are in the right order, otherwise `FALSE` (see next paragraph).

The given function is called step by step with an element of the first list as first argument and an element of the second list as second argument, until it returns `FALSE`. Then the element of the second list is inserted into the first list in *front* of the last proved element (see “Example 2” on page 17-9).

Note: The lists must be ordered with regard to the order function, otherwise the elements could be inserted at the wrong place.

If no third argument is given the function `_less` is used. If no order of the elements with regard to `_less` is defined, a function must be given, otherwise an error appears. The system function `sysorder` always can be used.

Examples

Example 1

Merging two ascending ordered lists:

```
listlib::merge([1, 3, 5, 7], [2, 4, 6, 8])
```

$$[1, 2, 3, 4, 5, 6, 7, 8]$$

Merging two descending ordered lists:

```
listlib::merge([7, 5, 3, 1], [8, 6, 4, 2], _not@_less)
```

$$[8, 7, 6, 5, 4, 3, 2, 1]$$

Example 2

The following example shows, how expressions can be ordered by a user defined priority. This order is given by the function named `priority`, which returns a smaller number, when the expression has a type with higher priority:

```
priority := X -> contains(["_power", "_mult", "_plus"], type(X)):
priority(x^2), priority(x + 2)
```

$$1, 3$$

The function `sortfunc` returns `TRUE`, if the both given arguments are in the right order, i.e., the first argument has a higher (or equal) priority than the second argument:

```
sortfunc := (X, Y) -> bool(priority(Y) > priority(X)):
sortfunc(x^2, x + 2), sortfunc(x + 2, x*2)
```

$$\text{TRUE}, \text{FALSE}$$

Now the both lists are merged with regard to the given priority:

```
listlib::merge([x^y, x*2, -y], [x^2, x*y, x + y], sortfunc)
```

$$[x^y, x^2, 2\,x, -y, x\,y, x+y]$$

```
delete priority, sortfunc:
```

Parameters

`list1, list2`

A MuPAD list

`function`

A function that determines the merging order

Return Values

Ordered list that contains the elements of both lists

See Also

MuPAD Functions

`_concat` | `listlib::insert` | `listlib::singleMerge` | `zip`

listlib::removeDuplicates

Removes duplicate entries

Syntax

```
listlib::removeDuplicates(list, <KeepOrder>)
```

Description

`listlib::removeDuplicates(list)` removes all duplicates of each entry of the list `list`. The new list is build up from right to left with the order of the *last* occurrence of each entry in `list`. Cf. “Example 1” on page 17-11.

A faster possibibliy to remove duplicate entries is to convert the list into a `set` and back into a list. You will loose the order of the list entries in this case. Cf. “Example 3” on page 17-12.

Examples

Example 1

Per default `listlib::removeDuplicates` removes duplicate entries in reverse order:

```
list:= [1, 1, 1, 3, 1, 5, 5, 1, 3, 3, 1, 7]:
listlib::removeDuplicates(list)
```

```
[5, 3, 1, 7]
```

Example 2

With option `KeepOrder` entries are selected in the order of their occurrence:

```
list:= [1, 1, 1, 3, 1, 5, 5, 1, 3, 3, 1, 7]:
listlib::removeDuplicates(list, KeepOrder)
```

```
[1, 3, 5, 7]
```

Example 3

If you don't need the order of list entries any more, you may convert the list into a set and back into a list, this is much faster:

```
list:= [1, 1, 1, 3, 1, 5, 5, 1, 3, 3, 1, 7]:
[op({op(list)})]
```

```
[1, 3, 5, 7]
```

Parameters

`list`

A MuPAD list

Options

`KeepOrder`

`listlib::removeDuplicates(list, KeepOrder)` returns a list of the entries of `list` in the order of their *first* occurrence. The list is build up from left to right. See “Example 2” on page 17-11.

Return Values

List that contains each entry only once

See Also

MuPAD Domains
`DOM_LIST`

MuPAD Functions
`listlib::removeDupSorted`

listlib::removeDupSorted

Remove duplicates of any element from ordered lists

Syntax

```
listlib::removeDupSorted(list)
```

Description

`listlib::removeDupSorted(list)` removes all duplicates of any element of the ordered list `list`.

`listlib::removeDupSorted` does the same as `listlib::removeDuplicates`, but it assumes that the list is sorted and, therefore, it is faster. A notable gain will only occur, if there are only few duplicates in a long list.

Examples

Example 1

`listlib::removeDupSorted` removes all duplicates from the given list:

```
listlib::removeDupSorted([1, 1, 1, 3, 5, 5, 5, 5, 5, 5, 5, 7, 7, 7])
```

```
[1, 3, 5, 7]
```

If the list is not ordered, `listlib::removeDupSorted` fails:

```
listlib::removeDupSorted([1, 3, 5, 7, 1, 3, 5, 7, 1, 3, 5, 7])
```

```
[1, 3, 5, 7, 1, 3, 5, 7, 1, 3, 5, 7]
```

Parameters

`list`

An ordered MuPAD list

Return Values

List that contains every element only once

See Also

MuPAD Functions

`listlib::removeDuplicates`

listlib::setDifference

Remove elements from a list

Syntax

```
listlib::setDifference(list1, list2)
```

Description

`listlib::setDifference(list1, list2)` removes all elements from `list1`, that are given by `list2`.

Note: The order of the list is not preserved.

Examples

Example 1

`listlib::setDifference` removes `2`, `4`, `6` and `8` from the given list:

```
listlib::setDifference([1, 2, 3, 4, 5, 6, 7, 8], [2, 4, 6, 8])
```

```
[1, 3, 5, 7]
```

Parameters

`list1`, `list2`

A MuPAD list

Return Values

First list without all elements of the second list

See Also

MuPAD Functions
`minus`

listlib::singleMerge

Merging of two ordered lists without duplicates

Syntax

```
listlib::singleMerge(list1, list2, <function>)
```

Description

`listlib::singleMerge(list1, list2)` merges the both lists into one list. It is assumed that the lists are "disjunct", no element appears in both lists. Otherwise such elements are inserted only once in the result list.

With the third optional argument a function can be given that compare the elements of the lists and therewith determines the order of the elements. The given function is called with two elements and have to return `TRUE`, if the two elements are in the right order, otherwise `FALSE` (see next paragraph).

The given function is called step by step with an element of the first list as first argument and an element of the second list as second argument, until it returns `FALSE`. Then the element of the second list is inserted into the first list in *front* of the last proved element (see "Example 3" on page 17-19).

Note: The lists must be ordered with regard to the order function, otherwise the elements could be inserted at the wrong place.

If no third argument is given the function `_less` is used. If no order of the elements with regard to `_less` is defined, a function must be given, otherwise an error appears. The system function `sysorder` always can be used.

Examples

Example 1

Merging two ascending ordered lists:

```
listlib::singleMerge([1, 3, 5, 7], [2, 4, 6, 8])
```

$$[1, 2, 3, 4, 5, 6, 7, 8]$$

Merging two descending ordered lists:

```
listlib::singleMerge([7, 5, 3, 1], [8, 6, 4, 2], _not@_less)
```

$$[8, 7, 6, 5, 4, 3, 2, 1]$$

Example 2

Merging two ascending ordered lists with duplicates:

```
listlib::singleMerge([1, 2, 5, 7], [2, 5, 6, 8])
```

$$[1, 2, 5, 6, 7, 8]$$

But the following lists does not contain mutual equal elements:

```
listlib::singleMerge([1, 1, 3, 3], [2, 2, 4, 4])
```

$$[1, 1, 2, 2, 3, 3, 4, 4]$$

Example 3

The following example shows, how expressions can be ordered by a user defined priority. This order is given by the function named `priority`, which returns a smaller number when the expression has a type with higher priority:

```
priority := X -> contains(["_power", "_mult", "_plus"], type(X)):
priority(x^2), priority(x + 2)
```

$$1, 3$$

The function `sortfunc` returns `TRUE`, if the both given arguments are in the right order, i.e., the first argument has a higher (or equal) priority than the second argument:

```
sortfunc := (X, Y) -> bool(priority(Y) > priority(X)):
sortfunc(x^2, x + 2), sortfunc(x + 2, x*2)
```

$$\text{TRUE}, \text{FALSE}$$

Now the both lists are merged with regard to the given priority:

```
listlib::singleMerge([x^y, x*2, -y], [x^2, x*y, x + y], sortfunc)
```

$$[x^y, x^2, 2\,x, -y, x\,y, x+y]$$

```
delete priority, sortfunc:
```

Parameters

`list1, list2`

A MuPAD list

`function`

A function that determines the merging order

Return Values

Ordered list that contains the elements of both lists

See Also

MuPAD Functions

`_concat` | `listlib::insert` | `listlib::merge` | `zip`

listlib::sublist

Search sublists

Syntax

```
listlib::sublist(list1, list2, <index>, <Consecutive>)
```

Description

`listlib::sublist(list1, list2)` determines, whether the list `list1` contains another list `list2`.

With `listlib::sublist` the position of the first appearance of a list in another list can be determined.

The position that was found is returned as integer. If the given list does not contain the given `sublist`, the number `0` is returned.

If an index is given, the search starts at this position. There with multiple occurrence of a sublist can be determined.

With the option `Consecutive`, the list must contain the sublist in one piece without elements in between.

Examples

Example 1

The sublist is a part of the list, but not in one piece:

```
listlib::sublist([1, 2, 3, 4, 5, 6, 7, 8], [2, 3, 5, 6])
```

```
2
```

```
listlib::sublist([1, 2, 3, 4, 5, 6, 7, 8], [2, 3, 5, 6], Consecutive)
```

```
    0
```

The list contains the sublist, coherent and incoherent:

```
listlib::sublist([1, 2, 3, 4, 5, 1, 3, 5], [1, 3, 5])
```

```
    1
```

```
listlib::sublist([1, 2, 3, 4, 5, 1, 3, 5], [1, 3, 5], Consecutive)
```

```
    6
```

Example 2

Find the last occurrence of the sublist inside of the list:

```
POS:= 0:
while listlib::sublist([1, 2, 3, 1, 3, 1, 2, 3], [1, 2, 3], POS + 1) > 0 do
  POS:= listlib::sublist([1, 2, 3, 1, 3, 1, 2, 3], [1, 2, 3], POS + 1)
end_while:
POS
```

```
    6
```

```
delete POS:
```

Parameters

`list1`, `list2`

MuPAD list

`index`

Integer that determines the first search position

Options

`Consecutive`

Determines that the sublist `list2` is containing coherent in `list1`

Return Values

Position of the first element of the containing sublist or zero

MuPAD Functions
`contains` | `op`

misc – Miscellanea

misc::breakmap
misc::genassop
misc::maprec
misc::pslq

misc::breakmap

Stops the mapping currently done by maprec

Syntax

```
misc::breakmap()
```

Description

`misc::breakmap`() stops the recursive application of a function to all subexpressions of an expression that `misc::maprec` is just working on.

`misc::breakmap` is useful as a command inside the procedure mapped by `misc::maprec` in case we know that we are finished with our work and the remaining recursive mapping is not necessary.

Examples

Example 1

We want to know whether a given expression contains a particular type `t`. As soon as we have found the first occurrence of `t`, we can terminate our search.

```
myfound := FALSE:
misc::maprec(hold(((23+5.0)/3+4*I)*PI),
            {DOM_COMPLEX}=proc()
                          begin
                            myfound := misc::breakmap();
                            args()
                          end_proc):
myfound
```

```
    TRUE
```

What did we do? We told `misc::maprec` just to go down the expression tree and look for subexpressions of type `DOM_COMPLEX`; and, whenever such subexpression should be

found, to apply a certain procedure to it. That procedure stops the recursive mapping, remembers that we have found the type we had searched for, and returns exactly its argument such that the result returned by `misc::maprec` equals the input. In the example below, we test whether our given expression contains the type `DOM_POLY`.

```
myfound := FALSE:
misc::maprec(hold(((23+5.0)/3+4*I)*PI),
             {DOM_POLY}=proc()
                        begin
                          myfound := misc::breakmap();
                          args()
                        end_proc):
myfound
```

```
FALSE
```

Note that you do not need to use this method when searching for subexpressions of a given type; calling `hastype` is certainly more convenient.

Return Values

`misc::breakmap` always returns `TRUE`.

See Also

MuPAD Functions

`misc::maprec`

misc::genassop

Generates an n-ary associative operator from a binary one

Syntax

```
misc::genassop(binaryop, zeroelement)
```

Description

`misc::genassop(binaryop, zeroelement)` generates an n-ary associative operator from the binary operator `binaryop`, where `zeroelement` is a neutral element for `binaryop`.

`binaryop` must be a function taking two arguments (no matter of what kind) and returning a valid argument to itself. It must satisfy the associative law `binaryop`(`binaryop`(a, b), c) = `binaryop`(a, `binaryop`(b, c)).

`zeroelement` is an object such that `binaryop(a, zeroelement) = a` holds for every `a`.

`misc::genassop` returns a procedure which returns `zeroelement` if it is called without arguments and the argument if it is called with one argument.

Note: `misc::genassop` doesn't check whether `binaryop` is really associative and whether `zeroelement` is really a neutral element for `binaryop`.

Examples

Example 1

We know that `_plus` is an n-ary operator anyway, but let us assume that `_plus` was only a binary operator. We can create an own n-ary addition as follows:

```
myplus := misc::genassop(_plus, 0)
```

```
proc genericAssop() ... end
```

Now we make `myplus` add some values.

```
myplus(3, 4, 8), myplus(-5), myplus()
```

```
15, -5, 0
```

As mentioned in the "Details" section, `myplus` returns the argument if is called with exactly one argument, and it returns the `zeroelement` `0` if it is called without arguments.

Parameters

`binaryop`

A function

`zeroelement`

An object

Return Values

`misc::genassop` returns a procedure `f`. That procedure accepts an arbitrary number of arguments of the same kind `binaryop` does; it returns `zeroelement` if it is called without argument, and its only argument if it is called with one argument; its value on *n* arguments is inductively defined by `f(x1, ..., xn)=f(binaryop(x1,x2), x3,...,xn)`.

MuPAD Functions

`operator`

misc::maprec

Map a function to subexpressions of an expression

Syntax

```
misc::maprec(ex, selector = funci, …, <PreMap | PostMap>, <NoOperators>, <Unsimplified>
```

Description

`misc::maprec(ex, selector=funci)` maps the function `funci` to all subexpressions of the expression `ex` that satisfy a given criterion (defined by `selector`) and replaces each selected subexpression `s` by `funci(s)`.

Several different functions may be mapped to subexpressions satisfying different selection criteria.

`misc::maprec(ex, selector`$_1$ `= funci`$_1$`, …, selector`$_n$ `= funci`$_n$`)` does two steps: it tests whether `ex` meets a selection criterion defined by some selector `selector_k` (and, if yes, replaces `ex` by `funci_k(ex)`); and it applies itself recursively to all operands of `ex`. The order of these steps is determined by the options `PreMap` and `PostMap`.

Selectors are applied from left to right; if the expression meets some selection criterion, no further selectors are tried.

`selector` can have two forms. It can be a set $\{t_1, \ldots, t_n\}$. Here a subexpression `s` of `ex` is selected if type(s1) is one of the types $t_1, \ldots, t_n$. If it is not a set, a subexpression `s` of `ex` is selected if `p`(s) returns `TRUE`. As every MuPAD object may be applied as a function to `s`, `p` may be of any type in the latter case.

In order not to select a subexpression, the selector need not return `FALSE`; it suffices that it does not return `TRUE`.

If neither the option `PreMap` nor the option `PostMap` is given, then `PreMap` is used.

Use a `misc::breakmap` command inside `funci` in order to stop the recursive mapping. See the help page of `misc::breakmap` for an example.

Note: Only subexpressions of domain type `DOM_ARRAY`, `DOM_EXPR`, `DOM_LIST`, `DOM_SET`, and `DOM_TABLE` are mapped recursively, as well as domain elements of a domain `T` for which a slot `T::enableMaprec` exists and equals `TRUE`; a slot `T::map` working properly must then exist, too. To subexpressions of other types, `selector` is applied, but `misc::maprec` is not mapped to their operands. (This is to avoid unwanted substitutions.) If you want to recurse on them, either add an `enableMaprec`-slot, or use a `selector` that selects such subexpressions, and make `funci` initiate another recursive mapping.

`misc::maprec` is overloadable. If the domain of a subexpression has a method `"maprec"`, then this method is called with the subexpression and the other arguments of the call.

Note: The subexpression is replaced by the result, but `misc::maprec` is not mapped to its operands; such recursive mapping must be done by the domain method if desired.

Note: The operators of expressions (`op(expression, 0)`) are also mapped recursively like all the other operands. Use `NoOperators` to switch this off.

Examples

Example 1

In the following example every integer of the given expression `a+3+4` is substituted by the value 10. Since `10(n)` returns `10` for every integer `n`, it suffices to write `10` instead of `n -> 10` here.

```
misc::maprec(hold(a+3+4), {DOM_INT} = 10)
```

$$a + 20$$

In the example above, we used `hold` to suppress the evaluation of the expression because otherwise `a+3+4` is evaluated to `a+7` and we get the result:

```
misc::maprec(a+3+4, {DOM_INT} = 10)
```

$$a + 10$$

The simplification of the resulting `10 + 10` to `20` can be avoided by using the option `Unsimplified`:

```
misc::maprec(hold(a+3+4), {DOM_INT} = 10, Unsimplified)
```

$$a + 10 + 10$$

Example 2

Now we give an example where the `selector` is a function. We want to eleminate all the prime numbers from an expression.

```
misc::maprec(hold(_plus)(i $ i=1..20), isprime= null(), PostMap)
```

133

Here `isprime` returns `TRUE` for every prime number between 1 and 20. Every prime number between 1 and 20 is replaced by null() (since `null()(p)` gives `null()`) which means the above call computes the sum of all non-prime numbers between 1 and 20.

Example 3

Normally, `misc::maprec` recurses also into the operators of subexpressions. This may be unwanted in many cases:

```
misc::maprec(a+b, {DOM_IDENT}= (x -> x.1))
```

plus1(a1, b1)

We just wanted to replace the summands, but not the operator. Using the option `NoOperators` helps:

```
misc::maprec(a+b, {DOM_IDENT}= (x -> x.1), NoOperators)
```

$$a1 + b1$$

Parameters

`ex`

Any MuPAD object

`selector`

Any MuPAD object

`funci`

Any MuPAD object

Options

`PreMap`

For each subexpressions `s` of `ex`, the selector is applied to it *after* visiting all of its subexpressions; `s` may have changed at that time due to substitutions in the subexpressions.

`PostMap`

For each subexpressions `s` of `ex`, the selector is applied to it *before* visiting its subexpressions. If `s` is selected by `selector`, it is replaced by `funci(s)`, and `misc::maprec` is *not* recursively applied to the operands of `funci(s)`; otherwise, `misc::maprec` is recursively applied to the operands of `s`.

`NoOperators`

The selector is not applied to the operator of `ex`.

`Unsimplified`

The resulting expressions are not further simplified.

Return Values

`misc::maprec` may return any MuPAD object.

Overloaded By

ex

MuPAD Functions
`map` | `mapcoeffs` | `misc::breakmap`

misc::pslq

Heuristic detection of relations between real numbers

Syntax

```
misc::pslq(numberlist, precision)
```

Description

`misc::pslq(numberlist, precision)` returns a list of integers `[k1, ..., kn]` such that — denoting the elements of `numberlist` by `a1, ..., an` — the absolute value of $\sum_{i=0}^{n} a_i k_i$ is less than $\frac{1}{10^{\text{precision}}}$ times the Euclidean norm of `numberlist`, or `FAIL` if such integers could not be detected.

This method can be used to get an idea about linear dependencies, before proving them.

Environment Interactions

`misc::pslq` is *not* affected by the current value of `DIGITS`. Numerical computations are carried out with more significant digits such that the output meets the specification given above.

Examples

Example 1

Does π satisfy a polynomial equation of degree at most 2 ?

```
misc::pslq([1, PI, PI^2], 20)
```

```
FAIL
```

Example 2

Having forgotten the relation between sine and cosine, we can try the heuristic way.

```
misc::pslq([1, sin(0.32), sin(0.32)^2, cos(0.32), cos(0.32)^2], 10)
```

```
(1 0 -1 0 -1)
```

Parameters

`numberlist`

List of real numbers or objects that can be converted to real numbers by the function `float`.

`precision`

Positive integer

Return Values

List of integers, or `FAIL`

Algorithms

This function has been written by Raymond Manzoni.

The algorithm has been taken from Bailey and Plouffe, *Recognizing numerical constants*. See also Helaman R.P. Ferguson and David Bailey, *A Polynomial Time, Numerically Stable Integer Relation Algorithm*, RNR Technical Report RNR-92-032.

numeric::butcher

Butcher parameters of Runge-Kutta schemes

Syntax

```
numeric::butcher(EULER1 | RKF43 | xRKF43 | RK4 | RKF34 | xRKF34 | RKF54a | xRKF54a | RK
```

Description

`numeric::butcher(method)` returns the Butcher parameters of the Runge-Kutta scheme named `method`.

An s-stage Runge-Kutta method for the numerical integration of a dynamical system $\frac{dy}{dt} = f(t, y)$ with step size h is a map

$$(t, y) \to \left(t + h,\ y + h\, b_1\, k_1 + \cdots + h\, b_s\, k_s\right).$$

The "intermediate stages" $k_1, \ldots, k_s$ are defined as the solutions of the algebraic equations

$$k_i = f\left(t + c_i\, h,\ y + h\, a_{i1}\, k_1 + \cdots + h\, a_{is}\, k_s\right),\ 1 \le i \le s.$$

If the $s \times s$ "Butcher matrix" a_{ij} is strictly lower triangular, the method is called "explicit". In this case, the intermediate stages are computed recursively as:

$$\begin{aligned} k_1 &= f(t, y) \\ k_2 &= f\left(t + c_2\, h,\ y + h\, a_{21}\, k_1\right) \\ &\vdots \\ k_s &= f\left(t + c_s\, h,\ y + h\, a_{s1}\, k_1 + \ldots + h\, a_{s,s-1}\, k_{s-1}\right). \end{aligned}$$

Various numerical schemes arise from different choices of the Butcher parameters: the $s \times s$-matrix a_{ij}, the weights $b = [b_1, \ldots, b_s]$ and the abscissae $c = [c_1, c_2, \ldots, c_s]$.

Embedded pairs of Runge-Kutta methods consist of two methods that share the matrix a_{ij} and the abscissae c_i, but use different weights b_i.

The returned list `[s, c, a, b1, b2, order1, order2]` contains the Butcher data of the method: `s` is the number of stages, `c` is the list of abscissae, `a` is the Butcher matrix, b_1 and b_2 are lists of weights. The integers $order_1$ and $order_2$ are the orders of the scheme when using the weights b_1 or b_2, respectively, in conjunction with the matrix `a` and the abscissae `c`.

The methods `EULER1` (order 1), `RK4` (order 4) and `BUTCHER6` (order 6) are single methods with $b_1 = b_2$ and $order_1 = order_2$. All other methods are embedded pairs of Runge-Kutta-Fehlberg (`RKFxx`), Dormand-Prince (`DOPRIxx`) or Cash-Karp (`CKxx`) type. The names indicate the orders of the subprocesses, e.g., `CK45` is the Cash-Karp pair of orders 4 and 5. `CK54` is the same pair with reversed ordering of the subprocesses. The second subprocess is used to produce a time step of the Runge-Kutta method, the first subprocess is used for estimating the error of the time step.

The methods `GAUSS(s)` or, equivalently, `GAUSS = s` are the implicit Gauss methods with `s` stages of order $2s$.

The data of all explicit methods are returned as exact rational numbers. The data of the Gauss methods are returned as floating-point numbers.

The Butcher data are called by the routines `numeric::odesolve`, `numeric::odesolve2`, and `numeric::odesolveGeometric`.

Environment Interactions

When computing the data for `GAUSS(s)`, the function is sensitive to the environment variable `DIGITS`, which determines the numerical working precision.

Examples

Example 1

The Butcher data of the classical 4 stage, 4th order Runge-Kutta scheme are:

```
numeric::butcher(RK4)
```

$$\left[4,\ \begin{pmatrix}0 & \frac{1}{2} & \frac{1}{2} & 1\end{pmatrix},\ \begin{pmatrix}0 & 0 & 0 & 0\\ \frac{1}{2} & 0 & 0 & 0\\ 0 & \frac{1}{2} & 0 & 0\\ 0 & 0 & 1 & 0\end{pmatrix},\ \begin{pmatrix}\frac{1}{6} & \frac{1}{3} & \frac{1}{3} & \frac{1}{6}\end{pmatrix},\ \begin{pmatrix}\frac{1}{6} & \frac{1}{3} & \frac{1}{3} & \frac{1}{6}\end{pmatrix},\ 4,\ 4\right]$$

Note that the weights b_1 and b_2 coincide: this classical method does not provide an embedded pair.

The Butcher data of the (implicit) 3 stage Gauss method:

```
DIGITS := 5:
numeric::butcher(GAUSS(3));
delete DIGITS:
```

$$\left[3,\ \begin{pmatrix}0.1127 & 0.5 & 0.8873\end{pmatrix},\ \begin{pmatrix}0.13889 & -0.035977 & 0.0097894\\ 0.30026 & 0.22222 & -0.022485\\ 0.26799 & 0.48042 & 0.13889\end{pmatrix},\ \begin{pmatrix}0.27778 & 0.44444 & 0.27778\end{pmatrix},\ \begin{pmatrix}0.27778 & 0.44444 & 0.27778\end{pmatrix},\ 6,\ 6\right]$$

Example 2

The Butcher data of the embedded Runge-Kutta-Fehlberg pair `RKF34` of orders 3 and 4 are:

```
[s, c, a, b1, b2, order1, order2] := numeric::butcher(RKF34):
```

The number of stages `s` of the 4th order subprocess is 5, the abscissae `c` and the matrix `a` are given by:

```
s, c, a
```

$$5, \left(0\ \frac{1}{4}\ \frac{4}{9}\ \frac{6}{7}\ 1\right), \begin{pmatrix} 0 & 0 & 0 & 0 & 0 \\ \frac{1}{4} & 0 & 0 & 0 & 0 \\ \frac{4}{81} & \frac{32}{81} & 0 & 0 & 0 \\ \frac{57}{98} & -\frac{432}{343} & \frac{1053}{686} & 0 & 0 \\ \frac{1}{6} & 0 & \frac{27}{52} & \frac{49}{156} & 0 \end{pmatrix}$$

Using these parameters with the weights

```
b1, b2
```

$$\left(\frac{1}{6}\ 0\ \frac{27}{52}\ \frac{49}{156}\ 0\right), \left(\frac{43}{288}\ 0\ \frac{243}{416}\ \frac{343}{1872}\ \frac{1}{12}\right)$$

yields a numerical scheme of order 3 or 4, respectively:

```
order1, order2
```

$$3, 4$$

```
delete s, c, a, b1, b2, order1, order2:
```

Example 3

We plot the stability regions of the two sub-methods of `DOPRI78`. The stability function of a Runge-Kutta scheme with Butcher parameters (c, a, b) is given by

$$p(z) = 1 + z\left(\left\langle b, \frac{e}{(1 - z\,a)}\right\rangle\right),$$

where e is the column vector $(1, 1, \ldots, 1)^T$. For an explicit s-stage scheme (the matrix a is strictly lower triangular), this stability function reduces to the polynomial

$$p(z) = 1 + \left(\sum_{i=1}^{s} z^i \left(\left\langle b,\, a^{i-1}\, e \right\rangle \right) \right).$$

We compute the coefficients of the stability polynomials associated with the Butcher matrix `a` and the weights b_1 and b_2 of the sub-methods of `DOPRI78`:

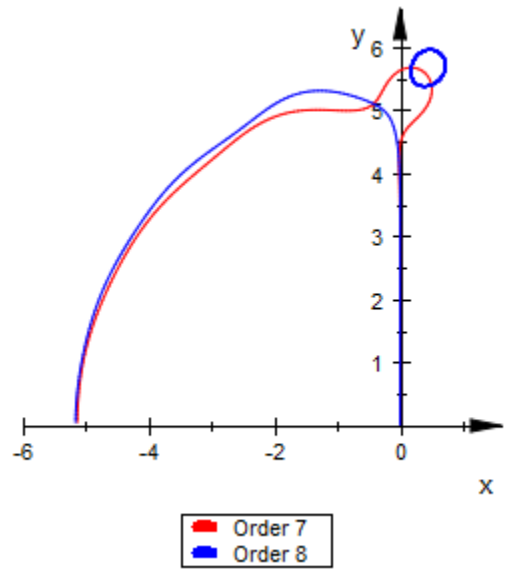
```
[s, c, a, b1, b2, order1, order2] := numeric::butcher(DOPRI78):
e := matrix([1 $ s]):
a := float(matrix(a)):
b1 := linalg::transpose(float(matrix(b1))):
b2 := linalg::transpose(float(matrix(b2))):
for i from 1 to s do
    c1[i] := (b1*a^(i-1)*e)[1, 1];
    c2[i] := (b2*a^(i-1)*e)[1, 1];
end_for:
```

We define the stability polynomials:

```
z := x + I*y:
p1 := 1 + _plus(c1[i]*z^i $ i = 1..s):
p2 := 1 + _plus(c2[i]*z^i $ i = 1..s):
```

The boundary of the stability region $\{z \in \mathbb{C} \mid |p(z)| < 1\}$ is the curve defined by $|p(z)| = 1$. We plot these implicit curves associated with the stability polynomials $p_1(z)$ and $p_2(z)$ defined above:

```
plot(plot::Implicit2d(abs(p1) = 1, x = -6..1, y = 0..6,
                      Color = RGB::Red, Legend = "Order 7"),
     plot::Implicit2d(abs(p2) = 1, x = -6..1, y = 0..6,
                      Color = RGB::Blue, Legend = "Order 8"),
     Scaling = Constrained):
```



```
delete s, c, a, b1, b2, order1, order2, e, c1, c2, z, p1, p2:
```

Parameters

s

The number of stages of the Gauss method: a positive integer

digits

The number of significant digits with which the Butcher data of the methods `GAUSS(s)` are computed. The default value for `digits` is the current value of the environment variable `DIGITS`. This argument is only relevant for the Gauss methods.

Return Values

A list `[s, c, a, b1, b2, order1, order2]` is returned.

Algorithms

The Butcher parameters provided in this original paper consist of rational *approximations* of solutions of the order equations of Runge-Kutta systems. The parameters provided by `numeric::butcher` are *exact* rational solutions of the order equations. The approximations given by Prince and Dormand coincide with the MuPAD exact values through 16 decimal digits.

MuPAD Functions

`numeric::odesolve` | `numeric::odesolve2` | `numeric::odesolveGeometric`

numeric::complexRound

Round a complex number towards the real or imaginary axis

Syntax

```
numeric::complexRound(z, <eps>)
```

Description

`numeric::complexRound(z)` discards small real or imaginary parts of complex floating-point numbers `z`.

If the real part of z satisfies $\Re(z) < eps\ |z|$, then it is replaced by zero and $\Im(z)$ i is returned.

If the imaginary part of z satisfies $\Im(z) < eps\ |z|$, then it is replaced by zero and $\Re(z)$ is returned.

With the default of `eps=10^-DIGITS`, this rounding changes a complex floating-point number by less than the relative standard precision.

Only precisions `eps >= 10^-DIGITS` are accepted.

Numerical expressions such as `eps` = $\pi\ \sqrt{2}\ 10^{-10}$ etc. are accepted as `eps`.

This function removes small real or imaginary parts of complex floating-points numbers generated by numerical roundoff. It is used to simplify the floating-point output of `numeric::fsolve`, `numeric::polyroots`, `numeric::polysysroots` and `numeric::sum`.

Environment Interactions

The function is sensitive to the environment variable `DIGITS`.

Examples

Example 1

Exact numbers are not changed:

```
numeric::complexRound(2 + I/10^20)
```

$$2 + \frac{i}{100000000000000000000}$$

Also the following number has an exact imaginary part and is not rounded:

```
numeric::complexRound(2.0 + sqrt(2)*I/10^20)
```

$$2.0 + \frac{\sqrt{2}\,i}{100000000000000000000}$$

Rounding occurs for complex floats, if this does not change its value significantly:

```
numeric::complexRound(1.0 + 2.0*I/10^10),
numeric::complexRound(1.0 + 2.0*I/10^11)
```

$$1.0 + 0.0000000002\,i,\ 1.0$$

Note that rounding is based on relative precision, i.e., only the ratio of real and imaginary parts is relevant:

```
numeric::complexRound((1.0 + 2.0*I)/10^100)
```

$$1.0\ 10^{-100} + 2.0\ 10^{-100}\,i$$

```
numeric::complexRound((1.0 + 1.0/10^11*I)/10^100)
```

$$1.0\ 10^{-100}$$

The relative precision for rounding may be reduced by the optional parameter `eps`:

```
numeric::complexRound(2.0/10^10 + I),
```

```
numeric::complexRound(2.0/10^10 + I, PI/10^5)
```

$$0.0000000002 + 1.0\,i,\ 1.0\,i$$

Parameters

z

An arbitrary MuPAD object

eps

A real number no less than $\frac{1}{10^{DIGITS}}$

Return Values

If `z` is a complex floating-point number, then a real or complex floating-point number is returned. For all other types, `z` is returned unchanged.

numeric::cubicSpline

Interpolation by cubic splines

Syntax

```
numeric::cubicSpline([x₀, y₀], [x₁, y₁], …, <BoundaryCondition>, <Symbolic>, <NoWarning>
numeric::cubicSpline([x₀, x₁, …], [y₀, y₁, …], <BoundaryCondition>, <Symbolic>, <NoWarni
numeric::cubicSpline([[x₀, x₁, …], [y₀, y₁, …]], <BoundaryCondition>, <Symbolic>, <NoWar
```

Description

`numeric::cubicSpline([x₀, y₀], [x₁, y₁], …)` returns the cubic spline function interpolating a sequence of coordinate pairs $[x_i, y_i]$.

The call `S := numeric::cubicSpline([x₀, y₀], …, [xₙ, yₙ])` yields the cubic spline function S interpolating the data $[x_0, y_0]$, …, $[x_n, y_n]$, i.e., $S(x_i) = y_i$ for $i = 0, \ldots, n$. The spline function is a piecewise polynomial of degree ≤ 3 on the intervals $(-\infty, x_1]$, $[x_1, x_2]$, …, $[x_{n-1}, \infty)$. S and its first two derivatives S', S'' are continuous at the points $x_1, \ldots, x_{n-1}$. Note that S extends the polynomial representation on $[x_0, x_1]$, $[x_{n-1}, x_n]$ to $(-\infty, x_0]$ and $[x_{n-1}, \infty)$, respectively.

By default, `NotAKnot` boundary conditions are assumed, i.e., the third derivative S''' is continuous at the points x_1 and x_{n-1}. With this boundary condition, S is a cubic polynomial on the intervals $(-\infty, x_2]$ and $[x_{n-2}, \infty)$.

By default, all input data are converted to floating-point numbers. This conversion may be suppressed by the option `Symbolic`.

Without the option `Symbolic`, the abscissae x_i must be numerical real values in ascending order. If these data are not ordered, then `numeric::cubicSpline` reorders the abscissae internally, issuing a warning. The warning may be switched off by the option `NoWarning`.

The function S returned by `numeric::cubicSpline` may be called with one, two or three arguments:

- The call `S(z)` returns an explicit expression or a number, if `z` is a real number. Otherwise, the symbolic call `S(z)` is returned.
- The call `S(z, [k])` with a nonnegative integer `k` returns the k-th derivative of S. Cf. "Example 4" on page 19-17. For $k > 3$, zero is returned for any z.
- The call `S(z, i)` is meant for symbolic arguments z. The argument i must be an integer. Internally, z is assumed to satisfy $x_i \le z < x_{i+1}$, and `S(z, i)` returns the polynomial expression in z representing the spline function on this interval.
- The call `S(z, i, [k])` with an integer i and a nonnegative integer k returns the polynomial representation of the k-th derivative of the spline function on the interval $x_i \le z < x_{i+1}$.

If `S` is generated with symbolic abscissae x_i (necessarily using the option `Symbolic`), then the call `S(z)` with numerical `z` leads to an error. The call `S(z, i)` must be used for symbolic abscissae!

Note: Note that the interpolation of 2 points (x_0, y_0), (x_1, y_1) must be specified by `numeric::cubicSpline( [x0, y0] , [x1, y1] )`, not by `numeric::cubicSpline( [x0, x1] , [y0, y1] )`!

Examples

Example 1

We demonstrate some calls with numerical input data:

```
data := [i, sin(i*PI/20)] $ i= 0..40:
S1 := numeric::cubicSpline(data):
S2 := numeric::cubicSpline(data, Natural):
S3 := numeric::cubicSpline(data, Periodic):
S4 := numeric::cubicSpline(data, Complete = [3, PI]):
```

At the abscissae, the corresponding input data are reproduced:

```
float(data[6][2]), S1(5), S2(5), S3(5), S4(5)
```

0.7071067812, 0.7071067812, 0.7071067812, 0.7071067812, 0.7071067812

0.7071067812, 0.7071067812, 0.7071067812, 0.7071067812, 0.7071067812

Interpolation between the abscissae depends on the boundary condition:

```
S1(4.5), S2(4.5), S3(4.5), S4(4.5)
```

0.6494470263, 0.6494470123, 0.6494470123, 0.6517696766

These are the cubic polynomials in z defining the spline on the interval $x_0 = 0 \le z < x_1 = 1$:

```
expand(S1(z, 0)); expand(S2(z, 0));
expand(S3(z, 0)); expand(S4(z, 0))
```

$$-0.000632116114\,z^3 - 0.00002961951081\,z^2 + 0.1570962007\,z$$

$$0.1570790998\,z - 0.0006446347923\,z^3$$

$$-0.0006446347923\,z^3 + 1.270549421\,10^{-21}\,z^2 + 0.1570790998\,z$$

$$2.080517906\,z^3 - 4.924083441\,z^2 + 3.0\,z$$

$$-0.000632116114\,z^3 - 0.00002961951081\,z^2 + 0.1570962007\,z$$

$$0.1570790998\,z - 0.0006446347923\,z^3$$

$$-0.0006446347923\,z^3 + 1.270549421\,10^{-21}\,z^2 + 0.1570790998\,z$$

$$2.080517906\,z^3 - 4.924083441\,z^2 + 3.0\,z$$

```
delete data, S1, S2, S3, S4:
```

Example 2

We demonstrate some calls with symbolic data:

```
S := numeric::cubicSpline([i, y.i] $ i = 0..3):
S(1/2)
```

$$0.3125\ y0 + 0.9375\ y1 - 0.3125\ y2 + 0.0625\ y3$$

This is the cubic polynomial in z defining the spline on the interval $x_0 = 0 \le z < x_1 = 1$:

```
S(z, 0)
```

$$y0 - z\,(1.833333333\ y0 - 3.0\ y1 + 1.5\ y2 - 0.3333333333\ y3 + z\,(2.5\ y1 - 1.0\ y0 - 2.0\ y2 + 0.5\ y3 + z\,(0.1666666667\ y0 - 0.5\ y1 + 0.5\ y2 - 0.1666666667\ y3)))$$

With the option `Symbolic`, exact arithmetic is used:

```
S := numeric::cubicSpline([i, y.i] $ i = 0..3, Symbolic):
S(1/2)
```

$$\frac{5\ y0}{16} + \frac{15\ y1}{16} - \frac{5\ y2}{16} + \frac{y3}{16}$$

Also symbolic boundary data are accepted:

```
S := numeric::cubicSpline([i, exp(i)] $ i = 0..10,
                          Complete = [a, b]):
S(0.1)
```

$$0.08341154273\ a + 0.00000005947817812\ b + 1.020064753$$

```
S := numeric::cubicSpline([0, y0], [1, y1], [2, y2],
                          Symbolic, Complete = [a, 5]):
collect(S(z, 0), z)
```

$$\left(\frac{3\ a}{4} + \frac{5\ y0}{4} - 2\ y1 + \frac{3\ y2}{4} - \frac{5}{4}\right) z^3 + \left(3\ y1 - \frac{9\ y0}{4} - \frac{7\ a}{4} - \frac{3\ y2}{4} + \frac{5}{4}\right) z^2 + a\ z + y0$$

$$\left(\frac{3\ a}{4} + \frac{5\ y0}{4} - 2\ y1 + \frac{3\ y2}{4} - \frac{5}{4}\right) z^3 + \left(3\ y1 - \frac{9\ y0}{4} - \frac{7\ a}{4} - \frac{3\ y2}{4} + \frac{5}{4}\right) z^2 + a\ z + y0$$

```
delete S:
```

Example 3

We demonstrate the use of symbolic abscissae. Here the option `Symbolic` is mandatory.

```
S := numeric::cubicSpline([x.i, y.i] $ i = 0..2, Symbolic):
```

The spline function `S` can only be called with 2 arguments. This is the cubic polynomial in `z` defining the spline on the interval $x_0 \le z < x_1$:

```
S(z, 0)
```

$$\mathrm{y0} + (\mathrm{x0} - z)\left((\mathrm{x0} - z)\left(\frac{\mathrm{y0} - \mathrm{y1}}{(\mathrm{x0} - \mathrm{x1})\,(\mathrm{x0} - \mathrm{x2})} - \frac{\mathrm{y1} - \mathrm{y2}}{(\mathrm{x0} - \mathrm{x2})\,(\mathrm{x1} - \mathrm{x2})}\right) + \frac{(\mathrm{y0} - \mathrm{y1})\,(\mathrm{x1} - 2\,\mathrm{x0} + \mathrm{x2})}{(\mathrm{x0} - \mathrm{x1})\,(\mathrm{x0} - \mathrm{x2})} + \frac{(\mathrm{x0} - \mathrm{x1})\,(\mathrm{y1} - \mathrm{y2})}{(\mathrm{x0} - \mathrm{x2})\,(\mathrm{x1} - \mathrm{x2})}\right)$$

$$\mathrm{y0} + (\mathrm{x0} - z)\left((\mathrm{x0} - z)\left(\frac{\mathrm{y0} - \mathrm{y1}}{(\mathrm{x0} - \mathrm{x1})\,(\mathrm{x0} - \mathrm{x2})} - \frac{\mathrm{y1} - \mathrm{y2}}{(\mathrm{x0} - \mathrm{x2})\,(\mathrm{x1} - \mathrm{x2})}\right) + \frac{(\mathrm{y0} - \mathrm{y1})\,(\mathrm{x1} - 2\,\mathrm{x0} + \mathrm{x2})}{(\mathrm{x0} - \mathrm{x1})\,(\mathrm{x0} - \mathrm{x2})} + \frac{(\mathrm{x0} - \mathrm{x1})\,(\mathrm{y1} - \mathrm{y2})}{(\mathrm{x0} - \mathrm{x2})\,(\mathrm{x1} - \mathrm{x2})}\right)$$

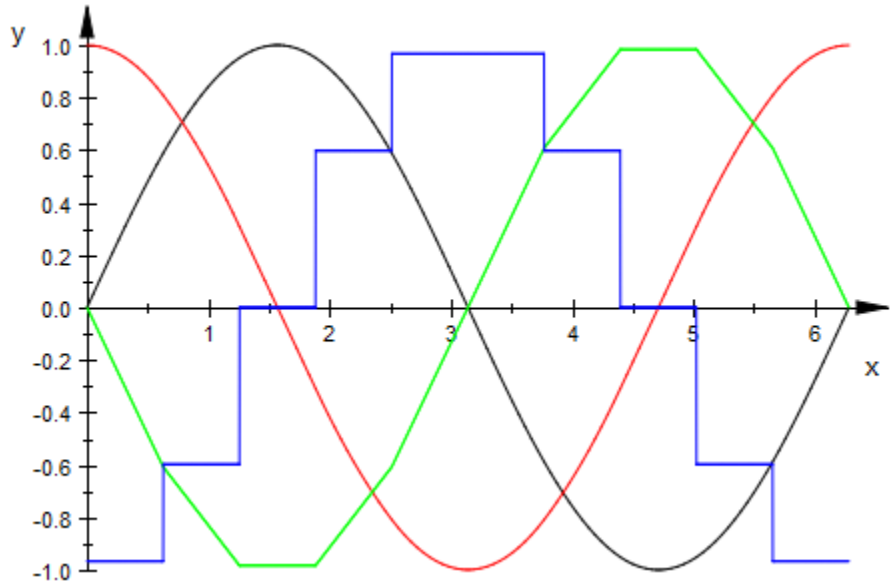
```
delete S:
```

Example 4

We plot a spline function together with its first three derivatives. The spline approximates the function $sin(x)$:

```
n := 10:
x := array(0..n, [i/n*2*PI $ i = 0..n]):
S := numeric::cubicSpline([x[i], sin(x[i])] $ i = 0..n, Natural):
delete x:
plot(
   plot::Function2d(S(x), x = 0..2*PI, Color = RGB::Black),
   plot::Function2d(S(x, [1]), x = 0..2*PI, Color = RGB::Red),
```

```
    plot::Function2d(S(x, [2]), x = 0..2*PI, Color = RGB::Green,
                     Mesh = 1000),
    plot::Function2d(S(x, [3]), x = 0..2*PI, Color = RGB::Blue,
                     Mesh = 1000)
)
```



```
delete n, S:
```

Example 5

We demonstrate how to generate a phase plot of the differential equation $x''(t) + x(t)^3 = \sin(t)$, with initial conditions $x(0) = x'(0) = 0$. First, we use `numeric::odesolve` to compute a numerical mesh of solution points $[x_i, y_i] = [x(t_i), x'(t_i)]$ with $n + 1$ equidistant time nodes $t_0, \ldots, t_n$ in the interval [0, 20]:

```
DIGITS := 4: n := 100:
for i from 0 to n do t[i] := 20/n*i: end_for:
f := (t, x) -> [x[2], sin(t) - x[1]^3]:
x[0] := 0: y[0] := 0:
for i from 1 to n do
  [x[i], y[i]] :=
```

```
  numeric::odesolve(t[i-1]..t[i], f, [x[i-1], y[i-1]]):
end_for:
```

The mesh of the $(x(t), x'(t))$ phase plot consists of the following points:

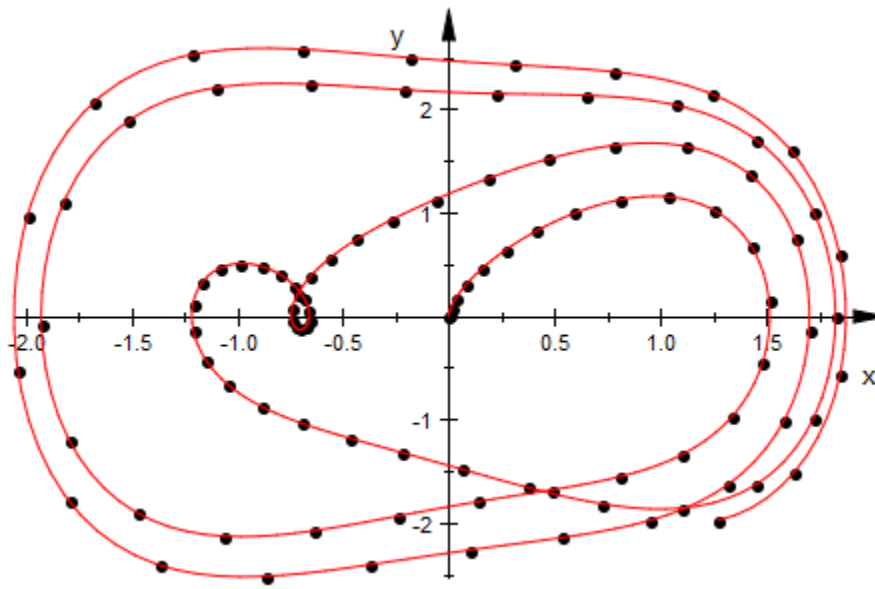
```
Plotpoints := [[x[i], y[i]] $ i = 0..n]:
```

We wish to connect these points by a spline curve. We define a spline interpoland $Sx(t)$ approximating the solution $x(t)$ by interpolating the data $[t_0, x_0]$, ..., $[t_n, x_n]$. A spline interpoland $Sy(t)$ approximating $x'(t)$ is obtained by interpolating the data $[t_0, y_0]$, ..., $[t_n, y_n]$:

```
Sx := numeric::cubicSpline([t[i], x[i]] $ i = 0..n):
Sy := numeric::cubicSpline([t[i], y[i]] $ i = 0..n):
```

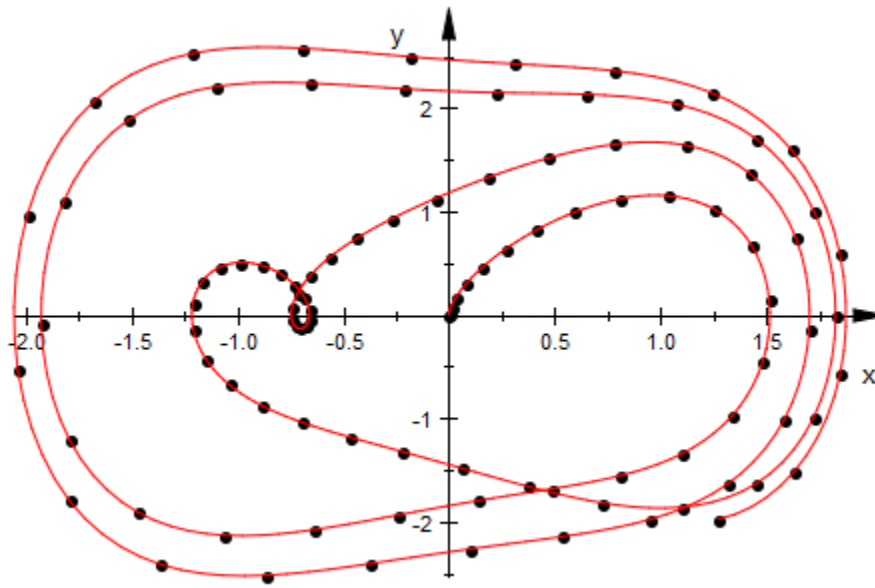
Finally, we plot the mesh points together with the interpolating spline curve:

```
plot(
     plot::PointList2d(Plotpoints, PointColor = RGB::Black),
     plot::Curve2d([Sx(z), Sy(z)], z = 0..20, Mesh = 5*(n - 1) + 1,
                   LineColor = RGB::Red)
    )
```



The functions `plot::Ode2d` and `plot::Ode3d` serve for displaying numerical solutions of ODEs. In fact, they are implemented as indicated by the previous commands. The following call produces the same plot:

```
plot(plot::Ode2d(
 [t[i] $ i = 0..n], f, [x[0], y[0]],
 [(t, x) -> [x[1], x[2]], Style = Points, Color = RGB::Black],
 [(t, x) -> [x[1], x[2]], Style = Splines, Color = RGB::Red])):
```



```
delete DIGITS, n, i, t, f, x, y, Plotpoints, Sx, Sy:
```

Parameters

x_0, x_1, …

Numerical real values in ascending order

y_0, y_1, …

Arbitrary expressions

BoundaryCondition

The type of the boundary condition: either `NotAKnot`, `Natural`, `Periodic`, or `Complete = [a, b]` with arbitrary arithmetical expressions `a, b`.

Options

Symbolic

With this option, no conversion of the input data to floating point numbers occurs.

Symbolic abscissae x_i are accepted.

The ordering $x_0 < x_1 < \ldots < x_n$ is assumed by `numeric::cubicSpline`. This ordering is not checked, even if the abscissae are numerical!

NoWarning

The x-values of the interpolation points must be in ascending order. If the input data violate this condition, the routine issues a warning and reorders the data automatically. With this option, the warning is switched off.

NotAKnot

With the default boundary condition `NotAKnot`, the third derivative S''' of the spline function is continuous at the points x_1 and x_{n-1}. With this boundary condition, S is a polynomial on the intervals $(-\infty, x_2]$ and $[x_{n-2}, \infty)$.

Natural

The boundary condition `Natural` produces a spline function S satisfying $S''(x_0) = S''(x_n) = 0$.

Periodic

The boundary condition `Periodic` produces a spline function S satisfying $S(x_0) = S(x_n)$, $S'(x_0) = S'(x_n)$, $S''(x_0) = S''(x_n)$. With this option, the input data y_0, y_n must coincide, otherwise an error is raised.

`Complete`

Option, specified as `Complete = [a, b]`

The boundary condition `Complete = [a, b]` produces a spline function S satisfying $S'(x_0) = a$, $S'(x_n) = b$. Symbolic data `a, b` are accepted.

Return Values

Spline interpoland: a MuPAD procedure.

See Also

MuPAD Functions

`interpolate` | `numeric::cubicSpline2d`

numeric::cubicSpline2d

Interpolation by 2-dimensional bi-cubic splines

Syntax

```
numeric::cubicSpline2d([x0, x1, …, xn], [y0, y1, …, ym], z, <[xBC, yBC]>, <Symbolic>)
```

Description

`numeric::cubicSpline2d([ x0, x1, ...], [ y0, y1, ...], z)` returns the bi-cubic spline function interpolating data $z_{i,j}$ over a rectangular mesh (x_i, y_j).

The call `S := numeric::cubicSpline2d([x0, …, xn], [y0, …, yn], z, Option)` yields the cubic spline function S interpolating the data $(x_i, y_j, z_{i,j})$, i.e, $S(x_i, y_j) = z_{i,j}$ for $i = 0, \ldots, n$, $j = 0, \ldots, m$. The spline function is a piecewise bi-cubic polynomial: on the 'patch'

$$p_{i,j} = \left\{ (x, y) \;\middle|\; x_i \le x < x_{i+1}, y_j \le y < y_{j+1} \right\},$$

it has the representation

$$S(x, y) = \sum_{u=0}^{3} \left(\sum_{v=0}^{3} a_{i,j}^{(u,v)} (x - x_i)^u \left(y - y_j\right)^v \right)$$

with suitable coefficients $a_{i,j}^{(u,v)}$ depending on the patch. The spline S and its partial derivatives S_x, S_y, S_{xx}, S_{xy}, S_{yy}, S_{xxy}, S_{xyy}, S_{xxyy} are continous functions over the entire x, y plane. In the x-direction, `S` extends the polynomial representation on the boundary patches $[x_0, x_1]$ and $[x_{n-1}, x_n]$ to $(-\infty, x_1]$ and $[x_{n-1}, \infty)$, respectively. The same holds with respect to the y-direction.

By default, `NotAKnot` boundary conditions are assumed, i.e., the partial derivatives S_{xxx}, S_{yyy}, …, S_{xxxyyy}, are continuous at the points with x-coordinates x_1 and x_{n-1} or y-coordinates y_1 and y_{m-1}.

By default, all input data are converted to floating-point numbers. This conversion may be suppressed by the option `Symbolic`.

Without the option `Symbolic`, the abscissae x_i, y_j must be numerical real values in ascending order. If these data are not ordered, then `numeric::cubicSpline2d` reorders the abscissae internally, issuing a warning.

The function `S` returned by `numeric::cubicSpline2d` may be called with two, three, four, or five arguments, respectively:

- The call `S(x, y)` returns an arithmetical expression if x and y are numerical expressions. A float is returned if either x or y is a float and all parameters involved can be converted to floats.

  If either x or y contains symbolic objects, the symbolic call `S(x, y)` is returned.

- The call `S(x, y, [u, v])` with nonnegative integers `u`, `v` returns the partial derivative $\frac{\partial^v}{\partial y^v}\frac{\partial^u}{\partial x^u}S$ of the spline. If either x or y contain symbolic objects, the symbolic call `S(x, y, [u, v])` is returned. The result is 0 if either $u > 3$ or $v > 3$. The calls `S(x, y, [0, 0])` and `S(x, y)` are equivalent.

- The call `S(x, y, i, j)` with nonnegative integers `i`, `j` returns the polynomial representation of the spline on the patch $p_{i,j}$. Here, x and y may be arbitrary numerical or symbolic arithmetical expressions. Internally, (x, y) are assumed to lie in the patch $p_{i,j}$.

- The call `S(x, y, i, j, [u, v])` with nonnegative integers `i`, `j`, `u`, `v` returns the polynomial representation of the partial derivatives of the spline function. In this call, x and y may be arbitrary numerical or symbolic arithmetical expressions which are assumed to lie in the patch $p_{i,j}$. The result is 0 if either $u > 3$ or $v > 3$. The calls `S(x, y, i, j, [0, 0])` and `S(x, y, i, j)` are equivalent.

If `S` is generated with symbolic abscissae x_i, y_j (necessarily using the option `Symbolic`), the call `S(x, y, [ u , v ])` is returned symbolically. The call `S(x, y, i, j, [ u , v ])` must be used for symbolic abscissae!

Examples

Example 1

We demonstrate some calls with numerical input data. The function $f(x, y) = sin(2\,\pi\,(x + y))$ with $0 \le x \le 1$, $0 \le y \le 1$ is to be interpolated by $n + 1 = 11$ equidistant points in the x-direction and $m + 1 = 13$ equidistant points in the y-direction:

```
f := (x, y) -> sin((x + y)*2*PI):
n := 10: x := [i/n $ i = 0..n]:
m := 12: y := [j/m $ j = 0..m]:
z := array(0..n, 0..m, [[f(i/n, j/m) $ j = 0..m] $ i = 0..n]):
S1 := numeric::cubicSpline2d(x, y, z, [NotAKnot, NotAKnot]):
S2 := numeric::cubicSpline2d(x, y, z, [Natural, Natural]):
S3 := numeric::cubicSpline2d(x, y, z, [NotAKnot, Periodic]):
```

We consider `Complete` boundary conditions in the y-direction. They consist of the values $f_y(x_i, y_0) = f_y(x_i, 0) = 2\,\pi\,cos(2\,\pi\,x_i)$ and $f_y(x_i, y_m) = f_y(x_i, 1) = 2\,\pi\,cos(2\,\pi\,x_i)$:

```
ybc:= [[2*PI*cos(2*PI*i/n) $ i = 0..n],
       [2*PI*cos(2*PI*i/n) $ i = 0..n]]:
S4 := numeric::cubicSpline2d(x, y, z, [Periodic, Complete = ybc]):
```

At the mesh points (x_i, y_j), the input data $z_{i,j}$ are reproduced:

```
x := 4/n: y := 8/m:
float(f(x, y)), S1(x, y), S2(x, y), S3(x, y), S4(x, y)
```

$$0.4067366431,\ 0.4067366431,\ 0.4067366431,\ 0.4067366431,\ 0.4067366431$$

Interpolation between the mesh points depends on the boundary condition:

```
x := 0.92: y:= 0.55: S1(x, y), S2(x, y), S3(x, y), S4(x, y)
```

$$0.1879484554,\ 0.1897776244,\ 0.1879457306,\ 0.1873726747$$

The approximation of the function value $f(0.92, 0.55)$ is good for the `NotAKnot`, `Periodic`, and `Complete` boundary conditions. The `Natural` boundary conditions are

less appropriate because the second partial derivatives of the function *f* do not vanish at the boundaries. Consequently, the approximation error of `S2` is larger than the other approximation errors:

```
z := float(f(x, y)):
S1(x, y) - z, S2(x, y) - z, S3(x, y) - z, S4(x, y) - z
```

$$0.0005671407743,\ 0.002396309797,\ 0.0005644160155,\ -0.00000863986878$$

This is the bi-cubic polynomial in `X`, `Y` defining the spline `S1` on the patch $x_0 = 0 \le X < x_1 = \frac{1}{n}, y_3 = \frac{3}{m} \le Y \le y_4 = \frac{4}{m}$:

```
expand(S1(X, Y, 0, 3))
```

$$-804.8629918\,X^3\,Y^3 + 6.210308852\,X^3\,Y^2 + 323.2124519\,X^3\,Y - 39.06086335\,X^3$$
$$-373.407714\,X^2\,Y^3 + 770.1743348\,X^2\,Y^2 - 297.137889\,X^2\,Y + 7.665899226\,X^2$$
$$+260.7571691\,X\,Y^3 - 199.7700052\,X\,Y^2 + 10.51686235\,X\,Y + 6.008422078\,X$$
$$+10.65805697\,Y^3 - 28.15535765\,Y^2 + 12.07773495\,Y - 0.426256024$$

```
delete f, n, m, ybc, x, y, z, S1, S2, S3, S4:
```

Example 2

We demonstrate some calls with symbolic data. With the option `Symbolic`, exact arithmetic is used:

```
S := numeric::cubicSpline2d(
       [i $ i = 0..3],
       [j $ j = 0..4],
       array(0..3, 0..4, [[z.i.j $ j = 0..4] $ i = 0..3]),
       Symbolic
    ):

S(1/2, 3/2)
```

$$\frac{5\,z01}{32} - \frac{15\,z00}{1024} + \frac{105\,z02}{512} - \frac{5\,z03}{128} + \frac{5\,z04}{1024} - \frac{45\,z10}{1024} + \frac{15\,z11}{32} + \frac{315\,z12}{512} - \frac{15\,z13}{128} + \frac{15\,z14}{1024}$$

$$+ \frac{15\,z20}{1024} - \frac{5\,z21}{32} - \frac{105\,z22}{512} + \frac{5\,z23}{128} - \frac{5\,z24}{1024} - \frac{3\,z30}{1024} + \frac{z31}{32} + \frac{21\,z32}{512} - \frac{z33}{128} + \frac{z34}{1024}$$

This is the bi-cubic polynomial in X, Y defining the spline with $x_0 = 0 \le X \le x_1 = 1$, $y_1 = 1 \le Y \le y_2 = 2$:

```
expand(S(X, Y, 0, 1))
```

$$z00 + X^2\,z00 - \frac{X^3\,z00}{6} - \frac{5\,X^2\,z10}{2} + \cdots - \frac{X\,Y\,z34}{36}$$

```
z00 - (11*X*z00)/6 + 3*X*z10 - (3*X*z20)/2 + (X*z30)/3 - (23*Y*z00)/12 + (10*Y*z01)/3

(X*Y^3*z34)/72 - (X^3*Y*z34)/72
```

```
delete S:
```

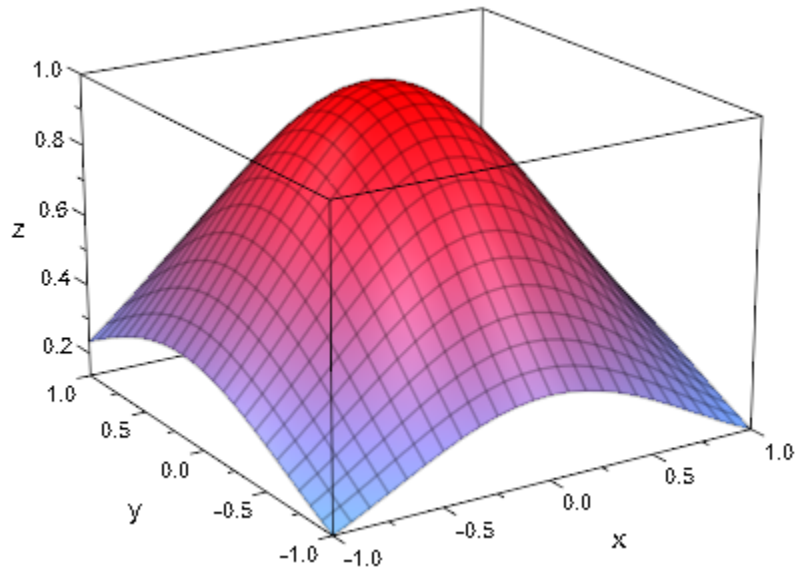
Example 3

We consider a spline interpolation of the function $f(x, y) = \frac{1}{e^{x^2+y^2}}$ with $-1 \le x \le 1$, $-1 \le y \le 1$:

```
n := 10: xmesh := [-1 + 2*i/n $ i = 0..n]:
m := 12: ymesh := [-1 + 2*j/n $ j = 0..m]:
f := (x, y) -> exp(-x^2 - y^2):
z := array(0..n, 0..m,
     [[f(-1 + 2*i/n, -1 + 2*j/m) $ j=0..m] $ i = 0..n]):
S := numeric::cubicSpline2d(xmesh, ymesh, z):
```

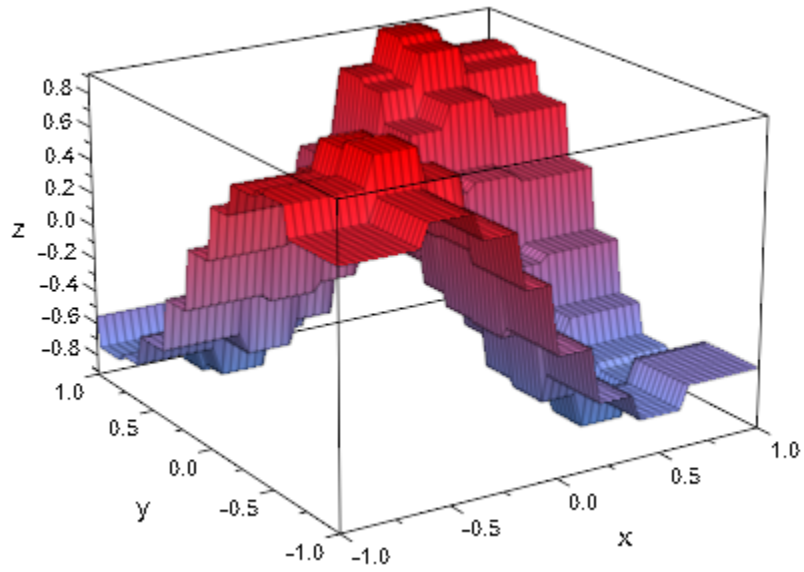
We plot the spline function $S(x, y)$:

```
plotfunc3d(S(x, y), x = -1 .. 1, y = -1 .. 1):
```



We plot the partial derivative $S_{xxxyyy}(x, y)$. It is constant on each patch with jumps at the boundaries of the patches. The renderer uses $[5\,n + 1, 5\,m + 1]$ mesh points: in each direction, 4 extra points between adjacent mesh points of the spline are used for the graphical representation:

```
plotfunc3d(S(x, y, [3, 3])/10, x = -1 .. 1, y = -1 .. 1,
           Mesh = [5*n + 1, 5*m+ 1])
```



```
delete n, xmesh, m, ymesh, f, z, S:
```

Example 4

We demonstrate the spline interpretation of a surface. We consider a sphere parametrized by spherical coordinates u, v with $0 \le u \le 2\,\pi$, $0 \le v \le \pi$:

$$x = \cos(u)\,\sin(v),\ y = \sin(u)\,\sin(v),\ z = \cos(v)$$

We interpolate the functions x, y, z over a rectangular mesh in the u-v-plane. Since x, y and (trivally) z are $2\,\pi$-periodic in u, we choose `Periodic` boundary conditions for u. For v, we choose `Complete` boundary conditions with boundary values of the first partial v-derivative fitting the parametrization:

```
x:= (u, v) -> cos(u)*sin(v): x_v := diff(x(u, v), v):
y:= (u, v) -> sin(u)*sin(v): y_v := diff(y(u, v), v):
z:= (u, v) -> cos(v): z_v := diff(z(u, v), v):
n := 4: umesh := [i*2*PI/n $ i = 0..n]:
m := 4: vmesh := [j*PI/m $ j = 0..m]:
```

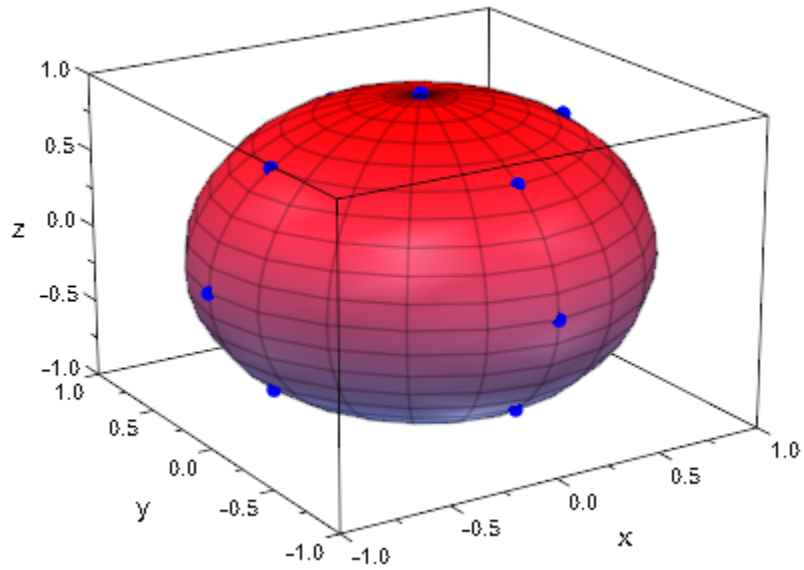
```
vBC := Complete = [
    [subs(x_v, u = umesh[i], v = vmesh[1]) $ i = 1 .. n+1],
    [subs(x_v, u = umesh[i], v = vmesh[n + 1]) $ i = 1 .. n+1]]:
X := numeric::cubicSpline2d(umesh, vmesh,
  array(0..n, 0..m, [[x(i*2*PI/n, j*PI/m) $ j=0..m] $ i=0..n]),
  [Periodic, vBC]):

vBC := Complete = [
    [subs(y_v, u = umesh[i], v = vmesh[1]) $ i = 1 .. n+1],
    [subs(y_v, u = umesh[i], v = vmesh[n + 1]) $ i = 1 .. n+1]]:
Y := numeric::cubicSpline2d(umesh, vmesh,
   array(0..n, 0..m, [[y(i*2*PI/n, j*PI/m) $ j=0..m] $ i=0..n]),
   [Periodic, vBC]):

vBC := Complete = [
    [subs(z_v, u = umesh[i], v = vmesh[1]) $ i = 1 .. n+1],
    [subs(z_v, u = umesh[i], v = vmesh[n + 1]) $ i = 1 .. n+1]]:
Z := numeric::cubicSpline2d(umesh, vmesh,
   array(0..n, 0..m, [[z(i*2*PI/n, j*PI/m) $ j=0..m] $ i=0..n]),
   [Periodic, vBC]):
```

With only $(n + 1)\times(m + 1) = 5\times5$ mesh points, the spline surface yields a respectable approximation of a sphere. The interpolation nodes are added to the plot as blue points:

```
plot(
  plot::Surface([X(u, v), Y(u, v), Z(u, v)],
                u = 0..2*PI, v = 0..PI,
                Mesh = [5*n + 1, 5*m + 1],
                Color = RGB::Red),
  plot::Point3d(x(umesh[i], vmesh[j]),
               y(umesh[i], vmesh[j]),
               z(umesh[i], vmesh[j]),
               PointSize = 2*unit::mm,
               Color = RGB::Blue
              ) $ i = 1..n+1 $ j = 1..m+1
):
```



```
delete x, x_v, y, y_v, z, z_v, n, m,
       umesh, vmesh, vBC, X, Y, Z:
```

Parameters

x_0, x_1, …, x_n

The *x*-coordinates of the nodes: distinct numerical real values in ascending order

y_0, y_1, …, y_m

The *y*-coordinates of the nodes: distinct numerical real values in ascending order

z

The function values: an array of the form `array(0..n, 0..m, [...])` with numerical or symbolic arithmetical expressions.

xBC, yBC

The type of the boundary condition: the boundary condition in the *x*- or *y*-direction may be one of the flags `NotAKnot`, `Natural`, `Periodic` or `Complete = [...]`.

`Complete` boundary conditions consist of prescribed values for the derivatives S_x or S_y, respectively, along the mesh boundaries in the x- or y-direction, respectively. In the x-direction, these value may be passed in the form `Complete = [[a0, …, am], [b0, …, bm]]` with arbitrary numerical or symbolic arithmetical expressions `a0, …, bm`.

In the y-direction, these value may be passed in the form `Complete = [[a0, …, an], [b0, …, bn]]` with arbitrary numerical or symbolic arithmetical expressions `a0, …, bn`.

Options

Symbolic

With this option, no conversion of the input data to floating point numbers occurs.

Symbolic abscissae x_i, y_j are accepted.

The ordering $x_0 < x_1 < \ldots < x_n$, $y_0 < y_1 < \ldots < y_m$ is assumed. This ordering is not checked even if the node coordinates are numerical!

NotAKnot

With the default boundary condition `xBC = yBC = NotAKnot`, all partial derivatives of the spline function are continuous at the nodes with x-coordinates x_1 and x_{n-1} or y-coordinates y_1 and y_{m-1}, respectively. With this boundary condition, `S` is a polynomial on the union of the patches $p_{0,j}$, $p_{1,j}$ and $p_{n-2,j}$, $p_{n-1,j}$ or $p_{i,0}$, $p_{i,1}$ and $p_{i,m-2}$, $p_{i,m-1}$, respectively.

This boundary condition is recommended if no information on the behaviour of the data near the mesh boundaries is available.

Natural

The boundary condition `Natural` produces a spline function `S` with vanishing second partial derivatives at the boundary of the mesh.

This boundary condition is recommended if it is known that the data correspond to a surface with vanishing curvature near the mesh boundaries.

Periodic

The boundary condition `Periodic` produces a spline function `S` satisfying

$$S(x_0, y) = S(x_n, y),\ S'(x_0, y) = S'(x_n, y),\ S''(x_0, y) = S''(x_n, y)$$

Or

$$S(x, y_0) = S(x, y_m),\ S'(x, y_0) = S'(x, y_m),\ S''(x, y_0) = S''(x, y_m)\ ,$$

Respectively. With this option, the input data $z_{0,j}$, $z_{n,j}$, respectively $z_{i,0}$, $z_{i,m}$, must coincide. Otherwise, an error is raised.

This boundary condition is recommended if the interpolation is to represent a periodic function.

`Complete`

Option, specified as `Complete = [...]`

The `xBC` boundary condition `Complete = [[a0, …, am], [b0, …, bm]]` produces a spline function S satisfying $S_x(x_0, y_j) = a_j$, $S_x(x_n, y_j) = b_j$, $j = 0, \ldots, m$.

The `yBC` boundary condition `Complete = [[a0, …, an], [b0, …, bn]]` produces a spline function S satisfying $S_y(x_i, y_0) = a_i$, $S_y(x_i, y_m) = b_i$, $i = 0, \ldots, n$.

Symbolic data a_k, b_k are accepted.

This boundary condition is recommended if the data $z_{i,j}$ correpond to a function with known values of the first partial derivatives at the mesh boundaries.

Return Values

Spline function: a MuPAD procedure.

MuPAD Functions

`interpolate` | `numeric::cubicSpline`

numeric::det

Determinant of a matrix

Syntax

```
numeric::det(A, <mode>, <MinorExpansion>, <NoWarning>)
```

Description

`numeric::det(A)` returns the determinant of the matrix *A*.

Without the option `Symbolic`, all entries of `A` must be numerical. Numerical expressions such as e^{π}, $\sqrt{2}$ etc. are accepted and converted to floats. If symbolic entries are found in the matrix, `numeric::det` automatically switches to `Symbolic` issuing a warning.

The option `Symbolic` should be used if the matrix contains symbolic objects that cannot be converted to floating point numbers.

Note: Matrices `A` of a matrix domain such as `Dom::Matrix(...)` or `Dom::SquareMatrix(...)` are internally converted to arrays over expressions via `expr(A)`. Note that `det` must be used, when the determinant is to be computed over the component domain. See “Example 2” on page 19-37. Note that the option `Symbolic` should be used if the entries cannot be converted to numerical expressions.

Environment Interactions

Without the option `Symbolic`, the function is sensitive to the environment variable `DIGITS`, which determines the numerical working precision.

Examples

Example 1

Numerical matrices can be processed with or without the option `Symbolic`:

```
A := array(1..3, 1..3,[[1, 1, I], [1, exp(1), I], [1, 2, 2]]):
numeric::det(A), numeric::det(A, Symbolic)
```

$$3.436563657 - 1.718281828\,i,\ e\,(2 - i) - 2 + i$$

The option `Symbolic` must be used when the matrix has non-numerical entries:

```
A := array(1..2, 1..2, [[1/(x + 1),  1], [1/(x + 2), PI]]):
numeric::det(A, Symbolic)
```

$$\frac{2\,\pi - x + \pi\,x - 1}{(x+1)\,(x+2)}$$

If the option `MinorExpansion` is used, symbolic entries are accepted, even if the option `Symbolic` is not specified:

```
detN := numeric::det(A, MinorExpansion);
detS := numeric::det(A, Symbolic, MinorExpansion)
```

$$\frac{0.0000000008\,(2676990817.0\,x + 6603981634.0)}{(x+1.0)\,(x+2.0)}$$

$$\frac{2\,\pi - x + \pi\,x - 1}{(x+1)\,(x+2)}$$

Simplify these results using `Simplify`:

```
Simplify(detN), Simplify(detS)
```

$$\frac{3.141592654}{x+1.0} - \frac{1.0}{x+2.0},\ \frac{\pi}{x+1} - \frac{1}{x+2}$$

```
delete A:
```

Example 2

The following matrix has domain components:

```
A := Dom::Matrix(Dom::IntegerMod(7))([[6, -1], [1, 6]])
```

$$\begin{pmatrix} 6 \bmod 7 & 6 \bmod 7 \\ 1 \bmod 7 & 6 \bmod 7 \end{pmatrix}$$

Note that `numeric::det` computes the determinant of the following matrix:

```
expr(A), numeric::det(A)
```

$$\begin{pmatrix} 6 & 6 \\ 1 & 6 \end{pmatrix}, 30.0$$

`det` must be used, if the determinant is to be computed over the component domain `Dom::IntegerMod(7)`:

```
det(A)
```

$$2 \bmod 7$$

```
delete A:
```

Example 3

We demonstrate the use of hardware floats. Hilbert matrices are notoriously ill-conditioned: the computation of the determinant is subject to severe cancellation effects. The following results, both with `HardwareFloats` as well as with `SoftwareFloats`, are marred by numerical roundoff:

```
A := linalg::hilbert(15):
float(numeric::det(A, Symbolic)),
numeric::det(A, HardwareFloats),
numeric::det(A, SoftwareFloats)
```

$$1.058542743\ 10^{-124},\ -3.822215463\ 10^{-121},\ 3.277553006\ 10^{-123}$$

```
delete A:
```

Parameters

A

A square matrix of domain type DOM_ARRAY, or DOM_HFARRAY, or of category Cat::Matrix

mode

One of the flags Hard, HardwareFloats, Soft, SoftwareFloats, or Symbolic

Options

Hard, HardwareFloats, Soft, SoftwareFloats

With Hard (or HardwareFloats), computations are done using fast hardware float arithmetic from within a MuPAD session. Hard and HardwareFloats are equivalent. With this option, the input data are converted to hardware floats and processed by compiled C code. The result is reconverted to MuPAD floats and returned to the MuPAD session.

With Soft (or SoftwareFloats) computations are dome using software float arithmetic provided by the MuPAD kernel. Soft and SoftwareFloats are equivalent. SoftwareFloats is used by default if the current value of DIGITS is larger than 15 and the input matrix A is not of domain type DOM_HFARRAY.

Compared to the SoftwareFloats used by the MuPAD kernel, the computation with HardwareFloats may be many times faster. Note, however, that the precision of hardware arithmetic is limited to about 15 digits. Further, the size of floating-point numbers may not be larger than approximately 10^{308} and not smaller than approximately 10^{-308}.

If no HardwareFloats or SoftwareFloats are requested explicitly, the following strategy is used: If the current value of DIGITS is smaller than 16 or if the matrix A is a hardware float array of domain type DOM_HFARRAY, then hardware arithmetic is tried. If this is successful, the result is returned.

If the result cannot be computed with hardware floats, software arithmetic by the MuPAD kernel is tried.

If the current value of `DIGITS` is larger than 15 and the input matrix `A` is not of domain type `DOM_HFARRAY`, or if one of the options `Soft`, `SoftwareFloats` or `Symbolic` is specified, MuPAD computes the result with its software arithmetic without trying to use hardware floats first.

There may be several reasons for hardware arithmetic to fail:

- The current value of `DIGITS` is larger than 15.
- The data contains symbolic objects.
- The data contains numbers larger than 10^{308} or smaller than 10^{-308} that cannot be represented by hardware floats.

If neither `HardwareFloats` nor `SoftwareFloats` is specified, the user is not informed whether hardware floats or software floats are used.

If `HardwareFloats` are specified but fail due to one of the reasons above, a warning is issued that the (much slower) software floating-point arithmetic of the MuPAD kernel is used.

Note that `HardwareFloats` can only be used if all input data can be converted to floating-point numbers.

The trailing digits in floating-point results computed with `HardwareFloats` and `SoftwareFloats` may differ.

Note: For ill conditioned matrices the results returned with `HardwareFloats` and `SoftwareFloats` may differ significantly! See “Example 3” on page 19-37.

`Symbolic`

This option prevents conversion of the input data to floats. With this option, symbolic entries are accepted. It overrides the option `HardwareFloats`.

Note: This option should not be used for floating-point matrices! The `Symbolic` algorithm does not implement safeguards against numerical instabilities in floating-point operations.

`MinorExpansion`

With this option, recursive minor expansion along the columns is used. This option may be useful for small matrices with symbolic entries.

This option implies `SoftwareFloats`.

With this option, symbolic entries are accepted even if the option `Symbolic` is not used.

`NoWarning`

Suppresses warnings

Return Values

By default, the determinant is returned as a floating-point number. With the option `Symbolic`, an expression is returned.

Algorithms

Without the option `Symbolic`, *QR*-factorization of *A* via Householder transformations is used.

With `Symbolic`, *LU*-factorization of *A* is used.

MuPAD Functions
`det`

numeric::eigenvalues

Numerical eigenvalues of a matrix

Syntax

```
numeric::eigenvalues(A, options)
```

Description

`numeric::eigenvalues(A)` returns numerical eigenvalues of the matrix `A`.

All entries of `A` must be numerical. Numerical expressions such as e^{π}, $\sqrt{2}$ etc. are accepted and converted to floats. Non-numerical symbolic entries lead to an error.

Note: Matrices `A` of a matrix domain such as `Dom::Matrix(...)` or `Dom::SquareMatrix(..)` are internally converted to arrays over expressions via `expr(A)`. Note that `linalg::eigenvalues` must be used, when the eigenvalues are to be computed over the component domain. Cf. “Example 2” on page 19-43.

The eigenvalues are sorted by `numeric::sort`.

Note: Eigenvalues are approximated with an *absolute* precision of $\frac{r}{10^{\mathrm{DIGITS}}}$, where r is the spectral radius of `A` (i.e., r is the maximum of the absolute values of the eigenvalues). Consequently, large eigenvalues should be computed correctly to `DIGITS` decimal places. The numerical approximations of the small eigenvalues are less accurate.

Environment Interactions

The function is sensitive to the environment variable `DIGITS`, which determines the numerical working precision.

Examples

Example 1

We compute the eigenvalues of the 3×3 Hilbert matrix:

```
numeric::eigenvalues(linalg::hilbert(3))
```

$$[1.408318927, 0.1223270659, 0.002687340356]$$

The following matrix is ill-conditioned. It has very large as well as very small eigenvalues:

```
A := array(1..3, 1..3,
           [[   I     ,     PI    ,  exp(1)  ],
            [   2     ,  10^100   ,    1     ],
            [10^(-100), 10^(-100), 10^(-100)]
           ]):
```

Precision goal and working precision are set by `DIGITS`. With the standard setting of *DIGITS* = 10, the following result is computed with `HardwareFloats`:

```
numeric::eigenvalues(A)
```

$$\left[1.0\,10^{100},\ 5.0\,10^{-101},\ 1.0\,i\right]$$

$$\left[1.0\,10^{100},\ 5.0\,10^{-101},\ 1.0\,i\right]$$

Note that small eigenvalues may be influenced by roundoff. We increase the working precision by increasing `DIGITS`. The smallest of the eigenvalues is computed more accurately:

```
DIGITS := 200:
eigenvals := numeric::eigenvalues(A):
DIGITS := 5:
eigenvals;
```

$$\left[1.0\,10^{100} + 6.2832\,10^{-200}\,i,\ 1.0\,10^{-100} + 2.7183\,10^{-100}\,i,\ -6.2832\,10^{-100} + 1.0\,i\right]$$

```
delete A, eigenvals, DIGITS:
```

Example 2

The following matrix has domain components:

```
A := Dom::Matrix(Dom::IntegerMod(7))(
    [[6, -1, 4], [0,  3, 3], [0,  0, 3]])
```

$$\begin{pmatrix} 6 \bmod 7 & 6 \bmod 7 & 4 \bmod 7 \\ 0 \bmod 7 & 3 \bmod 7 & 3 \bmod 7 \\ 0 \bmod 7 & 0 \bmod 7 & 3 \bmod 7 \end{pmatrix}$$

Note that `numeric::eigenvalues` computes the eigenvalues of the following matrix:

```
expr(A), numeric::eigenvalues(A)
```

$$\begin{pmatrix} 6 & 6 & 4 \\ 0 & 3 & 3 \\ 0 & 0 & 3 \end{pmatrix}, [6.0, 3.0, 3.0]$$

If the eigenvalues are to be computed over the component domain `Dom::IntegerMod(7)`, `linalg::eigenvalues` should be used:

```
linalg::eigenvalues(A, Multiple)
```

$$[[3 \bmod 7, 2], [6 \bmod 7, 1]]$$

```
delete A:
```

Example 3

We demonstrate the use of hardware floats. Hilbert matrices are notoriously ill-conditioned: the computation of small eigenvalues is subject to severe roundoff effects. In the following results, both with `HardwareFloats` as well as with `SoftwareFloats`, the small eigenvalues are marred by numerical roundoff:

```
A := linalg::hilbert(15):
```

```
numeric::eigenvalues(A, HardwareFloats),
numeric::eigenvalues(A, SoftwareFloats)
```

$$\left[1.845927746,\ \ldots,\ 8.619013323\ 10^{-17},\ 2.268836709\ 10^{-17}\right],$$

$$\left[1.845927746,\ \ldots,\ 2.095930088\ 10^{-18},\ 6.646989777\ 10^{-21}\right]$$

```
delete A:
```

Parameters

A

A numerical matrix of domain type `DOM_ARRAY`, `DOM_HFARRAY`, or of category `Cat::Matrix`.

Options

`Hard`, `HardwareFloats`, `Soft`, `SoftwareFloats`

With `Hard` (or `HardwareFloats`), computations are done using fast hardware float arithmetic from within a MuPAD session. `Hard` and `HardwareFloats` are equivalent. With this option, the input data are converted to hardware floats and processed by compiled C code. The result is reconverted to MuPAD floats and returned to the MuPAD session.

With `Soft` (or `SoftwareFloats`) computations are dome using software float arithmetic provided by the MuPAD kernel. `Soft` and `SoftwareFloats` are equivalent. `SoftwareFloats` is used by default if the current value of `DIGITS` is larger than 15 and the input matrix `A` is not of domain type `DOM_HFARRAY`.

Compared to the `SoftwareFloats` used by the MuPAD kernel, the computation with `HardwareFloats` may be many times faster. Note, however, that the precision of hardware arithmetic is limited to about 15 digits. Further, the size of floating-point numbers may not be larger than approximately 10^{308} and not smaller than approximately 10^{-308}.

If no HardwareFloats or SoftwareFloats are requested explicitly, the following strategy is used: If the current value of DIGITS is smaller than 16 or if the matrix A is a hardware float array of domain type DOM_HFARRAY, then hardware arithmetic is tried. If this is successful, the result is returned.

If the result cannot be computed with hardware floats, software arithmetic by the MuPAD kernel is tried.

If the current value of DIGITS is larger than 15 and the input matrix A is not of domain type DOM_HFARRAY, or if one of the options Soft, SoftwareFloats or Symbolic is specified, MuPAD computes the result with its software arithmetic without trying to use hardware floats first.

There may be several reasons for hardware arithmetic to fail:

- The current value of DIGITS is larger than 15.
- The data contains symbolic objects.
- The data contains numbers larger than 10^{308} or smaller than 10^{-308} that cannot be represented by hardware floats.

If neither HardwareFloats nor SoftwareFloats is specified, the user is not informed whether hardware floats or software floats are used.

If HardwareFloats are specified but fail due to one of the reasons above, a warning is issued that the (much slower) software floating-point arithmetic of the MuPAD kernel is used.

Note that HardwareFloats can only be used if all input data can be converted to floating-point numbers.

The trailing digits in floating-point results computed with HardwareFloats and SoftwareFloats may differ.

Note: For ill conditioned matrices the results returned with HardwareFloats and SoftwareFloats may differ significantly! See “Example 3” on page 19-43.

NoWarning

Suppresses warnings

Return Values

Ordered list of numerical eigenvalues

Algorithms

The function implements standard numerical algorithms from the Handbook of Automatic Computation by Wilkinson and Reinsch.

MuPAD Functions

`linalg::eigenvalues` | `linalg::eigenvectors` | `numeric::eigenvectors` | `numeric::singularvalues` | `numeric::singularvectors` | `numeric::spectralradius`

numeric::eigenvectors

Numerical eigenvalues and eigenvectors of a matrix

Syntax

```
numeric::eigenvectors(A, options)
```

Description

`numeric::eigenvectors(A)` returns numerical eigenvalues and eigenvectors of the matrix `A`.

All entries of the matrix must be numerical. Numerical expressions such as e^{π}, $\sqrt{2}$ etc. are accepted and converted to floats. Non-numerical symbolic entries lead to an error.

The eigenvalues are sorted by `numeric::sort`.

The matrix `X` provides the eigenvectors: the *i*-th column of `X` is a numerical eigenvector corresponding to the eigenvalue `d[i]`. Each column is either zero or normalized to the Euclidean length 1.0.

For matrices with multiple eigenvalues and an insufficient number of eigenvectors, some of the eigenvectors may coincide or may be zero, i.e., `X` is not necessarily invertible.

The list of residues *res* = [res_1, res_2, …] provides some control over the quality of the numerical spectral data. The residues are given by

$$\mathrm{res}_i = \left\| A\, x_i - d_i\, x_i \right\|_2 ,$$

where x_i is the normalized eigenvector (the *i*-th column of `X`) associated with the numerical eigenvalue d_i. For Hermitian matrices, res_i provides an upper bound for the absolute error of d_i.

With the option `NoResidues`, the computation of the residues is suppressed, the returned value is `NIL`.

If no return type is specified via the option `ReturnType = t`, the domain type of the eigenvector matrix `X` depends on the type of the input matrix `A`:

- The eigenvectors of an array are returned as an array.
- The eigenvectors of an hfarray are returned as an hfarray.
- The eigenvectors of a dense matrix of type `Dom::DenseMatrix()` are returned as a dense matrix of type `Dom::DenseMatrix()` over the ring of expressions.
- For all other matrices of category `Cat::Matrix`, the eigenvectors are returned as matrices of type `Dom::Matrix()` over the ring of MuPAD expressions. This includes input matrices `A` of type `Dom::Matrix(...)`, `Dom::SquareMatrix(...)`, `Dom::MatrixGroup(...)` etc.

Note: Matrices `A` of a matrix domain such as `Dom::Matrix(...)` or `Dom::SquareMatrix(...)` are internally converted to arrays over expressions via `expr(A)`. Note that `linalg::eigenvectors` must be used, when the eigenvalues/vectors are to be computed over the component domain. Cf. “Example 3” on page 19-50.

Note: Eigenvalues are approximated with an *absolute* precision of $\frac{r}{10^{\mathrm{DIGITS}}}$, where r is the spectral radius of `A` (i.e., r is the maximal singular value of `A`). Consequently, large eigenvalues should be computed correctly to `DIGITS` decimal places. The numerical approximations of the small eigenvalues are less accurate.

Note: For a numerical algorithm, it is not possible to distinguish between badly separated distinct eigenvalues and multiple eigenvalues. For this reason, `numeric::eigenvectors` and `linalg::eigenvectors` use different return formats: the latter can provide information on the multiplicity of eigenvalues due to its internal exact arithmetic.

Use `numeric::eigenvalues` if only eigenvalues are to be computed.

Environment Interactions

The function is sensitive to the environment variable `DIGITS`, which determines the numerical working precision.

Examples

Example 1

We compute the spectral data of the 2×2 Hilbert matrix:

```
A := linalg::hilbert(2)
```

$$\begin{pmatrix} 1 & \frac{1}{2} \\ \frac{1}{2} & \frac{1}{3} \end{pmatrix}$$

```
[d, X, res] := numeric::eigenvectors(A):
```

The eigenvalues:

```
d
```

$$[1.267591879,\ 0.06574145409]$$

The eigenvectors:

```
X
```

$$\begin{pmatrix} 0.8816745988 & -0.4718579255 \\ 0.4718579255 & 0.8816745988 \end{pmatrix}$$

Hilbert matrices are Hermitian, i.e., computing the spectral data is a numerically stable process. This is confirmed by the small residues:

```
res
```

$$[2.355138688\ 10^{-16},\ 1.388645872\ 10^{-16}]$$

The routine `linalg::hilbert` provides the input as a matrix of type `Dom::Matrix()`. Consequently, the eigenvectors also consist of such a matrix. For further processing, we convert the list of eigenvalues to a diagonal matrix:

```
d := matrix(2, 2, d, Diagonal):
```

We reconstruct the matrix from its spectral data:

```
X*d*X^(-1)
```

$$\begin{pmatrix} 1.0 & 0.5 \\ 0.5 & 0.3333333333 \end{pmatrix}$$

We extract an eigenvector from the matrix `X` and doublecheck its numerical quality:

```
eigenvector1 := X::dom::col(X, 1);
norm(A*eigenvector1 - d[1, 1]*eigenvector1)
```

$$\begin{pmatrix} 0.8816745988 \\ 0.4718579255 \end{pmatrix}$$

$$1.769417945\ 10^{-16}$$

```
delete A, d, X, res, eigenvector1:
```

Example 2

We demonstrate a numerically ill-conditioned case. The following matrix has only one eigenvector and cannot be diagonalized. Numerically, the zero vector is returned as the second column of the eigenvector matrix:

```
A := array(1..2, 1..2, [[5, -1], [4, 1]]):
DIGITS := 6:
numeric::eigenvectors(A)
```

$$\left[[3.0, 3.0], \begin{pmatrix} 0.447214 & 0 \\ 0.894427 & 0 \end{pmatrix}, \left[1.66533\ 10^{-16}, 0.0\right]\right]$$

```
delete A, DIGITS:
```

Example 3

The following matrix has domain components:

```
A := Dom::Matrix(Dom::IntegerMod(7))([[6, -1], [0,  3]])
```

$$\begin{pmatrix} 6 \bmod 7 & 6 \bmod 7 \\ 0 \bmod 7 & 3 \bmod 7 \end{pmatrix}$$

Note that `numeric::eigenvectors` computes the spectral data of the following matrix:

```
expr(A)
```

$$\begin{pmatrix} 6 & 6 \\ 0 & 3 \end{pmatrix}$$

```
numeric::eigenvectors(A, NoResidues)
```

$$\left[[6.0,\ 3.0],\ \begin{pmatrix} 1.0 & 0.894427191 \\ 0 & -0.4472135955 \end{pmatrix},\ \text{NIL}\right]$$

The routine `linalg::eigenvectors` should be used if the spectral data are to be computed over the component domain `Dom::IntegerMod(7)`:

```
linalg::eigenvectors(A)
```

$$\left[\left[3 \bmod 7,\ 1,\ \left[\begin{pmatrix} 5 \bmod 7 \\ 1 \bmod 7 \end{pmatrix}\right]\right],\ \left[6 \bmod 7,\ 1,\ \left[\begin{pmatrix} 1 \bmod 7 \\ 0 \bmod 7 \end{pmatrix}\right]\right]\right]$$

```
delete A:
```

Example 4

We demonstrate the use of hardware floats. The following matrix is degenerate: it has rank 1. For the double eigenvalue 0, different base vectors of the corresponding eigenspace are returned with `HardwareFloats` and `SoftwareFloats`, respectively:

```
A := array(1..3, 1..3, [[1, 2, 3], [2, 4, 6],
                        [3*10^12, 6*10^12, 9*10^12]]):
[d1, X1, res1] := numeric::eigenvectors(A, HardwareFloats):
```

```
d1, X1
```

$$\left[9.0\ 10^{12},\ 0.0,\ -4.543838814\ 10^{-16}\right],$$

$$\begin{pmatrix} 3.333333333\ 10^{-13} & 0.9486832981 & 0.9621023987 \\ 6.666666667\ 10^{-13} & -2.108185107\ 10^{-13} & -0.1012739367 \\ 1.0 & -0.316227766 & -0.2531848418 \end{pmatrix}$$

```
[d2, X2, res2] := numeric::eigenvectors(A, SoftwareFloats):
d2, X2
```

$$\left[9.0\ 10^{12},\ 5.421010862\ 10^{-20},\ 0.0\right],\ \begin{pmatrix} 0 & 0.9592641938 & 0.9486832981 \\ 0 & -0.06851887098 & 0 \\ 1.0 & -0.2740754839 & -0.316227766 \end{pmatrix}$$

```
delete A, d1, X1, res1, d2, X2, res2:
```

Parameters

A

A numerical matrix of domain type `DOM_ARRAY`, or `DOM_HFARRAY`, or of category `Cat::Matrix`.

Options

Hard, HardwareFloats, Soft, SoftwareFloats

With `Hard` (or `HardwareFloats`), computations are done using fast hardware float arithmetic from within a MuPAD session. `Hard` and `HardwareFloats` are equivalent. With this option, the input data are converted to hardware floats and processed by compiled C code. The result is reconverted to MuPAD floats and returned to the MuPAD session.

With `Soft` (or `SoftwareFloats`) computations are dome using software float arithmetic provided by the MuPAD kernel. `Soft` and `SoftwareFloats` are equivalent. `SoftwareFloats` is used by default if the current value of `DIGITS` is larger than 15 and the input matrix `A` is not of domain type `DOM_HFARRAY`.

Compared to the `SoftwareFloats` used by the MuPAD kernel, the computation with `HardwareFloats` may be many times faster. Note, however, that the precision of hardware arithmetic is limited to about 15 digits. Further, the size of floating-point numbers may not be larger than approximately 10^{308} and not smaller than approximately 10^{-308}.

If no `HardwareFloats` or `SoftwareFloats` are requested explicitly, the following strategy is used: If the current value of `DIGITS` is smaller than 16 or if the matrix `A` is a hardware float array of domain type `DOM_HFARRAY`, then hardware arithmetic is tried. If this is successful, the result is returned.

If the result cannot be computed with hardware floats, software arithmetic by the MuPAD kernel is tried.

If the current value of `DIGITS` is larger than 15 and the input matrix `A` is not of domain type `DOM_HFARRAY`, or if one of the options `Soft`, `SoftwareFloats` or `Symbolic` is specified, MuPAD computes the result with its software arithmetic without trying to use hardware floats first.

There may be several reasons for hardware arithmetic to fail:

- The current value of `DIGITS` is larger than 15.
- The data contains symbolic objects.
- The data contains numbers larger than 10^{308} or smaller than 10^{-308} that cannot be represented by hardware floats.

If neither `HardwareFloats` nor `SoftwareFloats` is specified, the user is not informed whether hardware floats or software floats are used.

If `HardwareFloats` are specified but fail due to one of the reasons above, a warning is issued that the (much slower) software floating-point arithmetic of the MuPAD kernel is used.

Note that `HardwareFloats` can only be used if all input data can be converted to floating-point numbers.

The trailing digits in floating-point results computed with `HardwareFloats` and `SoftwareFloats` may differ.

Note: For ill conditioned matrices the results returned with `HardwareFloats` and `SoftwareFloats` may differ significantly! See "Example 4" on page 19-51.

`NoResidues`

Suppresses the computation of error estimates

If no error estimates are required, this option may be used to suppress the computation of the residues `res`. The return values for these data are `NIL`.

The alternative option name `NoErrors` used in previous MuPAD versions is still available.

`ReturnType`

Option, specified as `ReturnType = t`

Return the eigenvectors as a matrix of domain type `t`. The following return types t are available: `DOM_ARRAY`, `DOM_HFARRAY`, `Dom::Matrix()`, or `Dom::DenseMatrix()`.

`NoWarning`

Suppresses warnings

Return Values

List `[d, X, res]`. The list `d = [d`$_1$`, d`$_2$`, …]` contains the numerical eigenvalue. The i-th column of the matrix `X` is the eigenvector associated with the eigenvalue `d`$_i$. The list of residues `res = [res`$_1$`, res`$_2$`, …]` provides error estimates for the numerical eigenvalues.

Algorithms

The routine implements standard numerical algorithms from the Handbook of Automatic Computation by Wilkinson and Reinsch.

MuPAD Functions

`linalg::eigenvalues` | `linalg::eigenvectors` | `numeric::eigenvalues` | `numeric::singularvalues` | `numeric::singularvectors` | `numeric::spectralradius`

numeric::expMatrix

Exponential of a matrix

Syntax

```
numeric::expMatrix(A, <mode>, <method>, options)
numeric::expMatrix(A, x, <mode>, <method>, options)
numeric::expMatrix(A, X, <mode>, <method>, options)
```

Description

`numeric::expMatrix(A)` returns the exponential e^A of a square matrix A.

`numeric::expMatrix(A, x)` with a vector x returns the vector $e^A x$.

`numeric::expMatrix(A, X)` with a matrix X returns the matrix $e^A X$.

If no return type is specified via the option `ReturnType = d`, the domain type of the result depends on the type of the input matrix `A`:

- For an array A, the result is returned as an array.
- For an hfarray A, the result is returned as an hfarray.
- For a dense matrix$A$ of type `Dom::DenseMatrix(Ring)`, the result is again a matrix of type `Dom::DenseMatrix()` over the ring of expressions.
- For all other matrices A of category `Cat::Matrix`, the result is returned as a `matrix` of type `Dom::Matrix()` over the ring of expressions. This includes input matrices `A` of type `Dom::Matrix(Ring)`, `Dom::SquareMatrix(Ring)`, `Dom::MatrixGroup(Ring)` etc.

The components of A must not contain symbolic objects which cannot be converted to numerical values via `float`. Numerical symbolic expressions such as π, $\sqrt{2}$, e^{-1} etc. are accepted. They are converted to floats.

The specification of a method such as `TaylorExpansion` etc. implies `SoftwareFloats`, i.e., the result is computed via the software arithmetic of the MuPAD kernel.

The methods `Diagonalization` and `Interpolation` do not work for all matrices (see below).

With `SoftwareFloats`, special algorithms are implemented for traceless 2×2 matrices and skew symmetric 3×3 matrices. Specification of a particular method does not have any effect for such matrices.

If $e^A x$ or $e^A X$ is required, one should not compute e^A first and then multiply the resulting matrix with the vector/matrix x/X. In general, the call `numeric::expMatrix(A, x)` or `numeric::expMatrix(A, X)`, respectively, is faster.

Environment Interactions

The function is sensitive to the environment variable `DIGITS`, which determines the numerical working precision.

Examples

Example 1

We consider a lower triangular matrix given by an array:

```
A := array(1..2, 1..2, [[1, 0] , [1, PI]]):
expA := numeric::expMatrix(A)
```

$$\begin{pmatrix} 2.718281828 & 0 \\ 9.536085572 & 23.14069263 \end{pmatrix}$$

We consider a vector given by a list `x1` and by an equivalent 1-dimensional array `x2`, respectively:

```
x1 := [1, 1]:
x2 := array(1..2, [1, 1]):
```

Further, an equivalent input vector X of type `Dom::Matrix()` is used:

```
X := matrix(x1):
```

The following three calls all yield a vector represented by an 2×1 array corresponding to the type of the input matrix A:

```
numeric::expMatrix(A, x1),
numeric::expMatrix(A, x2, Krylov),
numeric::expMatrix(A, X, Diagonalization)
```

$$\begin{pmatrix} 2.718281828 \\ 32.6767782 \end{pmatrix}, \begin{pmatrix} 2.718281828 \\ 32.6767782 \end{pmatrix}, \begin{pmatrix} 2.718281828 \\ 32.6767782 \end{pmatrix}$$

For further processing, the array `expA` is converted to an element of the matrix domain `Dom::Matrix()`:

```
expA := matrix(expA):
```

Now, the overloaded arithmetical operators `+`, `*`, `^` etc. can be used for further computations:

```
expA*X
```

$$\begin{pmatrix} 2.718281828 \\ 32.6767782 \end{pmatrix}$$

```
delete A, expA, x1, x2, X:
```

Example 2

We demonstrate the different precision goals of the methods. Note that software arithmetic is used when a method is specified:

```
A := array(1..3, 1..3, [[ 1000,    1,    0 ],
                        [   0,     1,    1 ],
                        [1/10^100, 0, -1000]]):
```

The default method `TaylorExpansion` computes *each component* of e^{-A} correctly:

```
numeric::expMatrix(A, SoftwareFloats)
```

$$\begin{pmatrix} 1.970071114\ 10^{434} & 1.972043157\ 10^{431} & 9.860215786\ 10^{427} \\ 9.860215786\ 10^{327} & 9.870085871\ 10^{324} & 4.935042936\ 10^{321} \\ 9.85035557\ 10^{330} & 9.860215786\ 10^{327} & 4.930107893\ 10^{324} \end{pmatrix}$$

The method `Diagonalization` produces a result, which is accurate in the sense that $\|\text{error}\|_\infty \le \|e^{-A}\|_\infty \frac{1}{10^{\text{DIGITS}}}$ holds. Indeed, the largest components of e^{-A} are correct.

However, `Diagonalization` does not even get the right order of magnitude of the smaller components:

```
numeric::expMatrix(A, Diagonalization)
```

$$\begin{pmatrix} 1.970071114\,10^{434} & 1.972043157\,10^{431} & 0 \\ 0 & 2.718281828 & 0 \\ 0 & 0 & 5.075958898\,10^{-435} \end{pmatrix}$$

Note that e^{A} is very sensitive to small changes in A. After elimination of the small lower triangular element, both methods yield the same result with correct digits for all entries:

```
B := array(1..3, 1..3, [[ 1000, 1,    0 ],
                        [   0 , 1,    1 ],
                        [   0 , 0, -1000]]):
numeric::expMatrix(B, SoftwareFloats)
```

$$\begin{pmatrix} 1.970071114\,10^{434} & 1.972043157\,10^{431} & 9.860215786\,10^{427} \\ 0 & 2.718281828 & 0.002715566262 \\ 0 & 0 & 5.075958897\,10^{-435} \end{pmatrix}$$

```
numeric::expMatrix(B, Diagonalization)
```

$$\begin{pmatrix} 1.970071114\,10^{434} & 1.972043157\,10^{431} & 9.860215786\,10^{427} \\ 0 & 2.718281828 & 0.002715566262 \\ 0 & 0 & 5.075958898\,10^{-435} \end{pmatrix}$$

```
delete A, B:
```

Example 3

Hilbert matrices $H_{ij} = \frac{1}{i+j-1}$ have real positive eigenvalues. For large dimension, most of these eigenvalues are small and may be regarded as a single cluster. Consequently, the option `Krylov` is useful:

```
numeric::expMatrix(linalg::hilbert(100), [1 $ 100], Krylov)
```

```
[25.47080919, 18.59337041, ..., 2.863083064, 2.848538965]
```

Parameters

A

A square $n \times n$ matrix of domain type DOM_ARRAY, DOM_HFARRAY, or of category `Cat::Matrix`

x

A vector represented by a list `[`x_1`, …, `x_n`]` or a 1-dimensional array `array(1..n, [`x_1`, …, `x_n`] )`, or a 1-dimensional hfarray `hfarray(1..n, [`x_1`, …, `x_n`] )`

X

An $n \times m$ matrix of domain type DOM_ARRAY, DOM_HFARRAY, `Dom::Matrix(Ring)` or `Dom::DenseMatrix(Ring)` with a suitable coefficient ring `Ring`

mode

One of the flags `Hard`, `HardwareFloats`, `Soft`, or `SoftwareFloats`

method

One of the flags `Diagonalization`, `Interpolation`, `Krylov`, or `TaylorExpansion`

Options

Hard, HardwareFloats, Soft, SoftwareFloats

With `Hard` (or `HardwareFloats`), computations are done using fast hardware float arithmetic from within a MuPAD session. `Hard` and `HardwareFloats` are equivalent. With this option, the input data are converted to hardware floats and processed by

compiled C code. The result is reconverted to MuPAD floats and returned to the MuPAD session.

With `Soft` (or `SoftwareFloats`) computations are dome using software float arithmetic provided by the MuPAD kernel. `Soft` and `SoftwareFloats` are equivalent. `SoftwareFloats` is used by default if the current value of `DIGITS` is larger than 15 and the input matrix `A` is not of domain type `DOM_HFARRAY`.

Compared to the `SoftwareFloats` used by the MuPAD kernel, the computation with `HardwareFloats` may be many times faster. Note, however, that the precision of hardware arithmetic is limited to about 15 digits. Further, the size of floating-point numbers may not be larger than approximately 10^{308} and not smaller than approximately 10^{-308}.

If no `HardwareFloats` or `SoftwareFloats` are requested explicitly, the following strategy is used: If the current value of `DIGITS` is smaller than 16 or if the matrix `A` is a hardware float array of domain type `DOM_HFARRAY`, then hardware arithmetic is tried. If this is successful, the result is returned.

If the result cannot be computed with hardware floats, software arithmetic by the MuPAD kernel is tried.

If the current value of `DIGITS` is larger than 15 and the input matrix `A` is not of domain type `DOM_HFARRAY`, or if one of the options `Soft`, `SoftwareFloats` or `Symbolic` is specified, MuPAD computes the result with its software arithmetic without trying to use hardware floats first.

There may be several reasons for hardware arithmetic to fail:

- The current value of `DIGITS` is larger than 15.
- The data contains symbolic objects.
- The data contains numbers larger than 10^{308} or smaller than 10^{-308} that cannot be represented by hardware floats.

If neither `HardwareFloats` nor `SoftwareFloats` is specified, the user is not informed whether hardware floats or software floats are used.

If `HardwareFloats` are specified but fail due to one of the reasons above, a warning is issued that the (much slower) software floating-point arithmetic of the MuPAD kernel is used.

Note that `HardwareFloats` can only be used if all input data can be converted to floating-point numbers.

The trailing digits in floating-point results computed with `HardwareFloats` and `SoftwareFloats` may differ.

`Diagonalization`, `Interpolation`, `Krylov`, `TaylorExpansion`

The specification of a method implies `SoftwareFloats`, i.e., the result is always computed via the software arithmetic of the MuPAD kernel.

The method `TaylorExpansion` is the default algorithm. It produces fast results for matrices with small norms.

The default method `TaylorExpansion` computes *each individual component* of e^A, $e^A x$, $e^A X$ to a relative precision of about `10^(-DIGITS)`, unless numerical roundoff prevents reaching this precision goal. Roughly speaking: all digits of all components of the result are reliable up to roundoff effects.

Note: The methods `Diagonalization`, `Interpolation`, and `Krylov` compute the result to a relative precision w.r.t. the norm: $||\text{error}||_\infty \le \frac{||\text{result}||_\infty}{10^{\text{DIGITS}}}$. Consequently, if the result has components of different orders of magnitude, then the smaller components have larger relative errors than the large components. Not all digits of the small components are reliable! Cf. “Example 2” on page 19-58.

Note: The method `Diagonalization` only works for diagonalizable matrices. For matrices without a basis of eigenvectors, `numeric::expMatrix` may either produce an error or the returned result is dominated by roundoff effects. For symmetric/Hermitian or skew/skew-Hermitian matrices, this method produces reliable results.

Note: The method `Interpolation` may become numerically unstable for certain matrices. The algorithm tries to detect such instabilities and stops with an error message.

The method `Krylov` is only available for computing $e^A x$ with a vector x. Also vectors represented by $n \times 1$ matrices are accepted.

This method is fast when x is spanned by few eigenvectors of A. Further, if A has only few clusters of similar eigenvalues, then this method can be much faster than the other methods. Cf. “Example 3” on page 19-59.

`NoWarning`

Suppresses warnings

`ReturnType`

Option, specified as `ReturnType = d`

Return the result matrix or vector as a matrix of domain type `d`. The following return types are available: `DOM_ARRAY`, `DOM_HFARRAY`, `Dom::Matrix()`, or `Dom::DenseMatrix()`.

Return Values

All results are float matrices/vectors. For an $n \times n$ matrix A:

- `numeric::expMatrix(A, method)` returns e^A as an $n \times n$ matrix,
- `numeric::expMatrix(A, x, method)` returns $e^A x$ as an $n \times 1$ matrix,
- `numeric::expMatrix(A, X, method)` returns $e^A X$ as an $n \times m$ matrix.

The domain type of the result depends on the domain type of the input matrix A unless a return type is requested explicitly via `ReturnType = d`.

Algorithms

The method `TaylorExpansion` sums the usual Taylor series

$$e^A = 1 + A + \frac{A^2}{2} + \cdots$$

in a suitable numerically stable way.

The method `Diagonalization` computes $e^A = T \operatorname{diag}\left(e^{\lambda_1}, e^{\lambda_2}, \ldots\right) T^{-1}$ by a diagonalization $A = T\,diag(\lambda_1, \lambda_2, \ldots)\,T^{-1}$.

The method `Interpolation` computes a polynomial P interpolating the function *exp* at the eigenvalues of A. Evaluation of the matrix polynomial yields $e^A = P(A)$.

The method `Krylov` reduces A to a Hessenberg matrix H and computes an approximation of $e^A x$ from e^H. Depending on A and x, the dimension of H may be smaller than the dimension of A.

`numeric::expMatrix` uses polynomial arithmetic to multiply matrices and vectors. Thus, sparse matrices are handled efficiently based on the MuPAD internal sparse representation of polynomials.

MuPAD Functions

`exp` | `funm` | `linalg::sqrtMatrix` | `numeric::fMatrix`

numeric::factorCholesky

Cholesky factorization of a matrix

Syntax

```
numeric::factorCholesky(A, options)
```

Description

`numeric::factorCholesky(A)` returns the factor L of the Cholesky factorization $A = L\,L^H$ of a positive definite Hermitian matrix A.

`numeric::factorCholesky(A, Symmetric)` returns the factor L of a Cholesky type factorization $A = L\,L^T$ of a symmetric matrix A.

The Cholesky factorization of a square Hermitian matrix is $A = L\,L^H$, where L is a regular complex lower triangular matrix and L^H is the Hermitian transpose of L (i.e., the complex conjugate of the transpose of L). Such a factorization only exists if A is positive definite.

By default, a numerical factorization is computed. If the option `Symbolic` is not used, all components of the matrix are converted to floating-point numbers. In this case, the matrix must not contain symbolic objects that cannot be converted to floats. Numerical symbolic expressions such as π, $\sqrt{2}$, e^{-1} etc. are accepted.

If no return type is specified via the option `ReturnType = d`, the domain type of the Cholesky factor L depends on the type of the input matrix `A`:

- The factor of an array is returned as an array.
- The factor of an hfarray is returned as an hfarray.
- The factor of a dense matrix of type `Dom::DenseMatrix()` is a dense matrix of type `Dom::DenseMatrix()` over the ring of MuPAD expressions.
- For all other matrices of category `Cat::Matrix`, the factor L is returned as a `matrix` of type `Dom::Matrix()` over the ring of MuPAD expressions. This includes

input matrices A of type `Dom::Matrix(...)`, `Dom::SquareMatrix(...)`, `Dom::MatrixGroup(...)` etc.

The Cholesky factor returned by `numeric::factorCholesky` is normalized such that its diagonal elements are real and positive.

Environment Interactions

Without the option `Symbolic`, the function is sensitive to the environment variable `DIGITS`, which determines the numerical working precision.

Examples

Example 1

We consider the matrix

```
A := array(1..2, 1..2, [[1, I] , [-I, PI]]):
```

We compute a numerical factorization

```
numeric::factorCholesky(A)
```

$$\begin{pmatrix} 1.0 & 0 \\ -1.0\,i & 1.46341814 \end{pmatrix}$$

and a symbolic factorization:

```
L := numeric::factorCholesky(A, Symbolic)
```

$$\begin{pmatrix} 1 & 0 \\ -i & \sqrt{\pi - 1} \end{pmatrix}$$

For further processing, the Cholesky factor (of domain type `DOM_ARRAY`) is converted to an element of the matrix domain `Dom::Matrix()`:

```
L := matrix(L):
```

Now, the overloaded arithmetical operators +, *, ^ etc. can be used for further computations:

```
L*linalg::transpose(conjugate(L))
```

$$\begin{pmatrix} 1 & i \\ -i & \pi \end{pmatrix}$$

```
delete A, L:
```

Example 2

The following matrix is not positive definite:

```
A := matrix([[-2, sqrt(2)], [sqrt(2), 1]]):
numeric::factorCholesky(A)
```

```
Error: The matrix is not positive definite within working precision. [stdlib::hfa::fact
  Evaluating: numeric::factorCholesky
```

However, a symmetric factorization with a complex Cholesky factor does exist:

```
numeric::factorCholesky(A, Symmetric)
```

$$\begin{pmatrix} 1.414213562\,i & 0 \\ -1.0\,i & 1.414213562 \end{pmatrix}$$

```
delete A:
```

Example 3

The option `NoCheck` should be used when the matrix contains symbolic objects:

```
assume(x > 0): assume(z > 0):
A := array(1..2, 1..2, [[x, conjugate(y)], [y, z]]):
```

```
numeric::factorCholesky(A, Symbolic, NoCheck)
```

$$\begin{pmatrix} \sqrt{x} & 0 \\ \frac{y}{\sqrt{x}} & \sqrt{z - \frac{|y|^2}{x}} \end{pmatrix}$$

Note that with `NoCheck`, it is assumed that the matrix is Hermitian and positive definite! All upper triangular entries are ignored. The following result implicitly assumes `u = conjugate(y)`:

```
A := array(1..2, 1..2, [[x, u], [y, z]]):
numeric::factorCholesky(A, Symbolic, NoCheck)
```

$$\begin{pmatrix} \sqrt{x} & 0 \\ \frac{y}{\sqrt{x}} & \sqrt{z - \frac{|y|^2}{x}} \end{pmatrix}$$

```
delete A:
```

Example 4

We demonstrate the use of hardware floats. Hilbert matrices are notoriously ill-conditioned and difficult to factor with low values of `DIGITS`. The following results, both with `HardwareFloats` as well as with `SoftwareFloats`, are marred by numerical roundoff. Consequently, the factorization with and without hardware floats, respectively, differ significantly:

```
A := linalg::hilbert(13):
L1 := numeric::factorCholesky(A, HardwareFloats):
L2 := numeric::factorCholesky(A, SoftwareFloats):
L1[13, 13] <> L2[13, 13]
```

$$0.0000001052365221 \neq 0.00000007585706698$$

All Hilbert matrices are positive definite. However, in the following call, numerical roundoff makes the hardware floating-point tool think that the matrix is not definite:

```
numeric::factorCholesky(linalg::hilbert(14), HardwareFloats):
```

```
Error: The matrix is not positive definite within working precision. [stdlib::hfa::fact
  Evaluating: numeric::factorCholesky
```

A factorization is computed successfully with `SoftwareFloats`:

```
L := numeric::factorCholesky(linalg::hilbert(14), SoftwareFloats):
norm(linalg::hilbert(14) - L*linalg::transpose(L))
```

$$8.67361738\ 10^{-19}$$

```
delete A, L1, L2, L:
```

Parameters

A

A square matrix of domain type `DOM_ARRAY`, `DOM_HFARRAY`, or of category `Cat::Matrix`

Options

`Hard`, `HardwareFloats`, `Soft`, `SoftwareFloats`

With `Hard` (or `HardwareFloats`), computations are done using fast hardware float arithmetic from within a MuPAD session. `Hard` and `HardwareFloats` are equivalent. With this option, the input data are converted to hardware floats and processed by compiled C code. The result is reconverted to MuPAD floats and returned to the MuPAD session.

With `Soft` (or `SoftwareFloats`) computations are dome using software float arithmetic provided by the MuPAD kernel. `Soft` and `SoftwareFloats` are equivalent. `SoftwareFloats` is used by default if the current value of `DIGITS` is larger than 15 and the input matrix `A` is not of domain type `DOM_HFARRAY`.

Compared to the `SoftwareFloats` used by the MuPAD kernel, the computation with `HardwareFloats` may be many times faster. Note, however, that the precision of

hardware arithmetic is limited to about 15 digits. Further, the size of floating-point numbers may not be larger than approximately 10^{308} and not smaller than approximately 10^{-308}.

If no `HardwareFloats` or `SoftwareFloats` are requested explicitly, the following strategy is used: If the current value of `DIGITS` is smaller than 16 or if the matrix `A` is a hardware float array of domain type `DOM_HFARRAY`, then hardware arithmetic is tried. If this is successful, the result is returned.

If the result cannot be computed with hardware floats, software arithmetic by the MuPAD kernel is tried.

If the current value of `DIGITS` is larger than 15 and the input matrix `A` is not of domain type `DOM_HFARRAY`, or if one of the options `Soft`, `SoftwareFloats` or `Symbolic` is specified, MuPAD computes the result with its software arithmetic without trying to use hardware floats first.

There may be several reasons for hardware arithmetic to fail:

- The current value of `DIGITS` is larger than 15.
- The data contains symbolic objects.
- The data contains numbers larger than 10^{308} or smaller than 10^{-308} that cannot be represented by hardware floats.

If neither `HardwareFloats` nor `SoftwareFloats` is specified, the user is not informed whether hardware floats or software floats are used.

If `HardwareFloats` are specified but fail due to one of the reasons above, a warning is issued that the (much slower) software floating-point arithmetic of the MuPAD kernel is used.

Note that `HardwareFloats` can only be used if all input data can be converted to floating-point numbers.

The trailing digits in floating-point results computed with `HardwareFloats` and `SoftwareFloats` may differ.

Note: For ill conditioned matrices the results returned with `HardwareFloats` and `SoftwareFloats` may differ significantly! See “Example 4” on page 19-68.

Symbolic

Prevents the conversion of the input data to floating-point numbers. Exact arithmetic is used. This option overrides `HardwareFloats` and `SoftwareFloats`.

The usual arithmetic for MuPAD expressions is used. With this option, the matrix A may contain symbolic objects. Note that the option `NoCheck` must be used for the Hermitian factorization when non-numerical symbolic objects are present.

Symmetric

Makes `numeric::factorCholesky` compute a symmetric factorization $A = L\,L^T$ rather than a Hermitian factorization $A = L\,L^H$

The symmetric Cholesky factorization of a square symmetric matrix is $A = L\,L^T$, where L is a regular complex lower triangular matrix and L^T is the transpose of L. The matrix A does not have to be positive definite. Consequently, with the option `Symmetric` no internal check is performed whether A is positive definite. Note that the symmetric factorization with regular L does not exist for all matrices.

For real symmetric positive definite matrices A the Cholesky factor L is real and the Hermitian factorization $A = L\,L^H$ coincides with the symmetric factorization $A = L\,L^T$.

NoCheck

Prevents `numeric::factorCholesky` from checking that the matrix is Hermitian and positive definite

Without the option `Symmetric`, `numeric::factorCholesky` checks that the matrix A is Hermitian and positive definite. The option `NoCheck` may be used to suppress these checks. It must be used when the matrix contains symbolic objects. Elements in the upper triangular part of the matrix will never be touched by the algorithm!

Note: With this option, `numeric::factorCholesky` returns a result for matrices that are not Hermitian or not positive definite (i.e., no Cholesky factorization exists)! When using this option, it is the user's responsibility to make sure that the input matrix is appropriate.

This option has no effect when the option `Symmetric` is used.

NoWarning

Suppresses warnings

If symbolic coefficients are found, `numeric::factorCholesky` automatically switches to the `Symbolic` mode with a warning. With this option, this warning is suppressed; the routine still uses the symbolic mode for symbolic coefficients, i.e., exact arithmetic without floating-point conversions is used.

ReturnType

Option, specified as `ReturnType = d`

Return the Cholesky factor as a matrix of domain type `d`. The following return types are available: `DOM_ARRAY`, `DOM_HFARRAY`, `Dom::Matrix()`, or `Dom::DenseMatrix()`.

Return Values

Depending on the type of the input matrix `A`, the lower triangular Cholesky factor L is returned as a matrix of domain type `DOM_ARRAY`, `DOM_HFARRAY`, `Dom::Matrix()`, or `Dom::DenseMatrix()`. Its components are real or complex floats, unless the option `Symbolic` is used. Without the option `NoCheck`, an error is raised if the matrix is not Hermitian or not positive definite.

MuPAD Functions

`linalg::factorCholesky` | `numeric::factorLU` | `numeric::factorQR`

numeric::factorLU

LU factorization of a matrix

Syntax

```
numeric::factorLU(A, options)
```

Description

`numeric::factorLU(A)` returns a LU factorization of the matrix A.

The LU factorization of a real or complex $m \times n$ matrix `A` is $PA = LU$. The $m \times m$ matrix L is lower triangular, normalized to 1 along the diagonal. The $m \times n$ matrix U is upper triangular, i.e., $U_{ij} = 0$ for $j < i$. The list `p = [p1, ..., pm]` returned by `numeric::factorLU` is a permutation of the numbers 1, …, m corresponding to row exchanges of A. It represents the following $m \times m$ permutation matrix P (we assume that the matrix indices range from 1 to m):

$$P_{ij} = \delta_{p_i, j} = \begin{cases} 1 & \text{if } j = p_i \\ 0 & \text{if } j \neq p_i \end{cases}.$$

Left multiplication of matrices and vectors with P is realized easily using the permutation list `p`: $Y_{i,j} := X_{p_i,j}$ defines the row permutation $Y = PX$ of a matrix X, $y_i := x_{p_i}$ defines the row permutation $y = Px$ of a vector x.

By default, a numerical factorization with partial pivoting is computed. If the option `Symbolic` is not used, all components of the matrix are converted to floating-point numbers. In this case, the matrix must not contain symbolic objects that cannot be converted to floats. Numerical symbolic expressions such as `PI`, $\sqrt{2}$, e^{-1} etc. are accepted.

The factorization depends on the pivoting strategy. The results obtained with/without the option `Symbolic` may differ. See “Example 2” on page 19-75. For numerical factorizations, the results obtained with `HardwareFloats` and `SoftwareFloats`, respectively, may differ. See “Example 3” on page 19-76.

If no return type is specified via the option `ReturnType = d`, the domain type of the factors L and U depends on the type of the input matrix `A`:

- The factors of an array are returned as arrays.
- The factors of an hfarray are returned as hfarrays.
- The factors of a dense matrix of type `Dom::DenseMatrix()` are again dense matrices of type `Dom::DenseMatrix()` over the ring of MuPAD expressions.
- For all other matrices of category `Cat::Matrix`, the factors are returned as matrices of type `Dom::Matrix()` over the ring of MuPAD expressions. This includes input matrices `A` of type `Dom::Matrix(...)`, `Dom::SquareMatrix(...)`, `Dom::MatrixGroup(...)` etc.

Environment Interactions

Without the optional argument `Symbolic`, the function is sensitive to the environment variable `DIGITS`, which determines the numerical working precision.

Examples

Example 1

We factor a matrix specified by an array:

```
A := array(1..3, 1..3, [[1, 2, 3], [2, 4, 6], [4, 8, 9]]):
[L, U, p] := numeric::factorLU(A)
```

$$\left[\begin{pmatrix} 1.0 & 0 & 0 \\ 0.5 & 1.0 & 0 \\ 0.25 & 0 & 1.0 \end{pmatrix}, \begin{pmatrix} 4.0 & 8.0 & 9.0 \\ 0 & 0 & 1.5 \\ 0 & 0 & 0.75 \end{pmatrix}, [3, 2, 1]\right]$$

The factors (of domain type `DOM_ARRAY`) are converted to elements of the matrix domain `Dom::Matrix()`. After the conversion, the overloaded arithmetical operators `+`, `*`, `^` etc. can be used for further processing:

```
L := matrix(L): U := matrix(U):
```

```
L*U
```

$$\begin{pmatrix} 4.0 & 8.0 & 9.0 \\ 2.0 & 4.0 & 6.0 \\ 1.0 & 2.0 & 3.0 \end{pmatrix}$$

The product $L\,U$ coincides with A after exchanging the rows according to the permutation stored in the list p:

```
PA := array(1..3, 1..3, [[A[p[i], j] $ j=1..3] $ i=1..3])
```

$$\begin{pmatrix} 4 & 8 & 9 \\ 2 & 4 & 6 \\ 1 & 2 & 3 \end{pmatrix}$$

```
delete A, L, U, p, PA:
```

Example 2

We consider a non-square matrix of dimension 3 ×2:

```
A := matrix([[3*I, 10], [I, 1], [I, 1]]):
[L1, U1, p1] := numeric::factorLU(A)
```

$$\left[\begin{pmatrix} 1.0 & 0 & 0 \\ 3.0 & 1.0 & 0 \\ 1.0 & 0 & 1.0 \end{pmatrix}, \begin{pmatrix} 1.0\,i & 1.0 \\ 0 & 7.0 \\ 0 & 0 \end{pmatrix}, [2, 1, 3]\right]$$

Note that the symbolic factorization is different, because a different pivoting strategy is used:

```
[L2, U2, p2] := numeric::factorLU(A, Symbolic)
```

$$\left[\begin{pmatrix} 1 & 0 & 0 \\ \frac{1}{3} & 1 & 0 \\ \frac{1}{3} & 1 & 1 \end{pmatrix}, \begin{pmatrix} 3\,i & 10 \\ 0 & -\frac{7}{3} \\ 0 & 0 \end{pmatrix}, [1, 2, 3]\right]$$

Here, the matrix factors are of type `Dom::Matrix()`, because the input matrix A was of this type. We can use the overloaded arithmetic directly. We convert the permutation lists `p1`, `p2` to matrices and verify the relation $PA = LU$ for the factorization:

```
P1 := matrix(3, 3):
P2 := matrix(3, 3):
for i from 1 to 3 do
  P1[i, p1[i]] := 1;
  P2[i, p2[i]] := 1;
end_for:
P1*A - L1*U1, P2*A - L2*U2
```

$$\begin{pmatrix} 0 & 0 \\ 0 & 0 \\ 0 & 0 \end{pmatrix}, \begin{pmatrix} 0 & 0 \\ 0 & 0 \\ 0 & 0 \end{pmatrix}$$

```
delete A, L1, U1, p1, L2, U2, p2:
```

Example 3

We demonstrate the use of hardware floats. The internal rounding of `HardwareFloats` and `SoftwareFloats` differs. Consequently, the following results do not coincide:

```
n := 14:
A := linalg::hilbert(n):
[L1, U1, p1] := numeric::factorLU(A, HardwareFloats):
[L2, U2, p2] := numeric::factorLU(A, SoftwareFloats):
p1, p2
```

$$[1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 14, 13], [1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14]$$

However, both factorizations satisfy $PA = LU$ numerically:

```
P1A := matrix([[A[p1[i], j] $ j = 1..n] $ i = 1..n]):
P2A := matrix([[A[p2[i], j] $ j = 1..n] $ i = 1..n]):
norm(P1A - L1*U1), norm(P2A - L2*U2)
```

$$8.131516294\ 10^{-17}, 5.421010862\ 10^{-19}$$

```
delete n, A, L1, U1, p1, L2, U2, p2, P1A, P2A:
```

Parameters

A

An $m \times n$ matrix of domain type DOM_ARRAY, DOM_HFARRAY, or of category Cat::Matrix

Options

Hard, HardwareFloats, Soft, SoftwareFloats

With Hard (or HardwareFloats), computations are done using fast hardware float arithmetic from within a MuPAD session. Hard and HardwareFloats are equivalent. With this option, the input data are converted to hardware floats and processed by compiled C code. The result is reconverted to MuPAD floats and returned to the MuPAD session.

With Soft (or SoftwareFloats) computations are dome using software float arithmetic provided by the MuPAD kernel. Soft and SoftwareFloats are equivalent. SoftwareFloats is used by default if the current value of DIGITS is larger than 15 and the input matrix A is not of domain type DOM_HFARRAY.

Compared to the SoftwareFloats used by the MuPAD kernel, the computation with HardwareFloats may be many times faster. Note, however, that the precision of hardware arithmetic is limited to about 15 digits. Further, the size of floating-point numbers may not be larger than approximately 10^{308} and not smaller than approximately 10^{-308}.

If no HardwareFloats or SoftwareFloats are requested explicitly, the following strategy is used: If the current value of DIGITS is smaller than 16 or if the matrix A is a hardware float array of domain type DOM_HFARRAY, then hardware arithmetic is tried. If this is successful, the result is returned.

If the result cannot be computed with hardware floats, software arithmetic by the MuPAD kernel is tried.

If the current value of DIGITS is larger than 15 and the input matrix A is not of domain type DOM_HFARRAY, or if one of the options Soft, SoftwareFloats or Symbolic is specified, MuPAD computes the result with its software arithmetic without trying to use hardware floats first.

There may be several reasons for hardware arithmetic to fail:

- The current value of `DIGITS` is larger than 15.
- The data contains symbolic objects.
- The data contains numbers larger than 10^{308} or smaller than 10^{-308} that cannot be represented by hardware floats.

If neither `HardwareFloats` nor `SoftwareFloats` is specified, the user is not informed whether hardware floats or software floats are used.

If `HardwareFloats` are specified but fail due to one of the reasons above, a warning is issued that the (much slower) software floating-point arithmetic of the MuPAD kernel is used.

Note that `HardwareFloats` can only be used if all input data can be converted to floating-point numbers.

The trailing digits in floating-point results computed with `HardwareFloats` and `SoftwareFloats` may differ.

Note: For ill conditioned matrices the results returned with `HardwareFloats` and `SoftwareFloats` may differ significantly! See “Example 3” on page 19-76.

`Symbolic`

Prevents the conversion of the input data to floating-point numbers. Exact arithmetic is used. This option overrides `HardwareFloats` and `SoftwareFloats`.

The usual arithmetic for MuPAD expressions is used. With this option, the matrix A may contain symbolic objects.

With this option, no row exchanges are performed in the internal Gaussian elimination unless necessary.

`NoWarning`

Suppresses warnings

If symbolic coefficients are found, `numeric::factorLU` automatically switches to the `Symbolic` mode with a warning. With this option, this warning is suppressed;

the routine still uses the symbolic mode for symbolic coefficients, i.e., exact arithmetic without floating-point conversions is used.

`ReturnType`

Option, specified as `ReturnType = d`

Return the factors as matrices of domain type `d`. The following return types are available: `DOM_ARRAY`, `DOM_HFARRAY`, `Dom::Matrix()`, or `Dom::DenseMatrix()`.

Return Values

List `[L, U, p]` is returned. The domain type of the $m \times m$ matrix `L` and the $m \times n$ matrix `U` depends on the type of the input matrix `A`; `p` is a list with m elements consisting of a permutation of the integers 1, …, m. It represents row exchanges in pivoting steps. The components of `L` and `U` are real or complex floats, unless the option `Symbolic` is used.

MuPAD Functions

`linalg::factorLU` | `numeric::factorCholesky` | `numeric::factorQR`

numeric::factorQR

QR factorization of a matrix

Syntax

```
numeric::factorQR(A, options)
```

Description

`numeric::factorQR(A)` returns a QR factorization $A = Q\,R$ of the matrix A.

The QR factorization of a real/complex $m \times n$ matrix is $A = Q\,R$, where the $m \times m$ matrix Q is orthogonal/unitary and the $m \times n$ matrix R is upper triangular (i.e., $R_{ij} = 0$ for $j < i$).

By default, a numerical factorization is computed. The matrix must not contain symbolic objects that cannot be converted to floats. Numerical symbolic expressions such as π, $\sqrt{2}$, e^{-1} etc. are accepted. They will be converted to floats, unless the option `Symbolic` is used.

The R factor is normalized such that its diagonal elements R_{ii} with $i = 1, \ldots, min(m, n)$ are real and nonnegative.

If no return type is specified via the option `ReturnType = d`, the domain type of the factors Q and R depends on the type of the input matrix `A`:

- The factors of an array are returned as arrays.
- The factors of an hfarray are returned as hfarrays.
- The factors of a dense matrix of type `Dom::DenseMatrix()` are dense matrices of type `Dom::DenseMatrix()` over the ring of expressions.
- For all other matrices of category`Cat::Matrix`, the factors are returned as matrices of type `Dom::Matrix()` over the ring of MuPAD expressions. This includes input matrices `A` of type `Dom::Matrix(...)`, `Dom::SquareMatrix(...)`, `Dom::MatrixGroup(...)`, etc.

Environment Interactions

Without the option `Symbolic`, the function is sensitive to the environment variable `DIGITS`, which determines the numerical working precision.

Examples

Example 1

We consider a quadratic matrix:

```
A := array(1..2, 1..2, [[1, 0] , [1, PI]]):
```

First, we compute a numerical factorization:

```
[Q1, R1] := numeric::factorQR(A)
```

$$\left[\begin{pmatrix} 0.7071067812 & -0.7071067812 \\ 0.7071067812 & 0.7071067812 \end{pmatrix}, \begin{pmatrix} 1.414213562 & 2.221441469 \\ 0 & 2.221441469 \end{pmatrix}\right]$$

Next, the symbolic factorization is computed:

```
[Q2, R2] := numeric::factorQR(A, Symbolic)
```

$$\left[\begin{pmatrix} \frac{\sqrt{2}}{2} & -\frac{\sqrt{2}}{2} \\ \frac{\sqrt{2}}{2} & \frac{\sqrt{2}}{2} \end{pmatrix}, \begin{pmatrix} \sqrt{2} & \frac{\pi\sqrt{2}}{2} \\ 0 & \frac{\pi\sqrt{2}}{2} \end{pmatrix}\right]$$

For further processing, the factors (of domain type `DOM_ARRAY`) are converted to elements of the matrix domain `Dom::Matrix()`:

```
Q1 := matrix(Q1): R1 := matrix(R1):
Q2 := matrix(Q2): R2 := matrix(R2):
```

Now, the overloaded arithmetical operators `+`, `*`, `^` etc. can be used for further computations:

```
Q1*R1, Q2*R2
```

$$\begin{pmatrix} 1.0 & -4.926614672\,10^{-16} \\ 1.0 & 3.141592654 \end{pmatrix}, \begin{pmatrix} 1 & 0 \\ 1 & \pi \end{pmatrix}$$

We finally verify the othogonality of the factors `Q1` and `Q2`:

```
Q1 * linalg::transpose(Q1), Q2 * linalg::transpose(Q2)
```

$$\begin{pmatrix} 1.0 & -1.569924746\,10^{-16} \\ -1.569924746\,10^{-16} & 1.0 \end{pmatrix}, \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}$$

```
delete A, Q1, R1, Q2, R2:
```

Example 2

We consider a non-square matrix of rank 1:

```
A := array(1..3, 1..2, [[0, 0], [I, 1], [I, 1]]):
numeric::factorQR(A, Symbolic)
```

$$\left[\begin{pmatrix} 0 & 1 & 0 \\ \frac{\sqrt{2}\,i}{2} & 0 & \frac{\sqrt{2}}{2} \\ \frac{\sqrt{2}\,i}{2} & 0 & -\frac{\sqrt{2}}{2} \end{pmatrix}, \begin{pmatrix} \sqrt{2} & -\sqrt{2}\,i \\ 0 & 0 \\ 0 & 0 \end{pmatrix}\right]$$

In this case, the *QR* factorization is not unique. Note that the numerical factorization yields different factors:

```
numeric::factorQR(A)
```

$$\left[\begin{pmatrix} 0 & 0.7071067812\,i & 0.7071067812\,i \\ 0.7071067812\,i & 0.5 & -0.5 \\ 0.7071067812\,i & -0.5 & 0.5 \end{pmatrix}, \begin{pmatrix} 1.414213562 & -1.414213562\,i \\ 0 & 0 \\ 0 & 0 \end{pmatrix}\right]$$

```
delete A:
```

Example 3

We demonstrate the difference between hardware floats and software floats. For rank deficient matrices, the *QR* factorization is not unique. Depending on the options, different results are returned for the following matrix of rank 1:

```
A := matrix([[1, 1], [10^4, 10^4], [10^8, 10^8]]):
[Q1, R1] := float(numeric::factorQR(A, Symbolic))
```

$$\left[\begin{pmatrix} 0.00000000999999995 & 1.0 & 0 \\ 0.0000999999995 & -9.9999999\,10^{-13} & 0.999999995 \\ 0.999999995 & -0.0000000099999999 & -0.0000999999995 \end{pmatrix}, \begin{pmatrix} 100000000.5 & 100000000.5 \\ 0 & 0 \\ 0 & 0 \end{pmatrix}\right]$$

```
[Q2, R2] := numeric::factorQR(A, SoftwareFloats)
```

$$\left[\begin{pmatrix} 0.00000000999999995 & -0.0000999999995 & -0.999999995 \\ 0.0000999999995 & 0.99999999 & -0.000099999998 \\ 0.999999995 & -0.000099999998 & 0.00000001999999975 \end{pmatrix}, \begin{pmatrix} 100000000.5 & 100000000.5 \\ 0 & 0 \\ 0 & 0 \end{pmatrix}\right]$$

```
[Q3, R3] := numeric::factorQR(A, HardwareFloats)
```

$$\left[\begin{pmatrix} 0.000000009999999939 & 0.9999999998 & -0.00002207031223 \\ 0.0000999999995 & -0.00002207031311 & -0.9999999948 \\ 0.999999995 & -0.000000007792968604 & 0.0000999999997 \end{pmatrix}, \begin{pmatrix} 100000000.5 & 100000000.5 \\ 0 & 0.0000000149011613 \\ 0 & 0 \end{pmatrix}\right]$$

However, all factorizations satisfy $A = Q\,R$ numerically:

```
norm(A - Q1*R1), norm(A - Q2*R2), norm(A - Q3*R3)
```

$$3.469446952\ 10^{-18},\ 7.327374818\ 10^{-11},\ 0.00000001583248377$$

```
delete A, Q1, R1, Q2, R2, Q3, R3:
```

Parameters

A

An $m \times n$ matrix of domain type `DOM_ARRAY`, `DOM_HFARRAY`, or of category `Cat::Matrix`

Options

Hard, HardwareFloats, Soft, SoftwareFloats

With `Hard` (or `HardwareFloats`), computations are done using fast hardware float arithmetic from within a MuPAD session. `Hard` and `HardwareFloats` are equivalent. With this option, the input data are converted to hardware floats and processed by compiled C code. The result is reconverted to MuPAD floats and returned to the MuPAD session.

With `Soft` (or `SoftwareFloats`) computations are dome using software float arithmetic provided by the MuPAD kernel. `Soft` and `SoftwareFloats` are equivalent.

`SoftwareFloats` is used by default if the current value of `DIGITS` is larger than 15 and the input matrix `A` is not of domain type `DOM_HFARRAY`.

Compared to the `SoftwareFloats` used by the MuPAD kernel, the computation with `HardwareFloats` may be many times faster. Note, however, that the precision of hardware arithmetic is limited to about 15 digits. Further, the size of floating-point numbers may not be larger than approximately 10^{308} and not smaller than approximately 10^{-308}.

If no `HardwareFloats` or `SoftwareFloats` are requested explicitly, the following strategy is used: If the current value of `DIGITS` is smaller than 16 or if the matrix `A` is a hardware float array of domain type `DOM_HFARRAY`, then hardware arithmetic is tried. If this is successful, the result is returned.

If the result cannot be computed with hardware floats, software arithmetic by the MuPAD kernel is tried.

If the current value of `DIGITS` is larger than 15 and the input matrix `A` is not of domain type `DOM_HFARRAY`, or if one of the options `Soft`, `SoftwareFloats` or `Symbolic` is specified, MuPAD computes the result with its software arithmetic without trying to use hardware floats first.

There may be several reasons for hardware arithmetic to fail:

- The current value of `DIGITS` is larger than 15.
- The data contains symbolic objects.
- The data contains numbers larger than 10^{308} or smaller than 10^{-308} that cannot be represented by hardware floats.

If neither `HardwareFloats` nor `SoftwareFloats` is specified, the user is not informed whether hardware floats or software floats are used.

If `HardwareFloats` are specified but fail due to one of the reasons above, a warning is issued that the (much slower) software floating-point arithmetic of the MuPAD kernel is used.

Note that `HardwareFloats` can only be used if all input data can be converted to floating-point numbers.

The trailing digits in floating-point results computed with `HardwareFloats` and `SoftwareFloats` may differ.

Note: For ill conditioned matrices the results returned with `HardwareFloats` and `SoftwareFloats` may differ significantly! See "Example 3" on page 19-83.

`Symbolic`

Prevents the conversion of the input data to floating-point numbers. Exact arithmetic is used. This option overrides `HardwareFloats` and `SoftwareFloats`.

The usual arithmetic for MuPAD expressions is used. With this option, the matrix A may contain symbolic objects.

`NoWarning`

Suppresses warnings

If symbolic coefficients are found, `numeric::factorQR` automatically switches to the `Symbolic` mode with a warning. With this option, this warning is suppressed; the routine still uses the symbolic mode for symbolic coefficients, i.e., exact arithmetic without floating-point conversions is used.

`ReturnType`

Option, specified as `ReturnType = d`

Return the Cholesky factor as a matrix of domain type `d`. The following return types are available: `DOM_ARRAY`, `DOM_HFARRAY`, `Dom::Matrix()`, or `Dom::DenseMatrix()`.

Return Values

List `[Q, R]` with matrices `Q` and `R` is returned. The domain type of the orthogonal/unitary $m \times m$ matrix `Q` and the upper triangular $m \times n$ matrix `R` depends on the type of the input matrix `A`. The components of `Q` and `R` are real or complex floats, unless the option `Symbolic` is used.

Algorithms

Householder transformations are used to compute the numerical factorization. With the option `Symbolic`, Gram-Schmidt orthonormalization of the columns of A is used.

For an invertible square matrix A, the QR factorization is unique up to scaling factors of modulus 1. The normalization of R to real positive diagonal elements determines the factorization uniquely. Consequently, the results obtained with/without the option `Symbolic` coincide for invertible square matrices.

For singular or non-square matrices, the factorization is not unique and the results obtained with/without the option `Symbolic` may differ. Cf. “Example 2” on page 19-82.

MuPAD Functions

`linalg::factorQR` | `numeric::factorCholesky` | `numeric::factorLU`

numeric::fft

Fast Fourier Transform

Syntax

```
numeric::fft(L, <mode>, <ReturnType = t>, <Clean>)
numeric::fft(M, <mode>, <ReturnType = t>, <Clean>)
numeric::fft(A, <mode>, <ReturnType = t>, <Clean>)
```

Description

`numeric::fft(data)` returns the discrete Fourier transform of the `data`.

The 1-dimensional discrete Fourier transform $F = fft(L)$ of N data elements L_j stored in the list $L = [L_1, \ldots, L_N]$ is the list $F = [F_1, \ldots, F_N]$ given by

$$F_k = \sum_{j=1}^{N} L_j \, e^{-\frac{i\,2\,\pi\,(j-1)\,(k-1)}{N}}, \; k = 1, \ldots, N$$

.

`fft` transforms the data by a Fast Fourier Transform (FFT) algorithm.

The d-dimensional discrete Fourier transform $F = fft(A)$ of $N = n_1 \times \cdots \times n_d$ data elements $(A_{j_1, \ldots, j_d})$ stored in the array A is the array $F = (F_{k_1, \ldots, k_d})$ given by

$$F_{k_1, \ldots, k_d} = \sum_{j_1=1}^{n_1} \cdots \sum_{j_d=1}^{n_d} A_{j_1, \ldots, j_d} \, e^{-i\,2\,\pi \left(\frac{(j_1-1)\,(k_1-1)}{n_1} + \ldots + \frac{(j_d-1)\,(k_d-1)}{n_d} \right)}$$

with $k_1 = 1, \ldots, n_1, \ldots, k_d = 1, \ldots, n_d$.

Data provided by lists or 1-dimensional `array`s or `hfarray`s are transformed according to the 1-dimensional transform. Data provided by matrices are transformed according to

the 2-dimensional transform. Data provided by multidimensional arrays or hfarrays are transformed according to the multi-dimensional transform matching the format of the input array.

If the data size factorizes ($N = p\,q$, say), the discrete Fourier transform can be computed by p different Fourier transforms of subsets of the data, each subset having the data size q. The corresponding 'divide and conquer' algorithm is known as FFT ('Fast Fourier Transform'). The `fft` routine employs the FFT algorithm. It is most efficient, when the data size N is an integer power of 2 ('radix 2 FFT'). In this case, the algorithm needs $O(N \log_2(N))$ elementary operations.

Note: More generally, FFT is efficient, if the data size is the product of many small factors!

Following Bluestein, the Fourier transform is written as a convolution if the data size N is a prime. The data are zero-padded to a data length that is an integer power of 2. The convolution is then computed via radix 2 FFTs. Thus, the algorithm needs $O(N \log_2(N))$ elementary operations even if N is a prime.

Environment Interactions

Without the option `Symbolic`, the function is sensitive to the environment variable `DIGITS`, which determines the numerical working precision.

Examples

Example 1

We give a demonstration of 1-dimensional transformations using lists. By default, numerical expressions are converted to floats:

```
L := [1, 2^(1/2), 3*I, PI]:
F := numeric::fft(L)
```

$$[5.555806216 + 3.0\,i,\ 1.0 - 1.272620909\,i,\ -3.555806216 + 3.0\,i,\ 1.0 - 4.727379091\,i]$$

```
numeric::invfft(F)
```

$$\left[1.0,\ 1.414213562 + 2.512840965\ 10^{-17}\ i,\ 3.0\ i,\ 3.141592654 - 2.512840965\ 10^{-17}\ i\right]$$

```
numeric::invfft(F, Clean)
```

$$[1.0,\ 1.414213562,\ 3.0\ i,\ 3.141592654]$$

Exact arithmetic is used with the option `Symbolic`:

```
F := numeric::fft(L, Symbolic)
```

$$[\pi + \sqrt{2} + 1 + 3\ i,\ \pi\ i - \sqrt{2}\ i + 1 - 3\ i,\ 1 - \sqrt{2} - \pi + 3\ i,\ 1 + \sqrt{2}\ i - \pi\ i - 3\ i]$$

```
numeric::invfft(F, Symbolic)
```

$$[1,\ \sqrt{2},\ 3\ i,\ \pi]$$

Symbolic expressions are accepted. Internally, however, the default method `HardwareFloats` (with `DIGITS < 16`) fails because of the symbolic parameter `x`. The following results are computed with the software arithmetic provided by the MuPAD kernel:

```
L := [x, 2, 3, x]:
numeric::fft(L)
```

$$[2\ x + 5.0,\ x\ (1.0 + 1.0\ i) - 3.0 - 2.0\ i,\ 1.0,\ x\ (1.0 - 1.0\ i) - 3.0 + 2.0\ i]$$

```
numeric::fft(L, Symbolic)
```

$$[2\ x + 5,\ x\ (1 + i) - 3 - 2\ i,\ 1,\ x\ (1 - i) - 3 + 2\ i]$$

```
delete L, F:
```

Example 2

We give a demonstration of multi-dimensional transformations. First, a 2-dimensional transformation is computed by using an array with 2 indices:

```
A := array(1..2, 1..4, [[1, 2, 3, 4], [a, b, c, d]]):
numeric::fft(A, Symbolic)
```

$$\begin{pmatrix} a+b+c+d+10 & a-b\,i-c+d\,i-2+2\,i & a-b+c-d-2 & a+b\,i-c-d\,i-2-2\,i \\ 10-b-c-d-a & c+b\,i-a-d\,i-2+2\,i & b-a-c+d-2 & c-b\,i-a+d\,i-2-2\,i \end{pmatrix}$$

```
numeric::invfft(%, Symbolic)
```

$$\begin{pmatrix} 1 & 2 & 3 & 4 \\ a & b & c & d \end{pmatrix}$$

The next example is 3-dimensional as indicated by the format of the array:

```
A := array(1..2, 1..4, 1..2,
          [[[sin(j1*PI/2)*cos(j2*3*PI/4)*sin(j3*PI/2)
          $ j3 = 1..2 ] $ j2 = 1..4 ] $ j1 = 1..2]):
numeric::fft(A)
```

```
array(1..2, 1..4, 1..2,
  (1, 1, 1) = -1.0

  (1, 1, 2) = -1.0

  (1, 2, 1) = - 1.414213562 - 1.0 I

  (1, 2, 2) = - 1.414213562 - 1.0 I

  (1, 3, 1) = 1.0

  (1, 3, 2) = 1.0

  (1, 4, 1) = - 1.414213562 + 1.0 I

  (1, 4, 2) = - 1.414213562 + 1.0 I

  (2, 1, 1) = -1.0

  (2, 1, 2) = -1.0

  (2, 2, 1) = - 1.414213562 - 1.0 I
```

```
  (2, 2, 2) = - 1.414213562 - 1.0 I

  (2, 3, 1) = 1.0

  (2, 3, 2) = 1.0

  (2, 4, 1) = - 1.414213562 + 1.0 I

  (2, 4, 2) = - 1.414213562 + 1.0 I
)
```

```
delete A:
```

Example 3

Data of arbitrary length can be transformed:

```
L := [1, 2 + I, PI/3]:
numeric::fft(L)
```

$$[4.047197551 + 1.0\,i,\ 0.3424266282 - 1.325151125\,i,\ -1.389624179 + 0.3251511255\,i]$$

```
delete L:
```

Parameters

L

A list or a 1-dimensional array(`1 .. N, [Symbol::hellip]`) or a 1-dimensional hfarray(`1 .. N, [Symbol::hellip]`) of arithmetical expressions.

M

A `matrix` of category `Cat::Matrix` of arithmetical expressions.

A

A *d*-dimensional `array( 1..n_1,Symbol::hellip,1..n_d, [Symbol::hellip] )` or a *d*-dimensional `hfarray( 1..n_1,Symbol::hellip,1..n_d, [Symbol::hellip] )` of arithmetical expressions.

mode

One of the flags Hard, HardwareFloats, Soft, SoftwareFloats, or Symbolic

Options

Hard, HardwareFloats, Soft, SoftwareFloats

With Hard (or HardwareFloats), computations are done using fast hardware float arithmetic from within a MuPAD session. Hard and HardwareFloats are equivalent. With this option, the input data are converted to hardware floats and processed by compiled C code. The result is reconverted to MuPAD floats and returned to the MuPAD session.

With Soft (or SoftwareFloats) computations are dome using software float arithmetic provided by the MuPAD kernel. Soft and SoftwareFloats are equivalent. SoftwareFloats is used by default if the current value of DIGITS is larger than 15 and the input matrix A is not of domain type DOM_HFARRAY.

Compared to the SoftwareFloats used by the MuPAD kernel, the computation with HardwareFloats may be many times faster. Note, however, that the precision of hardware arithmetic is limited to about 15 digits. Further, the size of floating-point numbers may not be larger than approximately 10^{308} and not smaller than approximately 10^{-308}.

If no HardwareFloats or SoftwareFloats are requested explicitly, the following strategy is used: If the current value of DIGITS is smaller than 16 or if the matrix A is a hardware float array of domain type DOM_HFARRAY, then hardware arithmetic is tried. If this is successful, the result is returned.

If the result cannot be computed with hardware floats, software arithmetic by the MuPAD kernel is tried.

If the current value of DIGITS is larger than 15 and the input matrix A is not of domain type DOM_HFARRAY, or if one of the options Soft, SoftwareFloats or Symbolic is specified, MuPAD computes the result with its software arithmetic without trying to use hardware floats first.

There may be several reasons for hardware arithmetic to fail:

- The current value of `DIGITS` is larger than 15.
- The data contains symbolic objects.
- The data contains numbers larger than 10^{308} or smaller than 10^{-308} that cannot be represented by hardware floats.

If neither `HardwareFloats` nor `SoftwareFloats` is specified, the user is not informed whether hardware floats or software floats are used.

If `HardwareFloats` are specified but fail due to one of the reasons above, a warning is issued that the (much slower) software floating-point arithmetic of the MuPAD kernel is used.

Note that `HardwareFloats` can only be used if all input data can be converted to floating-point numbers.

With `Soft` and `SoftwareFloats`, symbolic objects are accepted even if they cannot be converted to floating-point numbers. The result consists of arithmetical expressions involving both floating-point numbers as well as symbolic objects. See. “Example 1” on page 19-89.

The trailing digits in floating-point results computed with `HardwareFloats` and `SoftwareFloats` may differ.

`Symbolic`

Without this option, the floating-point converter `float` is applied to all input data. Use this option if no such conversion is desired. Exact arithmetic is used to compute the Fourier transformation.

This option prevents conversion of the input data to floats.

`ReturnType`

Option, specified as `ReturnType = t`

Return the result in a container of domain type `t`. The following return types `t` are available: `DOM_LIST`, or `DOM_ARRAY`, or `DOM_HFARRAY`, or `matrix`, or `densematrix`.

This option determines the domain type `t` of the result.

If no return type is specified by this option, the result if of the same type and format as the input data.

If the return type `DOM_LIST` is specified, the result is always a plain list of floating-point numbers. If the input data are given by a matrix or a multi-dimensional array, the returned list represents the operands of the multi-dimensional Fourier data. E.g., if an $n_1 \times n_2$ matrix is entered, the return value is a list with $n_1\, n_2$ values representing the entries of a $n_1 \times n_2$ matrix. The first n_2 entries of the list represent the first row of the result, the next n_2 entries represent the second row, etc.

With `ReturnType = matrix` or `ReturnType = densematrix`, only the results of 1 and 2 dimensional Fourier transformations can be represented.

`Clean`

Reduce roundoff garbage in the result. All entries of the result with absolute values smaller than `10^(-DIGITS)` times the maximal absolute value of all operands of the result are set to `0.0`. Further, the routine `numeric::complexRound` is applied to all entries of the result.

Note: The postprocessing of the result is done on the software float level. When using hardware floats, this option may increase the runtime significantly!

This option is ignored when used in conjunction with the option `Symbolic`.

Return Values

List/array/hfarray/matrix of the same length and format as the first input parameter L/A/M. The type of the return value can be changed with the option `ReturnType`.

`numeric::invfft`

More About

- "Discrete Fourier Transforms"

numeric::invfft

Inverse Fast Fourier Transform

Syntax

```
numeric::invfft(L, <mode>, <ReturnType = t>, <Clean>)
numeric::invfft(M, <mode>, <ReturnType = t>, <Clean>)
numeric::invfft(A, <mode>, <ReturnType = t>, <Clean>)
```

Description

`numeric::invfft(data)` returns the inverse discrete Fourier transform.

The inverse discrete Fourier transform $L = invfft(F)$ of N data elements F_k stored in the list $F = [F_1, \ldots, F_N]$ is the list $L = [L_1, \ldots, L_N]$ given by

$$L_j = \frac{1}{N} \sum_{k=1}^{N} F_k \, e^{\frac{i\,2\,\pi\,(j-1)\,(k-1)}{N}}, \; j = 1, \ldots, N$$

.

`invfft` transforms the data by a Fast Fourier Transform (FFT) algorithm.

The d-dimensional inverse discrete Fourier transform $A = invfft(F)$ is given by

$$A_{j_1,\ldots,j_d} = \frac{1}{N} \sum_{k_1=1}^{n_1} \cdots \sum_{j_d=1}^{n_d} F_{k_1,\ldots,k_d} \, e^{i\,2\,\pi \left(\frac{(j_1-1)\,(k_1-1)}{n_1} + \ldots + \frac{(j_d-1)\,(k_d-1)}{n_d} \right)}$$

with $j_1 = 1, \ldots, n_1, \ldots, j_d = 1, \ldots, n_d$.

Data provided by lists or 1-dimensional `array`s or `hfarray`s are transformed according to the 1-dimensional transform. Data provided by matrices are transformed according to the 2-dimensional transform. Data provided by multidimensional arrays or hfarrays

are transformed according to the multidimensional transform matching the format of the input array.

If the data size factorizes ($N = p\,q$, say), the inverse discrete Fourier transform can be computed by p different inverse Fourier transforms of subsets of the data, each subset having the data size q. The corresponding 'divide and conquer' algorithm is known as FFT ('Fast Fourier Transform'). The `invfft` routine employs the FFT algorithm. It is most efficient, when the data size N is an integer power of 2 ('radix 2 FFT'). In this case, the algorithm needs $O(N \log_2(N))$ elementary operations.

Note: More generally, FFT is efficient, if the data size is the product of many small factors!

Following Bluestein, the inverse Fourier transform is written as a convolution if the data size N is a prime. The data are zero-padded to a data length that is an integer power of 2. The convolution is then computed via radix 2 FFTs. Thus, the algorithm needs $O(N \log_2(N))$ elementary operations even if N is a prime.

Environment Interactions

Without the option `Symbolic`, the function is sensitive to the environment variable `DIGITS`, which determines the numerical working precision.

Examples

Example 1

We give a demonstration of 1-dimensional transformations using lists. By default, numerical expressions are converted to floats:

```
L := [1, 2^(1/2), 3*I, PI]:
F := numeric::fft(L)
```

$$[5.555806216 + 3.0\,i,\ 1.0 - 1.272620909\,i,\ -3.555806216 + 3.0\,i,\ 1.0 - 4.727379091\,i]$$

```
numeric::invfft(F)
```

$$\left[1.0,\ 1.414213562 + 2.512840965\ 10^{-17}\ i,\ 3.0\ i,\ 3.141592654 - 2.512840965\ 10^{-17}\ i\right]$$

```
numeric::invfft(F, Clean)
```

$$[1.0,\ 1.414213562,\ 3.0\ i,\ 3.141592654]$$

Exact arithmetic is used with the option `Symbolic`:

```
F := numeric::fft(L, Symbolic)
```

$$[\pi + \sqrt{2} + 1 + 3\ i,\ \pi\ i - \sqrt{2}\ i + 1 - 3\ i,\ 1 - \sqrt{2} - \pi + 3\ i,\ 1 + \sqrt{2}\ i - \pi\ i - 3\ i]$$

```
numeric::invfft(F, Symbolic)
```

$$[1,\ \sqrt{2},\ 3\ i,\ \pi]$$

Symbolic expressions are accepted. Internally, however, the default method `HardwareFloats` (with `DIGITS < 16`) fails because of the symbolic parameter `x`. The following results are computed with the software arithmetic provided by the MuPAD kernel:

```
L := [x, 2, 3, x]:
numeric::fft(L)
```

$$[2\ x + 5.0,\ x\ (1.0 + 1.0\ i) - 3.0 - 2.0\ i,\ 1.0,\ x\ (1.0 - 1.0\ i) - 3.0 + 2.0\ i]$$

```
numeric::fft(L, Symbolic)
```

$$[2\ x + 5,\ x\ (1 + i) - 3 - 2\ i,\ 1,\ x\ (1 - i) - 3 + 2\ i]$$

```
delete L, F:
```

Example 2

We give a demonstration of multi-dimensional transformations. First, a 2-dimensional transformation is computed by using an array with 2 indices:

```
A := array(1..2, 1..4, [[1, 2, 3, 4], [a, b, c, d]]):
numeric::fft(A, Symbolic)
```

$$\begin{pmatrix} a+b+c+d+10 & a-b\,i-c+d\,i-2+2\,i & a-b+c-d-2 & a+b\,i-c-d\,i-2-2\,i \\ 10-b-c-d-a & c+b\,i-a-d\,i-2+2\,i & b-a-c+d-2 & c-b\,i-a+d\,i-2-2\,i \end{pmatrix}$$

```
numeric::invfft(%, Symbolic)
```

$$\begin{pmatrix} 1 & 2 & 3 & 4 \\ a & b & c & d \end{pmatrix}$$

The next example is 3-dimensional as indicated by the format of the array:

```
A := array(1..2, 1..4, 1..2,
          [[[sin(j1*PI/2)*cos(j2*3*PI/4)*sin(j3*PI/2)
          $ j3 = 1..2 ] $ j2 = 1..4 ] $ j1 = 1..2]):
numeric::fft(A)
```

```
array(1..2, 1..4, 1..2,
  (1, 1, 1) = -1.0

  (1, 1, 2) = -1.0

  (1, 2, 1) = - 1.414213562 - 1.0 I

  (1, 2, 2) = - 1.414213562 - 1.0 I

  (1, 3, 1) = 1.0

  (1, 3, 2) = 1.0

  (1, 4, 1) = - 1.414213562 + 1.0 I

  (1, 4, 2) = - 1.414213562 + 1.0 I

  (2, 1, 1) = -1.0

  (2, 1, 2) = -1.0

  (2, 2, 1) = - 1.414213562 - 1.0 I
```

```
  (2, 2, 2) = - 1.414213562 - 1.0 I

  (2, 3, 1) = 1.0

  (2, 3, 2) = 1.0

  (2, 4, 1) = - 1.414213562 + 1.0 I

  (2, 4, 2) = - 1.414213562 + 1.0 I
)
```

```
delete A:
```

Example 3

Data of arbitrary length can be transformed:

```
L := [1, 2 + I, PI/3]:
numeric::fft(L)
```

$$[4.047197551 + 1.0\,i,\ 0.3424266282 - 1.325151125\,i,\ -1.389624179 + 0.3251511255\,i]$$

```
delete L:
```

Parameters

L

A list or a 1-dimensional array(`1 .. N, [Symbol::hellip]`) or a 1-dimensional hfarray(`1 .. N, [Symbol::hellip]`) of arithmetical expressions.

M

A `matrix` of category `Cat::Matrix` of arithmetical expressions.

A

A *d*-dimensional `array( 1..n_1,Symbol::hellip,1..n_d, [Symbol::hellip] )` or a *d*-dimensional `hfarray( 1..n_1,Symbol::hellip,1..n_d, [Symbol::hellip] )` of arithmetical expressions.

mode

One of the flags Hard, HardwareFloats, Soft, SoftwareFloats, or Symbolic

Options

Hard, HardwareFloats, Soft, SoftwareFloats

With Hard (or HardwareFloats), computations are done using fast hardware float arithmetic from within a MuPAD session. Hard and HardwareFloats are equivalent. With this option, the input data are converted to hardware floats and processed by compiled C code. The result is reconverted to MuPAD floats and returned to the MuPAD session.

With Soft (or SoftwareFloats) computations are dome using software float arithmetic provided by the MuPAD kernel. Soft and SoftwareFloats are equivalent. SoftwareFloats is used by default if the current value of DIGITS is larger than 15 and the input matrix A is not of domain type DOM_HFARRAY.

Compared to the SoftwareFloats used by the MuPAD kernel, the computation with HardwareFloats may be many times faster. Note, however, that the precision of hardware arithmetic is limited to about 15 digits. Further, the size of floating-point numbers may not be larger than approximately 10^{308} and not smaller than approximately 10^{-308}.

If no HardwareFloats or SoftwareFloats are requested explicitly, the following strategy is used: If the current value of DIGITS is smaller than 16 or if the matrix A is a hardware float array of domain type DOM_HFARRAY, then hardware arithmetic is tried. If this is successful, the result is returned.

If the result cannot be computed with hardware floats, software arithmetic by the MuPAD kernel is tried.

If the current value of DIGITS is larger than 15 and the input matrix A is not of domain type DOM_HFARRAY, or if one of the options Soft, SoftwareFloats or Symbolic is specified, MuPAD computes the result with its software arithmetic without trying to use hardware floats first.

There may be several reasons for hardware arithmetic to fail:

- The current value of `DIGITS` is larger than 15.
- The data contains symbolic objects.
- The data contains numbers larger than 10^{308} or smaller than 10^{-308} that cannot be represented by hardware floats.

If neither `HardwareFloats` nor `SoftwareFloats` is specified, the user is not informed whether hardware floats or software floats are used.

If `HardwareFloats` are specified but fail due to one of the reasons above, a warning is issued that the (much slower) software floating-point arithmetic of the MuPAD kernel is used.

Note that `HardwareFloats` can only be used if all input data can be converted to floating-point numbers.

With `Soft` and `SoftwareFloats`, symbolic objects are accepted even if they cannot be converted to floating-point numbers. The result consists of arithmetical expressions involving both floating-point numbers as well as symbolic objects. See. “Example 1” on page 19-97.

The trailing digits in floating-point results computed with `HardwareFloats` and `SoftwareFloats` may differ.

`Symbolic`

Without this option, the floating-point converter `float` is applied to all input data. Use this option if no such conversion is desired. Exact arithmetic is used to compute the Fourier transformation.

This option prevents conversion of the input data to floats.

`ReturnType`

Option, specified as `ReturnType = t`

Return the result in a container of domain type `t`. The following return types `t` are available: `DOM_LIST`, or `DOM_ARRAY`, or `DOM_HFARRAY`, or `matrix`, or `densematrix`.

This option determines the domain type `t` of the result.

If no return type is specified by this option, the result if of the same type and format as the input data.

If the return type `DOM_LIST` is specified, the result is always a plain list of floating-point numbers. If the input data are given by a matrix or a multi-dimensional array, the returned list represents the operands of the multi-dimensional Fourier data. E.g., if an $n_1 \times n_2$ matrix is entered, the return value is a list with $n_1\, n_2$ values representing the entries of a $n_1 \times n_2$ matrix. The first n_2 entries of the list represent the first row of the result, the next n_2 entries represent the second row, etc.

With `ReturnType = matrix` or `ReturnType = densematrix`, only the results of 1 and 2 dimensional Fourier transformations can be represented.

`Clean`

Reduce roundoff garbage in the result. All entries of the result with absolute values smaller than `10^(-DIGITS)` times the maximal absolute value of all operands of the result are set to `0.0`. Further, the routine `numeric::complexRound` is applied to all entries of the result.

Note: The postprocessing of the result is done on the software float level. When using hardware floats, this option may increase the runtime significantly!

This option is ignored when used in conjunction with the option `Symbolic`.

Return Values

List/array/hfarray/matrix of the same length and format as the first input parameter L/A/M. The type of the return value can be changed with the option `ReturnType`.

MuPAD Functions
`numeric::fft`

More About

- "Discrete Fourier Transforms"

numeric::fMatrix

Functional calculus for numerical square matrices

Syntax

```
numeric::fMatrix(f, A, p1, p2, …, options)
```

Description

`numeric::fMatrix(f, A)` computes the matrix $f(A)$ with a function f and a square matrix A.

If no return type is specified via the option `ReturnType = d`, the domain type of the result depends on the type of the input matrix `A`:

- For an array A, the result is returned as an array.
- For an hfarray A, the result is returned as an array.
- For a dense matrix A of type `Dom::DenseMatrix()` the result is a dense matrix of type `Dom::DenseMatrix()` over the ring of MuPAD expressions.
- For all other matrices A of category `Cat::Matrix`, the result is returned as a `matrix` of type `Dom::Matrix()` over the ring of MuPAD expressions. This includes input matrices `A` of type `Dom::Matrix(...)`, `Dom::SquareMatrix(...)`, `Dom::MatrixGroup(...)` etc.

The components of A must not contain symbolic objects which cannot be converted to numerical values via `float`. Numerical symbolic expressions such as π, $\sqrt{2}$, e^{-1} etc. are accepted. They are converted to floats.

Note: When you use `numeric::fMatrix`, the matrix must be diagonalizable, and all its elements must be convertible to floating-point numbers. Otherwise, use `funm`.

If `numeric::fMatrix` detects numerically that A is not diagonalizable, it aborts with an error message . Nevertheless, the numerical algorithm often fails to detect that the matrix is not diagonalizable, and the returned matrix is dominated by round-off

effects. When using`numeric::fMatrix`, ensure the diagonalization is possible and well conditioned.

Symmetric/Hermitian and skew/skew Hermitian matrices can always be diagonalized in a numerically stable way; `numeric::fMatrix` produces reliable numerical results for such matrices.

The procedure *f* must accept complex floating-point numbers as first argument. It may return arbitrary MuPAD expressions, provided these can be multiplied with floating-point numbers.

The parameters p_1, p_2, ... may be numerical or symbolic objects. They must be accepted by `f` as 2nd argument, 3rd argument etc.

In contrast to the components of *A*, numerical symbolic objects such as π, $\sqrt{2}$ etc. passed as parameters p_1, p_2, ... are not converted to floats.

Inversion or exponentiation of a matrix may be realized with the functions $a \to \frac{1}{a}$ and `exp`, respectively. However, it is recommended to use the specialized algorithms `numeric::inverse` and `numeric::expMatrix` instead. Also matrix evaluation of low degree polynomials should be done with standard matrix arithmetic rather than with `numeric::fMatrix`.

Environment Interactions

The function is sensitive to the environment variable `DIGITS`, which determines the numerical working precision.

Examples

Example 1

We compute the matrix power A^{100}:

```
A := array(1..2, 1..2, [[2, PI], [exp(-10), 0]]):
numeric::fMatrix(x -> x^100, A)
```

$$\begin{pmatrix} 1.272133133\ 10^{30} & 1.998190806\ 10^{30} \\ 2.887634784\ 10^{25} & 4.535724387\ 10^{25} \end{pmatrix}$$

Alternatively, you may use the function `_power` which takes the exponent as a second parameter:

```
numeric::fMatrix(_power, A, 100)
```

$$\begin{pmatrix} 1.272133133\ 10^{30} & 1.998190806\ 10^{30} \\ 2.887634784\ 10^{25} & 4.535724387\ 10^{25} \end{pmatrix}$$

```
delete A:
```

Example 2

We compute the square root of a matrix:

```
A := matrix([[0, 1], [-1, 1]]):
B := numeric::fMatrix(sqrt, A)
```

$$\begin{pmatrix} 0.5773502692 & 0.5773502692 + 1.110223025\ 10^{-16}\,i \\ -0.5773502692 + 5.551115123\ 10^{-17}\,i & 1.154700538 - 1.110223025\ 10^{-16}\,i \end{pmatrix}$$

The small imaginary parts are caused by numerical round-off. We eliminate them by extracting the real parts of the components:

```
B := map(B, Re)
```

$$\begin{pmatrix} 0.5773502692 & 0.5773502692 \\ -0.5773502692 & 1.154700538 \end{pmatrix}$$

We verify that `B^2` is `A`. Since A was passed as a matrix of type `Dom::Matrix()`, the matrix B is also of this type. We may compute the square by the overloaded standard arithmetic using the operator `^`:

```
B^2
```

$$\begin{pmatrix} -1.283695372\,10^{-16} & 1.0 \\ -1.0 & 1.0 \end{pmatrix}$$

```
delete A, B:
```

Example 3

We compute $e^{t\,\pi\,A}$ with a symbolic parameter t:

```
A := array(1..2, 1..2, [[0, 1], [-1, 0]]):
numeric::fMatrix(exp@_mult, A, t*PI)
```

$$\begin{pmatrix} \sigma_1 & -0.5\,e^{1.0\,\pi\,t\,i}\,i + 0.5\,e^{-1.0\,\pi\,t\,i}\,i \\ 0.5\,e^{1.0\,\pi\,t\,i}\,i - 0.5\,e^{-1.0\,\pi\,t\,i}\,i & \sigma_1 \end{pmatrix}$$

where

$$\sigma_1 = 0.5\,e^{1.0\,\pi\,t\,i} + 0.5\,e^{-1.0\,\pi\,t\,i}$$

```
delete A:
```

Example 4

We demonstrate the difference between `HardwareFloats` and `SoftwareFloats`. The diagonalization of the following matrix is ill-conditioned. The result is dominated by round-off effects:

```
A := array(1..3, 1..3, [[10, 1,    1    ],
                        [ 0, 1,    1    ],
                        [ 1, 0, 10^(-14)]]):
numeric::fMatrix(ln, A, SoftwareFloats)
```

$$\begin{pmatrix} 2.284572396 & 0.2635466905 & 0.2635466905 \\ -4.117444729 & 4.03009691 & 41.43799398 \\ 4.380991419 & -4.117444729 & -41.5253418 \end{pmatrix}$$

```
numeric::fMatrix(ln, A, HardwareFloats)
```

$$\begin{pmatrix} 2.284572396 & 0.2635466905 & 0.2635466905 \\ -3.532353481 & 3.445005663 & 35.5870815 \\ 3.795900172 & -3.532353481 & -35.67442932 \end{pmatrix}$$

In the following case, the round-off effects of `SoftwareFloats` makes the algorithm think that the matrix cannot be diagonalized. Consequently, `FAIL` is returned. With `HardwareFloats`, however, a result is computed:

```
A := array(1..3, 1..3, [[   1     , 1 ,    1    ],
                        [   0     , 1 ,    1    ],
                        [ 10^(-30), 0 , 10^(-30)]]):
numeric::fMatrix(ln, A, SoftwareFloats)
```

FAIL

```
numeric::fMatrix(ln, A, HardwareFloats)
```

$$\begin{pmatrix} -5.469808086\ 10^{-17} & 1.000000477 & 0.9999345993 \\ 9.98400946\ 10^{-31} & -5.632422161\ 10^{-17} & 69.07755279 \\ 0 & 0 & -69.07755279 \end{pmatrix}$$

```
delete A:
```

Parameters

f

A procedure representing a scalar function $f\colon \mathbb{C} \to \mathbb{C}$ or $f\colon \mathbb{C} \times P \times \cdots \times P \to \mathbb{C}$, where P is a set of parameters

A

A square matrix of domain type DOM_ARRAY, DOM_HFARRAY, or of category Cat::Matrix

p_1, p_2, …

Arbitrary MuPAD objects accepted by *f* as additional input parameters

Options

Hard, HardwareFloats, Soft, SoftwareFloats

With Hard (or HardwareFloats), computations are done using fast hardware float arithmetic from within a MuPAD session. Hard and HardwareFloats are equivalent. With this option, the input data are converted to hardware floats and processed by compiled C code. The result is reconverted to MuPAD floats and returned to the MuPAD session.

With Soft (or SoftwareFloats) computations are dome using software float arithmetic provided by the MuPAD kernel. Soft and SoftwareFloats are equivalent. SoftwareFloats is used by default if the current value of DIGITS is larger than 15 and the input matrix A is not of domain type DOM_HFARRAY.

Compared to the SoftwareFloats used by the MuPAD kernel, the computation with HardwareFloats may be many times faster. Note, however, that the precision of hardware arithmetic is limited to about 15 digits. Further, the size of floating-point numbers may not be larger than approximately 10^{308} and not smaller than approximately 10^{-308}.

If no HardwareFloats or SoftwareFloats are requested explicitly, the following strategy is used: If the current value of DIGITS is smaller than 16 or if the matrix A is a hardware float array of domain type DOM_HFARRAY, then hardware arithmetic is tried. If this is successful, the result is returned.

If the result cannot be computed with hardware floats, software arithmetic by the MuPAD kernel is tried.

If the current value of DIGITS is larger than 15 and the input matrix A is not of domain type DOM_HFARRAY, or if one of the options Soft, SoftwareFloats or Symbolic is

specified, MuPAD computes the result with its software arithmetic without trying to use hardware floats first.

There may be several reasons for hardware arithmetic to fail:

- The current value of `DIGITS` is larger than 15.
- The data contains symbolic objects.
- The data contains numbers larger than 10^{308} or smaller than 10^{-308} that cannot be represented by hardware floats.

If neither `HardwareFloats` nor `SoftwareFloats` is specified, the user is not informed whether hardware floats or software floats are used.

If `HardwareFloats` are specified but fail due to one of the reasons above, a warning is issued that the (much slower) software floating-point arithmetic of the MuPAD kernel is used.

Note: For ill-conditioned matrices, the result is subject to round-off errors. The results returned with `HardwareFloats` and `SoftwareFloats` may differ! See "Example 4" on page 19-107.

`NoWarning`

Suppresses warnings

`ReturnType`

Option, specified as `ReturnType = d`

Return the result as a matrix of domain type `d`. The following return types are available: `DOM_ARRAY`, `DOM_HFARRAY`, `Dom::Matrix()`, or `Dom::DenseMatrix()`.

Return Values

Depending on the type of the input matrix `A`, the matrix $f(A)$ is returned as a matrix of type `DOM_ARRAY`, `DOM_HFARRAY`, `Dom::Matrix()` or `Dom::DenseMatrix()`. If the algorithm thinks that `A` is not diagonalizable, then `FAIL` is returned.

Algorithms

A numerical diagonalization $A = X\,diag(\lambda_1, \lambda_2, \ldots)\,X^{-1}$ is computed. The columns of X are the (right) eigenvectors of A, the diagonal entries $\lambda_1, \lambda_2, \ldots$ are the corresponding eigenvalues. The function f is mapped to the eigenvalues, the matrix result is computed by

$$f(A, p_1, p_2, \ldots) = X\ \mathrm{diag}\big(f(\lambda_1, p_1, p_2, \ldots), f(\lambda_2, p_1, p_2, \ldots), \ldots\big)\ X^{-1}$$

.

The eigenvector matrix X may be obtained via `numeric::eigenvectors(A)[2]`.

The condition number $\|X\|_\infty \left\|\frac{1}{X}\right\|_\infty$ of the eigenvector matrix is a measure indicating how well conditioned the diagonalization of the matrix A is. If this number is larger than 10^{DIGITS}, then not a single digit of the diagonalization data is trustworthy.

The call `numeric::fMatrix(exp, A)` corresponds to `numeric::expMatrix(A, Diagonalization)`.

numeric::fsolve

Search for a numerical root of a system of equations

Syntax

```
numeric::fsolve(eq, x, options)
numeric::fsolve(eq, x = a, options)
numeric::fsolve(eq, x = a .. b, options)
numeric::fsolve(eqs, [x1, x2, …], options)
numeric::fsolve(eqs, {x1, x2, …}, options)
numeric::fsolve(eqs, [x1 = a1, x2 = a2, …], options)
numeric::fsolve(eqs, {x1 = a1, x2 = a2, …}, options)
numeric::fsolve(eqs, [x1 = a1 .. b1, x2 = a2 .. b2, …], options)
numeric::fsolve(eqs, {x1 = a1 .. b1, x2 = a2 .. b2, …}, options)
```

Description

`numeric::fsolve(eqs, ...)` returns a numerical approximation of a solution of the system of equations `eqs`.

This is the MuPAD numerical solver for non-linear systems of equations.

Note: By default, this routine returns only *one* numerical solution!

The equations must not contain symbolic objects other than the unknowns that cannot be converted to numerical values via `float`. Symbolic objects such as π or $\sqrt{2}$ etc. are accepted. The same holds true for starting values and search ranges. Search ranges may contain $\pm\infty$. Cf. “Example 2” on page 19-116.

`numeric::fsolve` implements a purely numerical Newton type root search with a working precision set by the environment variable `DIGITS`. Well separated simple roots

should be exact within this precision. However, multiple roots or badly separated roots may be computed with a restricted precision. Cf. "Example 3" on page 19-116.

Note: For systems of equations, the expressions defining the equations must have a symbolic derivative!

Overdetermined systems (i.e., more equations than indeterminates) are not accepted. However, there may be more indeterminates than equations. Cf. "Example 4" on page 19-117.

Specifying indeterminates `[x1, x2, ...]` without starting values or search ranges is equivalent to the search ranges `[x_1 = -infinity .. infinity, x_2 = -infinity .. infinity, dots]`. Note, however, that the user should assist `numeric::fsolve` by providing specific search ranges whenever possible! If a complex starting point or a search range involving a complex number is specified for at least one of the unknowns, the search is extended to the entire complex plane for all variables for which no explicit search interval is given.

For real equations and real starting points or search ranges, the internal Newton iteration will usually produce real values, i.e., `numeric::fsolve` searches for real roots only (unless square roots, logarithms etc. happen to produce complex values from real input). Use complex starting points or search ranges to search for complex roots of real equations. Cf. "Example 5" on page 19-117.

Starting values and search ranges can be mixed. Cf. "Example 6" on page 19-118.

Search ranges should only be provided if a solution is known to exist inside the search range. Otherwise, the search may take some time before `numeric::fsolve` gives up.

Specification of a search range primarily means that starting points from this range are used for the internal Newton search. For sufficiently small search ranges enclosing a solution the search will usually pick out this solution. However, it may also happen that the Newton iteration drifts towards other solutions.

With the default search strategy `RestrictedSearch`, only solutions from the search range are accepted, even if solutions outside the search range are found internally. More specifically, if a search range such as `x = a .. b` is specified for the variable `x`, then solutions satisfying `min(#(a), #(b)) ≤ #(x) ≤ max(#(a), #(b))` and `min(#(a), #(b)) ≤ #(x) ≤ max(#(a), #(b))` are searched for. Thus, the values `a, b` specify

the bottom left and top right corner of a rectangular search area in the complex plane when the `RestrictedSearch` strategy is used.

With the search strategy `UnrestrictedSearch`, any solution inside or outside the search range is accepted and returned. Cf. "Example 7" on page 19-118.

If starting values for all indeterminates are provided, then a *single* Newton iteration with these initial data is launched. It either leads to a solution or `numeric::fsolve` gives up and returns `FAIL`. The same holds true if search ranges `x = a .. a` or `[x_1 = a_1 .. a_1, x_2 = a_2 .. a_2, dots]` of zero length are specified.

Note: The risk of failure is high when providing bad starting values! Starting values are appropriate only if a sufficiently good approximation of the solution is known! On the other hand, providing good starting values is the fastest way to a solution. Cf. "Example 8" on page 19-119.

If at least one of the indeterminates has a non-trivial search range, then `numeric::fsolve` uses *several* Newton iterations with different starting values from the search range. Cf. "Example 9" on page 19-119. Search ranges in conjunction with the option `UnrestrictedSearch` provide a higher chance of detecting roots than (bad) starting values!

Note: User defined assumptions such as `assume(x > 0)` are not taken into account in the numerical search! Provide search ranges instead! Cf. "Example 2" on page 19-116.

Note: Convergence may be slow for multiple roots! Furthermore, `numeric::fsolve` may fail to detect such roots!

Use `linsolve` or `numeric::linsolve` for systems of *linear* equations.

Use `numeric::realroots`, if *all real roots* of a single non-polynomial real equation in a finite range are desired.

Use `polylib::realroots`, if *all real roots* of a real univariate polynomial are desired.

Use `numeric::polyroots`, if *all real and complex roots* of a univariate polynomial are desired.

Use `numeric::solve`, if *all roots* of a multivariate polynomial system are desired.

The routine `numeric::solve` provides a common interface to all these numerical solvers.

Environment Interactions

The function is sensitive to the environment variable `DIGITS`, which determines the numerical working precision.

Examples

Example 1

We compute roots of the sine function:

```
numeric::fsolve(sin(x) = 0, x)
```

$$[x = 0.0]$$

With the option `Random`, several calls may result in different roots:

```
numeric::fsolve(sin(x), x, Random)
```

$$[x = -226.1946711]$$

```
numeric::fsolve(sin(x), x, Random)
```

$$[x = 97.38937226]$$

Particular solutions can be chosen by an appropriate starting point close to the wanted solution, or by a search interval:

```
numeric::fsolve(sin(x), x = 3),
numeric::fsolve(sin(x), x = -4 .. -3)
```

$$[x = 3.141592653], [x = -3.141592654]$$

The solutions found by `numeric::fsolve` can be used in `subs` and `assign` to substitute or assign the indeterminates:

```
eqs := [x^2 = sin(y), y^2 = cos(x)]:
solution := numeric::fsolve(eqs, [x, y])
```

$$[x = -0.8517004887,\ y = 0.8116062151]$$

```
eval(subs(eqs, solution))
```

$$[0.7253937224 = 0.7253937224,\ 0.6587046485 = 0.6587046485]$$

```
assign(solution): x, y
```

$$-0.8517004887,\ 0.8116062151$$

```
delete eqs, solution, x, y:
```

Example 2

We demonstrate the use of search ranges. The following system has solutions with positive and negative x. The solution with $x \geq 0$ is obtained with the search interval `x = 0 .. infinity`:

```
numeric::fsolve([x^2 = exp(x*y), x^2 = y^2], [x = 0 .. infinity, y])
```

$$[x = 0.753089165,\ y = -0.753089165]$$

We search for a solution with $x \leq 0$:

```
numeric::fsolve([x^2 = exp(x*y), x^2 = y^2], [x = -infinity .. 0, y])
```

$$[x = -0.753089165,\ y = 0.753089165]$$

Example 3

Multiple roots can only be computed with a restricted precision:

```
numeric::fsolve(expand((x - 1/3)^5), x = 0.3)
```

$$[x = 0.3333672906]$$

Example 4

The following system of equations is degenerate and has a 1-parameter family of solutions. Each call to `numeric::fsolve` picks out one random solution:

```
numeric::fsolve([x^2 - y^2, x^2 - y^2], [x, y], Random) $ i = 1 .. 3
```

$$[x = 34.70258251,\ y = 34.70258251],\ [x = -29.16650501,\ y = 29.16650501],\ [x = 5.933941324,\ y = -5.933941324]$$

The equation may also be specified as an underdetermined system:

```
numeric::fsolve([x^2 - y^2], [x, y])
```

$$[x = 0.0,\ y = 0.0]$$

Example 5

The following equation has no real solution. Consequently, the numerical search with real starting values fails:

```
numeric::fsolve(sin(x) + cos(x)^2 = 3, x)
```

FAIL

With a complex starting value, a solution is found:

```
numeric::fsolve(sin(x) + cos(x)^2 = 3, x = I)
```

$$[x = 0.2972513613 + 1.128383965\ i]$$

Also complex search ranges may be specified. In the following, the internal starting point is a random value on the line from `2 + I` to `3 + 2*I`. Solutions are accepted if they lie in the complex rectangle with the bottom left corner `2 + I` and the top right corner `3 + 2*I`:

```
numeric::fsolve(sin(x) + cos(x)^2 = 3, x = 2 + I .. 3 + 2*I)
```

$$[x = 2.844341292 + 1.128383965\,i]$$

Example 6

Starting values and search intervals can be mixed:

```
numeric::fsolve([x^2 + y^2 = 1, y^2 + z^2 = 1, x^2 + z^2 = 1],
                [x = 1, y = 0 .. 10, z])
```

$$[x = 0.7071067812,\ y = 0.7071067812,\ z = 0.7071067812]$$

Example 7

With `UnrestrictedSearch`, search intervals are only used for choosing starting values for the internal Newton search. The numerical iteration may drift towards a solution outside the search range:

```
eqs := [x*sin(10*x) = y^3, y^2 = exp(-2*x/3)]:
numeric::fsolve(eqs, [x = 0 .. 1, y = -1 .. 0], UnrestrictedSearch)
```

$$[x = 1.232766201,\ y = -0.6630386021]$$

With the default strategy `RestrictedSearch`, only solutions inside the search range are accepted:

```
numeric::fsolve(eqs, [x = 0 .. 1, y = -1 .. 0])
```

$$[x = 0.9816416007,\ y = -0.7209295436]$$

In the last search, also the previous solution outside the search range was found. With the option `MultiSolutions`, `numeric::fsolve` returns a sequence of all solutions that were found in the internal search:

```
numeric::fsolve(eqs, [x = 0 .. 1, y = -1 .. 0], MultiSolutions)
```

$$[x = 0.9816416007,\ y = -0.7209295436],\ [x = 1.232766201,\ y = -0.6630386021]$$

```
delete eqs:
```

Example 8

Usually, most of the time is spent internally searching for some (crude) approximations of the root. If high precision roots are required, it is recommended to compute first approximations with moderate values of `DIGITS` and use them as starting values for a refined search:

```
eq := exp(-x) = x:
DIGITS := 10:
firstApprox := numeric::fsolve(eq, x)
```

$$[x = 0.5671432904]$$

This output is suitable as input defining a starting value for x:

```
DIGITS := 1000: numeric::fsolve(eq, firstApprox)
```

$$[x = 0.5671432904097838729999686622103555497538\ldots]$$

[x =
0.5671432904097838729999686622103555497538157871865125081351310792230457930866845666

```
delete eq, firstApprox, DIGITS:
```

Example 9

Specifying starting values for the indeterminates launches a *single* Newton iteration. This may fail, if the starting values are not sufficiently close to the solution:

```
eq := [x*y = x + y - 4, x/y = x - y + 4]:
numeric::fsolve(eq, [x = 1, y = 1])
```

$$\text{FAIL}$$

If a search range is specified for at least one of the unknowns, then *several* Newton iterations with random starting values in the search range are used, until a solution is found or until `numeric::fsolve` gives up:

```
numeric::fsolve(eq, [x = 1, y = 0 .. 10])
```

$$\left[x = 4.02644145\ 10^{-14},\ y = 4.0\right]$$

```
delete eq:
```

Parameters

eq

An arithmetical expression or an equation in one indeterminate `x`. An expression `eq` is interpreted as the equation `eq = 0`.

eqs

A list, set, `array`, or `matrix` (`Cat::Matrix`) of expressions or equations in several indeterminates `x1, x2, ...`. Expressions are interpreted as homogeneous equations.

x, x_1, x_2, …

Identifiers or indexed identifiers to be solved for.

a, a_1, a_2, …

Real or complex numerical starting values for the internal search. Typically, crude approximations of solution.

a .. b, a_1 .. b_1, a_2 .. b_2, …

Ranges of numerical values defining search intervals for the numerical root.

Options

RestrictedSearch

Makes `numeric::fsolve` return only numerical roots in the user-defined search range `x = a .. b` and `[x_1 = a_1 .. b_1, x_2 = a_2 .. b_2, Symbol::hellip]`, respectively. This is the default search strategy, if a search range is specified for at least one of the unknowns.

Once a root with components (r_1, r_2, …) is found, it is checked whether $min(\Re(a_i), \Re(b_i)) \le \Re(r_i) \le max(\Re(a_i), \Re(b_i))$ and $min(\Im(a_i), \Im(b_i)) \le \Im(r_i) \le max(\Im(a_i), \Im(b_i))$ is satisfied. If the root is not inside the search range, the search is continued. Note that solutions outside the search range may be found internally. These may be accessed with the option `MultiSolutions`. See "Example 7" on page 19-118.

`UnrestrictedSearch`

Allows `numeric::fsolve` to find and return solutions outside the specified search range. With this option, the search range is only used to choose random starting points for the internal numerical search.

This option switches off the search strategy `RestrictedSearch`. With `UnrestrictedSearch`, `numeric::fsolve` stops its internal search whenever a root is found, even if the root is not inside the specified search range. Starting points for the internal Newton search are taken from the search range.

`MultiSolutions`

Makes `numeric::fsolve` return all solutions found in the internal search

This option only has an effect when used with the default search strategy `RestrictedSearch`. A sequence of all roots found in the internal search is returned. Cf. "Example 7" on page 19-118.

`Random`

With this option, several calls to `numeric::fsolve` with the same input parameters may produce different roots.

With this option, random starting values are chosen for the internal search. Consequently, calling `numeric::fsolve` several times with the same parameters may lead to different solutions. This may be useful when several roots of one and the same equation or set of equations are desired.

Return Values

Single numerical root is returned as a list of equations `[x = value]` or `[`x_1 `= value`$_1$`,` x_2 `= value`$_2$`, …]`, respectively. `FAIL` is returned if no solution is found. With the option `MultiSolutions`, sequences of solutions may be returned.

Algorithms

Internally the set of equations $f(x) = 0$ is solved by a modified Newton iteration $x \to x - t\, f'(x)^{-1}\, f(x)$ with some adaptively chosen step size t. For degenerate or ill-conditioned Jacobians f' a minimization strategy for $\langle f, f \rangle$ is implemented. For scalar real equations, `numeric::realroot` is used, if a real finite search range is specified.

- "Solve Equations Numerically"

numeric::gaussAGM

Gauss' arithmetic geometric mean

Syntax

```
numeric::gaussAGM(a, b)
```

Description

`numeric::gaussAGM(a, b)` computes the arithmetic geometric mean of the numbers a and b.

The iteration

$$a_{n+1} = \frac{a_n + b_n}{2}, \quad b_{n+1} = (a_n + b_n)\sqrt{\frac{a_n b_n}{(a_n + b_n)^2}}$$

with the starting values $a_0 = a$, $b_0 = b$ converges quadratically to some value $\lim_{n\to\infty} a_n = \lim_{n\to\infty} b_n$. This limit is called Gauss' arithmetic geometric mean of the starting values a, b.

If both arguments a and b can be converted to real or complex floating-point numbers, then a floating point value is computed and returned. Otherwise, the symbolic call `numeric::gaussAGM(a, b)` is returned.

If $a = 0$ or $b = 0$ or $a + b = 0$, then 0.0 is returned, even if a or b are symbolic objects.

The following relation to elliptic integrals holds for all complex values a and b:

$$\text{numeric::gaussAGM}(a, b) = \frac{\pi}{4}\,\frac{a+b}{\mathrm{K}\left(\sqrt{1-\left(\frac{a-b}{a+b}\right)^2}\right)}.$$

Environment Interactions

The function is sensitive to the environment variable `DIGITS`.

Examples

Example 1

A floating-point number is returned if the arguments can be converted to floating-point numbers:

```
numeric::gaussAGM(0, 5)
```

$$0.0$$

```
numeric::gaussAGM(sqrt(2), PI)
```

$$2.192033978$$

```
numeric::gaussAGM(-10, PI)
```

$$-2.377943461 - 2.966350545\,i$$

```
numeric::gaussAGM(1 + I, 1 + 2*I)
```

$$1.020054126 + 1.471349363\,i$$

A symbolic call is returned if one of the arguments cannot be converted to a float:

```
numeric::gaussAGM(1, b)
```

$$\text{numeric::gaussAGM}(1, b)$$

For the special cases $a = 0$, $b = 0$ and $a + b = 0$, the result 0.0 is returned even for symbolic arguments:

```
numeric::gaussAGM(a, 0)
```

```
    0.0
```

```
numeric::gaussAGM(a, -a)
```

```
    0.0
```

Parameters

a, b

arithmetical expressions

Return Values

Floating point number or a symbolic call `numeric::gaussAGM(a, b)`.

MuPAD Functions
`ellipticK`

numeric::gldata

Weights and abscissae of Gauss-Legendre quadrature

Syntax

```
numeric::gldata(n, digits)
```

Description

`numeric::gldata(n, digits)` returns the weights and the abscissae of the Gauss-Legendre quadrature rule with n nodes with a precision of `digits` decimal digits.

The Gauss-Legendre quadrature rule $\sum_{i=1}^{n} b_i f(c_i)$ produces the exact integral $\int_0^1 f(x)\,\mathrm{d}x$ for all polynomial integrands $f(x)$ through degree $2n - 1$. The weights b_i and abscissae c_i are related to the roots of the n-th Legendre polynomial.

The weights and abscissae are computed by a straightforward numerical algorithm with a working precision set by the argument `digits`. The resulting floating-point numbers are correct to `digits` leading decimal places.

Typically, the argument `digits` is chosen as the current value of the environment variable `DIGITS`.

The data for `n = 20, 40, 80, 160` with `digits <= 200` are stored internally. They are returned immediately without any computational costs.

Due to the internal remember mechanism, only the first call to `numeric::gldata` leads to computational costs. For any further call with the same arguments, the data are returned immediately.

For odd n, the abscissa $c_{\frac{n+1}{2}} = \frac{1}{2}$ and the corresponding weight $b_{\frac{n+1}{2}}$ are rational numbers.

Environment Interactions

`numeric::gldata` is *not* sensitive to changes of the environment variable `DIGITS`, because the numerical working precision is specified by the second argument `digits`.

The function uses `option remember`.

Examples

Example 1

The following call computes the Gauss-Legendre data with a precision given by the current value of the environment variable `DIGITS` (the default value is `DIGITS = 10`):

```
[b, c] := numeric::gldata(4, DIGITS)
```

$$[[0.1739274226, 0.3260725774, 0.3260725774, 0.1739274226],\ [0.0694318442, 0.3300094782, 0.6699905218, 0.9305681558]]$$

The Gauss-Legendre data with 4 nodes provide exact numerical quadrature results for polynomials through degree 7:

```
f := x -> x^7:
int(f(x), x= 0..1) = _plus(b[i]*f(c[i]) $ i=1..4)
```

$$\frac{1}{8} = 0.125$$

```
delete b, c, f:
```

Example 2

For odd n, exact rational data for $c_{\frac{n+1}{2}}$ and $b_{\frac{n+1}{2}}$ are returned. The other data are computed as floating-point approximations:

```
DIGITS := 4: numeric::gldata(5, DIGITS)
```

$$\left[\left[0.1185,\ 0.2393,\ \frac{64}{225},\ 0.2393,\ 0.1185\right],\ \left[0.04691,\ 0.2308,\ \frac{1}{2},\ 0.7692,\ 0.9531\right]\right]$$

```
delete DIGITS:
```

Parameters

`n`

The number of nodes: a positive integer

`digits`

The number of decimal digits: a positive integer

Return Values

List `[b, c]` is returned. The lists `b = [b`$_1$`, …, b`$_n$`]` and `c = [c`$_1$`, …, c`$_n$`]` are numerical approximations of the weights and abscissae with `digits` significant digits.

Algorithms

The numerical integrator `numeric::quadrature` calls `numeric::gldata` to provide the data for Gaussian quadrature.

See Also

MuPAD Functions

`numeric::gtdata` | `numeric::int` | `numeric::ncdata` | `numeric::quadrature`

numeric::gtdata

Weights and abscissae of Gauss-Tschebyscheff quadrature

Syntax

```
numeric::gtdata(n)
```

Description

`numeric::gtdata(n)` returns the weights and the abscissae of the Gauss-Tschebyscheff quadrature rule with n nodes.

The Gauss-Tschebyscheff quadrature rule $\sum_{i=1}^{n} b_i f(c_i)$ produces the exact integral $\int_0^1 f(x)\,\mathrm{d}x$ for all integrands of the form $f(x) = \frac{p(x)}{\sqrt{x\,(1-x)}}$ with polynomials $p(x)$ through degree $2\,n$ - 1.

The exact weights $b = [b_1, \ldots, b_n]$ and abscissae $c = [c_1, \ldots, c_n]$ are given by

$$b_i = \frac{\pi}{2\,n}\,\sin\left(\frac{(2\,i-1)\,\pi}{2\,n}\right),\quad c_i = \frac{1+\cos\left(\frac{(2\,i-1)\,\pi}{2\,n}\right)}{2}.$$

Environment Interactions

`numeric::gtdata` is not sensitive to the environment variable `DIGITS`.

The function uses `option remember`.

Examples

Example 1

The following call produces exact data for the quadrature rule with two nodes:

```
numeric::gtdata(2)
```

$$\left[\left[\frac{\pi\sqrt{2}}{8}, \frac{\pi\sqrt{2}}{8}\right], \left[\frac{\sqrt{2}}{4}+\frac{1}{2}, \frac{1}{2}-\frac{\sqrt{2}}{4}\right]\right]$$

Parameters

n

The number of nodes: a positive integer

Return Values

List `[b,c]` is returned. The lists `b = [`b_1`, …, `b_n`]` and `c = [`c_1`, …, `c_n`]` are the exact weights and abscissae of the Gauss-Tschebyscheff quadrature rule, respectively.

Algorithms

The numerical integrator `numeric::quadrature` calls `numeric::gtdata` to provide the data for Gauss-Tschebyscheff quadrature.

numeric::indets

Search for indeterminates

Syntax

```
numeric::indets(object)
```

Description

`numeric::indets(object)` returns a set of the indeterminates contained in the `object`.

This is an auxiliary routine used by `numeric::polyroots`, `numeric::quadrature`, `numeric::realroots`, `numeric::solve` etc. to find indeterminates.

It recursively searches the operands of `object` for indeterminates. In particular, the search is applied to the elements of lists, sets, arrays, tables, etc.

Following objects are regarded as indeterminates: identifiers, indexed identifiers and the indeterminates of `DOM_POLY` objects. Also coefficients of such polynomials are searched for indeterminates.

The following objects are *not* regarded as indeterminates: the numerical constants PI, EULER, and CATALAN (cf. `Type::ConstantIdents`) and zero operands of expressions and subexpressions (i.e., the function names in unevaluated function calls such as `f(2)`, `sin(PI/13)` etc.). Also integration variables in unevaluated calls of `int`, `numeric::int` and `numeric::quadrature` and summation indices in unevaluated calls of `sum` and `numeric::sum` are not considered.

Examples

Example 1

Identifiers and indexed identifiers are regarded as indeterminates:

```
numeric::indets([{a + b*PI}, sin(c + sqrt(2) + EULER),
                 table(1 = d - cos(e), 2 = f + 0.1*I),
                 array(1..2, [g, h]), F(i[2], i[2]),
                 D([1], G)(j[1]), k[3 + L[4]]])
```

$$\left\{a, b, c, d, e, f, g, h, i_2, j_1, k_{L_4+3}\right\}$$

Both indeterminates as well as symbolic coefficients are considered in polynomials of domain type `DOM_POLY`:

```
numeric::indets(poly(a[1]*x^2 + a[2]*x +a, [x, y]))
```

$$\{a, x, y, a_1, a_2\}$$

Example 2

The zero operands of unevaluated function calls such as `f(…)` or `sin(…)` are not regarded as indeterminates:

```
numeric::indets(f(a + sin(b) + PI + EULER))
```

$$\{a, b\}$$

Integration variables and summation indices are not regarded as indeterminates:

```
numeric::indets({int(f(x), x = a..b),
                 sum(f(i), i = c..infinity)})
```

$$\{a, b, c\}$$

Parameters

`object`

An arbitrary MuPAD object

Return Values

Set of indeterminates is returned, if the argument is an object of some basic data type of the kernel. The empty set is returned, if the object is from some library domain.

MuPAD Functions
`freeIndets` | `indets`

numeric::int

Numerical integration (the Float attribute of Int)

Syntax

```
numeric::int(f(x), x = a .. b, options)
```

```
float(holdint(f(x), x = a .. b, options))
```

```
float(freezeint(f(x), x = a .. b, options))
```

Description

`numeric::int(f(x), x = a..b)` computes a numerical approximation of $\int_a^b f(x)\,\mathrm{d}x$.

The calls `numeric::int(...)`, `float ( freeze(int)(...))`, and `float ( hold(int)(...))` are equivalent.

The calls `numeric::int(...)` and `numeric::quadrature(...)` are almost equivalent: `numeric::int` calls `numeric::quadrature`. A numerical result produced by `numeric::quadrature` is returned as is. Otherwise, `hold(numeric::int)(...)` is returned.

See the help page of `numeric::quadrature` for details.

Environment Interactions

The function is sensitive to the environment variable `DIGITS`, which determines the numerical working precision.

Examples

Example 1

We demonstrate some equivalent calls for numerical integration:

```
numeric::int(exp(x^2), x = -1..1),
float(hold(int)(exp(x^2), x = -1..1)),
float(freeze(int)(exp(x^2), x = -1..1)),
numeric::quadrature(exp(x^2), x = -1..1)
```

$$2.925303492,\ 2.925303492,\ 2.925303492,\ 2.925303492$$

```
numeric::int(max(1/10, cos(PI*x)), x = -2..0.0123),
float(hold(int)(max(1/10, cos(PI*x)), x = -2..0.0123)),
float(freeze(int)(max(1/10, cos(PI*x)), x = -2..0.0123)),
numeric::quadrature(max(1/10, cos(PI*x)), x = -2..0.0123)
```

$$0.752102471,\ 0.752102471,\ 0.752102471,\ 0.752102471$$

```
numeric::int(exp(-x^2), x = -2..infinity),
float(hold(int)(exp(-x^2), x = -2..infinity)),
float(freeze(int)(exp(-x^2), x = -2..infinity)),
numeric::quadrature(exp(-x^2), x = -2..infinity)
```

$$1.768308316,\ 1.768308316,\ 1.768308316,\ 1.768308316$$

```
numeric::int(sin(x)/x, x = -1..10, GaussLegendre = 5),
float(hold(int)(sin(x)/x, x = -1..10, GaussLegendre = 5)),
float(freeze(int)(sin(x)/x, x = -1..10, GaussLegendre = 5)),
numeric::quadrature(sin(x)/x, x = -1..10, GaussLegendre = 5)
```

$$2.604430665,\ 2.604430665,\ 2.604430665,\ 2.604430665$$

The calls `numeric::int(...)`, `float(hold(int)(...))`, and `numeric::quadrature(...)` are equivalent in multiple numerical integrations, too:

```
numeric::int(numeric::int(x*y, x = 0..y), y = 0..1),
numeric::int(numeric::quadrature(x*y, x = 0..y), y = 0..1),
float(freeze(int)(numeric::int(x*y, x = 0..y), y = 0..1)),
float(hold(int)(numeric::quadrature(x*y, x = 0..y), y = 0..1)),
numeric::quadrature(numeric::int(x*y, x = 0..y), y = 0..1),
numeric::quadrature(numeric::quadrature(x*y, x = 0..y), y = 0..1)
```

$$0.125,\ 0.125,\ 0.125,\ 0.125,\ 0.125,\ 0.125$$

Example 2

The following integral do not exist. Consequently, numerical integration runs into problems:

```
numeric::quadrature(1/x, x = 0..infinity)
```

```
Warning: Precision goal is not achieved after 10000 function calls. Increase 'MaxCalls
```

$$172.711431$$

Note that `numeric::int` handles errors produced by `numeric::quadrature` and returns a symbolic call to `numeric::int`:

```
numeric::int(1/x, x = 0..infinity)
```

$$\text{numeric::int}\left(\frac{1}{x}, x = 0..\infty\right)$$

Parameters

`f(x)`

An arithmetical expression in x

`x`

An identifier or an indexed identifier

`a, b`

arithmetical expressions

Options

All options of `numeric::quadrature` can be used.

Return Values

Floating point number or a symbolic call `numeric::int(f(x), x = a..b)` if the integral cannot be evaluated numerically.

More About

- "Integration"

numeric::inverse

Inverse of a matrix

Syntax

```
numeric::inverse(A, options)
```

Description

`numeric::inverse(A)` returns the inverse of the matrix `A`.

If no return type is specified via the option `ReturnType = t`, the domain type of the inverse depends on the type of the input matrix `A`:

- The inverse of an array is returned as an array.
- The inverse of an hfarray is returned as an hfarray.
- The inverse of a dense matrix of type `Dom::DenseMatrix()` is a dense matrix of type `Dom::DenseMatrix()` over the ring of MuPAD expressions.
- For all other matrices of category `Cat::Matrix`, the inverse is returned as a `matrix` of type `Dom::Matrix()` over the ring of MuPAD expressions. This includes input matrices `A` of type `Dom::Matrix(...)`, `Dom::SquareMatrix(...)`, `Dom::MatrixGroup(...)` etc.

The option `Symbolic` should be used if the matrix contains symbolic objects that cannot be converted to floating point numbers.

Without the option `Symbolic`, all entries of `A` must be numerical. Floating point arithmetic is used, the working precision is set by the environment variable `DIGITS`. Exact numerical expressions such as $\pi + \sqrt{2}$, `sin(3)` etc. are accepted and converted to floats. If symbolic entries are found in the matrix, `numeric::inverse` automatically switches to `Symbolic`, issuing a warning. This warning may be suppressed via the option `NoWarning`.

Note: Invertibility of the matrix can only be safely detected with exact arithmetic, i.e., using the option `Symbolic`. See “Example 2” on page 19-140.

Note: Matrices `A` of a matrix domain such as `Dom::Matrix(..)` or `Dom::SquareMatrix(..)` are internally converted to arrays over expressions via `expr(A)`. Note that `Symbolic` should be used if the entries cannot be converted to numerical expressions.

Note that `1/A` must be used, when the inverse is to be computed over the component domain. See "Example 3" on page 19-142.

We recommend to use `numeric::linsolve` or `numeric::matlinsolve` if a sparse system of linear equations is to be solved. In particular, these routines are more efficient than `numeric::inverse` for large sparse systems.

`numeric::linsolve` uses sparse input and output via symbolic equations and features internal sparse arithmetic.

Alternatively, sparse matrices of domain type `Dom::Matrix()` may be used with `numeric::matlinsolve`.

Environment Interactions

Without the option `Symbolic`, the function is sensitive to the environment variable `DIGITS`, which determines the numerical working precision.

Examples

Example 1

Numerical matrices can be processed with or without the option `Symbolic`. In the following, the inverses are returned as arrays because the input matrix is an array:

```
A := array(1..2, 1..2, [[1, 2], [3, PI]]):
```

```
numeric::inverse(A), numeric::inverse(A, Symbolic)
```

$$\begin{pmatrix} -1.099071012 & 0.6996903372 \\ 1.049535506 & -0.3498451686 \end{pmatrix}, \begin{pmatrix} \frac{\pi}{\pi-6} & -\frac{2}{\pi-6} \\ -\frac{3}{\pi-6} & \frac{1}{\pi-6} \end{pmatrix}$$

Matrices of category `Cat::Matrix` are accepted. The inverse is returned as a corresponding matrix:

```
A := Dom::Matrix()([[2, PI], [0, 1]]):
numeric::inverse(A); domtype(%)
```

$$\begin{pmatrix} 0.5 & -1.570796327 \\ 0 & 1.0 \end{pmatrix}$$

Dom::Matrix()

```
delete A:
```

Example 2

The following matrix is not invertible:

```
A := linalg::hilbert(6):
A[6,6] := 5773/63504:
A
```

$$\begin{pmatrix} 1 & \frac{1}{2} & \frac{1}{3} & \frac{1}{4} & \frac{1}{5} & \frac{1}{6} \\ \frac{1}{2} & \frac{1}{3} & \frac{1}{4} & \frac{1}{5} & \frac{1}{6} & \frac{1}{7} \\ \frac{1}{3} & \frac{1}{4} & \frac{1}{5} & \frac{1}{6} & \frac{1}{7} & \frac{1}{8} \\ \frac{1}{4} & \frac{1}{5} & \frac{1}{6} & \frac{1}{7} & \frac{1}{8} & \frac{1}{9} \\ \frac{1}{5} & \frac{1}{6} & \frac{1}{7} & \frac{1}{8} & \frac{1}{9} & \frac{1}{10} \\ \frac{1}{6} & \frac{1}{7} & \frac{1}{8} & \frac{1}{9} & \frac{1}{10} & \frac{5773}{63504} \end{pmatrix}$$

With exact arithmetic, `numeric::inverse` detects this fact:

```
numeric::det(A, Symbolic), numeric::inverse(A, Symbolic)
```

0, FAIL

Due to internal round-off, the matrix is regarded as invertible if float arithmetic is used:

```
numeric::det(A, HardwareFloats), numeric::inverse(A, HardwareFloats);
```

$$-3.239912837\,10^{-28},\ \left[\left[-1.339975706\,10^{11},\ 4.019927119\,10^{12},\ \sigma_3,\ 7.503863956\,10^{13},\ \sigma_5,\ 3.37673878\,10^{13}\right],\right.$$

$$\left[4.019927119\,10^{12},\ -1.205978136\,10^{14},\ 8.441846951\,10^{14},\ \sigma_4,\ 2.532554085\,10^{15},\ \sigma_6\right],$$

$$\left[\sigma_3,\ 8.441846951\,10^{14},\ -5.909292865\,10^{15},\ 1.575811431\,10^{16},\ \sigma_2,\ 7.091151439\,10^{15}\right],$$

$$\left[7.503863956\,10^{13},\ \sigma_4,\ 1.575811431\,10^{16},\ -4.202163815\,10^{16},\ 4.727434292\,10^{16},\ \sigma_1\right],$$

$$\left[\sigma_5,\ 2.532554085\,10^{15},\ \sigma_2,\ 4.727434292\,10^{16},\ -5.318363579\,10^{16},\ 2.127345432\,10^{16}\right],$$

$$\left.\left[3.37673878\,10^{13},\ \sigma_6,\ 7.091151439\,10^{15},\ \sigma_1,\ 2.127345432\,10^{16},\ -8.509381726\,10^{15}\right]\right]$$

where

$$\sigma_1 = -1.890973717\,10^{16}$$

$$\sigma_2 = -1.77278786\,10^{16}$$

$$\sigma_3 = -2.813948983\,10^{13}$$

$$\sigma_4 = -2.251159187\,10^{15}$$

$$\sigma_5 = -8.441846951\,10^{13}$$

$$\sigma_6 = -1.013021634\,10^{15}$$

With `SoftwareFloats`, the internal rounding is slightly different and the kernel of the matrix is detected:

```
numeric::det(A, SoftwareFloats), numeric::inverse(A, SoftwareFloats)
```

$$-3.731550906\,10^{-30},\ \text{FAIL}$$

```
delete A:
```

Example 3

The following matrix has domain components:

```
A := Dom::Matrix(Dom::IntegerMod(7))([[6, -1], [1, 6]])
```

$$\begin{pmatrix} 6 \bmod 7 & 6 \bmod 7 \\ 1 \bmod 7 & 6 \bmod 7 \end{pmatrix}$$

Note that `numeric::inverse` computes the inverse of the following matrix:

```
expr(A), numeric::inverse(A)
```

$$\begin{pmatrix} 6 & 6 \\ 1 & 6 \end{pmatrix}, \begin{pmatrix} 0.2 & -0.2 \\ -0.03333333333 & 0.2 \end{pmatrix}$$

The overloaded arithmetic should be used if the inverse is to be computed over the component domain `Dom::IntegerMod(7)`:

```
1/A
```

$$\begin{pmatrix} 3 \bmod 7 & 4 \bmod 7 \\ 3 \bmod 7 & 3 \bmod 7 \end{pmatrix}$$

```
delete A:
```

Example 4

The option `Symbolic` should not be used for float matrices because no internal pivoting is used to stabilize the numerical algorithm:

```
A := matrix([[1.0/10^20, 1.0], [1.0, 1.0]]):
bad = numeric::inverse(A, Symbolic),
good = numeric::inverse(A)
```

$$\text{bad} = \begin{pmatrix} 0 & 1.0 \\ 1.0 & -1.0\,10^{-20} \end{pmatrix},\ \text{good} = \begin{pmatrix} -1.0 & 1.0 \\ 1.0 & -1.0\,10^{-20} \end{pmatrix}$$

```
delete A:
```

Example 5

We demonstrate the use of hardware floats. Hilbert matrices are notoriously ill-conditioned and difficult to invert with low values of `DIGITS`. The following results, both with `HardwareFloats` as well as with `SoftwareFloats`, are marred by numerical round-off. Consequently, the inverses with and without hardware floats, respectively, differ significantly:

```
A := linalg::hilbert(10):
DIGITS := 10:
B1 := numeric::inverse(A, HardwareFloats):
B2 := numeric::inverse(A, SoftwareFloats):
B1[8, 8] <> B2[8, 8]
```

$$3.267405722\,10^{12} \neq 3.26785917\,10^{12}$$

```
norm(B1 - B2)
```

$$1681640193.0$$

```
delete A, B1, B2:
```

Parameters

A

A square matrix of domain type `DOM_ARRAY`, `DOM_HFARRAY`, or of category `Cat::Matrix`

Options

Hard, HardwareFloats, Soft, SoftwareFloats

With `Hard` (or `HardwareFloats`), computations are done using fast hardware float arithmetic from within a MuPAD session. `Hard` and `HardwareFloats` are equivalent.

With this option, the input data are converted to hardware floats and processed by compiled C code. The result is reconverted to MuPAD floats and returned to the MuPAD session.

With `Soft` (or `SoftwareFloats`) computations are dome using software float arithmetic provided by the MuPAD kernel. `Soft` and `SoftwareFloats` are equivalent. `SoftwareFloats` is used by default if the current value of `DIGITS` is larger than 15 and the input matrix `A` is not of domain type `DOM_HFARRAY`.

Compared to the `SoftwareFloats` used by the MuPAD kernel, the computation with `HardwareFloats` may be many times faster. Note, however, that the precision of hardware arithmetic is limited to about 15 digits. Further, the size of floating-point numbers may not be larger than approximately 10^{308} and not smaller than approximately 10^{-308}.

If no `HardwareFloats` or `SoftwareFloats` are requested explicitly, the following strategy is used: If the current value of `DIGITS` is smaller than 16 or if the matrix `A` is a hardware float array of domain type `DOM_HFARRAY`, then hardware arithmetic is tried. If this is successful, the result is returned.

If the result cannot be computed with hardware floats, software arithmetic by the MuPAD kernel is tried.

If the current value of `DIGITS` is larger than 15 and the input matrix `A` is not of domain type `DOM_HFARRAY`, or if one of the options `Soft`, `SoftwareFloats` or `Symbolic` is specified, MuPAD computes the result with its software arithmetic without trying to use hardware floats first.

There may be several reasons for hardware arithmetic to fail:

- The current value of `DIGITS` is larger than 15.
- The data contains symbolic objects.
- The data contains numbers larger than 10^{308} or smaller than 10^{-308} that cannot be represented by hardware floats.

If neither `HardwareFloats` nor `SoftwareFloats` is specified, the user is not informed whether hardware floats or software floats are used.

If `HardwareFloats` are specified but fail due to one of the reasons above, a warning is issued that the (much slower) software floating-point arithmetic of the MuPAD kernel is used.

Note that `HardwareFloats` can only be used if all input data can be converted to floating-point numbers.

The trailing digits in floating-point results computed with `HardwareFloats` and `SoftwareFloats` may differ.

Note: For ill-conditioned matrices, the result is subject to round-off errors. The results returned with `HardwareFloats` and `SoftwareFloats` may differ! See "Example 2" on page 19-140 and "Example 5" on page 19-143.

`Symbolic`

Prevents the conversion of the input data to floating-point numbers. Exact arithmetic is used. This option overrides `HardwareFloats` and `SoftwareFloats`.

This option prevents conversion of the input data to floats. With this option, symbolic entries are accepted.

Note: This option should not be used for floating-point matrices! No internal pivoting is used, unless necessary. Consequently, numerical instabilities may occur in floating-point operations. See "Example 4" on page 19-142.

`NoWarning`

Without the option `Symbolic`, `numeric::inverse` automatically switches to the `Symbolic` mode with a warning if symbolic coefficients are found. With the option `NoWarning`, this warning is suppressed. Note, however, that `numeric::inverse` still uses the symbolic mode for symbolic coefficients, i.e., exact arithmetic without floating-point conversions is used.

`ReturnType`

Option, specified as `ReturnType = t`

Return the inverse as a matrix of domain type `t`. The following return types are available: `DOM_ARRAY`, `DOM_HFARRAY`, `Dom::Matrix()`, or `Dom::DenseMatrix()`.

Return Values

Depending on the type of the input matrix A, the inverse is returned as a matrix of domain type DOM_ARRAY, DOM_HFARRAY, Dom::Matrix(), or Dom::DenseMatrix(). FAIL is returned if the inverse cannot be computed.

Algorithms

Gaussian elimination with partial pivoting is used. Partial pivoting is switched off by the option Symbolic.

MuPAD Functions

linalg::matlinsolve | linsolve | numeric::linsolve | numeric::matlinsolve | solve

numeric::leastSquares

Least squares solution of linear equations

Syntax

```
numeric::leastSquares(A, B, <mode>, <method>, options)
```

Description

`numeric::leastSquares(A, B)` computes a matrix X that solves the linear matrix equation $A\,X = B$ in the least squares sense: the columns X_j of `X` minimize $\left\| A\,X_j - B_j \right\|_2$ where the B_j are the columns of `B`.

For a given vector B, a vector X minimizes $\left\| A\,X - B \right\|_2$ if and only if X is a solution of the "normal equations" $A^H A\,X = A^H B$, where A^H is the Hermitian transpose of the $m \times n$ matrix A. The solution is unique if $rank(A) = n$.

`numeric::leastSquares` allows to solve several least squares problems simultaneously by combining several 'right hand sides' B_j columnwise to a matrix `B`.

If no return type is specified via the option `ReturnType = d`, the domain type of the return data depends on the type of the input matrix `A`:

- The special solution X as well as the kernel of an array A are returned as arrays.
- The special solution and the kernel of an hfarray of domain type `DOM_HFARRAY` are returned as hfarrays.
- For a dense matrix A of type `Dom::DenseMatrix()`, both the special solution X as well as the kernel are returned as matrices of type `Dom::DenseMatrix()` over the ring of MuPAD expressions.
- For all other matrices of category `Cat::Matrix`, both the special solution X as well as the kernel are returned as matrices of type `Dom::Matrix()` over the ring of MuPAD expressions. This includes input matrices `A` of type `Dom::Matrix(...)`, `Dom::SquareMatrix(...)`, `Dom::MatrixGroup(...)` etc.

Without `Symbolic`, the input data are converted to floating-point numbers. The matrix A must not contain non-convertible parameters, unless `Symbolic` is used. If such objects are found, `numeric::leastSquares` automatically switches to its symbolic mode, issuing a warning. This warning may be suppressed via `NoWarning`.

Symbolic parameters in B are accepted without warning. However, `HardwareFloats` cannot be used if there are any symbolic parameters in A or B.

If $A^H A$ has a non-trivial kernel, the least squares solution X is not unique. The return value `X` is a *special* solution of the equation $A^H A X = A^H B$. With the `SVD` method, `X` is the special solution with columns of minimal Euclidean length.

Note: The result computed with `HardwareFloats` may differ from the solution computed with `SoftwareFloats` or `Symbolic`! In particular, this is the case for systems with a non-trivial kernel. Further, the The results computed with `QRD` and `SVD` may differ.

The kernel is computed only in the symbolic mode (option `Symbolic`). All floating-point methods return the value `NIL` for the kernel.

With `Symbolic`, the $n \times d$ matrix `KernelBasis` is the most general solution of $A^H A X = 0$. Its columns span the d-dimensional kernel of $A^H A$.

If the kernel is 0-dimensional, the return value of `KernelBasis` is the integer 0. If `KernelBasis` is returned as an array, the dimension d of the kernel is `d = op(KernelBasis, [0, 3, 2])`. If `KernelBasis` is returned as a matrix of type `Dom::Matrix()` or `Dom::DenseMatrix()`, the dimension d of the kernel is `d = KernelBasis::dom::matdim(KernelBasis)[2]`.

Note: Without the option `Symbolic`, the implemented algorithms take care of numerical stabilization.

With `Symbolic`, exact data are assumed. The least squares solutions is computed via `numeric::matlinsolve( A^H A, A^H B , Symbolic)`. The symbolic strategy tries do maximize speed and does not take care of numerical stabilization! Do not use `Symbolic` for systems involving floating-point entries! In particluar, due to round-off, it may happen that no solution of $A^H A X = A^H B$ is found. In such a case, `[FAIL, NIL, NIL]` is returned. Cf. “Example 4” on page 19-152.

All entries of A and B must be arithmetical expressions.

Note: Apart from matrices of type `Dom::Matrix(...)`, `Cat::Matrix` objects A from matrix domains such as `Dom::DenseMatrix(...)` or `Dom::SquareMatrix(...)` are internally converted to arrays over expressions via `expr(A)`. Note that the option `Symbolic` should be used if the entries cannot be converted to numerical expressions.

The same holds true for matrices B passed as `Cat::Matrix` objects.

Environment Interactions

The function is sensitive to the environment variable `DIGITS`, which determines the numerical working precision.

Examples

Example 1

We consider a matrix A of rank 1:

```
A := array(1..3, 1..2, [[1, 2], [1, 2], [1, 2]]):
B := [3, 4, 5]:
```

The normal equations have a 1-parameter set of of solutions:

```
[X, KernelBasis, Res] := numeric::leastSquares(A, B, Symbolic)
```

$$\left[\begin{pmatrix} 4 \\ 0 \end{pmatrix}, \begin{pmatrix} -2 \\ 1 \end{pmatrix}, [\sqrt{2}]\right]$$

The numerical method `QRD` produces a special solution:

```
[X, KernelBasis, Res] := numeric::leastSquares(A, B, QRD)
```

$$\left[\begin{pmatrix} 4.0 \\ 0 \end{pmatrix}, \text{NIL}, [1.414213562]\right]$$

The numerical method SVD produces a solution X of minimal norm:

```
[X, KernelBasis, Res] := numeric::leastSquares(A, B, SVD)
```

$$\left[\begin{pmatrix} 0.8 \\ 1.6 \end{pmatrix}, \text{NIL}, [1.414213562]\right]$$

```
delete A, B, X, KernelBasis, Res:
```

Example 2

We consider an ill-conditioned least squares problem. By construction, the following overdetermined system has an exact solution $X = [1, 2, \ldots, n]$:

```
m := 10: n := 8:
A := array(1..m, 1..n, [[1/(i + j + 100) $ j=1..n] $ i=1..m]):
B := array(1..m, [_plus(A[i,j]*j $ j=1..n) $ i=1..m]):
numeric::leastSquares(A, B, Symbolic)
```

$$\left[\begin{pmatrix} 1 \\ 2 \\ 3 \\ 4 \\ 5 \\ 6 \\ 7 \\ 8 \end{pmatrix}, 0, [0]\right]$$

The coefficient matrix A is rather ill-conditioned:

```
singvals := numeric::singularvalues(A):
conditionOfA := max(op(singvals))/min(op(singvals))
```

$$6.31539107\ 10^{16}$$

Consequently, round-off has a drastic effect in a numerical approximation. The methods yield results of different quality:

```
numeric::leastSquares(A, B, QRD)
```

$$\left[\begin{pmatrix} 205.7634088 \\ -506.7540812 \\ 336.9881724 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \end{pmatrix}, \text{NIL}, [0.000000007174860922]\right]$$

```
numeric::leastSquares(A, B, SVD)
```

$$\left[\begin{pmatrix} 44440.34961 \\ -36432.38255 \\ -44826.69677 \\ -14839.48585 \\ 23895.8882 \\ 45730.9635 \\ 28571.67227 \\ -46506.25357 \end{pmatrix}, \text{NIL}, [0.0000007416898216]\right]$$

```
delete m, n, A, B, singvals, conditionOfA:
```

Example 3

This example involves a symbolic parameter `c` in the matrix *A*. The option `Symbolic` must be used:

```
A:= matrix([[c, 2], [1/3, 2/3], [1/7, 2/7]]):
B:= [1, 2, 3]:
numeric::leastSquares(A, B, Symbolic)
```

$$\left[\begin{pmatrix} -\frac{425}{58\,(c-1)} \\ \frac{483\,c-58}{116\,(c-1)} \end{pmatrix}, 0, \left[\text{sqrt}\left(\left|\frac{425\,c}{58\,(c-1)} - \frac{483\,c-58}{58\,(c-1)} + 1\right|^2 + \left|\frac{425}{174\,(c-1)} - \frac{483\,c-58}{174\,(c-1)} + 2\right|^2 + \left|\frac{425}{406\,(c-1)} - \frac{483\,c-58}{406\,(c-1)} + 3\right|^2\right)\right]\right]$$

```
normal(%)
```

$$\left[\left(\begin{array}{c} -\frac{425}{58\,(c-1)} \\ \\ \frac{483\,c-58}{116\,(c-1)} \end{array}\right),\ 0,\ \left[\frac{15\,\sqrt{58}}{58}\right]\right]$$

```
delete A, B:
```

Example 4

Floating point entries may cause problems in conjunction with the option `Symbolic`, because the computation is not stabilized numerically in the symbolic node. The following matrix A has rank 2:

```
A := matrix([[1, 30], [10.0^(-15), 31*10.0^(-15)]]):
```

However, due to round-off, the 'normal matrix' $A^H A$ has rank 1. No solution is found with `Symbolic`:

```
A::dom::transpose(A) * A
```

$$\left(\begin{array}{cc} 1.0 & 30.0 \\ 30.0 & 900.0 \end{array}\right)$$

```
numeric::leastSquares(A, [31, 32*10^5], Symbolic)
```

$$[\text{FAIL},\ \text{NIL},\ \text{NIL}]$$

No such problem arises in the numerical schemes. Note, however, that the numerical methods yield different results in this extremely ill-conditioned problem:

```
numeric::leastSquares(A, [31, 32*10^5], QRD)
```

$$\left[\left(\begin{array}{c} -9.6\,10^{22} \\ \\ 3.2\,10^{21} \end{array}\right),\ \text{NIL},\ [31.0]\right]$$

```
numeric::leastSquares(A, [31, 32*10^5], SVD)
```

$$\left[\begin{pmatrix} 0.03440621532 \\ 1.03218646 \end{pmatrix},\ \text{NIL},\ [3200000.0]\right]$$

```
delete A:
```

Parameters

A

An $m \times n$ matrix of domain type `DOM_ARRAY` or of category `Cat::Matrix`

B

An $m \times p$ matrix of domain type `DOM_ARRAY` or of category `Cat::Matrix`. Column vectors `B` may also be represented by a 1-dimensional `array(1..m, [B1, B2, …] )` or by a list `[B1, B2, …]`.

mode

One of the flags `Hard`, `HardwareFloats`, `Soft`, `SoftwareFloats`, or `Symbolic`

method

One of the flags `QRD`, `SVD`

Options

Hard, HardwareFloats, Soft, SoftwareFloats

With `Hard` (or `HardwareFloats`), computations are done using fast hardware float arithmetic from within a MuPAD session. `Hard` and `HardwareFloats` are equivalent. With this option, the input data are converted to hardware floats and processed by compiled C code. The result is reconverted to MuPAD floats and returned to the MuPAD session.

With `Soft` (or `SoftwareFloats`) computations are dome using software float arithmetic provided by the MuPAD kernel. `Soft` and `SoftwareFloats` are equivalent.

SoftwareFloats is used by default if the current value of DIGITS is larger than 15 and the input matrix A is not of domain type DOM_HFARRAY.

Compared to the SoftwareFloats used by the MuPAD kernel, the computation with HardwareFloats may be many times faster. Note, however, that the precision of hardware arithmetic is limited to about 15 digits. Further, the size of floating-point numbers may not be larger than approximately 10^{308} and not smaller than approximately 10^{-308}.

If no HardwareFloats or SoftwareFloats are requested explicitly, the following strategy is used: If the current value of DIGITS is smaller than 16 or if the matrix A is a hardware float array of domain type DOM_HFARRAY, then hardware arithmetic is tried. If this is successful, the result is returned.

If the result cannot be computed with hardware floats, software arithmetic by the MuPAD kernel is tried.

If the current value of DIGITS is larger than 15 and the input matrix A is not of domain type DOM_HFARRAY, or if one of the options Soft, SoftwareFloats or Symbolic is specified, MuPAD computes the result with its software arithmetic without trying to use hardware floats first.

There may be several reasons for hardware arithmetic to fail:

- The current value of DIGITS is larger than 15.
- The data contains symbolic objects.
- The data contains numbers larger than 10^{308} or smaller than 10^{-308} that cannot be represented by hardware floats.

If neither HardwareFloats nor SoftwareFloats is specified, the user is not informed whether hardware floats or software floats are used.

If HardwareFloats are specified but fail due to one of the reasons above, a warning is issued that the (much slower) software floating-point arithmetic of the MuPAD kernel is used.

Note that HardwareFloats can only be used if all input data can be converted to floating-point numbers.

The trailing digits in floating-point results computed with HardwareFloats and SoftwareFloats may differ.

Symbolic

Prevents the conversion of the input data to floating-point numbers. Exact arithmetic is used. This option overrides `HardwareFloats` and `SoftwareFloats`.

This option *must* be used, if the matrix A contains symbolic parameters that cannot be converted to floating-point numbers.

The normal equations $A^H A X = A^H B$ are passed to `numeric::matlinsolve` with the option `Symbolic`.

If the least squares problem does not have a unique solution, a special solution X is returned together with the kernel of $A^H A$. Cf. "Example 1" on page 19-149.

Note: This option should not be used for systems with floating-point coefficients! Numerical instabilities may occur in floating-point operations. Further, if the rank of A is not maximal, then `numeric::leastSquares` may fail to find a solution due to numerical round-off. In such a case, `[FAIL, NIL, NIL]` is returned. Cf. "Example 4" on page 19-152.

QRD

Use a QR decomposition. All entries of A must be convertible to floating-point values.

This is the default method.

The matrix A must not contain symbolic parameters that cannot be converted to floating point numbers. If such objects are found, then `numeric::leastSquares` automatically switches to its `Symbolic` mode, issuing a warning. The computation proceeds with exact arithmetic, using the input data without floating-point conversions.

The warning may be suppressed by the option `NoWarning`.

Symbolic parameters in B are accepted without warning. They are processed by the floating-point algorithm.

Numerical expressions such as e^{π}, $\sqrt{2}$ etc. are accepted and converted to floats.

If the least squares problem does not have a unique solution, only a special solution is returned. The kernel is not computed: it is returned as `NIL`.

The method `QRD` provides a numerically stable way of solving the normal equations $A^H A X = A^H B$ by a QR decomposition. In extremely ill-conditioned situations, it may be worthwhile to consider the slower, yet more stable method `SVD`.

The conditioning is given by the ratio of the largest singular value of A divided by the smallest singular value of A. If this value is large, the problem is ill-conditioned.

Cf. “Example 2” on page 19-150.

`SVD`

Use a singular value decomposition. All entries of A must be convertible to floating-point values.

The matrix A must not contain symbolic parameters that cannot be converted to floating point numbers. If such objects are found, then `numeric::leastSquares` automatically switches to its symbolic mode, issuing a warning. The computation proceeds with exact arithmetic, using the input data without floating point conversions.

The warning may be suppressed by the option `NoWarning`.

Symbolic parameters in B are accepted without warning. They are processed by the floating-point algorithm.

Numerical expressions such as e^{π}, $\sqrt{2}$ etc. are accepted and converted to floats.

If the least squares problem does not have a unique solution, the columns X_j of the solution X have a minimal Euclidean length $\|X_j\|_2$.

The kernel is not computed: it is returned as `NIL`.

A singular value decomposition $A = U D V^H$ is used to solve the normal equations in the form $D^2 V^H X = D U^H B$. For small or zero singular values d_j in $D = diag(d_1, d_2, \ldots)$, the corresponding components of $V^H x$ are set to zero.

Usually, the numerical method `SVD` is slower than the default method `QRD`. However, in ill-conditioned situations, it is numerically more stable.

The conditioning is given by the ratio of the largest singular value of A divided by the smallest singular value of A. If this value is large, the problem is ill-conditioned.

NoWarning

Suppresses warnings

If symbolic coefficients are found in A, `numeric::leastSquares` automatically switches to the `Symbolic` mode with a warning. With this option, this warning is suppressed.

ReturnType

Option, specified as `ReturnType = d`

Return the (special) solution and the kernel as matrices of domain type `d`. The following return types d are available: `DOM_ARRAY`, or `DOM_HFARRAY`, `Dom::Matrix()`, or `Dom::DenseMatrix()`.

Return Values

A list `[X, KernelBasis, Residues]` is returned.

The (special) least squares solution `X` is an $n \times p$ matrix.

With `Symbolic`, `KernelBasis` is an $n \times d$ matrix (d is the dimension of the kernel of $A^H A$). Its columns span the kernel of $A^H A$. If the kernel is trivial, `KernelBasis` is the integer 0.

Without `Symbolic`, the kernel is not computed. The value `NIL` is returned for the `KernelBasis`.

The list of arithmetical expressions `Residues` consists of the minimized least squares deviations $\left\| A\,X_j - B_j \right\|_2$ corresponding to the columns of `X` and `B`.

numeric::linsolve

Solve a system of linear equations

Syntax

```
numeric::linsolve(eqs, <vars>, options)
```

Description

`numeric::linsolve(eqs, vars)` solves a system of linear equations `eqs` for the unknowns `vars`.

`numeric::linsolve` is a fast numerical linear solver. It is also a recommended solver for linear systems with exact or symbolic coefficients (using `Symbolic`).

Expressions are interpreted as homogeneous equations. E.g., the input `[x = y - 1, x - y]` is interpreted as the system of equations `[x = y - 1, x - y = 0]`.

Note: Without the option `Symbolic`, the input data are converted to floating-point numbers. The coefficient matrix A of the system $A\,x = b$ represented by `eqs` must not contain non-convertible parameters, unless the option `Symbolic` is used! If such objects are found, then `numeric::linsolve` automatically switches to its symbolic mode, issuing a warning. This warning may be suppressed via `NoWarning`. Symbolic parameters in the "right hand side" b are accepted without warning.

The numerical working precision is set by the environment variable `DIGITS`.

The solutions are returned as a list of solved equations of the form

$$[x_1 = \text{value}_1, x_2 = \text{value}_2, \ldots]\,,$$

where x_1, x_2, … are the unknowns. These simplified equations should be regarded as constraints on the unknowns. E.g., if an unknown x_1, say, does not turn up in the form [x_1

= …, …] in the solution, then there is no constraint on this unknown; it is an arbitrary parameter. Generally, all unknowns that do not turn up on the left hand side of the solved equations are arbitrary parameters spanning the solution space. Cf. “Example 9” on page 19-170.

In particular, if the empty list is returned as the solution, there are no constraints whatsoever on the unknowns, i.e., the system is trivial.

The ordering of the solved equations corresponds to the ordering of the unknowns `vars`. It is recommended that the user specifies `vars` by a *a list* of unknowns. This guarantees that the solved equations are returned in the expected order. If `vars` are specified by a set, or if no `vars` are specified at all, then an internal ordering is used.

If no unknowns are specified by `vars`, `numeric::linsolve` solves for all symbolic objects in `eqs`. The unknowns are determined internally by `indets(eqs, PolyExpr)`.

`numeric::linsolve` returns the general solution of the system `eqs`. It is valid for arbitrary complex values of the symbolic parameters which may be present in `eqs`. If no such solution exists, `FAIL` is returned. Solutions that are valid only for special values of the symbolic parameters may be obtained with the option `ShowAssumptions`. See “Example 2” on page 19-161, “Example 3” on page 19-161, “Example 4” on page 19-162, and “Example 11” on page 19-172.

The solved equations representing the solution are suitable as input for `assign` and `subs`. See “Example 8” on page 19-169.

`numeric::linsolve` is suitable for solving large sparse systems. See “Example 6” on page 19-163.

If `eqs` represents a system with a banded coefficient matrix, then this is detected and used by `numeric::linsolve`. Note that in this case, it is important to specify both the equations as well as the unknowns by lists to guarantee the desired form of the coefficient matrix. When using sets, the data may be reordered internally leading to a loss of band structure and, consequently, of efficiency. See “Example 6” on page 19-163.

Note: `numeric::linsolve` is tuned for speed. For this reason, it does not check systematically that the equations `eqs` are indeed linear in the unknowns! For non-linear equations, strange things may happen; `numeric::linsolve` might even return wrong results! See “Example 5” on page 19-162.

Note: `numeric::linsolve` does not react to any properties of the unknowns or of symbolic parameters that are set via `assume`.

Note: Gaussian elimination with partial pivoting is used. Without the option `Symbolic`, floating-point arithmetic is used and the pivoting strategy takes care of numerical stabilization. With `Symbolic`, exact data are assumed and the pivoting strategy tries do maximize speed, not taking care of numerical stabilization! See "Example 7" on page 19-169.

Environment Interactions

Without the option `Symbolic`, the function is sensitive to the environment variable `DIGITS`, which determines the numerical working precision.

Examples

Example 1

Equations and variables may be entered as sets or lists:

```
numeric::linsolve({x = y - 1, x + y = z}, {x, y});
numeric::linsolve([x = y - 1, x + y = z], {x, y});
numeric::linsolve({x = y - 1, x + y = z}, [x, y]);
numeric::linsolve([x = y - 1, x + y = z], [x, y])
```

$$[x = 0.5\,z - 0.5,\ y = 0.5\,z + 0.5]$$

$$[x = 0.5\,z - 0.5,\ y = 0.5\,z + 0.5]$$

$$[x = 0.5\,z - 0.5,\ y = 0.5\,z + 0.5]$$

$$[x = 0.5\,z - 0.5,\ y = 0.5\,z + 0.5]$$

With the option `Symbolic`, exact arithmetic is used. The following system has a 1-parameter set of solution; the unknown x_3 is arbitrary:

```
numeric::linsolve([x[1] + x[2] = 2, x[1] - x[2] = 2*x[3]],
```

```
                    [x[1], x[2], x[3]], Symbolic)
```

$$[x_1 = x_3 + 1,\ x_2 = 1 - x_3]$$

The unknowns may be expressions:

```
numeric::linsolve([f(0) - sin(x + 1) = 2, f(0) = 1 - sin(x + 1)],
                  [f(0), sin(x + 1)])
```

$$[f(0) = 1.5,\ \sin(x + 1) = -0.5]$$

The following system does not have a solution:

```
numeric::linsolve([x + y = 1, x + y = 2], [x, y])
```

FAIL

Example 2

We demonstrate some examples with symbolic coefficients. Note that the option `Symbolic` has to be used:

```
eqs := [x + a*y = b, x + A*y = b]:
numeric::linsolve(eqs, [x, y], Symbolic)
```

$$[x = b,\ y = 0]$$

Note that for $a = A$, this is not the general solution. Using the option `ShowAssumptions`, it turns out that the above result is the general solution subject to the assumption $a \neq A$:

```
numeric::linsolve(eqs, [x, y], Symbolic, ShowAssumptions)
```

$$[[x = b,\ y = 0],\ [],\ [A - a \neq 0]]$$

```
delete eqs:
```

Example 3

We give a further demonstration of the option `ShowAssumptions`. The following system does not have a solution for all values of the parameter `a`:

```
numeric::linsolve([x + y = 1, x + y = a], [x, y], Symbolic)
```

```
FAIL
```

With `ShowAssumptions`, `numeric::linsolve` investigates under which conditions (on the parameter `a`) there is a solution:

```
numeric::linsolve([x + y = 1, x + y = a], [x, y], Symbolic,
                  ShowAssumptions)
```

$$[[x = 1 - y], [a - 1 = 0], []]$$

We conclude that there is a 1-parameter set of solutions for $a = 1$. The constraint in `a` is a linear equation, since the parameter `a` enters the equations linearly. If `a` is regarded as an unknown rather than as a parameter, the constraint becomes part of the solution:

```
numeric::linsolve([x + y = 1, x + y = a], [x, y, a], Symbolic,
                  ShowAssumptions)
```

$$[[x = 1 - y, a = 1], [], []]$$

Example 4

With exact arithmetic, PI is regarded as a symbolic parameter. The following system has a solution subject to the constraint `PI = 1`:

```
numeric::linsolve([x = x - y + 1, y = PI], [x, y],
                  Symbolic, ShowAssumptions)
```

$$[[y = \pi], [1 - \pi = 0], []]$$

With floating-point arithmetic, PI is converted to `3.1415...`. The system has no solution:

```
numeric::linsolve([x = x - y + 1, y = PI], [x, y],
                  ShowAssumptions)
```

```
[FAIL, [], []]
```

Example 5

Since `numeric::linsolve` does not do a systematic internal check for non-linearities, the user should make sure that the equations to be solved are indeed linear in the

unknowns. Otherwise, strange things may happen. Garbage is produced for the following non-linear systems:

```
a := sin(x):
numeric::linsolve([y = 1 - a, x = y], [x, y], Symbolic)
```

$$[x = 1 - \sin(x17^3),\ y = 1 - \sin(x17^3)]$$

```
numeric::linsolve([a*x + y = 1, x = y], [x, y], Symbolic)
```

$$\left[x = \frac{1}{\sin(x18^3) + 1},\ y = \frac{1}{\sin(x18^3) + 1}\right]$$

Polynomial non-linearities are usually detected. Regarding `x, y, c` as unknowns, the following quadratic system yields an error:

```
numeric::linsolve([x*c + y = 1, x = y], Symbolic)
```

```
Error: This system does not seem to be linear. [numeric::linsolve]
```

```
 Error:
This system does not seem to be linear. [numeric::linsolve]
```

This system is linear in `x, y` if `c` is regarded as a parameter:

```
numeric::linsolve([x*c + y = 1, x = y], [x, y], Symbolic)
```

$$\left[x = \frac{1}{c + 1},\ y = \frac{1}{c + 1}\right]$$

```
delete a:
```

Example 6

We solve a large sparse system. The coefficient matrix has only 3 diagonal bands. Note that both the equations as well as the variables are passed as lists. This guarantees that the band structure is not lost internally:

```
n := 500: x[0] := 0: x[n + 1] := 0:
eqs := [x[i-1] - 2*x[i] + x[i+1] = 1 $ i = 1..n]:
vars := [x[i] $ i = 1..n]:
numeric::linsolve(eqs, vars)
```

$$[x_1 = -250.0,\ x_2 = -499.0,\ x_3 = -747.0,\ x_4 = -994.0,\ \ldots,\ x_{498} = -747.0,\ x_{499} = -499.0,\ x_{500} = -250.0]$$

$$x_{83} = -17347.0, x_{84} = -17514.0, x_{85} = -17680.0, x_{86} = -17845.0, x_{87} = -18009.0,$$
$$x_{88} = -18172.0, x_{89} = -18334.0, x_{90} = -18495.0, x_{91} = -18655.0, x_{92} = -18814.0,$$
$$x_{93} = -18972.0, x_{94} = -19129.0, x_{95} = -19285.0, x_{96} = -19440.0, x_{97} = -19594.0,$$
$$x_{98} = -19747.0, x_{99} = -19899.0, x_{100} = -20050.0, x_{101} = -20200.0, x_{102} = -20349.0,$$
$$x_{103} = -20497.0, x_{104} = -20644.0, x_{105} = -20790.0, x_{106} = -20935.0, x_{107} = -21079.0,$$
$$x_{108} = -21222.0, x_{109} = -21364.0, x_{110} = -21505.0, x_{111} = -21645.0, x_{112} = -21784.0,$$

```
delete n, x, eqs, vars:
```

Example 7

The option `Symbolic` should not be used for equations with floating-point coefficients, because the symbolic pivoting strategy favors efficiency instead of numerical stability.

```
eqs := [x + 10^20*y = 10^20, x + y = 0]:
```

The float approximation of the exact solution is:

```
map(numeric::linsolve(eqs, [x, y], Symbolic), map, float)
```

$$[x = -1.0,\ y = 1.0]$$

We now convert the exact coefficients to floating-point numbers:

```
feqs := map(eqs, map, float)
```

$$[x + 1.0\ 10^{20}\ y = 1.0\ 10^{20},\ x + y = 0.0]$$

The default pivoting strategy stabilizes floating-point operations. Consequently, one gets a correct result:

```
numeric::linsolve(feqs, [x, y])
```

$$[x = -1.0,\ y = 1.0]$$

With `Symbolic`, the pivoting strategy optimizes speed, assuming exact arithmetic. Numerical instabilities may occur if floating-point coefficients are involved. The following incorrect result is caused by internal round-off effects (“cancellation”):

```
numeric::linsolve(feqs, [x, y], Symbolic)
```

$$[x = 0.0,\ y = 1.0]$$

```
delete eqs, feqs:
```

Example 8

We demonstrate that the simplified equations representing the solution can be used for further processing with `subs`:

```
eqs := [x + y = 1, x + y = a]:
[Solution, Constraints, Pivots] :=
  numeric::linsolve(eqs, [x, y], ShowAssumptions)
```

$$[[x = 1.0 - 1.0\,y], [1.0\,a - 1.0 = 0], []]$$

```
subs(eqs, Solution)
```

$$[1.0 = 1, 1.0 = a]$$

The solution can be assigned to the unknowns via `assign`:

```
assign(Solution):
x, y, eqs
```

$$1.0 - 1.0\,y,\ y,\ [1.0 = 1, 1.0 = a]$$

```
delete eqs, Solution, Constraints, Pivots, x:
```

Example 9

If the solution of the linear system is not unique, then some of the unknowns are used as "free parameters" spanning the solution space. In the following example, the unknowns `z, w` are such parameters. They do not turn up on the left hand side of the solved equations:

```
eqs := [x + y = z, x + 2*y = 0, 2*x - z = -3*y, y + z = 0]:
vars := [x, y, z, w]:
Solution := numeric::linsolve(eqs, vars, Symbolic)
```

$$[x = 2\,z,\ y = -z]$$

You may define a function such as the following `NewSolutionList` to rename your free parameters to "myName1", "myName2" etc. and fill up your list of solved equations accordingly:

```
NewSolutionList :=
proc(Solution : DOM_LIST, vars : DOM_LIST, myName : DOM_STRING)
local i, solvedVars, newEquation;
begin
  solvedVars := map(Solution, op, 1);
```

```
  for i from 1 to nops(vars) do
     if not has(solvedVars, vars[i]) then
        newEquation := vars[i] = genident(myName);
        Solution := listlib::insertAt(
            subs(Solution, newEquation), newEquation, i)
     end_if
  end_for:
  Solution
end_proc:

NewSolutionList(Solution, vars, "FreeParameter")
```

$$[x = 2\,\text{FreeParameter1},\ y = -\text{FreeParameter1},\ z = \text{FreeParameter1},\ w = \text{FreeParameter2}]$$

```
delete eqs, vars, Solution, NewSolutionList:
```

Example 10

We demonstrate the difference between hardware and software arithmetic. The following problem is very ill-conditioned. The results, both with `HardwareFloats` as well as with `SoftwareFloats`, are marred by numerical round-off:

```
n:= 10:
eqs:= [(_plus(x[j]/(i + j -1) $ j = 1..n) = 1) $ i = 1..n]:
vars:= [x[i] $ i = 1..n]:
numeric::linsolve(eqs, vars, SoftwareFloats);
numeric::linsolve(eqs, vars, HardwareFloats)
```

$$[x_1 = -9.999986342,\ x_2 = 989.9988244,\ x_3 = -23759.97502,\ x_4 = 240239.7733,$$
$$x_5 = -1261258.92,\ x_6 = 3783777.035,\ x_7 = -6726715.139,\ x_8 = 7001275.306,$$
$$x_9 = -3938217.537,\ x_{10} = 923779.4586]$$

$$[x_1 = -9.997364824,\ x_2 = 989.7718609,\ x_3 = -23755.13378,\ x_4 = 240195.7143,$$
$$x_5 = -1261048.597,\ x_6 = 3783198.501,\ x_7 = -6725765.49,\ x_8 = 7000357.238,$$
$$x_9 = -3937735.418,\ x_{10} = 923673.4085]$$

This is the exact solution:

```
numeric::linsolve(eqs, vars, Symbolic);
```

$$[x_1 = -10,\ x_2 = 990,\ x_3 = -23760,\ x_4 = 240240,\ x_5 = -1261260,\ x_6 = 3783780,\ x_7 = -6726720,$$
$$x_8 = 7001280,\ x_9 = -3938220,\ x_{10} = 923780]$$

```
delete eqs, vars:
```

Example 11

We demonstrate how a complete solution of the following linear system in `x`, `y` with symbolic parameters `a`, `b`, `c`, `d` may be found:

```
eqs := [x + y = d, a*x + b*y = 1, x + c*y = 1]:
numeric::linsolve(eqs, [x, y], Symbolic, ShowAssumptions)
```

$$\left[\left[x = -\frac{b\,d-1}{a-b},\ y = \frac{a\,d-1}{a-b}\right],\ [a-b+c+b\,d-a\,c\,d-1=0],\ [b-a\neq 0]\right]$$

This is the general solution, assuming $a \neq b$. We now set $b = a$ to investigate further solution branches:

```
eqs := subs(eqs, b = a):
numeric::linsolve(eqs, [x, y], Symbolic, ShowAssumptions)
```

$$\left[\left[x = \frac{c\,d-1}{c-1},\ y = -\frac{d-1}{c-1}\right],\ [1-a\,d=0],\ [c-1\neq 0]\right]$$

This is the general solution for $a = b$, assuming $c \neq 1$. We finally set $c = 1$ to obtain the last solution branch:

```
eqs := subs(eqs, c = 1):
numeric::linsolve(eqs, [x, y], Symbolic, ShowAssumptions)
```

$$[[x = d-y],\ [1-a\,d=0,\ 1-d=0],\ []]$$

From the constraints on the symbolic parameters `a` and `d`, we conclude that there is a special 1-parameter solution $x = 1 - y$ for $a = b = c = d = 1$.

```
delete eqs:
```

Parameters

eqs

A list, set, `array`, or `matrix` (`Cat::Matrix`) of linear equations or arithmetical expressions

vars

A list or set of unknowns to solve for. Unknowns may be identifiers or indexed identifiers or arithmetical expressions.

Options

Hard, HardwareFloats, Soft, SoftwareFloats

With `Hard` (or `HardwareFloats`), computations are done using fast hardware float arithmetic from within a MuPAD session. `Hard` and `HardwareFloats` are equivalent. With this option, the input data are converted to hardware floats and processed by compiled C code. The result is reconverted to MuPAD floats and returned to the MuPAD session.

With `Soft` (or `SoftwareFloats`) computations are dome using software float arithmetic provided by the MuPAD kernel. `Soft` and `SoftwareFloats` are equivalent. `SoftwareFloats` is used by default if the current value of `DIGITS` is larger than 15 and the input matrix `A` is not of domain type `DOM_HFARRAY`.

Compared to the `SoftwareFloats` used by the MuPAD kernel, the computation with `HardwareFloats` may be many times faster. Note, however, that the precision of hardware arithmetic is limited to about 15 digits. Further, the size of floating-point numbers may not be larger than approximately 10^{308} and not smaller than approximately 10^{-308}.

If no `HardwareFloats` or `SoftwareFloats` are requested explicitly, the following strategy is used: If the current value of `DIGITS` is smaller than 16 or if the matrix `A` is a hardware float array of domain type `DOM_HFARRAY`, then hardware arithmetic is tried. If this is successful, the result is returned.

If the result cannot be computed with hardware floats, software arithmetic by the MuPAD kernel is tried.

If the current value of `DIGITS` is larger than 15 and the input matrix `A` is not of domain type `DOM_HFARRAY`, or if one of the options `Soft`, `SoftwareFloats` or `Symbolic` is specified, MuPAD computes the result with its software arithmetic without trying to use hardware floats first.

There may be several reasons for hardware arithmetic to fail:

- The current value of `DIGITS` is larger than 15.
- The data contains symbolic objects.
- The data contains numbers larger than 10^{308} or smaller than 10^{-308} that cannot be represented by hardware floats.

If neither `HardwareFloats` nor `SoftwareFloats` is specified, the user is not informed whether hardware floats or software floats are used.

If `HardwareFloats` are specified but fail due to one of the reasons above, a warning is issued that the (much slower) software floating-point arithmetic of the MuPAD kernel is used.

Note that `HardwareFloats` can only be used if all input data can be converted to floating-point numbers.

The trailing digits in floating-point results computed with `HardwareFloats` and `SoftwareFloats` may differ.

Note: For ill-conditioned systems, the result is subject to round-off errors. The results returned with `HardwareFloats` and `SoftwareFloats` may differ significantly! See“Example 10” on page 19-171.

`Symbolic`

Prevents conversion of input data to floating-point numbers. This option overrides `HardwareFloats` and `SoftwareFloats`.

This option *must* be used if the coefficients of the equations contain symbolic parameters that cannot be converted to floating-point numbers.

Note: This option should not be used for equations with floating-point coefficients! Numerical instabilities may occur in floating-point operations. See “Example 7” on page 19-169.

`ShowAssumptions`

Returns information on internal assumptions on symbolic parameters in `eqs`.

This option is only useful if the equations contain symbolic parameters. Consequently, it should only be used in conjunction with the option `Symbolic`.

Note: The format of the return value is changed to `[Solution, Constraints, Pivots]`.

`Solution` is a set of simplified equations representing the general solution subject to `Constraints` and `Pivots`.

`Constraints` is a list of equations for symbolic parameters in `eqs`, which are necessary and sufficient to make the system solvable.

Such constraints arise if Gaussian elimination of the original equations leads to equations of the form $0 = c$, where c is some expression involving symbolic parameters in the “right hand side” of the system. All such equations are collected in `Constraints`. `numeric::linsolve` assumes that these equations are satisfied and returns a solution.

If no such constraints arise, the return value of `Constraints` is the empty list.

`Pivots` is a list of inequalities involving symbolic parameters in the coefficient matrix A of the linear system $A\,x = b$ represented by `eqs`. Internally, division by pivot elements occurs in the Gaussian elimination. The expressions collected in `Pivots` are the numerators of the pivot elements that contain symbolic parameters. If only numerical pivot elements were used, the return value of `Pivots` is the empty list.

Note: The option `ShowAssumptions` changes the return strategy for “unsolvable” systems. Without the option `Symbolic`, `FAIL` is returned whenever Gaussian elimination produces an equation $0 = c$ with non-zero c. With `ShowAssumptions`, such equations are returned via `Constraints`, provided c involves symbolic parameters.

If *c* is a purely numerical value, then `[FAIL, [], []]` is returned.

See "Example 2" on page 19-161, "Example 3" on page 19-161, "Example 4" on page 19-162, and "Example 11" on page 19-172.

`NoWarning`

Suppresses warnings

If symbolic coefficients are found, `numeric::linsolve` automatically switches to the `Symbolic` mode with a warning. With this option, this warning is suppressed; `numeric::linsolve` still uses the symbolic mode for symbolic coefficients, i.e., exact arithmetic without floating-point conversions is used.

Return Values

Without the option `ShowAssumptions`, a list of simplified equations is returned. It represents the general solution of the system `eqs`. `FAIL` is returned if the system is not solvable.

With `ShowAssumptions`, a list `[Solution, Constraints, Pivots]` is returned. `Solution` is a list of simplified equations representing the general solution of `eqs`. The lists `Constraints` and `Pivots` contain equations and inequalities involving symbolic parameters in `eqs`. Internally, these were assumed to hold true when solving the system.

`[FAIL, [], []]` is returned if the system is not solvable.

numeric::matlinsolve

Solve a linear matrix equation

Syntax

```
numeric::matlinsolve(A, B, options)
```

Description

`numeric::matlinsolve(A, B)` returns the matrix solution X of the matrix equation $A\,X = B$ together with the kernel of the matrix A.

`numeric::matlinsolve` is a fast numerical linear solver for both sparse and dense systems. It is also a recommended solver for linear systems with exact or symbolic coefficients (use option `Symbolic`).

If no return type is specified via the option `ReturnType = d`, the domain type of the return data depends on the type of the input matrix `A`:

- The special solution X as well as the kernel of an array A are returned as arrays.
- The special solution X as well as the kernel of an hfarray A are returned as hfarrays.
- For a dense matrix$A$ of type `Dom::DenseMatrix()`, both the special solution X as well as the kernel of A are returned as matrices of type `Dom::DenseMatrix()` over the ring of MuPAD expressions.
- For all other matrices of category `Cat::Matrix`, both the special solution X as well as the kernel of A are returned as matrices of type `Dom::Matrix()` over the ring of MuPAD expressions. This includes input matrices `A` of type `Dom::Matrix(...)`, `Dom::SquareMatrix(...)`, `Dom::MatrixGroup(...)` etc.

Without `Symbolic`, exact numerical input data such as `PI + sqrt(2)`, `sin(3)` etc. are converted to floating-point numbers. Floating point arithmetic is used. Its precision is given the environment variable `DIGITS`. If symbolic data are found that cannot be converted to floating-point numbers, `numeric::matlinsolve` automatically switches to its symbolic mode, issuing a warning. This warning may be suppressed via `NoWarning`.

With `Symbolic`, symbolic parameters in the coefficient matrix `A` as well as in the right hand side `B` are accepted and processed without a warning.

With SofwareFloats, the right hand side B may contain symbolic parameters that cannot be converted to floating-point numbers. All entries of the coefficient matrix A, however, must be convertible to floating-point numbers.

With HardwareFloats, neither A nor B must contain symbolic parameters that cannot be converted to floating-point numbers.

X is a *special* solution of the equation $A\,X = B$. If A has a non-trivial kernel, the solution X is not unique.

Note: The result computed with HardwareFloats may differ from the solution computed with SoftwareFloats or Symbolic! In particular, this is the case for systems with a non-trivial kernel.

Cf. "Example 9" on page 19-186.

The $n \times d$ matrix KernelBasis is the most general solution of $A\,X = 0$. Its columns span the d-dimensional kernel of A.

Thus, the kernel of A may be computed via `numeric::matlinsolve(A, [0, ..., 0])[2]`.

If the kernel is 0-dimensional, the return value of KernelBasis is the integer 0. If KernelBasis is returned as an array, the dimension d of the kernel is `d = op(KernelBasis, [0, 3, 2])`. If KernelBasis is returned as a matrix of type Dom::Matrix() or Dom::DenseMatrix(), the dimension d of the kernel is `d = KernelBasis::dom::matdim(KernelBasis)[2]`.

Note: Due to round-off errors, some or all basis vectors in the kernel of A may be missed in the numerical modes.

The special solution X in conjunction with KernelBasis provides the general solution of $A\,X = B$. Solutions generated without the option ShowAssumptions are valid for arbitrary complex values of the symbolic parameters which may be present in A and B. If no such solution exists, then [FAIL,NIL] is returned. Solutions that are valid only for special values of the symbolic parameters may be obtained with ShowAssumptions. See "Example 3" on page 19-181, "Example 4" on page 19-182, and "Example 7" on page 19-184.

`numeric::matlinsolve` internally uses a sparse representation of the matrices. It is suitable for solving large sparse systems. See “Example 5” on page 19-182.

Note: `numeric::matlinsolve` does not react to any assumptions on symbolic parameters in `A,B` that are set via `assume`.

Note: Gaussian elimination with partial pivoting is used. Without the option `Symbolic`, the pivoting strategy takes care of numerical stabilization. With `Symbolic`, exact data are assumed. The symbolic pivoting strategy tries do maximize speed and does not take care of numerical stabilization! Do not use `Symbolic` for linear systems involving floating-point entries! See “Example 6” on page 19-183.

Note: Apart from matrices of type `Dom::Matrix(...)`, `Cat::Matrix` objects `A` from matrix domains such as `Dom::DenseMatrix(...)` or `Dom::SquareMatrix(...)` are internally converted to arrays over expressions via `expr(A)`. Note that the option `Symbolic` should be used if the entries cannot be converted to numerical expressions.

Note that `linalg::matlinsolve` must be used, when the solution is to be computed over the component domain. See . “Example 8” on page 19-185.

Environment Interactions

Without the option `Symbolic`, the function is sensitive to the environment variable `DIGITS`, which determines the numerical working precision.

Examples

Example 1

We use equivalent input formats `(B1, B2)` to represent a vector with components [a, π]. First, this vector is defined as a 2-dimensional array:

```
A := array(1..2, 1..3, [[1, 2, 3],[1, 1, 2]]):
B1 := array(1..2, 1..1, [[a], [PI]]):
```

```
numeric::matlinsolve(A, B1)
```

$$\left[\begin{pmatrix} 6.283185307 - 1.0\,a \\ 1.0\,a - 3.141592654 \\ 0 \end{pmatrix}, \begin{pmatrix} -1.0 \\ -1.0 \\ 1.0 \end{pmatrix}\right]$$

Next, we use a 1-dimensional array and compute an exact solution:

```
B2 := array(1..2, [a, PI]):
numeric::matlinsolve(A, B2, Symbolic)
```

$$\left[\begin{pmatrix} 2\,\pi - a \\ a - \pi \\ 0 \end{pmatrix}, \begin{pmatrix} -1 \\ -1 \\ 1 \end{pmatrix}\right]$$

Now, a list is used to specify the vector. No internal assumptions were used by `numeric::matlinsolve` to obtain the solution:

```
B3 := [a, PI]:
numeric::matlinsolve(A, B3, ShowAssumptions)
```

$$\left[\begin{pmatrix} 6.283185307 - 1.0\,a \\ 1.0\,a - 3.141592654 \\ 0 \end{pmatrix}, \begin{pmatrix} -1.0 \\ -1.0 \\ 1.0 \end{pmatrix}, [\,], [\,]\right]$$

Finally, we use `Dom::Matrix` objects to specify the system. Note that the results are returned as corresponding matrix objects:

```
A := matrix([[1, 2, 3],[1, 1, 2]]):
B4 := matrix([a, PI]):
numeric::matlinsolve(A, B4)
```

$$\left[\begin{pmatrix} 6.283185307 - 1.0\,a \\ 1.0\,a - 3.141592654 \\ 0 \end{pmatrix}, \begin{pmatrix} -1.0 \\ -1.0 \\ 1.0 \end{pmatrix}\right]$$

```
delete A, B1, B2, B3, B4:
```

Example 2

We invert a matrix by solving $A\,X = 1$:

```
A := hfarray(1..3, 1..3, [[1, 1, 0], [0, 1, 1], [0, 0, 1]]):
B := matrix::identity(3, 3):
InverseOfA := numeric::matlinsolve(A, B, Symbolic)[1]
```

$$\begin{pmatrix} 1.0 & -1.0 & 1.0 \\ 0.0 & 1.0 & -1.0 \\ 0.0 & 0.0 & 1.0 \end{pmatrix}$$

```
delete A, B, InverseOfA:
```

Example 3

We solve an equation with a symbolic parameter x:

```
A := matrix([[2, 2, 3], [1, 1, 2], [3, 3, 5]]):
B := matrix([sin(x)^2, cos(x)^2, 0]):
[X, Kernel, Constraints, Pivots] :=
 numeric::matlinsolve(A, B, Symbolic, ShowAssumptions)
```

$$\left[\begin{pmatrix} 5\sin(x)^2 \\ 0 \\ -3\sin(x)^2 \end{pmatrix}, \begin{pmatrix} -1 \\ 1 \\ 0 \end{pmatrix}, [\cos(x)^2 + \sin(x)^2 = 0], []\right]$$

This solution holds subject to the constraint $sin(x)^2 + cos(x)^2 = 0$ on the parameter x. `numeric::matlinsolve` does not investigate the `Constraints` and does not realize that they cannot be satisfied. We check the consistency of the "result" by inserting the solution into the original system. Since the input matrix A was of type `Dom::Matrix()`, the results `X` and `Kernel` were returned as corresponding matrices. The overloaded operators `*` and `-` for matrix multiplication and subtraction can be used:

```
A*X - B, A*Kernel
```

$$\left(\begin{matrix} 0 \\ -\cos(x)^2 - \sin(x)^2 \\ 0 \end{matrix}\right), \left(\begin{matrix} 0 \\ 0 \\ 0 \end{matrix}\right)$$

```
delete A, B, X, Kernel, Constraints, Pivots:
```

Example 4

We give a further demonstration of the option `ShowAssumptions`. The following system does not have a solution for all values of the parameter `a`:

```
A := array(1..2, 1..2, [[1, 1], [1, 1]]):
B := array(1..2, 1..1, [[1], [a]]):
numeric::matlinsolve(A, B, Symbolic)
```

$$[\text{FAIL}, \text{NIL}]$$

With `ShowAssumptions`, `numeric::matlinsolve` investigates under which conditions (on the parameter a `a`) there is a solution:

```
numeric::matlinsolve(A, B, Symbolic, ShowAssumptions)
```

$$\left[\left(\begin{matrix} 1 \\ 0 \end{matrix}\right), \left(\begin{matrix} -1 \\ 1 \end{matrix}\right), [a - 1 = 0], []\right]$$

We conclude that there is a 1-dimensional solution space for $a = 1$.

```
delete A, B:
```

Example 5

We solve a sparse system with 3 diagonal bands:

```
n := 100:
A := matrix(n, n, [1, -2, 1], Banded):
B := array(1..n, [1 $ n]):
numeric::matlinsolve(A, B)
```

$$\left[\begin{pmatrix} -50.0 \\ -99.0 \\ -147.0 \\ \cdots \\ -147.0 \\ -99.0 \\ -50.0 \end{pmatrix}, 0\right]$$

[matrix([[-50.0], [-99.0], [-147.0], [-194.0], [-240.0], [-285.0], [-329.0], [-372.0], [-414.0], [-455.0], [-495.0], [-534.0], [-572.0], [-609.0], [-645.0], [-680.0], [-714.0], [-747.0], [-779.0], [-810.0], [-840.0], [-869.0], [-897.0], [-924.0], [-950.0], [-975.0], [-999.0], [-1022.0], [-1044.0], [-1065.0], [-1085.0], [-1104.0], [-1122.0], [-1139.0], [-1155.0], [-1170.0], [-1184.0], [-1197.0], [-1209.0], [-1220.0], [-1230.0], [-1239.0], [-1247.0], [-1254.0], [-1260.0], [-1265.0], [-1269.0], [-1272.0], [-1274.0], [-1275.0], [-1275.0], [-1274.0], [-1272.0], [-1269.0], [-1265.0], [-1260.0], [-1254.0], [-1247.0], [-1239.0], [-1230.0], [-1220.0], [-1209.0], [-1197.0], [-1184.0], [-1170.0], [-1155.0], [-1139.0], [-1122.0], [-1104.0], [-1085.0], [-1065.0], [-1044.0], [-1022.0], [-999.0], [-975.0], [-950.0], [-924.0], [-897.0], [-869.0], [-840.0], [-810.0], [-779.0], [-747.0], [-714.0], [-680.0], [-645.0], [-609.0], [-572.0], [-534.0], [-495.0], [-455.0], [-414.0], [-372.0], [-329.0], [-285.0], [-240.0], [-194.0], [-147.0], [-99.0], [-50.0]]), 0]

```
delete n, A, B:
```

Example 6

The option `Symbolic` should not be used for equations with floating-point coefficients, because the symbolic pivoting strategy favors efficiency instead of numerical stability.

```
A := array(1..2, 1..2, [[1, 10^20], [1, 1]]):
B := array(1..2, 1..1, [[10^20], [0]]):
```

The float approximation of the exact solution is:

```
map(numeric::matlinsolve(A, B, Symbolic)[1], float)
```

$$\begin{pmatrix} -1.0 \\ 1.0 \end{pmatrix}$$

We now convert the exact input data to floating-point approximations:

```
A := map(A, float): B := map(B, float):
```

The default pivoting strategy of the floating-point algorithm stabilizes floating-point operations. Consequently, one gets a correct result:

```
numeric::matlinsolve(A, B)[1]
```

$$\begin{pmatrix} -1.0 \\ 1.0 \end{pmatrix}$$

With the option `Symbolic`, however, the pivoting strategy optimizes speed, assuming exact arithmetic. Numerical instabilities may occur if floating-point coefficients are involved. The following result is caused by internal round-off effects (“cancellation”):

```
numeric::matlinsolve(A, B, Symbolic)[1]
```

$$\begin{pmatrix} 0 \\ 1.0 \end{pmatrix}$$

We need to increase `DIGITS` to obtain a better result:

```
DIGITS := 20:
numeric::matlinsolve(A, B, Symbolic)[1]
```

$$\begin{pmatrix} -1.0000000149011611938 \\ 1.0 \end{pmatrix}$$

```
delete A, B, DIGITS:
```

Example 7

We demonstrate how a complete solution of the following linear system with symbolic parameters may be found:

```
A := array(1..3, 1..2, [[1, 1], [a, b], [1, c]]):
B := array(1..3, 1..1, [[1], [1], [1]]):
numeric::matlinsolve(A, B, Symbolic, ShowAssumptions)
```

$$\left[\begin{pmatrix} -\frac{b-1}{a-b} \\ \\ \frac{a-1}{a-b} \end{pmatrix}, 0, [-(a-1)(c-1)=0], [b-a \neq 0]\right]$$

This is the general solution assuming $a \neq b$. We now set $b = a$ to investigate further solution branches:

```
A := subs(A, b = a):
numeric::matlinsolve(A, B, Symbolic, ShowAssumptions)
```

$$\left[\begin{pmatrix}1\\0\end{pmatrix}, 0, [1-a=0], [c-1\neq 0]\right]$$

This is the general solution for $a = b$, assuming $c \neq 1$. We finally set $c = 1$ to obtain the last solution branch:

```
A := subs(A, c = 1):
numeric::matlinsolve(A, B, Symbolic, ShowAssumptions)
```

$$\left[\begin{pmatrix}1\\0\end{pmatrix}, \begin{pmatrix}-1\\1\end{pmatrix}, [1-a=0], []\right]$$

From the constraint on `a`, we conclude that there is a 1-dimensional solution space for the special values $a = b = c = 1$ of the symbolic parameters.

```
delete A, B:
```

Example 8

Matrices from a domain such as `Dom::Matrix(...)` are converted to arrays with numbers or expressions. Hence, `numeric::matlinsolve` finds no solution for the following system:

```
M := Dom::Matrix(Dom::IntegerMod(7)):
A := M([[1, 4], [6, 3], [3, 2]]):
B := M([[9], [5], [0]]):
numeric::matlinsolve(A, B)
```

$$[\text{FAIL}, \text{NIL}]$$

Use `linalg::matlinsolve` to solve the system over the coefficient field of the matrices. A solution does exist over the field `Dom::IntegerMod(7)`:

```
linalg::matlinsolve(A, B)
```

$$\begin{pmatrix} 1 \bmod 7 \\ 2 \bmod 7 \end{pmatrix}$$

```
delete M, A, B:
```

Example 9

We demonstrate the difference between `Symbolic`, `HardwareFloats`, and `SoftwareFloats`. The following matrix A has a 1-dimensional kernel. Due to round-off, a further spurious kernel vector appears with `SoftwareFloats`. No kernel vector is detected with `HardwareFloats`:

```
A := matrix([[2*10^14 + 2, 2*10^(-9), 2*10^(-4)],
             [3*10^15 + 3, 3*10^(-8), 3*10^(-3)],
             [4*10^16 + 4, 4*10^(-7), 4*10^(-2)]
            ]):
b := matrix([2*10^(-9), 3*10^(-8), 4*10^(-7)]):
float(numeric::matlinsolve(A, b, Symbolic));
numeric::matlinsolve(A, b, SoftwareFloats);
numeric::matlinsolve(A, b, HardwareFloats)
```

$$\left[\begin{pmatrix} 0 \\ 1.0 \\ 0 \end{pmatrix}, \begin{pmatrix} 0 \\ -100000.0 \\ 1.0 \end{pmatrix}\right]$$

$$\left[\begin{pmatrix} 1.0\,10^{-23} \\ 0 \\ 0 \end{pmatrix}, \begin{pmatrix} -1.0\,10^{-23} & -1.0\,10^{-18} \\ 1.0 & 0 \\ 0 & 1.0 \end{pmatrix}\right]$$

$$\left[\begin{pmatrix} 0 \\ 1.0 \\ 0 \end{pmatrix}, 0\right]$$

```
delete A, b:
```

Parameters

A

An $m \times n$ matrix of domain type DOM_ARRAY, DOM_HFARRAY, or of category Cat::Matrix

B

An $m \times p$ matrix of domain type DOM_ARRAY, DOM_HFARRAY, or of category Cat::Matrix. Column vectors B may also be represented by a 1-dimensional array(1..m, [B_1, B_2, …]), a 1-dimensional hfarray(1..m, [B_1, B_2, …]), or by a list [B_1, B_2, …].

Options

Hard, HardwareFloats, Soft, SoftwareFloats

With Hard (or HardwareFloats), computations are done using fast hardware float arithmetic from within a MuPAD session. Hard and HardwareFloats are equivalent. With this option, the input data are converted to hardware floats and processed by compiled C code. The result is reconverted to MuPAD floats and returned to the MuPAD session.

With Soft (or SoftwareFloats) computations are dome using software float arithmetic provided by the MuPAD kernel. Soft and SoftwareFloats are equivalent. SoftwareFloats is used by default if the current value of DIGITS is larger than 15 and the input matrix A is not of domain type DOM_HFARRAY.

Compared to the SoftwareFloats used by the MuPAD kernel, the computation with HardwareFloats may be many times faster. Note, however, that the precision of hardware arithmetic is limited to about 15 digits. Further, the size of floating-point numbers may not be larger than approximately 10^{308} and not smaller than approximately 10^{-308}.

If no HardwareFloats or SoftwareFloats are requested explicitly, the following strategy is used: If the current value of DIGITS is smaller than 16 or if the matrix A is a hardware float array of domain type DOM_HFARRAY, then hardware arithmetic is tried. If this is successful, the result is returned.

If the result cannot be computed with hardware floats, software arithmetic by the MuPAD kernel is tried.

If the current value of DIGITS is larger than 15 and the input matrix A is not of domain type DOM_HFARRAY, or if one of the options Soft, SoftwareFloats or Symbolic is specified, MuPAD computes the result with its software arithmetic without trying to use hardware floats first.

There may be several reasons for hardware arithmetic to fail:

- The current value of DIGITS is larger than 15.
- The data contains symbolic objects.
- The data contains numbers larger than 10^{308} or smaller than 10^{-308} that cannot be represented by hardware floats.

If neither HardwareFloats nor SoftwareFloats is specified, the user is not informed whether hardware floats or software floats are used.

If HardwareFloats are specified but fail due to one of the reasons above, a warning is issued that the (much slower) software floating-point arithmetic of the MuPAD kernel is used.

Note that HardwareFloats can only be used if all input data can be converted to floating-point numbers.

The trailing digits in floating-point results computed with HardwareFloats and SoftwareFloats may differ.

Note: For ill-conditioned matrices, the results returned with HardwareFloats and SoftwareFloats may differ significantly! See “Example 9” on page 19-186.

Symbolic

Prevents the conversion of the input data to floating-point numbers. Exact arithmetic is used. This option overrides HardwareFloats and SoftwareFloats.

This option *must* be used if the matrix *A* contains symbolic parameters that cannot be converted to floating-point numbers.

Note: This option should not be used for matrices with floating-point entries! Numerical instabilities may occur in floating-point operations. Cf. “Example 6” on page 19-183.

ShowAssumptions

Returns information on internal assumptions on symbolic parameters in A and B. With this option, either exact arithmetic or SoftwareFloats are used.

This option is only useful if the matrices contain symbolic parameters. Consequently, it should only be used in conjunction with the option Symbolic.

Note: This option changes the format of the return value to [X, KernelBasis, Constraints, Pivots].

X and KernelBasis represent the general solution subject to Constraints and Pivots.

Constraints is a list of equations for symbolic parameters in B which are necessary and sufficient for $A\,X = B$ to be solvable.

Such constraints arise if Gaussian elimination leads to equations of the form $0 = c$, where c is some expression involving symbolic parameters contained in B. All such equations are collected in Constraints; numeric::matlinsolve assumes that these equations are satisfied and returns a special solution X.

If no such constraints arise, the return value of Constraints is the empty list.

Pivots is a list of inequalities involving symbolic parameters in A. Internally, division by pivot elements occurs in the Gaussian elimination. The expressions collected in Pivots are the numerators of those pivot elements that involve symbolic parameters contained in A. If only numerical pivot elements are used, then the return value of Pivots is the empty list.

Note: Constraints usually is a list of *non-linear* equations for the symbolic parameters. It is not investigated by numeric::matlinsolve, i.e., solutions may be returned, even if the Constraints cannot be satisfied. See "Example 3" on page 19-181.

Note: This option changes the return strategy for "unsolvable" systems. Without the option ShowAssumptions, the result [FAIL,NIL] is returned, whenever Gaussian elimination produces an equation $0 = c$ with non-zero c. With ShowAssumptions, such

equations are returned via `Constraints`, provided *c* involves symbolic parameters. If *c* is a purely numerical value, then `[FAIL, NIL, [], []]` is returned.

See "Example 3" on page 19-181, "Example 4" on page 19-182, and "Example 7" on page 19-184.

`NoWarning`

Suppresses warnings

If symbolic coefficients are found, `numeric::matlinsolve` automatically switches to the `Symbolic` mode with a warning. With this option, this warning is suppressed; `numeric::matlinsolve` still uses the symbolic mode for symbolic coefficients, i.e., exact arithmetic without floating-point conversions is used.

`ReturnType`

Option, specified as `ReturnType = d`

Return the (special) solution and the kernel as matrices of domain type `d`. The following return types *d* are available: `DOM_ARRAY`, `DOM_HFARRAY`, `Dom::Matrix()`, or `Dom::DenseMatrix()`.

`Sparse`

Use a sparse internal representation for matrices.

This option only has an effect when used in conjunction with `HardwareFloats`. With the `Sparse` option, the linear solver uses a sparse representation of the matrices to save memory and increase efficiency. However, if the coefficient matrix is not sparse, this option will cost some additional memory and runtime.

Return Values

Without the option `ShowAssumptions`, a list `[X, KernelBasis]` is returned. The (special) solution `X` is an $n \times p$ matrix. `KernelBasis` is an $n \times d$ matrix (d is the dimension of the kernel of A). Its columns span the kernel of A. If the kernel is trivial, `KernelBasis` is the integer 0.

`[FAIL, NIL]` is returned if the system is not solvable.

With `ShowAssumptions`, a list `[X, KernelBasis, Constraints, Pivots]` is returned. The lists `Constraints` and `Pivots` contain equations and inequalities involving symbolic parameters in `A` and `B`. Internally these were assumed to hold true when solving the system. `[FAIL, NIL, [], []]` is returned if the system is not solvable.

MuPAD Functions

`linalg::matlinsolve` | `linsolve` | `numeric::inverse` | `numeric::linsolve` | `solve`

numeric::ncdata

Weights and abscissae of Newton-Cotes quadrature

Syntax

```
numeric::ncdata(n)
```

Description

`numeric::ncdata(n)` returns the weights and the abscissae of the Newton-Cotes quadrature rule with n equidistant nodes.

The Newton-Cotes quadrature rule $\sum_{i=1}^{n} b_i f(c_i)$ produces the exact integral $\int_0^1 f(x)\,\mathrm{d}x$ for all polynomials f through degree n - 1. If n is odd, then the quadrature rule is exact through degree n.

The equidistant abscissae $c = [c_1, \ldots, c_n]$ are given by $c_i = \frac{i-1}{n-1}$.

Environment Interactions

`numeric::ncdata` is not sensitive to the environment variable `DIGITS`.

The function uses `option remember`.

Examples

Example 1

The following call produces exact data for the quadrature rule with four nodes:

```
numeric::ncdata(4)
```

$$\left[\left[\frac{1}{8}, \frac{3}{8}, \frac{3}{8}, \frac{1}{8}\right], \left[0, \frac{1}{3}, \frac{2}{3}, 1\right]\right]$$

Parameters

n

The number of nodes: a positive integer

Return Values

List `[b,c]` is returned. The lists `b = [`b_1`, …, `b_n`]` and `c = [`c_1`, …, `c_n`]` are the rational weights and abscissae of the Newton-Cotes quadrature rule, respectively.

Algorithms

The numerical integrator `numeric::quadrature` calls `numeric::ncdata` to provide the data for Newton-Cotes quadrature.

numeric::odesolve

Numerical solution of an ordinary differential equation

Syntax

```
numeric::odesolve(f, t0 .. t, Y0, <method>, <RelativeError = rtol>, <AbsoluteError = at
```

```
numeric::odesolve(t0 .. t, f, Y0, <method>, <RelativeError = rtol>, <AbsoluteError = at
```

Description

`numeric::odesolve(f, t0..t, Y0)` returns a numerical approximation of the solution $Y(t)$ of the first order differential equation (dynamical system) $\frac{dY}{dt} = f(t, Y)$, $Y(t_0) = Y_0$ with $t, t_0 \in \mathbb{R}$ and $Y(t), Y_0 \in \mathbb{C}^n$.

`numeric::odesolve` is a general purpose solver able to deal with initial value problems of various kinds of ordinary differential equations. Equations $y^{(p)} = f\left(t, y, y', \ldots, y^{(p-1)}\right)$ of order p can be solved by `numeric::odesolve` after reformulation to dynamical system form. This can always be achieved by writing the equation as a first order system

$$\frac{d}{dt}\begin{pmatrix} Y_1 \\ \cdots \\ Y_{p-1} \\ Y_p \end{pmatrix} = \begin{pmatrix} Y_2 \\ \cdots \\ Y_p \\ f\left(t, Y_1, \ldots, Y_p\right) \end{pmatrix}$$

for the vector $Y = \left[Y_1, \ldots, Y_p\right] = \left[y, y', \ldots, y^{(p-1)}\right]$. See “Example 4” on page 19-199.

The following single-step Runge-Kutta-type methods are implemented:

- `EULER1` (order 1)

- `RKF43` (order 3)
- `xRKF43` (order 3)
- `RKF34` (order 4)
- `xRKF34` (order 4)
- `RK4` (order 4)
- `RKF54a` (order 4)
- `RKF54b` (order 4)
- `DOPRI54` (order 4)
- `xDOPRI54` (order 4)
- `CK54` (order 4)
- `xRKF54a` (order 4)
- `xRKF54b` (order 4)
- `xCK54` (order 4)
- `RKF45a` (order 5)
- `RKF45b` (order 5)
- `DOPRI45` (order 5)
- `CK45` (order 5)
- `xRKF45a` (order 5)
- `xRKF45b` (order 5)
- `xDOPRI45` (order 5)
- `xCK45` (order 5)
- `DOPRI65` (order 5)
- `xDOPRI65` (order 5)
- `DOPRI56` (order 6)
- `xDOPRI56` (order 6)
- `BUTCHER6` (order 6)
- `RKF87` (order 7)
- `xRKF87` (order 7)
- `DOPRI87` (order 7)

- `xDOPRI87` (order 7)
- `RKF78` (order 8)
- `xRKF78` (order 8)
- `DOPRI78` (order 8)
- `xDOPRI78` (order 8)
- `GAUSS(s)` (order 2 *s*)
- `GAUSS` = `s`

For the Gauss methods, `GAUSS(s)` is equivalent to `GAUSS = s`. The positive integer `s` indicates the number of stages. The order of the `s` stage Gauss method is 2 *s*.

The utility function `numeric::ode2vectorfield` may be used to produce the input parameters *f*, t_0, Y_0 from a set of differential expressions representing the ODE. See "Example 1" on page 19-198.

The input data t_0, t and Y_0 must not contain symbolic objects which cannot be converted to floating point values via `float`. Numerical expressions such as e^{π}, $\sqrt{2}$ etc. are accepted.

The vector field *f* defining the dynamical system $Y' = f(t, Y)$ must be represented by a procedure with two input parameters: the scalar time *t* and the vector *Y*. `numeric::odesolve` internally calls this function with real floating-point values *t* and a list *Y* of floating-point values. It has to return the vector *f*(*t*, *Y*) either as a list or as a 1-dimensional array. The output of *f* may contain numerical expressions such as π, e^2 etc. However, all values must be convertible to real or complex floating point numbers by `float`.

Autonomous systems, where *f*(*t*, *Y*) does not depend on *t*, must also be represented by a procedure with 2 arguments `t` and `Y`.

Scalar functions `Y` also must be represented by a list or an array with one element. For instance, the input data for the scalar initial value problem $y' = t\sin(y)$, $y(0) = 1$ may be of the form

```
f := proc(t,Y)                    /* Y is a 1-dimensional vector */
local y;                          /* represented by a list with */
```

```
begin                                   /* one element: Y = [y]. */
   y := Y[1];
   [t*sin(y)]                           /* the output is a list with 1 element */
end_proc:
Y0 := [1]:                              /* the initial value */
```

The numerical precision is controlled by the global variable `DIGITS`: an adaptive control of the step size keeps local relative discretization errors below `rtol=10^-DIGITS`, unless a different tolerance is specified via the option `RelativeError = rtol`. For small values of the solution vector *Y*, the absolute discretization error can be bounded by the threshold `atol` specified via the option `AbsoluteError = atol`.

If `AbsoluteError` is not specified, only relative discretization errors are controlled and kept below `rtol`.

The error control may be switched off by specifying a fixed `Stepsize = h`.

Note: Only local errors are controlled by the adaptive mechanism. No control of the global error is provided!

With `Y := t -> numeric::odesolve(f, t_0..t, Y_0)`, the numerical solution can be repesented by a MuPAD function: the call `Y(t)` will start the numerical integration from t_0 to `t`. A more sophisticated form of this function may be generated via `Y := numeric::odesolve2(f, t_0, Y_0)`.

This equips `Y` with a remember mechanism that uses previously computed values to speed up the computation. See “Example 2” on page 19-198.

For systems of the special form $Y' = f(t, Y)\,Y$ with a matrix valued function $f(t, Y)$, there is a special solver `numeric::odesolveGeometric` which preserves geometric features of the system more faithfully than `numeric::odesolve`.

Environment Interactions

The function is sensitive to the environment variable `DIGITS`, which determines the numerical working precision.

Examples

Example 1

We compute the numerical solution $y(10)$ of the initial value problem $y' = t \sin(y)$, $y(0) = 2$:

```
f := proc(t, Y) begin [t*sin(Y[1])] end_proc:
numeric::odesolve(f, 0..10, [2])
```

```
[3.141592654]
```

Alternatively, the utility function `numeric::ode2vectorfield` can be used to generate the input parameters in a more intuitive way:

```
[f, t0, Y0] :=
  [numeric::ode2vectorfield({y'(t) = t*sin(y(t)), y(0) = 2}, [y(t)])]
```

```
[proc f(t, Y) ... end, 0, [2]]
```

```
numeric::odesolve(f, t0..10, Y0)
```

```
[3.141592654]
```

```
delete f, t0, Y0:
```

Example 2

We consider $y' = y$, $y(0) = 1$. The numerical solution may be represented by the function

```
Y := t -> numeric::odesolve((t,Y) -> Y, 0..t, [1]):
```

Calling `Y(t)` starts the numerical integration:

```
Y(-5), Y(0), Y(1), Y(PI)
```

$$[0.006737946999], [1.0], [2.718281828], [23.14069263]$$

```
delete Y:
```

Example 3

We compute the numerical solution $Y(\pi) = [x(\pi), y(\pi)]$ of the system

$$x' = x + y,\ y' = x - y,\ x(0) = 1,\ y(0) = \sqrt{-1}$$

.

```
f := (t, Y) -> [Y[1] + Y[2], Y[1] - Y[2]]: Y0 := [1, I]:
numeric::odesolve(f, 0..PI, Y0)
```

$$[72.57057163 + 30.05484302\ i,\ 30.05484302 + 12.46088558\ i]$$

The solution of a linear dynamical system $Y' = A\ Y$ with a constant matrix A is $Y(t) = e^{t\ A}\ Y_0$. The solution of the system above can also be computed by:

```
t := PI: tA := array(1..2, 1..2, [[t, t], [t, -t]]):
numeric::expMatrix(tA, Y0)
```

$$\begin{pmatrix} 72.57057163 + 30.05484303\ i \\ 30.05484303 + 12.46088558\ i \end{pmatrix}$$

```
delete f, Y0, t, tA:
```

Example 4

We compute the numerical solution $y(1)$ of the differential equation $y'' = y^2$ with initial conditions $y(0) = 0$, $y'(0) = 1$. The second order equation is converted to a first order system for the vector $Y = [y, y'] = [y, z]$:

$$y' = z,\ z' = y^2,\ y(0) = 0,\ z(0) = 1$$

```
f := proc(t, Y) begin [Y[2], Y[1]^2] end_proc:
Y0 := [0, 1]:
numeric::odesolve(f, 0..1, Y0)
```

$$[1.087473533, 1.362851121]$$

```
delete f, Y0:
```

Example 5

We demonstrate how numerical data can be obtained on a user defined time mesh `t[i]`. The initial value problem is $y' = \sin(t) - y$, $y(0) = 1$, the sample points are $t_0 = 0.0$, $t_1 = 0.1$, ..., $t_{100} = 10.0$. First, we define the differential equation and the initial condition:

```
f := (t, Y) -> [sin(t) - Y[1]]:
Y[0] := [1]:
```

We define the time mesh:

```
for i from 0 to 100 do t[i] := i/10 end_for:
```

The equation is integrated iteratively from `t[i-1]` to `t[i]` with a working precision of 4 significant decimal places:

```
DIGITS := 4:
for i from 1 to 100 do
  Y[i] := numeric::odesolve(f, t[i-1]..t[i], Y[i-1])
end_for:
```

The following mesh data are produced:

```
[t[i], Y[i]] $ i = 0..100
```

$$\left[[0, [1]], \left[\frac{1}{10}, [0.9097]\right], \left[\frac{1}{5}, [0.8374]\right], \left[\frac{3}{10}, [0.7813]\right], \left[\frac{2}{5}, [0.7397]\right], \ldots, \left[\frac{99}{10}, [0.2159]\right], [10, [0.1476]]\right]$$

$$[0, [1]], \left[\frac{1}{10}, [0.9097]\right], \left[\frac{1}{5}, [0.8374]\right], \left[\frac{3}{10}, [0.7813]\right], \left[\frac{2}{5}, [0.7397]\right], \left[\frac{1}{2}, [0.7107]\right],$$

$$\left[\frac{3}{5}, [0.6929]\right], \left[\frac{7}{10}, [0.6846]\right], \left[\frac{4}{5}, [0.6843]\right], \left[\frac{9}{10}, [0.6907]\right], [1, [0.7024]], \left[\frac{11}{10}, [0.7181]\right],$$

$$\left[\frac{6}{5}, [0.7366]\right], \left[\frac{13}{10}, [0.7568]\right], \left[\frac{7}{5}, [0.7776]\right], \left[\frac{3}{2}, [0.7981]\right], \left[\frac{8}{5}, [0.8172]\right], \left[\frac{17}{10}, [0.8343]\right],$$

$$[7, [-0.04709]], \left[\frac{71}{10}, [0.02345]\right], \left[\frac{36}{5}, [0.09378]\right], \left[\frac{73}{10}, [0.1632]\right], \left[\frac{37}{5}, [0.231]\right],$$

$$\left[\frac{15}{2}, [0.2965]\right], \left[\frac{38}{5}, [0.3591]\right], \left[\frac{77}{10}, [0.4181]\right], \left[\frac{39}{5}, [0.4729]\right], \left[\frac{79}{10}, [0.523]\right], [8, [0.5679]],$$

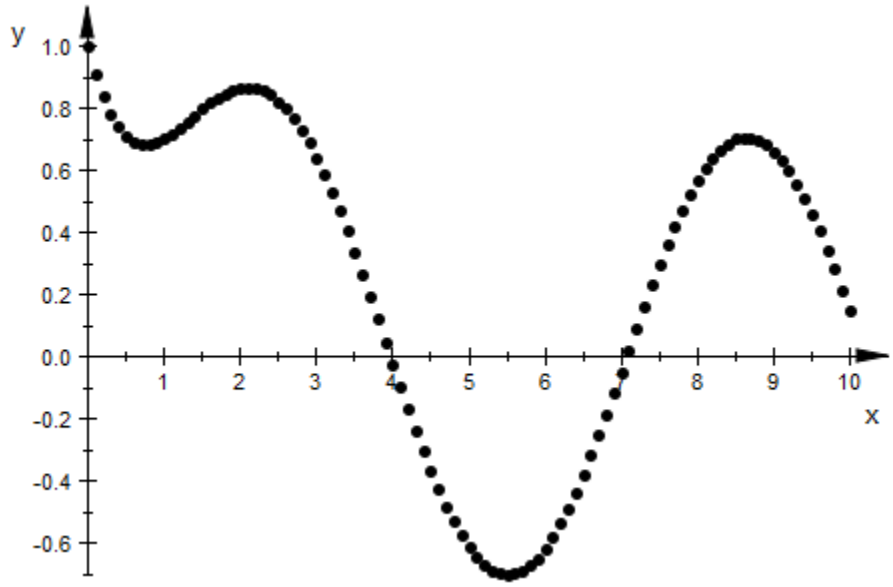
$$\left[\frac{81}{10}, [0.6072]\right], \left[\frac{41}{5}, [0.6404]\right], \left[\frac{83}{10}, [0.6671]\right], \left[\frac{42}{5}, [0.6873]\right], \left[\frac{17}{2}, [0.7006]\right],$$

$$\left[\frac{43}{5}, [0.7068]\right], \left[\frac{87}{10}, [0.7061]\right], \left[\frac{44}{5}, [0.6982]\right], \left[\frac{89}{10}, [0.6834]\right], [9, [0.6618]], \left[\frac{91}{10}, [0.6336]\right],$$

$$\left[\frac{46}{5}, [0.599]\right], \left[\frac{93}{10}, [0.5585]\right], \left[\frac{47}{5}, [0.5124]\right], \left[\frac{19}{2}, [0.4611]\right], \left[\frac{48}{5}, [0.4053]\right],$$

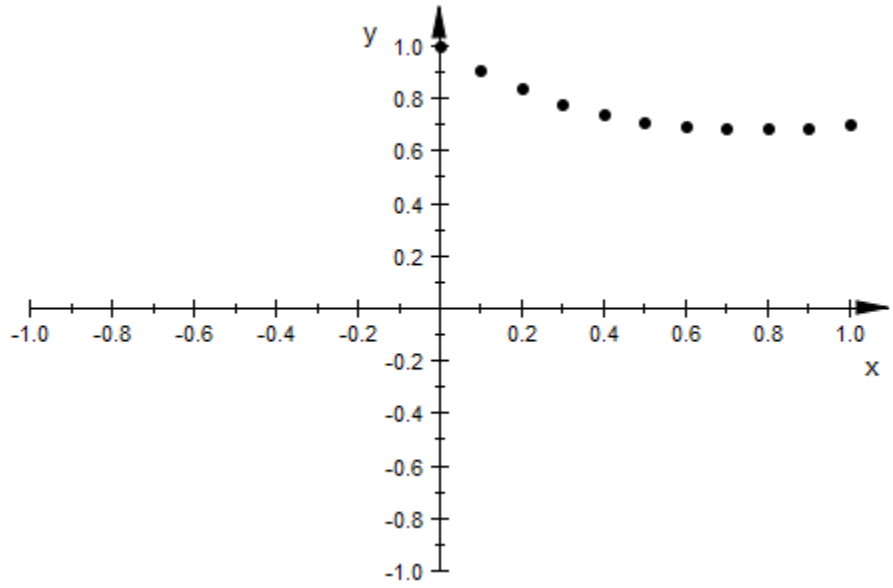
These data can be displayed by a list plot:

```
plotpoints := [[t[i], op(Y[i])] $ i = 0..100]:
plot(plot::PointList2d(plotpoints, PointColor = RGB::Black)):
```



The same plot can be obtained directly via `plot::Ode2d`:

```
plot(plot::Ode2d(
    [t[i] $ i = 0..100], f, Y[0],
    [(t, Y) -> [t, Y[1]], Style = Points, Color = RGB::Black]))
```



```
delete f, t, DIGITS, Y, plotpoints:
```

Example 6

We compute the numerical solution $y(1)$ of $y' = y$, $y(0) = 1$ by the classical 4-th order Runge-Kutta method RK4. By internal local extrapolation, its effective order is 5:

```
f := (t, Y) -> Y:
DIGITS := 13:
numeric::odesolve(f, 0..1, [1], RK4)
```

$$[2.718281828459]$$

Next, we use local extrapolation xRKF78 of the 8-th order submethod of the Runge-Kutta-Fehlberg pair RKF78. This scheme has effective order 9:

```
numeric::odesolve(f, 0..1, [1], xRKF78)
```

$$[2.718281828459]$$

Both methods yield the same result because of the internal adaptive error control. However, due to its higher order, the method `xRKF78` is faster.

```
delete f, DIGITS:
```

Example 7

We consider the stiff ODE $y' = 10^4\,(\cos(t) - y)$, $y(0) = 1$. The default method `DOPRI78` is explicit and not very efficient in solving very stiff problems:

```
f := (t, Y) -> [10^4*(cos(t) - Y[1])]:
t0 := time():
numeric::odesolve(f, 0..1, [1]), (time() - t0)*msec
```

$$[0.5403864476],\ 16065.004\ \text{msec}$$

We use the implicit A-stable method `GAUSS(6)`. For this stiff problem, it is more efficient than the default method `DOPRI78`:

```
t0 := time():
numeric::odesolve(f, 0..1, [1], GAUSS(6)), (time() - t0)*msec
```

$$[0.5403864476],\ 796.05\ \text{msec}$$

```
delete t0:
```

Example 8

We consider the initial value problem $y' = -10^{20}\,y\,(1 - \cos(y))$, $y(0) = 1$. We note that the numerical evaluation of the right hand side of the equation suffers from cancellation effects, when $|y|$ is small.

```
f := (t, Y) -> [-10^20*Y[1]*(1 - cos(Y[1]))]:
Y0 := [1]:
```

We first attempt to compute $y(1)$ with a working precision of 6 digits using the default setting `RelativeError = 10^-DIGITS=10^(-6)`:

```
DIGITS := 6: numeric::odesolve(f, 0..1, Y0)
```

```
[0.000000000329271]
```

Due to numerical round-off in the internal steps, no digit of this result is correct. Next, we use a working precision of 20 significant decimal places to eliminate roundoff effects:

```
DIGITS := 20:
numeric::odesolve(f, 0..1, Y0, RelativeError = 10^(-6))
```

```
[0.00000000010000000007495004558]
```

Since relative local discretization errors are of the magnitude 10^{-6}, not all displayed digits are trustworthy. We finally use a working precision of 20 digits and constrain the local relative discretization errors by the tolerance 10^{-10}:

```
numeric::odesolve(f, 0..1, Y0, RelativeError = 10^(-10))
```

```
[0.00000000010000000000003105061]
```

```
delete f, Y0, DIGITS:
```

Example 9

We compute the numerical solution $y(1)$ of $y' = y$, $y(0) = 1$ with various methods and various constant step sizes. We compare the result with the exact solution $y(1) = e = 2.718281828\ldots$.

```
f := (t, Y) -> Y:
Y0 := [1]:
```

We first use the Euler method of order 1 with two different step sizes:

```
Y := numeric::odesolve(f, 0..1, Y0, EULER1, Stepsize = 0.1):
Y, globalerror = float(exp(1)) - Y[1]
```

```
[2.59374246], globalerror = 0.1245393684
```

Decreasing the step size by a factor of 10 should reduce the global error by a factor of 10. Indeed:

```
Y := numeric::odesolve(f, 0..1, Y0, EULER1, Stepsize = 0.01):
```

```
Y, globalerror = float(exp(1)) - Y[1]
```

$$[2.704813829],\ \text{globalerror} = 0.01346799904$$

Next, we use the classical Runge-Kutta method of order 4 with two different step sizes:

```
Y := numeric::odesolve(f, 0..1, Y0, RK4, Stepsize = 0.1):
Y, globalerror = float(exp(1)) - Y[1]
```

$$[2.718279744],\ \text{globalerror} = 0.00000208432388$$

Decreasing the step size by a factor of 10 in a 4-th order scheme should reduce the global error by a factor of 10^4. Indeed:

```
Y := numeric::odesolve(f, 0..1, Y0, RK4, Stepsize = 0.01):
Y, globalerror = float(exp(1)) - Y[1]
```

$$[2.718281828],\ \text{globalerror} = 0.0000000002246438591$$

```
delete f, Y0, Y:
```

Example 10

We integrate $y' = y^2$, $y(0) = 1$ over the interval $t \in [0, 0.99]$ with a working precision of 4 digits. The exact solution is $y(t) = \frac{1}{1-t}$. Note the singularity at $t = 1$.

```
DIGITS := 4:
f := (t, Y) -> [Y[1]^2]:
Y0 := [1]:
```

The option `Alldata`, equivalent to `Alldata = 1`, yields all mesh data generated during the internal adaptive process:

```
numeric::odesolve(f, 0..0.99, Y0, Alldata)
```

$$[[0.0, [1.0]], [0.4933, [1.974]], [0.74, [3.846]], [0.8633, [7.314]], [0.9249, [13.32]],\ [0.9558, [22.61]], [0.9712, [34.71]], [0.9866, [74.68]], [0.99, [99.97]]]$$

With `Alldata = 2`, only each second point is returned:

```
numeric::odesolve(f, 0..0.99, Y0, Alldata = 2)
```

```
[[0.0, [1.0]], [0.74, [3.846]], [0.9249, [13.32]], [0.9712, [34.71]], [0.99, [99.97]]]
```

One can control the time mesh using the option `Stepsize = h`:

```
numeric::odesolve(f, 0..0.99, Y0, Stepsize=0.1, Alldata = 1)
```

```
[[0.0, [1.0]], [0.1, [1.111]], [0.2, [1.25]], [0.3, [1.429]], [0.4, [1.667]], [0.5, [2.0]], [0.6, [2.5]],
  [0.7, [3.333]], [0.8, [5.0]], [0.9, [10.0]], [0.99, [94.3]]]
```

However, with the option `Stepsize = h`, no automatic error control is provided by `numeric::odesolve`. Note the poor approximation $y(t) = 94.3$ for $t = 0.99$ (the exact value is $y(0.99) = 100.0$). The next computation with smaller step size yields better results:

```
numeric::odesolve(f, 0..0.99, Y0, Stepsize = 0.01, Alldata = 10)
```

```
[[0.0, [1.0]], [0.1, [1.111]], [0.2, [1.25]], [0.3, [1.429]], [0.4, [1.667]], [0.5, [2.0]], [0.6, [2.5]],
  [0.7, [3.333]], [0.8, [5.0]], [0.9, [10.0]], [0.99, [100.0]]]
```

"Example 5" on page 19-200 demonstrates how accurate numerical data on a user defined time mesh can be generated using the automatic error control of `numeric::odesolve`.

```
delete DIGITS, f, Y0:
```

Example 11

The second order equation $y'' + \sin(y) = 0$ is written as the dynamical system $y' = z$, $z' = -\sin(y)$ for the vector $Y = [y, z]$. A single symbolic step

$$[y(t_0), z(t_0)] \to [y(t_0 + h), z(t_0 + h)]$$

of the Euler method is computed:

```
f := proc(t, Y) begin [Y[2], -sin(Y[1])] end_proc:
numeric::odesolve(f, t0..t0+h, [y0, z0], EULER1, Symbolic)
```

$$[y0 + h\ z0,\ z0 - h\ \sin(y0)]$$

```
delete f:
```

Parameters

f

A procedure representing the vector field

t_0

A numerical real value for the initial time

t

A numerical real value (the “time”)

Y_0

A list or 1-dimensional array of numerical values representing the initial condition

method

One of the Runge-Kutta schemes listed below.

Options

BUTCHER6, CK45, CK54, DOPRI45, DOPRI54, DOPRI56, DOPRI65, DOPRI78, DOPRI87, EULER1, RK4, RKF34, RKF43, RKF45a, RKF45b, RKF54a, RKF54b, RKF78, RKF87, xCK45, xCK54, xDOPRI45, xDOPRI54, xDOPRI56, xDOPRI65, xDOPRI78, xDOPRI87, xRKF34, xRKF43, xRKF45a, xRKF45b, xRKF54a, xRKF54b, xRKF78, xRKF87

Name of the Runge-Kutta scheme. See “Example 6” on page 19-203. For details on these schemes, see the Algorithms section.

GAUSS

Name of the Runge-Kutta scheme specified as `GAUSS(s)` or `GAUSS = s`.

The methods `GAUSS(s)` or, equivalently, `GAUSS = s` are the implicit Gauss methods with `s` stages of order $2s$.

These methods are implicit A-stable schemes. The time steps are rather costly to compute. The Gauss methods are useful for integrating stiff ODEs. For non-stiff ODEs, there is usually no need to change the default method `DOPRI78`. This method is an embedded Runge-Kutta pair of orders 7 and 8.

Further, the Gauss methods are symplectic methods. When used with constant step size (`Stepsize = h`), numerical integration of Hamiltonian systems benefits from this property.

See “Example 7” on page 19-204.

`RelativeError`, `AbsoluteError`

Option specified as `RelativeError = rtol` forces internal numerical Runge-Kutta steps to use step sizes with relative local discretization errors below `rtol`. This tolerance must be a positive numerical real value not smaller than $\frac{1}{10^{\mathrm{DIGITS}}}$. The default tolerance is `RelativeError = 10^(-DIGITS)`.

Option specified as `AbsoluteError = atol` forces internal numerical Runge-Kutta steps to use step sizes with absolute local discretization errors below `atol`. This tolerance must be a nonnegative numerical real value. The default tolerance is `AbsoluteError = 10^(-10*DIGITS)`.

The internal control mechanism estimates the local discretization error of a Runge-Kutta step and adjusts the step size adaptively to keep this error below the specified tolerances `rtol` or `atol`, respectively. The code uses the criterion

$$\|\text{discretization error}\|_\infty = \max\left(\|Y\|_\infty \,\text{rtol},\ \text{atol}\right)$$

For accepting a solution vector Y. Roughly speaking, the relative error is controlled when the solution Y is sufficiently large. For very small solution values Y, absolute discretization errors are kept below the threshold `atol`.

Specify `AbsoluteError` = 0 if only control of the relative discretization errors is desired.

The error control may be switched off by specifying a fixed `Stepsize = h`.

The default setting of $\mathrm{rtol} = \frac{1}{10^{\mathrm{DIGITS}}}$, $\mathrm{atol} = \frac{1}{10^{10\ \mathrm{DIGITS}}}$ ensures that the local discretization errors are of the same order of magnitude as numerical roundoff.

Usually there is no need to use these options to change this setting. However, occasionally the numerical evaluation of the Runge-Kutta steps may be ill-conditioned or step sizes are so small that the time parameter cannot be incremented by the step size within working precision. In such a case these options may be used to bound the local discretization errors and use a higher working precision given by `DIGITS`.

Only positive real numerical values $\mathrm{rtol} \geq \frac{1}{10^{\mathrm{DIGITS}}}$ are accepted.

Note: The global error of the result returned by `numeric::odesolve` is usually larger than the local errors bounded by `rtol`, `atol`, respectively. Although the result is displayed with `DIGITS` decimal places one should not expect that all of them are correct. The relative precision of the final result is `rtol` at best!

See “Example 8” on page 19-204.

`Stepsize`

Option, specified as `Stepsize = h`

Switches off the internal error control and uses a Runge-Kutta iteration with constant step size `h` which must be a positive numerical value.

By default, `numeric::odesolve` uses an adaptive step size control mechanism in the numerical iteration. The option `Stepsize = h` switches off this adaptive mechanism and uses the Runge-Kutta method specified (or the default method `DOPRI78`) with constant step size `h`.

A final step with smaller step size is used to match the end `t` of the integration interval `t_0..t` if $\frac{t-t_0}{h}$ is not an integer.

Note: With this option, there is no automatic error control! Depending on the problem and on the order of the method the result may be a poor numerical approximation of the exact solution.

There is usually no need to invoke this option. However, occasionally the built-in adaptive error control mechanism may fail when integrating close to a singularity. In such a case this option may be used to customize a control mechanism for the global error by using different step sizes and investigating the convergence of the corresponding results.

Cf. “Example 9” on page 19-205.

MaxStepsize

Option, specified as `MaxStepsize = hmax`

Restricts adaptive step sizes to values not larger than `h_max`; `h_max` must be a positive numerical value.

By default, `numeric::odesolve` uses an adaptive step size control mechanism in the numerical iteration. The option `MaxStepsize = h_max` restricts the adaptive step size to values no larger than h_{max}.

If a larger stepsize `h` is requested explicitly by `Stepsize = h`, the option `MaxStepsize = h_max` reduces `h` to h_{max}.

Alldata

Option, specified as `Alldata = n`

Makes `numeric::odesolve` return a list of numerical mesh points generated by the internal Runge-Kutta iteration. The integer `n` controls the size of the output list.

With this option, `numeric::odesolve` returns a list of numerical mesh points $[[t_0, Y_0], [t_1, Y_1], \ldots, [t, Y(t)]]$ generated by the internal Runge-Kutta iteration.

The integer `n` controls the size of the output list. For $n = 1$, all internal mesh points are returned. This case may also be invoked by entering the simplified option `Alldata`, which is equivalent to `Alldata = 1`. For $n > 1$, only each n-th mesh point is stored in the list. The list always contains the initial point $[t_0, Y_0]$ and the final point $[t, Y(t)]$. For $n \leq 0$, only the data $[[t_0, Y_0], [t, Y(t)]]$ are returned.

The output list may be useful to inspect the internal numerical process. Also further graphical processing of the mesh data may be useful.

Cf. “Example 10” on page 19-206.

`Symbolic`

Makes `numeric::odesolve` return a vector of symbolic expressions representing a single symbolic step of the Runge-Kutta iteration.

The call `numeric::odesolve(f, t0..t, Y0, < method >, Symbolic)` returns a vector (list or array) of expressions representing a single step of the numerical scheme with step size t - t_0. In this mode symbolic values for t_0, t and the components of Y_0 are accepted.

This option may be useful if the specified numerical method applied to a given differential equation is to be investigated symbolically.

Cf. “Example 11” on page 19-207.

Return Values

The solution vector $Y(t)$ is returned as a list or as a 1-dimensional array of floating-point values. The type of the result vector coincides with the type of the input vector Y_0.

With the option `Alldata`, a list of mesh data is returned.

Algorithms

All methods presently implemented are adaptive versions of Runge-Kutta type single step schemes.

The methods `RKF43`, `RKF34`, `RKF54a`, `RKF54b`, `RKF45a`, `RKF45b`, `RKF87`, `RKF78`, `DOPRI54`, `DOPRI45`, `DOPRI65`, `DOPRI56`, `DOPRI87`, `DOPRI78`, `CK54`, `CK45` are embedded pairs of Runge-Kutta-Fehlberg, Dormand-Prince and Cash-Karp type, respectively. Estimates of the local discretization error are obtained in the usual way by comparing the results of the two submethods of the pair. The names indicate the orders of the subprocesses. For instance, `RKF34` and `RKF43` denote the same embedded Runge-Kutta-Fehlberg pair with orders 3 and 4. In `RKF34` the result of the fourth order submethod is accepted, whereas `RKF43` advances using the result of the third order submethod. In both cases the discretization error of the lower order subprocess is estimated and controlled.

For the single methods `EULER1` (the first order Euler scheme), `RK4` (the classical fourth order Runge-Kutta scheme) and `BUTCHER6` (a Runge-Kutta scheme of order 6), the

relative local error is controlled by comparing steps with different step sizes. The effective order of these methods is increased by one through local extrapolation.

Local extrapolation is also available for the submethods of the embedded pairs. For instance, the method `xRKF78` uses extrapolation of the 8-th order subprocess of `RKF78`, yielding a method of effective order 9. The 7-th order subprocess is ignored. The cheap error estimate based on the embedded pair is not used implying some loss of efficiency when comparing `RKF78` (order 8) and `xRKF78` (effective order 9).

The call `numeric::butcher(method)` returns the Butcher data of the methods used in `numeric::odesolve`. Here `method` is one of `EULER1`, `RKF43`, `RK4`, `RKF34`, `RKF54a`, `RKF54b`, `DOPRI54`, `CK54`, `RKF45a`, `RKF45b`, `DOPRI45`, `CK45`, `DOPRI65`, `DOPRI56`, `BUTCHER6`, `RKF87`, `DOPRI87`, `RKF78`, `DOPRI78`.

Note: Only local errors are controlled by the adaptive mechanism. No control of the global error is provided!

Note: The run time of the numerical integration with a method of order p grows like $O\left(10^{\frac{\text{DIGITS}}{p+1}}\right)$, when `DIGITS` is increased. Computations with high precision goals are very expensive! High order methods such as the default method `DOPRI78` should be used.

Presently, only single step methods of Runge-Kutta type are implemented. Stiff problems cannot be handled efficiently with explicit methods such as the default method `DOPRI78`. For stiff problems, one may use one of the implicit A-stable methods `GAUSS(s)`. See “Example 7” on page 19-204.

For problems of the special type $Y' = f(t, Y)\,Y$ with a matrix valued function $f(t, Y)$, there is a specialized (“geometric”) integration routine `numeric::odesolveGeometric`. Generally, `numeric::odesolve` is faster than the geometric integrator. However, `odesolveGeometric` preserves certain invariants of the system more faithfully.

- “Solve Equations Numerically”

numeric::odesolve2

Numerical solution of an ordinary differential equation

Syntax

```
numeric::odesolve2(f, t0, Y0, <method>, <RememberLast>, <RelativeError = rtol>, <Absolu
```

Description

`numeric::odesolve2( f, t0, Y0, … )` returns a function representing the numerical solution $Y(t)$ of the first order differential equation (dynamical system) $\frac{dY}{dt} = f(t, Y)$, $Y(t_0) = Y_0$ with $t, t_0 \in \mathbb{R}$ and $Y(t), Y_0 \in \mathbb{C}^n$.

The utility function `numeric::ode2vectorfield` may be used to produce the input parameters `f, t0, Y0` from a set of differential expressions representing the ODE. Cf. "Example 1" on page 19-216.

The function generated by `Y := numeric::odesolve2(f, t0, Y0)` is essentially

`Y := t -> numeric::odesolve(t_0..t, f, Y_0)`.

Numerical integration is launched, when `Y` is called with a real numerical argument. The call `Y(t)` returns the solution vector in a format corresponding to the type of the initial condition Y_0 with which `Y` was defined: `Y(t)` either yields a list or a 1-dimensional array.

If `t` is not a real numerical value, then `Y(t)` returns a symbolic function call.

See the help page of `numeric::odesolve` for details on the parameters and the options.

The options `Alldata = n` and `Symbolic` accepted by `numeric::odesolve` have no effect: `numeric::odesolve2` ignores these options.

Note: Without `RememberLast`, the function Y remembers all values it has computed. When calling $Y(T)$, it searches its remember table for the time $t0 < T < t$ closest to t, and integrates from T to t using the previously computed $Y(T)$ as initial value. Here,

t0 is the time for which the initial value of the ODE is given. This reduces the costs of a call considerably, if `Y` must be evaluated many times, for example, when plotting the ODE solution. The best approach is to call *Y* only with a monotonically increasing (or decreasing) sequence of values *t* starting from *t0*. Further, the function must be re-initialized whenever `DIGITS` is increased. See "Example 3" on page 19-218.

Environment Interactions

The function returned by `numeric::odesolve2` is sensitive to the environment variable `DIGITS`, which determines the numerical working precision.

Without `RememberLast`, the function returned by `numeric::odesolve2` uses `option remember`.

Examples

Example 1

The numerical solution of the initial value problem $y' = t\sin(y)$, $y(0) = 2$ is represented by the following function $Y = [y]$:

```
f := (t, Y) -> [t*sin(Y[1])]:
```

Alternatively, the utility function `numeric::ode2vectorfield` can be used to generate the input parameters in a more intuitive way:

```
[f, t0, Y0] :=
  [numeric::ode2vectorfield({y'(t) = t*sin(y(t)), y(0) = 2}, [y(t)])]
```

```
     [proc f(t, Y) ... end, 0, [2]]
```

```
Y := numeric::odesolve2(f, t0, Y0)
```

```
     proc Y(t) ... end
```

The procedure `Y` starts the numerical integration when called with a numerical argument:

```
Y(-2), Y(0), Y(0.1), Y(PI + sqrt(2))
```

$$[2.968232567], [2.0], [2.004541745], [3.141552691]$$

Calling `Y` with a symbolic argument yields a symbolic call:

```
Y(t), Y(t + 5), Y(t^2 - 4)
```

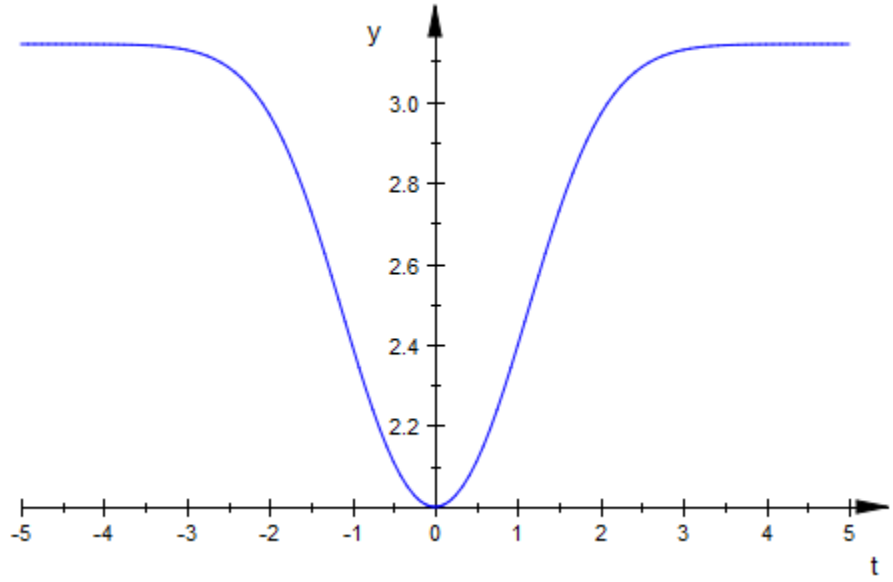
$$Y(t), Y(t+5), Y(t^2-4)$$

```
eval(subs(%, t = PI))
```

$$[3.132357009], [3.141592654], [3.141592611]$$

The numerical solution can be plotted. Note that `Y(t)` returns a list, so we plot the list element `Y(t)[1]`:

```
plotfunc2d(Y(t)[1], t = -5..5):
```



```
delete f, t0, Y0, Y:
```

Example 2

We consider the differential equation $y'' = y^2$ with initial conditions $y(0) = 0$, $y'(0) = 1$. The second order equation is converted to a first order system for $Y = [Y_1, Y_2] = [y, y']$:

$$Y_1' = Y_2,\ Y_2' = Y_1^2,\ Y_1(0) = 0,\ Y_2(0) = 1$$

```
f := (t, Y) -> [Y[2], Y[1]^2]:
t0 := 0: Y0 := [0, 1]:
Y := numeric::odesolve2(f, t0, Y0):
Y(1), Y(PI)
```

$$[1.087473533, 1.362851121], [1274.867469, 37166.52262]$$

```
delete f, t0, Y0, Y:
```

Example 3

We consider the system

$$x' = x + y,\ y' = x - y,\ x(0) = 1,\ y(0) = \sqrt{-1}:$$

```
f := (t, Y) -> [Y[1] + Y[2], Y[1] - Y[2]]:
Y := numeric::odesolve2(f, 0, [1, I]):
DIGITS := 5:
Y(1)
```

$$[3.5465 + 1.3683\ i,\ 1.3683 + 0.80988\ i]$$

Increasing `DIGITS` does not lead to a more accurate result because of the remember mechanism:

```
DIGITS := 15: Y(1)
```

$$[3.54648112716477 + 1.36829878277279\ i,\ 1.36829878277279 + 0.809883561619181\ i]$$

This is the previous value computed with 5 digits, printed with 15 digits. Indeed, only 5 digits are correct. For getting a result that is accurate to full precision, one has to erase the remember table via `Y:=subsop(Y,5=NIL)`. Alternatively, one may create a new numerical solution with a fresh (empty) remember table:

```
Y := numeric::odesolve2(f, 0, [1, I]):
Y(1)
```

$$[3.54648242861716 + 1.36829887200859\,i,\ 1.36829887200859 + 0.80988468459998\,i]$$

```
delete f, Y, DIGITS:
```

Example 4

We demonstrate the effect of the option `RememberLast`. We consider the ODE

$$y'(t) = -y + \sin(t),\ y(0) = 1$$:

```
f := (t, Y) -> [-Y[1] + sin(t)]:
Y := numeric::odesolve2(f, 0, [1]):
Z := numeric::odesolve2(f, 0, [1], RememberLast):
```

After many calls of `Y`, its remember table has grown large. In each call, searching the remember table for input parameters close to the present time value becomes expensive. Created with `RememberLast`, the procedure `Z` does not remember all its previously computed values apart from the last one. Consequently, it becomes faster than `Y`:

```
time(for i from 1 to 1000 do Y(i/100) end)*msec,
time(for i from 1 to 1000 do Z(i/100) end)*msec
```

11592.724 msec, 4352.272 msec

Apart from the efficiency, the values returned by `Y` and `Z` coincide:

```
Y(10.5), Z(10.5)
```

$$[-0.2020381113],\ [-0.2020381113]$$

```
delete f, Y, Z, i:
```

Parameters

f

A procedure representing the vector field of the dynamical system

t_0

A numerical real value for the initial time

Y_0

A list or 1-dimensional array of numerical values representing the initial value

method

One of the Runge-Kutta schemes listed below.

Options

BUTCHER6, CK45, CK54, DOPRI45, DOPRI54, DOPRI56, DOPRI65, DOPRI78, DOPRI87, EULER1, GAUSS, RK4, RKF34, RKF43, RKF45a, RKF45b, RKF54a, RKF54b, RKF78, RKF87, xCK45, xCK54, xDOPRI45, xDOPRI54, xDOPRI56, xDOPRI65, xDOPRI78, xDOPRI87, xRKF34, xRKF43, xRKF45a, xRKF45b, xRKF54a, xRKF54b, xRKF78, xRKF87

Option, specified as `GAUSS = s`

Name of the Runge-Kutta scheme. For details, see the documentation of `numeric::odesolve`.

RememberLast

Modifies the internal remember mechanism: the procedure returned by `numeric::odesolve2` does not remember the results of all previous calls, but only the result of the last call.

Without this option, the procedure returned by `numeric::odesolve2` employs `option remember` to remember the results of all preceding calls. If the function is

called very often (hundreds or thousands of times), the remember table grows large and searching this table for entries close to the current time value may become costly. With `RememberLast`, the procedure returned by `numeric::odesolve2` does not use `option remember` to remember *all* previous results but implements a very simple and inexpensive mechanism to remember only the result of the very last call.

This option is highly recommended when the numerical procedure returned by `numeric::odesolve2` is to be called often (hundreds of thousands of times) with monotonically increasing or decreasing time values. Cf. “Example 4” on page 19-219.

`RelativeError`

Option, specified as `RelativeError = rtol`

Forces internal numerical Runge-Kutta steps to use step sizes with relative local discretization errors below `rtol`. This tolerance must be a positive numerical real value not smaller than $\frac{1}{10^{DIGITS}}$. The default tolerance is `RelativeError = 10^(-DIGITS)`. See the help page of `numeric::odesolve` for further details.

`AbsoluteError`

Option, specified as `AbsoluteError = atol`

Forces internal numerical Runge-Kutta steps to use step sizes with absolute local discretization errors below `atol`. This tolerance must be a non-negative numerical real value. The default tolerance is `AbsoluteError = 10^(-10*DIGITS)`. See the help page of `numeric::odesolve` for further details.

`Stepsize`

Option, specified as `Stepsize = h`

Switches off the internal error control and uses a Runge-Kutta iteration with constant step size `h`. `h` must be a positive real value. See the help page of `numeric::odesolve` for further details.

`MaxStepsize`

Option, specified as `MaxStepsize = hmax`

Restricts adaptive step sizes to values not larger than h_{max}; h_{max} must be a positive numerical value. See the help page of `numeric::odesolve` for further details.

Return Values

Procedure.

numeric::odesolveGeometric

Numerical solution of an ordinary differential equation on a homogeneous manifold

Syntax

```
numeric::odesolveGeometric(f, t0 .. t, Y0, <LieGroupAction = LAMBDA>, <method>, <Relati
numeric::odesolveGeometric(t0 .. t, f, Y0, <LieGroupAction = LAMBDA>, <method>, <Relati
```

Description

`numeric::odesolveGeometric(f, t_0..t, Y_0 )` approximates the solution of $\frac{dY(t)}{dt} = f(t, Y(t))\, Y(t)$, where $f(t, Y(t))$ returns $n \times n$ matrices and $Y \in \mathbb{C}^{n \times m}$.

`numeric::odesolveGeometric` is a "geometrical integrator" for ordinary differential equations on homogeneous manifolds embedded in the space of $n \times m$ matrices.

The call `numeric::odesolveGeometric(f, t_0..t, Y_0 )` returns a numerical approximation of the solution $Y(t)$ of the first order differential equation (dynamical system)

$$\frac{dY(t)}{dt} = f(t, Y(t))\, Y(t),\ Y(t_0) = Y_0$$

with $t, t_0 \in \mathbb{R}$. Here, $Y(t)$ is a curve of $n \times m$ matrices (or vectors in $\mathbb{R}^n$ or $\mathbb{C}^n$). The function f must produce $n \times n$ matrices as return values.

The following geometrical feature is preserved by the numerical solution: If the matrices produced by f lie in some Lie subalgebra g of the $n \times n$ matrices, then, within the numerical working precision, the approximation produced by `numeric::odesolveGeometric` stays on the homogeneous manifold $\{m\, Y_0 \mid m \in G\}$, where G is the matrix Lie group of g.

As an introductory example, consider the ODE $\frac{dY}{dt} = f(t, Y)\, Y$, where Y is a vector in $\mathbb{R}^n$ and `f` produces skew symmetric matrices. The solution lies on the orbit of the orthogonal

group $SO(n)$ generated by the skew symmetric matrices through the initial point $Y_0 \in \mathbb{R}^n$. Here, $SO(n)$ acts on $\mathbb{R}^n$ by standard matrix multiplication. The homogeneous manifold given by the orbit of $SO(n)$ through Y_0 is the sphere

$$\{G\,Y_0 \mid G \in \mathrm{SO}(n)\} = \left\{Y \in \mathbb{R}^n \mid \langle Y, Y\rangle = \langle Y_0, Y_0\rangle\right\}.$$

Using standard numerical schemes, the numerical solution drifts away from this manifold in the course of the integration. The geometrical "Lie group" integrator `numeric::odesolveGeometric`, however, produces a numerical solution that stays on this manifold, preserving the invariants of the group action. In this case, the invariant $\langle Y, Y\rangle$ is preserved numerically. See "Example 1" on page 19-227.

With $Y(t) = G(t)\,Y_0$, the matrix ODE

$$\frac{dG(t)}{dt} = f\left(t, G(t)\,Y_0\right)\,G(t),\ G\left(t_0\right) = 1_{n,n}$$

is solved on the space $\mathbb{C}^{n\times n}$ of the complex $n\times n$ matrices ($1_{n,n}$ is the identity matrix). Following Munthe-Kaas [1], the ansatz $G(t) = e^{u(t)}$ reduces a time step for the ode above to the solution of the matrix ODE

$$\frac{du}{dt} = \mathrm{dexpinv}(u, f) = f - \frac{[u, f]}{2} + \frac{[u, [u, f]]}{12} + \cdots,\ u\left(t_0\right) = 0,$$

where $f = f\left(t, e^{u(t)}\,Y_0\right)$ and $[u, f] = u\,f - f\,u$ is the commutator on the Lie algebra of $n\times n$ matrices. In each step, the ODE for u is solved numerically in a classical way by the Runge-Kutta scheme specified by the parameter `method`. Finally, `numeric::odesolveGeometric` performs the time step $t_0 \to t_0 + h$ by computing $Y\left(t_0 + h\right) = G\left(t_0 + h\right)\,Y_0 = e^{u(h)}\,Y_0$.

If the matrices produced by $f(t, Y)$ lie in a Lie subalgebra g of the $n\times n$ matrices, then the numerical solution u also lies in g. The matrix $G = e^u$ is an element of the corresponding Lie group, and $Y = G\,Y_0$ lies on the orbit of the Lie group through the initial value Y_0. Thus, the geometrical invariants of the homogeneous manifold are preserved in the course of the numerical integration.

The input data t_0 and t must not contain symbolic objects which cannot be converted to floating point values via `float`. Numerical expressions such as e^{π}, $\sqrt{2}$ etc. are accepted.

The initial condition Y_0 defines the space in which the homogeneous manifold containing the solution is embedded.

If Y_0 is a list with n entries or a 1-dimensional array `array(1..n)`, then the solution $Y(t)$ consists of vectors from a submanifold of $\mathbb{R}^n$ or $\mathbb{C}^n$, respectively.

If Y_0 is specified as a 2-dimensional `array(1..n, 1..m)` or as a matrix of the corresponding dimension generated by the function `matrix`, then the solution $Y(t)$ consists of matrices from a submanifold of the space $\mathbb{C}^{n\times m}$ of $n\times m$ matrices.

Internally, 2-dimensional $n\times m$ arrays are used to represent the points on the manifold where $m = 1$ for vectors in $\mathbb{R}^n$ or $\mathbb{C}^n$. It is recommended to specify Y_0 in the form `array(1..n, 1..m)` in order to avoid the overhead of internal conversions.

The "vector field" `f` defining the dynamical system $\frac{dY}{dt} = f(t, Y)\,Y$ must be represented by a procedure with two input parameters: the scalar time t and the matrix or vector Y. Internally, f is called with real floating-point values t and matrices/vectors Y of the same domain type as the initial condition Y_0.

The procedure `f` has to return an $n\times n$ matrix either as an `array(1..n, 1..n)` or as a corresponding matrix object of category `Cat::Matrix` (generated by the function `matrix`).

It is recommended that the procedure returns an array of the type `array(1..n, 1..n)`. This avoids the overhead of internal conversions.

The return value of `f` may contain numerical expressions such as π, $\sqrt{2}$ etc. However, all values must be convertible to real or complex floating point numbers by `float`.

Autonomous systems, where $f(t, Y)$ does not depend on t, must be represented by a procedure with two arguments `t` and `Y`, too.

The optional arguments `method`, `RelativeError = tol`, and `Stepsize = h` determine how the ODE $\frac{du}{dt} = \mathrm{dexpinv}(u, f)$ is solved. They correspond to the methods of the classical ODE solver `numeric::odesolve`.

The numerical precision is controlled by the global variable `DIGITS`: an adaptive control of the step size keeps local relative discretization errors below $\mathrm{tol} = \frac{1}{10^{\mathrm{DIGITS}}}$, unless a different tolerance is specified via the option `RelativeError = tol`. The error control may be switched off by specifying a fixed `Stepsize = h`.

Note: Only local errors are controlled by the adaptive mechanism. No control of the global error is provided!

With `Y := t -> numeric::odesolveGeometric(f, t_0..t, Y_0)`, the numerical solution can be repesented by a MuPAD function: the call `Y(t)` will start the numerical integration from t_0 to t.

Classical integration preserves the geometrical invariants up to the relative precision of the solution whereas the geometrical integrator preserves the invariants independent of *tol* up to the working precision set by `DIGITS`: departure from the homogeneous manifold is a pure roundoff effect.

`numeric::odesolveGeometric` is useful when a tolerance *tol* much largerthan $\frac{1}{10^{\mathrm{DIGITS}}}$ is specified by `RelativeError = tol`. For small tolerances, you may consider to use the classical solver `numeric::odesolve` instead.

Since classical integration is significantly faster, larger values of `DIGITS` and smaller tolerances for the discretization error may be used in `numeric::odesolve`. Depending on the concrete problem, this may lead to better results than produced by `numeric::odesolveGeometric`.

Environment Interactions

The function is sensitive to the environment variable `DIGITS`, which determines the numerical working precision.

Examples

Example 1

We consider the initial value problem

$$\frac{dY}{dt} = \begin{pmatrix} (J_2 - J_3)\, Y_2\, Y_3 \\ (J_3 - J_1)\, Y_3\, Y_1 \\ (J_1 - J_2)\, Y_1\, Y_2 \end{pmatrix}, \quad Y(0) = \begin{pmatrix} 1 \\ 1 \\ 1 \end{pmatrix}$$

for $Y = [Y_1, Y_2, Y_3] \in \mathbb{R}^3$ with fixed parameters $J_1 = \frac{1}{2}$, $J_2 = 1$, $J_3 = 2$. Writing this ODE as

$$\frac{dY}{dt} = \begin{pmatrix} 0 & -J_3\, Y_3 & J_2\, Y_2 \\ J_3\, Y_3 & 0 & -J_1\, Y_1 \\ -J_2\, Y_2 & J_1\, Y_1 & 0 \end{pmatrix} \begin{pmatrix} Y_1 \\ Y_2 \\ Y_3 \end{pmatrix} = f_1(t, Y)\, Y \,,$$

it is clear that the solution is restricted to the orbit of the orthogonal group $SO(3)$ through the initial point (f_1 produces skew symmetric matrices). The invariant of this action is $H_1(Y) = \langle Y, Y \rangle = {Y_1}^2 + {Y_2}^2 + {Y_3}^2$, i.e., the solution is restricted to a sphere. Writing the ODE as

$$\frac{dY}{dt} = \begin{pmatrix} 0 & J_2\, Y_3 & -J_3\, Y_2 \\ -J_1\, Y_3 & 0 & J_3\, Y_1 \\ J_1\, Y_2 & -J_2\, Y_1 & 0 \end{pmatrix} \begin{pmatrix} Y_1 \\ Y_2 \\ Y_3 \end{pmatrix} = f_2(t, Y)\, Y$$

$$= \begin{pmatrix} 0 & Y_3 & -Y_2 \\ -Y_3 & 0 & Y_1 \\ Y_2 & -Y_1 & 0 \end{pmatrix} \begin{pmatrix} J_1 & 0 & 0 \\ 0 & J_2 & 0 \\ 0 & 0 & J_3 \end{pmatrix} \begin{pmatrix} Y_1 \\ Y_2 \\ Y_3 \end{pmatrix},$$

it is clear that the solution is also restricted to the orbit of the "J-orthogonal" group $SO(J, 3)$ through the initial point. This group consists of matrices G satisfying $G^T J G = J$, where $J = diag(J_1, J_2, J_3)$. The invariant of this group action is $H_2(Y) = \langle Y, J Y \rangle = J_1 Y_1^2 + J_2 Y_2^2 + J_3 Y_3^2$, i.e., the solution is restricted to an ellipsoid.

We consider the first representation and compute a numerical solution that is restricted to a sphere:

```
f1 := proc(t, Y) begin
      array(1..3, 1..3, [ [   0    , -J3*Y[3],  J2*Y[2]],
                          [ J3*Y[3],    0    , -J1*Y[1]],
                          [-J2*Y[2],  J1*Y[1],    0    ]])
end_proc:
J1 := 1/2: J2 := 1: J3 := 2:
tol := 10^(-2):
Gsolve:= (f, t0_t, Y0) ->
  numeric::odesolveGeometric(f, t0_t, Y0, RelativeError = tol):

Y(0) := [1.0, 1.0, 1.0];
Y(1) := Gsolve(f1, 0..1, Y(0));
Y(2) := Gsolve(f1, 1..2, Y(1));
Y(3) := Gsolve(f1, 2..3, Y(2));
Y(4) := Gsolve(f1, 3..4, Y(3));
Y(5) := Gsolve(f1, 4..5, Y(4))
```

```
[1.0, 1.0, 1.0]

[-0.1234874253, 1.573899124, 0.7124551935]

[-1.188837997, 0.6164504304, 1.098477621]

[-0.7811791671, -1.258922776, 0.8971468953]
```

$$[0.3530511101, -1.520952843, 0.7497048516]$$

$$[1.281782142, -0.1892246302, 1.149447075]$$

The invariant H_1 is preserved numerically up to the working precision set by `DIGITS`:

```
H1 := Y -> Y[1]^2 + Y[2]^2 + Y[3]^2:
H1(Y(i)) - H1(Y(0)) $ i = 1..5
```

$$3.045480534\,10^{-14}, -2.691596945\,10^{-14}, 4.011374566\,10^{-14}, 3.491859579\,10^{-13},$$

$$2.851746617\,10^{-13}$$

The invariant H_2 is only preserved within the relative precision of the solution set by the option `RelativeError = tol`:

```
H2 := Y -> J1*Y[1]^2 + J2*Y[2]^2 + J3*Y[3]^2:
H2(Y(i)) - H2(Y(0)) $ i = 1..5
```

$$-0.00003216929769, -0.00001480619998, -0.0002478937317, -0.0002651787298,$$
$$-0.0002541517488$$

Now, we solve the ODE using the second representation:

```
f2 := proc(t, Y) begin
      array(1..3, 1..3, [ [   0    ,  J2*Y[3], -J3*Y[2]],
                          [-J1*Y[3],    0    ,  J3*Y[1]],
                          [ J1*Y[2], -J2*Y[1],    0    ]])
end_proc:

Y(0) := [1.0, 1.0, 1.0];
Y(1) := Gsolve(f2, 0..1, Y(0));
Y(2) := Gsolve(f2, 1..2, Y(1));
Y(3) := Gsolve(f2, 2..3, Y(2));
Y(4) := Gsolve(f2, 3..4, Y(3));
Y(5) := Gsolve(f2, 4..5, Y(4))
```

$$[1.0, 1.0, 1.0]$$

$$[-0.1234661822, 1.573904531, 0.7124614294]$$

$$[-1.188842584,\ 0.6165012417,\ 1.098465492]$$

$$[-0.7810696492,\ -1.258800682,\ 0.8973254548]$$

$$[0.3534089311,\ -1.520647212,\ 0.7500610376]$$

$$[1.28178089,\ -0.1880404787,\ 1.149599855]$$

Now, the invariant H_2 is preserved to working precision, whilst H_1 is only preserved to the tolerance specified by `RelativeError = tol`:

```
H2(Y(i)) - H2(Y(0)) $ i = 1..5
```

Example 2

We consider the "Toda lattice equations"

$$\frac{da_i}{dt} = a_i\left(b_i - b_{i+1}\right),\ i \in \{1, \ldots, n-1\},$$

$$\frac{db_i}{dt} = 2\left({a_{i-1}}^2 - a_i^2\right),\ i \in \{1, \ldots, n\}$$

with $a_0 = a_n = 0$. Introducing the tridiagonal $n \times n$ matrices

$$Y = \begin{pmatrix} b_1 & a_1 & & \\ a_1 & \cdots & \cdots & \\ & \cdots & \cdots & a_{n-1} \\ & & a_{n-1} & b_n \end{pmatrix}, f(Y) = \begin{pmatrix} 0 & -a_1 & & \\ a_1 & \cdots & \cdots & \\ & \cdots & \cdots & -a_{n-1} \\ & & a_{n-1} & 0 \end{pmatrix},$$

these equations can be encoded by the matrix ODE $\frac{dY}{dt} = f(Y)\,Y - Y\,f(Y)$. The solution $Y(t)$ is known to be "isospectral", i.e., the eigenvalues of $Y(t)$ do not depend on the time parameter t. As mentioned in the description of the option `LieGroupAction`, the solution of this type of matrix ODE is given by the group action $Y(t) = G(t)\,Y(0)\,G(t)^{-1} = G(t)\,Y(0)\,G(t)^T$, where $G(t)$ are orthogonal matrices (note that $f(Y)$ is skew symmetric). The eigenvalues of the matrices $Y(t)$ are invariants of the group action.

The exact dynamics also preserves the tridiagonal form of the matrices. The numerical dynamics, however, fills in further elements. The following vector field f ignores alle elements outside the central bands:

```
f := proc(t, Y)
local i, r;
begin
  r := array(1..n, 1..n, [[0 $ n] $ n]);
  for i from 1 to n - 1 do
    r[i + 1, i] :=  Y[i, i + 1];
    r[i, i + 1] := -Y[i, i + 1];
  end_for;
  return(r)
end_proc:
```

In the following, the initial value $Y(0)$ is specified by a matrix generated by the function `matrix`. Consequently, both arguments G and Y are passed to the Lie group action `LAMBDA` as corresponding matrices. They can be multiplied by the multiplication operator `*`:

```
LAMBDA:= proc(G, Y)
begin
  G*Y*(G::dom::transpose(G))
end_proc:
```

We define the initial value:

```
n := 3:
Y(0) := matrix(n, n, [1, 1, 1], Banded)
```

$$\begin{pmatrix} 1 & 1 & 0 \\ 1 & 1 & 1 \\ 0 & 1 & 1 \end{pmatrix}$$

Now, the dynamics is integrated from $t = 0$ to $t = 1$:

```
tol := 10^(-4):
Y(1) := numeric::odesolveGeometric(f, 0..1, Y(0),
        LieGroupAction = LAMBDA, RelativeError = tol)
```

$$\begin{pmatrix} -0.256354686 & 0.4591148565 & -1.716329601\ 10^{-14} \\ 0.4591148565 & 1.0 & 0.4591148565 \\ -1.716329601\ 10^{-14} & 0.4591148565 & 2.256354686 \end{pmatrix}$$

The invariants of the dynamics are the eigenvalues of the matrices $Y(t)$. They are preserved numerically:

```
numeric::eigenvalues(Y(0)) = numeric::eigenvalues(Y(1))
```

$$[2.414213562,\ 1.0,\ -0.4142135624] = [2.414213562,\ 1.0,\ -0.4142135624]$$

For comparison, we also solve the Toda lattice equations by classical numerics using `numeric::odesolve`. The system is encoded by a vector $Y = [b_1, \ldots, b_n, a_1, \ldots, a_{n-1}]$ in $\mathbb{R}^{2n-1}$:

```
f := proc(t, Y)
local a, b, i;
begin
  b := [Y[i] $ i = 1..n];
  a := [Y[n + i] $ i = 1..n-1];
  [-2*a[1]^2,                          // = d/dt b[1]
    2*(a[i-1]^2 - a[i]^2) $ i = 2..n-1, // = d/dt b[i]
    2*a[n-1]^2,                        // = d/dt b[n]
    a[i]*(b[i] - b[i+1]) $ i = 1..n-1   // = d/dt a[i]
  ]
end_proc:
```

```
solution := numeric::odesolve(f, 0..1, [1 $ 2*n - 1],
                              RelativeError = tol);
```

$$[-0.2563650696,\ 1.0,\ 2.25636507,\ 0.459099923,\ 0.459099923]$$

The invariants are only preserved up to the precision of the solution determined by the tolerance set via `RelativeError = tol`:

```
Y(1) := array(1..n, 1..n, [[0 $ n] $ n]):
for i from 1 to n do
  Y(1)[i, i] := solution[i];
end_for:
for i from 1 to n-1 do
  Y(1)[i, i + 1] := solution[n + i];
  Y(1)[i + 1, i] := solution[n + i];
end_for:

Y(1)
```

$$\begin{pmatrix} -0.2563650696 & 0.459099923 & 0 \\ 0.459099923 & 1.0 & 0.459099923 \\ 0 & 0.459099923 & 2.25636507 \end{pmatrix}$$

```
numeric::eigenvalues(Y(1))
```

$$[2.414213091,\ 1.0,\ -0.4142130909]$$

Comparing these data with the previously computed eigenvalues of the initial condition $Y(0)$, one sees that the invariants are not preserved numerically to the working precision determined by `DIGITS`.

```
delete f, LAMBDA, n, Y, tol, solution, i:
```

Parameters

`f`

A procedure accepting two parameters `(t, Y)`

t_0

A numerical real value for the initial time

t

A numerical real value (the “time”)

Y_0

The initial condition: a list, a 1-dimensional `array(1..n)`, a 2-dimensional `array(1..n, 1..m)`, or an $n \times m$ `matrix` of category `Cat::Matrix` with numerical entries

Options

LieGroupAction

Option, specified as `LieGroupAction = LAMBDA`

The procedure `LAMBDA = proc(G, Y) ... end_proc` defines the action of the group element `G` (an $n \times n$ matrix) on the point Y on the homogeneous manifold (an $n \times m$ matrix or an n dimensional vector). This procedure must return a corresponding point (a matrix or a vector).

The default action is the usual matrix multiplication $(G, Y) \to G\,Y$.

With this option, the default group action `LAMBDA`: $(G, Y) \to G\,Y$ of the $n \times n$ matrices G acting on the $n \times m$ matrices or n dimensional vectors `Y` by left multiplication may be replaced by other group actions.

As a group action, the procedure `LAMBDA` must satisfy $LAMBDA(1_{n,n}, Y) = Y$ and

$$\mathrm{LAMBDA}(G_2, \mathrm{LAMBDA}(G_1, Y)) = \mathrm{LAMBDA}(G_2\,G_1, Y)$$

`numeric::odesolveGeometric` computes the solution of the matrix ODE

$$\frac{dG(t)}{dt} = f(t, \mathrm{LAMBDA}(G(t), Y_0))\,G(t),\ G(t_0) = 1_{n,n}$$

On the space $\mathbb{C}^{n \times n}$ of the $n \times n$ matrices and returns $Y(t) = LAMBDA(G(t), Y_0)$.

For the standard group action *LAMBDA*(*G*, *Y*) = *G Y*, this is the solution of the ODE $\frac{dY}{dt} = f(t, Y)\, Y$.

For homogeneous manifolds embedded in the *n*×*n* matrices, the group action *LAMBDA*(*G*, *Y*) = $G\, Y\, G^{-1}$ may be considered. For this action, the curve *Y*(*t*) = *LAMBDA*(*G*(*t*), Y_0) returned by `numeric::odesolveGeometric` is the solution of the ODE $\frac{dY}{dt} = f(t, Y)\, Y - Y\, f(t, Y)$. Cf. "Example 2" on page 19-230.

`LAMBDA(G, Y)` is called with *n*×*m* matrices or *n* dimensional vectors `Y` of the same domain type as the initial condition Y_0. If Y_0 is a matrix generated by the function `matrix`, then also the *n*×*n* matrix *G* is passed to `LAMBDA` as such a matrix object. In all other cases, *G* is passed as a 2-dimensional `array(1..n, 1..n)`.

The procedure `LAMBDA` should return a 2-dimensional `array(1..n, 1..m)` or a corresponding matrix of category `Cat::Matrix`.

If the initial condition Y_0 is specified by a list or a 1-dimensional `array(1..n)`, `LAMBDA` may also return a corresponding list or array.

Internally, the return value of `LAMBDA` is converted to a 2-dimensional `array(1..n, 1..m)` where *m* = 1 if a list or a 1-dimensional array is returned.

It is recommended that `LAMBDA` returns a 2-dimensional `array(1..n, 1..m)` in order to avoid the overhead of internal conversions.

`RelativeError`

Option, specified as `RelativeError = tol`

Forces internal numerical Runge-Kutta steps to use step sizes with local discretization errors below `tol`. This tolerance must be a numerical real value $\geq \frac{1}{10^{\mathrm{DIGITS}}}$. The default tolerance is $\frac{1}{10^{\mathrm{DIGITS}}}$.

The internal control mechanism estimates the local relative discretization error of a Runge-Kutta step and adjusts the step size adaptively to keep this error below `tol`.

The default setting of $\mathrm{tol} = \frac{1}{10^{\mathrm{DIGITS}}}$ ensures that the local discretization errors are of the same order of magnitude as numerical roundoff.

Usually there is no need to use this option to change this setting. However, occasionally the numerical evaluation of the Runge-Kutta steps may be ill-conditioned or step sizes are so small that the time parameter cannot be incremented by the step size within working precision. In such a case, this option may be used to bound the local discretization error by *tol* and use a higher working precision given by `DIGITS`.

Only real numerical values $\text{tol} \geq \frac{1}{10^{\text{DIGITS}}}$ are accepted.

Note: Usually, the global error of the numeric approximation returned by `numeric::odesolveGeometric` is larger than the local errors bounded by `tol`. Although the result is displayed with `DIGITS` decimal places, one should not expect that all of them are correct. The relative precision of the final result is `tol` at best!

`Stepsize`

Option, specified as `Stepsize = h`

Switches off the internal error control and uses a Runge-Kutta iteration with constant step size `h`. `h` must be a numerical real value.

By default, `numeric::odesolveGeometric` uses an adaptive step size control mechanism in the numerical iteration. The option `Stepsize = h` switches off this adaptive mechanism and uses the Runge-Kutta method specified by `method` (or the default method `DOPRI78`) with constant step size `h`.

A final step with smaller step size is used to match the end t of the integration interval $t_0 .. t$, if $\frac{t-t_0}{h}$ is not an integer.

Note: With this option, there is no automatic error control! Depending on the problem and on the order of the method, the result may be a poor numerical approximation of the exact solution.

There is usually no need to invoke this option. However, occasionally the builtin adaptive error control mechanism may fail when integrating close to a singularity. In such a case, this option may be used to customize a control mechanism for the global error by using different step sizes and investigating the convergence of the corresponding results.

Alldata

Option, specified as `Alldata = n`

With this option, `numeric::odesolveGeometric` returns a list of numerical mesh points $[[t_0, Y_0], [t_1, Y_1], \ldots, [t, Y(t)]]$ generated by the internal Runge-Kutta iteration.

The integer n controls the size of the output list. For $n = 1$, all internal mesh points are returned. This case may also be invoked by entering the simplified option `Alldata`, which is equivalent to `Alldata = 1`. For $n > 1$, only each n-th mesh point is stored in the list. The list always contains the initial point $[t_0, Y_0]$ and the final point $[t, Y(t)]$. For $n \leq 0$, only the data $[[t_0, Y_0], [t, Y(t)]]$ are returned.

The output list may be useful to inspect the internal numerical process. Also further graphical processing of the mesh data may be useful.

Return Values

The solution $Y(t)$ is returned as a list or as an array of floating-point values. The type of the result matrix/vector coincides with the type of the input matrix/vector Y_0.

With the option `Alldata`, a list of mesh data is returned.

numeric::ode2vectorfield

Convert an ode system to vectorfield notation

Syntax

```
numeric::ode2vectorfield(IVP, fields)
```

Description

`numeric::ode2vectorfield` converts a system of ordinary differential equations of arbitrary order to a vector field representation suitable for the numerical ODE solver `numeric::odesolve2`.

`numeric::ode2vectorfield` and `numeric::odeToVectorField` are equivalent.

`numeric::ode2vectorfield` is a utility function to generate input parameters for the numerical ODE solver `numeric::odesolve2`. This solver requires a procedure representing the vectorfield $f(t, Y)$ of a first order system of differential equations (dynamic system) $\frac{dY}{dt} = f(t, Y)$ and initial data $Y_0 = Y(t_0)$. Given an initial value problem `IVP` consisting of (possibly higher order) differential expressions together with initial conditions, `numeric::ode2vectorfield` converts the higher order equations to an equivalent system of first order ODEs and returns the input parameters for `numeric::odesolve2`.

Higher-order differential equations can always be represented as an equivalent dynamic system $\frac{dY}{dt} = f(t, Y)$ with some vector Y. E.g., the n-th order equation

$$y^{(n)} = g\left(t, y, y', \ldots, y^{(n-1)}\right)$$

may be written as the first order system

$$\frac{dY}{dt} = \left[y', \ldots, y^{(n-1)}, g\left(t, y, \ldots, y^{(n-1)}\right)\right]$$

for the vector $Y = \left[y, y', \ldots, y^{(n-1)}\right]$.

The input list `fields` correponds to the vector *Y*. It must be a *complete* specification of all functions and their derivatives through but *not including the highest derivates* of the unknown functions. E.g., for the second order differential equation $y''(t) = y(t)$, the appropriate list of unknown fields is $[y(t), y'(t)]$. The differential equations $y''(t) = z(t)$, $z'(t) = y(t)$ are of second order in *y* and of first order in *z*. Hence, the appropriate list of unknown fields is `[y(t), y'(t), z(t)]`.

The ordering of the fields in `list` determines the ordering of the components of the list that the numerical solver produces as the solution vector. Cf. “Example 2” on page 19-240.

The differential equations must be linear in the highest derivatives of the unknown functions involved. E.g., the ODE $y'(t)^2 = y(t)$ is not admitted. However, equations such as $y_2(t)\, y_1'(t) = y_1(t)$, $y_1(t)\, y_2'(t) = y_2(t)$ are accepted and converted to $y_1'(t) = \frac{y_1(t)}{y_2(t)}$, $y_2'(t) = \frac{y_2(t)}{y_1(t)}$.

A *complete* specification of initial conditions must be contained in `IVP`: for each component in `list`, an initial value must be provided. The initial conditions may be specified by linear equations which will be solved for the initial values of the unknown fields automatically. E.g., for `fields = [y(t), y'(t), z(t)]`, initial conditions may be specified explicitly by $y(t_0) = 1$, `y'(t_0) = 2`, $z(t_0) = 3$, say, or via linear equations such as `y(t_0) + z(t_0) = y'(t_0)`, $y(t_0) = z(t_0)$, $z(t_0) = 2\, y(t_0)$. Cf. “Example 3” on page 19-241.

The differential equations, the initial ‘time’ t_0, and the initial conditions may involve symbolic parameters. However, such parameters must evaluate to numerical objects, when the sequence returned by `numeric::ode2vectorfield` is passed to the numerical solver.

The vectorfield procedure `f` and the initial values Y_0 returned by `numeric::ode2vectorfield` can also be used by the functions `numeric::odesolve`, `plot::Ode2d`, `plot::Ode3d`. Cf. “Example 3” on page 19-241.

Examples

Example 1

We consider the initial value problem

$$y'(t) = t\sin(y(t)),\ y(0) = 1$$

.

The solver `numeric::odesolve2` requires the procedure `f:`$(t, Y) \to t\sin(Y_1)$ for the 1-dimensional vector $Y = [y(t)]$ specified by `fields`. The utility `numeric::ode2vectorfield` accepts a more convenient representation via arithmetical expressions:

```
IVP := {y'(t) = t*sin(y(t)), y(t0) = y0}:
fields := [y(t)]:
IVP := numeric::ode2vectorfield(IVP, fields)
```

```
proc(t, Y) ... end, t0, [y0]
```

This sequence may be passed to the numerical solver which returns a procedure representing the numerical solution:

```
t0 := 0: y0 := 1:
Y := numeric::odesolve2(IVP)
```

```
proc Y(t) ... end
```

Calling the numerical solution `Y` invokes the numerical integration from the intial 'time' $t_0 = 0$ to the 'time' specified in the call to `Y`:

```
Y(0), Y(1), Y(2), Y(3)
```

```
[1.0], [1.466404006], [2.655911348], [3.100928494]
```

```
delete IVP, fields, Y:
```

Example 2

We consider the second order initial value problem

$$y''(t) = t\sin(y(t)),\ y(0) = 1,\ y'(0) = 0$$

The corresponding vectorfield representation involves the vector $Y = [y(t), y'(t)]$ specified by `fields`:

```
IVP := {y''(t) = t*sin(y(t)), y(0) = 1, y'(0) = 0}:
fields := [y(t), y'(t)]:
numeric::ode2vectorfield(IVP, fields)
```

$$\text{proc(t, Y) ... end, 0, [1, 0]}$$

This sequence is accepted by `numeric::odesolve2`. The numerical solution `Y` returns lists representing the components of the vector specified by `fields`:

```
Y := numeric::odesolve2(%):
Y(5)
```

$$[1.916536393,\ -0.8765542819]$$

With a reordering of the unknown fields, the numerical solver returns the solution vector with rearranged components:

```
fields := [y'(t), y(t)]:
Y := numeric::odesolve2(numeric::ode2vectorfield(IVP, fields)):
Y(5)
```

$$[-0.8765542819,\ 1.916536393]$$

```
delete IVP, fields, Y:
```

Example 3

The following IVP involves the unknown fields $u(t)$, $v(t)$, $w(t)$. Since it is of second order in u, of first order in v and of third order in w, the list of unknowns `[y(t), y'(t), v(t), w(t), w'(t), w''(t)]` is appropriate:

```
IVP := {u''(t) - u(t)*v'(t) = exp(-t)*v'(t), v'(t) = w''(t),
        u'(t)*w'''(t) = t + u''(t),
```

```
        u(PI) = 3, u'(PI) = 1,
        v(PI) = 0,
        w(PI) = w'(PI), w'(PI) = 2 - w(PI), w''(PI) = 3*w(PI)}:
fields := [u(t), u'(t), v(t), w(t), w'(t), w''(t)]:
ivp := numeric::ode2vectorfield(IVP, fields)
```

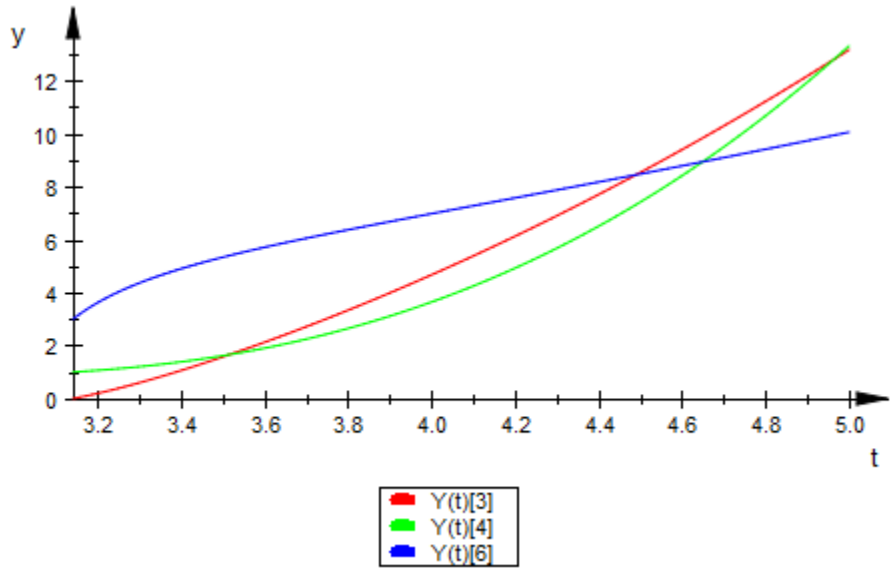
$$\text{proc(t, Y) ... end}, \pi, [3, 1, 0, 1, 1, 3]$$

```
Y := numeric::odesolve2(ivp):
Y(5)
```

$$[195.9501263, 604.3872242, 13.15053015, 13.29454726, 14.15053015, 10.04763196]$$

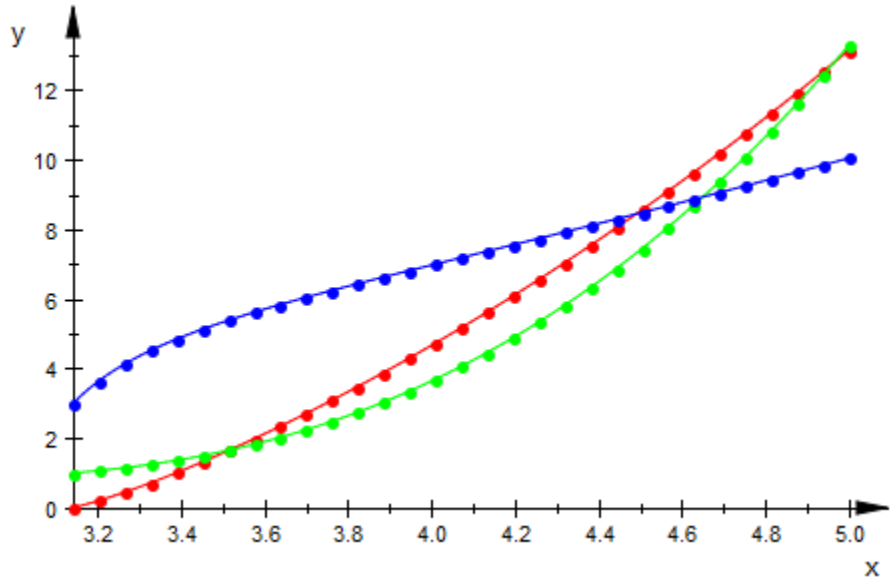
We plot the components v, w, and w'' of the solution vector:

```
plotfunc2d(Y(t)[3], Y(t)[4], Y(t)[6], t = PI .. 5,
           Colors = [RGB::Red, RGB::Green, RGB::Blue]):
```



Alternatively, we use the vectorfield procedure `ivp[1]` and the initial conditions `ivp[3]` as input parameters for `plot::Ode2d`:

```
plot(plot::Ode2d([PI + i*(5 - PI)/30 $ i = 0..30],
                 ivp[1], ivp[3],
                 [(t, Y) -> [t, Y[3]], Color = RGB::Red],
                 [(t, Y) -> [t, Y[4]], Color = RGB::Green],
                 [(t, Y) -> [t, Y[6]], Color = RGB::Blue])):
```



```
delete IVP, fields, ivp, Y:
```

Parameters

`IVP`

The initial value problem: a list or a set of equations involving univariate function calls $y_1(t)$, $y_2(t)$ etc. and derivates $y_1'(t)$, $y_1''(t)$, ..., $y_2'(t)$, $y_2''(t)$ etc. The differential equations must be quasi-linear: the highest derivative of each of the dependent functions $y_1(t)$, $y_2(t)$ etc. must enter the equations linearly. `IVP` must also contain corresponding initial conditions specified by linear equations in the expressions $y_1(t_0)$, $y_1'(t_0)$, ..., $y_2(t_0)$, $y_2'(t_0)$ etc. Alternatively, arithmetical expressions may be specified which are interpreted as equations with vanishing right hand side.

`fields`

The vector of the dynamical system equivalent to `IVP`: a list of symbolic function calls such as `[y_1(t), y_1'(t), dots, y_2(t), y_2'(t), dots]` representing the unknown fields to be solved for.

Return Values

Sequence `f, t0, Y0`. These data represent the dynamical system $\frac{dY}{dt} = f(t, Y)$ with the initial condition $Y(t_0) = Y_0$ equivalent to `IVP`. The vectorfield `f`: $(t, Y) \to f(t, Y)$ is a procedure, `t0` is a numerical expression representing the initial 'time', and `Y0` is a list of numerical expressions representing the components of the initial vector Y_0.

numeric::odeToVectorField

Convert an ode system to vectorfield notation

Syntax

```
numeric::odeToVectorField(IVP, fields)
```

Description

`numeric::odeToVectorField` converts a system of ordinary differential equations of arbitrary order to a vector field representation suitable for the numerical ODE solver `numeric::odesolve2`.

`numeric::odeToVectorField` and `numeric::ode2vectorfield` are equivalent.

`numeric::odeToVectorField` is a utility function to generate input parameters for the numerical ODE solver `numeric::odesolve2`. This solver requires a procedure representing the vectorfield $f(t, Y)$ of a first order system of differential equations (dynamic system) $\frac{dY}{dt} = f(t, Y)$ and initial data $Y_0 = Y(t_0)$. Given an initial value problem `IVP` consisting of (possibly higher order) differential expressions together with initial conditions, `numeric::odeToVectorField` converts the higher order equations to an equivalent system of first order ODEs and returns the input parameters for `numeric::odesolve2`.

Higher-order differential equations can always be represented as an equivalent dynamic system $\frac{dY}{dt} = f(t, Y)$ with some vector Y. E.g., the n-th order equation

$$y^{(n)} = g\left(t, y, y', \ldots, y^{(n-1)}\right)$$

may be written as the first order system

$$\frac{dY}{dt} = \left[y', \ldots, y^{(n-1)}, g\left(t, y, \ldots, y^{(n-1)}\right)\right]$$

for the vector $Y = \left[y, y', \ldots, y^{(n-1)}\right]$.

The input list `fields` correponds to the vector *Y*. It must be a *complete* specification of all functions and their derivatives through but *not including the highest derivates* of the unknown functions. E.g., for the second order differential equation $y''(t) = y(t)$, the appropriate list of unknown fields is $[y(t), y'(t)]$. The differential equations $y''(t) = z(t)$, $z'(t) = y(t)$ are of second order in *y* and of first order in *z*. Hence, the appropriate list of unknown fields is `[y(t), y'(t), z(t)]`.

The ordering of the fields in `list` determines the ordering of the components of the list that the numerical solver produces as the solution vector. Cf. “Example 2” on page 19-247.

The differential equations must be linear in the highest derivatives of the unknown functions involved. E.g., the ODE $y'(t)^2 = y(t)$ is not admitted. However, equations such as $y_2(t)\, y_1'(t) = y_1(t)$, $y_1(t)\, y_2'(t) = y_2(t)$ are accepted and converted to $y_1'(t) = \frac{y_1(t)}{y_2(t)}$, $y_2'(t) = \frac{y_2(t)}{y_1(t)}$.

A *complete* specification of initial conditions must be contained in `IVP`: for each component in `list`, an initial value must be provided. The initial conditions may be specified by linear equations which will be solved for the initial values of the unknown fields automatically. E.g., for `fields = [y(t), y'(t), z(t)]`, initial conditions may be specified explicitly by $y(t_0) = 1$, `y'(t_0) = 2`, $z(t_0) = 3$, say, or via linear equations such as `y(t_0) + z(t_0) = y'(t_0)`, $y(t_0) = z(t_0)$, $z(t_0) = 2\, y(t_0)$. Cf. “Example 3” on page 19-248.

The differential equations, the initial ‘time’ t_0, and the initial conditions may involve symbolic parameters. However, such parameters must evaluate to numerical objects, when the sequence returned by `numeric::odeToVectorField` is passed to the numerical solver.

The vectorfield procedure `f` and the initial values Y_0 returned by `numeric::odeToVectorField` can also be used by the functions `numeric::odesolve`, `plot::Ode2d`, `plot::Ode3d`. Cf. “Example 3” on page 19-248.

Examples

Example 1

We consider the initial value problem

$$y'(t) = t\sin(y(t)),\ y(0) = 1$$

.

The solver `numeric::odesolve2` requires the procedure `f:`$(t, Y) \to t\sin(Y_1)$ for the 1-dimensional vector $Y = [y(t)]$ specified by `fields`. The utility `numeric::ode2vectorfield` accepts a more convenient representation via arithmetical expressions:

```
IVP := {y'(t) = t*sin(y(t)), y(t0) = y0}:
fields := [y(t)]:
IVP := numeric::ode2vectorfield(IVP, fields)
```

```
proc(t, Y) ... end, t0, [y0]
```

This sequence may be passed to the numerical solver which returns a procedure representing the numerical solution:

```
t0 := 0: y0 := 1:
Y := numeric::odesolve2(IVP)
```

```
proc Y(t) ... end
```

Calling the numerical solution `Y` invokes the numerical integration from the intial 'time' $t_0 = 0$ to the 'time' specified in the call to `Y`:

```
Y(0), Y(1), Y(2), Y(3)
```

```
[1.0], [1.466404006], [2.655911348], [3.100928494]
```

```
delete IVP, fields, Y:
```

Example 2

We consider the second order initial value problem

$$y''(t) = t\sin(y(t)),\ y(0) = 1,\ y'(0) = 0$$

The corresponding vectorfield representation involves the vector $Y = [y(t), y'(t)]$ specified by `fields`:

```
IVP := {y''(t) = t*sin(y(t)), y(0) = 1, y'(0) = 0}:
fields := [y(t), y'(t)]:
numeric::ode2vectorfield(IVP, fields)
```

```
proc(t, Y) ... end, 0, [1, 0]
```

This sequence is accepted by `numeric::odesolve2`. The numerical solution `Y` returns lists representing the components of the vector specified by `fields`:

```
Y := numeric::odesolve2(%):
Y(5)
```

```
[1.916536393, -0.8765542819]
```

With a reordering of the unknown fields, the numerical solver returns the solution vector with rearranged components:

```
fields := [y'(t), y(t)]:
Y := numeric::odesolve2(numeric::ode2vectorfield(IVP, fields)):
Y(5)
```

```
[-0.8765542819, 1.916536393]
```

```
delete IVP, fields, Y:
```

Example 3

The following IVP involves the unknown fields $u(t)$, $v(t)$, $w(t)$. Since it is of second order in u, of first order in v and of third order in w, the list of unknowns `[y(t), y'(t), v(t), w(t), w'(t), w''(t)]` is appropriate:

```
IVP := {u''(t) - u(t)*v'(t) = exp(-t)*v'(t), v'(t) = w''(t),
        u'(t)*w'''(t) = t + u''(t),
```

```
        u(PI) = 3, u'(PI) = 1,
        v(PI) = 0,
        w(PI) = w'(PI), w'(PI) = 2 - w(PI), w''(PI) = 3*w(PI)}:
fields := [u(t), u'(t), v(t), w(t), w'(t), w''(t)]:
ivp := numeric::ode2vectorfield(IVP, fields)
```

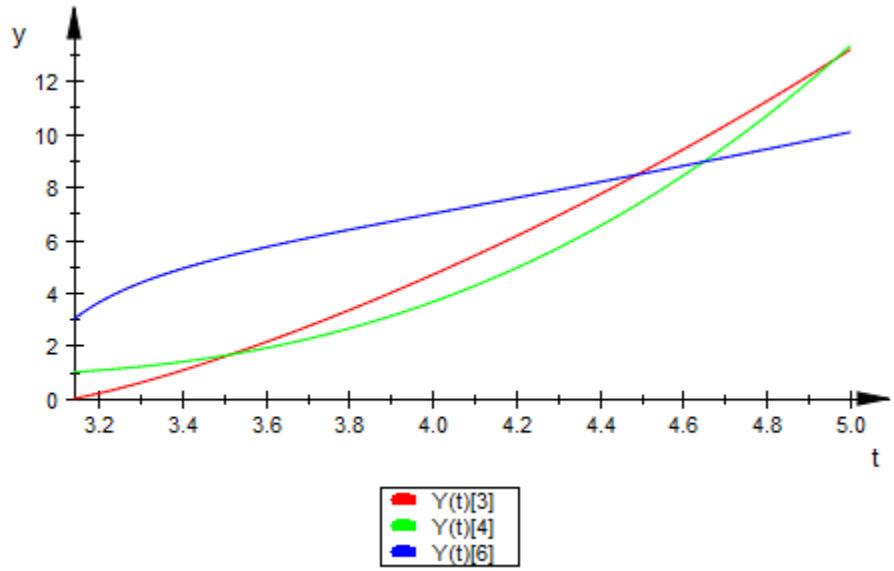
$$\text{proc(t, Y) ... end}, \pi, [3, 1, 0, 1, 1, 3]$$

```
Y := numeric::odesolve2(ivp):
Y(5)
```

$$[195.9501263, 604.3872242, 13.15053015, 13.29454726, 14.15053015, 10.04763196]$$

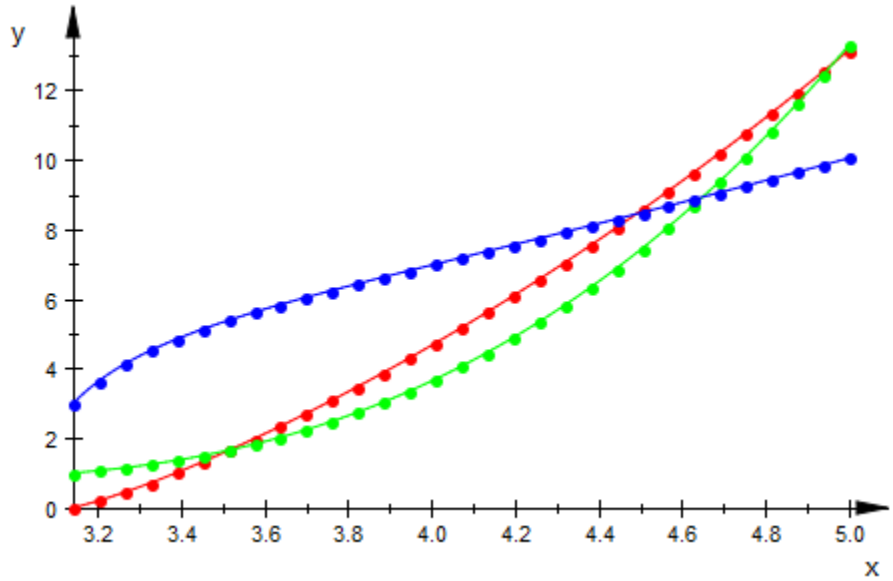
We plot the components v, w, and w''' of the solution vector:

```
plotfunc2d(Y(t)[3], Y(t)[4], Y(t)[6], t = PI .. 5,
           Colors = [RGB::Red, RGB::Green, RGB::Blue]):
```



Alternatively, we use the vectorfield procedure `ivp[1]` and the initial conditions `ivp[3]` as input parameters for `plot::Ode2d`:

```
plot(plot::Ode2d([PI + i*(5 - PI)/30 $ i = 0..30],
                 ivp[1], ivp[3],
                 [(t, Y) -> [t, Y[3]], Color = RGB::Red],
                 [(t, Y) -> [t, Y[4]], Color = RGB::Green],
                 [(t, Y) -> [t, Y[6]], Color = RGB::Blue])):
```



```
delete IVP, fields, ivp, Y:
```

Parameters

IVP

The initial value problem: a list or a set of equations involving univariate function calls $y_1(t)$, $y_2(t)$ etc. and derivates $y_1'(t)$, $y_1''(t)$, ..., $y_2'(t)$, $y_2''(t)$ etc. The differential equations must be quasi-linear: the highest derivative of each of the dependent functions $y_1(t)$, $y_2(t)$ etc. must enter the equations linearly. `IVP` must also contain corresponding initial conditions specified by linear equations in the expressions $y_1(t_0)$, $y_1'(t_0)$, ..., $y_2(t_0)$, $y_2'(t_0)$ etc. Alternatively, arithmetical expressions may be specified which are interpreted as equations with vanishing right hand side.

`fields`

The vector of the dynamical system equivalent to `IVP`: a list of symbolic function calls such as `[y_1(t), y_1'(t), dots, y_2(t), y_2'(t), dots]` representing the unknown fields to be solved for.

Return Values

Sequence `f, t0, Y0`. These data represent the dynamical system $\frac{dY}{dt} = f(t, Y)$ with the initial condition $Y(t_0) = Y_0$ equivalent to `IVP`. The vectorfield `f`: $(t, Y) \to f(t, Y)$ is a procedure, `t0` is a numerical expression representing the initial 'time', and `Y0` is a list of numerical expressions representing the components of the initial vector Y_0.

- "Solve Equations Numerically"

numeric::polyrootbound

Bound for the roots of a univariate polynomial

Syntax

```
numeric::polyrootbound(p)
```

Description

`numeric::polyrootbound(p)` returns a bound b, such that all real and complex roots z of the univariate polynomial p satisfy $|z| \le b$.

The coefficients of `p` may be real or complex numbers. Also exact numerical coefficients such as π, $\sqrt{2}$ etc. are accepted if they can be converted to floats.

For non-zero constant polynomials, `numeric::polyrootbound` returns `infinity`.

For monomials $p(x) = c_n x^n$ with $n > 0$, `numeric::polyrootbound` returns `0.0`.

Consider the polynomial $p(z) = z^n + c_{n-1} z^{n-1} + \cdots + c_0$. If $max(|c_{n-1}|, \ldots, |c_0|) > 0$, the polynomial

$$z^n - |c_{n-1}| z^{n-1} - \cdots - |c_0|$$

has a single real root $b > 0$ which is an upper bound for the absolute values of all real and complex roots of p. The bound returned by `numeric::polyrootbound(p)` approximates b to about 3 leading decimal digits.

Environment Interactions

The function is sensitive to the environment variable `DIGITS`, which determines the numerical working precision.

Examples

Example 1

Both polynomial expressions as well as DOM_POLY objects may be used to specify the polynomial:

```
p := x^3 + PI*x - sqrt(2): numeric::polyrootbound(p)
```

$$1.966316026$$

```
p := poly(p, [x]): numeric::polyrootbound(p)
```

$$1.966316026$$

The absolute values of all real and complex roots of p are bounded by this number:

```
numeric::polyroots(p)
```

$$[0.4256164232,\ -0.2128082116 + 1.810374176\,i,\ -0.2128082116 - 1.810374176\,i]$$

```
max(abs(z) $ z in %)
```

$$1.822838993$$

```
delete p:
```

Parameters

p

A univariate polynomial expression or a univariate polynomial of domain type DOM_POLY.

Return Values

Nonnegative real floating-point number or `infinity`.

MuPAD Functions

`numeric::fsolve` | `numeric::polyroots` | `numeric::polysysroots` | `numeric::realroot` | `numeric::realroots` | `polylib::realroots` | `RootOf` | `solve`

numeric::polyroots

Numerical roots of a univariate polynomial

Syntax

```
numeric::polyroots(eqs, <FixedPrecision>, <SquareFree>, <Factor>, <NoWarning>)
```

Description

`numeric::polyroots(eqs)` returns numerical approximations of all real and complex roots of the univariate polynomials `eqs`.

The coefficients may be real or complex numbers. Also symbolic coefficients are accepted if they can be converted to floats.

The trivial polynomial *eqs* = 0 results in an error message. The empty list is returned for constant polynomials *eqs* ≠ 0.

Multiple roots are listed according to their multiplicities, i.e., the length of the root list coincides with the degree of *eqs*.

The root list is sorted by `numeric::sort`.

Up to roundoff effects, the numerical roots should be accurate to `DIGITS` significant digits, unless the option `FixedPrecision` is used.

All floating-point entries in `eqs` are internally approximated by rational numbers: `numeric::polyroots(eqs)` computes the roots of `numeric::rationalize(eqs, Minimize)`.

For polynomial expressions in factored form, the numerical search is applied to each factor separately.

It is recommended to use `numeric::realroots` or `polylib::realroots` if `eqs` is a real polynomial and only real roots are of interest.

Environment Interactions

The function is sensitive to the environment variable `DIGITS`, which determines the numerical working precision.

Examples

Example 1

Both polynomial expressions as well as `DOM_POLY` objects may be used to specify the polynomial:

```
numeric::polyroots(x^3 - 3*x - sqrt(2))
```

$$[1.931851653,\ -0.5176380902,\ -1.414213562]$$

```
numeric::polyroots(PI*z^4 + I*z + 0.1)
```

$$[0.5936837297 - 0.3729248918\ i,\ 0.6455316068\ i,\ 0.1003181767\ i,\ -0.5936837297 - 0.3729248918\ i]$$

```
numeric::polyroots(poly(x^5 - x^2, [x]))
```

$$[1.0,\ 0.0,\ 0.0,\ -0.5 + 0.8660254038\ i,\ -0.5 - 0.8660254038\ i]$$

Example 2

The following polynomial has exact coefficients:

```
p := poly((x - 1)*(x - PI)^3, [x]):
numeric::polyroots(p)
```

$$[3.141592654,\ 3.141592654,\ 3.141592654,\ 1.0]$$

Note that roundoff errors in the coefficients of `eqs` have a dramatic effect on multiple roots:

```
p := poly((x - 1.0)*(x - float(PI))^3, [x]):
numeric::polyroots(p)
```

$$[3.144422386,\ 3.140177788 - 0.00244957836\,i,\ 3.140177788 + 0.00244957836\,i,\ 0.9999999995]$$

These are the roots of the following rationalized polynomial:

```
numeric::rationalize(p, Minimize)
```

$$\mathrm{poly}\left(x^4 - \frac{461286\,x^3}{44249} + \frac{176627\,x^2}{4525} - \frac{2515405\,x}{41498} + \frac{1837649}{59267},\ [x]\right)$$

```
delete p:
```

Example 3

The multiple root $\frac{i}{3}$ of the following polynomial can only be computed with restricted precision by fixed precision arithmetic:

```
p := poly((x^2 - 6*x +8)*(x - I/3)^5, [x]):
numeric::polyroots(p, FixedPrecision)
```

$$[4.0,\ 2.0,\ 0.006617926628 + 0.330782186\,i,\ 0.004459639998 + 0.3388505458\,i,\ -0.0003838250804 + 0.3262671926\,i,\ -0.003866386513 + 0.3392634968\,i,\ -0.006827355033 + 0.3315032456\,i]$$

Without the option `FixedPrecision`, the working precision is increased internally to compute better approximations:

```
numeric::polyroots(p)
```

$$[4.0,\ 2.0,\ 0.3333333333\,i,\ 0.3333333333\,i,\ 0.3333333333\,i,\ 0.3333333333\,i,\ 0.3333333333\,i]$$

```
delete p:
```

Example 4

The following polynomial has badly separated roots. `numeric::polyroots` does not manage to separate them properly:

```
p := poly(_mult((x - 1 - i/10^9) $ i=0..5), [x]):
numeric::polyroots(p)
```

```
[1.000000003, 1.000000003, 1.000000003, 1.000000003, 1.000000003, 0.9999999987]
```

One can preprocess the polynomial by a symbolic factorization:

```
numeric::polyroots(p, Factor)
```

```
[1.000000005, 1.000000004, 1.000000003, 1.000000002, 1.000000001, 1.0]
```

Alternatively, one can increase the working precision to separate the roots:

```
DIGITS := 20:
numeric::polyroots(p)
```

```
[1.000000005, 1.000000004, 1.000000003, 1.000000002, 1.000000001, 1.0]
```

```
delete p, DIGITS:
```

Parameters

eqs

A univariate polynomial expression or a univariate polynomial of domain type `DOM_POLY`. The function also accepts a list, set, `array`, or `matrix` (`Cat::Matrix`) of polynomial expressions.

Options

FixedPrecision

This option provides the fastest way to obtain approximations of the roots by a numerical search with a fixed internal precision of 2 *DIGITS* decimal places.

Note that badly isolated roots or multiple roots will usually not be approximated to `DIGITS` decimals when using this option. The problem of finding such roots is

numerically ill-conditioned, i.e., such roots cannot be found to full precision with fixed precision arithmetic. Typically, a q-fold root will be approximated only to about $\frac{2\,\mathrm{DIGITS}}{q}$ decimal places. Cf. “Example 3” on page 19-257.

Without this option, `numeric::polyroots` internally increases the working precision until all roots are found to `DIGITS` decimal places.

`SquareFree`

With this option, a symbolic square free factorization is computed via `polylib::sqrfree(eqs)`. The numerical root finding algorithm is then applied to each square free factor.

This option is recommended, when `p` is known to have multiple roots. Such roots force `numeric::polyroots` to increase the working precision internally increasing the costs of the numerical search. A square free factorization reduces the multiplicity of each root to one, speeding up the final numerical search.

For polynomials with real rational coefficients, a square free factorization is always used, i.e., this option does not have any effect for such polynomials. For all other types of coefficients, a square free factorization may be costly and must be requested by this option.

Multiple roots of `eqs` can be successfully dealt with by this option. However, for badly separated distinct roots the square free factorization will not improve the performance of the numerical search.

`Factor`

With this option, a symbolic factorizations of `eqs` via `factor` are computed. The numerical root finding algorithm is then applied to each factor.

This option is useful, when `eqs` can be successfully factorized (e.g., when each expression from `eqs` has multiple roots). The numerical search on the factors is much more efficient than the search on the original polynomial. On the other hand, symbolic factorization of `eqs` may be costly.

`NoWarning`

Suppresses warnings

Return Values

List of numerical roots.

Algorithms

The numerical root finding algorithm implemented by `numeric::polyroots` is Laguerre's method: W.H. Press, B.P. Flannery, S.A. Teukolsky and W.T. Vetterling: *Numerical Recipes in C*, Cambridge University Press, 1988.

numeric::polysysroots

Numerical roots of a system of polynomial equations

Syntax

```
numeric::polysysroots(eqs, <NoWarning>)
```

```
numeric::polysysroots(eqs, vars, <NoWarning>)
```

Description

`numeric::polysysroots(eqs, ...)` returns numerical approximations of all real and complex roots of the polynomial system of equations `eqs`.

The coefficients of the polynomials may contain symbolic parameters.

If no unknowns are specified by `vars`, then`numeric::indets(eqs)` is used in place of `vars`.

In most cases, the solution is returned as a set of lists of solved equations of the form

$$[x_1 = \text{value}_1, x_2 = \text{value}_2, \ldots],$$

where x_1, x_2, … are the unknowns. These simplified equations should be regarded as constraints on the unknowns. E.g., if an unknown x_1, say, does not turn up in the form x_1 = … in the solution, then there is no constraint on this unknown and it is an arbitrary parameter. This holds true in general for all unknowns that do not turn up on the left hand side of the solved equations. Cf. “Example 2” on page 19-263.

If no explicit solutions can be computed, expressions of the form $\begin{pmatrix} x_1 \\ x_2 \\ \ldots \end{pmatrix} \in S$ may be returned, where S is the solution set.

The ordering of the unknowns in `vars` determines the ordering of the solved equations. If a *set*`vars` is used, then an internal ordering is used.

Note: If the solution set of `eqs` is not finite, then `numeric::polysysroots` may return solutions with some of the unknowns remaining as free parameters. In this case the representation of the solution depends on the ordering of the unknowns! Cf. "Example 3" on page 19-263. Further, if higher degree polynomials are involved, then `numeric::polysysroots` may fail to compute roots. Cf. "Example 5" on page 19-264. The same may happen, when `eqs` contains symbolic parameters.

You may try `numeric::fsolve` to compute a single numerical root, if `numeric::polysysroots` cannot compute all roots of the system. Note, however, that `numeric::fsolve` does not accept symbolic parameters in the equations.

We recommend to use `numeric::polyroots` to compute all roots of a single univariate polynomial with numerical coefficients.

`numeric::polysysroots` is a hybrid routine: it calls the symbolic solver `solve(eqs, vars, BackSubstitution = FALSE)` and processes its symbolic result numerically. Cf. "Example 4" on page 19-264.

Environment Interactions

The function is sensitive to the environment variable `DIGITS`, which determines the numerical working precision.

Examples

Example 1

Equations, expressions as well as `DOM_POLY` objects may be used to specify the polynomials:

```
numeric::polysysroots(x^2 = PI^2, x)
```

$$\{[x = 3.141592654], [x = -3.141592654]\}$$

```
numeric::polysysroots({x^2 + y^2 - 1, x^2 - y^2 = 1/2}, [x, y])
```

$$\{[x = 0.8660254038,\ y = 0.5],\ [x = 0.8660254038,\ y = -0.5],\ [x = -0.8660254038,\ y = -0.5],\ [x = -0.8660254038,\ y = 0.5]\}$$

```
numeric::polysysroots({poly(x^2 + y + 1), y^2 + x = 1}, [x, y])
```

$$\{[x = -0.4533976515,\ y = -1.20556943],\ [x = 0.2266988258 + 1.467711509\,i,\ y = 1.102784715 - 0.6654569512\,i],\ [x = 0,\ y = -1.0],\ [x = 0.2266988258 - 1.467711509\,i,\ y = 1.102784715 + 0.6654569512\,i]\}$$

Symbolic parameters are accepted:

```
numeric::polysysroots(x^2 + y + exp(z), [x, y])
```

$$\left\{\left[x = \sqrt{-1.0\,y - 1.0\,e^z}\right],\ \left[x = -1.0\,\sqrt{-1.0\,y - 1.0\,e^z}\right]\right\}$$

Example 2

The returned solutions may contain some of the unknowns remaining as free parameters:

```
numeric::polysysroots({x^2 + y^2 = z}, [x, y, z])
```

$$\left\{\left[x = \sqrt{z - 1.0\,y^2}\right],\ \left[x = -1.0\,\sqrt{z - 1.0\,y^2}\right]\right\}$$

Example 3

The ordering of the unknowns determines the representation of the solution, if the solution set is not finite. First, the following equation is solved for `x` leaving `y` as a free parameter:

```
numeric::polysysroots({x^3 = y^2}, [x, y])
```

$$\left\{\left[x = (y^2)^{1/3}\right],\ \left[x = (y^2)^{1/3}\,(-0.5 + 0.8660254038\,i)\right],\ \left[x = (y^2)^{1/3}\,(-0.5 - 0.8660254038\,i)\right]\right\}$$

Reordering the unknowns leads to a representation with `x` as a free parameter:

```
numeric::polysysroots({x^3 = y^2}, [y, x])
```

$$\{[y = \sqrt{x^3}],\ [y = -1.0\sqrt{x^3}]\}$$

Example 4

The symbolic solver produces a `RootOf` solution of the following system:

```
eqs := {y^2 - y = x, x^3 = y^3 + x}:
solve(eqs, BackSubstitution = FALSE)
```

$$\begin{pmatrix} x \\ y \end{pmatrix} \in \left\{\begin{pmatrix} 0 \\ 0 \end{pmatrix}\right\} \cup \left\{\begin{pmatrix} y^2 - y \\ z1 \end{pmatrix} \;\middle|\; z1 \in \mathrm{RootOf}(z^5 - 3z^4 + 3z^3 - 2z^2 - z + 1,\ z)\right\}$$

Internally, `numeric::polysysroots` calls `solve` and processes this result numerically:

```
numeric::polysysroots(eqs, [x, y])
```

$$\{[x = 2.237302267,\ y = 2.077118343],\ [x = -1.445049623 - 0.1279930535\,i,\ y = 0.441542078 + 1.094745154\,i],\ [x = 0.8911259621,\ y = -0.5682349751],\ [x = -0.2383289841,\ y = 0.6080324763],\ [x = -1.445049623 + 0.1279930535\,i,\ y = 0.441542078 - 1.094745154\,i],\ [x = 0,\ y = 0]\}$$

```
delete eqs:
```

Example 5

The following equation is solved for the first of the specified unknowns:

```
eqs := y^5 - PI*y = x:
solve(eqs, [x, y])
```

$$\{[x = z^5 - \pi z,\ y = z]\}$$

`numeric::polysysroots` processes this output numerically:

```
numeric::polysysroots(eqs, [x, y])
```

$$\{[x = y^5 - 3.141592654\,y]\}$$

The equation is solved for `y` when the unknowns are reordered. However, no simple representation of the solution exists, so a `RootOf` object is returned:

```
solve(eqs, [y, x])
```

$$\begin{pmatrix} y \\ x \end{pmatrix} \in \bigcup_{z2 \in \mathbb{C}} \left\{ \begin{pmatrix} z1 \\ z2 \end{pmatrix} \;\middle|\; z1 \in \mathrm{RootOf}(z^5 - \pi\, z - z2,\, z) \right\}$$

The roots represented by the `RootOf` expression cannot be computed numerically, because the symbolic parameter `x` is involved:

```
numeric::polysysroots(eqs, [y, x])
```

$$\begin{pmatrix} y \\ x \end{pmatrix} \in \bigcup_{z2 \in \mathbb{C}} \left\{ \begin{pmatrix} z1 \\ z2 \end{pmatrix} \;\middle|\; z1 \in \mathrm{RootOf}(z^5 - \pi\, z - z2,\, z) \right\}$$

```
delete eqs:
```

Parameters

`eqs`

A polynomial equation or a list, set, `array`, or `matrix` (`Cat::Matrix`) of such equations. Also expressions and polynomials of domain type `DOM_POLY` are accepted wherever an equation is expected. They are interpreted as homogeneous equations.

`vars`

An unknown or a list or set of unknowns. Unknowns may be identifiers or indexed identifiers.

Options

`NoWarning`

By default, the roots are double-checked, automatically. Warnings are issued if a solution seems to be marred by some numerical instability. With this option, this check is suppressed and no warnings will be issued.

Return Values

a set of lists of equations or an expression of the form $\begin{pmatrix} x_1 \\ x_2 \\ \dots \end{pmatrix} \in S$, where x_1, x_2, … are the unknowns and S is the solution set.

The set {[]} containing an empty list is returned, if no solutions can be computed.

numeric::product

Numerical approximation of products

Syntax

```
numeric::product(f, i = a .. b)
numeric::product(f, i in RootOf(p, <x>))
numeric::product(f, i = RootOf(p, <x>))
numeric::product(f, i in {x1, x2, …})
numeric::product(f, i = {x1, x2, …})
```

Description

`numeric::product(f, i = a..b)` computes a numerical approximation of $\prod_{i=a}^{b} f(i)$.

`numeric::product (f, i = RootOf(p,x))` computes a numerical approximation of the product of `f` over the roots of the polynomial `p`.

`numeric::product(f, i in { x1, x2, …})` computes a numerical approximation of $\prod_{i \in \{x_1, x_2, \ldots\}} f(i)$.

The call `numeric::product(...)` is equivalent to calling the `float` attribute of `product` via `float ( hold( product )(...))`, `float ( freeze( product )(...))` or `product::float(...)`.

If there are other symbolic parameters in *f*, apart from the variable *i*, a symbolic call to `numeric::product` is returned. Numerical expressions such as e^{π}, $\sqrt{2}$ etc. are accepted and converted to floating-point numbers.

Note: For finite products, `numeric::product` just returns `_mult ( float(f) $ i=a..b)`. Cf. “Example 3” on page 19-269.

The call `numeric::product(f, i = { x1, x2, …})` computes numerical approximations of `x[1]`, `x[2]` etc., substitutes these values into *f*(*i*) and multiplies the results.

The calls `numeric::product(f, i in { x1, x2, …})` and `numeric::product(f, i = { x1, x2, …})` are equivalent.

The call `numeric::product (f, i in RootOf(p, x))` computes numerical approximations of all roots of *p*, substitutes these values into *f*(*i*) and multiplies the results. Cf. “Example 2” on page 19-269.

The calls `numeric::product(f, i in RootOf(p, x))` and `numeric::product(f, i = RootOf(p, x))` are equivalent.

Environment Interactions

The function is sensitive to the environment variable `DIGITS`, which determines the numerical working precision and influences the maximum number of steps used in the computation.

Examples

Example 1

We demonstrate some equivalent calls for numerical products:

```
numeric::product(1+1/k^2, k = 1..infinity),
float(hold(product)(1+1/k^2, k = 1..infinity)),
float(freeze(product)(1+1/k^2, k = 1..infinity)),
product::float(1+1/k^2, k = 1..infinity);
```

```
3.67607791, 3.67607791, 3.67607791, 3.67607791
```

`product` fails to find a closed form for the following product:

```
product(1 - 1/4^k, k = 1..infinity);
```

$$\prod_{k=1}^{\infty} \frac{2^{2k}-1}{2^{2k}}$$

`float` implicitly uses `numeric::product` to compute a numerical approximation:

```
float(%);
```

$$0.6885375371$$

The exact value of the following infinite product is $e^{(1-\sqrt{2})\,\zeta\left(\frac{1}{2}\right)}$:

```
numeric::product(exp((-1)^(k+1)*k^(-1/2)), k = 1..infinity)
 = float(exp((1-sqrt(2))*zeta(1/2)))
```

$$1.831066609 = 1.831066609$$

Example 2

We calculate an approximation of the product over the roots of a polynomial:

```
numeric::product(sin(r), r = RootOf(x^2 - PI^2/4, x))
```

$$-1.0$$

If the polynomial expression contains additional indeterminates, a symbolic call to `numeric::product` is returned:

```
numeric::product(r+PI, r = RootOf(x^8 + c*x - PI^2/4, x))
```

$$\text{numeric::product}(r + 3.141592654,\ r = \text{RootOf}(x^8 + c\,x - 2.4674011,\ x))$$

Example 3

`numeric::product` can also be used to compute finite products:

```
numeric::product(1-1/k^2, k = 2..10^n) $ n in { 2, 3, 4 }
```

$$0.505,\ 0.5005,\ 0.50005$$

However, since `numeric::product` uses `_mult` internally anyway, it is more efficient to call `_mult` directly:

```
_mult(float(1-1/k^2) $ k = 2..10^n) $ n in { 2, 3, 4 }
```

$$0.505,\ 0.5005,\ 0.50005$$

Example 4

The following product is returned symbolically because it contains the additional indeterminate `k`:

```
numeric::product(1-1/n^k, n = 2..infinity)
```

$$\text{numeric::product}\left(1.0 - \frac{1.0}{n^{1.0\,k}},\ n = 2..\infty\right)$$

Parameters

`f`

An arithmetical expression depending on `i`

`i`

The product index: an identifier or indexed indentifier

`a, b`

integers or $\pm\infty$ satisfying $a \le b$

`p`

A univariate polynomial expression in `x`

x

Indeterminate

x_1, x_2, …

numerical expressions

Return Values

floating-point number or a symbolic expression of type `numeric::product`.

Algorithms

Infinite products are calculated by summing the series $\sum_{i=a}^{\infty} \ln(f)$ via `numeric::sum`.

`numeric::product` uses `numeric::polyroots` to calculate numerical approximations to the roots of a polynomials.

`_mult` | `numeric::polyroots` | `numeric::sum` | `product`

numeric::quadrature

Numerical integration (Quadrature)

Syntax

```
numeric::quadrature(f(x), x = a .. b, <GaussLegendre = n | GaussTschebyscheff = n | Nev
```

Description

`numeric::quadrature(f(x), x = a..b)` computes a numerical approximation of $\int_a^b f(x)\,\mathrm{d}x$.

`numeric::quadrature` returns itself symbolically if the integrand `f(x)` contains symbolic objects apart from the integration variable `x` that cannot be converted to numerical values via `float`. Symbolic objects such as π or $\sqrt{2}$ etc. are accepted.

The integrand `f(x)` should be integrable in the Riemann sense. In particular, `f(x)` should be bounded on the integration interval `x = a..b`. Certain types of mild singularities are handled, but numerical convergence is not guaranteed and will be slow in most cases. Also discontinuities and singularities of (higher) derivatives of `f(x)` slow down numerical convergence. For integrands with irregular points, it is recommended to split the integration into several parts, using subintervals on which the integrand is smooth. Cf. “Example 4” on page 19-276.

Integrands given by user-defined procedures can be handled. See “Example 4” on page 19-276 and “Example 5” on page 19-277.

`numeric::quadrature` returns itself symbolically if the boundaries `a,b` contain symbolic objects that cannot be converted to numerical values via `float`. Symbolic objects such as π or $\sqrt{2}$ etc. as well as `infinity` and `-infinity` are accepted.

Note: For infinite ranges, the user should make sure that the integral exists! If `f(x)` does not decay as fast as $O\left(\frac{1}{|x|^2}\right)$ at infinity, then convergence may be slow.

Boundaries $a > b$ are accepted, using $\int_a^b f(x)\,\mathrm{d}x = -\int_b^a f(x)\,\mathrm{d}x$.

For complex values of `a,b`, the integration is to be understood as a contour integral along a straight line from `a` to `b`. Complex boundaries must not involve `infinity`.

Multi-dimensional integration such as

```
numeric::quadrature ( numeric::quadrature(f(x,y), y = A(x)..B(x)), x
= a..b)
```

is possible. See “Example 3” on page 19-275 and “Example 5” on page 19-277.

Internally, an adaptive mechanism based on a fixed quadrature rule specified by `method = n` is used. It tries to keep the relative quadrature error of the result below $\frac{1}{10^{\mathrm{DIGITS}}}$.

The last digit(s) of the result may be incorrect due to roundoff effects.

The routine `numeric::quadrature` is purely numerical: no symbolic check for singularities etc. is carried out.

Environment Interactions

The function is sensitive to the environment variable `DIGITS`, which determines the numerical working precision.

Examples

Example 1

We demonstrate the standard calls for adaptive numerical integration:

```
numeric::quadrature(exp(x^2), x = -1..1)
```

```
     2.925303492
```

```
numeric::quadrature(max(1/10, cos(PI*x)), x = -2..0.0123)
```

```
                0.752102471
```

```
numeric::quadrature(exp(-x^2), x = -2..infinity)
```

```
                1.768308316
```

The precision goal is set by `DIGITS`:

```
DIGITS := 50:
numeric::quadrature(besselJ(0, x), x = 0..PI)
```

```
                1.3475263146739901712314731279612149642205400522774
```

Note that due to the internal adaptive mechanism, the choice of different methods should not have any significant effect on the quadrature result:

```
DIGITS := 10:
numeric::quadrature(sin(x)/x, x = -1..10, GaussLegendre = 5),
numeric::quadrature(sin(x)/x, x = -1..10, GaussLegendre = 160),
numeric::quadrature(sin(x)/x, x = -1..10, NewtonCotes = 8)
```

```
                2.604430665, 2.604430665, 2.604430665
```

Example 2

The user should make sure that the integrand is well defined and sufficiently regular. The following fails, because Newton-Cotes quadrature tries to evaluate the integrand at the boundaries:

```
numeric::quadrature(sin(x)/x, x = 0..1, NewtonCotes = 8)
```

```
Error: Division by zero. [_power]
  Evaluating: Quadsum
```

One may cure this problem be assigning a value to `f(0)`. The integrand is passed to the integrator as `hold(f)` to prevent premature evaluation of `f(x)` to `sin(x)/x`. Internally, `numeric::quadrature` replaces `x` by numerical values and then evaluates the integrand. Note that one has to define `f(0.0) := 1` rather than `f(0) := 1`:

```
f := x -> sin(x)/x:
f(0.0) := 1:
numeric::quadrature(hold(f)(x), x = 0..1, NewtonCotes = 8)
```

$$0.9460830704$$

The default method (Gauss-Legendre quadrature) does not evaluate the integrand at the end points:

```
numeric::quadrature(sin(x)/x, x = 0..1)
```

$$0.9460830704$$

Nevertheless, problems may still arise for improper integrals:

```
numeric::quadrature(ln((1 + x^4)^2 - 1), x = 0 .. 1)
```

```
Warning: Precision goal is not achieved after 10000 function calls. Increase 'MaxCalls
```

$$-3.213735532$$

In this example, the integrand is evaluated close to 0. The expression $(1 + x^4)^2 - 1$ suffers from severe numerical cancellation and is dominated by round-off. A numerically stable representation is $(1 + x^4)^2 - 1 = x^4 (x^4 + 2)$:

```
numeric::quadrature(ln(x^4*(x^4 + 2)), x = 0..1)
```

$$-3.218234378$$

Note that convergence is rather slow, because the integrand is not bounded.

```
delete f:
```

Example 3

We demonstrate multi-dimensional quadrature:

```
Q := numeric::quadrature:
Q(Q(exp(x*y), x = 0..y), y = 0..1)
```

```
0.6589510757
```

Also more complex types of nested calls are possible. We use numerically defined functions

```
b := y -> Q(exp(-t^2-t*y), t = y..infinity):
```

and

```
f := y -> cos(y^2) +  Q(exp(x*y), x = 0..b(y)):
```

for the following quadrature:

```
Q(f(y), y = 0..1)
```

```
1.261578952
```

Multi dimensional quadrature is computationally expensive. Note that a call to `numeric::quadrature` evaluates the integrand at least $3\,n$ times, where n is the number of nodes of the internal quadrature rule (by default, $n = 20$ for $DIGITS \leq 10$). The following triple quadrature would call the *exp* function no less than $(3\,20)^3 = 216000$ times!

```
Q(Q(Q(exp(x*y*z), x = 0..y+z), y = 0..z), z = 0..1)
```

For low precision goals, low order quadrature rules suffice. In the following, we reduce the computational costs by using Gauss-Legendre quadrature with 5 nodes. We use the shorthand notation `GL` to specify the `GaussLegendre` method:

```
DIGITS := 4:
Q(Q(Q(exp(x*y*z), x=0..y+z, GL=5), y=0..z, GL=5), z=0..1, GL=5)
```

```
0.665
```

```
delete Q, b, f, DIGITS:
```

Example 4

We demonstrate how integrands given by user-defined procedures should be handled. The following integrand

```
f := proc(x) begin
      if x<1 then sin(x^2) else cos(x^5) end_if
    end_proc:
```

cannot be called with a symbolic argument:

```
f(x)
```

```
Error: Cannot evaluate to Boolean. [_less]
  Evaluating: f
```

Consequently, one must use `hold` to prevent premature evaluation of `f(x)`:

```
numeric::quadrature(hold(f)(x), x = -1..PI/2)
```

```
     0.5354101317
```

Note that the above integrand is discontinuous at $x = 1$, causing slow convergence of the numerical quadrature. It is much more efficient to split the integral into two subquadratures with smooth integrands:

```
numeric::quadrature(sin(x^2), x = -1..1) +
numeric::quadrature(cos(x^5), x = 1..PI/2)
```

```
     0.5354101318
```

See “Example 5” on page 19-277 for multi-dimensional quadrature of user-defined procedures.

```
delete f:
```

Example 5

The following integrand

```
f := proc(x, y) begin
       if x<y then x-y else (x-y) + (x-y)^5 end_if
     end_proc:
```

can only be called with numerical arguments and must be delayed twice for 2-dimensional quadrature:

```
Q := numeric::quadrature:

Q(Q(hold(hold(f))(x, y), x = 0..1), y = 0..1)
```

```
0.02380952381
```

Note that delaying the integrand via `hold` will not work for triple or higher-dimensional quadrature! The user can handle this by making sure that the integrand can also be evaluated for symbolic arguments:

```
f := proc(x, y, z)
     begin
       if not testtype([args()], Type::ListOf(Type::Numeric))
          then return(procname(args()))
       end_if;
       if x^2 + y^2 + z^2 <= 1
          then return(1)
          else return(0)
       end_if
     end_proc:
```

Note that this function is not continuous, implying slow convergence of the numerical quadrature. For this reason, we use a low precision goal of only 2 digits and reduce the costs by using a low order quadrature rule:

```
DIGITS := 2:
Q(Q(Q(f(x, y, z), x=0..1, GL=5), y=0..1, GL=5), z=0..1, GL=5)
```

```
0.52
```

```
delete f, Q, DIGITS:
```

Example 6

The following example uses non-adaptive Gauss-Tschebyscheff quadrature with an increasing number of nodes. The results converge quickly to the exact value:

```
a := exp(x)/sqrt(1 - x^2), x = -1..1:
numeric::quadrature(a, Adaptive = FALSE, GT = n) $ n = 3..7
```

```
3.97732196, 3.977462635, 3.977463259, 3.977463261, 3.977463261
```

```
delete a:
```

Example 7

The improper integral $\int_0^1 \frac{1}{x^{9/10}}\,dx = 10$ exists. Numerical convergence, however, is rather slow because of the singularity at $x = 0$:

```
numeric::quadrature(x^(-9/10), x = 0..1)
```

```
Warning: Precision goal is not achieved after 10000 function calls. Increase 'MaxCalls
```

```
     9.998221195
```

We remove the limit for the number of function calls and let `numeric::quadrature` grind along until a result is found. The time for the computation grows accordingly, the last digit is incorrect due to roundoff effects:

```
numeric::quadrature(x^(-9/10), x = 0..1, MaxCalls = infinity)
```

```
     9.999999993
```

Example 8

The following integral does not exist in the Riemann sense, because the integrand is not bounded:

```
numeric::quadrature(1/x, x = -1..2)
```

```
Warning: Precision goal is not achieved after 10000 function calls. Increase 'MaxCalls
```

```
     116.9391252
```

We increase `MaxCalls`. There is no convergence of the numerical algorithm, because the integral does not exist. Consequently, some internal problem must arise: `numeric::quadrature` reaches its maximal recursive depth:

```
numeric::quadrature(1/x, x = -1..2, MaxCalls = infinity)
```

```
Warning: Precision goal is not achieved after 'MAXDEPTH=500' recursive calls. There mig

    3.262987586
```

Parameters

`f(x)`

An arithmetical expression in x

`x`

An identifier or an indexed identifier

`a, b`

Real or complex numerical values or $\pm\infty$

Options

`GaussLegendre, GaussTschebyscheff, NewtonCotes`

Options, specified as `GaussLegendre = n`, `GaussTschebyscheff = n`, `NewtonCotes = n`

The name of the underlying quadrature scheme. Each quadrature rule can be used with an arbitrary number of nodes specified by the positive integer n.

Usually there is no need to use this option to change the default method `GaussLegendre = n` with `n = 20,40,80` or `160`, depending on the precision goal determined by the environment variable `DIGITS`. Due to the corresponding high quadrature orders 40, 80, 160 or 320, respectively, the default settings are suitable for high precision computations.

With `GaussLegendre = n`, an adaptive version of Gauss-Legendre quadrature with n nodes is used.

For $DIGITS \leq 200$, the weights and abscissae of Gaussian quadrature with n = 20, 40, 80, and 160 nodes are available and the integration starts immediately.

For *DIGITS* > 200, the routine `numeric::gldata` is called to compute the Gaussian data before the actual integration starts. This will be noted by some delay in the first call of `numeric::quadrature`.

For `DIGITS` much larger than 200, it is recommended not to use the default setting but to use `GaussLegendre = n` with sufficiently high `n` instead. A reasonable choice is $n \approx$ *DIGITS*.

With `GaussTschebyscheff = n`, non-adaptive Gauss-Tschebyscheff quadrature with n nodes is used. This method may only be used in conjunction with `Adaptive = FALSE`.

Note: With `NewtonCotes = n`, an adaptive version of Newton-Cotes quadrature with n nodes is used. Note that these quadrature rules become numerically unstable for large n (n much larger than 10).

Following alternative names for the methods are accepted:

`GaussLegendre`, `Gauss`, `GL`,

`GaussTschebyscheff`, `GT`, `GaussChebyshev`, `GC`,

`NewtonCotes`, `NC`.

`Adaptive`

Option, specified as `Adaptive = v`

`v` may be `TRUE` or `FALSE`. With `Adaptive = FALSE`, the internal error control is switched off.

The default setting is `Adaptive = TRUE`. An adaptive quadrature scheme with automatic control of the quadrature error is used.

The call `numeric::quadrature(f(x), x = a..b, method = n, Adaptive = FALSE)` returns the quadrature sum $(b-a)\left(\sum_{i=1}^{n} B_i f\left(a + C_i (b-a)\right)\right)$ approximating $\int_a^b f(x)\,\mathrm{d}x$ without any control of the quadrature error. The weights B_i and abscissae C_i are determined by the quadrature rule given by `method = n`. For the methods `GaussLegendre`, `GaussTschebyscheff` and `NewtonCotes`, these data are available via `numeric::gldata`, `numeric::gtdata` and `numeric::ncdata`, respectively.

`Adaptive = FALSE` may only be used in conjunction with `method = n`.

Usually there is no need to switch off the internal adaptive quadrature via `Adaptive = FALSE`. This option is meant to give easy access to standard non-adaptive quadrature rules of Gauss-Legendre, Gauss-Tschebyscheff and Newton-Cotes type, respectively. The user may want to build his own adaptive quadrature based on these non-adaptive rules. Cf. “Example 6” on page 19-278.

`MaxCalls`

Option, specified as `MaxCalls = m`

`m` must be a (large) positive integer or `infinity`. It is the maximal number of evaluations of the integrand, before `numeric::quadrature` gives up.

When called interactively, `numeric::quadrature` returns the approximation it has computed so far and issues a warning. See “Example 7” on page 19-279. When called from inside a procedure, `numeric::quadrature` returns `FAIL`.

The default value is `m = MAXDEPTH*n`. The environment variable `MAXDEPTH` (default value 500) represents the maximal recursive depth of a function. `n` is the number of nodes of the basic quadrature rule specified by the optional argument `method = n`. If no such method is specified by the user, then Gauss-Legendre quadrature is used with n = 20 for $DIGITS \le 10$, n = 40 for $10 < DIGITS \le 50$, n = 80 for $50 < DIGITS \le 100$, n = 160 for $100 < DIGITS$. Thus, for $DIGITS = 10$, the default setting is `MaxCalls = 10000`.

The default value of `m` ensures that the `MaxCalls` limit is reached before `numeric::quadrature` reaches its maximal internal recursive depth. Specifying `MaxCalls = infinity` removes this restriction and `numeric::quadrature` computes until it obtains an approximation with about `DIGITS` correct digits or until it runs into an internal error. The typical error that may occur is the evaluation of the integrand at a singularity. There also is the danger of `numeric::quadrature` reaching its maximal internal recursive depth. When called interactively, `numeric::quadrature` returns the approximation it has computed so far and issues a warning. See “Example 8” on page 19-279. When called from inside a procedure, `numeric::quadrature` returns `FAIL`.

Return Values

Floating point number is returned, unless non-numerical symbolic objects in the integrand `f(x)` or in the boundaries `a,b` prevent numerical evaluation. In this case,

`numeric::quadrature` returns itself symbolically. If numerical problems occur, then `FAIL` is returned.

MuPAD Functions

`int` | `numeric::gldata` | `numeric::gtdata` | `numeric::int` | `numeric::ncdata`

numeric::rank

Numerical estimate of the rank of a matrix

Syntax

```
numeric::rank(A, <eps>, options)
```

Description

`numeric::rank(A)` returns an integer indicating the rank of the matrix *A*.

All entries of the input matrix must be numerical, i.e., they must be floating-point numbers or expressions that can be converted to floating-point numbers.

The rank of a matrix coincides with the number of non-zero singular values.

A numerical estimate of the rank is computed by counting all singular values that are larger than $eps\, s_max$, where s_max is the largest singular value. (All smaller singular values are regarded as round-off artifacts and treated as zero.)

Environment Interactions

The function is sensitive to the environment variable `DIGITS`, which determines the numerical working precision.

Examples

Example 1

We consider a quadratic matrix of rank 2:

```
A := matrix([[1, 1, I],
             [1, 2, 3],
             [2, 4, 6]]):
```

```
numeric::rank(A)
```

$$2$$

Hilbert matrices have full rank. However, they are extremely ill-conditioned and it is difficult to compute their rank numerically. The 10×10 Hilbert matrix has rank 10. Numerically, however, some of the singular values are so small that they may be regarded as zero resulting in a smaller numerical rank. In particular, with the default value eps = $\frac{1}{10^{\mathrm{DIGITS}}}$, two singular values are smaller than $eps\, s_max$ where s_{max} = 1.7519... is the maximal singular value:

```
A := linalg::hilbert(10):
numeric::singularvalues(A)
```

$$\left[1.75191967,\ 0.3429295485,\ 0.03574181627,\ 0.002530890769,\ 0.0001287496143,\ 0.000004729689293,\ 0.0000001228967739,\ 0.00000000214743881 8,\ 2.26674678\ 10^{-11},\ 1.093197787\ 10^{-13}\right]$$

```
numeric::rank(A)
```

$$8$$

We specify a second argument `eps = 10^-14` to allow smaller singular values to be regarded as non-zero. Now, the numerical rank is 10:

```
numeric::rank(A, 10^(-14))
```

$$10$$

```
delete A:
```

Example 2

We consider a non-square matrix of rank 1:

```
A := matrix([[0, 0],
             [I, 1],
             [I, 1]]):
numeric::rank(A)
```

```
    1
```

```
delete A:
```

Example 3

We demonstrate the difference between hardware floats and software floats:

```
A := linalg::hilbert(15):
numeric::rank(A, 10^(-20), SoftwareFloats),
numeric::rank(A, 10^(-20), HardwareFloats)
```

```
    14, 15
```

```
delete A:
```

Parameters

A

An $m \times n$ matrix of domain type `DOM_ARRAY`, `DOM_HFARRAY`, or of category `Cat::Matrix`

eps

Relative tolerance: regard all singular values s of A as zero if they satisfy $s \leq eps\, s_max$, where s_max is the largest singular value of A. The default value of eps is $\frac{1}{10^{\mathrm{DIGITS}}}$.

Options

Hard, HardwareFloats, Soft, SoftwareFloats

With `Hard` (or `HardwareFloats`), computations are done using fast hardware float arithmetic from within a MuPAD session. `Hard` and `HardwareFloats` are equivalent.

With this option, the input data are converted to hardware floats and processed by compiled C code. The result is reconverted to MuPAD floats and returned to the MuPAD session.

With `Soft` (or `SoftwareFloats`) computations are dome using software float arithmetic provided by the MuPAD kernel. `Soft` and `SoftwareFloats` are equivalent. `SoftwareFloats` is used by default if the current value of `DIGITS` is larger than 15 and the input matrix `A` is not of domain type `DOM_HFARRAY`.

Compared to the `SoftwareFloats` used by the MuPAD kernel, the computation with `HardwareFloats` may be many times faster. Note, however, that the precision of hardware arithmetic is limited to about 15 digits. Further, the size of floating-point numbers may not be larger than approximately 10^{308} and not smaller than approximately 10^{-308}.

If no `HardwareFloats` or `SoftwareFloats` are requested explicitly, the following strategy is used: If the current value of `DIGITS` is smaller than 16 or if the matrix `A` is a hardware float array of domain type `DOM_HFARRAY`, then hardware arithmetic is tried. If this is successful, the result is returned.

If the result cannot be computed with hardware floats, software arithmetic by the MuPAD kernel is tried.

If the current value of `DIGITS` is larger than 15 and the input matrix `A` is not of domain type `DOM_HFARRAY`, or if one of the options `Soft`, `SoftwareFloats` or `Symbolic` is specified, MuPAD computes the result with its software arithmetic without trying to use hardware floats first.

There may be several reasons for hardware arithmetic to fail:

- The current value of `DIGITS` is larger than 15.
- The data contains symbolic objects.
- The data contains numbers larger than 10^{308} or smaller than 10^{-308} that cannot be represented by hardware floats.

If neither `HardwareFloats` nor `SoftwareFloats` is specified, the user is not informed whether hardware floats or software floats are used.

If `HardwareFloats` are specified but fail due to one of the reasons above, a warning is issued that the (much slower) software floating-point arithmetic of the MuPAD kernel is used.

Note that `HardwareFloats` can only be used if all input data can be converted to floating-point numbers.

Note: For ill-conditioned matrices, the results returned with `HardwareFloats` and `SoftwareFloats` may differ significantly! See “Example 3” on page 19-286.

Return Values

Positive integer.

MuPAD Functions
`linalg::rank`

numeric::rationalize

Approximate a floating-point number by a rational number

Syntax

```
numeric::rationalize(object, <Exact | Minimize | Restore>, <digits>)
```

Description

`numeric::rationalize(object)` replaces all floating-point numbers in `object` by rational numbers.

An object of a library domain, characterized by `domtype(extop(object,0))=DOM_DOMAIN` is returned unchanged. For all other objects, `numeric::rationalize` is applied recursively to all operands. Objects of library domains can be rationalized if the domain has an appropriate `map` method. See "Example 5" on page 19-293.

A floating-point number f is approximated by a rational number r satisfying $|f - r| < \varepsilon |f|$.

Note: With the options `Exact` and `Minimize`, the guaranteed precision is $\varepsilon = \frac{1}{10^{\text{digits}}}$.

With `Restore`, the guaranteed precision is only $\varepsilon = \frac{1}{10^{\frac{\text{digits}}{2}}}$.

The default precision is `digits = DIGITS`.

The user defined precision must not be larger than the internal floating-point precision set by `DIGITS`: an error occurs for `digits > DIGITS`.

Environment Interactions

The function is sensitive to the environment variable `DIGITS`.

Examples

Example 1

`numeric::rationalize` is applied to each operand of a composite object:

```
numeric::rationalize(0.2*a+b^(0.7*I))
```

$$\frac{a}{5} + b^{\frac{7\,i}{10}}$$

```
numeric::rationalize([{poly(0.2*x, [x]), sin(7.2*PI) + 1.0*I},
                      exp(3 + ln(2.0*x))])
```

$$\left[\left\{\sin\left(\frac{36\,\pi}{5}\right) + i,\ \mathrm{poly}\left(\frac{x}{5}, [x]\right)\right\},\ e^{\ln(2\,x)+3}\right]$$

Example 2

We demonstrate the default strategy `Exact`:

```
numeric::rationalize(12.3 + 0.5*I),
numeric::rationalize(0.33333),
numeric::rationalize(1/3.0)
```

$$\frac{123}{10} + \frac{i}{2},\ \frac{33333}{100000},\ \frac{33333333333}{100000000000}$$

```
numeric::rationalize(10^12/13.0),
numeric::rationalize(10^(-12)/13.0)
```

$$76923076923,\ \frac{76923076923}{1000000000000000000000000}$$

We reduce the precision of the approximation to 5 digits:

```
numeric::rationalize(10^12/13.0, 5),
```

```
numeric::rationalize(10^(-12)/13.0, 5)
```

$$76923100000,\ \frac{769231}{10000000000000000000}$$

Example 3

We demonstrate the strategy `Minimize` for minimizing the complexity of the resulting rational number:

```
numeric::rationalize(1/13.0, 5),
numeric::rationalize(1/13.0, Minimize, 5),
numeric::rationalize(0.333331, 5),
numeric::rationalize(0.333331, Minimize, 5),
numeric::rationalize(14.285, 5),
numeric::rationalize(14.2857, Minimize, 5),
numeric::rationalize(1234.1/56789.2),
numeric::rationalize(1234.1/56789.2, Minimize)
```

$$\frac{769231}{10000000},\ \frac{1}{13},\ \frac{333331}{1000000},\ \frac{1}{3},\ \frac{2857}{200},\ \frac{100}{7},\ \frac{21731244673}{1000000000000},\ \frac{12341}{567892}$$

We compute rational approximations of π with various precisions:

```
numeric::rationalize(float(PI), Minimize, i) $ i = 1..10
```

$$3,\ \frac{22}{7},\ \frac{22}{7},\ \frac{355}{113},\ \frac{355}{113},\ \frac{355}{113},\ \frac{355}{113},\ \frac{102573}{32650},\ \frac{104348}{33215},\ \frac{208341}{66317}$$

Example 4

We demonstrate the strategy `Restore` for restoring rational numbers after elementary float operations. In many cases, also the `Minimize` strategy restores:

```
numeric::rationalize(1/7.3, Exact),
numeric::rationalize(1/7.3, Minimize),
numeric::rationalize(1/7.3, Restore)
```

$$\frac{13698630137}{100000000000},\ \frac{10}{73},\ \frac{10}{73}$$

However, using `Restore` improves the chances of recovering from roundoff effects:

```
numeric::rationalize(10^9/13.0, Minimize),
numeric::rationalize(10^9/13.0, Restore)
```

$$\frac{923076923}{12}, \frac{1000000000}{13}$$

```
DIGITS:= 11:
numeric::rationalize(1234.56/12345.67, Minimize),
numeric::rationalize(1234.56/12345.67, Restore)
```

$$\frac{88183}{881835}, \frac{123456}{1234567}$$

In some cases, `Restore` manages to recover from roundoff error propagation in composite arithmetical operations:

```
DIGITS:= 10:
x:= float(122393/75025):
y:= float(121393/75025):
z := (x^2 - y^2)/(x + y)
```

$$0.01332889037$$

```
numeric::rationalize(z, Restore)
```

$$\frac{40}{3001}$$

The result with `Restore` corresponds to exact arithmetic:

```
rx := numeric::rationalize(x, Restore):
ry := numeric::rationalize(y, Restore):
rx, ry, (rx^2 - ry^2)/(rx + ry)
```

$$\frac{122393}{75025}, \frac{121393}{75025}, \frac{40}{3001}$$

Note that an approximation with `Restore` may have a reduced precision of only `digits/2`:

```
x := 1.0 + 1/10^6:
numeric::rationalize(x, Exact),
numeric::rationalize(x, Restore)
```

$$\frac{1000001}{1000000},\ 1$$

```
delete x, y, z, rx, ry:
```

Example 5

The floats inside objects of library domains are not rationalized directly. However, for most domains the corresponding `map` method can forward `numeric::rationalize` to the operands:

```
Dom::Multiset(0.2, 0.2, 1/5, 0.3)
```

$$\left\{[0.2,\ 2],\ \left[\frac{1}{5},\ 1\right],\ [0.3,\ 1]\right\}$$

```
numeric::rationalize(%), map(%, numeric::rationalize, Restore)
```

$$\left\{[0.2,\ 2],\ \left[\frac{1}{5},\ 1\right],\ [0.3,\ 1]\right\},\ \left\{\left[\frac{1}{5},\ 3\right],\ \left[\frac{3}{10},\ 1\right]\right\}$$

Parameters

`object`

An arbitrary MuPAD object

`digits`

A positive integer (the number of decimal digits) not bigger than the environment variable `DIGITS`. It determines the precision of the rational approximation.

Options

`Exact`

Specifies the strategy for approximating floating-point numbers by rational numbers. This is the default strategy, so there is no real need to pass `Exact` as a parameter to `numeric::rationalize`.

Any real floating-point number $f \neq 0.0$ has a unique representation

$$f = \text{sign}(f)\ \text{mantissa}\ 10^{\text{exponent}}$$

With integer exponent and $1.0 \leq \textit{mantissa} < 10.0$. With the option `Exact`, the float mantissa is replaced by the rational approximation

$$\frac{\text{round}(\text{mantissa}\ 10^{\text{digits}})}{10^{\text{digits}}}$$

.

This guarantees a relative precision of `digits` significant decimals of the rational approximation.

`Minimize`

Specifies the strategy for approximating floating-point numbers by rational numbers. This strategy tries to minimize the complexity of the rational approximation, i.e., numerators and denominators are to be small.

The guaranteed precision of the rational approximation is `digits`.

See “Example 3” on page 19-291.

`Restore`

Specifies the strategy for approximating floating-point numbers by rational numbers. This strategy tries to restore rational numbers obtained after *elementary* arithmetical operations applied to floating-point numbers. E.g., for rational `r`, the float division `f = 1/float(r)` introduces additional roundoff, which the `Restore` algorithm tries to eliminate: `numeric::rationalize(f, Restore) = 1/r`. This strategy, however, is purely heuristic and will not succeed when significant roundoff is caused by arithmetical float operations!

Note: The guaranteed precision of the rational approximation is only `digits/2`!

See “Example 4” on page 19-291.

Return Values

If the argument is an object of some kernel domain, then it is returned with all floating-point operands replaced by rational numbers. An object of some library domain is returned unchanged.

Overloaded By

object

Algorithms

Continued fraction (CF) expansion is used with the options `Minimize` and `Restore`.

With `Minimize`, the first CF approximation satisfying the precision criterion is returned.

The `Restore` algorithm stops, when large coefficients of the CF expansion are found.

numeric::realroot

Numerical search for a real root of a real univariate function

Syntax

```
numeric::realroot(f(x), x = a .. b, <SearchLevel = s>)
```

Description

`numeric::realroot(f(x), x = a..b)` computes a numerical real root of $f(x)$ in the interval $[a, b]$.

The expression `f(x)` must not contain symbolic objects other than the indeterminate `x` that cannot be converted to numerical values via `float`. Symbolic objects such as π or $\sqrt{2}$ etc. are accepted. The same holds true for the boundaries `a, b` of the search interval.

The function must produce real values. If `float(f(x))` does not yield real floating-point numbers for all real floating-point numbers `x` from the interval $[a, b]$, internal problems may occur. See "Example 5" on page 19-299.

`numeric::realroot` never tries to evaluate `f(x)` outside the search interval. Consequently, singularities outside the interval do not cause any problems. In many cases also singularities inside the interval do not affect the numerical search. However, `numeric::realroot` is not guaranteed to work in such a case. An error may occur, if the internal search accidentally hits a singularity. See "Example 5" on page 19-299.

Up to roundoff effects numerical roots r with $|r| \geq \frac{1}{10^{\mathrm{DIGITS}}}$ are computed to a relative precision of `DIGITS` significant decimal places. Roots of smaller absolute size are computed to an absolute precision of $\frac{1}{10^{2\ \mathrm{DIGITS}}}$. These precision goals are not achieved, if significant roundoff occurs in the numerical evaluation of $f(x)$.

If f takes opposite signs at the endpoints a, b of the search interval and does not have zero-crossing singularities, then `numeric::realroot` is bound to find a root in the interval $[a, b]$.

User defined functions can be handled. See “Example 2” on page 19-297.

Note: `numeric::realroot` approximates a point where `f(x)` changes its sign. This is a root only if the function `f` is continuous. See “Example 3” on page 19-298.

Note that `numeric::realroots` may be used to isolate *all* real roots. However, this function is much slower than `numeric::realroot`, if *f* is not a polynomial.

For univariate polynomials we recommend to use `numeric::realroots` or `polylib::realroots` rather than `numeric::realroot`.

Environment Interactions

The function is sensitive to the environment variable `DIGITS`, which determines the numerical working precision.

Examples

Example 1

The following functions assume different signs at the boundaries, so the searches are bound to succeed:

```
numeric::realroot(x^3 - exp(3), x = -PI..10)
```

```
     2.718281828
```

```
numeric::realroot(exp(-x[1]) = x[1], x[1] = 0..1)
```

```
     0.5671432904
```

Example 2

The following function cannot be evaluated for non-numerical `x`. So one has to delay evaluation via `hold`:

```
f := proc(x) begin
      if x<0 then 1 - x else exp(x) - 10*x end_if
     end_proc:
numeric::realroot(hold(f)(x), x = -10..10)
```

```
     0.1118325592
```

```
delete f:
```

Example 3

`numeric::realroot` approximates a point, where $f(x)$ changes its sign. For the following function this happens at the discontinuity $x = 1$:

```
f := proc(x) begin if x<1 then -1 else x end_if end_proc:
numeric::realroot(hold(f)(x), x = 0..3)
```

```
     1.0
```

```
delete f:
```

Example 4

The following function does not have a real root. Consequently, `numeric::realroot` fails:

```
numeric::realroot(x^2 + 1, x = -2..2)
```

```
     FAIL
```

The following function does not have a real root in the search interval:

```
numeric::realroot(x^2 - 1, x =  2..3)
```

```
     FAIL
```

Example 5

The following function is complex valued for $x^2 < 3.5$. An error occurs, when the internal search hits such a point:

```
numeric::realroot(ln(x^2 - 3.5), x = -2..3)
```

```
Error: Cannot evaluate to Boolean. [_less]
  Evaluating: numeric::BrentFindRoot
```

The singularity at $x = 1$ does not cause any problem in the following call:

```
numeric::realroot((x-2)/(x-1), x = -10..10)
```

```
    2.0
```

However, the singularity may be hit accidentally in the internal search:

```
numeric::realroot((x-2)/(x-1), x = 0..3)
```

```
Error: Division by zero. [_power]
  Evaluating: f
```

Example 6

The following function has a root close to 1.0, which is difficult to detect. With the default search level $s = 1$, this root is not found:

```
f := 2 - exp(-100*(x - 2)^2) - 2*exp(-1000*(x - 1)^2):
numeric::realroot(f, x = 0..5)
```

```
    FAIL
```

The root is detected with an increased search level:

```
numeric::realroot(f, x = 0..5, SearchLevel = 3)
```

```
    1.0
```

```
delete f:
```

Parameters

`f(x)`

An arithmetical expression in one unknown `x` or a list, set, `array`, or `matrix` (`Cat::Matrix`) of expressions. Alternatively, equations in the form $f_1(x) = f_2(x)$ equivalent to the expressions $f_1(x) - f_2(x)$.

`x`

An identifier or an indexed identifier

`a, b`

Finite real numerical values

Options

`SearchLevel`

Option, specified as `SearchLevel = s`

The nonnegative integer s controls the internal refinement of the search. The default value is $s = 1$. Increasing s increases the chance of finding roots that are difficult to detect numerically. See “Example 6” on page 19-299.

Note that increasing s by 1 may quadruple the time before `FAIL` is returned, if no real root is found. For this reason we recommend to restrict s to small values ($s \leq 5$, say).

Return Values

Single numerical real root of domain type `DOM_FLOAT`. If no solution is found, then `FAIL` is returned.

Algorithms

A mixture of bisectioning, secant steps and quadratic interpolation is used by `numeric::realroot`.

More About

- "Solve Equations Numerically"

numeric::realroots

Isolate intervals containing real roots of a univariate function

Syntax

```
numeric::realroots(f(x), <x = a .. b>, <eps>, <Merge = c>)
```

Description

`numeric::realroots(f(x), x = a..b)` searches for real roots of $f(x)$ in the interval $[a, b]$. It returns a list of subintervals in which real roots of $f(x)$ may exist. It is guaranteed that there are no real roots in the interval $[a, b]$ lying outside the union of the returned subintervals.

With `Merge = FALSE`, all intervals returned by `numeric::realroots` have length $b_i - a_i < eps$ with a default value $eps = 0.01$. The absolute precision of the root isolation may be redefined using the optional parameter `eps`.

Note: The intervals returned by `numeric::realroots` define a subset of $[a, b]$ that may contain real roots. For polynomial expressions $f(x)$, each of the subintervals of $[a, b]$ returned by `numeric::realroots` is guaranteed to contain exactly one root. For non-polynomial expressions $f(x)$, however, some of the subintervals may contain no root! Cf. "Example 6" on page 19-306.

In any case, the complement $[a, b] \setminus \left(\bigcup_{i \in \{1, \ldots, n\}} [a_i, b_i] \right)$ of the subintervals $[a_i, b_i]$ returned by `numeric::realroots` is guaranteed to contain no real roots. In particular, from the return value [], one may positively conclude that no root exists in the search interval $[a, b]$. Cf. "Example 2" on page 19-304.

Symbolic parameters in $f(x)$ are not allowed: `float(f(x))` must evaluate to a floating point number for all x from the interval $[a, b]$.

Infinite intervals of the form `x = -infinity..b` are not refined if $b \leq -10^5$.

Infinite intervals of the form `x = a..infinity` are not refined if $a \geq 10^5$.

Such intervals are returned directly if `numeric::realroots` thinks that they may contain roots. Cf. “Example 5” on page 19-305.

f(*x*) may contain complex expressions. Only the search parameter *x* is assumed to be real. For complex expressions `f(x)`, the intervals are returned where both the real and the imaginary part of the expression vanish simultaneously.

Note: The expression `f(x)` must be suitable for interval arithmetic. In particular, MuPAD must be able to evaluate `f(a...b)`. Note that not all MuPAD functions support this kind of arithmetic.

Presently, the following special functions support interval arithmetic: `abs`, `arccos`, `arccosh`, `arccoth`, `arccot`, `arccsc`, `arccsch`, `arcsec`, `arcsech`, `arcsin`, `arcsinh`, `arctan`, `arctanh`, `arg`, `beta`, `ceil`, `cos`, `cosh`, `cot`, `coth`, `csc`, `csch`, `dirac`, `exp`, `floor`, `gamma`, `Im`, `ln`, `Re`, `round`, `sec`, `sech`, `sin`, `sinh`, `sqrt`, `tan`, `tanh`, `trunc`. Real roots can be searched for any expression that is built from these functions using the standard arithmetical operations `+`, `-`, `*`, `/`, `^`.

The default value is *eps* = 0.01. User defined precision goals must satisfy $\mathrm{eps} \geq \frac{1}{10^{\mathrm{DIGITS}}}$.

Environment Interactions

The function is sensitive to the environment variable `DIGITS`, which determines the numerical working precision.

Examples

Example 1

The following expression has integer zeros. The solutions in the specified interval are approximated to the default precision 0.01:

```
numeric::realroots(sin(PI*x), x = -2..sqrt(2))
```

```
[[-2.0, -1.993331614], [-1.006410506, -0.9997421204],
  [-0.006152626661, 0.000515759203], [0.9941052529, 1.000773639]]
```

The following equation is solved with an absolute precision of 7 digits:

```
numeric::realroots(x*sin(x) = exp(-x), x = -1..1, 10^(-7))
```

```
[[0.7271005511, 0.7271006107]]
```

Example 2

The following expression does not have a real root:

```
numeric::realroots(exp(x) + x^2, x = -100..100)
```

```
[]
```

Example 3

We demonstrate the option `Merge`. If interval arithmetic can not isolate roots to the desired precision *eps* (default 0.01), then adjacent intervals are produced, each of length smaller than *eps*. This happens in the following example:

```
numeric::realroots(ln(x^2 -2*x + 2) = 0, x = -10..10,
                   Merge = FALSE)
```

```
[[0.869140625, 0.87890625], [0.87890625, 0.888671875], [0.888671875, 0.8984375], ...,
  [1.123046875, 1.1328125], [1.1328125, 1.142578125]]
```

[[0.869140625, 0.87890625], [0.87890625, 0.888671875], [0.888671875, 0.8984375], [0.8984375, 0.908203125], [0.908203125, 0.91796875], [0.91796875, 0.927734375], [0.927734375, 0.9375], [0.9375, 0.947265625], [0.947265625, 0.95703125], [0.95703125, 0.966796875], [0.966796875, 0.9765625], [0.9765625, 0.986328125], [0.986328125, 0.99609375], [0.99609375, 1.005859375], [1.005859375, 1.015625], [1.015625, 1.025390625], [1.025390625, 1.03515625], [1.03515625, 1.044921875], [1.044921875, 1.0546875], [1.0546875, 1.064453125], [1.064453125, 1.07421875], [1.07421875,

```
1.083984375], [1.083984375, 1.09375], [1.09375, 1.103515625], [1.103515625,
1.11328125], [1.11328125, 1.123046875], [1.123046875, 1.1328125], [1.1328125,
1.142578125]]
```

With `Merge = TRUE`, these intervals are combined to a single larger interval. Since `Merge = TRUE` is the default setting for non-polynomial functions, it suffices to omit the option `Merge = FALSE`:

```
numeric::realroots(ln(x^2 -2*x + 2) = 0, x = -10..10)
```

```
[[0.869140625, 1.142578125]]
```

Example 4

The following expression has infinitely many solutions $x = \frac{1}{n}$ with $n = 1, 2, \ldots$ in the search interval [0, 1]:

```
numeric::realroots(sin(PI/x), x = 0..1, 0.1, Merge = FALSE)
```

```
[[0.0, 0.0625], [0.0625, 0.125], [0.125, 0.1875], [0.1875, 0.25], [0.25, 0.3125], [0.3125, 0.375],
  [0.4375, 0.5], [0.5, 0.5625], [0.9375, 1.0]]
```

Omitting `Merge = FALSE`, adjacent intevals are merged to larger intervals. The first of the following intervals contains infinitely many roots:

```
numeric::realroots(sin(PI/x), x = 0..1, 0.1)
```

```
[[0.0, 0.375], [0.4375, 0.5625], [0.9375, 1.0]]
```

Example 5

If no search interval is specified, the entire real line is considered:

```
numeric::realroots(x^3 = exp(x))
```

```
[[1.841783524, 1.871585846], [4.523992538, 4.553794861], [100000.0, ∞]]
```

Apart from two finite intervals, `numeric::realroots` tells us that there may be a root close to infinity (but that there is positively no root close to -infinity). Analytically, it is clear that the subinterval $[10000.0, \infty]$ cannot contain a root, since e^x grows much faster than x^3 as x goes to infinity. If a finite upper limit for the search interval is specified, this fact is detected:

```
numeric::realroots(x^3 = exp(x), x = -infinity .. 10^100)
```

$$[[1.842076975, 1.877795331], [4.512024084, 4.556672029]]$$

We isolate the two finite roots more closely by specifying a precision goal of $\frac{1}{10^{\mathrm{DIGITS}}}$:

```
numeric::realroots(x^3 = exp(x), x = -infinity .. 10^100,
                   10^(-DIGITS))
```

$$[[1.85718386, 1.85718386], [4.536403655, 4.536403655]]$$

Example 6

The following equation has no root close to 0. However, interval arithmetic does not produce realistic values of $\frac{\sin(\pi x)}{x}$ for small intervals containing $x = 0$, so an isolating interval around 0 is returned:

```
numeric::realroots(sin(PI*x)/x = 0, x = -1..1.2)
```

$$[[-1.0, -0.99140625], [-0.003125, 0.00546875], [0.99375, 1.00234375]]$$

A similar phenomenon occurs with $x^x = e^{x \ln(x)}$ in a neighbourhood of $x = 0$. An isolating interval around 0 is returned, although no solution exists there:

```
numeric::realroots(x^x*cos(PI*x) = tan(x), x = 0..1)
```

$$[[0.0, 0.0078125], [0.328125, 0.3359375]]$$

This cannot be cured by increasing the precision goal:

```
numeric::realroots(x^x*cos(PI*x) = tan(x), x = 0..1,
                   10^(-DIGITS))
```

$$\left[\left[0.0,\ 5.820766091\ 10^{-11}\right],\ [0.3334737903,\ 0.3334737903]\right]$$

Parameters

`f(x)`

An expression in one indeterminate `x` or a list, set, `array`, or `matrix` (`Cat::Matrix`) of expressions. Alternatively, equations in the form $f_1(x) = f_2(x)$ equivalent to the expressions $f_1(x) - f_2(x)$.

`x`

An identifier or an indexed identifier

`a, b`

Real numbers or numerical expressions satisfying $a < b$. Also `- infinity` and `infinity` may be used.

`eps`

A (small) positive real numerical value defining the precision goal. The default value is 0.01.

Options

`Merge`

Option, specified as `Merge = b`

`b` can be `TRUE` or `FALSE`. With `Merge = FALSE`, `numeric::realroots` returns subintervals of length not larger than `eps`. With `Merge = TRUE`, `numeric::realroots` merges adjacent subintervals to larger intervals, i.e., subintervals of length larger than `eps` may be returned.

The default setting is `Merge = FALSE` for polynomial functions $f(x)$. Otherwise, it is `Merge = TRUE`.

`numeric::realroots` isolates intervals $[a_i, b_i]$ that may contain roots. Internally, all these intervals satisfy $b_i - a_i < eps$ where eps is the precision goal.

With `Merge = FALSE`, these intervals are returned.

With `Merge = TRUE`, adjacent intervals $[a_i, b_i]$, $[a_{i+1}, b_{i+1}]$ with $b_i = a_{i+1}$ are combined to larger intervals $[a_i, b_{i+1}]$. See “Example 3” on page 19-304 and “Example 4” on page 19-305.

The default setting is `Merge = FALSE` for polynomial functions. Otherwise, it is `Merge = TRUE`.

Return Values

List $[[a_1, b_1], [a_2, b_2], \ldots]$ of disjoint floating-point intervals $[a_i, b_i] \subset [a, b]$ which may contain roots of $f(x)$. The empty list is returned if no root exists in the search interval $[a, b]$.

Algorithms

Let X be a subset of the real numbers. Interval arithmetic produces a set $F(X)$ such that the set of image values $\{f(x) \mid x \in X\}$ is contained in $F(X)$. The MuPAD domain `DOM_INTERVAL` facilitates this kind of arithmetic. The routine `numeric::realroots` computes $F := f(a_i \ldots b_i)$ for various subintervals $[a_i, b_i]$ of $[a, b]$. If F does not contain zero, then this subinterval is eliminated from the search interval. Otherwise, the subinterval is returned as a candidate for containing zeros of $f(x)$. However, one cannot conclude that F does indeed contain at least one zero, since F is usually larger than the true image set $\{f(x) \mid x \in [a_i, b_i]\}$ (‘overestimation’).

For polynomials $f(x)$, the routine `polylib::realroots` is called. Its results are intersected with the search interval $[a, b]$. No interval arithmetic is used for

polynomial expressions. For polynomial equations, each isolating interval returned by `numeric::realroots` is guaranteed to contain at least one root if `Merge = TRUE` is specified. With the default setting of `Merge = FALSE` for polynomials, each isolating interval is guaranteed to contain exactly one root.

More About

- "Solve Equations Numerically"

numeric::rotationMatrix

Orthogonal matrix of the rotation about an axis

Syntax

```
numeric::rotationMatrix(angle, axis, <Symbolic>, <ReturnType = t>)
```

Description

`numeric::rotationMatrix(angle, axis)` returns an orthogonal matrix corresponding to the rotation about the given axis by the given angle.

The rotation by the angle *alpha* about the axis given by the vector [*x*, *y*, *z*] of Euclidean length 1 is given by the rotation matrix

$$e^{\text{alpha}\begin{pmatrix} 0 & -z & y \\ z & 0 & -x \\ -y & x & 0 \end{pmatrix}} = \begin{pmatrix} t\,x^2+c & t\,x\,y-s\,z & t\,x\,z+s\,y \\ t\,x\,y+s\,z & t\,y^2+c & t\,y\,z-s\,x \\ t\,x\,z-s\,y & t\,y\,z+s\,x & t\,z^2+c \end{pmatrix}$$

with $c = cos(alpha)$, $s = sin(alpha)$, and $t = 1 - c = 2\sin\left(\frac{\text{alpha}}{2}\right)^2$.

The rotation is implemented following the “right hand rule”: Stretch the thumb of your right hand and bend the fingers. When the thumb points into the direction of the rotation axis, your finger tips indicate the direction of the rotation.

Use negative angles to rotate in the opposite direction.

The axis parameter of the routine does not need to be normalized to the Euclidean length 1. However, it must not be of zero length.

If no return type is specified via the option `ReturnType = t`, the domain type of the result depends on the type of the input matrix `axis`:

- If the axis is of domain type array, then the rotation matrix is returned as an array.
- If the axis is of domain type hfarray, then the result is returned as an hfarray.
- If the axis is of domain type `Dom::DenseMatrix()`, then the rotation matrix is returned as a matrix of type `Dom::DenseMatrix()` over the ring of MuPAD expressions.
- If axis is of any different matrix type, the result is a `matrix` of type `Dom::Matrix()` over the ring of MuPAD expressions. This includes input matrices `axis` of type `Dom::Matrix(...)`, `Dom::SquareMatrix(...)`, `Dom::MatrixGroup(...)` etc.
- If axis is a list with 3 elements, the rotation matrix is also returned as an `Dom::Matrix()` over the ring of MuPAD expressions.

Without the option `Symbolic`, all arguments are automatically converted to floating-point arguments (if possible). Use the option `Symbolic` if no such conversion is desired.

Environment Interactions

The function is sensitive to the environment variable `DIGITS`, which determines the numerical working precision.

Examples

Example 1

The rotation around the z axis by 45 degrees is given by the following matrix:

```
numeric::rotationMatrix(PI/4, [0, 0, 1])
```

$$\begin{pmatrix} 0.7071067812 & -0.7071067812 & 0 \\ 0.7071067812 & 0.7071067812 & 0 \\ 0 & 0 & 1.0 \end{pmatrix}$$

Symbolic arguments are accepted:

```
numeric::rotationMatrix(a, [1, 2, 3])
```

$$\begin{bmatrix}0.9285714286\cos(a)+0.07142857143, & 0.1428571429-0.8017837257\sin(a)\\ -0.1428571429\cos(a), & 0.5345224838\sin(a)-0.2142857143\cos(a)+0.2142857143\end{bmatrix},$$
$$\begin{bmatrix}0.8017837257\sin(a)-0.1428571429\cos(a)+0.1428571429, & \\ 0.7142857143\cos(a)+0.2857142857, & 0.4285714286-0.2672612419\sin(a)\\ -0.4285714286\cos(a)\end{bmatrix},$$
$$\begin{bmatrix}0.2142857143-0.5345224838\sin(a)-0.2142857143\cos(a), & \\ 0.2672612419\sin(a)-0.4285714286\cos(a)+0.4285714286, & 0.3571428571\cos(a)\\ +0.6428571429\end{bmatrix}$$

With the option `Symbolic`, no automatic conversion to floating-point numbers occurs:

```
numeric::rotationMatrix(a, [1, 2, 3], Symbolic)
```

$$\begin{pmatrix}\frac{13\cos(a)}{14}+\frac{1}{14} & \frac{1}{7}-\sigma_1-\frac{\cos(a)}{7} & \frac{\sigma_4}{7}-\sigma_2+\frac{3}{14}\\ \sigma_1-\frac{\cos(a)}{7}+\frac{1}{7} & \frac{5\cos(a)}{7}+\frac{2}{7} & \frac{3}{7}-\frac{\sigma_4}{14}-\sigma_3\\ \frac{3}{14}-\frac{\sigma_4}{7}-\sigma_2 & \frac{\sigma_4}{14}-\sigma_3+\frac{3}{7} & \frac{5\cos(a)}{14}+\frac{9}{14}\end{pmatrix}$$

where

$$\sigma_1=\frac{3\sqrt{14}\sin(a)}{14}$$

$$\sigma_2=\frac{3\cos(a)}{14}$$

$$\sigma_3=\frac{3\cos(a)}{7}$$

$$\sigma_4=\sqrt{14}\sin(a)$$

Example 2

The return type coincides with the type of the input parameter representing the axis:

```
numeric::rotationMatrix(0.3, matrix([1,2,3]))
```

$$\begin{pmatrix} 0.9585267399 & -0.2305627908 & 0.1675329472 \\ 0.2433237939 & 0.9680974922 & -0.05983959278 \\ -0.1483914426 & 0.0981226021 & 0.9840487461 \end{pmatrix}$$

```
domtype(%)
```

Dom::Matrix()

```
numeric::rotationMatrix(0.3, hfarray(1..3, [1,2,3]))
```

$$\begin{pmatrix} 0.9585267399 & -0.2305627908 & 0.1675329472 \\ 0.2433237939 & 0.9680974922 & -0.05983959278 \\ -0.1483914426 & 0.0981226021 & 0.9840487461 \end{pmatrix}$$

```
domtype(%)
```

DOM_HFARRAY

The option `ReturnType` allows to specify the type of the result:

```
numeric::rotationMatrix(0.3, hfarray(1..3, [1,2,3]),
                                ReturnType = matrix)
```

$$\begin{pmatrix} 0.9585267399 & -0.2305627908 & 0.1675329472 \\ 0.2433237939 & 0.9680974922 & -0.05983959278 \\ -0.1483914426 & 0.0981226021 & 0.9840487461 \end{pmatrix}$$

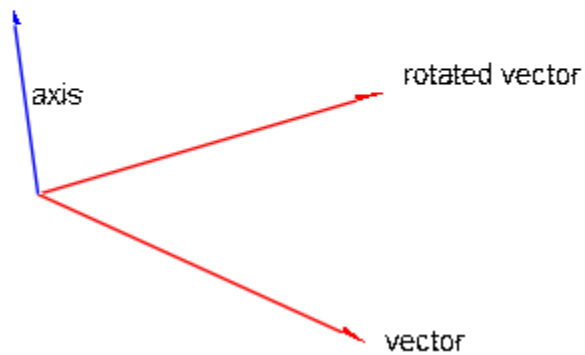
```
domtype(%)
```

Dom::Matrix()

Example 3

The direction of the rotation is given by the “right hand rule”: Stretch the thumb of your right hand and bend the fingers. When the thumb points into the direction of the rotation axis, your finger tips indicate the direction of the rotation:

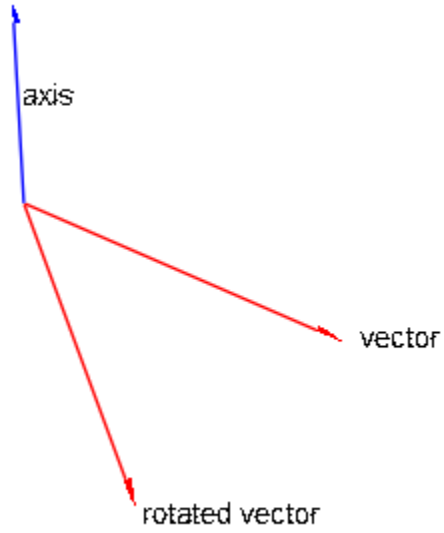
```
axis := matrix([0, 0, 1]):
vector := matrix([1, 0, 0]):
Q := numeric::rotationMatrix(PI/4, axis):
plot(plot::Arrow3d(axis, Color = RGB::Blue),
     plot::Arrow3d(vector, Color = RGB::Red),
     plot::Arrow3d(Q*vector, Color = RGB::Red),
     plot::Text3d("axis", [0.01, 0.01, 0.5]),
     plot::Text3d("vector", [1.05, 0, 0]),
     plot::Text3d("rotated vector", [0.75, 0.75, 0]),
     CameraDirection = [1, -2, 4],
     Scaling = Constrained, Axes = None):
```



Use negative angles to rotate in the opposite direction:

```
axis := matrix([0, 0, 1]):
vector := matrix([1, 0, 0]):
```

```
Q := numeric::rotationMatrix(-PI/4, axis):
plot(plot::Arrow3d(axis, Color = RGB::Blue),
     plot::Arrow3d(vector, Color = RGB::Red),
     plot::Arrow3d(Q*vector, Color = RGB::Red),
     plot::Text3d("axis", [0.01, 0.01, 0.5]),
     plot::Text3d("vector", [1.05, 0, 0]),
     plot::Text3d("rotated vector", [0.75, -0.75, 0]),
     CameraDirection = [1, -2, 4],
     Scaling = Constrained, Axes = None):
```



```
delete axis, vector, Q:
```

Parameters

`angle`

An arithmetical expression

`axis`

A vector represented by a list with 3 entries or by a 3 ×1 matrix of domain type `DOM_ARRAY`, `DOM_HFARRAY`, or of category `Cat::Matrix`

Options

`Symbolic`

Prevents the conversion of the input data to floating-point numbers. Exact arithmetic is used.

`ReturnType`

Option, specified as `ReturnType = t`

Return the result as a matrix of domain type `t`. The following return types are available: `DOM_ARRAY`, `DOM_HFARRAY`, `matrix`, or `densematrix`.

Return Values

Depending on the type of the input matrix `axis`, the 3×3 rotation matrix is returned as a matrix of domain type `DOM_ARRAY`, `DOM_HFARRAY`, `Dom::Matrix()`, or `Dom::DenseMatrix()`.

numeric::singularvalues

Numerical singular values of a matrix

Syntax

```
numeric::singularvalues(A, <Hard | HardwareFloats | Soft | SoftwareFloats>)
```

Description

`numeric::singularvalues(A)` returns numerical singular values of the matrix `A`.

The singular values of an $m \times n$ matrix A are the $p = min(m, n)$ real nonnegative square roots of the eigenvalues of $A^H A$ (for $p = n$) or of $A A^H$ (for $p = m$). The Hermitian transpose A^H is the complex conjugate of the transpose of A.

`numeric::singularvalues` returns a list of real singular values $[d_1, \ldots, d_p]$ sorted by `numeric::sort`, i.e., $d_1 \geq \ldots \geq d_p \geq 0.0$.

All entries of `A` must be numerical. Numerical expressions such as e^{π}, $\sqrt{2}$ etc. are accepted and converted to floats. Non-numerical symbolic entries lead to an error.

`Cat::Matrix` objects, i.e., matrices `A` of a matrix domain such as `Dom::Matrix(…)` or `Dom::SquareMatrix(…)` are internally converted to arrays over expressions via `expr(A)`.

Note: Singular values are approximated with an *absolute* precision of $\frac{1}{10^{\mathrm{DIGITS}}}\, r$ where r is largest singular value of `A`. Consequently, large singular values should be computed correctly to `DIGITS` decimal places. The numerical approximations of small singular values are less accurate.

Singular values may also be computed via `map ( numeric::eigenvalues( A  A^H), sqrt )` or `map ( numeric::eigenvalues( A^H  A ), sqrt )`, respectively. The use of `numeric::singularvalues` avoids the costs of the matrix multiplication. Further,

the eigenvalue routine requires about twice as many DIGITS to compute small singular values with the same precision as numeric::singularvalues. Cf. “Example 2” on page 19-318.

Environment Interactions

The function is sensitive to the environment variable DIGITS, which determines the numerical working precision.

Examples

Example 1

The singular values of A and A^H coincide:

```
A := array(1..3, 1..2, [[1, 2*I], [2, 3],[3, sqrt(2)]]):
numeric::singularvalues(A)
```

```
[4.994802008, 2.012946323]
```

The Hermitian transpose $B = A^H$:

```
B := array(1..2, 1..3, [[1, 2, 3], [-2*I, 3, sqrt(2)]]):
numeric::singularvalues(B)
```

```
[4.994802008, 2.012946323]
```

```
delete A, B:
```

Example 2

We use numeric::eigenvalues to compute singular values:

```
A := matrix([[1/15, 2/15*I],
             [PI, 314159265358980/50000000000000*I],
             [2, 4*I]]):
```

The Hermitian transpose $B = A^H$ can be computed by the methods `conjugate` and `transpose` of the matrix domain:

```
B := A::dom::conjugate(A::dom::transpose(A)):
```

Note that $A^H A$ is positive semi-definite and cannot have negative eigenvalues. However, computing small eigenvalues is numerically ill-conditioned, and a small negative value occurs due to roundoff:

```
numeric::eigenvalues(B*A)
```

$$\left[69.37024423,\ -2.310493271\ 10^{-15}\right]$$

Consequently, an (incorrect) imaginary singular value is computed:

```
map(%, sqrt)
```

$$[8.32888013,\ 0.00000004806759065\ i]$$

We have to increase `DIGITS` in order to compute this value more accurately:

```
DIGITS := 22:
map(numeric::eigenvalues(B*A), sqrt)
```

$$\left[8.328880130465871055353,\ 3.293453726225542754196\ 10^{-15}\right]$$

With `numeric::singularvalues`, the standard precision suffices:

```
DIGITS := 10:
numeric::singularvalues(A, SoftwareFloats)
```

$$\left[8.32888013,\ 3.249076763\ 10^{-15}\right]$$

```
numeric::singularvalues(A, HardwareFloats)
```

$$\left[8.32888013,\ 3.6920369\ 10^{-15}\right]$$

```
delete A, B:
```

Example 3

We demonstrate the use of hardware floats. Hilbert matrices are notoriously ill-conditioned: the computation of the small singular values is subject to severe roundoff effects. In the following results, both with `HardwareFloats` as well as with `SoftwareFloats`, the small singular values are dominated by numerical roundoff. Consequently, the results with `HardwareFloats` differ from those with with `SoftwareFloats`:

```
numeric::singularvalues(linalg::hilbert(13))
```

$$\left[1.813830119,\ 0.396833076,\ \ldots,\ 8.878210699\ 10^{-16},\ 3.222901015\ 10^{-18}\right]$$

[1.813830119, 0.396833076, 0.04902941942, 0.004348755075, 0.0002951777135, 0.0000156237036, 0.0000006466418563, 0.00000002076321421, 0.000000005076551851, 9.141268657e-12, 1.143562234e-13, 8.877867351e-16, 7.878607674e-19]

```
A := linalg::hilbert(15):
numeric::singularvalues(A, HardwareFloats);
numeric::singularvalues(A, SoftwareFloats)
```

$$\left[1.845927746,\ 0.426627957,\ 0.05721209253,\ \ldots,\ 1.351581189\ 10^{-17},\ 5.696479572\ 10^{-18}\right]$$

$$\left[1.845927746,\ 0.426627957,\ 0.05721209253,\ \ldots,\ 9.682265893\ 10^{-19},\ 3.017915363\ 10^{-21}\right]$$

[1.845927746, 0.426627957, 0.05721209253, 0.005639834756, 0.0004364765944, 0.00002710853923, 0.000001361582242, 0.00000005528988481, 0.000000001802959758,

```
delete A:
```

Parameters

A

A numerical matrix of domain type DOM_ARRAY, DOM_HFARRAY, or of category Cat::Matrix

Options

Hard, HardwareFloats, Soft, SoftwareFloats

With Hard (or HardwareFloats), computations are done using fast hardware float arithmetic from within a MuPAD session. Hard and HardwareFloats are equivalent. With this option, the input data are converted to hardware floats and processed by compiled C code. The result is reconverted to MuPAD floats and returned to the MuPAD session.

With Soft (or SoftwareFloats) computations are dome using software float arithmetic provided by the MuPAD kernel. Soft and SoftwareFloats are equivalent. SoftwareFloats is used by default if the current value of DIGITS is larger than 15 and the input matrix A is not of domain type DOM_HFARRAY.

Compared to the SoftwareFloats used by the MuPAD kernel, the computation with HardwareFloats may be many times faster. Note, however, that the precision of hardware arithmetic is limited to about 15 digits. Further, the size of floating-point numbers may not be larger than approximately 10^{308} and not smaller than approximately 10^{-308}.

If no HardwareFloats or SoftwareFloats are requested explicitly, the following strategy is used: If the current value of DIGITS is smaller than 16 or if the matrix A is a

hardware float array of domain type DOM_HFARRAY, then hardware arithmetic is tried. If this is successful, the result is returned.

If the result cannot be computed with hardware floats, software arithmetic by the MuPAD kernel is tried.

If the current value of DIGITS is larger than 15 and the input matrix A is not of domain type DOM_HFARRAY, or if one of the options Soft, SoftwareFloats or Symbolic is specified, MuPAD computes the result with its software arithmetic without trying to use hardware floats first.

There may be several reasons for hardware arithmetic to fail:

- The current value of DIGITS is larger than 15.
- The data contains symbolic objects.
- The data contains numbers larger than 10^{308} or smaller than 10^{-308} that cannot be represented by hardware floats.

If neither HardwareFloats nor SoftwareFloats is specified, the user is not informed whether hardware floats or software floats are used.

If HardwareFloats are specified but fail due to one of the reasons above, a warning is issued that the (much slower) software floating-point arithmetic of the MuPAD kernel is used.

Note that HardwareFloats can only be used if all input data can be converted to floating-point numbers.

The trailing digits in floating-point results computed with HardwareFloats and SoftwareFloats may differ.

Note: For ill-conditioned matrices, the result is subject to roundoff errors. The results returned with HardwareFloats and SoftwareFloats may differ! See “Example 3” on page 19-320.

Return Values

Ordered list of real floating-point values.

Algorithms

The code implements standard numerical algorithms from the Handbook of Automatic Computation by Wilkinson and Reinsch.

numeric::singularvectors

Numerical singular value decomposition of a matrix

Syntax

```
numeric::singularvectors(A, options)
```

Description

`numeric::singularvectors(A)` and the equivalent call `numeric::svd(A)` return numerical singular values and singular vectors of the matrix `A`.

All entries of `A` must be numerical. Numerical expressions such as e^{π}, $\sqrt{2}$ etc. are accepted and converted to floats. Non-numerical symbolic entries lead to an error.

`Cat::Matrix` objects, i.e., matrices `A` of a matrix domain such as `Dom::Matrix(…)` or `Dom::SquareMatrix(…)` are internally converted to arrays over expressions via `expr(A)`.

The list `[U, d, V, res`$_U$`, res`$_V$`]` returned by `numeric::singularvectors` corresponds to the singular data of an $m \times n$ matrix A as described below.

Let V^H denote the Hermitian transpose of the matrix V, i.e., the complex conjugate of the transpose. The singular value decomposition of an $m \times n$ matrix A is a factorization $A = U\,D\,V^H$. D is an $m \times n$ "diagonal" matrix with real nonnegative entries $D_{ii} = d_i$, $i = 1, \ldots, p$ where $p = min(m, n)$:

$$D = \begin{pmatrix} d_1 & & 0 \\ & \cdots & \\ & & d_p \\ 0 & & 0 \end{pmatrix}$$

or

$$D = \begin{pmatrix} d_1 & & 0 \\ & \dots & \\ 0 & & d_p \; 0 \end{pmatrix},$$

respectively. The list $d = [d_1, \dots, d_p]$ returned by `numeric::singularvectors` are the "singular values" of A. They are sorted by `numeric::sort`, i.e., $d_1 \geq \dots \geq d_p \geq 0.0$.

U is a unitary $m \times m$ matrix. Its i-th column is an eigenvector of $A\,A^H$ associated with the eigenvalue d_i^2 ($d_i = 0$ for $i > p$). These are the "left singular vectors" of A. They are returned by `numeric::singularvectors` as a matrix of floating-point numbers.

V is a unitary $n \times n$ matrix. Its i-th column is an eigenvector of $A^H\,A$ associated with the eigenvalue d_i^2 ($d_i = 0$ for $i > p$). These are the "right singular vectors" of A. They are returned by `numeric::singularvectors` as an array of floating-point numbers. The matrix `V` is normalized such that, in each column, the first entry of absolute size larger than $\frac{1}{10^{\mathrm{DIGITS}}}$ is real and positive.

If no return type is specified via the option `ReturnType = t`, the domain type of the singular vectors U and V depends on the type of the input matrix `A`:

- The singular vectors of an array are returned as arrays.
- The singular vectors of an hfarray are returned as hfarrays.
- The singular vectors of a dense matrix of type `Dom::DenseMatrix()` are returned as dense matrices of type `Dom::DenseMatrix()` over the ring of MuPAD expressions.
- For all other matrices of category `Cat::Matrix`, the singular vectors are returned as matrices of type `Dom::Matrix()` over the ring of MuPAD expressions. This includes input matrices `A` of type `Dom::Matrix(…)`, `Dom::SquareMatrix(…)`, `Dom::MatrixGroup(…)` etc.

$res_U = [resU_1, \dots, resU_m]$ is a list of float residues associated with the left singular vectors:

$$\mathrm{resU}_i = \left\langle A^H\,u_i,\; A^H\,u_i \right\rangle - d_i^2,\; 1 \leq i \leq m.$$

Here, u_i is the (normalized) i-th column of `U`, $\langle \dots, \dots \rangle$ is the usual complex Euclidean scalar product and $d_i = 0$ for $p < i \leq m$.

$res_V = [resV_1, \ldots, resV_n]$ is a list of float residues associated with the right singular vectors:

$$\mathrm{resV}_i = \langle A\,v_p, A\,v_i \rangle - d_i^2,\ 1 \le i \le n$$

.

Here, v_i is the (normalized) i-th column of `V`, $d_i = 0$ for $p < i \le n$.

The residues res_U, res_V vanish for exact singular data U, d, V. Their sizes indicate the quality of the numerical data `U, d, V`.

Note: Singular values are approximated with an *absolute* precision of $\frac{1}{10^{\mathrm{DIGITS}}}\,r$, where r is the largest singular value of `A`. Consequently, large singular values should be computed correctly to `DIGITS` decimal places. The numerical approximations of small singular values are less accurate.

The singular values computed by `numeric::singularvectors` are identical to those computed by `numeric::svd`.

Singular data may also be computed via `[d2, U, resU] := numeric::eigenvectors(A*A^H)` or `[d2, V, resV] := numeric::eigenvectors(A^H*A)`, respectively. The list `d2` is related to the singular values by

$$\mathrm{d2} = \left[d_1^2, d_2^2, \ldots, d_p^2, 0, \ldots, 0\right]$$

.

The use of `numeric::singularvectors` avoids the costs of the matrix multiplication. Further, the eigenvector routine requires about twice as many `DIGITS` to compute the data associated with small singular values with the same precision as `numeric::singularvectors`. Also note that the normalization of `U` and `V` may be different.

Environment Interactions

The function is sensitive to the environment variable `DIGITS`, which determines the numerical working precision.

Examples

Example 1

Numerical expressions are converted to floats:

```
DIGITS := 5:
A := array(1..3, 1..2, [[1, PI], [2, 3], [3, exp(sqrt(2))]]):
[U, d, V, resU, resV] := numeric::singularvectors(A):
```

The singular data are:

```
U, d, V
```

$$\begin{pmatrix} 0.45729 & -0.88078 & 0.12293 \\ 0.51483 & 0.14947 & -0.84416 \\ 0.72515 & 0.44932 & 0.5218 \end{pmatrix}, [6.9986, 0.89905], \begin{pmatrix} 0.5233 & 0.85215 \\ 0.85215 & -0.5233 \end{pmatrix}$$

The small residues indicate that these results are not severely affected by roundoff:

```
resU, resV
```

$$\left[2.247\ 10^{-14}, 2.247\ 10^{-14}, 3.898\ 10^{-32}\right], \left[5.6175\ 10^{-15}, 5.6175\ 10^{-15}\right]$$

```
delete DIGITS, A, U, d, V, resU, resV:
```

Example 2

We demonstrate how to reconstruct a matrix from its singular data. With the specified `ReturnType`, the singular vectors are returned as matrices of type `Dom::Matrix()` and can be handled with the overloaded arithmetic:

```
DIGITS := 3:
A := array(1..2, 1..3, [[1.0, I, PI], [2, 3, I]]):
[U, d, V, resU, resV] := numeric::singularvectors(A, NoResidues,
     ReturnType = Dom::Matrix())
```

$$\left[\begin{pmatrix} 0.514 - 0.028\,i & -0.788 + 0.336\,i \\ 0.857 + 0.014\,i & 0.487 - 0.168\,i \end{pmatrix}, [3.9,\ 3.27],\right.$$

$$\left.\begin{pmatrix} 0.571 & 0.0568 & 0.819 \\ 0.652 - 0.121\,i & 0.55 + 0.0871\,i & -0.493 + 0.0785\,i \\ 0.418 - 0.242\,i & -0.81 + 0.174\,i & -0.236 + 0.157\,i \end{pmatrix}, \text{NIL}, \text{NIL}\right]$$

A "diagonal" matrix is built from the singular values:

```
d := matrix(2, 3, d, Diagonal)
```

$$\begin{pmatrix} 3.9 & 0 & 0 \\ 0 & 3.27 & 0 \end{pmatrix}$$

We use the methods `conjugate` and `transpose` of the matrix domain to compute the Hermitian transpose of `V` and reconstruct `A`. Numerical roundoff is eliminated via `numeric::complexRound`:

```
VH := V::dom::conjugate(V::dom::transpose(V)):
map(U*d*VH, numeric::complexRound)
```

$$\begin{pmatrix} 1.0 & 1.0\,i & 3.14 \\ 2.0 & 3.0 & 1.0\,i \end{pmatrix}$$

```
delete DIGITS, A, U, d, V, resU, resV, VH:
```

Example 3

We demonstrate the use of hardware floats. The following matrix A is degenerate: it has rank 1. For the double eigenvalue 0 of the matrix $A^H A$, different base vectors of the corresponding eigenspace are returned with `HardwareFloats` and `SoftwareFloats`, respectively:

```
A := array(1..2, 1..3, [[1, 2, 3], [30, 60, 90]]):
[U1, d1, V1, resU1, resV1] :=
      numeric::singularvectors(A, HardwareFloats):
[U2, d2, V2, resU2, resV2] :=
```

```
      numeric::singularvectors(A, SoftwareFloats):
V1, V2
```

$$\begin{pmatrix} 0.2672612419 & 0.5345224838 & 0.8017837257 \\ 0.5345224838 & -0.7745419206 & 0.3381871191 \\ 0.8017837257 & 0.3381871191 & -0.4927193213 \end{pmatrix},$$

$$\begin{pmatrix} 0.2672612419 & 0.9561828875 & 0.1195228609 \\ 0.5345224838 & -0.04390192219 & -0.8440132318 \\ 0.8017837257 & -0.289459681 & 0.5228345342 \end{pmatrix}$$

```
delete A, U1, d1, V1, resU1, resV1, U2, d2, V2, resU2, resV2:
```

Parameters

A

A numerical matrix of domain type DOM_ARRAY, DOM_HFARRAY, or of category Cat::Matrix.

Options

Hard, HardwareFloats, Soft, SoftwareFloats

With Hard (or HardwareFloats), computations are done using fast hardware float arithmetic from within a MuPAD session. Hard and HardwareFloats are equivalent. With this option, the input data are converted to hardware floats and processed by compiled C code. The result is reconverted to MuPAD floats and returned to the MuPAD session.

With Soft (or SoftwareFloats) computations are dome using software float arithmetic provided by the MuPAD kernel. Soft and SoftwareFloats are equivalent. SoftwareFloats is used by default if the current value of DIGITS is larger than 15 and the input matrix A is not of domain type DOM_HFARRAY.

Compared to the SoftwareFloats used by the MuPAD kernel, the computation with HardwareFloats may be many times faster. Note, however, that the precision of

hardware arithmetic is limited to about 15 digits. Further, the size of floating-point numbers may not be larger than approximately 10^{308} and not smaller than approximately 10^{-308}.

If no `HardwareFloats` or `SoftwareFloats` are requested explicitly, the following strategy is used: If the current value of `DIGITS` is smaller than 16 or if the matrix `A` is a hardware float array of domain type `DOM_HFARRAY`, then hardware arithmetic is tried. If this is successful, the result is returned.

If the result cannot be computed with hardware floats, software arithmetic by the MuPAD kernel is tried.

If the current value of `DIGITS` is larger than 15 and the input matrix `A` is not of domain type `DOM_HFARRAY`, or if one of the options `Soft`, `SoftwareFloats` or `Symbolic` is specified, MuPAD computes the result with its software arithmetic without trying to use hardware floats first.

There may be several reasons for hardware arithmetic to fail:

- The current value of `DIGITS` is larger than 15.
- The data contains symbolic objects.
- The data contains numbers larger than 10^{308} or smaller than 10^{-308} that cannot be represented by hardware floats.

If neither `HardwareFloats` nor `SoftwareFloats` is specified, the user is not informed whether hardware floats or software floats are used.

If `HardwareFloats` are specified but fail due to one of the reasons above, a warning is issued that the (much slower) software floating-point arithmetic of the MuPAD kernel is used.

Note that `HardwareFloats` can only be used if all input data can be converted to floating-point numbers.

The trailing digits in floating-point results computed with `HardwareFloats` and `SoftwareFloats` may differ.

Note: For ill-conditioned matrices, the result is subject to roundoff errors. The results returned with `HardwareFloats` and `SoftwareFloats` may differ! See “Example 3” on page 19-328.

NoLeftVectors

Suppresses the computation of left singular vectors

If only right singular vectors are required, this option may be used to suppress the computation of `U` and the corresponding residues $\texttt{res}_{\texttt{U}}$. The return values for these data are `NIL`.

Depending on the size of `U`, this option may speed up the computation considerably.

NoRightVectors

Suppresses the computation of right singular vectors

If only left singular vectors are required, this option may be used to suppress the computation of `V` and the corresponding residues $\texttt{res}_{\texttt{V}}$. The return values for these data are `NIL`.

Depending on the size of `V`, this option may speed up the computation considerably.

NoResidues

Suppresses the computation of error estimates

If no error estimates are required, this option may be used to suppress the computation of the residues $\texttt{res}_{\texttt{U}}$ and $\texttt{res}_{\texttt{V}}$. The return values for these data are `NIL`.

The alternative option name `NoErrors` used in previous MuPAD versions is still available.

ReturnType

Option, specified as `ReturnType = t`

Return the left and right singular vectors as matrices of domain type `t`. The following return types *t* are available: `DOM_ARRAY`, or `DOM_HFARRAY`, or `Dom::Matrix()`, or `Dom::DenseMatrix()`.

This option determines the domain type of the matrices containing the singular vectors.

NoWarning

Suppresses warnings

Return Values

List `[U, d, V, res_U, res_V]`. `U` is a unitary square float matrix whose columns are left singular vectors. The list `d` contains the singular values. `V` is a unitary square float matrix whose columns are right singular vectors. The lists of float residues $\texttt{res}_U$ and $\texttt{res}_V$ provide error estimates for the numerical data.

numeric::svd

Numerical singular value decomposition of a matrix

Syntax

```
numeric::svd(A, options)
```

Description

`numeric::svd(A)` and the equivalent call `numeric::singularvectors(A)` return numerical singular values and singular vectors of the matrix `A`.

All entries of `A` must be numerical. Numerical expressions such as e^{π}, $\sqrt{2}$ etc. are accepted and converted to floats. Non-numerical symbolic entries lead to an error.

`Cat::Matrix` objects, i.e., matrices `A` of a matrix domain such as `Dom::Matrix(…)` or `Dom::SquareMatrix(…)` are internally converted to arrays over expressions via `expr(A)`.

The list `[U, d, V, res`$_U$`, res`$_V$`]` returned by `numeric::svd` corresponds to the singular data of an $m \times n$ matrix A as described below.

Let V^H denote the Hermitian transpose of the matrix V, i.e., the complex conjugate of the transpose. The singular value decomposition of an $m \times n$ matrix A is a factorization $A = U\,D\,V^H$. D is an $m \times n$ "diagonal" matrix with real nonnegative entries $D_{ii} = d_i$, $i = 1, \ldots, p$ where $p = min(m, n)$:

$$D = \begin{pmatrix} d_1 & & 0 \\ & \cdots & \\ & & d_p \\ 0 & & 0 \end{pmatrix}$$

or

$$D = \begin{pmatrix} d_1 & & 0 \\ & \dots & \\ 0 & & d_p \; 0 \end{pmatrix},$$

respectively. The list $d = [d_1, \dots, d_p]$ returned by `numeric::svd` are the "singular values" of A. They are sorted by `numeric::sort`, i.e., $d_1 \geq \dots \geq d_p \geq 0.0$.

U is a unitary $m \times m$ matrix. Its i-th column is an eigenvector of $A\,A^H$ associated with the eigenvalue d_i^2 ($d_i = 0$ for $i > p$). These are the "left singular vectors" of A. They are returned by `numeric::svd` as a matrix of floating-point numbers.

V is a unitary $n \times n$ matrix. Its i-th column is an eigenvector of $A^H\,A$ associated with the eigenvalue d_i^2 ($d_i = 0$ for $i > p$). These are the "right singular vectors" of A. They are returned by `numeric::svd` as an array of floating-point numbers. The matrix `V` is normalized such that, in each column, the first entry of absolute size larger than $\frac{1}{10^{\text{DIGITS}}}$ is real and positive.

If no return type is specified via the option `ReturnType = t`, the domain type of the singular vectors U and V depends on the type of the input matrix `A`:

- The singular vectors of an array are returned as arrays.
- The singular vectors of an hfarray are returned as hfarrays.
- The singular vectors of a dense matrix of type `Dom::DenseMatrix()` are returned as dense matrices of type `Dom::DenseMatrix()` over the ring of MuPAD expressions.
- For all other matrices of category `Cat::Matrix`, the singular vectors are returned as matrices of type `Dom::Matrix()` over the ring of MuPAD expressions. This includes input matrices `A` of type `Dom::Matrix(…)`, `Dom::SquareMatrix(…)`, `Dom::MatrixGroup(…)` etc.

$res_U = [resU_1, \dots, resU_m]$ is a list of float residues associated with the left singular vectors:

$$\text{resU}_i = \left\langle A^H\,u_i,\, A^H\,u_i \right\rangle - d_i^2,\; 1 \leq i \leq m.$$

Here, u_i is the (normalized) i-th column of `U`, $\langle \dots, \dots \rangle$ is the usual complex Euclidean scalar product and $d_i = 0$ for $p < i \leq m$.

$res_V = [resV_1, \ldots, resV_n]$ is a list of float residues associated with the right singular vectors:

$$\mathrm{resV}_i = \langle A\,v_p, A\,v_i\rangle - d_i^2,\ 1 \le i \le n$$

.

Here, v_i is the (normalized) i-th column of `V`, $d_i = 0$ for $p < i \le n$.

The residues res_U, res_V vanish for exact singular data U, d, V. Their sizes indicate the quality of the numerical data `U, d, V`.

Note: Singular values are approximated with an *absolute* precision of $\frac{1}{10^{\mathrm{DIGITS}}}\,r$, where r is the largest singular value of `A`. Consequently, large singular values should be computed correctly to `DIGITS` decimal places. The numerical approximations of small singular values are less accurate.

The singular values computed by `numeric::svd` are identical to those computed by `numeric::singularvalues`.

Singular data may also be computed via `[d2, U, resU] := numeric::eigenvectors(A*A^H)` or `[d2, V, resV] := numeric::eigenvectors(A^H*A)`, respectively. The list `d2` is related to the singular values by

$$\mathrm{d2} = \left[d_1^2, d_2^2, \ldots, d_p^2, 0, \ldots, 0\right]$$

.

The use of `numeric::svd` avoids the costs of the matrix multiplication. Further, the eigenvector routine requires about twice as many `DIGITS` to compute the data associated with small singular values with the same precision as `numeric::singularvectors`. Also note that the normalization of `U` and `V` may be different.

Environment Interactions

The function is sensitive to the environment variable `DIGITS`, which determines the numerical working precision.

Examples

Example 1

Numerical expressions are converted to floats:

```
DIGITS := 5:
A := array(1..3, 1..2, [[1, PI], [2, 3], [3, exp(sqrt(2))]]):
[U, d, V, resU, resV] := numeric::singularvectors(A):
```

The singular data are:

```
U, d, V
```

$$\begin{pmatrix} 0.45729 & -0.88078 & 0.12293 \\ 0.51483 & 0.14947 & -0.84416 \\ 0.72515 & 0.44932 & 0.5218 \end{pmatrix}, [6.9986, 0.89905], \begin{pmatrix} 0.5233 & 0.85215 \\ 0.85215 & -0.5233 \end{pmatrix}$$

The small residues indicate that these results are not severely affected by roundoff:

```
resU, resV
```

$$\left[2.247\ 10^{-14}, 2.247\ 10^{-14}, 3.898\ 10^{-32}\right], \left[5.6175\ 10^{-15}, 5.6175\ 10^{-15}\right]$$

```
delete DIGITS, A, U, d, V, resU, resV:
```

Example 2

We demonstrate how to reconstruct a matrix from its singular data. With the specified `ReturnType`, the singular vectors are returned as matrices of type `Dom::Matrix()` and can be handled with the overloaded arithmetic:

```
DIGITS := 3:
A := array(1..2, 1..3, [[1.0, I, PI], [2, 3, I]]):
[U, d, V, resU, resV] := numeric::singularvectors(A, NoResidues,
     ReturnType = Dom::Matrix())
```

$$\left[\begin{pmatrix} 0.514 - 0.028\,i & -0.788 + 0.336\,i \\ 0.857 + 0.014\,i & 0.487 - 0.168\,i \end{pmatrix}, [3.9,\ 3.27],\right.$$

$$\left.\begin{pmatrix} 0.571 & 0.0568 & 0.819 \\ 0.652 - 0.121\,i & 0.55 + 0.0871\,i & -0.493 + 0.0785\,i \\ 0.418 - 0.242\,i & -0.81 + 0.174\,i & -0.236 + 0.157\,i \end{pmatrix}, \text{NIL}, \text{NIL}\right]$$

A "diagonal" matrix is built from the singular values:

```
d := matrix(2, 3, d, Diagonal)
```

$$\begin{pmatrix} 3.9 & 0 & 0 \\ 0 & 3.27 & 0 \end{pmatrix}$$

We use the methods `conjugate` and `transpose` of the matrix domain to compute the Hermitian transpose of `V` and reconstruct `A`. Numerical roundoff is eliminated via `numeric::complexRound`:

```
VH := V::dom::conjugate(V::dom::transpose(V)):
map(U*d*VH, numeric::complexRound)
```

$$\begin{pmatrix} 1.0 & 1.0\,i & 3.14 \\ 2.0 & 3.0 & 1.0\,i \end{pmatrix}$$

```
delete DIGITS, A, U, d, V, resU, resV, VH:
```

Example 3

We demonstrate the use of hardware floats. The following matrix A is degenerate: it has rank 1. For the double eigenvalue 0 of the matrix $A^H A$, different base vectors of the corresponding eigenspace are returned with `HardwareFloats` and `SoftwareFloats`, respectively:

```
A := array(1..2, 1..3, [[1, 2, 3], [30, 60, 90]]):
[U1, d1, V1, resU1, resV1] :=
      numeric::singularvectors(A, HardwareFloats):
[U2, d2, V2, resU2, resV2] :=
```

```
      numeric::singularvectors(A, SoftwareFloats):
V1, V2
```

$$\begin{pmatrix} 0.2672612419 & 0.5345224838 & 0.8017837257 \\ 0.5345224838 & -0.7745419206 & 0.3381871191 \\ 0.8017837257 & 0.3381871191 & -0.4927193213 \end{pmatrix},$$

$$\begin{pmatrix} 0.2672612419 & 0.9561828875 & 0.1195228609 \\ 0.5345224838 & -0.04390192219 & -0.8440132318 \\ 0.8017837257 & -0.289459681 & 0.5228345342 \end{pmatrix}$$

```
delete A, U1, d1, V1, resU1, resV1, U2, d2, V2, resU2, resV2:
```

Parameters

A

A numerical matrix of domain type DOM_ARRAY, DOM_HFARRAY, or of category Cat::Matrix.

Options

Hard, HardwareFloats, Soft, SoftwareFloats

With Hard (or HardwareFloats), computations are done using fast hardware float arithmetic from within a MuPAD session. Hard and HardwareFloats are equivalent. With this option, the input data are converted to hardware floats and processed by compiled C code. The result is reconverted to MuPAD floats and returned to the MuPAD session.

With Soft (or SoftwareFloats) computations are dome using software float arithmetic provided by the MuPAD kernel. Soft and SoftwareFloats are equivalent. SoftwareFloats is used by default if the current value of DIGITS is larger than 15 and the input matrix A is not of domain type DOM_HFARRAY.

Compared to the SoftwareFloats used by the MuPAD kernel, the computation with HardwareFloats may be many times faster. Note, however, that the precision of

hardware arithmetic is limited to about 15 digits. Further, the size of floating-point numbers may not be larger than approximately 10^{308} and not smaller than approximately 10^{-308}.

If no `HardwareFloats` or `SoftwareFloats` are requested explicitly, the following strategy is used: If the current value of `DIGITS` is smaller than 16 or if the matrix `A` is a hardware float array of domain type `DOM_HFARRAY`, then hardware arithmetic is tried. If this is successful, the result is returned.

If the result cannot be computed with hardware floats, software arithmetic by the MuPAD kernel is tried.

If the current value of `DIGITS` is larger than 15 and the input matrix `A` is not of domain type `DOM_HFARRAY`, or if one of the options `Soft`, `SoftwareFloats` or `Symbolic` is specified, MuPAD computes the result with its software arithmetic without trying to use hardware floats first.

There may be several reasons for hardware arithmetic to fail:

- The current value of `DIGITS` is larger than 15.
- The data contains symbolic objects.
- The data contains numbers larger than 10^{308} or smaller than 10^{-308} that cannot be represented by hardware floats.

If neither `HardwareFloats` nor `SoftwareFloats` is specified, the user is not informed whether hardware floats or software floats are used.

If `HardwareFloats` are specified but fail due to one of the reasons above, a warning is issued that the (much slower) software floating-point arithmetic of the MuPAD kernel is used.

Note that `HardwareFloats` can only be used if all input data can be converted to floating-point numbers.

The trailing digits in floating-point results computed with `HardwareFloats` and `SoftwareFloats` may differ.

Note: For ill-conditioned matrices, the result is subject to roundoff errors. The results returned with `HardwareFloats` and `SoftwareFloats` may differ! See “Example 3” on page 19-337.

NoLeftVectors

Suppresses the computation of left singular vectors

If only right singular vectors are required, this option may be used to suppress the computation of `U` and the corresponding residues $\texttt{res}_{\texttt{U}}$. The return values for these data are `NIL`.

Depending on the size of `U`, this option may speed up the computation considerably.

NoRightVectors

Suppresses the computation of right singular vectors

If only left singular vectors are required, this option may be used to suppress the computation of `V` and the corresponding residues $\texttt{res}_{\texttt{V}}$. The return values for these data are `NIL`.

Depending on the size of `V`, this option may speed up the computation considerably.

NoResidues

Suppresses the computation of error estimates

If no error estimates are required, this option may be used to suppress the computation of the residues $\texttt{res}_{\texttt{U}}$ and $\texttt{res}_{\texttt{V}}$. The return values for these data are `NIL`.

The alternative option name `NoErrors` used in previous MuPAD versions is still available.

ReturnType

Option, specified as `ReturnType = t`

Return the left and right singular vectors as matrices of domain type `t`. The following return types *t* are available: `DOM_ARRAY`, or `DOM_HFARRAY`, or `Dom::Matrix()`, or `Dom::DenseMatrix()`.

This option determines the domain type of the matrices containing the singular vectors.

NoWarning

Suppresses warnings

Return Values

List `[U, d, V, res_U, res_V]`. `U` is a unitary square float matrix whose columns are left singular vectors. The list `d` contains the singular values. `V` is a unitary square float matrix whose columns are right singular vectors. The lists of float residues $\texttt{res}_U$ and $\texttt{res}_V$ provide error estimates for the numerical data.

numeric::solve

Numerical solution of equations (the float attribute of solve)

Syntax

```
numeric::solve(eqs, <vars>, options)

float(holdsolve(eqs, <vars>, options))

float(freezesolve(eqs, <vars>, options))
```

Description

`numeric::solve` computes numerical solutions of equations. For polynomial equations, *all* solutions are returned. For non-polynomial equations, only *one* solution, if any, is returned unless the option `AllRealRoots` is used.

Note: Note that only for polynomial/rational equations *all* solutions are searched for. For non-polynomial/non-rational equations, only one solution, if any, is returned unless the option `AllRealRoots` is used.

If the equations contain non-polynomial expressions, it is in general not possible to isolate *all* roots numerically. Think of equations such as $\sin\left(\frac{1}{x}\right) = 0$ that have infinitely many real solutions around the origin! If a complete set of *all* real solutions of a single non-polynomial/non-rational equation in one unknown is desired, you may try the opton `AllRealRoots`. With this option, a heuristics tries to isolate all real solutions of the equation. This, however, is purely heuristical: there is no rigor in the algorithm and it is not guaranteed that all solutions are found. Alternatively, you may also use the routine `numeric::realroots` to isolate the intervals in which solutions may exist.

`numeric::solve` is a simple interface function unifying the functionality of the numerical solvers `numeric::fsolve`, `numeric::linsolve`, `numeric::polyroots`, and `numeric::polysysroots`. The return format of these routines is changed to make it consistent with the return values of the symbolic solver `solve`.

You may call the specialized numerical solvers directly. However, note the return types specific to each of these solvers.

`numeric::solve` classifies the equations as follows:

- If `eqs` is a single univariate polynomial equation, then it is directly passed to `numeric::polyroots`. Cf. "Example 2" on page 19-345. The roots are returned as a set or as a `Dom::Multiset` if `Multiple` is used.
- If `eqs` is a multivariate polynomial equation or a list or set of such equations, then the equations and the appropriate optional arguments are passed to either `numeric::linsolve` or `numeric::polysysroots`. Cf. "Example 3" on page 19-345. The roots are returned as a set or as a `Dom::Multiset` if `Multiple` is used.
- A rational equation or a set or list of rational equations is replaced by its/their numerator(s). Such equations are processed like polynomial equations.
- If `eqs` is a non-polynomial/non-rational equation or a set or list containing such an equation, then the equations and the appropriate optional arguments are passed to the numerical solver `numeric::fsolve`.

Note: For non-polynomial equations, only a single numerical root is returned, unless `AllRealRoots` is specified! Cf. "Example 4" on page 19-346.

Note: For non-polynomial equations, there must not be more equations than unknowns!

Using `Multiple` for non-polynomial equations leads to an error, unless the option `AllRealRoots` is specified, too!

Note: For systems of multivariate non-polynomial equations, MuPAD uses a Newton search. It must be able to evaluate the partial derivatives of the equations with respect to the variables to be solved for.

For a single univariate equation, first a bisectioning scheme with quadratic interpolation is used that does not require any differentiation of the equation. If

this is not successful, a Newton search is started that requires the derivative of the functions involved.

For convenience, also polynomials of domain type `DOM_POLY` are accepted, wherever an equation is expected.

Note: In contrast to the symbolic solver `solve`, the numerical solver does not react to properties of identifiers set via `assume`. To use these properties, call `float ( hold( solve )(arguments))` instead.

If the user does not specify indeterminates to be solved for, then the indeterminates are internally chosen by `numeric::indets(eqs)`.

Starting points such as `x = a` or search ranges such as `x = a..b` specified in `vars` are ignored if `eqs` is a polynomial equation or a system of polynomial equations.

Environment Interactions

The function is sensitive to the environment variable `DIGITS`, which determines the numerical working precision.

Examples

Example 1

The following three solver calls are equivalent:

```
eqs := {x^2 = sin(y), y^2 = cos(x)}:
numeric::solve(eqs, {x, y}),
float(hold(solve)(eqs, {x, y})),
float(freeze(solve)(eqs, {x,y}))
```

$$\{[x = -0.8517004887,\ y = 0.8116062151]\},\ \{[x = -0.8517004887,\ y = 0.8116062151]\},\ \{[x = -0.8517004887,\ y = 0.8116062151]\}$$

```
delete eqs:
```

Example 2

We demonstrate the root search for univariate polynomials:

```
numeric::solve(x^6 - PI*x^2 = sin(3), x)
```

$$\{-1.339589766,\ 1.339589766,\ 1.322706295\,i,\ 0.2120113223\,i,\ -0.2120113223\,i,\ -1.322706294\,i\}$$

Polynomials of type `DOM_POLY` can be used as input:

```
numeric::solve(poly((x - 1/3)^3, [x]), x)
```

$$\{0.3333333333\}$$

With `Multiple`, a `Dom::Multiset` is returned, indicating the multiplicity of the root:

```
numeric::solve(x^3 - x^2 + x/3 -1/27, x, Multiple)
```

$$\{[0.3333333333,\ 3]\}$$

Example 3

We demonstrate the root search for polynomial systems. Note that the symbolic solver `solve` is involved if the system is nonlinear. Symbolic parameters are accepted:

```
numeric::solve({x^2 + y^2 = 1, x^2 - y^2 = exp(z)}, {x, y})
```

$$\left\{\left[x = -0.7071067812\sqrt{e^z + 1.0},\ y = -0.7071067812\sqrt{1.0 - 1.0\,e^z}\right],\ \ldots,\ \left[x = 0.7071067812\sqrt{e^z + 1.0},\ y = 0.7071067812\sqrt{1.0 - 1.0\,e^z}\right]\right\}$$

{[x = 0.7071067812*sqrt(exp(z) + 1.0), y = -0.7071067812*sqrt(1.0 - 1.0*exp(z))], [x = 0.7071067812*sqrt(exp(z) + 1.0), y = 0.7071067812*sqrt(1.0 - 1.0*exp(z))], [x = -0.7071067812*sqrt(exp(z) + 1.0), y = 0.7071067812*sqrt(1.0 - 1.0*exp(z))], [x = -0.7071067812*sqrt(exp(z) + 1.0), y = -0.7071067812*sqrt(1.0 - 1.0*exp(z))]}

Example 4

We demonstrate the root search for non-polynomial equations. Without the option `AllRealRoots`, only one solution is searched for:

```
eq := exp(-x) - 10*x^2:
numeric::solve(eq, x)
```

$$\{0.2755302947\}$$

Since `numeric::solve` just calls the root finder `numeric::fsolve`, one may also use this routine directly. Note the different output format:

```
numeric::fsolve(eq, x)
```

$$[x = 0.2755302947]$$

The input syntax of `numeric::solve` and `numeric::fsolve` are identical, i.e., starting points, search ranges and options may be used. E.g., another solution of the previous equation is found by a restricted search over the interval $[-1, 0]$:

```
numeric::solve(eq, x = -1..0, RestrictedSearch)
```

$$\{-0.3829657727\}$$

We use the option `AllRealRoots` to isolate all real solutions of the equation:

```
numeric::solve(eq, x, AllRealRoots)
```

$$\{-5.827897796, -0.3829657727, 0.2755302947\}$$

With the following call we restrict the search to the negative semi-axis:

```
numeric::solve(eq, x = -infinity..0, AllRealRoots)
```

$$\{-5.827897796, -0.3829657727\}$$

Example 5

For the following system, `numeric::solve` finds the solution with positive y:

```
eqs := [exp(x) = 2*y^2, sin(y) = y*x^3]:
numeric::solve(eqs, [x, y])
```

$$\{[x = 0.9290711314,\ y = 1.125201325]\}$$

Another solution with negative y is found with an appropriate search range:

```
numeric::solve(eqs, [x = 1, y = -infinity..0])
```

$$\{[x = 0.9290711314,\ y = -1.125201325]\}$$

```
delete eq, eqs:
```

Parameters

eqs

An equation, a list, set, `array`, or `matrix` (`Cat::Matrix`) of equations. Also arithmetical expressions are accepted and interpreted as homogeneous equations.

vars

An unknown, a list of unknowns or a set of unknowns. Unknowns may be identifiers or indexed identifiers. Also equations of the form `x=a` or `x=a..b` are accepted wherever an unknown `x` is expected. This way, starting points and search ranges are specified for the numerical search. They must be numerical; infinite search ranges are accepted.

Options

AllRealRoots

Only to be used if `eqs` is a single equation in one unknown. With this option, a *heuristics* is used to find *all* real solutions of the equation.

Note: Note that there is no guarantee that all real solutions will be found.

Note: Interval arithmetic is used to isolate search intervals for the solutions. The expressions in `eqs` must be suitable for such arithmetic. Internally, the procedure `numeric::realroots` is called. See the help page of `numeric::realroots` for restrictions on the expressions in `eqs`.

Note: The equation must be suitable for evaluation with interval arithmetic. See `numeric::realroots` for restrictions on the expressions in the equation.

With `AllRealRoots`, only the additonal options `Multiple` and `NoWarning` have an effect. All other options such as `UnrestrictedSearch` etc. are ignored.

It is highly recommend to specify a search interval by a call such as `numeric::solve(f(x), x = a..b, AllRealRoots)`. In this case, only the real solutions between `a` and `b` are searched for.

The search for all real solutions may be very time consuming!

`Multiple`

Only to be used if `eqs` is a polynomial equation or a system of polynomial equations or in conjunction with the option `AllRealRoots`. With this option, information on the multiplicity of degenerate polynomial roots is returned.

It changes the return type from `DOM_SET` to `Dom::Multiset`.

`FixedPrecision`

Only to be used if `eqs` is a single univariate polynomial. It launches a quick numerical search with fixed internal precision.

It is passed to `numeric::polyroots`, which uses a numerical search with fixed internal precision. This is fast, but degenerate roots may be returned with a restricted precision. See the help page of `numeric::polyroots` for details.

`SquareFree`

Only to be used if `eqs` is a single univariate polynomial. Symbolic square free factorization is applied, before the numerical search starts.

It is passed to `numeric::polyroots`, which preprocesses the polynomial by a symbolic square free factorization. See the help page of `numeric::polyroots` for details.

`Factor`

Only to be used if `eqs` is a single univariate polynomial. Symbolic factorization is applied, before the numerical search starts.

It is passed to `numeric::polyroots`, which preprocesses the polynomial by a symbolic factorization. See the help page of `numeric::polyroots` for details.

`RestrictedSearch`

The numerical search is restricted to the search ranges specified in `vars`.

This option is passed to `numeric::fsolve`, which uses a corresponding search strategy when looking for roots in the search range specified in `vars`. It must be used only in conjunction with search range and only for non-polynomial equations.

See `numeric::fsolve` for details.

`UnrestrictedSearch`

The numerical search may return results outside the search ranges specified in `vars`.

This option is passed to `numeric::fsolve`, which uses a corresponding search strategy when looking for roots in the search range specified in `vars`. It must be use only in conjunction with search ranges and only for non-polynomial equations.

See `numeric::fsolve` for details.

`MultiSolutions`

Only to be used for non-polynomial equations in conjunction with `RestrictedSearch`. Several roots may be returned.

It is passed to `numeric::fsolve`, which returns a sequence of all roots found in the internal search. See the help page of `numeric::fsolve` for details.

`Random`

Only to be used for non-polynomial equations. With this option, several calls to `numeric::solve` may lead to different solutions of the equation(s).

It is passed to `numeric::fsolve` which switches to a random search strategy. See the help page of `numeric::fsolve` for details.

`NoWarning`

This option only has an effect when it is used for polynomial equations in conjunction with `AllRealRoots`. When you use `AllRealRoots`, warnings are issued if interval arithmetic indicates technical difficulties such as serious overestimation (for example, when encountering multiple roots). With this option, the warnings are suppressed.

Note: This option has an effect if `eqs` is a multivariate polynomial system or a univariate polynomial with a symbolic parameter.

In such a case, this option is passed to `numeric::polysysroots`.

Return Values

Set of numerical solutions. With the option `Multiple`, a set of domain type `Dom::Multiset` is returned.

More About

- "Solve Equations Numerically"

numeric::sort

Sort a numerical list

Syntax

```
numeric::sort(list)
```

Description

`numeric::sort(list)` sorts the elements in `list`.

The elements of the list are sorted such that their real parts are descending. Elements with the same real part are sorted from large absolute value to small absolute value. In case of a tie (i.e., two elements form a complex conjugate pair), the element with positive imaginary part comes first.

The elements of the list are converted to floating-point numbers via `float`. Elements that cannot be converted lead to an error.

This function is used to sort the return values of `numeric::eigenvalues`, `numeric::eigenvectors`, `numeric::polyroots`, `numeric::singularvalues`, and `numeric::singularvectors`.

Environment Interactions

The function is sensitive to the environment variable `DIGITS`.

Examples

Example 1

The elements in the sorted list have descending real parts:

```
numeric::sort([1, 2.0, I, -3, -I, PI, sqrt(2)])
```

$$[3.141592654, 2.0, 1.414213562, 1.0, 1.0\,i, -1.0\,i, -3.0]$$

In the following example, the sorting criterion does not seem to be satisfied. Elements with the same real part are supposed to be ordered from large absolute values to small absolute values:

```
x := sin(PI/3):
L := numeric::sort([x, sin(float(PI/3)) - I, x + I])
```

$$[0.8660254038 + 1.0\,i, 0.8660254038 - 1.0\,i, 0.8660254038]$$

This is explained by the fact that the floating-point numbers internally have a more accurate representation than shown on the screen. The real part of the last element is indeed a little bit smaller than the other real parts:

```
DIGITS := 20:
L
```

$$[0.86602540378443864469 + 1.0\,i, 0.86602540378443864469 - 1.0\,i, 0.86602540378443864469]$$

```
delete x, L, DIGITS:
```

Parameters

`list`

A list of numbers or numerical expressions

Return Values

Sorted list.

MuPAD Functions

`sort`

numeric::spectralradius

Spectral radius of a matrix

Syntax

```
numeric::spectralradius(A, <x0>, <n>, <mode>, <ReturnType = t>, <NoWarning>)
```

Description

`numeric::spectralradius(A)` returns data corresponding to the eigenvalue of the matrix `A` that has the largest absolute value.

`numeric::spectralradius` and `numeric::spectralRadius` are equivalent.

The spectral radius of a matrix with eigenvalues λ_i is $max(|\lambda_i|)$.

The return value `lambda` is an approximation of the corresponding eigenvalue: `abs(lambda)` is the spectral radius.

The return value `x` is the corresponding normalized eigenvector: $||x||_2 = 1$.

The return value $\text{residue} = ||A\,x - \text{lambda}\,x||_2$ provides an error estimate for the eigenvalue. For Hermitian matrices this is a rigorous upper bound for the error $|lambda - \lambda_{exact}|$, where λ_{exact} is the exact eigenvalue.

`numeric::spectralradius` implements the power method to compute the eigenvalue and the associated eigenvector defining the spectral radius: the vector iteration $x_i = \frac{A^i x_0}{\|A^i x_0\|_2}$ "converges" towards the eigenspace associated with the spectral radius. The starting vector x_0 is provided by the second argument of `numeric::spectralradius`. If no starting vector is provided by the user, a randomly chosen vector is used.

Note: The iteration does not converge (converges slowly), if the spectral radius is generated by several distinct eigenvalues with the same (similar) absolute value.

Internally, the iteration stops, when the approximation of the eigenvalue becomes stationary within the relative precision given by `DIGITS`. If this does not happen within *n* iterations, then a warning is issued and the present values are returned. Cf. “Example 4” on page 19-357.

Environment Interactions

The function is sensitive to the environment variable `DIGITS`, which determines the numerical working precision.

Examples

Example 1

We let the routine choose a random starting vector:

```
A := matrix(2, 2, [[10, 1], [1, 20]]):
numeric::spectralradius(A)
```

$$\left[20.09901951,\ \begin{pmatrix} 0.0985376181 \\ 0.9951333267 \end{pmatrix},\ 0.000000001332123191\right]$$

We define a starting vector as a 1-dimensional array and allow a maximum of 1000 internal iterations:

```
A := array(1..2, 1..2, [[1, 2], [5, -10]]):
x0 := array(1..2, [1, 1]):
numeric::spectralradius(A, x0, 1000)
```

$$\left[-10.84428877,\ (\ 0.1665007247\ \ -0.9860413321\ ),\ 7.808576008\ 10^{-11}\right]$$

Next, we use a list to specify a starting vector:

```
A := array(1..2, 1..2, [[I, 3], [3, I]]):
numeric::spectralradius(A, [1, 1], 1000)
```

$$[3.0 + 1.0\,i,\ [0.7071067812,\ 0.7071067812],\ 0.0]$$

```
delete A, x0:
```

Example 2

With the default setting of `DIGITS` = 10, the following result is computed using `HardwareFloats`.

```
A := hfarray(1..2, 1..2, [[10^4, 10^4], [50,  60]]):
x0 := array(1..2, [1, 1]):
numeric::spectralradius(A, x0)
```

```
[10050.0498, ( 0.9999874753  0.00500491737 ), 0.000000004820940092]
```

We request `SoftwareFloats` in the next call. Note the difference in the trailing digits:

```
numeric::spectralradius(A, x0, Soft)
```

```
[10050.0498, ( 0.9999874753  0.00500491737 ), 0.000000004820942201]
```

```
delete DIGITS, A, x0:
```

Example 3

The eigenvector that is returned can have various types. If no starting vector is provided, the type of the matrix determines the type of the eigenvector:

```
A:= array(1..2, 1..2, [[1, 2], [3, 4]]):
[l, x, residue]:= numeric::spectralradius(A);
```

```
[5.372281324, ( 0.4159735579  0.9093767091 ), 0.0000000002881934691]
```

```
domtype(x)
```

```
DOM_ARRAY
```

```
A:= hfarray(1..2, 1..2, [[1, 2], [3, 4]]):
[l, x, residue]:= numeric::spectralradius(A):
domtype(x)
```

```
DOM_HFARRAY
```

```
A:= matrix(2, 2, [[1, 2], [3, 4]]):
[l, x, residue]:= numeric::spectralradius(A):
domtype(x)
```

```
Dom::Matrix()
```

If a starting vector is provided, its type determines the type of the return vector:

```
A:= hfarray(1..2, 1..2, [[1, 2], [3, 4]]):
x0:= [1, 1]:
[l, x, residue]:= numeric::spectralradius(A, x0):
domtype(x)
```

```
DOM_LIST
```

```
x0:= array(1..2, [1, 1]):
[l, x, residue]:= numeric::spectralradius(A, x0):
domtype(x)
```

```
DOM_ARRAY
```

```
x0:= hfarray(1..2, [1, 1]):
[l, x, residue]:= numeric::spectralradius(A, x0):
domtype(x)
```

```
DOM_HFARRAY
```

```
x0:= matrix([1, 1]):
[l, x, residue]:= numeric::spectralradius(A, x0):
domtype(x)
```

```
Dom::Matrix()
```

The return type can be requested explicitly:

```
[l, x, residue] :=
  numeric::spectralradius(A, x0, ReturnType = DOM_LIST):
domtype(x)
```

```
DOM_LIST
```

```
[l, x, residue] :=
  numeric::spectralradius(A, x0, ReturnType = DOM_HFARRAY):
domtype(x)
```

DOM_HFARRAY

```
delete A, x0, l, x, residue:
```

Example 4

The following matrix has two distinct eigenvalues 1 and -1 of the same absolute value. The power method must fail.

```
A := array(1..2, 1..2, [[1, 0], [0, -1]]):
```

We allow a maximum of 1000 internal steps. The call results in a warning. The large residue also indicates that the power method did not converge:

```
numeric::spectralradius(A, [1, 1], 1000)
```

```
Warning: There is no convergence of vector iteration. [numeric::spectralradius]
```

$$[1.0, [0.7071067812, -0.7071067812], 1.414213562]$$

```
delete A:
```

Parameters

A

An $m \times m$ array of domain type `DOM_ARRAY` or `DOM_HFARRAY` or a matrix of category `Cat::Matrix`

x_0

A starting vector: a 1-dimensional array, or an hfarray, or a list of length m. Also 2-dimensional arrays (`array(1..m, 1..1, ...)`, `hfarray(1..m, 1..1, ...)`) and matrices representing vectors are accepted.

n

The maximal number of iterations: a positive integer. The default value is 1000.

mode

One of the flags Hard, HardwareFloats, Soft, or SoftwareFloats

Options

Hard, HardwareFloats, Soft, SoftwareFloats

With Hard (or HardwareFloats), computations are done using fast hardware float arithmetic from within a MuPAD session. Hard and HardwareFloats are equivalent. With this option, the input data are converted to hardware floats and processed by compiled C code. The result is reconverted to MuPAD floats and returned to the MuPAD session.

With Soft (or SoftwareFloats) computations are dome using software float arithmetic provided by the MuPAD kernel. Soft and SoftwareFloats are equivalent. SoftwareFloats is used by default if the current value of DIGITS is larger than 15 and the input matrix A is not of domain type DOM_HFARRAY.

Compared to the SoftwareFloats used by the MuPAD kernel, the computation with HardwareFloats may be many times faster. Note, however, that the precision of hardware arithmetic is limited to about 15 digits. Further, the size of floating-point numbers may not be larger than approximately 10^{308} and not smaller than approximately 10^{-308}.

If no HardwareFloats or SoftwareFloats are requested explicitly, the following strategy is used: If the current value of DIGITS is smaller than 16 or if the matrix A is a hardware float array of domain type DOM_HFARRAY, then hardware arithmetic is tried. If this is successful, the result is returned.

If the result cannot be computed with hardware floats, software arithmetic by the MuPAD kernel is tried.

If the current value of DIGITS is larger than 15 and the input matrix A is not of domain type DOM_HFARRAY, or if one of the options Soft, SoftwareFloats or Symbolic is

specified, MuPAD computes the result with its software arithmetic without trying to use hardware floats first.

There may be several reasons for hardware arithmetic to fail:

- The current value of `DIGITS` is larger than 15.
- The data contains symbolic objects.
- The data contains numbers larger than 10^{308} or smaller than 10^{-308} that cannot be represented by hardware floats.

If neither `HardwareFloats` nor `SoftwareFloats` is specified, the user is not informed whether hardware floats or software floats are used.

If `HardwareFloats` are specified but fail due to one of the reasons above, a warning is issued that the (much slower) software floating-point arithmetic of the MuPAD kernel is used.

Note that `HardwareFloats` can only be used if all input data can be converted to floating-point numbers.

The trailing digits in floating-point results computed with `HardwareFloats` and `SoftwareFloats` may differ.

`ReturnType`

Option, specified as `ReturnType = t`

Return the eigenvector associated with the spectral radius as a vector of domain type `t`. The following return types are available: `DOM_ARRAY`, or `DOM_HFARRAY`, or `DOM_LIST`, or `Dom::Matrix()`, or `Dom::DenseMatrix()`.

`NoWarning`

Suppresses warnings

Return Values

A list `[lambda, x, residue]` is returned. The floating-point number `lambda` is an approximation of the eigenvalue of largest absolute value. The vector `x` is a numerical

eigenvector corresponding to `lambda`. `residue` is a floating-point number indicating the numerical quality of `lambda` and `x`.

If no return type is requested via the `ReturnType` option, the type of the returned vector `x` coincides with the type of the input vector x_0 (i.e., it is a 1-dimensional array of type `DOM_ARRAY` or `DOM_HFARRAY`, respectively, or a list, or a column vector of type `matrix` or `densematrix`. If no starting vector is specified, the type of `x` is determined by the type of `A`.

numeric::spectralRadius

Spectral radius of a matrix

Syntax

```
numeric::spectralRadius(A, <x0>, <n>, <mode>, <ReturnType = t>, <NoWarning>)
```

Description

`numeric::spectralRadius(A)` returns data corresponding to the eigenvalue of the matrix `A` that has the largest absolute value.

`numeric::spectralRadius` and `numeric::spectralradius` are equivalent.

The spectral radius of a matrix with eigenvalues λ_i is $max(|\lambda_i|)$.

The return value `lambda` is an approximation of the corresponding eigenvalue: `abs(lambda)` is the spectral radius.

The return value `x` is the corresponding normalized eigenvector: $||x||_2 = 1$.

The return value $\text{residue} = ||A\,x - \text{lambda}\,x||_2$ provides an error estimate for the eigenvalue. For Hermitian matrices this is a rigorous upper bound for the error $|lambda - \lambda_{exact}|$, where λ_{exact} is the exact eigenvalue.

`numeric::spectralRadius` implements the power method to compute the eigenvalue and the associated eigenvector defining the spectral radius: the vector iteration $x_i = \frac{A^i x_0}{\|A^i x_0\|_2}$ "converges" towards the eigenspace associated with the spectral radius. The starting vector x_0 is provided by the second argument of `numeric::spectralradius`. If no starting vector is provided by the user, a randomly chosen vector is used.

Note: The iteration does not converge (converges slowly), if the spectral radius is generated by several distinct eigenvalues with the same (similar) absolute value.

Internally, the iteration stops, when the approximation of the eigenvalue becomes stationary within the relative precision given by `DIGITS`. If this does not happen within n iterations, then a warning is issued and the present values are returned. Cf. “Example 4” on page 19-365.

Environment Interactions

The function is sensitive to the environment variable `DIGITS`, which determines the numerical working precision.

Examples

Example 1

We let the routine choose a random starting vector:

```
A := matrix(2, 2, [[10, 1], [1, 20]]):
numeric::spectralradius(A)
```

$$\left[20.09901951,\ \begin{pmatrix} 0.0985376181 \\ 0.9951333267 \end{pmatrix},\ 0.000000001332123191\right]$$

We define a starting vector as a 1-dimensional array and allow a maximum of 1000 internal iterations:

```
A := array(1..2, 1..2, [[1, 2], [5, -10]]):
x0 := array(1..2, [1, 1]):
numeric::spectralradius(A, x0, 1000)
```

$$\left[-10.84428877,\ (\ 0.1665007247\ \ -0.9860413321\ ),\ 7.808576008\ 10^{-11}\right]$$

Next, we use a list to specify a starting vector:

```
A := array(1..2, 1..2, [[I, 3], [3, I]]):
numeric::spectralradius(A, [1, 1], 1000)
```

$$[3.0 + 1.0\,i,\ [0.7071067812,\ 0.7071067812],\ 0.0]$$

```
delete A, x0:
```

Example 2

With the default setting of `DIGITS` = 10, the following result is computed using `HardwareFloats`.

```
A := hfarray(1..2, 1..2, [[10^4, 10^4], [50,  60]]):
x0 := array(1..2, [1, 1]):
numeric::spectralradius(A, x0)
```

```
[10050.0498, ( 0.9999874753  0.00500491737 ), 0.000000004820940092]
```

We request `SoftwareFloats` in the next call. Note the difference in the trailing digits:

```
numeric::spectralradius(A, x0, Soft)
```

```
[10050.0498, ( 0.9999874753  0.00500491737 ), 0.000000004820942201]
```

```
delete DIGITS, A, x0:
```

Example 3

The eigenvector that is returned can have various types. If no starting vector is provided, the type of the matrix determines the type of the eigenvector:

```
A:= array(1..2, 1..2, [[1, 2], [3, 4]]):
[l, x, residue]:= numeric::spectralradius(A);
```

```
[5.372281324, ( 0.4159735579  0.9093767091 ), 0.0000000002881934691]
```

```
domtype(x)
```

```
DOM_ARRAY
```

```
A:= hfarray(1..2, 1..2, [[1, 2], [3, 4]]):
[l, x, residue]:= numeric::spectralradius(A):
domtype(x)
```

```
DOM_HFARRAY
```

```
A:= matrix(2, 2, [[1, 2], [3, 4]]):
[l, x, residue]:= numeric::spectralradius(A):
domtype(x)
```

```
Dom::Matrix()
```

If a starting vector is provided, its type determines the type of the return vector:

```
A:= hfarray(1..2, 1..2, [[1, 2], [3, 4]]):
x0:= [1, 1]:
[l, x, residue]:= numeric::spectralradius(A, x0):
domtype(x)
```

```
DOM_LIST
```

```
x0:= array(1..2, [1, 1]):
[l, x, residue]:= numeric::spectralradius(A, x0):
domtype(x)
```

```
DOM_ARRAY
```

```
x0:= hfarray(1..2, [1, 1]):
[l, x, residue]:= numeric::spectralradius(A, x0):
domtype(x)
```

```
DOM_HFARRAY
```

```
x0:= matrix([1, 1]):
[l, x, residue]:= numeric::spectralradius(A, x0):
domtype(x)
```

```
Dom::Matrix()
```

The return type can be requested explicitly:

```
[l, x, residue] :=
  numeric::spectralradius(A, x0, ReturnType = DOM_LIST):
domtype(x)
```

```
DOM_LIST
```

```
[l, x, residue] :=
  numeric::spectralradius(A, x0, ReturnType = DOM_HFARRAY):
domtype(x)
```

DOM_HFARRAY

```
delete A, x0, l, x, residue:
```

Example 4

The following matrix has two distinct eigenvalues 1 and -1 of the same absolute value. The power method must fail.

```
A := array(1..2, 1..2, [[1, 0], [0, -1]]):
```

We allow a maximum of 1000 internal steps. The call results in a warning. The large residue also indicates that the power method did not converge:

```
numeric::spectralradius(A, [1, 1], 1000)
```

```
Warning: There is no convergence of vector iteration. [numeric::spectralradius]
```

$$[1.0, [0.7071067812, -0.7071067812], 1.414213562]$$

```
delete A:
```

Parameters

A

An $m \times m$ array of domain type `DOM_ARRAY` or `DOM_HFARRAY` or a matrix of category `Cat::Matrix`

x_0

A starting vector: a 1-dimensional array, or an hfarray, or a list of length m. Also 2-dimensional arrays (`array(1..m, 1..1, ...)`, `hfarray(1..m, 1..1, ...)`) and matrices representing vectors are accepted.

n

The maximal number of iterations: a positive integer. The default value is 1000.

mode

One of the flags Hard, HardwareFloats, Soft, or SoftwareFloats

Options

Hard, HardwareFloats, Soft, SoftwareFloats

With Hard (or HardwareFloats), computations are done using fast hardware float arithmetic from within a MuPAD session. Hard and HardwareFloats are equivalent. With this option, the input data are converted to hardware floats and processed by compiled C code. The result is reconverted to MuPAD floats and returned to the MuPAD session.

With Soft (or SoftwareFloats) computations are dome using software float arithmetic provided by the MuPAD kernel. Soft and SoftwareFloats are equivalent. SoftwareFloats is used by default if the current value of DIGITS is larger than 15 and the input matrix A is not of domain type DOM_HFARRAY.

Compared to the SoftwareFloats used by the MuPAD kernel, the computation with HardwareFloats may be many times faster. Note, however, that the precision of hardware arithmetic is limited to about 15 digits. Further, the size of floating-point numbers may not be larger than approximately 10^{308} and not smaller than approximately 10^{-308}.

If no HardwareFloats or SoftwareFloats are requested explicitly, the following strategy is used: If the current value of DIGITS is smaller than 16 or if the matrix A is a hardware float array of domain type DOM_HFARRAY, then hardware arithmetic is tried. If this is successful, the result is returned.

If the result cannot be computed with hardware floats, software arithmetic by the MuPAD kernel is tried.

If the current value of DIGITS is larger than 15 and the input matrix A is not of domain type DOM_HFARRAY, or if one of the options Soft, SoftwareFloats or Symbolic is

specified, MuPAD computes the result with its software arithmetic without trying to use hardware floats first.

There may be several reasons for hardware arithmetic to fail:

- The current value of `DIGITS` is larger than 15.
- The data contains symbolic objects.
- The data contains numbers larger than 10^{308} or smaller than 10^{-308} that cannot be represented by hardware floats.

If neither `HardwareFloats` nor `SoftwareFloats` is specified, the user is not informed whether hardware floats or software floats are used.

If `HardwareFloats` are specified but fail due to one of the reasons above, a warning is issued that the (much slower) software floating-point arithmetic of the MuPAD kernel is used.

Note that `HardwareFloats` can only be used if all input data can be converted to floating-point numbers.

The trailing digits in floating-point results computed with `HardwareFloats` and `SoftwareFloats` may differ.

`ReturnType`

Option, specified as `ReturnType = t`

Return the eigenvector associated with the spectral radius as a vector of domain type `t`. The following return types are available: `DOM_ARRAY`, or `DOM_HFARRAY`, or `DOM_LIST`, or `Dom::Matrix()`, or `Dom::DenseMatrix()`.

`NoWarning`

Suppresses warnings

Return Values

A list `[lambda, x, residue]` is returned. The floating-point number `lambda` is an approximation of the eigenvalue of largest absolute value. The vector `x` is a numerical

eigenvector corresponding to `lambda`. `residue` is a floating-point number indicating the numerical quality of `lambda` and `x`.

If no return type is requested via the `ReturnType` option, the type of the returned vector `x` coincides with the type of the input vector x_0 (i.e., it is a 1-dimensional array of type `DOM_ARRAY` or `DOM_HFARRAY`, respectively, or a list, or a column vector of type `matrix` or `densematrix`. If no starting vector is specified, the type of `x` is determined by the type of `A`.

numeric::sum

Numerical approximation of sums (the Float attribute of Sum)

Syntax

```
numeric::sum(f(x), x = a .. b)
numeric::sum(f(x), x in {x1, x2, …})
numeric::sum(f(x), x = {x1, x2, …})
numeric::sum(f(x), x in RootOf(p(X), X))
numeric::sum(f(x), x = RootOf(p(X), X))
float(hold(sum)(f(x), x = a .. b))
float(hold(sum)(f(x), x in {x1, x2, …}))
float(hold(sum)(f(x), x = {x1, x2, …}))
float(hold(sum)(f(x), x in RootOf(p(X), X)))
float(hold(sum)(f(x), x = RootOf(p(X), X)))
float(freeze(sum)(f(x), x = a .. b))
float(freeze(sum)(f(x), x in {x1, x2, …}))
float(freeze(sum)(f(x), x = {x1, x2, …}))
float(freeze(sum)(f(x), x in RootOf(p(X), X)))
float(freeze(sum)(f(x), x = RootOf(p(X), X)))
```

Description

`numeric::sum(f(i), i=a..b)` computes a numerical approximation of $\sum_{i=a}^{b} f(i)$.

`numeric::sum(f(x), x ∈ {x1, x2, …})` computes a numerical approximation of $\sum_{x \in \{x_1, x_2, \ldots\}} f(x)$.

`numeric::sum(f(x), x in RootOf(p(X), X))` computes a numerical approximation of $\sum_{x \in \mathrm{RootOf}(p(X), X)} f(x)$.

The call `numeric::sum(…)` is equivalent to calling the `float` attribute of `sum` via `float ( hold( sum )(…))` or `float ( freeze( sum )(…))`.

If there are other symbolic parameters in $f(x)$, apart from the summation variable x, a symbolic sum is returned. Numerical expressions such as e^{π}, $\sqrt{2}$ etc. are accepted and converted to floating-point numbers.

Note: For infinite sums, the expression $f(i)$ with integer i must have an extension $f(x)$ to all real x in the interval $[a, b]$. Internally, the integral $\int_a^b f(x)\,dx$ is computed numerically and used in the approximation process.

Note: For finite sums, `numeric::sum` just returns `_plus ( float(f(i)$i=a..b))`. Note that numerical cancellation may occur! If `f(i)` does not contain floating-point numbers, cancellation can be avoided summing the symbolic terms by `_plus(f(i)$i=a..b)` instead. Cf. “Example 3” on page 19-372.

Convergence is fast, if $f(x)$ decays rapidly for `x -> infinity` or `| x | -> infinity`, respectively

---

Note: Convergence may be slow for alternating sums containing expressions such as $(-1)^i$. Such sums are also often subject to cancellation problems!

The call `numeric::sum(f(x), x = {x1, x2, …})` computes numerical approximations of `x1, x2` etc., substitutes these values into $f(x)$ and adds up the results. This process may be subject to cancellation problems!

The calls `numeric::sum(f(x), x ∈ {x1, x2, …})` and `numeric::sum(f(x), x = {x1, x2, …})` are equivalent.

The call `numeric::sum(f(x), x in RootOf(p(X), X))` computes numerical approximations of all roots of p, substitutes these values into $f(x)$ and adds up the results. Cf. “Example 4” on page 19-372. This process may be subject to cancellation problems!

The calls `numeric::sum(f(x), x in RootOf(p(X), X))` and `numeric::sum(f(x), x = RootOf(p(X), X))` are equivalent.

Environment Interactions

The function is sensitive to the environment variable `DIGITS`, which determines the numerical working precision.

Examples

Example 1

We demonstrate some equivalent calls for numerical summation:

```
numeric::sum(1/i!, i = 0..infinity),
float(hold(sum)(1/i!, i = 0..infinity)),
float(freeze(sum)(1/i!, i = 0..infinity))
```

$$2.718281828,\ 2.718281828,\ 2.718281828$$

The MuPAD symbolic summation `sum` does not find a simple representation of the following sum:

```
sum(1/i!/(i^2+1)!, i = 0..infinity)
```

$$\sum_{i=0}^{\infty} \frac{1}{(i^2+1)!\,i!}$$

The following float evaluation calls `numeric::sum`:

```
float(%)
```

$$1.504166713$$

The exact value of the following sum is $\pi\,coth(\pi)$:

```
numeric::sum(1/(1+i^2), i = -infinity..infinity) =
```

```
float(PI*coth(PI))
```

$$3.153348095 = 3.153348095$$

Example 2

The following sum cannot be evaluated numerically because of the symbolic parameter `x`:

```
numeric::sum(1/(x+i^2), i = -infinity..infinity)
```

$$\text{numeric::sum}\left(\frac{1}{i^2+x}, i = -\infty..\infty\right)$$

Example 3

We demonstrate numerical cancellation when summing the Taylor series for e^{-20}:

```
exp(-20.0) <> numeric::sum((-20)^i/i!, i = 0..100)
```

$$0.000000002061153622 \neq 0.000000002148938644$$

Also the infinite sum suffers from cancellation:

```
exp(-20.0) <> numeric::sum((-20)^i/i!, i = 0..infinity)
```

$$0.000000002061153622 \neq 0.000000002205327316$$

Cancellation can be avoided using a finite sum with exact terms:

```
exp(-20.0) = float(_plus((-20)^i/i! $ i = 0..100))
```

$$0.000000002061153622 = 0.000000002061153622$$

Example 4

The following call computes the numerical roots of the polynomial in the `RootOf` expression and sums over all the roots:

```
numeric::sum(exp(x)/x, x in RootOf(X^10 - X - PI, X))
```

```
9.681693381
```

Parameters

`f(x)`

An arithmetical expression in x

`i, x`

Summation variables: identifiers or indexed identifiers

`a, b`

Integers or ±`infinity` satisfying $a \le b$

x_1, x_2, …

Numerical expressions

`p(X)`

A univariate polynomial expression in X

`X`

The indeterminate of p: an identifier or an indexed identifier

Return Values

Floating point number or a symbolic expression of type `numeric::sum`.

Algorithms

Depending on whether the series is alternating or monotone, `numeric::sum` tries a number of strategies to calculate its limit: Levin's u transformation, the Euler-MacLaurin formula or van Wijngaarden's trick.

The Euler-MacLaurin formula is

$$\sum_{i=a}^{b} f(i) = \frac{f(a)+f(b)}{2} + \int_a^b f(x)\,\mathrm{d}x + \left(\sum_{m=1}^{M} \frac{B_{2\,m}}{(2\,m)!}\left(f(b)^{(2\,m-1)} - f(a)^{(2\,m-1)}\right)\right) + \cdots$$

involving the Bernoulli numbers $B_{2\,m}$.

numlib::checkPrimalityCertificate

Test the primality certificate

Syntax

```
numlib::checkPrimalityCertificate(certificate)
```

Description

`numlib::checkPrimalityCertificate` tests the certificate of primality returned by `numlib::proveprime`. For large prime numbers, the `numlib::proveprime` function generates certificates that provide all data you need for proving primality of a number by the Atkin-Goldwasser-Kilian-Morain algorithm. See “Example 1” on page 20-3.

For small prime numbers, `numlib::proveprime` does not return a certificate of primality. Instead, it returns `TRUE`. For nonprime numbers `numlib::proveprime` returns `FALSE`. In both cases, you do not need to use `numlib::checkPrimalityCertificate`.

Examples

Example 1

Use the `numlib::proveprime` function to check the primality of the number 1299709. The function returns the following sequence of lists. This sequence is the certificate of primality:

```
certificate := numlib::proveprime(1299709)
```

```
[1299709, 15, [2, 2, 2, 2, 2, 107, 379], 700619, 67686, 0, 796444, [107, 379]]
```

The certificate provides all data that you need for proving primality of 1299709 by the Atkin-Goldwasser-Kilian-Morain algorithm. You can substitute the numbers into the algorithm and verify the primality of the number. Alternatively, you can verify the certificate by using the `numlib::checkPrimalityCertificate` function:

```
numlib::checkPrimalityCertificate(certificate)
```

```
    TRUE
```

Parameters

`certificate`

A list or a sequence of lists returned by `numlib::proveprime`

Return Values

TRUE or FALSE

More About

- "Primes and Factorizations"

numlib::contfrac

Domain of continued fractions

Syntax

```
numlib::contfrac(x, <n>)
```

Description

`numlib::contfrac(x)` creates a continued fraction approximation for the real number `x`.

If `x` is an integer or a rational number and `n` is not specified, a continued fraction is returned that represents `x` exactly. Cf. “Example 1” on page 20-6.

Irrational numerical values `x` such as `1 + sqrt(2)` or `PI/3` are first converted to floating-point numbers. The first `n` significant decimals of floating-point numbers are taken into account. If `n` is not specified, `n = DIGITS` is used. The value of the continued fraction (given by `numlib::contfrac ::rational`) satisfies

$$\left|x - \text{numlib::contfrac::rational}(x)\right| \le |x| \ \frac{1}{10^n}.$$

Integers or rational numbers are also converted to floating point numbers, if a precision `n` is specified.

Objects of type `numlib::contfrac` can be handled by the usual arithmetical operations. They are sensitive to the environment variable `DIGITS` if floating-point numbers or irrational numerical values are involved.

Use `contfrac` to compute continued fraction approximations of expressions involving symbolic parameters.

Examples

Example 1

For rational numbers, exact representations are returned:

```
numlib::contfrac(123/1234)
```

$$\frac{1}{10+\frac{1}{30+\frac{1}{1+\frac{1}{3+\ldots}}}}$$

The rational representation (the second operand of the continued fraction) coincides with the original rational:

```
numlib::contfrac::rational(%), expr(%), op(%, 2)
```

$$\frac{123}{1234}, \frac{123}{1234}, \frac{123}{1234}$$

Restricted continued fraction approximations can be computed by passing a precision as second argument:

```
numlib::contfrac(123/1234, 2),
numlib::contfrac(123/1234, 3),
numlib::contfrac(123/1234, 5)
```

$$\frac{1}{10+\ldots}, \frac{1}{10+\frac{1}{30+\ldots}}, \frac{1}{10+\frac{1}{30+\frac{1}{1+\frac{1}{3+\ldots}}}}$$

$$\frac{1}{10+\ldots}, \frac{1}{10+\frac{1}{30+\ldots}}, \frac{1}{10+\frac{1}{30+\frac{1}{1+\frac{1}{3+\ldots}}}}$$

Example 2

The coefficients are extracted by the method `nthcoeff`:

```
cf := numlib::contfrac(12/123)
```

$$\frac{1}{10+\frac{1}{4+\ldots}}$$

```
nthcoeff(cf, 1), nthcoeff(cf, 2), nthcoeff(cf, 3), nthcoeff(cf, 4)
```

$$0,\ 10,\ 4,\ \text{FAIL}$$

The internal list of coefficients can also be queried via `op`:

```
op(cf, 1)
```

$$[0,\ 10,\ 4]$$

```
delete cf:
```

Example 3

`numlib::contfrac` can also compute continued fraction approximations of irrational numbers:

```
numlib::contfrac(PI, 2),
numlib::contfrac(PI, 4),
numlib::contfrac(PI, 5)
```

$$3+\frac{1}{7+\ldots},\ 3+\frac{1}{7+\frac{1}{15+\ldots}},\ 3+\frac{1}{7+\frac{1}{15+\frac{1}{1+\ldots}}}$$

$$3+\frac{1}{7+\ldots},\ 3+\frac{1}{7+\frac{1}{15+\ldots}},\ 3+\frac{1}{7+\frac{1}{15+\frac{1}{1+\ldots}}}$$

A finite continued fraction approximation may be regarded as an interval of numbers (the symbol … represents a number between 0 and 1):

```
numlib::contfrac::rationalInterval(numlib::contfrac(PI, 2));
```

$$\left[\frac{25}{8}, \frac{22}{7}\right]$$

```
float(%)
```

$$[3.125, 3.142857143]$$

Example 4

All basic arithmetical operations are available for continued fractions:

```
x := numlib::contfrac(PI, 3):
y := numlib::contfrac(1/12):
DIGITS:= 3: 3/x + sqrt(2)*y^(1/3)
```

$$1 + \cfrac{1}{1 + \cfrac{1}{1 + \cfrac{1}{2 + \cfrac{1}{1 + \cfrac{1}{26 + \ldots}}}}}$$

$$1 + \cfrac{1}{1 + \cfrac{1}{1 + \cfrac{1}{2 + \cfrac{1}{1 + \cfrac{1}{26 + \ldots}}}}}$$

```
delete x, y, DIGITS:
```

Example 5

We search for a simple continued fraction in an interval:

```
numlib::contfrac::convert(1/2 - 1/10^8, 1/2 + 1/10^8)
```

$$\cfrac{1}{2 + \ldots}$$

$$\frac{1}{2+\ldots}$$

```
numlib::contfrac::convert(PI, PI + 1/10^10)
```

$$3+\frac{1}{7+\frac{1}{15+\frac{1}{1+\frac{1}{292+\frac{1}{1+\frac{1}{1+\frac{1}{1+\ldots}}}}}}}$$

$$3+\frac{1}{7+\frac{1}{15+\frac{1}{1+\frac{1}{292+\frac{1}{1+\frac{1}{1+\frac{1}{1+\ldots}}}}}}}$$

Parameters

x

A real numerical expression

n

The number of significant digits: a positive integer greater one

Methods

Mathematical Methods

`_plus` — Sum of two continued fractions

```
_plus(x, y)
```

`_mult` — Product of two continued fractions

```
_mult(x, y)
```

`_invert` — Reciprocal of a continued fraction

```
_invert(x)
```

Inverting a continued fraction means a shift of the coefficients by one to the left or to the right.

If `x` is an exact representation of a rational number, the continued fraction expansion of the reciprocal is also an exact representation.

`_power` — Power of a continued fraction

```
_power(x, m)
```

Access Methods

`print` — Print a continued fraction

```
print(cf)
```

See Also

MuPAD Functions

`contfrac` | `numeric::rationalize`

numlib::contfracPeriodic

Periodic continued fraction expansions

Syntax

```
numlib::contfracPeriodic(p, q, n)
```

Description

`numlib::contfracPeriodic(p, q, n)` returns the continued fraction expansion of `p + q*sqrt(n)` as a sequence of two lists: the first one contains the non-periodic part, the second one contains the periodic part of the expansion.

The non-periodic part may be an empty list. No periodic part is returned for rational input, i.e., $q = 0$ or `n` square.

Examples

Example 1

The non-periodic part may start with zero. All other coefficients of a continued fraction expansion are positive:

```
numlib::contfracPeriodic(2/7, 1/7, 2)
```

```
[0, 2, 19], [1, 8, 1, 18]
```

The result agrees with that one of `contfrac`:

```
op(contfrac(2/7 + 1/7 *sqrt(2)), 1)
```

```
[0, 2, 19, 1, 8, 1, 18, 1, 8, 1]
```

Example 2

The golden mean is famous for its simple continued fraction expansion:

```
numlib::contfracPeriodic(1/2, 1/2, 5)
```

$$[], [1]$$

Example 3

Since 81 is a perfect square, there is no periodic part in the continued fraction expansion of its square root:

```
numlib::contfracPeriodic(0, 1, 81)
```

$$[9]$$

Parameters

p

A rational number

q

A rational number

n

A positive integer

Return Values

If $p + q\sqrt{n}$ is a rational number, then `numlib::contfracPeriodic` returns one list, otherwise two lists of integers.

Algorithms

A real number has a periodic continued fraction expansion if and only if it is of the form $p + q\sqrt{n}$.

See Also

MuPAD Functions

`numlib::contfrac` | `numlib::sqrt2cfrac`

numlib::cornacchia

Cornachia's algorithm

Syntax

```
numlib::cornacchia(a, b, m)
```

Description

`numlib::cornacchia(a, b, m)` returns all pairs of positive and relatively prime integers x, y that solve the equation $ax^2 + by^2 = m$.

The arguments `a`, `b`, `m` must be pairwise relatively prime.

Examples

Example 1

We compute the solutions to $3\,x^2 + 5\,y^2 = 74533332452454382449233$:

```
numlib::cornacchia(3, 5, 74533332452454382449233)
```

```
{[22457088474, 120847316879]}
```

Example 2

For non-prime `m`, there may be many solutions:

```
numlib::cornacchia(1, 4, 5*13*17*29*73)
```

```
{[103, 763], [151, 761], [217, 757], [521, 719], [553, 713], [583, 707], [809, 649], [887, 623],
  [1081, 541], [1127, 517], [1159, 499], [1367, 343], [1369, 341], [1463, 223], [1481, 191],
  [1529, 19]}
```

Parameters

a

A positive integer

b

A positive integer

m

A positive integer

Return Values

`numlib::cornacchia` returns a set each element of which is a list of two positive integers.

See Also

MuPAD Functions
`numlib::msqrts`

numlib::decimal

Infinite representation of rational numbers

Syntax

```
numlib::decimal(q)
```

Description

`numlib::decimal(q)` computes the decimal expansion of a rational number `q`.

If `q` is a nonnegative rational number whose decimal expansion is finite, then `numlib::decimal(q)` returns the expression sequence starting with the integral part of `q` and followed by the digits after the decimal point.

If `q` is a nonnegative rational number whose decimal expansion is infinite, then `numlib::decimal(q)` returns the expression sequence starting with the integral part of `q`, followed by the digits of the pre-period and terminated with a list, containing the digits of a minimal period.

Examples

Example 1

Computing the decimal expansion of 1999:

```
numlib::decimal(1999)
```

```
1999
```

Example 2

Computing the (finite) decimal expansion of $\frac{52187}{78125}$:

```
numlib::decimal(52187/78125)
```

$$0, 6, 6, 7, 9, 9, 3, 6$$

Example 3

Computing the (infinite) decimal expansion of $\frac{111}{7}$:

```
numlib::decimal(111/7)
```

$$15, [8, 5, 7, 1, 4, 2]$$

Example 4

Computing the (infinite) decimal expansion of $\frac{37}{28}$:

```
numlib::decimal(37/28)
```

$$1, 3, 2, [1, 4, 2, 8, 5, 7]$$

Parameters

q

Nonnegative rational number

Return Values

`numlib::decimal(q)` returns an expression sequence consisting of nonnegative integers or an expression sequence consisting of nonnegative integers and terminated by a list of nonnegative integers.

numlib::divisors

Divisors of an integer

Syntax

```
numlib::divisors(n)
```

Description

`numlib::divisors(n)` returns the list of positive divisors of `n`.

If `a` is a non-zero integer then `numlib::divisors(a)` returns the sorted list of all positive divisors of `a`.

`numlib::divisors(0)` returns `[0]`.

`numlib::divisors` returns an error if the argument evaluates to a number of wrong type.

Examples

Example 1

We compute the list of all positive divisors of 72:

```
numlib::divisors(72)
```

```
[1, 2, 3, 4, 6, 8, 9, 12, 18, 24, 36, 72]
```

Example 2

`numlib::divisors` returns the positive divisors of negative numbers, too:

```
numlib::divisors(-63)
```

```
[1, 3, 7, 9, 21, 63]
```

Parameters

n

Integer

Return Values

`numlib::divisors` returns a list of nonnegative integers.

Algorithms

Internally, `ifactor` is used for factoring `n`.

See Also

MuPAD Functions

`ifactor` | `numlib::numdivisors` | `numlib::numprimedivisors` | `numlib::primedivisors` | `numlib::tau` | `polylib::divisors`

numlib::factorGaussInt

Factorization of Gaussian integers

Syntax

```
numlib::factorGaussInt(n)
```

Description

`numlib::factorGaussInt(n)` returns the factorization of the Gaussian integer `n` into Gaussian primes. Among associate primes, that one with smallest polar angle is chosen.

Examples

Example 1

In the Gaussian integers, 3 remains prime while 5 does not:

```
numlib::factorGaussInt(3), numlib::factorGaussInt(5)
```

$$[1, 3, 1], [-i, 1+2\,i, 1, 2+i, 1]$$

Example 2

The argument to `numlib::factorGaussInt` may be any Gaussian integer, that is, every complex number of the form $a + b\,\mathrm{i}$ where a and b are integers:

```
numlib::factorGaussInt(2+2*I)
```

$$[-i, 1+i, 3]$$

Parameters

n

An integer, or a complex number whose real and imaginary part are integers

Return Values

`numlib::factorGaussInt` returns a list `[u, p1, a1, ..., pk, ak]` where u is a unit in the Gaussian integers, the p_i are Gaussian primes and the a_i are positive integers, such that $n = u\left(\prod_{i=1}^{k} p_i^{a_i}\right)$.

Algorithms

The function `ifactor` is used to factor the norm; this step takes most of the running time. Hence, the running time of the algorithm mainly depends on the size of the prime factors of the norm of `n`.

See Also

MuPAD Functions
`factor`

numlib::fibonacci

Fibonacci numbers

Syntax

```
numlib::fibonacci(n)
```

Description

`numlib::fibonacci(n)` returns the `n`-th Fibonacci number.

If `n` is a nonnegative integer then `numlib::fibonacci(n)` returns the `n`-th Fibonacci number.

`numlib::fibonacci` returns an error if the argument evaluates to a number of wrong type. `numlib::fibonacci` returns the unevaluated function call if `n` does not evaluate to a number.

Examples

Example 1

We compute the 201st Fibonnacci number:

```
numlib::fibonacci(201)
```

```
453973694165307953197296969697410619233826
```

Parameters

n

A nonnegative integer

Return Values

Nonnegative integer, or the function call with its arguments evaluated.

Algorithms

The n-th Fibonacci number F_n is defined by the recursion formula $F_0 = 0$, $F_1 = 1$, and $F_{n+2} = F_n + F_{n+1}$.

`numlib::fibonacci` uses quadratic recursion formulas.

numlib::fromAscii

Decoding of ASCII codes

Syntax

```
numlib::fromAscii(listOfCodes)
```

Description

If `L` is a list of ASCII codes then `numlib::fromAscii(L)` returns the string coded by `L`.

ASCII codes of non-printable characters, i. e., codes between `0` and `8` and between `11` and `31`, are ignored.

`numlib::fromAscii` returns an error if its argument is not a list of integers between `0` and `127`, i. e., not a list of legal ASCII codes.

Examples

Example 1

Non-printable characters are ignored, but tabulator and newline characters are decoded.

```
L := [0,1,2,3,9,10,31,10,9,32,45,32,101,105,110,32,
            84,101,115,116,32,61,32,97,32,116,101,115,116]:

numlib::fromAscii(L)
```

```
"            - ein Test = a test"
```

Parameters

`listOfCodes`

A list of ASCII codes

Return Values

String

See Also

MuPAD Functions
`numlib::toAscii`

numlib::g_adic

G-adic representation of a nonnegative integer

Syntax

```
numlib::g_adic(number, base)
```

Description

`numlib::g_adic(0, g)` returns `[0]`.

`numlib::g_adic` returns an error if the arguments evaluate to numbers which are not both of the correct type.

If `a` is a natural number and `g` is an integer such that $|g| > 1$, `numlib::g_adic(a, g)` returns the `g`-adic representation of `a` as a list $[a_0, \ldots, a_r]$ such that

$$a = a_0 + a_1\, g + a_2\, g^2 + \ldots + a_r\, g^r$$

and $0 \le a_i < |g|$ für $i = 0, \ldots, r - 1$ and $0 < a_r < |g|$.

Examples

Example 1

Computing the dyadic representation of 1994:

```
numlib::g_adic(1994, 2)
```

```
[0, 1, 0, 1, 0, 0, 1, 1, 1, 1, 1]
```

Example 2

Computing the hexadecimal representation of 2001:

```
numlib::g_adic(2001, 16)
```

```
[1, 13, 7]
```

Parameters

`number`

An nonnegative integer

`base`

An integer with absolute value is greater than 1

Return Values

List of nonnegative integers, or the function call with evaluated arguments if one of the arguments is not a number.

See Also

MuPAD Functions

`genpoly` | `int2text` | `text2int`

numlib::ichrem

Chinese remainder theorem for integers

Syntax

```
numlib::ichrem(a, m)
```

Description

`numlib::ichrem(a,m)` returns the least nonnegative integer x such that $x \equiv a_i \pmod{m_i}$ for $i = 1, \ldots, nops(m)$ if such a number exists; otherwise `numlib::ichrem(a,m)` returns `FAIL`.

The entries in `m` need not be pairwise coprime.

`numlib::ichrem(a,m)` returns an error if `a` is not a list of integers or `m` is not a list of natural numbers or `a` and `m` are not lists of the same length.

Examples

Example 1

Here the moduli are pairwise coprime. In this case, a solution always exists:

```
numlib::ichrem([2,3,2],[3,5,7])
```

```
23
```

Example 2

Here the moduli are not pairwise coprime, and a solution does not exist:

```
numlib::ichrem([5,6,8],[20,21,22])
```

```
FAIL
```

Example 3

Also here the moduli are not pairwise coprime, but a solution nevertheless exists:

```
numlib::ichrem([5,6,7],[20,21,22])
```

```
4605
```

Parameters

a

A list of integers

m

A list of natural numbers of the same length as `a`

Return Values

Either a nonnegative integer or `FAIL`.

See Also

MuPAD Functions

`numlib::lincongruence`

numlib::igcdmult

Extended Euclidean algorithm for integers

Syntax

```
numlib::igcdmult(par1, par2, …)
```

Description

`numlib::igcdmult` is an extension of the kernel function `igcdex`.

`numlib::igcdmult` returns an error if the arguments evaluate to numbers which are not all of the correct type.

For integers `a_1,a_2,...,a_n`, `numlib::igcdmult(a_1,a_2,...,a_n)` returns a list $[d, v_1, \ldots, v_n]$ of integers such that `d` is the nonnegative greatest common divisor of `a_1,a_2,...,a_n` and `d = a_1*v_1 + a_2*v_2 + ...+ a_n*v_n`.

For integers `a_1,a_2,...,a_n`, `numlib::igcdmult(a_1,a_2,...,a_n)` returns a list $[d, v_1, \ldots, v_n]$ of integers such that `d` is the nonnegative greatest common divisor of `a_1,a_2,...,a_n` and `d = a_1*v_1 + a_2*v_2 + ...+ a_n*v_n`.

Examples

Example 1

Computing the greatest non-negative common divisor d of 455, 385, 165, 273 and integers v_1, v_2, v_3, v_4 such that $d = 455\,v_1 + 385\,v_2 + 165\,v_3 + 273\,v_4$:

```
numlib::igcdmult(455,385,165,273)
```

$$[1, -7630, 9156, -327, 2]$$

Parameters

`par1`

Integer

`par2, …`

Integers

Return Values

List of integers, or the function call with evaluated arguments if some argument is not a number.

See Also

MuPAD Functions

`igcd` | `igcdex`

numlib::invphi

Inverse of the Euler phi function

Syntax

```
numlib::invphi(n)
```

Description

`numlib::invphi(n)` computes all positive integers `i` with $\varphi(i) = n$.

Examples

Example 1

We compute all numbers `i` with $\varphi(i) = 500$:

```
s := numlib::invphi(500)
```

```
[625, 753, 1004, 1250, 1506]
```

Test for correctness:

```
map(s, numlib::phi)
```

```
[500, 500, 500, 500, 500]
```

Parameters

n

A positive integer

Return Values

List of positive integer numbers.

See Also

MuPAD Functions

`numlib::phi`

numlib::ispower

Test for perfect powers

Syntax

```
numlib::ispower(n)
```

Description

`numlib::ispower(n)` tests whether `n` is of the form a^k for some integers a, k with a, $k \geq 2$.

`numlib::ispower` returns `FALSE` if `n` is not a perfect power.

Among several pairs (a, k) for which $n = a^k$, that one with minimal a is returned.

Examples

Example 1

This number is a perfect power:

```
numlib::ispower(1977326743)
```

```
7, 11
```

This number is not a perfect power:

```
numlib::ispower(1977326744)
```

```
FALSE
```

Parameters

n

An integer

Return Values

`numlib::ispower` returns a sequence of two positive integers greater than 1, or `FALSE` if `n` is not a perfect power.

See Also

MuPAD Functions
`_power` | `ifactor` | `isqrt`

numlib::isquadres

Test for quadratic residues

Syntax

```
numlib::isquadres(a, m)
```

Description

If the integer number `a` is a quadratic residue modulo the natural number `m`numlib::isquadres(a,m) returns `TRUE`, and if `a` is a quadratic non-residue modulo `m`numlib::isquadres(a,m) returns `FALSE`.

If `a` and `m` are not coprime `numlib::isquadres(a,m)` returns an error.

`numlib::isquadres` returns an error if the arguments evaluate to numbers which are not both of the correct type.

`numlib::isquadres` returns the function call with its arguments evaluated if the arguments do not evaluate to numbers.

Examples

Example 1

132132 is a quadratic residue modulo 3231227:

```
numlib::isquadres(132132, 3231227)
```

```
    TRUE
```

Example 2

222222 is a quadratic non-residue modulo 324899:

```
numlib::isquadres(222222,324899)
```

```
    FALSE
```

Example 3

37 is a quadratic residue modulo 48884:

```
numlib::isquadres(37,48884)
```

```
    TRUE
```

Parameters

a

An integer

m

A natural number coprime to a

Return Values

`numlib::isquadres` returns `TRUE`, `FALSE`, or the function call with its arguments evaluated.

See Also

MuPAD Functions

`numlib::jacobi` | `numlib::legendre` | `numlib::msqrts`

numlib::issqr

Test for perfect squares

Syntax

```
numlib::issqr(a)
```

Description

`numlib::issqr(a)` returns `TRUE` if `a` is the square of an integer, and `FALSE` otherwise.

Examples

Example 1

361 is the square of 19:

```
numlib::issqr(361)
```

```
    TRUE
```

Example 2

362 is not a square:

```
numlib::issqr(362)
```

```
    FALSE
```

Example 3

Negative integers are not squares:

```
numlib::issqr(-361)
```

```
FALSE
```

Parameters

a

An integer

Return Values

`numlib::issqr` returns `TRUE`, `FALSE`, or the unevaluated call.

See Also

MuPAD Functions

`isqrt` | `numlib::ispower` | `sqrt`

numlib::jacobi

Jacobi symbol

Syntax

```
numlib::jacobi(a, m)
```

Description

`numlib::jacobi(a,m)` returns the Jacobi symbol `(a | m)`.

`numlib::jacobi` returns an error if one of its arguments evaluates to a number of wrong type.

Examples

Example 1

Computing the Jacobi symbol `(222222 | 304679)`:

```
numlib::jacobi(222222, 304679)
```

```
-1
```

Example 2

Computing the Jacobi-Symbol `(222222 | 324889)`:

```
numlib::jacobi(222222, 324899)
```

```
1
```

Example 3

Computing the Jacobi symbol `(222222 | 333333)`:

```
numlib::jacobi(222222, 333333)
```

```
    0
```

Parameters

a

An integer

m

An odd positive integer

Return Values

`numlib::jacobi(a,m)` returns 0, 1, or -1, or the function call with evaluated arguments if one of the arguments is not a number.

Algorithms

`numlib::jacobi` doesn't use `ifactor`.

If a is an integer and m is an odd integer not coprime to a then by definition the Jacobi Symbol `(a | m)` is zero.

See Also

MuPAD Functions

`numlib::isquadres` | `numlib::legendre`

numlib::Lambda

Von Mangoldt's function

Syntax

```
numlib::Lambda(m)
```

Description

`numlib::Lambda(m)` returns the value of von Mangoldt's function at `m`.

It is an error if `m` is a number but not a natural number.

If `m` is not a number, `numlib::Lambda` returns the unevaluated function call.

Examples

Example 1

`numlib::Lambda` takes on non-zero values only for prime powers:

```
numlib::Lambda(49)
```

$$\ln(7)$$

```
numlib::Lambda(48)
```

$$0$$

Example 2

`numlib::Lambda` returns the function call if its argument is not a number:

```
numlib::Lambda(3+n^4)
```

```
numlib::Lambda(n^4 + 3)
```

Parameters

`m`

Arithmetical expression

Return Values

`numlib::Lambda` returns an arithmetical expression

Algorithms

The function value of `Lambda` at `m` is defined to be $\log p$ if $m = p^n$ for some prime number p and some positive integer n, and to be zero for positive integers that are not prime powers.

See Also

MuPAD Functions

`numlib::ispower`

numlib::lambda

Carmichael function

Syntax

```
numlib::lambda(n)
```

Description

`numlib::lambda(n)` returns the value of the Carmichael function at `n`.

If `m` is a natural number then `numlib::lambda(m)` returns the value of the Carmichael function in `m`, i. e., the maximal order of an element in the group of units modulo `m`.

`numlib::lambda` returns an error if the argument evaluates to a number of wrong type. `numlib::lambda` returns the function call with its argument evaluated if `m` is not a number.

Examples

Example 1

We compute the value of the Carmichael function λ in 97:

```
numlib::lambda(97)
```

```
96
```

Example 2

We compute the value of the Carmichael function λ in 96:

```
numlib::lambda(96)
```

```
8
```

Parameters

n

A natural number

Return Values

`numlib::lambda(n)` returns a natural number, or the function call with its argument evaluated.

Algorithms

Internally, `ifactor` is used for factoring `n`.

See Also

MuPAD Functions

`numlib::order` | `numlib::phi`

numlib::legendre

Legendre symbol

Syntax

```
numlib::legendre(a, p)
```

Description

`numlib::legendre(a, p)` returns the Legendre symbol `(a | p)`.

`numlib::legendre` returns an error if one of its arguments evaluates to a number of wrong type.

`numlib::legendre` returns the function call with evaluated arguments if at least one of its arguments does not evaluate to a number.

Examples

Example 1

Computing the Legendre symbol `(132132 | 3231277)`:

```
numlib::legendre(132132,3231227)
```

```
1
```

Example 2

Computing the Legendre symbol `(132131 | 3231277)`:

```
numlib::legendre(132131,3231227)
```

```
-1
```

Example 3

Computing the Legendre symbol `(-303 | 101)`:

```
numlib::legendre(-303,101)
```

```
    0
```

Parameters

a

An integer

p

An odd prime

Return Values

`numlib::legendre(a,p)` returns `-1`, `0`, `1`, or the function call with evaluated arguments.

Algorithms

If p is an odd prime and if a is an integer divisible by p then by definition the Legendre symbol `(a | p)` is zero.

See Also

MuPAD Functions

`numlib::isquadres` | `numlib::jacobi`

numlib::lincongruence

Linear congruence

Syntax

```
numlib::lincongruence(a, b, m)
```

Description

`numlib::lincongruence(a,b,m)` returns an error if one of the arguments evaluates to a number of wrong type.

For integers `a` and `b` and a non-zero integer `m` `numlib::lincongruence(a,b,m)` returns the sorted list of all solutions $x \in \{0, 1, \ldots, m - 1\}$ of the linear congruence $a\,x \equiv b \pmod{m}$ if this congruence is solvable. Otherwise `FAIL` is returned.

For integers `a` and `b` and a non-zero integer `m` `numlib::lincongruence(a,b,m)` returns the sorted list of all solutions $x \in \{0, 1, \ldots, m - 1\}$ of the linear congruence $a\,x \equiv b \pmod{m}$ if this congruence is solvable. Otherwise `FAIL` is returned.

Examples

Example 1

A linear congruence possessing one solution:

```
numlib::lincongruence(7,19,23)
```

```
[6]
```

Example 2

A linear congruence possessing several solutions:

```
numlib::lincongruence(77,209,253)
```

```
[6, 29, 52, 75, 98, 121, 144, 167, 190, 213, 236]
```

Example 3

A linear congruence possessing no solutions:

```
numlib::lincongruence(77,208,253)
```

```
FAIL
```

Parameters

a

An integer

b

An integer

m

A non-zero integer

Return Values

`numlib::lincongruence(a,b,m)` returns a list of nonnegative integers if the linear congruence is solvable.

`numlib::lincongruence(a,b,m)` returns `FAIL` if the linear congruence is not solvable.

`numlib::lincongruence(a,b,m)` returns the function call with its arguments evaluated if one of the arguments is a symbolic expression.

See Also

MuPAD Functions
`numlib::ichrem` | `numlib::mroots` | `numlib::msqrts`

numlib::mersenne

Mersenne primes

Syntax

```
numlib::mersenne(n)
```

```
numlib::mersenne()
```

Description

`numlib::mersenne()` returns the list of known Mersenne primes `p`. For these numbers, the Mersenne number 2^p - 1 is prime.

`numlib::mersenne(n)` returns the `n`th currently known Mersenne prime. The numbers of the Mersenne primes after the 40th prime can change in the future. More Mersenne primes might be found.

Examples

Example 1

The following primes p are known to have the property that the Mersenne number 2^p - 1 is prime:

```
numlib::mersenne()
```

```
[2, 3, 5, 7, 13, 17, 19, 31, 61, 89, 107, 127, 521, 607, 1279, 2203, 2281, 3217, 4253, 4423, 9689,
  9941, 11213, 19937, 21701, 23209, 44497, 86243, 110503, 132049, 216091, 756839, 859433,
  1257787, 1398269, 2976221, 3021377, 6972593, 13466917, 20996011, 24036583, 25964951,
  30402457, 32582657, 37156667, 42643801, 43112609, 57885161]
```

Example 2

Display the `10`th Mersenne prime:

```
numlib::mersenne(10)
```

```
    89
```

Return Values

Natural number or a list of natural numbers.

References

See `http://www.mersenne.org/`

numlib::moebius

Möbius function

Syntax

```
numlib::moebius(n)
```

Description

`numlib::moebius(n)` returns the value of the Möbius function at `n`.

`numlib::moebius` returns an error if the argument evaluates to a number of wrong type.

If `n` is a natural number `numlib::moebius(n)` returns the value of the Möbius function in `n`.

If `n` is not a number, `numlib::moebius(n)` returns the function call with its argument evaluated.

Examples

Example 1

Computing the value of the Möbius function μ at 99937:

```
numlib::moebius(99937)
```

```
    0
```

Example 2

`numlib::moebius` works for arbitrarily large integers:

```
numlib::moebius(45397369416530795319729696969741061923382 6)
```

-1

Parameters

n

A natural number

Return Values

`numlib::moebius(n)` returns a nonnegative integer.

Algorithms

Internally, `ifactor` is used for factoring `n`.

See Also

MuPAD Functions
`numlib::lambda` | `numlib::phi`

numlib::mroots

Modular roots of polynomials

Syntax

```
numlib::mroots(P, m)
```

Description

`numlib::mroots(P,m)` returns an error if `P` is not a polynomial over the integers or `m` is not a natural number.

For a univariate polynomial `P` over the integers and for a natural number `m` the function call `numlib::mroots(P,m)` returns the sorted list of all integers $x \in \{0, 1, \ldots, m - 1\}$ such that $P(x) \equiv 0 \pmod{m}$.

For a multivariate polynomial `P`, `numlib::mroots(P, m)` returns a lexicographically sorted list of all lists $[x_1, \ldots, x_n]$ of integers between 0 and m - 1 such that $P(x_1, \ldots, x_n) \equiv 0 \pmod{m}$.

For a univariate polynomial `P` over the integers and for a natural number `m` the function call `numlib::mroots(P,m)` returns the sorted list of all integers $x \in \{0, 1, \ldots, m - 1\}$ such that $P(x) \equiv 0 \pmod{m}$.

For a multivariate polynomial `P`, `numlib::mroots(P, m)` returns a lexicographically sorted list of all lists $[x_1, \ldots, x_n]$ of integers between 0 and m - 1 such that $P(x_1, \ldots, x_n) \equiv 0 \pmod{m}$.

Examples

Example 1

Defining a polynomial

```
P := poly(3*T^7 + 2*T^2 + T - 17, [T])
```

$$\text{poly}(3\,T^7 + 2\,T^2 + T - 17, [T])$$

and computing its roots modulo 1751:

```
numlib::mroots(P, 1751)
```

$$[221, 260, 612, 736, 1127, 1496]$$

The polynomial `P` doesn't have roots modulo 1994:

```
numlib::mroots(P, 1994)
```

$$[]$$

Example 2

We use `numlib::mroots` to find all points on a particular elliptic curve modulo 13:

```
numlib::mroots(poly(y^2 - x^3 - x - 2, [x, y]), 13)
```

$$[[1, 2], [1, 11], [2, 5], [2, 8], [6, 4], [6, 9], [7, 1], [7, 12], [9, 5], [9, 8], [12, 0]]$$

Parameters

`P`

A polynomial over the integers

`m`

A natural number

Return Values

If `P` is univariate, `numlib::mroots` returns a list of nonnegative integers. If `P` has more than one variable, `numlib::mroots` returns a list of lists of nonnegative integers.

Algorithms

`numlib::mroots` uses `factor`.

See Also

MuPAD Functions
`numlib::lincongruence` | `numlib::msqrts`

numlib::msqrts

Modular square roots

Syntax

```
numlib::msqrts(a, m)
```

Description

`numlib::msqrts(a,m)` returns the list of all integers $x \in \{0, 1, \ldots, m - 1\}$ such that $x^2 \equiv a \pmod{m}$.

Examples

Example 1

Computing the square roots of 132132 modulo 3231227:

```
numlib::msqrts(132132,3231227)
```

```
[219207, 3012020]
```

Example 2

There are no square roots of 222222 modulo 324899:

```
numlib::msqrts(222222,324899)
```

```
[]
```

Example 3

48884 is a composite number, so a number can have more than two square roots modulo 48884:

```
numlib::msqrts(37,48884)
```

```
[383, 585, 23857, 24059, 24825, 25027, 48299, 48501]
```

Parameters

a

An integer

m

A natural number relatively prime to `a`

Return Values

`numlib::msqrts(a,m)` returns a list of nonnegative integers

Algorithms

`numlib::msqrts` uses D. Shanks' algorithm RESSOL.

See Also

MuPAD Functions

`numlib::lincongruence` | `numlib::mroots`

numlib::numdivisors

Number of divisors of an integer

Syntax

```
numlib::numdivisors(n)
```

Description

`numlib::numdivisors(n)` returns the number of positive divisors of `n`.

`numlib::numdivisors(0)` returns `0`.

`numlib::numdivisors` returns the function call with evaluated argument if the argument is not a number.

`numlib::numdivisors` returns an error if the argument evaluates to a number of wrong type.

`numlib::numdivisors` is the same function as `numlib::tau`.

Examples

Example 1

We compute the number of positive divisors of the number 6746328388800 (one of the highly composite numbers studied by S. Ramanujan in 1915):

```
numlib::numdivisors(6746328388800)
```

```
10080
```

Parameters

n

An integer

Return Values

`numlib::numdivisors(n)` returns a nonnegative integer.

Algorithms

Internally, `ifactor` is used for factoring `n`.

See Also

MuPAD Functions

`numlib::divisors` | `numlib::numprimedivisors` | `numlib::primedivisors`

numlib::numprimedivisors

Number of prime factors of an integer

Syntax

```
numlib::numprimedivisors(n)
```

Description

`numlib::numprimedivisors(n)` returns the number of prime factors of the integer `n`, counted without multiplicity.

`numlib::numprimedivisors` and `numlib::omega` are synonyms.

`numlib::numprimedivisors(0)` returns `0`.

`numlib::numprimedivisors` returns the function call with evaluated argument if the argument is not a number.

`numlib::numprimedivisors` returns an error if the argument evaluates to a number of wrong type.

Examples

Example 1

We compute the number of primes dividing 6746328388800:

```
numlib::numprimedivisors(6746328388800)
```

```
9
```

Parameters

n

An integer

Return Values

`numlib::numprimedivisors(n)` returns a nonnegative integer.

Algorithms

Internally, `ifactor` is used for factoring `n`.

See Also

MuPAD Functions

`numlib::numdivisors` | `numlib::omega` | `numlib::primedivisors`

numlib::omega

Number of prime factors of an integer

Syntax

```
numlib::omega(n)
```

Description

`numlib::omega(n)` returns the number of prime factors of the integer `n`, counted without multiplicity.

`numlib::numprimedivisors` and `numlib::omega` are synonyms.

`numlib::omega(0)` returns `0`.

`numlib::omega` returns the function call with evaluated argument if the argument is not a number.

`numlib::omega` returns an error if the argument evaluates to a number of wrong type.

Examples

Example 1

We compute the number of primes dividing 6746328388800:

```
numlib::numprimedivisors(6746328388800)
```

```
    9
```

Parameters

`n`

An integer

Return Values

`numlib::numprimedivisors(n)` returns a nonnegative integer.

Algorithms

Internally, `ifactor` is used for factoring `n`.

See Also

MuPAD Functions

`numlib::numdivisors` | `numlib::numprimedivisors` | `numlib::primedivisors`

numlib::Omega

Number of prime divisors (with multiplicity)

Syntax

```
numlib::Omega(a)
```

Description

`numlib::Omega(a)` returns, for a given positive integer `a`, the finite sum $\sum_p \alpha(p, a)$,

where p runs through all primes, and $\alpha(p, a)$ denotes the highest exponent for which p^α divides `a`.

Examples

Example 1

In contrast to `numlib::numprimedivisors`, the prime factor 2 of 120 is counted thrice:

```
numlib::Omega(120)
```

```
5
```

The same happens here:

```
numlib::Omega(8)
```

```
3
```

Parameters

a

Positive integer

Return Values

`numlib::Omega` returns a positive integer.

See Also

MuPAD Functions
`numlib::numprimedivisors`

numlib::order

Order of a residue class

Syntax

```
numlib::order(a, m)
```

Description

`numlib::order(a,m)` returns the order of the residue class modulo `m` of `a` in the group of units modulo `m` if `a` and `m` are coprime.

`numlib::order(a,m)` returns the function call with its arguments evaluated if `a` or `m` is not a number.

`numlib::order` returns an error if one of the arguments evaluates to a number of wrong type.

Examples

Example 1

We compute the order of the residue class of 23 in the unit group modulo 2161:

```
numlib::order(23, 2161)
```

```
2160
```

Example 2

We compute the order of all elements in the unit group modulo 13:

```
map([$ 1..12],numlib::order,13)
```

```
[1, 12, 3, 6, 4, 12, 12, 4, 3, 6, 12, 2]
```

Example 3

The residue class of 7 is not a unit in the ring $\mathbb{Z}$ modulo 21:

```
numlib::order(7,21)
```

```
FAIL
```

Parameters

a

An integer

m

A natural number

Return Values

`numlib::order(a,m)` returns a natural number if `a` is coprime to `m`, and `FAIL` if `a` is not coprime to `m`.

Algorithms

`numlib::order` uses `ifactor` and `numlib::phi`.

See Also

MuPAD Functions

`numlib::lambda` | `numlib::phi`

numlib::phi

Euler phi function

Syntax

```
numlib::phi(n)
```

Description

`numlib::phi(n)` calculates the Euler φ function of the argument `n`, i.e. the number of numbers smaller than $|n|$ which are relatively prime to `n`. Cf. “Example 1” on page 20-70.

`numlib::phi` returns an error if the argument is a number but not an integer unequal to zero.

`numlib::phi` returns the function call with evaluated arguments if the argument is not a number. Cf. “Example 2” on page 20-70.

Examples

Example 1

`numlib::phi` works on integers unequal zero:

```
numlib::phi(-7), numlib::phi(10)
```

```
6, 4
```

Example 2

`numlib::phi` is returned as a function call with evaluated argument:

```
x := a: numlib::phi(x)
```

numlib::phi(*a*)

Parameters

n

Integer not equal to zero

Return Values

`numlib::phi` returns a positive integer, if the argument evaluates to an integer unequal zero. If the argument cannot be evaluate to a number, the function call with evaluated arguments is returned .

Overloaded By

n

See Also

MuPAD Functions
`numlib::invphi`

numlib::pi

Number of primes up to a given bound

Syntax

```
numlib::pi(x)
```

Description

`numlib::pi(x)` returns the number of primes not exceeding *x*.

If the argument `x` is a real number (an integer, rational, or floating-point number), then the number of primes below `x` is returned. If `x` is a complex number, `numlib::pi` stops with an error. For every other kind of arithmetical expression `x`, an unevaluated call is returned.

`numlib::pi` becomes slightly faster if the internal prime number table is large. `ifactor(PrimeLimit)` displays the limit of the internal prime number table; it can be set by the user via the command line flag `-L`.

Internally, a fast kernel function with constant memory consumption is used for the computation.

Examples

Example 1

There are two primes less or equal 3:

```
numlib::pi(3)
```

```
2
```

Example 2

Also larger inputs can be handled fast:

```
numlib::pi(150000000)
```

```
8444396
```

Example 3

Floating point arguments are allowed, too.

```
numlib::pi(28.72)
```

```
9
```

Parameters

x

An arithmetical expression

Return Values

Non-negative integer or an unevaluated call to `numlib::pi`

Algorithms

A Lehmer-type algorithm is used, with no precomputed sieve array and no remember tables. In contrast to the algorithm in “Computing π: The Meissel-Lehmer method”, this means constant memory consumption, at the price of slowness.

References

[1] Lagarias, J.C., V.S. Miller, and A.M. Odlyzko. “Computing π: The Meissel-Lehmer method”, Math. Comp., Vol. 44, No. 170 (1985), pp. 537-560

See Also

MuPAD Functions
`isprime` | `ithprime` | `nextprime` | `prevprime`

numlib::proveprime

Primality proving using elliptic curves

Syntax

```
numlib::proveprime(n)
```

Description

`numlib::proveprime(n)` tests whether `n` is a prime. Unlike `isprime`, `numlib::proveprime` always returns a correct answer.

`numlib::proveprime` returns the following values:

- `TRUE` when it can prove that the number is a prime.
- `FALSE` when it can prove that the number is not a prime.
- `FAIL` when it cannot prove that the number is a prime and cannot prove otherwise. In such cases, the input most likely is a prime.
- A primality certificate, which is a list or a sequence of lists containing proof for the primality of the number. Typically, `numlib::proveprime` returns primality certificates for very large numbers.

A primality certificate is a sequence of lists of the form [N, D, l_m, a, b, x, y, l_s], where

- N is a pseudoprime
- D is an integer (fundamental discriminant)
- l_m is a list of prime factors
- a, b, x, y are integers modulo N
- l_s is another list of prime factors (subset of the factors in l_m)

`numlib::checkPrimalityCertificate` checks primality certificates produced by `numlib::proveprime`.

Examples

Example 1

Proving that 1159523 is prime can be reduced to proving that 10343 is prime:

```
certificate := numlib::proveprime(1159523)
```

```
[1159523, 7, [2, 2, 2, 2, 7, 10343], 1012280, 1061361, 0, 726669, [10343]]
```

Example 2

Typically, the primality of the input is reduced to the primality of a smaller integer, the primality of that integer is reduced to the primality of an even smaller integer, and so on.

```
numlib::proveprime(179424673)
```

```
[179424673, 7, [2, 2, 2, 2, 11213771], 116768436, 77845624, 1, 110562161, [11213771]],
  [11213771, 7, [2, 2, 2, 2, 487, 1439], 9255809, 9908463, 2, 1041453, [487, 1439]]
```

Use `numlib::checkPrimalityCertificate` to check the result:

```
numlib::checkPrimalityCertificate(%)
```

```
TRUE
```

Parameters

n

Positive integer.

Return Values

`TRUE`, `FALSE`, `FAIL`, or a list or sequence of lists.

References

`numlib::proveprime` implements the Atkin-Goldwasser-Kilian-Morain algorithm for proving primality. For information about primality proving and this particular algorithm, see:

`ifactor` | `isprime` | `ithprime` | `nextprime` | `prevprime`

numlib::primedivisors

Prime factors of an integer

Syntax

```
numlib::primedivisors(n)
```

Description

`numlib::primedivisors(n)` returns a list containing the different prime divisors of the integer `n`.

If `a` is a non-zero integer then, `numlib::primedivisors(a)` returns the sorted list of the different prime divisors of `a`.

`numlib::primedivisors(0)` returns `[0]`.

`numlib::primedivisors` returns the function call with evaluated argument if the argument is not a number.

`numlib::primedivisors` returns an error if the argument evaluates to a number of wrong type.

Examples

Example 1

We compute the list of prime divisors of the number 6746328388800 (one of the highly composite numbers studied by S. Ramanujan in 1915):

```
numlib::primedivisors(6746328388800)
```

```
[2, 3, 5, 7, 11, 13, 17, 19, 23]
```

Parameters

n

An integer

Return Values

`numlib::primedivisors(n)` returns a list of nonnegative integers.

Algorithms

Internally, `ifactor` is used for factoring `n`.

See Also

MuPAD Functions

`ifactor` | `isprime` | `numlib::divisors` | `numlib::numdivisors` | `numlib::numprimedivisors` | `numlib::proveprime`

numlib::primroot

Primitive roots

Syntax

```
numlib::primroot(m)
```

```
numlib::primroot(a, m)
```

Description

`numlib::primroot(m)` returns the least positive primitive root modulo `m` if there exist primitive roots modulo `m`.

`numlib::primroot(a, m)` returns the least primitive root modulo `m` not smaller than `a` if there exist primitive roots modulo `m`.

Examples

Example 1

We compute the least positive primitive root modulo the prime number 40487:

```
numlib::primroot(40487)
```

```
     5
```

Example 2

We compute the least primitive root modulo $40487^2 = 1639197169$:

```
numlib::primroot(1639197169)
```

```
     10
```

Example 3

Now we compute least primitive root modulo 40487 which is >=111111111:

```
numlib::primroot(111111111,40487)
```

```
111111116
```

Example 4

There are no primitive roots modulo 324013370:

```
numlib::primroot(324013370)
```

```
FAIL
```

Parameters

a

An integer

m

A natural number

Return Values

`numlib::primroot` returns an integer or `FAIL`.

Algorithms

`numlib::primroot` uses `ifactor`.

See Also

MuPAD Functions
`numlib::order`

numlib::reconstructRational

Rational number reconstruction

Syntax

```
numlib::reconstructRational(a,n)
```

Description

`numlib::reconstructRational(a,n)` returns two integers `p,q` of absolute value smaller than `sqrt(n/2)` with `p` congruent to `a*q` modulo `n`. It returns `FAIL` if such `p,q` do not exist.

`numlib::reconstructRational(a,n)` returns `p,q` by solving $p \equiv a\,q \pmod{n}$.

The solution `p,q` satisfies the following conditions: `p` is strictly between `-sqrt(n/2)` and `sqrt(n/2)`, `q` is strictly between `0` and `sqrt(n/2)`.

If several pairs `p,q` satisfy these conditions, then their ratios `p/q` are the same. In such case, `numlib::reconstructRational` returns the smallest of these pairs.

Examples

Example 1

Solve this linear congruence: $p \equiv 7\,q \pmod{12}$.

```
numlib::reconstructRational(7, 12)
```

$$2, 2$$

Modulo 98, the same congruence has no small solution. The solution `p=7, q=1` is not small enough as `7` is not smaller than `sqrt(98/2)` but just equal.

```
numlib::reconstructRational(7, 98)
```

```
FAIL
```

Example 2

Rational number reconstruction is mostly used as the last step of a modular algorithm. For example, find the greatest common divisors of the following polynomials.

```
f:=  poly(x^5 + 22/35*x^3 + 3/8*x^2 + 3/35*x + 9/56, [x]):
g:= poly(x^5 + 2/5*x^4 + 22/35*x^3 + 153/280*x^2 + 3/35*x + 9/56,
    [x]):
```

Typically, you can use `gcd` for this task. However, suppose you know that the greatest common divisor has small coefficients with numerator and denominator both smaller than 10. Then you can use a modular algorithm with a smaller modulus than `gcd` would do: to be able to reconstruct these from their residue class modulo `n`, it is sufficient that $\sqrt{\frac{n}{2}} > 10$, e.g., `n=211`.

```
gcd(poly(f, IntMod(211)), poly(g, IntMod(211)))
```

$$\mathrm{poly}(x^2 - 90, [x], \mathrm{IntMod}(211))$$

Rational number reconstruction shows that the constant coefficient must be `3/7`:

```
numlib::reconstructRational(-90, 211)
```

$$3, 7$$

```
gcd(f,g)
```

$$\mathrm{poly}\left(x^2 + \frac{3}{7}, [x]\right)$$

Parameters

a

An integer

n

A positive integer

Return Values

Sequence consisting of an integer and a positive integer, or `FAIL`

MuPAD Functions

`numlib::lincongruence`

numlib::sigma

Sum of divisors of an integer

Syntax

```
numlib::sigma(n)
```

```
numlib::sigma(n, k)
```

Description

`numlib::sigma(n)` returns the sum of the positive divisors of `n`.

`numlib::sigma(n, k)` returns the sum of the `k`-th powers of the positive divisors of `n`.

`numlib::sigma(0)` returns `0`.

`numlib::sigma` returns the function call with evaluated argument if at least one argument is not a number.

`numlib::sigma` returns an error if one of its arguments evaluates to a number of wrong type.

`numlib::sigma(n,0)` is the same as `numlib::numdivisors(n)` and `numlib::tau(n)`.

`numlib::sigma(n,1)` is the same function as `numlib::sumdivisors(n)` and `numlib::sigma(n)`.

Examples

Example 1

The sum of the positive divisors of 120 is 360:

```
numlib::sigma(120)
```

```
360
```

Example 2

The sum of the fifth powers of the positive divisors of 120 is 25799815800:

```
numlib::sigma(120,5)
```

```
25799815800
```

Parameters

n

An integer

k

A nonnegative integer

Return Values

`numlib::sigma` returns an integer.

Algorithms

Internally, `ifactor` is used for factoring `n`.

See Also

MuPAD Functions

`numlib::divisors` | `numlib::numdivisors`

numlib::sqrt2cfrac

Continued fraction expansion of square roots

Syntax

```
numlib::sqrt2cfrac(a)
```

Description

`numlib::sqrt2cfrac(a)` returns the continued fraction expansion of the square root of `a` as a sequence of two lists: the first one contains the non-periodic (integer) part, the second one contains the periodic part of the expansion.

Examples

Example 1

The square root of 87 can be written as $9 + q$, where q is a number satisfying $q = \frac{1}{3+\frac{1}{18+q}}$:

```
numlib::sqrt2cfrac(87)
```

```
[9], [3, 18]
```

Example 2

Since 81 is a perfect square, there is no periodic part in the continued fraction expansion of its square root:

```
numlib::sqrt2cfrac(81)
```

```
[9]
```

Parameters

a

A positive integer

Return Values

If `a` is a perfect square, `numlib::sqrt2cfrac` returns a list with one entry; otherwise `numlib::sqrt2cfrac` returns a sequence of two lists, the first consisting of one integer, the second consisting of one or more integers.

See Also

MuPAD Functions
`numlib::contfrac`

numlib::sqrtmodp

Square root of a quadratic residue modulo a prime

Syntax

```
numlib::sqrtmodp(a, p)
```

Description

`numlib::sqrtmodp(a, p)` computes a solution x to the congruence $x^2 \equiv a \pmod{p}$.

`numlib::sqrtmodp(a, p)` computes an integer x that satisfies $x^2 \equiv a \pmod{p}$.

`a` must be a quadratic residue modulo `p`, and `p` must be a prime. This is not checked! Unless this is known to be the case, `numlib::msqrts` must be used. On the other hand, `numlib::sqrtmodp` is faster than `numlib::msqrts`.

Examples

Example 1

One square root of 132132 modulo 3231227 is 3012020:

```
numlib::sqrtmodp(132132,3231227)
```

```
3012020
```

Parameters

a

An integer

p

A prime unequal to 2

Return Values

`numlib::sqrtmodp` returns an integer.

Algorithms

`numlib::sqrtmodp` uses D. Shanks' algorithm RESSOL.

See Also

MuPAD Functions
`numlib::msqrts`

numlib::sumdivisors

Sum of divisors of an integer

Syntax

```
numlib::sumdivisors(n)
```

Description

`numlib::sumdivisors(n)` returns the sum of the positive divisors of the integer `n`.

`numlib::sumdivisors(0)` returns `0`.

`numlib::sumdivisors` returns the function call with evaluated argument if the argument is not a number.

`numlib::sumdivisors` returns an error if the argument evaluates to a number of wrong type.

`numlib::sumdivisors(n)` is the same as `numlib::sigma(n, 1)`.

Examples

Example 1

The sum of the positive divisors of 120 is 360:

```
numlib::sumdivisors(120)
```

```
360
```

Example 2

The sum of the positive divisors of - 63 is 104:

```
numlib::sumdivisors(-63)
```

```
     104
```

Parameters

n

An integer

Return Values

`numlib::sumdivisors(n)` returns a nonnegative integer.

Algorithms

Internally, `ifactor` is used for factoring `n`.

See Also

MuPAD Functions

`numlib::divisors` | `numlib::numdivisors` | `numlib::sigma`

numlib::sumOfDigits

Sum of digits of an integer

Syntax

```
numlib::sumOfDigits(n, <base>)
```

Description

`numlib::sumOfDigits(n, base)` computes the sum of digits of `n` in the given base `base`); if the base is not given, it defaults to 10.

The sum of digits may be larger than the base. For certain purposes (testing divisibility by b - 1, where b is the base), it may be useful to apply `numlib::sumOfDigits` over and over to the result. This is not done automatically. See “Example 2” on page 20-94.

Examples

Example 1

We compute the decimal and the binary sum of digits of 11:

```
numlib::sumOfDigits(11), numlib::sumOfDigits(11, 2)
```

```
2, 3
```

Example 2

We want to test whether 9 divides a given number, using the school method:

```
n:= 24373463462374324:
repeat n:= numlib::sumOfDigits(n); print(n) until n < 10 end:
delete n:
```

```
67
```

```
13
```

```
4
```

This only makes sense for demonstration purposes, as the following command achieves the same but much faster:

```
24373463462374324 mod 9
```

```
4
```

Parameters

n

Non-negative integer

base

Integer greater than one

Return Values

Non-negative integer

See Also

MuPAD Functions
`numlib::g_adic`

numlib::tau

Number of divisors of an integer

Syntax

```
numlib::tau(n)
```

Description

`numlib::tau(n)` returns the number of positive divisors of `n`.

`numlib::tau(0)` returns `0`.

`numlib::tau` returns the function call with evaluated argument if the argument is not a number.

`numlib::tau` returns an error if the argument evaluates to a number of wrong type.

`numlib::tau` is the same function as `numlib::numdivisors`.

Examples

Example 1

We compute the number of positive divisors of the number 6746328388800 (one of the highly composite numbers studied by S. Ramanujan in 1915):

```
numlib::tau(6746328388800)
```

```
10080
```

Parameters

n

An integer

Return Values

`numlib::tau` returns a nonnegative integer.

Algorithms

Internally, `ifactor` is used for factoring `n`.

See Also

MuPAD Functions

`numlib::divisors` | `numlib::numprimedivisors` | `numlib::primedivisors`

numlib::toAscii

ASCII encoding of a string

Syntax

```
numlib::toAscii(s)
```

Description

`numlib::toAscii(s)` returns the list of ASCII codes of the characters in the string `s`.

`numlib::toAscii` returns an error if its argument is not a string.

Examples

Example 1

The ASCII coding of a well-known name:

```
numlib::toAscii("MuPAD - Multi Processing Algebra Data Tool")
```

```
[77, 117, 80, 65, 68, 32, 45, 32, 77, 117, 108, 116, 105, 32, 80, 114, 111, 99, 101, 115, 115, 105,
  110, 103, 32, 65, 108, 103, 101, 98, 114, 97, 32, 68, 97, 116, 97, 32, 84, 111, 111, 108]
```

and the ASCII coding of an empty string:

```
numlib::toAscii("")
```

```
[]
```

Parameters

s

A string

Return Values

`numlib::toAscii(s)` returns a list of nonnegative integers.

ode::companionSystem

Companion matrix of a linear homogeneous ordinary differential equation

Syntax

```
ode::companionSystem(Ly, y(x), <R>)
```

Description

`ode::companionSystem(Ly, y(x))` returns the companion matrix associated to `Ly`. If the optional argument `R` is given, the elements of the matrix are in `R`.

Examples

Example 1

We compute the companion matrix of the following differential equation:

```
Ly := 4*x^2*diff(y(x),x$3)+diff(y(x),x$2)+4*x*diff(y(x),x)-y(x)
```

$$4\,x\,\frac{\partial}{\partial x}\,y(x)-y(x)+4\,x^2\,\frac{\partial^3}{\partial x^3}\,y(x)+\frac{\partial^2}{\partial x^2}\,y(x)$$

```
ode::companionSystem(Ly, y(x))
```

$$\begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ \frac{1}{4\,x^2} & -\frac{1}{x} & -\frac{1}{4\,x^2} \end{pmatrix}$$

Parameters

`Ly`

A linear homogeneous ordinary differential equation.

`y(x)`

The dependent function of `Ly`.

`R`

A field of functions or numbers of characteristic zero, default is `Dom::ExpressionField(normal)`.

Return Values

Object of type `Dom::Matrix`.

ode::cyclicVector

Transforms a linear differential system to an equivalent linear differential system with a companion matrix.

Syntax

```
ode::cyclicVector(A, x, <v>)
```

Description

`ode::cyclicVector(A, x, v)` converts a first order homogeneous differential system $Y' = AY$ into a corresponding first order homogeneous differential system $Z' = BZ$, where `B` is a companion matrix, by substituting $Z = PY$ using the potential cyclic vector `v`. If `v` is not cyclic then an empty list is returned otherwise a list is returned whose first element is a list corresponding to the last row of `B` and second element is the invertible matrix `P`.

When the optional argument `v` is not given then the vector `[1,0,...,0]` is tested. If it is not cyclic then a suitable one is determined randomly by the procedure.

Examples

Example 1

We compute a differential system equivalent to the following differential system:

```
A := matrix( [ [x^2-1,1,0], [0,x^2+5*x+1/3,1], [0,0,2]])
```

$$\begin{pmatrix} x^2-1 & 1 & 0 \\ 0 & x^2+5x+\frac{1}{3} & 1 \\ 0 & 0 & 2 \end{pmatrix}$$

```
ode::cyclicVector(A, x)
```

$$\left[\left[2x^4+6x^3-\frac{49x^2}{3}-\frac{38x}{3}+\frac{19}{3},\ -x^4-5x^3-\frac{10x^2}{3}+x+\frac{20}{3},\ 2x^2+5x+\frac{4}{3}\right],\right.$$

$$\left.\begin{pmatrix} 1 & 0 & 0 \\ x^2-1 & 1 & 0 \\ 2x-2x^2+x^4+1 & 5x+2x^2-\frac{2}{3} & 1 \end{pmatrix}\right]$$

So `[1,0,0]` is a cyclic vector; `[x,0,0]` is also a cyclic vector:

```
l := ode::cyclicVector(A, x, [x,0,0])
```

$$\left[\left[\frac{6x^7+21x^6-34x^5-28x^4+28x^3+10x^2+8x+18}{3x^3},\right.\right.$$

$$\left.\left.-\frac{3x^6+15x^5+10x^4+9x^3+10x^2+8x+18}{3x^2},\ \frac{6x^3+15x^2+4x+9}{3x}\right],\right.$$

$$\left.\begin{pmatrix} x & 0 & 0 \\ -x+x^3+1 & x & 0 \\ x+4x^2-2x^3+x^5-2 & -\frac{2x}{3}+5x^2+2x^3+2 & x \end{pmatrix}\right]$$

And we can build easily a linear homogeneous differential equation associated to it (c.f. `ode::mkODE`):

```
-ode::mkODE(l[1].[-1], y, x)
```

$$\frac{(3x^6+15x^5+10x^4+9x^3+10x^2+8x+18)\,\frac{\partial}{\partial x}y(x)}{3x^2}-\frac{(6x^3+15x^2+4x+9)\,\frac{\partial^2}{\partial x^2}y(x)}{3x}$$
$$-\frac{y(x)\,(6x^7+21x^6-34x^5-28x^4+28x^3+10x^2+8x+18)}{3x^3}+\frac{\partial^3}{\partial x^3}y(x)$$

Parameters

A

A square matrix of type `Dom::Matrix`.

x

The independent variable.

v

A list of size the dimension of `A`, default is `[1,0,...,0]`.

Return Values

List, possibly empty, of two lists.

See Also

MuPAD Functions
`ode::scalarEquation`

ode::dAlembert

D'Alembert reduction of a linear homogeneous ordinary differential equation

Syntax

```
ode::dAlembert(Ly, y(x), v)
```

Description

`ode::dAlembert(Ly, y(x), v)` returns the reduced differential equation of `Ly` using the method of reduction of d'Alembert and the function `v`. If `v` is a solution of `Ly` and `u` is a solution of the reduced differential equation then $v \in t\,u$ is another solution of `Ly`.

Examples

Example 1

Consider the following differential equation:

```
Ly := 2/x^3*y(x)-2/x^2*diff(y(x),x)+1/x*diff(y(x),x$2)+
      diff(y(x),x$3)
```

$$\frac{2\,y(x)}{x^3} - \frac{2\,\frac{\partial}{\partial x}y(x)}{x^2} + \frac{\frac{\partial^2}{\partial x^2}y(x)}{x} + \frac{\partial^3}{\partial x^3}y(x)$$

We easily check that `x` is a particular solution of `Ly`:

```
ode::evalOde(Ly, y(x)=x)
```

$$0$$

Then we reduce the equation `Ly` using this special solution:

```
R := ode::dAlembert(Ly, y(x), x)
```

$$\frac{4\,\frac{\partial}{\partial x}\,y(x)}{x}+\frac{\partial^2}{\partial x^2}\,y(x)$$

The solutions of the equation R are not too hard to find:

```
ode::evalOde(R, y(x)=1), ode::evalOde(R, y(x)=1/x^3)
```

$$0,\ 0$$

So a basis of solutions of Ly is therefore $\left\{x,\ x\int 1\,\mathrm{d}x=x^2,\ x\int\frac{1}{x^3}\,\mathrm{d}x=-\frac{1}{2x}\right\}$ which can be checked directly:

```
ode::solve(Ly, y(x))
```

$$\left\{\frac{C4}{x}-\frac{x\,(C3+2\,C2\,x)}{6}\right\}$$

Parameters

Ly

A homogeneous linear differential equation.

y(x)

The dependent function of Ly.

v

An expression.

Return Values

Expression.

ode::evalOde

Applies an expression at a linear ordinary differential equation

Syntax

```
ode::evalOde(Ly, y(x))
```

Description

`ode::evalOde(Ly, y(x) = v)` evaluates `Ly` replacing `y(x)` by `v` and simplifying the result. This can be useful to check a solution candidate, for example.

Examples

Example 1

We evaluate the following differential equation for various expressions:

```
Ly := (x^2+1)*diff(y(x),x$2)+x*diff(y(x),x)-4*y(x)
```

$$(x^2+1)\,\frac{\partial^2}{\partial x^2}\,y(x)+x\,\frac{\partial}{\partial x}\,y(x)-4\,y(x)$$

```
ode::evalOde(Ly, y(x) = 2*x^2+1),
ode::evalOde(Ly, y(x) = exp(x)),
ode::evalOde(Ly, y(x) = RootOf(Z^3+x*Z+1, Z))
```

$$0,\ x^2\,e^x-3\,e^x+x\,e^x,\ -18\,Z^2\,x^4-54\,Z^2\,x^2+243\,Z^2\,x-60\,Z\,x^6-4\,Z\,x^4-756\,Z\,x^3+54\,Z\,x$$

$$-2916\,Z-12\,x^5-36\,x^3+162\,x^2$$

Parameters

`Ly`

A linear ordinary differential equation.

`y(x)`

The dependent function of `Ly`.

`v`

An expression.

Return Values

Expression.

ode::exponentialSolutions

Exponential solutions of a homogeneous linear ordinary differential equation

Syntax

```
ode::exponentialSolutions(Ly, y(x), <Generic>)
```

Description

`ode::exponentialSolutions(Ly, y(x))` returns a fundamental set of the exponential solutions of `Ly`, i.e. solutions `z` such that $\frac{z'}{z}$ is a rational function of `x`. When the option `Generic` is given, a generic form of them is returned.

Note: `ode::exponentialSolutions` does not return any eventual solution that is exponential over the algebraic closure of $\mathbb{Q}(x)$ but not over $\mathbb{Q}(x)$.

Examples

Example 1

We compute the exponential solutions of the following differential equation :

```
Ly:=diff(y(x),x$4)-2*x*diff(y(x),x$3)+(-x+x^2-5)*diff(y(x),x$2)+
    (4*x+2*x^2)*diff(y(x),x)+(2+x-x^3)*y(x)
```

$$\frac{\partial^4}{\partial x^4} y(x) - 2\,x\,\frac{\partial^3}{\partial x^3} y(x) - (-x^2+x+5)\,\frac{\partial^2}{\partial x^2} y(x) + (2\,x^2+4\,x)\,\frac{\partial}{\partial x} y(x) + y(x)\,(-x^3+x+2)$$

```
ode::exponentialSolutions(Ly, y(x)),
ode::exponentialSolutions(Ly, y(x), Generic)
```

$$\left\{ e^{\frac{x^2}{2}}, x\,e^{\frac{x^2}{2}} \right\}, C2\,e^{\frac{x^2}{2}} + C1\,x\,e^{\frac{x^2}{2}}$$

Example 2

No exponential solution over the algebraic closure of $\mathbb{Q}(x)$ is returned:

```
ode::exponentialSolutions(diff(y(x),x$2)+y(x), y(x))
```

$$\varnothing$$

whereas $\left\{e^{ix},\ e^{-ix}\right\}$ is a basis of solutions of the above differential equation.

Parameters

`Ly`

A homogeneous linear ordinary differential equation with coefficients in the field $\mathbb{Q}(x)$ of rational functions over the rationals.

`y(x)`

The dependent function of `Ly`.

Return Values

`set`, possibly empty, of functions or an expression.

ode::exponents

Exponents of a linear ordinary differential equation

Syntax

```
ode::exponents(Ly, y(x), p)
```

Description

`ode::exponents` returns the set of exponents of a homogeneous linear differential equation at a given point.

`ode::exponents(Ly, y(x), p)` returns the set of (local) exponents of `Ly` at the place `p`. If the place is infinity then one uses $\frac{1}{x}$ instead. They are defined as roots (in an algebraic closure of $\mathbb{Q}(x)$) of the indicial equation (c.f. `ode::indicialEquation`) of `Ly` so the set of exponents may be empty, see "Example 2" on page 21-14.

Examples

Example 1

We compute the exponents of the following differential equation at the regular point `0` and at the singular points `-1` and *infinity*:

```
Ly := diff(y(x),x$2)+4/(x+1)*diff(y(x),x)+2/(x+1)^2*y(x)
```

$$\frac{4\,\frac{\partial}{\partial x}y(x)}{x+1}+\frac{2\,y(x)}{(x+1)^2}+\frac{\partial^2}{\partial x^2}y(x)$$

```
ode::exponents(Ly, y(x), x)
```

$$\{0,\ 1\}$$

```
ode::exponents(Ly, y(x), x+1)
```

$$\{-2, -1\}$$

```
ode::exponents(Ly, y(x), 1/x)
```

$$\{1, 2\}$$

Example 2

It may happen that at a place the set of exponents is empty; this corresponds to an irregular singular point:

```
Ly := (2*x+4)*diff(y(x),x)/(2*x+x^2-2)-2*y(x)/(2*x+x^2-2)-
      (4*x+x^2)/(2*x+x^2-2)*diff(y(x),x$2)+diff(y(x),x$3)
```

$$\frac{(2x+4)\,\frac{\partial}{\partial x}y(x)}{x^2+2x-2} - \frac{(x^2+4x)\,\frac{\partial^2}{\partial x^2}y(x)}{x^2+2x-2} - \frac{2\,y(x)}{x^2+2x-2} + \frac{\partial^3}{\partial x^3}y(x)$$

```
ode::exponents(Ly, y(x), 1/x)
```

$$\varnothing$$

```
ode::exponents(Ly, y(x), x^2+2*x-2)
```

$$\{0, 1, 3\}$$

Parameters

Ly

A homogeneous linear differential equation over $\mathbb{Q}(x)$.

y(x)

The dependent function of `Ly`.

p

An irreducible polynomial in `x` or `1/x`.

Return Values

`set`, possibly empty.

See Also

MuPAD Functions

`ode::indicialEquation` | `ode::isFuchsian`

ode::getOrder

Order of an ordinary differential equation

Syntax

```
ode::getOrder(Ly, y(x))
```

Description

`ode::getOrder(Ly, y(x))` returns the order of `Ly` for the dependent function `y(x)`, i.e. the highest degree of derivative of `Ly`.

Examples

Example 1

We can compute orders for linear and nonlinear ordinary differential equations:

```
ode::getOrder(diff(y(x),x$2)-x*y(x)-airyAi(x), y(x))
```

$$2$$

```
ode::getOrder(y(x)*diff(y(x),x$3)^2-exp(y(x)), y(x))
```

$$3$$

```
ode::getOrder(y(x)*diff(y(x),x$3)^2-exp(y(x)), z(x))
```

$$-\infty$$

Parameters

`Ly`

An ordinary differential equation.

`y(x)`

The dependent function of `Ly`.

Return Values

Either `-infinity` or a positive integer.

ode::indicialEquation

Indicial equation of a linear ordinary differential equation

Syntax

```
ode::indicialEquation(Ly, y(x), p, u)
```

Description

`ode::indicialEquation(Ly, y(x), p, u)` returns the indicial equation in the variable `u` of `Ly` at the place `p`. If the place is infinity then one uses $\frac{1}{x}$ instead. The result if `FAIL` if the place corresponds to an irregular singular point of `Ly`.

Examples

Example 1

We compute the indicial equations of the following differential equation at the regular point `1` and at the singular points `0` and *infinity*:

```
Ly := 1/x^3*y(x)*(4*x-10)-1/x^2*(4*x^3-10)*diff(y(x),x)-
      9/2/x*diff(y(x),x$2)+diff(y(x),x$3)
```

$$\frac{y(x)\,(4x-10)}{x^3}-\frac{9\,\frac{\partial^2}{\partial x^2}y(x)}{2x}-\frac{(4x^3-10)\,\frac{\partial}{\partial x}y(x)}{x^2}+\frac{\partial^3}{\partial x^3}y(x)$$

```
ode::indicialEquation(Ly, y(x), x-1, U)
```

$$U^3-3\,U^2+2\,U$$

```
ode::indicialEquation(Ly, y(x), 1/x, U)
```

FAIL

```
ode::indicialEquation(Ly, y(x), x, U)
```

$$2\,U^3 - 15\,U^2 + 33\,U - 20$$

The roots of the indicial equation correspond to the (local) exponents:

```
solve(%, U), ode::exponents(Ly, y(x), x)
```

$$\left\{1, \frac{5}{2}, 4\right\}, \left\{1, \frac{5}{2}, 4\right\}$$

Parameters

`Ly`

A homogeneous linear differential equation over $\mathbb{Q}(x)$.

`y(x)`

The dependent function of `Ly`.

`p`

An irreducible polynomial in `x` or `1/x`.

`u`

An element of type `DOM_IDENT`.

Return Values

`FAIL` or a polynomial expression in `u`.

See Also

MuPAD Functions

`ode::indicialEquation` | `ode::isFuchsian`

ode::isFuchsian

Tests if a homogeneous linear ordinary differential equation is of Fuchsian type

Syntax

```
ode::isFuchsian(Ly, y(x), <AllExponents>)
```

Description

`ode::isFuchsian` returns `TRUE` if `Ly` is of Fuchsian type, i.e., all the singular points (including the point at infinity) of `Ly` are regular. It returns `FALSE` if at least one singular point is irregular. When the option `AllExponents` is given, either `FALSE` is returned or a list where each element is a table containing, at each regular singular point of `Ly` the place, the indicial equation and the exponents.

Examples

Example 1

We test if the following differential equation is Fuchsian:

```
Ly:=x*(1-x)*diff(y(x),x$2)+(1-x)*diff(y(x),x)+10*y(x)
```

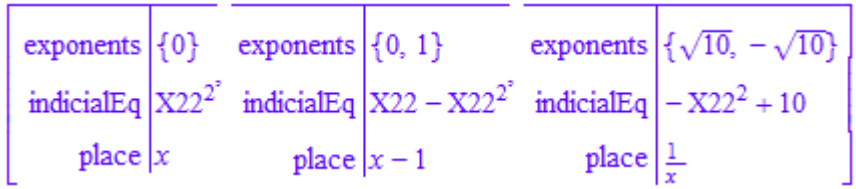
$$-x\,(x-1)\,\frac{\partial^2}{\partial x^2}\,y(x)-(x-1)\,\frac{\partial}{\partial x}\,y(x)+10\,y(x)$$

```
ode::isFuchsian(Ly, y(x))
```

TRUE

We can have a look of the indicial equations, exponents at each regular singular point of `Ly`:

```
ode::isFuchsian(Ly, y(x), AllExponents)
```



Example 2

In this example, the Airy equation, the only singular point is at infinity and is irregular:

```
ode::isFuchsian(diff(y(x),x$2)-x*y(x), y(x))
```

```
FALSE
```

Parameters

`Ly`

A homogeneous linear ordinary differential equation with coefficients in the field $\mathbb{Q}(x)$ of rational functions over the rationals.

`y(x)`

The dependent function of `Ly`.

Options

`AllExponents`

Return a list of tables of indical equations and exponents for regular singular points.

Return Values

`TRUE`, `FALSE` or a list.

ode::isLODE

Test for a linear ordinary differential equation

Syntax

```
ode::isLODE(Ly, y(x), <Homogeneous | HlodeOverRF | Hlode | LodeOverRF | Lode>)
```

Description

`ode::isLODE(Ly, y(x))` returns `TRUE` if `Ly` is a linear ordinary differential equation in `y(x)`, `FALSE` otherwise. If an optional argument is given then the result is discussed as follows:

- `Homogeneous`: returns `TRUE` if `Ly` is homogeneous, `FALSE` otherwise.
- `HlodeOverRF`: returns the sequence `Ly, y, x, n`, where `n` is the order of `Ly`, if `Ly` is homogeneous with rational functions coefficients, `FALSE` otherwise.
- `Hlode`: returns the sequence `Ly, y, x, n`, where `n` is the order of `Ly`, if `Ly` is homogeneous, `FALSE` otherwise.
- `LodeOverRF`: returns the sequence `Ly, y, x, n`, where `n` is the order of `Ly`, if `Ly` has rational functions coefficients, `FALSE` otherwise.
- `Lode`: returns the sequence `Ly, y, x, n`, where `n` is the order of `Ly`, if `Ly` is a linear ordinary differential equation, `FALSE` otherwise.

Examples

Example 1

We test the following differential equations:

```
ode::isLODE(y(x)^2+x^2*diff(y(x),x)+x, y(x))
```

```
FALSE
```

```
ode::isLODE(y(x)+x^2*diff(y(x),x)+x, y(x))
```

```
     TRUE
```

```
ode::isLODE(y(x)+x^2*diff(y(x),x)+x, y(x), Hlode)
```

```
     FALSE
```

```
ode::isLODE(
     y(x)+x^2*diff(y(x),x)+x*diff(y(x),x$2), y(x), HlodeOverRF)
```

$$y(x)+x^2\,\frac{\partial}{\partial x}\,y(x)+x\,\frac{\partial^2}{\partial x^2}\,y(x),\ y,\ x,\ 2$$

```
ode::isLODE(
     x+x^2*diff(y(x),x)+exp(x)*diff(y(x),x$2), y(x), LodeOverRF)
```

```
     FALSE
```

Parameters

`Ly`

An expression.

`y(x)`

The dependent function of `Ly`.

Return Values

Either `TRUE`, `FALSE` or a sequence of type `_exprseq`.

ode::mkODE

Builds a linear homogeneous ordinary differential equation from a list of coefficient functions

Syntax

```
ode::mkODE(l, y, x)
```

Description

`ode::mkODE(l, y, x)` returns a linear homogeneous ordinary differential equation `Ly` in `y(x)` where the coefficients are the entries of the list l. The last element of the list `l` corresponds to the leading coefficients of `Ly`.

Examples

Example 1

We generate the linear ODE for `y(x)` with the coefficients `-1`, `4*x` and `4*x^2` of `y(x)`, `y'(x)` and `y''(x)`, respectively:

```
ode::mkODE([-1, 4*x, 4*x^2], y, x)
```

$$4x^2 \frac{\partial^2}{\partial x^2} y(x) - y(x) + 4x \frac{\partial}{\partial x} y(x)$$

Parameters

`l`

A `list` of coefficient functions.

y

The dependent variable of the resulting differential equation.

x

The independent variable of the resulting differential equation.

Return Values

Expression.

ode::normalize

Normalized form of a linear ordinary differential equation

Syntax

```
ode::normalize(Ly, y, x, n)
```

Description

`ode::normalize(Ly, y, x, n)` computes the normalized form of the `n`-th order linear ordinary differential equation `Ly`, i.e. whose leading coefficient (the coefficient of the highest derivative of `y(x)` in `Ly`) is 1.

Examples

Example 1

We normalize the following differential equation:

```
Ly:=-diff(y(x),x,x)/x+y(x)/4/x^3-diff(y(x),x)/x^2
```

$$\frac{y(x)}{4\,x^3} - \frac{\frac{\partial}{\partial x}\,y(x)}{x^2} - \frac{\frac{\partial^2}{\partial x^2}\,y(x)}{x}$$

```
ode::normalize(Ly, y, x, 2)
```

$$\frac{\frac{\partial}{\partial x}\,y(x)}{x} - \frac{y(x)}{4\,x^2} + \frac{\partial^2}{\partial x^2}\,y(x)$$

Parameters

Ly

A homogeneous linear ordinary differential equation.

y

The dependent variable of `Ly`.

x

The independent variable of `Ly`.

n

The order of `Ly`.

Return Values

Expression representing a linear differential equation.

ode::polynomialSolutions

Polynomial solutions of a homogeneous linear ordinary differential equation

Syntax

```
ode::polynomialSolutions(Ly, y(x), <Generic>)
```

Description

`ode::polynomialSolutions` computes a fundamental set of polynomial solutions of a homogeneous linear ordinary differential equation.

`ode::polynomialSolutions` returns a fundamental set of the polynomial solutions of `Ly`, i.e., solutions in the ring $\mathbb{Q}[x]$. When the option `Generic` is given, a generic form of them is returned.

Examples

Example 1

We compute the polynomial solutions of the following differential equation:

```
Ly:=3*x*diff(y(x),x,x)-x*diff(y(x),x)+9*y(x)
```

$$3\,x\,\frac{\partial^2}{\partial x^2}\,y(x) - x\,\frac{\partial}{\partial x}\,y(x) + 9\,y(x)$$

```
ode::polynomialSolutions(Ly, y(x))
```

$$\{x^9 - 216\,x^8 + 18144\,x^7 - 762048\,x^6 + 17146080\,x^5 - 205752960\,x^4 + 1234517760\,x^3 - 3174474240\,x^2 + 2380855680\,x\}$$

```
ode::polynomialSolutions(Ly, y(x), Generic)
```

$$C1\,(x^9 - 216\,x^8 + 18144\,x^7 - 762048\,x^6 + 17146080\,x^5 - 205752960\,x^4 + 1234517760\,x^3 - 3174474240\,x^2 + 2380855680\,x)$$

Parameters

`Ly`

A homogeneous linear ordinary differential equation with coefficients in the field $\mathbb{Q}(x)$ of rational functions over the rationals.

`y(x)`

The dependent function of `Ly`.

Return Values

`set`, possibly empty, of functions or an expression

See Also

MuPAD Functions

`ode::rationalSolutions`

ode::rationalSolutions

Rational solutions of a homogeneous linear ordinary differential equation

Syntax

```
ode::rationalSolutions(Ly, y(x), <Generic>)
```

Description

`ode::rationalSolutions` returns a fundamental set of the rational solutions of `Ly`, i.e., solutions in the field $\mathbb{Q}(x)$. When the option `Generic` is given, a generic form of them is returned.

Examples

Example 1

We compute the rational solutions of the following differential equation:

```
Ly:=(4*x^5+8*x^3+4*x)*diff(y(x),x,x)+
    (36*x^4+32*x^2-4)*diff(y(x),x)+48*x^3*y(x)
```

$$48\,x^3\,y(x)+(4\,x^5+8\,x^3+4\,x)\,\frac{\partial^2}{\partial x^2}\,y(x)+(36\,x^4+32\,x^2-4)\,\frac{\partial}{\partial x}\,y(x)$$

```
ode::rationalSolutions(Ly, y(x))
```

$$\left\{\frac{1}{x^6+3\,x^4+3\,x^2+1},\ \frac{x^4+2\,x^2}{x^6+3\,x^4+3\,x^2+1}\right\}$$

```
ode::rationalSolutions(Ly, y(x), Generic)
```

$$\frac{C1}{x^6+3x^4+3x^2+1}+\frac{C2\,(x^4+2x^2)}{x^6+3x^4+3x^2+1}$$

Parameters

`Ly`

A homogeneous linear ordinary differential equation with coefficients in the field $\mathbb{Q}(x)$ of rational functions over the rationals.

`y(x)`

The dependent function of `Ly`.

Return Values

`set`, possibly empty, of functions or an expression

See Also

MuPAD Functions

`ode::polynomialSolutions`

ode::ratSys

Rational solutions of a first order homogeneous linear differential system

Syntax

```
ode::ratSys(M, x)
```

Description

`ode::ratSys(M, x)` computes a fundamental set of rational solutions of the first order homogeneous linear differential system `Y'=MY`. This method uses a cyclic vector and therefore is not optimal.

Examples

Example 1

We compute the rational solutions of the following differential system:

```
A := matrix([ [2*(x+x^2-9)/x/(x-2),2*(x^2-6)/x/(x-2)],
     [-3*(2*x+x^2-12)/x/(x-2),-(2*x+3*x^2-24)/x/(x-2)] ])
```

$$\begin{pmatrix} \frac{2x^2+2x-18}{x(x-2)} & \frac{2x^2-12}{x(x-2)} \\ -\frac{3x^2+6x-36}{x(x-2)} & -\frac{3x^2+2x-24}{x(x-2)} \end{pmatrix}$$

```
v := ode::ratSys(A, x)
```

$$\left\{ \begin{pmatrix} \frac{x+2}{x^3} \\ -\frac{x+4}{x^3} \end{pmatrix} \right\}$$

And we can check the result:

```
diff(v[1], x) = normal(A*v[1])
```

$$\begin{pmatrix} -\frac{2\,(x+3)}{x^4} \\ \frac{2\,(x+6)}{x^4} \end{pmatrix} = \begin{pmatrix} -\frac{2\,(x+3)}{x^4} \\ \frac{2\,(x+6)}{x^4} \end{pmatrix}$$

Parameters

M

A square matrix of type `Dom::Matrix` with coefficients in the field $\mathbb{Q}(x)$ of rational functions over the rationals.

x

The independent function.

Return Values

`set`, possibly empty, of objects of type `Dom::Matrix`.

See Also

MuPAD Functions

`ode::cyclicVector` | `ode::rationalSolutions` | `ode::scalarEquation`

ode::scalarEquation

Transforms a linear differential system to an equivalent scalar linear differential equation

Syntax

```
ode::scalarEquation(A, x, y, <Transform>)
```

Description

`ode::scalarEquation` converts a first order homogeneous linear differential system to an equivalent homogeneous scalar linear differential equation using the method of cyclic vector.

`ode::scalarEquation(A, x, y)` returns a scalar homogeneous linear differential equation in `y(x)` equivalent to the first order homogeneous differential system $Y' = \mathrm{AY}$ using the method of the cyclic vector. If the option `Transform` is given then a list is returned whose first element is the corresponding differential equation `Ly` and second element is an invertible matrix `P` such that $C = P' P^{-1} + P A P^{-1}$ is the companion matrix associated to `Ly`; hence if `Z` is a solution of the differential system $Y' = \mathrm{AY}$ then PZ is a solution of the system $Y' = \mathrm{CY}$.

Examples

Example 1

We compute a linear differential equation equivalent to the following differential system:

```
A := matrix( [ [x^2-1,1,0], [0,x^2+5*x+1/3,1], [0,0,2]])
```

$$\begin{pmatrix} x^2-1 & 1 & 0 \\ 0 & x^2+5x+\frac{1}{3} & 1 \\ 0 & 0 & 2 \end{pmatrix}$$

```
l := ode::scalarEquation(A, x, y, Transform)
```

$$\left[\frac{\partial^3}{\partial x^3} y(x) - \left(2x^2 + 5x + \frac{4}{3}\right) \frac{\partial^2}{\partial x^2} y(x) + \left(x^4 + 5x^3 + \frac{10x^2}{3} - x - \frac{20}{3}\right) \frac{\partial}{\partial x} y(x)\right.$$

$$\left. - y(x) \left(2x^4 + 6x^3 - \frac{49x^2}{3} - \frac{38x}{3} + \frac{19}{3}\right), \begin{pmatrix} 1 & 0 & 0 \\ x^2 - 1 & 1 & 0 \\ 2x - 2x^2 + x^4 + 1 & 5x + 2x^2 - \frac{2}{3} & 1 \end{pmatrix}\right]$$

And we can check that, for `P=l[2]`, $P' P^{-1} + P A P^{-1}$ is the companion matrix associated to `l[1]`:

```
P := l[2]:
bool( diff(P,x)*P^(-1)+P*A*P^(-1) =
      ode::companionSystem(l[1], y(x)) )
```

TRUE

Parameters

A

A square matrix of type `Dom::Matrix`.

x

The independent variable of the resulting scalar differential equation.

y

The dependent variable of the resulting scalar differential equation.

Return Values

Expression or a list.

MuPAD Functions
`ode::cyclicVector`

ode::series

Series solutions of an ordinary differential equation

Syntax

```
ode::series(Ly, y(x), x | x = x0, <order>)
```

```
ode::series({Ly, <inits>}, y(x), x | x = x0, <order>)
```

Description

`ode::series(Ly, y(x), x = x0)` computes the first terms of the series expansions of the solutions of `Ly` with respect to the variable `x` around the point `x0`.

`ode::series` tries to compute either the Taylor series, the Laurent series or the Puiseux series of the solutions of the differential equation `Ly` around the point `x=x0`.

Suppose that `Ly` is a nonlinear differential equation. If `x0` is an ordinary point of `Ly` then a Taylor series is computed otherwise an expression of type `"series"` is returned. If initial conditions are given at the point `x0` then the answer is expressed in terms of the function `y(x)` and its derivatives evaluated at the point `x0`. See “Example 1” on page 21-37.

Suppose that `Ly` is a linear differential equation. If `x0` is an ordinary point of `Ly` then a Taylor series is computed, if `Ly` is furthermore homogeneous and `x0` is a regular point then a Puiseux series is computed (containing possible logarithmic terms), otherwise an expression of type `"series"` is returned. If initial conditions are given at the point `x0` then the answer is either expressed in terms of the function `y(x)` and its derivatives evaluated at the point `x0` or it may be expressed in terms of arbitrary constants.

Examples

Example 1

Consider the following nonlinear differential equation:

```
Ly := x^2*diff(y(x),x)+y(x)-x
```

$$y(x) - x + x^2 \frac{\partial}{\partial x} y(x)$$

We compute the series solutions at the point 0 which is a singular point:

```
ode::series(Ly, y(x), x=0)
```

$$\text{series}\left(y(x) - x + x^2 \frac{\partial}{\partial x} y(x),\ y(x),\ x = 0\right)$$

Then we compute the series solutions at the regular point 1:

```
ode::series(Ly, y(x), x=1)
```

$$\left\{y(1) - (x-1)\,(y(1)-1) + \left(\frac{3\,y(1)}{2} - 1\right)(x-1)^2 - \left(\frac{13\,y(1)}{6} - \frac{4}{3}\right)(x-1)^3 + \left(\frac{73\,y(1)}{24} - \frac{11}{6}\right)(x-1)^4 - \left(\frac{167\,y(1)}{40} - \frac{5}{2}\right)(x-1)^5 + O((x-1)^6)\right\}$$

And we can also put some initial conditions at the point 1:

```
ode::series({y(1)=1, Ly}, y(x), x=1)
```

$$\left\{1 + \frac{(x-1)^2}{2} - \frac{5\,(x-1)^3}{6} + \frac{29\,(x-1)^4}{24} - \frac{67\,(x-1)^5}{40} + O((x-1)^6)\right\}$$

Example 2

Consider the following linear differential equation:

```
Ly := (2*x+x^3)*diff(y(x),x$2)-diff(y(x),x)-6*x*y(x)
```

$$(x^3 + 2x)\frac{\partial^2}{\partial x^2} y(x) - \frac{\partial}{\partial x} y(x) - 6x\,y(x)$$

We compute the series solutions at the regular point 1:

```
ode::series(Ly, y(x), x=1)
```

$$\left\{y(1)+y'(1)\,(x-1)+(x-1)^2\left(\frac{y'(1)}{6}+y(1)\right)-\left(\frac{y(1)}{9}-\frac{7\,y'(1)}{27}\right)(x-1)^3 + \left(\frac{y(1)}{12}-\frac{y'(1)}{36}\right)(x-1)^4+\left(\frac{y(1)}{90}-\frac{2\,y'(1)}{135}\right)(x-1)^5+O((x-1)^6)\right\}$$

The series solutions at the regular singular point 0:

```
ode::series(Ly, y(x), x=0)
```

$$\left\{1+3\,x^2+\frac{3\,x^4}{5}+O(x^6),\ x^{3/2}+\frac{3\,x^{7/2}}{8}-\frac{3\,x^{11/2}}{128}+O\left(x^{15/2}\right)\right\}$$

An also the series solutions at the regular singular point *infinity*:

```
ode::series(Ly, y(x), x=infinity)
```

$$\left\{\frac{1}{x^2}-\frac{1}{x^4}+\frac{11}{9\,x^6}+O\left(\frac{1}{x^8}\right),\ 2880\,x^3+4320\,x-\frac{1080}{x}+O\left(\frac{1}{x^3}\right)\right\}$$

Example 3

Consider the following linear differential equation:

```
Ly := x^2*diff(y(x),x$2)-x*diff(y(x),x)+(1-x)*y(x)
```

$$x^2\,\frac{\partial^2}{\partial x^2}\,y(x)-y(x)\,(x-1)-x\,\frac{\partial}{\partial x}\,y(x)$$

We compute the series solutions at the regular singular point 0:

```
ode::series(Ly, y(x), x)
```

$$\left\{x\ln(x)+x^2(\ln(x)-2)+x^3\left(\frac{\ln(x)}{4}-\frac{3}{4}\right)+x^4\left(\frac{\ln(x)}{36}-\frac{11}{108}\right)+x^5\left(\frac{\ln(x)}{576}-\frac{25}{3456}\right)\right.$$
$$\left.+x^6\left(\frac{\ln(x)}{14400}-\frac{137}{432000}\right)+O(x^7),\ x+x^2+\frac{x^3}{4}+\frac{x^4}{36}+\frac{x^5}{576}+\frac{x^6}{14400}+O(x^7)\right\}$$

And at the same point we look for solutions satisfying the initial condition $y(0) = 1$ and $y(0) = 0$:

```
ode::series({y(0)=1, Ly}, y(x), x)
```

$$\varnothing$$

```
ode::series({y(0)=0, Ly}, y(x), x)
```

$$\left\{C4\,x\ln(x)+C4\,x^2(\ln(x)-2)+C4\,x^3\left(\frac{\ln(x)}{4}-\frac{3}{4}\right)+C4\,x^4\left(\frac{\ln(x)}{36}-\frac{11}{108}\right)\right.$$
$$+C4\,x^5\left(\frac{\ln(x)}{576}-\frac{25}{3456}\right)+C4\,x^6\left(\frac{\ln(x)}{14400}-\frac{137}{432000}\right)+O(x^7),$$
$$\left.C3\,x+C3\,x^2+\frac{C3\,x^3}{4}+\frac{C3\,x^4}{36}+\frac{C3\,x^5}{576}+\frac{C3\,x^6}{14400}+O(x^7)\right\}$$

Parameters

Ly

An ordinary differential equation.

y(x)

The dependent function of `Ly`.

x

The independent variable of `Ly`.

`x0`

The expansion point: an arithmetical expression. If not specified, the default expansion point 0 is used .

`inits`

The initial or boundary conditions: a sequence of equations.

`order`

The number of terms to be computed: a nonnegative integer. The default order is given by the environment variable `ORDER` (default value 6).

Return Values

Either a `list`, maybe empty, of objects of type `Series::Puiseux` or an expression of type `"series"`.

ode::solve

Solving ordinary differential equations

Syntax

```
ode::solve(o, options)
```

```
solve(o, options)
```

Description

`ode::solve` computes solutions for ordinary differential equations.

`ode::solve(o)` returns the set of solutions of the ordinary differential equation `o`. You can also call the generic function `solve(o)`.

The solver detects the type of the differential equation and chooses an algorithm according to the detected equation type. If you know the type of the equation, you can use the option `Type` = OdeType to pass the equation type to the solver. Passing the equation type to the solver increases performance.

The solver recognizes the following values of `OdeType`:

- `Abel` - Abel differential equation
- `Bernoulli` - Bernoulli differential equation
- `Chini` - Chini differential equation
- `Clairaut` - Clairaut differential equation
- `ExactFirstOrder` - exact first order ordinary differential equation
- `ExactSecondOrder` - exact second order ordinary differential equation
- `Homogeneous` - homogeneous first order ordinary differential equation
- `Lagrange` - Lagrange differential equation
- `Riccati` - Riccati differential equation

See the Background section for more details on the classes of ordinary differential equations.

If the solver cannot identify the equation with the type you indicated, it issues a warning and returns the special value `FAIL`.

To solve an ordinary differential equation disregarding possible conditions on the parameters of the equation, use `IgnoreSpecialCases` option. This option eliminates receiving a set of special cases as an answer.

To solve an ordinary differential equation in a simplified manner, use the `IgnoreAnalyticConstraints` option. This option can provide simple solutions for the equations for which the direct use of the solver gives complicated results. If you use the `IgnoreAnalyticConstraints` option, always check the answer. This option can lead to wrong or incomplete results. See "Example 3" on page 21-45.

The solutions of ordinary differential equations can contain arbitrary constants of integration. The solver generates the constants of integration using the format of an uppercase letter `C` followed by an automatically generated number, for example `C13`.

The solver does not always verify the uniqueness and completeness of the returned solution. For example:

- The solver does not validate the Lipschitz-conditions on the ordinary differential equation for the Picard-Lindelöf Theorem.
- For some complex nonlinear systems of differential equations the solver returns constant solutions and does not warn you that other solutions exist.

The solver might ignore assumptions that you set on symbolic parameters and variables or use them only partially. More precisely, `ode::solve` passes assumptions to the functions that it calls internally. While these functions can use the specified assumptions, `ode::solve` itself does not use them in most of its internal algorithms. The same happens if you define an ordinary differential equation using `ode` and solve it using `solve`.

Examples

Example 1

To define an ordinary differential equation, use the `ode` command:

```
o:= ode(y'(x) = y(x)^2, y(x))
```

$$\text{ode}(y'(x) - y(x)^2,\ y(x))$$

To solve the equation, enter:

```
ode::solve(o)
```

$$\left\{0,\ -\frac{1}{C3 + x}\right\}$$

or more efficiently:

```
solve(o)
```

$$\left\{0,\ -\frac{1}{C7 + x}\right\}$$

Internally, the function `ode::solve` calls the function `solve`.

Example 2

You can solve an ordinary differential equation with a symbolic parameter and an initial condition:

```
o:= ode({y'(x) = a*y(x)^2, y(a) = ln(a)}, y(x)):
solve(o)
```

$$\begin{cases} \{0\} & \text{if } a = 1 \\ \left\{\dfrac{1}{\frac{1}{\ln(a)} - a\,x + a^2}\right\} & \text{if } a \neq 1 \end{cases}$$

To reduce the number of returned solutions, use the option `IgnoreSpecialCases`. For example, you can drop the solution for the parameter $a = 1$:

```
solve(o, IgnoreSpecialCases)
```

$$\left\{\frac{1}{\frac{1}{\ln(a)} - a\,x + a^2}\right\}$$

With the `IgnoreSpecialCases` option, a returned set of solutions can be incomplete.

Example 3

The solver can return `piecewise` solutions:

```
o:= ode(y'(x) = a/y(x)^2 + b*y(x), y(x)):
solve(o)
```

$$\begin{cases} \{C18\} & \text{if } a = 0 \wedge b = 0 \\ \left\{ \frac{\sigma_1}{b^{1/3}}, \sigma_3, \sigma_4, \frac{\sigma_1 \left(-\frac{1}{2}+\sigma_5\right)}{b^{1/3}}, \sigma_2, -\frac{\sigma_1 \left(\frac{1}{2}+\sigma_5\right)}{b^{1/3}} \right\} & \text{if } a \neq 0 \wedge b \neq 0 \\ \varnothing & \text{if } (a = 0 \vee b = 0) \wedge (a = 0 \vee b \neq 0) \wedge (a \neq 0 \vee b = 0) \wedge (a \neq 0 \vee b \neq 0) \\ \{\sigma_3, \sigma_4, \sigma_2\} & \text{if } ((a = 0 \wedge b \neq 0) \vee (a \neq 0 \wedge b = 0)) \wedge (a = 0 \vee b = 0) \wedge (a \neq 0 \vee b \neq 0) \end{cases}$$

where

$$\sigma_1 = (-a)^{1/3}$$

$$\sigma_2 = -\left(\frac{1}{2}+\sigma_5\right)\sigma_4$$

$$\sigma_3 = \left(-\frac{1}{2}+\sigma_5\right)\sigma_4$$

$$\sigma_4 = \left(-\frac{a - e^{3\,b\,(C19+x)}}{b}\right)^{1/3}$$

$$\sigma_5 = \frac{\sqrt{3}\,i}{2}$$

This solution is complete and mathematically correct for all possible values of the parameter a and variable x. Also you can try the option `IgnoreAnalyticConstraints` to obtain a particular solution that is correct under a set of common assumptions:

```
solve(o, IgnoreAnalyticConstraints)
```

$$\left\{ \frac{\sigma_2}{b^{1/3}}, \left(-\frac{1}{2}+\frac{\sqrt{3}\,i}{2}\right)\sigma_1, \sigma_1, \frac{\sigma_2\left(-\frac{1}{2}+\frac{\sqrt{3}\,i}{2}\right)}{b^{1/3}}, -\left(\frac{1}{2}+\frac{\sqrt{3}\,i}{2}\right)\sigma_1, -\frac{\sigma_2\left(\frac{1}{2}+\frac{\sqrt{3}\,i}{2}\right)}{b^{1/3}} \right\}$$

where

$$\sigma_1 = \left(-\frac{a-e^{3\,b\,(C24+x)}}{b}\right)^{1/3}$$

$$\sigma_2 = (-a)^{1/3}$$

The solver accepts several options:

```
solve(o, Type = Bernoulli, IgnoreAnalyticConstraints)
```

$$\left\{ \left(-\frac{1}{2}+\frac{\sqrt{3}\,i}{2}\right)\sigma_1, \sigma_1, -\left(\frac{1}{2}+\frac{\sqrt{3}\,i}{2}\right)\sigma_1 \right\}$$

where

$$\sigma_1 = \left(-\frac{a-C26\,b\,e^{3\,b\,x}}{b}\right)^{1/3}$$

Example 4

Suppose, you want to solve an ordinary differential equation from the class of Bernoulli equations:

```
o:= ode(y'(x) = (- 1/x + 2*I)*y(x) + 1/x*y(x)^2, y(x)):
solve(o)
```

$$\left\{0,\ \frac{e^{-\ln(x)+2\,x\,i}}{C28+2\,Ei(1,\ -2\,x\,i)\,i+\frac{e^{2\,x\,i}}{x}}\right\}$$

The solver recognizes the type of the equation and uses the algorithm for solving Bernoulli equations. To improve performance, you can explicitly pass the type of the equation to the solver:

```
solve(o, Type = Bernoulli)
```

$$\left\{0,\ \frac{x\,e^{-\ln(x)+2\,x\,i}}{e^{2\,x\,i}+C29\,x+2\,x\,Ei(1,\ -2\,x\,i)\,i}\right\}$$

To solve the Clairaut equation with the initial conditions, enter:

```
o:= ode({(x*y'(x)-y(x))^2 - y'(x)^2 - 1 = 0, y(1) = 1}, y(x)):
solve(o, Type = Clairaut)
```

$$\{1\}$$

If the solver cannot identify the equation with the type you indicated, it issues a warning and returns the special value `FAIL`:

```
o:= ode({(x*y'(x)-y(x))^2 - y'(x)^2 - 1 = 0, y(1) = 1}, y(x)):
solve(o, Type = Lagrange)
```

```
Warning: Cannot detect the Lagrange ODE. [ode::lagrange]
```

$$\text{FAIL}$$

Example 5

Some ordinary differential equations belong to several classes. For example, some Chini equations are also homogeneous and some Lagrange equations are also Clairaut equations. If an equation belongs to several classes simultaneously, the solver can present its solution in different forms. The form of a solution depends on the class with

which an equation is identified. For example, suppose you want to solve the Chini differential equation. You can explicitly pass the type of the equation to the solver:

```
o:= ode(y'(x) = 1/x*y(x)^2 + 1/x*y(x) + x, y(x)):
L:= solve(o, Type = Chini)
```

$$\{x \tan(C31 + x),\ -x\,i,\ x\,i\}$$

You also can let the solver recognize the type of the equation:

```
solve(o)
```

$$\left\{-x\,i,\ -x\,i + \frac{2\,e^{2\,x\,i}\,e^{\ln(x)-2\,x\,i}}{2\,C33\,e^{2\,x\,i} - i}\right\}$$

The solver does not return the type with which an ordinary differential equation is internally identified. If you want to verify that both solution sets are equivalent, use the `rewrite` function with target `exp` on the first set of solutions:

```
rewrite(L, exp)
```

$$\left\{-x\,i,\ x\,i,\ -\frac{x\left(e^{2\,C31\,i+2\,x\,i}\,i - i\right)}{e^{2\,C31\,i+2\,x\,i} + 1}\right\}$$

Example 6

MuPAD solves some classes of Riccati ordinary differential equations that involve arbitrary functions. For example, the following equation contains the arbitrary function `f(x)`:

```
eq := diff(y(x), x) - f(x)*y(x)^2 + a^2*x^(2*n)*f(x) - a*n*x^(n - 1)
```

$$\frac{\partial}{\partial x}\,y(x) - f(x)\,y(x)^2 + a^2\,x^{2\,n}\,f(x) - a\,n\,x^{n-1}$$

For this equation the solver returns:

```
solve(ode(eq,y(x)))
```

$$\left\{ a\,x^n,\ a\,x^n + \frac{e^{\int 2\,a\,x^n\,f(x)\,dx}}{C35 - \int e^{\int 2\,a\,x^n\,f(x)\,dx}\,f(x)\,dx} \right\}$$

You also can solve an equation with more than one arbitrary function. For example, the following equations contain `f(x)` and `g(x)`:

```
eq:= diff(y(x), x) - g(x)*f(x)*y(x) - g(x) - diff(f(x), x)*y(x)^2
```

$$-y(x)^2\,\frac{\partial}{\partial x}f(x) + \frac{\partial}{\partial x}y(x) - f(x)\,g(x)\,y(x) - g(x)$$

The returned solution is:

```
solve(ode(eq,y(x)))
```

$$\left\{ \frac{e^{\int f(x)\,g(x)\,dx - 2\ln(f(x))}}{C37 - \int e^{\int f(x)\,g(x)\,dx - 2\ln(f(x))}\,\frac{\partial}{\partial x}f(x)\,dx} - \frac{1}{f(x)},\ -\frac{1}{f(x)} \right\}$$

Example 7

Suppose, you want to solve the following second-order ordinary differential equation:

```
eq := x^2*(x^2 + 1)*diff(y(x),x,x) +
      x*(2*x^2 + 1)*diff(y(x),x) -
     (nu*(nu + 1)*x^2 + n^2)*y(x)
```

$$x\,(2\,x^2+1)\,\frac{\partial}{\partial x}y(x) - y(x)\,(n^2 + \mathrm{nu}\,(\mathrm{nu}+1)\,x^2) + x^2\,(x^2+1)\,\frac{\partial^2}{\partial x^2}y(x)$$

The solver returns the result in terms of the hypergeometric function ${}_1F_2$ (see `hypergeom`):

```
solve(ode(eq,y(x)))
```

$$\left\{ \frac{C39\ {}_2F_1\left(\frac{nu}{2}-\frac{n}{2}+\frac{1}{2}, \frac{n}{2}+\frac{nu}{2}+\frac{1}{2}; nu+\frac{3}{2}; \sigma_1\right)}{x^{nu+1}} + C40\ x^{nu}\ {}_2F_1\left(-\frac{n}{2}-\frac{nu}{2}, \frac{n}{2}-\frac{nu}{2}; \frac{1}{2}-nu; \sigma_1\right) \right\}$$

where

$$\sigma_1 = -\frac{1}{x^2}$$

Example 8

The solver can handle some third- and higher-order ordinary differential equations. For example, solve the following third-order linear differential equations:

```
eq := ode(sin(x)*y'''(x) + cos(x)*y(x), y(x)):
solve(eq)
```

$$\{C42\ \sin(x)\}$$

```
eq := ode(6*y(x) + x^3*y'''(x), y(x)):
solve(eq)
```

$$\left\{ C47\ \sigma_1 - \frac{\sigma_1\left(\frac{C46}{22}+\frac{3\sqrt{2}\ C46\ i}{44}\right)}{x^{3+\sqrt{2}\ i}} + \frac{\sqrt{2}\ C48\ \sigma_2\ \sigma_1\ i}{4} + \frac{\sqrt{2}\ \sigma_2\ \sigma_1\left(\frac{3\ C46}{11}+\frac{\sqrt{2}\ C46\ i}{11}\right) i}{4\ x^{3-\sqrt{2}\ i}} \right\}$$

where

$$\sigma_1 = x^{2+\sqrt{2}\ i}$$

$$\sigma_2 = \frac{1}{x^{2\sqrt{2}\ i}}$$

Example 9

The solver also can handle some nonlinear first-order ordinary differential equations. For example, solve the following first-order linear differential equations:

```
eq := ode(y(x)*diff(y(x), x) - y(x) - x^3 - 4*x^4 - 4*x^7, y(x)):
solve(eq)
```

$$\left\{x^4 + x + \frac{1}{4}\right\}$$

```
eq := ode(exp(x/2)/4 - 2*exp(x) - y(x) + x*exp(x/2) + y(x)*y'(x), y(x)):
solve(eq)
```

$$\left\{x - 2\,e^{\frac{x}{2}} + \frac{1}{4}\right\}$$

Parameters

o

An ordinary differential equation, an object of the type `ode`.

Options

Type

Option, specified as `Type = OdeType`

Indicates the type of the ordinary differential equation and accepts the following arguments: `Abel`, `Bernoulli`, `Chini`, `Clairaut`, `ExactFirstOrder`, `ExactSecondOrder`, `Homogeneous`, `Lagrange`, `Riccati`.

MaxDegree

Option, specified as `MaxDegree = n`

Pass the option to the generic solver, which is called internally for all intermediate equations. See the list of options for the `solve` function for further information.

IgnoreSpecialCases

Pass the option to the generic solver, which is called internally for all intermediate equations, and to the integrator `int`, which is called for computing all intermediate integrals. See the list of options for the `solve` function for further information.

`IgnoreAnalyticConstraints`

Pass the option to the generic solver, which is called internally for all intermediate equations, and to the integrator `int`, which is called for computing all intermediate integrals. See the list of options for the `solve` function for further information.

Return Values

Set of solutions of the ordinary differential equation or the special value `FAIL`. For additional information on the return values, see the `solve` help page.

ode::symmetricPower

Symmetric power of a homogeneous linear ordinary differential equation

Syntax

```
ode::symmetricPower(Ly, y(x), m)
```

Description

`ode::symmetricPower(Ly, y(x), m)` computes the m-th symmetric power of `Ly`. This is the lowest order linear ordinary differential equation whose solution space consists exactly of all possible m-th powerproducts of solutions of `Ly`.

Examples

Example 1

We compute the second symmetric power of the following differential equation:

```
Ly:=x^2*diff(y(x),x$2)-(36*x^6*exp(4*x^3)+9*x^6+2)*y(x)
```

$$x^2 \frac{\partial^2}{\partial x^2} y(x) - y(x) \left(36\, x^6\, e^{4\, x^3} + 9\, x^6 + 2\right)$$

```
ode::symmetricPower(Ly, y(x), 2)
```

$$\frac{\partial^3}{\partial x^3} y(x) - \left(144\, x^4\, e^{4\, x^3} + \frac{8}{x^2} + 36\, x^4\right) \frac{\partial}{\partial x} y(x)$$

$$- y(x) \left(288\, x^3\, e^{4\, x^3} + 864\, x^6\, e^{4\, x^3} - \frac{8}{x^3} + 72\, x^3\right)$$

Parameters

`Ly`

A homogeneous linear ordinary differential equation.

`y(x)`

The dependent function of `Ly`.

`m`

A positive integer.

Return Values

Linear differential equation

ode::unimodular

Unimodular transformation of a linear ordinary differential equation

Syntax

```
ode::unimodular(Ly, y(x), <Transform>)
```

Description

`ode::unimodular(Ly, y(x))` tests if the linear homogeneous differential equation `Ly` has a unimodular Galois group (i.e. the wronskian lies in the base field $\mathbb{Q}(x)$), if not transforms `Ly` into a unimodular one (by changing the second highest coefficient to zero) and returns a `table` with index `equation` and `factorOfTransformation` containing respectively the transformed differential equation and the factor of transformation `Wn` such that a solution of the transformed equation multiplied by `Wn` is a solution of `Ly`.

If the option `Transform` is given then `Ly` is transformed unconditionally even if `Ly` has yet a unimodular Galois group.

Examples

Example 1

We test if the following differential equation has a unimodular Galois group:

```
Ly := y(x)*6+x*diff(y(x),x)*(-2)+diff(y(x),x$2)*(-x^2+1)
```

$$-(x^2-1)\,\frac{\partial^2}{\partial x^2}\,y(x)-2\,x\,\frac{\partial}{\partial x}\,y(x)+6\,y(x)$$

```
ode::unimodular(Ly, y(x))
```

equation	$6\,y(x) - 2\,x\,\frac{\partial}{\partial x}\,y(x) - (x^2-1)\,\frac{\partial^2}{\partial x^2}\,y(x)$
factorOfTransformation	1

It is unimodular since the factor of transformation is 1. We can also check this by computing the wronskian of Ly which is a rational function:

```
ode::wronskian(Ly,y(x))
```

$$\frac{1}{x^2-1}$$

Now we transform Ly into a differential equation whose wronskian is 1:

```
ode::unimodular(Ly, y(x), Transform)
```

equation	$\frac{\partial^2}{\partial x^2}\,y(x) - \frac{y(x)\left(6\,x^2-7\right)}{-2\,x^2+x^4+1}$
factorOfTransformation	$\sqrt{\frac{1}{x^2-1}}$

```
ode::wronskian(%[equation], y(x))
```

$$1$$

Parameters

Ly

A homogeneous linear differential equation over $\mathbb{Q}(x)$.

y(x)

The dependent function of Ly.

Return Values

`table`.

See Also

MuPAD Functions
`ode::wronskian`

ode::vectorize

Coefficients of a homogeneous linear ODE

Syntax

```
ode::vectorize(Ly, y, x, n)
```

Description

`ode::vectorize(Ly, y, x, n)` returns the list of coefficients of the `n`-th order homogeneous linear ordinary differential equation `Ly`.

Examples

Example 1

We compute the list of coefficients of the following differential equation:

```
Ly := 4*x^2*diff(y(x), x$3)+exp(x^2)*diff(y(x),x$2)+
      4*x*diff(y(x),x)-y(x)
```

$$4\,x\,\frac{\partial}{\partial x}\,y(x)-y(x)+e^{x^2}\,\frac{\partial^2}{\partial x^2}\,y(x)+4\,x^2\,\frac{\partial^3}{\partial x^3}\,y(x)$$

```
ode::vectorize(Ly, y, x, 3)
```

$$\left[-1,\,4\,x,\,e^{x^2},\,4\,x^2\right]$$

Parameters

Ly

A homogeneous linear ordinary differential equation.

y

The dependent variable of `Ly`.

x

The independent variable of `Ly`.

n

The order of `Ly`, a positive integer.

Return Values

`list`

ode::wronskian

Wronskian of functions or of a linear homogeneous ordinary differential equation

Syntax

```
ode::wronskian(l, x, <R>)
```

```
ode::wronskian(Ly, y(x), <R>)
```

Description

`ode::wronskian` computes the wronskian (determinant) of functions or of a linear homogeneous ordinary differential equation.

`ode::wronskian(l, x)` returns the wronskian, i.e. the determinant of the wronskian matrix, of the elements of `l` with respect to `x`.

`ode::wronskian(Ly, y(x))` returns the wronskian of `Ly` defined as the element `w` such that $w' = -a_{n-1} w$, where a_{n-1} is the coefficient of `Ly` of degree n - 1 and n the order of `Ly`.

If the optional argument `R` is given, then the specified differential ring will be chosen for representing the entries of the wronskian matrix.

Examples

Example 1

We compute the wronskian of `[2*x^2+1, x*sqrt(1+x^2), y(x)]` which is a linear differential equation in `y(x)`:

```
Ly:=ode::wronskian([2*x^2+1, x*sqrt(1+x^2), y(x)], x)
```

$$4\,x\,\sigma_4\,\frac{\partial}{\partial x}\,y(x) - 4\,x^2\,\sigma_4\,\frac{\partial^2}{\partial x^2}\,y(x) - 4\,y(x)\,\sigma_3 - \sigma_1\,\sigma_2\,\frac{\partial}{\partial x}\,y(x) + 4\,x\,y(x)\,\sigma_2 + \sigma_1\,\sigma_3\,\frac{\partial^2}{\partial x^2}\,y(x)$$

where

$$\sigma_1 = 2\,x^2 + 1$$

$$\sigma_2 = \frac{3\,x}{\sigma_4} - \frac{x^3}{\left(x^2+1\right)^{3/2}}$$

$$\sigma_3 = \sigma_4 + \frac{x^2}{\sigma_4}$$

$$\sigma_4 = \sqrt{x^2+1}$$

```
Ly := numer( normal(Ly) )
```

$$x^2\,\frac{\partial^2}{\partial x^2}\,y(x) - 4\,y(x) + x\,\frac{\partial}{\partial x}\,y(x) + \frac{\partial^2}{\partial x^2}\,y(x)$$

And we can check that a basis of solutions of `Ly` is as expected:

```
ode::solve(Ly, y(x))
```

$$\left\{ C2\left(x+\sqrt{x^2+1}\right)^2 + \frac{C3}{\left(x+\sqrt{x^2+1}\right)^2} \right\}$$

We can also compute the wronskian of `Ly`, which is, up to a constant, the wronskian of `x^2+1` and `x*sqrt(x^2+1)`:

```
ode::wronskian(Ly, y(x)),
simplify(ode::wronskian([x^2+1/2,x*sqrt(1+x^2)], x))
```

$$\frac{1}{\sqrt{x^2+1}},\ \frac{1}{2\sqrt{x^2+1}}$$

Parameters

`l`

A list of functions of the variable `x`.

`Ly`

A homogeneous linear ordinary differential equation.

`y(x)`

The dependent function of `Ly`.

`R`

A differential ring, default is `Dom::ExpressionField(id, iszero@normal)`.

Return Values

Expression in `x`.

orthpoly – Orthogonal Polynomials

orthpoly::chebyshev1
orthpoly::chebyshev2
orthpoly::curtz
orthpoly::gegenbauer
orthpoly::hermite
orthpoly::jacobi
orthpoly::laguerre
orthpoly::legendre

orthpoly::chebyshev1

The Chebyshev polynomials of the first kind

Syntax

```
orthpoly::chebyshev1(n, x)
```

Description

`orthpoly::chebyshev1(n,x)` computes the value of the n-th degree Chebyshev polynomial of the first kind at the point x.

These polynomials have integer coefficients.

Evaluation is fast and numerically stable for real floating point values x from the interval [- 1.0, 1.0]. See “Example 2” on page 22-3.

`orthpoly::chebyshev2` implements the Chebyshev polynomials of the second kind.

Examples

Example 1

Polynomial expressions are returned if identifiers or indexed identifiers are specified:

```
orthpoly::chebyshev1(2, x)
```

$$2\,x^2 - 1$$

```
orthpoly::chebyshev1(3, x[1])
```

$$4\,x_1^{\,3} - 3\,x_1$$

Using arithmetical expressions as input, the “values” of these polynomials are returned:

```
orthpoly::chebyshev1(2, 3 + 2*I)
```

$$9 + 24\,i$$

```
orthpoly::chebyshev1(3, exp(x[1]+2))
```

$$4\,e^{6}\,e^{3\,x_1} - 3\,e^{x_1}\,e^{2}$$

"Arithmetical expressions" include numbers:

```
orthpoly::chebyshev1(2, sqrt(2)),
orthpoly::chebyshev1(3, 8 + I),
orthpoly::chebyshev1(1000, 0.3)
```

$$3,\ 1928 + 761\,i,\ -0.9991251116$$

If the degree of the polynomial is a variable or expression, then `orthpoly::chebyshev1` returns itself symbolically:

```
orthpoly::chebyshev1(n, x)
```

$$\text{orthpoly::chebyshev1}(n, x)$$

Example 2

If a floating-point value is desired, then a direct call such as

```
orthpoly::chebyshev1(200, 0.3)
```

$$-0.3169632681$$

is appropriate and yields a correct result. One should not evaluate the symbolic polynomial at a floating-point value, because this may be numerically unstable:

```
T200 := orthpoly::chebyshev1(200, x):

DIGITS := 10: evalp(T200, x = 0.3)
```

```
                                  - 3912167.235
```

This result is caused by numerical round-off. Also with increased `DIGITS` only a few leading digits are correct:

```
DIGITS := 20: evalp(T200, x = 0.3)
```

```
                                  - 0.31710101442512309682
```

```
delete DIGITS, T200:
```

Parameters

`n`

A nonnegative integer or an arithmetical expression representing a nonnegative integer: the degree of the polynomial.

`x`

An indeterminate or an arithmetical expression. An indeterminate is either an identifier (of domain type `DOM_IDENT`) or an indexed identifier (of type `"_index"`).

Return Values

The value of the Chebyshev polynomial at point `x` is returned as an arithmetical expression. If `n` is an arithmetical expression, then `orthpoly::chebyshev1` returns itself symbolically.

Algorithms

The Chebyshev polynomials are given by $T(n, x) = cos(n\ acos(x))$ for real $x \in [-1, 1]$. This representation is used by `orthpoly::chebyshev1` for floating-point values in this range.

These polynomials satisfy the recursion formula

$$T(n, x) = 2\,x\,T(n-1, x) - T(n-2, x)$$

with $T(0, x) = 1$ and $T(1, x) = x$.

They are orthogonal on the interval [- 1, 1] with respect to the weight function $w(x) = \frac{1}{\sqrt{(1-x^2)}}$.

$T(n, x)$ is a special Jacobi polynomial:

$$T(n, x) = \frac{2^{2n}\,n!^2}{(2\,n)!}\,P\left(n, -\frac{1}{2}, -\frac{1}{2}, x\right)$$

See Also

MuPAD Functions

`orthpoly::chebyshev2` | `orthpoly::jacobi`

orthpoly::chebyshev2

The Chebyshev polynomials of the second kind

Syntax

```
orthpoly::chebyshev2(n, x)
```

Description

`orthpoly::chebyshev2(n,x)` computes the value of the n-th degree Chebyshev polynomial of the second kind at the point x.

These polynomials have integer coefficients.

Evaluation is fast and numerically stable for real floating point values x from the interval [- 1.0, 1.0]. See “Example 2” on page 22-7.

`orthpoly::chebyshev1` implements the Chebyshev polynomials of the first kind.

Examples

Example 1

Polynomial expressions are returned if identifiers or indexed identifiers are specified:

```
orthpoly::chebyshev2(2, x)
```

$$4x^2 - 1$$

```
orthpoly::chebyshev2(3, x[1])
```

$$8x_1^3 - 4x_1$$

Using arithmetical expressions as input, the “values” of these polynomials are returned:

```
orthpoly::chebyshev2(2, 3 + 2*I)
```

$$19 + 48\,i$$

```
orthpoly::chebyshev2(3, exp(x[1] + 2))
```

$$8\,e^{6}\,e^{3\,x_1} - 4\,e^{x_1}\,e^{2}$$

"Arithmetical expressions" include numbers:

```
orthpoly::chebyshev2(2, sqrt(2)),
orthpoly::chebyshev2(3, 8 + I),
orthpoly::chebyshev2(1000, 0.3)
```

$$7,\ 3872 + 1524\,i,\ -1.012277265$$

If the degree of the polynomial is a variable or expression, then `orthpoly::chebyshev2` returns itself symbolically:

```
orthpoly::chebyshev2(n, x)
```

$$\text{orthpoly::chebyshev2}(n, x)$$

Example 2

If a floating-point value is desired, then a direct call such as

```
orthpoly::chebyshev2(200, 0.3)
```

$$-0.01869337443$$

is appropriate and yields a correct result. One should not evaluate the symbolic polynomial at a floating-point value, because this may be numerically unstable:

```
U200 := orthpoly::chebyshev2(200, x):

DIGITS := 10: evalp(U200, x = 0.3)
```

```
                    - 3872355.739
```

This result is caused by numerical round-off. Also with increased `DIGITS` only a few leading digits are correct:

```
DIGITS := 20: evalp(U200, x = 0.3)
```

```
                  - 0.018233184138451814741
```

```
delete DIGITS, U200:
```

Parameters

`n`

A nonnegative integer or an arithmetical expression representing a nonnegative integer: the degree of the polynomial.

`x`

An indeterminate or an arithmetical expression. An indeterminate is either an identifier (of domain type `DOM_IDENT`) or an indexed identifier (of type `"_index"`).

Return Values

The value of the Chebyshev polynomial at point `x` is returned as an arithmetical expression. If `n` is an arithmetical expression, then `orthpoly::chebyshev2` returns itself symbolically.

Algorithms

The Chebyshev polynomials of the second kind are given by

$$U(n, x) = \frac{\sin((n+1)\ \mathrm{acos}(x))}{\sin(\mathrm{acos}(x))}$$

for real $x \in [-1, 1]$. This representation is used by `orthpoly::chebyshev2` for floating-point values in this range.

These polynomials satisfy the recursion formula

$$U(n, x) = 2\,x\,U(n-1, x) - U(n-2, x)$$

with $U(0, x) = 1$ and $U(1, x) = 2\,x$.

They are orthogonal on the interval $[-1, 1]$ with respect to the weight function $w(x) = \sqrt{1-x^2}$.

$U(n, x)$ coincides with the Gegenbauer polynomial $G(n, 1, x)$.

$U(n, x)$ is a special Jacobi polynomial:

$$U(n, x) = \frac{2^{2n}\, n!\,(n+1)!}{(2n+1)!}\, P\left(n, \frac{1}{2}, \frac{1}{2}, x\right)$$

See Also

MuPAD Functions

`orthpoly::chebyshev1` | `orthpoly::gegenbauer` | `orthpoly::jacobi`

orthpoly::curtz

The Curtz polynomials

Syntax

```
orthpoly::curtz(n, x)
```

Description

`orthpoly::curtz(n,x)` computes the value of the n-th degree Curtz polynomial at the point x.

These polynomials have rational coefficients.

Evaluation for real floating-point values x is numerically stable. See "Example 2" on page 22-11.

Examples

Example 1

Polynomial expressions are returned if identifiers or indexed identifiers are specified:

```
orthpoly::curtz(2, x)
```

$$x^2 - x + \frac{1}{3}$$

```
orthpoly::curtz(3, x[1])
```

$$x_1^3 - \frac{3\,x_1^2}{2} + \frac{11\,x_1}{12} - \frac{1}{4}$$

Using arithmetical expressions as input, the "values" of these polynomials are returned:

```
orthpoly::curtz(2, 3+2*I)
```

$$\frac{7}{3} + 10\,i$$

```
orthpoly::curtz(3, exp(x[1] + 2))
```

$$\frac{11\,e^{x_1}\,e^{2}}{12} - \frac{3\,e^{4}\,e^{2\,x_1}}{2} + e^{6}\,e^{3\,x_1} - \frac{1}{4}$$

"Arithmetical expressions" include numbers:

```
orthpoly::curtz(2, sqrt(2)), orthpoly::curtz(3, 8 + I),
orthpoly::curtz(100, 0.3)
```

$$\frac{7}{3} - \sqrt{2},\ \frac{4807}{12} + \frac{2015\,i}{12},\ 0.001395122936$$

If the degree of the polynomial is a variable or expression, then `orthpoly::curtz` returns itself symbolically:

```
orthpoly::curtz(n, x)
```

$$\text{orthpoly::curtz}(n, x)$$

Example 2

If a floating-point value is desired, then a direct call such as

```
orthpoly::curtz(50, 1.2)
```

$$0.0003843630923$$

is appropriate and yields a correct result. One should not evaluate the symbolic polynomial at a floating-point value, because this may be numerically unstable:

```
orthpoly::curtz(50, x): evalp(%, x = 1.2)
```

$$0.0003849036173$$

Note that only 3 digits are correct due to numerical round-off.

Parameters

n

A nonnegative integer or an arithmetical expression representing a nonnegative integer: the degree of the polynomial.

x

An indeterminate or an arithmetical expression. An indeterminate is either an identifier (of domain type `DOM_IDENT`) or an indexed identifier (of type `"_index"`).

Return Values

The value of the Curtz polynomial at point `x` is returned as an arithmetical expression. If `n` is an arithmetical expression, then `orthpoly::curtz` returns itself symbolically.

Algorithms

The Curtz polynomials are given by the recursion formula

$$C(n, x) = x^n + x \left(\sum_{i=1}^{n-1} \frac{(-1)^i}{i+1} C(n-i-1, x) \right) + \frac{(-1)^n}{n+1}$$

with $C(0, x) = 1$.

orthpoly::gegenbauer

The Gegenbauer (ultraspherical) polynomials

Syntax

```
orthpoly::gegenbauer(n, a, x)
```

Description

`orthpoly::gegenbauer(n,a,x)` computes the value of the n-th degree Gegenbauer polynomial with parameter a at the point x.

Evaluation for real floating-point values x from the interval [- 1.0, 1.0] is numerically stable. See “Example 2” on page 22-14.

Examples

Example 1

Polynomial expressions are returned, if identifiers or indexed identifiers are specified:

```
orthpoly::gegenbauer(2, a, x)
```

$$x^2 (2 a^2 + 2 a) - a$$

```
orthpoly::gegenbauer(3, 2, x[1])
```

$$32 x_1^3 - 12 x_1$$

Using arithmetical expressions as input, the “values” of these polynomials are returned:

```
orthpoly::gegenbauer(2, 1, 3+2*I)
```

$$19 + 48\,i$$

```
orthpoly::gegenbauer(3, 2, exp(x[1] + 2))
```

$$32\,e^{6}\,e^{3\,x_1} - 12\,e^{x_1}\,e^{2}$$

"Arithmetical expressions" include numbers:

```
orthpoly::gegenbauer(2, a, sqrt(2)),
orthpoly::gegenbauer(3, 0.4, 8 + I),
orthpoly::gegenbauer(1000, -1/3, 0.3)
```

$$4\,a^2 + 3\,a,\ 865.536 + 341.152\,i,\ 0.00006046127974$$

If the degree of the polynomial is a variable or expression, then `orthpoly::gegenbauer` returns itself symbolically:

```
orthpoly::gegenbauer(n, a, x)
```

$$\text{orthpoly::gegenbauer}(n,\ a,\ x)$$

Example 2

If a floating-point value is desired, then a direct call such as

```
orthpoly::gegenbauer(200, 4, 0.3)
```

$$165549.7263$$

is appropriate and yields a correct result. One should not evaluate the symbolic polynomial at a floating-point value, because this may be numerically unstable:

```
G200 := orthpoly::gegenbauer(200, 4, x):
DIGITS := 10: evalp(G200, x = 0.3)
```

$$-6.270612376\ 10^{11}$$

This result is caused by numerical round-off. Also with increased `DIGITS` only a few leading digits are correct:

```
DIGITS := 20: evalp(G200, x = 0.3)
```

```
     165454.59819021060509
```

```
delete DIGITS, G200:
```

Parameters

n

A nonnegative integer or an arithmetical expression representing a nonnegative integer: the degree of the polynomial.

a

An arithmetical expression.

x

An indeterminate or an arithmetical expression. An indeterminate is either an identifier (of domain type `DOM_IDENT`) or an indexed identifier (of type `"_index"`).

Return Values

The value of the Gegenbauer polynomial at point `x` is returned as an arithmetical expression. If `n` is an arithmetical expression, then `orthpoly::gegenbauer` returns itself symbolically.

Algorithms

The Gegenbauer polynomials are given by the recursion formula

$$G(n, a, x) = \frac{2\,(n-1+a)}{n}\,x\,G(n-1, a, x) - \frac{n-2+2\,a}{n}\,G(n-2, a, x)$$

with $G(0, a, x) = 1$, $G(1, a, x) = 2\,a\,x$.

For fixed real $a > -\frac{1}{2}$ these polynomials are orthogonal on the interval [- 1, 1] with respect to the weight function $w(x) = (1 - x^2)^{a-\frac{1}{2}}$.

$G\left(n, \frac{1}{2}, x\right)$ coincides with the Legendre polynomial $P(n, x)$.

$G(n, 1, x)$ coincides with the Chebyshev polynomial $U(n, x)$ of the second kind.

The polynomials $G(n, 0, x)$ are trivial.

MuPAD Functions

`orthpoly::chebyshev2` | `orthpoly::legendre`

orthpoly::hermite

The Hermite polynomials

Syntax

```
orthpoly::hermite(n, x)
```

Description

`orthpoly::hermite(n,x)` computes the value of the n-th degree Hermite polynomial at the point x.

These polynomials have integer coefficients.

Examples

Example 1

Polynomial expressions are returned if identifiers or indexed identifiers are specified:

```
orthpoly::hermite(2, x)
```

$$4\,x^2 - 2$$

```
orthpoly::hermite(3, x[1])
```

$$8\,x_1^{\,3} - 12\,x_1$$

Using arithmetical expressions as input, the “values” of these polynomials are returned:

```
orthpoly::hermite(2, 3+2*I)
```

$$18 + 48\,\mathrm{i}$$

```
orthpoly::hermite(3, exp(x[1] + 2))
```

$$8\,e^6\,e^{3\,x_1} - 12\,e^{x_1}\,e^2$$

"Arithmetical expressions" include numbers:

```
orthpoly::hermite(2, sqrt(2)), orthpoly::hermite(3, 8 + I),
orthpoly::hermite(1000, 0.3);
```

$$6,\ 3808 + 1516\,i,\ 2.26821486\ 10^{1433}$$

If the degree of the polynomial is a variable or expression, then `orthpoly::hermite` returns itself symbolically:

```
orthpoly::hermite(n, x)
```

$$\text{orthpoly::hermite}(n, x)$$

Parameters

n

A nonnegative integer or an arithmetical expression representing a nonnegative integer: the degree of the polynomial.

x

An indeterminate or an arithmetical expression. An indeterminate is either an identifier (of domain type `DOM_IDENT`) or an indexed identifier (of type `"_index"`).

Return Values

The value of the Hermite polynomial at point `x` is returned as an arithmetical expression. If `n` is an arithmetical expression, then `orthpoly::hermite` returns itself symbolically.

Algorithms

The Hermite polynomials are given by the recursion formula

$$H(n, x) = 2\,x\,H(n-1, x) - 2\,(n-1)\,H(n-2, x)$$

with $H(0, x) = 1$ and $H(1, x) = 2\,x$.

These polynomials are orthogonal on the real line with respect to the weight function $w(x) = e^{-x^2}$.

orthpoly::jacobi

The Jacobi polynomials

Syntax

```
orthpoly::jacobi(n, a, b, x)
```

Description

`orthpoly::jacobi(n,a,b,x)` computes the value of the n-th degree Jacobi polynomial with parameters a and b at the point x.

Evaluation for real floating-point values x from the interval [- 1.0, 1.0] is numerically stable. See "Example 2" on page 22-21.

Examples

Example 1

Polynomial expressions are returned if identifiers or indexed identifiers are specified:

```
orthpoly::jacobi(2, a, b, x)
```

$$x^2\left(\frac{a^2}{8}+\frac{a\,b}{4}+\frac{7\,a}{8}+\frac{b^2}{8}+\frac{7\,b}{8}+\frac{3}{2}\right)-\frac{b}{8}-\frac{a\,b}{4}-\frac{a}{8}+\frac{a^2}{8}+\frac{b^2}{8}+x\left(\frac{a^2}{4}+\frac{3\,a}{4}-\frac{b^2}{4}-\frac{3\,b}{4}\right)$$

$$-\frac{1}{2}$$

```
orthpoly::jacobi(3, 4, 5, x[1])
```

$$\frac{455\,x_1^{\,3}}{8}-\frac{91\,x_1^{\,2}}{8}-\frac{91\,x_1}{8}+\frac{7}{8}$$

Using arithmetical expressions as input, the "values" of these polynomials are returned:

```
orthpoly::jacobi(2, 4, 1, 3+2*I)
```

$$63 + 120\,i$$

```
orthpoly::jacobi(2, 0, I, exp(x[1] + 2))
```

$$e^{x_1}\,e^{2}\left(\frac{1}{4}-\frac{3\,i}{4}\right)+e^{4}\,e^{2\,x_1}\left(\frac{11}{8}+\frac{7\,i}{8}\right)-\frac{5}{8}-\frac{i}{8}$$

"Arithmetical expressions" include numbers:

```
orthpoly::jacobi(2, 1/2, -1/2, sqrt(2)),
orthpoly::jacobi(3, 2, 5, 8 + I),
orthpoly::jacobi(1000, 1, 2, 0.3);
```

$$\frac{3\,\sqrt{2}}{4}+\frac{21}{8},\ \frac{31733}{2}+\frac{12859\,i}{2},\ -0.06546648097$$

If the degree of the polynomial is a variable or expression, then `orthpoly::jacobi` returns itself symbolically:

```
orthpoly::jacobi(n, a, b, x)
```

$$\text{orthpoly::jacobi}(n,\ a,\ b,\ x)$$

Example 2

If a floating-point value is desired, then a direct call such as

```
orthpoly::jacobi(100, 1/2, 3/2, 0.9)
```

$$0.2560339406$$

is appropriate and yields a correct result. One should not evaluate the symbolic polynomial at a floating-point value, because this may be numerically unstable:

```
P100 := orthpoly::jacobi(100, 1/2, 3/2, x):

evalp(P100, x = 0.9)
```

$$-8.6781052\ 10^{15}$$

This result is caused by numerical round-off. Also with increased `DIGITS` only a few leading digits are correct:

```
DIGITS := 30: evalp(P100, x = 0.9)
```

```
     0.256030968488207303016930946513
```

```
delete P100, DIGITS:
```

Parameters

n

A nonnegative integer or an arithmetical expression representing a nonnegative integer: the degree of the polynomial.

a, b

Arithmetical expressions.

x

An indeterminate or an arithmetical expression. An indeterminate is either an identifier (of domain type `DOM_IDENT`) or an indexed identifier (of type `"_index"`).

Return Values

The value of the Jacobi polynomial at point `x` is returned as an arithmetical expression. If `n` is an arithmetical expression, then `orthpoly::jacobi` returns itself symbolically.

Algorithms

The Jacobi polynomials are given by the recursion formula

$$2\,n\,c_n\,c_{2\,n-2}\,P(n,a,b,x) = c_{2\,n-1}\left(c_{2\,n-2}\,c_{2\,n}\,x + a^2 - b^2\right)P(n-1,a,b,x)$$

$$-2\,(n-1+a)\,(n-1+b)\,c_{2\,n}\,P(n-2,a,b,x)$$

with $c_i = i + a + b$ and

$$P(0, a, b, x) = 1,\ P(1, a, b, x) = \frac{a-b}{2} + \left(1 + \frac{a+b}{2}\right) x$$

.

For fixed real $a > -1$, $b > -1$ the Jacobi polynomials are orthogonal on the interval $[-1, 1]$ with respect to the weight function $w(x) = (1 - x)^a (1 + x)^b$.

For special values of the parameters a, b the Jacobi polynomials are related to the Legendre polynomials

$$P(n, x) = P(n, 0, 0, x)$$

,

to the Chebyshev polynomials of the first kind

$$T(n, x) = \frac{2^{2n} n!^2}{(2n)!} P\left(n, -\frac{1}{2}, -\frac{1}{2}, x\right)$$

,

to the Chebyshev polynomials of the second kind

$$U(n, x) = \frac{2^{2n} n!\,(n+1)!}{(2n+1)!} P\left(n, \frac{1}{2}, \frac{1}{2}, x\right)$$

,

and to the Gegenbauer polynomials, respectively:

$$G(n, a, x) = \frac{\Gamma\left(a + \frac{1}{2}\right) \Gamma(n + 2a)}{\Gamma(2a)\, \Gamma\left(n + a + \frac{1}{2}\right)} P\left(n, a - \frac{1}{2}, a - \frac{1}{2}, x\right)$$

.

MuPAD Functions

`orthpoly::chebyshev1` | `orthpoly::chebyshev2` | `orthpoly::gegenbauer` | `orthpoly::legendre`

orthpoly::laguerre

The (generalized) Laguerre polynomials

Syntax

```
orthpoly::laguerre(n, a, x)
```

Description

`orthpoly::laguerre(n,a,x)` computes the value of the generalized n-th degree Laguerre polynomial with parameter a at the point x.

The standard Laguerre polynomials correspond to $a = 0$. They have rational coefficients.

Examples

Example 1

Polynomial expressions are returned if identifiers or indexed identifiers are specified:

```
orthpoly::laguerre(2, a, x)
```

$$\frac{3\,a}{2} - x\,(a+2) + \frac{a^2}{2} + \frac{x^2}{2} + 1$$

```
orthpoly::laguerre(3, a, x[1])
```

$$\frac{11\,a}{6} - \frac{x_1^{\,3}}{6} - x_1\left(\frac{a^2}{2} + \frac{5\,a}{2} + 3\right) + \left(\frac{a}{2} + \frac{3}{2}\right)x_1^{\,2} + a^2 + \frac{a^3}{6} + 1$$

Using arithmetical expressions as input, the “values” of these polynomials are returned:

```
orthpoly::laguerre(2, 4, 3+2*I)
```

$$-\frac{1}{2}-6\,i$$

```
orthpoly::laguerre(2, 2/3*I, exp(x[1] + 2))
```

$$\frac{e^4\,e^{2\,x_1}}{2}+e^{x_1}\,e^2\left(-2-\frac{2\,i}{3}\right)+\frac{7}{9}+i$$

“Arithmetical expressions” include numbers:

```
orthpoly::laguerre(2, a, sqrt(2)),
orthpoly::laguerre(3, 0.4, 8 + I),
orthpoly::laguerre(1000, 3, 0.3);
```

$$\frac{3\,a}{2}-\sqrt{2}\,a-2\,\sqrt{2}+\frac{a^2}{2}+2,\ -4.969333333-8.713333333\,i,\ -15691.69498$$

If the degree of the polynomial is a variable or expression, then `orthpoly::laguerre` returns itself symbolically:

```
orthpoly::laguerre(n, a, x)
```

$$\text{orthpoly::laguerre}(n,\,a,\,x)$$

Parameters

n

A nonnegative integer or an arithmetical expression representing a nonnegative integer: the degree of the polynomial.

a

An arithmetical expression.

x

An indeterminate or an arithmetical expression. An indeterminate is either an identifier (of domain type `DOM_IDENT`) or an indexed identifier (of type `"_index"`).

Return Values

The value of the Laguerre polynomial at point `x` is returned as an arithmetical expression. If `n` is an arithmetical expression, then `orthpoly::laguerre` returns itself symbolically.

Algorithms

The Laguerre polynomials are given by the recursion formula

$$L(n, a, x) = \frac{2n + a - 1 - x}{n} L(n-1, a, x) - \frac{n + a - 1}{n} L(n-2, a, x)$$

with $L(0, a, x) = 1$ and $L(1, a, x) = 1 + a - x$.

For fixed real $a > -1$ these polynomials are orthogonal on the interval $[0, \infty)$ with respect to the weight function $w(x) = \frac{1}{(x^{ae})^x}$.

orthpoly::legendre

The Legendre polynomials

Syntax

```
orthpoly::legendre(n, x)
```

Description

`orthpoly::legendre(n,x)` computes the value of the n-th degree Legendre polynomial at the point x.

These polynomials have rational coefficients.

Evaluation for real floating-point values x from the interval [- 1.0, 1.0] is numerically stable. See “Example 2” on page 22-28.

Use `numeric::gldata` to compute the roots of the Legendre polynomials. Cf. “Example 3” on page 22-29.

Examples

Example 1

Polynomial expressions are returned if identifiers or indexed identifiers are specified:

```
orthpoly::legendre(2, x)
```

$$\frac{3\,x^2}{2} - \frac{1}{2}$$

```
orthpoly::legendre(3, x[1])
```

$$\frac{5\,x_1^{\,3}}{2} - \frac{3\,x_1}{2}$$

Using arithmetical expressions as input, the "values" of these polynomials are returned:

```
orthpoly::legendre(2, 3+2*I)
```

$$7 + 18\,i$$

```
orthpoly::legendre(3, exp(x[1] + 2))
```

$$\frac{5\,e^{6}\,e^{3\,x_1}}{2} - \frac{3\,e^{x_1}\,e^{2}}{2}$$

"Arithmetical expressions" include numbers:

```
orthpoly::legendre(2, sqrt(2)), orthpoly::legendre(3, 8 + I),
orthpoly::legendre(1000, 0.3)
```

$$\frac{5}{2},\ 1208 + 476\,i,\ -0.02566916751$$

If the degree of the polynomial is a variable or expression, then `orthpoly::legendre` returns itself symbolically:

```
orthpoly::legendre(n, x)
```

$$\text{orthpoly::legendre}(n, x)$$

Example 2

If a floating-point value is desired, then a direct call such as

```
orthpoly::legendre(100, 0.9)
```

$$0.1022658206$$

is appropriate and yields a correct result. One should not evaluate the symbolic polynomial at a floating-point value, because this may be numerically unstable:

```
P100 := orthpoly::legendre(100, x):

evalp(P100, x = 0.9)
```

$$8.284745953\ 10^{14}$$

This result is caused by numerical round-off. Also with increased `DIGITS` only a few leading digits are correct:

```
DIGITS := 30: evalp(P100, x = 0.9)
```

$$0.102276303910546875548266967112$$

```
delete P100, DIGITS:
```

Example 3

We recommend to use `numeric::gldata` for computing roots of the Legendre polynomial $P(n, x)$. This routine provides all roots of the function $Q(n, y) = P(n, 2\,y - 1)$:

```
QRoots := numeric::gldata(5, DIGITS)[2]
```

$$\left[0.04691007703,\ 0.2307653449,\ \frac{1}{2},\ 0.7692346551,\ 0.953089923\right]$$

These values are easily transformed to roots of $P(n, x)$:

```
PRoots := map(QRoots, y -> 2*y - 1)
```

$$[-0.9061798459,\ -0.5384693101,\ 0,\ 0.5384693101,\ 0.9061798459]$$

```
orthpoly::legendre(5, r) $ r in PRoots
```

$$-1.080385781\ 10^{-14},\ -1.387778781\ 10^{-18},\ 0,\ 1.387778781\ 10^{-18},\ 1.081218448\ 10^{-14}$$

```
delete QRoots, PRoots:
```

Parameters

n

A nonnegative integer or an arithmetical expression representing a nonnegative integer: the degree of the polynomial.

x

An indeterminate or an arithmetical expression. An indeterminate is either an identifier (of domain type `DOM_IDENT`) or an indexed identifier (of type `"_index"`).

Return Values

The value of the Legendre polynomial at point `x` is returned as an arithmetical expression. If `n` is an arithmetical expression, then `orthpoly::legendre` returns itself symbolically.

Algorithms

The Legendre polynomials are given by $P(n, x) = \frac{1}{2^n\, n!}\, \frac{d^n}{dx^n}(x^2 - 1)^n$.

They satisfy the recursion formula

$$P(n, x) = \frac{2\,n-1}{n}\, x\, P(n-1, x) - \frac{n-1}{n}\, P(n-2, x)$$

with $P(0, x) = 1$ and $P(1, x) = x$.

They are orthogonal on the interval [- 1, 1] with respect to the weight function $w(x) = 1$.

$P(n, x)$ coincides with the Gegenbauer polynomial $G\left(n, \frac{1}{2}, x\right)$.

$P(n, x)$ coincides with the Jacobi polynomial $P(n, 0, 0, x)$.

output::ordinal
output::roman
output::subexpr
output::tableForm
output::tree

output::asciiAbbreviate

Generates a procedure for creating an ASCII formatted output

Syntax

```
output::asciiAbbreviate(<varname>)
```

Description

`output::asciiAbbreviate` generates a procedure for creating ASCII formatted outputs of expressions

By default, MuPAD generates ASCII abbreviations using the # symbol followed by numbers. Using the argument `varname` you can customize the names of abbreviated subexpressions. See “Example 2” on page 23-3.

If you want to use abbreviations in all ASCII PrettyPrint output expressions, pass the procedure generated by `output::asciiAbbreviate` to `Pref::output`. See “Example 3” on page 23-3.

Examples

Example 1

The generated procedure `ascii` produces ASCII code for MuPAD expressions:

```
ascii:=output::asciiAbbreviate():
y := solve(x^3 + x + 1 = 0, x, MaxDegree = 3):
ascii(y)
```

```
{                                 /   1       \
{                          sqrt(3) | ---- + #1 | I
{        1     1    #1            \ 3 #1      /
{ #1 - ----, ---- - -- - ----------------------,
{      3 #1  6 #1    2               2
```

```
                      /   1       \    }
                sqrt(3) | ---- + #1 | I }
    1    #1            \ 3 #1      /    }
  ---- - -- + ----------------------- }
  6 #1    2               2            }

where

        / sqrt(31) sqrt(108)   1 \1/3
   #1 = | ------------------ - - |
        \          108         2 /
```

Example 2

You can customize the names of abbreviated subexpressions:

```
ascii:=output::asciiAbbreviate(t):
y := solve(x^3 + x + 1 = 0, x, MaxDegree = 3):
ascii(y)
```

```
{                                /   1       \
{                          sqrt(3) | ---- + t1 | I
{        1     1    t1            \ 3 t1      /
{ t1 - ----, ---- - -- - ----------------------,
{      3 t1  6 t1    2               2

                      /   1       \    }
                sqrt(3) | ---- + t1 | I }
    1    t1            \ 3 t1      /    }
  ---- - -- + ----------------------- }
  6 t1    2               2            }

where

        / sqrt(31) sqrt(108)   1 \1/3
   t1 = | ------------------ - - |
        \          108         2 /
```

Example 3

The generated procedure can serve as an input for `Pref::output`:

```
Pref::output(output::asciiAbbreviate(u)):
y := solve(x^3 + x + 1 = 0, x, MaxDegree = 3)
```

```
{                                  /   1       \
{                          sqrt(3) | ---- + u1 | I
{        1     1    u1            \ 3 u1      /
{ u1 - ----, ---- - -- + ----------------------,
{      3 u1  6 u1    2               2

                       /   1       \    }
               sqrt(3) | ---- + u1 | I }
    1    u1            \ 3 u1      /    }
  ---- - -- - ----------------------- }
  6 u1    2               2            }

where

        / sqrt(31) sqrt(108)   1 \1/3
   u1 = | ------------------ - - |
        \          108         2 /
```

Parameters

`varname`

A base name for the abbreviation variables

Return Values

Procedure for creating an ASCII formatted output

See Also

MuPAD Functions

`output::subexpr` | `Pref::abbreviateOutput` | `Pref::output`

output::fence

Put delimiters around multiline strings

Syntax

```
output::fence(left, right, string, <width, <base>>)
```

Description

`output::fence(left, right, string)` encloses the multiline string in the delimiters indicated by `left` and `right`

You can use `output::fence` in combination with `strprint` to overload `print` (and thereby, standard screen output) for pretty-printing. Note that it does not affect typeset output.

Examples

Example 1

Set `TEXTWIDTH` to 75:

```
TEXTWIDTH := 75:
```

First, define a domain that uses `output::fence` for output:

```
domain Fence
  print := x -> output::fence("(", ")", extop(x, 1));
  new   := x -> new(dom, x);
end_domain:
```

`Fence` expects a string in its constructor. The output uses `output::fence` to put parentheses around the input:

```
print(Plain, Fence("abc"))
```

```
(abc)
```

Strings of height two are only partly placed inside parentheses, for consistency with the pretty-printer:

```
print(Plain, Fence("abc\ndef"), sin(x^2))
```

```
 abc        2
(def), sin(x )
```

Strings of height more than two are fully bracketed:

```
print(Plain, Fence("abc\ndef\nghi"))
```

```
/ abc \
| def |
\ ghi /
```

Example 2

Set `TEXTWIDTH` to 75:

```
TEXTWIDTH := 75:
```

The next step in using `output::fence` is to enclose expressions in parentheses. For this, the information from `strprint` is useful:

```
domain FenceExpr
  print := proc(x)
             local str, h1, w1, h, w, b;
           begin
             [str, h1, w1, h, w, b] := strprint(All, extop(x));
             output::fence("{", "]", str, w, b);
           end_proc;
  new   := x -> new(dom, x);
end_domain:
```

The sixth operand of the return value of `strprint(All, …)` must be given to `output::fence` to align baselines properly:

```
print(Plain, FenceExpr(x), FenceExpr(x^2), FenceExpr(x^2/2*y))
```

```
           {  2   --
       2   { x  y  |
{x], {x ], { ----  |
           {   2  --
```

`strprint` reacts to `TEXTWIDTH` and can return a string consisting or more than one logical line. In this case, fencing the returned string leads to strange results:

```
print(Plain, FenceExpr(_plus(x.i $ i = 0..30)))
```

```
{ x0 + x1 + x2 + x3 + x4 + x5 + x6 + x7 + x8 + x9 + x10 + x11 + x12 + x13 \
   --
{                                                                        \
    |
{    + x14 + x15 + x16 + x17 + x18 + x19 + x20 + x21 + x22 + x23 + x24 + x\
25  |
{                                                                        \
    |
{    + x26 + x27 + x28 + x29 + x30                                       \
   --
```

Here, the string with added delimiter symbols is too wide for `TEXTWIDTH`. Also, `output::fence` does not let you control line breaks. Therefore, it is a good practice to avoid putting large delimiters to the left and right of long strings. For example, `abs` prints in functional notation for long arguments:

```
print(Plain, abs(_plus(x.i $ i = 0..30)))
```

```
abs(x0 + x1 + x2 + x3 + x4 + x5 + x6 + x7 + x8 + x9 + x10 + x11 + x12

   + x13 + x14 + x15 + x16 + x17 + x18 + x19 + x20 + x21 + x22 + x23 + x24

   + x25 + x26 + x27 + x28 + x29 + x30)
```

Parameters

`left, right`

Strings indicating the type of delimiter: `"("`, `")"`, `"["`, `"]"`, `"[+"`, `"+]"`, `"{"`, `"}"`, `"|"`, `"|  "`, or `"  |"`.

`string`

The string to enclose

`width`

The width of the string to enclose. Defaults to the width of the widest line in `string`.

`base`

The baseline of the string, counted from the first line. Defaults to the bottom line of the string. If set to `-1`, the baseline is vertically centered.

Return Values

String

See Also

MuPAD Functions
`strprint`

output::mathText

Pretty output of text combined with formulas

Syntax

```
output::mathText(str1, expr1, <str2, <expr2>, …>)
```

Description

`output::mathText( str1, expr1, str2, … )` creates an object of combined strings and expressions. This object prints itself nicely in various output formats.

Examples

Example 1

`output::mathText` creates an object representing combined text and formulas:

```
messageWithMath := output::mathText("The integral ",
                            hold(int(sin(x)*cos(x), x)),
                            " is equal to ", int(sin(x)*cos(x), x))
```

$$\text{The integral } \int \cos(x)\,\sin(x)\,dx \text{ is equal to } \frac{\sin(x)^2}{2}$$

They can be printed with the ASCII pretty-printer as well:

```
print(Plain, messageWithMath)
```

```
                /                                      2
               |                                   sin(x)
The integral   |  sin(x) cos(x) dx is equal to     -------
              /                                      2
```

Same for the ASCII lineprint output:

```
PRETTYPRINT := FALSE:
print(Plain, messageWithMath):
delete PRETTYPRINT:
```

```
The integral int(sin(x)*cos(x), x) is equal to (1/2)*sin(x)^2
```

Parameters

str_1, str_2

Strings

$expr_1$, $expr_2$

Expressions

Return Values

Object of type `output::mathText`

See Also

MuPAD Functions
`strprint`

output::ordinal

Ordinal numbers

Syntax

```
output::ordinal(i)
```

Description

`output::ordinal` converts an integer to the corresponding english ordinal number. The return value is a string and can be used in messages.

Examples

Example 1

Convert some numbers to the corresponding english ordinal string:

```
map([0, 1, 2, 3, 4, 22, 134, 2001], output::ordinal)
```

```
["0th", "1st", "2nd", "3rd", "4th", "22nd", "134th", "2001st"]
```

Parameters

`i`

An integer number

Return Values

String with the English ordinal number

See Also

MuPAD Functions
`info` | `print`

output::roman

Roman numerals

Syntax

```
output::roman(n)
```

Description

`output::roman` converts an integer to the corresponding roman numeral. The return value is a string and can be used in messages.

Examples

Example 1

Convert some numbers to the corresponding roman numerals:

```
map([1, 2, 3, 4, 22, 134, 2001], output::roman)
```

```
["I", "II", "III", "IV", "XXII", "CXXXIV", "MMI"]
```

Now, thanks to alias backsubstitution, we can trick MuPAD into computing with roman numerals:

```
alias(`I`=1): // I is a reserved word in MuPAD, so we use `I` instead
for i from 2 to 1000 do
    eval(text2expr("alias(".output::roman(i)."=".expr2text(i).");"));
end_for:
II+II;
XIII*XXIV
```

```
IV
```

CCCXII

```
unalias(`I`):
for i from 2 to 1000 do
    eval(text2expr("unalias(".output::roman(i).");"));
end_for:
```

Parameters

n

Positive integer

Return Values

String containing the roman numeral

See Also

MuPAD Functions

`info` | `print`

output::subexpr

Abbreviates a expression

Syntax

```
output::subexpr(e, <varname>)
```

Description

`output::subexpr` rewrites symbolic expression in terms of common subexpressions.

If an expression `e` contains common subexpressions, `output::subexpr(e)` returns a list that contains the abbreviated expression and the abbreviations in a form of equations. With `output::subexpr` you get the same abbreviations as you see in the outputs. See “Example 1” on page 23-15.

An output of this command does not depend on the current setting of `Pref::abbreviateOutput`.

By default, MuPAD generates abbreviations using the # symbol followed by numbers. Using the argument `varname`, you can customize the names of abbreviated subexpressions. See “Example 2” on page 23-16.

Examples

Example 1

You can abbreviate an expression:

```
y := solve(x^3 + x + 1 = 0, x, MaxDegree = 3):
output::subexpr(y)
```

$$\left[\left\{\#_1 - \frac{1}{3\,\#_1},\ \frac{1}{6\,\#_1} - \frac{\#_1}{2} + \frac{\sqrt{3}\left(\frac{1}{3\,\#_1} + \#_1\right)i}{2},\ \frac{1}{6\,\#_1} - \frac{\#_1}{2} - \frac{\sqrt{3}\left(\frac{1}{3\,\#_1} + \#_1\right)i}{2}\right\},\ \#_1 = \left(\frac{\sqrt{31}\,\sqrt{108}}{108} - \frac{1}{2}\right)^{1/3}\right]$$

Example 2

You can customize the names of abbreviated subexpressions:

```
y := solve(x^3 + x + 1 = 0, x, MaxDegree = 3):
output::subexpr(y, t)
```

$$\left[\left\{t1 - \frac{1}{3\,t1},\ \frac{1}{6\,t1} - \frac{t1}{2} - \frac{\sqrt{3}\left(\frac{1}{3\,t1} + t1\right)i}{2},\ \frac{1}{6\,t1} - \frac{t1}{2} + \frac{\sqrt{3}\left(\frac{1}{3\,t1} + t1\right)i}{2}\right\},\ t1 = \left(\frac{\sqrt{31}\,\sqrt{108}}{108} - \frac{1}{2}\right)^{1/3}\right]$$

Parameters

e

A MuPAD expression

varname

A base name for the abbreviation variables

Return Values

List that contains the abbreviated expression and the abbreviations as equations

See Also

MuPAD Functions

`output::asciiAbbreviate` | `Pref::abbreviateOutput`

output::tableForm

Printing objects in table form

Syntax

```
output::tableForm(obj, <separator>, options)
```

Description

`output::tableForm(obj)` prints the elements of the given object `obj` in table form.

The width of the table and the number of columns depends on the size of `TEXTWIDTH` (see options `Width` and `Columns`). The width of a column depends on the widest entry in this column.

`output::tableForm` determines the number of columns, that the total width of the table fits into `TEXTWIDTH`.

The columns are separated by one space by default.

If `separator` is given, then it is printed between each column (instead of one space). Appending spaces to the separator results additionally space between columns. By default the separator is one space.

If the first argument `obj` is a table or a domain, `output::tableForm` uses the option `Columns = 2` (two columns) and the separator `"= "` as default.

Without the option `Sort` the objects are converted to strings and then sorted alphabetically. To avoid any sorting the option `Sort = FALSE` must be given.

Examples

Example 1

For all examples on this page we assume the `TEXTWIDTH` 75:

```
TEXTWIDTH := 75:
```

Print some random numbers in table form:

```
SEED := -1:
output::tableForm([random(100000)() $ k = 1..30])
```

```
11647 12826 26280 26292 28315 30908 36523 42073 4682  47334 52640 56426

5829 615   62580 65904 66223 6719  69451 69903 77904 78221 80528 81013

86068 89016 90516 91008 92791 9532
```

Some random strings are created. The columns should have all the same width (`Unique`) and be printed centered. The strings should not be sorted:

```
output::tableForm([_concat("*" $ random(10)()) $ k = 1..20],
                  Unique, Center, Sort = FALSE)
```

```
 "********"  "******"   "*********" "********"      "*"     "******"

"*********"   "*****"     "****"    "********"    "****"    "*****"

"*********"  "*******"   "*******"   "******"      "**"     "****"
```

The option `Unquoted` prevents printing of quotes (see `fprint`):

```
output::tableForm([_concat("*" $ random(10)()) $ k = 1..20],
                  Unique, Center, Sort = FALSE, Unquoted)
```

```
********    *      ******   ******    ****    ******     **    **

  *****     *       ****     ****      **    ******** *******  **

    *    *******
```

Example 2

The next object is a MuPAD table and should be printed as a table with two columns. The table contains some random numbers and their sum of the digits:

```
SEED := -1:
T :=  table(op(map([random(100000000)() $ k = 1..10],
                   proc(X)
                     local Xs, k;
```

```
                    begin
                      Xs := expr2text(X);
                      X = _plus(text2expr(substring(Xs, k))
                                $ k = 1..length(Xs))
                    end_proc))):
output::tableForm(T)

19962580 = 40

25878221 = 35

37777904 = 44

41281013 = 20

43856426 = 38

46169451 = 36

66926292 = 42

80330908 = 31

89306719 = 43

94386068 = 44
```

Domains are also printed in this form by default:

```
output::tableForm(newDomain("Test",
                            table("type" = "Test",
                                  "info" = "only a testdomain")))

"info" = "only a testdomain"

"key" = "Test"

"type" = "Test"
```

Example 3

The next table should consist of four columns:

```
SEED := -1:
output::tableForm([random(100000)() $ k = 1..30], Columns = 4)
```

```
11647  12826  26280  26292

28315  30908  36523  42073

4682  47334  52640  56426

5829  615    62580  65904

66223  6719   69451  69903

77904  78221  80528  81013

86068  89016  90516  91008

92791  9532
```

The next table should have a maximal width of 50 characters:

```
SEED := -1:
output::tableForm([random(100000)() $ k = 1..30], Width = 50)
```

```
11647  12826  26280  26292  28315  30908  36523  42073

4682  47334  52640  56426  5829   615    62580  65904

66223  6719   69451  69903  77904  78221  80528  81013

86068  89016  90516  91008  92791  9532
```

```
delete T:
```

Example 4

The next examples show different usage of separators. First one single separator:

```
SEED := -1:
output::tableForm([random(100000)() $ k = 1..30], "|")
```

```
11647|12826|26280|26292|28315|30908|36523|42073|4682 |47334|52640|56426

5829|615  |62580|65904|66223|6719 |69451|69903|77904|78221|80528|81013

86068|89016|90516|91008|92791|9532
```

Now a list with a separator character between each column. If the list is too short, the characters are used from beginning of the list again etc.:

```
SEED := -1:
output::tableForm([random(100000)() $ k = 1..30], ["|", " ", " "])
```

```
11647|12826 26280 26292|28315 30908 36523|42073 4682  47334|52640 56426

5829|615   62580 65904|66223 6719  69451|69903 77904 78221|80528 81013

86068|89016 90516 91008|92791 9532
```

Only the first both colunms should be separated by a vertical line:

```
SEED := -1:
output::tableForm([random(100000)() $ k = 1..30], ["|", " " $ 10])
```

```
11647|12826 26280 26292 28315 30908 36523 42073 4682  47334 52640 56426

5829|615   62580 65904 66223 6719  69451 69903 77904 78221 80528 81013

86068|89016 90516 91008 92791 9532
```

Additionally a character can be appended to each entry:

```
SEED := -1:
output::tableForm([random(100000)() $ k = 1..30],
                  ["|", " " $ 10], Append = ",")
```

```
11647,|12826, 26280, 26292, 28315, 30908, 36523, 42073, 4682,  47334, 52640,

56426,|5829,  615,   62580, 65904, 66223, 6719,  69451, 69903, 77904, 78221,

80528,|81013, 86068, 89016, 90516, 91008, 92791, 9532,
```

Example 5

The next examples show different usage of sorting. Without the option `Sort` the numbers are sorted as strings in lexicographical order:

```
SEED := -1:
output::tableForm([random(100000)() $ k = 1..30])
```

```
11647 12826 26280 26292 28315 30908 36523 42073 4682  47334 52640 56426

5829 615   62580 65904 66223 6719  69451 69903 77904 78221 80528 81013

86068 89016 90516 91008 92791 9532
```

`Sort = FALSE` avoids any sorting:

```
SEED := -1:
output::tableForm([random(100000)() $ k = 1..30], Sort = FALSE)
```

```
30908 6719  26292 56426 81013 69451 77904 78221 86068 62580 47334 12826

9532 5829  28315 65904 42073 80528 4682  52640 69903 92791 36523 26280

89016 91008 615   66223 90516 11647
```

Any sorting can be done with a special defined procedure, e.g., sort the numbers in reverse order:

```
SEED := -1:
output::tableForm([random(100000)() $ k = 1..30],
                  Sort = ((X,Y) -> Y < X))
```

```
92791 91008 90516 89016 86068 81013 80528 78221 77904 69903 69451 66223

65904 62580 56426 52640 47334 42073 36523 30908 28315 26292 26280 12826

11647 9532  6719  5829  4682  615
```

At last a user defined procedure is given that sorts the numbers by the sum of their digits ascending:

```
SEED := -1:
output::tableForm([random(100000)() $ k = 1..30],
                  Sort = proc(X,Y)
                           local crossfoot;
                         begin
                           crossfoot :=
                             proc(X)
                               local Xs, k;
                             begin
                               Xs := expr2text(X);
                               _plus(text2expr(substring(Xs, k))
                                     $ k = 1..length(Xs))
                             end_proc;
                           crossfoot(X) < crossfoot(Y)
                         end_proc)
```

```
615  81013 42073 52640 91008 26280 36523 11647 12826 66223 9532 28315

30908 4682  78221 26292 90516 47334 62580 56426 80528 6719  5829 65904
```

```
89016  69451  77904  69903  92791  86068
```

Parameters

`obj`

A list, set or table of any MuPAD objects or a domain

`separator`

A string between columns

Options

`Unquoted`

Strings are printed without quotes

The output function `fprint` is called with the option `Unquoted`.

`Unique`

All columns are of the same width

All columns are printed with the same width, the widest column determines the width of each column.

`Width`

Option, specified as `Width = w`

The maximal width of the table is set to `w` (instead of `TEXTWIDTH`). `w` must be a positive integer.

`Columns`

Option, specified as `Columns = c`

The number of columns is set to `c`. The width of the table depends on the width of any column.

Note: `output::tableForm` called with this option takes not care about the value of `TEXTWIDTH`.

`c` must be a positive integer.

`Center, Left, Right`

The entries of each column are aligned left-justified, centered or justified.

`Sort`

Option, specified as `Sort = procedure`

The entries are sorted with the given procedure. Entries can be printed unsorted, when `procedure` is the object `FALSE`.

`Output`

Option, specified as `Output = file`

Output into a file. If `file` is a string, a file named `file` is opened and overwritten and closed after writing. If `file` is a file descriptor (the return value of `fopen`), the table is appended to `file` without closing `file`.

`String`

Return as a string that can be printed

The string contains line breaks, and can be printed with `print` or `fprint` and option `Unquoted`.

`Append`

Option, specified as `Append = string`

Character string is appended to each entry of the list

Return Values

Void object `null()`

MuPAD Functions
`fclose` | `fopen` | `fprint` | `output::tree` | `print` | `sort`

output::tree

Display of trees

Syntax

```
output::tree(Tree, <indentdepth, <charlist>, <Small>>)
```

Description

`output::tree` displays trees given as specially MuPAD lists.

The first object of the list is the root of the tree. All further objects are nodes or subtrees of the tree. A subtree is again a special list (as described), and any other MuPAD object will be interpreted as node of the tree.

The elements of the tree will be printed by MuPAD, when the tree will be displayed, so it's recommended to use strings as objects or objects with a well defined display.

The return value is a string that contains all chars to display the tree. With functions `print` and `fprint`*and* the option `Unquoted` the tree can be displayed.

The parameter `charlist` is a list with five characters. The default value is `["|", "+", "-", „", " "]`. The characters have the following meaning (described in the order of the list).

The vertical lines of the tree, the connection between vertical and horizontal line (i.e., an arm, but not the last arm), an arm (vertical line), the last connection to an arm in a subtree, a char between an arm and the description of the arm.

Examples

Example 1

`output::tree` displayes special nested lists as trees:

```
TREE := ["a1", "a2", ["b1", "b2", ["c1", "c2"], "b3"],
                ["d1", "d2", "d3"]]:
```

```
print(Unquoted, output::tree(TREE))
```

```
a1
|
+-- a2
|
+-- b1
|   |
|   +-- b2
|   |
|   +-- c1
|   |   |
|   |   `-- c2
|   |
|   `-- b3
|
`-- d1
    |
    +-- d2
    |
    `-- d3
```

```
print(Unquoted, output::tree(TREE, 3, Small)):
```

```
a1
+- a2
+- b1
|  +- b2
|  +- c1
|  |  `- c2
|  `- b3
`- d1
   +- d2
   `- d3
```

The chars can be defined by the user:

```
print(Unquoted, output::tree(TREE, 6, ["|", "|", ".", "\\", " "])):
```

```
a1
|
|.... a2
|
```

```
|.... b1
|      |
|      |.... b2
|      |
|      |.... c1
|      |      |
|      |      \.... c2
|      |
|      \.... b3
|
\.... d1
       |
       |.... d2
       |
       \.... d3
```

Parameters

`Tree`

The tree, given as a special list

`indentdepth`

Indent depth for each subtree

`charlist`

The chars that illustrate the tree structure

Options

`Small`

Suppresses the display of a space line between every tree entry to reduce the height of the tree

Return Values

String object to display

RGB::ColorNames

Find predefined colors by name

Syntax

```
RGB::ColorNames()

RGB::ColorNames(subname)
```

Description

`RGB::ColorNames(str)` returns a list of names of colors in the `RGB` name space whose names contain str.

`RGB::ColorNames` goes through the list of predefined color names and returns those whose names contain the string or identifier given as input, if any.

Environment Interactions

`RGB::plotColorPalette` plots a list of color samples with names.

Examples

Example 1

The following call returns all predefined color names containing "`Olive`":

```
RGB::ColorNames("Olive")
```

```
[Olive, OliveDrab, OliveGreen, OliveGreenDark]
```

The RGB values of these colors are:

```
RGB::Olive, RGB::OliveDrab, RGB::OliveGreen,
RGB::OliveGreenDark
```

```
[0.230003, 0.370006, 0.170003], [0.419599, 0.556902, 0.137303], [0.2, 0.2, 0.0],
  [0.333293, 0.419599, 0.184301]
```

Example 2

The following call plots all predefined colors containing "`Olive`":

```
RGB::plotColorPalette("Olive")
```

When the list of colors found gets larger, they are distributed over more lines:

```
RGB::plotColorPalette("Blue")
```

Colors containing 'Blue'

SlateBlueLight

Parameters

subname

A part of a color name: a string or an identifier

Return Values

`RGB::ColorNames` returns a list of predefined color names. `RGB::plotColorPalette` returns the empty object, `null()`.

See Also

MuPAD Functions
`RGB::plotColorPalette`

RGB::plotColorPalette

Display predefined colors

Syntax

```
RGB::plotColorPalette(subname)
```

Description

`RGB::plotColorPalette(str)` displays the colors in the `RGB` name space whose names contain str.

`RGB::plotColorPalette` uses `RGB::ColorNames` and plots samples of the colors found by this routine, in tabular fashion.

Environment Interactions

`RGB::plotColorPalette` plots a list of color samples with names.

Examples

Example 1

The following call returns all predefined color names containing "`Olive`":

```
RGB::ColorNames("Olive")
```

```
[Olive, OliveDrab, OliveGreen, OliveGreenDark]
```

The RGB values of these colors are:

```
RGB::Olive, RGB::OliveDrab, RGB::OliveGreen,
RGB::OliveGreenDark
```

```
[0.230003, 0.370006, 0.170003], [0.419599, 0.556902, 0.137303], [0.2, 0.2, 0.0],
  [0.333293, 0.419599, 0.184301]
```

Example 2

The following call plots all predefined colors containing "`Olive`":

```
RGB::plotColorPalette("Olive")
```

Parameters

subname

A part of a color name: a string or an identifier

Return Values

`RGB::ColorNames` returns a list of predefined color names. `RGB::plotColorPalette` returns the empty object, `null()`.

See Also

MuPAD Functions
`RGB::ColorNames`

RGB::colorName

Find names of predefined colors

Syntax

```
RGB::colorName(rgb, <Exact>)
```

Description

`RGB::colorName([r, g, b])` looks for the predefined color with values closest to `[r, g, b]` and returns its name.

`RGB::colorName([r, g, b], Exact)` looks for a predefined color with values exactly `[r, g, b]` and returns its name.

The `RGB` namespace contains predefined color names, accessible as `RGB::Blue` etc. `RGB::colorName` performs a reverse lookup, finding the name of a color given as RGB values.

Since rather often, colors will stem from calculations with floating-point numbers, no exact matches can be expected in this reverse lookup. Therefore, by default, `RGB::colorName` will perform a "fuzzy" search, returning the predefined color which is closest (in Euclidean distance in RGB space) to the input. Cf. "Example 2" on page 24-18.

Examples

Example 1

`RGB::colorName` returns the symbolic name of predefined colors:

```
RGB::colorName([0, 1, 0])
```

```
RGB::Green
```

```
RGB::colorName([0, 1, 0, 0.5])
```

```
RGB::Green.[0.5]
```

Example 2

When performing calculations on color values, the results will rarely be exact, even if the unavoidable round-off errors are too small to be displayed on the screen:

```
a := RGB::Olive;
b := RGB::fromHSV(RGB::toHSV(RGB::Olive))
```

```
[0.230003, 0.370006, 0.170003]
```

```
[0.230003, 0.370006, 0.170003]
```

```
bool(a = b)
```

```
FALSE
```

Therefore, `RGB::colorName` by default searches in a “fuzzy” fashion:

```
RGB::colorName(a);
RGB::colorName(b)
```

```
RGB::Olive
```

```
RGB::Olive
```

In cases where this is undesirable, the option `Exact` can be used to switch to exact searching:

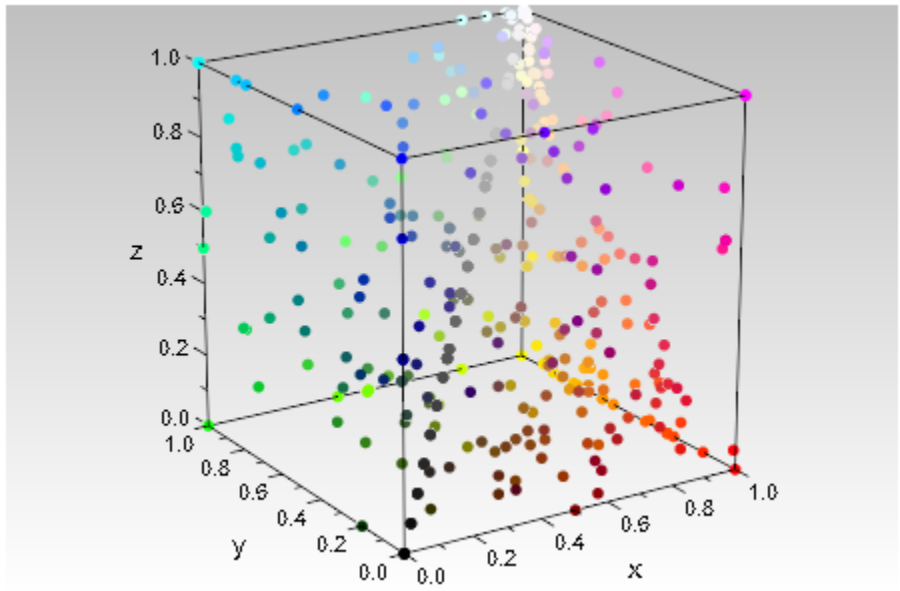
```
RGB::colorName(a, Exact);
RGB::colorName(b, Exact)
```

```
RGB::Olive
```

FAIL

The predefined color names do not fill RGB space uniformly, therefore, the color found by `RGB::colorName` may be quite different from the one entered. The following plot shows the predefined colors in RGB space:

```
plot(plot::Scene3d(
  plot::PointList3d([c.[c] $ c in RGB::ColorList]),
  ZXRatio = 1, BackgroundStyle = TopBottom,
  BackgroundColor = RGB::Grey,
  BackgroundColor2 = RGB::White,
  Margin=0))
```



Parameters

`rgb`

An RGB or RGBa color specification: A list of three or four real numbers in the interval [0, 1].

Options

`Exact`

Only return an exact match, FAIL if none exists.

Return Values

If a color was found, `RGB::colorName` returns an expression of the form `RGB::Name` or `RGB::Name.[a]`. If given `Exact` and no match was found, `FAIL` is returned. If given symbolic input parameters, an unevaluated call is returned.

See Also

MuPAD Functions
RGB

RGB::fromWaveLength

Get the RGB color of monochromatic light

Syntax

```
RGB::fromWaveLength(λ, <γ>)
```

Description

`RGB::fromWaveLength( λ )` returns an approximative RGB specification for light of wavelength $\lambda\, nm$.

Light consists of photons, each of which has a distinct wavelength. These different wavelengths cause color perception. `RGB::fromWaveLength` calculates an RGB triple corresponding to a given wave length.

Different displays show the same RGB color in slightly different ways. For this reason, the so-called "gamma correction" has been invented. `RGB::fromWaveLength` accepts a second argument, for fine-tuning the assumed gamma correction that enters the calculation.

Color perception depends on a number of factors, including individual differences. Therefore, such a calculation can only return an approximation. `RGB::fromWaveLength` uses the model published by Dan Bruton for the conversion.

For wavelengths outside the visible spectrum (which ranges from 380 nm to 780 nm), `RGB::fromWaveLength` returns black.

Examples

Example 1

White light, when sent through a prism, is split into the commonly known spectrum, because the prism refracts different wavelengths differently. This spectrum can easily be reproduced by `RGB::fromWaveLength`:

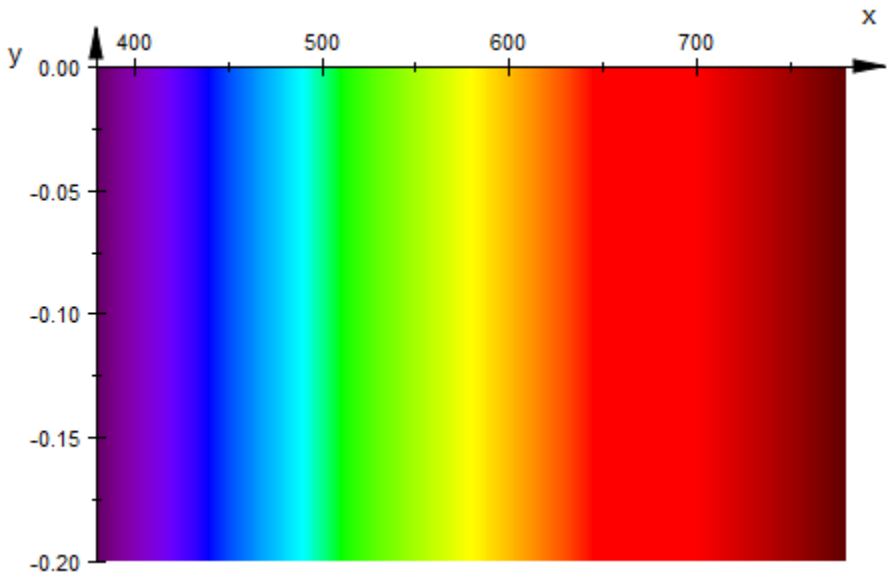
```
plot(plot::Raster([[RGB::fromWaveLength(i) $ i=380..780]]),
```

```
  Scaling = Unconstrained, Height = 20)
```

Example 2

Bruton's conversion model looks like this:

```
plotfunc2d(
  plot::Raster([[RGB::fromWaveLength(i) $ i = 380..780]],
    x = 380..780, y = -0.2..0),
  (x -> RGB::fromWaveLength(x)[i]) $ i = 1..3,
  x = 380..780,
  Colors = [RGB::Red, RGB::Green, RGB::Blue],
  LegendVisible = FALSE,
  XTicksNumber = Low,
  Scaling = Unconstrained,
  Axes = Automatic)
```



Parameters

λ

The wavelength: a real-valued constant (interpreted as nanometers) or a length expression

γ

The “gamma correcture” for the display, defaults to 0.8

Return Values

RGB color: a list of three floating-point values

See Also

MuPAD Functions
`RGB` | `RGB::fromHSV`

RGB::random

Pick a color uniformly at random in RGB color space

Syntax

```
RGB::random()
```

Description

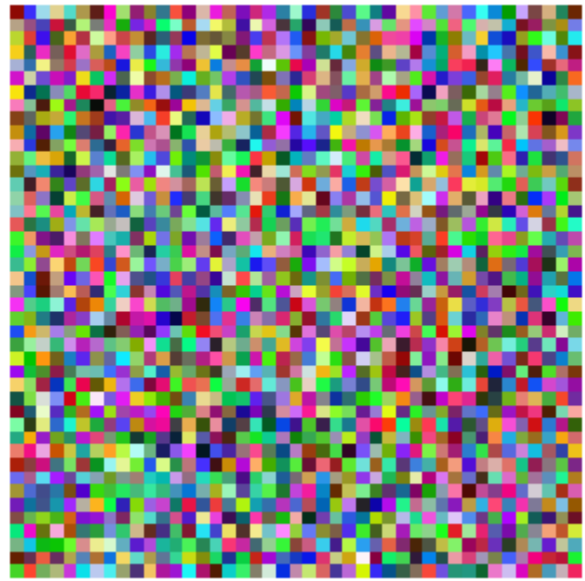
`RGB::random()` returns a random color. The colors returned are distributed independently and uniformly in the RGB color space.

Examples

Example 1

`RGB::random` can be used to produce high-frequency noise:

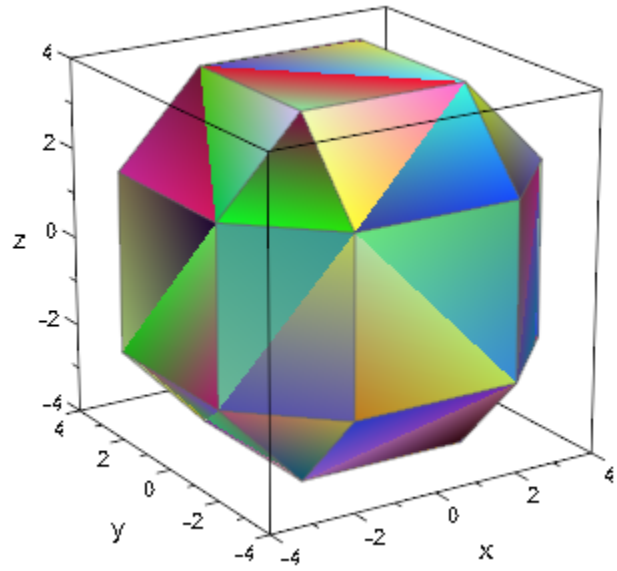
```
plot(plot::Raster([[RGB::random() $ x = 0..42] $ y = 0..42]))
```



Example 2

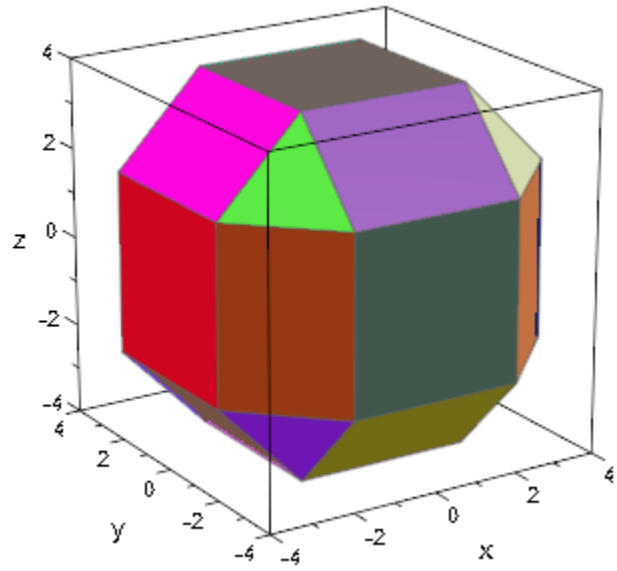
It is possible to use `RGB::random` directly as a color function, but the result may be unexpected:

```
plot(plot::Waterman(5, FillColorFunction = RGB::random))
```



The reason is that the color function will be called repeatedly if the same point is met again. It is a better idea to create a bunch of random colors and then use the parameters passed into the color functions to get some consistency into the choice of colors:

```
colors := [RGB::random() $ i = 1..42]:
plot(plot::Waterman(5, FillColorFunction=((x,y,z,i) -> colors[i])))
```



Return Values

RGB color: A list of three floating-point values.

See Also

MuPAD Functions
`frandom | RGB`

RGB::toHSV

Convert RGB colors to HSV

Syntax

```
RGB::toHSV([r, g, b, <a>])
```

Description

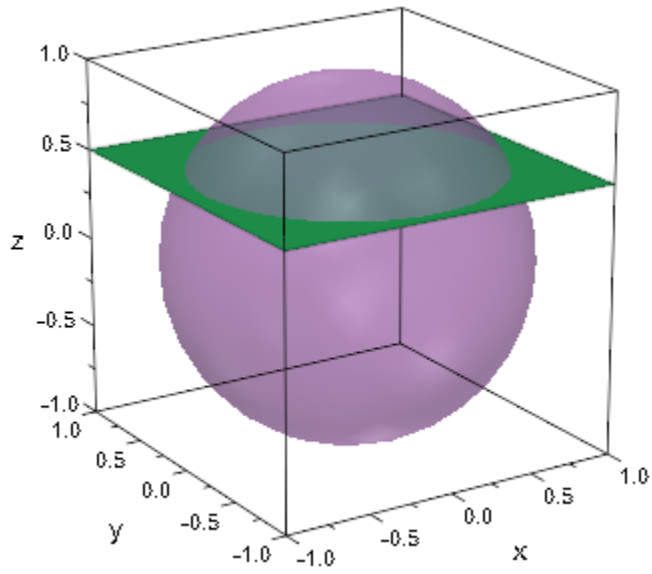
`RGB::toHSV(RGBcolor)` returns `RGBcolor` expressed in HSV values, with hue in the range `0..360` (i.e., in degrees) and saturation and value in the range `0..1`.

Examples

Example 1

With the `RGB::fromHSV` utility, all colors in a MuPAD graphics can be specified easily as HSV colors. For example, the color "violet" is given by the HSV values `[290, 0.4, 0.6]`, whereas "dark green" is given by the HSV specification `[120, 1, 0.4]`. Hence, a semi-transparent violet sphere intersected by an opaque dark green plain may be specified as follows:

```
plot(plot::Sphere(1, [0, 0, 0],
                  Color = RGB::fromHSV([290, 0.4, 0.6]).[0.5]),
     plot::Surface([x, y, 0.5], x = -1 .. 1, y = -1 .. 1,
                   Mesh = [2, 2],
                   Color = RGB::fromHSV([120, 1, 0.4]))
):
```



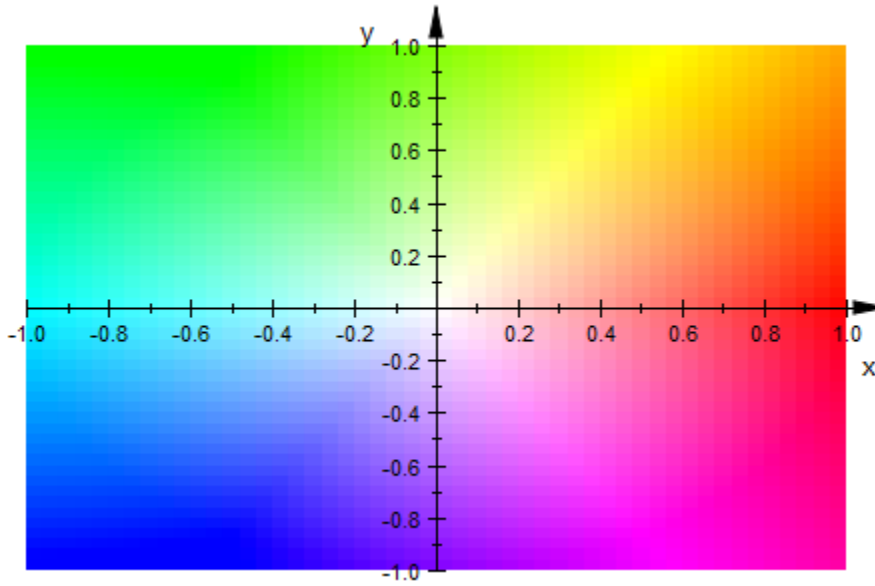
Example 2

There are numerous ways of displaying complex-valued functions of a complex argument, see for example `plot::Conformal`. One of these is to use a color scheme that interprets the complex plane as a section through HSV color space at a fixed value, say, 1. To plot this scheme in MuPAD, we use `plot::Density`, providing the following color function:

```
f_color := (x, y, fz, a) ->
           RGB::fromHSV([180/float(PI)*arg(fz), abs(fz), 1]):
```

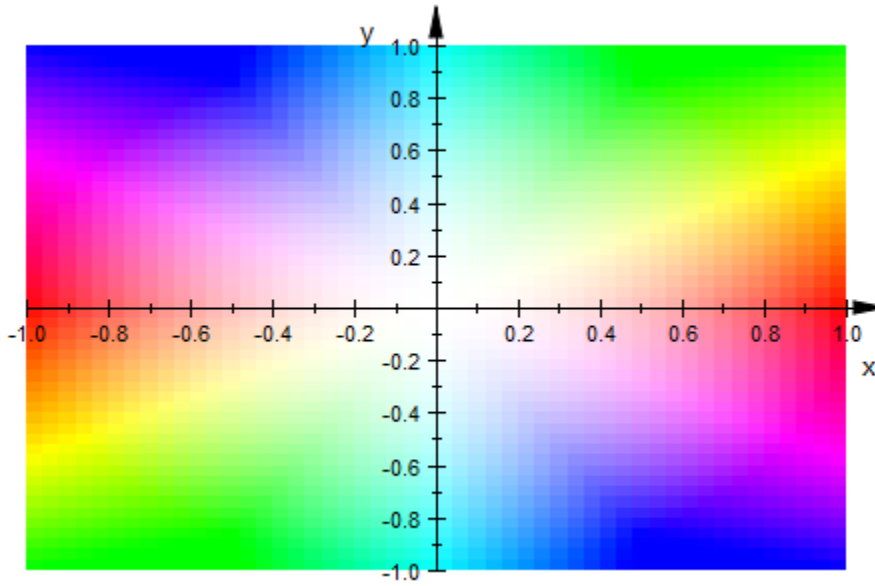
The identity function is thus shown as follows:

```
plot(plot::Density((x, y) -> x + I*y, x = -1..1, y = -1..1,
                   XMesh = 50, YMesh = 50,
                   FillColorFunction = f_color))
```



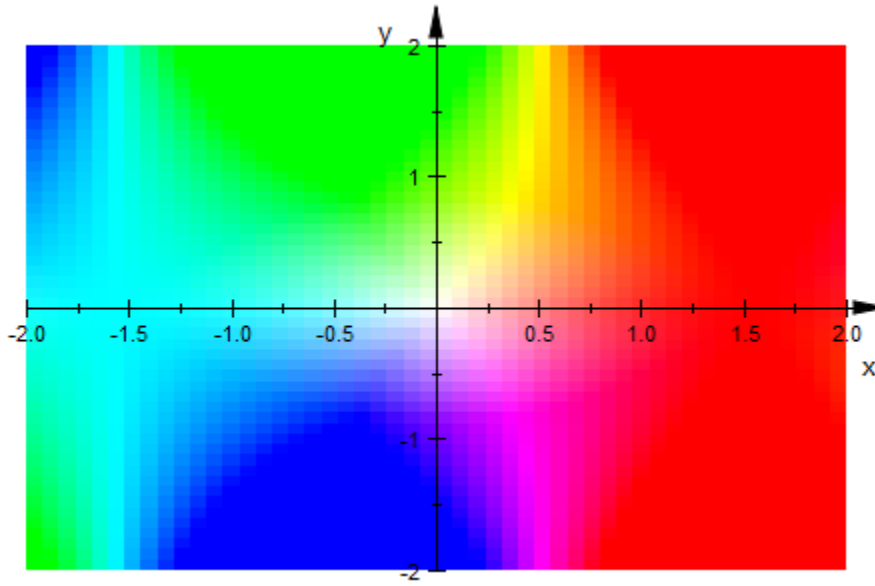
$z \to z^2$ doubles the argument of a complex function, resulting in the following picture:

```
plot(plot::Density((x, y) -> (x + I*y)^2, x = -1..1, y = -1..1,
                   XMesh = 50, YMesh = 50,
                   FillColorFunction = f_color))
```



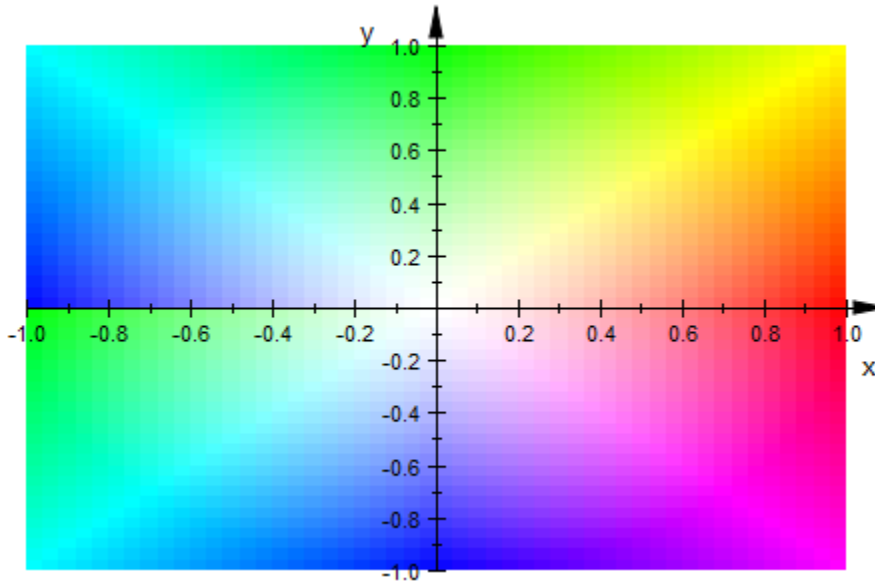
To plot the complex sine function, we choose a larger rectangle, since the sine is too similar to the identity in small neighborhoods of th origin to be of interest:

```
plot(plot::Density((x, y) -> sin(x + I*y), x = -2..2, y = -2..2,
                   XMesh = 50, YMesh = 50,
                   FillColorFunction = f_color))
```



$z \to z^{4/3}$ is clearly discontinuous along the negative real axis:

```
plot(plot::Density((x, y) -> (x + I*y)^(4/3),
                   x = -1..1, y = -1..1,
                   XMesh = 50, YMesh = 50,
                   FillColorFunction = f_color))
```



Parameters

r, g, b

The red, green, and blue contributions of an RGB color: numerical values between 0 and 1.

a

The translucency (alpha) value: a numerical value between 0 and 1.

Return Values

a list with three or four floating-point values, depending on whether a was given in the input.

See Also

MuPAD Functions
`RGB::fromHSV`

RGB::fromHSV

Convert HSV colors to RGB

Syntax

```
RGB::fromHSV([h, s, v, <a>])
```

Description

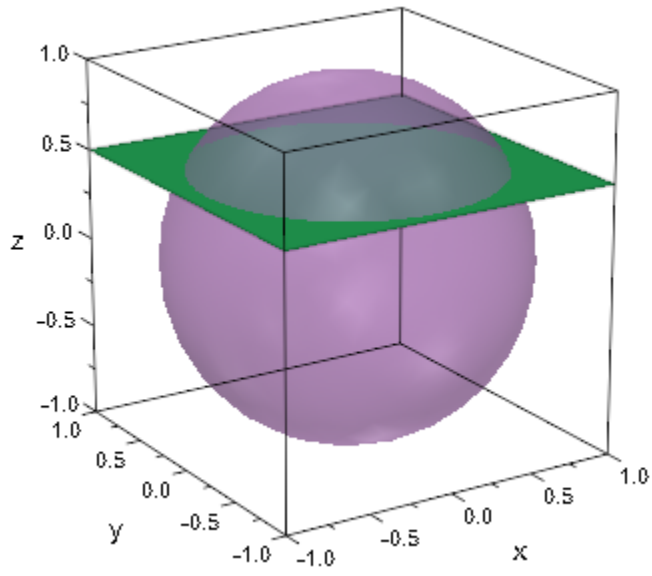
`RGB::fromHSV(HSVcolor)` is the inverse of `RGB::toHSV`: Given color coordinates in HSV, this function returns the corresponding RGB color. Cf. “Example 2” on page 24-36.

Examples

Example 1

With the `RGB::fromHSV` utility, all colors in a MuPAD graphics can be specified easily as HSV colors. For example, the color “violet” is given by the HSV values `[290, 0.4, 0.6]`, whereas “dark green” is given by the HSV specification `[120, 1, 0.4]`. Hence, a semi-transparent violet sphere intersected by an opaque dark green plain may be specified as follows:

```
plot(plot::Sphere(1, [0, 0, 0],
                  Color = RGB::fromHSV([290, 0.4, 0.6]).[0.5]),
     plot::Surface([x, y, 0.5], x = -1 .. 1, y = -1 .. 1,
                   Mesh = [2, 2],
                   Color = RGB::fromHSV([120, 1, 0.4]))
):
```



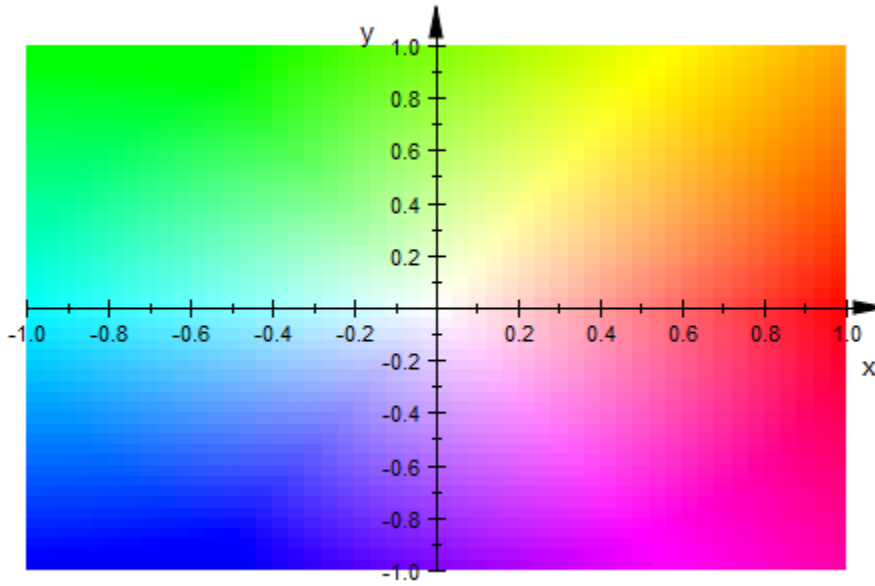
Example 2

There are numerous ways of displaying complex-valued functions of a complex argument, see for example `plot::Conformal`. One of these is to use a color scheme that interprets the complex plane as a section through HSV color space at a fixed value, say, 1. To plot this scheme in MuPAD, we use `plot::Density`, providing the following color function:

```
f_color := (x, y, fz, a) ->
           RGB::fromHSV([180/float(PI)*arg(fz), abs(fz), 1]):
```

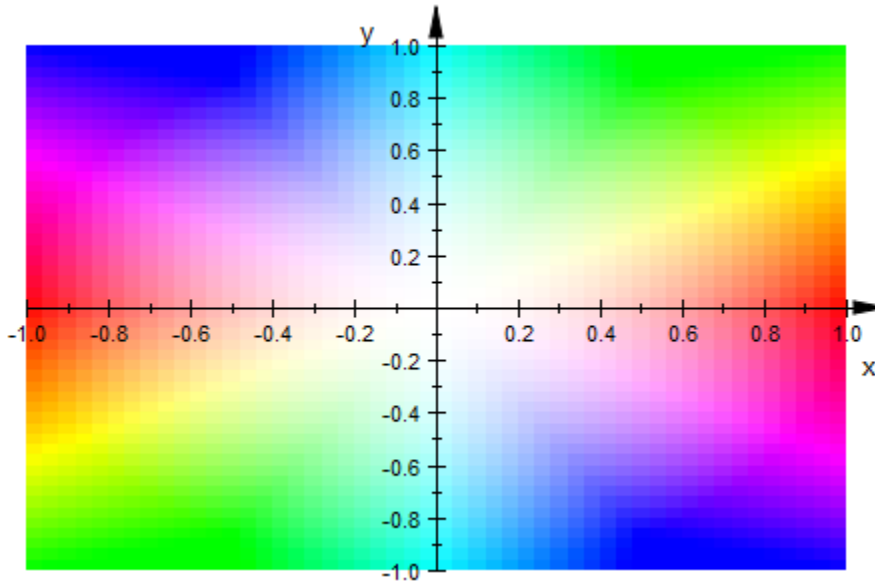
The identity function is thus shown as follows:

```
plot(plot::Density((x, y) -> x + I*y, x = -1..1, y = -1..1,
                   XMesh = 50, YMesh = 50,
                   FillColorFunction = f_color))
```



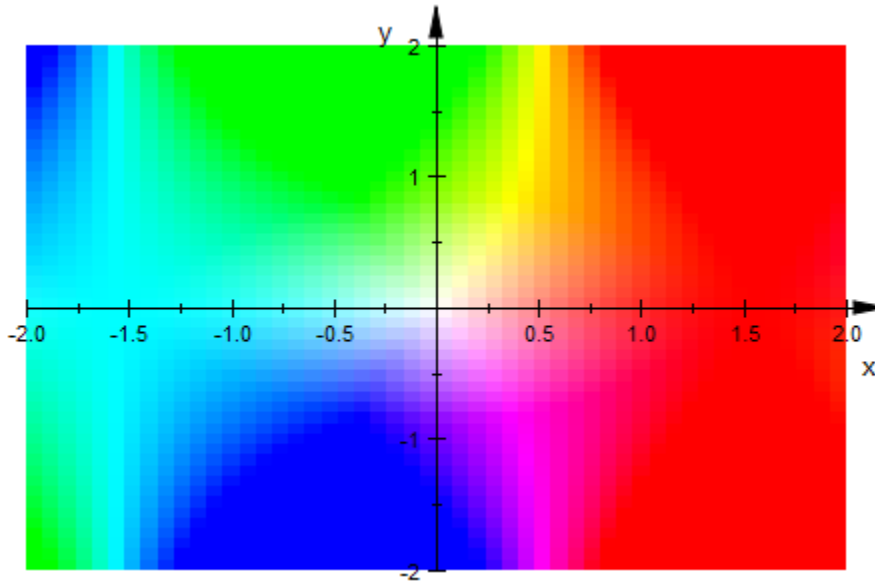
$z \to z^2$ doubles the argument of a complex function, resulting in the following picture:

```
plot(plot::Density((x, y) -> (x + I*y)^2, x = -1..1, y = -1..1,
                   XMesh = 50, YMesh = 50,
                   FillColorFunction = f_color))
```



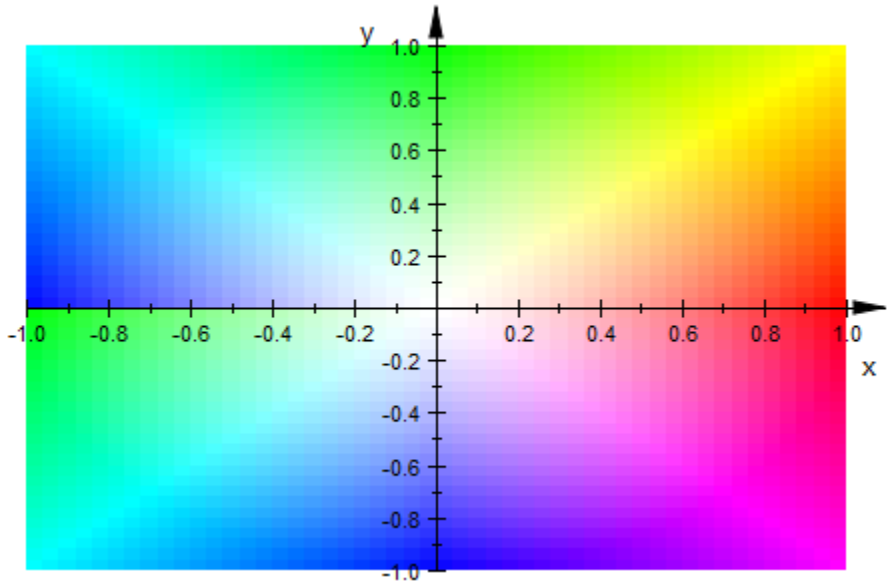
To plot the complex sine function, we choose a larger rectangle, since the sine is too similar to the identity in small neighborhoods of th origin to be of interest:

```
plot(plot::Density((x, y) -> sin(x + I*y), x = -2..2, y = -2..2,
                   XMesh = 50, YMesh = 50,
                   FillColorFunction = f_color))
```



$z \to z^{4/3}$ is clearly discontinuous along the negative real axis:

```
plot(plot::Density((x, y) -> (x + I*y)^(4/3),
                   x = -1..1, y = -1..1,
                   XMesh = 50, YMesh = 50,
                   FillColorFunction = f_color))
```



Parameters

a

The translucency (alpha) value: a numerical value between 0 and 1.

h

The “hue” in an HSV specification: a numerical value between 0 and 360

s

The “saturation” in an HSV specification: a numerical value between 0 and 1

v

The “value” in an HSV specification: a numerical value between 0 and 1

Return Values

a list with three or four floating-point values, depending on whether a was given in the input.

`RGB::toHSV`

plot::easy

Easy plotting

Syntax

```
plot::easy(<arg, …>, options)
```

Description

`plot::easy( arg , <options>, …)` transforms data and expressions into graphical objects.

`plot::easy` accepts graphical objects and graphical attributes as input and returns them unchanged.

`plot::easy` supports the options listed above. Additionally, it accepts arbitrary data and expressions and tries to transform them into valid graphical objects.

`plot::easy` supports the option `Colors`=[c_1,...c_2] for automatically coloring newly generated graphical objects. The given list is used instead of the internally defined default color list.

`plot::easy` accepts the options `Mesh` and `Submesh` and uses them for each newly generated graphical object.

The function `plot` calls `plot::easy` for preprocessing its input before plotting.

`plot::easy` tries to handle standard situations intuitively in order to make plotting as easy as possible. However, it supports only a small subset of the graphical objects, attributes and expressions available in MuPAD and thus does not claim to be complete.

Users that want to plot other objects or control specific details of their graphics explicitly, still have to create their graphical objects manually, e.g. using `plot::Function2d` and `plot::Point2d`, and to use graphical attributes like `LineStyle =Dashed` directly.

`plot::easy` sets a new color for each object that it creates, if no color is predefined in the given context.

`plot::easy` accepts sets {...} as group definition and transforms them into graphical objects of type `plot::Group2d(...)` or `plot::Group3d(...)`, respectively. All elements of a group share the same color, if colors were not specified explicitly for single objects.Note that, regular graphical objects usually have a predefined color.

`plot::easy` accepts a nested set {{...}} as scene definition and transforms it into the graphical object `plot::Scene2d(...)` or `plot::Scene3d(...)`, respectively.

Creating a graphical object may require the specification of value ranges for variables. If they are not specified explicitly then `plot::easy` tries use ranges specified for other variables and/or uses the default value range `-5..5`.

Examples

Example 1

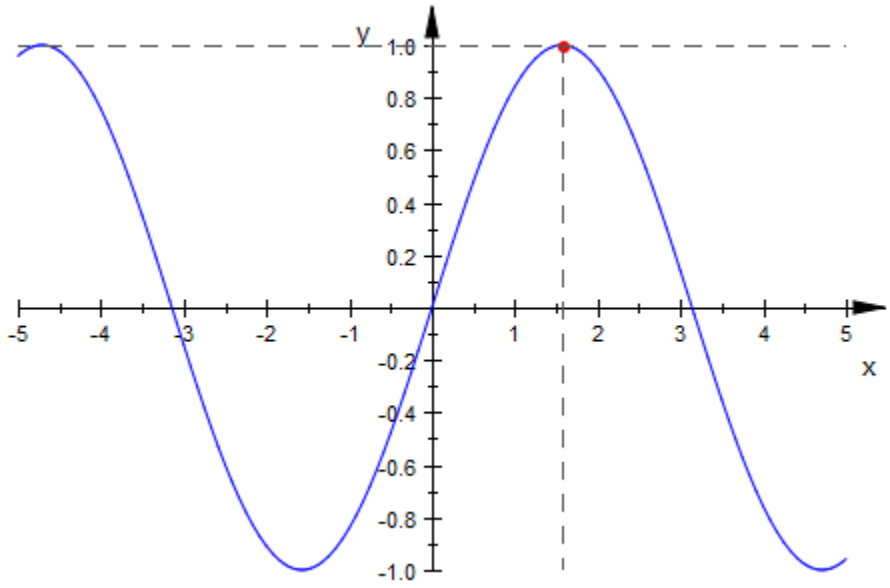
`plot::easy` tries to transform all given data and expressions into valid graphical objects and attributes:

```
plot::easy(sin(x), [PI/2,1])
```

$$\text{plot::Function2d}(\sin(x),\ x = -5..5),\ \text{plot::Point2d}\left(\frac{\pi}{2},\ 1,\ \text{PointColor} = \text{RGB::Red},\ \text{LegendText} = \text{"[PI/2, 1]"}\right)$$

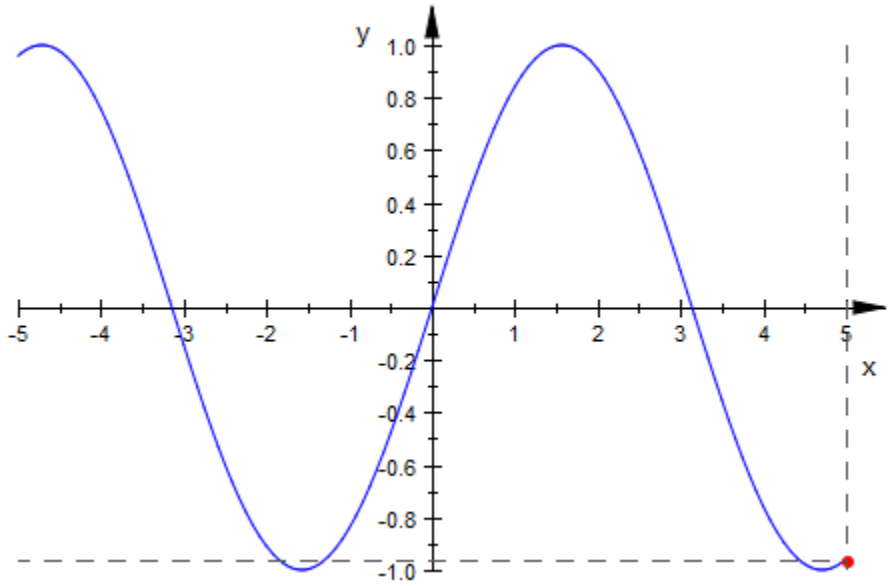
Since the function `plot` calls the function `plot::easy` for preprocessing its input data, scenes like above can directly be plotted using `plot`:

```
plot(sin(x), [PI/2,1], #x = PI/2, #y = 1)
```



Now, it is only a small step to animate this scene:

```
plot(sin(x), {[x,sin(x)], #Points}, #x = x, #y = sin(x))
```



Note: Graphical objects and attributes, as well as data that `plot::easy` cannot transform, are returned unchanged:

```
plot::easy(x, plot::Point2d(1,1), LineStyle=Dashed, "UnknownObject")
```

plot::Function2d(x, x = −5..5), plot::Point2d(1, 1), LineStyle = Dashed, "UnknownObject"

This is why `plot` returns the following error message when it is executed with the above arguments:

```
plot(x, plot::Point2d(1,1), LineStyle=Dashed, "UnknownObject");
```

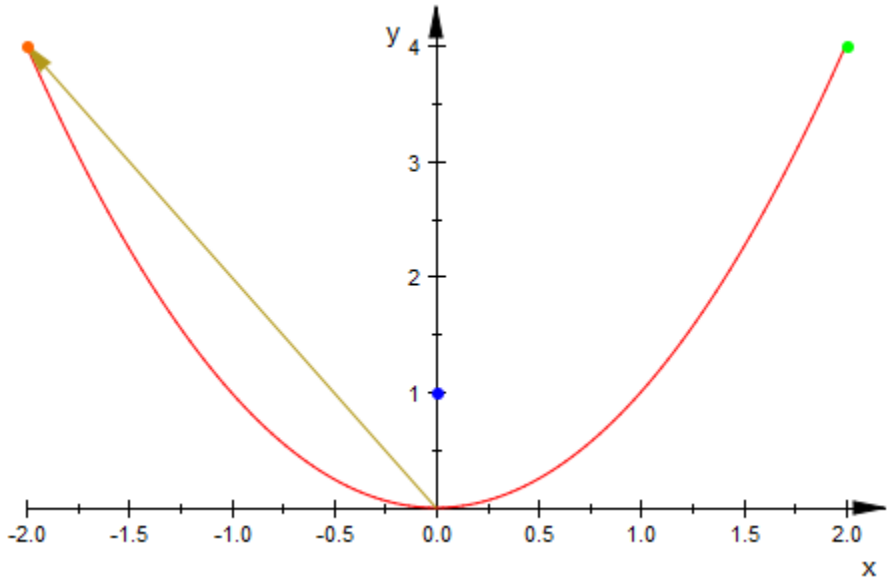
```
Error: The arguments 'UnknownObject' are unexpected. [plot::Canvas::new]
```

Example 2

Points can be entered as lists with two or three values. Alternatively, a corresponding column vector in combination with the option `#Points` (alias `#P`, see “Example 18” on page 24-75) can be used.

Note that for plotting animated points the option `#Points` is required. Otherwise a curve (when entered a list) or an arrow (when entered a vector) is plotted:

```
plot([0,1], [s,s^2], {[s,s^2], #Points}, s = -2.. 2,
     matrix([t,t^2]), {matrix([t,t^2]), #Points}, t = 2..-2
)
```

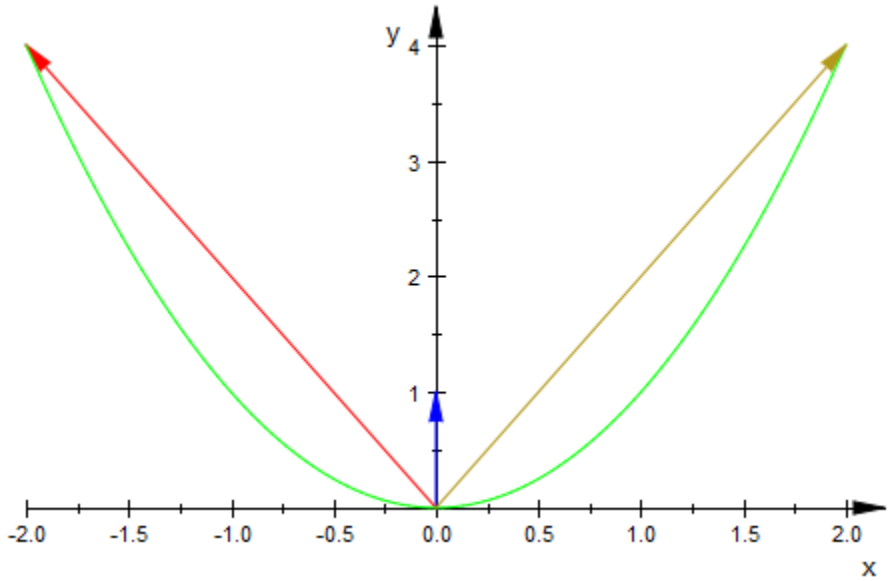


See also: `plot::Point2d`, `plot::Point3d`.

Example 3

Arrows can be specified as column vectors with two or three elements. Alternatively, a list in combination with the option `#Arrows` (alias `#A`, see “Example 13” on page 24-70) can be used:

```
plot(matrix([0,1]), matrix([s,s^2]), s = 2..-2,
     [t,t^2], {[t,t^2], #Arrows}, t = -2..2
)
```

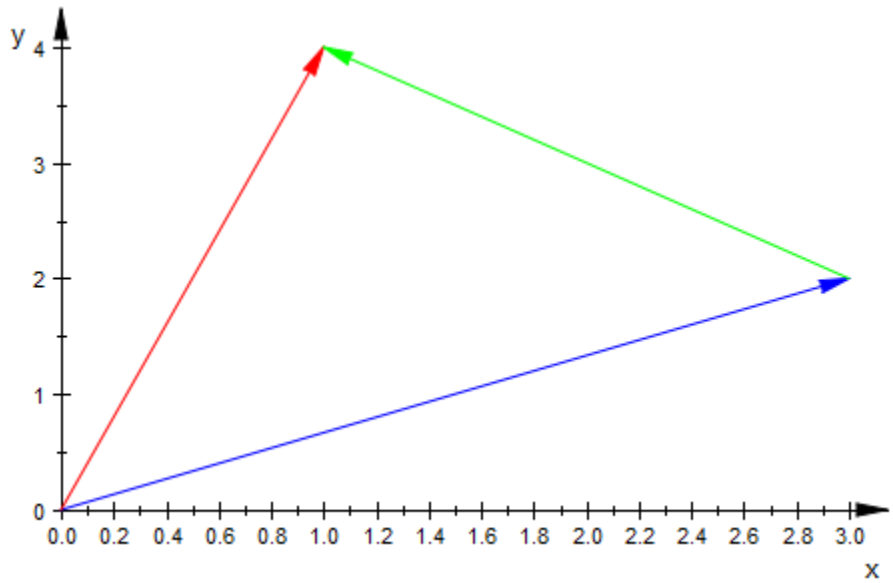


If an arrow should start at coordinates other than (0,0) or (0,0,0), respectively, then a list of two column vectors or a corresponding list of lists in combination with the option `#Arrows` (alias `#A`, see "Example 13" on page 24-70) can be used:

```
u := matrix([3,2]):
v := matrix([1,4]):
w := (1-a)*u + a*v:
u, v, w;
```

$$\begin{pmatrix} 3 \\ 2 \end{pmatrix}, \begin{pmatrix} 1 \\ 4 \end{pmatrix}, \begin{pmatrix} 3-2\,a \\ 2\,a+2 \end{pmatrix}$$

```
plot(u, v, [u,w], a = 0.1..1, #Arrows)
```



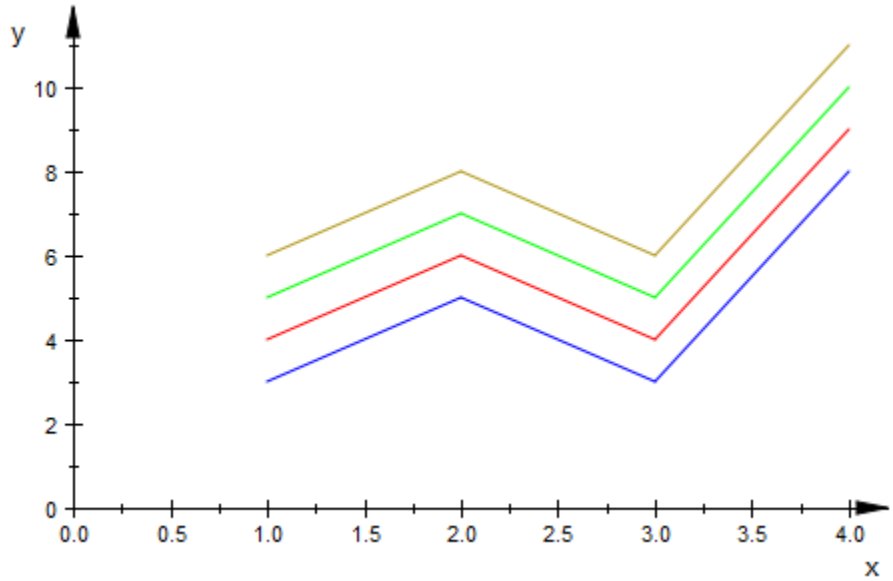
```
delete u, v, w:
```

See also: `plot::Arrow2d`, `plot::Arrow3d`.

Example 4

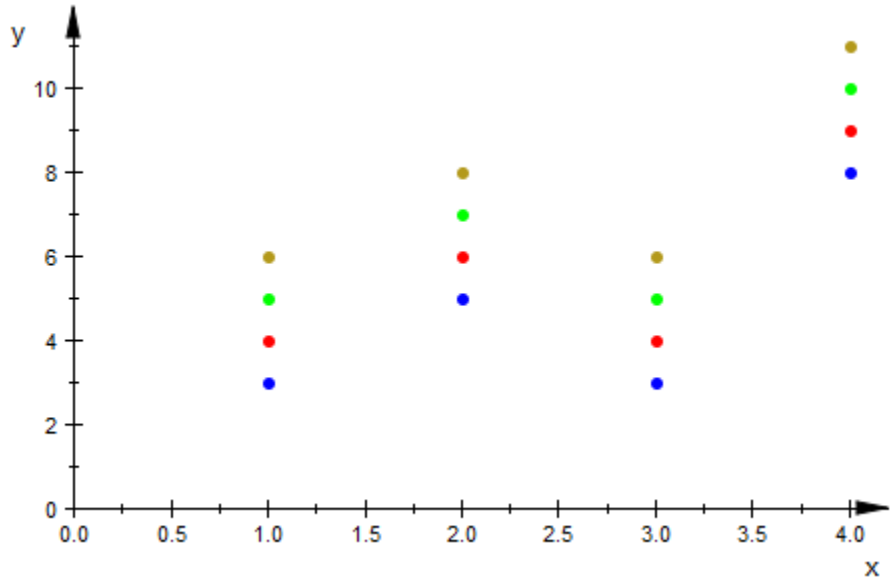
Polygons can be specified as lists, tables or matrices. In the following example, polygons are plotted using different input styles. The option `#Origin` (alias `#0`, see "Example 17" on page 24-74) ensures that the origin of the coordinate system is visible in the scene as well:

```
plot([[1,3],[2,5],[3,3],[4,8]],
     table(1=4,2=6,3=4,4=9),
     [matrix([1,5]),matrix([2,7]),matrix([3,5]),matrix([4,10])],
     matrix([[1,6],[2,8],[3,6],[4,11]]),
     #Origin)
```



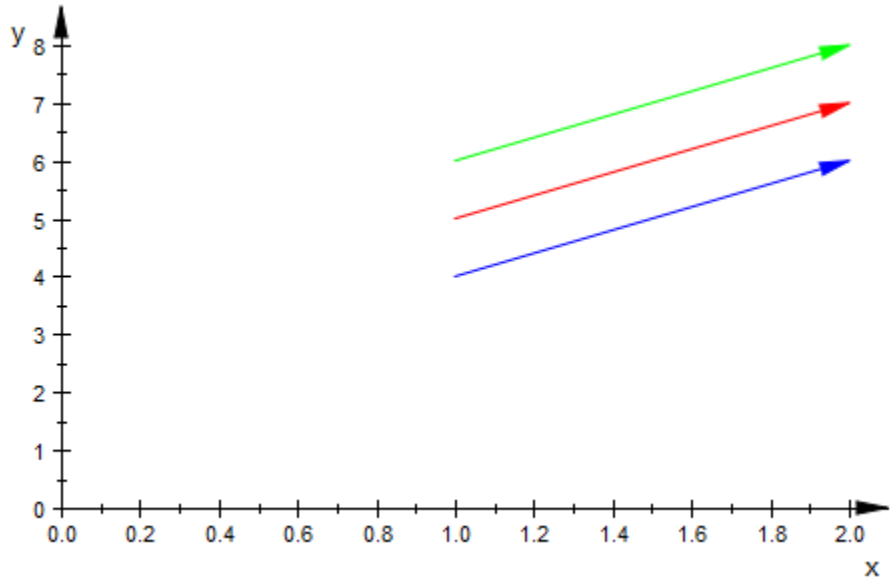
Note that polygons are displayed as points when option `#Points` (alias `#P`, see "Example 18" on page 24-75) is used:

```
plot([[1,3],[2,5],[3,3],[4,8]],
     table(1 = 4,2 = 6,3 = 4,4 = 9),
     [matrix([1,5]),matrix([2,7]),matrix([3,5]),matrix([4,10])],
     matrix([[1,6],[2,8],[3,6],[4,11]]),
     #Points, #Origin)
```



Note that the following polygons with two elements are displayed as arrows when option `#Arrows` (alias `#A`, see "Example 13" on page 24-70) is used:

```
plot([[1,4],[2,6]],
     [matrix([1,5]),matrix([2,7])],
     matrix([[1,6],[2,8]]),
     #Arrows, #Origin)
```

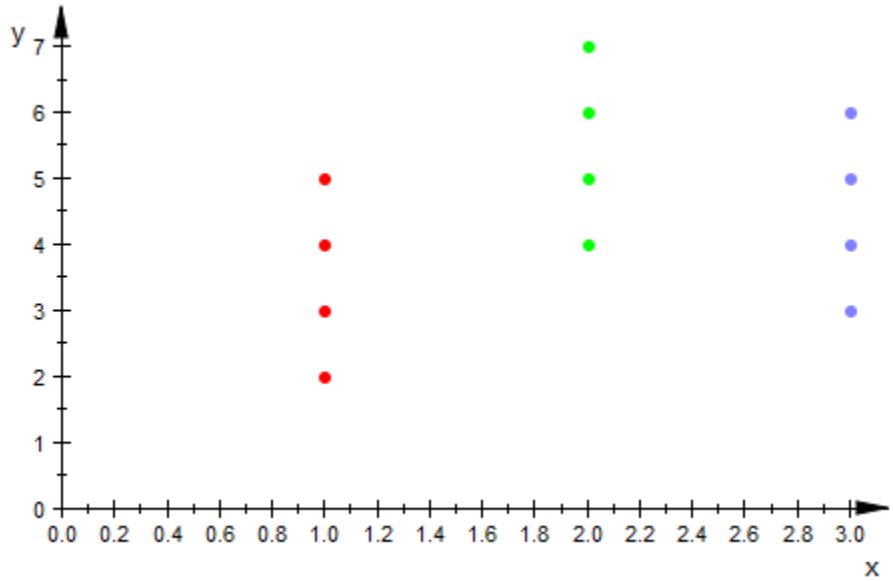


See also: `plot::Polygon2d`, `plot::Polygon3d`.

Example 5

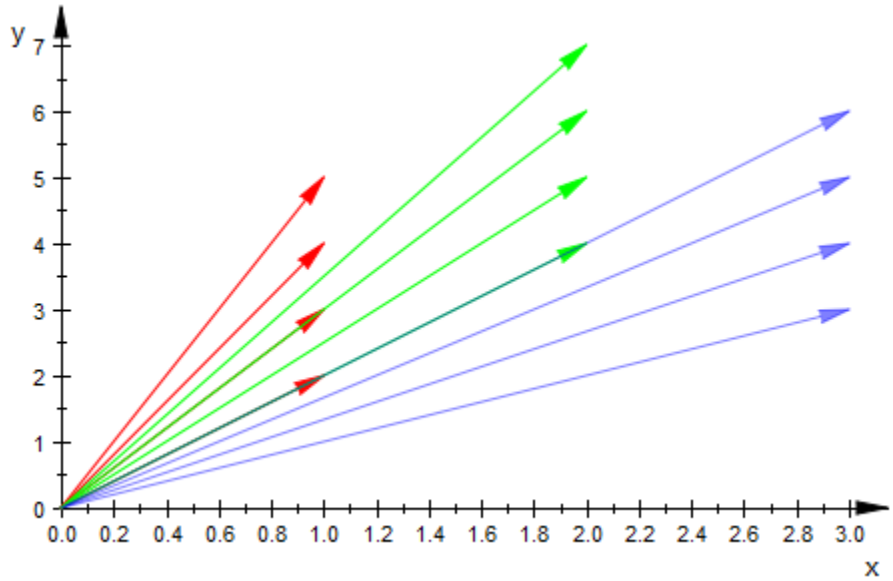
Point lists can be specified as lists, tables or matrices. For each point an RGBa color has to be specified. In the following example, point lists are plotted using different input styles. The option `#Origin` (alias `#0`, see "Example 17" on page 24-74) ensures that the origin of the coordinate system is visible in the scene as well:

```
plot([[1,2,RGB::Red], [2,4,[0,1,0]], [3,3,[0,0,1,0.5]]],
     [matrix([1,3,RGB::Red]), matrix([2,5,[0,1,0]]),
                              matrix([3,4,[0,0,1,0.5]])],
     matrix([[1,4,RGB::Red], [2,6,[0,1,0]],[3,5,[0,0,1,0.5]]]),
     table(1=[5,RGB::Red], 2=[7,[0,1,0]], 3=[6,[0,0,1,0.5]]),
     #Origin)
```



Note that the following point lists are displayed as arrows when option `#Arrows` (alias `#A`, see "Example 13" on page 24-70) is used:

```
plot([[1,2,RGB::Red], [2,4,[0,1,0]] ,[3,3,[0,0,1,0.5]]],
     [matrix([1,3,RGB::Red]), matrix([2,5,[0,1,0]]),
                              matrix([3,4,[0,0,1,0.5]])],
     matrix([[1,4,RGB::Red], [2,6,[0,1,0]], [3,5,[0,0,1,0.5]]]),
     table(1=[5,RGB::Red], 2=[7,[0,1,0]] ,3=[6,[0,0,1,0.5]]),
     #Arrows, #Origin)
```

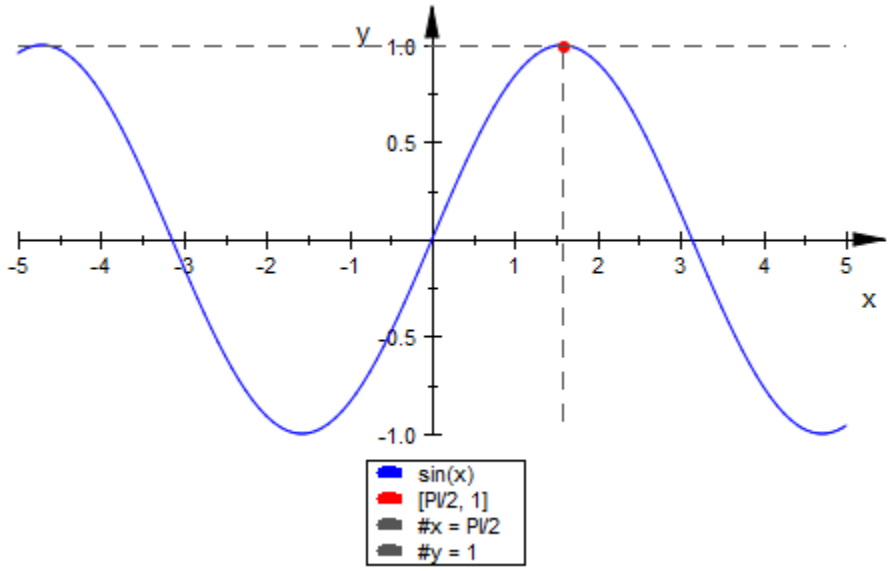


See also: `plot::PointList2d`, `plot::PointList2d`.

Example 6

For drawing horizontal and vertical infinite lines, the short syntax `#x = e` and `#y = e` with `e` is a real expression,can be used:

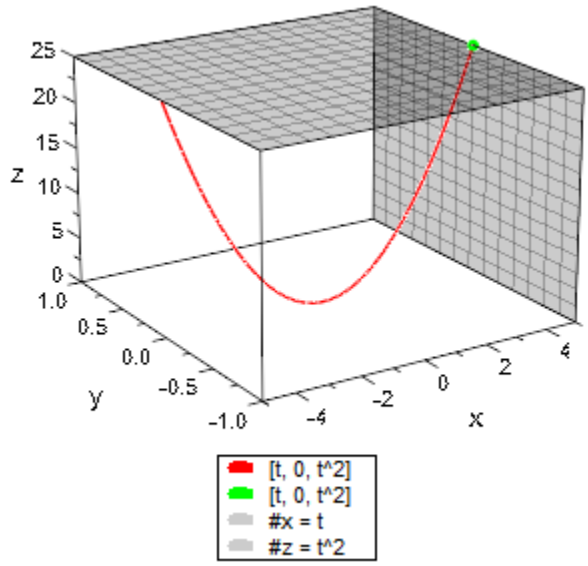
```
plot(sin(x), [PI/2,1], #x=PI/2, #y=1, #Legend)
```



For drawing horizontal and vertical infinite planes, the short syntax`#x = e`, `#y = e` and `#z = e`, with `e` is a real expression, can be used.

Both, lines and planes can also be animated:

```
plot([t,0,t^2], {[t,0,t^2], #Points}, #x=t, #z=t^2, #Legend)
```

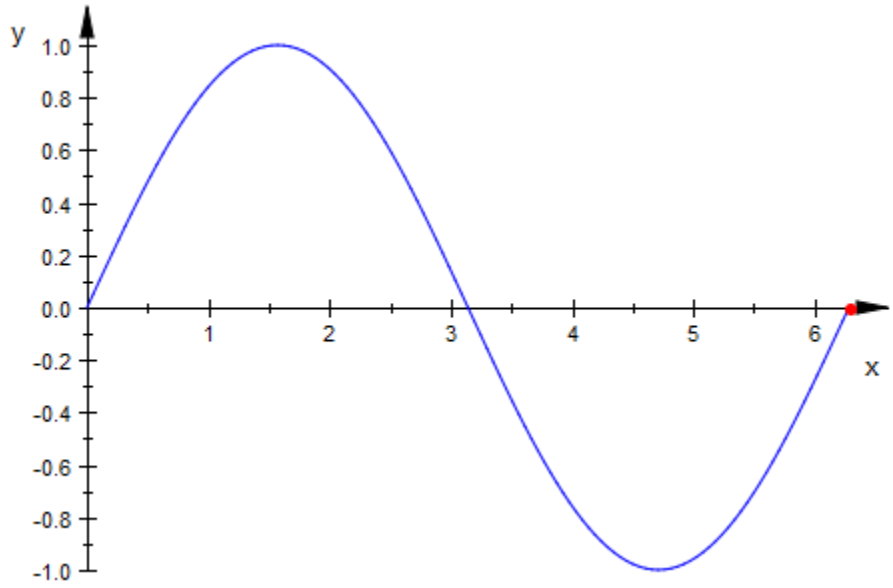


See also: `plot::Line2d`, `plot::Plane`.

Example 7

A curve can be specified as list with two or three elements, where at least one element depends on a free variable. If option `#Points` (alias `#P`, see “Example 18” on page 24-75) is set, then instead of a curve, an animated point is plotted that moves along the curve.

```
plot([t,sin(t)], {[t,sin(t)], #Points},  t=0..2*PI)
```

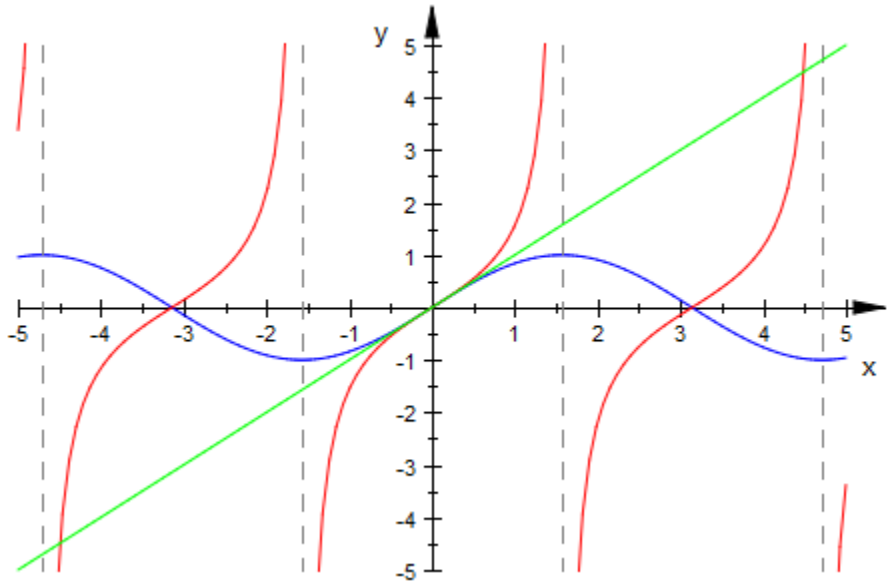


See also: `plot::Curve2d`, `plot::Curve3d`.

Example 8

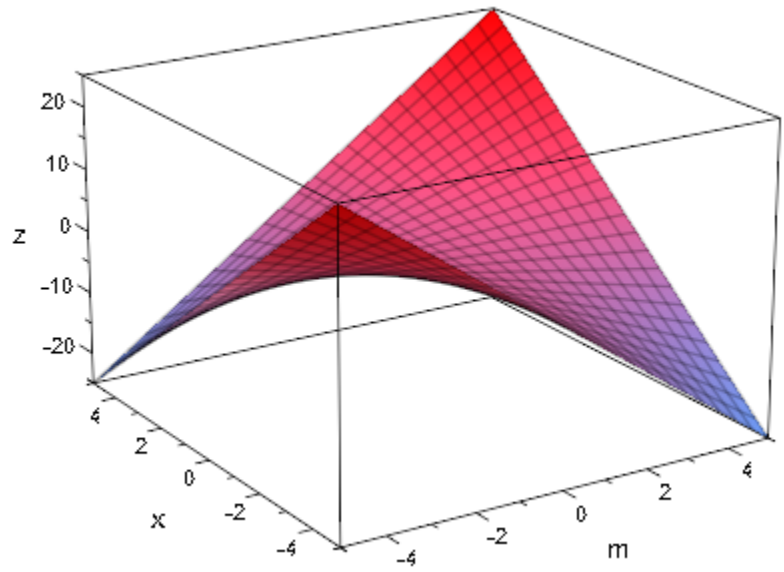
`plot::easy` tries to transform expressions that are no lists, sets, matrices, equations or inequalities into graphs of 2D or 3D functions. We plot some graphs of 2D functions:

```
plot(sin(x), tan(x), x)
```



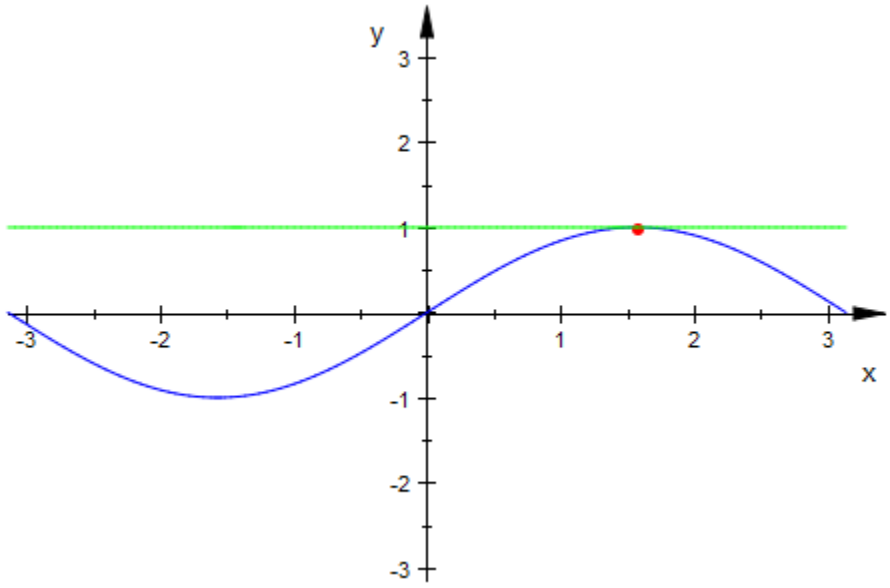
We plot a simple 3D function. Note that the option #3D (alias #3, see "Example 12" on page 24-67) is required in the following example for plotting a 3D function. Otherwise, an animated 2D function is created.

```
plot(m*x, #3D)
```



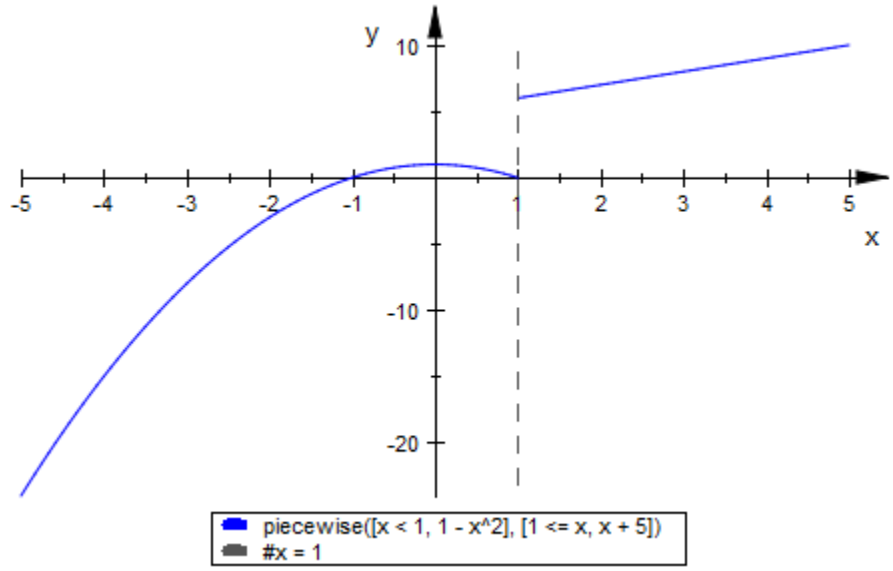
We plot a simple 2D animation: a point and the corresponding tangent of the sine function move along the sine function graph:

```
f:= x -> sin(x):
plot(f(x), x = -PI..PI,
     {[a, f(a)], #Points}, f'(a)*(x-a) + f(a), a = -PI/2..PI/2)
```



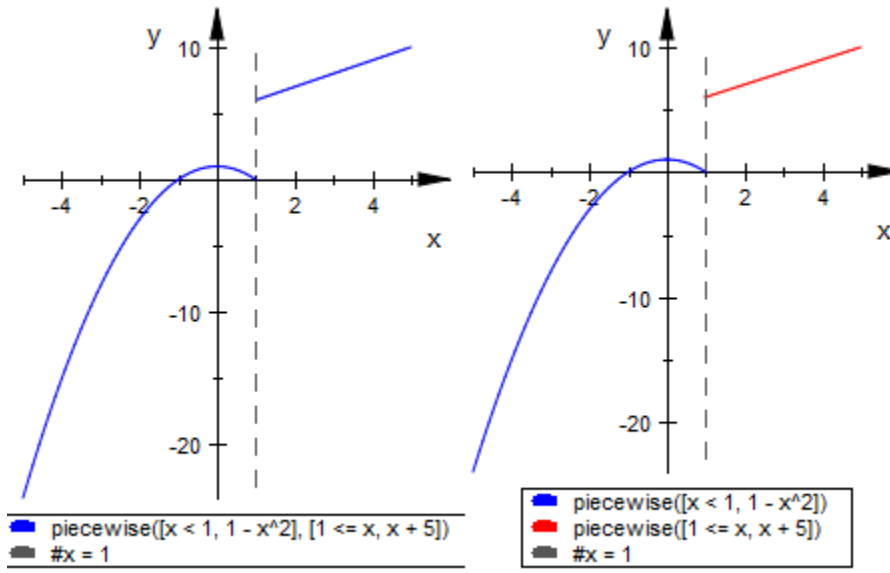
We plot a piecewise defined function:

```
plot(piecewise([x < 1, -x^2 + 1], [x >= 1, x + 5]), #x=1, #Legend)
```



The same piecewise defined function is now written in a shorter syntax. Note the difference between defining one function with two branches (left) and defining two functions (right):

```
plot({{[[x < 1, -x^2 + 1], [x >= 1, x + 5]], #x=1}},
     {{ [x < 1, -x^2 + 1], [x >= 1, x + 5] , #x=1}},
     #Legend)
```

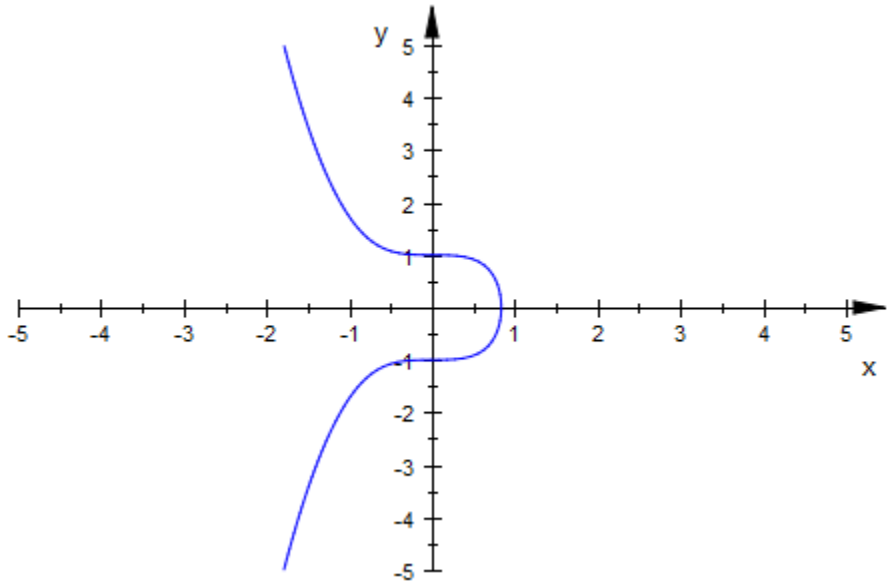


See also: `plot::Function2d`, `plot::Function3d`.

Example 9

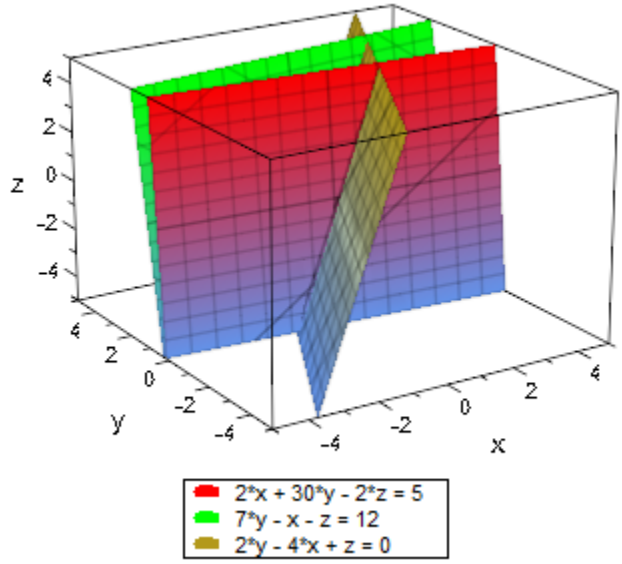
An implicit function can be specified as an equation:

```
plot(u^5 + x^2 = 1 - u^3)
```



Note that the option #3D (alias #3, see “Example 12” on page 24-67) may be required to plot planes given as cartesian equations. Otherwise, an animated 2D graph might be created. This depends on the number of variable of the equation.

```
E1:= 2*x + 30*y - 2*z = 5:
E2:= -x + 7*y - z = 12:
E3:= -4*x + 2*y + z = 0:
plot(E1, E2, E3, #3D, #Legend)
```



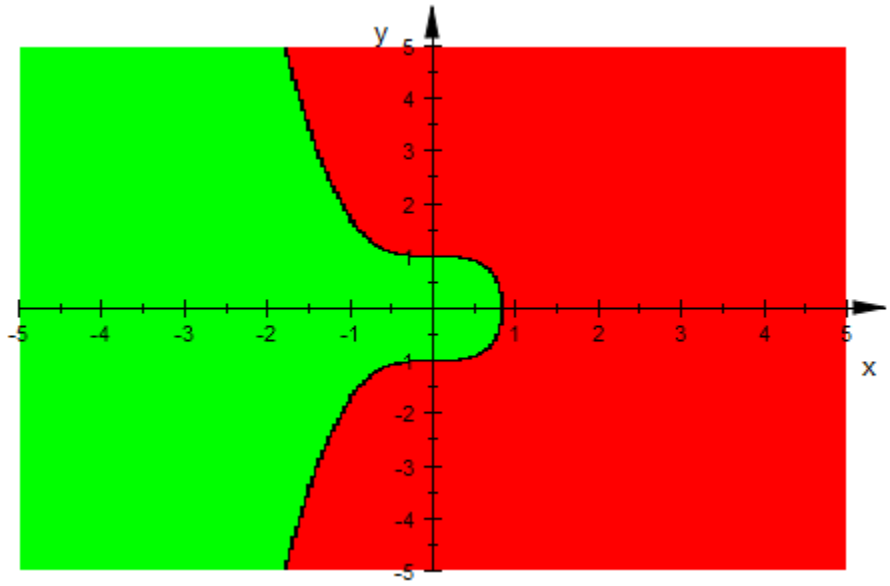
```
delete E1, E2, E3:
```

See also: `plot::Implicit2d`, `plot::Implicit3d`.

Example 10

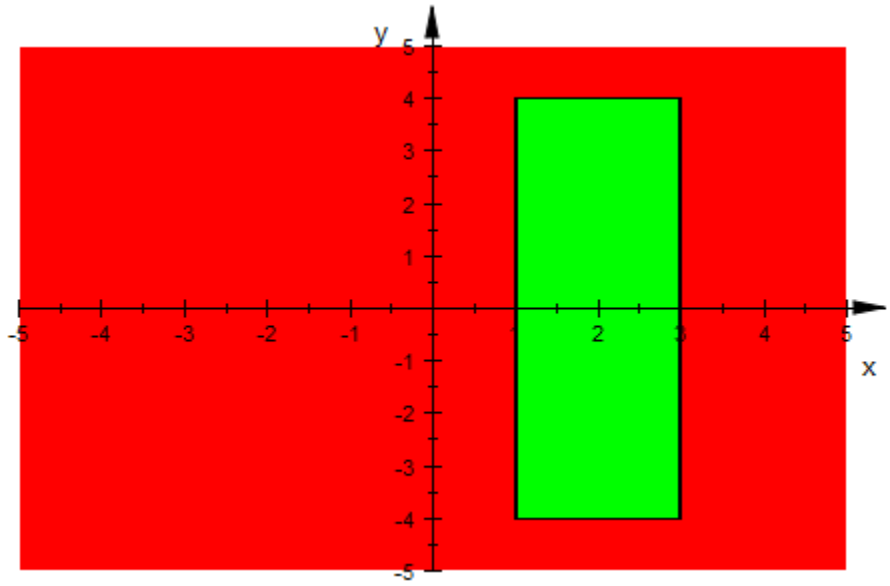
An inequality can be displayed directly:

```
plot(u^5+x^2 < 1-u^3)
```



The same is true for a list of inequalities and equations:

```
plot([x < 3, x > 1, y <  4, y > -4])
```

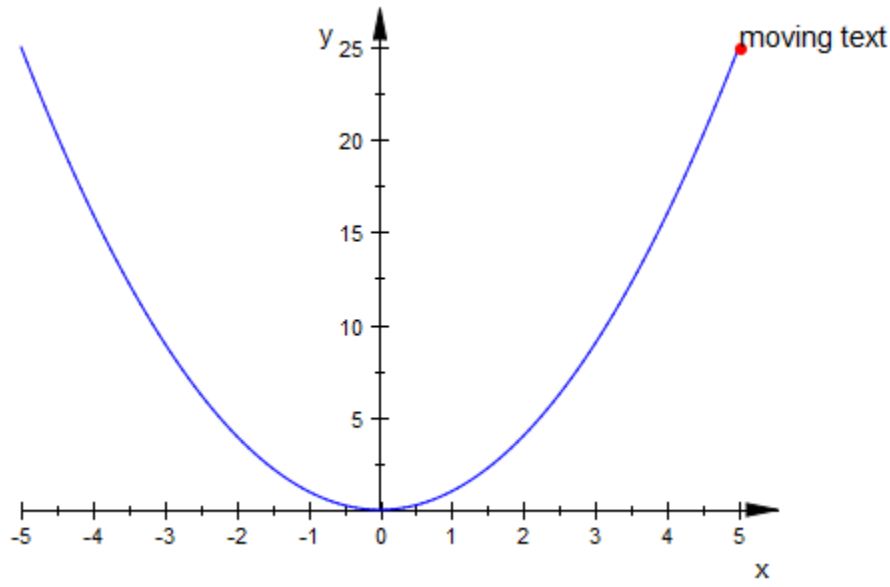


See also: `plot::Inequality`.

Example 11

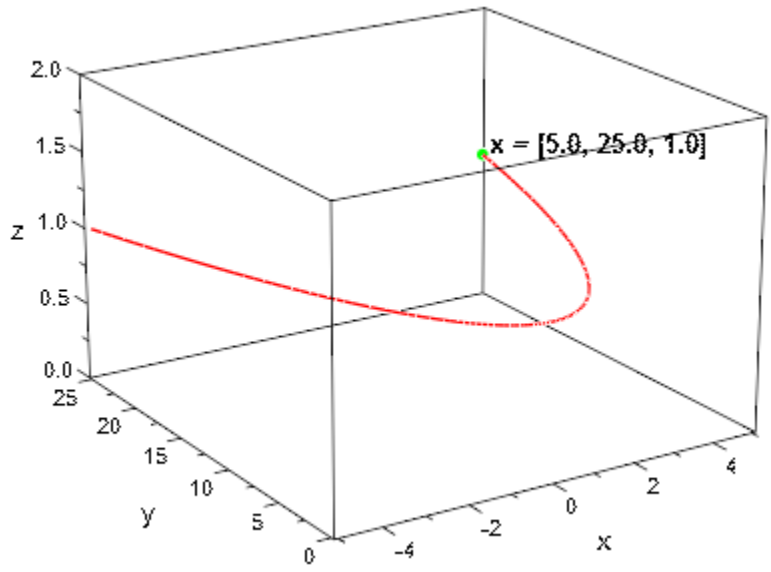
To display a 2D text at a certain position, an equation of a coordinate tuple and a character string or a procedure can be entered:

```
plot([t, t^2],
    {[t, t^2], #Points},
     [t, t^2] = "moving text")
```



We display a 3D text. As in any other context of `plot::easy`, we can use regular graphical attributes like `TextFont =Center` as well:

```
DIGITS := 2:
plot([t, t^2, 1],
    {[t, t^2, 1], #Points},
     [t, t^2, 1] = (t->" x = ".[t, t^2, 1.0]),
     TextFont=[Bold]):
delete DIGITS:
```

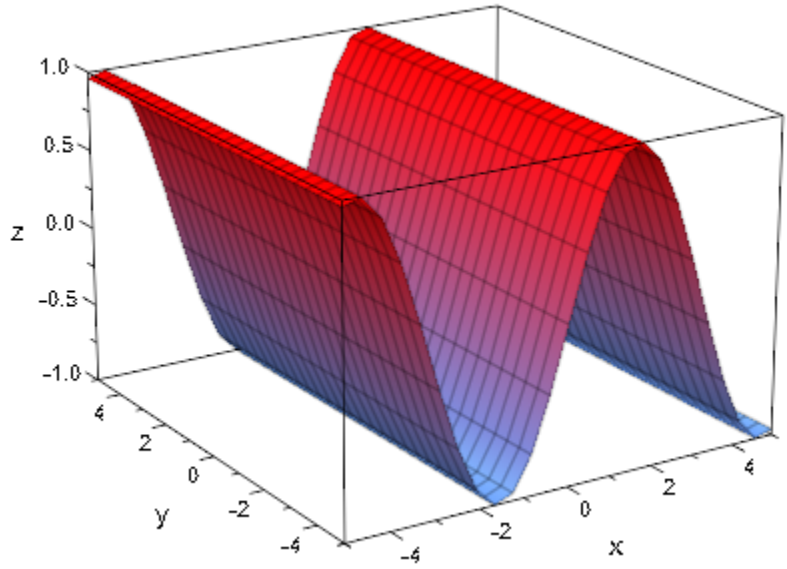


See also: `plot::Text2d`, `plot::Text3d`.

Example 12

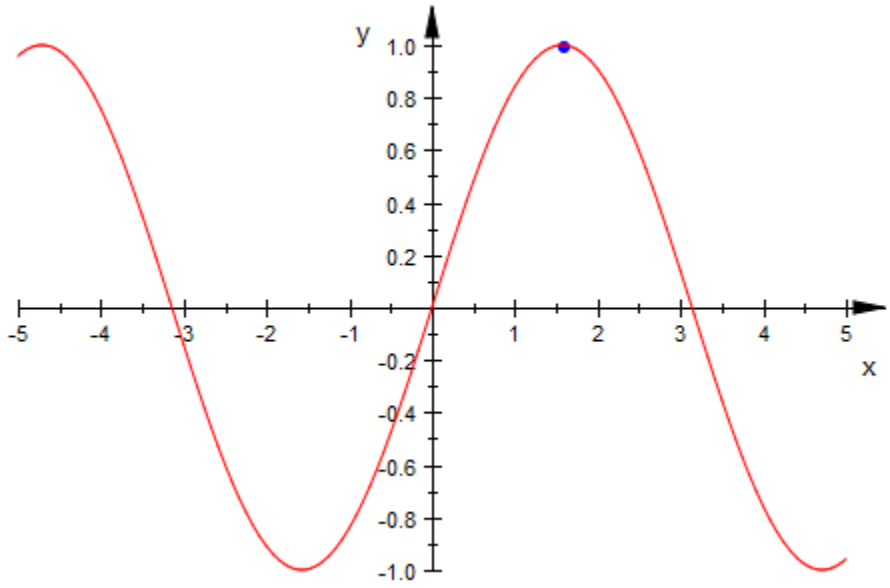
Usually `plot::easy` creates a 2D scene, unless one of the arguments is a 3D object or can only be transformed to a 3D object or the option `#3D` is used.

```
plot(sin(x), #3)
```



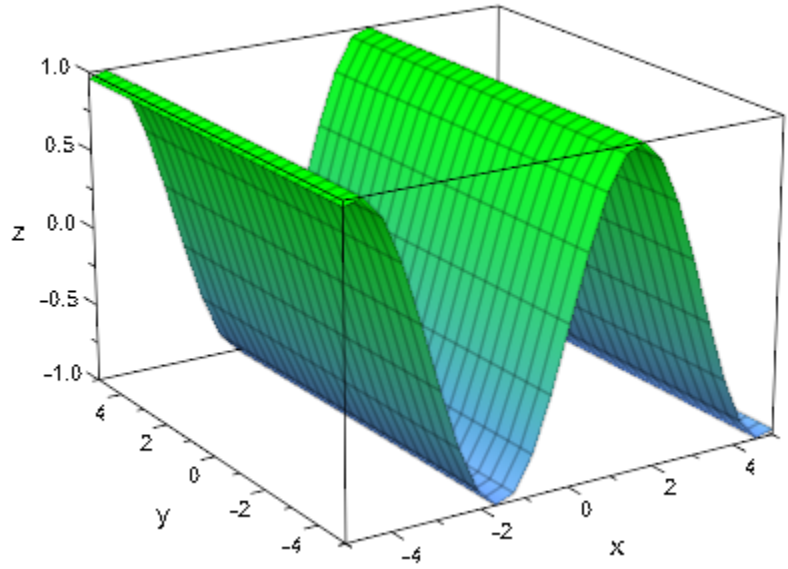
However, the option `#3D` is only a hint. It is ignored if the current scene can only be a 2D scene. In the following example, the 2D point determines the dimension of the scene:

```
plot([PI/2,1], sin(x), #3)
```



In the following example, the 3D point determines the dimension of the scene. There is no need to use option #3D in order to create a 3d scene:

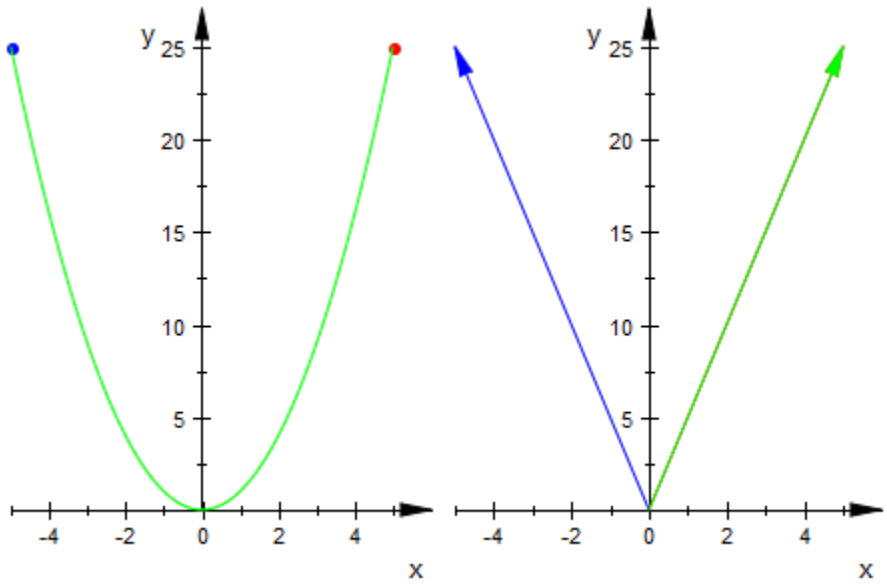
```
plot([PI/2,1,0], sin(x))
```



Example 13

With option `#Arrows`, arrows instead of points or curves are created. When used within a {...}-group, it affects the elements of this group or scene only.

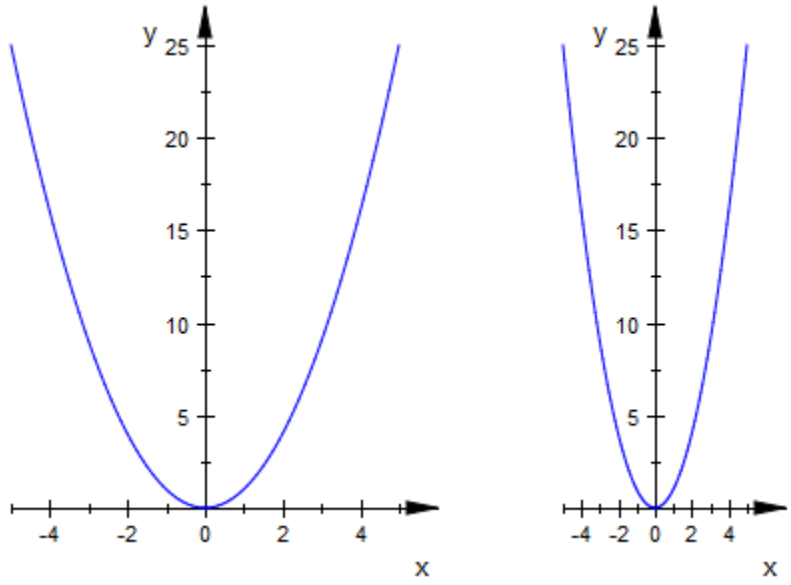
```
plot({{ [-5,25], [5,25], [x,x^2]     }},
     {{ [-5,25], [5,25], [x,x^2], #A }})
```



Example 14

Option `#Constrained` creates a coordinate system with constrained scaled axes. This is a shortcut for `Scaling = Constrained`.

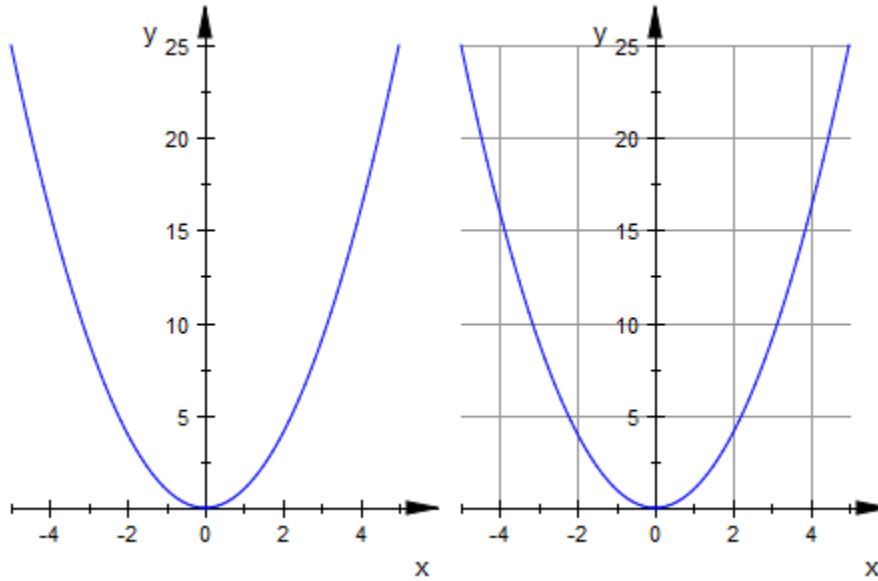
```
plot({{ x^2 }}, {{ x^2, #C }})
```



Example 15

Option `#Grid` creates a coordinate system with grid lines. This is a shortcut for `GridVisible = TRUE`.

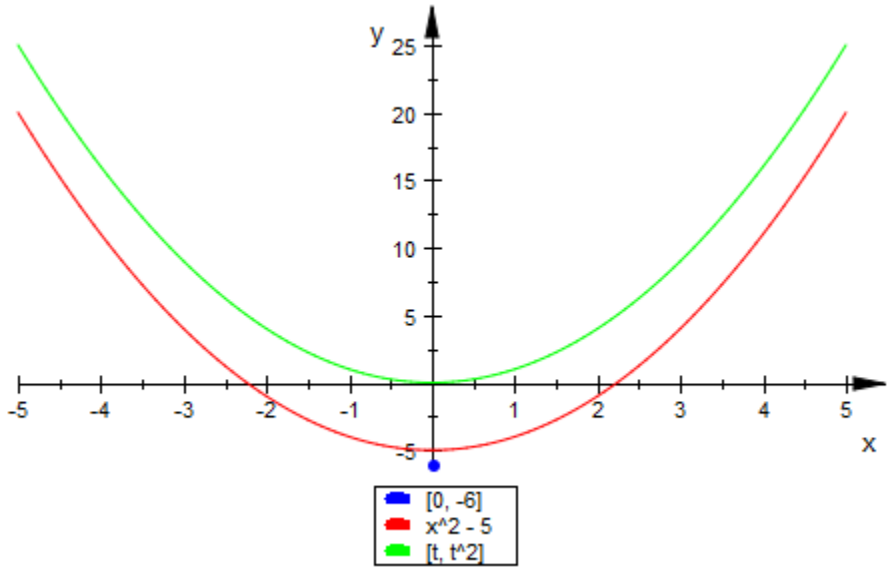
```
plot({{ x^2 }}, {{ x^2, #G }})
```



Example 16

Option `#Legend` creates a legend. This is a shortcut for `LegendVisible = TRUE` in combination with `LegendEntry = TRUE`. Note that `plot::easy` explicitly sets a legend text for each graphical object it creates.

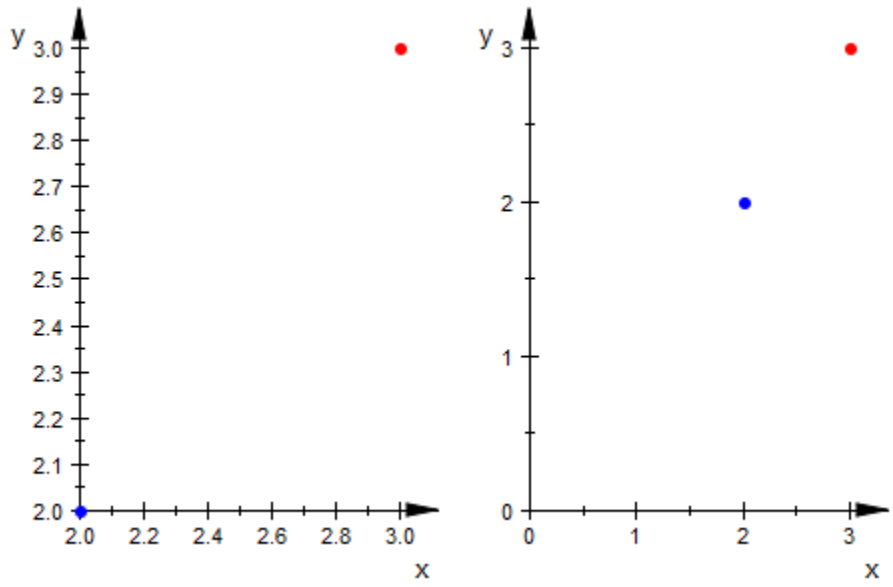
```
plot([0,-6], x^2-5, [t,t^2], #L)
```



Example 17

Option `#Origin` includes the coordinates (0,0) or (0,0,0), respectively, into the viewing box of the current scene.

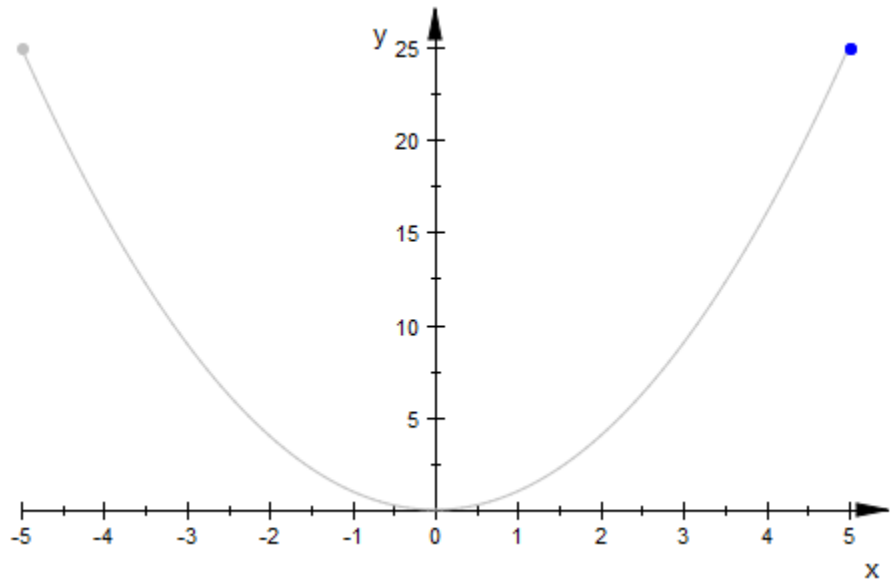
```
plot({{[2,2], [3,3]}}, {{[2,2], [3,3], #0}})
```



Example 18

Using option `#Points`, points instead of arrows or curves are created. Furthermore, this option sets the attributes `PointsVisible =TRUE` and `LinesVisible =FALSE`. When used within a {...}-group, it affects the elements of this group or scene only.

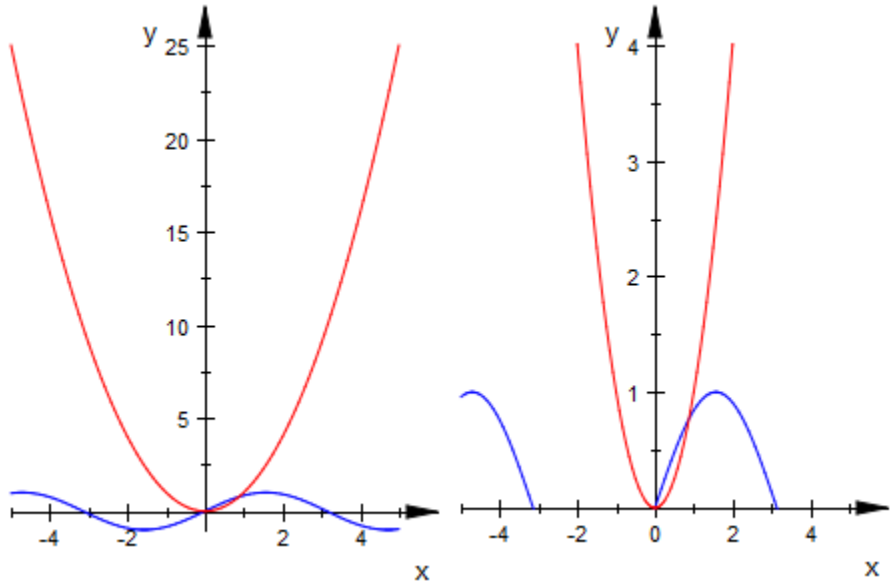
```
plot({[-5,25], [x,x^2], #Gray}, {matrix([5,25]), [x,x^2], #P})
```



Example 19

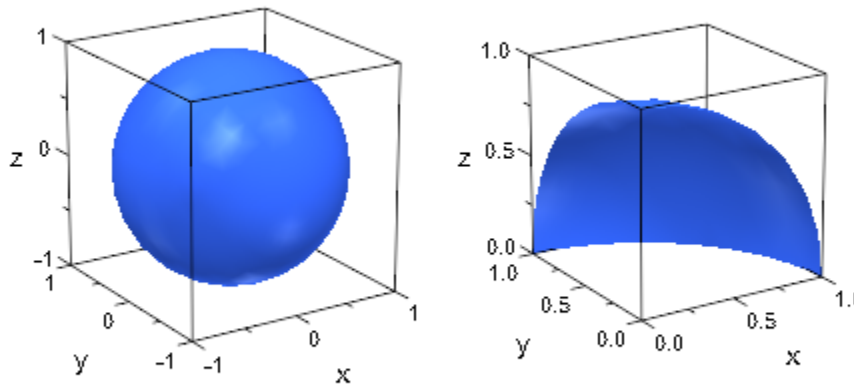
`#X / #Y / #Z = a..b` sets the x- / y- / z-range of the viewing box of the scene to `a..b`. This is a shortcut for `ViewingBoxXRange / ViewingBoxYRange / ViewingBoxZRange = a..b`.

```
plot({{x^2, sin(x)}}, {{x^2, sin(x), #Y=0..4}})
```



We draw a 3D scene with a restricted viewing box. Therefore, only a quater of the shere is visible:

```
plot({{plot::Sphere(1)}},
     {{plot::Sphere(1), #X=0..1, #Y=0..1, #Z=0..1}})
```



Parameters

`arg`

Any object

Options

`#3D`

Alias #3. Creates a 3D instead of a 2D scene, if possible. Usually, a 2D scene is created unless one of the arguments is a 3D object or can only be transformed into one.

`#Arrows`

Alias #A. Creates arrows instead of points. When used within a {...}-group, it affects the elements of this group or scene only.

#Constrained

Alias #C. Creates a coordinate system with axes having the same scaling. This is a shortcut for `Scaling =Constrained`.

#Grid

Alias #G. Creates a coordinate system with grid lines. This is a shortcut for `GridVisible =TRUE`.

#Legend

Alias #L. Creates a legend. This is a shortcut for `LegendEntry =TRUE` and `LegendVisible =TRUE`. When used within a {...}-group, it affects the elements of this group or scene only. Note that `plot::easy` explicitly sets a legend text for each graphical object it creates.

#Origin

Alias #O. Includes the coordinates (0,0) or (0,0,0), respectively, into the viewing box of the current scene.

#Points

Alias #P. Creates points instead arrows or curves. Furthermore, it sets the attributes `PointsVisible =TRUE` and `LinesVisible =FALSE`. When used within a {...}-group, it affects the elements of this group or scene only.

#XRange

Option, specified as `#XRange = a .. b`

Alias #X = a .. b. Sets the x-range of the viewing box of the scene to `a..b`. This is a shortcut for `ViewingBoxXRange =a..b`.

#YRange

Option, specified as `#YRange = a .. b`

Alias #Y = a .. b. Sets the y-range of the viewing box of the scene to `a..b`. This is a shortcut for `ViewingBoxYRange =a..b`.

#ZRange

Option, specified as `#ZRange = a .. b`

Alias `#Z` = a .. b. Sets the z-range of the viewing box of the scene to `a..b`. This is a shortcut for `ViewingBoxZRange =a..b`.

`#<Colorname>`

If `RGB ::<Colorname>` is a valid color name in MuPAD, `#<Colorname>` is transformed to: `Color = RGB ::<Colorname>`, `LineColorType =Flat` and for 3D objects additionally `FillColorType =Flat`. Transparent `RGB` colors can be specified as `#<Colorname>.[t]`, with t is in 0..1. If `#<Colorname>` is a valid color following the html conventions then instead of `RGB ::<Colorname>`, the corresponding RGB or RGBa color value is inserted. When used within a {...}-group, it affects the elements of this group or scene only.

`#<Colorname1> .. #<Colorname2>`

If `RGB ::<Colorname1>` and `RGB ::<Colorname2>` are valid color names in MuPAD, this option is transformed to:

`Color = RGB ::<Colorname1>`, `LineColorType =Dichromatic`, `LineColor2 = RGB ::<Colorname2>` in 2D scenes and to:

`Color = RGB ::<Colorname1>`, `FillColorType =Dichromatic`, `FillColor2 = RGB ::<Colorname2>` in 3D scenes.

Transparent `RGB` colors can be specified as `#<Colorname>.[t]`, with t is in 0..1. If `#<Colorname1>` and/or `#<Colorname2>` are valid colors following the html conventions then instead of `RGB ::<Colorname1>` and/or, `RGB ::<Colorname2>` the corresponding RGB or RGBa color values are inserted. When used within a {...}-group, it affects the elements of this group or scene only.

Return Values

A sequence of graphical objects and graphical attributes as well as objects that could not be transformed by `plot::easy`.

Overloaded By

arg

Algorithms

Let c_i be real constants and f and f_i be real functions. `plot::easy` automatically carries out the following transformations:

Graphical object	Data or mathematical expression
`plot::Point2d`:	$[c_1, c_2]$, {$[f_1(x), f_2(x)]$, #Points}, {matrix($[f_1(x), f_2(x)]$), #Points}.
`plot::Point3d`:	$[c_1, c_2, c_3]$, {$[f_1(x), f_2(x), f_3(x)]$, #Points}, {matrix($[f_1(x), f_2(x), f_3(x)]$), #Points}.
`plot::Arrow2d`:	matrix($[c_1, c_2]$), {$[c_1, c_2]$, #Arrows}, {[matrix($[f_1(x), f_2(x)]$), matrix($[f_3(x), f_4(x)]$)], #Arrows}, {matrix($[[f_1(x), f_2(x)], [f_3(x), f_4(x)]]$), #Arrows}, {$[[f_1(x), f_2(x)], [f_3(x), f_4(x)]]$, #Arrows}.
`plot::Arrow3d`:	matrix($[c_1, c_2, c_3]$), {$[c_1, c_2, c_3]$, #Arrows}, {[matrix($[f_1(x), f_2(x), f_3(x)]$), matrix($[f_4(x), f_5(x), f_6(x)]$)], #Arrows}, {matrix($[[f_1(x), f_2(x), f_3(x)], [f_4(x), f_5(x), f_6(x)]]$), #Arrows}, {$[[f_1(x), f_2(x), f_3(x)], [f_4(x), f_5(x), f_6(x)]]$, #Arrows}.
`plot::Polygon2d`:	$[[f_1(x), f_2(x)],...]$, [matrix($[f_1(x), f_2(x)]$),...], matrix($[[f_1(x), f_2(x)],...]$), table($f_1(x)=f_2(x)$,...).
`plot::Polygon3d`:	$[[f_1(x), f_2(x), f_3(x)],...]$, [matrix($[f_1(x), f_2(x), f_3(x)]$),...], matrix($[[f_1(x), f_2(x), f_3(x)],...]$). table($f_1(x)=[f_2(x), f_3(x)]$,...).
`plot::PointList2d`:	$[[f_1(x), f_2(x),$ RGBa$],...]$, [matrix($[f_1(x), f_2(x),$ RGBa$]$),...], matrix($[[f_1(x), f_2(x),$ RGBa$],...]$), table($f_1(x)=[f_2(x),$ RGBa$],...$).

Graphical object	Data or mathematical expression
plot::PointList3d:	[[f_1(x), f_2(x), f_3(x), RGBa],...], [matrix([f_1(x), f_2(x), f_3(x), RGBa]),...], matrix([[f_1(x), f_2(x), f_3(x), RGBa],...]). table(f_1(x)=[f_2(x), f_3(x), RGBa],...).
plot::Line2d:	#x= f(x), #y= f(x).
plot::Plane:	#z= f(x), {#x= f(x) , #3D}, {#y= f(x) , #3D}, {#z= f(x) , #3D}.
plot::Curve2d:	[f_1(x), f_2(x)].
plot::Curve3d:	[f_1(x), f_2(x), f_3(x)].
plot::Function2d:	f(x), f(x, a), [$cond_1$, f(x)], [[$cond_1$, f(x)],...].
plot::Function3d:	f(x, y, a), [$cond_1$, f(x, y, a)], [[$cond_1$, f(x, y, a)],...], {f(x), #3D}, {f(x, a), #3D}.
plot::Implicit2d:	f_1(x, y, a)=f_2(x, y, a).
plot::Implicit3d:	f_1(x, y, z, a)=f_2(x, y, z, a), {f_1(x, y, a)=f_2(x, y, a), #3D}.
plot::Inequality:	f_1(x, a) < f_2(x, a), f_1(x, a) ≤ f_2(x, a), f_1(x, a) > f_2(x, a), f_1(x, a) ≥ f_2(x, a), [f_1(x, a)<f_2(x, a), f_3(x, a)>f_4(x, a), f_5(x, a)=f_6(x, a),...].
plot::Text2d:	[f_1(x), f_2(x)]=text, matrix([f_1(x), f_2(x)])=text, [f_1(x), f_2(x)]=procedure, matrix([f_1(x), f_2(x)])=procedure.
plot::Text3d:	[f_1(x), f_2(x), f_3(x)]=text, matrix([f_1(x), f_2(x), f_3(x)])=text, [f_1(x), f_2(x), f_3(x)]=procedure, matrix([f_1(x), f_2(x), f_3(x)])=procedure.

MuPAD Functions
`plot`

plot::getDefault

Get current default setting of attributes

Syntax

```
plot::getDefault(type::attr)
```

Description

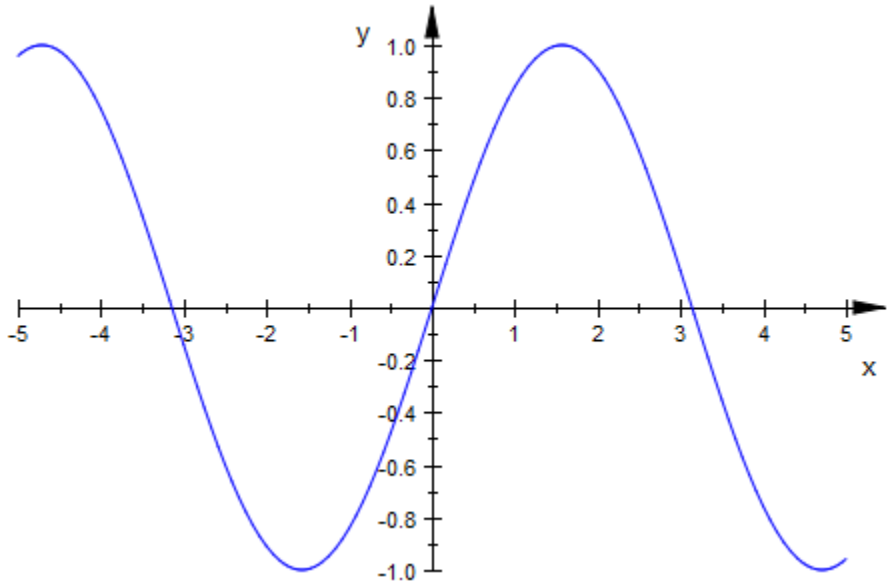
`plot::getDefault(plot::Object::Attribute)` enquires the current default.

Examples

Example 1

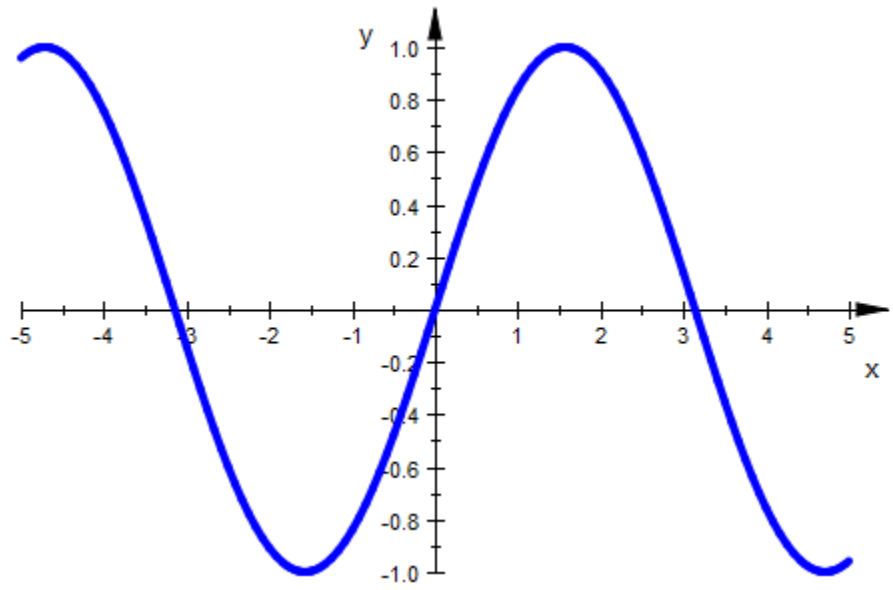
By default, function plots use relatively thin lines:

```
plotfunc2d(sin(x))
```



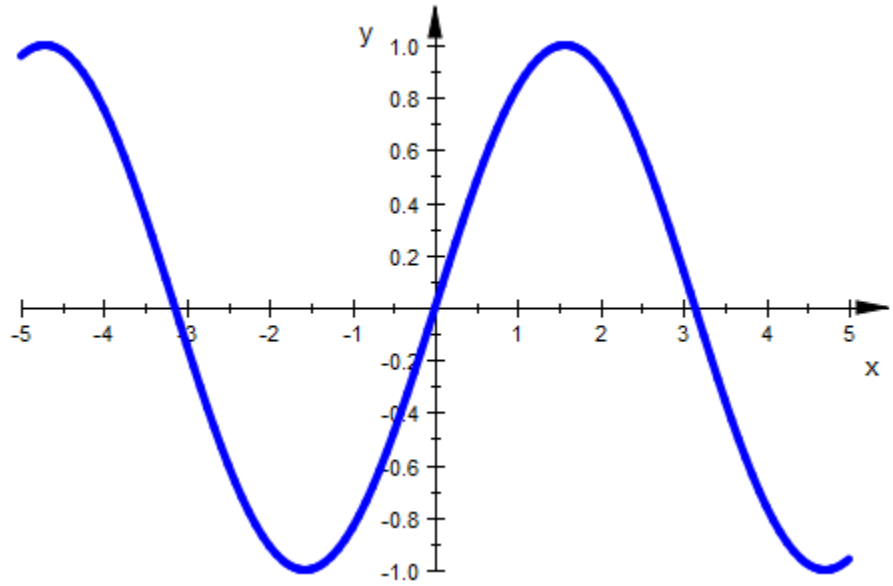
For some applications, this is undesirable, for example when projecting graphics for a larger audience. It is always possible to set thicker lines in the call:

```
plotfunc2d(sin(x), LineWidth = 1*unit::mm)
```



However, this is distracting and cumbersome. Using `plot::setDefault`, we change the default setting once and for the whole session:

```
plot::setDefault(plot::Function2d::LineWidth = 1*unit::mm):
plotfunc2d(sin(x))
```



One thing you should know in this context: `plotfunc2d` and `plotfunc3d` use `plot::Function2d` and `plot::Function3d` for the actual plotting. Changing color and legend settings of the latter two does not influence the former, however, since `plotfunc2d` and `plotfunc3d` set color and legend settings explicitly.

Parameters

`type`

A domain of the plot library, i.e., an object type such as `plot::Function2d`

`attr`

Attributes admissible for the object type `type`

Return Values

`plot::setDefault` returns the previous default value(s). `plot::getDefault` returns the current default value.

Algorithms

"Admissible attributes" includes all the attributes the object itself reacts to. Hints cannot be set or changed with `plot::setDefault`.

For attributes marked as "mandatory," default values are read and used the moment an object is created. Default values of attributes marked as "optional" or "inherited" are read when the object is plotted and can therefore be changed after creating an object.

See Also

MuPAD Functions

`plot::setDefault`

plot::setDefault

Set default setting of attributes

Syntax

```
plot::setDefault(type::attr = value, …)
```

Description

`plot::setDefault(plot::Object::Attribute = Value)` sets the default of the attribute `Attribute` for objects of type `plot::Object` to `Value`.

While not all attributes have defaults, it is in general possible to set defaults for them, although some examples like setting a default function to plot for `plot::Function2d` are probably more exotic than others, to say the least.

Defaults are set and retrieved per object; with the exception of `OutputFile` and `OutputOptions`, the attribute must be prefixed with the name of the object type the setting shall be valid for. There is, e.g., no function to turn of all lines on all 3D objects. `OutputFile` and `OutputOptions` are not associated with an object and must be set directly.

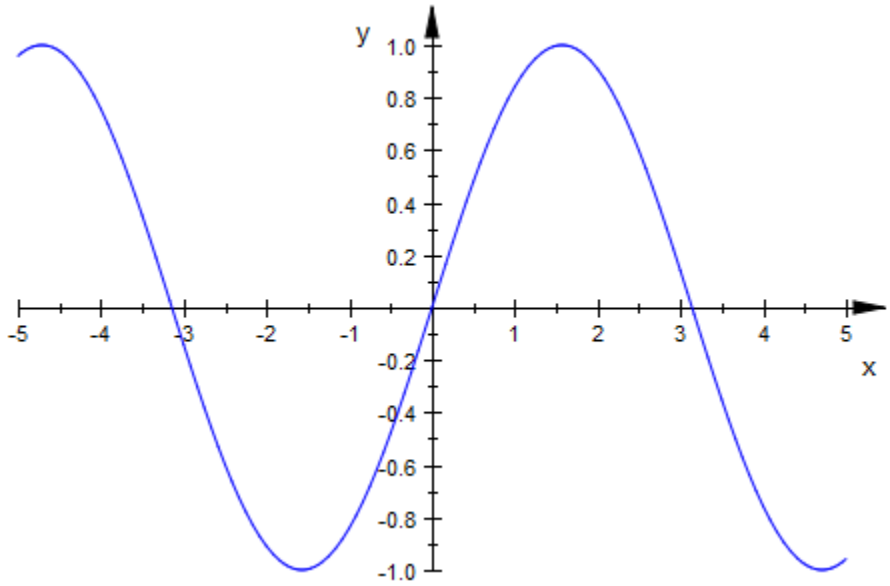
To delete a default (which is not recommended for attributes having a default in the standard installation), set `value` to `FAIL`.

Examples

Example 1

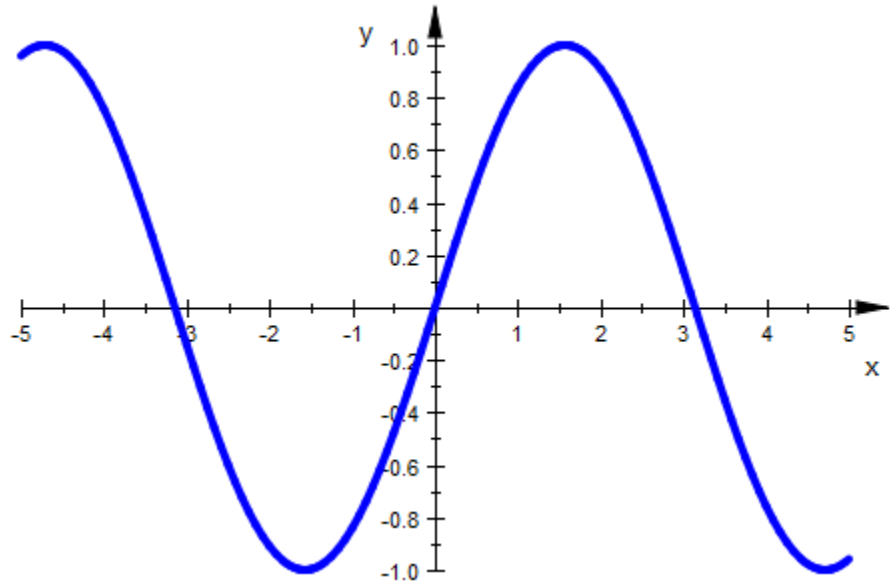
By default, function plots use relatively thin lines:

```
plotfunc2d(sin(x))
```



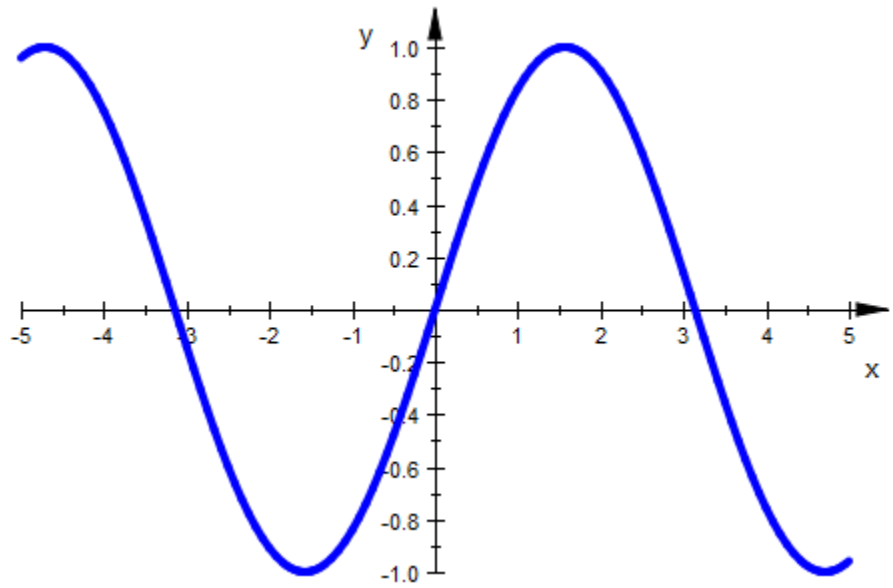
For some applications, this is undesirable, for example when projecting graphics for a larger audience. It is always possible to set thicker lines in the call:

```
plotfunc2d(sin(x), LineWidth = 1*unit::mm)
```



However, this is distracting and cumbersome. Using `plot::setDefault`, we change the default setting once and for the whole session:

```
plot::setDefault(plot::Function2d::LineWidth = 1*unit::mm):
plotfunc2d(sin(x))
```



One thing you should know in this context: `plotfunc2d` and `plotfunc3d` use `plot::Function2d` and `plot::Function3d` for the actual plotting. Changing color and legend settings of the latter two does not influence the former, however, since `plotfunc2d` and `plotfunc3d` set color and legend settings explicitly.

Parameters

`type`

A domain of the plot library, i.e., an object type such as `plot::Function2d`

`attr`

Attributes admissible for the object type `type`

`value`

The new default value: a value admissible for `attr` in objects of type `type`

Return Values

`plot::setDefault` returns the previous default value(s). `plot::getDefault` returns the current default value.

Algorithms

"Admissible attributes" includes all the attributes the object itself reacts to. Hints cannot be set or changed with `plot::setDefault`.

For attributes marked as "mandatory," default values are read and used the moment an object is created. Default values of attributes marked as "optional" or "inherited" are read when the object is plotted and can therefore be changed after creating an object.

MuPAD Functions
`plot::getDefault`

plot::copy

Make a physical copy of a plot object

Syntax

```
plot::copy(obj)
```

Description

Plot objects usually have a reference effect. `plot::copy` creates copies which are independent of the original.

Objects created from inside the `plot` library have a *reference effect:* If you make another reference to some object, say by calling `o2 := o1;` and then change an attribute of `o2`, e.g., setting `o2::Visible := FALSE`, this change will also effect the object referred to by `o1`, since they actually refer to the same object. To create an actual copy of an object instead, use `o2 := plot::copy(o1);`.

The function `plot::modify` is a variant of `plot::copy`. It allows setting new values of attributes in the same call, as in `o2 := plot::modify(o1, Visible = FALSE);`.

Examples

Example 1

The following call does *not* create two points, but rather one which we can access by two names:

```
A := plot::Point2d(0, 0):
B := A:
```

This surfaces as soon as we try to modify `one of the points':

```
B::Position := [1, 1]:
A
```

```
plot::Point2d(1, 1)
```

Instead, we can use `plot::modify` to achieve the desired effect:

```
B := plot::modify(A, Position = [2, 2]):
A, B
```

```
plot::Point2d(1, 1), plot::Point2d(2, 2)
```

Note: Note that `plot::modify` does not modify its argument, but returns a modified copy instead, whatever the name may suggest.

Parameters

`obj`

Plot objects

Return Values

Object of the same type as `obj`

See Also

MuPAD Functions

`plot::modify`

plot::modify

Make a physical copy of a plot object setting new values of attributes in the same call

Syntax

```
plot::modify(obj, <attr, …>)
```

Description

Plot objects usually have a reference effect. `plot::modify` creates copies which are independent of the original.

Objects created from inside the `plot` library have a *reference effect:* If you make another reference to some object, say by calling `o2 := o1;` and then change an attribute of `o2`, e.g., setting `o2::Visible := FALSE`, this change will also effect the object referred to by `o1`, since they actually refer to the same object. To create an actual copy of an object instead, use `o2 := plot::copy(o1);`.

The function `plot::modify` is a variant of `plot::copy`. It allows setting new values of attributes in the same call, as in `o2 := plot::modify(o1, Visible = FALSE);`.

Examples

Example 1

The following call does *not* create two points, but rather one which we can access by two names:

```
A := plot::Point2d(0, 0):
B := A:
```

This surfaces as soon as we try to modify `one of the points':

```
B::Position := [1, 1]:
A
```

```
plot::Point2d(1, 1)
```

Instead, we can use `plot::modify` to achieve the desired effect:

```
B := plot::modify(A, Position = [2, 2]):
A, B
```

```
plot::Point2d(1, 1), plot::Point2d(2, 2)
```

Note: Note that `plot::modify` does not modify its argument, but returns a modified copy instead, whatever the name may suggest.

Parameters

`obj`

Plot objects

`attr`

Attributes admissible for the object `obj`, in the form `Attribute = Value`

Return Values

Object of the same type as `obj`

MuPAD Functions

`plot::copy`

plot::delaunay

Compute the Delaunay triangulation of a set of points

Syntax

```
plot::delaunay(L)
```

Description

`plot::delaunay` computes the Delaunay triangulation of a list of points in arbitrary dimension.

The Delaunay triangulation of a list of points is a triangulation of their convex hull such that for each edge of the triangulation, there is a circle containing the two endpoints of this edge but no other point of the list.

Environment Interactions

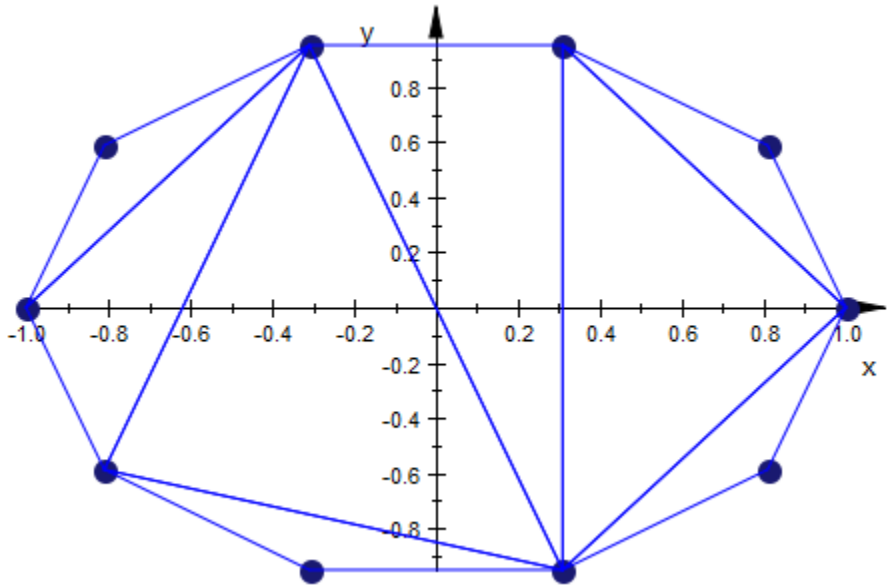
Although `plot::delaunay` accepts and returns floating-point values, the actual computations take place in hardware floating-points and are therefore *not* affected by the value of `DIGITS`.

Examples

Example 1

Delaunay triangulation does not introduce new points:

```
n0 := 10:
l := [[Re, Im](exp(float(2*I*PI*n)/n0)) $ n = 1.. n0]:
d := plot::delaunay(l):
plot(plot::PointList2d(l, PointSize=3),
     plot::Polygon2d(t, Closed) $ t in d)
```



Parameters

L

A list of points, which are given as lists of real values

Return Values

List of simplices in the dimension of the points in L, given as lists of lists of floating-point values.

Algorithms

`plot::delaunay` uses qhull from the Geometry Center of the University of Minnesota, see www.qhull.org.

plot::hull

Compute the convex hull of a set of points

Syntax

```
plot::hull(L)
```

Description

`plot::hull` computes the convex hull of a list of points in any dimension, i.e., the smallest convex region containing all the points. Such a region is bounded by simplices (straight lines in the plane, triangles in 3D) and it is these simplices which `plot::hull` returns.

Environment Interactions

Although `plot::hull` accepts and returns floating point values, the actual computations take place in hardware floating points and are therefore *not* affected by the value of `DIGITS`.

Examples

Example 1

We generate a list of random points and compute their convex hull:

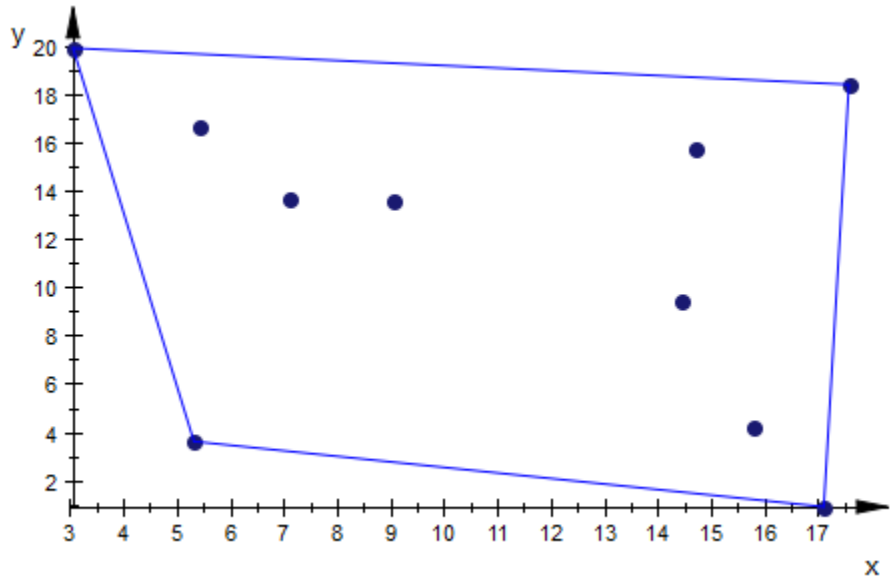
```
X := stats::uniformRandom(0, 20):
l := [[X(), X()] $ i = 1..10]:
h := plot::hull(l):
```

The convex hull is returned as lists of lists, as accepted by `plot::Polygon2d`:

```
h[1]
```

```
[[17.58320254, 18.38769696], [3.063130321, 19.89625562]]
```

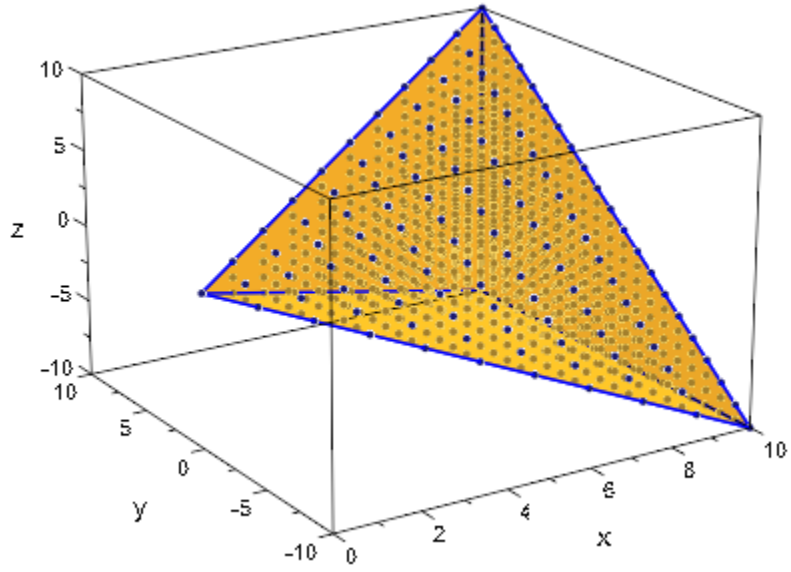
```
plot(plot::PointList2d(l),
     plot::Polygon2d(t) $ t in h,
     Closed, PointSize=2)
```



Example 2

The convex hull of a list of points in 3D is also easy to visualize:

```
l := [[x, y, z] $ y = z..x $ z = -x..x $ x = 0..10]:
h := plot::hull(l):
plot(plot::PointList3d(l, PointSize=1),
     plot::Polygon3d(t) $ t in h,
     Closed, Filled, FillColor=RGB::LightOrange.[0.6])
```



Parameters

L

A list of points, which are given as lists of real values

Return Values

List of simplices of dimension one less than that of the points in L, given as lists of lists of floating-point values.

Algorithms

`plot::hull` uses qhull from the Geometry Center of the University of Minnesota, see www.qhull.org.

plot::Arc2d

Circular and elliptical arcs in 2D

Syntax

```
plot::Arc2d(r, <[c_x, c_y]>, <α .. β>, <a = a_min .. a_max>, options)
```

```
plot::Arc2d([r_1, r_2], <[c_x, c_y]>, <α .. β>, <a = a_min .. a_max>, options)
```

Description

`plot::Arc2d(r, [x, y], α .. β )` creates a circular arc with radius *r* and center (*x*, *y*) with a polar angle between *α* and *β*.

`plot::Arc2d([ r_1, r_2], [x, y], α .. β )` creates a corresponding elliptical arc with semi-axes r_1, r_2.

The angle of a point on the arc is the usual polar angle to the positive *x*-axis known from polar coordinates. It is measured in radians.

If no range for the polar angle is specified, a full circle/ellipse is created.

If no center point is specified, an arc with center [0, 0] is created.

Attributes

Attribute	Purpose	Default Value
`AffectViewingBox`	influence of objects on the `ViewingBox` of a scene	`TRUE`
`Angle`	rotation angle	`0`
`AngleEnd`	end of angle range	`PI/2`
`AngleBegin`	begin of angle range	`0`
`AngleRange`	angle range	`0 .. PI/2`
`AntiAliased`	antialiased lines and points?	`TRUE`

Attribute	Purpose	Default Value
`Center`	center of objects, rotation center	[0, 0]
`CenterX`	center of objects, rotation center, x-component	`0`
`CenterY`	center of objects, rotation center, y-component	`0`
`Closed`	open or closed polygons	`FALSE`
`Filled`	filled or transparent areas and surfaces	`FALSE`
`FillColor`	color of areas and surfaces	`RGB::Red`
`FillPattern`	type of area filling	`DiagonalLines`
`Frames`	the number of frames in an animation	`50`
`Legend`	makes a legend entry	
`LegendText`	short explanatory text for legend	
`LegendEntry`	add this object to the legend?	`FALSE`
`LineColor`	color of lines	`RGB::Blue`
`LineWidth`	width of lines	`0.35`
`LineStyle`	solid, dashed or dotted lines?	`Solid`
`LinesVisible`	visibility of lines	`TRUE`
`Name`	the name of a plot object (for browser and legend)	
`ParameterEnd`	end value of the animation parameter	
`ParameterName`	name of the animation parameter	
`ParameterBegin`	initial value of the animation parameter	

Attribute	Purpose	Default Value
ParameterRange	range of the animation parameter	
SemiAxes	semi axes of ellipses and ellipsods	[1, 1]
SemiAxisX	first semi axis of ellipses and ellipsods	1
SemiAxisY	second semi axis of ellipses and ellipsods	1
TimeEnd	end time of the animation	10.0
TimeBegin	start time of the animation	0.0
TimeRange	the real time span of an animation	0.0 .. 10.0
Title	object title	
TitleFont	font of object titles	[" sans-serif ", 11]
TitlePosition	position of object titles	
TitleAlignment	horizontal alignment of titles w.r.t. their coordinates	Center
TitlePositionX	position of object titles, x component	
TitlePositionY	position of object titles, y component	
Visible	visibility	TRUE
VisibleAfter	object visible after this time value	
VisibleBefore	object visible until this time value	
VisibleFromTo	object visible during this time range	
VisibleAfterEnd	object visible after its animation time ended?	TRUE

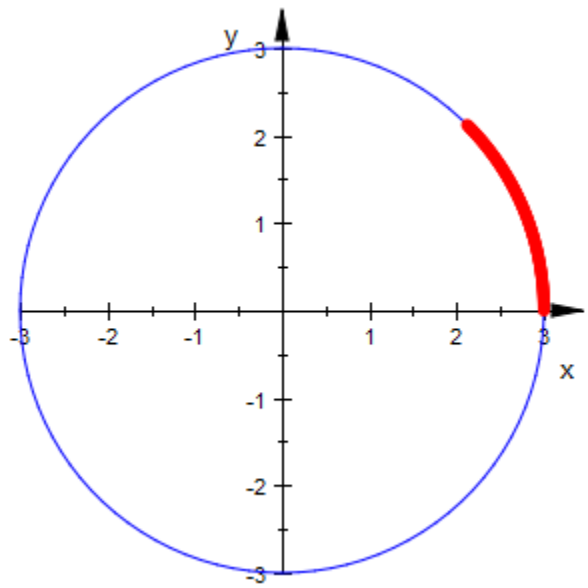
Attribute	Purpose	Default Value
`VisibleBeforeBegin`	object visible before its animation time starts?	`TRUE`

Examples

Example 1

An arc is a segment of a circle:

```
circle := plot::Circle2d(3, [0, 0]):
arc := plot::Arc2d(3, [0, 0], 0 .. PI/4, LineColor = RGB::Red,
                   LineWidth = 1.5*unit::mm):
plot(circle, arc)
```

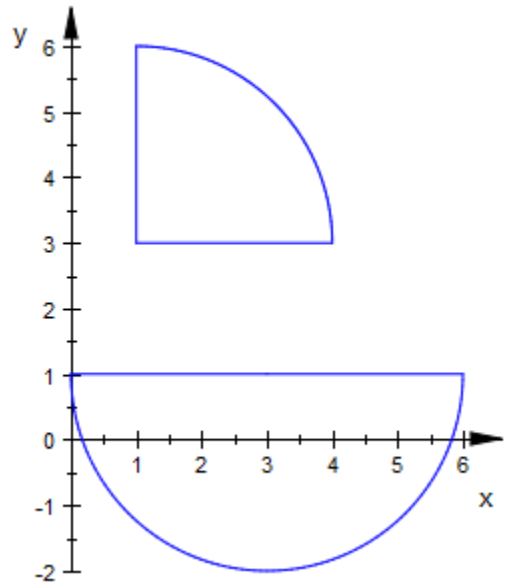


```
delete circle, arc:
```

Example 2

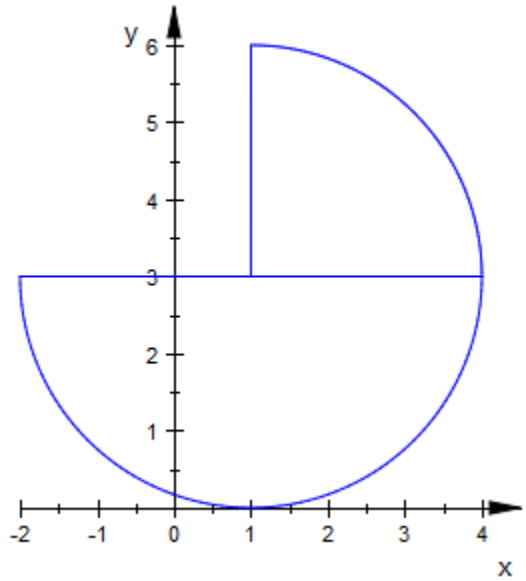
The center of an arc may be given as the second argument to `plot::Arc2d`:

```
arc1 := plot::Arc2d(3, [1, 3], 0..PI/2, Closed = TRUE):
arc2 := plot::Arc2d(3, [3, 1], -PI ..0, Closed = TRUE):
plot(arc1, arc2)
```



The center is accessible as the attribute `Center` of the arc object. We change the center of the second arc:

```
arc2::Center := [1, 3]:
plot(arc1, arc2)
```

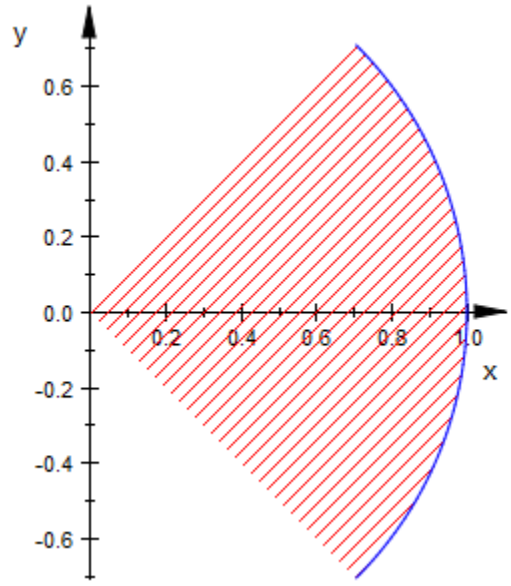


```
delete arc1, arc2:
```

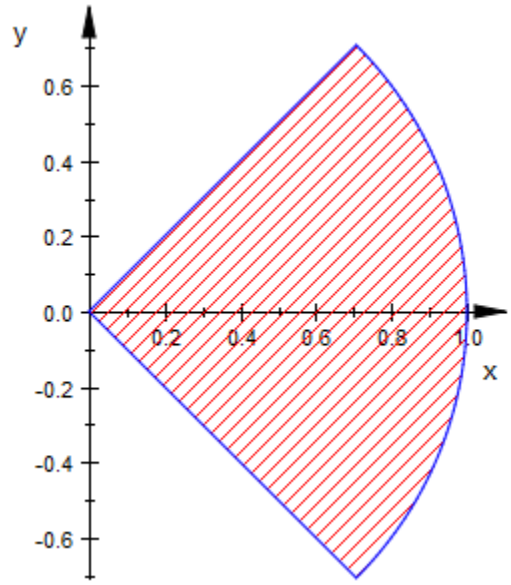
Example 3

A filled arc is a segment of a circle, like a piece of pie:

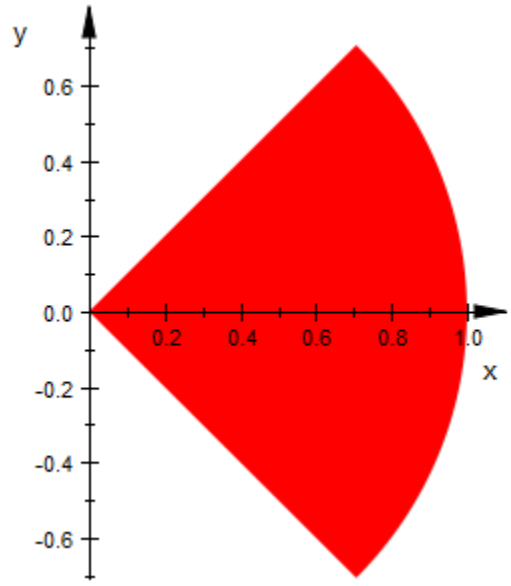
```
plot(plot::Arc2d(1, -PI/4..PI/4, Filled = TRUE))
```



```
plot(plot::Arc2d(1, -PI/4..PI/4, Filled = TRUE, Closed = TRUE))
```



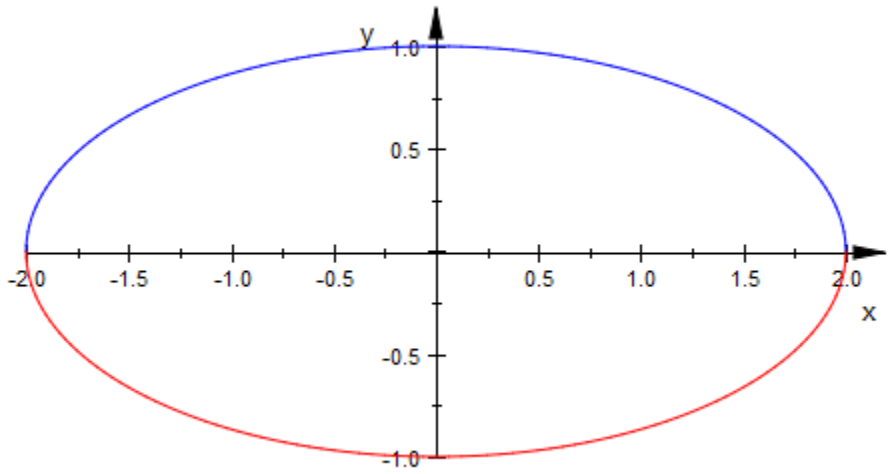
```
plot(plot::Arc2d(1, -PI/4..PI/4, Filled = TRUE,
                 FillPattern = Solid, LinesVisible = FALSE),
                 AxesInFront = TRUE)
```



Example 4

When giving a list of two radii, `plot::Arc2d` draws a segment of anellipse with the corresponding semi-axes:

```
arc1 := plot::Arc2d([2, 1], 0 .. PI, Color = RGB::Blue):
arc2 := plot::Arc2d([2, 1], -PI .. 0, Color = RGB::Red):
plot(arc1, arc2)
```

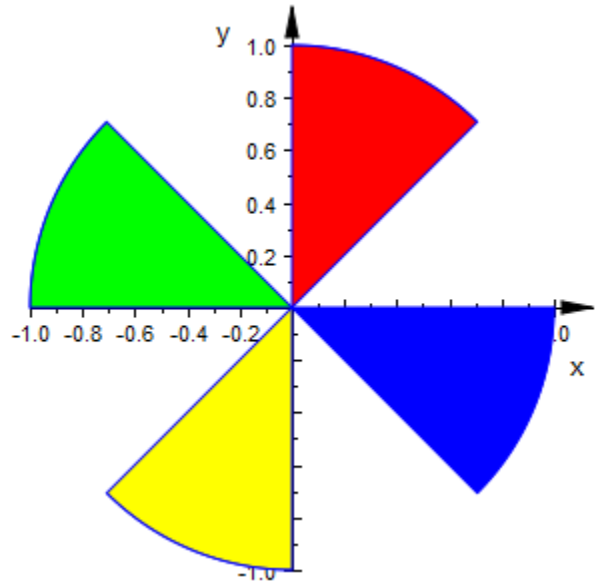


```
delete arc1, arc2:
```

Example 5

To plot or animate segments of a tilted ellipse, use the attribute `Angle`:

```
arc:= [1, 1], [0, 0], PI/4..PI/2, Filled, Closed, FillPattern=Solid:
plot(plot::Arc2d(arc, Angle=a+0,      a=0..2*PI, FillColor=RGB::Red),
     plot::Arc2d(arc, Angle=a+1/2*PI, a=0..2*PI, FillColor=RGB::Green),
     plot::Arc2d(arc, Angle=a+PI,     a=0..2*PI, FillColor=RGB::Yellow),
     plot::Arc2d(arc, Angle=a+3/2*PI, a=0..2*PI, FillColor=RGB::Blue))
```

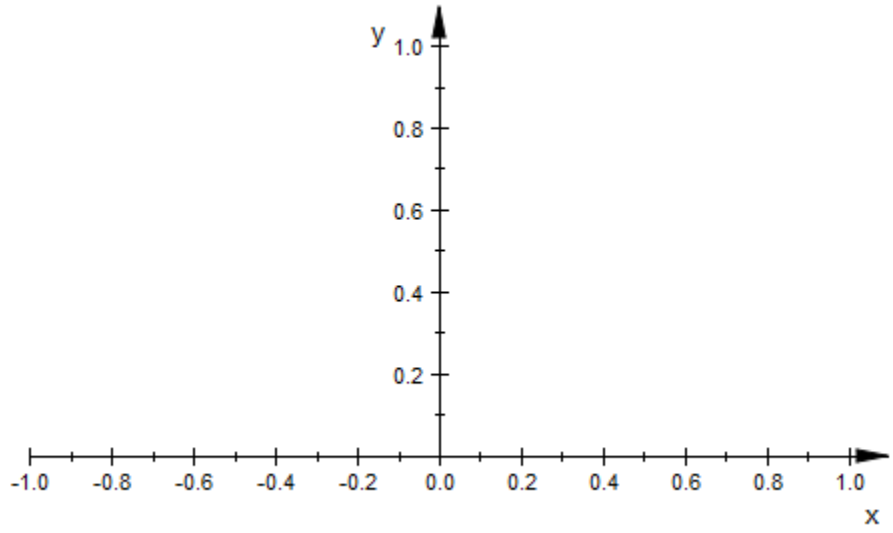


```
delete arc:
```

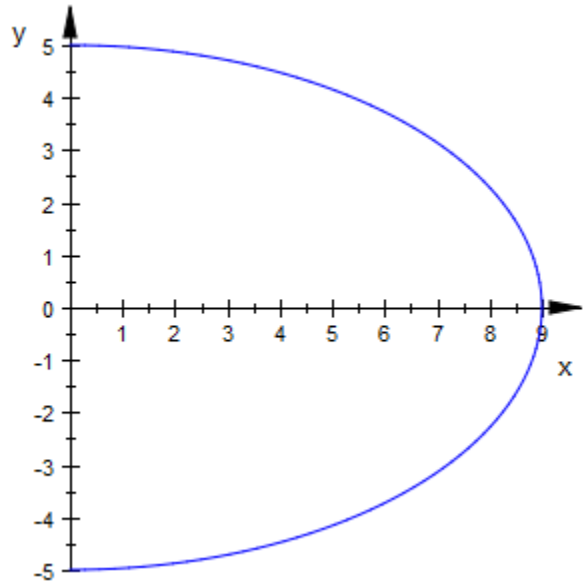
Example 6

Further examples of animated 2D arcs:

```
plot(plot::Arc2d(1, a .. PI, a = 0..PI))
```



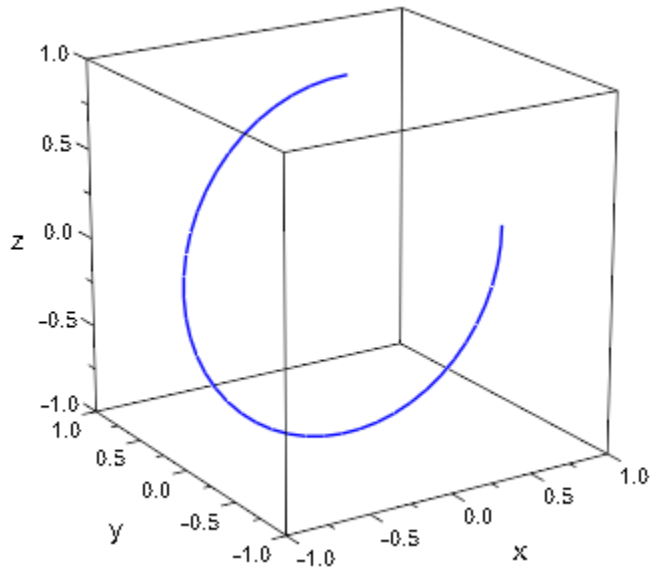
```
plot(plot::Arc2d([1 + a^2/2, 1 + a], -PI/2 .. PI/2, a = 0..4))
```



Example 7

We plot an animated 3D arc:

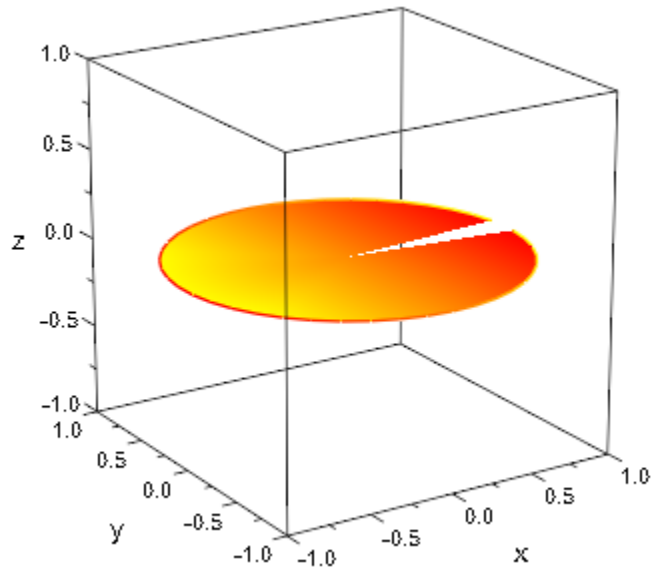
```
plot(plot::Arc3d(1, [0,0,0], [0,a,1-a], 0..3/2*PI, a = 0..1))
```



Example 8

We plot a colored 3D arcs:

```
plot(plot::Arc3d(1, [0,0,0], 0.1..2*PI-0.1, Filled,
                 LineColor=RGB::Yellow, LineColor2=RGB::Red,
                 LineColorType = Dichromatic, LineColorDirection=[+1,0,0],
                 FillColor=RGB::Yellow, FillColor2=RGB::Red,
                 FillColorType = Dichromatic, FillColorDirection=[-1,0,0]
))
```



Parameters

r

The radius of the circle. This must be a real numerical value or an arithmetical expression of the animation parameter `a`.

r is equivalent to the attributes `SemiAxisX`, `SemiAxisY`.

r_1, r_2

The semi-axes of an elliptical arc. They must be real numerical values or arithmetical expressions of the animation parameter `a`.

r_1, r_2 are equivalent to the attributes `SemiAxisX`, `SemiAxisY`.

c_x, c_y

The center point. The coordinates c_x, c_y must be real numerical values or arithmetical expressions of the animation parameter `a`. If no center is specified, an arc centered at the origin is created.

c_x, c_y are equivalent to the attribute `Center`.

α .. β

The angle range in radians: α and β must be real numerical values or arithmetical expressions of the animation parameter `a`. The default range is `0 .. 2*PI`.

α .. ß is equivalent to the attribute `AngleRange`.

a

Animation parameter, specified as `a = a_min..a_max`, where a_{min} is the initial parameter value, and a_{max} is the final parameter value.

MuPAD Functions
`plot` | `plot::copy`

MuPAD Graphical Primitives
`plot::Arc3d` | `plot::Circle2d` | `plot::Ellipse2d` | `plot::Ellipse3d`

plot::Arc3d

Circular and elliptical arcs in 3D

Syntax

```
plot::Arc3d(r, <[c_x, c_y, c_z], <[n_x, n_y, n_z]>>, <α .. β>, <a = a_min .. a_max>, options)
```

```
plot::Arc3d([r_1, r_2], <[c_x, c_y, c_z], <[n_x, n_y, n_z]>>, <α .. β>, <a = a_min .. a_max>, options
```

Description

`plot::Arc3d(r, [x, y, z], [nx, ny, nz], α .. β )` creates a circular arc with radius *r* and center (*x*, *y*, *z*) with a polar angle between *α* and *β* in the plane with the normal vector (*nx*, *ny*, *nz*).

`plot::Arc3d([ r_1, r_2], [x, y, z], [nx, ny, nz], α .. β )` creates a corresponding elliptical arc with semi-axes r_1, r_2.

The angle of a point on the arc is the usual polar angle to the positive *x*-axis known from polar coordinates. It is measured in radians.

If no range for the polar angle is specified, a full circle/ellipse is created.

If no center point is specified, an arc with center [0, 0, 0], is created.

Attributes

Attribute	Purpose	Default Value
`AffectViewingBox`	influence of objects on the `ViewingBox` of a scene	`TRUE`
`Angle`	rotation angle	`0`
`AngleEnd`	end of angle range	`PI/2`
`AngleBegin`	begin of angle range	`0`
`AngleRange`	angle range	`0 .. PI/2`

Attribute	Purpose	Default Value
`Center`	center of objects, rotation center	[0, 0, 0]
`CenterX`	center of objects, rotation center, x-component	0
`CenterY`	center of objects, rotation center, y-component	0
`CenterZ`	center of objects, rotation center, z-component	0
`Closed`	open or closed polygons	`FALSE`
`Filled`	filled or transparent areas and surfaces	`FALSE`
`FillColor`	color of areas and surfaces	`RGB::LightBlue`
`FillColor2`	second color of areas and surfaces for color blends	`RGB::CornflowerBlue`
`FillColorType`	surface filling types	`Flat`
`FillColorDirection`	the direction of color transitions on surfaces	[0, 0, 1]
`FillColorDirectionX`	x-component of the direction of color transitions on surfaces	0
`FillColorDirectionY`	y-component of the direction of color transitions on surfaces	0
`FillColorDirectionZ`	z-component of the direction of color transitions on surfaces	1
`Frames`	the number of frames in an animation	50
`Legend`	makes a legend entry	
`LegendText`	short explanatory text for legend	

Attribute	Purpose	Default Value
LegendEntry	add this object to the legend?	FALSE
LineColor	color of lines	RGB::Blue
LineWidth	width of lines	0.35
LineColor2	color of lines	RGB::DeepPink
LineStyle	solid, dashed or dotted lines?	Solid
LinesVisible	visibility of lines	TRUE
LineColorType	line coloring types	Flat
LineColorDirection	the direction of color transitions on lines	[0, 0, 1]
LineColorDirectionX	x-component of the direction of color transitions on lines	0
LineColorDirectionY	y-component of the direction of color transitions on lines	0
LineColorDirectionZ	z-component of the direction of color transitions on lines	1
Name	the name of a plot object (for browser and legend)	
Normal	normal vector of circles and discs, etc. in 3D	[0, 0, 1]
NormalX	normal vector of circles and discs, etc. in 3D, x-component	0
NormalY	normal vector of circles and discs, etc. in 3D, y-component	0
NormalZ	normal vector of circles and discs, etc. in 3D, z-component	1
ParameterEnd	end value of the animation parameter	

Attribute	Purpose	Default Value
ParameterName	name of the animation parameter	
ParameterBegin	initial value of the animation parameter	
ParameterRange	range of the animation parameter	
SemiAxes	semi axes of ellipses and ellipsods	
SemiAxisX	first semi axis of ellipses and ellipsods	1
SemiAxisY	second semi axis of ellipses and ellipsods	1
TimeEnd	end time of the animation	10.0
TimeBegin	start time of the animation	0.0
TimeRange	the real time span of an animation	0.0 .. 10.0
Title	object title	
TitleFont	font of object titles	[" sans-serif ", 11]
TitlePosition	position of object titles	
TitleAlignment	horizontal alignment of titles w.r.t. their coordinates	Center
TitlePositionX	position of object titles, x component	
TitlePositionY	position of object titles, y component	
TitlePositionZ	position of object titles, z component	
Visible	visibility	TRUE
VisibleAfter	object visible after this time value	

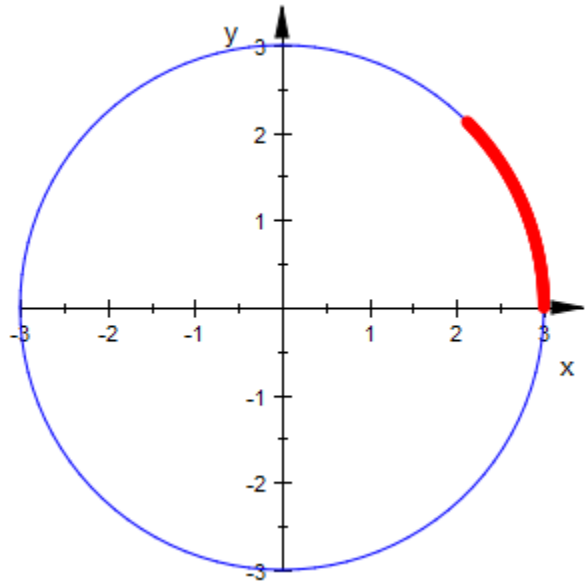
Attribute	Purpose	Default Value
`VisibleBefore`	object visible until this time value	
`VisibleFromTo`	object visible during this time range	
`VisibleAfterEnd`	object visible after its animation time ended?	`TRUE`
`VisibleBeforeBegin`	object visible before its animation time starts?	`TRUE`

Examples

Example 1

An arc is a segment of a circle:

```
circle := plot::Circle2d(3, [0, 0]):
arc := plot::Arc2d(3, [0, 0], 0 .. PI/4, LineColor = RGB::Red,
                   LineWidth = 1.5*unit::mm):
plot(circle, arc)
```

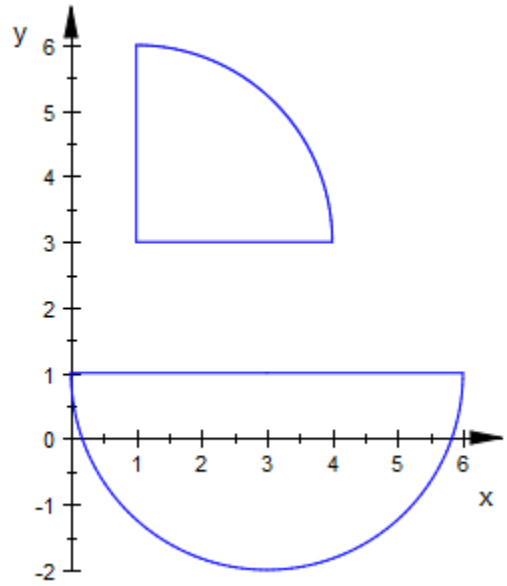


```
delete circle, arc:
```

Example 2

The center of an arc may be given as the second argument to `plot::Arc2d`:

```
arc1 := plot::Arc2d(3, [1, 3], 0..PI/2, Closed = TRUE):
arc2 := plot::Arc2d(3, [3, 1], -PI ..0, Closed = TRUE):
plot(arc1, arc2)
```



The center is accessible as the attribute `Center` of the arc object. We change the center of the second arc:

```
arc2::Center := [1, 3]:
plot(arc1, arc2)
```
