- `AICc` — Akaike information criterion corrected for sample size
- `BIC` — Bayesian information criterion
- `CAIC` — Consistent Akaike information criterion

To obtain any of these values as a scalar, index into the property using dot notation. For example, in a model `mdl`, the AIC value `aic` is:

```
aic = mdl.ModelCriterion.AIC
```

`NumCoefficients`

Number of coefficients in the model, a positive integer. `NumCoefficients` includes coefficients that are set to zero when the model terms are rank deficient.

`NumEstimatedCoefficients`

Number of estimated coefficients in the model, a positive integer. `NumEstimatedCoefficients` does not include coefficients that are set to zero when the model terms are rank deficient. `NumEstimatedCoefficients` is the degrees of freedom for regression.

`NumObservations`

Number of observations the fitting function used in fitting. This is the number of observations supplied in the original table, dataset, or matrix, minus any excluded rows (set with the `Excluded` name-value pair) or rows with missing values.

NumPredictors

Number of variables `fitlm` used as predictors for fitting.

NumVariables

Number of variables in the data. `NumVariables` is the number of variables in the original table or dataset, or the total number of columns in the predictor matrix and response vector when the fit is based on those arrays. It includes variables, if any, that are not used as predictors or as the response.

ObservationInfo

Table with the same number of rows as the input data (`tbl` or `X`).

Field	Description
`Weights`	Observation weights. Default is all `1`.
`Excluded`	Logical value, `1` indicates an observation that you excluded from the fit with the `Exclude` name-value pair.
`Missing`	Logical value, `1` indicates a missing value in the input. Missing values are not used in the fit.
`Subset`	Logical value, `1` indicates the observation is not excluded or missing, so is used in the fit.

ObservationNames

Cell array of strings containing the names of the observations used in the fit.

- If the fit is based on a table or dataset containing observation names, `ObservationNames` uses those names.
- Otherwise, `ObservationNames` is an empty cell array

Offset

Vector with the same length as the number of rows in the data, passed from `fitglm` or `stepwiseglm` in the `Offset` name-value pair. The fitting function used `Offset` as a predictor variable, but with the coefficient set to exactly `1`. In other words, the formula for fitting was

μ ~ `Offset + (terms involving real predictors)`

with the `Offset` predictor having coefficient `1`.

For example, consider a Poisson regression model. Suppose the number of counts is known for theoretical reasons to be proportional to a predictor `A`. By using the log link function and by specifying `log(A)` as an offset, you can force the model to satisfy this theoretical constraint.

`PredictorNames`

Cell array of strings, the names of the predictors used in fitting the model.

`Residuals`

Table containing residuals, with one row for each observation and these variables.

Field	Description
`Raw`	Observed minus fitted values.
`LinearPredictor`	Residuals on the linear predictor scale, equal to the adjusted response value minus the fitted linear combination of the predictors.
`Pearson`	Raw residuals divided by the estimated standard deviation of the response.
`Anscombe`	Residuals defined on transformed data with the transformation chosen to remove skewness.
`Deviance`	Residuals based on the contribution of each observation to the deviance.

To obtain any of these columns as a vector, index into the property using dot notation. For example, in a model `mdl`, the ordinary raw residual vector `r` is:

```
r = mdl.Residuals.Raw
```

Rows not used in the fit because of missing values (in `ObservationInfo.Missing`) contain `NaN` values.

Rows not used in the fit because of excluded values (in `ObservationInfo.Excluded`) contain `NaN` values, with the following exceptions:

- `raw` contains the difference between the observed and predicted values.
- `standardized` is the residual, standardized in the usual way.
- `studentized` matches the standardized values because this residual is not used in the estimate of the residual standard deviation.

`ResponseName`

String giving naming the response variable.

`Rsquared`

Proportion of total sum of squares explained by the model. The ordinary R-squared value relates to the `SSR` and `SST` properties:
`Rsquared = SSR/SST = 1 - SSE/SST`.

For a linear or nonlinear model, `Rsquared` is a structure with two fields:

- `Ordinary` — Ordinary (unadjusted) R-squared
- `Adjusted` — R-squared adjusted for the number of coefficients

For a generalized linear model, `Rsquared` is a structure with five fields:

- `Ordinary` — Ordinary (unadjusted) R-squared
- `Adjusted` — R-squared adjusted for the number of coefficients
- `LLR` — Log-likelihood ratio
- `Deviance` — Deviance
- `AdjGeneralized` — Adjusted generalized R-squared

To obtain any of these values as a scalar, index into the property using dot notation. For example, the adjusted R-squared value in `mdl` is

```
r2 = mdl.Rsquared.Adjusted
```

`SSE`

Sum of squared errors (residuals).

The Pythagorean theorem implies

`SST = SSE + SSR`.

`SSR`

Regression sum of squares, the sum of squared deviations of the fitted values from their mean.

The Pythagorean theorem implies
`SST = SSE + SSR`.

`SST`

Total sum of squares, the sum of squared deviations of `y` from `mean(y)`.

The Pythagorean theorem implies
`SST = SSE + SSR`.

`Steps`

Structure that is empty unless `stepwiselm` constructed the model.

Field	Description
`Start`	Formula representing the starting model
`Lower`	Formula representing the lower bound model, these terms that must remain in the model
`Upper`	Formula representing the upper bound model, model cannot contain more terms than `Upper`
`Criterion`	Criterion used for the stepwise algorithm, such as `'sse'`
`PEnter`	Value of the parameter, such as `0.05`
`PRemove`	Value of the parameter, such as `0.10`
`History`	Table representing the steps taken in the fit

The `History` table has one row for each step including the initial fit, and the following variables (columns).

Field	Description
`Action`	Action taken during this step, one of: • `'Start'` — First step

Field	Description
	• `'Add'` — A term is added • `'Remove'` — A term is removed
`TermName`	• `'Start'` step: The starting model specification • `'Add'` or `'Remove'` steps: The term moved in that step
`Terms`	Terms matrix (see `modelspec` of `fitlm`)
`DF`	Regression degrees of freedom after this step
`delDF`	Change in regression degrees of freedom from previous step (negative for steps that remove a term)
`Deviance`	Deviance (residual sum of squares) at that step
`FStat`	*F* statistic that led to this step
`PValue`	*p*-value of the *F* statistic

`VariableInfo`

Table containing metadata about `Variables`. There is one row for each term in the model, and the following columns.

Field	Description
`Class`	String giving variable class, such as `'double'`
`Range`	Cell array giving variable range: • Continuous variable — Two-element vector `[min,max]`, the minimum and maximum values • Categorical variable — Cell array of distinct variable values
`InModel`	Logical vector, where `true` indicates the variable is in the model
`IsCategorical`	Logical vector, where `true` indicates a categorical variable

`VariableNames`

Cell array of strings containing names of the variables in the fit.

- If the fit is based on a table or dataset, this property provides the names of the variables in that table or dataset.

- If the fit is based on a predictor matrix and response vector, `VariableNames` is the values in the `VarNames` name-value pair of the fitting method.
- Otherwise the variables have the default fitting names.

`Variables`

Table containing the data, both observations and responses, that the fitting function used to construct the fit. If the fit is based on a table or dataset array, `Variables` contains all of the data from that table or dataset array. Otherwise, `Variables` is a table created from the input data matrix `X` and response vector `y`.

Methods

addTerms	Add terms to generalized linear model
coefCI	Confidence intervals of coefficient estimates of generalized linear model
coefTest	Linear hypothesis test on generalized linear regression model coefficients
devianceTest	Analysis of deviance
disp	Display generalized linear regression model
feval	Evaluate generalized linear regression model prediction
fit	Create generalized linear regression model
plotDiagnostics	Plot diagnostics of generalized linear regression model
plotResiduals	Plot residuals of generalized linear regression model

plotSlice	Plot of slices through fitted generalized linear regression surface
predict	Predict response of generalized linear regression model
random	Simulate responses for generalized linear regression model
removeTerms	Remove terms from generalized linear model
step	Improve generalized linear regression model by adding or removing terms
stepwise	Create generalized linear regression model by stepwise regression

Definitions

Canonical Link Function

The default link function for a generalized linear model is the *canonical link function*.

Canonical Link Functions for Generalized Linear Models

Distribution	Link Function Name	Link Function	Mean (Inverse) Function
`'normal'`	`'identity'`	$f(\mu) = \mu$	$\mu = Xb$
`'binomial'`	`'logit'`	$f(\mu) = \log(\mu/(1-\mu))$	$\mu = \exp(Xb) / (1 + \exp(Xb))$
`'poisson'`	`'log'`	$f(\mu) = \log(\mu)$	$\mu = \exp(Xb)$
`'gamma'`	`-1`	$f(\mu) = 1/\mu$	$\mu = 1/(Xb)$
`'inverse gaussian'`	`-2`	$f(\mu) = 1/\mu^2$	$\mu = (Xb)^{-1/2}$

Hat Matrix

The *hat matrix H* is defined in terms of the data matrix X and a diagonal weight matrix W:
$H = X(X^TWX)^{-1}X^TW^T$.

W has diagonal elements w_i:

$$w_i = \frac{g'(\mu_i)}{\sqrt{V(\mu_i)}},$$

where

- g is the link function mapping y_i to x_ib.
- g' is the derivative of the link function g.
- V is the variance function.
- μ_i is the ith mean.

The diagonal elements H_{ii} satisfy

$$0 \le h_{ii} \le 1$$

$$\sum_{i=1}^{n} h_{ii} = p,$$

where n is the number of observations (rows of X), and p is the number of coefficients in the regression model.

Leverage

The *leverage* of observation i is the value of the ith diagonal term, h_{ii}, of the hat matrix H. Because the sum of the leverage values is p (the number of coefficients in the regression model), an observation i can be considered to be an outlier if its leverage substantially exceeds p/n, where n is the number of observations.

Cook's Distance

The Cook's distance D_i of observation i is

$$D_i = w_i \frac{e_i^2}{p\hat{\varphi}} \frac{h_{ii}}{(1-h_{ii})^2},$$

where

- $\hat{\varphi}$ is the dispersion parameter (estimated or theoretical).
- e_i is the linear predictor residual, $g(y_i) - x_i\hat{\beta}$, where
  - g is the link function.
  - y_i is the observed response.
  - x_i is the observation.
  - $\hat{\beta}$ is the estimated coefficient vector.
- p is the number of coefficients in the regression model.
- h_{ii} is the ith diagonal element of the Hat Matrix H.

Deviance

Deviance of a model M_1 is twice the difference between the loglikelihood of that model and the saturated model, M_S. The saturated model is the model with the maximum number of parameters that can be estimated. For example, if there are n observations y_i, $i = 1, 2, ..., n$, with potentially different values for $X_i^T\beta$, then you can define a saturated model with n parameters. Let $L(b,y)$ denote the maximum value of the likelihood function for a model. Then the deviance of model M_1 is

$$-2\left(\log L(b_1, y) - \log L(b_S, y)\right),$$

where b_1 are the estimated parameters for model M_1 and b_S are the estimated parameters for the saturated model. The deviance has a chi-square distribution with $n - p$ degrees of freedom, where n is the number of parameters in the saturated model and p is the number of parameters in model M_1.

If M_1 and M_2 are two different generalized linear models, then the fit of the models can be assessed by comparing the deviances D_1 and D_2 of these models. The difference of the deviances is

$$D = D_2 - D_1 = -2\left(\log L(b_2, y) - \log L(b_S, y)\right) + 2\left(\log L(b_1, y) - \log L(b_S, y)\right)$$
$$= -2\left(\log L(b_2, y) - \log L(b_1, y)\right).$$

Asymptotically, this difference has a chi-square distribution with degrees of freedom v equal to the number of parameters that are estimated in one model but fixed (typically at 0) in the other. That is, it is equal to the difference in the number of parameters estimated in M_1 and M_2. You can get the p-value for this test using `1 - chi2cdf(D,V)`, where $D = D_2 - D_1$.

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

Fit a Generalized Linear Model

Fit a logistic regression model of probability of smoking as a function of age, weight, and sex, using a two-way interactions model.

Load the `hospital` dataset array.

```
load hospital
ds = hospital; % just to use the ds name
```

Specify the model using a formula that allows up to two-way interactions.

```
modelspec = 'Smoker ~ Age*Weight*Sex - Age:Weight:Sex';
```

Create the generalized linear model.

```
mdl = fitglm(ds,modelspec,'Distribution','binomial')
```

```
mdl =

Generalized Linear regression model:
    logit(Smoker) ~ 1 + Sex*Age + Sex*Weight + Age*Weight
    Distribution = Binomial
```

```
Estimated Coefficients:
                       Estimate       SE           tStat       pValue
    (Intercept)            -6.0492       19.749     -0.3063    0.75938
    Sex_Male               -2.2859       12.424    -0.18399    0.85402
    Age                    0.11691      0.50977     0.22934    0.81861
    Weight                0.031109      0.15208     0.20455    0.83792
    Sex_Male:Age          0.020734      0.20681     0.10025    0.92014
    Sex_Male:Weight        0.01216     0.053168     0.22871     0.8191
    Age:Weight         -0.00071959    0.0038964    -0.18468    0.85348

100 observations, 93 error degrees of freedom
Dispersion: 1
Chi^2-statistic vs. constant model: 5.07, p-value = 0.535
```

The large *p*-value indicates the model might not differ statistically from a constant.

Create a Generalized Linear Model Stepwise

Create response data using just three of 20 predictors, and create a generalized linear model stepwise to see if it uses just the correct predictors.

Create data with 20 predictors, and Poisson response using just three of the predictors, plus a constant.

```
rng('default') % for reproducibility
X = randn(100,20);
mu = exp(X(:,[5 10 15])*[.4;.2;.3] + 1);
y = poissrnd(mu);
```

Fit a generalized linear model using the Poisson distribution.

```
mdl =  stepwiseglm(X,y,...
    'constant','upper','linear','Distribution','poisson')
```

```
1. Adding x5, Deviance = 134.439, Chi2Stat = 52.24814, PValue = 4.891229e-13
2. Adding x15, Deviance = 106.285, Chi2Stat = 28.15393, PValue = 1.1204e-07
3. Adding x10, Deviance = 95.0207, Chi2Stat = 11.2644, PValue = 0.000790094

mdl =

Generalized Linear regression model:
    log(y) ~ 1 + x5 + x10 + x15
    Distribution = Poisson

Estimated Coefficients:
                   Estimate    SE          tStat     pValue
    (Intercept)     1.0115     0.064275    15.737    8.4217e-56
    x5             0.39508     0.066665    5.9263    3.0977e-09
    x10            0.18863      0.05534    3.4085     0.0006532
    x15            0.29295     0.053269    5.4995    3.8089e-08

100 observations, 96 error degrees of freedom
```

```
Dispersion: 1
Chi^2-statistic vs. constant model: 91.7, p-value = 9.61e-20
```

prob.GeneralizedParetoDistribution class

Package: prob
Superclasses: prob.ToolboxFittableParametricDistribution

Generalized Pareto probability distribution object

Description

`prob.GeneralizedParetoDistribution` is an object consisting of parameters, a model description, and sample data for a generalized Pareto probability distribution.

Create a probability distribution object with specified parameter values using `makedist`. Alternatively, fit a distribution to data using `fitdist` or the Distribution Fitting app.

Construction

`pd = makedist('GeneralizedPareto')` creates a generalized Pareto probability distribution object using default parameter values.

`pd = makedist('GeneralizedPareto','k',k,'sigma',sigma,'theta',theta)` creates a generalized Pareto probability distribution object using the specified parameter values.

Input Arguments

`k` — Shape parameter

1 (default) | scalar value

Shape parameter for the generalized Pareto distribution, specified as a scalar value.

Data Types: `single` | `double`

`sigma` — Scale parameter

1 (default) | nonnegative scalar value

Scale parameter for the generalized Pareto distribution, specified as a nonnegative scalar value.

Data Types: `single` | `double`

`theta` — Location parameter

1 (default) | scalar value

Location parameter for the generalized Pareto distribution, specified as a scalar value.

Data Types: `single` | `double`

Properties

`k` — Shape parameter

scalar value

Shape parameter for the generalized Pareto distribution, stored as a scalar value.

Data Types: `single` | `double`

`sigma` — Scale parameter

nonnegative scalar value

Scale parameter for the generalized Pareto distribution, stored as a nonnegative scalar value.

Data Types: `single` | `double`

`theta` — Location parameter

scalar value

Location parameter for the generalized Pareto distribution, stored as a scalar value.

Data Types: `single` | `double`

`DistributionName` — Probability distribution name

probability distribution name string

Probability distribution name, stored as a valid probability distribution name string. This property is read-only.

Data Types: `char`

`InputData` — Data used for distribution fitting

structure

Data used for distribution fitting, stored as a structure containing the following:

- `data`: Data vector used for distribution fitting.
- `cens`: Censoring vector, or empty if none.
- `freq`: Frequency vector, or empty if none.

This property is read-only.

Data Types: `struct`

`IsTruncated` — Logical flag for truncated distribution

`0 | 1`

Logical flag for truncated distribution, stored as a logical value. If `IsTruncated` equals `0`, the distribution is not truncated. If `IsTruncated` equals `1`, the distribution is truncated. This property is read-only.

Data Types: `logical`

`NumParameters` — Number of parameters

positive integer value

Number of parameters for the probability distribution, stored as a positive integer value. This property is read-only.

Data Types: `single | double`

`ParameterCovariance` — Covariance matrix of the parameter estimates

matrix of scalar values

Covariance matrix of the parameter estimates, stored as a p-by-p matrix, where p is the number of parameters in the distribution. The (`i`,`j`) element is the covariance between the estimates of the `i`th parameter and the `j`th parameter. The (`i`,`i`) element is the estimated variance of the `i`th parameter. If parameter `i` is fixed rather than estimated by fitting the distribution to data, then the (`i`,`i`) elements of the covariance matrix are 0. This property is read-only.

Data Types: `single | double`

`ParameterDescription` — Distribution parameter descriptions

cell array of strings

Distribution parameter descriptions, stored as a cell array of strings. Each cell contains a short description of one distribution parameter. This property is read-only.

Data Types: `char`

`ParameterIsFixed` — Logical flag for fixed parameters
array of logical values

Logical flag for fixed parameters, stored as an array of logical values. If `0`, the corresponding parameter in the `ParameterNames` array is not fixed. If `1`, the corresponding parameter in the `ParameterNames` array is fixed. This property is read-only.

Data Types: `logical`

`ParameterNames` — Distribution parameter names
cell array of strings

Distribution parameter names, stored as a cell array of strings. This property is read-only.

Data Types: `char`

`ParameterValues` — Distribution parameter values
vector of scalar values

Distribution parameter values, stored as a vector. This property is read-only.

Data Types: `single | double`

`Truncation` — Truncation interval
vector of scalar values

Truncation interval for the probability distribution, stored as a vector containing the lower and upper truncation boundaries. This property is read-only.

Data Types: `single | double`

Definitions

Generalized Pareto Distribution

The generalized Pareto distribution is used to model the tails of another distribution. It allows a continuous range of possible shapes that include both the exponential and Pareto distributions as special cases. It has three basic forms, each corresponding to a limiting distribution of exceedence data from a different class of underlying distributions.

- Distributions whose tails decrease exponentially, such as the normal, lead to a generalized Pareto shape parameter of zero.
- Distributions whose tails decrease polynomially, such as the Student's *t*, lead to a positive shape parameter.
- Distributions whose tails are finite, such as the beta, lead to a negative shape parameter.

The generalized Pareto distribution uses the following parameters.

Parameter	Description	Support
`k`	Shape parameter	$-\infty < k < \infty$
`sigma`	Scale parameter	$\sigma \geq 0$
`theta`	Location parameter	$-\infty < \theta < \infty$

The probability density function (pdf) of the generalized Pareto distribution with shape parameter $k \neq 0$ is

$$f\left(x \mid k,\sigma,\theta\right) = \left(\frac{1}{\sigma}\right)\left(1 + k\frac{\left(x-\theta\right)}{\sigma}\right)^{-1-\frac{1}{k}}$$

for $x > \theta$, when $k > 0$, or for $\theta < x < -\frac{\sigma}{k}$, when $k < 0$.

For $k = 0$, the pdf is

$$y = f\left(x \mid 0,\sigma,\theta\right) = \left(\frac{1}{\sigma}\right)\exp\left(-\frac{\left(x-\theta\right)}{\sigma}\right)$$

for $x > \theta$.

If $k = 0$ and $\theta = 0$, the generalized Pareto distribution is equivalent to the exponential distribution. If $k > 0$ and $\theta = \frac{\sigma}{k}$, the generalized Pareto distribution is equivalent to the Pareto distribution.

Examples

Create a Generalized Pareto Distribution Object Using Default Parameters

Create a generalized Pareto distribution object using the default parameter values.

```
pd = makedist('GeneralizedPareto')
```

```
pd =

  GeneralizedParetoDistribution

  Generalized Pareto distribution
        k = 1
    sigma = 1
    theta = 1
```

Create a Generalized Pareto Distribution Object Using Specified Parameters

Create a generalized Pareto distribution object by specifying parameter values.

```
pd = makedist('GeneralizedPareto','k',0,'sigma',2,'theta',1)
```

```
pd =

  GeneralizedParetoDistribution

  Generalized Pareto distribution
        k = 0
    sigma = 2
```

```
    theta = 1
```

Compute the mean of the distribution.

```
m = mean(pd)
```

```
m =

    2.1544
```

geocdf

Geometric cumulative distribution function

Syntax

```
y = geocdf(x,p)
y = geocdf(x,p,'upper')
```

Description

`y = geocdf(x,p)` returns the cumulative distribution function (cdf) of the geometric distribution at each value in `x` using the corresponding probabilities in `p`. `x` and `p` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other input. The parameters in `p` must lie on the interval `[0,1]`.

`y = geocdf(x,p,'upper')` returns the complement of the geometric distribution cdf at each value in `x`, using an algorithm that more accurately computes the extreme upper tail probabilities.

Examples

Compute Geometric Distribution cdf

Suppose you toss a fair coin repeatedly, and a "success" occurs when the coin lands with heads facing up. What is the probability of observing three or fewer tails ("failures") before tossing a heads?

To solve, determine the value of the cumulative distribution function (cdf) for the geometric distribution at x equal to 3. The probability of success (tossing a heads) p in any given trial is 0.5.

```
x = 3;
p = 0.5;
y = geocdf(x,p)
```

```
y =

    0.9375
```

The returned value of y indicates that the probability of observing three or fewer tails before tossing a heads is 0.9375.

More About

Geometric Distribution cdf

The cumulative distribution function (cdf) of the geometric distribution is

$$y = F(x \mid p) = 1 - (1-p)^{x+1}\ ;\ x = 0, 1, 2, \ldots,$$

where p is the probability of success, and x is the number of failures before the first success. The result y is the probability of observing up to x trials before a success, when the probability of success in any given trial is p.

- "Geometric Distribution" on page B-65

See Also

`geopdf` | `geoinv` | `geostat` | `geornd` | `cdf` | `mle`

geoinv

Geometric inverse cumulative distribution function

Syntax

```
x = geoinv(y,p)
```

Description

`x = geoinv(y,p)` returns the inverse cumulative distribution function (icdf) of the geometric distribution at each value in `y` using the corresponding probabilities in `p`.

`geoinv` returns the smallest positive integer `x` such that the geometric cdf evaluated at `x` is equal to or exceeds `y`. You can think of `y` as the probability of observing `x` successes in a row in independent trials, where `p` is the probability of success in each trial.

`y` and `p` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input for `p` or `y` is expanded to a constant array with the same dimensions as the other input. The values in `p` and `y` must lie on the interval `[0,1]`.

Examples

Compute Geometric Distribution icdf

Suppose the probability of a five-year-old car battery not starting in cold weather is 0.03. If we want no more than a ten percent chance that the car does not start, what is the maximum number of days in a row that we should try to start the car?

To solve, compute the inverse cdf of the geometric distribution. In this example, a "success" means the car does not start, while a "failure" means the car does start. The probability of success for each trial p equals 0.03, while the probability of observing x failures in a row before observing a success y equals 0.1.

```
y = 0.1;
p = 0.03;
x = geoinv(y,p)
```

```
x =

     3
```

The returned result indicates that if we start the car three times, there is at least a ten percent chance that it will not start on one of those tries. Therefore, if we want no greater than a ten percent chance that the car will not start, we should only attempt to start it for a maximum of two days in a row.

We can confirm this result by evaluating the cdf at values of x equal to 2 and 3, given the probability of success for each trial p equal to 0.03.

```
y2 = geocdf(2,p)  % cdf for x = 2
y3 = geocdf(3,p)  % cdf for x = 3
```

```
y2 =

    0.0873

y3 =

    0.1147
```

The returned results indicate an 8.7% chance of the car not starting if we try two days in a row, and an 11.5% chance of not starting if we try three days in a row.

geomean

Geometric mean

Syntax

```
m = geomean(x)
geomean(X,dim)
```

Description

`m = geomean(x)` calculates the geometric mean of a sample. For vectors, `geomean(x)` is the geometric mean of the elements in `x`. For matrices, `geomean(X)` is a row vector containing the geometric means of each column. For N-dimensional arrays, `geomean` operates along the first nonsingleton dimension of `X`.

`geomean(X,dim)` takes the geometric mean along the dimension `dim` of `X`.

The geometric mean is

$$m = \left[\prod_{i=1}^{n} x_i \right]^{\frac{1}{n}}$$

Examples

The arithmetic mean is greater than or equal to the geometric mean.

```
x = exprnd(1,10,6);

geometric = geomean(x)
geometric =
  0.7466  0.6061  0.6038  0.2569  0.7539  0.3478

average = mean(x)
average =
```

```
  1.3509   1.1583   0.9741   0.5319   1.0088   0.8122
```

- "Geometric Distribution" on page B-65

See Also

`mean` | `median` | `harmmean` | `trimmean`

geopdf

Geometric probability density function

Syntax

```
y = geopdf(x,p)
```

Description

`y = geopdf(x,p)` returns the probability density function (pdf) of the geometric distribution at each value in `x` using the corresponding probabilities in `p`. `x` and `p` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other input. The parameters in `p` must lie on the interval `[0,1]`.

Examples

Compute Geometric Distribution pdf

Suppose you toss a fair coin repeatedly, and a "success" occurs when the coin lands with heads facing up. What is the probability of observing exactly three tails ("failures") before tossing a heads?

To solve, determine the value of the probability density function (pdf) for the geometric distributon at x equal to 3. The probability of success (tossing a heads) p in any given trial is 0.5.

```
x = 3;
p = 0.5;
y = geopdf(x,p)
```

```
y =

    0.0625
```

The returned value of y indicates that the probability of observing exactly three tails before tossing a heads is 0.0625.

More About

Geometric Distribution pdf

The probability distribution function (pdf) of the geometric distribution is

$$y = f(x \mid p) = p(1-p)^x \quad ; \quad x = 0,1,2,\ldots,$$

where p is the probability of success, and x is the number of failures before the first success. The result y is the probability of observing exactly x trials before a success, when the probability of success in any given trial is p. For discrete distributions, the probability distribution function is also known as the probability mass function (pmf).

geornd

Geometric random numbers

Syntax

```
r = geornd(p)
r = geornd(p,m,n,...)
r = geornd(p,[m,n,...])
```

Description

`r = geornd(p)` generates random numbers from a geometric distribution with probability parameter `p`. `p` can be a vector, a matrix, or a multidimensional array. The size of `r` is equal to the size of `p`. The parameters in `p` must lie in the interval `[0,1]`.

`r = geornd(p,m,n,...)` or `r = geornd(p,[m,n,...])` generates a multidimensional `m`-by-`n`-by-`...` array containing random numbers from the geometric distribution with probability parameter `p`. `p` can be a scalar or an array of the same size as `r`.

The geometric distribution is useful to model the number of failures before one success in a series of independent trials, where each trial results in either success or failure, and the probability of success in any individual trial is the constant `p`.

Examples

Generate Random Numbers from Geometric Distribution

Generate a single random number from a geometric distribution with probability parameter p equal to 0.01.

```
rng default  % For reproducibility
p = 0.01;
r1 = geornd(0.01)
```

```
r1 =

    20
```

The returned random number represents a single experiment in which 20 failures were observed before a success, where each independent trial has a probability of success p equal to 0.01.

Generate a 1-by-5 array of random numbers from a geometric distribution with probability parameter p equal to 0.01.

```
r2 = geornd(p,1,5)
```

```
r2 =

     9   205     9    45   231
```

Each random number in the returned array represents the result of an experiment to determine the number of failures observed before a success, where each independent trial has a probability of success p equal to 0.01.

Generate a 1-by-3 array containing one random number from each of the three geometric distributions corresponding to the parameters in the 1-by-3 array of probabilities p.

```
p = [0.01 0.1 0.5];
r3 = geornd(p,[1 3])
```

```
r3 =

   127     5     0
```

Each element of the returned 1-by-3 array `r3` contains one random number generated from the geometric distribution described by the corresponding parameter in `P`. For example, the first element in `r3` represents an experiment in which 127 failures were observed before a success, where each independent trial has a probability of success p equal to 0.01. The second element in `r3` represents an experiment in which 5 failures were observed before a success, where each independent trial has a probability of success p equal to 0.1. The third element in `r3` represents an experiment in which zero failures

were observed before a success - in other words, the first attempt was a success - where each independent trial has a probability of success p equal to 0.5.

`geopdf` | `geocdf` | `geoinv` | `geostat` | `random`

geostat

Geometric mean and variance

Syntax

```
[m,v] = geostat(p)
```

Description

`[m,v] = geostat(p)` returns the mean `m` and variance `v` of a geometric distribution with corresponding probability parameters in `p`. `p` can be a vector, a matrix, or a multidimensional array. The parameters in `p` must lie in the interval `[0,1]`.

Examples

Compute Mean and Variance of Geometric Distribution

Define a probability vector that contains six different parameter values.

```
p = 1./(1:6)
```

```
p =

    1.0000    0.5000    0.3333    0.2500    0.2000    0.1667
```

Compute the mean and variance of the geometric distribution that corresponds to each value contained in probability vector.

```
[m,v] = geostat(1./(1:6))
```

```
m =

         0    1.0000    2.0000    3.0000    4.0000    5.0000
```

```
v =

         0    2.0000    6.0000   12.0000   20.0000   30.0000
```

The returned values indicate that, for example, the mean of a geometric distribution with probability parameter p equal to 1/3 is 2, and its variance is 6.

More About

Geometric Distribution Mean and Variance

The mean of the geometric distribution is

$$\text{mean} = \frac{1-p}{p},$$

and the variance of the geometric distribution is

$$\text{var} = \frac{1-p}{p^2},$$

where p is the probability of success.

clustering.evaluation.GapEvaluation class

Package: clustering.evaluation
Superclasses: clustering.evaluation.ClusterCriterion

Gap criterion clustering evaluation object

Description

`clustering.evaluation.GapEvaluation` is an object consisting of sample data, clustering data, and gap criterion values used to evaluate the optimal number of clusters. Create a gap criterion clustering evaluation object using `evalclusters`.

Construction

`eva = evalclusters(x,clust,'Gap')` creates a gap criterion clustering evaluation object.

`eva = evalclusters(x,clust,'Gap',Name,Value)` creates a gap criterion clustering evaluation object using additional options specified by one or more name-value pair arguments.

Input Arguments

x — Input data

matrix

Input data, specified as an *N*-by-*P* matrix. *N* is the number of observations, and *P* is the number of variables.

Data Types: `single` | `double`

clust — Clustering algorithm

`'kmeans'` | `'linkage'` | `'gmdistribution'` | matrix of clustering solutions | function handle

Clustering algorithm, specified as one of the following.

`'kmeans'`	Cluster the data in x using the `kmeans` clustering algorithm, with `'EmptyAction'` set to `'singleton'` and `'Replicates'` set to `5`.
`'linkage'`	Cluster the data in x using the `clusterdata` agglomerative clustering algorithm, with `'Linkage'` set to `'ward'`.
`'gmdistribution'`	Cluster the data in x using the `gmdistribution` Gaussian mixture distribution algorithm, with `'SharedCov'` set to `true` and `'Replicates'` set to `5`.

If `Criterion` is `'CalinskHarabasz'`, `'DaviesBouldin'`, or `'silhouette'`, you can specify a clustering algorithm using the `function_handle` (`@`) operator. The function must be of the form `C = clustfun(DATA,K)`, where `DATA` is the data to be clustered, and `K` is the number of clusters. The output of `clustfun` must be one of the following:

- A vector of integers representing the cluster index for each observation in `DATA`. There must be `K` unique values in this vector.
- A numeric n-by-K matrix of score for n observations and K classes. In this case, the cluster index for each observation is determined by taking the largest score value in each row.

If `Criterion` is `'CalinskHarabasz'`, `'DaviesBouldin'`, or `'silhouette'`, you can also specify `clust` as a n-by-K matrix containing the proposed clustering solutions. n is the number of observations in the sample data, and K is the number of proposed clustering solutions. Column j contains the cluster indices for each of the N points in the jth clustering solution.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'KList',[1:5],'Distance','cityblock'` specifies to test 1, 2, 3, 4, and 5 clusters using the sum of absolute differences distance measure.

`'B'` — Number of reference data sets

`100` (default) | positive integer value

Number of reference data sets generated from the reference distribution ReferenceDistribution, specified as the comma-separated pair consisting of `'B'` and a positive integer value.

Example: `'B',150`

`'Distance'` — Distance metric

`'sqEuclidean'` (default) | `'Euclidean'` | `'cityblock'` | function | ...

Distance metric used for computing the criterion values, specified as the comma-separated pair consisting of `'Distance'` and one of the following.

`'sqEuclidean'`	Squared Euclidean distance
`'Euclidean'`	Euclidean distance
`'cityblock'`	Sum of absolute differences
`'cosine'`	One minus the cosine of the included angle between points (treated as vectors)
`'correlation'`	One minus the sample correlation between points (treated as sequences of values)
`'Hamming'`	Percentage of coordinates that differ
`'Jaccard'`	Percentage of nonzero coordinates that differ

For detailed information about each distance metric, see `pdist`.

You can also specify a function for the distance metric by using the `function_handle` (`@`) operator. The distance function must be of the form

```
d2 = distfun(XI,XJ),
```

where `XI` is a 1-by-n vector corresponding to a single row of the input matrix `X`, and `XJ` is an m_2-by-n matrix corresponding to multiple rows of `X`. `distfun` must return an m_2-by-1 vector of distances `d2`, whose kth element is the distance between `XI` and `XJ(k,:)`.

If `Criterion` is `'silhouette'`, you can also specify `Distance` as the output vector output created by the function `pdist`.

When `Clust` a string representing a built-in clustering algorithm, `evalclusters` uses the distance metric specified for `Distance` to cluster the data, except for the following:

- If `Clust` is `'linkage'`, and `Distance` is either `'sqEuclidean'` or `'Euclidean'`, then the clustering algorithm uses Euclidean distance and Ward linkage.

- If `Clust` is `'linkage'` and `Distance` is any other metric, then the clustering algorithm uses the specified distance metric and average linkage.

In all other cases, the distance metric specified for Distance must match the distance metric used in the clustering algorithm to obtain meaningful results.

Example: `'Distance','Euclidean'`

`'KList'` — List of number of clusters to evaluate

vector

List of number of clusters to evaluate, specified as the comma-separated pair consisting of `'KList'` and a vector of positive integer values. You must specify `KList` when clust is a clustering algorithm name string or a function handle. When criterion is `'gap'`, clust must be a string or a function handle, and you must specify KList.

Example: `'KList',[1:6]`

`'ReferenceDistribution'` — Reference data generation method

`'PCA'` (default) | `'uniform'`

Reference data generation method, specified as the comma-separated pair consisting of `'ReferenceDistributions'` and one of the following.

`'PCA'`	Generate reference data from a uniform distribution over a box aligned with the principal components of the data matrix `x`.
`'uniform'`	Generate reference data uniformly over the range of each feature in the data matrix `x`.

Example: `'ReferenceDistribution','uniform'`

`'SearchMethod'` — Method for selecting optimal number of clusters

`'globalMaxSE'` (default) | `'firstMaxSE'`

Method for selecting the optimal number of clusters, specified as the comma-separated pair consisting of `'SearchMethod'` and one of the following.

`'globalMaxSE'`	Evaluate each proposed number of clusters in KList and select the smallest number of clusters satisfying $$\mathrm{Gap}(K) \geq GAPMAX - \mathrm{SE}(GAPMAX),$$

where K is the number of clusters, Gap(K) is the gap value for the clustering solution with K clusters, *GAPMAX* is the largest gap value, and SE(*GAPMAX*) is the standard error corresponding to the largest gap value.

`'firstMaxSE'` Evaluate each proposed number of clusters in KList and select the smallest number of clusters satisfying

$$\mathrm{Gap}(K) \geq \mathrm{Gap}(K+1) - \mathrm{SE}(K+1),$$

where K is the number of clusters, Gap(K) is the gap value for the clustering solution with K clusters, and SE(K + 1) is the standard error of the clustering solution with K + 1 clusters.

Example: `'SearchMethod','globalMaxSE'`

Properties

B

Number of data sets generated from the reference distribution, stored as a positive integer value.

ClusteringFunction

Clustering algorithm used to cluster the input data, stored as a valid clustering algorithm name string or function handle. If the clustering solutions are provided in the input, `ClusteringFunction` is empty.

CriterionName

Name of the criterion used for clustering evaluation, stored as a valid criterion name string.

CriterionValues

Criterion values corresponding to each proposed number of clusters in `InspectedK`, stored as a vector of numerical values.

`Distance`

Distance measure used for clustering data, stored as a valid distance measure name string.

`ExpectedLogW`

Expectation of the natural logarithm of *W* based on the generated reference data, stored as a vector of scalar values. *W* is the within-cluster dispersion computed using the distance measurement `Distance`.

`InspectedK`

List of the number of proposed clusters for which to compute criterion values, stored as a vector of positive integer values.

`LogW`

Natural logarithm of *W* based on the input data, stored as a vector of scalar values. *W* is the within-cluster dispersion computed using the distance measurement `Distance`.

`Missing`

Logical flag for excluded data, stored as a column vector of logical values. If `Missing` equals `true`, then the corresponding value in the data matrix `x` is not used in the clustering solution.

`NumObservations`

Number of observations in the data matrix `X`, minus the number of missing (`NaN`) values in `X`, stored as a positive integer value.

`OptimalK`

Optimal number of clusters, stored as a positive integer value.

`OptimalY`

Optimal clustering solution corresponding to `OptimalK`, stored as a column vector of positive integer values. If the clustering solutions are provided in the input, `OptimalY` is empty.

`ReferenceDistribution`

Reference data generation method, stored as a valid reference distribution name string.

`SE`

Standard error of the natural logarithm of *W* with respect to the reference data for each number of clusters in `InspectedK`, stored as a vector of scalar values. *W* is the within-cluster dispersion computed using the distance measurement `Distance`.

`SearchMethod`

Method for determining the optimal number of clusters, stored as a valid search method name string.

`StdLogW`

Standard deviation of the natural logarithm of *W* with respect to the reference data for each number of clusters in `InspectedK`. *W* is the within-cluster dispersion computed using the distance measurement `Distance`.

`X`

Data used for clustering, stored as a matrix of numerical values.

Methods

increaseB	Increase reference data sets

Inherited Methods

addK	Evaluate additional numbers of clusters
plot	Plot clustering evaluation object criterion values

compact

Compact clustering evaluation object

Definitions

Gap Value

A common graphical approach to cluster evaluation involves plotting an error measurement versus several proposed numbers of clusters, and locating the “elbow” of this plot. The “elbow” occurs at the most dramatic decrease in error measurement. The gap criterion formalizes this approach by estimating the “elbow” location as the number of clusters with the largest gap value. Therefore, under the gap criterion, the optimal number of clusters occurs at the solution with the largest local or global gap value within a tolerance range.

The gap value is defined as

$$Gap_n(k) = E_n^*\{\log(W_k)\} - \log(W_k),$$

where n is the sample size, k is the number of clusters being evaluated, and W_k is the pooled within-cluster dispersion measurement

$$W_k = \sum_{r=1}^{k} \frac{1}{2n_r} D_r,$$

where n_r is the number of data points in cluster r, and D_r is the sum of the pairwise distances for all points in cluster r.

The expected value $E_n^*\{\log(W_k)\}$ is determined by Monte Carlo sampling from a reference distribution, and `log(`W_k`)` is computed from the sample data.

The gap value is defined even for clustering solutions that contain only one cluster, and can be used with any distance metric. However, the gap criterion is more computationally

expensive than other cluster evaluation criteria, because the clustering algorithm must be applied to the reference data for each proposed clustering solution.

Examples

Evaluate the Clustering Solution Using Gap Criterion

Evaluate the optimal number of clusters using the gap clustering evaluation criterion.

Load the sample data.

```
load fisheriris;
```

The data contains sepal and petal measurements from three species of iris flowers.

Evaluate the number of clusters based on the gap criterion values. Cluster the data using `kmeans`.

```
rng('default');  % For reproducibility
eva = evalclusters(meas,'kmeans','gap','KList',[1:6])
```

```
eva =

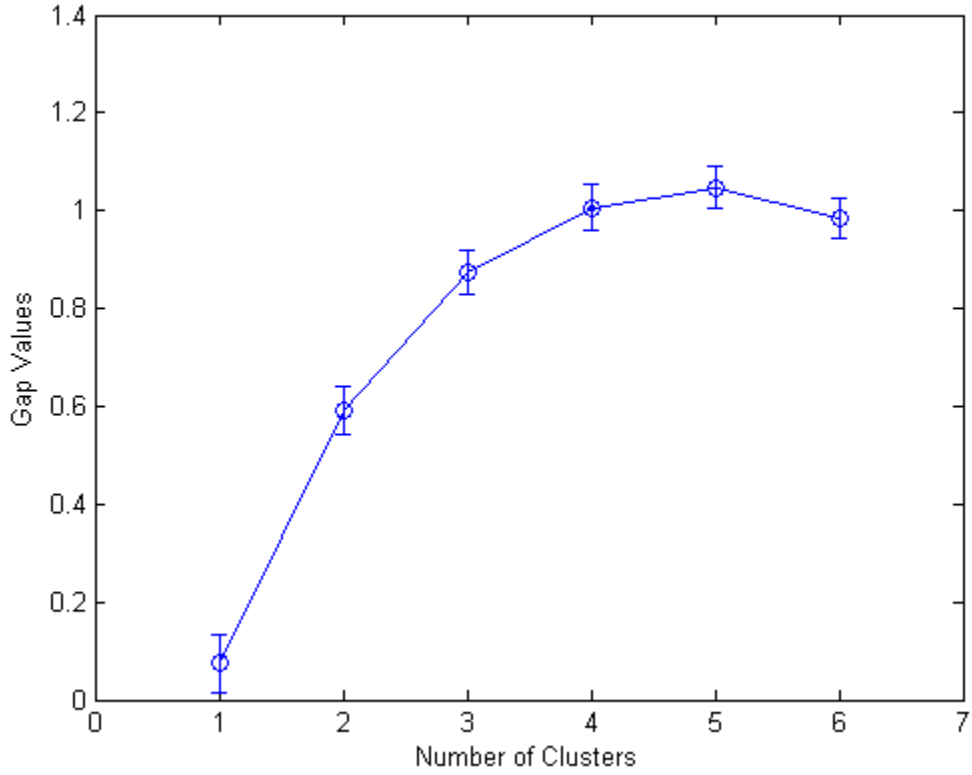
  GapEvaluation with properties:

    NumObservations: 150
       InspectecedK: [1 2 3 4 5 6]
    CriterionValues: [1x6 double]
           OptimalK: 4
```

The `OptimalK` value indicates that, based on the gap criterion, the optimal number of clusters is four.

Plot the gap criterion values for each number of clusters tested.

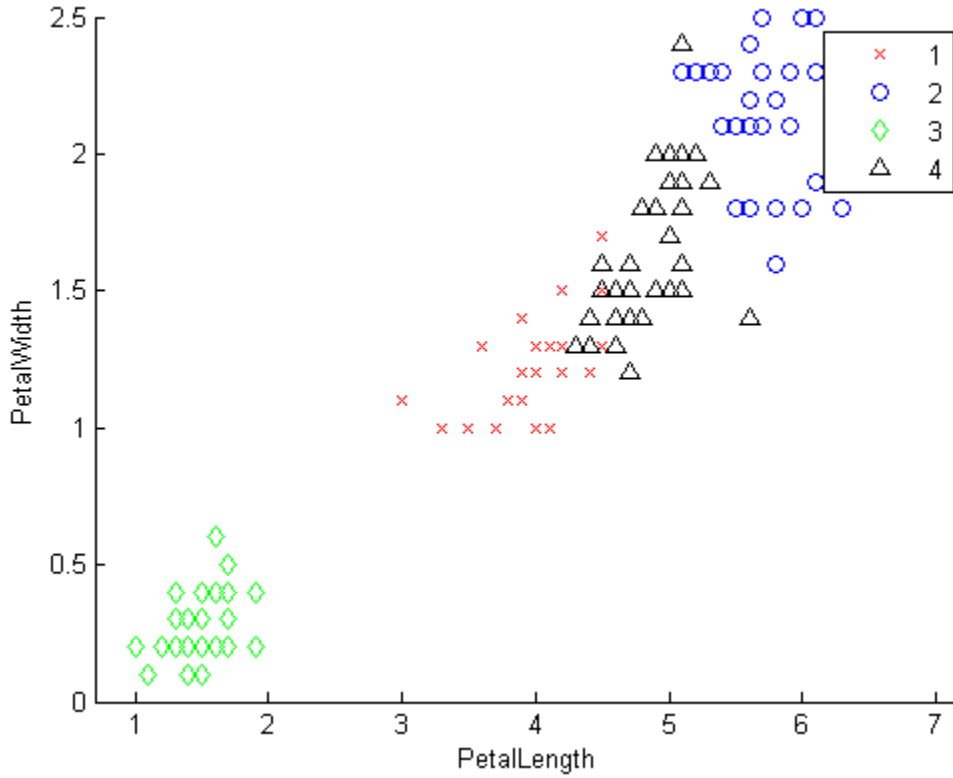
```
figure;
plot(eva);
```



Based on the plot, the maximum value of the gap criterion occurs at five clusters. However, the value at four clusters is within one standard error of the maximum, so the suggested optimal number of clusters is four.

Create a grouped scatter plot to examine the relationship between petal length and width. Group the data by suggested clusters.

```
figure;
PetalLength = meas(:,3);
PetalWidth = meas(:,4);
ClusterGroup = eva.OptimalY;
figure;
gscatter(PetalLength,PetalWidth,ClusterGroup,'rbgk','xod^');
```



The plot shows cluster 1 in the lower-left corner, completely separated from the other three clusters. Cluster 1 contains flowers with the smallest petal widths and lengths. Cluster 4 is in the upper-right corner, and contains flowers with the largest petal widths and lengths. Clusters 2 and 3 are near the center of the plot, and contain flowers with measurements between the two extremes.

get

Class: dataset

Access dataset array properties

Compatibility

The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

Syntax

```
get(A)
s = get(A)
p = get(A,PropertyName)
p = get(A,{PropertyName1,PropertyName2,...})
```

Description

`get(A)` displays a list of property/value pairs for the dataset array `A`.

`s = get(A)` returns the values in a scalar structure `s` with field names given by the properties.

`p = get(A,PropertyName)` returns the value of the property specified by the string *`PropertyName`*.

`p = get(A,{PropertyName1,PropertyName2,...})` allows multiple property names to be specified and returns their values in a cell array.

Examples

Create a dataset array from Fisher's iris data and access the information.

```
load fisheriris
NumObs = size(meas,1);
NameObs = strcat({'Obs'},num2str((1:NumObs)','%-d'));
iris = dataset({nominal(species),'species'},...
               {meas,'SL','SW','PL','PW'},...
               'ObsNames',NameObs);

get(iris)
   Description: ''
   Units: {}
   DimNames: {'Observations' 'Variables'}
   UserData: []
   ObsNames: {150x1 cell}
   VarNames: {'species' 'SL' 'SW' 'PL' 'PW'}

ON = get(iris,'ObsNames');
ON(1:3)
ans =
    'Obs1'
    'Obs2'
    'Obs3'
```

set | summary

getlabels

Access categorical array labels

Compatibility

The `nominal` and `ordinal` array data types might be removed in a future release. To represent ordered and unordered discrete, nonnumeric data, use the MATLAB `categorical` data type instead.

Syntax

```
labels = getlabels(A)
```

Description

`labels = getlabels(A)` returns the labels of the levels in the nominal or ordinal array A as a cell array of strings, labels. If A is an ordinal array, `getlabels` returns the labels in the order of the levels.

Examples

- “Change Category Labels” on page 2-9

Input Arguments

A — Nominal or ordinal array

`nominal` array | `ordinal` array

Nominal or ordinal array, specified as a `nominal` or `ordinal` array object created using `nominal` or `ordinal`.

More About

- Using nominal Objects

- Using ordinal Objects

See Also

`getlevels` | `nominal` | `ordinal`

getlevels

Access categorical array levels

Compatibility

The `nominal` and `ordinal` array data types might be removed in a future release. To represent ordered and unordered discrete, nonnumeric data, use the MATLAB `categorical` data type instead.

Syntax

```
L = getlevels(A)
```

Description

`L = getlevels(A)` returns the levels in the nominal or ordinal array A in L, a vector with the same type as A.

Examples

- “Add and Drop Category Levels” on page 2-21
- “Merge Category Levels” on page 2-19
- “Reorder Category Levels” on page 2-11

Input Arguments

A — Nominal or ordinal array

`nominal` array | `ordinal` array

Nominal or ordinal array, specified as a `nominal` or `ordinal` array object created using `nominal` or `ordinal`.

More About

- Using nominal Objects
- Using ordinal Objects

gevcdf

Generalized extreme value cumulative distribution function

Syntax

```
p = gevcdf(x,k,sigma,mu)
p = gevcdf(x,k,sigma,mu,'upper')
```

Description

`p = gevcdf(x,k,sigma,mu)` returns the cdf of the generalized extreme value (GEV) distribution with shape parameter `k`, scale parameter `sigma`, and location parameter, `mu`, evaluated at the values in `x`. The size of `p` is the common size of the input arguments. A scalar input functions as a constant matrix of the same size as the other inputs.

`p = gevcdf(x,k,sigma,mu,'upper')` returns the complement of the cdf of the GEV distribution, using an algorithm that more accurately computes the extreme upper tail probabilities.

Default values for `k`, `sigma`, and `mu` are 0, 1, and 0, respectively.

When `k < 0`, the GEV is the type III extreme value distribution. When `k > 0`, the GEV distribution is the type II, or Frechet, extreme value distribution. If `w` has a Weibull distribution as computed by the `wblcdf` function, then `-w` has a type III extreme value distribution and `1/w` has a type II extreme value distribution. In the limit as `k` approaches 0, the GEV is the mirror image of the type I extreme value distribution as computed by the `evcdf` function.

The mean of the GEV distribution is not finite when $k \geq 1$, and the variance is not finite when $k \geq 1/2$. The GEV distribution has positive density only for values of `X` such that `k*(X-mu)/sigma > -1`.

`cdf` | `gevpdf` | `gevinv` | `gevstat` | `gevfit` | `gevlike` | `gevrnd`

gevfit

Generalized extreme value parameter estimates

Syntax

```
parmhat = gevfit(X)
[parmhat,parmci] = gevfit(X)
[parmhat,parmci] = gevfit(X,alpha)
[...] = gevfit(X,alpha,options)
```

Description

`parmhat = gevfit(X)` returns maximum likelihood estimates of the parameters for the generalized extreme value (GEV) distribution given the data in X. `parmhat(1)` is the shape parameter, `k`, `parmhat(2)` is the scale parameter, `sigma`, and `parmhat(3)` is the location parameter, `mu`.

`[parmhat,parmci] = gevfit(X)` returns 95% confidence intervals for the parameter estimates.

`[parmhat,parmci] = gevfit(X,alpha)` returns `100(1-alpha)`% confidence intervals for the parameter estimates.

`[...] = gevfit(X,alpha,options)` specifies control parameters for the iterative algorithm used to compute ML estimates. This argument can be created by a call to `statset`. See `statset('gevfit')` for parameter names and default values. Pass in `[]` for `alpha` to use the default values.

When `k < 0`, the GEV is the type III extreme value distribution. When `k > 0`, the GEV distribution is the type II, or Frechet, extreme value distribution. If `w` has a Weibull distribution as computed by the `wblfit` function, then `-w` has a type III extreme value distribution and `1/w` has a type II extreme value distribution. In the limit as `k` approaches 0, the GEV is the mirror image of the type I extreme value distribution as computed by the `evfit` function.

The mean of the GEV distribution is not finite when $k \geq 1$, and the variance is not finite when $k \geq 1/2$. The GEV distribution is defined for `k*(X-mu)/sigma > -1`.

gevinv

Generalized extreme value inverse cumulative distribution function

Syntax

```
X = gevinv(P,k,sigma,mu)
```

Description

`X = gevinv(P,k,sigma,mu)` returns the inverse cdf of the generalized extreme value (GEV) distribution with shape parameter `k`, scale parameter `sigma`, and location parameter `mu`, evaluated at the values in `P`. The size of `X` is the common size of the input arguments. A scalar input functions as a constant matrix of the same size as the other inputs.

Default values for `k`, `sigma`, and `mu` are 0, 1, and 0, respectively.

When `k < 0`, the GEV is the type III extreme value distribution. When `k > 0`, the GEV distribution is the type II, or Frechet, extreme value distribution. If `w` has a Weibull distribution as computed by the `wblinv` function, then `-w` has a type III extreme value distribution and `1/w` has a type II extreme value distribution. In the limit as `k` approaches 0, the GEV is the mirror image of the type I extreme value distribution as computed by the `evinv` function.

The mean of the GEV distribution is not finite when $k \geq 1$, and the variance is not finite when $k \geq 1/2$. The GEV distribution has positive density only for values of `X` such that `k*(X-mu)/sigma > -1`.

gevlike

Generalized extreme value negative log-likelihood

Syntax

```
nlogL = gevlike(params,data)
[nlogL,ACOV] = gevlike(params,data)
```

Description

`nlogL = gevlike(params,data)` returns the negative of the log-likelihood `nlogL` for the generalized extreme value (GEV) distribution, evaluated at parameters `params`. `params(1)` is the shape parameter, `k`, `params(2)` is the scale parameter, `sigma`, and `params(3)` is the location parameter, `mu`.

`[nlogL,ACOV] = gevlike(params,data)` returns the inverse of Fisher's information matrix, `ACOV`. If the input parameter values in `params` are the maximum likelihood estimates, the diagonal elements of `ACOV` are their asymptotic variances. `ACOV` is based on the observed Fisher's information, not the expected information.

When `k < 0`, the GEV is the type III extreme value distribution. When `k > 0`, the GEV distribution is the type II, or Frechet, extreme value distribution. If `w` has a Weibull distribution as computed by the `wbllike` function, then `-w` has a type III extreme value distribution and `1/w` has a type II extreme value distribution. In the limit as `k` approaches 0, the GEV is the mirror image of the type I extreme value distribution as computed by the `evlike` function.

The mean of the GEV distribution is not finite when $k \geq 1$, and the variance is not finite when $k \geq 1/2$. The GEV distribution has positive density only for values of `X` such that `k*(X-mu)/sigma > -1`.

gevpdf

Generalized extreme value probability density function

Syntax

```
Y = gevpdf(X,k,sigma,mu)
```

Description

`Y = gevpdf(X,k,sigma,mu)` returns the pdf of the generalized extreme value (GEV) distribution with shape parameter `k`, scale parameter `sigma`, and location parameter, `mu`, evaluated at the values in `X`. The size of `Y` is the common size of the input arguments. A scalar input functions as a constant matrix of the same size as the other inputs.

Default values for `k`, `sigma`, and `mu` are 0, 1, and 0, respectively.

When `k < 0`, the GEV is the type III extreme value distribution. When `k > 0`, the GEV distribution is the type II, or Frechet, extreme value distribution. If `w` has a Weibull distribution as computed by the `wblpdf` function, then `-w` has a type III extreme value distribution and `1/w` has a type II extreme value distribution. In the limit as `k` approaches 0, the GEV is the mirror image of the type I extreme value distribution as computed by the `evcdf` function.

The mean of the GEV distribution is not finite when $k \geq 1$, and the variance is not finite when $k \geq 1/2$. The GEV distribution has positive density only for values of `X` such that `k*(X-mu)/sigma > -1`.

gevrnd

Generalized extreme value random numbers

Syntax

```
R = gevrnd(k,sigma,mu)
R = gevrnd(k,sigma,mu,m,n,...)
R = gevrnd(k,sigma,mu,[m,n,...])
```

Description

`R = gevrnd(k,sigma,mu)` returns an array of random numbers chosen from the generalized extreme value (GEV) distribution with shape parameter `k`, scale parameter `sigma`, and location parameter, `mu`. The size of `R` is the common size of the input arguments if all are arrays. If any parameter is a scalar, the size of `R` is the size of the other parameters.

`R = gevrnd(k,sigma,mu,m,n,...)` or `R = gevrnd(k,sigma,mu,[m,n,...])` generates an `m`-by-`n`-by-... array containing random numbers from the GEV distribution with parameters `k`, `sigma`, and `mu`. The `k`, `sigma`, `mu` parameters can each be scalars or arrays of the same size as `R`.

When `k < 0`, the GEV is the type III extreme value distribution. When `k > 0`, the GEV distribution is the type II, or Frechet, extreme value distribution. If `w` has a Weibull distribution as computed by the `wblrnd` function, then `-w` has a type III extreme value distribution and `1/w` has a type II extreme value distribution. In the limit as `k` approaches 0, the GEV is the mirror image of the type I extreme value distribution as computed by the `evrnd` function.

The mean of the GEV distribution is not finite when $k \geq 1$, and the variance is not finite when $k \geq 1/2$. The GEV distribution has positive density only for values of `X` such that `k*(X-mu)/sigma > -1`.

gevstat

Generalized extreme value mean and variance

Syntax

```
[M,V] = gevstat(k,sigma,mu)
```

Description

`[M,V] = gevstat(k,sigma,mu)` returns the mean of and variance for the generalized extreme value (GEV) distribution with shape parameter `k`, scale parameter `sigma`, and location parameter, `mu`. The sizes of `M` and `V` are the common size of the input arguments. A scalar input functions as a constant matrix of the same size as the other inputs.

Default values for `k`, `sigma`, and `mu` are 0, 1, and 0, respectively.

When `k < 0`, the GEV is the type III extreme value distribution. When `k > 0`, the GEV distribution is the type II, or Frechet, extreme value distribution. If `w` has a Weibull distribution as computed by the `wblstat` function, then `-w` has a type III extreme value distribution and `1/w` has a type II extreme value distribution. In the limit as `k` approaches 0, the GEV is the mirror image of the type I extreme value distribution as computed by the `evstat` function.

The mean of the GEV distribution is not finite when $k \geq 1$, and the variance is not finite when $k \geq 1/2$. The GEV distribution has positive density only for values of `X` such that `k*(X-mu)/sigma > -1`.

gline

Interactively add line to plot

Syntax

```
gline(h)
gline
hline = gline(...)
```

Description

`gline(h)` allows you to draw a line segment in the figure with handle `h` by clicking the pointer at the two endpoints. A rubber-band line tracks the pointer movement.

`gline` with no input arguments defaults to `h = gcf` and draws in the current figure.

`hline = gline(...)` returns the handle `hline` to the line.

Examples

Use `gline` to connect two points in a plot:

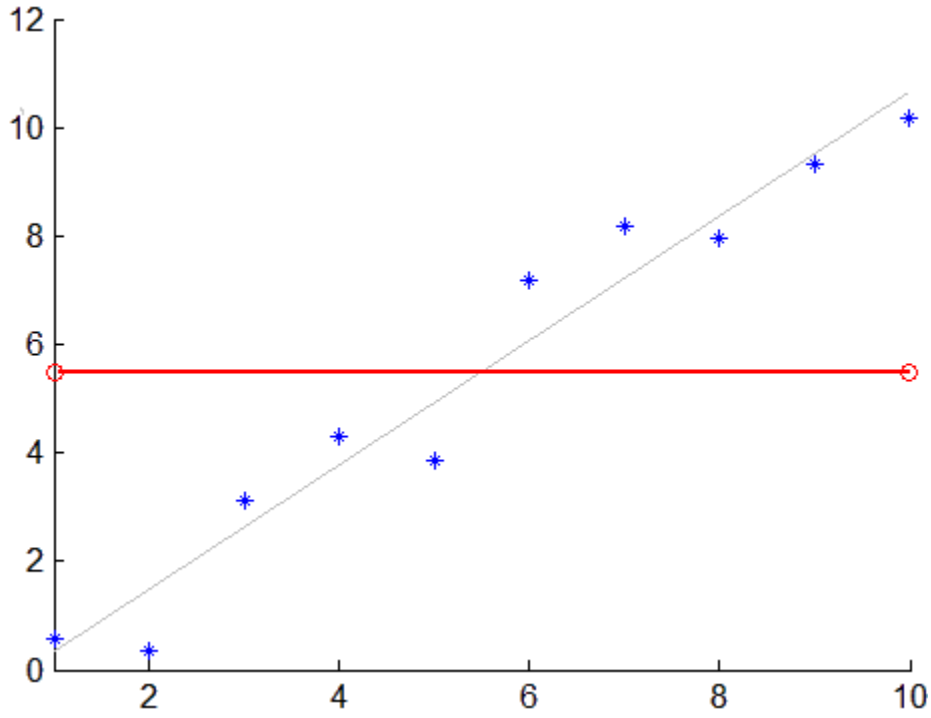
```
x = 1:10;

y = x + randn(1,10);
scatter(x,y,25,'b','*')

lsline

mu = mean(y);
hold on
plot([1 10],[mu mu],'ro')

hline = gline; % Connect circles
set(hline,'Color','r')
```



See Also

`refline` | `refcurve` | `lsline`

glmfit

Generalized linear model regression

Syntax

```
b = glmfit(X,y,distr)
b = glmfit(X,y,distr,param1,val1,param2,val2,...)
[b,dev] = glmfit(...)
[b,dev,stats] = glmfit(...)
```

Description

`b = glmfit(X,y,distr)` returns a (p + 1)-by-1 vector `b` of coefficient estimates for a generalized linear regression of the responses in `y` on the predictors in `X`, using the distribution `distr`. `X` is an n-by-p matrix of p predictors at each of n observations. `distr` can be any of the following strings: `'binomial'`, `'gamma'`, `'inverse gaussian'`, `'normal'` (the default), and `'poisson'`.

In most cases, `y` is an n-by-1 vector of observed responses. For the binomial distribution, `y` can be a binary vector indicating success or failure at each observation, or a two column matrix with the first column indicating the number of successes for each observation and the second column indicating the number of trials for each observation.

This syntax uses the canonical link (see below) to relate the distribution to the predictors.

Note: By default, `glmfit` adds a first column of 1s to `X`, corresponding to a constant term in the model. Do not enter a column of 1s directly into `X`. You can change the default behavior of `glmfit` using the `'constant'` parameter, below.

`glmfit` treats `NaN`s in either `X` or `y` as missing values, and ignores them.

`b = glmfit(X,y,distr,param1,val1,param2,val2,...)` additionally allows you to specify optional parameter name/value pairs to control the model fit. Acceptable parameters are as follows.

Parameter	Value	Description
`'link'`	`'identity'`, default for the distribution `'normal'`	$\mu = Xb$
	`'log'`, default for the distribution `'poisson'`	$\log(\mu) = Xb$
	`'logit'`, default for the distribution `'binomial'`	$\log(\mu/(1-\mu)) = Xb$
	`'probit'`	$\text{norminv}(\mu) = Xb$
	`'comploglog'`	$\log(-\log(1-\mu)) = Xb$
	`'reciprocal'`, default for the distribution `'gamma'`	$1/\mu = Xb$
	`'loglog'`	$\log(-\log(\mu)) = Xb$
	`p` (a number), default for the distribution `'inverse gaussian'` (with $p = -2$)	$\mu^p = Xb$
	cell array of the form `{FL FD FI}`, containing three function handles, created using `@`, that define the link (`FL`), the derivative of the link (`FD`), and the inverse link (`FI`).	Custom-defined link function. You must provide • `FL(mu)` • `FD = dFL(mu)/dmu` • `FI = FL^(-1)`
`'estdisp'`	`'on'`	Estimates a dispersion parameter for the binomial or Poisson distribution.
	`'off'` (Default for binomial or Poisson distribution)	Uses the theoretical value of 1.0 for those distributions.
`'offset'`	Vector	Used as an additional predictor variable, but with a coefficient value fixed at 1.0.
`'weights'`	Vector of prior weights, such as the inverses of the relative variance of each observation	

Parameter	Value	Description
`'constant'`	`'on'` (default)	Includes a constant term in the model. The coefficient of the constant term is the first element of `b`.
	`'off'`	Omit the constant term.

`[b,dev] = glmfit(...)` returns `dev`, the deviance of the fit at the solution vector. The deviance is a generalization of the residual sum of squares. It is possible to perform an analysis of deviance to compare several models, each a subset of the other, and to test whether the model with more terms is significantly better than the model with fewer terms.

`[b,dev,stats] = glmfit(...)` returns `dev` and `stats`.

`stats` is a structure with the following fields:

- `beta` — Coefficient estimates `b`
- `dfe` — Degrees of freedom for error
- `sfit` — Estimated dispersion parameter
- `s` — Theoretical or estimated dispersion parameter
- `estdisp` — 0 when the `'estdisp'` name-value pair argument value is `'off'` and 1 when the `'estdisp'` name-value pair argument value is `'on'`.
- `covb` — Estimated covariance matrix for B
- `se` — Vector of standard errors of the coefficient estimates `b`
- `coeffcorr` — Correlation matrix for `b`
- `t` — *t* statistics for `b`
- `p` — *p*-values for `b`
- `resid` — Vector of residuals
- `residp` — Vector of Pearson residuals
- `residd` — Vector of deviance residuals
- `resida` — Vector of Anscombe residuals

If you estimate a dispersion parameter for the binomial or Poisson distribution, then `stats.s` is set equal to `stats.sfit`. Also, the elements of `stats.se` differ by the factor `stats.s` from their theoretical values.

Examples

Fit Generalized Linear Model with Probit Link

Enter sample data.

```
x = [2100 2300 2500 2700 2900 3100 ...
     3300 3500 3700 3900 4100 4300]';
n = [48 42 31 34 31 21 23 23 21 16 17 21]';
y = [1 2 0 3 8 8 14 17 19 15 17 21]';
```

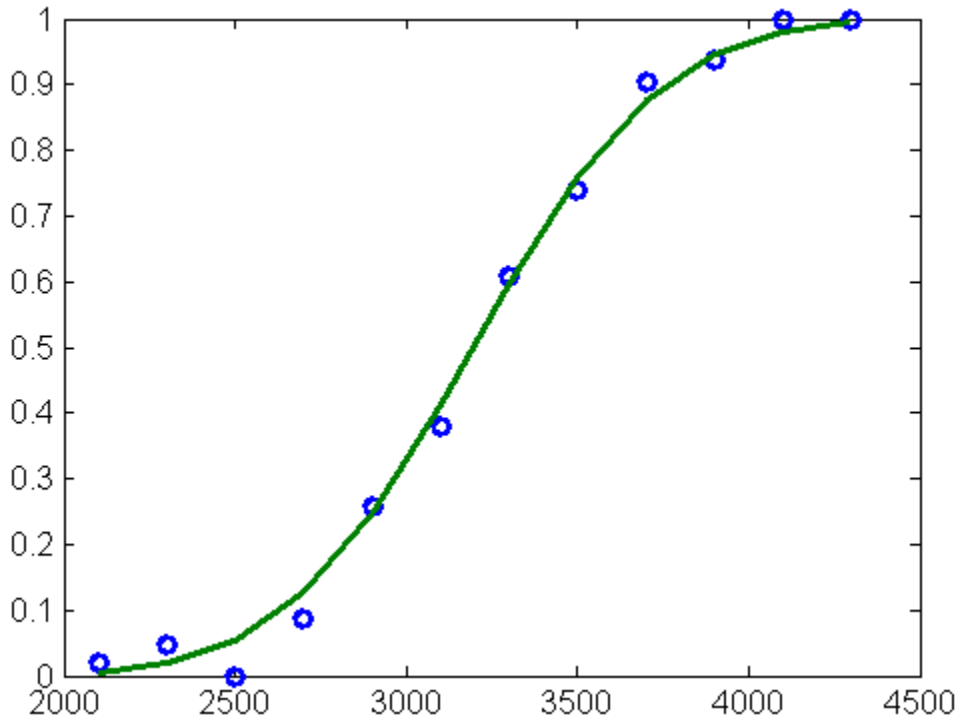
Each `y` value is the number of successes in corresponding number of trials in`n`, and `x` contains the predictor variable values.

Fit a probit regression model for `y` on `x`.

```
b = glmfit(x,[y n],'binomial','link','probit');
```

Compute the estimated number of successes and plot the percent observed and estimated percent success versus the `x` values.

```
yfit = glmval(b,x,'probit','size',n);
plot(x, y./n,'o',x,yfit./n,'-','LineWidth',2)
```



Use Custom-defined Link Function

Load the sample data.

```
load fisheriris
```

The column vector, `species`, consists of iris flowers of three different species, setosa, versicolor, virginica. The double matrix `meas` consists of four types of measurements on the flowers, the length and width of sepals and petals in centimeters, respectively.

Define the response and predictor variables.

```
X = meas(51:end,:);
y = strcmp('versicolor',species(51:end));
```

Define three function handles, created using `@`, that define the link, the derivative of the link, and the inverse link for a logit link function, and store them in a cell array.

```
link = @(mu) log(mu ./ (1-mu));
```

```
derlink = @(mu) 1 ./ (mu .* (1-mu));
invlink = @(resp) 1 ./ (1 + exp(-resp));
F = {link, derlink, invlink};
```

Fit a logistic regression using `glmfit` with the link function you defined.

```
b = glmfit(X,y,'binomial','link',F)
```

```
b =

   42.6378
    2.4652
    6.6809
   -9.4294
  -18.2861
```

Now, fit a generalized linear model using the `logit` link function and compare the results.

```
b = glmfit(X,y,'binomial','link','logit')
```

```
b =

   42.6378
    2.4652
    6.6809
   -9.4294
  -18.2861
```

glmval

Generalized linear model values

Syntax

```
yhat = glmval(b,X,link)
[yhat,dylo,dyhi] = glmval(b,X,link,stats)
[...] = glmval(...,param1,val1,param2,val2,...)
```

Description

`yhat = glmval(b,X,link)` computes predicted values for the generalized linear model with link function `link` and predictors `X`. Distinct predictor variables should appear in different columns of `X`. `b` is a vector of coefficient estimates as returned by the `glmfit` function. `link` can be any of the strings or the custom-defined link functions used as values for the `'link'` name-value pair argument in the `glmfit` function.

Note: By default, `glmval` adds a first column of 1s to `X`, corresponding to a constant term in the model. Do not enter a column of 1s directly into `X`. You can change the default behavior of `glmval` using the `'constant'` parameter, below.

`[yhat,dylo,dyhi] = glmval(b,X,link,stats)` also computes 95% confidence bounds for the predicted values. When the `stats` structure output of the `glmfit` function is specified, `dylo` and `dyhi` are also returned. `dylo` and `dyhi` define a lower confidence bound of `yhat-dylo`, and an upper confidence bound of `yhat+dyhi`. Confidence bounds are nonsimultaneous, and apply to the fitted curve, not to a new observation.

`[...] = glmval(...,param1,val1,param2,val2,...)` specifies optional parameter name/value pairs to control the predicted values. Acceptable parameters are:

Parameter	Value
`'confidence'` — the confidence level for the confidence bounds	A scalar between 0 and 1

Parameter	Value
`'size'` — the size parameter (N) for a binomial model	A scalar, or a vector with one value for each row of X
`'offset'` — used as an additional predictor variable, but with a coefficient value fixed at 1.0	A vector
`'constant'`	• `'on'` — Includes a constant term in the model. The coefficient of the constant term is the first element of `b`. • `'off'` — Omit the constant term
`'simultaneous'` — Compute simultaneous confidence intervals (`true`), or compute non-simultaneous confidence intervals (default `false`)	`true` or `false`

Examples

Fit Generalized Linear Model with Probit Link

Enter sample data.

```
x = [2100 2300 2500 2700 2900 3100 ...
     3300 3500 3700 3900 4100 4300]';
n = [48 42 31 34 31 21 23 23 21 16 17 21]';
y = [1 2 0 3 8 8 14 17 19 15 17 21]';
```

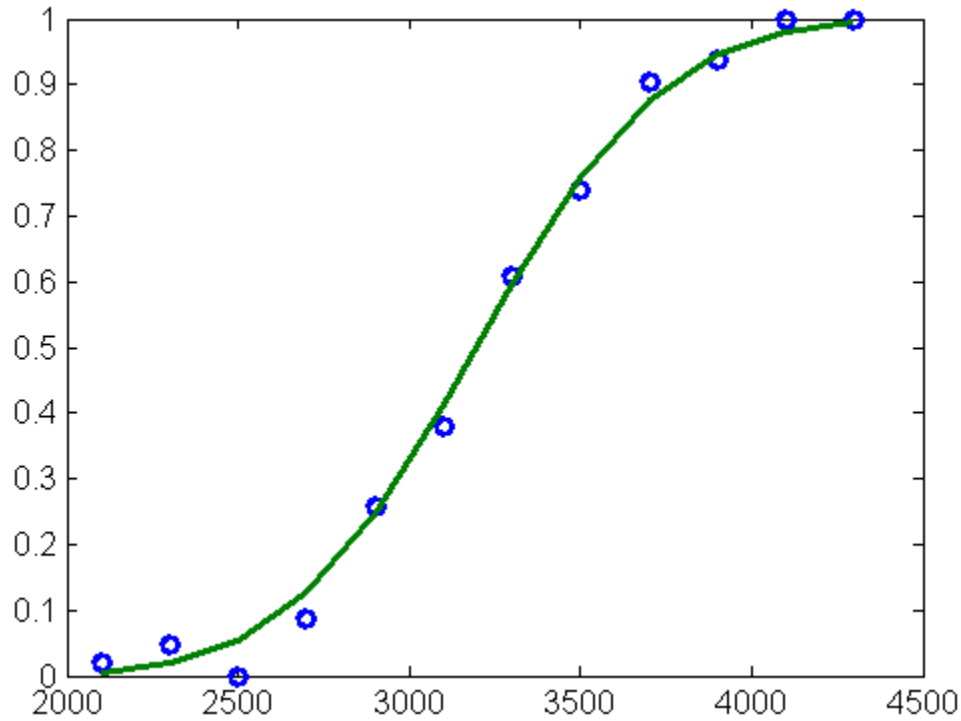
Each `y` value is the number of successes in corresponding number of trials in`n`, and `x` contains the predictor variable values.

Fit a generalized linear model for `y` on `x` using a probit link function.

```
b = glmfit(x,[y n],'binomial','link','probit');
```

Compute the estimated number of successes and plot the observed and estimated percent success versus the `x` values.

```
yfit = glmval(b,x,'probit','size',n);
plot(x, y./n,'o',x,yfit./n,'-','LineWidth',2)
```



Use Custom-defined Link Function

Enter sample data.

```
x = [2100 2300 2500 2700 2900 3100 ...
     3300 3500 3700 3900 4100 4300]';
n = [48 42 31 34 31 21 23 23 21 16 17 21]';
y = [1 2 0 3 8 8 14 17 19 15 17 21]';
```

Each `y` value is the number of successes in corresponding number of trials in `n`, and `x` contains the predictor variable values.

Now define three function handles, created using @, that define the link, the derivative of the link, and the inverse link for a probit link function, and store them in a cell array.

```
link = @(mu) norminv(mu);
derlink = @(mu) 1 ./ normpdf(norminv(mu));
invlink = @(resp) normcdf(resp);
```

```
F = {link, derlink, invlink};
```

Fit a generalized linear model for `y` on `x` using the link function you defined.

```
b = glmfit(x,[y n],'binomial','link',F);
```

Compute the estimated number of successes and plot the observed and estimated percent success versus the `x` values.

```
yfit = glmval(b,x,F,'size',n);
plot(x, y./n,'o',x,yfit./n,'-','LineWidth',2)
```

glyphplot

Glyph plot

Syntax

```
glyphplot(X)
glyphplot(X,'glyph','face')
glyphplot(X,'glyph','face','features',f)
glyphplot(X,...,'grid',[rows,cols])
glyphplot(X,...,'grid',[rows,cols],'page',p)
glyphplot(X,...,'centers',C)
glyphplot(X,...,'centers',C,'radius',r)
glyphplot(X,...,'obslabels',labels)
glyphplot(X,...,'standardize',method)
glyphplot(X,...,prop1,val1,...)
h = glyphplot(X,...)
```

Description

`glyphplot(X)` creates a star plot from the multivariate data in the n-by-p matrix `X`. Rows of `X` correspond to observations, columns to variables. A star plot represents each observation as a "star" whose ith spoke is proportional in length to the ith coordinate of that observation. `glyphplot` standardizes `X` by shifting and scaling each column separately onto the interval `[0,1]` before making the plot, and centers the glyphs on a rectangular grid that is as close to square as possible. `glyphplot` treats `NaN`s in `X` as missing values, and does not plot the corresponding rows of `X`. `glyphplot(X,'glyph','star')` is a synonym for `glyphplot(X)`.

`glyphplot(X,'glyph','face')` creates a face plot from `X`. A face plot represents each observation as a "face," whose ith facial feature is drawn with a characteristic proportional to the ith coordinate of that observation. The features are described in "Face Features" on page 22-2107.

`glyphplot(X,'glyph','face','features',f)` creates a face plot where the ith element of the index vector `f` defines which facial feature will represent the ith column of

`X`. `f` must contain integers from `0` to `17`, where `0` indicate that the corresponding column of `X` should not be plotted. See "Face Features" on page 22-2107 for more information.

`glyphplot(X,...,'grid',[rows,cols])` organizes the glyphs into a `rows`-by-`cols` grid.

`glyphplot(X,...,'grid',[rows,cols],'page',p)` organizes the glyph into one or more pages of a `rows`-by-`cols` grid, and displays the page `p`. If `p` is a vector, `glyphplot` displays multiple pages in succession. If `p` is `'all'`, `glyphplot` displays all pages. If `p` is `'scroll'`, `glyphplot` displays a single plot with a scrollbar.

`glyphplot(X,...,'centers',C)` creates a plot with each glyph centered at the locations in the *n*-by-2 matrix `C`.

`glyphplot(X,...,'centers',C,'radius',r)` creates a plot with glyphs positioned using `C`, and scale the glyphs so the largest has radius `r`.

`glyphplot(X,...,'obslabels',labels)` labels each glyph with the text in the character array or cell array of strings `labels`. By default, the glyphs are labelled `1:N`. Use `''` for blank labels.

`glyphplot(X,...,'standardize',`*`method`*`)` standardizes `X` before making the plot. Choices for *`method`* are

- `'column'` — Maps each column of `X` separately onto the interval [0,1]. This is the default.
- `'matrix'` — Maps the entire matrix `X` onto the interval `[0,1]`.
- `'PCA'` — Transforms `X` to its principal component scores, in order of decreasing eigenvalue, and maps each one onto the interval `[0,1]`.
- `'off'` — No standardization. Negative values in `X` may make a star plot uninterpretable.

`glyphplot(X,...,`*`prop1`*`,`*`val1`*`,...)` sets properties to the specified property values for all line graphics objects created by `glyphplot`.

`h = glyphplot(X,...)` returns a matrix of handles to the graphics objects created by `glyphplot`. For a star plot, `h(:,1)` and `h(:,2)` contain handles to the line objects for each star's perimeter and spokes, respectively. For a face plot, `h(:,1)` and `h(:,2)` contain object handles to the lines making up each face and to the pupils, respectively. `h(:,3)` contains handles to the text objects for the labels, if present.

Face Features

The following table describes the correspondence between the columns of the vector `f`, the value of the `'Features'` input parameter, and the facial features of the glyph plot. If `X` has fewer than 17 columns, unused features are displayed at their default value.

Column	Facial Feature
1	Size of face
2	Forehead/jaw relative arc length
3	Shape of forehead
4	Shape of jaw
5	Width between eyes
6	Vertical position of eyes
7	Height of eyes
8	Width of eyes (this also affects eyebrow width)
9	Angle of eyes (this also affects eyebrow angle)
10	Vertical position of eyebrows
11	Width of eyebrows (relative to eyes)
12	Angle of eyebrows (relative to eyes)
13	Direction of pupils
14	Length of nose
15	Vertical position of mouth
16	Shape of mouth
17	Mouth arc length

Examples

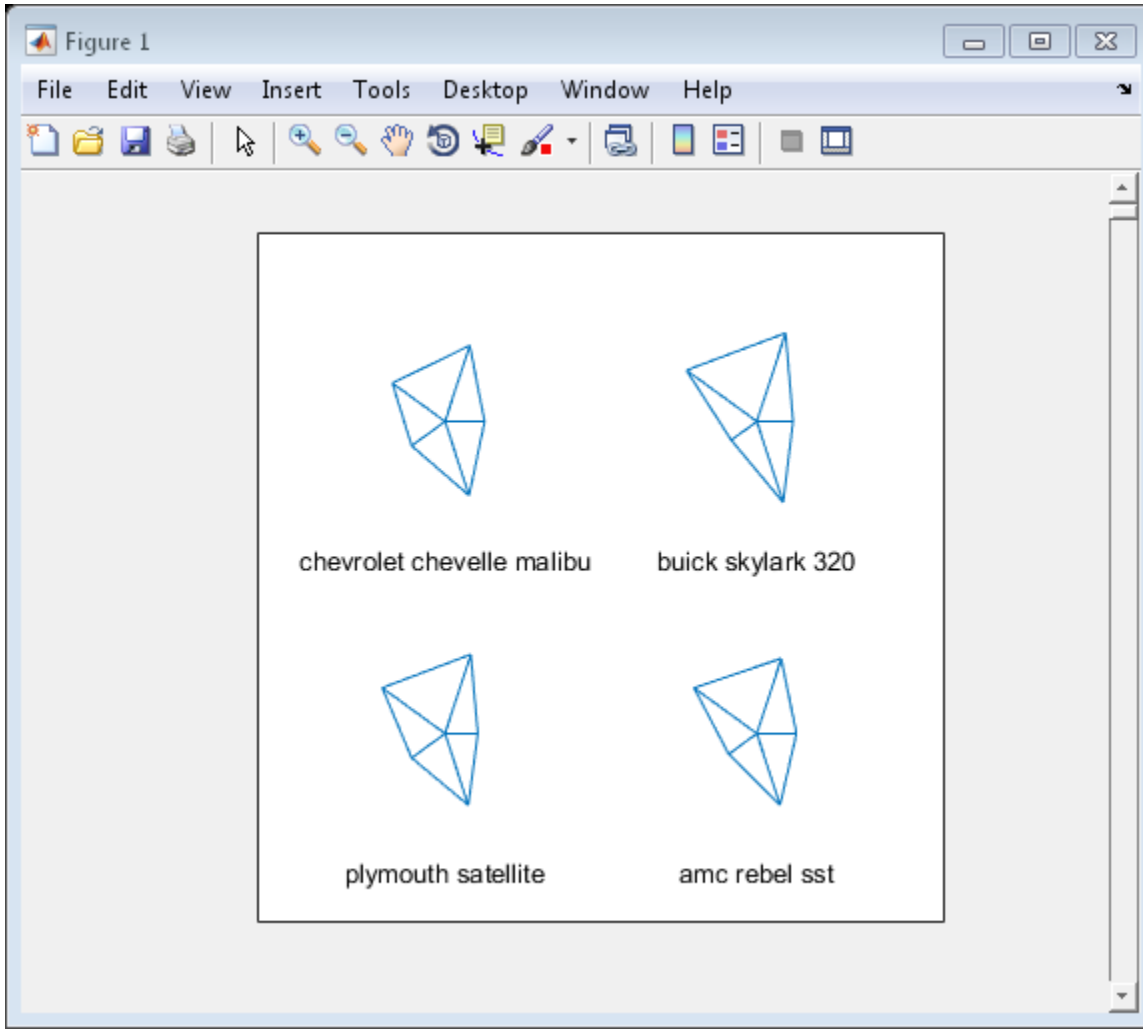
Star and Face Plots of Multivariate Data

Load the sample data.

```
load carsmall
X = [Acceleration Displacement Horsepower MPG Weight];
```

Create a star plot of the data in `X` . Standardize the data before plotting.

```
glyphplot(X,'standardize','column','obslabels',Model,'grid',[2 2],...
            'page','scroll');
```



Create a faceplot of the data in `X` .

```
glyphplot(X,'glyph','face','obslabels',Model,'grid',[2 3],'page',9);
```

gmdistribution class

Gaussian mixture models

Description

An object of the `gmdistribution` class defines a Gaussian mixture distribution, which is a multivariate distribution that consists of a mixture of one or more multivariate Gaussian distribution components. The number of components for a given `gmdistribution` object is fixed. Each multivariate Gaussian component is defined by its mean and covariance, and the mixture is defined by a vector of mixing proportions.

Construction

To create a Gaussian mixture distribution by specifying the distribution parameters, use the `gmdistribution` constructor. To fit a Gaussian mixture distribution model to data, use `fitgmdist`.

fit	Gaussian mixture parameter estimates
.gmdistribution	Construct Gaussian mixture distribution

Properties

All objects of the class have the properties listed in the following table.

CovarianceType	Type of covariance matrices
DistributionName	Type of distribution
mu	Input matrix of means `mu`
NumComponents	Number k of mixture components

NumVariables	Dimension d of multivariate Gaussian distributions
ComponentProportion	Input vector of mixing proportions
SharedCovariance	`true` if all covariance matrices are restricted to be the same
Sigma	Input array of covariances

Objects constructed with `fitgmdist` have the additional properties listed in the following table.

AIC	Akaike Information Criterion
BIC	Bayes Information Criterion
Converged	Determine if algorithm converged
NumIterations	Number of iterations
NegativeLogLikelihood	Negative of log-likelihood
RegularizationValue	Value of `'Regularize'` parameter

Methods

cdf	Cumulative distribution function for Gaussian mixture distribution
cluster	Construct clusters from Gaussian mixture distribution

disp	Display Gaussian mixture distribution object
display	Display Gaussian mixture distribution object
fit	Gaussian mixture parameter estimates
mahal	Mahalanobis distance to component means
pdf	Probability density function for Gaussian mixture distribution
posterior	Posterior probabilities of components
random	Random numbers from Gaussian mixture distribution
subsasgn	Subscripted reference for Gaussian mixture distribution object
subsref	Subscripted reference for Gaussian mixture distribution object

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

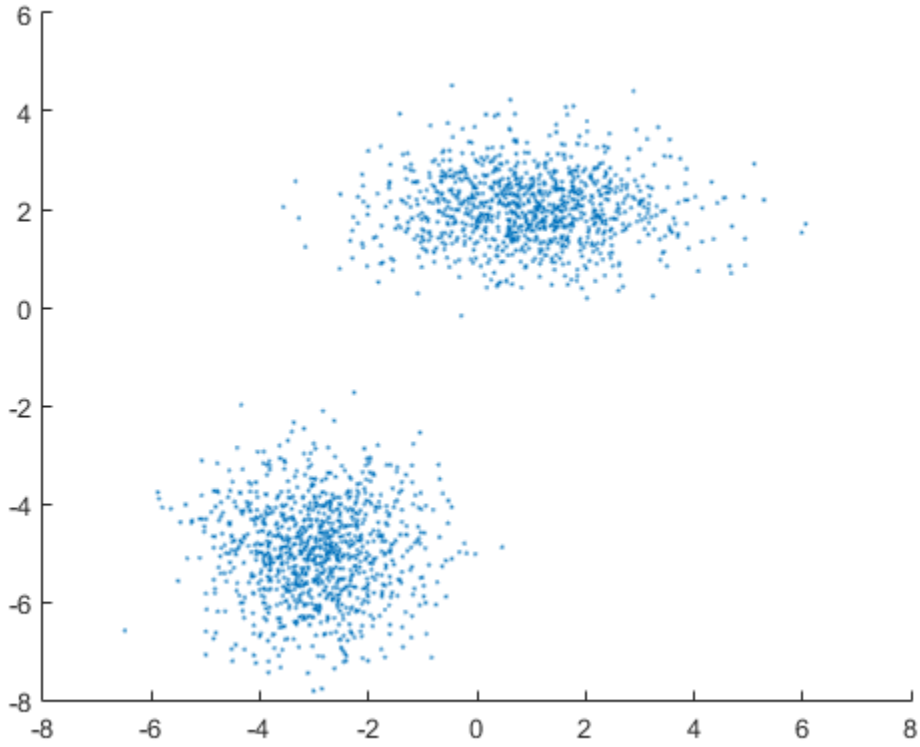
Fit a Gaussian Mixture Model

Generate data from a mixture of two bivariate Gaussian distributions using the `mvnrnd` function. Fit the resulting data.

Generate the data using 1000 points from each distribution.

```
MU1 = [1 2];
SIGMA1 = [2 0; 0 .5];
MU2 = [-3 -5];
SIGMA2 = [1 0; 0 1];
X = [mvnrnd(MU1,SIGMA1,1000);mvnrnd(MU2,SIGMA2,1000)];

scatter(X(:,1),X(:,2),10,'.')
hold on
```



Fit a two-component Gaussian mixture model.

```
options = statset('Display','final');
obj = fitgmdist(X,2,'Options',options);
```

```
18 iterations, log-likelihood = -7058.35
```

Plot the fit.

```
h = ezcontour(@(x,y)pdf(obj,[x y]),[-8 6],[-8 6]);
```

`fitgmdist`

gmdistribution

Class: gmdistribution

Construct Gaussian mixture distribution

Syntax

```
obj = gmdistribution(mu,sigma,p)
```

Description

`obj = gmdistribution(mu,sigma,p)` constructs an object `obj` of the `gmdistribution` class defining a Gaussian mixture distribution.

`mu` is a k-by-d matrix specifying the d-dimensional mean of each of the k components.

`sigma` specifies the covariance of each component. The size of `sigma` is:

- d-by-d-by-k if there are no restrictions on the form of the covariance. In this case, `sigma(:,:,I)` is the covariance of component `I`.
- 1-by-d-by-k if the covariance matrices are restricted to be diagonal, but not restricted to be same across components. In this case, `sigma(:,:,I)` contains the diagonal elements of the covariance of component I.
- d-by-d matrix if the covariance matrices are restricted to be the same across components, but not restricted to be diagonal. In this case, `sigma` is the pooled estimate of covariance.
- 1-by-d if the covariance matrices are restricted to be diagonal and the same across components. In this case, `sigma` contains the diagonal elements of the pooled estimate of covariance.

`p` is an optional 1-by-k vector specifying the mixing proportions of each component. If `p` does not sum to `1`, `gmdistribution` normalizes it. The default is equal proportions.

Examples

Construct a Gaussian Mixture Distribution

Create a `gmdistribution` distribution defining a two-component mixture of bivariate Gaussian distributions.

```
mu = [1 2;-3 -5];
sigma = cat(3,[2 0;0 .5],[1 0;0 1]);
p = ones(1,2)/2;
obj = gmdistribution(mu,sigma,p);

ezsurf(@(x,y)pdf(obj,[x y]),[-10 10],[-10 10])
```

gname

Add case names to plot

Syntax

```
gname(cases)
gname
h = gname(cases,line_handle)
```

Description

`gname(cases)` displays a figure window and waits for you to press a mouse button or a keyboard key. The input argument `cases` is a character array or a cell array of strings, in which each row of the character array or each element of the cell array contains the case name of a point. Moving the mouse over the graph displays a pair of cross-hairs. If you position the cross-hairs near a point with the mouse and click once, the graph displays the label corresponding to that point. Alternatively, you can click and drag the mouse to create a rectangle around several points. When you release the mouse button, the graph displays the labels for all points in the rectangle. Right-click a point to remove its label. When you are done labelling points, press the **Enter** or **Escape** key to stop labeling.

`gname` with no arguments labels each case with its case number.

`cases` typically contains unique case names for each point, and is a cell array of strings or a character matrix with each row representing a name. `cases` can also be any grouping variable, which `gname` converts to labels.

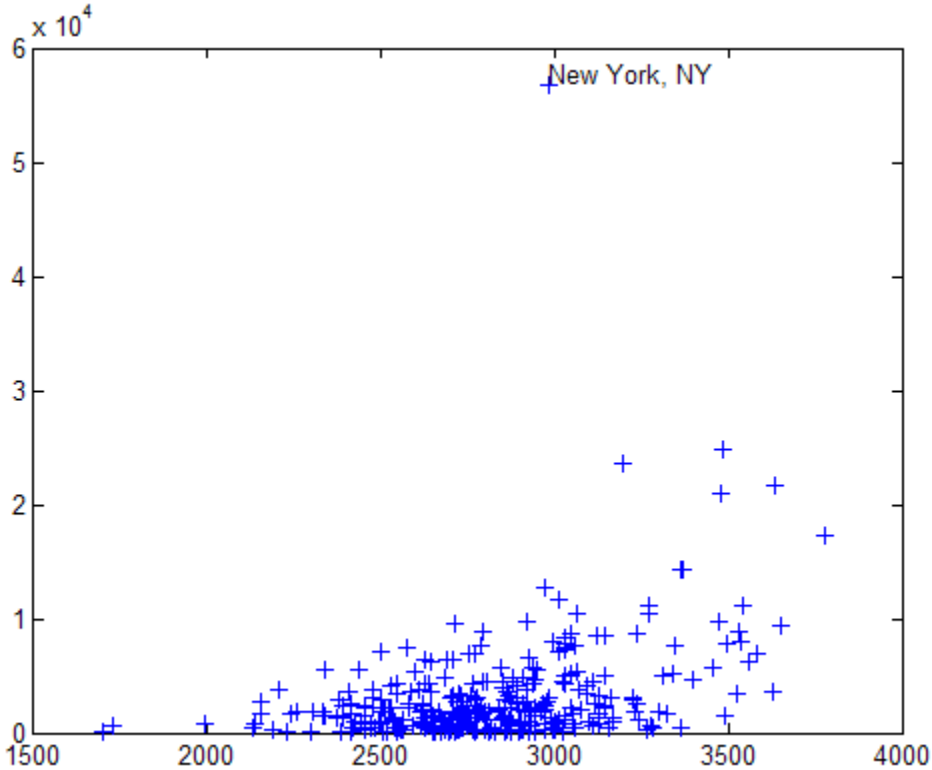
`h = gname(cases,line_handle)` returns a vector of handles to the text objects on the plot. Use the scalar `line_handle` to identify the correct line if there is more than one line object on the plot.

You can use `gname` to label plots created by the `plot`, `scatter`, `gscatter`, `plotmatrix`, and `gplotmatrix` functions.

Examples

This example uses the city ratings data sets to find out which cities are the best and worst for education and the arts.

```
load cities
education = ratings(:,6);
arts = ratings(:,7);
plot(education,arts,'+')
gname(names)
```



Click the point at the top of the graph to display its label, “New York.”

gtext | gscatter | gplotmatrix

gpcdf

Generalized Pareto cumulative distribution function

Syntax

```
p = gpcdf(x,k,sigma,theta)
p = gpcdf(x,k,sigma,theta,'upper')
```

Description

`p = gpcdf(x,k,sigma,theta)` returns the cdf of the generalized Pareto (GP) distribution with the tail index (shape) parameter `k`, scale parameter `sigma`, and threshold (location) parameter, `theta`, evaluated at the values in `x`. The size of `p` is the common size of the input arguments. A scalar input functions as a constant matrix of the same size as the other inputs.

`p = gpcdf(x,k,sigma,theta,'upper')` returns the complement of the cdf of the generalized Pareto (GP) distribution, using an algorithm that more accurately computes the extreme upper tail probabilities.

Default values for `k`, `sigma`, and `theta` are 0, 1, and 0, respectively.

When `k = 0` and `theta = 0`, the GP is equivalent to the exponential distribution. When `k > 0` and `theta = sigma/k`, the GP is equivalent to a Pareto distribution with a scale parameter equal to `sigma/k` and a shape parameter equal to `1/k`. The mean of the GP is not finite when $k \geq 1$, and the variance is not finite when $k \geq 1/2$. When $k \geq 0$, the GP has positive density for

`x > theta`, or, when

`k < 0`, $0 \leq \frac{x-\theta}{\sigma} \leq -\frac{1}{k}$.

`cdf` | `gppdf` | `gpinv` | `gpstat` | `gpfit` | `gplike` | `gprnd`

gpfit

Generalized Pareto parameter estimates

Syntax

```
parmhat = gpfit(x)
[parmhat,parmci] = gpfit(x)
[parmhat,parmci] = gpfit(x,alpha)
[...] = gpfit(x,alpha,options)
```

Description

`parmhat = gpfit(x)` returns maximum likelihood estimates of the parameters for the two-parameter generalized Pareto (GP) distribution given the data in `x`. `parmhat(1)` is the tail index (shape) parameter, `k` and `parmhat(2)` is the scale parameter, `sigma`. `gpfit` does not fit a threshold (location) parameter.

`[parmhat,parmci] = gpfit(x)` returns 95% confidence intervals for the parameter estimates.

`[parmhat,parmci] = gpfit(x,alpha)` returns `100(1-alpha)`% confidence intervals for the parameter estimates.

`[...] = gpfit(x,alpha,options)` specifies control parameters for the iterative algorithm used to compute ML estimates. This argument can be created by a call to `statset`. See `statset('gpfit')` for parameter names and default values.

Other functions for the generalized Pareto, such as `gpcdf` allow a threshold parameter, `theta`. However, `gpfit` does not estimate theta. It is assumed to be known, and subtracted from `x` before calling `gpfit`.

When `k = 0` and `theta = 0`, the GP is equivalent to the exponential distribution. When `k > 0` and `theta = sigma/k`, the GP is equivalent to a Pareto distribution with a scale parameter equal to `sigma/k` and a shape parameter equal to `1/k`. The mean of the GP is not finite when $k \geq 1$, and the variance is not finite when $k \geq 1/2$. When $k \geq 0$, the GP has positive density for

`k > theta`, or, when `k < 0`, for

$$0 \le \frac{x-\theta}{\sigma} \le -\frac{1}{k}$$

gpinv

Generalized Pareto inverse cumulative distribution function

Syntax

```
x = gpinv(p,k,sigma,theta)
```

Description

`x = gpinv(p,k,sigma,theta)` returns the inverse cdf for a generalized Pareto (GP) distribution with tail index (shape) parameter `k`, scale parameter `sigma`, and threshold (location) parameter `theta`, evaluated at the values in `p`. The size of `x` is the common size of the input arguments. A scalar input functions as a constant matrix of the same size as the other inputs.

Default values for `k`, `sigma`, and `theta` are 0, 1, and 0, respectively.

When `k = 0` and `theta = 0`, the GP is equivalent to the exponential distribution. When `k > 0` and `theta = sigma/k`, the GP is equivalent to a Pareto distribution with a scale parameter equal to `sigma/k` and a shape parameter equal to `1/k`. The mean of the GP is not finite when $k \geq 1$, and the variance is not finite when $k \geq 1/2$. When $k \geq 0$, the GP has positive density for

`x > theta`, or, when

`k < 0`, $0 \leq \frac{x-\theta}{\sigma} \leq -\frac{1}{k}$.

gplike

Generalized Pareto negative log-likelihood

Syntax

```
nlogL = gplike(params,data)
[nlogL,acov] = gplike(params,data)
```

Description

`nlogL = gplike(params,data)` returns the negative of the log-likelihood `nlogL` for the two-parameter generalized Pareto (GP) distribution, evaluated at parameters `params`. `params(1)` is the tail index (shape) parameter, `k`, and `params(2)` is the scale parameter. `gplike` does not allow a threshold (location) parameter.

`[nlogL,acov] = gplike(params,data)` returns the inverse of Fisher's information matrix, `acov`. If the input parameter values in `params` are the maximum likelihood estimates, the diagonal elements of `acov` are their asymptotic variances. `acov` is based on the observed Fisher's information, not the expected information.

When `k = 0` and `theta = 0`, the GP is equivalent to the exponential distribution. When `k > 0` and `theta = sigma/k`, the GP is equivalent to a Pareto distribution with a scale parameter equal to `sigma/k` and a shape parameter equal to `1/k`. The mean of the GP is not finite when $k \geq 1$, and the variance is not finite when $k \geq 1/2$. When $k \geq 0$, the GP has positive density for

`x > theta`, or, when

`k < 0`, $0 \leq \frac{x-\theta}{\sigma} \leq -\frac{1}{k}$.

gppdf

Generalized Pareto probability density function

Syntax

```
p = gppdf(x,k,sigma,theta)
```

Description

`p = gppdf(x,k,sigma,theta)` returns the pdf of the generalized Pareto (GP) distribution with the tail index (shape) parameter `k`, scale parameter `sigma`, and threshold (location) parameter, `theta`, evaluated at the values in `x`. The size of `p` is the common size of the input arguments. A scalar input functions as a constant matrix of the same size as the other inputs.

Default values for `k`, `sigma`, and `theta` are 0, 1, and 0, respectively.

When `k = 0` and `theta = 0`, the GP is equivalent to the exponential distribution. When `k > 0` and `theta = sigma/k`, the GP is equivalent to a Pareto distribution with a scale parameter equal to `sigma/k` and a shape parameter equal to `1/k`. The mean of the GP is not finite when $k \geq 1$, and the variance is not finite when $k \geq 1/2$. When $k \geq 0$, the GP has positive density for

`x > theta`, or, when

`k < 0`, $0 \leq \frac{x-\theta}{\sigma} \leq -\frac{1}{k}$.

gplotmatrix

Matrix of scatter plots by group

Syntax

```
gplotmatrix(x,y,group)
gplotmatrix(x,y,group,clr,sym,siz)
gplotmatrix(x,y,group,clr,sym,siz,doleg)
gplotmatrix(x,y,group,clr,sym,siz,doleg,dispopt)
gplotmatrix(x,y,group,clr,sym,siz,doleg,dispopt,xnam,ynam)
[h,ax,bigax] = gplotmatrix(...)
```

Description

`gplotmatrix(x,y,group)` creates a matrix of scatter plots. Each individual set of axes in the resulting figure contains a scatter plot of a column of `x` against a column of `y`. All plots are grouped by the grouping variable `group`.

`x` and `y` are matrices with the same number of rows. If `x` has p columns and `y` has q columns, the figure contains a p-by-q matrix of scatter plots. If you omit `y` or specify it as the empty matrix, `[]`, `gplotmatrix` creates a square matrix of scatter plots of columns of `x` against each other.

`group` is a grouping variable that can be a categorical variable, vector, string array, or cell array of strings. `group` must have the same number of rows as `x` and `y`. Points with the same value of `group` are placed in the same group, and appear on the graph with the same marker and color. Alternatively, `group` can be a cell array containing several grouping variables (such as `{g1 g2 g3}`); in that case, observations are in the same group if they have common values of all grouping variables.

`gplotmatrix(x,y,group,clr,sym,siz)` specifies the color, marker type, and size for each group. *`clr`* is a string array of colors recognized by the `plot` function. *`sym`* is a string array of symbols recognized by the `plot` command, with the default value `'.'`. `siz` is a vector of sizes, with the default determined by the `DefaultLineMarkerSize` property. If you do not specify enough values for all groups, `gplotmatrix` cycles through the specified values as needed.

`gplotmatrix(x,y,group,clr,sym,siz,doleg)` controls whether a legend is displayed on the graph (*`doleg`* is `'on'`, the default) or not (*`doleg`* is `'off'`).

`gplotmatrix(x,y,group,clr,sym,siz,doleg,dispopt)` controls what appears along the diagonal of a plot matrix of `y` versus `x`. Allowable values are `'none'`, to leave the diagonals blank, `'hist'`, to plot histograms, `'stairs'` to display the outlines of grouped histograms (default if there is more than one group), `'grpbars'` to plot grouped histogram bars. or `'variable'`, to write the variable names. `gplotmatrix` displays histograms along the diagonal only when there is only one variable (i.e., `gplotmatrix(x,[],[],[],[],[],[],'hist')`.

`gplotmatrix(x,y,group,clr,sym,siz,doleg,dispopt,xnam,ynam)` specifies the names of the columns in the `x` and `y` arrays. These names are used to label the *x*- and *y*-axes. `xnam` and `ynam` must be character arrays or cell arrays of strings, with one name for each column of `x` and `y`, respectively.

`[h,ax,bigax] = gplotmatrix(...)` returns three arrays of handles. `h` is an array of handles to the lines on the graphs. The array's third dimension corresponds to groups in the input argument `group`. `ax` is a matrix of handles to the axes of the individual plots. If *`dispopt`* is `'hist'`, `'stairs'`, or `'grpbars'`, `ax` contains one extra row of handles to invisible axes in which the histograms are plotted. `bigax` is a handle to big (invisible) axes framing the entire plot matrix. `bigax` is fixed to point to the current axes, so a subsequent `title`, `xlabel`, or `ylabel` command will produce labels that are centered with respect to the entire plot matrix.

Examples

Create Grouped Data Scatter Plot Matrix

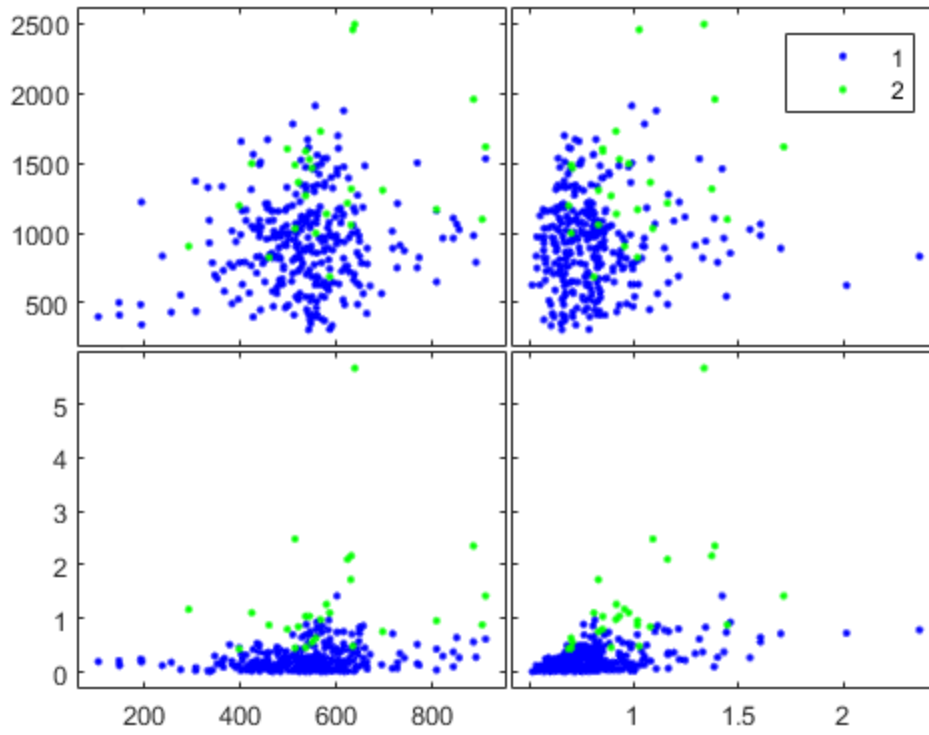
Load the sample data.

```
load discrim;
```

The `ratings` array contains rating values for 329 U.S. cities in the nine different categories listed in the `categories` array. The `group` array contains a city size code that is equal to `2` for the 26 largest cities, and `1` otherwise.

Create a matrix of scatter plots to compare the first two categories, `climate` and `housing`, with categories 4 (`crime`) and 7 (`arts`). Specify `group` as the grouping variable to visually distinguish the data for large and small cities.

```
figure;
gplotmatrix(ratings(:,1:2),ratings(:,[4 7]),group);
```



The figure displays a matrix of scatter plots for the specified comparisons, with each city size group represented by a different color.

For better clarity, you can adjust the appearance of the graphs by specifying colors and plotting symbols, and labeling the axes with the rating categories.

```
figure;
gplotmatrix(ratings(:,1:2),ratings(:,[4 7]),group,...
    'br','.o',[],'on','',categories(1:2,:),...
    categories([4 7],:));
```

gprnd

Generalized Pareto random numbers

Syntax

```
r = gprnd(k,sigma,theta)
r = gprnd(k,sigma,theta,m,n,...)
R = gprnd(K,sigma,theta,[m,n,...])
```

Description

`r = gprnd(k,sigma,theta)` returns an array of random numbers chosen from the generalized Pareto (GP) distribution with tail index (shape) parameter `k`, scale parameter `sigma`, and threshold (location) parameter, `theta`. The size of `r` is the common size of the input arguments if all are arrays. If any parameter is a scalar, the size of `r` is the size of the other parameters.

`r = gprnd(k,sigma,theta,m,n,...)` or `R = gprnd(K,sigma,theta,[m,n,...])` generates an `m`-by-`n`-by-... array. The `k`, `sigma`, `theta` parameters can each be scalars or arrays of the same size as `r`.

When `k = 0` and `theta = 0`, the GP is equivalent to the exponential distribution. When `k > 0` and `theta = sigma/k`, the GP is equivalent to a Pareto distribution with a scale parameter equal to `sigma/k` and a shape parameter equal to `1/k`. The mean of the GP is not finite when $k \geq 1$, and the variance is not finite when $k \geq 1/2$. When $k \geq 0$, the GP has positive density for

`x > theta`, or, when

$$0 \leq \frac{x-\theta}{\sigma} \leq -\frac{1}{k}$$

gpstat

Generalized Pareto mean and variance

Syntax

```
[m,v] = gpstat(k,sigma,theta)
```

Description

`[m,v] = gpstat(k,sigma,theta)` returns the mean of and variance for the generalized Pareto (GP) distribution with the tail index (shape) parameter `k`, scale parameter `sigma`, and threshold (location) parameter, `theta`.

The default value for `theta` is 0.

When `k = 0` and `theta = 0`, the GP is equivalent to the exponential distribution. When `k > 0` and `theta = sigma/k`, the GP is equivalent to a Pareto distribution with a scale parameter equal to `sigma/k` and a shape parameter equal to `1/k`. The mean of the GP is not finite when $k \geq 1$, and the variance is not finite when $k \geq 1/2$. When $k \geq 0$, the GP has positive density for `x > theta`, or when

`k < 0`, $0 \leq \frac{x-\theta}{\sigma} \leq -\frac{1}{k}$.

growTrees

Class: TreeBagger

Train additional trees and add to ensemble

Syntax

```
B = growTrees(B,ntrees)
B = growTrees(B,ntrees,'param1',val1,'param2',val2,...)
```

Description

`B = growTrees(B,ntrees)` grows `ntrees` new trees and appends them to those trees already stored in the ensemble `B`.

`B = growTrees(B,ntrees,'param1',val1,'param2',val2,...)` specifies optional parameter name/value pairs:

`'nprint'`	Specifies that a diagnostic message showing training progress should display after every `value` training cycles (grown trees). Default is no diagnostic messages.
`'options'`	A `struct` that specifies options that govern computation when growing the ensemble of decision trees. One option requests that the computation of decision trees on multiple bootstrap replicates uses multiple processors, if the Parallel Computing Toolbox is available. Two options specify the random number streams to use in selecting bootstrap replicates. You can create this argument with a call to `statset`. You can retrieve values of the individual fields with a call to `statget`. Applicable `statset` parameters are: • `'UseParallel'` — If `true` and if a `parpool` of the Parallel Computing Toolbox is open, compute decision trees drawn on separate boostrap replicates in parallel. If the Parallel Computing Toolbox is not installed, or a `parpool`

is not open, computation occurs in serial mode. Default is `false`, or serial computation.

- `UseSubstreams` — Set to `true` to compute in parallel in a reproducible fashion. Default is `false`. To compute reproducibly, set `Streams` to a type allowing substreams: `'mlfg6331_64'` or `'mrg32k3a'`.
- `Streams` — A `RandStream` object or cell array of such objects. If you do not specify `Streams`, `growTrees` uses the default stream or streams. If you choose to specify `Streams`, use a single object except in the case

  - You have an open Parallel pool
  - `UseParallel` is `true`
  - `UseSubstreams` is `false`

  In that case, use a cell array the same size as the Parallel pool.

grp2idx

Create index vector from grouping variable

Syntax

```
[G,GN]=grp2idx(S)
[G,GN,GL] = grp2idx(S)
```

Description

`[G,GN]=grp2idx(S)` creates an index vector `G` from the grouping variable `S`. `S` can be a categorical, numeric, logical, datetime, or duration vector; a cell vector of strings; or a character matrix with each row representing a group label. The result `G` is a vector taking integer values from 1 up to the number `K` of distinct groups. `GN` is a cell array of strings representing group labels. `GN(G)` reproduces `S` (aside from any differences in type).

The order of `GN` depends on the grouping variable:

- For numeric and logical grouping variables, the order is the sorted order of `S`.
- For categorical grouping variables, the order is the order of `getlabels(S)`.
- For string grouping variables, the order is the order of first appearance in `S`.

`[G,GN,GL] = grp2idx(S)` returns a column vector `GL` representing the group levels. The set of groups and their order in `GL` and `GN` are the same, except that `GL` has the same type as `S`. If `S` is a character matrix, `GL(G,:)` reproduces `S`, otherwise `GL(G)` reproduces `S`.

`grp2idx` treats `NaN`s (numeric, duration, or logical), empty strings (char or cell array of strings), or `<undefined>` values (categorical) or `NaT`s (datetime) in `S` as missing values and returns `NaN`s in the corresponding rows of `G`. `GN` and `GL` don't include entries for missing values.

Examples

Load the data in `hospital.mat` and create a categorical grouping variable:

```
load hospital
edges = 0:10:100;
labels = strcat(num2str((0:10:90)','%d'),{'s'});
AgeGroup = ordinal(hospital.Age,labels,[],edges);

ages = hospital.Age(1:5)

ages =
    38
    43
    38
    40
    49

group = AgeGroup(1:5)

group =
     30s
     40s
     30s
     40s
     40s

indices = grp2idx(group)

indices =
     4
     5
     4
     5
     5
```

grpstats

Summary statistics organized by group

Syntax

```
statarray = grpstats(tbl,groupvar)
statarray = grpstats(tbl,groupvar,whichstats)
statarray = grpstats(tbl,groupvar,whichstats,Name,Value)

means = grpstats(X,group)
[stats1,...,statsN] = grpstats(X,group,whichstats)
[stats1,...,statsN] = grpstats(X,group,whichstats,'Alpha',alpha)

grpstats(X,group,alpha)
```

Description

`statarray = grpstats(tbl,groupvar)` returns a table or dataset array with the means for the data groups specified in tbl determined by the values of the grouping variable or variables specified in groupvar.

- If there is a single grouping variable, then there is a row in `statarray` for each value of the grouping variable. `grpstats` sorts the groups by order of appearance (if the grouping variable is a character array), in ascending numeric order (if the grouping variable is numeric), or in order of the levels (if the grouping variable is categorical).
- If groupvar is a cell array of strings containing multiple grouping variable names, or a vector of column numbers, then there is a row in `statarray` for each observed unique combination of values of the grouping variables. `grpstats` sorts the groups by the values of the first grouping variable, then the second grouping variable, and so on.
- If any variables in tbl (other than those specified in `groupvar`) are not numeric or logical arrays, then you must specify the names or column numbers of the numeric and logical variables for which you want to calculate means using the name-value pair argument, DataVars.

`statarray = grpstats(tbl,groupvar,whichstats)` returns the group values for the summary statistics types specified in whichstats.

`statarray = grpstats(tbl,groupvar,whichstats,Name,Value)` uses additional options specified by one or more Name,Value pair arguments.

`means = grpstats(X,group)` returns a column vector or matrix with the means of the groups of the data in the matrix or vector X determined by the values of the grouping variable or variables, group. The rows of `means` correspond to the grouping variable values.

- If there is a single grouping variable, then there is a row in `means` for each value of the grouping variable. `grpstats` sorts the groups by order of appearance (if the grouping variable is a character array), in ascending numeric order (if the grouping variable is numeric), or in order of the levels (if the grouping variable is categorical).
- If group is a cell array of grouping variables, then there is a row in `means` for each observed unique combination of values of the grouping variables. `grpstats` sorts the groups by the values of the first grouping variable, then the second grouping variable, and so on.
- If X is a matrix, then means is a matrix with the same number of columns as `X`. Each column of `means` has the group means for the corresponding column of `X`.

`[stats1,...,statsN] = grpstats(X,group,whichstats)` returns column vectors or arrays with group values for the summary statistic types specified in whichstats.

`[stats1,...,statsN] = grpstats(X,group,whichstats,'Alpha',alpha)` specifies the significance level for confidence and prediction intervals.

`grpstats(X,group,alpha)` plots the means of the groups of data in the vector or matrix X determined by the values of the grouping variable, group. The grouping variable values are on the horizontal plot axis. Each group mean has 100×(1 – alpha)% confidence intervals.

- If X is a matrix, then `grpstats` plots the means and confidence intervals for each column of `X`.
- If group is a cell array of grouping variables, then `grpstats` plots the means and confidence intervals for the groups of data in `X` determined by the unique combinations of values of the grouping variables. For example, if there are two grouping variables, each with two values, there are four possible combinations of grouping variable values. The plot includes only the combinations of values that exist in the input grouping variables (not all possible combinations).

Examples

Dataset Array Summary Statistics Organized by Group

Load the sample data.

```
load('hospital')
```

The dataset array `hospital` has 100 observations and 7 variables.

Create a dataset array with only the variables `Sex`, `Age`, `Weight`, and `Smoker`.

```
ds = hospital(:,{'Sex','Age','Weight','Smoker'});
```

`Sex` is a nominal array, with levels `Male` and `Female`. The variables `Age` and `Weight` have numeric values, and `Smoker` has logical values.

Compute the mean for the numeric and logical arrays, `Age`, `Weight`, and `Smoker`, grouped by the levels in `Sex`.

```
statarray = grpstats(ds,'Sex')
```

```
statarray =

              Sex       GroupCount    mean_Age    mean_Weight    mean_Smoker
    Female    Female    53            37.717      130.47         0.24528
    Male      Male      47            38.915      180.53         0.44681
```

`statarray` is a dataset array with two rows, corresponding to the levels in `Sex`. `GroupCount` is the number of observations in each group. The means of `Age`, `Weight`, and `Smoker`, grouped by `Sex`, are given in `mean_Age`, `mean_Weight`, and `mean_Smoker`.

Compute the mean for `Age` and `Weight`, grouped by the values in `Smoker`.

```
statarray = grpstats(ds,'Smoker','mean','DataVars',{'Age','Weight'})
```

```
statarray =

          Smoker    GroupCount    mean_Age    mean_Weight
    0     false     66             37.97      149.91
    1     true      34            38.882      161.94
```

In this case, not all variables in `ds` (excluding the grouping variable, `Smoker`) are numeric or logical arrays; the variable `Sex` is a nominal array. When not all variables in

the input dataset array are numeric or logical arrays, you must specify the variables for which you want to calculate summary statistics using `DataVars`.

Compute the minimum and maximum weight, grouped by the combinations of values in `Sex` and `Smoker`.

```
statarray = grpstats(ds,{'Sex','Smoker'},{'min','max'},...
                     'DataVars','Weight')
```

```
statarray =

                Sex       Smoker    GroupCount    min_Weight    max_Weight
    Female_0    Female    false     40            111           147
    Female_1    Female    true      13            115           146
    Male_0      Male      false     26            158           194
    Male_1      Male      true      21            164           202
```

There are two unique values in `Smoker` and two levels in `Sex`, for a total of four possible combinations of values: Female Nonsmoker (`Female_0`), Female Smoker (`Female_1`), Male Nonsmoker (`Male_0`), and Male Smoker (`Male_1`).

Specify the names for the columns in the output.

```
statarray = grpstats(ds,{'Sex','Smoker'},{'min','max'},...
          'DataVars','Weight','VarNames',{'Gender','Smoker',...
     'GroupCount','LowestWeight','HighestWeight'})
```

```
statarray =

                Gender    Smoker    GroupCount    LowestWeight    HighestWeight
    Female_0    Female    false     40            111             147
    Female_1    Female    true      13            115             146
    Male_0      Male      false     26            158             194
    Male_1      Male      true      21            164             202
```

Summary Statistics for a Dataset Array Without Grouping

Load the sample data.

```
load('hospital')
```

The dataset array `hospital` has 100 observations and 7 variables.

Create a dataset array with only the variables `Age`, `Weight`, and `Smoker`.

```
ds = hospital(:,{'Age','Weight','Smoker'});
```

The variables `Age` and `Weight` have numeric values, and `Smoker` has logical values.

Compute the mean, minimum, and maximum for the numeric and logical arrays, `Age`, `Weight`, and `Smoker`, with no grouping.

```
statarray = grpstats(ds,[],{'mean','min','max'})
```

```
statarray =

           GroupCount    mean_Age    min_Age    max_Age    mean_Weight
    All    100           38.28       25         50         154

           min_Weight    max_Weight    mean_Smoker    min_Smoker    max_Smoker
    All    111           202           0.34           false         true
```

The observation name `All` indicates that all observations in `ds` were used to compute the summary statistics.

Group Means for a Matrix Using One or More Grouping Variables

Load the sample data.

```
load('carsmall')
```

All variables are measured for 100 cars. `Origin` is the country of origin for each car (France, Germany, Italy, Japan, Sweden, or USA). `Cylinders` has three unique values, `4`, `6`, and `8`, indicating the number of cylinders in each car.

Calculate the mean acceleration, grouped by country of origin.

```
means = grpstats(Acceleration,Origin)
```

```
means =

   14.4377
   18.0500
   15.8867
   16.3778
   16.6000
   15.5000
```

`means` is a 6-by-1 vector of mean accelerations, where each value corresponds to a country of origin.

Calculate the mean acceleration, grouped by both country of origin and number of cylinders.

```
means = grpstats(Acceleration,{Origin,Cylinders})
```

```
means =

   17.0818
   16.5267
   11.6406
   18.0500
   15.9143
   15.5000
   16.3375
   16.7000
   16.6000
   15.5000
```

There are 18 possible combinations of grouping variable values because `Origin` has 6 unique values and `Cylinders` has 3 unique values. Only 10 of the possible combinations appear in the data, so `means` is a 10-by-1 vector of group means corresponding to the observed combinations of values.

Return the group names along with the mean acceleration for each group.

```
[means,grps] = grpstats(Acceleration,{Origin,Cylinders},...
                        {'mean','gname'})
```

```
means =

   17.0818
   16.5267
   11.6406
   18.0500
   15.9143
   15.5000
   16.3375
   16.7000
   16.6000
   15.5000

grps =

    'USA'        '4'
```

```
    'USA'        '6'
    'USA'        '8'
    'France'     '4'
    'Japan'      '4'
    'Japan'      '6'
    'Germany'    '4'
    'Germany'    '6'
    'Sweden'     '4'
    'Italy'      '4'
```

The output `grps` shows the 10 observed combinations of grouping variable values. For example, the mean acceleration of 4-cylinder cars made in France is 18.05.

Multiple Summary Statistics for a Matrix Organized by Group

Load the sample data.

```
load('carsmall')
```

The variable `Acceleration` was measured for 100 cars. The variable `Origin` is the country of origin for each car (France, Germany, Italy, Japan, Sweden, or USA).

Return the minimum, median, and maximum acceleration, grouped by country of origin.

```
[grpMin,grpMed,grpMax,grp] = grpstats(Acceleration,Origin,...
                                {'min','median','max','gname'})
```

```
grpMin =

    8.0000
   15.3000
   13.9000
   12.2000
   15.7000
   15.5000

grpMed =

   14.7000
   17.5000
   15.7000
   15.3000
   16.6000
```

```
   15.5000

grpMax =

   22.2000
   21.9000
   18.2000
   24.6000
   17.5000
   15.5000

grp =

    'USA'
    'France'
    'Japan'
    'Germany'
    'Sweden'
    'Italy'
```

The sample car with the lowest acceleration is made in the USA, and the sample car with the highest acceleration is made in Germany.

Plot Prediction Intervals for a New Observation in Each Group

Load the sample data.

```
load('carsmall')
```

The variable `Weight` was measured for 100 cars. The variable `Model_Year` has three unique values, `70`, `76`, and `82`, which correspond to model years 1970, 1976, and 1982.

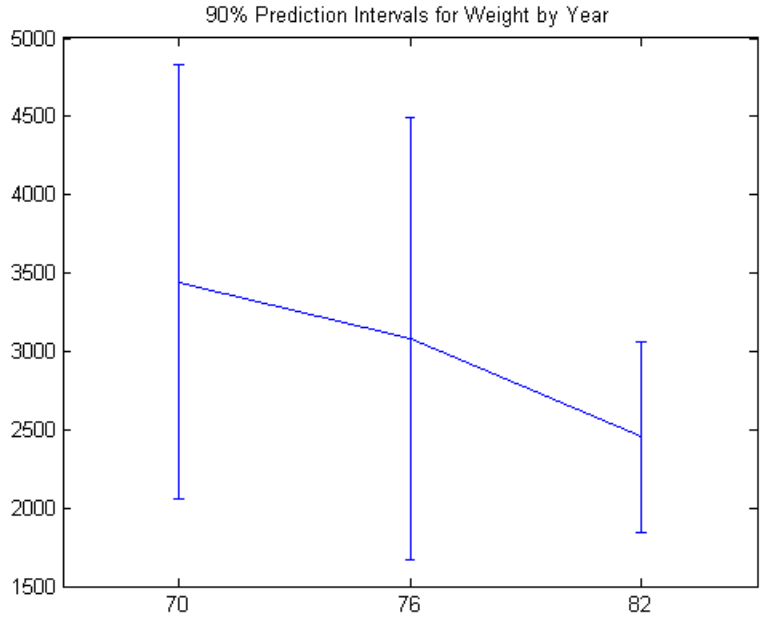
Calculate the mean weight and 90% prediction intervals for each model year.

```
[means,pred,grp] = grpstats(Weight,Model_Year,...
                      {'mean','predci','gname'},'Alpha',0.1);
```

Plot error bars showing the mean weight and 90% prediction intervals, grouped by model year. Label the horizontal axis with the group names.

```
ngrps = length(grp); % Number of groups
```

```
figure()
errorbar((1:ngrps)',means,pred(:,2)-means)
set(gca,'xtick',1:ngrps,'xticklabel',grp)
title('90% Prediction Intervals for Weight by Year')
```



Plot Group Means and Confidence Intervals

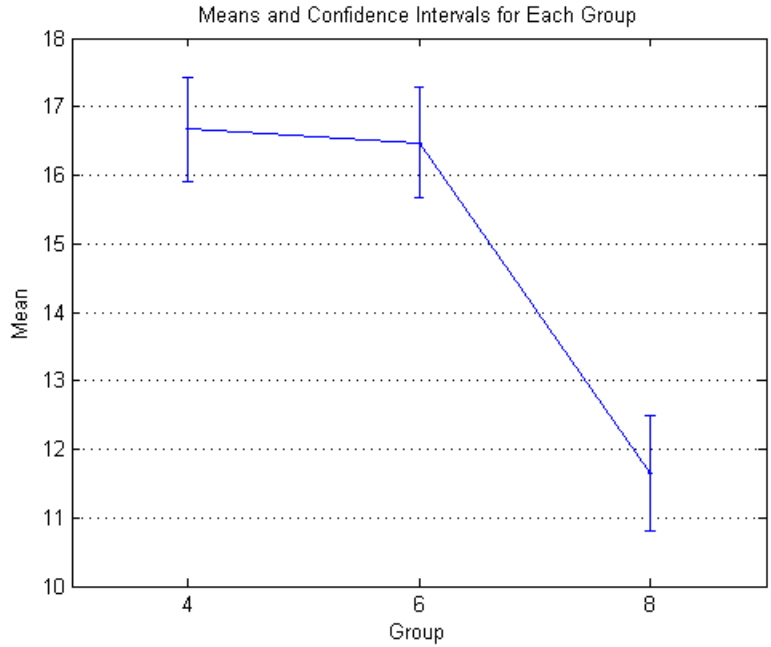
Load the sample data.

```
load('carsmall')
```

The variables `Acceleration` and `Weight` are the acceleration and weight values measured for 100 cars. The variable `Cylinders` is the number of cylinders in each car. The variable `Model_Year` has three unique values, `70`, `76`, and `82`, which correspond to model years 1970, 1976, and 1982.

Plot mean acceleration, grouped by `Cylinders`, with 95% confidence intervals.

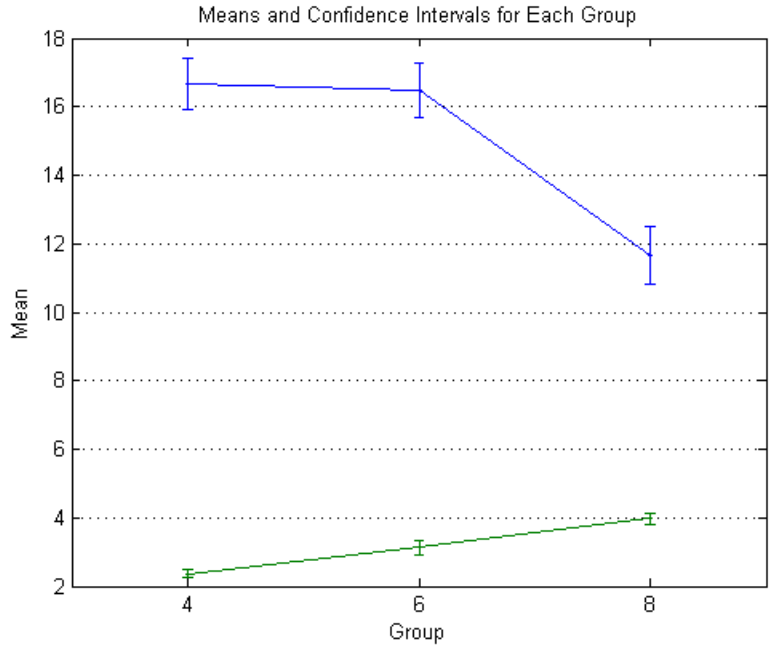
```
grpstats(Acceleration,Cylinders,0.05)
```



The mean acceleration for cars with 8 cylinders is significantly lower than for cars with 4 or 6 cylinders.

Plot mean acceleration and weight, grouped by `Cylinders`, and 95% confidence intervals. Scale the `Weight` values by 1000 so the means of `Weight` and `Acceleration` are the same order of magnitude.

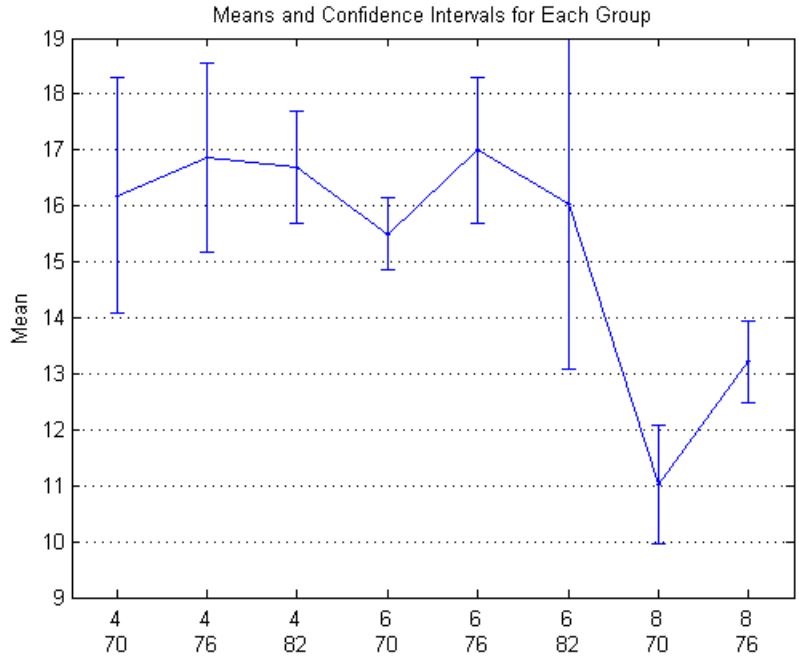
```
grpstats([Acceleration,Weight/1000],Cylinders,0.05)
```



The average weight of cars increases with the number of cylinders, and the average acceleration decreases with the number of cylinders.

Plot mean acceleration, grouped by both `Cylinders` and `Model_Year`. Specify 95% confidence intervals.

```
grpstats(Acceleration,{Cylinders,Model_Year},0.05)
```



There are nine possible combinations of grouping variable values because there are three unique values in `Cylinders` and three unique values in `Model_Year`. The plot does not show 8-cylinder cars with model year 1982 because the data did not include this combination.

The mean acceleration of 8-cylinder cars made in 1976 is significantly larger than the mean acceleration of 8-cylinder cars made in 1970.

- “Summary Statistics Grouped by Category” on page 2-38
- “Test Differences Between Category Means” on page 2-29
- “Plot Data Grouped by Category” on page 2-25
- “Calculations on Dataset Arrays” on page 2-108

Input Arguments

`tbl` — Input data

table | dataset array

Input data, specified as a table or dataset array. tbl must include at least one variable that is a grouping variable.

Summary statistics can only be calculated for variables that have a numeric or logical data type. If any variables in tbl (other than the grouping variables) are not numeric or logical arrays, then use the name-value pair argument DataVars to specify the names or column numbers of the numeric and logical variables for which to calculate summary statistics.

`groupvar` — Identifiers for the grouping variables

cell array of strings | vector of positive integers | logical vector | `[]`

Identifiers for the grouping variables in the input data, tbl, specified as one of the following:

String or cell array of strings	Names of the grouping variables
Positive integer or vector of positive integers	Variable numbers of the grouping variables
Vector of logical values with number of elements equal to the number of variables in tbl	Logical indicator with value `true` for grouping variables and `false` otherwise
`[]`	No groups (returns summary statistics for all data)

Any variable that is identified by `groupvar` as a grouping variable must have a valid grouping variable data type: categorical array, logical or numeric vector, datetime or duration vector, or cell array of strings.

For example, consider an input table, `tbl`, with six variables. The fourth variable is named `Gender`. To be a valid grouping variable, the data type of `Gender` might be a cell array of strings or a nominal array, with the unique values `Male` and `Female`. To specify the variable `Gender` as the grouping variable, you can use any of these syntaxes:

- `statarray = grpstats(tbl,'Gender')`
- `statarray = grpstats(tbl,4)`
- `statarray = grpstats(tbl,logical([0 0 0 1 0 0]))`

Data Types: `double` | `logical` | `cell` | `char`

`whichstats` — Types of summary statistics

string | function handle

Types of summary statistics to compute, specified as a string or function handle, or a cell array of strings and function handles. Use a cell array to specify multiple types of summary statistics.

Possible string values are:

`'mean'`	Mean
`'sem'`	Standard error of the mean
`'numel'`	Count, or number, of non-`NaN` elements
`'gname'`	Group name
`'std'`	Standard deviation
`'var'`	Variance
`'min'`	Minimum
`'max'`	Maximum
`'range'`	Range
`'meanci'`	95% confidence interval for the mean
`'predci'`	95% prediction interval for a new observation

Example: `[stat1,stat2] = grpstats(X,group,{'mean','sem'})`

You can specify different significance levels for the `'meanci'` and `'predci'` options using the name-value pair argument, Alpha.

To specify other types of summary statistics, you can use function handles. You can use the handle to any function that accepts a column or matrix of data, and returns the same size output each time `grpstats` calls it (even if the output for some groups is empty).

If the function accepts a column of data, then the function can return either a scalar value, or an *nvals*-by-1 column vector for descriptive statistics of length *nvals* (for example, confidence intervals have length two). If the function accepts a matrix, it must either return a 1-by-*ncols* row vector, or an *nvals*-by-*ncols* matrix, where *ncols* is the number of columns in the input data matrix.

Example:
```
[stat1,stat2,stat3] = grpstats(X,group,
{'mean','std',@skewness})
```

For functions that do not compute column-wise statistics, specify the computation direction while specifying the function.

Example: `stat1 = grpstats(X,group,@(x)sum(x,1))`

Data Types: `char` | `function_handle`

`alpha` — Significance level

scalar value in the range (0,1)

Significance level, specified as a scalar value in the range (0,1).

- When you specify `'meanci'` or `'predci'` in whichstats, you can use `alpha` to specify the significance level for the confidence or prediction intervals. If you specify `alpha`, then `grpstats` returns 100×(1 – `alpha`)% confidence or prediction intervals. If you do not specify `alpha`, then `grpstats` returns 95% intervals (`alpha = 0.05`).
- Use `alpha` with the grpstats(X,group,alpha) syntax to plot group means and corresponding 100×(1 – alpha)% confidence intervals.

Data Types: `double`

`X` — Input data

vector | matrix

Input data, specified as a vector or a matrix. If `X` is a matrix, then `grpstats` returns summary statistics for each column of `X`.

Data Types: `double` | `single`

`group` — Grouping variable

categorical array | logical or numeric vector | datetime or duration vector | cell array of strings | `[]`

Grouping variable, specified as a categorical array, logical or numeric vector, or cell array of strings. Each unique value in a grouping variable defines a group. `grpstats` groups data for summary statistics using the grouping variable values.

There must be a grouping variable value for each row of the input data X. Observations (rows) with the same value of the grouping variable are in the same group. Use `[]` to compute summary statistics for all data, without using groups.

For example, if `Gender` is a cell array of strings with values `'Male'` and `'Female'`, you can use `Gender` as a grouping variable to summarize your data by gender.

You can also use more than one grouping variable to group data for summary statistics. In this case, specify a cell array of grouping variables.

For example, if `Smoker` is a logical vector with values `0` for nonsmokers and `1` for smokers, then specifying the cell array `{Gender,Smoker}` divides observations into four groups: Male Smoker, Male Nonsmoker, Female Smoker, and Female Nonsmoker. `grpstats` returns summary statistics only for the combinations of values that exist in the input grouping variables (not all possible combinations).

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'DataVars',[1,3,4],'Alpha',0.01` specifies that summary statistics be calculated for the 1st, 3rd, and 4th variables in a dataset array, with 99% confidence intervals.

`'Alpha'` — Significance level

`0.05` (default) | scalar value in the range (0,1)

Significance level for confidence and prediction intervals, specified as the comma-separated pair consisting of `'Alpha'` and a scalar value in the range (0,1).

When you include `'meanci'` or `'predci'` in whichstats, you can use `Alpha` to specify the significance level for confidence or prediction intervals. If you specify the value α, then `grpstats` returns $100\times(1-\alpha)\%$ confidence or prediction intervals.

If you do not specify a value for `Alpha`, then `grpstats` returns 95% intervals ($\alpha = 0.05$).

Example: `'Alpha',0.1`

Data Types: `double`

`'DataVars'` — Variable names or columns

cell array of strings | vector of positive integers | logical vector

Variable names or columns indicating which variables in the input data tbl you want to compute summary statistics for, specified as the comma-separated pair consisting of `'DataVars'` and a cell array of strings, vector of positive integers, or a logical vector. Use a string to specify a variable name, a positive integer to specify a variable column

number, or logical values to indicate which variables to include (`true` if you want to compute summary statistics, `false` otherwise).

You must specify `DataVars` if there are any variables in tbl (other than the grouping variables specified in groupvar) that are not numeric or logical arrays. Summary statistics can only be calculated for variables that have a numeric or logical data type.

Example: `'DataVars',{'Height','Weight'}`

Data Types: `double | cell | char`

`'VarNames'` — Variable names for output

cell array of strings

Variable names for the output statarray, specified as the comma-separated pair consisting of `'VarNames'` and a cell array of strings. By default, `grpstats` constructs output variable names by appending a prefix to the variable names from the input data tbl. This prefix corresponds to the summary statistic name.

Example: `'VarNames',{'Gender','GroupCount','MaleMean','FemaleMean'}`

Data Types: `cell`

Output Arguments

`statarray` — Group summary statistics

table | dataset array

Group summary statistics, returned as a table or a dataset array. If tbl is a table, `grpstats` returns statarray as a table. If tbl is a dataset array, `grpstats` returns statarray as a dataset array.

`statarray` contains summary statistic values for the groups of data in tbl determined by the levels of the grouping variables specified by groupvar. There is a row in `statarray` for each observed value or combination of values in the variables specified by `groupvar`. The output `statarray` contains:

- All grouping variables specified by `groupvar`.
- The variable `GroupCount`, containing the number of observations in each group.
- Group summary statistic values for all variables in tbl (other than those specified by groupvar), or for only the variables specified using DataVars.

The total number of variables in `statarray` is *ngroupvars* + 1 + *ndatavars*×*nstats*, where *ngroupvars* is the number of variables in `groupvar`, *ndatavars* is the number of variables for which summary statistics are computed, and *nstats* is the number of summary statistic types specified in whichstats.

`grpstats` assigns default names to the variables in `statarray`, unless you specify variable names using the name-value pair argument VarNames.

`means` — Group means
column vector | array

Group means for the groups of data in the vector or matrix X determined by the levels of group, returned as an *ngroups*-by-*ncols* array. Here, *ngroups* is the number of unique values in the grouping variable, and *ncols* is the number of columns in X. If `X` is a vector, then `means` is a column vector.

`stats1,...,statsN` — Group summary statistics
column vectors | arrays

Group summary statistics for the groups of data in the vector or matrix X determined by the levels of group, returned as *ngroups*-by-*ncols* arrays. Here, *ngroups* is the number of unique values in the grouping variable, and *ncols* is the number of columns in X. You must specify an output argument for each type of summary statistic specified in whichstats.

If a summary statistic type in `whichstats` returns a value of length *nvals* (for example, a confidence interval is a descriptive statistic of length two), then the corresponding output argument is an *ngroups*-by-*ncols*-by-*nvals* array.

More About

Algorithms

- `grpstats` treats `NaN`s as missing values, and removes them from the input data before calculating summary statistics.
- `grpstats` ignores empty group names.

- "Dataset Arrays" on page 2-132
- "Grouping Variables" on page 2-52

- “Categorical Arrays” on page 2-42

See Also

`dataset` | `table`

grpstats

Class: RepeatedMeasuresModel

Compute descriptive statistics of repeated measures data by group

Syntax

```
statstbl = grpstats(rm,g)
statstbl = grpstats(rm,g,stats)
```

Description

`statstbl = grpstats(rm,g)` returns the count, mean, and variance for the data used to fit the repeated measures model rm, grouped by the factors, g.

`statstbl = grpstats(rm,g,stats)` returns the statistics specified by stats for the data used to fit the repeated measures model rm, grouped by the factors, g.

Tips

- `grpstats` computes results separately for each group. The results do not depend on the fitted repeated measures model. It computes the results on all available data, without omitting entire rows that contain `NaN`s.

Input Arguments

`rm` — Repeated measures model

`RepeatedMeasuresModel` object

Repeated measures model, returned as a `RepeatedMeasuresModel` object.

For properties and methods of this object, see `RepeatedMeasuresModel`.

g — Name of grouping factor or factors

string | cell array of strings

Name of grouping factor or factors, specified as a string or cell array of strings.

Example: `'Drug'`

Example: `{'Drug','Sex'}`

Data Types: `char`

stats — Statistics to compute

string | function handle | cell array of multiple strings and function handles

Statistics to compute, specified as one of the following:

- String specifying the name of the statistics to compute. Names can be one of the following.

Name	Description
`'mean'`	Mean
`'sem'`	Standard error of the mean
`'numel'`	Count or number of elements
`'gname'`	Group name
`'std'`	Standard deviation
`'var'`	Variance
`'min'`	Minimum
`'max'`	Maximum
`'range'`	Maximum minus minimum
`'meanci'`	95% confidence interval for the mean
`'predci'`	95% prediction interval for a new observation

- Function handle — The function you specify must accept a vector of response values for a single group, and compute descriptive statistics for it. A function should typically return a value that has one row. A function must return the same size output each time `grpstats` calls it, even if the input for some groups is empty.
- A cell array of strings and function handles.

Example: `@median`

Example: `@skewness`

Example: `'gname'`

Example: `{'gname','range','predci'}`

Data Types: `char` | `function_handle` | `cell`

Output Arguments

`statstbl` — Statistics values for each group

table

Statistics values for each group, returned as a table.

Examples

Compute Group Statistics

Load the sample data.

```
load fisheriris
```

The column vector, `species` consists of iris flowers of three different species: setosa, versicolor, and virginica. The double matrix `meas` consists of four types of measurements on the flowers: the length and width of sepals and petals in centimeters, respectively.

Store the data in a table array.

```
t = table(species,meas(:,1),meas(:,2),meas(:,3),meas(:,4),...
'VariableNames',{'species','meas1','meas2','meas3','meas4'});
Meas = dataset([1 2 3 4]','VarNames',{'Measurements'});
```

Fit a repeated measures model, where the measurements are the responses and the species is the predictor variable.

```
rm = fitrm(t,'meas1-meas4~species','WithinDesign',Meas);
```

Compute group counts, mean, and standard deviation with respect to species.

```
grpstats(rm,'species')
```

```
ans =

    species       GroupCount     mean      std
    ___________    __________    ______    ______

    'setosa'        200          2.5355    1.8483
    'versicolor'    200           3.573    1.7624
    'virginica'     200           4.285    1.9154
```

Now, compute the range of data and 95% confidence intervals for the group means for the factor species. Also display the group name.

```
grpstats(rm,'species',{'gname','range','predci'})
```

```
ans =

    species          gname        GroupCount    range          predci
    ___________    ___________    __________    _____    ____________________

    'setosa'        'setosa'        200           5.7       -1.1185      6.1895
    'versicolor'    'versicolor'    200             6      0.088976       7.057
    'virginica'     'virginica'     200           6.5        0.4985      8.0715
```

Statistics for Data Grouped by Two Factors

Load the sample data.

```
load repeatedmeas
```

The table `between` includes the between-subject variables age, IQ, group, gender, and eight repeated measures $y1$ through $y8$ as responses. The table `within` includes the within-subject variables $w1$ and $w2$. This is simulated data.

Fit a repeated measures model, where the repeated measures $y1$ through $y8$ are the responses, and age, IQ, group, gender, and the group-gender interaction are the predictor variables. Also specify the within-subject design matrix.

```
rm = fitrm(between,'y1-y8 ~ Group*Gender + Age + IQ','WithinDesign',within);
```

Compute group counts, mean, standard deviation, skewness, and kurtosis of data grouped by the factors `Group` and `Gender`.

```
GS = grpstats(rm,{'Group','Gender'},{'mean','std',@skewness,@kurtosis})
```

```
GS =
```

Group	Gender	GroupCount	mean	std	skewness	kurtosis
A	Female	40	16.554	21.498	0.35324	3.7807
A	Male	40	9.8335	20.602	-0.38722	2.7834
B	Female	40	11.261	25.779	-0.49177	4.1484
B	Male	40	3.6078	24.646	0.55447	2.7966
C	Female	40	-11.335	27.186	1.7499	6.1429
C	Male	40	-14.028	31.984	1.7362	5.141

See Also

`fitrm` | `plot`

gscatter

Scatter plot by group

Syntax

```
gscatter(x,y,group)
gscatter(x,y,group,clr,sym,siz)
gscatter(x,y,group,clr,sym,siz,doleg)
gscatter(x,y,group,clr,sym,siz,doleg,xnam,ynam)
h = gscatter(...)
```

Description

`gscatter(x,y,group)` creates a scatter plot of `x` and `y`, grouped by `group`. `x` and `y` are vectors of the same size. `group` is a grouping variable in the form of a categorical variable, vector, string array, or cell array of strings. Alternatively, `group` can be a cell array containing several grouping variables (such as `{g1 g2 g3}`), in which case observations are in the same group if they have common values of all grouping variables. Points in the same group and appear on the graph with the same marker and color.

`gscatter(x,y,group,clr,sym,siz)` specifies the color, marker type, and size for each group. *`clr`* is a string array of colors recognized by the `plot` function. *`sym`* is a string array of symbols recognized by the `plot` command, with the default value `'.'`. `siz` is a vector of sizes, with the default determined by the `'DefaultLineMarkerSize'` property. If you do not specify enough values for all groups, `gscatter` cycles through the specified values as needed.

`gscatter(x,y,group,clr,sym,siz,doleg)` controls whether a legend is displayed on the graph (*`doleg`* is `'on'`, the default) or not (*`doleg`* is `'off'`).

`gscatter(x,y,group,clr,sym,siz,doleg,xnam,ynam)` specifies the name to use for the *x*-axis and *y*-axis labels. If the `x` and `y` inputs are simple variable names and `xnam` and `ynam` are omitted, `gscatter` labels the axes with the variable names.

`h = gscatter(...)` returns an array of handles to the lines on the graph.

Examples

Scatter Plot of Climate and Housing Ratings

Load the sample data.

```
load discrim
```

The sample data contains ratings of cities according to nine factors such as climate, housing, education, and health in the matrix `ratings` .

Plot the relationship between the ratings for climate (first column) and housing (second column) grouped by city size in the matrix `group`. Choose different colors and plotting symbols for each group.

```
figure;
gscatter(ratings(:,1),ratings(:,2),group,'br','xo')
xlabel('climate');
ylabel('housing');
```

`gplotmatrix` | `grpstats` | `scatter`

gt

Class: qrandstream

Greater than relation for handles

Syntax

```
h1 > h2
```

Description

`h1 > h2` performs element-wise comparisons between handle arrays `h1` and `h2`. `h1` and `h2` must be of the same dimensions unless one is a scalar. The result is a logical array of the same dimensions, where each element is an element-wise > result.

If one of `h1` or `h2` is scalar, scalar expansion is performed and the result will match the dimensions of the array that is not scalar.

`tf = gt(h1, h2)` stores the result in a logical array of the same dimensions.

haltonset class

Superclasses: qrandset

Halton quasi-random point sets

Description

`haltonset` is a quasi-random point set class that produces points from the Halton sequence.

Construction

.haltonset	Construct Halton quasi-random point set

Methods

Inherited Methods

Methods in the following table are inherited from `qrandset`.

disp	Display qrandset object
end	Last index in indexing expression for point set
length	Length of point set
ndims	Number of dimensions in matrix
net	Generate quasi-random point set
scramble	Scramble quasi-random point set

size	Number of dimensions in matrix
subsref	Subscripted reference for qrandset

Properties

Inherited Properties

Properties in the following table are inherited from `qrandset`.

Dimensions	Number of dimensions
Leap	Interval between points
ScrambleMethod	Settings that control scrambling
Skip	Number of initial points to omit from sequence
Type	Name of sequence on which point set `P` is based

Copy Semantics

Handle. To learn how this affects your use of the class, see Comparing Handle and Value Classes in the MATLAB Object-Oriented Programming documentation.

`sobolset`

How To

- "Quasi-Random Point Sets" on page 6-17

haltonset

Class: haltonset

Construct Halton quasi-random point set

Syntax

```
p = haltonset(d)
p = haltonset(d,prop1,val1,prop2,val2,...)
```

Description

`p = haltonset(d)` constructs a `d`-dimensional point set `p` of the `haltonset` class, with default property settings.

`p = haltonset(d,prop1,val1,prop2,val2,...)` specifies property name/value pairs used to construct `p`.

The object `p` returned by `haltonset` encapsulates properties of a specified quasi-random sequence. The point set is finite, with a length determined by the `Skip` and `Leap` properties and by limits on the size of point set indices (maximum value of 2^{53}). Values of the point set are not generated and stored in memory until you access `p` using `net` or parenthesis indexing.

Examples

Generate a 3-D Halton point set, skip the first 1000 values, and then retain every 101st point:

```
p = haltonset(3,'Skip',1e3,'Leap',1e2)
p =
    Halton point set in 3 dimensions (8.918019e+013 points)
    Properties:
              Skip : 1000
              Leap : 100
    ScrambleMethod : none
```

Use `scramble` to apply reverse-radix scrambling:

```
p = scramble(p,'RR2')
p =
    Halton point set in 3 dimensions (8.918019e+013 points)
    Properties:
              Skip : 1000
              Leap : 100
    ScrambleMethod : RR2
```

Use `net` to generate the first four points:

```
X0 = net(p,4)
X0 =
    0.0928    0.6950    0.0029
    0.6958    0.2958    0.8269
    0.3013    0.6497    0.4141
    0.9087    0.7883    0.2166
```

Use parenthesis indexing to generate every third point, up to the 11th point:

```
X = p(1:3:11,:)
X =
    0.0928    0.6950    0.0029
    0.9087    0.7883    0.2166
    0.3843    0.9840    0.9878
    0.6831    0.7357    0.7923
```

See Also

`net` | `scramble` | `sobolset`

harmmean

Harmonic mean

Syntax

```
m = harmmean(X)
harmmean(X,dim)
```

Description

`m = harmmean(X)` calculates the harmonic mean of a sample. For vectors, `harmmean(x)` is the harmonic mean of the elements in `x`. For matrices, `harmmean(X)` is a row vector containing the harmonic means of each column. For *N*-dimensional arrays, `harmmean` operates along the first nonsingleton dimension of `X`.

`harmmean(X,dim)` takes the harmonic mean along dimension `dim` of `X`.

The harmonic mean is

$$m = \frac{n}{\sum_{i=1}^{n} \frac{1}{x_i}}$$

Examples

The arithmetic mean is greater than or equal to the harmonic mean.

```
x = exprnd(1,10,6);

harmonic = harmmean(x)
harmonic =
  0.3382  0.3200  0.3710  0.0540  0.4936  0.0907

average = mean(x)
average =
```

```
  1.3509   1.1583   0.9741   0.5319   1.0088   0.8122
```

See Also

`mean` | `median` | `geomean` | `trimmean`

hist3

Bivariate histogram

Syntax

```
hist3(X)
hist3(X,nbins)
hist3(X,ctrs)
hist3(X,'Edges',edges)
N = hist3(X,...)
[N,C] = hist3(X,...)
hist3(...,param1,val1,param2,val2,...)
```

Description

`hist3(X)` bins the elements of the *m*-by-2 matrix `X` into a 10-by-10 grid of equally spaced containers, and plots a histogram. Each column of **`X`** corresponds to one dimension in the bin grid.

`hist3(X,nbins)` plots a histogram using an `nbins(1)`-by-`nbins(2)` grid of bins. `hist3(X,'Nbins',nbins)` is equivalent to `hist3(X,nbins)`.

`hist3(X,ctrs)`, where `ctrs` is a two-element cell array of numeric vectors with monotonically non-decreasing values, uses a 2-D grid of bins centered on `ctrs{1}` in the first dimension and on `ctrs{2}` in the second. `hist3` assigns rows of `X` falling outside the range of that grid to the bins along the outer edges of the grid, and ignores rows of `X` containing `NaN`s. `hist3(X,'Ctrs',ctrs)` is equivalent to `hist3(X,ctrs)`.

`hist3(X,'Edges',edges)`, where `edges` is a two-element cell array of numeric vectors with monotonically non-decreasing values, uses a 2-D grid of bins with edges at `edges{1}` in the first dimension and at `edges{2}` in the second. The (*i*, *j*)th bin includes the value `X(k,:)` if

```
edges{1}(i) <= X(k,1) < edges{1}(i+1)
edges{2}(j) <= X(k,2) < edges{2}(j+1)
```

Rows of `X` that fall on the upper edges of the grid, `edges{1}(end)` or `edges{2}(end)`, are counted in the `(I,j)`th or `(i,J)`th bins, where `I` and `J` are the lengths of `edges{1}` and `edges{2}`. `hist3` does not count rows of `X` falling outside the range of the grid. Use `-Inf` and `Inf` in `edges` to include all non-`NaN` values.

`N = hist3(X,...)` returns a matrix containing the number of elements of `X` that fall in each bin of the grid, and does not plot the histogram.

`[N,C] = hist3(X,...)` returns the positions of the bin centers in a 1-by-2 cell array of numeric vectors, and does not plot the histogram. `hist3(ax,X,...)` plots onto an `axes` with handle `ax` instead of the current `axes`. See the `axes` reference page for more information about handles to plots.

`hist3(...,`*`param1`*`,`*`val1`*`,`*`param2`*`,`*`val2`*`,...)` allows you to specify graphics parameter name/value pairs to fine-tune the plot.

Examples

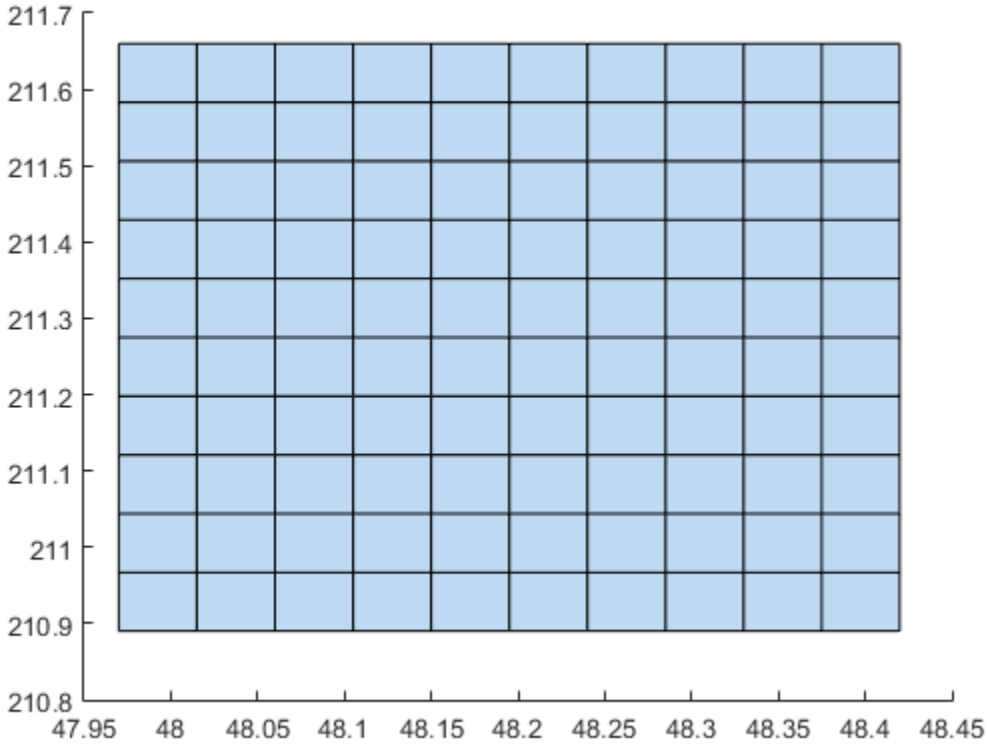
Plot Density Histogram with Intensity Map

Load the sample data.

```
load seamount
```

Correct grid for negative y-values and draw histogram in 2D.

```
hold on
dat = [-y,x];
hist3(dat)
```



Extract histogram data.

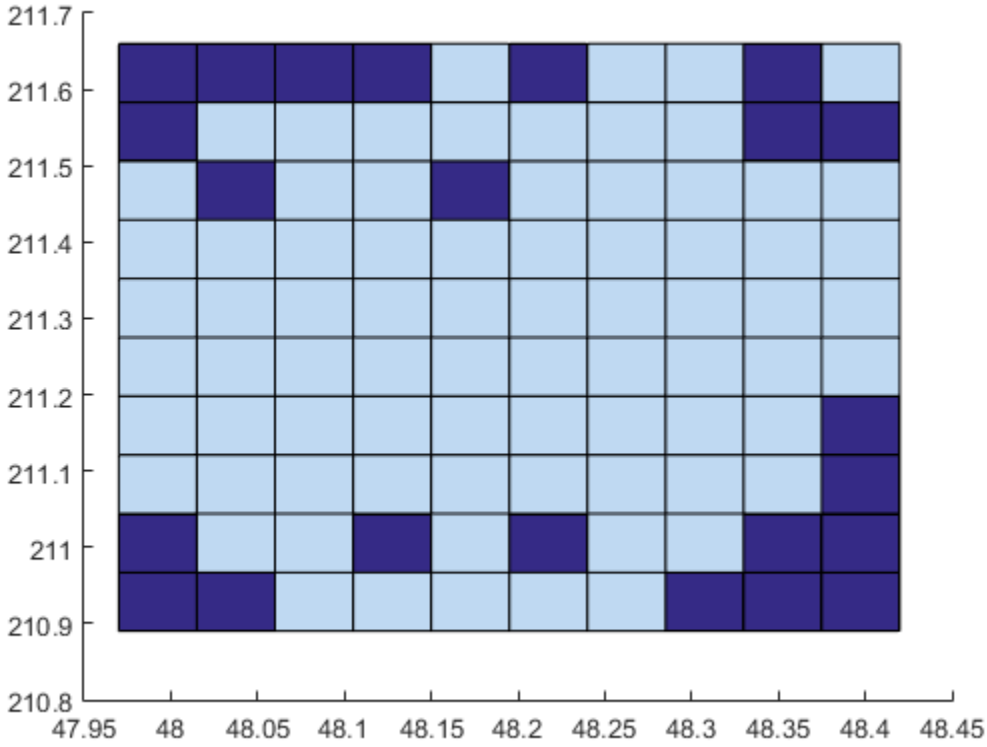
```
n = hist3(dat); % default is to 10x10 bins
n1 = n';
n1(size(n,1) + 1, size(n,2) + 1) = 0;
```

Generate grid for 2-D projected view of intensities.

```
xb = linspace(min(dat(:,1)),max(dat(:,1)),size(n,1)+1);
yb = linspace(min(dat(:,2)),max(dat(:,2)),size(n,1)+1);
```

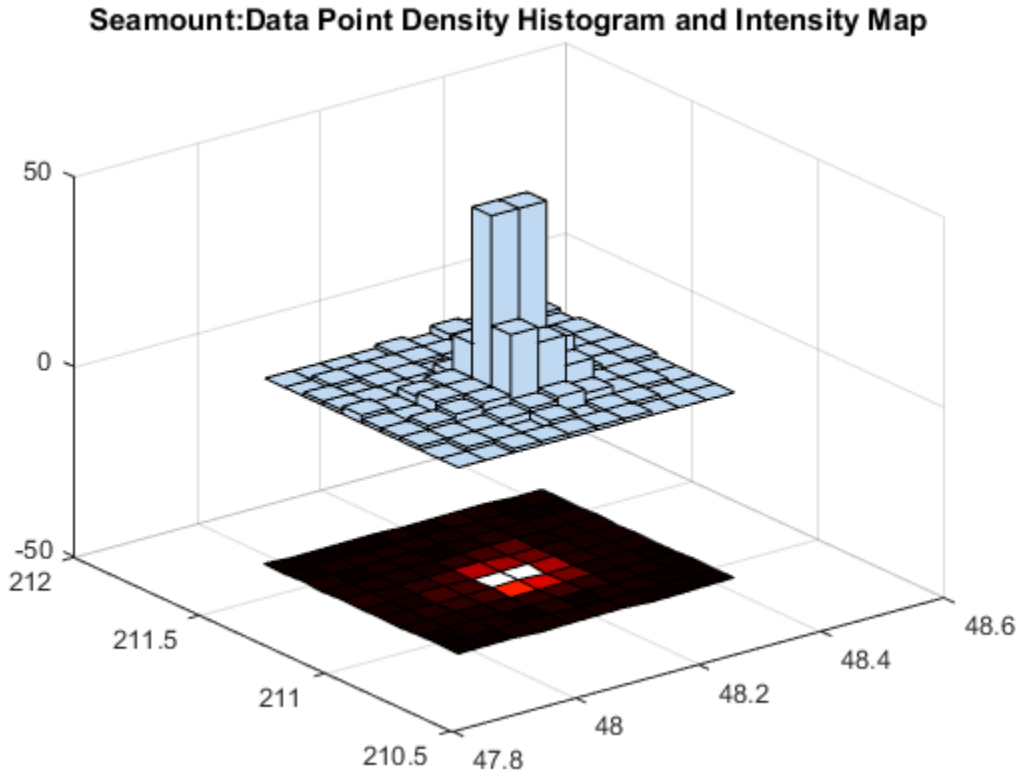
Make a pseudocolor plot.

```
h = pcolor(xb,yb,n1);
```



Set the z-level and colormap of the displayed grid, and display the default 3-D perspective view.

```
h.ZData = ones(size(n1)) * -max(max(n));
colormap(hot) % heat map
title('Seamount:Data Point Density Histogram and Intensity Map');
grid on
view(3);
```



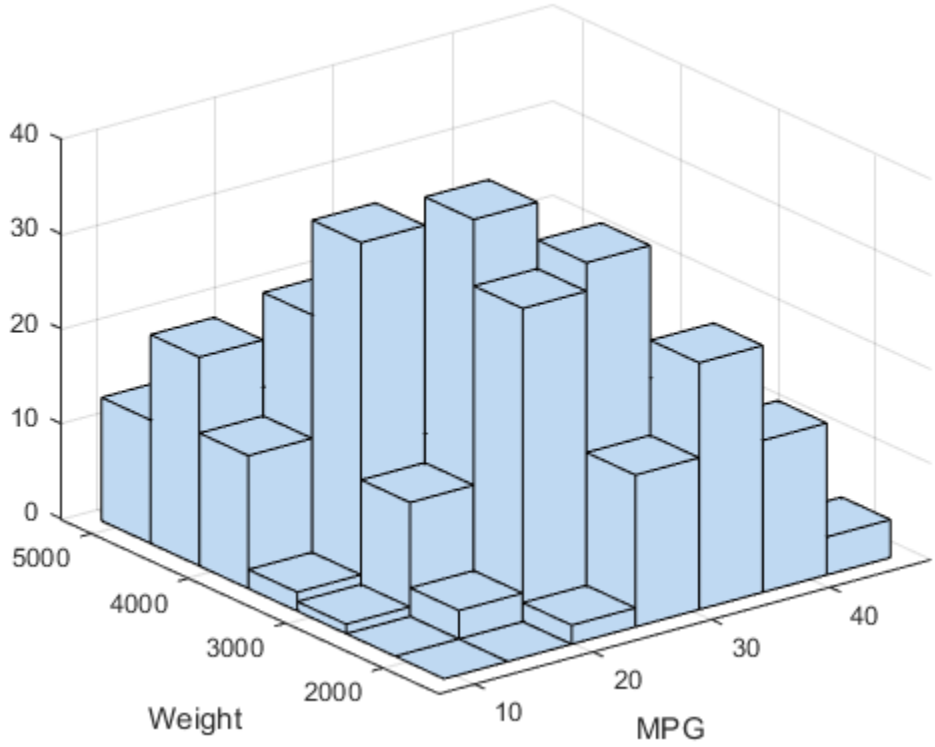
Histogram with Semi-Transparent Bars

Load the sample data.

```
load carbig
```

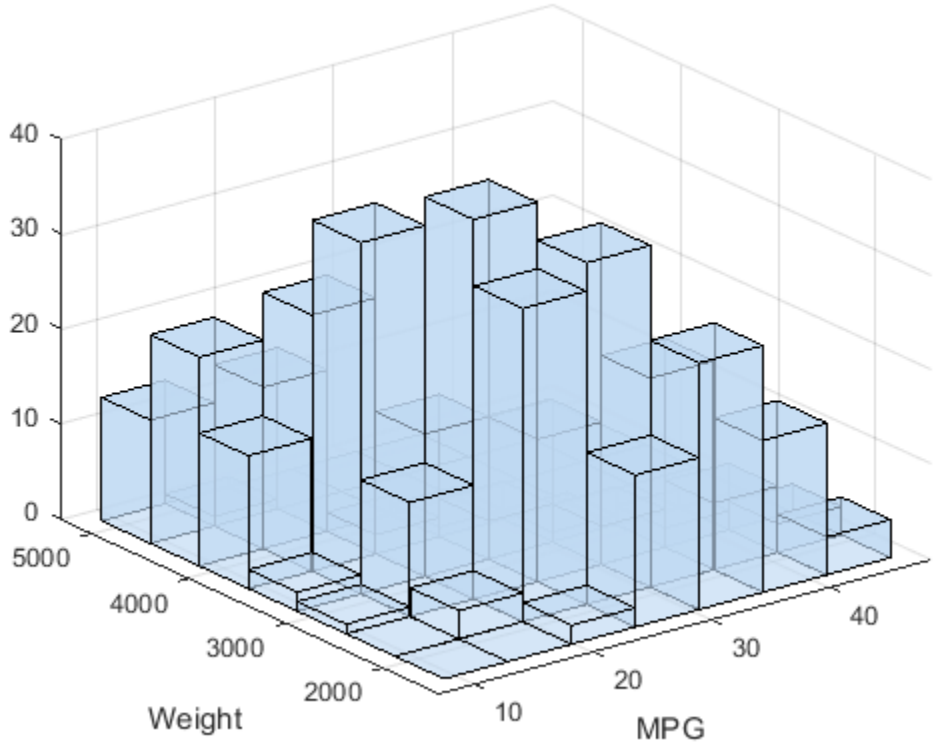
Use the data to make histogram on a 7-by-7 grid of bins.

```
X = [MPG,Weight];
hist3(X,[7 7]);
xlabel('MPG'); ylabel('Weight');
```



Make a histogram with semi-transparent bars.

```
hist3(X,[7 7],'FaceAlpha',.65);
xlabel('MPG'); ylabel('Weight');
set(gcf,'renderer','opengl');
```



Specify bin centers, different in each direction; get back counts, but don't make the plot.

```
cnt = hist3(X, {0:10:50 2000:500:5000});
```

Histogram Bars Colored According to Height

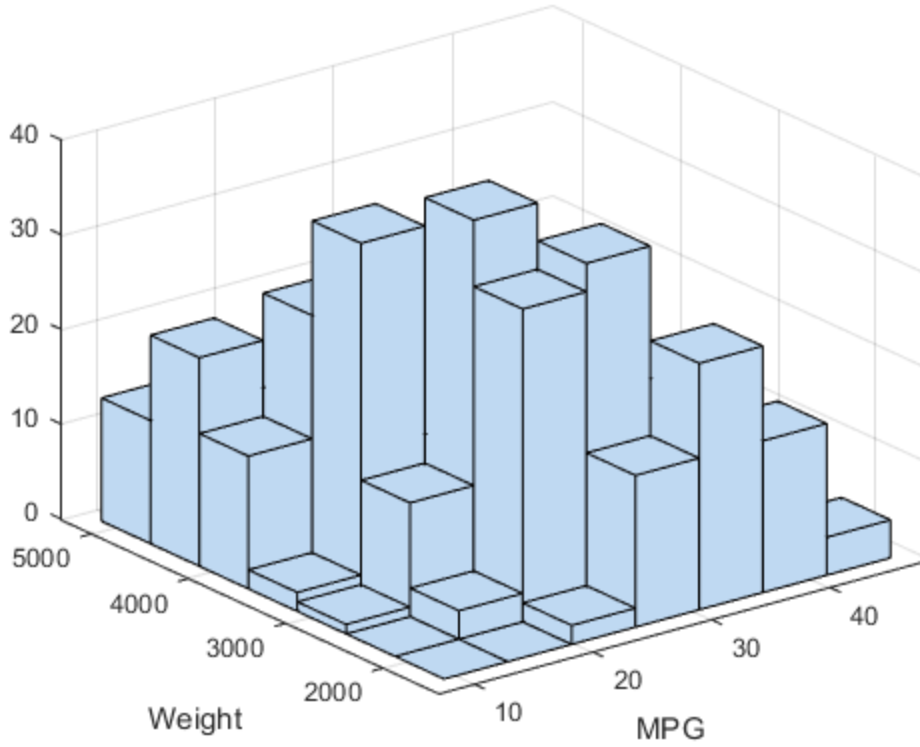
Load the sample data.

```
load carbig
```

Make a histogram on a 7-by-7 grid of bins.

```
X = [MPG,Weight];
hist3(X,[7 7]);
```

```
xlabel('MPG'); ylabel('Weight');
set(gcf,'renderer','opengl');
```



Color the bars based on the frequency of the observations, i.e. according to the height of the bars.

```
set(get(gca,'child'),'FaceColor','interp','CDataMode','auto');
```

`accumarray` | `histc` | `bar` | `bar3` | `histogram`

histfit

Histogram with a distribution fit

Syntax

```
histfit(data)
histfit(data,nbins)
histfit(data,nbins,dist)

h = histfit( ___ )
```

Description

`histfit(data)` plots a histogram of values in `data` using the number of bins equal to the square root of the number of elements in `data` and fits a normal density function.

`histfit(data,nbins)` plots a histogram using `nbins` bins and fits a normal density function.

`histfit(data,nbins,dist)` plots a histogram with `nbins` bins and fits a density function from the distribution specified by `dist`.

`h = histfit( ___ )` returns a vector of handles `h`, where `h(1)` is the handle to the histogram and `h(2)` is the handle to the density curve. It can include any of the input arguments in previous syntaxes.

Examples

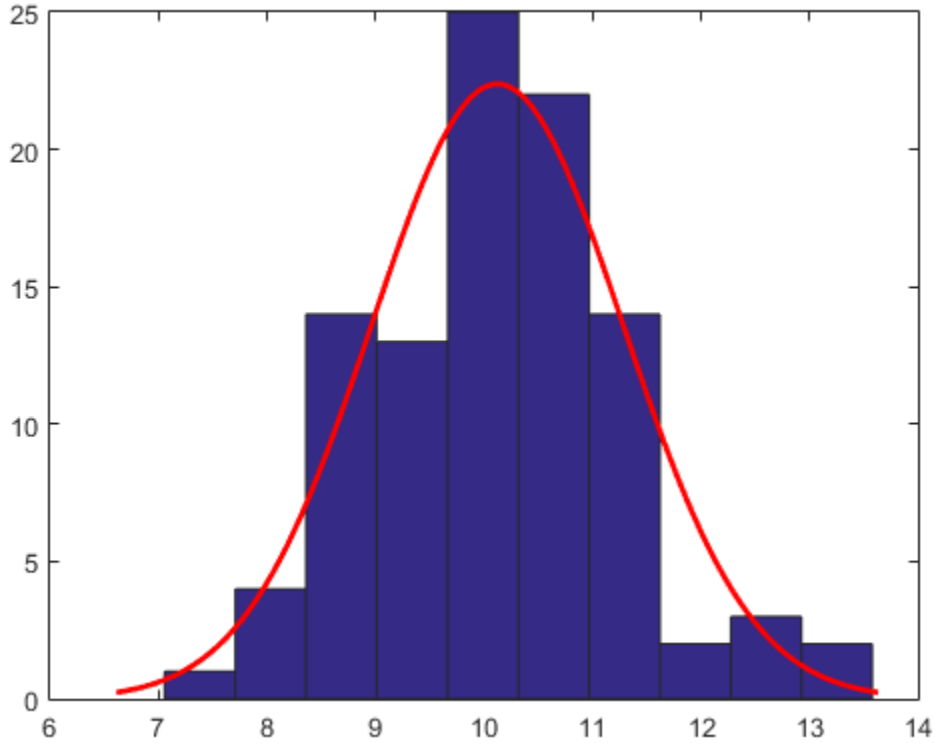
Histogram with a Normal Distribution Fit

Generate a sample of size 100 from a normal distribution with mean 10 and variance 1.

```
rng default; % For reproducibility
r = normrnd(10,1,100,1);
```

Construct a histogram with a normal distribution fit.

```
histfit(r)
```



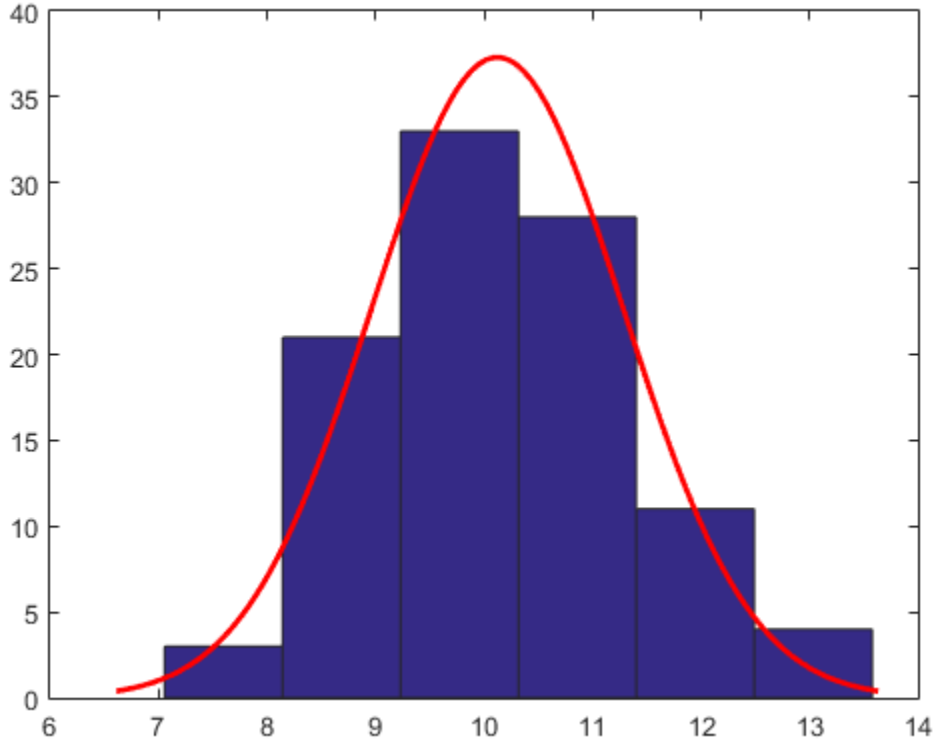
Histogram for a Given Number of Bins

Generate a sample of size 100 from a normal distribution with mean 10 and variance 1.

```
rng default; % For reproducibility
r = normrnd(10,1,100,1);
```

Construct a histogram using six bins with a normal distribution fit.

```
histfit(r,6)
```



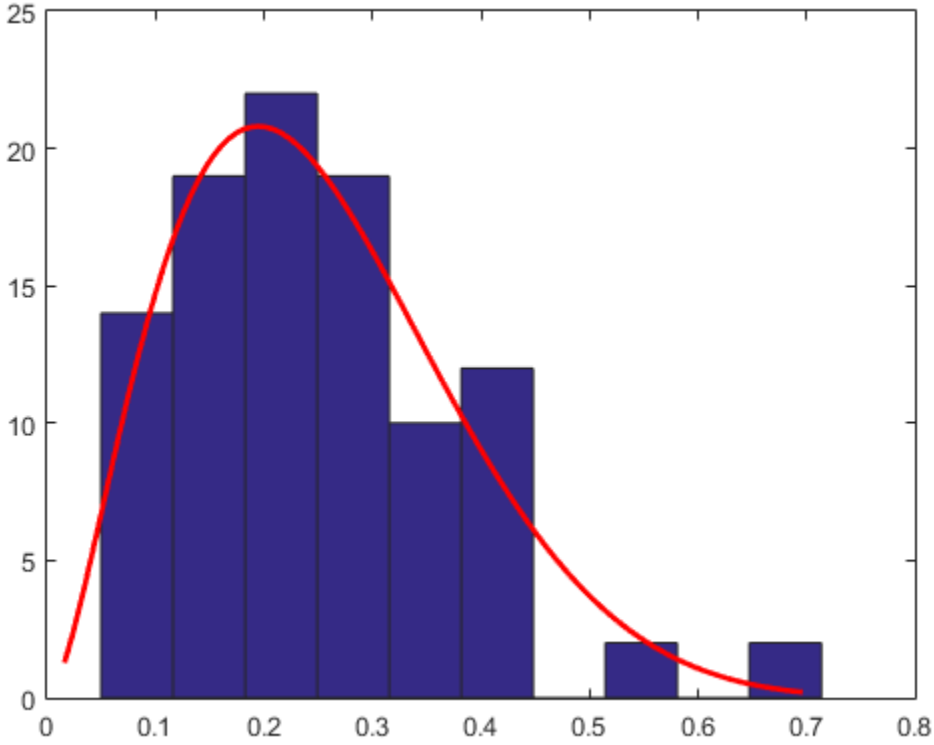
Histogram with a Specified Distribution Fit

Generate a sample of size 100 from a beta distribution with parameters (3,10).

```
rng default;  % For reproducibility
b = betarnd(3,10,100,1);
```

Construct a histogram using 10 bins with a beta distribution fit.

```
histfit(b,10,'beta')
```



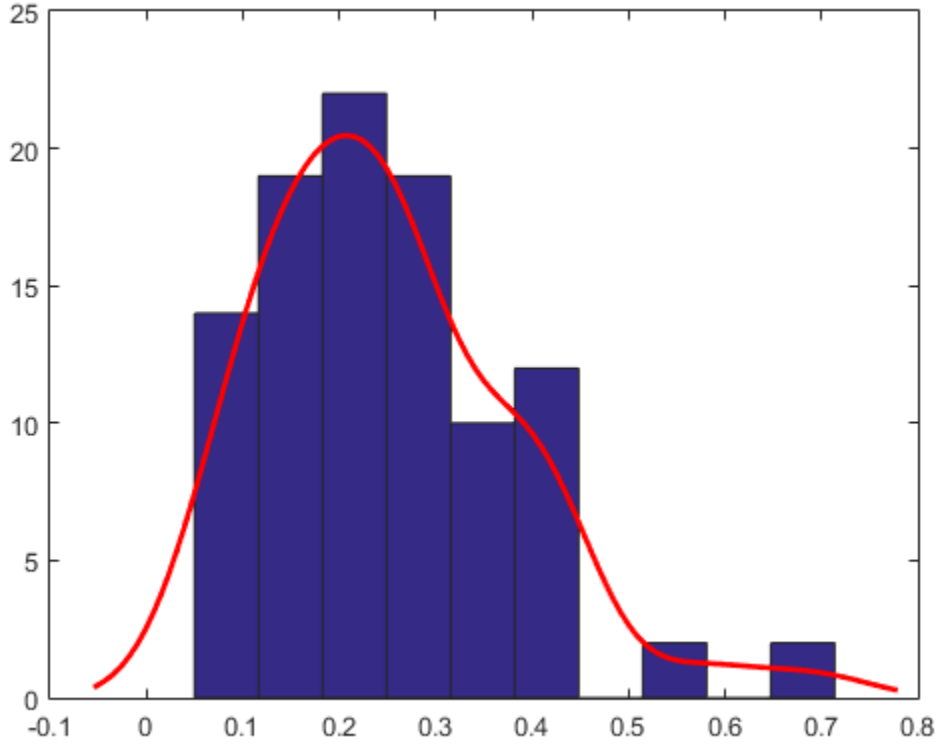
Histogram with a Kernel Smoothing Function Fit

Generate a sample of size 100 from a beta distribution with parameters (3,10).

```
rng default;  % For reproducibility
b = betarnd(3,10,[100,1]);
```

Construct a histogram using 10 bins with a smoothing function fit.

```
histfit(b,10,'kernel')
```



Handle for a Histogram with a Distribution Fit

Generate a sample of size 100 from a normal distribution with mean 10 and variance 1.

```
rng default % for reproducibility
r = normrnd(10,1,100,1);
```

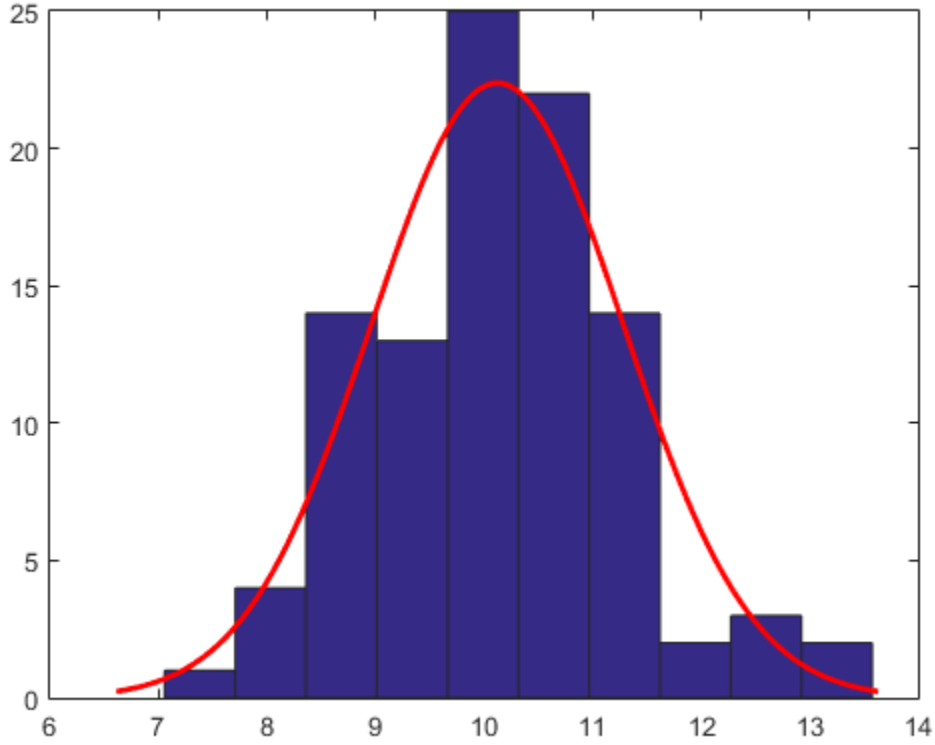
Construct a histogram with a normal distribution fit.

```
h = histfit(r,10,'normal')
```

```
h =
```

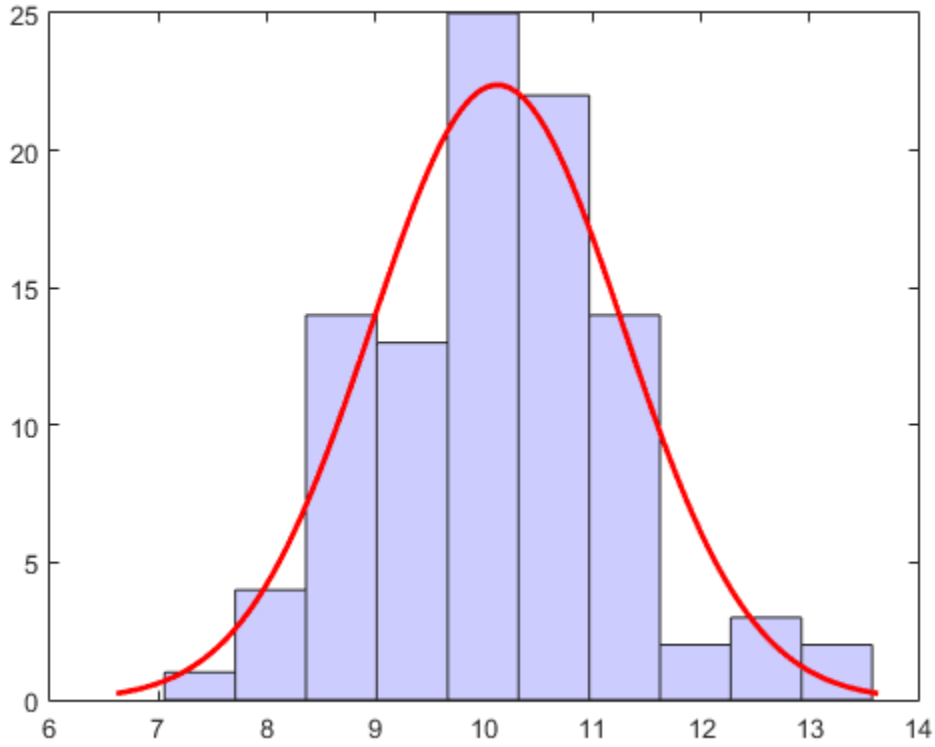
```
2x1 graphics array:

Patch
Line
```



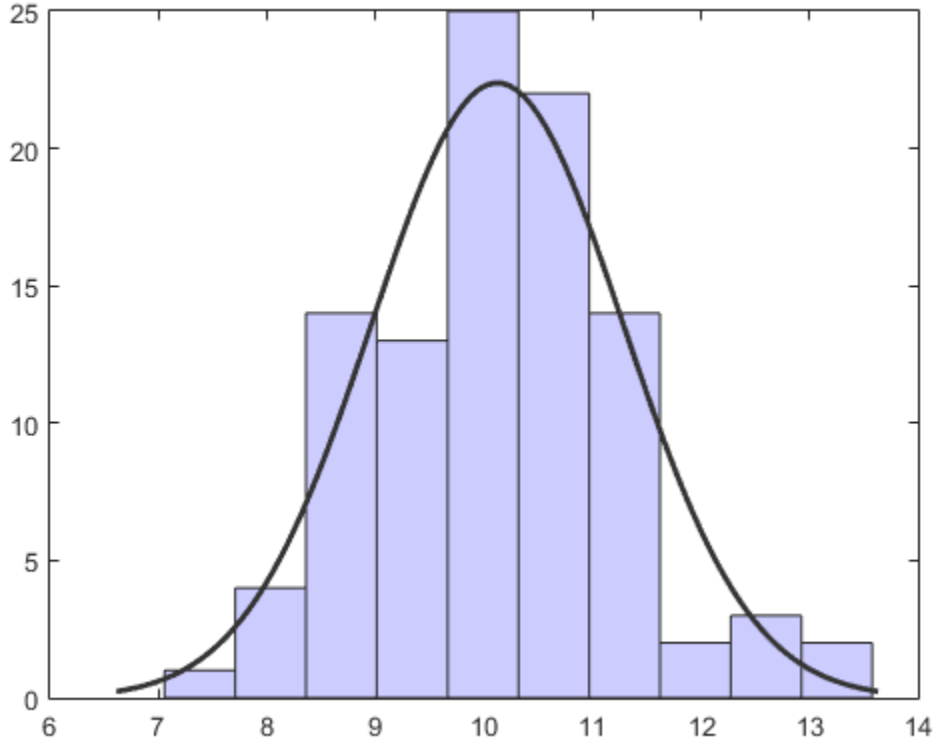
Change the bar colors of the histogram.

```
h(1).FaceColor = [.8 .8 1];
```



Change the color of the density curve.

```
h(2).Color = [.2 .2 .2];
```



Input Arguments

`data` — Input data

vector

Input data, specified as a vector.

Example: `data = [1.5 2.5 4.6 1.2 3.4]`

Example: `data = [1.5 2.5 4.6 1.2 3.4]'`

Data Types: `double` | `single`

`nbins` — Number of bins

positive integer | [ ]

Number of bins for the histogram, specified as a positive integer. Default value is the square root of the number of elements in `data`, rounded up. Use [ ] for the default number of bins when fitting a distribution.

Example: y = histfit(x,8)

Example: y = histfit(x,10,'gamma')

Example: y = histfit(x,[ ],'weibull')

Data Types: `double | single`

`dist` — Distribution to fit

`'normal'` (default) | string

Distribution to fit to the histogram, specified as a string. The following table shows the supported distributions.

`dist`	Description
`'beta'`	Beta
`'birnbaumsaunders'`	Birnbaum-Saunders
`'burr'`	Burr Type XII
`'exponential'`	Exponential
`'extreme value'` or `'ev'`	Extreme value
`'gamma'`	Gamma
`'generalized extreme value'` or `'gev'`	Generalized extreme value
`'generalized pareto'` or `'gp'`	Generalized Pareto (threshold 0)
`'inversegaussian'`	Inverse Gaussian
`'logistic'`	Logistic
`'loglogistic'`	Loglogistic
`'lognormal'`	Lognormal
`'nakagami'`	Nakagami
`'negative binomial'` or `'nbin'`	Negative binomial

dist	Description
'normal'	Normal
'poisson'	Poisson
'rayleigh'	Rayleigh
'rician'	Rician
'tlocationscale'	t location-scale
'weibull' or 'wbl'	Weibull
'kernel'	Nonparametric kernel-smoothing distribution. The density is evaluated at 100 equally spaced points that cover the range of the data in data. It works best with continuously distributed samples.

Data Types: char

Output Arguments

h — Handles for the plot
plot handle

Handles for the plot, returned as a vector, where h(1) is the handle to the histogram, and h(2) is the handle to the density curve.

dfittool | histogram | normfit

hmmdecode

Hidden Markov model posterior state probabilities

Syntax

```
PSTATES = hmmdecode(seq,TRANS,EMIS)
[PSTATES,logpseq] = hmmdecode(...)
[PSTATES,logpseq,FORWARD,BACKWARD,S] = hmmdecode(...)
hmmdecode(...,'Symbols',SYMBOLS)
```

Description

`PSTATES = hmmdecode(seq,TRANS,EMIS)` calculates the posterior state probabilities, `PSTATES`, of the sequence `seq`, from a hidden Markov model. The posterior state probabilities are the conditional probabilities of being at state k at step i, given the observed sequence of symbols, `sym`. You specify the model by a transition probability matrix, `TRANS`, and an emissions probability matrix, `EMIS`. `TRANS(i,j)` is the probability of transition from state `i` to state `j`. `EMIS(k,seq)` is the probability that symbol `seq` is emitted from state `k`.

`PSTATES` is an array with the same length as `seq` and one row for each state in the model. The (i, j)th element of `PSTATES` gives the probability that the model is in state i at the jth step, given the sequence `seq`.

Note The function `hmmdecode` begins with the model in state 1 at step 0, prior to the first emission. `hmmdecode` computes the probabilities in `PSTATES` based on the fact that the model begins in state 1.

`[PSTATES,logpseq] = hmmdecode(...)` returns `logpseq`, the logarithm of the probability of sequence `seq`, given transition matrix `TRANS` and emission matrix `EMIS`.

`[PSTATES,logpseq,FORWARD,BACKWARD,S] = hmmdecode(...)` returns the forward and backward probabilities of the sequence scaled by `S`.

`hmmdecode(...,'Symbols',SYMBOLS)` specifies the symbols that are emitted. `SYMBOLS` can be a numeric array or a cell array of the names of the symbols. The default symbols are integers `1` through `N`, where `N` is the number of possible emissions.

Examples

```
trans = [0.95,0.05;
         0.10,0.90];
emis = [1/6 1/6 1/6 1/6 1/6 1/6;
   1/10 1/10 1/10 1/10 1/10 1/2];

[seq,states] = hmmgenerate(100,trans,emis);
pStates = hmmdecode(seq,trans,emis);
[seq,states] = hmmgenerate(100,trans,emis,...
   'Symbols',{'one','two','three','four','five','six'})
pStates = hmmdecode(seq,trans,emis,...
   'Symbols',{'one','two','three','four','five','six'});
```

`hmmgenerate` | `hmmestimate` | `hmmviterbi` | `hmmtrain`

hmmestimate

Hidden Markov model parameter estimates from emissions and states

Syntax

```
[TRANS,EMIS] = hmmestimate(seq,states)
hmmestimate(...,'Symbols',SYMBOLS)
hmmestimate(...,'Statenames',STATENAMES)
hmmestimate(...,'Pseudoemissions',PSEUDOE)
hmmestimate(...,'Pseudotransitions',PSEUDOTR)
```

Description

`[TRANS,EMIS] = hmmestimate(seq,states)` calculates the maximum likelihood estimate of the transition, `TRANS`, and emission, `EMIS`, probabilities of a hidden Markov model for sequence, `seq`, with known states, `states`.

`hmmestimate(...,'Symbols',SYMBOLS)` specifies the symbols that are emitted. `SYMBOLS` can be a numeric array or a cell array of the names of the symbols. The default symbols are integers 1 through N, where N is the number of possible emissions.

`hmmestimate(...,'Statenames',STATENAMES)` specifies the names of the states. `STATENAMES` can be a numeric array or a cell array of the names of the states. The default state names are 1 through `M`, where `M` is the number of states.

`hmmestimate(...,'Pseudoemissions',PSEUDOE)` specifies pseudocount emission values in the matrix `PSEUDO`. Use this argument to avoid zero probability estimates for emissions with very low probability that might not be represented in the sample sequence. `PSEUDOE` should be a matrix of size m-by-n, where m is the number of states in the hidden Markov model and n is the number of possible emissions. If the $i \to k$ emission does not occur in `seq`, you can set `PSEUDOE(i,k)` to be a positive number representing an estimate of the expected number of such emissions in the sequence `seq`.

`hmmestimate(...,'Pseudotransitions',PSEUDOTR)` specifies pseudocount transition values. You can use this argument to avoid zero probability estimates for transitions with very low probability that might not be represented in the sample sequence. `PSEUDOTR` should be a matrix of size m-by-m, where m is the number of states

in the hidden Markov model. If the $i \to j$ transition does not occur in `states`, you can set `PSEUDOTR(i,j)` to be a positive number representing an estimate of the expected number of such transitions in the sequence `states`.

Pseudotransitions and Pseudoemissions

If the probability of a specific transition or emission is very low, the transition might never occur in the sequence `states`, or the emission might never occur in the sequence `seq`. In either case, the algorithm returns a probability of 0 for the given transition or emission in `TRANS` or `EMIS`. You can compensate for the absence of transition with the `'Pseudotransitions'` and `'Pseudoemissions'` arguments. The simplest way to do this is to set the corresponding entry of `PSEUDO` or `PSEUDOTR` to `1`. For example, if the transition $i \to j$ does not occur in `states`, set `PSEUOTR(i,j) = 1`. This forces `TRANS(i,j)` to be positive. If you have an estimate for the expected number of transitions $i \to j$ in a sequence of the same length as `states`, and the actual number of transitions $i \to j$ that occur in `seq` is substantially less than what you expect, you can set `PSEUOTR(i,j)` to the expected number. This increases the value of `TRANS(i,j)`. For transitions that do occur in states with the frequency you expect, set the corresponding entry of `PSEUDOTR` to `0`, which does not increase the corresponding entry of `TRANS`.

If you do not know the sequence of states, use `hmmtrain` to estimate the model parameters.

Examples

```
trans = [0.95,0.05; 0.10,0.90];
emis = [1/6 1/6 1/6 1/6 1/6 1/6;
   1/10 1/10 1/10 1/10 1/10 1/2];

[seq,states] = hmmgenerate(1000,trans,emis);
[estimateTR,estimateE] = hmmestimate(seq,states);
```

hmmgenerate

Hidden Markov model states and emissions

Syntax

```
[seq,states] = hmmgenerate(len,TRANS,EMIS)
hmmgenerate(...,'Symbols',SYMBOLS)
hmmgenerate(...,'Statenames',STATENAMES)
```

Description

`[seq,states] = hmmgenerate(len,TRANS,EMIS)` takes a known Markov model, specified by transition probability matrix `TRANS` and emission probability matrix `EMIS`, and uses it to generate

- A random sequence `seq` of emission symbols
- A random sequence `states` of states

The length of both `seq` and `states` is `len`. `TRANS(i,j)` is the probability of transition from state `i` to state `j`. `EMIS(k,l)` is the probability that symbol `l` is emitted from state `k`.

Note The function `hmmgenerate` begins with the model in state 1 at step 0, prior to the first emission. The model then makes a transition to state i_1, with probability T_{1i_1}, and generates an emission a_{k_1} with probability $E_{i_1k_1}$. `hmmgenerate` returns i_1 as the first entry of `states`, and a_{k_1} as the first entry of `seq`.

`hmmgenerate(...,'Symbols',SYMBOLS)` specifies the symbols that are emitted. `SYMBOLS` can be a numeric array or a cell array of the names of the symbols. The default symbols are integers `1` through `N`, where `N` is the number of possible emissions.

`hmmgenerate(...,'Statenames',STATENAMES)` specifies the names of the states. `STATENAMES` can be a numeric array or a cell array of the names of the states. The default state names are `1` through `M`, where `M` is the number of states.

Since the model always begins at state 1, whose transition probabilities are in the first row of TRANS, in the following example, the first entry of the output `states` is be 1 with probability 0.95 and 2 with probability 0.05.

Examples

```
 trans = [0.95,0.05;
          0.10,0.90];
 emis = [1/6 1/6 1/6 1/6 1/6 1/6;
    1/10 1/10 1/10 1/10 1/10 1/2];

[seq,states] = hmmgenerate(100,trans,emis)
[seq,states] = hmmgenerate(100,trans,emis,...
    'Symbols',{'one','two','three','four','five','six'},...
    'Statenames',{'fair';'loaded'})
```

`hmmviterbi` | `hmmdecode` | `hmmestimate` | `hmmtrain`

hmmtrain

Hidden Markov model parameter estimates from emissions

Syntax

```
[ESTTR,ESTEMIT] = hmmtrain(seq,TRGUESS,EMITGUESS)
hmmtrain(...,'Algorithm',algorithm)
hmmtrain(...,'Symbols',SYMBOLS)
hmmtrain(...,'Tolerance',tol)
hmmtrain(...,'Maxiterations',maxiter)
hmmtrain(...,'Verbose',true)
hmmtrain(...,'Pseudoemissions',PSEUDOE)
hmmtrain(...,'Pseudotransitions',PSEUDOTR)
```

Description

`[ESTTR,ESTEMIT] = hmmtrain(seq,TRGUESS,EMITGUESS)` estimates the transition and emission probabilities for a hidden Markov model using the Baum-Welch algorithm. `seq` can be a row vector containing a single sequence, a matrix with one row per sequence, or a cell array with each cell containing a sequence. `TRGUESS` and `EMITGUESS` are initial estimates of the transition and emission probability matrices. `TRGUESS(i,j)` is the estimated probability of transition from state `i` to state `j`. `EMITGUESS(i,k)` is the estimated probability that symbol `k` is emitted from state `i`.

`hmmtrain(...,'Algorithm',algorithm)` specifies the training algorithm. *`algorithm`* can be either `'BaumWelch'` or `'Viterbi'`. The default algorithm is `'BaumWelch'`.

`hmmtrain(...,'Symbols',SYMBOLS)` specifies the symbols that are emitted. `SYMBOLS` can be a numeric array or a cell array of the names of the symbols. The default symbols are integers `1` through `N`, where `N` is the number of possible emissions.

`hmmtrain(...,'Tolerance',tol)` specifies the tolerance used for testing convergence of the iterative estimation process. The default tolerance is `1e-4`.

`hmmtrain(...,'Maxiterations',maxiter)` specifies the maximum number of iterations for the estimation process. The default maximum is `100`.

`hmmtrain(...,'Verbose',true)` returns the status of the algorithm at each iteration.

`hmmtrain(...,'Pseudoemissions',PSEUDOE)` specifies pseudocount emission values for the Viterbi training algorithm. Use this argument to avoid zero probability estimates for emissions with very low probability that might not be represented in the sample sequence. `PSEUDOE` should be a matrix of size m-by-n, where m is the number of states in the hidden Markov model and n is the number of possible emissions. If the $i \rightarrow k$ emission does not occur in `seq`, you can set `PSEUDOE(i,k)` to be a positive number representing an estimate of the expected number of such emissions in the sequence `seq`.

`hmmtrain(...,'Pseudotransitions',PSEUDOTR)` specifies pseudocount transition values for the Viterbi training algorithm. Use this argument to avoid zero probability estimates for transitions with very low probability that might not be represented in the sample sequence. `PSEUDOTR` should be a matrix of size m-by-m, where m is the number of states in the hidden Markov model. If the $i \rightarrow j$ transition does not occur in `states`, you can set `PSEUDOTR(i,j)` to be a positive number representing an estimate of the expected number of such transitions in the sequence `states`.

If you know the states corresponding to the sequences, use `hmmestimate` to estimate the model parameters.

Tolerance

The input argument `'tolerance'` controls how many steps the `hmmtrain` algorithm executes before the function returns an answer. The algorithm terminates when all of the following three quantities are less than the value that you specify for `tolerance`:

- The log likelihood that the input sequence `seq` is generated by the currently estimated values of the transition and emission matrices
- The change in the norm of the transition matrix, normalized by the size of the matrix
- The change in the norm of the emission matrix, normalized by the size of the matrix

The default value of `'tolerance'` is `.0001`. Increasing the tolerance decreases the number of steps the `hmmtrain` algorithm executes before it terminates.

maxiterations

The maximum number of iterations, `'maxiterations'`, controls the maximum number of steps the algorithm executes before it terminates. If the algorithm

executes `maxiter` iterations before reaching the specified tolerance, the algorithm terminates and the function returns a warning. If this occurs, you can increase the value of `'maxiterations'` to make the algorithm reach the desired tolerance before terminating.

Examples

```
trans = [0.95,0.05;
      0.10,0.90];
emis = [1/6, 1/6, 1/6, 1/6, 1/6, 1/6;
   1/10, 1/10, 1/10, 1/10, 1/10, 1/2];

seq1 = hmmgenerate(100,trans,emis);
seq2 = hmmgenerate(200,trans,emis);
seqs = {seq1,seq2};
[estTR,estE] = hmmtrain(seqs,trans,emis);
```

hmmviterbi

Hidden Markov model most probable state path

Syntax

```
STATES = hmmviterbi(seq,TRANS,EMIS)
hmmviterbi(...,'Symbols',SYMBOLS)
hmmviterbi(...,'Statenames',STATENAMES)
```

Description

`STATES = hmmviterbi(seq,TRANS,EMIS)` given a sequence, `seq`, calculates the most likely path through the hidden Markov model specified by transition probability matrix, `TRANS`, and emission probability matrix `EMIS`. `TRANS(i,j)` is the probability of transition from state `i` to state `j`. `EMIS(i,k)` is the probability that symbol `k` is emitted from state `i`.

Note The function `hmmviterbi` begins with the model in state 1 at step 0, prior to the first emission. `hmmviterbi` computes the most likely path based on the fact that the model begins in state 1.

`hmmviterbi(...,'Symbols',SYMBOLS)` specifies the symbols that are emitted. `SYMBOLS` can be a numeric array or a cell array of the names of the symbols. The default symbols are integers `1` through `N`, where `N` is the number of possible emissions.

`hmmviterbi(...,'Statenames',STATENAMES)` specifies the names of the states. `STATENAMES` can be a numeric array or a cell array of the names of the states. The default state names are 1 through `M`, where `M` is the number of states.

Examples

```
trans = [0.95,0.05;
         0.10,0.90];
```

```
emis = [1/6 1/6 1/6 1/6 1/6 1/6;
   1/10 1/10 1/10 1/10 1/10 1/2];

[seq,states] = hmmgenerate(100,trans,emis);
estimatedStates = hmmviterbi(seq,trans,emis);

[seq,states] = ...
   hmmgenerate(100,trans,emis,...
               'Statenames',{'fair';'loaded'});
estimatesStates = ...
   hmmviterbi(seq,trans,emis,...
              'Statenames',{'fair';'loaded'});
```

horzcat

Class: dataset

Horizontal concatenation for dataset arrays

Compatibility

The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

Syntax

```
ds = horzcat(ds1, ds2, ...)
```

Description

`ds = horzcat(ds1, ds2, ...)` horizontally concatenates the dataset arrays `ds1, ds2, ...` . You may concatenate dataset arrays that have duplicate variable names, however, the variables must contain identical data, and `horzcat` includes only one copy of the variable in the output dataset.

Observation names for all dataset arrays that have them must be identical except for order. `horzcat` concatenates by matching observation names when present, or by position for datasets that do not have observation names.

See Also

`cat` | `vertcat`

hougen

Hougen-Watson model

Syntax

```
yhat = hougen(beta,x)
```

Description

`yhat = hougen(beta,x)` returns the predicted values of the reaction rate, `yhat`, as a function of the vector of parameters, `beta`, and the matrix of data, `X`. `beta` must have 5 elements and `X` must have three columns.

`hougen` is a utility function for `rsmdemo`.

The model form is:

$$\hat{y} = \frac{\beta_1 x_2 - x_3 \,/\, \beta_5}{1 + \beta_2 x_1 + \beta_3 x_2 + \beta_4 x_3}$$

References

[1] Bates, D. M., and D. G. Watts. *Nonlinear Regression Analysis and Its Applications*. Hoboken, NJ: John Wiley & Sons, Inc., 1988.

`rsmdemo`

hygecdf

Hypergeometric cumulative distribution function

Syntax

```
hygecdf(x,M,K,N)
hygecdf(x,M,K,N,'upper')
```

Description

`hygecdf(x,M,K,N)` computes the hypergeometric cdf at each of the values in `x` using the corresponding size of the population, `M`, number of items with the desired characteristic in the population, `K`, and number of samples drawn, `N`. Vector or matrix inputs for `x`, `M`, `K`, and `N` must all have the same size. A scalar input is expanded to a constant matrix with the same dimensions as the other inputs.

`hygecdf(x,M,K,N,'upper')` returns the complement of the hypergeometric cdf at each value in `x`, using an algorithm that more accurately computes the extreme upper tail probabilities.

The hypergeometric cdf is

$$p = F(x \mid M,K,N) = \sum_{i=0}^{x} \frac{\binom{K}{i}\binom{M-K}{N-i}}{\binom{M}{N}}$$

The result, p, is the probability of drawing up to x of a possible K items in N drawings without replacement from a group of M objects.

Examples

Compute Hypergeometric Distribution CDF

Suppose you have a lot of 100 floppy disks and you know that 20 of them are defective. What is the probability of drawing zero to two defective floppies if you select 10 at random?

```
p = hygecdf(2,100,20,10)
```

```
p =
  0.6812
```

See Also

`cdf` | `hygepdf` | `hygeinv` | `hygestat` | `hygernd`

hygeinv

Hypergeometric inverse cumulative distribution function

Syntax

```
hygeinv(P,M,K,N)
```

Description

`hygeinv(P,M,K,N)` returns the smallest integer `X` such that the hypergeometric cdf evaluated at `X` equals or exceeds `P`. You can think of `P` as the probability of observing `X` defective items in `N` drawings without replacement from a group of `M` items where `K` are defective.

Examples

Suppose you are the Quality Assurance manager for a floppy disk manufacturer. The production line turns out floppy disks in batches of 1,000. You want to sample 50 disks from each batch to see if they have defects. You want to accept 99% of the batches if there are no more than 10 defective disks in the batch. What is the maximum number of defective disks should you allow in your sample of 50?

```
x = hygeinv(0.99,1000,10,50)
x =
   3
```

What is the median number of defective floppy disks in samples of 50 disks from batches with 10 defective disks?

```
x = hygeinv(0.50,1000,10,50)
x =
   0
```

See Also

`icdf` | `hygecdf` | `hygepdf` | `hygestat` | `hygernd`

hygepdf

Hypergeometric probability density function

Syntax

```
Y = hygepdf(X,M,K,N)
```

Description

`Y = hygepdf(X,M,K,N)` computes the hypergeometric pdf at each of the values in `X` using the corresponding size of the population, `M`, number of items with the desired characteristic in the population, `K`, and number of samples drawn, `N`. `X`, `M`, `K`, and `N` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other inputs.

The parameters in `M`, `K`, and `N` must all be positive integers, with $N \le M$. The values in `X` must be less than or equal to all the parameter values.

The hypergeometric pdf is

$$y = f(x \mid M,K,N) = \frac{\binom{K}{x}\binom{M-K}{N-x}}{\binom{M}{N}}$$

The result, y, is the probability of drawing exactly x of a possible K items in n drawings without replacement from a group of M objects.

Examples

Suppose you have a lot of 100 floppy disks and you know that 20 of them are defective. What is the probability of drawing 0 through 5 defective floppy disks if you select 10 at random?

```
p = hygepdf(0:5,100,20,10)
p =
  0.0951   0.2679   0.3182   0.2092   0.0841   0.0215
```

See Also

pdf | hygecdf | hygeinv | hygestat | hygernd

hygernd

Hypergeometric random numbers

Syntax

```
R = hygernd(M,K,N)
R = hygernd(M,K,N,m,n,...)
R = hygernd(M,K,N,[m,n,...])
```

Description

`R = hygernd(M,K,N)` generates random numbers from the hypergeometric distribution with corresponding size of the population, `M`, number of items with the desired characteristic in the population, `K`, and number of samples drawn, `N`. `M`, `K`, and `N` can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of `R`. A scalar input for `M`, `K`, or `N` is expanded to a constant array with the same dimensions as the other inputs.

`R = hygernd(M,K,N,m,n,...)` or `R = hygernd(M,K,N,[m,n,...])` generates an `m`-by-`n`-by-... array. The `M`, `K`, `N` parameters can each be scalars or arrays of the same size as `R`.

Examples

```
numbers = hygernd(1000,40,50)
numbers =
   1
```

See Also

`random` | `hygepdf` | `hygecdf` | `hygeinv` | `hygestat`

hygestat

Hypergeometric mean and variance

Syntax

```
[MN,V] = hygestat(M,K,N)
```

Description

`[MN,V] = hygestat(M,K,N)` returns the mean of and variance for the hypergeometric distribution with corresponding size of the population, `M`, number of items with the desired characteristic in the population, `K`, and number of samples drawn, `N`. Vector or matrix inputs for `M`, `K`, and `N` must have the same size, which is also the size of `MN` and `V`. A scalar input for `M`, `K`, or `N` is expanded to a constant matrix with the same dimensions as the other inputs.

The mean of the hypergeometric distribution with parameters `M`, `K`, and `N` is `NK/M`, and the variance is `NK(M-K)(M-N)/[M^2(M-1)]`.

Examples

The hypergeometric distribution approaches the binomial distribution, where `p = K/M`, as `M` goes to infinity.

```
[m,v] = hygestat(10.^(1:4),10.^(0:3),9)
m =
  0.9000  0.9000  0.9000  0.9000
v =
  0.0900  0.7445  0.8035  0.8094

[m,v] = binostat(9,0.1)
m =
  0.9000
v =
  0.8100
```

See Also

`hygepdf` | `hygecdf` | `hygeinv` | `hygernd`

icdf

Inverse cumulative distribution functions

Syntax

```
x = icdf('name',y,A)
x = icdf('name',y,A,B)
x = icdf('name',y,A,B,C)

x = icdf(pd,y)
```

Description

`x = icdf('name',y,A)` returns the inverse cumulative distribution function (icdf) for the one-parameter distribution family specified by 'name', evaluated at the probability values in y. A contains the parameter value for the distribution.

`x = icdf('name',y,A,B)` returns the icdf for the two-parameter distribution family specified by 'name', evaluated at the probability values in y. A and B contain the parameter values for the distribution.

`x = icdf('name',y,A,B,C)` returns the icdf for the three-parameter distribution family specified by 'name', evaluated at the probability values in y. A, B, and C contain the parameter values for the distribution.

`x = icdf(pd,y)` returns the inverse cumulative distribution function of the probability distribution object, pd, evaluated at the probability values in y.

Examples

Compute the Normal Distribution icdf

Create a standard normal distribution object with the mean, μ, equal to 0 and the standard deviation, σ, equal to 1.

```
mu = 0;
sigma = 1;
```

```
pd = makedist('Normal',mu,sigma);
```

Define the input vector y to contain the probability values at which to calculate the icdf.

```
y = [0.1,0.25,0.5,0.75,0.9];
```

Compute the icdf values for the standard normal distribution at the values in y.

```
x = icdf(pd,y)
```

```
x =

   -1.2816   -0.6745         0    0.6745    1.2816
```

Each value in x corresponds to a value in the input vector y. For example, at the value y equal to 0.9, the corresponding icdf value x is equal to 1.2816.

Alternatively, you can compute the same icdf values without creating a probability distribution object. Use the `icdf` function and specify a standard normal distribution using the same parameter values for μ and σ.

```
x2 = icdf('Normal',y,mu,sigma)
```

```
x2 =

   -1.2816   -0.6745         0    0.6745    1.2816
```

The icdf values are the same as those computed using the probability distribution object.

Compute the Poisson Distribution icdf

Create a Poisson distribution object with the rate parameter, λ, equal to 2.

```
lambda = 2;
pd = makedist('Poisson',lambda);
```

Define the input vector y to contain the probability values at which to calculate the icdf.

```
y = [0.1,0.25,0.5,0.75,0.9];
```

Compute the icdf values for the Poisson distribution at the values in y.

```
x = icdf(pd,y)
```

```
x =

     0     1     2     3     4
```

Each value in x corresponds to a value in the input vector y. For example, at the value y equal to 0.9, the corresponding icdf value x is equal to 4.

Alternatively, you can compute the same icdf values without creating a probability distribution object. Use the `icdf` function and specify a Poisson distribution using the same value for the rate parameter λ.

```
x2 = icdf('Poisson',y,lambda)
```

```
x2 =

     0     1     2     3     4
```

The icdf values are the same as those computed using the probability distribution object.

Input Arguments

`'name'` — Probability distribution name

probability distribution name string

Probability distribution name, specified as one of the following probability distribution name strings.

name	Distribution	Input Parameter A	Input Parameter B	Input Parameter C
`'Beta'`	"Beta Distribution" on page B-4	a: first shape parameter	b: second shape parameter	—
`'Binomial'`	"Binomial Distribution" on page B-9	n: number of trials	p: probability of success for each trial	—
`'BirnbaumSaund`	"Birnbaum-Saunders Distribution" on page B-13	β: scale parameter	γ: shape parameter	—

name	Distribution	Input Parameter A	Input Parameter B	Input Parameter C

y — Probability values at which to evaluate icdf

scalar value | array of scalar values

Probability values at which to evaluate the icdf, specified as a scalar value, or an array of scalar values.

- If y is a scalar value, and if you specify distribution parameters A, B, or C as arrays, then `cdf` expands it into a constant matrix the same size as `A` and `B`.
- If y is an array, and if you specify distribution parameters A, B, or C as arrays, then y, A, B, and C must all be the same size.

Example: `[0.1,0.25,0.5,0.75,0.9]`

Data Types: `single` | `double`

A — First probability distribution parameter

scalar value | array of scalar values

First probability distribution parameter, specified as a scalar value, or an array of scalar values.

If x and A are arrays, they must be the same size. If x is a scalar, then `cdf` expands it into a constant matrix the same size as A. If A is a scalar, then `cdf` expands it into a constant matrix the same size as x.

Data Types: `single` | `double`

`B` — Second probability distribution parameter

scalar value | array of scalar values

Second probability distribution parameter, specified as a scalar value, or an array of scalar values.

If x, A, and B are arrays, they must be the same size. If x is a scalar, then `cdf` expands it into a constant matrix the same size as A and B. If A or B are scalars, then `cdf` expands them into constant matrices the same size as x

Data Types: `single` | `double`

`C` — Third probability distribution parameter

scalar value | array of scalar values

Third probability distribution parameter, specified as a scalar value, or an array of scalar values.

If x, A, B, and C are arrays, they must be the same size. If x is a scalar, then `cdf` expands it into a constant matrix the same size as A, B, and C. If any of A, B or C are scalars, then `cdf` expands them into constant matrices the same size as x.

Data Types: `single` | `double`

`pd` — Probability distribution

probability distribution object

Probability distribution, specified as a probability distribution object created using one of the following.

`makedist`	Create a probability distribution object using specified parameter values.
`fitdist`	Fit a probability distribution object to sample data.
`dfittool`	Fit a probability distribution object to sample data using the interactive Distribution Fitting app.
`paretotails`	Create a Pareto tails object.

`gmdistribution`	Create a Gaussian mixture distribution object.

Output Arguments

x — Inverse cumulative distribution function

array

Inverse cumulative distribution function of the specified probability distribution, returned as an array.

- If you specify distribution parameters A, B, orC, then x is the common size of y, A, B, and C after any necessary scalar expansion.
- If you specify a probability distribution object, pd, then x has the same dimensions as y.

See Also

`cdf` | `mle` | `pdf` | `random`

icdf

Class: piecewisedistribution

Inverse cumulative distribution function for piecewise distribution

Syntax

```
X = icdf(obj,P)
```

Description

`X = icdf(obj,P)` returns an array `X` of values of the inverse cumulative distribution function for the piecewise distribution object `obj`, evaluated at the values in the array `P`.

Examples

Fit Pareto tails to a t distribution at cumulative probabilities 0.1 and 0.9:

```
t = trnd(3,100,1);
obj = paretotails(t,0.1,0.9);
[p,q] = boundary(obj)
p =
    0.1000
    0.9000
q =
   -1.7766
    1.8432

icdf(obj,p)
ans =
   -1.7766
    1.8432
```

See Also

`paretotails` | `cdf`

icdf

Class: ProbDistUnivKernel

Return inverse cumulative distribution function (ICDF) for ProbDistUnivKernel object

Syntax

```
Y = icdf(PD, P)
```

Description

`Y = icdf(PD, P)` returns *Y*, an array containing the inverse cumulative distribution function (ICDF) for the ProbDistUnivKernel object *PD*, evaluated at values in *P*.

Input Arguments

PD	An object of the class `ProbDistUnivKernel`.
P	A numeric array of values from `0` to `1` where you want to evaluate the ICDF.

Output Arguments

Y	An array containing the inverse cumulative distribution function (ICDF) for the ProbDistUnivKernel object *PD*.

See Also

`icdf`

icdf

Class: ProbDistUnivParam

Return inverse cumulative distribution function (ICDF) for ProbDistUnivParam object

Syntax

```
Y = icdf(PD, P)
```

Description

`Y = icdf(PD, P)` returns *Y*, an array containing the inverse cumulative distribution function (ICDF) for the ProbDistUnivParam object *PD*, evaluated at values in *P*.

Input Arguments

PD	An object of the class `ProbDistUnivParam`.
P	A numeric array of values from `0` to `1` where you want to evaluate the ICDF.

Output Arguments

Y	An array containing the inverse cumulative distribution function (ICDF) for the ProbDistUnivParam object *PD*.

See Also

`icdf`

icdf

Class: prob.TruncatableDistribution
Package: prob

Inverse cumulative distribution function of probability distribution object

Syntax

```
y = icdf(pd,prob)
```

Description

`y = icdf(pd,prob)` returns the inverse cumulative distribution function (icdf) values of the probability distribution pd at the probabilities in prob.

Input Arguments

`pd` — Probability distribution

probability distribution object

Probability distribution, specified as a probability distribution object. Create a probability distribution object with specified parameter values using `makedist`. Alternatively, for fittable distributions, create a probability distribution object by fitting it to data using `fitdist` or the Distribution Fitting app.

`prob` — Probabilities

array of scalar values in the range [0,1]

Probabilities at which to compute the icdf, specified as an array of scalar values in the range [0,1]. For example, specifying `[.25 .5 .75]` returns a vector containing three icdf values corresponding to these probabilities.

Data Types: `single` | `double`

Output Arguments

y — Inverse cumulative distribution function

array

Inverse cumulative distribution function (icdf) values of the specified probability distribution, evaluated at the probabilities in prob, returned as an array. y has the same dimensions as x.

Examples

Compute Standard Normal Critical Values

Create a standard normal distribution object.

```
pd = makedist('Normal')
```

```
pd =

  NormalDistribution

  Normal distribution
       mu = 0
    sigma = 1
```

Determine the critical values at the 5% significance level for a test statistic with a standard normal distribution, by computing the upper and lower 2.5% values.

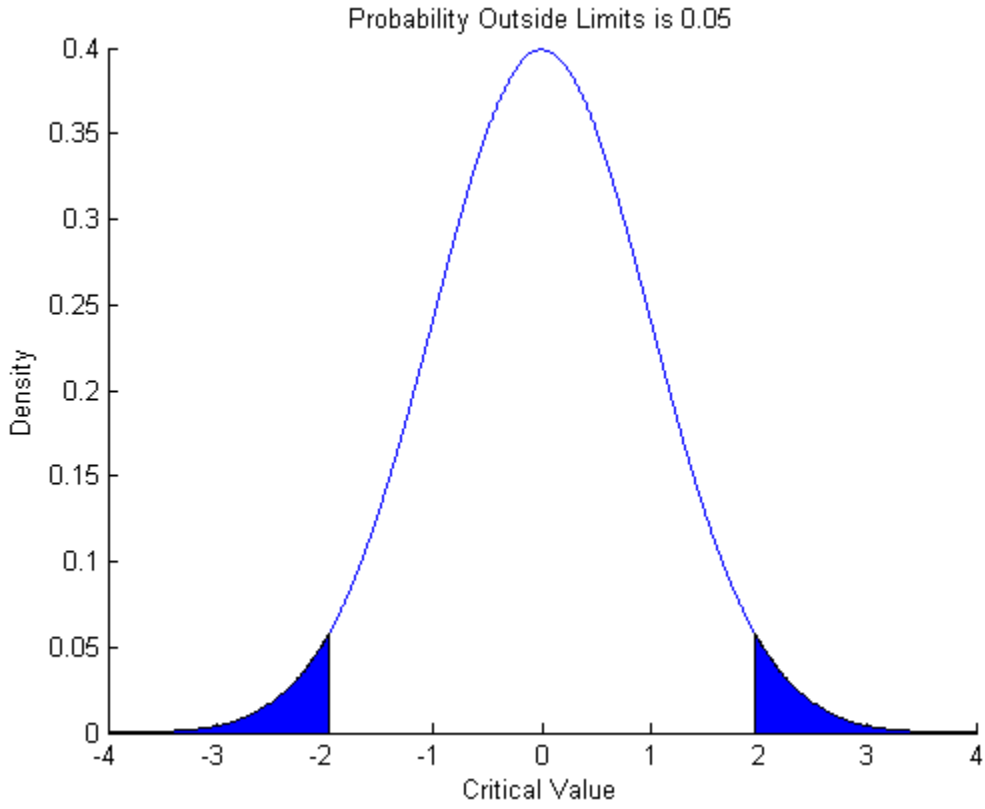
```
y = icdf(pd,[.025,.975])
```

```
y =

   -1.9600    1.9600
```

Plot the cdf and shade the critical regions.

```
p = normspec(y,0,1,'outside')
```



See Also

`cdf` | `dfittool` | `fitdist` | `makedist` | `normspec` | `pdf`

inconsistent

Inconsistency coefficient

Syntax

```
Y = inconsistent(Z)
Y = inconsistent(Z,d)
```

Description

`Y = inconsistent(Z)` computes the inconsistency coefficient for each link of the hierarchical cluster tree `Z`, where `Z` is an (m-1)-by-3 matrix generated by the `linkage` function. The inconsistency coefficient characterizes each link in a cluster tree by comparing its height with the average height of other links at the same level of the hierarchy. The higher the value of this coefficient, the less similar the objects connected by the link.

`Y = inconsistent(Z,d)` computes the inconsistency coefficient for each link in the hierarchical cluster tree `Z` to depth `d`, where `d` is an integer denoting the number of levels of the cluster tree that are included in the calculation. By default, `d=2`.

The output, `Y`, is an (m-1)-by-4 matrix formatted as follows.

Column	Description
1	Mean of the heights of all the links included in the calculation.
2	Standard deviation of the heights of all the links included in the calculation.
3	Number of links included in the calculation.
4	Inconsistency coefficient.

For each link, k, the inconsistency coefficient is calculated as:

$$Y(k,4) = (z(k,3) - Y(k,1)) / Y(k,2)$$

For leaf nodes, nodes that have no further nodes under them, the inconsistency coefficient is set to 0.

Examples

Compute Inconsistency Coefficient

Create the sample data.

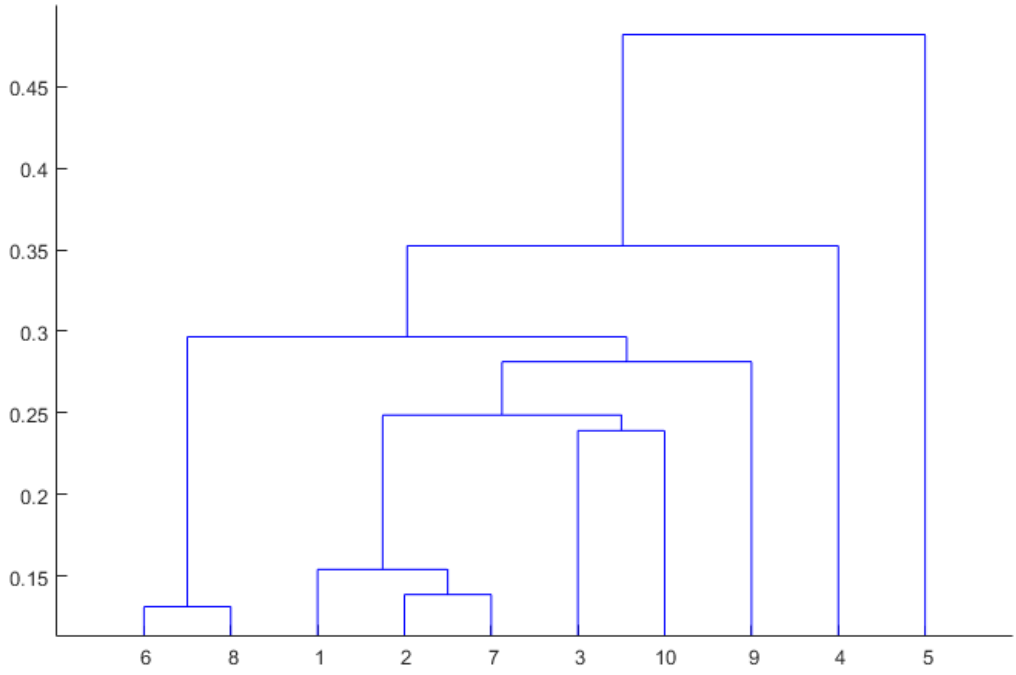
```
X = gallery('uniformdata',[10 2],12);
Y = pdist(X);
```

Generate the hierarchical cluster tree.

```
Z = linkage(Y,'single');
```

Generate a dendrogram plot of the hierarchical cluster tree.

```
dendrogram(Z)
```



Compute the inconsistency coefficient for each link in the cluster tree Z to depth 3.

```
W = inconsistent(Z,3)
```

```
W =

    0.1313         0    1.0000         0
    0.1386         0    1.0000         0
    0.1463    0.0109    2.0000    0.7071
    0.2391         0    1.0000         0
    0.1951    0.0568    4.0000    0.9425
    0.2308    0.0543    4.0000    0.9320
    0.2395    0.0748    4.0000    0.7636
    0.2654    0.0945    4.0000    0.9203
    0.3769    0.0950    3.0000    1.1040
```

increaseB

Class: clustering.evaluation.GapEvaluation
Package: clustering.evaluation

Increase reference data sets

Syntax

```
eva_out = increaseB(eva,nref)
```

Description

`eva_out = increaseB(eva,nref)` returns a gap criterion clustering evaluation object eva_out that uses the same evaluation criteria as the input object eva and an additional number of reference data sets as specified by nref.

Input Arguments

`eva` — Clustering evaluation data

clustering evaluation object

Clustering evaluation data, specified as a clustering evaluation object. Create a clustering evaluation object using `evalclusters`.

`nref` — Number of additional reference data sets

positive integer value

Number of additional reference data sets, specified as a positive integer value.

Output Arguments

`eva_out` — Updated clustering evaluation data

clustering evaluation object

Updated clustering evaluation data, returned as a gap criterion clustering evaluation object. eva_out contains evaluation data obtained using the reference data sets from the input object eva plus a number of additional reference data sets as specified in nref.

`increaseB` updates the `B` property of the input object eva to reflect the increase in the number of reference data sets used to compute the gap criterion values. `increaseB` also updates the `CriterionValues` property with gap criterion values computed using the total number of reference data sets. `increaseB` might also update the `OptimalK` and `OptimalY` properties to reflect the optimal number of clusters and optimal clustering solution as determined using the total number of reference data sets. Additionally, `increaseB` might also update the `LogW`, `ExpectedLogW`, `StdLogW`, and `SE` properties.

Examples

Evaluate Clustering Solutions Using Additional Reference Data

Create a gap clustering evaluation object using `evalclusters`, then use `increaseB` to increase the number of reference data sets used to compute the gap criterion values.

Load the sample data.

```
load fisheriris;
```

The data contains length and width measurements from the sepals and petals of three species of iris flowers.

Cluster the flower measurement data using `kmeans`, and use the gap criterion to evaluate proposed solutions of one through five clusters. Use 50 reference data sets.

```
eva = evalclusters(meas,'kmeans','gap','klist',1:5,'B',50)
```

```
eva =

  GapEvaluation with properties:

    NumObservations: 150
         InspectedK: [1 2 3 4 5]
    CriterionValues: [0.0848 0.5920 0.8750 1.0044 1.0462]
           OptimalK: 5
```

The clustering evaluation object `eva` contains data on each proposed clustering solution. The returned results indicate that the optimal number of clusters is five.

The value of the B property of eva shows 50 reference data sets.

```
eva.B
```

```
ans =

    50
```

Increase the number of reference data sets by 50, for a total of 100 sets.

```
eva = increaseB(eva,50)
```

```
eva =

  GapEvaluation with properties:

    NumObservations: 150
         InspectedK: [1 2 3 4 5]
    CriterionValues: [0.0824 0.5899 0.8742 1.0044 1.0463]
           OptimalK: 4
```

The returned results now indicate that the optimal number of clusters is four.

The value of the B property of eva now shows 100 reference data sets.

```
eva.B
```

```
ans =

   100
```

evalclusters

InputData property

Class: ProbDist

Read-only structure containing information about input data to ProbDist object

Description

`InputData` is a read-only property of the `ProbDist` class. `InputData` is a structure containing information about input data to a ProbDist object. It includes the following fields:

- `data`
- `cens`
- `freq`

Values

Possible values for the three fields in the structure are any data supplied to the `fitdist` function:

- `data` — Data passed to the `fitdist` function when creating the ProbDist object. This field is empty if the ProbDist object was created without fitting to data, that is by using the `ProbDistUnivParam` constructor.
- `cens` — The vector supplied with the `'censoring'` parameter when creating the ProbDist object using the `fitdist` function. This field is empty if the ProbDist object was created without fitting to data, that is by using the `ProbDistUnivParam` constructor.
- `freq` — The vector supplied with the `'frequency'` parameter when creating the ProbDist object using the `fitdist` function. This field is empty if the ProbDist object was created without fitting to data, that is by using the `ProbDistUnivParam` constructor.

Use this information to view and compare the data supplied to create distributions.

interactionplot

Interaction plot for grouped data

Syntax

```
interactionplot(Y,GROUP)
interactionplot(Y,GROUP,'varnames',VARNAMES)
[h,AX,bigax] = interactionplot(...)
```

Description

`interactionplot(Y,GROUP)` displays the two-factor interaction plot for the group means of matrix `Y` with groups defined by entries in the cell array `GROUP`. `Y` is a numeric matrix or vector. If `Y` is a matrix, the rows represent different observations and the columns represent replications of each observation. If `Y` is a vector, the rows give the means of each entry in the cell array `GROUP`. Each cell of `GROUP` must contain a grouping variable that can be a categorical variable, numeric vector, character matrix, or a single-column cell array of strings. `GROUP` can also be a matrix whose columns represent different grouping variables. Each grouping variable must have the same number of rows as `Y`. The number of grouping variables must be greater than 1.

The interaction plot is a matrix plot, with the number of rows and columns both equal to the number of grouping variables. The grouping variable names are printed on the diagonal of the plot matrix. The plot at off-diagonal position (*i*,*j*) is the interaction of the two variables whose names are given at row diagonal (*i*,*i*) and column diagonal (*j*,*j*), respectively.

`interactionplot(Y,GROUP,'varnames',VARNAMES)` displays the interaction plot with user-specified grouping variable names `VARNAMES`. `VARNAMES` is a character matrix or a cell array of strings, one per grouping variable. Default names are `'X1'`, `'X2'`, ...

`[h,AX,bigax] = interactionplot(...)` returns a handle `h` to the figure window, a matrix `AX` of handles to the subplot axes, and a handle `bigax` to the big (invisible) axes framing the subplots.

Examples

Display Interaction Plots

Randomly generate data for a response variable `y` .

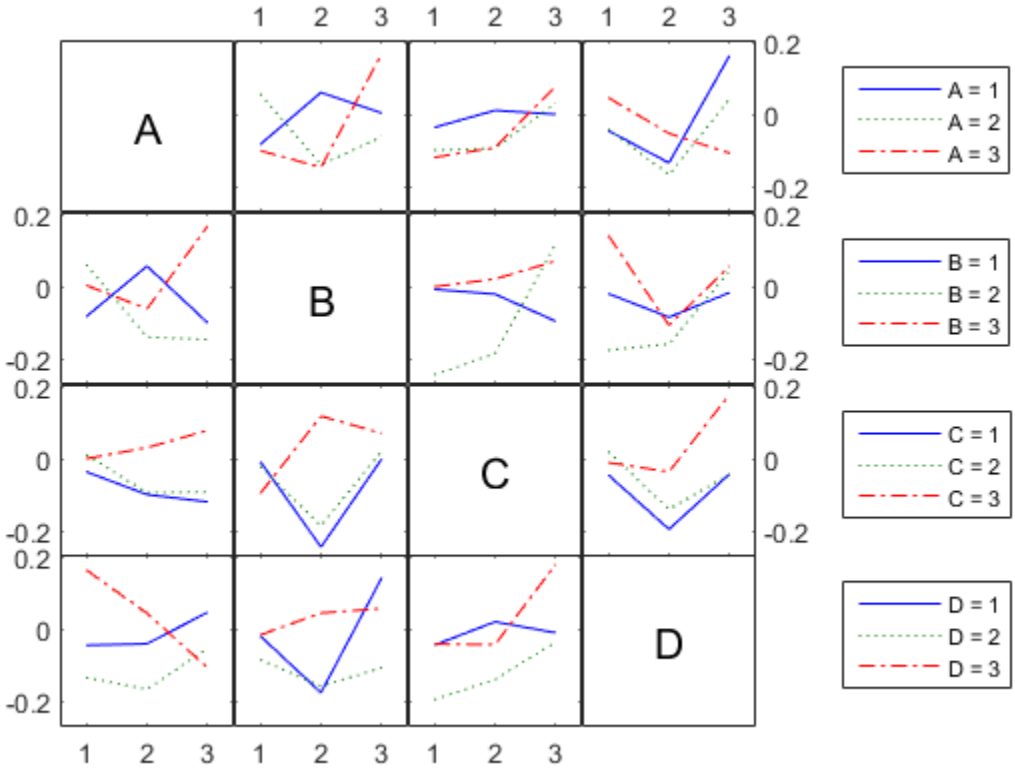
```
rng default;     % For reproducibility
y = randn(1000,1);
```

Randomly generate data for four three-level factors.

```
group = ceil(3*rand(1000,4));
```

Display the interaction plots for the factors and name the factors 'A', 'B', 'C', 'D'.

```
interactionplot(y,group,'varnames',{'A','B','C','D'})
```



See Also

`maineffectsplot` | `multivarichart`

intersect

Class: dataset

Set intersection for dataset array observations

Compatibility

The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

Syntax

```
C = intersect(A,B)
C = intersect(A,B,vars)
C = intersect(A,B,vars,setOrder)
[C,iA,iB] = intersect( ___ )
```

Description

`C = intersect(A,B)` for `dataset` arrays `A` and `B` returns the common set of observations from the two arrays, with repetitions removed. The observations in the dataset array `C` are in sorted order.

`C = intersect(A,B,vars)` returns the set of common observations from the two arrays, considering only the variables specified in vars, with repetitions removed. The observations in the dataset array C are sorted by those variables.

The values for variables not specified in vars for each observation in C are taken from the corresponding observations in `A`. If there are multiple observations in `A` that correspond to an observation in C, then those values are taken from the first occurrence.

`C = intersect(A,B,vars,setOrder)` returns the observations in C in the order specified by `setOrder`.

`[C,iA,iB] = intersect( ___ )` also returns index vectors iA and iB such that `C = A(iA,:)` and `C = B(iB,:)`. If there are repeated observations in `A` or `B`, then `intersect` returns the index of the first occurrence. You can use any of the previous input arguments.

Input Arguments

`A,B`

Input dataset arrays.

`vars`

Cell array of strings containing variable names or a vector of integers containing variable column numbers, indicating the variables in `A` and `B` that `intersect` considers.

Specify `vars` as `[]` to use its default value of all variables.

`setOrder`

Flag indicating the sorting order for the observations in C. The possible values of `setOrder` are:

`'sorted'`	Observations in C are in sorted order (default).
`'stable'`	Observations in C are in the same order that they appear in `A`.

Output Arguments

`C`

Dataset array with the common set of observations in `A` and `B`, with repetitions removed. C is in sorted order (by default), or the order specified by setOrder.

`iA`

Index vector, indicating the observations in `A` that are common to `B`. The vector `iA` contains the index to the first occurrence of any repeated observations in `A`.

iB

Index vector, indicating the observations in B that are common to A. The vector iB contains the index to the first occurrence of any repeated observations in B.

Examples

Intersection of Two Dataset Arrays

Navigate to the folder containing sample data, and load sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')

A = dataset('XLSFile','hospitalSmall.xlsx');
B = dataset('XLSFile','hospitalSmall.xlsx','Sheet',2);
```

Return the intersection and index vectors.

```
[C,iA,iB] = intersect(A,B);
```

```
C =

    id              name          sex        age    wgt    smoke
    'TRW-072'       'WHITE'       'm'        39     202    1
```

There is one observation in common between A and B.

Find the observation in the original dataset arrays.

```
A(iA,:)
```

```
ans =

    id              name          sex        age    wgt    smoke
    'TRW-072'       'WHITE'       'm'        39     202    1
```

```
B(iB,:)
```

```
ans =

    id              name          sex        age    wgt    smoke
    'TRW-072'       'WHITE'       'm'        39     202    1
```

prob.InverseGaussianDistribution class

Package: prob
Superclasses: prob.ToolboxFittableParametricDistribution

Inverse Gaussian probability distribution object

Description

`prob.InverseGaussianDistribution` is an object consisting of parameters, a model description, and sample data for an inverse Gaussian probability distribution.

Create a probability distribution object with specified parameter values using `makedist`. Alternatively, fit a distribution to data using `fitdist` or the Distribution Fitting app.

Construction

`pd = makedist('InverseGaussian')` creates an inverse Gaussian probability distribution object using the default parameter values.

`pd = makedist('InverseGaussian','mu',mu,'lambda',lambda)` creates an inverse Gaussian probability distribution object using the specified parameter values.

Input Arguments

`mu` — Scale parameter

1 (default) | positive scalar value

Scale parameter for the inverse Gaussian distribution, specified as a positive scalar value.

Data Types: `single` | `double`

`lambda` — Shape parameter

1 (default) | positive scalar value

Shape parameter for the inverse Gaussian distribution, specified as a positive scalar value.

Data Types: `single` | `double`

Properties

`mu` — Scale parameter

positive scalar value

Scale parameter for the inverse Gaussian distribution, stored as a positive scalar value.

Data Types: `single` | `double`

`lambda` — Shape parameter

positive scalar value

Shape parameter for the inverse Gaussian distribution, stored as a positive scalar value.

Data Types: `single` | `double`

`DistributionName` — Probability distribution name

probability distribution name string

Probability distribution name, stored as a valid probability distribution name string. This property is read-only.

Data Types: `char`

`InputData` — Data used for distribution fitting

structure

Data used for distribution fitting, stored as a structure containing the following:

- `data`: Data vector used for distribution fitting.
- `cens`: Censoring vector, or empty if none.
- `freq`: Frequency vector, or empty if none.

This property is read-only.

Data Types: `struct`

`IsTruncated` — Logical flag for truncated distribution

`0` | `1`

Logical flag for truncated distribution, stored as a logical value. If `IsTruncated` equals `0`, the distribution is not truncated. If `IsTruncated` equals `1`, the distribution is truncated. This property is read-only.

Data Types: `logical`

`NumParameters` — Number of parameters

positive integer value

Number of parameters for the probability distribution, stored as a positive integer value. This property is read-only.

Data Types: `single | double`

`ParameterCovariance` — Covariance matrix of the parameter estimates

matrix of scalar values

Covariance matrix of the parameter estimates, stored as a p-by-p matrix, where p is the number of parameters in the distribution. The (`i`,`j`) element is the covariance between the estimates of the `i`th parameter and the `j`th parameter. The (`i`,`i`) element is the estimated variance of the `i`th parameter. If parameter `i` is fixed rather than estimated by fitting the distribution to data, then the (`i`,`i`) elements of the covariance matrix are 0. This property is read-only.

Data Types: `single | double`

`ParameterDescription` — Distribution parameter descriptions

cell array of strings

Distribution parameter descriptions, stored as a cell array of strings. Each cell contains a short description of one distribution parameter. This property is read-only.

Data Types: `char`

`ParameterIsFixed` — Logical flag for fixed parameters

array of logical values

Logical flag for fixed parameters, stored as an array of logical values. If `0`, the corresponding parameter in the `ParameterNames` array is not fixed. If `1`, the corresponding parameter in the `ParameterNames` array is fixed. This property is read-only.

Data Types: `logical`

`ParameterNames` — Distribution parameter names

cell array of strings

Distribution parameter names, stored as a cell array of strings. This property is read-only.

Data Types: `char`

`ParameterValues` — Distribution parameter values

vector of scalar values

Distribution parameter values, stored as a vector. This property is read-only.

Data Types: `single | double`

`Truncation` — Truncation interval

vector of scalar values

Truncation interval for the probability distribution, stored as a vector containing the lower and upper truncation boundaries. This property is read-only.

Data Types: `single | double`

Methods

Inherited Methods

cdf	Cumulative distribution function of probability distribution object
icdf	Inverse cumulative distribution function of probability distribution object

truncate	Truncate probability distribution object
mean	Mean of probability distribution object
negloglik	Negative log likelihood of probability distribution object
paramci	Confidence intervals for probability distribution parameters
proflik	Profile likelihood function for probability distribution object
std	Standard deviation of probability distribution object
var	Variance of probability distribution object

Definitions

Inverse Gaussian Distribution

Also known as the Wald distribution, the inverse Gaussian is used to model nonnegative positively skewed data. Inverse Gaussian distributions have many similarities to standard Gaussian (normal) distributions, which lead to applications in inferential statistics.

The inverse Gaussian distribution uses the following parameters.

Parameter	Description	Support
`mu`	Scale parameter	$\mu > 0$
`lambda`	Shape parameter	$\lambda > 0$

The probability density function (pdf) is

$$f(x \mid \mu,\lambda) = \sqrt{\frac{\lambda}{2\pi x^3}} \exp\left\{-\frac{\lambda}{2\mu^2 x}(x-\mu)^2\right\} \quad ; \quad x > 0 .$$

Examples

Create an Inverse Gaussian Distribution Object Using Default Parameters

Create an inverse Gaussian distribution object using the default parameter values.

```
pd = makedist('InverseGaussian')
```

```
pd =

  InverseGaussianDistribution

  Inverse Gaussian distribution
        mu = 1
    lambda = 1
```

Create an Inverse Gaussian Distribution Object Using Specified Parameters

Create an inverse Gaussian distribution object by specifying parameter values.

```
pd = makedist('InverseGaussian','mu',2,'lambda',4)
```

```
pd =

  InverseGaussianDistribution

  Inverse Gaussian distribution
        mu = 2
    lambda = 4
```

Compute the standard deviation of the distribution.

```
s = std(pd)

s =

    1.4142
```

More About

- "Inverse Gaussian Distribution"
- Class Attributes
- Property Attributes

invpred

Inverse prediction

Syntax

```
X0 = invpred(X,Y,Y0)
[X0,DXLO,DXUP] = invpred(X,Y,Y0)
[X0,DXLO,DXUP] = invpred(X,Y,Y0,name1,val1,name2,val2,...)
```

Description

`X0 = invpred(X,Y,Y0)` accepts vectors `X` and `Y` of the same length, fits a simple regression, and returns the estimated value `X0` for which the height of the line is equal to `Y0`. The output, `X0`, has the same size as `Y0`, and `Y0` can be an array of any size.

`[X0,DXLO,DXUP] = invpred(X,Y,Y0)` also computes 95% inverse prediction intervals. `DXLO` and `DXUP` define intervals with lower bound `X0–DXLO` and upper bound `X0+DXUP`. Both `DXLO` and `DXUP` have the same size as `Y0`.

The intervals are not simultaneous and are not necessarily finite. Some intervals may extend from a finite value to `-Inf` or `+Inf`, and some may extend over the entire real line.

`[X0,DXLO,DXUP] = invpred(X,Y,Y0,name1,val1,name2,val2,...)` specifies optional argument name/value pairs chosen from the following list. Argument names are case insensitive and partial matches are allowed.

Name	Value
`'alpha'`	A value between 0 and 1 specifying a confidence level of `100*(1-alpha)`%. Default is `alpha=0.05` for 95% confidence.
`'predopt'`	Either `'observation'`, the default value to compute the intervals for `X0` at which a new observation could equal `Y0`, or `'curve'` to compute intervals for the `X0` value at which the curve is equal to `Y0`.

Examples

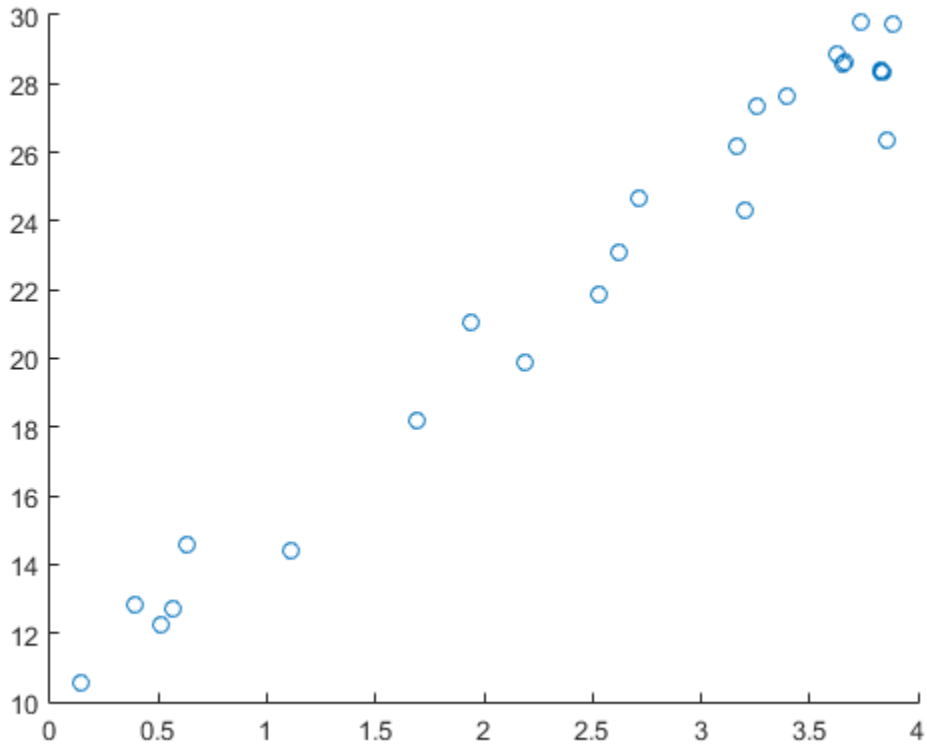
Inverse Prediction

Generate sample data.

```
x = 4*rand(25,1);
y = 10 + 5*x + randn(size(x));
```

Make a scatterplot of the data.

```
scatter(x,y)
```



Predict the *x* value for a given *y* value of 20.

```
x0 = invpred(x,y,20)

x0 =

    1.9967
```

See Also

polyfit | polyconf | polytool | polyval

iqr

Interquartile range

Syntax

```
r = iqr(x)
r = iqr(x,dim)

r = iqr(pd)
```

Description

`r = iqr(x)` returns the interquartile range of the values in x.

`r = iqr(x,dim)` returns the interquartile range along the dimension of x specified by dim.

`r = iqr(pd)` returns the interquartile range of the probability distribution, pd.

Examples

Compute the Interquartile Range

Generate a 4-by-4 matrix of random data from a normal distribution with parameter values μ equal to 10 and σ equal to 1.

```
rng default  % For reproducibility
x = normrnd(10,1,4)
```

```
x =

   10.5377   10.3188   13.5784   10.7254
   11.8339    8.6923   12.7694    9.9369
    7.7412    9.5664    8.6501   10.7147
   10.8622   10.3426   13.0349    9.7950
```

Compute the interquartile range for each column of data.

```
r = iqr(x)
```

```
r =

    2.2086    1.2013    2.5969    0.8541
```

Compute the interquartile range for each row of data.

```
r2 = iqr(x,2)
```

```
r2 =

    1.7237
    2.9870
    1.9449
    1.8797
```

Compute the Normal Distribution Interquartile Range

Create a standard normal distribution object with the mean, μ, equal to 0 and the standard deviation, σ, equal to 1.

```
pd = makedist('Normal',0,1);
```

Compute the interquartile range of the standard normal distribution.

```
r = iqr(pd)
```

```
r =

    1.3490
```

The returned value is the difference between the 75th and the 25th percentile values for the distribution. This is equivalent to computing the difference between the inverse cumulative distribution function (icdf) values at the probabilities y equal to 0.75 and 0.25.

```
r2 = icdf(pd,0.75) - icdf(pd,0.25)
```

```
r2 =

    1.3490
```

Input Arguments

x — Input array

vector | matrix | multidimensional array

Input array, specified as a vector, matrix, or multidimensional array.

Data Types: `single` | `double`

dim — Dimension

1 (default) | positive integer value

Dimension along which the interquartile range is calculated, specified as a positive integer. For example, for a matrix x, when dim is equal to 1, `iqr` returns the interquartile range for the columns of x. When dim is equal to 2, `iqr` returns the interquartile range for the rows of x. For *n*-dimensional arrays, `iqr` operates along the first nonsingleton dimension of `X`.

Data Types: `single` | `double`

pd — Probability distribution

probability distribution object

Probability distribution, specified as a probability distribution object created using one of the following.

`makedist`	Create a probability distribution object using specified parameter values.
`fitdist`	Fit a probability distribution object to sample data.
`dfittool`	Fit a probability distribution object to sample data using the interactive Distribution Fitting app.
`paretotails`	Create a Pareto tails object.

`gmdistribution`	Create a Gaussian mixture distribution object.

Output Arguments

r — Interquartile range

scalar value

Interquartile range, returned as a scalar value.

- If you input a vector for x, then r is the difference between the 75th and the 25th percentiles of the sample data contained in x.
- If you input a matrix for x, then r is a row vector containing the difference between the 75th and the 25th percentiles of the sample data contained each column of x.
- If you input a probability distribution, pd, then the value of r is the difference between the values of the 75th and 25th percentile of the probability distribution.

`icdf` | `mad` | `range` | `std`

iqr

Class: ProbDistUnivKernel

Return interquartile range (IQR) for ProbDistUnivKernel object

Syntax

```
Y = iqr(PD)
```

Description

`Y = iqr(PD)` returns *Y*, the interquartile range for the ProbDistUnivKernel object *PD*. The interquartile range is the distance between the 75th and 25th percentiles.

Input Arguments

PD	An object of the class `ProbDistUnivKernel`.

Output Arguments

Y	The value of the interquartile range for the ProbDistUnivKernel object *PD*.

See Also

`iqr` | `ProbDistUnivKernel.icdf`

iqr

Class: ProbDistUnivParam

Return interquartile range (IQR) for ProbDistUnivParam object

Syntax

```
Y = iqr(PD)
```

Description

`Y = iqr(PD)` returns *Y*, the interquartile range for the ProbDistUnivParam object *PD*. The interquartile range is the distance between the 75th and 25th percentiles.

Input Arguments

PD	An object of the class `ProbDistUnivParam`.

Output Arguments

Y	The value of the interquartile range for the ProbDistUnivParam object *PD*.

See Also

`iqr` | `ProbDistUnivParam.icdf`

iqr

Class: prob.TruncatableDistribution
Package: prob

Interquartile range of probability distribution object

Syntax

```
r = iqr(pd)
```

Description

`r = iqr(pd)` returns the interquartile range r of the probability distribution pd.

Input Arguments

`pd` — Probability distribution

probability distribution object

Probability distribution, specified as a probability distribution object. Create a probability distribution object with specified parameter values using `makedist`. Alternatively, for fittable distributions, create a probability distribution object by fitting it to data using `fitdist` or the Distribution Fitting app.

Output Arguments

`r` — Interquartile range

scalar value

Interquartile range of the probability distribution, returned as a scalar value. The value of r is the difference between the values of the 75th and 25th percentile of the probability distribution.

Examples

Interquartile Range of a Fitted Distribution

Load the sample data. Create a vector containing the first column of students' exam grade data.

```
load examgrades;
x = grades(:,1);
```

Crete a normal distribution object by fitting it to the data.

```
pd = fitdist(x,'Normal')
```

```
pd =

  NormalDistribution

  Normal distribution
       mu = 75.0083   [73.4321, 76.5846]
    sigma =  8.7202   [7.7391, 9.98843]
```

Compute the interquartile range of the fitted distribution.

```
r = iqr(pd)
```

```
r =

   11.7634
```

The returned result indicates that the difference between the 75th and 25th percentile of the students' grades is 11.7634.

Use `icdf` to determine the 75th and 25th percentiles of the students' grades.

```
y = icdf(pd,[0.25,0.75])
```

```
y =
   69.1266   80.8900
```

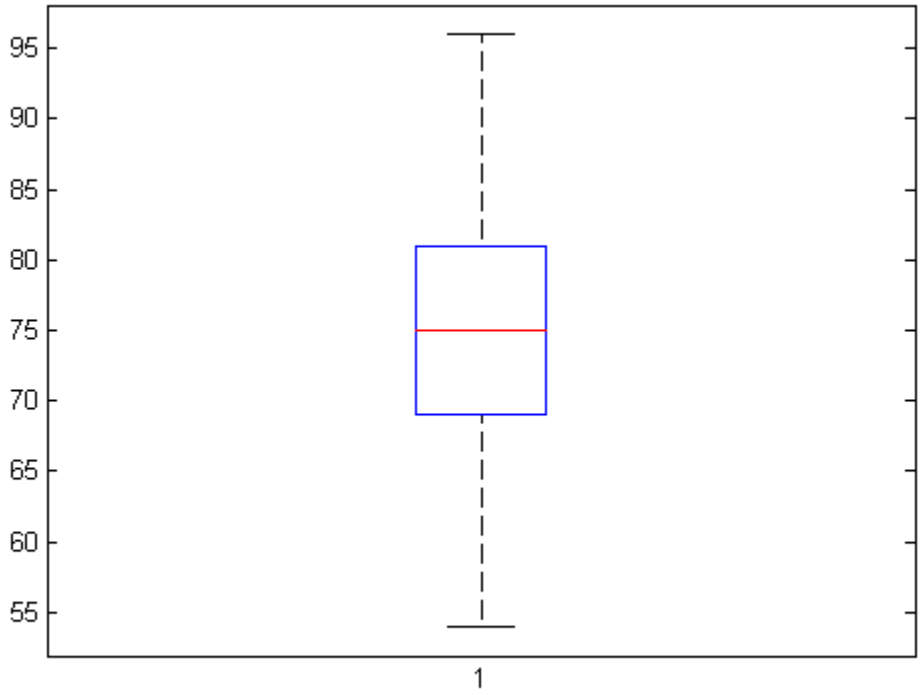
Calculate the difference between the 75th and 25th percentiles. This yields the same result as `iqr`.

```
y(2)-y(1)
```

```
ans =
   11.7634
```

Use `boxplot` to visualize the interquartile range.

```
boxplot(x)
```



The top line of the box shows the 75th percentile, and the bottom line shows the 25th percentile. The center line shows the median, which is the 50th percentile.

See Also

`boxplot` | `dfittool` | `fitdist` | `makedist`

isbranch

Class: classregtree

Test node for branch

Compatibility

`classregtree` will be removed in a future release. See `fitctree`, `fitrtree`, `ClassificationTree`, or `RegressionTree` instead.

Syntax

```
ib = isbranch(t)
ib = isbranch(t,nodes)
```

Description

`ib = isbranch(t)` returns an *n*-element logical vector `ib` that is `true` for each branch node and `false` for each leaf node.

`ib = isbranch(t,nodes)` takes a vector `nodes` of node numbers and returns a vector of logical values for the specified nodes.

Examples

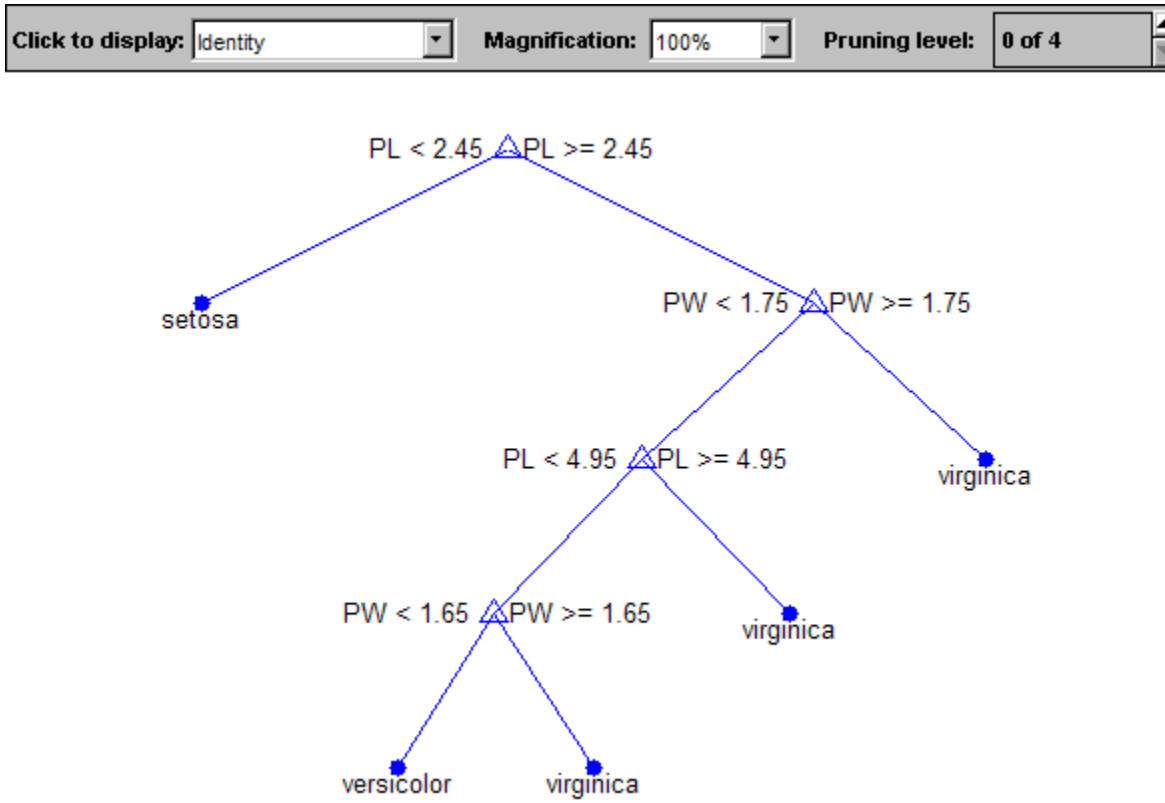
Create a classification tree for Fisher's iris data:

```
load fisheriris;

t = classregtree(meas,species,...
                 'names',{'SL' 'SW' 'PL' 'PW'})
t =
Decision tree for classification
1  if PL<2.45 then node 2 elseif PL>=2.45 then node 3 else setosa
2  class = setosa
3  if PW<1.75 then node 4 elseif PW>=1.75 then node 5 else versicolor
```

```
4  if PL<4.95 then node 6 elseif PL>=4.95 then node 7 else versicolor
5  class = virginica
6  if PW<1.65 then node 8 elseif PW>=1.65 then node 9 else versicolor
7  class = virginica
8  class = versicolor
9  class = virginica

view(t)
```



```
ib = isbranch(t)
ib =
     1
     0
     1
     1
     0
```

```
1
0
0
0
```

isempty

Class: dataset

True for empty dataset array

Compatibility

The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

Syntax

```
tf = isempty(A)
```

Description

`tf = isempty(A)` returns true (`1`) if `A` is an empty dataset and false (`0`) otherwise. An empty array has no elements, that is `prod(size(A))==0`.

See Also

`size`

islevel

Determine if levels are in nominal or ordinal array

Compatibility

The `nominal` and `ordinal` array data types might be removed in a future release. To represent ordered and unordered discrete, nonnumeric data, use the MATLAB `categorical` data type instead.

Syntax

```
tf = islevel(levels,A)
```

Description

`tf = islevel(levels,A)` returns a logical array indicating which of the levels in levels correspond to a level in the nominal or ordinal array A.

Input Arguments

A — Nominal or ordinal array

`nominal` array | `ordinal` array

Nominal or ordinal array, specified as a `nominal` or `ordinal` array object created using `nominal` or `ordinal`.

`levels` — Levels to test

string | cell array of strings | 2-D character matrix

Levels to test, specified as a string, cell array of strings, or 2-D character matrix.

Data Types: `char` | `cell`

Output Arguments

`tf` — Logical array

array the same size as levels

Logical array, returned as an array the same size as levels. tf has value `1` (true) where the corresponding element of levels is the label of a level in the nominal or ordinal array A, even if the level contains no elements. tf has value `0` (false) otherwise.

`isequal` | `ismember` | `nominal` | `ordinal`

ismember

Class: dataset

Dataset array elements that are members of set

Compatibility

The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

Syntax

```
LiA = ismember(A,B)
LiA = ismember(A,B,vars)
[LiA,LocB] = ismember( ___ )
```

Description

`LiA = ismember(A,B)` for `dataset` arrays A and B returns a vector of logical values the same length as `A`. The output vector, `LiA`, has value `1` (true) in the elements that correspond to observations in `A` that are also present in `B`, and `0` (false) otherwise.

`LiA = ismember(A,B,vars)` returns a vector of logical values the same length as `A`. The output vector, `LiA`, has value `1` (true) in the elements that correspond to observations in `A` that are also present in `B` for the variables specified in vars only, and `0` (false) otherwise.

`[LiA,LocB] = ismember( ___ )` also returns a vector the same length as `A` containing the index to the first observation in B that corresponds to each observation in A, or `0` if there is no such observation. You can use any of the previous input arguments.

Input Arguments

A

Query dataset array, containing the observations to be found in B.

B

Set dataset array. When an observation in A is found in `B`, for all variables or only those variables specified in vars, the corresponding element of LiA is `1`.

vars

Cell array of strings containing variable names or a vector of integers containing variable column numbers, indicating which variables to match observations on in A and B.

Output Arguments

LiA

Vector of logical values the same length as A. LiA has value `1` (true) when the corresponding observation in A is present in B. Otherwise, `LiA` has value `0` (false).

If you specify vars, LiA has value `1` when the corresponding observation in A is present in B for the variables in vars only.

LocB

Vector the same length as A containing the index to the first observation in B that corresponds to each observation in A, for all variables or only those variables specified in vars.

Examples

Find Observations That Are Members of a Dataset Array

Load sample data.

```
load('hospital')
```

```
B = hospital(1:50,1:5);
```

This set dataset array, B, has 50 observations on 5 variables.

Specify a query dataset array.

```
rng('default')
rIx = randsample(100,10);
A = hospital(rIx,1:5)
```

```
A =

              LastName           Sex       Age    Weight    Smoker
    YLN-495    'COLEMAN'         Male      39     188       false
    LQW-768    'TAYLOR'          Female    31     132       false
    DGC-290    'BUTLER'          Male      38     184       true
    DAU-529    'REED'            Male      50     186       true
    REV-997    'ALEXANDER'       Male      25     171       true
    QEQ-082    'COX'             Female    28     111       false
    AGR-528    'SIMMONS'         Male      45     181       false
    PUE-347    'YOUNG'           Female    25     114       false
    HVR-372    'RUSSELL'         Male      44     188       true
    XUE-826    'JACKSON'         Male      25     174       false
```

Check which observations in A are present in B.

More About

- “Dataset Arrays” on page 2-132

ismissing

Class: dataset

Find dataset array elements with missing values

Compatibility

The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

Syntax

```
I = ismissing(ds)
I = ismissing(ds,Name,Value)
```

Description

`I = ismissing(ds)` returns a logical array that indicates which elements in the dataset array, `ds`, contain a missing value. By default, `ismissing` recognizes `NaN` as a missing value in numeric variables, `''` as a missing value in string variables, and `<undefined>` as a missing value in categorical arrays.

- `ds2 = ds(~any(I,2),:)` creates a new dataset array containing only the complete observations in `ds`.
- `ds2 = ds(:,~any(I,1))` creates a new dataset array containing only the variables from `ds` with no missing values.

`I = ismissing(ds,Name,Value)` returns missing value indices with additional options specified by one or more Name,Value pair arguments.

Input Arguments

`ds`

`dataset` array

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'NumericTreatAsMissing'`

Vector of numeric values to treat as missing value indicators in floating point ds variables. `ismissing` always treats a `NaN` value as a missing value.

Default:

`'StringTreatAsMissing'`

String or cell array of strings to treat as missing value indicators in string ds variables. `ismissing` always treats the empty string `''` as a missing value.

Output Arguments

`I`

Logical array indicating which elements in ds contain a missing value. `I` is the same size as `ds`, with value `1` for elements that contain a missing value.

See Also

`dataset` | `isempty` | `isnan` | `isundefined` | `replaceWithMissing`

More About

- “Dataset Arrays” on page 2-132

isvalid

Class: qrandstream

Test handle validity

Syntax

```
tf = isvalid(h)
```

Description

`tf = isvalid(h)` performs an element-wise check for validity on the handle elements of `h`. The result is a logical array of the same dimensions as `h`, where each element is the element-wise validity result.

A handle is invalid if it has been deleted or if it is an element of a handle array and has not yet been initialized.

See Also

`delete` | `qrandstream`

NumIterations property

Class: gmdistribution

Number of iterations

Description

The number of iterations of the algorithm.

Note: This property applies only to `gmdistribution` objects constructed with `fitgmdist`.

---

iwishrnd

Inverse Wishart random numbers

Syntax

```
W = iwishrnd(Tau,df)
W = iwishrnd(Tau,df,DI)
[W,DI] = iwishrnd(Tau,df)
```

Description

`W = iwishrnd(Tau,df)` generates a random matrix `W` from the inverse Wishart distribution with parameters `Tau` and `df`. The inverse of `W` has the Wishart distribution with covariance matrix `Sigma = inv(Tau)` and with `df` degrees of freedom. `Tau` is a symmetric and positive definite matrix.

`W = iwishrnd(Tau,df,DI)` expects `DI` to be the transpose of the inverse of the Cholesky factor of `Tau`, so that `DI'*DI = inv(Tau)`, where `inv` is the MATLAB inverse function. `DI` is lower-triangular and the same size as `Tau`. If you call `iwishrnd` multiple times using the same value of `Tau`, it is more efficient to supply `DI` instead of computing it each time.

`[W,DI] = iwishrnd(Tau,df)` returns `DI` so you can use it as an input in future calls to `iwishrnd`.

Note that different sources use different parametrizations for the inverse Wishart distribution. This function defines the parameter `tau` so that the mean of the output matrix is `Tau/(df-d-1)` where `d` is the dimension of `Tau`.

`wishrnd`

jackknife

Jackknife sampling

Syntax

```
jackstat = jackknife(jackfun,X)
jackstat = jackknife(jackfun,X,Y,...)
jackstat = jackknife(jackfun,...,'Options',option)
```

Description

`jackstat = jackknife(jackfun,X)` draws jackknife data samples from the `n`-by-`p` data array `X`, computes statistics on each sample using the function `jackfun`, and returns the results in the matrix `jackstat`. `jackknife` regards each row of `X` as one data sample, so there are `n` data samples. Each of the `n` rows of `jackstat` contains the results of applying `jackfun` to one jackknife sample. `jackfun` is a function handle specified with `@`. Row `i` of `jackstat` contains the results for the sample consisting of `X` with the `i`th row omitted:

```
s = x;
s(i,:) = [];
jackstat(i,:) = jackfun(s);
```

If `jackfun` returns a matrix or array, then this output is converted to a row vector for storage in `jackstat`. If `X` is a row vector, it is converted to a column vector.

`jackstat = jackknife(jackfun,X,Y,...)` accepts additional arguments to be supplied as inputs to `jackfun`. They may be scalars, column vectors, or matrices. `jackknife` creates each jackknife sample by sampling with replacement from the rows of the non-scalar data arguments (these must have the same number of rows). Scalar data are passed to `jackfun` unchanged. Non-scalar arguments must have the same number of rows, and each jackknife sample omits the same row from these arguments.

`jackstat = jackknife(jackfun,...,'Options',option)` provides an option to perform jackknife iterations in parallel, if the Parallel Computing Toolbox is available. Set `'Options'` as a structure you create with `statset`. `jackknife` uses the following field in the structure:

`'UseParallel'`	If `true` and if a `parpool` of the Parallel Computing Toolbox is open, use multiple processors to compute jackknife iterations. If the Parallel Computing Toolbox is not installed, or a `parpool` is not open, computation occurs in serial mode. Default is `false`, or serial computation.

Examples

Estimate the bias of the MLE variance estimator of random samples taken from the vector `y` using `jackknife`. The bias has a known formula in this problem, so you can compare the `jackknife` value to this formula.

```
sigma = 5;
y = normrnd(0,sigma,100,1);
m = jackknife(@var, y, 1);
n = length(y);
bias = -sigma^2 / n % known bias formula
jbias = (n - 1)*(mean(m)-var(y,1)) % jackknife bias estimate

bias =
   -0.2500

jbias =
   -0.3378
```

jbtest

Jarque-Bera test

Syntax

```
h = jbtest(x)
h = jbtest(x,alpha)
h = jbtest(x,alpha,mctol)
[h,p] = jbtest(___)
[h,p,jbstat,critval] = jbtest(___)
```

Description

`h = jbtest(x)` returns a test decision for the null hypothesis that the data in vector `x` comes from a normal distribution with an unknown mean and variance, using the Jarque-Bera test. The alternative hypothesis is that it does not come from such a distribution. The result `h` is `1` if the test rejects the null hypothesis at the 5% significance level, and `0` otherwise.

`h = jbtest(x,alpha)` returns a test decision for the null hypothesis at the significance level specified by `alpha`.

`h = jbtest(x,alpha,mctol)` returns a test decision based on a *p*-value computed using a Monte Carlo simulation with a maximum Monte Carlo standard error less than or equal to `mctol`.

`[h,p] = jbtest(___)` also returns the *p*-value `p` of the hypothesis test, using any of the input arguments from the previous syntaxes.

`[h,p,jbstat,critval] = jbtest(___)` also returns the test statistic `jbstat`and the critical value `critval` for the test.

Examples

Test for a Normal Distribution

Load the data set.

```
load carbig;
```

Test the null hypothesis that car mileage, in miles per gallon (MPG), follows a normal distribution across different makes of cars.

```
h = jbtest(MPG)
```

```
h =

     1
```

The returned value of `h = 1` indicates that `jbtest` rejects the null hypothesis at the default 5% significance level.

Test the Hypothesis at a Different Significance Level

Load the data set.

```
load carbig;
```

Test the null hypothesis that car mileage in miles per gallon (MPG) follows a normal distribution across different makes of cars at the 1% significance level.

```
[h,p] = jbtest(MPG,0.01)
```

```
h =

     1

p =

    0.0022
```

The returned value of `h = 1`, and the returned *p*-value less than `α = 0.01` indicate that `jbtest` rejects the null hypothesis.

Test for a Normal Distribution Using Monte Carlo Simulation

Load the data set.

```
load carbig;
```

Test the null hypothesis that car mileage, in miles per gallon (MPG), follows a normal distribution across different makes of cars. Use a Monte Carlo simulation to obtain an exact *p*-value.

```
[h,p,jbstat,critval] = jbtest(MPG,[],0.0001)
h =

     1

p =

    0.0022

jbstat =

   18.2275

critval =

    5.8461
```

The returned value of `h = 1` indicates that `jbtest` rejects the null hypothesis at the default 5% significance level. Additionally, the test statistic, `jbstat`, is larger than the critical value, `critval`, which indicates rejection of the null hypothesis.

Input Arguments

x — Sample data

vector

Sample data for the hypothesis test, specified as a vector. `jbtest` treats `NaN` values in `x` as missing values and ignores them.

Data Types: `single` | `double`

alpha — Significance level

`0.05` (default) | scalar value in the range (0,1)

Significance level of the hypothesis test, specified as a scalar value in the range (0,1). If `alpha` is in the range [0.001,0.50], and if the sample size is less than or equal to 2000, `jbtest` looks up the critical value for the test in a table of precomputed values. To conduct the test at a significance level outside of these specifications, use `mctol`.

Example: `0.01`

Data Types: `single` | `double`

`mctol` — Maximum Monte Carlo standard error

nonnegative scalar value

Maximum Monte Carlo standard error for the *p*-value, `p`, specified as a nonnegative scalar value. If you specify a value for `mctol`, `jbtest` computes a Monte Carlo approximation for `p` directly, rather than interpolating into a table of precomputed values. `jbtest` chooses the number of Monte Carlo replications large enough to make the Monte Carlo standard error for `p` less than `mctol`.

If you specify a value for `mctol`, you must also specify a value for `alpha`. You can specify `alpha` as `[]` to use the default value of 0.05.

Example: `0.0001`

Data Types: `single` | `double`

Output Arguments

`h` — Hypothesis test result

`1` | `0`

Hypothesis test result, returned as a logical value.

- If `h = 1`, this indicates the rejection of the null hypothesis at the alpha significance level.
- If `h = 0`, this indicates a failure to reject the null hypothesis at the alpha significance level.

`p` — *p*-value

scalar value in the range (0,1)

p-value of the test, returned as a scalar value in the range (0,1). p is the probability of observing a test statistic as extreme as, or more extreme than, the observed value under the null hypothesis. Small values of p cast doubt on the validity of the null hypothesis.

`jbtest` warns when `p` is not found within the tabulated range of [0.001,0.50], and returns either the smallest or largest tabulated value. In this case, you can use `mctol` to compute a more accurate *p*-value.

`jbstat` — Test statistic
nonnegative scalar value

Test statistic for the Jarque-Bera test, returned as a nonnegative scalar value.

`critval` — Critical value
nonnegative scalar value

Critical value for the Jarque-Bera test at the `alpha` significance level, returned as a nonnegative scalar value. If `alpha` is in the range [0.001,0.50], and if the sample size is less than or equal to 2000, `jbtest` looks up the critical value for the test in a table of precomputed values. If you use `mctol`, `jbtest` determines the critical value of the test using a Monte Carlo simulation. The null hypothesis is rejected when `jbstat > critval`.

More About

Jarque-Bera Test

The Jarque-Bera test is a two-sided goodness-of-fit test suitable when a fully specified null distribution is unknown and its parameters must be estimated.

The test is specifically designed for alternatives in the Pearson system of distributions. The test statistic is

$$JB = \frac{n}{6}\left(s^2 + \frac{(k-3)^2}{4}\right),$$

where n is the sample size, s is the sample skewness, and k is the sample kurtosis. For large sample sizes, the test statistic has a chi-square distribution with two degrees of freedom.

Monte Carlo Standard Error

The Monte Carlo standard error is the error due to simulating the p-value.

The Monte Carlo standard error is calculated as

$$SE = \sqrt{\frac{(\hat{p})(1-\hat{p})}{\text{mcreps}}},$$

where $\hat{p}$ is the estimated p-value of the hypothesis test, and `mcreps` is the number of Monte Carlo replications performed. `jbtest` chooses the number of Monte Carlo replications, `mcreps`, large enough to make the Monte Carlo standard error for $\hat{p}$ less than the value specified for `mctol`.

Algorithms

Jarque-Bera tests often use the chi-square distribution to estimate critical values for large samples, deferring to the Lilliefors test (see `lillietest`) for small samples. `jbtest`, by contrast, uses a table of critical values computed using Monte Carlo simulation for sample sizes less than 2000 and significance levels from 0.001 to 0.50. Critical values for a test are computed by interpolating into the table, using the analytic chi-square approximation only when extrapolating for larger sample sizes.

johnsrnd

Johnson system random numbers

Syntax

```
r = johnsrnd(quantiles,m,n)
r = johnsrnd(quantiles)
[r,type] = johnsrnd(...)
[r,type,coefs] = johnsrnd(...)
```

Description

`r = johnsrnd(quantiles,m,n)` returns an `m`-by-`n` matrix of random numbers drawn from the distribution in the Johnson system that satisfies the quantile specification given by `quantiles`. `quantiles` is a four-element vector of quantiles for the desired distribution that correspond to the standard normal quantiles [–1.5 –0.5 0.5 1.5]. In other words, you specify a distribution from which to draw random values by designating quantiles that correspond to the cumulative probabilities [0.067 0.309 0.691 0.933]. `quantiles` may also be a `2`-by-`4` matrix whose first row contains four standard normal quantiles, and whose second row contains the corresponding quantiles of the desired distribution. The standard normal quantiles must be spaced evenly.

Note: Because `r` is a random sample, its sample quantiles typically differ somewhat from the specified distribution quantiles.

`r = johnsrnd(quantiles)` returns a scalar value.

`r = johnsrnd(quantiles,m,n,...)` or `r = johnsrnd(quantiles,[m,n,...])` returns an `m`-by-`n`-by-... array.

`[r,type] = johnsrnd(...)` returns the type of the specified distribution within the Johnson system. `type` is `'SN'`, `'SL'`, `'SB'`, or `'SU'`. Set `m` and `n` to zero to identify the distribution type without generating any random values.

The four distribution types in the Johnson system correspond to the following transformations of a normal random variate:

- `'SN'` — Identity transformation (normal distribution)
- `'SL'` — Exponential transformation (lognormal distribution)
- `'SB'` — Logistic transformation (bounded)
- `'SU'` — Hyperbolic sine transformation (unbounded)

`[r,type,coefs] = johnsrnd(...)` returns coefficients `coefs` of the transformation that defines the distribution. `coefs` is `[gamma, eta, epsilon, lambda]`. If `z` is a standard normal random variable and `h` is one of the transformations defined above, `r = lambda*h((z-gamma)/eta)+epsilon` is a random variate from the distribution type corresponding to `h`.

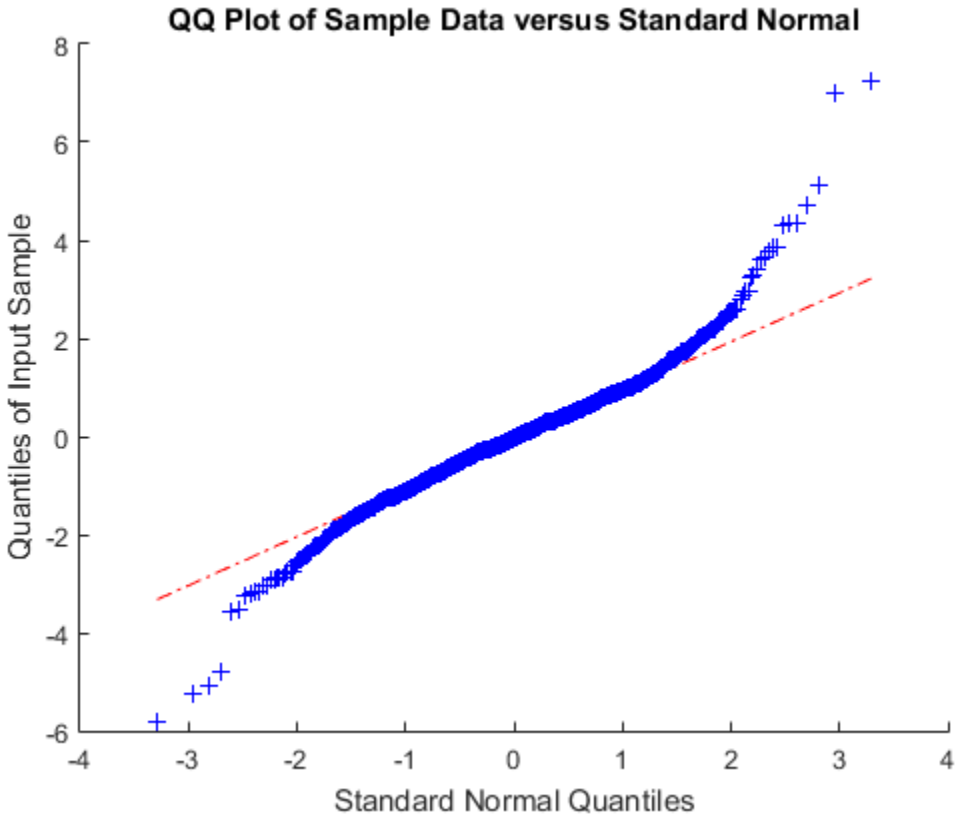
Examples

Generate Random Samples Using the Johnson System

This example shows several different approaches to using the Johnson system of flexible distribution families to generate random numbers and fit a distribution to sample data.

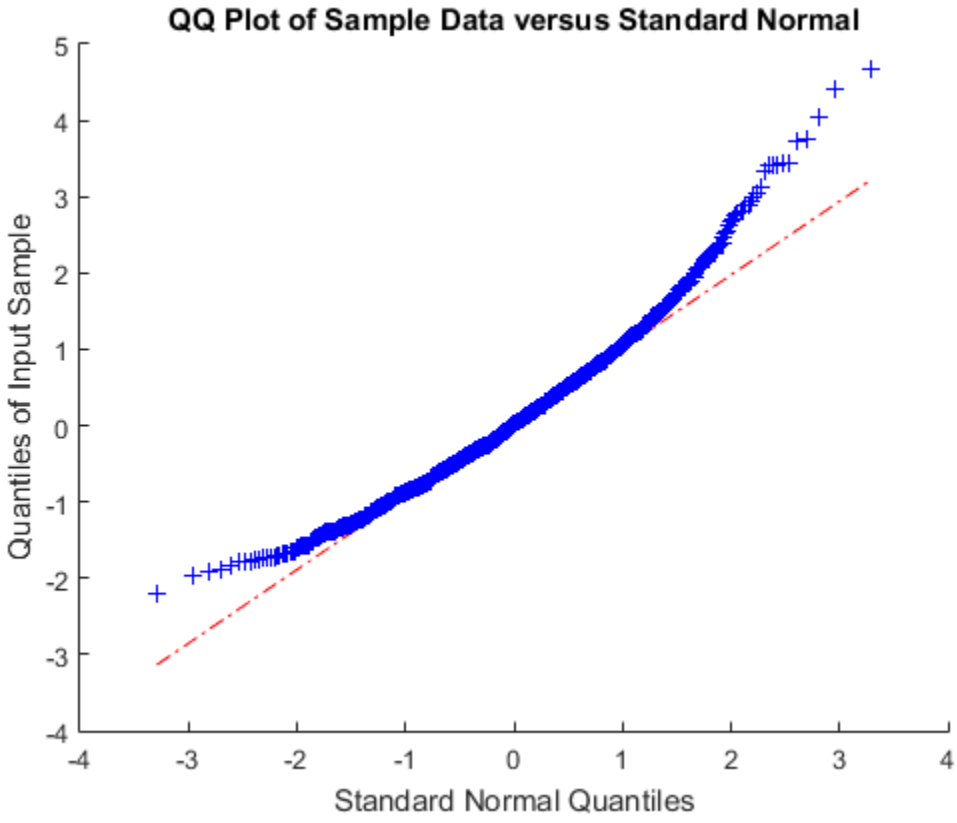
Generate random values with longer tails than a standard normal.

```
rng default;  % For reproducibility
r = johnsrnd([-1.7 -.5 .5 1.7],1000,1);
figure;
qqplot(r);
```



Generate random values skewed to the right.

```
r = johnsrnd([-1.3 -.5 .5 1.7],1000,1);
figure;
qqplot(r);
```



Generate random values that match some sample data well in the right-hand tail.

```
load carbig;
qnorm = [.5 1 1.5 2];
q = quantile(Acceleration, normcdf(qnorm));
r = johnsrnd([qnorm;q],1000,1);
[q;quantile(r,normcdf(qnorm))]
```

```
ans =

   16.7000   18.2086   19.5376   21.7263
   16.6986   18.2220   19.9078   22.0918
```

Determine the distribution type and the coefficients.

```
[r,type,coefs] = johnsrnd([qnorm;q],0)

r =

     []

type =

SU

coefs =

    1.0920    0.5829   18.4382    1.4494
```

join

Class: dataset

Merge observations

Compatibility

The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

Syntax

```
C = join(A,B)
C = join(A,B,keys)
C = join(A,B,param1,val1,param2,val2,...)
[C,IB] = join(...)
C = join(A,B,'Type',TYPE,...)
C = join(A,B,'Type',TYPE,'MergeKeys',true,...)
[C,IA,IB] = join(A,B,'Type',TYPE,...)
```

Description

`C = join(A,B)` creates a dataset array `C` by merging observations from the two dataset arrays `A` and `B`. `join` performs the merge by first finding *key variables*, that is, pairs of dataset variables, one in `A` and one in `B`, that share the same name. Each observation in `B` must contain a unique combination of values in the key variables, and must contain all combinations of values that are present in the keys from `A`. `join` then uses these key variables to define a many-to-one correspondence between observations in `A` and those in `B`. `join` uses this correspondence to replicate the observations in `B` and combine them with the observations in `A` to create `C`.

`C = join(A,B,keys)` performs the merge using the variables specified by `keys` as the key variables in both `A` and `B`. `keys` is a positive integer, a vector of positive integers, a variable name, a cell array of variable names, or a logical vector.

C contains one observation for each observation in A. Variables in C include all of the variables from A, as well as one variable corresponding to each variable in B (except for the keys from B). If A and B contain variables with identical names, join adds the suffix '_left' and '_right' to the corresponding variables in C.

C = join(A,B,*param1*,*val1*,*param2*,*val2*,...) specifies optional parameter name/value pairs to control how the dataset variables in A and B are used in the merge. Parameters are:

- 'Keys' — Specifies the variables to use as keys in both A and B.
- 'LeftKeys' — Specifies the variables to use as keys in A.
- 'RightKeys' — Specifies the variables to use as keys in B.

You may provide either the 'Keys' parameter, or both the 'LeftKeys' and 'RightKeys' parameters. The value for these parameters is a positive integer, a vector of positive integers, a variable name, a cell array containing variable names, or a logical vector. 'LeftKeys' or 'RightKeys' must both specify the same number of key variables, and join pairs the left and right keys in the order specified.

- 'LeftVars' — Specifies which variables from A to include in C. By default, join includes all variables from A.
- 'RightVars' — Specifies which variables from B to include in C. By default, join includes all variables from B except the key variables.

You can use 'LeftVars' or 'RightVars' to include or exclude key variables as well as data variables. The value for these parameters is a positive integer, a vector of positive integers, a variable name, a cell array containing one or more variable names, or a logical vector.

[C,IB] = join(...) returns an index vector IB, where join constructs C by horizontally concatenating A(:,LeftVars) and B(IB,RightVars). join can also perform more complicated inner and outer join operations that allow a many-to-many correspondence between A and B, and allow unmatched observations in either A or B.

C = join(A,B,'Type',TYPE,...) performs the join operation specified by TYPE. TYPE is one of 'inner', 'leftouter', 'rightouter', 'fullouter', or 'outer' (which is a synonym for 'fullouter'). For an inner join, C only contains observations corresponding to a combination of key values that occurred in both A and B. For a left (or right) outer join, C also contains observations corresponding to keys in A (or B) that did not match any in B (or A). Variables in C taken from A (or B) contain null values in those observations. A full outer join is equivalent to a left and right outer join. C contains

variables corresponding to the key variables from both A and B, and join sorts the observations in C by the key values.

For inner and outer joins, C contains variables corresponding to the key variables from both A and B by default, as well as all the remaining variables. join sorts the observations in the result C by the key values.

C = join(A,B,'Type',TYPE,'MergeKeys',true,...) includes a single variable in C for each key variable pair from A and B, rather than including two separate variables. For outer joins, join creates the single variable by merging the key values from A and B, taking values from A where a corresponding observation exists in A, and from B otherwise. Setting the 'MergeKeys' parameter to true overrides inclusion or exclusion of any key variables specified via the 'LeftVars' or 'RightVars' parameter. Setting the 'MergeKeys' parameter to false is equivalent to not passing in the 'MergeKeys' parameter.

[C,IA,IB] = join(A,B,'Type',TYPE,...) returns index vectors IA and IB indicating the correspondence between observations in C and those in A and B. For an inner join, join constructs C by horizontally concatenating A(IA,LeftVars) and B(IB,RightVars). For an outer join, IA or IB may also contain zeros, indicating the observations in C that do not correspond to observations in A or B, respectively.

Examples

Create a dataset array from Fisher's iris data:

```
load fisheriris
NumObs = size(meas,1);
NameObs = strcat({'Obs'},num2str((1:NumObs)','%-d'));
iris = dataset({nominal(species),'species'},...
               {meas,'SL','SW','PL','PW'},...
               'ObsNames',NameObs);
```

Create a separate dataset array with the diploid chromosome counts for each species of iris:

```
snames = nominal({'setosa';'versicolor';'virginica'});
CC = dataset({snames,'species'},{[38;108;70],'cc'})
CC =
    species       cc
    setosa         38
    versicolor    108
```

```
    virginica      70
```

Broadcast the data in `CC` to the rows of `iris` using the key variable `species` in each dataset:

```
iris2 = join(iris,CC);
iris2([1 2 51 52 101 102],:)
ans =
            species       SL     SW     PL     PW     cc
 Obs1       setosa        5.1    3.5    1.4    0.2     38
 Obs2       setosa        4.9      3    1.4    0.2     38
 Obs51      versicolor      7    3.2    4.7    1.4    108
 Obs52      versicolor    6.4    3.2    4.5    1.5    108
 Obs101     virginica     6.3    3.3      6    2.5     70
 Obs102     virginica     5.8    2.7    5.1    1.9     70
```

Create two datasets and join them using the `'MergeKeys'` flag:

```
% Create two data sets that both contain the key variable
% 'Key1'. The two arrays contain observations with common
% values of Key1, but each array also contains observations
% with values of Key1 not present in the other.
a = dataset({'a' 'b' 'c' 'e' 'h'},[1 2 3 11 17]',...
   'VarNames',{'Key1' 'Var1'})
b = dataset({'a' 'b' 'd' 'e'},[4 5 6 7]',...
   'VarNames',{'Key1' 'Var2'})

% Combine a and b with an outer join, which matches up
% observations with common key values, but also retains
% observations whose key values don't have a match.
% Keep the key values as separate variables in the result.
couter = join(a,b,'key','Key1','Type','outer')

% Join a and b, merging the key values as a single variable
% in the result.
coutermerge = join(a,b,'key','Key1','Type','outer',...
   'MergeKeys',true)

% Join a and b, retaining only observations whose key
% values match.
cinner = join(a,b,'key','Key1','Type','inner',...
   'MergeKeys',true)

a =
```

```
    Key1       Var1
    'a'         1
    'b'         2
    'c'         3
    'e'        11
    'h'        17

b =

    Key1       Var2
    'a'        4
    'b'        5
    'd'        6
    'e'        7

couter =

    Key1_left    Var1    Key1_right    Var2
    'a'            1     'a'             4
    'b'            2     'b'             5
    'c'            3     ''            NaN
    ''           NaN     'd'             6
    'e'           11     'e'             7
    'h'           17     ''            NaN

coutermerge =

    Key1       Var1    Var2
    'a'          1       4
    'b'          2       5
    'c'          3     NaN
    'd'        NaN       6
    'e'         11       7
    'h'         17     NaN

cinner =

    Key1       Var1    Var2
    'a'         1      4
    'b'         2      5
```

```
    'e'         11       7
```

`sortrows`

KDTreeSearcher

Grow *K*d-tree

Syntax

```
Mdl = KDTreeSearcher(X)
Mdl = KDTreeSearcher(X,Name,Value)
```

Description

`Mdl = KDTreeSearcher(X)` grows a default *K*d-tree (`Mdl`) using the *n*-by-*K* numeric matrix of training data (`X`). `Mdl` is a `KDTreeSearcher` model object that stores the results of the grown *K*d-tree. You can use `Mdl` to search the training data (`X`) for the nearest neighbors to the query data.

`Mdl = KDTreeSearcher(X,Name,Value)` grows a *K*d-tree (`Mdl`) with additional options specified by one or more `Name,Value` pair arguments. For example, you can specify a distance metric or the maximum number of observations in each leaf node (i.e., the bucket size).

Examples

Grow a Default *K* d-Tree

Load Fisher's iris data set.

```
load fisheriris
X = meas;
[n,k] = size(X)
```

```
n =

   150
```

```
k =

     4
```

`X` has 150 observations and 4 predictors.

Grow a 4-dimensional K d-tree using the entire data set as training data.

```
Mdl = KDTreeSearcher(X)
```

```
Mdl =

  KDTreeSearcher with properties:

      BucketSize: 50
        Distance: 'euclidean'
    DistParameter: []
                X: [150x4 double]
```

`Mdl` is a `KDTreeSearcher` model object, and its properties appear in the Command Window. It contains information about the grown 4-dimensional K d-tree, such as the distance metric. You can alter property values using dot notation

To find the nearest neighbors in `X` to a batch of query data, pass `Mdl` and the query data to `knnsearch` or `rangesearch`.

Specify the Minkowski Distance for Nearest Neighbor Search

Load Fisher's iris data. Focus on the petal dimensions.

```
load fisheriris
X = meas(:,[3 4]); % Predictors
```

Grow a two-dimensional K d-tree using `createns` and the training data. Specify the Minkowski distance metric.

```
Mdl = createns(X,'NSMethod','kdtree','Distance','Minkowski')
```

```
Mdl =

  KDTreeSearcher with properties:
```

```
       BucketSize: 50
         Distance: 'minkowski'
    DistParameter: 2
                X: [150x2 double]
```

`Mdl` is a `KDTreeSearcher` model object. Access properties of `Mdl` using dot notation. For example, use `Mdl.DistParameter` to access the Minkowski distance exponent.

```
Mdl.DistParameter
```

```
ans =

     2
```

You can pass query data and `Mdl` to:

- searcher.knnsearch to find indices and distances of nearest neighbors.
- searcher.rangesearch to find indices of all nearest neighbors within a distance that you specify.

Search for Nearest Neighbors of Query Data Using the Minkowski Distance

Load Fisher's iris data set.

```
load fisheriris
```

Remove five irises randomly from the predictor data to use as a query set.

```
rng(1);                      % For reproducibility
n = size(meas,1);            % Sample size
qIdx = randsample(n,5);      % Indices of query data
tIdx = ~ismember(1:n,qIdx); % Indices of training data
Q = meas(qIdx,:);
X = meas(tIdx,:);
```

Grow a four-dimensional K d-tree using the training data. Specify to use the Minkowski distance for finding nearest neighbors later.

```
Mdl = createns(X,'NSMethod','kdtree','Distance','minkowski')
```

```
Mdl =

  KDTreeSearcher with properties:

      BucketSize: 50
        Distance: 'minkowski'
    DistParameter: 2
                X: [145x4 double]
```

`Mdl` is a `KDTreeSearcher` model object. By default, the Minkowski distance exponent is `2`.

Find the indices of the training data (`X`) that are the two nearest neighbors of each point in the query data (`Q`).

```
IdxNN = knnsearch(Mdl,Q,'K',2)
```

```
IdxNN =

    17     4
     6     2
     1    12
    89    66
   124   100
```

Each row of `NN` corresponds to a query data observation, and the column order corresponds to the order of the nearest neighbors. For example, using the Minkowski distance, the second nearest neighbor of `Q(3,:)` is `X(12,:)`.

Input Arguments

`X` — Training data

numeric matrix

Training data that grows the *K*d-tree, specified as a numeric matrix. `X` has n rows, each corresponding to an observation (i.e., an instance or example), and K columns, each corresponding to a predictor or feature.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'Distance','minkowski','P',3,'BucketSize',10` specifies to use the Minkowski distance when searching for nearest neighbors, to use `3` for the Minkowski distance metric exponent, and to use `10` for the bucket size.

`'Distance'` — Distance metric

`'euclidean'` (default) | `'chebychev'` | `'cityblock'` | `'minkowski'`

Distance metric used to find nearest neighbors of query points, specified as the comma-separated pair consisting of `'Distance'` and one of these strings.

Value	Description
`'chebychev'`	Chebychev distance (maximum coordinate difference)
`'cityblock'`	City block distance
`'euclidean'`	Euclidean distance
`'minkowski'`	Minkowski distance

For more details, see “Distance Metrics”.

The software does not use the distance metric for training the *K*d-tree, so you can alter it after training using dot notation.

Example: `'Distance','minkowski'`

Data Types: `char`

`'P'` — Exponent for Minkowski distance metric

`2` (default) | positive scalar

Exponent for the Minkowski distance metric, specified as the comma-separated pair consisting of `'P'` and a positive scalar. If you specify `P` and do not specify `'Distance','minkowski'`, then the software throws an error.

Example: `'P',3`

Data Types: `double` | `single`

`'BucketSize'` — Maximum number of data points in each leaf node
`50` (default) | positive integer

Maximum number of data points in each leaf node of the *K*d-tree, specified as the comma-separated pair consisting of `'BucketSize'` and a positive integer.

Example: `'BucketSize',10`

Data Types: `double` | `single`

Output Arguments

`Mdl` — Grown *K*d-tree
`KDTreeSearcher` model object

Grown *K*d-tree, returned as a `KDTreeSearcher` model object. To search the training data for the nearest neighbors of the query data, pass the query data and `Mdl` to `knnsearch` or `rangesearch`.

More About

- Using KDTreeSearcher Objects

Introduced in R2010a

Using KDTreeSearcher Objects

Nearest neighbor search using *K*d-tree

`KDTreeSearcher` model objects store results of a nearest neighbors search using the *K*d-tree algorithm. Results that you can store include the training data, the distance metric and its parameters, and the maximal number of data points in each leaf node (i.e., the bucket size). The *K*d-tree algorithm partitions an *n*-by-*K* data set by recursively splitting *n* points in *K*-dimensional space into a binary tree. To find the nearest neighbors of a query observation, `KDTreeSearcher` restricts the training data space to the training observations in the leaf node that the query observation belongs to.

Once you create or train a `KDTreeSearcher` model object, you can search the stored tree to find all neighboring points to the query data by performing a nearest neighbors search using `knnsearch` or radius search using `rangesearch`. The *K*d-tree algorithm is particularly useful when:

- *K* is relatively small (i.e., $K < 10$).
- The training and query sets are not sparse.
- The training and query sets have many observations.

Examples

Grow a Default *K* d-Tree

Load Fisher's iris data set.

```
load fisheriris
X = meas;
[n,k] = size(X)
```

```
n =

   150

k =

     4
```

`X` has 150 observations and 4 predictors.

Grow a 4-dimensional K d-tree using the entire data set as training data.

```
Mdl = KDTreeSearcher(X)
```

```
Mdl =

  KDTreeSearcher with properties:

      BucketSize: 50
        Distance: 'euclidean'
    DistParameter: []
                X: [150x4 double]
```

`Mdl` is a `KDTreeSearcher` model object, and its properties appear in the Command Window. It contains information about the grown 4-dimensional K d-tree, such as the distance metric. You can alter property values using dot notation

To find the nearest neighbors in `X` to a batch of query data, pass `Mdl` and the query data to `knnsearch` or `rangesearch`.

Alter Properties of `KDTreeSearcher` Model

Load Fisher's iris data set.

```
load fisheriris
X = meas;
```

Grow a default four-dimensional K d-tree using the entire data set as training data.

```
Mdl = KDTreeSearcher(X)
```

```
Mdl =

  KDTreeSearcher with properties:

      BucketSize: 50
        Distance: 'euclidean'
    DistParameter: []
                X: [150x4 double]
```

Specify that the neighbor searcher use the Minkowski metric to compute the distances between the training and query data.

```
Mdl.Distance = 'minkowski'
```

```
Mdl =

  KDTreeSearcher with properties:

      BucketSize: 50
        Distance: 'minkowski'
    DistParameter: 2
                X: [150x4 double]
```

Pass `Mdl` and the query data to either `knnsearch` or `rangesearch` to find the nearest neighbors to the points in the query data using the Minkowski distance.

Search for Nearest Neighbors of Query Data Using the Minkowski Distance

Load Fisher's iris data set.

```
load fisheriris
```

Remove five irises randomly from the predictor data to use as a query set.

```
rng(1);                      % For reproducibility
n = size(meas,1);            % Sample size
qIdx = randsample(n,5);      % Indices of query data
tIdx = ~ismember(1:n,qIdx); % Indices of training data
Q = meas(qIdx,:);
X = meas(tIdx,:);
```

Grow a four-dimensional K d-tree using the training data. Specify to use the Minkowski distance for finding nearest neighbors later.

```
Mdl = createns(X,'NSMethod','kdtree','Distance','minkowski')
```

```
Mdl =

  KDTreeSearcher with properties:

      BucketSize: 50
```

```
        Distance: 'minkowski'
    DistParameter: 2
                X: [145x4 double]
```

`Mdl` is a `KDTreeSearcher` model object. By default, the Minkowski distance exponent is `2`.

Find the indices of the training data (`X`) that are the two nearest neighbors of each point in the query data (`Q`).

```
IdxNN = knnsearch(Mdl,Q,'K',2)
```

```
IdxNN =

    17     4
     6     2
     1    12
    89    66
   124   100
```

Each row of `NN` corresponds to a query data observation, and the column order corresponds to the order of the nearest neighbors. For example, using the Minkowski distance, the second nearest neighbor of `Q(3,:)` is `X(12,:)`.

Properties

`Distance` — Distance metric

`'chebychev' | 'cityblock' | 'euclidean' | 'minkowski'`

Distance metric used to find nearest neighbors of query points, specified as one of these strings.

Value	Description
`'chebychev'`	Chebychev distance (maximum coordinate difference)
`'cityblock'`	City block distance
`'euclidean'`	Euclidean distance

Value	Description
`'minkowski'`	Minkowski distance

For more details, see “Distance Metrics”.

The software does not use the distance metric for training the *K*d-tree, so you can alter it after training using dot notation.

Data Types: `char`

`DistParameter` — Distance metric parameter values

`[]` | positive scalar

Distance metric parameter values, specified as empty (`[]`) or as a positive scalar.

If `Distance` is `'minkowski'`, then:

- `DistParameter` is the exponent in the Minkowski distance formula.
- You can alter `DistParameter` of a trained `KDTreeSearcher` model.

Otherwise, `DistParameter` is `[]`, indicating that the specified distance metric formula has no parameters.

Data Types: `single` | `double`

`X` — Training data

numeric matrix

Training data that grows the *K*d-tree, specified as a numeric matrix. `X` has *n* rows, each corresponding to an observation (i.e., an instance or example), and *K* columns, each corresponding to a predictor or feature.

Data Types: `single` | `double`

Object Functions

`knnsearch` `rangesearch`

Create Object

Train a `KDTreeSearcher` model object using `KDTreeSearcher` or `createns`.

Kernel property

Class: ProbDistKernel

Read-only string specifying name of kernel smoothing function for ProbDistKernel object

Description

`Kernel` is a read-only property of the `ProbDistKernel` class. `Kernel` is a string specifying the name of the kernel smoothing function used to create a ProbDistKernel object.

Values

```
'normal'
'box'
'triangle'
'epanechnikov'
```

Use this information to view and compare the kernel smoothing function used to create distributions.

See Also

`ksdensity`

prob.KernelDistribution class

Package: prob
Superclasses: prob.TruncatableDistribution

Kernel probability distribution object

Description

`prob.KernelDistribution` is an object consisting of parameters, a model description, and sample data for a nonparametric kernel-smoothing distribution. Create a `prob.KernelDistribution` object using `fitdist` or `dfittool`.

Construction

`pd = fitdist(x,'Kernel')` creates a probability distribution object by fitting a kernel-smoothing distribution to the data in x.

`pd = fitdist(x,'Kernel',Name,Value)` creates a probability distribution object with additional options specified by one or more name-value pair arguments. For example, you can change the kernel function or specify the kernel bandwidth.

Input Arguments

x — Input data

column vector

Input data to fit with a kernel-smoothing distribution, specified as a column vector of scalar values. `fitdist` ignores `NaN` values in x.

Data Types: `single | double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'Kernel'` — Kernel smoother type

`'normal'` (default) | `'box'` | `'triangle'` | `'epanechnikov'`

Kernel smoother type, specified as the comma-separated pair consisting of `'Kernel'` and one of the following kernel smoothing function types:

- `'normal'`
- `'box'`
- `'triangle'`
- `'epanechnikov'`

`'Support'` — Kernel density support

`'unbounded'` (default) | `'positive'` | two-element vector

Kernel density support, specified as the comma-separated pair consisting of `'Support'` and a string or two-element vector. The string must be one of the following.

`'unbounded'`	Density can extend over the whole real line.
`'positive'`	Density is restricted to positive values.

Alternatively, you can specify a two-element vector giving finite lower and upper limits for the support of the density.

Data Types: `single` | `double`

`'Width'` — Bandwidth of kernel smoothing window

scalar value

Bandwidth of the kernel smoothing window, specified as the comma-separated pair consisting of `'Width'` and a scalar value. The default value used by `fitdist` is optimal for estimating normal densities, but you might want to choose a smaller value to reveal features such as multiple modes.

Data Types: `single` | `double`

Properties

`Kernel` — Kernel smoother type

`'normal'` | `'box'` | `'triangle'` | `'epanechnikov'`

Kernel function type, stored as a valid kernel function type name.

`BandWidth` — Bandwidth of kernel smoothing window

positive scalar value

Bandwidth of the kernel smoothing window, stored as a positive scalar value.

Data Types: `single | double`

`DistributionName` — Probability distribution name

probability distribution name string

Probability distribution name, stored as a valid probability distribution name string. This property is read-only.

Data Types: `char`

`InputData` — Data used for distribution fitting

structure

Data used for distribution fitting, stored as a structure containing the following:

- `data`: Data vector used for distribution fitting.
- `cens`: Censoring vector, or empty if none.
- `freq`: Frequency vector, or empty if none.

This property is read-only.

Data Types: `struct`

`IsTruncated` — Logical flag for truncated distribution

`0 | 1`

Logical flag for truncated distribution, stored as a logical value. If `IsTruncated` equals `0`, the distribution is not truncated. If `IsTruncated` equals `1`, the distribution is truncated. This property is read-only.

Data Types: `logical`

`Truncation` — Truncation interval

vector of scalar values

Truncation interval for the probability distribution, stored as a vector containing the lower and upper truncation boundaries. This property is read-only.

Data Types: `single` | `double`

Methods

mean	Mean of probability distribution object
negloglik	Negative loglikelihood
std	Standard deviation of probability distribution object
var	Variance of probability distribution object

Inherited Methods

cdf	Cumulative distribution function of probability distribution object
icdf	Inverse cumulative distribution function of probability distribution object
iqr	Interquartile range of probability distribution object
median	Median of probability distribution object
pdf	Probability density function of probability distribution object
random	Generate random numbers from probability distribution object

truncate

Truncate probability distribution object

Definitions

Kernel Distribution

The kernel distribution is a nonparametric estimation of the probability density function (pdf) of a random variable.

The kernel distribution uses the following options.

Option	Description	Possible Values
`Kernel`	Kernel function type	`normal`, `box`, `triangle`, `epanechnikov`
`BandWidth`	Kernel smoothing parameter	`BandWidth > 0`

The kernel density estimator is

$$\hat{f}_h(x) = \frac{1}{nh}\sum_{i=1}^{n} K\left(\frac{x - x_i}{h}\right) \quad ; \quad -\infty < x < \infty ,$$

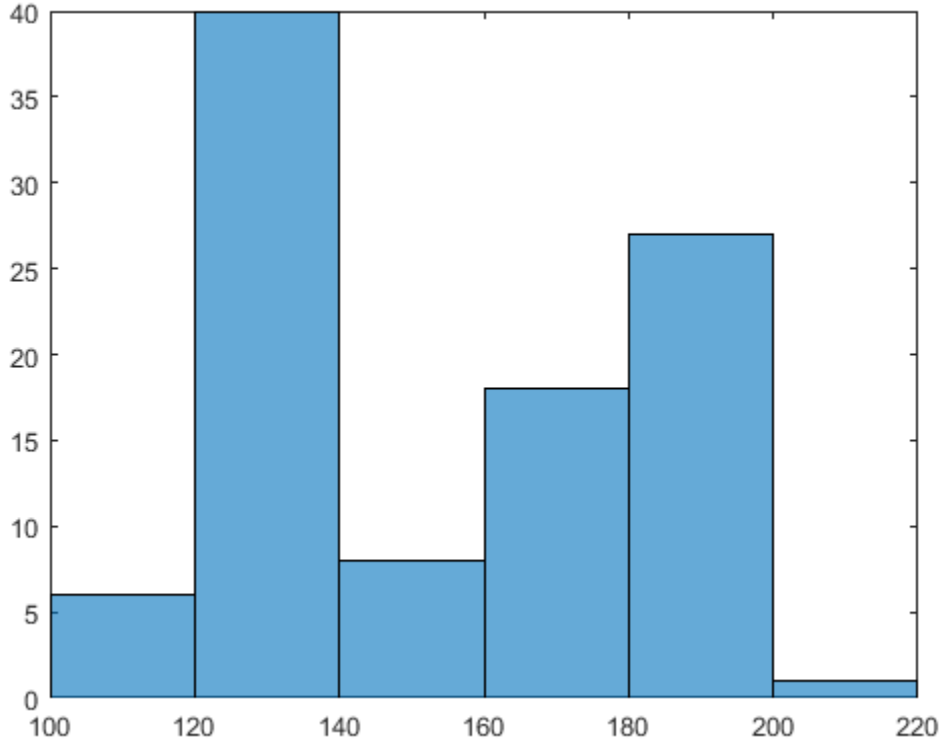
where n is the sample size, $K(\bullet)$ is the kernel function, and h is the bandwidth.

Examples

Fit a Kernel Distribution Object to Data

Load the sample data. Visualize the patient weight data using a histogram.

```
load hospital
histogram(hospital.Weight)
```



The histogram shows that the data has two modes, one for female patients and one for male patients.

Create a probability distribution object by fitting a kernel distribution to the patient weight data.

```
pd_kernel = fitdist(hospital.Weight,'Kernel')
```

```
pd_kernel =

  KernelDistribution

    Kernel = normal
    Bandwidth = 14.3792
```

```
    Support = unbounded
```

For comparison, create another probability distribution object by fitting a normal distribution to the patient weight data.

```
pd_normal = fitdist(hospital.Weight,'Normal')
```

```
pd_normal =

  NormalDistribution

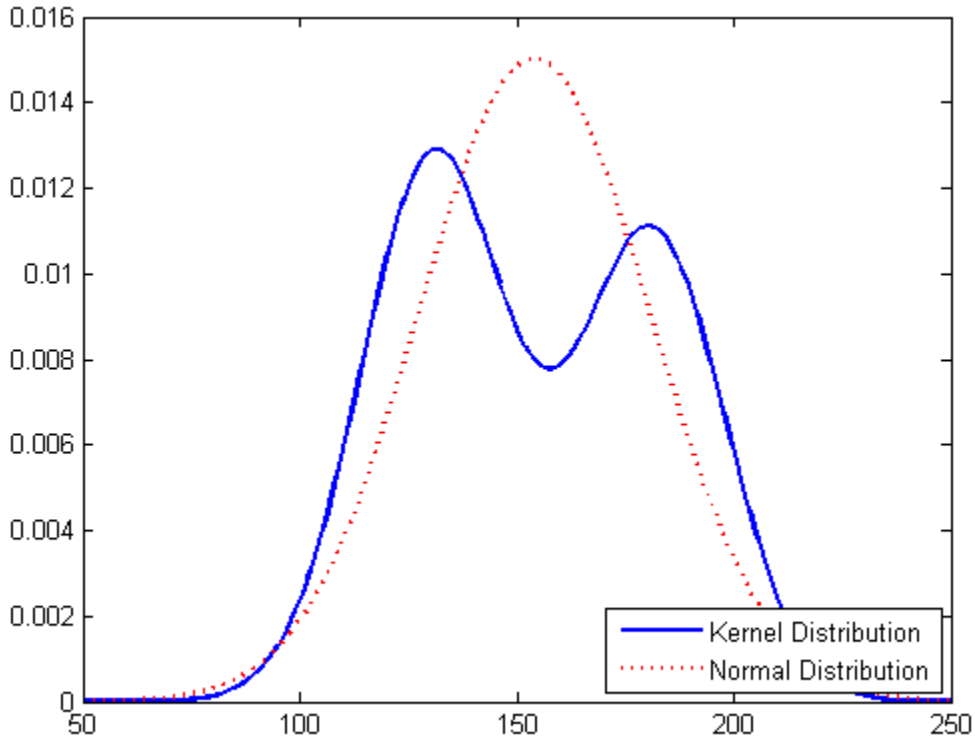
  Normal distribution
       mu =     154   [148.728, 159.272]
    sigma = 26.5714   [23.3299, 30.8674]
```

Define the x values and compute the pdf of each distribution.

```
x = 50:1:250;
pdf_kernel = pdf(pd_kernel,x);
pdf_normal = pdf(pd_normal,x);
```

Plot the pdf of each distribution.

```
plot(x,pdf_kernel,'Color','b','LineWidth',2);
hold on;
plot(x,pdf_normal,'Color','r','LineStyle',':','LineWidth',2);
legend('Kernel Distribution','Normal Distribution','Location','SouthEast');
hold off;
```



Fitting a kernel distribution instead of a unimodal distribution such as the normal reveals the separate modes for the female and male patients.

kfoldEdge

Classification edge for observations not used for training

Syntax

```
edge = kfoldEdge(CVMdl)
edge = kfoldEdge(CVMdl,Name,Value)
```

Description

`edge = kfoldEdge(CVMdl)` returns the classification edge obtained by the cross-validated ECOC model (`ClassificationPartitionedECOC`) `CVMdl`. For every fold, `kfoldEdge` computes the classification edge for in-fold observations using an ECOC model trained on out-of-fold observations. `CVMdl.X` contains both sets of observations.

`edge = kfoldEdge(CVMdl,Name,Value)` returns the classification edge with additional options specified by one or more Name,Value pair arguments.

For example, specify the number of folds, decoding scheme, or verbosity level.

Input Arguments

`CVMdl` — Cross-validated ECOC model

`ClassificationPartitionedECOC` model

Cross-validated ECOC model, specified as a `ClassificationPartitionedECOC` model. You can create a `ClassificationPartitionedECOC` model by:

- Passing a trained ECOC model (`ClassificationECOC`) to `crossval`
- Training an ECOC model using `fitcecoc` and setting any one of these cross-validation name-value pair arguments: `'CrossVal'`, `'KFold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'`

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'BinaryLoss'` — Binary learner loss function

`CVMdl.BinaryLoss` (default) | function handle | `'hamming'` | `'linear'` | `'exponential'` | `'binodeviance'` | `'hinge'` | `'quadratic'`

Binary learner loss function, specified as the comma-separated pair consisting of `'BinaryLoss'` and a function handle or string.

- If the value is a string, then it must correspond to a built-in function. This table summarizes the built-in functions, where y_j is a class label for a particular binary learner (in {-1,1,0}) and f_j is the score for observation j.

Value	Description	Score Domain	Formula
`'binodeviance'`	Binomial deviance	$(-\infty,\infty)$	$\log[1 + \exp(-2yf)]/\log(2)$
`'exponential'`	Exponential	$(-\infty,\infty)$	$\exp(-yf)$
`'hamming'`	Hamming	$(-\infty,\infty)$ or $[0,1]$	$1 - \text{sign}(yf)$
`'hinge'`	Hinge	$(-\infty,\infty)$	$\max(0,1 - yf)$
`'linear'`	Linear	$(-\infty,\infty)$	$1 - yf$
`'quadratic'`	Quadratic	$[0,1]$	$[1 - y(2f - 1)]^2$

- For a custom binary loss function, e.g., `customFunction`, specify its function handle `'BinaryLoss',@customFunction`.

  `customFunction` should have this form

  ```
  bLoss = customFunction(M,f)
  ```
  where:

  - `M` is the K-by-L coding matrix stored in `CVMdl.CodingMatrix`.
  - `f` is the 1-by-L row vector of classification scores.
  - `bLoss` is the classification loss.

- K is the number of classes.
- L is the number of binary learners.

Example: `'BinaryLoss','binodeviance'`

Data Types: `char` | `function_handle`

`'Decoding'` — Decoding scheme

`'lossweighted'` (default) | `'lossbased'`

Decoding scheme that aggregates the binary losses, specified as the comma-separated pair consisting of `'Decoding'` and `'lossweighted'` or `'lossbased'`.

Example: `'Decoding','lossbased'`

Data Types: `char`

`'Folds'` — Fold indices for prediction

`1:Mdl.KFold` (default) | numeric vector of positive integers

Fold indices for prediction, specified as the comma-separated pair consisting of `'Folds'` and a numeric vector of positive integers. The elements of `Folds` must range from `1` through `Mdl.KFold`.

The software only uses the folds specified in `Folds` for prediction.

Example: `'Folds',[1 4 10]`

Data Types: `single` | `double`

`'Mode'` — Edge meaning

`'average'` (default) | `'individual'`

Edge meaning, specified as the comma-separated pair consisting of `'Mode'` and `'average'` or `'individual'`.

This table describes the values.

Value	Description
`'average'`	`edge` is the scalar average over all folds.
`'individual'`	`edge` is a vector of length k containing one edge per fold. k is the number of folds.

Example: `'Mode','individual'`

Data Types: `char`

`'Options'` — Estimation options

`[]` (default) | structure array returned by `statset`

Estimation options, specified as the comma-separated pair consisting of `'Options'` and a structure array returned by `statset`.

To invoke parallel computing:

- You need a Parallel Computing Toolbox license.
- Specify `'Options',statset('UseParallel',1)`.

`'Verbose'` — Verbosity level

`0` (default) | `1`

Verbosity level, specified as the comma-separated pair consisting of `'Verbose'` and `0` or `1`. `Verbose` controls the amount of diagnostic messages that the software displays in the Command Window.

If `Verbose` is `0`, then the software does not display diagnostic messages. Otherwise, the software displays diagnostic messages.

Example: `'Verbose',1`

Data Types: `single` | `double`

Output Arguments

`edge` — Classification edge

numeric scalar | numeric row vector

Classification edge, returned as a numeric scalar or numeric row vector.

If Mode is `'average'`, then `edge` is the average classification edge among all binary learners. Otherwise, `edge` is a 1-by-`L` numeric row vector containing the classification edge for each, respective binary learner, where `L` is the number of binary learners (`size(`CVMdl`.CodingMatrix,2)`).

Data Types: `single` | `double`

Definitions

Classification Edge

The *classification edge* is the weighted mean of the *classification margins*.

One way to choose among multiple classifiers, e.g., to perform feature selection, is to choose the classifier that yields the highest edge.

Classification Margin

The *classification margins* are, for each observation, the difference between the negative loss for the positive class and maximal negative loss among the negative classes. If the margins are on the same scale, then they serve as a classification confidence measure, i.e., among multiple classifiers, those that yield larger margins are better [4].

Binary Loss

A *binary loss* is a function of the class and classification score that determines how well a binary learner classifies an observation into the class.

Let:

- m_{kj} be element (k,j) of the coding design matrix M (i.e., the code corresponding to class k of binary learner j)
- s_j be the score of binary learner j for an observation
- g be the binary loss function
- $\hat{k}$ be the predicted class for the observation

In *loss-based decoding* [3], the class producing the minimum sum of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \underset{k}{\operatorname{argmin}} \sum_{j=1}^{L} \left|m_{kj}\right| g(m_{kj}, s_j).$$

In *loss-weighted decoding* [3], the class producing the minimum average of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \underset{k}{\operatorname{argmin}} \frac{\sum_{j=1}^{L} |m_{kj}| \, g(m_{kj}, s_j)}{\sum_{j=1}^{L} |m_{kj}|}.$$

Allwein et al. [1] suggest that loss-weighted decoding improves classification accuracy by keeping loss values for all classes in the same dynamic range.

This table summarizes the supported loss functions, where y_j is a class label for a particular binary learner (in the set {-1,1,0}), s_j is the score for observation j, and $g(y_j,s_j)$.

Value	Description	Score Domain	$g(y_j,s_j)$
`'binodeviance'`	Binomial deviance	$(-\infty,\infty)$	$\log[1 + \exp(-2y_js_j)]/[2\log(2)]$
`'exponential'`	Exponential	$(-\infty,\infty)$	$\exp(-y_js_j)/2$
`'hamming'`	Hamming	{-1,1}	$[1 - \text{sign}(y_js_j)]/2$
`'hinge'`	Hinge	$(-\infty,\infty)$	$\max(0,1 - y_js_j)/2$
`'linear'`	Linear	$(-\infty,\infty)$	$(1 - y_js_j)/2$
`'quadratic'`	Quadratic	[0,1]	$[1 - y_j(2s_j - 1)]^2/2$

The software normalizes the binary losses such that the loss is 0.5 when $y_j = 0$, and aggregates using the average of the binary learners [1].

Do not confuse the binary loss with the overall classification loss (specified by the LossFun name-value pair argument of `predict` and `loss`), e.g., classification error, which measures how well an ECOC classifier performs as a whole.

Examples

Estimate *k*-Fold Cross-Validation Edge of ECOC Models

Load Fisher's iris data set.

```
load fisheriris
```

```
X = meas;
Y = categorical(species);
classOrder = unique(Y);
rng(1); % For reproducibility
```

Train an ECOC model using SVM binary classifiers and specify to cross validate. It is good practice to standardize the predictors and define the class order. Specify to standardize the predictors using an SVM template.

```
t = templateSVM('Standardize',1);
CVMdl = fitcecoc(X,Y,'CrossVal','on','Learners',t,'ClassNames',classOrder);
```

`CVMdl` is a `ClassificationPartitionedModel` model. By default, the software implements 10-fold cross validation. You can alter the number of folds using the `'KFold'` name-value pair argument.

Estimate the average of the out-of-fold edges.

```
edge = kfoldEdge(CVMdl)
```

```
edge =

    0.4825
```

Alternatively, you can obtain the per-fold edges by specifying the name-value pair `'Mode','individual'` in `kfoldEdge`.

Display Individual Edges for Each Cross-Validation Fold

The classification edge is a relative measure of classifier quality. You can determine ill-performing folds by displaying the edges for each fold.

Load Fisher's iris data set.

```
load fisheriris
X = meas;
Y = categorical(species);
classOrder = unique(Y);
rng(1); % For reproducibility
```

Train an ECOC model using SVM binary classifiers and specify to use 8-fold cross validation. It is good practice to standardize the predictors and define the class order. Specify to standardize the predictors using an SVM template.

```
t = templateSVM('Standardize',1);
CVMdl = fitcecoc(X,Y,'KFold',8,'Learners',t,'ClassNames',classOrder);
```

Estimate the classification edge for each fold.

```
edges = kfoldEdge(CVMdl,'Mode','individual')
```

```
edges =

    0.4791
    0.4872
    0.4260
    0.5302
    0.5064
    0.4575
    0.4860
    0.4687
```

The edges have similar magnitudes across folds. Ill-performing folds have low edges relative to the other folds.

You can return the classification edge for the entire model by specifying the well-performing folds using the `'Folds'` name-value pair argument.

Select ECOC Model Features by Comparing Cross-Validation Edges

The classifier edge measures the average of the classifier margins. One way to perform feature selection is to compare cross-validation edges from multiple models. Based solely on this criterion, the classifier with the highest edge is the best classifier.

Load Fisher's iris data set.

```
load fisheriris
X = meas;
Y = categorical(species);
classOrder = unique(Y); % Class order
rng(1); % For reproducibility
```

Define these two data sets:

- `fullX` contains all predictors.
- `partX` contains the petal dimensions.

```
fullX = X;
partX = X(:,3:4);
```

Train an ECOC model using SVM binary classifiers for each predictor set, and specify to cross validate. It is good practice to standardize the predictors and define the class order. Specify to standardize the predictors using an SVM template.

```
t = templateSVM('Standardize',1);
CVMdl = fitcecoc(fullX,Y,'CrossVal','on','Learners',t,...
    'ClassNames',classOrder);
PCVMdl = fitcecoc(partX,Y,'CrossVal','on','Learners',t,...
    'ClassNames',classOrder);
```

`CVMdl` and `PCVMdl` are `ClassificationPartitionedECOC` models. By default, the software implements 10-fold cross validation.

Estimate the test-sample edge for each classifier.

```
fullEdge = kfoldEdge(CVMdl)
partEdge = kfoldEdge(PCVMdl)
```

```
fullEdge =

    0.4825

partEdge =

    0.4951
```

`PCVMdl` achieves an edge that is similar to the more complex model `CVMdl`.

kfoldEdge

Class: ClassificationPartitionedEnsemble

Classification edge for observations not used for training

Syntax

```
E = kfoldEdge(obj)
E = kfoldEdge(obj,Name,Value)
```

Description

`E = kfoldEdge(obj)` returns classification edge (average classification margin) obtained by cross-validated classification ensemble `obj`. For every fold, this method computes classification edge for in-fold observations using an ensemble trained on out-of-fold observations.

`E = kfoldEdge(obj,Name,Value)` calculates edge with additional options specified by one or more Name,Value pair arguments. You can specify several name-value pair arguments in any order as `Name1,Value1,…,NameN,ValueN`.

Input Arguments

`ens`

Object of class `ClassificationPartitionedEnsemble`. Create `ens` with `fitensemble` along with one of the cross-validation options: `'crossval'`, `'kfold'`, `'holdout'`, `'leaveout'`, or `'cvpartition'`. Alternatively, create `ens` from a classification ensemble with `crossval`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'folds'`

Indices of folds ranging from `1` to `ens.KFold`. Use only these folds for predictions.

Default: `1:ens.KFold`

`'mode'`

String representing the meaning of the output edge:

- `'average'` — `edge` is a scalar value, the average over all folds.
- `'individual'` — `edge` is a vector of length `ens.KFold` with one element per fold.
- `'cumulative'` — `edge` is a vector of length `min(ens.NTrainedPerFold)` in which element `J` is obtained by averaging values across all folds for weak learners `1:J` in each fold.

Default: `'average'`

Output Arguments

`E`

The average classification margin. `E` is a scalar or vector, depending on the setting of the `mode` name-value pair.

Definitions

Edge

The *edge* is the weighted mean value of the classification margin. The weights are the class probabilities in `obj.Prior`.

Margin

The classification *margin* is the difference between the classification *score* for the true class and maximal classification score for the false classes. Margin is a column vector with the same number of rows as in the matrix `obj.X`.

Score (ensemble)

For ensembles, a classification *score* represents the confidence of a classification into a class. The higher the score, the higher the confidence.

Different ensemble algorithms have different definitions for their scores. Furthermore, the range of scores depends on ensemble type. For example:

- `AdaBoostM1` scores range from $-\infty$ to ∞.
- `Bag` scores range from `0` to `1`.

Examples

Compute the k-fold edge for an ensemble trained on the Fisher iris data:

```
load fisheriris
ens = fitensemble(meas,species,'AdaBoostM2',100,'Tree');
cvens = crossval(ens);
E = kfoldEdge(cvens)

E =
    3.2078
```

kfoldEdge

Class: ClassificationPartitionedModel

Classification edge for observations not used for training

Syntax

```
E = kfoldEdge(obj)
E = kfoldEdge(obj,Name,Value)
```

Description

`E = kfoldEdge(obj)` returns classification edge (average classification margin) obtained by cross-validated classification model `obj`. For every fold, this method computes classification edge for in-fold observations using an ensemble trained on out-of-fold observations.

`E = kfoldEdge(obj,Name,Value)` calculates edge with additional options specified by one or more Name,Value pair arguments. You can specify several name-value pair arguments in any order as `Name1,Value1,…,NameN,ValueN`.

Input Arguments

`obj`

Object of class `ClassificationPartitionedModel`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'folds'`

Indices of folds ranging from `1` to `obj.KFold`. Use only these folds for predictions.

Default: `1:obj.KFold`

`'mode'`

String representing the meaning of the output edge:

- `'average'` — `edge` is a scalar value, the average over all folds.
- `'individual'` — `edge` is a vector of length `obj.KFold` with one element per fold.

Default: `'average'`

Output Arguments

`E`

The average classification margin. `E` is a scalar or vector, depending on the setting of the `mode` name-value pair.

Definitions

Edge

The *edge* is the weighted mean value of the classification *margin*. The weights are class prior probabilities. If you supply additional weights, those weights are normalized to sum to the prior probabilities in the respective classes, and are then used to compute the weighted average.

Margin

The classification *margin* is the difference between the classification *score* for the true class and maximal classification score for the false classes.

The classification margin is a column vector with the same number of rows as in the matrix X. A high value of margin indicates a more reliable prediction than a low value.

Score

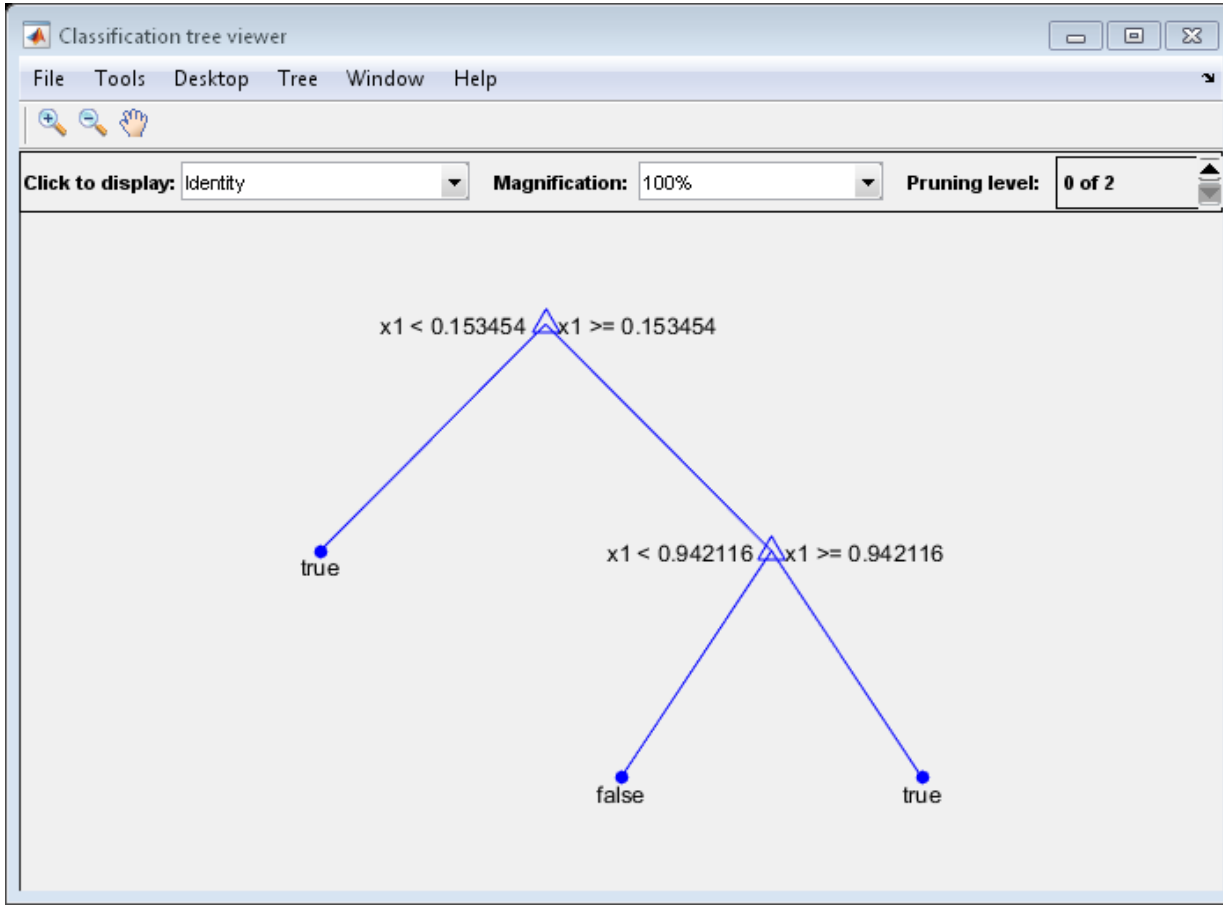
For discriminant analysis, the *score* of a classification is the posterior probability of the classification. For the definition of posterior probability in discriminant analysis, see “Posterior Probability” on page 15-7.

For trees, the *score* of a classification of a leaf node is the posterior probability of the classification at that node. The posterior probability of the classification at a node is the number of training sequences that lead to that node with the classification, divided by the number of training sequences that lead to that node.

For example, consider classifying a predictor `X` as `true` when `X < 0.15` or `X > 0.95`, and `X` is false otherwise.

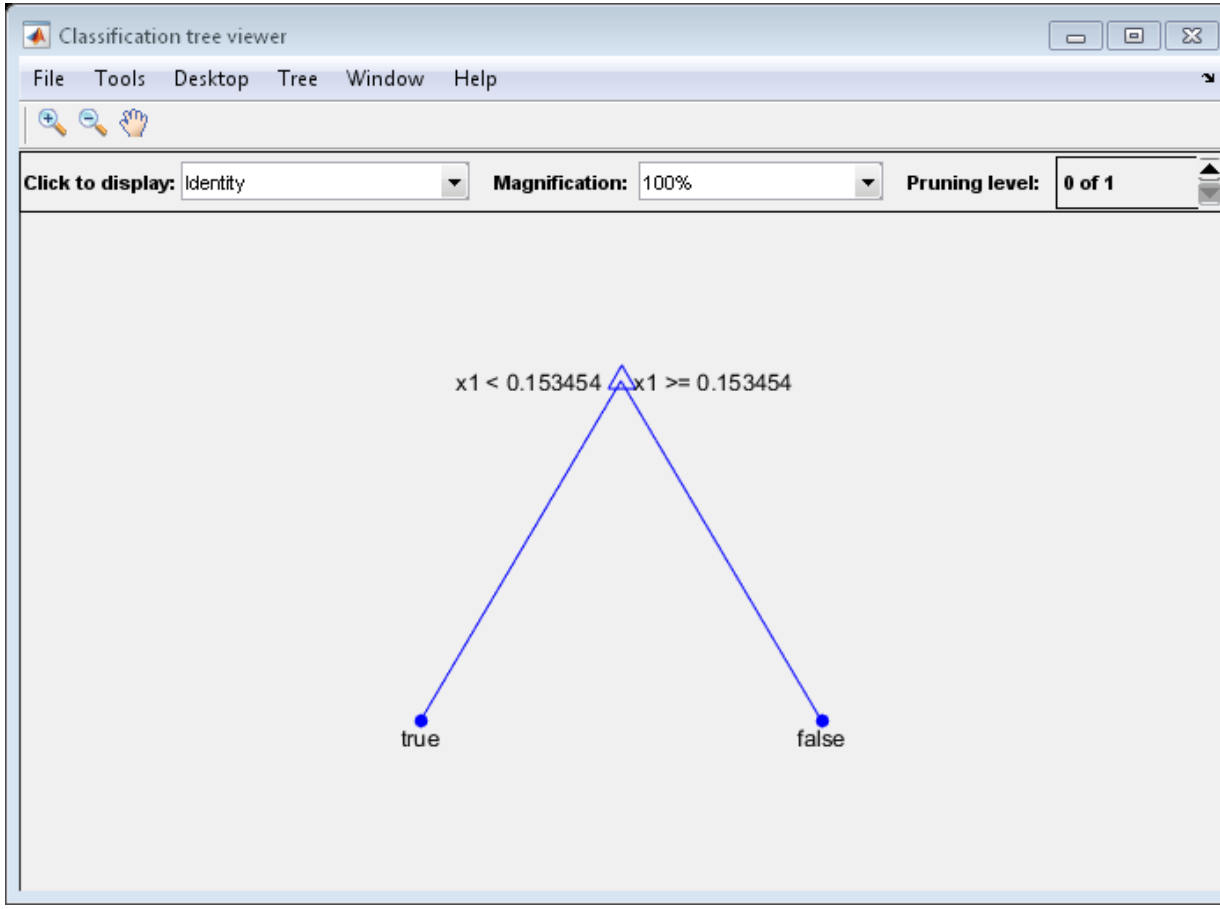
Generate 100 random points and classify them:

```
rng(0,'twister') % for reproducibility
X = rand(100,1);
Y = (abs(X - .55) > .4);
tree = fitctree(X,Y);
view(tree,'Mode','Graph')
```



Prune the tree:

```
tree1 = prune(tree,'Level',1);
view(tree1,'Mode','Graph')
```



The pruned tree correctly classifies observations that are less than 0.15 as `true`. It also correctly classifies observations from .15 to .94 as `false`. However, it incorrectly classifies observations that are greater than .94 as `false`. Therefore, the score for observations that are greater than .15 should be about .05/.85=.06 for `true`, and about .8/.85=.94 for `false`.

Compute the prediction scores for the first 10 rows of `X`:

```
[~,score] = predict(tree1,X(1:10));
[score X(1:10,:)]
```

```
ans =

    0.9059    0.0941    0.8147
    0.9059    0.0941    0.9058
         0    1.0000    0.1270
    0.9059    0.0941    0.9134
    0.9059    0.0941    0.6324
         0    1.0000    0.0975
    0.9059    0.0941    0.2785
    0.9059    0.0941    0.5469
    0.9059    0.0941    0.9575
    0.9059    0.0941    0.9649
```

Indeed, every value of `X` (the right-most column) that is less than 0.15 has associated scores (the left and center columns) of `0` and `1`, while the other values of `X` have associated scores of `0.91` and `0.09`. The difference (score `0.09` instead of the expected `.06`) is due to a statistical fluctuation: there are `8` observations in `X` in the range `(.95,1)` instead of the expected `5` observations.

Examples

Esimtate the *k*-fold Edge of a Classifier

Compute the *k*-fold edge for a model trained on Fisher's iris data.

Load Fisher's iris data set.

```
load fisheriris
```

Train a classification tree classifier.

```
tree = fitctree(meas,species);
```

Cross validate the classifier using 10-fold cross validation.

```
cvtree = crossval(tree);
```

Compute the *k*-fold edge.

```
edge = kfoldEdge(cvtree)
```

```
edge =

    0.8578
```

kfoldfun

Class: ClassificationPartitionedECOC

Cross validate function

Syntax

```
vals = kfoldfun(CVMdl,fun)
```

Description

`vals = kfoldfun(CVMdl,fun)` cross validates the function `fun` by applying `fun` to the data stored in the cross-validated model `CVMdl`. You must pass `fun` as a function handle.

Input Arguments

`CVMdl` — Cross-validated model

`ClassificationPartitionedECOC` model | `ClassificationPartitionedEnsemble` model | `ClassificationPartitionedModel` model

Cross-validated model, specified as a `ClassificationPartitionedECOC` model, `ClassificationPartitionedEnsemble` model, or a `ClassificationPartitionedModel` model.

`fun` — Cross-validated function

function handle

Cross-validated function, specified as a function handle. `fun` has the syntax

```
testvals = fun(CMP,Xtrain,Ytrain,Wtrain,Xtest,Ytest,Wtest)
```

- `CMP` is a compact model stored in one element of the CVMdl`.Trained` property.
- `Xtrain` is the training matrix of predictor values.
- `Ytrain` is the training array of response values.
- `Wtrain` are the training weights for observations.

- `Xtest` and `Ytest` are the test data, with associated weights `Wtest`.
- The returned value `testvals` needs the same size across all folds.

Data Types: `function_handle`

Output Arguments

`vals` — Cross-validation results

numeric matrix

Cross-validation results, returned as an numeric matrix. `vals` is the arrays of `testvals` output, concatenated vertically over all folds. For example, if `testvals` from every fold is a numeric vector of length `N`, `kfoldfun` returns a `KFold`-by-`N` numeric matrix with one row per fold.

Data Types: `double`

Examples

Estimate Classification Error Using a Custom Loss Function

Train an ECOC multiclass classifier, and then cross validate it using a custom *k*-fold loss function.

Load Fisher's iris data set.

```
load fisheriris
X = meas;
Y = categorical(species);
classOrder = unique(Y); % Class order
rng(1); % For reproducibility
```

Train an ECOC model using SVM binary classifiers for each predictor set, and specify to cross validate. It is good practice to standardize the predictors and define the class order. Specify to standardize the predictors using an SVM template.

```
t = templateSVM('Standardize',1);
CVMdl = fitcecoc(X,Y,'CrossVal','on','Learners',t,...
    'ClassNames',classOrder);
```

`CVMdl` is a `ClassificationPartitionedECOC` model. By default, the software implements 10-fold cross validation.

Compute the classification error (proportion of misclassified observations) for the out-of-fold observations.

```
L = kfoldLoss(CVMdl)
```

```
L =

    0.0400
```

Examine the result when the cost of misclassifying a flower as `'versicolor'` is `10`, and any other error is `1`. Write a function called `noversicolor.m` that attributes a cost of `1` for misclassification, but `10` for misclassifying a flower as `versicolor`, and save it on your MATLAB path.

```
function averageCost = noversicolor(CMP,Xtrain,Ytrain,Wtrain,Xtest,Ytest,Wtest)
%noversicolor Example custom cross-validation function
%   Attributes a cost of 10 for misclassifying versicolor irises, and 1 for
%   the other irises.  This example function requires the |fisheriris| data
%   set.
Ypredict = predict(CMP,Xtest);
misclassified = not(strcmp(Ypredict,Ytest)); % Different result
classifiedAsVersicolor = strcmp(Ypredict,'versicolor'); % Index of bad decisions
cost = sum(misclassified) + ...
    9*sum(misclassified & classifiedAsVersicolor); % Total differences
averageCost = cost/numel(Ytest); % Average error
end
```

Compute the mean misclassification error with the `noversicolor` cost.

```
foldLoss = kfoldfun(CVMdl,@noversicolor);
mean(foldLoss)
```

```
ans =

    0.0667
```

kfoldfun

Class: ClassificationPartitionedModel

Cross validate function

Syntax

```
vals = kfoldfun(CVMdl,fun)
```

Description

`vals = kfoldfun(CVMdl,fun)` cross validates the function `fun` by applying `fun` to the data stored in the cross-validated model `CVMdl`. You must pass `fun` as a function handle.

Input Arguments

`CVMdl` — Cross-validated model

`ClassificationPartitionedECOC` model | `ClassificationPartitionedEnsemble` model | `ClassificationPartitionedModel` model

Cross-validated model, specified as a `ClassificationPartitionedECOC` model, `ClassificationPartitionedEnsemble` model, or a `ClassificationPartitionedModel` model.

`fun` — Cross-validated function

function handle

Cross-validated function, specified as a function handle. `fun` has the syntax

```
testvals = fun(CMP,Xtrain,Ytrain,Wtrain,Xtest,Ytest,Wtest)
```

- `CMP` is a compact model stored in one element of the CVMdl.`Trained` property.
- `Xtrain` is the training matrix of predictor values.
- `Ytrain` is the training array of response values.

- `Wtrain` are the training weights for observations.
- `Xtest` and `Ytest` are the test data, with associated weights `Wtest`.
- The returned value `testvals` needs the same size across all folds.

Data Types: `function_handle`

Output Arguments

`vals` — Cross-validation results

numeric matrix

Cross-validation results, returned as an numeric matrix. `vals` is the arrays of `testvals` output, concatenated vertically over all folds. For example, if `testvals` from every fold is a numeric vector of length `N`, `kfoldfun` returns a `KFold`-by-`N` numeric matrix with one row per fold.

Data Types: `double`

Examples

Estimate Classification Error Using a Custom Loss Function

Train a classification tree classifier, and then cross validate it using a custom *k*-fold loss function.

Load Fisher's iris data set.

```
load fisheriris
```

Train a classification tree classifier.

```
Mdl = fitctree(meas,species);
```

`Mdl` is a `ClassificationTree` model.

Cross validate `Mdl` using the default 10-fold cross validation. Compute the classification error (proportion of misclassified observations) for the out-of-fold observations.

```
rng(1); % For reproducibility
CVMdl = crossval(Mdl);
```

```
L = kfoldLoss(CVMdl)
```

```
L =

    0.0467
```

Examine the result when the cost of misclassifying a flower as `'versicolor'` is `10`, and any other error is `1`. Write a function called `noversicolor.m` that attributes a cost of `1` for misclassification, but `10` for misclassifying a flower as `versicolor`, and save it on your MATLAB path.

```
function averageCost = noversicolor(CMP,Xtrain,Ytrain,Wtrain,Xtest,Ytest,Wtest)
%noversicolor Example custom cross-validation function
%   Attributes a cost of 10 for misclassifying versicolor irises, and 1 for
%   the other irises.  This example function requires the |fisheriris| data
%   set.
Ypredict = predict(CMP,Xtest);
misclassified = not(strcmp(Ypredict,Ytest)); % Different result
classifiedAsVersicolor = strcmp(Ypredict,'versicolor'); % Index of bad decisions
cost = sum(misclassified) + ...
    9*sum(misclassified & classifiedAsVersicolor); % Total differences
averageCost = cost/numel(Ytest); % Average error
end
```

Compute the mean misclassification error with the `noversicolor` cost.

```
mean(kfoldfun(CVMdl,@noversicolor))
```

```
ans =

    0.2267
```

`ClassificationPartitionedModel` | `kfoldEdge` | `kfoldMargin` | `kfoldLoss` | `crossval` | `ClassificationPartitionedECOC` | `kfoldPredict` | `crossval`

kfoldfun

Class: RegressionPartitionedModel

Cross validate function

Syntax

```
vals = kfoldfun(obj,fun)
```

Description

`vals = kfoldfun(obj,fun)` cross validates the function `fun` by applying `fun` to the data stored in the cross-validated model `obj`. You must pass `fun` as a function handle.

Input Arguments

`obj`

Object of class `RegressionPartitionedModel` or `RegressionPartitionedEnsemble`. Create `obj` with `fitrtree` or `fitensemble` along with one of the cross-validation options: `'CrossVal'`, `'KFold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'`. Alternatively, create `obj` from a regression tree or regression ensemble with `crossval`.

`fun`

A function handle for a cross-validation function. `fun` has the syntax

```
testvals = fun(CMP,Xtrain,Ytrain,Wtrain,Xtest,Ytest,Wtest)
```

- `CMP` is a compact model stored in one element of the obj`.Trained` property.
- `Xtrain` is the training matrix of predictor values.
- `Ytrain` is the training array of response values.
- `Wtrain` are the training weights for observations.
- `Xtest` and `Ytest` are the test data, with associated weights `Wtest`.

- The returned value `testvals` must have the same size across all folds.

Output Arguments

`vals`

The arrays of `testvals` output, concatenated vertically over all folds. For example, if `testvals` from every fold is a numeric vector of length `N`, `kfoldfun` returns a `KFold`-by-`N` numeric matrix with one row per fold.

Examples

Cross validate a regression tree, and obtain the mean squared error (see `kfoldLoss`):

```
load imports-85
t = fitrtree(X(:,[4 5]),X(:,16),...
    'predictornames',{'length' 'width'},...
    'responsename','price');
cv = crossval(t);
L = kfoldLoss(cv)

L =
  1.5489e+007
```

Examine the result of simple averaging of responses instead of using predictions:

```
f = @(cmp,Xtrain,Ytrain,Wtrain,Xtest,Ytest,Wtest)...
    mean((Ytest-mean(Ytrain)).^2)
mean(kfoldfun(cv,f))

ans =
  6.3497e+007
```

See Also

`RegressionPartitionedEnsemble` | `kfoldLoss` | `crossval` | `fitrtree` | `kfoldPredict` | `RegressionPartitionedModel`

kfoldLoss

Classification loss for observations not used for training

Syntax

```
loss = kfoldLoss(CVMdl)
loss = kfoldLoss(CVMdl,Name,Value)
```

Description

`loss = kfoldLoss(CVMdl)` returns the classification loss obtained by the cross-validated ECOC model (`ClassificationPartitionedECOC`) `CVMdl`. For every fold, this function computes the classification loss for in-fold observations using a model trained on out-of-fold observations. `CVMdl.X` contains both sets of observations.

`loss = kfoldLoss(CVMdl,Name,Value)` returns the classification loss with additional options specified by one or more Name,Value pair arguments.

For example, specify the number of folds, decoding scheme, or verbosity level.

Input Arguments

`CVMdl` — Cross-validated ECOC model

`ClassificationPartitionedECOC` model

Cross-validated ECOC model, specified as a `ClassificationPartitionedECOC` model. You can create a `ClassificationPartitionedECOC` model by:

- Passing a trained ECOC model (`ClassificationECOC`) to `crossval`
- Training an ECOC model using `fitcecoc` and setting any one of these cross-validation name-value pair arguments: `'CrossVal'`, `'KFold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'`

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'BinaryLoss'` — Binary learner loss function

`CVMdl.BinaryLoss` (default) | function handle | `'hamming'` | `'linear'` | `'exponential'` | `'binodeviance'` | `'hinge'` | `'quadratic'`

Binary learner loss function, specified as the comma-separated pair consisting of `'BinaryLoss'` and a function handle or string.

- If the value is a string, then it must correspond to a built-in function. This table summarizes the built-in functions, where y_j is a class label for a particular binary learner (in {-1,1,0}) and f_j is the score for observation j.

Value	Description	Score Domain	Formula
`'binodeviance'`	Binomial deviance	$(-\infty,\infty)$	$\log[1 + \exp(-2yf)]/\log(2)$
`'exponential'`	Exponential	$(-\infty,\infty)$	$\exp(-yf)$
`'hamming'`	Hamming	$(-\infty,\infty)$ or $[0,1]$	$1 - \text{sign}(yf)$
`'hinge'`	Hinge	$(-\infty,\infty)$	$\max(0,1 - yf)$
`'linear'`	Linear	$(-\infty,\infty)$	$1 - yf$
`'quadratic'`	Quadratic	$[0,1]$	$[1 - y(2f - 1)]^2$

- For a custom binary loss function, e.g., `customFunction`, specify its function handle `'BinaryLoss',@customFunction`.

  `customFunction` should have this form

  ```
  bLoss = customFunction(M,f)
  ```
  where:

  - `M` is the K-by-L coding matrix stored in `CVMdl.CodingMatrix`.
  - `f` is the 1-by-L row vector of classification scores.
  - `bLoss` is the classification loss.

- K is the number of classes.
- L is the number of binary learners.

Example: `'BinaryLoss','binodeviance'`

Data Types: `char` | `function_handle`

`'Decoding'` — Decoding scheme

`'lossweighted'` (default) | `'lossbased'`

Decoding scheme that aggregates the binary losses, specified as the comma-separated pair consisting of `'Decoding'` and `'lossweighted'` or `'lossbased'`.

Example: `'Decoding','lossbased'`

Data Types: `char`

`'Folds'` — Fold indices for prediction

`1:Mdl.KFold` (default) | numeric vector of positive integers

Fold indices for prediction, specified as the comma-separated pair consisting of `'Folds'` and a numeric vector of positive integers. The elements of `Folds` must range from `1` through `Mdl.KFold`.

The software only uses the folds specified in `Folds` for prediction.

Example: `'Folds',[1 4 10]`

Data Types: `single` | `double`

`'LossFun'` — Loss function

`'classiferror'` (default) | function handle

Loss function, specified as the comma-separated pair consisting of `'LossFun'` and a function handle or `'classiferror'`.

You can:

- Specify the built-in function `'classiferror'`, then the loss function is the classification error, in other words, the proportion of misclassified observations.
- Specify your own function using function handle notation.

  Suppose that `n = size(X,1)` is the sample size and `k` is the number of classes. Your function needs the signature `lossvalue = lossfun(C,S,W,Cost)`, where:

- The output argument `lossvalue` is a scalar.
- You choose the function name (*`lossfun`*).
- `C` is an `n`-by-`k` logical matrix with rows indicating which class the corresponding observation belongs. The column order corresponds to the class order in `CVMdl.ClassNames`.

  Construct `C` by setting `C(p,q) = 1` if observation `p` is in class `q`, for each row. Set every element of row `p` to `0`.
- `S` is an `n`-by-`k` numeric matrix of negated loss values for classes. Each row corresponds to an observation. The column order corresponds to the class order in `CVMdl.ClassNames`. `S` resembles the output argument `negLoss` of `kfoldPredict`.
- `W` is an `n`-by-1 numeric vector of observation weights. If you pass `W`, the software normalizes its elements to sum to `1`.
- `Cost` is a `k`-by-`k` numeric matrix of misclassification costs. For example, `Cost = ones(K) -eye(K)` specifies a cost of 0 for correct classification, and 1 for misclassification.

Specify your function using `'LossFun',@lossfun`.

Data Types: `function_handle | char`

`'Mode'` — Edge meaning

`'average'` (default) | `'individual'`

Edge meaning, specified as the comma-separated pair consisting of `'Mode'` and `'average'` or `'individual'`.

This table describes the values.

Value	Description
`'average'`	`edge` is the scalar average over all folds.
`'individual'`	`edge` is a vector of length *k* containing one edge per fold. *k* is the number of folds.

Example: `'Mode','individual'`

Data Types: `char`

`'Options'` — Estimation options

`[]` (default) | structure array returned by `statset`

Estimation options, specified as the comma-separated pair consisting of `'Options'` and a structure array returned by `statset`.

To invoke parallel computing:

- You need a Parallel Computing Toolbox license.
- Specify `'Options',statset('UseParallel',1)`.

`'Verbose'` — Verbosity level

`0` (default) | `1`

Verbosity level, specified as the comma-separated pair consisting of `'Verbose'` and `0` or `1`. `Verbose` controls the amount of diagnostic messages that the software displays in the Command Window.

If `Verbose` is `0`, then the software does not display diagnostic messages. Otherwise, the software displays diagnostic messages.

Example: `'Verbose',1`

Data Types: `single` | `double`

Output Arguments

`loss` — Classification loss

numeric scalar | numeric row vector

Classification loss, returned as a numeric scalar or numeric row vector.

If Mode is `'average'`, then `loss` is the average classification loss among all binary learners. Otherwise, `loss` is a 1-by-`L` numeric row vector containing the classification loss for each, respective binary leanrer, where `L` is the number of binary learners (`size(`CVMdl`.CodingMatrix,2)`).

Data Types: `single` | `double`

Definitions

Classification Error

The *classification error* is a binary classification error measure that has the form

$$L = \frac{\sum_{j=1}^{n} w_j e_j}{\sum_{j=1}^{n} w_j},$$

where:

- w_j is the weight for observation j. The software renormalizes the weights to sum to 1.
- e_j = 1 if the predicted class of observation j differs from its true class, and 0 otherwise.

In other words, it is the proportion of observations that the classifier misclassifies.

Binary Loss

A *binary loss* is a function of the class and classification score that determines how well a binary learner classifies an observation into the class.

Let:

- m_{kj} be element (k,j) of the coding design matrix M (i.e., the code corresponding to class k of binary learner j)
- s_j be the score of binary learner j for an observation
- g be the binary loss function
- $\hat{k}$ be the predicted class for the observation

In *loss-based decoding* [3], the class producing the minimum sum of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \underset{k}{\operatorname{argmin}} \sum_{j=1}^{L} \left| m_{kj} \right| g(m_{kj}, s_j).$$

In *loss-weighted decoding* [3], the class producing the minimum average of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \underset{k}{\operatorname{argmin}} \frac{\sum_{j=1}^{L} |m_{kj}| \, g(m_{kj}, s_j)}{\sum_{j=1}^{L} |m_{kj}|}.$$

Allwein et al. [1] suggest that loss-weighted decoding improves classification accuracy by keeping loss values for all classes in the same dynamic range.

This table summarizes the supported loss functions, where y_j is a class label for a particular binary learner (in the set {-1,1,0}), s_j is the score for observation j, and $g(y_j,s_j)$.

Value	Description	Score Domain	$g(y_j,s_j)$
`'binodeviance'`	Binomial deviance	$(-\infty,\infty)$	$\log[1 + \exp(-2y_js_j)]/[2\log(2)]$
`'exponential'`	Exponential	$(-\infty,\infty)$	$\exp(-y_js_j)/2$
`'hamming'`	Hamming	{-1,1}	$[1 - \text{sign}(y_js_j)]/2$
`'hinge'`	Hinge	$(-\infty,\infty)$	$\max(0,1 - y_js_j)/2$
`'linear'`	Linear	$(-\infty,\infty)$	$(1 - y_js_j)/2$
`'quadratic'`	Quadratic	[0,1]	$[1 - y_j(2s_j - 1)]^2/2$

The software normalizes the binary losses such that the loss is 0.5 when $y_j = 0$, and aggregates using the average of the binary learners [1].

Do not confuse the binary loss with the overall classification loss (specified by the LossFun name-value pair argument of `predict` and `loss`), e.g., classification error, which measures how well an ECOC classifier performs as a whole.

Examples

Determine *k*-Fold Cross-Validation Loss of ECOC Models

Load Fisher's iris data set.

```
load fisheriris
X = meas;
Y = categorical(species);
classOrder = unique(Y); % Class order
rng(1); % For reproducibility
```

Train an ECOC model using SVM binary classifiers, and specify to cross validate. It is good practice to standardize the predictors and define the class order. Specify to standardize the predictors using an SVM template.

```
t = templateSVM('Standardize',1);
CVMdl = fitcecoc(X,Y,'CrossVal','on','Learners',t,'ClassNames',classOrder);
```

`CVMdl` is a `ClassificationPartitionedECOC` model. By default, the software implements 10-fold cross validation. You can alter the number of folds using the `'KFold'` name-value pair argument.

Estimate the average out-of-fold classification error.

```
L = kfoldLoss(CVMdl)
```

```
L =

    0.0400
```

The average classification error for the folds is 4%.

Alternatively, you can obtain the per-fold losses by specifying the name-value pair `'Mode','individual'` in `kfoldLoss`.

Display Individual Losses for Each Cross-Validation Fold

The classification loss is a measure of classifier quality. You can determine ill-performing folds by displaying the losses for each fold.

Load Fisher's iris data set.

```
load fisheriris
X = meas;
Y = categorical(species);
classOrder = unique(Y);
rng(1); % For reproducibility
```

Train an ECOC model using SVM binary classifiers and specify to use 8-fold cross validation. It is good practice to standardize the predictors and define the class order. Specify to standardize the predictors using an SVM template.

```
t = templateSVM('Standardize',1);
CVMdl = fitcecoc(X,Y,'KFold',8,'Learners',t,'ClassNames',classOrder);
```

Estimate the average classification loss across folds, and the losses for each fold.

```
loss = kfoldLoss(CVMdl)
losses = kfoldLoss(CVMdl,'Mode','individual')
```

```
loss =

    0.0333

losses =

    0.0556
    0.0526
    0.1579
         0
         0
         0
         0
         0
```

The third fold misclassifies a much higher portion of observations than any other fold.

Return the classification loss for the entire model by specifying the well-performing folds using the `'Folds'` name-value pair argument.

```
loss = kfoldLoss(CVMdl,'Folds',[1:2 4:8])
```

```
loss =

    0.0153
```

The total classification loss decreased by approximately half its original size.

Consider adjusting parameters of the binary classifiers or the coding design to see if performance for all folds improves.

Determine ECOC Model Quality Using a Custom Cross-Validation Loss

Suppose that it is interesting to know how well a model classifies a particular class. This example shows how to pass such a custom loss function to `kfoldLoss`.

Load Fisher's iris data set.

```
load fisheriris
X = meas;
Y = categorical(species);
n = numel(Y);           % Sample size
classOrder = unique(Y)  % Class order
K = numel(classOrder);  % Number of classes
rng(1) % For reproducibility
```

```
classOrder =

     setosa
     versicolor
     virginica
```

Train an ECOC model using SVM binary classifiers, and specify to cross validate. It is good practice to standardize the predictors and define the class order. Specify to standardize the predictors using an SVM template.

```
t = templateSVM('Standardize',1);
CVMdl = fitcecoc(X,Y,'CrossVal','on','Learners',t,'ClassNames',classOrder);
```

`CVMdl` is a `ClassificationPartitionedECOC` model. By default, the software implements 10-fold cross validation. You can alter the number of folds using the `'KFold'` name-value pair argument.

Compute the negated losses for the out-of-fold observations.

```
[~,negLoss] = kfoldPredict(CVMdl);
```

Create a function that takes the minimal loss for each observation, and then averages the minimal losses across all observations.

```
lossfun = @(C,S,~,~)mean(min(-negLoss,[],2));
```

Compute the cross-validated custom loss.

```
kfoldLoss(CVMdl,'LossFun',lossfun)
```

```
ans =

    0.0101
```

The average, minimal, binary loss for the out-of-fold observations is 0.0101.

kfoldLoss

Class: ClassificationPartitionedEnsemble

Classification loss for observations not used for training

Syntax

```
L = kfoldLoss(ens)
L = kfoldLoss(ens,Name,Value)
```

Description

`L = kfoldLoss(ens)` returns loss obtained by cross-validated classification model `ens`. For every fold, this method computes classification loss for in-fold observations using a model trained on out-of-fold observations.

`L = kfoldLoss(ens,Name,Value)` calculates loss with additional options specified by one or more Name,Value pair arguments. You can specify several name-value pair arguments in any order as `Name1,Value1,…,NameN,ValueN`.

Input Arguments

`ens`

Object of class `ClassificationPartitionedEnsemble`. Create `ens` with `fitensemble` along with one of the cross-validation options: `'crossval'`, `'kfold'`, `'holdout'`, `'leaveout'`, or `'cvpartition'`. Alternatively, create `ens` from a classification ensemble with `crossval`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'folds'`

Indices of folds ranging from `1` to ens`.KFold`. Use only these folds for predictions.

Default: `1:ens.KFold`

`'lossfun '`

Function handle or string representing a loss function. Built-in loss functions:

- `'binodeviance'` — See "Loss Functions" on page 22-2365
- `'classiferror'` — Fraction of misclassified data
- `'exponential'` — See "Loss Functions" on page 22-2365
- `'hinge'` — See "Loss Functions" on page 22-2365.
- `'mincost'` — Smallest misclassification cost as given by the obj`.Cost` matrix. See "Loss Functions" on page 22-2365.

You can write your own loss function in the syntax described in "Loss Functions" on page 22-2365.

Default: `'classiferror'`

`'mode'`

A string for determining the output of `kfoldLoss`:

- `'average'` — L is a scalar, the loss averaged over all folds.
- `'individual'` — L is a vector of length ens`.KFold`, where each entry is the loss for a fold.
- `'cumulative'` — L is a vector in which element `J` is obtained by using learners `1:J` from the input list of learners.

Default: `'average'`

Output Arguments

`L`

Loss, by default the fraction of misclassified data. `L` can be a vector, and can mean different things, depending on the name-value pair settings.

Definitions

Loss Functions

The built-in loss functions are:

- `'binodeviance'` — For binary classification, assume the classes y_n are `-1` and `1`. With weight vector w normalized to have sum `1`, and predictions of row n of data X as $f(X_n)$, the binomial deviance is

$$\sum w_n \log\left(1+\exp\left(-2y_n f\left(X_n\right)\right)\right).$$

- `'classiferror'` — Fraction of misclassified data, weighted by w.
- `'exponential'` — With the same definitions as for `'binodeviance'`, the exponential loss is

$$\sum w_n \exp\left(-y_n f\left(X_n\right)\right).$$

- `'hinge'` — Classification error measure that has the form

$$L=\frac{\sum_{j=1}^{n} w_j \max\left\{0,1-y_j' f\left(X_j\right)\right\}}{\sum_{j=1}^{n} w_j},$$

where:

- w_j is weight j.
- For binary classification, $y_j = 1$ for the positive class and -1 for the negative class. For problems where the number of classes $K > 3$, y_j is a vector of 0s, but with a 1 in the position corresponding to the true class, e.g., if the second observation is in the third class and $K = 4$, then $y_2 = [0\ 0\ 1\ 0]'$.
- $f(X_j)$ is, for binary classification, the posterior probability or, for $K > 3$, a vector of posterior probabilities for each class given observation j.

- `'mincost'` — Predict the label with the smallest expected misclassification cost, with expectation taken over the posterior probability, and cost as given by the `Cost` property of the classifier (a matrix). The loss is then the true misclassification cost averaged over the observations.

To write your own loss function, create a function file of the form

```
function loss = lossfun(C,S,W,COST)
```

- `N` is the number of rows of `ens.X`.
- `K` is the number of classes in ens, represented in `ens.ClassNames`.
- `C` is an `N`-by-`K` logical matrix, with one `true` per row for the true class. The index for each class is its position in `tree.ClassNames`.
- `S` is an `N`-by-`K` numeric matrix. `S` is a matrix of posterior probabilities for classes with one row per observation, similar to the `score` output from `predict`.
- `W` is a numeric vector with `N` elements, the observation weights.
- `COST` is a `K`-by-`K` numeric matrix of misclassification costs. The default `'classiferror'` gives a cost of `0` for correct classification, and `1` for misclassification.
- The output `loss` should be a scalar.

Pass the function handle `@lossfun` as the value of the `lossfun` name-value pair.

Examples

Find the average cross-validated classification error for an ensemble model of the `ionosphere` data:

```
load ionosphere
ens = fitensemble(X,Y,'AdaBoostM1',100,'Tree');
cvens = crossval(ens);
L = kfoldLoss(cvens)

L =
    0.0826
```

kfoldLoss

Class: ClassificationPartitionedModel

Classification loss for observations not used for training

Syntax

```
L = kfoldLoss(obj)
L = kfoldLoss(obj,Name,Value)
```

Description

`L = kfoldLoss(obj)` returns loss obtained by cross-validated classification model `obj`. For every fold, this method computes classification loss for in-fold observations using a model trained on out-of-fold observations.

`L = kfoldLoss(obj,Name,Value)` calculates loss with additional options specified by one or more Name,Value pair arguments. You can specify several name-value pair arguments in any order as `Name1,Value1,…,NameN,ValueN`.

Input Arguments

`obj`

Object of class `ClassificationPartitionedModel`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'folds'`

Indices of folds ranging from `1` to obj`.KFold`. Use only these folds for predictions.

Default: `1:obj.KFold`

`'lossfun '`

Function handle or string representing a loss function. Built-in loss functions:

- `'binodeviance'` — See "Loss Functions" on page 22-2369.
- `'classiferror'` — Fraction of misclassified observations. See "Loss Functions" on page 22-2369.
- `'exponential'` — See "Loss Functions" on page 22-2369.
- `'hinge'` — See "Loss Functions" on page 22-2369.
- `'mincost'` — Smallest misclassification cost as given by the obj`.Cost` matrix. See "Loss Functions" on page 22-2369.

You can write your own loss function in the syntax described in "Loss Functions" on page 22-2369.

Default: `'mincost'`

`'mode'`

A string for determining the output of `kfoldLoss`:

- `'average'` — L is a scalar, the loss averaged over all folds.
- `'individual'` — L is a vector of length obj`.KFold`, where each entry is the loss for a fold.

Default: `'average'`

Output Arguments

`L`

Loss, by default the fraction of misclassified data. `L` can be a vector, and can mean different things, depending on the name-value pair settings.

Definitions

Classification Error

The default classification error is the fraction of the data X that obj misclassifies, where Y are the true classifications.

Weighted classification error is the sum of weight i times the Boolean value that is `1` when obj misclassifies the ith row of `X`, divided by the sum of the weights.

Loss Functions

The built-in loss functions are:

- `'binodeviance'` — For binary classification, assume the classes y_n are `-1` and `1`. With weight vector w normalized to have sum `1`, and predictions of row n of data X as $f(X_n)$, the binomial deviance is

  $$\sum w_n \log\left(1+\exp\left(-2y_n f\left(X_n\right)\right)\right).$$

- `'exponential'` — With the same definitions as for `'binodeviance'`, the exponential loss is

  $$\sum w_n \exp\left(-y_n f\left(X_n\right)\right).$$

- `'classiferror'` — Predict the label with the largest posterior probability. The loss is then the fraction of misclassified observations.
- `'hinge'` — Classification error measure that has the form

  $$L=\frac{\sum_{j=1}^{n} w_j \max\left\{0,1-y_j' f\left(X_j\right)\right\}}{\sum_{j=1}^{n} w_j},$$

  where:

  - w_j is weight j.

  - For binary classification, $y_j = 1$ for the positive class and -1 for the negative class. For problems where the number of classes $K > 3$, y_j is a vector of 0s, but with a 1 in the position corresponding to the true class, e.g., if the second observation is in the third class and $K = 4$, then $y_2 = [0\ 0\ 1\ 0]'$.
  - $f(X_j)$ is, for binary classification, the posterior probability or, for $K > 3$, a vector of posterior probabilities for each class given observation j.
- `'mincost'` — Predict the label with the smallest expected misclassification cost, with expectation taken over the posterior probability, and cost as given by the `Cost` property of the classifier (a matrix). The loss is then the true misclassification cost averaged over the observations.

To write your own loss function, create a function file in this form:

```
function loss = lossfun(C,S,W,COST)
```

- `N` is the number of rows of X.
- `K` is the number of classes in the classifier, represented in the `ClassNames` property.
- `C` is an `N`-by-`K` logical matrix, with one `true` per row for the true class. The index for each class is its position in the `ClassNames` property.
- `S` is an `N`-by-`K` numeric matrix. `S` is a matrix of posterior probabilities for classes with one row per observation, similar to the `posterior` output from `predict`.
- `W` is a numeric vector with `N` elements, the observation weights. If you pass `W`, the elements are normalized to sum to the prior probabilities in the respective classes.
- `COST` is a `K`-by-`K` numeric matrix of misclassification costs. For example, you can use `COST = ones(K) - eye(K)`, which means a cost of `0` for correct classification, and `1` for misclassification.
- The output `loss` should be a scalar.

Pass the function handle `@lossfun` as the value of the `LossFun` name-value pair.

Examples

Find the average cross-validated classification error for a model of the `ionosphere` data:

```
load ionosphere
tree = fitctree(X,Y);
```

```
cvtree = crossval(tree);
L = kfoldLoss(cvtree)

L =
    0.1197
```

How To

- “Examine the Quality of a KNN Classifier” on page 16-29

kfoldLoss

Class: RegressionPartitionedEnsemble

Cross-validation loss of partitioned regression ensemble

Syntax

```
L = kfoldLoss(cvens)
L = kfoldLoss(cvens,Name,Value)
```

Description

`L = kfoldLoss(cvens)` returns the cross-validation loss of `cvens`.

`L = kfoldLoss(cvens,Name,Value)` returns cross-validation loss with additional options specified by one or more Name,Value pair arguments. You can specify several name-value pair arguments in any order as `Name1,Value1,…,NameN,ValueN`.

Input Arguments

`cvens`

Object of class `RegressionPartitionedEnsemble`. Create `obj` with `fitensemble` along with one of the cross-validation options: `'crossval'`, `'kfold'`, `'holdout'`, `'leaveout'`, or `'cvpartition'`. Alternatively, create `obj` from a regression ensemble with `crossval`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'folds'`

Indices of folds ranging from `1` to `cvens.KFold`. Use only these folds for predictions.

Default: `1:cvens.KFold`

`'lossfun'`

Function handle for loss function, or the string `'mse'`, meaning mean squared error. If you pass a function handle `fun`, `loss` calls it as

```
fun(Y,Yfit,W)
```

where `Y`, `Yfit`, and `W` are numeric vectors of the same length.

- `Y` is the observed response.
- `Yfit` is the predicted response.
- `W` is the observation weights.

The returned value `fun(Y,Yfit,W)` should be a scalar.

Default: `'mse'`

`'mode'`

String representing the meaning of the output L:

- `'ensemble'` — `L` is a scalar value, the loss for the entire ensemble.
- `'individual'` — `L` is a vector with one element per trained learner.
- `'cumulative'` — `L` is a vector in which element `J` is obtained by using learners `1:J` from the input list of learners.

Default: `'ensemble'`

Output Arguments

`L`

The loss (mean squared error) between the observations in a fold when compared against predictions made with an ensemble trained on the out-of-fold data. `L` can be a vector, and can mean different things, depending on the name-value pair settings.

Examples

Find the cross-validation loss for a regression ensemble of the `carsmall` data:

```
load carsmall
X = [Displacement Horsepower Weight];
rens = fitensemble(X,MPG,'LSboost',100,'Tree');
cvrens = crossval(rens);
L = kfoldLoss(cvrens)

L =
   25.6935
```

See Also

`RegressionPartitionedEnsemble` | `loss` | `kfoldPredict`

kfoldLoss

Class: RegressionPartitionedModel

Cross-validation loss of partitioned regression model

Syntax

```
L = kfoldLoss(cvmodel)
L = kfoldLoss(cvmodel,Name,Value)
```

Description

`L = kfoldLoss(cvmodel)` returns the cross-validation loss of `cvmodel`.

`L = kfoldLoss(cvmodel,Name,Value)` returns cross-validation loss with additional options specified by one or more Name,Value pair arguments. You can specify several name-value pair arguments in any order as `Name1,Value1,…,NameN,ValueN`.

Input Arguments

`cvmodel`

Object of class `RegressionPartitionedModel`. Create `obj` with `fitrtree` along with one of the cross-validation options: `'CrossVal'`, `'KFold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'`. Alternatively, create `obj` from a regression tree with `crossval`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'folds'`

Indices of folds ranging from `1` to `obj.KFold`. Use only these folds for predictions.

Default: `1:obj.KFold`

`'lossfun'`

Function handle for loss function, or the string `'mse'`, meaning mean squared error. If you pass a function handle `fun`, `kfoldLoss` calls it as

```
fun(Y,Yfit,W)
```

where `Y`, `Yfit`, and `W` are numeric vectors of the same length.

- `Y` is the observed response.
- `Yfit` is the predicted response.
- `W` is the observation weights.

The returned value `fun(Y,Yfit,W)` should be a scalar.

Default: `'mse'`

`'mode'`

One of the following strings:

- `'average'` — L is the average loss over all folds.
- `'individual'` — L is a vector of the individual losses of in-fold observations trained on out-of-fold data.

Default: `'average'`

Output Arguments

`L`

The loss (mean squared error) between the observations in a fold when compared against predictions made with a tree trained on the out-of-fold data. If `mode` is `'individual'`, `L` is a vector of the losses. If `mode` is `'average'`, `L` is the average loss.

Examples

Construct a partitioned regression model, and examine the cross-validation losses for the folds:

```
load carsmall
XX = [Cylinders Displacement Horsepower Weight];
YY = MPG;
cvmodel = fitrtree(XX,YY,'crossval','on');
L = kfoldLoss(cvmodel,'mode','individual')

L =
   44.9635
   11.8525
   18.2046
    9.2965
   29.4329
   54.8659
   24.6446
    8.2085
   19.7593
   16.7394
```

Alternatives

You can avoid constructing a cross-validated tree model by calling `cvLoss` instead of `kfoldLoss`. The cross-validated tree can save time if you are going to examine it more than once.

See Also

`loss` | `kfoldPredict` | `fitrtree`

kfoldMargin

Classification margins for observations not used for training

Syntax

```
margin = kfoldMargin(CVMdl)
margin = kfoldMargin(CVMdl,Name,Value)
```

Description

`margin = kfoldMargin(CVMdl)` returns classification margins obtained by the cross-validated ECOC model (`ClassificationPartitionedECOC`) `CVMdl`. For every fold, this method computes classification margins for in-fold observations using a model trained on out-of-fold observations. `CVMdl.X` contains both sets of observations.

`margin = kfoldMargin(CVMdl,Name,Value)` returns classification margins with additional options specified by one or more Name,Value pair arguments.

For example, specify the binary learner loss function, decoding scheme, or verbosity level.

Input Arguments

`CVMdl` — Cross-validated ECOC model

`ClassificationPartitionedECOC` model

Cross-validated ECOC model, specified as a `ClassificationPartitionedECOC` model. You can create a `ClassificationPartitionedECOC` model by:

- Passing a trained ECOC model (`ClassificationECOC`) to `crossval`
- Training an ECOC model using `fitcecoc` and setting any one of these cross-validation name-value pair arguments: `'CrossVal'`, `'KFold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'`

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'BinaryLoss'` — Binary learner loss function

`CVMdl.BinaryLoss` (default) | function handle | `'hamming'` | `'linear'` | `'exponential'` | `'binodeviance'` | `'hinge'` | `'quadratic'`

Binary learner loss function, specified as the comma-separated pair consisting of `'BinaryLoss'` and a function handle or string.

- If the value is a string, then it must correspond to a built-in function. This table summarizes the built-in functions, where y_j is a class label for a particular binary learner (in {-1,1,0}) and f_j is the score for observation j.

Value	Description	Score Domain	Formula
`'binodeviance'`	Binomial deviance	$(-\infty,\infty)$	$\log[1 + \exp(-2yf)]/\log(2)$
`'exponential'`	Exponential	$(-\infty,\infty)$	$\exp(-yf)$
`'hamming'`	Hamming	$(-\infty,\infty)$ or $[0,1]$	$1 - \text{sign}(yf)$
`'hinge'`	Hinge	$(-\infty,\infty)$	$\max(0,1 - yf)$
`'linear'`	Linear	$(-\infty,\infty)$	$1 - yf$
`'quadratic'`	Quadratic	$[0,1]$	$[1 - y(2f - 1)]^2$

- For a custom binary loss function, e.g., `customFunction`, specify its function handle `'BinaryLoss',@customFunction`.

  `customFunction` should have this form

  ```
  bLoss = customFunction(M,f)
  ```
  where:

  - `M` is the K-by-L coding matrix stored in `CVMdl.CodingMatrix`.
  - `f` is the 1-by-L row vector of classification scores.
  - `bLoss` is the classification loss.

- K is the number of classes.
- L is the number of binary learners.

Example: `'BinaryLoss','binodeviance'`

Data Types: `char` | `function_handle`

`'Decoding'` — Decoding scheme

`'lossweighted'` (default) | `'lossbased'`

Decoding scheme that aggregates the binary losses, specified as the comma-separated pair consisting of `'Decoding'` and `'lossweighted'` or `'lossbased'`.

Example: `'Decoding','lossbased'`

Data Types: `char`

`'Options'` — Estimation options

`[ ]` (default) | structure array returned by `statset`

Estimation options, specified as the comma-separated pair consisting of `'Options'` and a structure array returned by `statset`.

To invoke parallel computing:

- You need a Parallel Computing Toolbox license.
- Specify `'Options',statset('UseParallel',1)`.

`'Verbose'` — Verbosity level

`0` (default) | `1`

Verbosity level, specified as the comma-separated pair consisting of `'Verbose'` and `0` or `1`. `Verbose` controls the amount of diagnostic messages that the software displays in the Command Window.

If `Verbose` is `0`, then the software does not display diagnostic messages. Otherwise, the software displays diagnostic messages.

Example: `'Verbose',1`

Data Types: `single` | `double`

Output Arguments

`margin` — Classification margins

numeric vector

Classification margins, returned as a numeric vector. `margin` is an `n`-by-1 vector, where each row is the margin of the corresponding observation, and `n` is the number of observations (i.e., `size(`CVMdl`.X,1)`).

Data Types: `single` | `double`

Definitions

Classification Margin

The *classification margins* are, for each observation, the difference between the negative loss for the positive class and maximal negative loss among the negative classes. If the margins are on the same scale, then they serve as a classification confidence measure, i.e., among multiple classifiers, those that yield larger margins are better [4].

Binary Loss

A *binary loss* is a function of the class and classification score that determines how well a binary learner classifies an observation into the class.

Let:

- m_{kj} be element (k,j) of the coding design matrix M (i.e., the code corresponding to class k of binary learner j)
- s_j be the score of binary learner j for an observation
- g be the binary loss function
- $\hat{k}$ be the predicted class for the observation

In *loss-based decoding* [3], the class producing the minimum sum of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \underset{k}{\operatorname{argmin}} \sum_{j=1}^{L} \left| m_{kj} \right| g(m_{kj}, s_j).$$

In *loss-weighted decoding* [3], the class producing the minimum average of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \underset{k}{\operatorname{argmin}} \frac{\sum_{j=1}^{L} \left| m_{kj} \right| g(m_{kj}, s_j)}{\sum_{j=1}^{L} \left| m_{kj} \right|}.$$

Allwein et al. [1] suggest that loss-weighted decoding improves classification accuracy by keeping loss values for all classes in the same dynamic range.

This table summarizes the supported loss functions, where y_j is a class label for a particular binary learner (in the set {-1,1,0}), s_j is the score for observation j, and $g(y_j,s_j)$.

Value	Description	Score Domain	$g(y_j,s_j)$
`'binodeviance'`	Binomial deviance	$(-\infty,\infty)$	$\log[1 + \exp(-2y_js_j)]/[2\log(2)]$
`'exponential'`	Exponential	$(-\infty,\infty)$	$\exp(-y_js_j)/2$
`'hamming'`	Hamming	{-1,1}	$[1 - \text{sign}(y_js_j)]/2$
`'hinge'`	Hinge	$(-\infty,\infty)$	$\max(0,1 - y_js_j)/2$
`'linear'`	Linear	$(-\infty,\infty)$	$(1 - y_js_j)/2$
`'quadratic'`	Quadratic	[0,1]	$[1 - y_j(2s_j - 1)]^2/2$

The software normalizes the binary losses such that the loss is 0.5 when $y_j = 0$, and aggregates using the average of the binary learners [1].

Do not confuse the binary loss with the overall classification loss (specified by the LossFun name-value pair argument of `predict` and `loss`), e.g., classification error, which measures how well an ECOC classifier performs as a whole.

Examples

Estimate *k*-Fold Cross-Validated Margins of ECOC Models

Load Fisher's iris data set.

```
load fisheriris
X = meas;
Y = categorical(species);
classOrder = unique(Y);
rng(1); % For reproducibility
```

Train an ECOC model using SVM binary classifiers and specify to cross validate. It is good practice to standardize the predictors and define the class order. Specify to standardize the predictors using an SVM template.

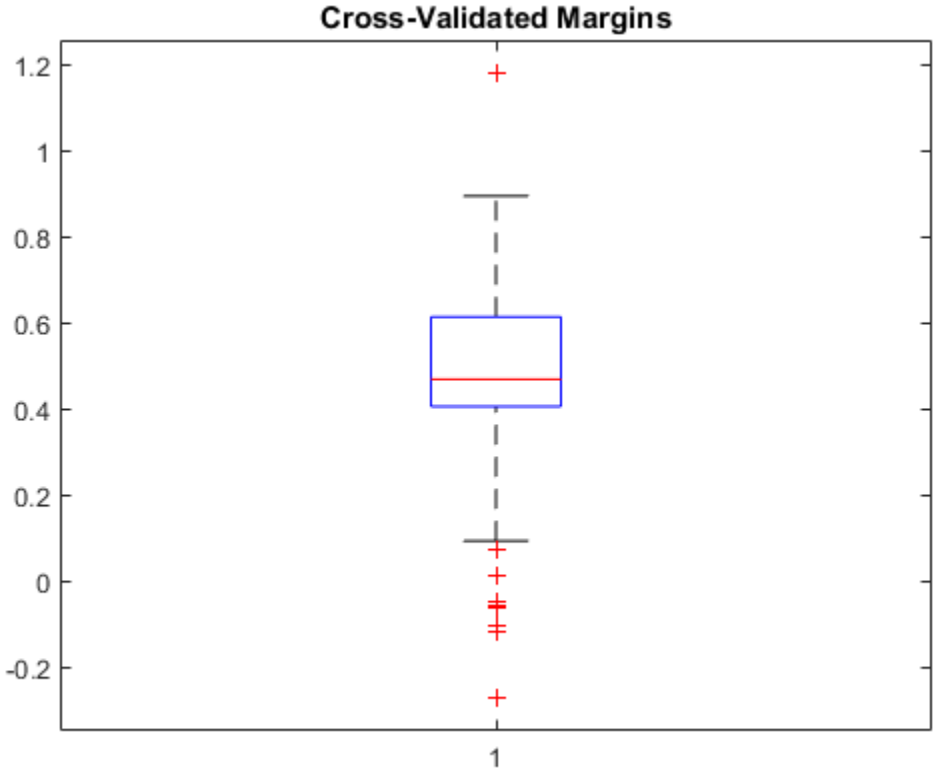
```
t = templateSVM('Standardize',1);
CVMdl = fitcecoc(X,Y,'CrossVal','on','Learners',t,'ClassNames',classOrder);
```

`CVMdl` is a `ClassificationPartitionedModel` model. By default, the software implements 10-fold cross validation. You can alter the number of folds using the `'KFold'` name-value pair argument.

Estimate the out-of-fold margins. Display the distribution of the mnargins using a boxplot.

```
margin = kfoldMargin(CVMdl);

figure;
boxplot(margin);
title('Cross-Validated Margins')
```



An observation margin is the positive-class, negated loss minus the maximum negative-class, negated loss. Classifiers that yield relatively large margins are desirable.

Select ECOC Model Features by Comparing Cross-Validation Margins

The classifier margin measures the average of the classifier margins. One way to perform feature selection is to compare cross-validation margins from multiple models. Based solely on this criterion, the classifier with the greater margins is the best classifier.

Load Fisher's iris data set.

```
load fisheriris
X = meas;
```

```
Y = categorical(species);
classOrder = unique(Y); % Class order
rng(1); % For reproducibility
```

Define these two data sets:

- `fullX` contains all predictors.
- `partX` contains the petal dimensions.

```
fullX = X;
partX = X(:,3:4);
```

Train an ECOC model using SVM binary classifiers for each predictor set, and specify to cross validate. It is good practice to standardize the predictors and define the class order. Specify to standardize the predictors using an SVM template.

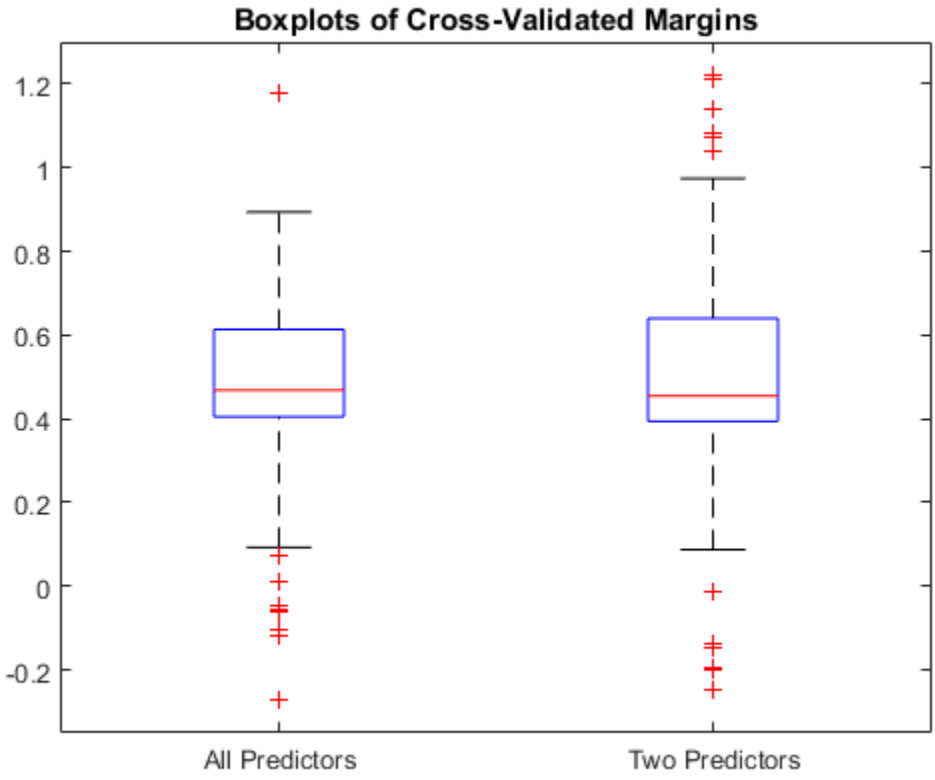
```
t = templateSVM('Standardize',1);
CVMdl = fitcecoc(fullX,Y,'CrossVal','on','Learners',t,...
    'ClassNames',classOrder);
PCVMdl = fitcecoc(partX,Y,'CrossVal','on','Learners',t,...
    'ClassNames',classOrder);
```

`CVMdl` and `PCVMdl` are `ClassificationPartitionedECOC` models. By default, the software implements 10-fold cross validation.

Estimate the test sample margin for each classifier. Specify to use loss-based decoding for aggregating the binary learner results. For each model, display the distribution of the margins using a boxplot.

```
fullMargins = kfoldMargin(CVMdl,'Decoding','lossbased');
partMargins = kfoldMargin(PCVMdl,'Decoding','lossbased');

figure;
boxplot([fullMargins partMargins],'Labels',{'All Predictors','Two Predictors'});
title('Boxplots of Cross-Validated Margins')
```



The margin distributions are approximately the same, but `PCVMdl` is a less complex model, which might make it more desirable.

kfoldMargin

Class: ClassificationPartitionedModel

Classification margins for observations not used for training

Syntax

```
M = kfoldMargin(obj)
```

Description

`M = kfoldMargin(obj)` returns classification margins obtained by cross-validated classification model `obj`. For every fold, this method computes classification margins for in-fold observations using a model trained on out-of-fold observations.

Input Arguments

`obj`

A partitioned classification model of type `ClassificationPartitionedModel` or `ClassificationPartitionedEnsemble`.

Output Arguments

`M`

The classification margin.

Definitions

Margin

The classification *margin* is the difference between the classification *score* for the true class and maximal classification score for the false classes.

The classification margin is a column vector with the same number of rows as in the matrix X. A high value of margin indicates a more reliable prediction than a low value.

Score

For discriminant analysis, the *score* of a classification is the posterior probability of the classification. For the definition of posterior probability in discriminant analysis, see "Posterior Probability" on page 15-7.

For ensembles, a classification *score* represents the confidence of a classification into a class. The higher the score, the higher the confidence.

Different ensemble algorithms have different definitions for their scores. Furthermore, the range of scores depends on ensemble type. For example:

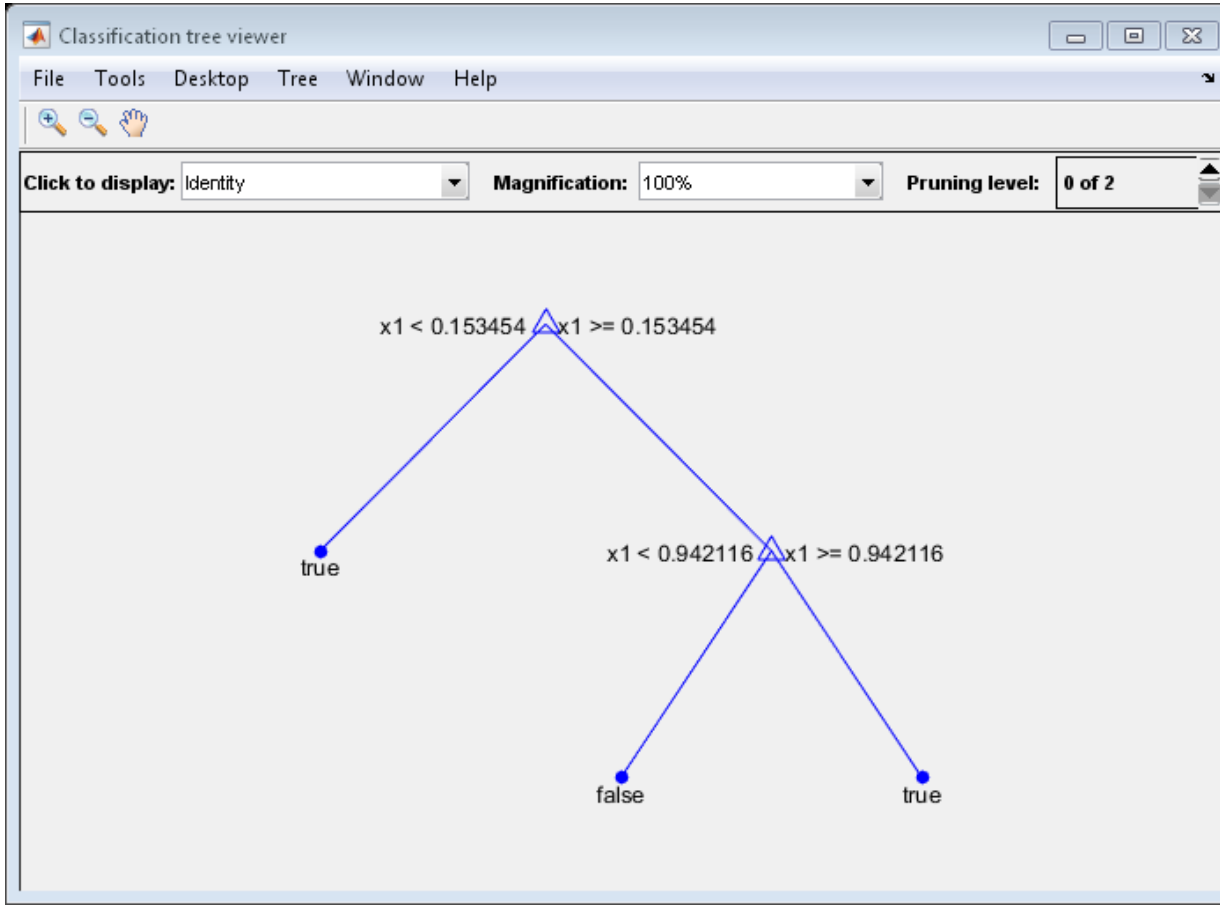
- `AdaBoostM1` scores range from $-\infty$ to ∞.
- `Bag` scores range from `0` to `1`.

For trees, the *score* of a classification of a leaf node is the posterior probability of the classification at that node. The posterior probability of the classification at a node is the number of training sequences that lead to that node with the classification, divided by the number of training sequences that lead to that node.

For example, consider classifying a predictor `X` as `true` when `X < 0.15` or `X > 0.95`, and `X` is false otherwise.

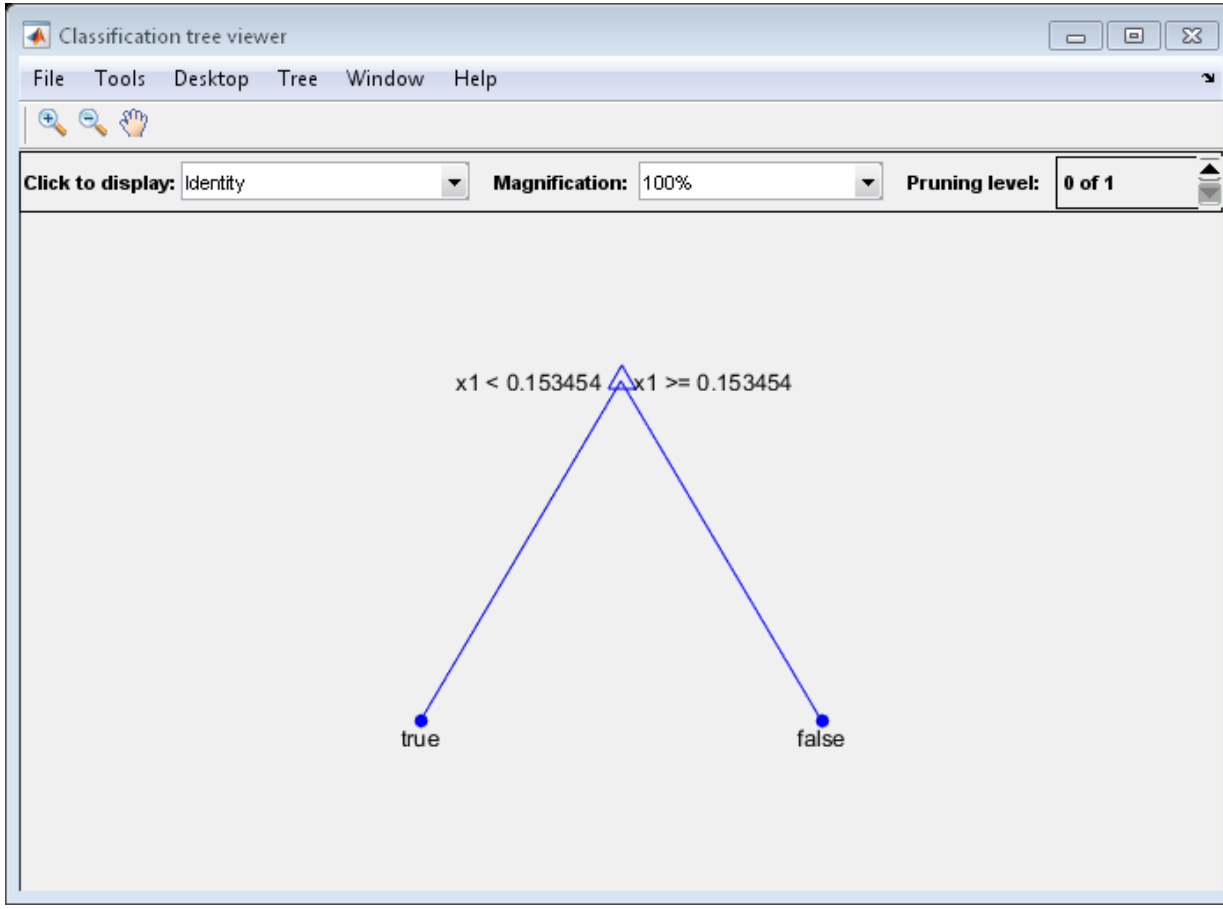
Generate 100 random points and classify them:

```
rng(0,'twister') % for reproducibility
X = rand(100,1);
Y = (abs(X - .55) > .4);
tree = fitctree(X,Y);
view(tree,'Mode','Graph')
```



Prune the tree:

```
tree1 = prune(tree,'Level',1);
view(tree1,'Mode','Graph')
```



The pruned tree correctly classifies observations that are less than 0.15 as `true`. It also correctly classifies observations from .15 to .94 as `false`. However, it incorrectly classifies observations that are greater than .94 as `false`. Therefore, the score for observations that are greater than .15 should be about .05/.85=.06 for `true`, and about .8/.85=.94 for `false`.

Compute the prediction scores for the first 10 rows of `X`:

```
[~,score] = predict(tree1,X(1:10));
[score X(1:10,:)]
```

```
ans =

    0.9059    0.0941    0.8147
    0.9059    0.0941    0.9058
         0    1.0000    0.1270
    0.9059    0.0941    0.9134
    0.9059    0.0941    0.6324
         0    1.0000    0.0975
    0.9059    0.0941    0.2785
    0.9059    0.0941    0.5469
    0.9059    0.0941    0.9575
    0.9059    0.0941    0.9649
```

Indeed, every value of `X` (the right-most column) that is less than 0.15 has associated scores (the left and center columns) of `0` and `1`, while the other values of `X` have associated scores of `0.91` and `0.09`. The difference (score `0.09` instead of the expected `.06`) is due to a statistical fluctuation: there are `8` observations in `X` in the range `(.95,1)` instead of the expected `5` observations.

Examples

Esimtate the *k*-fold Margins of a Classifier

Find the *k*-fold margins for an ensemble that classifies the `ionosphere` data.

Load the `ionosphere` data set.

```
load ionosphere
```

Train a classification ensemble of decision trees.

```
Mdl = fitensemble(X,Y,'AdaBoostM1',100,'Tree');
```

Cross validate the classifier using 10-fold cross validation.

```
cvens = crossval(Mdl);
```

Compute the _k_fold margins. Disaply summary statistics for the margins.

```
m = kfoldMargin(cvens);
marginStats = table(min(m),mean(m),max(m),...
    'VariableNames',{'Min','Mean','Max'})
```

```
marginStats =

      Min        Mean       Max
    _______    _______    ______

    -11.312    7.3236     23.517
```

See Also

ClassificationPartitionedModel | kfoldEdge | kfoldLoss | kfoldfun | crossval | kfoldPredict

kfoldPredict

Predict responses for observations not used for training

Syntax

```
label = kfoldPredict(CVMdl)
label = kfoldPredict(CVMdl,Name,Value)
[label,NegLoss,PBScore] = kfoldPredict( ___ )
[label,NegLoss,PBScore,Posterior] = kfoldPredict( ___ )
```

Description

`label = kfoldPredict(CVMdl)` returns class labels predicted by the cross-validated ECOC model (`ClassificationPartitionedECOC`) `CVMdl`. For every fold, `kfoldPredict` predicts class labels for in-fold observations using a model trained on out-of-fold observations. `CVMdl.X` contains both sets of observations.

The software predicts the classification of an observation by assigning the observation to the class yielding the largest negated average binary loss (or, equivalently, the smallest average binary loss).

`label = kfoldPredict(CVMdl,Name,Value)` returns predicted class labels with additional options specified by one or more Name,Value pair arguments.

For example, specify the posterior probability estimation method, decoding scheme, or verbosity level.

`[label,NegLoss,PBScore] = kfoldPredict( ___ )` additionally returns negated values of the average binary loss per class (`NegLoss`) for in-fold observations, and positive-class scores (`PBScore`) for in-fold observations classified by each binary learner.

If the coding matrix varies across folds (that is, if the coding scheme is `sparserandom` or `denserandom`), then `PBScore` is empty (`[]`).

`[label,NegLoss,PBScore,Posterior] = kfoldPredict( ___ )` additionally returns posterior class probability estimates for in-fold observations (`Posterior`).

To obtain posterior class probabilities, you must set `'FitPosterior',1` when training the ECOC model using `fitcecoc`. Otherwise, `kfoldPredict` throws an error.

Input Arguments

`CVMdl` — Cross-validated ECOC model

`ClassificationPartitionedECOC` model

Cross-validated ECOC model, specified as a `ClassificationPartitionedECOC` model. You can create a `ClassificationPartitionedECOC` model by:

- Passing a trained ECOC model (`ClassificationECOC`) to `crossval`
- Training an ECOC model using `fitcecoc` and setting any one of these cross-validation name-value pair arguments: `'CrossVal'`, `'KFold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'`

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'BinaryLoss'` — Binary learner loss function

`CVMdl.BinaryLoss` (default) | function handle | `'hamming'` | `'linear'` | `'exponential'` | `'binodeviance'` | `'hinge'` | `'quadratic'`

Binary learner loss function, specified as the comma-separated pair consisting of `'BinaryLoss'` and a function handle or string.

- If the value is a string, then it must correspond to a built-in function. This table summarizes the built-in functions, where y_j is a class label for a particular binary learner (in {-1,1,0}) and f_j is the score for observation j.

Value	Description	Score Domain	Formula
`'binodeviance'`	Binomial deviance	(-∞,∞)	$\log[1 + \exp(-2yf)]/\log(2)$
`'exponential'`	Exponential	(-∞,∞)	$\exp(-yf)$
`'hamming'`	Hamming	(-∞,∞) or [0,1]	$1 - \text{sign}(yf)$
`'hinge'`	Hinge	(-∞,∞)	$\max(0,1 - yf)$
`'linear'`	Linear	(-∞,∞)	$1 - yf$

Value	Description	Score Domain	Formula
`'quadratic'`	Quadratic	[0,1]	$[1 - y(2f - 1)]^2$

- For a custom binary loss function, e.g., `customFunction`, specify its function handle `'BinaryLoss',@customFunction`.

  `customFunction` should have this form

  ```
  bLoss = customFunction(M,f)
  ```
  where:

  - `M` is the K-by-L coding matrix stored in `CVMdl.CodingMatrix`.
  - `f` is the 1-by-L row vector of classification scores.
  - `bLoss` is the classification loss.
  - K is the number of classes.
  - L is the number of binary learners.

Example: `'BinaryLoss','binodeviance'`

Data Types: `char` | `function_handle`

`'Decoding'` — Decoding scheme

`'lossweighted'` (default) | `'lossbased'`

Decoding scheme that aggregates the binary losses, specified as the comma-separated pair consisting of `'Decoding'` and `'lossweighted'` or `'lossbased'`.

Example: `'Decoding','lossbased'`

Data Types: `char`

`'NumKLInitializations'` — Number of random initial values

`0` (default) | nonnegative integer

Number of random initial values for fitting posterior probabilities by Kullback-Leibler divergence minimization, specified as the comma-separated pair consisting of `'NumKLInitializations'` and a nonnegative integer.

If you do not request the fourth output argument (Posterior) and set `'PosteriorMethod','kl'` (the default), then the software ignores the value of `NumKLInitializations`.

For more details, see "Posterior Estimation Using Kullback-Leibler Divergence" on page 22-3679.

Example: `'NumKLInitializations',5`

Data Types: `single` | `double`

`'Options'` — Estimation options

`[ ]` (default) | structure array returned by `statset`

Estimation options, specified as the comma-separated pair consisting of `'Options'` and a structure array returned by `statset`.

To invoke parallel computing:

- You need a Parallel Computing Toolbox license.
- Specify `'Options',statset('UseParallel',1)`.

`'PosteriorMethod'` — Posterior probability estimation method

`'kl'` (default) | `'qp'`

Posterior probability estimation method, specified as the comma-separated pair consisting of `'PosteriorMethod'` and `'kl'` or `'qp'`.

- If `PosteriorMethod` is `'kl'`, then the software estimates multiclass posterior probabilities by minimizing the Kullback-Leibler divergence between the predicted and expected posterior probabilities returned by binary learners. For details, see "Posterior Estimation Using Kullback-Leibler Divergence".
- If `PosteriorMethod` is `'qp'`, then the software estimates multiclass posterior probabilities by solving a least-squares problem using quadratic programming. You need an Optimization Toolbox license to use this option. For details, see "Posterior Estimation Using Quadratic Programming".
- If you do not request the fourth output argument (Posterior), then the software ignores the value of `PosteriorMethod`.

Example: `'PosteriorMethod','qp'`

Data Types: `char`

`'Verbose'` — Verbosity level

`0` (default) | `1`

Verbosity level, specified as the comma-separated pair consisting of `'Verbose'` and `0` or `1`. `Verbose` controls the amount of diagnostic messages that the software displays in the Command Window.

If `Verbose` is `0`, then the software does not display diagnostic messages. Otherwise, the software displays diagnostic messages.

Example: `'Verbose',1`

Data Types: `single | double`

Output Arguments

`label` — Predicted class labels

categorical array | character array | logical vector | vector of numeric values | cell array of strings

Predicted class labels, returned as a categorical or character array, logical or numeric vector, or cell array of strings.

`label`:

- Is the same data type as CVMdl.Y
- Has length equal to the number of rows of CVMdl.X

The software predicts the classification of an observation by assigning the observation to the class yielding the largest negated average binary loss (or, equivalently, the smallest average binary loss).

`NegLoss` — Negated average binary losses

numeric matrix

Negated average binary losses, returned as a numeric matrix. `NegLoss` is an `n`-by-`K` matrix, where `n` is the number of observations (`size(`CVMdl`.X,1)`) and `K` is the number of unique classes (`size(CVMdl.ClassNames,1)`).

`PBScore` — Positive-class scores

numeric matrix

Positive-class scores for each binary learner, returned as a numeric matrix. `PBScore` is an `n`-by-`L` matrix, where `n` is the number of observations (`size(`CVMdl`.X,1)`) and `L` is the number of binary learners (`size(CVMdl.CodingMatrix,2)`).

If the coding matrix varies across folds (that is, if the coding scheme is `sparserandom` or `denserandom`), then `PBScore` is empty (`[]`).

`Posterior` — Posterior class probabilities
numeric matrix

Posterior class probabilities, returned as a numeric matrix. `Posterior` is an `n`-by-`K` matrix, where `n` is the number of observations (`size(`CVMdl`.X,1)`) and `K` is the number of unique classes (`size(CVMdl.ClassNames,1)`).

You must set `'FitPosterior',1` when training the ECOC model using `fitcecoc` to request `Posterior`. Otherwise, the software throws an error.

Definitions

Binary Loss

A *binary loss* is a function of the class and classification score that determines how well a binary learner classifies an observation into the class.

Let:

- m_{kj} be element (k,j) of the coding design matrix M (i.e., the code corresponding to class k of binary learner j)
- s_j be the score of binary learner j for an observation
- g be the binary loss function
- $\hat{k}$ be the predicted class for the observation

In *loss-based decoding* [3], the class producing the minimum sum of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \underset{k}{\arg\min} \sum_{j=1}^{L} \left|m_{kj}\right| g(m_{kj}, s_j).$$

In *loss-weighted decoding* [3], the class producing the minimum average of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \underset{k}{\operatorname{argmin}} \frac{\sum_{j=1}^{L} |m_{kj}|\, g(m_{kj}, s_j)}{\sum_{j=1}^{L} |m_{kj}|}.$$

Allwein et al. [1] suggest that loss-weighted decoding improves classification accuracy by keeping loss values for all classes in the same dynamic range.

This table summarizes the supported loss functions, where y_j is a class label for a particular binary learner (in the set {-1,1,0}), s_j is the score for observation j, and $g(y_j,s_j)$.

Value	Description	Score Domain	$g(y_j,s_j)$
`'binodeviance'`	Binomial deviance	$(-\infty,\infty)$	$\log[1 + \exp(-2y_js_j)]/[2\log(2)]$
`'exponential'`	Exponential	$(-\infty,\infty)$	$\exp(-y_js_j)/2$
`'hamming'`	Hamming	{-1,1}	$[1 - \text{sign}(y_js_j)]/2$
`'hinge'`	Hinge	$(-\infty,\infty)$	$\max(0,1 - y_js_j)/2$
`'linear'`	Linear	$(-\infty,\infty)$	$(1 - y_js_j)/2$
`'quadratic'`	Quadratic	[0,1]	$[1 - y_j(2s_j - 1)]^2/2$

The software normalizes the binary losses such that the loss is 0.5 when $y_j = 0$, and aggregates using the average of the binary learners [1].

Do not confuse the binary loss with the overall classification loss (specified by the LossFun name-value pair argument of `predict` and `loss`), e.g., classification error, which measures how well an ECOC classifier performs as a whole.

Examples

Predict *k*-Fold Cross-Validation Labels of ECOC Models

Load Fisher's iris data set.

```
load fisheriris
X = meas;
Y = categorical(species);
```

```
classOrder = unique(Y);
rng(1); % For reproducibility
```

Train an ECOC model using SVM binary classifiers and specify to cross validate. It is good practice to standardize the predictors and define the class order. Specify to standardize the predictors using an SVM template.

```
t = templateSVM('Standardize',1);
CVMdl = fitcecoc(X,Y,'CrossVal','on','Learners',t,'ClassNames',classOrder);
```

`CVMdl` is a `ClassificationPartitionedModel` model. By default, the software implements 10-fold cross validation. You can alter the number of folds using the `'KFold'` name-value pair argument.

Predict the out-of-fold labels. Print a random subset of true and predicted labels.

```
labels = kfoldPredict(CVMdl);
idx = randsample(numel(labels),10);
table(Y(idx),labels(idx),...
    'VariableNames',{'TrueLabels','PredictedLabels'})
```

```
ans =

    TrueLabels    PredictedLabels
    __________    _______________

    setosa        setosa
    versicolor    versicolor
    setosa        setosa
    virginica     virginica
    versicolor    versicolor
    setosa        setosa
    virginica     virginica
    virginica     virginica
    setosa        setosa
    setosa        setosa
```

`CVMdl` correctly labeled the out-of-fold observations with indices `idx`.

Predict Cross-Validation Labels of ECOC Models Using Custom Binary Loss Function

Load Fisher's iris data set.

```
load fisheriris
```

```
X = meas;
Y = categorical(species);
classOrder = unique(Y); % Class order
K = numel(classOrder);  % Number of classes
rng(1); % For reproducibility
```

Train an ECOC model using SVM binary classifiers and specify to cross validate. It is good practice to standardize the predictors and define the class order. Specify to standardize the predictors using an SVM template.

```
t = templateSVM('Standardize',1);
CVMdl = fitcecoc(X,Y,'CrossVal','on','Learners',t,'ClassNames',classOrder);
```

`CVMdl` is a `ClassificationPartitionedModel` model. By default, the software implements 10-fold cross validation. You can alter the number of folds using the `'KFold'` name-value pair argument.

SVM scores are signed distances from the observation to the decision boundary. Therefore, the domain is $(-\infty,\infty)$. Create a custom binary loss function that:

- Maps the coding design matrix (*M*) and positive-class classification scores (*s*) for each learner to the binary loss for each observation
- Uses linear loss
- Aggregates the binary learner loss using the median.

You can create a separate function for the binary loss function, and then save it on the MATLAB® path. Or, you can specify an anonymous binary loss function.

```
customBL = @(M,s)nanmedian(1 - bsxfun(@times,M,s),2)/2;
```

Predict cross-validation labels and estimate the median binary loss per class. Print the median negative binary losses per class for a random set of 10 out-of-fold observations.

```
[label,NegLoss] = kfoldPredict(CVMdl,'BinaryLoss',customBL);

idx = randsample(numel(label),10);
classOrder
table(Y(idx),label(idx),NegLoss(idx,:),'VariableNames',...
    {'TrueLabel','PredictedLabel','NegLoss'})

classOrder =

     setosa
```

```
     versicolor
     virginica

ans =

    TrueLabel     PredictedLabel                NegLoss
    __________    ______________    ____________________________________

    setosa        versicolor        0.37141       2.1292      -4.0006
    versicolor    versicolor        -1.2167       0.3669     -0.65017
    setosa        versicolor        0.23927         2.08      -3.8193
    virginica     virginica         -1.9154     -0.19947       0.6149
    versicolor    versicolor        -1.3746      0.45535     -0.58076
    setosa        versicolor        0.20061       2.2774      -3.9781
    virginica     versicolor        -1.4928     0.090689    -0.097935
    virginica     virginica         -1.7669     -0.13464       0.4015
    setosa        versicolor        0.19999       1.9113      -3.6113
    setosa        versicolor        0.16108       1.9684      -3.6295
```

The order of the columns corresponds to the elements of `classOrder`. The software predicts the label based on the maximum negated loss. The results seem to indicate that the median of the linear losses might not perform as well as other losses.

Estimate Cross-Validation Posterior Probabilities of ECOC Models

Load Fisher's iris data set. Train the classifier using the petal dimensions as predictors.

```
load fisheriris
X = meas(:,3:4);
Y = categorical(species);
classOrder = unique(Y);
rng(1); % For reproducibility
```

Create an SVM template, and specify the Gaussian kernel. It is good practice to standardize the predictors.

```
t = templateSVM('Standardize',1,'KernelFunction','gaussian');
```

`t` is an SVM template. Most of its properties are empty. When the software trains the ECOC classifier, it sets the applicable properties to their default values.

Train the ECOC classifier using the SVM template, and specify to cross validate. Transform classification scores to class posterior probabilities (returned by

`kfoldPredict`) using the `'FitPosterior'` name-value pair argument. It is good practice to specify the class order.

```
CVMdl = fitcecoc(X,Y,'Learners',t,'CrossVal','on','FitPosterior',true,...
    'ClassNames',classOrder);
```

`CVMdl` is a `ClassificationPartitionedECOC` model. By default, the software uses 10-fold cross validation.

Predict the out-of-fold class posterior probabilities. Specify to use 10 random initial values for the Kullback-Leibler algorithm.

```
[label,~,~,Posterior] = kfoldPredict(CVMdl,'NumKLInitializations',10);
```

The software assigns an observation to the class that yields the smallest average binary loss. Since all binary learners are computing posterior probabilities, the binary loss function is `quadratic`.

Display a random set of results.

```
idx = randsample(size(X,1),10);
CVMdl.ClassNames
table(Y(idx),label(idx),Posterior(idx,:),...
    'VariableNames',{'TrueLabel','PredLabel','Posterior'})
```

```
ans =

     setosa
     versicolor
     virginica

ans =

    TrueLabel     PredLabel                  Posterior
    __________    __________    ___________________________________

    versicolor    versicolor     0.0086394       0.98243     0.0089291
    versicolor    virginica     2.2197e-14       0.12447       0.87553
    setosa        setosa             0.999    0.00022837    0.00076884
    versicolor    versicolor    2.2194e-14       0.98916      0.010839
    virginica     virginica       0.012318      0.012925       0.97476
    virginica     virginica      0.0015571     0.0015638       0.99688
    virginica     virginica      0.0042895     0.0043556       0.99135
```

```
    setosa        setosa             0.999     0.00028329     0.00071382
    virginica     virginica      0.0094719      0.0098229        0.98071
    setosa        setosa             0.999     0.00013562     0.00086192
```

The columns of `Posterior` correspond to the class order of `Mdl.ClassNames`.

Estimate Cross-Validation Posterior Probabilities Using Parallel Computing

Train an error-correcting output codes, multiclass model and estimate posterior probabilities using parallel computing.

Load the `arrhythmia` data set.

```
load arrhythmia
Y = categorical(Y);
tabulate(Y)
n = numel(Y);
K = numel(unique(Y));
```

```
  Value    Count   Percent
      1      245     54.20%
      2       44      9.73%
      3       15      3.32%
      4       15      3.32%
      5       13      2.88%
      6       25      5.53%
      7        3      0.66%
      8        2      0.44%
      9        9      1.99%
     10       50     11.06%
     14        4      0.88%
     15        5      1.11%
     16       22      4.87%
```

Several classes are not represented in the data, and many of the other classes have low relative frequencies.

Specify an ensemble learning template that uses the GentleBoost method, and 50 weak, classification tree learners.

```
t = templateEnsemble('GentleBoost',50,'Tree');
```

`t` is a template object. Most of the options are empty (`[ ]`). The software uses default values for all empty options during training.

Since there are many classes, specify a sparse random coding design.

```
rng(1); % For reproducibility
Coding = designecoc(K,'sparserandom');
```

Train an ECOC model using parallel computing, and specify to cross validate and fit posterior probabilities (returned by `kfoldPredict`).

```
pool = parpool;                       % Invokes workers
options = statset('UseParallel',1);
CVMdl = fitcecoc(X,Y,'Learner',t,'Options',options,'Coding',Coding,...
    'FitPosterior',1,'CrossVal','on');
```

```
Starting parallel pool (parpool) using the 'local' profile ... connected to 4 workers.
Warning: One or more folds do not contain points from all the groups.
```

`CVMdl` is a `ClassificationPartitionedECOC` model. By default, the software implements 10-fold cross validation. You can alter the number of folds using the `'KFold'` name-value pair argument.

The pool invokes four workers. The number of workers might vary among systems. Also, there is a good chance that one or more folds do not contain observations from all classes since some classes have low relative frequency.

Estimate posterior probabilities, and display the posterior probability of being classified as not having arrhythmia (class 1) given the data for a random set of out-of-fold observations.

```
[~,~,~,posterior] = kfoldPredict(CVMdl,'Options',options);
idx = randsample(n,10);
table(idx,Y(idx),posterior(idx,1),...
    'VariableNames',{'OOFSampleIndex','TrueLabel','PosteriorNoArrhythmia'})
```

```
ans =

    OOFSampleIndex    TrueLabel    PosteriorNoArrhythmia
    ______________    _________    _____________________

    171               1             0.33654
    221               1             0.85135
     72               16             0.9174

    202               1              0.8438
    243               1             0.94338
     18               1             0.81789
```

```
 49          6          0.090153
234          1           0.61626
315          1           0.97187
```

- "Quick Start Parallel Computing for Statistics and Machine Learning Toolbox" on page 21-2

Algorithms

The software can estimate class posterior probabilities using quadratic programming or by minimizing the Kullback-Leibler divergence. For the following descriptions of the posterior estimation algorithms, let:

- m_{kj} be the element (k,j) of the coding design matrix M.
- I be the indicator function.
- $\hat{p}_k$ be the class posterior probability estimate for class k of an observation, $k = 1,...,K$.
- r_j be the positive-class posterior probability for binary learner j. That is, r_j is the probability that binary learner j classifies an observation into the positive class, given the training data.

Posterior Estimation Using Kullback-Leibler Divergence

By default, the software minimizes the Kullback-Leibler divergence to estimate class posterior probabilities. The Kullback-Leibler divergence between the expected and observed positive-class posterior probabilities is

$$\Delta(r,r) = \sum_{j=1}^{L} w_j \left[r_j \log \frac{r_j}{r_j} + \left(1 - r_j\right) \log \frac{1 - r_j}{1 - r_j} \right],$$

where $w_j = \sum_{S_j} w_i^*$ is the weight for binary learner j with S_j the set of observation indices that binary learner j is trained on and w_i^* is the weight of observation i. The software minimizes the divergence iteratively. The first step is to choose initial values $\hat{p}_k^{(0)};\ k = 1,...,K$ for the class posterior probabilities.

- If you do not specify NumKLIterations, then the software uses both sets of deterministic initial values described next, and uses the one that minimizes Δ.
  - $\hat{p}_k^{(0)} = 1/K;\ k = 1,...,K.$
  - $\hat{p}_k^{(0)};\ k = 1,...,K$ is the solution of the system

$$M_{01}\hat{p}^{(0)} = r,$$

    where M_{01} is M with all $m_{kj} = -1$ replaced with 0, and r is a vector of positive-class posterior probabilities returned by the L binary learners [2]. The software uses `lsqnonneg` to solve the system.
- If you specify `'NumKLIterations',c`, where `c` is a natural number, then the software does the following to choose $\hat{p}_k^{(0)};\ k = 1,...,K$, and uses the one that minimizes Δ.
  - The software chooses both sets of deterministic initial values as described previously.
  - The software randomly generates `c` vectors of length K using `rand`, and then normalizes each vector to sum to 1.

At iteration t, the software:

1. Computes

$$\hat{r}_j^{(t)} = \frac{\sum_{k=1}^{K} \hat{p}_k^{(t)} I(m_{kj} = +1)}{\sum_{k=1}^{K} \hat{p}_k^{(t)} I(m_{kj} = +1 \cup m_{kj} = -1)}.$$

2. Estimates the next class posterior probability using

$$\hat{p}_k^{(t+1)} = \hat{p}_k^{(t)} \frac{\sum_{j=1}^{L} w_j \left[r_j I\left(m_{kj} = +1\right) + \left(1 - r_j\right) I\left(m_{kj} = -1\right) \right]}{\sum_{j=1}^{L} w_j \left[\hat{r}_j^{(t)} I\left(m_{kj} = +1\right) + \left(1 - \hat{r}_j^{(t)}\right) I\left(m_{kj} = -1\right) \right]}.$$

3 Normalizes $\hat{p}_k^{(t+1)};\ k = 1,...,K$ so that they sum to 1.

4 Checks for convergence.

For more details, see [5] and [7].

Posterior Estimation Using Quadratic Programming

Posterior probability estimation using quadratic programming requires an Optimization Toolbox license. To estimate posterior probabilities for an observation using this method, the software:

1 Estimates the positive-class posterior probabilities, r_j, for binary learners $j = 1,...,L$.

2 Using the relationship between r_j and $\hat{p}_k$ [6], minimizes

$$\sum_{j=1}^{L} \left[-r_j \sum_{k=1}^{K} \hat{p}_k I\left(m_{kj} = -1\right) + \left(1 - r_j\right) \sum_{k=1}^{K} \hat{p}_k I\left(m_{kj} = +1\right) \right]^2$$

with respect to $\hat{p}_k$ and the restrictions

$$0 \le \hat{p}_k \le 1$$
$$\sum_k \hat{p}_k = 1.$$

The software performs minimization using `quadprog`.

kfoldPredict

Class: ClassificationPartitionedModel

Predict response for observations not used for training

Syntax

```
label = kfoldPredict(obj)
[label,score] = kfoldPredict(obj)
[label,score,cost] = kfoldPredict(obj)
```

Description

`label = kfoldPredict(obj)` returns class labels predicted by `obj`, a cross-validated classification. For every fold, `kfoldPredict` predicts class labels for in-fold observations using a model trained on out-of-fold observations.

`[label,score] = kfoldPredict(obj)` returns the predicted classification scores for in-fold observations using a model trained on out-of-fold observations.

`[label,score,cost] = kfoldPredict(obj)` returns misclassification costs.

Input Arguments

`obj`

Object of class `ClassificationPartitionedModel` or `ClassificationPartitionedEnsemble`.

Output Arguments

`label`

Vector of class labels of the same type as the response data used in training obj. Each entry of `label` corresponds to a predicted class label for the corresponding row of `X`.

`score`

Numeric matrix of size `N`-by-`K`, where `N` is the number of observations (rows) in `obj.X`, and `K` is the number of classes (in `obj.ClassNames`). `score(i,j)` represents the confidence that row `i` of `obj.X` is of class `j`. For details, see "Definitions" on page 22-2412.

`cost`

Numeric matrix of misclassification costs of size `N`-by-`K`. `cost(i,j)` is the average misclassification cost of predicting that row `i` of `obj.X` is of class `j`.

Definitions

Cost (discriminant analysis)

The *average misclassification cost* is the mean misclassification cost for predictions made by the cross-validated classifiers trained on out-of-fold observations. The matrix of expected costs per observation is defined in "Cost" on page 15-8.

Score

For discriminant analysis, the *score* of a classification is the posterior probability of the classification. For the definition of posterior probability in discriminant analysis, see "Posterior Probability" on page 15-7.

For ensembles, a classification *score* represents the confidence of a classification into a class. The higher the score, the higher the confidence.

Different ensemble algorithms have different definitions for their scores. Furthermore, the range of scores depends on ensemble type. For example:

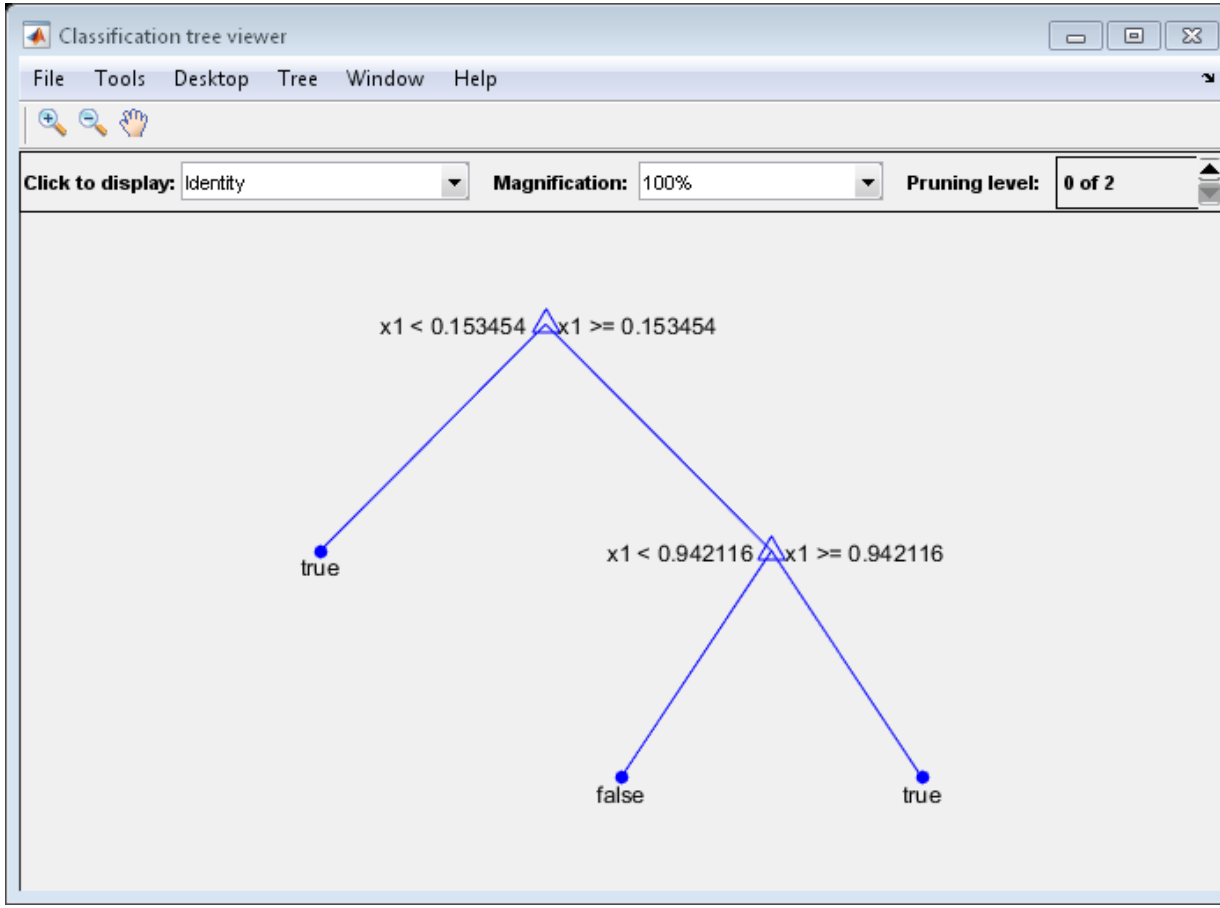
- `AdaBoostM1` scores range from $-\infty$ to ∞.
- `Bag` scores range from `0` to `1`.

For trees, the *score* of a classification of a leaf node is the posterior probability of the classification at that node. The posterior probability of the classification at a node is the number of training sequences that lead to that node with the classification, divided by the number of training sequences that lead to that node.

For example, consider classifying a predictor `X` as `true` when `X < 0.15` or `X > 0.95`, and `X` is false otherwise.

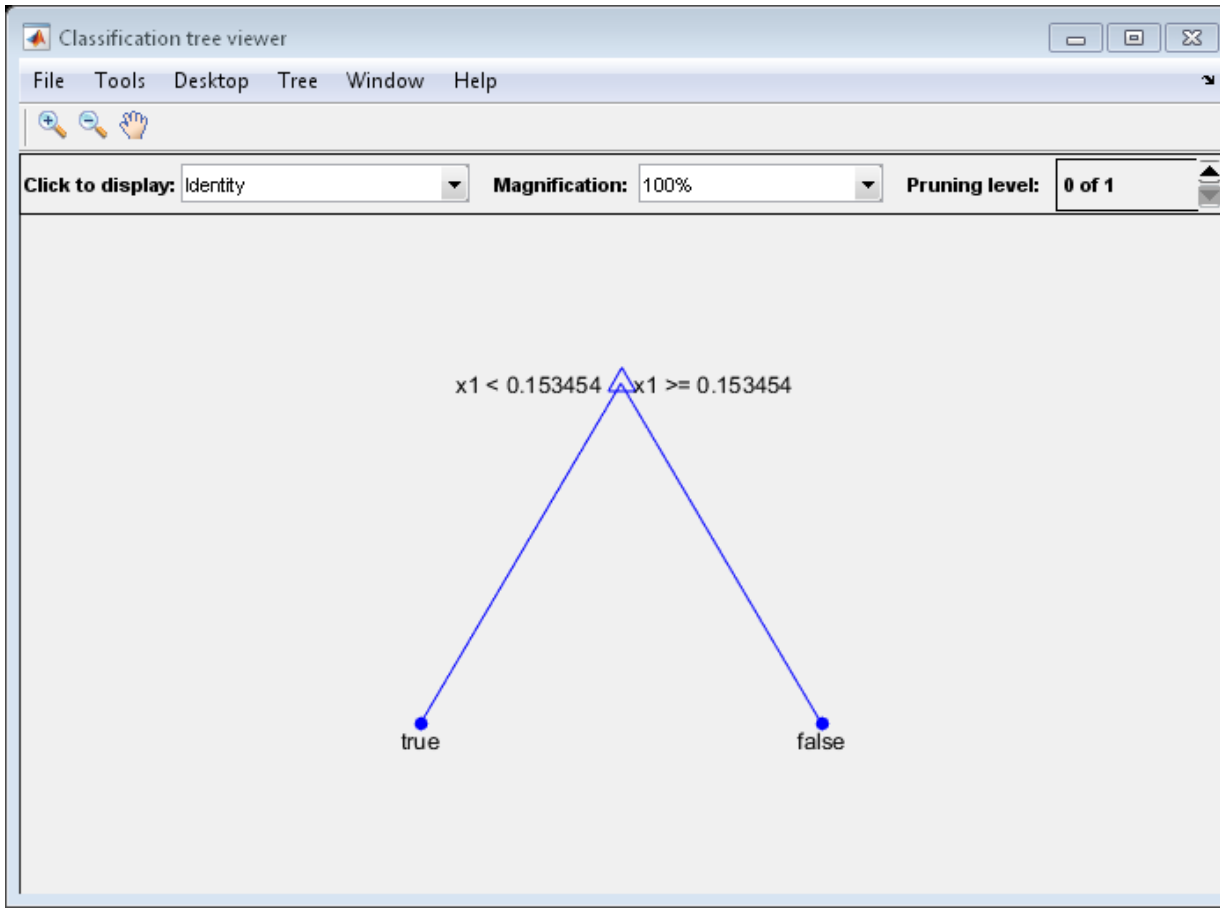
Generate 100 random points and classify them:

```
rng(0,'twister') % for reproducibility
X = rand(100,1);
Y = (abs(X - .55) > .4);
tree = fitctree(X,Y);
view(tree,'Mode','Graph')
```



Prune the tree:

```
tree1 = prune(tree,'Level',1);
view(tree1,'Mode','Graph')
```



The pruned tree correctly classifies observations that are less than 0.15 as `true`. It also correctly classifies observations from .15 to .94 as `false`. However, it incorrectly classifies observations that are greater than .94 as `false`. Therefore, the score for observations that are greater than .15 should be about .05/.85=.06 for `true`, and about .8/.85=.94 for `false`.

Compute the prediction scores for the first 10 rows of `X`:

```
[~,score] = predict(tree1,X(1:10));
```

```
[score X(1:10,:)]

ans =

    0.9059    0.0941    0.8147
    0.9059    0.0941    0.9058
         0    1.0000    0.1270
    0.9059    0.0941    0.9134
    0.9059    0.0941    0.6324
         0    1.0000    0.0975
    0.9059    0.0941    0.2785
    0.9059    0.0941    0.5469
    0.9059    0.0941    0.9575
    0.9059    0.0941    0.9649
```

Indeed, every value of `X` (the right-most column) that is less than 0.15 has associated scores (the left and center columns) of `0` and `1`, while the other values of `X` have associated scores of `0.91` and `0.09`. The difference (score `0.09` instead of the expected `.06`) is due to a statistical fluctuation: there are `8` observations in `X` in the range `(.95,1)` instead of the expected `5` observations.

Examples

Estimate Cross-Validation Predictions from an Ensemble

Find the cross-validation predictions for a model based on Fisher's iris data.

Load Fisher's iris data set.

```
load fisheriris
```

Train an ensemble of classification trees.

```
rng(1); % For reproducibility
Mdl = fitensemble(meas,species,'AdaBoostM2',100,'Tree');
```

Cross valdate the trained ensemble using 10-fold cross validation.

```
CVMdl = crossval(Mdl);
```

Estimate cross-validation predicted labels and scores.

```
[elabel escore] = kfoldPredict(CVMdl);
```

Display the maximum and minimum scores of each class.

```
max(escore)
min(escore)
```

```
ans =

    9.3862    8.9871   10.1866

ans =

    0.0017    3.8359    0.8981
```

See Also

ClassificationPartitionedModel | kfoldEdge | kfoldMargin | kfoldLoss | kfoldfun | crossval

kfoldPredict

Class: RegressionPartitionedModel

Predict response for observations not used for training.

Syntax

```
yfit = kfoldPredict(obj)
```

Description

`yfit = kfoldPredict(obj)` returns the predicted values for the responses of the training data based on `obj`, an object trained on out-of-fold observations.

Input Arguments

`obj`

Object of class `RegressionPartitionedModel`. Create `obj` with `fitrtree` or `fitensemble` along with one of the cross-validation options: `'crossval'`, `'kfold'`, `'holdout'`, `'leaveout'`, or `'cvpartition'`. Alternatively, create `obj` from a regression tree or regression ensemble with `crossval`.

Output Arguments

`yfit`

A vector of predicted values for the response data based on a model trained on out-of-fold observations.

Examples

Construct a partitioned regression model, and examine the cross-validation loss. The cross-validation loss is the mean squared error between yfit and the true response data:

```
load carsmall
XX = [Cylinders Displacement Horsepower Weight];
YY = MPG;
tree = fitrtree(XX,YY);
cvmodel = crossval(tree);
L = kfoldLoss(cvmodel)

L =
   26.5271

yfit = kfoldPredict(cvmodel);
mean( (yfit - tree.Y).^2 )

ans =
   26.5271
```

See Also

`kfoldLoss` | `fitrtree`

kmeans

k-means clustering

Syntax

```
idx = kmeans(X,k)
idx = kmeans(X,k,Name,Value)
[idx,C] = kmeans(___)
[idx,C,sumd] = kmeans(___)
[idx,C,sumd,D] = kmeans(___)
```

Description

`idx = kmeans(X,k)` performs *k*-means clustering to partition the observations of the *n*-by-*p* data matrix `X` into `k` clusters, and returns an *n*-by-1 vector (`idx`) containing cluster indices of each observation. Rows of `X` correspond to points and columns correspond to variables.

By default, `kmeans` uses the squared Euclidean distance measure and the *k*-means++ algorithm for cluster center initialization.

`idx = kmeans(X,k,Name,Value)` returns the cluster indices with additional options specified by one or more `Name,Value` pair arguments.

For example, specify the cosine distance, the number of times to repeat the clustering using new initial values, or to use parallel computing.

`[idx,C] = kmeans(___)` returns the `k` cluster centroid locations in the `k`-by-*p* matrix `C`.

`[idx,C,sumd] = kmeans(___)` returns the within-cluster sums of point-to-centroid distances in the `k`-by-1 vector `sumd`.

`[idx,C,sumd,D] = kmeans(___)` returns distances from each point to every centroid in the *n*-by-`k` matrix `D`.

Examples

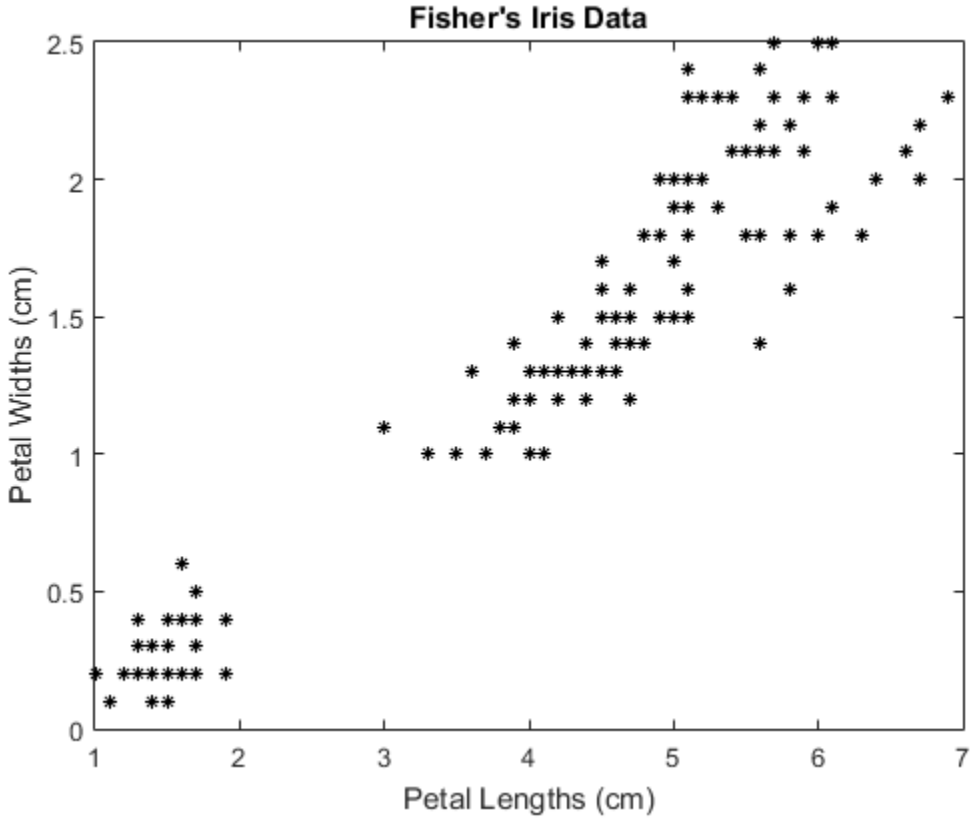
Train a *k*-Means Clustering Algorithm

Cluster data using *k*-means clustering, then plot the cluster regions.

Load Fisher's iris data set. Use the petal lengths and widths as predictors.

```
load fisheriris
X = meas(:,3:4);

figure;
plot(X(:,1),X(:,2),'k*','MarkerSize',5);
title 'Fisher''s Iris Data';
xlabel 'Petal Lengths (cm)';
ylabel 'Petal Widths (cm)';
```



The larger cluster seems to be split into a lower variance region and a higher variance region. This might indicate that the larger cluster is two, overlapping clusters.

Cluster the data. Specify $k = 3$ clusters.

```
rng(1); % For reproducibility
[idx,C] = kmeans(X,3);
```

`kmeans` uses the *k*-means++ algorithm for centroid initialization and squared Euclidean distance by default. It is good practice to search for lower, local minima by setting the `'Replicates'` name-value pair argument.

`idx` is a vector of predicted cluster indices corrresponding to the observations in `X`. `C` is a 3-by-2 matrix containing the final centroid locations.

Use `kmeans` to compute the distance from each centroid to points on a grid. To do this, pass the centroids (`C`) and points on a grid to `kmeans`, and implement one iteration of the algorithm.

```
x1 = min(X(:,1)):0.01:max(X(:,1));
x2 = min(X(:,2)):0.01:max(X(:,2));
[x1G,x2G] = meshgrid(x1,x2);
XGrid = [x1G(:),x2G(:)]; % Defines a fine grid on the plot

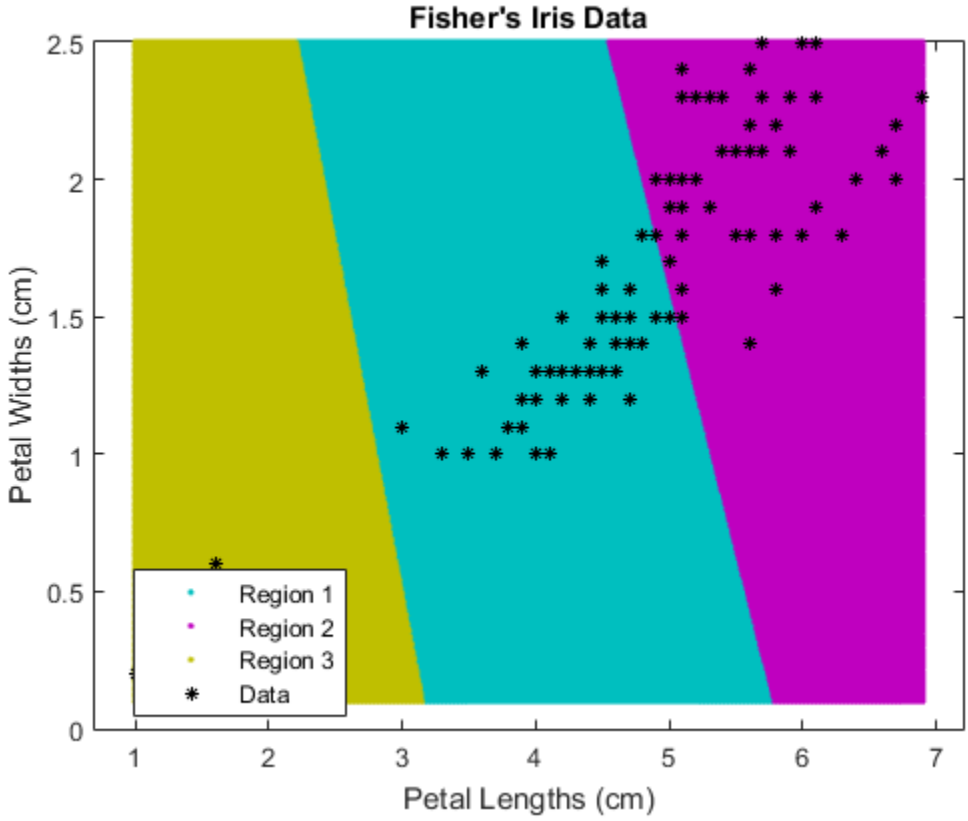
idx2Region = kmeans(XGrid,3,'MaxIter',1,'Start',C);...
    % Assigns each node in the grid to the closest centroid
```

```
Warning: Failed to converge in 1 iterations.
```

`kmeans` displays a warning stating that the algorithm did not converge, which you should expect since the software only implemented one iteration.

Plot the cluster regions.

```
figure;
gscatter(XGrid(:,1),XGrid(:,2),idx2Region,...
    [0,0.75,0.75;0.75,0,0.75;0.75,0.75,0],'..');
hold on;
plot(X(:,1),X(:,2),'k*','MarkerSize',5);
title 'Fisher''s Iris Data';
xlabel 'Petal Lengths (cm)';
ylabel 'Petal Widths (cm)';
legend('Region 1','Region 2','Region 3','Data','Location','Best');
hold off;
```

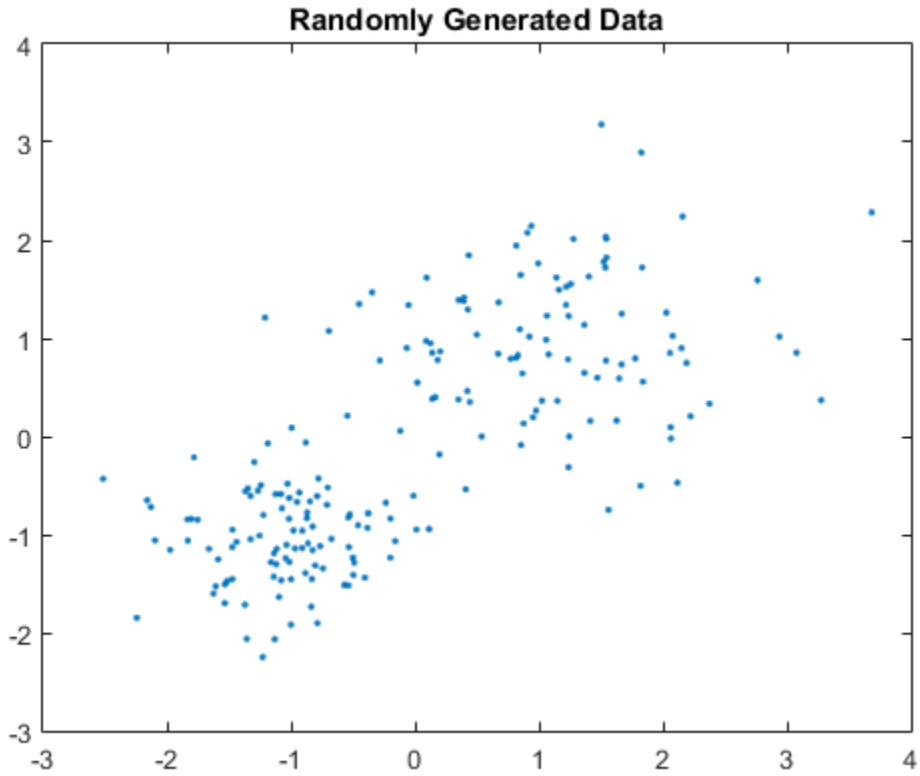


Partition Data into Two Clusters

Randomly generate the sample data.

```
rng default; % For reproducibility
X = [randn(100,2)*0.75+ones(100,2);
    randn(100,2)*0.5-ones(100,2)];

figure;
plot(X(:,1),X(:,2),'.');
title 'Randomly Generated Data';
```



There appears to be two clusters in the data.

Partition the data into two clusters, and choose the best arrangement out of five intializations. Display the final output.

```
opts = statset('Display','final');
[idx,C] = kmeans(X,2,'Distance','cityblock',...
    'Replicates',5,'Options',opts);
```

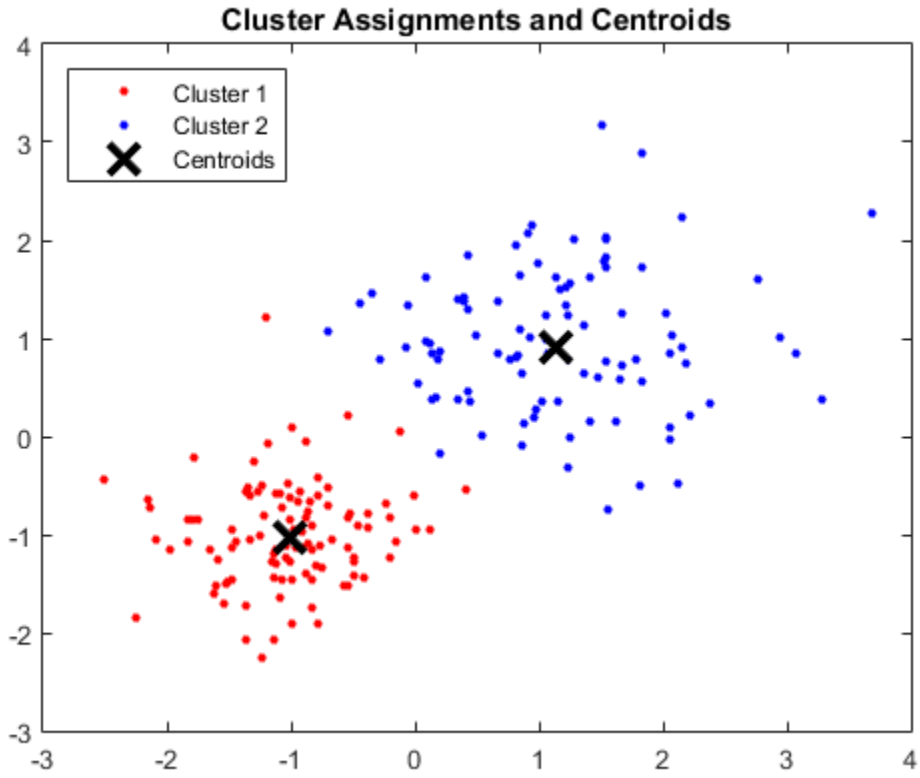
```
Replicate 1, 4 iterations, total sum of distances = 201.533.
Replicate 2, 6 iterations, total sum of distances = 201.533.
Replicate 3, 4 iterations, total sum of distances = 201.533.
Replicate 4, 4 iterations, total sum of distances = 201.533.
Replicate 5, 3 iterations, total sum of distances = 201.533.
```

```
Best total sum of distances = 201.533
```

By default, the software initializes the replicates separatly using *k*-means++.

Plot the clusters and the cluster centroids.

```
figure;
plot(X(idx==1,1),X(idx==1,2),'r.','MarkerSize',12)
hold on
plot(X(idx==2,1),X(idx==2,2),'b.','MarkerSize',12)
plot(C(:,1),C(:,2),'kx',...
     'MarkerSize',15,'LineWidth',3)
legend('Cluster 1','Cluster 2','Centroids',...
       'Location','NW')
title 'Cluster Assignments and Centroids'
hold off
```



You can determine how well separated the clusters are by passing `idx` to silhouette.

Cluster Data Using Parallel Computing

Clustering large data sets might take time, particularly if you use online updates (set by default). If you have a Parallel Computing Toolbox license and you invoke a pool of workers, then `kmeans` runs each clustering task (or replicate) in parallel. Therefore, if `Replicates` > 1, then the parallel computing decreases time to convergence.

Randomly generate a large data set from a Gaussian mixture model.

```
Mu = bsxfun(@times,ones(20,30),(1:20)'); % Gaussian mixture mean
rn30 = randn(30,30);
Sigma = rn30'*rn30; % Symmetric and positive-definite covariance
```

```
Mdl = gmdistribution(Mu,Sigma);

rng(1); % For reproducibility
X = random(Mdl,10000);
```

`Mdl` is a 30-dimensional `gmdistribution` model with 20 components. `X` is a `10000`-by-`30` matrix of data generated from `Mdl`.

Invoke a parallel pool of workers. Specify options for parallel computing.

```
pool = parpool;                       % Invokes workers
stream = RandStream('mlfg6331_64');  % Random number stream
options = statset('UseParallel',1,'UseSubstreams',1,...
    'Streams',stream);
```

```
Starting parallel pool (parpool) using the 'local' profile ... connected to 2 workers.
```

The input argument `'mlfg6331_64'` of `RandStream` specifies to use the multiplicative lagged Fibonacci generator algorithm. `options` is a structure array containing fields that specify options for controlling estimation.

The Command Window indicates that two workers are available. The number of workers might vary on your system.

Cluster the data using k-means clustering. Specify that there are $k = 20$ clusters in the data and increase the number of iterations. Typically, the objective function contains local minima. Specify 10 replicates to help find a lower, local minimum.

```
tic; % Start stopwatch timer
[idx,C,sumd,D] = kmeans(X,20,'Options',options,'MaxIter',10000,...
    'Display','final','Replicates',10);
toc % Terminate stopwatch timer
```

```
Replicate 4, 121 iterations, total sum of distances = 7.58059e+06.
Replicate 7, 234 iterations, total sum of distances = 7.5904e+06.
Replicate 3, 146 iterations, total sum of distances = 7.59086e+06.
Replicate 2, 179 iterations, total sum of distances = 7.57758e+06.
Replicate 6, 118 iterations, total sum of distances = 7.58614e+06.
Replicate 5, 88 iterations, total sum of distances = 7.59462e+06.
Replicate 1, 99 iterations, total sum of distances = 7.57765e+06.
Replicate 9, 147 iterations, total sum of distances = 7.57639e+06.
Replicate 10, 107 iterations, total sum of distances = 7.60079e+06.
Replicate 8, 144 iterations, total sum of distances = 7.58117e+06.
Best total sum of distances = 7.57639e+06
Elapsed time is 123.857736 seconds.
```

The Command Window displays the number of iterations and the terminal objective function value for each replicate. The output arguments contain the results of replicate 9 because it has the lowest total sum of distances.

- "Determine the Correct Number of Clusters" on page 14-24
- "Avoid Local Minima" on page 14-27

Input Arguments

X — Data

numeric matrix

Data, specified as a numeric matrix. The rows of X correspond to observations, and the columns correspond to variables.

If X is a numeric vector, then kmeans treats it as an *n*-by-1 data matrix, regardless of its orientation.

Data Types: single | double

k — Number of clusters

positive integer

Number of clusters in the data, specified as a positive integer.

Data Types: single | double

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Example: 'Distance','cosine','Replicates',10,'Options',statset('UseParallel',1) specifies the cosine distance, 10 replicate clusters at different starting values, and to use parallel computing.

'Display' — Level of output to display

'off' (default) | 'final' | 'iter'

Level of output to display in the Command Window, specified as the comma-separated pair consisting of `'Display'` and a string. Available options are:

- `'final'` — Displays results of the final iteration
- `'iter'` — Displays results of each iteration
- `'off'` — Displays nothing

Example: `'Display','final'`

Data Types: `char`

`'Distance'` — Distance measure

`'sqeuclidean'` (default) | `'cityblock'` | `'cosine'` | `'correlation'` | `'hamming'`

Distance measure, in `p`-dimensional space, used for minimization, specified as the comma-separated pair consisting of `'Distance'` and a string.

`kmeans` computes centroid clusters differently for the different, supported distance measures. This table summarizes the available distance measures. In the formulae, x is an observation (that is, a row of X) and c is a centroid (a row vector).

Distance Measure	Description	Formula
`'sqeuclidean'`	Squared Euclidean distance (default). Each centroid is the mean of the points in that cluster.	$d(x,c) = (x-c)(x-c)'$
`'cityblock'`	Sum of absolute differences, i.e., the $L1$ distance. Each centroid is the component-wise median of the points in that cluster.	$d(x,c) = \sum_{j=1}^{p} \left\| x_j - c_j \right\|$
`'cosine'`	One minus the cosine of the included angle between points (treated as vectors). Each centroid is the mean of the points in that cluster, after normalizing those points to unit Euclidean length.	$d(x,c) = 1 - \frac{xc'}{\sqrt{(xx')(cc')}}$

Distance Measure	Description	Formula
`'correlation'`	One minus the sample correlation between points (treated as sequences of values). Each centroid is the component-wise mean of the points in that cluster, after centering and normalizing those points to zero mean and unit standard deviation.	$$d(x,c) = 1 - \frac{\left(x-\bar{\vec{x}}\right)\left(c-\bar{\vec{c}}\right)'}{\sqrt{\left(x-\bar{\vec{x}}\right)\left(x-\bar{\vec{x}}\right)'}\sqrt{\left(c-\bar{\vec{c}}\right)\left(c-\right.}}$$ where • $\bar{\vec{x}} = \frac{1}{p}\left(\sum_{j=1}^{p} x_j\right)\vec{1}_p$ • $\bar{\vec{c}} = \frac{1}{p}\left(\sum_{j=1}^{p} c_j\right)\vec{1}_p$ • $\vec{1}_p$ is a row vector of p ones.
`'hamming'`	This measure is only suitable for binary data. It is the proportion of bits that differ. Each centroid is the component-wise median of points in that cluster.	$$d(x,y) = \frac{1}{p}\sum_{j=1}^{p} I\left\{x_j \neq y_j\right\},$$ where I is the indicator function.

Example: `'Distance','cityblock'`

Data Types: `char`

`'EmptyAction'` — Action to take if cluster loses all member observations

`'singleton'` (default) | `'error'` | `'drop'`

Action to take if a cluster loses all its member observations, specified as the comma-separated pair consisting of `'EmptyAction'` and a string. This table summarizes the available options.

Value	Description
`'error'`	Treat an empty cluster as an error.

Value	Description
`'drop'`	Remove any clusters that become empty. `kmeans` sets the corresponding return values in C and D to `NaN`.
`'singleton'`	Create a new cluster consisting of the one point furthest from its centroid (default).

Example: `'EmptyAction','error'`

Data Types: `char`

`'MaxIter'` — Maximum number of iterations

`100` (default) | positive integer

Maximum number of iterations, specified as the comma-separated pair consisting of `'MaxIter'` and a positive integer.

Example: `'MaxIter',1000`

Data Types: `double | single`

`'OnlinePhase'` — Online update flag

`'on'` (default) | `'off'`

Online update flag, specified as the comma-separated pair consisting of `'OnlinePhase'` and `'on'` or `'off'`.

If `OnlinePhase` is `on` (the default), then `kmeans` performs an online update phase in addition to a batch update phase. The online phase can be time consuming for large data sets, but guarantees a solution that is a local minimum of the distance criterion. In other words, the software finds a partition of the data in which moving any single point to a different cluster increases the total sum of distances.

Example: `'OnlinePhase','off'`

Data Types: `char`

`'Options'` — Options for controlling iterative algorithm for minimizing fitting criteria

`[]` (default) | structure array returned by `statset`

Options for controlling the iterative algorithm for minimizing the fitting criteria, specified as the comma-separated pair consisting of `'Options'` and a structure array returned by `statset`. These options require Parallel Computing Toolbox.

This table summarizes the available options.

Option	Description
`'Streams'`	A `RandStream` object or cell array of such objects. If you do not specify `Streams`, `kmeans` uses the default stream or streams. If you specify `Streams`, use a single object except when: • You have an open parallel pool • `UseParallel` is `true`. • `UseSubstreams` is `false`. In that case, use a cell array the same size as the parallel pool. If a parallel pool is not open, then `Streams` must supply a single random number stream.
`'UseParallel'`	• If `true`, Replicates > 1, and if a parallel pool of workers from the Parallel Computing Toolbox is open, then the software implements *k*-means on each replicate in parallel. • If the Parallel Computing Toolbox is not installed, or a parallel pool of workers is not open, computation occurs in serial mode. Default is `default`, meaning serial computation.
`'UseSubstreams'`	Set to `true` to compute in parallel in a reproducible fashion. Default is `false`. To compute reproducibly, set `Streams` to a type allowing substreams: `'mlfg6331_64'` or `'mrg32k3a'`.

To ensure more predictable results, use `parpool` and explicitly create a parallel pool before invoking `kmeans` and setting `'Options',statset('UseParallel',1)`.

Example: `'Options',statset('UseParallel',1)`

Data Types: `struct`

`'Replicates'` — Number of times to repeat clustering using new initial cluster centroid positions

`1` (default) | positive integer

Number of times to repeat clustering using new initial cluster centroid positions, specified as the comma-separated pair consisting of `'Replicates'` and an integer. `kmeans` returns the solution with the lowest sumd.

You can set `'Replicates'` implicitly by supplying a 3-D array as the value for the `'Start'` name-value pair argument.

Example: `'Replicates',5`

Data Types: `double` | `single`

`'Start'` — Method for choosing initial cluster centroid positions

`'plus'` (default) | `'cluster'` | `'sample'` | `'uniform'` | numeric matrix | numeric array

Method for choosing initial cluster centroid positions (or *seeds*), specified as the comma-separated pair consisting of `'Start'` and a string, a numeric matrix, or a numeric array. This table summarizes the available options for choosing seeds.

Value	Description
`'cluster'`	Perform a preliminary clustering phase on a random 10% subsample of `X`. This preliminary phase is itself initialized using `'sample'`.
`'plus'` (default)	Select `k` seeds by implementing the *k*-means++ algorithm for cluster center initialization.
`'sample'`	Select `k` observations from `X` at random.
`'uniform'`	Select `k` points uniformly at random from the range of `X`. Not valid with the Hamming distance.
numeric matrix	`k`-by-*p* matrix of centroid starting locations. The rows of `Start` correspond to seeds. The software infers `k` from the first dimension of `Start`, so you can pass in `[]` for `k`.

Value	Description
numeric array	k-by-*p*-*r* array of centroid starting locations. The rows of each page correspond to seeds. The third dimension invokes replication of the clustering routine. Page *j* contains the set of seeds for replicate *j*. The software infers the number of replicates (specified by the `'Replicates'` name-value pair argument) from the size of the third dimension.

Example: `'Start','sample'`

Data Types: `char` | `double` | `single`

Note: The software treats `NaN`s as missing data, and removes any row of `X` containing at least one `NaN`. Removing rows of `X` reduces the sample size.

Output Arguments

`idx` — Cluster indices

numeric column vector

Cluster indices, returned as a numeric column vector. `idx` has as many rows as `X`, and each row indicates the cluster assignment of the corresponding observation.

`C` — Cluster centroid locations

numeric matrix

Cluster centroid locations, returned as a numeric matrix. `C` is a k-by-*p* matrix, where row *j* is the centroid of cluster *j*.

`sumd` — Within-cluster sums of point-to-centroid distances

numeric column vector

Within-cluster sums of point-to-centroid distances, returned as a numeric column vector. `sumd` is a k-by-1 vector, where element *j* is the sum of point-to-centroid distances within cluster *j*.

D — Distances from each point to every centroid

numeric matrix

Distances from each point to every centroid, returned as a numeric matrix. D is an n-by-k matrix, where element (j,m) is the distance from observation j to centroid m.

More About

k-Means Clustering

k-means clustering, or Lloyd's algorithm [2], is an iterative, data-partitioning algorithm that assigns n observations to exactly one of k clusters defined by centroids, where k is chosen before the algorithm starts.

The algorithm proceeds as follows:

1. Choose k initial cluster centers (*centroid*). For example, choose k observations at random (by using `'Start','sample'`) or use the k-means ++ algorithm for cluster center initialization (the default).
2. Compute point-to-cluster-centroid distances of all observations to each centroid.
3. There are two ways to proceed (specified by OnlinePhase):

   - Batch update — Assign each observation to the cluster with the closest centroid.
   - Online update — Individually assign observations to a different centroid if the reassignment decreases the sum of the within-cluster, sum-of-squares point-to-cluster-centroid distances.

   For more details, see "Algorithms" on page 22-2436.
4. Compute the average of the observations in each cluster to obtain k new centroid locations.
5. Repeat steps 2 through 4 until cluster assignments do not change, or the maximum number of iterations is reached.

k-means++ Algorithm

The *k-means++ algorithm* uses an heuristic to find centroid seeds for k-means clustering. According to Arthur and Vassilvitskii [1], k-means++ improves the running time of Lloyd's algorithm, and the quality of the final solution.

The k-means++ algorithm chooses seeds as follows, assuming the number of clusters is k.

1. Select an observation uniformly at random from the data set, X. The chosen observation is the first centroid, and is denoted c_1.
2. Compute distances from each observation to c_1. Denote the distance observation m is from c_j $d(x_m, c_j)$.
3. Select the next centroid, c_2 at random from X with probability

$$\frac{d^2(x_m, c_1)}{\sum_{j=1}^{n} d^2(x_j, c_1)}.$$

4. To choose center j:
   a. Compute the distances from each observation to each centroid, and assign each observation to its closest centroid.
   b. For $m = 1,...,n$ and $p = 1,...,j-1$, select centroid j at random from X with probability

$$\frac{d^2(x_m, c_p)}{\sum_{\{h; x_h \in C_p\}} d^2(x_h, c_p)},$$

   where C_p is the set of all observations closest to centroid c_p and x_m belongs to C_p.

   That is, select each subsequent center with a probability proportional to the distance from itself to the closest center that you already chose.
5. Repeat step 4 until k centroids are chosen.

Arthur and Vassilvitskii [1] demonstrate, using a simulation study for several cluster orientations, that k-means++ achieves faster convergence to a lower sum of within-cluster, sum-of-squares point-to-cluster-centroid distances than Lloyd's algorithm.

Algorithms

- `kmeans` uses a two-phase iterative algorithm to minimize the sum of point-to-centroid distances, summed over all `k` clusters.

1. This first phase uses *batch updates*, where each iteration consists of reassigning points to their nearest cluster centroid, all at once, followed by recalculation of cluster centroids. This phase occasionally does not converge to solution that is a local minimum. That is, a partition of the data where moving any single point to a different cluster increases the total sum of distances. This is more likely for small data sets. The batch phase is fast, but potentially only approximates a solution as a starting point for the second phase.
2. This second phase uses *online updates*, where points are individually reassigned if doing so reduces the sum of distances, and cluster centroids are recomputed after each reassignment. Each iteration during this phase consists of one pass though all the points. This phase converges to a local minimum, although there might be other local minima with lower total sum of distances. In general, finding the global minimum is solved by an exhaustive choice of starting points, but using several replicates with random starting points typically results in a solution that is a global minimum.

- If Replicates = $r > 1$ and Start is `plus` (the default), then the software selects r possibly different sets of seeds according to the k-means++ algorithm.
- If you enable the `UseParallel` option in Options and `Replicates` > 1, then each worker selects seeds and clusters in parallel.

kmedoids

k-medoids clustering

Syntax

```
[idx,C] = kmedoids( ___ )
[idx,C,sumd] = kmedoids( ___ )
[idx,C,sumd,D] = kmedoids( ___ )
[idx,C,sumd,D,midx] = kmedoids( ___ )
[idx,C,sumd,D,midx,info] = kmedoids( ___ )
```

Description

`idx = kmedoids(X,k)` performs "k-medoids Clustering" on page 22-2453 to partition the observations of the n-by-p matrix X into k clusters, and returns an n-by-1 vector idx containing cluster indices of each observation. Rows of X correspond to points and columns correspond to variables. By default, `kmedoids` uses squared Euclidean distance measure and the k-means++ algorithm for choosing initial cluster medoid positions.

`idx = kmedoids(X,k,Name,Value)` uses additional options specified by one or more Name,Value pair arguments.

`[idx,C] = kmedoids( ___ )` returns the k cluster medoid locations in the k-by-p matrix C.

`[idx,C,sumd] = kmedoids( ___ )` returns the within-cluster sums of point-to-medoid distances in the k-by-1 vector sumd.

`[idx,C,sumd,D] = kmedoids( ___ )` returns distances from each point to every medoid in the n-by-k matrix D.

`[idx,C,sumd,D,midx] = kmedoids( ___ )` returns the indices midx such that C = X(midx,:). midx is a k-by-1 vector.

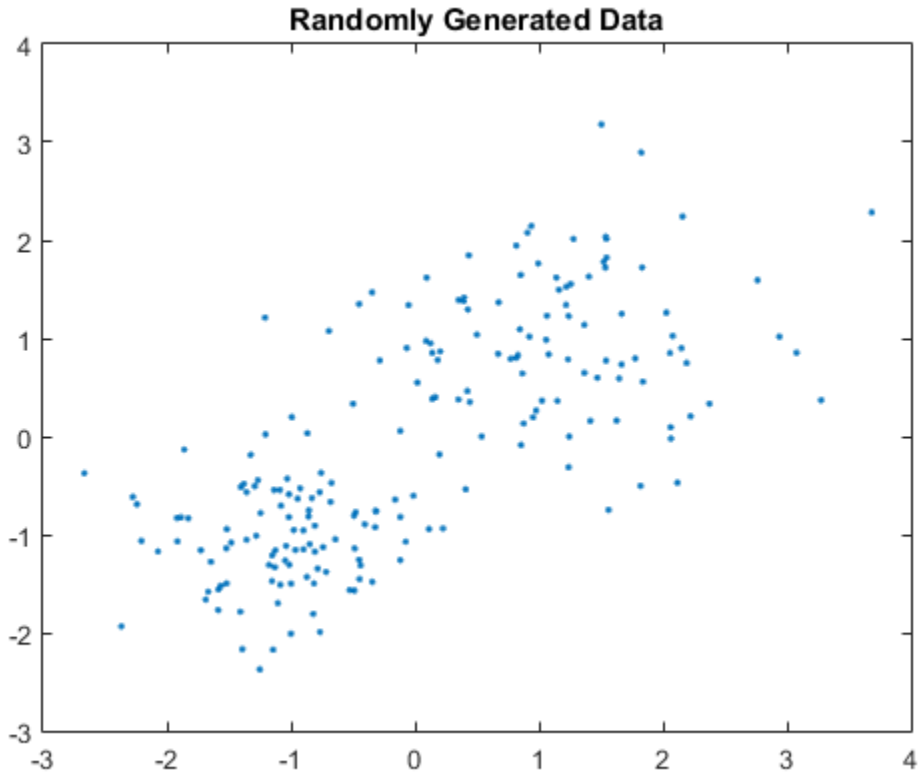
`[idx,C,sumd,D,midx,info] = kmedoids( ___ )` returns a structure info with information about the options used by the algorithm when executed.

Examples

Group Data into Two Clusters

Randomly generate data.

```
rng('default'); % For reproducibility
X = [randn(100,2)*0.75+ones(100,2);
     randn(100,2)*0.55-ones(100,2)];
figure;
plot(X(:,1),X(:,2),'.');
title('Randomly Generated Data');
```



Group data into two clusters using `kmedoids`. Use the `cityblock` distance measure.

```
opts = statset('Display','iter');
[idx,C,sumd,d,midx,info] = kmedoids(X,2,'Distance','cityblock','Options',opts);

   rep     iter          sum
     1        1      209.856
     1        2      209.856
Best total sum of distances = 209.856
```

`info` is a struct that contains information about how the algorithm was executed. For example, `bestReplicate` field indicates the replicate that was used to produce the final solution. In this example, the replicate number 1 was used since the default number of replicates is 1 for the default algorithm, which is `pam` in this case.

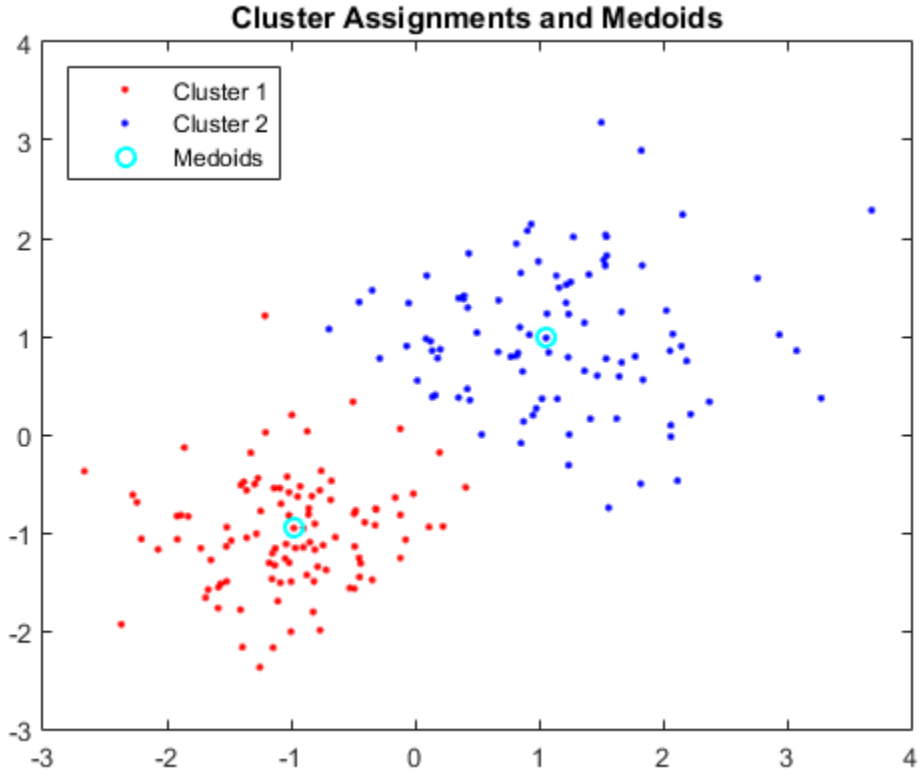
```
info
```

```
info =

        algorithm: 'pam'
            start: 'plus'
         distance: 'cityblock'
       iterations: 2
    bestReplicate: 1
```

Plot the clusters and the cluster medoids.

```
figure;
plot(X(idx==1,1),X(idx==1,2),'r.','MarkerSize',7)
hold on
plot(X(idx==2,1),X(idx==2,2),'b.','MarkerSize',7)
plot(C(:,1),C(:,2),'co',...
     'MarkerSize',7,'LineWidth',1.5)
legend('Cluster 1','Cluster 2','Medoids',...
       'Location','NW');
title('Cluster Assignments and Medoids');
hold off
```



Cluster Categorical Data Using k-Medoids

This example uses "Mushroom" data set [3][4][5] [6][7] from the UCI machine learning archive [7], described in http://archive.ics.uci.edu/ml/datasets/Mushroom. The data set includes 22 predictors for 8,124 observations of various mushrooms. The predictors are categorical data types. For example, cap shape is categorized with features of `'b'` for bell-shaped cap and `'c'` for conical. Mushroom color is also categorized with features of `'n'` for brown, and `'p'` for pink. The data set also includes a classification for each mushroom of either edible or poisonous.

Since the features of the mushroom data set are categorical, it is not possible to define the mean of several data points, and therefore the widely-used *k*-means clustering algorithm cannot be meaningfully applied to this data set. *k*-medoids is a related

algorithm that partitions data into k distinct clusters, by finding medoids that minimize the sum of dissimilarities between points in the data and their nearest medoid.

The medoid of a set is a member of that set whose average dissimilarity with the other members of the set is the smallest. Similarity can be defined for many types of data that do not allow a mean to be calculated, allowing k-medoids to be used for a broader range of problems than k-means.

Using k-medoids, this example clusters the mushrooms into two groups, based on the predictors provided. It then explores the relationship between those clusters and the classifications of the mushrooms as either edible or poisonous.

This example assumes that you have downloaded the "Mushroom" data set [3][4][5] [6][7] from the UCI database (http://archive.ics.uci.edu/ml/machine-learning-databases/mushroom/) and saved it in your current directory as a text file named agaricus-lepiota.txt. There is no column headers in the data, so `readtable` uses the default variable names.

```
clear all
data = readtable('agaricus-lepiota.txt','ReadVariableNames',false);
```

Display the first 5 mushrooms with their first few features.

```
data(1:5,1:10)
```

```
ans =

    Var1    Var2    Var3    Var4    Var5    Var6    Var7    Var8    Var9    Var10
    ____    ____    ____    ____    ____    ____    ____    ____    ____    _____

    'p'     'x'     's'     'n'     't'     'p'     'f'     'c'     'n'     'k'
    'e'     'x'     's'     'y'     't'     'a'     'f'     'c'     'b'     'k'
    'e'     'b'     's'     'w'     't'     'l'     'f'     'c'     'b'     'n'
    'p'     'x'     'y'     'w'     't'     'p'     'f'     'c'     'n'     'n'
    'e'     'x'     's'     'g'     'f'     'n'     'f'     'w'     'b'     'k'
```

Extract the first column, labeled data for edible and poisonous groups. Then delete the column.

```
labels = data(:,1);
labels = categorical(labels{:,:});
data(:,1) = [];
```

Store the names of predictors (features), which are described in http://archive.ics.uci.edu/ml/machine-learning-databases/mushroom/agaricus-lepiota.names.

```
VarNames = {'cap_shape' 'cap_surface' 'cap_color' 'bruises' 'odor' ...
    'gill_attachment' 'gill_spacing' 'gill_size' 'gill_color' ...
    'stalk_shape' 'stalk_root' 'stalk_surface_above_ring' ...
    'stalk_surface_below_ring' 'stalk_color_above_ring' ...
    'stalk_color_below_ring' 'veil_type' 'veil_color' 'ring_number' ....
    'ring_type' 'spore_print_color' 'population' 'habitat'};
```

Set the variable names.

```
data.Properties.VariableNames = VarNames;
```

There are a total of 2480 missing values denoted as `'?'`.

```
sum(char(data{:,:}) == '?')
```

```
ans =

        2480
```

Based on the inspection of the data set and its description, the missing values belong only to the 11th variable (`stalk_root`). Remove the column from the table.

```
data(:,11) = [];
```

`kmedoids` only accepts numeric data. You need to cast the categories you have into numeric type. The distance function you will use to define the dissimilarity of the data will be based on the double representation of the categorical data.

```
cats = categorical(data{:,:});
data = double(cats);
```

`kmedoids` can use any distance metric supported by pdist2 to cluster. For this example you will cluster the data using the Hamming distance because this is an appropriate distance metric for categorical data as illustrated below. The Hamming distance between two vectors is the percentage of the vector components that differ. For instance, consider these two vectors.

```
v1 = [1 0 2 1];
```

```
v2 = [1 1 2 1];
```

They are equal in the 1st, 3rd and 4th coordinate. Since 1 of the 4 coordinates differ, the Hamming distance between these two vectors is .25.

You can use the function `pdist2` to measure the Hamming distance between the first and second row of data, the numerical representation of the categorical mushroom data. The value .2857 means that 6 of the 21 features of the mushroom differ.

```
pdist2(data(1,:),data(2,:),'hamming')
```

```
ans =

    0.2857
```

In this example, you're clustering the mushroom data into two clusters based on features to see if the clustering corresponds to edibility. The `kmedoids` function is guaranteed to converge to a local minima of the clustering criterion; however, this may not be a global minimum for the problem. It is a good idea to cluster the problem a few times using the `'replicates'` parameter. When `'replicates'` is set to a value, *n*, greater than 1, the k-medoids algorithm is run *n* times, and the best result is returned.

To run `kmedoids` to cluster data into 2 clusters, based on the Hamming distance and to return the best result of 3 replicates, you run the following.

```
rng('default'); %For reproducibility
[IDX, C, SUMD, D, MIDX, INFO] = kmedoids(data,2,'distance','hamming','replicates',3);
```

Let's assume that mushrooms in the predicted group 1 are poisonous and group 2 are all edible. To determine the performance of clustering results, calculate how many mushrooms in group 1 are indeed poisonous and group 2 are edible based on the known labels. In other words, calculate the number of false positives, false negatives, as well as true positives and true negatives.

Construct a confusion matrix (or matching matrix), where the diagonal elements represent the number of true positives and true negatives, respectively. The off-diagonal elements represent false negatives and false positives, respectively. For convenience, use the `confusionmat` function, which calculates a confusion matrix given known labels and predicted labels. Get the predicted label information from the `IDX` variable. `IDX` contains values of 1 and 2 for each data point, representing poisonous and edible groups, respectively.

```
predLabels = labels; %Initialize a vector for predicted labels.
predLabels(IDX==1) = categorical({'p'}); %Assign group 1 to be poisonous.
predLabels(IDX==2) = categorical({'e'}); %Assign group 2 to be edible.
confMatrix = confusionmat(labels,predLabels)
```

```
confMatrix =
```

```
        4176          32
         816        3100
```

Out of 4208 edible mushrooms, 4176 were correctly predicted to be in group 2 (edible group), and 32 were incorrectly predicted to be in group 1 (poisonous group). Similarly, out of 3916 poisonous mushrooms, 3100 were correctly predicted to be in group 1 (poisonous group), and 816 were incorrectly predicted to be in group 2 (edible group).

Given this confusion matrix, calculate the accuracy, which is the proportion of true results (both true positives and true negatives) against the overall data, and precision, which is the proportion of the true positives against all the positive results (true positives and false positives).

```
accuracy = (confMatrix(1,1)+confMatrix(2,2))/(sum(sum(confMatrix)))
```

```
accuracy =

    0.8956
```

```
precision = confMatrix(1,1) / (confMatrix(1,1)+confMatrix(2,1))
```

```
precision =

    0.8365
```

The results indicated that applying the k-medoids algorithm to the categorical features of mushrooms resulted in clusters that were associated with edibility.

Input Arguments

X — Data

numeric matrix

Data, specified as a numeric matrix. The rows of `X` correspond to observations, and the columns correspond to variables.

k — Number of medoids

positive integer

Number of medoids in the data, specified as a positive integer.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example:
`'Distance','euclidean','Replicates',3,'Options',statset('UseParallel',1)`
specifies Euclidean distance, three replicate medoids at different starting values, and to use parallel computing.

`'Algorithm'` — Algorithm to find medoids

`'pam' | 'small' | 'clara' | 'large'`

Algorithm to find medoids, specified as the comma-separated pair consisting of `'Algorithm'` and a string. The default algorithm depends on the number of rows of X.

- If the number of rows of X is less than 3000, `'pam'` is the default algorithm.
- If the number of rows is between 3000 and 10000, `'small'` is the default algorithm.
- For all other cases, `'large'` is the default algorithm.

You can override the default choice by explicitly stating the algorithm. This table summarizes the available algorithms.

Algorithm	Description
`'pam'`	Partitioning Around Medoids (PAM) is the classical algorithm for solving the *k*-medoids problem described in [1]. After applying the initialization function to select initial medoid positions, the program performs the swap-step of the PAM algorithm, that is, it searches over all possible swaps between medoids and non-medoids to see if the sum of medoid to cluster member distances goes down. You can specify which initialization function to use via the `'Start'` name-value pair argument. The algorithm proceeds as follows. **1** Build-step: Each of *k* clusters is associated with a potential medoid. This assignment is performed using a technique specified by the `'Start'` name-value pair argument.

Algorithm	Description
	2 Swap-step: Within each cluster, each point is tested as a potential medoid by checking if the sum of within-cluster distances gets smaller using that point as the medoid. If so, the point is defined as a new medoid. Every point is then assigned to the cluster with the closest medoid. The algorithm iterates the build- and swap-steps until the medoids do not change, or other termination criteria are met. The algorithm can produce better solutions than the other algorithms in some situations, but it can be prohibitively long running.
`'small'`	Use an algorithm similar to the k-means algorithm to find k medoids. This option employs a variant of the Lloyd's iterations based on [2]. The algorithm proceeds as follows. 1 For each point in each cluster, calculate the sum of distances from the point to every other point in the cluster. Choose the point that minimizes the sum as the new medoid. 2 Update the cluster membership for each data point to reflect the new medoid. The algorithm repeats these steps until no further updates occur or other termination criteria are met. The algorithm has an optional PAM-like online update phase (specified by the `'OnlinePhase'` name-value pair argument) that improves cluster quality. It tends to return higher quality solutions than the `clara` or `large` algorithms, but it may not be the best choice for very large data.

Algorithm	Description
`'clara'`	Clustering LARge Applications (CLARA) [1] repeatedly performs the PAM algorithm on random subsets of the data. It aims to overcome scaling challenges posed by the PAM algorithm through sampling. The algorithm proceeds as follows. **1** Select a subset of the data and apply the PAM algorithm to the subset. **2** Assign points of the full data set to clusters by picking the closest medoid. The algorithm repeats these steps until the medoids do not change, or other termination criteria are met. For the best performance, it is recommended that you perform multiple replicates. By default, the program performs five replicates. Each replicate samples `s` rows from X (specified by `'NumSamples'` name-value pair argument) to perform clustering on. By default, `40+2*k` samples are selected.
`'large'`	This is similar to the `small` scale algorithm and repeatedly performs searches using a k-means like update. However, the algorithm examines only a random sample of cluster members during each iteration. The user-adjustable parameter, `'PercentNeighbors'`, controls the number of neighbors to examine. If there is no improvement after the neighbors are examined, the algorithm terminates the local search. The algorithm performs a total of *r* replicates (specified by `'Replicates'` name-value pair argument) and returns the best clustering result. The algorithm has an optional PAM-like online phase (specified by the `'OnlinePhase'` name-value pair argument) that improves cluster quality.

Example: `'Algorithm','pam'`

`'OnlinePhase'` — Flag to perform PAM-like online update phase
`'on'` (default) | `'off'`

A flag to perform PAM-like online update phase, specified as a comma-separated pair consisting of `'OnlinePhase'` and `'on'` or `'off'`.

If it is `on`, then `kmedoids` performs a PAM-like update to the medoids after the Lloyd iterations in the `small` and `large` algorithms. During this online update phase, the algorithm chooses a small subset of data points in each cluster that are the furthest from and nearest to medoid. For each chosen point, it reassigns the clustering of the entire data set and check if this creates a smaller sum of distances than the best known.

In other words, the swap considerations are limited to the points near the medoids and far from the medoids. The near points are considered in order to refine the clustering. The far points are considered in order to escape local minima. Turning on this feature tends to improve the quality of solutions generated by both algorithms. Total run time tends to increase as well, but the increase typically is less than one iteration of PAM.

Example: `OnlinePhase,'off'`

`'Distance'` — Distance measure

`'sqeuclidean'` (default) | `'euclidean'` | `'seuclidean'` | `'cityblock'` | `'minkowski'` | `'chebychev'` | `'mahalanobis'` | `'cosine'` | `'correlation'` | `'spearman'` | `'hamming'` | `'jaccard'` | custom distance function

Distance measure, in p-dimensional space, specified as the comma-separate pair consisting of `'Distance'` and a string. `kmedoids` minimizes the sum of medoid to cluster member distances. See `pdist` for the definition of each distance measure. `kmedoids` supports all distance measures supported by `pdist`.

Example: `'Distance','hamming'`

`'Options'` — Options to control iterative algorithm to minimize fitting criteria

`[ ]` (default) | structure array returned by `statset`

Options to control the iterative algorithm to minimize fitting criteria, specified as the comma-separated pair consisting of `'Options'` and a structure array returned by `statset`. This table summarizes these options.

Option	Description
`Display`	Level of display output. Choices are `'off'` (default) and `'iter'`.
`MaxIter`	Maximum number of iterations allowed. The default is `100`.
`UseParallel`	If `true` and a `parpool` is open, compute in parallel. If Parallel Computing Toolbox is not available, or a `parpool` is not open,

Option	Description
	computation occurs in serial mode. The default is `false`, meaning serial computation.
`UseSubstreams`	Set to `true` to compute in parallel in a reproducible fashion. The default is `false`. To compute reproducibly, you must also set `Streams` to a type allowing substreams: `'mlfg6331_64'` or `'mrg32k3a'`.
`Streams`	A `RandStream` object or cell array of such objects. For details about these options and parallel computing in Statistics and Machine Learning Toolbox, see "Speed Up Statistical Computations" or enter `help parallelstats` at the command line.

Example: `'Options',statset('Display','off')`

`'Replicates'` — Number of times to repeat clustering using new initial cluster medoid positions

positive integer

Number of times to repeat clustering using new initial cluster medoid positions, specified as a positive integer. The default value depends on the choice of algorithm. For `pam` and `small`, the default is 1. For `clara`, the default is 5. For `large`, the default is 3.

Example: `'Replicates',4`

`'NumSamples'` — Number of samples to take from data when executing clara algorithm

`40+2*k` (default) | positive integer

Number of samples to take from the data when executing the `clara` algorithm, specified as a positive integer. The default number of samples is calculated as `40+2*k`.

Example: `'NumSamples',160`

`'PercentNeighbors'` — Percent of data set to examine using large algorithm

0.001 (default) | scalar value between 0 and 1

Percent of the data set to examine using the `large` algorithm, specified as a positive number.

The program examines `percentneighbors*size(X,1)` number of neighbors for the medoids. If there is no improvement in the within-cluster sum of distances, then the algorithm terminates.

The value of this parameter between 0 and 1, where a value closer to 1 tends to give higher quality solutions, but the algorithm takes longer to run, and a value closer to 0 tends to give lower quality solutions, but finishes faster.

Example: `'PercentNeighbors',0.01`

`'Start'` — Method for choosing initial cluster medoid positions

`'plus'` (default) | `'sample'` | `'cluster'` | matrix

Method for choosing initial cluster medoid positions, specified as the comma-separated pair consisting of `'Start'` and a string or a matrix. This table summarizes the available methods.

Method	Description
`'plus'` (default)	Select k observations from X according to the *k*-means++ algorithm for cluster center initialization.
`'sample'`	Select k observations from X at random.
`'cluster'`	Perform preliminary clustering phase on a random subsample (10%) of X. This preliminary phase is itself initialized using `sample`, that is, the observations are selected at random.
matrix	A custom k-by-*p* matrix of starting locations. In this case, you can pass in `[]` for the k input argument, and `kmedoids` infers k from the first dimension of the matrix. You can also supply a 3-D array, implying a value for `'Replicates'` from the array's third dimension.

Example: `'Start','sample'`

Output Arguments

`idx` — Medoid indices

numeric column vector

Medoid indices, returned as a numeric column vector. idx has as many rows as X, and each row indicates the medoid assignment of the corresponding observation.

`C` — Cluster medoid locations

numeric matrix

Cluster medoid locations, returned as a numeric matrix. C is a *k*-by-*p* matrix, where row *j* is the medoid of cluster *j*

`sumd` — Within-cluster sums of point-to-medoid distances

numeric column vector

Within-cluster sums of point-to-medoid distances, returned as a numeric column vector. sumd is a k-by1 vector, where element *j* is the sum of point-to-medoid distances within cluster *j*.

`D` — Distances from each point to every medoid

numeric matrix

Distances from each point to every medoid, returned as a numeric matrix. `D` is an *n*-by-k matrix, where element (*j*,*m*) is the distance from observation *j* to medoid *m*.

`midx` — Index to `X`

column vector

Index to X, returned as a column vector of indices. midx is a k-by-1 vector and the indices satisfy `C = X(midx,:)`.

`info` — Algorithm information

struct

Algorithm information, returned as a struct. info contains options used by the function when executed such as *k*-medoid clustering algorithm (`algorithm`), method used to choose initial cluster medoid positions (`start`), distance measure (`distance`), number of iterations taken in the best replicate (`iterations`) and the replicate number of the returned results (`bestReplicate`).

More About

k-medoids Clustering

k-medoids clustering is a partitioning method commonly used in domains that require robustness to outlier data, arbitrary distance metrics, or ones for which the mean or median does not have a clear definition.

It is similar to *k*-means, and the goal of both methods is to divide a set of measurements or observations into *k* subsets or clusters so that the subsets minimize the sum of distances between a measurement and a center of the measurement's cluster. In the *k*-means algorithm, the center of the subset is the mean of measurements in the subset, often called a centroid. In the *k*-medoids algorithm, the center of the subset is a member of the subset, called a medoid.

The *k*-medoids algorithm returns medoids which are the actual data points in the data set. This allows you to use the algorithm in situations where the mean of the data does not exist within the data set. This is the main difference between *k*-medoids and *k*-means where the centroids returned by *k*-means may not be within the data set. Hence *k*-medoids is useful for clustering categorical data where a mean is impossible to define or interpret.

The function `kmedoids` provides several iterative algorithms that minimize the sum of distances from each object to its cluster medoid, over all clusters. One of the algorithms is called partitioning around medoids (PAM) [1] which proceeds in two steps.

1. Build-step: Each of *k* clusters is associated with a potential medoid. This assignment is performed using a technique specified by the `'Start'` name-value pair argument.
2. Swap-step: Within each cluster, each point is tested as a potential medoid by checking if the sum of within-cluster distances gets smaller using that point as the medoid. If so, the point is defined as a new medoid. Every point is then assigned to the cluster with the closest medoid.

The algorithm iterates the build- and swap-steps until the medoids do not change, or other termination criteria are met.

You can control the details of the minimization using several optional input parameters to `kmedoids`, including ones for the initial values of the cluster medoids, and for the maximum number of iterations. By default, `kmedoids` uses the *k*-means++ algorithm for cluster medoid initialization and the squared Euclidean metric to determine distances.

knnsearch

k-nearest neighbors search using *K*d-tree or exhaustive search

Syntax

```
Idx = knnsearch(Mdl,Y)
Idx = knnsearch(Mdl,Y,Name,Value)
[Idx,D] = knnsearch(___)
```

Description

`Idx = knnsearch(Mdl,Y)` searches for the nearest neighbor (i.e., the closest point, row, or observation) in `Mdl.X` to each point (i.e., row or observation) in the query data `Y` using an exhaustive search or a *K*d-tree. `knnsearch` returns `Idx`, which is a column vector of the indices in `Mdl.X` representing the nearest neighbors.

`Idx = knnsearch(Mdl,Y,Name,Value)` returns the indices of the closest points in `Mdl.X` to `Y` with additional options specified by one or more `Name,Value` pair arguments. For example, specify the number of nearest neighbors to search for, distance metric different from the one stored in `Mdl.Distance`. You can also specify which action to take if the closest distances are tied.

`[Idx,D] = knnsearch(___)` additionally returns the matrix `D` using any of the input arguments in the previous syntaxes. `D` contains the distances between each observation in `Y` that correspond to the closest observations in `Mdl.X`. The function arranges the columns of `D` in ascending order by closeness, with respect to the distance metric.

Examples

Search for Nearest Neighbors Using a *K* d-tree and Exhaustive Search

`knnsearch` accepts `ExhaustiveSearcher` or `KDTreeSearcher` model objects to search the training data for the nearest neighbors to the query data. An `ExhaustiveSearcher` model invokes the exhaustive searcher algorithm, and a `KDTreeSearcher` model defines a *K* d-tree, which `knnsearch` uses to search for nearest neighbors.

Load Fisher's iris data set. Randomly reserve five observations from the data for query data.

```
load fisheriris
rng(1); % For reproducibility
n = size(meas,1);
idx = randsample(n,5);
X = meas(~ismember(1:n,idx),:); % Training data
Y = meas(idx,:);                % Query data
```

The variable `meas` contains 4 predictors.

Grow a default four-dimensional K d-tree.

```
MdlKDT = KDTreeSearcher(X)
```

```
MdlKDT =

  KDTreeSearcher with properties:

      BucketSize: 50
        Distance: 'euclidean'
    DistParameter: []
                X: [145x4 double]
```

`MdlKDT` is a `KDTreeSearcher` model object. You can alter its writable properties using dot notation.

Prepare an exhaustive nearest neighbors searcher.

```
MdlES = ExhaustiveSearcher(X)
```

```
MdlES =

  ExhaustiveSearcher with properties:

        Distance: 'euclidean'
    DistParameter: []
                X: [145x4 double]
```

`MdlKDT` is an `ExhaustiveSearcher` model object. It contains the options, such as the distance metric, to use to find nearest neighbors.

Alternatively, you can grow a *K* d-tree or prepare an exhaustive nearest neighbors searcher using `createns`.

Search the training data for the nearest neighbors indices that correspond to each query observation. Conduct both types of searches using the default settings. By default, the number of neighbors to search for per query observation is 1.

```
IdxKDT = knnsearch(MdlKDT,Y);
IdxES = knnsearch(MdlES,Y);
[IdxKDT IdxES]
```

```
ans =

    17    17
     6     6
     1     1
    89    89
   124   124
```

In this case, the results of the search are the same.

Search for Nearest Neighbors of Query Data Using the Minkowski Distance

Load Fisher's iris data set.

```
load fisheriris
```

Remove five irises randomly from the predictor data to use as a query set.

```
rng(1);                      % For reproducibility
n = size(meas,1);            % Sample size
qIdx = randsample(n,5);      % Indices of query data
X = meas(~ismember(1:n,qIdx),:);
Y = meas(qIdx,:);
```

Grow a four-dimensional *K* d-tree using the training data. Specify to use the Minkowski distance for finding nearest neighbors later.

```
Mdl = KDTreeSearcher(X,'Distance','minkowski')
```

```
Mdl =
```

```
  KDTreeSearcher with properties:

      BucketSize: 50
        Distance: 'minkowski'
    DistParameter: 2
                X: [145x4 double]
```

`Mdl` is a `KDTreeSearcher` model object. By default, the Minkowski distance exponent is `2`.

Find the indices of the training data (`X`) that are the two nearest neighbors of each point in the query data (`Y`).

```
Idx = knnsearch(Mdl,Y,'K',2)
```

```
Idx =

    17     4
     6     2
     1    12
    89    66
   124   100
```

Each row of `Idx` corresponds to a query data observation, and the column order corresponds to the order of the nearest neighbors, with respect to ascending distance. For example, using the Minkowski distance, the second nearest neighbor of `Y(3,:)` is `X(12,:)`.

Include Ties in Nearest Neighbors Search

Load Fisher's iris data set.

```
load fisheriris
```

Remove five irises randomly from the predictor data to use as a query set.

```
rng(4);                      % For reproducibility
n = size(meas,1);            % Sample size
qIdx = randsample(n,5);      % Indices of query data
X = meas(~ismember(1:n,qIdx),:);
Y = meas(qIdx,:);
```

Grow a four-dimensional K d-tree using the training data. Specify to use the Minkowski distance for finding nearest neighbors later.

```
Mdl = KDTreeSearcher(X);
```

`Mdl` is a `KDTreeSearcher` model object. By default, the distance metric for finding nearest neighbors is the Euclidean metric.

Find the indices of the training data (`X`) that are the seven nearest neighbors of each point in the query data (`Y`).

```
[Idx,D] = knnsearch(Mdl,Y,'K',7,'IncludeTies',true);
```

`Idx` and `D` are five-element cell arrays of vectors, with each vector having at least seven elements.

Display the lengths of the vectors in `Idx`.

```
cellfun('length',Idx)
```

```
ans =

     8
     7
     7
     7
     7
```

Because cell `1` contains a vector with length greater than $k = 7$, query observation 1 (`Y(1,:)`) is equally close to at least two observations in `X`.

Display the indices of the nearest neighbors to `Y(1,:)` and their distances.

```
nn5 = Idx{1}
nn5d = D{1}
```

```
nn5 =

    91    98    67    69    71    93    88    95

nn5d =
```

```
Columns 1 through 7

  0.1414    0.2646    0.2828    0.3000    0.3464    0.3742    0.3873

Column 8

  0.3873
```

Training observations `88` and `95` are 0.3873 cm away from query observation `1`.

Input Arguments

`Mdl` — Nearest neighbors searcher

`ExhaustiveSearcher` model object | `KDTreeSearcher` model object

Nearest neighbors searcher, specified as an `ExhaustiveSearcher` or `KDTreeSearcher` model object, respectively. To create `Mdl`, with the appropriate mode creator. You can also use `createns`.

If `Mdl` is an `ExhaustiveSearcher` model, then `knnsearch` searches for nearest neighbors using an exhaustive search. Otherwise, `knnsearch` uses the grown *K*d-tree to search for nearest neighbors.

`Y` — Query data

numeric matrix

Query data, specified as a numeric matrix.

`Y` is an *m*-by-*K* matrix. Rows of `Y` correspond to observations (i.e., examples), and columns correspond to predictors (i.e., variables or features). `Y` must have the same number of columns as the training data stored in `Mdl.X`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'K',2,'Distance','minkowski'` specifies to find the two nearest neighbors of `Mdl.X` to each point in `Y` and to use the Minkowski distance metric.

For Both Nearest Neighbor Searchers

`'Distance'` — Distance metric
`Mdl.Distance` (default) | `'cityblock'` | `'euclidean'` | `'mahalanobis'` | `'minkowski'` | `'seuclidean'` | function handle | ...

Distance metric used to find neighbors of the training data to the query observations, specified as the comma-separated pair consisting of `'Distance'` and a string or function handle.

For both types of nearest neighbor searchers, `Mdl` supports these distance metrics.

Value	Description
`'chebychev'`	Chebychev distance (maximum coordinate difference)
`'cityblock'`	City block distance
`'euclidean'`	Euclidean distance
`'minkowski'`	Minkowski distance

If Mdl is an `ExhaustiveSearcher` model object, then `knnsearch` supports these distance metrics.

Value	Description
`'correlation'`	One minus the sample linear correlation between observations (treated as sequences of values)
`'cosine'`	One minus the cosine of the included angle between observations (row vectors)
`'hamming'`	Hamming distance, which is the percentage of coordinates that differ.
`'jaccard'`	One minus the Jaccard coefficient, which is the percentage of nonzero coordinates that differ

Value	Description
'mahalanobis'	Mahalanobis distance
'seuclidean'	Standardized Euclidean distance
'spearman'	One minus the sample Spearman's rank correlation between observations (treated as sequences of values)

If Mdl is an ExhaustiveSearcher model object, then you can also specify a function handle for a custom distance metric using @ (for example, @distfun). The custom distance function must:

- Have the form function D2 = distfun(ZI, ZJ)
- Take as arguments:
  - A 1-by-*K* vector ZI containing a single row from X or from the query points Y
  - An *m*-by-*K* matrix ZJ containing multiple rows of X or Y
- Return an *m*-by-1 vector of distances D2, whose *j*th element is the distance between the observations ZI and ZJ(*j*,:)

For more details, see "Distance Metrics".

Example: 'Distance','minkowski'

Data Types: char | function_handle

'IncludeTies' — Flag to include nearest neighbors that have the same distance from query observations

false (0) (default) | true (1)

Flag to include nearest neighbors that have the same distance from query observations, specified as the comma-separated pair consisting of 'IncludeTies' and false (0) or true (1).

If IncludeTies is true, then:

- knnsearch includes all nearest neighbors whose distances are equal to the Kth smallest distance in the output arguments.
- Idx and D are *m*-by-1 cell arrays such that each cell contains a vector of at least K indices and distances, respectively. Each vector in D contains arranged distances

in ascending order. Each row in `Idx` contains the indices of the nearest neighbors corresponding to these smallest distances in `D`.

If `IncludeTies` is `false`, then `knnsearch` chooses the observation with the smallest index among the observations that have the same distance from a query point.

Example: `'IncludeTies',true`

`'K'` — Number of nearest neighbors to search for in the training data per query observation

1 (default) | positive integer

Number of nearest neighbors to search for in the training data per query observation, specified as the comma-separated pair consisting of `'IncludeTies'` and a positive integer.

Example: `'K',2`

Data Types: `single` | `double`

`'P'` — Exponent for Minkowski distance metric

2 (default) | positive scalar

Exponent for the Minkowski distance metric, specified as the comma-separated pair consisting of `'P'` and a positive scalar. If you specify `P` and do not specify `'Distance','minkowski'`, then the software throws an error.

Example: `'P',3`

Data Types: `double` | `single`

For Exhaustive Nearest Neighbor Searchers

`'Cov'` — Covariance matrix for Mahalanobis distance metric

`nancov(X)` (default) | positive definite matrix

Covariance matrix for the Mahalanobis distance metric, specified as the comma-separated pair consisting of `'Cov'` and a positive definite matrix. `Cov` is a K-by-K matrix, where K is the number of columns of X. If you specify `Cov` and do not specify `'Distance','mahalanobis'`, then `knnsearch` throws an error.

Example: `'Cov',eye(3)`

Data Types: `double` | `single`

'Scale' — Scale parameter value for standard Euclidean distance metric

nanstd(X) (default) | nonnegative numeric vector

Scale parameter value for the standard Euclidean distance metric, specified as the comma-separated pair consisting of 'Scale' and a nonnegative numeric vector. Scale has length K, where K is the number of columns of X.

The software scales each difference between the training and query data using the corresponding element of Scale. If you specify Scale and do not specify 'Distance','seuclidean', then knnsearch throws an error.

Example: 'Scale',quantile(X,0.75) - quantile(X,0.25)

Data Types: double | single

Note: If you specify 'Distance', 'Cov', 'P', or 'Scale', then Mdl.Distance and Mdl.DistParameter do not change value.

Output Arguments

Idx — Training data indices of nearest neighbors

numeric matrix | cell array of numeric vectors

Training data indices of nearest neighbors, returned as a numeric matrix or cell array of numeric vectors.

- If you do not specify IncludeTies (false by default), then Idx is an m-by-K numeric matrix, where m is the number of rows in Y and K is the number of searched nearest neighbors. Idx(j,k) indicates that Mdl.X(Idx(j,k),:) is the observation with the kth smallest distance to the query observation Y(j,:).
- If you specify 'IncludeTies',true, then Idx is an m-by-1 cell array such that cell j (Idx{j}) contains a vector of at least K indices of the closest observations in Mdl.X to the query observation Y(j,:). The function arranges the elements of the vectors in ascending order by distance.

D — Distances of nearest neighbors to the query data

numeric matrix | cell array of numeric vectors

Distances of the nearest neighbors to the query data, returned as a numeric matrix or cell array of numeric vectors.

- If you do not specify IncludeTies (`false` by default), then `D` is an *m*-by-K numeric matrix, where *m* is the number of rows in Y and `K` is the number of searched nearest neighbors. `D(j,k)` is the distance `Mdl.X(Idx(j,k),:)` is from the query observation `Y(j,:)` with respect to the distance metric, and it represents the `k`th smallest distance.
- If you specify `'IncludeTies',true`, then D is an *m*-by-`1` cell array such that cell `j` (`D{j}`) contains a vector of at least K distances of the closest observations in `Mdl.X` to the query observation `Y(j,:)`. The function arranges the elements of the vectors in ascending order by distance.

Alternatives

- `knnsearch` is an object function that requires an `ExhaustiveSearcher` or a `KDTreeSearcher` model object and query data. Under equivalent conditions, `knnsearch` returns the same results as `knnsearch` when you specify the name-value pair argument `'NSMethod','exhaustive'` or `'NSMethod','kdtree'`, respectively.
- For *k*-nearest neighbors classification, see `fitcknn` and `ClassificationKNN`.

More About

Algorithms

For positive integer `K`, `knnsearch` finds the `K` points in `Mdl.X` that are nearest each `Y` point. In contrast, for positive scalar `r`, `rangesearch` finds all the points in `Mdl.X` that are within a distance `r` of each `Y` point.

Introduced in R2010a

knnsearch

Find *k*-nearest neighbors using data

Syntax

```
IDX = knnsearch(X,Y)
[IDX,D] = knnsearch(X,Y)
[IDX,D] = knnsearch(X,Y,'Name',Value)
```

Description

`IDX = knnsearch(X,Y)` finds the nearest neighbor in `X` for each point in `Y`. `IDX` is a column vector with *my* rows. Each row in `IDX` contains the index of nearest neighbor in `X` for the corresponding row in `Y`.

`[IDX,D] = knnsearch(X,Y)` returns an *my*-by-1 vector `D` containing the distances between each observation in `Y` and the corresponding closest observation in `X`. That is, `D(i)` is the distance between `X(IDX(i),:)` and `Y(i,:)`.

`[IDX,D] = knnsearch(X,Y,'Name',Value)` accepts one or more optional comma-separated name-value pair arguments. Specify `Name` inside single quotes.

`knnsearch` does not save a search object. To create a search object, use `createns`.

Input Arguments

X

An *mx*-by-*n* numeric matrix. Rows of `X` correspond to observations and columns correspond to variables.

Y

An *my*-by-*n* numeric matrix of query points. Rows of `Y` correspond to observations and columns correspond to variables.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'K'`

Positive integer specifying the number of nearest neighbors in `X` for each point in `Y`. Default is 1. `IDX` and `D` are *my*-by-`K` matrices. `D` sorts the distances in each row in ascending order. Each row in `IDX` contains the indices of the `K` closest neighbors in `X` corresponding to the `K` smallest distances in `D`.

`'IncludeTies'`

A logical value indicating whether `knnsearch` includes all the neighbors whose distance values are equal to the `K`th smallest distance. If `IncludeTies` is `true`, `knnsearch` includes all these neighbors. In this case, `IDX` and `D` are *my*-by-`1` cell arrays. Each row in `IDX` and `D` contains a vector with at least `K` numeric numbers. `D` sorts the distances in each vector in ascending order. Each row in `IDX` contains the indices of the closest neighbors corresponding to these smallest distances in `D`.

Default: `false`

`'NSMethod'`

Nearest neighbors search method. Value is either:

- `'kdtree'` — Creates and uses a `K`d-tree to find nearest neighbors. This is the default value when the number of columns of `X` is less than 10, `X` is not sparse, and the distance measure is one of the following measures. `'kdtree'` is only valid when the distance measure is one of the following:
  - `'euclidean'`
  - `'cityblock'`
  - `'minkowski'`
  - `'chebychev'`
- `'exhaustive'` — Uses the exhaustive search algorithm by computing the distance values from all the points in `X` to each point in `Y` to find nearest neighbors.

`'Distance'`

A string or a function handle specifying the distance metric. The value can be one of the following:

- `'euclidean'` — Euclidean distance (default).
- `'seuclidean'` — Standardized Euclidean distance. Each coordinate difference between rows in `X` and the query matrix is scaled by dividing by the corresponding element of the standard deviation computed from `X`, `S=nanstd(X)`. To specify another value for `S`, use the `Scale` argument.
- `'cityblock'` — City block distance.
- `'chebychev'` — Chebychev distance (maximum coordinate difference).
- `'minkowski'` — Minkowski distance. The default exponent is 2. To specify a different exponent, use the `'P'` argument.
- `'mahalanobis'` — Mahalanobis distance, computed using a positive definite covariance matrix `C`. The default value of `C` is `nancov(X)`. To change the value of `C`, use the `Cov` parameter.
- `'cosine'` — 1 minus the cosine of the included angle between observations (treated as vectors).
- `'correlation'` — One minus the sample linear correlation between observations (treated as sequences of values).
- `'spearman'` — One minus the sample Spearman's rank correlation between observations (treated as sequences of values).
- `'hamming'` — Hamming distance, which is the percentage of coordinates that differ.
- `'jaccard'` — One minus the Jaccard coefficient, which is the percentage of nonzero coordinates that differ.
- custom distance function — A distance function specified using `@` (for example, `@distfun`). A custom distance function must
  - Have the form `function D2 = distfun(ZI,ZJ)`
  - Take as arguments:
    - A 1-by-n vector `ZI` containing a single row from `X` or from the query points `Y`
    - An m2-by-n matrix `ZJ` containing multiple rows of `X` or `Y`
  - Return an m2-by-1 vector of distances `D2`, whose jth element is the distance between the observations `ZI` and `ZJ(j,:)`

For more information on these distance metrics, see “Distance Metrics”.

`'P'`

A positive scalar, p, indicating the exponent of the Minkowski distance. This parameter is only valid if the `Distance` is `'minkowski'`. Default is 2.

`'Cov'`

A positive definite matrix indicating the covariance matrix when computing the Mahalanobis distance. This parameter is only valid when `Distance` is `'mahalanobis'`. Default is `nancov(X)`.

`'Scale'`

A vector `S` containing nonnegative values, with length equal to the number of columns in `X`. Each coordinate of `X` and each query point is scaled by the corresponding element of `S` when computing the standardized Euclidean distance. This argument is only valid when `Distance` is `'seuclidean'`. Default is `nanstd(X)`.

`'BucketSize'`

The maximum number of data points in the leaf node of the *k*d-tree. This argument is only meaningful when using the *k*d-tree search method. Default is 50.

Examples

Classify Using k-Nearest Neighbors

Find the 10 nearest neighbors in `x` to each point in `y` using first the `'minkowski'` distance metric with a p value of `5`, and then using the `'chebychev'` distance metric.

Load Fisher's iris data set

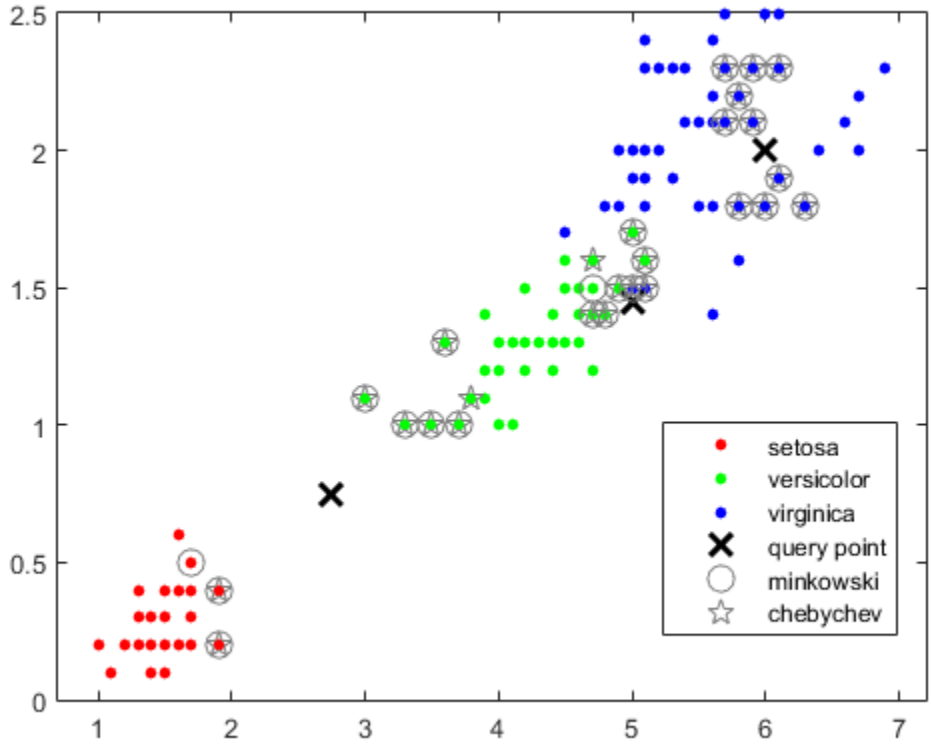
```
load fisheriris
x = meas(:,3:4);
y = [5 1.45;6 2;2.75 .75];
```

Perform a `knnsearch` between `x` and the query points in `y`, using first Minkowski then Chebychev distance metrics.

```
[n,d]=knnsearch(x,y,'k',10,'distance','minkowski','p',5);
[ncb,dcb] = knnsearch(x,y,'k',10,...
   'distance','chebychev');
```

Visualize the results of the two different nearest neighbors searches. Plot the training data. Plot an X for the query points. Use circles to denote the Minkowski nearest neighbors. Use pentagrams to denote the Chebychev nearest neighbors.

```
gscatter(x(:,1),x(:,2),species)
line(y(:,1),y(:,2),'marker','x','color','k',...
   'markersize',10,'linewidth',2,'linestyle','none')
line(x(n,1),x(n,2),'color',[.5 .5 .5],'marker','o',...
   'linestyle','none','markersize',10)
line(x(ncb,1),x(ncb,2),'color',[.5 .5 .5],'marker','p',...
   'linestyle','none','markersize',10)
legend('setosa','versicolor','virginica','query point',...
'minkowski','chebychev','Location','best')
```



Alternatives

`knnsearch` is the object function of `ExhaustiveSearcher` and `KDTreeSearcher` models for a *k*-nearest neighbors search. If you set the `NSMethod` name-value pair argument to the appropriate value (`'exhaustive'` for an exhaustive search or `'kdtree'` for a *K*d-tree), then the search results are equivalent to conducting a distance search using `knnsearch` and without using model objects.

More About

Tips

- For a fixed positive integer `K`, `knnsearch` finds the `K` points in `X` that are nearest each point in `Y`. In contrast, for a fixed positive real value `r`, `rangesearch` finds all the points in `X` that are within a distance `r` of each point in `Y`.

Algorithms

For information on a specific search algorithm, see "Distance Metrics".

kruskalwallis

Kruskal-Wallis test

Syntax

```
p = kruskalwallis(x)
p = kruskalwallis(x,group)
p = kruskalwallis(x,group,displayopt)
[p,tbl,stats] = kruskalwallis( ___ )
```

Description

`p = kruskalwallis(x)` returns the *p*-value for the null hypothesis that the data in each column of the matrix x comes from the same distribution, using a Kruskal-Wallis test. The alternative hypothesis is that not all samples come from the same distribution. `kruskalwallis` also returns an ANOVA table and a box plot.

`p = kruskalwallis(x,group)` returns the *p*-value for a test of the null hypothesis that the data in each categorical group, as specified by the grouping variable group comes from the same distribution. The alternative hypothesis is that not all groups come from the same distribution.

`p = kruskalwallis(x,group,displayopt)` returns the *p*-value of the test and lets you display or suppress the ANOVA table and box plot.

`[p,tbl,stats] = kruskalwallis( ___ )` also returns the ANOVA table as the cell array `tbl` and the structure `stats` containing information about the test statistics.

Examples

Test Data Samples for the Same Distribution

Create two different normal probability distribution objects. The first distribution has `mu = 0` and `sigma = 1`, and the second distribution has `mu = 2` and `sigma = 1`.

```
pd1 = makedist('Normal');
pd2 = makedist('Normal','mu',2,'sigma',1);
```

Create a matrix of sample data by generating random numbers from these two distributions.

```
rng('default'); % for reproducibility
x = [random(pd1,20,2),random(pd2,20,1)];
```

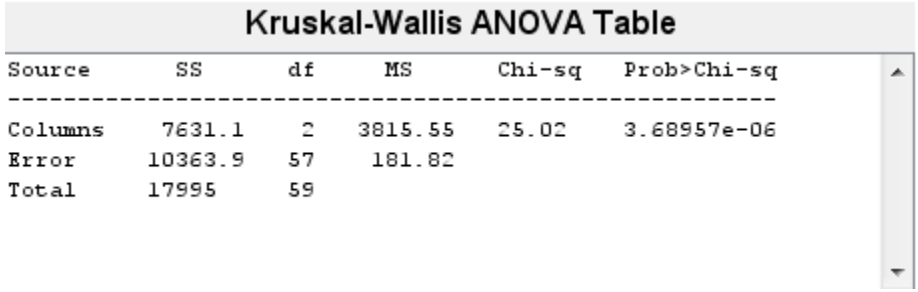
The first two columns of `x` contain data generated from the first distribution, while the third column contains data generated from the second distribution.

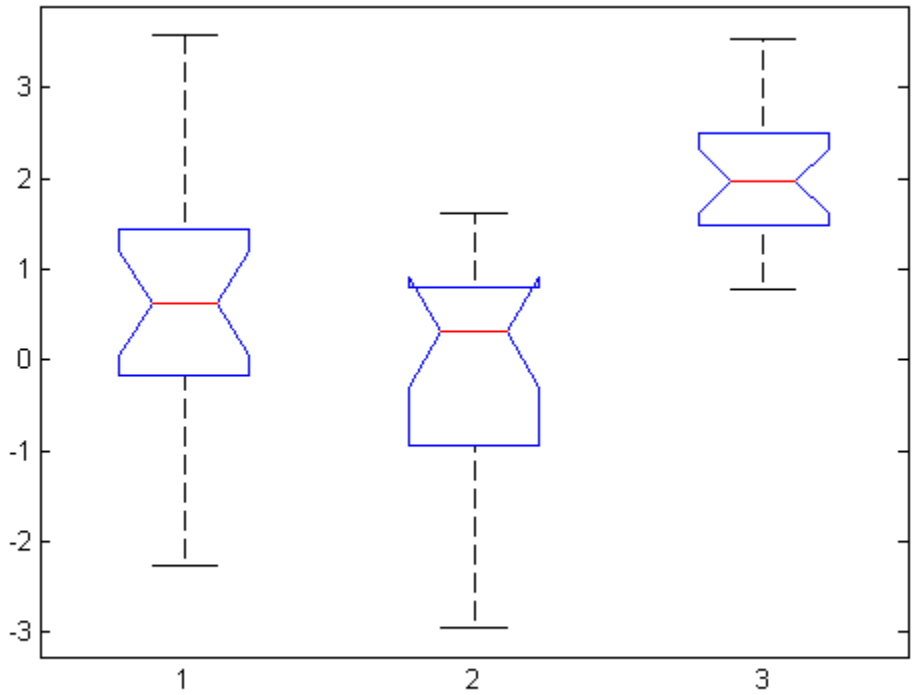
Test the null hypothesis that the sample data from each column in `x` comes from the same distribution.

```
p = kruskalwallis(x)
```

```
p =

   3.6896e-06
```





The returned value of `p` indicates that `kruskalwallis` rejects the null hypothesis that all three data samples come from the same distribution at a 1% significance level. The ANOVA table provides additional test results, and the box plot visually presents the summary statistics for each column in `x`.

Conduct Followup Tests for Unequal Medians

Create two different normal probability distribution objects. The first distribution has `mu = 0` and `sigma = 1`. The second distribution has `mu = 2` and `sigma = 1`.

```
pd1 = makedist('Normal');
pd2 = makedist('Normal','mu',2,'sigma',1);
```

Create a matrix of sample data by generating random numbers from these two distributions.

```
rng('default'); % for reproducibility
x = [random(pd1,20,2),random(pd2,20,1)];
```

The first two columns of `x` contain data generated from the first distribution, while the third column contains data generated from the second distribution.

Test the null hypothesis that the sample data from each column in `x` comes from the same distribution. Suppress the output displays, and generate the structure `stats` to use in further testing.

```
[p,tbl,stats] = kruskalwallis(x,[],'off')
```

```
p =

   3.6896e-06

tbl =

  Columns 1 through 4

    'Source'     'SS'            'df'    'MS'
    'Columns'    [7.6311e+03]    [ 2]    [3.8155e+03]
    'Error'      [1.0364e+04]    [57]    [  181.8228]
    'Total'      [     17995]    [59]              []

  Columns 5 through 6

    'Chi-sq'     'Prob>Chi-sq'
    [25.0200]    [ 3.6896e-06]
           []                []
           []                []

stats =

       gnames: [3x1 char]
            n: [20 20 20]
       source: 'kruskalwallis'
    meanranks: [26.7500 18.9500 45.8000]
         sumt: 0
```

The returned value of `p` indicates that the test rejects the null hypothesis at the 1% significance level. You can use the structure `stats` to perform additional followup testing. The cell array `tbl` contains the same data as the graphical ANOVA table, including column and row labels.

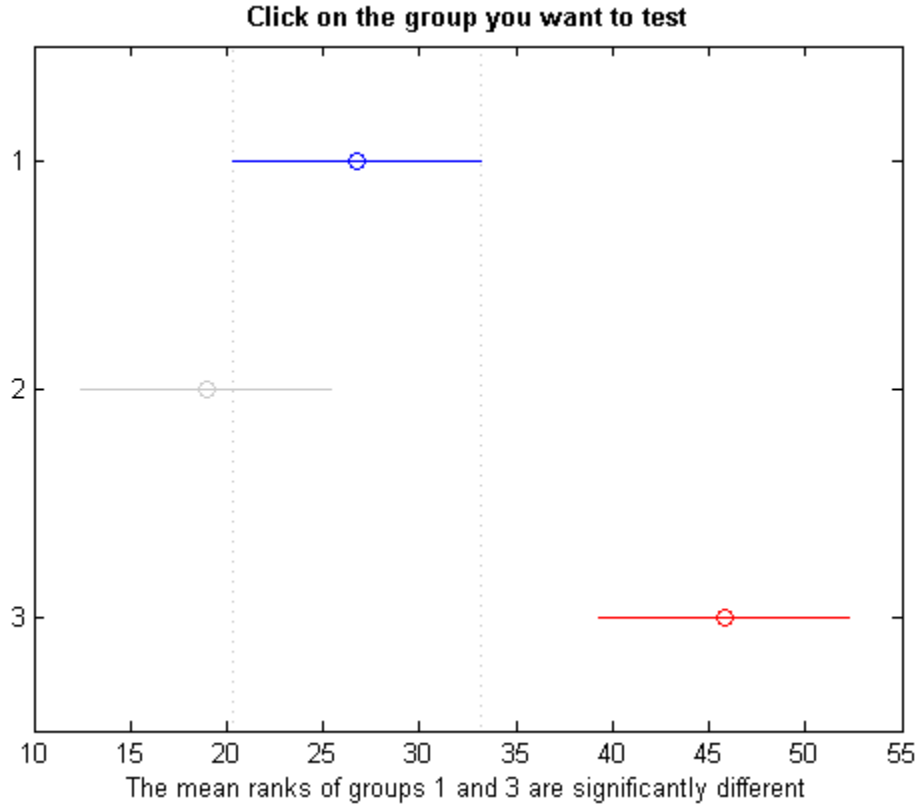
Conduct a followup test to identify which data sample comes from a different distribution.

```
c = multcompare(stats)

Note: Intervals can be used for testing but are not simultaneous confidence intervals.

c =

    1.0000    2.0000   -5.1435    7.8000   20.7435
    1.0000    3.0000  -31.9935  -19.0500   -6.1065
    2.0000    3.0000  -39.7935  -26.8500  -13.9065
```



The results indicate that there is a significant difference between groups 1 and 3, so the test rejects the null hypothesis that the data in these two groups comes from the same distribution. The same is true for groups 2 and 3. However, there is not a significant difference between groups 1 and 2, so the test does not reject the null hypothesis that these two groups come from the same distribution. Therefore, these results suggest that the data in groups 1 and 2 come from the same distribution, and the data in group 3 comes from a different distribution.

Test for the Same Distribution Across Groups

Create a vector, `strength`, containing measurements of the strength of metal beams. Create a second vector, `alloy`, containing strings indicating the type of metal alloy from which the corresponding beam is made.

```
strength = [82 86 79 83 84 85 86 87 74 82 ...
            78 75 76 77 79 79 77 78 82 79];

alloy = {'st','st','st','st','st','st','st','st',...
         'al1','al1','al1','al1','al1','al1',...
         'al2','al2','al2','al2','al2','al2'};
```

Test the null hypothesis that the beam strength measurements have the same distribution across all three alloys.

```
p = kruskalwallis(strength,alloy,'off')
```

```
p =

    0.0018
```

The returned value of `p` indicates that the test rejects the null hypothesis at the 1% significance level.

Input Arguments

x — Sample data

vector | matrix

Sample data for the hypothesis test, specified as a vector or an *m*-by-*n* matrix. If `x` is an *m*-by-*n* matrix, each of the *n* columns represents an independent sample containing *m* mutually independent observations.

Data Types: `single` | `double`

group — Grouping variable

categorical variable | vector | character array | cell array

Grouping variable, specified as a categorical variable, vector, character array, or cell array.

- If `x` is a vector, then each element in `group` identifies the group to which the corresponding element in `x` belongs, and `group` must be a vector of the same length as `x`. If a row of `group` contains an empty cell or empty string, that row and the corresponding observation in `x` are disregarded. `NaN` values in either `x` or `group` are similarly ignored.

- If `x` is a matrix, then each column in `x` represents a different group, and you can use `group` to specify labels for these columns. The number of elements in `group` and the number of columns in `x` must be equal.

The labels contained in `group` also annotate the box plot.

Example:
`{'red','blue','green','blue','red','blue','green','green','red'}`

Data Types: `single` | `double` | `char`

`displayopt` — Display option
`'on'` (default) | `'off'`

Display option, specified as `'on'` or `'off'`. If `displayopt` is `'on'`, `kruskalwallis` displays the following figures:

- An ANOVA table containing the sums of squares, degrees of freedom, and other quantities calculated based on the ranks of the data in x.
- A box plot of the data in each column of the data matrix x. The box plots are based on the actual data values, rather than on the ranks.

If `displayopt` is `'off'`, `kruskalwallis` does not display these figures.

If you specify a value for `displayopt`, you must also specify a value for `group`. If you do not have a grouping variable, specify `group` as `[]`.

Example: `'off'`

Output Arguments

`p` — *p*-value
scalar value in the range [0,1]

p-value of the test, returned as a scalar value in the range [0,1]. p is the probability of observing a test statistic as extreme as, or more extreme than, the observed value under the null hypothesis. Small values of p cast doubt on the validity of the null hypothesis.

`tbl` — ANOVA table
cell array

ANOVA table of test results, returned as a cell array. `tbl` includes the sums of squares, degrees of freedom, and other quantities calculated based on the ranks of the data in x, as well as column and row labels.

`stats` — Test data
structure

Test data, returned as a structure. You can perform followup multiple comparison tests on pairs of sample medians by using `multcompare`, with `stats` as the input value.

More About

Kruskal-Wallis Test

The Kruskal-Wallis test is a nonparametric version of classical one-way ANOVA, and an extension of the Wilcoxon rank sum test to more than two groups. It compares the medians of the groups of data in `x` to determine if the samples come from the same population (or, equivalently, from different populations with the same distribution).

The Kruskal-Wallis test uses ranks of the data, rather than numeric values, to compute the test statistics. It finds ranks by ordering the data from smallest to largest across all groups, and taking the numeric index of this ordering. The rank for a tied observation is equal to the average rank of all observations tied with it. The *F*-statistic used in classical one-way ANOVA is replaced by a chi-square statistic, and the *p*-value measures the significance of the chi-square statistic.

The Kruskal-Wallis test assumes that all samples come from populations having the same continuous distribution, apart from possibly different locations due to group effects, and that all observations are mutually independent. By contrast, classical one-way ANOVA replaces the first assumption with the stronger assumption that the populations have normal distributions.

ksdensity

Kernel smoothing function estimate

Syntax

```
[f,xi] = ksdensity(x)
[f,xi] = ksdensity(x,pts)
[f,xi] = ksdensity(x,pts,Name,Value)
[f,xi,bw] = ksdensity( ___ )

ksdensity( ___ )
ksdensity(ax, ___ )
```

Description

`[f,xi] = ksdensity(x)` returns a probability density estimate, `f`, for the sample in the vector `x`. The estimate is based on a normal kernel function, and is evaluated at 100 equally spaced points, `xi`, that cover the range of the data in `x`.

`ksdensity` works best with continuously distributed samples.

`[f,xi] = ksdensity(x,pts)` returns a probability density estimate, `f`, for the sample in the vector `x`, evaluated at the specified values in vector `pts`. Here, the `xi` and `pts` vectors contain identical values.

`[f,xi] = ksdensity(x,pts,Name,Value)` returns a probability density estimate, `f`, for the sample in the vector `x`, with additional options specified by one or more `Name,Value` pair arguments.

For example, you can define the function type `ksdensity` evaluates, such as probability density, cumulative probability, survivor function, and so on. Or you can specify the bandwidth of the smoothing window.

`[f,xi,bw] = ksdensity( ___ )` also returns the bandwidth of the kernel smoothing window, `bw`. The default bandwidth is the optimal for normal densities.

`ksdensity( ___ )` plots the kernel smoothing function estimate.

`ksdensity(ax, ___ )` plots the results using axes with the handle, `ax`, instead of the current axes returned by `gca`.

Examples

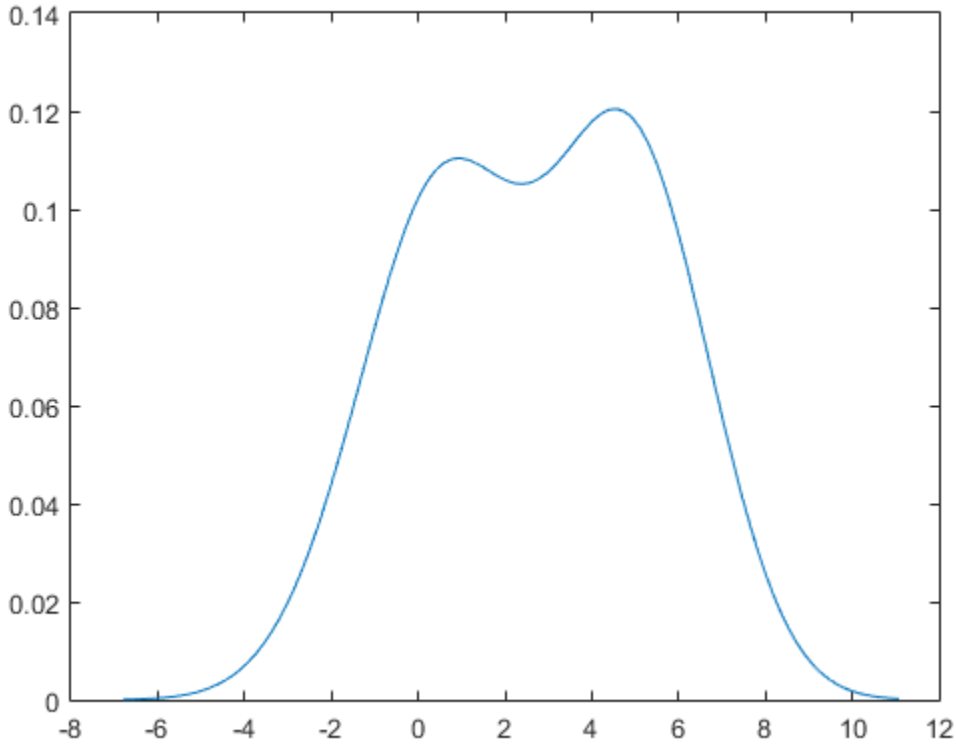
Estimate Density

Generate a sample data set from a mixture of two normal distributions.

```
rng default  % for reproducibility
x = [randn(30,1); 5+randn(30,1)];
```

Plot the estimated density.

```
[f,xi] = ksdensity(x);
figure
plot(xi,f);
```



The density estimate shows the bimodality of the sample.

Estimate Cumulative Distribution Function at Specified Values

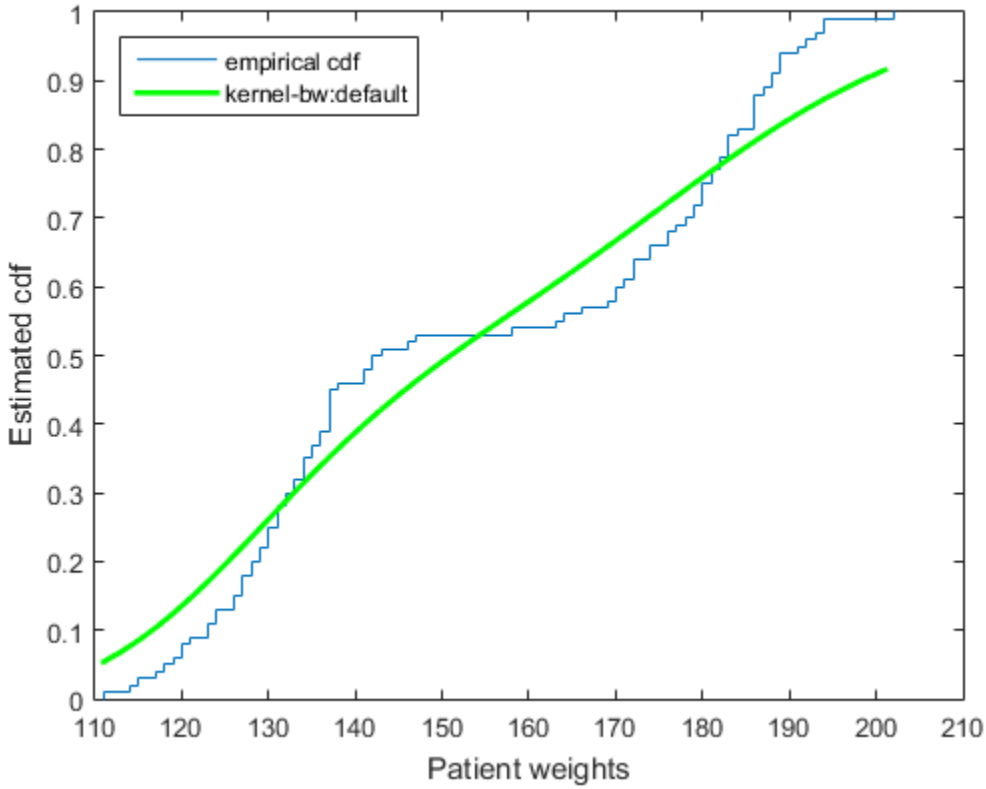
Load the sample data.

```
load hospital
```

Compute and plot the estimated cdf evaluated at a specified set of values.

```
pts = (min(hospital.Weight):2:max(hospital.Weight));
figure()
ecdf(hospital.Weight)
hold on
```

```
[f,xi,bw] = ksdensity(hospital.Weight,pts,'support','positive',...
 'function','cdf');
plot(xi,f,'-g','LineWidth',2)
legend('empirical cdf','kernel-bw:default','Location','NorthWest')
xlabel('Patient weights')
ylabel('Estimated cdf')
```



`ksdensity` seems to smooth the cumulative distribution function estimate too much. An estimate with a smaller bandwidth might produce a closer estimate to the empirical cumulative distribution function.

Return the bandwidth of the smoothing window.

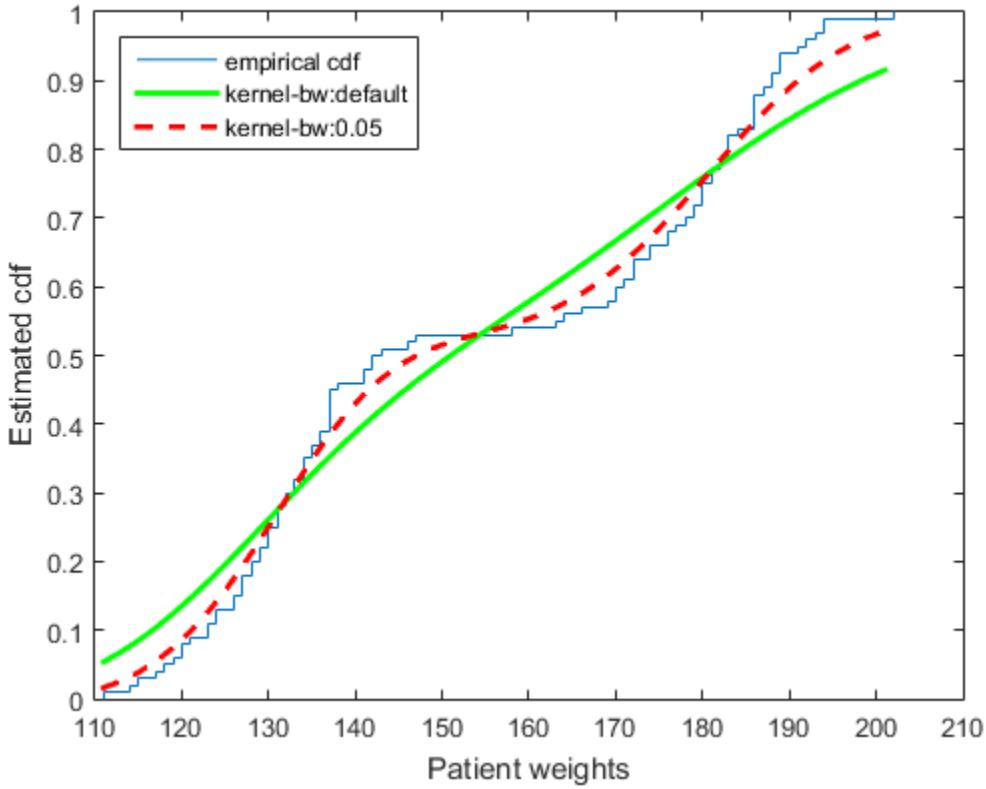
`bw`

```
bw =

    0.1070
```

Plot the cumulative distribution function estimate using a smaller bandwidth.

```
[f,xi] = ksdensity(hospital.Weight,pts,'support','positive',...
 'function','cdf','bandwidth',0.05);
plot(xi,f,'--r','LineWidth',2)
legend('empirical cdf','kernel-bw:default','kernel-bw:0.05',...
 'Location','NorthWest')
hold off
```



The `ksdensity` estimate with a smaller bandwidth matches the empirical cumulative distribution function better.

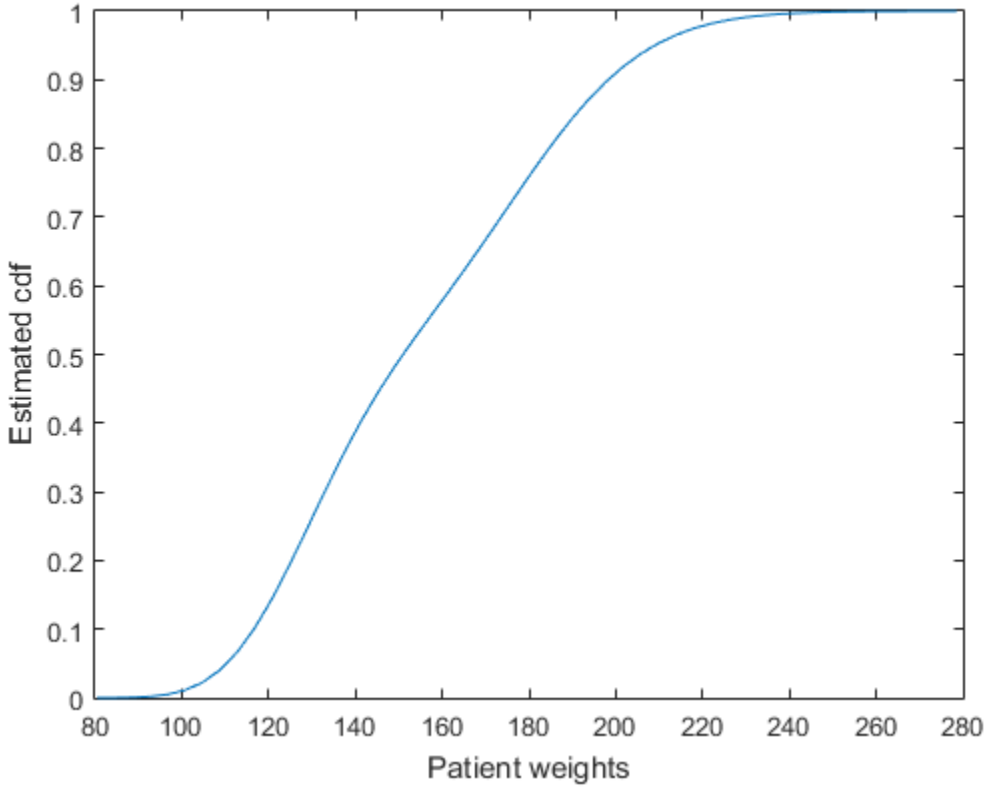
Plot Estimated Cumulative Density Function for Given Number of Points

Load the sample data.

```
load hospital
```

Plot the estimated cdf evaluated at 50 equally spaced points.

```
figure()
ksdensity(hospital.Weight,'support','positive','function','cdf',...
'npoints',50)
xlabel('Patient weights')
ylabel('Estimated cdf')
```



Estimate Survivor and Cumulative Hazard for Censored Failure Data

Generate sample data from an exponential distribution with mean 3.

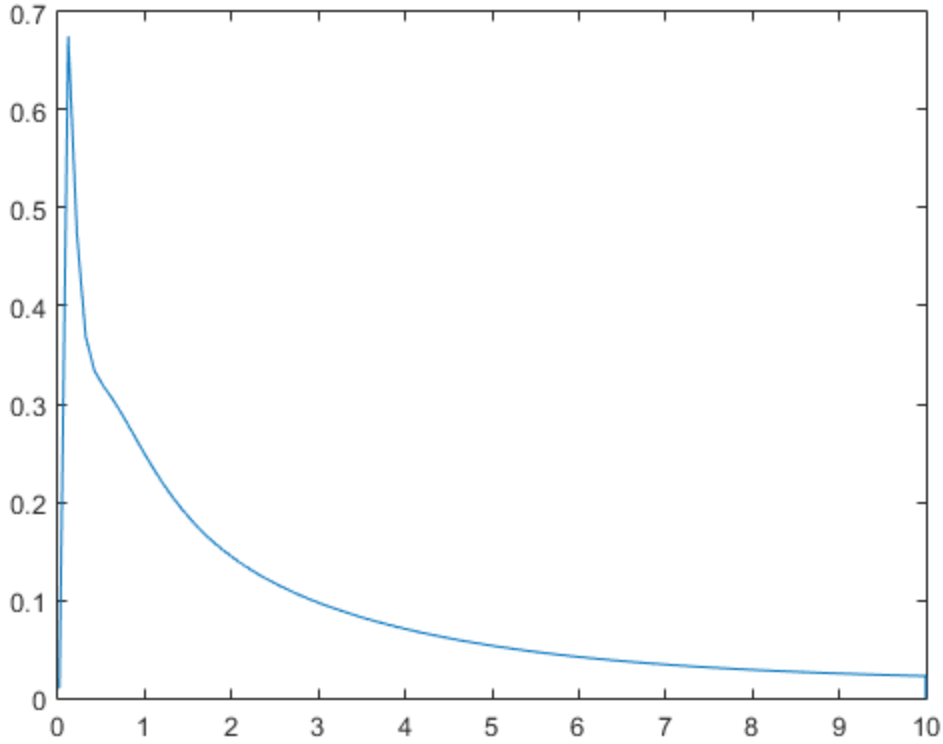
```
rng default  % for reproducibility
x = random('exp',3,100,1);
```

Create a logical vector that indicates censoring. Here, observations with lifetimes longer than 10 are censored.

```
T = 10;
cens = (x>10);
```

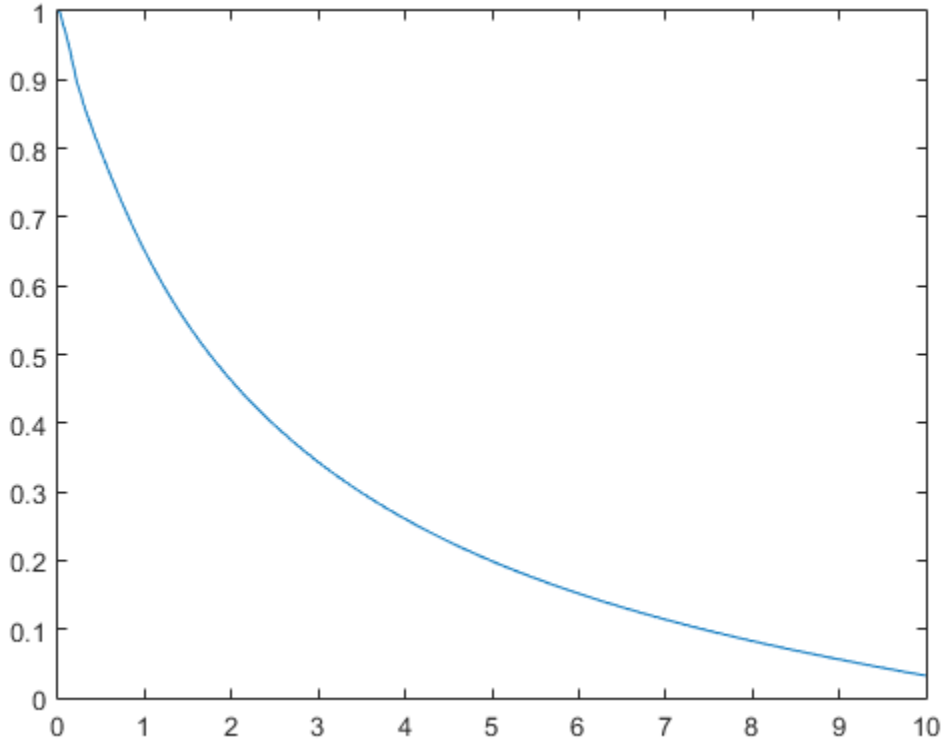
Compute and plot the estimated density function.

```
figure
ksdensity(x,'support','positive','censoring',cens);
```



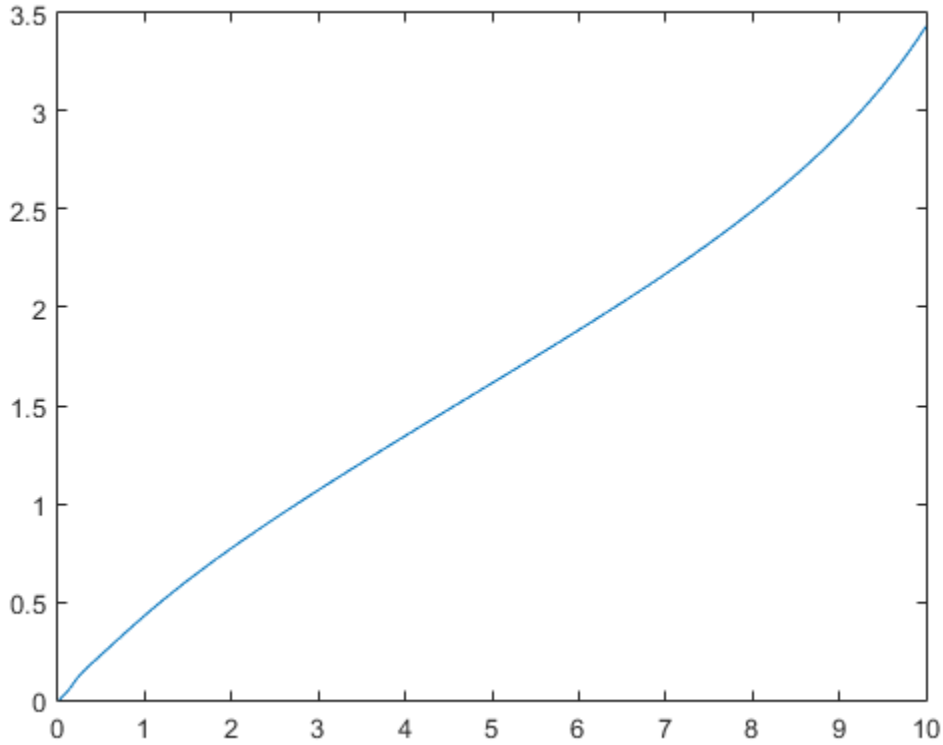
Compute and plot the survivor function.

```
figure
ksdensity(x,'support','positive','censoring',cens,...
'function','survivor');
```



Compute and plot the cumulative hazard function.

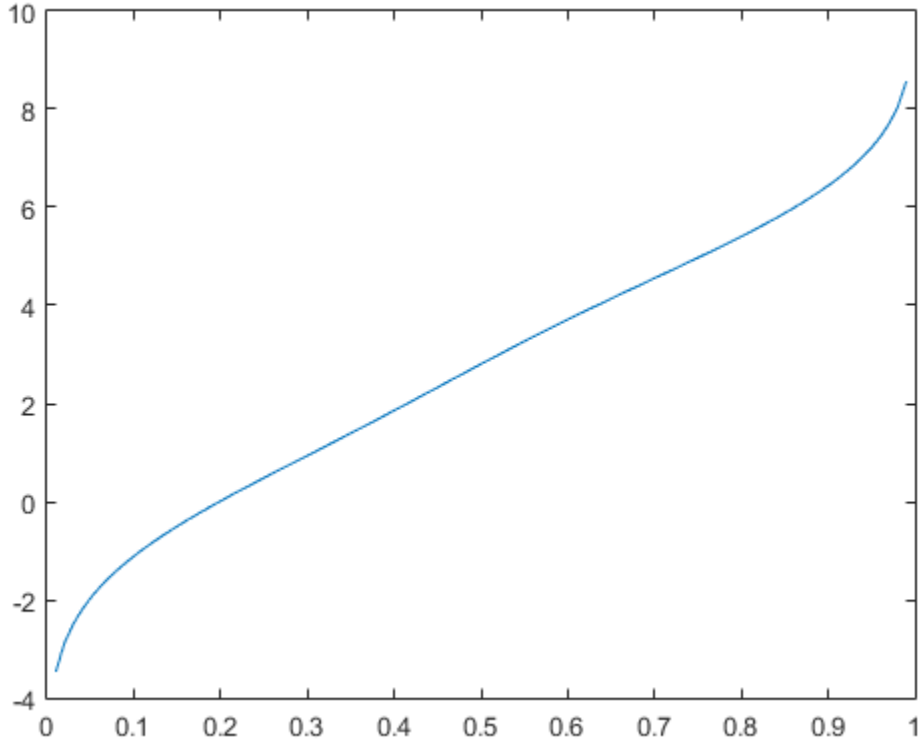
```
figure
ksdensity(x,'support','positive','censoring',cens,...
'function','cumhazard');
```



Estimate Inverse Cumulative Distribution Function for Specified Probability Values

Generate a mixture of two normal distributions, and plot the estimated inverse cumulative distribution function at a specified set of probability values.

```
rng default  % for reproducibility
x = [randn(30,1); 5+randn(30,1)];
pi = linspace(.01,.99,99);
figure
ksdensity(x,pi,'function','icdf');
```



Return Bandwidth of Smoothing Window

Generate a mixture of two normal distributions.

```
rng default  % For reproducibility
x = [randn(30,1); 5+randn(30,1)];
```

Return the bandwidth of the smoothing window for the probability density estimate.

```
[f,xi,bw] = ksdensity(x);
bw
```

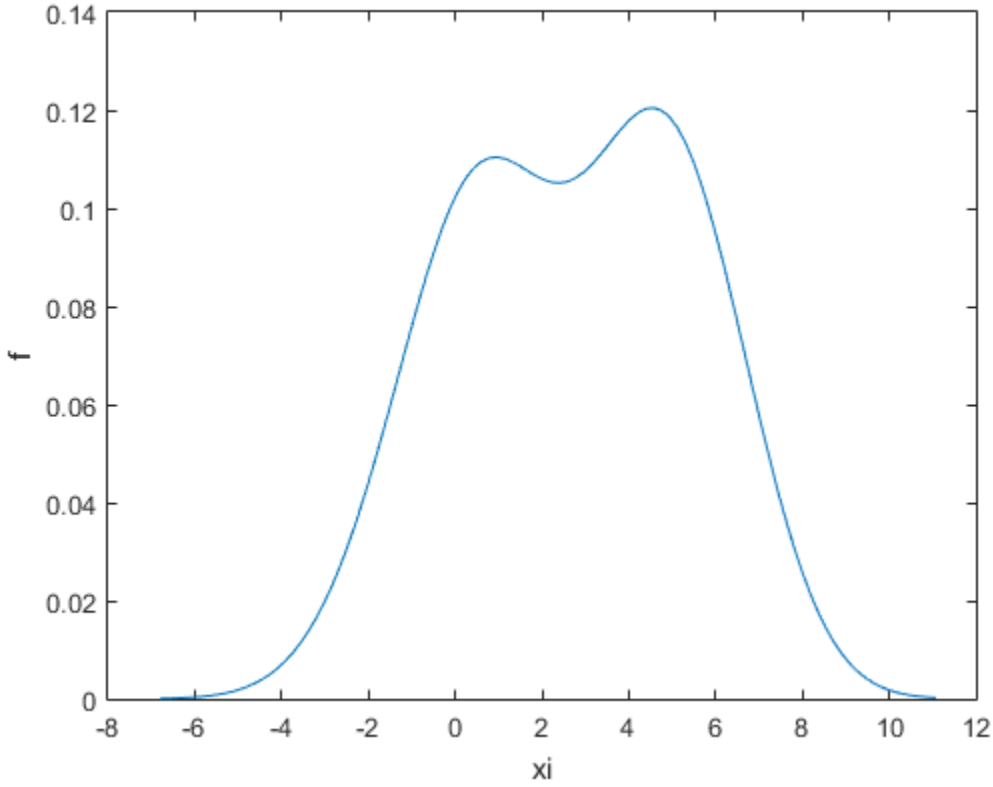
```
bw =
```

```
    1.5141
```

The default bandwidth is optimal for normal densities.

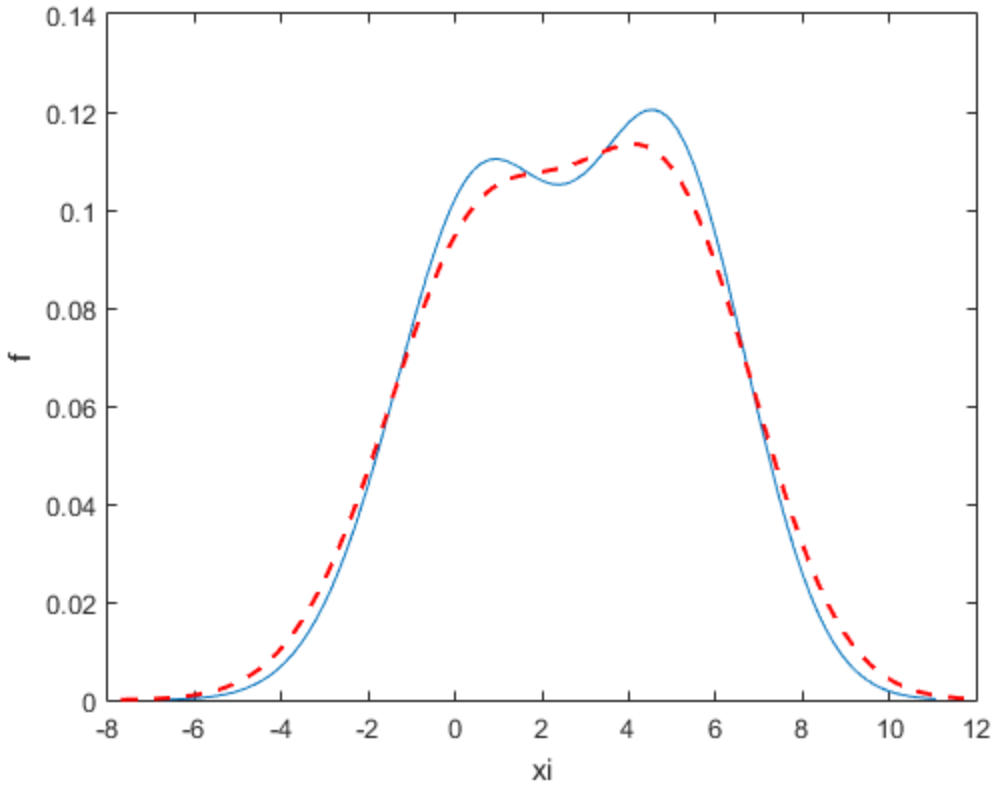
Plot the estimated density.

```
figure
plot(xi,f);
xlabel('xi')
ylabel('f')
hold on
```



Plot the density using an increased bandwidth value.

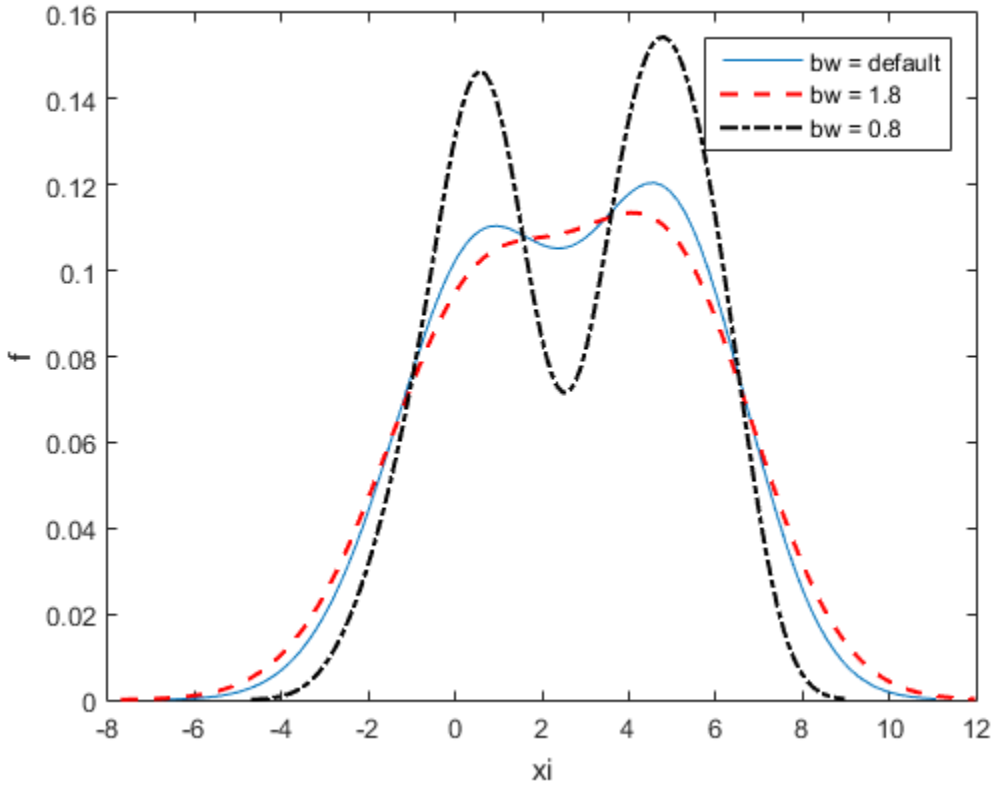
```
[f,xi] = ksdensity(x,'width',1.8);
plot(xi,f,'--r','LineWidth',1.5)
```



A higher bandwidth further smooths the density estimate, which might mask some characteristics of the distribution.

Now, plot the density using a decreased bandwidth value.

```
[f,xi] = ksdensity(x,'width',0.8);
plot(xi,f,'-.k','LineWidth',1.5)
legend('bw = default','bw = 1.8','bw = 0.8')
hold off
```



A smaller bandwidth smooths the density estimate less, which exaggerates some characteristics of the sample.

- "Fit Kernel Distribution Using ksdensity" on page 5-54
- "Fit Distributions to Grouped Data Using ksdensity" on page 5-57

Input Arguments

x — Sample data

column vector

Sample data, for which `ksdensity` returns f values, specified as a column vector.

Example: `[f,xi] = ksdensity(x)`

Data Types: `single` | `double`

`pts` — Points to evaluate `f`

vector

Points to evaluate f at, specified as a vector. `pts` can be a row or column vector. `f` has the same dimensions as `pts`.

Example: `pts = (0:1:25); ksdensity(x,pts);`

Data Types: `single` | `double`

`ax` — Axes handle

handle

Axes handle for the figure `ksdensity` plots to, specified as a handle.

For example, if `h` is a handle for a figure, then `ksdensity` can plot to that figure as follows.

Example: `ksdensity(h,x)`

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'censoring',cens,'kernel','triangle','npoints',20,'function','cdf'` specifies that `ksdensity` estimates the cdf by evaluating at 20 equally spaced points that covers the range of data, using the triangle kernel smoothing function and accounting for the censored data information in vector `cens`.

`'censoring'` — Logical vector

vector of 0s (default) | vector of 0s and 1s

Logical vector indicating which entries are censored, specified as a vector of binary values. A value of 0 indicates there is no censoring, 1 indicates that observation is censored. Default is there is no censoring.

Example: `'censoring',censdata`

Data Types: `logical`

`'kernel'` — Type of kernel smoother

`'normal'` (default) | `'box'` | `'triangle'` | `'epanechnikov'` | `function handle` | `string`

Type of kernel smoother, specified as the comma-separated pair consisting of `'kernel'` and one of the following.

- `'normal'` (default)
- `'box'`
- `'triangle'`
- `'epanechnikov'`
- You can also specify a custom kernel function, as a function handle or as a string, e.g., `@normpdf` or `'normpdf'`. This calls the function with one argument that is an array of distances between data values and locations where the density is evaluated. The function must return an array of the same size containing corresponding values of the kernel function.

  When `'function'` is `'pdf'`, this kernel function returns density values. Otherwise, it returns cumulative probability values.

  Specifying a custom kernel when `'function'` is `'icdf'` returns an error.

If `'support'` is `'positive'`, then `ksdensity` transforms x using a log function, estimates the density of the transformed values, and transforms back to the original scale. If `'support'` is a vector `[L U]`, then `ksdensity` uses the transformation `log((X-L)/(U-X))`. The `width` parameter and bw outputs are on the scale of the transformed values.

Example: `'kernel','box'`

Data Types: `char` | `function_handle`

`'npoints'` — Number of equally spaced points

100 (default) | scalar value

Number of equally spaced points in `xi`, specified as the comma-separated pair consisting of `'npoints'` and a scalar value.

For instance, for a kernel smooth estimate of a specified function at 80 equally spaced points within the range of sample data, input:

Example: `'npoints',80`

Data Types: `single` | `double`

`'support'` — Support for the density

`'unbounded'` (default) | `'positive'` | two-element vector, `[L U]`

Support for the density, specified as the comma-separated pair consisting of `'support'` and one of the following.

`'unbounded'`	Default. Allow the density to extend over the whole real line.
`'positive'`	Restrict the density to positive values.
Two-element vector, `[L U]`	Give the finite lower and upper bounds for the support of the density.

Example: `'support','positive'`

Example: `'support',[0 10]`

Data Types: `single` | `double` | `char`

`'weights'` — Weights for each x value

vector

Weights for each x value, specified as the comma-separated pair consisting of `'weights'` and a vector of the same length as x.

For instance, if the weights for the data values are in vector `xw`, then you can specify the weights as follows.

Example: `'weights',xw`

Data Types: `single` | `double`

`'bandwidth'` — Bandwidth of the kernel smoothing window

optimal value for normal densities (default) | scalar value

The bandwidth of the kernel-smoothing window, which is a function of the number of points in `x`, specified as the comma-separated pair consisting of `'width'` and a scalar. The default is optimal for estimating normal densities, but you might want to choose a larger or smaller value to smooth more or less.

Example: `'bandwidth',0.8`

Data Types: `single` | `double`

`'function'` — Function to estimate

`'pdf'` (default) | `'cdf'` | `'icdf'` | `'survivor'` | `'cumhazard'`

Function to estimate, specified as the comma-separated pair consisting of `'function'` and one of the following.

`'pdf'`	Default. Probability density function.
`'cdf'`	Cumulative distribution function.
`'icdf'`	Inverse cumulative distribution function. For `'icdf'`, `f = ksdensity(x,pi,'function','icdf')` computes the estimated inverse cdf of the values in `x`, and evaluates it at the probability values specified in `pi`.
`'survivor'`	Survivor function.
`'cumhazard'`	Cumulative hazard function.

Example: `'function','icdf'`

Data Types: `char`

Output Arguments

`f` — Estimated function values

vector

Estimated function values, returned as a vector of the same dimension as xi or pts.

`xi` — Evaluation points

100 equally spaced points (default) | vector

Evaluation points at which `ksdensity` calculates f, returned as a vector. Default is 100 equally spaced points that cover the range of data in x.

`bw` — Bandwidth of smoothing window

scalar value

Bandwidth of smoothing window, returned as a scalar value.

`histogram`

kstest

One-sample Kolmogorov-Smirnov test

Syntax

```
h = kstest(x)
h = kstest(x,Name,Value)
[h,p] = kstest( ___ )
[h,p,ksstat,cv] = kstest( ___ )
```

Description

`h = kstest(x)` returns a test decision for the null hypothesis that the data in vector x comes from a standard normal distribution, against the alternative that it does not come from such a distribution, using the one-sample Kolmogorov-Smirnov test. The result h is `1` if the test rejects the null hypothesis at the 5% significance level, or `0` otherwise.

`h = kstest(x,Name,Value)` returns a test decision for the one-sample Kolmogorov-Smirnov test with additional options specified by one or more name-value pair arguments. For example, you can test for a distribution other than standard normal, change the significance level, or conduct a one-sided test.

`[h,p] = kstest( ___ )` also returns the *p*-value p of the hypothesis test, using any of the input arguments from the previous syntaxes.

`[h,p,ksstat,cv] = kstest( ___ )` also returns the value of the test statistic ksstat and the approximate critical value cv of the test.

Examples

Test for a Standard Normal Distribution

Load the sample data. Create a vector containing the first column of the students' exam grades data.

```
load examgrades;
test1 = grades(:,1);
```

Test the null hypothesis that the data comes from a normal distribution with a mean of 75 and a standard deviation of 10. Use these parameters to center and scale each element of the data vector since, by default, `kstest` tests for a standard normal distribution.

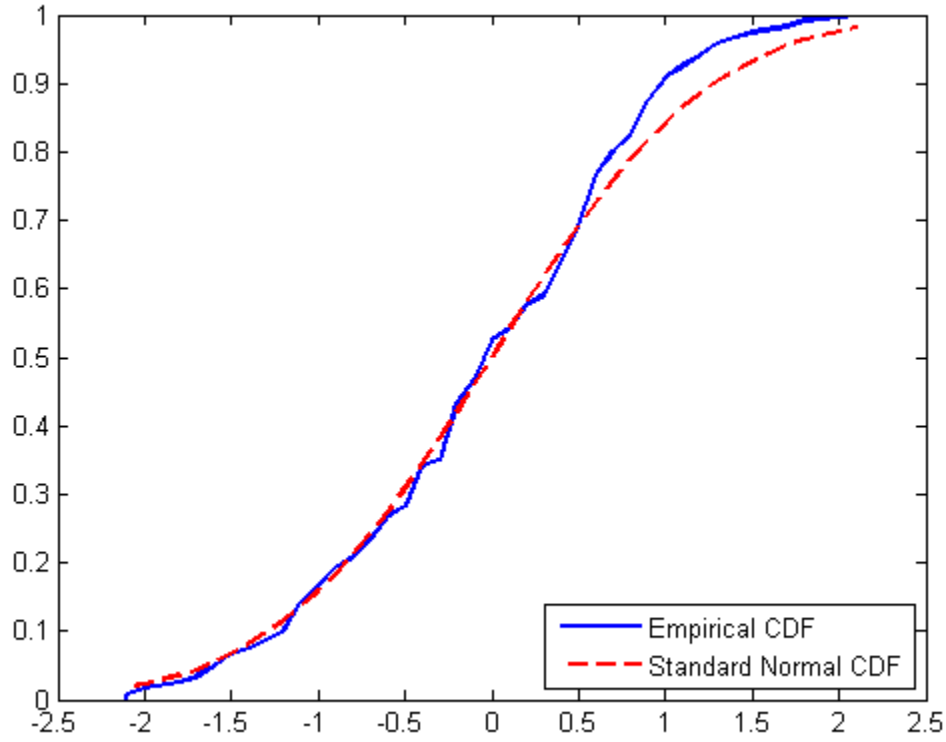
```
x = (test1-75)/10;
h = kstest(x)
```

```
h =
 0
```

The returned value of `h = 0` indicates that `kstest` fails to reject the null hypothesis at the default 5% significance level.

Plot the empirical cumulative distribution function (cdf) and the standard normal cdf for a visual comparison.

```
[f,x_values] = ecdf(x);
F = plot(x_values,f);
set(F,'LineWidth',2);
hold on;
G = plot(x_values,normcdf(x_values,0,1),'r-');
set(G,'LineWidth',2);
legend([F G],...
       'Empirical CDF','Standard Normal CDF',...
       'Location','SE');
```



The plot shows the similarity between the empirical cdf of the centered and scaled data vector and the cdf of the standard normal distribution.

Specify the Hypothesized Distribution Using a Two-Column Matrix

Load the sample data. Create a vector containing the first column of the students' exam grades data.

```
load examgrades;
x = grades(:,1);
```

Specify the hypothesized distribution as a two-column matrix. Column 1 contains the data vector `x`. Column 2 contains cdf values evaluated at each value in `x` for a

hypothesized Student's t distribution with a location parameter of 75, a scale parameter of 10, and one degree of freedom.

```
test_cdf = [x,cdf('tlocationscale',x,75,10,1)];
```

Test if the data are from the hypothesized distribution.

```
h = kstest(x,'CDF',test_cdf)
```

```
h =
 1
```

The returned value of `h = 1` indicates that `kstest` rejects the null hypothesis at the default 5% significance level.

Specify the Hypothesized Distribution Using a Probability Distribution Object

Load the sample data. Create a vector containing the first column of the students' exam grades data.

```
load examgrades;
x = grades(:,1);
```

Create a probability distribution object to test if the data comes from a Student's t distribution with a location parameter of 75, a scale parameter of 10, and one degree of freedom.

```
test_cdf = makedist('tlocationscale','mu',75,'sigma',10,'nu',1);
```

Test the null hypothesis that the data comes from the hypothesized distribution.

```
h = kstest(x,'CDF',test_cdf)
```

```
h =
 1
```

The returned value of `h = 1` indicates that `kstest` rejects the null hypothesis at the default 5% significance level.

Test the Hypothesis at Different Significance Levels

Load the sample data. Create a vector containing the first column of the students' exam grades.

```
load examgrades;
test1 = grades(:,1);
```

Create a probability distribution object to test if the data comes from a Student's t distribution with a location parameter of 75, a scale parameter of 10, and one degree of freedom.

```
test_cdf = makedist('tlocationscale','mu',75,'sigma',10,'nu',1);
```

Test the null hypothesis that data comes from the hypothesized distribution at the 1% significance level.

```
[h,p] = kstest(x,'CDF',test_cdf,'Alpha',0.01)
```

```
h =
     1

p =
    0.0021
```

The returned value of `h = 1` indicates that `kstest` rejects the null hypothesis at the 1% significance level.

Conduct a One-Sided Hypothesis Test

Load the sample data. Create a vector containing the third column of the stock return data matrix.

```
load stockreturns;
x = stocks(:,3);
```

Test the null hypothesis that the data comes from a standard normal distribution, against the alternative hypothesis that the population cdf of the data is larger than the standard normal cdf.

```
[h,p,k,c] = kstest(x,'Tail','larger')
```

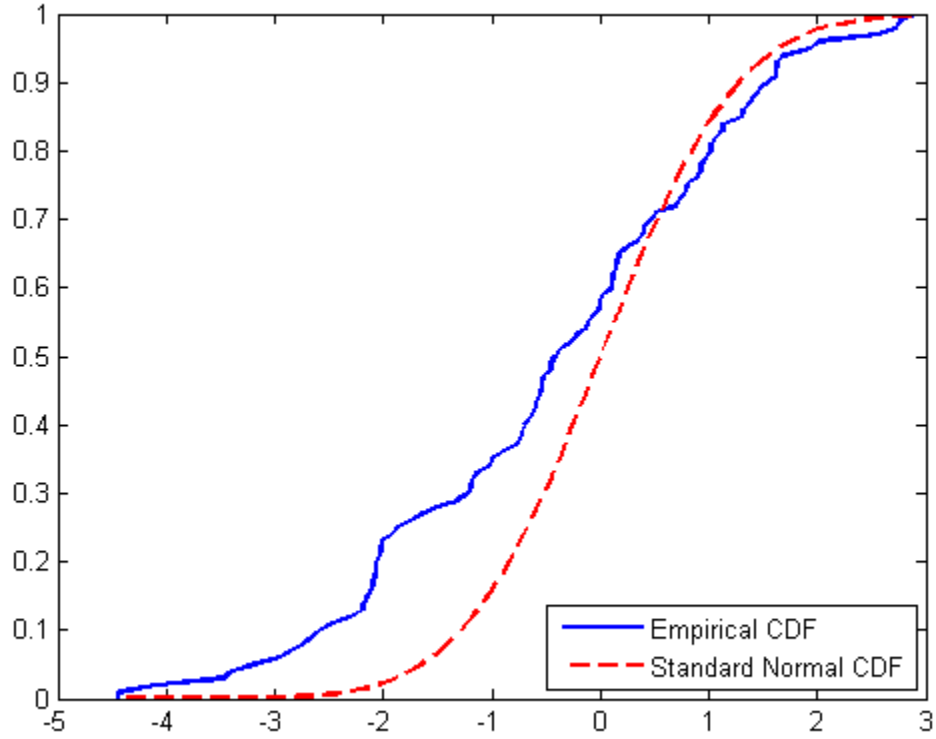
```
h =
 1
p =
 5.0854e-05
k =
 0.2197
c =
```

```
0.1207
```

The returned value of `h = 1` indicates that `kstest` rejects the null hypothesis in favor of the alternative hypothesis at the default 5% significance level.

Plot the empirical cdf and the standard normal cdf for a visual comparison.

```
[f,x_values] = ecdf(x);
J = plot(x_values,f);
hold on;
K = plot(x_values,normcdf(x_values),'r--');
set(J,'LineWidth',2);
set(K,'LineWidth',2);
legend([J K],'Empirical CDF','Standard Normal CDF','Location','SE');
```



The plot shows the difference between the empirical cdf of the data vector `x` and the cdf of the standard normal distribution.

Input Arguments

`x` — Sample data

vector

Sample data, specified as a vector.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'Tail','right','Alpha',0.01` specifies a right-tailed hypothesis test at the 1% significance level.

`'Alpha'` — Significance level

`0.05` (default) | scalar value in the range (0,1)

Significance level of the hypothesis test, specified as the comma-separated pair consisting of `'Alpha'` and a scalar value in the range (0,1).

Example: `'Alpha',0.01`

Data Types: `single` | `double`

`'CDF'` — cdf of hypothesized continuous distribution

matrix | probability distribution object

cdf of hypothesized continuous distribution, specified the comma-separated pair consisting of `'CDF'` and either a two-column matrix or a continuous probability distribution object. When CDF is a matrix, column 1 contains a set of possible x values, and column 2 contains the corresponding hypothesized cumulative distribution function values $G(x)$. The calculation is most efficient if CDF is specified such that column 1 contains the values in the data vector x. If there are values in x not found in column 1 of CDF, `kstest` approximates $G(x)$ by interpolation. All values in x must lie in the interval

between the smallest and largest values in the first column of CDF. By default, `kstest` tests for a standard normal distribution.

The one-sample Kolmogorov-Smirnov test is only valid for continuous cumulative distribution functions, and requires CDF to be predetermined. The result is not accurate if CDF is estimated from the data. To test x against the normal, lognormal, extreme value, Weibull, or exponential distribution without specifying distribution parameters, use `lillietest` instead.

Data Types: `single` | `double`

`'Tail'` — Type of alternative hypothesis

`'unequal'` (default) | `'larger'` | `'smaller'`

Type of alternative hypothesis to evaluate, specified as the comma-separated pair consisting of `'Tail'` and one of the following.

`'unequal'`	Test the alternative hypothesis that the cdf of the population from which x is drawn is not equal to the cdf of the hypothesized distribution.
`'larger'`	Test the alternative hypothesis that the cdf of the population from which x is drawn is greater than the cdf of the hypothesized distribution.
`'smaller'`	Test the alternative hypothesis that the cdf of the population from which x is drawn is less than the cdf of the hypothesized distribution.

If the values in the data vector x tend to be larger than expected from the hypothesized distribution, the empirical distribution function of x tends to be smaller, and vice versa.

Example: `'Tail','larger'`

Output Arguments

h — Hypothesis test result

`1` | `0`

Hypothesis test result, returned as a logical value.

- If h = `1`, this indicates the rejection of the null hypothesis at the Alpha significance level.

- If h = 0, this indicates a failure to reject the null hypothesis at the Alpha significance level.

p — *p*-value
scalar value in the range [0,1]

p-value of the test, returned as a scalar value in the range [0,1]. p is the probability of observing a test statistic as extreme as, or more extreme than, the observed value under the null hypothesis. Small values of p cast doubt on the validity of the null hypothesis.

`ksstat` — Test statistic
nonnegative scalar value

Test statistic of the hypothesis test, returned as a nonnegative scalar value.

`cv` — Critical value
nonnegative scalar value

Critical value, returned as a nonnegative scalar value.

More About

One-Sample Kolmogorov-Smirnov Test

The one-sample Kolmogorov-Smirnov test is a nonparametric test of the null hypothesis that the population cdf of the data is equal to the hypothesized cdf.

The two-sided test for "unequal" cdf functions tests the null hypothesis against the alternative that the population cdf of the data is not equal to the hypothesized cdf. The test statistic is the maximum absolute difference between the empirical cdf calculated from x and the hypothesized cdf:

$$D^* = \max_x \left(\left| \hat{F}(x) - G(x) \right| \right),$$

where $\hat{F}(x)$ is the empirical cdf and $G(x)$ is the cdf of the hypothesized distribution.

The one-sided test for a "larger" cdf function tests the null hypothesis against the alternative that the population cdf of the data is greater than the hypothesized cdf.

The test statistic is the maximum amount by which the empirical cdf calculated from x exceeds the hypothesized cdf:

$$D^* = \max_x \left(\hat{F}(x) - G(x) \right).$$

The one-sided test for a "smaller" cdf function tests the null hypothesis against the alternative that the population cdf of the data is less than the hypothesized cdf. The test statistic is the maximum amount by which the hypothesized cdf exceeds the empirical cdf calculated from x:

$$D^* = \max_x \left(G(x) - \hat{F}(x) \right).$$

`kstest` computes the critical value cv using an approximate formula or by interpolation in a table. The formula and table cover the range $0.01 \le \texttt{alpha} \le 0.2$ for two-sided tests and $0.005 \le \texttt{alpha} \le 0.1$ for one-sided tests. cv is returned as `NaN` if `alpha` is outside this range.

Algorithms

`kstest` decides to reject the null hypothesis by comparing the p-value p with the significance level Alpha, not by comparing the test statistic ksstat with the critical value cv. Since cv is approximate, comparing ksstat with cv occasionally leads to a different conclusion than comparing p with Alpha.

`adtest` | `kstest2` | `lillietest`

kstest2

Two-sample Kolmogorov-Smirnov test

Syntax

```
h = kstest2(x1,x2)
h = kstest2(x1,x2,Name,Value)
[h,p] = kstest2(___)
[h,p,ks2stat] = kstest2(___)
```

Description

`h = kstest2(x1,x2)` returns a test decision for the null hypothesis that the data in vectors x1 and x2 are from the same continuous distribution, using the two-sample Kolmogorov-Smirnov test. The alternative hypothesis is that x1 and x2 are from different continuous distributions. The result h is `1` if the test rejects the null hypothesis at the 5% significance level, and `0` otherwise.

`h = kstest2(x1,x2,Name,Value)` returns a test decision for a two-sample Kolmogorov-Smirnov test with additional options specified by one or more name-value pair arguments. For example, you can change the significance level or conduct a one-sided test.

`[h,p] = kstest2(___)` also returns the asymptotic *p*-value p, using any of the input arguments from the previous syntaxes.

`[h,p,ks2stat] = kstest2(___)` also returns the test statistic ks2stat.

Examples

Test Two Samples for the Same Distribution

Generate sample data from two different Weibull distributions.

```
rng(1);     % For reproducibility
x1 = wblrnd(1,1,1,50);
x2 = wblrnd(1.2,2,1,50);
```

Test the null hypothesis that data in vectors `x1` and `x2` comes from populations with the same distribution.

```
h = kstest2(x1,x2)
```

```
h =
 1
```

The returned value of `h = 1` indicates that `kstest` rejects the null hypothesis at the default 5% significance level.

Test the Hypothesis at Different Significance Levels

Generate sample data from two different Weibull distributions.

```
rng(1);      % For reproducibility
x1 = wblrnd(1,1,1,50);
x2 = wblrnd(1.2,2,1,50);
```

Test the null hypothesis that data vectors `x1` and `x2` are from populations with the same distribution at the 1% significance level.

```
[h,p] = kstest2(x1,x2,'Alpha',0.01)
```

```
h =
 0
p =
 0.0317
```

The returned value of `h = 0` indicates that `kstest` does not reject the null hypothesis at the 1% significance level.

One-Sided Hypothesis Test

Generate sample data from two different Weibull distributions.

```
rng(1);      % For reproducibility
x1 = wblrnd(1,1,1,50);
x2 = wblrnd(1.2,2,1,50);
```

Test the null hypothesis that data in vectors `x1` and `x2` comes from populations with the same distribution, against the alternative hypothesis that the cdf of the distribution of `x1` is larger than the cdf of the distribution of `x2`.

```
[h,p,k] = kstest2(x1,x2,'Tail','larger')
```

```
h =
 1
p =
 0.0158
k =
 0.2800
```

The returned value of `h = 1` indicates that `kstest` rejects the null hypothesis, in favor of the alternative hypothesis that the cdf of the distribution of `x1` is larger than the cdf of the distribution of `x2`, at the default 5% significance level. The returned value of `k` is the test statistic for the two-sample Kolmogorov-Smirnov test.

Input Arguments

`x1` — Sample data

vector

Sample data from the first sample, specified as a vector. Data vectors x1 and x2 do not need to be the same size.

Data Types: `single` | `double`

`x2` — Sample data

vector

Sample data from the second sample, specified as a vector. Data vectors x1 and x2 do not need to be the same size.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example:

`'Alpha'` — Significance level

`0.05` (default) | scalar value in the range (0,1)

Significance level of the hypothesis test, specified as the comma-separated pair consisting of `'Alpha'` and a scalar value in the range (0,1).

Example: `'Alpha',0.01`

Data Types: `single | double`

`'Tail'` — Type of alternative hypothesis

`'unequal'` (default) | `'larger'` | `'smaller'`

Type of alternative hypothesis to evaluate, specified as the comma-separated pair consisting of `'Tail'` and one of the following.

`'unequal'`	Test the alternative hypothesis that the empirical cdf of x1 is unequal to the empirical cdf of x2.
`'larger'`	Test the alternative hypothesis that the empirical cdf of x1 is larger than the empirical cdf of x2.
`'smaller'`	Test the alternative hypothesis that the empirical cdf of x1 is smaller than the empirical cdf of x2.

If the data values in x1 tend to be larger than those in x2, the empirical distribution function of x1 tends to be smaller than that of x2, and vice versa.

Example: `'Tail','larger'`

Output Arguments

h — Hypothesis test result

`1` | `0`

Hypothesis test result, returned as a logical value.

- If h = `1`, this indicates the rejection of the null hypothesis at the Alpha significance level.
- If h = `0`, this indicates a failure to reject the null hypothesis at the Alpha significance level.

p — Asymptotic *p*-value

scalar value in the range (0,1)

Asymptotic *p*-value of the test, returned as a scalar value in the range (0,1). p is the probability of observing a test statistic as extreme as, or more extreme than, the observed value under the null hypothesis. The asymptotic *p*-value becomes very accurate for large sample sizes, and is believed to be reasonably accurate for sample sizes `n1` and `n2`, such that `(n1*n2)/(n1 + n2)` ≥ 4.

`ks2stat` — Test statistic
nonnegative scalar value

Test statistic, returned as a nonnegative scalar value.

More About

Two-Sample Kolmogorov-Smirnov Test

The two-sample Kolmogorov-Smirnov test is a nonparametric hypothesis test that evaluates the difference between the cdfs of the distributions of the two sample data vectors over the range of *x* in each data set.

The two-sided test uses the maximum absolute difference between the cdfs of the distributions of the two data vectors. The test statistic is

$$D^* = \max_x\left(\left|F_1(x) - F_2(x)\right|\right),$$

where $\hat{F}_1(x)$ is the proportion of x1 values less than or equal to *x* and $\hat{F}_2(x)$ is the proportion of x2 values less than or equal to *x*.

The one-sided test uses the actual value of the difference between the cdfs of the distributions of the two data vectors rather than the absolute value. The test statistic is

$$D^* = \max_x\left(F_1(x) - F_2(x)\right).$$

Algorithms

In `kstest2`, the decision to reject the null hypothesis is based on comparing the *p*-value p with the significance level Alpha, not by comparing the test statistic ks2stat with a critical value.

`adtest` | `kstest` | `lillietest`

kurtosis

Kurtosis

Syntax

```
k = kurtosis(X)
k = kurtosis(X,flag)
k = kurtosis(X,flag,dim)
```

Description

`k = kurtosis(X)` returns the sample kurtosis of `X`. For vectors, `kurtosis(x)` is the kurtosis of the elements in the vector `x`. For matrices `kurtosis(X)` returns the sample kurtosis for each column of `X`. For N-dimensional arrays, `kurtosis` operates along the first nonsingleton dimension of `X`.

`k = kurtosis(X,flag)` specifies whether to correct for bias (`flag` is `0`) or not (`flag` is `1`, the default). When `X` represents a sample from a population, the kurtosis of `X` is biased, that is, it will tend to differ from the population kurtosis by a systematic amount that depends on the size of the sample. You can set `flag` to `0` to correct for this systematic bias.

`k = kurtosis(X,flag,dim)` takes the kurtosis along dimension `dim` of `X`.

`kurtosis` treats `NaN`s as missing values and removes them.

Examples

```
X = randn([5 4])
X =
  1.1650  1.6961  -1.4462  -0.3600
  0.6268  0.0591  -0.7012  -0.1356
  0.0751  1.7971   1.2460  -1.3493
  0.3516  0.2641  -0.6390  -1.2704
  -0.6965  0.8717  0.5774  0.9846
```

```
k = kurtosis(X)
k =
  2.1658  1.2967  1.6378  1.9589
```

More About

Algorithms

Kurtosis is a measure of how outlier-prone a distribution is. The kurtosis of the normal distribution is 3. Distributions that are more outlier-prone than the normal distribution have kurtosis greater than 3; distributions that are less outlier-prone have kurtosis less than 3.

The kurtosis of a distribution is defined as

$$k = \frac{E(x-\mu)^4}{\sigma^4}$$

where μ is the mean of x, σ is the standard deviation of x, and $E(t)$ represents the expected value of the quantity t. `kurtosis` computes a sample version of this population value.

Note Some definitions of kurtosis subtract 3 from the computed value, so that the normal distribution has kurtosis of 0. The `kurtosis` function does not use this convention.

When you set `flag` to 1, the following equation applies:

$$k_1 = \frac{\frac{1}{n}\sum_{i=1}^{n}(x_i-\bar{x})^4}{\left(\frac{1}{n}\sum_{i=1}^{n}(x_i-\bar{x})^2\right)^2}$$

When you set `flag` to 0, the following equation applies:

$$k_0 = \frac{n-1}{(n-2)(n-3)}\left((n+1)k_1 - 3(n-1)\right) + 3$$

This bias-corrected formula requires that `X` contain at least four elements.

lasso

Regularized least-squares regression using lasso or elastic net algorithms

Syntax

```
B = lasso(X,Y)
[B,FitInfo] = lasso(X,Y)
[B,FitInfo] = lasso(X,Y,Name,Value)
```

Description

`B = lasso(X,Y)` returns fitted least-squares regression coefficients for a set of regularization coefficients Lambda.

`[B,FitInfo] = lasso(X,Y)` returns a structure containing information about the fits.

`[B,FitInfo] = lasso(X,Y,Name,Value)` fits regularized regressions with additional options specified by one or more Name,Value pair arguments.

Input Arguments

`X`

Numeric matrix with `n` rows and `p` columns. Each row represents one observation, and each column represents one predictor (variable).

`Y`

Numeric vector of length `n`, where `n` is the number of rows of X. `Y(i)` is the response to row `i` of `X`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single

quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'Alpha'`

Scalar value from `0` to `1` (excluding `0`) representing the weight of lasso (L^1) versus ridge (L^2) optimization. `Alpha = 1` represents lasso regression, `Alpha` close to `0` approaches ridge regression, and other values represent elastic net optimization. See "Definitions" on page 22- .

Default: `1`

`'CV'`

Method `lasso` uses to estimate mean squared error:

- `K`, a positive integer — `lasso` uses `K`-fold cross validation.
- `cvp`, a `cvpartition` object — `lasso` uses the cross-validation method expressed in `cvp`. You cannot use a `'leaveout'` partition with `lasso`.
- `'resubstitution'` — `lasso` uses X and Y to fit the model and to estimate the mean squared error, without cross validation.

Default: `'resubstitution'`

`'DFmax'`

Maximum number of nonzero coefficients in the model. `lasso` returns results only for Lambda values that satisfy this criterion.

Default: `Inf`

`'Lambda'`

Vector of nonnegative `Lambda` values. See "Definitions" on page 22- .

- If you do not supply `Lambda`, `lasso` calculates the largest value of `Lambda` that gives a nonnull model. In this case, `LambdaRatio` gives the ratio of the smallest to the largest value of the sequence, and NumLambda gives the length of the vector.
- If you supply `Lambda`, `lasso` ignores `LambdaRatio` and NumLambda.

Default: Geometric sequence of `NumLambda` values, the largest just sufficient to produce `B = 0`

`'LambdaRatio'`

Positive scalar, the ratio of the smallest to the largest Lambda value when you do not set `Lambda`.

If you set `LambdaRatio = 0`, `lasso` generates a default sequence of `Lambda` values, and replaces the smallest one with `0`.

Default: `1e-4`

`'MCReps'`

Positive integer, the number of Monte Carlo repetitions for cross validation.

- If `CV` is `'resubstitution'` or a `cvpartition` of type `'resubstitution'`, `MCReps` must be `1`.
- If `CV` is a `cvpartition` of type `'holdout'`, `MCReps` must be greater than `1`.

Default: `1`

`'NumLambda'`

Positive integer, the number of Lambda values `lasso` uses when you do not set `Lambda`. `lasso` can return fewer than `NumLambda` fits if the if the residual error of the fits drops below a threshold fraction of the variance of `Y`.

Default: `100`

`'Options'`

Structure that specifies whether to cross validate in parallel, and specifies the random stream or streams. Create the `Options` structure with `statset`. Option fields:

- `UseParallel` — Set to `true` to compute in parallel. Default is `false`.
- `UseSubstreams` — Set to `true` to compute in parallel in a reproducible fashion. To compute reproducibly, set `Streams` to a type allowing substreams: `'mlfg6331_64'` or `'mrg32k3a'`. Default is `false`.

- `Streams` — A `RandStream` object or cell array consisting of one such object. If you do not specify `Streams`, `lasso` uses the default stream.

`'PredictorNames'`

Cell array of strings representing names of the predictor variables, in the order in which they appear in X.

Default: `{}`

`'RelTol'`

Convergence threshold for the coordinate descent algorithm (see Friedman, Tibshirani, and Hastie [3]). The algorithm terminates when successive estimates of the coefficient vector differ in the L^2 norm by a relative amount less than `RelTol`.

Default: `1e-4`

`'Standardize'`

Boolean value specifying whether `lasso` scales X before fitting the models. This affects whether the regularization is applied to the coefficients on the standardized scale or original scale. The results are always presented on the original data scale.

X and Y are always centered.

Default: `true`

`'Weights'`

Observation weights, a nonnegative vector of length `n`, where `n` is the number of rows of X. `lasso` scales `Weights` to sum to `1`.

Default: `1/n * ones(n,1)`

Output Arguments

`B`

Fitted coefficients, a `p`-by-`L` matrix, where `p` is the number of predictors (columns) in X, and `L` is the number of Lambda values.

`FitInfo`

Structure containing information about the model fits.

Field in FitInfo	Description
`Intercept`	Intercept term β_0 for each linear model, a 1-by-`L` vector
`Lambda`	Lambda parameters in ascending order, a 1-by-`L` vector
`Alpha`	Value of Alpha parameter, a scalar
`DF`	Number of nonzero coefficients in B for each value of `Lambda`, a 1-by-`L` vector
`MSE`	Mean squared error (MSE), a 1-by-`L` vector

If you set the CV name-value pair to cross validate, the `FitInfo` structure contains additional fields.

Field in FitInfo	Description
`SE`	The standard error of MSE for each `Lambda`, as calculated during cross validation, a 1-by-`L` vector
`LambdaMinMSE`	The `Lambda` value with minimum MSE, a scalar
`Lambda1SE`	The largest `Lambda` such that MSE is within one standard error of the minimum, a scalar
`IndexMinMSE`	The index of `Lambda` with value `LambdaMinMSE`, a scalar
`Index1SE`	The index of `Lambda` with value `Lambda1SE`, a scalar

Examples

Remove Redundant Predictors

Construct a data set with redundant predictors, and identify those predictors using cross-validated `lasso`.

Create a matrix `X` of 100 five-dimensional normal variables and a response vector `Y` from just two components of `X`, with small added noise.

```
X = randn(100,5);
r = [0;2;0;-3;0]; % only two nonzero coefficients
Y = X*r + randn(100,1)*.1; % small added noise
```

Construct the default lasso fit.

```
B = lasso(X,Y);
```

Find the coefficient vector for the 25th value in `B`.

```
B(:,25)
```

```
ans =

         0
    1.6093
         0
   -2.5865
         0
```

`lasso` identifies and removes the redundant predictors.

Plot a Regularized Fit with Cross Validation

Visually examine the cross-validated error of various levels of regularization.

Load the `acetylene` data and prepare the data with interactions for fitting.

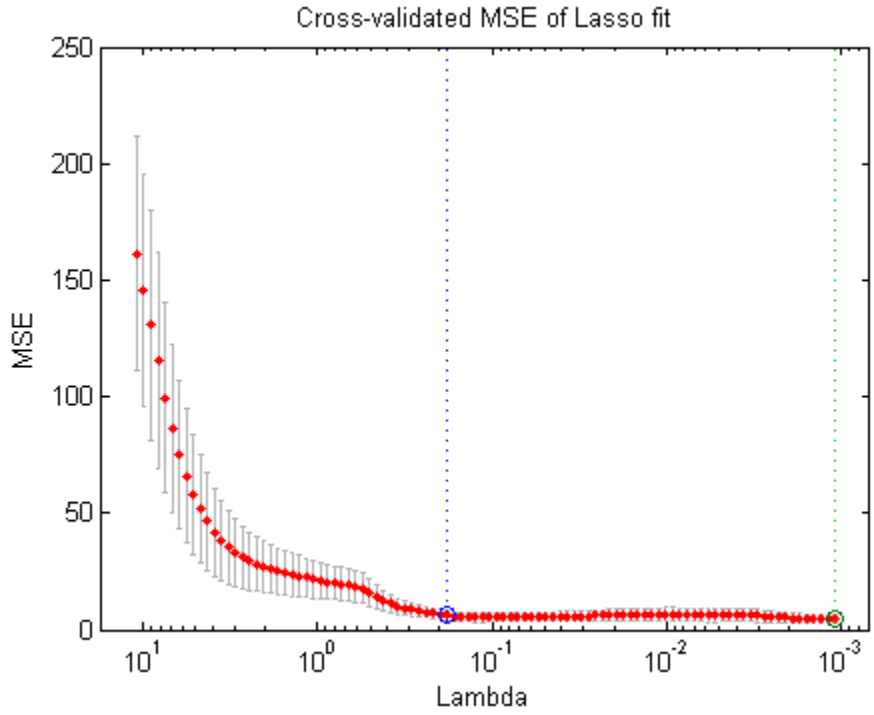
```
load acetylene
Xs = [x1 x2 x3];
X = x2fx(Xs,'interaction');
X(:,1) = []; % No constant term
```

Construct the lasso fit using ten-fold cross validation. Include the `FitInfo` output so you can plot the result.

```
[B FitInfo] = lasso(X,y,'CV',10);
```

Plot the cross-validated fits.

```
lassoPlot(B,FitInfo,'PlotType','CV');
```



More About

Lasso

For a given value of λ, a nonnegative parameter, `lasso` solves the problem

$$\min_{\beta_0,\beta}\left(\frac{1}{2N}\sum_{i=1}^{N}\left(y_i-\beta_0-x_i^T\beta\right)^2+\lambda\sum_{j=1}^{p}\left|\beta_j\right|\right),$$

where

- N is the number of observations.
- y_i is the response at observation i.

- x_i is data, a vector of p values at observation i.
- λ is a nonnegative regularization parameter corresponding to one value of Lambda.
- The parameters β_0 and β are scalar and p-vector respectively.

As λ increases, the number of nonzero components of β decreases.

The lasso problem involves the L^1 norm of β, as contrasted with the elastic net algorithm.

Elastic Net

For an α strictly between 0 and 1, and a nonnegative λ, elastic net solves the problem

$$\min_{\beta_0,\beta}\left(\frac{1}{2N}\sum_{i=1}^{N}\left(y_i-\beta_0-x_i^T\beta\right)^2+\lambda P_\alpha(\beta)\right),$$

where

$$P_\alpha(\beta)=\frac{(1-\alpha)}{2}\|\beta\|_2^2+\alpha\|\beta\|_1=\sum_{j=1}^{p}\left(\frac{(1-\alpha)}{2}\beta_j^2+\alpha\left|\beta_j\right|\right).$$

Elastic net is the same as lasso when $\alpha = 1$. As α shrinks toward 0, elastic net approaches `ridge` regression. For other values of α, the penalty term $P_\alpha(\beta)$ interpolates between the L^1 norm of β and the squared L^2 norm of β.

lassoglm

Lasso or elastic net regularization for generalized linear model regression

Syntax

```
B = lassoglm(X,Y)
[B,FitInfo] = lassoglm(X,Y)
[B,FitInfo] = lassoglm(X,Y,distr)
[B,FitInfo] = lassoglm(X,Y,distr,Name,Value)
```

Description

`B = lassoglm(X,Y)` returns penalized maximum-likelihood fitted coefficients for a generalized linear model of the response `Y` to the data matrix `X`. `Y` are assumed to have a Gaussian probability distribution.

`[B,FitInfo] = lassoglm(X,Y)` returns a structure containing information about the fits.

`[B,FitInfo] = lassoglm(X,Y,distr)` fits the model using the probability distribution type for `Y` as specified in `distr`.

`[B,FitInfo] = lassoglm(X,Y,distr,Name,Value)` fits regularized generalized linear regressions with additional options specified by one or more Name,Value pair arguments.

Input Arguments

X

Numeric matrix with `n` rows and `p` columns. Each row represents one observation, and each column represents one predictor (variable).

Y

When `distr` is not `'binomial'`, `Y` is a numeric vector or categorical array of length `n`, where `n` is the number of rows of X. `Y(i)` is the response to row `i` of `X`.

When `distr` is `'binomial'`, `Y` is either a:

- Numeric vector of length `n`, where each entry represents success (`1`) or failure (`0`)
- Logical vector of length `n`, where each entry represents success or failure
- Categorical array of length `n`, where each entry represents success or failure
- Two column numeric matrix, where the first column contains the number of successes for each observation, and the second column contains the total number of trials

`distr`

Distributional family for the nonsystematic variation in the responses, a string. Choices:

- `'normal'`
- `'binomial'`
- `'poisson'`
- `'gamma'`
- `'inverse gaussian'`

By default, `lassoglm` uses the canonical link function corresponding to `distr`. Specify another link function using the `'link'` name-value pair.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'Alpha'`

Scalar value from `0` to `1` (excluding `0`) representing the weight of lasso (L^1) versus ridge (L^2) optimization. `Alpha = 1` represents lasso regression, and other values represent elastic net optimization. `Alpha` close to `0` approaches ridge regression. See “Definitions” on page 22- .

Default: 1

`'CV'`

Method `lassoglm` uses to estimate deviance:

- K, a positive integer — lassoglm uses K-fold cross validation.
- cvp, a cvpartition object — lassoglm uses the cross-validation method expressed in cvp. You cannot use a 'leaveout' partition with lassoglm.
- 'resubstitution' — lassoglm uses X and Y to fit the model and to estimate the deviance, without cross validation.

Default: 'resubstitution'

'DFmax'

Maximum number of nonzero coefficients in the model. lassoglm returns results for Lambda values that satisfy this criterion.

Default: Inf

'Lambda'

Vector of nonnegative Lambda values. See “Lasso” on page 22-2539.

- If you do not supply Lambda, lassoglm estimates the largest value of Lambda that gives a nonnull model. In this case, LambdaRatio gives the ratio of the smallest to the largest value of the sequence, and NumLambda gives the length of the vector.
- If you supply Lambda, lassoglm ignores LambdaRatio and NumLambda.

Default: Geometric sequence of NumLambda values, the largest just sufficient to produce B = 0

'LambdaRatio'

Positive scalar, the ratio of the smallest to the largest Lambda value when you do not explicitly set Lambda.

If you set LambdaRatio = 0, lassoglm generates a default sequence of Lambda values, and replaces the smallest one with 0.

Default: 1e-4

'Link'

Specify the mapping between the mean μ of the response and the linear predictor Xb.

Value	Description
`'comploglog'`	$\log(-\log((1-\mu))) = Xb$
`'identity'`, default for the distribution `'normal'`	$\mu = Xb$
`'log'`, default for the distribution `'poisson'`	$\log(\mu) = Xb$
`'logit'`, default for the distribution `'binomial'`	$\log(\mu/(1-\mu)) = Xb$
`'loglog'`	$\log(-\log(\mu)) = Xb$
`'probit'`	$\Phi^{-1}(\mu) = Xb$, where Φ is the normal (Gaussian) CDF function
`'reciprocal'`, default for the distribution `'gamma'`	$\mu^{-1} = Xb$
`p` (a number), default for the distribution `'inverse gaussian'` (with $p = -2$)	$\mu^p = Xb$
Cell array of the form `{FL FD FI}`, containing three function handles, created using `@`, that define the link (`FL`), the derivative of the link (`FD`), and the inverse link (`FI`). Equivalently, can be a structure of function handles with field `Link` containing `FL`, field `Derivative` containing `FD`, and field `Inverse` containing `FI`.	User-specified link function (see "Custom Link Function" on page 10-16)

`'MCReps'`

Positive integer, the number of Monte Carlo repetitions for cross validation.

- If `CV` is `'resubstitution'` or a `cvpartition` of type `'resubstitution'`, `MCReps` must be `1`.
- If `CV` is a `cvpartition` of type `'holdout'`, `MCReps` must be greater than `1`.

Default: `1`

'NumLambda'

Positive integer, the number of Lambda values `lassoglm` uses when you do not set `Lambda`. `lassoglm` can return fewer than `NumLambda` fits if the deviance of the fits drops below a threshold fraction of the null deviance (deviance of the fit without any predictors `X`).

Default: `100`

'Offset'

Numeric vector with the same number of rows as `X`. `lassoglm` uses `Offset` as an additional predictor variable, but keeps its coefficient value fixed at `1.0`.

'Options'

Structure that specifies whether to cross validate in parallel, and specifies the random stream or streams. Create the `Options` structure with `statset`. Option fields:

- `UseParallel` — Set to `true` to compute in parallel. Default is `false`.
- `UseSubstreams` — Set to `true` to compute in parallel in a reproducible fashion. To compute reproducibly, set `Streams` to a type allowing substreams: `'mlfg6331_64'` or `'mrg32k3a'`. Default is `false`.
- `Streams` — `RandStream` object or cell array consisting of one such object. If you do not specify `Streams`, `lassoglm` uses the default stream.

'PredictorNames'

Cell array of strings representing names of the predictor variables, in the order in which they appear in X.

Default: `{}`

'RelTol'

Convergence threshold for the coordinate descent algorithm (see Friedman, Tibshirani, and Hastie [3]). The algorithm terminates when successive estimates of the coefficient vector differ in the L^2 norm by a relative amount less than `RelTol`.

Default: `1e-4`

`'Standardize'`

Boolean value specifying whether `lassoglm` scales X before fitting the models. This affects whether the regularization is applied to the coefficients on the standardized scale or original scale. The results are always presented on the original scale.

Default: `true`

`'Weights'`

Observation weights, a nonnegative vector of length `n`, where `n` is the number of rows of X. At least two values must be positive.

Default: `1/n * ones(n,1)`

Output Arguments

`B`

Fitted coefficients, a `p`-by-`L` matrix, where `p` is the number of predictors (columns) in X, and `L` is the number of Lambda values.

`FitInfo`

Structure containing information about the model fits.

Field in FitInfo	Description
`Alpha`	Value of Alpha parameter, a scalar.
`Deviance`	Deviance of the fitted model for each value of `Lambda`, a `1`-by-`L` vector. If cross validation was performed, the values for `Deviance` represent the estimated expected deviance of the model applied to new data, as calculated by cross validation. Otherwise, `Deviance` is the deviance of the fitted model applied to the data used to perform the fit.
`DF`	Number of nonzero coefficients in B for each `Lambda` value, a `1`-by-`L` vector.
`Intercept`	Intercept term β_0 for each linear model, a `1`-by-`L` vector.

Field in FitInfo	Description
`Lambda`	`Lambda` parameters in ascending order, a 1-by-`L` vector.

If you set the CV name-value pair to cross validate, the `FitInfo` structure contains additional fields.

Field in FitInfo	Description
`IndexMinDeviance`	Index of `Lambda` with value `LambdaMinDeviance`, a scalar.
`Index1SE`	Index of `Lambda` with value `Lambda1SE`, a scalar.
`LambdaMinDeviance`	`Lambda` value with minimum expected deviance, as calculated by cross validation, a scalar.
`Lambda1SE`	Largest `Lambda` such that `Deviance` is within one standard error of the minimum, a scalar.
`SE`	Standard error of `Deviance` for each `Lambda`, as calculated during cross validation, a 1-by-`L` vector.

Examples

Lasso Regularization of a Generalized Linear Model

Construct data from a Poisson model, and identify the important predictors using `lassoglm`.

Create data with 20 predictors, and Poisson responses using just three of the predictors, plus a constant.

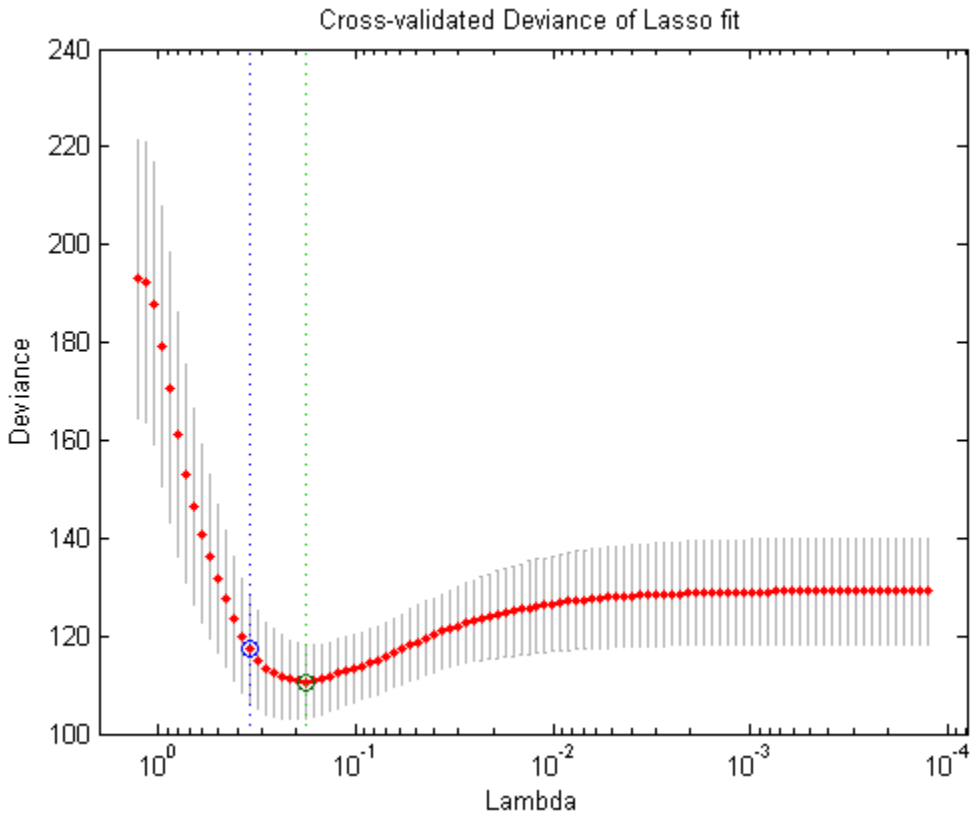
```
rng('default') % for reproducibility
X = randn(100,20);
mu = exp(X(:,[5 10 15])*[.4;.2;.3] + 1);
y = poissrnd(mu);
```

Construct a cross-validated lasso regularization of a Poisson regression model of the data.

```
[B FitInfo] = lassoglm(X,y,'poisson','CV',10);
```

Examine the cross-validation plot to see the effect of the `Lambda` regularization parameter.

```
lassoPlot(B,FitInfo,'plottype','CV');
```



The green circle and dashed line locate the `Lambda` with minimal cross-validation error. The blue circle and dashed line locate the point with minimal cross-validation error plus one standard deviation.

Find the nonzero model coefficients corresponding to the two identified points.

```
minpts = find(B(:,FitInfo.IndexMinDeviance))
```

```
minpts =

     3
     5
```

```
     6
    10
    11
    15
    16

min1pts = find(B(:,FitInfo.Index1SE))

min1pts =

     5
    10
    15
```

The coefficients from the minimal plus one standard error point are exactly those coefficients used to create the data.

- "Regularize Wide Data in Parallel" on page 10-55

More About

Link Function

A link function $f(\mu)$ maps a distribution with mean μ to a linear model with data X and coefficient vector b using the formula
$f(\mu) = Xb$.

Find the formulas for the link functions in the `Link` name-value pair description. Here, "typical" means a link function that is typically used for the listed distribution.

Distributional Family	Link Function (typical, {default})
`'normal'`	`{'identity'}`
`'binomial'`	`'comploglog'`, `'loglog'`, `'probit'`, `{'logit'}`
`'poisson'`	`{'log'}`
`'gamma'`	`{'reciprocal'}`
`'inverse gaussian'`	`{-2}`

Lasso

For a nonnegative value of λ, `lasso` solves the problem

$$\min_{\beta_0,\beta}\left(\frac{1}{N}\text{Deviance}\left(\beta_0,\beta\right)+\lambda\sum_{j=1}^{p}\left|\beta_j\right|\right),$$

where

- Deviance is the deviance of the model fit to the responses using intercept β_0 and predictor coefficients β. The formula for Deviance depends on the `distr` parameter you supply to `lassoglm`. Minimizing the λ-penalized deviance is equivalent to maximizing the λ-penalized log likelihood.
- N is the number of observations.
- λ is a nonnegative regularization parameter corresponding to one value of Lambda.
- Parameters β_0 and β are scalar and p-vector respectively.

As λ increases, the number of nonzero components of β decreases.

The lasso problem involves the L^1 norm of β, as contrasted with the elastic net algorithm.

Elastic Net

For an α strictly between 0 and 1, and a nonnegative λ, elastic net solves the problem

$$\min_{\beta_0,\beta}\left(\frac{1}{N}\text{Deviance}\left(\beta_0,\beta\right)+\lambda P_\alpha\left(\beta\right)\right),$$

where

$$P_\alpha\left(\beta\right)=\frac{(1-\alpha)}{2}\|\beta\|_2^2+\alpha\|\beta\|_1=\sum_{j=1}^{p}\left(\frac{(1-\alpha)}{2}\beta_j^2+\alpha\left|\beta_j\right|\right).$$

Elastic net is the same as lasso when $\alpha = 1$. For other values of α, the penalty term $P_\alpha(\beta)$ interpolates between the L^1 norm of β and the squared L^2 norm of β. As α shrinks toward 0, elastic net approaches `ridge` regression.

- “Lasso Regularization of Generalized Linear Models” on page 10-45

lassoPlot

Trace plot of lasso fit

Syntax

```
ax = lassoPlot(B)
ax = lassoPlot(B,FitInfo)
ax = lassoPlot(B,FitInfo,Name,Value)
[ax,figh] = lassoPlot(B,...)
```

Description

`ax = lassoPlot(B)` creates a trace plot of the values in `B` against the L^1 norm of `B`. `ax` is a handle to the plot axis.

`ax = lassoPlot(B,FitInfo)` creates a plot with type depending on the data type of `FitInfo` and the value, if any, of the plotType name-value pair.

`ax = lassoPlot(B,FitInfo,Name,Value)` creates a plot with additional options specified by one or more Name,Value pair arguments.

`[ax,figh] = lassoPlot(B,...)` returns a handle to the figure window.

Input Arguments

`B`

Coefficients of a sequence of regression fits, as returned from the `lasso` or `lassoglm` functions. `B` is a `p`-by-`NLambda` matrix, where `p` is the number of predictors, and each column of `B` is a set of coefficients `lasso` calculates using one `Lambda` penalty value.

`FitInfo`

Information controlling the plot:

- `FitInfo` is a structure, especially as returned from `lasso` or `lassoglm` — `lassoPlot` creates a plot based on the PlotType name-value pair.

- `FitInfo` is a vector — `lassoPlot` forms the *x*-axis of the plot from the values in `FitInfo`. The length of `FitInfo` must equal the number of columns of `B`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'Parent'`

Axis in which to draw the plot.

Default: New plot

`'PlotType'`

Choose the plot type when you give a FitInfo vector or structure:

FitInfo Type	PlotType	Plot
Vector or Structure	`'L1'`	`plotLasso` creates the *x*-axis from the L^1 norm of the coefficients in B. The *x*-axis at the top of the plot contains the degrees of freedom (`df`), meaning the number of nonzero coefficients of `B`.
Structure	`'Lambda'`	`plotLasso` creates the x-axis from the `Lambda` field of `FitInfo`. The x-axis at the top of the plot contains the degrees of freedom (`df`), meaning the number of nonzero coefficients of `B`.
Cross-Validated Structure	`'CV'`	• For each `Lambda`, plots an estimate of the mean squared prediction error on new data for the model fitted by `lasso` with that value of `Lambda`. • Plots error bars for the estimates. • Plots the value of `Lambda` with minimum cross-validated MSE. • Plots the greatest `Lambda` that is within one standard error of minimum MSE (so makes the sparsest model within that region).

Default: `'L1'`

`'PredictorNames'`

Cell array of strings to label each coefficient of B. If the length of `PredictorNames` is less than the number of rows of `B`, the remaining labels are padded with default values.

`lassoPlot` uses the predictor names in `FitInfo` only if:

- You created `FitInfo` with a call to `lasso` that included a `PredictorNames` name-value pair.
- You call `lassoPlot` *without* a `PredictorNames` name-value pair.
- You include `FitInfo` in your `lassoPlot` call.

Default: `{'B1','B2',...}`

`'XScale'`

- `'linear'` for linear x-axis
- `'log'` for logarithmic scaled x-axis

Default: `'linear'`, except `'log'` for the `'CV'` plot type

Output Arguments

`ax`

Handle to the axis of the plot (see "Coordinate System").

`figh`

Handle to the figure window (see "Special Object Identifiers").

Examples

Lasso Plot with Default Plot Type

Load the sample data

```
load acetylene
```

Prepare the design matrix for lasso fit with interactions.

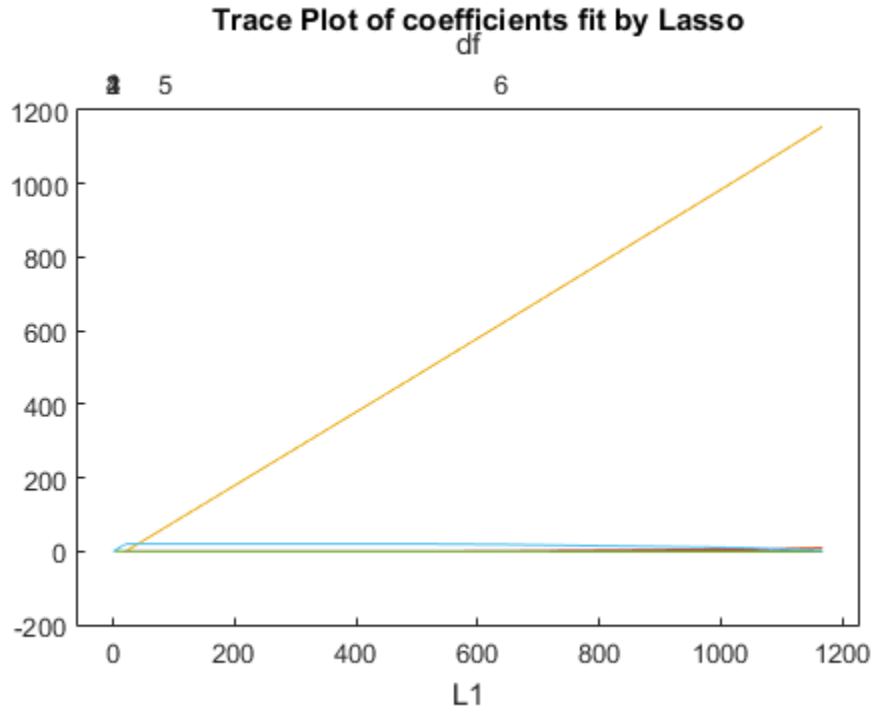
```
X = [x1 x2 x3];
D = x2fx(X,'interaction');
D(:,1) = []; % No constant term
```

Fit a regularized model of the data using `lasso` .

```
B = lasso(D,y);
```

Plot the fits with the default plot type.

```
lassoPlot(B);
```



Lasso Plot with Lambda Plot Type

Load the sample data.

```
load acetylene
```

Prepare the data for lasso fit with interactions.

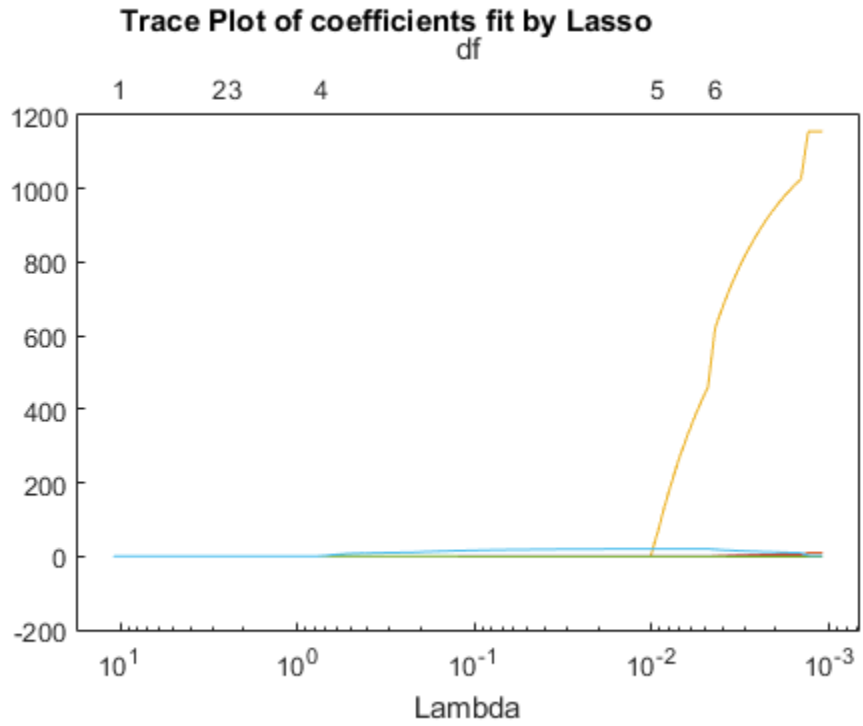
```
X = [x1 x2 x3];
D = x2fx(X,'interaction');
D(:,1) = []; % No constant term
```

Fit a regularized model of the data with `lasso` .

```
[B FitInfo] = lasso(D,y);
```

Plot the fits with the `Lambda` plot type and logarithmic scaling.

```
lassoPlot(B,FitInfo,'PlotType','Lambda','XScale','log');
```



Lasso Plot with Cross-Validated Fits

Load the sample data.

```
load acetylene
```

Prepare the design matrix for a lasso fit with interactions.

```
X = [x1 x2 x3];
D = x2fx(X,'interaction');
D(:,1) = []; % No constant term
```

Fit a regularized model of the data with `lasso` and cross validation.

```
[B FitInfo] = lasso(D,y,'CV',10);
```

Plot the cross-validated fits.

```
lassoPlot(B,FitInfo,'PlotType','CV');
```

le

Class: qrandstream

Less than or equal relation for handles

Syntax

```
h1 <= h2
```

Description

Handles are equal if they are handles for the same object. All comparisons use a number associated with each handle object. Nothing can be assumed about the result of a handle comparison except that the repeated comparison of two handles in the same MATLAB session will yield the same result. The order of handle values is purely arbitrary and has no connection to the state of the handle objects being compared.

`h1 <= h2` performs element-wise comparisons between handle arrays `h1` and `h2`. `h1` and `h2` must be of the same dimensions unless one is a scalar. The result is a logical array of the same dimensions, where each element is an element-wise `<=` result.

If one of `h1` or `h2` is scalar, scalar expansion is performed and the result will match the dimensions of the array that is not scalar.

`tf = le(h1, h2)` stores the result in a logical array of the same dimensions.

`qrandstream` | `ge` | `gt` | `ne` | `eq` | `lt`

Leap property

Class: qrandset

Interval between points

Description

Number of points to leap over and omit for each point taken from the sequence. The `Leap` property of a point set contains a positive integer which specifies the number of points in the sequence to leap over and omit for every point taken. The default `Leap` value is 0, which corresponds to taking every point from the sequence.

Leaping is a technique used to improve the quality of a point set. However, you must choose the `Leap` values with care; many `Leap` values create sequences that fail to touch on large sub-hyper-rectangles of the unit hypercube, and so fail to be a uniform quasi-random point set.

Choosing Leap Values for Halton Sets

A known rule for choosing `Leap` values for Halton sets is to set it to (`P`-1) where `P` is a prime number that has not been used to generate one of the dimensions, i.e. for a `k`-dimensional point set `P` would be the (`k`+1)th or greater prime.

Examples

Experiment with different leap values:

```
% No leaping produces the standard Halton sequence.
P = haltonset(5);
P(1:5,:)

% Set a leap of 1.  The point set now includes every other
% point from the sequence.
P.Leap = 1;
P(1:5,:)
```

length

Class: dataset

Length of dataset array

Compatibility

The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

Syntax

```
n = length(A)
```

Description

`n = length(A)` returns the number of observations in the dataset `A`. `length` is equivalent to `size(A,1)`.

See Also

`size`

length

Class: qrandset

Length of point set

Syntax

```
length(p)
```

Description

`length(p)` returns the number of points in the point set `p`. It is equivalent to `size(p, 1)`.

See Also

`qrandset` | `size`

levelcounts

Element counts by level of a nominal or ordinal array

Compatibility

The `nominal` and `ordinal` array data types might be removed in a future release. To represent ordered and unordered discrete, nonnumeric data, use the MATLAB `categorical` data type instead.

Syntax

```
C = levelcounts(A)
C = levelcounts(A,dim)
```

Description

`C = levelcounts(A)` returns counts of the number of elements in the nominal or ordinal array A equal to each of the possible levels in A into the vector C, which has as many elements as A has levels.

- If A is a matrix, then C is a matrix of column counts.
- If A is an *N*-dimensional array, `levelcounts` operates along the first nonsingleton dimension.

`C = levelcounts(A,dim)` operates along the dimension dim.

Examples

Count Observations in Each Level

Create a nominal array from string data in a cell array.

```
colors = nominal({'r','b','g';'g','r','b';'b','r','g'},...
                 {'blue','green','red'})
```

```
colors =

     red        blue      green
     green      red       blue
     blue       red       green
```

Count the number of observations of each level in each column.

```
levelcounts(colors)
```

```
ans =

     1     1     1
     1     0     2
     1     2     0
```

Count the number of observations of each level in each row.

```
levelcounts(colors,2)
```

```
ans =

     1     1     1
     1     1     1
     1     1     1
```

Alternatively, you can use `summary` to display the counts with their labels. The default is to count elements in each column.

```
summary(colors)
```

```
     blue       1      1      1
     green      1      0      2
     red        1      2      0
```

You can also count elements in each row.

```
summary(colors,2)
```

```
    blue      green      red
       1          1        1
       1          1        1
       1          1        1
```

Input Arguments

A — Nominal or ordinal array

`nominal` array | `ordinal` array

Nominal or ordinal array, specified as a `nominal` or `ordinal` array object created using `nominal` or `ordinal`.

dim — Dimension along which to count

positive integer value

Dimension along which to count the number of elements in each level, specified as a positive integer value. For example, if the dimension is `1`, then `levelcounts` counts along each column, while if the dimension is `2`, then `levelcounts` counts along each row.

Data Types: `double` | `single`

`nominal` | `ordinal` | `summary`

leverage

Leverage

Syntax

```
h = leverage(data)
h = leverage(data,model)
```

Description

`h = leverage(data)` finds the leverage of each row (point) in the matrix `data` for a linear additive regression model.

`h = leverage(data,model)` finds the leverage on a regression, using a specified model type, where *`model`* can be one of these strings:

- `'linear'` - includes constant and linear terms
- `'interaction'` - includes constant, linear, and cross product terms
- `'quadratic'` - includes interactions and squared terms
- `'purequadratic'` - includes constant, linear, and squared terms

Leverage is a measure of the influence of a given observation on a regression due to its location in the space of the inputs.

Examples

One rule of thumb is to compare the leverage to $2p/n$ where n is the number of observations and p is the number of parameters in the model. For the Hald data set this value is 0.7692.

```
load hald
h = max(leverage(ingredients,'linear'))
h =
  0.7004
```

Since 0.7004 < 0.7692, there are no high leverage points using this rule.

More About

Algorithms

```
[Q,R] = qr(x2fx(data,'model'));

leverage = (sum(Q'.*Q'))'
```

- `regstats`

lhsdesign

Latin hypercube sample

Syntax

```
X = lhsdesign(n,p)
X = lhsdesign(...,'smooth','off')
X = lhsdesign(...,'criterion',criterion)
X = lhsdesign(...,'iterations',k)
```

Description

`X = lhsdesign(n,p)` returns an *n*-by-*p* matrix, `X`, containing a latin hypercube sample of `n` values on each of `p` variables. For each column of `X`, the `n` values are randomly distributed with one from each interval `(0,1/n)`, `(1/n,2/n)`, ..., `(1-1/n,1)`, and they are randomly permuted.

`X = lhsdesign(...,'smooth','off')` produces points at the midpoints of the above intervals: `0.5/n`, `1.5/n`, ..., `1-0.5/n`. The default is `'on'`.

`X = lhsdesign(...,'criterion',criterion)` iteratively generates latin hypercube samples to find the best one according to the criterion *`criterion`*, which can be one of the following strings.

Criterion	Description
`'none'`	No iteration.
`'maximin'`	Maximize minimum distance between points. This is the default.
`'correlation'`	Reduce correlation.

`X = lhsdesign(...,'iterations',k)` iterates up to `k` times in an attempt to improve the design according to the specified criterion. The default is `k = 5`.

`haltonset` | `sobolset` | `lhsnorm` | `unifrnd`

lhsnorm

Latin hypercube sample from normal distribution

Syntax

```
X = lhsnorm(mu,sigma,n)
X = lhsnorm(mu,sigma,n,flag)
[X,Z] = lhsnorm(...)
```

Description

`X = lhsnorm(mu,sigma,n)` returns an *n*-by-*p* matrix, `X`, containing a latin hypercube sample of size `n` from a *p*-dimensional multivariate normal distribution with mean vector, `mu`, and covariance matrix, `sigma`.

`X` is similar to a random sample from the multivariate normal distribution, but the marginal distribution of each column is adjusted so that its sample marginal distribution is close to its theoretical normal distribution.

`X = lhsnorm(mu,sigma,n,flag)` controls the amount of smoothing in the sample. If `flag` is `'off'`, each column has points equally spaced on the probability scale. In other words, each column is a permutation of the values `G(0.5/n), G(1.5/n), ..., G(1-0.5/n)`, where`G` is the inverse normal cumulative distribution for that column's marginal distribution. If `flag` is `'on'` (the default), each column has points uniformly distributed on the probability scale. For example, in place of `0.5/n` you use a value having a uniform distribution on the interval `(0/n,1/n)`.

`[X,Z] = lhsnorm(...)` also returns `Z`, the original multivariate normal sample before the marginals are adjusted to obtain `X`.

lillietest

Lilliefors test

Syntax

```
h = lillietest(x)
h = lillietest(x,Name,Value)
[h,p] = lillietest( ___ )
[h,p,kstat,critval] = lillietest( ___ )
```

Description

`h = lillietest(x)` returns a test decision for the null hypothesis that the data in vector x comes from a distribution in the normal family, against the alternative that it does not come from such a distribution, using a Lilliefors test. The result h is `1` if the test rejects the null hypothesis at the 5% significance level, and `0` otherwise.

`h = lillietest(x,Name,Value)` returns a test decision with additional options specified by one or more name-value pair arguments. For example, you can test the data against a different distribution family, change the significance level, or calculate the *p*-value using a Monte Carlo approximation.

`[h,p] = lillietest( ___ )` also returns the *p*-value p, using any of the input arguments from the previous syntaxes.

`[h,p,kstat,critval] = lillietest( ___ )` also returns the test statistic kstat and the critical value critval for the test.

Examples

Test for a Normal Distribution

Load the sample data. Test the null hypothesis that car mileage, in miles per gallon (`MPG`), follows a normal distribution across different makes of cars.

```
load carbig.mat;
```

```
[h,p,k,c] = lillietest(MPG)
```

```
Warning: P is less than the smallest tabulated value, returning 0.001.
h =
 1
p =
 1.0000e-003
k =
 0.0789
c =
 0.0451
```

The test statistic `k` is greater than the critical value `c`, so `lillietest` returns a result of `h = 1` to indicate rejection of the null hypothesis at the default 5% significance level. The warning indicates that the returned *p*-value is the smallest value in the table of precomputed values. To find a more accurate *p*-value, use MCTol to run a Monte Carlo approximation.

Test the Hypothesis at Different Significance Levels

Load the sample data. Create a vector containing the first column of the students' exam grades data.

```
load examgrades;
x = grades(:,1);
```

Test the null hypothesis that the sample data comes from a normal distribution at the 1% significance level.

```
[h,p] = lillietest(x,'Alpha',0.01)
```

```
h =
 0
p =
 0.0348
```

The returned value of `h = 0` indicates that `lillietest` does not reject the null hypothesis at the 1% significance level.

Test for an Exponential Distribution

Load the sample data. Test the null hypothesis that car mileage, in miles per gallon (`MPG`), follows an exponential distribution across different makes of cars.

```
load carbig.mat;
```

```
h = lillietest(MPG,'Distr','exp')

h =
 1
```

The returned value of `h = 1` indicates that `lillietest` rejects the null hypothesis at the default 5% significance level.

Determine the *p*-value Using Monte Carlo Approximation

Load the sample data. Test the null hypothesis that car mileage, in miles per gallon (`MPG`), follows a normal distribution across different makes of cars. Determine the *p*-value using a Monte Carlo approximation with a maximum Monte Carlo standard error of `1e-4`.

```
load carbig.mat;
[h,p] = lillietest(MPG,'MCTol',1e-4)

h =
 1
p =
 0
```

The returned value of `h = 1` indicates that `lillietest` rejects the null hypothesis that the data comes from a normal distribution at the 5% significance level.

Input Arguments

x — Sample data

vector

Sample data, specified as a vector.

Data Types: `single | double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'Distr','exp','Alpha',0.01` tests the null hypothesis that the population distribution belongs to the exponential distribution family at the 1% significance level.

`'Alpha'` — Significance level

`0.05` (default) | scalar value in the range (0,1)

Significance level of the hypothesis test, specified as the comma-separated pair consisting of `'Alpha'` and a scalar value in the range (0,1).

- If MCTol is not used, Alpha must be in the range [0.001,0.50].
- If MCTol is used, Alpha must be in the range (0,1).

Example: `'Alpha',0.01`

Data Types: `single` | `double`

`'Distr'` — Distribution family

`'norm'` (default) | `'exp'` | `'ev'`

Distribution family for the hypothesis test, specified as the comma-separated pair consisting of `'Distr'` and one of the following.

`'norm'`	Normal distribution
`'exp'`	Exponential distribution
`'ev'`	Extreme value distribution

Example: `'Distr','exp'`

`'MCTol'` — Maximum Monte Carlo standard error

scalar value in the range (0,1)

Maximum Monte Carlo standard error for p, the *p*-value of the test, specified as the comma-separated pair consisting of `'MCTol'` and a scalar value in the range (0,1).

Example: `'MCTol',0.001`

Data Types: `single` | `double`

Output Arguments

`h` — Hypothesis test result

`1` | `0`

Hypothesis test result, returned as a logical value.

- If h = `1`, this indicates the rejection of the null hypothesis at the Alpha significance level.
- If h = `0`, this indicates a failure to reject the null hypothesis at the Alpha significance level.

p — *p*-value
scalar value in the range (0,1)

p-value of the test, returned as a scalar value in the range (0,1). p is the probability of observing a test statistic as extreme as, or more extreme than, the observed value under the null hypothesis. Small values of p cast doubt on the validity of the null hypothesis.

- If MCTol is not used, p is computed using inverse interpolation into the table of critical values, and is returned as a scalar value in the range [0.001,0.50]. `lillietest` warns when p is not found within the tabulated range and returns either the smallest or largest tabulated value.
- If MCTol is used, `lillietest` conducts a Monte Carlo simulation to compute a more accurate *p*-value, and p is returned as a scalar value in the range (0,1).

`kstat` — Test statistic
nonnegative scalar value

Test statistic, returned as a nonnegative scalar value.

`critval` — Critical value
nonnegative scalar value

Critical value for the hypothesis test, returned as a nonnegative scalar value.

More About

Lilliefors Test

The Lilliefors test is a two-sided goodness-of-fit test suitable when the parameters of the null distribution are unknown and must be estimated. This is in contrast to the one-sample Kolmogorov-Smirnov test, which requires the null distribution to be completely specified.

The Lilliefors test statistic is:

$$D^* = \max_x \left| F(x) - G(x) \right|,$$

where $\hat{F}(x)$ is the empirical cdf of the sample data and $G(x)$ is the cdf of the hypothesized distribution with estimated parameters equal to the sample parameters.

`lillietest` can be used to test whether the data vector x has a lognormal or Weibull distribution by applying a transformation to the data vector and running the appropriate Lilliefors test:

- To test x for a lognormal distribution, test if `log(x)` has a normal distribution.
- To test x for a Weibull distribution, test if `log(x)` has an extreme value distribution.

The Lilliefors test cannot be used when the null hypothesis is not a location-scale family of distributions.

Monte Carlo Standard Error

The Monte Carlo standard error is the error due to simulating the *p*-value.

The Monte Carlo standard error is calculated as:

$$SE = \sqrt{\frac{(\hat{p})(1-\hat{p})}{\text{mcreps}}},$$

where $\hat{p}$ is the estimated *p*-value of the hypothesis test, and `mcreps` is the number of Monte Carlo replications performed.

The number of Monte Carlo replications, `mcreps`, is determined such that the Monte Carlo standard error for $\hat{p}$ less than the value specified for MCTol.

Algorithms

To compute the critical value for the hypothesis test, `lillietest` interpolates into a table of critical values pre-computed using Monte Carlo simulation for sample sizes less than 1000 and significance levels between 0.001 and 0.50. The table used by `lillietest` is larger and more accurate than the table originally introduced by

Lilliefors. If a more accurate *p*-value is desired, or if the desired significance level is less than 0.001 or greater than 0.50, the MCTol input argument can be used to run a Monte Carlo simulation to calculate the *p*-value more exactly.

When the computed value of the test statistic is greater than the critical value, `lillietest` rejects the null hypothesis at significance level Alpha.

`lillietest` treats `NaN` values in x as missing values and ignores them.

LinearModel class

Linear regression model class

Description

An object comprising training data, model description, diagnostic information, and fitted coefficients for a linear regression. Predict model responses with the `predict` or `feval` methods.

Construction

`mdl = fitlm(tbl)` or `mdl = fitlm(X,y)` create a linear model of a table or dataset array `tbl`, or of the responses `y` to a data matrix `X`. For details, see `fitlm`.

`mdl = stepwiselm(tbl)` or `mdl = stepwiselm(X,y)` create a linear model of a table or dataset array `tbl`, or of the responses `y` to a data matrix `X`, with unimportant predictors excluded. For details, see `stepwiselm`.

Input Arguments

`tbl` — Input data

table | dataset array

Input data, specified as a table or dataset array. When modelspec is a `formula`, it specifies the variables to be used as the predictors and response. Otherwise, if you do not specify the predictor and response variables, the last variable is the response variable and the others are the predictor variables by default.

Predictor variables can be numeric, or any grouping variable type, such as logical or categorical (see “Grouping Variables” on page 2-52). The response must be numeric or logical.

To set a different column as the response variable, use the ResponseVar name-value pair argument. To use a subset of the columns as predictors, use the PredictorVars name-value pair argument.

Data Types: `single` | `double` | `logical`

X — Predictor variables

matrix

Predictor variables, specified as an n-by-p matrix, where n is the number of observations and p is the number of predictor variables. Each column of `X` represents one variable, and each row represents one observation.

By default, there is a constant term in the model, unless you explicitly remove it, so do not include a column of 1s in `X`.

Data Types: `single | double | logical`

y — Response variable

vector

Response variable, specified as an n-by-1 vector, where n is the number of observations. Each entry in `y` is the response for the corresponding row of `X`.

Data Types: `single | double`

Properties

CoefficientCovariance

Covariance matrix of coefficient estimates.

CoefficientNames

Cell array of strings containing a label for each coefficient.

Coefficients

Coefficient values stored as a table. `Coefficients` has one row for each coefficient and these columns:

- `Estimate` — Estimated coefficient value
- `SE` — Standard error of the estimate
- `tStat` — t statistic for a test that the coefficient is zero
- `pValue` — p-value for the t statistic

To obtain any of these columns as a vector, index into the property using dot notation. For example, in `mdl` the estimated coefficient vector is

```
beta = mdl.Coefficients.Estimate
```

Use `coefTest` to perform other tests on the coefficients.

`DFE`

Degrees of freedom for error (residuals), equal to the number of observations minus the number of estimated coefficients.

`Diagnostics`

Table with the same number of rows as the input data (`tbl` or `X`). `Diagnostics` contains diagnostics helpful in finding outliers and influential observations. Many diagnostics describe the effect on the fit of deleting single observations. `Diagnostics` contains the following fields.

Field	Meaning	Utility
`Leverage`	Diagonal elements of `HatMatrix`	`Leverage` indicates to what extent the predicted value for an observation is determined by the observed value for that observation. A value close to `1` indicates that the prediction is largely determined by that observation, with little contribution from the other observations. A value close to `0` indicates the fit is largely determined by the other observations. For a model with `P` coefficients and `N` observations, the average value of `Leverage` is `P/N`. An observation with `Leverage` larger than `2*P/N` can be regarded as having high leverage.
`CooksDistance`	Cook's measure of scaled change in fitted values	`CooksDistance` is a measure of scaled change in fitted values. An observation with `CooksDistance` larger than three times the mean Cook's distance can be an outlier.
`Dffits`	Delete-1 scaled differences in fitted values vs. observation number	`Dffits` is the scaled change in the fitted values for each observation that would result from excluding that observation from the fit. Values with an absolute value larger than `2*sqrt(P/N)` may be considered influential.
`S2_i`	Delete-1 variance vs. observation number	`S2_i` is a set of residual variance estimates obtained by deleting each observation in turn. These can be compared with the value of the `MSE` property.

Field	Meaning	Utility
`CovRatio`	Delete-1 ratio of determinant of covariance vs. observation number	`CovRatio` is the ratio of the determinant of the coefficient covariance matrix with each observation deleted in turn to the determinant of the covariance matrix for the full model. Values larger than `1+3*P/N` or smaller than `1-3*P/N` indicate influential points.
`Dfbetas`	Delete-1 scaled differences in covariance estimates vs. observation number	`Dfbetas` is an `N`-by-`P` matrix of the scaled change in the coefficient estimates that would result from excluding each observation in turn. Values larger than `3/sqrt(N)` in absolute value indicate that the observation has a large influence on the corresponding coefficient.
`HatMatrix`	Projection matrix to compute fitted from observed responses	`HatMatrix` is an `N`-by-`N` matrix such that `Fitted = HatMatrix*Y`, where `Y` is the response vector and `Fitted` is the vector of fitted response values.

Rows not used in the fit because of missing values (in `ObservationInfo.Missing`) contain `NaN` values.

Rows not used in the fit because of excluded values (in `ObservationInfo.Excluded`) contain `NaN` values, with the following exception: Delete-1 diagnostics refer to the statistic with and without that observation (row) included in the fit. These diagnostics help identify important observations.

`Fitted`

Predicted response to the input data by using the model. Use `predict` to compute predictions for other predictor values, or to compute confidence bounds on `Fitted`.

`Formula`

Object containing information about the model.

`LogLikelihood`

Log likelihood of the model distribution at the response values, with mean fitted from the model, and other parameters estimated as part of the model fit.

ModelCriterion

AIC and other information criteria for comparing models. A structure with fields:

- AIC — Akaike information criterion
- AICc — Akaike information criterion corrected for sample size
- BIC — Bayesian information criterion
- CAIC — Consistent Akaike information criterion

To obtain any of these values as a scalar, index into the property using dot notation. For example, in a model mdl, the AIC value aic is:

```
aic = mdl.ModelCriterion.AIC
```

MSE

Mean squared error (residuals), SSE/DFE.

NumCoefficients

Number of coefficients in the model, a positive integer. NumCoefficients includes coefficients that are set to zero when the model terms are rank deficient.

NumEstimatedCoefficients

Number of estimated coefficients in the model, a positive integer. NumEstimatedCoefficients does not include coefficients that are set to zero when the model terms are rank deficient. NumEstimatedCoefficients is the degrees of freedom for regression.

NumObservations

Number of observations the fitting function used in fitting. This is the number of observations supplied in the original table, dataset, or matrix, minus any excluded rows (set with the Excluded name-value pair) or rows with missing values.

NumPredictors

Number of variables fitlm used as predictors for fitting.

NumVariables

Number of variables in the data. NumVariables is the number of variables in the original table or dataset, or the total number of columns in the predictor matrix and

response vector when the fit is based on those arrays. It includes variables, if any, that are not used as predictors or as the response.

`ObservationInfo`

Table with the same number of rows as the input data (`tbl` or `X`).

Field	Description
`Weights`	Observation weights. Default is all `1`.
`Excluded`	Logical value, `1` indicates an observation that you excluded from the fit with the `Exclude` name-value pair.
`Missing`	Logical value, `1` indicates a missing value in the input. Missing values are not used in the fit.
`Subset`	Logical value, `1` indicates the observation is not excluded or missing, so is used in the fit.

`ObservationNames`

Cell array of strings containing the names of the observations used in the fit.

- If the fit is based on a table or dataset containing observation names, `ObservationNames` uses those names.
- Otherwise, `ObservationNames` is an empty cell array

`PredictorNames`

Cell array of strings, the names of the predictors used in fitting the model.

`Residuals`

Table of residuals, with one row for each observation and these variables.

Field	Description
`Raw`	Observed minus fitted values.
`Pearson`	Raw residuals divided by RMSE.
`Standardized`	Raw residuals divided by their estimated standard deviation.

Field	Description
`Studentized`	Residual divided by an independent estimate of the residual standard deviation. The residual for observation i is divided by an estimate of the error standard deviation based on all observations except for observation i.

To obtain any of these columns as a vector, index into the property using dot notation. For example, in a model `mdl`, the ordinary raw residual vector `r` is:

```
r = mdl.Residuals.Raw
```

Rows not used in the fit because of missing values (in `ObservationInfo.Missing`) contain `NaN` values.

Rows not used in the fit because of excluded values (in `ObservationInfo.Excluded`) contain `NaN` values, with the following exceptions:

- `raw` contains the difference between the observed and predicted values.
- `standardized` is the residual, standardized in the usual way.
- `studentized` matches the standardized values because this residual is not used in the estimate of the residual standard deviation.

`ResponseName`

String giving naming the response variable.

`RMSE`

Root mean squared error (residuals), `sqrt(MSE)`.

`Robust`

Structure that is empty unless `fitlm` constructed the model using robust regression.

Field	Description
`WgtFun`	Robust weighting function, such as `'bisquare'` (see `robustfit`)
`Tune`	Value specified for tuning parameter (can be `[]`)

Field	Description
`Weights`	Vector of weights used in final iteration of robust fit

`Rsquared`

Proportion of total sum of squares explained by the model. The ordinary R-squared value relates to the `SSR` and `SST` properties:
`Rsquared = SSR/SST = 1 - SSE/SST`.

For a linear or nonlinear model, `Rsquared` is a structure with two fields:

- `Ordinary` — Ordinary (unadjusted) R-squared
- `Adjusted` — R-squared adjusted for the number of coefficients

For a generalized linear model, `Rsquared` is a structure with five fields:

- `Ordinary` — Ordinary (unadjusted) R-squared
- `Adjusted` — R-squared adjusted for the number of coefficients
- `LLR` — Log-likelihood ratio
- `Deviance` — Deviance
- `AdjGeneralized` — Adjusted generalized R-squared

To obtain any of these values as a scalar, index into the property using dot notation. For example, the adjusted R-squared value in `mdl` is

```
r2 = mdl.Rsquared.Adjusted
```

`SSE`

Sum of squared errors (residuals).

The Pythagorean theorem implies
`SST = SSE + SSR`.

`SSR`

Regression sum of squares, the sum of squared deviations of the fitted values from their mean.

The Pythagorean theorem implies
`SST = SSE + SSR`.

SST

Total sum of squares, the sum of squared deviations of `y` from `mean(y)`.

The Pythagorean theorem implies
`SST = SSE + SSR`.

Steps

Structure that is empty unless `stepwiselm` constructed the model.

Field	Description
`Start`	Formula representing the starting model
`Lower`	Formula representing the lower bound model, these terms that must remain in the model
`Upper`	Formula representing the upper bound model, model cannot contain more terms than `Upper`
`Criterion`	Criterion used for the stepwise algorithm, such as `'sse'`
`PEnter`	Value of the parameter, such as `0.05`
`PRemove`	Value of the parameter, such as `0.10`
`History`	Table representing the steps taken in the fit

The `History` table has one row for each step including the initial fit, and the following variables (columns).

Field	Description
`Action`	Action taken during this step, one of: • `'Start'` — First step • `'Add'` — A term is added • `'Remove'` — A term is removed
`TermName`	• `'Start'` step: The starting model specification • `'Add'` or `'Remove'` steps: The term moved in that step
`Terms`	Terms matrix (see `modelspec` of `fitlm`)
`DF`	Regression degrees of freedom after this step

Field	Description
`delDF`	Change in regression degrees of freedom from previous step (negative for steps that remove a term)
`Deviance`	Deviance (residual sum of squares) at that step
`FStat`	F statistic that led to this step
`PValue`	p-value of the F statistic

`VariableInfo`

Table containing metadata about `Variables`. There is one row for each term in the model, and the following columns.

Field	Description
`Class`	String giving variable class, such as `'double'`
`Range`	Cell array giving variable range: • Continuous variable — Two-element vector `[min,max]`, the minimum and maximum values • Categorical variable — Cell array of distinct variable values
`InModel`	Logical vector, where `true` indicates the variable is in the model
`IsCategorical`	Logical vector, where `true` indicates a categorical variable

`VariableNames`

Cell array of strings containing names of the variables in the fit.

- If the fit is based on a table or dataset, this property provides the names of the variables in that table or dataset.
- If the fit is based on a predictor matrix and response vector, `VariableNames` is the values in the `VarNames` name-value pair of the fitting method.
- Otherwise the variables have the default fitting names.

`Variables`

Table containing the data, both observations and responses, that the fitting function used to construct the fit. If the fit is based on a table or dataset array, `Variables` contains

all of the data from that table or dataset array. Otherwise, `Variables` is a table created from the input data matrix `X` and response vector `y`.

Methods

addTerms	Add terms to linear regression model
anova	Analysis of variance for linear model
coefCI	Confidence intervals of coefficient estimates of linear model
coefTest	Linear hypothesis test on linear regression model coefficients
disp	Display linear regression model
dwtest	Durbin-Watson test of linear model
feval	Evaluate linear regression model prediction
fit	Create linear regression model
plot	Scatter plot or added variable plot of linear model
plotAdded	Added variable plot or leverage plot for linear model
plotAdjustedResponse	Adjusted response plot for linear regression model
plotDiagnostics	Plot diagnostics of linear regression model

plotEffects	Plot main effects of each predictor in linear regression model
plotInteraction	Plot interaction effects of two predictors in linear regression model
plotResiduals	Plot residuals of linear regression model
plotSlice	Plot of slices through fitted linear regression surface
predict	Predict response of linear regression model
random	Simulate responses for linear regression model
removeTerms	Remove terms from linear model
step	Improve linear regression model by adding or removing terms
stepwise	Create linear regression model by stepwise regression

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

Definitions

Hat Matrix

The *hat matrix H* is defined in terms of the data matrix *X*:

$H = X(X^TX)^{-1}X^T$.

The diagonal elements H_{ii} satisfy

$$0 \le h_{ii} \le 1$$
$$\sum_{i=1}^{n} h_{ii} = p,$$

where n is the number of observations (rows of X), and p is the number of coefficients in the regression model.

Leverage

The *leverage* of observation i is the value of the ith diagonal term, h_{ii}, of the hat matrix H. Because the sum of the leverage values is p (the number of coefficients in the regression model), an observation i can be considered to be an outlier if its leverage substantially exceeds p/n, where n is the number of observations.

Cook's Distance

Cook's distance is the scaled change in fitted values. Each element in `CooksDistance` is the normalized change in the vector of coefficients due to the deletion of an observation. The Cook's distance, D_i, of observation i is

$$D_i = \frac{\sum_{j=1}^{n} \left(\hat{y}_j - \hat{y}_{j(i)}\right)^2}{p\,MSE},$$

where

- $\hat{y}_j$ is the jth fitted response value.
- $\hat{y}_{j(i)}$ is the jth fitted response value, where the fit does not include observation i.
- MSE is the mean squared error.

- p is the number of coefficients in the regression model.

Cook's distance is algebraically equivalent to the following expression:

$$D_i = \frac{r_i^2}{p\,MSE}\left(\frac{h_{ii}}{(1-h_{ii})^2}\right),$$

where r_i is the ith residual, and h_{ii} is the ith leverage value.

`CooksDistance` is an n-by-1 column vector in the `Diagnostics` table of the `LinearModel` object.

Examples

Linear Regression Model of Matrix Data

Fit a linear model of the Hald data.

Load the data.

```
load hald
X = ingredients; % predictor variables
y = heat; % response
```

Fit a default linear model to the data.

```
mdl = fitlm(X,y)
```

```
mdl =

Linear regression model:
    y ~ 1 + x1 + x2 + x3 + x4

Estimated Coefficients:
                   Estimate    SE         tStat       pValue
    (Intercept)      62.405     70.071      0.8906     0.39913
    x1               1.5511    0.74477      2.0827    0.070822
    x2              0.51017    0.72379     0.70486      0.5009
    x3              0.10191    0.75471     0.13503     0.89592
    x4             -0.14406    0.70905    -0.20317     0.84407
```

```
Number of observations: 13, Error degrees of freedom: 8
Root Mean Squared Error: 2.45
R-squared: 0.982,  Adjusted R-Squared 0.974
F-statistic vs. constant model: 111, p-value = 4.76e-07
```

Linear Regression with Categorical Predictor and Nonlinear Model

Fit a model of a table that contains a categorical predictor. Use a nonlinear response formula.

Load the `carsmall` data.

```
load carsmall
```

Construct a table containing continuous predictor variable `Weight`, nominal predictor variable `Year`, and response variable `MPG`.

```
tbl = table(MPG,Weight);
tbl.Year = nominal(Model_Year);
```

Create a fitted model of `MPG` as a function of `Year`, `Weight`, and Weight^2. (You don't have to include `Weight` explicitly in your formula because it is a lower-order term of Weight^2.

```
mdl = fitlm(tbl,'MPG ~ Year + Weight^2')
```

```
mdl =

Linear regression model:
    MPG ~ 1 + Weight + Year + Weight^2

Estimated Coefficients:
                   Estimate      SE            tStat      pValue
    (Intercept)       54.206       4.7117      11.505    2.6648e-19
    Weight         -0.016404    0.0031249     -5.2493    1.0283e-06
    Year_76           2.0887      0.71491      2.9215     0.0044137
    Year_82           8.1864      0.81531      10.041    2.6364e-16
    Weight^2       1.5573e-06   4.9454e-07      3.149     0.0022303

Number of observations: 94, Error degrees of freedom: 89
Root Mean Squared Error: 2.78
R-squared: 0.885,  Adjusted R-Squared 0.88
F-statistic vs. constant model: 172, p-value = 5.52e-41
```

`fitlm` creates two dummy (indicator) variables for the nominal variate, `Year`. The dummy variable `Year_76` takes the value 1 if model year is 1976 and takes the value 0 if it is not. The dummy variable `Year_82` takes the value 1 if model year is 1982 and takes the value 0 if it is not. And the year 1970 is the reference year. The corresponding model is

$$\hat{MPG} = 54.206 - 0.0164(Weight) + 2.0887(Year\_76) + 8.1864(Year\_82) + (1.557e-06)(Weight)^2$$

Robust Linear Regression Model

Fit a linear regression model of the Hald data using robust fitting.

Load the data.

```
load hald
X = ingredients; % predictor variables
y = heat; % response
```

Fit a robust linear model to the data.

```
mdl = fitlm(X,y,'linear','RobustOpts','on')
```

```
mdl =

Linear regression model (robust fit):
    y ~ 1 + x1 + x2 + x3 + x4

Estimated Coefficients:
                   Estimate    SE         tStat       pValue
    (Intercept)       60.09     75.818     0.79256      0.4509
    x1               1.5753    0.80585      1.9548    0.086346
    x2               0.5322    0.78315     0.67957     0.51596
    x3              0.13346     0.8166     0.16343     0.87424
    x4             -0.12052     0.7672    -0.15709     0.87906

Number of observations: 13, Error degrees of freedom: 8
Root Mean Squared Error: 2.65
R-squared: 0.979,  Adjusted R-Squared 0.969
F-statistic vs. constant model: 94.6, p-value = 9.03e-07
```

- “Linear Regression Workflow” on page 9-41
- “Robust Regression versus Standard Least-Squares Fit” on page 9-128

Algorithms

The main fitting algorithm is QR decomposition. For robust fitting, the algorithm is `robustfit`.

Alternatives

To remove redundant predictors in linear regression using lasso or elastic net, use the `lasso` function.

To regularize a regression with correlated terms using ridge regression, use the `ridge` or `lasso` functions.

To regularize a regression with correlated terms using partial least squares, use the `plsregress` function.

How To

- “Linear Regression” on page 9-11

LinearMixedModel class

Linear mixed-effects model class

Description

A `LinearMixedModel` object represents a model of a response variable with fixed and random effects. It comprises data, a model description, fitted coefficients, covariance parameters, design matrices, residuals, residual plots, and other diagnostic information for a linear mixed-effects model. You can predict model responses with the `predict` function and generate random data at new design points using the `random` function.

Construction

You can fit a linear mixed-effects model using `fitlme(tbl,formula)` if your data is in a table or dataset array. Alternatively, if your model is not easily described using a formula, you can create matrices to define the fixed and random effects, and fit the model using `fitlmematrix(X,y,Z,G)`.

Input Arguments

`tbl` — Input data

table | `dataset` array

Input data, which includes the response variable, predictor variables, and grouping variables, specified as a table or `dataset` array. The predictor variables can be continuous or grouping variables (see "Grouping Variables" on page 2-52). You must specify the model for the variables using formula.

Data Types: `single` | `double` | `char` | `cell`

`formula` — Formula for model specification

string of the form `'y ~ fixed + (random1|grouping1) + ... + (randomR|groupingR)'`

Formula for model specification, specified as a string of the form `'y ~ fixed + (random1|grouping1) + ... + (randomR|groupingR)'`. For a full description, see "Formula" on page 22-2595.

Example: `'y ~ treatment +(1|block)'`

X — Fixed-effects design matrix

n-by-*p* matrix

Fixed-effects design matrix, specified as an *n*-by-*p* matrix, where *n* is the number of observations, and *p* is the number of fixed-effects predictor variables. Each row of `X` corresponds to one observation, and each column of `X` corresponds to one variable.

Data Types: `single | double`

y — Response values

n-by-1 vector

Response values, specified as an *n*-by-1 vector, where *n* is the number of observations.

Data Types: `single | double`

Z — Random-effects design

n-by-*q* matrix | cell array of *R* *n*-by-*q*(*r*) matrices, *r* = 1, 2, ..., *R*

Random-effects design, specified as either of the following.

- If there is one random-effects term in the model, then `Z` must be an *n*-by-*q* matrix, where *n* is the number of observations and *q* is the number of variables in the random-effects term.
- If there are *R* random-effects terms, then `Z` must be a cell array of length *R*. Each cell of `Z` contains an *n*-by-*q*(*r*) design matrix `Z{r}`, *r* = 1, 2, ..., *R*, corresponding to each random-effects term. Here, *q*(*r*) is the number of random effects term in the *r*th random effects design matrix, `Z{r}`.

Data Types: `single | double | cell`

G — Grouping variable or variables

n-by-1 vector | cell array of *R* *n*-by-1 vectors

Grouping variable or variables, specified as either of the following.

- If there is one random-effects term, then `G` must be an *n*-by-1 vector corresponding to a single grouping variable with *M* levels or groups.

  `G` can be a categorical vector, numeric vector, character array, or cell array of strings.

- If there are multiple random-effects terms, then `G` must be a cell array of length R. Each cell of `G` contains a grouping variable `G{r}`, $r = 1, 2, ..., R$, with $M(r)$ levels.

  `G{r}` can be a categorical vector, numeric vector, character array, or cell array of strings.

Data Types: `single | double | char | cell`

Properties

`Coefficients` — Fixed-effects coefficient estimates

dataset array

Fixed-effects coefficient estimates and related statistics, stored as a dataset array containing the following fields.

`Name`	Name of the term.
`Estimate`	Estimated value of the coefficient.
`SE`	Standard error of the coefficient.
`tStat`	t-statistics for testing the null hypothesis that the coefficient is equal to zero.
`DF`	Degrees of freedom for the t-test. Method to compute `DF` is specified by the `'DFMethod'` name-value pair argument. `Coefficients` always uses the `'Residual'` method for `'DFMethod'`.
`pValue`	p-value for the t-test.
`Lower`	Lower limit of the confidence interval for coefficient. `Coefficients` always uses the 95% confidence level, i.e.`'alpha'` is 0.05.
`Upper`	Upper limit of confidence interval for coefficient. `Coefficients` always uses the 95% confidence level, i.e.`'alpha'` is 0.05.

You can change `'DFMethod'` and `'alpha'` while computing confidence intervals for or testing hypotheses involving fixed- and random-effects, using the `coefCI` and `coefTest` methods.

`CoefficientCovariance` — Covariance of the estimated fixed-effects coefficients

p-by-p matrix

Covariance of the estimated fixed-effects coefficients of the linear mixed-effects model, stored as a p-by-p matrix, where p is the number of fixed-effects coefficients.

You can display the covariance parameters associated with the random effects using the `covarianceParameters` method.

Data Types: `double`

`CoefficientNames` — Names of the fixed-effects coefficients

1-by-p cell array of strings

Names of the fixed-effects coefficients of a linear mixed-effects model, stored as a 1-by-p cell array of strings.

Data Types: `cell`

`DFE` — Residual degrees of freedom

positive integer value

Residual degrees of freedom, stored as a positive integer value. $DFE = n - p$, where n is the number of observations, and p is the number of fixed-effects coefficients.

This corresponds to the `'Residual'` method of calculating degrees of freedom in the `fixedEffects` and `randomEffects` methods.

Data Types: `double`

`FitMethod` — Method used to fit the linear mixed-effects model

`ML | REML`

Method used to fit the linear mixed-effects model, stored as either of the following strings.

- `ML`, if the fitting method is maximum likelihood
- `REML`, if the fitting method is restricted maximum likelihood

Data Types: `char`

`Formula` — Specification of the fixed- and random-effects terms, and grouping variables

object

Specification of the fixed-effects terms, random-effects terms, and grouping variables that define the linear mixed-effects model, stored as an object.

For more information on how to specify the model to fit using a formula, see "Formula" on page 22-2595.

`LogLikelihood` — Maximized log or restricted log likelihood

scalar value

Maximized log likelihood or maximized restricted log likelihood of the fitted linear mixed-effects model depending on the fitting method you choose, stored as a scalar value.

Data Types: `double`

`ModelCriterion` — Model criterion

dataset array

Model criterion to compare fitted linear mixed-effects models, stored as a dataset array with the following columns.

`AIC`	Akaike Information Criterion
`BIC`	Bayesian Information Criterion
`Loglikelihood`	Log likelihood value of the model
`Deviance`	–2 times the log likelihood of the model

If n is the number of observations used in fitting the model, and p is the number of fixed-effects coefficients, then for calculating AIC and BIC,

- The total number of parameters is $nc + p + 1$, where nc is the total number of parameters in the random-effects covariance excluding the residual variance
- The effective number of observations is
  - n, when the fitting method is maximum likelihood (ML)
  - $n - p$, when the fitting method is restricted maximum likelihood (REML)

`MSE` — ML or REML estimate

positive scalar value

ML or REML estimate, based on the fitting method used for estimating σ^2, stored as a positive scalar value. σ^2 is the residual variance or variance of the observation error term of the linear mixed-effects model.

Data Types: `double`

`NumCoefficients` — Number of fixed-effects coefficients

positive integer value

Number of fixed-effects coefficients in the fitted linear mixed-effects model, stored as a positive integer value.

Data Types: `double`

`NumEstimatedCoefficients` — Number of estimated fixed-effects coefficients

positive integer value

Number of estimated fixed-effects coefficients in the fitted linear mixed-effects model, stored as a positive integer value.

Data Types: `double`

`NumObservations` — Number of observations

positive integer value

Number of observations used in the fit, stored as a positive integer value. This is the number of rows in the table or dataset array, or the design matrices minus the excluded rows or rows with `NaN` values.

Data Types: `double`

`NumPredictors` — Number of predictors

positive integer value

Number of variables used as predictors in the linear mixed-effects model, stored as a positive integer value.

Data Types: `double`

`NumVariables` — Total number of variables

positive integer value

Total number of variables including the response and predictors, stored as a positive integer value.

- If the sample data is in a table or dataset array `tbl`, `NumVariables` is the total number of variables in `tbl` including the response variable.

- If the fit is based on matrix input, `NumVariables` is the total number of columns in the predictor matrix or matrices, and response vector.

`NumVariables` includes variables, if there are any, that are not used as predictors or as the response.

Data Types: `double`

`ObservationInfo` — Information about the observations

table

Information about the observations used in the fit, stored as a table.

`ObservationInfo` has one row for each observation and the following four columns.

`Weights`	The value of the weighted variable for that observation. Default value is 1.
`Excluded`	`true`, if the observation was excluded from the fit using the `'Exclude'` name-value pair argument, `false`, otherwise. 1 stands for `true` and 0 stands for `false`.
`Missing`	`true`, if the observation was excluded from the fit because any response or predictor value is missing, `false`, otherwise. Missing values include `NaN` for numeric variables, empty cells for cell arrays, blank rows for character arrays, and the `<undefined>` value for categorical arrays.
`Subset`	`true`, if the observation was used in the fit, `false`, if it was not used because it is missing or excluded.

Data Types: `table`

`ObservationNames` — Names of observations

cell array of strings

Names of observations used in the fit, stored as a cell array of strings.

- If the data is in a table or dataset array, `tbl`, containing observation names, `ObservationNames` has those names.
- If the data is provided in matrices, or a table or dataset array without observation names, then `ObservationNames` is an empty cell array.

Data Types: `cell`

`PredictorNames` — Names of predictors

cell array of strings

Names of the variables that you use as predictors in the fit, stored as a cell array of strings that has the same length as `NumPredictors`.

Data Types: `cell`

`ResponseName` — Names of response variable

character string

Name of the variable used as the response variable in the fit, stored as a character string.

Data Types: `char`

`Rsquared` — Proportion of variability in the response explained by the fitted model

structure

Proportion of variability in the response explained by the fitted model, stored as a structure. It is the multiple correlation coefficient or R-squared. `Rsquared` has two fields.

`Ordinary`	R-squared value, stored as a scalar value in a structure. `Rsquared.Ordinary = 1 – SSE./SST`
`Adjusted`	R-squared value adjusted for the number of fixed-effects coefficients, stored as a scalar value in a structure. `Rsquared.Adjusted = 1 – (SSE./SST)*(DFT./DFE)`, where `DFE = n – p`, `DFT = n – 1`, and `n` is the total number of observations, `p` is the number of fixed-effects coefficients.

Data Types: `struct`

`SSE` — Error sum of squares
positive scalar value

Error sum of squares, that is, sum of the squared conditional residuals, stored as a positive scalar value.

`SSE = sum((y – F).^2)`, where `y` is the response vector, and `F` is the fitted conditional response of the linear mixed-effects model. The conditional model has contributions from both fixed and random effects.

Data Types: `double`

`SSR` — Regression sum of squares
positive scalar value

Regression sum of squares, that is, the sum of squares explained by the linear mixed-effects regression, stored as a positive scalar value. It is the sum of squared deviations of the conditional fitted values from their mean.

`SSR = sum((F – mean(F)).^2)`, where `F` is the fitted conditional response of the linear mixed-effects model. The conditional model has contributions from both fixed and random effects.

Data Types: `double`

`SST` — Total sum of squares
positive scalar value

Total sum of squares, that is, the sum of the squared deviations of the observed response values from their mean, stored as a positive scalar value.

`SST = sum((y – mean(y)).^2) = SSR + SSE`, where `y` is the response vector.

Data Types: `double`

`Variables` — Variables
table

Variables, stored as a table.

- If the fit is based on a table or dataset array `tbl`, then `Variables` is identical to `tbl`.

- If the fit is based on matrix input, then `Variables` is a table containing all the variables in the predictor matrix or matrices, and response variable.

Data Types: `table`

`VariableInfo` — Information about the variables

table

Information about the variables used in the fit, stored as a table.

`VariableInfo` has one row for each variable and contains the following four columns.

`Class`	Class of the variable (`'double'`, `'cell'`, `'nominal'`, and so on).
`Range`	Value range of the variable. • For a numerical variable, it is a two-element vector of the form `[min,max]`. • For a cell or categorical variable, it is a cell or categorical array containing all unique values of the variable.
`InModel`	`true`, if the variable is a predictor in the fitted model. `false`, if the variable is not in the fitted model.
`IsCategorical`	`true`, if the variable has a type that is treated as a categorical predictor, such as cell, logical, or categorical, or if it is specified as categorical by the `'Categorical'` name-value pair argument of the `fit` method. `false`, if it is a continuous predictor.

Data Types: `table`

`VariableNames` — Names of the variables

cell array of strings

Names of the variables used in the fit, stored as a cell array of strings.

- If sample data is in a table or dataset array `tbl`, `VariableNames` contains the names of the variables in `tbl`.
- If sample data is in matrix format, then `VariableInfo` includes variable names you supply while fitting the model. If you do not supply the variable names, then `VariableInfo` contains the default names.

Data Types: `cell`

Methods

anova	Analysis of variance for linear mixed-effects model
coefCI	Confidence intervals for coefficients of linear mixed-effects model
coefTest	Hypothesis test on fixed and random effects of linear mixed-effects model
compare	Compare linear mixed-effects models
covarianceParameters	Extract covariance parameters of linear mixed-effects model
designMatrix	Fixed- and random-effects design matrices
disp	Display linear mixed-effects model
fit	Fit linear mixed-effects model using tables
fitmatrix	Fit linear mixed-effects model using design matrices
fitted	Fitted responses from a linear mixed-effects model

fixedEffects	Estimates of fixed effects and related statistics
plotResiduals	Plot residuals of linear mixed-effects model
predict	Predict response of linear mixed-effects model
random	Generate random responses from fitted linear mixed-effects model
randomEffects	Estimates of random effects and related statistics
residuals	Residuals of fitted linear mixed-effects model
response	Response vector of the linear mixed-effects model

Definitions

Formula

In general, a formula for model specification is a string of the form `'y ~ terms'`. For the linear mixed-effects models, this formula is in the form `'y ~ fixed + (random1|grouping1) + ... + (randomR|groupingR)'`, where `fixed` and `random` contain the fixed-effects and the random-effects terms.

Suppose a table `tbl` contains the following:

- A response variable, `y`
- Predictor variables, X_j, which can be continuous or grouping variables
- Grouping variables, g_1, g_2, ..., g_R,

where the grouping variables in X_j and g_r can be categorical, logical, character arrays, or cell arrays of strings.

Then, in a formula of the form, `'y ~ fixed + (random1|g1) + ... + (randomR|gR)'`, the term `fixed` corresponds to a specification of the fixed-effects design matrix `X`, $random_1$ is a specification of the random-effects design matrix Z_1 corresponding to grouping variable g_1, and similarly $random_R$ is a specification of the random-effects design matrix Z_R corresponding to grouping variable g_R. You can express the `fixed` and `random` terms using Wilkinson notation.

Wilkinson notation describes the factors present in models. The notation relates to factors present in models, not to the multipliers (coefficients) of those factors.

Wilkinson Notation	Factors in Standard Notation
`1`	Constant (intercept) term
`X^k`, where `k` is a positive integer	`X`, X^2, ..., X^k
`X1 + X2`	`X1`, `X2`
`X1*X2`	`X1`, `X2`, `X1.*X2 (elementwise multiplication of X1 and X2)`
`X1:X2`	`X1.*X2` only
`- X2`	Do not include `X2`
`X1*X2 + X3`	`X1`, `X2`, `X3`, `X1*X2`
`X1 + X2 + X3 + X1:X2`	`X1`, `X2`, `X3`, `X1*X2`
`X1*X2*X3 - X1:X2:X3`	`X1`, `X2`, `X3`, `X1*X2`, `X1*X3`, `X2*X3`
`X1*(X2 + X3)`	`X1`, `X2`, `X3`, `X1*X2`, `X1*X3`

Statistics and Machine Learning Toolbox notation always includes a constant term unless you explicitly remove the term using `-1`. Here are some examples for linear mixed-effects model specification.

Examples:

Formula	Description
`'y ~ X1 + X2'`	Fixed effects for the intercept, `X1` and `X2`. This is equivalent to `'y ~ 1 + X1 + X2'`.

Formula	Description
`'y ~ -1 + X1 + X2'`	No intercept and fixed effects for `X1` and `X2`. The implicit intercept term is suppressed by including `-1`.
`'y ~ 1 + (1 | g1)'`	Fixed effects for the intercept plus random effect for the intercept for each level of the grouping variable `g1`.
`'y ~ X1 + (1 | g1)'`	Random intercept model with a fixed slope.
`'y ~ X1 + (X1 | g1)'`	Random intercept and slope, with possible correlation between them. This is equivalent to `'y ~ 1 + X1 + (1 + X1| g1)'`.
`'y ~ X1 + (1 | g1) + (-1 + X1 | g1)'`	Independent random effects terms for intercept and slope.
`'y ~ 1 + (1 | g1) + (1 | g2) + (1 | g1:g2)'`	Random intercept model with independent main effects for `g1` and `g2`, plus an independent interaction effect.

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

Random Intercept Model with Categorical Predictor

Load the sample data.

```
load flu
```

The `flu` dataset array has a `Date` variable, and 10 variables containing estimated influenza rates (in 9 different regions, estimated from Google searches, plus a nationwide estimate from the Center for Disease Control and Prevention, CDC).

To fit a linear-mixed effects model, your data must be in a properly formatted dataset array. To fit a linear mixed-effects model with the influenza rates as the responses

and region as the predictor variable, combine the nine columns corresponding to the regions into a tall array. The new dataset array, `flu2`, must have the response variable, `FluRate`, the nominal variable, `Region`, that shows which region each estimate is from, and the grouping variable `Date`.

```
flu2 = stack(flu,2:10,'NewDataVarName','FluRate',...
    'IndVarName','Region');
flu2.Date = nominal(flu2.Date);
```

Fit a linear mixed-effects model with fixed effects for region and a random intercept that varies by `Date`.

Because region is a nominal variable, `fitlme` takes the first region, `NE`, as the reference and creates eight dummy variables representing the other eight regions. For example, $I[MidAtl]$ is the dummy variable representing the region `MidAtl`. For details, see "Dummy Indicator Variables" on page 2-55.

The corresponding model is

$$\begin{aligned} y_{im} &= \beta_0 + \beta_1 I[MidAtl]_i + \beta_2 I[ENCentral]_i + \beta_3 I[WNCentral]_i + \beta_4 I[SAtl]_i \\ &\quad + \beta_5 I[ESCentral]_i + \beta_6 I[WSCentral]_i + \beta_7 I[Mtn]_i + \beta_8 I[Pac]_i + b_{0m} + \varepsilon_{im}, \quad m = 1,2,\ldots,52, \end{aligned}$$

where y_{im} is the observation i for level m of grouping variable `Date`, β_j, j = 0, 1, ..., 8, are the fixed-effects coefficients, b_{0m} is the random effect for level m of the grouping variable `Date`, and ε_{im} is the observation error for observation i. The random effect has the prior distribution, $b \sim N(0,\sigma^2_b)$ and the error term has the distribution, $\varepsilon \sim N(0,\sigma^2)$.

```
lme = fitlme(flu2,'FluRate ~ 1 + Region + (1|Date)')
```

```
Linear mixed-effects model fit by ML

    'Region_SAtl'             0.075481    0.052221     1.4454    459       0.14902
    'Region_ESCentral'         0.33917    0.052221      6.495    459    2.1623e-10
    'Region_WSCentral'           0.069    0.052221     1.3213    459       0.18705
    'Region_Mtn'              0.046673    0.052221    0.89377    459       0.37191
    'Region_Pac'              -0.16013    0.052221    -3.0665    459     0.0022936

Random effects covariance parameters (95% CIs):
Group: Date (52 Levels)
    Name1               Name2               Type         Estimate    Lower     Upper
    '(Intercept)'       '(Intercept)'       'std'        0.6443      0.5297    0.7836

Group: Error
    Name            Estimate    Lower      Upper
    'Res Std'       0.26627     0.24878    0.285
```

The *p*-values 7.3324e-06 and 2.1623e-10 respectively show that the fixed effects of the flu rates in regions `WNCentral` and `ESCentral` are significantly different relative to the flu rates in region `NE`.

The confidence limits for the standard deviation of the random-effects term, σ^2_b, do not include 0 (0.5297, 0.78368), which indicates that the random-effects term is significant. You can also test the significance of the random-effects terms using the `compare` method.

The estimated value of an observation is the sum of the fixed effects and the random-effect value at the grouping variable level corresponding to that observation. For example, the estimated best linear unbiased predictor (BLUP) of the flu rate for region `WNCentral` in week 10/9/2005 is

$$\begin{aligned}\hat{y}_{WNCentral,10/9/2005} &= \hat{\beta}_0 + \hat{\beta}_3 I[WNCentral] + \hat{b}_{10/9/2005} \\ &= 1.2233 + 0.23687 - 0.1718 \\ &= 1.28837.\end{aligned}$$

This is the fitted conditional response, since it includes contribution to the estimate from both the fixed and random effects. You can compute this value as follows.

```
beta = fixedEffects(lme);
[~,~,STATS] = randomEffects(lme); % Compute the random-effects statistics (STATS)
STATS.Level = nominal(STATS.Level);
y_hat = beta(1) + beta(4) + STATS.Estimate(STATS.Level=='10/9/2005')
```

```
y_hat =

    1.2884
```

You can simply display the fitted value using the `fitted` method.

```
F = fitted(lme);
F(flu2.Date == '10/9/2005' & flu2.Region == 'WNCentral')
```

```
ans =

    1.2884
```

Compute the fitted marginal response for region `WNCentral` in week 10/9/2005.

```
F = fitted(lme,'Conditional',false);
F(flu2.Date == '10/9/2005' & flu2.Region == 'WNCentral')
```

```
ans =

    1.4602
```

Linear Mixed-Effects Model with a Random Slope

Load the sample data.

```
load carbig
```

Fit a linear mixed-effects model for miles per gallon (MPG), with fixed effects for acceleration, horsepower and cylinders, and potentially correlated random effect for intercept and acceleration grouped by model year. This model corresponds to

$$MPG_{im} = \beta_0 + \beta_1 Acc_i + \beta_2 HP + b_{0m} + b_{1m} Acc_{im} + \varepsilon_{im}, \quad m = 1,2,3,$$

with the random-effects terms having the following prior distribution

$$b_m = \begin{pmatrix} b_{0m} \\ b_{1m} \end{pmatrix} \sim N\left(0, \begin{pmatrix} \sigma_0^2 & \sigma_{0,1} \\ \sigma_{0,1} & \sigma_1^2 \end{pmatrix}\right),$$

where $D(\theta)$ is the covariance matrix.

First, prepare the design matrices for fitting the linear mixed-effects model.

```
X = [ones(406,1) Acceleration Horsepower];
Z = [ones(406,1) Acceleration];
Model_Year = nominal(Model_Year);
G = Model_Year;
```

Now, fit the model using `fitlmematrix` with the defined design matrices and grouping variables. Use the `'fminunc'` optimization algorithm.

```
lme = fitlmematrix(X,MPG,Z,G,'FixedEffectPredictors',....
{'Intercept','Acceleration','Horsepower'},'RandomEffectPredictors',...
{{'Intercept','Acceleration'}},'RandomEffectGroups',{'Model_Year'},...
'FitMethod','REML')
```

```
lme =

Linear mixed-effects model fit by REML

Model information:
    Number of observations             392
    Fixed effects coefficients           3
    Random effects coefficients         26
    Covariance parameters                4

Formula:
    y ~ Intercept + Acceleration + Horsepower + (Intercept + Acceleration | Model_Year)

Model fit statistics:
    AIC       BIC       LogLikelihood    Deviance
    2202.9    2230.7    -1094.5          2188.9

Fixed effects coefficients (95% CIs):
    Name                 Estimate    SE           tStat      DF     pValue        Lowe
    'Intercept'            50.064      2.3176      21.602    389    1.4185e-68      45
    'Acceleration'        -0.57897     0.13843    -4.1825    389    3.5654e-05    -0.8
    'Horsepower'          -0.16958    0.0073242    -23.153    389    3.5289e-75    -0.1
```

```
Random effects covariance parameters (95% CIs):
Group: Model_Year (13 Levels)
    Name1                Name2                Type          Estimate    Lower      U
    'Intercept'          'Intercept'          'std'            3.72       1.5215
    'Acceleration'       'Intercept'          'corr'        -0.8769     -0.98275    -
    'Acceleration'       'Acceleration'       'std'          0.3593      0.19418

Group: Error
    Name             Estimate    Lower     Upper
    'Res Std'        3.6913      3.4331    3.9688
```

The fixed effects coefficients display includes the estimate, standard errors (`SE`), and the 95% confidence interval limits (`Lower` and `Upper`). The *p*-values for (`pValue`) indicate that all three fixed-effects coefficients are significant.

The confidence intervals for the standard deviations and the correlation between the random effects for intercept and acceleration do not include zeros, hence they seem significant. Use the `compare` method to test for the random effects.

Display the covariance matrix of the estimated fixed-effects coefficients.

```
lme.CoefficientCovariance
```

```
ans =

    5.3711   -0.2809   -0.0126
   -0.2809    0.0192    0.0005
   -0.0126    0.0005    0.0001
```

The diagonal elements show the variances of the fixed-effects coefficient estimates. For example, the variance of the estimate of the intercept is 5.3711. Note that the standard errors of the estimates are the square roots of the variances. For example, the standard error of the intercept is 2.3176, which is `sqrt(5.3711)`.

The off-diagonal elements show the correlation between the fixed-effects coefficient estimates. For example, the correlation between the intercept and acceleration is –0.2809 and the correlation between acceleration and horsepower is 0.0005.

Display the coefficient of determination for the model.

```
lme.Rsquared
```

```
ans =
```

```
    Ordinary: 0.7826
    Adjusted: 0.7815
```

The adjusted value is the R-squared value adjusted for the number of predictors in the model.

linhyptest

Linear hypothesis test

Syntax

```
p = linhyptest(beta,COVB,c,H,dfe)
[p,t,r] = linhyptest(...)
```

Description

`p = linhyptest(beta,COVB,c,H,dfe)` returns the *p* value `p` of a hypothesis test on a vector of parameters. `beta` is a vector of *k* parameter estimates. `COVB` is the *k*-by-*k* estimated covariance matrix of the parameter estimates. `c` and `H` specify the null hypothesis in the form `H*b = c`, where `b` is the vector of unknown parameters estimated by `beta`. `dfe` is the degrees of freedom for the `COVB` estimate, or `Inf` if `COVB` is known rather than estimated.

`beta` is required. The remaining arguments have default values:

- `COVB = eye(k)`
- `c = zeros(k,1)`
- `H = eye(K)`
- `dfe = Inf`

If `H` is omitted, `c` must have *k* elements and it specifies the null hypothesis values for the entire parameter vector.

Note: The following functions return outputs suitable for use as the `COVB` input argument to `linhyptest`: `nlinfit`, `coxphfit`, `glmfit`, `mnrfit`, `regstats`, `robustfit`. `nlinfit` returns `COVB` directly; the other functions return `COVB` in `stats.covb`.

`[p,t,r] = linhyptest(...)` also returns the test statistic `t` and the rank `r` of the hypothesis matrix `H`. If `dfe` is `Inf` or is not given, `t*r` is a chi-square statistic with `r`

degrees of freedom . If `dfe` is specified as a finite value, `t` is an *F* statistic with `r` and `dfe` degrees of freedom.

`linhyptest` performs a test based on an asymptotic normal distribution for the parameter estimates. It can be used after any estimation procedure for which the parameter covariances are available, such as `regstats` or `glmfit`. For linear regression, the *p*-values are exact. For other procedures, the *p*-values are approximate, and may be less accurate than other procedures such as those based on a likelihood ratio.

Examples

Fit a multiple linear model to the data in `hald.mat`:

```
load hald
stats = regstats(heat,ingredients,'linear');
beta = stats.beta
beta =
   62.4054
    1.5511
    0.5102
    0.1019
   -0.1441
```

Perform an *F*-test that the last two coefficients are both 0:

```
SIGMA = stats.covb;
dfe = stats.fstat.dfe;
H = [0 0 0 1 0;0 0 0 0 1];
c = [0;0];
[p,F] = linhyptest(beta,SIGMA,c,H,dfe)
p =
    0.4668
F =
    0.8391
```

See Also

`regstats` | `glmfit` | `robustfit` | `mnrfit` | `nlinfit` | `coxphfit`

linkage

Agglomerative hierarchical cluster tree

Syntax

```
Z = linkage(X)
Z = linkage(X,method)
Z = linkage(X,method,metric)
Z = linkage(X,method,pdist_inputs)
Z = linkage(X,method,metric,'savememory',value)
Z = linkage(Y)
Z = linkage(Y,method)
```

Description

`Z = linkage(X)` returns a matrix `Z` that encodes a tree of hierarchical clusters of the rows of the real matrix `X`.

`Z = linkage(X,method)` creates the tree using the specified *`method`*, where *`method`* describes how to measure the distance between clusters.

`Z = linkage(X,method,metric)` performs clustering using the distance measure `metric` to compute distances between the rows of `X`.

`Z = linkage(X,method,pdist_inputs)` passes parameters to the `pdist` function, which is the function that computes the distance between rows of `X`.

`Z = linkage(X,method,metric,'savememory',value)` uses a memory-saving algorithm when *`value`* is `'true'`, and uses the standard algorithm when *`value`* is `'false'`.

`Z = linkage(Y)` uses a vector representation `Y` of a distance matrix. `Y` can be a distance matrix as computed by `pdist`, or a more general dissimilarity matrix conforming to the output format of `pdist`.

`Z = linkage(Y,method)` creates the tree using the specified *`method`*, where *`method`* describes how to measure the distance between clusters.

Input Arguments

X

Matrix with two or more rows. The rows represent observations, the columns represent categories or dimensions.

method

Algorithm for computing distance between clusters.

Method	Description
`'average'`	Unweighted average distance (UPGMA)
`'centroid'`	Centroid distance (UPGMC), appropriate for Euclidean distances only
`'complete'`	Furthest distance
`'median'`	Weighted center of mass distance (WPGMC), appropriate for Euclidean distances only
`'single'`	Shortest distance
`'ward'`	Inner squared distance (minimum variance algorithm), appropriate for Euclidean distances only
`'weighted'`	Weighted average distance (WPGMA)

Default: `'single'`

metric

Any distance metric that the `pdist` function accepts.

Metric	Description
`'euclidean'`	Euclidean distance (default).
`'seuclidean'`	Standardized Euclidean distance. Each coordinate difference between rows in X is scaled by dividing by the corresponding element of the standard deviation `S=nanstd(X)`. To specify another value for `S`, use `D=pdist(X,'seuclidean',S)`.
`'cityblock'`	City block metric.

Metric	Description
`'minkowski'`	Minkowski distance. The default exponent is 2. To specify a different exponent, use `D = pdist(X,'minkowski',P)`, where `P` is a scalar positive value of the exponent.
`'chebychev'`	Chebychev distance (maximum coordinate difference).
`'mahalanobis'`	Mahalanobis distance, using the sample covariance of `X` as computed by `nancov`. To compute the distance with a different covariance, use `D = pdist(X,'mahalanobis',C)`, where the matrix `C` is symmetric and positive definite.
`'cosine'`	One minus the cosine of the included angle between points (treated as vectors).
`'correlation'`	One minus the sample correlation between points (treated as sequences of values).
`'spearman'`	One minus the sample Spearman's rank correlation between observations (treated as sequences of values).
`'hamming'`	Hamming distance, which is the percentage of coordinates that differ.
`'jaccard'`	One minus the Jaccard coefficient, which is the percentage of nonzero coordinates that differ.

custom distance function	A distance function specified using @:
	`D = pdist(X,@distfun)`
	
	A distance function must be of form
	
	`d2 = distfun(XI,XJ)`
	taking as arguments a 1-by-n vector `XI`, corresponding to a single row of `X`, and an m2-by-n matrix `XJ`, corresponding to multiple rows of `X`. `distfun` must accept a matrix `XJ` with an arbitrary number of rows. `distfun` must return an m2-by-1 vector of distances `d2`, whose kth element is the distance between `XI` and `XJ(k,:)`.

Default: `'euclidean'`

`pdist_inputs`

A cell array of parameters accepted by the `pdist` function. For example, to set the *`metric`* to `minkowski` and use an exponent of `5`, set `pdist_inputs` to `{'minkowski',5}`.

`savememory`

A string, either `'on'` or `'off'`. When applicable, the `'on'` setting causes `linkage` to construct clusters without computing the distance matrix. `savememory` is applicable when:

- `linkage` is `'centroid'`, `'median'`, or `'ward'`
- `distance` is `'euclidean'` (default)

When `savememory` is `'on'`, `linkage` run time is proportional to the number of dimensions (number of columns of `X`). When `savememory` is `'off'`, `linkage` memory requirement is proportional to N^2, where `N` is the number of observations. So choosing the best (least-time) setting for `savememory` depends on the problem dimensions, number of observations, and available memory. The default `savememory` setting is a rough approximation of an optimal setting.

Default: `'on'` when `X` has 20 columns or fewer, or the computer does not have enough memory to store the distance matrix; otherwise `'off'`

`Y`

A vector of distances with the same format as the output of the `pdist` function:

- A row vector of length $m(m–1)/2$, corresponding to pairs of observations in a matrix `X` with m rows
- Distances arranged in the order (2,1), (3,1), ..., (m,1), (3,2), ..., (m,2), ..., (m,m–1))

`Y` can be a more general dissimilarity matrix conforming to the output format of `pdist`.

Output Arguments

`Z`

`Z` is a (`m` – 1)-by-3 matrix, where `m` is the number of observations in the original data. Columns 1 and 2 of `Z` contain cluster indices linked in pairs to form a binary tree. The

leaf nodes are numbered from 1 to `m`. Leaf nodes are the singleton clusters from which all higher clusters are built. Each newly-formed cluster, corresponding to row `Z(I,:)`, is assigned the index `m+I`. `Z(I,1:2)` contains the indices of the two component clusters that form cluster `m+I`. There are `m`-1 higher clusters which correspond to the interior nodes of the clustering tree. `Z(I,3)` contains the linkage distances between the two clusters merged in row `Z(I,:)`.

For example, suppose there are 30 initial nodes and at step 12 cluster 5 and cluster 7 are combined. Suppose their distance at that time is 1.5. Then `Z(12,:)` will be `[5, 7, 1.5]`. The newly formed cluster will have index 12 + 30 = 42. If cluster 42 appears in a later row, it means the cluster created at step 12 is being combined into some larger cluster.

Examples

Compare Cluster Assignments to Clusters

Load the sample data.

```
load fisheriris
```

Compute four clusters of the Fisher iris data using Ward linkage and ignoring species information.

```
Z = linkage(meas,'ward','euclidean');
c = cluster(Z,'maxclust',4);
```

See how the cluster assignments correspond to the three species.

```
crosstab(c,species)
```

```
ans =

     0    25     1
     0    24    14
     0     1    35
    50     0     0
```

Display the first five rows of Z.

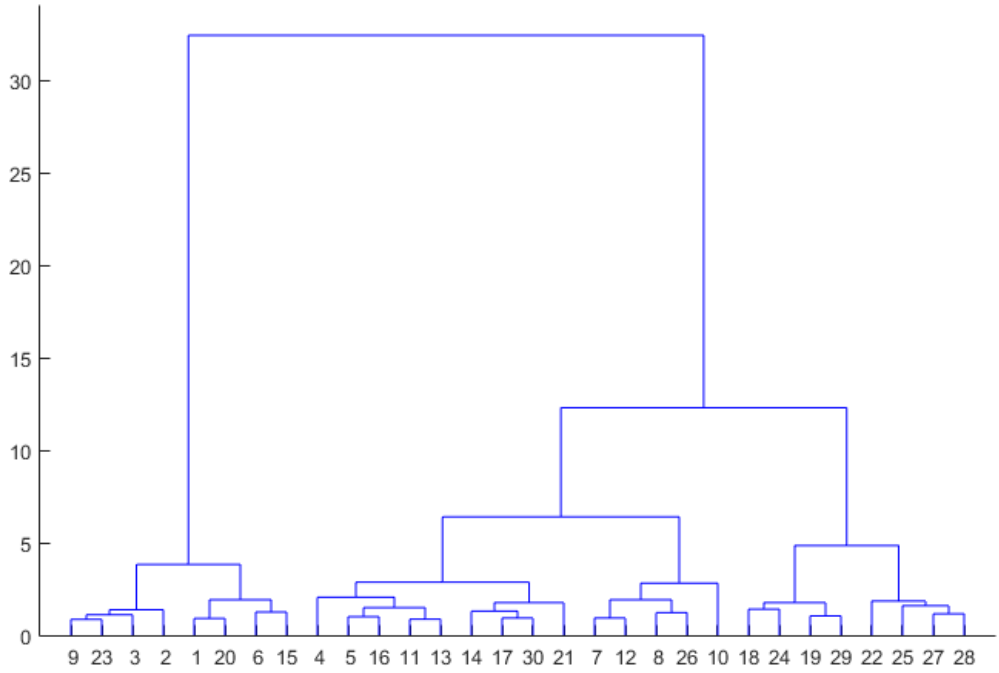
```
firstfive = Z(1:5,:)
```

```
firstfive =

  102.0000  143.0000         0
    8.0000   40.0000    0.1000
    1.0000   18.0000    0.1000
   10.0000   35.0000    0.1000
  129.0000  133.0000    0.1000
```

Create a dendrogram plot of `Z` .

```
dendrogram(Z)
```



Cluster Data and Plot the Result

Randomly generate the sample data with 20000 observations.

```
rng default; % For reproducibility
X = rand(20000,3);
```

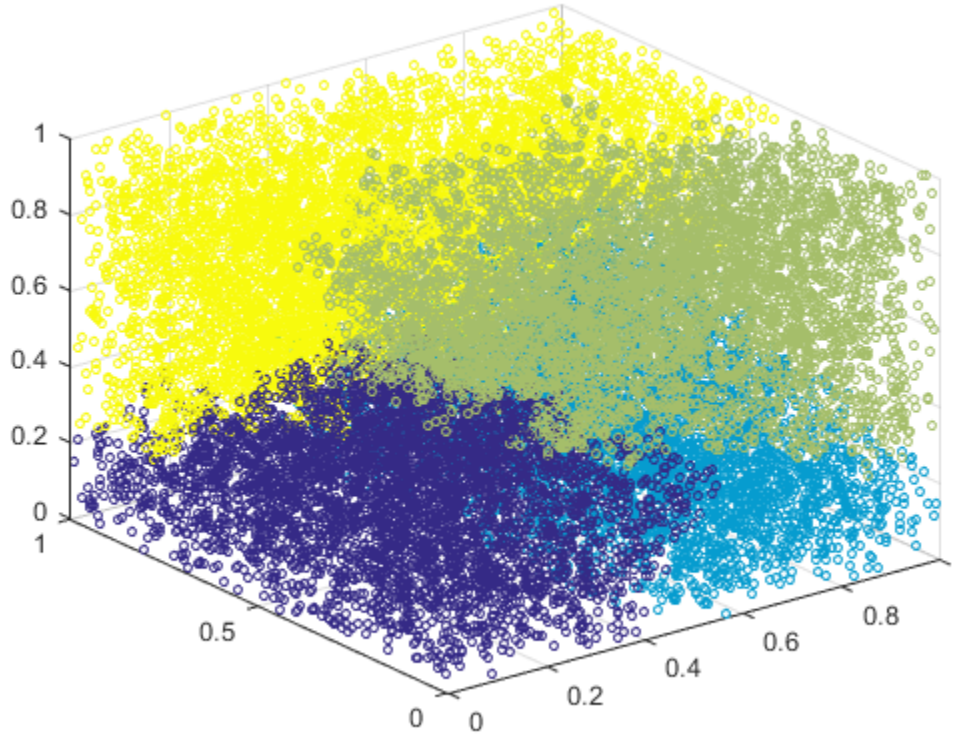
Create a hierarchical cluster tree using Ward's linkage.

```
Z = linkage(X,'ward','euclidean','savememory','on');
```

If you set `savememory` to `'off'` , you can get an out-of-memory error if your machine doesn't have enough memory to hold the distance matrix.

Cluster data into four groups and plot the result.

```
c = cluster(Z,'maxclust',4);
scatter3(X(:,1),X(:,2),X(:,3),10,c)
```



More About

Linkages

The following notation is used to describe the linkages used by the various methods:

- Cluster `r` is formed from clusters `p` and `q`.
- n_r is the number of objects in cluster r.
- x_{ri} is the `i`th object in cluster `r`.
- *Single linkage*, also called *nearest neighbor*, uses the smallest distance between objects in the two clusters:

$$d(r,s) = \min(dist(x_{ri}, x_{sj})), i \in (i,\ldots,n_r), j \in (1,\ldots,n_s)$$

- *Complete linkage*, also called *furthest neighbor*, uses the largest distance between objects in the two clusters:

$$d(r,s) = \max(dist(x_{ri}, x_{sj})), i \in (1,\ldots,n_r), j \in (1,\ldots,n_s)$$

- *Average linkage* uses the average distance between all pairs of objects in any two clusters:

$$d(r,s) = \frac{1}{n_r n_s} \sum_{i=1}^{n_r} \sum_{j=1}^{n_s} dist(x_{ri}, x_{sj})$$

- *Centroid linkage* uses the Euclidean distance between the centroids of the two clusters:

$$d(r,s) = \left\| \bar{x}_r - \bar{x}_s \right\|_2$$

where

$$\bar{x}_r = \frac{1}{n_r} \sum_{i=1}^{n_r} x_{ri}$$

- *Median linkage* uses the Euclidean distance between weighted centroids of the two clusters,

$$d(r,s) = \left\| \tilde{x}_r - \tilde{x}_s \right\|_2$$

where $\tilde{x}_r$ and $\tilde{x}_s$ are weighted centroids for the clusters *r* and *s*. If cluster *r* was created by combining clusters *p* and *q*, $\tilde{x}_r$ is defined recursively as

$$\tilde{x}_r = \frac{1}{2}(\tilde{x}_p + \tilde{x}_q)$$

- *Ward's linkage* uses the incremental sum of squares; that is, the increase in the total within-cluster sum of squares as a result of joining two clusters. The within-cluster

sum of squares is defined as the sum of the squares of the distances between all objects in the cluster and the centroid of the cluster. The sum of squares measure is equivalent to the following distance measure $d(r,s)$, which is the formula `linkage` uses:

$$d(r,s) = \sqrt{\frac{2n_r n_s}{(n_r + n_s)}} \left\| \bar{x}_r - \bar{x}_s \right\|_2,$$

where

- $\| \ \|_2$ is Euclidean distance
- $\bar{x}_r$ and $\bar{x}_s$ are the centroids of clusters r and s
- n_r and n_s are the number of elements in clusters r and s

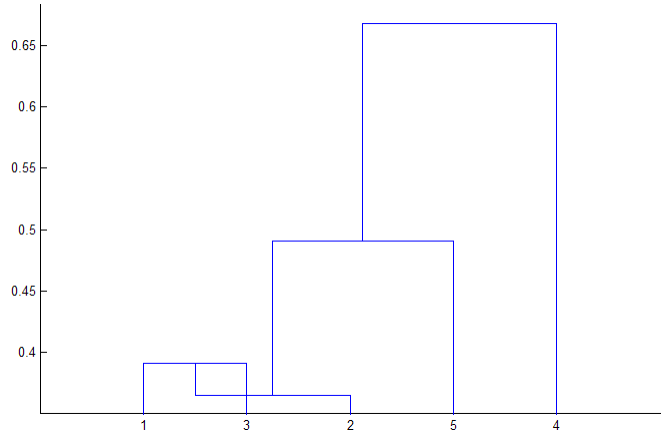
In some references the Ward linkage does not use the factor of 2 multiplying $n_r n_s$. The `linkage` function uses this factor so the distance between two singleton clusters is the same as the Euclidean distance.

- *Weighted average linkage* uses a recursive definition for the distance between two clusters. If cluster r was created by combining clusters p and q, the distance between r and another cluster s is defined as the average of the distance between p and s and the distance between q and s:

$$d(r,s) = \frac{\left(d(p,s) + d(q,s)\right)}{2}$$

Tips

- Computing `linkage(Y)` can be slow when `Y` is a vector representation of the distance matrix. For the `'centroid'`, `'median'`, and `'ward'` methods, `linkage` checks whether `Y` is a Euclidean distance. Avoid this time-consuming check by passing in `X` instead of `Y`.
- The `centroid` and `median` methods can produce a cluster tree that is not monotonic. This occurs when the distance from the union of two clusters, r and s, to a third cluster is less than the distance between r and s. In this case, in a dendrogram drawn with the default orientation, the path from a leaf to the root node takes some downward steps. To avoid this, use another method. The following image shows a nonmonotonic cluster tree.



In this case, cluster 1 and cluster 3 are joined into a new cluster, while the distance between this new cluster and cluster 2 is less than the distance between cluster 1 and cluster 3. This leads to a nonmonotonic tree.

- You can provide the output `Z` to other functions including `dendrogram` to display the tree, `cluster` to assign points to clusters, `inconsistent` to compute inconsistent measures, and `cophenet` to compute the cophenetic correlation coefficient.

prob.LogisticDistribution class

Package: prob
Superclasses: prob.ToolboxFittableParametricDistribution

Logistic probability distribution object

Description

`prob.LogisticDistribution` is an object consisting of parameters, a model description, and sample data for a logistic probability distribution.

Create a probability distribution object with specified parameter values using `makedist`. Alternatively, fit a distribution to data using `fitdist` or the Distribution Fitting app.

Construction

`pd = makedist('Logistic')` creates a logistic probability distribution object using the default parameter values.

`pd = makedist('Logistic','mu',mu,'sigma',sigma)` creates a logistic probability distribution object using the specified parameter values.

Input Arguments

`mu` — Mean

0 (default) | scalar value

Mean of the logistic distribution, specified as a scalar value.

Data Types: `single` | `double`

`sigma` — Scale parameter

1 (default) | nonnegative scalar value

Scale parameter of the logistic distribution, specified as a nonnegative scalar value.

Data Types: `single` | `double`

Properties

`mu` — Mean

scalar value

Mean of the logistic distribution, stored as a scalar value.

Data Types: `single` | `double`

`sigma` — Scale parameter

nonnegative scalar value

Scale parameter of the logistic distribution, stored as a nonnegative scalar value.

Data Types: `single` | `double`

`DistributionName` — Probability distribution name

probability distribution name string

Probability distribution name, stored as a valid probability distribution name string. This property is read-only.

Data Types: `char`

`InputData` — Data used for distribution fitting

structure

Data used for distribution fitting, stored as a structure containing the following:

- `data`: Data vector used for distribution fitting.
- `cens`: Censoring vector, or empty if none.
- `freq`: Frequency vector, or empty if none.

This property is read-only.

Data Types: `struct`

`IsTruncated` — Logical flag for truncated distribution

`0` | `1`

Logical flag for truncated distribution, stored as a logical value. If `IsTruncated` equals `0`, the distribution is not truncated. If `IsTruncated` equals `1`, the distribution is truncated. This property is read-only.

Data Types: `logical`

`NumParameters` — Number of parameters

positive integer value

Number of parameters for the probability distribution, stored as a positive integer value. This property is read-only.

Data Types: `single | double`

`ParameterCovariance` — Covariance matrix of the parameter estimates

matrix of scalar values

Covariance matrix of the parameter estimates, stored as a p-by-p matrix, where p is the number of parameters in the distribution. The (`i`,`j`) element is the covariance between the estimates of the `i`th parameter and the `j`th parameter. The (`i`,`i`) element is the estimated variance of the `i`th parameter. If parameter `i` is fixed rather than estimated by fitting the distribution to data, then the (`i`,`i`) elements of the covariance matrix are 0. This property is read-only.

Data Types: `single | double`

`ParameterDescription` — Distribution parameter descriptions

cell array of strings

Distribution parameter descriptions, stored as a cell array of strings. Each cell contains a short description of one distribution parameter. This property is read-only.

Data Types: `char`

`ParameterIsFixed` — Logical flag for fixed parameters

array of logical values

Logical flag for fixed parameters, stored as an array of logical values. If `0`, the corresponding parameter in the `ParameterNames` array is not fixed. If `1`, the corresponding parameter in the `ParameterNames` array is fixed. This property is read-only.

Data Types: `logical`

`ParameterNames` — Distribution parameter names

cell array of strings

Distribution parameter names, stored as a cell array of strings. This property is read-only.

Data Types: `char`

`ParameterValues` — Distribution parameter values
vector of scalar values

Distribution parameter values, stored as a vector. This property is read-only.

Data Types: `single | double`

`Truncation` — Truncation interval
vector of scalar values

Truncation interval for the probability distribution, stored as a vector containing the lower and upper truncation boundaries. This property is read-only.

Data Types: `single | double`

Definitions

Logistic Distribution

The logistic distribution is used for growth models and in logistic regression. It has longer tails and a higher kurtosis than the normal distribution.

The logistic distribution uses the following parameters.

Parameter	Description	Support
`mu`	Mean	$-\infty < \mu < \infty$
`sigma`	Scale parameter	$\sigma \geq 0$

The probability density function (pdf) is

$$f(x \mid \mu,\sigma) = \frac{\exp\left\{\frac{x-\mu}{\sigma}\right\}}{\sigma\left(1+\exp\left\{\frac{x-\mu}{\sigma}\right\}\right)^2} \quad ; \quad -\infty < x < \infty.$$

Examples

Create a Logistic Distribution Object Using Default Parameters

Create a logistic distribution object using the default parameter values.

```
pd = makedist('Logistic')
```

```
pd =

  LogisticDistribution

  Logistic distribution
       mu = 0
    sigma = 1
```

Create a Logistic Distribution Object Using Specified Parameters

Create a logistic distribution object by specifying parameter values.

```
pd = makedist('Logistic', 'mu',2,'sigma',4)
```

```
pd =

  LogisticDistribution

  Logistic distribution
       mu = 2
    sigma = 4
```

Compute the standard deviation of the distribution.

```
s = std(pd)
```

```
s =
```

```
    7.2552
```

Loglogistic probability distribution object

Description

`prob.LoglogisticDistribution` is an object consisting of parameters, a model description, and sample data for a loglogistic probability distribution.

Create a probability distribution object with specified parameter values using `makedist`. Alternatively, fit a distribution to data using `fitdist` or the Distribution Fitting app.

Construction

`pd = makedist('Loglogistic')` creates a loglogistic probability distribution object using the default parameter values.

`pd = makedist('Loglogistic','mu',mu,'sigma',sigma)` creates a loglogistic probability distribution object using the specified parameter values .

Input Arguments

`mu` — Log mean

0 (default) | positive scalar value

Log mean for the loglogistic distribution, specified as a positive scalar value.

Data Types: `single` | `double`

`sigma` — Log scale parameter

1 (default) | positive scalar value

Log scale parameter for the loglogistic distribution, specified as a positive scalar value.

Data Types: `single` | `double`

Properties

`mu` — Log mean

positive scalar value

Log mean for the loglogistic distribution, stored as a positive scalar value.

Data Types: `single` | `double`

`sigma` — Log scale parameter

positive scalar value

Log scale parameter for the loglogistic distribution, stored as a positive scalar value.

Data Types: `single` | `double`

`DistributionName` — Probability distribution name

probability distribution name string

Probability distribution name, stored as a valid probability distribution name string. This property is read-only.

Data Types: `char`

`InputData` — Data used for distribution fitting

structure

Data used for distribution fitting, stored as a structure containing the following:

- `freq`: Frequency vector, or empty if none.

This property is read-only.

Data Types: `struct`

`IsTruncated` — Logical flag for truncated distribution

`0` | `1`

Logical flag for truncated distribution, stored as a logical value. If `IsTruncated` equals `0`, the distribution is not truncated. If `IsTruncated` equals `1`, the distribution is truncated. This property is read-only.

Data Types: `logical`

`NumParameters` — Number of parameters

positive integer value

Number of parameters for the probability distribution, stored as a positive integer value. This property is read-only.

Data Types: `single | double`

`ParameterCovariance` — Covariance matrix of the parameter estimates

matrix of scalar values

Covariance matrix of the parameter estimates, stored as a p-by-p matrix, where p is the number of parameters in the distribution. The (`i`,`j`) element is the covariance between the estimates of the `i`th parameter and the `j`th parameter. The (`i`,`i`) element is the estimated variance of the `i`th parameter. If parameter `i` is fixed rather than estimated by fitting the distribution to data, then the (`i`,`i`) elements of the covariance matrix are 0. This property is read-only.

Data Types: `single | double`

`ParameterDescription` — Distribution parameter descriptions

cell array of strings

Distribution parameter descriptions, stored as a cell array of strings. Each cell contains a short description of one distribution parameter. This property is read-only.

Data Types: `char`

`ParameterIsFixed` — Logical flag for fixed parameters

array of logical values

Logical flag for fixed parameters, stored as an array of logical values. If `0`, the corresponding parameter in the `ParameterNames` array is not fixed. If `1`, the corresponding parameter in the `ParameterNames` array is fixed. This property is read-only.

Data Types: `logical`

`ParameterNames` — Distribution parameter names

cell array of strings

Distribution parameter names, stored as a cell array of strings. This property is read-only.

Data Types: `char`

`ParameterValues` — Distribution parameter values
vector of scalar values

Distribution parameter values, stored as a vector. This property is read-only.

Data Types: `single | double`

`Truncation` — Truncation interval
vector of scalar values

Truncation interval for the probability distribution, stored as a vector containing the lower and upper truncation boundaries. This property is read-only.

Data Types: `single | double`

Definitions

Loglogistic Distribution

The loglogistic distribution is closely related to the logistic distribution. If x is distributed loglogistically with parameters μ and σ, then $\log(x)$ is distributed logistically with mean and standard deviation. This distribution is often used in survival analysis to model events that experience an initial rate increase, followed by a rate decrease.

The loglogistic distribution uses the following parameters.

Parameter	Description	Support
`mu`	Log mean	$\mu > 0$
`sigma`	Log scale parameter	$\sigma > 0$

The probability density function (pdf) is

$$f(x \mid \mu,\sigma) = \frac{1}{\sigma}\frac{1}{x}\frac{e^z}{\left(1+e^z\right)^2} \quad ; \quad x \geq 0,$$

where $z = \dfrac{\log(x)-\mu}{\sigma}$.

Examples

Create a Loglogistic Distribution Object Using Default Parameters

Create a loglogistic distribution object using the default parameter values.

```
pd = makedist('Loglogistic')
```

```
pd =

  LoglogisticDistribution

  Log-Logistic distribution
       mu = 0
    sigma = 1
```

Create a Loglogistic Distribution Object Using Specified Parameters

Create a loglogistic distribution object by specifying the parameter values.

```
pd = makedist('Loglogistic','mu',5,'sigma',2)
```

```
pd =

  LoglogisticDistribution

  Log-Logistic distribution
       mu = 5
    sigma = 2
```

Generate random numbers from the loglogistic distribution and compute their log values.

```
rng(19) % for reproducibility
x = random(pd,10000,1);
logx = log(x);
```

Compute the mean of the log values.

```
m = mean(logx)
```

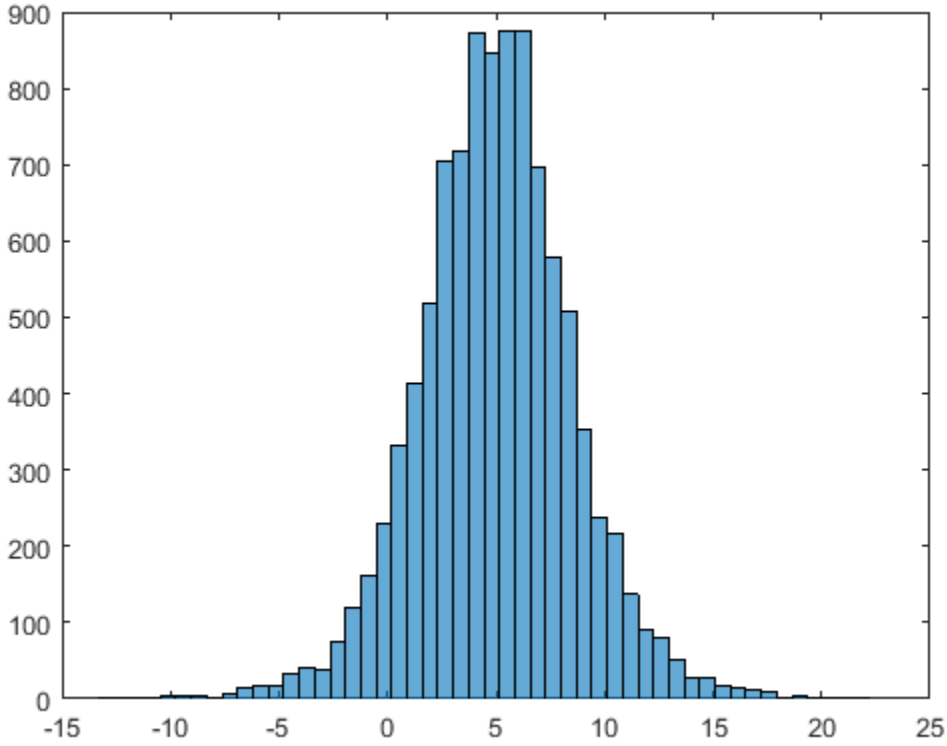
```
m =

    4.9828
```

The mean of the log of `x` is equal to the `mu` parameter of `x`, since `x` has a loglogistic distribution.

Plot `logx`.

```
histogram(logx,50)
```



The plot shows that the log values of `x` have a logistic distribution.

- "Loglogistic Distribution"
- Class Attributes
- Property Attributes

logncdf

Lognormal cumulative distribution function

Syntax

```
p = logncdf(x,mu,sigma)
[p,plo,pup] = logncdf(x,mu,sigma,pcov,alpha)
[p,plo,pup] = logncdf( ___ ,'upper')
```

Description

`p = logncdf(x,mu,sigma)` returns values at `x` of the lognormal cdf with distribution parameters `mu` and `sigma`. `mu` and `sigma` are the mean and standard deviation, respectively, of the associated normal distribution. `x`, `mu`, and `sigma` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input for `x`, `mu`, or `sigma` is expanded to a constant array with the same dimensions as the other inputs.

`[p,plo,pup] = logncdf(x,mu,sigma,pcov,alpha)` returns confidence bounds for `p` when the input parameters `mu` and `sigma` are estimates. `pcov` is the covariance matrix of the estimated `parameters`. `alpha` specifies 100(1 - `alpha`)% confidence bounds. The default value of `alpha` is 0.05. `plo` and `pup` are arrays of the same size as `p` containing the lower and upper confidence bounds.

`[p,plo,pup] = logncdf( ___ ,'upper')` returns the complement of the lognormal cdf at each value in `x`, using an algorithm that more accurately computes the extreme upper tail probabilities. You can use `'upper'` with any of the previous syntaxes.

`logncdf` computes confidence bounds for `p` using a normal approximation to the distribution of the estimate

$$\frac{x-\hat{\mu}}{\hat{\sigma}}$$

and then transforming those bounds to the scale of the output `p`. The computed bounds give approximately the desired confidence level when you estimate `mu`, `sigma`, and `pcov`

from large samples, but in smaller samples other methods of computing the confidence bounds might be more accurate.

The lognormal cdf is

$$p = F(x \mid \mu, \sigma) = \frac{1}{\sigma\sqrt{2\pi}} \int_0^x \frac{e^{\frac{-(\ln(t)-\mu)^2}{2\sigma^2}}}{t} dt$$

Examples

Compute the Lognormal Distribution cdf

Compute the cdf of a lognormal distribution with `mu = 0` and `sigma = 1`.

```
x = (0:0.2:10);
y = logncdf(x,0,1);
```

Plot the cdf.

```
plot(x,y);
grid;
xlabel('x');
ylabel('p');
```

cdf | lognpdf | logninv | lognstat | lognfit | lognlike | lognrnd

lognfit

Lognormal parameter estimates

Syntax

```
parmhat = lognfit(data)
[parmhat,parmci] = lognfit(data)
[parmhat,parmci] = lognfit(data,alpha)
[...] = lognfit(data,alpha,censoring)
[...] = lognfit(data,alpha,censoring,freq)
[...] = lognfit(data,alpha,censoring,freq,options)
```

Description

`parmhat = lognfit(data)` returns a vector of maximum likelihood estimates `parmhat(1) = mu` and `parmhat(2) = sigma` of parameters for a lognormal distribution fitting `data`. `mu` and `sigma` are the mean and standard deviation, respectively, of the associated normal distribution.

`[parmhat,parmci] = lognfit(data)` returns 95% confidence intervals for the parameter estimates `mu` and `sigma` in the 2-by-2 matrix `parmci`. The first column of the matrix contains the lower and upper confidence bounds for parameter `mu`, and the second column contains the confidence bounds for parameter `sigma`.

`[parmhat,parmci] = lognfit(data,alpha)` returns 100(1 - `alpha`) % confidence intervals for the parameter estimates, where `alpha` is a value in the range `(0 1)` specifying the width of the confidence intervals. By default, `alpha` is `0.05`, which corresponds to 95% confidence intervals.

`[...] = lognfit(data,alpha,censoring)` accepts a Boolean vector `censoring`, of the same size as `data`, which is 1 for observations that are right-censored and 0 for observations that are observed exactly.

`[...] = lognfit(data,alpha,censoring,freq)` accepts a frequency vector, `freq`, of the same size as `data`. Typically, `freq` contains integer frequencies for the corresponding elements in `data`, but can contain any nonnegative values. Pass in `[]` for `alpha`, `censoring`, or `freq` to use their default values.

`[...] = lognfit(data,alpha,censoring,freq,options)` accepts a structure, `options`, that specifies control parameters for the iterative algorithm the function uses to compute maximum likelihood estimates when there is censoring. The lognormal fit function accepts an `options` structure which can be created using the function `statset`. Enter `statset('lognfit')` to see the names and default values of the parameters that `lognfit` accepts in the `options` structure. See the reference page for `statset` for more information about these options.

Note: With no censoring, `lognfit` computes `sigma` using the square root of the unbiased estimator of the variance. With censoring, `sigma` is the maximum likelihood estimate.

Examples

This example generates 100 independent samples of lognormally distributed data with $\mu = 0$ and $\sigma = 3$. `parmhat` estimates μ and σ and `parmci` gives 99% confidence intervals around `parmhat`. Notice that `parmci` contains the true values of μ and σ.

```
data = lognrnd(0,3,100,1);
[parmhat,parmci] = lognfit(data,0.01)
parmhat =
  -0.2480  2.8902
parmci =
  -1.0071  2.4393
   0.5111  3.5262
```

More About

- “Lognormal Distribution” on page B-95

See Also

`mle` | `lognlike` | `lognpdf` | `logncdf` | `logninv` | `lognstat` | `lognrnd`

logninv

Lognormal inverse cumulative distribution function

Syntax

```
X = logninv(P,mu,sigma)
[X,XLO,XUP] = logninv(P,mu,sigma,pcov,alpha)
```

Description

`X = logninv(P,mu,sigma)` returns values at `P` of the inverse lognormal cdf with distribution parameters `mu` and `sigma`. `mu` and `sigma` are the mean and standard deviation, respectively, of the associated normal distribution. `mu` and `sigma` can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of `X`. A scalar input for `P`, `mu`, or `sigma` is expanded to a constant array with the same dimensions as the other inputs.

`[X,XLO,XUP] = logninv(P,mu,sigma,pcov,alpha)` returns confidence bounds for `X` when the input parameters `mu` and `sigma` are estimates. `pcov` is the covariance matrix of the estimated parameters. `alpha` specifies 100(1 - `alpha`)% confidence bounds. The default value of `alpha` is 0.05. `XLO` and `XUP` are arrays of the same size as `X` containing the lower and upper confidence bounds.

`logninv` computes confidence bounds for `P` using a normal approximation to the distribution of the estimate

$$\hat{\mu} + \hat{\sigma} q$$

where q is the `P`th quantile from a normal distribution with mean 0 and standard deviation 1. The computed bounds give approximately the desired confidence level when you estimate `mu`, `sigma`, and `pcov` from large samples, but in smaller samples other methods of computing the confidence bounds might be more accurate.

The lognormal inverse function is defined in terms of the lognormal cdf as

$$x = F^{-1}(p \mid \mu,\sigma) = \{x : F(x \mid \mu,\sigma) = p\}$$

where

$$p = F(x \mid \mu,\sigma) = \frac{1}{\sigma\sqrt{2\pi}} \int_0^x \frac{e^{\frac{-(\ln(t)-\mu)^2}{2\sigma^2}}}{t} dt$$

Examples

Compute the Lognormal Distribution Inverse cdf

Compute the inverse cdf of a lognormal distribution with `mu = 0` and `sigma = 0.5`.

```
p = (0.005:0.01:0.995);
crit = logninv(p,1,0.5);
```

Plot the inverse cdf.

```
figure;
plot(p,crit)
xlabel('Probability');
ylabel('Critical Value');
grid
```

```

Description

`nlogL = lognlike(params,data)` returns the negative log-likelihood of `data` for the lognormal distribution with parameters `params`. `params(1)` is the mean of the associated normal distribution, `mu`, and `params(2)` is the standard deviation of the associated normal distribution, `sigma`. The values of `mu` and `sigma` are scalars, and the output `nlogL` is a scalar.

`[nlogL,avar] = lognlike(params,data)` returns the inverse of Fisher's information matrix. If the input parameter value in `params` is the maximum likelihood estimate, `avar` is its asymptotic variance. `avar` is based on the observed Fisher's information, not the expected information.

`[...] = lognlike(params,data,censoring)` accepts a Boolean vector, `censoring`, of the same size as `data`, which is 1 for observations that are right-censored and 0 for observations that are observed exactly.

`[...] = lognlike(params,data,censoring,freq)` accepts a frequency vector, `freq`, of the same size as `data`. The vector `freq` typically contains integer frequencies for the corresponding elements in `data`, but can contain any nonnegative values. Pass in `[]` for `censoring` to use its default value.

prob.LognormalDistribution class

Package: prob
Superclasses: prob.ToolboxFittableParametricDistribution

Lognormal probability distribution object

Description

`prob.LognormalDistribution` is an object consisting of parameters, a model description, and sample data for a lognormal probability distribution.

Create a probability distribution object with specified parameter values using `makedist`. Alternatively, fit a distribution to data using `fitdist` or the Distribution Fitting app.

Construction

`pd = makedist('Lognormal')` creates a lognormal probability distribution object using the default parameter values.

`pd = makedist('Lognormal','mu',mu,'sigma',sigma)` creates a lognormal probability distribution object using the specified parameter values.

Input Arguments

`mu` — Log mean

`0` (default) | scalar value

Log mean for the lognormal distribution, specified as a scalar value. `mu` is the mean of the log of *x*, when *x* has a lognormal distribution.

Data Types: `single` | `double`

`sigma` — Log standard deviation

`1` (default) | nonnegative scalar value

Log standard deviation for the lognormal distribution, specified as a nonnegative scalar value. `sigma` is the standard deviation of the log of *x*, when *x* has a lognormal distribution.

Data Types: `single` | `double`

Properties

`mu` — Log mean

scalar value

Log mean for the lognormal distribution, stored as a scalar value.

Data Types: `single` | `double`

`sigma` — Log standard deviation

nonnegative scalar value

Log standard deviation for the lognormal distribution, stored as a nonnegative scalar value.

Data Types: `single` | `double`

`DistributionName` — Probability distribution name

probability distribution name string

Probability distribution name, stored as a valid probability distribution name string. This property is read-only.

Data Types: `char`

`InputData` — Data used for distribution fitting

structure

Data used for distribution fitting, stored as a structure containing the following:

- `data`: Data vector used for distribution fitting.
- `cens`: Censoring vector, or empty if none.
- `freq`: Frequency vector, or empty if none.

This property is read-only.

Data Types: `struct`

`IsTruncated` — Logical flag for truncated distribution

`0` | `1`

Logical flag for truncated distribution, stored as a logical value. If `IsTruncated` equals `0`, the distribution is not truncated. If `IsTruncated` equals `1`, the distribution is truncated. This property is read-only.

Data Types: `logical`

`NumParameters` — Number of parameters

positive integer value

Number of parameters for the probability distribution, stored as a positive integer value. This property is read-only.

Data Types: `single | double`

`ParameterCovariance` — Covariance matrix of the parameter estimates

matrix of scalar values

Covariance matrix of the parameter estimates, stored as a p-by-p matrix, where p is the number of parameters in the distribution. The (`i`,`j`) element is the covariance between the estimates of the `i`th parameter and the `j`th parameter. The (`i`,`i`) element is the estimated variance of the `i`th parameter. If parameter `i` is fixed rather than estimated by fitting the distribution to data, then the (`i`,`i`) elements of the covariance matrix are 0. This property is read-only.

Data Types: `single | double`

`ParameterDescription` — Distribution parameter descriptions

cell array of strings

Distribution parameter descriptions, stored as a cell array of strings. Each cell contains a short description of one distribution parameter. This property is read-only.

Data Types: `char`

`ParameterIsFixed` — Logical flag for fixed parameters

array of logical values

Logical flag for fixed parameters, stored as an array of logical values. If `0`, the corresponding parameter in the `ParameterNames` array is not fixed. If `1`, the corresponding parameter in the `ParameterNames` array is fixed. This property is read-only.

Data Types: `logical`

`ParameterNames` — Distribution parameter names

cell array of strings

Distribution parameter names, stored as a cell array of strings. This property is read-only.

Data Types: `char`

`ParameterValues` — Distribution parameter values

vector of scalar values

Distribution parameter values, stored as a vector. This property is read-only.

Data Types: `single | double`

`Truncation` — Truncation interval

vector of scalar values

Truncation interval for the probability distribution, stored as a vector containing the lower and upper truncation boundaries. This property is read-only.

Data Types: `single | double`

Definitions

Lognormal Distribution

The lognormal distribution is closely related to the normal distribution. If x is distributed lognormally with parameters μ and σ, then $\log(x)$ is distributed normally with mean μ and standard deviation σ. The lognormal distribution is applicable when the quantity of interest must be positive, since $\log(x)$ exists only when x is positive.

The lognormal distribution uses the following parameters.

Parameter	Description	Support
`mu`	Log mean	$-\infty < \mu < \infty$
`sigma`	Log standard deviation	$\sigma \geq 0$

The probability density function (pdf) of the lognormal distribution is

$$f(x \mid \mu,\sigma) = \frac{1}{x\sigma\sqrt{2\pi}} \exp\left\{\frac{-(\ln x - \mu)^2}{2\sigma^2}\right\} \quad ; \quad x > 0 .$$

Examples

Create a Lognormal Distribution Object Using Default Parameters

Create a lognormal distribution object using the default parameter values.

```
pd = makedist('Lognormal')
```

```
pd =

  LognormalDistribution

  Lognormal distribution
       mu = 0
    sigma = 1
```

Create a Lognormal Distribution Object Using Specified Parameters

Create a lognormal distribution object by specifying the parameter values.

```
pd = makedist('Lognormal','mu',5,'sigma',2)
```

```
pd =

  LognormalDistribution
```

```
  Lognormal distribution
       mu = 5
    sigma = 2
```

Compute the mean of the lognormal distribution.

```
mean(pd)
```

```
ans =

   1.0966e+03
```

The mean of the lognormal distribution is not equal to the `mu` parameter.

Generate random numbers from the lognormal distribution and compute their log values.

```
rng(47);  % for reproducibility
x = random(pd,10000,1);
logx = log(x);
```

Compute the mean of the log values.

```
m = mean(logx)
```

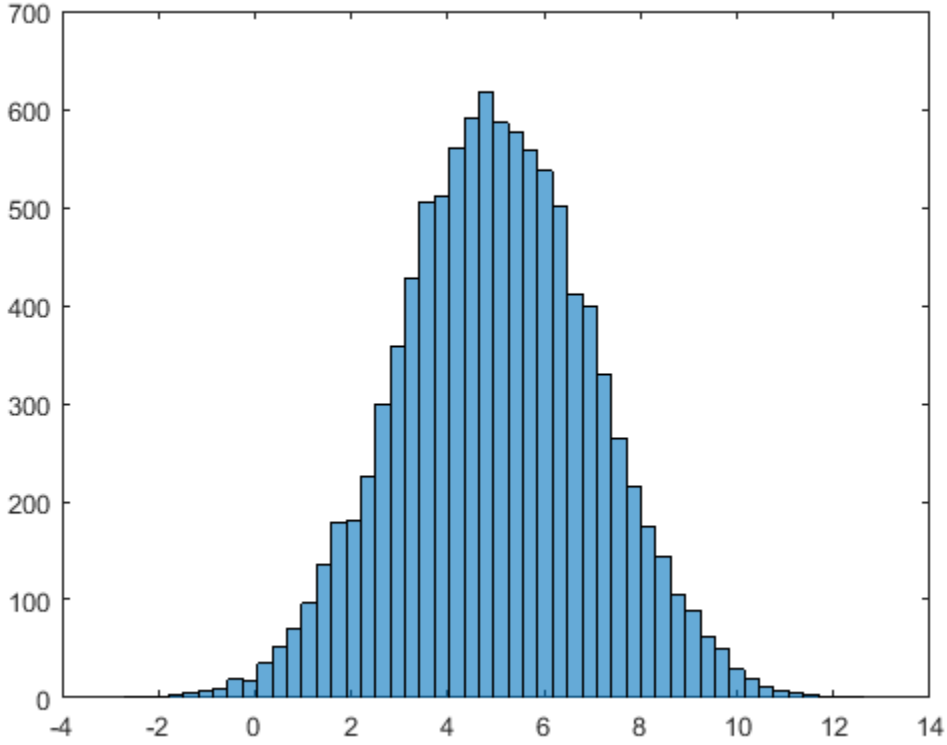
```
m =

    4.9999
```

The mean of the log of `x` is equal to the `mu` parameter of `x`, since `x` has a lognormal distribution.

Plot `logx`.

```
histogram(logx,50)
```



The plot shows that the log values of `x` are normally distributed with a mean equal to 5 and a standard deviation equal to 2.

lognpdf

Lognormal probability density function

Syntax

```
Y = lognpdf(X,mu,sigma)
```

Description

`Y = lognpdf(X,mu,sigma)` returns values at `X` of the lognormal pdf with distribution parameters `mu` and `sigma`. `mu` and `sigma` are the mean and standard deviation, respectively, of the associated normal distribution. `X`, `mu`, and `sigma` can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of `Y`. A scalar input for `X`, `mu`, or `sigma` is expanded to a constant array with the same dimensions as the other inputs.

The lognormal pdf is

$$y = f(x \mid \mu,\sigma) = \frac{1}{x\sigma\sqrt{2\pi}} e^{\frac{-(\ln x-\mu)^2}{2\sigma^2}}$$

The normal and lognormal distributions are closely related. If X is distributed lognormally with parameters μ and σ, then $\log(X)$ is distributed normally with mean μ and standard deviation σ.

The mean m and variance v of a lognormal random variable are functions of μ and σ that can be calculated with the `lognstat` function. They are:

$$m = \exp\left(\mu + \sigma^2 / 2\right)$$
$$v = \exp\left(2\mu + \sigma^2\right)\left(\exp\left(\sigma^2\right) - 1\right)$$

So, a lognormal distribution with mean m and variance v has parameters

$$\mu = \log\left(m^2 / \sqrt{v + m^2} \right)$$
$$\sigma = \sqrt{\log\left(v / m^2 + 1 \right)}$$

If you do not know the population mean and variance, m and v, for the lognormal distribution, you can estimate μ and σ in the following way:

```
mu = mean(log(X))
sigma = std(log(X))
```

The lognormal distribution is applicable when the quantity of interest must be positive, since log(X) exists only when X is positive.

Examples

Compute the Lognormal Distribution pdf

Compute the pdf of a lognormal distribution with `mu = 0` and `sigma = 1`.

```
x = (0:0.02:10);
y = lognpdf(x,0,1);
```

Plot the pdf.

```
plot(x,y); grid;
xlabel('x'); ylabel('p')
```

lognrnd

Lognormal random numbers

Syntax

```
R = lognrnd(mu,sigma)
R = lognrnd(mu,sigma,m,n,...)
R = lognrnd(mu,sigma,[m,n,...])
```

Description

`R = lognrnd(mu,sigma)` returns an array of random numbers generated from the lognormal distribution with parameters `mu` and `sigma`. `mu` and `sigma` are the mean and standard deviation, respectively, of the associated normal distribution. `mu` and `sigma` can be vectors, matrices, or multidimensional arrays that have the same size, which is also the size of `R`. A scalar input for `mu` or `sigma` is expanded to a constant array with the same dimensions as the other input.

`R = lognrnd(mu,sigma,m,n,...)` or `R = lognrnd(mu,sigma,[m,n,...])` generates an `m`-by-`n`-by-... array. The `mu`, `sigma` parameters can each be scalars or arrays of the same size as `R`.

The normal and lognormal distributions are closely related. If X is distributed lognormally with parameters μ and σ, then $\log(X)$ is distributed normally with mean μ and standard deviation σ.

The mean m and variance v of a lognormal random variable are functions of μ and σ that can be calculated with the `lognstat` function. They are:

$$m = \exp\left(\mu + \sigma^2 / 2\right)$$
$$v = \exp\left(2\mu + \sigma^2\right)\left(\exp\left(\sigma^2\right) - 1\right)$$

A lognormal distribution with mean m and variance v has parameters

$$\mu = \log\left(m^2 / \sqrt{v + m^2} \right)$$

$$\sigma = \sqrt{\log\left(v / m^2 + 1 \right)}$$

Examples

Generate one million lognormally distributed random numbers with mean 1 and variance 2:

```
m = 1;
v = 2;
mu = log((m^2)/sqrt(v+m^2));
sigma = sqrt(log(v/(m^2)+1));

[M,V]= lognstat(mu,sigma)
M =
     1
V =
    2.0000

X = lognrnd(mu,sigma,1,1e6);

MX = mean(X)
MX =
    0.9974
VX = var(X)
VX =
    1.9776
```

lognstat

Lognormal mean and variance

Syntax

```
[M,V] = lognstat(mu,sigma)
```

Description

`[M,V] = lognstat(mu,sigma)` returns the mean of and variance of the lognormal distribution with parameters `mu` and `sigma`. `mu` and `sigma` are the mean and standard deviation, respectively, of the associated normal distribution. `mu` and `sigma` can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of `M` and `V`. A scalar input for `mu` or `sigma` is expanded to a constant array with the same dimensions as the other input.

The normal and lognormal distributions are closely related. If X is distributed lognormally with parameters μ and σ, then $\log(X)$ is distributed normally with mean μ and standard deviation σ.

The mean m and variance v of a lognormal random variable are functions of μ and σ that can be calculated with the `lognstat` function. They are:

$$m = \exp\left(\mu + \sigma^2 / 2\right)$$
$$v = \exp\left(2\mu + \sigma^2\right)\left(\exp\left(\sigma^2\right) - 1\right)$$

A lognormal distribution with mean m and variance v has parameters

$$\mu = \log\left(m^2 / \sqrt{v + m^2}\right)$$
$$\sigma = \sqrt{\log\left(v / m^2 + 1\right)}$$

Examples

Generate one million lognormally distributed random numbers with mean 1 and variance 2:

```
m = 1;
v = 2;
mu = log((m^2)/sqrt(v+m^2));
sigma = sqrt(log(v/(m^2)+1));

[M,V]= lognstat(mu,sigma)
M =
     1
V =
    2.0000

X = lognrnd(mu,sigma,1,1e6);

MX = mean(X)
MX =
    0.9974
VX = var(X)
VX =
    1.9776
```

logP

Class: CompactClassificationDiscriminant

Log unconditional probability density for discriminant analysis classifier

Syntax

```
lp = logP(obj,Xnew)
```

Description

`lp = logP(obj,Xnew)` returns the log of the unconditional probability density of each row of `Xnew`, computed using the discriminant analysis model `obj`.

Input Arguments

`obj`

Discriminant analysis classifier, produced using `fitcdiscr`.

`Xnew`

Matrix where each row represents an observation, and each column represents a predictor. The number of columns in `Xnew` must equal the number of predictors in `obj`.

Output Arguments

`lp`

Column vector with the same number of rows as `Xnew`. Each entry is the logarithm of the unconditional probability density of the corresponding row of `Xnew`.

Definitions

Unconditional Probability Density

The unconditional probability density of a point x of a discriminant analysis model is

$$P(x) = \sum_{k=1}^{K} P(x,k),$$

where $P(x,k)$ is the conditional density of the model at x for class k, when the total number of classes is K.

The conditional density $P(x,k)$ is
$P(x,k) = P(k)P(x \mid k)$,

where $P(k)$ is the prior probability of class k, and $P(x \mid k)$ is the conditional density of x given class k. The conditional density function of the multivariate normal with mean μ_k and covariance Σ_k at a point x is

$$P(x \mid k) = \frac{1}{\left(2\pi|\Sigma_k|\right)^{1/2}} \exp\left(-\frac{1}{2}(x-\mu_k)^T \Sigma_k^{-1}(x-\mu_k)\right),$$

where $|\Sigma_k|$ is the determinant of Σ_k, and Σ_k^{-1} is the inverse matrix.

Examples

Compute the Log Unconditional Probabiltiy Density of an Observation

Construct a discriminant analysis classifier for Fisher's iris data, and examine its prediction for an average measurement.

Load Fisher's iris data and construct a default discriminant analysis classifier.

```
load fisheriris
Mdl = fitcdiscr(meas,species);
```

Find the log probability of the discriminant model applied to an average iris.

```
logPAverage = logP(Mdl,mean(meas))

logPAverage =

   -1.7254
```

See Also

`CompactClassificationDiscriminant` | `fitcdiscr` | `mahal`

More About

- "Discriminant Analysis" on page 15-3

logP

Class: CompactClassificationNaiveBayes

Log unconditional probability density for naive Bayes classifier

Syntax

```
lp = logP(Mdl,X)
```

Description

`lp = logP(Mdl,X)` returns the log unconditional probability density of the observations (rows) in `X` using the naive Bayes model `Mdl`.

You can use `lp` to identify outliers in the training data.

Input Arguments

`Mdl` — Naive Bayes classifier

`ClassificationNaiveBayes` model | `CompactClassificationNaiveBayes` model

Naive Bayes classifier, specified as a `ClassificationNaiveBayes` model or `CompactClassificationNaiveBayes` model returned by `fitcnb` or `compact`, respectively.

`X` — Predictor data

numeric matrix

Predictor data, specified as a numeric matrix.

Each row of `X` corresponds to one observation (also known as an instance or example), and each column corresponds to one variable (also known as a feature). The variables making up the columns of `X` should be the same as the variables that trained `Mdl`.

Data Types: `double` | `single`

Output Arguments

`lp` — Log of unconditional probability density

numeric column vector

Log of the unconditional probability density of the predictors, returned as a numeric column vector. `lp` has as many elements as rows in X, and each element is the log probability density of the corresponding row in `X`.

If any rows in X contain at least one `NaN`, then the corresponding element of `lp` is `NaN`.

Definitions

Unconditional Probability Density

The *unconditional probability density* of the predictors is its distribution marginalized over the classes.

In other words, the unconditional probability density is

$$P(X_1,..,X_P) = \sum_{k=1}^{K} P(X_1,..,X_P,Y=k) = \sum_{k=1}^{K} P(X_1,..,X_P \mid y=k)\pi(Y=k),$$

where $\pi(Y=k)$ is the class prior probability. The conditional distribution of the data given the class ($P(X_1,..,X_P \mid y=k)$) and the class prior probability distributions are training options (i.e., are specified when training the classifier).

Prior Probability

The *prior probability* is the believed relative frequency that observations from a class occur in the population for each class.

Examples

Compute Unconditional Probability Densities of Observations

Load Fisher's iris data set.

```
load fisheriris
X = meas;    % Predictors
Y = species; % Response
```

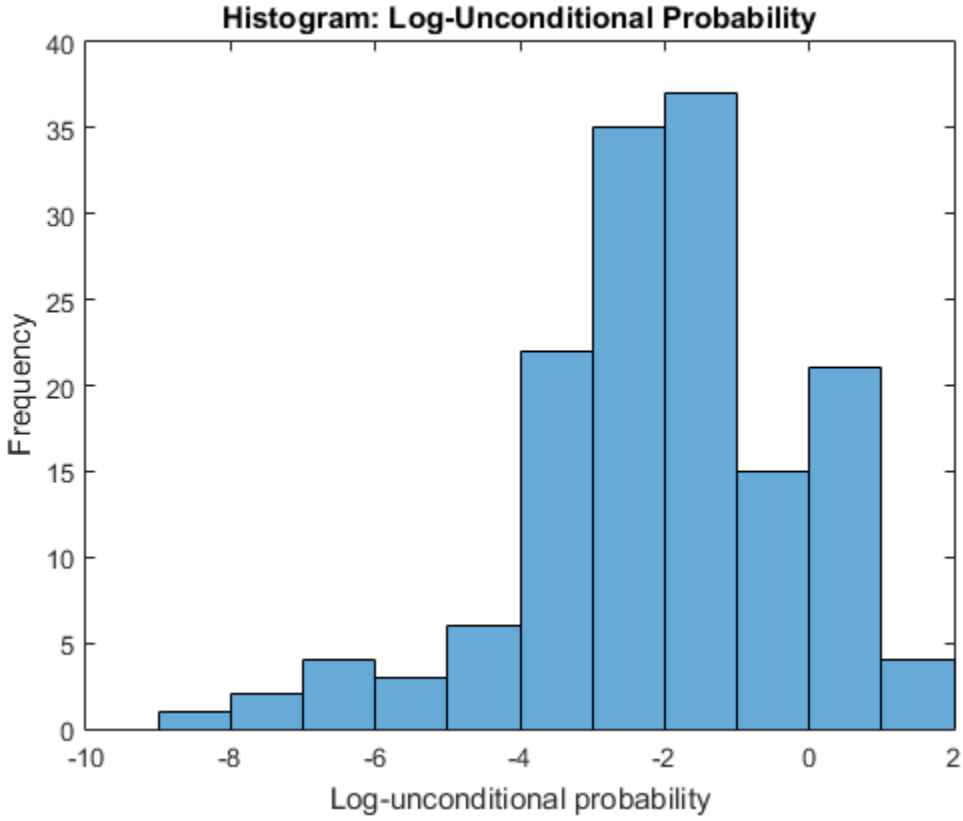
Train a naive Bayes classifier. It is good practice to specify the class order. Assume that each predictor is conditionally normally distributed given its label.

```
Mdl = fitcnb(X,Y,'ClassNames',{'setosa','versicolor','virginica'});
```

`Mdl` is a trained `ClassificationNaiveBayes` classifier.

Compute the unconditional probability densities of the in-sample observations.

```
lp = logP(Mdl,X);
histogram(lp)
xlabel 'Log-unconditional probability'
ylabel 'Frequency'
title 'Histogram: Log-Unconditional Probability'
```



Identify indices of observations having log-unconditional probability less than -7.

```
idx = find(lp < -7)
```

```
idx =

    61
   118
   132
```

More About

- “Naive Bayes Classification” on page 15-31

loss

Class: ClassificationKNN

Loss of *k*-nearest neighbor classifier

Syntax

```
L = loss(mdl,X,Y)
L = loss(mdl,X,Y,Name,Value)
```

Description

`L = loss(mdl,X,Y)` returns a scalar representing how well `mdl` classifies the data in `X`, when `Y` contains the true classifications.

When computing the loss, `loss` normalizes the class probabilities in Y to the class probabilities used for training, stored in the `Prior` property of mdl.

`L = loss(mdl,X,Y,Name,Value)` returns the loss with additional options specified by one or more Name,Value pair arguments.

Input Arguments

`mdl` — Classifier model

classifier model object

k-nearest neighbor classifier model, returned as a classifier model object.

Note that using the `'CrossVal'`, `'KFold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'` options results in a model of class `ClassificationPartitionedModel`. You cannot use a partitioned tree for prediction, so this kind of tree does not have a `predict` method.

Otherwise, mdl is of class `ClassificationKNN`, and you can use the `predict` method to make predictions.

`X` — Matrix of predictor values

matrix

Matrix of predictor values. Each column of `X` represents one variable, and each row represents one observation.

`Y` — Categorical variables
categorical array | cell array of strings | character array | logical vector | numeric vector

A categorical array, cell array of strings, character array, logical vector, or a numeric vector with the same number of rows as `X`. Each row of `Y` represents the classification of the corresponding row of `X`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'lossfun '`

Function handle or string representing a loss function. The built-in loss functions are:

- `'binodeviance'` — See "Loss Functions" on page 22-2671.
- `'classiferror'` — Fraction of misclassified observations. See "Loss Functions" on page 22-2671.
- `'exponential'` — See "Loss Functions" on page 22-2671.
- `'hinge'` — See "Loss Functions" on page 22-2671.
- `'mincost'` — Smallest misclassification cost as given by the mdl`.Cost` matrix. See "Loss Functions" on page 22-2671.

You can write your own loss function using the syntax described in "Loss Functions" on page 22-2671.

Default: `'mincost'`

`'weights'`

Numeric vector of length `N`, where `N` is the number of rows of X. `weights` are nonnegative. `loss` normalizes the weights so that observation weights in each class sum to the prior probability of that class. When you supply `weights`, `loss` computes weighted classification loss.

Default: `ones(N,1)`

Output Arguments

`L`

Classification error, a scalar. The meaning of the error depends on the values in `weights` and `lossfun`. See "Classification Error" on page 22-2677.

Definitions

Classification Error

The default classification error is the fraction of data X that mdl misclassifies, where Y represents the true classifications.

The weighted classification error is the sum of weight i times the Boolean value that is `1` when mdl misclassifies the ith row of `X`, divided by the sum of the weights.

Loss Functions

The built-in loss functions are:

- `'binodeviance'` — For binary classification, assume the classes y_n are `-1` and `1`. With weight vector w normalized to have sum `1`, and predictions of row n of data X as $f(X_n)$, the binomial deviance is

  $$\sum w_n \log\left(1+\exp\left(-2y_n f\left(X_n\right)\right)\right).$$

- `'exponential'` — With the same definitions as for `'binodeviance'`, the exponential loss is

  $$\sum w_n \exp\left(-y_n f\left(X_n\right)\right).$$

- `'classiferror'` — Predict the label with the largest posterior probability. The loss is then the fraction of misclassified observations.

- `'hinge'` — Classification error measure that has the form

$$L = \frac{\sum_{j=1}^{n} w_j \max\left\{0, 1 - y_j' f\left(X_j\right)\right\}}{\sum_{j=1}^{n} w_j},$$

  where:

  - w_j is weight j.
  - For binary classification, $y_j = 1$ for the positive class and -1 for the negative class. For problems where the number of classes $K > 3$, y_j is a vector of 0s, but with a 1 in the position corresponding to the true class, e.g., if the second observation is in the third class and $K = 4$, then $y_2 = [0\ 0\ 1\ 0]'$.
  - $f(X_j)$ is, for binary classification, the posterior probability or, for $K > 3$, a vector of posterior probabilities for each class given observation j.

- `'mincost'` — Predict the label with the smallest expected misclassification cost, with expectation taken over the posterior probability, and cost as given by the `Cost` property of the classifier (a matrix). The loss is then the true misclassification cost averaged over the observations.

To write your own loss function, create a function file in this form:

```
function loss = lossfun(C,S,W,COST)
```

- `N` is the number of rows of X.
- `K` is the number of classes in the classifier, represented in the `ClassNames` property.
- `C` is an `N`-by-`K` logical matrix, with one `true` per row for the true class. The index for each class is its position in the `ClassNames` property.
- `S` is an `N`-by-`K` numeric matrix. `S` is a matrix of posterior probabilities for classes with one row per observation, similar to the `posterior` output from `predict`.
- `W` is a numeric vector with `N` elements, the observation weights. If you pass `W`, the elements are normalized to sum to the prior probabilities in the respective classes.
- `COST` is a `K`-by-`K` numeric matrix of misclassification costs. For example, you can use `COST = ones(K) - eye(K)`, which means a cost of `0` for correct classification, and `1` for misclassification.

- The output `loss` should be a scalar.

Pass the function handle `@lossfun` as the value of the `LossFun` name-value pair.

True Misclassification Cost

There are two costs associated with KNN classification: the true misclassification cost per class, and the expected misclassification cost per observation.

You can set the true misclassification cost per class in the `Cost` name-value pair when you run `fitcknn`. `Cost(i,j)` is the cost of classifying an observation into class `j` if its true class is `i`. By default, `Cost(i,j)=1` if `i~=j`, and `Cost(i,j)=0` if `i=j`. In other words, the cost is `0` for correct classification, and `1` for incorrect classification.

Expected Cost

There are two costs associated with KNN classification: the true misclassification cost per class, and the expected misclassification cost per observation. The third output of `predict` is the expected misclassification cost per observation.

Suppose you have `Nobs` observations that you want to classify with a trained classifier `mdl`. Suppose you have `K` classes. You place the observations into a matrix `Xnew` with one observation per row. The command

```
[label,score,cost] = predict(mdl,Xnew)
```

returns, among other outputs, a `cost` matrix of size `Nobs`-by-`K`. Each row of the `cost` matrix contains the expected (average) cost of classifying the observation into each of the `K` classes. `cost(n,k)` is

$$\sum_{i=1}^{K} \hat{P}(i \mid Xnew(n)) C(k \mid i),$$

where

- K is the number of classes.
- $\hat{P}(i \mid Xnew(n))$ is the posterior probability of class i for observation $Xnew(n)$.

- $C(k|i)$ is the true misclassification cost of classifying an observation as k when its true class is i.

Examples

Loss Calculation

Construct a k-nearest neighbor classifier for the Fisher iris data, where $k = 5$.

Load the data.

```
load fisheriris
```

Construct a classifier for 5-nearest neighbors.

```
mdl = fitcknn(meas,species,'NumNeighbors',5);
```

Examine the loss of the classifier for a mean observation classified `'versicolor'`.

```
X = mean(meas);
Y = {'versicolor'};
L = loss(mdl,X,Y)
```

```
L =

     0
```

The classifier has no doubt that `'versicolor'` is the correct classification (all five nearest neighbors classify as `'versicolor'`).

loss

Class: CompactClassificationDiscriminant

Classification error

Syntax

```
L = loss(obj,X,Y)
L = loss(obj,X,Y,Name,Value)
```

Description

`L = loss(obj,X,Y)` returns a scalar representing how well `obj` classifies the data in `X`, when `Y` contains the true classifications.

When computing the loss, `loss` normalizes the class probabilities in Y to the class probabilities used for training, stored in the `Prior` property of obj.

`L = loss(obj,X,Y,Name,Value)` returns the loss with additional options specified by one or more Name,Value pair arguments.

Input Arguments

`obj`

Discriminant analysis classifier of class `ClassificationDiscriminant` or `CompactClassificationDiscriminant`, typically constructed with `fitcdiscr`.

`X`

Matrix where each row represents an observation, and each column represents a predictor. The number of columns in `X` must equal the number of predictors in `obj`.

`Y`

Class labels, with the same data type as exists in `obj`. The number of elements of `Y` must equal the number of rows of `X`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'lossfun '`

Function handle or string representing a loss function. Built-in loss functions:

- `'binodeviance'` — See "Loss Functions" on page 22-2677.
- `'classiferror'` — Fraction of misclassified observations. See "Loss Functions" on page 22-2677.
- `'exponential'` — See "Loss Functions" on page 22-2677.
- `'hinge'` — See "Loss Functions" on page 22-2677.
- `'mincost'` — Smallest misclassification cost as given by the obj`.Cost` matrix. See "Loss Functions" on page 22-2677.

You can write your own loss function using the syntax described in "Loss Functions" on page 22-2677.

Default: `'mincost'`

`'weights'`

Numeric vector of length `N`, where `N` is the number of rows of X. `weights` are nonnegative. `loss` normalizes the weights so that observation weights in each class sum to the prior probability of that class. When you supply `weights`, `loss` computes weighted classification loss.

Default: `ones(N,1)`

Output Arguments

`L`

Classification error, a scalar. The meaning of the error depends on the values in `weights` and `lossfun`. See "Classification Error" on page 22-2677.

Definitions

Classification Error

The default classification error is the fraction of data X that obj misclassifies, where Y represents the true classifications.

Weighted classification error is the sum of weight i times the Boolean value that is `1` when obj misclassifies the ith row of `X`, divided by the sum of the weights.

Loss Functions

The built-in loss functions are:

- `'binodeviance'` — For binary classification, assume the classes y_n are `-1` and `1`. With weight vector w normalized to have sum `1`, and predictions of row n of data X as $f(X_n)$, the binomial deviance is

$$\sum w_n \log\left(1+\exp\left(-2y_n f\left(X_n\right)\right)\right).$$

- `'exponential'` — With the same definitions as for `'binodeviance'`, the exponential loss is

$$\sum w_n \exp\left(-y_n f\left(X_n\right)\right).$$

- `'classiferror'` — Predict the label with the largest posterior probability. The loss is then the fraction of misclassified observations.
- `'hinge'` — Classification error measure that has the form

$$L=\frac{\sum_{j=1}^{n} w_j \max\left\{0,1-y_j' f\left(X_j\right)\right\}}{\sum_{j=1}^{n} w_j},$$

where:

- w_j is weight j.
- For binary classification, $y_j = 1$ for the positive class and -1 for the negative class. For problems where the number of classes $K > 3$, y_j is a vector of 0s, but with a 1 in the position corresponding to the true class, e.g., if the second observation is in the third class and $K = 4$, then $y_2 = [0\ 0\ 1\ 0]'$.
- $f(X_j)$ is, for binary classification, the posterior probability or, for $K > 3$, a vector of posterior probabilities for each class given observation j.

- `'mincost'` — Predict the label with the smallest expected misclassification cost, with expectation taken over the posterior probability, and cost as given by the `Cost` property of the classifier (a matrix). The loss is then the true misclassification cost averaged over the observations.

To write your own loss function, create a function file in this form:

```
function loss = lossfun(C,S,W,COST)
```

- `N` is the number of rows of X.
- `K` is the number of classes in the classifier, represented in the `ClassNames` property.
- `C` is an `N`-by-`K` logical matrix, with one `true` per row for the true class. The index for each class is its position in the `ClassNames` property.
- `S` is an `N`-by-`K` numeric matrix. `S` is a matrix of posterior probabilities for classes with one row per observation, similar to the `posterior` output from `predict`.
- `W` is a numeric vector with `N` elements, the observation weights. If you pass `W`, the elements are normalized to sum to the prior probabilities in the respective classes.
- `COST` is a `K`-by-`K` numeric matrix of misclassification costs. For example, you can use `COST = ones(K) - eye(K)`, which means a cost of `0` for correct classification, and `1` for misclassification.
- The output `loss` should be a scalar.

Pass the function handle `@lossfun` as the value of the `LossFun` name-value pair.

Posterior Probability

The posterior probability that a point z belongs to class j is the product of the prior probability and the multivariate normal density. The density function of the multivariate normal with mean μ_j and covariance Σ_j at a point z is

$$P(x \mid k) = \frac{1}{\left(2\pi|\Sigma_k|\right)^{1/2}} \exp\left(-\frac{1}{2}(x-\mu_k)^T \Sigma_k^{-1}(x-\mu_k) \right),$$

where $|\Sigma_k|$ is the determinant of Σ_k, and Σ_k^{-1} is the inverse matrix.

Let $P(k)$ represent the prior probability of class k. Then the posterior probability that an observation x is of class k is

$$\hat{P}(k \mid x) = \frac{P(x \mid k)P(k)}{P(x)},$$

where $P(x)$ is a normalization constant, the sum over k of $P(x \mid k)P(k)$.

Prior Probability

The prior probability is one of three choices:

- `'uniform'` — The prior probability of class `k` is one over the total number of classes.
- `'empirical'` — The prior probability of class `k` is the number of training samples of class `k` divided by the total number of training samples.
- Custom — The prior probability of class `k` is the `k`th element of the `prior` vector. See `fitcdiscr`.

After creating a classifier `obj`, you can set the prior using dot notation:

```
obj.Prior = v;
```

where `v` is a vector of positive elements representing the frequency with which each element occurs. You do not need to retrain the classifier when you set a new prior.

Cost

The matrix of expected costs per observation is defined in “Cost” on page 15-8.

Examples

Compute the resubstituted classification error for the Fisher iris data:

```
load fisheriris
obj = fitcdiscr(meas,species);
L = loss(obj,meas,species)

L =
    0.0200
```

How To

- “Discriminant Analysis” on page 15-3

loss

Class: CompactClassificationECOC

Classification loss for error-correcting output code multiclass classifiers

Syntax

```
L = loss(Mdl,X,Y)
L = loss(Mdl,X,Y,Name,Value)
```

Description

`L = loss(Mdl,X,Y)` returns the classification loss (`L`), a scalar representing how well the trained error-correcting output code (ECOC) multiclass classifer Mdl classifies the predictor data (X) as compared to the true class labels (Y). Each row of `X` and `Y` is an observation.

`L = loss(Mdl,X,Y,Name,Value)` returns the classification loss with additional options specified by one or more Name,Value pair arguments.

For example, specify a decoding scheme, classification loss function, or verbosity level.

Input Arguments

`Mdl` — ECOC multiclass classifier

`ClassificationECOC` model | `CompactClassificationECOC` model

ECOC multiclass classifier, specified as a `ClassificationECOC` or `CompactClassificationECOC` model. You can create a:

- `ClassificationECOC` model by training the ECOC classifier using `fitcecoc`
- `CompactClassificationECOC` model by passing a `ClassificationECOC` classifier to `compact`

`X` — Predictor data

numeric matrix

Predictor data, specified as a numeric matrix.

Each row of `X` corresponds to one observation (also called an instance or example), and each column corresponds to one variable (also known as a feature). The variables composing the columns of `X` should be the same as the variables that trained the `Mdl` classifier.

The length of `Y` and the number of rows of `X` must be equal.

If you trained `Mdl` specifying to standardize the predictor data, then the software standardizes the columns of `X` using the corresponding means and standard deviations that the software stored in `Mdl.BinaryLearner{j}.Mu` and `Mdl.BinaryLearner{j}.Sigma` for learner `j`.

Data Types: `double` | `single`

`Y` — Class labels

categorical array | character array | logical vector | vector of numeric values | cell array of strings

Class labels, specified as a categorical or character array, logical or numeric vector, or cell array of strings. `Y` must be the same as the data type of `Mdl.ClassNames`.

The length of `Y` and the number of rows of `X` must be equal.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'BinaryLoss'` — Binary learner loss function

function handle | `'hamming'` | `'linear'` | `'exponential'` | `'binodeviance'` | `'hinge'` | `'quadratic'`

Binary learner loss function, specified as the comma-separated pair consisting of `'BinaryLoss'` and a function handle or string.

- If the value is a string, then it must correspond to a built-in function. This table summarizes the built-in functions, where y_j is a class label for a particular binary learner (in the set {-1,1,0}), s_j is the score for observation j, and $g(y_j,s_j)$ is the binary loss formula.

Value	Description	Score Domain	$g(y_j,s_j)$
`'binodeviance'`	Binomial deviance	$(-\infty,\infty)$	$\log[1 + \exp(-2y_js_j)]/[2\log(2)]$
`'exponential'`	Exponential	$(-\infty,\infty)$	$\exp(-y_js_j)/2$
`'hamming'`	Hamming	$\{-1,1\}$	$[1 - \text{sign}(y_js_j)]/2$
`'hinge'`	Hinge	$(-\infty,\infty)$	$\max(0,1 - y_js_j)/2$
`'linear'`	Linear	$(-\infty,\infty)$	$(1 - y_js_j)/2$
`'quadratic'`	Quadratic	$[0,1]$	$[1 - y_j(2s_j - 1)]^2/2$

The software normalizes the binary losses such that the loss is 0.5 when $y_j = 0$. Also, the software calculates the mean binary loss for each class.

- For a custom binary loss function, e.g., `customFunction`, specify its function handle `'BinaryLoss',@customFunction`.

  `customFunction` should have this form

  ```
  bLoss = customFunction(M,s)
  ```
  where:

  - `M` is the K-by-L coding matrix stored in `Mdl.CodingMatrix`.
  - `s` is the 1-by-L row vector of classification scores.
  - `bLoss` is the classification loss. This scalar aggregates the binary losses for every learner in a particular class. For example, you can use the mean binary loss to aggregate the loss over the learners for each class.
  - K is the number of classes.
  - L is the number of binary learners.

  For an example on passing a custom binary loss function, see "Predict Test-Sample Labels of ECOC Models Using Custom Binary Loss Function".

This list describes the default values of `BinayLoss`. If all binary learners are:

- SVMs, then `BinaryLoss` is `'hinge'`
- Ensembles trained by `AdaboostM1` or `GentleBoost`, then `BinaryLoss` is `'exponential'`

- Ensembles trained by `LogitBoost`, then `BinaryLoss` is `'binodeviance'`
- Predicting class posterior probabilities (i.e., set `'FitPosterior',1` in `fitcecoc`), then `BinaryLoss` is `'quadratic'`

Otherwise, the default `BinaryLoss` is `'hamming'`.

Example: `'BinaryLoss','binodeviance'`

Data Types: `char` | `function_handle`

`'Decoding'` — Decoding scheme

`'lossweighted'` (default) | `'lossbased'`

Decoding scheme that aggregates the binary losses, specified as the comma-separated pair consisting of `'Decoding'` and `'lossweighted'` or `'lossbased'`.

Example: `'Decoding','lossbased'`

Data Types: `char`

`'Options'` — Estimation options

`[]` (default) | structure array returned by `statset`

Estimation options, specified as the comma-separated pair consisting of `'Options'` and a structure array returned by `statset`.

To invoke parallel computing:

- You need a Parallel Computing Toolbox license.
- Specify `'Options',statset('UseParallel',1)`.

`'LossFun'` — Loss function

`'classiferror'` (default) | function handle

Loss function, specified as the comma-separated pair consisting of `'LossFun'` and a function handle or `'classiferror'`.

You can:

- Specify the built-in function `'classiferror'`. Subsequently, the loss function is classification error, i.e., the proportion of misclassified observations.
- Specify your own function using function handle notation.

Suppose that `n = size(X,1)` is the sample size and `k` is the number of classes. Your function must have the signature `lossvalue = lossfun(C,S,W,Cost)`, where:

- The output argument `lossvalue` is a scalar.
- You choose the function name (*`lossfun`*).
- `C` is an `n`-by-`k` logical matrix with rows indicating which class the corresponding observation belongs. The column order corresponds to the class order in `Mdl.ClassNames`.

  Construct `C` by setting `C(p,q) = 1` if observation `p` is in class `q`, for each row. Set all other elements of row `p` to `0`.
- `S` is an `n`-by-`k` numeric matrix of negated loss values for classes. Each row corresponds to an observation. The column order corresponds to the class order in `Mdl.ClassNames`. `S` resembles the output argument `negLoss` of `predict`.
- `W` is an `n`-by-1 numeric vector of observation weights. If you pass `W`, the software normalizes its elements to sum to `1`.
- `Cost` is a `k`-by-`k` numeric matrix of misclassification costs. For example, `Cost = ones(K) -eye(K)` specifies a cost of 0 for correct classification, and 1 for misclassification.

Specify your function using `'LossFun',@lossfun`.

Data Types: `function_handle | char`

`'Verbose'` — Verbosity level

`0` (default) | `1`

Verbosity level, specified as the comma-separated pair consisting of `'Verbose'` and `0` or `1`. `Verbose` controls the amount of diagnostic messages that the software displays in the Command Window.

If `Verbose` is `0`, then the software does not display diagnostic messages. Otherwise, the software displays diagnostic messages.

Example: `'Verbose',1`

Data Types: `single | double`

`'Weights'` — Observation weights

`ones(size(X,1))` (default) | numeric vector

Observation weights, specified as the comma-separated pair consisting of `'Weights'` and a numeric vector. `Weights` requires the same length as the number of rows of `X`, i.e., `size(X,1)`. The software normalizes `Weights` to sum up to the value of the prior probability in the respective class.

If you do not specify your own loss function (using LossFun), then the software normalizes `Weights` to sum up to the value of the prior probability in the respective class.

Output Arguments

`L` — Classification loss

scalar

Classification loss, returned as a scalar. `L` is a generalization or resubstitution quality measure. Its interpretation depends on the loss function and weighting scheme, but, in general, better classifiers yield smaller loss values.

Definitions

Classification Error

The *classification error* is a binary classification error measure that has the form

$$L = \frac{\sum_{j=1}^{n} w_j e_j}{\sum_{j=1}^{n} w_j},$$

where:

- w_j is the weight for observation j. The software renormalizes the weights to sum to 1.
- $e_j = 1$ if the predicted class of observation j differs from its true class, and 0 otherwise.

In other words, it is the proportion of observations that the classifier misclassifies.

Binary Loss

A *binary loss* is a function of the class and classification score that determines how well a binary learner classifies an observation into the class.

Let:

- m_{kj} be element (k,j) of the coding design matrix M (i.e., the code corresponding to class k of binary learner j)
- s_j be the score of binary learner j for an observation
- g be the binary loss function
- $\hat{k}$ be the predicted class for the observation

In *loss-based decoding* [3], the class producing the minimum sum of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \underset{k}{\operatorname{argmin}} \sum_{j=1}^{L} \left|m_{kj}\right| g(m_{kj}, s_j).$$

In *loss-weighted decoding* [3], the class producing the minimum average of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \underset{k}{\operatorname{argmin}} \frac{\sum_{j=1}^{L} \left|m_{kj}\right| g(m_{kj}, s_j)}{\sum_{j=1}^{L} \left|m_{kj}\right|}.$$

Allwein et al. [1] suggest that loss-weighted decoding improves classification accuracy by keeping loss values for all classes in the same dynamic range.

This table summarizes the supported loss functions, where y_j is a class label for a particular binary learner (in the set {-1,1,0}), s_j is the score for observation j, and $g(y_j,s_j)$.

Value	Description	Score Domain	$g(y_j,s_j)$
`'binodeviance'`	Binomial deviance	$(-\infty,\infty)$	$\log[1 + \exp(-2y_js_j)]/[2\log(2)]$
`'exponential'`	Exponential	$(-\infty,\infty)$	$\exp(-y_js_j)/2$
`'hamming'`	Hamming	{-1,1}	$[1 - \text{sign}(y_js_j)]/2$
`'hinge'`	Hinge	$(-\infty,\infty)$	$\max(0,1 - y_js_j)/2$
`'linear'`	Linear	$(-\infty,\infty)$	$(1 - y_js_j)/2$
`'quadratic'`	Quadratic	[0,1]	$[1 - y_j(2s_j - 1)]^2/2$

The software normalizes the binary losses such that the loss is 0.5 when $y_j = 0$, and aggregates using the average of the binary learners [1].

Do not confuse the binary loss with the overall classification loss (specified by the LossFun name-value pair argument of `predict` and `loss`), e.g., classification error, which measures how well an ECOC classifier performs as a whole.

Examples

Determine the Test Sample Loss of ECOC Models

Load Fisher's iris data set.

```
load fisheriris
X = meas;
Y = categorical(species);
classOrder = unique(Y); % Class order
rng(1); % For reproducibility
```

Train an ECOC model using SVM binary classifiers, and specify a 15% holdout sample. It is good practice to standardize the predictors and define the class order. Specify to standardize the predictors using an SVM template.

```
t = templateSVM('Standardize',1);
CVMdl = fitcecoc(X,Y,'Holdout',0.15,'Learners',t,'ClassNames',classOrder);
CMdl = CVMdl.Trained{1};           % Extract trained, compact classifier
testInds = test(CVMdl.Partition);  % Extract the test indices
XTest = X(testInds,:);
YTest = Y(testInds,:);
```

`CVMdl` is a `ClassificationPartitionedECOC` model. It contains the property `Trained`, which is a 1-by-1 cell array holding a `CompactClassificationECOC` model that the software trained using the training set.

Estimate the test-sample loss.

```
L = loss(CMdl,XTest,YTest)
```

```
L =

     0
```

The ECOC model correctly classifies all out-of-sample irises.

Determine ECOC Model Quality Using a Custom Loss

Suppose that it is interesting to know how well a model classifies a particular class. This example shows how to pass such a custom loss function to `loss`.

Load Fisher's iris data set.

```
load fisheriris
X = meas;
Y = categorical(species);
n = numel(Y);           % Sample size
classOrder = unique(Y)  % Class order
K = numel(classOrder);  % Number of classes
rng(1) % For reproducibility
```

```
classOrder =

     setosa
     versicolor
     virginica
```

Train an ECOC model using SVM binary classifiers and specifying a 15% holdout sample. It is good practice to standardize the predictors and define the class order. Specify to standardize the predictors using an SVM template.

```
t = templateSVM('Standardize',1);
CVMdl = fitcecoc(X,Y,'Holdout',0.15,'Learners',t,'ClassNames',classOrder);
```

```
CMdl = CVMdl.Trained{1};           % Extract trained, compact classifier
testInds = test(CVMdl.Partition);  % Extract the test indices
XTest = X(testInds,:);
YTest = Y(testInds,:);
```

`CVMdl` is a `ClassificationPartitionedECOC` model. It contains the property `Trained`, which is a 1-by-1 cell array holding a `CompactClassificationECOC` model that the software trained using the training set.

Compute the negated losses for the test-sample observations.

```
[~,negLoss] = predict(CMdl,XTest);
```

Create a function that takes the minimal loss for each observation, and then averages the minimal losses across all observations.

```
lossfun = @(C,S,~,~)mean(min(-negLoss,[],2));
```

Compute the test-sample custom loss.

```
loss(CMdl,XTest,YTest,'LossFun',lossfun)
```

```
ans =

    0.0033
```

The average, minimal, binary loss in the test sample is 0.0033.

loss

Class: CompactClassificationEnsemble

Classification error

Syntax

```
L = loss(ens,X,Y)
L = loss(ens,X,Y,Name,Value)
```

Description

`L = loss(ens,X,Y)` returns the classification error for ensemble ens computed using matrix of predictors `X` and true class labels `Y`.

When computing the loss, `loss` normalizes the class probabilities in Y to the class probabilities used for training, stored in the `Prior` property of ens.

`L = loss(ens,X,Y,Name,Value)` computes classification error with additional options specified by one or more Name,Value pair arguments.

Input Arguments

`ens`

Classification ensemble created with `fitensemble`, or a compact classification ensemble created with `compact`.

`X`

Matrix of data to classify. Each row of `X` represents one observation, and each column represents one predictor. `X` must have the same number of columns as the data used to train ens. `X` should have the same number of rows as the number of elements in `Y`.

`Y`

Classification of X. `Y` should be of the same type as the classification used to train ens, and its number of elements should equal the number of rows of X.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'learners'`

Indices of weak learners in the ensemble ranging from `1` to `ens.NumTrained`. `loss` uses only these learners for calculating loss.

Default: `1:NumTrained`

`'lossfun '`

Function handle or string representing a loss function. Built-in loss functions:

- `'binodeviance'` — See "Loss Functions" on page 22-2694
- `'classiferror'` — Fraction of misclassified data
- `'exponential'` — See "Loss Functions" on page 22-2694
- `'hinge'` — See "Loss Functions" on page 22-2694.
- `'mincost'` — Smallest misclassification cost as given by the `obj.Cost` matrix. See "Loss Functions" on page 22-2694.

You can write your own loss function in the syntax described in "Loss Functions" on page 22-2694.

Default: `'classiferror'`

`'mode'`

String representing the meaning of the output L:

- `'ensemble'` — `L` is a scalar value, the loss for the entire ensemble.
- `'individual'` — `L` is a vector with one element per trained learner.
- `'cumulative'` — `L` is a vector in which element `J` is obtained by using learners `1:J` from the input list of learners.

Default: `'ensemble'`

`'UseObsForLearner'`

A logical matrix of size `N`-by-`T`, where:

- `N` is the number of rows of X.
- `T` is the number of weak learners in ens.

When `UseObsForLearner(i,j)` is `true`, learner `j` is used in predicting the class of row `i` of X.

Default: `true(N,T)`

`'weights'`

Vector of observation weights, with nonnegative entries. The length of `weights` must equal the number of rows in X. When you specify weights, `loss` normalizes the weights so that observation weights in each class sum to the prior probability of that class.

Default: `ones(size(X,1),1)`

Output Arguments

`L`

Loss, by default the fraction of misclassified data. `L` can be a vector, and can mean different things, depending on the name-value pair settings.

Definitions

Classification Error

The default classification error is the fraction of the data X that ens misclassifies, where Y are the true classifications.

Weighted classification error is the sum of weight *i* times the Boolean value that is `1` when tree misclassifies the *i*th row of `X`, divided by the sum of the weights.

Loss Functions

The built-in loss functions are:

- `'binodeviance'` — For binary classification, assume the classes y_n are `-1` and `1`. With weight vector w normalized to have sum `1`, and predictions of row n of data X as $f(X_n)$, the binomial deviance is

$$\sum w_n \log\left(1+\exp\left(-2y_n f\left(X_n\right)\right)\right).$$

- `'classiferror'` — Fraction of misclassified data, weighted by w.
- `'exponential'` — With the same definitions as for `'binodeviance'`, the exponential loss is

$$\sum w_n \exp\left(-y_n f\left(X_n\right)\right).$$

- `'hinge'` — Classification error measure that has the form

$$L=\frac{\sum_{j=1}^{n} w_j \max\left\{0,1-y_j' f\left(X_j\right)\right\}}{\sum_{j=1}^{n} w_j},$$

  where:

  - w_j is weight j.
  - For binary classification, $y_j = 1$ for the positive class and -1 for the negative class. For problems where the number of classes $K > 3$, y_j is a vector of 0s, but with a 1 in the position corresponding to the true class, e.g., if the second observation is in the third class and $K = 4$, then $y_2 = [0\ 0\ 1\ 0]'$.
  - $f(X_j)$ is, for binary classification, the posterior probability or, for $K > 3$, a vector of posterior probabilities for each class given observation j.
- `'mincost'` — Predict the label with the smallest expected misclassification cost, with expectation taken over the posterior probability, and cost as given by the `Cost` property of the classifier (a matrix). The loss is then the true misclassification cost averaged over the observations.

To write your own loss function, create a function file of the form

```
function loss = lossfun(C,S,W,COST)
```

- `N` is the number of rows of ens`.X`.
- `K` is the number of classes in ens, represented in `ens.ClassNames`.
- `C` is an `N`-by-`K` logical matrix, with one `true` per row for the true class. The index for each class is its position in `tree.ClassNames`.
- `S` is an `N`-by-`K` numeric matrix. `S` is a matrix of posterior probabilities for classes with one row per observation, similar to the `score` output from `predict`.
- `W` is a numeric vector with `N` elements, the observation weights.
- `COST` is a `K`-by-`K` numeric matrix of misclassification costs. The default `'classiferror'` gives a cost of `0` for correct classification, and `1` for misclassification.
- The output `loss` should be a scalar.

Pass the function handle `@`*`lossfun`* as the value of the `lossfun` name-value pair.

Examples

Create a compact classification ensemble for the ionosphere data, and find the fraction of training data that the ensemble misclassifies:

```
load ionosphere
ada = fitensemble(X,Y,'AdaBoostM1',100,'tree');
adb = compact(ada);
L = loss(adb,X,Y)

L =
    0.0085
```

See Also

`loss` | `margin` | `predict` | `edge`

loss

Class: CompactClassificationNaiveBayes

Classification error for naive Bayes classifier

Syntax

```
L = loss(Mdl,X,Y)
L = loss(Mdl,X,Y,Name,Value)
```

Description

`L = loss(Mdl,X,Y)` returns the minimum misclassification cost loss (`L`), a scalar representing how well the trained naive Bayes classifer Mdl classifies the predictor data (X) as compared to the true class labels (Y).

`loss` normalizes the class probabilities in Y to the prior class probabilities `fitcnb` used for training, stored in the `Prior` property of `Mdl`.

`L = loss(Mdl,X,Y,Name,Value)` returns the classification loss with additional options specified by one or more Name,Value pair arguments.

Input Arguments

`Mdl` — Naive Bayes classifier

`ClassificationNaiveBayes` model | `CompactClassificationNaiveBayes` model

Naive Bayes classifier, specified as a `ClassificationNaiveBayes` model or `CompactClassificationNaiveBayes` model returned by `fitcnb` or `compact`, respectively.

`X` — Predictor data

numeric matrix

Predictor data, specified as a numeric matrix.

Each row of `X` corresponds to one observation (also known as an instance or example), and each column corresponds to one variable (also known as a feature). The variables making up the columns of `X` should be the same as the variables that trained `Mdl`.

The length of `Y` and the number of rows of `X` must be equal.

Data Types: `double` | `single`

`Y` — Class labels

categorical array | character array | logical vector | vector of numeric values | cell array of strings

Class labels, specified as a categorical or character array, logical or numeric vector, or cell array of strings. `Y` must be the same as the data type of `Mdl.ClassNames`.

The length of `Y` and the number of rows of `X` must be equal.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'LossFun'` — Loss function

`'classiferror'` (default) | `'binodeviance'` | `'exponential'` | `'hinge'` | `'mincost'` | function handle

Loss function, specified as the comma-separated pair consisting of `'LossFun'` and a function handle or string.

- This table describes the built-in loss functions. Specify one using its corresponding string.

String	Loss Function
`'binodeviance'`	Binomial deviance
`'classiferror'`	Classification error
`'exponential'`	Exponential loss
`'hinge'`	Hinge loss
`'mincost'`	Minimum misclassification cost loss

- Specify your own function using function handle notation.

  Suppose that `n = size(X,1)` is the sample size and `k = size(Mdl.ClassNames,1)` is the number of classes. Your function must have the signature `lossvalue = lossfun(C,S,W,Cost)`, where:

  - The output argument `lossvalue` is a scalar.
  - You choose the function name (`lossfun`).
  - `C` is an `n`-by-`k` logical matrix with rows indicating to which class the corresponding observation belongs. The column order corresponds to the class order in `Mdl.ClassNames`.

    Construct `C` by setting `C(p,q) = 1` if observation `p` is in class `q`, for each row. Set all other elements of row `p` to `0`.
  - `S` is an `n`-by-`k` numeric matrix of classification scores. The column order corresponds to the class order in `Mdl.ClassNames`. `S` is a matrix of posterior probabilities, similar to the output of `predict`.
  - `W` is an `n`-by-1 numeric vector of observation weights. If you pass `W`, the software normalizes the weights to sum to the prior probability of their respective class. If `Mdl` is a compact model, then you must also supply the weights using the `'Weights'` name-value pair argument.
  - `Cost` is a `k`-by-`k` numeric matrix of misclassification costs. For example, `Cost = ones(K) - eye(K)` specifies a cost of `0` for correct classification, and `1` for misclassification.

  Specify your function using `'LossFun',@lossfun`.

`'Weights'` — Observation weights

`ones(size(X,1),1)` (default) | numeric vector

Observation weights, specified as the comma-separated pair consisting of `'Weights'` and a numeric vector.

The size of `Weights` must be equal to the number of rows of X. The software weighs the observations in each row of X with the corresponding weight in `Weights`.

If you do not specify your own loss function, then the software normalizes `Weights` to add up to `1`.

Data Types: `double`

Output Arguments

L — Classification loss

scalar

Classification loss, returned as a scalar. `L` is a generalization or resubstitution quality measure. Its interpretation depends on the loss function and weighting scheme, but, in general, better classifiers yield smaller loss values.

Definitions

Binomial Deviance

The *binomial deviance* (or *multinomial deviance* for number of classes $K > 3$) is a classification error measure that has the form

$$L = \frac{\sum_{j=1}^{n} w_j \log\left(1 + \exp\left(-2 y_j' f\left(X_j\right)\right)\right)}{\sum_{j=1}^{n} w_j},$$

where:

- w_j is weight j.
- For binary classification, $y_j = 1$ for the positive class and -1 for the negative class. For problems where the number of classes $K > 3$, y_j is a vector of 0s, but with a 1 in the position corresponding to the true class, e.g., if the second observation is in the third class and $K = 4$, then $y_2 = [0\ 0\ 1\ 0]'$.
- $f(X_j)$ is, for binary classification, the posterior probability or, for $K > 3$, a vector of posterior probabilities for each class given observation j.

The binomial deviance has connections to the maximization of the binomial likelihood function. For details on binomial deviance, see [1].

Classification Error

The *classification error* is a binary classification error measure that has the form

$$L = \frac{\sum_{j=1}^{n} w_j e_j}{\sum_{j=1}^{n} w_j},$$

where:

- w_j is the weight for observation j. The software renormalizes the weights to sum to 1.
- $e_j = 1$ if the predicted class of observation j differs from its true class, and 0 otherwise.

In other words, it is the proportion of observations that the classifier misclassifies.

Exponential Loss

Exponential loss is a classification error measure that is similar to binomial deviance, and has the form

$$L = \frac{\sum_{j=1}^{n} w_j \exp\left(-y_j' f\left(X_j\right)\right)}{\sum_{j=1}^{n} w_j},$$

where:

- w_j is weight j.
- For binary classification, $y_j = 1$ for the positive class and -1 for the negative class. For problems where the number of classes $K > 3$, y_j is a vector of 0s, but with a 1 in the position corresponding to the true class, e.g., if the second observation is in the third class and $K = 4$, then $y_2 = [0\ 0\ 1\ 0]'$.
- $f(X_j)$ is, for binary classification, the posterior probability or, for $K > 3$, a vector of posterior probabilities for each class given observation j.

Hinge Loss

Hinge loss is a binary classification error measure that has the form

$$L = \frac{\sum_{j=1}^{n} w_j \max\left\{0, 1 - y_j' f\left(X_j\right)\right\}}{\sum_{j=1}^{n} w_j},$$

where:

- w_j is weight j.
- For binary classification, $y_j = 1$ for the positive class and -1 for the negative class. For problems where the number of classes $K > 3$, y_j is a vector of 0s, but with a 1 in the position corresponding to the true class, e.g., if the second observation is in the third class and $K = 4$, then $y_2 = [0\ 0\ 1\ 0]'$.
- $f(X_j)$ is, for binary classification, the posterior probability or, for $K > 3$, a vector of posterior probabilities for each class given observation j.

Hinge loss linearly penalizes for misclassified observations, and is related to the support vector machine (SVM) objective function used for optimization. For more details on hinge loss, see [1].

Minimum Misclassification Cost Loss

The *minimum misclassification cost loss* is the weighted average of the minimum expected misclassification costs for each observation.

In other words, the minimum misclassification cost is

$$L = \frac{\sum_{j=1}^{n} w_j c_j}{\sum_{j}^{n} w_j},$$

where:

- w_j is the weight of observation j.
- c_j is the minimum of the expected misclassification costs for observation j.

Misclassification Cost

A *misclassification cost* is the relative severity of a classifier labeling an observation into the wrong class.

There are two types of misclassification costs: true and expected. Let K be the number of classes.

- *True misclassification cost* — A K-by-K matrix, where element (i,j) indicates the misclassification cost of predicting an observation into class j if its true class is i. The software stores the misclassification cost in the property `Mdl.Cost`, and used in computations. By default, `Mdl.Cost(i,j)` = 1 if `i` ≠ `j`, and `Mdl.Cost(i,j)` = 0 if `i` = `j`. In other words, the cost is `0` for correct classification, and `1` for any incorrect classification.
- *Expected misclassification cost* — A K-dimensional vector, where element k is the weighted average misclassification cost of classifying an observation into class k, weighted by the class posterior probabilities. In other words,

$$c_k = \sum_{j=1}^{K} \hat{P}(Y = j \mid x_1,...,x_P)\texttt{Cost}_{jk}.$$

the software classifies observations to the class corresponding with the lowest expected misclassification cost.

Posterior Probability

The *posterior probability* is the probability that an observation belongs in a particular class, given the data.

For naive Bayes, the posterior probability that a classification is k for a given observation $(x_1,...,x_P)$ is

$$\hat{P}(Y = k \mid x_1,..,x_P) = \frac{P(X_1,...,X_P \mid y = k)\pi(Y = k)}{P(X_1,...,X_P)},$$

where:

- $P(X_1,...,X_P \mid y = k)$ is the conditional joint density of the predictors given they are in class k. `Mdl.DistributionNames` stores the distribution names of the predictors.
- $\pi(Y = k)$ is the class prior probability distribution. `Mdl.Prior` stores the prior distribution.
- $P(X_1,..,X_P)$ is the joint density of the predictors. The classes are discrete, so

$$P(X_1,...,X_P) = \sum_{k=1}^{K} P(X_1,...,X_P \mid y = k)\pi(Y = k).$$

Prior Probability

The *prior probability* is the believed relative frequency that observations from a class occur in the population for each class.

Examples

Determine Test Sample Minimum Cost Loss of Naive Bayes Classifiers

Load Fisher's iris data set.

```
load fisheriris
X = meas;    % Predictors
Y = species; % Response
rng(1);      % For reproducibility
```

Train a naive Bayes classifier. Specify a 15% holdout sample for testing. It is good practice to specify the class order. Assume that each predictor is conditionally normally distributed given its label.

```
CVMdl = fitcnb(X,Y,'ClassNames',{'setosa','versicolor','virginica'},...
    'Holdout',0.15);
CMdl = CVMdl.Trained{1}; % Extract the trained, compact classifier
testInds = test(CVMdl.Partition);   % Extract the test indices
XTest = X(testInds,:);
YTest = Y(testInds);
```

`CVMdl` is a `ClassificationPartitionedModel` classifier. It contains the property `Trained`, which is a 1-by-1 cell array holding a `CompactClassificationNaiveBayes` classifier that the software trained using the training set.

Determine how well the algorithm generalizes by estimating the test sample minimum cost loss.

```
L = loss(CMdl,XTest,YTest)
```

```
L =

    0.0476
```

The test sample average classification cost is approximately 0.05.

You might improve the classification error by specifying better predictor distributions when you train the classifier.

Determine the Test Sample Classification Error of Naive Bayes Classifiers

Load Fisher's iris data set.

```
load fisheriris
X = meas;    % Predictors
Y = species; % Response
rng(1); % For reproducibility
```

Train a naive Bayes classifier. Specify a 15% holdout sample for testing. It is good practice to specify the class order. Assume that each predictor is conditionally normally distributed given its label.

```
CVMdl = fitcnb(X,Y,'ClassNames',{'setosa','versicolor','virginica'},...
    'Holdout',0.15);
CMdl = CVMdl.Trained{1}; % Extract the trained, compact classifier
testInds = test(CVMdl.Partition);   % Extract the test indices
XTest = X(testInds,:);
YTest = Y(testInds);
```

`CVMdl` is a `ClassificationPartitionedModel` classifier. It contains the property `Trained`, which is a 1-by-1 cell array holding a `CompactClassificationNaiveBayes` classifier that the software trained using the training set.

Determine how well the algorithm generalizes by estimating the test sample classification error.

```
L = loss(CMdl,XTest,YTest,'LossFun','classiferror')
```

```
L =

    0.0476
```

The classifier misclassified approximately 5% of the test sample observations.

loss

Class: CompactClassificationSVM

Classification error for support vector machine classifiers

Syntax

```
L = loss(SVMModel,X,Y)
L = loss(SVMModel,X,Y,Name,Value)
```

Description

`L = loss(SVMModel,X,Y)` returns the classification error (`L`), a scalar representing how well the trained support vector machine (SVM) classifer SVMModel classifies the predictor data (X) as compared to the true class labels (Y).

`loss` normalizes the class probabilities in Y to the prior class probabilities `fitcsvm` used for training, stored in the `Prior` property of `SVMModel`.

`L = loss(SVMModel,X,Y,Name,Value)` returns the classification error with additional options specified by one or more Name,Value pair arguments.

Input Arguments

`SVMModel` — SVM classifier

`ClassificationSVM` classifier | `CompactClassificationSVM` classifier

SVM classifier, specified as a `ClassificationSVM` classifier or `CompactClassificationSVM` classifier returned by `fitcsvm` or `compact`, respectively.

`X` — Predictor data

numeric matrix

Predictor data, specified as a numeric matrix.

Each row of `X` corresponds to one observation (also known as an instance or example), and each column corresponds to one variable (also known as a feature). The variables making up the columns of `X` should be the same as the variables that trained the `SVMModel` classifier.

The length of `Y` and the number of rows of `X` must be equal.

If you set `'Standardize',true` in `fitcsvm` to train `SVMModel`, then the software standardizes the columns of `X` using the corresponding means in `SVMModel.Mu` and standard deviations in `SVMModel.Sigma`.

Data Types: `double` | `single`

`Y` — Class labels

categorical array | character array | logical vector | vector of numeric values | cell array of strings

Class labels, specified as a categorical or character array, logical or numeric vector, or cell array of strings. `Y` must be the same as the data type of `SVMModel.ClassNames`.

The length of `Y` and the number of rows of `X` must be equal.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'LossFun'` — Loss function

`'classiferror'` (default) | `'binodeviance'` | `'exponential'` | `'hinge'` | function handle

Loss function, specified as the comma-separated pair consisting of `'LossFun'` and a function handle or string.

- The following lists available loss functions. Specify one using its corresponding string.

Value	Loss Function
`'binodeviance'`	Binomial deviance
`'classiferror'`	Classification error

Value	Loss Function
`'exponential'`	Exponential loss
`'hinge'`	Hinge loss

- Specify your own function using function handle notation.

  Suppose that `n = size(X,1)` is the sample size and `K= size(SVMModel.ClassNames,1)` is the number of classes. Your function must have the signature `lossvalue = lossfun(C,S,W,Cost)`, where:

  - The output argument `lossvalue` is a scalar.
  - You choose the function name (*`lossfun`*).
  - `C` is an `n`-by-`K` logical matrix with rows indicating which class the corresponding observation belongs. The column order corresponds to the class order in `SVMModel.ClassNames`.

    Construct `C` by setting `C(p,q) = 1` if observation `p` is in class `q`, for each row. Set all other elements of row `p` to `0`.
  - `S` is an `n`-by-`K` numeric matrix of classification scores. The column order corresponds to the class order in `SVMModel.ClassNames`. `S` is a matrix of classification scores, similar to the output of `predict`.
  - `W` is an `n`-by-1 numeric vector of observation weights. If you pass `W`, the software normalizes them to sum to `1`.
  - `Cost` is a `K`-by-`K` numeric matrix of misclassification costs. For example, `Cost = ones(K) - eye(K)` specifies a cost of `0` for correct classification, and `1` for misclassification.

  Specify your function using `'LossFun',@lossfun`.

Data Types: `char` | `function_handle`

`'Weights'` — Observation weights

`ones(size(X,1),1)` (default) | numeric vector

Observation weights, specified as the comma-separated pair consisting of `'Weights'` and a numeric vector.

The size of `Weights` must be equal to the number of rows of X. The software weighs the observations in each row of X with the corresponding weight in `Weights`.

If you do not specify your own loss function, then the software normalizes `Weights` to sum up to the value of the prior probability in the respective class.

Data Types: `double`

Output Arguments

`L` — Classification loss

scalar

Classification loss, returned as a scalar. `L` is a generalization or resubstitution quality measure. Its interpretation depends on the loss function and weighting scheme, but, in general, better classifiers yield smaller loss values.

Definitions

Binomial Deviance

The binomial deviance is a binary classification error measure that has the form

$$L = \frac{\sum_{j=1}^{n} w_j \log\left(1 + \exp\left(-2 y_j' f\left(X_j\right)\right)\right)}{\sum_{j=1}^{n} w_j},$$

where:

- w_j is weight j. The software renormalizes the weights to sum to 1.
- $y_j = \{-1,1\}$.
- $f(X_j)$ is the score for observation j.

The binomial deviance has connections to the maximization of the binomial likelihood function. For details on binomial deviance, see [1].

Classification Error

The *classification error* is a binary classification error measure that has the form

$$L = \frac{\sum_{j=1}^{n} w_j e_j}{\sum_{j=1}^{n} w_j},$$

where:

- w_j is the weight for observation j. The software renormalizes the weights to sum to 1.
- $e_j = 1$ if the predicted class of observation j differs from its true class, and 0 otherwise.

In other words, it is the proportion of observations that the classifier misclassifies.

Exponential Loss

A binary classification error measure that is similar to binomial deviance, and has the form

$$L = \frac{\sum_{j=1}^{n} w_j \exp\left(-y_j' f\left(X_j\right)\right)}{\sum_{j=1}^{n} w_j},$$

where:

- w_j is weight j. The software renormalizes the weights to sum to 1.
- $y_j = \{-1,1\}$.
- $f(X_j)$ is the score for observation j.

Hinge Loss

Hinge loss is a binary classification error measure that has the form

$$L = \frac{\sum_{j=1}^{n} w_j \max\left\{0, 1 - y_j' f\left(X_j\right)\right\}}{\sum_{j=1}^{n} w_j},$$

where:

- w_j is weight j. The software renormalizes the weights to sum to 1.
- y_j = {-1,1}.
- $f(X_j)$ is the score for observation j.

Hinge loss linearly penalizes for misclassified observations, and is related to the SVM objective function used for optimization. For more details on hinge loss, see [1].

Score

The SVM *score* for classifying observation x is the signed distance from x to the decision boundary ranging from -∞ to +∞. A positive score for a class indicates that x is predicted to be in that class, a negative score indicates otherwise.

The score is also the numerical, predicted response for x, $f(x)$, computed by the trained SVM classification function

$$f(x) = \sum_{j=1}^{n} \alpha_j y_j G(x_j, x) + b,$$

where $(\alpha_1, ..., \alpha_n, b)$ are the estimated SVM parameters, $G(x_j, x)$ is the dot product in the predictor space between x and the support vectors, and the sum includes the training set observations.

If $G(x_j, x) = x_j' x$ (the linear kernel), then the score function reduces to

$$f\left(x\right) = \left(x / s\right)'\beta + b.$$

s is the kernel scale and β is the vector of fitted linear coefficients.

Examples

Determine the Test Sample Classification Error of SVM Classifiers

Load the `ionosphere` data set.

```
load ionosphere
rng(1); % For reproducibility
```

Train an SVM classifier. Specify a 15% holdout sample for testing. It is good practice to specify the class order and standardize the data.

```
CVSVMModel = fitcsvm(X,Y,'Holdout',0.15,'ClassNames',{'b','g'},...
    'Standardize',true);
CompactSVMModel = CVSVMModel.Trained{1}; % Extract the trained, compact classifier
testInds = test(CVSVMModel.Partition);   % Extract the test indices
XTest = X(testInds,:);
YTest = Y(testInds,:);
```

`CVSVMModel` is a `ClassificationPartitionedModel` classifier. It contains the property `Trained`, which is a 1-by-1 cell array holding a `CompactClassificationSVM` classifier that the software trained using the training set.

Determine how well the algorithm generalizes by estimating the test sample classification error.

```
L = loss(CompactSVMModel,XTest,YTest)
```

```
L =

    0.0787
```

The SVM classifier misclassifies approximately 8% of the test sample radar returns.

Determine the Test Sample Hinge Loss of SVM Classifiers

Load the `ionosphere` data set.

```
load ionosphere
```

```
rng(1); % For reproducibility
```

Train an SVM classifier. Specify a 15% holdout sample for testing. It is good practice to specify the class order and standardize the data.

```
CVSVMModel = fitcsvm(X,Y,'Holdout',0.15,'ClassNames',{'b','g'},...
    'Standardize',true);
CompactSVMModel = CVSVMModel.Trained{1}; % Extract the trained, compact classifier
testInds = test(CVSVMModel.Partition);   % Extract the test indices
XTest = X(testInds,:);
YTest = Y(testInds,:);
```

`CVSVMModel` is a `ClassificationPartitionedModel` classifier. It contains the property `Trained`, which is a 1-by-1 cell array holding a `CompactClassificationSVM` classifier that the software trained using the training set.

Determine how well the algorithm generalizes by estimating the test sample hinge loss.

```
L = loss(CompactSVMModel,XTest,YTest,'LossFun','Hinge')
```

```
L =

    0.2998
```

The hinge loss is approximately 0.3. Classifiers with hinge losses close to 0 are desirable.

loss

Class: CompactClassificationTree

Classification error

Syntax

```
L = loss(tree,X,Y)
L = loss(tree,X,Y,Name,Value)
L = loss(tree,X,Y,'Subtrees',subtreevector)
[L,se] = loss(tree,X,Y,'Subtrees',subtreevector)
[L,se,NLeaf] = loss(tree,X,Y,'Subtrees',subtreevector)
[L,se,NLeaf,bestlevel] = loss(tree,X,Y,'Subtrees',subtreevector)
[L,...] = loss(tree,X,Y,'Subtrees',subtreevector,Name,Value)
```

Description

`L = loss(tree,X,Y)` returns a scalar representing how well `tree` classifies the data in `X`, when `Y` contains the true classifications.

When computing the loss, `loss` normalizes the class probabilities in Y to the class probabilities used for training, stored in the `Prior` property of tree.

`L = loss(tree,X,Y,Name,Value)` returns the loss with additional options specified by one or more Name,Value pair arguments.

`L = loss(tree,X,Y,'Subtrees',subtreevector)` returns a vector of classification errors for the trees in the pruning sequence `subtreevector`.

`[L,se] = loss(tree,X,Y,'Subtrees',subtreevector)` returns the vector of standard errors of the classification errors.

Note: `loss` returns `se` and further outputs only when the `LossFun` name-value pair is the default `'classiferror'`.

`[L,se,NLeaf] = loss(tree,X,Y,'Subtrees',subtreevector)` returns the vector of numbers of leaf nodes in the trees of the pruning sequence.

`[L,se,NLeaf,bestlevel] = loss(tree,X,Y,'Subtrees',subtreevector)` returns the best pruning level as defined in the `TreeSize` name-value pair. By default, `bestlevel` is the pruning level that gives loss within one standard deviation of minimal loss.

`[L,...] = loss(tree,X,Y,'Subtrees',subtreevector,Name,Value)` returns loss statistics with additional options specified by one or more Name,Value pair arguments.

Input Arguments

`tree`

A classification tree or compact classification tree constructed by `fitctree` or `compact`.

`X`

Matrix of data to classify. Each row of `X` represents one observation, and each column represents one predictor. `X` must have the same number of columns as the data used to train tree. `X` should have the same number of rows as the number of elements in `Y`.

`Y`

Classification of X. `Y` should be of the same type as the classification used to train tree, and its number of elements should equal the number of rows of X.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'LossFun '`

Function handle or string representing a loss function. Built-in loss functions:

- `'binodeviance'` — See "Loss Functions" on page 22-2719
- `'classiferror'` — Fraction of misclassified observations. See "Loss Functions" on page 22-2719.
- `'exponential'` — See "Loss Functions" on page 22-2719
- `'hinge'` — See "Loss Functions" on page 22-2719.
- `'mincost'` — Smallest misclassification cost as given by the tree`.Cost` matrix. See "Loss Functions" on page 22-2719.

You can write your own loss function in the syntax described in "Loss Functions" on page 22-2719.

Default: `'mincost'`

`'Weights'`

A numeric vector of length `N`, where `N` is the number of rows of X. `Weights` are nonnegative. `loss` normalizes the weights so that observation weights in each class sum to the prior probability of that class. When you supply `Weights`, `loss` computes weighted classification loss.

Default: `ones(N,1)`

Name,Value arguments associated with pruning subtrees:

`'Subtrees'`

A vector of nonnegative integers in ascending order or `'all'`.

If you specify a vector, then all elements must be at least `0` and at most `max(tree.PruneList)`. `0` indicates the full, unpruned tree and `max(tree.PruneList)` indicates the a completely pruned tree (i.e., just the root node).

If you specify `'all'`, then `CompactClassificationTree.loss` operates on all subtrees (i.e., the entire pruning sequence). This specification is equivalent to using `0:max(tree.PruneList)`.

`CompactClassificationTree.loss` prunes tree to each level indicated in `Subtrees`, and then estimates the corresponding output arguments. The size of `Subtrees` determines the size of some output arguments.

To invoke `Subtrees`, the properties `PruneList` and `PruneAlpha` of tree must be nonempty. In other words, grow `tree` by setting `'Prune','on'`, or by pruning `tree` using `prune`.

Default: `0`

`'TreeSize'`

One of the following strings:

- `'se'` — `loss` returns the highest pruning level with loss within one standard deviation of the minimum (`L+se`, where `L` and `se` relate to the smallest value in `Subtrees`).
- `'min'` — `loss` returns the element of `Subtrees` with smallest loss, usually the smallest element of `Subtrees`.

Output Arguments

`L`

Classification error, a vector the length of `Subtrees`. The meaning of the error depends on the values in `Weights` and `LossFun`; see “Classification Error” on page 22-2719.

`se`

Standard error of loss, a vector the length of `Subtrees`.

`NLeaf`

Number of leaves (terminal nodes) in the pruned subtrees, a vector the length of `Subtrees`.

`bestlevel`

A scalar whose value depends on `TreeSize`:

- `TreeSize` = `'se'` — `loss` returns the highest pruning level with loss within one standard deviation of the minimum (`L+se`, where `L` and `se` relate to the smallest value in `Subtrees`).

- `TreeSize` = `'min'` — `loss` returns the element of `Subtrees` with smallest loss, usually the smallest element of `Subtrees`.

Definitions

Classification Error

The default classification error is the fraction of data X that tree misclassifies, where Y represents the true classifications.

Weighted classification error is the sum of weight i times the Boolean value that is `1` when tree misclassifies the ith row of `X`, divided by the sum of the weights.

Loss Functions

The built-in loss functions are:

- `'binodeviance'` — For binary classification, assume the classes y_n are `-1` and `1`. With weight vector w normalized to have sum `1`, and predictions of row n of data X as $f(X_n)$, the binomial deviance is

$$\sum w_n \log\left(1+\exp\left(-2y_n f\left(X_n\right)\right)\right).$$

- `'exponential'` — With the same definitions as for `'binodeviance'`, the exponential loss is

$$\sum w_n \exp\left(-y_n f\left(X_n\right)\right).$$

- `'classiferror'` — Predict the label with the largest posterior probability. The loss is then the fraction of misclassified observations.
- `'hinge'` — Classification error measure that has the form

$$L=\frac{\sum_{j=1}^{n} w_j \max\left\{0,1-y_j' f\left(X_j\right)\right\}}{\sum_{j=1}^{n} w_j},$$

where:

- w_j is weight j.
- For binary classification, $y_j = 1$ for the positive class and -1 for the negative class. For problems where the number of classes $K > 3$, y_j is a vector of 0s, but with a 1 in the position corresponding to the true class, e.g., if the second observation is in the third class and $K = 4$, then $y_2 = [0\ 0\ 1\ 0]'$.
- $f(X_j)$ is, for binary classification, the posterior probability or, for $K > 3$, a vector of posterior probabilities for each class given observation j.

- `'mincost'` — Predict the label with the smallest expected misclassification cost, with expectation taken over the posterior probability, and cost as given by the `Cost` property of the classifier (a matrix). The loss is then the true misclassification cost averaged over the observations.

To write your own loss function, create a function file in this form:

```
function loss = lossfun(C,S,W,COST)
```

- `N` is the number of rows of X.
- `K` is the number of classes in the classifier, represented in the `ClassNames` property.
- `C` is an `N`-by-`K` logical matrix, with one `true` per row for the true class. The index for each class is its position in the `ClassNames` property.
- `S` is an `N`-by-`K` numeric matrix. `S` is a matrix of posterior probabilities for classes with one row per observation, similar to the `posterior` output from `predict`.
- `W` is a numeric vector with `N` elements, the observation weights. If you pass `W`, the elements are normalized to sum to the prior probabilities in the respective classes.
- `COST` is a `K`-by-`K` numeric matrix of misclassification costs. For example, you can use `COST = ones(K) - eye(K)`, which means a cost of `0` for correct classification, and `1` for misclassification.
- The output `loss` should be a scalar.

Pass the function handle `@lossfun` as the value of the `LossFun` name-value pair.

True Misclassification Cost

There are two costs associated with classification: the true misclassification cost per class, and the expected misclassification cost per observation.

You can set the true misclassification cost per class in the `Cost` name-value pair when you create the classifier using the `fitctree` method. `Cost(i,j)` is the cost of classifying an observation into class `j` if its true class is `i`. By default, `Cost(i,j)=1` if `i~=j`, and `Cost(i,j)=0` if `i=j`. In other words, the cost is `0` for correct classification, and `1` for incorrect classification.

Expected Misclassification Cost

There are two costs associated with classification: the true misclassification cost per class, and the expected misclassification cost per observation.

Suppose you have `Nobs` observations that you want to classify with a trained classifier. Suppose you have `K` classes. You place the observations into a matrix `Xnew` with one observation per row.

The expected cost matrix `CE` has size `Nobs`-by-`K`. Each row of `CE` contains the expected (average) cost of classifying the observation into each of the `K` classes. `CE(n,k)` is

$$\sum_{i=1}^{K} \hat{P}(i \mid Xnew(n)) C(k \mid i),$$

where

- K is the number of classes.
- $\hat{P}(i \mid Xnew(n))$ is the posterior probability of class i for observation $Xnew(n)$.
- $C(k \mid i)$ is the true misclassification cost of classifying an observation as k when its true class is i.

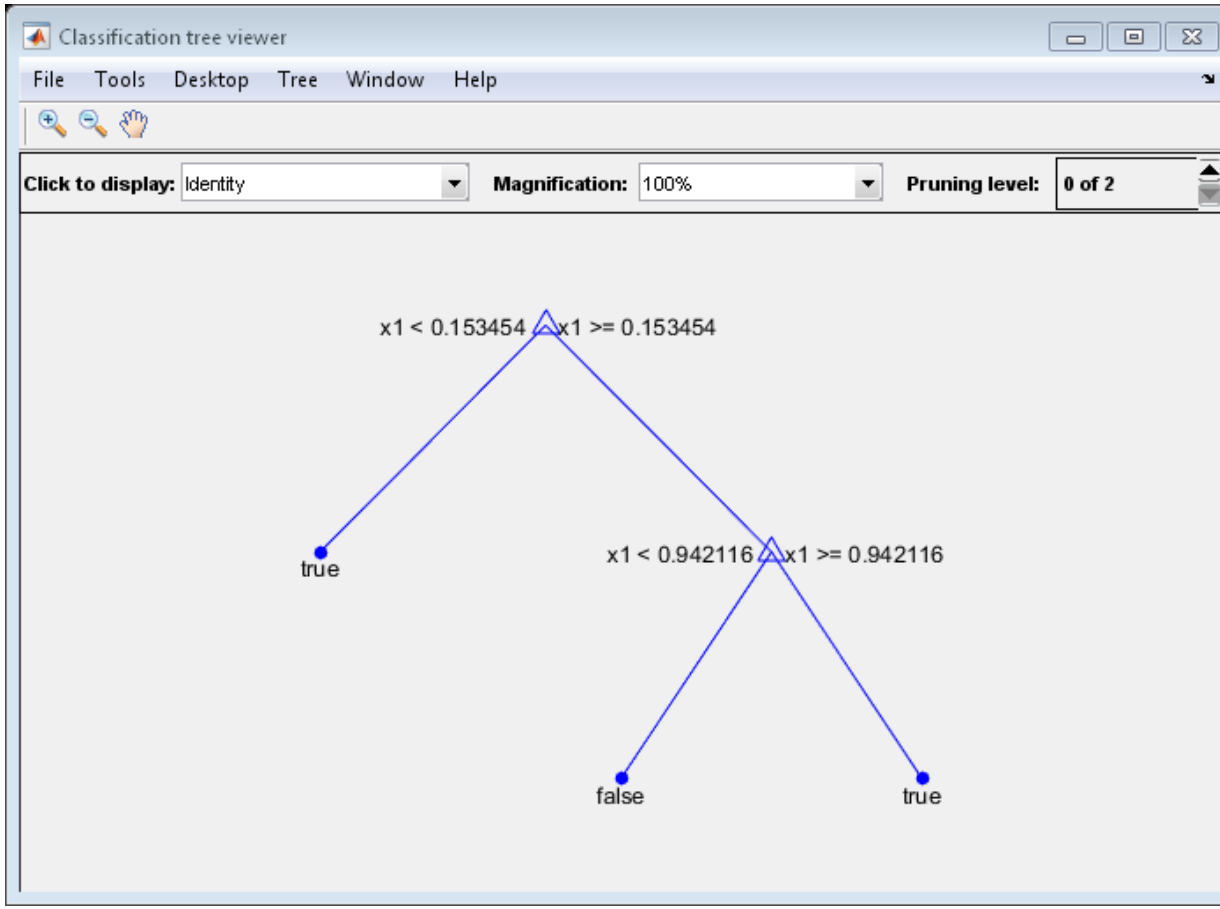
Score (tree)

For trees, the *score* of a classification of a leaf node is the posterior probability of the classification at that node. The posterior probability of the classification at a node is the number of training sequences that lead to that node with the classification, divided by the number of training sequences that lead to that node.

For example, consider classifying a predictor `X` as `true` when `X < 0.15` or `X > 0.95`, and `X` is false otherwise.

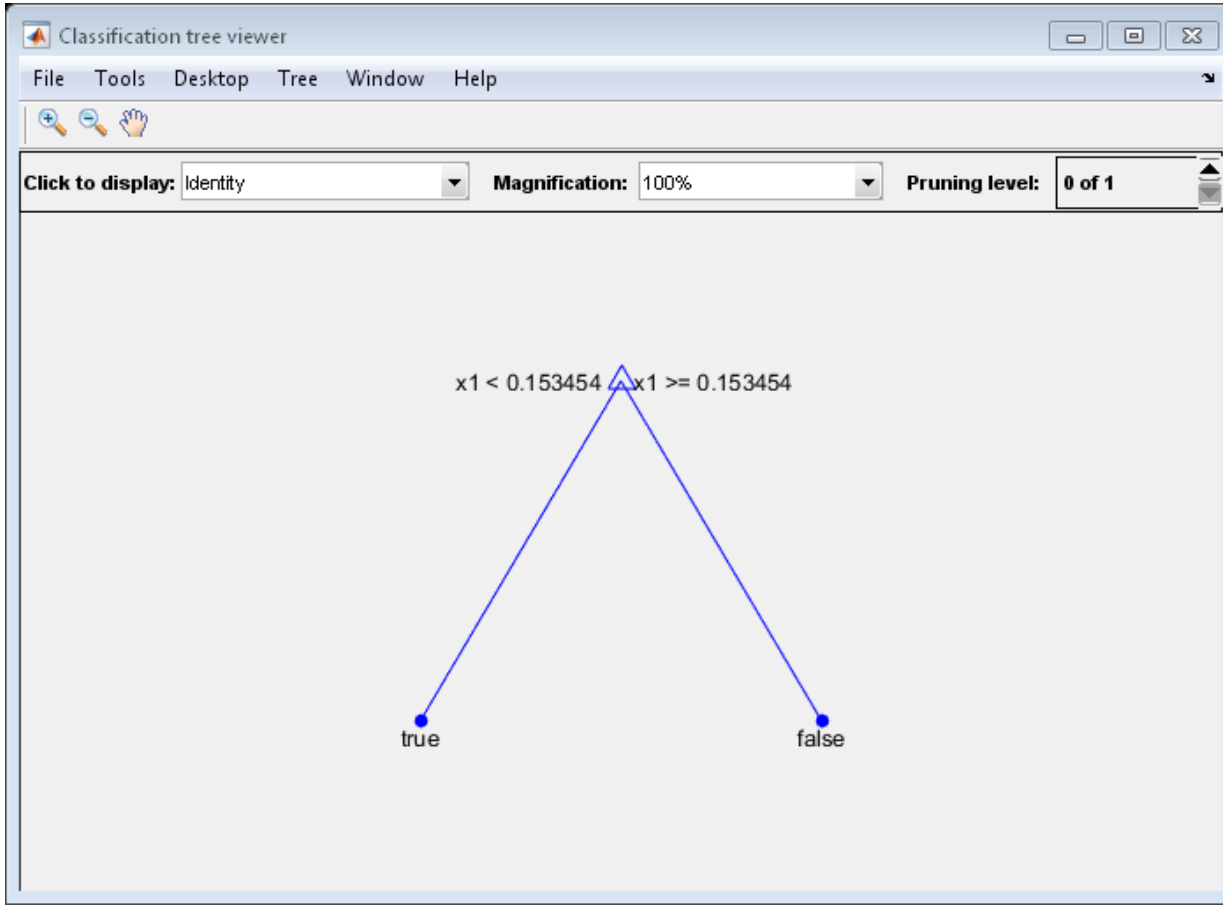
Generate 100 random points and classify them:

```
rng(0,'twister') % for reproducibility
X = rand(100,1);
Y = (abs(X - .55) > .4);
tree = fitctree(X,Y);
view(tree,'Mode','Graph')
```



Prune the tree:

```
tree1 = prune(tree,'Level',1);
view(tree1,'Mode','Graph')
```



The pruned tree correctly classifies observations that are less than 0.15 as `true`. It also correctly classifies observations from .15 to .94 as `false`. However, it incorrectly classifies observations that are greater than .94 as `false`. Therefore, the score for observations that are greater than .15 should be about .05/.85=.06 for `true`, and about .8/.85=.94 for `false`.

Compute the prediction scores for the first 10 rows of `X`:

```
[~,score] = predict(tree1,X(1:10));
[score X(1:10,:)]
```

```
ans =

    0.9059    0.0941    0.8147
    0.9059    0.0941    0.9058
         0    1.0000    0.1270
    0.9059    0.0941    0.9134
    0.9059    0.0941    0.6324
         0    1.0000    0.0975
    0.9059    0.0941    0.2785
    0.9059    0.0941    0.5469
    0.9059    0.0941    0.9575
    0.9059    0.0941    0.9649
```

Indeed, every value of `X` (the right-most column) that is less than 0.15 has associated scores (the left and center columns) of `0` and `1`, while the other values of `X` have associated scores of `0.91` and `0.09`. The difference (score `0.09` instead of the expected `.06`) is due to a statistical fluctuation: there are `8` observations in `X` in the range `(.95,1)` instead of the expected `5` observations.

Examples

Compute the In-sample Classification Error

Compute the resubstituted classification error for the `ionosphere` data set.

```
load ionosphere
tree = fitctree(X,Y);
L = loss(tree,X,Y)
```

```
L =

    0.0114
```

Examine the Classification Error for Each Subtree

Unpruned decision trees tend to overfit. One way to balance model complexity and out-of-sample performance is to prune a tree (or restrict its growth) so that in-sample and out-of-sample performance are satisfactory.

Load Fisher's iris data set. Partition the data into training (50%) and validation (50%) sets.

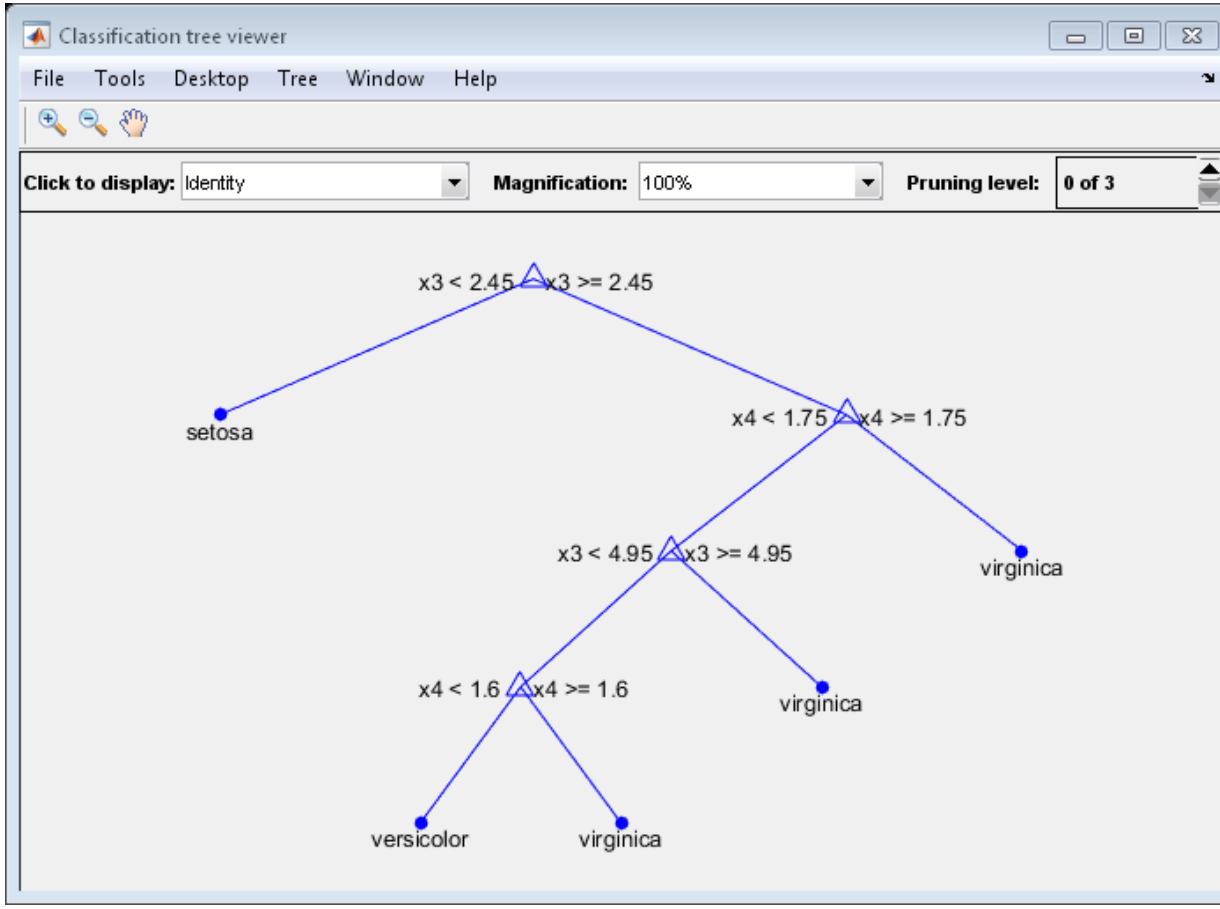
```
load fisheriris
n = size(meas,1);
rng(1) % For reproducibility
idxTrn = false(n,1);
idxTrn(randsample(n,round(0.5*n))) = true; % Training set logical indices
idxVal = idxTrn == false;                  % Validation set logical indices
```

Grow a classification tree using the training set.

```
Mdl = fitctree(meas(idxTrn,:),species(idxTrn));
```

View the classification tree.

```
view(Mdl,'Mode','graph');
```



The classification tree has four pruning levels. Level 0 is the full, unpruned tree (as displayed). Level 3 is just the root node (i.e., no splits).

Examine the training sample classification error for each subtree (or pruning level) excluding the highest level.

```
m = max(Mdl.PruneList) - 1;
trnLoss = resubLoss(Mdl,'SubTrees',0:m)
```

```
trnLoss =
```

```
    0.0267
    0.0533
    0.3067
```

- The full, unpruned tree misclassifies about 2.7% of the training observations.
- The tree pruned to level 1 misclassifies about 5.3% of the training observations.
- The tree pruned to level 2 (i.e., a stump) misclassifies about 30.6% of the training observations.

Examine the validation sample classification error at each level excluding the highest level.

```
valLoss = loss(Mdl,meas(idxVal,:),species(idxVal),'SubTrees',0:m)
```

```
valLoss =

    0.0369
    0.0237
    0.3067
```

- The full, unpruned tree misclassifies about 3.7% of the validation observations.
- The tree pruned to level 1 misclassifies about 2.4% of the validation observations.
- The tree pruned to level 2 (i.e., a stump) misclassifies about 30.7% of the validation observations.

To balance model complexity and out-of-sample performance, consider pruning `Mdl` to level 1.

```
pruneMdl = prune(Mdl,'Level',1);
view(pruneMdl,'Mode','graph')
```

`margin` | `predict` | `fitctree` | `edge`

loss

Class: CompactRegressionEnsemble

Regression error

Syntax

```
L = loss(ens,X,Y)
L = loss(ens,X,Y,Name,Value)
```

Description

`L = loss(ens,X,Y)` returns the mean squared error between the predictions of `ens` to the data in `X`, compared to the true responses `Y`.

`L = loss(ens,X,Y,Name,Value)` computes the error in prediction with additional options specified by one or more Name,Value pair arguments.

Input Arguments

`ens`

A regression ensemble created with `fitensemble`, or the `compact` method.

`X`

A matrix of predictor values. Each column of `X` represents one variable, and each row represents one observation.

`NaN` values in `X` are taken to be missing values. Observations with all missing values for `X` are not used in the calculation of loss.

`Y`

A numeric column vector with the same number of rows as `X`. Each entry in `Y` is the response to the data in the corresponding row of `X`.

`NaN` values in `Y` are taken to be missing values. Observations with missing values for `Y` are not used in the calculation of loss.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'learners'`

Indices of weak learners in the ensemble ranging from `1` to `ens.NumTrained`. `oobEdge` uses only these learners for calculating loss.

Default: `1:NumTrained`

`'lossfun'`

Function handle for loss function, or the string `'mse'`, meaning mean squared error. If you pass a function handle `fun`, `loss` calls it as

```
fun(Y,Yfit,W)
```

where `Y`, `Yfit`, and `W` are numeric vectors of the same length.

- `Y` is the observed response.
- `Yfit` is the predicted response.
- `W` is the observation weights.

The returned value `fun(Y,Yfit,W)` should be a scalar.

Default: `'mse'`

`'mode'`

String representing the meaning of the output L:

- `'ensemble'` — `L` is a scalar value, the loss for the entire ensemble.
- `'individual'` — `L` is a vector with one element per trained learner.
- `'cumulative'` — `L` is a vector in which element `J` is obtained by using learners `1:J` from the input list of learners.

Default: `'ensemble'`

`'UseObsForLearner'`

A logical matrix of size `N`-by-`NumTrained`, where `N` is the number of observations in `ens.X`, and `NumTrained` is the number of weak learners. When `UseObsForLearner(I,J)` is `true`, `predict` uses learner `J` in predicting observation `I`.

Default: `true(N,NumTrained)`

`'weights'`

Numeric vector of observation weights with the same number of elements as Y. The formula for `loss` with `weights` is in "Weighted Mean Squared Error" on page 22-2731.

Default: `ones(size(Y))`

Output Arguments

`L`

Weighted mean squared error of predictions. The formula for `loss` is in "Weighted Mean Squared Error" on page 22-2731.

Definitions

Weighted Mean Squared Error

Let n be the number of rows of data, x_j be the jth row of data, y_j be the true response to x_j, and let $f(x_j)$ be the response prediction of ens to x_j. Let w be the vector of weights (all one by default).

First the weights are divided by their sum so they add to one: $w \to w/\Sigma w$. The mean squared error L is

$$L = \sum_{j=1}^{n} w_j \left(f\left(x_j\right) - y_j \right)^2 .$$

Examples

Find the loss of an ensemble predictor of the `carsmall` data to find `MPG` as a function of engine displacement, horsepower, and vehicle weight:

```
load carsmall
X = [Displacement Horsepower Weight];
ens = fitensemble(X,MPG,'LSBoost',100,'Tree');
L = loss(ens,X,MPG)

L =
    4.3904
```

See Also

`predict` | `fitensemble`

loss

Class: CompactRegressionTree

Regression error

Syntax

```
L = loss(tree,X,Y)
[L,se] = loss(tree,X,Y)
[L,se,NLeaf] = loss(tree,X,Y)
[L,se,NLeaf,bestlevel] = loss(tree,X,Y)
L = loss(tree,X,Y,Name,Value)
```

Description

`L = loss(tree,X,Y)` returns the mean squared error between the predictions of `tree` to the data in `X`, compared to the true responses `Y`.

`[L,se] = loss(tree,X,Y)` returns the standard error of the loss.

`[L,se,NLeaf] = loss(tree,X,Y)` returns the number of leaves (terminal nodes) in the tree.

`[L,se,NLeaf,bestlevel] = loss(tree,X,Y)` returns the optimal pruning level for `tree`.

`L = loss(tree,X,Y,Name,Value)` computes the error in prediction with additional options specified by one or more Name,Value pair arguments.

Input Arguments

`tree`

Regression tree created with `fitrtree`, or the `compact` method.

`X`

A matrix of predictor values. Each column of `X` represents one variable, and each row represents one observation.

`Y`

A numeric column vector with the same number of rows as `X`. Each entry in `Y` is the response to the data in the corresponding row of `X`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'LossFun'`

Function handle for loss, or the string `'mse'` representing mean-squared error. If you pass a function handle `fun`, `loss` calls `fun` as:

```
fun(Y,Yfit,W)
```

- `Y` is the vector of true responses.
- `Yfit` is the vector of predicted responses.
- `W` is the observation weights. If you pass `W`, the elements are normalized to sum to `1`.

All the vectors have the same number of rows as Y.

Default: `'mse'`

`'Subtrees'`

A vector of nonnegative integers in ascending order or `'all'`.

If you specify a vector, then all elements must be at least `0` and at most `max(tree.PruneList)`. `0` indicates the full, unpruned tree and `max(tree.PruneList)` indicates the a completely pruned tree (i.e., just the root node).

If you specify `'all'`, then `CompactRegressionTree.loss` operates on all subtrees (i.e., the entire pruning sequence). This specification is equivalent to using `0:max(tree.PruneList)`.

`CompactRegressionTree.loss` prunes tree to each level indicated in `Subtrees`, and then estimates the corresponding output arguments. The size of `Subtrees` determines the size of some output arguments.

To invoke `Subtrees`, the properties `PruneList` and `PruneAlpha` of tree must be nonempty. In other words, grow `tree` by setting `'Prune','on'`, or by pruning `tree` using `prune`.

Default: `0`

`'TreeSize'`

A string, either:

- `'se'` — `loss` returns `bestlevel` that corresponds to the smallest tree whose mean squared error (MSE) is within one standard error of the minimum MSE.
- `'min'` — `loss` returns `bestlevel` that corresponds to the minimal MSE tree.

`'Weights'`

Numeric vector of observation weights with the same number of elements as Y.

Default: `ones(size(Y))`

Output Arguments

`L`

Classification error, a vector the length of `Subtrees`. The error for each tree is the mean squared error, weighted with `Weights`. If you include `LossFun`, `L` reflects the loss calculated with `LossFun`.

`se`

Standard error of loss, a vector the length of `Subtrees`.

`NLeaf`

Number of leaves (terminal nodes) in the pruned subtrees, a vector the length of `Subtrees`.

`bestlevel`

A scalar whose value depends on `TreeSize`:

- `TreeSize` = `'se'` — `loss` returns the highest pruning level with loss within one standard deviation of the minimum (`L+se`, where `L` and `se` relate to the smallest value in `Subtrees`).
- `TreeSize` = `'min'` — `loss` returns the element of `Subtrees` with smallest loss, usually the smallest element of `Subtrees`.

Definitions

Mean Squared Error

The mean squared error m of the predictions $f(X_n)$ with weight vector w is

$$m = \frac{\sum w_n \left(f(X_n) - Y_n\right)^2}{\sum w_n}.$$

Examples

Compute the In-Sample MSE

Load the `carsmall` data set. Consider `Displacement`, `Horsepower`, and `Weight` as predictors of the response `MPG`.

```
load carsmall
X = [Displacement Horsepower Weight];
```

Grow a regression tree using all observations.

```
tree = fitrtree(X,MPG);
```

Estimate the in-sample MSE.

```
L = loss(tree,X,MPG)
```

```
L =

    4.8952
```

Find the Pruning Level Yielding the Optimal In-sample Loss

Load the `carsmall` data set. Consider `Displacement`, `Horsepower`, and `Weight` as predictors of the response `MPG`.

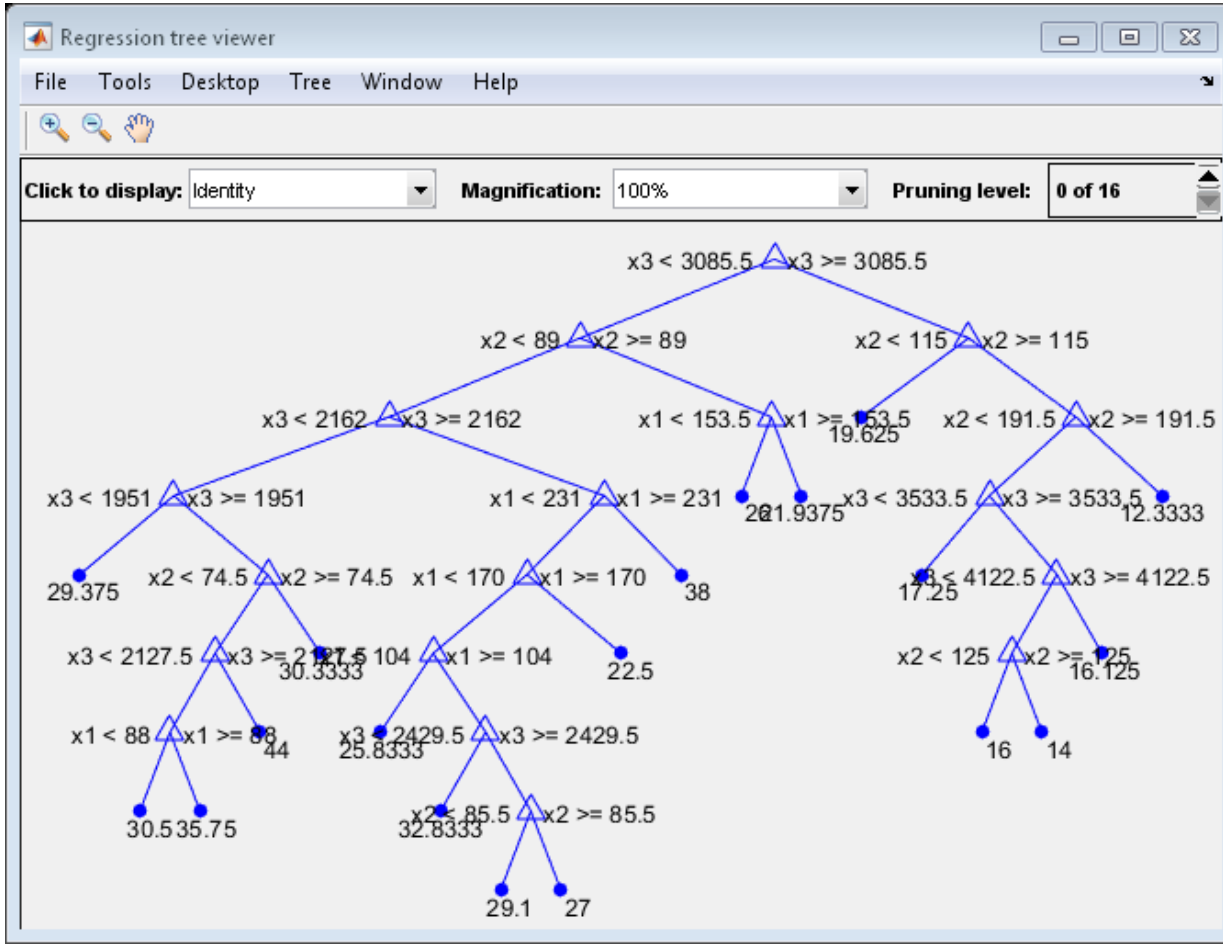
```
load carsmall
X = [Displacement Horsepower Weight];
```

Grow a regression tree using all observations.

```
Mdl = fitrtree(X,MPG);
```

View the regression tree.

```
view(Mdl,'Mode','graph');
```



Find the best pruning level that yields the optimal in-sample loss.

```
[L,se,NLeaf,bestLevel] = loss(Mdl,X,MPG,'Subtrees','all');
bestLevel
```

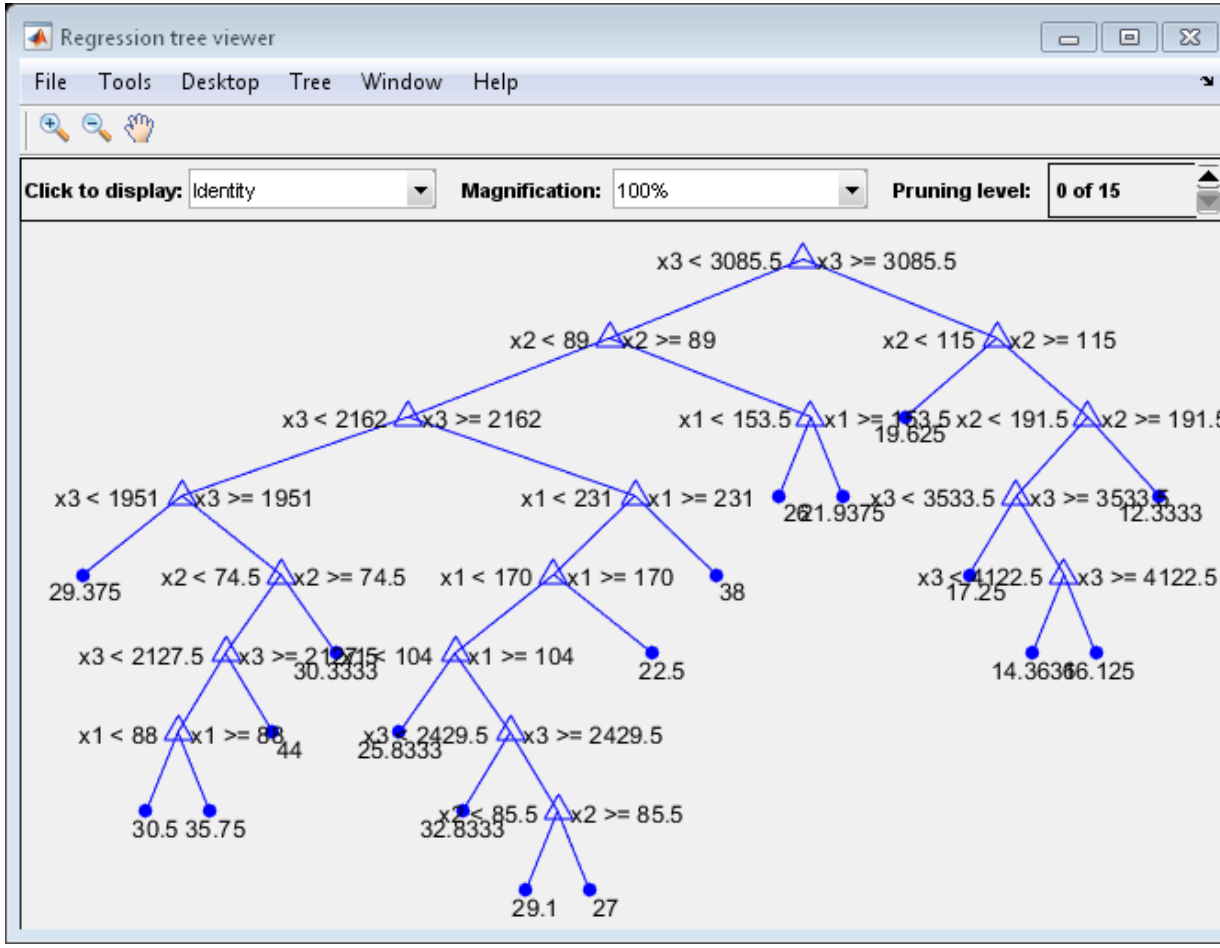
```
bestLevel =

     1
```

The best pruning level is level 1.

Prune the tree to level 1.

```
pruneMdl = prune(Mdl,'Level',bestLevel);
view(pruneMdl,'Mode','graph');
```



Examine the MSE for Each Subtree

Unpruned decision trees tend to overfit. One way to balance model complexity and out-of-sample performance is to prune a tree (or restrict its growth) so that in-sample and out-of-sample performance are satisfactory.

Load the `carsmall` data set. Consider `Displacement`, `Horsepower`, and `Weight` as predictors of the response `MPG`.

```
load carsmall
```

```
X = [Displacement Horsepower Weight];
Y = MPG;
```

Partition the data into training (50%) and validation (50%) sets.

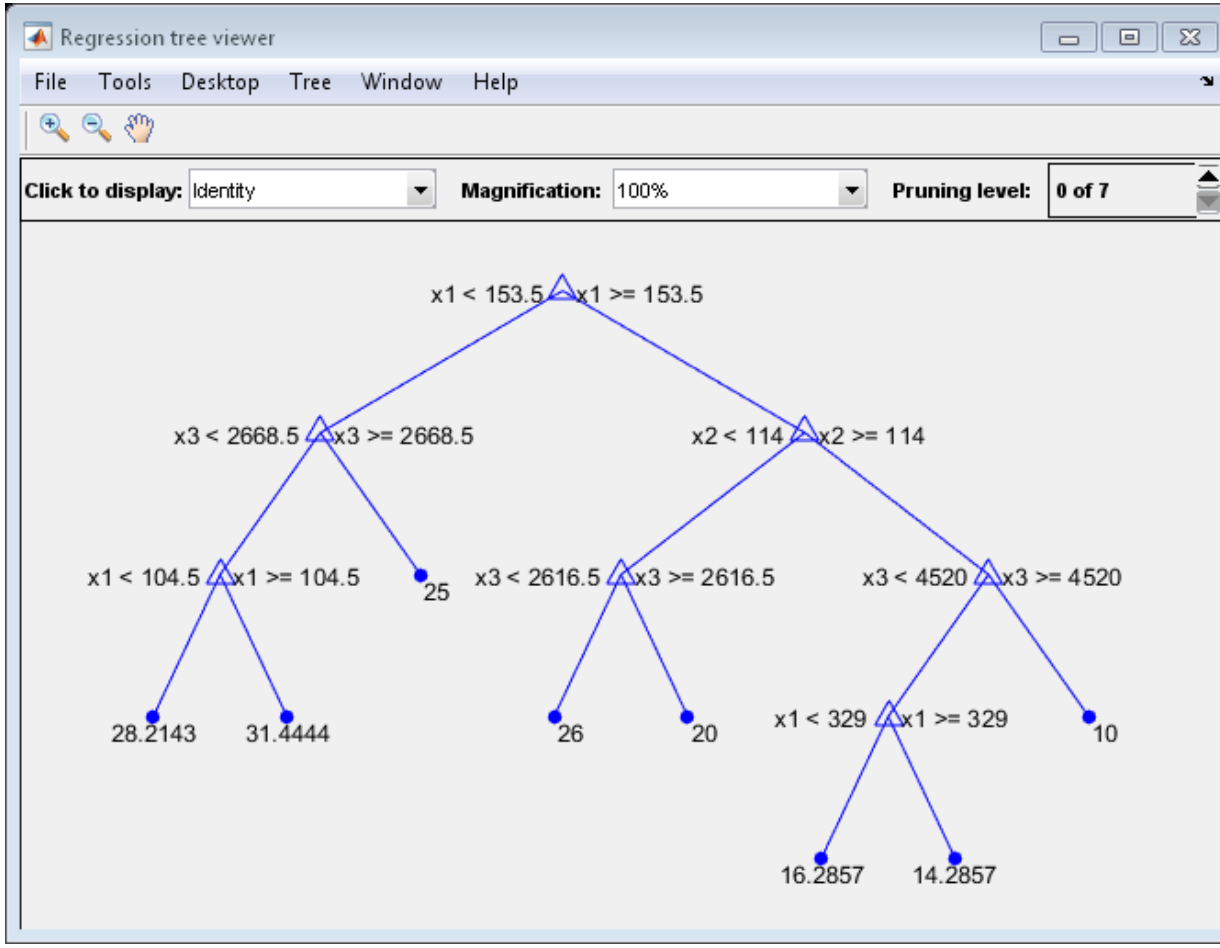
```
n = size(X,1);
rng(1) % For reproducibility
idxTrn = false(n,1);
idxTrn(randsample(n,round(0.5*n))) = true; % Training set logical indices
idxVal = idxTrn == false;                  % Validation set logical indices
```

Grow a regression tree using the training set.

```
Mdl = fitrtree(X(idxTrn,:),Y(idxTrn));
```

View the regression tree.

```
view(Mdl,'Mode','graph');
```



The regression tree has seven pruning levels. Level 0 is the full, unpruned tree (as displayed). Level 7 is just the root node (i.e., no splits).

Examine the training sample MSE for each subtree (or pruning level) excluding the highest level.

```
m = max(Mdl.PruneList) - 1;
trnLoss = resubLoss(Mdl,'SubTrees',0:m)
```

```
trnLoss =

    5.9789
    6.2768
    6.8316
    7.5209
    8.3951
   10.7452
   14.8445
```

- The MSE for the full, unpruned tree is about 6 units.
- The MSE for the tree pruned to level 1 is about 6.3 units.
- The MSE for the tree pruned to level 6 (i.e., a stump) is about 14.8 units.

Examine the validation sample MSE at each level excluding the highest level.

```
valLoss = loss(Mdl,X(idxVal,:),Y(idxVal),'SubTrees',0:m)
```

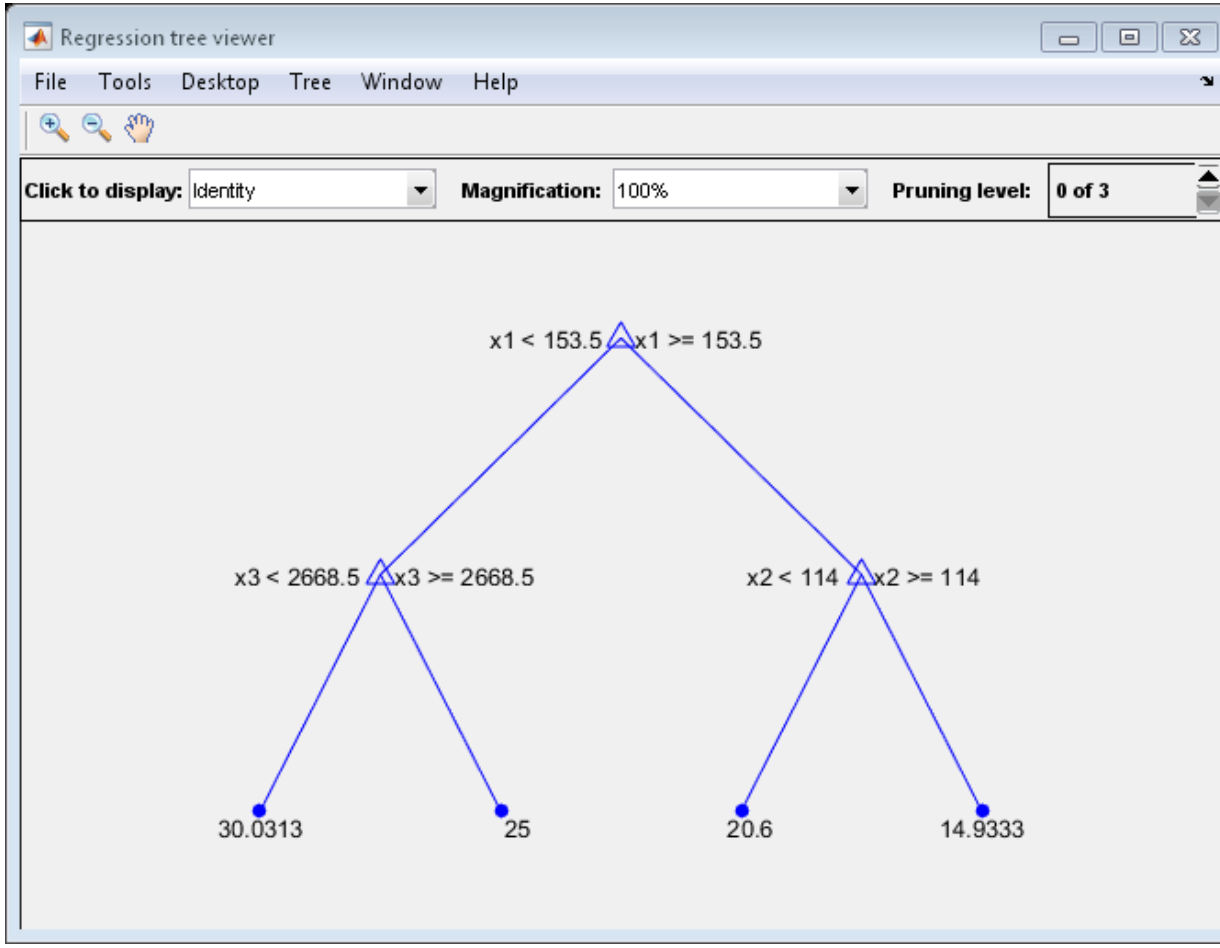
```
valLoss =

   32.1205
   31.5035
   32.0541
   30.8183
   26.3535
   30.0137
   38.4695
```

- The MSE for the full, unpruned tree (level 0) is about 32.1 units.
- The MSE for the tree pruned to level 4 is about 26.4 units.
- The MSE for the tree pruned to level 5 is about 30.0 units.
- The MSE for the tree pruned to level 6 (i.e., a stump) is about 38.5 units.

To balance model complexity and out-of-sample performance, consider pruning `Mdl` to level 4.

```
pruneMdl = prune(Mdl,'Level',4);
view(pruneMdl,'Mode','graph')
```



See Also

`predict` | `fitrtree`

lowerparams

Class: paretotails

Lower Pareto tails parameters

Syntax

```
params = lowerparams(obj)
```

Description

`params = lowerparams(obj)` returns the 2-element vector `params` of shape and scale parameters, respectively, of the lower tail of the Pareto tails object `obj`. `lowerparams` does not return a location parameter.

Examples

Fit Pareto tails to a t distribution at cumulative probabilities 0.1 and 0.9:

```
t = trnd(3,100,1);
obj = paretotails(t,0.1,0.9);

lowerparams(obj)
ans =
   -0.1901    1.1898
upperparams(obj)
ans =
    0.3646    0.5103
```

See Also

`paretotails` | `upperparams`

lt

Class: qrandstream

Less than relation for handles

Syntax

```
h1 < h2
```

Description

`h1 < h2` performs element-wise comparisons between handle arrays `h1` and `h2`. `h1` and `h2` must be of the same dimensions unless one is a scalar. The result is a logical array of the same dimensions, where each element is an element-wise < result.

If one of `h1` or `h2` is scalar, scalar expansion is performed and the result will match the dimensions of the array that is not scalar.

`tf = lt(h1, h2)` stores the result in a logical array of the same dimensions.

See Also

`qrandstream` | `ge` | `gt` | `ne` | `eq` | `le`

lsline

Add least-squares line to scatter plot

Syntax

```
lsline
lsline(ax)
h = lsline( ___ )
```

Description

`lsline` superimposes a least-squares line on each scatter plot in the current axes. Scatter plots are produced by the MATLAB `scatter` and `plot` functions. Data points connected with solid, dashed, or dash-dot lines (`'-'`, `'--'`, or `'.-'`) are not considered to be scatter plots by `lsline`, and are ignored.

`lsline(ax)` superimposes a least-squares line on the scatter plot in axis `ax`.

`h = lsline( ___ )` returns a column vector of handles `h` to the least-squares lines, using any of the previous syntaxes.

Examples

Plot a Least-Squares Line

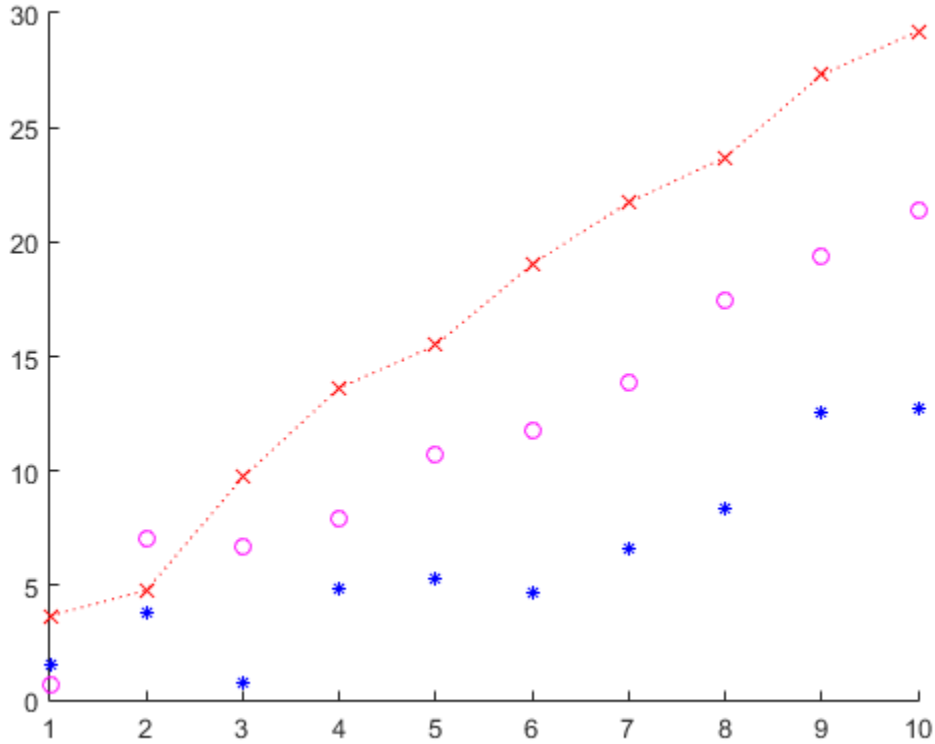
Generate three sets of sample data and plot on the same figure.

```
x = 1:10;
rng default;  % For reproducibility
figure;

y1 = x + randn(1,10);
scatter(x,y1,25,'b','*')
hold on
```

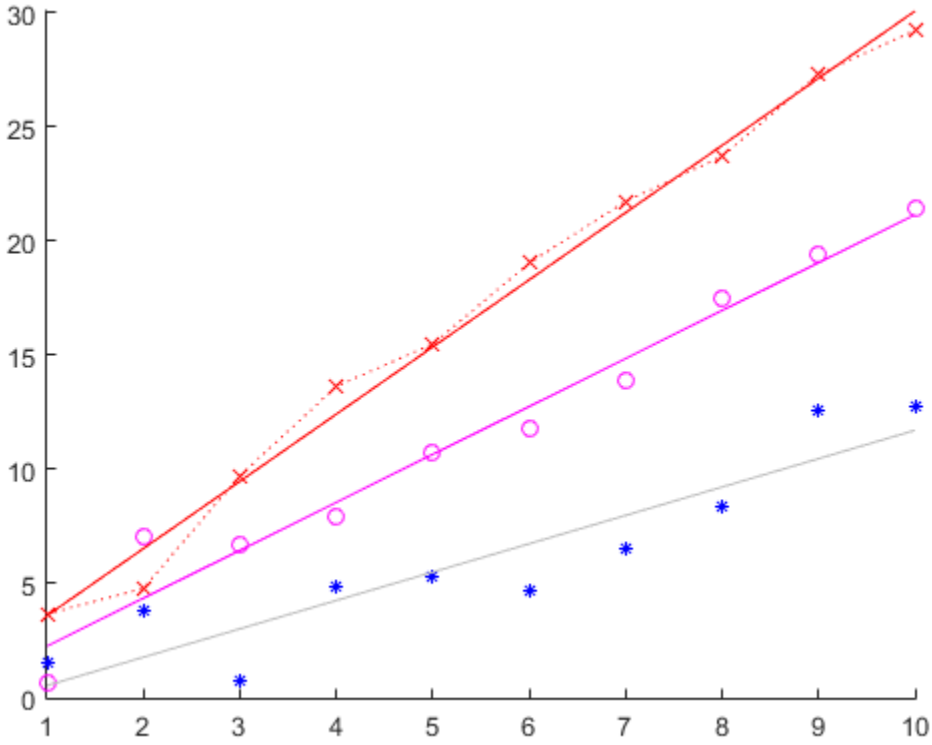
```
y2 = 2*x + randn(1,10);
plot(x,y2,'mo')

y3 = 3*x + randn(1,10);
plot(x,y3,'rx:')
```



Add a least-squares line for each set of sample data.

```
lsline
```



Specify Axes for Least-Squares and Reference Lines

Define the x-variable and two different y-variables to use for the plots.

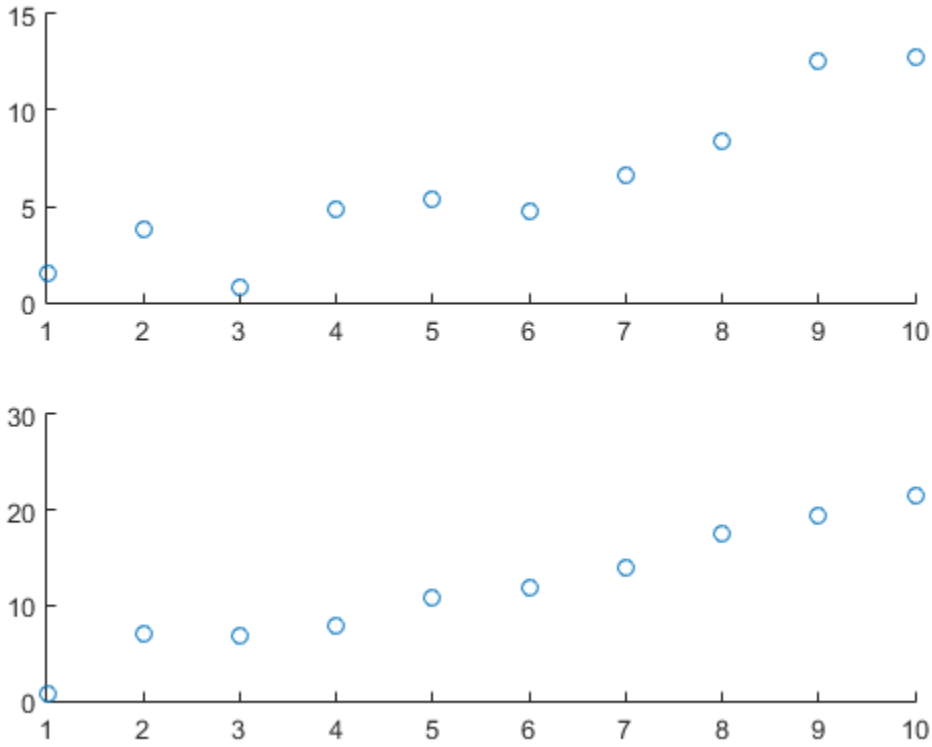
```
rng default  % For reproducibility
x = 1:10;
y1 = x + randn(1,10);
y2 = 2*x + randn(1,10);
```

Define `ax1` as the top half of the figure, and `ax2` as the bottom half of the figure. Create the first scatter plot on the top axis using `y1`, and the second scatter plot on the bottom axis using `y2`.

```
figure
```

```
ax1 = subplot(2,1,1);
ax2 = subplot(2,1,2);

scatter(ax1,x,y1)
scatter(ax2,x,y2)
```



Superimpose a least-squares line on the top plot, and a reference line at the mean of the `y2` values in the bottom plot.

```
lsline(ax1)

mu = mean(y2);
refline(ax2,[0 mu])
```

`scatter` | `plot` | `refline` | `refcurve` | `gline`

mad

Mean or median absolute deviation

Syntax

```
y = mad(X)
Y = mad(X,1)
Y = mad(X,0)
```

Description

`y = mad(X)` returns the mean absolute deviation of the values in `X`. For vector input, `y` is `mean(abs(X-mean(X)))`. For a matrix input, `y` is a row vector containing the mean absolute deviation of each column of `X`. For *N*-dimensional arrays, `mad` operates along the first nonsingleton dimension of `X`.

`Y = mad(X,1)` returns the median absolute deviation of the values in `X`. For vector input, `y` is `median(abs(X-median(X)))`. For a matrix input, `y` is a row vector containing the median absolute deviation of each column of `X`. For *N*-dimensional arrays, `mad` operates along the first nonsingleton dimension of `X`.

`Y = mad(X,0)` is the same as `mad(X)`, and returns the mean absolute deviation of the values in `X`.

`mad(X,flag,dim)` computes absolute deviations along the dimension `dim` of `X`. `flag` is `0` or `1` to indicate mean or median absolute deviation, respectively.

`mad` treats `NaNs` as missing values and removes them.

For normally distributed data, multiply `mad` by one of the following factors to obtain an estimate of the normal scale parameter σ:

- `sigma = 1.253*mad(X,0)` — For mean absolute deviation
- `sigma = 1.4826*mad(X,1)` — For median absolute deviation

Examples

The following compares the robustness of different scale estimates for normally distributed data in the presence of outliers:

```
x = normrnd(0,1,1,50);
xo = [x 10]; % Add outlier

r1 = std(xo)/std(x)
r1 =
    1.7385

r2 = mad(xo,0)/mad(x,0)
r2 =
    1.2306

r3 = mad(xo,1)/mad(x,1)
r3 =
    1.0602
```

`std` | `range` | `iqr`

mahal

Mahalanobis distance

Syntax

```
d = mahal(Y,X)
```

Description

`d = mahal(Y,X)` computes the Mahalanobis distance (in squared units) of each observation in `Y` from the reference sample in matrix `X`. If `Y` is n-by-m, where n is the number of observations and m is the dimension of the data, `d` is n-by-1. `X` and `Y` must have the same number of columns, but can have different numbers of rows. `X` must have more rows than columns.

For observation `I`, the Mahalanobis distance is defined by `d(I) = (Y(I,:)-mu)*inv(SIGMA)*(Y(I,:)-mu)'`, where `mu` and `SIGMA` are the sample mean and covariance of the data in `X`. `mahal` performs an equivalent, but more efficient, computation.

Examples

Compare Mahalanobis and Squared Euclidean Distances

Generate correlated bivariate data.

```
X = mvnrnd([0;0],[1 .9;.9 1],100);
```

Input observations.

```
Y = [1 1;1 -1;-1 1;-1 -1];
```

Compute the Mahalanobis distance of observations in `Y` from the reference sample in `X` .

```
d1 = mahal(Y,X)
```

```
d1 =

    0.6288
   19.3520
   21.1384
    0.9404
```

Compute their squared Euclidean distances from the mean of `X` .

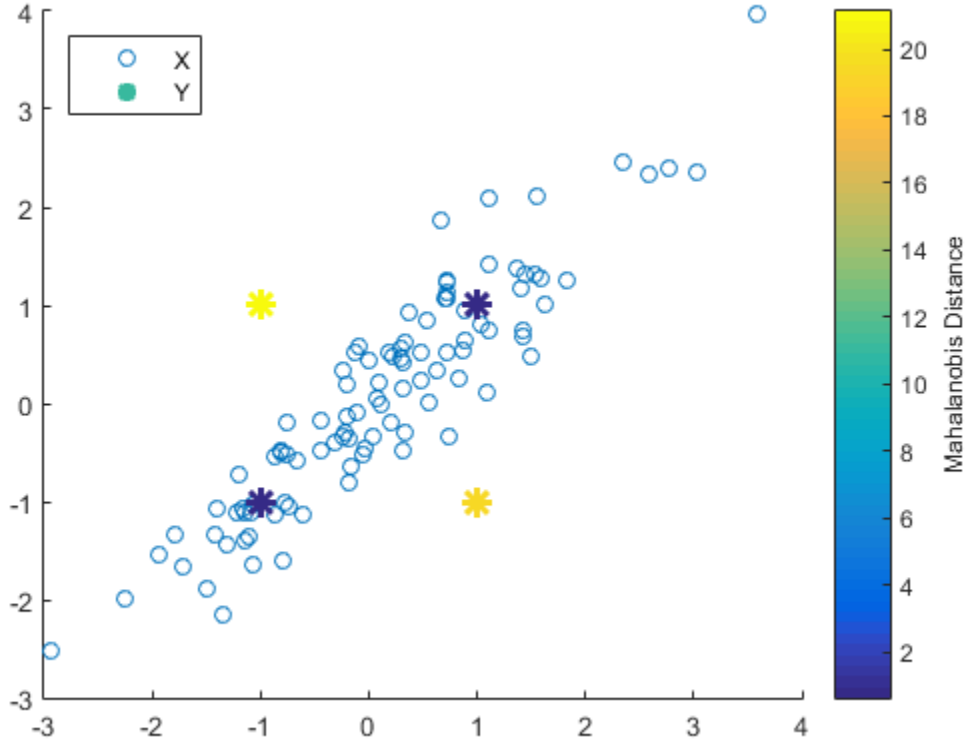
```
d2 = sum((Y-repmat(mean(X),4,1)).^2, 2)
```

```
d2 =

    1.6170
    1.9334
    2.1094
    2.4258
```

Plot the observations with `Y` values colored according to the Mahalanobis distance.

```
scatter(X(:,1),X(:,2))
hold on
scatter(Y(:,1),Y(:,2),100,d1,'*','LineWidth',2)
hb = colorbar;
ylabel(hb,'Mahalanobis Distance')
legend('X','Y','Location','NW')
```



The observations in Y with equal coordinate values are much closer to X in Mahalanobis distance than observations with opposite coordinate values, even though all observations are approximately equidistant from the mean of X in Euclidean distance. The Mahalanobis distance, by considering the covariance of the data and the scales of the different variables, is useful for detecting outliers in such cases.

`pdist` | `mahal`

mahal

Class: CompactClassificationDiscriminant

Mahalanobis distance to class means

Syntax

```
M = mahal(obj,X)
M = mahal(obj,X,Name,Value)
```

Description

`M = mahal(obj,X)` returns the squared Mahalanobis distances from observations in `X` to the class means in `obj`.

`M = mahal(obj,X,Name,Value)` computes the squared Mahalanobis distance with additional options specified by one or more Name,Value pair arguments.

Input Arguments

`obj`

Discriminant analysis classifier of class `ClassificationDiscriminant` or `CompactClassificationDiscriminant`, typically constructed with `fitcdiscr`.

`X`

Numeric matrix of size `n`-by-`p`, where `p` is the number of predictors in obj, and `n` is any positive integer. `mahal` computes the Mahalanobis distances from the rows of `X` to each of the `K` means of the classes in `obj`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single

quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'ClassLabels'`

Class labels consisting of `n` elements of obj`.Y`, where `n` is the number of rows of X.

Output Arguments

`M`

Size and meaning of output `M` depends on whether the `ClassLabels` name-value pair is present:

- No `ClassLabels` — `M` is a numeric matrix of size `n`-by-`K`, where `K` is the number of classes in obj, and `n` is the number of rows in X. `M(i,j)` is the squared Mahalanobis distance from the `i`th row of `X` to the mean of class `j`.
- `ClassLabels` exists — `M` is a column vector with `n` elements. `M(i)` is the squared Mahalanobis distance from the `i`th row of `X` to the mean for the class of the `i`th element of `ClassLabels`.

Definitions

Mahalanobis Distance

The Mahalanobis distance $d(x,y)$ between n-dimensional points x and y, with respect to a given n-by-n covariance matrix S, is

$$d(x,y) = \sqrt{(x-y)^T S^{-1} (x-y)}.$$

Examples

Find the Mahalanobis distances from the mean of the Fisher iris data to the class means, using distinct covariance matrices for each class:

```
load fisheriris
obj = fitcdiscr(meas,species,...
    'DiscrimType','quadratic');
mahadist = mahal(obj,mean(meas))

mahadist =
  220.0667    5.0254   30.5804
```

How To

- “Discriminant Analysis” on page 15-3

mahal

Class: gmdistribution

Mahalanobis distance to component means

Syntax

```
D = mahal(obj,X)
```

Description

`D = mahal(obj,X)` computes the Mahalanobis distance (in squared units) of each observation in `X` to the mean of each of the k components of the Gaussian mixture distribution defined by `obj`. `obj` is an object created by `gmdistribution` or `fitgmdist`. `X` is an n-by-d matrix, where n is the number of observations and d is the dimension of the data. `D` is n-by-k, with `D(I,J)` the distance of observation `I` from the mean of component `J`.

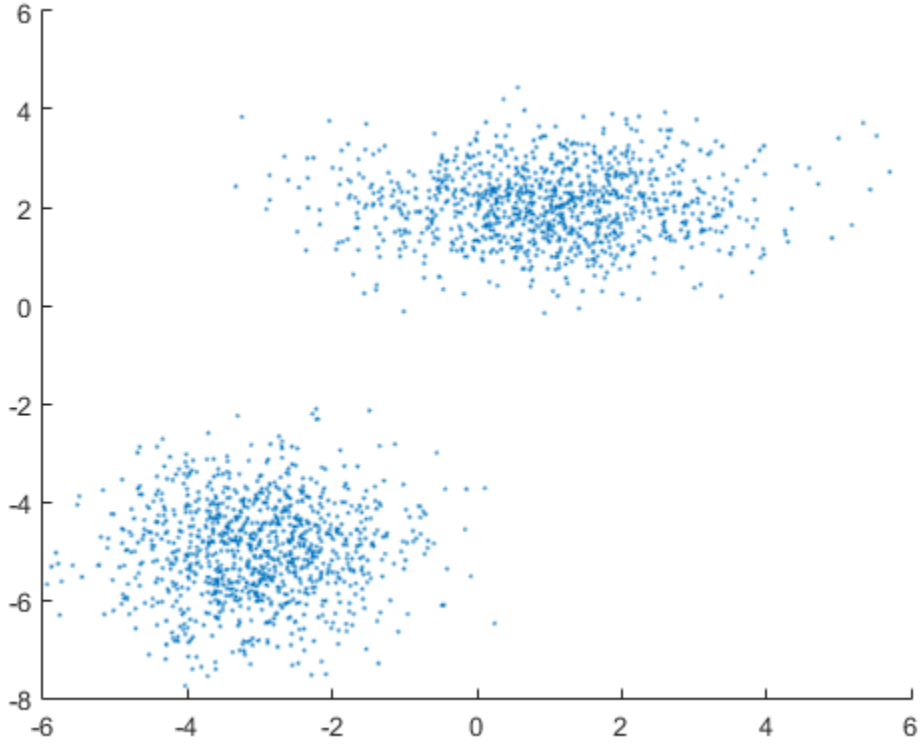
Examples

Measure Mahalanobis Distances in Gaussian Mixture Data

Generate data from a mixture of two bivariate Gaussian distributions using the `mvnrnd` function.

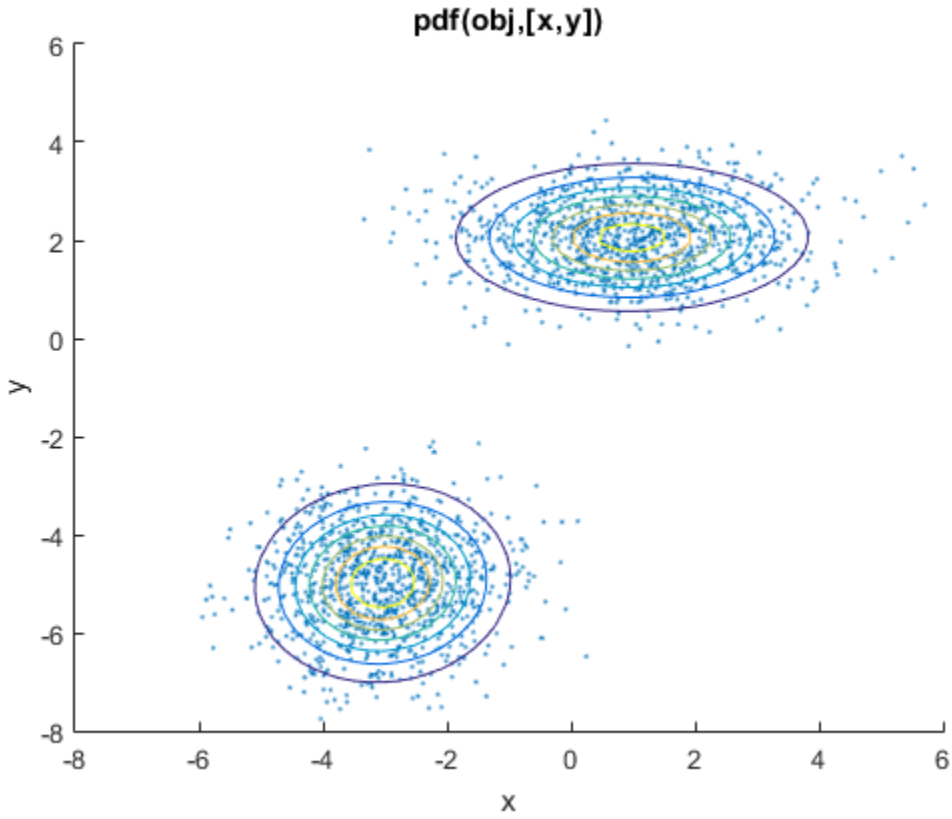
```
MU1 = [1 2];
SIGMA1 = [2 0; 0 .5];
MU2 = [-3 -5];
SIGMA2 = [1 0; 0 1];
rng(1); % For reproducibility
X = [mvnrnd(MU1,SIGMA1,1000);mvnrnd(MU2,SIGMA2,1000)];

scatter(X(:,1),X(:,2),10,'.')
hold on
```



Fit a two-component Gaussian mixture model.

```
obj = fitgmdist(X,2);
h = ezcontour(@(x,y)pdf(obj,[x y]),[-8 6],[-8 6]);
```



Compute the Mahalanobis distance of each point in `X` to the mean of each component of `obj`.

```
D = mahal(obj,X);

delete(h)
scatter(X(:,1),X(:,2),10,D(:,1),'.')
hb = colorbar;
ylabel(hb,'Mahalanobis Distance to Component 1')
```

`gmdistribution` | `posterior` | `cluster` | `mahal`

maineffectsplot

Main effects plot for grouped data

Syntax

```
maineffectsplot(Y,GROUP)
maineffectsplot(Y,GROUP,param1,val1,param2,val2,...)
[figh,AXESH] = maineffectsplot(...)
```

Description

`maineffectsplot(Y,GROUP)` displays main effects plots for the group means of matrix `Y` with groups defined by entries in the cell array `GROUP`. `Y` is a numeric matrix or vector. If `Y` is a matrix, the rows represent different observations and the columns represent replications of each observation. Each cell of `GROUP` must contain a grouping variable that can be a categorical variable, numeric vector, character matrix, or single-column cell array of strings. `GROUP` can also be a matrix whose columns represent different grouping variables. Each grouping variable must have the same number of rows as `Y`. The number of grouping variables must be greater than 1.

The display has one subplot per grouping variable, with each subplot showing the group means of `Y` as a function of one grouping variable.

`maineffectsplot(Y,GROUP,param1,val1,param2,val2,...)` specifies one or more of the following name/value pairs:

- `'varnames'` — Grouping variable names in a character matrix or a cell array of strings, one per grouping variable. Default names are `'X1'`, `'X2'`, ...
- `'statistic'` — String values that indicate whether the group mean or the group standard deviation should be plotted. Use `'mean'` or `'std'`. The default is `'mean'`. If the value is `'std'`, `Y` is required to have multiple columns.
- `'parent'` — A handle to the figure window for the plots. The default is the current figure window.

`[figh,AXESH] = maineffectsplot(...)` returns the handle `figh` to the figure window and an array of handles `AXESH` to the subplot axes.

Examples

Main Effects Plot

Load the sample data.

```
load carsmall;
```

Display main effects plots for car weight with two grouping variables, model year and number of cylinders.

```
maineffectsplot(Weight,{Model_Year,Cylinders}, ...
                'varnames',{'Model Year','# of Cylinders'})
```

ClassificationDiscriminant.make

Class: ClassificationDiscriminant

Construct discriminant analysis classifier from parameters (to be removed)

Compatibility

`ClassificationDiscriminant.make` will be removed in a future release. Use `makecdiscr` instead.

Syntax

```
cobj = ClassificationDiscriminant.make(Mu,Sigma)
cobj = ClassificationDiscriminant.make(Mu,Sigma,Name,Value)
```

Description

`cobj = ClassificationDiscriminant.make(Mu,Sigma)` constructs a compact discriminant analysis classifier from the class means `Mu` and covariance matrix `Sigma`.

`cobj = ClassificationDiscriminant.make(Mu,Sigma,Name,Value)` constructs a compact classifier with additional options specified by one or more Name,Value pair arguments.

Input Arguments

`Mu` — Class means

matrix of scalar values

Class means, specified as a `K`-by-`p` matrix of scalar values class means of size. `K` is the number of classes, and `p` is the number of predictors. Each row of `Mu` represents the mean of the multivariate normal distribution of the corresponding class. The class indices are in the ClassNames attribute.

`Sigma` — Within-class covariance
matrix of scalar values

Within-class covariance, specified as a matrix of scalar values.

- For a linear discriminant, `Sigma` is a symmetric, positive semidefinite matrix of size `p`-by-`p`, where `p` is the number of predictors.
- For a quadratic discriminant, `Sigma` is an array of size `p`-by-`p`-by-`K`, where `K` is the number of classes. For each `i`, `Sigma(:,:,i)` is a symmetric, positive semidefinite matrix.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'ClassNames'` — Class names
numeric vector | categorical vector | logical vector | character array | cell array of strings

Class names as ordered in Mu, specified as the comma-separated pair consisting of `'ClassNames'` and an array containing grouping variables. Use any data type for a grouping variable, including numeric vector, categorical vector, logical vector, character array, or cell array of strings.

`ClassNames` names the classes, as ordered in `Mu`.

Default is `1:K`, where `K` is the number of classes (the number of rows of Mu).

Data Types: `single` | `double` | `logical` | `char` | `cell`

`'Cost'` — Cost of misclassification
square matrix | structure

Cost of misclassification, specified as the comma-separated pair consisting of `'Cost'` and a square matrix, where `Cost(i,j)` is the cost of classifying a point into class

`j` if its true class is `i`. Alternatively, `Cost` can be a structure `S` having two fields: `S.ClassNames` containing the group names as a variable of the same type as y, and `S.ClassificationCosts` containing the cost matrix.

The default is `Cost(i,j)=1` if `i~=j`, and `Cost(i,j)=0` if `i=j`.

Data Types: `single` | `double` | `struct`

`'PredictorNames'` — Predictor variable names

`{'x1','x2',...}` (default) | cell array of strings

Predictor variable names, specified as the comma-separated pair consisting of `'PredictorNames'` and a cell array of strings containing the names for the predictor variables, in the order in which they appear in x.

Data Types: `cell`

`'Prior'` — Prior probabilities

`'uniform'` (default) | vector of scalar values | structure

Prior probabilities for each class, specified as the comma-separated pair consisting of `'Prior'` and one of the following.

- `'uniform'`, a string meaning all class prior probabilities are equal.
- A vector containing one scalar value for each class.
- A structure `S` with two fields:
  - `S.ClassNames` containing the class names as a variable of the same type as `ClassNames`.
  - `S.ClassProbs` containing a vector of corresponding probabilities.

Data Types: `single` | `double` | `struct`

`'ResponseName'` — Response variable name

`'Y'` (default) | string

Response variable name, specified as the comma-separated pair consisting of `'ResponseName'` and a string containing the name of the response variable y.

Example: `'ResponseName','Response'`

Data Types: `char`

Output Arguments

`cobj` — Discriminant analysis classifier

discriminant analysis classifier object

Discriminant analysis classifier, returned as a discriminant analysis classifier object of class `CompactClassificationDiscriminant`. You can use the `predict` method to predict classification labels for new data.

Examples

Construct a Compact Linear Discriminant Analysis Classifier

Construct a compact linear discriminant analysis classifier from the means and covariances of the Fisher iris data.

```
load fisheriris
mu(1,:) = mean(meas(1:50,:));
mu(2,:) = mean(meas(51:100,:));
mu(3,:) = mean(meas(101:150,:));

mm1 = repmat(mu(1,:),50,1);
mm2 = repmat(mu(2,:),50,1);
mm3 = repmat(mu(3,:),50,1);
cc = meas;
cc(1:50,:) = cc(1:50,:) - mm1;
cc(51:100,:) = cc(51:100,:) - mm2;
cc(101:150,:) = cc(101:150,:) - mm3;
sigstar = cc' * cc / 147; % unbiased estimator of sigma
cpct = ClassificationDiscriminant.make(mu,sigstar,...
   'ClassNames',{'setosa','versicolor','virginica'})

cpct =
classreg.learning.classif.CompactClassificationDiscriminant:
    PredictorNames: {'x1'  'x2'  'x3'  'x4'}
      ResponseName: 'Y'
        ClassNames: {'setosa'  'versicolor'  'virginica'}
    ScoreTransform: 'none'
       DiscrimType: 'linear'
                Mu: [3x4 double]
```

```
            Coeffs: [3x3 struct]
```

See Also

`compact` | `CompactClassificationDiscriminant` | `fitcdiscr` | `makecdiscr`

How To

- “Discriminant Analysis” on page 15-3

makecdiscr

Construct discriminant analysis classifier from parameters

Syntax

```
cobj = makecdiscr(Mu,Sigma)
cobj = makecdiscr(Mu,Sigma,Name,Value)
```

Description

`cobj = makecdiscr(Mu,Sigma)` constructs a compact discriminant analysis classifier from the class means `Mu` and covariance matrix `Sigma`.

`cobj = makecdiscr(Mu,Sigma,Name,Value)` constructs a compact classifier with additional options specified by one or more name-value pair arguments. For example, you can specify the cost of misclassification or the prior probabilities for each class.

Examples

Construct a Compact Linear Discriminant Analysis Classifier

Construct a compact linear discriminant analysis classifier from the means and covariances of the Fisher iris data.

```
load fisheriris
mu(1,:) = mean(meas(1:50,:));
mu(2,:) = mean(meas(51:100,:));
mu(3,:) = mean(meas(101:150,:));

mm1 = repmat(mu(1,:),50,1);
mm2 = repmat(mu(2,:),50,1);
mm3 = repmat(mu(3,:),50,1);
cc = meas;
cc(1:50,:) = cc(1:50,:) - mm1;
cc(51:100,:) = cc(51:100,:) - mm2;
cc(101:150,:) = cc(101:150,:) - mm3;
sigstar = cc' * cc / 147; % unbiased estimator of sigma
```

```
cpct = makecdiscr(mu,sigstar,...
   'ClassNames',{'setosa','versicolor','virginica'})

cpct =
classreg.learning.classif.CompactClassificationDiscriminant:
    PredictorNames: {'x1'  'x2'  'x3'  'x4'}
      ResponseName: 'Y'
        ClassNames: {'setosa'  'versicolor'  'virginica'}
    ScoreTransform: 'none'
       DiscrimType: 'linear'
                Mu: [3x4 double]
            Coeffs: [3x3 struct]
```

Input Arguments

`Mu` — Class means

matrix of scalar values

Class means, specified as a `K`-by-`p` matrix of scalar values class means of size. `K` is the number of classes, and `p` is the number of predictors. Each row of `Mu` represents the mean of the multivariate normal distribution of the corresponding class. The class indices are in the ClassNames attribute.

Data Types: `single` | `double`

`Sigma` — Within-class covariance

matrix of scalar values

Within-class covariance, specified as a matrix of scalar values.

- For a linear discriminant, `Sigma` is a symmetric, positive semidefinite matrix of size `p`-by-`p`, where `p` is the number of predictors.
- For a quadratic discriminant, `Sigma` is an array of size `p`-by-`p`-by-`K`, where `K` is the number of classes. For each `i`, `Sigma(:,:,i)` is a symmetric, positive semidefinite matrix.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single

quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'ClassNames',{'setosa' 'versicolor' 'virginica'}` specifies a discriminant analysis classifier that uses `'setosa'`, `'versicolor'`, and `'virginica'` as the grouping variables.

`'ClassNames'` — Class names

numeric vector | categorical vector | logical vector | character array | cell array of strings

Class names as ordered in `Mu`, specified as the comma-separated pair consisting of `'ClassNames'` and an array containing grouping variables. Use any data type for a grouping variable, including numeric vector, categorical vector, logical vector, character array, or cell array of strings.

The default is `1:K`, where `K` is the number of classes (the number of rows of Mu).

Example: `'ClassNames',{'setosa' 'versicolor' 'virginica'}`

Data Types: `single` | `double` | `logical` | `char` | `cell`

`'Cost'` — Cost of misclassification

square matrix | structure

Cost of misclassification, specified as the comma-separated pair consisting of `'Cost'` and a square matrix, where `Cost(i,j)` is the cost of classifying a point into class `j` if its true class is `i`. Alternatively, `Cost` can be a structure `S` having two fields: `S.ClassNames` containing the group names as a variable of the same type as y, and `S.ClassificationCosts` containing the cost matrix.

The default is `Cost(i,j)=1` if `i~=j`, and `Cost(i,j)=0` if `i=j`.

Data Types: `single` | `double` | `struct`

`'PredictorNames'` — Predictor variable names

`{'x1','x2',...}` (default) | cell array of strings

Predictor variable names, specified as the comma-separated pair consisting of `'PredictorNames'` and a cell array of strings containing the names for the predictor variables, in the order in which they appear in x.

Data Types: `cell`

`'Prior'` — Prior probabilities
`'uniform'` (default) | vector of scalar values | structure

Prior probabilities for each class, specified as the comma-separated pair consisting of `'Prior'` and one of the following:

- `'uniform'`, a string meaning all class prior probabilities are equal
- A vector containing one scalar value for each class
- A structure `S` with two fields:
  - `S.ClassNames` containing the class names as a variable of the same type as `ClassNames`
  - `S.ClassProbs` containing a vector of corresponding probabilities

Data Types: `single` | `double` | `struct`

`'ResponseName'` — Response variable name
`'Y'` (default) | string

Response variable name, specified as the comma-separated pair consisting of `'ResponseName'` and a string containing the name of the response variable y.

Example: `'ResponseName','Response'`

Data Types: `char`

Output Arguments

`cobj` — Discriminant analysis classifier
discriminant analysis classifier object

Discriminant analysis classifier, returned as a discriminant analysis classifier object of class `CompactClassificationDiscriminant`. You can use the `predict` method to predict classification labels for new data.

More About

Tips

- You can change the discriminant type using dot notation after constructing cobj:

```
cobj.DiscrimType = 'discrimType'
```

where *discrimType* is one of `'linear'`, `'quadratic'`, `'diagLinear'`, `'diagQuadratic'`, `'pseudoLinear'`, or `'pseudoQuadratic'`. You can change between linear types or between quadratic types, but cannot change between a linear and a quadratic type.

- `cobj` is a linear classifier when `Sigma` is a matrix. `cobj` is a quadratic classifier when `Sigma` is a three-dimensional array.

- "Discriminant Analysis" on page 15-3

makedist

Create probability distribution object

Syntax

```
pd = makedist(distname)
pd = makedist(distname,Name,Value)
```

Description

`pd = makedist(distname)` creates a probability distribution object for the distribution `distname`, using the default parameter values.

`pd = makedist(distname,Name,Value)` creates a probability distribution object with one or more distribution parameter values specified by name-value pair arguments.

Examples

Create a Normal Distribution Object

Create a normal distribution object using the default parameter values.

```
pd = makedist('Normal')
```

```
pd =

  NormalDistribution

  Normal distribution
       mu = 0
    sigma = 1
```

Compute the interquartile range of the distribution.

```
r = iqr(pd)
```

```
r =
```

```
    1.3490
```

Create a Gamma Distribution Object

Create a gamma distribution object using the default parameter values.

```
pd = makedist('Gamma')
```

```
pd =

  GammaDistribution

  Gamma distribution
    a = 1
    b = 1
```

Compute the mean of the gamma distribution.

```
mean = mean(pd)
```

```
mean =

     1
```

Specify Parameters for a Normal Distribution Object

Create a normal distribution object with parameter values `mu = 75` and `sigma = 10`.

```
pd = makedist('Normal','mu',75,'sigma',10)
```

```
pd =

  NormalDistribution

  Normal distribution
       mu = 75
    sigma = 10
```

Specify Parameters for a Gamma Distribution Object

Create a gamma distribution object with the parameter value `a = 3` and the default value `b = 1`.

```
pd = makedist('Gamma','a',3)
```

```
pd =

  GammaDistribution

  Gamma distribution
    a = 3
    b = 1
```

Input Arguments

`distname` — Distribution name

string

Distribution name, specified as one of the following strings. The distribution specified by `distname` determines the class type of the returned probability distribution object.

Distribution Name	Description	Distribution Class
`'Beta'`	Beta distribution	`prob.BetaDistribution`
`'Binomial'`	Binomial distribution	`prob.BinomialDistribution`
`'BirnbaumSaunders'`	Birnbaum-Saunders distribution	`prob.BirnbaumSaundersDistributio`
`'Burr'`	Burr distribution	`prob.BurrDistribution`
`'Exponential'`	Exponential distribution	`prob.ExponentialDistribution`
`'ExtremeValue'`	Extreme Value distribution	`prob.ExtremeValueDistribution`
`'Gamma'`	Gamma distribution	`prob.GammaDistribution`
`'GeneralizedExtremeVal`	Generalized Extreme Value distribution	`prob.GeneralizedExtremeValueDist`
`'GeneralizedPareto'`	Generalized Pareto distribution	`prob.GeneralizedParetoDistributi`
`'InverseGaussian'`	Inverse Gaussian distribution	`prob.InverseGaussianDistribution`
`'Logistic'`	Logistic distribution	`prob.LogisticDistribution`
`'Loglogistic'`	Loglogistic distribution	`prob.LoglogisticDistribution`
`'Lognormal'`	Lognormal distribution	`prob.LognormalDistribution`

Distribution Name	Description	Distribution Class
'Multinomial'	Multinomial distribution	prob.MultinomialDistribution
'Nakagami'	Nakagami distribution	prob.NakagamiDistribution
'NegativeBinomial'	Negative Binomial distribution	prob.NegativeBinomialDistributio
'Normal'	Normal distribution	prob.NormalDistribution
'PiecewiseLinear'	Piecewise Linear distribution	prob.PiecewiseLinearDistribution
'Poisson'	Poisson distribution	prob.PoissonDistribution
'Rayleigh'	Rayleigh distribution	prob.RayleighDistribution
'Rician'	Rician distribution	prob.RicianDistribution
'tLocationScale'	*t* Location-Scale distribution	prob.tLocationScaleDistribution
'Triangular'	Triangular distribution	prob.TriangularDistribution
'Uniform'	Uniform distribution	prob.UniformDistribution
'Weibull'	Weibull distribution	prob.WeibullDistribution

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `makedist('Normal','mu',10)` specifies a normal distribution with parameter `mu` equal to 10, and parameter `sigma` equal to the default value of 1.

Beta Distribution

'a' — First shape parameter

1 (default) | nonnegative scalar value

Example: `'a',3`

Data Types: `single` | `double`

'b' — Second shape parameter

1 (default) | nonnegative scalar value

Example: `'b',5`

Data Types: `single` | `double`

Binomial Distribution

`'N'` — Number of trials
1 (default) | positive integer value

Example: `'N',25`

Data Types: `single` | `double`

`'p'` — Probability of success
`0.5` (default) | scalar value in the range [0,1]

Example: `'p',0.25`

Data Types: `single` | `double`

Birnbaum-Saunders Distribution

`'beta'` — Scale parameter
1 (default) | positive scalar value

Example: `'beta',2`

Data Types: `single` | `double`

`'gamma'` — Shape parameter
1 (default) | nonnegative scalar value

Example: `'gamma',0`

Data Types: `single` | `double`

Burr Distribution

`'alpha'` — Scale parameter
1 (default) | positive scalar value

Example: `'alpha',2`

Data Types: `single` | `double`

`'c'` — First shape parameter
1 (default) | positive scalar value

Example: `'c',2`

Data Types: `single` | `double`

`'k'` — Second shape parameter
1 (default) | positive scalar value

Example: `'k',5`

Data Types: `single` | `double`

Exponential Distribution

`'mu'` — Mean parameter
1 (default) | positive scalar value

Example: `'mu',5`

Data Types: `single` | `double`

Extreme Value Distribution

`'mu'` — Location parameter
0 (default) | scalar value

Example: `'mu',-2`

Data Types: `single` | `double`

`'sigma'` — Scale parameter
1 (default) | nonnegative scalar value

Example: `'sigma',2`

Data Types: `single` | `double`

Gamma Distribution

`'a'` — Shape parameter
1 (default) | positive scalar value

Example: `'a',2`

Data Types: `single` | `double`

`'b'` — Scale parameter
1 (default) | nonnegative scalar value

Example: `'b',0`

Data Types: `single` | `double`

Generalized Extreme Value Distribution

`'k'` — Shape parameter
0 (default) | scalar value

Example: `'k',0`

Data Types: `single` | `double`

`'sigma'` — Scale parameter
1 (default) | nonnegative scalar value

Example: `'sigma',2`

Data Types: `single` | `double`

`'mu'` — Location parameter
0 (default) | scalar value

Example: `'mu',1`

Data Types: `single` | `double`

Generalized Pareto Distribution

`'k'` — Shape parameter
1 (default) | scalar value

Example: `'k',0`

Data Types: `single` | `double`

`'sigma'` — Scale parameter
1 (default) | nonnegative scalar value

Example: `'sigma',2`

Data Types: `single` | `double`

`'theta'` — Location parameter
1 (default) | scalar value

Example: `'theta',2`

Data Types: `single` | `double`

Inverse Gaussian Distribution

`'mu'` — Scale parameter
1 (default) | positive scalar value

Example: `'mu',2`

Data Types: `single` | `double`

`'lambda'` — Shape parameter
1 (default) | positive scalar value

Example: `'lambda',4`

Data Types: `single` | `double`

Logistic Distribution

`'mu'` — Mean
0 (default) | scalar value

Example: `'mu',2`

Data Types: `single` | `double`

`'sigma'` — Scale parameter
1 (default) | nonnegative scalar value

Example: `'sigma',4`

Data Types: `single` | `double`

Loglogistic Distribution

`'mu'` — Log mean
0 (default) | scalar value

Example: `'mu',2`

Data Types: `single` | `double`

`'sigma'` — Log scale parameter
1 (default) | nonnegative scalar value

Example: `'sigma',4`

Data Types: `single` | `double`

Lognormal Distribution

`'mu'` — Log mean
0 (default) | scalar value

Example: `'mu',2`

Data Types: `single` | `double`

`'sigma'` — Log standard deviation
1 (default) | nonnegative scalar value

Example: `'sigma',2`

Data Types: `single` | `double`

Multinomial Distribution

`'probabilities'` — Outcome probabilities
`[0.500 0.500]` (default) | vector of scalar values in the range [0,1]

Example: `'probabilities',[0.1 0.2 0.5 0.2]`

Data Types: `single` | `double`

Nakagami Distribution

`'mu'` — Shape parameter
1 (default) | positive scalar value

Example: `'mu',5`

Data Types: `single` | `double`

`'omega'` — Scale parameter
1 (default) | positive scalar value

Example: `'omega',5`

Data Types: `single` | `double`

Negative Binomial Distribution

`'R'` — Number of successes
1 (default) | positive scalar value

Example: `'R',5`

Data Types: `single` | `double`

`'p'` — Probability of success

`0.5` (default) | scalar value in the range (0,1]

Example: `'p',0.1`

Data Types: `single` | `double`

Normal Distribution

`'mu'` — Mean

`0` (default) | scalar value

Example: `'mu',2`

Data Types: `single` | `double`

`'sigma'` — Standard deviation

`1` (default) | nonnegative scalar value

Example: `'sigma',2`

Data Types: `single` | `double`

Piecewise Linear Distribution

`'x'` — Data values

`1` (default) | vector of scalar values

Example: `'x',[1 2 3]`

Data Types: `single` | `double`

`'Fx'` — cdf values

`1` (default) | vector of scalar values

Example: `'Fx',[.2 .5 1]`

Data Types: `single` | `double`

Poisson Distribution

`'lambda'` — Mean

`1` (default) | nonnegative scalar value

Example: `'lambda',5`

Data Types: `single` | `double`

Rayleigh Distribution

`'b'` — Defining parameter

1 (default) | positive scalar value

Example: `'b',3`

Data Types: `single` | `double`

Rician Distribution

`'s'` — Noncentrality parameter

1 (default) | nonnegative scalar value

Example: `'s',0`

Data Types: `single` | `double`

`'sigma'` — Scale parameter

1 (default) | positive scalar value

Example: `'sigma',2`

Data Types: `single` | `double`

t Location-Scale Distribution

`'mu'` — Location parameter

0 (default) | scalar value

Example: `'mu',-2`

Data Types: `single` | `double`

`'sigma'` — Scale parameter

1 (default) | positive scalar value

Example: `'sigma',2`

Data Types: `single` | `double`

`'nu'` — Degrees of freedom

5 (default) | positive scalar value

Example: `'nu',20`

Data Types: `single` | `double`

Triangular Distribution

`'a'` — Lower limit
`0` (default) | scalar value

Example: `'a',-2`

Data Types: `single` | `double`

`'b'` — Peak location
`0.5` (default) | scalar value greater than or equal to `a`

Example: `'b',1`

Data Types: `single` | `double`

`'c'` — Upper limit
`1` (default) | scalar value greater than or equal to `b`

Example: `'c',5`

Data Types: `single` | `double`

Uniform Distribution

`'lower'` — Lower parameter
`0` (default) | scalar value

Example: `'lower',-4`

Data Types: `single` | `double`

`'upper'` — Upper parameter
`1` (default) | scalar value greater than `lower`

Example: `'upper',2`

Data Types: `single` | `double`

Weibull Distribution

`'a'` — Scale parameter
`1` (default) | positive scalar value

Example: `'a',2`

Data Types: `single` | `double`

`'b'` — Shape parameter

1 (default) | positive scalar value

Example: `'b',5`

Data Types: `single` | `double`

Output Arguments

`pd` — Probability distribution

probability distribution object

Probability distribution, returned as a probability distribution object of the type specified by distname.

Alternative Functionality

App

The Distribution Fitting app opens a graphical user interface for you to import data from the workspace and interactively fit a probability distribution to that data. You can then save the distribution to the workspace as a probability distribution object. Open the Distribution Fitting app using `dfittool`, or click Distribution Fitting on the Apps tab.

manova

Class: RepeatedMeasuresModel

Multivariate analysis of variance

Syntax

```
manovatbl = manova(rm)
manovatbl = manova(rm,Name,Value)
[manovatbl,A,C,D] = manova( ___ )
```

Description

`manovatbl = manova(rm)` returns the results of multivariate analysis of variance (manova) for the repeated measures model rm.

`manovatbl = manova(rm,Name,Value)` also returns manova results with additional options, specified by one or more Name,Value pair arguments.

`[manovatbl,A,C,D] = manova( ___ )` also returns arrays A, C, and D for the hypotheses tests of the form `A*B*C = D`, where `D` is zero.

Tips

- The multivariate response for each observation (subject) is the vector of repeated measures.
- To test a more general hypothesis `A*B*C = D`, use `coeftest`.

Input Arguments

`rm` — Repeated measures model

`RepeatedMeasuresModel` object

Repeated measures model, returned as a `RepeatedMeasuresModel` object.

For properties and methods of this object, see `RepeatedMeasuresModel`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'WithinModel'` — Model specifying within-subjects hypothesis test

`'separatemeans'` (default) | model specification using formula

Model specifying the within-subjects hypothesis test, specified as one of the following:

- `'separatemeans'` — Compute a separate mean for each group, and test for equality among the means.
- Model specification — This is a model specification in the within-subject factors. Test each term in the model. In this case, `tbl` contains a separate manova for each term in the formula, with the multivariate response equal to the vector of coefficients of that term.
- An *r*-by-*nc* matrix, *C*, specifying *nc* contrasts among the *r* repeated measures. If *Y* represents the matrix of repeated measures you use in the repeated measures model `rm`, then the output `tbl` contains a separate manova for each column of *Y***C*.

Example: `'WithinModel','separatemeans'`

`'By'` — Single between-subjects factor

string

Single between-subjects factor, specified as the comma-separated pair consisting of `'By'` and a string. `manova` performs a separate test of the within-subjects model for each value of this factor.

For example, if you have a between-subjects factor, Drug, then you can specify that factor to perform manova as follows.

Example: `'By','Drug'`

Output Arguments

`manovatbl` — Results of multivariate analysis of variance

table

Results of multivariate analysis of variance for the repeated measures model rm, returned as a `table`.

`manova` uses these methods to measure the contributions of the model terms to the overall covariance:

- Wilks' Lambda
- Pillai's trace
- Hotelling-Lawley trace
- Roy's maximum root statistic

For details, see "Multivariate Analysis of Variance for Repeated Measures" on page 8-83.

`manova` returns the results for these tests for each group. manovatbl contains the following columns.

Column Name	Definition
`Within`	Within-subject terms
`Between`	Between-subject terms
`Statistic`	Name of the statistic computed
`Value`	Value of the corresponding statistic
`F`	*F*-statistic value
`RSquare`	Measure for variance explained
`df1`	Numerator degrees of freedom
`df2`	Denominator degrees of freedom
`pValue`	*p*-value for the corresponding *F*-statistic value

Data Types: `table`

`A` — Specification based on between-subjects model

matrix | cell array

Specification based on the between-subjects model, returned as a matrix or a cell array. It permits the hypothesis on the elements within given columns of `B` (within time hypothesis). If manovatbl contains multiple hypothesis tests, A might be a cell array.

Data Types: `single` | `double` | `cell`

`C` — Specification based on within-subjects model

matrix | cell array

Specification based on the within-subjects model, returned as a matrix or a cell array. It permits the hypotheses on the elements within given rows of `B` (between time hypotheses). If manovatbl contains multiple hypothesis tests, C might be a cell array.

Data Types: `single` | `double` | `cell`

`D` — Hypothesis value

0

Hypothesis value, returned as 0.

Examples

Perform Multivariate Analysis of Variance

Load the sample data.

```
load fisheriris
```

The column vector `species`consists of iris flowers of three different species: setosa, versicolor, virginica. The double matrix `meas` consists of four types of measurements on the flowers: the length and width of sepals and petals in centimeters, respectively.

Store the data in a table array.

```
t = table(species,meas(:,1),meas(:,2),meas(:,3),meas(:,4),...
'VariableNames',{'species','meas1','meas2','meas3','meas4'});
Meas = table([1 2 3 4]','VariableNames',{'Measurements'});
```

Fit a repeated measures model where the measurements are the responses and the species is the predictor variable.

```
rm = fitrm(t,'meas1-meas4~species','WithinDesign',Meas);
```

Perform multivariate analysis of variance.

```
manova(rm)
```

```
ans =

    Within       Between       Statistic       Value        F        RSquare    df1    df

```

Return Arrays of the Hypothesis Test

Load the sample data.

```
load fisheriris
```

The column vector `species` consists of iris flowers of three different species: setosa, versicolor, virginica. The double matrix `meas` consists of four types of measurements on the flowers: the length and width of sepals and petals in centimeters, respectively.

Store the data in a table array.

```
t = table(species,meas(:,1),meas(:,2),meas(:,3),meas(:,4),...
'VariableNames',{'species','meas1','meas2','meas3','meas4'});
Meas = dataset([1 2 3 4]','VarNames',{'Measurements'});
```

Fit a repeated measures model where the measurements are the responses and the species is the predictor variable.

```
rm = fitrm(t,'meas1-meas4~species','WithinDesign',Meas);
```

Perform multivariate analysis of variance. Also return the arrays for constructing the hypothesis test.

```
[manovatbl,A,C,D] = manova(rm)
```

```
manovatbl =

More About

- "Model Specification for Repeated Measures Models" on page 8-77
- "Multivariate Analysis of Variance for Repeated Measures" on page 8-83

manova1

One-way multivariate analysis of variance

Syntax

```
d = manova1(X,group)
d = manova1(X,group,alpha)
[d,p] = manova1(...)
[d,p,stats] = manova1(...)
```

Description

`d = manova1(X,group)` performs a one-way Multivariate Analysis of Variance (MANOVA) for comparing the multivariate means of the columns of `X`, grouped by `group`. `X` is an m-by-n matrix of data values, and each row is a vector of measurements on n variables for a single observation. `group` is a grouping variable defined as a categorical variable, vector, string array, or cell array of strings. Two observations are in the same group if they have the same value in the `group` array. The observations in each group represent a sample from a population.

The function returns `d`, an estimate of the dimension of the space containing the group means. `manova1` tests the null hypothesis that the means of each group are the same n-dimensional multivariate vector, and that any difference observed in the sample `X` is due to random chance. If `d = 0`, there is no evidence to reject that hypothesis. If `d = 1`, then you can reject the null hypothesis at the 5% level, but you cannot reject the hypothesis that the multivariate means lie on the same line. Similarly, if `d = 2` the multivariate means may lie on the same plane in n-dimensional space, but not on the same line.

`d = manova1(X,group,alpha)` gives control of the significance level, `alpha`. The return value `d` will be the smallest dimension having `p > alpha`, where `p` is a p-value for testing whether the means lie in a space of that dimension.

`[d,p] = manova1(...)` also returns a `p`, a vector of p-values for testing whether the means lie in a space of dimension 0, 1, and so on. The largest possible dimension is either the dimension of the space, or one less than the number of groups. There is one element of `p` for each dimension up to, but not including, the largest.

If the ith p-value is near zero, this casts doubt on the hypothesis that the group means lie on a space of i-1 dimensions. The choice of a critical p-value to determine whether the result is judged statistically significant is left to the researcher and is specified by the value of the input argument `alpha`. It is common to declare a result significant if the p-value is less than 0.05 or 0.01.

`[d,p,stats] = manova1(...)` also returns `stats`, a structure containing additional MANOVA results. The structure contains the following fields.

Field	Contents
`W`	Within-groups sum of squares and cross-products matrix
`B`	Between-groups sum of squares and cross-products matrix
`T`	Total sum of squares and cross-products matrix
`dfW`	Degrees of freedom for `W`
`dfB`	Degrees of freedom for `B`
`dfT`	Degrees of freedom for `T`
`lambda`	Vector of values of Wilk's lambda test statistic for testing whether the means have dimension 0, 1, etc.
`chisq`	Transformation of `lambda` to an approximate chi-square distribution
`chisqdf`	Degrees of freedom for `chisq`
`eigenval`	Eigenvalues of W^1B
`eigenvec`	Eigenvectors of W^1B; these are the coefficients for the canonical variables `C`, and they are scaled so the within-group variance of the canonical variables is 1
`canon`	Canonical variables `C`, equal to `XC*eigenvec`, where `XC` is `X` with columns centered by subtracting their means
`mdist`	A vector of Mahalanobis distances from each point to the mean of its group
`gmdist`	A matrix of Mahalanobis distances between each pair of group means

The canonical variables `C` are linear combinations of the original variables, chosen to maximize the separation between groups. Specifically, `C(:,1)` is the linear combination of the `X` columns that has the maximum separation between groups. This means that among all possible linear combinations, it is the one with the most significant F statistic

in a one-way analysis of variance. `C(:,2)` has the maximum separation subject to it being orthogonal to `C(:,1)`, and so on.

You may find it useful to use the outputs from `manova1` along with other functions to supplement your analysis. For example, you may want to start with a grouped scatter plot matrix of the original variables using `gplotmatrix`. You can use `gscatter` to visualize the group separation using the first two canonical variables. You can use `manovacluster` to graph a dendrogram showing the clusters among the group means.

Assumptions

The MANOVA test makes the following assumptions about the data in `X`:

- The populations for each group are normally distributed.
- The variance-covariance matrix is the same for each population.
- All observations are mutually independent.

Examples

you can use `manova1` to determine whether there are differences in the averages of four car characteristics, among groups defined by the country where the cars were made.

```
load carbig
[d,p] = manova1([MPG Acceleration Weight Displacement],...
                Origin)
d =
   3
p =
     0
  0.0000
  0.0075
  0.1934
```

There are four dimensions in the input matrix, so the group means must lie in a four-dimensional space. `manova1` shows that you cannot reject the hypothesis that the means lie in a 3-D subspace.

manovacluster

Dendrogram of group mean clusters following MANOVA

Syntax

```
manovacluster(stats)
manovacluster(stats,method)
H = manovacluster(stats,method)
```

Description

`manovacluster(stats)` generates a dendrogram plot of the group means after a multivariate analysis of variance (MANOVA). `stats` is the output `stats` structure from `manova1`. The clusters are computed by applying the single linkage method to the matrix of Mahalanobis distances between group means.

See `dendrogram` for more information on the graphical output from this function. The dendrogram is most useful when the number of groups is large.

`manovacluster(stats,method)` uses the specified method in place of single linkage. *`method`* can be any of the following character strings that identify ways to create the cluster hierarchy. (See `linkage` for additional information.)

Method	Description
`'single'`	Shortest distance (default)
`'complete'`	Largest distance
`'average'`	Average distance
`'centroid'`	Centroid distance
`'ward'`	Incremental sum of squares

`H = manovacluster(stats,method)` returns a vector of handles to the lines in the figure.

Examples

Dendrogram of Group Means After MANOVA

Load the sample data.

```
load carbig
```

Define the variable matrix.

```
X = [MPG Acceleration Weight Displacement];
```

Perform one-way MANOVA to compare the means of MPG, Acceleration, Weight,and Displacement grouped by Origin.

```
[d,p,stats] = manova1(X,Origin);
```

Create a dendrogram plot of the group means.

```
manovacluster(stats)
```

`cluster` | `dendrogram` | `linkage` | `manova1`

margin

Class: ClassificationKNN

Margin of *k*-nearest neighbor classifier

Syntax

```
m = margin(mdl,X,Y)
```

Description

`m = margin(mdl,X,Y)` returns the classification margins for the matrix of predictors `X` and class labels `Y`. For the definition, see "Margin" on page 22-2805.

Input Arguments

`mdl` — Classifier model

classifier model object

k-nearest neighbor classifier model, returned as a classifier model object.

Note that using the `'CrossVal'`, `'KFold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'` options results in a model of class `ClassificationPartitionedModel`. You cannot use a partitioned tree for prediction, so this kind of tree does not have a `predict` method.

Otherwise, mdl is of class `ClassificationKNN`, and you can use the `predict` method to make predictions.

`X` — Matrix of predictor values

matrix

Matrix of predictor values. Each column of `X` represents one variable, and each row represents one observation.

Y — Categorical variables

categorical array | cell array of strings | character array | logical vector | numeric vector

A categorical array, cell array of strings, character array, logical vector, or a numeric vector with the same number of rows as `X`. Each row of `Y` represents the classification of the corresponding row of `X`.

Output Arguments

m

Numeric column vector of length `size(X,1)`. Each entry in `m` represents the margin for the corresponding rows of X and (true class) Y, computed using mdl.

Definitions

Margin

The classification *margin* is the difference between the classification *score* for the true class and maximal classification score for the false classes.

Score

The *score* of a classification is the posterior probability of the classification. The posterior probability is the number of neighbors that have that classification, divided by the number of neighbors. For a more detailed definition that includes weights and prior probabilities, see "Posterior Probability" on page 22-3654.

Examples

Margin Calculation

Construct a k-nearest neighbor classifier for the Fisher iris data, where $k = 5$.

Load the data.

```
load fisheriris
```

Construct a classifier for 5-nearest neighbors.

```
mdl = fitcknn(meas,species,'NumNeighbors',5);
```

Examine the margin of the classifier for a mean observation classified `'versicolor'`.

```
X = mean(meas);
Y = {'versicolor'};
m = margin(mdl,X,Y)
```

```
m =

     1
```

The classifier has no doubt that `'versicolor'` is the correct classification (all five nearest neighbors classify as `'versicolor'`).

See Also

`ClassificationKNN` | `edge` | `fitcknn` | `loss`

More About

- “Classification Using Nearest Neighbors” on page 16-8

margin

Class: CompactClassificationDiscriminant

Classification margins

Syntax

```
m = margin(obj,X,Y)
```

Description

`m = margin(obj,X,Y)` returns the classification margins for the matrix of predictors `X` and class labels `Y`. For the definition, see "Definitions" on page 22-2808.

Input Arguments

`obj`

Discriminant analysis classifier of class `ClassificationDiscriminant` or `CompactClassificationDiscriminant`, typically constructed with `fitcdiscr`.

`X`

Matrix where each row represents an observation, and each column represents a predictor. The number of columns in `X` must equal the number of predictors in `obj`.

`Y`

Class labels, with the same data type as exists in `obj`. The number of elements of `Y` must equal the number of rows of `X`.

Output Arguments

`m`

Numeric column vector of length `size(X,1)`. Each entry in `m` represents the margin for the corresponding rows of X and (true class) Y, computed using obj.

Definitions

Margin

The classification *margin* is the difference between the classification *score* for the true class and maximal classification score for the false classes.

The classification margin is a column vector with the same number of rows as in the matrix X. A high value of margin indicates a more reliable prediction than a low value.

Score (discriminant analysis)

For discriminant analysis, the *score* of a classification is the posterior probability of the classification. For the definition of posterior probability in discriminant analysis, see "Posterior Probability" on page 15-7.

Examples

Compute the classification margin for the Fisher iris data, trained on its first two columns of data, and view the last 10 entries:

```
load fisheriris
X = meas(:,1:2);
obj = fitcdiscr(X,species);
M = margin(obj,X,species);
M(end-10:end)

ans =
    0.6551
    0.4838
    0.6551
   -0.5127
    0.5659
    0.4611
    0.4949
    0.1024
    0.2787
   -0.1439
   -0.4444
```

The classifier trained on all the data is better:

```
obj = fitcdiscr(meas,species);
M = margin(obj,meas,species);
M(end-10:end)

ans =
    0.9983
    1.0000
    0.9991
    0.9978
    1.0000
    1.0000
    0.9999
    0.9882
    0.9937
    1.0000
    0.9649
```

How To

- “Discriminant Analysis” on page 15-3

margin

Class: CompactClassificationECOC

Classification margins for error-correcting output code multiclass classifiers

Syntax

```
m = margin(Mdl,X,Y)
m = margin(Mdl,X,Y,Name,Value)
```

Description

`m = margin(Mdl,X,Y)` returns the classification margins (`m`) for the trained error-correcting output code (ECOC) multiclass classifier `Mdl` using the predictor data `X` and class labels `Y`. Each row of `X` and `Y` is an observation.

`m = margin(Mdl,X,Y,Name,Value)` returns the classification margins with additional options specified by one or more Name,Value pair arguments.

For example, specify a decoding scheme, binary learner loss function, or verbosity level.

Input Arguments

`Mdl` — ECOC multiclass classifier

`ClassificationECOC` model | `CompactClassificationECOC` model

ECOC multiclass classifier, specified as a `ClassificationECOC` or `CompactClassificationECOC` model. You can create a:

- `ClassificationECOC` model by training the ECOC classifier using `fitcecoc`
- `CompactClassificationECOC` model by passing a `ClassificationECOC` classifier to `compact`

`X` — Predictor data

numeric matrix

Predictor data, specified as a numeric matrix.

Each row of `X` corresponds to one observation (also called an instance or example), and each column corresponds to one variable (also known as a feature). The variables composing the columns of `X` should be the same as the variables that trained the `Mdl` classifier.

The length of `Y` and the number of rows of `X` must be equal.

If you trained `Mdl` specifying to standardize the predictor data, then the software standardizes the columns of `X` using the corresponding means and standard deviations that the software stored in `Mdl.BinaryLearner{j}.Mu` and `Mdl.BinaryLearner{j}.Sigma` for learner `j`.

Data Types: `double` | `single`

`Y` — Class labels

categorical array | character array | logical vector | vector of numeric values | cell array of strings

Class labels, specified as a categorical or character array, logical or numeric vector, or cell array of strings. `Y` must be the same as the data type of `Mdl.ClassNames`.

The length of `Y` and the number of rows of `X` must be equal.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'BinaryLoss'` — Binary learner loss function

function handle | `'hamming'` | `'linear'` | `'exponential'` | `'binodeviance'` | `'hinge'` | `'quadratic'`

Binary learner loss function, specified as the comma-separated pair consisting of `'BinaryLoss'` and a function handle or string.

- If the value is a string, then it must correspond to a built-in function. This table summarizes the built-in functions, where y_j is a class label for a particular binary learner (in the set {-1,1,0}), s_j is the score for observation j, and $g(y_j,s_j)$ is the binary loss formula.

Value	Description	Score Domain	$g(y_j,s_j)$
`'binodeviance'`	Binomial deviance	$(-\infty,\infty)$	$\log[1 + \exp(-2y_js_j)]/[2\log(2)]$
`'exponential'`	Exponential	$(-\infty,\infty)$	$\exp(-y_js_j)/2$
`'hamming'`	Hamming	{-1,1}	$[1 - \text{sign}(y_js_j)]/2$
`'hinge'`	Hinge	$(-\infty,\infty)$	$\max(0,1 - y_js_j)/2$
`'linear'`	Linear	$(-\infty,\infty)$	$(1 - y_js_j)/2$
`'quadratic'`	Quadratic	[0,1]	$[1 - y_j(2s_j - 1)]^2/2$

The software normalizes the binary losses such that the loss is 0.5 when $y_j = 0$. Also, the software calculates the mean binary loss for each class.

- For a custom binary loss function, e.g., `customFunction`, specify its function handle `'BinaryLoss',@customFunction`.

  `customFunction` should have this form

  ```
  bLoss = customFunction(M,s)
  ```
  where:

  - `M` is the K-by-L coding matrix stored in `Mdl.CodingMatrix`.
  - `s` is the 1-by-L row vector of classification scores.
  - `bLoss` is the classification loss. This scalar aggregates the binary losses for every learner in a particular class. For example, you can use the mean binary loss to aggregate the loss over the learners for each class.
  - K is the number of classes.
  - L is the number of binary learners.

  For an example on passing a custom binary loss function, see "Predict Test-Sample Labels of ECOC Models Using Custom Binary Loss Function".

This list describes the default values of `BinayLoss`. If all binary learners are:

- SVMs, then `BinaryLoss` is `'hinge'`
- Ensembles trained by `AdaboostM1` or `GentleBoost`, then `BinaryLoss` is `'exponential'`

- Ensembles trained by `LogitBoost`, then `BinaryLoss` is `'binodeviance'`
- Predicting class posterior probabilities (i.e., set `'FitPosterior',1` in `fitcecoc`), then `BinaryLoss` is `'quadratic'`

Otherwise, the default `BinaryLoss` is `'hamming'`.

Example: `'BinaryLoss','binodeviance'`

Data Types: `char | function_handle`

`'Decoding'` — Decoding scheme

`'lossweighted'` (default) | `'lossbased'`

Decoding scheme that aggregates the binary losses, specified as the comma-separated pair consisting of `'Decoding'` and `'lossweighted'` or `'lossbased'`.

Example: `'Decoding','lossbased'`

Data Types: `char`

`'Options'` — Estimation options

`[]` (default) | structure array returned by `statset`

Estimation options, specified as the comma-separated pair consisting of `'Options'` and a structure array returned by `statset`.

To invoke parallel computing:

- You need a Parallel Computing Toolbox license.
- Specify `'Options',statset('UseParallel',1)`.

`'Verbose'` — Verbosity level

`0` (default) | `1`

Verbosity level, specified as the comma-separated pair consisting of `'Verbose'` and `0` or `1`. `Verbose` controls the amount of diagnostic messages that the software displays in the Command Window.

If `Verbose` is `0`, then the software does not display diagnostic messages. Otherwise, the software displays diagnostic messages.

Example: `'Verbose',1`

Data Types: `single` | `double`

Output Arguments

`m` — Classification margins

numeric column vector

Classification margins, returned as a numeric column vector.

`m` has the same length as `Y`. The software estimates each entry of `m` using the trained ECOC model Mdl, the corresponding row of X, and the true class label Y.

Definitions

Classification Margin

The *classification margins* are, for each observation, the difference between the negative loss for the positive class and maximal negative loss among the negative classes. If the margins are on the same scale, then they serve as a classification confidence measure, i.e., among multiple classifiers, those that yield larger margins are better [4].

Binary Loss

A *binary loss* is a function of the class and classification score that determines how well a binary learner classifies an observation into the class.

Let:

- m_{kj} be element (k,j) of the coding design matrix M (i.e., the code corresponding to class k of binary learner j)
- s_j be the score of binary learner j for an observation
- g be the binary loss function
- $\hat{k}$ be the predicted class for the observation

In *loss-based decoding* [3], the class producing the minimum sum of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \underset{k}{\operatorname{argmin}} \sum_{j=1}^{L} \left| m_{kj} \right| g(m_{kj}, s_j).$$

In *loss-weighted decoding* [3], the class producing the minimum average of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \underset{k}{\operatorname{argmin}} \frac{\sum_{j=1}^{L} \left| m_{kj} \right| g(m_{kj}, s_j)}{\sum_{j=1}^{L} \left| m_{kj} \right|}.$$

Allwein et al. [1] suggest that loss-weighted decoding improves classification accuracy by keeping loss values for all classes in the same dynamic range.

This table summarizes the supported loss functions, where y_j is a class label for a particular binary learner (in the set {-1,1,0}), s_j is the score for observation j, and $g(y_j,s_j)$.

Value	Description	Score Domain	$g(y_j,s_j)$
`'binodeviance'`	Binomial deviance	$(-\infty,\infty)$	$\log[1 + \exp(-2y_js_j)]/[2\log(2)]$
`'exponential'`	Exponential	$(-\infty,\infty)$	$\exp(-y_js_j)/2$
`'hamming'`	Hamming	{-1,1}	$[1 - \text{sign}(y_js_j)]/2$
`'hinge'`	Hinge	$(-\infty,\infty)$	$\max(0,1 - y_js_j)/2$
`'linear'`	Linear	$(-\infty,\infty)$	$(1 - y_js_j)/2$
`'quadratic'`	Quadratic	[0,1]	$[1 - y_j(2s_j - 1)]^2/2$

The software normalizes the binary losses such that the loss is 0.5 when $y_j = 0$, and aggregates using the average of the binary learners [1].

Do not confuse the binary loss with the overall classification loss (specified by the LossFun name-value pair argument of `predict` and `loss`), e.g., classification error, which measures how well an ECOC classifier performs as a whole.

Examples

Estimate Test-Sample Classification Margins of ECOC Models

Load Fisher's iris data set.

```
load fisheriris
X = meas;
Y = categorical(species);
classOrder = unique(Y); % Class order
rng(1); % For reproducibility
```

Train an ECOC model using SVM binary classifiers, and specify a 30% holdout sample. It is good practice to standardize the predictors and define the class order. Specify to standardize the predictors using an SVM template.

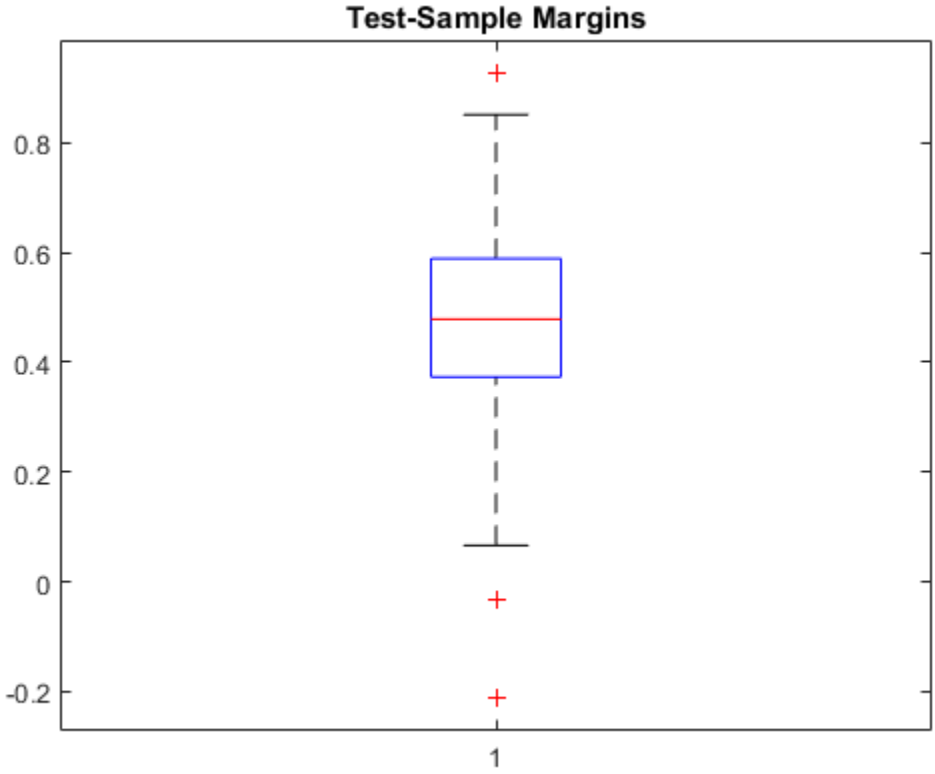
```
t = templateSVM('Standardize',1);
CVMdl = fitcecoc(X,Y,'Holdout',0.30,'Learners',t,'ClassNames',classOrder);
CMdl = CVMdl.Trained{1};           % Extract trained, compact classifier
testInds = test(CVMdl.Partition);  % Extract the test indices
XTest = X(testInds,:);
YTest = Y(testInds,:);
```

`CVMdl` is a `ClassificationPartitionedECOC` model. It contains the property `Trained`, which is a 1-by-1 cell array holding a `CompactClassificationECOC` model that the software trained using the training set.

Estimate the test-sample classification margins. Display the distribution of the margins using a boxplot.

```
m = margin(CMdl,XTest,YTest);

figure;
boxplot(m);
title 'Test-Sample Margins'
```



An observation margin is the positive-class, negated loss minus the maximum negative-class, negated loss. Classifiers that yield relatively large margins are desirable.

Select ECOC Model Features by Examining Test-Sample Margins

The classifier margins measure, for each observation, the difference between the positive-class, negated loss score and the maximal negative-class, negated loss. One way to perform feature selection is to compare test-sample margins from multiple models. Based solely on this criterion, the model with the highest margins is the best model.

Load Fisher's iris data set.

```
load fisheriris
```

```
X = meas;
Y = categorical(species);
classOrder = unique(Y); % Class order
rng(1); % For reproducibility
```

Partition the data set into training and test sets. Specify a 30% holdout sample for testing.

```
Partition = cvpartition(Y,'Holdout',0.30);
testInds = test(Partition); % Indices for the test set
XTest = X(testInds,:);
YTest = Y(testInds,:);
```

Define these two data sets:

- `fullX` contains all four predictors.
- `partX` contains the sepal measurements.

```
fullX = X;
partX = X(:,1:2);
```

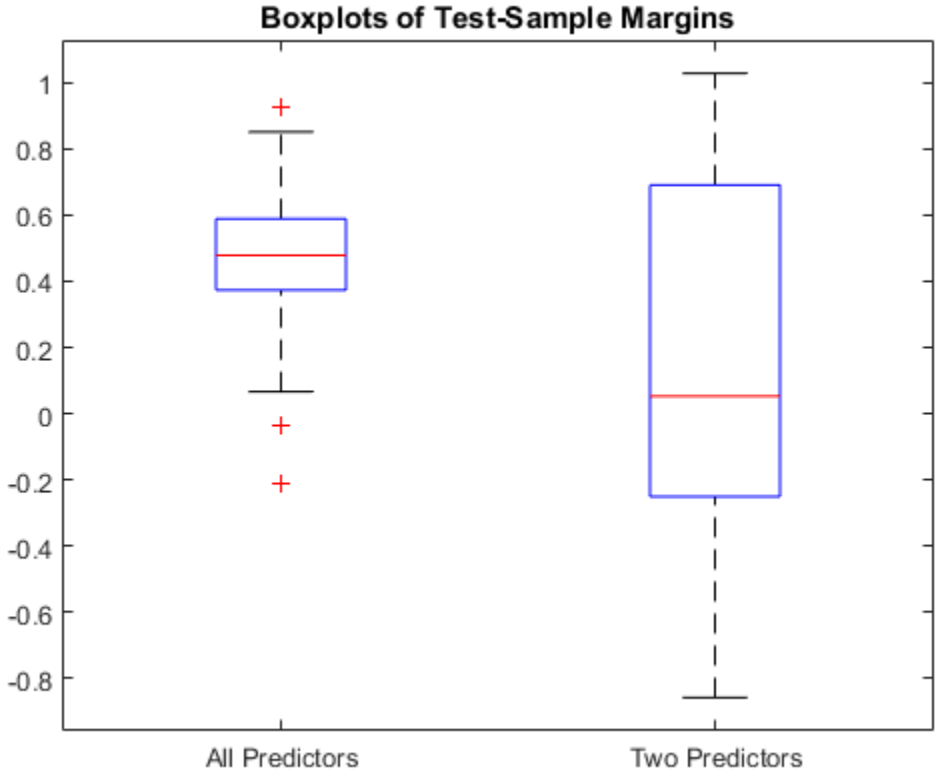
Train an ECOC model using SVM binary classifiers for each predictor set, and specify the partition definition. It is good practice to standardize the predictors and define the class order. Specify to standardize the predictors using an SVM template.

```
t = templateSVM('Standardize',1);
CVMdl = fitcecoc(fullX,Y,'CVPartition',Partition,'Learners',t,...
    'ClassNames',classOrder);
PCVMdl = fitcecoc(partX,Y,'CVPartition',Partition,'Learners',t,...
    'ClassNames',classOrder);
CMdl = CVMdl.Trained{1};
PCMdl = PCVMdl.Trained{1};
```

Estimate the test-sample margins for each classifier. For each model, display the distribution of the margins using a boxplot.

```
fullMargins = margin(CMdl,XTest,YTest);
partMargins = margin(PCMdl,XTest(:,3:4),YTest);

figure;
boxplot([fullMargins partMargins],'Labels',{'All Predictors','Two Predictors'});
title('Boxplots of Test-Sample Margins')
```



The margin distribution of `CMdl` is situated higher, and with less variability than the margin distribution of `PCMdl`.

- "Quick Start Parallel Computing for Statistics and Machine Learning Toolbox" on page 21-2

Tip

To compare margins or edges of several classifiers, use template objects to specify a common score transform function among the classifiers when you train them using `fitcecoc`.

margin

Class: CompactClassificationEnsemble

Classification margins

Syntax

```
M = margin(ens,X,Y)
M = margin(ens,X,Y,Name,Value)
```

Description

`M = margin(ens,X,Y)` returns the classification margin for the predictions of `ens` on data `X`, when the true classifications are `Y`.

`M = margin(ens,X,Y,Name,Value)` calculates margin with additional options specified by one or more Name,Value pair arguments.

Input Arguments

`ens`

Classification ensemble created with `fitensemble`, or a compact classification ensemble created with `compact`.

`X`

Matrix of data to classify. Each row of `X` represents one observation, and each column represents one predictor. `X` must have the same number of columns as the data used to train ens. `X` should have the same number of rows as the number of elements in `Y`.

`Y`

Classification of X. `Y` should be of the same type as the classification used to train ens, and its number of elements should equal the number of rows of X.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'learners'`

Indices of weak learners in the ensemble ranging from `1` to ens`.NumTrained`. `oobEdge` uses only these learners for calculating loss.

Default: `1:NumTrained`

`'UseObsForLearner'`

A logical matrix of size `N`-by-`T`, where:

- `N` is the number of rows of X.
- `T` is the number of weak learners in ens.

When `UseObsForLearner(i,j)` is `true`, learner `j` is used in predicting the class of row `i` of X.

Default: `true(N,T)`

Output Arguments

`M`

A numeric column vector with the same number of rows as X. Each row of `M` gives the classification margin for that row of `X`.

Definitions

Margin

The classification *margin* is the difference between the classification *score* for the true class and maximal classification score for the false classes. Margin is a column vector with the same number of rows as in the matrix X.

Score (ensemble)

For ensembles, a classification *score* represents the confidence of a classification into a class. The higher the score, the higher the confidence.

Different ensemble algorithms have different definitions for their scores. Furthermore, the range of scores depends on ensemble type. For example:

- `AdaBoostM1` scores range from $-\infty$ to ∞.
- `Bag` scores range from `0` to `1`.

Examples

Find the margin for classifying an average flower from the `Fisheriris` data as `'versicolor'`:

```
load fisheriris % X = meas, Y = species
ens = fitensemble(meas,species,'AdaBoostM2',100,'Tree');
flower = mean(meas);
predict(ens,flower)

ans =
    'versicolor'

margin(ens,mean(meas),'versicolor')

ans =
    3.2140
```

See Also

`predict` | `edge` | `loss`

margin

Class: CompactClassificationNaiveBayes

Classification margins for naive Bayes classifiers

Syntax

```
m = margin(Mdl,X,Y)
```

Description

`m = margin(Mdl,X,Y)` returns the classification margins (`m`) for the trained naive Bayes classifier `Mdl` using the predictor data `X` and class labels `Y`.

Input Arguments

`Mdl` — Naive Bayes classifier

`ClassificationNaiveBayes` model | `CompactClassificationNaiveBayes` model

Naive Bayes classifier, specified as a `ClassificationNaiveBayes` model or `CompactClassificationNaiveBayes` model returned by `fitcnb` or `compact`, respectively.

`X` — Predictor data

numeric matrix

Predictor data, specified as a numeric matrix.

Each row of `X` corresponds to one observation (also known as an instance or example), and each column corresponds to one variable (also known as a feature). The variables making up the columns of `X` should be the same as the variables that trained `Mdl`.

The length of `Y` and the number of rows of `X` must be equal.

Data Types: `double` | `single`

`Y` — Class labels

categorical array | character array | logical vector | vector of numeric values | cell array of strings

Class labels, specified as a categorical or character array, logical or numeric vector, or cell array of strings. `Y` must be the same as the data type of `Mdl.ClassNames`.

The length of `Y` and the number of rows of `X` must be equal.

Output Arguments

`m` — Classification margins

numeric vector

Classification margins, returned as a numeric vector.

`m` has the same length equal to `size(X,1)`. Each entry of `m` is the classification margin of the corresponding observation (row) of X and element of Y.

Definitions

Classification Edge

The *classification edge* is the weighted mean of the classification margins.

If you supply weights, then the software normalizes them to sum to the prior probability of their respective class. The software uses the normalized weights to compute the weighted mean.

One way to choose among multiple classifiers, e.g., to perform feature selection, is to choose the classifier that yields the highest edge.

Classification Margin

The *classification margins* are, for each observation, the difference between the score for the true class and maximal score for the false classes. Provided that they are on the same scale, margins serve as a classification confidence measure, i.e., among multiple classifiers, those that yield larger margins are better [2].

Posterior Probability

The *posterior probability* is the probability that an observation belongs in a particular class, given the data.

For naive Bayes, the posterior probability that a classification is k for a given observation $(x_1,...,x_P)$ is

$$\hat{P}(Y = k \mid x_1,..,x_P) = \frac{P(X_1,...,X_P \mid y = k)\pi(Y = k)}{P(X_1,...,X_P)},$$

where:

- $P(X_1,...,X_P \mid y = k)$ is the conditional joint density of the predictors given they are in class k. `Mdl.DistributionNames` stores the distribution names of the predictors.
- $\pi(Y = k)$ is the class prior probability distribution. `Mdl.Prior` stores the prior distribution.
- $P(X_1,..,X_P)$ is the joint density of the predictors. The classes are discrete, so

  $$P(X_1,...,X_P) = \sum_{k=1}^{K} P(X_1,...,X_P \mid y = k)\pi(Y = k).$$

Prior Probability

The *prior probability* is the believed relative frequency that observations from a class occur in the population for each class.

Score

The naive Bayes *score* is the class posterior probability given the observation.

Examples

Estimate Test-Sample Classification Margins of Naive Bayes Classifiers

Load Fisher's iris data set.

```
load fisheriris
X = meas;    % Predictors
Y = species; % Response
rng(1);
```

Train a naive Bayes classifier. Specify a 30% holdout sample for testing. It is good practice to specify the class order. Assume that each predictor is conditionally normally distributed given its label.

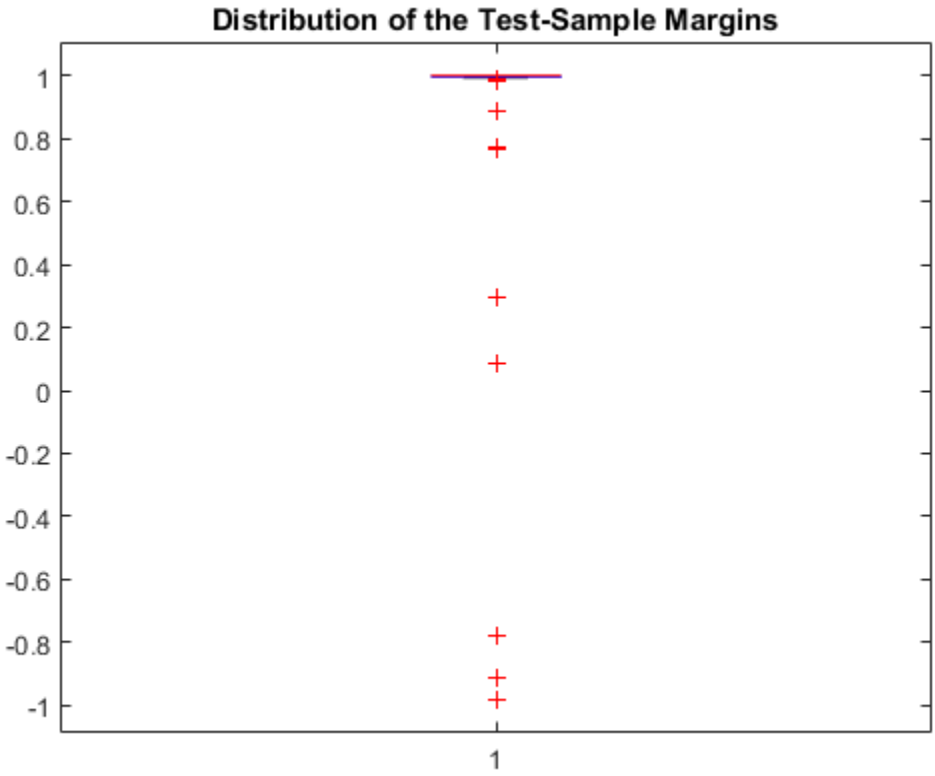
```
CVMdl = fitcnb(X,Y,'Holdout',0.30,...
    'ClassNames',{'setosa','versicolor','virginica'});
CMdl = CVMdl.Trained{1}; ...
    % Extract the trained, compact classifier
testInds = test(CVMdl.Partition);   % Extract the test indices
XTest = X(testInds,:);
YTest = Y(testInds);
```

`CVMdl` is a `ClassificationPartitionedModel` classifier. It contains the property `Trained`, which is a 1-by-1 cell array holding a `CompactClassificationNaiveBayes` classifier that the software trained using the training set.

Estimate the test sample classification margins. Display the distribution of the margins using a boxplot.

```
m = margin(CMdl,XTest,YTest);

figure;
boxplot(m);
title 'Distribution of the Test-Sample Margins';
```



An observation margin is the observed true class score minus the maximum false class score among all scores in the respective class. Classifiers that yield relatively large margins are desirable.

Select Naive Bayes Classifier Features by Examining Test Sample Margins

The classifier margins measure, for each observation, the difference between the true class observed score and the maximal false class score for a particular class. One way to perform feature selection is to compare test sample margins from multiple models. Based solely on this criterion, the model with the highest margins is the best model.

Load Fisher's iris data set.

```
load fisheriris
```

```
X = meas;    % Predictors
Y = species; % Response
rng(1);
```

Partition the data set into training and test sets. Specify a 30% holdout sample for testing.

```
Partition = cvpartition(Y,'Holdout',0.30);
testInds = test(Partition); % Indices for the test set
XTest = X(testInds,:);
YTest = Y(testInds);
```

Partition defines the data set partition.

Define these two data sets:

- `fullX` contains all predictors.
- `partX` contains the last 2 predictors.

```
fullX = X;
partX = X(:,3:4);
```

Train naive Bayes classifiers for each predictor set. Specify the partition definition.

```
FCVMdl = fitcnb(fullX,Y,'CVPartition',Partition);
PCVMdl = fitcnb(partX,Y,'CVPartition',Partition);
FCMdl = FCVMdl.Trained{1};
PCMdl = PCVMdl.Trained{1};
```

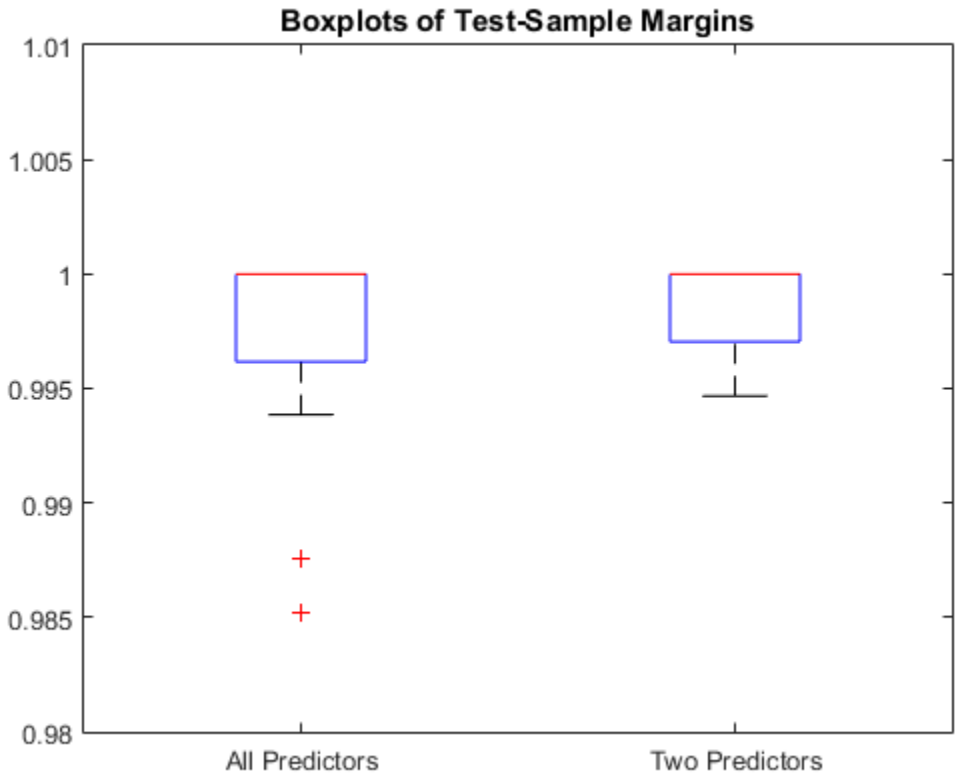
`FullCVMdl` and `PartCVMdl` are `ClassificationPartitionedModel` classifiers. They contain the property `Trained`, which is a 1-by-1 cell array holding a `CompactClassificationNaiveBayes` classifier that the software trained using the training set.

Estimate the test sample margins for each classifier. Display the distributions of the margins for each model using boxplots.

```
fullM = margin(FCMdl,XTest,YTest);
partM = margin(PCMdl,XTest(:,3:4),YTest);

figure;
boxplot([fullM partM],'Labels',{'All Predictors','Two Predictors'})
h = gca;
h.YLim = [0.98 1.01]; % Modify axis to see boxes.
```

```
title 'Boxplots of Test-Sample Margins';
```



The margins have a similar distribution, but `PCMdl` is less complex.

margin

Class: CompactClassificationSVM

Classification margins for support vector machine classifiers

Syntax

```
m = margin(SVMModel,X,Y)
```

Description

`m = margin(SVMModel,X,Y)` returns the classification margins (`m`) for the trained support vector machine (SVM) classifier `SVMModel` using the predictor data `X` and class labels `Y`.

Input Arguments

`SVMModel` — SVM classifier

`ClassificationSVM` classifier | `CompactClassificationSVM` classifier

SVM classifier, specified as a `ClassificationSVM` classifier or `CompactClassificationSVM` classifier returned by `fitcsvm` or `compact`, respectively.

`X` — Predictor data

numeric matrix

Predictor data, specified as a numeric matrix.

Each row of `X` corresponds to one observation (also known as an instance or example), and each column corresponds to one variable (also known as a feature). The variables making up the columns of `X` should be the same as the variables that trained the `SVMModel` classifier.

The length of `Y` and the number of rows of `X` must be equal.

If you set `'Standardize',true` in `fitcsvm` to train `SVMModel`, then the software standardizes the columns of `X` using the corresponding means in `SVMModel.Mu` and standard deviations in `SVMModel.Sigma`.

Data Types: `double` | `single`

`Y` — Class labels

categorical array | character array | logical vector | vector of numeric values | cell array of strings

Class labels, specified as a categorical or character array, logical or numeric vector, or cell array of strings. `Y` must be the same as the data type of `SVMModel.ClassNames`.

The length of `Y` and the number of rows of `X` must be equal.

Output Arguments

`m` — Classification margins

numeric vector

Classification margins, returned as a numeric vector.

`m` has the same length as `Y`. The software estimates each entry of `m` using the trained SVM classifier SVMModel, the corresponding row of X, and the true class label Y.

Definitions

Classification Margin

The *classification margins* are, for each observation, the difference between the score for the true class and maximal score for the false classes. Provided that they are on the same scale, margins serve as a classification confidence measure, i.e., among multiple classifiers, those that yield larger margins are better [2].

Classification Edge

The *edge* is the weighted mean of the *classification margins*.

The weights are the prior class probabilities. If you supply weights, then the software normalizes them to sum to the prior probabilities in the respective classes. The software uses the renormalized weights to compute the weighted mean.

One way to choose among multiple classifiers, e.g., to perform feature selection, is to choose the classifier that yields the highest edge.

Score

The SVM *score* for classifying observation x is the signed distance from x to the decision boundary ranging from -∞ to +∞. A positive score for a class indicates that x is predicted to be in that class, a negative score indicates otherwise.

The score is also the numerical, predicted response for x, $f(x)$, computed by the trained SVM classification function

$$f(x) = \sum_{j=1}^{n} \alpha_j y_j G(x_j, x) + b,$$

where $(\alpha_1, ..., \alpha_n, b)$ are the estimated SVM parameters, $G(x_j, x)$ is the dot product in the predictor space between x and the support vectors, and the sum includes the training set observations.

If $G(x_j, x) = x_j' x$ (the linear kernel), then the score function reduces to

$$f(x) = (x / s)'\beta + b.$$

s is the kernel scale and β is the vector of fitted linear coefficients.

Examples

Estimate Test Sample Classification Margins of SVM Classifiers

Load the `ionosphere` data set.

```
load ionosphere
rng(1); % For reproducibility
```

Train an SVM classifier. Specify a 15% holdout sample for testing. It is good practice to specify the class order and standardize the data.

```
CVSVMModel = fitcsvm(X,Y,'Holdout',0.15,'ClassNames',{'b','g'},...
    'Standardize',true);
CompactSVMModel = CVSVMModel.Trained{1}; ...
    % Extract the trained, compact classifier
testInds = test(CVSVMModel.Partition);   % Extract the test indices
XTest = X(testInds,:);
YTest = Y(testInds,:);
```

`CVSVMModel` is a `ClassificationPartitionedModel` classifier. It contains the property `Trained`, which is a 1-by-1 cell array holding a `CompactClassificationSVM` classifier that the software trained using the training set.

Estimate the test sample classification margins.

```
m = margin(CompactSVMModel,XTest,YTest);
m(10:20)
```

```
ans =

    3.5461
    5.5939
    4.9948
    4.5611
   -4.7963
    5.5127
   -2.8776
    1.8673
    9.4986
    9.5018
   20.9954
```

An observation margin is the observed true class score minus the maximum false class score among all scores in the respective class. Classifiers that yield relatively large margins are desirable.

Select SVM Classifier Features by Examining Test Sample Margins

The classifier margins measure, for each observation, the difference between the true class observed score and the maximal false class score for a particular class. One way to

perform feature selection is to compare test sample margins from multiple models. Based solely on this criterion, the model with the highest margins is the best model.

Load the `ionosphere` data set.

```
load ionosphere
rng(1); % For reproducibility
```

Partition the data set into training and test sets. Specify a 15% holdout sample for testing.

```
Partition = cvpartition(Y,'Holdout',0.15);
testInds = test(Partition); % Indices for the test set
XTest = X(testInds,:);
YTest = Y(testInds,:);
```

Partition defines the data set partition.

Define these two data sets:

- `fullX` contains all predictors (except the removed column of 0s).
- `partX` contains the last 20 predictors.

```
fullX = X;
partX = X(:,end-20:end);
```

Train SVM classifiers for each predictor set. Specify the partition definition.

```
FullCVSVMModel = fitcsvm(fullX,Y,'CVPartition',Partition);
PartCVSVMModel = fitcsvm(partX,Y,'CVPartition',Partition);
FCSVMModel = FullCVSVMModel.Trained{1};
PCSVMModel = PartCVSVMModel.Trained{1};
```

`FullCVSVMModel` and `PartCVSVMModel` are `ClassificationPartitionedModel` classifiers. They contain the property `Trained`, which is a 1-by-1 cell array holding a `CompactClassificationSVM` classifier that the software trained using the training set.

Estimate the test sample margins for each classifier.

```
fullM = margin(FCSVMModel,XTest,YTest);
partM = margin(PCSVMModel,XTest(:,end-20:end),YTest);
n = size(XTest,1);
p = sum(fullM < partM)/n
```

```
p =

    0.2500
```

Approximately 25% of the margins from the full model are less than those from the model with fewer predictors. This suggests that the model trained using all of the predictors is better.

Algorithms

For binary classification, the software defines the margin for observation j, m_j, as

$$m_j = 2y_j f(x_j),$$

where $y_j \in \{-1,1\}$, and $f(x_j)$ is the predicted score of observation j for the positive class. However, the literature commonly uses $m_j = y_j f(x_j)$ to define the margin.

margin

Class: CompactClassificationTree

Classification margins

Syntax

```
m = margin(tree,X,Y)
```

Description

`m = margin(tree,X,Y)` returns the classification margins for the matrix of predictors `X` and class labels `Y`. For the definition, see “Margin” on page 22-2839.

Input Arguments

`tree`

A classification tree created by `fitctree`, or a compact classification tree created by `compact`.

`X`

A matrix where each row represents an observation, and each column represents a predictor. The number of columns in `X` must equal the number of predictors in `tree`.

`Y`

Class labels, with the same data type as exists in `tree`.

Output Arguments

`m`

A numeric column vector of length `size(X,1)`. Each entry in `m` represents the margin for the corresponding rows of X and (true class) Y, computed using tree.

Definitions

Margin

The classification *margin* is the difference between the classification *score* for the true class and maximal classification score for the false classes. Margin is a column vector with the same number of rows as in the matrix X.

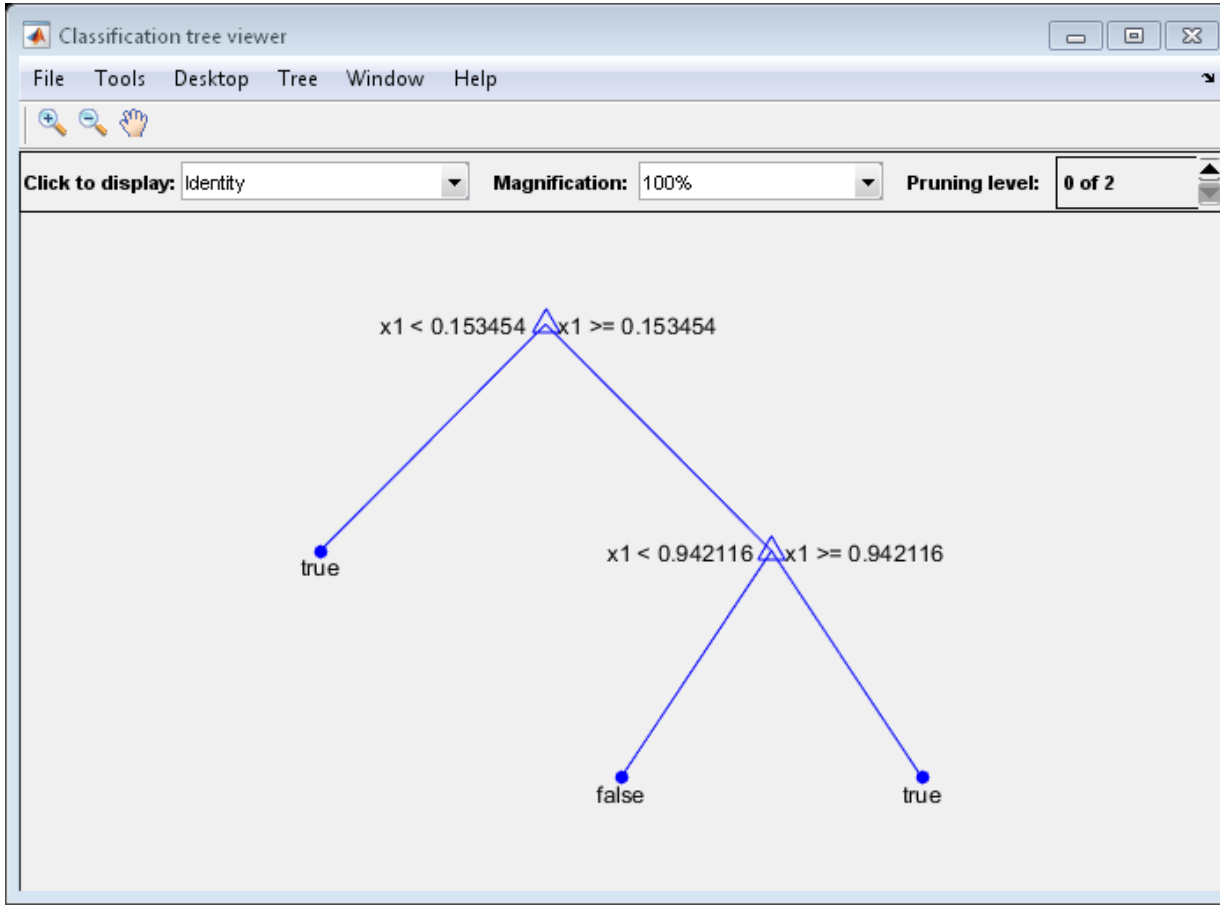
Score (tree)

For trees, the *score* of a classification of a leaf node is the posterior probability of the classification at that node. The posterior probability of the classification at a node is the number of training sequences that lead to that node with the classification, divided by the number of training sequences that lead to that node.

For example, consider classifying a predictor `X` as `true` when `X < 0.15` or `X > 0.95`, and `X` is false otherwise.

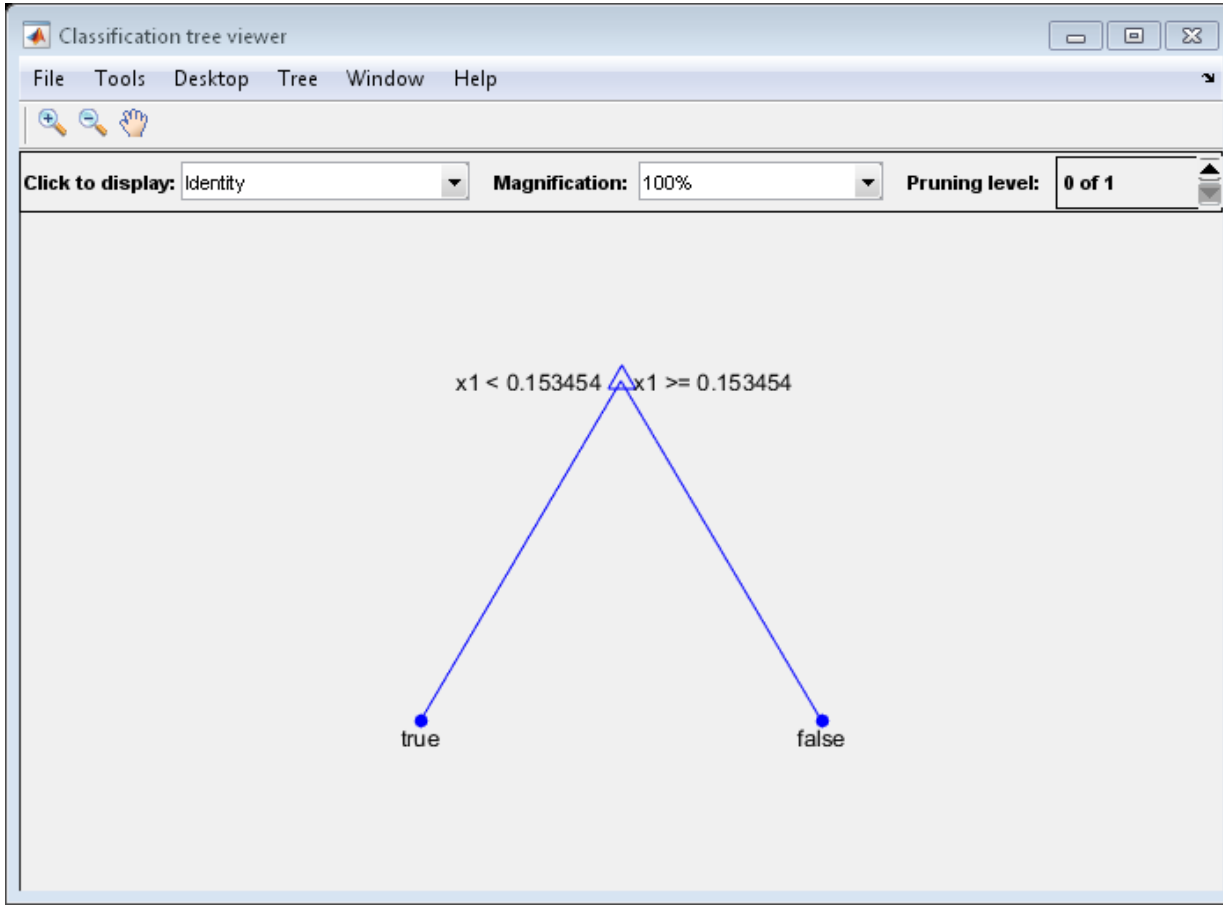
Generate 100 random points and classify them:

```
rng(0,'twister') % for reproducibility
X = rand(100,1);
Y = (abs(X - .55) > .4);
tree = fitctree(X,Y);
view(tree,'Mode','Graph')
```



Prune the tree:

```
tree1 = prune(tree,'Level',1);
view(tree1,'Mode','Graph')
```



The pruned tree correctly classifies observations that are less than 0.15 as `true`. It also correctly classifies observations from .15 to .94 as `false`. However, it incorrectly classifies observations that are greater than .94 as `false`. Therefore, the score for observations that are greater than .15 should be about .05/.85=.06 for `true`, and about .8/.85=.94 for `false`.

Compute the prediction scores for the first 10 rows of `X`:

```
[~,score] = predict(tree1,X(1:10));
[score X(1:10,:)]
```

```
ans =

    0.9059    0.0941    0.8147
    0.9059    0.0941    0.9058
         0    1.0000    0.1270
    0.9059    0.0941    0.9134
    0.9059    0.0941    0.6324
         0    1.0000    0.0975
    0.9059    0.0941    0.2785
    0.9059    0.0941    0.5469
    0.9059    0.0941    0.9575
    0.9059    0.0941    0.9649
```

Indeed, every value of `X` (the right-most column) that is less than 0.15 has associated scores (the left and center columns) of `0` and `1`, while the other values of `X` have associated scores of `0.91` and `0.09`. The difference (score `0.09` instead of the expected `.06`) is due to a statistical fluctuation: there are `8` observations in `X` in the range `(.95,1)` instead of the expected `5` observations.

Examples

Compute the classification margin for the Fisher iris data, trained on its first two columns of data, and view the last 10 entries.

```
load fisheriris
X = meas(:,1:2);
tree = fitctree(X,species);
M = margin(tree,X,species);
M(end-10:end)
```

```
ans =
    0.1111
    0.1111
    0.1111
   -0.2857
    0.6364
    0.6364
    0.1111
    0.7500
    1.0000
    0.6364
```

```
    0.2000
```

The classification tree trained on all the data is better.

```
tree = fitctree(meas,species);
M = margin(tree,meas,species);
M(end-10:end)
```

```
ans =
    0.9565
    0.9565
    0.9565
    0.9565
    0.9565
    0.9565
    0.9565
    0.9565
    0.9565
    0.9565
    0.9565
```

margin

Class: CompactTreeBagger

Classification margin

Syntax

```
mar = margin(B,X,Y)
mar = margin(B,X,Y,'param1',val1,'param2',val2,...)
```

Description

`mar = margin(B,X,Y)` computes the classification margins for predictors `X` given true response `Y`. The `Y` can be either a numeric vector, character matrix, cell array of strings, categorical vector or logical vector. `mar` is a numeric array of size `Nobs`-by-`NTrees`, where `Nobs` is the number of rows of `X` and `Y`, and `NTrees` is the number of trees in the ensemble `B`. For observation `I` and tree `J`, `mar(I,J)` is the difference between the score for the true class and the largest score for other classes. This method is available for classification ensembles only.

`mar = margin(B,X,Y,'param1',val1,'param2',val2,...)` specifies optional parameter name/value pairs:

`'mode'`	String indicating how the method computes errors. If set to `'cumulative'` (default), `margin` computes cumulative errors and `mar` is an `Nobs`-by-`NTrees` matrix, where the first column gives error from `trees(1)`, second column gives error from`trees(1:2)` etc, up to `trees(1:NTrees)`. If set to `'individual'`, `mar` is a `Nobs`-by-`NTrees` matrix, where each element is an error from each tree in the ensemble. If set to `'ensemble'`, `mar` a single column of length `Nobs` showing the cumulative margins for the entire ensemble.
`'trees'`	Vector of indices indicating what trees to include in this calculation. By default, this argument is set to `'all'` and the method uses all trees. If `'trees'` is a numeric vector, the method returns a vector of length `NTrees` for `'cumulative'` and `'individual'` modes,

	where `NTrees` is the number of elements in the input vector, and a scalar for `'ensemble'` mode. For example, in the `'cumulative'` mode, the first element gives error from `trees(1)`, the second element gives error from `trees(1:2)` etc.
`'treeweights'`	Vector of tree weights. This vector must have the same length as the `'trees'` vector. The method uses these weights to combine output from the specified trees by taking a weighted average instead of the simple non-weighted majority vote. You cannot use this argument in the `'individual'` mode.
`'useifort'`	Logical matrix of size `Nobs`-by-`NTrees` indicating which trees should be used to make predictions for each observation. By default the method uses all trees for all observations.

`TreeBagger.margin`

margin

Class: TreeBagger

Classification margin

Syntax

```
mar = margin(B,X,Y)
mar = margin(B,X,Y,'param1',val1,'param2',val2,...)
```

Description

`mar = margin(B,X,Y)` computes the classification margins for predictors `X` given true response `Y`. The `Y` can be either a numeric vector, character matrix, cell array of strings, categorical vector or logical vector. `mar` is a numeric array of size `Nobs`-by-`NTrees`, where `Nobs` is the number of rows of `X` and `Y`, and `NTrees` is the number of trees in the ensemble `B`. For observation `I` and tree `J`, `mar(I,J)` is the difference between the score for the true class and the largest score for other classes. This method is available for classification ensembles only.

`mar = margin(B,X,Y,'param1',val1,'param2',val2,...)` specifies optional parameter name/value pairs:

`'mode'`	String indicating how the method computes errors. If set to `'cumulative'` (default), `margin` computes cumulative errors and `mar` is an `Nobs`-by-`NTrees` matrix, where the first column gives error from `trees(1)`, second column gives error from`trees(1:2)` etc, up to `trees(1:NTrees)`. If set to `'individual'`, `mar` is a `Nobs`-by-`NTrees` matrix, where each element is an error from each tree in the ensemble. If set to `'ensemble'`, `mar` a single column of length `Nobs` showing the cumulative margins for the entire ensemble.
`'trees'`	Vector of indices indicating what trees to include in this calculation. By default, this argument is set to `'all'` and the method uses all trees. If `'trees'` is a numeric vector, the method returns a vector of length `NTrees` for `'cumulative'` and `'individual'` modes,

	where `NTrees` is the number of elements in the input vector, and a scalar for `'ensemble'` mode. For example, in the `'cumulative'` mode, the first element gives error from `trees(1)`, the second element gives error from `trees(1:2)` etc.
`'treeweights'`	Vector of tree weights. This vector must have the same length as the `'trees'` vector. The method uses these weights to combine output from the specified trees by taking a weighted average instead of the simple non-weighted majority vote. You cannot use this argument in the `'individual'` mode.
`'useifort'`	Logical matrix of size `Nobs`-by-`NTrees` indicating which trees should be used to make predictions for each observation. By default the method uses all trees for all observations.

See Also

`CompactTreeBagger.margin`

margmean

Class: RepeatedMeasuresModel

Estimate marginal means

Syntax

```
tbl = margmean(rm,vars)
tbl = margmean(rm,vars,'alpha',alpha)
```

Description

`tbl = margmean(rm,vars)` returns the estimated marginal means for the variables vars, in the table tbl.

`tbl = margmean(rm,vars,'alpha',alpha)` returns the 100*(1–`alpha`)% confidence intervals for the marginal means.

Input Arguments

`rm` — Repeated measures model

`RepeatedMeasuresModel` object

Repeated measures model, returned as a `RepeatedMeasuresModel` object.

For properties and methods of this object, see `RepeatedMeasuresModel`.

`vars` — Variables for which to compute the marginal means

string | cell array of strings

Variables for which to compute the marginal means, specified as a string representing the name of a between or within-subjects factor in rm, or a cell array of strings representing the names of multiple variables. Each between-subjects factor must be categorical.

For example, if you want to compute the marginal means for the variables Drug and Gender, then you can specify as follows.

Example: `{'Drug','Gender'}`

Data Types: `char` | `cell`

`alpha` — Confidence level

0.05 (default) | scalar value in the range of 0 to 1

Confidence level of the confidence intervals for population marginal means, specified as a scalar value in the range of 0 to 1. The confidence level is 100*(1–`alpha`)%.

For example, you can specify a 99% confidence level as follows.

Example: `'alpha',0.01`

Data Types: `double` | `single`

Output Arguments

`tbl` — Estimated marginal means

table

Estimated marginal means, returned as a table. tbl contains one row for each combination of the groups of the variables you specify in vars, one column for each variable, and the following columns.

Column name	Description
`Mean`	Estimated marginal means
`StdErr`	Standard errors of the estimates
`Lower`	Lower limit of a 95% confidence interval for the true population mean
`Upper`	Upper limit of a 95% confidence interval for the true population mean

Examples

Compute Marginal Means Grouped by Two Factors

Load the sample data.

```
load repeatedmeas
```

The table `between` includes the between-subject variables age, IQ, group, gender, and eight repeated measures $y1$ to $y8$ as responses. The table `within` includes the within-subject variables $w1$ and $w2$. This is simulated data.

Fit a repeated measures model, where the repeated measures $y1$ to $y8$ are the responses, and age, IQ, group, gender, and the group-gender interaction are the predictor variables. Also specify the within-subject design matrix.

```
rm = fitrm(between,'y1-y8 ~ Group*Gender + Age + IQ','WithinDesign',within);
```

Compute the marginal means grouped by the between-subjects factor `Group` and the within-subject factor `Time`.

```
M = margmean(rm,{'Group' 'Time'})
```

```
M =

    Group    Time     Mean      StdErr     Lower       Upper
    _____    ____    _______    ______    ________    _______

```

Display the description for table M.

```
M.Properties.Description
```

```
ans =

Estimated marginal means
Means computed with Age=13.7, IQ=98.2667
```

Compute Estimated Marginal Means and Confidence Intervals

Load the sample data.

```
load fisheriris
```

The column vector, `species`, consists of iris flowers of three different species, setosa, versicolor, virginica. The double matrix `meas` consists of four types of measurements on the flowers, the length and width of sepals and petals in centimeters, respectively.

Store the data in a table array.

```
t = table(species,meas(:,1),meas(:,2),meas(:,3),meas(:,4),...
'VariableNames',{'species','meas1','meas2','meas3','meas4'});
Meas = dataset([1 2 3 4]','VarNames',{'Measurements'});
```

Fit a repeated measures model, where the measurements are the responses and the species is the predictor variable.

```
rm = fitrm(t,'meas1-meas4~species','WithinDesign',Meas);
```

Compute the marginal means grouped by the factor species.

```
margmean(rm,'species')
```

```
ans =

      species         Mean      StdErr     Lower     Upper
    ____________    ______    _________    ______    ______

    'setosa'        2.5355    0.042807     2.4509    2.6201
    'versicolor'     3.573    0.042807     3.4884    3.6576
    'virginica'      4.285    0.042807     4.2004    4.3696
```

`StdError` field shows the standard errors of the estimated marginal means. The `Lower` and `Upper` fields show the lower and upper bounds for the 95% confidence intervals

of the group marginal means, respectively. None of the confidence intervals overlap, which indicates that marginal means differ with species. You can also plot the estimated marginal means using the `plotprofile` method.

Compute the 99% confidence intervals for the marginal means.

```
margmean(rm,'species','alpha',0.01)
```

```
ans =

      species         Mean      StdErr     Lower     Upper
    _____________    ______    _________    ______    ______

    'setosa'         2.5355    0.042807    2.4238    2.6472

mauchly

Class: RepeatedMeasuresModel

Mauchly's test for sphericity

Syntax

```
tbl = mauchly(rm)
tbl = mauchly(rm,C)
```

Description

`tbl = mauchly(rm)` returns the result of the Mauchly's test for sphericity for the repeated measures model rm.

It tests the null hypothesis that the sphericity assumption is true for the response variables in `rm`.

For more information, see "Mauchly's Test of Sphericity" on page 8-81.

`tbl = mauchly(rm,C)` returns the result of the Mauchly's test based on the contrast matrix C.

Input Arguments

`rm` — Repeated measures model

`RepeatedMeasuresModel` object

Repeated measures model, returned as a `RepeatedMeasuresModel` object.

For properties and methods of this object, see `RepeatedMeasuresModel`.

`C` — Contrasts

matrix

Contrasts, specified as a matrix. The default value of C is the Q factor in a QR decomposition of the matrix M, where M is defined so that Y*M is the difference between all successive pairs of columns of the repeated measures matrix Y.

Data Types: `single | double`

Output Arguments

`tbl` — Results of Mauchly's test of sphericity

table

Results of Mauchly's test for sphericity for the repeated measures model rm, returned as a `table`.

`tbl` contains the following columns.

Column Name	Definition
`W`	Value of Mauchly's *W* statistic
`ChiStat`	Chi-square statistic value
`DF`	Degrees of freedom of the Chi-square statistic
`pValue`	*p*-value corresponding to the Chi-square statistic

Data Types: `table`

Examples

Perform Mauchly's Test

Load the sample data.

```
load fisheriris
```

The column vector `species`consists of iris flowers of three different species: setosa, versicolor, and virginica. The double matrix `meas` consists of four types of measurements on the flowers: the length and width of sepals and petals in centimeters, respectively.

Store the data in a table array.

```
t = table(species,meas(:,1),meas(:,2),meas(:,3),meas(:,4),...
'VariableNames',{'species','meas1','meas2','meas3','meas4'});
Meas = dataset([1 2 3 4]','VarNames',{'Measurements'});
```

Fit a repeated measures model, where the measurements are the responses and the species is the predictor variable.

```
rm = fitrm(t,'meas1-meas4~species','WithinDesign',Meas);
```

Perform Mauchly's test to assess the sphericity assumption.

```
mauchly(rm)
```

```
ans =

       W        ChiStat     DF       pValue
    _______    ________    __    ___________

    0.55814     84.976     5     1.1102e-16
```

The small p-value (in the `pValue` field) indicates that the sphericity, hence the compound symmetry assumption, does not hold. You should use epsilon corrections to compute the p-values for a repeated measures anova. You can compute the epsilon corrections using the `epsilon` method and perform the repeated measures anova with the corrected p-values using the `ranova` method.

mat2dataset

Convert matrix to dataset array

Compatibility

The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

Syntax

```
ds = mat2dataset(X)
ds = mat2dataset(X,Name,Value)
```

Description

`ds = mat2dataset(X)` converts a matrix to a `dataset` array.

`ds = mat2dataset(X,Name,Value)` performs the conversion using additional options specified by one or more Name,Value pair arguments.

Examples

Convert Matrix to Dataset Array

Convert a matrix to a dataset array using the default options.

Load sample data.

```
load('fisheriris')
X = meas;
size(X)

ans =
```

```
   150     4
```

Convert the matrix to a dataset array.

```
ds = mat2dataset(X);
size(ds)
```

```
ans =

   150     4
```

```
ds(1:5,:)
```

```
ans =

    X1     X2     X3     X4
    5.1    3.5    1.4    0.2
    4.9      3    1.4    0.2
    4.7    3.2    1.3    0.2
    4.6    3.1    1.5    0.2
      5    3.6    1.4    0.2
```

When you do not specify variable names, `mat2dataset` uses the matrix name and column numbers to create default variable names.

Convert Matrix to Dataset Array with Variable Names

Load sample data.

```
load('fisheriris')
X = meas;
size(X)
```

```
ans =

   150     4
```

Convert the matrix to a dataset array, providing a variable name for each of the four column of `X`.

```
ds = mat2dataset(X,'VarNames',{'SLength',...
'SWidth','PLength','PWidth'});
size(ds)
```

```
ans =
```

```
   150     4

ds(1:5,:)

ans =

    SWidth    SLength    PWidth    PLength
    5.1       3.5        1.4       0.2
    4.9         3        1.4       0.2
    4.7       3.2        1.3       0.2
    4.6       3.1        1.5       0.2
      5       3.6        1.4       0.2
```

Create a Dataset Array with Multicolumn Variables

Convert a matrix to a dataset array containing multicolumn variables.

Load sample data.

```
load('fisheriris')
X = meas;
size(X)

ans =

   150     4
```

Convert the matrix to a dataset array, combining the sepal measurements (the first two columns) into one variable named `SepalMeas`, and the petal measurements (third and fourth columns) into one variable names `PetalMeas`.

```
ds = mat2dataset(X,'NumCols',[2,2],...
'VarNames',{'SepalMeas','PetalMeas'});
ds(1:5,:)

ans =

    SepalMeas           PetalMeas
    5.1         3.5     1.4         0.2
    4.9           3     1.4         0.2
    4.7         3.2     1.3         0.2
    4.6         3.1     1.5         0.2
      5         3.6     1.4         0.2
```

The output dataset array has 150 observations and 2 variables.

```
size(ds)

ans =

   150     2
```

- "Create a Dataset Array from Workspace Variables" on page 2-63
- "Create a Dataset Array from a File" on page 2-69

Input Arguments

X — Input matrix

matrix

Input matrix to convert to a dataset array, specified as an *M*-by-*N* numeric matrix. Each column of `X` becomes a variable in the output *M*-by-*N* dataset array.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'NumCols',[1,1,2,1]` specifies that the 3rd and 4th columns of the input matrix should be combined into a single variable.

'VarNames' — Variable names for output dataset array

cell array of strings

Variable names for the output dataset array, specified as the comma-separated pair consisting of `'VarNames'` and a cell array of strings. You must provide a variable name for each variable in ds. The names must be valid MATLAB identifiers, and must be unique.

Example: `'VarNames',{'myVar1','myVar2','myVar3'}`

'ObsNames' — Observation names for output dataset array

cell array of strings

Observation names for the output dataset array, specified as the comma-separated pair consisting of `'ObsNames'` and a cell array of strings. The names do not need to be valid MATLAB identifiers, but they must be unique.

`'NumCols'` — Number of columns for each variable

vector of nonnegative integers

Number of columns for each variable in ds, specified as the comma-separated pair consisting of `'NumCols'` and a vector of nonnegative integers. When the number of columns for a variable is greater than one, `mat2dataset` combines multiple columns in X into a single variable in `ds`. The vector you assign to `NumCols` must sum to `size(X,2)`.

For example, to convert a matrix with eight columns into a dataset array with five variables, specify a vector with five elements that sum to eight, such as `'NumCols', [1,1,3,1,2]`.

Output Arguments

`ds` — Output dataset array

dataset array

Output dataset array, returned by default with a variable for each column of X, and an observation for each row of `X`. If you specify NumCols, then the number of variables in `ds` is equal to the length of the specified vector of column numbers.

mdscale

Nonclassical multidimensional scaling

Syntax

```
Y = mdscale(D,p)
[Y,stress] = mdscale(D,p)
[Y,stress,disparities] = mdscale(D,p)
[...] = mdscale(D,p,'Name',value)
```

Description

`Y = mdscale(D,p)` performs nonmetric multidimensional scaling on the n-by-n dissimilarity matrix `D`, and returns `Y`, a configuration of n points (rows) in `p` dimensions (columns). The Euclidean distances between points in `Y` approximate a monotonic transformation of the corresponding dissimilarities in `D`. By default, `mdscale` uses Kruskal's normalized stress1 criterion.

You can specify `D` as either a full n-by-n matrix, or in upper triangle form such as is output by `pdist`. A full dissimilarity matrix must be real and symmetric, and have zeros along the diagonal and non-negative elements everywhere else. A dissimilarity matrix in upper triangle form must have real, non-negative entries. `mdscale` treats `NaN`s in `D` as missing values, and ignores those elements. `Inf` is not accepted.

You can also specify `D` as a full similarity matrix, with ones along the diagonal and all other elements less than one. `mdscale` transforms a similarity matrix to a dissimilarity matrix in such a way that distances between the points returned in `Y` approximate `sqrt(1-D)`. To use a different transformation, transform the similarities prior to calling `mdscale`.

`[Y,stress] = mdscale(D,p)` returns the minimized stress, i.e., the stress evaluated at `Y`.

`[Y,stress,disparities] = mdscale(D,p)` returns the disparities, that is, the monotonic transformation of the dissimilarities `D`.

`[...] = mdscale(D,p,'Name',value)` specifies one or more optional parameter name/value pairs that control further details of `mdscale`. Specify *`Name`* in single quotes. Available parameters are

- `Criterion`— The goodness-of-fit criterion to minimize. This also determines the type of scaling, either non-metric or metric, that `mdscale` performs. Choices for non-metric scaling are:
  - `'stress'` — Stress normalized by the sum of squares of the inter-point distances, also known as stress1. This is the default.
  - `'sstress'` — Squared stress, normalized with the sum of 4th powers of the inter-point distances.

  Choices for metric scaling are:
  - `'metricstress'` — Stress, normalized with the sum of squares of the dissimilarities.
  - `'metricsstress'` — Squared stress, normalized with the sum of 4th powers of the dissimilarities.
  - `'sammon'` — Sammon's nonlinear mapping criterion. Off-diagonal dissimilarities must be strictly positive with this criterion.
  - `'strain'` — A criterion equivalent to that used in classical multidimensional scaling.
- `Weights` — A matrix or vector the same size as `D`, containing nonnegative dissimilarity weights. You can use these to weight the contribution of the corresponding elements of `D` in computing and minimizing stress. Elements of `D` corresponding to zero weights are effectively ignored.

  Note: When you specify weights as a full matrix, its diagonal elements are ignored and have no effect, since the corresponding diagonal elements of `D` do not enter into the stress calculation.
- `Start` — Method used to choose the initial configuration of points for Y. The choices are
  - `'cmdscale'` — Use the classical multidimensional scaling solution. This is the default. `'cmdscale'` is not valid when there are zero weights.
  - `'random'` — Choose locations randomly from an appropriately scaled p-dimensional normal distribution with uncorrelated coordinates.

  - An *n*-by-`p` matrix of initial locations, where n is the size of the matrix `D` and `p` is the number of columns of the output matrix `Y`. In this case, you can pass in `[]` for `p` and `mdscale` infers `p` from the second dimension of the matrix. You can also supply a 3-D array, implying a value for `'Replicates'` from the array's third dimension.
- `Replicates` — Number of times to repeat the scaling, each with a new initial configuration. The default is `1`.
- `Options` — Options for the iterative algorithm used to minimize the fitting criterion. Pass in an options structure created by `statset`. For example,

  ```
  opts = statset(param1,val1,param2,val2, ...);
  [...] = mdscale(...,'Options',opts)
  ```

  The choices of `statset` parameters are

  - `'Display'` — Level of display output. The choices are `'off'` (the default), `'iter'`, and `'final'`.
  - `'MaxIter'` — Maximum number of iterations allowed. The default is `200`.
  - `'TolFun'` — Termination tolerance for the stress criterion and its gradient. The default is `1e-4`.
  - `'TolX'`— Termination tolerance for the configuration location step size. The default is `1e-4`.

Examples

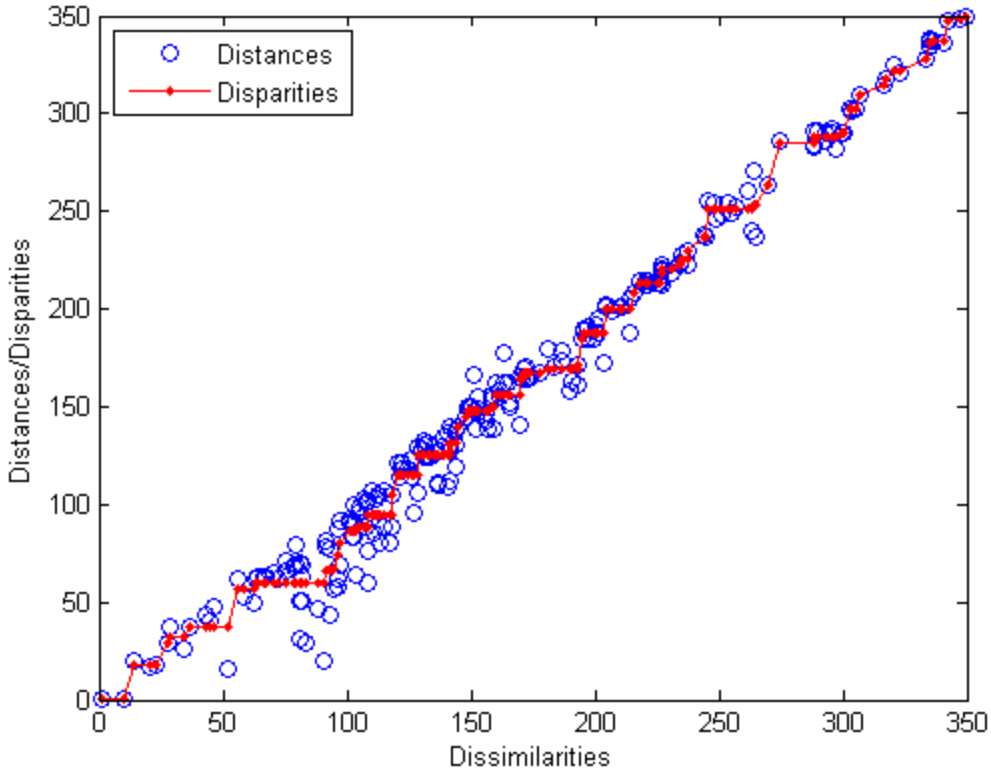
```
load cereal.mat
X = [Calories Protein Fat Sodium Fiber ...
     Carbo Sugars Shelf Potass Vitamins];

% Take a subset from a single manufacturer.
X = X(strcmp('K',cellstr(Mfg)),:);

% Create a dissimilarity matrix.
dissimilarities = pdist(X);

% Use non-metric scaling to recreate the data in 2D,
% and make a Shepard plot of the results.
[Y,stress,disparities] = mdscale(dissimilarities,2);
distances = pdist(Y);
```

```
[dum,ord] = sortrows([disparities(:) dissimilarities(:)]);
plot(dissimilarities,distances,'bo', ...
dissimilarities(ord),disparities(ord),'r.-');
xlabel('Dissimilarities'); ylabel('Distances/Disparities')
legend({'Distances' 'Disparities'},'Location','NW');
```



```
% Do metric scaling on the same dissimilarities.
figure
[Y,stress] = ...
mdscale(dissimilarities,2,'criterion','metricsstress');
distances = pdist(Y);
plot(dissimilarities,distances,'bo', ...
[0 max(dissimilarities)],[0 max(dissimilarities)],'r.-');
xlabel('Dissimilarities'); ylabel('Distances')
```

mdsProx

Class: CompactTreeBagger

Multidimensional scaling of proximity matrix

Syntax

```
[SC,EIGEN] = mdsProx(B,X)
[SC,EIGEN] = mdsProx(B,X,'param1',val1,'param2',val2,...)
```

Description

`[SC,EIGEN] = mdsProx(B,X)` applies classical multidimensional scaling to the proximity matrix computed for the data in the matrix `X`, and returns scaled coordinates `SC` and eigenvalues `EIGEN` of the scaling transformation. The method applies multidimensional scaling to the matrix of distances defined as 1-`prox`, where `prox` is the proximity matrix returned by the `proximity` method.

You can supply the proximity matrix directly by using the `'data'` parameter.

`[SC,EIGEN] = mdsProx(B,X,'param1',val1,'param2',val2,...)` specifies optional parameter name/value pairs:

`'data'`	Flag indicating how the method treats the `X` input argument. If set to `'predictors'` (default), `mdsProx` assumes `X` to be a matrix of predictors and used for computation of the proximity matrix. If set to `'proximity'`, the method treats `X` as a proximity matrix returned by the `proximity` method.
`'colors'`	If you supply this argument, `mdsProx` makes overlaid scatter plots of two scaled coordinates using specified colors for different classes. You must supply the colors as a string with one character for each color. If there are more classes in the data than characters in the supplied string, `mdsProx` only plots the first `C` classes, where `C` is the length of the string. For regression or if you do not provide the vector of true class labels, the method uses the first color for all observations in `X`.

`'labels'`	Vector of true class labels for a classification ensemble. True class labels can be either a numeric vector, character matrix, or cell array of strings. If supplied, this vector must have as many elements as there are observations (rows) in `X`. This argument has no effect unless you also supply the `'colors'` argument.
`'mdscoords'`	Indices of the two scaled coordinates to plot. By default, `mdsProx` makes a scatter plot of the first and second scaled coordinates which correspond to the two largest eigenvalues. You can specify any other two or three indices not exceeding the dimensionality of the scaled data. This argument has no effect unless you also supply the `'colors'` argument.

mdsProx

Class: TreeBagger

Multidimensional scaling of proximity matrix

Syntax

```
[S,E] = mdsProx(B)
[S,E] = mdsProx(B,'param1',val1,'param2',val2,...)
```

Description

`[S,E] = mdsProx(B)` returns scaled coordinates, `S`, and eigenvalues, `E`, for the proximity matrix in the ensemble `B`. An earlier call to `fillProximities(B)` must create the proximity matrix.

`[S,E] = mdsProx(B,'param1',val1,'param2',val2,...)` specifies optional parameter name/value pairs:

`'keep'`	Array of indices of observations in the training data to use for multidimensional scaling. By default, this argument is set to `'all'`. If you provide numeric or logical indices, the method uses only the subset of the training data specified by these indices to compute the scaled coordinates and eigenvalues.
`'colors'`	If you supply this argument, `mdsProx` makes overlaid scatter plots of two scaled coordinates using specified colors for different classes. You must supply the colors as a string with one character for each color. If there are more classes in the data than characters in the supplied string, `mdsProx` only plots the first `C` classes, where `C` is the length of the string. For regression or if you do not provide the vector of true class labels, the method uses the first color for all observations in `X`.
`'mdscoords'`	Indices of the two scaled coordinates to plot. By default, `mdsProx` makes a scatter plot of the first and second scaled coordinates which correspond to the two largest eigenvalues. You can specify any

other two or three indices not exceeding the dimensionality of the scaled data. This argument has no effect unless you also supply the `'colors'` argument.

`cmdscale` | `CompactTreeBagger.mdsProx` | `fillProximities`

mean

Mean of probability distribution

Syntax

```
m = mean(pd)
```

Description

`m = mean(pd)` returns the mean m of the probability distribution pd.

Examples

Mean of a Fitted Distribution

Load the sample data. Create a vector containing the first column of students' exam grade data.

```
load examgrades;
x = grades(:,1);
```

Create a normal distribution object by fitting it to the data.

```
pd = fitdist(x,'Normal')
```

```
pd =

  NormalDistribution

  Normal distribution
       mu = 75.0083   [73.4321, 76.5846]
    sigma =  8.7202   [7.7391, 9.98843]
```

Compute the mean of the fitted distribution.

```
m = mean(pd)
```

```
m =
```

```
   75.0083
```

The mean of the normal distribution is equal to the parameter `mu`.

Mean of a Skewed Distribution

Create a Weibull probability distribution object.

```
pd = makedist('Weibull','a',5,'b',2)
```

```
pd =

  WeibullDistribution

  Weibull distribution
    A = 5
    B = 2
```

Compute the mean of the distribution.

```
mean = mean(pd)
```

```
mean =
    4.4311
```

Input Arguments

`pd` — Probability distribution

probability distribution object

Probability distribution, specified as a probability distribution object. Create a probability distribution object with specified parameter values using `makedist`. Alternatively, create a probability distribution object by fitting it to data using `fitdist` or the Distribution Fitting app.

Output Arguments

`m` — Mean

scalar value

Mean of the probability distribution, returned as a scalar value.

See Also

`dfittool` | `fitdist` | `makedist`

mean

Class: prob.KernelDistribution
Package: prob

Mean of probability distribution object

Syntax

```
m = mean(pd)
```

Description

`m = mean(pd)` returns the mean m of the probability distribution pd.

Input Arguments

`pd` — Probability distribution

probability distribution object

Probability distribution, specified as a probability distribution object. Fit a probability distribution object to data using `fitdist` or the Distribution Fitting app.

Output Arguments

`m` — Mean

scalar value

Mean of the probability distribution, returned as a scalar value.

Examples

Mean of a Kernel Distribution

Load the sample data. Create a probability distribution object by fitting a kernel distribution to the miles per gallon (`MPG`) data.

```
load carsmall;
pd = fitdist(MPG,'Kernel')

pd =

  KernelDistribution

    Kernel = normal
    Bandwidth = 4.11428
    Support = unbounded
```

Compute the mean of the distribution.

```
mean(pd)

ans =

   23.7181
```

See Also

`dfittool` | `fitdist`

mean

Class: ProbDistUnivParam

Return mean of ProbDistUnivParam object

Syntax

```
M = mean(PD)
```

Description

`M = mean(PD)` returns *M*, the mean of the ProbDistUnivParam object *PD*.

Input Arguments

PD	An object of the class `ProbDistUnivParam`.

Output Arguments

M	The mean of the ProbDistUnivParam object *PD*.

See Also

`mean`

mean

Class: prob.ParametricTruncatableDistribution
Package: prob

Mean of probability distribution object

Syntax

```
m = mean(pd)
```

Description

`m = mean(pd)` returns the mean m of the probability distribution pd.

Input Arguments

`pd` — Probability distribution

probability distribution object

Probability distribution, specified as a probability distribution object. Create a probability distribution object with specified parameter values using `makedist`.

Output Arguments

`m` — Mean

scalar value

Mean of the probability distribution, returned as a scalar value.

Examples

Mean of a Uniform Distribution

Create a uniform distribution object

```
pd = makedist('Uniform','lower',-3,'upper',5)

pd =

  UniformDistribution

  Uniform distribution
    Lower = -3
    Upper =  5
```

Compute the mean of the distribution.

```
m = mean(pd)

m =
     1
```

`makedist`

mean

Class: prob.ToolboxFittableParametricDistribution
Package: prob

Mean of probability distribution object

Syntax

```
m = mean(pd)
```

Description

`m = mean(pd)` returns the mean m of the probability distribution pd.

Input Arguments

`pd` — Probability distribution

probability distribution object

Probability distribution, specified as a probability distribution object. Create a probability distribution object with specified parameter values using `makedist`. Alternatively, create a probability distribution object by fitting it to data using `fitdist` or the Distribution Fitting app.

Output Arguments

`m` — Mean

scalar value

Mean of the probability distribution, returned as a scalar value.

Examples

Mean of a Fitted Distribution

Load the sample data. Create a vector containing the first column of students' exam grade data.

```
load examgrades;
x = grades(:,1);
```

Create a normal distribution object by fitting it to the data.

```
pd = fitdist(x,'Normal')
```

```
pd =

  NormalDistribution

  Normal distribution
       mu = 75.0083   [73.4321, 76.5846]
    sigma =  8.7202   [7.7391, 9.98843]
```

Compute the mean of the fitted distribution.

```
m = mean(pd)
```

```
m =

   75.0083
```

The mean of the normal distribution is equal to the parameter `mu`.

Mean of a Skewed Distribution

Create a Weibull probability distribution object.

```
pd = makedist('Weibull','a',5,'b',2)
```

```
pd =

  WeibullDistribution

  Weibull distribution
    A = 5
    B = 2
```

Compute the mean of the distribution.

```
mean = mean(pd)
```

```
mean =
    4.4311
```

`dfittool` | `fitdist` | `makedist`

meanMargin

Class: CompactTreeBagger

Mean classification margin

Syntax

```
mar = meanMargin(B,X,Y)
mar = meanMargin(B,X,Y,'param1',val1,'param2',val2,...)
```

Description

`mar = meanMargin(B,X,Y)` computes average classification margins for predictors `X` given true response `Y`. The `Y` can be either a numeric vector, character matrix, cell array of strings, categorical vector or logical vector. `meanMargin` averages the margins over all observations (rows) in `X` for each tree. `mar` is a matrix of size 1-by-`NTrees`, where `NTrees` is the number of trees in the ensemble `B`. This method is available for classification ensembles only.

`mar = meanMargin(B,X,Y,'param1',val1,'param2',val2,...)` specifies optional parameter name/value pairs:

`'mode'`	String indicating how `meanMargin` computes errors. If set to `'cumulative'` (default), is a vector of length NTrees where the first element gives mean margin from `trees(1)`, second column gives mean margins from `trees(1:2)` etc, up to `trees(1:NTrees)`. If set to `'individual'`, `mar` is a vector of length `NTrees`, where each element is a mean margin from each tree in the ensemble . If set to `'ensemble'`, `mar` is a scalar showing the cumulative mean margin for the entire ensemble.
`'trees'`	Vector of indices indicating what trees to include in this calculation. By default, this argument is set to `'all'` and the method uses all trees. If `'trees'` is a numeric vector, the method returns a vector of length `NTrees` for `'cumulative'` and `'individual'` modes, where `NTrees` is the number of elements in the input vector, and a scalar for `'ensemble'` mode. For example, in the `'cumulative'`

mode, the first element gives mean margin from `trees(1)`, the second element gives mean margin from `trees(1:2)` etc.

`'treeweights'` Vector of tree weights. This vector must have the same length as the `'trees'` vector. `meanMargin` uses these weights to combine output from the specified trees by taking a weighted average instead of the simple nonweighted majority vote. You cannot use this argument in the `'individual'` mode.

meansurrvarassoc

Class: classregtree

Mean predictive measure of association for surrogate splits in decision tree

Compatibility

`classregtree` will be removed in a future release. See `fitctree`, `fitrtree`, `ClassificationTree`, or `RegressionTree` instead.

Syntax

```
MA = meansurrvarassoc(T)
MA = meansurrvarassoc(T,N)
```

Description

`MA = meansurrvarassoc(T)` returns a p-by-p matrix, `MA`, with predictive measures of association for p predictors. Element `MA`(i,j) is the predictive measure of association averaged over surrogate splits on predictor j for which predictor i is the optimal split predictor. This average is computed by summing positive values of the predictive measure of association over optimal splits on predictor i and surrogate splits on predictor j and dividing by the total number of optimal splits on predictor i, including splits for which the predictive measure of association between predictors i and j is negative.

`MA = meansurrvarassoc(T,N)` takes an array `N` of node numbers and returns the predictive measure of association averaged over the specified nodes.

surrogateAssociation

Class: CompactClassificationTree

Mean predictive measure of association for surrogate splits in decision tree

Syntax

```
ma = surrogateAssociation(tree)
ma = surrogateAssociation(tree,N)
```

Description

`ma = surrogateAssociation(tree)` returns a matrix of predictive measures of association for the predictors in `tree`.

`ma = surrogateAssociation(tree,N)` returns a matrix of predictive measures of association averaged over the nodes in vector `N`.

Input Arguments

`tree`

A classification tree constructed with `fitctree`, or a compact regression tree constructed with `compact`.

`N`

Vector of node numbers in `tree`.

Output Arguments

`ma`

- `ma = surrogateAssociation(tree)` returns a `P`-by-`P` matrix, where `P` is the number of predictors in tree. `ma(i,j)` is the predictive measure of association

between the optimal split on variable `i` and a surrogate split on variable `j`. See "Predictive Measure of Association" on page 22-2887.

- `ma = surrogateAssociation(tree,N)` returns a `P`-by-`P` representing the predictive measure of association between variables averaged over nodes in the vector `N`. `N` contains node numbers from `1` to `max(tree.NumNodes)`.

Definitions

Predictive Measure of Association

The predictive measure of association between the optimal split on variable i and a surrogate split on variable j is:

$$\lambda_{i,j} = \frac{\min(P_L, P_R) - \left(1 - P_{L_i L_j} - P_{R_i R_j}\right)}{\min(P_L, P_R)}.$$

Here

- P_L and P_R are the node probabilities for the optimal split of node i into Left and Right nodes respectively.
- $P_{L_i L_j}$ is the probability that both (optimal) node i and (surrogate) node j send an observation to the Left.
- $P_{R_i R_j}$ is the probability that both (optimal) node i and (surrogate) node j send an observation to the Right.

Clearly, $\lambda_{i,j}$ lies from $-\infty$ to 1. Variable j is a worthwhile surrogate split for variable i if $\lambda_{i,j}>0$.

Element `ma(i,j)` is the predictive measure of association averaged over surrogate splits on predictor `j` for which predictor `i` is the optimal split predictor. This average is computed by summing positive values of the predictive measure of association over optimal splits on predictor `i` and surrogate splits on predictor `j` and dividing by the total number of optimal splits on predictor `i`, including splits for which the predictive measure of association between predictors `i` and `j` is negative.

Examples

Find the mean predictive measure of association between the variables in the Fisher iris data:

```
load fisheriris
obj = fitctree(meas,species,'surrogate','on');
msva = surrogateAssociation(obj)

msva =
    1.0000         0         0         0
         0    1.0000         0         0
    0.4633    0.2500    1.0000    0.5000
    0.2065    0.1413    0.4022    1.0000
```

Find the mean predictive measure of association averaged over the odd-numbered nodes in `obj`:

```
N = 1:2:obj.NumNodes;
msva = surrogateAssociation(obj,N)

msva =
    1.0000         0         0         0
         0    1.0000         0         0
    0.7600    0.5000    1.0000    1.0000
    0.4130    0.2826    0.8043    1.0000
```

See Also

`ClassificationTree` | `fitctree`

surrogateAssociation

Class: CompactRegressionTree

Mean predictive measure of association for surrogate splits in decision tree

Syntax

```
ma = surrogateAssociation(tree)
ma = surrogateAssociation(tree,N)
```

Description

`ma = surrogateAssociation(tree)` returns a matrix of predictive measures of association for the predictors in `tree`.

`ma = surrogateAssociation(tree,N)` returns a matrix of predictive measures of association averaged over the nodes in vector `N`.

Input Arguments

`tree`

A regression tree constructed with `fitrtree`, or a compact regression tree constructed with `compact`.

`N`

Vector of node numbers in `tree`.

Output Arguments

`ma`

- `ma = surrogateAssociation(tree)` returns a `P`-by-`P` matrix, where `P` is the number of predictors in tree. `ma(i,j)` is the predictive measure of association

between the optimal split on variable `i` and a surrogate split on variable `j`. See "Predictive Measure of Association" on page 22-2890.

- `ma = surrogateAssociation(tree,N)` returns a `P`-by-`P` representing the predictive measure of association between variables averaged over nodes in the vector `N`. `N` contains node numbers from `1` to `max(tree.NumNodes)`.

Definitions

Predictive Measure of Association

The predictive measure of association between the optimal split on variable i and a surrogate split on variable j is:

$$\lambda_{i,j} = \frac{\min(P_L, P_R) - \left(1 - P_{L_i L_j} - P_{R_i R_j}\right)}{\min(P_L, P_R)}.$$

Here

- P_L and P_R are the node probabilities for the optimal split of node i into Left and Right nodes respectively.
- $P_{L_i L_j}$ is the probability that both (optimal) node i and (surrogate) node j send an observation to the Left.
- $P_{R_i R_j}$ is the probability that both (optimal) node i and (surrogate) node j send an observation to the Right.

Clearly, $\lambda_{i,j}$ lies from $-\infty$ to 1. Variable j is a worthwhile surrogate split for variable i if $\lambda_{i,j} > 0$.

Element `ma(i,j)` is the predictive measure of association averaged over surrogate splits on predictor `j` for which predictor `i` is the optimal split predictor. This average is computed by summing positive values of the predictive measure of association over optimal splits on predictor `i` and surrogate splits on predictor `j` and dividing by the total number of optimal splits on predictor `i`, including splits for which the predictive measure of association between predictors `i` and `j` is negative.

Examples

Find the mean predictive measure of association between the `Displacement`, `Horsepower`, and `Weight` variables in the `carsmall` data:

```
load carsmall
X = [Displacement Horsepower Weight];
tree = fitrtree(X,MPG,'surrogate','on');
ma = surrogateAssociation(tree)

ma =
    1.0000    0.2708    0.3854
    0.4764    1.0000    0.4568
    0.3472    0.2326    1.0000
```

Find the mean predictive measure of association averaged over the odd-numbered nodes in `tree`:

```
N = 1:2:tree.NumNodes;
ma = surrogateAssociation(tree,N)

ma =
    1.0000    0.2500    0.3750
    0.5910    1.0000    0.5861
    0.5000    0.2361    1.0000
```

median

Median of probability distribution

Syntax

```
m = median(pd)
```

Description

`m = median(pd)` returns the median m for the probability distribution pd

Examples

Median of a Fitted Distribution

Load the sample data. Create a vector containing the first column of students' exam grade data.

```
load examgrades;
x = grades(:,1);
```

Create a normal distribution object by fitting it to the data.

```
pd = fitdist(x,'Normal')
```

```
pd =

  NormalDistribution

  Normal distribution
       mu = 75.0083   [73.4321, 76.5846]
    sigma =  8.7202   [7.7391, 9.98843]
```

Compute the median of the fitted distribution.

```
m = median(pd)
```

```
m =

   75.0083
```

For a symmetrical distribution such as the normal distribution, the median will be equal to the mean, `mu`.

Median of a Skewed Distribution

Create a Weibull probability distribution object.

```
pd = makedist('Weibull','a',5,'b',2)
```

```
pd =

  WeibullDistribution

  Weibull distribution
    A = 5
    B = 2
```

Compute the median of the distribution.

```
m = median(pd)
```

```
m =
    4.1628
```

For a skewed distribution such as the Weibull distribution, the median and the mean may not be equal.

Calculate the mean of the Weibull distribution and compare it to the median.

```
mean = mean(pd)
```

```
mean =
    4.4311
```

The mean of the distribution is greater than the median.

Plot the pdf to visualize the distribution.

```
x = [0:.1:15];
pdf = pdf(pd,x);
```

```
plot(x,pdf)
```

Input Arguments

pd — Probability distribution

probability distribution object

Probability distribution, specified as a probability distribution object. Create a probability distribution object with specified parameter values using `makedist`. Alternatively, for fittable distributions, create a probability distribution object by fitting it to data using `fitdist` or the Distribution Fitting app.

Output Arguments

`m` — Median

scalar value

Median of the probability distribution, returned as a scalar value. The value of m is the 50th percentile of the probability distribution.

See Also

`dfittool` | `fitdist` | `makedist` | `mean` | `median`

median

Class: ProbDistUnivKernel

Return median of ProbDistUnivKernel object

Syntax

```
M = median(PD)
```

Description

`M = median(PD)` returns *M*, the median of the ProbDistUnivKernel object *PD*.

Input Arguments

PD	An object of the class `ProbDistUnivKernel`.

Output Arguments

M	The median of the ProbDistUnivKernel object *PD*.

See Also

`median`

median

Class: ProbDistUnivParam

Return median of ProbDistUnivParam object

Syntax

```
M = median(PD)
```

Description

`M = median(PD)` returns *M*, the median of the ProbDistUnivParam object *PD*.

Input Arguments

PD	An object of the class `ProbDistUnivParam`.

Output Arguments

M	The median of the ProbDistUnivParam object *PD*.

See Also

Package: prob

Median of probability distribution object

Syntax

```
m = median(pd)
```

Description

`m = median(pd)` returns the median m for the probability distribution pd.

Input Arguments

`pd` — Probability distribution

probability distribution object

Probability distribution, specified as a probability distribution object. Create a probability distribution object with specified parameter values using `makedist`. Alternatively, for fittable distributions, create a probability distribution object by fitting it to data using `fitdist` or the Distribution Fitting app.

Output Arguments

`m` — Median

scalar value

Median of the probability distribution, returned as a scalar value. The value of m is the 50th percentile of the probability distribution.

Examples

Median of a Fitted Distribution

Load the sample data. Create a vector containing the first column of students' exam grade data.

```
load examgrades;
x = grades(:,1);
```

Create a normal distribution object by fitting it to the data.

```
pd = fitdist(x,'Normal')
```

```
pd =

  NormalDistribution

  Normal distribution
       mu = 75.0083   [73.4321, 76.5846]
    sigma =  8.7202   [7.7391, 9.98843]
```

Compute the median of the fitted distribution.

```
m = median(pd)
```

```
m =

   75.0083
```

For a symmetrical distribution such as the normal distribution, the median will be equal to the mean, `mu`.

Median of a Skewed Distribution

Create a Weibull probability distribution object.

```
pd = makedist('Weibull','a',5,'b',2)
```

```
pd =

  WeibullDistribution
```

```
  Weibull distribution
    A = 5
    B = 2
```

Compute the median of the distribution.

```
m = median(pd)
```

```
m =
    4.1628
```

For a skewed distribution such as the Weibull distribution, the median and the mean may not be equal.

Calculate the mean of the Weibull distribution and compare it to the median.

```
mean = mean(pd)
```

```
mean =
    4.4311
```

The mean of the distribution is greater than the median.

Plot the pdf to visualize the distribution.

```
x = [0:.1:15];
pdf = pdf(pd,x);
plot(x,pdf)
```

MergeLeaves property

Class: TreeBagger

Flag to merge leaves that do not improve risk

Description

The `MergeLeaves` property is true if decision trees have their leaves with the same parent merged for splits that do not decrease the total risk, and false otherwise. The default value is false.

See Also

`ClassificationTree` | `RegressionTree` | `TreeBagger` | `fitctree` | `fitrtree`

mergelevels

Merge levels of nominal or ordinal arrays

Compatibility

The `nominal` and `ordinal` array data types might be removed in a future release. To represent ordered and unordered discrete, nonnumeric data, use the MATLAB `categorical` data type instead.

Syntax

```
B = mergelevels(A,oldlevels)
B = mergelevels(A,oldlevels,newlevel)
```

Description

`B = mergelevels(A,oldlevels)` merges two or more levels of A.

- If A is a `nominal` array, `mergelevels` uses the first label in oldlevels as the new level.
- If A is an `ordinal` array, the levels specified by oldlevels must be consecutive, and `mergelevels` uses the label corresponding to the lowest level in oldlevels as the label for the new level.

`B = mergelevels(A,oldlevels,newlevel)` merges two or more levels into the new level with label newlevel.

Examples

Create New Category From Merged Levels

Create a nominal array from string data in a cell array.

```
colors = nominal({'r','b','g';'g','r','b';'b','r','g'},...
```

```
                {'blue','green','red'})

colors =

     red        blue       green
     green      red        blue
     blue       red        green
```

Merge the elements of the `'red'` and `'blue'` levels into a new level labeled `'purple'`.

```
colors = mergelevels(colors,{'red','blue'},'purple')

colors =

     purple     purple     green
     green      purple     purple
     purple     purple     green
```

Display the levels of `colors`.

```
getlevels(colors)

ans =

     purple     green
```

- “Merge Category Levels” on page 2-19

Input Arguments

A — Nominal or ordinal array

`nominal` array | `ordinal` array

Nominal or ordinal array, specified as a `nominal` or `ordinal` array object created using `nominal` or `ordinal`.

`oldlevels` — Levels to merge

cell array of strings | 2-D character matrix

Levels to merge, specified as a cell array of strings or 2-D character matrix. For ordinal arrays, the levels in oldlevels must be consecutive.

Data Types: `char` | `cell`

`newlevel` — Level to create

string

Level to create from the merged levels, specified as a string that gives the label for the new level.

Data Types: `char`

Output Arguments

`B` — Nominal or ordinal array

`nominal` array | `ordinal` array

Nominal or ordinal array, returned as a `nominal` or `ordinal` array object.

More About

- Using nominal Objects
- Using ordinal Objects

See Also

Method property

Class: TreeBagger

Method used by trees (classification or regression)

Description

The `Method` property is `'classification'` for classification ensembles and `'regression'` for regression ensembles.

mhsample

Metropolis-Hastings sample

Syntax

```
smpl = mhsample(start,nsamples,'pdf',pdf,'proppdf',proppdf,
'proprnd',proprnd)
smpl = mhsample(...,'symmetric',sym)
smpl = mhsample(...,'burnin',K)
smpl = mhsample(...,'thin',m)
smpl = mhsample(...,'nchain',n)
[smpl,accept] = mhsample(...)
```

Description

`smpl = mhsample(start,nsamples,'pdf',pdf,'proppdf',proppdf, 'proprnd',proprnd)` draws `nsamples` random samples from a target stationary distribution `pdf` using the Metropolis-Hastings algorithm.

`start` is a row vector containing the start value of the Markov Chain, `nsamples` is an integer specifying the number of samples to be generated, and `pdf`, `proppdf`, and `proprnd` are function handles created using `@`. `proppdf` defines the proposal distribution density, and `proprnd` defines the random number generator for the proposal distribution. `pdf` and `proprnd` take one argument as an input with the same type and size as `start`. `proppdf` takes two arguments as inputs with the same type and size as `start`.

`smpl` is a column vector or matrix containing the samples. If the log density function is preferred, `'pdf'` and `'proppdf'` can be replaced with `'logpdf'` and `'logproppdf'`. The density functions used in Metropolis-Hastings algorithm are not necessarily normalized.

The proposal distribution $q(x,y)$ gives the probability density for choosing x as the next point when y is the current point. It is sometimes written as $q(x|y)$.

If the `proppdf` or `logproppdf` satisfies $q(x,y) = q(y,x)$, that is, the proposal distribution is symmetric, `mhsample` implements Random Walk Metropolis-Hastings sampling. If

the `proppdf` or `logproppdf` satisfies $q(x,y) = q(x)$, that is, the proposal distribution is independent of current values, `mhsample` implements Independent Metropolis-Hastings sampling.

`smpl = mhsample(...,'symmetric',sym)` draws `nsamples` random samples from a target stationary distribution `pdf` using the Metropolis-Hastings algorithm. `sym` is a logical value that indicates whether the proposal distribution is symmetric. The default value is false, which corresponds to the asymmetric proposal distribution. If `sym` is true, for example, the proposal distribution is symmetric, `proppdf` and `logproppdf` are optional.

`smpl = mhsample(...,'burnin',K)` generates a Markov chain with values between the starting point and the k^{th} point omitted in the generated sequence. Values beyond the k^{th} point are kept. `k` is a nonnegative integer with default value of `0`.

`smpl = mhsample(...,'thin',m)` generates a Markov chain with `m-1` out of `m` values omitted in the generated sequence. `m` is a positive integer with default value of `1`.

`smpl = mhsample(...,'nchain',n)` generates `n` Markov chains using the Metropolis-Hastings algorithm. `n` is a positive integer with a default value of 1. `smpl` is a matrix containing the samples. The last dimension contains the indices for individual chains.

`[smpl,accept] = mhsample(...)` also returns `accept`, the acceptance rate of the proposed distribution. `accept` is a scalar if a single chain is generated and is a vector if multiple chains are generated.

Examples

Estimate Moments Using Independent Metropolis-Hastings Sampling

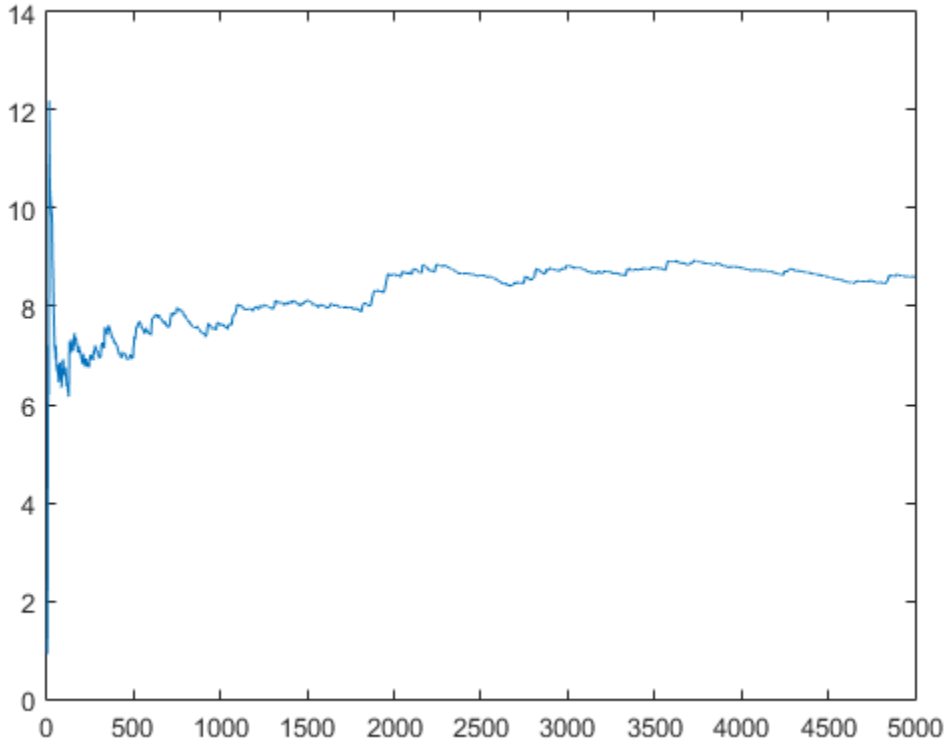
Use Independent Metropolis-Hastings sampling to estimate the second order moment of a Gamma distribution.

```
rng default;  % For reproducibility
alpha = 2.43;
beta = 1;
pdf = @(x)gampdf(x,alpha,beta); % Target distribution
proppdf = @(x,y)gampdf(x,floor(alpha),floor(alpha)/alpha);
proprnd = @(x)sum(...
              exprnd(floor(alpha)/alpha,floor(alpha),1));
```

```
nsamples = 5000;
smpl = mhsample(1,nsamples,'pdf',pdf,'proprnd',proprnd,...
                'proppdf',proppdf);
```

Plot the results.

```
xxhat = cumsum(smpl.^2)./(1:nsamples)';
figure;
plot(1:nsamples,xxhat)
```



Random Walk Metropolis-Hastings Sampling

Use Random Walk Metropolis-Hastings sampling to generate sample data from a standard normal distribution.

```
rng default  % For reproducibility
delta = .5;
pdf = @(x) normpdf(x);
proppdf = @(x,y) unifpdf(y-x,-delta,delta);
proprnd = @(x) x + rand*2*delta - delta;
nsamples = 15000;
x = mhsample(1,nsamples,'pdf',pdf,'proprnd',proprnd,'symmetric',1);
```

Plot the sample data.

```
figure;
h = histfit(x,50);
h(1).FaceColor = [.8 .8 1];
```

MinLeaf property

Class: TreeBagger

Minimum number of observations per tree leaf

Description

The `MinLeaf` property specifies the minimum number of observations per tree leaf. The default values are 1 for classification and 5 for regression. For `fitctree` or `fitrtree` training, the `'minparent'` value is set to `2*MinLeaf`.

mle

Maximum likelihood estimates

Syntax

```
phat = mle(data)
phat = mle(data,'distribution',dist)

phat = mle(data,'pdf',pdf,'start',start)
phat = mle(data,'pdf',pdf,'start',start,'cdf',cdf)

phat = mle(data,'logpdf',logpdf,'start',start)
phat = mle(data,'logpdf',logpdf,'start',start,'logsf',logsf)

phat = mle(data,'nloglf',nloglf,'start',start)

phat = mle(___,Name,Value)
[phat,pci] = mle(___)
```

Description

`phat = mle(data)` returns maximum likelihood estimates (MLEs) for the parameters of a normal distribution, using the sample data in the vector `data`.

`phat = mle(data,'distribution',dist)` returns parameter estimates for a distribution specified by `dist`.

`phat = mle(data,'pdf',pdf,'start',start)` returns parameter estimates for a custom distribution specified by the probability density function `pdf`. You must also specify the initial parameter values, `start`.

`phat = mle(data,'pdf',pdf,'start',start,'cdf',cdf)` returns parameter estimates for a custom distribution specified by the probability density function `pdf` and custom cumulative distribution function `cdf`.

`phat = mle(data,'logpdf',logpdf,'start',start)` returns parameter estimates for a custom distribution specified by the log probability density function `logpdf`. You must also specify the initial parameter values, `start`.

`phat = mle(data,'logpdf',logpdf,'start',start,'logsf',logsf)` returns parameter estimates for a custom distribution specified by the log probability density function `logpdf` and custom log survival function `logsf`.

`phat = mle(data,'nloglf',nloglf,'start',start)` returns parameter estimates for the custom distribution specified by the negative loglikelihood function `nloglf`. You must also specify the initial parameter values, `start`.

`phat = mle(___,Name,Value)` also returns the parameter estimates with additional options specified by one or more name-value pair arguments. You can use any of the input arguments in the previous syntaxes.

`[phat,pci] = mle(___)` also returns the 95% confidence intervals for the parameters.

Examples

Estimate Parameters of Burr Distribution

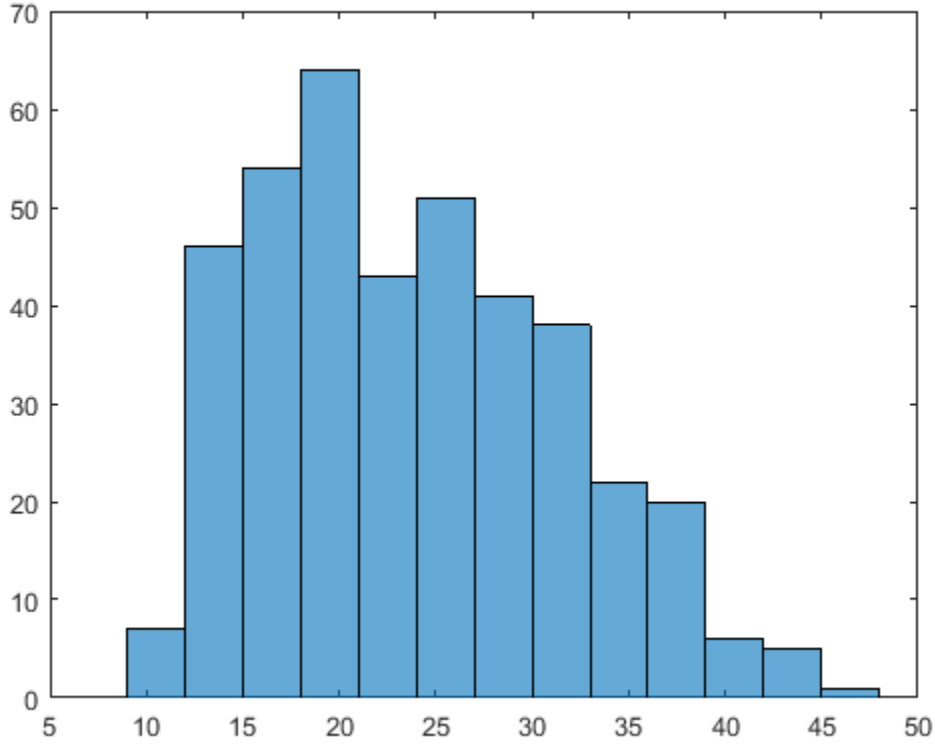
Load the sample data.

```
load carbig
```

The variable `MPG` has the miles per gallon for different models of cars.

Draw a histogram of `MPG` data.

```
histogram(MPG)
```



The distribution is somewhat right skewed. A symmetric distribution, such as normal distribution, might not be a good fit.

Estimate the parameters of the Burr Type XII distribution for the `MPG` data.

```
phat = mle(MPG,'distribution','burr')
```

```
phat =

   34.6447    3.7898    3.5722
```

The maximum likelihood estimates for the scale parameter α is 34.6447. The estimates for the two shape parameters c and k of the Burr Type XII distribution are 3.7898 and 3.5722, respectively.

Fit Custom Distribution to Censored Data

Navigate to a folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load readmissiontimes
```

The data includes `ReadmissionTime`, which has readmission times for 100 patients. The column vector `Censored` has the censorship information for each patient, where 1 indicates a censored observation, and 0 indicates the exact readmission time is observed. This is simulated data.

Define a custom probability density and cumulative distribution function.

```
custpdf = @(data,lambda) lambda*exp(-lambda*data);
custcdf = @(data,lambda) 1-exp(-lambda*data);
```

Estimate the parameter, `lambda`, of the custom distribution for the censored sample data.

```
phat = mle(ReadmissionTime,'pdf',custpdf,...
'cdf',custcdf,'start',0.05,'Censoring',Censored)
phat
```

```
phat =

    0.1096
```

Estimate Parameters of a Noncentral Chi-Square Distribution

Generate sample data of size 1000 from a noncentral chi-square distribution with degrees of freedom 8 and noncentrality parameter 3.

```
rng('default') % for reproducibility
x = ncx2rnd(8,3,1000,1);
```

Estimate the parameters of the noncentral chi-square distribution from the sample data. To do this, custom define the noncentral chi-square pdf using the pdf input argument.

```
[phat,pci] = mle(x,'pdf',@(x,v,d)ncx2pdf(x,v,d),'start',[1,1])

phat =

    8.1052    2.6693

pci =

    7.1121    1.6025
    9.0983    3.7362
```

The estimate for the degrees of freedom is 8.1052 and the noncentrality parameter is 2.6693. The 95% confidence interval for the degrees of freedom is (7.0983,9.0983) and the noncentrality parameter is (1.6025,3.7362). The confidence intervals include the true parameter values of 8 and 3, respectively.

Fit Custom Log pdf and Survival Function

Navigate to a folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load readmissiontimes
```

The data includes `ReadmissionTime`, which has readmission times for 100 patients. The column vector `Censored` has the censorship information for each patient, where 1 indicates a censored observation, and 0 indicates the exact readmission time is observed. This is simulated data.

Define a custom log probability density and survival function.

```
custlogpdf = @(data,lambda,k) log(k)-k*log(lambda)...
             +(k-1)*log(data)-(data/lambda).^k;
custlogsf = @(data,lambda,k) -(data/lambda).^k;
```

Estimate the parameters, `lambda` and `k`, of the custom distribution for the censored sample data.

```
phat = mle(ReadmissionTime,'logpdf',custlogpdf,...
'logsf',custlogsf,'start',[1,0.75],'Censoring',Censored)

phat =
```

```
    9.2090    1.4223
```

The scale and shape parameters of the custom-defined distribution are 9.2090 and 1.4223, respectively.

Fit Custom Log Negative Likelihood Function

Navigate to a folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load readmissiontimes
```

The data includes `ReadmissionTime`, which has readmission times for 100 patients. This is simulated data.

Define a negative log likelihood function.

```
custnloglf = @(lambda,data,cens,freq) -length(data)*log(lambda)...
+ nansum(lambda*data);
```

Estimate the parameters of the defined distribution.

```
phat = mle(ReadmissionTime,'nloglf',custnloglf,'start',0.05)
```

```
phat =

    0.1462
```

Estimate Probability of Success

Generate 100 random observations from a binomial distribution with the number of trials, $n = 20$, and the probability of success, $p = 0.75$.

```
data = binornd(20,0.75,100,1);
```

Estimate the probability of success and 95% confidence limits using the simulated sample data.

```
[phat,pci] = mle(data,'distribution','binomial',...
                 'alpha',.05,'ntrials',20)
```

```
phat =
    0.7370
```

```
pci =
    0.7171
    0.7562
```

The estimate of probability of success is 0.737 and the lower and upper limits of the 95% confidence interval are 0.7171 and 0.7562. This interval covers the true value used to simulate the data.

Fit a Distribution with Known Parameter

Generate sample data of size 1000 from a noncentral chi-square distribution with degrees of freedom 10 and noncentrality parameter 5.

```
rng('default') % for reproducibility
x = ncx2rnd(10,5,1000,1);
```

Suppose the noncentrality parameter is fixed at the value 5. Estimate the degrees of freedom of the noncentral chi-square distribution from the sample data. To do this, custom define the noncentral chi-square pdf using the pdf input argument.

```
[phat,pci] = mle(x,'pdf',@(x,v,d)ncx2pdf(x,v,5),'start',1)
```

```
phat =

    9.9307

pci =

    9.5626
   10.2989
```

The estimate for the noncentrality parameter is 9.9307, with a 95% confidence interval of 9.5626 and 10.2989. The confidence interval includes the true parameter value of 10.

Fit Rician Distribution with Known Scale Parameter

Generate sample data of size 1000 from a Rician distribution with noncentrality parameter of 8 and scale parameter of 5. First create the Rician distribution.

```
r = makedist('Rician','s',8,'sigma',5);
```

Now, generate sample data from the distribution you created above.

```
rng('default');
x = random(r,1000,1);
```

Suppose the scale parameter is known, and estimate the noncentrality parameter from sample data. To do this using `mle`, you must custom define the Rician probability density function.

```
[phat,pci] = mle(x,'pdf',@(x,s,sigma) pdf('rician',x,s,5),'start',10)
```

```
phat =

    7.8953

pci =

    7.5405
    8.2501
```

The estimate for the noncentrality parameter is 7.8953, with a 95% confidence interval of 7.5404 and 8.2501. The confidence interval includes the true parameter value of 8.

Fit a Distribution with Additional Parameter

Add a scale parameter to the chi-square distribution for adapting to the scale of data and fit it. First, generate sample data of size 1000 from a chi-square distribution with degrees of freedom 5, and scale it by the factor of 100.

```
rng('default') % for reproducibility
x = 100*chi2rnd(5,1000,1);
```

Estimate the degrees of freedom and the scaling factor. To do this, custom define the chi-square probability density function using the pdf input argument. The density function requires a 1/*s* factor for data scaled by *s*.

```
[phat,pci] = mle(x,'pdf',@(x,v,s)chi2pdf(x/s,v)/s,'start',[1,200])
```

```
phat =

    5.1079   99.1681

pci =

    4.6862   90.1215
    5.5297  108.2146
```

The estimate for the degrees of freedom is 5.1079 and the scale is 99.1681. The 95% confidence interval for the degrees of freedom is (4.6862,5.5279) and the scale parameter

is (90.1215,108.2146). The confidence intervals include the true parameter values of 5 and 100, respectively.

Input Arguments

`data` — Sample data

vector

Sample data `mle` uses to estimate the distribution parameters, specified as a vector.

Data Types: `single` | `double`

`dist` — Distribution type

`'normal'` (default) | string

Distribution type to estimate parameters for, specified as one of the following.

`dist`	Description	Parameter 1	Parameter 2	Parameter 3
`'bernoulli'`	"Bernoulli Distribution" on page B-2	`p`: probability of success for each trial	—	—
`'beta'` or `'Beta'`	"Beta Distribution" on page B-4	`a`	`b`	—
`'bino'` or `'Binomial'`	"Binomial Distribution" on page B-9	`n`: number of trials	`p`: probability of success for each trial	—
`'birnbaumsaunder`	"Birnbaum-Saunders Distribution" on page B-13	β: scale	γ: shape	—
`'burr'` or `'Burr'`	"Burr Type XII Distribution" on page B-15	α: scale	`c`: first shape	`k`: second shape
`'Discrete Uniform'` or `'unid'`	"Uniform Distribution (Discrete)" on page B-169	`N`: maximum observable value	—	—
`'exp'` or `'Exponential'`	"Exponential Distribution" on page B-35	μ: mean	—	—

dist	Description	Parameter 1	Parameter 2	Parameter 3
'ev' or 'Extreme Value'	"Extreme Value Distribution" on page B-39	μ: location	σ: scale	—
'gam' or 'Gamma'	"Gamma Distribution" on page B-48	a: shape	b: scale	—
'gev' or 'Generalized Extreme Value'	"Generalized Extreme Value Distribution" on page B-54	k: shape	σ: scale	μ: location
'gp' or 'Generalized Pareto'	"Generalized Pareto Distribution" on page B-60	k: tail index (shape)	σ: scale	θ: threshold
'geo' or 'Geometric'	"Geometric Distribution" on page B-65	p: probability	—	—
'inversegaussian'	"Inverse Gaussian Distribution" on page B-77	μ: scale	λ: shape	—
'logistic'	"Logistic Distribution" on page B-91	μ: location	σ: scale	—
'loglogistic'	"Loglogistic Distribution" on page B-93	μ: log location	σ: log scale	—
'logn' or 'Lognormal'	"Lognormal Distribution" on page B-95	μ: log location	σ: log scale	—
'nakagami'	"Nakagami Distribution" on page B-113	μ: shape	ω: scale	—
'nbin' or 'Negative Binomial'	"Negative Binomial Distribution" on page B-115	r: number of successes	p: probability of success in a single trial	—
'norm' or 'Normal'	"Normal Distribution" on page B-130	μ: location (mean)	σ: scale (standard deviation)	—
'poiss' or 'Poisson'	"Poisson Distribution" on page B-138	λ: mean	—	—

dist	Description	Parameter 1	Parameter 2	Parameter 3
'rayl' or 'Rayleigh'	"Rayleigh Distribution" on page B-141	b: scale	—	—
'rician'	"Rician Distribution" on page B-144	s: noncentrality	σ: scale	—
'tlocationscale'	"t Location-Scale Distribution" on page B-154	μ: location	σ: scale	ν: degrees of freedom
'unif' or 'Uniform'	"Uniform Distribution (Continuous)" on page B-163	a: lower endpoint (minimum)	b: upper endpoint (maximum)	—
'wbl' or 'Weibull'	"Weibull Distribution" on page B-172	a: scale	b: shape	—

Example: 'rician'

pdf — Custom probability density function

function handle

Custom probability distribution function, specified as a function handle created using @.

This custom function accepts the vector data and one or more individual distribution parameters as input parameters, and returns a vector of probability density values.

For example, if the name of the custom probability density function is newpdf, then you can specify the function handle in mle as follows.

Example: @newpdf

Data Types: function_handle

cdf — Custom cumulative distribution function

function handle

Custom cumulative distribution function, specified as a function handle created using @.

This custom function accepts the vector data and one or more individual distribution parameters as input parameters, and returns a vector of cumulative probability values.

You must define `cdf` with `pdf` if data is censored and you use the `'censoring'` name-value pair argument. If `'censoring'` is not present, you do not have to specify `cdf` while using `pdf`.

For example, if the name of the custom cumulative distribution function is `newcdf`, then you can specify the function handle in `mle` as follows.

Example: `@newcdf`

Data Types: `function_handle`

`logpdf` — Custom log probability density function

function handle

Custom log probability density function, specified as a function handle created using `@`.

This custom function accepts the vector `data` and one or more individual distribution parameters as input parameters, and returns a vector of log probability values.

For example, if the name of the custom log probability density function is `customlogpdf`, then you can specify the function handle in `mle` as follows.

Example: `@customlogpdf`

Data Types: `function_handle`

`logsf` — Custom log survival function

function handle

Custom log survival function, specified as a function handle created using `@`.

This custom function accepts the vector `data` and one or more individual distribution parameters as input parameters, and returns a vector of log survival probability values.

You must define `logsf` with `logpdf` if data is censored and you use the `'censoring'` name-value pair argument. If `'censoring'` is not present, you do not have to specify `logsf` while using `logpdf`.

For example, if the name of the custom log survival function is `logsurvival`, then you can specify the function handle in `mle` as follows.

Example: `@logsurvival`

Data Types: `function_handle`

`nloglf` — Custom negative loglikelihood function

function handle

Custom negative loglikelihood function, specified as a function handle created using `@`.

This custom function accepts the following input arguments.

`params`	Vector of distribution parameter values. `mle` detects the number of parameters from the number of elements in start.
`data`	Vector of data.
`cens`	Boolean vector of censored values.
`freq`	Vector of integer data frequencies.

`nloglf` must accept all four arguments even if you do not use the `'censoring'` or `'frequency'` name-value pair arguments. You can write `'nloglf'` to ignore `cens` and `freq` arguments in that case.

`nloglf` returns a scalar negative loglikelihood value and optionally, a negative loglikelihood gradient vector (see the `'GradObj'` field in `'options'`).

If the name of the custom negative log likelihood function is `negloglik`, then you can specify the function handle in `mle` as follows.

Example: `@negloglik`

Data Types: `function_handle`

`start` — Initial parameter values

scalar | vector

Initial parameter values for the custom functions, specified as a scalar value or a vector of scalar values.

Use `start` when you fit custom distributions, that is, when you use pdf and cdf, logpdf and logsf, or nloglf input arguments.

Example: `0.05`

Example: `[100,2]`

Data Types: `single | double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'censoring',Cens,'alpha',0.01,'options',Opt` specifies that `mle` estimates the parameters for the distribution of censored data specified by array `Cens`, computes the 99% confidence limits for the parameter estimates, and uses the algorithm control parameters specified by the structure `Opt`.

`'censoring'` — Indicator for censoring

array of 0s (default) | array of 0s and 1s

Indicator for censoring, specified as the comma-separated pair consisting of `'censoring'` and a Boolean array of the same size as data. Use 1 for observations that are right censored and 0 for observations that are fully observed. The default is all observations are fully observed.

For example, if the censored data information is in the binary array called `Censored`, then you can specify the censored data as follows.

Example: `'censoring',Censored`

`mle` supports censoring for the following distributions:

Birnbaum-Saunders	Logistic
Burr	Lognormal
Exponential	Nakagami
Extreme Value	Normal
Gamma	Rician
Inverse Gaussian	t Location-Scale
Kernel	Weibull
Log-Logistic	

Data Types: `logical`

`'frequency'` — Frequency of observations

array of 1s (default) | vector of nonnegative integer counts

Frequency of observations, specified as the comma-separated pair consisting of `'frequency'` and an array containing nonnegative integer counts, which is the same size as `data`. The default is one observation per element of `data`.

For example, if the observation frequencies are stored in an array named `Freq`, you can specify the frequencies as follows.

Example: `'frequency',Freq`

Data Types: `single | double`

`'alpha'` — Confidence level

0.05 (default) | scalar value in the range (0,1)

Confidence level for the confidence interval of parameter estimates, `pci`, specified as the comma-separated pair consisting of `'alpha'` and a scalar value in the range (0,1). The confidence level of `pci` is `100(1-alpha)`% . The default is `0.05` for 95% confidence.

For example, for 99% confidence limits, you can specify the confidence level as follows.

Example: `'alpha',0.01`

Data Types: `single | double`

`'ntrials'` — Number of trials

scalar value | vector

Number of trials for the corresponding element of `data`, specified as the comma-separated pair consisting of `'ntrials'` and a scalar or a vector of the same size as `data`.

Applies only to binomial distribution.

Example: `'ntrials',total`

Data Types: `single | double`

`'options'` — Fitting algorithm control parameters

structure

Fitting algorithm control parameters, specified as the comma-separated pair consisting of `'options'` and a structure returned by `statset`.

Not applicable to all distributions.

Use the `'options'` name-value pair argument to control details of the maximum likelihood optimization when fitting a custom distribution. For parameter names and

default values, type `statset('mlecustom')`. You can set the options under a new name and use that in the name-value pair argument. `mle` interprets the following `statset` parameters for custom distribution fitting.

Parameter	Value
`'GradObj'`	Default is `'off'`. `'on'` or `'off'`, indicating whether or not `fmincon` can expect the custom function provided with the `nloglf` input argument to return the gradient vector of the negative log-likelihood as a second output. `mle` ignores `'GradObj'` when using `fminsearch`.
`'DerivStep'`	Default is `eps^(1/3)`. The relative difference, specified as a scalar or a vector the same size as `start`, used in finite difference derivative approximations when using `fmincon`, and `'GradObj'` is `'off'`. `mle` ignores `'DerivStep'` when using `fminsearch`.
`'FunValCheck'`	Default is `'on'`. `'on'` or `'off'`, indicating whether or not `mle` should check the values returned by the custom distribution functions for validity. A poor choice of starting point can sometimes cause these functions to return `NaN`s, infinite values, or out-of-range values if they are written without suitable error checking.
`'TolBnd'`	Default is `1e-6`. An offset for upper and lower bounds when using `fmincon`. `mle` treats upper and lower bounds as strict inequalities, that is, open bounds. With `fmincon`, this is approximated by creating closed bounds inset from the specified upper and lower bounds by `TolBnd`.

Example: `'options',statset('mlecustom')`

Data Types: `struct`

`'lowerbound'` — Lower bounds for distribution parameters

– ∞ (default) | vector

Lower bounds for distribution parameters, specified as the comma-separated pair consisting of `'lowerbound'` and a vector the same size as start.

This name-value pair argument is valid only when you use the `pdf` and `cdf`, `logpdf` and `logcdf`, or `nloglf` input arguments.

Example: `'lowerbound',0`

Data Types: `single` | `double`

`'upperbound'` — Upper bounds for distribution parameters

∞ (default) | vector

Upper bounds for distribution parameters, specified as the comma-separated pair consisting of `'upperbound'` and a vector the same size as start.

This name-value pair argument is valid only when you use the pdf and cdf, logpdf and logsf, or nloglf input arguments.

Example: `'upperbound',1`

Data Types: `single` | `double`

`'optimfun'` — Optimization function

`'fminsearch'` (default) | `'fmincon'`

Optimization function `mle` uses in maximizing the likelihood, specified as the comma-separated pair consisting of `'optimfun'` and either `'fminsearch'` or `'fmincon'`.

Default is `'fminsearch'`.

You can only specify `'fmincon'` if Optimization Toolbox is available.

The `'optimfun'` name-value pair argument is valid only when you fit custom distributions, that is, when you use the pdf and cdf, logpdf and logsf, or nloglf input arguments.

Example: `'optimfun','fmincon'`

Output Arguments

`phat` — Parameter estimates

scalar value | row vector

Parameter estimates, returned as a scalar value or a row vector.

`pci` — Confidence intervals for parameter estimates

2-by-*k* matrix

Confidence intervals for parameter estimates, returned as a column vector or a matrix depending on the number of parameters, hence the size of phat.

`pci` is a 2-by-*k* matrix, where *k* is the number of parameters `mle` estimates. The first and second rows of the `pci` show the upper and lower confidence limits, respectively.

More About

Survival Function

The survival function is the probability of survival as a function of time. It is also called the survivor function. It gives the probability that the survival time of an individual exceeds a certain value. Since the cumulative distribution function, $F(t)$, is the probability that the survival time is less than or equal to a given point in time, the survival function for a continuous distribution, $S(t)$, is the complement of the cumulative distribution function: $S(t) = 1 - F(t)$.

Tips

When you supply distribution functions, `mle` computes the parameter estimates using an iterative maximization algorithm. With some models and data, a poor choice of starting point can cause `mle` to converge to a local optimum that is not the global maximizer, or to fail to converge entirely. Even in cases for which the log-likelihood is well-behaved near the global maximum, the choice of starting point is often crucial to convergence of the algorithm. In particular, if the initial parameter values are far from the MLEs, underflow in the distribution functions can lead to infinite log-likelihoods.

- "What Is Survival Analysis?" on page 12-2

`fitdist` | `mlecov` | `statset`

mlecov

Asymptotic covariance of maximum likelihood estimators

Syntax

```
acov = mlecov(params,data,'pdf',pdf)
acov = mlecov(params,data,'pdf',pdf,'cdf',cdf)

acov = mlecov(params,data,'logpdf',logpdf)
acov = mlecov(params,data,'logpdf',logpdf,'logsf',logsf)

acov = mlecov(params,data,'nloglf',nloglf)

acov = mlecov(___,Name,Value)
```

Description

`acov = mlecov(params,data,'pdf',pdf)` returns an approximation to the asymptotic covariance matrix of the maximum likelihood estimators of the parameters for a distribution specified by the custom probability density function `pdf`.

`mlecov` computes a finite difference approximation to the Hessian of the log-likelihood at the maximum likelihood estimates `params`, given the observed `data`, and returns the negative inverse of that Hessian.

`acov = mlecov(params,data,'pdf',pdf,'cdf',cdf)` returns an approximation to the asymptotic covariance matrix of the maximum likelihood estimators of the parameters for a distribution specified by the custom probability density function `pdf` and cumulative distribution function `cdf`.

`acov = mlecov(params,data,'logpdf',logpdf)` returns an approximation to the asymptotic covariance matrix of the maximum likelihood estimators of the parameters for a distribution specified by the custom log probability density function `logpdf`.

`acov = mlecov(params,data,'logpdf',logpdf,'logsf',logsf)` returns an approximation to the asymptotic covariance matrix of the maximum likelihood estimators of the parameters for a distribution specified by the custom log probability density function `logpdf` and custom log survival function `logsf`.

`acov = mlecov(params,data,'nloglf',nloglf)` returns an approximation to the asymptotic covariance matrix of the maximum likelihood estimators of the parameters for a distribution specified by the custom negative loglikelihood function `nloglf`.

`acov = mlecov(___,Name,Value)` also returns an approximation to the asymptotic covariance matrix of the maximum likelihood estimators of the parameters with additional options specified by one or more name-value pair arguments. You can use any of the input arguments in the previous syntaxes.

Examples

Custom Probability Density Function

Load the sample data.

```
load carbig
```

The vector `Weight` shows the weights of 406 cars.

In the MATLAB Editor, create a function that returns the probability density function (pdf) of a lognormal distribution. Save the file in your current working folder as `lognormpdf.m`.

```
function newpdf = lognormpdf(data,mu,sigma)
newpdf = exp((-(log(data)-mu).^2)/(2*sigma^2))./(data*sigma*sqrt(2*pi));
```

Estimate the parameters, `mu` and `sigma`, of the custom-defined distribution.

```
phat = mle(Weight,'pdf',@lognormpdf,'start',[4.5 0.3])
```

```
phat =

    7.9600    0.2804
```

Compute the approximate covariance matrix of the parameter estimates.

```
acov = mlecov(phat,Weight,'pdf',@lognormpdf)
```

```
acov =

   1.0e-03 *

    0.1937   -0.0000
```

```
   -0.0000    0.0968
```

Estimate the standard errors of estimates.

```
se = sqrt(diag(acov))
```

```
se =

    0.0139
    0.0098
```

The standard error of the estimates of mu and sigma are 0.0139 and 0.0098, respectively.

Custom Log Probability Density Function

In the MATLAB Editor, create a function that returns the log probability density function of a beta distribution. Save the file in your current working folder as `betalogpdf.m`.

```
function logpdf = betalogpdf(x,a,b)
logpdf = (a-1)*log(x)+(b-1)*log(1-x)-betaln(a,b);
```

Generate sample data from a beta distribution with parameters 1.23 and 3.45 and estimate the parameters using the simulated data.

```
rng('default')
x = betarnd(1.23,3.45,25,1);
phat = mle(x,'dist','beta')
```

```
phat =

    1.1213    2.7182
```

Compute the approximate covariance matrix of the parameter estimates.

```
acov = mlecov(phat,x,'logpdf',@betalogpdf)
```

```
acov =

    0.0810    0.1646
    0.1646    0.6074
```

Custom Log pdf and Survival Function

Navigate to a folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load readmissiontimes
```

The sample data includes `ReadmissionTime`, which has readmission times for 100 patients. The column vector `Censored` has the censorship information for each patient, where 1 indicates a censored observation, and 0 indicates the exact readmission time is observed. This is simulated data.

Define a custom log probability density and survival function.

```
custlogpdf = @(data,lambda,k) log(k)-k*log(lambda)...
             +(k-1)*log(data)-(data/lambda).^k;
custlogsf = @(data,lambda,k) -(data/lambda).^k;
```

Estimate the parameters, `lambda` and `k`, of the custom distribution for the censored sample data.

```
phat = mle(ReadmissionTime,'logpdf',custlogpdf,...
'logsf',custlogsf,'start',[1,0.75],'Censoring',Censored)
```

```
phat =

    9.2090    1.4223
```

The scale and shape parameters of the custom-defined distribution are 9.2090 and 1.4223, respectively.

Compute the approximate covariance matrix of the parameter estimates.

```
acov = mlecov(phat,ReadmissionTime,...
'logpdf',custlogpdf,'logsf',custlogsf,'Censoring',Censored)
```

```
acov =

    0.5653    0.0102
    0.0102    0.0163
```

Custom Log Negative Likelihood Function

Navigate to a folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load readmissiontimes
```

The sample data includes `ReadmissionTime`, which has readmission times for 100 patients. This is simulated data.

Define a negative log likelihood function.

```
custnloglf = @(lambda,data,cens,freq) -length(data)*log(lambda)...
+ nansum(lambda*data);
```

Estimate the parameters of the defined distribution.

```
phat = mle(ReadmissionTime,'nloglf',custnloglf,'start',0.05)
```

```
phat =

    0.1462
```

Compute the variance of the parameter estimate.

```
acov = mlecov(phat,ReadmissionTime,'nloglf',custnloglf)
```

```
acov =

   2.1374e-04
```

Compute the standard error.

```
sqrt(acov)
```

```
ans =

    0.0146
```

Input Arguments

`params` — Parameter estimates

scalar value | vector

Parameter estimates, specified as a scalar value or vector of scalar values. These parameter estimates must be maximum likelihood estimates. For example, you can specify parameter estimates returned by `mle`.

Data Types: `single | double`

`data` — Sample data

vector

Sample data `mle` uses to estimate the distribution parameters, specified as a vector.

Data Types: `single | double`

`pdf` — Custom probability density function

function handle

Custom probability distribution function, specified as a function handle created using `@`.

This custom function accepts the vector `data` and one or more individual distribution parameters as input parameters, and returns a vector of probability density values.

For example, if the name of the custom probability density function is `newpdf`, then you can specify the function handle in `mlecov` as follows.

Example: `@newpdf`

Data Types: `function_handle`

`cdf` — Custom cumulative distribution function

function handle

Custom cumulative distribution function, specified as a function handle created using `@`.

This custom function accepts the vector `data` and one or more individual distribution parameters as input parameters, and returns a vector of cumulative probability values.

You must define `cdf` with `pdf` if data is censored and you use the `'censoring'` name-value pair argument. If `'censoring'` is not present, you do not have to specify `cdf` while using `pdf`.

For example, if the name of the custom cumulative distribution function is `newcdf`, then you can specify the function handle in `mlecov` as follows.

Example: `@newcdf`

Data Types: `function_handle`

`logpdf` — Custom log probability density function

function handle

Custom log probability density function, specified as a function handle created using `@`.

This custom function accepts the vector `data` and one or more individual distribution parameters as input parameters, and returns a vector of log probability values.

For example, if the name of the custom log probability density function is `customlogpdf`, then you can specify the function handle in `mlecov` as follows.

Example: `@customlogpdf`

Data Types: `function_handle`

`logsf` — Custom log survival function

function handle

Custom log survival function, specified as a function handle created using `@`.

This custom function accepts the vector `data` and one or more individual distribution parameters as input parameters, and returns a vector of log survival probability values.

You must define `logsf` with `logpdf` if data is censored and you use the `'censoring'` name-value pair argument. If `'censoring'` is not present, you do not have to specify `logsf` while using `logpdf`.

For example, if the name of the custom log survival function is `logsurvival`, then you can specify the function handle in `mlecov` as follows.

Example: `@logsurvival`

Data Types: `function_handle`

`nloglf` — Custom negative loglikelihood function

function handle

Custom negative loglikelihood function, specified as a function handle created using `@`.

This custom function accepts the following input arguments.

`params`	Vector of distribution parameter values

`data`	Vector of data
`cens`	Boolean vector of censored values
`freq`	Vector of integer data frequencies

`nloglf` must accept all four arguments even if you do not use the `'censoring'` or `'frequency'` name-value pair arguments. You can write `'nloglf'` to ignore `cens` and `freq` arguments in that case.

`nloglf` returns a scalar negative loglikelihood value and optionally, a negative loglikelihood gradient vector (see the `'GradObj'` field in `'options'`).

If the name of the custom negative log likelihood function is `negloglik`, then you can specify the function handle in `mlecov` as follows.

Example: `@negloglik`

Data Types: `function_handle`

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'censoring',cens,'options',opt` specifies that `mlecov` reads the censored data information from the vector `cens` and performs according to the new options structure `opt`.

`'censoring'` — Indicator for censoring

array of 0s (default) | array of 0s and 1s

Indicator for censoring, specified as the comma-separated pair consisting of `'censoring'` and a Boolean array of the same size as data. Use 1 for observations that are right censored and 0 for observations that are fully observed. The default is all observations are fully observed.

For censored data, you must use cdf with pdf, or logsf with logpdf, or nloglf must be defined to account for censoring.

For example, if the censored data information is in the binary array called `Censored`, then you can specify the censored data as follows.

Example: `'censoring',Censored`

Data Types: `logical`

`'frequency'` — Frequency of observations

array of 1s (default) | vector of nonnegative integer counts

Frequency of observations, specified as the comma-separated pair consisting of `'frequency'` and an array containing nonnegative integer counts, which is the same size as `data`. The default is one observation per element of `data`.

For example, if the observation frequencies are stored in an array named `Freq`, you can specify the frequencies as follows.

Example: `'frequency',Freq`

Data Types: `single | double`

`'options'` — Numerical options

structure

Numerical options for the finite difference Hessian calculation, specified as the comma-separated pair consisting of `'options'` and a structure returned by `statset`.

You can set the options under a new name and use it in the name-value pair argument. The applicable `statset` parameters are as follows.

Parameter	Value
`'GradObj'`	Default is `'off'`. `'on'` or `'off'`, indicating whether or not the function provided with the `nloglf` input argument can return the gradient vector of the negative log-likelihood as a second output.
`'DerivStep'`	Default is `eps^(1/4)`. Relative step size used in finite difference for Hessian calculations. It can be a scalar, or the same size as `params`. A smaller value than the default might be appropriate if `'GradObj'` is `'on'`.

Example: `'options',statset('mlecov')`

Data Types: `struct`

Output Arguments

`acov` — Approximation to asymptotic covariance matrix
p-by-*p* matrix

Approximation to asymptotic covariance matrix, returned as a *p*-by-*p* matrix, where *p* is the number of parameters in params.

More About

Survival Function

The survival function is the probability of survival as a function of time. It is also called the survivor function. It gives the probability that the survival time of an individual exceeds a certain value. Since the cumulative distribution function, $F(t)$, is the probability that the survival time is less than or equal to a given point in time, the survival function for a continuous distribution, $S(t)$, is the complement of the cumulative distribution function: $S(t) = 1 - F(t)$.

See Also

`mle`

mnpdf

Multinomial probability density function

Syntax

```
Y = mnpdf(X,PROB)
```

Description

`Y = mnpdf(X,PROB)` returns the pdf for the multinomial distribution with probabilities `PROB`, evaluated at each row of `X`. `X` and `PROB` are m-by-k matrices or 1-by-k vectors, where k is the number of multinomial bins or categories. Each row of `PROB` must sum to one, and the sample sizes for each observation (rows of `X`) are given by the row sums `sum(X,2)`. `Y` is an m-by-k matrix, and `mnpdf` computes each row of `Y` using the corresponding rows of the inputs, or replicates them if needed.

Examples

Compute the Multinomial Distribution pdf

Compute the pdf of a multinomial distribution with a sample size of `n = 10`. The probabilities are `p = 1/2` for outcome 1, `p = 1/3` for outcome 2, and `p = 1/6` for outcome 3.

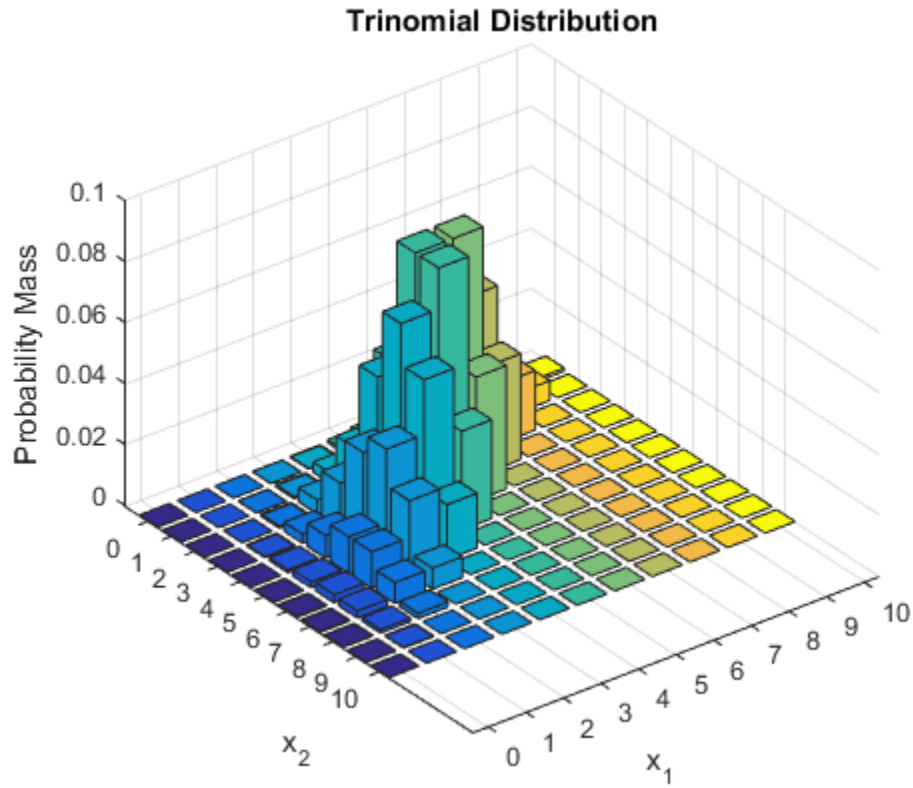
```
p = [1/2 1/3 1/6];
n = 10;
x1 = 0:n;
x2 = 0:n;
[X1,X2] = meshgrid(x1,x2);
X3 = n-(X1+X2);
```

Compute the pdf of the distribution.

```
Y = mnpdf([X1(:),X2(:),X3(:)],repmat(p,(n+1)^2,1));
```

Plot the pdf on a 3-dimensional figure.

```
Y = reshape(Y,n+1,n+1);
bar3(Y)
h = gca;
h.XTickLabel = [0:n];
h.YTickLabel = [0:n];
xlabel('x_1')
ylabel('x_2')
zlabel('Probability Mass')
title('Trinomial Distribution')
```



Note that the visualization does not show `x3`, which is determined by the constraint `x1 + x2 + x3 = n`.

`mnrnd`

mnrfit

Multinomial logistic regression

Syntax

```
B = mnrfit(X,Y)
B = mnrfit(X,Y,Name,Value)
[B,dev,stats] = mnrfit( ___ )
```

Description

`B = mnrfit(X,Y)` returns a matrix, `B`, of coefficient estimates for a multinomial logistic regression of the nominal responses in `Y` on the predictors in `X`.

`B = mnrfit(X,Y,Name,Value)` returns a matrix, `B`, of coefficient estimates for a multinomial model fit with additional options specified by one or more `Name,Value` pair arguments.

For example, you can fit a nominal, an ordinal, or a hierarchical model, or change the link function.

`[B,dev,stats] = mnrfit( ___ )` also returns the deviance of the fit, `dev`, and the structure `stats` for any of the previous input arguments. `stats` contains model statistics such as degrees of freedom, standard errors for coefficient estimates, and residuals.

Examples

Multinomial Regression for Nominal Responses

Fit a multinomial regression for nominal outcomes and interpret the results.

Load the sample data.

```
load fisheriris
```

The column vector, `species`, consists of iris flowers of three different species, setosa, versicolor, virginica. The double matrix `meas` consists of four types of measurements on the flowers, the length and width of sepals and petals in centimeters, respectively.

Define the nominal response variable using a categorical array.

```
sp = categorical(species);
```

Fit a multinomial regression model to predict the species using the measurements.

```
[B,dev,stats] = mnrfit(meas,sp);
B
```

```
B =

   13.3860   15.4492
    2.4623    1.8196
    5.2948    2.5700
   -7.4916   -4.3714
   -8.9322   -7.6467
```

This is a nominal model for the response category relative risks, with separate slopes on all four predictors, that is, each category of `meas`. The first row of `B` contains the intercept terms for the relative risk of the first two response categories, setosa and versicolor versus the reference category, virginica. The last four rows contain the slopes for the models for the first two categories. `mnrfit` accepts the third category as the reference category.

The models for the relative risk of an iris flower being a setosa versus a virginica, and the relative risk of an iris flower being a versicolor species versus a virginica species are respectively

$$\ln\left(\frac{\pi_{setosa}}{\pi_{virginica}}\right) = 13.38 + 2.46X_1 + 5.29X_2 - 7.49X_3 - 8.93X_4$$

and

$$\ln\left(\frac{\pi_{versicolor}}{\pi_{virginica}}\right) = 15.45 + 1.82X_1 + 2.57X_2 - 4.37X_3 - 7.65X_4$$

The coefficients express the effects of the predictor variables on the relative risk or the log odds of being in one category versus the reference category.

For example, the estimated coefficient 2.46 indicates that the probability of being species 1 (setosa) compared to the probability of being species 3 (virginica) (the relative risk of being a setosa versus a virginica) increases exp(2.46) times for each unit increase in X_1, the first measurement, given all else equal.

In terms of log odds, you can say that the relative log odds of being a setosa versus a virginica increases 2.46 times with a one-unit increase in X_1 given all else is equal.

Check the statistical significance of the model coefficients.

```
stats.p
```

```
ans =

    0.2457    0.0031
    0.4543    0.1048
    0.0773    0.0815
    0.0258    0.0007
    0.1856    0.0002
```

The p-value of 0.0258 indicates that the third measure is significant on the relative risk of being a setosa versus a virginica (species 1 compared to species 3). The p-values of 0.0007 and 0.0002 indicate that the third and fourth measures are significant on the relative risk of being a versicolor versus a virginica (species 2 compared to species 3).

Request the standard errors of coefficient estimates.

```
stats.se
```

    3.3609    1.2869
    6.7474    2.0846
```

Calculate the 95% confidence limits for the coefficients.

```
LL = stats.beta - 1.96.*stats.se;
```

```
UL = stats.beta + 1.96.*stats.se;
```

Display the confidence intervals for the coefficients of the model for the relative risk of being a setosa versus a virginica (the first column of coefficients in B).

```
[LL(:,1) UL(:,1)]
```

```
ans =

   -9.2160   35.9880
   -3.9869    8.9116
   -0.5805   11.1701
  -14.0790   -0.9043
  -22.1570    4.2926
```

Find the confidence intervals for the coefficients of the model for the relative risk of being a versicolor versus a virginica (the second column of coefficients in B).

```
[LL(:,2) UL(:,2)]
```

```
ans =

    5.2177   25.6807
   -0.3791    4.0184
   -0.3216    5.4615
   -6.8938   -1.8490
  -11.7324   -3.5610
```

Multinomial Regression for Ordinal Responses

Fit a multinomial regression model for categorical responses with natural ordering among categories.

Load the sample data and define the predictor variables.

```
load carbig
X = [Acceleration Displacement Horsepower Weight];
```

The predictor variables are the acceleration, engine displacement, horsepower, and weight of the cars. The response variable is miles per gallon (mpg).

Create an ordinal response variable categorizing `MPG` into four levels from 9 to 48 mpg by labeling the response values in the range 9-19 as 1, 20-29 as 2, 30-39 as 3, and 40-48 as 4.

```
miles = ordinal(MPG,{'1','2','3','4'},[],[9,19,29,39,48]);
```

Fit an ordinal response model for the response variable `miles`.

```
[B,dev,stats] = mnrfit(X,miles,'model','ordinal');
B
```

```
B =

  -16.6895
  -11.7208
   -8.0606
    0.1048
    0.0103
    0.0645
    0.0017
```

The first three elements of `B` are the intercept terms for the models, and the last four elements of `B` are the coefficients of the covariates, assumed common across all categories. This model corresponds to *parallel regression*, which is also called the *proportional odds* model, where there is a different intercept but common slopes among categories. You can specify this using the `'interactions','off'` name-value pair argument, which is the default for ordinal models.

```
[B(1:3)'; repmat(B(4:end),1,3)]
```

```
ans =

  -16.6895  -11.7208   -8.0606
    0.1048    0.1048    0.1048
    0.0103    0.0103    0.0103
    0.0645    0.0645    0.0645
    0.0017    0.0017    0.0017
```

The link function in the model is logit (`'link','logit'`), which is the default for an ordinal model. The coefficients express the relative risk or log odds of the mpg of a car being less than or equal to one value versus greater than that value.

The proportional odds model in this example is

$$\ln\left(\frac{P(mpg\leq 19)}{P(mpg>19)}\right) = -16.6895 + 0.1048X_A + 0.0103X_D + 0.0645X_H + 0.0017X_W$$

$$\ln\left(\frac{P(mpg\leq 29)}{P(mpg>29)}\right) = -11.7208 + 0.1048X_A + 0.0103X_D + 0.0645X_H + 0.0017X_W$$

$$\ln\left(\frac{P(mpg\leq 39)}{P(mpg>39)}\right) = -8.0606 + 0.1048X_A + 0.0103X_D + 0.0645X_H + 0.0017X_W$$

For example, the coefficient estimate of 0.1048 indicates that a unit change in acceleration would impact the odds of the mpg of a car being less than or equal to 19 versus more than 19, or being less than or equal to 29 versus greater than 29, or being less than or equal to 39 versus greater than 39, by a factor of exp(0.01048) given all else is equal.

Assess the significance of the coefficients.

```
stats.p
```

```
ans =

    0.0000
    0.0000
    0.0000
    0.1899
    0.0350
    0.0000
    0.0118
```

The p-values of 0.035, 0.0000, and 0.0118 for engine displacement, horsepower, and weight of a car, respectively, indicate that these factors are significant on the odds of mpg of a car being less than or equal to a certain value versus being greater than that value.

Hierarchical Multinomial Regression Model

Fit a hierarchical multinomial regression model.

Navigate to the folder containing sample data.

```
cd(matlabroot)
```

```
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load smoking
```

The data set `smoking` contains five variables: sex, age, weight, and systolic and diastolic blood pressure. Sex is a binary variable where 1 indicates female patients, and 0 indicates male patients.

Define the response variable.

```
Y = categorical(smoking.Smoker);
```

The data in `Smoker` has four categories:

- 0: Nonsmoker, 0 cigarettes a day
- 1: Smoker, 1–5 cigarettes a day
- 2: Smoker, 6–10 cigarettes a day
- 3: Smoker, 11 or more cigarettes a day

Define the predictor variables.

```
X = [smoking.Sex smoking.Age smoking.Weight...
    smoking.SystolicBP smoking.DiastolicBP];
```

Fit a hierarchical multinomial model.

```
[B,dev,stats] = mnrfit(X,Y,'model','hierarchical');
B
```

```
B =

   43.8148    5.9571   44.0712
    1.8709   -0.0230    0.0662
    0.0188    0.0625    0.1335
    0.0046   -0.0072   -0.0130
   -0.2170    0.0416   -0.0324
   -0.2273   -0.1449   -0.4824
```

The first column of `B` includes the intercept and the coefficient estimates for the model of the relative risk of being a nonsmoker versus a smoker. The second column includes the parameter estimates for modeling the log odds of smoking 1–5 cigarettes a day versus

more than five cigarettes a day given that a person is a smoker. Finally, the third column includes the parameter estimates for modeling the log odds of a person smoking 6–10 cigarettes a day versus more than 10 cigarettes a day given he/she smokes more than 5 cigarettes a day.

The coefficients differ across categories. You can specify this using the `'interactions','on'` name-value pair argument, which is the default for hierarchical models. So, the model in this example is

$$\ln\left(\frac{P(y=0)}{P(y>0)}\right)=43.8148+1.8709X_S+0.0188X_A+0.0046X_W-0.2170X_{SBP}-0.2273X_{DBP}$$

$$\ln\left(\frac{P(1\le y\le 5)}{P(y>5)}\right)=5.9571-0.0230X_S+0.0625X_A+0.0072X_W+0.0416X_{SBP}-0.1449X_{DBP}$$

$$\ln\left(\frac{P(6\le y\le 10)}{P(y>10)}\right)=44.0712+0.0662X_S+0.1335X_A-0.0130X_W-0.0324X_{SBP}-0.4824X_{DBP}$$

For example, the coefficient estimate of 1.8709 indicates that the likelihood of being a smoker versus a nonsmoker increases by exp(1.8709) = 6.49 times as the gender changes from female to male given everything else held constant.

Assess the statistical significance of the terms.

```
stats.p
```

```
ans =

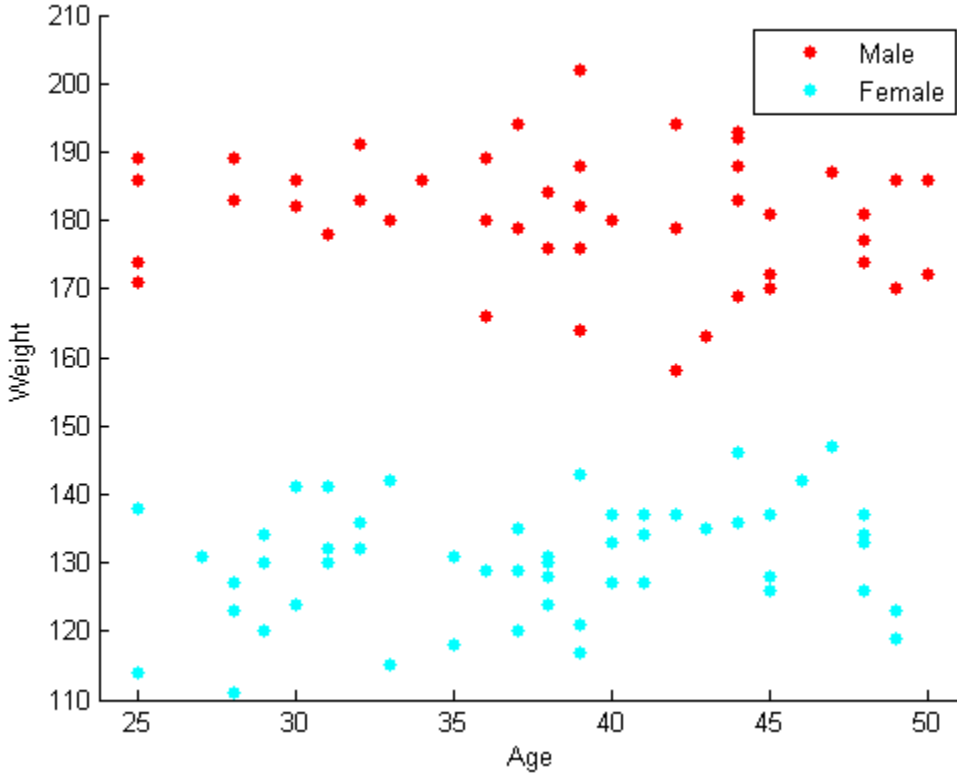
    0.0000    0.5363    0.2149
    0.3549    0.9912    0.9835
    0.6850    0.2676    0.2313
    0.9032    0.8523    0.8514
    0.0009    0.5187    0.8165
    0.0004    0.0483    0.0545
```

Sex, age, or weight don't appear significant on any level. The *p*-values of 0.0009 and 0.0004 indicate that both types of blood pressure are significant on the relative risk of a person being a smoker versus a nonsmoker. The *p*-value of 0.0483 shows that only

diastolic blood pressure is significant on the odds of a person smoking 0–5 cigarettes a day versus more than 5 cigarettes a day. Similarly, the *p*-value of 0.0545 indicates that diastolic blood pressure is significant on the odds of a person smoking 6–10 cigarettes a day versus more than 10 cigarettes a day.

Check if any nonsignificant factors are correlated to each other. Draw a scatterplot of age versus weight grouped by sex.

```
figure()
gscatter(smoking.Age,smoking.Weight,smoking.Sex)
legend('Male','Female')
xlabel('Age')
ylabel('Weight')
```



The range of weight of an individual seems to differ according to gender. Age does not seem to have any obvious correlation with sex or weight. Age is insignificant and weight seems to be correlated with sex, so you can eliminate both and reconstruct the model.

Eliminate age and weight from the model and fit a hierarchical model with sex, systolic blood pressure, and diastolic blood pressure as the predictor variables.

```
X = double([smoking.Sex smoking.SystolicBP...
smoking.DiastolicBP]);
[B,dev,stats] = mnrfit(X,Y,'model','hierarchical');
B
```

```
B =

    44.8456    5.3230   25.0248
    1.6045    0.2330    0.4982
   -0.2161    0.0497    0.0179
   -0.2222   -0.1358   -0.3092
```

Here, a coefficient estimate of 1.6045 indicates that the likelihood of being a nonsmoker versus a smoker increases by exp(1.6045) = 4.97 times as sex changes from male to female. A unit increase in the systolic blood pressure indicates an exp(–.2161) = 0.8056 decrease in the likelihood of being a nonsmoker versus a smoker. Similarly, a unit increase in the diastolic blood pressure indicates an exp(–.2222) = 0.8007 decrease in the relative rate of being a nonsmoker versus being a smoker.

Assess the statistical significance of the terms.

```
stats.p
```

```
ans =

    0.0000    0.4715    0.2325
    0.0210    0.7488    0.6362
    0.0010    0.4107    0.8899
    0.0003    0.0483    0.0718
```

The *p*-values of 0.0210, 0.0010, and 0.0003 indicate that the terms sex and both types of blood pressure are significant on the relative risk of a person being a nonsmoker versus a smoker, given the other terms in the model. Based on the *p*-value of 0.0483, diastolic blood pressure appears significant on the relative risk of a person smoking 1–5 cigarettes versus more than 5 cigarettes a day, given that this person is a smoker. Because none of the *p*-values on the third column are less than 0.05, you can say that none of the

variables are statistically significant on the relative risk of a person smoking from 6–10 cigarettes versus more than 10 cigarettes, given that this person smokes more than 5 cigarettes a day.

Input Arguments

X — Observations on predictor variables

n-by-*p* matrix

Observations on predictor variables, specified as an *n*-by-*p* matrix. `X` contains *n* observations for *p* predictors.

Note: `mnrfit` automatically includes a constant term (intercept) in all models. Do not include a column of 1s in `X`.

Data Types: `single` | `double`

Y — Response values

n-by-*k* matrix | *n*-by-1 column vector

Response values, specified as a column vector or a matrix. `Y` can be one of the following:

- An *n*-by-*k* matrix, where *Y*(*i*,*j*) is the number of outcomes of the multinomial category *j* for the predictor combinations given by *X*(*i*,:). In this case, the number of observations are made at each predictor combination.
- An *n*-by-1 column vector of scalar integers from 1 to *k* indicating the value of the response for each observation. In this case, all sample sizes are 1.
- An *n*-by-1 categorical array indicating the nominal or ordinal value of the response for each observation. In this case, all sample sizes are 1.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'Model','ordinal','Link','probit'` specifies an ordinal model with a probit link function.

`'Model'` — Type of model to fit

`'nominal'` (default) | `'ordinal'` | `'hierarchical'`

Type of model to fit, specified as the comma-separated pair consisting of `'Model'` and one of the following.

`'nominal'`	Default. There is no ordering among the response categories.
`'ordinal'`	There is a natural ordering among the response categories.
`'hierarchical'`	The choice of response category is sequential/nested.

Example: `'Model','ordinal'`

`'Interactions'` — Indicator for interaction between multinomial categories and coefficients

`'on'` | `'off'`

Indicator for an interaction between the multinomial categories and coefficients, specified as the comma-separated pair consisting of `'Interactions'` and one of the following.

`'on'`	Default for nominal and hierarchical models. Fit a model with different coefficients across categories.
`'off'`	Default for ordinal models. Fit a model with a common set of coefficients for the predictor variables, across all multinomial categories. This is often described as *parallel regression* or the *proportional odds model*.

In all cases, the model has different intercepts across categories. The choice of `'Interactions'` determines the dimensions of the output array B.

Example: `'Interactions','off'`

Data Types: `logical`

`'Link'` — Link function

`'logit'` (default) | `'probit'` | `'comploglog'` | `'loglog'`

Link function to use for ordinal and hierarchical models, specified as the comma-separated pair consisting of `'Link'` and one of the following.

`'logit'`	Default. $f(\gamma) = \ln(\gamma/(1-\gamma))$
`'probit'`	$f(\gamma) = \Phi^{-1}(\gamma)$ — error term is normally distributed with variance 1
`'comploglog'`	Complementary log-log $f(\gamma) = \ln(-\ln(1-\gamma))$
`'loglog'`	$f(\gamma) = \ln(-\ln(\gamma))$

The link function defines the relationship between response probabilities and the linear combination of predictors, $X\beta$. The link functions might be functions of cumulative or conditional probabilities based on whether the model is for an ordinal or a sequential/nested response. For example, for an ordinal model, γ represents the cumulative probability of being in categories 1 to j and the model with a logit link function as follows:

$$\ln\left(\frac{\gamma}{1-\gamma}\right) = \ln\left(\frac{\pi_1+\pi_2+\cdots+\pi_j}{\pi_{j+1}+\cdots+\pi_k}\right) = \beta_{0j} + \beta_1 X_1 + \beta_2 X_2 + \cdots + \beta_p X_p,$$

where k represents the last category.

You cannot specify the `'Link'` parameter for nominal models; these always use a multinomial logit link,

$$\ln\left(\frac{\pi_j}{\pi_r}\right) = \beta_{j0} + \beta_{j1} X_{j1} + \beta_{j2} X_{j2} + \cdots + \beta_{jp} X_{jp}, \quad j = 1, \ldots, k-1,$$

where π stands for a categorical probability, and r corresponds to the reference category. `mnrfit` uses the last category as the reference category for nominal models.

Example: `'Link','loglog'`

`'EstDisp'` — Indicator for estimating dispersion parameter

`'off'` (default) | `'on'`

Indicator for estimating a dispersion parameter, specified as the comma-separated pair consisting of `'EstDisp'` and one of the following.

`'off'`	Default. Use the theoretical dispersion value of 1.
`'on'`	Estimate a dispersion parameter for the multinomial distribution in computing standard errors.

Example: `'EstDisp','on'`

Output Arguments

`B` — Coefficient estimates

vector | matrix

Coefficient estimates for a multinomial logistic regression of the responses in Y, returned as a vector or a matrix.

- If `'Interaction'` is `'off'`, then `B` is a $k - 1 + p$ vector. The first $k - 1$ rows of `B` correspond to the intercept terms, one for each $k - 1$ multinomial categories, and the remaining p rows correspond to the predictor coefficients, which are common for all of the first $k - 1$ categories.
- If `'Interaction'` is `'on'`, then `B` is a $(p + 1)$-by-$(k - 1)$ matrix. Each column of `B` corresponds to the estimated intercept term and predictor coefficients, one for each of the first $k - 1$ multinomial categories.

The estimates for the kth category are taken to be zero as `mnrfit` takes the last category as the reference category.

`dev` — Deviance of the fit

scalar value

Deviance of the fit, returned as a scalar value. It is twice the difference between the maximum achievable log likelihood and that attained under the fitted model. This corresponds to the sum of deviance residuals,

$$dev = 2 * \sum_{i}^{n} \sum_{j}^{k} y_{ij} * \log\left(\frac{y_{ij}}{\pi_{ij} * m_i}\right) = \sum_{i}^{n} rd_i,$$

where rd_i are the deviance residuals. For deviance residuals see stats.

`stats` — Model statistics

structure

Model statistics, returned as a structure that contains the following fields.

`beta`	The coefficient estimates. These are the same as `B`.
`dfe`	Degrees of freedom for error • If `'Interactions'` is `'off'`, then degrees of freedom is $n*(k-1)-(k-1+p)$. • If `'Interactions'` is `'on'`, then degrees of freedom is $(n-p+1)*(k-1)$.
`sfit`	Estimated dispersion parameter.
`s`	Theoretical or estimated dispersion parameter. • If `'Estdisp'` is `'off'`, then `s` is the theoretical dispersion parameter, 1. • If `'Estdisp'` is `'on'`, then `s` is equal to the estimated dispersion parameter, `sfit`.
`estdisp`	Indicator for a theoretical or estimated dispersion parameter.
`se`	Standard errors of coefficient estimates, `B`.
`coeffcorr`	Estimated correlation matrix for `B`.
`covb`	Estimated covariance matrix for `B`.
`t`	t statistics for `B`.
`p`	p-values for `B`.
`resid`	Raw residuals. Observed minus fitted values, $$r_{ij} = y_{ij} - \hat{\pi}_{ij} * m_i, \quad \begin{cases} i = 1,\cdots,n \\ j = 1,\cdots,k \end{cases},$$ where π_{ij} is the categorical, cumulative or conditional probability, and m_i is the corresponding sample size.
`residp`	Pearson residuals, which are the raw residuals scaled by the estimated standard deviation:

	$$rp_{ij} = \frac{r_{ij}}{\hat{\sigma}_{ij}} = \frac{y_{ij} - \hat{\pi}_{ij} * m_i}{\sqrt{\hat{\pi}_{ij} * \left(1 - \hat{\pi}_{ij}\right) * m_i}}, \quad \begin{cases} i = 1, \cdots, n \\ j = 1, \cdots, k \end{cases},$$ where π_{ij} is the categorical, cumulative, or conditional probability, and m_i is the corresponding sample size.
`residd`	Deviance residuals: $$rd_i = 2 * \sum_j^k y_{ij} * \log\left(\frac{y_{ij}}{\pi_{ij} * m_i}\right), \quad i = 1, \cdots, n.$$ where π_{ij} is the categorical, cumulative, or conditional probability, and m_i is the corresponding sample size.

mnrnd

Multinomial random numbers

Syntax

```
r = mnrnd(n,p)
R = mnrnd(n,p,m)
R = mnrnd(N,P)
```

Description

`r = mnrnd(n,p)` returns random values `r` from the multinomial distribution with parameters `n` and `p`. `n` is a positive integer specifying the number of trials (sample size) for each multinomial outcome. `p` is a 1-by-*k* vector of multinomial probabilities, where *k* is the number of multinomial bins or categories. `p` must sum to one. (If `p` does not sum to one, `r` consists entirely of `NaN` values.) `r` is a 1-by-*k* vector, containing counts for each of the *k* multinomial bins.

`R = mnrnd(n,p,m)` returns `m` random vectors from the multinomial distribution with parameters `n` and `p`. `R` is a `m`-by-*k* matrix, where *k* is the number of multinomial bins or categories. Each row of `R` corresponds to one multinomial outcome.

`R = mnrnd(N,P)` generates outcomes from different multinomial distributions. `P` is a *m*-by-*k* matrix, where *k* is the number of multinomial bins or categories and each of the *m* rows contains a different set of multinomial probabilities. Each row of `P` must sum to one. (If any row of `P` does not sum to one, the corresponding row of `R` consists entirely of `NaN` values.) `N` is a *m*-by-1 vector of positive integers or a single positive integer (replicated by `mnrnd` to a *m*-by-1 vector). `R` is a `m`-by-*k* matrix. Each row of `R` is generated using the corresponding rows of `N` and `P`.

Examples

Generate 2 random vectors with the same probabilities:

```
n = 1e3;
```

```
p = [0.2,0.3,0.5];
R = mnrnd(n,p,2)
R =
   215   282   503
   194   303   503
```

Generate 2 random vectors with different probabilities:

```
n = 1e3;
P = [0.2, 0.3, 0.5; ...
     0.3, 0.4, 0.3;];
R = mnrnd(n,P)
R =
   186   290   524
   290   389   321
```

`mnpdf`

mnrval

Multinomial logistic regression values

Syntax

```
pihat = mnrval(B,X)
[pihat,dlow,dhi] = mnrval(B,X,stats)
[pihat,dlow,dhi] = mnrval(B,X,stats,Name,Value)

yhat = mnrval(B,X,ssize)
[yhat,dlow,dhi] = mnrval(B,X,ssize,stats)
[yhat,dlow,dhi] = mnrval(B,X,ssize,stats,Name,Value)
```

Description

`pihat = mnrval(B,X)` returns the predicted probabilities for the multinomial logistic regression model with predictors, `X`, and the coefficient estimates, `B`.

`pihat` is an n-by-k matrix of predicted probabilities for each multinomial category. `B` is the vector or matrix that contains the coefficient estimates returned by `mnrfit`. And `X` is an n-by-p matrix which contains n observations for p predictors.

Note: `mnrval` automatically includes a constant term in all models. Do not enter a column of 1s in `X`.

`[pihat,dlow,dhi] = mnrval(B,X,stats)` also returns 95% error bounds on the predicted probabilities, `pihat`, using the statistics in the structure, `stats`, returned by `mnrfit`.

The lower and upper confidence bounds for `pihat` are `pihat` minus `dlow` and `pihat` plus `dhi`, respectively. Confidence bounds are nonsimultaneous and only apply to the fitted curve, not to new observations.

`[pihat,dlow,dhi] = mnrval(B,X,stats,Name,Value)` returns the predicted probabilities and 95% error bounds on the predicted probabilities `pihat`, with additional options specified by one or more `Name,Value` pair arguments.

For example, you can specify the model type, link function, and the type of probabilities to return.

`yhat = mnrval(B,X,ssize)` returns the predicted category counts for sample sizes, `ssize`.

`[yhat,dlow,dhi] = mnrval(B,X,ssize,stats)` also computes 95% error bounds on the predicted counts `yhat`, using the statistics in the structure, `stats`, returned by `mnrfit`.

The lower and upper confidence bounds for `yhat` are `yhat` minus `dlo` and `yhat` plus `dhi`, respectively. Confidence bounds are nonsimultaneous and they apply to the fitted curve, not to new observations.

`[yhat,dlow,dhi] = mnrval(B,X,ssize,stats,Name,Value)` returns the predicted category counts and 95% error bounds on the predicted counts `yhat`, with additional options specified by one or more `Name,Value` pair arguments.

For example, you can specify the model type, link function, and the type of predicted counts to return.

Examples

Estimate Category Probabilities for Nominal Responses

Fit a multinomial regression for nominal outcomes and estimate the category probabilities.

Load the sample data.

```
load('fisheriris.mat')
```

The column vector, `species`, consists of iris flowers of three different species, setosa, versicolor, virginica. The double matrix `meas` consists of four types of measurements on the flowers, the length and width of sepals and petals in centimeters, respectively.

Define the nominal response variable.

```
sp = nominal(species);
sp = double(sp);
```

Now in `sp`, 1, 2, and 3 indicate the species setosa, versicolor, and virginica, respectively.

Fit a nominal model to estimate the species using the flower measurements as the predictor variables.

```
[B,dev,stats] = mnrfit(meas,sp);
```

Estimate the probability of being a certain kind of species for an iris flower having the measurements (6.2, 3.7, 5.8, 0.2).

```
x = [6.2, 3.7, 5.8, 0.2];
pihat = mnrval(B,x);
pihat
```

```
pihat =

    0.0017    0.9982    0.0001
```

The probability of an iris flower having the measurements (6.2, 3.7, 5.8, 0.2) being a setosa is 0.0017, a versicolor is 0.9982, and a virginica is 0.0001.

Estimate Upper and Lower Error Bounds for Probability Estimates of Ordinal Responses

Fit a multinomial regression model for categorical responses with natural ordering among categories. Then estimate the upper and lower confidence bounds for the category probability estimates.

Load the sample data and define the predictor variables.

```
load('carbig.mat')
X = [Acceleration Displacement Horsepower Weight];
```

The predictor variables are the acceleration, engine displacement, horsepower, and the weight of the cars. The response variable is miles per gallon (`MPG`).

Create an ordinal response variable categorizing `MPG` into four levels from 9 to 48 mpg.

```
miles = ordinal(MPG,{'1','2','3','4'},[],[9,19,29,39,48]);
miles = double(miles);
```

Now in miles, 1 indicates the cars with miles per gallon from 9 to 19, and 2 indicates the cars with miles per gallon from 20 to 29. Similarly, 3 and 4 indicate the cars with miles per gallon from 30 to 39 and 40 to 48, respectively.

Fit a multinomial regression model for the response variable `miles`. For an ordinal model, the default `'link'` is `logit` and the default `'interactions'` is `'off'`.

```
[B,dev,stats] = mnrfit(X,miles,'model','ordinal');
```

Compute the probability estimates and 95% error bounds for probability confidence intervals for miles per gallon of a car with $x = (12, 113, 110, 2670)$.

```
x = [12,113,110,2670];
[pihat,dlow,hi] = mnrval(B,x,stats,'model','ordinal');
pihat
```

```
pihat =

   0.0615    0.8426    0.0932    0.0027
```

Calculate the confidence bounds for the category probability estimates.

```
LL = pihat - dlow;
UL = pihat + hi;
[LL;UL]
```

```
ans =

    0.0073    0.7829    0.0283   -0.0003
    0.1157    0.9022    0.1580    0.0057
```

Estimate Category Counts and Error Bounds for Nominal Responses

Fit a multinomial regression for nominal outcomes and estimate the category counts.

Load the sample data.

```
load('fisheriris.mat')
```

The column vector, `species`, consists of iris flowers of three different species, setosa, versicolor, and virginica. The double matrix `meas` consists of four types of measurements on the flowers, the length and width of sepals and petals in centimeters, respectively.

Define the nominal response variable.

```
sp = nominal(species);
sp = double(sp);
```

Now in `sp`, 1, 2, and 3 indicate the species setosa, versicolor, and virginica, respectively.

Fit a nominal model to estimate the species based on the flower measurements.

```
[B,dev,stats] = mnrfit(meas,sp);
```

Estimate the number in each species category for a sample of 100 iris flowers all with the measurements (6.2, 3.7, 5.8, 0.2).

```
x = [6.2,3.7,5.8,0.2];
yhat = mnrval(B,x,18)
```

```
yhat =

    0.0314   17.9671    0.0016
```

Estimate the error bounds for the counts.

```
[yhat,dlow,hi] = mnrval(B,x,18,stats,'model','nominal');
```

Calculate the confidence bounds for the category probability estimates.

```
LL = yhat - dlow;
UL = yhat + hi;
[LL;UL]
```

```
ans =

   -0.7084   17.2272   -0.0115
    0.7711   18.7069    0.0146
```

Plot the Count Estimates

Create sample data with one predictor variable and a categorical response variable with three categories.

```
x = [-3 -2 -1 0 1 2 3]';
Y = [1 11 13; 2 9 14; 6 14 5; 5 10 10;...
   5 14 6; 7 13 5; 8 11 6];
[Y x]
```

```
ans =

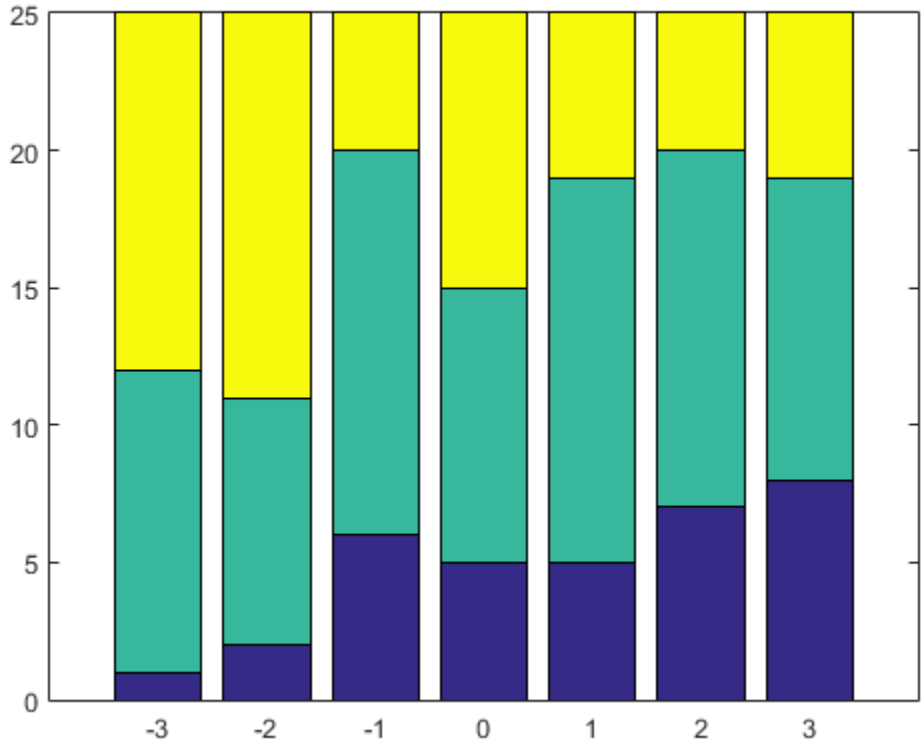
     1    11    13    -3
     2     9    14    -2
     6    14     5    -1
     5    10    10     0
     5    14     6     1
     7    13     5     2
```

```
     8    11     6     3
```

There are observations on seven different values of the predictor variable `x` . The response variable `Y` has three categories and the data shows how many of the 25 individuals are in each category of `Y` for each observation of `x`. For example, when `x` is -3, 1 of 25 individuals is observed in category 1, 11 observed in category 2, and 13 observed in category 3. Similarly, when `x` is 1, 5 of the individuals are observed in category 1, 14 are observed in category 2, and 6 are observed in category 3.

Plot the number in each category versus the `x` values, on a stacked bar graph.

```
bar(x,Y,'stacked');
ylim([0 25]);
```



Fit a nominal model for the individual response category probabilities, with separate slopes on the single predictor variable, `x`, for each category.

```
betaHatNom = mnrfit(x,Y,'model','nominal',...
    'interactions','on')
```

```
betaHatNom =

   -0.6028    0.3832
    0.4068    0.1948
```

The first row of `betaHatOrd` contains the intercept terms for the first two response categories. The second row contains the slopes. `mnrfit` accepts the third category as the reference category and hence assumes the coefficients for the third category are zero.

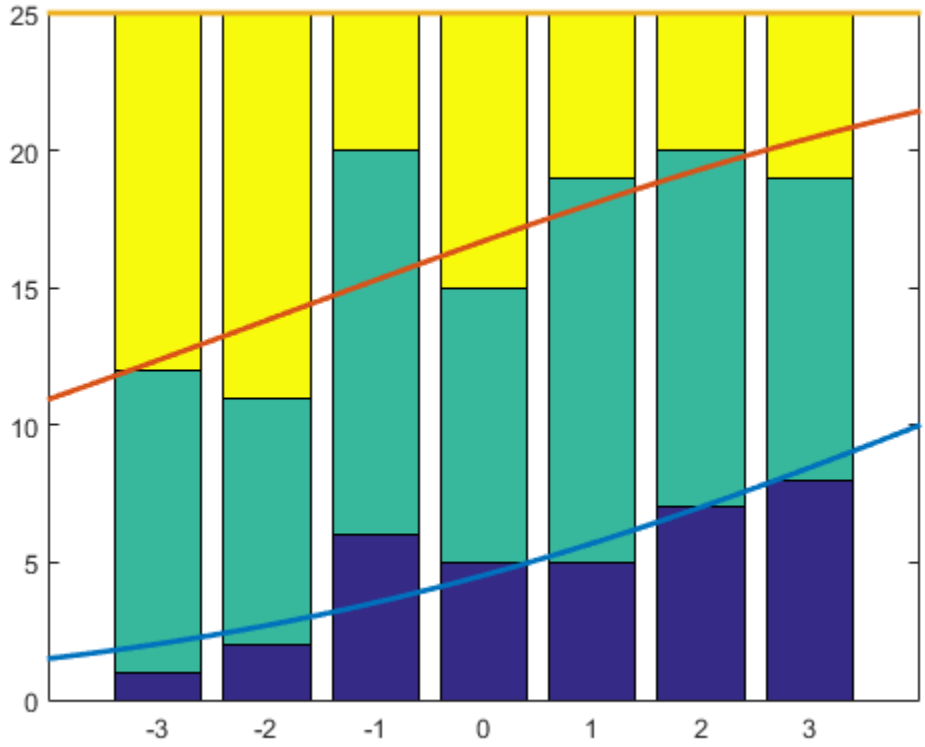
Compute the predicted probabilities for the three response categories.

```
xx = linspace(-4,4)';
piHatNom = mnrval(betaHatNom,xx,'model','nominal',...
    'interactions','on');
```

The probability of being in the third category is simply 1 - P(y = 1) - P(y = 2).

Plot the estimated cumulative number in each category on the bar graph.

```
line(xx,cumsum(25*piHatNom,2),'LineWidth',2);
```



The cumulative probability for the third category is always 1.

Now, fit a "parallel" ordinal model for the cumulative response category probabilities, with a common slope on the single predictor variable, `x`, across all categories:

```
betaHatOrd = mnrfit(x,Y,'model','ordinal',...
    'interactions','off')
```

```
betaHatOrd =

   -1.5001
    0.7266
    0.2642
```

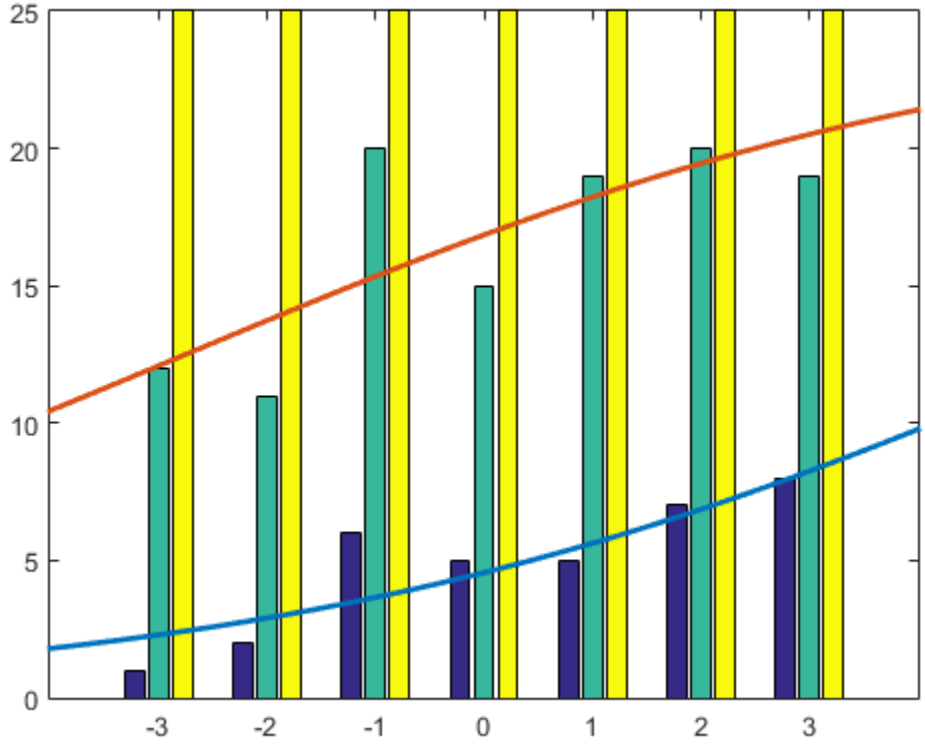
The first two elements of `betaHatOrd` are the intercept terms for the first two response categories. The last element of `betaHatOrd` is the common slope.

Compute the predicted cumulative probabilities for the first two response categories. The cumulative probability for the third category is always 1.

```
piHatOrd = mnrval(betaHatOrd,xx,'type','cumulative',...
    'model','ordinal','interactions','off');
```

Plot the estimated cumulative number on the bar graph of the observed cumulative number.

```
figure()
bar(x,cumsum(Y,2),'grouped');
ylim([0 25]);
line(xx,25*piHatOrd,'LineWidth',2);
```



Input Arguments

B — Coefficient estimates

vector or matrix returned by `mnrfit`

Coefficient estimates for the multinomial logistic regression model, specified as a vector or matrix returned by `mnrfit`. It is a vector or matrix depending on the model and interactions.

Example: `B = mnrfit(X,y); pihat = mnrval(B,X)`

Data Types: `single | double`

X — Sample data

matrix

Sample data on predictors, specified as an n-by-p. `X` contains n observations for p predictors.

Note: `mnrval` automatically includes a constant term in all models. Do not enter a column of 1s in `X`.

Example: `pihat = mnrval(B,X)`

Data Types: `single | double`

stats — Model statistics

structure returned by `mnrfit`

Model statistics, specified as a structure returned by `mnrfit`. You must use the `stats` input argument in `mnrval` to compute the lower and upper error bounds on the category probabilities and counts.

Example: `[B,dev,stats] = mnrfit(X,y);[pihat,dlo,dhi] = mnrval(B,X,stats)`

ssize — Sample sizes

column vector of positive integers

Sample sizes to return the number of items in response categories for each combination of the predictor variables, specified as an n-by-1 column vector of positive integers.

For example, for a response variable having three categories, if an observation of the number of individuals in each category is y_1, y_2, and y_3, respectively, then the sample size, m, for that observation is $m = y_1 + y_2 + y_3$.

If the sample sizes for n observations are in vector `sample`, then you can enter the sample sizes as follows.

Example: `yhat = mnrval(B,X,sample)`

Data Types: `single | double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'model','ordinal','link','probit','type','cumulative'` specifies that `mnrval` returns the estimates for cumulative probabilities for an ordinal model with a probit link function.

`'model'` — Type of multinomial model

`'nominal'` (default) | `'ordinal'` | `'hierarchical'`

Type of multinomial model fit by `mnrfit`, specified as the comma-separated pair consisting of `'model'` and one of the following.

`'nominal'`	Default. Specify when there is no ordering among the response categories.
`'ordinal'`	Specify when there is a natural ordering among the response categories.
`'hierarchica`	Specify when the choice of response category is sequential.

Example: `'model','ordinal'`

`'interactions'` — Indicator for interaction between multinomial categories and coefficients

`'on'` | `'off'`

Indicator for an interaction between the multinomial categories and coefficients in the model fit by `mnrfit`, specified as the comma-separated pair consisting of `'interactions'` and one of the following.

`'on'`	Default for nominal and hierarchical models. Specify to fit a model with different intercepts and coefficients across categories.
`'off'`	Default for ordinal models. Specify to fit a model with different intercepts, but a common set of coefficients for the predictor variables, across all multinomial categories. This is often described as *parallel regression* or *proportional odds model*.

Example: `'interactions','off'`

Data Types: `logical`

`'link'` — Link function

`'logit'` (default) | `'probit'` | `'comploglog'` | `'loglog'`

Link function `mnrfit` uses for ordinal and hierarchical models, specified as the comma-separated pair consisting of `'link'` and one of the following.

`'logit'`	Default. $f(\gamma) = \ln(\gamma/(1-\gamma))$
`'probit'`	$f(\gamma) = \Phi^{-1}(\gamma)$ — error term is normally distributed with variance 1
`'comploglog'`	Complementary log-log $f(\gamma) = \ln(-\ln(1-\gamma))$
`'loglog'`	$f(\gamma) = \ln(-\ln(\gamma))$

The link function defines the relationship between response probabilities and the linear combination of predictors, $X\beta$.

γ might be cumulative or conditional probabilities based on whether the model is for an ordinal or a sequential/nested response.

You cannot specify the `'link'` parameter for nominal models; these always use a multinomial logit link,

$$\ln\left(\frac{\pi_j}{\pi_r}\right) = \beta_{j0} + \beta_{j1}X_{j1} + \beta_{j2}X_{j2} + \cdots + \beta_{jp}X_{jp}, \quad j = 1, \ldots, k-1,$$

where π stands for a categorical probability, and r corresponds to the reference category, k is the total number of response categories, p is the number of predictor variables. `mnrfit` uses the last category as the reference category for nominal models.

Example: `'link','loglog'`

`'type'` — Type of probabilities or counts to estimate

`'category'` (default) | `'cumulative'` | `'conditional'`

Type of probabilities or counts to estimate, specified as the comma-separated pair including `'type'` and one of the following.

`'category'`	Default. Specify to return predictions and error bounds for the probabilities (or counts) of the k multinomial categories.
`'cumulative'`	Specify to return predictions and confidence bounds for the cumulative probabilities (or counts) of the first k – 1 multinomial categories, as an n-by-(k – 1) matrix. The predicted cumulative probability for the kth category is always 1.
`'conditional'`	Specify to return predictions and error bounds in terms of the first k – 1 conditional category probabilities (counts), i.e., the probability (count) for category j, given an outcome in category j or higher. When `'type'` is `'conditional'`, and you supply the sample size argument `ssize`, the predicted counts at each row of `X` are conditioned on the corresponding element of `ssize`, across all categories.

Example: `'type','cumulative'`

`'confidence'` — Confidence level

0.95 (default) | Scalar value in the range (0,1)

Confidence level for the error bounds, specified as the comma-separated pair consisting of `'confidence'` and a scalar value in the range (0,1).

For example, for 99% error bounds, you can specify the confidence as follows:

Example: `'confidence',0.99`

Data Types: `single | double`

Output Arguments

`pihat` — Probability estimates

n-by-(k – 1) matrix

Probability estimates for each multinomial category, returned as an n-by-(k – 1) matrix, where n is the number of observations, and k is the number of response categories.

`yhat` — Count estimates

n-by-k– 1 matrix

Count estimates for the number in each response category, returned as an n-by-k – 1 matrix, where n is the number of observations, and k is the number of response categories.

`dlow` — Lower error bound

column vector

Lower error bound to compute the lower confidence bound for pihat or yhat, returned as a column vector.

The lower confidence bound for `pihat` is `pihat` minus `dlow`. Similarly, the lower confidence bound for `yhat` is `yhat` minus `dlow`. Confidence bounds are nonsimultaneous and only apply to the fitted curve, not to new observations.

`dhi` — Upper error bound

column vector

Upper error bound to compute the upper confidence bound for pihat or yhat, returned as a column vector.

The upper confidence bound for `pihat` is `pihat` plus `dhi`. Similarly, the upper confidence bound for `yhat` is `yhat` plus `dhi`. Confidence bounds are nonsimultaneous and only apply to the fitted curve, not to new observations.

moment

Central moments

Syntax

```
m = moment(X,order)
moment(X,order,dim)
```

Description

`m = moment(X,order)` returns the central sample moment of `X` specified by the positive integer `order`. For vectors, `moment(x,order)` returns the central moment of the specified order for the elements of `x`. For matrices, `moment(X,order)` returns central moment of the specified order for each column. For N-dimensional arrays, `moment` operates along the first nonsingleton dimension of `X`.

`moment(X,order,dim)` takes the moment along dimension `dim` of `X`.

Examples

```
X = randn([6 5])
X =
  1.1650  0.0591  1.2460 -1.2704 -0.0562
  0.6268  1.7971 -0.6390  0.9846  0.5135
  0.0751  0.2641  0.5774 -0.0449  0.3967
  0.3516  0.8717 -0.3600 -0.7989  0.7562
 -0.6965 -1.4462 -0.1356 -0.7652  0.4005
  1.6961 -0.7012 -1.3493  0.8617 -1.3414

m = moment(X,3)
m =
  -0.0282  0.0571  0.1253  0.1460  -0.4486
```

More About

Tips

Note that the central first moment is zero, and the second central moment is the variance computed using a divisor of n rather than $n – 1$, where n is the length of the vector `x` or the number of rows in the matrix `X`.

The central moment of order k of a distribution is defined as

$$m_k = E(x - \mu)^k$$

where $E(x)$ is the expected value of x.

`kurtosis` | `mean` | `skewness` | `std` | `var`

mu property

Class: gmdistribution

Input matrix of means `mu`

Description

Input matrix of means `mu`.

multcompare

Multiple comparison test

Syntax

```
c = multcompare(stats)
c = multcompare(stats,Name,Value)
[c,m] = multcompare( ___ )
[c,m,h] = multcompare( ___ )
[c,m,h,gnames] = multcompare( ___ )
```

Description

`c = multcompare(stats)` returns a matrix c of the pairwise comparison results from a multiple comparison test using the information contained in the stats structure. `multcompare` also displays an interactive graph of the estimates and comparison intervals. Each group mean is represented by a symbol, and the interval is represented by a line extending out from the symbol. Two group means are significantly different if their intervals are disjoint; they are not significantly different if their intervals overlap. If you use your mouse to select any group, then the graph will highlight all other groups that are significantly different, if any.

`c = multcompare(stats,Name,Value)` returns a matrix of pairwise comparison results, c, using additional options specified by one or more `Name,Value` pair arguments. For example, you can specify the confidence interval, or the type of critical value to use in the multiple comparison.

`[c,m] = multcompare( ___ )` also returns a matrix, m, which contains estimated values of the means (or whatever statistics are being compared) for each group and the corresponding standard errors. You can use any of the previous syntaxes.

`[c,m,h] = multcompare( ___ )` also returns a handle, h, to the comparison graph.

`[c,m,h,gnames] = multcompare( ___ )` also returns a cell array, `gnames`, which contains the names of the groups.

Examples

Multiple Comparison of Group Means

Load the sample data.

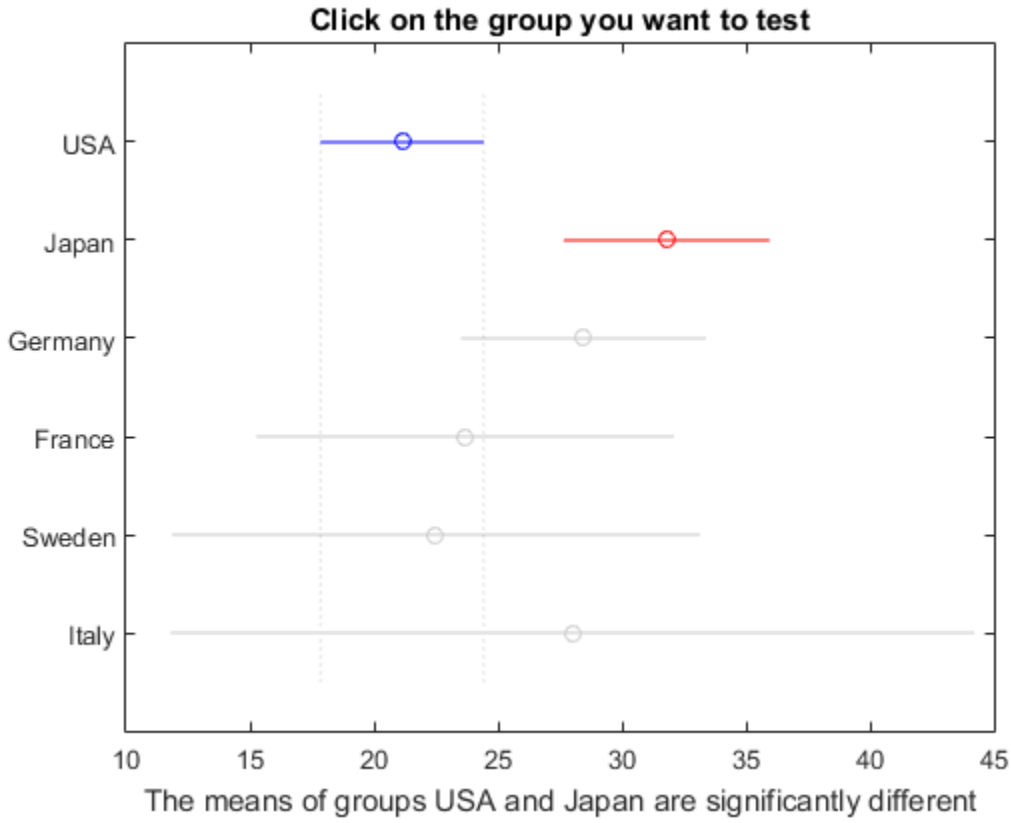
```
load carsmall
```

Perform a one-way analysis of variance (ANOVA) to see if there is any difference between the mileage of the cars by origin.

```
[p,t,stats] = anova1(MPG,Origin,'off');
```

Perform a multiple comparison of the group means.

```
[c,m,h,nms] = multcompare(stats);
```



`multcompare` displays the estimates with comparison intervals around them. You can click the graphs of each country to compare its mean to those of other countries.

Now display the mean estimates and the standard errors with the corresponding group names.

```
[nms num2cell(m)]
```

```
ans =

    'USA'        [21.1328]    [0.8814]
    'Japan'      [31.8000]    [1.8206]
    'Germany'    [28.4444]    [2.3504]
```

```
    'France'     [23.6667]    [4.0711]
    'Sweden'     [22.5000]    [4.9860]
    'Italy'      [     28]    [7.0513]
```

Multiple Comparisons for Two-Way ANOVA

Load the sample data.

```
load popcorn
popcorn
```

```
popcorn =

    5.5000    4.5000    3.5000
    5.5000    4.5000    4.0000
    6.0000    4.0000    3.0000
    6.5000    5.0000    4.0000
    7.0000    5.5000    5.0000
    7.0000    5.0000    4.5000
```

The data is from a study of popcorn brands and popper types (Hogg 1987). The columns of the matrix `popcorn` are brands (Gourmet, National, and Generic). The rows are popper types oil and air. In the study, researchers popped a batch of each brand three times with each popper. The values are the yield in cups of popped popcorn.

Perform a two-way ANOVA. Also compute the statistics that you need to perform a multiple comparison test on the main effects.

```
[~,~,stats] = anova2(popcorn,3,'off')
```

```
stats =

      source: 'anova2'
     sigmasq: 0.1389
    colmeans: [6.2500 4.7500 4]
        coln: 6
    rowmeans: [4.5000 5.5000]
        rown: 9
       inter: 1
        pval: 0.7462
```

```
          df: 12
```

The `stats` structure includes

- The mean squared error (`sigmasq`)
- The estimates of the mean yield for each popcorn brand (`colmeans`)
- The number of observations for each popcorn brand (`coln`)
- The estimate of the mean yield for each popper type (`rowmeans`)
- The number of observations for each popper type (`rown`)
- The number of interactions (`inter`)
- The *p*-value that shows the significance level of the interaction term (`pval`)
- The error degrees of freedom (`df`).

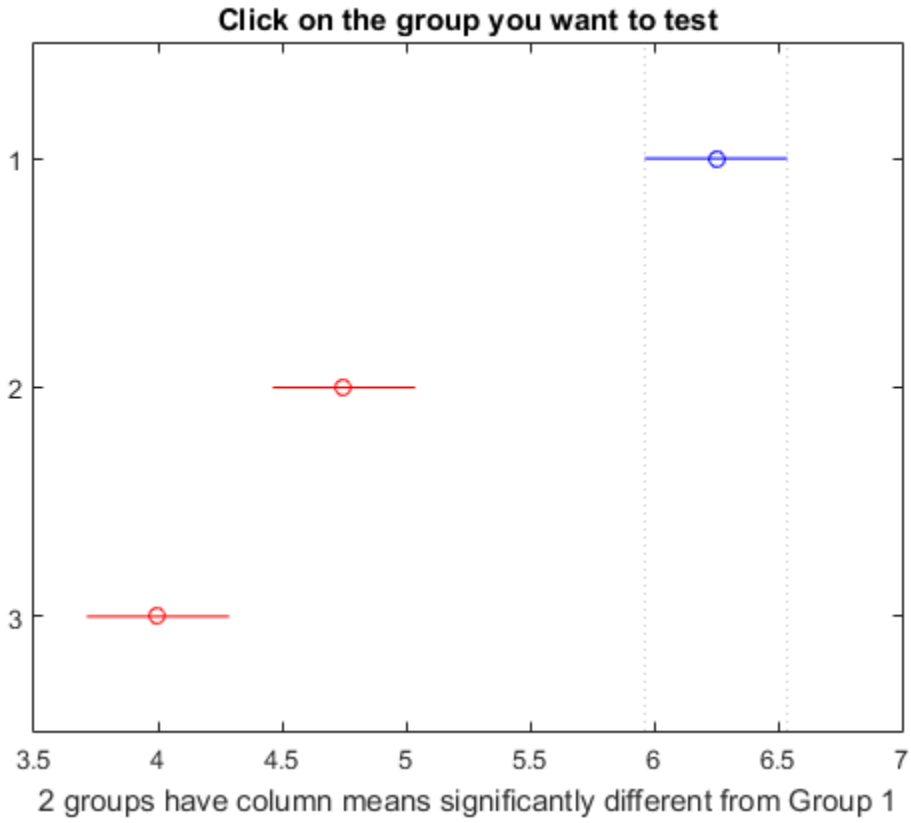
Perform a multiple comparison test to see if the popcorn yield differs between pairs of popcorn brands (columns).

```
c = multcompare(stats)
```

```
Note: Your model includes an interaction term.  A test of main effects can be
difficult to interpret when the model includes interactions.

c =

    1.0000    2.0000    0.9260    1.5000    2.0740    0.0000
    1.0000    3.0000    1.6760    2.2500    2.8240    0.0000
    2.0000    3.0000    0.1760    0.7500    1.3240    0.0116
```



The first two columns of `c` show the groups that are compared. The fourth column shows the difference between the estimated group means. The third and fifth columns show the lower and upper limits for 95% confidence intervals for the true mean difference. The sixth column contains the *p*-value for a hypothesis test that the corresponding mean difference is equal to zero. All *p*-values (0, 0, and 0.0116) are very small, which indicates that the popcorn yield differs across all three brands.

The figure shows the multiple comparison of the means. By default, the group 1 mean is highlighted and the comparison interval is in blue. Because the comparison intervals for the other two groups do not intersect with the intervals for the group 1 mean, they are highlighted in red. This lack of intersection indicates that both means are different than group 1 mean. Select other group means to confirm that all group means are significantly different from each other.

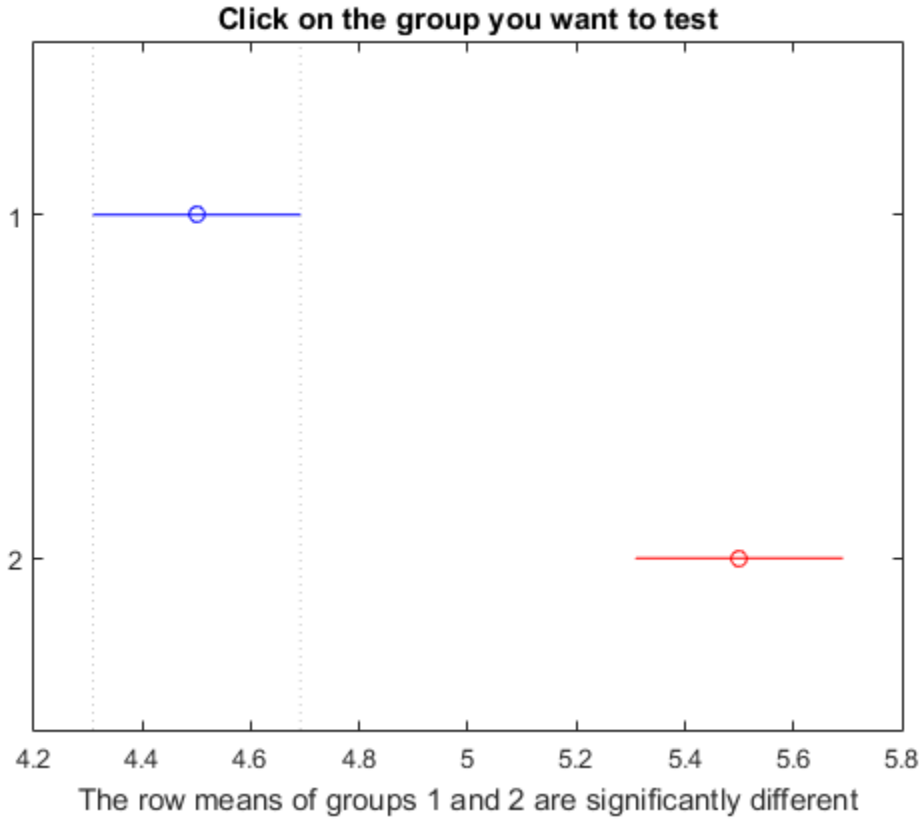
Perform a multiple comparison test to see the popcorn yield differs between the two popper types (rows).

```
c = multcompare(stats,'Estimate','row')
```

```
Note: Your model includes an interaction term.  A test of main effects can be
difficult to interpret when the model includes interactions.

c =

    1.0000    2.0000   -1.3828   -1.0000   -0.6172    0.0001
```



The small *p*-value of 0.0001 indicates that the popcorn yield differs between the two popper types (air and oil). The figure shows the same results. The disjoint comparison intervals indicate that the group means are significantly different from each other.

Multiple Comparisons for Three-Way ANOVA

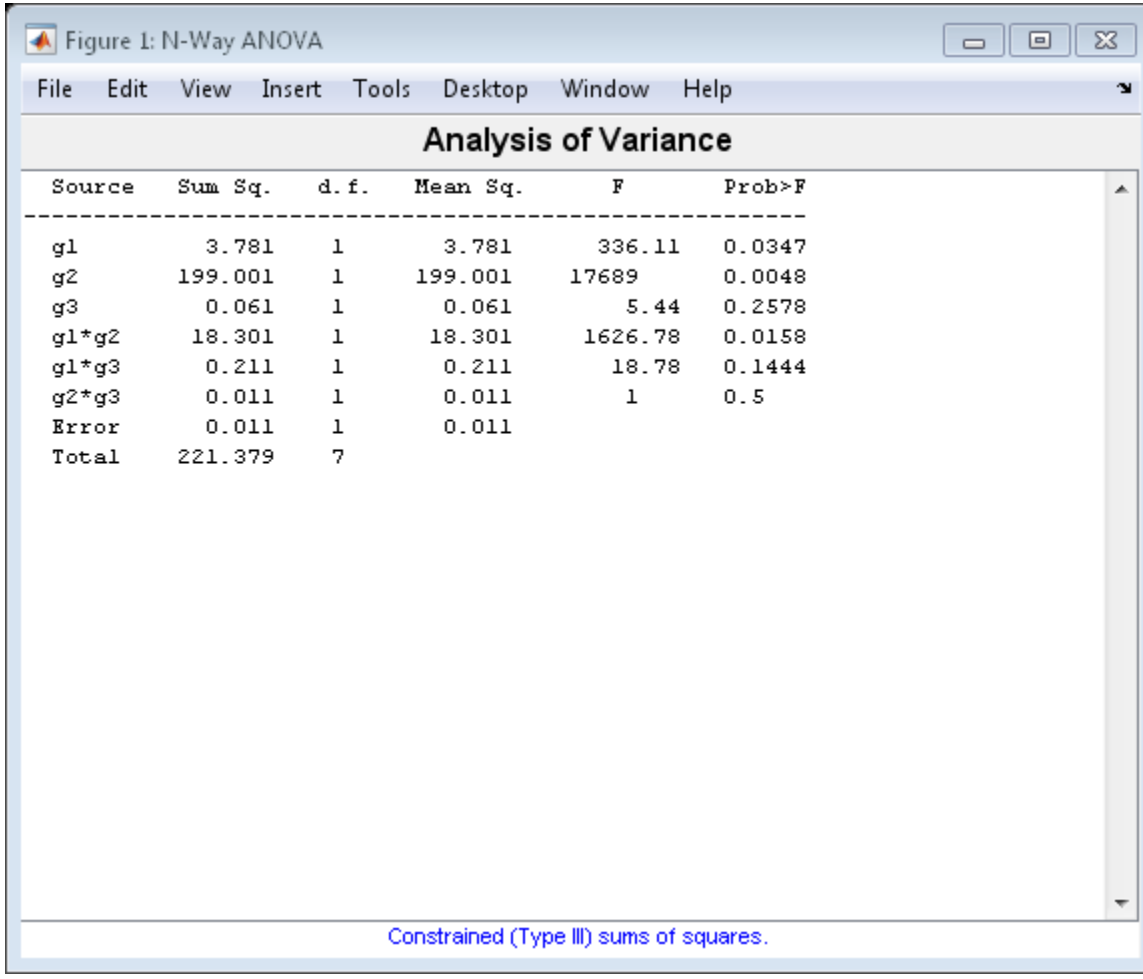
Load the sample data.

```
y = [52.7 57.5 45.9 44.5 53.0 57.0 45.9 44.0]';
g1 = [1 2 1 2 1 2 1 2];
g2 = {'hi';'hi';'lo';'lo';'hi';'hi';'lo';'lo'};
g3 = {'may';'may';'may';'may';'june';'june';'june';'june'};
```

`y` is the response vector and `g1`, `g2`, and `g3` are the grouping variables (factors). Each factor has two levels, and every observation in `y` is identified by a combination of factor levels. For example, observation `y(1)` is associated with level 1 of factor `g1`, level `'hi'` of factor `g2`, and level `'may'` of factor `g3`. Similarly, observation `y(6)` is associated with level 2 of factor `g1`, level `'hi'` of factor `g2`, and level `'june'` of factor `g3`.

Test if the response is the same for all factor levels. Also compute the statistics required for multiple comparison tests.

```
[~,~,stats] = anovan(y,{g1 g2 g3},'model','interaction',...
    'varnames',{'g1','g2','g3'});
```



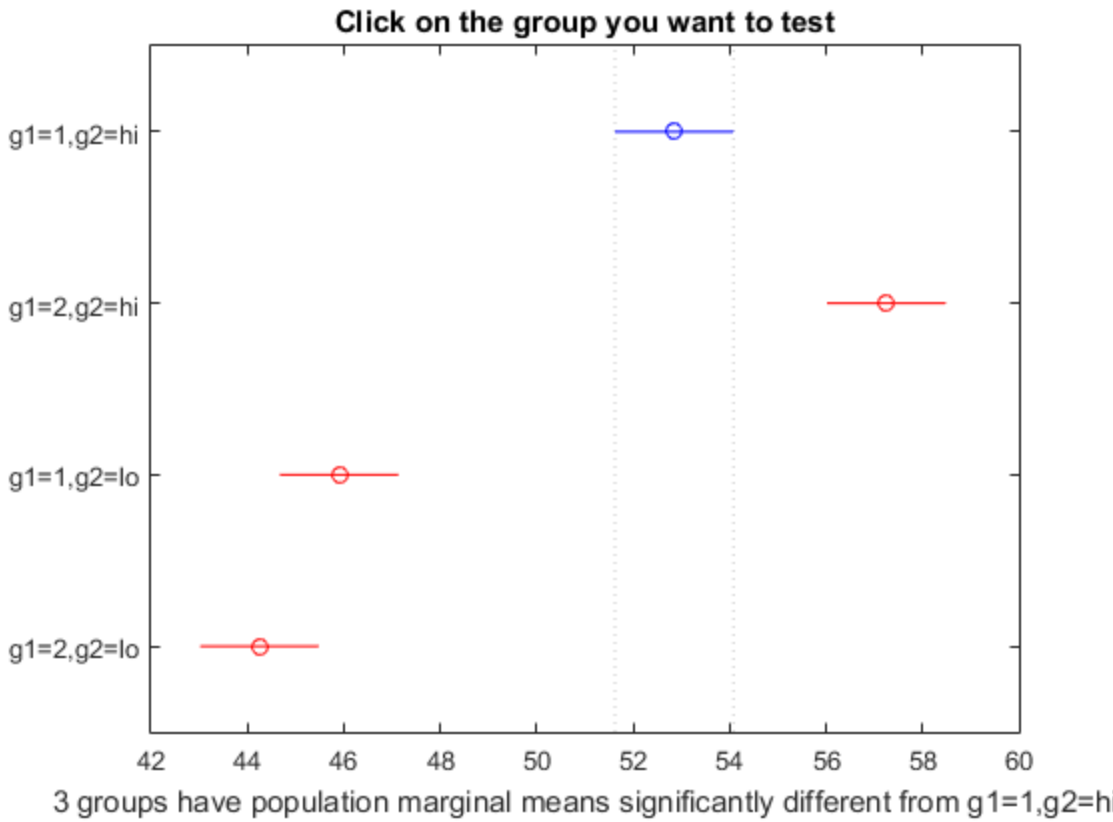
The p-value of 0.2578 indicates that the mean responses for levels `'may'` and `'june'` of factor `g3` are not significantly different. The p-value of 0.0347 indicates that the mean responses for levels `1` and `2` of factor `g1` are significantly different. Similarly, the p-value of 0.0048 indicates that the mean responses for levels `'hi'` and `'lo'` of factor `g2` are significantly different.

Perform multiple comparison tests to find out which groups of the factors `g1` and `g2` are significantly different.

```
results = multcompare(stats,'Dimension',[1 2])
```

```
results =

    1.0000    2.0000   -6.8604   -4.4000   -1.9396    0.0280
    1.0000    3.0000    4.4896    6.9500    9.4104    0.0177
    1.0000    4.0000    6.1396    8.6000   11.0604    0.0143
    2.0000    3.0000    8.8896   11.3500   13.8104    0.0108
    2.0000    4.0000   10.5396   13.0000   15.4604    0.0095
    3.0000    4.0000   -0.8104    1.6500    4.1104    0.0745
```



multcompare compares the combinations of groups (levels) of the two grouping variables, `g1` and `g2`. In the `results` matrix, the number 1 corresponds to the combination of level `1` of `g1` and level `hi` of `g2`, the number 2 corresponds to the combination of level `2` of `g1` and level `hi` of `g2`. Similarly, the number 3 corresponds to the combination of level `1` of `g1` and level `lo` of `g2`, and the number 4 corresponds to the combination of level `2` of `g1` and level `lo` of `g2`. The last column of the matrix contains the *p*-values.

For example, the first row of the matrix shows that the combination of level `1` of `g1` and level `hi` of `g2` has the same mean response values as the combination of level `2` of `g1` and level `hi` of `g2`. The *p*-value corresponding to this test is 0.0280, which indicates that the mean responses are significantly different. You can also see this result in the figure. The blue bar shows the comparison interval for the mean response for the combination of level `1` of `g1` and level `hi` of `g2`. The red bars are the comparison intervals for the mean response for other group combinations. None of the red bars overlap with the blue bar, which means the mean response for the combination of level `1` of `g1` and level `hi` of `g2` is significantly different from the mean response for other group combinations.

You can test the other groups by clicking on the corresponding comparison interval for the group. The bar you click on turns to blue. The bars for the groups that are significantly different are red. The bars for the groups that are not significantly different are gray. For example, if you click on the comparison interval for the combination of level `1` of `g1` and level `lo` of `g2`, the comparison interval for the combination of level `2` of `g1` and level `lo` of `g2` overlaps, and is therefore gray. Conversely, the other comparison intervals are red, indicating significant difference.

Input Arguments

`stats` — Test data

structure

Test data, specified as a structure. You can create a structure using one of the following functions:

- `anova1` — One-way analysis of variance.
- `anova2` — Two-way analysis of variance.
- `anovan` — *N*-way analysis of variance.
- `aoctool` — Interactive analysis of covariance tool.
- `friedman` — Friedman's test.

- `kruskalwallis` — Kruskal-Wallis test.

`multcompare` does not support multiple comparisons using `anovan` output for a model that includes random or nested effects. The calculations for a random effects model produce a warning that all effects are treated as fixed. Nested models are not accepted.

Data Types: `struct`

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'Alpha',0.01,'CType','bonferroni','Display','off'` computes the Bonferroni critical values, conducts the hypothesis tests at the 1% significance level, and omits the interactive display.

`'Alpha'` — Significance level

`0.05` (default) | scalar value in the range (0,1)

Significance level of the multiple comparison test, specified as the comma-separated pair consisting of `'Alpha'` and a scalar value in the range (0,1). The value specified for `'Alpha'` determines the $100 \times (1 - \alpha)$ confidence levels of the intervals returned in the matrix c and in the figure.

Example: `'Alpha',0.01`

Data Types: `single` | `double`

`'CType'` — Type of critical value

`'tukey-kramer'` (default) | `'hsd'` | `'lsd'` | `'bonferroni'` | `'dunn-sidak'` | `'scheffe'`

Type of critical value to use for the multiple comparison, specified as the comma-separated pair consisting of `'CType'` and one of the following.

Value	Description
`'tukey-kramer'` or `'hsd'`	Tukey's honest significant difference criterion
`'bonferroni'`	Bonferroni method

Value	Description
'dunn-sidak'	Dunn and Sidák's approach
'lsd'	Fisher's least significant difference procedure
'scheffe'	Scheffé's S procedure

Example: 'CType','bonferroni'

'Display' — Display toggle

'on' (default) | 'off'

Display toggle, specified as the comma-separated pair consisting of 'Display' and either 'on' or 'off'. If you specify 'on', then multcompare displays a graph of the estimates and their comparison intervals. If you specify 'off', then multcompare omits the graph.

Example: 'Display','off'

'Dimension' — Dimension over which to calculate marginal means

1 (default) | positive integer value | vector of positive integer values

A vector specifying the dimension or dimensions over which to calculate the population marginal means, specified as a positive integer value, or a vector of such values. Use the 'Dimension' name-value pair only if you create the input structure stats using the function anovan.

For example, if you specify 'Dimension' as 1, then multcompare compares the means for each value of the first grouping variable, adjusted by removing effects of the other grouping variables as if the design were balanced. If you specify 'Dimension'as [1,3], then multcompare computes the population marginal means for each combination of the first and third grouping variables, removing effects of the second grouping variable. If you fit a singular model, some cell means may not be estimable and any population marginal means that depend on those cell means will have the value NaN.

Population marginal means are described by Milliken and Johnson (1992) and by Searle, Speed, and Milliken (1980). The idea behind population marginal means is to remove any effect of an unbalanced design by fixing the values of the factors specified by 'Dimension', and averaging out the effects of other factors as if each factor combination occurred the same number of times. The definition of population marginal means does not depend on the number of observations at each factor combination. For designed experiments where the number of observations at each factor combination has no meaning, population marginal means can be easier to interpret than simple means

ignoring other factors. For surveys and other studies where the number of observations at each combination does have meaning, population marginal means may be harder to interpret.

Example: `'Dimension',[1,3]`

Data Types: `single` | `double`

`'Estimate'` — Estimates to be compared

`'column'` (default) | `'row'` | `'slope'` | `'intercept'` | `'pmm'`

Estimates to be compared, specified as the comma-separated pair consisting of `'Estimate'` and an allowable value. The allowable values for `'Estimate'` depend on the function used to generate the input structure stats, according to the following table.

Source	Values
`anova1`	None. This name-value pair is ignored, and `multcompare` always compares the group means.
`anova2`	Either `'column'` to compare column means, or `'row'` to compare row means.
`anovan`	None. This name-value pair is ignored, and `multcompare` always compares the population marginal means as specified by the `'Dimension'` name-value pair argument.
`aoctool`	Either `'slope'`, `'intercept'`, or `'pmm'` to compare slopes, intercepts, or population marginal means, respectively. If the analysis of covariance model did not include separate slopes, then `'slope'` is not allowed. If it did not include separate intercepts, then no comparisons are possible.
`friedman`	None. This name-value pair is ignored, and `multcompare` always compares the average column ranks.
`kruskalwallis`	None. This name-value pair is ignored, and `multcompare` always compares the average group ranks.

Example: `'Estimate','row'`

Output Arguments

`c` — Matrix of multiple comparison results

matrix of scalar values

Matrix of multiple comparison results, returned as an p-by-6 matrix of scalar values, where p is the number of pairs of groups. Each row of the matrix contains the result of one paired comparison test. Columns 1 and 2 contain the indices of the two samples being compared. Column 3 contains the lower confidence interval, column 4 contains the estimate, and column 5 contains the upper confidence interval. Column 6 contains the p-value for the hypothesis test that the corresponding mean difference is not equal to 0.

For example, suppose one row contains the following entries.

```
2.0000   5.0000   1.9442   8.2206   14.4971 0.0432
```

These numbers indicate that the mean of group 2 minus the mean of group 5 is estimated to be 8.2206, and a 95% confidence interval for the true difference of the means is [1.9442, 14.4971]. The p-value for the corresponding hypothesis test that the difference of the means of groups 2 and 5 is significantly different from zero is 0.0432.

In this example the confidence interval does not contain 0, so the difference is significant at the 5% significance level. If the confidence interval did contain 0, the difference would not be significant. The p-value of 0.0432 also indicates that the difference of the means of groups 2 and 5 is significantly different from 0.

`m` — Matrix of estimates

matrix of scalar values

Matrix of the estimates, returned as a matrix of scalar values. The first column of `m` contains the estimated values of the means (or whatever statistics are being compared) for each group, and the second column contains their standard errors.

`h` — Handle to the figure

handle

Handle to the figure containing the interactive graph, returned as a handle. The title of this graph contains instructions for interacting with the graph, and the x-axis label contains information about which means are significantly different from the selected mean. If you plan to use this graph for presentation, you may want to omit the title and the x-axis label. You can remove them using interactive features of the graph window, or you can use the following commands.

```
title('')
xlabel('')
```

`gnames` — Group names

cell array of strings

Group names, returned as a cell array of strings. Each row of gnames contains the name of a group.

More About

Multiple Comparison Tests

Analysis of variance compares the means of several groups to test the hypothesis that they are all equal, against the general alternative that they are not all equal. Sometimes this alternative may be too general. You may need information about which pairs of means are significantly different, and which are not. A *multiple comparison test* can provide this information.

When you perform a simple *t*-test of one group mean against another, you specify a significance level that determines the cutoff value of the *t*-statistic. For example, you can specify the value `alpha = 0.05` to insure that when there is no real difference, you will incorrectly find a significant difference no more than 5% of the time. When there are many group means, there are also many pairs to compare. If you applied an ordinary *t*-test in this situation, the `alpha` value would apply to each comparison, so the chance of incorrectly finding a significant difference would increase with the number of comparisons. Multiple comparison procedures are designed to provide an upper bound on the probability that *any* comparison will be incorrectly found significant.

multcompare

Class: RepeatedMeasuresModel

Multiple comparison of estimated marginal means

Syntax

```
tbl = multcompare(rm,var)
tbl = multcompare(rm,var,Name,Value)
```

Description

`tbl = multcompare(rm,var)` returns multiple comparisons of the estimated marginal means based on the variable var in the repeated measures model rm.

`tbl = multcompare(rm,var,Name,Value)` returns multiple comparisons of the estimated marginal means with additional options specified by one or more Name,Value pair arguments.

For example, you can specify the comparison type or which variable to group by.

Input Arguments

`rm` — Repeated measures model

`RepeatedMeasuresModel` object

Repeated measures model, returned as a `RepeatedMeasuresModel` object.

For properties and methods of this object, see `RepeatedMeasuresModel`.

`var` — Variables for which to compute marginal means

string

Variables for which to compute the marginal means, specified as a string representing the name of a between- or within-subjects factor in rm. If `var` is a between-subjects factor, it must be categorical.

Data Types: `char` | `cell`

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'Alpha'` — Confidence level

0.05 (default) | scalar value in the range of 0 through 1

Confidence level of the confidence intervals for population marginal means, specified as the comma-separated pair consisting of `'alpha'` and a scalar value in the range of 0 through 1. The confidence level is 100*(1–`alpha`)%.

Example: `'alpha',0.01`

Data Types: `double | single`

`'By'` — Factor to perform comparisons by

string

Factor to do the comparisons by, specified as the comma-separated pair consisting of `'By'` and a string. The comparison between levels of var occurs separately for each value of the factor you specify.

If you have more then one between-subjects factors, *A*, *B*, and *C*, and if you want to do the comparisons of *A* levels separately for each level of *C*, then specify *A* as the `var` argument and specify *C* using the `'By'` argument as follows.

Example: `'By',C`

Data Types: `char`

`'ComparisonType'` — Type of critical value to use

`'tukey-kramer'` (default) | `'dunn-sidak'` | `'bonferroni'` | `'scheffe'` | `'lsd'`

Type of critical value to use, specified as the comma-separated pair consisting of `'ComparisonType'` and one of the following.

Comparison Type	Definition
`'tukey-kramer'`	Default. Also called Tukey's Honest Significant Difference procedure. It is based on the Studentized range

Comparison Type	Definition
	distribution. According to the unproven Tukey-Kramer conjecture, it is also accurate for problems where the quantities being compared are correlated, as in analysis of covariance with unbalanced covariate values.
`'dunn-sidak'`	Use critical values from the *t* distribution, after an adjustment for multiple comparisons that was proposed by Dunn and proved accurate by Sidák. The critical value is $$\left|t\right| = \frac{\left|\bar{y}_i - \bar{y}_j\right|}{\sqrt{MSE\left(\frac{1}{n_i} + \frac{1}{n_j}\right)}} > t_{1-\eta/2,v},$$ where $$\eta = 1 - \left(1-\alpha\right)^{1/\binom{k}{2}}$$ and *ng* is the number of groups (marginal means). This procedure is similar to, but less conservative than, the Bonferroni procedure.

Comparison Type	Definition
`'bonferroni'`	Use critical values from the t distribution, after a Bonferroni adjustment to compensate for multiple comparisons. The critical value is $t_{\alpha/2\binom{ng}{2},v}$, where ng is the number of groups (marginal means), and v is the error degrees of freedom. This procedure is conservative, but usually less so than the Scheffé procedure.
`'scheffe'`	Use critical values from Scheffé's S procedure, derived from the Fdistribution. The critical value is $\sqrt{(ng-1)F_{\alpha,ng-1,v}}$, where ng is the number of groups (marginal means), and v is the error degrees of freedom. This procedure provides a simultaneous confidence level for comparisons of all linear combinations of the means, and it is conservative for comparisons of simple differences of pairs.
`'lsd'`	Least significant difference. This option uses plain t-tests. The critical value is $t_{\alpha/2,v}$, where v is the error degrees of freedom. It provides no protection against the multiple comparison problem.

Example: `'ComparisonType','dunn-sidak'`

Output Arguments

`tbl` — Results of multiple comparison

table

Results of multiple comparisons of estimated marginal means, returned as a table. tbl has the following columns.

Column Name	Description
`Difference`	Estimated difference between the corresponding two marginal means
`StdErr`	Standard error of the estimated difference between the corresponding two marginal means
`pValue`	*p*-value for a test that the difference between the corresponding two marginal means is 0
`Lower`	Lower limit of simultaneous 95% confidence intervals for the true difference
`Upper`	Upper limit of simultaneous 95% confidence intervals for the true difference

Examples

Multiple Comparison of Estimated Marginal Means

Load the sample data.

```
load fisheriris
```

The column vector `species`consists of iris flowers of three different species: setosa, versicolor, and virginica. The double matrix `meas` consists of four types of measurements on the flowers: the length and width of sepals and petals in centimeters, respectively.

Store the data in a table array.

```
t = table(species,meas(:,1),meas(:,2),meas(:,3),meas(:,4),...
'VariableNames',{'species','meas1','meas2','meas3','meas4'});
Meas = dataset([1 2 3 4]','VarNames',{'Measurements'});
```

Fit a repeated measures model, where the measurements are the responses and the species is the predictor variable.

```
rm = fitrm(t,'meas1-meas4~species','WithinDesign',Meas);
```

Perform a multiple comparison of the estimated marginal means of species.

```
tbl = multcompare(rm,'species')
```

```
tbl =

     species_1       species_2      Difference     StdErr       pValue       Lower
    ____________    ____________    __________    ________    __________    ________

    'setosa'        'versicolor'    -1.0375       0.060539    9.5606e-10     -1.1794
    'setosa'        'virginica'     -1.7495       0.060539    9.5606e-10     -1.8914
    'versicolor'    'setosa'         1.0375       0.060539    9.5606e-10     0.89562
    'versicolor'    'virginica'      -0.712       0.060539    9.5606e-10    -0.85388
    'virginica'     'setosa'         1.7495       0.060539    9.5606e-10      1.6076
    'virginica'     'versicolor'      0.712       0.060539    9.5606e-10     0.57012
```

The small p-values (in the `pValue` field) indicate that the estimated marginal means for the three species significantly differ from each other.

Perform Multiple Comparisons with Specified Options

Load the sample data.

```
load repeatedmeas
```

The table `between` includes the between-subject variables age, IQ, group, gender, and eight repeated measures $y1$ through $y8$ as responses. The table `within` includes the within-subject variables $w1$ and $w2$. This is simulated data.

Fit a repeated measures model, where the repeated measures $y1$ through $y8$ are the responses, and age, IQ, group, gender, and the group-gender interaction are the predictor variables. Also specify the within-subject design matrix.

```
R = fitrm(between,'y1-y8 ~ Group*Gender + Age + IQ','WithinDesign',within);
```

Perform a multiple comparison of the estimated marginal means based on the variable `Group`.

```
T = multcompare(R,'Group')
```

```
T =

    Group_1    Group_2    Difference    StdErr      pValue        Lower       Upper
```

A	B	4.9875	5.6271	0.65436	-9.1482	19.123
A	C	23.094	5.9261	0.0021493	8.2074	37.981
B	A	-4.9875	5.6271	0.65436	-19.123	9.1482
B	C	18.107	5.8223	0.013588	3.4805	32.732
C	A	-23.094	5.9261	0.0021493	-37.981	-8.2074
C	B	-18.107	5.8223	0.013588	-32.732	-3.4805

The small *p*-value of 0.0021493 indicates that there is significant difference between the marginal means of groups A and C. The *p*-values of 0.65436 indicates that the difference between the marginal means for groups A and B is not significantly different from 0.

`multcompare` uses the Tukey-Kramer test statistic by default. Change the comparison type to the Scheffe procedure.

```
T = multcompare(R,'Group','ComparisonType','Scheffe')
```

```
T =
```

Group_1	Group_2	Difference	StdErr	pValue	Lower	Upper
A	B	4.9875	5.6271	0.67981	-9.7795	19.755
A	C	23.094	5.9261	0.0031072	7.5426	38.646
B	A	-4.9875	5.6271	0.67981	-19.755	9.7795
B	C	18.107	5.8223	0.018169	2.8273	33.386
C	A	-23.094	5.9261	0.0031072	-38.646	-7.5426
C	B	-18.107	5.8223	0.018169	-33.386	-2.8273

The Scheffe test produces larger *p*-values, but similar conclusions.

Perform multiple comparisons of estimated marginal means based on the variable `Group` for each gender separately.

```
T = multcompare(R,'Group','By','Gender')
```

```
T =
```

Gender	Group_1	Group_2	Difference	StdErr	pValue	Lower	
Female	A	B	4.1883	8.0177	0.86128	-15.953	
Female	A	C	24.565	8.2083	0.017697	3.9449	
Female	B	A	-4.1883	8.0177	0.86128	-24.329	

```
Female    B          C           20.376       8.1101     0.049957     0.0033459
Female    C          A          -24.565       8.2083     0.017697       -45.184
Female    C          B          -20.376       8.1101     0.049957       -40.749    -(
Male      A          B           5.7868       7.9498      0.74977       -14.183
Male      A          C            21.624      8.1829     0.038022        1.0676
Male      B          A          -5.7868       7.9498      0.74977       -25.757
Male      B          C           15.837       8.0511      0.14414       -4.3881
Male      C          A          -21.624       8.1829     0.038022       -42.179
Male      C          B          -15.837       8.0511      0.14414       -36.062
```

The results indicate that the difference between marginal means for groups A and B is not significant from 0 for either gender (corresponding p-values are 0.86128 for females and 0.74977 for males). The difference between marginal means for groups A and C is significant for both genders (corresponding p-values are 0.017697 for females and 0.038022 for males). While the difference between marginal means for groups B and C is significantly different from 0 for females (p-value is 0.049957), it is not significantly different from 0 for males (p-value is 0.14414).

prob.MultinomialDistribution class

Package: prob
Superclasses: prob.ParametricTruncatableDistribution

Multinomial probability distribution object

Description

`prob.MultinomialDistribution` is an object consisting of parameters and a model description for a multinomial probability distribution. Create a probability distribution object with specified parameters using `makedist`.

Construction

`pd = makedist('Multinomial')` creates a multinomial probability distribution object using the default parameter values.

`pd = makedist('Multinomial','Probabilities',probabilities)` creates a multinomial distribution object using the specified parameter value.

Input Arguments

`probabilities` — outcome probabilities
`[0.500 0.500]` (default) | vector of scalar values in the range `[0,1]`

Outcome probabilities, specified as a vector of scalar values in the range `[0,1]`. Each vector element is the probability that a multinomial trial has a particular corresponding outcome. The values in `probabilities` must sum to 1.

Data Types: `single` | `double`

Properties

`probabilities` — outcome probabilities
vector of scalar values in the range `[0,1]`

Outcome probabilities for the multinomial distribution, stored as a vector of scalar values in the range `[0,1]`. The values in `probabilities` must sum to 1.

Data Types: `single | double`

`DistributionName` — Probability distribution name

probability distribution name string

Probability distribution name, stored as a valid probability distribution name string. This property is read-only.

Data Types: `char`

`IsTruncated` — Logical flag for truncated distribution

`0 | 1`

Logical flag for truncated distribution, stored as a logical value. If `IsTruncated` equals `0`, the distribution is not truncated. If `IsTruncated` equals `1`, the distribution is truncated. This property is read-only.

Data Types: `logical`

`NumParameters` — Number of parameters

positive integer value

Number of parameters for the probability distribution, stored as a positive integer value. This property is read-only.

Data Types: `single | double`

`ParameterDescription` — Distribution parameter descriptions

cell array of strings

Distribution parameter descriptions, stored as a cell array of strings. Each cell contains a short description of one distribution parameter. This property is read-only.

Data Types: `char`

`ParameterNames` — Distribution parameter names

cell array of strings

Distribution parameter names, stored as a cell array of strings. This property is read-only.

Data Types: `char`

`ParameterValues` — Distribution parameter values
vector of scalar values

Distribution parameter values, stored as a vector. This property is read-only.

Data Types: `single | double`

`Truncation` — Truncation interval
vector of scalar values

Truncation interval for the probability distribution, stored as a vector containing the lower and upper truncation boundaries. This property is read-only.

Data Types: `single | double`

Methods

Inherited Methods

cdf	Cumulative distribution function of probability distribution object
icdf	Inverse cumulative distribution function of probability distribution object
iqr	Interquartile range of probability distribution object
median	Median of probability distribution object
pdf	Probability density function of probability distribution object
random	Generate random numbers from probability distribution object

truncate	Truncate probability distribution object
mean	Mean of probability distribution object
std	Standard deviation of probability distribution object
var	Variance of probability distribution object

Definitions

Multinomial Distribution

The multinomial distribution is a generalization of the binomial distribution. While the binomial distribution gives the probability of the number of "successes" in n independent trials of a two-outcome process, the multinomial distribution gives the probability of each combination of outcomes in n independent trials of a k-outcome process. The probability of each outcome in any one trial is given by the fixed probabilities p_1, ..., p_k.

The multinomial distribution uses the following parameters.

Parameter	Description	Support
`probabilities`	Outcome probabilities	$0 \le probabilities(i) \le 1$; $\sum_{all(i)} probabilities(i) = 1$

The probability density function (pdf) is

$$f(x \mid n, p) = \frac{n!}{x_1! \ldots x_k!} {p_1}^{x_1} \cdots {p_k}^{x_k} \quad ; \quad \sum_1^k x_i = n \, , \, \sum_1^k p_i = 1 \, ,$$

where $x = (x_1,...,x_k)$ gives the number of each k outcome in n trials of a process with fixed probabilities $p = (p_1,...,p_k)$ of individual outcomes in any one trial.

Examples

Create a Multinomial Distribution Object Using Default Parameters

Create a multinomial distribution object using the default parameter values.

```
pd = makedist('Multinomial')
```

```
pd =

  MultinomialDistribution

  Probabilities:
    0.5000    0.5000
```

Create a Multinomial Distribution Object Using Specified Parameters

Create a multinomial distribution object for a distribution with three possible outcomes. Outcome 1 has a probability of 1/2, outcome 2 has a probability of 1/3, and outcome 3 has a probability of 1/6.

```
pd = makedist('Multinomial','probabilities',[1/2 1/3 1/6])
```

```
pd =

  MultinomialDistribution

  Probabilities:
    0.5000    0.3333    0.1667
```

Generate a random outcome from the distribution.

```
rng('default');  % for reproducibility
r = random(pd)
```

```
r =

     2
```

The result of this trial is outcome 2. By default, the number of trials in each experiment, n, equals 1.

Generate random outcomes from the distribution when the number of trials in each experiment, n, equals 1, and the experiment is repeated ten times.

```
rng('default');  % for reproducibility
```

```
r = random(pd,10,1)

r =

     2
     3
     1
     3
     2
     1
     1
     2
     3
     3
```

Each element in the array is the outcome of an individual experiment that contains one trial.

Generate random outcomes from the distribution when the number of trials in each experiment, n, equals 5, and the experiment is repeated ten times.

```
rng('default');  % for reproducibility
r = random(pd,10,5)

r =

     2     1     2     2     1
     3     3     1     1     1
     1     3     3     1     2
     3     1     3     1     2
     2     2     2     1     1
     1     1     2     2     1
     1     1     2     2     1
     2     3     1     1     2
     3     2     2     3     2
     3     3     1     1     2
```

Each element in the resulting matrix is the outcome of one trial. The columns correspond to the five trials in each experiment, and the rows correspond to the ten experiments. For example, in the first experiment (corresponding to the first row), 2 of the 5 trials resulted in outcome 1, and 3 of the 5 trials resulted in outcome 2.

multivarichart

Multivari chart for grouped data

Syntax

```
multivarichart(y,GROUP)
multivarichart(Y)
multivarichart(...,param1,val1,param2,val2,...)
[charthandle,AXESH] = multivarichart(...)
```

Description

`multivarichart(y,GROUP)` displays the multivari chart for the vector `y` grouped by entries in the cell array `GROUP`. Each cell of `GROUP` must contain a grouping variable that can be a categorical variable, numeric vector, character matrix, or single-column cell array of strings. `GROUP` can also be a matrix whose columns represent different grouping variables. Each grouping variable must have the same number of elements as `y`. The number of grouping variables must be 2, 3, or 4.

Each subplot of the plot matrix contains a multivari chart for the first and second grouping variables. The *x*-axis in each subplot indicates values of the first grouping variable. The legend at the bottom of the figure window indicates values of the second grouping variable. The subplot at position (*i*,*j*) is the multivari chart for the subset of `y` at the *i*th level of the third grouping variable and the *j*th level of the fourth grouping variable. If the third or fourth grouping variable is absent, it is considered to have only one level.

`multivarichart(Y)` displays the multivari chart for a matrix `Y`. The data in different columns represent changes in one factor. The data in different rows represent changes in another factor.

`multivarichart(...,param1,val1,param2,val2,...)` specifies one or more of the following name/value pairs:

- `'varnames'` — Grouping variable names in a character matrix or a cell array of strings, one per grouping variable. Default names are `'X1'`, `'X2'`, ...

- `'plotorder'` — A string with the value `'sorted'` or a vector containing a permutation of the integers from 1 to the number of grouping variables.

  If `'plotorder'` is a string with value `'sorted'`, the grouping variables are rearranged in descending order according to the number of levels in each variable.

  If `'plotorder'` is a vector, it indicates the order in which each grouping variable should be plotted. For example, `[2,3,1,4]` indicates that the second grouping variable should be used as the *x*-axis of each subplot, the third grouping variable should be used as the legend, the first grouping variable should be used as the columns of the plot, and the fourth grouping variable should be used as the rows of the plot.

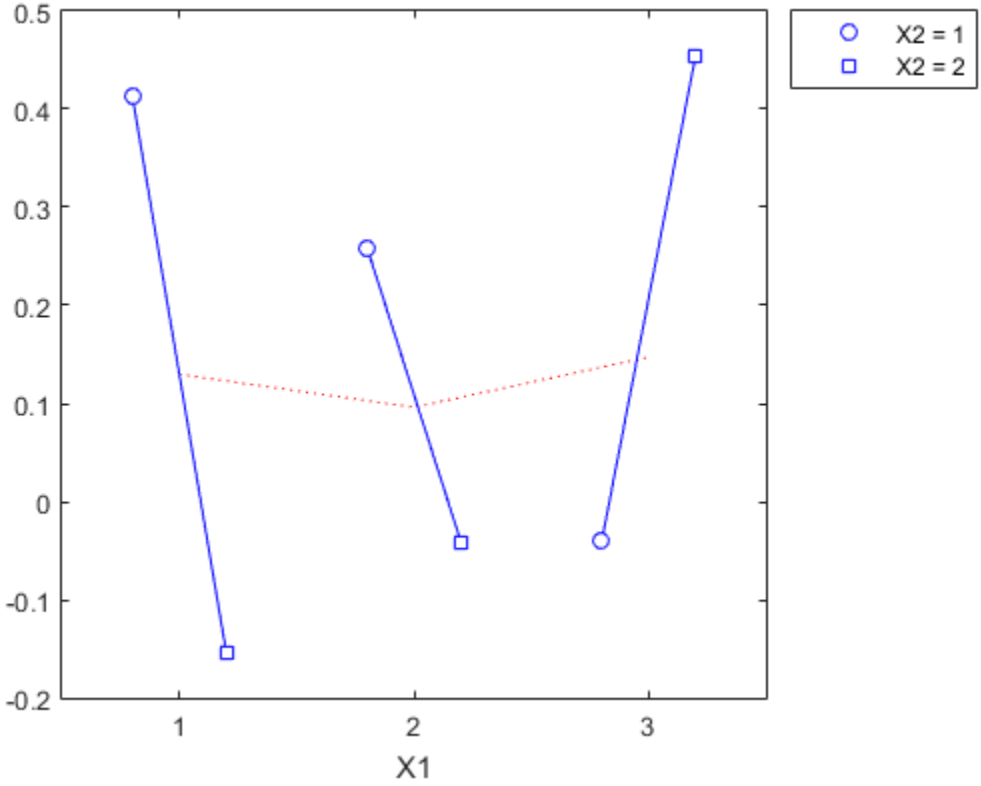
`[charthandle,AXESH] = multivarichart(...)` returns a handle `charthandle` to the figure window and a matrix `AXESH` of handles to the subplot axes.

Examples

Multivari Chart for Grouped Data

Display a multivari chart for data with two grouping variables.

```
rng default; % For reproducibility
y = randn(100,1); % Randomly generate response
group = [ceil(3*rand(100,1)) ceil(2*rand(100,1))];
multivarichart(y,group)
```



Display a multivari chart for data with four grouping variables.

```
y = randn(1000,1); % Randomly generate response
group = {ceil(2*rand(1000,1)),ceil(3*rand(1000,1)), ...
         ceil(2*rand(1000,1)),ceil(3*rand(1000,1))};
multivarichart(y,group)
```

mvncdf

Multivariate normal cumulative distribution function

Syntax

```
y = mvncdf(X)
y = mvncdf(X,mu,SIGMA)
y = mvncdf(xl,xu,mu,SIGMA)
[y,err] = mvncdf(...)
[...] = mvncdf(...,options)
```

Description

`y = mvncdf(X)` returns the cumulative probability of the multivariate normal distribution with zero mean and identity covariance matrix, evaluated at each row of `X`. Rows of the n-by-d matrix `X` correspond to observations or points, and columns correspond to variables or coordinates. `y` is an n-by-`1` vector.

`y = mvncdf(X,mu,SIGMA)` returns the cumulative probability of the multivariate normal distribution with mean `mu` and covariance `SIGMA`, evaluated at each row of `X`. `mu` is a `1`-by-d vector, and `SIGMA` is a d-by-d symmetric, positive definite matrix. `mu` can also be a scalar value, which `mvncdf` replicates to match the size of `X`. If the covariance matrix is diagonal, containing variances along the diagonal and zero covariances off the diagonal, `SIGMA` may also be specified as a `1`-by-d vector containing just the diagonal. Pass in the empty matrix `[]` for `mu` to use as its default value when you want to only specify `SIGMA`.

The multivariate normal cumulative probability at `X` is defined as the probability that a random vector `V`, distributed as multivariate normal, will fall within the semi-infinite rectangle with upper limits defined by `X`, for example, $\texttt{Pr\{V(1)} \le \texttt{X(1),V(2)} \le \texttt{X(2),...,V(}d\texttt{)} \le \texttt{X(}d\texttt{)\}}$.

`y = mvncdf(xl,xu,mu,SIGMA)` returns the multivariate normal cumulative probability evaluated over the rectangle with lower and upper limits defined by `xl` and `xu`, respectively.

`[y,err] = mvncdf(...)` returns an estimate of the error in `y`. For bivariate and trivariate distributions, `mvncdf` uses adaptive quadrature on a transformation of the t density, based on methods developed by Drezner and Wesolowsky and by Genz, as described in the references. The default absolute error tolerance for these cases is `1e-8`. For four or more dimensions, `mvncdf` uses a quasi-Monte Carlo integration algorithm based on methods developed by Genz and Bretz, as described in the references. The default absolute error tolerance for these cases is `1e-4`.

`[...] = mvncdf(...,options)` specifies control parameters for the numerical integration used to compute `y`. This argument can be created by a call to `statset`. Choices of `statset` parameters:

- `'TolFun'` — Maximum absolute error tolerance. Default is `1e-8` when $d < 4$, or `1e-4` when $d \geq 4$.
- `'MaxFunEvals'` — Maximum number of integrand evaluations allowed when $d \geq 4$. Default is `1e7`. `'MaxFunEvals'` is ignored when $d < 4$.
- `'Display'` — Level of display output. Choices are `'off'` (the default), `'iter'`, and `'final'`. `'Display'` is ignored when $d < 4$.

Examples

Compute the Multivariate Normal cdf

Compute and plot the cdf of a multivariate normal distribution with parameters `mu = [1 -1]` and `SIGMA = [.9 .4; .4 .3]`.

```
mu = [1 -1];
SIGMA = [.9 .4; .4 .3];
figure;
[X1,X2] = meshgrid(linspace(-1,3,25)',linspace(-3,1,25)');
X = [X1(:) X2(:)];
p = mvncdf(X,mu,SIGMA);
surf(X1,X2,reshape(p,25,25));
```

Syntax

```
y = mvnpdf(X)
y = mvnpdf(X,MU)
y = mvnpdf(X,MU,SIGMA)
```

Description

`y = mvnpdf(X)` returns the n-by-`1` vector `y`, containing the probability density of the multivariate normal distribution with zero mean and identity covariance matrix, evaluated at each row of the n-by-d matrix `X`. Rows of `X` correspond to observations and columns correspond to variables or coordinates.

`y = mvnpdf(X,MU)` returns the density of the multivariate normal distribution with mean `mu` and identity covariance matrix, evaluated at each row of `X`. `MU` is a `1`-by-d vector, or an n-by-d matrix. If `MU` is a matrix, the density is evaluated for each row of `X` with the corresponding row of `MU`. `MU` can also be a scalar value, which `mvnpdf` replicates to match the size of `X`.

`y = mvnpdf(X,MU,SIGMA)` returns the density of the multivariate normal distribution with mean `MU` and covariance `SIGMA`, evaluated at each row of `X`. `SIGMA` is a d-by-d matrix, or a d-by-d-by-n array, in which case the density is evaluated for each row of `X` with the corresponding page of `SIGMA`, i.e., `mvnpdf` computes `y(i)` using `X(i,:)` and `SIGMA(:,:,i)`. If the covariance matrix is diagonal, containing variances along the diagonal and zero covariances off the diagonal, `SIGMA` may also be specified as a `1`-by-d vector or a 1-by-d-by-n array, containing just the diagonal. Specify `[]` for `MU` to use its default value when you want to specify only `SIGMA`.

If `X` is a 1-by-d vector, `mvnpdf` replicates it to match the leading dimension of `mu` or the trailing dimension of `SIGMA`.

Examples

```
mu = [1 -1];
```

```
SIGMA = [.9 .4; .4 .3];
X = mvnrnd(mu,SIGMA,10);
p = mvnpdf(X,mu,SIGMA);
```

mvregress

Multivariate linear regression

Syntax

```
beta = mvregress(X,Y)
beta = mvregress(X,Y,Name,Value)
[beta,Sigma] = mvregress( ___ )
[beta,Sigma,E,CovB,logL] = mvregress( ___ )
```

Description

`beta = mvregress(X,Y)` returns the estimated coefficients for a multivariate normal regression of the *d*-dimensional responses in Y on the design matrices in X.

`beta = mvregress(X,Y,Name,Value)` returns the estimated coefficients using additional options specified by one or more name-value pair arguments. For example, you can specify the estimation algorithm, initial estimate values, or maximum number of iterations for the regression.

`[beta,Sigma] = mvregress( ___ )` also returns the estimated *d*-by-*d* variance-covariance matrix of Y, using any of the input arguments from the previous syntaxes.

`[beta,Sigma,E,CovB,logL] = mvregress( ___ )` also returns a matrix of residuals `E`, estimated variance-covariance matrix of the regression coefficients `CovB`, and the value of the log likelihood objective function after the last iteration `logL`.

Examples

Multivariate Regression Model for Panel Data with Different Intercepts

Fit a multivariate regression model to panel data, assuming different intercepts and common slopes.

Load the sample data.

```
load('flu')
```

The dataset array `flu` contains national CDC flu estimates, and nine separate regional estimates based on Google query data.

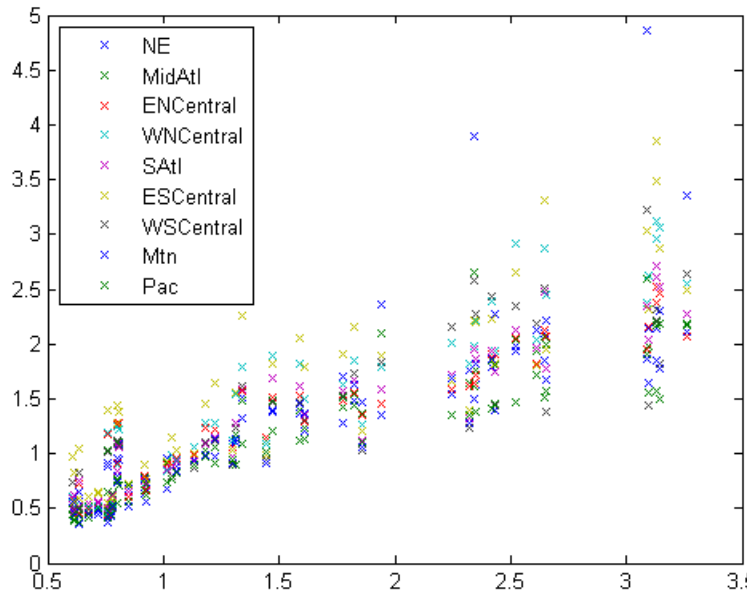
Extract the response and predictor data.

```
Y = double(flu(:,2:end-1));
[n,d] = size(Y);
x = flu.WtdILI;
```

The responses in `Y` are the nine regional flu estimates. Observations exist for every week over a one-year period, so $n = 52$. The dimension of the responses corresponds to the regions, so $d = 9$. The predictors in `x` are the weekly national flu estimates.

Plot the flu data, grouped by region.

```
figure;
regions = flu.Properties.VarNames(2:end-1);
plot(x,Y,'x')
legend(regions,'Location','NorthWest')
```



Fit the multivariate regression model

$$y_{ij} = \alpha_j + \beta x_{ij} + \varepsilon_{ij},\ i = 1,\ldots,n;\ j = 1,\ldots,d,$$

with between-region concurrent correlation

$$COV(\varepsilon_{ij},\varepsilon_{ij'}) = \sigma_{jj'},\ j = 1,\ldots,d.$$

There are $K = 10$ regression coefficients to estimate: nine intercept terms and a common slope. The input argument `X` should be an n-element cell array of d-by-K design matrices.

```
X = cell(n,1);
for i=1:n
  X{i} = [eye(d) repmat(x(i),d,1)];
end
[beta,Sigma] = mvregress(X,Y);
```

`beta` contains estimates of the K-dimensional coefficient vector

$$(\alpha_1,\alpha_2,\ldots,\alpha_9,\beta)'.$$

`Sigma` contains estimates of the d-by-d variance-covariance matrix for the between-region concurrent correlations

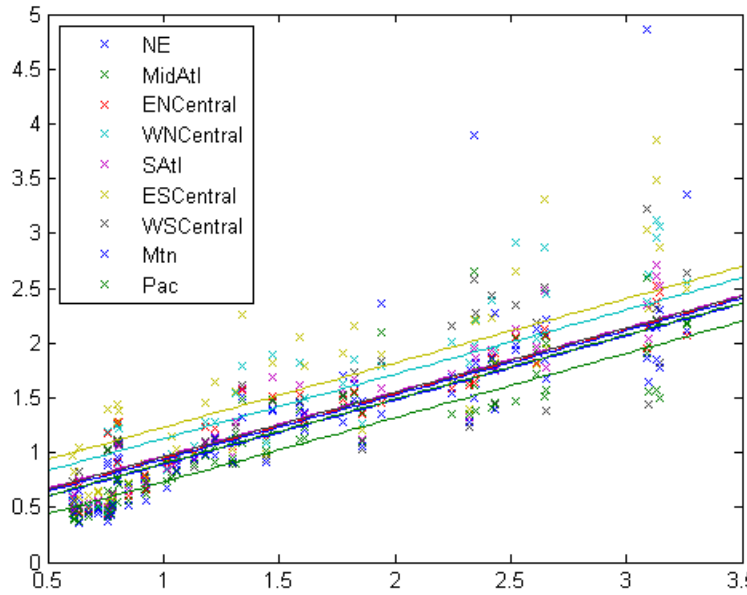
$$\begin{pmatrix} \sigma_{11} & \cdots & \sigma_{1,9} \\ \vdots & \ddots & \vdots \\ \sigma_{9,1} & \cdots & \sigma_{9,9} \end{pmatrix}.$$

Plot the fitted regression model.

```
B = [beta(1:d)';repmat(beta(end),1,d)];
xx = linspace(.5,3.5)';
fits = [ones(size(xx)),xx]*B;

figure;
h = plot(x,Y,'x',xx,fits,'-');
```

```
for i = 1:d
 set(h(d+i),'color',get(h(i),'color'));
end
legend(regions,'Location','NorthWest');
```



The plot shows that each regression line has a different intercept but the same slope. Upon visual inspection, some regression lines appear to fit the data better than others.

Multivariate Regression for Panel Data with Different Slopes

Fit a multivariate regression model to panel data using least squares, assuming different intercepts and slopes.

Load the sample data.

```
load('flu');
```

The dataset array `flu` contains national CDC flu estimates, and nine separate regional estimates based on Google queries.

Extract the response and predictor data.

```
Y = double(flu(:,2:end-1));
[n,d] = size(Y);
x = flu.WtdILI;
```

The responses in `Y` are the nine regional flu estimates. Observations exist for every week over a one-year period, so $n = 52$. The dimension of the responses corresponds to the regions, so $d = 9$. The predictors in `x` are the weekly national flu estimates.

Fit the multivariate regression model

$$y_{ij} = \alpha_j + \beta_j x_{ij} + \varepsilon_{ij},\ i = 1,\ldots,n;\ j = 1,\ldots,d,$$

with between-region concurrent correlation

$$COV(\varepsilon_{ij},\varepsilon_{ij'}) = \sigma_{jj'},\ j = 1,\ldots,d.$$

There are $K = 18$ regression coefficients to estimate: nine intercept terms, and nine slope terms. `X` is an n-element cell array of d-by-K design matrices.

```
X = cell(n,1);
for i=1:n
  X{i} = [eye(d) x(i)*eye(d)];
end
[beta,Sigma] = mvregress(X,Y,'algorithm','cwls');
```

`beta` contains estimates of the K-dimensional coefficient vector,

$$(\alpha_1,\alpha_2,\ldots,\alpha_9,\beta_1,\beta_2,\ldots,\beta_9)'.$$

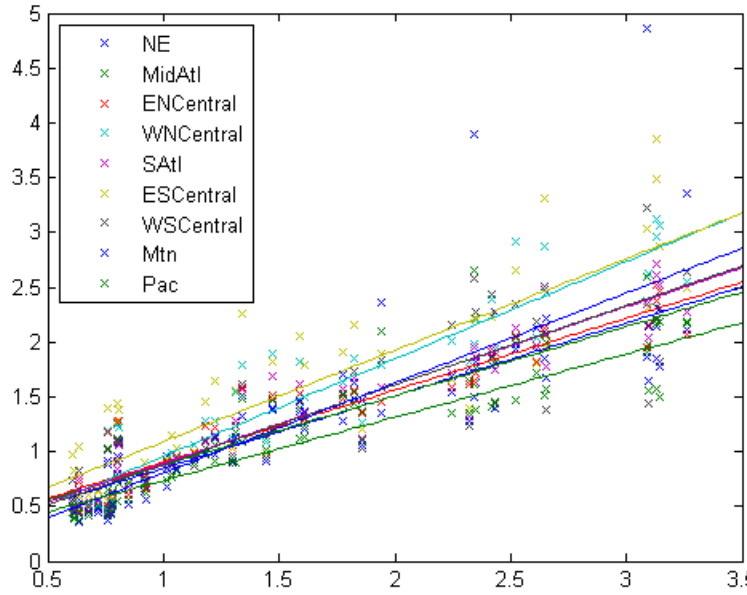
Plot the fitted regression model.

```
B = [beta(1:d)';beta(d+1:end)'];
xx = linspace(.5,3.5)';
fits = [ones(size(xx)),xx]*B;

figure;
h = plot(x,Y,'x',xx,fits,'-');
for i = 1:d
```

```
 set(h(d+i),'color',get(h(i),'color'));
end

regions = flu.Properties.VarNames(2:end-1);
legend(regions,'Location','NorthWest');
```



The plot shows that each regression line has a different intercept and slope.

Multivariate Regression With a Single Design Matrix

Fit a multivariate regression model using a single n-by-P design matrix for all response dimensions.

Load the sample data.

```
load('flu');
```

The dataset array `flu` contains national CDC flu estimates, and nine separate regional estimates based on Google queries.

Extract the response and predictor data.

```
Y = double(flu(:,2:end-1));
[n,d] = size(Y);
x = flu.WtdILI;
```

The responses in `Y` are the nine regional flu estimates. Observations exist for every week over a one-year period, so $n = 52$. The dimension of the responses corresponds to the regions, so $d = 9$. The predictors in `x` are the weekly national flu estimates.

Create an n-by-P design matrix `X`. Add a column of ones to include a constant term in the regression.

```
X = [ones(size(x)),x];
```

Fit the multivariate regression model

$$y_{ij} = \alpha_j + \beta_j x_{ij} + \varepsilon_{ij},\ i = 1,\ldots,n;\ j = 1,\ldots,d,$$

with between-region concurrent correlation

$$COV(\varepsilon_{ij}, \varepsilon_{ij'}) = \sigma_{jj'},\ j = 1,\ldots,d.$$

There are 18 regression coefficients to estimate: nine intercept terms, and nine slope terms.

```
[beta,Sigma,E,CovB,logL] = mvregress(X,Y);
```

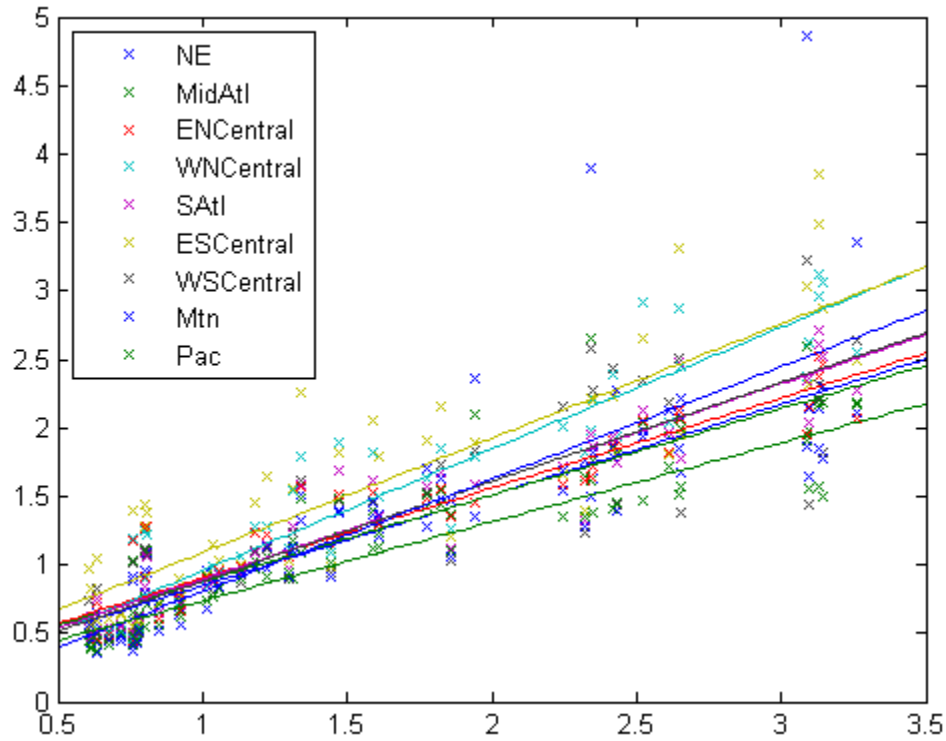
`beta` contains estimates of the P-by-d coefficient matrix. `Sigma` contains estimates of the d-by-d variance-covariance matrix for the between-region concurrent correlations. `E` is a matrix of the residuals. `CovB` is the estimated variance-covariance matrix of the regression coefficients. `logL` is the value of the log likelihood objective function after the last iteration.

Plot the fitted regression model.

```
B = beta;
xx = linspace(.5,3.5)';
fits = [ones(size(xx)),xx]*B;
```

```
figure;
h = plot(x,Y,'x', xx,fits,'-');
for i = 1:d
    set(h(d+i),'color',get(h(i),'color'));
end

regions = flu.Properties.VarNames(2:end-1);
legend(regions,'Location','NorthWest');
```



The plot shows that each regression line has a different intercept and slope.

Input Arguments

`X` — Design matrices

matrix | cell array of matrices

Design matrices for the multivariate regression, specified as a matrix or cell array of matrices. n is the number of observations in the data, K is the number of regression coefficients to estimate, p is the number of predictor variables, and d is the number of dimensions in the response variable matrix Y.

- If $d = 1$, then specify `X` as a single n-by-K design matrix.
- If $d > 1$ and all d dimensions have the same design matrix, then you can specify `X` as a single n-by-p design matrix (not in a cell array).
- If $d > 1$ and all n observations have the same design matrix, then you can specify `X` as a cell array containing a single d-by-K design matrix.
- If $d > 1$ and all n observations do not have the same design matrix, then specify X as a cell array of length n containing d-by-K design matrices.

To include a constant term in the regression model, each design matrix should contain a column of ones.

`mvregress` treats `NaN` values in X as missing values, and ignores rows in X with missing values.

Data Types: `single` | `double` | `cell`

`Y` — Response variables

matrix

Response variables, specified as an n-by-d matrix. n is the number of observations in the data, and d is the number of dimensions in the response. When $d = 1$, `mvregress` treats the values in `Y` like n independent response values.

`mvregress` treats `NaN` values in Y as missing values, and handles them according to the estimation algorithm specified using the name-value pair argument algorithm.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'algorithm','cwls','covar0',C` specifies covariance-weighted least squares estimation using the covariance matrix `C`.

`'algorithm'` — Estimation algorithm

`'mvn' | 'ecm' | 'cwls'`

Estimation algorithm, specified as the comma-separated pair consisting of `'algorithm'` and one of the following.

`'mvn'`	Ordinary multivariate normal maximum likelihood estimation.
`'ecm'`	Maximum likelihood estimation via the ECM algorithm.
`'cwls'`	Covariance-weighted least squares estimation.

The default algorithm depends on the presence of missing data.

- For complete data, the default is `'mvn'`.
- If there are any missing responses (indicated by `NaN`), the default is `'ecm'`, provided the sample size is sufficient to estimate all parameters. Otherwise, the default algorithm is `'cwls'`.

Note: If algorithm has the value `'mvn'`, then `mvregress` removes observations with missing response values before estimation.

Example: `'algorithm','ecm'`

`'beta0'` — Initial estimates for regression coefficients

vector

Initial estimates for the regression coefficients, specified as the comma-separated pair consisting of `'beta0'` and a vector with K elements. The default value is a vector of 0s.

The `beta0` argument is not used if the estimation algorithm is `'mvn'`.

`'covar0'` — Initial estimate for variance-covariance matrix

matrix

Initial estimate for the variance-covariance matrix, Sigma, specified as the comma-separated pair consisting of `'covar0'` and a symmetric, positive definite, d-by-d matrix. The default value is the identity matrix.

If the estimation algorithm is `'cwls'`, then `mvregress` uses `covar0` as the weighting matrix at each iteration, without changing it.

`'covtype'` — Type of variance-covariance matrix

`'full'` (default) | `'diagonal'`

Type of variance-covariance matrix to estimate for Y, specified as the comma-separated pair consisting of `'covtype'` and one of the following.

`'full'`	Estimate all $d(d + 1)/2$ variance-covariance elements.
`'diagonal'`	Estimate only the d diagonal elements of the variance-covariance matrix.

Example: `'covtype','diagonal'`

`'maxiter'` — Maximum number of iterations

100 (default) | positive integer

Maximum number of iterations for the estimation algorithm, specified as the comma-separated pair consisting of `'maxiter'` and a positive integer.

Iterations continue until estimates are within the convergence tolerances tolbeta and tolobj, or the maximum number of iterations specified by maxiter is reached. If both tolbeta and tolobj are 0, then `mvregress` performs `maxiter` iterations with no convergence tests.

Example: `'maxiter',50`

`'outputfcn'` — Function to evaluate each iteration

function handle

Function to evaluate at each iteration, specified as the comma-separated pair consisting of `'outputfcn'` and a function handle. The function must return a logical `true` or `false`. At each iteration, `mvregress` evaluates the function. If the result is `true`, iterations stop. Otherwise, iterations continue. For example, you could specify a function that plots or displays current iteration results, and returns `true` if you close the figure.

The function must accept three input arguments, in this order:

- Vector of current coefficient estimates
- Structure containing these three fields:

`Covar`	Current value of the variance-covariance matrix
`iteration`	Current iteration number
`fval`	Current value of the loglikelihood objective function

- Text string that takes these three values:

`'init'`	When the function is called during initialization
`'iter'`	When the function is called after an iteration
`'done'`	When the function is called after completion

`'tolbeta'` — Convergence tolerance for regression coefficients

`sqrt(eps)` (default) | positive scalar value

Convergence tolerance for regression coefficients, specified as the comma-separated pair consisting of `'tolbeta'` and a positive scalar value.

Let $\mathbf{b}^t$ denote the estimate of the coefficient vector at iteration t, and τ_β be the tolerance specified by `tolbeta`. The convergence criterion for regression coefficient estimation is

$$\left\|\mathbf{b}^t - \mathbf{b}^{t-1}\right\| < \tau_\beta \sqrt{K}\left(1 + \left\|\mathbf{b}^t\right\|\right),$$

where K is the length of $\mathbf{b}^t$ and $\|\mathbf{v}\|$ is the norm of a vector $\mathbf{v}$.

Iterations continue until estimates are within the convergence tolerances tolbeta and tolobj, or the maximum number of iterations specified by maxiter is reached. If

both tolbeta and tolobj are 0, then `mvregress` performs `maxiter` iterations with no convergence tests.

Example: `'tolbeta',1e-5`

`'tolobj'` — Convergence tolerance for loglikelihood objective function

`eps^(3/4)` (default) | positive scalar value

Convergence tolerance for the loglikelihood objective function, specified as the comma-separated pair consisting of `'tolobj'` and a positive scalar value.

Let L^t denote the value of the loglikelihood objective function at iteration t, and τ_ℓ be the tolerance specified by `tolobj`. The convergence criterion for the objective function is

$$\left|L^t - L^{t-1}\right| < \tau_\ell \left(1 + \left|L^t\right|\right).$$

Iterations continue until estimates are within the convergence tolerances tolbeta and tolobj, or the maximum number of iterations specified by maxiter is reached. If both tolbeta and tolobj are 0, then `mvregress` performs `maxiter` iterations with no convergence tests.

Example: `'tolobj',1e-5`

`'varformat'` — Format for parameter estimate variance-covariance matrix

`'beta'` (default) | `'full'`

Format for the parameter estimate variance-covariance matrix, CovB, specified as the comma-separated pair consisting of `'varformat'` and one of the following.

`'beta'`	Return the variance-covariance matrix for only the regression coefficient estimates, beta.
`'full'`	Return the variance-covariance matrix for both the regression coefficient estimates, beta, and the variance-covariance matrix estimate, Sigma.

Example: `'varformat','full'`

`'vartype'` — Type of variance-covariance matrix for parameter estimates

`'hessian'` (default) | `'fisher'`

Type of variance-covariance matrix for parameter estimates, specified as the comma-separated pair consisting of `'vartype'` and either `'hessian'` or `'fisher'`.

- If the value is `'hessian'`, then `mvregress` uses the Hessian, or observed information, matrix to compute CovB.
- If the value is `'fisher'`, then `mvregress` uses the complete-data Fisher, or expected information, matrix to compute CovB.

The `'hessian'` method takes into account the increase uncertainties due to missing data, while the `'fisher'` method does not.

Example: `'vartype','fisher'`

Output Arguments

`beta` — Estimated regression coefficients

column vector | matrix

Estimated regression coefficients, returned as a column vector or matrix.

- If you specify X as a single n-by-K design matrix, then `mvregress` returns beta as a column vector of length K. For example, if X is a 20-by-5 design matrix, then beta is a 5-by-1 column vector.
- If you specify X as a cell array containing one or more d-by-K design matrices, then `mvregress` returns beta as a column vector of length K. For example, if X is a cell array containing 2-by-10 design matrices, then beta is a 10-by-1 column vector.
- If you specify X as a single n-by-p design matrix (not in a cell array), and Y has dimension $d > 1$, then `mvregress` returns beta as a p-by-d matrix. For example, if X is a 20-by-5 design matrix, and Y has two dimensions such that $d = 2$, then beta is a 5-by-2 matrix, and the fitted Y values are X × beta.

`Sigma` — Estimated variance-covariance matrix

square matrix

Estimated variance-covariance matrix for the responses in Y, returned as a d-by-d square matrix.

Note: The estimated variance-covariance matrix, `Sigma`, is not the sample covariance matrix of the residual matrix, E.

`E` — Residuals

matrix

Residuals for the fitted regression model, returned as an n-by-d matrix.

If algorithm has the value `'ecm'` or `'cwls'`, then `mvregress` computes the residual values corresponding to missing values in Y as the difference between the conditionally imputed values and the fitted values.

Note: If algorithm has the value `'mvn'`, then `mvregress` removes observations with missing response values before estimation.

`CovB` — Parameter estimate variance-covariance matrix

square matrix

Parameter estimate variance-covariance matrix, returned as a square matrix.

- If varformat has the value `'beta'` (default), then `CovB` is the estimated variance-covariance matrix of the coefficient estimates in beta.
- If varformat has the value `'full'`, then `CovB` is the estimated variance-covariance matrix of the combined estimates in beta and Sigma.

`logL` — Loglikelihood objective function value

scalar value

Loglikelihood objective function value after the last iteration, returned as a scalar value.

More About

Multivariate Normal Regression

Multivariate normal regression is the regression of a d-dimensional response on a design matrix of predictor variables, with normally distributed errors. The errors can be heteroscedastic and correlated.

The model is

$$\mathbf{y}_i = \mathbf{X}_i\beta + \mathbf{e}_i, \quad i = 1,\ldots,n,$$

where

- $\mathbf{y}_i$ is a d-dimensional vector of responses.
- $\mathbf{X}_i$ is a design matrix of predictor variables.
- β is vector or matrix of regression coefficients.
- $\mathbf{e}_i$ is a d-dimensional vector of error terms, with multivariate normal distribution

  $$\mathbf{e}_i \sim MVN_d(\mathbf{0}, \Sigma).$$

Conditionally Imputed Values

The expectation/conditional maximization (`'ecm'`) and covariance-weighted least squares (`'cwls'`) estimation algorithms include imputation of missing response values.

Let $\tilde{\mathbf{y}}$ denote missing observations. The conditionally imputed values are the expected value of the missing observation given the observed data, $\mathrm{E}(\tilde{\mathbf{y}} \mid \mathbf{y})$.

The joint distribution of the missing and observed responses is a multivariate normal distribution,

$$\begin{pmatrix} \tilde{\mathbf{y}} \\ \mathbf{y} \end{pmatrix} \sim MVN\left\{ \begin{pmatrix} \tilde{\mathbf{X}}\beta \\ \mathbf{X}\beta \end{pmatrix}, \begin{pmatrix} \Sigma_{\tilde{y}} & \Sigma_{\tilde{y}y} \\ \Sigma_{y\tilde{y}} & \Sigma_{y} \end{pmatrix} \right\}.$$

Using properties of the multivariate normal distribution, the imputed conditional expectation is given by

$$\mathrm{E}(\tilde{\mathbf{y}} \mid \mathbf{y}) = \tilde{\mathbf{X}}\beta + \Sigma_{\tilde{y}y}\Sigma_{y}^{-1}(\mathbf{y} - \mathbf{X}\beta).$$

Note: `mvregress` only imputes missing response values. Observations with missing values in the design matrix are removed.

`manova1` | `mvregresslike`

mvregresslike

Negative log-likelihood for multivariate regression

Syntax

```
nlogL = mvregresslike(X,Y,b,SIGMA,alg)
[nlogL,COVB] = mvregresslike(...)
[nlogL,COVB] = mvregresslike(...,type,format)
```

Description

`nlogL = mvregresslike(X,Y,b,SIGMA,alg)` computes the negative log-likelihood `nlogL` for a multivariate regression of the d-dimensional multivariate observations in the n-by-d matrix `Y` on the predictor variables in the matrix or cell array `X`, evaluated for the p-by-1 column vector `b` of coefficient estimates and the d-by-d matrix `SIGMA` specifying the covariance of a row of `Y`. If $d = 1$, `X` can be an n-by-p design matrix of predictor variables. For any value of d, `X` can also be a cell array of length n, with each cell containing a d-by-p design matrix for one multivariate observation. If all observations have the same d-by-p design matrix, `X` can be a single cell.

`NaN` values in `X` or `Y` are taken as missing. Observations with missing values in `X` are ignored. Treatment of missing values in `Y` depends on the algorithm specified by *`alg`*.

`alg` should match the algorithm used by `mvregress` to obtain the coefficient estimates `b`, and must be one of the following:

- `'ecm'` — ECM algorithm
- `'cwls'` — Least squares conditionally weighted by `SIGMA`
- `'mvn'` — Multivariate normal estimates computed after omitting rows with any missing values in `Y`

`[nlogL,COVB] = mvregresslike(...)` also returns an estimated covariance matrix `COVB` of the parameter estimates `b`.

`[nlogL,COVB] = mvregresslike(...,type,format)` specifies the type and format of `COVB`.

type is either:

- `'hessian'` — To use the Hessian or observed information. This method takes into account the increased uncertainties due to missing data. This is the default.
- `'fisher'` — To use the Fisher or expected information. This method uses the complete data expected information, and does not include uncertainty due to missing data.

format is either:

- `'beta'` — To compute `COVB` for `b` only. This is the default.
- `'full'` — To compute `COVB` for both `b` and `SIGMA`.

`mvregress` | `manova1`

mvnrnd

Multivariate normal random numbers

Syntax

```
R = mvnrnd(MU,SIGMA)
r = mvnrnd(MU,SIGMA,cases)
```

Description

`R = mvnrnd(MU,SIGMA)` returns an n-by-d matrix `R` of random vectors chosen from the multivariate normal distribution with mean `MU`, and covariance `SIGMA`. `MU` is a vector or n-by-d matrix, and `mvnrnd` generates each row of `R` using the corresponding row of `mu`. `SIGMA` is a d-by-d symmetric positive semi-definite matrix, or a d-by-d-by-n array. If `SIGMA` is an array, `mvnrnd` generates each row of `R` using the corresponding page of `SIGMA`, i.e., `mvnrnd` computes `R(i,:)` using `MU(i,:)` and `SIGMA(:,:,i)`. If the covariance matrix is diagonal, containing variances along the diagonal and zero covariances off the diagonal, `SIGMA` may also be specified as a `1`-by-d vector or a 1-by-d-by-n array, containing just the diagonal. If `MU` is a `1`-by-d vector, `mvnrnd` replicates it to match the trailing dimension of `SIGMA`.

`r = mvnrnd(MU,SIGMA,cases)` returns a `cases`-by-d matrix `R` of random vectors chosen from the multivariate normal distribution with a common `1`-by-`d` mean vector `MU`, and a common `d`-by-`d` covariance matrix `SIGMA`.

Examples

Generate Multivariate Normal Random Numbers

Generate random numbers from a multivariate normal distribution with parameters `mu = [2,3]` and `sigma = [1,1.5;1.5,3]`.

```
mu = [2,3];
sigma = [1,1.5;1.5,3];
rng default  % For reproducibility
r = mvnrnd(mu,sigma,100);
```

Plot the random numbers.

```
figure
plot(r(:,1),r(:,2),'+')
```

`mvnpdf` | `mvncdf` | `normrnd`

mvtcdf

Multivariate *t* cumulative distribution function

Syntax

```
y = mvtcdf(X,C,DF)
y = mvtcdf(xl,xu,C,DF)
[y,err] = mvtcdf(...)
[...] = mvntdf(...,options)
```

Description

`y = mvtcdf(X,C,DF)` returns the cumulative probability of the multivariate *t* distribution with correlation parameters `C` and degrees of freedom `DF`, evaluated at each row of `X`. Rows of the *n*-by-*d* matrix `X` correspond to observations or points, and columns correspond to variables or coordinates. `y` is an `n`-by-`1` vector.

`C` is a symmetric, positive definite, *d*-by-*d* matrix, typically a correlation matrix. If its diagonal elements are not 1, `mvtcdf` scales `C` to correlation form. `mvtcdf` does not rescale `X`. `DF` is a scalar, or a vector with *n* elements.

The multivariate *t* cumulative probability at `X` is defined as the probability that a random vector `T`, distributed as multivariate *t*, will fall within the semi-infinite rectangle with upper limits defined by `X`, i.e., $\Pr\{T(1) \le X(1), T(2) \le X(2), \ldots T(d) \le X(d)\}$.

`y = mvtcdf(xl,xu,C,DF)` returns the multivariate *t* cumulative probability evaluated over the rectangle with lower and upper limits defined by `xl` and `xu`, respectively.

`[y,err] = mvtcdf(...)` returns an estimate of the error in `y`. For bivariate and trivariate distributions, `mvtcdf` uses adaptive quadrature on a transformation of the *t* density, based on methods developed by Genz, as described in the references. The default absolute error tolerance for these cases is `1e-8`. For four or more dimensions, `mvtcdf` uses a quasi-Monte Carlo integration algorithm based on methods developed by Genz and Bretz, as described in the references. The default absolute error tolerance for these cases is `1e-4`.

`[...] = mvntdf(...,options)` specifies control parameters for the numerical integration used to compute `y`. This argument can be created by a call to `statset`. Choices of `statset` parameters are:

- `'TolFun'` — Maximum absolute error tolerance. Default is `1e-8` when $d < 4$, or `1e-4` when $d \geq 4$.
- `'MaxFunEvals'` — Maximum number of integrand evaluations allowed when $d \geq 4$. Default is `1e7`. `'MaxFunEvals'` is ignored when $d < 4$.
- `'Display'` — Level of display output. Choices are `'off'` (the default), `'iter'`, and `'final'`. `'Display'` is ignored when $d < 4$.

Examples

Compute the Multivariate *t* Distribution cdf

Compute the cdf of a multivariate t distribution with correlation parameters `C = [1 .4; .4 1]` and 2 degrees of freedom.

```
C = [1 .4; .4 1];
df = 2;
[X1,X2] = meshgrid(linspace(-2,2,25)',linspace(-2,2,25)');
X = [X1(:) X2(:)];
p = mvtcdf(X,C,df);
```

Plot the cdf.

```
figure;
surf(X1,X2,reshape(p,25,25));
```

`mvtpdf` | `mvtrnd`

mvtpdf

Multivariate *t* probability density function

Syntax

```
y = mvtpdf(X,C,df)
```

Description

`y = mvtpdf(X,C,df)` returns the probability density of the multivariate *t* distribution with correlation parameters `C` and degrees of freedom `df`, evaluated at each row of `X`. Rows of the *n*-by-*d* matrix `X` correspond to observations or points, and columns correspond to variables or coordinates. `C` is a symmetric, positive definite, *d*-by-*d* matrix, typically a correlation matrix. If its diagonal elements are not 1, `mvtpdf` scales `C` to correlation form. `mvtcdf` does not rescale `X`. `df` is a scalar, or a vector with *n* elements. `y` is an *n*-by-1 vector.

Examples

Compute the Multivariate *t* Distribution pdf

Compute the pdf of a multivariate *t* distribution with correlation parameters `C = [1 .4; .4 1]` and 2 degrees of freedom.

```
[X1,X2] = meshgrid(linspace(-2,2,25)',linspace(-2,2,25)');
X = [X1(:) X2(:)];
C = [1 .4; .4 1];
df = 2;
p = mvtpdf(X,C,df);
```

Plot the pdf.

```
figure;
surf(X1,X2,reshape(p,25,25))
```

`mvtcdf` | `mvtrnd`

mvtrnd

Multivariate *t* random numbers

Syntax

```
R = mvtrnd(C,df,cases)
R = mvtrnd(C,df)
```

Description

`R = mvtrnd(C,df,cases)` returns a matrix of random numbers chosen from the multivariate *t* distribution, where `C` is a correlation matrix. `df` is the degrees of freedom and is either a scalar or is a vector with `cases` elements. If `p` is the number of columns in `C`, then the output `R` has `cases` rows and `p` columns.

Let `t` represent a row of `R`. Then the distribution of `t` is that of a vector having a multivariate normal distribution with mean 0, variance 1, and covariance matrix `C`, divided by an independent chi-square random value having `df` degrees of freedom. The rows of `R` are independent.

`C` must be a square, symmetric and positive definite matrix. If its diagonal elements are not all 1 (that is, if `C` is a covariance matrix rather than a correlation matrix), `mvtrnd` rescales `C` to transform it to a correlation matrix before generating the random numbers.

`R = mvtrnd(C,df)` returns a single random number from the multivariate *t* distribution.

Examples

Generate Multivariate *t* Distribution Random Numbers

Generate random numbers from a multivariate *t* distribution with correlation parameters `SIGMA = [1 0.8;0.8 1]` and 3 degrees of freedom.

```
rng default;  % For reproducibility
SIGMA = [1 0.8;0.8 1];
R = mvtrnd(SIGMA,3,100);
```

Plot the random numbers.

```
figure;
plot(R(:,1),R(:,2),'+')
```

NumObservations property

Class: cvpartition

Number of observations (including observations with missing `group` values)

Description

Number of observations (including observations with missing `group` values).

NaiveBayes class

Naive Bayes classifier

Description

A `NaiveBayes` object defines a Naive Bayes classifier. A Naive Bayes classifier assigns a new observation to the most probable class, assuming the features are conditionally independent given the class value.

Construction

.NaiveBayes	Create NaiveBayes object

Methods

disp	Display `NaiveBayes` classifier object
display	Display `NaiveBayes` classifier object
fit	Create Naive Bayes classifier object by fitting training data
posterior	Compute posterior probability of each class for test data
predict	Predict class label for test data
subsasgn	Subscripted reference for `NaiveBayes` object

subsref	Subscripted reference for `NaiveBayes` object

Properties

CIsNonEmpty	Flag for non-empty classes
ClassLevels	Class levels
Prior	Class priors
Dist	Distribution names
NClasses	Number of classes
NDims	Number of dimensions
Params	Parameter estimates

Copy Semantics

Value. To learn how this affects your use of the class, see Comparing Handle and Value Classes in the MATLAB Object-Oriented Programming documentation.

Examples

Predict the class label using the Naive Bayes classifier:

```
load fisheriris
```

Use the default Gaussian distribution and a confusion matrix:

```
O1 = fitNaiveBayes(meas,species);
```

```
C1 = O1.predict(meas);
cMat1 = confusionmat(species,C1)
```
This returns:

```
cMat1 =

    50     0     0
     0    47     3
     0     3    47
```
Use the Gaussian distribution for features 1 and 3 and use the kernel density estimation for features 2 and 4:

```
O2 = fitNaiveBayes(meas,species,'dist',...
{'normal','kernel','normal','kernel'});
C2 = O2.predict(meas);
cMat2 = confusionmat(species,C2)
```
This returns:

```
cMat2 =

    50     0     0
     0    47     3
     0     3    47
```

NaiveBayes

Class: NaiveBayes

Create NaiveBayes object

Description

You cannot create a `NaiveBayes` classifier by calling the constructor. Use `fitNaiveBayes` to create a `NaiveBayes` classifier by fitting the object to training data.

See Also

`fitNaiveBayes`

prob.NakagamiDistribution class

Package: prob
Superclasses: prob.ToolboxFittableParametricDistribution

Nakagami probability distribution object

Description

`prob.NakagamiDistribution` is an object consisting of parameters, a model description, and sample data for a Nakagami probability distribution.

Create a probability distribution object with specified parameter values using `makedist`. Alternatively, fit a distribution to data using `fitdist` or the Distribution Fitting app.

Construction

`pd = makedist('Nakagami')` creates a Nakagami probability distribution object using the default parameter values.

`pd = makedist('Nakagami','mu',mu,'omega',omega)` creates a Nakagami probability distribution object using the specified parameter values.

Input Arguments

`mu` — Shape parameter

1 (default) | positive scalar value

Shape parameter for the Nakagami distribution, specified as a positive scalar value.

Data Types: `single` | `double`

`omega` — Scale parameter

1 (default) | positive scalar value

Scale parameter for the Nakagami distribution, specified as a positive scalar value.

Data Types: `single` | `double`

Properties

`mu` — Shape parameter

positive scalar value

Shape parameter for the Nakagami distribution, stored as a positive scalar value.

Data Types: `single | double`

`omega` — Scale parameter

positive scalar value

Scale parameter for the Nakagami distribution, stored as a positive scalar value.

Data Types: `single | double`

`DistributionName` — Probability distribution name

probability distribution name string

Probability distribution name, stored as a valid probability distribution name string. This property is read-only.

Data Types: `char`

`InputData` — Data used for distribution fitting

structure

Data used for distribution fitting, stored as a structure containing the following:

- `data`: Data vector used for distribution fitting.
- `cens`: Censoring vector, or empty if none.
- `freq`: Frequency vector, or empty if none.

This property is read-only.

Data Types: `struct`

`IsTruncated` — Logical flag for truncated distribution

`0 | 1`

Logical flag for truncated distribution, stored as a logical value. If `IsTruncated` equals `0`, the distribution is not truncated. If `IsTruncated` equals `1`, the distribution is truncated. This property is read-only.

Data Types: `logical`

`NumParameters` — Number of parameters

positive integer value

Number of parameters for the probability distribution, stored as a positive integer value. This property is read-only.

Data Types: `single | double`

`ParameterCovariance` — Covariance matrix of the parameter estimates

matrix of scalar values

Covariance matrix of the parameter estimates, stored as a p-by-p matrix, where p is the number of parameters in the distribution. The (`i`,`j`) element is the covariance between the estimates of the `i`th parameter and the `j`th parameter. The (`i`,`i`) element is the estimated variance of the `i`th parameter. If parameter `i` is fixed rather than estimated by fitting the distribution to data, then the (`i`,`i`) elements of the covariance matrix are 0. This property is read-only.

Data Types: `single | double`

`ParameterDescription` — Distribution parameter descriptions

cell array of strings

Distribution parameter descriptions, stored as a cell array of strings. Each cell contains a short description of one distribution parameter. This property is read-only.

Data Types: `char`

`ParameterIsFixed` — Logical flag for fixed parameters

array of logical values

Logical flag for fixed parameters, stored as an array of logical values. If `0`, the corresponding parameter in the `ParameterNames` array is not fixed. If `1`, the corresponding parameter in the `ParameterNames` array is fixed. This property is read-only.

Data Types: `logical`

`ParameterNames` — Distribution parameter names

cell array of strings

Distribution parameter names, stored as a cell array of strings. This property is read-only.

Data Types: `char`

`ParameterValues` — Distribution parameter values
vector of scalar values

Distribution parameter values, stored as a vector. This property is read-only.

Data Types: `single | double`

`Truncation` — Truncation interval
vector of scalar values

Truncation interval for the probability distribution, stored as a vector containing the lower and upper truncation boundaries. This property is read-only.

Data Types: `single | double`

Methods

Inherited Methods

cdf	Cumulative distribution function of probability distribution object
icdf	Inverse cumulative distribution function of probability distribution object
iqr	Interquartile range of probability distribution object
median	Median of probability distribution object
pdf	Probability density function of probability distribution object
random	Generate random numbers from probability distribution object

truncate	Truncate probability distribution object
mean	Mean of probability distribution object
negloglik	Negative log likelihood of probability distribution object
paramci	Confidence intervals for probability distribution parameters
proflik	Profile likelihood function for probability distribution object
std	Standard deviation of probability distribution object
var	Variance of probability distribution object

Definitions

Nakagami Distribution

The Nakagami distribution is commonly used in communication theory to model scattered signals that reach a receiver using multiple paths.

The Nakagami distribution uses the following parameters.

Parameter	Description	Support
`mu`	Shape parameter	$\mu > 0$
`omega`	Scale parameter	$\omega > 0$

The probability density function (pdf) is

$$f(x \mid \mu,\omega) = 2\left(\frac{\mu^{\mu}}{\omega}\right)\frac{1}{\Gamma(\mu)}x^{(2\mu-1)}\exp\left\{\frac{-\mu}{\omega}x^{2}\right\} \quad ; \quad x > 0\,,$$

where $\Gamma(\cdot)$ is the Gamma function.

Examples

Create a Nakagami Distribution Object Using Default Parameters

Create a Nakagami distribution object using the default parameter values.

```
pd = makedist('Nakagami')
```

```
pd =

  NakagamiDistribution

  Nakagami distribution
       mu = 1
    omega = 1
```

Create a Nakagami Distribution Object Using Specified Parameters

Create a Nakagami distribution object by specifying parameter values.

```
pd = makedist('Nakagami','mu',5,'omega',2)
```

```
pd =

  NakagamiDistribution

  Nakagami distribution
       mu = 5
    omega = 2
```

Compute the mean of the distribution.

```
m = mean(pd)
```

```
m =
```

```
1.3794
```

nancov

Covariance ignoring NaN values

Syntax

```
Y = nancov(X)
Y = nancov(X1,X2)
Y = nancov(...,1)
Y = nancov(...,'pairwise')
```

Description

`Y = nancov(X)` is the covariance `cov` of `X`, computed after removing observations with `NaN` values.

For vectors `x`, `nancov(x)` is the sample variance of the remaining elements, once `NaN` values are removed. For matrices `X`, `nancov(X)` is the sample covariance of the remaining observations, once observations (rows) containing any `NaN` values are removed.

`Y = nancov(X1,X2)`, where `X1` and `X2` are matrices with the same number of elements, is equivalent to `nancov(X)`, where `X = [X1(:) X2(:)]`.

`nancov` removes the mean from each variable (column for matrix `X`) before calculating `Y`. If n is the number of remaining observations after removing observations with `NaN` values, `nancov` normalizes `Y` by either $n - 1$ or n , depending on whether $n > 1$ or $n = 1$, respectively. To specify normalization by n, use `Y = nancov(...,1)`.

`Y = nancov(...,'pairwise')` computes `Y(i,j)` using rows with no `NaN` values in columns `i` or `j`. The result `Y` may not be a positive definite matrix.

Examples

Generate random data for two variables (columns) with random missing values:

```
X = rand(10,2);
```

```
p = randperm(numel(X));
X(p(1:5)) = NaN
X =
    0.8147    0.1576
       NaN       NaN
    0.1270    0.9572
    0.9134       NaN
    0.6324       NaN
    0.0975    0.1419
    0.2785    0.4218
    0.5469    0.9157
    0.9575    0.7922
    0.9649       NaN
```

Establish a correlation between a third variable and the other two variables:

```
X(:,3) = sum(X,2)
X =
    0.8147    0.1576    0.9723
       NaN       NaN       NaN
    0.1270    0.9572    1.0842
    0.9134       NaN       NaN
    0.6324       NaN       NaN
    0.0975    0.1419    0.2394
    0.2785    0.4218    0.7003
    0.5469    0.9157    1.4626
    0.9575    0.7922    1.7497
    0.9649       NaN       NaN
```

Compute the covariance matrix for the three variables after removing observations (rows) with `NaN` values:

```
Y = nancov(X)
Y =
    0.1311    0.0096    0.1407
    0.0096    0.1388    0.1483
    0.1407    0.1483    0.2890
```

See Also

`NaN` | `cov` | `var` | `nanvar`

nanmax

Maximum ignoring NaN values

Syntax

```
y = nanmax(X)
Y = nanmax(X1,X2)
y = nanmax(X,[],dim)
[y,indices] = nanmax(...)
```

Description

`y = nanmax(X)` is the maximum `max` of `X`, computed after removing `NaN` values.

For vectors `x`, `nanmax(x)` is the maximum of the remaining elements, once `NaN` values are removed. For matrices `X`, `nanmax(X)` is a row vector of column maxima, once `NaN` values are removed. For multidimensional arrays `X`, `nanmax` operates along the first nonsingleton dimension.

`Y = nanmax(X1,X2)` returns an array `Y` the same size as `X1` and `X2` with `Y(i,j) = nanmax(X1(i,j),X2(i,j))`. Scalar inputs are expanded to an array of the same size as the other input.

`y = nanmax(X,[],dim)` operates along the dimension `dim` of `X`.

`[y,indices] = nanmax(...)` also returns the row indices of the maximum values for each column in the vector `indices`.

Examples

Find column maxima and their indices for data with missing values:

```
X = magic(3);
X([1 6:9]) = repmat(NaN,1,5)
X =
   NaN     1   NaN
```

```
     3     5   NaN
     4   NaN   NaN
[y,indices] = nanmax(X)
y =
     4     5   NaN
indices =
     3     2     1
```

See Also

NaN | max | nanmin

nanmean

Mean ignoring NaN values

Syntax

```
y = nanmean(X)
y = nanmean(X,dim)
```

Description

`y = nanmean(X)` is the `mean` of `X`, computed after removing `NaN` values.

For vectors `x`, `nanmean(x)` is the mean of the remaining elements, once `NaN` values are removed. For matrices `X`, `nanmean(X)` is a row vector of column means, once `NaN` values are removed. For multidimensional arrays `X`, `nanmean` operates along the first nonsingleton dimension.

`y = nanmean(X,dim)` takes the mean along dimension `dim` of `X`.

Note: If `X` contains a vector of all `NaN` values along some dimension, the vector is empty once the `NaN` values are removed, so the sum of the remaining elements is `0`. Since the mean involves division by `0`, its value is `NaN`. The output `NaN` is not a mean of `NaN` values.

Examples

Find column means for data with missing values:

```
X = magic(3);
X([1 6:9]) = repmat(NaN,1,5)
X =
   NaN     1   NaN
     3     5   NaN
     4   NaN   NaN
y = nanmean(X)
y =
```

```
   3.5000   3.0000   NaN
```

See Also

NaN | mean | nanmedian

nanmedian

Median ignoring NaN values

Syntax

```
y = nanmedian(X)
y = nanmedian(X,dim)
```

Description

`y = nanmedian(X)` is the `median` of `X`, computed after removing `NaN` values.

For vectors `x`, `nanmedian(x)` is the median of the remaining elements, once `NaN` values are removed. For matrices `X`, `nanmedian(X)` is a row vector of column medians, once `NaN` values are removed. For multidimensional arrays `X`, `nanmedian` operates along the first nonsingleton dimension.

`y = nanmedian(X,dim)` takes the mean along dimension `dim` of `X`.

Examples

Find column medians for data with missing values:

```
X = magic(3);
X([1 6:9]) = repmat(NaN,1,5)
X =
   NaN     1   NaN
     3     5   NaN
     4   NaN   NaN
y = nanmedian(X)
y =
   3.5000  3.0000  NaN
```

See Also

`NaN` | `median` | `nanmean`

nanmin

Minimum ignoring NaN values

Syntax

```
y = nanmin(X)
Y = nanmin(X1,X2)
y = nanmin(X,[],dim)
[y,indices] = nanmin(...)
```

Description

`y = nanmin(X)` is the minimum `min` of `X`, computed after removing `NaN` values.

For vectors `x`, `nanmin(x)` is the minimum of the remaining elements, once `NaN` values are removed. For matrices `X`, `nanmin(X)` is a row vector of column minima, once `NaN` values are removed. For multidimensional arrays `X`, `nanmin` operates along the first nonsingleton dimension.

`Y = nanmin(X1,X2)` returns an array `Y` the same size as `X1` and `X2` with `Y(i,j) = nanmin(X1(i,j),X2(i,j))`. Scalar inputs are expanded to an array of the same size as the other input.

`y = nanmin(X,[],dim)` operates along the dimension `dim` of `X`.

`[y,indices] = nanmin(...)` also returns the row indices of the minimum values for each column in the vector `indices`.

Examples

Find column minima and their indices for data with missing values:

```
X = magic(3);
X([1 6:9]) = repmat(NaN,1,5)
X =
   NaN     1   NaN
```

```
     3     5   NaN
     4   NaN   NaN
[y,indices] = nanmin(X)
y =
     3     1   NaN
indices =
     2     1     1
```

See Also

NaN | min | nanmax

nanstd

Standard deviation ignoring NaN values

Syntax

```
y = nanstd(X)
y = nanstd(X,1)
y = nanstd(X,flag,dim)
```

Description

`y = nanstd(X)` is the standard deviation `std` of `X`, computed after removing `NaN` values.

For vectors `x`, `nanstd(x)` is the sample standard deviation of the remaining elements, once `NaN` values are removed. For matrices `X`, `nanstd(X)` is a row vector of column sample standard deviations, once `NaN` values are removed. For multidimensional arrays `X`, `nanstd` operates along the first nonsingleton dimension.

If n is the number of remaining observations after removing observations with `NaN` values, `nanstd` normalizes `y` by $n–1$. To specify normalization by n, use `y = nanstd(X,1)`.

`y = nanstd(X,flag,dim)` takes the standard deviation along the dimension `dim` of `X`. The `flag` is `0` or `1` to specify normalization by $n - 1$ or n, respectively, where n is the number of remaining observations after removing observations with `NaN` values.

Examples

Find column standard deviations for data with missing values:

```
X = magic(3);
X([1 6:9]) = repmat(NaN,1,5)
X =
   NaN     1   NaN
     3     5   NaN
```

```
     4   NaN   NaN
y = nanstd(X)
y =
   0.7071  2.8284  NaN
```

See Also

NaN | std | nanvar | nanmean

nansum

Sum ignoring NaN values

Syntax

```
y = nansum(X)
y = nansum(X,dim)
```

Description

`y = nansum(X)` is the `sum` of `X`, computed after removing `NaN` values.

For vectors `x`, `nansum(x)` is the sum of the remaining elements, once `NaN` values are removed. For matrices `X`, `nansum(X)` is a row vector of column sums, once `NaN` values are removed. For multidimensional arrays `X`, `nansum` operates along the first nonsingleton dimension.

`y = nansum(X,dim)` takes the sum along dimension `dim` of `X`.

Note: If `X` contains a vector of all `NaN` values along some dimension, the vector is empty once the `NaN` values are removed, so the sum of the remaining elements is `0`. The output `0` is not a sum of `NaN` values.

Examples

Find column sums for data with missing values:

```
X = magic(3);
X([1 6:9]) = repmat(NaN,1,5)
X =
   NaN     1   NaN
     3     5   NaN
     4   NaN   NaN
y = nansum(X)
y =
```

```
     7     6     0
```

See Also

`NaN` | `sum`

nanvar

Variance, ignoring NaN values

Syntax

```
y = nanvar(X)
y = nanvar(X,1)
y = nanvar(X,w)
y = nanvar(X,w,dim)
```

Description

`y = nanvar(X)` is the variance `var` of `X`, computed after removing `NaN` values.

For vectors `x`, `nanvar(x)` is the sample variance of the remaining elements, once `NaN` values are removed. For matrices `X`, `nanvar(X)` is a row vector of column sample variances, once `NaN` values are removed. For multidimensional arrays `X`, `nanvar` operates along the first nonsingleton dimension.

`nancov` removes the mean from each variable (column for matrix `X`) before calculating `Y`. If n is the number of remaining observations after removing observations with `NaN` values, `nanvar` normalizes `y` by either $n - 1$ or n , depending on whether $n > 1$ or $n = 1$, respectively. To specify normalization by n, use `y = nanvar(X,1)`.

`y = nanvar(X,w)` computes the variance using the weight vector `w`. The length of `w` must equal the length of the dimension over which `nanvar` operates, and its elements must be nonnegative. Elements of `X` corresponding to `NaN` values of `w` are ignored.

`y = nanvar(X,w,dim)` takes the variance along the dimension `dim` of `X`. Set `w` to `[]` to use the default normalization by $n - 1$.

Examples

Find column standard deviations for data with missing values:

```
X = magic(3);
```

```
X([1 6:9]) = repmat(NaN,1,5)
X =
   NaN     1   NaN
     3     5   NaN
     4   NaN   NaN
y = nanvar(X)
y =
   0.5000  8.0000  NaN
```

nbincdf

Negative binomial cumulative distribution function

Syntax

```
y = nbincdf(x,R,p)
y = nbincdf(x,R,p,'upper')
```

Description

`y = nbincdf(x,R,p)` computes the negative binomial cdf at each of the values in `x` using the corresponding number of successes, `R` and probability of success in a single trial, `p`. `x`, `R`, and `p` can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of `y`. A scalar input for `x`, `R`, or `p` is expanded to a constant array with the same dimensions as the other inputs.

`y = nbincdf(x,R,p,'upper')` returns the complement of the negative binomial cdf at each value in `x`, using an algorithm that more accurately computes the extreme upper tail probabilities.

The negative binomial cdf is

$$y = F(x \mid r, p) = \sum_{i=0}^{x} \binom{r+i-1}{i} p^r q^i I_{(0,1,\ldots)}(i)$$

The simplest motivation for the negative binomial is the case of successive random trials, each having a constant probability `p` of success. The number of *extra* trials you must perform in order to observe a given number `R` of successes has a negative binomial distribution. However, consistent with a more general interpretation of the negative binomial, `nbincdf` allows `R` to be any positive value, including nonintegers. When `R` is noninteger, the binomial coefficient in the definition of the cdf is replaced by the equivalent expression

$$\frac{\Gamma(r+i)}{\Gamma(r)\Gamma(i+1)}$$

Examples

Compute Negative Binomial Distribution CDF

```
x = (0:15);
p = nbincdf(x,3,0.5);
stairs(x,p)
```

cdf | nbinpdf | nbininv | nbinstat | nbinfit | nbinrnd

nbinfit

Negative binomial parameter estimates

Syntax

```
parmhat = nbinfit(data)
[parmhat,parmci] = nbinfit(data,alpha)
[...] = nbinfit(data,alpha,options)
```

Description

`parmhat = nbinfit(data)` returns the maximum likelihood estimates (MLEs) of the parameters of the negative binomial distribution given the data in the vector `data`.

`[parmhat,parmci] = nbinfit(data,alpha)` returns MLEs and `100(1-alpha)` percent confidence intervals. By default, `alpha = 0.05`, which corresponds to 95% confidence intervals.

`[...] = nbinfit(data,alpha,options)` accepts a structure, `options`, that specifies control parameters for the iterative algorithm the function uses to compute maximum likelihood estimates. The negative binomial fit function accepts an `options` structure which you can create using the function `statset`. Enter `statset('nbinfit')` to see the names and default values of the parameters that `nbinfit` accepts in the `options` structure. See the reference page for `statset` for more information about these options.

Note The variance of a negative binomial distribution is greater than its mean. If the sample variance of the data in `data` is less than its sample mean, `nbinfit` cannot compute MLEs. You should use the `poissfit` function instead.

nbincdf | nbininv | nbinpdf | nbinrnd | nbinstat | mle | statset

nbininv

Negative binomial inverse cumulative distribution function

Syntax

```
X = nbininv(Y,R,P)
```

Description

`X = nbininv(Y,R,P)` returns the inverse of the negative binomial cdf with corresponding number of successes, `R` and probability of success in a single trial, `P`. Since the binomial distribution is discrete, `nbininv` returns the least integer `X` such that the negative binomial cdf evaluated at `X` equals or exceeds `Y`. `Y`, `R`, and `P` can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of `X`. A scalar input for `Y`, `R`, or `P` is expanded to a constant array with the same dimensions as the other inputs.

The simplest motivation for the negative binomial is the case of successive random trials, each having a constant probability `P` of success. The number of *extra* trials you must perform in order to observe a given number `R` of successes has a negative binomial distribution. However, consistent with a more general interpretation of the negative binomial, `nbininv` allows `R` to be any positive value, including nonintegers.

Examples

How many times would you need to flip a fair coin to have a 99% probability of having observed 10 heads?

```
flips = nbininv(0.99,10,0.5) + 10
flips =
  33
```

Note that you have to flip at least 10 times to get 10 heads. That is why the second term on the right side of the equals sign is a 10.

`icdf` | `nbincdf` | `nbinpdf` | `nbinstat` | `nbinfit` | `nbinrnd`

nbinpdf

Negative binomial probability density function

Syntax

```
Y = nbinpdf(X,R,P)
```

Description

`Y = nbinpdf(X,R,P)` returns the negative binomial pdf at each of the values in `X` using the corresponding number of successes, `R` and probability of success in a single trial, `P`. `X`, `R`, and `P` can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of `Y`. A scalar input for `X`, `R`, or `P` is expanded to a constant array with the same dimensions as the other inputs. Note that the density function is zero unless the values in `X` are integers.

The negative binomial pdf is

$$y = f(x \mid r, p) = \binom{r + x - 1}{x} p^r q^x I_{(0,1,\ldots)}(x)$$

The simplest motivation for the negative binomial is the case of successive random trials, each having a constant probability `P` of success. The number of *extra* trials you must perform in order to observe a given number `R` of successes has a negative binomial distribution. However, consistent with a more general interpretation of the negative binomial, `nbinpdf` allows `R` to be any positive value, including nonintegers. When `R` is noninteger, the binomial coefficient in the definition of the pdf is replaced by the equivalent expression

$$\frac{\Gamma(r + x)}{\Gamma(r)\Gamma(x + 1)}$$

Examples

Compute the Negative Binomial Distribution pdf

Compute the pdf of a negative binomial distribution with parameters `R = 3` and `p = 0.5`.

```
x = (0:10);
y = nbinpdf(x,3,0.5);
```

Plot the pdf.

```
figure;
plot(x,y,'+')
xlim([-0.5,10.5])
```

nbinrnd

Negative binomial random numbers

Syntax

```
RND = nbinrnd(R,P)
RND = nbinrnd(R,P,m,n,...)
RND = nbinrnd(R,P,[m,n,...])
```

Description

`RND = nbinrnd(R,P)` is a matrix of random numbers chosen from a negative binomial distribution with corresponding number of successes, `R` and probability of success in a single trial, `P`. `R` and `P` can be vectors, matrices, or multidimensional arrays that have the same size, which is also the size of `RND`. A scalar input for `R` or `P` is expanded to a constant array with the same dimensions as the other input.

`RND = nbinrnd(R,P,m,n,...)` or `RND = nbinrnd(R,P,[m,n,...])` generates an `m`-by-`n`-by-... array. The `R`, `P` parameters can each be scalars or arrays of the same size as `R`.

The simplest motivation for the negative binomial is the case of successive random trials, each having a constant probability `P` of success. The number of *extra* trials you must perform in order to observe a given number `R` of successes has a negative binomial distribution. However, consistent with a more general interpretation of the negative binomial, `nbinrnd` allows `R` to be any positive value, including nonintegers.

Examples

Suppose you want to simulate a process that has a defect probability of 0.01. How many units might Quality Assurance inspect before finding three defective items?

```
r = nbinrnd(3,0.01,1,6)+3
r =
  496  142  420  396  851  178
```

nbinstat

Negative binomial mean and variance

Syntax

```
[M,V] = nbinstat(R,P)
```

Description

`[M,V] = nbinstat(R,P)` returns the mean of and variance for the negative binomial distribution with corresponding number of successes, `R` and probability of success in a single trial, `P`. `R` and `P` can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of `M` and `V`. A scalar input for `R` or `P` is expanded to a constant array with the same dimensions as the other input.

The mean of the negative binomial distribution with parameters r and p is rq / p, where $q = 1 - p$. The variance is rq / p^2.

The simplest motivation for the negative binomial is the case of successive random trials, each having a constant probability `P` of success. The number of *extra* trials you must perform in order to observe a given number `R` of successes has a negative binomial distribution. However, consistent with a more general interpretation of the negative binomial, `nbinstat` allows `R` to be any positive value, including nonintegers.

Examples

```
p = 0.1:0.2:0.9;
r = 1:5;
[R,P] = meshgrid(r,p);
[M,V] = nbinstat(R,P)
M =

ncfcdf

Noncentral F cumulative distribution function

Syntax

```
p = ncfcdf(x,nu1,nu2,delta)
p = ncfcdf(x,nu1,nu2,delta,'upper')
```

Description

`p = ncfcdf(x,nu1,nu2,delta)` computes the noncentral F cdf at each value in `x` using the corresponding numerator degrees of freedom in `nu1`, denominator degrees of freedom in `nu2`, and positive noncentrality parameters in `delta`. `nu1`, `nu2`, and `delta` can be vectors, matrices, or multidimensional arrays that have the same size, which is also the size of `p`. A scalar input for `x`, `nu1`, `nu2`, or `delta` is expanded to a constant array with the same dimensions as the other inputs.

`p = ncfcdf(x,nu1,nu2,delta,'upper')` returns the complement of the noncentral F cdf at each value in `x`, using an algorithm that more accurately computes the extreme upper tail probabilities.

The noncentral F cdf is

$$F(x \mid \nu_1,\nu_2,\delta) = \sum_{j=0}^{\infty}\left(\frac{\left(\frac{1}{2}\delta\right)^j}{j!}e^{\frac{-\delta}{2}}\right) I\left(\frac{\nu_1 \cdot x}{\nu_2+\nu_1 \cdot x}\middle|\frac{\nu_1}{2}+j,\frac{\nu_2}{2}\right)$$

where $I(x \mid a,b)$ is the incomplete beta function with parameters a and b.

Examples

Compute Noncentral F Distribution cdf

Compare the noncentral F cdf with $\delta = 10$ to the F cdf with the same number of numerator and denominator degrees of freedom (5 and 20 respectively).

```
x = (0.01:0.1:10.01)';
p1 = ncfcdf(x,5,20,10);
p = fcdf(x,5,20);
plot(x,p,'-',x,p1,'-')
```

`cdf` | `ncfpdf` | `ncfinv` | `ncfstat` | `ncfrnd`

ncfinv

Noncentral F inverse cumulative distribution function

Syntax

```
X = ncfinv(P,NU1,NU2,DELTA)
```

Description

`X = ncfinv(P,NU1,NU2,DELTA)` returns the inverse of the noncentral F cdf with numerator degrees of freedom `NU1`, denominator degrees of freedom `NU2`, and positive noncentrality parameter `DELTA` for the corresponding probabilities in `P`. `P`, `NU1`, `NU2`, and `DELTA` can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of `X`. A scalar input for `P`, `NU1`, `NU2`, or `DELTA` is expanded to a constant array with the same dimensions as the other inputs.

Examples

One hypothesis test for comparing two sample variances is to take their ratio and compare it to an F distribution. If the numerator and denominator degrees of freedom are 5 and 20 respectively, then you reject the hypothesis that the first variance is equal to the second variance if their ratio is less than that computed below.

```
critical = finv(0.95,5,20)
critical =
  2.7109
```

Suppose the truth is that the first variance is twice as big as the second variance. How likely is it that you would detect this difference?

```
prob = 1 - ncfcdf(critical,5,20,2)
prob =
  0.1297
```

If the true ratio of variances is 2, what is the typical (median) value you would expect for the F statistic?

```
ncfinv(0.5,5,20,2)
ans =
    1.2786
```

ncfpdf

Noncentral *F* probability density function

Syntax

```
Y = ncfpdf(X,NU1,NU2,DELTA)
```

Description

`Y = ncfpdf(X,NU1,NU2,DELTA)` computes the noncentral *F* pdf at each of the values in `X` using the corresponding numerator degrees of freedom in `NU1`, denominator degrees of freedom in `NU2`, and positive noncentrality parameters in `DELTA`. `X`, `NU1`, `N2`, and `B` can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of `Y`. A scalar input for `P`, `NU1`, `NU2`, or `DELTA` is expanded to a constant array with the same dimensions as the other inputs.

The *F* distribution is a special case of the noncentral *F* where $\delta = 0$. As δ increases, the distribution flattens like the plot in the example.

Examples

Compute Noncentral *F* Distribution pdf

Compute the pdf of a noncentral *F* distribution with degrees of freedom `NU1 = 5` and `NU2 = 20`, and noncentrality parameter `DELTA = 10`. For comparison, also compute the pdf of an *F* distribution with the same degrees of freedom.

```
x = (0.01:0.1:10.01)';
p1 = ncfpdf(x,5,20,10);
p = fpdf(x,5,20);
```

Plot the pdf of the noncentral *F* distribution and the pdf of the *F* distribution on the same figure.

```
figure;
plot(x,p1,'b-','LineWidth',2)
hold on
```

```
plot(x,p,'g--','LineWidth',2)
legend('Noncentral F','F distribution')
```

ncfrnd

Noncentral F random numbers

Syntax

```
R = ncfrnd(NU1,NU2,DELTA)
R = ncfrnd(NU1,NU2,DELTA,m,n,...)
R = ncfrnd(NU1,NU2,DELTA,[m,n,...])
```

Description

`R = ncfrnd(NU1,NU2,DELTA)` returns a matrix of random numbers chosen from the noncentral F distribution with corresponding numerator degrees of freedom in `NU1`, denominator degrees of freedom in `NU2`, and positive noncentrality parameters in `DELTA`. `NU1`, `NU2`, and `DELTA` can be vectors, matrices, or multidimensional arrays that have the same size, which is also the size of `R`. A scalar input for `NU1`, `NU2`, or `DELTA` is expanded to a constant matrix with the same dimensions as the other inputs.

`R = ncfrnd(NU1,NU2,DELTA,m,n,...)` or `R = ncfrnd(NU1,NU2,DELTA,[m,n,...])` generates an `m`-by-`n`-by-... array. The `NU1`, `NU2`, `DELTA` parameters can each be scalars or arrays of the same size as `R`.

Examples

Compute six random numbers from a noncentral F distribution with 10 numerator degrees of freedom, 100 denominator degrees of freedom and a noncentrality parameter, δ, of 4.0. Compare this to the F distribution with the same degrees of freedom.

```
r = ncfrnd(10,100,4,1,6)
r =
  2.5995  0.8824  0.8220  1.4485  1.4415  1.4864

r1 = frnd(10,100,1,6)
r1 =
  0.9826  0.5911  1.0967  0.9681  2.0096  0.6598
```

`random` | `ncfpdf` | `ncfcdf` | `ncfinv` | `ncfstat`

ncfstat

Noncentral F mean and variance

Syntax

```
[M,V] = ncfstat(NU1,NU2,DELTA)
```

Description

`[M,V] = ncfstat(NU1,NU2,DELTA)` returns the mean of and variance for the noncentral F pdf with corresponding numerator degrees of freedom in `NU1`, denominator degrees of freedom in `NU2`, and positive noncentrality parameters in `DELTA`. `NU1`, `NU2`, and `DELTA` can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of `M` and `V`. A scalar input for `NU1`, `NU2`, or `DELTA` is expanded to a constant array with the same dimensions as the other input.

The mean of the noncentral F distribution with parameters ν_1, ν_2, and δ is

$$\frac{\nu_2(\delta+\nu_1)}{\nu_1(\nu_2-2)}$$

where $\nu_2 > 2$.

The variance is

$$2\left(\frac{\nu_2}{\nu_1}\right)^2\left[\frac{(\delta+\nu_1)^2+(2\delta+\nu_1)(\nu_2-2)}{(\nu_2-2)^2(\nu_2-4)}\right]$$

where $\nu_2 > 4$.

Examples

```
[m,v]= ncfstat(10,100,4)
```

```
m =
  1.4286
v =
  0.4252
```

Syntax

```
[M,V] = nctstat(NU,DELTA)
```

Description

`[M,V] = nctstat(NU,DELTA)` returns the mean of and variance for the noncentral t pdf with `NU` degrees of freedom and noncentrality parameter `DELTA`. `NU` and `DELTA` can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of `M` and `V`. A scalar input for `NU` or `DELTA` is expanded to a constant array with the same dimensions as the other input.

The mean of the noncentral t distribution with parameters ν and δ is

$$\frac{\delta(\nu/2)^{1/2}\Gamma((\nu-1)/2)}{\Gamma(\nu/2)}$$

where $\nu > 1$.

The variance is

$$\frac{\nu}{(\nu-2)}(1+\delta^2)-\frac{\nu}{2}\delta^2\left[\frac{\Gamma((\nu-1)/2)}{\Gamma(\nu/2)}\right]^2$$

where $\nu > 2$.

Examples

```
[m,v] = nctstat(10,1)

m =
```

```
    1.0837

v =
    1.3255
```

`nctpdf` | `nctcdf` | `nctinv` | `nctrnd`

ncx2cdf

Noncentral chi-square cumulative distribution function

Syntax

```
p = ncx2cdf(x,v,delta)
p = ncx2cdf(x,v,delta,'upper')
```

Description

`p = ncx2cdf(x,v,delta)` computes the noncentral chi-square cdf at each value in `x` using the corresponding degrees of freedom in `v` and positive noncentrality parameters in `delta`. `x`, `v`, and `delta` can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of `p`. A scalar input for `x`, `v`, or `delta` is expanded to a constant array with the same dimensions as the other inputs.

`p = ncx2cdf(x,v,delta,'upper')` returns the complement of the noncentral chi-square cdf at each value in `x`, using an algorithm that more accurately computes the extreme upper tail probabilities.

Some texts refer to this distribution as the generalized Rayleigh, Rayleigh-Rice, or Rice distribution.

The noncentral chi-square cdf is

$$F(x \mid \nu,\delta) = \sum_{j=0}^{\infty} \left(\frac{\left(\frac{1}{2}\delta\right)^j}{j!} e^{\frac{-\delta}{2}} \right) \Pr\left[\chi^2_{\nu+2j} \le x\right]$$

Examples

Compute Noncentral Chi-Square cdf

Compare the noncentral chi-square cdf with `DELTA = 2` to the chi-square cdf with the same number of degrees of freedom (4):

```
x = (0:0.1:10)';
ncx2 = ncx2cdf(x,4,2);
chi2 = chi2cdf(x,4);

plot(x,ncx2,'b-','LineWidth',2)
hold on
plot(x,chi2,'g--','LineWidth',2)
legend('ncx2','chi2','Location','NW')
```

ncx2inv

Noncentral chi-square inverse cumulative distribution function

Syntax

```
X = ncx2inv(P,V,DELTA)
```

Description

`X = ncx2inv(P,V,DELTA)` returns the inverse of the noncentral chi-square cdf using the corresponding degrees of freedom in `V` and positive noncentrality parameters in `DELTA`, at the corresponding probabilities in `P`. `P`, `V`, and `DELTA` can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of `X`. A scalar input for `P`, `V`, or `DELTA` is expanded to a constant array with the same dimensions as the other inputs.

Examples

```
ncx2inv([0.01 0.05 0.1],4,2)
ans =
  0.4858  1.1498  1.7066
```

More About

Algorithms

`ncx2inv` uses Newton's method to converge to the solution.

ncx2pdf

Noncentral chi-square probability density function

Syntax

```
Y = ncx2pdf(X,V,DELTA)
```

Description

`Y = ncx2pdf(X,V,DELTA)` computes the noncentral chi-square pdf at each of the values in `X` using the corresponding degrees of freedom in `V` and positive noncentrality parameters in `DELTA`. Vector or matrix inputs for `X`, `V`, and `DELTA` must have the same size, which is also the size of `Y`. A scalar input for `X`, `V`, or `DELTA` is expanded to a constant array with the same dimensions as the other inputs.

Some texts refer to this distribution as the generalized Rayleigh, Rayleigh-Rice, or Rice distribution.

Examples

Compute Noncentral Chi-Square Distribution pdf

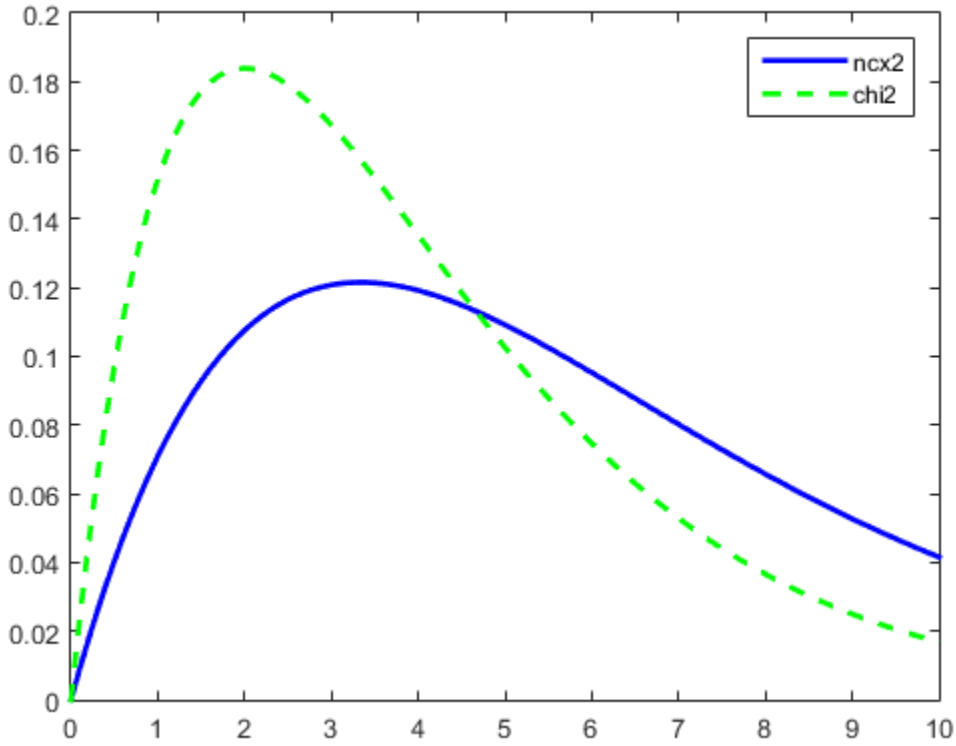
Compute the pdf of a noncentral chi-square distribution with degrees of freedom `V = 4` and noncentrality parameter `DELTA = 2`. For comparison, also compute the pdf of a chi-square distribution with the same degrees of freedom.

```
x = (0:0.1:10)';
ncx2 = ncx2pdf(x,4,2);
chi2 = chi2pdf(x,4);
```

Plot the pdf of the noncentral chi-square distribution on the same figure as the pdf of the chi-square distribution.

```
figure;
plot(x,ncx2,'b-','LineWidth',2)
hold on
plot(x,chi2,'g--','LineWidth',2)
```

```
legend('ncx2','chi2')
```



More About

ncx2rnd

Noncentral chi-square random numbers

Syntax

```
R = ncx2rnd(V,DELTA)
R = ncx2rnd(V,DELTA,m,n,...)
R = ncx2rnd(V,DELTA,[m,n,...])
```

Description

`R = ncx2rnd(V,DELTA)` returns a matrix of random numbers chosen from the noncentral chi-square distribution using the corresponding degrees of freedom in `V` and positive noncentrality parameters in `DELTA`. `V` and `DELTA` can be vectors, matrices, or multidimensional arrays that have the same size, which is also the size of `R`. A scalar input for `V` or `DELTA` is expanded to a constant array with the same dimensions as the other input.

`R = ncx2rnd(V,DELTA,m,n,...)` or `R = ncx2rnd(V,DELTA,[m,n,...])` generates an `m`-by-`n`-by-... array. The `V`, `DELTA` parameters can each be scalars or arrays of the same size as `R`.

Examples

```
ncx2rnd(4,2,6,3)
ans =
  6.8552  5.9650  11.2961
  5.2631  4.2640  5.9495
  9.1939  6.7162  3.8315
 10.3100  4.4828  7.1653
  2.1142  1.9826  4.6400
  3.8852  5.3999  0.9282
```

ncx2stat

Noncentral chi-square mean and variance

Syntax

```
[M,V] = ncx2stat(NU,DELTA)
```

Description

`[M,V] = ncx2stat(NU,DELTA)` returns the mean of and variance for the noncentral chi-square pdf with `NU` degrees of freedom and noncentrality parameter `DELTA`. `NU` and `DELTA` can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of `M` and `V`. A scalar input for `NU` or `DELTA` is expanded to a constant array with the same dimensions as the other input.

The mean of the noncentral chi-square distribution with parameters v and δ is v+δ, and the variance is 2(v+2δ).

Examples

```
[m,v] = ncx2stat(4,2)
m =
   6
v =
  16
```

NumVariables property

Class: gmdistribution

Dimension d of multivariate Gaussian distributions

Description

The dimension d of the multivariate Gaussian distributions.

ndims

Class: dataset

Number of dimensions of dataset array

Compatibility

The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

Syntax

```
n = ndims(A)
```

Description

`n = ndims(A)` returns the number of dimensions in the dataset `A`. The number of dimensions in an array is always 2.

See Also

`size`

ndims

Class: qrandset

Number of dimensions in matrix

Syntax

```
n = ndims(p)
```

Description

`n = ndims(p)` returns the number of dimensions in the matrix that is created by the syntax `p(:,:)`. Since this is always a 2-D matrix, `n` is always equal to 2.

See Also

`qrandset` | `size`

NDims property

Class: NaiveBayes

Number of dimensions

Description

The `NDims` property specifies the number of dimensions, which is equal to the number of features in the training data used to create the Naive Bayes classifier.

ne

Class: qrandstream

Not equal relation for handles

Syntax

```
h1 ~= h2
```

Description

Handles are equal if they are handles for the same object and are unequal otherwise.

`h1 ~= h2` performs element-wise comparisons between handle arrays `h1` and `h2`. `h1` and `h2` must be of the same dimensions unless one is a scalar. The result is a logical array of the same dimensions, where each element is an element-wise `~=` result.

If one of `h1` or `h2` is scalar, scalar expansion is performed and the result will match the dimensions of the array that is not scalar.

`tf = ne(h1, h2)` stores the result in a logical array of the same dimensions.

prob.NegativeBinomialDistribution class

Package: prob
Superclasses: prob.ToolboxFittableParametricDistribution

Negative binomial distribution object

Description

`prob.NegativeBinomialDistribution` is an object consisting of parameters, a model description, and sample data for a negative binomial probability distribution.

Create a probability distribution object with specified parameter values using `makedist`. Alternatively, fit a distribution to data using `fitdist` or the Distribution Fitting app.

Construction

`pd = makedist('NegativeBinomial')` creates a negative binomial probability distribution object using the default parameter values.

`pd = makedist('NegativeBinomial','R',R,'p',p)` creates a negative binomial probability distribution object using the specified parameter values.

Input Arguments

`R` — Number of successes

1 (default) | positive scalar value

Number of successes for the negative binomial distribution, specified as a positive scalar value.

Data Types: `single` | `double`

`p` — Probability of success

0.5 (default) | positive scalar value in the range (0,1]

Probability of success of any individual trial for the negative binomial distribution, specified as a positive scalar value in the range (0,1].

Data Types: `single` | `double`

Properties

`R` — Number of successes
positive scalar value

Number of successes for the negative binomial distribution, stored as a positive scalar value.

Data Types: `single` | `double`

`p` — Probability of success
positive scalar value in the range (0,1]

Probability of success of any individual trial for the negative binomial distribution, specified as a positive scalar value in the range (0,1].

Data Types: `single` | `double`

`DistributionName` — Probability distribution name
probability distribution name string

Probability distribution name, stored as a valid probability distribution name string. This property is read-only.

Data Types: `char`

`InputData` — Data used for distribution fitting
structure

Data used for distribution fitting, stored as a structure containing the following:

- `data`: Data vector used for distribution fitting.
- `cens`: Censoring vector, or empty if none.
- `freq`: Frequency vector, or empty if none.

This property is read-only.

Data Types: `struct`

`IsTruncated` — Logical flag for truncated distribution
`0` | `1`

Logical flag for truncated distribution, stored as a logical value. If `IsTruncated` equals `0`, the distribution is not truncated. If `IsTruncated` equals `1`, the distribution is truncated. This property is read-only.

Data Types: `logical`

`NumParameters` — Number of parameters

positive integer value

Number of parameters for the probability distribution, stored as a positive integer value. This property is read-only.

Data Types: `single | double`

`ParameterCovariance` — Covariance matrix of the parameter estimates

matrix of scalar values

Covariance matrix of the parameter estimates, stored as a p-by-p matrix, where p is the number of parameters in the distribution. The (`i`,`j`) element is the covariance between the estimates of the `i`th parameter and the `j`th parameter. The (`i`,`i`) element is the estimated variance of the `i`th parameter. If parameter `i` is fixed rather than estimated by fitting the distribution to data, then the (`i`,`i`) elements of the covariance matrix are 0. This property is read-only.

Data Types: `single | double`

`ParameterDescription` — Distribution parameter descriptions

cell array of strings

Distribution parameter descriptions, stored as a cell array of strings. Each cell contains a short description of one distribution parameter. This property is read-only.

Data Types: `char`

`ParameterIsFixed` — Logical flag for fixed parameters

array of logical values

Logical flag for fixed parameters, stored as an array of logical values. If `0`, the corresponding parameter in the `ParameterNames` array is not fixed. If `1`, the corresponding parameter in the `ParameterNames` array is fixed. This property is read-only.

Data Types: `logical`

`ParameterNames` — Distribution parameter names

cell array of strings

Distribution parameter names, stored as a cell array of strings. This property is read-only.

Data Types: `char`

`ParameterValues` — Distribution parameter values

vector of scalar values

Distribution parameter values, stored as a vector. This property is read-only.

Data Types: `single | double`

`Truncation` — Truncation interval

vector of scalar values

Truncation interval for the probability distribution, stored as a vector containing the lower and upper truncation boundaries. This property is read-only.

Data Types: `single | double`

Methods

Inherited Methods

cdf	Cumulative distribution function of probability distribution object
icdf	Inverse cumulative distribution function of probability distribution object
iqr	Interquartile range of probability distribution object
median	Median of probability distribution object

pdf	Probability density function of probability distribution object
random	Generate random numbers from probability distribution object
truncate	Truncate probability distribution object
mean	Mean of probability distribution object
negloglik	Negative log likelihood of probability distribution object
paramci	Confidence intervals for probability distribution parameters
proflik	Profile likelihood function for probability distribution object
std	Standard deviation of probability distribution object
var	Variance of probability distribution object

Definitions

Negative Binomial Distribution

The negative binomial distribution models the number of failures x before a specified number of successes is reached in a series of independent, identical trials. This distribution can also model count data, in which case r does not need to be an integer value.

The negative binomial distribution uses the following parameters.

Parameter	Description	Support
R	Number of successes	$r > 0$
p	Probability of success	$0 < p \le 1$

The probability density function (pdf) when R is an integer is

$$f(x \mid R,p) = \binom{R+x+1}{x} p^R q^x \quad ; \quad x = 1,2,\ldots,\infty ,$$

where $q = 1 - p$ and $\binom{R+x+1}{x}$ is the binomial coefficient.

When R is not an integer, the binomial coefficient in the definition of the pdf is replaced by the equivalent expression

$$\frac{\Gamma(r+x)}{\Gamma(r)\Gamma(x+1)},$$

where $\Gamma(\cdot)$ is the Gamma function.

Examples

Create a Negative Binomial Distribution Object Using Default Parameters

Create a negative binomial distribution object using the default parameter values.

```
pd = makedist('NegativeBinomial')
```

```
pd =

  NegativeBinomialDistribution

  Negative Binomial distribution
    R =   1
```

```
    P = 0.5
```

Create a Negative Binomial Distribution Object Using Specified Parameters

Create a negative binomial distribution object by specifying the parameter values.

```
pd = makedist('NegativeBinomial','r',5,'p',.1)
```

```
pd =

  NegativeBinomialDistribution

  Negative Binomial distribution
    R =   5
    P = 0.1
```

Compute the mean of the distribution.

```
m = mean(pd)
```

```
m =

    45
```

negloglik

Negative log likelihood of probability distribution

Syntax

```
nll = negloglik(pd)
```

Description

`nll = negloglik(pd)` returns the value of the negative loglikelihood function for the data used to fit the probability distribution pd.

Examples

Negative Log Likelihood for a Fitted Distribution

Load the sample data.

```
load carsmall;
```

Create a Weibull distribution object by fitting it to the mile per gallon (MPG) data.

```
pd = fitdist(MPG,'Weibull')
```

```
pd =

  WeibullDistribution

  Weibull distribution
    A = 26.5079   [24.8333, 28.2954]
    B = 3.27193   [2.79441, 3.83104]
```

Compute the negative log likelihood for the fitted Weibull distribution.

```
wnll = negloglik(pd)
```

```
wnll =
```

```
327.4942
```

Input Arguments

`pd` — Probability distribution

probability distribution object

Probability distribution, specified as a probability distribution object. Create a probability distribution object with specified parameter values using `makedist`. Alternatively, create a probability distribution object by fitting it to data using `fitdist` or the Distribution Fitting app.

Output Arguments

`nll` — Negative log likelihood

scalar value

Negative log likelihood value for the data used to fit the distribution, returned as a scalar value.

dfittool | fitdist | makedist

net

Class: qrandset

Generate quasi-random point set

Syntax

```
X = net(p,n)
```

Description

`X = net(p,n)` returns the first `n` points `X` from the point set `p` of the `qrandset` class. `X` is `n`-by-*d*, where *d* is the dimension of the point set.

Objects `p` of the `@qrandset` class encapsulate properties of a specified quasi-random sequence. Values of the point set are not generated and stored in memory until `p` is accessed using `net` or parenthesis indexing.

Examples

Use `haltonset` to generate a 3-D Halton point set, skip the first 1000 values, and then retain every 101st point:

```
p = haltonset(3,'Skip',1e3,'Leap',1e2)
p =
    Halton point set in 3 dimensions (8.918019e+013 points)
    Properties:
              Skip : 1000
              Leap : 100
    ScrambleMethod : none
```

Use `scramble` to apply reverse-radix scrambling:

```
p = scramble(p,'RR2')
p =
    Halton point set in 3 dimensions (8.918019e+013 points)
    Properties:
```

```
              Skip : 1000
              Leap : 100
    ScrambleMethod : RR2
```

Use `net` to generate the first four points:

```
X0 = net(p,4)
X0 =
    0.0928    0.6950    0.0029
    0.6958    0.2958    0.8269
    0.3013    0.6497    0.4141
    0.9087    0.7883    0.2166
```

Use parenthesis indexing to generate every third point, up to the 11th point:

```
X = p(1:3:11,:)
X =
    0.0928    0.6950    0.0029
    0.9087    0.7883    0.2166
    0.3843    0.9840    0.9878
    0.6831    0.7357    0.7923
```

See Also

`haltonset` | `sobolset` | `qrandstream`

nLinearCoeffs

Class: CompactClassificationDiscriminant

Number of nonzero linear coefficients

Syntax

```
ncoeffs = nLinearCoeffs(obj)
ncoeffs = nLinearCoeffs(obj,delta)
```

Description

`ncoeffs = nLinearCoeffs(obj)` returns the number of nonzero linear coefficients in the linear discriminant model `obj`.

`ncoeffs = nLinearCoeffs(obj,delta)` returns the number of nonzero linear coefficients for threshold parameter `delta`.

Input Arguments

`obj`

Discriminant analysis classifier, produced using `fitcdiscr`.

`delta`

Scalar or vector value of the `Delta` parameter. See “Gamma and Delta” on page 22-3152.

Output Arguments

`ncoeffs`

Nonnegative integer, the number of nonzero coefficients in the discriminant analysis model `obj`.

If you call `nLinearCoeffs` with a `delta` argument, `ncoeffs` is the number of nonzero linear coefficients for threshold parameter `delta`. If `delta` is a vector, `ncoeffs` is a vector with the same number of elements.

If `obj` is a quadratic discriminant model, `ncoeffs` is the number of predictors in `obj`.

Definitions

Gamma and Delta

Regularization is the process of finding a small set of predictors that yield an effective predictive model. For linear discriminant analysis, there are two parameters, γ and δ, that control regularization as follows. `cvshrink` helps you select appropriate values of the parameters.

Let Σ represent the covariance matrix of the data X, and let $\hat{X}$ be the centered data (the data X minus the mean by class). Define

$$D = \mathrm{diag}\left(\hat{X}^T * \hat{X}\right).$$

The regularized covariance matrix $\tilde{\Sigma}$ is

$$\tilde{\Sigma} = (1-\gamma)\Sigma + \gamma D.$$

Whenever $\gamma \geq$ `MinGamma`, $\tilde{\Sigma}$ is nonsingular.

Let μ_k be the mean vector for those elements of X in class k, and let μ_0 be the global mean vector (the mean of the rows of X). Let C be the correlation matrix of the data X, and let $\tilde{C}$ be the regularized correlation matrix:

$$\tilde{C} = (1-\gamma)C + \gamma I,$$

where I is the identity matrix.

The linear term in the regularized discriminant analysis classifier for a data point x is

$$(x-\mu_0)^T\tilde{\Sigma}^{-1}(\mu_k-\mu_0)=\left[(x-\mu_0)^T D^{-1/2}\right]\left[\tilde{C}^{-1}D^{-1/2}(\mu_k-\mu_0)\right].$$

The parameter δ enters into this equation as a threshold on the final term in square brackets. Each component of the vector $\left[\tilde{C}^{-1}D^{-1/2}(\mu_k-\mu_0)\right]$ is set to zero if it is smaller in magnitude than the threshold δ. Therefore, for class k, if component j is thresholded to zero, component j of x does not enter into the evaluation of the posterior probability.

The `DeltaPredictor` property is a vector related to this threshold. When $\delta \geq$ `DeltaPredictor(i)`, all classes k have

$$\left|\tilde{C}^{-1}D^{-1/2}(\mu_k-\mu_0)\right|\leq\delta.$$

Therefore, when $\delta \geq$ `DeltaPredictor(i)`, the regularized classifier does not use predictor `i`.

Examples

Find the Number of Nonzero Coefficients in a Discriminant Analysis Classifier

Find the number of nonzero coefficients in a discriminant analysis classifier for various `Delta` values.

Create a discriminant analysis classifier from the `fishseriris` data.

```
load fisheriris
obj = fitcdiscr(meas,species);
```

Find the number of nonzero coefficients in `obj`.

```
ncoeffs = nLinearCoeffs(obj)
```

```
ncoeffs =

     4
```

Find the number of nonzero coefficients for `delta` = 1, 2, 4, and 8.

```
delta = [1 2 4 8];
ncoeffs = nLinearCoeffs(obj,delta)
```

```
ncoeffs =

     4
     4
     3
     0
```

The `DeltaPredictor` property gives the values of `delta` where the number of nonzero coefficients changes.

```
ncoeffs2 = nLinearCoeffs(obj,obj.DeltaPredictor)
```

```
ncoeffs2 =

     4
     3
     1
     2
```

nlinfit

Nonlinear regression

Syntax

```
beta = nlinfit(X,Y,modelfun,beta0)
beta = nlinfit(X,Y,modelfun,beta0,options)
beta = nlinfit(___,Name,Value)
[beta,R,J,CovB,MSE,ErrorModelInfo] = nlinfit(___)
```

Description

`beta = nlinfit(X,Y,modelfun,beta0)` returns a vector of estimated coefficients for the nonlinear regression of the responses in Y on the predictors in X using the model specified by modelfun. The coefficients are estimated using iterative least squares estimation, with initial values specified by beta0.

`beta = nlinfit(X,Y,modelfun,beta0,options)` fits the nonlinear regression using the algorithm control parameters in the structure options. You can return any of the output arguments in the previous syntaxes.

`beta = nlinfit(___,Name,Value)` uses additional options specified by one or more name-value pair arguments. For example, you can specify observation weights or a nonconstant error model. You can use any of the input arguments in the previous syntaxes.

`[beta,R,J,CovB,MSE,ErrorModelInfo] = nlinfit(___)` additionally returns the residuals, R, the Jacobian of `modelfun`, J, the estimated variance-covariance matrix for the estimated coefficients, CovB, an estimate of the variance of the error term, MSE, and a structure containing details about the error model, ErrorModelInfo.

Examples

Nonlinear Regression Model Using Default Options

Load sample data.

```
S = load('reaction');
X = S.reactants;
y = S.rate;
beta0 = S.beta;
```

Fit the Hougen-Watson model to the rate data using the initial values in `beta0`.

```
beta = nlinfit(X,y,@hougen,beta0)
```

```
beta =

    1.2526
    0.0628
    0.0400
    0.1124
    1.1914
```

Nonlinear Regression Using Robust Options

Generate sample data from the nonlinear regression model

$$y = b_1 + b_2 \exp\{-b_3 x\} + \varepsilon,$$

where b_1, b_2, and b_3 are coefficients, and the error term is normally distributed with mean 0 and standard deviation 0.1.

```
modelfun = @(b,x)(b(1)+b(2)*exp(-b(3)*x));

rng('default') % for reproducibility
b = [1;3;2];
x = exprnd(2,100,1);
y = modelfun(b,x) + normrnd(0,0.1,100,1);
```

Set robust fitting options.

```
opts = statset('nlinfit');
opts.RobustWgtFun = 'bisquare';
```

Fit the nonlinear model using the robust fitting options.

```
beta0 = [2;2;2];
beta = nlinfit(x,y,modelfun,beta0,opts)
```

```
beta =
```

```
    1.0041
    3.0997
    2.1483
```

Nonlinear Regression Using Observation Weights

Load sample data.

```
S = load('reaction');
X = S.reactants;
y = S.rate;
beta0 = S.beta;
```

Specify a vector of known observation weights.

```
W = [8 2 1 6 12 9 12 10 10 12 2 10 8]';
```

Fit the Hougen-Watson model to the rate data using the specified observation weights.

```
[beta,R,J,CovB] = nlinfit(X,y,@hougen,beta0,'Weights',W);
beta
```

```
beta =

    2.2068
    0.1077
    0.0766
    0.1818
    0.6516
```

Display the coefficient standard errors.

```
sqrt(diag(CovB))
```

```
ans =

    2.5721
    0.1251
    0.0950
    0.2043
    0.7735
```

Nonlinear Regression Using Weights Function Handle

Load sample data.

```
S = load('reaction');
```

```
X = S.reactants;
y = S.rate;
beta0 = S.beta;
```

Specify a function handle for observation weights. The function accepts the model fitted values as input, and returns a vector of weights.

```
a = 1; b = 1;
weights = @(yhat) 1./((a + b*abs(yhat)).^2);
```

Fit the Hougen-Watson model to the rate data using the specified observation weights function.

```
[beta,R,J,CovB] = nlinfit(X,y,@hougen,beta0,'Weights',weights);
beta
```

```
beta =

    0.8308
    0.0409
    0.0251
    0.0801
    1.8261
```

Display the coefficient standard errors.

```
sqrt(diag(CovB))
```

```
ans =

    0.5822
    0.0297
    0.0197
    0.0578
    1.2810
```

Nonlinear Regression Using Nonconstant Error Model

Load sample data.

```
S = load('reaction');
X = S.reactants;
y = S.rate;
beta0 = S.beta;
```

Fit the Hougen-Watson model to the rate data using the combined error model.

```
[beta,R,J,CovB,MSE,ErrorModelInfo] = nlinfit(X,y,@hougen,beta0,'ErrorModel','combined')
beta
```

```
beta =

    1.2526
    0.0628
    0.0400
    0.1124
    1.1914
```

Display the error model information.

```
ErrorModelInfo
```

```
ErrorModelInfo =

              ErrorModel: 'combined'
         ErrorParameters: [0.1517 5.6783e-08]
           ErrorVariance: @(x)mse*(errorparam(1)+errorparam(2)*abs(model(beta,x))).^2
                     MSE: 1.6245
          ScheffeSimPred: 6
          WeightFunction: 0
            FixedWeights: 0
    RobustWeightFunction: 0
```

Input Arguments

X — Predictor variables

matrix

Predictor variables for the nonlinear regression function, specified as a matrix. Typically, `X` is a design matrix of predictor (independent variable) values, with one row for each value in Y, and one column for each coefficient. However, `X` can be any array that modelfun can accept.

Data Types: `single` | `double`

Y — Response values

vector

Response values (dependent variable) for fitting the nonlinear regression function, specified as a vector with the same number of rows as X.

Data Types: `single` | `double`

`modelfun` — Nonlinear regression model function

function handle

Nonlinear regression model function, specified as a function handle. `modelfun` must accept two input arguments, a coefficient vector and an array `X`—in that order—and return a vector of fitted response values.

For example, to specify the `hougen` nonlinear regression function, use the function handle `@hougen`.

Data Types: `function_handle`

`beta0` — Initial coefficient values

vector

Initial coefficient values for the least squares estimation algorithm, specified as a vector.

Note: Poor starting values can lead to a solution with large residual error.

Data Types: `single` | `double`

`options` — Estimation algorithm options

structure created using `statset`

Estimation algorithm options, specified as a structure you create using `statset`. The following `statset` parameters are applicable to `nlinfit`.

`DerivStep` — Relative difference for finite difference gradient

`eps^(1/3)` (default) | positive scalar value | vector

Relative difference for the finite difference gradient calculation, specified as a positive scalar value, or a vector the same size as beta. Use a vector to specify a different relative difference for each coefficient.

`Display` — Level of output display

`'off'` (default) | `'iter'` | `'final'`

Level of output display during estimation, specified as one of `'off'`, `'iter'`, or `'final'`. If you specify `'iter'`, output is displayed at each iteration. If you specify `'final'`, output is displayed after the final iteration.

`FunValCheck` — Indicator for whether to check for invalid values

`'on'` (default) | `'off'`

Indicator for whether to check for invalid values such as `NaN` or `Inf` from the objective function, specified as `'on'` or `'off'`.

`MaxIter` — Maximum number of iterations

100 (default) | positive integer

Maximum number of iterations for the estimation algorithm, specified as a positive integer. Iterations continue until estimates are within the convergence tolerance, or the maximum number of iterations specified by `MaxIter` is reached.

`RobustWgtFun` — Weight function

string | function handle | `[ ]`

Weight function for robust fitting, specified as a valid string or function handle.

Note: `RobustWgtFun` must have value `[ ]` when you use observation weights, `W`.

The following table describes the possible string values. Let r denote normalized residuals and w denote robust weights. The indicator function I[x] is equal to 1 if the expression x is true, and 0 otherwise.

Weight Function	Equation	Default Tuning Constant
`''` (default)	No robust fitting	—
`'andrews'`	$w = I\left[\lvert r\rvert < \pi\right] \times \sin(r) / r$	1.339
`'bisquare'`	$w = I\left[\lvert r\rvert < 1\right] \times \left(1 - r^2\right)^2$	4.685
`'cauchy'`	$w = 1 \Big/ \left(1 + r^2\right)$	2.385
`'fair'`	$w = 1 \Big/ \left(1 + \lvert r\rvert\right)$	1.400

Weight Function	Equation	Default Tuning Constant
`'huber'`	$w = 1 / \max(1, \lvert r \rvert)$	1.345
`'logistic'`	$w = \tanh(r) / r$	1.205
`'talwar'`	$w = I[\lvert r \rvert < 1]$	2.795
`'welsch'`	$w = \exp\{-r^2\}$	2.985

You can alternatively specify a function handle that accepts a vector of normalized residuals as input, and returns a vector of robust weights as output. If you use a function handle, you must provide a Tune constant.

`Tune` — Tuning constant

positive scalar value

Tuning constant for robust fitting, specified as a positive scalar value. The tuning constant is used to normalize residuals before applying a robust weight function. The default tuning constant depends on the function specified by RobustWgtFun.

If you use a function handle to specify RobustWgtFun, then you must specify a value for `Tune`.

`TolFun` — Termination tolerance on residual sum of squares

`1e-8` (default) | positive scalar value

Termination tolerance for the residual sum of squares, specified as a positive scalar value. Iterations continue until estimates are within the convergence tolerance, or the maximum number of iterations specified by `MaxIter` is reached.

`TolX` — Termination tolerance on estimated coefficients

`1e-8` (default) | positive scalar value

Termination tolerance on the estimated coefficients, beta, specified as a positive scalar value. Iterations continue until estimates are within the convergence tolerance, or the maximum number of iterations specified by `MaxIter` is reached.

`Robust` — Indicator for robust fitting

`'off'` (default) | `'on'`

Indicator for robust fitting, specified as `'off'` or `'on'`.

Note: `Robust` will be removed in a future software release. Use `RobustWgtFun` for robust fitting.

`WgtFun` — Weight function for robust fitting

string | function handle

Weight function for robust fitting, specified as a string indicating a weight function, or a function handle. `WgtFun` is valid only when `Robust` has value `'on'`.

Note: `WgtFun` will be removed in a future software release. Use `RobustWgtFun` instead.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'ErrorModel','proportional','ErrorParameters',0.5` specifies a proportional error model, with initial value 0.5 for the error parameter estimation

`'ErrorModel'` — Form of error term

`'constant'` (default) | `'proportional'` | `'combined'`

Form of the error term, specified as the comma-separated pair consisting of `'ErrorModel'` and one of the following strings indicating the error model. Each model defines the error using a standard mean-zero and unit-variance variable e in combination with independent components: the function value f, and one or two parameters a and b.

`'constant'` (default)	$y = f + ae$
`'proportional'`	$y = f + bfe$
`'combined'`	$y = f + \left(a + b\left\|f\right\|\right)e$

The only allowed error model when using Weights is `'constant'`.

Note: `options.RobustWgtFun` must have value `[]` when using an error model other than `'constant'`.

`'ErrorParameters'` — Initial estimates for error model parameters

1 or `[1,1]` (default) | scalar value | two-element vector

Initial estimates for the error model parameters in the chosen ErrorModel, specified as the comma-separated pair consisting of `'ErrorParameters'` and a scalar value or two-element vector.

Error Model	Parameters	Default Values
`'constant'`	a	1
`'proportional'`	b	1
`'combined'`	a, b	`[1,1]`

For example, if `'ErrorModel'` has the value `'combined'`, you can specify the starting value 1 for a and the starting value 2 for b as follows.

Example: `'ErrorParameters',[1,2]`

You can only use the `'constant'` error model when using Weights.

Note: `options.RobustWgtFun` must have value `[]` when using an error model other than `'constant'`.

Data Types: `double` | `single`

`'Weights'` — Observation weights

vector | function handle

Observation weights, specified as the comma-separated pair consisting of `'Weights'` and a vector of real positive weights or a function handle. You can use observation weights to down-weight the observations that you want to have less influence on the fitted model.

- If `W` is a vector, then it must be the same size as Y.
- If `W` is a function handle, then it must accept a vector of predicted response values as input, and return a vector of real positive weights as output.

Note: `options.RobustWgtFun` must have value `[]` when you use observation weights.

Data Types: `double` | `single` | `function_handle`

Output Arguments

`beta` — Estimated regression coefficients

vector

Estimated regression coefficients, returned as a vector. The number of elements in `beta` equals the number of elements in beta0.

Let $f(X_i,\mathbf{b})$ denote the nonlinear function specified by modelfun, where $\mathbf{x}_i$ are the predictors for observation i, $i = 1,...,N$, and $\mathbf{b}$ are the regression coefficients. The vector of coefficients returned in `beta` minimizes the weighted least squares equation,

$$\sum_{i=1}^{N} w_i \left[y_i - f(\mathbf{x}_i,\mathbf{b})\right]^2.$$

For unweighted nonlinear regression, all of the weight terms are equal to 1.

`R` — Residuals

vector

Residuals for the fitted model, returned as a vector.

- If you specify observation weights using the name-value pair argument Weights, then `R` contains weighted residuals.
- If you specify an error model other than `'constant'` using the name-value pair argument ErrorModel, then you can no longer interpret R as model fit residuals.

`J` — Jacobian

matrix

Jacobian of the nonlinear regression model, modelfun, returned as an N-by-p matrix, where N is the number of observations and p is the number of estimated coefficients.

- If you specify observation weights using the name-value pair argument Weights, then `J` is the weighted model function Jacobian.

- If you specify an error model other than `'constant'` using the name-value pair argument ErrorModel, then you can no longer interpret J as the model function Jacobian.

`CovB` — Estimated variance-covariance matrix

matrix

Estimated variance-covariance matrix for the fitted coefficients, beta, returned as a *p*-by-*p* matrix, where *p* is the number of estimated coefficients. If the model Jacobian, J, has full column rank, then `CovB = inv(J'*J)*MSE`, where MSE is the mean squared error.

`MSE` — Mean squared error

scalar value

Mean squared error (MSE) of the fitted model, returned as a scalar value. MSE is an estimate of the variance of the error term. If the model Jacobian, J, has full column rank, then `MSE = (R'*R)/(N-p)`, where `N` is the number of observations, and `p` is the number of estimated coefficients.

`ErrorModelInfo` — Information about error model fit

structure

Information about the error model fit, returned as a structure with the following fields:

`ErrorModel`	Chosen error model
`ErrorParameters`	Estimated error parameters
`ErrorVariance`	Function handle that accepts an *N*-by-*p* matrix, `X`, and returns an *N*-by-1 vector of error variances using the estimated error model
`MSE`	Mean squared error
`ScheffeSimPred`	Scheffé parameter for simultaneous prediction intervals when using the estimated error model
`WeightFunction`	Logical with value `true` if you used a custom weight function previously in `nlinfit`
`FixedWeights`	Logical with value `true` if you used fixed weights previously in `nlinfit`
`RobustWeightFunction`	Logical with value `true` if you used robust fitting previously in

More About

Weighted Residuals

A *weighted residual* is a residual multiplied by the square root of the corresponding observation weight.

Given estimated regression coefficients, $\mathbf{b}$, the residual for observation i is

$$r_i = y_i - f(\mathbf{x}_i, \mathbf{b}),$$

where y_i is the observed response and $f(\mathbf{x}_i, \mathbf{b})$ is the fitted response at predictors $\mathbf{x}_i$.

When you fit a weighted nonlinear regression with weights w_i, $i = 1,...,N$, `nlinfit` returns the weighted residuals,

$$r_i^* = \sqrt{w_i}\left(y_i - f(\mathbf{x}_i, \mathbf{b})\right).$$

Weighted Model Function Jacobian

The *weighted model function Jacobian* is the nonlinear model Jacobian multiplied by the square root of the observation weight matrix.

Given estimated regression coefficients, $\mathbf{b}$, the estimated model Jacobian, $\mathbf{J}$, for the nonlinear function $f(\mathbf{x}_i, \mathbf{b})$ has elements

$$\mathbf{J}_{ij} = \frac{\partial f(\mathbf{x}_i, \mathbf{b})}{\partial b_j},$$

where b_j is the jth element of $\mathbf{b}$.

When you fit a weighted nonlinear regression with diagonal weights matrix $\mathbf{W}$, `nlinfit` returns the weighted Jacobian matrix,

$$\mathbf{J}^* = \mathbf{W}^{1/2}\mathbf{J}.$$

Tips

- To produce error estimates on predictions, use the optional output arguments `R`, `J`, `CovB`, or `MSE` as inputs to `nlpredci`.
- To produce error estimates on the estimated coefficients, `beta`, use the optional output arguments `R`, `J`, `CovB`, or `MSE` as inputs to `nlparci`.
- If you use the robust fitting option, RobustWgtFun, you must use `CovB`—and might need `MSE`—as inputs to `nlpredci` or `nlparci` to ensure that the confidence intervals take the robust fit properly into account.

Algorithms

- `nlinfit` treats `NaN` values in Y or `modelfun(beta0,X)` as missing data, and ignores the corresponding observations.
- For nonrobust estimation, `nlinfit` uses the Levenberg-Marquardt nonlinear least squares algorithm [1].
- For robust estimation, `nlinfit` uses an iterative reweighted least squares algorithm ([2], [3]). At each iteration, the robust weights are recalculated based on each observation's residual from the previous iteration. These weights downweight outliers, so that their influence on the fit is decreased. Iterations continue until the weights converge.
- When you specify a function handle for observation weights, the weights depend on the fitted model. In this case, `nlinfit` uses an iterative generalized least squares algorithm to fit the nonlinear regression model.

nlintool

Interactive nonlinear regression

Syntax

```
nlintool(X,y,fun,beta0)
nlintool(X,y,fun,beta0,alpha)
nlintool(X,y,fun,beta0,alpha,'xname','yname')
```

Description

`nlintool(X,y,fun,beta0)` is a graphical user interface to the `nlinfit` function, and uses the same input arguments. The interface displays plots of the fitted response against each predictor, with the other predictors held fixed. The fixed values are in the text boxes below each predictor axis. Change the fixed values by typing in a new value or by dragging the vertical lines in the plots to new positions. When you change the value of a predictor, all plots update to display the model at the new point in predictor space. Dashed red curves show 95% simultaneous confidence bands for the function.

`nlintool(X,y,fun,beta0,alpha)` shows `100(1-alpha)`% confidence bands. These are simultaneous confidence bounds for the function value. Using the **Bounds** menu you can switch between simultaneous and non-simultaneous bounds, and between bounds on the function and bounds for predicting a new observation.

`nlintool(X,y,fun,beta0,alpha,'xname','yname')` labels the plots using the string matrix `'xname'` for the predictors and the string `'yname'` for the response.

Examples

The data in `reaction.mat` are partial pressures of three chemical reactants and the corresponding reaction rates. The function `hougen` implements the nonlinear Hougen-Watson model for reaction rates. The following fits the model to the data:

```
load reaction
nlintool(reactants,rate,@hougen,beta,0.01,xn,yn)
```

`nlinfit` | `polytool` | `rstool`

nlmefit

Nonlinear mixed-effects estimation

Syntax

```
beta = nlmefit(X,y,group,V,fun,beta0)
[beta,PSI] = nlmefit(X,y,group,V,fun,beta0)
[beta,PSI,stats] = nlmefit(X,y,group,V,fun,beta0)
[beta,PSI,stats,B] = nlmefit(X,y,group,V,fun,beta0)
[beta,PSI,stats,B] = nlmefit(X,y,group,V,fun,beta0,'Name',value)
```

Description

`beta = nlmefit(X,y,group,V,fun,beta0)` fits a nonlinear mixed-effects regression model and returns estimates of the fixed effects in `beta`. By default, `nlmefit` fits a model in which each parameter is the sum of a fixed and a random effect, and the random effects are uncorrelated (their covariance matrix is diagonal).

`X` is an n-by-h matrix of n observations on h predictors.

`y` is an n-by-1 vector of responses.

`group` is a grouping variable indicating m groups in the observations. `group` is a categorical variable, a numeric vector, a character matrix with rows for group names, or a cell array of strings. For more information on grouping variables, see “Grouping Variables” on page 2-52.

`V` is an m-by-g matrix or cell array of g group-specific predictors. These are predictors that take the same value for all observations in a group. The rows of `V` are assigned to groups using `grp2idx`, according to the order specified by `grp2idx(group)`. Use a cell array for `V` if group predictors vary in size across groups. Use `[]` for `V` if there are no group-specific predictors.

`fun` is a handle to a function that accepts predictor values and model parameters and returns fitted values. `fun` has the form

```
yfit = modelfun(PHI,XFUN,VFUN)
```

The arguments are:

- `PHI` — A 1-by-p vector of model parameters.
- `XFUN` — A k-by-h array of predictors, where:
  - $k = 1$ if `XFUN` is a single row of `X`.
  - $k = n_i$ if `XFUN` contains the rows of `X` for a single group of size n_i.
  - $k = n$ if `XFUN` contains all rows of `X`.
- `VFUN` — Group-specific predictors given by one of:
  - A 1-by-g vector corresponding to a single group and a single row of `V`.
  - An n-by-g array, where the jth row is V(`I`,:) if the jth observation is in group `I`.

  If `V` is empty, `nlmefit` calls `modelfun` with only two inputs.
- `yfit` — A k-by-1 vector of fitted values

When either `PHI` or `VFUN` contains a single row, it corresponds to all rows in the other two input arguments.

Note: If `modelfun` can compute `yfit` for more than one vector of model parameters per call, use the `'Vectorization'` parameter (described later) for improved performance.

`beta0` is a q-by-1 vector with initial estimates for q fixed effects. By default, q is the number of model parameters p.

`nlmefit` fits the model by maximizing an approximation to the marginal likelihood with random effects integrated out, assuming that:

- Random effects are multivariate normally distributed and independent between groups.
- Observation errors are independent, identically normally distributed, and independent of the random effects.

`[beta,PSI] = nlmefit(X,y,group,V,fun,beta0)` also returns `PSI`, an r-by-r estimated covariance matrix for the random effects. By default, r is equal to the number of model parameters p.

`[beta,PSI,stats] = nlmefit(X,y,group,V,fun,beta0)` also returns `stats`, a structure with fields:

- `dfe` — The error degrees of freedom for the model

- `logl` — The maximized loglikelihood for the fitted model
- `rmse` — The square root of the estimated error variance (computed on the log scale for the `exponential` error model)
- `errorparam` — The estimated parameters of the error variance model
- `aic` — The Akaike information criterion, calculated as `aic` = -2 * `logl` + 2 * `numParam`, where `numParam` is the number of fitting parameters, including the degree of freedom for covariance matrix of the random effects, the number of fixed effects and the number of parameters of the error model, and `logl` is a field in the `stats` structure
- `bic` — The Bayesian information criterion, calculated as `bic` = –2*`logl` + log(`M`) * `numParam`

  - `M` is the number of groups.
  - `numParam` and `logl` are defined as in `aic`.

  Note that some literature suggests that the computation of `bic` should be , `bic` = –2*`logl` + log(`N`) * `numParam`, where `N` is the number of observations.
- `covb` — The estimated covariance matrix of the parameter estimates
- `sebeta` — The standard errors for `beta`
- `ires` — The population residuals `(y-y_population)`, where `y_population` is the individual predicted values
- `pres` — The population residuals `(y-y_population)`, where `y_population` is the population predicted values
- `iwres` — The individual weighted residuals
- `pwres` — The population weighted residuals
- `cwres` — The conditional weighted residuals

`[beta,PSI,stats,B] = nlmefit(X,y,group,V,fun,beta0)` also returns `B`, an *r*-by-*m* matrix of estimated random effects for the *m* groups. By default, *r* is equal to the number of model parameters *p*.

`[beta,PSI,stats,B] = nlmefit(X,y,group,V,fun,beta0,'`*`Name`*`,`*`value`*`)` specifies one or more optional parameter name/value pairs. Specify *`Name`* inside single quotes.

Use the following parameters to fit a model different from the default. (The default model is obtained by setting both `FEConstDesign` and `REConstDesign` to `eye(p)`, or by setting both `FEParamsSelect` and `REParamsSelect` to `1:p`.) Use at most one

parameter with an 'FE' prefix and one parameter with an 'RE' prefix. The nlmefit function requires you to specify at least one fixed effect and one random effect.

Parameter	Value
FEParamsSelect	A vector specifying which elements of the parameter vector PHI include a fixed effect, given as a numeric vector of indices from 1 to p or as a 1-by-*p* logical vector. If *q* is the specified number of elements, then the model includes *q* fixed effects.
FEConstDesign	A *p*-by-*q* design matrix ADESIGN, where ADESIGN*beta are the fixed components of the *p* elements of PHI.
FEGroupDesign	A *p*-by-*q*-by-*m* array specifying a different *p*-by-*q* fixed-effects design matrix for each of the *m* groups.
FEObsDesign	A *p*-by-*q*-by-*n* array specifying a different *p*-by-*q* fixed-effects design matrix for each of the *n* observations.
REParamsSelect	A vector specifying which elements of the parameter vector PHI include a random effect, given as a numeric vector of indices from 1 to p or as a 1-by-*p* logical vector. The model includes *r* random effects, where *r* is the specified number of elements.
REConstDesign	A *p*-by-*r* design matrix BDESIGN, where BDESIGN*B are the random components of the *p* elements of PHI.
REGroupDesign	A *p*-by-*r*-by-*m* array specifying a different *p*-by-*r* random-effects design matrix for each of *m* groups.
REObsDesign	A *p*-by-*r*-by-*n* array specifying a different *p*-by-*r* random-effects design matrix for each of *n* observations.

Use the following parameters to control the iterative algorithm for maximizing the likelihood:

Parameter	Value
RefineBeta0	Determines whether nlmefit makes an initial refinement of beta0 by first fitting modelfun without random effects and replacing beta0 with beta.

Parameter	Value
	Choices are 'on' and 'off'. The default value is 'on'.
ErrorModel	A string specifying the form of the error term. Default is 'constant'. Each model defines the error using a standard normal (Gaussian) variable e, the function value f, and one or two parameters a and b. Choices are: • 'constant': $y = f + a*e$ • 'proportional': $y = f + b*f*e$ • 'combined': $y = f + (a+b*f)*e$ • 'exponential': $y = f*\exp(a*e)$, or equivalently $\log(y) = \log(f) + a*e$ If this parameter is given, the output stats.errorparam field has the value • a for 'constant' and 'exponential' • b for 'proportional' • $[a\ b]$ for 'combined'
ApproximationType	The method used to approximate the likelihood of the model. Choices are: • 'LME' — Use the likelihood for the linear mixed-effects model at the current conditional estimates of beta and B. This is the default. • 'RELME' — Use the restricted likelihood for the linear mixed-effects model at the current conditional estimates of beta and B. • 'FO' — First-order Laplacian approximation without random effects. • 'FOCE' — First-order Laplacian approximation at the conditional estimates of B.

Parameter	Value
`Vectorization`	Indicates acceptable sizes for the `PHI`, `XFUN`, and `VFUN` input arguments to `modelfun`. Choices are: • `'SinglePhi'` — `modelfun` can only accept a single set of model parameters at a time, so `PHI` must be a single row vector in each call. `nlmefit` calls `modelfun` in a loop, if necessary, with a single `PHI` vector and with `XFUN` containing rows for a single observation or group at a time. `VFUN` may be a single row that applies to all rows of `XFUN`, or a matrix with rows corresponding to rows in `XFUN`. This is the default. • `'SingleGroup'` — `modelfun` can only accept inputs corresponding to a single group in the data, so `XFUN` must contain rows of `X` from a single group in each call. Depending on the model, `PHI` is a single row that applies to the entire group or a matrix with one row for each observation. `VFUN` is a single row. • `'Full'` — `modelfun` can accept inputs for multiple parameter vectors and multiple groups in the data. Either `PHI` or `VFUN` may be a single row that applies to all rows of `XFUN` or a matrix with rows corresponding to rows in `XFUN`. This option can improve performance by reducing the number of calls to `modelfun`, but may require `modelfun` to perform singleton expansion on `PHI` or `V`.
`CovParameterization`	Specifies the parameterization used internally for the scaled covariance matrix. Choices are `'chol'` for the Cholesky factorization or `'logm'` the matrix logarithm. The default is `'logm'`.

Parameter	Value
CovPattern	Specifies an *r*-by-*r* logical or numeric matrix P that defines the pattern of the random-effects covariance matrix PSI. nlmefit estimates the variances along the diagonal of PSI and the covariances specified by nonzeros in the off-diagonal elements of P. Covariances corresponding to zero off-diagonal elements in P are constrained to be zero. If P does not specify a row-column permutation of a block diagonal matrix, nlmefit adds nonzero elements to P as needed. The default value of P is eye(r), corresponding to uncorrelated random effects. Alternatively, P may be a 1-by-*r* vector containing values in 1:r, with equal values specifying groups of random effects. In this case, nlmefit estimates covariances only within groups, and constrains covariances across groups to be zero.
ParamTransform	A vector of *p*-values specifying a transformation function *f*() for each of the P parameters: XB = ADESIGN*BETA + BDESIGN*B PHI = *f*(XB). Each element of the vector must be one of the following integer codes specifying the transformation for the corresponding value of PHI: • 0: PHI = XB (default for all parameters) • 1: log(PHI) = XB • 2: probit(PHI) = XB • 3: logit(PHI) = XB

Parameter	Value

`Options`	A structure of the form returned by `statset`. `nlmefit` uses the following `statset` parameters:
	• `'DerivStep'` — Relative difference used in finite difference gradient calculation. May be a scalar, or a vector whose length is the number of model parameters p. The default is `eps^(1/3)`.
	• `'Display'` — Level of iterative display during estimation. Choices are:
	  • `'off'` (default) — Displays no information
	  • `'final'` — Displays information after the final iteration
	  • `'iter'` — Displays information at each iteration
	• `'FunValCheck'` — Check for invalid values, such as `NaN` or `Inf`, from `modelfun`. Choices are `'on'` and `'off'`. The default is `'on'`.
	• `'MaxIter'` — Maximum number of iterations allowed. The default is `200`.
	• `'OutputFcn'` — Function handle specified using `@`, a cell array with function handles or an empty array (default). The solver calls all output functions after each iteration.
	• `'TolFun'` — Termination tolerance on the loglikelihood function. The default is `1e-4`.
	• `'TolX'` — Termination tolerance on the estimated fixed and random effects. The default is `1e-4`.

`OptimFun`	Specifies the optimization function used in maximizing the likelihood. Choices are `'fminsearch'` to use `fminsearch` or `'fminunc'` to use `fminunc`. The default is `'fminsearch'`. You can specify `'fminunc'` only if Optimization Toolbox software is installed.

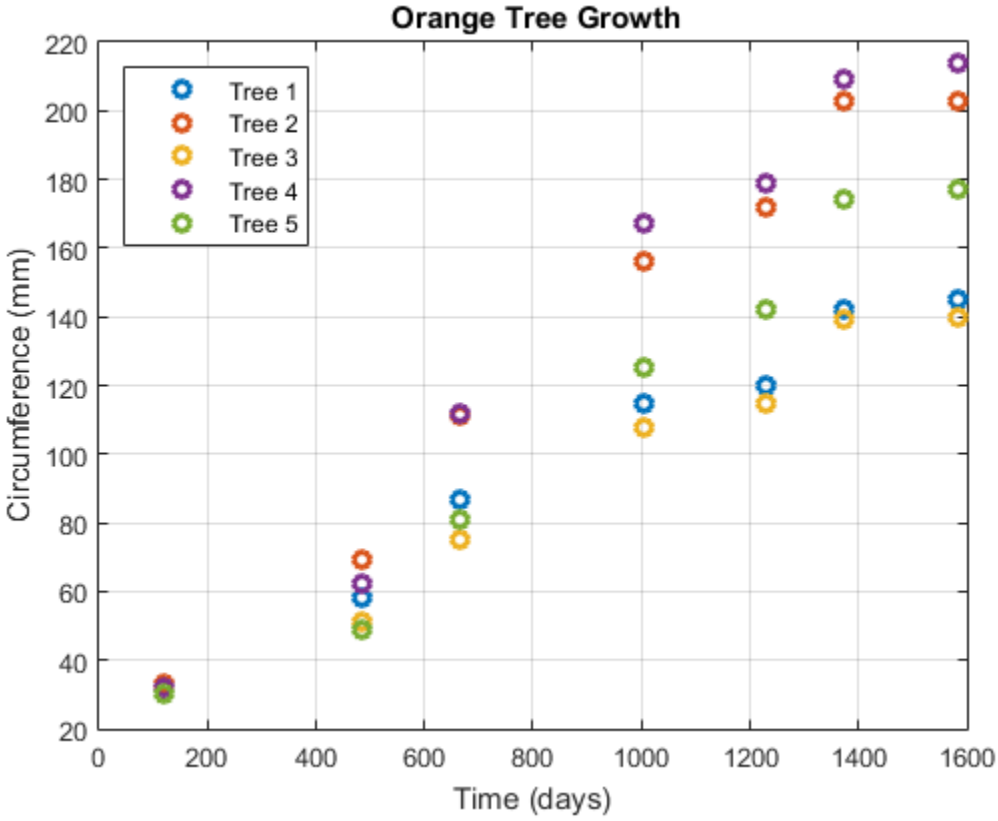
Examples

Nonlinear Mixed-Effects Model

Enter and display data on the growth of five orange trees.

```
CIRC = [30 58 87 115 120 142 145;
        33 69 111 156 172 203 203;
        30 51 75 108 115 139 140;
        32 62 112 167 179 209 214;
        30 49 81 125 142 174 177];
time = [118 484 664 1004 1231 1372 1582];

h = plot(time,CIRC','o','LineWidth',2);
xlabel('Time (days)')
ylabel('Circumference (mm)')
title('{\bf Orange Tree Growth}')
legend([repmat('Tree ',5,1),num2str((1:5)')],...
       'Location','NW')
grid on
hold on
```



Use an anonymous function to specify a logistic growth model.

```
model = @(PHI,t)(PHI(:,1))./(1+exp(-(t-PHI(:,2))./PHI(:,3)));
```

Fit the model using `nlmefit` with default settings (that is, assuming each parameter is the sum of a fixed and a random effect, with no correlation among the random effects):

```
TIME = repmat(time,5,1);
NUMS = repmat((1:5)',size(time));

beta0 = [100 100 100];
[beta1,PSI1,stats1] = nlmefit(TIME(:),CIRC(:),NUMS(:),...
                              [],model,beta0)
```

```
beta1 =

  191.3189
  723.7608
  346.2517

PSI1 =

  962.1533         0         0
         0    0.0000         0
         0         0  297.9880

stats1 =

           dfe: 28
          logl: -131.5457
           mse: 59.7882
          rmse: 7.9016
    errorparam: 7.7323
           aic: 277.0913
           bic: 274.3574
          covb: [3x3 double]
        sebeta: [15.2249 33.1579 26.8235]
          ires: [35x1 double]
          pres: [35x1 double]
         iwres: [35x1 double]
         pwres: [35x1 double]
         cwres: [35x1 double]
```

The negligible variance of the second random effect, `PSI1(2,2)`, suggests that it can be removed to simplify the model.

```
[beta2,PSI2,stats2,b2] = nlmefit(TIME(:),CIRC(:),...
    NUMS(:),[],model,beta0,'REParamsSelect',[1 3])

beta2 =

  191.3189
  723.7613
  346.2502
```

```
PSI2 =

  962.5602         0
         0  297.4975

stats2 =

           dfe: 29
          logl: -131.5457
           mse: 59.7869
          rmse: 7.7645
    errorparam: 7.7322
           aic: 275.0913
           bic: 272.7479
          covb: [3x3 double]
        sebeta: [15.2275 33.1579 26.8214]
          ires: [35x1 double]
          pres: [35x1 double]
         iwres: [35x1 double]
         pwres: [35x1 double]
         cwres: [35x1 double]

b2 =

  -28.5275   31.6066  -36.5086   39.0762   -5.6467
    9.9837   -0.7608    5.9959   -9.4449   -5.7738
```

The loglikelihood `logl` is unaffected, and both the Akaike and Bayesian information criteria (`aic` and `bic`) are reduced, supporting the decision to drop the second random effect from the model.

Use the estimated fixed effects in `beta2` and the estimated random effects for each tree in `b2` to plot the model through the data.

```
PHI = repmat(beta2,1,5) + ...          % Fixed effects
      [b2(1,:);zeros(1,5);b2(2,:)];    % Random effects

tplot = 0:0.1:1600;
for I = 1:5
  fitted_model=@(t)(PHI(1,I))./(1+exp(-(t-PHI(2,I))./ ...
```

```
        PHI(3,I)));
    plot(tplot,fitted_model(tplot),'Color',h(I).Color, ...
      'LineWidth',2)
end
```

nlmefitsa

Fit nonlinear mixed-effects model with stochastic EM algorithm

Syntax

```
[BETA,PSI,STATS,B] = nlmefitsa(X,Y,GROUP,V,MODELFUN,BETA0)
[BETA,PSI,STATS,B] =
nlmefitsa(X,Y,GROUP,V,MODELFUN,BETA0,'Name',Value)
```

Description

`[BETA,PSI,STATS,B] = nlmefitsa(X,Y,GROUP,V,MODELFUN,BETA0)` fits a nonlinear mixed-effects regression model and returns estimates of the fixed effects in `BETA`. By default, `nlmefitsa` fits a model where each model parameter is the sum of a corresponding fixed and random effect, and the covariance matrix of the random effects is diagonal, i.e., uncorrelated random effects.

The `BETA`, `PSI`, and other values this function returns are the result of a random (Monte Carlo) simulation designed to converge to the maximum likelihood estimates of the parameters. Because the results are random, it is advisable to examine the plot of simulation to results to be sure that the simulation has converged. It may also be helpful to run the function multiple times, using multiple starting values, or use the `'Replicates'` parameter to perform multiple simulations.

`[BETA,PSI,STATS,B] = nlmefitsa(X,Y,GROUP,V,MODELFUN,BETA0,'Name',Value)` accepts one or more comma-separated parameter name/value pairs. Specify *`Name`* inside single quotes.

Input Arguments

Definitions:

In the following list of arguments, the following variable definitions apply:

- n — number of observations

- h — number of predictor variables
- m — number of groups
- g — number of group-specific predictor variables
- p — number of parameters
- f — number of fixed effects

`X`

An n-by-h matrix of n observations on h predictor variables.

`Y`

An n-by-1 vector of responses.

`GROUP`

A grouping variable indicating to which of m groups each observation belongs. `GROUP` can be a categorical variable, a numeric vector, a character matrix with rows for group names, or a cell array of strings.

`V`

An m-by-g matrix of g group-specific predictor variables for each of the m groups in the data. These are predictor values that take on the same value for all observations in a group. Rows of `V` are ordered according to `GRP2IDX(GROUP)`. Use an m-by-g cell array for `V` if any of the group-specific predictor values vary in size across groups. Specify `[]` for `V` if there are no group predictors.

`MODELFUN`

A handle to a function that accepts predictor values and model parameters, and returns fitted values. `MODELFUN` has the form `YFIT = MODELFUN(PHI,XFUN,VFUN)` with input arguments

- `PHI` — A 1-by-p vector of model parameters.
- `XFUN` — An l-by-h array of predictor variables where
  - l is 1 if `XFUN` is a single row of `X`
  - l is n_i if `XFUN` contains the rows of `X` for a single group of size n_i
  - l is n if `XFUN` contains all rows of `X`.

- VFUN — Either
  - A 1-by-*g* vector of group-specific predictors for a single group, corresponding to a single row of V
  - An *n*-by-*g* matrix, where the *k*-th row of VFUN is V(*i*,:) if the *k*-th observation is in group *i*.

  If V is empty, nlmefitsa calls MODELFUN with only two inputs.

MODELFUN returns an *l*-by-1 vector of fitted values YFIT. When either PHI or VFUN contains a single row, that one row corresponds to all rows in the other two input arguments. For improved performance, use the 'Vectorization' parameter name/value pair (described below) if MODELFUN can compute YFIT for more than one vector of model parameters in one call.

BETA0

An *f*-by-1 vector with initial estimates for the *f* fixed effects. By default, *f* is equal to the number of model parameters *p*. BETA0 can also be an *f*-by-REPS matrix, and the estimation is repeated REPS times using each column of BETA0 as a set of starting values.

Name-Value Pair Arguments

By default, nlmefitsa fits a model where each model parameter is the sum of a corresponding fixed and random effect. Use the following parameter name/value pairs to fit a model with a different number of or dependence on fixed or random effects. Use at most one parameter name with an 'FE' prefix and one parameter name with an 'RE' prefix. Note that some choices change the way nlmefitsa calls MODELFUN, as described further below.

'FEParamsSelect'

A vector specifying which elements of the model parameter vector PHI include a fixed effect, as a numeric vector with elements in 1:*p*, or as a 1-by-*p* logical vector. The model will include *f* fixed effects, where *f* is the specified number of elements.

'FEConstDesign'

A *p*-by-*f* design matrix ADESIGN, where ADESIGN*BETA are the fixed components of the *p* elements of PHI.

'FEGroupDesign'

A *p*-by-*f*-by-*m* array specifying a different *p*-by-*f* fixed effects design matrix for each of the *m* groups.

'REParamsSelect'

A vector specifying which elements of the model parameter vector PHI include a random effect, as a numeric vector with elements in 1:*p*, or as a 1-by-*p* logical vector. The model will include *r* random effects, where *r* is the specified number of elements.

'REConstDesign'

A *p*-by-*r* design matrix BDESIGN, where BDESIGN*B are the random components of the *p* elements of PHI. This matrix must consist of 0s and 1s, with at most one 1 per row.

The default model is equivalent to setting both FEConstDesign and REConstDesign to eye(p), or to setting both FEParamsSelect and REParamsSelect to 1:*p*.

Additional optional parameter name/value pairs control the iterative algorithm used to maximize the likelihood:

'CovPattern'

Specifies an *r*-by-*r* logical or numeric matrix PAT that defines the pattern of the random effects covariance matrix PSI. nlmefitsa computes estimates for the variances along the diagonal of PSI as well as covariances that correspond to non-zeroes in the off-diagonal of PAT. nlmefitsa constrains the remaining covariances, i.e., those corresponding to off-diagonal zeroes in PAT, to be zero. PAT must be a row-column permutation of a block diagonal matrix, and nlmefitsa adds non-zero elements to PAT as needed to produce such a pattern. The default value of PAT is eye(r), corresponding to uncorrelated random effects.

Alternatively, specify PAT as a 1-by-*r* vector containing values in 1:*r*. In this case, elements of PAT with equal values define groups of random effects, nlmefitsa estimates covariances only within groups, and constrains covariances across groups to be zero.

'CovO'

Initial value for the covariance matrix PSI. Must be an *r*-by-*r* positive definite matrix. If empty, the default value depends on the values of BETA0.

'ComputeStdErrors'

`true` to compute standard errors for the coefficient estimates and store them in the output `STATS` structure, or `false` (default) to omit this computation.

'ErrorModel'

A string specifying the form of the error term. Default is `'constant'`. Each model defines the error using a standard normal (Gaussian) variable e, the function value f, and one or two parameters a and b. Choices are

- `'constant'` — $y = f + a*e$
- `'proportional'` — $y = f + b*f*e$
- `'combined'` — $y = f + (a+b*f)*e$
- `'exponential'` — $y = f*\exp(a*e)$, or equivalently $\log(y) = \log(f) + a*e$

If this parameter is given, the output `STATS.errorparam` field has the value

- a for `'constant'` and `'exponential'`
- b for `'proportional'`
- [a b] for `'combined'`

'ErrorParameters'

A scalar or two-element vector specifying starting values for parameters of the error model. This specifies the a, b, or [a b] values depending on the `ErrorModel` parameter.

'LogLikMethod'

Specifies the method for approximating the loglikelihood. Choices are:

- `'is'` — Importance sampling
- `'gq'` — Gaussian quadrature
- `'lin'` — Linearization
- `'none'` — Omit the loglikelihood approximation (default)

'NBurnIn'

Number of initial burn-in iterations during which the parameter estimates are not recomputed. Default is 5.

`'NChains'`

Number *c* of "chains" simulated. Default is 1. Setting *c*>1 causes *c* simulated coefficient vectors to be computed for each group during each iteration. Default depends on the data, and is chosen to provide about 100 groups across all chains.

`'NIterations'`

Number of iterations. This can be a scalar or a three-element vector. Controls how many iterations are performed for each of three phases of the algorithm:

1 simulated annealing

2 full step size

3 reduced step size

Default is `[150 150 100]`. A scalar is distributed across the three phases in the same proportions as the default.

`'NMCMCIterations'`

Number of Markov Chain Monte Carlo (MCMC) iterations. This can be a scalar or a three-element vector. Controls how many of three different types of MCMC updates are performed during each phase of the main iteration:

1 full multivariate update

2 single coordinate update

3 multiple coordinate update

Default is `[2 2 2]`. A scalar value is treated as a three-element vector with all elements equal to the scalar.

`'OptimFun'`

Either `'fminsearch'` or `'fminunc'`, specifying the optimization function to be used during the estimation process. Default is `'fminsearch'`. Use of `'fminunc'` requires Optimization Toolbox.

`'Options'`

A structure created by a call to `statset`. `nlmefitsa` uses the following `statset` parameters:

- `'DerivStep'` — Relative difference used in finite difference gradient calculation. May be a scalar, or a vector whose length is the number of model parameters p. The default is `eps^(1/3)`.
- `Display` — Level of display during estimation.
  - `'off'` (default) — Displays no information
  - `'final'` — Displays information after the final iteration of the estimation algorithm
  - `'iter'` — Displays information at each iteration
- `FunValCheck`
  - `'on'` (sdefault) — Check for invalid values (such as `NaN` or `Inf`) from `MODELFUN`
  - `'off'` — Skip this check
- `OutputFcn` — Function handle specified using `@`, a cell array with function handles or an empty array. `nlmefitsa` calls all output functions after each iteration. See `nlmefitoutputfcn.m` (the default output function for `nlmefitsa`) for an example of an output function.

`'ParamTransform'`

A vector of p-values specifying a transformation function `f()` for each of the p parameters:

```
XB = ADESIGN*BETA + BDESIGN*B
PHI = f(XB)
```

Each element of the vector must be one of the following integer codes specifying the transformation for the corresponding value of `PHI`:

- 0: `PHI = XB` (default for all parameters)
- 1: `log(PHI) = XB`
- 2: `probit(PHI) = XB`
- 3: `logit(PHI) = XB`

`'Replicates'`

Number `REPS` of estimations to perform starting from the starting values in the vector `BETA0`. If `BETA0` is a matrix, `REPS` must match the number of columns in `BETA0`. Default is the number of columns in `BETA0`.

'Vectorization'

Determines the possible sizes of the PHI, XFUN, and VFUN input arguments to MODELFUN. Possible values are:

- 'SinglePhi' — MODELFUN is a function (such as an ODE solver) that can only compute YFIT for a single set of model parameters at a time, i.e., PHI must be a single row vector in each call. nlmefitsa calls MODELFUN in a loop if necessary using a single PHI vector and with XFUN containing rows for a single observation or group at a time. VFUN may be a single row that applies to all rows of XFUN, or a matrix with rows corresponding to rows in XFUN.
- 'SingleGroup' — MODELFUN can only accept inputs corresponding to a single group in the data, i.e., XFUN must contain rows of X from a single group in each call. Depending on the model, PHI is a single row that applies to the entire group, or a matrix with one row for each observation. VFUN is a single row.
- 'Full' — MODELFUN can accept inputs for multiple parameter vectors and multiple groups in the data. Either PHI or VFUN may be a single row that applies to all rows of XFUN, or a matrix with rows corresponding to rows in XFUN. Using this option can improve performance by reducing the number of calls to MODELFUN, but may require MODELFUN to perform singleton expansion on PHI or V.

The default for 'Vectorization' is 'SinglePhi'. In all cases, if V is empty, nlmefitsa calls MODELFUN with only two inputs.

Output Arguments

BETA

Estimates of the fixed effects

PSI

An *r*-by-*r* estimated covariance matrix for the random effects. By default, *r* is equal to the number of model parameters *p*.

STATS

A structure with the following fields:

- `logl` — The maximized loglikelihood for the fitted model; empty if the `LogLikMethod` parameter has its default value of `'none'`
- `rmse` — The square root of the estimated error variance (computed on the log scale for the `exponential` error model)
- `errorparam` — The estimated parameters of the error variance model
- `aic` — The Akaike information criterion (empty if `logl` is empty), calculated as `aic` = –2 * `logl` + 2 * `numParam`, where
  - `logl` is the maximized loglikelihood.
  - `numParam` is the number of fitting parameters, including the degree of freedom for covariance matrix of the random effects, the number of fixed effects and the number of parameters of the error model.
- `bic` — The Bayesian information criterion (empty if `logl` is empty), calculated as `bic` = -2*`logl` + log(`M`) * `numParam`
  - `M` is the number of groups.
  - `logl` and `numParam` are defined as in `aic`.

  Note that some literature suggests that the computation of `bic` should be , `bic` = -2*`logl` + log(`N`) * `numParam`, where `N` is the number of observations. To adjust the value of the output you can redefine `bic` as follows: `bic` = `bic` - `numel`(`unique`(`group`)) + `numel`(`Y`)
- `sebeta` — The standard errors for BETA (empty if the `ComputeStdErrors` parameter has its default value of false)
- `covb` — The estimated covariance of the parameter estimates (empty if `ComputeStdErrors` is false)
- `dfe` — The error degrees of freedom
- `pres` — The population residuals `(y-y_population)`, where `y_population` is the population predicted values
- `ires` — The population residuals `(y-y_population)`, where `y_population` is the individual predicted values
- `pwres` — The population weighted residuals
- `cwres` — The conditional weighted residuals
- `iwres` — The individual weighted residuals

Examples

Nonlinear Mixed-Effects Model with Stochastic EM Algorithm

Load the sample data.

```
load indomethacin
```

Fit a model to data on concentrations of the drug indomethacin in the bloodstream of six subjects over eight hours.

```
model = @(phi,t)(phi(:,1).*exp(-phi(:,2).*t)+phi(:,3).*exp(-phi(:,4).*t));
phi0 = [1 1 1 1];

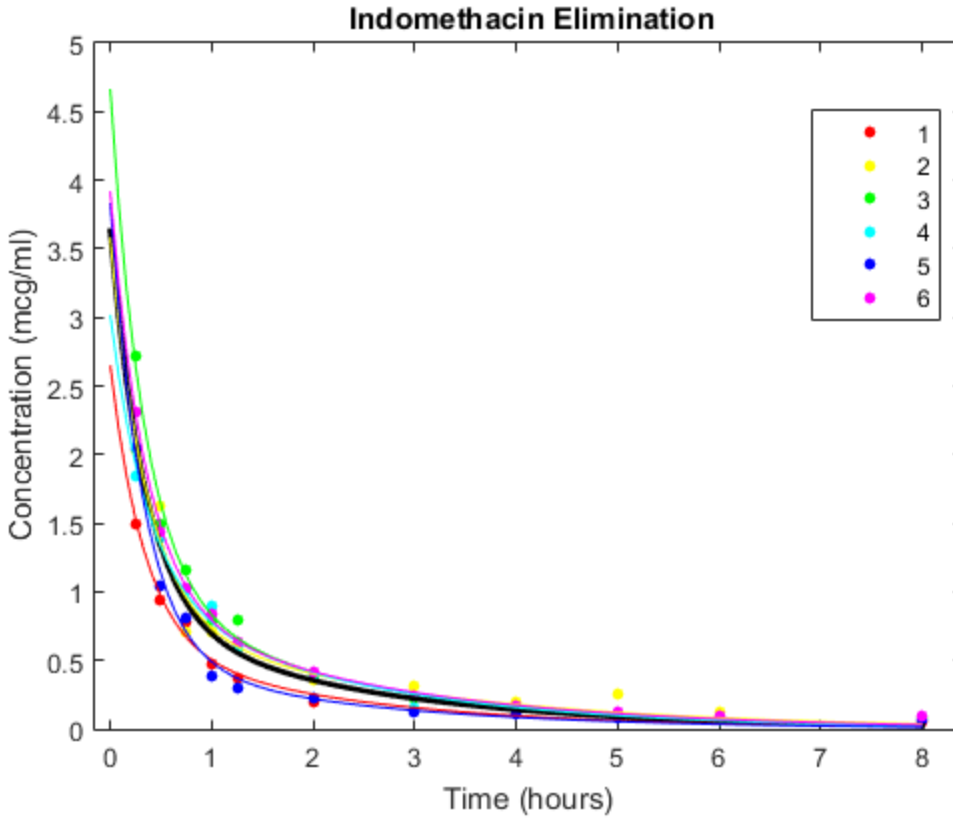
            beta(3)+br(3,j), exp(beta(4)+br(4,j))];
    line(xx,model(phir,xx),'color',get(h(j),'color'))
end
```



More About

Algorithms

In order to estimate the parameters of a nonlinear mixed effects model, we would like to choose the parameter values that maximize a likelihood function. These values are called the maximum likelihood estimates. The likelihood function can be written in the form

$$p\left(y \mid \beta, \sigma^2, \Sigma\right) = \int p\left(y \mid \beta, b, \sigma^2\right) p\left(b \mid \Sigma\right) db$$

where

- y is the response data
- ß is the vector of population coefficients
- σ^2 is the residual variance
- $\sum$ is the covariance matrix for the random effects
- b is the set of unobserved random effects

Each $p()$ function on the right-hand-side is a normal (Gaussian) likelihood function that may depend on covariates.

Since the integral does not have a closed form, it is difficult to find parameters that maximize it. Delyon, Lavielle, and Moulines [1] proposed to find the maximum likelihood estimates using an Expectation-Maximization (EM) algorithm in which the E step is replaced by a stochastic procedure. They called their algorithm SAEM, for Stochastic Approximation EM. They demonstrated that this algorithm has desirable theoretical properties, including convergence under practical conditions and convergence to a local maximum of the likelihood function. Their proposal involves three steps:

1. Simulation: Generate simulated values of the random effects b from the posterior density $p(b \mid \Sigma)$ given the current parameter estimates.
2. Stochastic approximation: Update the expected value of the loglikelihood function by taking its value from the previous step, and moving part way toward the average value of the loglikelihood calculated from the simulated random effects.
3. Maximization step: Choose new parameter estimates to maximize the loglikelihood function given the simulated values of the random effects.

NegativeLogLikelihood property

Class: gmdistribution

Negative of log-likelihood

Description

The negative of the log-likelihood of the data.

Note: This property applies only to `gmdistribution` objects constructed with `fitgmdist`.

NLogL property

Class: ProbDistParametric

Read-only value specifying negative log likelihood for input data to ProbDistParametric object

Description

`NLogL` is a read-only property of the `ProbDistParametric` class. `NLogL` is a value specifying the negative log likelihood for input data used to fit a distribution represented by a ProbDistParametric object.

Values

The value is a numeric scalar for a distribution fit to input data, that is, a distribution created using the `fitdist` function. This property is empty for distributions created without fitting to data, that is, by using the `ProbDistUnivParam` constructor. Use this information to view and compare the negative log likelihood for input data supplied to create distributions.

NLogL property

Class: ProbDistUnivKernel

Read-only value specifying negative log likelihood for input data to ProbDistUnivKernel object

Description

`NLogL` is a read-only property of the `ProbDistUnivKernel` class. `NLogL` is a value specifying the negative log likelihood for input data used to fit a distribution represented by a ProbDistUnivKernel object.

Values

The value is a numeric scalar for a distribution fit to input data, that is, a distribution created using the `fitdist` function. Use this information to view and compare the negative log likelihood for input data used to create distributions.

nlparci

Nonlinear regression parameter confidence intervals

Syntax

```
ci = nlparci(beta,resid,'covar',sigma)
ci = nlparci(beta,resid,'jacobian',J)
ci = nlparci(...,'alpha',alpha)
```

Description

`ci = nlparci(beta,resid,'covar',sigma)` returns the 95% confidence intervals `ci` for the nonlinear least squares parameter estimates `beta`. Before calling `nlparci`, use `nlinfit` to fit a nonlinear regression model and get the coefficient estimates `beta`, residuals `resid`, and estimated coefficient covariance matrix `sigma`.

`ci = nlparci(beta,resid,'jacobian',J)` is an alternative syntax that also computes 95% confidence intervals. `J` is the Jacobian computed by `nlinfit`. If the `'robust'` option is used with `nlinfit`, use the `'covar'` input rather than the `'jacobian'` input so that the required `sigma` parameter takes the robust fitting into account.

`ci = nlparci(...,'alpha',alpha)` returns `100(1-alpha)`% confidence intervals.

`nlparci` treats `NaN`s in `resid` or `J` as missing values, and ignores the corresponding observations.

The confidence interval calculation is valid for systems where the length of `resid` exceeds the length of `beta` and `J` has full column rank. When `J` is ill-conditioned, confidence intervals may be inaccurate.

Examples

Fit to exponential decay

Suppose you have data, and want to fit a model of the form

$y_i = a_1 + a_2\exp(-a_3 x_i) + \varepsilon_i$.

Here the a_i are the parameters you want to estimate, x_i are the data points, the y_i are the responses, and the ε_i are noise terms.

1. Write a function handle that represents the model:

```
mdl = @(a,x)(a(1) + a(2)*exp(-a(3)*x));
```

2. Generate synthetic data with parameters `a = [1;3;2]`, with the `x` data points distributed exponentially with parameter `2`, and normally distributed noise with standard deviation `0.1`:

```
rng(9845,'twister') % for reproducibility
a = [1;3;2];
x = exprnd(2,100,1);
epsn = normrnd(0,0.1,100,1);
y = mdl(a,x) + epsn;
```

3. Fit the model to data starting from the arbitrary guess `a0 = [2;2;2]`:

```
a0 = [2;2;2];
[ahat,r,J,cov,mse] = nlinfit(x,y,mdl,a0);
ahat

ahat =
    1.0153
    3.0229
    2.1070
```

4. Check whether `[1;3;2]` is in a 95% confidence interval using the Jacobian argument in `nlparci`:

```
ci = nlparci(ahat,r,'Jacobian',J)

ci =
    0.9869    1.0438
    2.9401    3.1058
    1.9963    2.2177
```

5. You can obtain the same result using the covariance argument:

```
ci = nlparci(ahat,r,'covar',cov)

ci =
    0.9869    1.0438
    2.9401    3.1058
```

```
    1.9963    2.2177
```

See Also

`nlinfit` | `nlpredci`

nlpredci

Nonlinear regression prediction confidence intervals

Syntax

```
[Ypred,delta] = nlpredci(modelfun,X,beta,R,'Covar',CovB)
[Ypred,delta] = nlpredci(modelfun,X,beta,R,'Covar',CovB,Name,Value)

[Ypred,delta] = nlpredci(modelfun,X,beta,R,'Jacobian',J)
[Ypred,delta] = nlpredci(modelfun,X,beta,R,'Jacobian',J,Name,Value)
```

Description

`[Ypred,delta] = nlpredci(modelfun,X,beta,R,'Covar',CovB)` returns predictions, Ypred, and 95% confidence interval half-widths, delta, for the nonlinear regression model `modelfun` at input values `X`. Before calling `nlpredci`, use `nlinfit` to fit `modelfun` and get the estimated coefficients, `beta`, residuals, `R`, and variance-covariance matrix, `CovB`.

`[Ypred,delta] = nlpredci(modelfun,X,beta,R,'Covar',CovB,Name,Value)` uses additional options specified by one or more name-value pair arguments.

`[Ypred,delta] = nlpredci(modelfun,X,beta,R,'Jacobian',J)` returns predictions, Ypred, and 95% confidence interval half-widths, delta, for the nonlinear regression model `modelfun` at input values `X`. Before calling `nlpredci`, use `nlinfit` to fit `modelfun` and get the estimated coefficients, `beta`, residuals, `R`, and Jacobian, `J`.

If you use a robust option with `nlinfit`, then you should use the `Covar` syntax rather than the `Jacobian` syntax. The variance-covariance matrix, CovB, is required to properly take the robust fitting into account.

`[Ypred,delta] = nlpredci(modelfun,X,beta,R,'Jacobian',J,Name,Value)` uses additional options specified by one or more name-value pair arguments.

Examples

Confidence Interval for Nonlinear Regression Curve

Load sample data.

```
S = load('reaction');
X = S.reactants;
y = S.rate;
beta0 = S.beta;
```

Fit the Hougen-Watson model to the rate data using the initial values in `beta0`.

```
[beta,R,J] = nlinfit(X,y,@hougen,beta0);
```

Obtain the predicted response and 95% confidence interval half-width for the value of the curve at average reactant levels.

```
[ypred,delta] = nlpredci(@hougen,mean(X),beta,R,'Jacobian',J)
```

```
ypred =

    5.4622

delta =

    0.1921
```

Compute the 95% confidence interval for the value of the curve.

```
[ypred-delta,ypred+delta]
```

```
ans =

    5.2702    5.6543
```

Prediction Interval for New Observation

Load sample data.

```
S = load('reaction');
X = S.reactants;
y = S.rate;
beta0 = S.beta;
```

Fit the Hougen-Watson model to the rate data using the initial values in `beta0`.

```
[beta,R,J] = nlinfit(X,y,@hougen,beta0);
```

Obtain the predicted response and 95% prediction interval half-width for a new observation with reactant levels `[100,100,100]`.

```
[ypred,delta] = nlpredci(@hougen,[100,100,100],beta,R,'Jacobian',J,...
                         'PredOpt','observation')
```

```
ypred =

    1.8346

delta =

    0.5101
```

Compute the 95% prediction interval for the new observation.

```
[ypred-delta,ypred+delta]
```

```
ans =

    1.3245    2.3447
```

Simultaneous Confidence Intervals for Robust Fit Curve

Generate sample data from the nonlinear regression model

$$y = b_1 + b_2 \exp\{-b_3 x\} + \varepsilon,$$

where b_1, b_2, and b_3 are coefficients, and the error term is normally distributed with mean 0 and standard deviation 0.5.

```
modelfun = @(b,x)(b(1)+b(2)*exp(-b(3)*x));

rng('default') % for reproducibility
b = [1;3;2];
x = exprnd(2,100,1);
y = modelfun(b,x) + normrnd(0,0.5,100,1);
```

Fit the nonlinear model using robust fitting options.

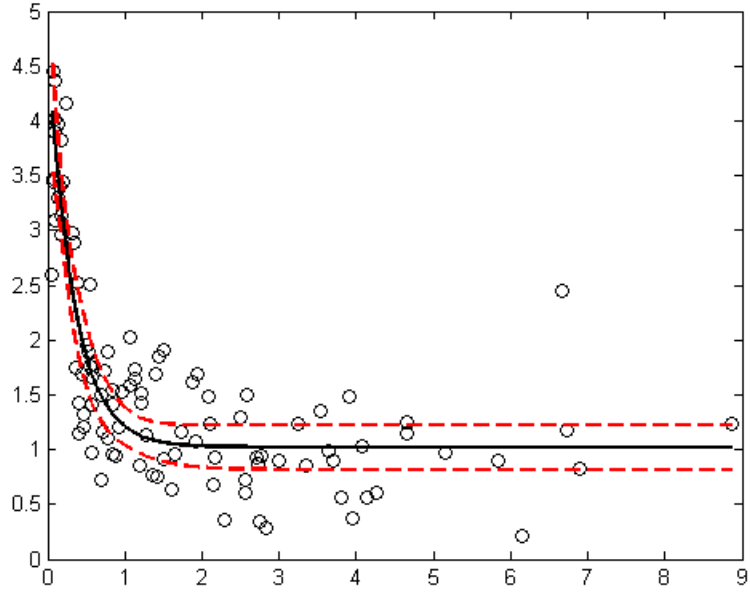
```
opts = statset('nlinfit');
```

```
opts.RobustWgtFun = 'bisquare';
beta0 = [2;2;2];
[beta,R,J,CovB,MSE] = nlinfit(x,y,modelfun,beta0,opts);
```

Plot the fitted regression model and simultaneous 95% confidence bounds.

```
xrange = min(x):.01:max(x);
[ypred,delta] = nlpredci(modelfun,xrange,beta,R,'Covar',CovB,...
                         'MSE',MSE,'SimOpt','on');
lower = ypred - delta;
upper = ypred + delta;

figure()
plot(x,y,'ko') % observed data
hold on
plot(xrange,ypred,'k','LineWidth',2)
plot(xrange,[lower;upper],'r--','LineWidth',1.5)
```



Confidence Interval Using Observation Weights

Load sample data.

```
S = load('reaction');
X = S.reactants;
y = S.rate;
beta0 = S.beta;
```

Specify a function handle for observation weights, then fit the Hougen-Watson model to the rate data using the specified observation weights function.

```
a = 1; b = 1;
weights = @(yhat) 1./((a + b*abs(yhat)).^2);
[beta,R,J,CovB] = nlinfit(X,y,@hougen,beta0,'Weights',weights);
```

Compute the 95% prediction interval for a new observation with reactant levels `[100,100,100]` using the observation weight function.

```
[ypred,delta] = nlpredci(@hougen,[100,100,100],beta,R,'Jacobian',J,...
                         'PredOpt','observation','Weights',weights);
[ypred-delta,ypred+delta]
```

```
ans =

    1.5264    2.1033
```

Confidence Interval Using Nonconstant Error Model

Load sample data.

```
S = load('reaction');
X = S.reactants;
y = S.rate;
beta0 = S.beta;
```

Fit the Hougen-Watson model to the rate data using the combined error variance model.

```
[beta,R,J,CovB,MSE,S] = nlinfit(X,y,@hougen,beta0,'ErrorModel','combined');
```

Compute the 95% prediction interval for a new observation with reactant levels `[100,100,100]` using the fitted error variance model.

```
[ypred,delta] = nlpredci(@hougen,[100,100,100],beta,R,'Jacobian',J,...
                         'PredOpt','observation','ErrorModelInfo',S);
[ypred-delta,ypred+delta]
```

```
ans =
```

```
    1.3245    2.3447
```

Input Arguments

`modelfun` — Nonlinear regression model function

function handle

Nonlinear regression model function, specified as a function handle. `modelfun` must accept two input arguments, a coefficient vector and an array `X`—in that order—and return a vector of fitted response values.

For example, to specify the `hougen` nonlinear regression function, use the function handle `@hougen`.

Data Types: `function_handle`

`X` — Input values for predictions

matrix

Input values for predictions, specified as a matrix. `nlpredci` makes a prediction for the covariates in each row of `X`. There should be a column in `X` for each coefficient in the model.

Data Types: `single | double`

`beta` — Estimated regression coefficients

vector returned by `nlinfit`

Estimated regression coefficients, specified as the vector of fitted coefficients returned by a previous call to `nlinfit`.

Data Types: `single | double`

`R` — Residuals

vector returned by `nlinfit`

Residuals for the fitted modelfun, specified as the vector of residuals returned by a previous call to `nlinfit`.

`CovB` — Estimated variance-covariance matrix

matrix returned by `nlinfit`

Estimated variance-covariance matrix for the fitted coefficients, beta, specified as the variance-covariance matrix returned by a previous call to `nlinfit`.

`J` — Estimated Jacobian

matrix returned by `nlinfit`

Estimated Jacobian of the nonlinear regression model, modelfun, specified as the Jacobian matrix returned by a previous call to `nlinfit`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'Alpha',0.1,'PredOpt','observation'` specifies 90% prediction intervals for new observations.

`'Alpha'` — Significance level

`0.05` (default) | scalar value in the range (0,1)

Significance level for the confidence interval, specified as the comma-separated pair consisting of `'Alpha'` and a scalar value in the range (0,1). If `Alpha` has value α, then `nlpredci` returns intervals with $100\times(1-\alpha)\%$ confidence level.

The default confidence level is 95% ($\alpha = 0.05$).

Example: `'Alpha',0.1`

Data Types: `single` | `double`

`'ErrorModelInfo'` — Information about error model fit

structure returned by `nlinfit`

Information about the error model fit, specified as the comma-separated pair consisting of `'ErrorModelInfo'` and a structure returned by a previous call to `nlinfit`.

ErrorModelInfo only has an effect on the returned prediction interval when PredOpt has the value `'observation'`. If you do not use ErrorModelInfo, then `nlpredci` assumes the error variance model is `'constant'`.

The error model structure returned by `nlinfit` has the following fields:

`ErrorModel`	Chosen error model
`ErrorParameters`	Estimated error parameters
`ErrorVariance`	Function handle that accepts an *N*-by-*p* matrix, `X`, and returns an *N*-by-1 vector of error variances using the estimated error model
`MSE`	Mean squared error
`ScheffeSimPred`	Scheffé parameter for simultaneous prediction intervals when using the estimated error model
`WeightFunction`	Logical with value `true` if you used a custom weight function previously in `nlinfit`
`FixedWeights`	Logical with value `true` if you used fixed weights previously in `nlinfit`
`RobustWeightFunction`	Logical with value `true` if you used robust fitting previously in

`'MSE'` — Mean squared error

MSE returned by `nlinfit`

Mean squared error (MSE) for the fitted nonlinear regression model, specified as the comma-separated pair consisting of `'MSE'` and the MSE value returned by a previous call to `nlinfit`.

If you use a robust option with `nlinfit`, then you must specify the MSE when predicting new observations to properly take the robust fitting into account. If you do not specify the MSE, then `nlpredci` computes the MSE from the residuals, R, and does not take the robust fitting into account.

For example, if `mse` is the MSE value returned by `nlinfit`, then you can specify `'MSE',mse`.

Data Types: `single` | `double`

`'PredOpt'` — Prediction interval to compute

`'curve'` (default) | `'observation'`

Prediction interval to compute, specified as the comma-separated pair consisting of `'PredOpt'` and either `'curve'` or `'observation'`.

- If you specify the value `'curve'`, then `nlpredci` returns confidence intervals for the estimated curve (function value) at the observations X.
- If you specify the value `'observation'`, then `nlpredci` returns prediction intervals for new observations at X.

If you specify `'observation'` after using a robust option with `nlinfit`, then you must also specify a value for MSE to provide the robust estimate of the mean squared error.

Example: `'PredOpt','observation'`

Data Types: `char`

`'SimOpt'` — Indicator for specifying simultaneous bounds

`'off'` (default) | `'on'`

Indicator for specifying simultaneous bounds, specified as the comma-separated pair consisting of `'SimOpt'` and either `'off'` or `'on'`. Use the value `'off'` to compute nonsimultaneous bounds, and `'on'` for simultaneous bounds.

`'Weights'` — Observation weights

vector | function handle

Observation weights, specified as the comma-separated pair consisting of `'Weights'` and a vector of positive scalar values or a function handle. The default is no weights.

- If you specify a vector of weights, then it must have the same number of elements as the number of observations (rows) in X.
- If you specify a function handle for the weights, then it must accept a vector of predicted response values as input, and return a vector of real positive weights as output.

Given weights, `W`, `nlpredci` estimates the error variance at observation `i` by `mse*(1/W(i))`, where `mse` is the mean squared error value specified using MSE.

Example: `'Weights',@WFun`

Data Types: `double | single | function_handle`

Output Arguments

`Ypred` — Predicted responses

vector

Predicted responses, returned as a vector with the same number of rows as X.

`delta` — Confidence interval half-widths

vector

Confidence interval half-widths, returned as a vector with the same number of rows as X. By default, `delta` contains the half-widths for nonsimultaneous 95% confidence intervals for modelfun at the observations in X. You can compute the lower and upper bounds of the confidence intervals as `Ypred-delta` and `Ypred+delta`, respectively.

If `'PredOpt'` has value `'observation'`, then `delta` contains the half-widths for prediction intervals of new observations at the values in X.

More About

Confidence Intervals for Estimable Predictions

When the estimated model Jacobian is not of full rank, then it might not be possible to construct sensible confidence intervals at all prediction points. In this case, `nlpredci` still tries to construct confidence intervals for any *estimable* prediction points.

For example, suppose you fit the linear function $f(\mathbf{x}_i, \beta) = \beta_1 x_{i1} + \beta_2 x_{i2} + \beta_3 x_{i3}$ at the points in the design matrix

$$\mathbf{X} = \begin{pmatrix} 1 & 1 & 0 \\ 1 & 1 & 0 \\ 1 & 1 & 0 \\ 1 & 0 & 1 \\ 1 & 0 & 1 \\ 1 & 0 & 1 \end{pmatrix}.$$

The estimated Jacobian at the values in $\mathbf{X}$ is the design matrix itself, $\mathbf{J} = \mathbf{X}$. Thus, the Jacobian is not of full rank:

```
rng('default') % For reproducibility
y = randn(6,1);

linfun = @(b,x) x*b;
```

```
beta0 = [1;1;1];
X = [repmat([1 1 0],3,1); repmat([1 0 1],3,1)];

[beta,R,J]  = nlinfit(X,y,linfun,beta0);

Warning: The Jacobian at the solution is ill-conditioned, and
some model parameters may not be estimated well (they are not
identifiable).  Use caution in making predictions.
> In nlinfit at 283
```

In this example, `nlpredci` can only compute prediction intervals at points that satisfy the linear relationship

$$x_{i1} = x_{i2} + x_{i3}.$$

If you try to compute confidence intervals for predictions at nonidentifiable points, `nlpredci` returns `NaN` for the corresponding interval half-widths:

```
xpred = [1 1 1;0 1 -1;2 1 1];
[ypred,delta] = nlpredci(linfun,xpred,beta,R,'Jacobian',J)

ypred =

   -0.0035
    0.0798
   -0.0047

delta =

       NaN
    3.8102
    3.8102
```

Here, the first element of `delta` is `NaN` because the first row in `xpred` does not satisfy the required linear dependence, and is therefore not an estimable contrast.

Tips

- To compute confidence intervals for complex parameters or data, you need to split the problem into its real and imaginary parts. When calling `nlinfit`:

  1. Define your parameter vector beta as the concatenation of the real and imaginary parts of the original parameter vector.

2 Concatenate the real and imaginary parts of the response vector `Y` as a single vector.

3 Modify your model function modelfun to accept X and the purely real parameter vector, and return a concatenation of the real and imaginary parts of the fitted values.

With the problem formulated this way, `nlinfit` computes real estimates, and confidence intervals are feasible.

Algorithms

- `nlpredci` treats `NaN` values in the residuals, R, or the Jacobian, J, as missing values, and ignores the corresponding observations.
- If the Jacobian, J, does not have full column rank, then some of the model parameters might be nonidentifiable. In this case, `nlpredci` tries to construct confidence intervals for estimable predictions, and returns `NaN` for those that are not.

`nlinfit` | `nlparci` | `NonLinearModel`

nnmf

Nonnegative matrix factorization

Syntax

```
[W,H] = nnmf(A,k)
[W,H] = nnmf(A,k,param1,val1,param2,val2,...)
[W,H,D] = nnmf(...)
```

Description

`[W,H] = nnmf(A,k)` factors the nonnegative n-by-m matrix `A` into nonnegative factors `W` (n-by-`k`) and `H` (`k`-by-m). The factorization is not exact; `W*H` is a lower-rank approximation to `A`. The factors `W` and `H` are chosen to minimize the root-mean-squared residual `D` between `A` and `W*H`:

```
D = norm(A-W*H,'fro')/sqrt(N*M)
```

The factorization uses an iterative method starting with random initial values for `W` and `H`. Because the root-mean-squared residual `D` may have local minima, repeated factorizations may yield different `W` and `H`. Sometimes the algorithm converges to a solution of lower rank than k, which may indicate that the result is not optimal.

`W` and `H` are normalized so that the rows of `H` have unit length. The columns of `W` are ordered by decreasing length.

`[W,H] = nnmf(A,k,param1,val1,param2,val2,...)` specifies optional parameter name/value pairs from the following table.

Parameter	Value
`'algorithm'`	Either `'als'` (the default) to use an alternating least-squares algorithm, or `'mult'` to use a multiplicative update algorithm. In general, the `'als'` algorithm converges faster and more consistently. The `'mult'` algorithm is more sensitive to initial values, which makes it a good choice when using `'replicates'` to find `W` and `H` from multiple random starting values.

Parameter	Value
`'w0'`	An *n*-by-`k` matrix to be used as the initial value for `W`.
`'h0'`	A `k`-by-*m* matrix to be used as the initial value for `H`.

`'options'`	An options structure as created by the `statset` function. `nnmf` uses the following fields of the options structure:
	• `Display` — Level of display. Choices:
	  • `'off'` (default) — No display
	  • `'final'` — Display final result
	  • `'iter'` — Iterative display of intermediate results
	• `MaxIter` — Maximum number of iterations. Default is `100`. Unlike in optimization settings, reaching `MaxIter` iterations is treated as convergence.
	• `TolFun` — Termination tolerance on change in size of the residual. Default is `1e-4`.
	• `TolX` — Termination tolerance on relative change in the elements of `W` and `H`. Default is `1e-4`.
	• `UseParallel` — Set to `true` to compute in parallel. Default is `false`.
	• `UseSubstreams` — Set to `true` to compute in parallel in a reproducible fashion. Default is `false`. To compute reproducibly, set `Streams` to a type allowing substreams: `'mlfg6331_64'` or `'mrg32k3a'`.
	• `Streams` — A `RandStream` object or cell array of such objects. If you do not specify `Streams`, `nnmf` uses the default stream or streams. If you choose to specify `Streams`, use a single object except in the case
	  • You have an open Parallel pool
	  • `UseParallel` is `true`
	  • `UseSubstreams` is `false`
	  In that case, use a cell array the same size as the Parallel pool.

Parameter	Value
`'replicates'`	The number of times to repeat the factorization, using new random starting values for `W` and `H`, except at the first replication if `'w0'` and `'h0'` are given. This is most beneficial with the `'mult'` algorithm. The default is `1`.

`[W,H,D] = nnmf(...)` also returns `D`, the root mean square residual.

Examples

Nonnegative Rank-Two Approximation and Biplot

Load the sample data.

```
load fisheriris
```

Compute a nonnegative rank-two approximation of the measurements of the four variables in Fisher's iris data.

```
[W,H] = nnmf(meas,2);
H
```

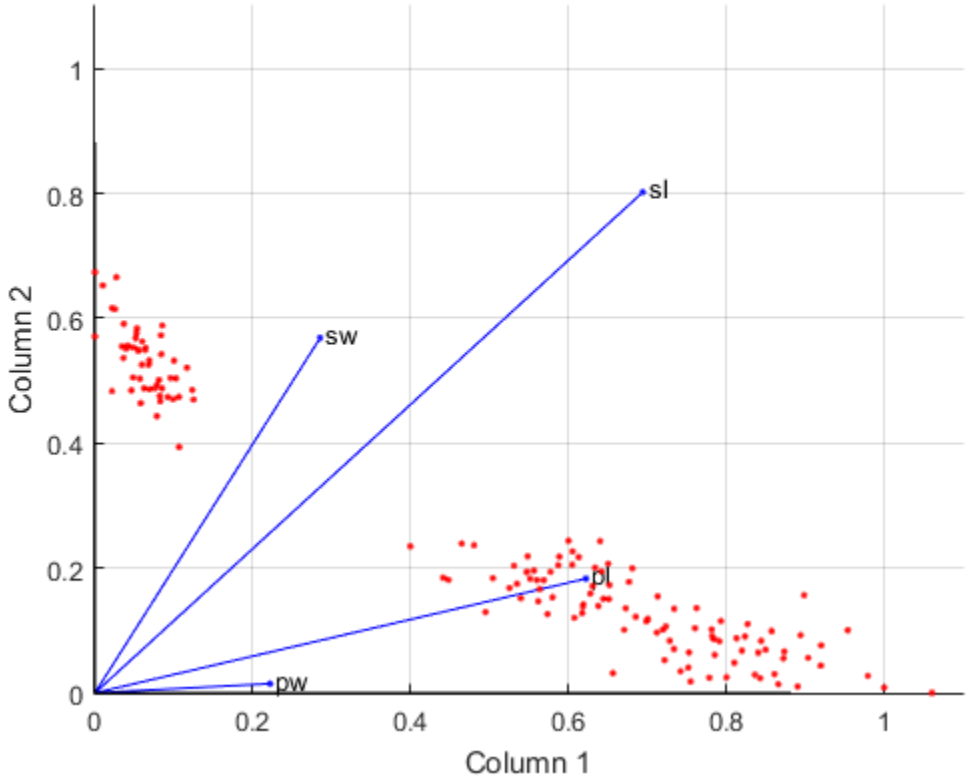
```
H =

    0.6943    0.2853    0.6223    0.2220
    0.8020    0.5685    0.1830    0.0147
```

The first and third variables in `meas` (sepal length and petal length, with coefficients 0.6852 and 0.6357, respectively) provide relatively strong weights to the first column of `W`. The first and second variables in `meas` (sepal length and sepal width, with coefficients 0.8011 and 0.5740) provide relatively strong weights to the second column of `W`.

Create a `biplot` of the data and the variables in `meas` in the column space of `W`.

```
biplot(H','scores',W,'varlabels',{'sl','sw','pl','pw'});
axis([0 1.1 0 1.1])
xlabel('Column 1')
ylabel('Column 2')
```



Change Algorithm

Starting from a random array `X` with rank 20, try a few iterations at several replicates using the multiplicative algorithm:

```
X = rand(100,20)*rand(20,50);
opt = statset('MaxIter',5,'Display','final');
[W0,H0] = nnmf(X,5,'replicates',10,...
                   'options',opt,...
                   'algorithm','mult');

   rep iteration     rms resid     |delta x|
     1         5      0.560887     0.0245182
     2         5       0.66418     0.0364471
```

```
      3         5     0.609125    0.0358355
      4         5     0.608894    0.0415491
      5         5     0.619291    0.0455135
      6         5     0.621549    0.0299965
      7         5     0.640549    0.0438758
      8         5     0.673015    0.0366856
      9         5     0.606835    0.0318931
     10         5     0.633526    0.0319591
Final root mean square residual = 0.560887
```

Continue with more iterations from the best of these results using alternating least squares:

```
opt = statset('Maxiter',1000,'Display','final');
[W,H] = nnmf(X,5,'w0',W0,'h0',H0,...
                 'options',opt,...
                 'algorithm','als');
```

```
  rep    iteration    rms resid   |delta x|
      1        24     0.257336   0.00271859
Final root mean square residual = 0.257336
```

`pca` | `factoran` | `statset`

nodeclass

Class: classregtree

Class values of nodes of classification tree

Compatibility

`classregtree` will be removed in a future release. See `fitctree`, `fitrtree`, `ClassificationTree`, or `RegressionTree` instead.

Syntax

```
NAME=nodeclass(T)
NAME=nodeclass(T,J)
[NAME,ID]=nodeclass(...)
```

Description

`NAME=nodeclass(T)` returns an *n*-element cell array with the names of the most probable classes in each node of the tree `T`, where *n* is the number of nodes in the tree. Every element of this array is a string equal to one of the class names returned by `classname(T)`. For regression trees, `nodeclass` returns an empty cell array.

`NAME=nodeclass(T,J)` takes an array `J` of node numbers and returns the class names for the specified nodes.

`[NAME,ID]=nodeclass(...)` also returns a numeric array with the class index for each node. The class index is determined by the order of classes `classname` returns.

See Also

`classregtree` | `numnodes` | `classname`

nodeerr

Class: classregtree

Return vector of node errors

Compatibility

`classregtree` will be removed in a future release. See `fitctree`, `fitrtree`, `ClassificationTree`, or `RegressionTree` instead.

Syntax

```
e = nodeerr(t)
e = nodeerr(t,nodes)
```

Description

`e = nodeerr(t)` returns an *n*-element vector `e` of the errors of the nodes in the tree `t`, where *n* is the number of nodes. For a regression tree, the error `e(i)` for node `i` is the variance of the observations assigned to node `i`. For a classification tree, `e(i)` is the misclassification probability for node `i`.

`e = nodeerr(t,nodes)` takes a vector `nodes` of node numbers and returns the errors for the specified nodes.

The error `e` is the so-called *resubstitution error* computed by applying the tree to the same data used to create the tree. This error is likely to under estimate the error you would find if you applied the tree to new data. The `test` function provides options to compute the error (or cost) using cross-validation or a test sample.

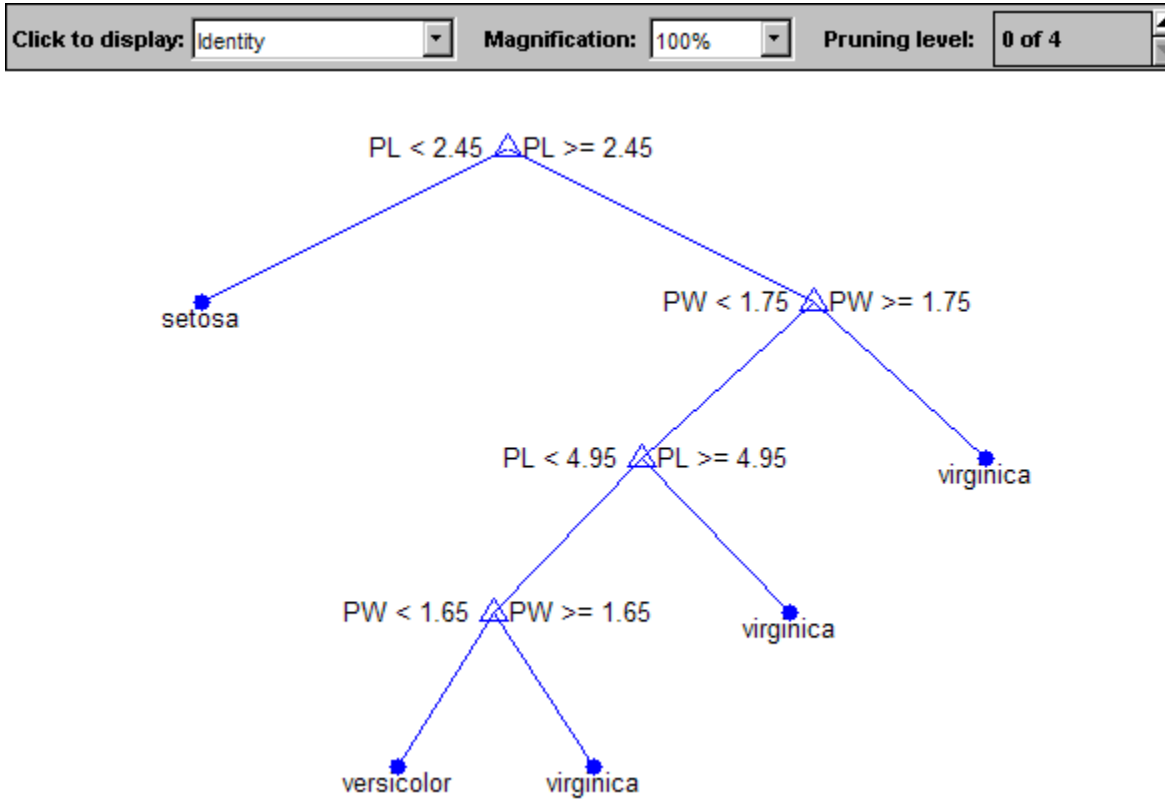
Examples

Create a classification tree for Fisher's iris data:

```
load fisheriris;
```

```
t = classregtree(meas,species,...
                 'names',{'SL' 'SW' 'PL' 'PW'})
t =
Decision tree for classification
1  if PL<2.45 then node 2 elseif PL>=2.45 then node 3 else setosa
2  class = setosa
3  if PW<1.75 then node 4 elseif PW>=1.75 then node 5 else versicolor
4  if PL<4.95 then node 6 elseif PL>=4.95 then node 7 else versicolor
5  class = virginica
6  if PW<1.65 then node 8 elseif PW>=1.65 then node 9 else versicolor
7  class = virginica
8  class = versicolor
9  class = virginica

view(t)
```



```
e = nodeerr(t)
```

```
e =
    0.6667
         0
    0.5000
    0.0926
    0.0217
    0.0208
    0.3333
         0
         0
```

See Also

`classregtree` | `test` | `numnodes`

nodemean

Class: classregtree

Mean values of nodes of regression tree

Compatibility

`classregtree` will be removed in a future release. See `fitctree`, `fitrtree`, `ClassificationTree`, or `RegressionTree` instead.

Syntax

```
NM = nodemean(T)
NM = nodemean(T,J)
```

Description

`NM = nodemean(T)` returns an n-element numeric array with mean values in each node of the tree `T`, where n is the number of nodes in the tree. Every element of this array is computed by averaging true `Y` values over all observations in the node. For classification trees, `nodemean` returns an empty numeric array.

`NM = nodemean(T,J)` takes an array `J` of node numbers and returns the mean values for the specified nodes.

See Also

`classregtree` | `numnodes`

nodeprob

Class: classregtree

Node probabilities

Compatibility

`classregtree` will be removed in a future release. See `fitctree`, `fitrtree`, `ClassificationTree`, or `RegressionTree` instead.

Syntax

```
p = nodeprob(t)
p = nodeprob(t,nodes)
```

Description

`p = nodeprob(t)` returns an n-element vector `p` of the probabilities of the nodes in the tree `t`, where n is the number of nodes. The probability of a node is computed as the proportion of observations from the original data that satisfy the conditions for the node. For a classification tree, this proportion is adjusted for any prior probabilities assigned to each class.

`p = nodeprob(t,nodes)` takes a vector `nodes` of node numbers and returns the probabilities for the specified nodes.

Examples

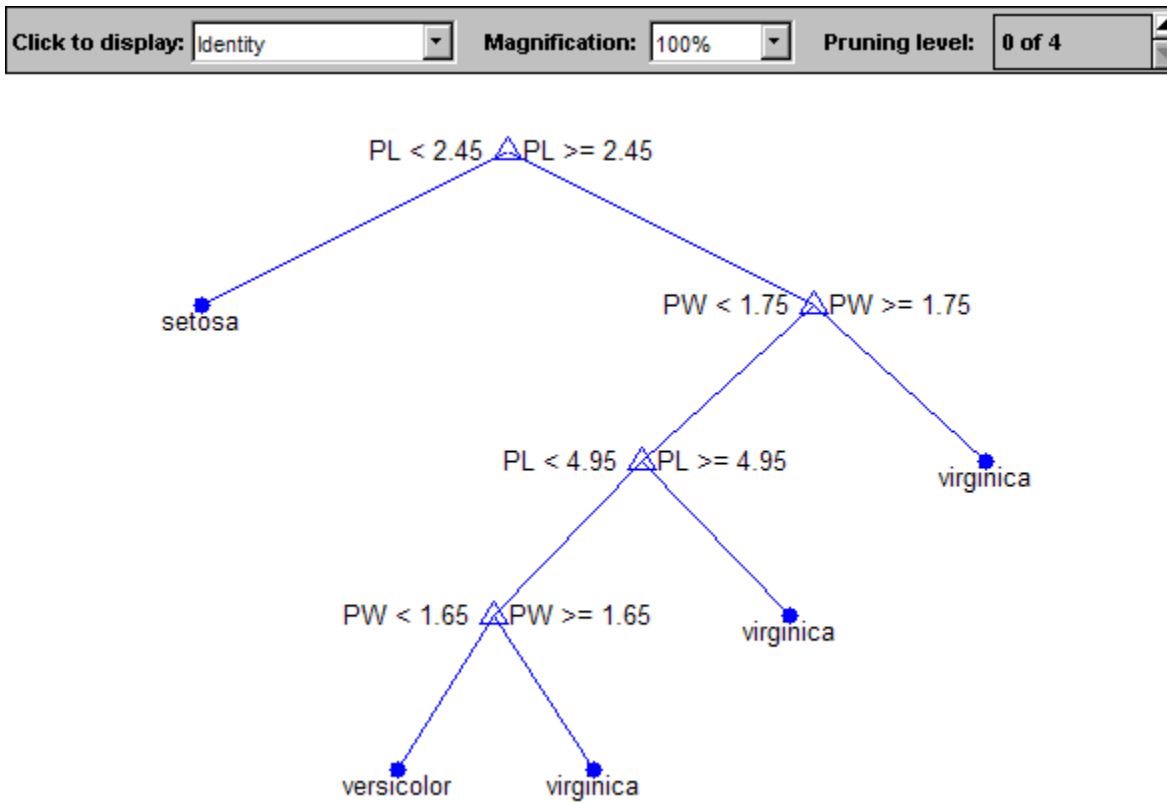
Create a classification tree for Fisher's iris data:

```
load fisheriris;

t = classregtree(meas,species,...
                 'names',{'SL' 'SW' 'PL' 'PW'})
t =
Decision tree for classification
```

```
1  if PL<2.45 then node 2 elseif PL>=2.45 then node 3 else setosa
2  class = setosa
3  if PW<1.75 then node 4 elseif PW>=1.75 then node 5 else versicolor
4  if PL<4.95 then node 6 elseif PL>=4.95 then node 7 else versicolor
5  class = virginica
6  if PW<1.65 then node 8 elseif PW>=1.65 then node 9 else versicolor
7  class = virginica
8  class = versicolor
9  class = virginica

view(t)
```



```
p = nodeprob(t)
p =
    1.0000

See Also

`classregtree` | `numnodes` | `nodesize`

nodesize

Class: classregtree

Return node size

Compatibility

`classregtree` will be removed in a future release. See `fitctree`, `fitrtree`, `ClassificationTree`, or `RegressionTree` instead.

Syntax

```
sizes = nodesize(t)
sizes = nodesize(t,nodes)
```

Description

`sizes = nodesize(t)` returns an n-element vector `sizes` of the sizes of the nodes in the tree `t`, where n is the number of nodes. The size of a node is defined as the number of observations from the data used to create the tree that satisfy the conditions for the node.

`sizes = nodesize(t,nodes)` takes a vector `nodes` of node numbers and returns the sizes for the specified nodes.

Examples

Create a classification tree for Fisher's iris data:

```
load fisheriris;

t = classregtree(meas,species,...
                 'names',{'SL' 'SW' 'PL' 'PW'})
t =
Decision tree for classification
1  if PL<2.45 then node 2 elseif PL>=2.45 then node 3 else setosa
2  class = setosa
```

```

`classregtree` | `numnodes`

nominal

Create nominal array

After creating a `nominal` array, you can use related functions to add, drop, or merge categories, and more.

For more information, see Using nominal Objects.

Compatibility

The `nominal` and `ordinal` array data types might be removed in a future release. To represent ordered and unordered discrete, nonnumeric data, use the MATLAB `categorical` data type instead.

Syntax

```
B = nominal(X)
B = nominal(X,labels)
B = nominal(X,labels,levels)

B = nominal(X,labels,[],edges)
```

Description

`B = nominal(X)` creates a nominal array B from the array X. `nominal` creates the levels of B from the sorted unique values in X, and creates default labels for them.

`B = nominal(X,labels)` labels the levels in B according to labels.

`B = nominal(X,labels,levels)` creates a nominal array with possible levels defined by levels.

`B = nominal(X,labels,[],edges)` creates a nominal array by binning a numeric array X with bin edges given by the numeric vector edges.

Examples

Create and Label Nominal Arrays

Create nominal arrays from a cell array of strings and from integer data, and provide explicit labels.

Create a nominal array from a cell array of strings with values `'r'`, `'g'`, and `'b'`. Label these levels `'red'`, `'green'`, and `'blue'`, respectively. Note that the labels are specified according to the sorted (alphabetical) order of the elements in `X`.

```
X = {'r' 'b' 'g';'g' 'r' 'b';'b' 'r' 'g'}
B = nominal(X,{'blue','green','red'})
```

```
X =

    'r'    'b'    'g'
    'g'    'r'    'b'
    'b'    'r'    'g'

B =

     red        blue      green
     green      red       blue
     blue       red       green
```

Create a nominal array from integer data with values 1 to 4, merging odd and even values into two nominal levels with labels `'odd'` and `'even'`. Achieve the merging by duplicating the labels.

```
X = randi([1 4],5,2)
B = nominal(X,{'odd','even','odd','even'})
```

```
X =

     4     1
     4     2
     1     3
     4     4
     3     4
```

```
B =

    even    odd
    even    even
    odd     odd
    even    even
    odd     even
```

- "Create Nominal and Ordinal Arrays" on page 2-4
- "Plot Data Grouped by Category" on page 2-25

Input Arguments

X — Input array

numeric | logical | character | categorical | cell array of strings

Input array to convert to `nominal`, specified as a numeric, logical, character, or categorical array, or a cell array of strings. The levels of the resulting `nominal` array correspond to the sorted unique values in X.

`labels` — Labels for the discrete levels

character array | cell array of strings

Labels for the discrete levels, specified as a character array or cell array of strings. By default, `nominal` assigns the labels to the levels in B in order according to the sorted unique values in X.

You can include duplicate labels in labels in order to merge multiple values in X into a single level in B.

Data Types: `char` | `cell`

`levels` — Possible nominal levels

vector

Possible nominal levels for the output `nominal` array, specified as a vector whose values can be compared to those in X using the equality operator. `nominal` assigns labels to each level from the corresponding elements of labels. If X contains any values not present in levels, the levels of the corresponding elements of B are undefined.

`edges` — Bin edges

numeric vector

Bin edges to create a nominal array by binning a numeric array, specified as a numeric vector. The uppermost bin includes values equal to the right-most edge. `nominal` assigns labels to each level in the resulting nominal array from the corresponding elements of labels. When you specify edges, it must have one more element than labels.

Output Arguments

`B` — Nominal array

`nominal` array object

Nominal array, returned as a `nominal` array object.

By default, an element of B is undefined if the corresponding element of X is `NaN` (when X is numeric), an empty string (when X is a character), or undefined (when X is categorical). `nominal` treats such elements as "undefined" or "missing" and does not include entries for them among the possible levels. To create an explicit level for such elements instead of treating them as undefined, you must use the levels input argument, and include `NaN`, the empty string, or an undefined element.

More About

- Using nominal Objects

See Also

`ordinal`

Using nominal Objects

Arrays for nominal data

Nominal data are discrete, nonnumeric values that do not have a natural ordering. `nominal` array objects provide efficient storage and convenient manipulation of such data, while also maintaining meaningful labels for the values.

You can manipulate `nominal` arrays much like ordinary numeric arrays, including subscripting, concatenating, and reshaping. It can be useful to use `nominal` arrays as grouping variables when the elements indicate the group an observation belongs to.

Note: The `nominal` and `ordinal` array data types might be removed in a future release. To represent ordered and unordered discrete, nonnumeric data, use the MATLAB `categorical` data type instead.

Examples

Create and Manipulate Nominal Arrays

Create a nominal array from string data in a cell array.

```
colors = nominal({'r','b','g';'g','r','b';'b','r','g'},...
                 {'blue','green','red'})
```

```
colors =

     red        blue       green
     green      red        blue
     blue       red        green
```

Identify the elements in `colors` that are members of the level `'red'`. A value of `1` in the resulting array indicates that the corresponding element of `colors` is a member of `'red'`.

```
colors == 'red'
```

```
ans =

     1     0     0
     0     1     0
     0     1     0
```

Identify the elements of `colors` that are members of either `'red'` or `'blue'`.

```
ismember(colors,{'red' 'blue'})
```

```
ans =

     1     1     0
     0     1     1
     1     1     0
```

Merge the elements of the `'red'` and `'blue'` levels into a new level labeled `'purple'`.

```
colors = mergelevels(colors,{'red','blue'},'purple')
```

```
colors =

     purple      purple      green
     green       purple      purple
     purple      purple      green
```

Display the levels of `colors`.

```
getlevels(colors)
```

```
ans =

     purple      green
```

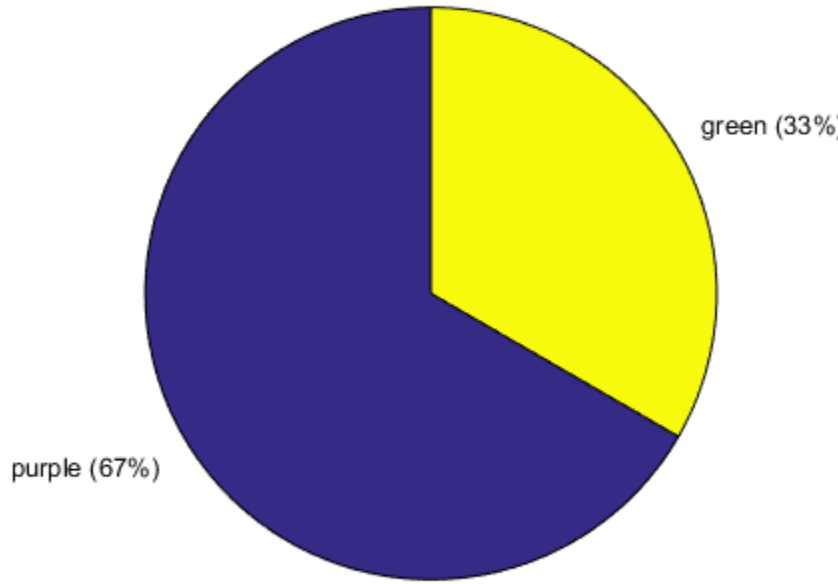
Summarize the number of elements in each level. By default, `summary` returns counts for each column of the input array.

```
summary(colors)
```

```
purple      2       3       1
green       1       0       2
```

Create a pie chart for the data in `colors`.

```
pie(colors)
```



- "Create Nominal and Ordinal Arrays" on page 2-4
- "Add and Drop Category Levels" on page 2-21
- "Plot Data Grouped by Category" on page 2-25
- "Summary Statistics Grouped by Category" on page 2-38

Properties

`labels` — Level labels
cell array of strings

Level labels, specified as a cell array of string. Access labels using `getlabels`.

Data Types: `cell`

`undeflabel` — Label for undefined levels
`'<undefined>'` (default)

Label for undefined levels, specified as `'<undefined>'`. You can find undefined elements in categorical arrays using `isundefined`.

Object Functions

`addlevels` `droplevels` `getlabels` `getlevels` `islevel` `levelcounts` `mergelevels` `reorderlevels` `setlabels`

You can also use many other MATLAB array functions with categorical arrays. The following is a partial list. For a complete list, see "Other MATLAB Functions Supporting Nominal and Ordinal Arrays" on page 2-3.
`double` `histogram` `isequal` `isundefined` `piesummary` `times`

Create Object

Create `nominal` arrays using the `nominal` function.

See Also

`ordinal`

- "Grouping Variables" on page 2-52

notify

Class: qrandstream

Notify listeners of event

Syntax

```
notify(h,'eventname')
notify(h,'eventname',data)
```

Description

`notify(h,'eventname')` notifies listeners added to the event named `eventname` on handle object array `h` that the event is taking place. `h` is the array of handles to objects triggering the event, and `eventname` must be a string.

`notify(h,'eventname',data)` provides a way of encapsulating information about an event which can then be accessed by each registered listener. `data` must belong to the `event.eventdata` class.

See Also

`addlistener` | `event.EventData` | `events` | `qrandstream`

NonLinearModel class

Nonlinear regression model class

Description

An object comprising training data, model description, diagnostic information, and fitted coefficients for a nonlinear regression. Predict model responses with the `predict` or `feval` methods.

Construction

`nlm = fitnlm(tbl,modelfun,beta0)` or `nlm = fitnlm(X,y,modelfun,beta0)` create a nonlinear model of a table or dataset array `tbl`, or of the responses `y` to a data matrix `X`. For details, see `fitnlm`.

Input Arguments

`tbl` — Input data

table | dataset array

Input data, specified as a table or dataset array. When modelspec is a `formula`, it specifies the variables to be used as the predictors and response. Otherwise, if you do not specify the predictor and response variables, the last variable is the response variable and the others are the predictor variables by default.

Predictor variables can be numeric, or any grouping variable type, such as logical or categorical (see “Grouping Variables” on page 2-52). The response must be numeric or logical.

To set a different column as the response variable, use the ResponseVar name-value pair argument. To use a subset of the columns as predictors, use the PredictorVars name-value pair argument.

Data Types: `single` | `double` | `logical`

`X` — Predictor variables

matrix

Predictor variables, specified as an n-by-p matrix, where n is the number of observations and p is the number of predictor variables. Each column of `X` represents one variable, and each row represents one observation.

By default, there is a constant term in the model, unless you explicitly remove it, so do not include a column of 1s in `X`.

Data Types: `single` | `double` | `logical`

`y` — Response variable

vector

Response variable, specified as an n-by-1 vector, where n is the number of observations. Each entry in `y` is the response for the corresponding row of `X`.

Data Types: `single` | `double`

`modelfun` — Functional form of the model

function handle | string of the form `'y ~ f(b1,b2,...,bj,x1,x2,...,xk)'`

Functional form of the model, specified as either of the following.

- Function handle `@modelfun` or `@(b,x)modelfun`, where

  - `b` is a coefficient vector with the same number of elements as `beta0`.
  - `x` is a matrix with the same number of columns as `X` or the number of predictor variable columns of `tbl`.

  `modelfun(b,x)` returns a column vector that contains the same number of rows as `x`. Each row of the vector is the result of evaluating `modelfun` on the corresponding row of `x`. In other words, `modelfun` is a vectorized function, one that operates on all data rows and returns all evaluations in one function call. `modelfun` should return real numbers to obtain meaningful coefficients.
- String of the form `'y ~ f(b1,b2,...,bj,x1,x2,...,xk)'`, where `f` represents a scalar function of the scalar coefficient variables `b1`,...,`bj` and the scalar data variables `x1`,...,`xk`.

`beta0` — Coefficients

numeric vector

Coefficients for the nonlinear model, specified as a numeric vector. `NonLinearModel` starts its search for optimal coefficients from `beta0`.

Data Types: `single` | `double`

Properties

`CoefficientCovariance`

Covariance matrix of coefficient estimates.

`CoefficientNames`

Cell array of strings containing a label for each coefficient.

`Coefficients`

Coefficient values stored as a table. `Coefficients` has one row for each coefficient and these columns:

- `Estimate` — Estimated coefficient value
- `SE` — Standard error of the estimate
- `tStat` — t statistic for a test that the coefficient is zero
- `pValue` — p-value for the t statistic

To obtain any of these columns as a vector, index into the property using dot notation. For example, in `mdl` the estimated coefficient vector is

```
beta = mdl.Coefficients.Estimate
```

Use `coefTest` to perform other tests on the coefficients.

`Diagnostics`

Table with diagnostics helpful in finding outliers and influential observations. The table contains the following fields.

Field	Meaning	Utility
`Leverage`	Diagonal elements of `HatMatrix`	Leverage indicates to what extent the predicted value for an observation is determined by the observed value for that observation. A value close to `1` indicates that the prediction is largely determined by that observation, with little contribution from the

Field	Meaning	Utility
		other observations. A value close to `0` indicates the fit is largely determined by the other observations. For a model with `P` coefficients and `N` observations, the average value of `Leverage` is `P/N`. An observation with `Leverage` larger than `2*P/N` can be regarded as having high leverage.
`CooksDistance`	Cook's measure of scaled change in fitted values	`CooksDistance` is a measure of scaled change in fitted values. An observation with `CooksDistance` larger than three times the mean Cook's distance can be an outlier.
`HatMatrix`	Projection matrix to compute fitted from observed responses	`HatMatrix` is an `N`-by-`N` matrix such that `Fitted = HatMatrix*Y`, where `Y` is the response vector and `Fitted` is the vector of fitted response values.

`DFE`

Degrees of freedom for error (residuals), equal to the number of observations minus the number of estimated coefficients.

`Fitted`

Vector of predicted values based on the training data. `fitnlm` attempts to make `Fitted` as close as possible to the response data.

`Formula`

Object that represents the mathematical form of the model.

`Iterative`

Structure with information about the fitting process. Fields:

- `InitialCoefs` — Initial coefficient values (the `beta0` vector)
- `IterOpts` — Options included in the `Options` name-value pair argument for `fitnlm`.

`LogLikelihood`

Log likelihood of the model distribution at the response values, with mean fitted from the model, and other parameters estimated as part of the model fit.

ModelCriterion

`AIC` and other information criteria for comparing models. A structure with fields:

- `AIC` — Akaike information criterion
- `AICc` — Akaike information criterion corrected for sample size
- `BIC` — Bayesian information criterion
- `CAIC` — Consistent Akaike information criterion

To obtain any of these values as a scalar, index into the property using dot notation. For example, in a model `mdl`, the AIC value `aic` is:

```
aic = mdl.ModelCriterion.AIC
```

MSE

Mean squared error, a scalar that is an estimate of the variance of the error term in the model.

NumCoefficients

Number of coefficients in the fitted model, a scalar. `NumCoefficients` is the same as `NumEstimatedCoefficients` for `NonLinearModel` objects. `NumEstimatedCoefficients` is equal to the degrees of freedom for regression.

NumEstimatedCoefficients

Number of estimated coefficients in the fitted model, a scalar. `NumEstimatedCoefficients` is the same as `NumCoefficients` for `NonLinearModel` objects. `NumEstimatedCoefficients` is equal to the degrees of freedom for regression.

NumPredictors

Number of variables `fitnlm` used as predictors for fitting.

NumVariables

Number of variables in the data. `NumVariables` is the number of variables in the original table or dataset, or the total number of columns in the predictor matrix and response vector when the fit is based on those arrays. It includes variables, if any, that are not used as predictors or as the response.

`ObservationInfo`

Table with the same number of rows as the input data (`tbl` or `X`).

Field	Description
`Weights`	Observation weights. Default is all `1`.
`Excluded`	Logical value, `1` indicates an observation that you excluded from the fit with the `Exclude` name-value pair.
`Missing`	Logical value, `1` indicates a missing value in the input. Missing values are not used in the fit.
`Subset`	Logical value, `1` indicates the observation is not excluded or missing, so is used in the fit.

`ObservationNames`

Cell array of strings containing the names of the observations used in the fit.

- If the fit is based on a table or dataset containing observation names, `ObservationNames` uses those names.
- Otherwise, `ObservationNames` is an empty cell array

`PredictorNames`

Cell array of strings, the names of the predictors used in fitting the model.

`Residuals`

Table of residuals, with one row for each observation and these variables.

Field	Description
`Raw`	Observed minus fitted values.
`Pearson`	Raw residuals divided by RMSE.
`Standardized`	Raw residuals divided by their estimated standard deviation.
`Studentized`	Residual divided by an independent estimate of the residual standard deviation. The residual for observation i is divided by an estimate of the error standard deviation based on all observations except for observation i.

To obtain any of these columns as a vector, index into the property using dot notation. For example, in a model `mdl`, the ordinary raw residual vector `r` is:

```
r = mdl.Residuals.Raw
```

Rows not used in the fit because of missing values (in `ObservationInfo.Missing`) contain `NaN` values.

Rows not used in the fit because of excluded values (in `ObservationInfo.Excluded`) contain `NaN` values, with the following exceptions:

- `raw` contains the difference between the observed and predicted values.
- `standardized` is the residual, standardized in the usual way.
- `studentized` matches the standardized values because this residual is not used in the estimate of the residual standard deviation.

`ResponseName`

String giving naming the response variable.

`RMSE`

Root mean squared error, a scalar that is an estimate of the standard deviation of the error term in the model.

`Robust`

Structure that is empty unless `fitnlm` constructed the model using robust regression.

Field	Description
`WgtFun`	Robust weighting function, such as `'bisquare'` (see `robustfit`)
`Tune`	Value specified for tuning parameter (can be `[]`)
`Weights`	Vector of weights used in final iteration of robust fit

`Rsquared`

Proportion of total sum of squares explained by the model. The ordinary R-squared value relates to the `SSR` and `SST` properties:

`Rsquared = SSR/SST = 1 - SSE/SST`.

For a linear or nonlinear model, `Rsquared` is a structure with two fields:

- `Ordinary` — Ordinary (unadjusted) R-squared
- `Adjusted` — R-squared adjusted for the number of coefficients

For a generalized linear model, `Rsquared` is a structure with five fields:

- `Ordinary` — Ordinary (unadjusted) R-squared
- `Adjusted` — R-squared adjusted for the number of coefficients
- `LLR` — Log-likelihood ratio
- `Deviance` — Deviance
- `AdjGeneralized` — Adjusted generalized R-squared

To obtain any of these values as a scalar, index into the property using dot notation. For example, the adjusted R-squared value in `mdl` is

```
r2 = mdl.Rsquared.Adjusted
```

SSE

Sum of squared errors (residuals).

The Pythagorean theorem implies
`SST = SSE + SSR`.

SSR

Regression sum of squares, the sum of squared deviations of the fitted values from their mean.

The Pythagorean theorem implies
`SST = SSE + SSR`.

SST

Total sum of squares, the sum of squared deviations of `y` from `mean(y)`.

The Pythagorean theorem implies
`SST = SSE + SSR`.

VariableInfo

Table containing metadata about `Variables`. There is one row for each term in the model, and the following columns.

Field	Description
`Class`	String giving variable class, such as `'double'`
`Range`	Cell array giving variable range: • Continuous variable — Two-element vector `[min,max]`, the minimum and maximum values • Categorical variable — Cell array of distinct variable values
`InModel`	Logical vector, where `true` indicates the variable is in the model
`IsCategorical`	Logical vector, where `true` indicates a categorical variable

VariableNames

Cell array of strings containing names of the variables in the fit.

- If the fit is based on a table or dataset, this property provides the names of the variables in that table or dataset.
- If the fit is based on a predictor matrix and response vector, `VariableNames` is the values in the `VarNames` name-value pair of the fitting method.
- Otherwise the variables have the default fitting names.

Variables

Table containing the data, both observations and responses, that the fitting function used to construct the fit. If the fit is based on a table or dataset array, `Variables` contains all of the data from that table or dataset array. Otherwise, `Variables` is a table created from the input data matrix `X` and response vector `y`.

Methods

coefCI	Confidence intervals of coefficient estimates of nonlinear regression model

coefTest	Linear hypothesis test on nonlinear regression model coefficients
disp	Display nonlinear regression model
feval	Evaluate nonlinear regression model prediction
fit	Fit nonlinear regression model
plotDiagnostics	Plot diagnostics of nonlinear regression model
plotResiduals	Plot residuals of nonlinear regression model
plotSlice	Plot of slices through fitted nonlinear regression surface
predict	Predict response of nonlinear regression model
random	Simulate responses for nonlinear regression model

Definitions

Hat Matrix

The *hat matrix H* is defined in terms of the data matrix *X* and the Jacobian matrix *J*:

$$J_{i,j} = \left.\frac{\partial f}{\partial \beta_j}\right|_{x_i,\beta}$$

Here f is the nonlinear model function, and β is the vector of model coefficients.

The Hat Matrix H is
$H = J(J^TJ)^{-1}J^T$.

The diagonal elements H_{ii} satisfy

$$0 \le h_{ii} \le 1$$

$$\sum_{i=1}^{n} h_{ii} = p,$$

where n is the number of observations (rows of X), and p is the number of coefficients in the regression model.

Leverage

The *leverage* of observation i is the value of the ith diagonal term, h_{ii}, of the hat matrix H. Because the sum of the leverage values is p (the number of coefficients in the regression model), an observation i can be considered to be an outlier if its leverage substantially exceeds p/n, where n is the number of observations.

Cook's Distance

The Cook's distance D_i of observation i is

$$D_i = \frac{\sum_{j=1}^{n} \left(\hat{y}_j - \hat{y}_{j(i)}\right)^2}{p\,MSE},$$

where

- $\hat{y}_j$ is the jth fitted response value.
- $\hat{y}_{j(i)}$ is the jth fitted response value, where the fit does not include observation i.
- MSE is the mean squared error.
- p is the number of coefficients in the regression model.

Cook's distance is algebraically equivalent to the following expression:

$$D_i = \frac{r_i^2}{p\,MSE}\left(\frac{h_{ii}}{(1-h_{ii})^2}\right),$$

where e_i is the ith residual.

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

Nonlinear Model

Create a nonlinear model for auto mileage based on the `carbig` data. Predict the mileage of an average car.

Load the data and create a nonlinear model.

```
load carbig
X = [Horsepower,Weight];
y = MPG;
modelfun = @(b,x)b(1) + b(2)*x(:,1).^b(3) + ...
    b(4)*x(:,2).^b(5);
beta0 = [-50 500 -1 500 -1];
mdl = fitnlm(X,y,modelfun,beta0)
```

```
mdl =

Nonlinear regression model:
    y ~ b1 + b2*x1^b3 + b4*x2^b5

Estimated Coefficients:
          Estimate      SE        tStat       pValue
          ________    _______    ________    ________
```

```
    b1      -49.383      119.97    -0.41164      0.68083
    b2       376.43      567.05     0.66384      0.50719
    b3    -0.78193     0.47168     -1.6578     0.098177
    b4       422.37      776.02     0.54428      0.58656
    b5    -0.24127     0.48325    -0.49926      0.61788

Number of observations: 392, Error degrees of freedom: 387
Root Mean Squared Error: 3.96
R-Squared: 0.745,  Adjusted R-Squared 0.743
F-statistic vs. constant model: 283, p-value = 1.79e-113
```

Find the predicted mileage of an average auto. The data contain some observations with `NaN`, so compute the mean using `nanmean`.

```
Xnew = nanmean(X)

Xnew =
   1.0e+03 *
    0.1051    2.9794

MPGnew = predict(mdl,Xnew)

MPGnew =

   21.8073
```

prob.NormalDistribution class

Package: prob
Superclasses: prob.ToolboxFittableParametricDistribution

Normal probability distribution object

Description

`prob.NormalDistribution` is an object consisting of parameters, a model description, and sample data for a normal probability distribution.

Create a probability distribution object with specified parameter values using `makedist`. Alternatively, fit a distribution to data using `fitdist` or the Distribution Fitting app.

Construction

`pd = makedist('Normal')` creates a normal probability distribution object using the default parameter values.

`pd = makedist('Normal','mu',mu,'sigma',sigma)` creates a normal distribution object using the specified parameter values.

Input Arguments

`mu` — Mean

0 (default) | scalar value

Mean of the normal distribution, specified as a scalar value.

Data Types: `single` | `double`

`sigma` — Standard deviation

1 (default) | nonnegative scalar value

Standard deviation of the normal distribution, specified as a nonnegative scalar value.

Data Types: `single` | `double`

Properties

`mu` — Mean

scalar value

Mean of the normal distribution, stored as a scalar value.

Data Types: `single` | `double`

`sigma` — Standard deviation

nonnegative scalar value

Standard deviation of the normal distribution, stored as a nonnegative scalar value.

Data Types: `single` | `double`

`DistributionName` — Probability distribution name

probability distribution name string

Probability distribution name, stored as a valid probability distribution name string. This property is read-only.

Data Types: `char`

`InputData` — Data used for distribution fitting

structure

Data used for distribution fitting, stored as a structure containing the following:

- `data`: Data vector used for distribution fitting.
- `cens`: Censoring vector, or empty if none.
- `freq`: Frequency vector, or empty if none.

This property is read-only.

Data Types: `struct`

`IsTruncated` — Logical flag for truncated distribution

`0` | `1`

Logical flag for truncated distribution, stored as a logical value. If `IsTruncated` equals `0`, the distribution is not truncated. If `IsTruncated` equals `1`, the distribution is truncated. This property is read-only.

Data Types: `logical`

`NumParameters` — Number of parameters

positive integer value

Number of parameters for the probability distribution, stored as a positive integer value. This property is read-only.

Data Types: `single | double`

`ParameterCovariance` — Covariance matrix of the parameter estimates

matrix of scalar values

Covariance matrix of the parameter estimates, stored as a p-by-p matrix, where p is the number of parameters in the distribution. The (`i`,`j`) element is the covariance between the estimates of the `i`th parameter and the `j`th parameter. The (`i`,`i`) element is the estimated variance of the `i`th parameter. If parameter `i` is fixed rather than estimated by fitting the distribution to data, then the (`i`,`i`) elements of the covariance matrix are 0. This property is read-only.

Data Types: `single | double`

`ParameterDescription` — Distribution parameter descriptions

cell array of strings

Distribution parameter descriptions, stored as a cell array of strings. Each cell contains a short description of one distribution parameter. This property is read-only.

Data Types: `char`

`ParameterIsFixed` — Logical flag for fixed parameters

array of logical values

Logical flag for fixed parameters, stored as an array of logical values. If `0`, the corresponding parameter in the `ParameterNames` array is not fixed. If `1`, the corresponding parameter in the `ParameterNames` array is fixed. This property is read-only.

Data Types: `logical`

`ParameterNames` — Distribution parameter names

cell array of strings

Distribution parameter names, stored as a cell array of strings. This property is read-only.

Data Types: `char`

`ParameterValues` — Distribution parameter values
vector of scalar values

Distribution parameter values, stored as a vector. This property is read-only.

Data Types: `single | double`

`Truncation` — Truncation interval
vector of scalar values

Truncation interval for the probability distribution, stored as a vector containing the lower and upper truncation boundaries. This property is read-only.

Data Types: `single | double`

Definitions

Normal Distribution

The normal distribution, sometimes called the Gaussian distribution, is a two-parameter family of curves. The usual justification for using the normal distribution for modeling is the Central Limit theorem, which states (roughly) that the sum of independent samples from any distribution with finite mean and variance converges to the normal distribution as the sample size goes to infinity.

The normal distribution uses the following parameters.

Parameter	Description	Support
`mu`	Mean	$-\infty < \mu < \infty$
`sigma`	Standard deviation	$\sigma \geq 0$

The probability density function (pdf) is

$$f(x \mid \mu,\sigma) = \frac{1}{\sigma\sqrt{2\pi}} e^{\frac{-(x-\mu)^2}{2\sigma^2}} \quad , \quad -\infty < x < \infty.$$

Examples

Create a Normal Distribution Object Using Default Parameters

Create a normal distribution object using the default parameter values.

```
pd = makedist('Normal')
```

```
pd =

  NormalDistribution

  Normal distribution
       mu = 0
    sigma = 1
```

Create a Normal Distribution Object Using Specified Parameters

Create a normal distribution object by specifying the parameter values.

```
pd = makedist('Normal','mu',75,'sigma',10)
```

```
pd =

  NormalDistribution

  Normal distribution
       mu = 75
    sigma = 10
```

Compute the interquartile range of the distribution.

```
r = iqr(pd)
```

```
r =
```

```
   13.4898
```

Fit a Normal Distribution Object

Load the sample data. Create a vector containing the first column of students' exam grades data.

```
load examgrades;
x = grades(:,1);
```

Create a normal distribution object by fitting it to the data.

```
pd = fitdist(x,'Normal')
```

```
pd =

  NormalDistribution

  Normal distribution
       mu = 75.0083   [73.4321, 76.5846]
    sigma =  8.7202   [7.7391, 9.98843]
```

normcdf

Normal cumulative distribution function

Syntax

```
p = normcdf(x)
p = normcdf(x,mu,sigma)
[p,plo,pup] = normcdf(x,mu,sigma,pcov,alpha)
[p,plo,pup] = normcdf( ___ ,'upper')
```

Description

`p = normcdf(x)` returns the standard normal cdf at each value in `x`. The standard normal distribution has parameters `mu = 0` and `sigma = 1`. `x` can be a vector, matrix, or multidimensional array.

`p = normcdf(x,mu,sigma)` returns the normal cdf at each value in `x` using the specified values for the mean `mu` and standard deviation `sigma`. `x`, `mu`, and `sigma` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other inputs. The parameters in `sigma` must be positive.

`[p,plo,pup] = normcdf(x,mu,sigma,pcov,alpha)` returns confidence bounds for `p` when the input parameters `mu` and `sigma` are estimates. `pcov` is the covariance matrix of the estimated parameters. `alpha` specifies 100(1 - `alpha`)% confidence bounds. The default value of `alpha` is 0.05. `plo` and `pup` are arrays of the same size as `p` containing the lower and upper confidence bounds.

`[p,plo,pup] = normcdf( ___ ,'upper')` returns the complement of the normal cdf at each value in `x`, using an algorithm that more accurately computes the extreme upper tail probabilities. You can use `'upper'` with any of the previous syntaxes.

The function `normcdf` computes confidence bounds for `p` using a normal approximation to the distribution of the estimate

$$\frac{X - \hat{\mu}}{\hat{\sigma}}$$

and then transforming those bounds to the scale of the output `p`. The computed bounds give approximately the desired confidence level when you estimate `mu`, `sigma`, and `pcov` from large samples, but in smaller samples other methods of computing the confidence bounds might be more accurate.

The normal cdf is

$$p = F(x \mid \mu, \sigma) = \frac{1}{\sigma\sqrt{2\pi}} \int_{-\infty}^{x} e^{\frac{-(t-\mu)^2}{2\sigma^2}} dt$$

The result, p, is the probability that a single observation from a normal distribution with parameters μ and σ will fall in the interval $(-\infty\ x]$.

The *standard normal* distribution has $\mu = 0$ and $\sigma = 1$.

Examples

Compute Normal Distribution cdf

What is the probability that an observation from a standard normal distribution will fall on the interval [-1 1]?

```
p = normcdf([-1 1]);
p(2)-p(1)
```

```
ans =
  0.6827
```

More generally, about 68% of the observations from a normal distribution fall within one standard deviation, σ, of the mean, μ.

`cdf` | `normpdf` | `norminv` | `normstat` | `normfit` | `normlike` | `normrnd`

normfit

Normal parameter estimates

Syntax

```
[muhat,sigmahat] = normfit(data)
[muhat,sigmahat,muci,sigmaci] = normfit(data)
[muhat,sigmahat,muci,sigmaci] = normfit(data,alpha)
[...] = normfit(data,alpha,censoring)
[...] = normfit(data,alpha,censoring,freq)
[...] = normfit(data,alpha,censoring,freq,options)
```

Description

`[muhat,sigmahat] = normfit(data)` returns an estimate of the mean μ in `muhat`, and an estimate of the standard deviation σ in `sigmahat`, of the normal distribution given the data in `data`.

`[muhat,sigmahat,muci,sigmaci] = normfit(data)` returns 95% confidence intervals for the parameter estimates on the mean and standard deviation in the arrays `muci` and `sigmaci`, respectively. The first row of `muci` contains the lower bounds of the confidence intervals for μ the second row contains the upper bounds. The first row of `sigmaci` contains the lower bounds of the confidence intervals for σ, and the second row contains the upper bounds.

`[muhat,sigmahat,muci,sigmaci] = normfit(data,alpha)` returns 100(1 - `alpha`) % confidence intervals for the parameter estimates, where `alpha` is a value in the range `[0 1]` specifying the width of the confidence intervals. By default, `alpha` is `0.05`, which corresponds to 95% confidence intervals.

`[...] = normfit(data,alpha,censoring)` accepts a Boolean vector, `censoring`, of the same size as `data`, which is `1` for observations that are right-censored and `0` for observations that are observed exactly. `data` must be a vector in order to pass in the argument `censoring`.

`[...] = normfit(data,alpha,censoring,freq)` accepts a frequency vector, `freq`, of the same size as `data`. Typically, `freq` contains integer frequencies for the

corresponding elements in `data`, but can contain any nonnegative values. Pass in `[]` for `alpha`, `censoring`, or `freq` to use their default values.

`[...] = normfit(data,alpha,censoring,freq,options)` accepts a structure, `options`, that specifies control parameters for the iterative algorithm the function uses to compute maximum likelihood estimates when there is censoring. The normal fit function accepts an `options` structure which you can create using the function `statset`. Enter `statset('normfit')` to see the names and default values of the parameters that `normfit` accepts in the `options` structure. See the reference page for `statset` for more information about these options.

Note: With no censoring, `normfit` computes `muhat` using the sample mean and `sigmahat` using the square root of the unbiased estimator of the variance. With censoring, both `muhat` and `sigmahat` are the maximum likelihood estimates.

Examples

In this example the data is a two-column random normal matrix. Both columns have $\mu = 10$ and $\sigma = 2$. Note that the confidence intervals below contain the "true values."

```
data = normrnd(10,2,100,2);
[mu,sigma,muci,sigmaci] = normfit(data)
mu =
  10.1455  10.0527
sigma =
  1.9072  2.1256
muci =
  9.7652  9.6288
  10.5258  10.4766
sigmaci =
  1.6745  1.8663
  2.2155  2.4693
```

`mle` | `normlike` | `normpdf` | `normcdf` | `norminv` | `normstat` | `normrnd`

norminv

Normal inverse cumulative distribution function

Syntax

```
X = norminv(P,mu,sigma)
[X,XLO,XUP] = norminv(P,mu,sigma,pcov,alpha)
```

Description

`X = norminv(P,mu,sigma)` computes the inverse of the normal cdf using the corresponding mean `mu` and standard deviation `sigma` at the corresponding probabilities in `P`. `P`, `mu`, and `sigma` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other inputs. The parameters in `sigma` must be positive, and the values in `P` must lie in the interval [0 1].

`[X,XLO,XUP] = norminv(P,mu,sigma,pcov,alpha)` produces confidence bounds for `X` when the input parameters `mu` and `sigma` are estimates. `pcov` is the covariance matrix of the estimated parameters. `alpha` specifies 100(1 - `alpha`)% confidence bounds. The default value of `alpha` is `0.05`. `XLO` and `XUP` are arrays of the same size as `X` containing the lower and upper confidence bounds.

The function `norminv` computes confidence bounds for `P` using a normal approximation to the distribution of the estimate

$$\hat{\mu} + \hat{\sigma} q$$

where q is the `P`th quantile from a normal distribution with mean 0 and standard deviation 1. The computed bounds give approximately the desired confidence level when you estimate `mu`, `sigma`, and `pcov` from large samples, but in smaller samples other methods of computing the confidence bounds may be more accurate.

The normal inverse function is defined in terms of the normal cdf as

$$x = F^{-1}(p \mid \mu,\sigma) = \{x : F(x \mid \mu,\sigma) = p\}$$

where

$$p = F(x \mid \mu, \sigma) = \frac{1}{\sigma\sqrt{2\pi}} \int_{-\infty}^{x} e^{\frac{-(t-\mu)^2}{2\sigma^2}} dt$$

The result, x, is the solution of the integral equation above where you supply the desired probability, p.

Examples

Find an interval that contains 95% of the values from a standard normal distribution.

```
x = norminv([0.025 0.975],0,1)
x =
  -1.9600  1.9600
```

Note that the interval `x` is not the only such interval, but it is the shortest.

```
xl = norminv([0.01 0.96],0,1)
xl =
  -2.3263  1.7507
```

The interval `xl` also contains 95% of the probability, but it is longer than `x`.

normlike

Normal negative log-likelihood

Syntax

```
nlogL = normlike(params,data)
[nlogL,AVAR] = normlike(params,data)
[...] = normlike(param,data,censoring)
[...] = normlike(param,data,censoring,freq)
```

Description

`nlogL = normlike(params,data)` returns the negative of the normal log-likelihood function. `params(1)` is the mean, `mu`, and `params(2)` is the standard deviation, `sigma`.

`[nlogL,AVAR] = normlike(params,data)` also returns the inverse of Fisher's information matrix, `AVAR`. If the input parameter values in `params` are the maximum likelihood estimates, the diagonal elements of `AVAR` are their asymptotic variances. `AVAR` is based on the observed Fisher's information, not the expected information.

`[...] = normlike(param,data,censoring)` accepts a Boolean vector, `censoring`, of the same size as `data`, which is 1 for observations that are right-censored and 0 for observations that are observed exactly.

`[...] = normlike(param,data,censoring,freq)` accepts a frequency vector, `freq`, of the same size as `data`. The vector `freq` typically contains integer frequencies for the corresponding elements in `data`, but can contain any nonnegative values. Pass in `[]` for `censoring` to use its default value.

`normlike` is a utility function for maximum likelihood estimation.

normpdf

Normal probability density function

Syntax

```
Y = normpdf(X,mu,sigma)
Y = normpdf(X)
Y = normpdf(X,mu)
```

Description

`Y = normpdf(X,mu,sigma)` computes the pdf at each of the values in `X` using the normal distribution with mean `mu` and standard deviation `sigma`. `X`, `mu`, and `sigma` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other inputs. The parameters in `sigma` must be positive.

The normal pdf is

$$y = f(x \mid \mu,\sigma) = \frac{1}{\sigma\sqrt{2\pi}} e^{\frac{-(x-\mu)^2}{2\sigma^2}}$$

The *likelihood function* is the pdf viewed as a function of the parameters. Maximum likelihood estimators (MLEs) are the values of the parameters that maximize the likelihood function for a fixed value of `x`.

The *standard normal* distribution has $\mu = 0$ and $\sigma = 1$.

If x is standard normal, then $x\sigma + \mu$ is also normal with mean μ and standard deviation σ. Conversely, if y is normal with mean μ and standard deviation σ, then $x = (y - \mu) / \sigma$ is standard normal.

`Y = normpdf(X)` uses the standard normal distribution (`mu = 0`, `sigma = 1`).

`Y = normpdf(X,mu)` uses the normal distribution with unit standard deviation (`sigma = 1`).

Examples

```
mu = [0:0.1:2];
[y i] = max(normpdf(1.5,mu,1));
MLE = mu(i)
MLE =
  1.5000
```

pdf | normcdf | norminv | normstat | normfit | normlike | normrnd | mvnpdf

normplot

Normal probability plot

Syntax

```
h = normplot(X)
```

Description

`h = normplot(X)` displays a normal probability plot of the data in `X`. For matrix `X`, normplot displays a line for each column of `X`. `h` is a handle to the plotted lines.

The plot has the sample data displayed with the plot symbol `'+'`. Superimposed on the plot is a line joining the first and third quartiles of each column of `X` (a robust linear fit of the sample order statistics.) This line is extrapolated out to the ends of the sample to help evaluate the linearity of the data.

The purpose of a normal probability plot is to graphically assess whether the data in `X` could come from a normal distribution. If the data are normal the plot will be linear. Other distribution types will introduce curvature in the plot. `normplot` uses midpoint probability plotting positions. Use `probplot` when the data included censored observations.

Examples

Generate a Normal Probability Plot

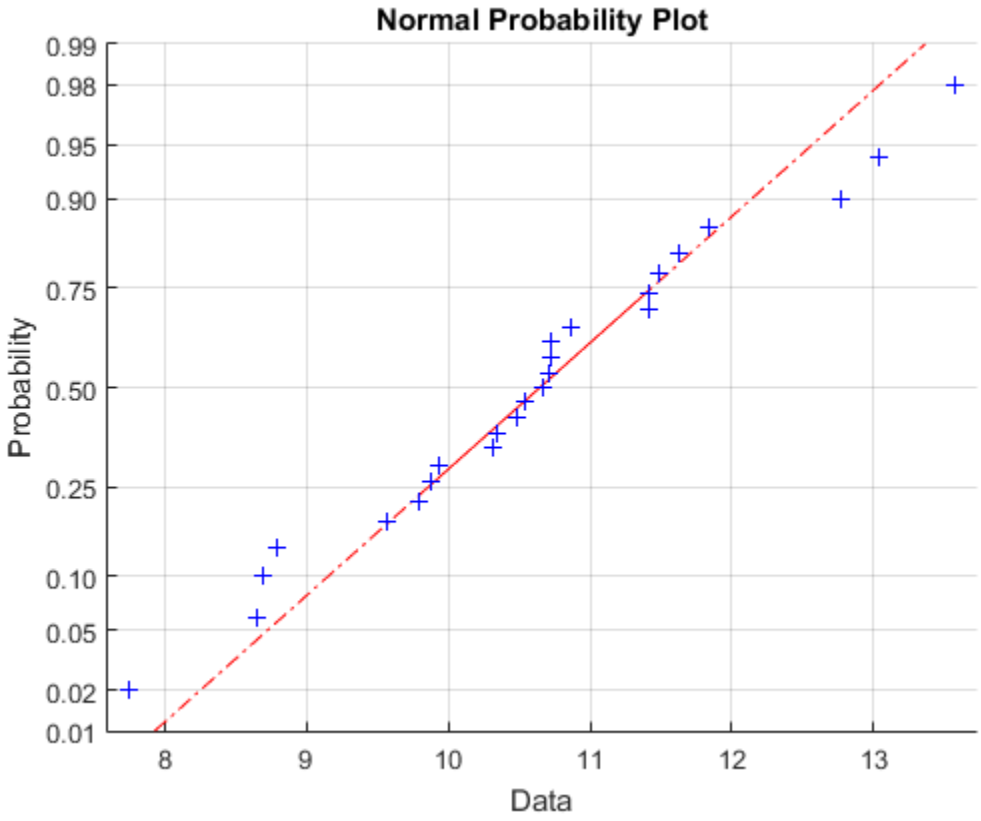
Generate random sample data from a normal distribution with `mu = 10` and `sigma = 1`.

```
rng default;  % For reproducibility
x = normrnd(10,1,25,1);
```

Create a normal probability plot of the sample data.

```
figure;
```

```
normplot(x)
```



The plot indicates that the data follows a normal distribution.

normrnd

Normal random numbers

Syntax

```
R = normrnd(mu,sigma)
R = normrnd(mu,sigma,m,n,...)
R = normrnd(mu,sigma,[m,n,...])
```

Description

`R = normrnd(mu,sigma)` generates random numbers from the normal distribution with mean parameter `mu` and standard deviation parameter `sigma`. `mu` and `sigma` can be vectors, matrices, or multidimensional arrays that have the same size, which is also the size of `R`. A scalar input for `mu` or `sigma` is expanded to a constant array with the same dimensions as the other input.

`R = normrnd(mu,sigma,m,n,...)` or `R = normrnd(mu,sigma,[m,n,...])` generates an `m`-by-`n`-by-... array. The `mu`, `sigma` parameters can each be scalars or arrays of the same size as `R`.

Examples

```
n1 = normrnd(1:6,1./(1:6))
n1 =
  2.1650  2.3134  3.0250  4.0879  4.8607  6.2827

n2 = normrnd(0,1,[1 5])
n2 =
  0.0591  1.7971  0.2641  0.8717  -1.4462

n3 = normrnd([1 2 3;4 5 6],0.1,2,3)
n3 =
  0.9299  1.9361  2.9640
  4.1246  5.0577  5.9864
```

normspec

Normal density plot between specifications

Syntax

```
normspec(specs)
normspec(specs,mu,sigma)
normspec(specs,mu,sigma,region)
p = normspec(...)
[p,h] = normspec(...)
```

Description

`normspec(specs)` plots the standard normal density, shading the portion inside the specification limits given by the two-element vector `specs`. Set `specs(1)` to `-Inf` if there is no lower limit; set `specs(2)` to `Inf` if there is no upper limit.

`normspec(specs,mu,sigma)` shades the portion inside the specification limits of a normal density with parameters `mu` and `sigma`. The defaults are `mu = 0` and `sigma = 1`.

`normspec(specs,mu,sigma,region)` shades the *`region`* either `'inside'` or `'outside'` the specification limits. The default is `'inside'`.

`p = normspec(...)` also returns the probability, `p`, of the shaded area.

`[p,h] = normspec(...)` also returns a handle `h` to the line objects.

Examples

Create a Normal Density Plot

This example shows how to create a normal density plot.

A production process fills cans of paint. The average amount of paint in any can is 1 gallon, but variability in the process produces a standard deviation of 2 ounces (2/128

gallons). What is the probability that the cans will be filled under specification by 3 or more ounces?

```
p = normspec([1-3/128,Inf],1,2/128,'outside')
```

```
p =

    0.0668
```

`capaplot` | `histfit`

normstat

Normal mean and variance

Syntax

```
[M,V] = normstat(mu,sigma)
```

Description

`[M,V] = normstat(mu,sigma)` returns the mean of and variance for the normal distribution using the corresponding mean `mu` and standard deviation `sigma`. `mu` and `sigma` can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of `M` and `V`. A scalar input for `mu` or `sigma` is expanded to a constant array with the same dimensions as the other input.

The mean of the normal distribution with parameters μ and σ is μ, and the variance is σ^2.

Examples

```
n = 1:5;
[m,v] = normstat(n'*n,n'*n)
m =
   1   2   3   4   5
   2   4   6   8  10
   3   6   9  12  15
   4   8  12  16  20
   5  10  15  20  25

v =
   1   4   9  16  25
   4  16  36  64 100
   9  36  81 144 225
  16  64 144 256 400
  25 100 225 400 625
```

nsegments

Class: piecewisedistribution

Number of segments

Syntax

```
n = nsegments(obj)
```

Description

`n = nsegments(obj)` returns the number of segments `n` in the piecewise distribution object `obj`.

Examples

Fit Pareto tails to a t distribution at cumulative probabilities 0.1 and 0.9:

```
t = trnd(3,100,1);
obj = paretotails(t,0.1,0.9);

n = nsegments(obj)
n =
     3
```

See Also

`paretotails` | `boundary` | `segment`

NTrees property

Class: TreeBagger

Number of decision trees in ensemble

Description

The `NTrees` property is a scalar equal to the number of decision trees in the ensemble.

See Also

`Trees`

NumParams property

Class: ProbDistParametric

Read-only value specifying number of parameters of ProbDistParametric object

Description

`NumParams` is a read-only property of the `ProbDistParametric` class. `NumParams` is a value specifying the number of parameters of a distribution represented by a ProbDistParametric object.

Values

This value is an integer that counts both the specified parameters and parameters that are fit to the data. Use this information to view and compare the number of parameters supplied to create distributions.

numel

Class: dataset

Number of elements in dataset array

Compatibility

The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

Syntax

```
n = numel(A)
n = numel(A, varargin)
```

Description

`n = numel(A)` returns 1. To find the number of elements, `n`, in the dataset array `A`, use `prod(size(A))` or `numel(A,':',':')`.

`n = numel(A, varargin)` returns the number of subscripted elements, `n`, in `A(index1, index2, ..., indexn)`, where `varargin` is a cell array whose elements are `index1, index2, ... indexn`.

See Also

`length` | `size`

numnodes

Class: classregtree

Number of nodes

Compatibility

`classregtree` will be removed in a future release. See `fitctree`, `fitrtree`, `ClassificationTree`, or `RegressionTree` instead.

Syntax

```
n = numnodes(t)
```

Description

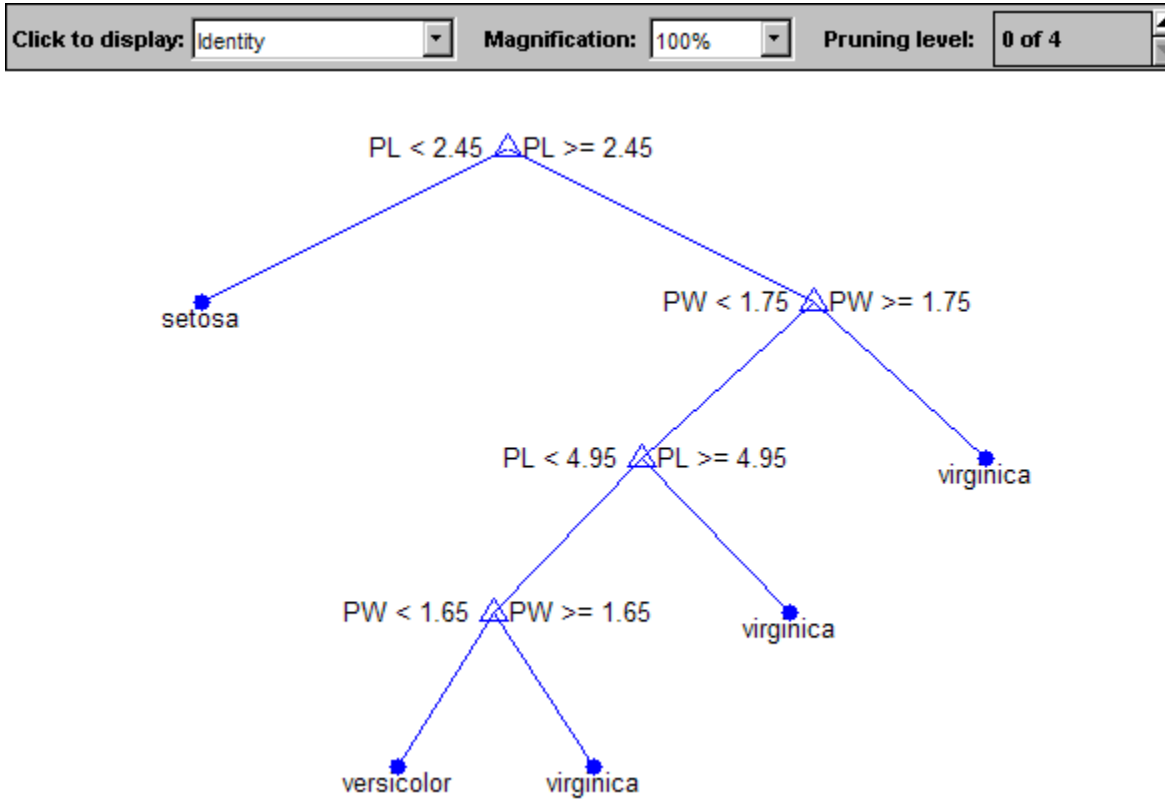
`n = numnodes(t)` returns the number of nodes `n` in the tree `t`.

Examples

Create a classification tree for Fisher's iris data:

```
load fisheriris;

t = classregtree(meas,species,...
                 'names',{'SL' 'SW' 'PL' 'PW'})
t=
Decision tree for classification
1  if PL<2.45 then node 2 elseif PL>=2.45 then node 3 else setosa
2  class = setosa
3  if PW<1.75 then node 4 elseif PW>=1.75 then node 5 else versicolor
4  if PL<4.95 then node 6 elseif PL>=4.95 then node 7 else versicolor
5  class = virginica
6  if PW<1.65 then node 8 elseif PW>=1.65 then node 9 else versicolor
7  class = virginica
8  class = versicolor
9  class = virginica
view(t)
```



```
n = numnodes(t)
n =
     9
```

See Also

`classregtree`

NumTestSets property

Class: cvpartition

Number of test sets

Description

Value is the number of folds in partitions of type `'kfold'` and `'leaveout'`.

Value is `1` in partitions of type `'holdout'` and `'resubstitution'`.

NVarToSample property

Class: TreeBagger

Number of variables for random feature selection

Description

The `NVarToSample` property specifies the number of predictor or feature variables to select at random for each decision split. By default, it is set to the square root of the total number of variables for classification and one third of the total number of variables for regression. Setting this argument to any valid value except `'all'` invokes Breiman's "random forest" algorithm.

See Also

`ClassificationTree` | `RegressionTree` | `TreeBagger` | `fitctree` | `fitrtree`

ObsNames property

Class: dataset

Cell array of nonempty, distinct strings giving names of observations in data set

Compatibility

The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

Description

A cell array of nonempty, distinct strings giving the names of the observations in the data set. This property may be empty, but if not empty, the number of strings must equal the number of observations.

optimalleaforder

Optimal leaf ordering for hierarchical clustering

Syntax

```
leafOrder = optimalleaforder(tree,D)
leafOrder = optimalleaforder(tree,D,Name,Value)
```

Description

`leafOrder = optimalleaforder(tree,D)` returns an optimal leaf ordering for the hierarchical binary cluster tree, `tree`, using the distances, D. An optimal leaf ordering of a binary tree maximizes the sum of the similarities between adjacent leaves by flipping tree branches without dividing the clusters.

`leafOrder = optimalleaforder(tree,D,Name,Value)` returns the optimal leaf ordering using one or more name-value pair arguments.

Examples

Plot Dendrogram With Optimal Leaf Order

Create a hierarchical binary cluster tree using `linkage`. Then, compare the dendrogram plot with the default ordering to a dendrogram with an optimal leaf ordering.

Generate sample data.

```
rng('default') % For reproducibility
X = rand(10,2);
```

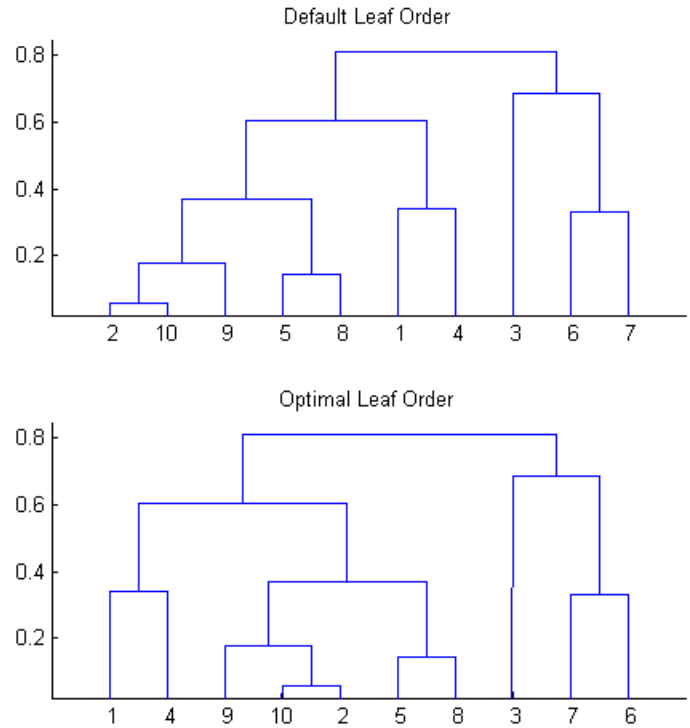
Create a distance vector and a hierarchical binary clustering tree. Use the distances and clustering tree to determine an optimal leaf order.

```
D = pdist(X);
tree = linkage(D,'average');
leafOrder = optimalleaforder(tree,D);
```

Plot the dendrogram with the default ordering and the dendrogram with the optimal leaf ordering.

```
figure()
subplot(2,1,1)
dendrogram(tree)
title('Default Leaf Order')

subplot(2,1,2)
dendrogram(tree,'reorder',leafOrder)
title('Optimal Leaf Order')
```



The order of the leaves in the bottom figure corresponds to the elements in `leafOrder`.

```
leafOrder
```

```
leafOrder =

     1     4     9    10     2     5     8     3     7     6
```

Optimal Leaf Order Using Inverse Distance Similarity

Generate sample data.

```
rng('default') % For reproducibility
X = rand(10,2);
```

Create a distance vector and a hierarchical binary clustering tree.

```
D = pdist(X);
tree = linkage(D,'average');
```

Use the inverse distance similarity transformation to determine an optimal leaf order.

```
leafOrder = optimalleaforder(tree,D,'Transformation','inverse')
```

```
leafOrder =

     1     4     9    10     2     5     8     3     7     6
```

Input Arguments

`tree` — Hierarchical binary cluster tree

matrix returned by `linkage`

Hierarchical binary cluster tree, specified as an $(M-1)$-by-3 matrix that you generate using `linkage`, where M is the number of leaves.

`D` — Distances

matrix | vector

Distances for determining similarities between leaves, specified as a matrix or vector of distances. For example, you can generate distances using `pdist`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single

quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'Criteria','group','Transformation','inverse'` specifies that the sum of similarities be maximized between every leaf and all other leaves in adjacent clusters, using an inverse similarity transformation.

`'Criteria'` — Optimization criterion

`'adjacent'` (default) | `'group'`

Optimization criterion for determining an optimal leaf ordering, specified as the comma-separated pair consisting of `'criteria'` and one of these strings:

`'adjacent'`	Maximize the sum of similarities between adjacent leaves.
`'group'`	Maximize the sum of similarities between every leaf and all other leaves in the adjacent clusters at the same level of the dendrogram.

Example: `'Criteria','group'`

Data Types: `char`

`'Transformation'` — Method for transforming distances to similarities

`'linear'` (default) | `'inverse'` | function handle

Method for transforming distances to similarities, specified as the comma-separated pair consisting of `'Transformation'` and one of `'linear'`, `'inverse'`, or a function handle.

Let $d_{i,j}$ and $Sim_{i,j}$ denote the distance and similarity between leaves i and j, respectively. The included similarity transformations are:

`'linear'`	$Sim_{i,j} = \max_{i,j}(d_{i,j}) - d_{i,j}$
`'inverse'`	$Sim_{i,j} = 1/d_{i,j}$

To use a custom transformation function, specify a handle to a function that accepts a matrix of distances, `D`, and returns a matrix of similarities, `S`. The function should be monotonic decreasing in the range of distance values. `S` must have the same size as `D`, with `S(i,j)` being the similarity computed based on `D(i,j)`.

Example: `'Transformation',@myTransform`

Data Types: `char | function_handle`

Output Arguments

`leafOrder` — Optimal leaf order

vector

Optimal leaf order, returned as a length-*M* vector, where *M* is the number of leaves. `leafOrder` is a permutation of the vector `1:M`, giving an optimal leaf ordering based on the specified distances and similarity transformation.

References

[1] Bar-Joseph, Z., Gifford, D.K., and Jaakkola, T.S. (2001). Fast optimal leaf ordering for hierarchical clustering. Bioinformatics *17*, Suppl 1:S22–9. PMID: 11472989.

`dendrogram` | `linkage` | `pdist`

oobEdge

Class: ClassificationBaggedEnsemble

Out-of-bag classification edge

Syntax

```
edge = oobEdge(ens)
edge = oobEdge(ens,Name,Value)
```

Description

`edge = oobEdge(ens)` returns out-of-bag classification edge for `ens`.

`edge = oobEdge(ens,Name,Value)` computes classification edge with additional options specified by one or more Name,Value pair arguments. You can specify several name-value pair arguments in any order as `Name1,Value1,…,NameN,ValueN`.

Input Arguments

`ens`

A classification bagged ensemble, constructed with `fitensemble`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'learners'`

Indices of weak learners in the ensemble ranging from `1` to `ens.NumTrained`. `oobEdge` uses only these learners for calculating loss.

Default: `1:NumTrained`

`'mode'`

String representing the meaning of the output L:

- `'ensemble'` — `L` is a scalar value, the loss for the entire ensemble.
- `'individual'` — `L` is a vector with one element per trained learner.
- `'cumulative'` — `L` is a vector in which element `J` is obtained by using learners `1:J` from the input list of learners.

Default: `'ensemble'`

Output Arguments

`edge`

Classification edge, a weighted average of the classification margin.

Definitions

Edge

The *edge* is the weighted mean value of the classification margin. The weights are the class probabilities in `ens.Prior`.

Margin

The classification *margin* is the difference between the classification *score* for the true class and maximal classification score for the false classes. Margin is a column vector with the same number of rows as in the matrix `ens.X`.

Out of Bag

Bagging, which stands for "bootstrap aggregation", is a type of ensemble learning. To bag a weak learner such as a decision tree on a dataset, `fitensemble` generates

many bootstrap replicas of the dataset and grows decision trees on these replicas. `fitensemble` obtains each bootstrap replica by randomly selecting `N` observations out of `N` with replacement, where `N` is the dataset size. To find the predicted response of a trained ensemble, `predict` take an average over predictions from individual trees.

Drawing `N` out of `N` observations with replacement omits on average 37% (1/*e*) of observations for each decision tree. These are "out-of-bag" observations. For each observation, `oobLoss` estimates the out-of-bag prediction by averaging over predictions from all trees in the ensemble for which this observation is out of bag. It then compares the computed prediction against the true response for this observation. It calculates the out-of-bag error by comparing the out-of-bag predicted responses against the true responses for all observations used for training. This out-of-bag average is an unbiased estimator of the true ensemble error.

Examples

Find the out-of-bag edge for a bagged ensemble from the Fisher iris data:

```
load fisheriris
ens = fitensemble(meas,species,'Bag',100,...
    'Tree','type','classification');
edge = oobEdge(ens)

edge =
    0.8730
```

See Also

`oobMargin` | `oobPredict` | `oobLoss`

oobError

Class: TreeBagger

Out-of-bag error

Syntax

```
err = oobError(B)
err = oobError(B,'param1',val1,'param2',val2,...)
```

Description

`err = oobError(B)` computes the misclassification probability (for classification trees) or mean squared error (for regression trees) for out-of-bag observations in the training data, using the trained bagger `B`. `err` is a vector of length `NTrees`, where `NTrees` is the number of trees in the ensemble.

`err = oobError(B,'param1',val1,'param2',val2,...)` specifies optional parameter name/value pairs:

`'mode'`	String indicating how `oobError` computes errors. If set to `'cumulative'` (default), the method computes cumulative errors and `err` is a vector of length `NTrees`, where the first element gives error from `trees(1)`, second element gives error from `trees(1:2)` etc, up to `trees(1:NTrees)`. If set to `'individual'`, `err` is a vector of length `NTrees`, where each element is an error from each tree in the ensemble. If set to `'ensemble'`, `err` is a scalar showing the cumulative error for the entire ensemble.
`'trees'`	Vector of indices indicating what trees to include in this calculation. By default, this argument is set to `'all'` and the method uses all trees. If `'trees'` is a numeric vector, the method returns a vector of length `NTrees` for `'cumulative'` and `'individual'` modes, where `NTrees` is the number of elements in the input vector, and a scalar for `'ensemble'` mode. For example, in the `'cumulative'` mode, the first element

	gives error from `trees(1)`, the second element gives error from `trees(1:2)` etc.
`'treeweights'`	Vector of tree weights. This vector must have the same length as the `'trees'` vector. `oobError` uses these weights to combine output from the specified trees by taking a weighted average instead of the simple nonweighted majority vote. You cannot use this argument in the `'individual'` mode.

See Also

`CompactTreeBagger.error`

OOBIndices property

Class: TreeBagger

Indicator matrix for out-of-bag observations

Description

The `OOBIndices` property is a logical array of size `Nobs`-by-`NTrees` where `Nobs` is the number of observations in the training data and `NTrees` is the number of trees in the ensemble. The `(I,J)` element is true if observation `I` is out-of-bag for tree `J` and false otherwise. In other words, a true value means observation `I` was not selected for the training data used to grow tree `J`.

See Also

`ClassificationTree` | `RegressionTree` | `TreeBagger` | `fitctree` | `fitrtree`

OOBInstanceWeight property

Class: TreeBagger

Count of out-of-bag trees for each observation

Description

The `OOBInstanceWeight` property is a numeric array of size `Nobs`-by-1 containing the number of trees used for computing out-of-bag response for each observation. `Nobs` is the number of observations in the training data used to create the ensemble.

oobLoss

Class: ClassificationBaggedEnsemble

Out-of-bag classification error

Syntax

```
L = oobloss(ens)
L = oobloss(ens,Name,Value)
```

Description

`L = oobloss(ens)` returns the classification error for `ens` computed for out-of-bag data.

`L = oobloss(ens,Name,Value)` computes error with additional options specified by one or more Name,Value pair arguments. You can specify several name-value pair arguments in any order as `Name1,Value1,…,NameN,ValueN`.

Input Arguments

`ens`

A classification bagged ensemble, constructed with `fitensemble`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'learners'`

Indices of weak learners in the ensemble ranging from `1` to `NumTrained`. `oobLoss` uses only these learners for calculating loss.

Default: `1:NumTrained`

`'lossfun'`

Function handle or string representing a loss function. Built-in loss functions:

- `'binodeviance'` — See "Loss Functions" on page 22-3306
- `'classiferror'` — Fraction of misclassified data
- `'exponential'` — See "Loss Functions" on page 22-3306
- `'hinge'` — See "Loss Functions" on page 22-3306.
- `'mincost'` — Smallest misclassification cost as given by the obj`.Cost` matrix. See "Loss Functions" on page 22-3306.

You can write your own loss function in the syntax described in "Loss Functions" on page 22-3306.

Default: `'classiferror'`

`'mode'`

String representing the meaning of the output L:

- `'ensemble'` — `L` is a scalar value, the loss for the entire ensemble.
- `'individual'` — `L` is a vector with one element per trained learner.
- `'cumulative'` — `L` is a vector in which element `J` is obtained by using learners `1:J` from the input list of learners.

Default: `'ensemble'`

Output Arguments

`L`

Classification error of the out-of-bag observations, a scalar. `L` can be a vector, or can represent a different quantity, depending on the name-value settings.

Definitions

Out of Bag

Bagging, which stands for "bootstrap aggregation", is a type of ensemble learning. To bag a weak learner such as a decision tree on a dataset, `fitensemble` generates many bootstrap replicas of the dataset and grows decision trees on these replicas. `fitensemble` obtains each bootstrap replica by randomly selecting `N` observations out of `N` with replacement, where `N` is the dataset size. To find the predicted response of a trained ensemble, `predict` take an average over predictions from individual trees.

Drawing `N` out of `N` observations with replacement omits on average 37% (1/*e*) of observations for each decision tree. These are "out-of-bag" observations. For each observation, `oobLoss` estimates the out-of-bag prediction by averaging over predictions from all trees in the ensemble for which this observation is out of bag. It then compares the computed prediction against the true response for this observation. It calculates the out-of-bag error by comparing the out-of-bag predicted responses against the true responses for all observations used for training. This out-of-bag average is an unbiased estimator of the true ensemble error.

Loss Functions

The built-in loss functions are:

- `'binodeviance'` — For binary classification, assume the classes y_n are `-1` and `1`. With weight vector w normalized to have sum `1`, and predictions of row n of data X as $f(X_n)$, the binomial deviance is

  $$\sum w_n \log\left(1+\exp\left(-2y_n f\left(X_n\right)\right)\right).$$

- `'classiferror'` — Fraction of misclassified data, weighted by w.
- `'exponential'` — With the same definitions as for `'binodeviance'`, the exponential loss is

  $$\sum w_n \exp\left(-y_n f\left(X_n\right)\right).$$

- `'hinge'` — Classification error measure that has the form

$$L = \frac{\sum_{j=1}^{n} w_j \max\left\{0, 1 - y_j' f\left(X_j\right)\right\}}{\sum_{j=1}^{n} w_j},$$

where:

- w_j is weight j.
- For binary classification, $y_j = 1$ for the positive class and -1 for the negative class. For problems where the number of classes $K > 3$, y_j is a vector of 0s, but with a 1 in the position corresponding to the true class, e.g., if the second observation is in the third class and $K = 4$, then $y_2 = [0\ 0\ 1\ 0]'$.
- $f(X_j)$ is, for binary classification, the posterior probability or, for $K > 3$, a vector of posterior probabilities for each class given observation j.

- `'mincost'` — Predict the label with the smallest expected misclassification cost, with expectation taken over the posterior probability, and cost as given by the `Cost` property of the classifier (a matrix). The loss is then the true misclassification cost averaged over the observations.

To write your own loss function, create a function file of the form

```
function loss = lossfun(C,S,W,COST)
```

- `N` is the number of rows of X.
- `K` is the number of classes in tree, represented in `tree.ClassNames`.
- `C` is an `N`-by-`K` logical matrix, with one `true` per row for the true class. The index for each class is its position in `tree.ClassNames`.
- `S` is an `N`-by-`K` numeric matrix. `S` is a matrix of posterior probabilities for classes with one row per observation, similar to the `posterior` output from `predict`.
- `W` is a numeric vector with `N` elements, the observation weights.
- `COST` is a `K`-by-`K` numeric matrix of misclassification costs. The default `'classiferror'` cost function uses a cost of `0` for correct classification, and `1` for misclassification. In other words, `'classiferror'` uses `COST=ones(K)-eye(K)`.
- The output `loss` should be a scalar.

Pass the function handle `@lossfun` as the value of the `lossfun` name-value pair.

Examples

Find the out-of-bag error for a bagged ensemble from the Fisher iris data:

```
load fisheriris
ens = fitensemble(meas,species,'Bag',100,...
    'Tree','type','classification');
L = oobLoss(ens)

L =
    0.0467
```

See Also

`loss` | `oobMargin` | `oobPredict` | `oobEdge`

oobLoss

Class: RegressionBaggedEnsemble

Out-of-bag regression error

Syntax

```
L = oobLoss(ens)
L = oobLoss(ens,Name,Value)
```

Description

`L = oobLoss(ens)` returns the mean squared error for `ens` computed for out-of-bag data.

`L = oobLoss(ens,Name,Value)` computes error with additional options specified by one or more Name,Value pair arguments. You can specify several name-value pair arguments in any order as `Name1,Value1,…,NameN,ValueN`.

Input Arguments

`ens`

A regression bagged ensemble, constructed with `fitensemble`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'learners'`

Indices of weak learners in the ensemble ranging from `1` to `NumTrained`. `oobLoss` uses only these learners for calculating loss.

Default: `1:NumTrained`

`'lossfun'`

Function handle for loss function, or the string `'mse'`, meaning mean squared error. If you pass a function handle `fun`, `oobLoss` calls it as

```
FUN(Y,Yfit,W)
```

where `Y`, `Yfit`, and `W` are numeric vectors of the same length. `Y` is the observed response, `Yfit` is the predicted response, and `W` is the observation weights.

Default: `'mse'`

`'mode'`

String representing the meaning of the output L:

- `'ensemble'` — `L` is a scalar value, the loss for the entire ensemble.
- `'individual'` — `L` is a vector with one element per trained learner.
- `'cumulative'` — `L` is a vector in which element `J` is obtained by using learners `1:J` from the input list of learners.

Default: `'ensemble'`

Output Arguments

`L`

Mean squared error of the out-of-bag observations, a scalar. `L` can be a vector, or can represent a different quantity, depending on the name-value settings.

Definitions

Out of Bag

Bagging, which stands for "bootstrap aggregation", is a type of ensemble learning. To bag a weak learner such as a decision tree on a dataset, `fitensemble` generates

many bootstrap replicas of the dataset and grows decision trees on these replicas. `fitensemble` obtains each bootstrap replica by randomly selecting `N` observations out of `N` with replacement, where `N` is the dataset size. To find the predicted response of a trained ensemble, `predict` take an average over predictions from individual trees.

Drawing `N` out of `N` observations with replacement omits on average 37% (1/*e*) of observations for each decision tree. These are "out-of-bag" observations. For each observation, `oobLoss` estimates the out-of-bag prediction by averaging over predictions from all trees in the ensemble for which this observation is out of bag. It then compares the computed prediction against the true response for this observation. It calculates the out-of-bag error by comparing the out-of-bag predicted responses against the true responses for all observations used for training. This out-of-bag average is an unbiased estimator of the true ensemble error.

Examples

Compute the out-of-bag error for the `carsmall` data:

```
load carsmall
X = [Displacement Horsepower Weight];
ens = fitensemble(X,MPG,'bag',100,'Tree',...
    'type','regression');
L = oobLoss(ens)

L =
   17.0665
```

`oobPredict` | `loss`

oobMargin

Class: ClassificationBaggedEnsemble

Out-of-bag classification margins

Syntax

```
margin = oobMargin(ens)
margin = oobMargin(ens,Name,Value)
```

Description

`margin = oobMargin(ens)` returns out-of-bag classification margins.

`margin = oobMargin(ens,Name,Value)` calculates margins with additional options specified by one or more Name,Value pair arguments.

Input Arguments

`ens`

A classification bagged ensemble, constructed with `fitensemble`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'learners'`

Indices of weak learners in the ensemble ranging from `1` to ens`.NumTrained`. `oobEdge` uses only these learners for calculating loss.

Default: `1:NumTrained`

Output Arguments

`margin`

A numeric column vector of length `size(ens.X,1)`.

Definitions

Out of Bag

Bagging, which stands for “bootstrap aggregation”, is a type of ensemble learning. To bag a weak learner such as a decision tree on a dataset, `fitensemble` generates many bootstrap replicas of the dataset and grows decision trees on these replicas. `fitensemble` obtains each bootstrap replica by randomly selecting `N` observations out of `N` with replacement, where `N` is the dataset size. To find the predicted response of a trained ensemble, `predict` take an average over predictions from individual trees.

Drawing `N` out of `N` observations with replacement omits on average 37% (1/*e*) of observations for each decision tree. These are "out-of-bag" observations. For each observation, `oobLoss` estimates the out-of-bag prediction by averaging over predictions from all trees in the ensemble for which this observation is out of bag. It then compares the computed prediction against the true response for this observation. It calculates the out-of-bag error by comparing the out-of-bag predicted responses against the true responses for all observations used for training. This out-of-bag average is an unbiased estimator of the true ensemble error.

Margin

The classification *margin* is the difference between the classification *score* for the true class and maximal classification score for the false classes. Margin is a column vector with the same number of rows as in the matrix `ens.X`.

Examples

Find the out-of-bag margin for a bagged ensemble from the Fisher iris data: Find how many elements of margin are equal to `1`.

```
load fisheriris
ens = fitensemble(meas,species,'Bag',100,...
    'Tree','type','classification');
margin = oobMargin(ens);
sum(margin == 1)

ans =
   108
```

oobPredict | oobLoss | oobEdge | margin

oobMargin

Class: TreeBagger

Out-of-bag margins

Syntax

```
mar = oobMargin(B)
mar = oobMargin(B,'param1',val1,'param2',val2,...)
```

Description

`mar = oobMargin(B)` computes an `Nobs`-by-`NTrees` matrix of classification margins for out-of-bag observations in the training data, using the trained bagger `B`.

`mar = oobMargin(B,'param1',val1,'param2',val2,...)` specifies optional parameter name/value pairs:

`'mode'`	String indicating how `oobMargin` computes errors. If set to `'cumulative'` (default), the method computes cumulative margins and `mar` is an `Nobs`-by-`NTrees` matrix, where the first column gives margins from `trees(1)`, second column gives margins from `trees(1:2)` etc, up to `trees(1:NTrees)`. If set to `'individual'`, `mar` is an `Nobs`-by-`NTrees` matrix, where each column gives margins from each tree in the ensemble. If set to `'ensemble'`, `mar` is a single column of length `Nobs` showing the cumulative margins for the entire ensemble.
`'trees'`	Vector of indices indicating what trees to include in this calculation. By default, this argument is set to `'all'` and the method uses all trees. If 'trees' is a numeric vector, the method returns an `Nobs`-by-`NTrees` matrix for `'cumulative'` and `'individual'` modes, where `NTrees` is the number of elements in the input vector, and a single column for `'ensemble'` mode. For example, in the `'cumulative'` mode, the first column gives margins from `trees(1)`, the second column gives margins from `trees(1:2)` etc.

`'treeweights'`	Vector of tree weights. This vector must have the same length as the `'trees'` vector. `oobMargin` uses these weights to combine output from the specified trees by taking a weighted average instead of the simple nonweighted majority vote. You cannot use this argument in the `'individual'` mode.

`CompactTreeBagger.margin`

oobMeanMargin

Class: TreeBagger

Out-of-bag mean margins

Syntax

```
mar = oobMeanMargin(B)
mar = oobMeanMargin(B,'param1',val1,'param2',val2,...)
```

Description

`mar = oobMeanMargin(B)` computes average classification margins for out-of-bag observations in the training data, using the trained bagger `B`. `oobMeanMargin` averages the margins over all out-of-bag observations. `mar` is a row-vector of length `NTrees`, where `NTrees` is the number of trees in the ensemble.

`mar = oobMeanMargin(B,'param1',val1,'param2',val2,...)` specifies optional parameter name/value pairs:

`'mode'`	String indicating how `oobMargin` computes errors. If set to `'cumulative'` (default), is a vector of length NTrees where the first element gives mean margin from `trees(1)`, second column gives mean margins from `trees(1:2)` etc, up to `trees(1:NTrees)`. If set to `'individual'`, `mar` is a vector of length `NTrees`, where each element is a mean margin from each tree in the ensemble . If set to `'ensemble'`, `mar` is a scalar showing the cumulative mean margin for the entire ensemble .
`'trees'`	Vector of indices indicating what trees to include in this calculation. By default, this argument is set to `'all'` and the method uses all trees. If `'trees'` is a numeric vector, the method returns a vector of length `NTrees` for `'cumulative'` and `'individual'` modes, where `NTrees` is the number of elements in the input vector, and a scalar for `'ensemble'` mode. For example, in the `'cumulative'` mode, the first element gives mean margin from `trees(1)`, the second element gives mean margin from `trees(1:2)` etc.

`'treeweights'`	Vector of tree weights. This vector must have the same length as the `'trees'` vector. `oobMeanMargin` uses these weights to combine output from the specified trees by taking a weighted average instead of the simple nonweighted majority vote. You cannot use this argument in the `'individual'` mode.

`CompactTreeBagger.meanMargin`

OOBPermutedVarCountRaiseMargin property

Class: TreeBagger

Variable importance for raising margin

Description

The `OOBPermutedVarCountRaiseMargin` property is a numeric array of size 1-by-`Nvars` containing a measure of variable importance for each predictor. For any variable, the measure is the difference between the number of raised margins and the number of lowered margins if the values of that variable are permuted across the out-of-bag observations. This measure is computed for every tree, then averaged over the entire ensemble and divided by the standard deviation over the entire ensemble. This property is empty for regression trees.

OOBPermutedVarDeltaError property

Class: TreeBagger

Variable importance for prediction error

Description

The `OOBPermutedVarDeltaError` property is a numeric array of size 1-by-*Nvars* containing a measure of importance for each predictor variable (feature). For any variable, the measure is the increase in prediction error if the values of that variable are permuted across the out-of-bag observations. This measure is computed for every tree, then averaged over the entire ensemble and divided by the standard deviation over the entire ensemble.

OOBPermutedVarDeltaMeanMargin property

Class: TreeBagger

Variable importance for classification margin

Description

The `OOBPermutedVarDeltaMeanMargin` property is a numeric array of size 1-by-`Nvars` containing a measure of importance for each predictor variable (feature). For any variable, the measure is the decrease in the classification margin if the values of that variable are permuted across the out-of-bag observations. This measure is computed for every tree, then averaged over the entire ensemble and divided by the standard deviation over the entire ensemble. This property is empty for regression trees.

oobPredict

Class: ClassificationBaggedEnsemble

Predict out-of-bag response of ensemble

Syntax

```
[label,score] = oobPredict(ens)
[label,score] = oobPredict(ens,Name,Value)
```

Description

`[label,score] = oobPredict(ens)` returns class labels and scores for `ens` for out-of-bag data.

`[label,score] = oobPredict(ens,Name,Value)` computes labels and scores with additional options specified by one or more Name,Value pair arguments.

Input Arguments

`ens`

A classification bagged ensemble, constructed with `fitensemble`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'learners'`

Indices of weak learners in the ensemble ranging from `1` to ens`.NumTrained`. `oobEdge` uses only these learners for calculating loss.

Default: `1:NumTrained`

Output Arguments

`label`

Classification labels of the same data type as the training data `Y`. There are `N` elements or rows, where `N` is the number of training observations. The label is the class with the highest score. In case of a tie, the label is earliest in ens`.ClassNames`.

`score`

An `N`-by-`K` numeric matrix for `N` observations and `K` classes. A high score indicates that an observation is likely to come from this class. Scores are in the range `0` to `1`.

Definitions

Out of Bag

Bagging, which stands for "bootstrap aggregation", is a type of ensemble learning. To bag a weak learner such as a decision tree on a dataset, `fitensemble` generates many bootstrap replicas of the dataset and grows decision trees on these replicas. `fitensemble` obtains each bootstrap replica by randomly selecting `N` observations out of `N` with replacement, where `N` is the dataset size. To find the predicted response of a trained ensemble, `predict` take an average over predictions from individual trees.

Drawing `N` out of `N` observations with replacement omits on average 37% (1/*e*) of observations for each decision tree. These are "out-of-bag" observations. For each observation, `oobLoss` estimates the out-of-bag prediction by averaging over predictions from all trees in the ensemble for which this observation is out of bag. It then compares the computed prediction against the true response for this observation. It calculates the out-of-bag error by comparing the out-of-bag predicted responses against the true responses for all observations used for training. This out-of-bag average is an unbiased estimator of the true ensemble error.

Score (ensemble)

For ensembles, a classification *score* represents the confidence of a classification into a class. The higher the score, the higher the confidence.

Different ensemble algorithms have different definitions for their scores. Furthermore, the range of scores depends on ensemble type. For example:

- `AdaBoostM1` scores range from $-\infty$ to ∞.
- `Bag` scores range from `0` to `1`.

Examples

Find the out-of-bag predictions and scores for the Fisher iris data. Find the scores in the range `(0.2,0.8)`; these are the scores where there is notable uncertainty in the resulting classifications.

```
load fisheriris
ens = fitensemble(meas,species,'Bag',100,...
    'Tree','type','classification');
[label score] = oobPredict(ens);
unsure = ( (score > .2) & (score < .8));
sum(sum(unsure)) % How many uncertain predictions?

ans =
    16
```

See Also

`oobMargin` | `oobPredict` | `oobLoss` | `oobEdge` | `predict`

oobPredict

Class: RegressionBaggedEnsemble

Predict out-of-bag response of ensemble

Syntax

```
Yfit = oobPredict(ens)
Yfit = oobPredict(ens,Name,Value)
```

Description

`Yfit = oobPredict(ens)` returns the predicted responses for the out-of-bag data in `ens`.

`Yfit = oobPredict(ens,Name,Value)` predicts responses with additional options specified by one or more Name,Value pair arguments.

Input Arguments

`ens`

A regression bagged ensemble, constructed with `fitensemble`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'learners'`

Indices of weak learners in the ensemble ranging from `1` to `NumTrained`. `oobLoss` uses only these learners for calculating loss.

Default: `1:NumTrained`

Output Arguments

`Yfit`

A vector of predicted responses for out-of-bag data. `Yfit` has `size(ens.X,1)` elements.

You can find the indices of out-of-bag observations for weak learner `L` with the command

```
~ens.UseObsForLearner(:,L)
```

Definitions

Out of Bag

Bagging, which stands for “bootstrap aggregation”, is a type of ensemble learning. To bag a weak learner such as a decision tree on a dataset, `fitensemble` generates many bootstrap replicas of the dataset and grows decision trees on these replicas. `fitensemble` obtains each bootstrap replica by randomly selecting `N` observations out of `N` with replacement, where `N` is the dataset size. To find the predicted response of a trained ensemble, `predict` take an average over predictions from individual trees.

Drawing `N` out of `N` observations with replacement omits on average 37% (1/*e*) of observations for each decision tree. These are "out-of-bag" observations. For each observation, `oobLoss` estimates the out-of-bag prediction by averaging over predictions from all trees in the ensemble for which this observation is out of bag. It then compares the computed prediction against the true response for this observation. It calculates the out-of-bag error by comparing the out-of-bag predicted responses against the true responses for all observations used for training. This out-of-bag average is an unbiased estimator of the true ensemble error.

Examples

Compute out-of-bag predictions for the `carsmall` data. Look at the first three terms of the fit:

```
load carsmall
X = [Displacement Horsepower Weight];
ens = fitensemble(X,MPG,'bag',100,'Tree',...
    'type','regression');
Yfit = oobPredict(ens);
Yfit(1:3) % first three terms

ans =
   15.7964
   14.7162
   14.8062
```

See Also

oobLoss | predict

oobPredict

Class: TreeBagger

Ensemble predictions for out-of-bag observations

Syntax

```
Y = oobPredict(B)
Y = oobPredict(B,'param1',val1,'param2',val2,...)
```

Description

`Y = oobPredict(B)` computes predicted responses using the trained bagger `B` for out-of-bag observations in the training data. The output has one prediction for each observation in the training data. The returned Y is a cell array of strings for classification and a numeric array for regression.

`Y = oobPredict(B,'param1',val1,'param2',val2,...)` specifies optional parameter name/value pairs:

`'trees'`	Array of tree indices to use for computation of responses. Default is `'all'`.
`'treeweights'`	Array of `NTrees` weights for weighting votes from the specified trees.

`CompactTreeBagger.predict` | `OOBIndices`

ordinal

Create ordinal array

After creating an `ordinal` array, you can use related functions to add, drop, or merge categories, and more.

For more information, see Using ordinal Objects.

Compatibility

The `nominal` and `ordinal` array data types might be removed in a future release. To represent ordered and unordered discrete, nonnumeric data, use the MATLAB `categorical` data type instead.

Syntax

```
B = ordinal(X)
B = ordinal(X,labels)
B = ordinal(X,labels,levels)

B = ordinal(X,labels,[],edges)
```

Description

`B = ordinal(X)` creates an `ordinal` array object B from the array X. `ordinal` creates the levels of B from the sorted unique values in X, and creates default labels for them.

`B = ordinal(X,labels)` labels the levels in B according to labels.

`B = ordinal(X,labels,levels)` creates an ordinal array with possible levels defined by levels.

`B = ordinal(X,labels,[],edges)` creates an ordinal array by binning a numeric array X with bin edges given by the numeric vector edges.

Examples

Create and Label Ordinal Arrays

Create an ordinal array from integer data, providing explicit labels.

```
quality = ordinal([1 2 3 3 2 1 2 1 3],...
   {'low' 'medium' 'high'})
```

```
quality =

  Columns 1 through 7

     low      medium      high      high      medium      low      medium

  Columns 8 through 9

     low      high
```

Show that the first element is less than the second element (low is less than medium).

```
quality(1) < quality(2)
```

```
ans =

     1
```

Create an ordinal array by binning values between 0 and 1 into thirds with labels `'small'`, `'medium'`, and `'large'`.

```
X = rand(5,2)
A = ordinal(X,{'small' 'medium' 'large'},[],[0 1/3 2/3 1])
```

```
X =

    0.8147    0.0975
    0.9058    0.2785
    0.1270    0.5469
    0.9134    0.9575
```

```
    0.6324    0.9649

A =

     large       small
     large       small
     small       medium
     large       large
     medium      large
```

- “Create Nominal and Ordinal Arrays” on page 2-4

Input Arguments

X — Input array

numeric | logical | character | categorical | cell array of strings

Input array to convert to `ordinal`, specified as a numeric, logical, character, or categorical array, or a cell array of strings. The levels of the resulting `ordinal` array correspond to the sorted unique values in X.

`labels` — Labels for the discrete levels

character array | cell array of strings

Labels for the discrete levels, specified as a character array or cell array of strings. By default, `ordinal` assigns the labels to the levels in B in order according to the sorted unique values in X.

You can include duplicate labels in labels in order to merge multiple values in X into a single level in B.

Data Types: `char` | `cell`

`levels` — Possible ordinal levels

vector

Possible ordinal levels for the output `ordinal` array, specified as a vector whose values can be compared to those in X using the equality operator. `ordinal` assigns labels to each level from the corresponding elements of labels. If X contains any values not present in levels, the levels of the corresponding elements of B are undefined.

`edges` — Bin edges

numeric vector

Bin edges to create a ordinal array by binning a numeric array, specified as a numeric vector. The uppermost bin includes values equal to the right-most edge. `ordinal` assigns labels to each level in the resulting nominal array from the corresponding elements of labels. When you specify edges, it must have one more element than labels.

Output Arguments

`B` — Ordinal array

`ordinal` array object

Nominal array, returned as an `ordinal` array object.

By default, an element of B is undefined if the corresponding element of X is `NaN` (when X is numeric), an empty string (when X is a character), or undefined (when X is categorical). `nominal` treats such elements as "undefined" or "missing" and does not include entries for them among the possible levels. To create an explicit level for such elements instead of treating them as undefined, you must use the levels input argument, and include `NaN`, the empty string, or an undefined element.

More About

- Using ordinal Objects

See Also

`nominal`

Using ordinal Objects

Arrays for ordinal data

Ordinal data are discrete, nonnumeric values that have a natural ordering. `ordinal` array objects provide efficient storage and convenient manipulation of such data, while also maintaining meaningful labels for the values.

You can manipulate `ordinal` arrays much like ordinary numeric arrays, including subscripting, concatenating, and reshaping. It can be useful to use `ordinal` arrays as grouping variables when the elements indicate the group an observation belongs to.

Note: The `nominal` and `ordinal` array data types might be removed in a future release. To represent ordered and unordered discrete, nonnumeric data, use the MATLAB `categorical` data type instead.

Examples

Create and Manipulate Ordinal Arrays

Create an ordinal array from integer data.

```
quality = ordinal([1 2 3; 3 2 1; 2 1 3],{'low' 'medium' 'high'})
```

```
quality =

     low         medium      high
     high        medium      low
     medium      low         high
```

Identify the elements in `quality` that are members of a level that is greater than or equal to `'medium'`. A value of `1` in the resulting array indicates that the corresponding element of `quality` is in this category.

```
quality >= 'medium'
```

```
ans =
```

```
     0     1     1
     1     1     0
     1     0     1
```

Identify the elements of `quality` that are members of either `'low'` or `'high'`.

```
ismember(quality,{'low' 'high'})
```

```
ans =

     1     0     1
     1     0     1
     0     1     1
```

Merge the elements of the `'medium'` and `'high'` levels into a new level labeled `'ok'`.

```
quality = mergelevels(quality,{'medium','high'},'ok')
```

```
quality =

     low       ok        ok
     ok        ok        low
     ok        low       ok
```

Display the levels of `quality`.

```
getlevels(quality)
```

```
ans =

     low       ok
```

Summarize the number of elements in each level. By default, `summary` returns counts for each column of the input array.

```
summary(quality)
```

```
     low       1       1       1
```

```
ok       2       2       2
```

- "Categorize Numeric Data" on page 2-16
- "Merge Category Levels" on page 2-19
- "Sort Ordinal Arrays" on page 2-40

Properties

`labels` — Level labels

cell array of strings

Level labels, specified as a cell array of string. Access labels using `getlabels`.

Data Types: `cell`

`undeflabel` — Label for undefined levels

`'<undefined>'` (default)

Label for undefined levels, specified as `'<undefined>'`. You can find undefined elements in categorical arrays using `isundefined`.

Object Functions

`addlevels` `droplevels` `getlabels` `getlevels` `islevel` `levelcounts` `mergelevels` `reorderlevels` `setlabels`

You can also use many other MATLAB array functions with categorical arrays. The following is a partial list. For a complete list, see "Other MATLAB Functions Supporting Nominal and Ordinal Arrays" on page 2-3.

`double` `histogram` `isequal` `isundefined` `pie` `summary` `times`

Create Object

Create `ordinal` arrays using the `ordinal` function.

outlierMeasure

Class: CompactTreeBagger

Outlier measure for data

Syntax

```
out = outlierMeasure(B,X)
out = outlierMeasure(B,X,'param1',val1,'param2',val2,...)
```

Description

`out = outlierMeasure(B,X)` computes outlier measures for predictors `X` using trees in the ensemble `B`. The method computes the outlier measure for a given observation by taking an inverse of the average squared proximity between this observation and other observations. `outlierMeasure` then normalizes these outlier measures by subtracting the median of their distribution, taking the absolute value of this difference, and dividing by the median absolute deviation. A high value of the outlier measure indicates that this observation is an outlier.

You can supply the proximity matrix directly by using the `'data'` parameter.

`out = outlierMeasure(B,X,'param1',val1,'param2',val2,...)` specifies optional parameter name/value pairs:

`'data'`	Flag indicating how to treat the `X` input argument. If set to `'predictors'` (default), the method assumes `X` is a matrix of predictors and uses it for computation of the proximity matrix. If set to `'proximity'`, the method treats `X` as a proximity matrix returned by the `proximity` method. If you do not supply the proximity matrix, `outlierMeasure` computes it internally. If you use the `proximity` method to compute a proximity matrix, supplying it as input to `outlierMeasure` reduces computing time.
`'labels'`	Vector of true class labels. True class labels can be either a numeric vector, character matrix, or cell array of strings. When you supply this parameter, the method performs the outlier calculation for any

observations using only other observations from the same class. This parameter must specify one label for each observation (row) in `X`.

See Also

`proximity`

OutlierMeasure property

Class: TreeBagger

Measure for determining outliers

Description

The `OutlierMeasure` property is a numeric array of size `Nobs`-by-1, where `Nobs` is the number of observations in the training data, containing outlier measures for each observation.

`CompactTreeBagger.outlierMeasure`

parallelcoords

Parallel coordinates plot

Syntax

```
parallelcoords(X)
parallelcoords(X,...,'Standardize','on')
parallelcoords(X,...,'Standardize','PCA')
parallelcoords(X,...,'Standardize','PCAStd')
parallelcoords(X,...,'Quantile',alpha)
parallelcoords(X,...,'Group',group)
parallelcoords(X,...,'Labels',labels)
parallelcoords(X,...,PropertyName,PropertyValue,...)
h = parallelcoords(X,...)
parallelcoords(axes,...)
```

Description

`parallelcoords(X)` creates a parallel coordinates plot of the multivariate data in the *n*-by-*p* matrix `X`. Rows of `X` correspond to observations, columns to variables. A parallel coordinates plot is a tool for visualizing high dimensional data, where each observation is represented by the sequence of its coordinate values plotted against their coordinate indices. `parallelcoords` treats `NaN`s in `X` as missing values and does not plot those coordinate values.

`parallelcoords(X,...,'Standardize','on')` scales each column of `X` to have mean 0 and standard deviation 1 before making the plot.

`parallelcoords(X,...,'Standardize','PCA')` creates a parallel coordinates plot from the principal component scores of `X`, in order of decreasing eigenvalues. `parallelcoords` removes rows of `X` containing missing values (`NaN`s) for principal components analysis (PCA) standardization.

`parallelcoords(X,...,'Standardize','PCAStd')` creates a parallel coordinates plot using the standardized principal component scores.

`parallelcoords(X,...,'Quantile',alpha)` plots only the median and the `alpha` and `1-alpha` quantiles of $f(t)$ at each value of t. This is useful if `X` contains many observations.

`parallelcoords(X,...,'Group',group)` plots the data in different groups with different colors. Groups are defined by `group`, a numeric array containing a group index for each observation. `group` can also be a categorical variable, character matrix, or cell array of strings, containing a group name for each observation.

`parallelcoords(X,...,'Labels',labels)` labels the coordinate tick marks along the horizontal axis using `labels`, a character array or cell array of strings.

`parallelcoords(X,...,`*`PropertyName`*`,`*`PropertyValue`*`,...)` sets properties to the specified property values for all line graphics objects created by `parallelcoords`.

`h = parallelcoords(X,...)` returns a column vector of handles to the line objects created by parallelcoords, one handle per row of `X`. If you use the `'Quantile'` input argument, `h` contains one handle for each of the three lines objects created. If you use both the `'Quantile'` and the `'Group'` input arguments, `h` contains three handles for each group.

`parallelcoords(axes,...)` plots into the axes with handle `axes`.

Examples

```
% Make a grouped plot of the raw data
load fisheriris
labels = {'Sepal Length','Sepal Width',...
          'Petal Length','Petal Width'};
parallelcoords(meas,'group',species,'labels',labels);

% Plot only the median and quartiles of each group
parallelcoords(meas,'group',species,'labels',labels,...
               'quantile',.25);
```

paramci

Confidence intervals for probability distribution parameters

Syntax

```
ci = paramci(pd)
ci = paramci(pd,Name,Value)
```

Description

`ci = paramci(pd)` returns the array ci containing the lower and upper boundaries of the 95% confidence interval for each parameter in probability distribution pd.

`ci = paramci(pd,Name,Value)` returns confidence intervals with additional options specified by one or more name-value pair arguments. For example, you can specify a different percentage for the confidence interval, or compute confidence intervals only for selected parameters.

Examples

Parameter Confidence Intervals

Load the sample data. Create a vector containing the first column of students' exam grade data.

```
load examgrades;
x = grades(:,1);
```

Fit a normal distribution object to the data.

```
pd = fitdist(x,'Normal')
```

```
pd =

  NormalDistribution
```

```
  Normal distribution
       mu = 75.0083   [73.4321, 76.5846]
    sigma =  8.7202   [7.7391, 9.98843]
```

Compute the 95% confidence interval for the distribution parameters.

```
ci = paramci(pd)

ci =

   73.4321    7.7391
   76.5846    9.9884
```

Column 1 of `ci` contains the lower and upper 95% confidence interval boundaries for the mu parameter, and column 2 contains the boundaries for the sigma parameter.

Change Parameter Confidence Intervals

Load the sample data. Create a vector containing the first column of students' exam grade data.

```
load examgrades;
x = grades(:,1);
```

Fit a normal distribution object to the data.

```
pd = fitdist(x,'Normal')

pd =

  NormalDistribution

  Normal distribution
       mu = 75.0083   [73.4321, 76.5846]
    sigma =  8.7202   [7.7391, 9.98843]
```

Compute the 99% confidence interval for the distribution parameters.

```
ci = paramci(pd,'Alpha',.01)

ci =

   72.9245    7.4627
   77.0922   10.4403
```

Column 1 of `ci` contains the lower and upper 99% confidence interval boundaries for the mu parameter, and column 2 contains the boundaries for the sigma parameter.

Input Arguments

`pd` — Probability distribution

probability distribution object

Probability distribution, specified as a probability distribution object. Create a probability distribution object with specified parameter values using `makedist`. Alternatively, create a probability distribution object by fitting it to data using `fitdist` or the Distribution Fitting app.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'Alpha',0.01` specifies a 99% confidence interval.

`'Alpha'` — Alpha level

`0.05` (default) | scalar value in the range (0,1)

Alpha level for the confidence interval, specified as the comma-separated pair consisting of `'Alpha'` and a scalar value in the range (0,1). The default value `0.05` corresponds to a 95% confidence interval.

Example: `'Alpha',0.01`

Data Types: `single` | `double`

`'Parameter'` — Parameter list

vector | cell array of strings

Parameter list for which to compute confidence intervals, specified as the comma-separated pair consisting of `'Parameter'` and a vector or a cell array of strings containing the parameter names. By default, `paramci` computes confidence intervals for all distribution parameters.

Example: `'Parameter','mu'`

Data Types: `char`

`'Type'` — Computation method

`'exact' | 'Wald' | 'lr'`

Computation method for the confidence intervals, specified as the comma-separated pair consisting of `'Type'` and `'exact'`, `'Wald'`, or `'lr'`.

`'exact'` computes the confidence intervals using an exact method, and is available for the following distributions.

Binomial	Compute using the Clopper-Pearson method based on exact probability calculations. This method does not provide exact coverage probabilities.
Exponential	Compute using a method based on a chi-square distribution. This method provides exact coverage for complete and Type 2 censored samples.
Normal	Computation method based on *t* and chi-square distributions for uncensored samples provides exact coverage for uncensored samples. For censored samples, `paramci` uses the Wald method if `Type` is `exact`.
Lognormal	Computation method based on *t* and chi-square distributions for uncensored samples provides exact coverage. For censored samples, `paramci` uses the Wald method if `Type` is `exact`.
Poisson	Computation method based on a chi-square distribution provides exact coverage. For large degrees of freedom, the chi-square is approximated by a normal distribution for numerical efficiency.
Rayleigh	Computation method based on a chi-square distribution provides exact coverage probabilities.

`'exact'` is the default when it is available. Alternatively, you can specify `'Wald'` to compute the confidence intervals using the Wald method, or `'lr'` to compute the confidence intervals using the likelihood radio method.

Example: `'Type','Wald'`

`'LogFlag'` — Boolean flag for log scale

vector

Boolean flag for the log scale, specified as the comma-separated pair consisting of `'LogFlag'` and a vector containing Boolean values corresponding to each distribution parameter. The flag specifies which Wald intervals to compute on a log scale. The default values depend on the distribution.

Example: `'LogFlag',[0,1]`

Data Types: `logical`

Output Arguments

`ci` — Confidence interval

array

Confidence interval, returned as a *p*-by-2 array containing the lower and upper bounds of the (1 - `Alpha`)% confidence interval for each distribution parameter. *p* is the number of distribution parameters.

`dfittool` | `fitdist` | `makedist`

paramci

Class: ProbDistUnivParam

Return parameter confidence intervals of ProbDistUnivParam object

Syntax

```
CI = paramci(PD)
CI = paramci(PD, Alpha)
```

Description

`CI = paramci(PD)` returns `CI`, a 2-by-`N` array containing 95% confidence intervals for the parameters of the `ProbDistUnivParam` object `PD`. `N` is the number of parameters in the distribution. When you create `PD` by specifying parameters (such as using the `ProbDistUnivParam` constructor or using the `fitdist` function and specifying a `'binomial'` or `'generalized pareto'` distribution) rather than by fitting to data, the confidence intervals have a width of `0` because the parameters are viewed as estimates of an unknown parameter.

`CI = paramci(PD, Alpha)` returns `100*(1 - Alpha)`% confidence intervals. Default `Alpha` is `0.05`, which specifies 95% confidence intervals.

Note: If you create `PD` with a distribution that does not support confidence intervals, then `CI` contains `NaN` values.

Input Arguments

`PD`	An object of the class `ProbDistUnivParam`.
`Alpha`	A value between `0` and `1` that specifies a confidence interval. Default is `0.05`, which specifies 95% confidence intervals.

Output Arguments

`CI`	A 2-by-`N` array containing `100*(1 - Alpha)`% confidence intervals for the parameters of the `ProbDistUnivParam` object `PD`. `N` is the number of parameters in the distribution.

Package: prob

Confidence intervals for probability distribution parameters

Syntax

```
ci = paramci(pd)
ci = paramci(pd,Name,Value)
```

Description

`ci = paramci(pd)` returns the array ci containing the lower and upper boundaries of the 95% confidence interval for each parameter in probability distribution pd.

`ci = paramci(pd,Name,Value)` returns confidence intervals with additional options specified by one or more name-value pair arguments. For example, you can specify a different percentage for the confidence interval, or compute confidence intervals only for selected parameters.

Input Arguments

`pd` — Probability distribution

probability distribution object

Probability distribution, specified as a probability distribution object. Create a probability distribution object with specified parameter values using `makedist`. Alternatively, create a probability distribution object by fitting it to data using `fitdist` or the Distribution Fitting app.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single

quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'Alpha',0.01` specifies a 99% confidence interval.

`'Alpha'` — Alpha level

`0.05` (default) | scalar value in the range (0,1)

Alpha level for the confidence interval, specified as the comma-separated pair consisting of `'Alpha'` and a scalar value in the range (0,1). The default value `0.05` corresponds to a 95% confidence interval.

Example: `'Alpha',0.01`

Data Types: `single` | `double`

`'Parameter'` — Parameter list

vector | cell array of strings

Parameter list for which to compute confidence intervals, specified as the comma-separated pair consisting of `'Parameter'` and a vector or a cell array of strings containing the parameter names. By default, `paramci` computes confidence intervals for all distribution parameters.

Example: `'Parameter','mu'`

Data Types: `char`

`'Type'` — Computation method

`'exact'` | `'Wald'` | `'lr'`

Computation method for the confidence intervals, specified as the comma-separated pair consisting of `'Type'` and `'exact'`, `'Wald'`, or `'lr'`.

`'exact'` computes the confidence intervals using an exact method, and is available for the following distributions.

Binomial	Compute using the Clopper-Pearson method based on exact probability calculations. This method does not provide exact coverage probabilities.
Exponential	Compute using a method based on a chi-square distribution. This method provides exact coverage for complete and Type 2 censored samples.

Normal	Computation method based on *t* and chi-square distributions for uncensored samples provides exact coverage for uncensored samples. For censored samples, `paramci` uses the Wald method if `Type` is `exact`.
Lognormal	Computation method based on *t* and chi-square distributions for uncensored samples provides exact coverage. For censored samples, `paramci` uses the Wald method if `Type` is `exact`.
Poisson	Computation method based on a chi-square distribution provides exact coverage. For large degrees of freedom, the chi-square is approximated by a normal distribution for numerical efficiency.
Rayleigh	Computation method based on a chi-square distribution provides exact coverage probabilities.

`'exact'` is the default when it is available. Alternatively, you can specify `'Wald'` to compute the confidence intervals using the Wald method, or `'lr'` to compute the confidence intervals using the likelihood radio method.

Example: `'Type','Wald'`

`'LogFlag'` — Boolean flag for log scale

vector

Boolean flag for the log scale, specified as the comma-separated pair consisting of `'LogFlag'` and a vector containing Boolean values corresponding to each distribution parameter. The flag specifies which Wald intervals to compute on a log scale. The default values depend on the distribution.

Example: `'LogFlag',[0,1]`

Data Types: `logical`

Output Arguments

`ci` — Confidence interval

array

Confidence interval, returned as a *p*-by-2 array containing the lower and upper bounds of the (1 - `Alpha`)% confidence interval for each distribution parameter. *p* is the number of distribution parameters.

Examples

Parameter Confidence Intervals

Load the sample data. Create a vector containing the first column of students' exam grade data.

```
load examgrades;
x = grades(:,1);
```

Fit a normal distribution object to the data.

```
pd = fitdist(x,'Normal')
```

```
pd =

  NormalDistribution

  Normal distribution
       mu = 75.0083   [73.4321, 76.5846]
    sigma =  8.7202   [7.7391, 9.98843]
```

Compute the 95% confidence interval for the distribution parameters.

```
ci = paramci(pd)
```

```
ci =

   73.4321    7.7391
   76.5846    9.9884
```

Column 1 of `ci` contains the lower and upper 95% confidence interval boundaries for the mu parameter, and column 2 contains the boundaries for the sigma parameter.

Change Parameter Confidence Intervals

Load the sample data. Create a vector containing the first column of students' exam grade data.

```
load examgrades;
x = grades(:,1);
```

Fit a normal distribution object to the data.

```
pd = fitdist(x,'Normal')
```

```
pd =

`dfittool` | `fitdist` | `makedist`

ParamCov property

Class: ProbDistParametric

Read-only covariance matrix of parameter estimates of ProbDistParametric object

Description

`ParamCov` is a read-only property of the `ProbDistParametric` class. `ParamCov` is a covariance matrix containing the parameter estimates of a distribution represented by a ProbDistParametric object. `ParamCov` has a size of `NumParams`-by-`NumParams`.

Values

This covariance matrix includes estimates for both the specified parameters and parameters that are fit to the data. For specified parameters, the covariance is `0`, indicating the parameter is known exactly. Use this information to view and compare the descriptions of parameters supplied to create distributions.

ParamDescription property

Class: ProbDistParametric

Read-only cell array specifying descriptions of parameters of ProbDistParametric object

Description

`ParamDescription` is a read-only property of the `ProbDistParametric` class. `ParamDescription` is a cell array of strings specifying the descriptions or meanings of the parameters of a distribution represented by a ProbDistParametric object. `ParamDescription` has a length of `NumParams`.

Values

This cell array includes a brief description of the meaning of both the specified parameters and parameters that are fit to the data. The description is the same as the parameter name when no further description information is available. Use this information to view and compare the descriptions of parameters used to create distributions.

ParamIsFixed property

Class: ProbDistParametric

Read-only logical array specifying fixed parameters of ProbDistParametric object

Description

`ParamIsFixed` is a read-only property of the `ProbDistParametric` class. `ParamIsFixed` is a logical array specifying the fixed parameters of a distribution represented by a ProbDistParametric object. `ParamIsFixed` has a length of `NumParams`.

Values

This array specifies a `1` (`true`) for fixed parameters, and a `0` (`false`) for parameters that are estimated from the input data. Use this information to view and compare the fixed parameters used to create distributions.

ParamNames property

Class: ProbDistParametric

Read-only cell array specifying names of parameters of ProbDistParametric object

Description

`ParamNames` is a read-only property of the `ProbDistParametric` class. `ParamNames` is a cell array of strings specifying the names of the parameters of a distribution represented by a ProbDistParametric object. `ParamNames` has a length of `NumParams`.

Values

This cell array includes the names of both the specified parameters and parameters that are fit to the data. Use this information to view and compare the names of parameters used to create distributions.

Params property

Class: NaiveBayes

Parameter estimates

Description

The `Params` property is an `NClasses`-by-`NDims` cell array containing the parameter estimates, excluding the class priors. `Params(i,j)` contains the parameter estimates for the `j`th feature in the `i`th class. `Params(i,j)` is an empty cell if the `i`th class is empty.

The entry in `Params(i,j)` depends on the distribution type used for the `jth` feature, as follows:

`'normal'`	A vector of length two. The first element is the mean, and the second element is standard deviation.
`'kernel'`	A `ProbDistUnivKernel` object
`'mvmn'`	A vector containing the probability for each possible value of the `j`th feature in the `i`th class. The order of the probabilities is decided by the sorted order of all the unique values of the `j`th feature.
`'mn'`	A scalar representing the probability the `j`th token appearing in the `i`th class, `Prob(token j | class i)`. It is estimated as `(1 + the number of occurrence of token J in class I)/ (NDims + the total number of token occurrence in class I)`.

Params property

Class: ProbDistParametric

Read-only array specifying values of parameters of ProbDistParametric object

Description

`Params` is a read-only property of the `ProbDistParametric` class. `Params` is an array of values specifying the values of the parameters of a distribution represented by a ProbDistParametric object. `Params` has a length of `NumParams`.

Values

This array includes the values of both the specified parameters and parameters that are fit to the data. Use this information to view and compare the values of parameters used to create distributions.

prob.ParametricTruncatableDistribution class

Package: prob
Superclasses: prob.TruncatableDistribution

Parametric truncatable probability distribution object

Description

Create a probability distribution object with specified parameter values using `makedist`.

Methods

mean	Mean of probability distribution object
std	Standard deviation of probability distribution object
var	Variance of probability distribution object

Inherited Methods

cdf	Cumulative distribution function of probability distribution object
icdf	Inverse cumulative distribution function of probability distribution object
iqr	Interquartile range of probability distribution object
median	Median of probability distribution object

pdf	Probability density function of probability distribution object
random	Generate random numbers from probability distribution object
truncate	Truncate probability distribution object

parent

Class: classregtree

Parent node

Compatibility

`classregtree` will be removed in a future release. See `fitctree`, `fitrtree`, `ClassificationTree`, or `RegressionTree` instead.

Syntax

```
p = parent(t)
p = parent(t,nodes)
```

Description

`p = parent(t)` returns an n-element vector `p` containing the number of the parent node for each node in the tree `t`, where n is the number of nodes. The parent of the root node is `0`.

`p = parent(t,nodes)` takes a vector `nodes` of node numbers and returns the parent nodes for the specified nodes.

Examples

Create a classification tree for Fisher's iris data:

```
load fisheriris;

t = classregtree(meas,species,...
                 'names',{'SL' 'SW' 'PL' 'PW'})
t =
Decision tree for classification
```

```
1  if PL<2.45 then node 2 else node 3
2  class = setosa
3  if PW<1.75 then node 4 else node 5
4  if PL<4.95 then node 6 else node 7
5  class = virginica
6  if PW<1.65 then node 8 else node 9
7  class = virginica
8  class = versicolor
9  class = virginica

view(t)
```

paretotails class

Superclasses: piecewisedistribution

Empirical distributions with Pareto tails

Construction

.paretotails	Construct Pareto tails object

Methods

lowerparams	Lower Pareto tails parameters
upperparams	Upper Pareto tails parameters

Inherited Methods

Methods in the following table are inherited from `piecewisedistribution`.

boundary	Piecewise distribution boundaries
cdf	Cumulative distribution function for piecewise distribution
disp	Display piecewisedistribution object
display	Display piecewisedistribution object
icdf	Inverse cumulative distribution function for piecewise distribution

nsegments	Number of segments
pdf	Probability density function for piecewise distribution
random	Random numbers from piecewise distribution
segment	Segments containing values

Properties

Objects of the `paretotails` class have no properties accessible by dot indexing, `get` methods, or `set` methods. To obtain information about a `paretotails` object, use the appropriate method.

Copy Semantics

Value. To learn how this affects your use of the class, see Comparing Handle and Value Classes in the MATLAB Object-Oriented Programming documentation.

How To

- “Generalized Pareto Distribution”

paretotails

Class: paretotails

Construct Pareto tails object

Syntax

```
obj = paretotails(x,pl,pu)
obj = paretotails(x,pl,pu,cdffun)
```

Description

`obj = paretotails(x,pl,pu)` creates an object `obj` defining a distribution consisting of the empirical distribution of `x` in the center and Pareto distributions in the tails. `x` is a real-valued vector of data values whose extreme observations are fit to generalized Pareto distributions (GPDs). `pl` and `pu` identify the lower- and upper-tail cumulative probabilities such that `100*pl` and `100*(1-pu)` percent of the observations in `x` are, respectively, fit to a GPD by maximum likelihood. If `pl` is `0`, or if there are not at least two distinct observations in the lower tail, then no lower Pareto tail is fit. If `pu` is `1`, or if there are not at least two distinct observations in the upper tail, then no upper Pareto tail is fit.

`obj = paretotails(x,pl,pu,cdffun)` uses *`cdffun`* to estimate the cdf of `x` between the lower and upper tail probabilities. *`cdffun`* may be any of the following:

- `'ecdf'` — Uses an interpolated empirical cdf, with data values as the midpoints in the vertical steps in the empirical cdf, and computed by linear interpolation between data values. This is the default.
- `'kernel'` — Uses a kernel-smoothing estimate of the cdf.
- `@fun` — Uses a handle to a function of the form `[p,xi] = fun(x)` that accepts the input data vector `x` and returns a vector `p` of cdf values and a vector `xi` of evaluation points. Values in `xi` must be sorted and distinct but need not equal the values in `x`.

`cdffun` is used to compute the quantiles corresponding to `pl` and `pu` by inverse interpolation, and to define the fitted distribution between these quantiles.

The output object `obj` is a Pareto tails object with methods to evaluate the cdf, inverse cdf, and other functions of the fitted distribution. These methods are well-suited to copula and other Monte Carlo simulations. The pdf method in the tails is the GPD density, but in the center it is computed as the slope of the interpolated cdf.

The `paretotails` class is a subclass of the `piecewisedistribution` class, and many of its methods are derived from that class.

Examples

Fit Pareto Tails to a Probability Distribution

Generate sample data containing 100 random numbers from a *t* distribution with 3 degrees of freedom.

```
rng default;  % For reproducibility
t = trnd(3,100,1);
```

Fit pareto tails to the distribution at cumulative probabilities 0.1 and 0.9.

```
obj = paretotails(t,0.1,0.9);
[p,q] = boundary(obj);
```

Plot the cdf of the Pareto tails and the cdf of the fitted *t* distribution on the same figure.

```
x = linspace(-5,5);
plot(x,cdf(obj,x),'b-','LineWidth',2)
hold on;
plot(x,tcdf(x,3),'r:','LineWidth',2)
plot(q,p,'bo','LineWidth',2,'MarkerSize',5)
legend('Pareto Tails Object','t Distribution',...

partialcorr

Linear or rank partial correlation coefficients

Syntax

```
rho = partialcorr(x)
rho = partialcorr(x,z)
rho = partialcorr(x,y,z)
rho = partialcorr( ___ ,Name,Value)
[rho,pval] = partialcorr( ___ )
```

Description

`rho = partialcorr(x)` returns the sample linear partial correlation coefficients between pairs of variables in x, controlling for the remaining variables in x.

`rho = partialcorr(x,z)` returns the sample linear partial correlation coefficients between pairs of variables in x, controlling for the variables in z.

`rho = partialcorr(x,y,z)` returns the sample linear partial correlation coefficients between pairs of variables in x and y, controlling for the variables in z.

`rho = partialcorr( ___ ,Name,Value)` returns the sample linear partial correlation coefficients with additional options specified by one or more name-value pair arguments, using input arguments from any of the previous syntaxes. For example, you can specify whether to use Pearson or Spearman partial correlations, or specify how to treat missing values.

`[rho,pval] = partialcorr( ___ )` also returns a matrix pval of *p*-values for testing the hypothesis of no partial correlation against the one- or two-sided alternative that there is a nonzero partial correlation.

Examples

Compute Partial Correlation Coefficients

Compute partial correlation coefficients between pairs of variables in the input matrix.

Load the sample data. Convert the strings in `hospital.Sex` to numeric group identifiers.

```
load hospital;
hospital.SexID = grp2idx(hospital.Sex);
```

Create an input matrix containing the sample data.

```
x = [hospital.SexID hospital.Age hospital.Smoker hospital.Weight];
```

Each row in `x` contains a patient's gender, age, smoking status, and weight.

Compute partial correlation coefficients between pairs of variables in `x`, while controlling for the effects of the remaining variables in `x`.

```
rho = partialcorr(x)
```

```
rho =

    1.0000   -0.0105    0.0273    0.9421
   -0.0105    1.0000    0.0419    0.0369
    0.0273    0.0419    1.0000    0.0451
    0.9421    0.0369    0.0451    1.0000
```

The matrix `rho` indicates, for example, a correlation of 0.9421 between gender and weight after controlling for all other variables in `x`. You can return the *p*-values as a second output, and examine them to confirm whether these correlations are statistically significant.

For a clearer display, create a table with appropriate variable and row labels.

```
rho = array2table(rho, ...
    'VariableNames',{'SexID','Age','Smoker','Weight'},...
    'RowNames',{'SexID','Age','Smoker','Weight'});

disp('Partial Correlation Coefficients')
disp(rho)
```

```
Partial Correlation Coefficients
               SexID        Age         Smoker      Weight
               --------    --------    --------    --------
    SexID           1    -0.01052    0.027324      0.9421
    Age       -0.01052           1    0.041945    0.036873
    Smoker    0.027324    0.041945           1    0.045106
```

```
    Weight      0.9421    0.036873    0.045106           1
```

Test for Partial Correlations with Controlled Variables

Test for partial correlation between pairs of variables in the input matrix, while controlling for the effects of a second set of variables.

Load the sample data. Convert the strings in `hospital.Sex` to numeric group identifiers.

```
load hospital;
hospital.SexID = grp2idx(hospital.Sex);
```

Create two matrices containing the sample data.

```
x = [hospital.Age hospital.BloodPressure];
z = [hospital.SexID hospital.Smoker hospital.Weight];
```

The `x` matrix contains the variables to test for partial correlation. The `z` matrix contains the variables to control for. The measurements for `BloodPressure` are contained in two columns: The first column contains the upper (systolic) number, and the second column contains the lower (diastolic) number. `partialcorr` treats each column as a separate variable.

Test for partial correlation between pairs of variables in `x`, while controlling for the effects of the variables in `z`. Compute the correlation coefficients.

```
[rho,pval] = partialcorr(x,z)
```

```
rho =

    1.0000    0.1300    0.0462
    0.1300    1.0000    0.0012
    0.0462    0.0012    1.0000

pval =

         0    0.2044    0.6532
    0.2044         0    0.9903
    0.6532    0.9903         0
```

The large values in `pval` indicate that there is no significant correlation between age and either blood pressure measurement after controlling for gender, smoking status, and weight.

For a clearer display, create tables with appropriate variable and row labels.

```
rho = array2table(rho, ...
    'VariableNames',{'Age','BPTop','BPBottom'},...
    'RowNames',{'SexID','Smoker','Weight'});

pval = array2table(pval, ...
    'VariableNames',{'Age','BPTop','BPBottom'},...
    'RowNames',{'SexID','Smoker','Weight'});

disp('Partial Correlation Coefficients')
disp(rho)
disp('p-values')
disp(pval)
```

```
Partial Correlation Coefficients
                Age          BPTop       BPBottom
              --------    ---------    ---------
    SexID            1         0.13     0.046202
    Smoker        0.13            1    0.0012475
    Weight    0.046202    0.0012475            1

p-values
                Age        BPTop     BPBottom
              -------    -------    --------
    SexID           0    0.20438     0.65316
    Smoker    0.20438          0     0.99032
    Weight    0.65316    0.99032           0
```

Test for Paired Partial Correlation Coefficients

Test for partial correlation between pairs of variables in the `x` and `y` input matrices, while controlling for the effects of a third set of variables.

Load the sample data. Convert the strings in `hospital.Sex` to numeric group identifiers.

```
load hospital;
hospital.SexID = grp2idx(hospital.Sex);
```

Create three matrices containing the sample data.

```
x = [hospital.BloodPressure];
y = [hospital.Weight hospital.Age];
z = [hospital.SexID hospital.Smoker];
```

`partialcorr` can test for partial correlation between the pairs of variables in `x` (the systolic and diastolic blood pressure measurements) and `y` (weight and age), while controlling for the variables in `z` (gender and smoking status). The measurements for `BloodPressure` are contained in two columns: The first column contains the upper (systolic) number, and the second column contains the lower (diastolic) number. `partialcorr` treats each column as a separate variable.

Test for partial correlation between pairs of variables in `x` and `y`, while controlling for the effects of the variables in `z`. Compute the correlation coefficients.

```
[rho,pval] = partialcorr(x,y,z)
```

```
rho =

   -0.0257    0.1289
    0.0292    0.0472

pval =

    0.8018    0.2058
    0.7756    0.6442
```

The results in `pval` indicate that, after controlling for gender and smoking status, there is no significant correlation between either of a patient's blood pressure measurements and that patient's weight or age.

For a clearer display, create tables with appropriate variable and row labels.

```
rho = array2table(rho, ...
    'VariableNames',{'BPTop','BPBottom'},...
    'RowNames',{'Weight','Age'});

pval = array2table(pval, ...
    'VariableNames',{'BPTop','BPBottom'},...
    'RowNames',{'Weight','Age'});

disp('Partial Correlation Coefficients')
disp(rho)
disp('p-values')
disp(pval)
```

```
Partial Correlation Coefficients
               BPTop      BPBottom
```

```
                 --------    --------
    Weight      -0.02568     0.12893
    Age         0.029168    0.047226

p-values
                  BPTop     BPBottom
                 -------    --------
    Weight      0.80182     0.2058
    Age         0.77556     0.64424
```

One-Tailed Partial Correlation Test

Test the hypothesis that pairs of variables have no correlation, against the alternative hypothesis that the correlation is greater than 0.

Load the sample data. Convert the strings in `hospital.Sex` to numeric group identifiers.

```
load hospital;
hospital.SexID = grp2idx(hospital.Sex);
```

Create three matrices containing the sample data.

```
x = [hospital.BloodPressure];
y = [hospital.Weight hospital.Age];
z = [hospital.SexID hospital.Smoker];
```

`partialcorr` can test for partial correlation between the pairs of variables in `x` (the systolic and diastolic blood pressure measurements) and `y` (weight and age), while controlling for the variables in `z` (gender and smoking status). The measurements for `BloodPressure` are contained in two columns: The first column contains the upper (systolic) number, and the second column contains the lower (diastolic) number. `partialcorr` treats each column as a separate variable.

Compute the correlation coefficients using a right-tailed test.

```
[rho,pval] = partialcorr(x,y,z,'Tail','right')

rho =

   -0.0257    0.1289
    0.0292    0.0472
```

```
pval =

    0.5991    0.1029
    0.3878    0.3221
```

The results in `pval` indicate that `partialcorr` does not reject the null hypothesis of nonzero correlations between the variables in `x` and `y`, after controlling for the variables in `z`, when the alternative hypothesis is that the correlations are greater than 0.

For a clearer display, create tables with appropriate variable and row labels.

```
rho = array2table(rho, ...
    'VariableNames',{'BPTop','BPBottom'},...
    'RowNames',{'Weight','Age'});

pval = array2table(pval, ...
    'VariableNames',{'BPTop','BPBottom'},...
    'RowNames',{'Weight','Age'});

disp('Partial Correlation Coefficients')
disp(rho)
disp('p-values')
disp(pval)
```

```
Partial Correlation Coefficients
              BPSys       BPDia
    Weight    -0.02568     0.12893
    Age       0.029168    0.047226

p-values
              BPSys      BPDia
    Weight    0.59909     0.1029
    Age       0.38778    0.32212
```

Input Arguments

x — Data matrix

matrix

Data matrix, specified as an n-by-p_x matrix. The rows of `x` correspond to observations, and the columns correspond to variables.

Data Types: `single` | `double`

y — Data matrix
matrix

Data matrix, specified as an n-by-p_y matrix. The rows of `y` correspond to observations, and the columns correspond to variables.

Data Types: `single` | `double`

z — Data matrix
matrix

Data matrix, specified as an n-by-p_z matrix. The rows of `z` correspond to observations, and columns correspond to variables.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'Type','Spearman','Rows','complete'` computes Spearman partial correlations using only the data in rows that contain no missing values.

`'Type'` — Type of partial correlations
`'Pearson'` (default) | `'Spearman'`

Type of partial correlations to compute, specified as the comma-separated pair consisting of `'Type'` and one of the following.

`'Pearson'`	Compute Pearson (linear) partial correlations.
`'Spearman'`	Compute Spearman (rank) partial correlations.

Example: `'Type','Spearman'`

`'Rows'` — Rows to use in computation
`'all'` (default) | `'complete'` | `'pairwise'`

Rows to use in computation, specified as the comma-separated pair consisting of `'Rows'` and one of the following.

`'all'`	Use all rows regardless of missing (`NaN`) values.
`'complete'`	Use only rows with no missing values.
`'pairwise'`	Compute `rho(i,j)` using rows with no missing values in column `i` or `j`.

Using `'pairwise'` can produce a rho that is not positive definite. `'complete'` always produces a positive definite rho, but when data is missing, the estimates are generally based on fewer observations.

Example: `'Rows','complete'`

`'Tail'` — Alternative hypothesis

`'both'` (default) | `'right'` | `'left'`

Alternative hypothesis to test against, specified as the comma-separated pair consisting of `'Tail'` and one of the following.

`'both'`	Test the alternative hypothesis that the correlation is not 0.
`'right'`	Test the alternative hypothesis that the correlation is greater than 0.
`'left'`	Test the alternative hypothesis that the correlation is less than 0.

Example: `'Tail','right'`

Output Arguments

`rho` — Sample linear partial correlation coefficients

matrix

Sample linear partial correlation coefficients, returned as a matrix.

- If you input only an x matrix, `rho` is a symmetric p_x-by-p_x matrix. The (i,j)th entry is the sample linear partial correlation between the i-th and j-th columns in x.

- If you input x and z matrices, `rho` is a symmetric p_x-by-p_x matrix. The (i,j)th entry is the sample linear partial correlation between the ith and jth columns in x, controlled for the variables in z.
- If you input x, y, and z matrices, `rho` is a p_x-by-p_y matrix, where the (i,j)th entry is the sample linear partial correlation between the ith column in x and the jth column in y, controlled for the variables in z.

If the covariance matrix of `[x,z]` is

$$S = \begin{pmatrix} S_{xx} & S_{xz} \\ S_{xz}^T & S_{zz} \end{pmatrix},$$

then the partial correlation matrix of `x`, controlling for `z`, can be defined formally as a normalized version of the covariance matrix $S_{xy} = S_{xx} - (S_{xz}S_{zz}^{-1}S_{xz}^T)$

`pval` — *p*-values

matrix

p-values, returned as a matrix. Each element of `pval` is the *p*-value for the corresponding element of rho.

If `pval(i,j)` is small, then the corresponding partial correlation `rho(i,j)` is statistically significantly different from 0.

`partialcorr` computes *p*-values for linear and rank partial correlations using a Student's *t* distribution for a transformation of the correlation. This is exact for linear partial correlation when x and z are normal, but is a large-sample approximation otherwise.

See Also

`corr` | `corrcoef` | `partialcorri` | `tiedrank`

partialcorri

Partial correlation coefficients adjusted for internal variables

Syntax

```
rho = partialcorri(y,x)
rho = partialcorri(y,x,z)
rho = partialcorri( ___ ,Name,Value)
[rho,pval] = partialcorri( ___ )
```

Description

`rho = partialcorri(y,x)` returns the sample linear partial correlation coefficients between pairs of variables in y and x, adjusting for the remaining variables in x.

`rho = partialcorri(y,x,z)` returns the sample linear partial correlation coefficients between pairs of variables in y and x, adjusting for the remaining variables in x, after first controlling both x and y for the variables in z.

`rho = partialcorri( ___ ,Name,Value)` returns the sample linear partial correlation coefficients with additional options specified by one or more name-value pair arguments, using input arguments from any of the previous syntaxes. For example, you can specify whether to use Pearson or Spearman partial correlations, or specify how to treat missing values.

`[rho,pval] = partialcorri( ___ )` also returns a matrix pval of *p*-values for testing the hypothesis of no partial correlation against the one- or two-sided alternative that there is a nonzero partial correlation.

Examples

Compute Partial Correlation Coefficients

Compute partial correlation coefficients for each pair of variables in the `x` and `y` input matrices, while controlling for the effects of the remaining variables in `x`.

Load the sample data.

```
load carsmall;
```

The data contains measurements from cars manufactured in 1970, 1976, and 1982. It includes `MPG` and `Acceleration` as performance measures, and `Displacement`, `Horsepower`, and `Weight` as design variables. `Acceleration` is the time required to accelerate from 0 to 60 miles per hour, so a high value for `Acceleration` corresponds to a vehicle with low acceleration.

Define the input matrices. The `y` matrix includes the performance measures, and the `x` matrix includes the design variables.

```
y = [MPG,Acceleration];
x = [Displacement,Horsepower,Weight];
```

Compute the correlation coefficients. Include only rows with no missing values in the computation.

```
rho = partialcorri(y,x,'Rows','complete')
```

```
rho =

   -0.0537   -0.1520   -0.4856
   -0.3994   -0.4008    0.4912
```

The results suggest, for example, a 0.4912 correlation between weight and acceleration after controlling for the effects of displacement and horsepower. You can return the *p*-values as a second output, and examine them to confirm whether these correlations are statistically significant.

For a clearer display, create a table with appropriate variable and row labels.

```
rho = array2table(rho, ...
   'VariableNames',{'Displacement','Horsepower','Weight'}, ...
   'RowNames',{'MPG','Acceleration'});

disp('Partial Correlation Coefficients')
disp(rho)
```

```
Partial Correlation Coefficients
                    Displacement    Horsepower     Weight
                    ------------    ----------    --------
    MPG             -0.053684       -0.15199      -0.48563
```

```
    Acceleration      -0.39941        -0.40075        0.49123
```

Test Partial Correlations While Controlling for Additional Variables

Test for partial correlation between pairs of variables in the `x` and `y` input matrices, while controlling for the effects of the remaining variables in `x` plus additional variables in matrix `z`.

Load the sample data.

```
load carsmall;
```

The data contains measurements from cars manufactured in 1970, 1976, and 1982. It includes `MPG` and `Acceleration` as performance measures, and `Displacement`, `Horsepower`, and `Weight` as design variables. `Acceleration` is the time required to accelerate from 0 to 60 miles per hour, so a high value for `Acceleration` corresponds to a vehicle with low acceleration.

Create a new variable `Headwind`, and randomly generate data to represent the notion of an average headwind along the performance measurement route.

```
rng('default');  % For reproducibility
Headwind = (10:-0.2:-9.8)' + 5*randn(100,1);
```

Since headwind can affect the performance measures, control for its effects when testing for partial correlation between the remaining variables.

Define the input matrices. The `y` matrix includes the performance measures, and the `x` matrix includes the design variables. The `z` matrix contains additional variables to control for when computing the partial correlations, such as headwind.

```
y = [MPG,Acceleration];
x = [Displacement,Horsepower,Weight];
z = Headwind;
```

Compute the partial correlation coefficients. Include only rows with no missing values in the computation.

```
[rho,pval] = partialcorri(y,x,z,'Rows','complete')
```

```
rho =

    0.0572   -0.1055   -0.5736
   -0.3845   -0.3966    0.4674
```

```
pval =

    0.5923    0.3221    0.0000
    0.0002    0.0001    0.0000
```

The small returned p-value of 0.001 in `pval` indicates, for example, a significant negative correlation between horsepower and acceleration, after controlling for displacement, weight, and headwind.

For a clearer display, create tables with appropriate variable and row labels.

```
rho = array2table(rho, ...
   'VariableNames',{'Displacement','Horsepower','Weight'}, ...
   'RowNames',{'MPG','Acceleration'});

pval = array2table(pval, ...
   'VariableNames',{'Displacement','Horsepower','Weight'}, ...
   'RowNames',{'MPG','Acceleration'});

disp('Partial Correlation Coefficients, Accounting for Headwind')
disp(rho)
disp('p-values, Accounting for Headwind')
disp(pval)
```

```
Partial Correlation Coefficients, Accounting for Headwind
                   Displacement    Horsepower     Weight
                   ------------    ----------    --------
    MPG            0.057197        -0.10555      -0.57358
    Acceleration   -0.38452        -0.39658        0.4674

P-values, Accounting for Headwind
                   Displacement    Horsepower      Weight
                   ------------    ----------    ----------
    MPG               0.59233         0.32212    3.4401e-09
    Acceleration   0.00018272      0.00010902    3.4091e-06
```

Input Arguments

x — Data matrix

matrix

Data matrix, specified as an n-by-p_x matrix. The rows of `x` correspond to observations, and the columns correspond to variables.

Data Types: `single` | `double`

y — Data matrix

matrix

Data matrix, specified as an n-by-p_y matrix. The rows of `y` correspond to observations, and the columns correspond to variables.

Data Types: `single` | `double`

z — Data matrix

matrix

Data matrix, specified as an n-by-p_z matrix. The rows of `z` correspond to observations, and the columns correspond to variables.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'Type','Spearman','Rows','complete'` computes Spearman partial correlations using only the data in rows that contain no missing values.

'Type' — Type of partial correlations

`'Pearson'` (default) | `'Spearman'`

Type of partial correlations to compute, specified as the comma-separated pair consisting of `'Type'` and either `'Pearson'` or `'Spearman'`. `Pearson` computes the Pearson (linear) partial correlations. `Spearman` computes the Spearman (rank) partial correlations.

Example: `'Type','Spearman'`

'Rows' — Rows to use in computation

`'all'` (default) | `'complete'` | `'pairwise'`

Rows to use in computation, specified as the comma-separated pair consisting of `'Rows'` and one of the following.

`'all'`	Use all rows regardless of missing (`NaN`) values.
`'complete'`	Use only rows with no missing values.
`'pairwise'`	Use all available values in each column of y when computing the partial correlation coefficients and *p*-values corresponding to that column. For each column of y, rows will be dropped corresponding to missing values in x (and/or z, if supplied). However, remaining rows with valid values in that column of y are used, even if there are missing values in other columns of y.

Example: `'Rows','complete'`

`'Tail'` — Alternative hypothesis

`'both'` (default) | `'right'` | `'left'`

Alternative hypothesis to test against, specified as the comma-separated pair consisting of `'Tail'` and one of the following.

`'both'`	Test the alternative hypothesis that the correlation is not zero.
`'right'`	Test the alternative hypothesis that the correlation is greater than 0.
`'left'`	Test the alternative hypothesis that the correlation is less than 0.

Example: `'Tail','right'`

Output Arguments

`rho` — Sample linear partial correlation coefficients

matrix

Sample linear partial correlation coefficients, returned as a p_y-by-p_x matrix.

- If you input x and y matrices, the (i,j)th entry is the sample linear partial correlation between the ith column in y and the jth column in x, controlled for all the columns of x except column j.

- If you input x, y, and z matrices, the (*i*,*j*)th entry is the sample linear partial correlation between the *i*th column in y and the *j*th column in x, adjusted for all the columns of x except column *j*, after first controlling both x and y for the variables in z.

`pval` — *p*-values

matrix

p-values, returned as a matrix. Each element of `pval` is the *p*-value for the corresponding element of rho. If `pval(i,j)` is small, then the corresponding partial correlation `rho(i,j)` is statistically significantly different from zero.

`partialcorri` computes *p*-values for linear and rank partial correlations using a Student's *t* distribution for a transformation of the correlation. This is exact for linear partial correlation when x and z are normal, but is a large-sample approximation otherwise.

See Also

`corr` | `partialcorr`

pca

Principal component analysis of raw data

Syntax

```
coeff = pca(X)
coeff = pca(X,Name,Value)
[coeff,score,latent] = pca(___)
[coeff,score,latent,tsquared] = pca(___)
[coeff,score,latent,tsquared,explained,mu] = pca(___)
```

Description

`coeff = pca(X)` returns the principal component coefficients, also known as loadings, for the *n*-by-*p* data matrix `X`. Rows of `X` correspond to observations and columns correspond to variables. The coefficient matrix is *p*-by-*p*. Each column of `coeff` contains coefficients for one principal component, and the columns are in descending order of component variance. By default, `pca` centers the data and uses the singular value decomposition (SVD) algorithm.

`coeff = pca(X,Name,Value)` returns any of the output arguments in the previous syntaxes using additional options for computation and handling of special data types, specified by one or more `Name,Value` pair arguments.

For example, you can specify the number of principal components `pca` returns or an algorithm other than SVD to use.

`[coeff,score,latent] = pca(___)` also returns the principal component scores in `score` and the principal component variances in `latent`. You can use any of the input arguments in the previous syntaxes.

Principal component scores are the representations of `X` in the principal component space. Rows of `score` correspond to observations, and columns correspond to components.

The principal component variances are the eigenvalues of the covariance matrix of `X`.

`[coeff,score,latent,tsquared] = pca( ___ )` also returns the Hotelling's T-squared statistic for each observation in `X`.

`[coeff,score,latent,tsquared,explained,mu] = pca( ___ )` also returns `explained`, the percentage of the total variance explained by each principal component and `mu`, the estimated mean of each variable in `X`.

Examples

Principal Components of a Data Set

Load the sample data set.

```
load hald
```

The ingredients data has 13 observations for 4 variables.

Find the principal components for the ingredients data.

```
coeff = pca(ingredients)
```

```
coeff =

   -0.0678   -0.6460    0.5673    0.5062
   -0.6785   -0.0200   -0.5440    0.4933
    0.0290    0.7553    0.4036    0.5156
    0.7309   -0.1085   -0.4684    0.4844
```

The rows of `coeff` contain the coefficients for the four ingredient variables, and its columns correspond to four principal components.

PCA in the Presence of Missing Data

Find the principal component coefficients when there are missing values in a data set.

Load the sample data set.

```
load imports-85
```

Data matrix `X` has 13 continuous variables in columns 3 to 15: wheel-base, length, width, height, curb-weight, engine-size, bore, stroke, compression-ratio, horsepower, peak-rpm, city-mpg, and highway-mpg. The variables bore and stroke are missing four values in

rows 56 to 59, and the variables horsepower and peak-rpm are missing two values in rows 131 and 132.

Perform principal component analysis.

```
coeff = pca(X(:,3:15));
```

By default, `pca` performs the action specified by the `'Rows','complete'` name-value pair argument. This option removes the observations with `NaN` values before calculation. Rows of `NaN`s are reinserted into `score` and `tsquared` at the corresponding locations, namely rows 56 to 59, 131, and 132.

Use `'pairwise'` to perform the principal component analysis.

```
coeff = pca(X(:,3:15),'Rows','pairwise');
```

In this case, `pca` computes the (i,j) element of the covariance matrix using the rows with no `NaN` values in the columns i or j of `X`. Note that the resulting covariance matrix might not be positive definite. This option applies when the algorithm `pca` uses is eigenvalue decomposition. When you don't specify the algorithm, as in this example, `pca` sets it to `'eig'`. If you require `'svd'` as the algorithm, with the `'pairwise'` option, then `pca` returns a warning message, sets the algorithm to `'eig'` and continues.

If you use the `'Rows','all'` name-value pair argument, `pca` terminates because this option assumes there are no missing values in the data set.

```
coeff = pca(X(:,3:15),'Rows','all');
```

```
Error using pca (line 180)
Raw data contains NaN missing value while 'Rows' option is set to 'all'. Consider using
```

Weighted PCA

Use the inverse variable variances as weights while performing the principal components analysis.

Load the sample data set.

```
load hald
```

Perform the principal component analysis using the inverse of variances of the ingredients as variable weights.

```
[wcoeff,~,latent,~,explained] = pca(ingredients,...
```

```
'VariableWeights','variance')

wcoeff =

   -2.7998    2.9940   -3.9736    1.4180
   -8.7743   -6.4411    4.8927    9.9863
    2.5240   -3.8749   -4.0845    1.7196
    9.1714    7.5529    3.2710   11.3273

latent =

    2.2357
    1.5761
    0.1866
    0.0016

explained =

   55.8926
   39.4017
    4.6652
    0.0406
```

Note that the coefficient matrix, `wcoeff`, is not orthonormal.

Calculate the orthonormal coefficient matrix.

```
coefforth = inv(diag(std(ingredients)))* wcoeff

coefforth =

   -0.4760    0.5090   -0.6755    0.2411
   -0.5639   -0.4139    0.3144    0.6418
    0.3941   -0.6050   -0.6377    0.2685
    0.5479    0.4512    0.1954    0.6767
```

Check orthonormality of the new coefficient matrix, `coefforth`.

```
 coefforth*coefforth'

ans =

    1.0000    0.0000   -0.0000   -0.0000
    0.0000    1.0000   -0.0000   -0.0000
   -0.0000   -0.0000    1.0000         0
```

```
   -0.0000   -0.0000         0    1.0000
```

PCA Using ALS for Missing Data

Find the principal components using the alternating least squares (ALS) algorithm when there are missing values in the data.

Load the sample data.

```
load hald
```

The ingredients data has 13 observations for 4 variables.

Perform principal component analysis using the ALS algorithm and display the component coefficients.

```
[coeff,score,latent,tsquared,explained] = pca(ingredients);
coeff
```

```
coeff =

   -0.0678   -0.6460    0.5673    0.5062
   -0.6785   -0.0200   -0.5440    0.4933
    0.0290    0.7553    0.4036    0.5156
    0.7309   -0.1085   -0.4684    0.4844
```

Introduce missing values randomly.

```
y = ingredients;
rng('default'); % for reproducibility
ix = random('unif',0,1,size(y))<0.30;
y(ix) = NaN
```

```
y =

     7    26     6   NaN
     1    29    15    52
   NaN   NaN     8    20
    11    31   NaN    47
     7    52     6    33
   NaN    55   NaN   NaN
   NaN    71   NaN     6
     1    31   NaN    44
     2   NaN   NaN    22
    21    47     4    26
```

```
   NaN    40    23    34
    11    66     9   NaN
    10    68     8    12
```

Approximately 30% of the data has missing values now, indicated by `NaN`.

Perform principal component analysis using the ALS algorithm and display the component coefficients.

```
[coeff1,score1,latent,tsquared,explained,mu1] = pca(y,...
'algorithm','als');
coeff1
```

```
coeff1 =

   -0.0362    0.8215   -0.5252    0.2190
   -0.6831   -0.0998    0.1828    0.6999
    0.0169    0.5575    0.8215   -0.1185
    0.7292   -0.0657    0.1261    0.6694
```

Display the estimated mean.

```
mu1
```

```
mu1 =

    8.9956   47.9088    9.0451   28.5515
```

Reconstruct the observed data.

```
t = score1*coeff1' + repmat(mu1,13,1)
```

```
t =

 7.0000   26.0000    6.0000   51.5250
 1.0000   29.0000   15.0000   52.0000
10.7819   53.0230    8.0000   20.0000
11.0000   31.0000   13.5500   47.0000
 7.0000   52.0000    6.0000   33.0000
10.4818   55.0000    7.8328   17.9362
 3.0982   71.0000   11.9491    6.0000
 1.0000   31.0000   -0.5161   44.0000
 2.0000   53.7914    5.7710   22.0000
21.0000   47.0000    4.0000   26.0000
21.5809   40.0000   23.0000   34.0000
11.0000   66.0000    9.0000    5.7078
```

```
10.0000   68.0000    8.0000   12.0000
```

The ALS algorithm estimates the missing values in the data.

Another way to compare the results is to find the angle between the two spaces spanned by the coefficient vectors. Find the angle between the coefficients found for complete data and data with missing values using ALS.

```
subspace(coeff,coeff1)
```

```
ans =

   2.2925e-16
```

This is a small value. It indicates that the results if you use `pca` with `'Rows','complete'` name-value pair argument when there is no missing data and if you use `pca` with `'algorithm','als'` name-value pair argument when there is missing data are close to each other.

Perform the principal component analysis using `'Rows','complete'` name-value pair argument and display the component coefficients.

```
[coeff2,score2,latent,tsquared,explained,mu2] = pca(y,...
'Rows','complete');
coeff2
```

```
coeff2 =

   -0.2054    0.8587    0.0492
   -0.6694   -0.3720    0.5510
    0.1474   -0.3513   -0.5187
    0.6986   -0.0298    0.6518
```

In this case, `pca` removes the rows with missing values, and `y` has only four rows with no missing values. `pca` returns only three principal components. You cannot use the `'Rows','pairwise'` option because the covariance matrix is not positive semidefinite and `pca` returns an error message.

Find the angle between the coefficients found for complete data and data with missing values using listwise deletion (when `'Rows','complete'`).

```
subspace(coeff(:,1:3),coeff2)
```

```
ans =
```

```
    0.3576
```

The angle between the two spaces is substantially larger. This indicates that these two results are different.

Display the estimated mean.

```
mu2
```

```
mu2 =

     7.8889   46.9091    9.8750   29.6000
```

In this case, the mean is just the sample mean of `y`.

Reconstruct the observed data.

```
score2*coeff2'
```

```
ans =

       NaN       NaN       NaN       NaN
   -7.5162  -18.3545    4.0968   22.0056
       NaN       NaN       NaN       NaN
       NaN       NaN       NaN       NaN
   -0.5644    5.3213   -3.3432    3.6040
       NaN       NaN       NaN       NaN
       NaN       NaN       NaN       NaN
       NaN       NaN       NaN       NaN
       NaN       NaN       NaN       NaN
   12.8315   -0.1076   -6.3333   -3.7758
       NaN       NaN       NaN       NaN
       NaN       NaN       NaN       NaN
    1.4680   20.6342   -2.9292  -18.0043
```

This shows that deleting rows containing `NaN` values does not work as well as the ALS algorithm. Using ALS is better when the data has too many missing values.

Principal Component Coefficients, Scores, and Variances

Find the coefficients, scores, and variances of the principal components.

Load the sample data set.

```
load hald
```

The ingredients data has 13 observations for 4 variables.

Find the principal component coefficients, scores, and variances of the components for the ingredients data.

```
[coeff,score,latent] = pca(ingredients)
```

```
coeff =

   -0.0678   -0.6460    0.5673    0.5062
   -0.6785   -0.0200   -0.5440    0.4933
    0.0290    0.7553    0.4036    0.5156
    0.7309   -0.1085   -0.4684    0.4844

score =

   36.8218   -6.8709   -4.5909    0.3967
   29.6073    4.6109   -2.2476   -0.3958
  -12.9818   -4.2049    0.9022   -1.1261
   23.7147   -6.6341    1.8547   -0.3786
   -0.5532   -4.4617   -6.0874    0.1424
  -10.8125   -3.6466    0.9130   -0.1350
  -32.5882    8.9798   -1.6063    0.0818
   22.6064   10.7259    3.2365    0.3243
   -9.2626    8.9854   -0.0169   -0.5437
   -3.2840  -14.1573    7.0465    0.3405
    9.2200   12.3861    3.4283    0.4352
  -25.5849   -2.7817   -0.3867    0.4468
  -26.9032   -2.9310   -2.4455    0.4116

latent =

  517.7969
   67.4964
   12.4054
    0.2372
```

Each column of `score` corresponds to one principal component. The vector, `latent`, stores the variances of the four principal components.

Reconstruct the centered ingredients data.

```
Xcentered = score*coeff'

Xcentered =

   -0.4615  -22.1538   -5.7692   30.0000
   -6.4615  -19.1538    3.2308   22.0000
    3.5385    7.8462   -3.7692  -10.0000
    3.5385  -17.1538   -3.7692   17.0000
   -0.4615    3.8462   -5.7692    3.0000
    3.5385    6.8462   -2.7692   -8.0000
   -4.4615   22.8462    5.2308  -24.0000
   -6.4615  -17.1538   10.2308   14.0000
   -5.4615    5.8462    6.2308   -8.0000
   13.5385   -1.1538   -7.7692   -4.0000
   -6.4615   -8.1538   11.2308    4.0000
    3.5385   17.8462   -2.7692  -18.0000
    2.5385   19.8462   -3.7692  -18.0000
```

The new data in `Xcentered` is the original ingredients data centered by subtracting the column means from corresponding columns.

T-Squared Statistic

Find the Hotelling's T-squared statistic values.

Load the sample data set.

```
load hald
```

The ingredients data has 13 observations for 4 variables.

Perform the principal component analysis and request the T-squared values.

```
[coeff,score,latent,tsquared] = pca(ingredients);
tsquared

tsquared =

    5.6803
    3.0758
    6.0002
    2.6198
    3.3681
    0.5668
    3.4818
```

```
    3.9794
    2.6086
    7.4818
    4.1830
    2.2327
    2.7216
```

Request only the first two principal components and compute the T-squared values in the reduced space of requested principal components.

```
[coeff,score,latent,tsquared] = pca(ingredients,'NumComponents',2);
tsquared
```

```
tsquared =

    5.6803
    3.0758
    6.0002
    2.6198
    3.3681
    0.5668
    3.4818
    3.9794
    2.6086
    7.4818
    4.1830
    2.2327
    2.7216
```

Note that even when you specify a reduced component space, `pca` computes the T-squared values in the full space, using all four components.

The T-squared value in the reduced space corresponds to the Mahalanobis distance in the reduced space.

```
tsqreduced = mahal(score,score)
```

```
tsqreduced =

    3.3179
    2.0079
    0.5874
    1.7382
    0.2955
    0.4228
```

```
    3.2457
    2.6914
    1.3619
    2.9903
    2.4371
    1.3788
    1.5251
```

Calculate the T-squared values in the discarded space by taking the difference of the T-squared values in the full space and Mahalanobis distance in the reduced space.

```
tsqdiscarded = tsquared - tsqreduced
```

```
tsqdiscarded =

    2.3624
    1.0679
    5.4128

    1.7459
    0.8539
    1.1965
```

Percent Variability Explained by Principal Components

Find the percent variability explained by the principal components.

Load the sample data set.

```
load imports-85
```

Data matrix `X` has 13 continuous variables in columns 3 to 15: wheel-base, length, width, height, curb-weight, engine-size, bore, stroke, compression-ratio, horsepower, peak-rpm, city-mpg, and highway-mpg.

Find the percent variability explained by principal components of these variables.

```
[coeff,score,latent,tsquared,explained] = pca(X(:,3:15));
```

```
explained
```

```
explained =

   64.3429
   35.4484
    0.1550
    0.0379
    0.0078
    0.0048
    0.0013
    0.0011
    0.0005
    0.0002
    0.0002
    0.0000
    0.0000
```

The first two components explain 99.79% of all variability.

To skip any of the outputs, you can use ~ instead in the corresponding element. For example, if you don't want to get the T-squared values, specify

```
[coeff,score,latent,~,explained] = pca(X(:,3:15));
```

- "Quality of Life in U.S. Cities" on page 13-76

Input Arguments

X — Input data

matrix

Input data for which to compute the principal components, specified as an n-by-p matrix. Rows of `X` correspond to observations and columns to variables.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single

quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'Algorithm','eig','Centered',false,'Rows','all','NumComponents',3` specifies that `pca` uses eigenvalue decomposition algorithm, not center the data, use all of the observations, and return only the first three principal components.

`'Algorithm'` — Principal component algorithm

`'svd'` (default) | `'eig'` | `'als'`

Principal component algorithm that `pca` uses to perform the principal component analysis, specified as the comma-separated pair consisting of `'Algorithm'` and one of the following.

`'svd'`	Default. Singular value decomposition (SVD) of `X`.
`'eig'`	Eigenvalue decomposition (EIG) of the covariance matrix. The EIG algorithm is faster than SVD when the number of observations, *n*, exceeds the number of variables, *p*, but is less accurate because the condition number of the covariance is the square of the condition number of `X`.
`'als'`	Alternating least squares (ALS) algorithm. This algorithm finds the best rank-*k* approximation by factoring `X` into a *n*-by-*k* left factor matrix, L, and a *p*-by-*k* right factor matrix, R, where *k* is the number of principal components. The factorization uses an iterative method starting with random initial values. ALS is designed to better handle missing values. It is preferable to pairwise deletion (`'Rows','pairwise'`) and deals with missing values without listwise deletion (`'Rows','complete'`). It can work well for data sets with a small percentage of missing data at random, but might not perform well on sparse data sets.

Example: `'Algorithm','eig'`

Data Types: `char`

`'Centered'` — Indicator for centering columns

`true` (default) | `false`

Indicator for centering the columns, specified as the comma-separated pair consisting of `'Centered'` and one of these logical expressions.

`true`	Default. `pca` centers `X` by subtracting column means before computing singular value decomposition or eigenvalue decomposition. If `X` contains `NaN` missing values, `nanmean` is used to find the mean with any available data. You can reconstruct the centered data using `score*coeff'`.
`false`	In this case `pca` does not center the data. You can reconstruct the original data using `score*coeff'`.

Example: `'Centered',false`

Data Types: `logical`

`'Economy'` — Indicator for economy size output

`true` (default) | `false`

Indicator for the economy size output when the degrees of freedom, d, is smaller than the number of variables, p, specified as the comma-separated pair consisting of `'Economy'` and one of these logical expressions.

`true`	Default. `pca` returns only the first d elements of `latent` and the corresponding columns of `coeff` and `score`. This option can be significantly faster when the number of variables p is much larger than d.
`false`	`pca` returns all elements of `latent`. The columns of `coeff` and `score` corresponding to zero elements in `latent` are zeros.

Note that when $d < p$, `score(:,d+1:p)` and `latent(d+1:p)` are necessarily zero, and the columns of `coeff(:,d+1:p)` define directions that are orthogonal to `X`.

Example: `'Economy',false`

Data Types: `logical`

`'NumComponents'` — Number of components requested

number of variables (default) | scalar integer

Number of components requested, specified as the comma-separated pair consisting of `'NumComponents'` and a scalar integer k satisfying $0 < k \leq p$, where p is the number of original variables in `X`. When specified, `pca` returns the first k columns of `coeff` and `score`.

Example: `'NumComponents',3`

Data Types: `single` | `double`

`'Rows'` — Action to take for `NaN` values

`'complete'` (default) | `'pairwise'` | `'all'`

Action to take for `NaN` values in the data matrix `X`, specified as the comma-separated pair consisting of `'Rows'` and one of the following.

`'complete'`	Default. Observations with `NaN` values are removed before calculation. Rows of `NaN`s are reinserted into `score` and `tsquared` at the corresponding locations.
`'pairwise'`	This option only applies when the algorithm is `'eig'`. If you don't specify the algorithm along with `'pairwise'`, then `pca` sets it to `'eig'`. If you specify `'svd'` as the algorithm, along with the option `'Rows','pairwise'`, then `pca` returns a warning message, sets the algorithm to `'eig'` and continues. When you specify the `'Rows','pairwise'` option, `pca` computes the (i,j) element of the covariance matrix using the rows with no `NaN` values in the columns i or j of `X`. Note that the resulting covariance matrix might not be positive definite. In that case, `pca` terminates with an error message.
`'all'`	`X` is expected to have no missing values. `pca` uses all of the data and terminates if any `NaN` value is found.

Example: `'Rows','pairwise'`

Data Types: `char`

`'Weights'` — Observation weights

ones (default) | row vector

Observation weights, specified as the comma-separated pair consisting of `'Weights'` and a vector of length n containing all positive elements.

Data Types: `single` | `double`

`'VariableWeights'` — Variable weights

row vector | `'variance'`

Variable weights, specified as the comma-separated pair consisting of `'VariableWeights'` and one of the following.

Vector of length p containing all positive elements.
The string `'variance'`. The variable weights are the inverse of sample variance. If you also assign weights to observations using `'Weights'`, then the variable weights become the inverse of weighted sample variance. If `'Centered'` is set to `true` at the same time, the data matrix `X` is centered and standardized. In this case, `pca` returns the principal components based on the correlation matrix.

Example: `'VariableWeights','variance'`

Data Types: `single` | `double` | `char`

`'Coeff0'` — Initial value for coefficients

matrix of random values (default) | p-by-k matrix

Initial value for the coefficient matrix coeff, specified as the comma-separated pair consisting of `'Coeff0'` and a p-by-k matrix, where p is the number of variables, and k is the number of principal components requested.

Note: You can use this name-value pair only when `'algorithm'` is `'als'`.

Data Types: `single` | `double`

`'Score0'` — Initial value for scores

matrix of random values (default) | k-by-m matrix

Initial value for scores matrix score, specified as a comma-separated pair consisting of `'Score0'` and an n-by-k matrix, where n is the number of observations and k is the number of principal components requested.

Note: You can use this name-value pair only when `'algorithm'` is `'als'`.

Data Types: `single` | `double`

'Options' — Options for iterations

structure

Options for the iterations, specified as a comma-separated pair consisting of 'Options' and a structure created by the statset function. pca uses the following fields in the options structure.

'Display'	Level of display output. Choices are 'off', 'final', and 'iter'.
'MaxIter'	Maximum number steps allowed. The default is 1000. Unlike in optimization settings, reaching the MaxIter value is regarded as convergence.
'TolFun'	Positive number giving the termination tolerance for the cost function. The default is 1e-6.
'TolX'	Positive number giving the convergence threshold for the relative change in the elements of the left and right factor matrices, L and R, in the ALS algorithm. The default is 1e-6.

Note: You can use this name-value pair only when 'algorithm' is 'als'.

You can change the values of these fields and specify the new structure in pca using the 'Options' name-value pair argument.

Example: `opt = statset('pca'); opt.MaxIter = 2000; coeff = pca(X,'Options',opt);`

Data Types: struct

Output Arguments

coeff — Principal component coefficients

matrix

Principal component coefficients, returned as a p-by-p matrix. Each column of coeff contains coefficients for one principal component. The columns are in the order of descending component variance, latent.

`score` — Principal component scores

matrix

Principal component scores, returned as a matrix. Rows of `score` correspond to observations, and columns to components.

`latent` — Principal component variances

column vector

Principal component variances, that is the eigenvalues of the covariance matrix of X, returned as a column vector.

`tsquared` — Hotelling's T-squared statistic

column vector

"Hotelling's T-Squared Statistic" on page 22-3406, which is the sum of squares of the standardized scores for each observation, returned as a column vector.

`explained` — Percentage of total variance explained

column vector

Percentage of the total variance explained by each principal component, returned as a column vector.

`mu` — Estimated means

row vector

Estimated means of the variables in X, returned as a row vector. When `'algorithm'` is `'als'`, this is estimated by ALS algorithm. When `'algorithm'` is not `'als'`, `mu` is equal to the sample mean of `X`.

More About

Hotelling's T-Squared Statistic

Hotelling's T-squared statistic is a statistical measure of the multivariate distance of each observation from the center of the data set.

Even when you request fewer components than the number of variables, `pca` uses all principal components to compute the T-squared statistic (computes it in the full space). If you want the T-squared statistic in the reduced or the discarded space, do one of the following:

- For the T-squared statistic in the reduced space, use `mahal(score,score)`.
- For the T-squared statistic in the discarded space, first compute the T-squared statistic using `[coeff,score,latent,tsquared] = pca(X,'NumComponents',k,...)`, compute the T-squared statistic in the reduced space using `tsqreduced = mahal(score,score)`, and then take the difference: `tsquared - tsqreduced`.

Degrees of Freedom

The degrees of freedom, d, is equal to $n - 1$, if data is centered and n otherwise, where:

- n is the number of rows without any `NaN`s if you use `'Rows','complete'`.
- n is the number of rows without any `NaN`s in the column pair that has the maximum number of rows without `NaN`s if you use `'Rows','pairwise'`.

Variable Weights

Note that when variable weights are used, the coefficient matrix is not orthonormal. Suppose the variable weights vector you used is called `varwei`, and the principal component coefficients vector `pca` returned is `wcoeff`. You can then calculate the orthonormal coefficients using the transformation `diag(sqrt(varwei))*wcoeff`.

pcacov

Principal component analysis on covariance matrix

Syntax

```
COEFF = pcacov(V)
[COEFF,latent] = pcacov(V)
[COEFF,latent,explained] = pcacov(V)
```

Description

`COEFF = pcacov(V)` performs principal components analysis on the p-by-p covariance matrix `V` and returns the principal component coefficients, also known as loadings. `COEFF` is a p-by-p matrix, with each column containing coefficients for one principal component. The columns are in order of decreasing component variance.

`pcacov` does not standardize `V` to have unit variances. To perform principal components analysis on standardized variables, use the correlation matrix `R = V./(SD*SD')`, where `SD = sqrt(diag(V))`, in place of `V`. To perform principal components analysis directly on the data matrix, use `pca`.

`[COEFF,latent] = pcacov(V)` returns `latent`, a vector containing the principal component variances, that is, the eigenvalues of `V`.

`[COEFF,latent,explained] = pcacov(V)` returns `explained`, a vector containing the percentage of the total variance explained by each principal component.

Examples

```
load hald
covx = cov(ingredients);
[COEFF,latent,explained] = pcacov(covx)
COEFF =
  0.0678 -0.6460  0.5673 -0.5062
  0.6785 -0.0200 -0.5440 -0.4933
 -0.0290  0.7553  0.4036 -0.5156
```

```
 -0.7309 -0.1085 -0.4684 -0.4844

latent =
  517.7969
  67.4964
  12.4054
  0.2372

explained =
  86.5974
  11.2882
  2.0747
  0.0397
```

pcares

Residuals from principal component analysis

Syntax

```
residuals = pcares(X,ndim)
[residuals,reconstructed] = pcares(X,ndim)
```

Description

`residuals = pcares(X,ndim)` returns the `residuals` obtained by retaining `ndim` principal components of the n-by-p matrix `X`. Rows of `X` correspond to observations, columns to variables. `ndim` is a scalar and must be less than or equal to p. `residuals` is a matrix of the same size as `X`. Use the data matrix, *not* the covariance matrix, with this function.

`pcares` does not normalize the columns of X. To perform the principal components analysis based on standardized variables, that is, based on correlations, use `pcares(zscore(X), ndim)`. You can perform principal components analysis directly on a covariance or correlation matrix, but without constructing residuals, by using `pcacov`.

`[residuals,reconstructed] = pcares(X,ndim)` returns the reconstructed observations; that is, the approximation to `X` obtained by retaining its first `ndim` principal components.

Examples

This example shows the drop in the residuals from the first row of the Hald data as the number of component dimensions increases from one to three.

```
load hald
r1 = pcares(ingredients,1);
r2 = pcares(ingredients,2);
r3 = pcares(ingredients,3);
```

```
r11 = r1(1,:)
r11 =
  2.0350  2.8304  -6.8378  3.0879

r21 = r2(1,:)
r21 =
  -2.4037  2.6930  -1.6482  2.3425

r31 = r3(1,:)
r31 =
  0.2008  0.1957  0.2045  0.1921
```

ppca

Probabilistic principal component analysis

Syntax

```
[coeff,score,pcvar] = ppca(Y,K)
[coeff,score,pcvar] = ppca(Y,K,Name,Value)
[coeff,score,pcvar,mu] = ppca( ___ )
[coeff,score,pcvar,mu,v,S] = ppca( ___ )
```

Description

`[coeff,score,pcvar] = ppca(Y,K)` returns the principal component coefficients for the *n*-by-*p* data matrix `Y` based on a probabilistic principal component analysis (PPCA). It also returns the principal component scores, which are the representations of `Y` in the principal component space, and the principal component variances, which are the eigenvalues of the covariance matrix of `Y`, in `pcvar`.

Each column of `coeff` contains coefficients for one principal component, and the columns are in descending order of component variance. Rows of `score` correspond to observations, and columns correspond to components. Rows of `Y` correspond to observations and columns correspond to variables.

Probabilistic principal component analysis might be preferable to other algorithms that handle missing data, such as the alternating least squares algorithm when any data vector has one or more missing values. It assumes that the values are missing at random through the data set. An expectation-maximization algorithm is used for both complete and missing data.

`[coeff,score,pcvar] = ppca(Y,K,Name,Value)` returns the principal component coefficients, scores, and variances using additional options for computation and handling of special data types, specified by one or more `Name,Value` pair arguments.

For example, you can introduce initial values for the residual variance, `v`, or change the termination criteria.

`[coeff,score,pcvar,mu] = ppca( ___ )` also returns the estimated mean of each variable in `Y`. You can use any of the input arguments in the previous syntaxes.

`[coeff,score,pcvar,mu,v,S] = ppca( ___ )` also returns the isotropic residual variance in `v` and the final results at convergence in structure `S`.

Examples

Perform Probabilistic Principal Component Analysis

Load the sample data.

```
load fisheriris
```

The double matrix `meas` consists of four types of measurements on the flowers, which, respectively, are the length and width of sepals and petals.

Introduce missing values randomly.

```
y = meas;
rng('default'); % for reproducibility
ix = random('unif',0,1,size(y))<0.20;
y(ix) = NaN;
```

Now, approximately 20% of the data is missing, indicated by `NaN`.

Perform probabilistic principal component analysis and request the component coefficients and variances.

```
[coeff,score,pcvar,mu] = ppca(y,3);
coeff
```

```
coeff =

    0.3562    0.6709   -0.5518
   -0.0765    0.7121    0.6332
    0.8592   -0.1596    0.0596
    0.3592   -0.1318    0.5395
```

```
pcvar
```

```
pcvar =

   4.0912
   0.2126
   0.0617
```

Perform principal component analysis using the alternating least squares algorithm and request the component coefficients and variances.

```
[coeff2,score2,pcvar2,mu2] = pca(y,'algorithm','als',...
'NumComponents',3);
coeff2
```

```
coeff2 =

    0.3376    0.4955    0.7404
   -0.0731    0.8607   -0.4479
    0.8657   -0.1169   -0.1231
    0.3623   -0.0087   -0.4859
```

```
pcvar2
```

```
pcvar2 =

    4.0734
    0.2651
    0.1221
```

The coefficients and the variances of the first two principal components are similar.

Another way to compare the results is to find the angle between the two spaces spanned by the coefficient vectors.

```
subspace(coeff,coeff2)
```

```
ans =

     0.0881
```

The angle between the two spaces is pretty small. This indicates that these two results are close to each other.

Change the Termination Criteria for Probabilistic Principal Component Analysis

Load the sample data set.

```
load imports-85
```

Data matrix `X` has 13 continuous variables in columns 3 to 15: wheel-base, length, width, height, curb-weight, engine-size, bore, stroke, compression-ratio, horsepower, peak-rpm, city-mpg, and highway-mpg. The variables bore and stroke are missing four values in

rows 56 to 59, and the variables horsepower and peak-rpm are missing two values in rows 131 and 132.

Perform probabilistic principal component analysis and display the first three principal components.

```
[coeff,score,pcvar] = ppca(X(:,3:15),3);
```

```
Warning: Maximum number of iterations 1000 reached'.
> In ppca at 249
```

Change the termination tolerance for the cost function to 0.01.

```
opt = statset('ppca');
opt.TolFun = 0.01;
```

Perform probabilistic principal component analysis.

```
[coeff,score,pcvar] = ppca(X(:,3:15),3,'Options',opt);
```

`ppca` now terminates before the maximum number of iterations is reached because it meets the tolerance for the cost function.

Reconstruct Observations

Load the sample data.

```
load hald
y = ingredients;
```

The ingredients data has 13 observations for 4 variables.

Introduce missing values to the data.

```
y(2:16:end) = NaN;
```

Every 16th value is `NaN`. This corresponds to 7.69% of the data.

Find the first three principal components of data using PPCA and display the reconstructed observations.

```
[coeff,score,pcvar,mu,v,S] = ppca(y,3);
S.Recon
```

```
ans =
```

```
    6.8533   25.8675    5.8388   59.8755
    1.0431   28.9690   14.9652   51.9758
   11.5770   56.5080    8.6352   20.5062
   11.0833   31.0707    8.0920   47.0764
    7.0684   52.2539    6.0753   33.0597
   11.0486   55.0442    9.0534   22.0410
    2.8494   70.8719   16.8338    5.8624
    1.0331   31.0267   19.6906   44.0321
    2.0401   54.0364   18.0440   22.0337
   20.7823   46.8096    3.7603   25.8075
    0.9540   39.9590   22.9495   31.1540
   10.8251   65.8498    8.8072   11.8420
    9.9174   67.9309    7.9087   11.9230
```

You can also reconstruct the observations using the principal components and the estimated mean.

```
t = score*coeff' + repmat(mu,13,1);
```

Results at Convergence

Load the sample data.

```
load hald
```

Here, `ingredients` is a real-valued matrix of predictor variables.

Perform the probabilistic principal components analysis and display coefficients.

```
[coeff,score,pcvariance,mu,v,S] = ppca(ingredients,3);
coeff
```

```
coeff =

   -0.0693   -0.6459    0.5673
   -0.6786   -0.0184   -0.5440
    0.0308    0.7552    0.4036
    0.7306   -0.1102   -0.4684
```

Display the algorithm results at convergence of the PPCA.

```
S
```

```
S =

           W: [4x3 double]
```

```
        Xexp: [13x3 double]
       Recon: [13x4 double]
           v: 0.2372
     NumIter: 1000
    RMSResid: 0.2340
      nloglk: 149.3388
```

Display the matrix `W`.

```
S.W
```

```
ans =

    0.5624    2.0279    5.4075
    4.8320  -10.3894    5.9202
   -3.7521   -3.0555   -4.1552
   -1.5144   11.7122   -7.2564
```

Orthogonalizing `W` recovers the coefficients.

```
orth(S.W)
```

```
ans =

   -0.0693    0.6459    0.5673
   -0.6786    0.0184   -0.5440
    0.0308   -0.7552    0.4036
    0.7306    0.1102   -0.4684
```

Input Arguments

Y — Input data

n-by-*p* matrix

Input data for which to compute the principal components, specified as an *n*-by-*p* matrix. Rows of `Y` correspond to observations and columns correspond to variables.

Data Types: `single` | `double`

K — Number of principal components

positive integer value less than rank

Number of principal components to return, specified as an integer value less than the rank of data. The maximum possible rank is min(*n*,*p*), where *n* is the number of

observations and p is the number of variables. However, if the data is correlated, the rank might be smaller than min(n,p).

`ppca` orders the components based on their variance.

If `K` is min(n,p), `ppca` sets `K` equal to min(n,p) – 1, and `'W0'` is truncated to min(p,n) – 1 columns if you specify a p-by-p `W0` matrix.

For example, you can request only the first three components, based on the component variance as follows.

Example: `coeff = ppca(Y,3)`

Data Types: `single | double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'W0',init,'Options',opt` specifies that the initial values for `'W0'` are in matrix `init` and `ppca` uses the options defined by `opt`.

`'W0'` — Initial value of *W*

matrix of random values (default) | p-by-k matrix

Initial value of W in the probabilistic principal component analysis algorithm, specified as a comma-separated pair consisting of `'W0'` and a p-by-k matrix.

Data Types: `single | double`

`'v0'` — Initial value of residual variance

random number (default) | positive scalar value

Initial value of residual variance, specified as the comma-separated pair consisting of `'v0'` and a positive scalar value.

Data Types: `single | double`

`'Options'` — Options for iterations

structure

Options for the iterations, specified as a comma-separated pair `'Options'` and a structure created by the `statset` function. `ppca` uses the following fields in the options structure.

`'Display'`	Level of display output. Choices are `'off'`, `'final'`, and `'iter'`.
`'MaxIter'`	Maximum number of steps allowed. The default is 1000. Unlike in optimization settings, reaching the `MaxIter` value is regarded as convergence.
`'TolFun'`	Positive integer stating the termination tolerance for the cost function. The default is 1e-6.
`'TolX'`	Positive integer stating the convergence threshold for the relative change in the elements of *W*. The default is 1e-6.

You can change the values of these fields and specify the new structure in `ppca` using the `'Options'` name-value pair argument.

Example: `opt = statset('ppca'); opt.MaxIter = 2000; coeff = ppca(Y,3,'Options',opt);`

Data Types: `struct`

Output Arguments

`coeff` — Principal component coefficients

p-by-*k* matrix

Principal component coefficients, returned as a *p*-by-*k* matrix. Each column of `coeff` contains coefficients for one principal component. The columns are in the order of descending component variance, pcvar.

`score` — Principal component scores

n-by-*k* matrix

Principal component scores, returned as an *n*-by-*k* matrix. Rows of `score` correspond to observations, and columns correspond to components.

`pcvar` — Principal component variances

column vector

Principal component variances, which are the eigenvalues of the covariance matrix of Y, returned as a column vector.

`mu` — Estimated mean

row vector

Estimated mean of each variable in Y, returned as a row vector.

`v` — Isotropic residual variance

scalar value

Isotropic residual variance, returned as a scalar value.

`S` — Final results at convergence

structure

Final results at convergence, returned as a structure containing the following fields.

`W`	*W* at convergence.
`Xexp`	Conditional expectation of the estimated latent variable *x*.
`Recon`	Reconstructed observations using *k* principal components. This is a low dimension approximation of the input data `Y`, and is equal to `mu` + `score*coeff'`.
`v`	Residual variance.
`RMSResid`	Root mean square of residuals.
`NumIter`	Number of iteration counts.
`nloglk`	Negative loglikelihood function value.

More About

Probabilistic Principal Component Analysis

Probabilistic principal component analysis (PPCA) is a method to estimate the principal axes when any data vector has one or more missing values.

PPCA is based on an isotropic error model. It seeks to relate a *p*-dimensional observation vector *y* to a corresponding *k*-dimensional vector of latent (or unobserved) variable *x*, which is normal with mean zero and covariance I(*k*). The relationship is

$$y^T = W * x^T + \mu + \varepsilon,$$

where y is the row vector of observed variable, x is the row vector of latent variables, and ε is the isotropic error term. ε is Gaussian with mean zero and covariance of v*I(k), where v is the residual variance. Here, k needs to be smaller than the rank for the residual variance to be greater than 0 (v>0). Standard principal component analysis, where the residual variance is zero, is the limiting case of PPCA. The observed variables, y, are conditionally independent given the values of the latent variables, x. So, the latent variables explain the correlations between the observation variables and the error explains the variability unique to a particular y_i. The p-by-k matrix W relates the latent and observation variables, and the vector μ permits the model to have a nonzero mean. PPCA assumes that the values are missing at random through the data set. This means that whether a data value is missing or not does not depend on the latent variable given the observed data values.

Under this model,

$$y \sim N\left(\mu, W * W^T + v * I(k)\right).$$

There is no closed-form analytical solution for W and v, so their estimates are determined by iterative maximization of the corresponding loglikelihood using an expectation-maximization (EM) algorithm. This EM algorithm handles missing values by treating them as additional latent variables. At convergence, the columns of W spans the subspace, but they are not orthonormal. `ppca` obtains the orthonormal coefficients, `coeff`, for the components by orthogonalization of W.

ComponentProportion property

Class: gmdistribution

Input vector of mixing proportions

Description

Optional input vector of mixing proportions p, or its default value.

pdf

Probability density functions

Syntax

```
y = pdf('name',x,A)
y = pdf('name',x,A,B)
y = pdf('name',x,A,B,C)

y = pdf(pd,x)
```

Description

`y = pdf('name',x,A)` returns the probability density function (pdf) for the one-parameter distribution family specified by 'name', evaluated at the values in x. A contains the parameter value for the distribution.

`y = pdf('name',x,A,B)` returns the pdf for the two-parameter distribution family specified by 'name', evaluated at the values in x. A and B contain the parameter values for the distribution.

`y = pdf('name',x,A,B,C)` returns the pdf for the three-parameter distribution family specified by 'name', evaluated at the values in x. A, B, and C contain the parameter values for the distribution.

`y = pdf(pd,x)` returns the probability density function of the probability distribution object, pd, evaluated at the values in x.

Examples

Compute the Normal Distribution pdf

Create a standard normal distribution object with the mean μ equal to 0 and the standard deviation σ equal to 1.

```
mu = 0;
sigma = 1;
```

```
pd = makedist('Normal',mu,sigma);
```

Define the input vector x to contain the values at which to calculate the pdf.

```
x = [-2 -1 0 1 2];
```

Compute the pdf values for the standard normal distribution at the values in x.

```
y = pdf(pd,x)
```

```
y =

    0.0540    0.2420    0.3989    0.2420    0.0540
```

Each value in y corresponds to a value in the input vector x. For example, at the value x equal to 1, the corresponding pdf value y is equal to 0.2420.

Alternatively, you can compute the same pdf values without creating a probability distribution object. Use the `pdf` function, and specify a standard normal distribution using the same parameter values for μ and σ.

```
y2 = pdf('Normal',x,mu,sigma)
```

```
y2 =

    0.0540    0.2420    0.3989    0.2420    0.0540
```

The pdf values are the same as those computed using the probability distribution object.

Compute the Poisson Distribution pdf

Create a Poisson distribution object with the rate parameter, λ, equal to 2.

```
lambda = 2;
pd = makedist('Poisson',lambda);
```

Define the input vector x to contain the values at which to calculate the pdf.

```
x = [0 1 2 3 4];
```

Compute the pdf values for the Poisson distribution at the values in x.

```
y = pdf(pd,x)
```

```
y =

    0.1353    0.2707    0.2707    0.1804    0.0902
```

Each value in y corresponds to a value in the input vector x. For example, at the value x equal to 3, the corresponding pdf value in y is equal to 0.1804.

Alternatively, you can compute the same pdf values without creating a probability distribution object. Use the `pdf` function, and specify a Poisson distribution using the same value for the rate parameter, λ.

```
y2 = pdf('Poisson',x,lambda)
```

```
y2 =

    0.1353    0.2707    0.2707    0.1804    0.0902
```

The pdf values are the same as those computed using the probability distribution object.

Input Arguments

`'name'` — Probability distribution name

probability distribution name string

Probability distribution name, specified as one of the following probability distribution name strings.

name	Distribution	Input Parameter A	Input Parameter B	Input Parameter C
`'Beta'`	"Beta Distribution" on page B-4	a: first shape parameter	b: second shape parameter	—
`'Binomial'`	"Binomial Distribution" on page B-9	n: number of trials	p: probability of success for each trial	—
`'BirnbaumSaund`	"Birnbaum-Saunders Distribution" on page B-13	β: scale parameter	γ: shape parameter	—

x — Values at which to evaluate pdf

scalar value | array of scalar values

Values at which to evaluate the pdf, specified as a scalar value, or an array of scalar values.

- If x is a scalar value, and if you specify distribution parameters A, B, or C as arrays, then `cdf` expands x into a constant matrix the same size as `A` and `B`.
- If x is an array, and if you specify distribution parameters A, B, or C as arrays, then x, A, B, and C must all be the same size.

Example: `[0.1,0.25,0.5,0.75,0.9]`

Data Types: `single` | `double`

A — First probability distribution parameter

scalar value | array of scalar values

First probability distribution parameter, specified as a scalar value, or an array of scalar values.

If x and A are arrays, they must be the same size. If x is a scalar, then `cdf` expands it into a constant matrix the same size as A. If A is a scalar, then `cdf` expands it into a constant matrix the same size as x.

Data Types: `single` | `double`

`B` — Second probability distribution parameter

scalar value | array of scalar values

Second probability distribution parameter, specified as a scalar value, or an array of scalar values.

If x, A, and B are arrays, they must be the same size. If x is a scalar, then `cdf` expands it into a constant matrix the same size as A and B. If A or B are scalars, then `cdf` expands them into constant matrices the same size as x

Data Types: `single` | `double`

`C` — Third probability distribution parameter

scalar value | array of scalar values

Third probability distribution parameter, specified as a scalar value, or an array of scalar values.

If x, A, B, and C are arrays, they must be the same size. If x is a scalar, then `cdf` expands it into a constant matrix the same size as A, B, and C. If any of A, B or C are scalars, then `cdf` expands them into constant matrices the same size as x.

Data Types: `single` | `double`

`pd` — Probability distribution

probability distribution object

Probability distribution, specified as a probability distribution object created using one of the following.

`makedist`	Create a probability distribution object using specified parameter values.
`fitdist`	Fit a probability distribution object to sample data.
`dfittool`	Fit a probability distribution object to sample data using the interactive Distribution Fitting app.
`paretotails`	Create a Pareto tails object.

`gmdistribution`	Create a Gaussian mixture distribution object.

Output Arguments

y — Probability density function

array

Probability density function of the specified probability distribution, returned as an array.

- If you specify distribution parameters A, B, or C, then y is the common size of x, A, B, and C after any necessary scalar expansion.
- If you specify a probability distribution object, pd, then y has the same dimensions as x.

See Also

`cdf` | `icdf` | `mle` | `random`

pdf

Class: gmdistribution

Probability density function for Gaussian mixture distribution

Syntax

```
y = pdf(obj,X)
```

Description

`y = pdf(obj,X)` returns a vector `y` of length n containing the values of the probability density function (pdf) for the `gmdistribution` object `obj`, evaluated at the n-by-d data matrix `X`, where n is the number of observations and d is the dimension of the data. `obj` is an object created by `gmdistribution` or `fitgmdist`. `y(I)` is the pdf of observation `I`.

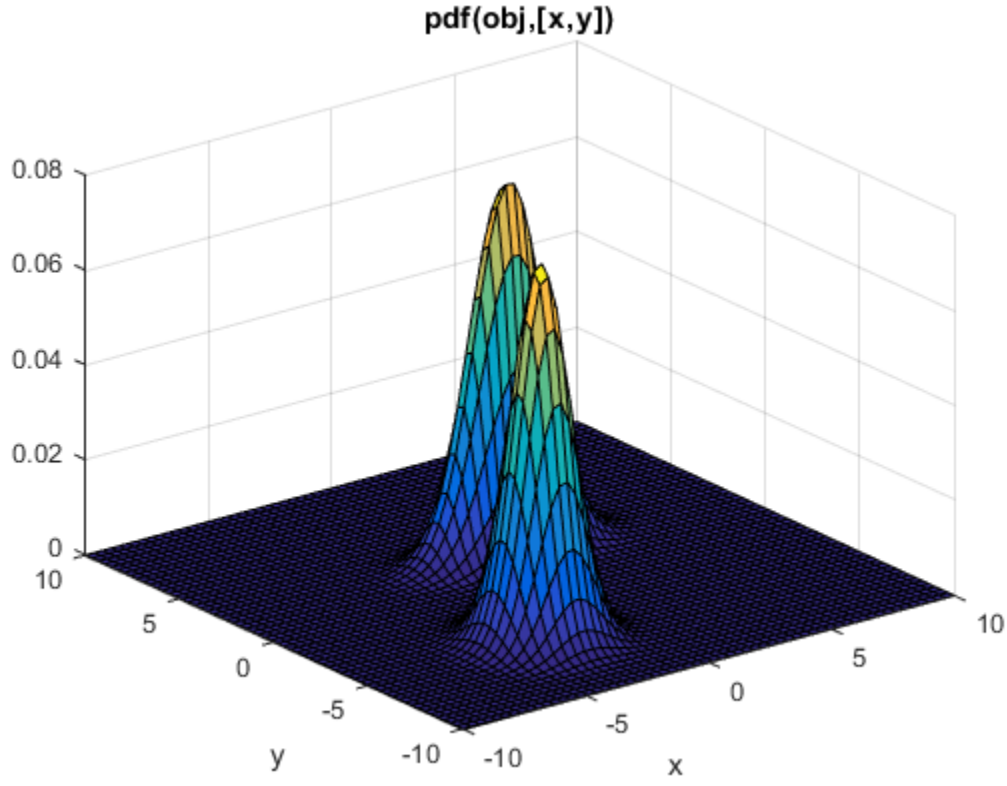
Examples

Construct a Gaussian Mixture Distribution

Create a `gmdistribution` distribution defining a two-component mixture of bivariate Gaussian distributions.

```
mu = [1 2;-3 -5];
sigma = cat(3,[2 0;0 .5],[1 0;0 1]);
p = ones(1,2)/2;
obj = gmdistribution(mu,sigma,p);

ezsurf(@(x,y)pdf(obj,[x y]),[-10 10],[-10 10])
```



See Also

`gmdistribution` | `fitgmdist` | `cdf` | `mvnpdf`

pdf

Class: piecewisedistribution

Probability density function for piecewise distribution

Syntax

```
P = pdf(obj,X)
```

Description

`P = pdf(obj,X)` returns an array `P` of values of the probability density function for the piecewise distribution object `obj`, evaluated at the values in the array `X`.

Note: For a Pareto tails object, the pdf is computed using the generalized Pareto distribution in the tails. In the center, the pdf is computed using the slopes of the cdf, which are interpolated between a set of discrete values. Therefore the pdf in the center is piecewise constant. It is noisy for a *`cdffun`* specified in `paretotails` via the `'ecdf'` option, and somewhat smoother for the `'kernel'` option, but generally not a good estimate of the underlying density of the original data.

Examples

Fit Pareto tails to a t distribution at cumulative probabilities 0.1 and 0.9:

```
t = trnd(3,100,1);
obj = paretotails(t,0.1,0.9);
[p,q] = boundary(obj)
p =
    0.1000
    0.9000
q =
   -1.7766
    1.8432
```

```
pdf(obj,q)
ans =
    0.2367
    0.1960
```

See Also

paretotails | cdf

pdf

Class: ProbDist

Return probability density function (PDF) for ProbDist object

Syntax

```
Y = pdf(PD, X)
```

Description

`Y = pdf(PD, X)` returns `Y`, an array containing the probability density function (PDF) for the ProbDist object `PD`, evaluated at values in `X`.

Input Arguments

`PD`	An object of the class `ProbDistUnivParam` or `ProbDistUnivKernel`.
`X`	A numeric array of values where you want to evaluate the PDF.

Output Arguments

`Y`	An array containing the probability density function (PDF) for the ProbDist object `PD`.

See Also

`pdf`

pdf

Class: prob.TruncatableDistribution
Package: prob

Probability density function of probability distribution object

Syntax

```
y = pdf(pd,x)
```

Description

`y = pdf(pd,x)` returns the probability density function (pdf) of the continuous probability distribution pd at the values in x. For discrete distributions, pdf returns the probability mass function.

Input Arguments

pd — Probability distribution

probability distribution object

Probability distribution, specified as a probability distribution object. Create a probability distribution object with specified parameter values using `makedist`. Alternatively, for fittable distributions, create a probability distribution object by fitting it to data using `fitdist` or the Distribution Fitting app.

x — Values at which to calculate pdf

array

Values at which to calculate pdf, specified as an array.

Data Types: `single` | `double`

Output Arguments

y — Probability density function

array

Probability density function of pd, evaluated at the values in data vector x, returned as a array. y has the same dimensions as input x.

Examples

Plot the pdf of a Standard Normal Distribution

Create a standard normal distribution object.

```
pd = makedist('Normal')
```

```
pd =

  NormalDistribution

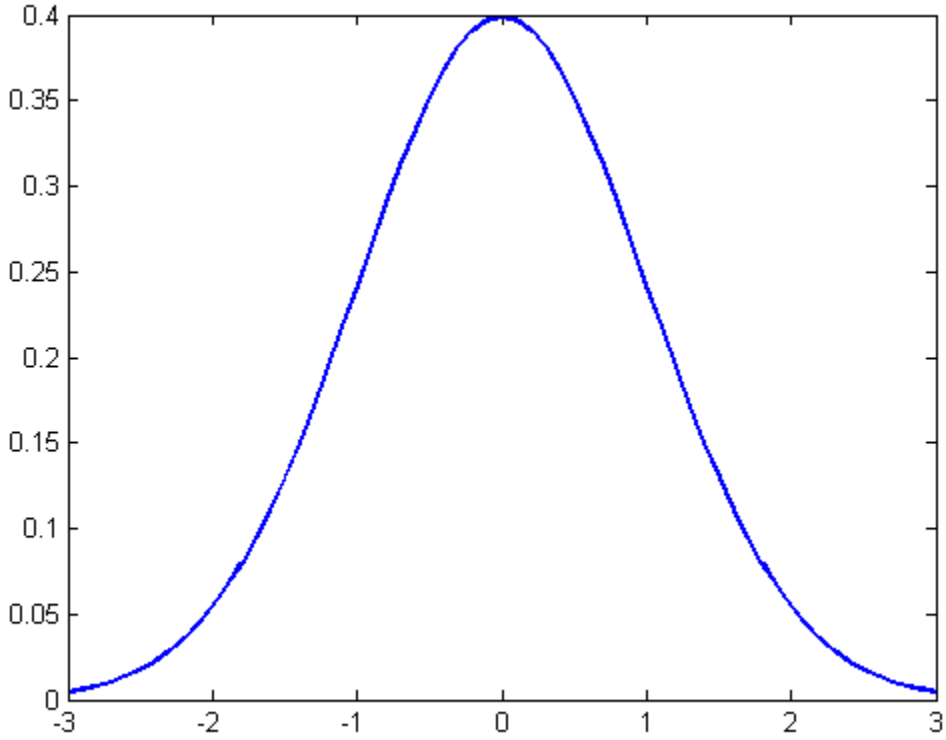
  Normal distribution
       mu = 0
    sigma = 1
```

Specify the `x` values and compute the pdf.

```
x = -3:.1:3;
pdf_normal = pdf(pd,x);
```

Plot the pdf.

```
plot(x,pdf_normal,'LineWidth',2)
```



Plot the pdf of a Weibull Distribution

Create a Weibull probability distribution object.

```
pd = makedist('Weibull','a',5,'b',2)
```

```
pd =

  WeibullDistribution

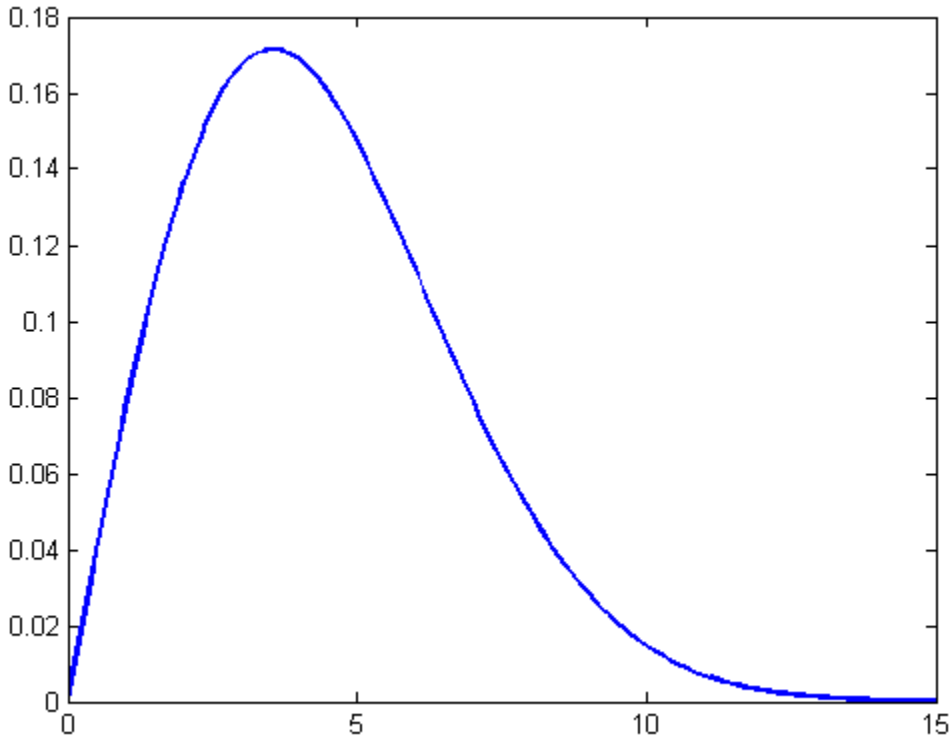
  Weibull distribution
    A = 5
    B = 2
```

Specify the `x` values and compute the pdf.

```
x = 0:.1:15;
y = pdf(pd,x);
```

Plot the pdf.

```
plot(x,y,'LineWidth',2)
```



See Also

cdf | dfittool | fitdist | icdf | makedist | pdf

pdist

Pairwise distance between pairs of objects

Syntax

```
D = pdist(X)
D = pdist(X,distance)
```

Description

`D = pdist(X)` computes the Euclidean distance between pairs of objects in m-by-n data matrix `X`. Rows of `X` correspond to observations, and columns correspond to variables. `D` is a row vector of length $m(m-1)/2$, corresponding to pairs of observations in `X`. The distances are arranged in the order (2,1), (3,1), ..., (m,1), (3,2), ..., (m,2), ..., (m,m–1)). `D` is commonly used as a dissimilarity matrix in clustering or multidimensional scaling.

To save space and computation time, `D` is formatted as a vector. However, you can convert this vector into a square matrix using the `squareform` function so that element i, j in the matrix, where $i < j$, corresponds to the distance between objects i and j in the original data set.

`D = pdist(X,distance)` computes the distance between objects in the data matrix, `X`, using the method specified by *`distance`*, which can be any of the following character strings.

Metric	Description
`'euclidean'`	Euclidean distance (default).
`'seuclidean'`	Standardized Euclidean distance. Each coordinate difference between rows in X is scaled by dividing by the corresponding element of the standard deviation `S=nanstd(X)`. To specify another value for `S`, use `D=pdist(X,'seuclidean',S)`.
`'cityblock'`	City block metric.
`'minkowski'`	Minkowski distance. The default exponent is 2. To specify a different exponent, use `D = pdist(X,'minkowski',P)`, where `P` is a scalar positive value of the exponent.

Metric	Description
`'chebychev'`	Chebychev distance (maximum coordinate difference).
`'mahalanobis'`	Mahalanobis distance, using the sample covariance of `X` as computed by `nancov`. To compute the distance with a different covariance, use `D = pdist(X,'mahalanobis',C)`, where the matrix `C` is symmetric and positive definite.
`'cosine'`	One minus the cosine of the included angle between points (treated as vectors).
`'correlation'`	One minus the sample correlation between points (treated as sequences of values).
`'spearman'`	One minus the sample Spearman's rank correlation between observations (treated as sequences of values).
`'hamming'`	Hamming distance, which is the percentage of coordinates that differ.
`'jaccard'`	One minus the Jaccard coefficient, which is the percentage of nonzero coordinates that differ.

custom distance function	A distance function specified using @:
	`D = pdist(X,@distfun)`
	
	A distance function must be of form
	
	`d2 = distfun(XI,XJ)`
	taking as arguments a 1-by-n vector `XI`, corresponding to a single row of `X`, and an $m2$-by-n matrix `XJ`, corresponding to multiple rows of `X`. `distfun` must accept a matrix `XJ` with an arbitrary number of rows. `distfun` must return an $m2$-by-1 vector of distances `d2`, whose kth element is the distance between `XI` and `XJ(k,:)`.

The output `D` is arranged in the order of ((2,1),(3,1),..., (m,1),(3,2),...(m,2),.....(m,m–1)), i.e. the lower left triangle of the full m-by-m distance matrix in column order. To get the distance between the ith and jth observations ($i < j$), either use the formula $D((i–1)*(m–i/2)+j–i)$, or use the helper function `Z = squareform(D)`, which returns an m-by-m square symmetric matrix, with the (i,j) entry equal to distance between observation i and observation j.

Metrics

Given an m-by-n data matrix X, which is treated as m (1-by-n) row vectors x_1, x_2, ..., x_m, the various distances between the vector x_s and x_t are defined as follows:

- Euclidean distance

  $$d_{st}^2 = (x_s - x_t)(x_s - x_t)'$$

  Notice that the Euclidean distance is a special case of the Minkowski metric, where p = 2.

- Standardized Euclidean distance

  $$d_{st}^2 = (x_s - x_t)V^{-1}(x_s - x_t)'$$

  where V is the n-by-n diagonal matrix whose jth diagonal element is $S(j)^2$, where S is the vector of standard deviations.

- Mahalanobis distance

  $$d_{st}^2 = (x_s - x_t)C^{-1}(x_s - x_t)'$$

  where C is the covariance matrix.

- City block metric

  $$d_{st} = \sum_{j=1}^{n} \left| x_{sj} - x_{tj} \right|$$

  Notice that the city block distance is a special case of the Minkowski metric, where p=1.

- Minkowski metric

  $$d_{st} = \sqrt[p]{\sum_{j=1}^{n} \left| x_{sj} - x_{tj} \right|^p}$$

Notice that for the special case of p = 1, the Minkowski metric gives the city block metric, for the special case of p = 2, the Minkowski metric gives the Euclidean distance, and for the special case of p = ∞, the Minkowski metric gives the Chebychev distance.

- Chebychev distance

$$d_{st} = \max_j \left\{ \left| x_{sj} - x_{tj} \right| \right\}$$

Notice that the Chebychev distance is a special case of the Minkowski metric, where p = ∞.

- Cosine distance

$$d_{st} = 1 - \frac{x_s x_t'}{\sqrt{(x_s x_s')(x_t x_t')}}$$

- Correlation distance

$$d_{st} = 1 - \frac{(x_s - \bar{x}_s)(x_t - \bar{x}_t)'}{\sqrt{(x_s - \bar{x}_s)(x_s - \bar{x}_s)'}\sqrt{(x_t - \bar{x}_t)(x_t - \bar{x}_t)'}}$$

where

$$\bar{x}_s = \frac{1}{n}\sum_j x_{sj} \quad \text{and} \quad \bar{x}_t = \frac{1}{n}\sum_j x_{tj}$$

- Hamming distance

$$d_{st} = (\#(x_{sj} \neq x_{tj}) / n)$$

- Jaccard distance

$$d_{st} = \frac{\#\left[\left(x_{sj} \neq x_{tj}\right) \cap \left(\left(x_{sj} \neq 0\right) \cup \left(x_{tj} \neq 0\right)\right)\right]}{\#\left[\left(x_{sj} \neq 0\right) \cup \left(x_{tj} \neq 0\right)\right]}$$

- Spearman distance

$$d_{st} = 1 - \frac{(r_s - \bar{r}_s)(r_t - \bar{r}_t)'}{\sqrt{(r_s - \bar{r}_s)(r_s - \bar{r}_s)'}\sqrt{(r_t - \bar{r}_t)(r_t - \bar{r}_t)'}}$$

  where

  - r_{sj} is the rank of x_{sj} taken over x_{1j}, x_{2j}, ...x_{mj}, as computed by `tiedrank`
  - r_s and r_t are the coordinate-wise rank vectors of x_s and x_t, i.e., $r_s = (r_{s1}, r_{s2}, \ldots r_{sn})$
  - $\bar{r}_s = \frac{1}{n}\sum_j r_{sj} = \frac{(n+1)}{2}$
  - $\bar{r}_t = \frac{1}{n}\sum_j r_{tj} = \frac{(n+1)}{2}$

Examples

Generate random data and find the unweighted Euclidean distance and then find the weighted distance using two different methods:

```
% Compute the ordinary Euclidean distance.
X = randn(100, 5);
D = pdist(X,'euclidean');  % euclidean distance

% Compute the Euclidean distance with each coordinate
% difference scaled by the standard deviation.
Dstd = pdist(X,'seuclidean');

% Use a function handle to compute a distance that weights
% each coordinate contribution differently.
Wgts = [.1 .3 .3 .2 .1];     % coordinate weights
weuc = @(XI,XJ,W)(sqrt(bsxfun(@minus,XI,XJ).^2 * W'));
Dwgt = pdist(X, @(Xi,Xj) weuc(Xi,Xj,Wgts));
```

pdist2

Pairwise distance between two sets of observations

Syntax

```
D = pdist2(X,Y)
D = pdist2(X,Y,distance)
D = pdist2(X,Y,'minkowski',P)
D = pdist2(X,Y,'mahalanobis',C)
D = pdist2(X,Y,distance,'Smallest',K)
D = pdist2(X,Y,distance,'Largest',K)
[D,I] = pdist2(X,Y,distance,'Smallest',K)
[D,I] = pdist2(X,Y,distance,'Largest',K)
```

Description

`D = pdist2(X,Y)` returns a matrix `D` containing the Euclidean distances between each pair of observations in the *mx*-by-*n* data matrix `X` and *my*-by-*n* data matrix `Y`. Rows of `X` and `Y` correspond to observations, columns correspond to variables. `D` is an *mx*-by-*my* matrix, with the (*i*,*j*) entry equal to distance between observation *i* in `X` and observation *j* in `Y`. The (*i*,*j*) entry will be `NaN` if observation *i* in `X` or observation *j* in `Y` contain `NaN`s.

`D = pdist2(X,Y,distance)` computes `D` using `distance`. Choices are:

Metric	Description
`'euclidean'`	Euclidean distance (default).
`'seuclidean'`	Standardized Euclidean distance. Each coordinate difference between rows in `X` and `Y` is scaled by dividing by the corresponding element of the standard deviation computed from `X`, `S=nanstd(X)`. To specify another value for `S`, use `D = PDIST2(X,Y,'seuclidean',S)`.
`'cityblock'`	City block metric.
`'minkowski'`	Minkowski distance. The default exponent is 2. To compute the distance with a different exponent, use `D =`

Metric	Description
	`pdist2(X,Y,'minkowski',P)`, where the exponent `P` is a scalar positive value.
`'chebychev'`	Chebychev distance (maximum coordinate difference).
`'mahalanobis'`	Mahalanobis distance, using the sample covariance of `X` as computed by `nancov`. To compute the distance with a different covariance, use `D = pdist2(X,Y,'mahalanobis',C)` where the matrix `C` is symmetric and positive definite.
`'cosine'`	One minus the cosine of the included angle between points (treated as vectors).
`'correlation'`	One minus the sample correlation between points (treated as sequences of values).
`'spearman'`	One minus the sample Spearman's rank correlation between observations, treated as sequences of values.
`'hamming'`	Hamming distance, the percentage of coordinates that differ.
`'jaccard'`	One minus the Jaccard coefficient, the percentage of nonzero coordinates that differ.
function	A distance function specified using @: `D = pdist2(X,Y,@distfun)`. A distance function must be of the form `function D2 = distfun(ZI, ZJ)` taking as arguments a 1-by-*n* vector `ZI` containing a single observation from `X` or `Y`, an *m2*-by-*n* matrix `ZJ` containing multiple observations from `X` or `Y`, and returning an *m2*-by-1 vector of distances `D2`, whose `J`th element is the distance between the observations `ZI` and `ZJ(J,:)`. If your data is not sparse, generally it is faster to use a built-in `distance` than to use a function handle.

`D = pdist2(X,Y,distance,'Smallest',K)` returns a `K`-by-*my* matrix `D` containing the `K` smallest pairwise distances to observations in `X` for each observation in `Y`. `pdist2` sorts the distances in each column of `D` in ascending order. `D = pdist2(X,Y,distance,'Largest',K)` returns the `K` largest pairwise distances sorted in descending order. If `K` is greater than *mx*, `pdist2` returns an *mx*-by-*my* distance

matrix. For each observation in Y, pdist2 finds the K smallest or largest distances by computing and comparing the distance values to all the observations in X.

[D,I] = pdist2(X,Y,distance,'Smallest',K) returns a K-by-*my* matrix I containing indices of the observations in X corresponding to the K smallest pairwise distances in D. [D,I] = pdist2(X,Y,distance,'Largest',K) returns indices corresponding to the K largest pairwise distances.

Metrics

Given an *mx*-by-*n* data matrix X, which is treated as *mx* (1-by-*n*) row vectors x_1, x_2, ..., x_{mx}, and *my*-by-*n* data matrix Y, which is treated as *my* (1-by-*n*) row vectors y_1, y_2, ...,y_{my}, the various distances between the vector x_s and y_t are defined as follows:

- Euclidean distance

  $$d_{st}^2 = (x_s - y_t)(x_s - y_t)'$$

  Notice that the Euclidean distance is a special case of the Minkowski metric, where p=2.

- Standardized Euclidean distance

  $$d_{st}^2 = (x_s - y_t)V^{-1}(x_s - y_t)'$$

  where V is the *n*-by-*n* diagonal matrix whose *j*th diagonal element is $S(j)^2$, where S is the vector of standard deviations.

- Mahalanobis distance

  $$d_{st}^2 = (x_s - y_t)C^{-1}(x_s - y_t)'$$

  where C is the covariance matrix.

- City block metric

  $$d_{st} = \sum_{j=1}^{n} \left| x_{sj} - y_{tj} \right|$$

Notice that the city block distance is a special case of the Minkowski metric, where p=1.

- Minkowski metric

$$d_{st} = \sqrt[p]{\sum_{j=1}^{n} \left| x_{sj} - y_{tj} \right|^p}$$

Notice that for the special case of p = 1, the Minkowski metric gives the City Block metric, for the special case of p = 2, the Minkowski metric gives the Euclidean distance, and for the special case of p=∞, the Minkowski metric gives the Chebychev distance.

- Chebychev distance

$$d_{st} = \max_j \left\{ \left| x_{sj} - y_{tj} \right| \right\}$$

Notice that the Chebychev distance is a special case of the Minkowski metric, where p=∞.

- Cosine distance

$$d_{st} = \left(1 - \frac{x_s y_t'}{\sqrt{(x_s x_s')(y_t y_t')}} \right)$$

- Correlation distance

$$d_{st} = 1 - \frac{(x_s - \bar{x}_s)(y_t - \bar{y}_t)'}{\sqrt{(x_s - \bar{x}_s)(x_s - \bar{x}_s)'} \sqrt{(y_t - \bar{y}_t)(y_t - \bar{y}_t)'}}$$

where

$\bar{x}_s = \frac{1}{n} \sum_j x_{sj}$ and

$$\bar{y}_t = \frac{1}{n}\sum_j y_{tj}$$

- Hamming distance

$$d_{st} = (\#(x_{sj} \neq y_{tj}) / n)$$

- Jaccard distance

$$d_{st} = \frac{\#\left[\left(x_{sj} \neq y_{tj}\right) \cap \left(\left(x_{sj} \neq 0\right) \cup \left(y_{tj} \neq 0\right)\right)\right]}{\#\left[\left(x_{sj} \neq 0\right) \cup \left(y_{tj} \neq 0\right)\right]}$$

- Spearman distance

$$d_{st} = 1 - \frac{(r_s - \bar{r}_s)(r_t - \bar{r}_t)'}{\sqrt{(r_s - \bar{r}_s)(r_s - \bar{r}_s)'}\sqrt{(r_t - \bar{r}_t)(r_t - \bar{r}_t)'}}$$

  where

  - r_{sj} is the rank of x_{sj} taken over x_{1j}, x_{2j}, ...$x_{mx,j}$, as computed by `tiedrank`
  - r_{tj} is the rank of y_{tj} taken over y_{1j}, y_{2j}, ...$y_{my,j}$, as computed by `tiedrank`
  - r_s and r_t are the coordinate-wise rank vectors of x_s and y_t, i.e. $r_s = (r_{s1}, r_{s2}, \ldots r_{sn})$ and $r_t = (r_{t1}, r_{t2}, \ldots r_{tn})$
  - $$\bar{r}_s = \frac{1}{n}\sum_j r_{sj} = \frac{(n+1)}{2}$$
  - $$\bar{r}_t = \frac{1}{n}\sum_j r_{tj} = \frac{(n+1)}{2}$$

Examples

Generate random data and find the unweighted Euclidean distance, then find the weighted distance using two different methods:

```
% Compute the ordinary Euclidean distance
X = randn(100, 5);
Y = randn(25, 5);
D = pdist2(X,Y,'euclidean'); % euclidean distance

% Compute the Euclidean distance with each coordinate
% difference scaled by the standard deviation
Dstd = pdist2(X,Y,'seuclidean');

% Use a function handle to compute a distance that weights
% each coordinate contribution differently.
Wgts = [.1 .3 .3 .2 .1];
weuc = @(XI,XJ,W)(sqrt(bsxfun(@minus,XI,XJ).^2 * W'));
Dwgt = pdist2(X,Y, @(Xi,Xj) weuc(Xi,Xj,Wgts));
```

pearsrnd

Pearson system random numbers

Syntax

```
r = pearsrnd(mu,sigma,skew,kurt,m,n)
r = pearsrnd(mu,sigma,skew,kurt)
r = pearsrnd(mu,sigma,skew,kurt,m,n,...)
r = pearsrnd(mu,sigma,skew,kurt,[m,n,...])
[r,type] = pearsrnd(...)
[r,type,coefs] = pearsrnd(...)
```

Description

`r = pearsrnd(mu,sigma,skew,kurt,m,n)` returns an `m`-by-`n` matrix of random numbers drawn from the distribution in the Pearson system with mean `mu`, standard deviation `sigma`, skewness `skew`, and kurtosis `kurt`. The parameters `mu`, `sigma`, `skew`, and `kurt` must be scalars.

Note: Because `r` is a random sample, its sample moments, especially the skewness and kurtosis, typically differ somewhat from the specified distribution moments.

`pearsrnd` uses the definition of kurtosis for which a normal distribution has a kurtosis of 3. Some definitions of kurtosis subtract 3, so that a normal distribution has a kurtosis of 0. The `pearsrnd` function does not use this convention.

Some combinations of moments are not valid; in particular, the kurtosis must be greater than the square of the skewness plus 1. The kurtosis of the normal distribution is defined to be 3.

`r = pearsrnd(mu,sigma,skew,kurt)` returns a scalar value.

`r = pearsrnd(mu,sigma,skew,kurt,m,n,...)` or `r = pearsrnd(mu,sigma,skew,kurt,[m,n,...])` returns an `m`-by-`n`-by-... array.

`[r,type] = pearsrnd(...)` returns the type of the specified distribution within the Pearson system. `type` is a scalar integer from `0` to `7`. Set `m` and `n` to `0` to identify the distribution type without generating any random values.

The seven distribution types in the Pearson system correspond to the following distributions:

- `0` — Normal distribution
- `1` — Four-parameter beta distribution
- `2` — Symmetric four-parameter beta distribution
- `3` — Three-parameter gamma distribution
- `4` — Not related to any standard distribution. The density is proportional to: $(1 + ((x - a)/b)^2)^{-c} \exp(-d \arctan((x - a)/b))$.
- `5` — Inverse gamma location-scale distribution
- `6` — F location-scale distribution
- `7` — Student's t location-scale distribution

`[r,type,coefs] = pearsrnd(...)` returns the coefficients `coefs` of the quadratic polynomial that defines the distribution via the differential equation

$$\frac{d}{dx}\log(p(x)) = \frac{-(a+x)}{c(0) + c(1)x + c(2)x^2}.$$

Examples

Generate random values from the standard normal distribution:

```
r = pearsrnd(0,1,0,3,100,1);  % Equivalent to randn(100,1)
```

Determine the distribution type:

```
[r,type] = pearsrnd(0,1,1,4,0,0);
r =
     []
type =
     1
```

perfcurve

Receiver operating characteristic (ROC) curve or other performance curve for classifier output

Syntax

```
[X,Y] = perfcurve(labels,scores,posclass)
[X,Y,T] = perfcurve(labels,scores,posclass)
[X,Y,T,AUC] = perfcurve(labels,scores,posclass)
[X,Y,T,AUC,OPTROCPT] = perfcurve(labels,scores,posclass)
[X,Y,T,AUC,OPTROCPT,SUBY] = perfcurve(labels,scores,posclass)
[X,Y,T,AUC,OPTROCPT,SUBY,SUBYNAMES] = perfcurve(labels,scores,
posclass)
[ ___ ] = perfcurve(labels,scores,posclass,Name,Value)
```

Description

`[X,Y] = perfcurve(labels,scores,posclass)` returns the X and Y coordinates of an ROC curve for a vector of classifier predictions, scores, given true class labels, labels, and the positive class label, posclass. You can visualize the performance curve using `plot(X,Y)`.

`[X,Y,T] = perfcurve(labels,scores,posclass)` returns an array of thresholds on classifier scores for the computed values of X and Y.

`[X,Y,T,AUC] = perfcurve(labels,scores,posclass)` returns the area under the curve for the computed values of X and Y.

`[X,Y,T,AUC,OPTROCPT] = perfcurve(labels,scores,posclass)` returns the optimal operating point of the ROC curve.

`[X,Y,T,AUC,OPTROCPT,SUBY] = perfcurve(labels,scores,posclass)` returns the Y values for negative subclasses.

`[X,Y,T,AUC,OPTROCPT,SUBY,SUBYNAMES] = perfcurve(labels,scores,posclass)` returns the negative class names.

`[ ___ ] = perfcurve(labels,scores,posclass,Name,Value)` returns the coordinates of a ROC curve and any other output argument from the previous syntaxes, with additional options specified by one or more Name,Value pair arguments.

For example, you can provide a list of negative classes, change the X or Y criterion, compute pointwise confidence bounds using cross validation or bootstrap, specify the misclassification cost, or compute the confidence bounds in parallel.

Examples

Plot ROC Curve for Classification by Logistic Regression

Load the sample data.

```
load fisheriris
```

Use only the first two features as predictor variables. Define a binary classification problem by using only the measurements that correspond to the species versicolor and virginica.

```
pred = meas(51:end,1:2);
```

Define the binary response variable.

```
resp = (1:100)'>50;  % Versicolor = 0, virginica = 1
```

Fit a logistic regression model.

```
mdl = fitglm(pred,resp,'Distribution','binomial','Link','logit');
```

Compute the ROC curve. Use the probability estimates from the logistic regression model as scores.

```
scores = mdl.Fitted.Probability;
[X,Y,T,AUC] = perfcurve(species(51:end,:),scores,'virginica');
```

`perfcurve` stores the threshold values in the array `T`.

Display the area under the curve.

```
AUC
```

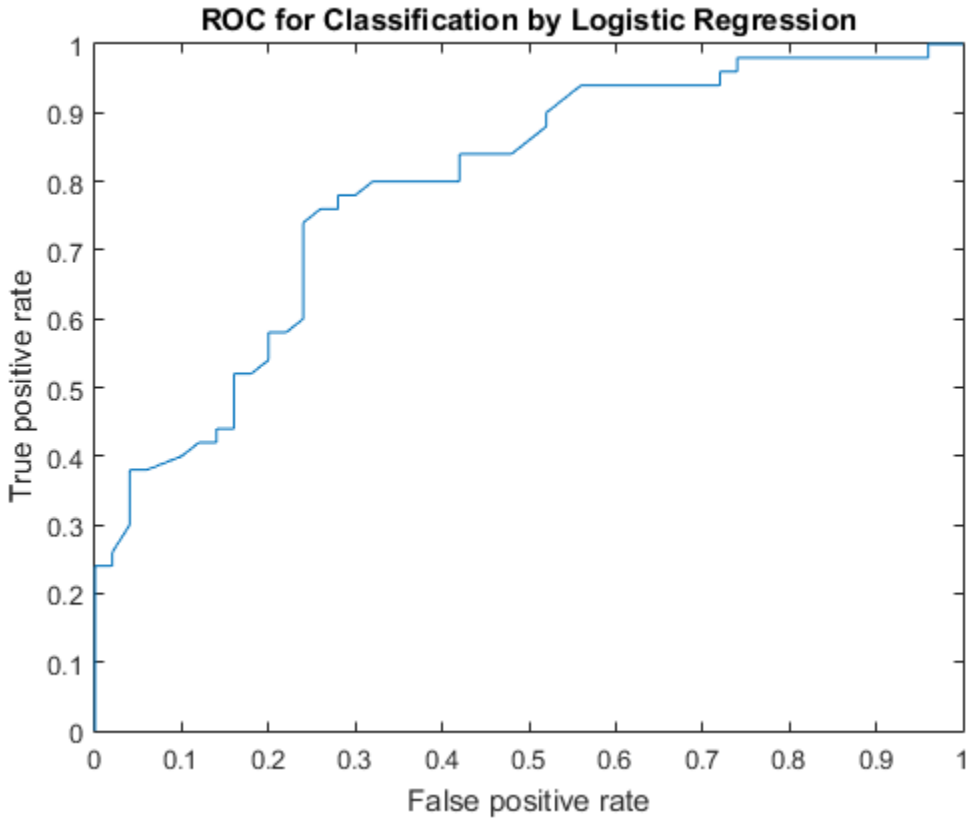
```
AUC =

    0.7918
```

The area under the curve is 0.7918. The maximum AUC is 1, which corresponds to a perfect classifier. Larger AUC values indicate better classifier performance.

Plot the ROC curve.

```
plot(X,Y)
xlabel('False positive rate')
ylabel('True positive rate')
title('ROC for Classification by Logistic Regression')
```



Compare Classification Methods Using ROC Curve

Load the sample data.

```
load ionosphere
```

`X` is a 351x34 real-valued matrix of predictors. `Y` is a character array of class labels: `'b'` for bad radar returns and `'g'` for good radar returns.

Reformat the response to fit a logistic regression. Use the predictor variables 3 through 34.

```
resp = strcmp(Y,'b'); % resp = 1, if Y = 'b', or 0 if Y = 'g'
```

```
pred = X(:,3:34);
```

Fit a logistic regression model to estimate the posterior probabilities for an iris to be a virginica.

```
mdl = fitglm(pred,resp,'Distribution','binomial','Link','logit');
score_log = mdl.Fitted.Probability; % Probability estimates
```

Compute the standard ROC curve using the probabilities for scores.

```
[Xlog,Ylog,Tlog,AUClog] = perfcurve(resp,score_log,'true');
```

Train an SVM classifier on the same sample data. Standardize the data.

```
mdlSVM = fitcsvm(pred,resp,'Standardize',true);
```

Compute the posterior probabilities (scores).

```
mdlSVM = fitPosterior(mdlSVM);
[~,score_svm] = resubPredict(mdlSVM);
```

The second column of `score_svm` contains the posterior probabilities of bad radar returns.

Compute the standard ROC curve using the scores from the SVM model.

```
[Xsvm,Ysvm,Tsvm,AUCsvm] = perfcurve(resp,score_svm(:,mdlSVM.ClassNames),'true');
```

Fit a naive Bayes classifier on the same sample data.

```
mdlNB = fitcnb(pred,resp);
```

Compute the posterior probabilities (scores).

```
[~,score_nb] = resubPredict(mdlNB);
```

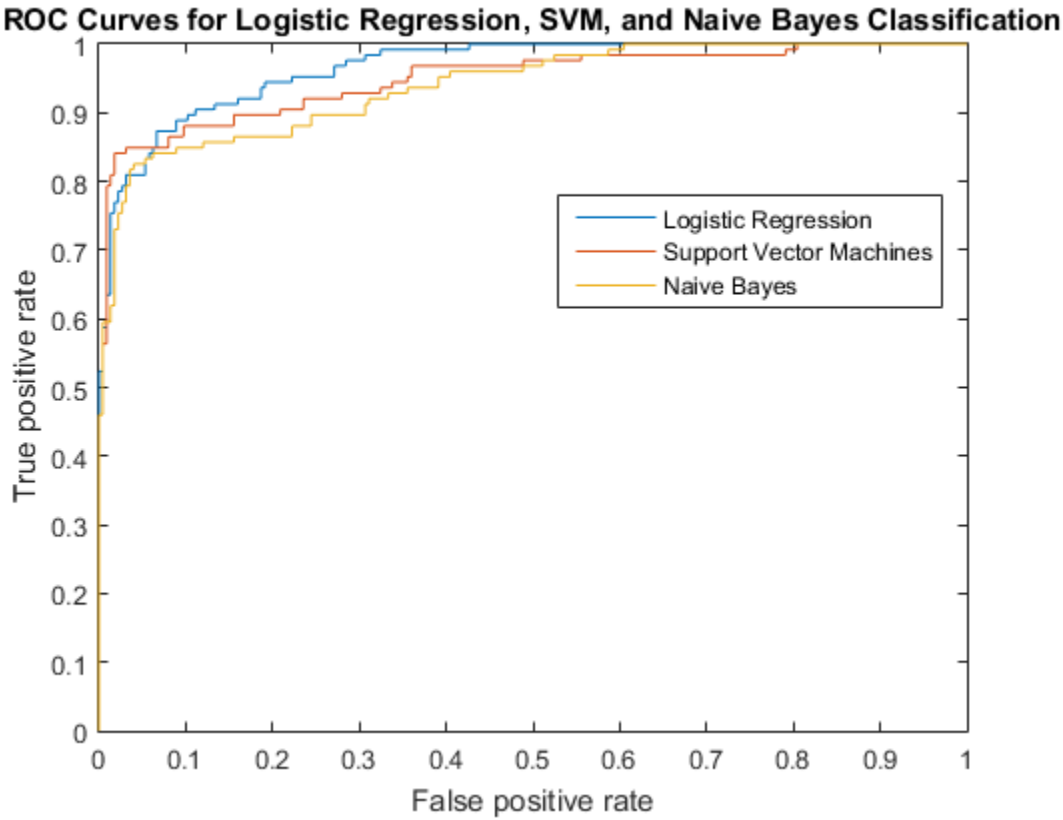
Compute the standard ROC curve using the scores from the naive Bayes classification.

```
[Xnb,Ynb,Tnb,AUCnb] = perfcurve(resp,score_nb(:,mdlNB.ClassNames),'true');
```

Plot the ROC curves on the same graph.

```
plot(Xlog,Ylog)
hold on
```

```
plot(Xsvm,Ysvm)
plot(Xnb,Ynb)
legend('Logistic Regression','Support Vector Machines','Naive Bayes','Location','Best')
xlabel('False positive rate'); ylabel('True positive rate');
title('ROC Curves for Logistic Regression, SVM, and Naive Bayes Classification')
hold off
```



Although SVM produces better ROC values for higher thresholds, logistic regression is usually better at distinguishing the bad radar returns from the good ones. The ROC curve for naive Bayes is generally lower than the other two ROC curves, which indicates worse in-sample performance than the other two classifier methods.

Compare the area under the curve for all three classifiers.

```
AUClog
AUCsvm
AUCnb

AUClog =

    0.9659

AUCsvm =

    0.9488

AUCnb =

    0.9393
```

Logistic regression has the highest AUC measure for classification and naive Bayes has the lowest. This result suggests that logistic regression has better in-sample average performance for this sample data.

Determine the Parameter Value for Custom Kernel Function

Generate a random set of points within the unit circle.

```
rng(1);  % For reproducibility
n = 100; % Number of points per quadrant

r1 = sqrt(rand(2*n,1));                     % Random radii
t1 = [pi/2*rand(n,1); (pi/2*rand(n,1)+pi)]; % Random angles for Q1 and Q3
X1 = [r1.*cos(t1) r1.*sin(t1)];             % Polar-to-Cartesian conversion

r2 = sqrt(rand(2*n,1));
t2 = [pi/2*rand(n,1)+pi/2; (pi/2*rand(n,1)-pi/2)]; % Random angles for Q2 and Q4
X2 = [r2.*cos(t2) r2.*sin(t2)];
```

Define the predictor variables. Label points in the first and third quadrants as belonging to the positive class, and those in the second and fourth quadrants in the negative class.

```
pred = [X1; X2];
```

```
resp = ones(4*n,1);
resp(2*n + 1:end) = -1; % Labels
```

Create the function `mysigmoid.m`, which accepts two matrices in the feature space as inputs, and transforms them into a Gram matrix using the sigmoid kernel.

```
function G = mysigmoid(U,V)
% Sigmoid kernel function with slope gamma and intercept c
gamma = 1;
c = -1;
G = tanh(gamma*U*V' + c);
end
```

Train an SVM classifier using the sigmoid kernel function. It is good practice to standardize the data.

```
SVMModel1 = fitcsvm(pred,resp,'KernelFunction','mysigmoid',...
    'Standardize',true);
SVMModel1 = fitPosterior(SVMModel1);
[~,scores1] = resubPredict(SVMModel1);
```

Set `gamma = 0.5`; within `mysigmoid.m`. Then, train an SVM classifier using the adjusted sigmoid kernel.

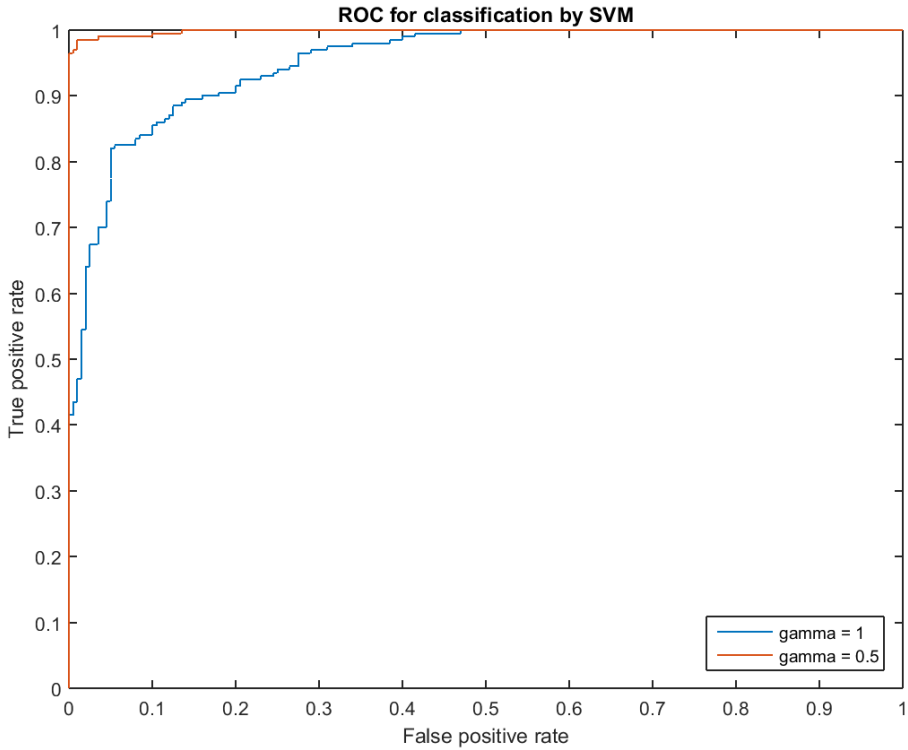
```
SVMModel2 = fitcsvm(pred,resp,'KernelFunction','mysigmoid',...
    'Standardize',true);
SVMModel2 = fitPosterior(SVMModel2);
[~,scores2] = resubPredict(SVMModel2);
```

Compute the ROC curves and the area under the curve (AUC) for both models.

```
[x1,y1,~,auc1] = perfcurve(resp,scores1(:,2),1);
[x2,y2,~,auc2] = perfcurve(resp,scores2(:,2),1);
```

Plot the ROC curves.

```
plot(x1,y1)
hold on
plot(x2,y2)
hold off
legend('gamma = 1','gamma = 0.5','Location','SE');
xlabel('False positive rate'); ylabel('True positive rate');
title('ROC for classification by SVM');
```



The kernel function with the gamma parameter set to 0.5 gives better in-sample results.

Compare the AUC measures.

```
auc1
auc2
```

```
auc1 =

    0.9518
auc2 =

    0.9985
```

The area under the curve for gamma set to 0.5 is higher than that for gamma set to 1. This also confirms that gamma parameter value of 0.5 produces better results. For visual

comparison of the classification performance with these two gamma parameter values, see “Train SVM Classifiers Using a Custom Kernel” on page 16-183.

Plot ROC Curve for Classification Tree

Load the sample data.

```
load fisheriris
```

The column vector, `species`, consists of iris flowers of three different species: setosa, versicolor, virginica. The double matrix `meas` consists of four types of measurements on the flowers: sepal length, sepal width, petal length, and petal width. All measures are in centimeters.

Train a classification tree using the sepal length and width as the predictor variables. It is a good practice to specify the class names.

```
Model = fitctree(meas(:,1:2),species,...
    'ClassNames',{'setosa','versicolor','virginica'});
```

Predict the class labels and scores for the species based on the tree `Model`.

```
[~,score] = resubPredict(Model);
```

The scores are the posterior probabilities that an observation (a row in the data matrix) belongs to a class. The columns of `score` correspond to the classes specified by `'ClassNames'`. So, the first column corresponds to setosa, the second corresponds to versicolor, and the third column corresponds to virginica.

Compute the ROC curve for the predictions that an observation belongs to versicolor, given the true class labels `species`. Also compute the optimal operating point and y values for negative subclasses. Return the names of the negative classes.

```
[X,Y,T,~,OPTROCPT,suby,subnames] = perfcurve(species,...
    score(:,2),'versicolor');
```

`X`, by default, is the false positive rate (fallout or 1-specificity) and `Y`, by default, is the true positive rate (recall or sensitivity). The positive class label is `versicolor`. Because a negative class is not defined, `perfcurve` assumes that the observations that do not belong to the positive class are in one class. The function accepts it as the negative class.

```
OPTROCPT
```

```
suby
subnames
```

```
OPTROCPT =

    0.1000    0.8000

suby =

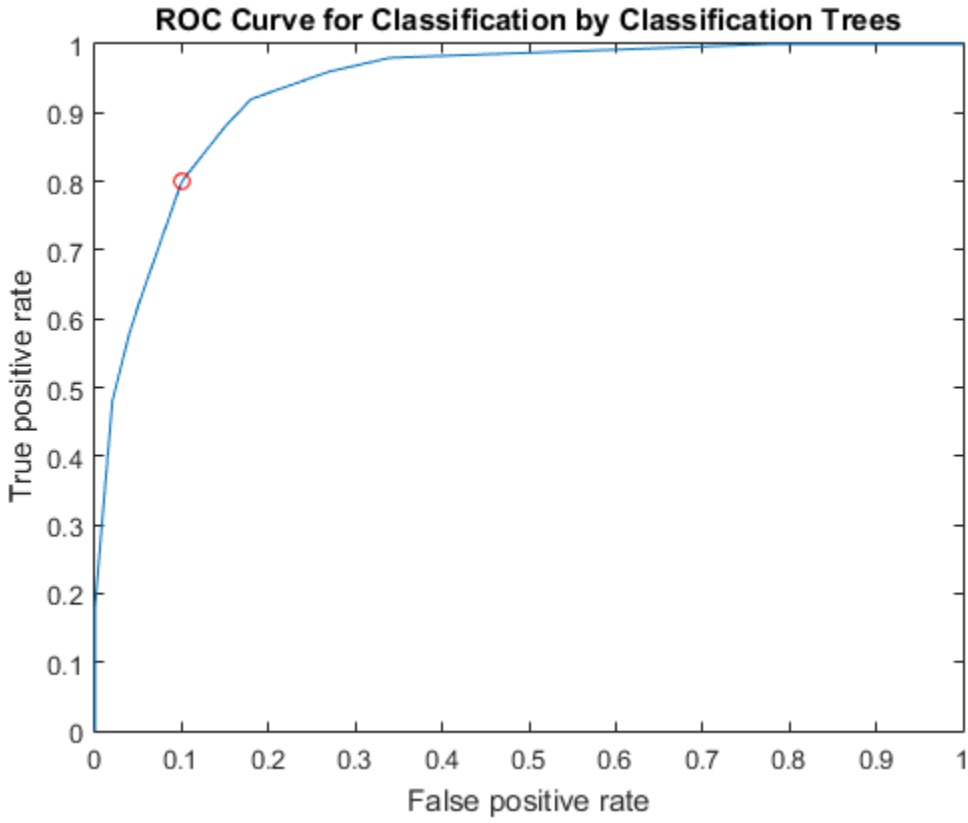
         0         0
    0.1800    0.1800
    0.4800    0.4800
    0.5800    0.5800
    0.6200    0.6200
    0.8000    0.8000
    0.8800    0.8800
    0.9200    0.9200
    0.9600    0.9600
    0.9800    0.9800
    1.0000    1.0000
    1.0000    1.0000

subnames =

    'setosa'    'virginica'
```

Plot the ROC curve and the optimal operating point on the ROC curve.

```
plot(X,Y)
hold on
plot(OPTROCPT(1),OPTROCPT(2),'ro')
xlabel('False positive rate')
ylabel('True positive rate')
title('ROC Curve for Classification by Classification Trees')
hold off
```



Find the threshold that corresponds to the optimal operating point.

```
T((X==OPTROCPT(1))&(Y==OPTROCPT(2)))
```

```
ans =

    0.6429
```

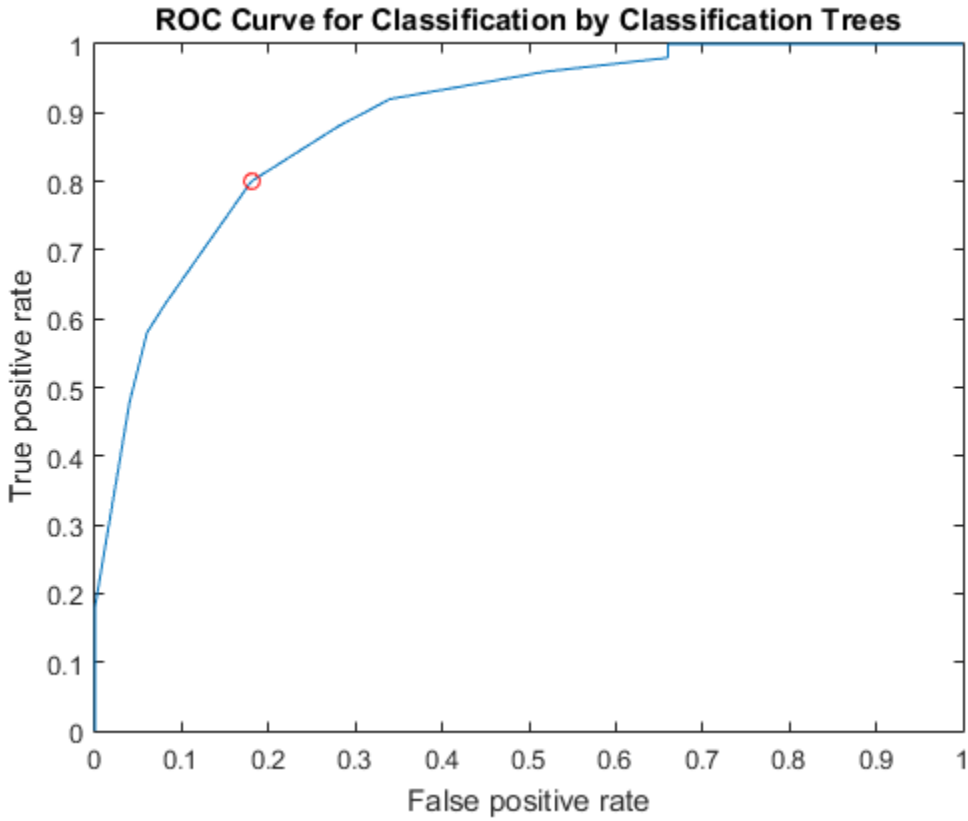
Specify `virginica` as the negative class and compute and plot the ROC curve for `versicolor`.

```
[X,Y,~,~,OPTROCPT] = perfcurve(species,score(:,2),...
```

```
    'versicolor','negClass','virginica');
OPTROCPT
plot(X,Y)
hold on
plot(OPTROCPT(1),OPTROCPT(2),'ro')
xlabel('False positive rate')
ylabel('True positive rate')
title('ROC Curve for Classification by Classification Trees')
hold off
```

```
OPTROCPT =

    0.1800    0.8000
```



Compute Pointwise Confidence Intervals for ROC Curve

Load the sample data.

```
load fisheriris
```

The column vector `species` consists of iris flowers of three different species: setosa, versicolor, virginica. The double matrix `meas` consists of four types of measurements on the flowers: sepal length, sepal width, petal length, and petal width. All measures are in centimeters.

Use only the first two features as predictor variables. Define a binary problem by using only the measurements that correspond to the versicolor and virginica species.

```
pred = meas(51:end,1:2);
```

Define the binary response variable.

```
resp = (1:100)'>50;  % Versicolor = 0, virginica = 1
```

Fit a logistic regression model.

```
mdl = fitglm(pred,resp,'Distribution','binomial','Link','logit');
```

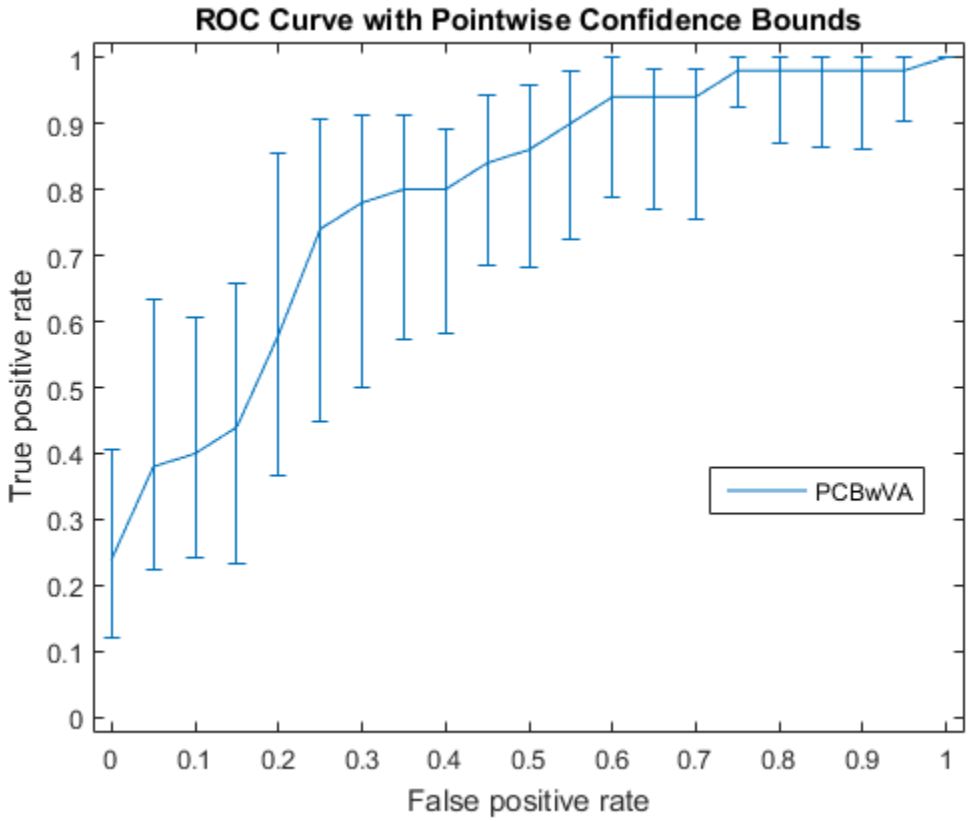
Compute the pointwise confidence intervals on the true positive rate (TPR) by vertical averaging (VA) and sampling using bootstrap.

```
[X,Y,T] = perfcurve(species(51:end,:),mdl.Fitted.Probability,...
       'virginica','NBoot',1000,'XVals',[0:0.05:1]);
```

`'NBoot',1000` sets the number of bootstrap replicas to 1000. `'XVals','All'` prompts `perfcurve` to return `X`, `Y`, and `T` values for all scores, and average the `Y` values (true positive rate) at all `X` values (false positive rate) using vertical averaging. If you do not specify `XVals`, then `perfcurve` computes the confidence bounds using threshold averaging by default.

Plot the pointwise confidence intervals.

```
errorbar(X,Y(:,1),Y(:,1)-Y(:,2),Y(:,3)-Y(:,1));
xlim([-0.02,1.02]); ylim([-0.02,1.02]);
xlabel('False positive rate')
ylabel('True positive rate')
title('ROC Curve with Pointwise Confidence Bounds')
legend('PCBwVA','Location','Best')
```



It might not always be possible to control the false positive rate (FPR, the `X` value in this example). So you might want to compute the pointwise confidence intervals on true positive rates (TPR) by threshold averaging.

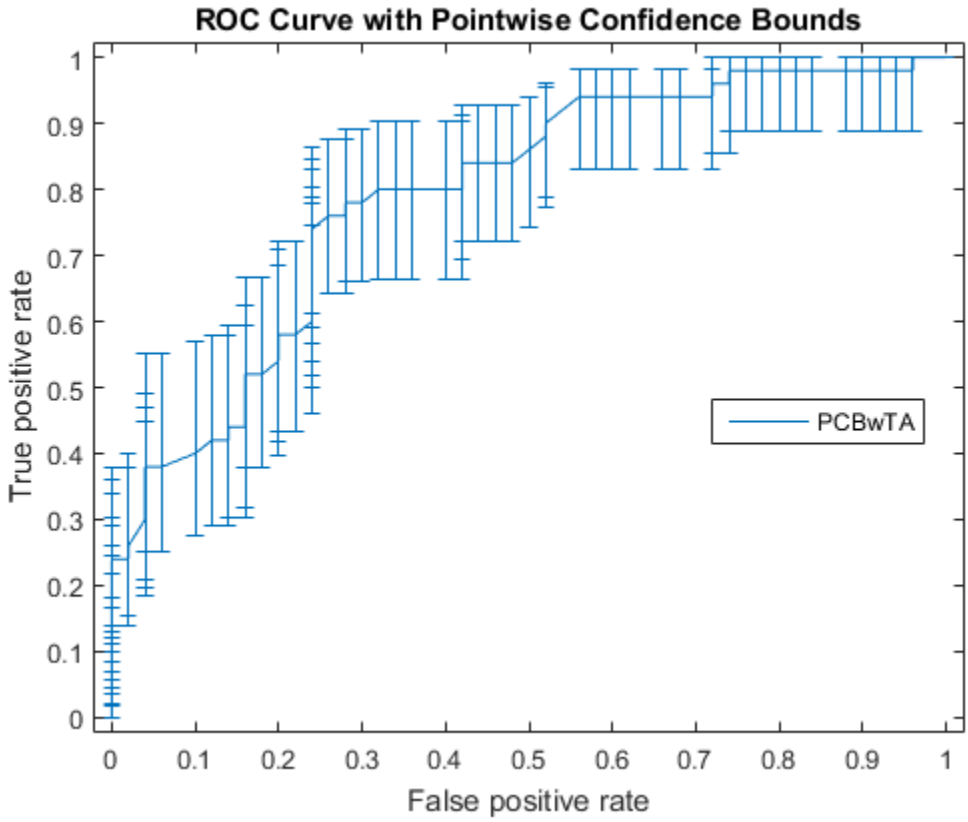
```
[X1,Y1,T1] = perfcurve(species(51:end,:),mdl.Fitted.Probability,...
    'virginica','NBoot',1000);
```

If you set `'TVals'` to `'All'`, or if you do not specify `'TVals'` or `'Xvals'`, then `perfcurve` returns `X`, `Y`, and `T` values for all scores and computes pointwise confidence bounds for `X` and `Y` using threshold averaging.

Plot the confidence bounds.

```
figure()
```

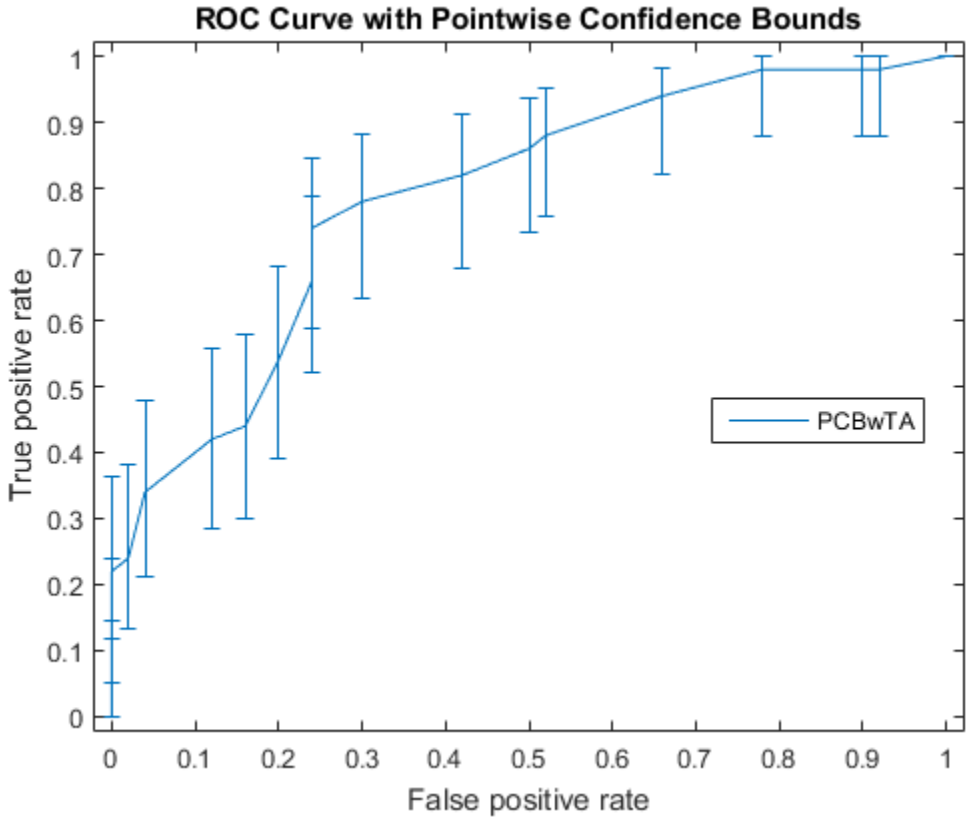
```
errorbar(X1(:,1),Y1(:,1),Y1(:,1)-Y1(:,2),Y1(:,3)-Y1(:,1));
xlim([-0.02,1.02]); ylim([-0.02,1.02]);
xlabel('False positive rate')
ylabel('True positive rate')
title('ROC Curve with Pointwise Confidence Bounds')
legend('PCBwTA','Location','Best')
```



Specify the threshold values to fix and compute the ROC curve. Then plot the curve.

```
[X1,Y1,T1] = perfcurve(species(51:end,:),mdl.Fitted.Probability,...
    'virginica','NBoot',1000,'TVals',0:0.05:1);
figure()
errorbar(X1(:,1),Y1(:,1),Y1(:,1)-Y1(:,2),Y1(:,3)-Y1(:,1));
xlim([-0.02,1.02]); ylim([-0.02,1.02]);
```

```
xlabel('False positive rate')
ylabel('True positive rate')
title('ROC Curve with Pointwise Confidence Bounds')
legend('PCBwTA','Location','Best')
```



Input Arguments

`labels` — True class labels

numeric vector | logical vector | character matrix | cell array of strings | categorical array

True class labels, specified as a numeric vector, a logical vector, a character matrix, a cell array of strings, or a categorical array. For more information, see “Grouping Variables” on page 2-52.

Example: `{'hi','mid','hi','low',...,'mid'}`

Example: `['H','M','H','L',...,'M']`

Data Types: `single` | `double` | `logical` | `char` | `cell`

`scores` — Scores returned by a classifier

vector of floating points

Scores returned by a classifier for some sample data, specified as a vector of floating points. scores must have the same number of elements as labels.

Data Types: `single` | `double`

`posclass` — Positive class label

numeric value | logical value | character array | cell array of strings | categorical value

Positive class label, specified as a numeric value, a logical value, a character array, or a cell array of strings. The positive class must be a member of the input labels. The value of posclass that you can specify depends on the value of labels.

`labels` value	`posclass` value
Numeric vector	Numeric scalar
Logical vector	Logical scalar
Character matrix	Character string
Cell array of strings	Character string or cell containing character string
Categorical vector	Categorical scalar

For example, in a cancer diagnosis problem, if a malignant tumor is the positive class, then specify `posclass` as `'malignant'`.

Data Types: `single` | `double` | `logical` | `char` | `cell`

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single

quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example:
`'NegClass','versicolor','XCrit','fn','NBoot',1000,'BootType','per'`
specifies the species versicolor as the negative class, the criterion for the X-coordinate as false negative, the number of bootstrap samples as 1000. It also specifies that the pointwise confidence bounds are computed using the percentile method.

`'NegClass'` — List of negative classes

`'all'` (default) | numeric array | categorical array

List of negative classes, specified as the comma-separated pair consisting of `'NegClass'`, and a numeric array or a categorical array. By default, `perfcurve` sets NegClass to `'all'` and considers all nonpositive classes found in the input array of labels to be negative.

If NegClass is a subset of the classes found in the input array of labels, then `perfcurve` discards the instances with labels that do not belong to either positive or negative classes.

Example: `'nNegClass',{'versicolor','setosa'}`

Data Types: `single` | `double`

`'XCrit'` — Criterion to compute for X

`'fpr'` (default) | `'fnr'` | `'tnr'` | `'ppv'` | `'ecost'` | ...

Criterion to compute for X, specified as the comma-separated pair consisting of `'XCrit'` and one of the following.

Criterion	Description
`tp`	Number of true positive instances
`fn`	Number of false negative instances.
`fp`	Number of false positive instances.
`tn`	Number of true negative instances.
`tp+fp`	Sum of true positive and false positive instances.
`rpp`	Rate of positive predictions. `rpp = (tp+fp)/(tp+fn+fp+tn)`
`rnp`	Rate of negative predictions.

Criterion	Description
	`rnp = (tn+fn)/(tp+fn+fp+tn)`
`accu`	Accuracy. `accu = (tp+tn)/(tp+fn+fp+tn)`
`tpr`, or `sens`, or `reca`	True positive rate, or sensitivity, or recall. `tpr= sens = reca = tp/(tp+fn)`
`fnr`, or `miss`	False negative rate, or miss. `fnr = miss = fn/(tp+fn)`
`fpr`, or `fall`	False positive rate, or fallout, or 1 – specificity. `fpr = fall = fp/(tn+fp)`
`tnr`, or `spec`	True negative rate, or specificity. `tnr = spec = tn/(tn+fp)`
`ppv`, or `prec`	Positive predictive value, or precision. `ppv = prec = tp/(tp+fp)`
`npv`	Negative predictive value. `npv = tn/(tn+fn)`
`ecost`	Expected cost. `ecost = (tp*Cost(P|P)+fn*Cost(N|P)+fp*Cost(P|N)+tn*Cost(N|N))/(tp+fn+fp+tn)`
Custom criterion	A custom-defined function with the input arguments `(C,scale,cost)`, where `C` is a 2-by-2 confusion matrix, `scale` is a 2-by-1 array of class scales, and `cost` is a 2-by-2 misclassification cost matrix.

Caution Some of these criteria return `NaN` values at one of the two special thresholds, `'reject all'` and `'accept all'`.

Example: `'XCrit','ecost'`

`'YCrit'` — Criterion to compute for `Y`

`tpr` (default) | same criteria options for X

Criterion to compute for Y, specified as the comma-separated pair consisting of `'YCrit'` and one of the same criteria options as for X. This criterion does not have to be a monotone function of the positive class score.

Example: 'YCrit','ecost'

'XVals' — Values for the X criterion

'all' (default) | numeric array

Values for the X criterion, specified as the comma-separated pair consisting of 'XVals' and a numeric array.

- If you specify XVals, then perfcurve computes X and Y and the pointwise confidence bounds for Y (when applicable) only for the specified XVals.
- If you do not specify XVals, then perfcurve, computes X and Y and the values for all scores by default.

Note: You cannot set XVals and TVals at the same time.

Example: 'XVals',[0:0.05:1]

Data Types: single | double

'TVals' — Thresholds for the positive class score

'all' (default) | numeric array

Thresholds for the positive class score, specified as the comma-separated pair consisting of 'TVals' and either 'all' or a numeric array.

- If TVals is set to 'all' or not specified, and XVals is not specified, then perfcurve returns X, Y, and T values for all scores and computes pointwise confidence bounds for X and Y using threshold averaging.
- If TVals is set to a numeric array, then perfcurve returns X, Y, and T values for the specified thresholds and computes pointwise confidence bounds for X and Y at these thresholds using threshold averaging.

Note: You cannot set XVals and TVals at the same time.

Example: 'TVals',[0:0.05:1]

Data Types: single | double

`'UseNearest'` — Indicator to use the nearest values in the data

`'on'` (default) | `'off'`

Indicator to use the nearest values in the data instead of the specified numeric `XVals` or `TVals`, specified as the comma-separated pair consisting of `'UseNearest'` and either `'on'` or `'off'`.

- If you specify numeric XVals and set UseNearest to `'on'`, then `perfcurve` returns the nearest unique X values found in the data, and it returns the corresponding values of Y and T.
- If you specify numeric XVals and set UseNearest to `'off'`, then `perfcurve` returns the sorted XVals.
- If you compute confidence bounds by cross validation or bootstrap, then this parameter is always `'off'`.

Example: `'UseNearest','off'`

`'ProcessNaN'` — `perfcurve` method for processing `NaN` scores

`'ignore'` (default) | `'addtofalse'`

`perfcurve` method for processing `NaN` scores, specified as the comma-separated pair consisting of `'ProcessNaN'` and `'ignore'` or `'addtofalse'`.

- If ProcessNaN is `'ignore'`, then `perfcurve` removes observations with `NaN` scores from the data.
- If ProcessNaN is `'addtofalse'`, then `perfcurve` adds instances with `NaN` scores to false classification counts in the respective class. That is, `perfcurve` always counts instances from the positive class as false negative (FN), and it always counts instances from the negative class as false positive (FP).

Example: `'ProcessNaN','addtofalse'`

`'Prior'` — Prior probabilities for positive and negative classes

`'empirical'` (default) | `'uniform'` | array with two elements

Prior probabilities for positive and negative classes, specified as the comma-separated pair consisting of `'Prior'` and `'empirical'`, `'uniform'`, or an array with two elements.

If Prior is `'empirical'`, then `perfcurve` derives prior probabilities from class frequencies.

If Prior is `'uniform'` , then `perfcurve` sets all prior probabilities to be equal.

Example: `'Prior',[0.3,0.7]`

Data Types: `single` | `double` | `char`

`'Cost'` — Misclassification costs

`[0 0.5;0.5 0]` (default) | 2-by-2 matrix

Misclassification costs, specified as the comma-separated pair consisting of `'Cost'` and a 2-by-2 matrix, containing `[Cost(P|P),Cost(N|P);Cost(P|N),Cost(N|N)]`.

`Cost(N|P)` is the cost of misclassifying a positive class as a negative class. `Cost(P|N)` is the cost of misclassifying a negative class as a positive class. Usually, `Cost(P|P)` = 0 and `Cost(N|N)` = 0, but `perfcurve` allows you to specify nonzero costs for correct classification as well.

Example: `'Cost',[0 0.7;0.3 0]`

Data Types: `single` | `double`

`'Alpha'` — Confidence level

0.05 (default) | scalar value in the range 0 through 1

Confidence level for the confidence bounds, specified as the comma-separated pair consisting of `'Alpha'` and a scalar value in the range 0 through 1. `perfcurve` computes 100*(1 – *a*) percent pointwise confidence bounds for X, Y, T, and AUC for a confidence level of *a*.

Example: `'Alpha',0.01` specifies 99% confidence bounds

Data Types: `single` | `double`

`'Weights'` — Observation weights

(default) | vector of nonnegative scalar values | cell array of vectors of nonnegative scalar values

Observation weights, specified as the comma-separated pair consisting of `'Weights'` and a vector of nonnegative scalar values. This vector must have as many elements as scores or labels do.

If scores and labels are in cell arrays and you need to supply Weights, the weights must be in a cell array as well. In this case, every element in Weights must be a numeric vector with as many elements as the corresponding element in scores. For example, `numel(weights{1}) == numel(scores{1})`.

When `perfcurve` computes the X, Y and T or confidence bounds using cross-validation, it uses these observation weights instead of observation counts.

When `perfcurve` computes confidence bounds using bootstrap, it samples *N* out of *N* observations with replacement, using these weights as multinomial sampling probabilities.

Data Types: `single` | `double` | `cell`

`'NBoot'` — Number of bootstrap replicas

0 (default) | positive integer

Number of bootstrap replicas for computation of confidence bounds, specified as the comma-separated pair consisting of `'NBoot'` and a positive integer. The default value 0 means the confidence bounds are not computed.

If labels and scores are cell arrays, this parameter must be 0 because `perfcurve` can use either cross-validation or bootstrap to compute confidence bounds.

Example: `'NBoot',500`

Data Types: `single` | `double`

`'BootType'` — Confidence interval type for `bootci`

`'bca'` (default) | `'norm` | `'per'` | `'cper'` | `'stud'`

Confidence interval type for `bootci` to use to compute confidence bounds, specified as the comma-separated pair consisting of `'BootType'` and one of the following:

- `'bca'` — Bias corrected and accelerated percentile method
- `'norm` or `'normal'` — Normal approximated interval with bootstrapped bias and standard error
- `'per'` or `'percentile'` — Percentile method
- `'cper'` or `'corrected percentile'` — Bias corrected percentile method
- `'stud'` or `'student'` — Studentized confidence interval

Example: `'BootType','cper'`

`'BootArg'` — Optional input arguments for `bootci`

[ ] (default) |

Optional input arguments for `bootci` to compute confidence bounds, specified as the comma-separated pair consisting of `'BootArg'` and one of the inputs or name-value pair arguments that `bootci` accepts.

Example: `'BootArg',{'stderr',stderr}` specifies the standard error of the bootstrap statistics

`'Options'` — Options for controlling the computation of confidence intervals

`[ ]` (default) | structure array returned by `statset`

Options for controlling the computation of confidence intervals, specified as the comma-separated pair consisting of `'Options'` and a structure array returned by `statset`. These options require Parallel Computing Toolbox. `perfcurve` uses this argument for computing pointwise confidence bounds only. To compute these bounds, you must pass cell arrays for labels and scores or set NBoot to a positive integer.

This table summarizes the available options.

Option	Description
`'UseParallel'`	• `false` — Serial computation (default). • `true` — Parallel computation. You need Parallel Computing Toolbox for this option to work.
`'UseSubstreams'`	• `false` — Do not use a separate substream for each iteration (default). • `true` — Use a separate substream for each iteration to compute in parallel in a reproducible fashion. To compute reproducibly, set `Streams` to a type allowing substreams: `'mlfg6331_64'` or `'mrg32k3a'`.
`'Streams'`	A `RandStream` object, or a cell array of such objects. If you specify `Streams`, use a single object, except when: • You have an open parallel pool. • `UseParallel` is `true`. • `UseSubstreams` is `false`.

Option	Description
	In that case, use a cell array of the same size as the parallel pool. If a parallel pool is not open, then `Streams` must supply a single random number stream.

If `'UseParallel'` is `true` and `'UseSubstreams'` is `false`, then the length of `'Streams'` must equal the number of workers used by `perfcurve`. If a parallel pool is already open, then the length of `'Streams'` is the size of the parallel pool. If a parallel pool is not already open, then MATLAB might open a pool for you, depending on your installation and preferences. To ensure more predictable results, use `parpool` and explicitly create a parallel pool before invoking `perfcurve` and setting `'Options',statset('UseParallel',true)`.

Example: `'Options',statset('UseParallel',true)`

Data Types: `struct`

Output Arguments

X — *x*-coordinates for the performance curve

vector, `fpr` (default) | *m*-by-3 matrix

x-coordinates for the performance curve, returned as a vector or an *m*-by-3 matrix. By default, X values are the false positive rate, FPR (fallout or 1 – specificity). To change X, use the XCrit name-value pair argument.

- If `perfcurve` does not compute the pointwise confidence bounds, or if it computes them using vertical averaging, then X is a vector.
- If `perfcurve` computes the confidence bounds using threshold averaging, then X is an *m*-by-3 matrix, where *m* is the number of fixed threshold values. The first column of X contains the mean value. The second and third columns contain the lower bound and the upper bound, respectively, of the pointwise confidence bounds.

Y — *y*-coordinates for the performance curve

vector, `tpr` (default) | *m*-by-3 matrix

y-coordinates for the performance curve, returned as a vector or an *m*-by-3 matrix. By default, Y values are the true positive rate, TPR (recall or sensitivity). To change Y, use YCrit name-value pair argument.

- If `perfcurve` does not compute the pointwise confidence bounds, then Y is a vector.
- If `perfcurve` computes the confidence bounds, then Y is an *m*-by-3 matrix, where *m* is the number of fixed X values or thresholds (T values). The first column of Y contains the mean value. The second and third columns contain the lower bound and the upper bound, respectively, of the pointwise confidence bounds.

`T` — Thresholds on classifier scores

vector | *m*-by-3 matrix

Thresholds on classifier scores for the computed values of X and Y, returned as a vector or *m*-by-3 matrix.

- If `perfcurve` does not compute the pointwise confidence bounds, or computes them using threshold averaging, then T is a vector.
- If `perfcurve` computes the confidence bounds using vertical averaging, T is an *m*-by-3 matrix, where *m* is the number of fixed X values. The first column of T contains the mean value. The second and third columns contain the lower bound, and the upper bound, respectively, of the pointwise confidence bounds.

For each threshold, `TP` is the count of true positive observations with scores greater than or equal to this threshold, and `FP` is the count of false positive observations with scores greater than or equal to this threshold. `perfcurve` defines negative counts, `TN` and `FN`, in a similar way. The function then sorts the thresholds in the descending order that corresponds to the ascending order of positive counts.

For the *m* distinct thresholds found in the array of scores, `perfcurve` returns the X, Y and T arrays with *m* + 1 rows. `perfcurve` sets elements `T(2:`*m*`+1)` to the distinct thresholds, and `T(1)` replicates `T(2)`. By convention, `T(1)` represents the highest `'reject all'` threshold, and `perfcurve` computes the corresponding values of X and Y for `TP = 0` and `FP = 0`. The `T(end)` value is the lowest `'accept all'` threshold for which `TN = 0` and `FN = 0`.

`AUC` — Area under the curve

scalar value | 3-by-1 vector

Area under the curve (AUC) for the computed values of X and Y, returned as a scalar value or a 3-by-1 vector.

- If `perfcurve` does not compute the pointwise confidence bounds, AUC is a scalar value.

- If `perfcurve` computes the confidence bounds using vertical averaging, AUC is a 3-by-1 vector. The first column of AUC contains the mean value. The second and third columns contain the lower bound and the upper bound, respectively, of the confidence bound.

For a perfect classifier, AUC = 1. For a classifier that randomly assigns observations to classes, AUC = 0.5.

If you set XVals to `'all'` (default), then `perfcurve` computes AUC using the returned X and Y values.

If XVals is a numeric array, then `perfcurve` computes AUC using X and Y values from all distinct scores in the interval, which are specified by the smallest and largest elements of XVals. More precisely, `perfcurve` finds X values for all distinct thresholds as if XVals were set to `'all'`, and then uses a subset of these (with corresponding Y values) between `min(XVals)` and `max(XVals)` to compute AUC.

`perfcurve` uses trapezoidal approximation to estimate the area. If the first or last value of X or Y are `NaN`s, then `perfcurve` removes them to allow calculation of AUC. This takes care of criteria that produce `NaN`s for the special `'reject all'` or `'accept all'` thresholds, for example, positive predictive value (PPV) or negative predictive value (NPV).

`OPTROCPT` — Optimal operating point of the ROC curve

1-by-2 array

Optimal operating point of the ROC curve, returned as a 1-by-2 array with false positive rate (FPR) and true positive rate (TPR) values for the optimal ROC operating point.

`perfcurve` computes OPTROCPT for the standard ROC curve only, and sets to `NaN`s otherwise. To obtain the optimal operating point for the ROC curve, `perfcurve` first finds the slope, S, using

$$S = \frac{\text{Cost}(P \mid N) - \text{Cost}(N \mid N)}{\text{Cost}(N \mid P) - \text{Cost}(P \mid P)} * \frac{N}{P}$$

- $\text{Cost}(N \mid P)$ is the cost of misclassifying a positive class as a negative class. $\text{Cost}(P \mid N)$ is the cost of misclassifying a negative class as a positive class.
- $P = TP + FN$ and $N = TN + FP$. They are the total instance counts in the positive and negative class, respectively.

`perfcurve` then finds the optimal operating point by moving the straight line with slope S from the upper left corner of the ROC plot (`FPR = 0`, `TPR = 1`) down and to the right, until it intersects the ROC curve.

SUBY — Values for negative subclasses

array

Values for negative subclasses, returned as an array.

- If you specify only one negative class, then SUBY is identical to Y.
- If you specify k negative classes, then SUBY is a matrix of size m-by-k, where m is the number of returned values for X and Y, and k is the number of negative classes. `perfcurve` computes Y values by summing counts over all negative classes.

SUBY gives values of the Y criterion for each negative class separately. For each negative class, `perfcurve` places a new column in SUBY and fills it with Y values for true negative (TN) and false positive (FP) counted just for this class.

SUBYNAMES — Negative class names

cell array

Negative class names, returned as a cell array.

- If you provide an input array of negative class names, , NegClass, then `perfcurve` copies names into SUBYNAMES.
- If you do not provide NegClass, then `perfcurve` extracts SUBYNAMES from the input labels. The order of SUBYNAMES is the same as the order of columns in SUBY. That is, `SUBY(:,1)` is for negative class `SUBYNAMES{1}`, `SUBY(:,2)` is for negative class `SUBYNAMES{2}`, and so on.

More About

Algorithms

Pointwise Confidence Bounds

If you supply cell arrays for labels and scores, or if you set NBoot to a positive integer, then `perfcurve` returns pointwise confidence bounds for X,Y,T, and AUC. You cannot

supply cell arrays for labels and scores and set NBoot to a positive integer at the same time.

`perfcurve` resamples data to compute confidence bounds using either cross validation or bootstrap.

- Cross-validation — If you supply cell arrays for labels and scores, then `perfcurve` uses cross-validation and treats elements in the cell arrays as cross-validation folds. labels can be a cell array of numeric vectors, logical vectors, character matrices, cell arrays of strings, or categorical vectors. All elements in `labels` must have the same type. scores can be a cell array of numeric vectors. The cell arrays for labels and scores must have the same number of elements. The number of labels in cell *j* of `labels` must be equal to the number of scores in cell *j* of `scores` for any *j* in the range from 1 to the number of elements in scores.
- Bootstrap — If you set NBoot to a positive integer *n*, `perfcurve` generates *n* bootstrap replicas to compute pointwise confidence bounds. If you use XCrit or YCrit to set the criterion for X or Y to an anonymous function, `perfcurve` can compute confidence bounds only using bootstrap.

`perfcurve` estimates the confidence bounds using one of two methods:

- Vertical averaging (VA) — `perfcurve` estimates confidence bounds on Y and T at fixed values of X. That is, `perfcurve` takes samples of the ROC curves for fixed X values, averages the corresponding Y and T values, and computes the standard errors. You can use the XVals name-value pair argument to fix the X values for computing confidence bounds. If you do not specify XVals, then `perfcurve` computes the confidence bounds at all X values.
- Threshold averaging (TA) — `perfcurve` takes samples of the ROC curves at fixed thresholds T for the positive class score, averages the corresponding X and Y values, and estimates the confidence bounds. You can use the TVals name-value pair argument to use this method for computing confidence bounds. If you set TVals to `'all'` or do not specify TVals or XVals, then `perfcurve` returns X, Y, and T values for all scores and computes pointwise confidence bounds for Y and X using threshold averaging.

When you compute the confidence bounds, Y is an *m*-by-3 array, where *m* is the number of fixed X values or thresholds (T values). The first column of Y contains the mean value. The second and third columns contain the lower bound and the upper bound, respectively, of the pointwise confidence bounds. AUC is a row vector with three elements, following the same convention. If `perfcurve` computes the confidence bounds

using VA, then T is an *m*-by-3 matrix, and X is a column vector. If `perfcurve` uses TA, then X is an *m*-by-3 matrix and T is a column-vector.

`perfcurve` returns pointwise confidence bounds. It does not return a simultaneous confidence band for the entire curve.

perms

Enumeration of permutations

Syntax

```
P = perms(v)
```

Description

`P = perms(v)`, where `v` is a row vector of length `n`, creates a matrix whose rows consist of all possible permutations of the `n` elements of `v`. The matrix `P` contains `n!` rows and `n` columns.

`perms` is only practical when `n` is less than about 11 (for `n = 11`, the output takes over 3 gigabytes).

Examples

```
perms([2 4 6])

ans =

   6   4   2
   6   2   4
   4   6   2
   4   2   6
   2   4   6
   2   6   4
```

`combnk`

piecewisedistribution class

Piecewise-defined distributions

Construction

`piecewisedistribution` is an abstract class. To construct a `piecewisedistribution` object, use the subclass constructor, `paretotails`.

Methods

boundary	Piecewise distribution boundaries
cdf	Cumulative distribution function for piecewise distribution
disp	Display piecewisedistribution object
display	Display piecewisedistribution object
icdf	Inverse cumulative distribution function for piecewise distribution
nsegments	Number of segments
pdf	Probability density function for piecewise distribution
random	Random numbers from piecewise distribution
segment	Segments containing values

Properties

Objects of the `piecewisedistribution` class have no properties accessible by dot indexing, `get` methods, or `set` methods. To obtain information about a `piecewisedistribution` object, use the appropriate method.

Copy Semantics

Value. To learn how this affects your use of the class, see Comparing Handle and Value Classes in the MATLAB Object-Oriented Programming documentation.

piecewisedistribution

Class: piecewisedistribution

Create piecewise distribution object

Description

`piecewisedistribution` is an abstract class, and you cannot create instances of it directly. You can create `paretotails` objects that are derived from this class.

See Also

`paretotails`

prob.PiecewiseLinearDistribution class

Package: prob
Superclasses: prob.ParametricTruncatableDistribution

Piecewise linear probability distribution object

Description

`prob.PiecewiseLinearDistribution` is an object consisting of a model description for a piecewise linear probability distribution. Create a probability distribution object with specified parameters using `makedist`.

Construction

`pd = makedist('PiecewiseLinear')` creates a piecewise linear probability distribution object using the default parameter values.

`pd = makedist('PiecewiseLinear','x',x,'Fx',Fx)` creates a piecewise linear probability distribution object using the specified values.

Input Arguments

x — Data values

1 (default) | vector of scalar values

Data values at which the cumulative distribution function (cdf) changes slope, specified as a vector of scalar values.

Data Types: `single` | `double`

Fx — cdf value

1 (default) | vector of scalar values

cdf value at each value in x, specified as a vector of scalar values. x and Fx must be the same size. The first value in the vector `Fx` must be `0`, and the last element must be `1`. `Fx` increases linearly between `x`(*j*) and `x`(*j*+1), for all *j*.

Data Types: `single` | `double`

Properties

x — Data values

vector of scalar values

Data values at which the cumulative distribution function (cdf) changes slope, stored as a vector of scalar values.

Data Types: `single | double`

Fx — cdf value

vector of scalar values

cdf value at each value in `x`, stored as a vector of scalar values.

Data Types: `single | double`

DistributionName — Probability distribution name

probability distribution name string

Probability distribution name, stored as a valid probability distribution name string. This property is read-only.

Data Types: `char`

IsTruncated — Logical flag for truncated distribution

`0 | 1`

Logical flag for truncated distribution, stored as a logical value. If `IsTruncated` equals `0`, the distribution is not truncated. If `IsTruncated` equals `1`, the distribution is truncated. This property is read-only.

Data Types: `logical`

NumParameters — Number of parameters

positive integer value

Number of parameters for the probability distribution, stored as a positive integer value. This property is read-only.

Data Types: `single | double`

ParameterDescription — Distribution parameter descriptions

cell array of strings

Distribution parameter descriptions, stored as a cell array of strings. Each cell contains a short description of one distribution parameter. This property is read-only.

Data Types: `char`

`ParameterNames` — Distribution parameter names
cell array of strings

Distribution parameter names, stored as a cell array of strings. This property is read-only.

Data Types: `char`

`ParameterValues` — Distribution parameter values
vector of scalar values

Distribution parameter values, stored as a vector. This property is read-only.

Data Types: `single | double`

`Truncation` — Truncation interval
vector of scalar values

Truncation interval for the probability distribution, stored as a vector containing the lower and upper truncation boundaries. This property is read-only.

Data Types: `single | double`

Methods

Inherited Methods

cdf	Cumulative distribution function of probability distribution object
icdf	Inverse cumulative distribution function of probability distribution object
iqr	Interquartile range of probability distribution object

median	Median of probability distribution object
pdf	Probability density function of probability distribution object
random	Generate random numbers from probability distribution object
truncate	Truncate probability distribution object
mean	Mean of probability distribution object
std	Standard deviation of probability distribution object
var	Variance of probability distribution object

Definitions

Piecewise Linear Distribution

The piecewise linear distribution is a nonparametric probability distribution created using a piecewise linear representation of the cumulative distribution function (cdf). The options specified for the piecewise linear distribution specify the form of the cdf. The probability density function (pdf) is a step function.

Examples

Create a Piecewise Linear Distribution Object Using Default Parameters

Create a piecewise linear distribution object using the default parameter values.

```
pd = makedist('PiecewiseLinear')
```

```
pd =
```

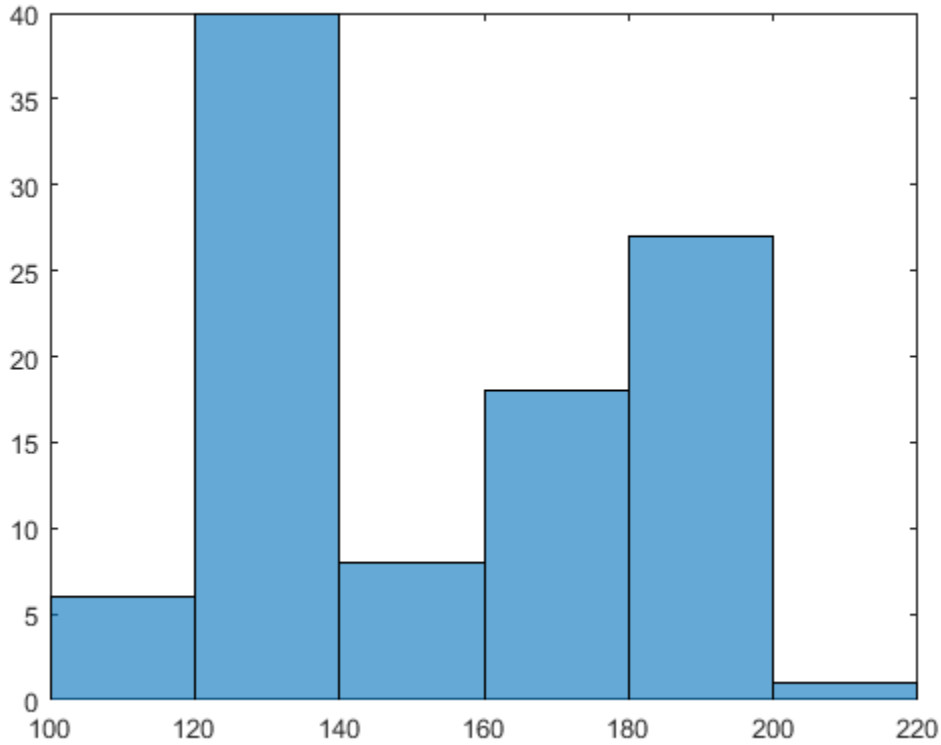
```
  PiecewiseLinearDistribution

F(0) = 0
F(1) = 1
```

Create a Piecewise Linear Distribution Object Using Specified Parameters

Load the sample data. Visualize the patient weight data using a histogram.

```
load hospital
histogram(hospital.Weight)
```



The histogram shows that the data has two modes, one for female patients and one for male patients.

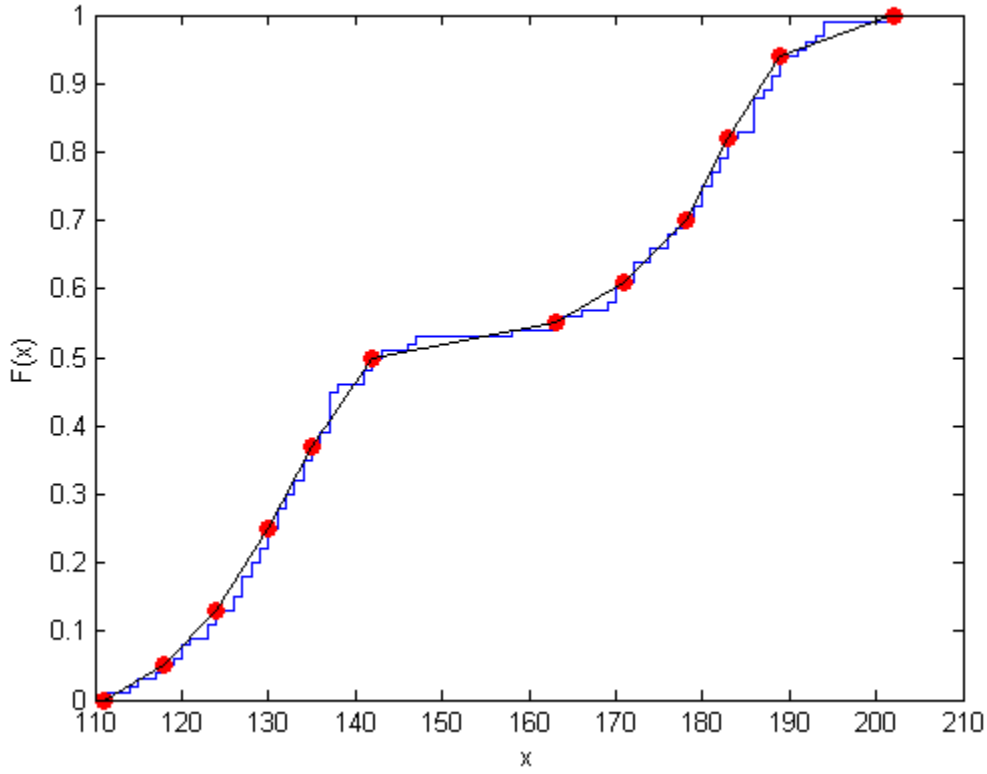
Compute the empirical cumulative distribution function (ecdf) for the data.

```
[f,x] = ecdf(hospital.Weight);
```

Construct a piecewise linear approximation to the ecdf and plot both functions.

```
f = f(1:5:end); % keep a less dense grid of points
x = x(1:5:end);

figure;
ecdf(hospital.Weight)
hold on
plot(x,f,'ro','MarkerFace','r') % overlay grid
plot(x,f,'k') % show interpolation
```



Create a piecewise linear probability distribution object using the piecewise approximation of the ecdf.

```
pd = makedist('PiecewiseLinear','x',x,'Fx',f)
```

```
pd =

  PiecewiseLinearDistribution

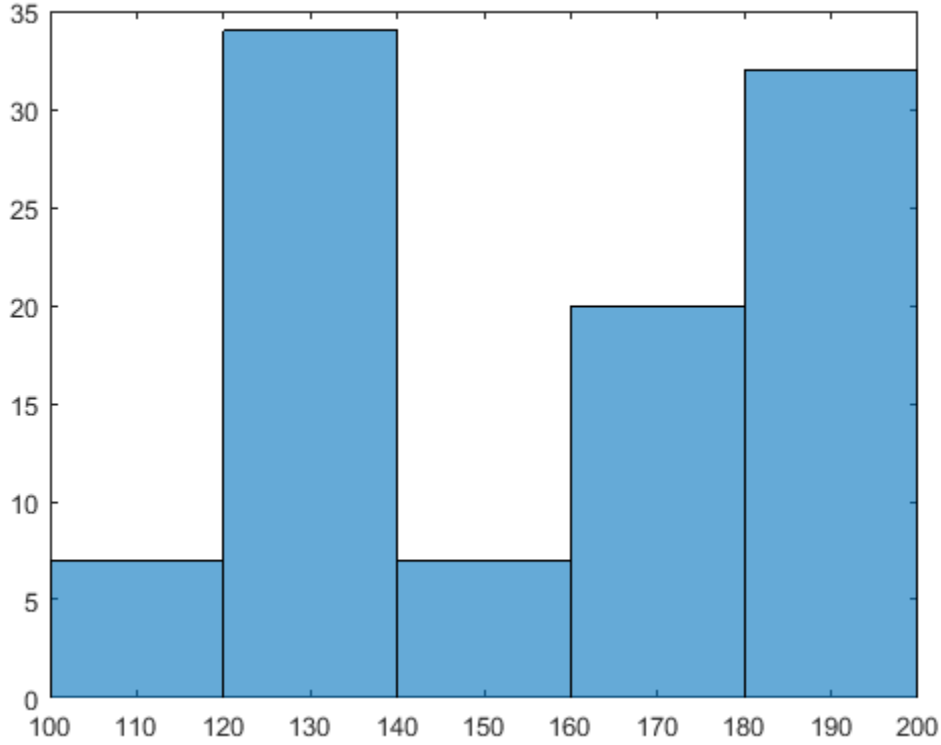
F(111) = 0
F(118) = 0.05
F(124) = 0.13
F(130) = 0.25
F(135) = 0.37
F(142) = 0.5
F(163) = 0.55
F(171) = 0.61
F(178) = 0.7
F(183) = 0.82
F(189) = 0.94
F(202) = 1
```

Generate 100 random numbers from the distribution.

```
rng default  % For reproducibility
rw = random(pd,100,1);
```

Plot the random numbers to visually compare their distribution to the original data.

```
figure;
histogram(rw)
```



The random numbers generated from the piecewise linear distribution have the same bimodal distribution as the original data.

plot

Class: clustering.evaluation.ClusterCriterion
Package: clustering.evaluation

Plot clustering evaluation object criterion values

Syntax

```
plot(eva)
h = plot(eva)
```

Description

`plot(eva)` displays a plot of the criterion values versus the number of clusters, based on the values stored in the clustering evaluation object eva.

`h = plot(eva)` returns a handle to the plot line.

Input Arguments

`eva` — Clustering evaluation data

clustering evaluation object

Clustering evaluation data, specified as a clustering evaluation object. Create a clustering evaluation object using `evalclusters`.

Output Arguments

`h` — Handle to plot line

scalar value

Handle to the plot line, returned as a scalar value.

Examples

Plot the Clustering Evaluation Criterion Values

Plot the criterion values versus the number of clusters for each clustering solution stored in a clustering evaluation object.

Load the sample data.

```
load fisheriris;
```

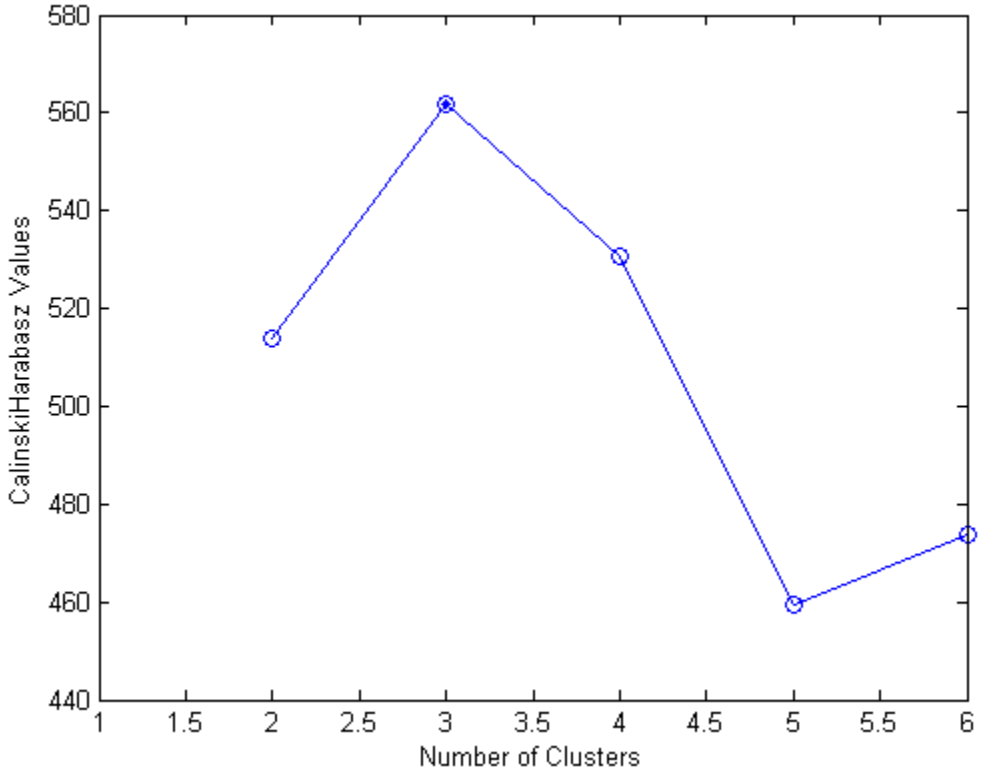
The data contains length and width measurements from the sepals and petals of three species of iris flowers.

Create a clustering evaluation object. Cluster the data using `kmeans`, and evaluate the optimal number of clusters using the Calinski-Harabasz criterion.

```
rng('default');  % For reproducibility
eva = evalclusters(meas,'kmeans','CalinskiHarabasz','KList',[1:6]);
```

Plot the Calinski-Harabasz criterion values for each number of clusters tested.

```
figure;
plot(eva);
```



The plot shows that the highest Calinski-Harabasz value occurs at three clusters, suggesting that the optimal number of clusters is three.

See Also

`evalclusters`

plot

Class: LinearModel

Scatter plot or added variable plot of linear model

Syntax

```
plot(mdl)
h = plot(mdl)
```

Description

`plot(mdl)` creates a plot of the fitted linear model. The plot type depends on the number of predictor variables.

- If there is just one predictor variable, `plot` creates a scatter plot of the data along with a fitted curve and confidence bounds.
- If there are multiple predictor variables, `plot` creates an added variable plot.
- If there are no predictors, `plot` creates a histogram of the residuals.

`h = plot(mdl)` returns handles to the lines in the plot.

Input Arguments

`mdl`

Linear model, as constructed by `fitlm` or `stepwiselm`.

Output Arguments

`h`

Vector of handles to lines or patches in the plot.

Definitions

Added Variable Plot, Adjusted Response

An added variable plot illustrates the incremental effect on the response of specified terms by removing the effects of all other terms. The slope of the fitted line is the coefficient of the linear combination of the specified terms projected onto the best-fitting direction. The adjusted response includes the constant (intercept) terms, and averages out all other terms.

Examples

Create an Added Variable Plot

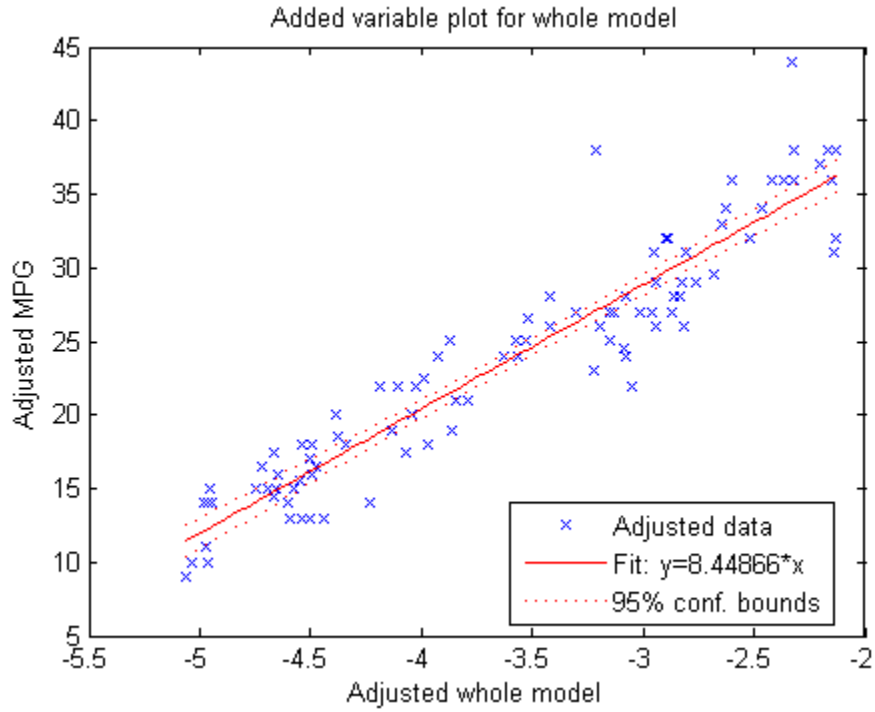
Create a model of car mileage as a function of weight and model year. Then create a plot to see the significance of the model.

Create a linear model of mileage from the `carsmall` data.

```
load carsmall
tbl = table(MPG,Weight);
tbl.Year = ordinal(Model_Year);
mdl = fitlm(tbl,'MPG ~ Year + Weight^2');
```

Create an added variable plot.

```
plot(mdl)
```



The plot illustrates that the model is significant—a horizontal line does not fit between the confidence bounds.

Alternatives

Use `plotAdded` to select particular predictors for an added variable plot.

plot

Class: RepeatedMeasuresModel

Plot data with optional grouping

Syntax

```
plot(rm)
plot(rm,Name,Value)
H = plot( ___ )
```

Description

`plot(rm)` plots the measurements in the repeated measures model rm for each subject as a function of time. If there is a single numeric within-subjects factor, `plot` uses the values of that factor as the time values. Otherwise, `plot` uses the discrete values 1 through *r* as the time values, where *r* is the number of repeated measurements.

`plot(rm,Name,Value)` also plots the measurements in the repeated measures model rm, with additional options specified by one or more Name,Value pair arguments.

For example, you can specify the factors to group by or change the line colors.

`H = plot( ___ )` returns handles, `H`, to the plotted lines.

Input Arguments

`rm` — Repeated measures model

`RepeatedMeasuresModel` object

Repeated measures model, returned as a `RepeatedMeasuresModel` object.

For properties and methods of this object, see `RepeatedMeasuresModel`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'Group'` — Name of between-subject factor or factors

string | cell array of strings

Name of between-subject factor or factors, specified as the comma-separated pair consisting of `'Group'` and a string or cell array of strings. This name-value pair argument groups the lines according to the factor values.

For example, if you have two between-subject factors, drug and sex, and you want to group the lines in the plot according to them, you can specify these factors as follows.

Example: `'Group',{'Drug','Sex'}`

Data Types: `char | cell`

`'Marker'` — Marker to use for each group

cell array of strings

Marker to use for each group, specified as the comma-separated pair consisting of `'Marker'` and a cell array of strings.

For example, if you have two between-subject factors, drug and sex, with each having two groups, you can specify `o` as the marker for the groups of drug and `x` as the marker for the groups of sex as follows.

Example: `'Marker',{'o','o','x','x'}`

Data Types: `cell`

`'Color'` — Color for each group

string | cell array of strings | rows of a three-column RGB matrix

Color for each group, specified as the comma-separated pair consisting of `'Color'` and a string, cell array of strings, or rows of a three-column RGB matrix.

For example, if you have two between-subject factors, drug and sex, with each having two groups, you can specify red as the color for the groups of drug and blue as the color for the groups of sex as follows.

Example: `'Color','rrbb'`

Data Types: `single | double | cell`

`'LineStyle'` — Line style for each group

cell array of strings

Line style for each group, specified as the comma-separated pair consisting of `'LineStyle'` and a cell array of strings.

For example, if you have two between-subject factors, drug and sex, with each having two groups, you can specify `-` as the line style of one group and `:` as the line style for the other group as follows.

Example: `'LineStyle',{'-' ':' '-' ':'}`

Data Types: `cell`

Output Arguments

`H` — Handle to plotted lines

handle

Handle to plotted lines, returned as a handle.

Examples

Plot Data by Group

Load the sample data.

```
load fisheriris
```

The column vector `species` consists of iris flowers of three different species: setosa, versicolor, and virginica. The double matrix `meas` consists of four types of measurements on the flowers: the length and width of sepals and petals in centimeters, respectively.

Store the data in a table array.

```
t = table(species,meas(:,1),meas(:,2),meas(:,3),meas(:,4),...
'VariableNames',{'species','meas1','meas2','meas3','meas4'});
```

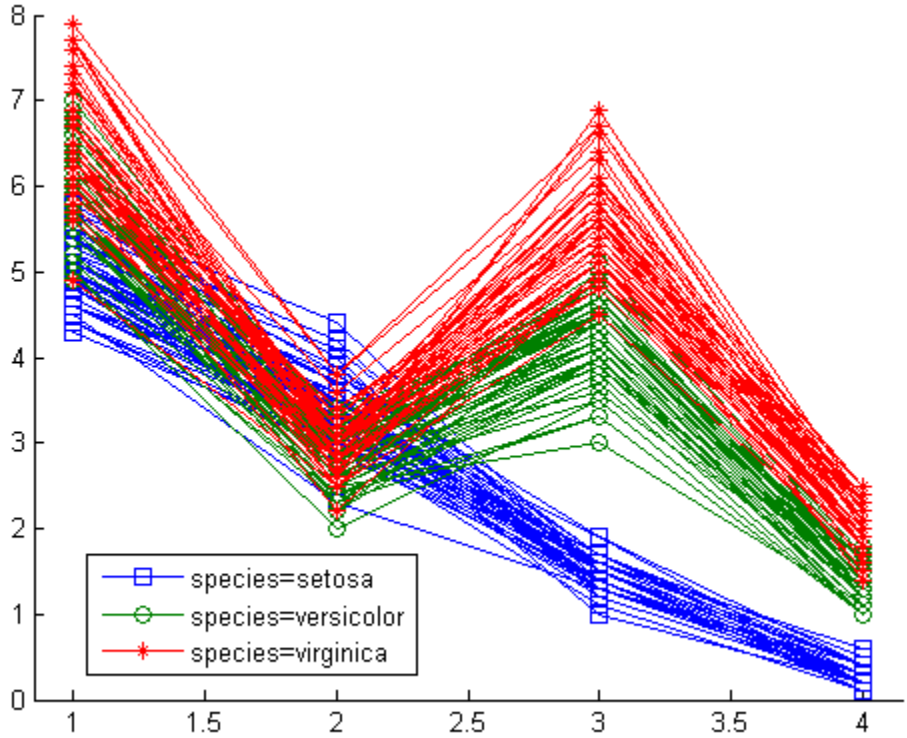
```
Meas = dataset([1 2 3 4]','VarNames',{'Measurements'});
```

Fit a repeated measures model, where the measurements are the responses and the species is the predictor variable.

```
rm = fitrm(t,'meas1-meas4~species','WithinDesign',Meas);
```

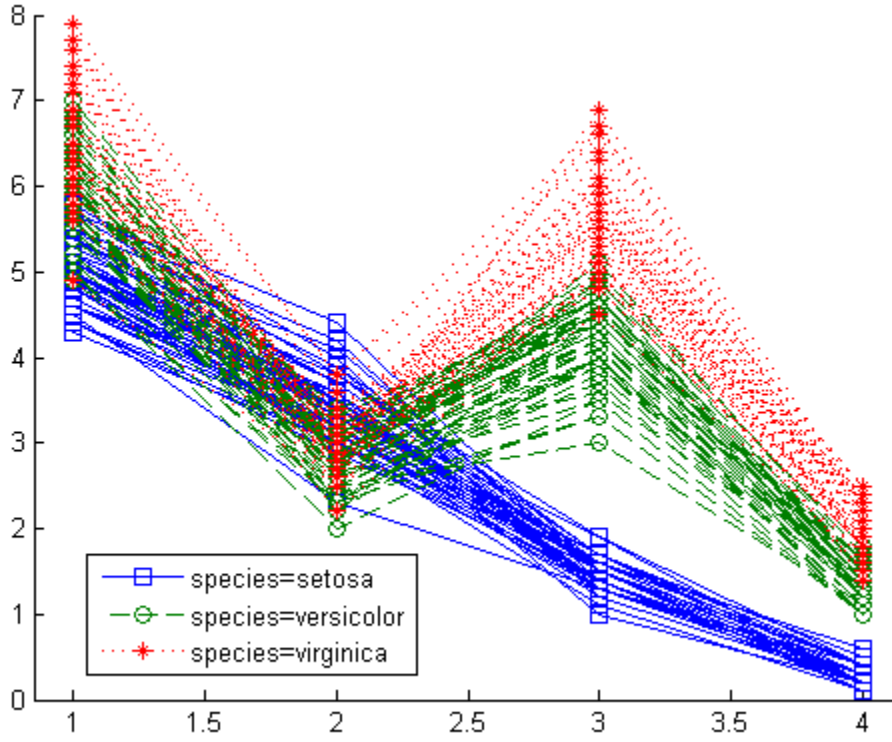
Plot data grouped by the factor species.

```
plot(rm,'group','species')
```



Change the line style for each group.

```
plot(rm,'group','species','LineStyle',{'-','--',':'})
```



Plot Data Grouped by Two Factors

Load the sample data.

```
load repeatedmeas
```

The table `between` includes the between-subject variables age, IQ, group, gender, and eight repeated measures $y1$ through $y8$ as responses. The table `within` includes the within-subject variables $w1$ and $w2$. This is simulated data.

Fit a repeated measures model, where the repeated measures $y1$ through $y8$ are the responses, and age, IQ, group, gender, and the group-gender interaction are the predictor variables. Also specify the within-subject design matrix.

```
rm = fitrm(between,'y1-y8 ~ Group*Gender + Age + IQ','WithinDesign',within);
```

Plot data with `Group` coded by color and `Gender` coded by line type.

```
plot(R,'group',{'Group' 'Gender'},'Color','rrbbgg',...
               'LineStyle',{'-' ':' '-' ':' '-' ':'},'Marker','.')
```

plotAdded

Class: LinearModel

Added variable plot or leverage plot for linear model

Syntax

```
plotAdded(mdl)
plotAdded(mdl,coef)
h = plotAdded(mdl,...)
h = plotAdded(mdl,coef,Name,Value)
```

Description

`plotAdded(mdl)` produces a generalized added variable plot for all terms in `mdl` except the constant term.

`plotAdded(mdl,coef)` produces an added variable plot for the `coef` terms in `mdl`, after adjusting for all other terms.

`h = plotAdded(mdl,...)` returns handles to the lines in the plot.

`h = plotAdded(mdl,coef,Name,Value)` plots with additional options specified by one or more Name,Value pair arguments.

Tips

- For many plots, the Data Cursor tool in the figure window displays the *x* and *y* values for any data point, along with the observation name or number.

Input Arguments

`mdl`

Linear model, as constructed by `fitlm` or `stepwiselm`.

`coef`

Coefficients in `mdl`. Represent as:

- String giving a single coefficient name
- Vector of coefficient numbers in the `mdl.CoefficientNames` property

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Note: The plot property name-value pairs apply to the first returned handle `h(1)`.

`'Color'`

Color of the line or marker, a string or `ColorSpec` specification. For details, see `linespec`.

`'LineStyle'`

Type of line, a string or Chart Line Properties specification. For details, see `linespec`.

`'LineWidth'`

Width of the line or edges of filled area, in points, a positive scalar. One point is 1/72 inch.

Default: `0.5`

`'MarkerEdgeColor'`

Color of the marker or edge color for filled markers, a string or `ColorSpec` specification. For details, see `linespec`.

`'MarkerFaceColor'`

Color of the marker face for filled markers, a string or `ColorSpec` specification. For details, see `linespec`.

'MarkerSize'

Size of the marker in points, a strictly positive scalar. One point is 1/72 inch.

Output Arguments

h

Vector of handles to lines or patches in the plot.

Definitions

Added Variable Plot, Adjusted Response

An added variable plot illustrates the incremental effect on the response of specified terms by removing the effects of all other terms. The slope of the fitted line is the coefficient of the linear combination of the specified terms projected onto the best-fitting direction. The adjusted response includes the constant (intercept) terms, and averages out all other terms.

Examples

Create an Added Variable Plot

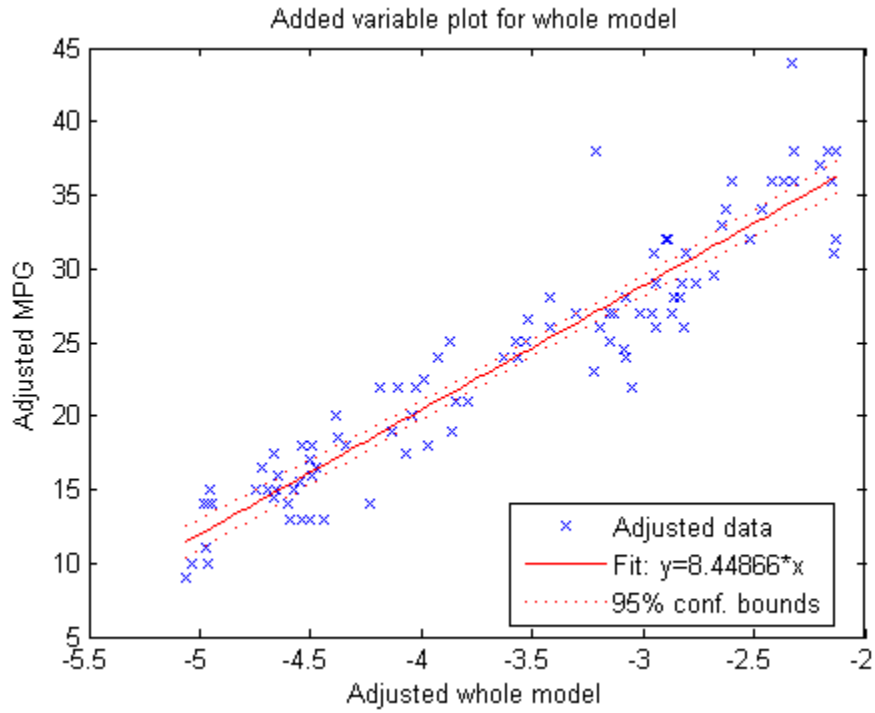
Create a model of car mileage as a function of weight and model year. Then create a plot to see the significance of the model.

Create a linear model of mileage from the `carsmall` data.

```
load carsmall
ds = dataset(MPG,Weight);
ds.Year = ordinal(Model_Year);
mdl = fitlm(ds,'MPG ~ Year + Weight^2');
```

Create an added variable plot.

```
plotAdded(mdl)
```



The plot illustrates that the model is significant—a horizontal line does not fit between the confidence bounds.

Create an Added Variable Plot for Particular Variables

Create a model of car mileage as a function of weight and model year. Then create a plot to see the effect of the weight terms (`Weight` and `Weight^2`).

Create a linear model of mileage from the `carsmall` data.

```
load carsmall
ds = dataset(MPG,Weight);
ds.Year = ordinal(Model_Year);
mdl = fitlm(ds,'MPG ~ Year + Weight^2');
```

Find the terms in the model corresponding to the `Weight` and `Weight^2`.

```
mdl.CoefficientNames
```

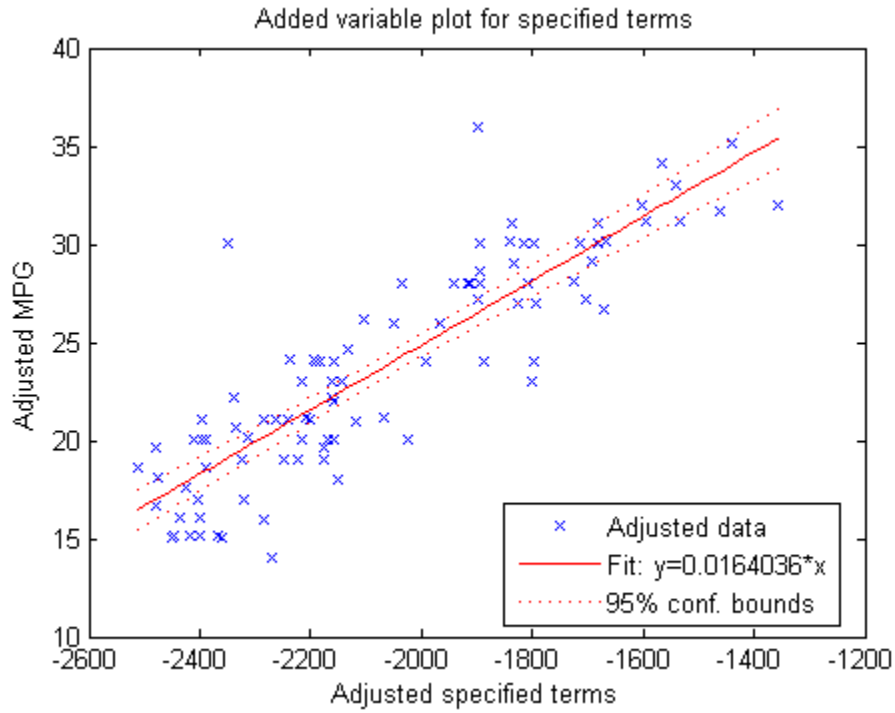
```
ans =

    '(Intercept)' 'Weight' 'Year_76' 'Year_82' 'Weight^2'
```

The weight terms are 2 and 5.

Create an added variable plot with the weight terms.

```
coef = [2 5];
plotAdded(mdl,coef)
```



The plot illustrates that the weight terms are significant—a horizontal line does not fit between the confidence bounds.

How To

- “Linear Regression” on page 9-11

plotAdjustedResponse

Class: LinearModel

Adjusted response plot for linear regression model

Syntax

```
plotAdjustedResponse(mdl,var)
h = plotAdjustedResponse(mdl,var)
h = plotAdjustedResponse(mdl,var,Name,Value)
```

Description

`plotAdjustedResponse(mdl,var)` gives an adjusted response plot for the variable `var` in the `mdl` regression model.

`h = plotAdjustedResponse(mdl,var)` returns handles to the lines in the plot.

`h = plotAdjustedResponse(mdl,var,Name,Value)` plots with additional options specified by one or more Name,Value pair arguments.

Tips

- For many plots, the Data Cursor tool in the figure window displays the *x* and *y* values for any data point, along with the observation name or number.

Input Arguments

`mdl`

Linear model, as constructed by `fitlm` or `stepwiselm`.

`var`

Variable name, or scalar index of variable in `mdl.CoefficientNames`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Note: The plot property name-value pairs apply to the first returned handle `h(1)`.

`'Color'`

Color of the line or marker, a string or `ColorSpec` specification. For details, see `linespec`.

`'LineStyle'`

Type of line, a string or Chart Line Properties specification. For details, see `linespec`.

`'LineWidth'`

Width of the line or edges of filled area, in points, a positive scalar. One point is 1/72 inch.

Default: `0.5`

`'MarkerEdgeColor'`

Color of the marker or edge color for filled markers, a string or `ColorSpec` specification. For details, see `linespec`.

`'MarkerFaceColor'`

Color of the marker face for filled markers, a string or `ColorSpec` specification. For details, see `linespec`.

`'MarkerSize'`

Size of the marker in points, a strictly positive scalar. One point is 1/72 inch.

Output Arguments

h

Vector of handles to lines or patches in the plot.

Definitions

Adjusted Response Plot

The adjusted response plot shows the fitted response as a function of `var`, with the other predictors averaged out by averaging the fitted values over the data used in the fit. Adjusted data points are computed by adding the residual to the adjusted fitted value for each observation.

Examples

Plot Adjusted Responses

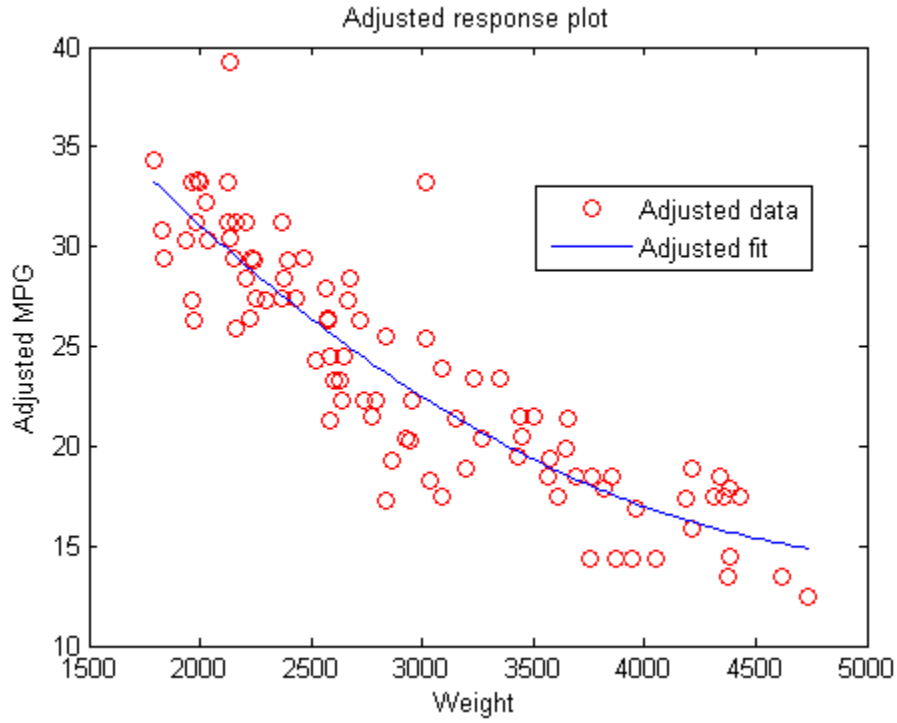
Plot the adjusted responses of a fitted linear model.

Load the `carsmall` data and fit a linear model of the mileage as a function of model year, weight, and weight squared.

```
load carsmall
ds = dataset(MPG,Weight);
ds.Year = ordinal(Model_Year);
mdl = fitlm(ds,'MPG ~ Year + Weight^2');
```

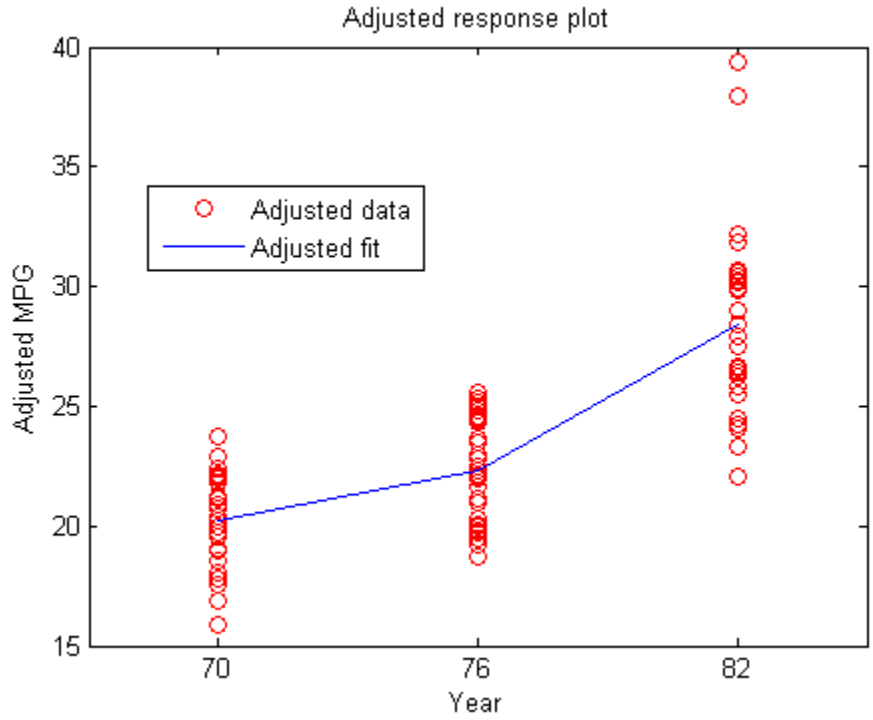
Plot the effect of `'Weight'` averaged over `Year` values.

```
plotAdjustedResponse(mdl,'Weight')
```



Plot the effect of `Year` averaged over `'Weight'` values. Include the `h` output.

```
h = plotAdjustedResponse(mdl,'Year');
```



Change the adjusted data to black `x` instead of red `o`.

```
set(h(1),'Marker','x','Color','k')
```

plotDiagnostics

Class: GeneralizedLinearModel

Plot diagnostics of generalized linear regression model

Syntax

```
plotDiagnostics(mdl)
plotDiagnostics(mdl,plottype)
h = plotDiagnostics(...)
h = plotDiagnostics(mdl,plottype,Name,Value)
```

Description

`plotDiagnostics(mdl)` plots diagnostics from the `mdl` linear model using leverage as the plot type.

`plotDiagnostics(mdl,plottype)` plots diagnostics from the `mdl` generalized linear model in a plot of type `plottype`.

`h = plotDiagnostics(...)` returns handles to the lines in the plot.

`h = plotDiagnostics(mdl,plottype,Name,Value)` plots with additional options specified by one or more Name,Value pair arguments.

Tips

- For many plots, the Data Cursor tool in the figure window displays the *x* and *y* values for any data point, along with the observation name or number.

Input Arguments

`mdl`

Generalized linear model, as constructed by `fitglm` or `stepwiseglm`.

`plottype`

String specifying the type of plot:

`'contour'`	Residual vs. leverage with overlayed Cook's contours
`'cookd'`	Cook's distance
`'leverage'`	Leverage (diagonal of Hat matrix)

Default: `'leverage'`

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Note: The plot property name-value pairs apply to the first returned handle `h(1)`.

`'Color'`

Color of the line or marker, a string or `ColorSpec` specification. For details, see `linespec`.

`'LineStyle'`

Type of line, a string or Chart Line Properties specification. For details, see `linespec`.

`'LineWidth'`

Width of the line or edges of filled area, in points, a positive scalar. One point is 1/72 inch.

Default: `0.5`

`'MarkerEdgeColor'`

Color of the marker or edge color for filled markers, a string or `ColorSpec` specification. For details, see `linespec`.

'MarkerFaceColor'

Color of the marker face for filled markers, a string or `ColorSpec` specification. For details, see `linespec`.

'MarkerSize'

Size of the marker in points, a strictly positive scalar. One point is 1/72 inch.

Output Arguments

h

Vector of handles to lines or patches in the plot.

Definitions

Hat Matrix

The *hat matrix H* is defined in terms of the data matrix X and a diagonal weight matrix W:
$H = X(X^TWX)^{-1}X^TW^T$.

W has diagonal elements w_i:

$$w_i = \frac{g'(\mu_i)}{\sqrt{V(\mu_i)}},$$

where

- g is the link function mapping y_i to x_ib.
- g' is the derivative of the link function g.
- V is the variance function.

- μ_i is the ith mean.

The diagonal elements H_{ii} satisfy

$$0 \le h_{ii} \le 1$$
$$\sum_{i=1}^{n} h_{ii} = p,$$

where n is the number of observations (rows of X), and p is the number of coefficients in the regression model.

Leverage

The *leverage* of observation i is the value of the ith diagonal term, h_{ii}, of the hat matrix H. Because the sum of the leverage values is p (the number of coefficients in the regression model), an observation i can be considered to be an outlier if its leverage substantially exceeds p/n, where n is the number of observations.

Cook's Distance

The Cook's distance D_i of observation i is

$$D_i = w_i \frac{e_i^2}{p\hat{\varphi}} \frac{h_{ii}}{\left(1-h_{ii}\right)^2},$$

where

- $\hat{\varphi}$ is the dispersion parameter (estimated or theoretical).
- e_i is the linear predictor residual, $g\left(y_i\right) - x_i\hat{\beta}$, where
  - g is the link function.
  - y_i is the observed response.
  - x_i is the observation.

  - $\hat{\beta}$ is the estimated coefficient vector.
- p is the number of coefficients in the regression model.
- h_{ii} is the ith diagonal element of the Hat Matrix H.

Examples

Diagnostic Plots for Generalized Linear Models

Create leverage and Cook's distance plots of a fitted generalized linear model.

Generate artificial data for the model, Poisson random numbers with two underlying predictors `X(1)` and `X(2)`.

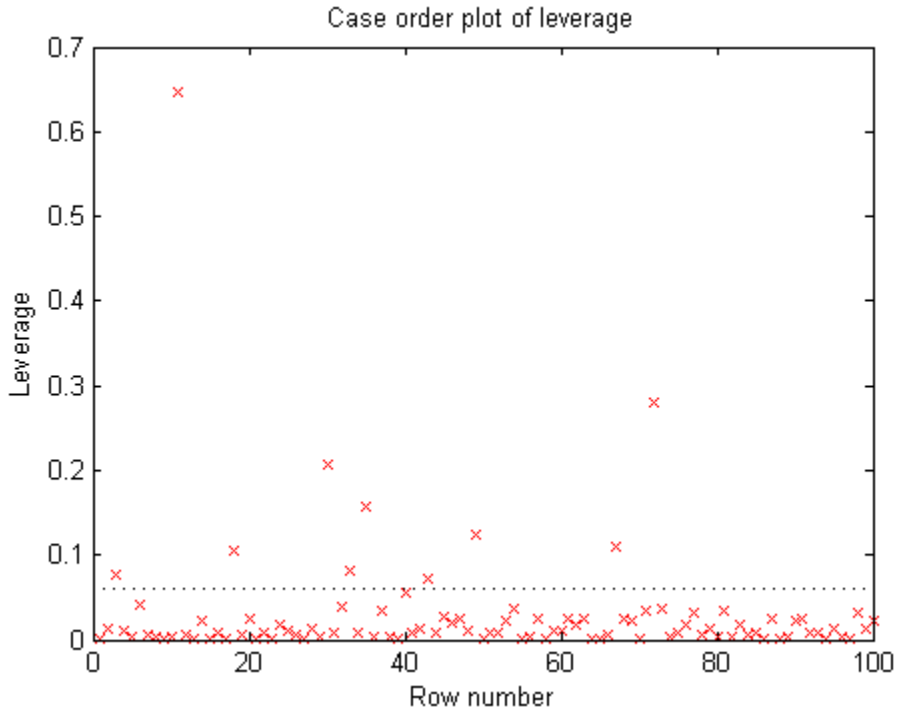
```
rng('default') % for reproducibility
rndvars = randn(100,2);
X = [2+rndvars(:,1),rndvars(:,2)];
mu = exp(1 + X*[1;2]);
y = poissrnd(mu);
```

Create a generalized linear regression model of Poisson data.

```
mdl = fitglm(X,y,...
    'y ~ x1 + x2','distr','poisson');
```

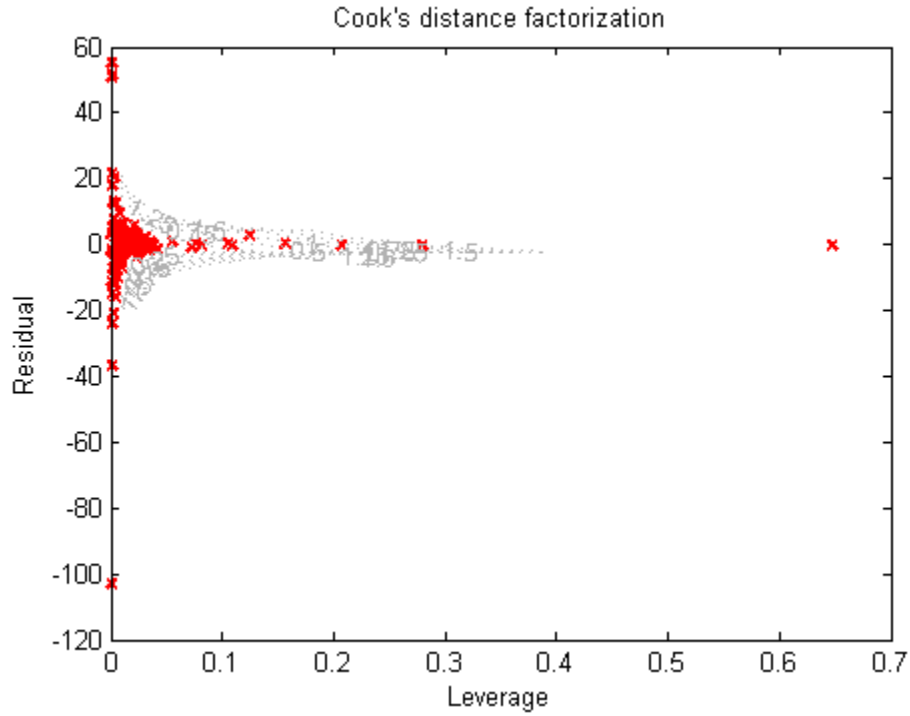
Create a leverage plot.

```
plotDiagnostics(mdl)
```



Create a contour plot with Cook's distance.

```
plotDiagnostics(mdl,'contour')
```



- “Diagnostic Plots” on page 10-25

More About

- “Generalized Linear Models” on page 10-12

plotDiagnostics

Class: LinearModel

Plot diagnostics of linear regression model

Syntax

```
plotDiagnostics(mdl)
plotDiagnostics(mdl,plottype)
h = plotDiagnostics(...)
h = plotDiagnostics(mdl,plottype,Name,Value)
```

Description

`plotDiagnostics(mdl)` plots diagnostics from the `mdl` linear model using scaled delete-1 fitted values.

`plotDiagnostics(mdl,plottype)` plots diagnostics in a plot of type `plottype`.

`h = plotDiagnostics(...)` returns handles to the lines in the plot.

`h = plotDiagnostics(mdl,plottype,Name,Value)` plots with additional options specified by one or more Name,Value pair arguments.

Tips

- For many plots, the Data Cursor tool in the figure window displays the *x* and *y* values for any data point, along with the observation name or number.

Input Arguments

`mdl`

Linear model, as constructed by `fitlm` or `stepwiselm`.

`plottype`

String specifying the type of plot:

`'contour'`	Residual vs. leverage with overlayed Cook's contours
`'cookd'`	Cook's distance
`'covratio'`	Delete-1 ratio of determinant of covariance
`'dfbetas'`	Scaled delete-1 coefficient estimates
`'dffits'`	Scaled delete-1 fitted values
`'leverage'`	Leverage
`'s2_i'`	Delete-1 variance estimate

Delete-1 means compute a new model without the current observation. If the delete-1 calculation differs significantly from the model using all observations, then the observation is influential.

Default: `'leverage'`

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Note: The plot property name-value pairs apply to the first returned handle `h(1)`.

`'Color'`

Color of the line or marker, a string or `ColorSpec` specification. For details, see `linespec`.

`'LineStyle'`

Type of line, a string or Chart Line Properties specification. For details, see `linespec`.

`'LineWidth'`

Width of the line or edges of filled area, in points, a positive scalar. One point is 1/72 inch.

Default: `0.5`

`'MarkerEdgeColor'`

Color of the marker or edge color for filled markers, a string or `ColorSpec` specification. For details, see `linespec`.

`'MarkerFaceColor'`

Color of the marker face for filled markers, a string or `ColorSpec` specification. For details, see `linespec`.

`'MarkerSize'`

Size of the marker in points, a strictly positive scalar. One point is 1/72 inch.

Output Arguments

`h`

Vector of handles to lines or patches in the plot.

Definitions

Hat Matrix

The *hat matrix H* is defined in terms of the data matrix *X*:
$H = X(X^TX)^{-1}X^T$.

The diagonal elements H_{ii} satisfy

$$0 \le h_{ii} \le 1$$

$$\sum_{i=1}^{n} h_{ii} = p,$$

where n is the number of observations (rows of X), and p is the number of coefficients in the regression model.

Leverage

The *leverage* of observation i is the value of the ith diagonal term, h_{ii}, of the hat matrix H. Because the sum of the leverage values is p (the number of coefficients in the regression model), an observation i can be considered to be an outlier if its leverage substantially exceeds p/n, where n is the number of observations.

Cook's Distance

Cook's distance is the scaled change in fitted values. Each element in `CooksDistance` is the normalized change in the vector of coefficients due to the deletion of an observation. The Cook's distance, D_i, of observation i is

$$D_i = \frac{\sum_{j=1}^{n} \left(\hat{y}_j - \hat{y}_{j(i)}\right)^2}{p\,MSE},$$

where

- $\hat{y}_j$ is the jth fitted response value.
- $\hat{y}_{j(i)}$ is the jth fitted response value, where the fit does not include observation i.
- MSE is the mean squared error.
- p is the number of coefficients in the regression model.

Cook's distance is algebraically equivalent to the following expression:

$$D_i = \frac{r_i^2}{p\,MSE}\left(\frac{h_{ii}}{\left(1-h_{ii}\right)^2}\right),$$

where r_i is the ith residual, and h_{ii} is the ith leverage value.

`CooksDistance` is an n-by-1 column vector in the `Diagnostics` table of the `LinearModel` object.

Examples

Leverage Plot of Linear Model

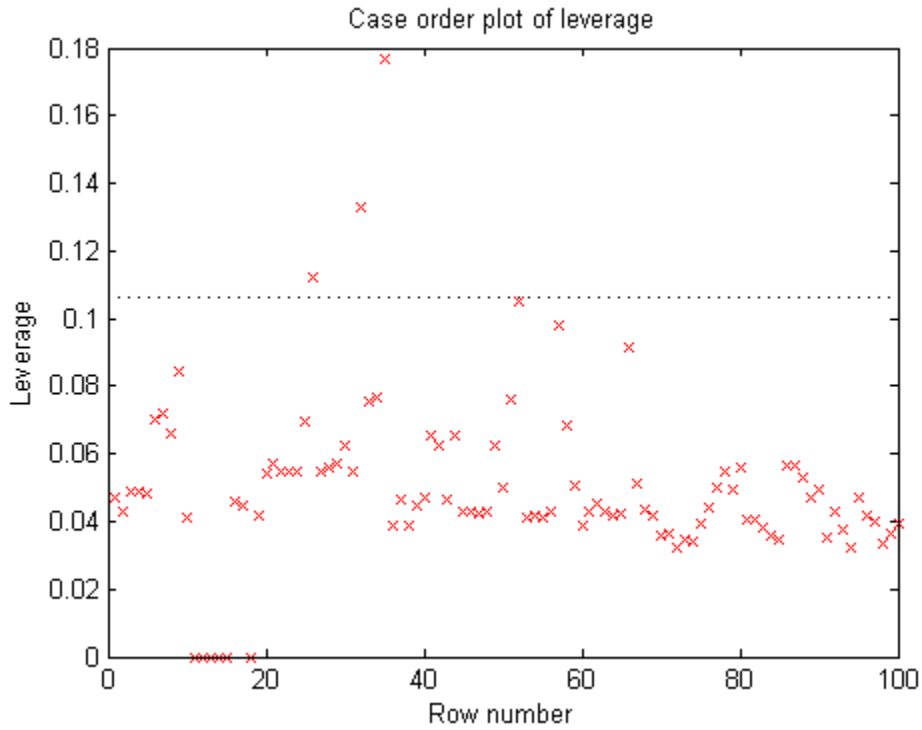
Plot the leverage values of observations in a fitted model.

Load the `carsmall` data and fit a linear model of the mileage as a function of model year, weight, and weight squared.

```
load carsmall
ds = dataset(MPG,Weight);
ds.Year = ordinal(Model_Year);
mdl = fitlm(ds,'MPG ~ Year + Weight^2');
```

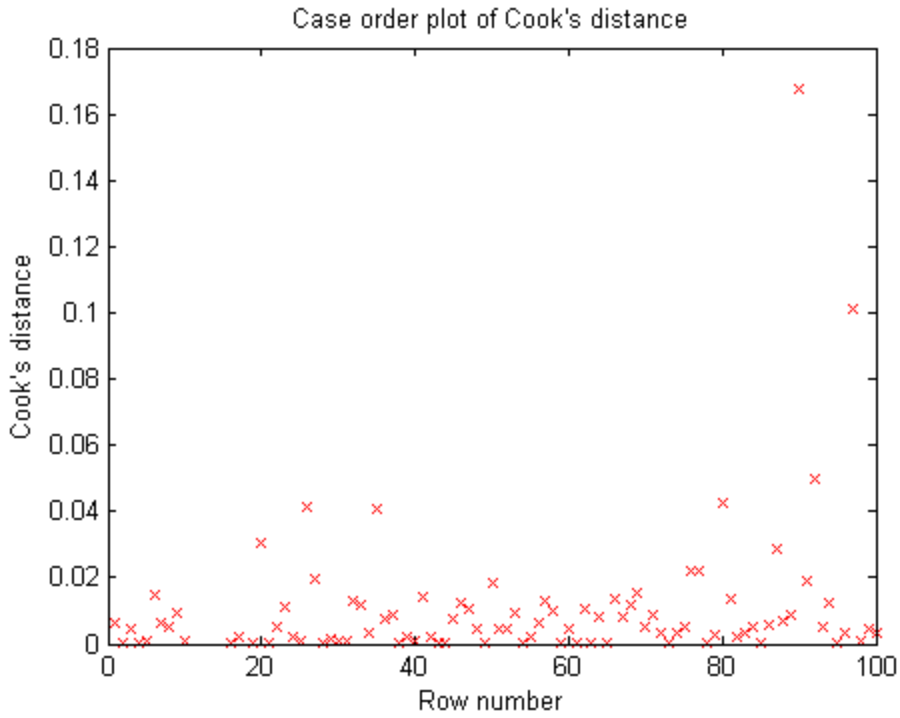
Plot the leverage values.

```
plotDiagnostics(mdl)
```



Plot the Cook's distance.

```
plotDiagnostics(mdl,'cookd')
```



The two diagnostic plots give different results.

plotDiagnostics

Class: NonLinearModel

Plot diagnostics of nonlinear regression model

Syntax

```
plotDiagnostics(mdl)
plotDiagnostics(mdl,plottype)
h = plotDiagnostics(...)
h = plotDiagnostics(mdl,plottype,Name,Value)
```

Description

`plotDiagnostics(mdl)` plots diagnostics from the `mdl` linear model using leverage as the plot type.

`plotDiagnostics(mdl,plottype)` plots diagnostics in a plot of type `plottype`.

`h = plotDiagnostics(...)` returns handles to the lines in the plot.

`h = plotDiagnostics(mdl,plottype,Name,Value)` plots with additional options specified by one or more Name,Value pair arguments.

Tips

- For many plots, the Data Cursor tool in the figure window displays the *x* and *y* values for any data point, along with the observation name or number.

Input Arguments

`mdl`

Nonlinear regression model, constructed by `fitnlm`.

`plottype`

String specifying the type of plot:

`'contour'`	Residual vs. leverage with overlayed Cook's contours
`'cookd'`	Cook's distance
`'leverage'`	Leverage (diagonal of Hat matrix)

Default: `'leverage'`

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Note: The plot property name-value pairs apply to the first returned handle `h(1)`.

`'Color'`

Color of the line or marker, a string or `ColorSpec` specification. For details, see `linespec`.

`'LineStyle'`

Type of line, a string or Chart Line Properties specification. For details, see `linespec`.

`'LineWidth'`

Width of the line or edges of filled area, in points, a positive scalar. One point is 1/72 inch.

Default: `0.5`

`'MarkerEdgeColor'`

Color of the marker or edge color for filled markers, a string or `ColorSpec` specification. For details, see `linespec`.

'MarkerFaceColor'

Color of the marker face for filled markers, a string or `ColorSpec` specification. For details, see `linespec`.

'MarkerSize'

Size of the marker in points, a strictly positive scalar. One point is 1/72 inch.

Output Arguments

h

Vector of handles to lines or patches in the plot.

Definitions

Hat Matrix

The *hat matrix H* is defined in terms of the data matrix X and the Jacobian matrix J:

$$J_{i,j} = \left.\frac{\partial f}{\partial \beta_j}\right|_{x_i,\beta}$$

Here f is the nonlinear model function, and β is the vector of model coefficients.

The Hat Matrix H is
$H = J(J^TJ)^{-1}J^T$.

The diagonal elements H_{ii} satisfy

$$0 \le h_{ii} \le 1$$

$$\sum_{i=1}^{n} h_{ii} = p,$$

where n is the number of observations (rows of X), and p is the number of coefficients in the regression model.

Leverage

The *leverage* of observation i is the value of the ith diagonal term, h_{ii}, of the hat matrix H. Because the sum of the leverage values is p (the number of coefficients in the regression model), an observation i can be considered to be an outlier if its leverage substantially exceeds p/n, where n is the number of observations.

Cook's Distance

The Cook's distance D_i of observation i is

$$D_i = \frac{\sum_{j=1}^{n} \left(\hat{y}_j - \hat{y}_{j(i)}\right)^2}{p\,MSE},$$

where

- $\hat{y}_j$ is the jth fitted response value.
- $\hat{y}_{j(i)}$ is the jth fitted response value, where the fit does not include observation i.
- MSE is the mean squared error.
- p is the number of coefficients in the regression model.

Cook's distance is algebraically equivalent to the following expression:

$$D_i = \frac{r_i^2}{p\,MSE}\left(\frac{h_{ii}}{\left(1-h_{ii}\right)^2}\right),$$

where e_i is the ith residual.

Examples

Nonlinear Model Leverage Plot

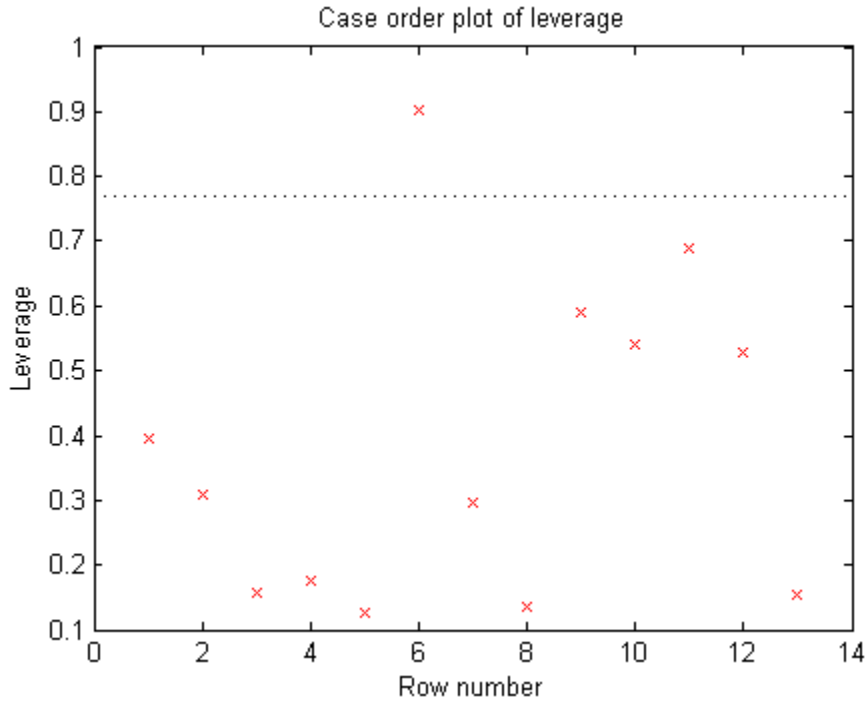
Create a leverage plot of a fitted nonlinear model, and find the points with high leverage.

Load the reaction data and fit a model of the reaction rate as a function of reactants.

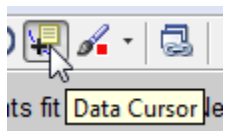
```
load reaction
mdl = fitnlm(reactants,rate,@hougen,[1 .05 .02 .1 2]);
```

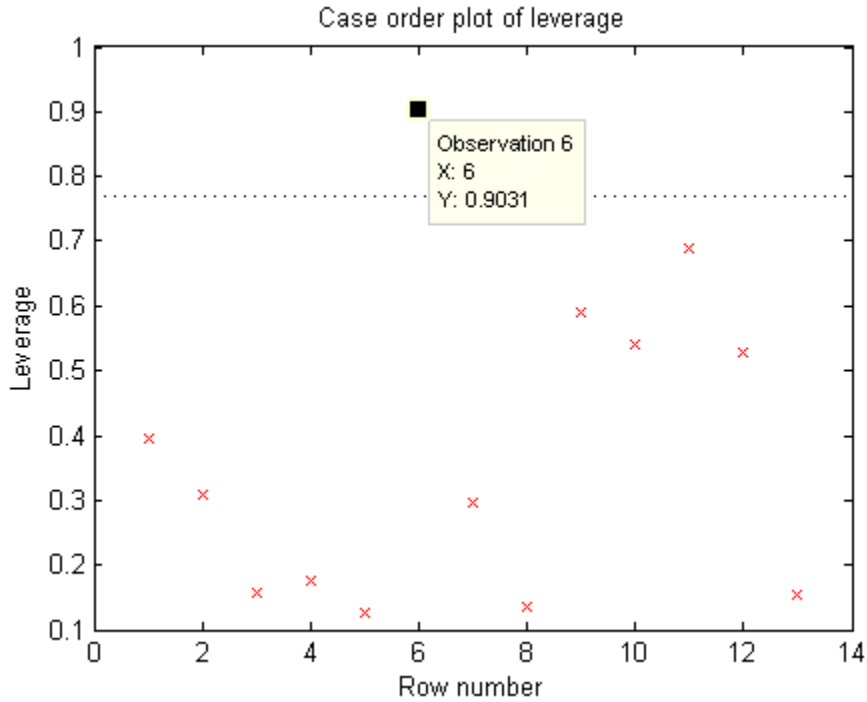
Create a leverage plot of the fitted model.

```
plotDiagnostics(mdl)
```



To examine the observation with high leverage, activate the Data Cursor and click the observation.





Alternatively, find the high-leverage observation at the command line.

```
find(mdl.Diagnostics.Leverage > 0.8)
```

```
ans =

     6
```

More About

- “Nonlinear Regression” on page 11-2

plotEffects

Class: LinearModel

Plot main effects of each predictor in linear regression model

Syntax

```
plotEffects(mdl)
h = plotEffects(mdl)
```

Description

`plotEffects(mdl)` produces an effects plot for the predictors in the `mdl` regression model. The plot shows the estimated effect on the response from changing each predictor value, averaging out the effects of the other predictors. `plotEffects` chooses values to produce a relatively large effect on the response.

`h = plotEffects(mdl)` returns handles to the lines in the plot.

Tips

- For many plots, the Data Cursor tool in the figure window displays the x and y values for any data point, along with the observation name or number.

Input Arguments

`mdl`

Linear model, as constructed by `fitlm` or `stepwiselm`.

Output Arguments

h

Vector of handles to lines or patches in plot. `h(1)` is a handle to the circles that represent the main effect estimates. `h(j+1)` is a handle to the line that defines the confidence interval for the effect of predictor `j`.

Examples

Effects Plot

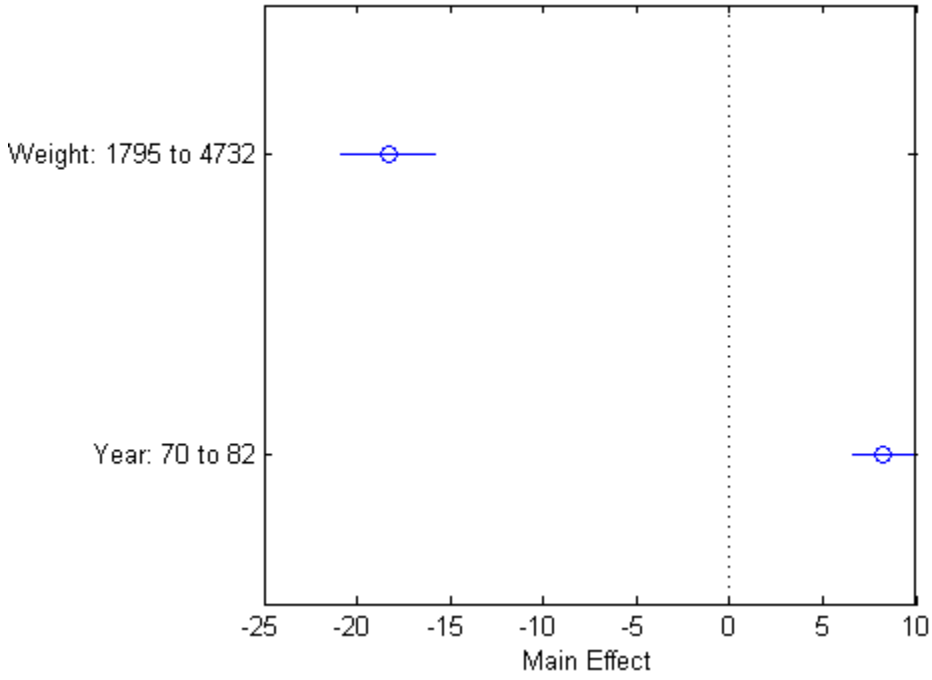
Plot the effects of two predictors in a fitted linear model.

Load the `carsmall` data and fit a linear model of the mileage as a function of model year, weight, and weight squared.

```
load carsmall
ds = dataset(MPG,Weight);
ds.Year = ordinal(Model_Year);
mdl = fitlm(ds,'MPG ~ Year + Weight^2');
```

Create an effects plot.

```
plotEffects(mdl)
```



The width of each horizontal line in the figure shows a confidence interval for the effect on the response of the listed change in each predictor. The estimated effect of changing `Year` from `70` to `82` is an increase of about 8, and is between 6 and 10 with 95% confidence.

- "Plots to Understand Predictor Effects" on page 9-28

Alternatives

Use `plotInteraction` for an effects plot of the interactions of two specified variables.

See Also

`LinearModel` | `plotAdjustedResponse` | `plotInteraction`

How To

- “Linear Regression” on page 9-11

plotInteraction

Class: LinearModel

Plot interaction effects of two predictors in linear regression model

Syntax

```
plotInteraction(mdl,var1,var2)
plotInteraction(mdl,var1,var2,ptype)
h = plotInteraction(...)
```

Description

`plotInteraction(mdl,var1,var2)` creates a plot of the interaction effects of the predictors `var1` and `var2` in `mdl`. The plot shows the estimated effect on the response from changing each predictor value, averaging out the effects of the other predictors. The plot also shows the estimated effect with the other predictor fixed at certain values. `plotInteraction` chooses values to produce a relatively large effect on the response. The plot lets you examine whether the effect of one predictor depends on the value of the other predictor.

`plotInteraction(mdl,var1,var2,ptype)` returns a plot of the type specified in `ptype`.

`h = plotInteraction(...)` returns handles to the lines in the plot.

Tips

- For many plots, the Data Cursor tool in the figure window displays the *x* and *y* values for any data point, along with the observation name or number.

Input Arguments

`mdl`

Linear model, as constructed by `fitlm` or `stepwiselm`.

`var1`

String naming the variable for plot. `plotInteraction` chooses values of `var1` to create relatively large changes in the response. When you set `ptype` = `'predictions'`, the plot shows curves as a function of `var2` with various fixed values of `var1`.

`var2`

String naming the variable for plot. `plotInteraction` chooses values of `var2` to create relatively large changes in the response. When you set `ptype` = `'predictions'`, the plot shows curves as a function of `var2` various fixed values of `var1`.

`ptype`

String naming the plot type.

- `'effects'` — The plot shows each effect as a circle, with a horizontal bar showing the confidence interval for the estimated effect. `plotInteraction` computes the effect values from the adjusted response curve, as shown by the `plotAdjustedResponse` function.
- `'predictions'` — The plot shows the adjusted response curve as a function of `var2`, with `var1` fixed at certain values.

Default: `'effects'`

Output Arguments

`h`

Vector of handles to lines or patches in the plot.

Examples

Interaction Plot

Create a model of car mileage as a function of weight and model year. Then create a plot to see if the predictors have interactions.

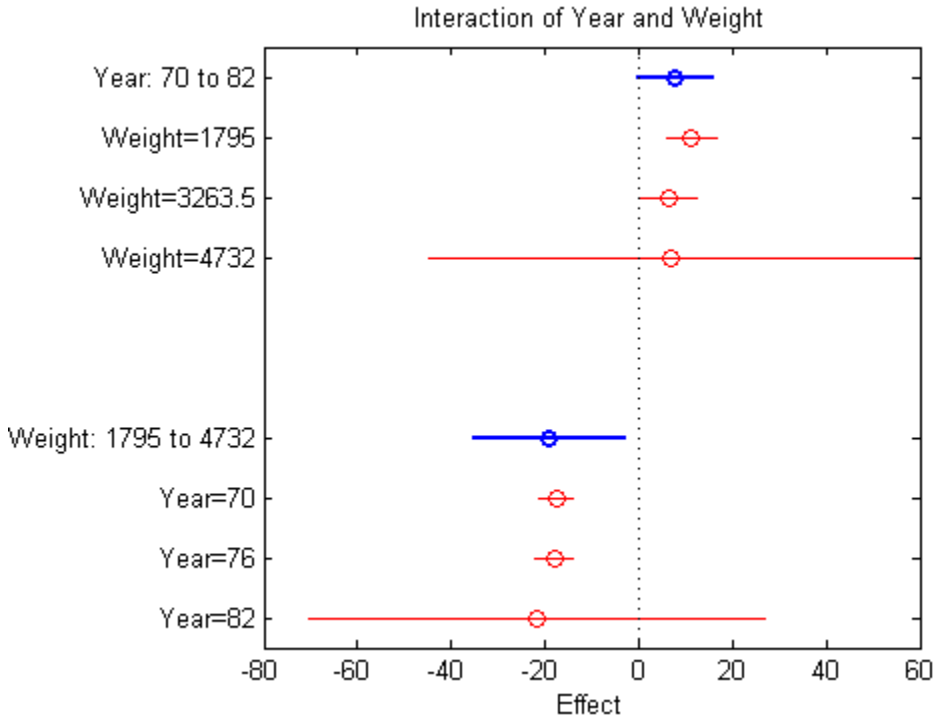
Create a linear model of mileage from the `carsmall` data.

```
load carsmall
```

```
ds = dataset(MPG,Weight);
ds.Year = ordinal(Model_Year);
var1 = 'Year';
var2 = 'Weight';
mdl = fitlm(ds,'MPG ~ Year * Weight^2');
```

Create an interaction plot.

```
plotInteraction(mdl,var1,var2)
```



The plot might show an interaction, because the groups of points are not perfectly vertical. But the error bars seem large enough that a vertical line could pass within all of the confidence intervals for each group, possibly indicating no interaction.

Prediction Curve Interaction Plot

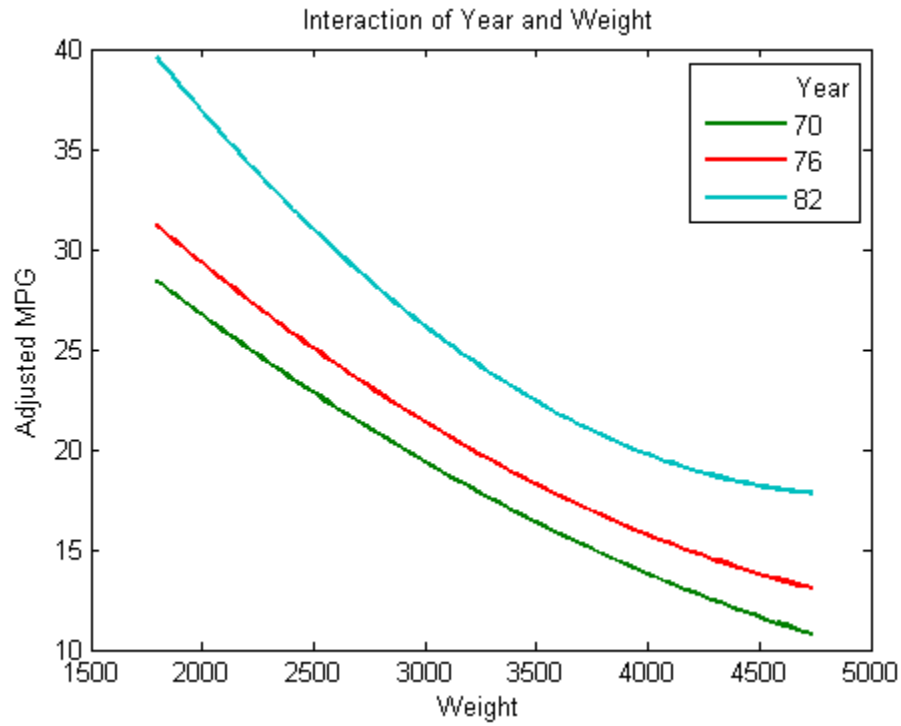
Create a model of car mileage as a function of weight and model year. Then create an interaction curve plot to see if the predictors have interactions.

Create a linear model of mileage from the `carsmall` data.

```
load carsmall
ds = dataset(MPG,Weight);
ds.Year = ordinal(Model_Year);
var1 = 'Year';
var2 = 'Weight';
mdl = fitlm(ds,'MPG ~ Year * Weight^2');
```

Create an interaction plot with type `'predictions'`.

```
plotInteraction(mdl,var1,var2,'predictions')
```



The curves are not parallel. This indicates interactions between the predictors. The effect is subtle enough not to definitively indicate a interaction.

- “Plots to Understand Predictor Effects” on page 9-28

Alternatives

Use `plotEffects` for an effects plot showing separate effects for all predictors.

plotprofile

Class: RepeatedMeasuresModel

Plot expected marginal means with optional grouping

Syntax

```
plotprofile(rm,X)
plotprofile(rm,Name,Value)
H = plotprofile( ___ )
```

Description

`plotprofile(rm,X)` plots the expected marginal means computed from the repeated measures model rm as a function of the variable X.

`plotprofile(rm,Name,Value)` plots the expected marginal means computed from the repeated measures model rm with additional options specified by one or more Name,Value pair arguments.

For example, you can specify the factors to group by or change the line colors.

`H = plotprofile( ___ )` returns handles, `H`, to the plotted lines.

Input Arguments

`rm` — Repeated measures model

`RepeatedMeasuresModel` object

Repeated measures model, returned as a `RepeatedMeasuresModel` object.

For properties and methods of this object, see `RepeatedMeasuresModel`.

`X` — Name of between-subjects or within-subjects factor

string

Name of a between-subjects or within-subjects factor, specified as a string.

For example, if you want to plot the marginal means as a function of the groups of a between-subjects variable drug, you can specify it as follows.

Example: `'Drug'`

Data Types: `char`

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'Group'` — Name of between-subject factor or factors

string | cell array of strings

Name of between-subject factor or factors, specified as the comma-separated pair consisting of `'Group'` and a string or cell array of strings. This name-value pair argument groups the lines according to the factor values.

For example, if you have two between-subject factors, drug and sex, and you want to group the lines in the plot according to them, you can specify these factors as follows.

Example: `'Group',{'Drug','Sex'}`

Data Types: `char | cell`

`'Marker'` — Marker to use for each group

cell array of strings

Marker to use for each group, specified as the comma-separated pair consisting of `'Marker'` and a cell array of strings.

For example, if you have two between-subject factors, drug and sex, with each having two groups, you can specify `o` as the marker for the groups of drug and `x` as the marker for the groups of sex as follows.

Example: `'Marker',{'o','o','x','x'}`

Data Types: `cell`

`'Color'` — Color for each group

string | cell array of strings | rows of a three-column RGB matrix

Color for each group, specified as the comma-separated pair consisting of `'Color'` and a string, cell array of strings, or rows of a three-column RGB matrix.

For example, if you have two between-subject factors, drug and sex, with each having two groups, you can specify red as the color for the groups of drug and blue as the color for the groups of sex as follows.

Example: `'Color','rrbb'`

Data Types: `single | double | cell`

`'LineStyle'` — Line style for each group

cell array of strings

Line style for each group, specified as the comma-separated pair consisting of `'LineStyle'` and a cell array of strings.

For example, if you have two between-subject factors, drug and sex, with each having two groups, you can specify `-` as the line style of one group and `:` as the line style for the other group as follows.

Example: `'LineStyle',{'-' ':' '-' ':'}`

Data Types: `cell`

Output Arguments

`H` — Handle to plotted lines

handle

Handle to plotted lines, returned as a handle.

Examples

Plot Expected Marginal Means

Load the sample data.

```
load fisheriris
```

The column vector `species`consists of iris flowers of three different species: setosa, versicolor, and virginica. The double matrix `meas` consists of four types of measurements on the flowers: the length and width of sepals and petals in centimeters, respectively.

Store the data in a table array.

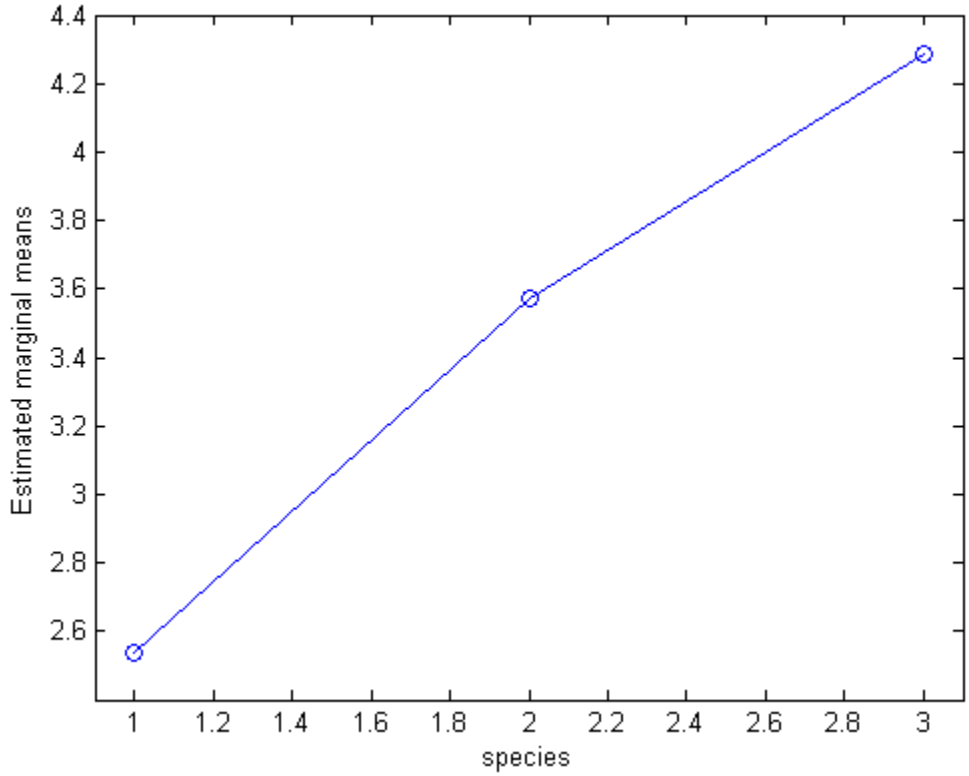
```
t = table(species,meas(:,1),meas(:,2),meas(:,3),meas(:,4),...
'VariableNames',{'species','meas1','meas2','meas3','meas4'});
Meas = dataset([1 2 3 4]','VarNames',{'Measurements'});
```

Fit a repeated measures model, where the measurements are the responses and the species is the predictor variable.

```
rm = fitrm(t,'meas1-meas4~species','WithinDesign',Meas);
```

Perform data grouped by the factor species.

```
plotprofile(rm,'species')
```



The estimated marginal means seem to differ with group. You can compute the standard error and the 95% confidence intervals for the marginal means using the `margmean` method.

Plot Marginal Means for Two Groups

Load the sample data.

```
load repeatedmeas
```

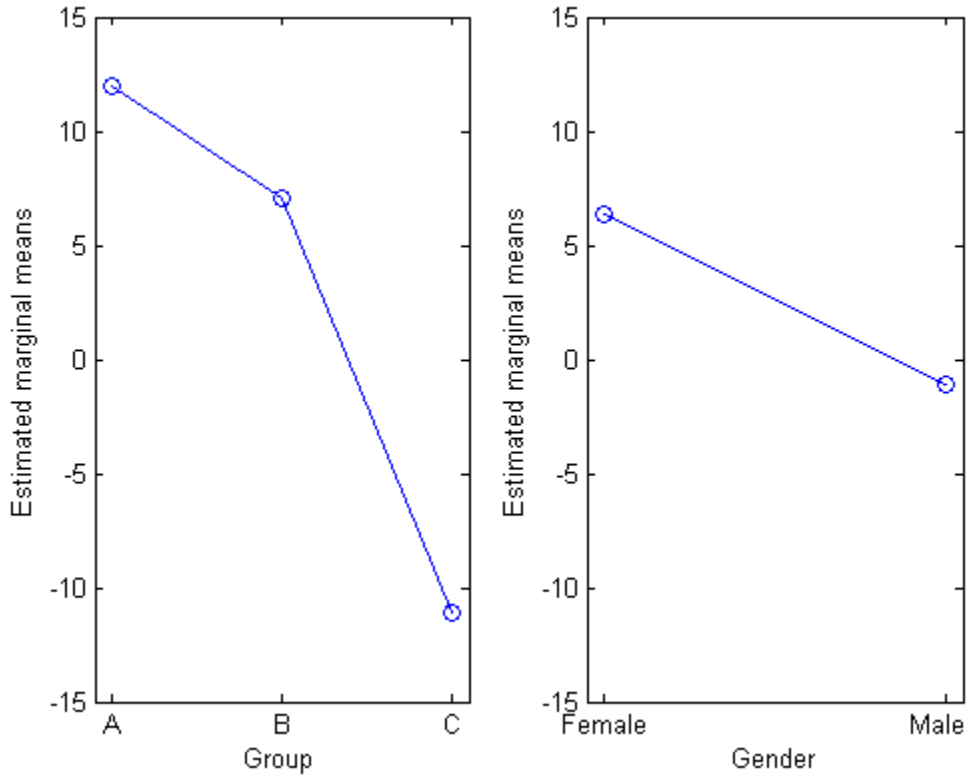
The table `between` includes the between-subject variables age, IQ, group, gender, and eight repeated measures $y1$ through $y8$ as responses. The table `within` includes the within-subject variables $w1$ and $w2$. This is simulated data.

Fit a repeated measures model, where the repeated measures $y1$ through $y8$ are the responses, and age, IQ, group, gender, and the group-gender interaction are the predictor variables. Also specify the within-subject design matrix.

```
rm = fitrm(between,'y1-y8 ~ Group*Gender + Age + IQ','WithinDesign',within);
```

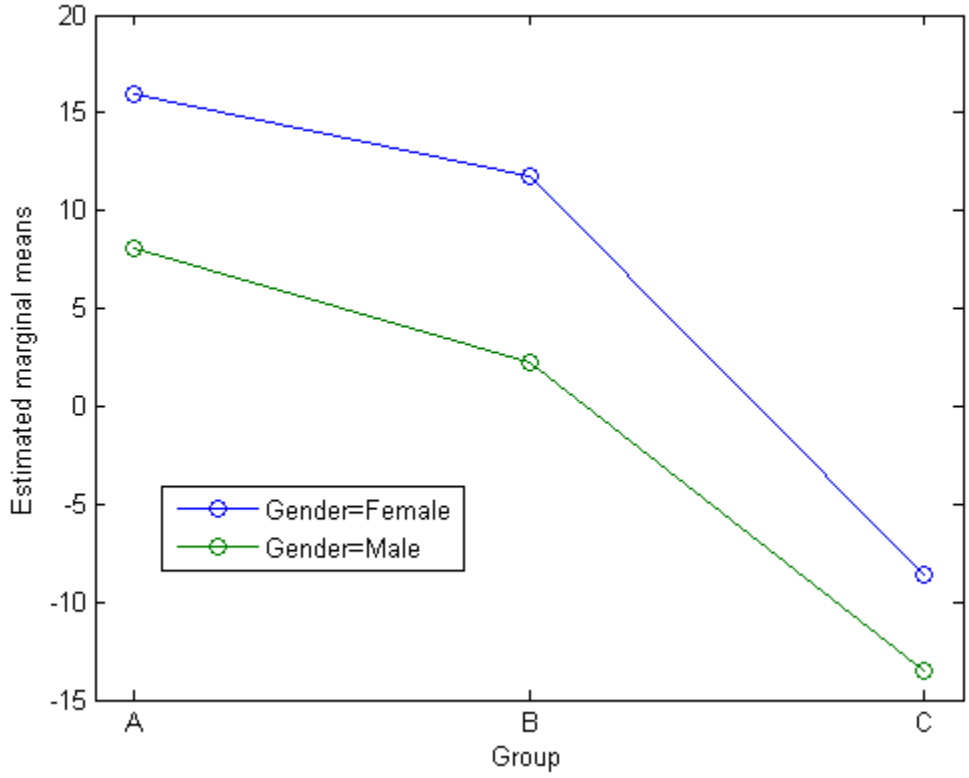
Plot the estimated marginal means based on the factors `Group` and `Gender`.

```
ax1 = subplot(1,2,1);
plotprofile(R,'Group')
ax2 = subplot(1,2,2);
plotprofile(R,'Gender')
linkaxes([ax1 ax2],'y')
```



Plot the estimated marginal means based on the factor `Group` and grouped by `Gender`.

```
figure()
plotprofile(R,'Group','Group','Gender')
```



See Also

`fitrm` | `margmean` | `plot`

plotResiduals

Class: GeneralizedLinearModel

Plot residuals of generalized linear regression model

Syntax

```
plotResiduals(mdl)
plotResiduals(mdl,plottype)
h = plotResiduals(...)
h = plotResiduals(mdl,plottype,Name,Value)
```

Description

`plotResiduals(mdl)` gives a histogram plot of the residuals of the `mdl` nonlinear model.

`plotResiduals(mdl,plottype)` plots residuals in a plot of type `plottype`.

`h = plotResiduals(...)` returns handles to the lines in the plot.

`h = plotResiduals(mdl,plottype,Name,Value)` plots with additional options specified by one or more Name,Value pair arguments.

Tips

- For many plots, the Data Cursor tool in the figure window displays the *x* and *y* values for any data point, along with the observation name or number.

Input Arguments

`mdl`

Generalized linear model, as constructed by `fitglm` or `stepwiseglm`.

`plottype`

String specifying the type of plot:

`'caseorder'`	Residuals vs. case (row) order
`'fitted'`	Residuals vs. fitted values
`'histogram'`	Histogram
`'lagged'`	Residuals vs. lagged residual ($r(t)$ vs. $r(t–1)$)
`'probability'`	Normal probability plot
`'symmetry'`	Symmetry plot

Default: `'histogram'`

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Note: The plot property name-value pairs apply to the first returned handle `h(1)`.

`'Color'`

Color of the line or marker, a string or `ColorSpec` specification. For details, see `linespec`.

`'LineStyle'`

Type of line, a string or Chart Line Properties specification. For details, see `linespec`.

`'LineWidth'`

Width of the line or edges of filled area, in points, a positive scalar. One point is 1/72 inch.

Default: `0.5`

`'MarkerEdgeColor'`

Color of the marker or edge color for filled markers, a string or `ColorSpec` specification. For details, see `linespec`.

`'MarkerFaceColor'`

Color of the marker face for filled markers, a string or `ColorSpec` specification. For details, see `linespec`.

`'MarkerSize'`

Size of the marker in points, a strictly positive scalar. One point is 1/72 inch.

`'ResidualType'`

String giving type of residual used in the plot.

`'Raw'`	Observed minus fitted values
`'LinearPredictor'`	Residuals on the linear predictor scale, equal to the adjusted response value minus the fitted linear combination of the predictors
`'Pearson'`	Raw residuals divided by RMSE
`'Anscombe'`	Residuals defined on transformed data with the transformation chosen to remove skewness
`'Deviance'`	Residuals based on the contribution of each observation to the deviance

Default: `'Raw'`

Output Arguments

`h`

Vector of handles to lines or patches in the plot.

Definitions

Deviance

Deviance is twice the log likelihood of the model. Because this overall log likelihood is a sum of log likelihoods for each observation, the residual plot of deviance type shows the log likelihood per observation.

Examples

Residual Plots for Generalized Linear Models

Create residual plots of a fitted generalized linear model.

Generate artificial data for the model, Poisson random numbers with two underlying predictors `X(1)` and `X(2)`.

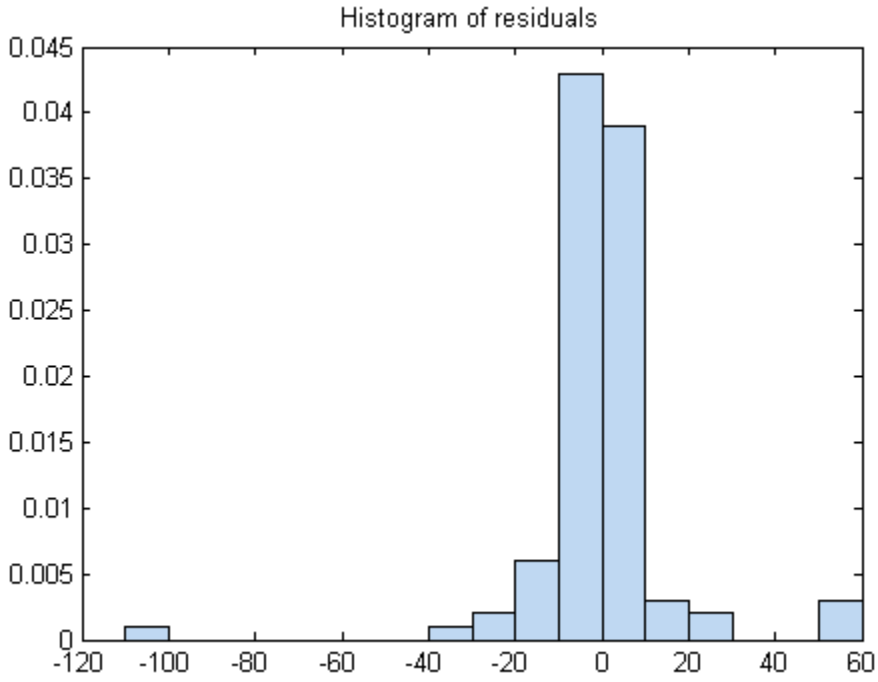
```
rng('default') % for reproducibility
rndvars = randn(100,2);
X = [2+rndvars(:,1),rndvars(:,2)];
mu = exp(1 + X*[1;2]);
y = poissrnd(mu);
```

Create a generalized linear regression model of Poisson data.

```
mdl = fitglm(X,y,'y ~ x1 + x2','distr','poisson');
```

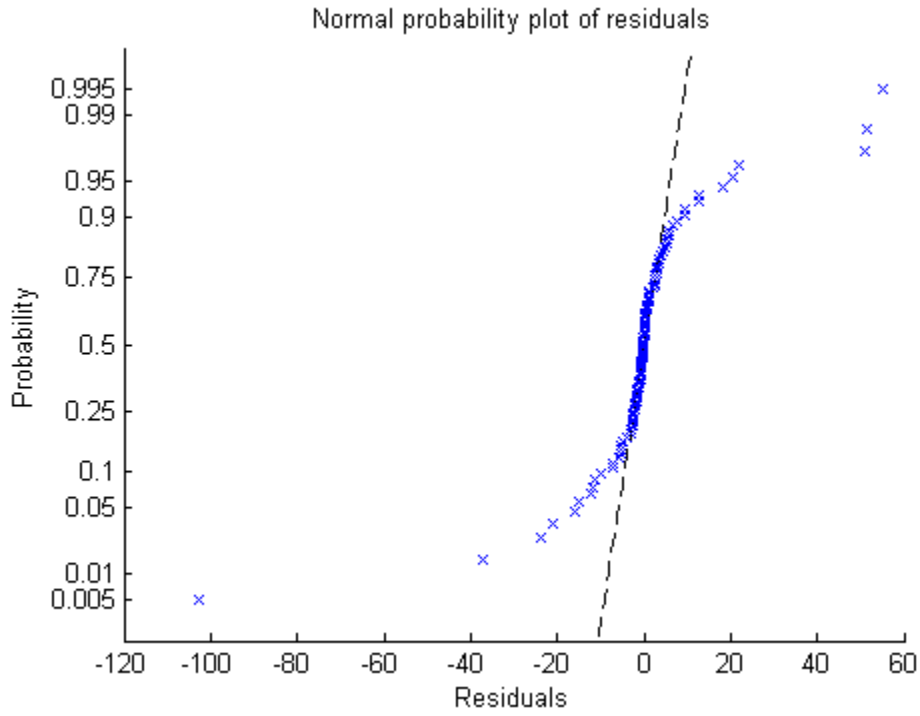
Create a default residuals plot.

```
plotResiduals(mdl)
```



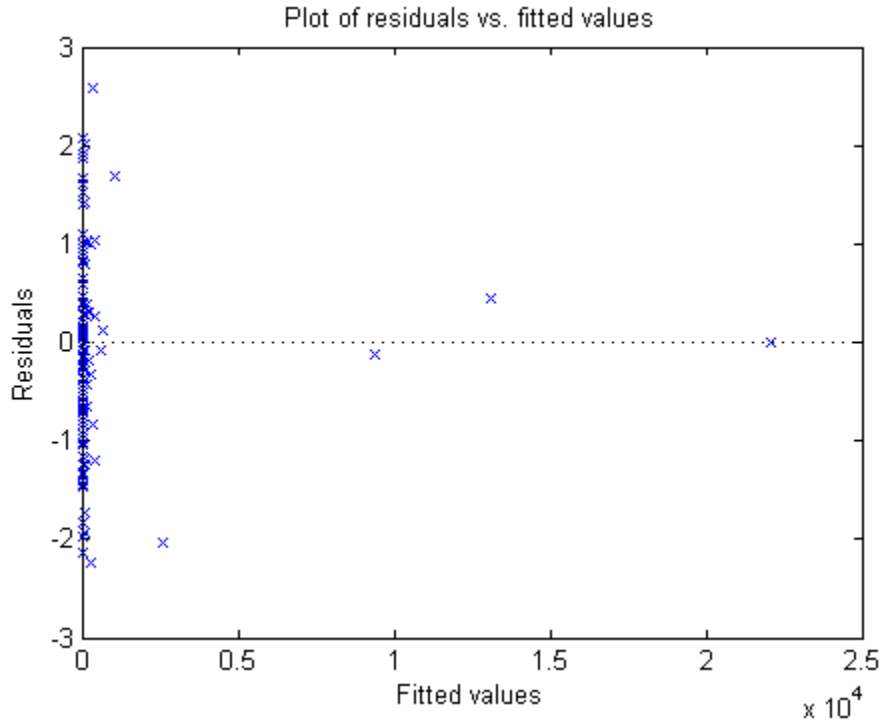
Create a probability plot.

```
plotResiduals(mdl,'probability')
```



The residuals do not match a normal distribution in the tails—they are more spread out.

Create a plot of the fitted residuals of Anscombe type.



- "Residuals — Model Quality for Training Data" on page 10-27

`GeneralizedLinearModel`

More About

- "Generalized Linear Models" on page 10-12

plotResiduals

Class: GeneralizedLinearMixedModel

Plot residuals of generalized linear mixed-effects model

Syntax

```
plotResiduals(glme,plottype)
plotResiduals(glme,plottype,Name,Value)

h = plotResiduals( ___ )
```

Description

`plotResiduals(glme,plottype)` plots the raw conditional residuals of the generalized linear mixed-effects model glme in a plot of the type specified by plottype.

`plotResiduals(glme,plottype,Name,Value)` plots the conditional residuals of glme using additional options specified by one or more `Name,Value` pair arguments. For example, you can specify to plot the Pearson residuals.

`h = plotResiduals( ___ )` returns a handle, h, to the lines or patches in the plot of residuals.

Input Arguments

`glme` — Generalized linear mixed-effects model

`GeneralizedLinearMixedModel` object

Generalized linear mixed-effects model, specified as a `GeneralizedLinearMixedModel` object. For properties and methods of this object, see `GeneralizedLinearMixedModel`.

`plottype` — Type of residual plot

`'histogram'` (default) | `'caseorder'` | `'fitted'` | `'lagged'` | `'probability'` | `'symmetry'`

Type of residual plot, specified as one of the following strings.

`'histogram'`	Histogram of residuals
`'caseorder'`	Residuals versus case order. Case order is the same as the row order used in the input data `tbl` when fitting the model using `fitglme`.
`'fitted'`	Residuals versus fitted values
`'lagged'`	Residuals versus lagged residual ($r(t)$ versus $r(t-1)$)
`'probability'`	Normal probability plot
`'symmetry'`	Symmetry plot

Example: `plotResiduals(glme,'lagged')`

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'ResidualType'` — Residual type

`'raw'` (default) | `'Pearson'`

Residual type, specified by the comma-separated pair consisting of `ResidualType` and one of the following.

Residual Type	Formula
`'raw'`	$r_{ci} = y_i - g^{-1}\left(x_i^T\hat{\beta} + z_i^T\hat{b} + \delta_i\right)$
`'Pearson'`	$r_{ci}^{pearson} = \dfrac{r_{ci}}{\sqrt{\dfrac{\widehat{\sigma^2}}{w_i}v_i\left(\mu_i\left(\hat{\beta},\hat{b}\right)\right)}}$

In each of these equations:

- y_i is the ith element of the n-by-1 response vector, y, where $i = 1, ..., n$.
- g^{-1} is the inverse link function for the model.
- x_i^T is the ith row of the fixed-effects design matrix X.
- z_i^T is the ith row of the random-effects design matrix Z.
- δ_i is the ith offset value.
- σ^2 is the dispersion parameter.
- w_i is the ith observation weight.
- v_i is the variance term for the ith observation.
- μ_i is the mean of the response for the ith observation.
- $\hat{\beta}$ and $\hat{b}$ are estimated values of β and b.

Raw residuals from a generalized linear mixed-effects model have nonconstant variance. Pearson residuals are expected to have an approximately constant variance, and are generally used for analysis.

Example: `'ResidualType','Pearson'`

Output Arguments

h — Handle to residual plot

graphics object

Handle to the residual plot, returned as a graphics object. You can use dot notation to change certain property values of the object, including face color for a histogram, and marker style and color for a scatterplot. For more information, see “Access Property Values”.

Examples

Create Plots of Residuals

Navigate to the folder containing the sample data. Load the sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')

load mfr
```

This simulated data is from a manufacturing company that operates 50 factories across the world, with each factory running a batch process to create a finished product. The company wants to decrease the number of defects in each batch, so it developed a new manufacturing process. To test the effectiveness of the new process, the company selected 20 of its factories at random to participate in an experiment: Ten factories implemented the new process, while the other ten continued to run the old process. In each of the 20 factories, the company ran five batches (for a total of 100 batches) and recorded the following data:

- Flag to indicate whether the batch used the new process (`newprocess`)
- Processing time for each batch, in hours (`time`)
- Temperature of the batch, in degrees Celsius (`temp`)
- Categorical variable indicating the supplier (`A`, `B`, or `C`) of the chemical used in the batch (`supplier`)
- Number of defects in the batch (`defects`)

The data also includes `time_dev` and `temp_dev`, which represent the absolute deviation of time and temperature, respectively, from the process standard of 3 hours at 20 degrees Celsius.

Fit a generalized linear mixed-effects model using `newprocess`, `time_dev`, `temp_dev`, and `supplier` as fixed-effects predictors. Include a random-effects term for intercept grouped by `factory`, to account for quality differences that might exist due to factory-specific variations. The response variable `defects` has a Poisson distribution, and the appropriate link function for this model is log. Use the Laplace fit method to estimate the coefficients. Specify the dummy variable encoding as `'effects'`, so the dummy variable coefficients sum to 0.

The number of defects can be modeled using a Poisson distribution

$$defects_{ij} \sim Poisson\left(\mu_{ij}\right)$$

This corresponds to the generalized linear mixed-effects model

$$\log\left(\mu_{ij}\right) = \beta_0 + \beta_1 newprocess_{ij} + \beta_2 time\_dev_{ij} + \beta_3 temp\_dev_{ij} + \beta_4 supplier\_C_{ij} + \beta_5 supplier\_B_{ij} +$$

where

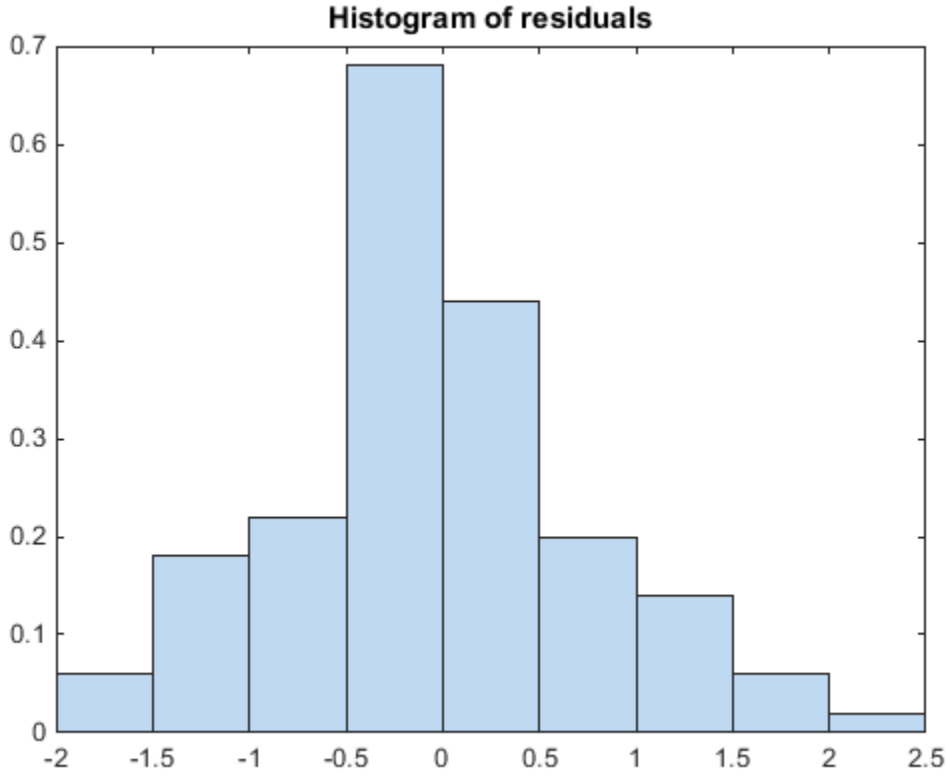
- $defects_{ij}$ is the number of defects observed in the batch produced by factory i during batch j.
- μ_{ij} is the mean number of defects corresponding to factory i (where i = 1, 2, ..., 20) during batch j (where j = 1, 2, ..., 5).
- $newprocess_{ij}$, $time\_dev_{ij}$, and $temp\_dev_{ij}$ are the measurements for each variable that correspond to factory i during batch j. For example, $newprocess_{ij}$ indicates whether the batch produced by factory i during batch j used the new process.
- $supplier\_C_{ij}$ and $supplier\_B_{ij}$ are dummy variables that use effects (sum-to-zero) coding to indicate whether company `C` or `B`, respectively, supplied the process chemicals for the batch produced by factory i during batch j.
- $b_i \sim N(0,\sigma_b^2)$ is a random-effects intercept for each factory i that accounts for factory-specific variation in quality.

```
glme = fitglme(mfr,'defects ~ 1 + newprocess + time_dev + temp_dev + supplier + (1|fact
```

Create diagnostic plots using Pearson residuals to test the model assumptions.

Plot a histogram to visually confirm that the mean of the Pearson residuals is equal to 0. If the model is correct, we expect the Pearson residuals to be centered at 0.

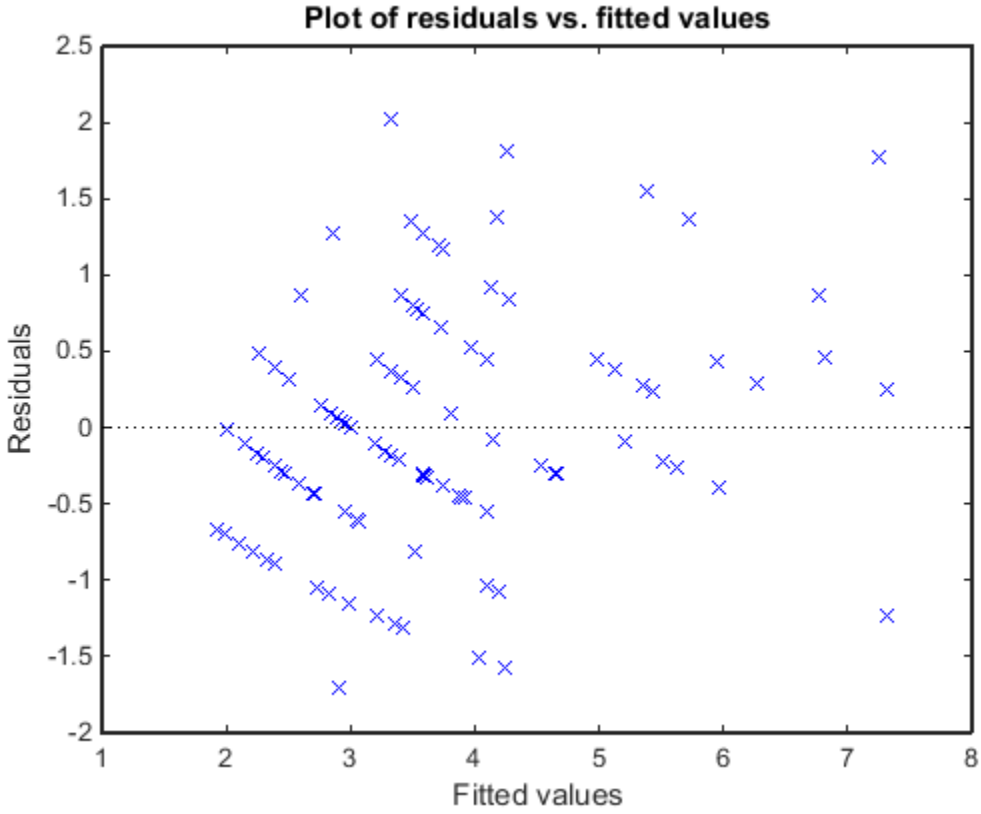
```
plotResiduals(glme,'histogram','ResidualType','Pearson')
```



The histogram shows that the Pearson residuals are centered at 0.

Plot the Pearson residuals versus the fitted values, to check for signs of nonconstant variance among the residuals (heteroscedasticity). We expect the conditional Pearson residuals to have a constant variance. Therefore, a plot of conditional Pearson residuals versus conditional fitted values should not reveal any systematic dependence on the conditional fitted values.

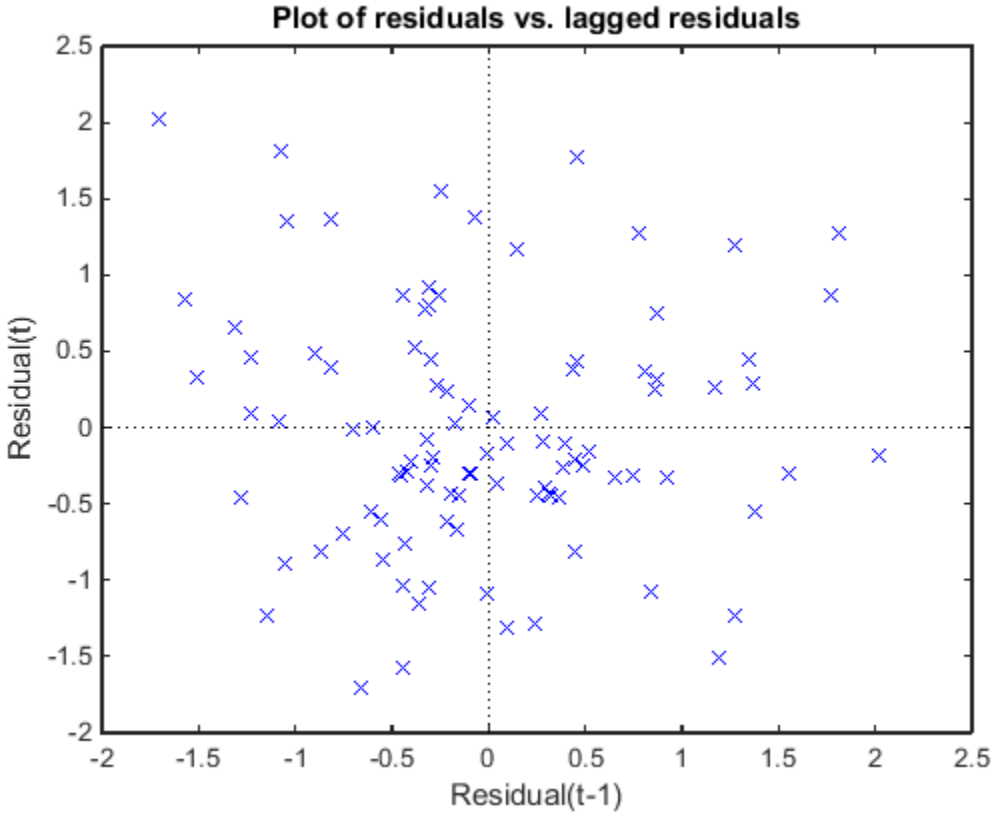
```
plotResiduals(glme,'fitted','ResidualType','Pearson')
```



The plot does not show a systematic dependence on the fitted values, so there are no signs of nonconstant variance among the residuals.

Plot the Pearson residuals versus lagged residuals, to check for correlation among the residuals. The conditional independence assumption in GLME implies that the conditional Pearson residuals are approximately uncorrelated.

```
plotResiduals(glme,'lagged','ResidualType','Pearson')
```



There is no pattern to the plot, so there are no signs of correlation among the residuals.

`GeneralizedLinearMixedModel` | `fitglme` | `fitted` | `plot` | `residuals`

plotResiduals

Class: LinearModel

Plot residuals of linear regression model

Syntax

```
plotResiduals(mdl)
plotResiduals(mdl,plottype)
h = plotResiduals(...)
h = plotResiduals(mdl,plottype,Name,Value)
```

Description

`plotResiduals(mdl)` gives a histogram plot of the residuals of the `mdl` linear model.

`plotResiduals(mdl,plottype)` plots residuals in a plot of type `plottype`.

`h = plotResiduals(...)` returns handles to the lines in the plot.

`h = plotResiduals(mdl,plottype,Name,Value)` plots with additional options specified by one or more Name,Value pair arguments.

Tips

- For many plots, the Data Cursor tool in the figure window displays the *x* and *y* values for any data point, along with the observation name or number.

Input Arguments

`mdl`

Linear model, as constructed by `fitlm` or `stepwiselm`.

`plottype`

String specifying the type of plot:

`'caseorder'`	Residuals vs. case (row) order
`'fitted'`	Residuals vs. fitted values
`'histogram'`	Histogram
`'lagged'`	Residuals vs. lagged residual ($r(t)$ vs. $r(t–1)$)
`'probability'`	Normal probability plot
`'symmetry'`	Symmetry plot

Default: `'histogram'`

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Note: The plot property name-value pairs apply to the first returned handle `h(1)`.

`'Color'`

Color of the line or marker, a string or `ColorSpec` specification. For details, see `linespec`.

`'LineStyle'`

Type of line, a string or Chart Line Properties specification. For details, see `linespec`.

`'LineWidth'`

Width of the line or edges of filled area, in points, a positive scalar. One point is 1/72 inch.

Default: `0.5`

`'MarkerEdgeColor'`

Color of the marker or edge color for filled markers, a string or `ColorSpec` specification. For details, see `linespec`.

`'MarkerFaceColor'`

Color of the marker face for filled markers, a string or `ColorSpec` specification. For details, see `linespec`.

`'MarkerSize'`

Size of the marker in points, a strictly positive scalar. One point is 1/72 inch.

`'ResidualType'`

Type of residual used in the plot:

`'Raw'`	Observed minus fitted values
`'Pearson'`	Raw residuals divided by RMSE
`'Standardized'`	Raw residuals divided by their estimated standard deviation
`'Studentized'`	Raw residuals divided by an independent (delete-1) estimate of their standard deviation

Default: `'Raw'`

Output Arguments

`h`

Vector of handles to lines or patches in the plot.

Examples

Linear Residuals Plot

Plot the residuals of a fitted linear model.

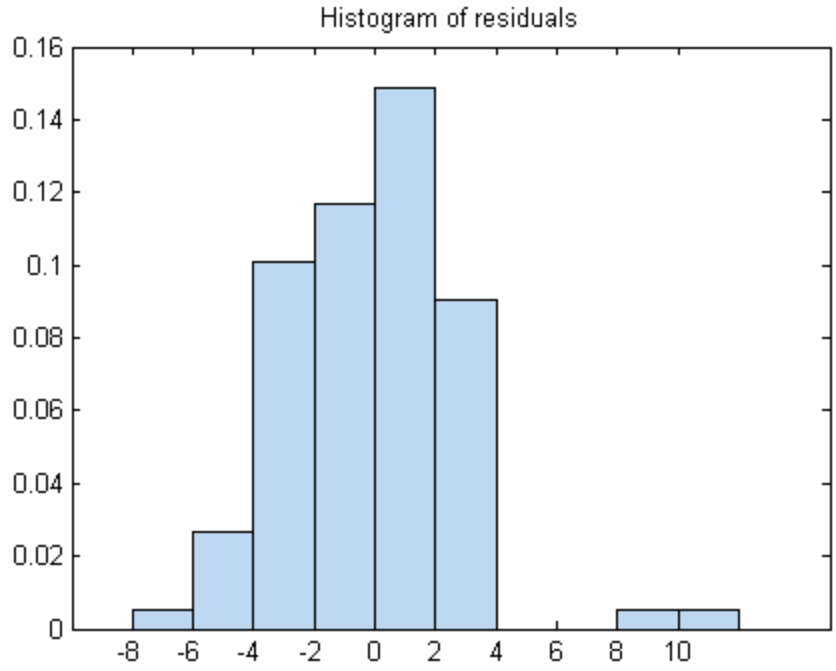
Load the `carsmall` data and fit a linear model of the mileage as a function of model year, weight, and weight squared.

```
load carsmall
```

```
tbl = table(MPG,Weight);
tbl.Year = ordinal(Model_Year);
mdl = fitlm(tbl,'MPG ~ Year + Weight^2');
```

Plot the raw residuals.

```
plotResiduals(mdl)
```



Residual Probability Plot

Create a normal probability plot of the residuals of a fitted linear model.

Load the `carsmall` data and fit a linear model of the mileage as a function of model year, weight, and weight squared.

```
load carsmall
X = [Weight,Model_Year];
mdl = fitlm(X,MPG,...
    'y ~ x2 + x1^2','Categorical',2);
```

Create a normal probability plot of the residuals of the fitted model.

```
plotResiduals(mdl,'probability')
```

plotResiduals

Class: LinearMixedModel

Plot residuals of linear mixed-effects model

Syntax

```
plotResiduals(lme,plottype)
plotResiduals(lme,plottype,Name,Value)

h = plotResiduals( ___ )
```

Description

`plotResiduals(lme,plottype)` plots the raw conditional residuals of the linear mixed-effects model `lme` in a plot of the type specified by `plottype`.

`plotResiduals(lme,plottype,Name,Value)` also plots the residuals of the linear mixed-effects model `lme` with additional options specified by one or more name-value pair arguments. For example, you can specify the residual type to plot.

`plotResiduals` also accepts some other name-value pair arguments that specify the properties of the primary line in the plot. For those name-value pairs, see `plot`.

`h = plotResiduals( ___ )` returns a handle, `h`, to the lines or patches in the plot of residuals.

Input Arguments

`lme` — Linear mixed-effects model

`LinearMixedModel` object

Linear mixed-effects model, returned as a `LinearMixedModel` object.

For properties and methods of this object, see `LinearMixedModel`.

`plottype` — Type of residual plot

`'histogram'` (default) | `'caseorder'` | `'fitted'` | `'lagged'` | `'probability'` | `'symmetry'`

Type of residual plot, specified as one of the following strings.

`'histogram'`	Default. Histogram of residuals
`'caseorder'`	Residuals versus case (row) order
`'fitted'`	Residuals versus fitted values
`'lagged'`	Residuals versus lagged residual ($r(t)$ versus $r(t-1)$)
`'probability'`	Normal probability plot
`'symmetry'`	Symmetry plot

Example: `plotResiduals(lme,'lagged')`

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'ResidualType'` — Residual type

`'Raw'` (default) | `'Pearson'` | `'Standardized'`

Residual type, specified by the comma-separated pair consisting of `ResidualType` and one of the following.

Residual Type	Conditional	Marginal
`'Raw'`	$r_i^C = \left[y - X\hat{\beta} - Z\hat{b} \right]_i$	$r_i^M = \left[y - X\hat{\beta} \right]_i$
`'Pearson'`	$pr_i^C = \frac{r_i^C}{\sqrt{\left[\widehat{Var}_{y,b}\left(y - X\beta\right.\right.}}$	$pr_i^M = \frac{r_i^M}{\sqrt{\left[\widehat{Var}_y\left(y - X\beta\right) \right]_{ii}}}$

Residual Type	Conditional	Marginal
`'Standardized'`	$st_i^C = \frac{r_i^C}{\sqrt{\left[\widehat{Var}_y\left(r^C\right)\right]_{ii}}}$	$st_i^M = \frac{r_i^M}{\sqrt{\left[\widehat{Var}_y\left(r^M\right)\right]_{ii}}}$

For more information on the conditional and marginal residuals and residual variances, see `Definitions` at the end of this page.

Example: `'ResidualType','Standardized'`

Output Arguments

h — Handle to residual plot

handle

Handle to the residual plot, returned as a handle.

Examples

Examine Residuals

Navigate to a folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load weight
```

`weight` contains data from a longitudinal study, where 20 subjects are randomly assigned to 4 exercise programs, and their weight loss is recorded over six 2-week time periods. This is simulated data.

Store the data in a table. Define `Subject` and `Program` as categorical variables.

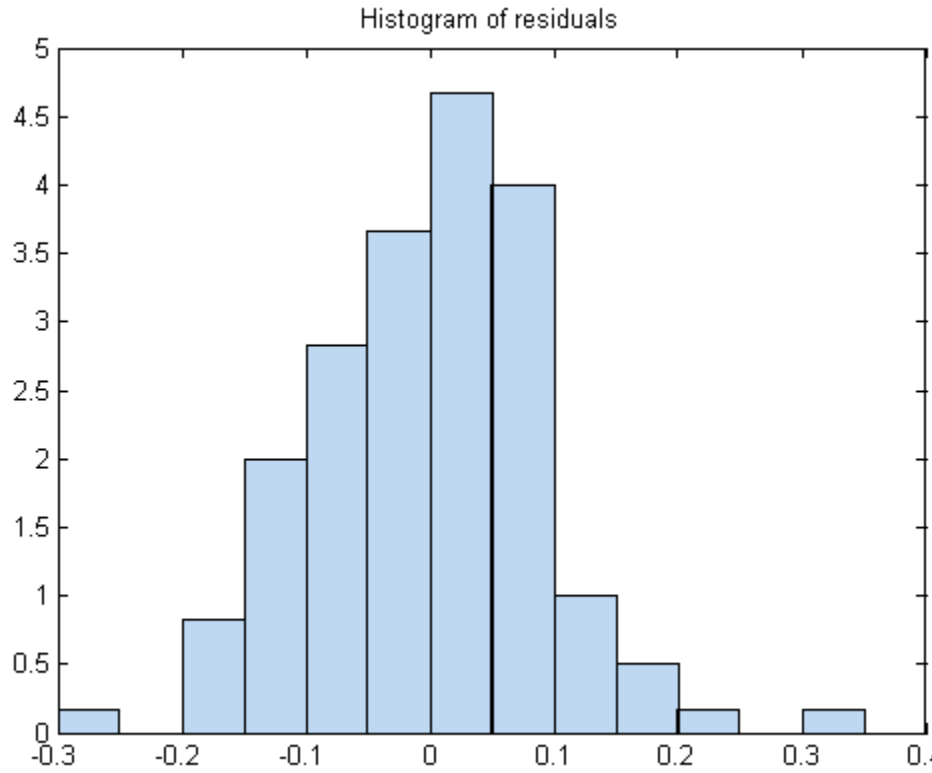
```
tbl = table(InitialWeight,Program,Subject,Week,y);
tbl.Subject = nominal(tbl.Subject);
tbl.Program = nominal(tbl.Program);
```

Fit a linear mixed-effects model where the initial weight, type of program, week, and the interaction between the week and type of program are the fixed effects. The intercept and week vary by subject.

```
lme = fitlme(tbl,'y ~ InitialWeight + Program*Week + (Week|Subject)');
```

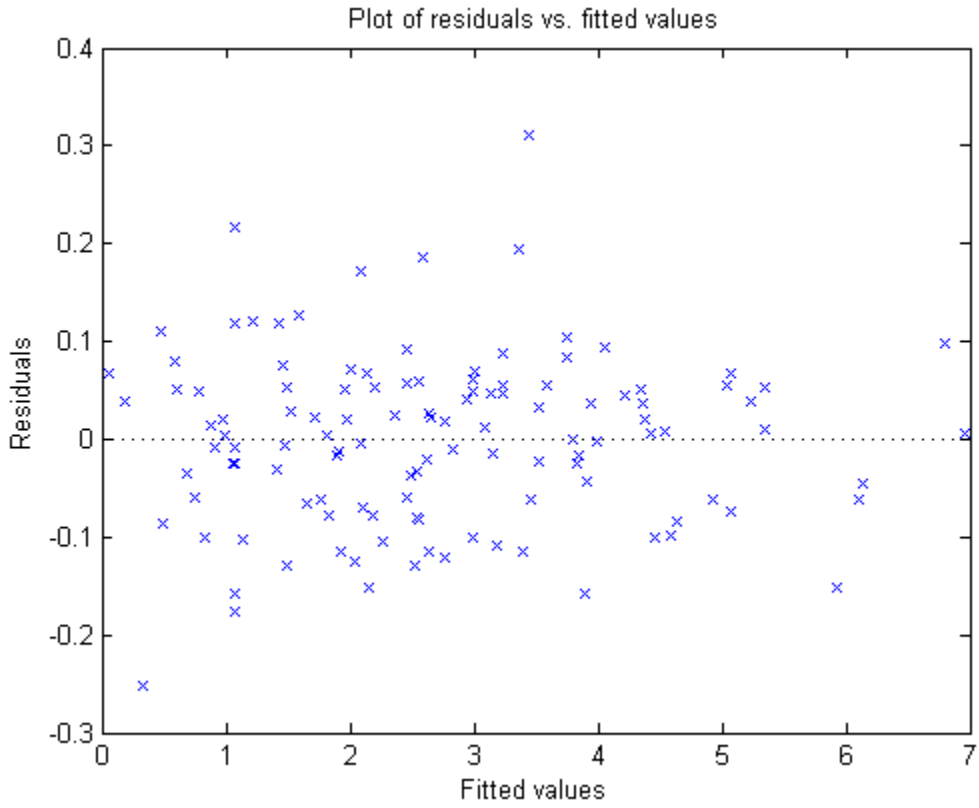
Plot the histogram of the raw residuals.

```
plotResiduals(lme)
```



Plot the residuals versus the fitted values.

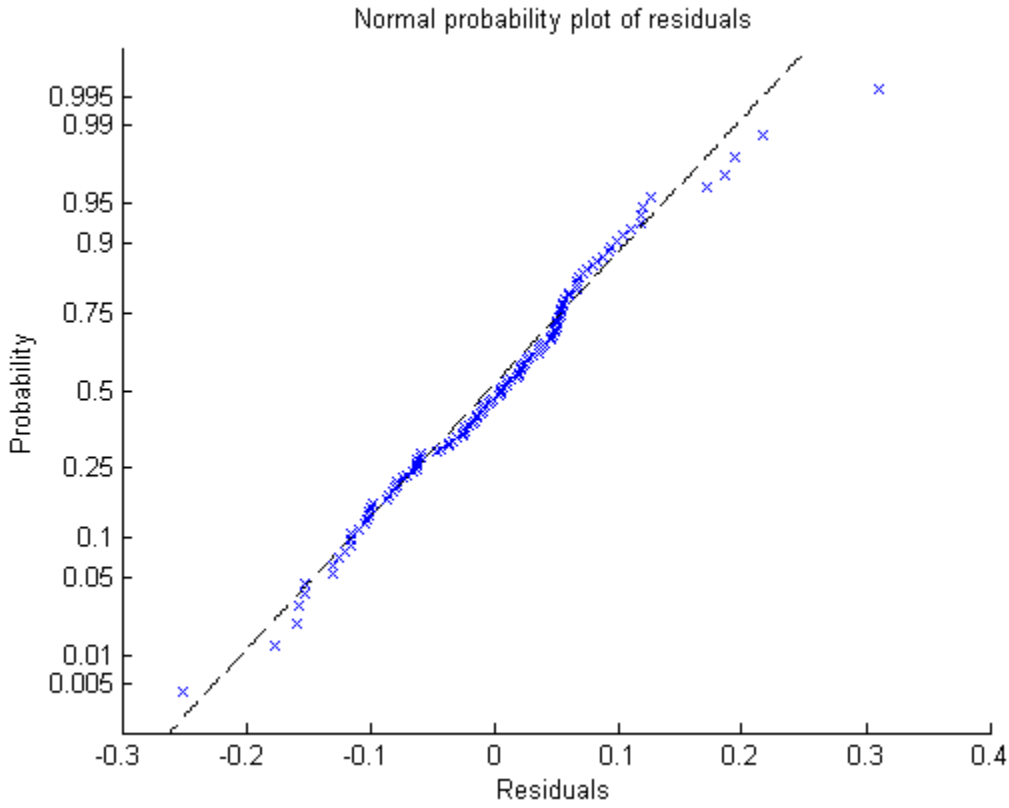
```
figure();
plotResiduals(lme,'fitted')
```



There is no obvious pattern, so there are no immediate signs of heteroscedasticity.

Create the normal probability plot of residuals.

```
figure();
plotResiduals(lme,'probability')
```



Data appears to be normal.

Find the observation number for the data that appears to be an outlier to the right of the plot.

```
find(residuals(lme)>0.25)
```

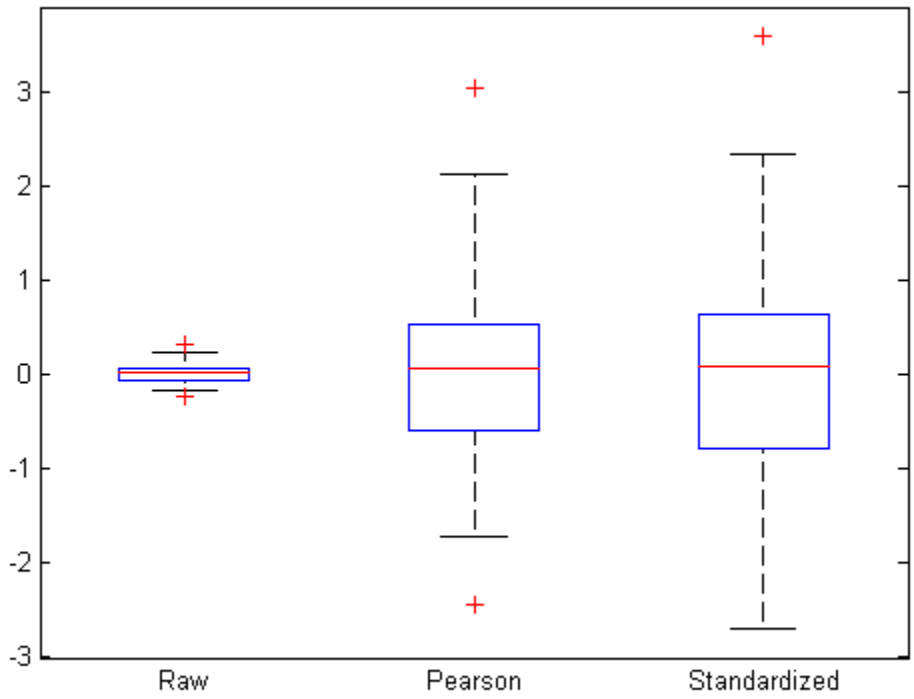
```
ans =

   101
```

Create a box plot of the raw, Pearson, and standardized residuals.

```
r = residuals(lme);
```

```
pr = residuals(lme,'ResidualType','Pearson');
st = residuals(lme,'ResidualType','Standardized');
X = [r pr st];
boxplot(X,'labels',{'Raw','Pearson','Standardized'});
```



All three box plots point out the outlier on the right tail of the distribution. The box plots of raw and Pearson residuals also point out a second possible outlier on the left tail. Find the corresponding observation number.

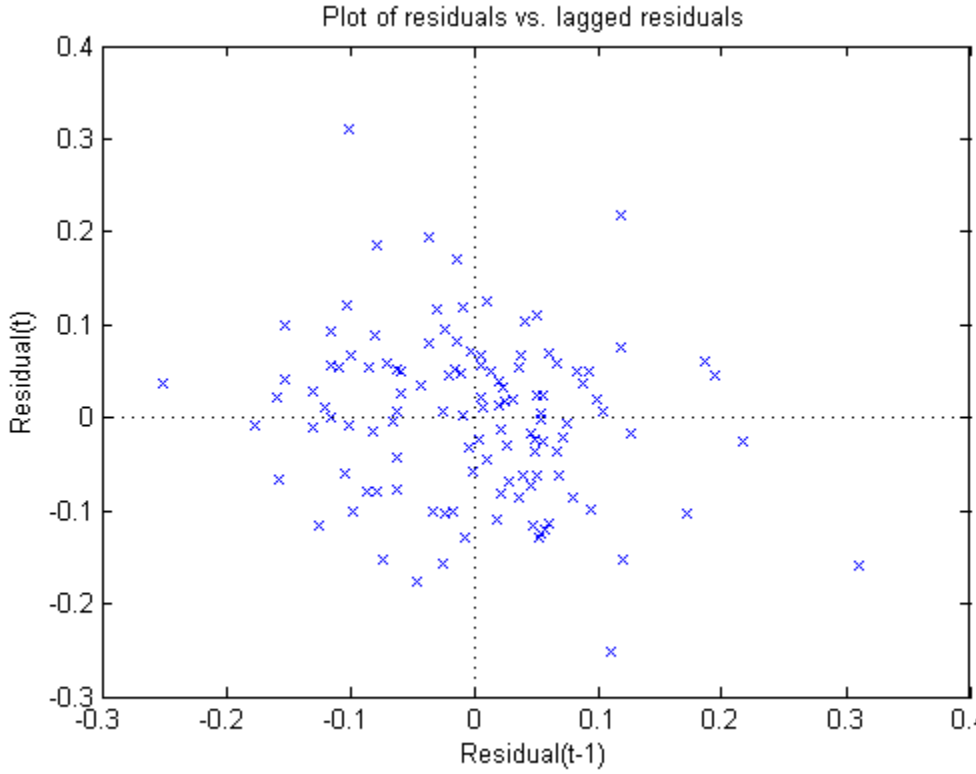
```
find(pr<-2)
```

```
ans =

    10
```

Plot the raw residuals versus lagged residuals.

```
plotResiduals(lme,'lagged')
```



There is no obvious pattern in the graph. The residuals do not appear to be correlated.

`fitted` | `LinearMixedModel` | `residuals`

plotResiduals

Class: NonLinearModel

Plot residuals of nonlinear regression model

Syntax

```
plotResiduals(mdl)
plotResiduals(mdl,plottype)
h = plotResiduals(...)
h = plotResiduals(mdl,plottype,Name,Value)
```

Description

`plotResiduals(mdl)` gives a histogram plot of the residuals of the `mdl` nonlinear model.

`plotResiduals(mdl,plottype)` plots residuals in a plot of type `plottype`.

`h = plotResiduals(...)` returns handles to the lines in the plot.

`h = plotResiduals(mdl,plottype,Name,Value)` plots with additional options specified by one or more Name,Value pair arguments.

Tips

- For many plots, the Data Cursor tool in the figure window displays the *x* and *y* values for any data point, along with the observation name or number.

Input Arguments

`mdl`

Nonlinear regression model, constructed by `fitnlm`.

`plottype`

String specifying the type of plot:

`'caseorder'`	Residuals vs. case (row) order
`'fitted'`	Residuals vs. fitted values
`'histogram'`	Histogram
`'lagged'`	Residuals vs. lagged residual ($r(t)$ vs. $r(t-1)$)
`'probability'`	Normal probability plot
`'symmetry'`	Symmetry plot

Default: `'histogram'`

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Note: The plot property name-value pairs apply to the first returned handle `h(1)`.

`'Color'`

Color of the line or marker, a string or `ColorSpec` specification. For details, see `linespec`.

`'LineStyle'`

Type of line, a string or Chart Line Properties specification. For details, see `linespec`.

`'LineWidth'`

Width of the line or edges of filled area, in points, a positive scalar. One point is 1/72 inch.

Default: `0.5`

`'MarkerEdgeColor'`

Color of the marker or edge color for filled markers, a string or `ColorSpec` specification. For details, see `linespec`.

`'MarkerFaceColor'`

Color of the marker face for filled markers, a string or `ColorSpec` specification. For details, see `linespec`.

`'MarkerSize'`

Size of the marker in points, a strictly positive scalar. One point is 1/72 inch.

`'ResidualType'`

Type of residual used in the plot:

`'Raw'`	Observed minus fitted values
`'Pearson'`	Raw residuals divided by RMSE
`'Standardized'`	Raw residuals divided by their estimated standard deviation
`'Studentized'`	Raw residuals divided by an independent (delete-1) estimate of their standard deviation

Default: `'Raw'`

Output Arguments

`h`

Vector of handles to lines or patches in the plot.

Examples

Residual Plot

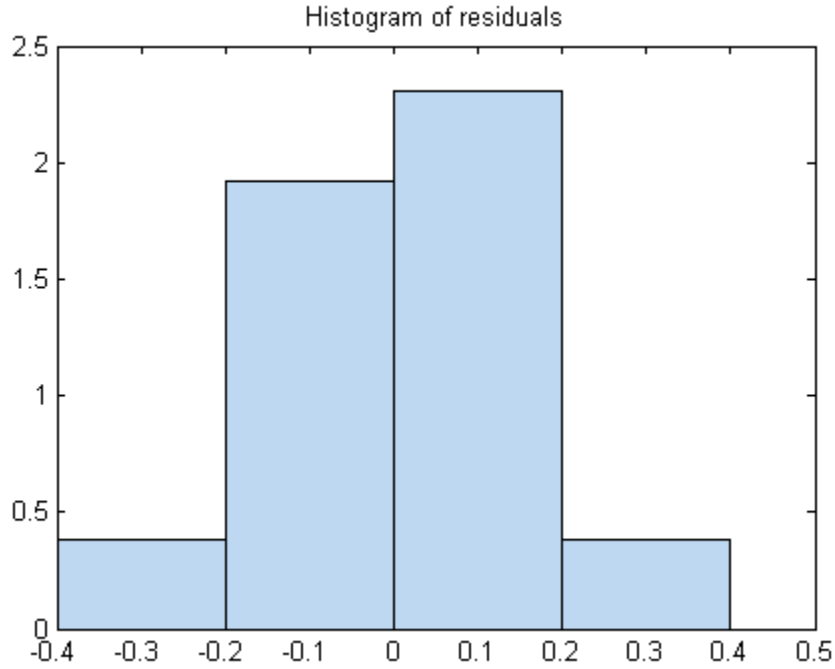
Plot the residuals of a fitted nonlinear model.

Load the `reaction` data and fit a model of the reaction rate as a function of reactants.

```
load reaction
mdl = fitnlm(reactants,rate,@hougen,[1 .05 .02 .1 2]);
```

Plot the residuals of the fitted model.

```
plotResiduals(mdl)
```



Residual Probability Plot

Create a normal probability plot of the residuals of a fitted nonlinear model.

Load the `reaction` data and fit a model of the reaction rate as a function of reactants.

```
load reaction
mdl = fitnlm(reactants,rate,@hougen,[1 .05 .02 .1 2]);
```

Create a normal probability plot of the residuals of the fitted model.

```
plotResiduals(mdl,'probability')
```

More About

- "Nonlinear Regression" on page 11-2

plotSlice

Class: GeneralizedLinearModel

Plot of slices through fitted generalized linear regression surface

Syntax

```
plotSlice(mdl)
h = plotSlice(mdl)
```

Description

`plotSlice(mdl)` creates a new figure containing a series of plots, each representing a slice through the regression surface predicted by `mdl`. For each plot, the surface slice is shown as a function of a single predictor variable, with the other predictor variables held constant.

`h = plotSlice(mdl)` returns handles to the lines in the plot.

Tips

- If there are more than eight predictors, `plotSlice` selects the first five for plotting. Use the **Predictors** menu to control which predictors are plotted.
- The **Bounds** menu lets you choose between simultaneous or non-simultaneous bounds, and between bounds on the function or bounds on a new observation.

Input Arguments

`mdl`

Generalized linear model, as constructed by `fitglm` or `stepwiseglm`.

Output Arguments

h

Vector of handles to lines or patches in the plot.

Examples

Slice Plot of Generalized Linear Regression Model

Create a slice plot of a Poisson generalized linear model.

Generate artificial data for the model using Poisson random numbers with two underlying predictors `X(1)` and `X(2)`.

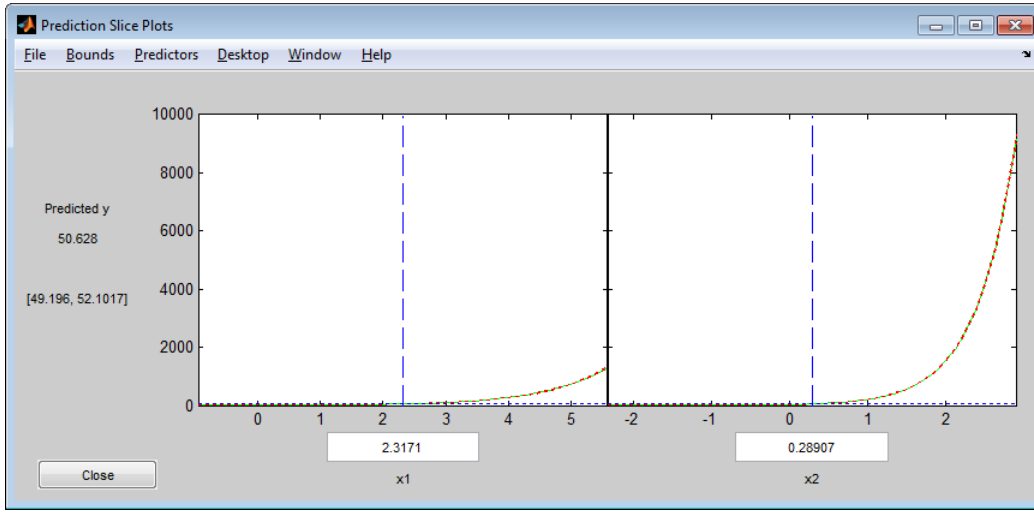
```
rng('default') % for reproducibility
rndvars = randn(100,2);
X = [2+rndvars(:,1),rndvars(:,2)];
mu = exp(1 + X*[1;2]);
y = poissrnd(mu);
```

Create a generalized linear regression model of Poisson data.

```
mdl = fitglm(X,y,'y ~ x1 + x2','distr','poisson');
```

Create the slice plot.

```
plotSlice(mdl)
```



Drag the `x1` prediction line to the right and view the changes in the prediction and the response curve for the `x2` predictor.

plotSlice

Class: LinearModel

Plot of slices through fitted linear regression surface

Syntax

```
plotSlice(mdl)
h = plotSlice(mdl)
```

Description

`plotSlice(mdl)` creates a new figure containing a series of plots, each representing a slice through the regression surface predicted by `mdl`. For each plot, the surface slice is shown as a function of a single predictor variable, with the other predictor variables held constant.

`h = plotSlice(mdl)` returns handles to the lines in the plot.

Tips

- If there are more than eight predictors, `plotSlice` selects the first five for plotting. Use the **Predictors** menu to control which predictors are plotted.
- The **Bounds** menu lets you choose between simultaneous or non-simultaneous bounds, and between bounds on the function or bounds on a new observation.

Input Arguments

`mdl`

Linear model, as constructed by `fitlm` or `stepwiselm`.

Output Arguments

h

Vector of handles to lines or patches in the plot.

Examples

Slice Plot

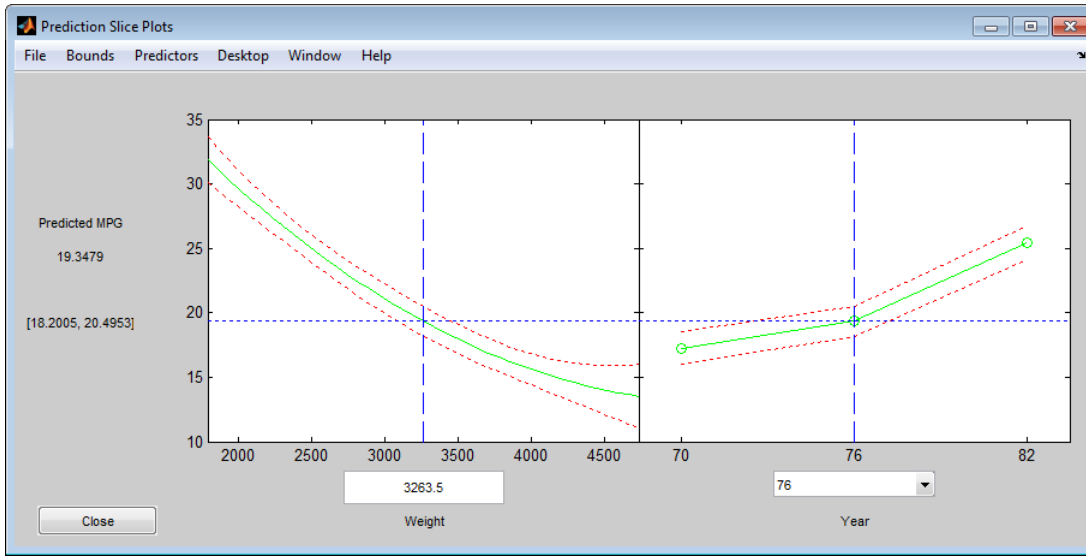
Plot the slices through a fitted linear model.

Load the `carsmall` data and fit a linear model of the mileage as a function of model year, weight, and weight squared.

```
load carsmall
tbl = table(MPG,Weight);
tbl.Year = ordinal(Model_Year);
mdl = fitlm(tbl,'MPG ~ Year + Weight^2');
```

Create a slice plot.

```
plotSlice(mdl)
```



Drag the `Weight` prediction line to the right and observe the change in the predicted `MPG` and the response curve for `Year`.

plotSlice

Class: NonLinearModel

Plot of slices through fitted nonlinear regression surface

Syntax

```
plotSlice(mdl)
h = plotSlice(mdl)
```

Description

`plotSlice(mdl)` creates a new figure containing a series of plots, each representing a slice through the regression surface predicted by `mdl`. For each plot, the surface slice is shown as a function of a single predictor variable, with the other predictor variables held constant.

`h = plotSlice(mdl)` returns handles to the lines in the plot.

Tips

- If there are more than eight predictors, `plotSlice` selects the first five for plotting. Use the **Predictors** menu to control which predictors are plotted.
- The **Bounds** menu lets you choose between simultaneous or non-simultaneous bounds, and between bounds on the function or bounds on a new observation.

Input Arguments

`mdl`

Nonlinear regression model, constructed by `fitnlm`.

Output Arguments

h

Vector of handles to lines or patches in the plot.

Examples

Slice Plot

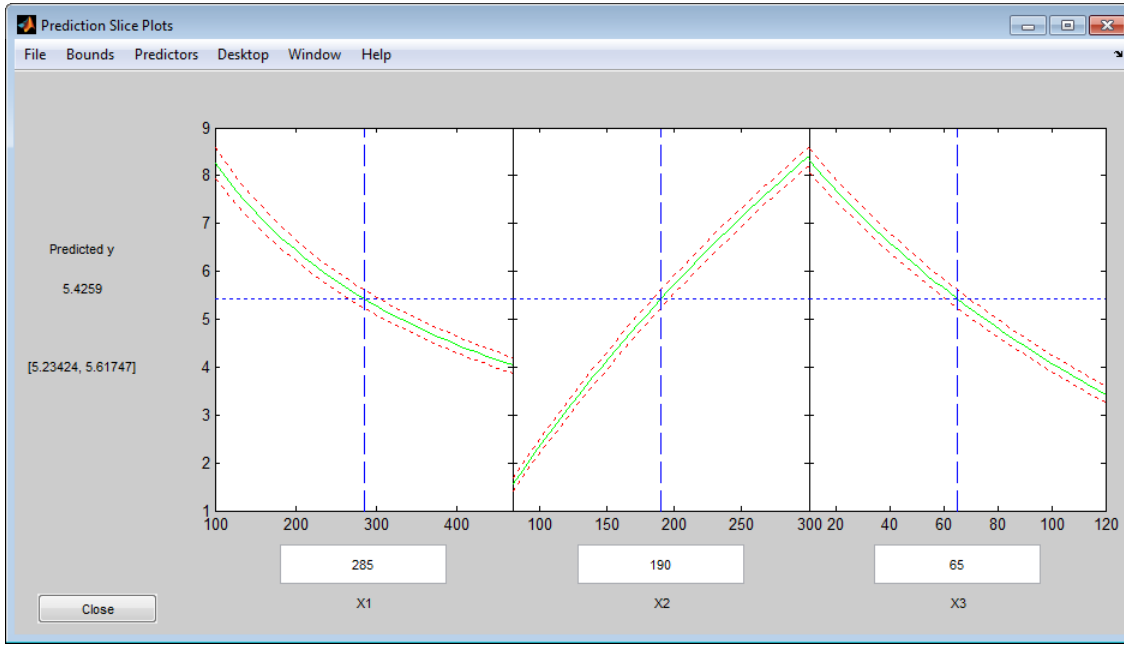
Plot slices of a fitted nonlinear model.

Load the `reaction` data and fit a model of the reaction rate as a function of reactants.

```
load reaction
mdl = fitnlm(reactants,...
    rate,@hougen,[1 .05 .02 .1 2]);
```

Create a slice plot

```
plotSlice(mdl)
```



Drag the `X1` prediction line to the right, and observe the change in the predicted response `y` and in the predicted response curves to `X2` and `X3`.

plsregress

Partial least-squares regression

Syntax

```
[XL,YL] = plsregress(X,Y,ncomp)
[XL,YL,XS] = plsregress(X,Y,ncomp)
[XL,YL,XS,YS] = plsregress(X,Y,ncomp)
[XL,YL,XS,YS,BETA] = PLSREGRESS(X,Y,ncomp,...)
[XL,YL,XS,YS,BETA,PCTVAR] = plsregress(X,Y,ncomp)
[XL,YL,XS,YS,BETA,PCTVAR,MSE] = plsregress(X,Y,ncomp)
[XL,YL,XS,YS,BETA,PCTVAR,MSE] =
plsregress(...,param1,val1,param2,val2,...)
[XL,YL,XS,YS,BETA,PCTVAR,MSE,stats] = PLSREGRESS(X,Y,ncomp,...)
```

Description

`[XL,YL] = plsregress(X,Y,ncomp)` computes a partial least-squares (PLS) regression of `Y` on `X`, using `ncomp` PLS components, and returns the predictor and response loadings in `XL` and `YL`, respectively. `X` is an n-by-p matrix of predictor variables, with rows corresponding to observations and columns to variables. `Y` is an n-by-m response matrix. `XL` is a p-by-`ncomp` matrix of predictor loadings, where each row contains coefficients that define a linear combination of PLS components that approximate the original predictor variables. `YL` is an m-by-`ncomp` matrix of response loadings, where each row contains coefficients that define a linear combination of PLS components that approximate the original response variables.

`[XL,YL,XS] = plsregress(X,Y,ncomp)` returns the predictor scores `XS`, that is, the PLS components that are linear combinations of the variables in `X`. `XS` is an n-by-`ncomp` orthonormal matrix with rows corresponding to observations and columns to components.

`[XL,YL,XS,YS] = plsregress(X,Y,ncomp)` returns the response scores `YS`, that is, the linear combinations of the responses with which the PLS components `XS` have maximum covariance. `YS` is an n-by-`ncomp` matrix with rows corresponding to observations and columns to components. `YS` is neither orthogonal nor normalized.

`plsregress` uses the SIMPLS algorithm, first centering `X` and `Y` by subtracting off column means to get centered variables `X0` and `Y0`. However, it does not rescale the columns. To perform PLS with standardized variables, use `zscore` to normalize `X` and `Y`.

If `ncomp` is omitted, its default value is `min(size(X,1)-1,size(X,2))`.

The relationships between the scores, loadings, and centered variables `X0` and `Y0` are:

`XL = (XS\X0)' = X0'*XS`,

`YL = (XS\Y0)' = Y0'*XS`,

`XL` and `YL` are the coefficients from regressing `X0` and `Y0` on `XS`, and `XS*XL'` and `XS*YL'` are the PLS approximations to `X0` and `Y0`.

`plsregress` initially computes `YS` as:

`YS = Y0*YL = Y0*Y0'*XS`,

By convention, however, `plsregress` then orthogonalizes each column of `YS` with respect to preceding columns of `XS`, so that `XS'*YS` is lower triangular.

`[XL,YL,XS,YS,BETA] = PLSREGRESS(X,Y,ncomp,...)` returns the PLS regression coefficients `BETA`. `BETA` is a (p+1)-by-m matrix, containing intercept terms in the first row:

`Y = [ones(n,1),X]*BETA + Yresiduals`,

`Y0 = X0*BETA(2:end,:) + Yresiduals`. Here `Yresiduals` is the vector of response residuals.

`[XL,YL,XS,YS,BETA,PCTVAR] = plsregress(X,Y,ncomp)` returns a 2-by-`ncomp` matrix `PCTVAR` containing the percentage of variance explained by the model. The first row of `PCTVAR` contains the percentage of variance explained in `X` by each PLS component, and the second row contains the percentage of variance explained in `Y`.

`[XL,YL,XS,YS,BETA,PCTVAR,MSE] = plsregress(X,Y,ncomp)` returns a 2-by-(`ncomp`+1) matrix `MSE` containing estimated mean-squared errors for PLS models with `0:ncomp` components. The first row of `MSE` contains mean-squared errors for the predictor variables in `X`, and the second row contains mean-squared errors for the response variable(s) in `Y`.

`[XL,YL,XS,YS,BETA,PCTVAR,MSE] = plsregress(...,param1,val1,param2,val2,...)` specifies optional parameter name/value pairs from the following table to control the calculation of `MSE`.

Parameter	Value
`'cv'`	The method used to compute `MSE`. • When the value is a positive integer `k`, `plsregress` uses `k`-fold cross-validation. • When the value is an object of the `cvpartition` class, other forms of cross-validation can be specified. • When the value is `'resubstitution'`, `plsregress` uses `X` and `Y` both to fit the model and to estimate the mean-squared errors, without cross-validation. The default is `'resubstitution'`.
`'mcreps'`	A positive integer indicating the number of Monte-Carlo repetitions for cross-validation. The default value is `1`. The value must be `1` if the value of `'cv'` is `'resubstitution'`.
`options`	A structure that specifies whether to run in parallel, and specifies the random stream or streams. Create the `options` structure with `statset`. Option fields: • `UseParallel` — Set to `true` to compute in parallel. Default is `false`. • `UseSubstreams` — Set to `true` to compute in parallel in a reproducible fashion. Default is `false`. To compute reproducibly, set `Streams` to a type allowing substreams: `'mlfg6331_64'` or `'mrg32k3a'`. • `Streams` — A `RandStream` object or cell array consisting of one such object. If you do not specify `Streams`, `plsregress` uses the default stream.

`[XL,YL,XS,YS,BETA,PCTVAR,MSE,stats] = PLSREGRESS(X,Y,ncomp,...)` returns a structure `stats` with the following fields:

- `W` — A p-by-`ncomp` matrix of PLS weights so that `XS = XO*W`.
- `T2` — The T^2 statistic for each point in `XS`.
- `Xresiduals` — The predictor residuals, that is, `XO-XS*XL'`.
- `Yresiduals` — The response residuals, that is, `YO-XS*YL'`.

Examples

Perform Partial Least-Squares Regression

Load data on near infrared (NIR) spectral intensities of 60 samples of gasoline at 401 wavelengths, and their octane ratings.

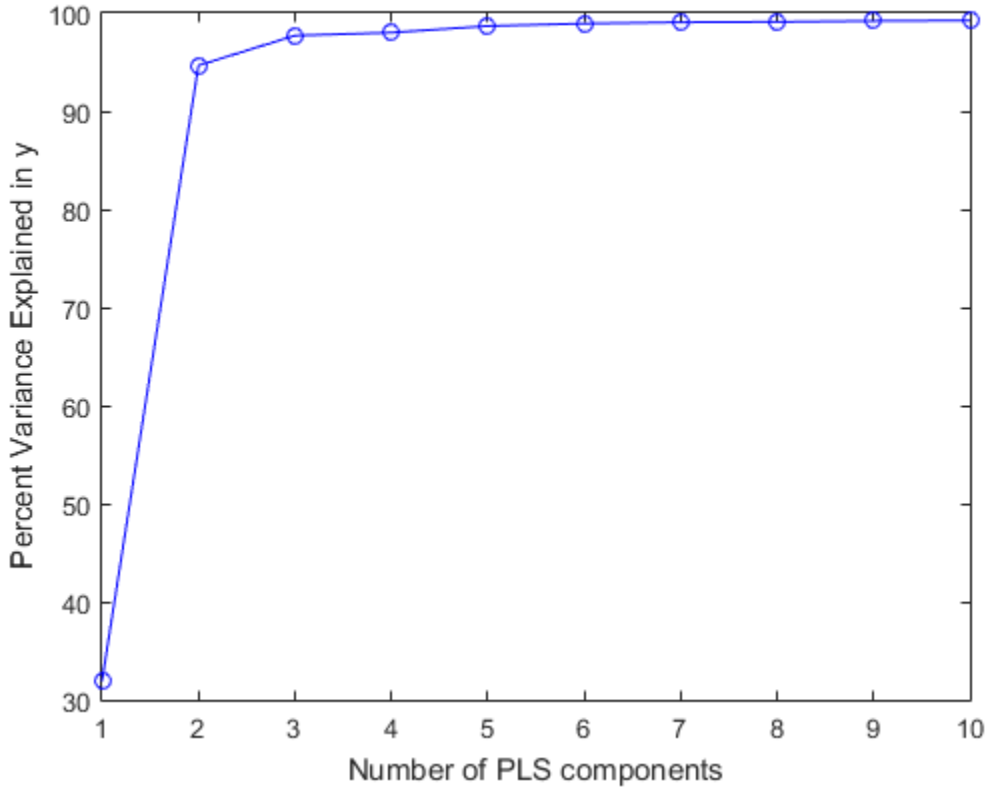
```
load spectra
X = NIR;
y = octane;
```

Perform PLS regression with ten components.

```
[XL,yl,XS,YS,beta,PCTVAR] = plsregress(X,y,10);
```

Plot the percent of variance explained in the response variable as a function of the number of components.

```
plot(1:10,cumsum(100*PCTVAR(2,:)),'-bo');
xlabel('Number of PLS components');
ylabel('Percent Variance Explained in y');
```



Compute the fitted response and display the residuals.

```
yfit = [ones(size(X,1),1) X]*beta;
residuals = y - yfit;
stem(residuals)
xlabel('Observation');
ylabel('Residual');
```

`regress` | `sequentialfs`

PointOrder property

Class: sobolset

Point generation method

Description

The `PointOrder` property contains a string that specifies the order in which the Sobol sequence points are produced. The property value must be one of `'standard'` or `'graycode'`. When set to `'standard'` the points produced match the original Sobol sequence implementation. When set to `'graycode'`, the sequence is generated using an implementation that uses the Gray code of the index instead of the index itself.

PointSet property

Class: qrandstream

Point set from which stream is drawn

Description

The `PointSet` property contains a copy of the point set from which the stream is providing points. The point set is specified during construction of a quasi-random stream and cannot subsequently be altered.

Examples

```
Q = qrandstream('sobol', 5, 'Skip', 8);
% Create a new stream based on the same sequence as that in Q
Q2 = qrandstream(Q.PointSet);
u1 = qrand(Q, 10)
u2 = qrand(Q2, 10) % contains exactly the same values as u1
```

poisscdf

Poisson cumulative distribution function

Syntax

```
p = poisscdf(x,lambda)
p = poisscdf(x,lambda,'upper')
```

Description

`p = poisscdf(x,lambda)` returns the Poisson cdf at each value in `x` using the corresponding mean parameters in `lambda`. `x` and `lambda` can be vectors, matrices, or multidimensional arrays that have the same size. A scalar input is expanded to a constant array with the same dimensions as the other input. The parameters in `lambda` must be positive.

`p = poisscdf(x,lambda,'upper')` returns the complement of the Poisson cdf at each value in `x`, using an algorithm that more accurately computes the extreme upper tail probabilities.

The Poisson cdf is

$$p = F(x \mid \lambda) = e^{-\lambda} \sum_{i=0}^{floor(x)} \frac{\lambda^i}{i!}$$

Examples

Compute Poisson Distribution cdf

For example, consider a Quality Assurance department that performs random tests of individual hard disks. Their policy is to shut down the manufacturing process if an inspector finds more than four bad sectors on a disk. What is the probability of shutting down the process if the mean number of bad sectors (λ) is two?

```
probability = 1-poisscdf(4,2)
```

```
probability =
  0.0527
```

About 5% of the time, a normally functioning manufacturing process produces more than four flaws on a hard disk.

Suppose the average number of flaws (λ) increases to four. What is the probability of finding fewer than five flaws on a hard drive?

```
probability = poisscdf(4,4)
```

```
probability =
  0.6288
```

This means that this faulty manufacturing process continues to operate after this first inspection almost 63% of the time.

`cdf` | `poisspdf` | `poissinv` | `poisstat` | `poissfit` | `poissrnd`

poissfit

Poisson parameter estimates

Syntax

```
lambdahat = poissfit(data)
[lambdahat,lambdaci] = poissfit(data)
[lambdahat,lambdaci] = poissfit(data,alpha)
```

Description

`lambdahat = poissfit(data)` returns the maximum likelihood estimate (MLE) of the parameter of the Poisson distribution, λ, given the data `data`.

`[lambdahat,lambdaci] = poissfit(data)` also gives 95% confidence intervals in `lamdaci`.

`[lambdahat,lambdaci] = poissfit(data,alpha)` gives `100(1 - alpha)`% confidence intervals. For example `alpha = 0.001` yields 99.9% confidence intervals.

The sample mean is the MLE of λ.

$$\hat{\lambda} = \frac{1}{n}\sum_{i=1}^{n} x_i$$

Examples

```
r = poissrnd(5,10,2);
[l,lci] = poissfit(r)
l =
    7.4000    6.3000
lci =
    5.8000    4.8000
    9.1000    7.9000
```

More About

- "Poisson Distribution" on page B-138

See Also

`mle` | `poisspdf` | `poisscdf` | `poissinv` | `poisstat` | `poissrnd`

poissinv

Poisson inverse cumulative distribution function

Syntax

```
X = poissinv(P,lambda)
```

Description

`X = poissinv(P,lambda)` returns the smallest value `X` such that the Poisson cdf evaluated at `X` equals or exceeds `P`, using mean parameters in `lambda`. `P` and `lambda` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other input.

Examples

If the average number of defects (λ) is two, what is the 95th percentile of the number of defects?

```
poissinv(0.95,2)
ans =
   5
```

What is the median number of defects?

```
median_defects = poissinv(0.50,2)
median_defects =
   2
```

prob.PoissonDistribution class

Package: prob
Superclasses: prob.ToolboxFittableParametricDistribution

Poisson probability distribution object

Description

`prob.PoissonDistribution` is an object consisting of parameters, a model description, and sample data for a Poisson probability distribution.

Create a probability distribution object with specified parameter values using `makedist`. Alternatively, fit a distribution to data using `fitdist` or the Distribution Fitting app.

Construction

`pd = makedist('Poisson')` creates a Poisson probability distribution object using the default parameter values.

`pd = makedist('Poisson','lambda',lambda)` creates a Poisson distribution object using the specified parameter value.

Input Arguments

`lambda` — Mean
1 (default) | nonnegative scalar value

Mean of the Poisson distribution, specified as a nonnegative scalar value.

Data Types: `single` | `double`

Properties

`lambda` — Mean
nonnegative scalar value

Mean of the Poisson distribution, stored as a nonnegative scalar value.

Data Types: `single` | `double`

`DistributionName` — Probability distribution name

probability distribution name string

Probability distribution name, stored as a valid probability distribution name string. This property is read-only.

Data Types: `char`

`InputData` — Data used for distribution fitting

structure

Data used for distribution fitting, stored as a structure containing the following:

- `data`: Data vector used for distribution fitting.
- `cens`: Censoring vector, or empty if none.
- `freq`: Frequency vector, or empty if none.

This property is read-only.

Data Types: `struct`

`IsTruncated` — Logical flag for truncated distribution

`0` | `1`

Logical flag for truncated distribution, stored as a logical value. If `IsTruncated` equals `0`, the distribution is not truncated. If `IsTruncated` equals `1`, the distribution is truncated. This property is read-only.

Data Types: `logical`

`NumParameters` — Number of parameters

positive integer value

Number of parameters for the probability distribution, stored as a positive integer value. This property is read-only.

Data Types: `single` | `double`

`ParameterCovariance` — Covariance matrix of the parameter estimates

matrix of scalar values

Covariance matrix of the parameter estimates, stored as a p-by-p matrix, where p is the number of parameters in the distribution. The `(i,j)` element is the covariance between

the estimates of the `i`th parameter and the `j`th parameter. The (`i`,`i`) element is the estimated variance of the `i`th parameter. If parameter `i` is fixed rather than estimated by fitting the distribution to data, then the (`i`,`i`) elements of the covariance matrix are 0. This property is read-only.

Data Types: `single | double`

`ParameterDescription` — Distribution parameter descriptions

cell array of strings

Distribution parameter descriptions, stored as a cell array of strings. Each cell contains a short description of one distribution parameter. This property is read-only.

Data Types: `char`

`ParameterIsFixed` — Logical flag for fixed parameters

array of logical values

Logical flag for fixed parameters, stored as an array of logical values. If `0`, the corresponding parameter in the `ParameterNames` array is not fixed. If `1`, the corresponding parameter in the `ParameterNames` array is fixed. This property is read-only.

Data Types: `logical`

`ParameterNames` — Distribution parameter names

cell array of strings

Distribution parameter names, stored as a cell array of strings. This property is read-only.

Data Types: `char`

`ParameterValues` — Distribution parameter values

vector of scalar values

Distribution parameter values, stored as a vector. This property is read-only.

Data Types: `single | double`

`Truncation` — Truncation interval

vector of scalar values

Truncation interval for the probability distribution, stored as a vector containing the lower and upper truncation boundaries. This property is read-only.

Data Types: `single` | `double`

Methods

Inherited Methods

cdf	Cumulative distribution function of probability distribution object
icdf	Inverse cumulative distribution function of probability distribution object
iqr	Interquartile range of probability distribution object
median	Median of probability distribution object
pdf	Probability density function of probability distribution object

negloglik	Negative log likelihood of probability distribution object
paramci	Confidence intervals for probability distribution parameters

proflik	Profile likelihood function for probability distribution object
std	Standard deviation of probability distribution object
var	Variance of probability distribution object

Definitions

Poisson Distribution

The Poisson distribution is appropriate for applications that involve counting the number of times a random event occurs in a given amount of time, distance, area, etc. If the number of counts follows the Poisson distribution, then the interval between individual counts follows the exponential distribution.

The Poisson distribution uses the following parameters.

Parameter	Description	Support
`lambda`	Mean	$\lambda \geq 0$

The probability density function of the Poisson distribution is

$$f(x \mid \lambda) = \frac{\lambda^x}{x!} e^{-\lambda} \quad ; \quad x = 0,1,2,\ldots,\infty .$$

Examples

Create a Poisson Distribution Object Using Default Parameters

Create a Poisson distribution object using the default parameter values.

```
pd = makedist('Poisson')
```

```
pd =

  PoissonDistribution

  Poisson distribution
    lambda = 1
```

Create a Poisson Distribution Object Using Specified Parameters

Create a Poisson distribution object by specifying the parameter values.

```
pd = makedist('Poisson','lambda',5)
```

```
pd =

  PoissonDistribution

  Poisson distribution
    lambda = 5
```

Compute the variance of the distribution.

```
v = var(pd)
```

```
v =

     5
```

For the Poisson distribution, both the mean and variance are equal to the parameter lambda.

poisspdf

Poisson probability density function

Syntax

```
Y = poisspdf(X,lambda)
```

Description

`Y = poisspdf(X,lambda)` computes the Poisson pdf at each of the values in `X` using mean parameters in `lambda`. `X` and `lambda` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other input. The parameters in `lambda` must all be positive.

The Poisson pdf is

$$f(x \mid \lambda) = \frac{\lambda^x}{x!} e^{-\lambda}; x = 0,1,2,\ldots,\infty .$$

The density function is zero unless x is an integer.

Examples

A computer hard disk manufacturer has observed that flaws occur randomly in the manufacturing process at the average rate of two flaws in a 4 GB hard disk and has found this rate to be acceptable. What is the probability that a disk will be manufactured with no defects?

In this problem, $\lambda = 2$ and $x = 0$.

```
p = poisspdf(0,2)
p =
  0.1353
```

poissrnd

Poisson random numbers

Syntax

```
R = poissrnd(lambda)
R = poissrnd(lambda,m,n,...)
R = poissrnd(lambda,[m,n,...])
```

Description

`R = poissrnd(lambda)` generates random numbers from the Poisson distribution with mean parameter `lambda`. `lambda` can be a vector, a matrix, or a multidimensional array. The size of `R` is the size of `lambda`.

`R = poissrnd(lambda,m,n,...)` or `R = poissrnd(lambda,[m,n,...])` generates an `m`-by-`n`-by-... array. The `lambda` parameter can be a scalar or an array of the same size as `R`.

Examples

Generate a random sample of 10 pseudo-observations from a Poisson distribution with $\lambda = 2$.

```
lambda = 2;

random_sample1 = poissrnd(lambda,1,10)
random_sample1 =
   1   0   1   2   1   3   4   2   0   0

random_sample2 = poissrnd(lambda,[1 10])
random_sample2 =
   1   1   1   5   0   3   2   2   3   4

random_sample3 = poissrnd(lambda(ones(1,10)))
random_sample3 =
```

```
    3     2     1     1     0     0     4     0     2     0
```

poisstat

Poisson mean and variance

Syntax

```
M = poisstat(lambda)
[M,V] = poisstat(lambda)
```

Description

`M = poisstat(lambda)` returns the mean of the Poisson distribution using mean parameters in `lambda`. The size of `M` is the size of `lambda`.

`[M,V] = poisstat(lambda)` also returns the variance `V` of the Poisson distribution.

For the Poisson distribution with parameter λ, both the mean and variance are equal to λ.

Examples

Find the mean and variance for the Poisson distribution with λ = 2.

```
[m,v] = poisstat([1 2; 3 4])
m =
   1   2
   3   4
v =
   1   2
   3   4
```

polyconf

Polynomial confidence intervals

Syntax

```
Y = polyconf(p,X)
[Y,DELTA] = polyconf(p,X,S)
[Y,DELTA] = polyconf(p,X,S,param1,val1,param2,val2,...)
```

Description

`Y = polyconf(p,X)` evaluates the polynomial `p` at the values in `X`. `p` is a vector of coefficients in descending powers.

`[Y,DELTA] = polyconf(p,X,S)` takes outputs `p` and `S` from `polyfit` and generates 95% prediction intervals `Y ± DELTA` for new observations at the values in `X`.

`[Y,DELTA] = polyconf(p,X,S,param1,val1,param2,val2,...)` specifies optional parameter name/value pairs chosen from the following list.

Parameter	Value
`'alpha'`	A value between 0 and 1 specifying a confidence level of `100*(1-alpha)`%. The default is `0.05`.
`'mu'`	A two-element vector containing centering and scaling parameters. With this option, `polyconf` uses `(X-mu(1))/mu(2)` in place of `X`.
`'predopt'`	Either `'observation'` (the default) to compute prediction intervals for new observations at the values in `X`, or `'curve'` to compute confidence intervals for the fit evaluated at the values in `X`. See below.
`'simopt'`	Either `'off'` (the default) for nonsimultaneous bounds, or `'on'` for simultaneous bounds. See below.

The `'predopt'` and `'simopt'` parameters can be understood in terms of the following functions:

- $p(x)$ — the unknown mean function estimated by the fit
- $l(x)$ — the lower confidence bound
- $u(x)$ — the upper confidence bound

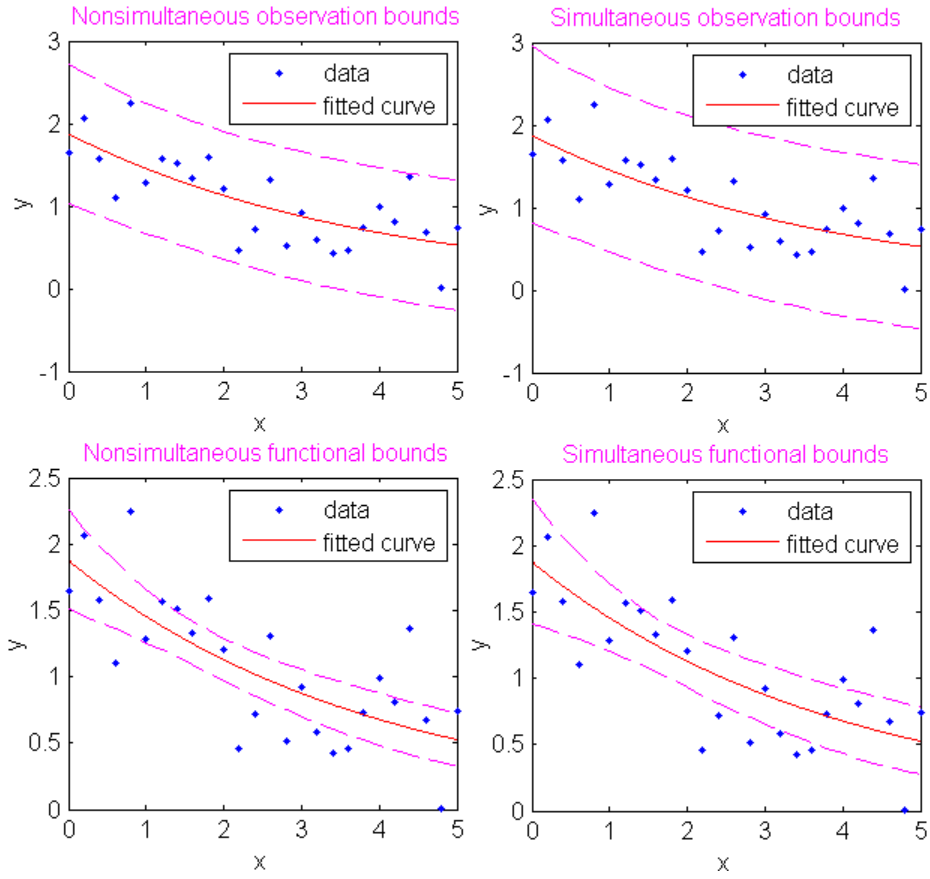
Suppose you make a new observation y_{n+1} at x_{n+1}, so that $y_{n+1}(x_{n+1}) = p(x_{n+1}) + \varepsilon_{n+1}$

By default, the interval $[l_{n+1}(x_{n+1}), u_{n+1}(x_{n+1})]$ is a 95% confidence bound on $y_{n+1}(x_{n+1})$.

The following combinations of the `'predopt'` and `'simopt'` parameters allow you to specify other bounds.

`'simopt'`	`'predopt'`	Bounded Quantity
`'off'`	`'observation'`	$y_{n+1}(x_{n+1})$ (default)
`'off'`	`'curve'`	$p(x_{n+1})$
`'on'`	`'observation'`	$y_{n+1}(x)$, for all x
`'on'`	`'curve'`	$p(x)$, for all x

In general, `'observation'` intervals are wider than `'curve'` intervals, because of the additional uncertainty of predicting a new response value (the curve plus random errors). Likewise, simultaneous intervals are wider than nonsimultaneous intervals, because of the additional uncertainty of bounding values for all predictors x.



Examples

This example uses code from the documentation example function `polydemo`, and calls the documentation example function `polystr` to convert the coefficient vector `p` into a string for the polynomial expression displayed in the figure title. It combines the functions `polyfit`, `polyval`, `roots`, and `polyconf` to produce a formatted display of data with a polynomial fit.

Note: Statistics and Machine Learning Toolbox documentation example files are located in the `\help\toolbox\stats\examples` subdirectory of your MATLAB root folder (`matlabroot`). This subdirectory is not on the MATLAB path at installation. To use the files in this subdirectory, either add the subdirectory to the MATLAB path (`addpath`) or make the subdirectory your current working folder (`cd`).

Display simulated data with a quadratic trend, a fitted quadratic polynomial, and 95% prediction intervals for new observations:

```
xdata = -5:5;
ydata = xdata.^2 - 5*xdata - 3 + 5*randn(size(xdata));

degree = 2;  % Degree of the fit
alpha = 0.05; % Significance level

% Compute the fit and return the structure used by
% POLYCONF.
[p,S] = polyfit(xdata,ydata,degree);

% Compute the real roots and determine the extent of the
% data.
r = roots(p)';        % Roots as a row vector.
real_r = r(imag(r) == 0);  % Real roots.

% Assure that the data are row vectors.
xdata = reshape(xdata,1,length(xdata));
ydata = reshape(ydata,1,length(ydata));

% Extent of the data.
mx = min([real_r,xdata]);
Mx = max([real_r,xdata]);
my = min([ydata,0]);
My = max([ydata,0]);

% Scale factors for plotting.
sx = 0.05*(Mx-mx);
sy = 0.05*(My-my);

% Plot the data, the fit, and the roots.
hdata = plot(xdata,ydata,'md','MarkerSize',5,...
  'LineWidth',2);
hold on
xfit = mx-sx:0.01:Mx+sx;
```

```
yfit = polyval(p,xfit);
hfit = plot(xfit,yfit,'b-','LineWidth',2);
hroots = plot(real_r,zeros(size(real_r)),...
              'bo','MarkerSize',5,...
              'LineWidth',2,...
              'MarkerFaceColor','b');
grid on
plot(xfit,zeros(size(xfit)),'k-','LineWidth',2)
axis([mx-sx Mx+sx my-sy My+sy])

% Add prediction intervals to the plot.
[Y,DELTA] = polyconf(p,xfit,S,'alpha',alpha);
hconf = plot(xfit,Y+DELTA,'b--');
plot(xfit,Y-DELTA,'b--')

% Display the polynomial fit and the real roots.
approx_p = round(100*p)/100; % Round for display.
htitle = title(['{\bf Fit:   }',...
  texlabel(polystr(approx_p))]);
set(htitle,'Color','b')
approx_real_r = round(100*real_r)/100; % Round for display.
hxlabel = xlabel(['{\bf Real Roots:     }',...
    num2str(approx_real_r)]);
set(hxlabel,'Color','b')

% Add a legend.
legend([hdata,hfit,hroots,hconf],...
        'Data','Fit','Real Roots of Fit',...
        '95% Prediction Intervals')
```

`polyfit` | `polytool` | `polyval`

polytool

Interactive polynomial fitting

Syntax

```
polytool(x,y)
polytool(x,y,n)
polytool(x,y,n,alpha)
polytool(x,y,n,alpha,xname,yname)
h = polytool(...)
```

Description

`polytool(x,y)` fits a line to the vectors `x` and `y` and displays an interactive plot of the result in a graphical interface. You can use the interface to explore the effects of changing the parameters of the fit and to export fit results to the workspace.

`polytool(x,y,n)` initially fits a polynomial of degree `n`. The default is `1`, which produces a linear fit.

`polytool(x,y,n,alpha)` initially plots `100(1 - alpha)`% confidence intervals on the predicted values. The default is `0.05` which results in 95% confidence intervals.

`polytool(x,y,n,alpha,xname,yname)` labels the `x` and `y` values on the graphical interface using the strings `xname` and `yname`. Specify `n` and `alpha` as `[]` to use their default values.

`h = polytool(...)` outputs a vector of handles, `h`, to the line objects in the plot. The handles are returned in the degree: data, fit, lower bounds, upper bounds.

Examples

Interactive polynomial fitting

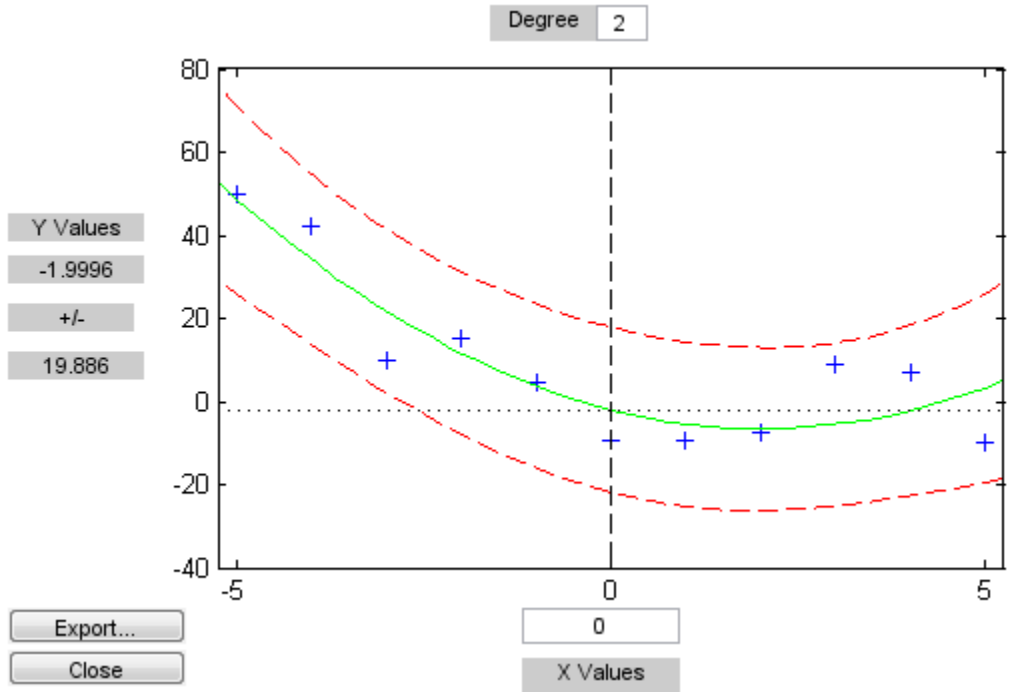
This example shows how to start an interactive fitting session with `polytool`.

Generate data from a quadratic curve with added noise.

```
rng('default') % for reproducibility
x = -5:5;
y = x.^2 - 5*x - 3 + 5*randn(size(x));
```

Fit a quadratic (degree-2) model with `0.90` confidence intervals.

```
n = 2;
alpha = 0.1;
polytool(x,y,n,alpha)
```



See Also

posterior

Class: gmdistribution

Posterior probabilities of components

Syntax

```
P = posterior(obj,X)
[P,nlogl] = posterior(obj,X)
```

Description

`P = posterior(obj,X)` returns the posterior probabilities of each of the k components in the Gaussian mixture distribution defined by `obj` for each observation in the data matrix `X`. `X` is n-by-d, where n is the number of observations and d is the dimension of the data. `obj` is an object created by `gmdistribution` or `fitgmdist`. `P` is n-by-k, with `P(I,J)` the probability of component `J` given observation `I`.

`posterior` treats `NaN` values as missing data. Rows of `X` with `NaN` values are excluded from the computation.

`[P,nlogl] = posterior(obj,X)` also returns `nlogl`, the negative log-likelihood of the data.

Examples

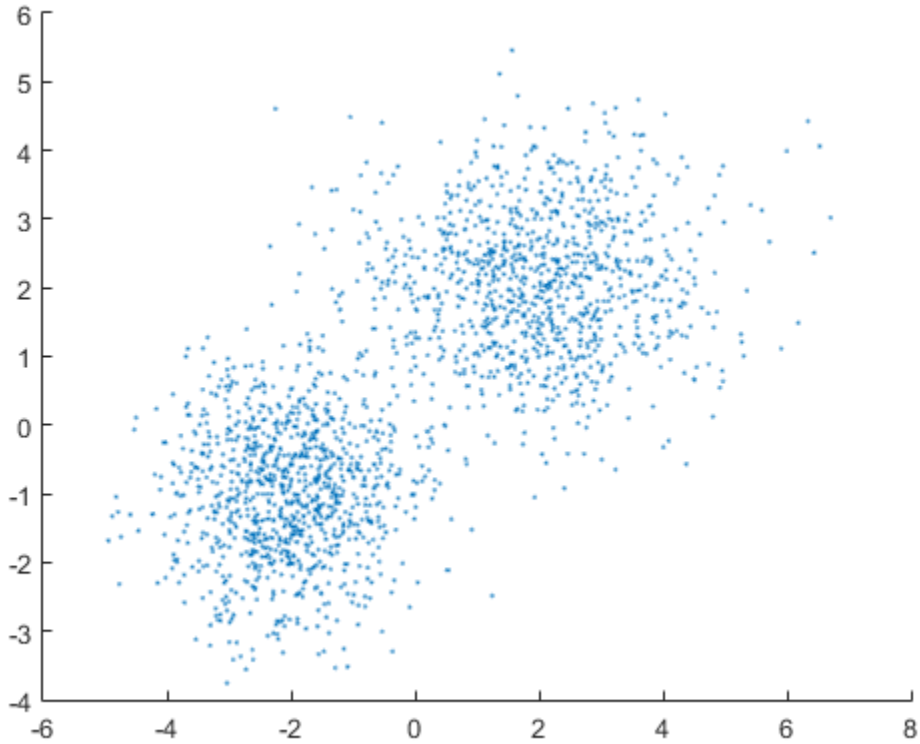
Compute Posterior Probabilities for Gaussian Mixture Variates

Generate data from a mixture of two bivariate Gaussian distributions using the `mvnrnd` function.

```
MU1 = [2 2];
SIGMA1 = [2 0; 0 1];
MU2 = [-2 -1];
```

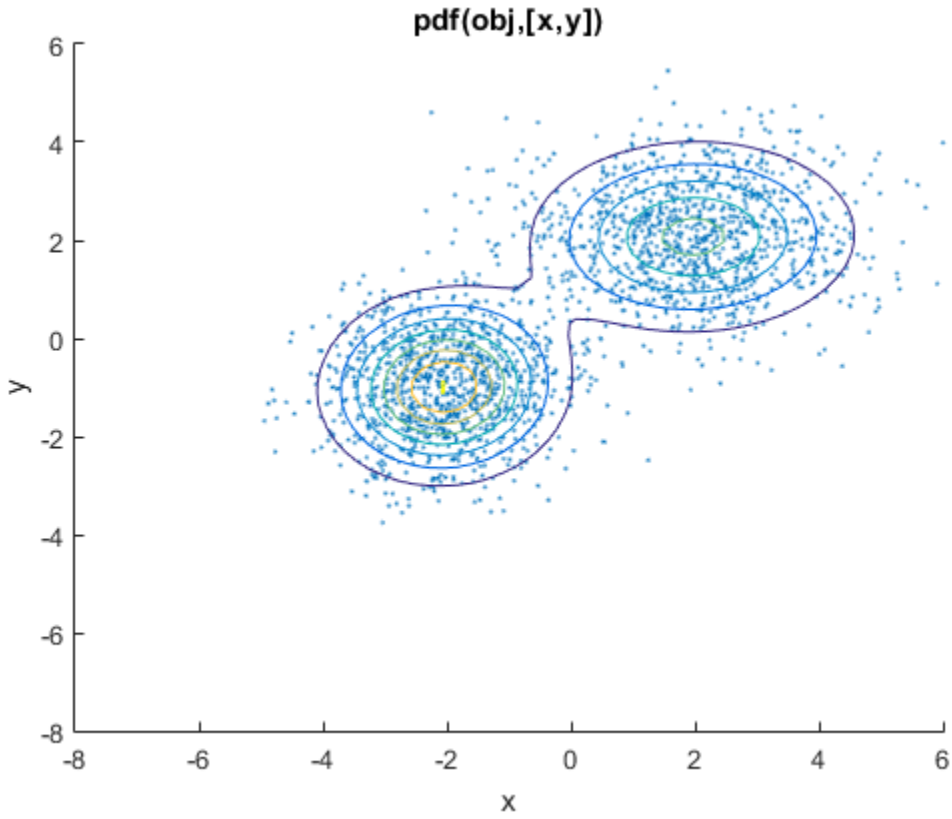
```
SIGMA2 = [1 0; 0 1];
rng(1); % For reproducibility
X = [mvnrnd(MU1,SIGMA1,1000);mvnrnd(MU2,SIGMA2,1000)];

scatter(X(:,1),X(:,2),10,'.')
hold on
```



Fit a two-component Gaussian mixture model.

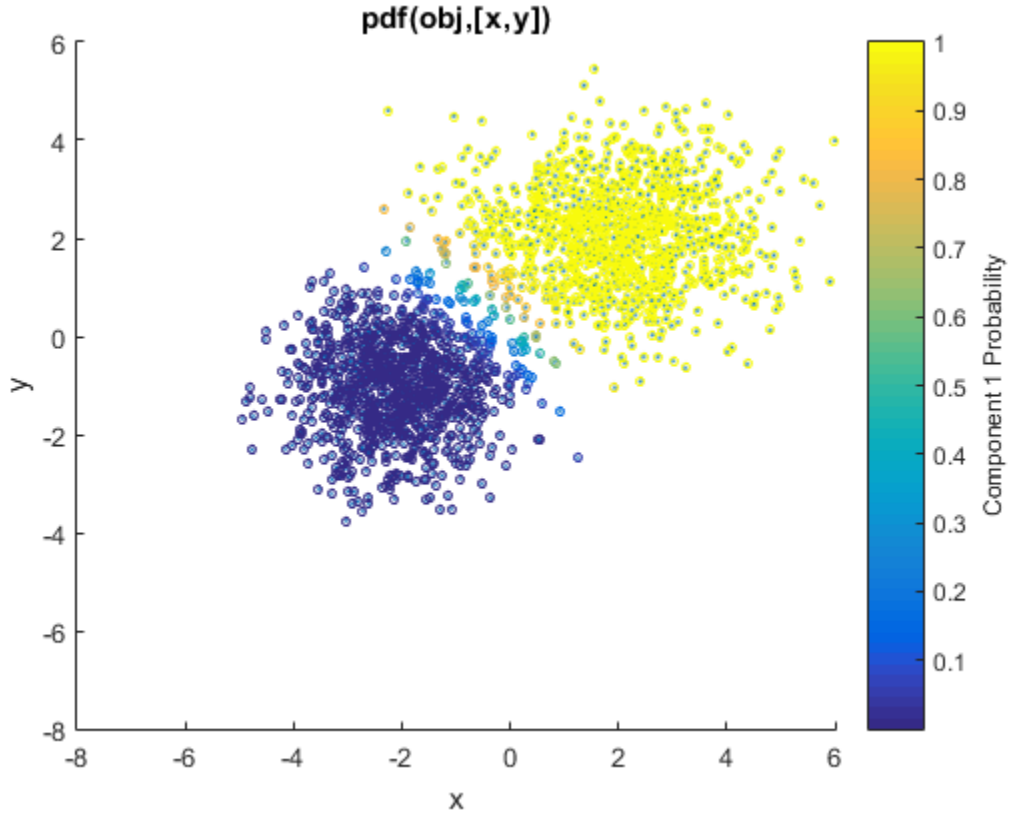
```
obj = fitgmdist(X,2);
h = ezcontour(@(x,y)pdf(obj,[x y]),[-8 6],[-8 6]);
```



Compute posterior probabilities of the components.

```
P = posterior(obj,X);

delete(h)
scatter(X(:,1),X(:,2),10,P(:,1))
hb = colorbar;
ylabel(hb,'Component 1 Probability')
```



See Also

`gmdistribution` | `mahal` | `fitgmdist` | `cluster`

posterior

Class: NaiveBayes

Compute posterior probability of each class for test data

Syntax

```
post = posterior(nb,test)
[post,cpre] = posterior(nb,test)
[post,cpre,logp] = posterior(nb,test)
[...] = posterior(..., 'HandleMissing',val)
```

Description

`post = posterior(nb,test)` returns the posterior probability of the observations in `test` according to the `NaiveBayes` object `nb`. `test` is a `N`-by-`nb.ndims` matrix, where `N` is the number of observations in the test data. Rows of `test` correspond to points, columns of `test` correspond to features. `post` is a `N`-by-`nb.nclasses` matrix containing the posterior probability of each observation for each class. `post(i,j)` is the posterior probability of point I belonging to class `j`. Classes are ordered the same as `nb.clevels`, i.e., column `j` of `post` corresponds to the `j`th class in `nb.clevels`. The posterior probabilities corresponding to any empty classes are `NaN`.

`[post,cpre] = posterior(nb,test)` returns `cpre`, an `N`-by-1 vector, containing the class to which each row of `test` has been assigned. `cpre` has the same type as `nb.CLevels`.

`[post,cpre,logp] = posterior(nb,test)` returns `logp`, an `N`-by-1 vector containing estimates of the log of the probability density function (PDF). `logp(i)` is the log of the PDF of point `i`. The PDF value of point `i` is the sum of `Prob(point I | class J) * Pr{class J}` taken over all classes.

`[...] = posterior(..., 'HandleMissing',val)` specifies how `posterior` treats NaN (missing values). `val` can be one of the following:

`'off'` (default)	Observations with `NaN` in any of the columns are not classified into any class. The corresponding rows in `post` and `logp` are `NaN`. The

	corresponding rows in `cpre` are `NaN` (if `obj.clevels` is numeric or logical), empty strings (if `obj.clevels` is char or cell array of strings) or `<undefined>` (if `obj.clevels` is categorical).
`'on'`	For observations having `NaN` in some (but not all) columns, `post` and `cpre` are computed using the columns with non-`NaN` values. Corresponding `logp` values are `NaN`.

See Also

`NaiveBayes` | `fitNaiveBayes` | `predict`

prctile

Percentiles of a data set

Syntax

```
Y = prctile(X,p)
Y = prctile(X,p,dim)
```

Description

`Y = prctile(X,p)` returns percentiles of the values in a data vector or matrix `X` for the percentages `p` in the interval [0,100].

- If `X` is a vector, then `Y` is a scalar or a vector with the same length as the number of percentiles required (`length(p)`). `Y(i)` contains the `p(i)` percentile.
- If `X` is a matrix, then `Y` is a row vector or a matrix, where the number of rows of `Y` is equal to the number of percentiles required (`length(p)`). The `i`th row of `Y` contains the `p(i)` percentiles of each column of `X`.
- For multidimensional arrays, `prctile` operates along the first nonsingleton dimension of `X`.

`Y = prctile(X,p,dim)` returns percentiles along dimension `dim`.

Examples

Percentiles of a Data Vector

Generate a data set of size 10.

```
rng('default'); % for reproducibility
x = normrnd(5,2,1,10)
```

```
x =
    6.0753    8.6678    0.4823    6.7243    5.6375    2.3846    4.1328    5.6852    12.
```

Calculate the 42nd percentile.

```
Y = prctile(x,42)
```

```
Y =
    5.6709
```

Percentiles of a Data Matrix

Calculate the percentiles along the columns and rows of a data matrix for specified percentages.

Generate a 5-by-5 data matrix.

```
X = (1:5)'*(2:6)
```

```
X =
     2     3     4     5     6
     4     6     8    10    12
     6     9    12    15    18
     8    12    16    20    24
    10    15    20    25    30
```

Calculate the 25th, 50th, and 75th percentiles along the columns of `X`.

```
Y = prctile(X,[25 50 75],1)
```

```
Y =
    3.5000    5.2500    7.0000    8.7500   10.5000
    6.0000    9.0000   12.0000   15.0000   18.0000
    8.5000   12.7500   17.0000   21.2500   25.5000
```

The rows of `Y` correspond to the percentiles of columns of `X`. For example, the 25th, 50th, and 75th percentiles of the third column of `X` with elements (4, 8, 12, 16, 20) are 7, 12, and 17, respectively. `Y = prctile(X,[25 50 75])` returns the same percentile matrix.

Calculate the 25th, 50th, and 75th percentiles along the rows of `X`.

```
Y = prctile(X,[25 50 75],2)
```

```
Y =

    2.7500    4.0000    5.2500
    5.5000    8.0000   10.5000
    8.2500   12.0000   15.7500
   11.0000   16.0000   21.0000
```

```
   13.7500   20.0000   26.2500
```

The rows of `Y` correspond to the percentiles of rows of `X`. For example, the 25th, 50th, and 75th percentiles of the first row of `X` with elements (2, 3, 4, 5, 6) are 2.75, 4, and 5.25, respectively.

Input Arguments

`X` — Input data

vector | array

Input data, specified as a vector or array.

Data Types: `double` | `single`

`p` — Percentages

scalar | vector

Percentages for which to compute percentiles, returned as a scalar or vector of scalars from 0 to 100.

Example: 25

Example: [25, 50, 75]

Data Types: `double` | `single`

`dim` — Dimension

1 (default) | positive integer

Dimension along which the percentiles of `X` are required, specified as a positive integer. For example, for a matrix `X`, when `dim` = 1, `prctile` returns the quantile(s) of the columns of `X` and when `dim` = 2, quantile returns the quantile(s) of the rows of `X`. For a multidimensional array `X`, the length of the `dim`th dimension of `Y` is equal to the length of `p`.

Data Types: `double`

Output Arguments

`Y` — Percentiles

scalar | array

Percentiles of a data vector or array, specified as a scalar or array for one or more percentage values.

- If `X` is a vector, then `Y` is a scalar or a vector with the same length as the number of percentiles required (`length(p)`). `Y(i)` contains the `p(i)`th percentile.
- If `X` is a matrix, then `Y` is a vector or a matrix with the length of the `dim`th dimension equal to the number percentiles required (`length(p)`). When `dim` = 1, for example, the `i`th row of `Y` contains the `p(i)`th percentiles of columns of `X`.
- If `X` is an array of dimension *d*, then `Y` is an array with the length of the `dim`th dimension equal to the number of percentiles required (`length(p)`).

More About

Multidimensional Array

A *multidimensional array* is an array with more than two dimensions. For example, if X is a 1-by-3-by-4 array, then X is a 3-D array.

Nonsingleton Dimension

A *first nonsingleton dimension* is the first dimension of an array whose size is not equal to 1. For example, if X is a 1-by-2-by-3-by-4 array, then the second dimension is the first nonsingleton dimension of X.

Linear Interpolation

Linear interpolation uses linear polynomials to find $y_i = f(x_i)$, the values of the underlying function $Y = f(X)$ at the points in the vector or array x. Given the data points (x_1, y_1) and (x_2, y_2), where $y_1 = f(x_1)$ and $y_2 = f(x_2)$, linear interpolation finds $y = f(x)$ for a given x between x_1 and x_2 as follows:

$$y = f(x) = y_1 + \frac{(x - x_1)}{(x_2 - x_1)}(y_2 - y_1).$$

Similarly, if the 100(1.5/n)th percentile is $y_{1.5/n}$ and the 100(2.5/n)th percentile is $y_{2.5/n}$, then linear interpolation finds the 100(2.3/n)th percentile, $y_{2.3/n}$ as:

$$y_{\frac{2.3}{n}} = y_{\frac{1.5}{n}} + \frac{\left(\frac{2.3}{n} - \frac{1.5}{n}\right)}{\left(\frac{2.5}{n} - \frac{1.5}{n}\right)}\left(y_{\frac{2.5}{n}} - y_{\frac{1.5}{n}}\right).$$

Algorithms

For an n-element vector `X`, `prctile` returns percentiles as follows:

1. The sorted values in `X` are taken as the 100(0.5/n)th, 100(1.5/n)th, ..., 100([n – 0.5]/n)th percentiles. For example:
   - For a data vector of five elements such as {6, 3, 2, 10, 1}, the sorted elements {1, 2, 3, 6, 10} respectively correspond to the 10th, 30th, 50th, 70th, and 90th percentiles.
   - For a data vector of six elements such as {6, 3, 2, 10, 8, 1}, the sorted elements {1, 2, 3, 6, 8, 10} respectively correspond to the (50/6)th, (150/6)th, (250/6)th, (350/6)th, (450/6)th, and (550/6)th percentiles.
2. `prctile` uses linear interpolation to compute percentiles for percentages between 100(0.5/n) and 100([n – 0.5]/n).
3. `prctile` assigns the minimum or maximum values in `X` to the percentiles corresponding to the percentages outside that range.

`prctile` treats `NaN`s as missing values and removes them.

predict

Class: ClassificationKNN

Predict *k*-nearest neighbor classification

Syntax

```
label = predict(mdl,Xnew)
[label,score] = predict(mdl,Xnew)
[label,score,cost] = predict(mdl,Xnew)
```

Description

`label = predict(mdl,Xnew)` returns a vector of predicted class labels for a matrix `Xnew`, based on `mdl`, a `ClassificationKNN` model.

`[label,score] = predict(mdl,Xnew)` returns a matrix of scores, indicating the likelihood that a label comes from a particular class.

`[label,score,cost] = predict(mdl,Xnew)` returns a matrix of costs; `label` is the vector of minimal costs for each row of `cost`

Input Arguments

`mdl` — Classifier model

classifier model object

k-nearest neighbor classifier model, returned as a classifier model object.

Note that using the `'CrossVal'`, `'KFold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'` options results in a model of class `ClassificationPartitionedModel`. You cannot use a partitioned tree for prediction, so this kind of tree does not have a `predict` method.

Otherwise, mdl is of class `ClassificationKNN`, and you can use the `predict` method to make predictions.

`Xnew` — Prediction points
matrix

Points at which `mdl` predicts classifications. Each row of `Xnew` is one point. The number of columns in `Xnew` must equal the number of predictors in `mdl`.

If you specified to standardize the predictor data, that is, `mdl.Mu` and `mdl.Sigma` are not empty (`[]`), then `predict` standardizes `Xnew` before predicting labels.

Output Arguments

`label`

Predicted class labels for the points in `Xnew`, a vector with length equal to the number of rows of `Xnew`. The label is the class with minimal expected cost. See "Predicted Class Label" on page 22-3653.

`score`

Numeric matrix of size `N`-by-`K`, where `N` is the number of observations (rows) in `Xnew`, and `K` is the number of classes (in `mdl.ClassNames`). `score(i,j)` is the posterior probability that row `i` of `Xnew` is of class `j`. See "Posterior Probability" on page 22-3654.

`cost`

Matrix of expected costs of size `N`-by-`K`, where `N` is the number of observations (rows) in `Xnew`, and `K` is the number of classes (in `mdl.ClassNames`). `cost(i,j)` is the cost of classifying row `i` of `X` as class `j`. See "Expected Cost" on page 22-3655.

Definitions

Predicted Class Label

`predict` classifies so as to minimize the expected classification cost:

$$\hat{y} = \underset{y=1,\ldots,K}{\arg\min} \sum_{k=1}^{K} \hat{P}(k \mid x) C(y \mid k),$$

where

- $\hat{y}$ is the predicted classification.
- K is the number of classes.
- $\hat{P}(k \mid x)$ is the posterior probability of class k for observation x.
- $C(y \mid k)$ is the cost of classifying an observation as y when its true class is k.

Posterior Probability

For a vector (single query point) `Xnew` and model `mdl`, let:

- `K` be the number of nearest neighbors used in prediction, `mdl.NumNeighbors`
- `nbd(mdl,Xnew)` be the `K` nearest neighbors to `Xnew` in `mdl.X`
- `Y(nbd)` be the classifications of the points in `nbd(mdl,Xnew)`, namely `mdl.Y(nbd)`
- `W(nbd)` be the weights of the points in `nbd(mdl,Xnew)`
- `prior` be the priors of the classes in `mdl.Y`

If there is a vector of prior probabilities, then the observation weights `W` are normalized by class to sum to the priors. This might involve a calculation for the point `Xnew`, because weights can depend on the distance from `Xnew` to the points in `mdl.X`.

The posterior probability $p(j \mid \texttt{Xnew})$ is

$$p(j \mid \text{Xnew}) = \frac{\sum_{i \in \text{nbd}} W(i) 1_{Y(X(i)=j)}}{\sum_{i \in \text{nbd}} W(i)}.$$

Here, $1_{Y(X(i)=j)}$ means `1` when `mdl.Y(i) = j`, and `0` otherwise.

True Misclassification Cost

There are two costs associated with KNN classification: the true misclassification cost per class, and the expected misclassification cost per observation.

You can set the true misclassification cost per class in the `Cost` name-value pair when you run `fitcknn`. `Cost(i,j)` is the cost of classifying an observation into class `j` if its

true class is `i`. By default, `Cost(i,j)=1` if `i~=j`, and `Cost(i,j)=0` if `i=j`. In other words, the cost is `0` for correct classification, and `1` for incorrect classification.

Expected Cost

There are two costs associated with KNN classification: the true misclassification cost per class, and the expected misclassification cost per observation. The third output of `predict` is the expected misclassification cost per observation.

Suppose you have `Nobs` observations that you want to classify with a trained classifier `mdl`. Suppose you have `K` classes. You place the observations into a matrix `Xnew` with one observation per row. The command

```
[label,score,cost] = predict(mdl,Xnew)
```

returns, among other outputs, a `cost` matrix of size `Nobs`-by-`K`. Each row of the `cost` matrix contains the expected (average) cost of classifying the observation into each of the `K` classes. `cost(n,k)` is

$$\sum_{i=1}^{K}\hat{P}(i\mid Xnew(n))C(k\mid i),$$

where

- K is the number of classes.
- $\hat{P}(i\mid Xnew(n))$ is the posterior probability of class i for observation $Xnew(n)$.
- $C(k\mid i)$ is the true misclassification cost of classifying an observation as k when its true class is i.

Examples

k-Nearest Neighbor Classification Predictions

Construct a k-nearest neighbor classifier for Fisher's iris data, where $k = 5$. Evaluate some model predictions on new data.

Load the data.

```
load fisheriris
X = meas;
Y = species;
```

Construct a classifier for 5-nearest neighbors. It is good practice to standardize non-categorical predictor data.

```
mdl = fitcknn(X,Y,'NumNeighbors',5,'Standardize',1);
```

Predict the classifications for flowers with minimum, mean, and maximum characteristics.

```
Xnew = [min(X);mean(X);max(X)];
[label,score,cost] = predict(mdl,Xnew)
```

```
label =

    'versicolor'
    'versicolor'
    'virginica'

score =

    0.4000    0.6000         0
         0    1.0000         0
         0         0    1.0000

cost =

    0.6000    0.4000    1.0000
    1.0000         0    1.0000
    1.0000    1.0000         0
```

The classifications have binary values for the score and cost matrices, meaning all five nearest neighbors of each of the three points have identical classifications.

predict

Class: CompactClassificationDiscriminant

Predict classification

Syntax

```
label = predict(obj,X)
[label,score] = predict(obj,X)
[label,score,cost] = predict(obj,X)
```

Description

`label = predict(obj,X)` returns a vector of predicted class labels for a matrix `X`, based on `obj`, a trained full or compact classifier.

`[label,score] = predict(obj,X)` returns a matrix of scores (posterior probabilities).

`[label,score,cost] = predict(obj,X)` returns a matrix of costs; `label` is the vector of minimal costs for each row of `cost`.

Input Arguments

`obj`

Discriminant analysis classifier of class `ClassificationDiscriminant` or `CompactClassificationDiscriminant`, typically constructed with `fitcdiscr`.

`X`

Matrix where each row represents an observation, and each column represents a predictor. The number of columns in `X` must equal the number of predictors in `obj`.

Output Arguments

`label`

Vector of class labels of the same type as the response data used in training obj. Each entry of `labels` corresponds to a predicted class label for the corresponding row of `X`; see "Predicted Class Label" on page 22-3660.

`score`

Numeric matrix of size `N`-by-`K`, where `N` is the number of observations (rows) in `X`, and `K` is the number of classes (in `obj.ClassNames`). `score(i,j)` is the posterior probability that row `i` of `X` is of class `j`; see "Posterior Probability" on page 22-3659.

`cost`

Matrix of expected costs of size `N`-by-`K`. `cost(i,j)` is the cost of classifying row `i` of `X` as class `j`. See "Cost" on page 22-3660.

Definitions

Posterior Probability

The posterior probability that a point z belongs to class j is the product of the prior probability and the multivariate normal density. The density function of the multivariate normal with mean μ_j and covariance Σ_j at a point z is

$$P(x \mid k) = \frac{1}{\left(2\pi|\Sigma_k|\right)^{1/2}} \exp\left(-\frac{1}{2}(x-\mu_k)^T \Sigma_k^{-1}(x-\mu_k) \right),$$

where $|\Sigma_k|$ is the determinant of Σ_k, and Σ_k^{-1} is the inverse matrix.

Let $P(k)$ represent the prior probability of class k. Then the posterior probability that an observation x is of class k is

$$\hat{P}(k \mid x) = \frac{P(x \mid k)P(k)}{P(x)},$$

where $P(x)$ is a normalization constant, the sum over k of $P(x \mid k)P(k)$.

Prior Probability

The prior probability is one of three choices:

- `'uniform'` — The prior probability of class `k` is one over the total number of classes.
- `'empirical'` — The prior probability of class `k` is the number of training samples of class `k` divided by the total number of training samples.
- Custom — The prior probability of class `k` is the `k`th element of the `prior` vector. See `fitcdiscr`.

After creating a classifier `obj`, you can set the prior using dot notation:

```
obj.Prior = v;
```

where `v` is a vector of positive elements representing the frequency with which each element occurs. You do not need to retrain the classifier when you set a new prior.

Cost

The matrix of expected costs per observation is defined in “Cost” on page 15-8.

Predicted Class Label

`predict` classifies so as to minimize the expected classification cost:

$$\hat{y} = \underset{y=1,\ldots,K}{\arg\min} \sum_{k=1}^{K} \hat{P}(k \mid x) C(y \mid k),$$

where

- $\hat{y}$ is the predicted classification.
- K is the number of classes.
- $\hat{P}(k \mid x)$ is the posterior probability of class k for observation x.
- $C(y \mid k)$ is the cost of classifying an observation as y when its true class is k.

Examples

Examine predictions for a few rows in the Fisher iris data:

```
load fisheriris
obj = fitcdiscr(meas,species);
X = meas(99:102,:); % take four rows
[label score cost] = predict(obj,X)

label =
    'versicolor'
    'versicolor'
    'virginica'
    'virginica'

score =
    0.0000    1.0000    0.0000
    0.0000    0.9999    0.0001
    0.0000    0.0000    1.0000
    0.0000    0.0011    0.9989

cost =
    1.0000    0.0000    1.0000
    1.0000    0.0001    0.9999
    1.0000    1.0000    0.0000
    1.0000    0.9989    0.0011
```

How To

- “Discriminant Analysis” on page 15-3

predict

Class: CompactClassificationECOC

Predict labels for error-correcting output code multiclass classifiers

Syntax

```
label = predict(Mdl,X)
label = predict(Mdl,X,Name,Value)
[label,NegLoss,PBScore] = predict(___)
[label,NegLoss,PBScore,Posterior] = predict(___)
```

Description

`label = predict(Mdl,X)` returns a vector of predicted class labels for the predictor data, based on the full or compact, trained error-correcting output code multiclass classifier `Mdl`. Each row of `X` is an observation.

The software predicts the classification of an observation by assigning the observation to the class yielding the largest negated average binary loss (or, equivalently, the smallest average binary loss).

`label = predict(Mdl,X,Name,Value)` returns predicted class labels with additional options specified by one or more Name,Value pair arguments.

For example, specify the posterior probability estimation method, decoding scheme, or verbosity level.

`[label,NegLoss,PBScore] = predict(___)` additionally returns negated average binary loss per class (`NegLoss`) for observations, and positive-class scores (`PBScore`) for the observations classified by each binary learner.

`[label,NegLoss,PBScore,Posterior] = predict(___)` additionally returns posterior class probability estimates for observations (`Posterior`).

To obtain posterior class probabilities, you must set `'FitPosterior',1` when training the ECOC model using `fitcecoc`. Otherwise, `predict` throws an error.

Input Arguments

`Mdl` — ECOC multiclass classifier

`ClassificationECOC` model | `CompactClassificationECOC` model

ECOC multiclass classifier, specified as a `ClassificationECOC` or `CompactClassificationECOC` model. You can create a:

- `ClassificationECOC` model by training the ECOC classifier using `fitcecoc`
- `CompactClassificationECOC` model by passing a `ClassificationECOC` classifier to `compact`

`X` — Predictor data

numeric matrix

Predictor data, specified as a numeric matrix.

Each row of `X` corresponds to one observation (also called an instance or example), and each column corresponds to one variable (also known as a feature). The variables composing the columns of `X` should be the same as the variables that trained the `Mdl` classifier.

If you trained `Mdl` specifying to standardize the predictor data, then the software standardizes the columns of `X` using the corresponding means and standard deviations that the software stored in `Mdl.BinaryLearner{j}.Mu` and `Mdl.BinaryLearner{j}.Sigma` for learner `j`.

Data Types: `double` | `single`

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'BinaryLoss'` — Binary learner loss function

function handle | `'hamming'` | `'linear'` | `'exponential'` | `'binodeviance'` | `'hinge'` | `'quadratic'`

Binary learner loss function, specified as the comma-separated pair consisting of `'BinaryLoss'` and a function handle or string.

- If the value is a string, then it must correspond to a built-in function. This table summarizes the built-in functions, where y_j is a class label for a particular binary learner (in the set {-1,1,0}), s_j is the score for observation j, and $g(y_j,s_j)$ is the binary loss formula.

Value	Description	Score Domain	$g(y_j,s_j)$
`'binodeviance'`	Binomial deviance	$(-\infty,\infty)$	$\log[1 + \exp(-2y_js_j)]/[2\log(2)]$
`'exponential'`	Exponential	$(-\infty,\infty)$	$\exp(-y_js_j)/2$
`'hamming'`	Hamming	{-1,1}	$[1 - \text{sign}(y_js_j)]/2$
`'hinge'`	Hinge	$(-\infty,\infty)$	$\max(0,1 - y_js_j)/2$
`'linear'`	Linear	$(-\infty,\infty)$	$(1 - y_js_j)/2$
`'quadratic'`	Quadratic	[0,1]	$[1 - y_j(2s_j - 1)]^2/2$

  The software normalizes the binary losses such that the loss is 0.5 when $y_j = 0$. Also, the software calculates the mean binary loss for each class.

- For a custom binary loss function, e.g., `customFunction`, specify its function handle `'BinaryLoss',@customFunction`.

  `customFunction` should have this form

  ```
  bLoss = customFunction(M,s)
  ```
  where:

  - `M` is the K-by-L coding matrix stored in `Mdl.CodingMatrix`.
  - `s` is the 1-by-L row vector of classification scores.
  - `bLoss` is the classification loss. This scalar aggregates the binary losses for every learner in a particular class. For example, you can use the mean binary loss to aggregate the loss over the learners for each class.
  - K is the number of classes.
  - L is the number of binary learners.

  For an example on passing a custom binary loss function, see "Predict Test-Sample Labels of ECOC Models Using Custom Binary Loss Function".

This list describes the default values of `BinayLoss`. If all binary learners are:

- SVMs, then `BinaryLoss` is `'hinge'`
- Ensembles trained by `AdaboostM1` or `GentleBoost`, then `BinaryLoss` is `'exponential'`
- Ensembles trained by `LogitBoost`, then `BinaryLoss` is `'binodeviance'`
- Predicting class posterior probabilities (i.e., set `'FitPosterior',1` in `fitcecoc`), then `BinaryLoss` is `'quadratic'`

Otherwise, the default `BinaryLoss` is `'hamming'`.

Example: `'BinaryLoss','binodeviance'`

Data Types: `char | function_handle`

`'Decoding'` — Decoding scheme

`'lossweighted'` (default) | `'lossbased'`

Decoding scheme that aggregates the binary losses, specified as the comma-separated pair consisting of `'Decoding'` and `'lossweighted'` or `'lossbased'`.

Example: `'Decoding','lossbased'`

Data Types: `char`

`'NumKLInitializations'` — Number of random initial values

`0` (default) | nonnegative integer

Number of random initial values for fitting posterior probabilities by Kullback-Leibler divergence minimization, specified as the comma-separated pair consisting of `'NumKLInitializations'` and a nonnegative integer.

If you do not request the fourth output argument (Posterior) and set `'PosteriorMethod','kl'` (the default), then the software ignores the value of `NumKLInitializations`.

For more details, see “Posterior Estimation Using Kullback-Leibler Divergence” on page 22-3679.

Example: `'NumKLInitializations',5`

Data Types: `single | double`

`'Options'` — Estimation options

`[]` (default) | structure array returned by `statset`

Estimation options, specified as the comma-separated pair consisting of `'Options'` and a structure array returned by `statset`.

To invoke parallel computing:

- You need a Parallel Computing Toolbox license.
- Specify `'Options',statset('UseParallel',1)`.

`'PosteriorMethod'` — Posterior probability estimation method

`'kl'` (default) | `'qp'`

Posterior probability estimation method, specified as the comma-separated pair consisting of `'PosteriorMethod'` and `'kl'` or `'qp'`.

- If `PosteriorMethod` is `'kl'`, then the software estimates multiclass posterior probabilities by minimizing the Kullback-Leibler divergence between the predicted and expected posterior probabilities returned by binary learners. For details, see "Posterior Estimation Using Kullback-Leibler Divergence".
- If `PosteriorMethod` is `'qp'`, then the software estimates multiclass posterior probabilities by solving a least-squares problem using quadratic programming. You need an Optimization Toolbox license to use this option. For details, see "Posterior Estimation Using Quadratic Programming".
- If you do not request the fourth output argument (Posterior), then the software ignores the value of `PosteriorMethod`.

Example: `'PosteriorMethod','qp'`

Data Types: `char`

`'Verbose'` — Verbosity level

`0` (default) | `1`

Verbosity level, specified as the comma-separated pair consisting of `'Verbose'` and `0` or `1`. `Verbose` controls the amount of diagnostic messages that the software displays in the Command Window.

If `Verbose` is `0`, then the software does not display diagnostic messages. Otherwise, the software displays diagnostic messages.

Example: `'Verbose',1`

Data Types: `single` | `double`

Output Arguments

`label` — Predicted class labels

categorical array | character array | logical vector | vector of numeric values | cell array of strings

Predicted class labels, returned as a categorical or character array, logical or numeric vector, or cell array of strings.

`label`:

- Is the same data type as the Mdl.ClassNames
- Has length equal to the number of rows of X

The software predicts the classification of an observation by assigning the observation to the class yielding the largest negated average binary loss (or, equivalently, the smallest average binary loss).

`NegLoss` — Negated average binary losses

numeric matrix

Negated, average binary losses, returned as a numeric matrix. `NegLoss` is an `n`-by-`K` matrix, where `n` is the number of observations (`size(X,1)`) and `K` is the number of unique classes (`size(Mdl.ClassNames,1)`).

`PBScore` — Positive-class scores

numeric matrix

Positive-class scores for each binary learner, returned as a numeric matrix. `PBScore` is an `n`-by-`L` matrix, where `n` is the number of observations (`size(X,1)`) and `L` is the number of binary learners (`size(Mdl.CodingMatrix,2)`).

`Posterior` — Posterior class probabilities

numeric matrix

Posterior class probabilities, returned as a numeric matrix. `Posterior` is an `n`-by-`K` matrix, where `n` is the number of observations (`size(X,1)`) and `K` is the number of unique classes (`size(Mdl.ClassNames,1)`).

You must set `'FitPosterior',1` when training the ECOC model using `fitcecoc` to request `Posterior`. Otherwise, the software throws an error.

Definitions

Binary Loss

A *binary loss* is a function of the class and classification score that determines how well a binary learner classifies an observation into the class.

Let:

- m_{kj} be element (k,j) of the coding design matrix M (i.e., the code corresponding to class k of binary learner j)
- s_j be the score of binary learner j for an observation
- g be the binary loss function
- $\hat{k}$ be the predicted class for the observation

In *loss-based decoding* [3], the class producing the minimum sum of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \underset{k}{\operatorname{argmin}} \sum_{j=1}^{L} \left|m_{kj}\right| g(m_{kj}, s_j).$$

In *loss-weighted decoding* [3], the class producing the minimum average of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \underset{k}{\operatorname{argmin}} \frac{\sum_{j=1}^{L} \left|m_{kj}\right| g(m_{kj}, s_j)}{\sum_{j=1}^{L} \left|m_{kj}\right|}.$$

Allwein et al. [1] suggest that loss-weighted decoding improves classification accuracy by keeping loss values for all classes in the same dynamic range.

This table summarizes the supported loss functions, where y_j is a class label for a particular binary learner (in the set {-1,1,0}), s_j is the score for observation j, and $g(y_j,s_j)$.

Value	Description	Score Domain	$g(y_j,s_j)$
`'binodeviance'`	Binomial deviance	$(-\infty,\infty)$	$\log[1 + \exp(-2y_js_j)]/[2\log(2)]$
`'exponential'`	Exponential	$(-\infty,\infty)$	$\exp(-y_js_j)/2$
`'hamming'`	Hamming	{-1,1}	$[1 - \text{sign}(y_js_j)]/2$
`'hinge'`	Hinge	$(-\infty,\infty)$	$\max(0,1 - y_js_j)/2$
`'linear'`	Linear	$(-\infty,\infty)$	$(1 - y_js_j)/2$
`'quadratic'`	Quadratic	[0,1]	$[1 - y_j(2s_j - 1)]^2/2$

The software normalizes the binary losses such that the loss is 0.5 when $y_j = 0$, and aggregates using the average of the binary learners [1].

Do not confuse the binary loss with the overall classification loss (specified by the LossFun name-value pair argument of `predict` and `loss`), e.g., classification error, which measures how well an ECOC classifier performs as a whole.

Examples

Predict Test-Sample Labels of Training Data Using ECOC Models

Load Fisher's iris data set.

```
load fisheriris
X = meas;
Y = categorical(species);
classOrder = unique(Y);
rng(1); % For reproducibility
```

Train an ECOC model using SVM binary classifiers and specify a 30% holdout sample. It is good practice to standardize the predictors and define the class order. Specify to standardize the predictors using an SVM template.

```
t = templateSVM('Standardize',1);
```

```
CVMdl = fitcecoc(X,Y,'Holdout',0.30,'Learners',t,'ClassNames',classOrder);
CMdl = CVMdl.Trained{1};           % Extract trained, compact classifier
testInds = test(CVMdl.Partition);  % Extract the test indices
XTest = X(testInds,:);
YTest = Y(testInds,:);
```

`CVMdl` is a `ClassificationPartitionedECOC` model. It contains the property `Trained`, which is a 1-by-1 cell array holding a `CompactClassificationECOC` model that the software trained using the training set.

Predict the test-sample labels. Print a random subset of true and predicted labels.

```
labels = predict(CMdl,XTest);
idx = randsample(sum(testInds),10);
table(YTest(idx),labels(idx),...
    'VariableNames',{'TrueLabels','PredictedLabels'})
```

```
ans =

    TrueLabels    PredictedLabels
    __________    _______________

    setosa        setosa
    versicolor    virginica
    setosa        setosa
    virginica     virginica
    versicolor    versicolor
    setosa        setosa
    virginica     virginica
    virginica     virginica
    setosa        setosa
    setosa        setosa
```

`Mdl` correctly labeled all except one of the test-sample observations with indices `idx`.

Predict Test-Sample Labels of ECOC Models Using Custom Binary Loss Function

Load Fisher's iris data set.

```
load fisheriris
X = meas;
Y = categorical(species);
```

```
classOrder = unique(Y); % Class order
K = numel(classOrder);  % Number of classes
rng(1); % For reproducibility
```

Train an ECOC model using SVM binary classifiers and specify a 30% holdout sample. It is good practice to standardize the predictors and define the class order. Specify to standardize the predictors using an SVM template.

```
t = templateSVM('Standardize',1);
CVMdl = fitcecoc(X,Y,'Holdout',0.30,'Learners',t,'ClassNames',classOrder);
CMdl = CVMdl.Trained{1};           % Extract trained, compact classifier
testInds = test(CVMdl.Partition);  % Extract the test indices
XTest = X(testInds,:);
YTest = Y(testInds,:);
```

`CVMdl` is a `ClassificationPartitionedECOC` model. It contains the property `Trained`, which is a 1-by-1 cell array holding a `CompactClassificationECOC` model that the software trained using the training set.

SVM scores are signed distances from the observation to the decision boundary. Therefore, the domain is $(-\infty,\infty)$. Create a custom binary loss function that:

- Maps the coding design matrix (*M*) and positive-class classification scores (*s*) for each learner to the binary loss for each observation
- Uses linear loss
- Aggregates the binary learner loss using the median.

You can create a separate function for the binary loss function, and then save it on the MATLAB® path. Or, you can specify an anonymous binary loss function.

```
customBL = @(M,s)nanmedian(1 - bsxfun(@times,M,s),2)/2;
```

Predict test-sample labels and estimate the median binary loss per class. Print the median negative binary losses per class for a random set of 10 test-sample observations.

```
[label,NegLoss] = predict(CMdl,XTest,'BinaryLoss',customBL);

idx = randsample(sum(testInds),10);
classOrder
table(YTest(idx),label(idx),NegLoss(idx,:),'VariableNames',...
    {'TrueLabel','PredictedLabel','NegLoss'})
```

```
classOrder =

     setosa
     versicolor
     virginica

ans =

    TrueLabel     PredictedLabel                NegLoss
    __________    ______________    ____________________________________

    setosa        versicolor          0.1857       1.9878      -3.6735
    versicolor    virginica          -1.3316      -0.12333    -0.045053
    setosa        versicolor         0.13898       1.9261      -3.5651
    virginica     virginica          -1.5133      -0.38263      0.39592
    versicolor    versicolor        -0.87209       0.74777      -1.3757
    setosa        versicolor         0.48381       1.9972       -3.981
    virginica     virginica          -1.9364      -0.67508       1.1114
    virginica     virginica           -1.579      -0.83339      0.91235
    setosa        versicolor         0.51001       2.1208      -4.1308
    setosa        versicolor         0.36119       2.0594      -3.9206
```

The order of the columns corresponds to the elements of `classOrder`. The software predicts the label based on the maximum negated loss. The results seem to indicate that the median of the linear losses might not perform as well as other losses.

Estimate Posterior Probabilities Using ECOC Classifiers

Load Fisher's iris data set. Train the classifier using the petal dimensions as predictors.

```
load fisheriris
X = meas(:,3:4);
Y = species;
rng(1); % For reproducibility
```

Create an SVM template, and specify the Gaussian kernel. It is good practice to standardize the predictors.

```
t = templateSVM('Standardize',1,'KernelFunction','gaussian');
```

`t` is an SVM template. Most of its properties are empty. When the software trains the ECOC classifier, it sets the applicable properties to their default values.

Train the ECOC classifier using the SVM template. Transform classification scores to class posterior probabilities (which are returned by `predict` or `resubPredict`) using the `'FitPosterior'` name-value pair argument. Display diagnostic messages during the training using the `'Verbose'` name-value pair argument. It is good practice to specify the class order.

```
Mdl = fitcecoc(X,Y,'Learners',t,'FitPosterior',1,...
    'ClassNames',{'setosa','versicolor','virginica'},...
    'Verbose',2);
```

```
Training binary learner 1 (SVM) out of 3 with 50 negative and 50 positive observations.
Negative class indices: 2
Positive class indices: 1

Fitting posterior probabilities for learner 1 (SVM).
Training binary learner 2 (SVM) out of 3 with 50 negative and 50 positive observations.
Negative class indices: 3
Positive class indices: 1

Fitting posterior probabilities for learner 2 (SVM).
Training binary learner 3 (SVM) out of 3 with 50 negative and 50 positive observations.
Negative class indices: 3
Positive class indices: 2

Fitting posterior probabilities for learner 3 (SVM).
```

`Mdl` is a `ClassificationECOC` model. The same SVM template applies to each binary learner, but you can adjust options for each binary learner by passing in a cell vector of templates.

Predict the in-sample labels and class posterior probabilities. Display diagnostic messages during the computation of labels and class posterior probabilities using the `'Verbose'` name-value pair argument.

```
[label,~,~,Posterior] = resubPredict(Mdl,'Verbose',1);
Mdl.BinaryLoss
```

```
Predictions from all learners have been computed.
Loss for all observations has been computed.
Computing posterior probabilities...

ans =

quadratic
```

The software assigns an observation to the class that yields the smallest average binary loss. Since all binary learners are computing posterior probabilities, the binary loss function is `quadratic`.

Display a random set of results.

```
idx = randsample(size(X,1),10,1);
Mdl.ClassNames
table(Y(idx),label(idx),Posterior(idx,:),...
    'VariableNames',{'TrueLabel','PredLabel','Posterior'})
```

```
ans =

    'setosa'
    'versicolor'
    'virginica'

ans =

     TrueLabel       PredLabel                  Posterior
    ____________    ____________    ____________________________________

    'virginica'     'virginica'      0.0039321     0.0039869       0.99208
    'virginica'     'virginica'       0.017067      0.018263       0.96467
    'virginica'     'virginica'       0.014948      0.015856        0.9692
    'versicolor'    'versicolor'    2.2197e-14       0.87317       0.12683
    'setosa'        'setosa'             0.999    0.00025091    0.00074639
    'versicolor'    'virginica'     2.2195e-14      0.059429       0.94057
    'versicolor'    'versicolor'    2.2194e-14       0.97001      0.029986
    'setosa'        'setosa'             0.999     0.0002499    0.00074741
    'versicolor'    'versicolor'     0.0085646       0.98259      0.008849
    'setosa'        'setosa'             0.999    0.00025013    0.00074718
```

The columns of `Posterior` correspond to the class order of `Mdl.ClassNames`.

Define a grid of values in the observed predictor space. Predict the posterior probabilities for each instance in the grid.

```
xMax = max(X);
```

```
xMin = min(X);

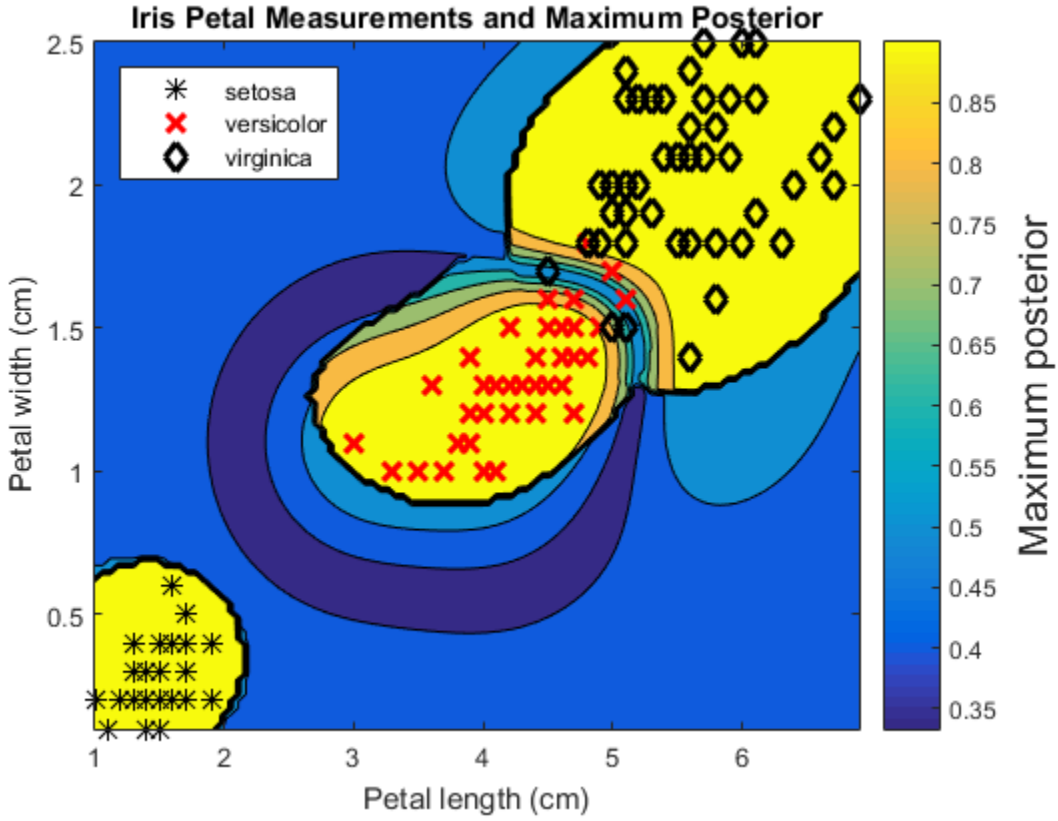
x1Pts = linspace(xMin(1),xMax(1));
x2Pts = linspace(xMin(2),xMax(2));
[x1Grid,x2Grid] = meshgrid(x1Pts,x2Pts);

[~,~,~,PosteriorRegion] = predict(Mdl,[x1Grid(:),x2Grid(:)]);
```

For each coordinate on the grid, plot the maximum class posterior probability among all classes.

```
figure;
contourf(x1Grid,x2Grid,...
        reshape(max(PosteriorRegion,[],2),size(x1Grid,1),size(x1Grid,2)));
h = colorbar;
h.YLabel.String = 'Maximum posterior';
h.YLabel.FontSize = 15;
hold on
gh = gscatter(X(:,1),X(:,2),Y,'krk','*xd',8);
gh(2).LineWidth = 2;
gh(3).LineWidth = 2;

title 'Iris Petal Measurements and Maximum Posterior';
xlabel 'Petal length (cm)';
ylabel 'Petal width (cm)';
axis tight
legend(gh,'Location','NorthWest')
hold off
```



Estimate Test-Sample Posterior Probabilities Using Parallel Computing

Train an error-correcting output codes, multiclass model and estimate posterior probabilities using parallel computing.

Load the `arrhythmia` data set.

```
load arrhythmia
Y = categorical(Y);
tabulate(Y)
n = numel(Y);
K = numel(unique(Y));
```

```
  Value    Count   Percent
```

```
     1      245     54.20%
     2       44      9.73%
     3       15      3.32%
     4       15      3.32%
     5       13      2.88%
     6       25      5.53%
     7        3      0.66%
     8        2      0.44%
     9        9      1.99%
    10       50     11.06%
    14        4      0.88%
    15        5      1.11%
    16       22      4.87%
```

Several classes are not represented in the data, and many of the other classes have low relative frequencies.

Specify an ensemble learning template that uses the GentleBoost method and 50 weak, classification tree learners.

```
t = templateEnsemble('GentleBoost',50,'Tree');
```

`t` is a template object. Most of the options are empty ([ ]). The software uses default values for all empty options during training.

Since there are many classes, specify a sparse random coding design.

```
rng(1); % For reproducibility
Coding = designecoc(K,'sparserandom');
```

Train an ECOC model using parallel computing. Specify to hold out 15% of the data and fit posterior probabilities.

```
pool = parpool;                       % Invokes workers
options = statset('UseParallel',1);
CVMdl = fitcecoc(X,Y,'Learner',t,'Options',options,'Coding',Coding,...
    'FitPosterior',1,'Holdout',0.15);

CMdl = CVMdl.Trained{1};           % Extract trained, compact classifier
testInds = test(CVMdl.Partition);  % Extract the test indices
XTest = X(testInds,:);
YTest = Y(testInds,:);
```

```
Starting parallel pool (parpool) using the 'local' profile ... connected to 4 workers.
```

`CVMdl` is a `ClassificationPartitionedECOC` model. It contains the property `Trained`, which is a 1-by-1 cell array holding a `CompactClassificationECOC` model that the software trained using the training set.

The pool invokes four workers. The number of workers might vary among systems.

Estimate posterior probabilities, and display the posterior probability of being classified as not having arrhythmia (class 1) given the data for a random set of test-sample observations.

```
[~,~,~,posterior] = predict(CMdl,XTest,'Options',options);
idx = randsample(sum(testInds),10);
table(idx,YTest(idx),posterior(idx,1),...
    'VariableNames',{'TestSampleIndex','TrueLabel','PosteriorNoArrhythmia'})
```

```
ans =

    TestSampleIndex    TrueLabel    PosteriorNoArrhythmia
    _______________    _________    _____________________

    11                 6            0.60631
    41                 4            0.23674
    51                 2            0.13802
    33                 10           0.43831
    12                 1            0.94332
     8                 1            0.97278
    37                 1            0.62807
    24                 10           0.96876
    56                 16           0.29375
    30                 1            0.64512
```

- “Quick Start Parallel Computing for Statistics and Machine Learning Toolbox” on page 21-2

Algorithms

The software can estimate class posterior probabilities using quadratic programming or by minimizing the Kullback-Leibler divergence. For the following descriptions of the posterior estimation algorithms, let:

- m_{kj} be the element (k,j) of the coding design matrix M.

- I be the indicator function.
- $\hat{p}_k$ be the class posterior probability estimate for class k of an observation, $k = 1,...,K$.
- r_j be the positive-class posterior probability for binary learner j. That is, r_j is the probability that binary learner j classifies an observation into the positive class, given the training data.

Posterior Estimation Using Kullback-Leibler Divergence

By default, the software minimizes the Kullback-Leibler divergence to estimate class posterior probabilities. The Kullback-Leibler divergence between the expected and observed positive-class posterior probabilities is

$$\Delta(r,r) = \sum_{j=1}^{L} w_j \left[r_j \log \frac{r_j}{r_j} + \left(1 - r_j\right) \log \frac{1 - r_j}{1 - r_j} \right],$$

where $w_j = \sum_{S_j} w_i^*$ is the weight for binary learner j with S_j the set of observation indices that binary learner j is trained on and w_i^* is the weight of observation i. The software minimizes the divergence iteratively. The first step is to choose initial values $\hat{p}_k^{(0)};\ k = 1,...,K$ for the class posterior probabilities.

- If you do not specify NumKLIterations, then the software uses both sets of deterministic initial values described next, and uses the one that minimizes Δ.
  - $\hat{p}_k^{(0)} = 1/K;\ k = 1,...,K.$
  - $\hat{p}_k^{(0)};\ k = 1,...,K$ is the solution of the system

    $$M_{01}\hat{p}^{(0)} = r,$$

    where M_{01} is M with all $m_{kj} = -1$ replaced with 0, and r is a vector of positive-class posterior probabilities returned by the L binary learners [2]. The software uses `lsqnonneg` to solve the system.

- If you specify `'NumKLIterations',c`, where `c` is a natural number, then the software does the following to choose $\hat{p}_k^{(0)};\ k = 1,\ldots,K$, and uses the one that minimizes Δ.
  - The software chooses both sets of deterministic initial values as described previously.
  - The software randomly generates `c` vectors of length K using `rand`, and then normalizes each vector to sum to 1.

At iteration t, the software:

1. Computes

$$\hat{r}_j^{(t)} = \frac{\sum_{k=1}^{K} \hat{p}_k^{(t)} I(m_{kj} = +1)}{\sum_{k=1}^{K} \hat{p}_k^{(t)} I(m_{kj} = +1 \cup m_{kj} = -1)}.$$

2. Estimates the next class posterior probability using

$$\hat{p}_k^{(t+1)} = \hat{p}_k^{(t)} \frac{\sum_{j=1}^{L} w_j \left[r_j I\left(m_{kj} = +1\right) + \left(1 - r_j\right) I\left(m_{kj} = -1\right) \right]}{\sum_{j=1}^{L} w_j \left[\hat{r}_j^{(t)} I\left(m_{kj} = +1\right) + \left(1 - \hat{r}_j^{(t)}\right) I\left(m_{kj} = -1\right) \right]}.$$

3. Normalizes $\hat{p}_k^{(t+1)};\ k = 1,\ldots,K$ so that they sum to 1.

4. Checks for convergence.

For more details, see [5] and [7].

Posterior Estimation Using Quadratic Programming

Posterior probability estimation using quadratic programming requires an Optimization Toolbox license. To estimate posterior probabilities for an observation using this method, the software:

1 Estimates the positive-class posterior probabilities, r_j, for binary learners $j = 1,...,L$.

2 Using the relationship between r_j and $\hat{p}_k$ [6], minimizes

$$\sum_{j=1}^{L}\left[-r_j\sum_{k=1}^{K}\hat{p}_k I\left(m_{kj}=-1\right)+\left(1-r_j\right)\sum_{k=1}^{K}\hat{p}_k I\left(m_{kj}=+1\right)\right]^2$$

with respect to $\hat{p}_k$ and the restrictions

$$0 \le \hat{p}_k \le 1$$
$$\sum_k \hat{p}_k = 1.$$

The software performs minimization using `quadprog`.

predict

Class: CompactClassificationEnsemble

Predict classification

Syntax

```
labels = predict(ens,X)
[labels,score] = predict(ens,X)
[labels,...] = predict(ens,X,Name,Value)
```

Description

`labels = predict(ens,X)` returns a vector of predicted class labels for a matrix `X`, based on `ens`, a trained full or compact classification ensemble.

`[labels,score] = predict(ens,X)` also returns scores for all classes.

`[labels,...] = predict(ens,X,Name,Value)` predicts classifications with additional options specified by one or more Name,Value pair arguments.

Input Arguments

`ens`

A classification ensemble created by `fitensemble`, or a compact classification ensemble created by `compact`.

`X`

A matrix where each row represents an observation, and each column represents a predictor. The number of columns in `X` must equal the number of predictors in `ens`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single

quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'learners'`

Indices of weak learners `predict` uses for computation of responses, a numeric vector.

Default: `1:T`, where `T` is the number of weak learners in ens

`'UseObsForLearner'`

A logical matrix of size `N`-by-`T`, where:

- `N` is the number of rows of X.
- `T` is the number of weak learners in ens.

When `UseObsForLearner(i,j)` is `true`, learner `j` is used in predicting the class of row `i` of X.

Default: `true(N,T)`

Output Arguments

`labels`

Vector of classification labels. `labels` has the same data type as the labels used in training ens.

`score`

A matrix with one row per observation and one column per class. For each observation and each class, the score generated by each tree is the probability of this observation originating from this class computed as the fraction of observations of this class in a tree leaf. `predict` averages these scores over all trees in the ensemble.

Definitions

Score (ensemble)

For ensembles, a classification *score* represents the confidence of a classification into a class. The higher the score, the higher the confidence.

Different ensemble algorithms have different definitions for their scores. Furthermore, the range of scores depends on ensemble type. For example:

- `AdaBoostM1` scores range from $-\infty$ to ∞.
- `Bag` scores range from `0` to `1`.

Examples

Train a boosting ensemble for the `ionosphere` data, and predict the classification of the mean of the data:

```
load ionosphere;
ada = fitensemble(X,Y,'AdaBoostM1',100,'tree');
Xbar = mean(X);
[ypredict score] = predict(ada,Xbar)

ypredict =
    'g'

score =
   -2.9460    2.9460
```

See Also

`margin` | `edge` | `loss`

predict

Class: CompactClassificationNaiveBayes

Predict classification for naive Bayes models

Syntax

```
label = predict(Mdl,X)
[label,Posterior,Cost] = predict(Mdl,X)
```

Description

`label = predict(Mdl,X)` returns a vector of predicted class labels for predictor data (`X`), based on the trained, full or compact naive Bayes classifier `Mdl`.

`[label,Posterior,Cost] = predict(Mdl,X)` additionally returns posterior probabilities (`Posterior`) and predicted (expected) misclassification costs (`Cost`) corresponding to the observations (rows) in `X`.

Input Arguments

`Mdl` — Naive Bayes classifier

`ClassificationNaiveBayes` model | `CompactClassificationNaiveBayes` model

Naive Bayes classifier, specified as a `ClassificationNaiveBayes` model or `CompactClassificationNaiveBayes` model returned by `fitcnb` or `compact`, respectively.

`X` — Predictor data

numeric matrix

Predictor data, specified as a numeric matrix.

Each row of `X` corresponds to one observation (also known as an instance or example), and each column corresponds to one variable (also known as a feature). The variables making up the columns of `X` should be the same as the variables that trained `Mdl`.

The length of `Y` and the number of rows of `X` must be equal.

Data Types: `double` | `single`

Notes:

- If `Mdl.DistributionNames` is `'mn'`, then the software returns `NaN`s corresponding to rows of X containing at least one `NaN`.
- If `Mdl.DistributionNames` is not `'mn'`, then the software ignores `NaN` values when estimating misclassification costs and posterior probabilities. Specifically, the software computes the conditional density of the predictors given the class by leaving out the factors corresponding to missing predictor values.
- For predictor distribution specified as `'mvmn'`, if X contains levels that are not represented in the training data (i.e., not in `Mdl.CategoricalLevels` for that predictor), then the conditional density of the predictors given the class is 0. For those observations, the software returns the corresponding value of `Posterior` as a `NaN`. The software determines the class label for such observations using the class prior probability, stored in `Mdl.Prior`.

Output Arguments

`label` — Predicted class labels

categorical vector | character array | logical vector | numeric vector | cell vector of strings

Predicted class labels, returned as a categorical vector, character array, logical or numeric vector, or cell vector of strings.

`label`:

- Is the same data type as the observed class labels (`Mdl.Y`) that trained Mdl
- Has length equal to the number of rows of Mdl.X
- Is the class yielding the lowest expected misclassification cost (Cost)

`Posterior` — Class posterior probabilities

numeric matrix

Class posterior probabilities, returned as a numeric matrix. `Posterior` has rows equal to the number of rows of X and columns equal to the number of distinct classes in the training data (`size(Mdl.ClassNames,1)`).

`Posterior(j,k)` is the predicted posterior probability of class `k` (i.e., in class `Mdl.ClassNames(k)`) given the observation in row `j` of `X`.

Data Types: `double`

`Cost` — Expected misclassification costs
numeric matrix

Expected misclassification costs, returned as a numeric matrix. `Cost` has rows equal to the number of rows of X and columns equal to the number of distinct classes in the training data (`size(Mdl.ClassNames,1)`).

`Cost(j,k)` is the expected misclassification cost of the observation in row `j` of `X` being predicted into class `k` (i.e., in class `Mdl.ClassNames(k)`).

Definitions

Misclassification Cost

A *misclassification cost* is the relative severity of a classifier labeling an observation into the wrong class.

There are two types of misclassification costs: true and expected. Let K be the number of classes.

- *True misclassification cost* — A K-by-K matrix, where element (i,j) indicates the misclassification cost of predicting an observation into class j if its true class is i. The software stores the misclassification cost in the property `Mdl.Cost`, and used in computations. By default, `Mdl.Cost(i,j)` = 1 if `i` ≠ `j`, and `Mdl.Cost(i,j)` = 0 if `i` = `j`. In other words, the cost is `0` for correct classification, and `1` for any incorrect classification.
- *Expected misclassification cost* — A K-dimensional vector, where element k is the weighted average misclassification cost of classifying an observation into class k, weighted by the class posterior probabilities. In other words,

$$c_k = \sum_{j=1}^{K} \hat{P}(Y = j \mid x_1,...,x_P)\texttt{Cost}_{jk}.$$

the software classifies observations to the class corresponding with the lowest expected misclassification cost.

Posterior Probability

The *posterior probability* is the probability that an observation belongs in a particular class, given the data.

For naive Bayes, the posterior probability that a classification is k for a given observation $(x_1,...,x_P)$ is

$$\hat{P}(Y = k \mid x_1,..,x_P) = \frac{P(X_1,...,X_P \mid y = k)\pi(Y = k)}{P(X_1,...,X_P)},$$

where:

- $P(X_1,...,X_P \mid y = k)$ is the conditional joint density of the predictors given they are in class k. `Mdl.DistributionNames` stores the distribution names of the predictors.
- $\pi(Y = k)$ is the class prior probability distribution. `Mdl.Prior` stores the prior distribution.
- $P(X_1,..,X_P)$ is the joint density of the predictors. The classes are discrete, so

  $$P(X_1,...,X_P) = \sum_{k=1}^{K} P(X_1,...,X_P \mid y = k)\pi(Y = k).$$

Prior Probability

The *prior probability* is the believed relative frequency that observations from a class occur in the population for each class.

Examples

Label Test Sample Observations of Naive Bayes Classifiers

Load Fisher's iris data set.

```
load fisheriris
X = meas;    % Predictors
Y = species; % Response
rng(1);
```

Train a naive Bayes classifier and specify to holdout 30% of the data for a test sample. It is good practice to specify the class order. Assume that each predictor is conditionally, normally distributed given its label.

```
CVMdl = fitcnb(X,Y,'Holdout',0.30,...
    'ClassNames',{'setosa','versicolor','virginica'});
CMdl = CVMdl.Trained{1};          % Extract trained, compact classifier
testIdx = test(CVMdl.Partition); % Extract the test indices
XTest = X(testIdx,:);
YTest = Y(testIdx);
```

`CVMdl` is a `ClassificationPartitionedModel` classifier. It contains the property `Trained`, which is a 1-by-1 cell array holding a `CompactClassificationNaiveBayes` classifier that the software trained using the training set.

Label the test sample observations. Display the results for a random set of 10 observations in the test sample.

```
idx = randsample(sum(testIdx),10);
label = predict(CMdl,XTest);
table(YTest(idx),label(idx),'VariableNames',...
    {'TrueLabel','PredictedLabel'})
```

```
ans =

     TrueLabel      PredictedLabel
    ____________    ______________

    'setosa'        'setosa'
    'versicolor'    'versicolor'
    'setosa'        'setosa'
    'virginica'     'virginica'
    'versicolor'    'versicolor'
    'setosa'        'setosa'
    'virginica'     'virginica'
    'virginica'     'virginica'
    'setosa'        'setosa'
    'setosa'        'setosa'
```

Estimate Posterior Probabilities and Misclassification Costs

A goal of classification is to estimate posterior probabilities of new observations using a trained algorithm. Many applications train algorithms on large data sets, which can use resources that are better used elsewhere. This example shows how to efficiently estimate posterior probabilities of new observations using a Naive Bayes classifier.

Load Fisher's iris data set.

```
load fisheriris
X = meas;    % Predictors
Y = species; % Response
rng(1);
```

Partition the data set into two sets: one in the training set, and the other is new unobserved data. Reserve 10 observations for the new data set.

```
n = size(X,1);
newInds = randsample(n,10);
inds = ~ismember(1:n,newInds);
XNew = X(newInds,:);
YNew = Y(newInds);
```

Train a naive Bayes classifier. It is good practice to specify the class order. Assume that each predictor is conditionally, normally distributed given its label. Conserve memory by reducing the size of the trained SVM classifier.

```
Mdl = fitcnb(X(inds,:),Y(inds),...
    'ClassNames',{'setosa','versicolor','virginica'});
CMdl = compact(Mdl);
whos('Mdl','CMdl')
```

```
  Name      Size            Bytes  Class

  CMdl      1x1              4772  classreg.learning.classif.CompactClassificationNaive
  Mdl       1x1             12541  ClassificationNaiveBayes
```

The `CompactClassificationNaiveBayes` classifier (`CMdl`) uses less space than the `ClassificationNaiveBayes` classifier (`Mdl`) because the latter stores the data.

Predict the labels, posterior probabilities, and expected class misclassification costs. Since true labels are available, compare them with the predicted labels.

```
CMdl.ClassNames
[labels,PostProbs,MisClassCost] = predict(CMdl,XNew);
table(YNew,labels,PostProbs,'VariableNames',...
    {'TrueLabels','PredictedLabels',...
    'PosteriorProbabilities'})
MisClassCost
```

```
ans =

    'setosa'
    'versicolor'
    'virginica'
```

```
ans =

     TrueLabels     PredictedLabels            PosteriorProbabilities
    ____________    _______________    ____________________________________

    'setosa'        'setosa'                    1     4.1259e-16     1.1846e-23
    'versicolor'    'versicolor'         1.0373e-60        0.99999     5.8053e-06
    'virginica'     'virginica'         4.8708e-211     0.00085645        0.99914
    'setosa'        'setosa'                    1     1.4053e-19     2.2672e-26
    'versicolor'    'versicolor'         2.9308e-75        0.99987     0.00012869
    'setosa'        'setosa'                    1      2.629e-18     4.4297e-25
    'versicolor'    'versicolor'         1.4238e-67        0.99999      9.733e-06
    'versicolor'    'versicolor'        2.0667e-110        0.94237       0.057625
    'setosa'        'setosa'                    1     4.3779e-19     3.5139e-26
    'setosa'        'setosa'                    1     1.1792e-17     2.2912e-24
```

```
MisClassCost =

    0.0000    1.0000    1.0000
    1.0000    0.0000    1.0000
    1.0000    0.9991    0.0009
    0.0000    1.0000    1.0000
    1.0000    0.0001    0.9999
    0.0000    1.0000    1.0000
    1.0000    0.0000    1.0000
    1.0000    0.0576    0.9424
    0.0000    1.0000    1.0000
    0.0000    1.0000    1.0000
```

`PostProbs` and `MisClassCost` are 15-by- 3 numeric matrices, where each row corresponds to a new observation and each column corresponds to a class. The order of the columns corresponds to the order of `CMdl.ClassNames`.

Plot Posterior Probability Regions for Naive Bayes Classifiers

Load Fisher's iris data set. Train the classifier using the petal lengths and widths.

```
load fisheriris
X = meas(:,3:4);
Y = species;
```

Train a naive Bayes classifier. It is good practice to specify the class order. Assume that each predictor is conditionally, normally distributed given its label.

```
Mdl = fitcnb(X,Y,...
    'ClassNames',{'setosa','versicolor','virginica'});
```

`Mdl` is a `ClassificationNaiveBayes` model. You can access its properties using dot notation.

Define a grid of values in the observed predictor space. Predict the posterior probabilities for each instance in the grid.

```
xMax = max(X);
xMin = min(X);
h = 0.01;
[x1Grid,x2Grid] = meshgrid(xMin(1):h:xMax(1),xMin(2):h:xMax(2));

[~,PosteriorRegion] = predict(Mdl,[x1Grid(:),x2Grid(:)]);
```

Plot the posterior probability regions and the training data.

```
figure;
% Plot posterior regions
scatter(x1Grid(:),x2Grid(:),1,PosteriorRegion);
% Adjust color bar options
h = colorbar;
h.Ticks = [0 0.5 1];
h.TickLabels = {'setosa','versicolor','virginica'};
h.YLabel.String = 'Posterior';
h.YLabel.Position = [-0.5 0.5 0];
% Adjust color map options
d = 1e-2;
cmap = zeros(201,3);
cmap(1:101,1) = 1:-d:0;
```

```
cmap(1:201,2) = [0:d:1 1-d:-d:0];
cmap(101:201,3) = 0:d:1;
colormap(cmap);
% Plot data
hold on
gh = gscatter(X(:,1),X(:,2),Y,'k','dx*');
title 'Iris Petal Measurements and Posterior Probabilities';
xlabel 'Petal length (cm)';
ylabel 'Petal width (cm)';
axis tight
legend(gh,'Location','Best')
hold off
```

predict

Class: CompactClassificationSVM

Predict labels for support vector machine classifiers

Syntax

```
label = predict(SVMModel,X)
[label,Score] = predict(SVMModel,X)
```

Description

`label = predict(SVMModel,X)` returns a vector of predicted class labels for predictor data `X`, based on the full or compact, trained SVM classifier `SVMModel`.

`[label,Score] = predict(SVMModel,X)` additionally returns class likelihood measures, i.e., either scores or posterior probabilities.

Input Arguments

`SVMModel` — SVM classifier

`ClassificationSVM` classifier | `CompactClassificationSVM` classifier

SVM classifier, specified as a `ClassificationSVM` classifier or `CompactClassificationSVM` classifier returned by `fitcsvm` or `compact`, respectively.

`X` — Predictor data

numeric matrix

Predictor data, specified as a numeric matrix.

Each row of `X` corresponds to one observation (also known as an instance or example), and each column corresponds to one variable (also known as a feature). The variables making up the columns of `X` should be the same as the variables that trained the `SVMModel` classifier.

The length of Y and the number of rows of X must be equal.

If you set 'Standardize',true in fitcsvm to train SVMModel, then the software standardizes the columns of X using the corresponding means in SVMModel.Mu and standard deviations in SVMModel.Sigma.

Data Types: double | single

Output Arguments

label — Predicted class labels

categorical array | character array | logical vector | vector of numeric values | cell array of strings

Predicted class labels, returned as a categorical or character array, logical or numeric vector, or cell array of strings.

label:

- Is the same data type as the observed class labels (Y) that trained SVMModel
- Has length equal to the number of rows of X

For one-class learning, the elements of label are the one class represented in the observed class labels.

Score — Predicted class scores or posterior probabilities

numeric column vector | numeric matrix

Predicted class scores or posterior probabilities, returned as a numeric column vector or numeric matrix.

- For one-class learning, Score is a column vector with the same number of rows as the training observations (X). The elements are the positive class scores for the corresponding observations. You cannot obtain posterior probabilities for one-class learning.
- For two-class learning, Score is a two column matrix with the same number of rows as X.
    - If you fit the optimal score-to-posterior probability transformation function using fitPosterior or fitSVMPosterior, then Score contains class posterior

probabilities. That is, if the value of `SVMModel.ScoreTransform` is not `none`, then the elements of the first and second columns of `Score` are the negative class (`SVMModel.ClassNames{1}`) and positive class (`SVMModel.ClassNames{2}`) posterior probabilities for the corresponding observations, respectively.

- Otherwise, the elements of the first column are the negative class scores and the elements of the second column are the positive class scores for the corresponding observations.

If SVMModel`.KernelParameters.Function` is `'linear'`, then the software estimates the classification score for the observation x using

$$f(x) = (x / s)'\beta + b.$$

SVMModel stores β, b, s in the properties Beta, Bias, and KernelParameters`.Scale`, respectively.

Data Types: `double | single`

Definitions

Score

The SVM *score* for classifying observation x is the signed distance from x to the decision boundary ranging from -∞ to +∞. A positive score for a class indicates that x is predicted to be in that class, a negative score indicates otherwise.

The score is also the numerical, predicted response for x, $f(x)$, computed by the trained SVM classification function

$$f(x) = \sum_{j=1}^{n} \alpha_j y_j G(x_j, x) + b,$$

where $(\alpha_1, ..., \alpha_n, b)$ are the estimated SVM parameters, $G(x_j, x)$ is the dot product in the predictor space between x and the support vectors, and the sum includes the training set observations.

If $G(x_j,x) = x_j'x$ (the linear kernel), then the score function reduces to

$$f(x) = (x / s)'\beta + b.$$

s is the kernel scale and β is the vector of fitted linear coefficients.

Posterior Probability

The probability that an observation belongs in a particular class, given the data.

For SVM, the posterior probability is a function of the score, $P(s)$, that observation j is in class $k = \{-1,1\}$.

- For separable classes, the posterior probability is the step function

$$P(s_j) = \begin{cases} 0; & s < \max_{y_k=-1} s_k \\ \pi; & \max_{y_k=-1} s_k \le s_j \le \min_{y_k=+1} s_k \\ 1; & s_j > \min_{y_k=+1} s_k \end{cases},$$

  where:

  - s_j is the score of observation j.
  - +1 and –1 denote the positive and negative classes, respectively.
  - π is the prior probability that an observation is in the positive class.
- For inseparable classes, the posterior probability is the sigmoid function

$$P(s_j) = \frac{1}{1 + \exp(As_j + B)},$$

  where the parameters A and B are the slope and intercept parameters.

Prior Probability

The *prior probability* is the believed relative frequency that observations from a class occur in the population for each class.

Examples

Label Test Sample Observations of SVM Classifiers

Load the `ionosphere` data set.

```
load ionosphere
rng(1); % For reproducibility
```

Train an SVM classifier. Specify a 15% holdout sample for testing. It is good practice to specify the class order and standardize the data.

```
CVSVMModel = fitcsvm(X,Y,'Holdout',0.15,'ClassNames',{'b','g'},...
    'Standardize',true);
CompactSVMModel = CVSVMModel.Trained{1}; % Extract trained, compact classifier
testInds = test(CVSVMModel.Partition);   % Extract the test indices
XTest = X(testInds,:);
YTest = Y(testInds,:);
```

`CVSVMModel` is a `ClassificationPartitionedModel` classifier. It contains the property `Trained`, which is a 1-by-1 cell array holding a `CompactClassificationSVM` classifier that the software trained using the training set.

Label the test sample observations. Display the results for the first 10 observations in the test sample.

```
[label,score] = predict(CompactSVMModel,XTest);
table(YTest(1:10),label(1:10),score(1:10,2),'VariableNames',...
    {'TrueLabel','PredictedLabel','Score'})
```

```
ans =

    TrueLabel    PredictedLabel     Score
    _________    ______________    ________

    'b'          'b'               -1.7177
    'g'          'g'                2.0003
    'b'          'b'               -9.6841
    'g'          'g'                2.5618
    'b'          'b'                -1.548
    'g'          'g'                2.0984
    'b'          'b'               -2.7018
```

```
    'b'          'b'              -0.66291
    'g'          'g'                1.6046
    'g'          'g'                1.7731
```

Predict Labels and Posterior Probabilities of SVM Classifiers

A goal of classification is to predict labels of new observations using a trained algorithm. Many applications train algorithms on large data sets, which can use resources that are better used elsewhere. This example shows how to efficiently label new observations using an SVM classifier.

Load the ionosphere data set. Suppose that the last 10 observations become available after training the SVM classifier.

```
load ionosphere

n = size(X,1);       % Training sample size
isInds = 1:(n-10);   % In-sample indices
oosInds = (n-9):n;   % Out-of-sample indices
```

Train an SVM classifier. It is good practice to standardize the predictors and specify the order of the classes. Conserve memory by reducing the size of the trained SVM classifier.

```
SVMModel = fitcsvm(X(isInds,:),Y(isInds),'Standardize',true,...
    'ClassNames',{'b','g'});
CompactSVMModel = compact(SVMModel);
whos('SVMModel','CompactSVMModel')
```

```
  Name                 Size              Bytes  Class

  CompactSVMModel      1x1               29576  classreg.learning.classif.CompactClassif
  SVMModel             1x1              137550  ClassificationSVM
```

The positive class is `'g'`. The `CompactClassificationSVM` classifier (`CompactSVMModel`) uses less space than the `ClassificationSVM` classifier (`SVMModel`) because the latter stores the data.

Estimate the optimal score-to-posterior-probability-transformation function.

```
CompactSVMModel = fitPosterior(CompactSVMModel,...
    X(isInds,:),Y(isInds))
```

```
CompactSVMModel =

  classreg.learning.classif.CompactClassificationSVM
         PredictorNames: {1x34 cell}
           ResponseName: 'Y'
             ClassNames: {'b'  'g'}
         ScoreTransform: '@(S)sigmoid(S,-1.968452e+00,3.121267e-01)'
                  Alpha: [88x1 double]
                   Bias: -0.2143
       KernelParameters: [1x1 struct]
                     Mu: [1x34 double]
                  Sigma: [1x34 double]
         SupportVectors: [88x34 double]
    SupportVectorLabels: [88x1 double]
```

The optimal score transformation function (`CompactSVMModel.ScoreTransform`) is the sigmoid function because the classes are inseparable.

Predict the out-of-sample labels and positive class posterior probabilities. Since true labels are available, compare them with the predicted labels.

```
[labels,PostProbs] = predict(CompactSVMModel,X(oosInds,:));
table(Y(oosInds),labels,PostProbs(:,2),'VariableNames',...
    {'TrueLabels','PredictedLabels','PosClassPosterior'})
```

```
ans =

    TrueLabels    PredictedLabels    PosClassPosterior
    __________    _______________    _________________

    'g'           'g'                0.98419
    'g'           'g'                0.95545
    'g'           'g'                0.67792
    'g'           'g'                0.94448
    'g'           'g'                0.98744
    'g'           'g'                0.92482
    'g'           'g'                0.97111
    'g'           'g'                0.96986
    'g'           'g'                0.97803
    'g'           'g'                0.94361
```

`PostProbs` is a 10-by-2 matrix; its first column is the negative class posterior probabilities, and second column is the positive class posterior probabilities corresponding to the new observations.

- "Plot Posterior Probability Regions for SVM Classification Models" on page 16-201
- "Train SVM Classifiers Using a Custom Kernel" on page 16-183
- "Analyze Images Using Linear Support Vector Machines" on page 16-204

Algorithms

- By default, the software computes optimal posterior probabilities using Platt's method [1]:

  1. Performing 10-fold cross validation
  2. Fitting the sigmoid function parameters to the scores returned from the cross validation
  3. Estimating the posterior probabilities by entering the cross-validation scores into the fitted sigmoid function

- The software incorporates prior probabilities in the SVM objective function during training.
- For SVM, `predict` classifies observations into the class yielding the largest score (i.e., the largest posterior probability). The software accounts for misclassification costs by applying the average-cost correction before training the classifier. That is, given the class prior vector P, misclassification cost matrix C, and observation weight vector w, the software defines a new vector of observation weights (W) such that

$$W_j = w_j P_j \sum_{k=1}^{K} C_{jk}.$$

predict

Class: CompactClassificationTree

Predict classification

Syntax

```
label = predict(tree,X)
[label,score] = predict(tree,X)
[label,score,node] = predict(tree,X)
[label,score,node,cnum] = predict(tree,X)
[label,...] = predict(tree,X,Name,Value)
```

Description

`label = predict(tree,X)` returns a vector of predicted class labels for a matrix `X`, based on `tree`, a trained full or compact classification tree.

`[label,score] = predict(tree,X)` returns a matrix of scores, indicating the likelihood that a label comes from a particular class.

`[label,score,node] = predict(tree,X)` returns a vector of predicted node numbers for the classification, based on `tree`.

`[label,score,node,cnum] = predict(tree,X)` returns a vector of predicted class number for the classification, based on `tree`.

`[label,...] = predict(tree,X,Name,Value)` returns labels with additional options specified by one or more Name,Value pair arguments.

Input Arguments

`tree`

A classification tree created by `fitctree`, or a compact classification tree created by `compact`.

`X`

A matrix where each row represents an observation, and each column represents a predictor. The number of columns in `X` must equal the number of predictors in `tree`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'Subtrees'`

A vector of nonnegative integers in ascending order or `'all'`.

If you specify a vector, then all elements must be at least `0` and at most `max(tree.PruneList)`. `0` indicates the full, unpruned tree and `max(tree.PruneList)` indicates the a completely pruned tree (i.e., just the root node).

If you specify `'all'`, then `CompactClassificationTree.predict` operates on all subtrees (i.e., the entire pruning sequence). This specification is equivalent to using `0:max(tree.PruneList)`.

`CompactClassificationTree.predict` prunes tree to each level indicated in `Subtrees`, and then estimates the corresponding output arguments. The size of `Subtrees` determines the size of some output arguments.

To invoke `Subtrees`, the properties `PruneList` and `PruneAlpha` of tree must be nonempty. In other words, grow `tree` by setting `'Prune','on'`, or by pruning `tree` using `prune`.

Default: `0`

Output Arguments

`label`

Vector of class labels of the same type as the response data used in training tree. Each entry of `label` corresponds to the class with minimal expected cost for the corresponding row of `X`. See “Predicted Class Label” on page 22-3708.

If `Subtrees` has `T` elements, and X has `N` rows, then labels is an `N`-by-`T` matrix. The `i`th column of `labels` contains the fitted values produced by the `Subtrees(I)` subtree.

`score`

Numeric matrix of size `N`-by-`K`, where `N` is the number of observations (rows) in `X`, and `K` is the number of classes (in `tree.ClassNames`). `score(i,j)` is the posterior probability that row `i` of `X` is of class `j`.

If `Subtrees` has `T` elements, and X has `N` rows, then score is an `N`-by-`K`-by-`T` array, and node and cnum are `N`-by-`T` matrices.

`node`

Numeric vector of node numbers for the predicted classes. Each entry corresponds to the predicted node in tree for the corresponding row of X.

`cnum`

Numeric vector of class numbers corresponding to the predicted labels. Each entry of `cnum` corresponds to a predicted class number for the corresponding row of `X`.

Definitions

Predicted Class Label

`predict` classifies so as to minimize the expected classification cost:

$$\hat{y} = \underset{y=1,\ldots,K}{\arg\min} \sum_{k=1}^{K} \hat{P}(k \mid x) C(y \mid k),$$

where

- $\hat{y}$ is the predicted classification.
- K is the number of classes.

- $\hat{P}(k \mid x)$ is the posterior probability of class k for observation x.
- $C(y \mid k)$ is the cost of classifying an observation as y when its true class is k.

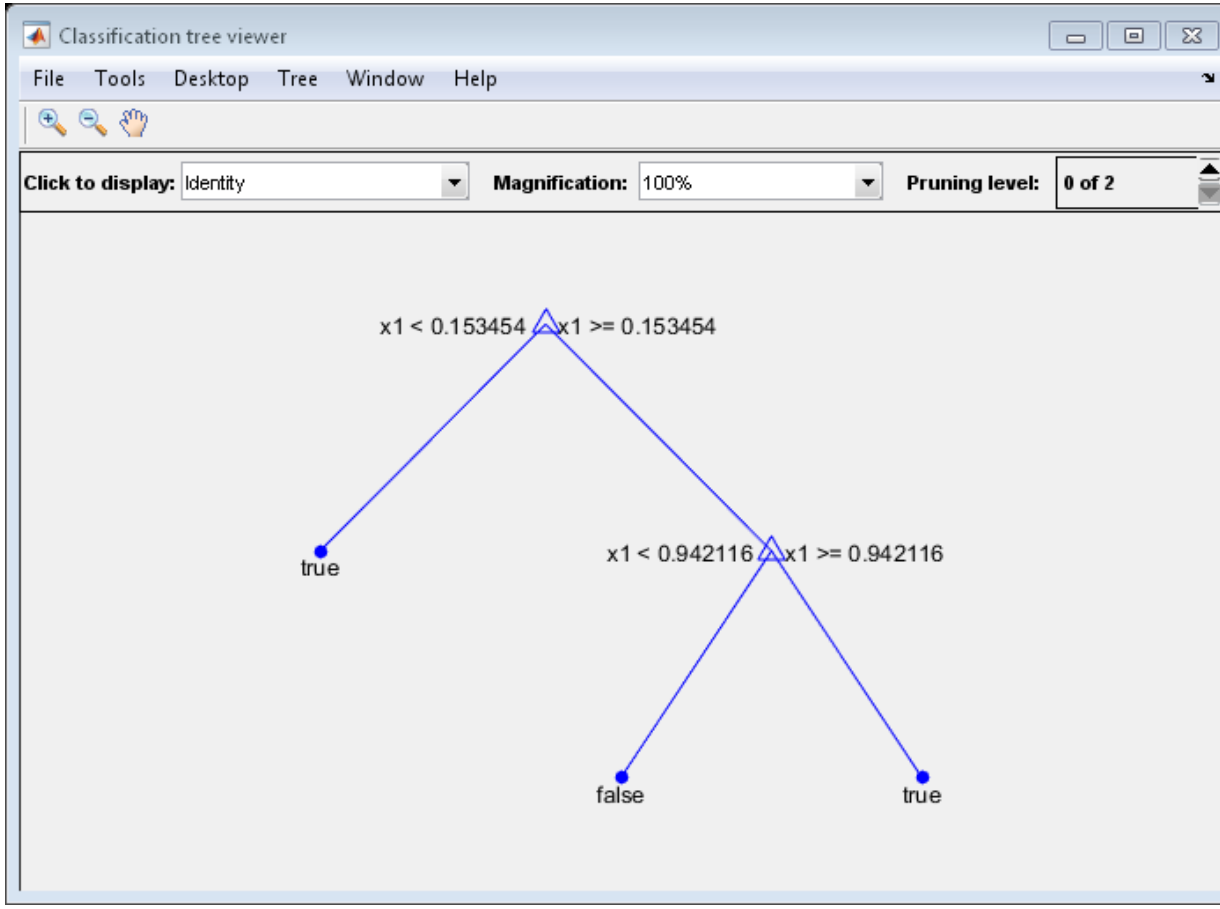
Score (tree)

For trees, the *score* of a classification of a leaf node is the posterior probability of the classification at that node. The posterior probability of the classification at a node is the number of training sequences that lead to that node with the classification, divided by the number of training sequences that lead to that node.

For example, consider classifying a predictor `X` as `true` when `X < 0.15` or `X > 0.95`, and `X` is false otherwise.

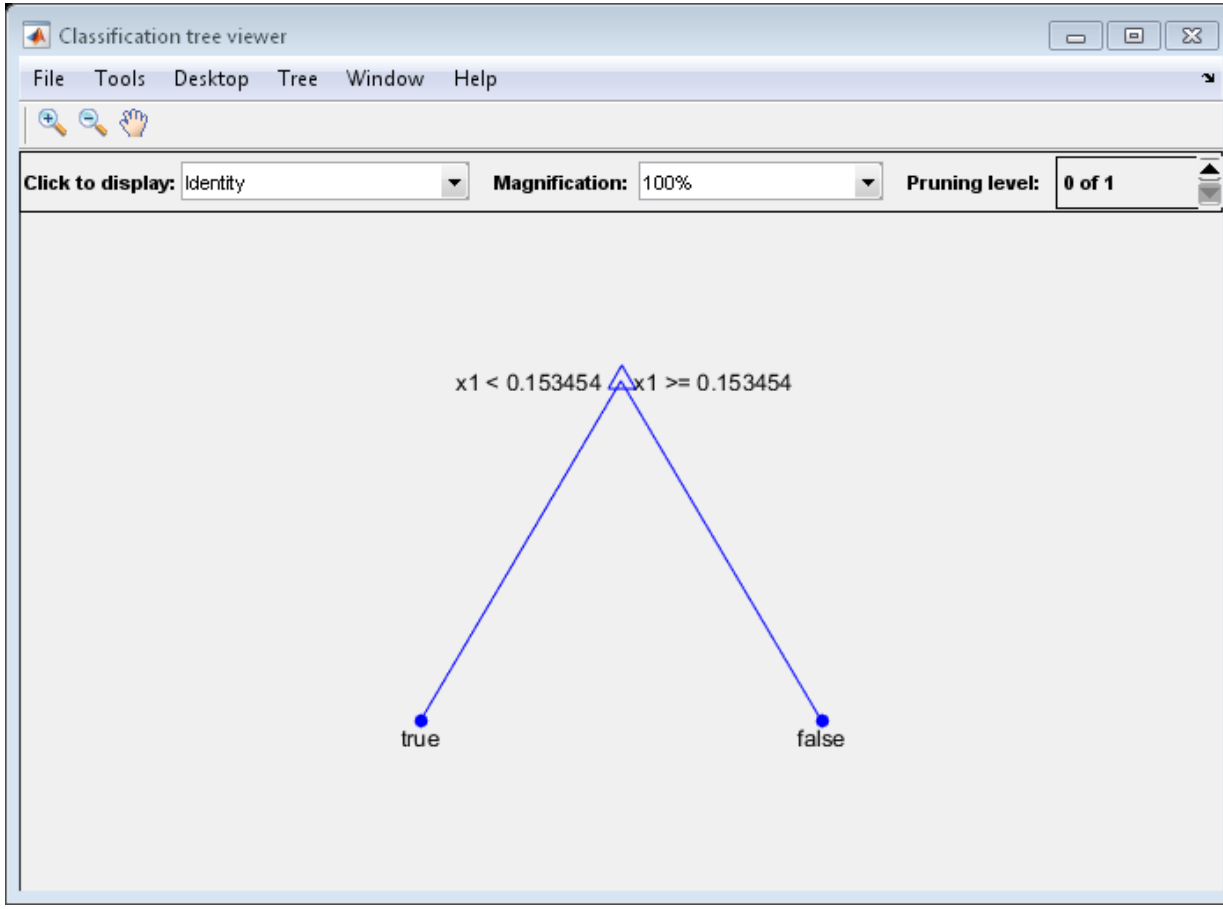
Generate 100 random points and classify them:

```
rng(0,'twister') % for reproducibility
X = rand(100,1);
Y = (abs(X - .55) > .4);
tree = fitctree(X,Y);
view(tree,'Mode','Graph')
```



Prune the tree:

```
tree1 = prune(tree,'Level',1);
view(tree1,'Mode','Graph')
```



The pruned tree correctly classifies observations that are less than 0.15 as `true`. It also correctly classifies observations from .15 to .94 as `false`. However, it incorrectly classifies observations that are greater than .94 as `false`. Therefore, the score for observations that are greater than .15 should be about .05/.85=.06 for `true`, and about .8/.85=.94 for `false`.

Compute the prediction scores for the first 10 rows of `X`:

```
[~,score] = predict(tree1,X(1:10));
[score X(1:10,:)]
```

```
ans =

    0.9059    0.0941    0.8147
    0.9059    0.0941    0.9058
         0    1.0000    0.1270
    0.9059    0.0941    0.9134
    0.9059    0.0941    0.6324
         0    1.0000    0.0975
    0.9059    0.0941    0.2785
    0.9059    0.0941    0.5469
    0.9059    0.0941    0.9575
    0.9059    0.0941    0.9649
```

Indeed, every value of `X` (the right-most column) that is less than 0.15 has associated scores (the left and center columns) of `0` and `1`, while the other values of `X` have associated scores of `0.91` and `0.09`. The difference (score `0.09` instead of the expected `.06`) is due to a statistical fluctuation: there are `8` observations in `X` in the range `(.95,1)` instead of the expected `5` observations.

True Misclassification Cost

There are two costs associated with classification: the true misclassification cost per class, and the expected misclassification cost per observation.

You can set the true misclassification cost per class in the `Cost` name-value pair when you create the classifier using the `fitctree` method. `Cost(i,j)` is the cost of classifying an observation into class `j` if its true class is `i`. By default, `Cost(i,j)=1` if `i~=j`, and `Cost(i,j)=0` if `i=j`. In other words, the cost is `0` for correct classification, and `1` for incorrect classification.

Expected Cost

There are two costs associated with classification: the true misclassification cost per class, and the expected misclassification cost per observation.

Suppose you have `Nobs` observations that you want to classify with a trained classifier. Suppose you have `K` classes. You place the observations into a matrix `Xnew` with one observation per row.

The expected cost matrix `CE` has size `Nobs`-by-`K`. Each row of `CE` contains the expected (average) cost of classifying the observation into each of the `K` classes. `CE(n,k)` is

$$\sum_{i=1}^{K} \hat{P}(i \mid Xnew(n))C(k \mid i),$$

where

- K is the number of classes.
- $\hat{P}(i \mid Xnew(n))$ is the posterior probability of class i for observation $Xnew(n)$.
- $C(k \mid i)$ is the true misclassification cost of classifying an observation as k when its true class is i.

Predictive Measure of Association

The predictive measure of association between the optimal split on variable i and a surrogate split on variable j is:

$$\lambda_{i,j} = \frac{\min(P_L, P_R) - \left(1 - P_{L_i L_j} - P_{R_i R_j}\right)}{\min(P_L, P_R)}.$$

Here

- P_L and P_R are the node probabilities for the optimal split of node i into Left and Right nodes respectively.
- $P_{L_i L_j}$ is the probability that both (optimal) node i and (surrogate) node j send an observation to the Left.
- $P_{R_i R_j}$ is the probability that both (optimal) node i and (surrogate) node j send an observation to the Right.

Clearly, $\lambda_{i,j}$ lies from $-\infty$ to 1. Variable j is a worthwhile surrogate split for variable i if $\lambda_{i,j} > 0$.

Examples

Predict Labels Using a Classification Tree

Examine predictions for a few rows in a data set left out of training.

Load Fisher's iris data set.

```
load fisheriris
```

Partition the data into training (50%) and validation (50%) sets.

```
n = size(meas,1);
rng(1) % For reproducibility
idxTrn = false(n,1);
idxTrn(randsample(n,round(0.5*n))) = true; % Training set logical indices
idxVal = idxTrn == false;                  % Validation set logical indices
```

Grow a classification tree using the training set.

```
Mdl = fitctree(meas(idxTrn,:),species(idxTrn));
```

Predict labels for the validation data. Count the number of misclassified observations.

```
label = predict(Mdl,meas(idxVal,:));
label(randsample(numel(label),5)) % Display several predicted labels
numMisclass = sum(~strcmp(label,species(idxVal)))
```

```
ans =

    'setosa'
    'setosa'
    'setosa'
    'virginica'
    'versicolor'

numMisclass =

     3
```

The software misclassifies three out-of-sample observations.

Estimate Class Posterior Probabilities Using a Classification Tree

Load Fisher's iris data set.

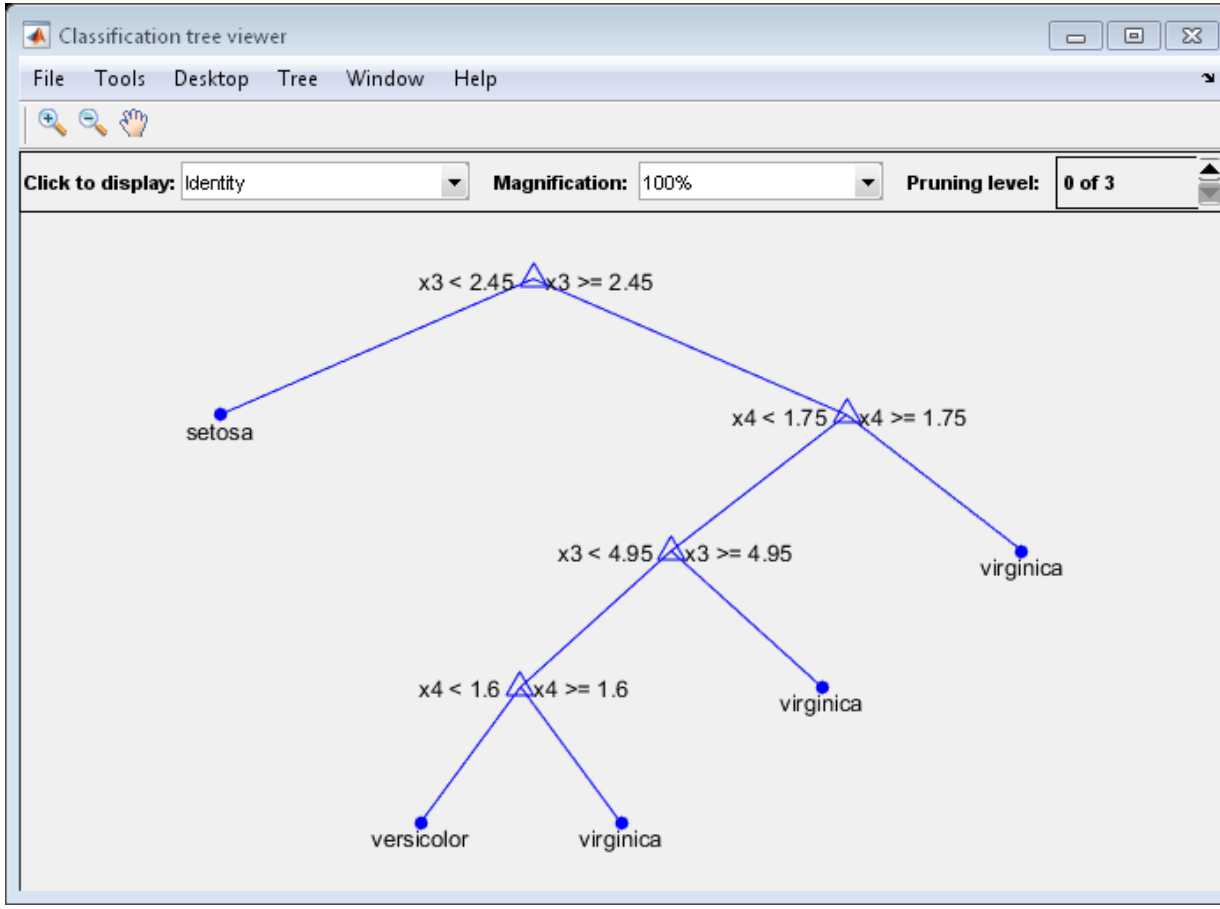
```
load fisheriris
```

Partition the data into training (50%) and validation (50%) sets.

```
n = size(meas,1);
rng(1) % For reproducibility
idxTrn = false(n,1);
idxTrn(randsample(n,round(0.5*n))) = true; % Training set logical indices
idxVal = idxTrn == false;                  % Validation set logical indices
```

Grow a classification tree using the training set, and then view it.

```
Mdl = fitctree(meas(idxTrn,:),species(idxTrn));
view(Mdl,'Mode','graph')
```



The resulting tree has four levels.

Estimate posterior probabilities for the test set using subtrees pruned to levels 1 and 3.

```
[~,Posterior] = predict(Mdl,meas(idxVal,:),'SubTrees',[1 3]);
Mdl.ClassNames
Posterior(randsample(size(Posterior,1),5),:,:),...
    % Display several posterior probabilities
```

```
ans =
```

```
    'setosa'
    'versicolor'
    'virginica'

ans(:,:,1) =

    1.0000         0         0
    1.0000         0         0
    1.0000         0         0
         0         0    1.0000
         0    0.8571    0.1429

ans(:,:,2) =

    0.3733    0.3200    0.3067
    0.3733    0.3200    0.3067
    0.3733    0.3200    0.3067
    0.3733    0.3200    0.3067
    0.3733    0.3200    0.3067
```

The elements of `Posterior` are class posterior probabilities:

- Rows correspond to observations in the validation set.
- Columns correspond to the classes as listed in `Mdl.ClassNames`.
- Pages correspond to the subtrees.

The subtree pruned to level 1 is more sure of its predictions than the subtree pruned to level 3 (i.e., the root node).

Algorithms

`predict` generates predictions by following the branches of `tree` until it reaches a leaf node or a missing value. If `predict` reaches a leaf node, it returns the classification of that node.

If `predict` reaches a node with a missing value for a predictor, its behavior depends on the setting of the `Surrogate` name-value pair when `fitctree` constructs `tree`.

- **`Surrogate = 'off'`** (default) — `predict` returns the label with the largest number of training samples that reach the node.
- **`Surrogate = 'on'`** — `predict` uses the best surrogate split at the node. If all surrogate split variables with positive *predictive measure of association* are missing, `predict` returns the label with the largest number of training samples that reach the node. For a definition, see “Predictive Measure of Association” on page 22-3713.

predict

Class: CompactRegressionEnsemble

Predict response of ensemble

Syntax

```
Yfit = predict(ens,Xdata)
Yfit = predict(ens,Xdata,Name,Value)
```

Description

`Yfit = predict(ens,Xdata)` returns predicted responses to the data in `Xdata`, based on the `ens` regression ensemble model.

`Yfit = predict(ens,Xdata,Name,Value)` predicts with additional options specified by one or more Name,Value pair arguments.

Input Arguments

`ens`

Regression ensemble created by `fitensemble`, or by the `compact` method.

`Xdata`

Numeric array with the same number of columns as the array used for creating `ens`. Each row of `Xdata` corresponds to one data point, and each column corresponds to one predictor.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'learners'`

Indices of weak learners in the ensemble ranging from `1` to `ens.NumTrained`. `oobEdge` uses only these learners for calculating loss.

Default: `1:NumTrained`

`'UseObsForLearner'`

A logical matrix of size `N`-by-`NumTrained`, where `N` is the number of observations in `ens.X`, and `NumTrained` is the number of weak learners. When `UseObsForLearner(I,J)` is `true`, `predict` uses learner `J` in predicting observation `I`.

Default: `true(N,NumTrained)`

Output Arguments

`Yfit`

A numeric column vector with the same number of rows as Xdata. Each row of `Yfit` gives the predicted response to the corresponding row of `Xdata`, based on the ens regression model.

Examples

Find the predicted mileage for a four-cylinder car, with 200 cubic inch engine displacement, 150 horsepower, weighing 3000 lbs, based on the `carsmall` data:

```
load carsmall
X = [Cylinders Displacement Horsepower Weight];
rens = fitensemble(X,MPG,'LSBoost',100,'Tree');
Mileage = predict(rens,[4 200 150 3000])

Mileage =
   20.4982
```

See Also

`loss` | `fitensemble`

predict

Class: CompactRegressionTree

Predict response of regression tree

Syntax

```
Yfit = predict(tree,Xdata)
[Yfit,node] = predict(tree,Xdata)
[Yfit,node] = predict(tree,Xdata,Name,Value)
```

Description

`Yfit = predict(tree,Xdata)` returns predicted responses to the data in `Xdata`, based on the `tree` regression tree.

`[Yfit,node] = predict(tree,Xdata)` returns the predicted node numbers of `tree` in response to `Xdata`.

`[Yfit,node] = predict(tree,Xdata,Name,Value)` predicts response with additional options specified by one or more Name,Value pair arguments.

Input Arguments

`tree`

Regression tree created by `fitrtree`, or by the `compact` method.

`Xdata`

Numeric array with the same number of columns as the array used for creating `tree`. Each row of `Xdata` corresponds to one data point, and each column corresponds to one predictor.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'Subtrees'`

A vector of nonnegative integers in ascending order or `'all'`.

If you specify a vector, then all elements must be at least `0` and at most `max(tree.PruneList)`. `0` indicates the full, unpruned tree and `max(tree.PruneList)` indicates the a completely pruned tree (i.e., just the root node).

If you specify `'all'`, then `CompactRegressionTree.predict` operates on all subtrees (i.e., the entire pruning sequence). This specification is equivalent to using `0:max(tree.PruneList)`.

`CompactRegressionTree.predict` prunes tree to each level indicated in `Subtrees`, and then estimates the corresponding output arguments. The size of `Subtrees` determines the size of some output arguments.

To invoke `Subtrees`, the properties `PruneList` and `PruneAlpha` of tree must be nonempty. In other words, grow `tree` by setting `'Prune','on'`, or by pruning `tree` using `prune`.

Default: `0`

Output Arguments

`Yfit`

A numeric column vector with the same number of rows as Xdata. Each row of `Yfit` gives the predicted response to the corresponding row of `Xdata`, based on the tree regression model.

`node`

Numeric vector of node numbers for the predictions. Each entry corresponds to the predicted leaf node in tree for the corresponding row of Xdata.

Examples

Predict a Response Using a Regression Tree

Load the `carsmall` data set. Consider `Displacement`, `Horsepower`, and `Weight` as predictors of the response `MPG`.

```
load carsmall
X = [Displacement Horsepower Weight];
```

Grow a regression tree using the entire data set.

```
Mdl = fitrtree(X,MPG);
```

Predict the MPG for a car with 200 cubic inch engine displacement, 150 horsepower, and that weighs 3000 lbs.

```
X0 = [200 150 3000];
MPG0 = predict(Mdl,X0)
```

```
MPG0 =

   21.9375
```

The regression tree predicts the car's efficiency to be 21.94 mpg.

predict

Class: CompactTreeBagger

Predict response

Syntax

```
YFIT = predict(B,X)
[YFIT,stdevs] = predict(B,X)
[YFIT,scores] = predict(B,X)
[YFIT,scores,stdevs] = predict(B,X)
Y = predict(B,X,'param1',val1,'param2',val2,...)
```

Description

`YFIT = predict(B,X)` computes the predicted response of the trained ensemble `B` for predictors `X`. By default, `predict` takes a democratic (nonweighted) average vote from all trees in the ensemble. In `X`, rows represent observations and columns represent variables. `YFIT` is a cell array of strings for classification and a numeric array for regression.

For regression, `[YFIT,stdevs] = predict(B,X)` also returns standard deviations of the computed responses over the ensemble of the grown trees.

For classification, `[YFIT,scores] = predict(B,X)` returns scores for all classes. `scores` is a matrix with one row per observation and one column per class. For each observation and each class, the score generated by each tree is the probability of this observation originating from this class computed as the fraction of observations of this class in a tree leaf. `predict` averages these scores over all trees in the ensemble.

`[YFIT,scores,stdevs] = predict(B,X)` also returns standard deviations of the computed scores for classification. `stdevs` is a matrix with one row per observation and one column per class, with standard deviations taken over the ensemble of the grown trees.

`Y = predict(B,X,'param1',val1,'param2',val2,...)` specifies optional parameter name/value pairs:

`'trees'`	Array of tree indices to use for computation of responses. Default is `'all'`.
`'treeweights'`	Array of `NTrees` weights for weighting votes from the specified trees.
`'useifort'`	Logical matrix of size `Nobs`-by-`NTrees` indicating which trees to use to make predictions for each observation. By default all trees are used for all observations.

`RegressionTree.predict` | `ClassificationTree.predict` | `TreeBagger.predict`

predict

Class: GeneralizedLinearModel

Predict response of generalized linear regression model

Syntax

```
ypred = predict(mdl,Xnew)
[ypred,yci] = predict(mdl,Xnew)
[ypred,yci] = predict(mdl,Xnew,Name,Value)
```

Description

`ypred = predict(mdl,Xnew)` returns the predicted response of the `mdl` generalized linear regression model to the points in `Xnew`.

`[ypred,yci] = predict(mdl,Xnew)` returns confidence intervals for the true mean responses.

`[ypred,yci] = predict(mdl,Xnew,Name,Value)` predicts responses with additional options specified by one or more Name,Value pair arguments.

Tips

- For predictions with added noise, use `random`.
- For a syntax that can be easier to use with models created from dataset arrays, try `feval`.

Input Arguments

`mdl`

Generalized linear model, as constructed by `fitglm` or `stepwiseglm`.

`Xnew`

Points at which `mdl` predicts responses.

- If `Xnew` is a table or dataset array, it must contain the predictor names in `mdl`.
- If `Xnew` is a numeric matrix, it must have the same number of variables (columns) as was used to create `mdl`. Furthermore, all variables used in creating `mdl` must be numeric.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'alpha'`

Positive scalar from `0` to `1`. Confidence level of `yci` is 100(1 – `alpha`)%.

Default: `0.05`, meaning a 95% confidence interval.

`'BinomialSize'`

Value of the binomial *n* parameter for each row in the training data. `BinomialSize` can be a vector the same length as `Xnew`, or a scalar that applies to each row. The default value `1` produces `ypred` values that are predicted proportions. Use `BinomialSize` only if `mdl` is fit to a binomial distribution.

Default: `1`

`'Offset'`

Value of the offset for each row in `Xnew`. `Offset` can be a vector the same length as `Xnew`, or a scalar that applies to each row. The offset is used as an additional predictor with a coefficient value fixed at `1`. In other words, if `b` is the fitted coefficient vector, and `link` is the link function,
`link(ypred) = Offset + Xnew * b`.

Default: `zeros(size(Xnew,1))`

`'Simultaneous'`

Logical value specifying whether the confidence bounds are for all predictor values simultaneously (`true`), or hold for each individual predictor value (`false`). Simultaneous bounds are wider than separate bounds, because it is more stringent to require that the entire curve be within the bounds than to require that the curve at a single predictor value be within the bounds.

For details, see `polyconf`.

Default: `false`

Output Arguments

`ypred`

Vector of predicted mean values at `Xnew`.

`yci`

Confidence intervals, a two-column matrix with each row providing one interval. The meaning of the confidence interval depends on the settings of the name-value pairs.

Examples

Generalized Linear Model Predictions

Create a generalized linear model, and predict its response to new data.

Generate artificial data for the model using Poisson random numbers with two underlying predictors `X(1)` and `X(2)`.

```
rng('default') % for reproducibility
rndvars = randn(100,2);
X = [2+rndvars(:,1),rndvars(:,2)];
mu = exp(1 + X*[1;2]);
y = poissrnd(mu);
```

Create a generalized linear regression model of Poisson data.

```
mdl = fitglm(X,y,'y ~ x1 + x2','distr','poisson');
```

Create points for prediction.

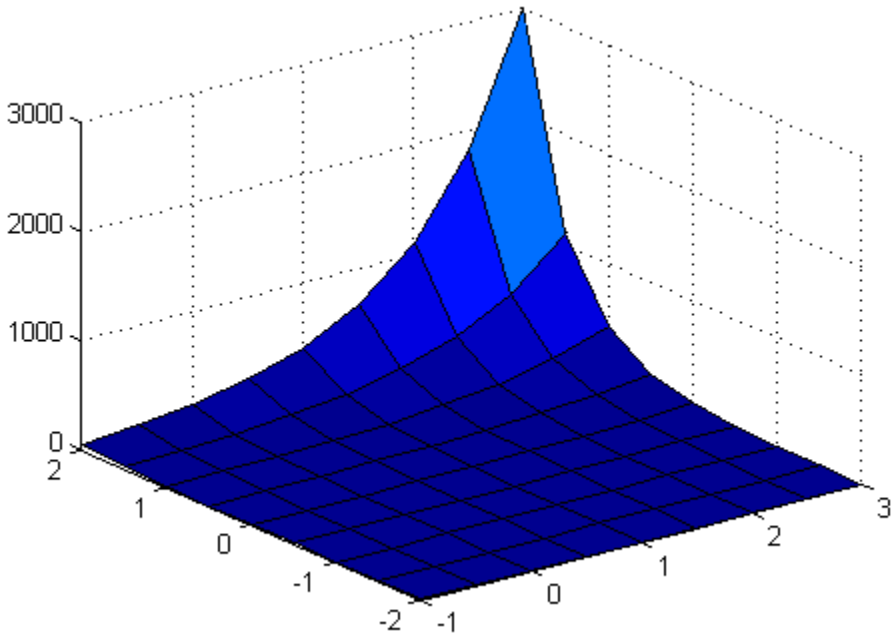
```
[Xtest1 Xtest2] = meshgrid(-1:.5:3,-2:.5:2);
Xnew = [Xtest1(:),Xtest2(:)];
```

Predict responses at the new points.

```
ypred = predict(mdl,Xnew);
```

Plot the predictions.

```
surf(Xtest1,Xtest2,reshape(ypred,9,9))
```



Create confidence intervals on the predictions.

```
[ypred yci] = predict(mdl,Xnew);
```

- “predict” on page 10-34

- “Generalized Linear Model Workflow” on page 10-39

Alternatives

`feval` gives the same predictions, but uses separate input arrays for each predictor, instead of one input array containing all predictors.

`random` predicts with added noise.

`GeneralizedLinearModel` | `random`

More About

- “Generalized Linear Models” on page 10-12

predict

Class: GeneralizedLinearMixedModel

Predict response of generalized linear mixed-effects model

Syntax

```
ypred = predict(glme)
ypred = predict(glme,tblnew)
ypred = predict( ___ ,Name,Value)
[ypred,ypredCI] = predict( ___ )
[ypred,ypredCI,DF] = predict( ___ )
```

Description

`ypred = predict(glme)` returns the predicted conditional means of the response, ypred, using the original predictor values used to fit the generalized linear mixed-effects model glme.

`ypred = predict(glme,tblnew)` returns the predicted conditional means using the new predictor values specified in tblnew.

If a grouping variable in `tblnew` has levels that are not in the original data, then the random effects for that grouping variable do not contribute to the `'Conditional'` prediction at observations where the grouping variable has new levels.

`ypred = predict( ___ ,Name,Value)` returns the predicted conditional means of the response using additional options specified by one or more `Name,Value` pair arguments. For example, you can specify the confidence level, simultaneous confidence bounds, or contributions from only fixed effects. You can use any of the input arguments in the previous syntaxes.

`[ypred,ypredCI] = predict( ___ )` also returns 95% point-wise confidence intervals, ypredCI, for each predicted value.

`[ypred,ypredCI,DF] = predict( ___ )` also returns the degrees of freedom, DF, used to compute the confidence intervals.

Input Arguments

`glme` — Generalized linear mixed-effects model

`GeneralizedLinearMixedModel` object

Generalized linear mixed-effects model, specified as a `GeneralizedLinearMixedModel` object. For properties and methods of this object, see `GeneralizedLinearMixedModel`.

`tblnew` — New input data

table | `dataset` array

New input data, which includes the response variable, predictor variables, and grouping variables, specified as a table or dataset array. The predictor variables can be continuous or grouping variables. tblnew must have the same variables as the original table or dataset array used in `fitglme` to fit the generalized linear mixed-effects model glme.

Data Types: `single` | `double` | `logical` | `char`

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'Alpha'` — Confidence level

0.05 (default) | scalar value in the range [0,1]

Confidence level, specified as the comma-separated pair consisting of `'Alpha'` and a scalar value in the range [0,1]. For a value α, the confidence level is 100 × (1 – α)%.

For example, for 99% confidence intervals, you can specify the confidence level as follows.

Example: `'Alpha',0.01`

Data Types: `single` | `double`

`'Conditional'` — Indicator for conditional predictions

`true` (default) | `false`

Indicator for conditional predictions, specified as the comma-separated pair consisting of `'Conditional'` and one of the following.

`true`	Contributions from both fixed effects and random effects (conditional)
`false`	Contribution from only fixed effects (marginal)

Example: `'Conditional',false`

`'DFMethod'` — Method for computing approximate degrees of freedom

`'residual'` (default) | `'none'`

Method for computing approximate degrees of freedom, specified as the comma-separated pair consisting of `'DFMethod'` and one of the following.

`'residual'`	The degrees of freedom are assumed to be constant and equal to $n - p$, where n is the number of observations and p is the number of fixed effects.
`'none'`	All degrees of freedom are set to infinity.

Example: `'DFMethod','none'`

`'Offset'` — Model offset

`zeros(m,1)` (default) | m-by-1 vector of scalar values

Model offset, specified as a vector of scalar values of length m, where m is the number of rows in tblnew. The offset is used as an additional predictor and has a coefficient value fixed at `1`.

`'Simultaneous'` — Type of confidence bounds

`false` (default) | `true`

Type of confidence bounds, specified as the comma-separated pair consisting of `'Simultaneous'` and either `false` or `true`.

- If `'Simultaneous'` is `false`, then `predict` computes nonsimultaneous confidence bounds.
- If `'Simultaneous'` is `true`, `predict` returns simultaneous confidence bounds.

Example: `'Simultaneous',true`

Output Arguments

`ypred` — Predicted responses

vector

Predicted responses, returned as a vector. If the 'Conditional' name-value pair argument is specified as `true`, ypred contains predictions for the conditional means of the responses given the random effects. Conditional predictions include contributions from both fixed and random effects. Marginal predictions include only contributions from fixed effects.

To compute marginal predictions, `predict` computes conditional predictions, but substitutes a vector of zeros in place of the empirical Bayes predictors (EBPs) of the random effects.

`ypredCI` — Point-wise confidence intervals

two-column matrix

Point-wise confidence intervals for the predicted values, returned as a two-column matrix. The first column of ypredCI contains the lower bound, and the second column contains the upper bound. By default, ypredCI contains the 95% nonsimultaneous confidence intervals for the predictions. You can change the confidence level using the Alpha name-value pair argument, and make them simultaneous using the Simultaneous name-value pair argument.

When fitting a GLME model using `fitglme` and one of the maximum likelihood fit methods (`'Laplace'` or `'ApproximateLaplace'`), `predict` computes the confidence intervals using the conditional mean squared error of prediction (CMSEP) approach conditional on the estimated covariance parameters and the observed response. Alternatively, you can interpret the confidence intervals as approximate Bayesian credible intervals conditional on the estimated covariance parameters and the observed response.

When fitting a GLME model using `fitglme` and one of the pseudo likelihood fit methods (`'MPL'` or `'REMPL'`), `predict` bases the computations on the fitted linear mixed-effects model from the final pseudo likelihood iteration.

`DF` — Degrees of freedom

vector | scalar value

Degrees of freedom used in computing the confidence intervals, returned as a vector or a scalar value.

- If 'Simultaneous' is `false`, then `DF` is a vector.
- If 'Simultaneous' is `true`, then `DF` is a scalar value.

Examples

Predict Responses at Original Design Values

Navigate to the folder containing the sample data. Load the sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')

load mfr
```

This simulated data is from a manufacturing company that operates 50 factories across the world, with each factory running a batch process to create a finished product. The company wants to decrease the number of defects in each batch, so it developed a new manufacturing process. To test the effectiveness of the new process, the company selected 20 of its factories at random to participate in an experiment: Ten factories implemented the new process, while the other ten continued to run the old process. In each of the 20 factories, the company ran five batches (for a total of 100 batches) and recorded the following data:

- Flag to indicate whether the batch used the new process (`newprocess`)
- Processing time for each batch, in hours (`time`)
- Temperature of the batch, in degrees Celsius (`temp`)
- Categorical variable indicating the supplier (`A`, `B`, or `C`) of the chemical used in the batch (`supplier`)
- Number of defects in the batch (`defects`)

The data also includes `time_dev` and `temp_dev`, which represent the absolute deviation of time and temperature, respectively, from the process standard of 3 hours at 20 degrees Celsius.

Fit a generalized linear mixed-effects model using `newprocess`, `time_dev`, `temp_dev`, and `supplier` as fixed-effects predictors. Include a random-effects term for intercept grouped by `factory`, to account for quality differences that might exist due to factory-specific variations. The response variable `defects` has a Poisson distribution, and the

appropriate link function for this model is log. Use the Laplace fit method to estimate the coefficients. Specify the dummy variable encoding as `'effects'`, so the dummy variable coefficients sum to 0.

The number of defects can be modeled using a Poisson distribution

$$defects_{ij} \sim Poisson\left(\mu_{ij}\right)$$

This corresponds to the generalized linear mixed-effects model

$$\log\left(\mu_{ij}\right) = \beta_0 + \beta_1 newprocess_{ij} + \beta_2 time\_dev_{ij} + \beta_3 temp\_dev_{ij} + \beta_4 supplier\_C_{ij} + \beta_5 supplier\_B_{ij} +$$

where

- $defects_{ij}$ is the number of defects observed in the batch produced by factory i during batch j.
- μ_{ij} is the mean number of defects corresponding to factory i (where i = 1, 2, ..., 20) during batch j (where j = 1, 2, ..., 5).
- $newprocess_{ij}$, $time\_dev_{ij}$, and $temp\_dev_{ij}$ are the measurements for each variable that correspond to factory i during batch j. For example, $newprocess_{ij}$ indicates whether the batch produced by factory i during batch j used the new process.
- $supplier\_C_{ij}$ and $supplier\_B_{ij}$ are dummy variables that use effects (sum-to-zero) coding to indicate whether company `C` or `B`, respectively, supplied the process chemicals for the batch produced by factory i during batch j.
- $b_i \sim N(0,\sigma_b^2)$ is a random-effects intercept for each factory i that accounts for factory-specific variation in quality.

```
glme = fitglme(mfr,'defects ~ 1 + newprocess + time_dev + temp_dev + supplier + (1|fact
```

Predict the response values at the original design values. Display the first ten predictions along with the observed response values.

```
ypred = predict(glme);
[ypred(1:10),mfr.defects(1:10)]
```

```
ans =

    4.9883    6.0000
```

```
    5.9423    7.0000
    5.1318    6.0000
    5.6295    5.0000
    5.3499    6.0000
    5.2134    5.0000
    4.6430    4.0000
    4.5342    4.0000
    5.3903    9.0000
    4.6529    4.0000
```

Column 1 contains the predicted response values at the original design values. Column 2 contains the observed response values.

Predict Responses at Values in New Table

Navigate to the folder containing the sample data. Load the sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')

load mfr
```

This simulated data is from a manufacturing company that operates 50 factories across the world, with each factory running a batch process to create a finished product. `GeneralizedLinearMixedModel` | `fitglme` | `fitted` | `random`

predict

Class: LinearModel

Predict response of linear regression model

Syntax

```
ypred = predict(mdl,Xnew)
[ypred,yci] = predict(mdl,Xnew)
[ypred,yci] = predict(mdl,Xnew,Name,Value)
```

Description

`ypred = predict(mdl,Xnew)` returns the predicted response of the `mdl` linear regression model to the points in `Xnew`.

`[ypred,yci] = predict(mdl,Xnew)` returns confidence intervals for the true mean responses.

`[ypred,yci] = predict(mdl,Xnew,Name,Value)` predicts responses with additional options specified by one or more Name,Value pair arguments.

Tips

- For predictions with added noise, use `random`.

Input Arguments

`mdl`

Linear model, as constructed by `fitlm` or `stepwiselm`.

`Xnew`

Points at which `mdl` predicts responses.

- If `Xnew` is a table or dataset array, it must contain the predictor names in `mdl`.
- If `Xnew` is a numeric matrix, it must have the same number of variables (columns) as was used to create `mdl`. Furthermore, all variables used in creating `mdl` must be numeric.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'alpha'`

Positive scalar from `0` to `1`. Confidence level of `yci` is 100(1 – `alpha`)%.

Default: `0.05`, meaning a 95% confidence interval.

`'Prediction'`

String specifying the type of prediction:

- `'curve'` — `predict` predicts confidence bounds for the fitted mean values.
- `'observation'` — `predict` predicts confidence bounds for the new observations. This results in wider bounds because the error in a new observation is equal to the error in the estimated mean value, plus the variability in the observation from the true mean.

For details, see `polyconf`.

Default: `'curve'`

`'Simultaneous'`

Logical value specifying whether the confidence bounds are for all predictor values simultaneously (`true`), or hold for each individual predictor value (`false`). Simultaneous bounds are wider than separate bounds, because it is more stringent to require that the entire curve be within the bounds than to require that the curve at a single predictor value be within the bounds.

For details, see `polyconf`.

Default: `false`

Output Arguments

`ypred`

Vector of predicted mean values at `Xnew`.

`yci`

Confidence intervals, a two-column matrix with each row providing one interval. The meaning of the confidence interval depends on the settings of the name-value pairs.

Examples

Predict Response to Data

Create a model of car mileage as a function of weight, and predict the response.

Create a quadratic model of car mileage as a function of weight from the `carsmall` data.

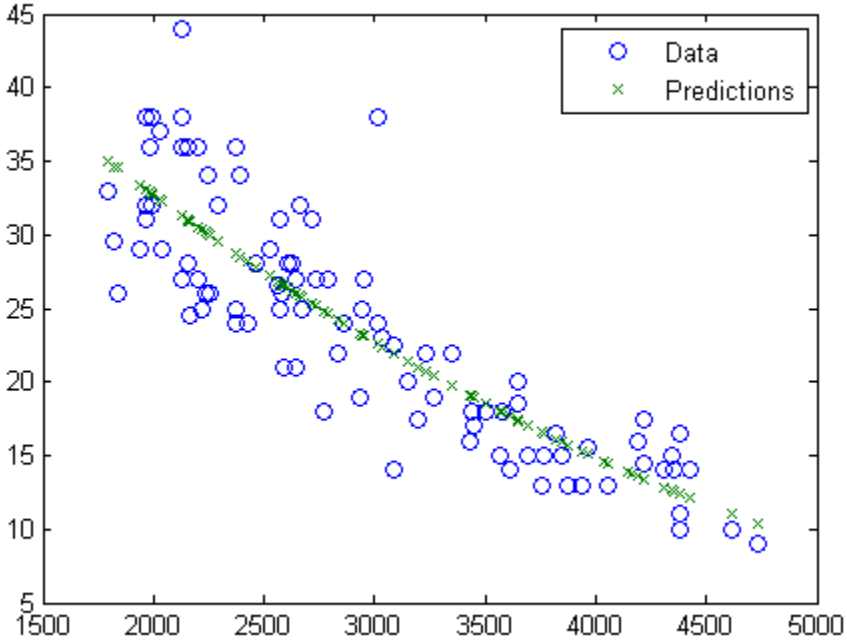
```
load carsmall
X = Weight;
y = MPG;
mdl = fitlm(X,y,'quadratic');
```

Create predicted responses to the data.

```
Xnew = X;
ypred = predict(mdl,Xnew);
```

Plot the original responses and the predicted responses to see how they differ.

```
plot(X,y,'o',Xnew,ypred,'x')
legend('Data','Predictions')
```



- “predict” on page 9-37
- “Linear Regression Workflow” on page 9-41

Alternatives

`feval` gives the same predictions, but uses multiple input arrays with one component in each input argument. `feval` can be simpler to use with a model created from a table or dataset array `tbl`. `feval` does not give confidence intervals on its predictions.

`random` predicts with added noise.

`random` | `stepwiselm` | `feval` | `LinearModel` | `fitlm`

How To

- “Linear Regression” on page 9-11

predict

Class: LinearMixedModel

Predict response of linear mixed-effects model

Syntax

```
ypred = predict(lme)
ypred = predict(lme,tblnew)
ypred = predict(lme,Xnew,Znew)
ypred = predict(lme,Xnew,Znew,Gnew)
ypred = predict(___,Name,Value)
[ypred,ypredCI] = predict(___)
[ypred,ypredCI,DF] = predict(___)
```

Description

`ypred = predict(lme)` returns a vector of conditional predicted responses `ypred` at the original predictors used to fit the linear mixed-effects model `lme`.

`ypred = predict(lme,tblnew)` returns a vector of conditional predicted responses `ypred` from the fitted linear mixed-effects model `lme` at the values in the new table or dataset array `tblnew`. Use a table or dataset array for `predict` if you use a table or dataset array for fitting the model lme.

If a particular grouping variable in `tblnew` has levels that are not in the original data, then the random effects for that grouping variable do not contribute to the `'Conditional'` prediction at observations where the grouping variable has new levels.

`ypred = predict(lme,Xnew,Znew)` returns a vector of conditional predicted responses `ypred` from the fitted linear mixed-effects model `lme` at the values in the new fixed- and random-effects design matrices, `Xnew` and `Znew`, respectively. `Znew` can also be a cell array of matrices. In this case, the grouping variable G is `ones(n,1)`, where n is the number of observations used in the fit.

Use the matrix format for `predict` if using design matrices for fitting the model `lme`.

`ypred = predict(lme,Xnew,Znew,Gnew)` returns a vector of conditional predicted responses `ypred` from the fitted linear mixed-effects model `lme` at the values in the new fixed- and random-effects design matrices, `Xnew` and `Znew`, respectively, and the grouping variable `Gnew`.

`Znew` and `Gnew` can also be cell arrays of matrices and grouping variables, respectively.

`ypred = predict( ___ ,Name,Value)` returns a vector of predicted responses `ypred` from the fitted linear mixed-effects model `lme` with additional options specified by one or more Name,Value pair arguments.

For example, you can specify the confidence level, simultaneous confidence bounds, or contributions from only fixed effects.

`[ypred,ypredCI] = predict( ___ )` also returns confidence intervals `ypredCI` for the predictions `ypred` for any of the input arguments in the previous syntaxes.

`[ypred,ypredCI,DF] = predict( ___ )` also returns the degrees of freedom `DF` used in computing the confidence intervals for any of the input arguments in the previous syntaxes.

Input Arguments

`lme` — Linear mixed-effects model

`LinearMixedModel` object

Linear mixed-effects model, returned as a `LinearMixedModel` object.

For properties and methods of this object, see `LinearMixedModel`.

`tblnew` — New input data

table | `dataset` array

New input data, which includes the response variable, predictor variables, and grouping variables, specified as a table or dataset array. The predictor variables can be continuous or grouping variables. `tblnew` must have the same variables as in the original table or dataset array used to fit the linear mixed-effects model `lme`.

Data Types: `single` | `double` | `logical` | `char`

`Xnew` — New fixed-effects design matrix

n-by-*p* matrix

New fixed-effects design matrix, specified as an *n*-by-*p* matrix, where *n* is the number of observations and *p* is the number of fixed predictor variables. Each row of `X` corresponds to one observation and each column of `X` corresponds to one variable.

Data Types: `single` | `double`

`Znew` — New random-effects design

n-by-*q* matrix | cell array of length *R*

New random-effects design, specified as an *n*-by-*q* matrix or a cell array of *R* design matrices `Z{r}`, where *r* = 1, 2, ..., *R*. If `Znew` is a cell array, then each `Z{r}` is an *n*-by-*q*(*r*) matrix, where *n* is the number of observations, and *q*(*r*) is the number of random predictor variables.

Data Types: `single` | `double` | `logical` | `char` | `cell`

`Gnew` — New grouping variable or variables

vector | cell array of grouping variables of length *R*

New grouping variable or variables, specified as a vector or a cell array, of length *R*, of grouping variables with the same levels or groups as the original grouping variables used to fit the linear mixed-effects model lme.

Data Types: `single` | `double` | `logical` | `char` | `cell`

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'Alpha'` — Confidence level

0.05 (default) | scalar value in the range 0 to 1

Confidence level, specified as the comma-separated pair consisting of `'Alpha'` and a scalar value in the range 0 to 1. For a value α, the confidence level is 100*(1–α)%.

For example, for 99% confidence intervals, you can specify the confidence level as follows.

Example: `'Alpha',0.01`

Data Types: `single` | `double`

`'Conditional'` — Indicator for conditional predictions

True (default) | False

Indicator for conditional predictions, specified as the comma-separated pair consisting of `'Conditional'` and one of the following.

`True`	Contributions from both fixed effects and random effects (conditional)
`False`	Contribution from only fixed effects (marginal)

Example: `'Conditional','False'`

`'DFMethod'` — Method for computing approximate degrees of freedom

`'Residual'` (default) | `'Satterthwaite'` | `'None'`

Method for computing approximate degrees of freedom to use in the confidence interval computation, specified as the comma-separated pair consisting of `'DFMethod'` and one of the following.

`'Residual'`	Default. The degrees of freedom are assumed to be constant and equal to $n - p$, where n is the number of observations and p is the number of fixed effects.
`'Satterthwaite'`	Satterthwaite approximation.
`'None'`	All degrees of freedom are set to infinity.

For example, you can specify the Satterthwaite approximation as follows.

Example: `'DFMethod','Satterthwaite'`

`'Simultaneous'` — Type of confidence bounds

`false` (default) | `true`

Type of confidence bounds, specified as the comma-separated pair consisting of `'Simultaneous'` and one of the following.

`false`	Default. Nonsimultaneous bounds.
`true`	Simultaneous bounds.

Example: `'Simultaneous',true`

`'Prediction'` — Type of prediction
`'curve'` (default) | `'observation'`

Type of prediction, specified as the comma-separated pair consisting of `'Prediction'` and one of the following.

`'curve'`	Default. Confidence bounds for the predictions based on the fitted function.
`'observation'`	Variability due to observation error for the new observations is also included in the confidence bound calculations and this results in wider bounds.

Example: `'Prediction','observation'`

Output Arguments

`ypred` — Predicted responses
vector

Predicted responses, returned as a vector. `ypred` can contain the conditional or marginal responses, depending on the value choice of the 'Conditional' name-value pair argument. Conditional predictions include contributions from both fixed and random effects.

`ypredCI` — Point-wise confidence intervals
two-column matrix

Point-wise confidence intervals for the predicted values, returned as a two-column matrix. The first column of `yCI` contains the lower bounds, and the second column contains the upper bound. By default, `yCI` contains the 95% confidence intervals for the predictions. You can change the confidence level using the Alpha name-value pair

argument, make them simultaneous using the Simultaneous name-value pair argument, and also make them for a new observation rather than for the curve using the Prediction name-value pair argument.

`DF` — Degrees of freedom

vector | scalar value

Degrees of freedom used in computing the confidence intervals, returned as a vector or a scalar value.

- If the 'Simultaneous' name-value pair argument is `false`, then `DF` is a vector.
- If the 'Simultaneous' name-value pair argument is `true`, then `DF` is a scalar value.

Examples

Predict Responses at the Original Design Values

Navigate to a folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load fertilizer
```

The dataset array includes data from a split-plot experiment, where soil is divided into three blocks based on the soil type: sandy, silty, and loamy. Each block is divided into five plots, where five different types of tomato plants (cherry, heirloom, grape, vine, and plum) are randomly assigned to these plots. The tomato plants in the plots are then divided into subplots, where each subplot is treated by one of four fertilizers. This is simulated data.

Store the data in a dataset array called `ds`, for practical purposes, and define `Tomato`, `Soil`, and `Fertilizer` as categorical variables.

```
ds = fertilizer;
ds.Tomato = nominal(ds.Tomato);
ds.Soil = nominal(ds.Soil);
ds.Fertilizer = nominal(ds.Fertilizer);
```

Fit a linear mixed-effects model, where `Fertilizer` and `Tomato` are the fixed-effects variables, and the mean yield varies by the block (soil type), and the plots within blocks (tomato types within soil types) independently.

```
lme = fitlme(ds,'Yield ~ Fertilizer * Tomato + (1|Soil) + (1|Soil:Tomato)');
```

Predict the response values at the original design values. Display the first five predictions with the observed response values.

```
yhat = predict(lme);
[yhat(1:5) ds.Yield(1:5)]
```

```
ans =

  115.4788  104.0000
  135.1455  136.0000
  152.8121  158.0000
  160.4788  174.0000
   58.0839   57.0000
```

Plot Predictions vs. Observed Responses

Load the sample data.

```
load carsmall
```

Fit a linear mixed-effects model, with a fixed effect for `Weight`, and a random intercept grouped by `Model_Year`. First, store the data in a table.

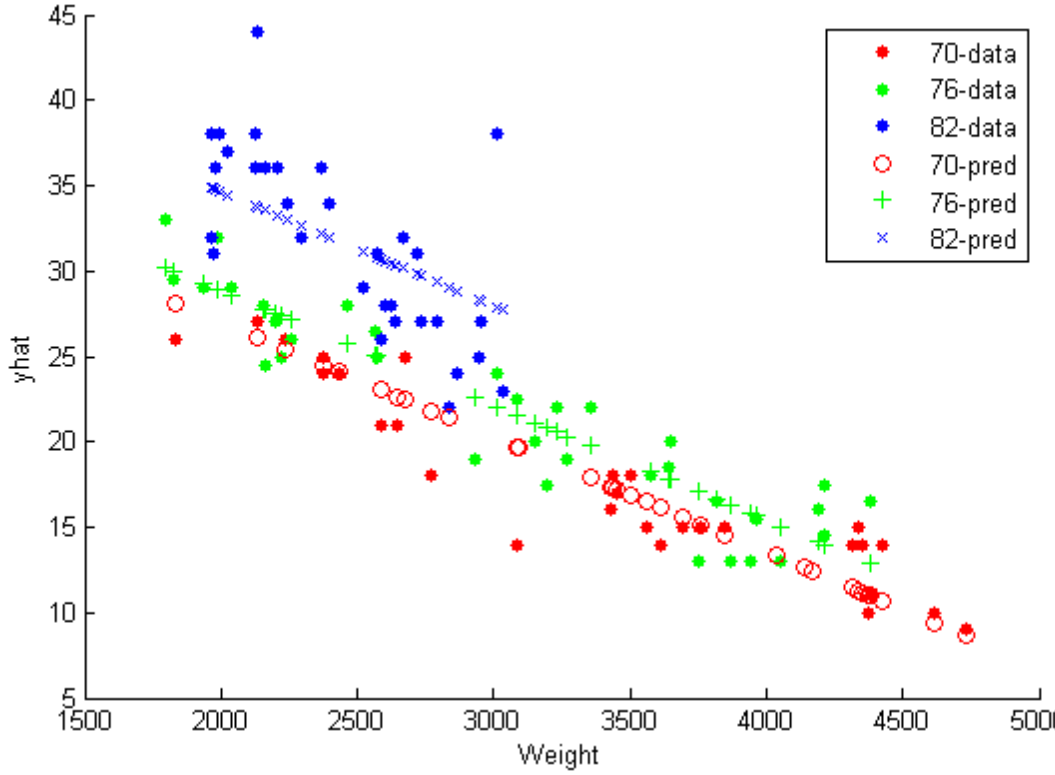
```
tbl = table(MPG,Weight,Model_Year);
lme = fitlme(tbl,'MPG ~ Weight + (1|Model_Year)');
```

Create predicted responses to the data.

```
yhat = predict(lme,tbl);
```

Plot the original responses and the predicted responses to see how they differ. Group them by model year.

```
figure()
gscatter(Weight,MPG,Model_Year)
hold on
gscatter(Weight,yhat,Model_Year,[],'o+x')
legend('70-data','76-data','82-data','70-pred','76-pred','82-pred')
hold off
```



Predict Responses at Values in a New Dataset Array

Navigate to a folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load fertilizer
```

The dataset array includes data from a split-plot experiment, where soil is divided into three blocks based on the soil type: sandy, silty, and loamy. Each block is divided into five plots, where five different types of tomato plants (cherry, heirloom, grape, vine, and

plum) are randomly assigned to these plots. The tomato plants in the plots are then divided into subplots, where each subplot is treated by one of four fertilizers. This is simulated data.

Store the data in a dataset array called `ds`, for practical purposes, and define `Tomato`, `Soil`, and `Fertilizer` as categorical variables.

```
ds = fertilizer;
ds.Tomato = nominal(ds.Tomato);
ds.Soil = nominal(ds.Soil);
ds.Fertilizer = nominal(ds.Fertilizer);
```

Fit a linear mixed-effects model, where `Fertilizer` and `Tomato` are the fixed-effects variables, and the mean yield varies by the block (soil type), and the plots within blocks (tomato types within soil types) independently.

```
lme = fitlme(ds,'Yield ~ Fertilizer * Tomato + (1|Soil) + (1|Soil:Tomato)');
```

Create a new dataset array with design values. The new dataset array must have the same variables as the original dataset array you use for fitting the model `lme`.

```
dsnew = dataset();
dsnew.Soil = nominal({'Sandy';'Silty'});
dsnew.Tomato = nominal({'Cherry';'Vine'});
dsnew. Fertilizer = nominal([2;2]);
```

Predict the conditional and marginal responses at the original design points.

```
yhatC = predict(lme,dsnew);
yhatM = predict(lme,dsnew,'Conditional',false);
[yhatC yhatM]
```

```
ans =

   92.7505  111.6667
   87.5891   82.6667
```

Predict Responses at the Values in New Design Matrices

Load the sample data.

```
load carbig
```

Fit a linear mixed-effects model for miles per gallon (MPG), with fixed effects for acceleration, horsepower, and cylinders, and potentially correlated random effects for intercept and acceleration grouped by model year.

First, prepare the design matrices for fitting the linear mixed-effects model.

```
X = [ones(406,1) Acceleration Horsepower];
Z = [ones(406,1) Acceleration];
Model_Year = nominal(Model_Year);
G = Model_Year;
```

Now, fit the model using `fitlmematrix` with the defined design matrices and grouping variables.

```
lme = fitlmematrix(X,MPG,Z,G,'FixedEffectPredictors',....
{'Intercept','Acceleration','Horsepower'},'RandomEffectPredictors',...
{{'Intercept','Acceleration'}},'RandomEffectGroups',{'Model_Year'});
```

Create the design matrices that contain the data at which to predict the response values. `Xnew` must have three columns as in `X`. The first column must be a column of 1s. And the values in the last two columns must correspond to `Acceleration` and `Horsepower`, respectively. The first column of `Znew` must be a column of 1s, and the second column must contain the same `Acceleration` values as in `Xnew`. The original grouping variable in `G` is the model year. So, `Gnew` must contain values for the model year. Note that `Gnew` must contain nominal values.

```
Xnew = [1,13.5,185; 1,17,205; 1,21.2,193];
Znew = [1,13.5; 1,17; 1,21.2]; % alternatively Znew = Xnew(:,1:2);
Gnew = nominal([73 77 82]);
```

Predict the responses for the data in the new design matrices.

```
yhat = predict(lme,Xnew,Znew,Gnew)
```

```
yhat =

    8.7063
    5.4423
   12.5384
```

Now, repeat the same for a linear mixed-effects model with uncorrelated random-effects terms for intercept and acceleration. First, change the original random effects design and the random effects grouping variables. Then, refit the model.

```
Z = {ones(406,1),Acceleration};
G = {Model_Year,Model_Year};

lme = fitlmematrix(X,MPG,Z,G,'FixedEffectPredictors',....
{'Intercept','Acceleration','Horsepower'},'RandomEffectPredictors',...
```

```
{{'Intercept'},{'Acceleration'}},'RandomEffectGroups',{'Model_Year','Model_Year'})
```

Now, recreate the new random effects design, `Znew`, and the grouping variable design, `Gnew`, using which to predict the response values.

```
Znew = {[1;1;1],[13.5;17;21.2]};
MY = nominal([73 77 82]);
Gnew = {MY,MY};
```

Predict the responses using the new design matrices.

```
yhat = predict(lme,Xnew,Znew,Gnew)
```

```
yhat =

    8.6365
    5.9199
   12.1247
```

Compute Confidence Intervals for Predictions

Load the sample data.

```
load carbig
```

Fit a linear mixed-effects model for miles per gallon (MPG), with fixed effects for acceleration, horsepower, and cylinders, and potentially correlated random effects for intercept and acceleration grouped by model year. First, store the variables in a table.

```
tbl = table(MPG,Acceleration,Horsepower,Model_Year);
```

Now, fit the model using `fitlme` with the defined design matrices and grouping variables.

```
lme = fitlme(tbl,'MPG ~ Acceleration + Horsepower + (Acceleration|Model_Year)');
```

Create the new data and store it in a new table.

```
tblnew = table();
tblnew.Acceleration = linspace(8,25)';
tblnew.Horsepower = linspace(nanmin(Horsepower),nanmax(Horsepower))';
tblnew.Model_Year = repmat(70,100,1);
```

`linspace` creates 100 equally distanced values between the lower and the upper input limits. `Model_Year` is fixed at 70. You can repeat this for any model year.

Compute and plot the predicted values and 95% confidence limits (nonsimultaneous).

```
[ypred,yCI,DF] = predict(lme,tblnew);
figure();
h1 = line(tblnew.Acceleration,ypred);
hold on;
h2 = plot(tblnew.Acceleration,yCI,'g-.');
```

Display the degrees of freedom.

```
DF(1)
```

```
ans =

   389
```

Compute and plot the simultaneous confidence bounds.

```
[ypred,yCI,DF] = predict(lme,tblnew,'Simultaneous',true);
h3 = plot(tblnew.Acceleration,yCI,'r--');
```

Display the degrees of freedom.

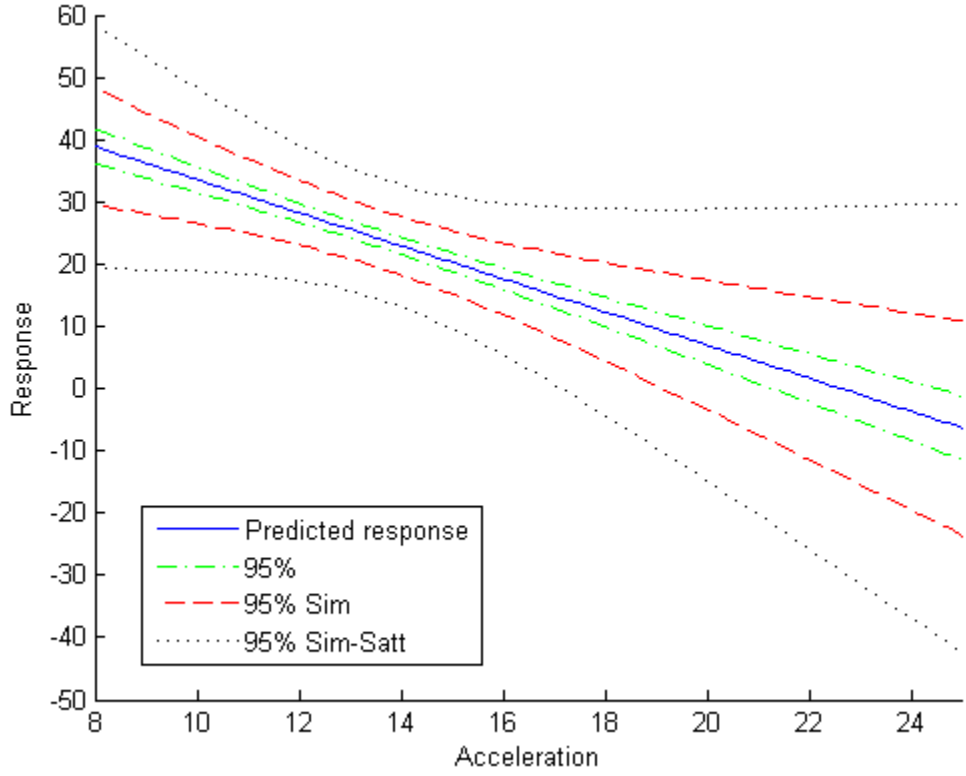
```
DF
```

```
DF =

   389
```

Compute the simultaneous confidence bounds using the Satterthwaite method to compute the degrees of freedom.

```
[ypred,yCI,DF] = predict(lme,tblnew,'Simultaneous',true,'DFMethod','Satterthwaite');
h4 = plot(tblnew.Acceleration,yCI,'k:');
hold off
xlabel('Acceleration')
ylabel('Response')
ylim([-50,60])
xlim([8,25])
legend([h1,h2(1),h3(1),h4(1)],'Predicted response','95%','95% Sim',...
'95% Sim-Satt','Location','Best')
```



Display the degrees of freedom.

```
DF
```

```
DF =
```

```
3.6001
```

Definitions

Conditional and Marginal Predictions

A conditional prediction includes contributions from both fixed and random effects, whereas a marginal model includes contribution from only fixed effects.

Suppose the linear mixed-effects model `lme` has an n-by-p fixed-effects design matrix `X` and an n-by-q random-effects design matrix `Z`. Also, suppose the estimated p-by-1 fixed-effects vector is $\hat{\beta}$, and the q-by-1 estimated best linear unbiased predictor (BLUP) vector of random effects is $\hat{b}$. The predicted conditional response is

$$\hat{y}_{Cond} = X\hat{\beta} + Z\hat{b},$$

which corresponds to the `'Conditional','true'` name-value pair argument.

The predicted marginal response is

$$\hat{y}_{Mar} = X\hat{\beta},$$

which corresponds to the `'Conditional','false'` name-value pair argument.

When making predictions, if a particular grouping variable has new levels (1s that were not in the original data), then the random effects for the grouping variable do not contribute to the `'Conditional'` prediction at observations where the grouping variable has new levels.

predict

Class: NaiveBayes

Predict class label for test data

Syntax

```
cpre = predict(nb,test)
cpre = predict(...,'HandleMissing',val)
```

Description

`cpre = predict(nb,test)` classifies each row of data in `test` into one of the classes according to the `NaiveBayes` classifier `nb`, and returns the predicted class level `cpre`. `test` is an `N`-by-`nb.ndims` matrix, where `N` is the number of observations in the test data. Rows of `test` correspond to points, columns of `test` correspond to features. `cpre` is an `N`-by-1 vector of the same type as `nb.CLevels`, and it indicates the class to which each row of `test` has been assigned.

`cpre = predict(...,'HandleMissing',val)` specifies how `predict` treats `NaN` (missing values). `val` can be one of the following:

`'off'` (default)	Observations with `NaN` in any of the columns are not classified into any class. The corresponding rows in `cpre` are `NaN` (if `obj.clevels` is numeric or logical), empty strings (if `obj.clevels` is char or cell array of strings) or `<undefined>` (if `obj.clevels` is categorical).
`'on'`	For observations having `NaN` in some (but not all) columns, `predict` computes `cpre` using the columns with non-`NaN` values. Corresponding `cpre` values are `NaN`.

predict

Class: NonLinearModel

Predict response of nonlinear regression model

Syntax

```
ypred = predict(mdl,Xnew)
[ypred,yci] = predict(mdl,Xnew)
[ypred,yci] = predict(mdl,Xnew,Name,Value)
```

Description

`ypred = predict(mdl,Xnew)` returns the predicted response of the `mdl` nonlinear regression model to the points in `Xnew`.

`[ypred,yci] = predict(mdl,Xnew)` returns confidence intervals for the true mean responses.

`[ypred,yci] = predict(mdl,Xnew,Name,Value)` predicts responses with additional options specified by one or more Name,Value pair arguments.

Tips

- For predictions with added noise, use `random`.
- For a syntax that can be easier to use with models created from tables or dataset arrays, try `feval`.

Input Arguments

`mdl`

Nonlinear regression model, constructed by `fitnlm`.

`Xnew`

Points at which `mdl` predicts responses.

- If `Xnew` is a table or dataset array, it must contain the predictor names in `mdl`.
- If `Xnew` is a numeric matrix, it must have the same number of variables (columns) as was used to create `mdl`. Furthermore, all variables used in creating `mdl` must be numeric.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'alpha'`

Positive scalar from `0` to `1`. Confidence level of `yci` is 100(1 – `alpha`)%.

Default: `0.05`, meaning a 95% confidence interval.

`'Prediction'`

String specifying the type of prediction:

- `'curve'` — `predict` predicts confidence bounds for the fitted mean values.
- `'observation'` — `predict` predicts confidence bounds for the new observations. This results in wider bounds because the error in a new observation is equal to the error in the estimated mean value, plus the variability in the observation from the true mean.

For details, see `polyconf`.

Default: `'curve'`

`'Simultaneous'`

Logical value specifying whether the confidence bounds are for all predictor values simultaneously (`true`), or hold for each individual predictor value (`false`). Simultaneous bounds are wider than separate bounds, because it is more stringent to require that the entire curve be within the bounds than to require that the curve at a single predictor value be within the bounds.

For details, see `polyconf`.

Default: `false`

`'Weights'`

Vector of real, positive value weights or a function handle.

- If you specify a vector, then it must have the same number of elements as the number of observations (or rows) in `Xnew`.
- If you specify a function handle, then the function must accept a vector of predicted response values as input, and return a vector of real positive weights as output.

Given weights, `W`, `predict` estimates the error variance at observation `i` by `MSE*(1/W(i))`, where MSE is the mean squared error.

Default: No weights

Output Arguments

`ypred`

Vector of predicted mean values at `Xnew`.

`yci`

Confidence intervals, a two-column matrix with each row providing one interval. The meaning of the confidence interval depends on the settings of the name-value pairs.

Examples

Predict Responses

Create a nonlinear model of car mileage as a function of weight, and predict the response.

Create an exponential model of car mileage as a function of weight from the `carsmall` data. Scale the weight by a factor of 1000 so all the variables are roughly equal in size.

```
load carsmall
X = Weight;
```

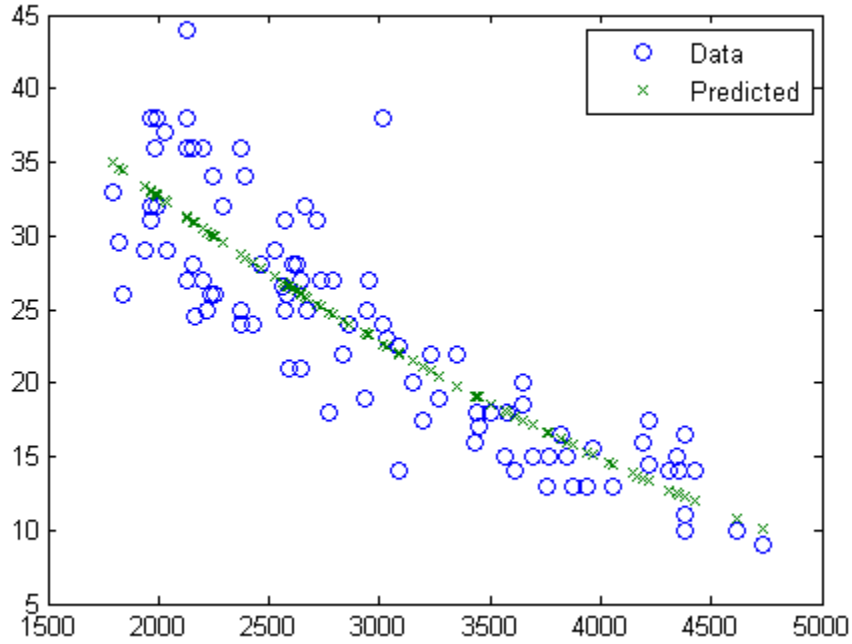
```
y = MPG;
modelfun = 'y ~ b1 + b2*exp(-b3*x/1000)';
beta0 = [1 1 1];
mdl = fitnlm(X,y,modelfun,beta0);
```

Create predicted responses to the data.

```
Xnew = X;
ypred = predict(mdl,Xnew);
```

Plot the original responses and the predicted responses to see how they differ.

```
plot(X,y,'o',X,ypred,'x')
legend('Data','Predicted')
```



Confidence Intervals for Predictions

Create a nonlinear model of car mileage as a function of weight, and examine confidence intervals of some responses.

Create an exponential model of car mileage as a function of weight from the `carsmall` data. Scale the weight by a factor of 1000 so all the variables are roughly equal in size.

```
load carsmall
X = Weight;
y = MPG;
modelfun = 'y ~ b1 + b2*exp(-b3*x/1000)';
beta0 = [1 1 1];
mdl = fitnlm(X,y,modelfun,beta0);
```

Create predicted responses to the smallest, mean, and largest data points.

```
Xnew = [min(X);mean(X);max(X)];
[ypred,yci] = predict(mdl,Xnew)
```

```
ypred =
   34.9469
   22.6868
   10.0617

yci =
   32.5212   37.3726
   21.4061   23.9674
    7.0148   13.1086
```

Simultaneous Confidence Intervals for Robust Fit Curve

Generate sample data from the nonlinear regression model

$$y = b_1 + b_2 \exp\{-b_3 x\} + \varepsilon,$$

where b_1, b_2, and b_3 are coefficients, and the error term is normally distributed with mean 0 and standard deviation 0.5.

```
modelfun = @(b,x)(b(1)+b(2)*exp(-b(3)*x));

rng('default') % for reproducibility
b = [1;3;2];
x = exprnd(2,100,1);
y = modelfun(b,x) + normrnd(0,0.5,100,1);
```

Fit the nonlinear model using robust fitting options.

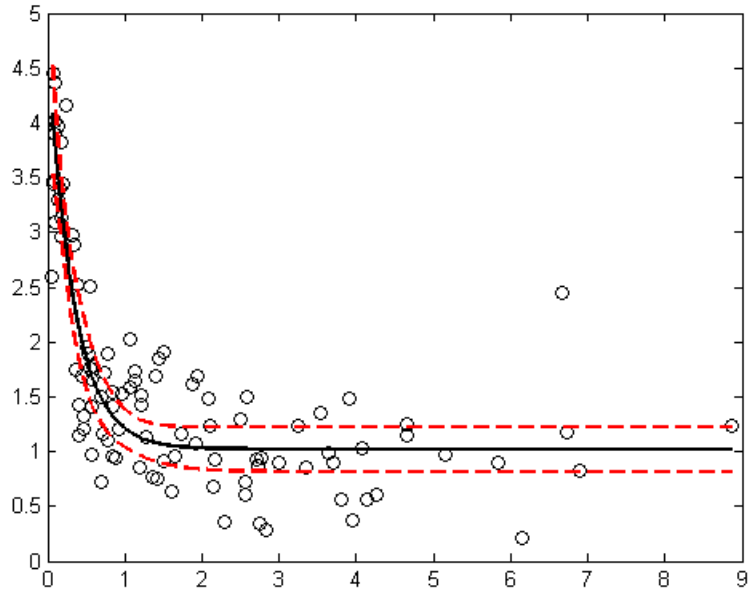
```
opts = statset('nlinfit');
opts.RobustWgtFun = 'bisquare';
```

```
b0 = [2;2;2];
mdl = fitnlm(x,y,modelfun,b0,'Options',opts);
```

Plot the fitted regression model and simultaneous 95% confidence bounds.

```
xrange = [min(x):.01:max(x)]';
[ypred,yci] = predict(mdl,xrange,'Simultaneous',true);

figure()
plot(x,y,'ko') % observed data
hold on
plot(xrange,ypred,'k','LineWidth',2)
plot(xrange,yci','r--','LineWidth',1.5)
```



Confidence Interval Using Observation Weights

Load sample data.

```
S = load('reaction');
X = S.reactants;
```

```
y = S.rate;
beta0 = S.beta;
```

Specify a function handle for observation weights, then fit the Hougen-Watson model to the rate data using the specified observation weights function.

```
a = 1; b = 1;
weights = @(yhat) 1./((a + b*abs(yhat)).^2);
mdl = fitnlm(X,y,@hougen,beta0,'Weights',weights);
```

Compute the 95% prediction interval for a new observation with reactant levels `[100,100,100]` using the observation weight function.

```
[ypred,yci] = predict(mdl,[100,100,100],'Prediction','observation',...
                      'Weights',weights)
```

```
ypred =

    1.8149

yci =

    1.5264    2.1033
```

predict

Class: RepeatedMeasuresModel

Compute predicted values given predictor values

Syntax

```
ypred = predict(rm,tnew)
ypred = predict(rm,tnew,Name,Value)
[ypred,yci] = predict( ___ )
```

Description

`ypred = predict(rm,tnew)` returns the predicted values from the repeated measures model rm using the predictor values from the table t.

`ypred = predict(rm,tnew,Name,Value)` returns the predicted values from the repeated measures model rm with additional options specified by one or more Name,Value pair arguments.

For example, you can specify the within-subjects design matrix.

`[ypred,yci] = predict( ___ )` also returns the 95% confidence interval for the predicted values.

Input Arguments

`rm` — Repeated measures model

`RepeatedMeasuresModel` object

Repeated measures model, returned as a `RepeatedMeasuresModel` object.

For properties and methods of this object, see `RepeatedMeasuresModel`.

`tnew` — New data

table used to create `rm` (default) | table

New data including the values of the response variables and the between-subject factors used as predictors in the repeated measures model, rm, specified as a table. `tnew` must contain all of the between-subject factors used to create rm.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'Alpha'` — Confidence level

0.05 (default) | scalar value in the range of 0 through 1

Confidence level of the confidence intervals for the predicted values, specified as the comma-separated pair consisting of `'alpha'` and a scalar value in the range of 0 to 1. The confidence level is 100*(1–`alpha`)%.

Example: `'alpha',0.01`

Data Types: `double` | `single`

`'WithinModel'` — Model for within-subject factors

`'separatemeans'` | `'orthogonalcontrats'` | text string

Model for the within-subject factors, specified as the comma-separated pair consisting of `'WithinModel'` and one of the following:

- `'separatemeans'` — Compute a separate mean for each group.
- `'orthogonalcontrasts'` — Valid when the within-subject design consists of a single numeric factor T. This specifies a model consisting of orthogonal polynomials up to order $T^{(r-1)}$, where r is the number of repeated measures.
- A string that defines a model specification in the within-subject factors.

Example: `'WithinModel','orthogonalcontrasts'`

`'WithinDesign'` — Design for within-subject factors

vector | matrix | table

Design for within-subject factors, specified as the comma-separated pair consisting of `'WithinDesign'` and a vector, matrix, or a table. It provides the values of the within-subject factors in the same form as the `RM.WithinDesign` property.

Example: `'WithinDesign','Time'`

Data Types: `single | double | table`

Output Arguments

`ypred` — Predicted values

n-by-*r* matrix

Predicted values from the repeated measures model `rm`, returned as an *n*-by-*r* matrix, where *n* is the number of rows in tnew and *r* is the number of repeated measures in rm.

`yci` — Confidence intervals for predicted values

n-by-*r*-by-2 matrix

Confidence intervals for predicted values from the repeated measures model `rm`, returned as an *n*-by-*r*-by-2 matrix.

These are nonsimultaneous intervals for predicting the mean response at the specified predictor values. For predicted value `ypred(i,j)`, the lower limit of the interval is `yci(i,j,1)` and the upper limit is `yci(i,j,2)`.

Examples

Predict Response Values

Load the sample data.

```
load fisheriris
```

The column vector,`species`consists of iris flowers of three different species: setosa, versicolor, and virginica. The double matrix `meas` consists of four types of measurements on the flowers: the length and width of sepals and petals in centimeters, respectively.

Store the data in a table array.

```
t = table(species,meas(:,1),meas(:,2),meas(:,3),meas(:,4),...
'VariableNames',{'species','meas1','meas2','meas3','meas4'});
Meas = dataset([1 2 3 4]','VarNames',{'Measurements'});
```

Fit a repeated measures model, where the measurements are the responses and the `species` is the predictor variable.

```
rm = fitrm(t,'meas1-meas4~species','WithinDesign',Meas);
```

Predict responses for the three species.

```
Y = predict(rm,t([1 51 101],:))
```

```
Y =

    5.0060    3.4280    1.4620    0.2460
    5.9360    2.7700    4.2600    1.3260
    6.5880    2.9740    5.5520    2.0260
```

Predict Response Values and Plot Predictions

Navigate to the folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load('longitudinalData')
```

The matrix Y contains response data for 16 individuals. The response is the blood level of a drug measured at five time points (time = 0, 2, 4, 6, and 8). Each row of Y corresponds to an individual, and each column corresponds to a time point. The first eight subjects are female, and the second eight subjects are male. This is simulated data.

Define a variable that stores gender information.

```
Gender = ['F' 'F' 'F' 'F' 'F' 'F' 'F' 'F' 'M' 'M' 'M' 'M' 'M' 'M' 'M' 'M']';
```

Store the data in a proper table array format to perform repeated measures analysis.

```
t = table(Gender,Y(:,1),Y(:,2),Y(:,3),Y(:,4),Y(:,5),...
'VariableNames',{'Gender','t0','t2','t4','t6','t8'});
```

Define the within-subjects variable.

```
Time = [0 2 4 6 8]';
```

Fit a repeated measures model, where the blood levels are the responses and gender is the predictor variable.

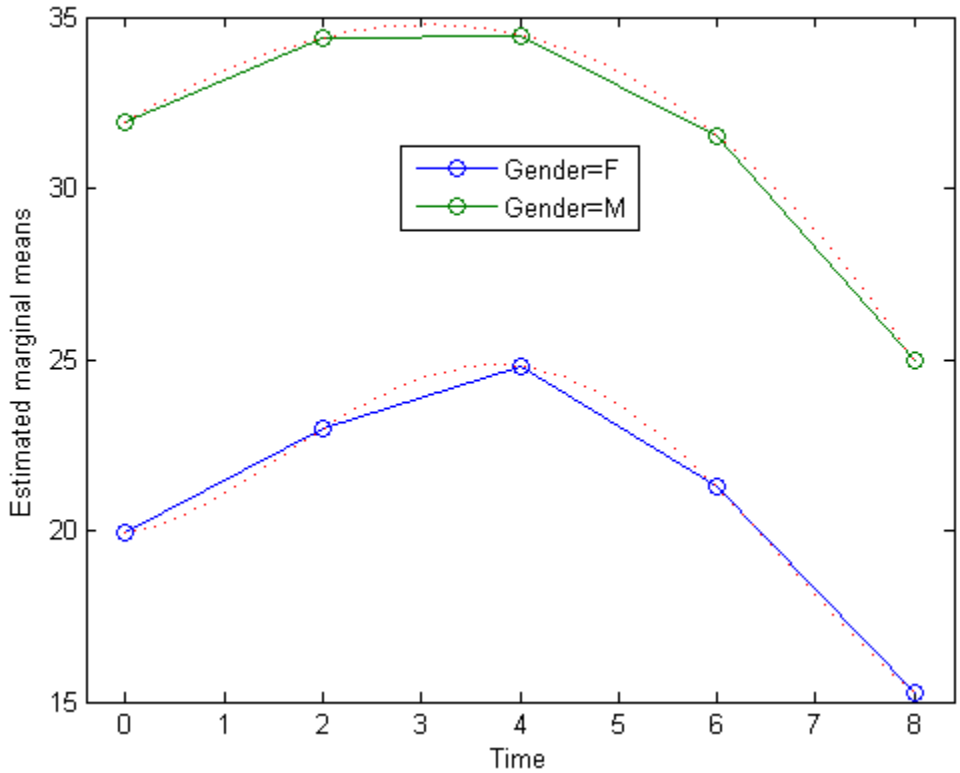
```
rm = fitrm(t,'t0-t8 ~ Gender','WithinDesign',Time);
```

Predict the responses at intermediate times.

```
time = linspace(0,8)';
Y = predict(rm,t([1 5 8 12],:), ...
    'WithinModel','orthogonalcontrasts','WithinDesign',time);
```

Plot the predictions along with the estimated marginal means.

```
plotprofile(rm,'Time','Group',{'Gender'})
hold on;
plot(time,Y,'Color','r','LineStyle',':');
hold off
```



Compute and Plot Confidence Intervals

Navigate to the folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load('longitudinalData')
```

The matrix Y contains response data for 16 individuals. The response is the blood level of a drug measured at five time points (time = 0, 2, 4, 6, and 8). Each row of Y corresponds to an individual, and each column corresponds to a time point. The first eight subjects are female, and the second eight subjects are male. This is simulated data.

Define a variable that stores gender information.

```
Gender = ['F' 'F' 'F' 'F' 'F' 'F' 'F' 'F' 'M' 'M' 'M' 'M' 'M' 'M' 'M' 'M']';
```

Store the data in a proper table array format to perform repeated measures analysis.

```
t = table(Gender,Y(:,1),Y(:,2),Y(:,3),Y(:,4),Y(:,5),...
'VariableNames',{'Gender','t0','t2','t4','t6','t8'});
```

Define the within-subjects variable.

```
Time = [0 2 4 6 8]';
```

Fit a repeated measures model, where the blood levels are the responses and gender is the predictor variable.

```
rm = fitrm(t,'t0-t8 ~ Gender','WithinDesign',Time);
```

Predict the responses at intermediate times.

```
time = linspace(0,8)';
[ypred,ypredci] = predict(rm,t([1 5 8 12],:), ...
    'WithinModel','orthogonalcontrasts','WithinDesign',time);
```

Plot the predictions and the confidence intervals for predictions along with the estimated marginal means.

```
plotprofile(rm,'Time','Group',{'Gender'})

`fitrm` | `random`

predict

Class: TreeBagger

Predict response

Syntax

```
Y = predict(B,X)
[Y,stdevs] = predict(B,X)
[Y,scores] = predict(B,X)
[Y,scores,stdevs] = predict(B,X)
Y = predict(B,X,'param1',val1,'param2',val2,...)
```

Description

`Y = predict(B,X)` computes predicted response of the trained ensemble `B` for data `X`. The output has one prediction for each row of `X`. The returned `Y` is a cell array of strings for classification and a numeric array for regression.

For regression, `[Y,stdevs] = predict(B,X)` also returns standard deviations of the computed responses over the ensemble of the grown trees.

For classification, `[Y,scores] = predict(B,X)` returns scores for all classes. `scores` is a matrix with one row per observation and one column per class. For each observation and each class, the score generated by each tree is the probability of this observation originating from this class computed as the fraction of observations of this class in a tree leaf. `predict` averages these scores over all trees in the ensemble.

`[Y,scores,stdevs] = predict(B,X)` also returns standard deviations of the computed scores for classification. `stdevs` is a matrix with one row per observation and one column per class, with standard deviations taken over the ensemble of the grown trees.

`Y = predict(B,X,'param1',val1,'param2',val2,...)` specifies optional parameter name/value pairs:

`'trees'`	Array of tree indices to use for computation of responses. Default is `'all'`.

`'treeweights'`	Array of `NTrees` weights for weighting votes from the specified trees.
`'useifort'`	Logical matrix of size `Nobs`-by-`NTrees` indicating which trees to use to make predictions for each observation. By default all trees are used for all observations.

See Also

`CompactTreeBagger.predict`

predictorImportance

Class: CompactClassificationEnsemble

Estimates of predictor importance

Syntax

```
imp = predictorImportance(ens)
[imp,ma] = predictorImportance(ens)
```

Description

`imp = predictorImportance(ens)` computes estimates of predictor importance for `ens` by summing these estimates over all weak learners in the ensemble. `imp` has one element for each input predictor in the data used to train this ensemble. A high value indicates that this predictor is important for `ens`.

`[imp,ma] = predictorImportance(ens)` returns a `P`-by-`P` matrix with predictive measures of association for `P` predictors, when the learners in `ens` contain surrogate splits. See "Definitions" on page 22-3778.

Input Arguments

`ens`

A classification ensemble created by `fitensemble`, or by the `compact` method.

Output Arguments

`imp`

A row vector with the same number of elements as the number of predictors (columns) in `ens.X`. The entries are the estimates of predictor importance, with `0` representing the smallest possible importance.

ma

A P-by-P matrix of predictive measures of association for P predictors. Element ma(I,J) is the predictive measure of association averaged over surrogate splits on predictor J for which predictor I is the optimal split predictor. predictorImportance averages this predictive measure of association over all trees in the ensemble.

Definitions

Predictor Importance

predictorImportance computes estimates of predictor importance for ens by summing changes in the *risk* due to splits on every predictor and dividing the sum by the number of branch nodes. If ens is grown without surrogate splits, this sum is taken over best splits found at each branch node. If ens is grown with surrogate splits, this sum is taken over all splits at each branch node including surrogate splits. imp has one element for each input predictor in the data used to train ens. Predictor importance associated with this split is computed as the difference between the risk for the parent node and the total risk for the two children.

Impurity and Node Error

ClassificationTree splits nodes based on either *impurity* or *node error*.

Impurity means one of several things, depending on your choice of the SplitCriterion name-value pair argument:

- Gini's Diversity Index (gdi) — The Gini index of a node is

  $$1-\sum_i p^2(i),$$

  where the sum is over the classes i at the node, and $p(i)$ is the observed fraction of classes with class i that reach the node. A node with just one class (a *pure* node) has Gini index 0; otherwise the Gini index is positive. So the Gini index is a measure of node impurity.
- Deviance ('deviance') — With $p(i)$ defined the same as for the Gini index, the deviance of a node is

$$-\sum_i p(i)\log p(i).$$

A pure node has deviance `0`; otherwise, the deviance is positive.

- Twoing rule (`'twoing'`) — Twoing is not a purity measure of a node, but is a different measure for deciding how to split a node. Let $L(i)$ denote the fraction of members of class i in the left child node after a split, and $R(i)$ denote the fraction of members of class i in the right child node after a split. Choose the split criterion to maximize

$$P(L)P(R)\left(\sum_i |L(i)-R(i)|\right)^2,$$

where $P(L)$ and $P(R)$ are the fractions of observations that split to the left and right respectively. If the expression is large, the split made each child node purer. Similarly, if the expression is small, the split made each child node similar to each other, and hence similar to the parent node, and so the split did not increase node purity.

- Node error — The node error is the fraction of misclassified classes at a node. If j is the class with the largest number of training samples at a node, the node error is $1 - p(j)$.

Predictive Measure of Association

The predictive measure of association between the optimal split on variable i and a surrogate split on variable j is:

$$\lambda_{i,j} = \frac{\min(P_L, P_R) - \left(1 - P_{L_i L_j} - P_{R_i R_j}\right)}{\min(P_L, P_R)}.$$

Here

- P_L and P_R are the node probabilities for the optimal split of node i into Left and Right nodes respectively.

- $P_{L_iL_j}$ is the probability that both (optimal) node i and (surrogate) node j send an observation to the Left.
- $P_{R_iR_j}$ is the probability that both (optimal) node i and (surrogate) node j send an observation to the Right.

Clearly, $\lambda_{i,j}$ lies from $-\infty$ to 1. Variable j is a worthwhile surrogate split for variable i if $\lambda_{i,j} > 0$.

Element `ma(i,j)` is the predictive measure of association averaged over surrogate splits on predictor `j` for which predictor `i` is the optimal split predictor. This average is computed by summing positive values of the predictive measure of association over optimal splits on predictor `i` and surrogate splits on predictor `j` and dividing by the total number of optimal splits on predictor `i`, including splits for which the predictive measure of association between predictors `i` and `j` is negative.

Examples

Estimate the predictor importance for all variables in the Fisher iris data:

```
load fisheriris
ens = fitensemble(meas,species,'AdaBoostM2',100,'Tree');
imp = predictorImportance(ens)

imp =
    0.0001    0.0005    0.0384    0.0146
```

The first two predictors are not very important in `ens`.

Estimate the predictor importance for all variables in the Fisher iris data for an ensemble where the trees contain surrogate splits:

```
load fisheriris
surrtree = templateTree('Surrogate','on');
ens2 = fitensemble(meas,species,'AdaBoostM2',100,surrtree);
[imp2,ma] = predictorImportance(ens2)

imp2 =
    0.0224    0.0142    0.0525    0.0508

ma =
```

```
    1.0000         0    0.0001    0.0001
    0.0115    1.0000    0.0023    0.0054
    0.2810    0.1747    1.0000    0.5372
    0.0789    0.0463    0.2339    1.0000
```

The first two predictors show much more importance than in the previous example.

`predictorImportance` | `templateTree`

predictorImportance

Class: CompactClassificationTree

Estimates of predictor importance

Syntax

```
imp = predictorImportance(tree)
```

Description

`imp = predictorImportance(tree)` computes estimates of predictor importance for `tree` by summing changes in the risk due to splits on every predictor and dividing the sum by the number of branch nodes.

Input Arguments

`tree`

A classification tree created by `fitctree`, or by the `compact` method.

Output Arguments

`imp`

A row vector with the same number of elements as the number of predictors (columns) in tree`.X`. The entries are the estimates of predictor importance, with `0` representing the smallest possible importance.

Definitions

Predictor Importance

`predictorImportance` computes estimates of predictor importance for tree by summing changes in the *risk* due to splits on every predictor and dividing the sum by the number of branch nodes. If `tree` is grown without surrogate splits, this sum is taken over best splits found at each branch node. If `tree` is grown with surrogate splits, this sum is taken over all splits at each branch node including surrogate splits. imp has one element for each input predictor in the data used to train tree. Predictor importance associated with this split is computed as the difference between the risk for the parent node and the total risk for the two children.

Estimates of predictor importance do not depend on the order of predictors if you use surrogate splits, but do depend on the order if you do not use surrogate splits.

If you use surrogate splits, `predictorImportance` computes estimates before the tree is reduced by pruning or merging leaves. If you do not use surrogate splits, `predictorImportance` computes estimates after the tree is reduced by pruning or merging leaves. Therefore, reducing the tree by pruning affects the predictor importance for a tree grown without surrogate splits, and does not affect the predictor importance for a tree grown with surrogate splits.

Impurity and Node Error

`ClassificationTree` splits nodes based on either *impurity* or *node error*.

Impurity means one of several things, depending on your choice of the `SplitCriterion` name-value pair argument:

- Gini's Diversity Index (`gdi`) — The Gini index of a node is

  $$1 - \sum_i p^2(i),$$

  where the sum is over the classes i at the node, and $p(i)$ is the observed fraction of classes with class i that reach the node. A node with just one class (a *pure* node) has Gini index `0`; otherwise the Gini index is positive. So the Gini index is a measure of node impurity.

- Deviance (`'deviance'`) — With $p(i)$ defined the same as for the Gini index, the deviance of a node is

  $$-\sum_i p(i)\log p(i).$$

  A pure node has deviance `0`; otherwise, the deviance is positive.
- Twoing rule (`'twoing'`) — Twoing is not a purity measure of a node, but is a different measure for deciding how to split a node. Let $L(i)$ denote the fraction of members of class i in the left child node after a split, and $R(i)$ denote the fraction of members of class i in the right child node after a split. Choose the split criterion to maximize

  $$P(L)P(R)\left(\sum_i |L(i)-R(i)|\right)^2,$$

  where $P(L)$ and $P(R)$ are the fractions of observations that split to the left and right respectively. If the expression is large, the split made each child node purer. Similarly, if the expression is small, the split made each child node similar to each other, and hence similar to the parent node, and so the split did not increase node purity.
- Node error — The node error is the fraction of misclassified classes at a node. If j is the class with the largest number of training samples at a node, the node error is $1 - p(j)$.

Examples

Estimate the predictor importance for all variables in the Fisher iris data:

```
load fisheriris
tree = fitctree(meas,species);
imp = predictorImportance(tree)

imp =
         0         0    0.0403    0.0303
```

The first two elements of `imp` are zero. Therefore, the first two predictors do not enter into `tree` calculations for classifying irises.

Estimate the predictor importance for all variables in the Fisher iris data for a tree grown with surrogate splits:

```
tree2 = fitctree(meas,species,...
    'Surrogate','on');
imp2 = predictorImportance(tree2)

imp2 =
    0.0287    0.0136    0.0560    0.0556
```

In this case, all predictors have some importance. As you expect by comparing to the first example, the first two predictors are less important than the final two.

Estimates of predictor importance do not depend on the order of predictors if you use surrogate splits, but do depend on the order if you do not use surrogate splits. For example, permute the order of the data columns in the previous example:

```
load fisheriris
meas3 = meas(:,[4 1 3 2]);
tree3 = fitctree(meas3,species);
imp3 = predictorImportance(tree2)

imp3 =
    0.0674         0    0.0033         0
```

The estimates of predictor importance are not a permutation of `imp` from the first example.

Estimate the predictor importance using surrogate splits.

```
tree4 = fitctree(meas3,species,...
    'Surrogate','on');
imp4 = predictorImportance(tree4)

imp4 =
    0.0556    0.0287    0.0560    0.0136
```

`imp4` is a permutation of `imp2`, demonstrating that estimates of predictor importance do not depend on the order of predictors with surrogate splits.

`predictorImportance` | `fitctree`

predictorImportance

Class: CompactRegressionEnsemble

Estimates of predictor importance

Syntax

```
imp = predictorImportance(ens)
[imp,ma] = predictorImportance(ens)
```

Description

`imp = predictorImportance(ens)` computes estimates of predictor importance for `ens` by summing these estimates over all weak learners in the ensemble. `imp` has one element for each input predictor in the data used to train this ensemble. A high value indicates that this predictor is important for `ens`.

`[imp,ma] = predictorImportance(ens)` returns a `P`-by-`P` matrix with predictive measures of association for `P` predictors.

Input Arguments

`ens`

A regression ensemble created by `fitensemble`, or by the `compact` method.

Output Arguments

`imp`

A row vector with the same number of elements as the number of predictors (columns) in `ens.X`. The entries are the estimates of predictor importance, with `0` representing the smallest possible importance.

`ma`

A `P`-by-`P` matrix of predictive measures of association for `P` predictors. Element `ma(I,J)` is the predictive measure of association averaged over surrogate splits on predictor `J` for which predictor `I` is the optimal split predictor. `predictorImportance` averages this predictive measure of association over all trees in the ensemble.

Definitions

Predictor Importance

`predictorImportance` computes estimates of predictor importance for tree by summing changes in the mean squared error (MSE) due to splits on every predictor and dividing the sum by the number of branch nodes. If the tree is grown without surrogate splits, this sum is taken over best splits found at each branch node. If the tree is grown with surrogate splits, this sum is taken over all splits at each branch node including surrogate splits. imp has one element for each input predictor in the data used to train this tree. At each node, MSE is estimated as node error weighted by the node probability. Variable importance associated with this split is computed as the difference between MSE for the parent node and the total MSE for the two children.

Predictive Measure of Association

The predictive measure of association between the optimal split on variable i and a surrogate split on variable j is:

$$\lambda_{i,j} = \frac{\min(P_L, P_R) - \left(1 - P_{L_i L_j} - P_{R_i R_j}\right)}{\min(P_L, P_R)}.$$

Here

- P_L and P_R are the node probabilities for the optimal split of node i into Left and Right nodes respectively.
- $P_{L_i L_j}$ is the probability that both (optimal) node i and (surrogate) node j send an observation to the Left.

- $P_{R_i R_j}$ is the probability that both (optimal) node i and (surrogate) node j send an observation to the Right.

Clearly, $\lambda_{i,j}$ lies from $-\infty$ to 1. Variable j is a worthwhile surrogate split for variable i if $\lambda_{i,j} > 0$.

Element `ma(i,j)` is the predictive measure of association averaged over surrogate splits on predictor `j` for which predictor `i` is the optimal split predictor. This average is computed by summing positive values of the predictive measure of association over optimal splits on predictor `i` and surrogate splits on predictor `j` and dividing by the total number of optimal splits on predictor `i`, including splits for which the predictive measure of association between predictors `i` and `j` is negative.

Examples

Estimate the predictor importance for all numeric variables in the `carsmall` data:

```
load carsmall
X = [Acceleration Cylinders Displacement ...
    Horsepower Model_Year Weight];
ens = fitensemble(X,MPG,'LSBoost',100,'Tree');
imp = predictorImportance(ens)

imp =
    0.0082         0    0.0049    0.0133    0.0142    0.1737
```

The weight (last predictor) has the most impact on mileage (MPG). The second predictor has importance 0; this means the number of cylinders has no impact on predictions made with `ens`.

Estimate the predictor importance for all variables in the `carsmall` data for an ensemble where the trees contain surrogate splits:

```
load carsmall
surrtree = templateTree('Surrogate','on');
X = [Acceleration Cylinders Displacement ...
    Horsepower Model_Year Weight];
ens2 = fitensemble(X,MPG,'LSBoost',100,surrtree);
[imp2,ma] = predictorImportance(ens2)

imp2 =
```

```
    0.0725    0.1342    0.1425    0.1397    0.1380    0.1855

ma =
    1.0000    0.0414    0.0607    0.0782    0.0102    0.0322
         0    1.0000         0         0         0         0
    0.0441    0.0704    1.0000    0.0883    0.0175    0.0913
    0.0944    0.1166    0.1400    1.0000    0.0390    0.1308
    0.0121    0.0139    0.0127    0.0127    1.0000    0.0113
    0.0818    0.1317    0.2072    0.1878    0.0340    1.0000
```

While weight (last predictor) still has the most impact on mileage (MPG), this estimate has the second predictor (number of cylinders) is essentially tied for third most important predictor.

See Also

`predictorImportance` | `templateTree`

predictorImportance

Class: CompactRegressionTree

Estimates of predictor importance

Syntax

```
imp = predictorImportance(tree)
```

Description

`imp = predictorImportance(tree)` computes estimates of predictor importance for `tree` by summing changes in the mean squared error due to splits on every predictor and dividing the sum by the number of branch nodes.

Input Arguments

`tree`

A regression tree created by `fitrtree`, or by the `compact` method.

Output Arguments

`imp`

A row vector with the same number of elements as the number of predictors (columns) in `tree.X`. The entries are the estimates of predictor importance, with `0` representing the smallest possible importance.

Definitions

Predictor Importance

`predictorImportance` computes estimates of predictor importance for tree by summing changes in the mean squared error (MSE) due to splits on every predictor and dividing the sum by the number of branch nodes. If the tree is grown without surrogate splits, this sum is taken over best splits found at each branch node. If the tree is grown with surrogate splits, this sum is taken over all splits at each branch node including surrogate splits. imp has one element for each input predictor in the data used to train this tree. At each node, MSE is estimated as node error weighted by the node probability. Variable importance associated with this split is computed as the difference between MSE for the parent node and the total MSE for the two children.

Estimates of predictor importance do not depend on the order of predictors if you use surrogate splits, but do depend on the order if you do not use surrogate splits.

If you use surrogate splits, `predictorImportance` computes estimates before the tree is reduced by pruning or merging leaves. If you do not use surrogate splits, `predictorImportance` computes estimates after the tree is reduced by pruning or merging leaves. Therefore, reducing the tree by pruning affects the predictor importance for a tree grown without surrogate splits, and does not affect the predictor importance for a tree grown with surrogate splits.

Examples

Find predictor importance for the `carsmall` data. Use just the numeric predictors:

```
load carsmall
X = [Acceleration Cylinders Displacement ...
    Horsepower Model_Year Weight];
tree = fitrtree(X,MPG);
imp = predictorImportance(tree)

imp =
    0.0315         0    0.1082    0.0686    0.1629    1.2924
```

The weight (last predictor) has the most impact on mileage (MPG). The second predictor has importance 0; this means the number of cylinders has no impact on predictions made with `tree`.

Estimate the predictor importance for all variables in the `carsmall` data for a tree grown with surrogate splits:

```
load carsmall
X = [Acceleration Cylinders Displacement ...
    Horsepower Model_Year Weight];
tree2 = fitrtree(X,MPG,...
    'Surrogate','on');
imp2 = predictorImportance(tree2)

imp2 =
    0.5287    1.1977    1.2400    0.7059    1.0677    1.4106
```

While weight (last predictor) still has the most impact on mileage (MPG), this estimate has the second predictor (number of cylinders) as the third most important predictor.

See Also

`predictorImportance` | `fitrtree`

princomp

Principal component analysis (PCA) on data

Compatibility

`princomp` will be removed in a future release. Use `pca` instead.

Syntax

```
[COEFF,SCORE] = princomp(X)
[COEFF,SCORE,latent] = princomp(X)
[COEFF,SCORE,latent,tsquare] = princomp(X)
[...] = princomp(X,'econ')
```

Description

`COEFF = princomp(X)` performs principal components analysis (PCA) on the *n*-by-*p* data matrix `X`, and returns the principal component coefficients, also known as loadings. Rows of `X` correspond to observations, columns to variables. `COEFF` is a *p*-by-*p* matrix, each column containing coefficients for one principal component. The columns are in order of decreasing component variance.

`princomp` centers `X` by subtracting off column means, but does not rescale the columns of `X`. To perform principal components analysis with standardized variables, that is, based on correlations, use `princomp(zscore(X))`. To perform principal components analysis directly on a covariance or correlation matrix, use `pcacov`.

`[COEFF,SCORE] = princomp(X)` returns `SCORE`, the principal component scores; that is, the representation of `X` in the principal component space. Rows of `SCORE` correspond to observations, columns to components.

`[COEFF,SCORE,latent] = princomp(X)` returns `latent`, a vector containing the eigenvalues of the covariance matrix of `X`.

`[COEFF,SCORE,latent,tsquare] = princomp(X)` returns `tsquare`, which contains Hotelling's T^2 statistic for each data point.

The scores are the data formed by transforming the original data into the space of the principal components. The values of the vector `latent` are the variance of the columns of `SCORE`. Hotelling's T^2 is a measure of the multivariate distance of each observation from the center of the data set.

When `n <= p`, `SCORE(:,n:p)` and `latent(n:p)` are necessarily zero, and the columns of `COEFF(:,n:p)` define directions that are orthogonal to `X`.

`[...] = princomp(X,'econ')` returns only the elements of `latent` that are not necessarily zero, and the corresponding columns of `COEFF` and `SCORE`, that is, when `n <= p`, only the first `n-1`. This can be significantly faster when `p` is much larger than `n`.

Examples

Compute principal components for the `ingredients` data in the Hald data set, and the variance accounted for by each component.

```
load hald;
[pc,score,latent,tsquare] = princomp(ingredients);
pc,latent

pc =

   -0.0678   -0.6460    0.5673    0.5062
   -0.6785   -0.0200   -0.5440    0.4933
    0.0290    0.7553    0.4036    0.5156
    0.7309   -0.1085   -0.4684    0.4844

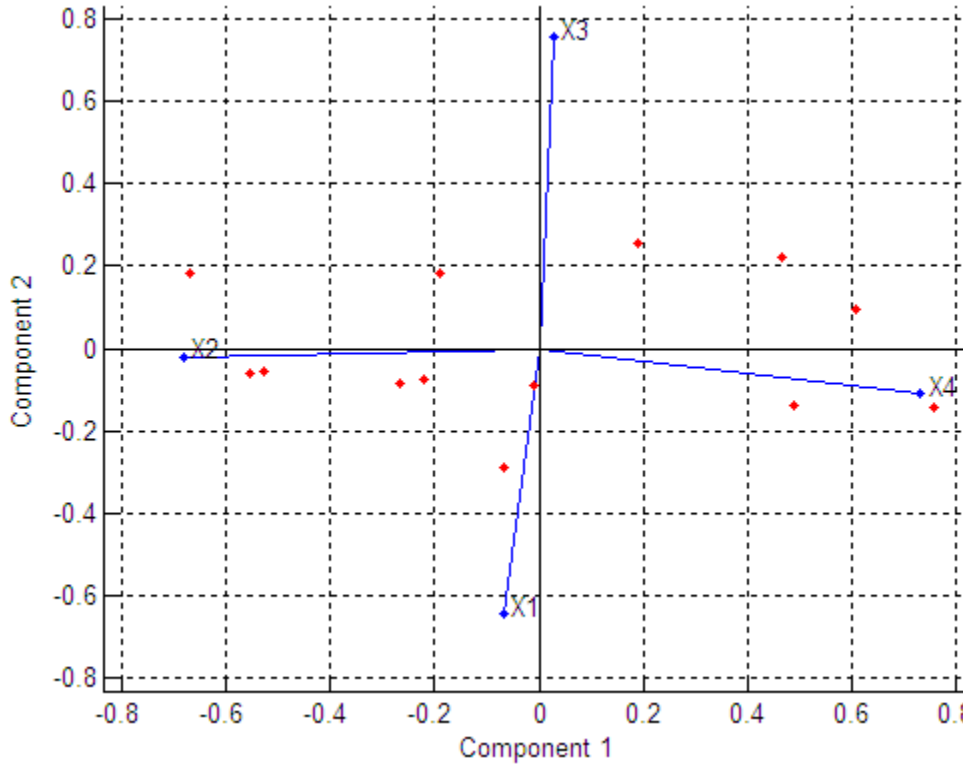
latent =

  517.7969
   67.4964
   12.4054
    0.2372
```

The following command and plot show that two components account for 98% of the variance:

```
cumsum(latent)./sum(latent)
ans =
```

```
       0.86597
       0.97886
        0.9996
             1
biplot(pc(:,1:2),'Scores',score(:,1:2),'VarLabels',...
  {'X1' 'X2' 'X3' 'X4'})
```



For a more detailed example and explanation of this analysis method, see “Principal Component Analysis (PCA)” on page 13-75.

Prior property

Class: TreeBagger

Prior class probabilities

Description

The `Prior` property is a vector with prior probabilities for classes. This property is empty for ensembles of regression trees.

See Also

`ClassificationTree` | `TreeBagger` | `fitctree`

ProbDist class

Object representing probability distribution

Compatibility

`ProbDist` will be removed in a future release. To create and fit probability distribution objects, use `makedist` and `fitdist` instead.

Description

`ProbDist` is an abstract class representing a probability distribution.

Construction

`ProbDist` is an abstract class. You cannot create instances of this class directly. You can construct an object in a subclass, such as `ProbDistUnivParam` or `ProbDistUnivKernel`, by calling the subclass constructors (`ProbDistUnivParam` or `ProbDistUnivKernel`).

Methods

cdf	Return cumulative distribution function (CDF) for ProbDist object
pdf	Return probability density function (PDF) for ProbDist object
random	Generate random number drawn from ProbDist object

Properties

DistName	Read-only string containing probability distribution name of ProbDist object
InputData	Read-only structure containing information about input data to ProbDist object
Support	Read-only structure containing information about support of ProbDist object

Copy Semantics

Value. To learn how this affects your use of the class, see Copying Objects in the MATLAB Programming Fundamentals documentation.

ProbDistKernel class

Superclasses: ProbDist

Object representing nonparametric probability distribution defined by kernel smoothing

Compatibility

`ProbDistKernel` will be removed in a future release. To create and fit probability distribution objects, use `makedist` and `fitdist` instead.

Description

`ProbDistKernel` is an abstract class defining the properties and methods of a nonparametric distribution defined by a kernel smoothing function.

Construction

`ProbDistKernel` is an abstract class. You cannot create instances of this class directly. You can construct an object in a subclass, `ProbDistUnivKernel` by calling the subclass constructor, `ProbDistUnivKernel`.

Methods

cdf	Return cumulative distribution function (CDF) for ProbDist object
pdf	Return probability density function (PDF) for ProbDist object
random	Generate random number drawn from ProbDist object

Note: The above methods are inherited from the `ProbDist` class.

Properties

BandWidth

Read-only value specifying bandwidth of kernel smoothing function for ProbDistKernel object

DistName

Read-only string containing probability distribution name of ProbDist object

InputData

Read-only structure containing information about input data to ProbDist object

Kernel

Read-only string specifying name of kernel smoothing function for ProbDistKernel object

Support

Read-only structure containing information about support of ProbDist object

Note: Some of the above properties are inherited from the `ProbDist` class.

Copy Semantics

Value. To learn how this affects your use of the class, see Copying Objects in the MATLAB Programming Fundamentals documentation.

ProbDistParametric class

Superclasses: ProbDist

Object representing parametric probability distribution

Compatibility

`ProbDistParametric` will be removed in a future release. To create and fit probability distribution objects, use `makedist` and `fitdist` instead.

Description

`ProbDistParametric` is an abstract class defining the properties and methods of a parametric probability distribution.

Construction

`ProbDistParametric` is an abstract class. You cannot create instances of this class directly. You can construct an object in its subclass, `ProbDistUnivParam`, by calling the subclass constructor, `ProbDistUnivParam`.

Methods

cdf	Return cumulative distribution function (CDF) for ProbDist object
pdf	Return probability density function (PDF) for ProbDist object
random	Generate random number drawn from ProbDist object

Note: The above methods are inherited from the `ProbDist` class.

Properties

DistName	Read-only string containing probability distribution name of ProbDist object
InputData	Read-only structure containing information about input data to ProbDist object
NLogL	Read-only value specifying negative log likelihood for input data to ProbDistParametric object
NumParams	Read-only value specifying number of parameters of ProbDistParametric object
ParamCov	Read-only covariance matrix of parameter estimates of ProbDistParametric object
ParamDescription	Read-only cell array specifying descriptions of parameters of ProbDistParametric object
ParamIsFixed	Read-only logical array specifying fixed parameters of ProbDistParametric object
ParamNames	Read-only cell array specifying names of parameters of ProbDistParametric object
Params	Read-only array specifying values of parameters of ProbDistParametric object
Support	Read-only structure containing information about support of ProbDist object

Note: Some of the above properties are inherited from the `ProbDist` class.

Copy Semantics

Value. To learn how this affects your use of the class, see Copying Objects in the MATLAB Programming Fundamentals documentation.

ProbDistUnivKernel class

Superclasses: ProbDistKernel

Object representing univariate kernel probability distribution

Compatibility

`ProbDistUnivKernel` will be removed in a future release. To create and fit probability distribution objects, use `makedist` and `fitdist` instead.

Description

A `ProbDistUnivKernel` object represents a univariate nonparametric probability distribution defined by kernel smoothing. You create this object using the `ProbDistUnivKernel` function to fit the distribution to data.

Construction

Methods

cdf	Return cumulative distribution function (CDF) for ProbDist object
icdf	Return inverse cumulative distribution function (ICDF) for ProbDistUnivKernel object
iqr	Return interquartile range (IQR) for ProbDistUnivKernel object
median	Return median of ProbDistUnivKernel object

pdf	Return probability density function (PDF) for ProbDist object
random	Generate random number drawn from ProbDist object

Note: Some of the above methods are inherited from the `ProbDistKernel` class.

Properties

BandWidth	Read-only value specifying bandwidth of kernel smoothing function for ProbDistKernel object
DistName	Read-only string containing probability distribution name of ProbDist object
InputData	Read-only structure containing information about input data to ProbDist object
Kernel	Read-only string specifying name of kernel smoothing function for ProbDistKernel object
NLogL	Read-only value specifying negative log likelihood for input data to ProbDistUnivKernel object
Support	Read-only structure containing information about support of ProbDist object

Note: Some of the above properties are inherited from the `ProbDistKernel` class.

Copy Semantics

Value. To learn how this affects your use of the class, see Copying Objects in the MATLAB Programming Fundamentals documentation.

ProbDistUnivKernel

Class: ProbDistUnivKernel

Construct ProbDistUnivKernel object

Syntax

```
PD = ProbDistUnivKernel(X)
PD = ProbDistUnivKernel(X, param1, val1, param2, val2, ...)
```

Description

`PD = ProbDistUnivKernel(X)` creates *PD*, a ProbDistUnivKernel object, which represents a nonparametric probability distribution, based on a normal kernel smoothing function.

`PD = ProbDistUnivKernel(X, param1, val1, param2, val2, ...)` specifies optional parameter name/value pairs, as described in the Parameter/Values table. Parameter and value names are case insensitive.

Compatibility

`ProbDistUnivKernel` will be removed in a future release. To create and fit probability distribution objects, use `makedist` and `fitdist` instead.

Input Arguments

X — A column vector of data.

Note: Any NaN values in *X* are ignored by the fitting calculations.

Parameter	Values
`'censoring'`	A Boolean vector the same size as *X*, containing `1`s when the corresponding elements in *X* are right-censored observations and `0`s

Parameter	Values
	when the corresponding elements are exact observations. Default is a vector of 0s. **Note:** Any NaN values in this censoring vector are ignored by the fitting calculations.
`'frequency'`	A vector the same size as *X*, containing nonnegative integers specifying the frequencies for the corresponding elements in *X*. Default is a vector of 1s. **Note:** Any NaN values in this frequency vector are ignored by the fitting calculations.
`'kernel'`	A string specifying the type of kernel smoother to use. Choices are: • `'normal'` (default) • `'box'` • `'triangle'` • `'epanechnikov'`
`'support'`	Any of the following to specify the support: • `'unbounded'` — Default. If the density can extend over the whole real line. • `'positive'` — To restrict it to positive values. • A two-element vector giving finite lower and upper limits for the support of the density.
`'width'`	A value specifying the bandwidth of the kernel smoothing window. The default is optimal for estimating normal densities, but you may want to choose a smaller value to reveal features such as multiple modes.

Output Arguments

PD — An object in the `ProbDistUnivKernel` class, which is derived from the `ProbDist` class. It represents a nonparametric probability distribution.

ProbDistUnivParam class

Superclasses: ProbDistParametric

Object representing univariate parametric probability distribution

Compatibility

`ProbDistUnivParam` will be removed in a future release. To create and fit probability distribution objects, use `makedist` and `fitdist` instead.

Description

A `ProbDistUnivParam` object represents a univariate parametric probability distribution. You create this object by using the constructor (`ProbDistUnivParam`) and supplying parameter values.

Construction

.ProbDistUnivParam	Construct ProbDistUnivParam object

Methods

cdf	Return cumulative distribution function (CDF) for ProbDist object
icdf	Return inverse cumulative distribution function (ICDF) for ProbDistUnivParam object
iqr	Return interquartile range (IQR) for ProbDistUnivParam object

mean	Return mean of ProbDistUnivParam object
median	Return median of ProbDistUnivParam object
paramci	Return parameter confidence intervals of ProbDistUnivParam object
pdf	Return probability density function (PDF) for ProbDist object
random	Generate random number drawn from ProbDist object
std	Return standard deviation of ProbDistUnivParam object
var	Return variance of ProbDistUnivParam object

Note: Some of the above methods are inherited from the `ProbDistParametric` class.

Properties

DistName	Read-only string containing probability distribution name of ProbDist object
InputData	Read-only structure containing information about input data to ProbDist object
NLogL	Read-only value specifying negative log likelihood for input data to ProbDistParametric object

NumParams	Read-only value specifying number of parameters of ProbDistParametric object
ParamCov	Read-only covariance matrix of parameter estimates of ProbDistParametric object
ParamDescription	Read-only cell array specifying descriptions of parameters of ProbDistParametric object
ParamIsFixed	Read-only logical array specifying fixed parameters of ProbDistParametric object
ParamNames	Read-only cell array specifying names of parameters of ProbDistParametric object
Params	Read-only array specifying values of parameters of ProbDistParametric object
Support	Read-only structure containing information about support of ProbDist object

Note: The above properties are inherited from the `ProbDistParametric` class.

Note: Parameter values are also properties. For example, if you create `PD`, a univariate parametric probability distribution object that represents a normal distribution, then `PD.mu` and `PD.sigma` are properties that give the values of the mu and sigma parameters.

Copy Semantics

Value. To learn how this affects your use of the class, see Copying Objects in the MATLAB Programming Fundamentals documentation.

How To

- Appendix B

ProbDistUnivParam

Class: ProbDistUnivParam

Construct ProbDistUnivParam object

Syntax

```
PD = ProbDistUnivParam(DistName, Params)
```

Description

`PD = ProbDistUnivParam(DistName, Params)` creates *PD*, a ProbDistUnivParam object, which represents a probability distribution. This distribution is defined by the parametric distribution specified by *DistName*, with parameters specified by the numeric vector *Params*.

Compatibility

`ProbDistUnivParam` will be removed in a future release. To create and fit probability distribution objects, use `makedist` and `fitdist` instead.

Input Arguments

DistName — A string specifying a distribution. Choices are:

- `'beta'`
- `'binomial'`
- `'birnbaumsaunders'`
- `'exponential'`
- `'extreme value'` or `ev'`
- `'gamma'`
- `'generalized extreme value'` or `'gev'`

- `'generalized pareto'` or `'gp'`
- `'inversegaussian'`
- `'logistic'`
- `'loglogistic'`
- `'lognormal'`
- `'nakagami'`
- `'negative binomial'` or `'nbin'`
- `'normal'`
- `'poisson'`
- `'rayleigh'`
- `'rician'`
- `'tlocationscale'`
- `'weibull'` or `'wbl'`

For more information on these parametric distributions, see Appendix B.

Params — Numeric vector of distribution parameters. The number and type of parameters depends on the distribution you specify with *DistName*. For information on parameters for each distribution type, see Appendix B.

Output Arguments

PD — An object in the `ProbDistUnivParam` class, which is derived from the `ProbDist` class. It represents a parametric probability distribution.

Examples

1 Create an object representing a normal distribution with a mean of 100 and a standard deviation of 10.

```
pd = ProbDistUnivParam('normal',[100 10])
```

```
pd =

normal distribution

    mu = 100
    sigma = 10
```

2 Generate a 4-by-5 matrix of random values from this distribution.

```
random(pd,4,5)

ans =

  105.3767  103.1877  135.7840  107.2540   98.7586
  118.3389   86.9231  127.6944   99.3695  114.8970
   77.4115   95.6641   86.5011  107.1474  114.0903
  108.6217  103.4262  130.3492   97.9503  114.1719
```

`fitdist`

How To

- Appendix B

probplot

Probability plots

Syntax

```
probplot(Y)
probplot(distribution,Y)
probplot(Y,cens,freq)
probplot(ax,Y)
probplot(...,'noref')
probplot(ax,PD)
probplot(ax,fun,params)
h = probplot(...)
```

Description

`probplot(Y)` produces a normal probability plot comparing the distribution of the data `Y` to the normal distribution. `Y` can be a single vector, or a matrix with a separate sample in each column. The plot includes a reference line useful for judging whether the data follow a normal distribution.

`probplot` uses midpoint probability plotting positions. The i^{th} sorted value from a sample of size N is plotted against the midpoint in the jump of the empirical CDF on the y axis. With uncensored data, that midpoint is $(i–0.5)/N$. With censored data (see below), the y value is more complicated to compute.

`probplot(distribution,Y)` creates a probability plot for the distribution specified by *`distribution`*. Acceptable strings for *`distribution`* are:

- `'exponential'` — Exponential probability plot (nonnegative values)
- `'extreme value'` — Extreme value probability plot (all values)
- `'lognormal'` — Lognormal probability plot (positive values)
- `'normal'` — Normal probability plot (all values)
- `'rayleigh'` — Rayleigh probability plot (positive values)
- `'weibull'` — Weibull probability plot (positive values)

The *y* axis scale is based on the selected distribution. The *x* axis has a log scale for the Weibull and lognormal distributions, and a linear scale for the others.

Not all distributions are appropriate for all data sets, and `probplot` will error when asked to create a plot with a data set that is inappropriate for a specified distribution. Appropriate data ranges for each distribution are given parenthetically in the list above.

`probplot(Y,cens,freq)` or `probplot(distname,Y,cens,freq)` requires a vector `Y`. `cens` is a vector of the same size as `Y` and contains `1` for observations that are right-censored and `0` for observations that are observed exactly. `freq` is a vector of the same size as Y, containing integer frequencies for the corresponding elements in `Y`.

`probplot(ax,Y)` takes a handle `ax` to an existing probability plot, and adds additional lines for the samples in `Y`. `ax` is a handle for a set of axes.

`probplot(...,'noref')` omits the reference line.

`probplot(ax,PD)` takes a probability distribution object, `PD`, and adds a fitted line to the axes specified by `ax` to represent the probability distribution specified by `PD`. `PD` is a ProbDist object of the `ProbDistUnivParam` class or `ProbDistUnivKernel` class.

`probplot(ax,fun,params)` takes a function `fun` and a set of parameters, `params`, and adds fitted lines to the axes of an existing probability plot specified by `ax`. `fun` is a function handle to a cdf function, specified with `@` (for example, `@wblcdf`). `params` is the set of parameters required to evaluate `fun`, and is specified as a cell array or vector. The function must accept a vector of `X` values as its first argument, then the optional parameters, and must return a vector of cdf values evaluated at `X`.

`h = probplot(...)` returns handles to the plotted lines.

Examples

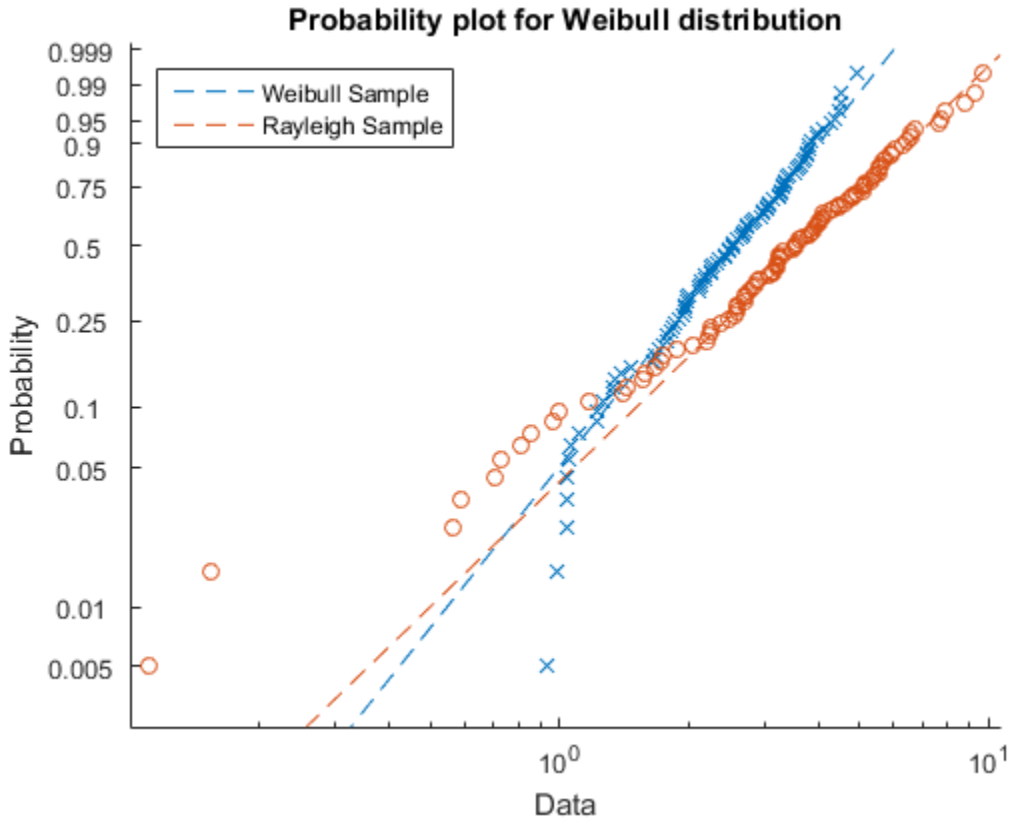
Test Data for Weibull Distribution Using `probplot`

Generate sample data. The sample `x1` contains 100 random numbers from a Weibull distribution with scale parameter `A = 3` and shape parameter `B = 3`. The sample `x2` contains 100 random numbers from a Rayleigh distribution with scale parameter `B = 3`.

```
rng('default');  % For reproducibility
x1 = wblrnd(3,3,100,1);
x2 = raylrnd(3,100,1);
```

Create a probability plot to assess whether the data in `x1` and `x2` comes from a Weibull distribution.

```
figure;
probplot('weibull',[x1 x2])
legend('Weibull Sample','Rayleigh Sample','Location','NW')
```



The probability plot shows that the data in `x1` comes from a Weibull distribution, while the data in `x2` does not.

Test Data for Normal Distribution Using `probplot`

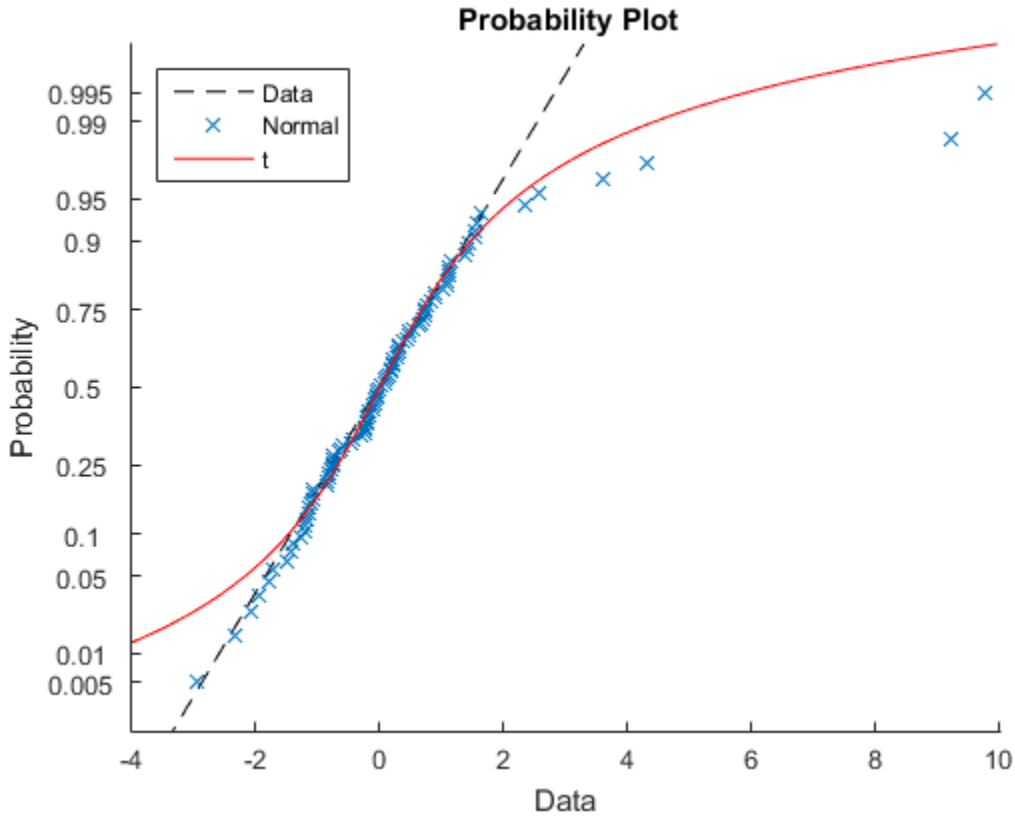
Generate sample data containing about 20% outliers in the tails. The left tail of the sample data contains 10 values randomly generated from an exponential distribution

with parameter `mu = 1`. The right tail contains 10 values randomly generated from an exponential distribution with parameter `mu = 5`. The center of the sample data contains 80 values randomly generated from a standard normal distribution.

```
rng default  % For reproducibility
left_tail = -exprnd(1,10,1);
right_tail = exprnd(5,10,1);
center = randn(80,1);
data = [left_tail;center;right_tail];
```

Create a probability plot to assess whether the data in `data` comes from a normal distribution. Plot a *t* location-scale curve on the same figure to compare with `data`.

```
figure;
probplot(data);
p = mle(data,'dist','tlo');
t = @(data,mu,sig,df)cdf('tlocationscale',data,mu,sig,df);
h = probplot(gca,t,p);
h.Color = 'r';
h.LineStyle = '-';
title('{\bf Probability Plot}')
legend('Data','Normal','t','Location','NW')
```



The plot shows that neither the normal line nor the *t* location-scale curve fit the tails very well because of the outliers.

procrustes

Procrustes analysis

Syntax

```
d = procrustes(X,Y)
[d,Z] = procrustes(X,Y)
[d,Z,transform] = procrustes(X,Y)
[...] = procrustes(...,'scaling',flag)
[...] = procrustes(...,'reflection',flag)
```

Description

`d = procrustes(X,Y)` determines a linear transformation (translation, reflection, orthogonal rotation, and scaling) of the points in matrix `Y` to best conform them to the points in matrix `X`. The goodness-of-fit criterion is the sum of squared errors. `procrustes` returns the minimized value of this dissimilarity measure in `d`. `d` is standardized by a measure of the scale of `X`, given by:

```
sum(sum((X-repmat(mean(X,1),size(X,1),1)).^2,1))
```

That is, the sum of squared elements of a centered version of `X`. However, if `X` comprises repetitions of the same point, the sum of squared errors is not standardized.

`X` and `Y` must have the same number of points (rows), and `procrustes` matches `Y(i)` to `X(i)`. Points in `Y` can have smaller dimension (number of columns) than those in `X`. In this case, `procrustes` adds columns of zeros to `Y` as necessary.

`[d,Z] = procrustes(X,Y)` also returns the transformed `Y` values.

`[d,Z,transform] = procrustes(X,Y)` also returns the transformation that maps `Y` to `Z`. `transform` is a structure array with fields:

- `c` — Translation component
- `T` — Orthogonal rotation and reflection component

- `b` — Scale component

That is:

```
c = transform.c;
T = transform.T;
b = transform.b;

Z = b*Y*T + c;
```

`[...] = procrustes(...,'scaling',flag)`, when *`flag`* is `false`, allows you to compute the transformation without a scale component (that is, with `b` equal to `1`). The default *`flag`* is `true`.

`[...] = procrustes(...,'reflection',flag)`, when *`flag`* is `false`, allows you to compute the transformation without a reflection component (that is, with `det(T)` equal to `1`). The default *`flag`* is `'best'`, which computes the best-fitting transformation, whether or not it includes a reflection component. A *`flag`* of `true` forces the transformation to be computed with a reflection component (that is, with `det(T)` equal to `-1`)

Examples

Procrustes Analysis

Generate the sample data in two dimensions.

```
rng('default')
n = 10;
X = normrnd(0,1,[n 2]);
```

Rotate, scale, translate, and add some noise to sample points.

```
S = [0.5 -sqrt(3)/2; sqrt(3)/2 0.5];
Y = normrnd(0.5*X*S+2,0.05,n,2);
```

Conform `Y` to `X` using procrustes analysis.

```
[d,Z,tr] = procrustes(X,Y);
```

Plot the original `X` and `Y` with the transformed `Y` .

```
plot(X(:,1),X(:,2),'rx',Y(:,1),Y(:,2),'b.',Z(:,1),Z(:,2),'bx');
```

proflik

Profile likelihood function for probability distribution

Syntax

```
[ll,param] = proflik(pd,pnum)
[ll,param] = proflik(pd,pnum,'Display',display)
[ll,param] = proflik(pd,pnum,setparam)
[ll,param] = proflik(pd,pnum,setparam,'Display',display)
[ll,param,other] = proflik( ___ )
```

Description

`[ll,param] = proflik(pd,pnum)` returns a vector ll of log likelihood values and a vector param of corresponding parameter values for the parameter in the position indicated by pnum.

`[ll,param] = proflik(pd,pnum,'Display',display)` returns the log likelihood values and corresponding parameter values, and plots the profile likelihood overlaid on an approximation of the log likelihood.

`[ll,param] = proflik(pd,pnum,setparam)` returns the log likelihood values and corresponding parameter values as specified by `setparam`.

`[ll,param] = proflik(pd,pnum,setparam,'Display',display)` returns the log likelihood values and corresponding parameter values as specified by setparam, and plots the profile likelihood overlaid on an approximation of the log likelihood.

`[ll,param,other] = proflik( ___ )` also returns a matrix other containing the values of the other parameters that maximize the likelihood, using any of the input arguments from the previous syntaxes.

Examples

Profile Likelihood of a Distribution Parameter

Load the sample data. Create a probability distribution object by fitting a Weibull distribution to the miles per gallon (MPG) data.

```
load carsmall;
pd = fitdist(MPG,'Weibull')
```

```
pd =

  WeibullDistribution

  Weibull distribution
    A = 26.5079   [24.8333, 28.2954]
    B = 3.27193   [2.79441, 3.83104]
```

View the parameter names for the distribution.

```
pd.ParameterNames
```

```
ans =

    'A'    'B'
```

For the Weibull distribution, A is in position 1, and B is in position 2.

Compute the profile likelihood for B, which is in position `pnum = 2`.

```
[ll,param] = proflik(pd,2);
```

Display the loglikelihood values for the estimated values of B.

```
[ll',param']
```

```
ans =

 -329.9688    2.7132
 -329.4312    2.7748
 -328.9645    2.8365
 -328.5661    2.8981
 -328.2340    2.9597
 -327.9658    3.0213
```

```
-327.7596    3.0830
-327.6135    3.1446
-327.5256    3.2062
-327.4943    3.2678
-327.5178    3.3295
-327.5946    3.3911
-327.7233    3.4527
-327.9023    3.5143
-328.1303    3.5760
-328.4060    3.6376
-328.7281    3.6992
-329.0956    3.7608
-329.5071    3.8224
-329.9617    3.8841
-330.4583    3.9457
```

These results show that the profile log likelihood is maximized between the estimated B values of 3.2678 and 3.3295, which correspond to loglikelihood values -327.4943 and -327.5178. From the earlier fit, the MLE of B is 3.27193, which is in this interval as expected.

Profile Likelihood With Restricted Parameter Values

Load the sample data. Create a probability distribution object by fitting a generalized extreme value distribution to the miles per gallon (MPG) data.

```
load carsmall;
pd = fitdist(MPG,'GeneralizedExtremeValue')
```

```
pd =

  GeneralizedExtremeValueDistribution

  Generalized Extreme Value distribution
        k = -0.207765   [-0.381674, -0.0338564]
    sigma =   7.49674   [6.31755, 8.89603]
       mu =   20.6233   [18.8859, 22.3606]
```

View the parameter names for the distribution.

```
pd.ParameterNames
```

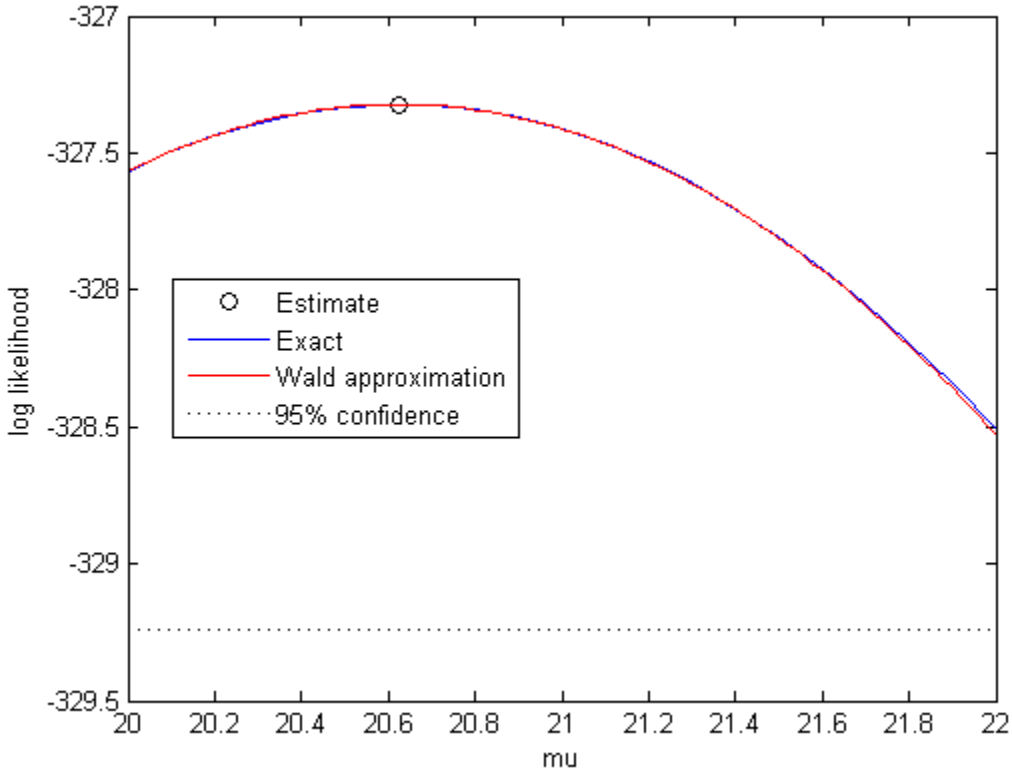
```
ans =

    'k'    'sigma'    'mu'
```

For the generalized extreme value distribution, `k` is in position 1, `sigma` is in position 2, and `mu` is in position 3.

Compute the profile likelihood for `mu`, which is in position `pnum = 3`. Restrict the computation to parameter values from 20 to 22, and display the plot.

```
[ll,param,other] = proflik(pd,3,20:.1:22,'display','on');
```



The plot shows the estimated value for the parameter `mu` that maximizes the loglikelihood.

Display the loglikelihood values for the estimated values of `mu`, and the values of the other distribution parameters that maximize the corresponding loglikelihood.

```
[ll',param',other]

ans =

 -327.5706   20.0000   -0.1803    7.4087
 -327.4971   20.1000   -0.1846    7.4218
 -327.4364   20.2000   -0.1890    7.4354
 -327.3887   20.3000   -0.1934    7.4493
 -327.3538   20.4000   -0.1978    7.4636
 -327.3317   20.5000   -0.2023    7.4783
 -327.3223   20.6000   -0.2067    7.4932
 -327.3257   20.7000   -0.2112    7.5084
 -327.3418   20.8000   -0.2156    7.5240
 -327.3706   20.9000   -0.2201    7.5399
 -327.4119   21.0000   -0.2245    7.5560
 -327.4659   21.1000   -0.2289    7.5723
 -327.5324   21.2000   -0.2333    7.5889
 -327.6113   21.3000   -0.2378    7.6057
 -327.7027   21.4000   -0.2422    7.6228
 -327.8065   21.5000   -0.2465    7.6400
 -327.9227   21.6000   -0.2509    7.6575
 -328.0511   21.7000   -0.2553    7.6751
 -328.1917   21.8000   -0.2596    7.6930
 -328.3446   21.9000   -0.2639    7.7111
 -328.5095   22.0000   -0.2682    7.7293
```

The first column contains the log likelihood value that corresponds to the estimate of `mu` in the second column. The log likelihood is maximized between the parameter values 20.6000 and 20.7000, corresponding to log likelihood values -327.3223 and -327.3257. The third column contains the value of `k` that maximizes the corresponding log likelihood for `mu`. The fourth column contains the value of `sigma` that maximizes the corresponding log likelihood for `mu`.

Input Arguments

`pd` — Probability distribution

probability distribution object

Probability distribution, specified as a probability distribution object. Create a probability distribution object with specified parameter values using `makedist`. Alternatively, create a probability distribution object by fitting it to data using `fitdist` or the Distribution Fitting app.

pnum — Parameter number

positive integer value

Parameter number for which to compute the profile likelihood, specified as a positive integer value corresponding to the position of the desired parameter in the parameter name vector. For example, a Weibull distribution has a parameter name vector `{'A','B'}`, so specify `pnum` as `2` to compute the profile likelihood for `B`.

Data Types: `single` | `double`

setparam — Parameter value restriction

scalar value | vector of scalar values

Parameter value restriction, specified as a scalar value or a vector of such values. If you do not specify `setparam`, `proflik` chooses the values for output vector param based on the default confidence interval method for the probability distribution pd. If the parameter can take only restricted values, and if the confidence interval violates that restriction, you can use `setparam` to specify valid values.

Example: `[3,3.5,4]`

display — Display toggle

`'off'` (default) | `'on'`

Display toggle, specified as either `'on'` or `'off'`. Specify `'on'` to display a plot of the profile log likelihood overlaid on an approximation of the log likelihood. Specify `'off'` to omit the display. The approximation is based on a Taylor series expansion around the estimated parameter value, as a function of the parameter in position pnum or its logarithm. The intersection of the curves with the horizontal dotted line marks the endpoints of 95% confidence intervals.

Output Arguments

ll — Log likelihood values

vector

Log likelihood values, returned as a vector. The log likelihood is the value of the likelihood with the parameter in position pnum set to the values in param, maximized over the remaining parameters.

param — Parameter values

vector

Parameter values corresponding to the loglikelihood values in ll, returned as a vector. If you specify parameter values using setparam, then `param` is equal to `setparam`.

`other` — Other parameter values

matrix

Other parameter values that maximize the likelihood, returned as a matrix. Each row of other contains the values for all parameters except the parameter in position pnum.

Profile likelihood function for probability distribution object

Syntax

```
[ll,param] = proflik(pd,pnum)
[ll,param] = proflik(pd,pnum,'Display',display)
[ll,param] = proflik(pd,pnum,setparam)
[ll,param] = proflik(pd,pnum,setparam,'Display',display)
[ll,param,other] = proflik( ___ )
```

Description

`[ll,param] = proflik(pd,pnum)` returns a vector ll of loglikelihood values and a vector param of corresponding parameter values for the parameter in the position indicated by pnum.

`[ll,param] = proflik(pd,pnum,'Display',display)` returns the loglikelihood values and corresponding parameter values, and plots the profile likelihood overlaid on an approximation of the loglikelihood.

`[ll,param] = proflik(pd,pnum,setparam)` returns the loglikelihood values and corresponding parameter values as specified by `setparam`.

`[ll,param] = proflik(pd,pnum,setparam,'Display',display)` returns the loglikelihood values and corresponding parameter values as specified by setparam, and plots the profile likelihood overlaid on an approximation of the loglikelihood.

`[ll,param,other] = proflik( ___ )` also returns a matrix other containing the values of the other parameters that maximize the likelihood, using any of the input arguments from the previous syntaxes.

Input Arguments

`pd` — Probability distribution
probability distribution object

Probability distribution, specified as a probability distribution object. Create a probability distribution object with specified parameter values using `makedist`. Alternatively, create a probability distribution object by fitting it to data using `fitdist` or the Distribution Fitting app.

`pnum` — Parameter number
positive integer value

Parameter number for which to compute the profile likelihood, specified as a positive integer value corresponding to the position of the desired parameter in the parameter name vector. For example, a Weibull distribution has a parameter name vector `{'A','B'}`, so specify `pnum` as `2` to compute the profile likelihood for `B`.

Data Types: `single` | `double`

`setparam` — Parameter value restriction
scalar value | vector of scalar values

Parameter value restriction, specified as a scalar value or a vector of such values. If you do not specify `setparam`, `proflik` chooses the values for output vector param based on the default confidence interval method for the probability distribution pd. If the parameter can take only restricted values, and if the confidence interval violates that restriction, you can use `setparam` to specify valid values.

Example: `[3,3.5,4]`

`display` — Display toggle
`'off'` (default) | `'on'`

Display toggle, specified as either `'on'` or `'off'`. Specify `'on'` to display a plot of the profile loglikelihood overlaid on an approximation of the loglikelihood. Specify `'off'` to omit the display. The approximation is based on a Taylor series expansion around the estimated parameter value, as a function of the parameter in position pnum or its logarithm. The intersection of the curves with the horizontal dotted line marks the endpoints of 95% confidence intervals.

Output Arguments

`ll` — Loglikelihood values

vector

Loglikelihood values, returned as a vector. The loglikelihood is the value of the likelihood with the parameter in position pnum set to the values in param, maximized over the remaining parameters.

`param` — Parameter values

vector

Parameter values corresponding to the loglikelihood values in ll, returned as a vector. If you specify parameter values using setparam, then `param` is equal to `setparam`.

`other` — Other parameter values

matrix

Other parameter values that maximize the likelihood, returned as a matrix. Each row of other contains the values for all parameters except the parameter in position pnum.

Examples

Profile Likelihood of a Distribution Parameter

Load the sample data. Create a probability distribution object by fitting a Weibull distribution to the miles per gallon (`MPG`) data.

```
load carsmall;
pd = fitdist(MPG,'Weibull')
```

```
pd =

  WeibullDistribution

  Weibull distribution
    A = 26.5079   [24.8333, 28.2954]
    B = 3.27193   [2.79441, 3.83104]
```

View the parameter names for the distribution.

```
pd.ParameterNames
```

```
ans =
```

```
    'A'    'B'
```

For the Weibull distribution, A is in position 1, and B is in position 2.

Compute the profile likelihood for B, which is in position `pnum = 2`.

```
[ll,param] = proflik(pd,2);
```

Display the loglikelihood values for the estimated values of B.

```
[ll',param']
```

```
ans =

 -329.9688    2.7132
 -329.4312    2.7748
 -328.9645    2.8365
 -328.5661    2.8981
 -328.2340    2.9597
 -327.9658    3.0213
 -327.7596    3.0830
 -327.6135    3.1446
 -327.5256    3.2062
 -327.4943    3.2678
 -327.5178    3.3295
 -327.5946    3.3911
 -327.7233    3.4527
 -327.9023    3.5143
 -328.1303    3.5760
 -328.4060    3.6376
 -328.7281    3.6992
 -329.0956    3.7608
 -329.5071    3.8224
 -329.9617    3.8841
 -330.4583    3.9457
```

These results show that the profile loglikelihood is maximized between the estimated B values of 3.2678 and 3.3295, which correspond to loglikelihood values -327.4943 and -327.5178. From the earlier fit, the MLE of B is 3.27193, which is in this interval as expected.

Profile Likelihood With Restricted Parameter Values

Load the sample data. Create a probability distribution object by fitting a generalized extreme value distribution to the miles per gallon (MPG) data.

```
load carsmall;
pd = fitdist(MPG,'GeneralizedExtremeValue')

pd =

  GeneralizedExtremeValueDistribution

  Generalized Extreme Value distribution
        k = -0.207765   [-0.381674, -0.0338564]
    sigma =   7.49674   [6.31755, 8.89603]
       mu =   20.6233   [18.8859, 22.3606]
```

View the parameter names for the distribution.

```
pd.ParameterNames

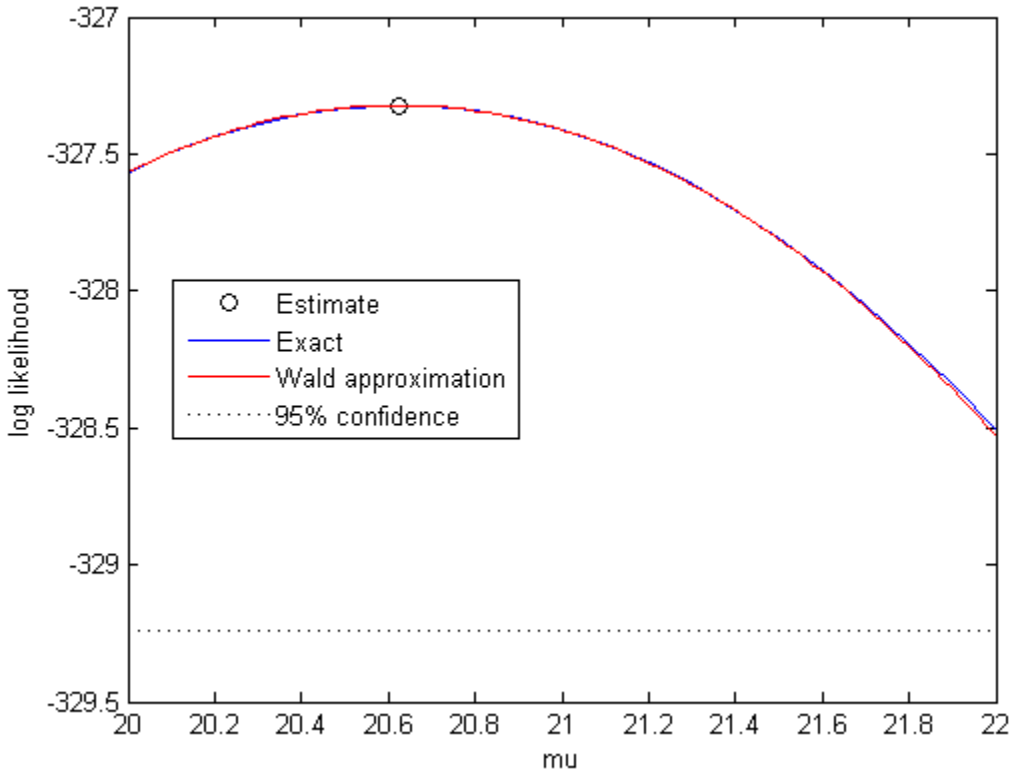
ans =

    'k'    'sigma'    'mu'
```

For the generalized extreme value distribution, `k` is in position 1, `sigma` is in position 2, and `mu` is in position 3.

Compute the profile likelihood for `mu`, which is in position `pnum = 3`. Restrict the computation to parameter values from 20 to 22, and display the plot.

```
[ll,param,other] = proflik(pd,3,20:.1:22,'display','on');
```



The plot shows the estimated value for the parameter `mu` that maximizes the loglikelihood.

Display the loglikelihood values for the estimated values of `mu`, and the values of the other distribution parameters that maximize the corresponding loglikelihood.

```
[ll',param',other]

ans =

  -327.5706    20.0000    -0.1803     7.4087

-327.3418   20.8000   -0.2156    7.5240
-327.3706   20.9000   -0.2201    7.5399
-327.4119   21.0000   -0.2245    7.5560
-327.4659   21.1000   -0.2289    7.5723
-327.5324   21.2000   -0.2333    7.5889
-327.6113   21.3000   -0.2378    7.6057
-327.7027   21.4000   -0.2422    7.6228
-327.8065   21.5000   -0.2465    7.6400
-327.9227   21.6000   -0.2509    7.6575
-328.0511   21.7000   -0.2553    7.6751
-328.1917   21.8000   -0.2596    7.6930
-328.3446   21.9000   -0.2639    7.7111
-328.5095   22.0000   -0.2682    7.7293
```

The first column contains the loglikelihood value that corresponds to the estimate of `mu` in the second column. The loglikelihood is maximized between the parameter values 20.6000 and 20.7000, corresponding to loglikelihood values -327.3223 and -327.3257. The third column contains the value of `k` that maximizes the corresponding loglikelihood for `mu`. The fourth column contains the value of `sigma` that maximizes the corresponding loglikelihood for `mu`.

`dfittool` | `fitdist` | `makedist`

proximity

Class: CompactTreeBagger

Proximity matrix for data

Syntax

```
prox = proximity(B,X)
```

Description

`prox = proximity(B,X)` computes a numeric matrix of size `Nobs`-by-`Nobs` of proximities for data `X`, where `Nobs` is the number of observations (rows) in `X`. Proximity between any two observations in the input data is defined as a fraction of trees in the ensemble `B` for which these two observations land on the same leaf. This is a symmetric matrix with ones on the diagonal and off-diagonal elements ranging from 0 to 1.

Proximity property

Class: TreeBagger

Proximity matrix for observations

Description

The `Proximity` property is a numeric matrix of size `Nobs`-by-`Nobs`, where `Nobs` is the number of observations in the training data, containing measures of the proximity between observations. For any two observations, their proximity is defined as the fraction of trees for which these observations land on the same leaf. This is a symmetric matrix with 1s on the diagonal and off-diagonal elements ranging from 0 to 1.

`ClassificationTree` | `proximity` | `fitctree` | `fitrtree` | `RegressionTree` | `TreeBagger`

prune

Class: ClassificationTree

Produce sequence of subtrees by pruning

Syntax

```
tree1 = prune(tree)
tree1 = prune(tree,Name,Value)
```

Description

`tree1 = prune(tree)` creates a copy of the classification tree `tree` with its optimal pruning sequence filled in.

`tree1 = prune(tree,Name,Value)` creates a pruned tree with additional options specified by one Name,Value pair argument. You can specify several name-value pair arguments in any order as `Name1,Value1,…,NameN,ValueN`.

Tips

- `tree1 = prune(tree)` returns the decision tree `tree1` that is the full, unpruned `tree`, but with optimal pruning information added. This is useful only if you created `tree` by pruning another tree, or by using the `fitctree` function with pruning set `'off'`. If you plan to prune a tree multiple times along the optimal pruning sequence, it is more efficient to create the optimal pruning sequence first.

Input Arguments

`tree`

A classification tree created with `fitctree`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'Alpha'`

A numeric scalar. `prune` prunes `tree` to the specified value of the pruning cost.

`'Level'`

A numeric scalar from `0` (no pruning) to the largest pruning level of this tree `max(tree.PruneList)`. `prune` returns the tree pruned to this level.

`'Nodes'`

A numeric vector with elements from `1` to `tree.NumNodes`. Any tree branch nodes listed in `nodes` become leaf nodes in tree1, unless their parent nodes are also pruned.

Output Arguments

`tree1`

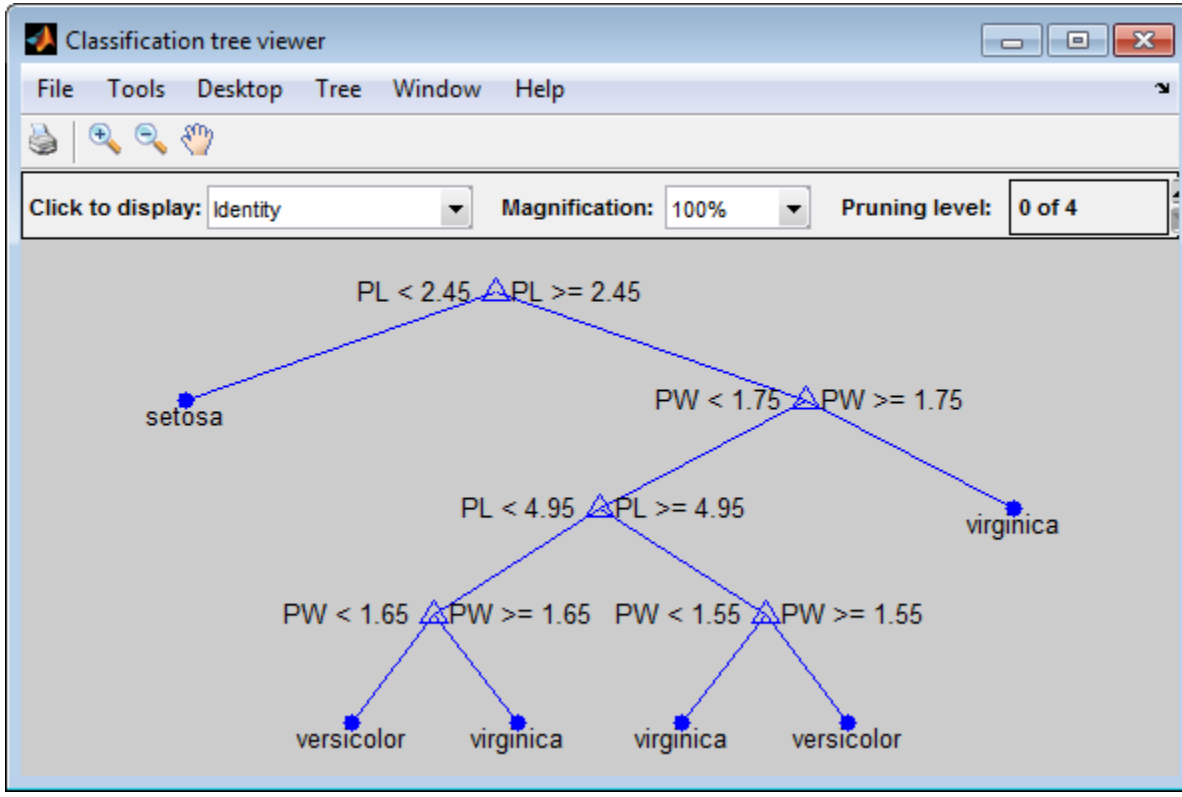
A classification tree.

Examples

Prune and Display a Classification Tree

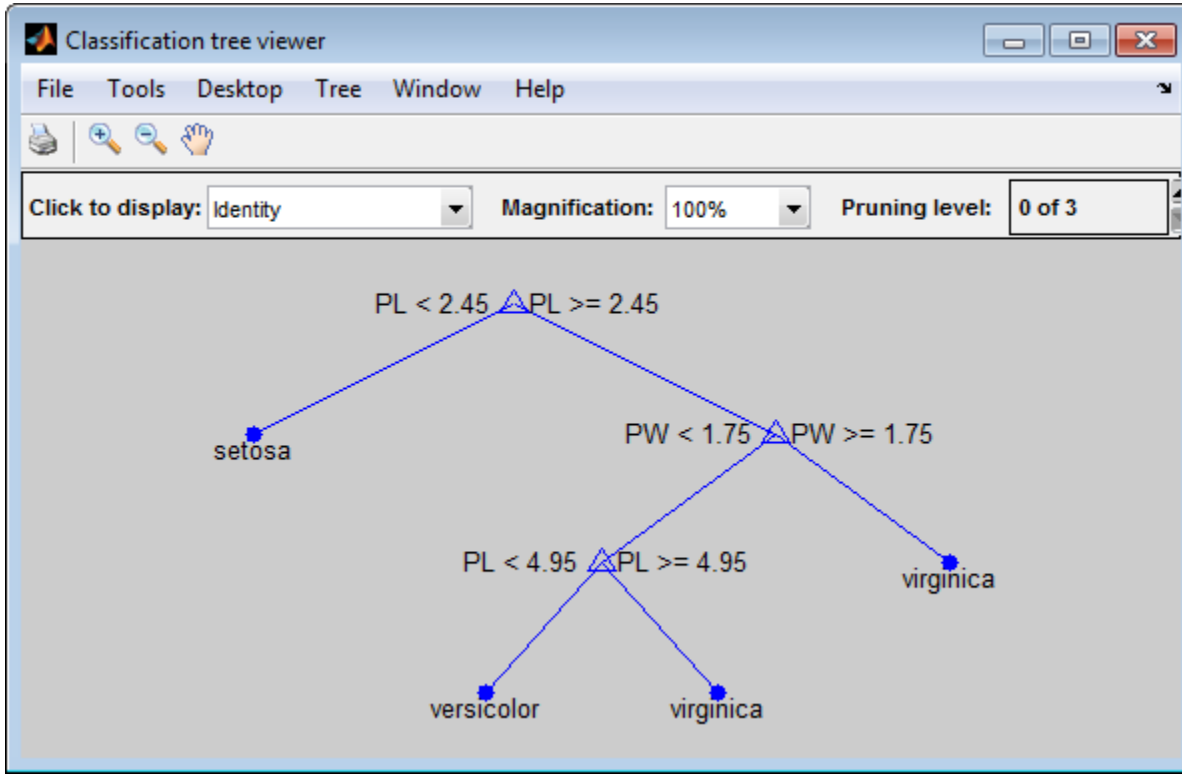
Construct and display a full classification tree for Fisher's iris data.

```
load fisheriris;
varnames = {'SL' 'SW' 'PL' 'PW'};
t1 = fitctree(meas,species,...
    'minparent',5,'predictornames',varnames);
view(t1,'mode','graph');
```



Construct and display the next largest tree from the optimal pruning sequence.

```
t2 = prune(t1,'level',1);
view(t2,'mode','graph');
```



See Also

`fitctree`

prune

Class: classregtree

Prune tree

Compatibility

`classregtree` will be removed in a future release. See `fitctree`, `fitrtree`, `ClassificationTree`, or `RegressionTree` instead.

Syntax

```
t2 = prune(t1,'level',level)
t2 = prune(t1,'nodes',nodes)
t2 = prune(t1)
```

Description

`t2 = prune(t1,'level',level)` takes a decision tree `t1` and a pruning level `level`, and returns the decision tree `t2` pruned to that level. If `level` is 0, there is no pruning. Trees are pruned based on an optimal pruning scheme that first prunes branches giving less improvement in error cost.

`t2 = prune(t1,'nodes',nodes)` prunes the nodes listed in the `nodes` vector from the tree. Any `t1` branch nodes listed in `nodes` become leaf nodes in `t2`, unless their parent nodes are also pruned. Use `view` to display the node numbers for any node you select.

`t2 = prune(t1)` returns the decision tree `t2` that is the full, unpruned `t1`, but with optimal pruning information added. This is useful only if `t1` is created by pruning another tree, or by using the `classregtree` function with the `'prune'` parameter set to `'off'`. If you plan to prune a tree multiple times along the optimal pruning sequence, it is more efficient to create the optimal pruning sequence first.

Pruning is the process of reducing a tree by turning some branch nodes into leaf nodes and removing the leaf nodes under the original branch.

Examples

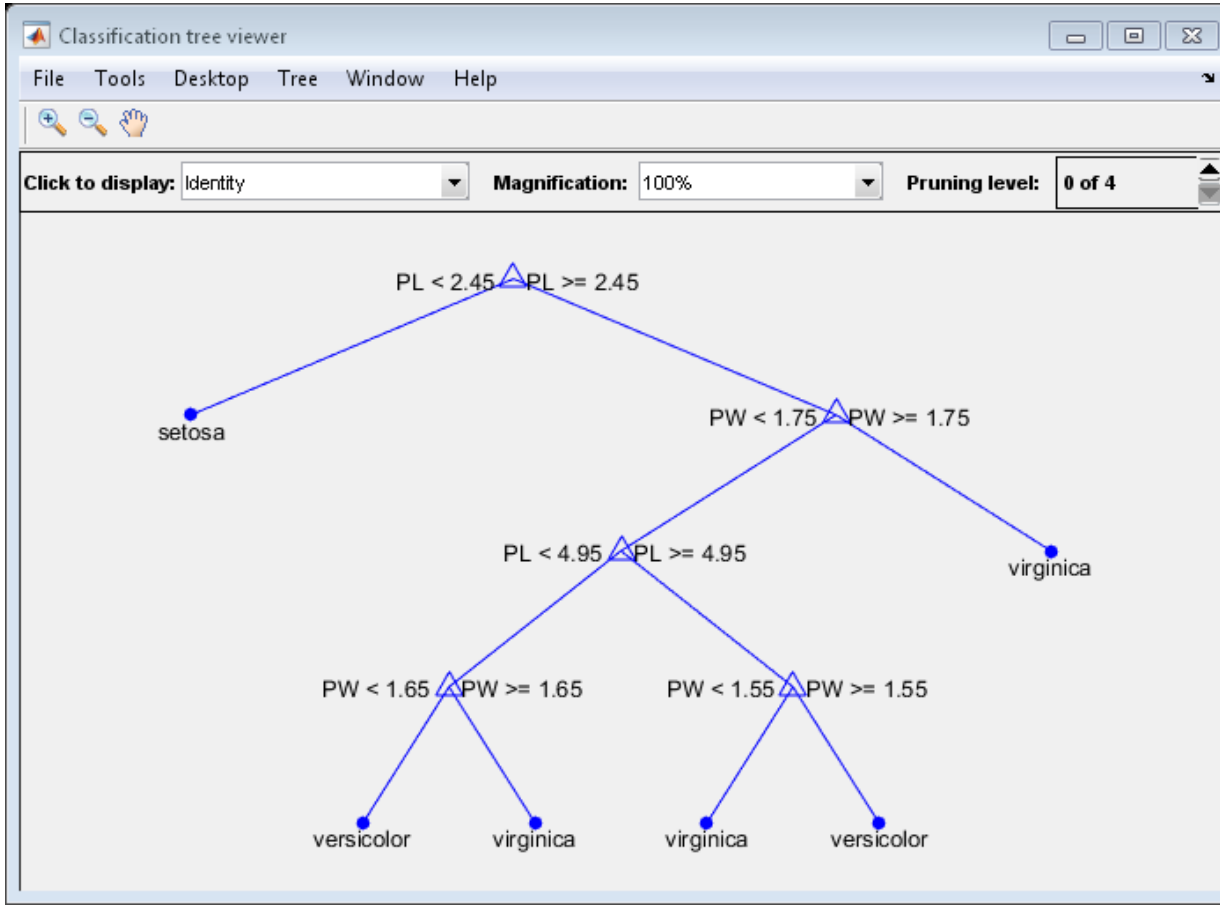
Prune a Decision Tree

Display the full tree for Fisher's iris data:

```
load fisheriris;
t1 = classregtree(meas,species,...
                  'names',{'SL' 'SW' 'PL' 'PW'},...
                  'minparent',5)
view(t1)
```

```
t1 =

Decision tree for classification
 1  if PL<2.45 then node 2 elseif PL>=2.45 then node 3 else setosa
 2  class = setosa
 3  if PW<1.75 then node 4 elseif PW>=1.75 then node 5 else versicolor
 4  if PL<4.95 then node 6 elseif PL>=4.95 then node 7 else versicolor
 5  class = virginica
 6  if PW<1.65 then node 8 elseif PW>=1.65 then node 9 else versicolor
 7  if PW<1.55 then node 10 elseif PW>=1.55 then node 11 else virginica
 8  class = versicolor
 9  class = virginica
10  class = virginica
11  class = versicolor
```



Display the next largest tree from the optimal pruning sequence:

```
t2 = prune(t1,'level',1)
view(t2)
```

```
t2 =

Decision tree for classification
1  if PL<2.45 then node 2 elseif PL>=2.45 then node 3 else setosa
2  class = setosa
3  if PW<1.75 then node 4 elseif PW>=1.75 then node 5 else versicolor
```

```
4  if PL<4.95 then node 6 elseif PL>=4.95 then node 7 else versicolor
5  class = virginica
6  class = versicolor
7  class = virginica
```

prune

Class: RegressionTree

Produce sequence of subtrees by pruning

Syntax

```
tree1 = prune(tree)
tree1 = prune(tree,Name,Value)
```

Description

`tree1 = prune(tree)` creates a copy of the regression tree `tree` with its optimal pruning sequence filled in.

`tree1 = prune(tree,Name,Value)` creates a pruned tree with additional options specified by one Name,Value pair argument. You can specify several name-value pair arguments in any order as `Name1,Value1,…,NameN,ValueN`.

Tips

- `tree1 = prune(tree)` returns the decision tree `tree1` that is the full, unpruned `tree`, but with optimal pruning information added. This is useful only if you created `tree` by pruning another tree, or by using `fitrtree` with pruning set `'off'`. If you plan to prune a tree multiple times along the optimal pruning sequence, it is more efficient to create the optimal pruning sequence first.

Input Arguments

`tree`

A regression tree created with `fitrtree`.

Name-Value Pair Arguments

Optional comma-separated pair of Name,Value arguments, where `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify only one name-value pair argument.

`'Alpha'`

A numeric scalar from `0` (no pruning) to `1` (prune to one node). Prunes to minimize the sum of (`Alpha` times the number of leaf nodes) and a cost (mean squared error).

`'Level'`

A numeric scalar from `0` (no pruning) to the largest pruning level of this tree `max(tree.PruneList)`. `prune` returns the tree pruned to this level.

`'Nodes'`

A numeric vector with elements from `1` to `tree.NumNodes`. Any tree branch nodes listed in `Nodes` become leaf nodes in tree1, unless their parent nodes are also pruned.

Output Arguments

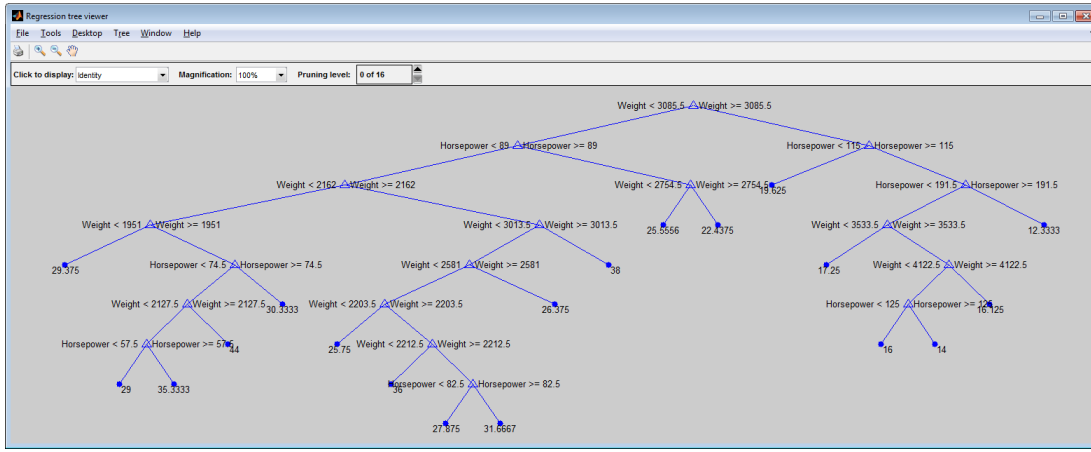
`tree1`

A regression tree.

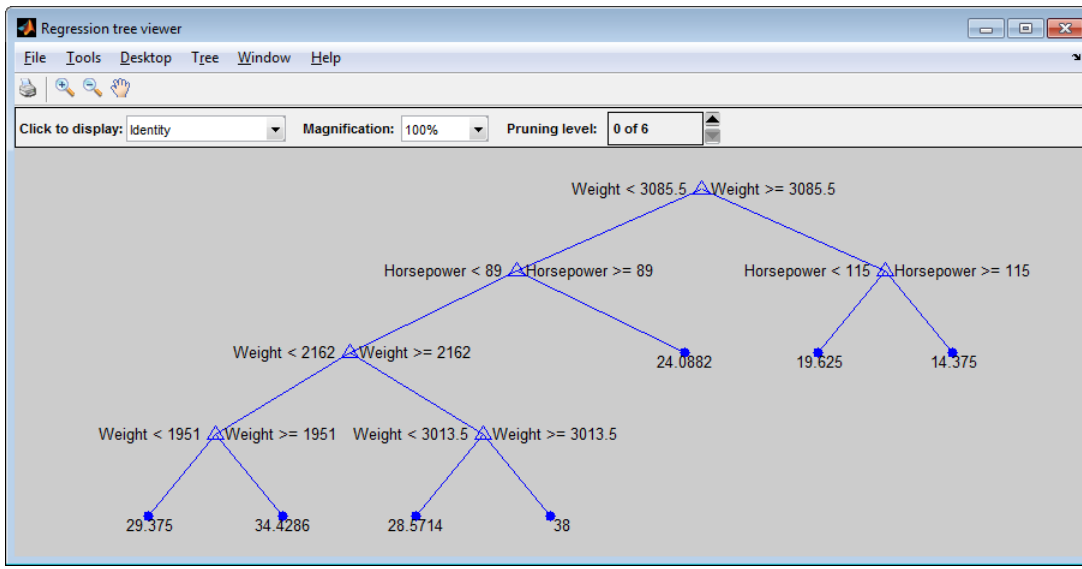
Examples

Display a full tree for the `carsmall` data, as well as the tree pruned to level `10`:

```
load carsmall;
varnames = {'Weight' 'Horsepower'};
t1 = fitrtree([Weight Horsepower],MPG,...
    'predictornames',varnames)
view(t1,'Mode','graph');
```



```
t2 = prune(t1,'Level',10);
view(t2,'Mode','graph');
```



See Also

`fitrtree`

Prune property

Class: TreeBagger

Flag to prune trees

Description

The `Prune` property is true if decision trees are pruned and false if they are not. Pruning decision trees is not recommended for ensembles. The default value is false.

See Also

`ClassificationTree` | `RegressionTree` | `TreeBagger` | `fitctree` | `fitrtree`

prunelist

Class: classregtree

Pruning levels for decision tree nodes

Compatibility

`classregtree` will be removed in a future release. See `fitctree`, `fitrtree`, `ClassificationTree`, or `RegressionTree` instead.

Syntax

```
P = prunelist(T)
P = prunelist(T,J)
```

Description

`P = prunelist(T)` returns an *n*-element numeric vector with the pruning levels in each node of the tree `T`, where *n* is the number of nodes. When you call `prune(T,'level',level)`, nodes with the pruning levels below *`level`* are pruned, and nodes with the pruning levels greater or equal to *`level`* are not pruned.

`P = prunelist(T,J)` takes an array `J` of node numbers and returns the pruning levels for the specified nodes.

See Also

`classregtree` | `numnodes`

qrand

Class: qrandstream

Generate quasi-random points from stream

Syntax

```
x = qrand(q)
X = qrand(q,n)
```

Description

`x = qrand(q)` returns the next value `x` in the quasi-random number stream `q` of the `qrandstream` class. `x` is a 1-by-*d* vector, where *d* is the dimension of the stream. The command sets `q.State` to the index in the underlying point set of the next value to be returned.

`X = qrand(q,n)` returns the next `n` values `X` in an `n`-by-*d* matrix.

Objects `q` of the `qrandstream` class encapsulate properties of a specified quasi-random number stream. Values of the stream are not generated and stored in memory until `q` is accessed using `qrand`.

Examples

Use `qrandstream` to construct a 3-D Halton stream, based on a point set that skips the first 1000 values and then retains every 101st point:

```
q = qrandstream('halton',3,'Skip',1e3,'Leap',1e2)
q =
   Halton quasi-random stream in 3 dimensions
   Point set properties:
              Skip : 1000
              Leap : 100
    ScrambleMethod : none
```

```
nextIdx = q.State
nextIdx =
     1
```

Use `qrand` to generate two samples of size four:

```
X1 = qrand(q,4)
X1 =
    0.0928    0.3475    0.0051
    0.6958    0.2035    0.2371
    0.3013    0.8496    0.4307
    0.9087    0.5629    0.6166
nextIdx = q.State
nextIdx =
     5

X2 = qrand(q,4)
X2 =
    0.2446    0.0238    0.8102
    0.5298    0.7540    0.0438
    0.3843    0.5112    0.2758
    0.8335    0.2245    0.4694
nextIdx = q.State
nextIdx =
     9
```

Use `reset` to reset the stream, then generate another sample:

```
reset(q)
nextIdx = q.State
nextIdx =
     1

X = qrand(q,4)
X =
    0.0928    0.3475    0.0051
    0.6958    0.2035    0.2371
    0.3013    0.8496    0.4307
    0.9087    0.5629    0.6166
```

qrandset class

Quasi-random point sets

Description

`qrandset` is a base class that encapsulates a sequence of multi- dimensional quasi-random numbers. This base class is abstract and cannot be instantiated directly. Concrete subclasses include `sobolset` and `haltonset`.

Construction

.qrandset	Abstract quasi-random point set class

Methods

disp	Display qrandset object
end	Last index in indexing expression for point set
length	Length of point set
ndims	Number of dimensions in matrix
net	Generate quasi-random point set
scramble	Scramble quasi-random point set
size	Number of dimensions in matrix

subsref	Subscripted reference for qrandset

Properties

Dimensions	Number of dimensions
Leap	Interval between points
ScrambleMethod	Settings that control scrambling
Skip	Number of initial points to omit from sequence
Type	Name of sequence on which point set P is based

Copy Semantics

Value. To learn how this affects your use of the class, see Comparing Handle and Value Classes in the MATLAB Object-Oriented Programming documentation.

How To

- “Quasi-Random Point Sets” on page 6-17

qrandset

Class: qrandset

Abstract quasi-random point set class

Description

`qrandset` is an abstract class, and you cannot create instances of it directly. You must use `haltonset` or `sobolset` to create a `qrandset` object.

See Also

`haltonset` | `sobolset`

qrandstream class

Quasi-random number streams

Construction

.qrandstream	Construct quasi-random number stream

Methods

addlistener	Add listener for event
delete	Delete handle object
disp	Display `qrandstream` object
eq	Test handle equality
findobj	Find objects matching specified conditions
findprop	Find property of MATLAB handle object
ge	Greater than or equal relation for handles
gt	Greater than relation for handles
isvalid	Test handle validity
le	Less than or equal relation for handles
lt	Less than relation for handles

ne	Not equal relation for handles
notify	Notify listeners of event
qrand	Generate quasi-random points from stream
rand	Generate quasi-random points from stream
reset	Reset state

Properties

PointSet	Point set from which stream is drawn
State	Current state of the stream

Copy Semantics

Handle. To learn how this affects your use of the class, see Comparing Handle and Value Classes in the MATLAB Object-Oriented Programming documentation.

qrandstream

Class: qrandstream

Construct quasi-random number stream

Syntax

```
q = qrandstream(type,d)
q = qrandstream(type,d,prop1,val1,prop2,val2,...)
q = qrandstream(p)
```

Description

`q = qrandstream(type,d)` constructs a `d`-dimensional quasi-random number stream `q` of the `qrandstream` class, of type specified by the string *`type`*. *`type`* is either `'halton'` or `'sobol'`, and `q` is based on a point set from either the `haltonset` class or `sobolset` class, respectively, with default property settings.

`q = qrandstream(type,d,prop1,val1,prop2,val2,...)` specifies property name/value pairs for the point set on which the stream is based. Applicable properties depend on *`type`*.

`q = qrandstream(p)` constructs a stream based on the specified point set `p`. `p` must be a point set from either the `haltonset` class or `sobolset` class.

Examples

Construct a 3-D Halton stream, based on a point set that skips the first 1000 values and then retains every 101st point:

```
q = qrandstream('halton',3,'Skip',1e3,'Leap',1e2)
q =
   Halton quasi-random stream in 3 dimensions
   Point set properties:
              Skip : 1000
              Leap : 100
```

```
    ScrambleMethod : none

nextIdx = q.State
nextIdx =
     1
```

Use `qrand` to generate two samples of size four:

```
X1 = qrand(q,4)
X1 =
    0.0928    0.3475    0.0051
    0.6958    0.2035    0.2371
    0.3013    0.8496    0.4307
    0.9087    0.5629    0.6166
nextIdx = q.State
nextIdx =
     5

X2 = qrand(q,4)
X2 =
    0.2446    0.0238    0.8102
    0.5298    0.7540    0.0438
    0.3843    0.5112    0.2758
    0.8335    0.2245    0.4694
nextIdx = q.State
nextIdx =
     9
```

Use `reset` to reset the stream, and then generate another sample:

```
reset(q)
nextIdx = q.State
nextIdx =
     1

X = qrand(q,4)
X =
    0.0928    0.3475    0.0051
    0.6958    0.2035    0.2371
    0.3013    0.8496    0.4307
    0.9087    0.5629    0.6166
```

See Also

`haltonset` | `reset` | `sobolset` | `qrand`

qqplot

Quantile-quantile plot

Syntax

```
qqplot(X)
qqplot(X,Y)
qqplot(X,PD)
qqplot(X,Y,pvec)
h = qqplot(X,Y,pvec)
```

Description

`qqplot(X)` displays a quantile-quantile plot of the sample quantiles of `X` versus theoretical quantiles from a normal distribution. If the distribution of `X` is normal, the plot will be close to linear.

`qqplot(X,Y)` displays a quantile-quantile plot of two samples. If the samples do come from the same distribution, the plot will be linear.

`qqplot(X,PD)` makes an empirical quantile-quantile plot of the quantiles of the data in the vector `X` versus the quantiles of the distribution specified by `PD`, a `ProbDist` object of the `ProbDistUnivParam` class or `ProbDistUnivKernel` class.

For matrix `X` and `Y`, `qqplot` displays a separate line for each pair of columns. The plotted quantiles are the quantiles of the smaller data set.

The plot has the sample data displayed with the plot symbol `'+'`. Superimposed on the plot is a line joining the first and third quartiles of each distribution (this is a robust linear fit of the order statistics of the two samples). This line is extrapolated out to the ends of the sample to help evaluate the linearity of the data.

Use `qqplot(X,Y,pvec)` to specify the quantiles in the vector `pvec`.

`h = qqplot(X,Y,pvec)` returns handles to the lines in `h`.

Examples

Quantile-Quantile Plot With Two Samples

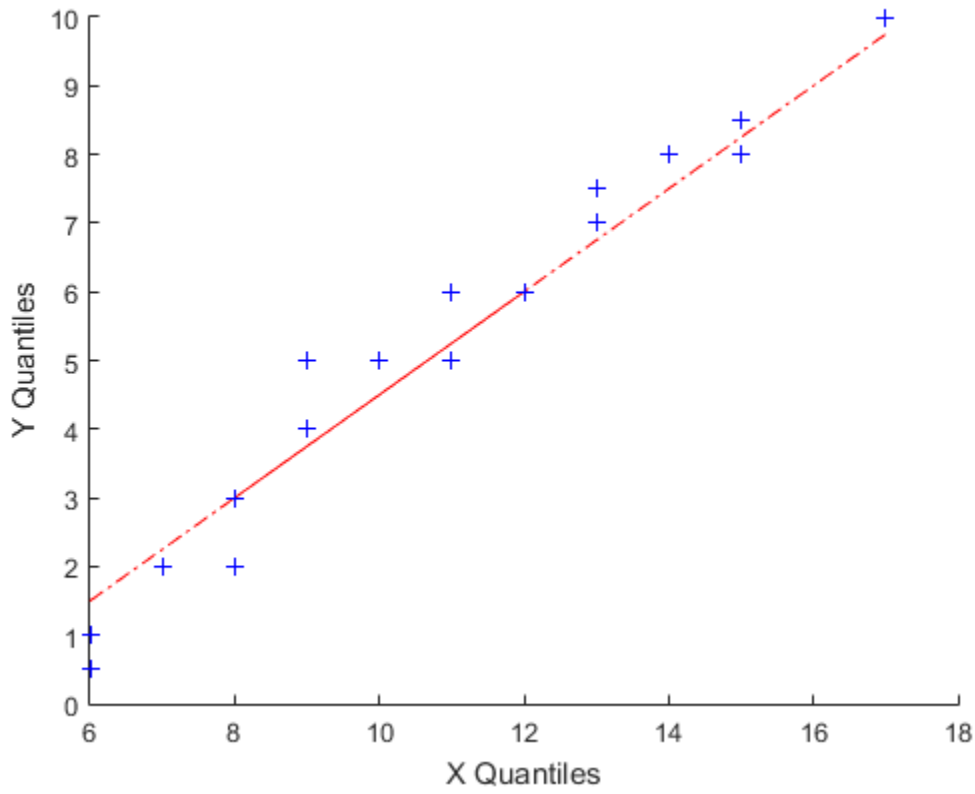
This example shows how to create a quantile-quantile plot using two sets of sample data.

Generate random numbers from two Poisson distributions. The vector `x` contains 50 random numbers from a Poisson distribution with `lambda = 10`. The vector `y` contains 100 random numbers from a Poisson distribution with `lambda = 5`.

```
rng default;  % For reproducibility
x = poissrnd(10,50,1);
y = poissrnd(5,100,1);
```

Create a quantile-quantile plot using the two sets of sample data.

```
qqplot(x,y);
```



The solid line in the plot joins the first and third quartiles. The dashed line extrapolates the solid line.

More About

- `normplot`

quantile

Quantiles of a data set

Syntax

```
Y = quantile(X,p)
Y = quantile(X,p,dim)

Y = quantile(X,N)
Y = quantile(X,N,dim)
```

Description

`Y = quantile(X,p)` returns quantiles of the values in data vector or matrix `X` for the cumulative probability or probabilities `p` in the interval [0,1].

- If `X` is a vector, then `Y` is a scalar or a vector having the same length as `p`.
- If `X` is a matrix, then `Y` is a row vector or a matrix where the number of rows of `Y` is equal to the length of `p`.
- For multidimensional arrays, `quantile` operates along the first nonsingleton dimension of `X`.

`Y = quantile(X,p,dim)` returns quantiles along dimension `dim`.

`Y = quantile(X,N)` returns quantiles for `N` evenly spaced cumulative probabilities (1/(`N` + 1), 2/(`N` + 1), ..., `N`/(`N` + 1)) for integer `N`>1.

- If `X` is a vector, then `Y` is a scalar or a vector with length `N`.
- If `X` is a matrix, then `Y` is a matrix where the number of rows of `Y` is equal to `N`.
- For multidimensional arrays, `quantile` operates along the first nonsingleton dimension of `X`.

`Y = quantile(X,N,dim)` returns quantiles at the `N` evenly-spaced cumulative probabilities (1/(`N`+1), 2/(`N`+1), ..., `N`/(`N`+1)) for integer `N`>1 along dimension `dim`.

Examples

Quantiles for Given Probabilities

Calculate the quantiles of a data set for specified probabilities.

Generate a data set of size 10.

```
rng('default'); % for reproducibility
x = normrnd(0,1,1,10)
```

```
x =
    0.5377    1.8339   -2.2588    0.8622    0.3188   -1.3077   -0.4336    0.3426    3.5
```

Calculate the 0.3 quantile.

```
y = quantile(x,0.30)
```

```
y =
   -0.0574
```

Calculate the quantiles for the cumulative probabilities 0.025, 0.25, 0.5, 0.75, and 0.975.

```
y = quantile(x,[0.025 0.25 0.50 0.75 0.975])
```

```
y =
   -2.2588   -0.4336    0.4401    1.8339    3.5784
```

Quantiles of a Matrix for Given Probabilities

Calculate the quantiles along the columns and rows of a data matrix for specified probabilities.

Generate a 4-by-6 data matrix.

```
rng('default'); % for reproducibility
X = normrnd(0,1,4,6)
```

```
X =
    0.5377    0.3188    3.5784    0.7254   -0.1241    0.6715
    1.8339   -1.3077    2.7694   -0.0631    1.4897   -1.2075
   -2.2588   -0.4336   -1.3499    0.7147    1.4090    0.7172
    0.8622    0.3426    3.0349   -0.2050    1.4172    1.6302
```

Calculate the 0.3 quantile for each column of `X` (`dim` = 1).

```
y = quantile(x,0.3,1)
```

```
y =
   -0.3013   -0.6958    1.5336   -0.1056    0.9491    0.1078
```

`quantile` returns a row vector `y` when calculating one quantile for each column of a matrix. For example, `-0.3013` is the 0.3 quantile of the first column of `X` with elements (0.5377, 1.8339, -2.2588, 0.8622). `y = quantile(X,0.3)` returns the same answer because the default value of `dim` is 1.

Calculate the 0.3 quantile for each row of `X` (`dim` = 2).

```
y = quantile(x,0.3,2)
```

```
y =
    0.3844
   -0.8642
   -1.0750
    0.4985
```

`quantile` returns a column vector `y` when calculating one quantile for each row of a matrix. For example `0.3844` is the 0.3 quantile of the first row of `X` with elements (0.5377, 0.3188, 3.5784, 0.7254, -0.1241, 0.6715).

Quantiles for *N* Evenly Spaced Cumulative Probabilities

Calculate the quantiles of a data set for a given number of quantiles.

Generate a data set of size 10.

```
rng('default'); % for reproducibility
x = normrnd(0,1,1,10)
```

```
x =
    0.5377    1.8339   -2.2588    0.8622    0.3188   -1.3077   -0.4336    0.3426    3.5
```

Calculate four evenly spaced quantiles.

```
y = quantile(x,4)
```

```
y =
   -0.8706    0.3307    0.6999    2.3017
```

Using `y = quantile(x,[0.2,0.4,0.6,0.8])` is another way to return the four evenly spaced quantiles.

Quantiles of a Matrix for Given Number of Quantiles

Calculate the *N* evenly spaced quantiles along the columns and rows of a data matrix.

Generate a 6-by-10 data matrix.

```
rng('default');  % for reproducibility
X = unidrnd(10,6,7)
```

```
X =

     9     3    10     8     7     8     7
    10     6     5    10     8     1     4
     2    10     9     7     8     3    10
    10    10     2     1     4     1     1
     7     2     5     9     7     1     5
     1    10    10    10     2     9     4
```

Calculate three evenly spaced quantiles for each column of `X` (`dim` = 1).

```
y = quantile(X,3,1)
```

```
y =

    2.0000    3.0000    5.0000    7.0000    4.0000    1.0000    4.0000
    8.0000    8.0000    7.0000    8.5000    7.0000    2.0000    4.5000
   10.0000   10.0000   10.0000   10.0000    8.0000    8.0000    7.0000
```

Each column of matrix `y` corresponds to the three evenly spaced quantiles of each column of matrix `X`. For example, the first column of `y` with elements (2, 8, 10) has the quantiles for the first column of `X` with elements (9, 10, 2, 10, 7, 1). `y = quantile(X,3)` returns the same answer because the default value of `dim` is 1.

Calculate three evenly spaced quantiles for each row of `X` (`dim` = 2).

```
y = quantile(X,3,2)
```

```
y =

    7.0000    8.0000    8.7500
    4.2500    6.0000    9.5000
    4.0000    8.0000    9.7500
```

```
    1.0000    2.0000    8.5000
    2.7500    5.0000    7.0000
    2.5000    9.0000   10.0000
```

Each row of matrix `y` corresponds to the three evenly spaced quantiles of each row of matrix `X`. For example, the first row of `y` with elements (7, 8, 8.75) has the quantiles for the first column of `X` with elements (9, 3, 10, 8, 7, 8, 7).

Median and Quartiles for Even Number of Data Elements

Find median and quartiles of a vector, `x`, with even number of elements.

Enter the data.

```
x = [2 5 6 10 11 13]
```

```
x =
     2     5     6    10    11    13
```

Calculate the median of `x`.

```
y = quantile(x,0.50)
```

```
y =
     8
```

Calculate the quartiles of `x`.

```
y = quantile(x,[0.25, 0.5, 0.75])
```

```
y =
     5     8    11
```

Using `y = quantile(x,3)` is another way to compute the quartiles of `x`.

These results might be different than the textbook definitions because `quantile` uses linear interpolation to find the median and quartiles.

Median and Quartiles for Odd Number of Data Elements

Find median and quartiles of a vector, `x`, with odd number of elements.

Enter the data.

```
x = [2 4 6 8 10 12 14]
```

```
x =

     2     4     6     8    10    12    14
```

Find the median of `x`.

```
y = quantile(x,0.50)
```

```
y =
     8
```

Find the quartiles of `x`.

```
y = quantile(x,[0.25, 0.5, 0.75])
```

```
y =
    4.5000    8.0000   11.5000
```

Using `y = quantile(x,3)` is another way to compute the quartiles of `x`.

These results might be different than the textbook definitions because `quantile` uses linear interpolation to find the median and quartiles.

Input Arguments

`X` — Input data

vector | array

Input data, specified as a vector or array.

Data Types: `double` | `single`

`p` — Cumulative probabilities

scalar | vector

Cumulative probabilities, for which to compute the quantiles, specified as a scalar or vector of scalars from 0 to 1.

Example: 0.3

Example: [0.25, 0.5, 0.75]

Example: (0:0.25:1)

Data Types: `double` | `single`

N — Number of quantiles

positive integer

Number of quantiles to compute, specified as a positive integer. `quantile` returns `N` quantiles that divide the data set into evenly distributed `N`+1 segments.

Data Types: `double` | `single`

dim — Dimension

1 (default) | positive integer

Dimension along which the quantiles of a matrix `X` are required, specified as a positive integer. For example, for a matrix `X`, when `dim` = 1, `quantile` returns the quantile(s) of the columns of `X` and when `dim` = 2, quantile returns the quantile(s) of the rows of `X`. For a multidimensional array `X`, the length of the `dim`th dimension of `Y` is same as length of `p`.

Output Arguments

Y — Quantiles

scalar | array

Quantiles of a data vector or matrix, returned as a scalar or array for one or multiple values of cumulative probabilities.

- If `X` is a vector, then `Y` is a scalar or a vector with the same length as the number of quantiles required (`N` or `length(p)`). `Y(i)` contains the `p(i)` quantile.
- If `X` is a matrix, then `Y` is a vector or a matrix with the length of `dim`th dimension equal to the number of quantiles required (`N` or `length(p)`). When `dim` = 1, for example, the `i`th row of `Y` contains the `p(i)` quantiles of columns of `X`.
- If `X` is an array of dimension *d*, then `Y` is an array with the length of `dim`th dimension equal to the number of quantiles required (`N` or `length(p)`).

More About

Multidimensional Array

A *multidimensional array* is an array with more than two dimensions. For example, if `X` is a 1-by-3-by-4 array, then `X` is a 3-D array.

First Nonsingleton Dimension

A *first nonsingleton dimension* is the first dimension of an array whose size is not equal to 1. For example, if `X` is a 1-by-2-by-3-by-4 array, then the second dimension is the first nonsingleton dimension of `X`.

Linear Interpolation

Linear interpolation uses linear polynomials to find $y_i = f(x_i)$, the values of the underlying function $Y = f(X)$ at the points in the vector or array x. Given the data points (x_1, y_1) and (x_2, y_2), where $y_1 = f(x_1)$ and $y_2 = f(x_2)$, linear interpolation finds $y = f(x)$ for a given x between x_1 and x_2 as follows:

$$y = f(x) = y_1 + \frac{(x - x_1)}{(x_2 - x_1)}(y_2 - y_1).$$

Similarly, if the $1.5/n$ quantile is $y_{1.5/n}$ and the $2.5/n$ quantile is $y_{2.5/n}$, then linear interpolation finds the $2.3/n$ quantile $y_{2.3/n}$ as

$$y_{\frac{2.3}{n}} = y_{\frac{1.5}{n}} + \frac{\left(\frac{2.3}{n} - \frac{1.5}{n}\right)}{\left(\frac{2.5}{n} - \frac{1.5}{n}\right)}\left(y_{\frac{2.5}{n}} - y_{\frac{1.5}{n}}\right).$$

Algorithms

For an n-element vector `X`, `quantile` computes quantiles as follows:

1. The sorted values in `X` are taken as the $(0.5/n)$, $(1.5/n)$, ..., $([n - 0.5]/n)$ quantiles. For example:
   - For a data vector of five elements such as {6, 3, 2, 10, 1}, the sorted elements {1, 2, 3, 6, 10} respectively correspond to the 0.1, 0.3, 0.5, 0.7, 0.9 quantiles.
   - For a data vector of six elements such as {6, 3, 2, 10, 8, 1}, the sorted elements {1, 2, 3, 6, 8, 10} respectively correspond to the (0.5/6), (1.5/6), (2.5/6), (3.5/6), (4.5/6), (5.5/6) quantiles.
2. `quantile` uses Linear interpolation to compute quantiles for probabilities between $(0.5/n)$ and $([n - 0.5]/n)$.

3 For the quantiles corresponding to the probabilities outside that range, `quantile` assigns the minimum or maximum values in `X`.

`quantile` treats `NaN`s as missing values and removes them.

rand

Class: qrandstream

Generate quasi-random points from stream

Syntax

```
rand
rand(q,n)
rand(q)
rand(q,m,n)
rand(q,[m,n])
rand(q,m,n,p,...)
rand(q,[m,n,p,...])
```

Description

`rand` returns a matrix of quasi-random values and is intended to allow objects of the `qrandstream` class to be used in code that contains calls to the `rand` method of the MATLAB pseudo-random `randstream` class. Due to the multidimensional nature of quasi-random numbers, only some syntaxes of `rand` are supported by the `qrandstream` class.

`rand(q,n)` returns an `n`-by-`n` matrix only when `n` is equal to the number of dimensions. Any other value of `n` produces an error.

`rand(q)` returns a scalar only when the stream is in one dimension. Having more than one dimension in `q` produces an error.

`rand(q,m,n)` or `rand(q,[m,n])` returns an `m`-by-`n` matrix only when `n` is equal to the number of dimensions in the stream. Any other value of `n` produces an error.

`rand(q,m,n,p,...)` or `rand(q,[m,n,p,...])` produces an error unless `p` and all following dimensions sizes are equal to one.

Examples

Generate the first 256 points from a 5-D Sobol sequence:

```
q = qrandstream('sobol',5);
X = rand(q,256,5);
```

See Also

`qrandstream` | `qrand` | `rand`

randg

Gamma random numbers with unit scale

Syntax

```
Y = randg
Y = randg(A)
Y = randg(A,m)
Y = randg(A,m,n,p,...)
Y = randg(A,[m,n,p,...])
```

Description

`Y = randg` returns a scalar random value chosen from a gamma distribution with unit scale and shape.

`Y = randg(A)` returns a matrix of random values chosen from gamma distributions with unit scale. `Y` is the same size as `A`, and `randg` generates each element of `Y` using a shape parameter equal to the corresponding element of `A`.

`Y = randg(A,m)` returns an `m`-by-`m` matrix of random values chosen from gamma distributions with shape parameters `A`. `A` is either an `m`-by-`m` matrix or a scalar. If `A` is a scalar, `randg` uses that single shape parameter value to generate all elements of `Y`.

`Y = randg(A,m,n,p,...)` or `Y = randg(A,[m,n,p,...])` returns an `m`-by-`n`-by-`p`-by-`...` array of random values chosen from gamma distributions with shape parameters `A`. `A` is either an `m`-by-`n`-by-`p`-by-`...` array or a scalar.

`randg` produces pseudo-random numbers using the MATLAB functions `rand` and `randn`. The sequence of numbers generated is determined by the settings of the uniform random number generator that underlies `rand` and `randn`. Control that shared random number generator using `rng`. See the `rng` documentation for more information.

Note: To generate gamma random numbers and specify both the scale and shape parameters, you should call `gamrnd`.

Examples

Example 1

Generate a 100-by-1 array of values drawn from a gamma distribution with shape parameter 3.

```
r = randg(3,100,1);
```

Example 2

Generate a 100-by-2 array of values drawn from gamma distributions with shape parameters 3 and 2.

```
A = [ones(100,1)*3,ones(100,1)*2];
r = randg(A,[100,2]);
```

Example 3

To create reproducible output from `randg`, reset the random number generator used by `rand` and `randn` to its default startup settings. This way `randg` produces the same random numbers as if you restarted MATLAB.

```
rng('default')
randg(3,1,5)

ans =

    6.9223    4.3369    1.0505    3.2662   11.3269
```

Example 4

Save the settings for the random number generator used by `rand` and `randn`, generate 5 values from `randg`, restore the settings, and repeat those values.

```
s = rng; % Obtain the current state of the random stream
r1 = randg(10,1,5)

r1 =
```

```
    9.4719    9.0433   15.0774   14.7763    6.3775

rng(s); % Reset the stream to the previous state
r2 = randg(10,1,5)

r2 =

    9.4719    9.0433   15.0774   14.7763    6.3775
```

`r2` contains exactly the same values as `r1`.

Example 5

Reinitialize the random number generator used by `rand` and `randn` with a seed based on the current time. `randg` returns different values each time you do this. Note that it is usually not necessary to do this more than once per MATLAB session.

```
rng('shuffle');
randg(2,1,5);
```

`gamrnd`

random

Random numbers

Syntax

```
Y = random(pd)
Y = random(pd,m,n,...)
Y = random(pd,[m,n,...])
Y = random(name,A)
Y = random(name,A,B)
Y = random(name,A,B,C)
Y = random(name,A,m,n,...)
Y = random(name,A,[m,n,...])
Y = random(name,A,B,m,n,...)
Y = random(name,A,B,[m,n,...])
Y = random(name,A,B,C,m,n,...)
Y = random(name,A,B,C,[m,n,...])
```

Description

`Y = random(pd)` returns a random number `Y` from the distribution specified by the probability distribution object `pd`. You can create a probability distribution object with specified parameter values using `makedist`, or fit a probability distribution object to sample data using `fitdist`.

`Y = random(pd,m,n,...)` or `Y = random(pd,[m,n,...])` returns an `m`-by-`n`-by... matrix of random numbers from the probability distribution specified by `pd`.

`Y = random(name,A)` where `name` is the name of a distribution that takes a single parameter, returns random numbers `Y` from the one-parameter family of distributions specified by `name`. Parameter values for the distribution are given in `A`.

`Y` is the same size as `A`.

`Y = random(name,A,B)` returns random numbers `Y` from a two-parameter family of distributions. Parameter values for the distribution are given in `A` and `B`.

If A and B are arrays, they must be the same size. If either A or B are scalars, they are expanded to constant matrices of the same size.

`Y = random(name,A,B,C)` returns random numbers Y from a three-parameter family of distributions. Parameter values for the distribution are given in A, B, and C.

If A, B, and C are arrays, they must be the same size. If any of A, B, or C are scalars, they are expanded to constant matrices of the same size.

`Y = random(name,A,m,n,...)` or `Y = random(name,A,[m,n,...])` returns an m-by-n-by... matrix of random numbers.

Similarly, `Y = random(name,A,B,m,n,...)` or `Y = random(name,A,B,[m,n,...])` returns an m-by-n-by... matrix of random numbers for distributions that require two parameters. `Y = random(name,A,B,C,m,n,...)` or `Y = random(name,A,B,C,[m,n,...])` returns an m-by-n-by... matrix of random numbers for distributions that require three parameters.

If any of A, B, or C are arrays, then the specified dimensions must match the common dimensions of A, B, and C after any necessary scalar expansion.

The following table denotes the acceptable strings for name, as well as the parameters for that distribution:

name	Distribution	Input Parameter A	Input Parameter B	Input Parameter C
'beta' or 'Beta'	"Beta Distribution" on page B-4	a	b	—
'bino' or 'Binomial'	"Binomial Distribution" on page B-9	n: number of trials	p: probability of success for each trial	—

Examples

Generate a 2-by-4 array of random values from the normal distribution with mean 0 and standard deviation 1:

```
x1 = random('Normal',0,1,2,4)
```

```
x1 =
  1.1650   0.0751   -0.6965   0.0591
  0.6268   0.3516   1.6961   1.7971
```

The order of the parameters is the same as for normrnd.

Generate a single random value from Poisson distributions with rate parameters 1, 2, ..., 6, respectively:

```
x2 = random('Poisson',1:6,1,6)
```

```
x2 = random('Poisson',1:6,1,6)
x2 =
```

```
    0    0    1    2    5    7
```

random

Class: GeneralizedLinearModel

Simulate responses for generalized linear regression model

Syntax

```
ysim = random(mdl,Xnew)
ysim = random(mdl,Xnew,Name,Value)
```

Description

`ysim = random(mdl,Xnew)` simulates responses from the `mdl` generalized linear model to the data in `Xnew`.

`ysim = random(mdl,Xnew,Name,Value)` simulates responses with additional options specified by one or more Name,Value pair arguments.

Input Arguments

`mdl`

Generalized linear model, as constructed by `fitglm` or `stepwiseglm`.

`Xnew`

Points at which `mdl` predicts responses.

- If `Xnew` is a table or dataset array, it must contain the predictor names in `mdl`.
- If `Xnew` is a numeric matrix, it must have the same number of variables (columns) as was used to create `mdl`. Furthermore, all variables used in creating `mdl` must be numeric.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single

quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'BinomialSize'`

The value of the binomial n parameter for each row in the training data. `BinomialSize` can be a vector the same length as `Xnew`, or a scalar that applies to each row. The default value `1` produces `ysim` values that are predicted proportions. Use `BinomialSize` only if `mdl` is fit to a binomial distribution.

Default: `1`

`'Offset'`

Value of the offset for each row in `Xnew`. `Offset` can be a vector the same length as `Xnew`, or a scalar that applies to each row. The offset is used as an additional predictor with a coefficient value fixed at `1`. In other words, if `b` is the fitted coefficient vector, and `link` is the link function,
`link(ysim) = Offset + Xnew * b`.

Default: `zeros(size(Xnew,1))`

Output Arguments

`ysim`

Vector of simulated values at `Xnew`.

`random` generates `ysim` using random values with mean given by the fitted model, and with the distribution used in `mdl`. The values in `ysim` are independent conditional on the predictors. For binomial and Poisson fits, `random` generates `ysim` with the specified distribution with no adjustment for any estimated dispersion.

Examples

Generalized Linear Model Simulation

Create a generalized linear model, and simulate its response to new data.

Generate artificial data for the model, Poisson random numbers with one underlying predictors X.

```
rng('default') % reproducible
X = rand(20,1);
mu = exp(1 + 2*X);
y = poissrnd(mu);
```

Create a generalized linear regression model of Poisson data.

```
mdl = fitglm(X,y,'y ~ x1','distr','poisson');
```

Create points for prediction.

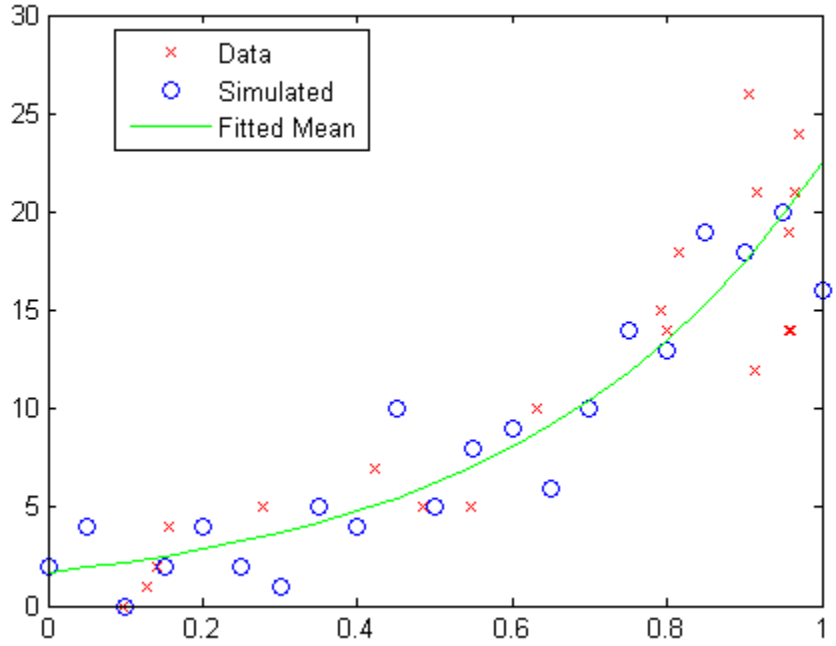
```
Xnew = (0:.05:1)';
```

Simulate responses at the new points.

```
ysim = random(mdl,Xnew);
```

Plot the simulated values along with the original values.

```
plot(X,y,'rx',Xnew,ysim,'bo',...
    Xnew,feval(mdl,Xnew),'g-')
legend('Data','Simulated','Fitted Mean',...
    'Location','best')
```



- “random” on page 10-37

Alternatives

For predictions without random noise, use `predict` or `feval`.

More About

- “Generalized Linear Models” on page 10-12

random

Class: GeneralizedLinearMixedModel

Generate random responses from fitted generalized linear mixed-effects model

Syntax

```
ysim = random(glme)
ysim = random(glme,tblnew)
ysim = random( ___ ,Name,Value)
```

Description

`ysim = random(glme)` returns simulated responses, ysim, from the fitted generalized linear mixed-effects model glme, at the original design points.

`ysim = random(glme,tblnew)` returns simulated responses using new input values specified in the table or dataset array, tblnew.

`ysim = random( ___ ,Name,Value)` returns simulated responses using additional options specified by one or more `Name,Value` pair arguments, using any of the previous syntaxes. For example, you can specify observation weights, binomial sizes, or offsets for the model.

Input Arguments

`glme` — Generalized linear mixed-effects model

`GeneralizedLinearMixedModel` object

Generalized linear mixed-effects model, specified as a `GeneralizedLinearMixedModel` object. For properties and methods of this object, see `GeneralizedLinearMixedModel`.

`tblnew` — New input data

table | dataset array

New input data, which includes the response variable, predictor variables, and grouping variables, specified as a table or dataset array. The predictor variables can be continuous or grouping variables. tblnew must contain the same variables as the original table or dataset array, `tbl`, used to fit the generalized linear mixed-effects model glme.

Data Types: `single` | `double` | `logical` | `char`

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'BinomialSize'` — Number of trials for binomial distribution

`ones(m,1)` (default) | *m*-by-1 vector of positive integer values

Number of trials for binomial distribution, specified as the comma-separated pair consisting of 'BinomialSize' and an *m*-by-1 vector of positive integer values, where *m* is the number of rows in tblnew. The 'BinomialSize' name-value pair applies only to the binomial distribution. The value specifies the number of binomial trials when generating the random response values.

Data Types: `single` | `double`

`'Offset'` — Model offset

`zeros(m,1)` (default) | vector of scalar values

Model offset, specified as a vector of scalar values of length *m*, where *m* is the number of rows in tblnew. The offset is used as an additional predictor and has a coefficient value fixed at `1`.

`'Weights'` — Observation weights

m-by-1 vector of nonnegative scalar values

Observation weights, specified as the comma-separated pair consisting of 'Weights' and an *m*-by-1 vector of nonnegative scalar values, where *m* is the number of rows in tblnew. If the response distribution is binomial or Poisson, then 'Weights' must be a vector of positive integers.

Data Types: `single` | `double`

Output Arguments

`ysim` — Simulated response values

m-by-1 vector

Simulated response values, returned as an *m*-by-1 vector, where *m* is the number of rows in tblnew. `random` creates ysim by first generating the random-effects vector based on its fitted prior distribution. `random` then generates ysim from its fitted conditional distribution given the random effects. `random` takes into account the effect of observation weights specified when fitting the model using `fitglme`, if any.

Definitions

Conditional Distribution Method

`random` generates random data from the fitted generalized linear mixed-effects model as follows:

- Sample $b_{sim} \sim P\left(b \mid \theta, \sigma^2\right)$, where $P\left(b \mid \theta, \sigma^2\right)$ is the estimated prior distribution of random effects, and $\hat{\theta}$ is a vector of estimated covariance parameters, and $\hat{\sigma}^2$ is the estimated dispersion parameter.
- Given b_{sim}, for $i = 1$ to m, sample $y_{sim\_i} \sim P\left(y_{new\_i} \mid b_{sim}, \beta, \theta, \sigma^2\right)$, where $P\left(y_{new\_i} \mid b_{sim}, \beta, \theta, \sigma^2\right)$ is the conditional distribution of the ith new response y_{new_i} given b_{sim} and the model parameters.

Examples

Simulate Random Responses From a GLME Model

Navigate to the folder containing the sample data. Load the sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

```
load mfr
```

This simulated data is from a manufacturing company that operates 50 factories across the world, with each factory running a batch process to create a finished product. The company wants to decrease the number of defects in each batch, so it developed a new manufacturing process. To test the effectiveness of the new process, the company selected 20 of its factories at random to participate in an experiment: Ten factories implemented the new process, while the other ten continued to run the old process. In each of the 20 factories, the company ran five batches (for a total of 100 batches) and recorded the following data:

- Flag to indicate whether the batch used the new process (`newprocess`)
- Processing time for each batch, in hours (`time`)
- Temperature of the batch, in degrees Celsius (`temp`)
- Categorical variable indicating the supplier (`A`, `B`, or `C`) of the chemical used in the batch (`supplier`)
- Number of defects in the batch (`defects`)

The data also includes `time_dev` and `temp_dev`, which represent the absolute deviation of time and temperature, respectively, from the process standard of 3 hours at 20 degrees Celsius.

Fit a generalized linear mixed-effects model using `newprocess`, `time_dev`, `temp_dev`, and `supplier` as fixed-effects predictors. Include a random-effects term for intercept grouped by `factory`, to account for quality differences that might exist due to factory-specific variations. The response variable `defects` has a Poisson distribution, and the appropriate link function for this model is log. Use the Laplace fit method to estimate the coefficients. Specify the dummy variable encoding as `'effects'`, so the dummy variable coefficients sum to 0.

The number of defects can be modeled using a Poisson distribution

$$defects_{ij} \sim Poisson\left(\mu_{ij}\right)$$

This corresponds to the generalized linear mixed-effects model

$$\log\left(\mu_{ij}\right) = \beta_0 + \beta_1 newprocess_{ij} + \beta_2 time\_dev_{ij} + \beta_3 temp\_dev_{ij} + \beta_4 supplier\_C_{ij} + \beta_5 supplier\_B_{ij} +$$

where

- $defects_{ij}$ is the number of defects observed in the batch produced by factory i during batch j.
- μ_{ij} is the mean number of defects corresponding to factory i (where i = 1, 2, ..., 20) during batch j (where j = 1, 2, ..., 5).
- $newprocess_{ij}$, $time\_dev_{ij}$, and $temp\_dev_{ij}$ are the measurements for each variable that correspond to factory i during batch j. For example, $newprocess_{ij}$ indicates whether the batch produced by factory i during batch j used the new process.
- $supplier\_C_{ij}$ and $supplier\_B_{ij}$ are dummy variables that use effects (sum-to-zero) coding to indicate whether company `C` or `B`, respectively, supplied the process chemicals for the batch produced by factory i during batch j.
- $b_i \sim N(0,\sigma_b^2)$ is a random-effects intercept for each factory i that accounts for factory-specific variation in quality.

```
glme = fitglme(mfr,'defects ~ 1 + newprocess + time_dev + temp_dev + supplier + (1|fact
```

Use `random` to simulate a new response vector from the fitted model.

```
rng(0,'twister');  % For reproducibility
ynew = random(glme);
```

Display the first 10 rows of the simulated response vector.

```
ynew(1:10)
```

```
ans =

     3
     3
     1
     7
     5
     8
     7
     9
     5
     9
```

Simulate a new response vector using new input values. Create a new table by copying the first 10 rows of `mfr` into `tblnew`.

```
tblnew = mfr(1:10,:);
```

The first 10 rows of `mfr` include data collected from trials 1 through 5 for factories 1 and 2. Both factories used the old process for all of their trials during the experiment, so `newprocess = 0` for all 10 observations.

Change the value of `newprocess` to `1` for the observations in `tblnew`.

```
tblnew.newprocess = ones(height(tblnew),1);
```

Simulate new responses using the new input values in `tblnew`.

```
ynew2 = random(glme,tblnew)
```

```
ynew2 =

     2
     3
     5
     4
     2
     2
     2
     1
     2
     0
```

random

Class: gmdistribution

Random numbers from Gaussian mixture distribution

Syntax

```
y = random(obj)
Y = random(obj,n)
[Y,idx] = random(obj,n)
```

Description

`y = random(obj)` generates a 1-by-*d* vector `y` drawn at random from the *d*-dimensional Gaussian mixture distribution defined by `obj`. `obj` is an object created by `gmdistribution` or `fitgmdist`.

`Y = random(obj,n)` generates an `n`-by-*d* matrix `Y` of `n` *d*-dimensional random samples.

`[Y,idx] = random(obj,n)` also returns an `n`-by-1 vector `idx`, where `idx(I)` is the index of the component used to generate `Y(I,:)`.

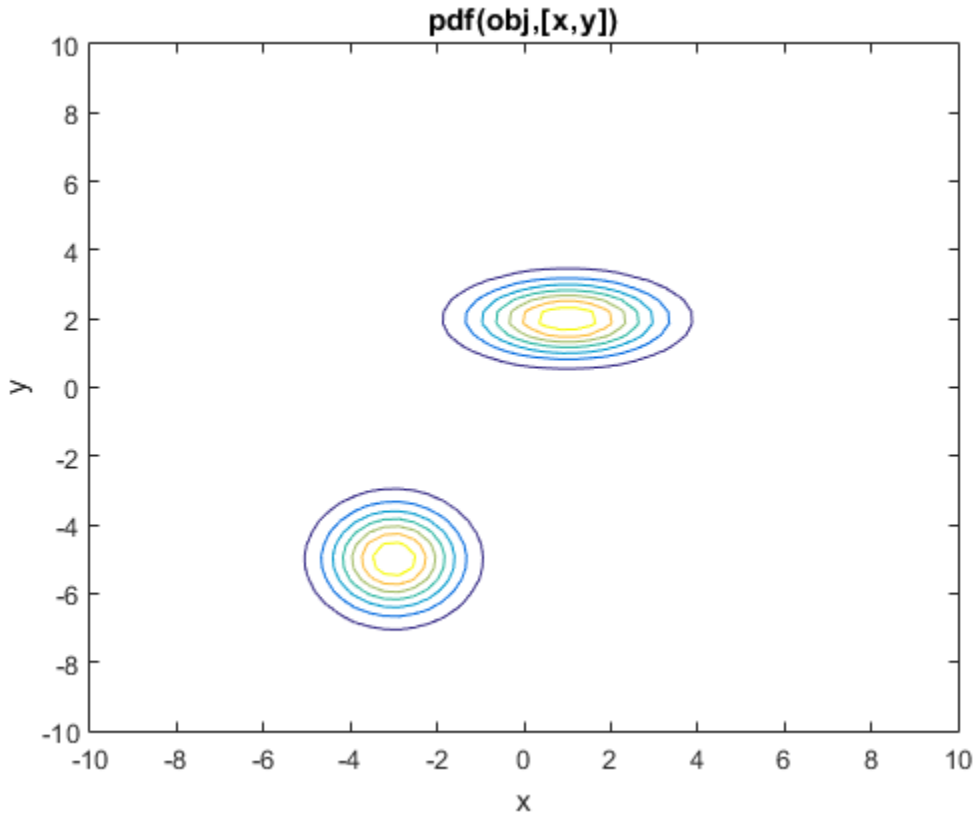
Examples

Generate Gaussian Mixture Variates

Create a `gmdistribution` object defining a two-component mixture of bivariate Gaussian distributions.

```
MU = [1 2;-3 -5];
SIGMA = cat(3,[2 0;0 .5],[1 0;0 1]);
p = ones(1,2)/2;
obj = gmdistribution(MU,SIGMA,p);

ezcontour(@(x,y)pdf(obj,[x y]),[-10 10],[-10 10])
hold on
```



Generate 1000 random values.

```
rng(1); % For reproducibility
Y = random(obj,1000);

scatter(Y(:,1),Y(:,2),10,'.')
```

`gmdistribution` | `mvnrnd` | `fitgmdist`

random

Class: LinearModel

Simulate responses for linear regression model

Syntax

```
ysim = random(mdl)
ysim = random(mdl,Xnew)
```

Description

`ysim = random(mdl)` simulates responses from the fitted linear model `mdl` at the original design points.

`ysim = random(mdl,Xnew)` simulates responses from the `mdl` linear model to the data in `Xnew`, adding random noise.

Input Arguments

`mdl`

Linear model, as constructed by `fitlm` or `stepwiselm`.

`Xnew`

Points at which `mdl` predicts responses.

- If `Xnew` is a table or dataset array, it must contain the predictor names in `mdl`.
- If `Xnew` is a numeric matrix, it must have the same number of variables (columns) as was used to create `mdl`. Furthermore, all variables used in creating `mdl` must be numeric.

Output Arguments

`ysim`

Vector of predicted mean values at `Xnew`, perturbed by random noise. The noise is independent, normally distributed, with mean zero, and variance equal to the estimated error variance of the model.

Examples

Simulate Response Data

Create a model of car mileage as a function of weight, and simulate the response.

Create a quadratic model of car mileage as a function of weight from the `carsmall` data.

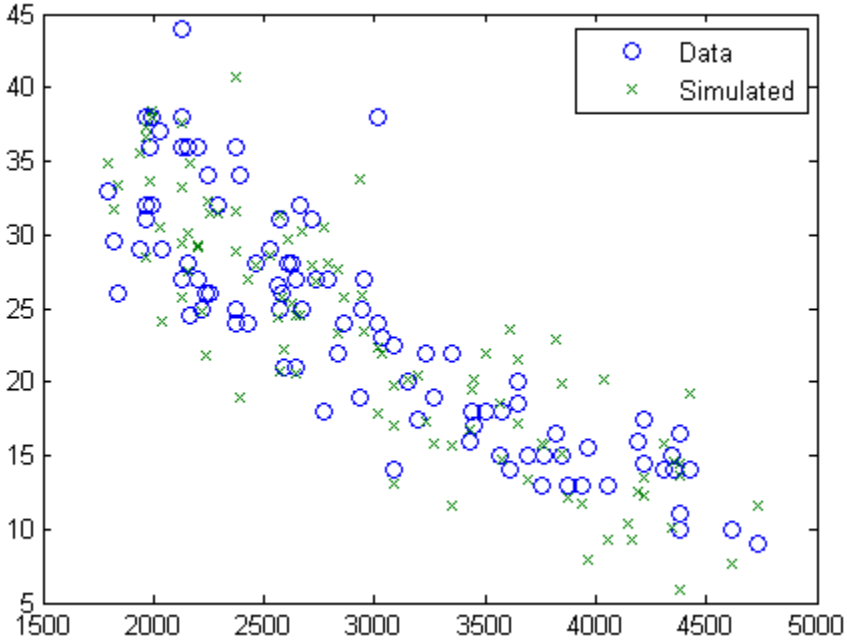
```
load carsmall
X = Weight;
y = MPG;
mdl = fitlm(X,y,'quadratic');
```

Create simulated responses to the data.

```
Xnew = X;
ysim = random(mdl,Xnew);
```

Plot the original responses and the simulated responses to see how they differ.

```
plot(X,y,'o',X,ysim,'x')
legend('Data','Simulated')
```



- “random” on page 9-39

Alternatives

For predictions without random noise, use `predict` or `feval`.

How To

- “Linear Regression” on page 9-11

random

Class: LinearMixedModel

Generate random responses from fitted linear mixed-effects model

Syntax

```
ysim = random(lme)
ysim = random(lme,tblnew)
ysim = random(lme,Xnew,Znew)
ysim = random(lme,Xnew,Znew,Gnew)
```

Description

`ysim = random(lme)` returns a vector of simulated responses ysim from the fitted linear mixed-effects model lme at the original fixed- and random-effects design points, used to fit lme.

`random` simulates new random-effects vector and new observation errors. So, the simulated response is

$$y_{sim} = X\hat{\beta} + Z\hat{b} + \varepsilon,$$

where $\hat{\beta}$ is the estimated fixed-effects coefficients, $\hat{b}$ is the new random effects, and ε is the new observation error.

`random` also accounts for the effect of observation weights, if you use any when fitting the model.

`ysim = random(lme,tblnew)` returns a vector of simulated responses ysim from the fitted linear mixed-effects model lme at the values in the new table or dataset array `tblnew`. Use a table or dataset array for `random` if you use a table or dataset array for fitting the model lme.

`ysim = random(lme,Xnew,Znew)` returns a vector of simulated responses ysim from the fitted linear mixed-effects model lme at the values in the new fixed- and random-

effects design matrices, `Xnew` and `Znew`, respectively. `Znew` can also be a cell array of matrices. Use the matrix format for `random` if you use design matrices for fitting the model `lme`.

`ysim = random(lme,Xnew,Znew,Gnew)` returns a vector of simulated responses `ysim` from the fitted linear mixed-effects model `lme` at the values in the new fixed- and random-effects design matrices, `Xnew` and `Znew`, respectively, and the grouping variable `Gnew`.

`Znew` and `Gnew` can also be cell arrays of matrices and grouping variables, respectively.

Input Arguments

`lme` — Linear mixed-effects model

`LinearMixedModel` object

Linear mixed-effects model, returned as a `LinearMixedModel` object.

For properties and methods of this object, see `LinearMixedModel`.

`tblnew` — New input data

table | `dataset` array

New input data, which includes the response variable, predictor variables, and grouping variables, specified as a table or dataset array. The predictor variables can be continuous or grouping variables. `tblnew` must have the same variables as in the original table or dataset array used to fit the linear mixed-effects model `lme`.

Data Types: `single` | `double` | `logical` | `char`

`Xnew` — New fixed-effects design matrix

n-by-p matrix

New fixed-effects design matrix, specified as an n-by-p matrix, where n is the number of observations and p is the number of fixed predictor variables. Each row of `X` corresponds to one observation and each column of `X` corresponds to one variable.

Data Types: `single` | `double`

`Znew` — New random-effects design

n-by-q matrix | cell array of length R

New random-effects design, specified as an n-by-q matrix or a cell array of R design matrices `Z{r}`, where $r = 1, 2, ..., R$. If `Znew` is a cell array, then each `Z{r}` is an n-by-$q(r)$ matrix, where n is the number of observations, and $q(r)$ is the number of random predictor variables.

Data Types: `single` | `double` | `logical` | `char` | `cell`

`Gnew` — New grouping variable or variables

vector | cell array of grouping variables of length R

New grouping variable or variables, specified as a vector or a cell array, of length R, of grouping variables used to fit the linear mixed-effects model, lme.

`random` treats all levels of each grouping variable as new levels. It draws an independent random effects vector for each level of each grouping variable.

Data Types: `single` | `double` | `logical` | `char` | `cell`

Output Arguments

`ysim` — Simulated response values

n-by-1 vector

Simulated response values, returned as an n-by-1 vector, where n is the number of observations.

Examples

Generate Random Responses at the Original Design Values

Navigate to a folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load fertilizer
```

The dataset array includes data from a split-plot experiment, where soil is divided into three blocks based on the soil type: sandy, silty, and loamy. Each block is divided into

five plots, where five different types of tomato plants (cherry, heirloom, grape, vine, and plum) are randomly assigned to these plots. The tomato plants in the plots are then divided into subplots, where each subplot is treated by one of four fertilizers. This is simulated data.

Store the data in a dataset array called `ds`, for practical purposes, and define `Tomato`, `Soil`, and `Fertilizer` as categorical variables.

```
ds = fertilizer;
ds.Tomato = nominal(ds.Tomato);
ds.Soil = nominal(ds.Soil);
ds.Fertilizer = nominal(ds.Fertilizer);
```

Fit a linear mixed-effects model, where `Fertilizer` and `Tomato` are the fixed-effects variables, and the mean yield varies by the block (soil type), and the plots within blocks (tomato types within soil types) independently.

```
lme = fitlme(ds,'Yield ~ Fertilizer * Tomato + (1|Soil) + (1|Soil:Tomato)');
```

Generate random response values at the original design points. Display the first five values.

```
rng(123,'twister') % For reproducibility
ysim = random(lme);
ysim(1:5)
```

```
ans =

  114.8785
  134.2018
  154.2818
  169.7554
   84.6089
```

Plot Randomly Generated vs. Observed Response Values

Load the sample data.

```
load carsmall
```

Fit a linear mixed-effects model, with a fixed-effects for `Weight`, and a random intercept grouped by `Model_Year`. First, store the data in a table.

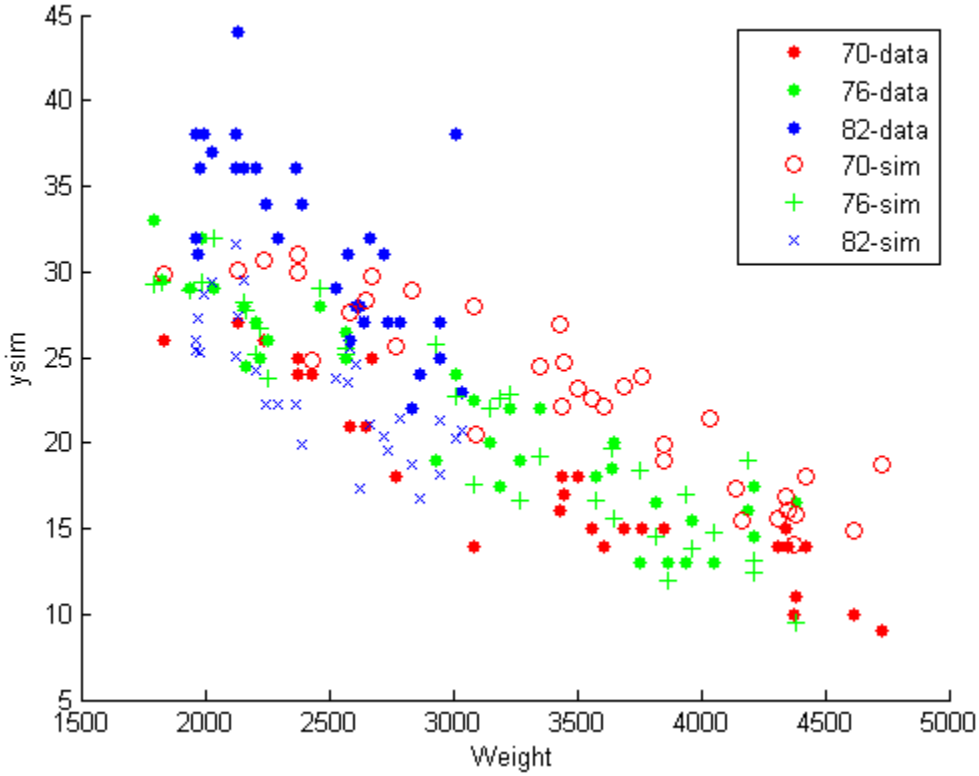
```
tbl = table(MPG,Weight,Model_Year);
lme = fitlme(tbl,'MPG ~ Weight + (1|Model_Year)');
```

Randomly generate responses using the original data.

```
rng(123,'twister') % For reproducibility
ysim = random(lme,tbl);
```

Plot the original and the randomly generated responses to see how they differ. Group them by model year.

```
figure()
gscatter(Weight,MPG,Model_Year)
hold on
gscatter(Weight,ysim,Model_Year,[],'o+x')
legend('70-data','76-data','82-data','70-sim','76-sim','82-sim')
hold off
```



Note that the simulated random response values for year 82 are lower than the original data for that year. This might be due to a lower simulated random effect for year 82 than the estimated random effect in the original data.

Generate Responses Using a New Dataset Array

Navigate to a folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load fertilizer
```

The dataset array includes data from a split-plot experiment, where soil is divided into three blocks based on the soil type: sandy, silty, and loamy. Each block is divided into five plots, where five different types of tomato plants (cherry, heirloom, grape, vine, and plum) are randomly assigned to these plots. The tomato plants in the plots are then divided into subplots, where each subplot is treated by one of four fertilizers. This is simulated data.

Store the data in a dataset array called `ds`, for practical purposes, and define `Tomato`, `Soil`, and `Fertilizer` as categorical variables.

```
ds = fertilizer;
ds.Tomato = nominal(ds.Tomato);
ds.Soil = nominal(ds.Soil);
ds.Fertilizer = nominal(ds.Fertilizer);
```

Fit a linear mixed-effects model, where `Fertilizer` and `Tomato` are the fixed-effects variables, and the mean yield varies by the block (soil type), and the plots within blocks (tomato types within soil types) independently.

```
lme = fitlme(ds,'Yield ~ Fertilizer * Tomato + (1|Soil) + (1|Soil:Tomato)');
```

Create a new dataset array with design values. The new dataset array must have the same variables as the original dataset array you use for fitting the model `lme`.

```
dsnew = dataset();
dsnew.Soil = nominal({'Sandy';'Silty';'Silty'});
dsnew.Tomato = nominal({'Cherry';'Vine';'Plum'});
dsnew.Fertilizer = nominal([2;2;4]);
```

Generate random responses at the new points.

```
rng(123,'twister') % For reproducibility
ysim = random(lme,dsnew)
```

```
ysim =

   99.6006
  101.9911
  161.4026
```

Generate Random Responses Using New Design Matrices

Load the sample data.

```
load carbig
```

Fit a linear mixed-effects model for miles per gallon (MPG), with fixed effects for acceleration, horsepower, and cylinders, and potentially correlated random effect for intercept and acceleration grouped by model year.

First, prepare the design matrices for fitting the linear mixed-effects model.

```
X = [ones(406,1) Acceleration Horsepower];
Z = [ones(406,1) Acceleration];
Model_Year = nominal(Model_Year);
G = Model_Year;
```

Now, fit the model using `fitlmematrix` with the defined design matrices and grouping variables.

```
lme = fitlmematrix(X,MPG,Z,G,'FixedEffectPredictors',....
{'Intercept','Acceleration','Horsepower'},'RandomEffectPredictors',...
{{'Intercept','Acceleration'}},'RandomEffectGroups',{'Model_Year'});
```

Create the design matrices that contain the data at which to predict the response values. `Xnew` must have three columns as in `X`. The first column must be a column of 1s. And the values in the last two columns must correspond to `Acceleration` and `Horsepower`, respectively. The first column of `Znew` must be a column of 1s, and the second column must contain the same `Acceleration` values as in `Xnew`. The original grouping variable in `G` is the model year. So, `Gnew` must contain values for the model year. Note that `Gnew` must contain nominal values.

```
Xnew = [1,13.5,185; 1,17,205; 1,21.2,193];
Znew = [1,13.5; 1,17; 1,21.2];
```

```
Gnew = nominal([73 77 82]);
```

Generate random responses for the data in the new design matrices.

```
rng(123,'twister') % For reproducibility
ysim = random(lme,Xnew,Znew,Gnew)
```

```
ysim =

   15.7416
   10.6085
    6.8796
```

Now, repeat the same for a linear mixed-effects model with uncorrelated random-effects terms for intercept and acceleration. First, change the original random effects design and the random effects grouping variables. Then, fit the model.

```
Z = {ones(406,1),Acceleration};
G = {Model_Year,Model_Year};

lme = fitlmematrix(X,MPG,Z,G,'FixedEffectPredictors',....
{'Intercept','Acceleration','Horsepower'},'RandomEffectPredictors',...
{{'Intercept'},{'Acceleration'}},'RandomEffectGroups',{'Model_Year','Model_Year'});
```

Now, recreate the new random effects design, `Znew`, and the grouping variable design, `Gnew`, using which to predict the response values.

```
Znew = {[1;1;1],[13.5;17;21.2]};
MY = nominal([73 77 82]);
Gnew = {MY,MY};
```

Generate random responses using the new design matrices.

```
rng(123,'twister') % For reproducibility
ysim = random(lme,Xnew,Znew,Gnew)
```

```
ysim =

   16.8280
   10.4375
    4.1027
```

random

Class: NonLinearModel

Simulate responses for nonlinear regression model

Syntax

```
ysim = random(mdl)
ysim = random(mdl,Xnew)
ysim = random(mdl,Xnew,'Weights',W)
```

Description

`ysim = random(mdl)` simulates responses from the fitted nonlinear model `mdl` at the original design points.

`ysim = random(mdl,Xnew)` simulates responses from the fitted nonlinear model `mdl` to the data in `Xnew`, adding random noise.

`ysim = random(mdl,Xnew,'Weights',W)` simulates responses using the observation weights, `W`.

Input Arguments

`mdl`

Nonlinear regression model, constructed by `fitnlm`.

`Xnew`

Points at which `mdl` predicts responses.

- If `Xnew` is a table or dataset array, it must contain the predictor names in `mdl`.
- If `Xnew` is a numeric matrix, it must have the same number of variables (columns) as was used to create `mdl`. Furthermore, all variables used in creating `mdl` must be numeric.

`W`

Vector of real, positive value weights or a function handle.

- If you specify a vector, then it must have the same number of elements as the number of observations (or rows) in `Xnew`.
- If you specify a function handle, the function must accept a vector of predicted response values as input, and returns a vector of real positive weights as output.

Given weights, `W`, `random` estimates the error variance at observation `i` by `MSE*(1/W(i))`, where MSE is the mean squared error.

Default: No weights

Output Arguments

`ysim`

Vector of predicted mean values at `Xnew`, perturbed by random noise. The noise is independent, normally distributed, with mean zero, and variance equal to the estimated error variance of the model.

Examples

Simulate Responses

Create a nonlinear model of car mileage as a function of weight, and simulate the response.

Create an exponential model of car mileage as a function of weight from the `carsmall` data. Scale the weight by a factor of 1000 so all the variables are roughly equal in size.

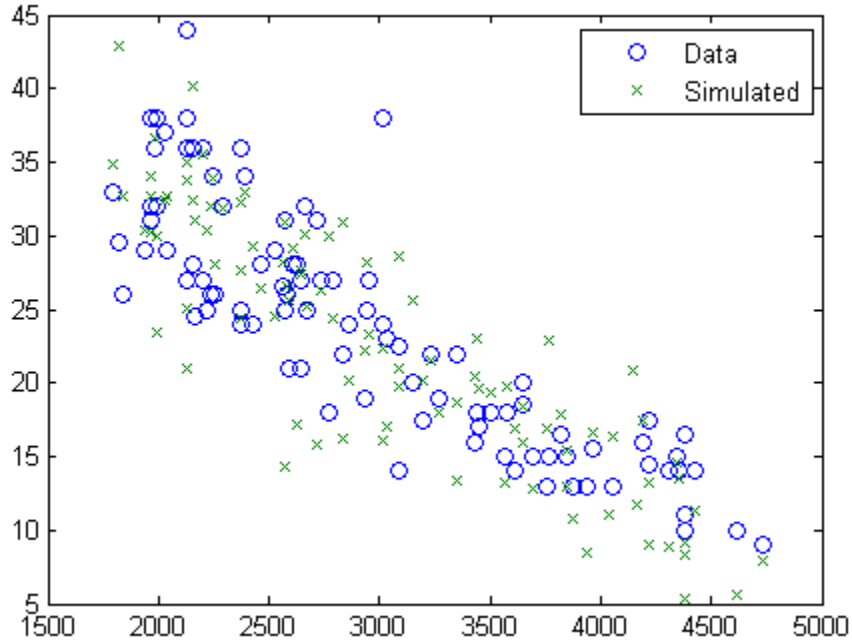
```
load carsmall
X = Weight;
y = MPG;
modelfun = 'y ~ b1 + b2*exp(-b3*x/1000)';
beta0 = [1 1 1];
mdl = fitnlm(X,y,modelfun,beta0);
```

Create simulated responses to the data.

```
Xnew = X;
ysim = random(mdl,Xnew);
```

Plot the original responses and the simulated responses to see how they differ.

```
plot(X,y,'o',X,ysim,'x')
legend('Data','Simulated')
```



- “Predict or Simulate Responses Using a Nonlinear Model” on page 11-10

Alternatives

For predictions without added noise, use `predict`.

`feval` | `NonLinearModel` | `predict`

More About

- “Nonlinear Regression” on page 11-2

random

Class: piecewisedistribution

Random numbers from piecewise distribution

Syntax

```
r = random(obj)
R = random(obj,n)
R = random(obj,m,n)
R = random(obj,[m,n])
R = random(obj,m,n,p,...)
R = random(obj,[m,n,p,...])
```

Description

`r = random(obj)` generates a pseudo-random number `r` drawn from the piecewise distribution object `obj`.

`R = random(obj,n)` generates an *n*-by-*n* matrix of pseudo-random numbers `R`.

`R = random(obj,m,n)` or `R = random(obj,[m,n])` generates an *m*-by-*n* matrix of pseudo-random numbers `R`.

`R = random(obj,m,n,p,...)` or `R = random(obj,[m,n,p,...])` generates an *m*-by-*n*-by-*p*-by-... array of pseudo-random numbers `R`.

Examples

Fit Pareto tails to a *t* distribution at cumulative probabilities 0.1 and 0.9:

```
t = trnd(3,100,1);
obj = paretotails(t,0.1,0.9);

r = random(obj)
r =
```

```
    0.8285
```

See Also

`paretotails` | `icdf` | `cdf`

random

Class: ProbDist

Generate random number drawn from ProbDist object

Syntax

```
Y = random(PD)
Y = random(PD, N)
Y = random(PD, N, M, ...)
```

Description

`Y = random(PD)` generates a random number drawn from the distribution specified by *PD*, a ProbDist object.

`Y = random(PD, N)` generates an *N*-by-*N* array of random numbers drawn from the distribution specified by *PD*, a ProbDist object.

`Y = random(PD, N, M, ...)` generates an *N*-by-*M*-by`...` array of random numbers drawn from the distribution specified by *PD*, a ProbDist object.

Input Arguments

PD	An object of the class `ProbDistUnivParam` or `ProbDistUnivKernel`.
N	A positive integer.
M	A positive integer.

Output Arguments

Y	A random number drawn from the distribution specified by *PD*.

See Also

`random`

random

Class: RepeatedMeasuresModel

Generate new random response values given predictor values

Syntax

```
ysim = random(rm,tnew)
```

Description

`ysim = random(rm,tnew)` generates random response values from the repeated measures model rm using the predictor variables from table tnew.

Input Arguments

`rm` — Repeated measures model

`RepeatedMeasuresModel` object

Repeated measures model, returned as a `RepeatedMeasuresModel` object.

For properties and methods of this object, see `RepeatedMeasuresModel`.

`tnew` — New data

table used to create `rm` (default) | table

New data including the values of the response variables and the between-subject factors used as predictors in the repeated measures model, rm, specified as a table. `tnew` must contain all of the between-subject factors used to create rm.

Output Arguments

`ysim` — Random response values

n-by-*r* matrix

Random response values random generates, returned as an n-by-r matrix, where n is the number of rows in tnew, and r is the number of repeated measures in rm.

Examples

Randomly Generate New Response Values

Load the sample data.

```
load fisheriris
```

The column vector `species`consists of iris flowers of three different species: setosa, versicolor, and virginica. The double matrix `meas` consists of four types of measurements on the flowers: the length and width of sepals and petals in centimeters, respectively.

Store the data in a table array.

```
t = table(species,meas(:,1),meas(:,2),meas(:,3),meas(:,4),...
'VariableNames',{'species','meas1','meas2','meas3','meas4'});
Meas = dataset([1 2 3 4]','VarNames',{'Measurements'});
```

Fit a repeated measures model, where the measurements are the responses and the `species` is the predictor variable.

```
  rm = fitrm(t,'meas1-meas4~species','WithinDesign',Meas);
```

Randomly generate new response values.

```
ysim = random(rm);
```

`random` uses the predictor values in the original sample data you use to fit the repeated measures model `rm` in table `t`.

Randomly Generate Response Values Using New Data

Load the sample data.

```
load repeatedmeas
```

The table `between` includes the between-subject variables age, IQ, group, gender, and eight repeated measures $y1$ through $y8$ as responses. The table `within` includes the within-subject variables $w1$ and $w2$. This is simulated data.

Fit a repeated measures model, where the repeated measures $y1$ through $y8$ are the responses, and age, IQ, group, gender, and the group-gender interaction are the predictor variables. Also specify the within-subject design matrix.

```
rm = fitrm(between,'y1-y8 ~ Group*Gender + Age + IQ','WithinDesign',within);
```

Define a table with new values for the predictor variables.

```
tnew = table(16,93,{'B'},{'Male'},'VariableNames',{'Age','IQ','Group','Gender'})
```

```
tnew =

    Age    IQ    Group    Gender
    ___    __    _____    ______

    16     93    'B'      'Male'
```

Randomly generate new response values using the values in the new table `tnew`.

```
ysim = random(rm,tnew)
```

```
ysim =

  159.0920  114.8927   -6.5618   46.9944   38.6707   -5.6725   70.8690   11.7813
```

Algorithms

`random` computes `ysim` by creating predicted values and adding random noise values. For each row, the noise has a multivariate normal distribution with covariance the same as `rm.Covariance`.

random

Class: prob.TruncatableDistribution
Package: prob

Generate random numbers from probability distribution object

Syntax

```
r = random(pd)
r = random(pd,sz1,...,szN)
r = random(pd,[sz1,...,szN])
```

Description

`r = random(pd)` generates a random number r from the probability distribution pd.

`r = random(pd,sz1,...,szN)` generates a sz1-by-...-by-szN array of random numbers from the probability distribution pd.

`r = random(pd,[sz1,...,szN])` generates a sz1-by-...-by-szN array of random numbers from the probability distribution pd.

Input Arguments

`pd` — Probability distribution

probability distribution object

Probability distribution, specified as a probability distribution object. Create a probability distribution object with specified parameter values using `makedist`. Alternatively, for fittable distributions, create a probability distribution object by fitting it to data using `fitdist` or the Distribution Fitting app.

`sz1,...,szN` — Size of each dimension

two or more integer values | vector of integer values

Size of each dimension, specified as two or more integer values, or a vector of such values. For example, specifying `5,3,2` or `[5,3,2]` generates a 5-by-3-by-2 array of random numbers from the probability distribution pd.

Data Types: `single` | `double`

Output Arguments

`r` — Random number

scalar value | array of values

Random number generated from the probability distribution, returned as a scalar value or an array of scalar values with the dimensions specified by sz1,...,szN.

Examples

Generate One Random Number

Create a standard normal probability distribution object.

```
pd = makedist('Normal')
```

```
pd =

  NormalDistribution

  Normal distribution
       mu = 0
    sigma = 1
```

Generate one random number from the distribution.

```
r = random(pd)
```

```
r =

    0.5377
```

Generate Multiple Random Numbers

Create a Weibull probability distribution object using the default parameter values.

```
pd = makedist('Weibull')
```

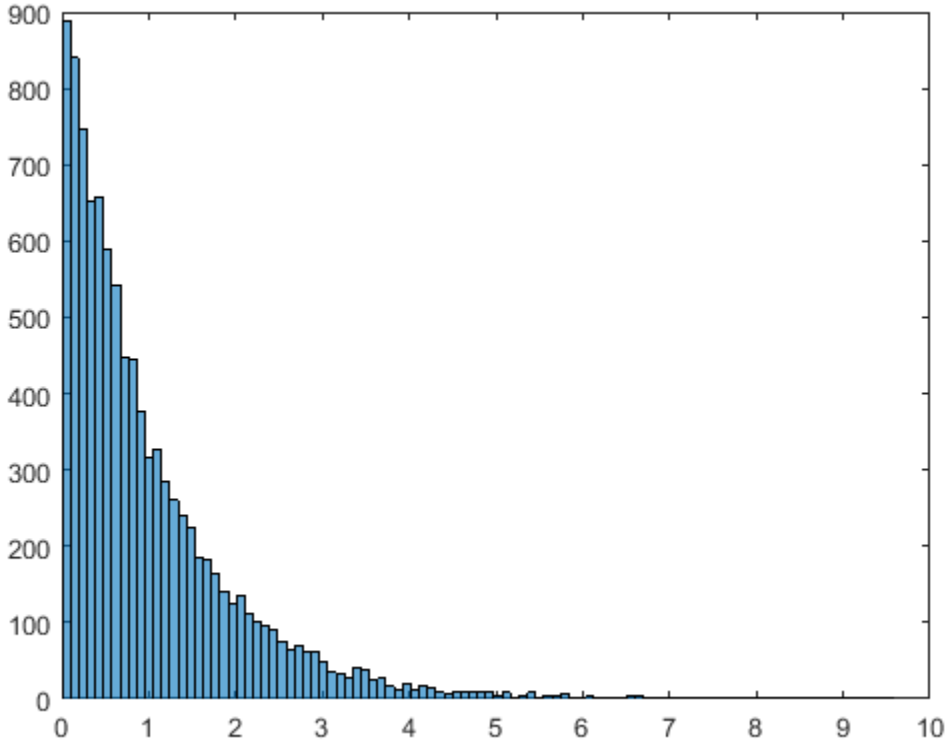
```
pd =

  WeibullDistribution
```

```
  Weibull distribution
    A = 1
    B = 1
```

Generate random numbers from distribution and visualize with a histogram.

```
rng default  % For reproducibility
r = random(pd,10000,1);
histogram(r,100)
```



Generate a Multidimensional Array of Random Numbers

Create a standard normal probability distribution object.

```
pd = makedist('Normal')

pd =

  NormalDistribution

  Normal distribution
       mu = 0
    sigma = 1
```

Generate a 2-by-3-by-2 array of random numbers from the distribution.

```
r = random(pd,[2,3,2])

random_make_array(:,:,1) =

   -1.0689   -2.9443    0.3252
   -0.8095    1.4384   -0.7549

random_make_array(:,:,2) =

    1.3703   -0.1022    0.3192
   -1.7115   -0.2414    0.3129
```

randomEffects

Class: GeneralizedLinearMixedModel

Estimates of random effects and related statistics

Syntax

```
B = randomEffects(glme)
[B,BNames] = randomEffects(glme)
[B,BNames,stats] = randomEffects(glme)
[B,BNames,stats] = randomEffects(glme,Name,Value)
```

Description

`B = randomEffects(glme)` returns the estimates of the empirical Bayes predictors (EPBs) of random effects in the generalized linear mixed-effects model glme conditional on the estimated covariance parameters and the observed response.

`[B,BNames] = randomEffects(glme)` also returns the names of the coefficients, BNames. Each name corresponds to a coefficient in B.

`[B,BNames,stats] = randomEffects(glme)` also returns related statistics, stats, for the estimated EBPs of random effects in glme.

`[B,BNames,stats] = randomEffects(glme,Name,Value)` returns any of the above output arguments using additional options specified by one or more `Name,Value` pair arguments. For example, you can specify the confidence interval level, or the method for computing the approximate degrees of freedom.

Input Arguments

`glme` — Generalized linear mixed-effects model

`GeneralizedLinearMixedModel` object

Generalized linear mixed-effects model, specified as a `GeneralizedLinearMixedModel` object. For properties and methods of this object, see `GeneralizedLinearMixedModel`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'Alpha'` — Confidence level

0.05 (default) | scalar value in the range [0,1]

Confidence level, specified as the comma-separated pair consisting of `'Alpha'` and a scalar value in the range [0,1]. For a value α, the confidence level is $100 \times (1 - \alpha)\%$.

For example, for 99% confidence intervals, you can specify the confidence level as follows.

Example: `'Alpha',0.01`

Data Types: `single | double`

`'DFMethod'` — Method for computing approximate degrees of freedom

`'residual'` (default) | `'none'`

Method for computing approximate degrees of freedom, specified as the comma-separated pair consisting of `'DFMethod'` and one of the following.

`'residual'`	The degrees of freedom are assumed to be constant and equal to $n - p$, where n is the number of observations and p is the number of fixed effects.
`'none'`	All degrees of freedom are set to infinity.

Example: `'DFMethod','none'`

Output Arguments

`B` — Estimated empirical Bayes predictors for the random effects

column vector

Estimated empirical Bayes predictors (EBPs) for the random effects in the generalized linear mixed-effects model glme, returned as a column vector. The EBPs in B are

approximated by the mode of the empirical posterior distribution of the random effects given the estimated covariance parameters and the observed response.

Suppose glme has R grouping variables g_1, g_2, ..., g_R, with levels m_1, m_2, ..., m_R, respectively. Also suppose q_1, q_2, ..., q_R are the lengths of the random-effects vectors that are associated with g_1, g_2, ..., g_R, respectively. Then, `B` is a column vector of length $q_1*m_1 + q_2*m_2 + ... + q_R*m_R$.

`randomEffects` creates `B` by concatenating the empirical Bayes predictors of random-effects vectors corresponding to each level of each grouping variable as `[`g_1`level`$_1$`; `g_1`level`$_2$`; ...; `g_1`level`$_{m_1}$`; `g_2`level`$_1$`; `g_2`level`$_2$`; ...; `g_2`level`$_{m_2}$`; ...; `g_R`level`$_1$`; `g_R`level`$_2$`; ...; `g_R`level`$_{m_R}$`]'`.

`BNames` — Names of random-effects coefficients

table

Names of random-effects coefficients in B, returned as a table.

`stats` — Estimated empirical Bayes predictors and related statistics

table

Estimated empirical Bayes predictors (EBPs) and related statistics for the random effects in the generalized linear mixed-effects model glme, returned as a table. stats has one row for each of the random effects, and one column for each of the following statistics.

`Group`	Grouping variable associated with the random effect
`Level`	Level within the grouping variable corresponding to the random effect
`Name`	Name of the random-effect coefficient
`Estimate`	Empirical Bayes predictor (EBP) of random effect
`SEPred`	Square root of the conditional mean squared error of prediction (CMSEP) given covariance parameters and response
`tStat`	t-statistic for a test that the random-effects coefficient is equal to 0
`DF`	Estimated degrees of freedom for the t-statistic

`pValue`	*p*-value for the *t*-statistic
`Lower`	Lower limit of a 95% confidence interval for the random-effects coefficient
`Upper`	Upper limit of a 95% confidence interval for the random-effects coefficient

`randomEffects` computes the confidence intervals using the conditional mean squared error of prediction (CMSEP) approach conditional on the estimated covariance parameters and the observed response. An alternative interpretation of the confidence intervals is that they are approximate Bayesian credible intervals conditional on the estimated covariance parameters and the observed response.

When fitting a GLME model using `fitglme` and one of the pseudo likelihood fit methods (`'MPL'` or `'REMPL'`), `randomEffects` computes confidence intervals and related statistics based on the fitted linear mixed-effects model from the final pseudo likelihood iteration.

Examples

Compute and Plot Estimated Random Effects

Navigate to the folder containing the sample data. Load the sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')

load mfr
```

This simulated data is from a manufacturing company that operates 50 factories across the world, with each factory running a batch process to create a finished product. The company wants to decrease the number of defects in each batch, so it developed a new manufacturing process. To test the effectiveness of the new process, the company selected 20 of its factories at random to participate in an experiment: Ten factories implemented the new process, while the other ten continued to run the old process. In each of the 20 factories, the company ran five batches (for a total of 100 batches) and recorded the following data:

- Flag to indicate whether the batch used the new process (`newprocess`)
- Processing time for each batch, in hours (`time`)

- Temperature of the batch, in degrees Celsius (`temp`)
- Categorical variable indicating the supplier (`A`, `B`, or `C`) of the chemical used in the batch (`supplier`)
- Number of defects in the batch (`defects`)

The data also includes `time_dev` and `temp_dev`, which represent the absolute deviation of time and temperature, respectively, from the process standard of 3 hours at 20 degrees Celsius.

Fit a generalized linear mixed-effects model using `newprocess`, `time_dev`, `temp_dev`, and `supplier` as fixed-effects predictors. Include a random-effects term for intercept grouped by `factory`, to account for quality differences that might exist due to factory-specific variations. The response variable `defects` has a Poisson distribution, and the appropriate link function for this model is log. Use the Laplace fit method to estimate the coefficients. Specify the dummy variable encoding as `'effects'`, so the dummy variable coefficients sum to 0.

The number of defects can be modeled using a Poisson distribution

$$defects_{ij} \sim Poisson\left(\mu_{ij}\right)$$

This corresponds to the generalized linear mixed-effects model

$$\log\left(\mu_{ij}\right) = \beta_0 + \beta_1 newprocess_{ij} + \beta_2 time\_dev_{ij} + \beta_3 temp\_dev_{ij} + \beta_4 supplier\_C_{ij} + \beta_5 supplier\_B_{ij} +$$

where

- $defects_{ij}$ is the number of defects observed in the batch produced by factory i during batch j.
- μ_{ij} is the mean number of defects corresponding to factory i (where $i = 1, 2, ..., 20$) during batch j (where $j = 1, 2, ..., 5$).
- $newprocess_{ij}$, $time\_dev_{ij}$, and $temp\_dev_{ij}$ are the measurements for each variable that correspond to factory i during batch j. For example, $newprocess_{ij}$ indicates whether the batch produced by factory i during batch j used the new process.
- $supplier\_C_{ij}$ and $supplier\_B_{ij}$ are dummy variables that use effects (sum-to-zero) coding to indicate whether company `C` or `B`, respectively, supplied the process chemicals for the batch produced by factory i during batch j.

- $b_i \sim N(0,\sigma_b^2)$ is a random-effects intercept for each factory i that accounts for factory-specific variation in quality.

```
glme = fitglme(mfr,'defects ~ 1 + newprocess + time_dev + temp_dev + supplier + (1|fact
```

Compute and display the names and estimated values of the empirical Bayes predictors (EBPs) for the random effects.

```
[B,BNames] = randomEffects(glme)
```

'factory'    '19'     '(Intercept)'
'factory'    '20'     '(Intercept)'
```

Each row of `B` contains the estimated EPB for the random-effects coefficient named in the corresponding row of `Bnames`. For example, the value –0.2633 in row 3 of `B` is the estimated EPB for `'(Intercept)'` for level `'3'` of `factory`.

Compute 99% Confidence Intervals for Random Effects

Navigate to the folder containing the sample data. Load the sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')

load mfr
```

This simulated data is from a manufacturing company that operates 50 factories across the world, with each factory running a batch process to create a finished product. The company wants to decrease the number of defects in each batch, so it developed a new manufacturing process. To test the effectiveness of the new process, the company selected 20 of its factories at random to participate in an experiment: Ten factories implemented the new process, while the other ten continued to run the old process. In each of the 20 factories, the company ran five batches (for a total of 100 batches) and recorded the following data:

- Flag to indicate whether the batch used the new process (`newprocess`)
- Processing time for each batch, in hours (`time`)
- Temperature of the batch, in degrees Celsius (`temp`)
- Categorical variable indicating the supplier (`A`, `B`, or `C`) of the chemical used in the batch (`supplier`)

- Number of defects in the batch (`defects`)

The data also includes `time_dev` and `temp_dev`, which represent the absolute deviation of time and temperature, respectively, from the process standard of 3 hours at 20 degrees Celsius.

Fit a generalized linear mixed-effects model using `newprocess`, `time_dev`, `temp_dev`, and `supplier` as fixed-effects predictors. Include a random-effects term for intercept grouped by `factory`, to account for quality differences that might exist due to factory-specific variations. The response variable `defects` has a Poisson distribution, and the appropriate link function for this model is log. Use the Laplace fit method to estimate the coefficients. Specify the dummy variable encoding as `'effects'`, so the dummy variable coefficients sum to 0.

The number of defects can be modeled using a Poisson distribution

$$defects_{ij} \sim Poisson\left(\mu_{ij}\right)$$

This corresponds to the generalized linear mixed-effects model

$$\log\left(\mu_{ij}\right) = \beta_0 + \beta_1 newprocess_{ij} + \beta_2 time\_dev_{ij} + \beta_3 temp\_dev_{ij} + \beta_4 supplier\_C_{ij} + \beta_5 supplier\_B_{ij} +$$

where

- $defects_{ij}$ is the number of defects observed in the batch produced by factory i during batch j.
- μ_{ij} is the mean number of defects corresponding to factory i (where i = 1, 2, ..., 20) during batch j (where j = 1, 2, ..., 5).
- $newprocess_{ij}$, $time\_dev_{ij}$, and $temp\_dev_{ij}$ are the measurements for each variable that correspond to factory i during batch j. For example, $newprocess_{ij}$ indicates whether the batch produced by factory i during batch j used the new process.
- $supplier\_C_{ij}$ and $supplier\_B_{ij}$ are dummy variables that use effects (sum-to-zero) coding to indicate whether company `C` or `B`, respectively, supplied the process chemicals for the batch produced by factory i during batch j.
- $b_i \sim N(0,\sigma_b^2)$ is a random-effects intercept for each factory i that accounts for factory-specific variation in quality.

```

The first three columns of `stats` contain the group name, level, and random-effects coefficient name. Column 4 contains the estimated EBP of the random-effects coefficient. The last two columns of `stats`, `Lower` and `Upper`, contain the lower and upper bounds of the 99% confidence interval, respectively. For example, for the coefficient for `'(Intercept)'` for level `3` of `factory`, the estimated EBP is –0.26325, and the 99% confidence interval is [-0.82191,0.29541].

randomEffects

Class: LinearMixedModel

Estimates of random effects and related statistics

Syntax

```
B = randomEffects(lme)
[B,Bnames] = randomEffects(lme)
[B,Bnames,stats] = randomEffects(lme)
[B,Bnames,stats] = randomEffects(lme,Name,Value)
```

Description

`B = randomEffects(lme)` returns the estimates of the best linear unbiased predictors (BLUPs) of random effects in the linear mixed-effects model `lme`.

`[B,Bnames] = randomEffects(lme)` also returns the names of the coefficients in `Bnames`. Each name corresponds to a coefficient in `B`.

`[B,Bnames,stats] = randomEffects(lme)` also returns the estimated BLUPs of random effects in the linear mixed-effects model `lme` and related statistics.

`[B,Bnames,stats] = randomEffects(lme,Name,Value)` also returns the BLUPs of random effects in the linear mixed-effects model `lme` and related statistics with additional options specified by one or more Name,Value pair arguments.

Input Arguments

`lme` — Linear mixed-effects model

`LinearMixedModel` object

Linear mixed-effects model, returned as a `LinearMixedModel` object.

For properties and methods of this object, see `LinearMixedModel`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'Alpha'` — Confidence level

0.05 (default) | scalar value in the range 0 to 1

Confidence level, specified as the comma-separated pair consisting of `'Alpha'` and a scalar value in the range 0 to 1. For a value α, the confidence level is 100*(1–α)%.

For example, for 99% confidence intervals, you can specify the confidence level as follows.

Example: `'Alpha',0.01`

Data Types: `single` | `double`

`'DFMethod'` — Method for computing approximate degrees of freedom

`'Residual'` (default) | `'Satterthwaite'` | `'None'`

Method for computing approximate degrees of freedom for the *t*-statistics that test the random-effects coefficients against 0, specified as the comma-separated pair consisting of `'DFMethod'` and one of the following.

`'Residual'`	Default. The degrees of freedom are assumed to be constant and equal to $n - p$, where n is the number of observations and p is the number of fixed effects.
`'Satterthwaite'`	Satterthwaite approximation.
`'None'`	All degrees of freedom are set to infinity.

For example, you can specify the Satterthwaite approximation as follows.

Example: `'DFMethod','Satterthwaite'`

Output Arguments

`B` — Estimated best linear unbiased predictors of random effects

column vector

Estimated best linear unbiased predictors of random effects of linear mixed-effects model `lme`, returned as a column vector.

Suppose `lme` has R grouping variables g_1, g_2, ..., g_R, with levels m_1, m_2, ..., m_R, respectively. Also suppose q_1, q_2, ..., q_R are the lengths of the random-effects vectors that are associated with g_1, g_2, ..., g_R, respectively. Then, `B` is a column vector of length $q_1*m_1 + q_2*m_2 + ... + q_R*m_R$.

`randomEffects` creates `B` by concatenating the best linear unbiased predictors of random-effects vectors corresponding to each level of each grouping variable as $[g_1level_1; g_1level_2; ...; g_1level_{m_1}; g_2level_1; g_2level_2; ...; g_2level_{m_2}; ...; g_Rlevel_1; g_Rlevel_2; ...; g_Rlevel_{m_R}]'$.

`Bnames` — Names of random-effects coefficients

table

Names of random-effects coefficients in B, returned as a table.

`stats` — Estimates of random effects BLUPs and related statistics

dataset array

Estimates of random effects BLUPs and related statistics, returned as a dataset array that has one row for each of the fixed effects and one column for each of the following statistics.

`Group`	Grouping variable associated with the random effect
`Level`	Level within the grouping variable corresponding to the random effect
`Name`	Name of the random-effect coefficient
`Estimate`	Best linear unbiased predictor (BLUP) of random effect
`SEPred`	Standard error of the estimate (BLUP minus random effect)
`tStat`	t-statistic for a test that the random effect is zero
`DF`	Estimated degrees of freedom for the t-statistic

`pValue`	p-value for the t-statistic
`Lower`	Lower limit of a 95% confidence interval for the random effect
`Upper`	Upper limit of a 95% confidence interval for the random effect

Examples

Display Random-Effects Estimates and Coefficient Names

Load the sample data.

```
load carbig
```

Fit a linear mixed-effects model for miles per gallon (MPG), with fixed effects for acceleration and horsepower, and potentially correlated random effects for intercept and acceleration, grouped by the model year. First, store the data in a table.

```
tbl = table(Acceleration,Horsepower,Model_Year,MPG);
```

Fit the model.

```
lme = fitlme(tbl, 'MPG ~ Acceleration + Horsepower + (Acceleration|Model_Year)');
```

Compute the BLUPs of the random-effects coefficients and display the names of the corresponding random effects.

```
[B,Bnames] = randomEffects(lme)
```

```

    'Model_Year'       '80'       'Acceleration'
    'Model_Year'       '81'       '(Intercept)'
    'Model_Year'       '81'       'Acceleration'
    'Model_Year'       '82'       '(Intercept)'
```

```
    'Model_Year'        '82'        'Acceleration'
```

Since intercept and acceleration have potentially correlated random effects, grouped by model year of the cars, `randomEffects` creates a separate row for intercept and acceleration at each level of the grouping variable.

Compute the covariance parameters of the random effects.

```
[~,~,stats] = covarianceParameters(lme)
stats{1}
```

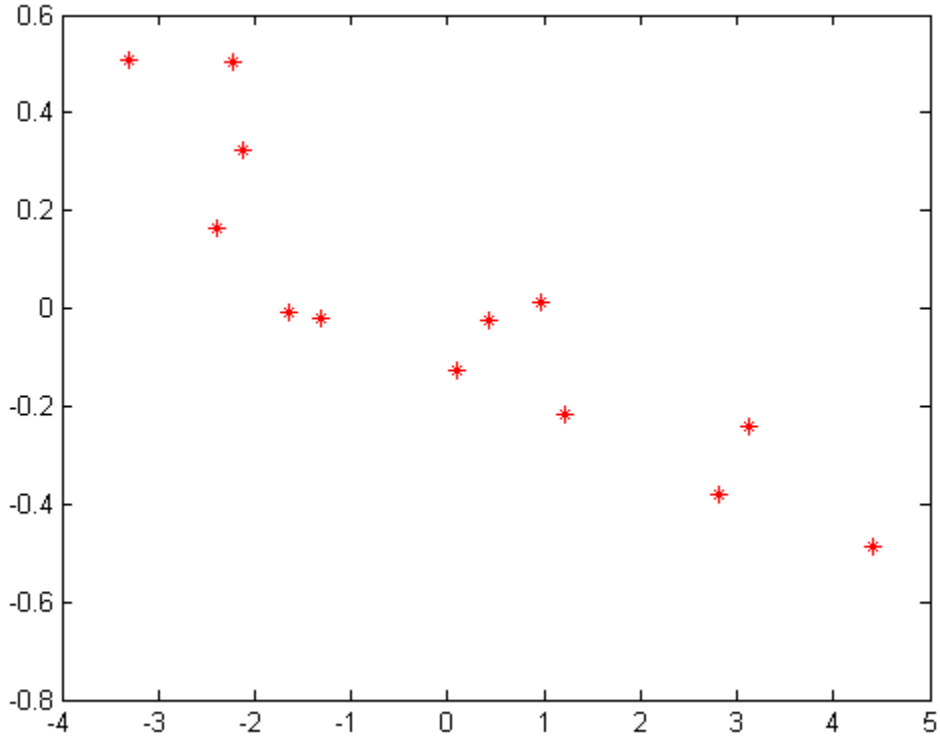
```
ans =

    Covariance Type: FullCholesky

    Group         Name1               Name2               Type          Estimate
    Model_Year    '(Intercept)'       '(Intercept)'       'std'            6.6672
    Model_Year    'Weight'            '(Intercept)'       'corr'               -1
    Model_Year    'Weight'            'Weight'            'std'         0.0014668
```

The correlation value suggests that random effects seem negatively correlated. Plot the random effects for intercept versus acceleration to confirm this.

```
plot(B(1:2:end),B(2:2:end),'r*')
```



Compute Random-Effects Estimates and Related Statistics

Navigate to a folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load fertilizer
```

The dataset array includes data from a split-plot experiment, where soil is divided into three blocks based on the soil type: sandy, silty, and loamy. Each block is divided into five plots, where five different types of tomato plants (cherry, heirloom, grape, vine, and

plum) are randomly assigned to these plots. The tomato plants in the plots are then divided into subplots, where each subplot is treated by one of four fertilizers. This is simulated data.

Store the data in a dataset array called `ds`, for practical purposes, and define `Tomato`, `Soil`, and `Fertilizer` as categorical variables.

```
ds = fertilizer;
ds.Tomato = nominal(ds.Tomato);
ds.Soil = nominal(ds.Soil);
ds.Fertilizer = nominal(ds.Fertilizer);
```

Fit a linear mixed-effects model, where `Fertilizer` and `Tomato` are the fixed-effects variables, and the mean yield varies by the block (soil type), and the plots within blocks (tomato types within soil types) independently.

```
lme = fitlme(ds,'Yield ~ Fertilizer * Tomato + (1|Soil) + (1|Soil:Tomato)');
```

Compute the BLUPs and related statistics for random effects.

```
[~,~,stats] = randomEffects(lme)
```

```
stats =

    Random effect coefficients: DFMethod = 'Residual', Alpha = 0.05

    'Soil:Tomato'       'Loamy Vine'         '(Intercept)'       -4.6874     7.176
    'Soil:Tomato'       'Sandy Cherry'       '(Intercept)'       -17.393     7.176
    'Soil:Tomato'       'Sandy Grape'        '(Intercept)'       -7.3679     7.176
    'Soil:Tomato'       'Sandy Heirloom'     '(Intercept)'        -8.621     7.176
    'Soil:Tomato'       'Sandy Plum'         '(Intercept)'         7.669     7.176
    'Soil:Tomato'       'Sandy Vine'         '(Intercept)'       0.28246     7.176
    'Soil:Tomato'       'Silty Cherry'       '(Intercept)'        4.9326     7.176
    'Soil:Tomato'       'Silty Grape'        '(Intercept)'         10.011    7.176
    'Soil:Tomato'       'Silty Heirloom'     '(Intercept)'       -8.0599     7.176
```

```
    'Soil:Tomato'        'Silty Plum'            '(Intercept)'        -2.6519     7.176
    'Soil:Tomato'        'Silty Vine'            '(Intercept)'          4.405     7.176
```

The first three rows contain the random-effects estimates and the statistics for the three levels, `Loamy`, `Sandy`, and `Silty` of the grouping variable `Soil`. The corresponding *p*-values 0.66918, 0.51825, and 0.82593 indicate that these random-effects are not significantly different from 0. The following 15 rows include the BLUPS of random-effects estimates for the intercept, grouped by the variable Tomato nested in Soil, i.e. interaction of `Tomato` and `Soil`.

Compute Confidence Intervals with Specified Options

Load the sample data.

```
load carsmall
```

`Shift` and `Operator` are nominal variables.

```
shift.Shift = nominal(shift.Shift);
shift.Operator = nominal(shift.Operator);
```

Fit a linear mixed-effects model with a random intercept grouped by operator, to assess if there is a significant difference in the performance according to the time of the shift. Use the restricted maximum likelihood method.

```
lme = fitlme(shift,'QCDev ~ Shift + (1|Operator)');
```

Compute the 99% confidence intervals for random effects using the residuals option to compute the degrees of freedom. This is the default method.

```
[~,~,stats] = randomEffects(lme,'alpha',0.01)
```

```
stats =

    Random effect coefficients: DFMethod = 'Residual', Alpha = 0.01

    Group            Level      Name                Estimate    SEPred     tStat
    'Operator'       '1'        '(Intercept)'       0.57753     0.90378    0.63902
    'Operator'       '2'        '(Intercept)'        1.1757     0.90378     1.3009
    'Operator'       '3'        '(Intercept)'       -2.1715     0.90378    -2.4027
    'Operator'       '4'        '(Intercept)'        2.3655     0.90378     2.6174
    'Operator'       '5'        '(Intercept)'       -1.9472     0.90378    -2.1546
```

Compute the 99% confidence intervals for random effects using the Satterthwaite approximation to compute the degrees of freedom.

```
[~,~,stats] = randomEffects(lme,'DFMethod','Satterthwaite','alpha',0.01)
```

```
stats =

    Random effect coefficients: DFMethod = 'Satterthwaite', Alpha = 0.01

    Group             Level      Name                Estimate    SEPred     tStat
    'Operator'        '1'        '(Intercept)'        0.57753    0.90378    0.63902
    'Operator'        '2'        '(Intercept)'         1.1757    0.90378     1.3009
    'Operator'        '3'        '(Intercept)'        -2.1715    0.90378    -2.4027
    'Operator'        '4'        '(Intercept)'         2.3655    0.90378     2.6174
    'Operator'        '5'        '(Intercept)'        -1.9472    0.90378    -2.1546
```

The Satterhwaite method usually produces smaller values for the degrees of freedom (`DF`), which results in larger *p*-values (`pValue`) and larger confidence intervals (`Lower` and `Upper`) for the random-effects estimates.

randsample

Random sample

Syntax

```
y = randsample(n,k)
y = randsample(population,k)
y = randsample(n,k,replacement)
y = randsample(population,k,replacement)
y = randsample(n,k,true,w)
y = randsample(population,k,true,w)
y = randsample(s,...)
```

Description

`y = randsample(n,k)` returns a `k`-by-`1` vector `y` of values sampled uniformly at random, without replacement, from the integers 1 to `n`.

`y = randsample(population,k)` returns a vector of `k` values sampled uniformly at random, without replacement, from the values in the vector `population`. The orientation of `y` (row or column) is the same as `population`.

`y = randsample(n,k,replacement)` or `y = randsample(population,k,replacement)` returns a sample taken with replacement if `replacement` is `true`, or without replacement if `replacement` is `false`. The default is `false`.

`y = randsample(n,k,true,w)` or `y = randsample(population,k,true,w)` returns a weighted sample taken with replacement, using a vector of positive weights `w`, whose length is `n`. The probability that the integer `i` is selected for an entry of `y` is `w(i)/sum(w)`. Usually, `w` is a vector of probabilities. `randsample` does not support weighted sampling without replacement.

`y = randsample(s,...)` uses the stream `s` for random number generation. `s` is a member of the `RandStream` class. Default is the MATLAB default random number stream.

Examples

Draw a single value from the integers `1` through `10`:

```
n = 10;
x = randsample(n,1);
```

Draw a single value from the population `1` through `n`, where `n > 1`:

```
y = randsample(1:n,1);
```

Note: If `population` is a numeric vector containing only nonnegative integer values, and `population` can have length `1`, use

```
y = population(randsample(length(population),k))
```

instead of `y = randsample(population,k)`.

Generate a random sequence of the characters `A`, `C`, `G`, and `T`, with replacement, according to the specified probabilities.

```
R = randsample('ACGT',48,true,[0.15 0.35 0.35 0.15])
```

More About

Tips

- To randomly sample data, with or without replacement, use `datasample`.

randtool

Interactive random number generation

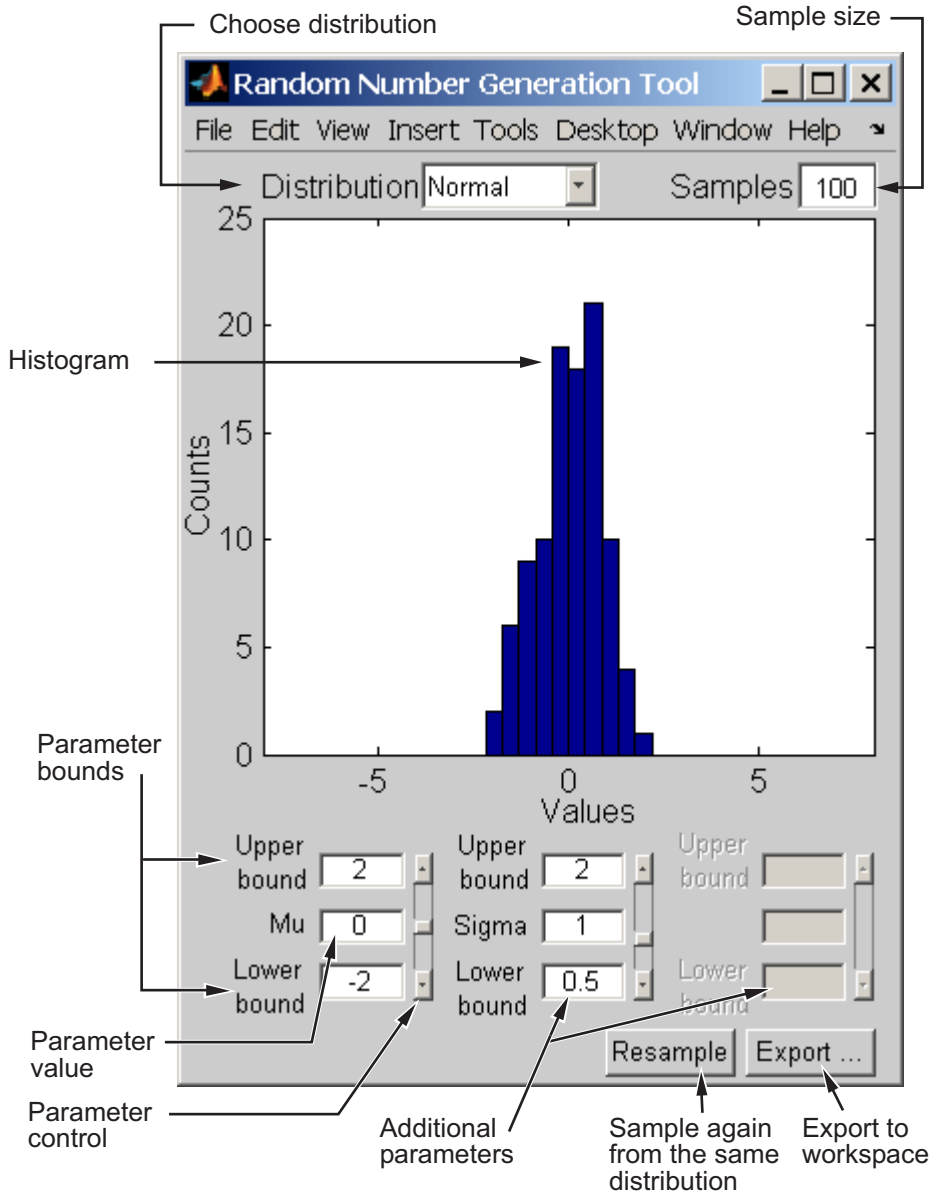
Syntax

```
randtool
```

Description

`randtool` opens the Random Number Generation Tool.

The Random Number Generation Tool is a graphical user interface that generates random samples from specified probability distributions and displays the samples as histograms. Use the tool to explore the effects of changing parameters and sample size on the distributions.



Start by selecting a distribution, then enter the desired sample size.

You can also

- Use the controls at the bottom of the window to set parameter values for the distribution and to change their upper and lower bounds.
- Draw another sample from the same distribution, with the same size and parameters.
- Export the current sample to your workspace. A dialog box enables you to provide a name for the sample.

range

Range of values

Syntax

```
range(X)
y = range(X,dim)
```

Description

`range(X)` returns the difference between the maximum and the minimum of a sample. For vectors, `range(x)` is the range of the elements. For matrices, `range(X)` is a row vector containing the range of each column of X. For N-dimensional arrays, `range` operates along the first nonsingleton dimension of `X`.

`y = range(X,dim)` operates along the dimension `dim` of `X`.

`range` treats `NaN`s as missing values and ignores them.

The range is an easily-calculated estimate of the spread of a sample. Outliers have an undue influence on this statistic, which makes it an unreliable estimator.

Examples

The range of a large sample of standard normal random numbers is approximately six. This is the motivation for the process capability indices C_p and C_{pk} in statistical quality control applications.

```
rv = normrnd(0,1,1000,5);
near6 = range(rv)
near6 =
  6.1451  6.4986  6.2909  5.8894  7.0002
```

rangesearch

Find all neighbors within specified distance using exhaustive search or *K*d-tree

Syntax

```
Idx = rangesearch(Mdl,Y,r)
Idx = rangesearch(Mdl,Y,r,Name,Value)
[Idx,D] = rangesearch( ___ )
```

Description

`Idx = rangesearch(Mdl,Y,r)` searches for all neighbors (i.e., points, rows, or observations) in `Mdl.X` within radius `r` of each point (i.e., row or observation) in the query data `Y` using an exhaustive search or a *K*d-tree. `rangesearch` returns `Idx`, which is a column vector of the indices of `Mdl.X` within `r` units.

`Idx = rangesearch(Mdl,Y,r,Name,Value)` returns the indices of the observation in `Mdl.X` within radius `r` of each observation in `Y` with additional options specified by one or more `Name,Value` pair arguments. For example, you can specify to use a different distance metric than is stored in `Mdl.Distance` or a different distance metric parameter than is stored in `Mdl.DistParameter`.

`[Idx,D] = rangesearch( ___ )` additionally returns the matrix `D` using any of the input arguments in the previous syntaxes. `D` contains the distances between the observations in `Mdl.X` within radius `r` of each observation in `Y`. The function arranges the columns of `D` in ascending order by closeness, with respect to the distance metric.

Examples

Search for Neighbors Within A Radius Using a *K* d-tree and Exhaustive Search

`rangesearch` accepts `ExhaustiveSearcher` or `KDTreeSearcher` model objects to search the training data for the nearest neighbors to the query data. An

`ExhaustiveSearcher` model invokes the exhaustive searcher algorithm, and a `KDTreeSearcher` model defines a K d-tree, which `rangesearch` uses to search for nearest neighbors.

Load Fisher's iris data set. Randomly reserve five observations from the data for query data. Focus on the petal dimensions.

```
load fisheriris
rng(1); % For reproducibility
n = size(meas,1);
idx = randsample(n,5);
X = meas(~ismember(1:n,idx),3:4); % Training data
Y = meas(idx,3:4);                % Query data
```

Grow a default two-dimensional K d-tree.

```
MdlKDT = KDTreeSearcher(X)
```

```
MdlKDT =

  KDTreeSearcher with properties:

      BucketSize: 50
        Distance: 'euclidean'
    DistParameter: []
                X: [145x2 double]
```

`MdlKDT` is a `KDTreeSearcher` model object. You can alter its writable properties using dot notation.

Prepare an exhaustive nearest neighbors searcher.

```
MdlES = ExhaustiveSearcher(X)
```

```
MdlES =

  ExhaustiveSearcher with properties:

        Distance: 'euclidean'
    DistParameter: []
                X: [145x2 double]
```

`MdlKDT` is an `ExhaustiveSearcher` model object. It contains the options, such as the distance metric, to use to find nearest neighbors.

Alternatively, you can grow a K d-tree or prepare an exhaustive nearest neighbors searcher using `createns`.

Search training data for the nearest neighbor indices that correspond to each query observation that are within a 0.5 cm radius. Conduct both types of searches and use the default settings.

```
r = 0.15; % Search radius
IdxKDT = rangesearch(MdlKDT,Y,r);
IdxES = rangesearch(MdlES,Y,r);
[IdxKDT IdxES]
```

```
ans =

    [1x27 double]    [1x27 double]
    [         13]    [         13]
    [1x27 double]    [1x27 double]
    [1x2  double]    [1x2  double]
    [1x0  double]    [1x0  double]
```

`IdxKDT` and `IdxES` are cell arrays of vectors corresponding to the indices of `X` that are within 0.15 cm of the observations in `Y`. Each row of the index matrices corresponds to a query observation.

Compare the results between the methods.

```
cellfun(@isequal,IdxKDT,IdxES)
```

```
ans =

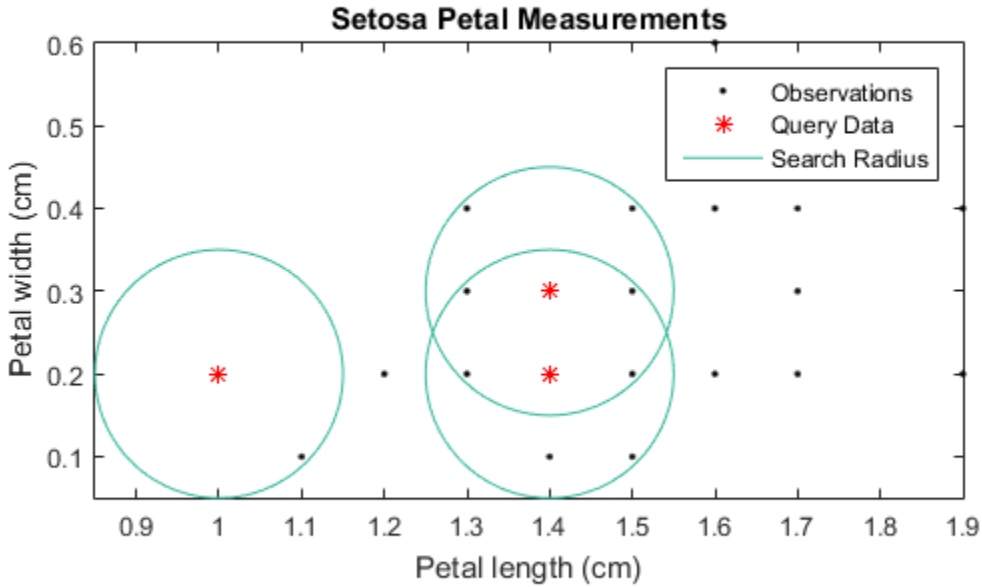
     1
     1
     1
     1
     1
```

In this case, the results are the same.

Plot the results for the setosa irises.

```
setosaIdx = strcmp(species(~ismember(1:n,idx)),'setosa');
XSetosa = X(setosaIdx,:);
ySetosaIdx = strcmp(species(idx),'setosa');
YSetosa = Y(ySetosaIdx,:);

figure;
plot(XSetosa(:,1),XSetosa(:,2),'.k');
hold on;
plot(YSetosa(:,1),YSetosa(:,2),'*r');
for j = 1:sum(ySetosaIdx);
    c = YSetosa(j,:);
    circleFun = @(x1,x2)r^2 - (x1 - c(1)).^2 - (x2 - c(2)).^2;
    ezplot(circleFun,[c(1) + [-1 1]*r, c(2) + [-1 1]*r])
end
xlabel 'Petal length (cm)';
ylabel 'Petal width (cm)';
title 'Setosa Petal Measurements';
legend('Observations','Query Data','Search Radius');
axis equal
hold off
```



Search for Neighbors Within a Radius Using the Mahalanobis Distance

Load Fisher's iris data set.

```
load fisheriris
```

Remove five irises randomly from the predictor data to use as a query set.

```
rng(1);                      % For reproducibility
n = size(meas,1);            % Sample size
qIdx = randsample(n,5);      % Indices of query data
X = meas(~ismember(1:n,qIdx),:);
Y = meas(qIdx,:);
```

Prepare a default exhaustive nearest neighbors searcher.

```
Mdl = ExhaustiveSearcher(X)
```

```
Mdl =

  ExhaustiveSearcher with properties:

         Distance: 'euclidean'
    DistParameter: []
                X: [145x4 double]
```

`Mdl` is an `ExhaustiveSearcher` model.

Find the indices of the training data (`X`) that are within 0.15 cm of each point in the query data (`Y`). Specify that the distances are with respect to the Mahalanobis metric.

```
r = 1;
Idx = rangesearch(Mdl,Y,r,'Distance','mahalanobis')
Idx{3}
```

```
Idx =

    [1x15 double]
    [1x5  double]
    [1x6  double]
    [         84]
    [         69]

ans =

     1    34    33    22    24     2
```

Each cell of `Idx` corresponds to a query data observation and contains in `X` a vector of indices of the neighbors within 0.15cm of the query data. `rangesearch` arranges the indices in ascending order by distance. For example, using thre Mahalanobis distance, the second nearest neighbor of `Y(3,:)` is `X(34,:)`.

Compute Distances of Neighbors Within a Radius

Load Fisher's iris data set.

```
load fisheriris
```

Remove five irises randomly from the predictor data to use as a query set.

```
rng(4);                      % For reproducibility
n = size(meas,1);            % Sample size
qIdx = randsample(n,5);      % Indices of query data
X = meas(~ismember(1:n,qIdx),:);
Y = meas(qIdx,:);
```

Grow a four-dimensional K d-tree using the training data. Specify to use the Minkowski distance for finding nearest neighbors later.

```
Mdl = KDTreeSearcher(X);
```

`Mdl` is a `KDTreeSearcher` model. By default, the distance metric for finding nearest neighbors is the Euclidean metric.

Find the indices of the training data (`X`) that are within 0.5 cm from each point in the query data (`Y`).

```
r = 0.5;
[Idx,D] = rangesearch(Mdl,Y,r);
```

`Idx` and `D` are five-element cell arrays of vectors. The vector values in `Idx` are the indices in `X`. The `X` indices represent the observations that are within 0.5 cm of the query data, `Y`. `D` contains the distances that correspond to the observations.

Display the results for query observation 3.

```
Idx{3}
D{3}
```

```
ans =

   127   122

ans =

    0.2646    0.4359
```

The closest observation to `Y(3,:)` is `X(127,:)`, which is `0.2646` cm away. The next closest is `X(122,:)`, which is `0.4359` cm away. All other observations are greater than `0.5` cm away from `Y(5,:)`.

Input Arguments

`Mdl` — Nearest neighbors searcher

`ExhaustiveSearcher` model object | `KDTreeSearcher` model object

Nearest neighbors searcher, specified as an `ExhaustiveSearcher` or `KDTreeSearcher` model object, respectively. To create `Mdl`, with the appropriate mode creator. You can also use `createns`.

If `Mdl` is an `ExhaustiveSearcher` model, then `rangesearch` searches for nearest neighbors using an exhaustive search. Otherwise, `rangesearch` uses the grown *K*d-tree to search for nearest neighbors.

`Y` — Query data

numeric matrix

Query data, specified as a numeric matrix.

`Y` is an *m*-by-*K* matrix. Rows of `Y` correspond to observations (i.e., examples), and columns correspond to predictors (i.e., variables or features). `Y` must have the same number of columns as the training data stored in `Mdl.X`.

`r` — Search radius

nonnegative scalar

Search radius around each point in the query data, specified as a nonnegative scalar.

`rangesearch` finds all observations in Mdl.`X` that are within distance `r` of each observation in Y. The property `Mdl.Distance` stores the distance.

Data Types: `double` | `single`

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single

quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'Distance','minkowski','P',3` specifies to find all observations in `Mdl.X` within distance `r` of each observation in `Y`, using the Minkowski distance metric with exponent 3.

For Both Nearest Neighbor Searchers

`'Distance'` — Distance metric
`Mdl.Distance` (default) | `'cityblock'` | `'euclidean'` | `'mahalanobis'` | `'minkowski'` | `'seuclidean'` | function handle | ...
