## Getting Started

## 1

Financial Toolbox Product Description ..... 1-2
Key Features ..... 1-2
Expected Users ..... 1-3
Analyze Sets of Numbers Using Matrix Functions ..... 1-4
Introduction ..... 1-4
Key Definitions ..... 1-4
Referencing Matrix Elements ..... 1-5
Transposing Matrices ..... 1-6
Matrix Algebra Refresher ..... 1-7
Introduction ..... 1-7
Adding and Subtracting Matrices ..... 1-7
Multiplying Matrices ..... 1-8
Dividing Matrices ..... 1-12
Solving Simultaneous Linear Equations ..... 1-13
Operating Element by Element ..... 1-16
Using Input and Output Arguments with Functions ..... 1-17
Input Arguments ..... 1-17
Output Arguments ..... 1-19
Interest Rate Arguments ..... 1-20
Performing Common Financial Tasks
Introduction ..... 2-2
Handle and Convert Dates ..... 2-4
Date Formats ..... 2-4
Date Conversions ..... 2-5
Current Date and Time ..... 2-8
Determining Dates ..... 2-8
Format Currency ..... 2-11
Charting Financial Data ..... 2-12
Introduction ..... 2-12
High-Low-Close Chart ..... 2-13
Bollinger Chart ..... 2-14
Analyzing and Computing Cash Flows ..... 2-17
Introduction ..... 2-17
Interest Rates/Rates of Return ..... 2-17
Present or Future Values ..... 2-18
Depreciation ..... 2-19
Annuities ..... 2-19
Pricing and Computing Yields for Fixed-Income Securities ..... 2-21
Introduction ..... 2-21
Fixed-Income Terminology ..... 2-21
Framework ..... 2-25
Default Parameter Values ..... 2-26
Coupon Date Calculations ..... 2-28
Yield Conventions ..... 2-29
Pricing Functions ..... 2-29
Yield Functions ..... 2-30
Fixed-Income Sensitivities ..... 2-31
Treasury Bills Defined ..... 2-34
Computing Treasury Bill Price and Yield ..... 2-35
Introduction ..... 2-35
Treasury Bill Repurchase Agreements ..... 2-35
Treasury Bill Yields ..... 2-37
Term Structure of Interest Rates ..... 2-39
Introduction ..... 2-39
Deriving an Implied Zero Curve ..... 2-40
Pricing and Analyzing Equity Derivatives ..... 2-42
Introduction ..... 2-42
Sensitivity Measures ..... 2-42
Analysis Models ..... 2-43
About Life Tables ..... 2-47
Life Tables Theory ..... 2-48
Case Study for Life Tables Analysis ..... 2-50
Portfolio Analysis
3
Analyzing Portfolios ..... 3-2
Portfolio Optimization Functions ..... 3-4
Portfolio Construction Examples ..... 3-7
Introduction ..... 3-7
Efficient Frontier Example ..... 3-7
Portfolio Selection and Risk Aversion ..... 3-9
Introduction ..... 3-9
Optimal Risky Portfolio ..... 3-10
portopt Migration to Portfolio Object ..... 3-14
Migrate portopt Without Output Arguments ..... 3-14
Migrate portopt with Output Arguments ..... 3-16
Migrate portopt for Target Returns Within Range of Efficient Portfolio Returns ..... 3-18
Migrate portopt for Target Return Outside Range of Efficient Portfolio Returns ..... 3-19
Migrate portopt Using portcons Output for ConSet ..... 3-20
Integrate Output from portcons pcalims, pcglims, and pcgcomp with a Portfolio Object ..... 3-22
frontcon Migration to Portfolio Object ..... 3-25
Migrate frontcon Without Output Arguments ..... 3-25
Migrate frontcon with Output Arguments ..... 3-26
Migrate frontcon for Target Returns Within Range of Efficient Portfolio Returns ..... 3-27
Migrate frontcon for Target Returns Outside Range of Efficient Portfolio Returns ..... 3-29
Migrate frontcon Syntax When Using Bounds ..... 3-30
Migrate frontcon Syntax When Using Groups ..... 3-31
Constraint Specification Using a Portfolio Object ..... 3-34
Constraints for Efficient Frontier ..... 3-34
Linear Constraint Equations ..... 3-36
Specifying Group Constraints ..... 3-39
Active Returns and Tracking Error Efficient Frontier ..... 3-43
Mean-Variance Portfolio Optimization Tools
4
Portfolio Optimization Theory ..... 4-2
Portfolio Optimization Problems ..... 4-2
Portfolio Problem Specification ..... 4-2
Return Proxy ..... 4-3
Risk Proxy ..... 4-5
Portfolio Set for Optimization Using Portfolio Object ..... 4-7
Default Portfolio Problem ..... 4-15
Portfolio Object Workflow ..... 4-17
Portfolio Object ..... 4-19
Portfolio Object Properties and Functions ..... 4-19
Working with Portfolio Objects ..... 4-19
Setting and Getting Properties ..... 4-20
Displaying Portfolio Objects ..... 4-21
Saving and Loading Portfolio Objects ..... 4-21
Estimating Efficient Portfolios and Frontiers ..... 4-21
Arrays of Portfolio Objects ..... 4-21
Subclassing Portfolio Objects ..... 4-22
Conventions for Representation of Data ..... 4-22
Creating the Portfolio Object ..... 4-24
Syntax ..... 4-24
Portfolio Problem Sufficiency ..... 4-25
Portfolio Function Examples ..... 4-25
Common Operations on the Portfolio Object ..... 4-32
Naming a Portfolio Object ..... 4-32
Configuring the Assets in the Asset Universe ..... 4-32
Setting Up a List of Asset Identifiers ..... 4-33
Truncating and Padding Asset Lists ..... 4-34
Setting Up an Initial or Current Portfolio ..... 4-35
Setting Up a Tracking Portfolio ..... 4-37
Asset Returns and Moments of Asset Returns Using Portfolio Object ..... 4-41
Assignment Using the Portfolio Function ..... 4-41
Assignment Using the setAssetMoments Function ..... 4-43
Scalar Expansion of Arguments ..... 4-43
Estimating Asset Moments from Prices or Returns ..... 4-45
Estimating Asset Moments with Missing Data ..... 4-48
Estimating Asset Moments from Time Series Data ..... 4-50
Working with a Riskless Asset ..... 4-51
Working with Transaction Costs ..... 4-52
Working with Portfolio Constraints ..... 4-57
Setting Default Constraints for Portfolio Weights Using Portfolio Object ..... 4-57
Working with Bound Constraints Using Portfolio Object ..... 4-60
Working with Budget Constraints Using Portfolio Object ..... 4-62
Working with Group Constraints Using Portfolio Object ..... 4-64
Working with Group Ratio Constraints Using Portfolio Object ..... 4-67
Working with Linear Equality Constraints Using Portfolio Object ..... 4-69
Working with Linear Inequality Constraints Using Portfolio Object ..... 4-71
Working with Average Turnover Constraints Using Portfolio Object ..... 4-73
Working with One-way Turnover Constraints Using Portfolio Object ..... 4-75
Working with Tracking Error Constraints Using Portfolio Object ..... 4-78
Validate the Portfolio Problem for Portfolio Object ..... 4-82
Validating a Portfolio Set ..... 4-82
Validating Portfolios ..... 4-84
Estimate Efficient Portfolios for Portfolio Object ..... 4-87
Obtaining Portfolios Along the Entire Efficient Frontier ..... 4-87
Obtaining Endpoints of the Efficient Frontier ..... 4-88
Obtaining Efficient Portfolios for Target Returns ..... 4-90
Obtaining Efficient Portfolios for Target Risks ..... 4-93
Efficient Portfolio That Maximizes Sharpe Ratio ..... 4-95
Choosing and Controlling the Solver ..... 4-97
Estimate Efficient Frontiers for Portfolio Object ..... 4-99
Obtaining Portfolio Risks and Returns ..... 4-99
Plotting the Efficient Frontier for a Portfolio Object ..... 4-101
Postprocessing Results ..... 4-107
Setting Up Tradable Portfolios ..... 4-107
Troubleshooting Portfolio Optimization Results ..... 4-108
Portfolio Optimization Examples ..... 4-114
Asset Allocation Case Study ..... 4-142
Portfolio Optimization Against a Benchmark ..... 4-157
CVaR Portfolio Optimization Tools
5
Portfolio Optimization Theory ..... 5-2
Portfolio Optimization Problems ..... 5-2
Portfolio Problem Specification ..... 5-2
Return Proxy ..... 5-3
Risk Proxy ..... 5-5
Portfolio Set for Optimization Using PortfolioCVaR Object ..... 5-7
Default Portfolio Problem ..... 5-14
PortfolioCVaR Object Workflow ..... 5-16
PortfolioCVaR Object ..... 5-18
PortfolioCVaR Object Properties and Functions ..... 5-18
Working with PortfolioCVaR Objects ..... 5-18
Setting and Getting Properties ..... 5-19
Displaying PortfolioCVaR Objects ..... 5-20
Saving and Loading PortfolioCVaR Objects ..... 5-20
Estimating Efficient Portfolios and Frontiers ..... 5-20
Arrays of PortfolioCVaR Objects ..... 5-20
Subclassing PortfolioCVaR Objects ..... 5-21
Conventions for Representation of Data ..... 5-21
Creating the PortfolioCVaR Object ..... 5-23
Syntax ..... 5-23
PortfolioCVaR Problem Sufficiency ..... 5-24
PortfolioCVaR Function Examples ..... 5-24
Common Operations on the PortfolioCVaR Object ..... 5-31
Naming a PortfolioCVaR Object ..... 5-31
Configuring the Assets in the Asset Universe ..... 5-31
Setting Up a List of Asset Identifiers ..... 5-32
Truncating and Padding Asset Lists ..... 5-33
Setting Up an Initial or Current Portfolio ..... 5-34
Asset Returns and Scenarios Using PortfolioCVaR Object ..... 5-38
How Stochastic Optimization Works ..... 5-38
What Are Scenarios? ..... 5-39
Setting Scenarios Using the PortfolioCVaR Function ..... 5-39
Setting Scenarios Using the setScenarios Function ..... 5-41
Estimating the Mean and Covariance of Scenarios ..... 5-41
Simulating Normal Scenarios ..... 5-42
Simulating Normal Scenarios from Returns or Prices ..... 5-42
Simulating Normal Scenarios with Missing Data ..... 5-44
Simulating Normal Scenarios from Time Series Data ..... 5-45
Simulating Normal Scenarios with Mean and Covariance ..... 5-47
Working with a Riskless Asset ..... 5-48
Working with Transaction Costs ..... 5-48
Working with CVaR Portfolio Constraints ..... 5-53
Setting Default Constraints for Portfolio Weights Using PortfolioCVaR Object ..... 5-53
Working with Bound Constraints Using PortfolioCVaR Object ..... 5-56
Working with Budget Constraints Using PortfolioCVaR Object ..... 5-58
Working with Group Constraints Using PortfolioCVaR Object ..... 5-60
Working with Group Ratio Constraints Using PortfolioCVaR Object ..... 5-63
Working with Linear Equality Constraints Using PortfolioCVaR Object ..... 5-65
Working with Linear Inequality Constraints Using PortfolioCVaR Object ..... 5-67
Working with Average Turnover Constraints Using PortfolioCVaR Object ..... 5-69
Working with One-way Turnover Constraints Using PortfolioCVaR Object ..... 5-71
Validate the CVaR Portfolio Problem ..... 5-75
Validating a CVaR Portfolio Set ..... 5-75
Validating CVaR Portfolios ..... 5-77
Estimate Efficient Portfolios for PortfolioCVaR Object ..... 5-80
Obtaining Portfolios Along the Entire Efficient Frontier ..... 5-80
Obtaining Endpoints of the Efficient Frontier ..... 5-82
Obtaining Efficient Portfolios for Target Returns ..... 5-84
Obtaining Efficient Portfolios for Target Risks ..... 5-86
Choosing and Controlling the Solver ..... 5-89
Estimate Efficient Frontiers for PortfolioCVaR Object ..... 5-92
Obtaining CVaR Portfolio Risks and Returns ..... 5-92
Obtaining Portfolio Standard Deviation and VaR ..... 5-94
Plotting the Efficient Frontier for a PortfolioCVaR Object ..... 5-95
Postprocessing Results ..... 5-101
Setting Up Tradable Portfolios ..... 5-101
Working with Other Portfolio Objects ..... 5-102
Troubleshooting CVaR Portfolio Optimization Results ..... 5-105
MAD Portfolio Optimization Tools
6
Portfolio Optimization Theory ..... 6-2
Portfolio Optimization Problems ..... 6-2
Portfolio Problem Specification ..... 6-2
Return Proxy ..... 6-3
Risk Proxy ..... 6-5
Portfolio Set for Optimization Using PortfolioMAD Object ..... 6-7
Default Portfolio Problem ..... 6-14
PortfolioMAD Object Workflow ..... 6-16
PortfolioMAD Object ..... 6-17
PortfolioMAD Object Properties and Functions ..... 6-17
Working with PortfolioMAD Objects ..... 6-17
Setting and Getting Properties ..... 6-18
Displaying PortfolioMAD Objects ..... 6-19
Saving and Loading PortfolioMAD Objects ..... 6-19
Estimating Efficient Portfolios and Frontiers ..... 6-19
Arrays of PortfolioMAD Objects ..... 6-19
Subclassing PortfolioMAD Objects ..... 6-20
Conventions for Representation of Data ..... 6-20
Creating the PortfolioMAD Object ..... 6-22
Syntax ..... 6-22
PortfolioMAD Problem Sufficiency ..... 6-23
PortfolioMAD Function Examples ..... 6-23
Common Operations on the PortfolioMAD Object ..... 6-30
Naming a PortfolioMAD Object ..... 6-30
Configuring the Assets in the Asset Universe ..... 6-30
Setting Up a List of Asset Identifiers ..... 6-31
Truncating and Padding Asset Lists ..... 6-32
Setting Up an Initial or Current Portfolio ..... 6-33
Asset Returns and Scenarios Using PortfolioMAD Object ..... 6-37
How Stochastic Optimization Works ..... 6-37
What Are Scenarios? ..... 6-38
Setting Scenarios Using the PortfolioMAD Function ..... 6-38
Setting Scenarios Using the setScenarios Function ..... 6-40
Estimating the Mean and Covariance of Scenarios ..... 6-40
Simulating Normal Scenarios ..... 6-41
Simulating Normal Scenarios from Returns or Prices ..... 6-41
Simulating Normal Scenarios with Missing Data ..... 6-43
Simulating Normal Scenarios from Time Series Data ..... 6-45
Simulating Normal Scenarios for Mean and Covariance ..... 6-46
Working with a Riskless Asset ..... 6-47
Working with Transaction Costs ..... 6-47
Working with MAD Portfolio Constraints ..... 6-52
Setting Default Constraints for Portfolio Weights Using PortfolioMAD Object ..... 6-52
Working with Bound Constraints Using PortfolioMAD Object ..... 6-55
Working with Budget Constraints Using PortfolioMAD Object ..... 6-57
Working with Group Constraints Using PortfolioMAD Object ..... 6-59
Working with Group Ratio Constraints Using PortfolioMAD Object ..... 6-62
Working with Linear Equality Constraints Using PortfolioMAD Object ..... 6-64
Working with Linear Inequality Constraints Using PortfolioMAD Object ..... 6-66
Working with Average Turnover Constraints Using PortfolioMAD Object ..... 6-68
Working with One-way Turnover Constraints Using PortfolioMAD Object ..... 6-70
Validate the MAD Portfolio Problem ..... 6-74
Validating a MAD Portfolio Set ..... 6-74
Validating MAD Portfolios ..... 6-76
Estimate Efficient Portfolios for PortfolioMAD Object ..... 6-79
Obtaining Portfolios Along the Entire Efficient Frontier ..... 6-79
Obtaining Endpoints of the Efficient Frontier ..... 6-81
Obtaining Efficient Portfolios for Target Returns ..... 6-83
Obtaining Efficient Portfolios for Target Risks ..... 6-85
Choosing and Controlling the Solver ..... 6-88
Estimate Efficient Frontiers for PortfolioMAD Object ..... 6-90
Obtaining MAD Portfolio Risks and Returns ..... 6-90
Obtaining the PortfolioMAD Standard Deviation ..... 6-92
Plotting the Efficient Frontier for a PortfolioMAD Object ..... 6-93
Postprocessing Results ..... 6-100
Setting Up Tradable Portfolios ..... 6-100
Working with Other Portfolio Objects ..... 6-101
Troubleshooting MAD Portfolio Optimization Results ..... 6-104
Overview of Performance Metrics ..... 7-2
Performance Metrics Types ..... 7-2
Performance Metrics ..... 7-2
Using the Sharpe Ratio ..... 7-5
Introduction ..... 7-5
Sharpe Ratio ..... 7-5
Using the Information Ratio ..... 7-7
Introduction ..... 7-7
Information Ratio ..... 7-7
Tracking Error ..... 7-9
Introduction ..... 7-9
Tracking Error ..... 7-9
Risk-Adjusted Return ..... 7-11
Introduction ..... 7-11
Risk-Adjusted Return ..... 7-11
Sample and Expected Lower Partial Moments ..... 7-14
Introduction ..... 7-14
Sample Lower Partial Moments ..... 7-14
Expected Lower Partial Moments ..... 7-15
Maximum and Expected Maximum Drawdown ..... 7-17
Introduction ..... 7-17
Maximum Drawdown ..... 7-17
Expected Maximum Drawdown ..... 7-20
Credit Risk Analysis
8
Credit Rating by Bagging Decision Trees ..... 8-2
Estimation of Transition Probabilities ..... 8-21
Introduction ..... 8-21
Estimate Transition Probabilities ..... 8-21
Estimate Transition Probabilities for Different Rating Scales ..... 8-24
Estimate Point-in-Time and Through-the-Cycle Probabilities ..... 8-25
Estimate $t$-Year Default Probabilities ..... 8-28
Estimate Bootstrap Confidence Intervals ..... 8-29
Group Credit Ratings ..... 8-30
Work with Nonsquare Matrices ..... 8-32
Remove Outliers ..... 8-34
Estimate Probabilities for Different Segments ..... 8-35
Work with Large Datasets ..... 8-36
Forecasting Corporate Default Rates ..... 8-39
Credit Quality Thresholds ..... 8-70
Introduction ..... 8-70
Compute Credit Quality Thresholds ..... 8-70
Visualize Credit Quality Thresholds ..... 8-71
About Credit Scorecards ..... 8-75
What Is a Credit Scorecard? ..... 8-75
Credit Scorecard Development Process ..... 8-78
Credit Scorecard Modeling Workflow ..... 8-80
Troubleshooting Credit Scorecard Results ..... 8-83
Predictor Name Is Unspecified and the Parser Returns an Error ..... 8-83
Using bininfo or plotbins Before Binning ..... 8-83
If Categorical Data Is Given as Numeric ..... 8-86
NaNs Returned When Scoring a "Test" Dataset ..... 8-89
Case Study for a Credit Scorecard Analysis ..... 8-93
Regression with Missing
9
Multivariate Normal Regression ..... 9-2
Introduction ..... 9-2
Multivariate Normal Linear Regression ..... 9-2
Maximum Likelihood Estimation ..... 9-3
Special Case of Multiple Linear Regression Model ..... 9-4
Least-Squares Regression ..... 9-5
Mean and Covariance Estimation ..... 9-5
Convergence ..... 9-5
Fisher Information ..... 9-6
Statistical Tests ..... 9-7
Maximum Likelihood Estimation with Missing Data ..... 9-9
Introduction ..... 9-9
ECM Algorithm ..... 9-10
Standard Errors ..... 9-10
Data Augmentation ..... 9-11
Multivariate Normal Regression Functions ..... 9-12
Multivariate Normal Regression Without Missing Data ..... 9-13
Multivariate Normal Regression with Missing Data ..... 9-14
Least-Squares Regression with Missing Data ..... 9-14
Multivariate Normal Parameter Estimation with Missing Data ..... 9-15
Support Functions ..... 9-15
Multivariate Normal Regression Types ..... 9-17
Regressions ..... 9-17
Multivariate Normal Regression ..... 9-18
Multivariate Normal Regression Without Missing Data ..... 9-18
Multivariate Normal Regression with Missing Data ..... 9-18
Least-Squares Regression ..... 9-18
Least-Squares Regression Without Missing Data ..... 9-19
Least-Squares Regression with Missing Data ..... 9-19
Covariance-Weighted Least Squares ..... 9-19
Covariance-Weighted Least Squares Without Missing Data ..... 9-20
Covariance-Weighted Least Squares with Missing Data ..... 9-20
Feasible Generalized Least Squares ..... 9-20
Feasible Generalized Least Squares Without Missing Data ..... 9-20
Feasible Generalized Least Squares with Missing Data ..... 9-21
Seemingly Unrelated Regression ..... 9-21
Seemingly Unrelated Regression Without Missing Data ..... 9-22
Seemingly Unrelated Regression with Missing Data ..... 9-22
Mean and Covariance Parameter Estimation ..... 9-23
Troubleshooting Multivariate Normal Regression ..... 9-23
Slow Convergence ..... 9-24
Nonrandom Residuals ..... 9-24
Nonconvergence ..... 9-25
Portfolios with Missing Data ..... 9-26
Valuation with Missing Data ..... 9-33
Introduction ..... 9-33
Capital Asset Pricing Model ..... 9-33
Estimation of the CAPM ..... 9-34
Estimation with Missing Data ..... 9-35
Estimation of Some Technology Stock Betas ..... 9-35
Grouped Estimation of Some Technology Stock Betas ..... 9-37
References ..... 9-40
Solving Sample Problems
Introduction ..... 10-2
Sensitivity of Bond Prices to Interest Rates ..... 10-3
Step 1 ..... 10-3
Step 2 ..... 10-4
Step 3 ..... 10-4
Step 4 ..... 10-4
Step 5 ..... 10-5
Step 6 ..... 10-5
Step 7 ..... 10-5
Bond Portfolio for Hedging Duration and Convexity ..... 10-7
Step 1 ..... 10-7
Step 2 ..... 10-7
Step 3 ..... 10-8
Step 4 ..... 10-8
Step 5 ..... 10-8
Step 6 ..... 10-9
Bond Prices and Yield Curve Parallel Shifts ..... 10-10
Step 1 ..... 10-10
Step 2 ..... 10-10
Step 3 ..... 10-11
Step 4 ..... 10-11
Step 5 ..... 10-12
Bond Prices and Yield Curve Nonparallel Shifts ..... 10-15
Step 1 ..... 10-16
Step 2 ..... 10-16
Step 3 ..... 10-16
Greek-Neutral Portfolios of European Stock Options ..... 10-18
Step 1 ..... 10-18
Step 2 ..... 10-19
Step 3 ..... 10-20
Step 4 ..... 10-20
Term Structure Analysis and Interest-Rate Swaps ..... 10-22
Step 1 ..... 10-22
Step 2 ..... 10-23
Step 3 ..... 10-23
Step 4 ..... 10-24
Step 5 ..... 10-24
Step 6 ..... 10-24
Producing Graphics with the Toolbox ..... 10-26
Introduction ..... 10-26
Plotting an Efficient Frontier ..... 10-26
Plotting Sensitivities of an Option ..... 10-30
Plotting Sensitivities of a Portfolio of Options ..... 10-31
Financial Time Series Analysis
Analyzing Financial Time Series ..... 11-2
Creating Financial Time Series Objects ..... 11-3
Introduction ..... 11-3
Using the Constructor ..... 11-3
Transforming a Text File ..... 11-13
Visualizing Financial Time Series Objects ..... 11-16
Introduction ..... 11-16
Using chartfts ..... 11-16
Zoom Tool ..... 11-19
Combine Axes Tool ..... 11-22
Introduction ..... 12-2
Working with Financial Time Series Objects ..... 12-3
Introduction ..... 12-3
Financial Time Series Object Structure ..... 12-3
Data Extraction ..... 12-4
Object-to-Matrix Conversion ..... 12-6
Indexing a Financial Time Series Object ..... 12-7
Financial Time Series Operations ..... 12-14
Data Transformation and Frequency Conversion ..... 12-17
Using Time Series to Predict Equity Return ..... 12-23
Financial Time Series App
What Is the Financial Time Series App? ..... 13-2
Getting Started with the Financial Time Series App ..... 13-4
Loading Data with the Financial Time Series App ..... 13-7
Overview ..... 13-7
Obtaining External Data ..... 13-7
Obtaining Internal Data ..... 13-9
Viewing the MATLAB Workspace ..... 13-10
Using the Financial Time Series App ..... 13-13
Creating a Financial Time Series Object ..... 13-13
Merge Financial Time Series Objects ..... 13-14
Converting a Financial Time Series Object to a MATLAB Double-Precision Matrix ..... 13-14
Plotting the Output in Several Formats ..... 13-15
Viewing Data for a Financial Time Series Object in the Data Table ..... 13-16
Modifying Data for a Financial Time Series Object in the Data Table ..... 13-17
Viewing and Modifying the Properties for a FINTS Object ..... 13-19
Using the Financial Time Series App with GUIs ..... 13-21
Financial Time Series User Interface
14
Financial Time Series User Interface ..... 14-2
Main Window ..... 14-2
Using the Financial Time Series GUI ..... 14-7
Getting Started ..... 14-7
Data Menu ..... 14-9
Analysis Menu ..... 14-13
Graphs Menu ..... 14-14
Saving Time Series Data ..... 14-18
Trading Date Utilities
15
Trading Calendars User Interface ..... 15-2
UICalendar User Interface ..... 15-4
Using UICalendar in Standalone Mode ..... 15-4
Using UICalendar with an Application ..... 15-4
Technical Analysis
Technical Indicators ..... 16-2
Technical Analysis Examples ..... 16-4
Overview ..... 16-4
Moving Average Convergence/Divergence (MACD) ..... 16-4
Williams \%R ..... 16-6
Relative Strength Index (RSI) ..... 16-8
On-Balance Volume (OBV) ..... 16-10
Stochastic Differential Equations
17
SDEs ..... 17-2
SDE Modeling ..... 17-2
Trials vs. Paths ..... 17-3
NTRIALS, NPERIODS, and NSTEPS ..... 17-3
SDE Class Hierarchy ..... 17-5
SDE Models ..... 17-7
Introduction ..... 17-7
Creating SDE Objects ..... 17-7
Drift and Diffusion ..... 17-12
Available Models ..... 17-13
SDE Methods ..... 17-14
Base SDE Models ..... 17-15
Overview ..... 17-15
Example: Base SDE Models ..... 17-15
Drift and Diffusion Models ..... 17-18
Overview ..... 17-18
Example: Drift and Diffusion Rates ..... 17-19
Example: SDEDDO Models ..... 17-20
Linear Drift Models ..... 17-22
Overview ..... 17-22
Example: SDELD Models ..... 17-22
Parametric Models ..... 17-24
Creating Brownian Motion (BM) Models ..... 17-24

## Financial Toolbox Product Description <br> Analyze financial data and develop financial models

Financial Toolbox provides functions for mathematical modeling and statistical analysis of financial data. You can optimize portfolios of financial instruments, optionally taking into account turnover and transaction costs. The toolbox enables you to estimate risk, analyze interest rate levels, price equity and interest rate derivatives, and measure investment performance. Time series analysis functions and an app let you perform transformations or regressions with missing data and convert between different trading calendars and day-count conventions.

## Key Features

- Mean-variance and CVaR-based object-oriented portfolio optimization
- Cash flow analysis, risk analysis, financial time-series modeling, date math, and calendar math
- Basic SIA-compliant fixed-income security analysis
- Basic Black-Scholes, Black, and binomial option pricing
- Regression and estimation with missing data
- Basic GARCH estimation, simulation, and forecasting
- Technical indicators and financial charts

## Expected Users

In general, this guide assumes experience working with financial derivatives and some familiarity with the underlying models.

In designing Financial Toolbox documentation, we assume that your title is like one of these:

- Analyst, quantitative analyst
- Risk manager
- Portfolio manager
- Asset allocator
- Financial engineer
- Trader
- Student, professor, or other academic

We also assume that your background, education, training, and responsibilities match some aspects of this profile:

- Finance, economics, perhaps accounting
- Engineering, mathematics, physics, other quantitative sciences
- Focus on quantitative approaches to financial problems

# Analyze Sets of Numbers Using Matrix Functions 

In this section...<br>"Introduction" on page 1-4<br>"Key Definitions" on page 1-4<br>"Referencing Matrix Elements" on page 1-5<br>"Transposing Matrices" on page 1-6

## Introduction

Many financial analysis procedures involve sets of numbers; for example, a portfolio of securities at various prices and yields. Matrices, matrix functions, and matrix algebra are the most efficient ways to analyze sets of numbers and their relationships. Spreadsheets focus on individual cells and the relationships between cells. While you can think of a set of spreadsheet cells (a range of rows and columns) as a matrix, a matrixoriented tool like MATLAB ${ }^{\circledR}$ software manipulates sets of numbers more quickly, easily, and naturally. For more information, see "Matrix Algebra Refresher" on page 1-7.

## Key Definitions

## Matrix

A rectangular array of numeric or algebraic quantities subject to mathematical operations; the regular formation of elements into rows and columns. Described as a " $m$ -by- $n$ " matrix, with $m$ the number of rows and $n$ the number of columns. The description is always "row-by-column." For example, here is a 2 -by- 3 matrix of two bonds (the rows) with different par values, coupon rates, and coupon payment frequencies per year (the columns) entered using MATLAB notation:
Bonds $=\left[\begin{array}{rll}1000 & 0.06 & 2 \\ 500 & 0.055 & 4\end{array}\right]$

## Vector

A matrix with only one row or column. Described as a "1-by-n" or " $m$-by-1" matrix. The description is always "row-by-column." For example, here is a 1-by-4 vector of cash flows in MATLAB notation:

```
Cash = [1500 4470 5280 -1299]
```

## Scalar

A 1-by-1 matrix; that is, a single number.

## Referencing Matrix Elements

To reference specific matrix elements, use (row, column) notation. For example:

```
Bonds(1,2)
ans =
    0.06
Cash(3)
ans =
5280.00
```

You can enlarge matrices using small matrices or vectors as elements. For example,

```
AddBond = [1000 0.065
2];
```

Bonds = [Bonds; AddBond]
adds another row to the matrix and creates

```
Bonds =
```

| 1000 | 0.06 | 2 |
| ---: | :--- | :--- |
| 500 | 0.055 | 4 |
| 1000 | 0.065 | 2 |

Likewise,
Prices = [987.50
475.00 $995.00]$

Bonds = [Prices, Bonds]
adds another column and creates
Bonds =

| 987.50 | 1000 | 0.06 | 2 |
| :--- | ---: | :--- | :--- |
| 475.00 | 500 | 0.055 | 4 |
| 995.00 | 1000 | 0.065 | 2 |

Finally, the colon (:) is important in generating and referencing matrix elements. For example, to reference the par value, coupon rate, and coupon frequency of the second bond:

BondItems $=$ Bonds(2, 2:4)
BondItems =
$500.00 \quad 0.055 \quad 4$

## Transposing Matrices

Sometimes matrices are in the wrong configuration for an operation. In MATLAB, the apostrophe or prime character (') transposes a matrix: columns become rows, rows become columns. For example,

Cash $=\left[\begin{array}{llll}1500 & 4470 & 5280 & -1299\end{array}\right]^{\prime}$
produces
Cash =

1500
4470
5280

- 1299

## Matrix Algebra Refresher

In this section...<br>"Introduction" on page 1-7<br>"Adding and Subtracting Matrices" on page 1-7<br>"Multiplying Matrices" on page 1-8<br>"Dividing Matrices" on page 1-12<br>"Solving Simultaneous Linear Equations" on page 1-13<br>"Operating Element by Element" on page 1-16

## Introduction

The explanations in the sections that follow should help refresh your skills for using matrix algebra and using MATLAB functions.

In addition, William Sharpe's Macro-Investment Analysis also provides an excellent explanation of matrix algebra operations using MATLAB. It is available on the Web at:
http://www.stanford.edu/~wfsharpe/mia/mia.htm

Tip When you are setting up a problem, it helps to "talk through" the units and dimensions associated with each input and output matrix. In the example under "Multiplying Matrices" on page 1-8, one input matrix has "five days' closing prices for three stocks," the other input matrix has "shares of three stocks in two portfolios," and the output matrix therefore has "five days' closing values for two portfolios." It also helps to name variables using descriptive terms.

## Adding and Subtracting Matrices

Matrix addition and subtraction operate element-by-element. The two input matrices must have the same dimensions. The result is a new matrix of the same dimensions where each element is the sum or difference of each corresponding input element. For example, consider combining portfolios of different quantities of the same stocks ("shares of stocks A, B, and C [the rows] in portfolios P and Q [the columns] plus shares of A, B, and $C$ in portfolios $R$ and $S "$ ).

```
Portfolios_PQ = [100200
```

```
    500 400
    300 150];
Portfolios_RS = [175 125
    200 200
    100 500];
NewPortfolios = Portfolios_PQ + Portfolios_RS
NewPortfolios =
```

    \(275 \quad 325\)
    700600
    400650
    Adding or subtracting a scalar and a matrix is allowed and also operates element-byelement.

```
SmallerPortf = NewPortfolios-10
```

SmallerPortf =
$265.00 \quad 315.00$
$690.00 \quad 590.00$
$390.00 \quad 640.00$

## Multiplying Matrices

Matrix multiplication does not operate element-by-element. It operates according to the rules of linear algebra. In multiplying matrices, it helps to remember this key rule: the inner dimensions must be the same. That is, if the first matrix is $m$-by- 3 , the second must be 3-by- $n$. The resulting matrix is $m$-by- $n$. It also helps to "talk through" the units of each matrix, as mentioned in "Analyze Sets of Numbers Using Matrix Functions" on page 1-4.

Matrix multiplication also is not commutative; that is, it is not independent of order. $\mathrm{A} * \mathrm{~B}$ does not equal $\mathrm{B} * \mathrm{~A}$. The dimension rule illustrates this property. If A is 1-by- 3 matrix and B is 3 -by- 1 matrix, $\mathrm{A} * \mathrm{~B}$ yields a scalar (1-by- 1 ) matrix but $\mathrm{B} * \mathrm{~A}$ yields a 3-by-3 matrix.

## Multiplying Vectors

Vector multiplication follows the same rules and helps illustrate the principles. For example, a stock portfolio has three different stocks and their closing prices today are:

```
ClosePrices = [42.5 15 78.875]
```

The portfolio contains these numbers of shares of each stock.

```
NumShares = [100
```

    500
    300]
    To find the value of the portfolio, multiply the vectors

```
PortfValue = ClosePrices * NumShares
```

which yields:
PortfValue =

## $3.5413 \mathrm{e}+004$

The vectors are 1-by-3 and 3-by-1; the resulting vector is 1-by-1, a scalar. Multiplying these vectors thus means multiplying each closing price by its respective number of shares and summing the result.

To illustrate order dependence, switch the order of the vectors

```
Values = NumShares * ClosePrices
Values =
    1.0e+004 *
\begin{tabular}{lll}
0.4250 & 0.1500 & 0.7887 \\
2.1250 & 0.7500 & 3.9438 \\
1.2750 & 0.4500 & 2.3663
\end{tabular}
```

which shows the closing values of 100,500 , and 300 shares of each stock, not the portfolio value, and meaningless for this example.

## Computing Dot Products of Vectors

In matrix algebra, if $X$ and $Y$ are vectors of the same length

$$
\begin{aligned}
& Y=\left[y_{1}, y_{2}, \ldots, y_{n}\right] \\
& X=\left[x_{1}, x_{2}, \ldots, x_{n}\right]
\end{aligned}
$$

then the dot product

$$
X \cdot Y=x_{1} y_{1}+x_{2} y_{2}+\ldots+x_{n} y_{n}
$$

is the scalar product of the two vectors. It is an exception to the commutative rule. To compute the dot product in MATLAB, use sum (X .* Y) or sum (Y .* X). Be sure that the two vectors have the same dimensions. To illustrate, use the previous vectors.

```
Value = sum(NumShares .* ClosePrices')
Value =
    3.5413e+004
Value = sum(ClosePrices .* NumShares')
Value =
    3.5413e+004
```

As expected, the value in these cases matches the PortfValue computed previously.

## Multiplying Vectors and Matrices

Multiplying vectors and matrices follows the matrix multiplication rules and process. For example, a portfolio matrix contains closing prices for a week. A second matrix (vector) contains the stock quantities in the portfolio.

| WeekClosePr = [42.5 |  | 15 | 78.875 |
| :---: | :---: | :---: | :---: |
|  | 42.125 | 15.5 | 78.75 |
|  | 42.125 | 15.125 | 79 |
|  | 42.625 | 15.25 | 78.875 |
|  | 43 | 15.25 | 78.625]; |
| PortQuan = [100 |  |  |  |
| 500 |  |  |  |
| 300]; |  |  |  |

To see the closing portfolio value for each day, simply multiply

```
WeekPortValue = WeekClosePr * PortQuan
WeekPortValue =
1.0e+004
```

3.5412
3.5587
3.5475
3.5550
3.5513

The prices matrix is 5 -by- 3 , the quantity matrix (vector) is 3 -by- 1 , so the resulting matrix (vector) is 5 -by- 1 .

## Multiplying Two Matrices

Matrix multiplication also follows the rules of matrix algebra. In matrix algebra notation, if $A$ is an $m$-by- $n$ matrix and $B$ is an $n$-by- $p$ matrix

$$
A=\left[\begin{array}{cccc}
a_{11} & a_{12} & \cdots & a_{1 n} \\
\vdots & \vdots & & \vdots \\
a_{i 1} & a_{i 2} & \cdots & a_{i n} \\
\vdots & \vdots & & \vdots \\
a_{m 1} & a_{m 2} & \cdots & a_{m n}
\end{array}\right], B=\left[\begin{array}{ccccc}
b_{11} & \cdots & b_{1 j} & \cdots & b_{1 p} \\
b_{21} & \cdots & b_{2 j} & \cdots & b_{2 p} \\
\vdots & & \vdots & & \vdots \\
b_{n 1} & \cdots & b_{n j} & \cdots & b_{n p}
\end{array}\right]
$$

then $C=A^{*} B$ is an $m$-by- $p$ matrix; and the element $c_{\mathrm{ij}}$ in the $i$ th row and $j$ th column of $C$ is

$$
c_{i j}=a_{i 1} b_{1 j}+a_{i 2} b_{12}+\ldots+a_{i n} b_{n j}
$$

To illustrate, assume that there are two portfolios of the same three stocks above but with different quantities.

```
Portfolios = [100 200
    500 400
    300 150];
```

Multiplying the 5 -by- 3 week's closing prices matrix by the 3-by-2 portfolios matrix yields a 5-by-2 matrix showing each day's closing value for both portfolios.

PortfolioValues $=$ WeekClosePr * Portfolios
PortfolioValues =
$1.0 e+004$ *

| 3.5412 | 2.6331 |
| :--- | :--- |
| 3.5587 | 2.6437 |
| 3.5475 | 2.6325 |
| 3.5550 | 2.6456 |
| 3.5513 | 2.6494 |

Monday's values result from multiplying each Monday closing price by its respective number of shares and summing the result for the first portfolio, then doing the same for the second portfolio. Tuesday's values result from multiplying each Tuesday closing price by its respective number of shares and summing the result for the first portfolio, then doing the same for the second portfolio. And so on, through the rest of the week. With one simple command, MATLAB quickly performs many calculations.

## Multiplying a Matrix by a Scalar

Multiplying a matrix by a scalar is an exception to the dimension and commutative rules. It just operates element-by-element.

```
Portfolios = [100 200
    500 400
    300 150];
DoublePort = Portfolios * 2
DoublePort =
    200 400
    1000 800
        600 300
```

## Dividing Matrices

Matrix division is useful primarily for solving equations, and especially for solving simultaneous linear equations (see "Solving Simultaneous Linear Equations" on page 1-13). For example, you want to solve for $X$ in $A^{*} X=B$.

In ordinary algebra, you would divide both sides of the equation by $A$, and $X$ would equal $B / A$. However, since matrix algebra is not commutative ( $A^{*} X \neq X^{*} A$ ), different processes apply. In formal matrix algebra, the solution involves matrix inversion. MATLAB, however, simplifies the process by providing two matrix division symbols, left and right ( $\backslash$ and /). In general,
$X=A \backslash B$ solves for $X$ in $A^{*} X=B$ and
$X=B / A$ solves for $X$ in $X^{*} A=B$.
In general, matrix A must be a nonsingular square matrix; that is, it must be invertible and it must have the same number of rows and columns. (Generally, a matrix is invertible if the matrix times its inverse equals the identity matrix. To understand the theory and proofs, consult a textbook on linear algebra such as Elementary Linear Algebra by Hill listed in Appendix A.) MATLAB gives a warning message if the matrix is singular or nearly so.

## Solving Simultaneous Linear Equations

Matrix division is especially useful in solving simultaneous linear equations. Consider this problem: Given two portfolios of mortgage-based instruments, each with certain yields depending on the prime rate, how do you weight the portfolios to achieve certain annual cash flows? The answer involves solving two linear equations.

A linear equation is any equation of the form

$$
a_{1} x+a_{2} y=b,
$$

where $a_{1}, a_{2}$, and $b$ are constants (with $a_{1}$ and $a_{2}$ not both 0 ), and $x$ and $y$ are variables. (It is a linear equation because it describes a line in the $x y$-plane. For example, the equation $2 x+y=8$ describes a line such that if $x=2$, then $y=4$.)

A system of linear equations is a set of linear equations that you usually want to solve at the same time; that is, simultaneously. A basic principle for exact answers in solving simultaneous linear equations requires that there be as many equations as there are unknowns. To get exact answers for $x$ and $y$, there must be two equations. For example, to solve for $x$ and $y$ in the system of linear equations

$$
\begin{aligned}
& 2 x+y=13 \\
& x-3 y=-18
\end{aligned}
$$

there must be two equations, which there are. Matrix algebra represents this system as an equation involving three matrices: $A$ for the left-side constants, $X$ for the variables, and $B$ for the right-side constants

$$
A=\left[\begin{array}{cc}
2 & 1 \\
1 & -3
\end{array}\right], \quad X=\left[\begin{array}{l}
x \\
y
\end{array}\right], \quad B=\left[\begin{array}{c}
13 \\
-18
\end{array}\right],
$$

where $A^{*} X=B$.
Solving the system simultaneously means solving for $X$. Using MATLAB,
$\left.A=\begin{array}{cc}2 & 1 \\ 1 & -3\end{array}\right] ;$
$B=[13$
-18];
$X=A \backslash B$
solves for $X$ in $A * X=B$.
X = [37]
So $x=3$ and $y=7$ in this example. In general, you can use matrix algebra to solve any system of linear equations such as

$$
\begin{gathered}
a_{11} x_{1}+a_{12} x_{2}+\ldots+a_{1 n} x_{n}=b_{1} \\
a_{21} x_{1}+a_{22} x_{2}+\ldots+a_{2 n} x_{n}=b_{2} \\
\vdots \\
a_{m 1} x_{1}+a_{m 2} x_{2}+\ldots+a_{m n} x_{n}=b_{m}
\end{gathered}
$$

by representing them as matrices

$$
A=\left[\begin{array}{cccc}
a_{11} & a_{12} & \cdots & a_{1 n} \\
a_{21} & a_{22} & \cdots & a_{2 n} \\
\vdots & \vdots & & \vdots \\
a_{m 1} & a_{m 2} & \cdots & a_{m n}
\end{array}\right], \quad X=\left[\begin{array}{c}
x_{1} \\
x_{2} \\
\vdots \\
x_{n}
\end{array}\right], \quad B=\left[\begin{array}{c}
b_{1} \\
b_{2} \\
\vdots \\
b_{m}
\end{array}\right]
$$

and solving for $X$ in $A^{*} X=B$.
To illustrate, consider this situation. There are two portfolios of mortgage-based instruments, M1 and M2. They have current annual cash payments of \$100 and \$70 per unit, respectively, based on today's prime rate. If the prime rate moves down one percentage point, their payments would be $\$ 80$ and $\$ 40$. An investor holds 10 units of M1 and 20 units of M2. The investor's receipts equal cash payments times units, or $\mathrm{R}=\mathrm{C}$ * U , for each prime-rate scenario. As word equations:

|  | M1 | M2 |
| :--- | :--- | :--- |
| Prime flat: | $\$ 100 * 10$ units | $+\$ 70 * 20$ units $=\$ 2400$ <br> receipts |
| Prime down: | $\$ 80 * 10$ units | $+\$ 40 * 20$ units $=\$ 1600$ <br> receipts |

As MATLAB matrices:

```
Cash = [100 70
    80 40];
Units = [10
    20];
Receipts = Cash * Units
Receipts =
```

    2400
    1600
    Now the investor asks this question: Given these two portfolios and their characteristics, how many units of each should I hold to receive $\$ 7000$ if the prime rate stays flat and $\$ 5000$ if the prime drops one percentage point? Find the answer by solving two linear equations.

|  | M1 | M2 |
| :--- | :--- | :--- |
| Prime flat: | $\$ 100 * x$ units | $+\$ 70 * y$ units $=\$ 7000$ <br> receipts |
| Prime down: | $\$ 80 * x$ units | $+\$ 40 * y$ units $=\$ 5000$ <br> receipts |

In other words, solve for U (units) in the equation R (receipts) = C (cash) * U (units). Using MATLAB left division

```
Cash = [ll00 70
    80 40];
```

Receipts $=[7000$
5000];

```
Units = Cash \ Receipts
Units =
    43.7500
    37.5000
```

The investor should hold 43.75 units of portfolio M1 and 37.5 units of portfolio M2 to achieve the annual receipts desired.

## Operating Element by Element

Finally, element-by-element arithmetic operations are called array operations. To indicate a MATLAB array operation, precede the operator with a period (.). Addition and subtraction, and matrix multiplication and division by a scalar, are already array operations so no period is necessary. When using array operations on two matrices, the dimensions of the matrices must be the same. For example, given vectors of stock dividends and closing prices

```
Dividends = [1.90 0.40 1.56 4.50];
Prices = [\begin{array}{llll}{25.625 17.75 26.125 60.50];}\end{array}]
Yields = Dividends ./ Prices
Yields =
\begin{tabular}{llll}
0.0741 & 0.0225 & 0.0597 & 0.0744
\end{tabular}
```

# Using Input and Output Arguments with Functions 

In this section...<br>"Input Arguments" on page 1-17<br>"Output Arguments" on page 1-19<br>"Interest Rate Arguments" on page 1-20

## Input Arguments

## Matrix Input

MATLAB software was designed to be a large-scale array (vector or matrix) processor. In addition to its linear algebra applications, the general array-based processing facility can perform repeated operations on collections of data. When MATLAB code is written to operate simultaneously on collections of data stored in arrays, the code is said to be vectorized. Vectorized code is not only clean and concise, but is also efficiently processed by MATLAB.

Because MATLAB can process vectors and matrices easily, most Financial Toolbox functions allow vector or matrix input arguments, rather than single (scalar) values. For example, the irr function computes the internal rate of return of a cash flow stream. It accepts a vector of cash flows and returns a scalar-valued internal rate of return. However, it also accepts a matrix of cash flow streams, a column in the matrix representing a different cash flow stream. In this case, irr returns a vector of internal rates of return, each entry in the vector corresponding to a column of the input matrix. Many other toolbox functions work similarly.

As an example, suppose that you make an initial investment of $\$ 100$, from which you then receive by a series of annual cash receipts of $\$ 10, \$ 20, \$ 30, \$ 40$, and $\$ 50$. This cash flow stream may be stored in a vector

```
CashFlows = [-100 10 20 30 40 50]'
```

which MATLAB displays as

```
CashFlows =
```

    - 100
        10
        20
    The irr function can compute the internal rate of return of this stream.

```
Rate = irr(CashFlows)
```

The internal rate of return of this investment is

## Rate =

$$
0.1201
$$

or 12.01\%.
In this case, a single cash flow stream (written as an input vector) produces a scalar output - the internal rate of return of the investment.

Extending this example, if you process a matrix of identical cash flow streams

```
Rate = irr([CashFlows CashFlows CashFlows])
```

you should expect to see identical internal rates of return for each of the three investments.

## Rate =

$$
\begin{array}{lll}
0.1201 & 0.1201 & 0.1201
\end{array}
$$

This simple example illustrates the power of vectorized programming. The example shows how to collect data into a matrix and then use a toolbox function to compute answers for the entire collection. This feature can be useful in portfolio management, for example, where you might want to organize multiple assets into a single collection. Place data for each asset in a different column or row of a matrix, then pass the matrix to a Financial Toolbox function. MATLAB performs the same computation on all of the assets at once.

## Matrices of String Input

Enter MATLAB strings surrounded by single quotes ('string ').
Strings are stored as character arrays, one ASCII character per element. Thus, the date string

DateString = '9/16/2001'
is actually a 1 -by- 9 vector. Strings making up the rows of a matrix or vector all must have the same length. To enter several date strings, therefore, use a column vector and be sure that all strings are the same length. Fill in with spaces or zeros. For example, to create a vector of dates corresponding to irregular cash flows

```
DateFields = ['01/12/2001'
    '02/14/2001'
    '03/03/2001'
    '06/14/2001'
    '12/01/2001'];
```

DateFields actually becomes a 5 -by- 10 character array.
Do not mix numbers and strings in a matrix. If you do, MATLAB treats all entries as characters. For example,

```
Item = [\begin{array}{lll}{83}&{90}&{99}\\{'14-Sep-1999']}\end{array}]
```

becomes a 1-by-14 character array, not a 1-by-4 vector, and it contains

```
Item =
```

SZc14-Sep-1999

## Output Arguments

Some functions return no arguments, some return just one, and some return multiple arguments. Functions that return multiple arguments use the syntax
[A, B, C] = function(variables...)
to return arguments $A, B$, and $C$. If you omit all but one, the function returns the first argument. Thus, for this example if you use the syntax

X = function(variables...)
function returns a value for A , but not for B or C .
Some functions that return vectors accept only scalars as arguments. Why could such functions not accept vectors as arguments and return matrices, where each column in the output matrix corresponds to an entry in the input vector? The answer is that the output
vectors can be variable length and thus will not fit in a matrix without some convention to indicate that the shorter columns are missing data.

Functions that require asset life as an input, and return values corresponding to different periods over that life, cannot generally handle vectors or matrices as input arguments. Those functions are:

| amortize | Amortization |
| :--- | :--- |
| depfixdb | Fixed declining-balance depreciation |
| depgendb | General declining-balance depreciation |
| depsoyd | Sum of years' digits depreciation |

For example, suppose you have a collection of assets such as automobiles and you want to compute the depreciation schedules for them. The function depfixdb computes a stream of declining-balance depreciation values for an asset. You might want to set up a vector where each entry is the initial value of each asset. depfixdb also needs the lifetime of an asset. If you were to set up such a collection of automobiles as an input vector, and the lifetimes of those automobiles varied, the resulting depreciation streams would differ in length according to the life of each automobile, and the output column lengths would vary. A matrix must have the same number of rows in each column.

## Interest Rate Arguments

One common argument, both as input and output, is interest rate. All Financial Toolbox functions expect and return interest rates as decimal fractions. Thus an interest rate of $9.5 \%$ is indicated as 0.095 .

## Introduction

Financial Toolbox software contains functions that perform many common financial tasks, including:

- "Handle and Convert Dates" on page 2-4

Calendar functions convert dates among different formats (including Excel ${ }^{\circledR}$ formats), determine future or past dates, find dates of holidays and business days, compute time differences between dates, find coupon dates and coupon periods for coupon bonds, and compute time periods based on 360-, 365 -, or 366 -day years.

- "Format Currency" on page 2-11

The toolbox includes functions for handling decimal values in bank (currency) formats and as fractional prices.

- "Charting Financial Data" on page 2-12

Charting functions produce various financial charts including Bollinger bands, high-low-close charts, candlestick plots, point and figure plots, and moving-average plots.

- "Analyzing and Computing Cash Flows" on page 2-17

Cash-flow evaluation and financial accounting functions compute interest rates, rates of return, payments associated with loans and annuities, future and present values, depreciation, and other standard accounting calculations associated with cash-flow streams.

- "Pricing and Computing Yields for Fixed-Income Securities" on page 2-21

Securities Industry Association (SIA) compliant fixed-income functions compute prices, yields, accrued interest, and sensitivities for securities such as bonds, zerocoupon bonds, and Treasury bills. They handle odd first and last periods in price/yield calculations, compute accrued interest and discount rates, and calculate convexity and duration. Another set of functions analyzes term structure of interest rates, including pricing bonds from yield curves and bootstrapping yield curves from market prices.

- "Pricing and Analyzing Equity Derivatives" on page 2-42

Derivatives analysis functions compute prices, yields, and sensitivities for derivative securities. They deal with both European and American options.

Black-Scholes functions work with European options. They compute delta, gamma, lambda, rho, theta, and vega, as well as values of call and put options.

Binomial functions work with American options, computing put and call prices.

- "Analyzing Portfolios" on page 3-2

Portfolio analysis functions provide basic utilities to compute variances and covariance of portfolios, find combinations to minimize variance, compute Markowitz efficient frontiers, and calculate combined rates of return.

- Modeling volatility in time series.

Generalized Autoregressive Conditional Heteroskedasticity (GARCH) functions model the volatility of univariate economic time series. (Econometrics Toolbox ${ }^{\mathrm{TM}}$ software provides a more comprehensive and integrated computing environment. For information, see the Econometrics Toolbox documentation or the financial products Web page at http://www.mathworks.com/products/finprod.)

## Handle and Convert Dates

In this section...<br>"Date Formats" on page 2-4<br>"Date Conversions" on page 2-5<br>"Current Date and Time" on page 2-8<br>"Determining Dates" on page 2-8

## Date Formats

Since virtually all financial data is dated or derives from a time series, financial functions must have extensive date-handling capabilities. You most often work with date strings (14-Sep-1999) when dealing with dates. Financial Toolbox software works internally with serial date numbers (for example, 730377). A serial date number represents a calendar date as the number of days that has passed since a fixed base date. In MATLAB software, serial date number 1 is January 1, 0000 A.D. MATLAB also uses serial time to represent fractions of days beginning at midnight; for example, 6 p.m. equals 0.75 serial days. So 6:00 p.m. on 14-Sep-1999, in MATLAB, is date number 730377.75.

Note If you specify a two-digit year, MATLAB assumes that the year lies within the 100-year period centered about the current year. See the function datenum for specific information. MATLAB internal date handling and calculations generate no ambiguous values. However, whenever possible, programmers should use serial date numbers or date strings containing four-digit years.

Many toolbox functions that require dates accept either date strings or serial date numbers. If you are dealing with a few dates at the MATLAB command-line level, date strings are more convenient. If you are using toolbox functions on large numbers of dates, as in analyzing large portfolios or cash flows, performance improves if you use date numbers.

The Financial Toolbox software provides functions that convert date strings to serial date numbers, and vice versa.

## Date Conversions

Functions that convert between date formats are

| datedisp | Displays a numeric matrix with date entries formatted as date <br> strings |
| :--- | :--- |
| datenum | Converts a date string to a serial date number |
| datestr | Converts a serial date number to a date string |
| m2xdate | Converts MATLAB serial date number to Excel serial date number |
| x2mdate | Converts Excel serial date number to MATLAB serial date number |

Another function, datevec, converts a date number or date string to a date vector whose elements are [Year Month Day Hour Minute Second]. Date vectors are mostly an internal format for some MATLAB functions; you would not often use them in financial calculations.

## Input Conversions

The datenum function is important for using Financial Toolbox software efficiently. datenum takes an input string in any of several formats, with 'dd-mmm-yyyy', 'mm/ dd/yyyy', or 'dd-mmm-yyyy, hh:mm:ss.ss' most common. The input string can have up to six fields formed by letters and numbers separated by any other characters:

- The day field is an integer from 1 through 31.
- The month field is either an integer from 1 through 12 or an alphabetical string with at least three characters.
- The year field is a nonnegative integer: if only two numbers are specified, then the year is assumed to lie within the 100-year period centered about the current year; if the year is omitted, the current year is used as the default.
- The hours, minutes, and seconds fields are optional. They are integers separated by colons or followed by 'am' or 'pm'.

For example, if the current year is 1999, then these are all equivalent
'17-May-1999 '
'17-May-99'
'17-may'
'May 17, 1999

```
'5/17/99'
'5/17'
```

and both of these represent the same time.

```
'17-May-1999, 18:30'
'5/17/99/6:30 pm'
```

The default format for numbers-only input follows the American convention. Thus $3 / 6$ is March 6, not June 3.

With datenum you can convert dates into serial date format, store them in a matrix variable, then later pass the variable to a function. Alternatively, you can use datenum directly in a function input argument list.

For example, consider the function bndprice that computes the price of a bond given the yield-to-maturity. First set up variables for the yield-to-maturity, coupon rate, and the necessary dates.

```
Yield = 0.07;
CouponRate = 0.08;
Settle = datenum('17-May-2000');
Maturity = datenum('01-Oct-2000');
```

Then call the function with the variables
bndprice(Yield, CouponRate, Settle, Maturity)
Alternatively, convert date strings to serial date numbers directly in the function input argument list.

```
bndprice(0.07, 0.08, datenum('17-May-2000'),...
```

datenum('01-0ct-2000'))
bndprice is an example of a function designed to detect the presence of date strings and make the conversion automatically. For these functions date strings may be passed directly.

```
bndprice(0.07, 0.08, '17-May-2000', '01-Oct-2000')
```

The decision to represent dates as either date strings or serial date numbers is often a matter of convenience. For example, when formatting data for visual display or for debugging date-handling code, it is often much easier to view dates as date strings because serial date numbers are difficult to interpret. Alternatively, serial date numbers
are just another type of numeric data, and can be placed in a matrix along with any other numeric data for convenient manipulation.

Remember that if you create a vector of input date strings, use a column vector, and be sure that all strings are the same length. Fill with spaces or zeros. See "Matrices of String Input" on page 1-18.

## Output Conversions

The function datestr converts a serial date number to one of 19 different date string output formats showing date, time, or both. The default output for dates is a day-monthyear string, for example, 24-Aug-2000. This function is useful for preparing output reports.

| Format | Description |
| :--- | :--- |
| 01-Mar-2000 15:45:17 | day-month-year hour:minute:second |
| 01-Mar-2000 | day-month-year |
| 03/01/00 | month/day/year |
| Mar | month, three letters |
| M | month, single letter |
| 3 | month |
| 03/01 | month/day |
| 1 | day of month |
| Wed | day of week, three letters |
| W | day of week, single letter |
| 2000 | year, four numbers |
| 99 | year, two numbers |
| Mar01 | month year |
| $15: 45: 17$ | hour:minute:second |
| $03: 45: 17$ PM | hour:minute:second AM or PM |
| $15: 45$ | hour:minute |
| $03: 45$ PM | hour:minute AM or PM |
| Q1-99 | calendar quarter-year |
| Q1 | calendar quarter |

## Current Date and Time

The functions today and now return serial date numbers for the current date, and the current date and time, respectively.
today
ans =
730693
now
ans $=$
730693.48

The MATLAB function date returns a string for today's date.
date
ans $=$
26-Jul-2000

## Determining Dates

The Financial Toolbox software provides many functions for determining specific dates, including functions which account for holidays and other nontrading days. For example, you schedule an accounting procedure for the last Friday of every month. The lweekdate function returns those dates for 2000; the 6 specifies Friday.

Fridates = lweekdate(6, 2000, 1:12);
Fridays = datestr(Fridates)
Fridays =
28-Jan-2000
25-Feb-2000
31-Mar-2000
28-Apr-2000
26-May-2000
30-Jun-2000
28-Jul-2000

25-Aug-2000
29-Sep-2000
27-0ct-2000
24 -Nov-2000
29-Dec-2000
Or your company closes on Martin Luther King Jr. Day, which is the third Monday in January. The nweekdate function determines those dates for 2001 through 2004.

```
MLKDates = nweekdate(3, 2, 2001:2004, 1);
MLKDays = datestr(MLKDates)
MLKDays =
15-Jan-2001
21-Jan-2002
20-Jan-2003
19-Jan-2004
```

Accounting for holidays and other nontrading days is important when examining financial dates. The Financial Toolbox software provides the holidays function, which contains holidays and special nontrading days for the New York Stock Exchange from 1950 through 2030, inclusive. In addition, you can use nyseclosures to evaluate all known or anticipated closures of the New York Stock Exchange from January 1, 1885 to December 31, 2050. nyseclosures returns a vector of serial date numbers corresponding to market closures between the dates StartDate and EndDate, inclusive.

In this example, you can use holidays to determine the standard holidays in the last half of 2000:

LHHDates = holidays('1-Jul-2000', '31-Dec-2000');
LHHDays = datestr(LHHDates)
LHHDays =
04-Jul-2000
04-Sep-2000
23-Nov-2000
25-Dec-2000
Now use the toolbox busdate function to determine the next business day after these holidays.

```
LHNextDates = busdate(LHHDates);
LHNextDays = datestr(LHNextDates)
LHNextDays =
```

05-Jul-2000
05-Sep-2000
24-Nov-2000
26-Dec-2000

The toolbox also provides the cfdates function to determine cash-flow dates for securities with periodic payments. This function accounts for the coupons per year, the day-count basis, and the end-of-month rule. For example, to determine the cash-flow dates for a security that pays four coupons per year on the last day of the month, on an actual/365 day-count basis, enter the settlement date, the maturity date, and the parameters.

```
PayDates = cfdates('14-Mar-2000', '30-Nov-2001', 4, 3, 1);
```

PayDays = datestr(PayDates)
PayDays =
31-May-2000
31-Aug-2000
30-Nov-2000
28-Feb-2001
31-May-2001
31-Aug-2001
30-Nov-2001

## Related Examples

- "Format Currency" on page 2-11
- "Charting Financial Data" on page 2-12

## Format Currency

Financial Toolbox software provides several functions to format currency and chart financial data. The currency formatting functions are

| cur2frac | Converts decimal currency values to fractional values |
| :--- | :--- |
| cur2str | Converts a value to Financial Toolbox bank format |
| frac2cur | Converts fractional currency values to decimal values |

These examples show their use.

```
Dec = frac2cur('12.1', 8)
```

returns Dec $=12.125$, which is the decimal equivalent of $12-1 / 8$. The second input variable is the denominator of the fraction.

```
Str = cur2str(-8264, 2)
```

returns the string ( $\$ 8264.00$ ). For this toolbox function, the output format is a numerical format with dollar sign prefix, two decimal places, and negative numbers in parentheses; for example, (\$123.45) and \$6789.01. The standard MATLAB bank format uses two decimal places, no dollar sign, and a minus sign for negative numbers; for example, -123.45 and 6789.01.

## Charting Financial Data

In this section...<br>"Introduction" on page 2-12<br>"High-Low-Close Chart" on page 2-13<br>"Bollinger Chart" on page 2-14

## Introduction

The following toolbox financial charting functions plot financial data and produce presentation-quality figures quickly and easily.

| bolling | Bollinger band chart |
| :--- | :--- |
| bollinger | Time series Bollinger band |
| candle | Candlestick chart |
| candle | Time series candle plot |
| pointfig | Point and figure chart |
| highlow | High, low, open, close chart |
| highlow | Time series High-Low plot |
| movavg | Leading and lagging moving averages chart |

These functions work with standard MATLAB functions that draw axes, control appearance, and add labels and titles. The toolbox also provides a comprehensive set of charting functions that work with financial time series objects, see "Chart Technical Indicators".

Here are two plotting examples: a high-low-close chart of sample IBM $^{\circledR}$ stock price data, and a Bollinger band chart of the same data. These examples load data from an external file (ibm. dat), then call the functions using subsets of the data. The MATLAB variable ibm, which is created by loading ibm. dat, is a six-column matrix where each row is a trading day's data and where columns 2,3 , and 4 contain the high, low, and closing prices, respectively.

Note The data in ibm.dat is fictional and for illustrative use only.

## High-Low-Close Chart

Load the data and set up matrix dimensions. load and size are standard MATLAB® functions.

```
load ibm.dat;
[ro, co] = size(ibm);
```

Open a figure window for the chart. Use the Financial Toolbox ${ }^{\text {TM }}$ highlow function to plot high, low, and close prices for the last 50 trading days in the data file. Add labels and title, and set axes with standard MATLAB functions. Use the Financial Toolbox dateaxis function to provide dates for the $x$-axis ticks.

```
figure;
highlow(ibm(ro-50:ro,2),ibm(ro-50:ro,3),ibm(ro-50:ro,4),[],'b');
xlabel('');
ylabel('Price ($)');
title('International Business Machines, 941231 - 950219');
axis([0 50 -inf inf]);
dateaxis('x',6,'31-Dec-1994')
```

## Bollinger Chart

The bolling function in Financial Toolbox ${ }^{\mathrm{TM}}$ software produces a Bollinger band chart using all the closing prices in an IBM® stock price matrix. A Bollinger band chart plots actual data along with three other bands of data. The upper band is two standard deviations above a moving average; the lower band is two standard deviations below that moving average; and the middle band is the moving average itself. This example uses a 15 -day moving average. First, load the data using the ibm.dat data file and then execute the bolling function to plot the Bollinger bands.

```
load ibm.dat;
[ro, co] = size(ibm);
bolling(ibm(:,4), 15, 0);
```

```
axis([0 ro min(ibm(:,4)) max(ibm(:,4))]);
ylabel('Price ($)');
title(['International Business Machines']);
dateaxis('x', 6,'31-Dec-1994')
```

International Business Machines

Specify the axes, labels, and titles. Use dateaxis to add the $x$-axis dates.

For help using MATLAB® plotting functions, see "Create 2-D Graph and Customize Lines" in the MATLAB documentation. See the MATLAB documentation for details on the axis, title, xlabel, and ylabel functions.

```

## Analyzing and Computing Cash Flows

```
In this section...
"Introduction" on page 2-17
"Interest Rates/Rates of Return" on page 2-17
"Present or Future Values" on page 2-18
"Depreciation" on page 2-19
"Annuities" on page 2-19
```

## Introduction

Financial Toolbox cash-flow functions compute interest rates and rates of return, present or future values, depreciation streams, and annuities.

Some examples in this section use this income stream: an initial investment of \$20,000 followed by three annual return payments, a second investment of $\$ 5,000$, then four more returns. Investments are negative cash flows, return payments are positive cash flows.

```
Stream = [-20000, 2000, 2500, 3500, -5000, 6500,...
    9500, 9500, 9500];
```

## Interest Rates/Rates of Return

Several functions calculate interest rates involved with cash flows. To compute the internal rate of return of the cash stream, execute the toolbox function irr

```
ROR = irr(Stream)
```

which gives a rate of return of $11.72 \%$.
The internal rate of return of a cash flow may not have a unique value. Every time the sign changes in a cash flow, the equation defining irr can give up to two additional answers. An irr computation requires solving a polynomial equation, and the number of real roots of such an equation can depend on the number of sign changes in the coefficients. The equation for internal rate of return is

$$
\frac{c f_{1}}{(1+r)}+\frac{c f_{2}}{(1+r)^{2}}+\ldots+\frac{c f_{n}}{(1+r)^{n}}+\text { Investment }=0
$$

where Investment is a (negative) initial cash outlay at time $0, c f_{\mathrm{n}}$ is the cash flow in the $n$th period, and $n$ is the number of periods. irr finds the rate $r$ such that the present value of the cash flow equals the initial investment. If all of the $c f_{\mathrm{n}} \mathrm{s}$ are positive there is only one solution. Every time there is a change of sign between coefficients, up to two additional real roots are possible.

Another toolbox rate function, effrr, calculates the effective rate of return given an annual interest rate (also known as nominal rate or annual percentage rate, APR) and number of compounding periods per year. To find the effective rate of a 9\% APR compounded monthly, enter

Rate $=\operatorname{effrr}(0.09,12)$
The answer is $9.38 \%$.
A companion function nomrr computes the nominal rate of return given the effective annual rate and the number of compounding periods.

## Present or Future Values

The toolbox includes functions to compute the present or future value of cash flows at regular or irregular time intervals with equal or unequal payments: fvfix, fvvar, pvfix, and pvvar. The -fix functions assume equal cash flows at regular intervals, while the - var functions allow irregular cash flows at irregular periods.

Now compute the net present value of the sample income stream for which you computed the internal rate of return. This exercise also serves as a check on that calculation because the net present value of a cash stream at its internal rate of return should be zero. Enter

NPV = pvvar(Stream, ROR)
which returns an answer very close to zero. The answer usually is not exactly zero due to rounding errors and the computational precision of the computer.

Note Other toolbox functions behave similarly. The functions that compute a bond's yield, for example, often must solve a nonlinear equation. If you then use that yield to compute the net present value of the bond's income stream, it usually does not exactly equal the purchase price, but the difference is negligible for practical applications.

## Depreciation

The toolbox includes functions to compute standard depreciation schedules: straight line, general declining-balance, fixed declining-balance, and sum of years' digits. Functions also compute a complete amortization schedule for an asset, and return the remaining depreciable value after a depreciation schedule has been applied.

This example depreciates an automobile worth $\$ 15,000$ over five years with a salvage value of $\$ 1,500$. It computes the general declining balance using two different depreciation rates: $50 \%$ (or 1.5), and $100 \%$ (or 2.0 , also known as double declining balance). Enter

Decline1 = depgendb(15000, 1500, 5, 1.5)

```
Decline2 = depgendb(15000, 1500, 5, 2.0)
```

which returns

```
Decline1 =
    4500.00 3150.00 2205.00 1543.50 2101.50
Docin
    6000.00 3600.00 2160.00 1296.00 444.00
```

These functions return the actual depreciation amount for the first four years and the remaining depreciable value as the entry for the fifth year.

## Annuities

Several toolbox functions deal with annuities. This first example shows how to compute the interest rate associated with a series of loan payments when only the payment amounts and principal are known. For a loan whose original value was $\$ 5000.00$ and which was paid back monthly over four years at $\$ 130.00 /$ month:

Rate $=$ annurate (4*12, 130, 5000, 0, 0)
The function returns a rate of 0.0094 monthly, or about $11.28 \%$ annually.
The next example uses a present-value function to show how to compute the initial principal when the payment and rate are known. For a loan paid at $\$ 300.00 /$ month over four years at $11 \%$ annual interest

Principal = pvfix(0.11/12, 4*12, 300, 0, 0)
The function returns the original principal value of $\$ 11,607.43$.

The final example computes an amortization schedule for a loan or annuity. The original value was $\$ 5000.00$ and was paid back over 12 months at an annual rate of $9 \%$.

```
[Prpmt, Intpmt, Balance, Payment] = ...
    amortize(0.09/12, 12, 5000, 0, 0);
```

This function returns vectors containing the amount of principal paid,

```
Prpmt = [lllla9.76 402.76 405.78 408.82 411.89 414.97
    418.09 421.22 424.38 427.56 430.77 434.00]
```

the amount of interest paid,

```
Intpmt = [lllllllll}37.50 34.50 31.48 28.44 25.37 22.28
    19.17 16.03 12.88 9.69 6.49 3.26]
```

the remaining balance for each period of the loan,

```
Balance = [l4600.24 4197.49 3791.71 3382.89 2971.01
    2556.03 2137.94 1716.72 1292.34 864.77
        434.00 0.00]
```

and a scalar for the monthly payment.

```
Payment = 437.26
```

## Pricing and Computing Yields for Fixed-Income Securities

In this section...<br>"Introduction" on page 2-21<br>"Fixed-Income Terminology" on page 2-21<br>"Framework" on page 2-25<br>"Default Parameter Values" on page 2-26<br>"Coupon Date Calculations" on page 2-28<br>"Yield Conventions" on page 2-29<br>"Pricing Functions" on page 2-29<br>"Yield Functions" on page 2-30<br>"Fixed-Income Sensitivities" on page 2-31

## Introduction

The Financial Toolbox product provides functions for computing accrued interest, price, yield, convexity, and duration of fixed-income securities. Various conventions exist for determining the details of these computations. The Financial Toolbox software supports conventions specified by the Securities Industry and Financial Markets Association (SIFMA), used in the US markets, the International Capital Market Association (ICMA), used mainly in the European markets, and the International Swaps and Derivatives Association (ISDA). For historical reasons, SIFMA is referred to in Financial Toolbox documentation as SIA and ISMA is referred to as International Capital Market Association (ICMA).

## Fixed-Income Terminology

Since terminology varies among texts on this subject, here are some basic definitions that apply to these Financial Toolbox functions. The Glossary contains additional definitions.

The settlement date of a bond is the date when money first changes hands; that is, when a buyer pays for a bond. It need not coincide with the issue date, which is the date a bond is first offered for sale.

The first coupon date and last coupon date are the dates when the first and last coupons are paid, respectively. Although bonds typically pay periodic annual or semiannual coupons, the length of the first and last coupon periods may differ from the standard
coupon period. The toolbox includes price and yield functions that handle these odd first and/or last periods.

Successive quasi-coupon dates determine the length of the standard coupon period for the fixed income security of interest, and do not necessarily coincide with actual coupon payment dates. The toolbox includes functions that calculate both actual and quasicoupon dates for bonds with odd first and/or last periods.

Fixed-income securities can be purchased on dates that do not coincide with coupon payment dates. In this case, the bond owner is not entitled to the full value of the coupon for that period. When a bond is purchased between coupon dates, the buyer must compensate the seller for the pro-rata share of the coupon interest earned from the previous coupon payment date. This pro-rata share of the coupon payment is called accrued interest. The purchase price, the price paid for a bond, is the quoted market price plus accrued interest.

The maturity date of a bond is the date when the issuer returns the final face value, also known as the redemption value or par value, to the buyer. The yield-to-maturity of a bond is the nominal compound rate of return that equates the present value of all future cash flows (coupons and principal) to the current market price of the bond.

The period of a bond refers to the frequency with which the issuer of a bond makes coupon payments to the holder.

Period of a Bond

| Period Value | Payment Schedule |
| :--- | :--- |
| 0 | No coupons (Zero coupon bond) |
| 1 | Annual |
| 2 | Semiannual |
| 3 | Tri-annual |
| 4 | Quarterly |
| 6 | Bi-monthly |
| 12 | Monthly |

The basis of a bond refers to the basis or day-count convention for a bond. Basis is normally expressed as a fraction in which the numerator determines the number of days between two dates, and the denominator determines the number of days in the year. For example, the numerator of actual/actual means that when determining the number of days between two dates, count the actual number of days; the denominator means that
you use the actual number of days in the given year in any calculations (either 365 or 366 days depending on whether the given year is a leap year).

The day count convention determines how accrued interest is calculated and determines how cash flows for the bond are discounted, by that means effecting price and yield calculations. Furthermore, the SIA convention is to use the actual/actual day count convention for discounting cash flows in all cases.

Basis of a Bond
$\left.\begin{array}{|l|l|l|}\hline \text { Basis Value } & \text { Meaning } & \text { Description } \\ \hline 0 \text { (default) } & \text { actual/actual } & \begin{array}{l}\text { Actual days held over actual } \\ \text { days in coupon period. } \\ \text { Denominator is 365 in most } \\ \text { years and 366 in a leap year. }\end{array} \\ \hline 1 & 30 / 360 \text { (SIA) } & \begin{array}{l}\text { Each month contains 30 } \\ \text { days; a year contains 360 } \\ \text { days. | Basis Value | Meaning | Description |
| :--- | :--- | :--- |
|  |  | by 252. BUS/252 business <br> days are non-weekend, <br> non-holiday days. The <br> holidays.m file defines <br> holidays. |

Note Although the concept of day count sounds deceptively simple, the actual calculation of day counts can be complex. You can find a good discussion of day counts and the formulas for calculating them in Chapter 5 of Stigum and Robinson, Money Market and Bond Calculations in Appendix A.

The end-of-month rule affects a bond's coupon payment structure. When the rule is in effect, a security that pays a coupon on the last actual day of a month will always pay coupons on the last day of the month. This means, for example, that a semiannual bond that pays a coupon on February 28 in nonleap years will pay coupons on August 31 in all years and on February 29 in leap years.

## End-of-Month Rule

| End-of-Month Rule Value | Meaning |
| :--- | :--- |
| 1 (default) | Rule in effect. |
| 0 | Rule not in effect. |

## Framework

Although not all Financial Toolbox functions require the same input arguments, they all accept the following common set of input arguments.

## Common Input Arguments

| Input | Meaning |
| :--- | :--- |
| Settle | Settlement date |
| Maturity | Maturity date |
| Period | Coupon payment period |
| Basis | Day-count basis |

| Input | Meaning |
| :--- | :--- |
| EndMonthRule | End-of-month payment rule |
| IssueDate | Bond issue date |
| FirstCouponDate | First coupon payment date |
| LastCouponDate | Last coupon payment date |

Of the common input arguments, only Settle and Maturity are required. All others are optional. They are set to the default values if you do not explicitly set them. By default, the FirstCouponDate and LastCouponDate are nonapplicable. In other words, if you do not specify FirstCouponDate and LastCouponDate, the bond is assumed to have no odd first or last coupon periods. In this case, the bond is a standard bond with a coupon payment structure based solely on the maturity date.

## Default Parameter Values

To illustrate the use of default values in Financial Toolbox functions, consider the cfdates function, which computes actual cash flow payment dates for a portfolio of fixed income securities regardless of whether the first and/or last coupon periods are normal, long, or short.

The complete calling syntax with the full input argument list is

```
CFlowDates = cfdates(Settle, Maturity, Period, Basis, ...
EndMonthRule, IssueDate, FirstCouponDate, LastCouponDate)
```

while the minimal calling syntax requires only settlement and maturity dates
CFlowDates = cfdates(Settle, Maturity)

## Single Bond Example

As an example, suppose that you have a bond with these characteristics:

```
Settle = '20-Sep-1999'
Maturity = '15-Oct-2007'
Period = 2
Basis = 0
EndMonthRule = 1
IssueDate = NaN
FirstCouponDate = NaN
LastCouponDate = NaN
```

Note that Period, Basis, and EndMonthRule are set to their default values, and IssueDate, FirstCouponDate, and LastCouponDate are set to NaN.

Formally, a NaN is an IEEE $^{\circledR}$ arithmetic standard for Not-a-Number and is used to indicate the result of an undefined operation (for example, zero divided by zero). However, NaN is also a convenient placeholder. In the SIA functions of Financial Toolbox software, NaN indicates the presence of a nonapplicable value. It tells the Financial Toolbox functions to ignore the input value and apply the default. Setting IssueDate, FirstCouponDate, and LastCouponDate to NaN in this example tells cfdates to assume that the bond has been issued before settlement and that no odd first or last coupon periods exist.

Having set these values, all these calls to cfdates produce the same result.

```
cfdates(Settle, Maturity)
cfdates(Settle, Maturity, Period)
cfdates(Settle, Maturity, Period, [])
cfdates(Settle, Maturity, [], Basis)
cfdates(Settle, Maturity, [], [])
cfdates(Settle, Maturity, Period, [], EndMonthRule)
cfdates(Settle, Maturity, Period, [], NaN)
cfdates(Settle, Maturity, Period, [], [], IssueDate)
cfdates(Settle, Maturity, Period, [], [], IssueDate, [], [])
cfdates(Settle, Maturity, Period, [], [], [], [],LastCouponDate)
cfdates(Settle, Maturity, Period, Basis, EndMonthRule, ...
IssueDate, FirstCouponDate, LastCouponDate)
```

Thus, leaving a particular input unspecified has the same effect as passing an empty matrix ([ ]) or passing a NaN - all three tell cfdates (and other Financial Toolbox functions) to use the default value for a particular input parameter.

## Bond Porffolio Example

Since the previous example included only a single bond, there was no difference between passing an empty matrix or passing a NaN for an optional input argument. For a portfolio of bonds, however, using NaN as a placeholder is the only way to specify default acceptance for some bonds while explicitly setting nondefault values for the remaining bonds in the portfolio.

Now suppose that you have a portfolio of two bonds.

```
Settle = '20-Sep-1999'
Maturity = ['15-Oct-2007'; '15-0ct-2010']
```

These calls to cfdates all set the coupon period to its default value (Period $=2$ ) for both bonds.

```
cfdates(Settle, Maturity, 2)
cfdates(Settle, Maturity, [2 2])
cfdates(Settle, Maturity, [])
cfdates(Settle, Maturity, NaN)
cfdates(Settle, Maturity, [NaN NaN])
cfdates(Settle, Maturity)
```

The first two calls explicitly set Period $=2$. Since Maturity is a 2 -by- 1 vector of maturity dates, cfdates knows that you have a two-bond portfolio.

The first call specifies a single (that is, scalar) 2 for Period. Passing a scalar tells cfdates to apply the scalar-valued input to all bonds in the portfolio. This is an example of implicit scalar-expansion. The settlement date has been implicit scalar-expanded as well.

The second call also applies the default coupon period by explicitly passing a two-element vector of 2's. The third call passes an empty matrix, which cfdates interprets as an invalid period, for which the default value is used. The fourth call is similar, except that a NaN has been passed. The fifth call passes two NaN's, and has the same effect as the third. The last call passes the minimal input set.

Finally, consider the following calls to cfdates for the same two-bond portfolio.

```
cfdates(Settle, Maturity, [4 NaN])
```

cfdates(Settle, Maturity, [4 2])

The first call explicitly sets Period $=4$ for the first bond and implicitly sets the default Period $=2$ for the second bond. The second call has the same effect as the first but explicitly sets the periodicity for both bonds.

The optional input Period has been used for illustrative purpose only. The defaulthandling process illustrated in the examples applies to any of the optional input arguments.

## Coupon Date Calculations

Calculating coupon dates, either actual or quasi dates, is notoriously complicated. Financial Toolbox software follows the SIA conventions in coupon date calculations.

The first step in finding the coupon dates associated with a bond is to determine the reference, or synchronization date (the sync date). Within the SIA framework, the order of precedence for determining the sync date is:

1 The first coupon date
2 The last coupon date
3 The maturity date
In other words, a Financial Toolbox function first examines the FirstCouponDate input. If FirstCouponDate is specified, coupon payment dates and quasi-coupon dates are computed with respect to FirstCouponDate; if FirstCouponDate is unspecified, empty ([ ]), or NaN, then the LastCouponDate is examined. If LastCouponDate is specified, coupon payment dates and quasi-coupon dates are computed with respect to LastCouponDate. If both FirstCouponDate and LastCouponDate are unspecified, empty ([ ]), or NaN, the Maturity (a required input argument) serves as the synchronization date.

## Yield Conventions

There are two yield and time factor conventions that are used in the Financial Toolbox software - these are determined by the input basis. Specifically, bases 0 to 7 are assumed to have semiannual compounding, while bases 8 to 12 are assumed to have annual compounding regardless of the period of the bond's coupon payments (including zero-coupon bonds). In addition, any yield-related sensitivity (that is, duration and convexity), when quoted on a periodic basis, follows this same convention. (See bndconvp, bndconvy, bnddurp, bnddury, and bndkrdur.)

## Pricing Functions

This example shows how easily you can compute the price of a bond with an odd first period using the function bndprice. Assume that you have a bond with these characteristics:

```
Settle = '11-Nov-1992';
Maturity = '01-Mar-2005';
IssueDate = '15-Oct-1992';
FirstCouponDate = '01-Mar-1993';
CouponRate = 0.0785;
Yield = 0.0625;
```

Allow coupon payment period (Period = 2), day-count basis (Basis $=0$ ), and end-of-month rule (EndMonthRule $=1$ ) to assume the default values. Also, assume that there is no odd last coupon date and that the face value of the bond is $\$ 100$. Calling the function
[Price, AccruedInt] = bndprice(Yield, CouponRate, Settle, ... Maturity, [], [], [], IssueDate, FirstCouponDate)
returns a price of $\$ 113.60$ and accrued interest of $\$ 0.59$.
Similar functions compute prices with regular payments, odd first and last periods, and prices of Treasury bills and discounted securities such as zero-coupon bonds.

Note bndprice and other functions use nonlinear formulas to compute the price of a security. For this reason, Financial Toolbox software uses Newton's method when solving for an independent variable within a formula. See any elementary numerical methods textbook for the mathematics underlying Newton's method.

## Yield Functions

To illustrate toolbox yield functions, compute the yield of a bond that has odd first and last periods and settlement in the first period. First set up variables for settlement, maturity date, issue, first coupon, and a last coupon date.

```
Settle = '12-Jan-2000';
Maturity = '01-Oct-2001';
IssueDate = '01-Jan-2000';
FirstCouponDate = '15-Jan-2000';
LastCouponDate = '15-Apr-2000';
```

Assume a face value of $\$ 100$. Specify a purchase price of $\$ 95.70$, a coupon rate of $4 \%$, quarterly coupon payments, and a 30/360 day-count convention (Basis = 1).

```
Price = 95.7;
CouponRate = 0.04;
Period = 4;
Basis = 1;
EndMonthRule = 1;
```

Calling the function

```
Yield = bndyield(Price, CouponRate, Settle, Maturity, Period,...
```

Basis, EndMonthRule, IssueDate, FirstCouponDate, LastCouponDate)
returns
Yield $=0.0659$ (6.60\%).

## Fixed-Income Sensitivities

Financial Toolbox software supports the following options for managing interest-rate risk for one or more bonds:

- bnddurp and bnddury support duration and convexity analysis based on market quotes and assume parallel shifts in the bond yield curve.
- bndkrdur supports key rate duration based on a market yield curve and can model nonparallel shifts in the bond yield curve.

## Calculating Duration and Convexity for Bonds

The toolbox includes functions to perform sensitivity analysis such as convexity and the Macaulay and modified durations for fixed-income securities. The Macaulay duration of an income stream, such as a coupon bond, measures how long, on average, the owner waits before receiving a payment. It is the weighted average of the times payments are made, with the weights at time T equal to the present value of the money received at time T. The modified duration is the Macaulay duration discounted by the per-period interest rate; that is, divided by (1+rate/frequency).

To illustrate, the following example computes the annualized Macaulay and modified durations, and the periodic Macaulay duration for a bond with settlement (12-Jan-2000) and maturity (01-Oct-2001) dates as above, a $5 \%$ coupon rate, and a $4.5 \%$ yield to maturity. For simplicity, any optional input arguments assume default values (that is, semiannual coupons, and day-count basis = 0 (actual/actual), coupon payment structure synchronized to the maturity date, and end-of-month payment rule in effect).

CouponRate $=0.05$;
Yield = 0.045;
[ModDuration, YearDuration, PerDuration] = bnddury(Yield,... CouponRate, Settle, Maturity)

The durations are
ModDuration $=1.6107$ (years)

```
YearDuration = 1.6470 (years)
PerDuration = 3.2940 (semiannual periods)
```

Note that the semiannual periodic Macaulay duration (PerDuration) is twice the annualized Macaulay duration (YearDuration).

## Calculating Key Rate Durations for Bonds

Key rate duration enables you to evaluate the sensitivity and price of a bond to nonparallel changes in the spot or zero curve by decomposing the interest rate risk along the spot or zero curve. Key rate duration refers to the process of choosing a set of key rates and computing a duration for each rate. Specifically, for each key rate, while the other rates are held constant, the key rate is shifted up and down (and intermediate cash flow dates are interpolated), and then the present value of the security given the shifted curves is computed.

The calculation of bndkrdur supports:

$$
k r d u r_{i}=\frac{\left(P V_{\text {down }}-P V_{u p}\right)}{(P V \times \text { ShiftValue } \times 2)}
$$

Where $P V$ is the current value of the instrument, $P V_{-} u p$ and $P V_{-} d o w n$ are the new values after the discount curve has been shocked, and ShiftValue is the change in interest rate. For example, if key rates of 3 months, $1,2,3,5,7,10,15,20,25,30$ years were chosen, then a 30 -year bond might have corresponding key rate durations of:

| 3 M | 1 Y | 2 Y | 3 Y | 5 Y | 7 Y | 10 Y | 15 Y | 20 Y | 25 Y | 30 Y |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| .01 | .04 | .09 | .21 | .4 | .65 | 1.27 | 1.71 | 1.68 | 1.83 | 7.03 |

The key rate durations add up to approximately equal the duration of the bond.
For example, compute the key rate duration of the U.S. Treasury Bond with maturity date of August 15, 2028 and coupon rate of $5.5 \%$.

```
Settle = datenum('18-Nov-2008');
CouponRate = 5.500/100;
Maturity = datenum('15-Aug-2028');
Price = 114.83;
```

For the ZeroData information on the current spot curve for this bond, refer to http:// www.treas.gov/offices/domestic-finance/debt-management/interest-rate/yield.shtml:

```
ZeroDates = daysadd(Settle ,[30 90 180 360 360*2 360*3 360*5 ...
```

360*7 360*10 360*20 360*30]);

```
ZeroRates =([[0.06 0.12 0.81 1.08 1.22 1.53 2.32 2.92 3.68 4.42 4.20]/100)';
```

Compute the key rate duration for a specific set of rates (choose this based on the maturities of the available hedging instruments):

```
krd = bndkrdur([ZeroDates ZeroRates],CouponRate,Settle,Maturity,'keyrates',[2 5 10 20])
krd =
    0.2865 0.8729 2.6451 8.5778
```

Note, the sum of the key rate durations approximately equals the duration of the bond:

```
[sum(krd) bnddurp(Price,CouponRate,Settle,Maturity)]
ans =
    12.3823 12.3919
```

## Treasury Bills Defined

Treasury bills are short-term securities (issued with maturities of 1 year or less) sold by the United States Treasury. Sales of these securities are frequent, usually weekly. From time to time, the Treasury also offers longer duration securities called Treasury notes and Treasury bonds.

A Treasury bill is a discount security. The holder of the Treasury bill does not receive periodic interest payments. Instead, at the time of sale, a percentage discount is applied to the face value. At maturity, the holder redeems the bill for full face value.

The basis for Treasury bill interest calculation is actual/360. Under this system, interest accrues on the actual number of elapsed days between purchase and maturity, and each year contains 360 days.

## Computing Treasury Bill Price and Yield

```
In this section...
"Introduction" on page 2-35
"Treasury Bill Repurchase Agreements" on page 2-35
"Treasury Bill Yields" on page 2-37
```

## Introduction

Financial Toolbox software provides the following suite of functions for computing price and yield on Treasury bills.

Treasury Bill Functions

| Function | Purpose |
| :--- | :--- |
| tbilldisc2yield | Convert discount rate to yield. |
| tbillprice | Price Treasury bill given its yield or discount rate. |
| tbillrepo | Break-even discount of repurchase agreement. |
| tbillyield | Yield and discount of Treasury bill given its price. |
| tbillyield2disc | Convert yield to discount rate. |
| tbillval01 | The value of 1 basis point given the characteristics of <br> the Treasury bill, as represented by its settlement and <br> maturity dates. You can relate the basis point to discount, <br> money-market, or bond-equivalent yield. |

For all functions with yield in the computation, you can specify yield as money-market or bond-equivalent yield. The functions all assume a face value of $\$ 100$ for each Treasury bill.

## Treasury Bill Repurchase Agreements

The following example shows how to compute the break-even discount rate. This is the rate that correctly prices the Treasury bill such that the profit from selling the tail equals 0 .

Maturity = '26-Dec-2002';

```
InitialDiscount = 0.0161;
PurchaseDate = '26-Sep-2002';
SaleDate = '26-0ct-2002';
RepoRate = 0.0149;
BreakevenDiscount = tbillrepo(RepoRate, InitialDiscount, ...
PurchaseDate, SaleDate, Maturity)
BreakevenDiscount =
    0.0167
```

You can check the result of this computation by examining the cash flows in and out from the repurchase transaction. First compute the price of the Treasury bill on the purchase date (September 26).

```
PriceOnPurchaseDate = tbillprice(InitialDiscount, ...
```

PurchaseDate, Maturity, 3)
Price0nPurchaseDate =
99.5930

Next compute the interest due on the repurchase agreement.

```
RepoInterest = ...
RepoRate*Price0nPurchaseDate*days360(PurchaseDate,SaleDate) / 360
RepoInterest =
```

    0.1237
    RepoInterest for a $1.49 \%$ 30-day term repurchase agreement (30/360 basis) is 0.1237 .
Finally, compute the price of the Treasury bill on the sale date (October 26).
PriceOnSaleDate = tbillprice(BreakevenDiscount, SaleDate, ... Maturity, 3)

PriceOnSaleDate =
99.7167

Examining the cash flows, observe that the break-even discount causes the sum of the price on the purchase date plus the accrued 30 -day interest to be equal to the price on sale date. The next table shows the cash flows.

## Cash Flows from Repurchase Agreement

| Date | Cash Out Flow |  | Cash In Flow |  |
| :--- | :--- | :--- | :--- | :--- |
| $9 / 26 / 2002$ | Purchase T-bill | 99.593 | Repo money | 99.593 |
| $10 / 26 / 2002$ | Payment of repo | 99.593 | Sell T-bill | 99.7168 |
|  | Repo interest | 0.1238 |  |  |
|  | Total | 199.3098 |  | 199.3098 |

## Treasury Bill Yields

Using the same data as before, you can examine the money-market and bondequivalent yields of the Treasury bill at the time of purchase and sale. The function tbilldisc2yield can perform both computations at one time.

```
Maturity = '26-Dec-2002';
InitialDiscount = 0.0161;
PurchaseDate = '26-Sep-2002';
SaleDate = '26-Oct-2002';
RepoRate = 0.0149;
BreakevenDiscount = tbillrepo(RepoRate, InitialDiscount, ...
PurchaseDate, SaleDate, Maturity)
[BEYield, MMYield] = ...
tbilldisc2yield([InitialDiscount; BreakevenDiscount], ...
[PurchaseDate; SaleDate], Maturity)
BreakevenDiscount =
    0.0167
BEYield =
    0.0164
    0.0170
```

MMYield =
0.0162
0.0168

For the short Treasury bill (fewer than 182 days to maturity), the money-market yield is 360/365 of the bond-equivalent yield, as this example shows.

## Term Structure of Interest Rates

In this section...
"Introduction" on page 2-39
"Deriving an Implied Zero Curve" on page 2-40

## Introduction

The Financial Toolbox product contains several functions to derive and analyze interest rate curves, including data conversion and extrapolation, bootstrapping, and interestrate curve conversion functions.

One of the first problems in analyzing the term structure of interest rates is dealing with market data reported in different formats. Treasury bills, for example, are quoted with bid and asked bank-discount rates. Treasury notes and bonds, on the other hand, are quoted with bid and asked prices based on $\$ 100$ face value. To examine the full spectrum of Treasury securities, analysts must convert data to a single format. Financial Toolbox functions ease this conversion. This brief example uses only one security each; analysts often use 30,100 , or more of each.

First, capture Treasury bill quotes in their reported format

```
% Maturity Days Bid Ask AskYield
TBill = [datenum('12/26/2000') 53 0.0503 0.0499 0.0510];
```

then capture Treasury bond quotes in their reported format

```
Clloll
```

and note that these quotes are based on a November 3, 2000 settlement date.

```
Settle = datenum('3-Nov-2000');
```

Next use the toolbox tbl2bond function to convert the Treasury bill data to Treasury bond format.

TBTBond $=$ tbl2bond(TBill)
тBTBond =

| 0 | 730846 | 99.26 | 99.27 | 0.05 |
| :--- | :--- | :--- | :--- | :--- |

(The second element of TBTBond is the serial date number for December 26, 2000.)
Now combine short-term (Treasury bill) with long-term (Treasury bond) data to set up the overall term structure.

```
TBondsAll = [TBTBond; TBond]
```

TBondsAll =

| 0 | 730846 | 99.26 | 99.27 | 0.05 |
| ---: | ---: | ---: | ---: | ---: |
| 0.09 | 731160 | 103.13 | 103.19 | 0.06 |

The Financial Toolbox software provides a second data-preparation function,tr2bonds, to convert the bond data into a form ready for the bootstrapping functions. tr2bonds generates a matrix of bond information sorted by maturity date, plus vectors of prices and yields.
[Bonds, Prices, Yields] = tr2bonds(TBondsAll);

## Deriving an Implied Zero Curve

Using this market data, you can use one of the Financial Toolbox bootstrapping functions to derive an implied zero curve. Bootstrapping is a process whereby you begin with known data points and solve for unknown data points using an underlying arbitrage theory. Every coupon bond can be valued as a package of zero-coupon bonds which mimic its cash flow and risk characteristics. By mapping yields-to-maturity for each theoretical zero-coupon bond, to the dates spanning the investment horizon, you can create a theoretical zero-rate curve. The Financial Toolbox software provides two bootstrapping functions: zbtprice derives a zero curve from bond data and prices, and zbtyield derives a zero curve from bond data and yields. Using zbtprice
[ZeroRates, CurveDates] = zbtprice(Bonds, Prices, Settle)
ZeroRates =
0.05
0.06

CurveDates =
730846
731160
CurveDates gives the investment horizon.

```
datestr(CurveDates)
ans =
26-Dec-2000
05-Nov-2001
```

Additional Financial Toolbox functions construct discount, forward, and par yield curves from the zero curve, and vice versa.

```
[DiscRates, CurveDates] = zero2disc(ZeroRates, CurveDates,...
Settle);
[FwdRates, CurveDates] = zero2fwd(ZeroRates, CurveDates, Settle);
[PYldRates, CurveDates] = zero2pyld(ZeroRates, CurveDates,...
Settle);
```

## Pricing and Analyzing Equity Derivatives

```
In this section...
"Introduction" on page 2-42
"Sensitivity Measures" on page 2-42
"Analysis Models" on page 2-43
```

## Introduction

These toolbox functions compute prices, sensitivities, and profits for portfolios of options or other equity derivatives. They use the Black-Scholes model for European options and the binomial model for American options. Such measures are useful for managing portfolios and for executing collars, hedges, and straddles.

## Sensitivity Measures

There are six basic sensitivity measures associated with option pricing: delta, gamma, lambda, rho, theta, and vega - the "greeks." The toolbox provides functions for calculating each sensitivity and for implied volatility.

## Delta

Delta of a derivative security is the rate of change of its price relative to the price of the underlying asset. It is the first derivative of the curve that relates the price of the derivative to the price of the underlying security. When delta is large, the price of the derivative is sensitive to small changes in the price of the underlying security.

## Gamma

Gamma of a derivative security is the rate of change of delta relative to the price of the underlying asset; that is, the second derivative of the option price relative to the security price. When gamma is small, the change in delta is small. This sensitivity measure is important for deciding how much to adjust a hedge position.

## Lambda

Lambda, also known as the elasticity of an option, represents the percentage change in the price of an option relative to a $1 \%$ change in the price of the underlying security.

## Rho

Rho is the rate of change in option price relative to the risk-free interest rate.

## Theta

Theta is the rate of change in the price of a derivative security relative to time. Theta is usually very small or negative since the value of an option tends to drop as it approaches maturity.

## Vega

Vega is the rate of change in the price of a derivative security relative to the volatility of the underlying security. When vega is large the security is sensitive to small changes in volatility. For example, options traders often must decide whether to buy an option to hedge against vega or gamma. The hedge selected usually depends upon how frequently one rebalances a hedge position and also upon the standard deviation of the price of the underlying asset (the volatility). If the standard deviation is changing rapidly, balancing against vega is usually preferable.

## Implied Volatility

The implied volatility of an option is the standard deviation that makes an option price equal to the market price. It helps determine a market estimate for the future volatility of a stock and provides the input volatility (when needed) to the other Black-Scholes functions.

## Analysis Models

Toolbox functions for analyzing equity derivatives use the Black-Scholes model for European options and the binomial model for American options. The Black-Scholes model makes several assumptions about the underlying securities and their behavior. The binomial model, on the other hand, makes far fewer assumptions about the processes underlying an option. For further explanation, see Options, Futures, and Other Derivatives by John Hull in Appendix A.

## Black-Scholes Model

Using the Black-Scholes model entails several assumptions:

- The prices of the underlying asset follow an Ito process. (See Hull, page 222.)
- The option can be exercised only on its expiration date (European option).
- Short selling is permitted.
- There are no transaction costs.
- All securities are divisible.
- There is no riskless arbitrage.
- Trading is a continuous process.
- The risk-free interest rate is constant and remains the same for all maturities.

If any of these assumptions is untrue, Black-Scholes may not be an appropriate model.
To illustrate toolbox Black-Scholes functions, this example computes the call and put prices of a European option and its delta, gamma, lambda, and implied volatility. The asset price is $\$ 100.00$, the exercise price is $\$ 95.00$, the risk-free interest rate is $10 \%$, the time to maturity is 0.25 years, the volatility is 0.50 , and the dividend rate is 0 . Simply executing the toolbox functions

```
[OptCall, OptPut] = blsprice(100, 95, 0.10, 0.25, 0.50, 0);
[CallVal, PutVal] = blsdelta(100, 95, 0.10, 0.25, 0.50, 0);
GammaVal = blsgamma(100, 95, 0.10, 0.25, 0.50, 0);
VegaVal = blsvega(100, 95, 0.10, 0.25, 0.50, 0);
[LamCall, LamPut] = blslambda(100, 95, 0.10, 0.25, 0.50, 0);
```

yields:

- The option call price OptCall $=\$ 13.70$
- The option put price OptPut $=\$ 6.35$
- delta for a call CallVal $=0.6665$ and delta for a put PutVal $=-0.3335$
- gamma GammaVal = 0.0145
- vega VegaVal = 18.1843
- lambda for a call LamCall $=4.8664$ and lambda for a put LamPut $=-5.2528$

Now as a computation check, find the implied volatility of the option using the call option price from blsprice.

Volatility $=$ blsimpv(100, 95, 0.10, 0.25, OptCall);
The function returns an implied volatility of 0.500 , the original blsprice input.

## Binomial Model

The binomial model for pricing options or other equity derivatives assumes that the probability over time of each possible price follows a binomial distribution. The basic
assumption is that prices can move to only two values, one up and one down, over any short time period. Plotting the two values, and then the subsequent two values each, and then the subsequent two values each, and so on over time, is known as "building a binomial tree." This model applies to American options, which can be exercised any time up to and including their expiration date.

This example prices an American call option using a binomial model. Again, the asset price is $\$ 100.00$, the exercise price is $\$ 95.00$, the risk-free interest rate is $10 \%$, and the time to maturity is 0.25 years. It computes the tree in increments of 0.05 years, so there are $0.25 / 0.05=5$ periods in the example. The volatility is 0.50 , this is a call $(f l a g=1)$, the dividend rate is 0 , and it pays a dividend of $\$ 5.00$ after three periods (an ex-dividend date). Executing the toolbox function

```
[StockPrice, OptionPrice] = binprice(100, 95, 0.10, 0.25,...
0.05, 0.50, 1, 0, 5.0, 3);
```

returns the tree of prices of the underlying asset

| StockPrice $=$ |  |  |  |  |  |  |
| ---: | ---: | ---: | ---: | ---: | ---: | :---: |
|  |  |  |  |  |  |  |
| 100.00 | 111.27 | 123.87 | 137.96 | 148.69 | 166.28 |  |
| 0 | 89.97 | 100.05 | 111.32 | 118.90 | 132.96 |  |
| 0 | 0 | 81.00 | 90.02 | 95.07 | 106.32 |  |
| 0 | 0 | 0 | 72.98 | 76.02 | 85.02 |  |
| 0 | 0 | 0 | 0 | 60.79 | 67.98 |  |
| 0 | 0 | 0 | 0 | 0 | 54.36 |  |

and the tree of option values.
OptionPrice =

| 12.10 | 19.17 | 29.35 | 42.96 | 54.17 | 71.28 |
| ---: | ---: | ---: | ---: | ---: | ---: |
| 0 | 5.31 | 9.41 | 16.32 | 24.37 | 37.96 |
| 0 | 0 | 1.35 | 2.74 | 5.57 | 11.32 |
| 0 | 0 | 0 | 0 | 0 | 0 |
| 0 | 0 | 0 | 0 | 0 | 0 |
| 0 | 0 | 0 | 0 | 0 | 0 |

The output from the binomial function is a binary tree. Read the StockPrice matrix this way: column 1 shows the price for period 0 , column 2 shows the up and down prices for period 1, column 3 shows the up-up, up-down, and down-down prices for period 2 , and so on. Ignore the zeros. The OptionPrice matrix gives the associated option value for each node in the price tree. Ignore the zeros that correspond to a zero in the price tree.

## About Life Tables

Life tables are used for life insurance and work with the probability distribution of human mortality. This distribution, which is age-dependent, has a number of characteristic features that are consequences of biological, cultural, and behavioral factors. In most cases, the practitioners of life studies use life tables that contain agedependent series for specific demographics. The tables are in a standard format with standard notation that is specific to the life studies field. An example of a life table is shown in Table 1 from CDC life tables for the United States.

| Age (years) | $\begin{gathered} \text { Probability } \\ \text { of dying } \\ \text { between } \\ \text { ages } x \text { and } x+1 \end{gathered}$ | $\begin{gathered} \text { Number } \\ \text { sunvinging to } \\ \text { age } x \end{gathered}$ | $\begin{gathered} \text { Number } \\ \text { bying } \\ \text { befween } \\ \text { ages } x a n d x+1 \end{gathered}$ | $\begin{gathered} \text { Person-years } \\ \text { bived } \\ \text { begeen } \\ \text { ages } x \text { and } x+1 \end{gathered}$ |  | $\begin{aligned} & \text { Expectation } \\ & \text { of 㣂e } \\ & \text { at age } x \end{aligned}$ |

| 19-20 | 0.000691 | 98,925 | ® | 98,891 | 5,962,175 | 60.3 |

In many cases, these life tables can have numerous variations such as abridged tables (which pose challenges due to the granularity of the data) and different termination criteria (that can make it difficult to compare tables or to compute life expectancies).

Most raw life tables have one or more of the first three series in this table ( $q_{x}, l_{x}$, and $d_{x}$ ) and the notation for these three series is standard in the field.

- The $q_{x}$ series is basically the discrete hazard function for human mortality.
- The $l_{x}$ series is the survival function multiplied by a radix of 100,000 .
- The $d_{x}$ series is the discrete probability density for the distribution as a function of age.

Financial Toolbox can handle arbitrary life table data supporting several standard models of mortality and provides various interpolation methods to calibrate and analyze the life table data.

Although primarily designed for life insurance applications, the life tables functions (lifetableconv, lifetablefit, and lifetablegen can also be used by social scientists, behavioral psychologists, public health officials, and medical researchers.

## Life Tables Theory

Life tables are based on hazard functions and survival functions which are, in turn, derived from probability distributions. Specifically, given a continuous probability distribution, its cumulative distribution function is $\mathrm{F}(x)$ and its probability density function is $\mathrm{f}(x)=\mathrm{d} \mathrm{F}(x) / \mathrm{d} x$.

For the analysis of mortality, the random variable of interest $X$ is the distribution of ages at which individuals die within a population. So, the probability that someone dies by age $x$ is

$$
\operatorname{Pr}[X \leq x]=F(x)
$$

The survival function, $(s(x))$, which characterizes the probability that an individual lives beyond a specified age $x>0$, is

$$
\begin{aligned}
& s(x)=\operatorname{Pr}[X>x] \\
& =1-F(x)
\end{aligned}
$$

For a continuous probability distribution, the hazard function is a function of the survival function with

$$
\begin{aligned}
& h(x)=\lim _{\Delta x \rightarrow 0} \frac{\operatorname{Pr}[x \leq X<x+\Delta x \mid X \geq x]}{\Delta x} \\
& =-\frac{1}{s(x)} \frac{d(s(x)}{d x}
\end{aligned}
$$

and the survival functions is a function of the hazard function with

$$
s(x)=\exp \left(-\int_{0}^{x} h(\xi) d \xi\right)
$$

Life table models generally specify either the hazard function or the survival function. However, life tables are discrete and work with discrete versions of the hazard and survival functions. Three series are used for life tables and the notation is the convention. The discrete hazard function is denoted as

$$
\begin{aligned}
& q_{x} \approx h(x) \\
& =1-\frac{s(x+1)}{s(x)}
\end{aligned}
$$

which is the probability a person at age $x$ dies by age $x+1$ (where $x$ is in years). The discrete survival function is presented in terms of an initial number of survivors at birth called the life table radix (which is usually 100,000 individuals) and is denoted as

$$
l_{x}=l_{0} s(x)
$$

with radix $l_{0}=100000$. This number, $l_{x}$, represents the number of individuals out of 100,000 at birth who are still alive at age $x$.

A third series is related to the probability density function which is the number of "standardized" deaths in a given year denoted as

$$
d_{x}=l_{x}-l_{x+1}
$$

Based on a few additional rules about how to initialize and terminate these series, any one series can be derived from any of the other series.

## Analyzing Porffolios

Portfolio managers concentrate their efforts on achieving the best possible trade-off between risk and return. For portfolios constructed from a fixed set of assets, the risk/ return profile varies with the portfolio composition. Portfolios that maximize the return, given the risk, or, conversely, minimize the risk for the given return, are called optimal. Optimal portfolios define a line in the risk/return plane called the efficient frontier.

A portfolio may also have to meet additional requirements to be considered. Different investors have different levels of risk tolerance. Selecting the adequate portfolio for a particular investor is a difficult process. The portfolio manager can hedge the risk related to a particular portfolio along the efficient frontier with partial investment in risk-free assets. The definition of the capital allocation line, and finding where the final portfolio falls on this line, if at all, is a function of:

- The risk/return profile of each asset
- The risk-free rate
- The borrowing rate
- The degree of risk aversion characterizing an investor

Financial Toolbox software includes a set of portfolio optimization functions designed to find the portfolio that best meets investor requirements.

Warning frontcon has been removed. Use Portfolio instead.
portopt has been partially removed and will no longer accept ConSet or varargin arguments. portopt will only solve the portfolio problem for long-only fully invested portfolios. Use Portfolio instead.

## Portfolio Optimization Functions

The portfolio optimization functions assist portfolio managers in constructing portfolios that optimize risk and return.

| Capital Allocation | Description |
| :--- | :--- |
| portalloc | Computes the optimal risky portfolio on the efficient frontier, based <br> on the risk-free rate, the borrowing rate, and the investor's degree <br> of risk aversion. Also generates the capital allocation line, which <br> provides the optimal allocation of funds between the risky portfolio <br> and the risk-free asset. |

| Efficient Frontier <br> Computation | Description |
| :--- | :--- |
| frontcon | Computes portfolios along the efficient frontier for a given group of <br> assets. The computation is based on sets of constraints representing <br> the maximum and minimum weights for each asset, and the <br> maximum and minimum total weight for specified groups of assets. |
| frontier | Warning frontcon has been removed. Use Portfolio instead. <br> For more information on migrating frontcon code to Portfolio, <br> see "frontcon Migration to Portfolio Object" on page 3-25. |
| portopt | Computes portfolios along the efficient frontier for a given group of <br> assets. Generates a surface of efficient frontiers showing how asset <br> allocation influences risk and return over time. |
|  | Computes portfolios along the efficient frontier for a given group of <br> assets. The computation is based on a set of user-specified linear <br> constraints. Typically, these constraints are generated using the <br> constraint specification functions described below. |
|  | Warning portopt has been partially removed and will no longer <br> accept ConSet or varargin arguments. portopt will only solve <br> the portfolio problem for long-only fully invested portfolios. Use <br> Portfolio instead. For more information on migrating portopt <br> code to Portfolio, see "portopt Migration to Portfolio Object" on <br> page 3-14. |

| Constraint <br> Specification | Description |
| :--- | :--- |
| portcons | Generates the portfolio constraints matrix for a portfolio of asset <br> investments using linear inequalities. The inequalities are of the <br> type A*Wts ' <= b, where Wts is a row vector of weights. |
| portvrisk | Portfolio value at risk (VaR) returns the maximum potential loss <br> in the value of a portfolio over one period of time, given the loss <br> probability level RiskThreshold. |
| pcalims | Asset minimum and maximum allocation. Generates a constraint <br> set to fix the minimum and maximum weight for each individual <br> asset. |
| pcgcomp | Group-to-group ratio constraint. Generates a constraint set <br> specifying the maximum and minimum ratios between pairs of <br> groups. |
| pcglims | Asset group minimum and maximum allocation. Generates a <br> constraint set to fix the minimum and maximum total weight for <br> each defined group of assets. |
| pcpval | Total portfolio value. Generates a constraint set to fix the total <br> value of the portfolio. |

| Constraint <br> Conversion | Descripfion |
| :--- | :--- |
| abs2active | Transforms a constraint matrix expressed in absolute weight <br> format to an equivalent matrix expressed in active weight format. |
| active2abs | Transforms a constraint matrix expressed in active weight format <br> to an equivalent matrix expressed in absolute weight format. |

Note: An alternative to using these portfolio optimization functions is to use the Portfolio object (Portfolio) for mean-variance portfolio optimization. This object supports gross or net portfolio returns as the return proxy, the variance of portfolio returns as the risk proxy, and a portfolio set that is any combination of the specified constraints to form a portfolio set. For information on the workflow when using Portfolio objects, see "Portfolio Object Workflow" on page 4-17.

## Porffolio Construction Examples

In this section...<br>"Introduction" on page 3-7<br>"Efficient Frontier Example" on page 3-7

## Introduction

The efficient frontier computation functions require information about each asset in the portfolio. This data is entered into the function via two matrices: an expected return vector and a covariance matrix. The expected return vector contains the average expected return for each asset in the portfolio. The covariance matrix is a square matrix representing the interrelationships between pairs of assets. This information can be directly specified or can be estimated from an asset return time series with the function ewstats.

Note: An alternative to using these portfolio optimization functions is to use the Portfolio object (Portfolio) for mean-variance portfolio optimization. This object supports gross or net portfolio returns as the return proxy, the variance of portfolio returns as the risk proxy, and a portfolio set that is any combination of the specified constraints to form a portfolio set. For information on the workflow when using Portfolio objects, see "Portfolio Object Workflow" on page 4-17.

## Efficient Frontier Example

frontcon has been removed. To model the efficient frontier, use the Portfolio object instead. For example, using the Portfolio object, you can model an efficient frontier:

- "Obtaining Portfolios Along the Entire Efficient Frontier" on page 4-87
- "Obtaining Endpoints of the Efficient Frontier" on page 4-88
- "Obtaining Efficient Portfolios for Target Returns" on page 4-90
- "Obtaining Efficient Portfolios for Target Risks" on page 4-93

## Portfolio Selection and Risk Aversion

In this section...<br>"Introduction" on page 3-9<br>"Optimal Risky Portfolio" on page 3-10

## Introduction

One of the factors to consider when selecting the optimal portfolio for a particular investor is degree of risk aversion. This level of aversion to risk can be characterized by defining the investor's indifference curve. This curve consists of the family of risk/return pairs defining the trade-off between the expected return and the risk. It establishes the increment in return that a particular investor requires to make an increment in risk worthwhile. Typical risk aversion coefficients range from 2.0 through 4.0, with the higher number representing lesser tolerance to risk. The equation used to represent risk aversion in Financial Toolbox software is
$U=E(r)-0.005 * A^{*} \operatorname{sig}^{\wedge} 2$
where:
U is the utility value.
$E(r)$ is the expected return.
A is the index of investor's aversion.
sig is the standard deviation.

Note: An alternative to using these portfolio optimization functions is to use the Portfolio object (Portfolio) for mean-variance portfolio optimization. This object supports gross or net portfolio returns as the return proxy, the variance of portfolio returns as the risk proxy, and a portfolio set that is any combination of the specified constraints to form a portfolio set. For information on the workflow when using Portfolio objects, see "Portfolio Object Workflow" on page 4-17.

## Optimal Risky Porffolio

This example computes the optimal risky portfolio on the efficient frontier based on the risk-free rate, the borrowing rate, and the investor's degree of risk aversion. You do this with the function portalloc.

First generate the efficient frontier data using portopt.
ExpReturn $=\left[\begin{array}{lll}0.1 & 0.2 & 0.15\end{array}\right] ;$
ExpCovariance $=\left[\begin{array}{rrr}0.005 & -0.010 & 0.004 ; \\ & -0.010 & 0.040 \\ -0.002 ;\end{array}\right.$

$$
0.004 \quad-0.002 \quad 0.023]
$$

Consider 20 different points along the efficient frontier.

```
NumPorts = 20;
```

[PortRisk, PortReturn, PortWts] = portopt(ExpReturn,...
ExpCovariance, NumPorts);

Calling portopt, while specifying output arguments, returns the corresponding vectors and arrays representing the risk, return, and weights for each of the portfolios along the efficient frontier. Use these as the first three input arguments to the function portalloc.

Now find the optimal risky portfolio and the optimal allocation of funds between the risky portfolio and the risk-free asset, using these values for the risk-free rate, borrowing rate, and investor's degree of risk aversion.

```
RisklessRate = 0.08
BorrowRate = 0.12
RiskAversion = 3
```

Calling portalloc without specifying any output arguments gives a graph displaying the critical points.

```
portalloc (PortRisk, PortReturn, PortWts, RisklessRate,...
```

BorrowRate, RiskAversion);

Calling portalloc while specifying the output arguments returns the variance (RiskyRisk), the expected return (RiskyReturn), and the weights (RiskyWts) allocated to the optimal risky portfolio. It also returns the fraction (RiskyFraction) of the complete portfolio allocated to the risky portfolio, and the variance (OverallRisk) and expected return (OverallReturn) of the optimal overall portfolio. The overall portfolio combines investments in the risk-free asset and in the risky portfolio. The actual proportion assigned to each of these two investments is determined by the degree of risk aversion characterizing the investor.

```
[RiskyRisk, RiskyReturn, RiskyWts,RiskyFraction, OverallRisk,...
OverallReturn] = portalloc (PortRisk, PortReturn, PortWts,...
RisklessRate, BorrowRate, RiskAversion)
RiskyRisk = 0.1288
RiskyReturn = 0.1791
RiskyWts = 0.0057 0.5879 0.4064
RiskyFraction = 1.1869
OverallRisk = 0.1529
OverallReturn = 0.1902
```

The value of RiskyFraction exceeds 1 (100\%), implying that the risk tolerance specified allows borrowing money to invest in the risky portfolio, and that no money is invested in the risk-free asset. This borrowed capital is added to the original capital available for investment. In this example, the customer tolerates borrowing 18.69\% of the original capital amount.

on page 3-22
```

## Migrate portopt Without Output Arguments

This example shows how to migrate portopt without output arguments to a Portfolio object.

The basic portopt functionality is represented as:

```
ExpReturn = [ 0.0054; 0.0531; 0.0779; 0.0934; 0.0130 ];
ExpCovariance = [ 0.0569, 0.0092, 0.0039, 0.0070, 0.0022;
0.0092, 0.0380, 0.0035, 0.0197, 0.0028;
0.0039, 0.0035, 0.0997, 0.0100, 0.0070;
0.0070, 0.0197, 0.0100, 0.0461, 0.0050;
0.0022, 0.0028, 0.0070, 0.0050, 0.0573 ];
NumPorts = 10;
```

portopt(ExpReturn, ExpCovariance, NumPorts);

To migrate a portopt syntax without output arguments to a Portfolio object:

```
ExpReturn = [ 0.0054; 0.0531; 0.0779; 0.0934; 0.0130 ];
ExpCovariance = [ 0.0569, 0.0092, 0.0039, 0.0070, 0.0022;
    0.0092, 0.0380, 0.0035, 0.0197, 0.0028;
    0.0039, 0.0035, 0.0997, 0.0100, 0.0070;
    0.0070, 0.0197, 0.0100, 0.0461, 0.0050;
    0.0022, 0.0028, 0.0070, 0.0050, 0.0573 ];
NumPorts = 10;
p = Portfolio;
p = setAssetMoments(p, ExpReturn, ExpCovariance);
p = setDefaultConstraints(p);
plotFrontier(p, NumPorts);
```

Without output arguments, portopt plots the efficient frontier. The Portfolio object has similar behavior although the Portfolio object writes to the current figure window rather than create a new window each time a plot is generated.

## Migrate portopt with Output Arguments

This example shows how to migrate portopt with output arguments to a Portfolio object.

With output arguments, the basic functionality of portopt returns portfolio moments and weights. Once the Portfolio object is set up, moments and weights are obtained in separate steps.

```
ExpReturn = [ 0.0054; 0.0531; 0.0779; 0.0934; 0.0130 ];
ExpCovariance = [ 0.0569, 0.0092, 0.0039, 0.0070, 0.0022;
    0.0092, 0.0380, 0.0035, 0.0197, 0.0028;
```

```
0.0039, 0.0035, 0.0997, 0.0100, 0.0070;
0.0070, 0.0197, 0.0100, 0.0461, 0.0050;
0.0022, 0.0028, 0.0070, 0.0050, 0.0573 ];
NumPorts = 10;
[PortRisk, PortReturn, PortWts] = portopt(ExpReturn, ExpCovariance, NumPorts);
display(PortWts);
```

PortWts =

| 0.2103 | 0.2746 | 0.1157 | 0.1594 | 0.2400 |
| ---: | ---: | ---: | ---: | ---: |
| 0.1744 | 0.2657 | 0.1296 | 0.2193 | 0.2110 |
| 0.1386 | 0.2567 | 0.1436 | 0.2791 | 0.1821 |
| 0.1027 | 0.2477 | 0.1575 | 0.3390 | 0.1532 |
| 0.0668 | 0.2387 | 0.1714 | 0.3988 | 0.1242 |
| 0.0309 | 0.2298 | 0.1854 | 0.4587 | 0.0953 |
| 0 | 0.2168 | 0.1993 | 0.5209 | 0.0629 |
| 0 | 0.1791 | 0.2133 | 0.5985 | 0.0091 |
| 0 | 0.0557 | 0.2183 | 0.7260 | 0 |
| 0 | 0 | 0 | 1.0000 | 0 |

To migrate a portopt syntax with output arguments:

```
ExpReturn = [ 0.0054; 0.0531; 0.0779; 0.0934; 0.0130 ];
ExpCovariance = [ 0.0569, 0.0092, 0.0039, 0.0070, 0.0022;
    0.0092, 0.0380, 0.0035, 0.0197, 0.0028;
    0.0039, 0.0035, 0.0997, 0.0100, 0.0070;
    0.0070, 0.0197, 0.0100, 0.0461, 0.0050;
    0.0022, 0.0028, 0.0070, 0.0050, 0.0573 ];
NumPorts = 10;
p = Portfolio;
p = setAssetMoments(p, ExpReturn, ExpCovariance);
p = setDefaultConstraints(p);
PortWts = estimateFrontier(p, NumPorts);
[PortRisk, PortReturn] = estimatePortMoments(p, PortWts);
```

display(PortWts);
PortWts =

| 0.2103 | 0.1744 | 0.1386 | 0.1027 | 0.0668 | 0.0309 | 0 | 0 | 0 | 0 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 0.2746 | 0.2657 | 0.2567 | 0.2477 | 0.2387 | 0.2298 | 0.2168 | 0.1791 | 0.0557 | 0 |
| 0.1157 | 0.1296 | 0.1436 | 0.1575 | 0.1714 | 0.1854 | 0.1993 | 0.2133 | 0.2183 | 0 |
| 0.1594 | 0.2193 | 0.2791 | 0.3390 | 0.3988 | 0.4587 | 0.5209 | 0.5985 | 0.7260 | 1.0000 |
| 0.2400 | 0.2110 | 0.1821 | 0.1532 | 0.1242 | 0.0953 | 0.0629 | 0.0091 | 0 | 0 |

The Portfolio object returns PortWts with portfolios going down columns, not across rows. Portfolio risks and returns are still in column format.

## Migrate portopt for Target Returns Within Range of Efficient Portfolio Returns

This example shows how to migrate portopt target returns within range of efficient portfolio returns to a Portfolio object.
portopt can obtain portfolios with specific targeted levels of return but requires that the targeted returns fall within the range of efficient returns. The Portfolio object handles this by selecting portfolios at the ends of the efficient frontier.

```
ExpReturn = [ 0.0054; 0.0531; 0.0779; 0.0934; 0.0130 ];
ExpCovariance = [ 0.0569, 0.0092, 0.0039, 0.0070, 0.0022;
    0.0092, 0.0380, 0.0035, 0.0197, 0.0028;
    0.0039, 0.0035, 0.0997, 0.0100, 0.0070;
    0.0070, 0.0197, 0.0100, 0.0461, 0.0050;
    0.0022, 0.0028, 0.0070, 0.0050, 0.0573 ];
NumPorts = 10;
TargetReturn = [ 0.05; 0.06; 0.07; 0.08; 0.09 ];
[PortRisk, PortReturn, PortWts] = portopt(ExpReturn, ExpCovariance, [], TargetReturn);
disp(' Efficient Target');
disp([PortReturn, TargetReturn]);
    Efficient Target
    0.0500 0.0500
    0.0600 0.0600
    0.0700 0.0700
    0.0800 0.0800
    0.0900 0.0900
```

To migrate a portopt syntax for target returns within range of efficient portfolio returns to a Portfolio object:

```
ExpReturn = [ 0.0054; 0.0531; 0.0779; 0.0934; 0.0130 ];
ExpCovariance = [ 0.0569, 0.0092, 0.0039, 0.0070, 0.0022;
    0.0092, 0.0380, 0.0035, 0.0197, 0.0028;
    0.0039, 0.0035, 0.0997, 0.0100, 0.0070;
    0.0070, 0.0197, 0.0100, 0.0461, 0.0050;
    0.0022, 0.0028, 0.0070, 0.0050, 0.0573 ];
NumPorts = 10;
```

```
TargetReturn = [ 0.05; 0.06; 0.07; 0.08; 0.09 ];
p = Portfolio;
p = setAssetMoments(p, ExpReturn, ExpCovariance);
p = setDefaultConstraints(p);
PortWts = estimateFrontierByReturn(p, TargetReturn)
[PortRisk, PortReturn] = estimatePortMoments(p, PortWts);
disp(' Efficient Target');
disp([PortReturn, TargetReturn]);
Efficient Target
    0.0500 0.0500
    0.0600 0.0600
    0.0700 0.0700
    0.0800 0.0800
    0.0900 0.0900
```

## Migrate portopt for Target Return Outside Range of Efficient Portfolio Returns

This example shows how to migrate portopt target returns outside of range of efficient portfolio returns to a Portfolio object.

When the target return is outside of the range of efficient portfolio returns, portopt generates an error. The Portfolio object handles this effectively by selecting portfolios at the ends of the efficient frontier.

```
ExpReturn = [ 0.0054; 0.0531; 0.0779; 0.0934; 0.0130 ];
ExpCovariance = [ 0.0569, 0.0092, 0.0039, 0.0070, 0.0022;
    0.0092, 0.0380, 0.0035, 0.0197, 0.0028;
    0.0039, 0.0035, 0.0997, 0.0100, 0.0070;
    0.0070, 0.0197, 0.0100, 0.0461, 0.0050;
    0.0022, 0.0028, 0.0070, 0.0050, 0.0573 ];
NumPorts = 10;
TargetReturn = [ 0.05; 0.06; 0.07; 0.08; 0.09; 0.10 ];
[PortRisk, PortReturn, PortWts] = portopt(ExpReturn, ExpCovariance, [], TargetReturn);
disp(' Efficient Target');
disp([PortReturn, TargetReturn]);
\ In portopt at 85
Error using portopt (line 297)
One or more requested returns are greater than the maximum achievable return of 0.093400.
```

To migrate a portopt syntax for target returns outside of the range of efficient portfolio returns to a Portfolio object:

```
ExpReturn = [ 0.0054; 0.0531; 0.0779; 0.0934; 0.0130 ];
ExpCovariance = [ 0.0569, 0.0092, 0.0039, 0.0070, 0.0022;
    0.0092, 0.0380, 0.0035, 0.0197, 0.0028;
    0.0039, 0.0035, 0.0997, 0.0100, 0.0070;
    0.0070, 0.0197, 0.0100, 0.0461, 0.0050;
    0.0022, 0.0028, 0.0070, 0.0050, 0.0573 ];
NumPorts = 10;
TargetReturn = [ 0.05; 0.06; 0.07; 0.08; 0.09; 0.10 ];
p = Portfolio;
p = setAssetMoments(p, ExpReturn, ExpCovariance);
p = setDefaultConstraints(p);
PortWts = estimateFrontierByReturn(p, TargetReturn);
[PortRisk, PortReturn] = estimatePortMoments(p, PortWts);
disp(' Efficient Target');
disp([PortReturn, TargetReturn]);
Warning: One or more target return values are outside the feasible range [
0.0427391, 0.0934 ].
    Will return portfolios associated with endpoints of the range for these
        values.
> In Portfolio/estimateFrontierByReturn (line 106)
    Efficient Target
        0.0500 0.0500

## Migrate portopt Using portcons Output for ConSet

This example shows how to migrate portopt when the ConSet output from portcons is used with portopt.
portopt accepts as input the outputs from portcons, pcalims, pcglims, and pcgcomp. This example focuses on portcons. portcons sets up linear constraints for portopt in the form $A *$ Port $<=\mathrm{b}$. In a matrix ConSet $=$ [ A, b ] and break into separate $A$ and $b$ arrays with $A=\operatorname{ConSet}(:, 1: e n d-1) ;$ and $b=\operatorname{ConSet}(:, e n d) ;$ In addition, to illustrate default problem with additional group constraints, consider three groups. Assets 2, 3, and 4 can constitute up to $80 \%$ of portfolio, Assets 1 and 2 can constitute up to $70 \%$ of portfolio, and Assets 3, 4, and 5 can constitute up to $90 \%$ of portfolio.

```
ExpReturn = [ 0.0054; 0.0531; 0.0779; 0.0934; 0.0130 ];
```

```
ExpCovariance = [ 0.0569, 0.0092, 0.0039, 0.0070, 0.0022;
    0.0092, 0.0380, 0.0035, 0.0197, 0.0028;
    0.0039, 0.0035, 0.0997, 0.0100, 0.0070;
    0.0070, 0.0197, 0.0100, 0.0461, 0.0050;
    0.0022, 0.0028, 0.0070, 0.0050, 0.0573 ];
NumPorts = 10;
Groups = [ 0 1 1 1 0; 1 1 0 0 0; 0 0 1 1 1 ];
GroupBounds = [ 0, 0.8; 0, 0.7; 0, 0.9 ];
LowerGroup = GroupBounds(:,1);
UpperGroup = GroupBounds(:,2);
ConSet = portcons('default', 5, 'grouplims', Groups, LowerGroup, UpperGroup);
[PortRisk, PortReturn, PortWts] = portopt(ExpReturn, ExpCovariance, NumPorts, [], ConSet);
disp([PortRisk, PortReturn]);
Error using portopt (line 83)
In the current and future releases, portopt will no longer accept ConSet or varargin arguments.
'It will only solve the portfolio problem for long-only fully-invested portfolios.
To solve more general problems, use the Portfolio object.
See the release notes for details, including examples to make the conversion.
```

To migrate portopt to a Portfolio object when the ConSet output from portcons is used with portopt:

```
ExpReturn = [ 0.0054; 0.0531; 0.0779; 0.0934; 0.0130 ];
ExpCovariance = [ 0.0569, 0.0092, 0.0039, 0.0070, 0.0022;
    0.0092, 0.0380, 0.0035, 0.0197, 0.0028;
    0.0039, 0.0035, 0.0997, 0.0100, 0.0070;
    0.0070, 0.0197, 0.0100, 0.0461, 0.0050;
    0.0022, 0.0028, 0.0070, 0.0050, 0.0573 ];
NumPorts = 10;
Groups = [ 0 1 1 1 0; 1 1 0 0 0; 0 0 1 1 1 ];
GroupBounds = [ 0, 0.8; 0, 0.7; 0, 0.9 ];
LowerGroup = GroupBounds(:,1);
UpperGroup = GroupBounds(:,2);
ConSet = portcons('default', 5, 'grouplims', Groups, LowerGroup, UpperGroup);
A = ConSet(:,1:end-1);
b = ConSet(:,end);
p = Portfolio;
p = setAssetMoments(p, ExpReturn, ExpCovariance);
p = setInequality(p, A, b); % implement group constraints here
```

PortWts = estimateFrontier(p, NumPorts);
[PortRisk, PortReturn] = estimatePortMoments(p, PortWts);
disp([PortRisk, PortReturn]);
$0.1288 \quad 0.0427$

The constraints are entered directly into the Portfolio object with the setInequality or addInequality functions.

## Integrate Output from portcons pcalims, pcglims, and pcgcomp with a Porifolio Object

This example shows how to integrate output from pcalims, pcalims, pcglims, or pcgcomp with a Portfolio object implementation.
portcons, pcalims, pcglims, and pcgcomp setup linear constraints for portopt in the form A*Port <= b. Although some functions permit two outputs, assume that the output is a single matrix ConSet. Break into separate A and b arrays with:

- $A=\operatorname{ConSet}(:, 1: e n d-1)$;
- b = ConSet (:,end);

In addition, to illustrate default problem with additional group constraints, consider three groups:

- Assets 2, 3, and 4 can constitute up to $80 \%$ of portfolio.
- Assets 1 and 2 can constitute up to $70 \%$ of portfolio.
- Assets 3, 4, and 5 can constitute up to $90 \%$ of portfolio.

```
Groups = [ 0 1 1 1 1 0; 1 1 0 0 0; 0 0 1 1 1 1 ];
GroupBounds = [ 0, 0.8; 0, 0.7; 0, 0.9 ];
```

To integrate the ConSet output of portcons with a Portfolio object implementation:

```
ExpReturn = [ 0.0054; 0.0531; 0.0779; 0.0934; 0.0130 ];
ExpCovariance = [ 0.0569, 0.0092, 0.0039, 0.0070, 0.0022;
    0.0092, 0.0380, 0.0035, 0.0197, 0.0028;
    0.0039, 0.0035, 0.0997, 0.0100, 0.0070;
    0.0070, 0.0197, 0.0100, 0.0461, 0.0050;
    0.0022, 0.0028, 0.0070, 0.0050, 0.0573 ];
```

```
NumPorts = 10;
Groups = [ 0 1 1 1 0; 1 1 0 0 0; 000 1 1 1 ];
GroupBounds = [ 0, 0.8; 0, 0.7; 0, 0.9 ];
LowerGroup = GroupBounds(:,1);
UpperGroup = GroupBounds(:,2);
ConSet = portcons('default', 5, 'grouplims', Groups, LowerGroup, UpperGroup);
A = ConSet(:,1:end-1);
b = ConSet(:,end);
p = Portfolio;
p = setAssetMoments(p, ExpReturn, ExpCovariance);
p = setDefaultConstraints(p); % implement default constraints here
p = setInequality(p, A, b); % implement group constraints here
PortWts = estimateFrontier(p, NumPorts);
[PortRisk, PortReturn] = estimatePortMoments(p, PortWts);
disp([PortRisk, PortReturn]);
\begin{tabular}{ll}

## Migrate frontcon Without Output Arguments

This example shows how to migrate frontcon without output arguments to a Portfolio object.

The basic frontcon functionality is represented as:

```
ExpReturn = [ 0.0054; 0.0531; 0.0779; 0.0934; 0.0130 ];
ExpCovariance = [ 0.0569, 0.0092, 0.0039, 0.0070, 0.0022;
    0.0092, 0.0380, 0.0035, 0.0197, 0.0028;
    0.0039, 0.0035, 0.0997, 0.0100, 0.0070;
    0.0070, 0.0197, 0.0100, 0.0461, 0.0050;
    0.0022, 0.0028, 0.0070, 0.0050, 0.0573 ];
NumPorts = 10;
frontcon(ExpReturn, ExpCovariance, NumPorts);
Error using frontcon (line 89)
In a future release, frontcon will be removed. Use the Portfolio object instead.
See the release notes for details, including examples to make the conversion.
```

To migrate a frontcon syntax without output arguments to a Portfolio object:

```
ExpReturn = [ 0.0054; 0.0531; 0.0779; 0.0934; 0.0130 ];
ExpCovariance = [ 0.0569, 0.0092, 0.0039, 0.0070, 0.0022;
    0.0092, 0.0380, 0.0035, 0.0197, 0.0028;
    0.0039, 0.0035, 0.0997, 0.0100, 0.0070;
    0.0070, 0.0197, 0.0100, 0.0461, 0.0050;
    0.0022, 0.0028, 0.0070, 0.0050, 0.0573 ];
```

```
NumPorts = 10;
p = Portfolio;
p = setAssetMoments(p, ExpReturn, ExpCovariance);
p = setDefaultConstraints(p);
plotFrontier(p, NumPorts);
```

The Portfolio object writes to the current figure window rather than create a new window each time a plot is generated.

## Migrate frontcon with Output Arguments

This example shows how to migrate frontcon with output arguments to a Portfolio object.

The basic frontcon functionality is represented as:

```
ExpReturn = [ 0.0054; 0.0531; 0.0779; 0.0934; 0.0130 ];
ExpCovariance = [ 0.0569, 0.0092, 0.0039, 0.0070, 0.0022;
    0.0092, 0.0380, 0.0035, 0.0197, 0.0028;
    0.0039, 0.0035, 0.0997, 0.0100, 0.0070;
    0.0070, 0.0197, 0.0100, 0.0461, 0.0050;
    0.0022, 0.0028, 0.0070, 0.0050, 0.0573 ];
NumPorts = 10;
[PortRisk, PortReturn, PortWts] = frontcon(ExpReturn, ExpCovariance, NumPorts);
display(PortWts);
Error using frontcon (line 89)
In a future release, frontcon will be removed. Use the Portfolio object instead
See the release notes for details, including examples to make the conversion.
```

To migrate a portopt syntax with output arguments:

```
ExpReturn = [ 0.0054; 0.0531; 0.0779; 0.0934; 0.0130 ];
ExpCovariance = [ 0.0569, 0.0092, 0.0039, 0.0070, 0.0022;
    0.0092, 0.0380, 0.0035, 0.0197, 0.0028;
    0.0039, 0.0035, 0.0997, 0.0100, 0.0070;
    0.0070, 0.0197, 0.0100, 0.0461, 0.0050;
    0.0022, 0.0028, 0.0070, 0.0050, 0.0573 ];
NumPorts = 10;
p = Portfolio;
p = setAssetMoments(p, ExpReturn, ExpCovariance);
p = setDefaultConstraints(p);
```

PortWts = estimateFrontier(p, NumPorts);
[PortRisk, PortReturn] = estimatePortMoments(p, PortWts);
display(PortWts);
PortWts =

| 0.2103 | 0.1744 | 0.1386 | 0.1027 | 0.0668 | 0.0309 | 0 | 0 | 0 | 0 |
| ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| 0.2746 | 0.2657 | 0.2567 | 0.2477 | 0.2387 | 0.2298 | 0.2168 | 0.1791 | 0.0557 | 0 |
| 0.1157 | 0.1296 | 0.1436 | 0.1575 | 0.1714 | 0.1854 | 0.1993 | 0.2133 | 0.2183 | 0 |
| 0.1594 | 0.2193 | 0.2791 | 0.3390 | 0.3988 | 0.4587 | 0.5209 | 0.5985 | 0.7260 | 1.0000 |
| 0.2400 | 0.2110 | 0.1821 | 0.1532 | 0.1242 | 0.0953 | 0.0629 | 0.0091 | 0 | 0 |

The Portfolio object returns PortWts with portfolios going down columns, not across rows. Portfolio risks and returns are still in column format.

## Migrate frontcon for Target Returns Within Range of Efficient Portfolio Returns

This example shows how to migrate frontcon target returns within range of efficient portfolio returns to a Portfolio object.
frontcon can obtain portfolios with specific targeted levels of return but requires that the targeted returns fall within the range of efficient returns. The Portfolio object handles this by selecting portfolios at the ends of the efficient frontier.

```
ExpReturn = [ 0.0054; 0.0531; 0.0779; 0.0934; 0.0130 ];
ExpCovariance = [ 0.0569, 0.0092, 0.0039, 0.0070, 0.0022;
    0.0092, 0.0380, 0.0035, 0.0197, 0.0028;
    0.0039, 0.0035, 0.0997, 0.0100, 0.0070;
    0.0070, 0.0197, 0.0100, 0.0461, 0.0050;
    0.0022, 0.0028, 0.0070, 0.0050, 0.0573 ];
NumPorts = 10;
TargetReturn = [ 0.05; 0.06; 0.07; 0.08; 0.09 ];
[PortRisk, PortReturn, PortWts] = frontcon(ExpReturn, ExpCovariance, [], TargetReturn);
disp(' Efficient Target');
disp([PortReturn, TargetReturn]);
Error using frontcon (line 89)
In a future release, frontcon will be removed. Use the Portfolio object instead.
See the release notes for details, including examples to make the conversion.
```

To migrate a frontcon syntax for target returns within range of efficient portfolio returns to a Portfolio object:

```
ExpReturn = [ 0.0054; 0.0531; 0.0779; 0.0934; 0.0130 ];
ExpCovariance = [ 0.0569, 0.0092, 0.0039, 0.0070, 0.0022;
    0.0092, 0.0380, 0.0035, 0.0197, 0.0028;
    0.0039, 0.0035, 0.0997, 0.0100, 0.0070;
    0.0070, 0.0197, 0.0100, 0.0461, 0.0050;
    0.0022, 0.0028, 0.0070, 0.0050, 0.0573 ];
NumPorts = 10;
TargetReturn = [ 0.05; 0.06; 0.07; 0.08; 0.09 ];
p = Portfolio;
p = setAssetMoments(p, ExpReturn, ExpCovariance);
p = setDefaultConstraints(p);
PortWts = estimateFrontierByReturn(p, TargetReturn);
[PortRisk, PortReturn] = estimatePortMoments(p, PortWts);
disp(' Efficient Target');
disp([PortReturn, TargetReturn]);
Efficient Target
    0.0500 0.0500
    0.0600 0.0600
    0.0700 0.0700
    0.0800 0.0800
```

## Migrate frontcon for Target Returns Outside Range of Efficient Porffolio Returns

This example shows how to migrate frontcon target returns outside of range of efficient portfolio returns to a Portfolio object.

When the target return is outside of the range of efficient portfolio returns, frontcon generates an error. The Portfolio object handles this effectively by selecting portfolios at the ends of the efficient frontier.

```
ExpReturn = [ 0.0054; 0.0531; 0.0779; 0.0934; 0.0130 ];
ExpCovariance = [ 0.0569, 0.0092, 0.0039, 0.0070, 0.0022;
    0.0092, 0.0380, 0.0035, 0.0197, 0.0028;
    0.0039, 0.0035, 0.0997, 0.0100, 0.0070;
    0.0070, 0.0197, 0.0100, 0.0461, 0.0050;
    0.0022, 0.0028, 0.0070, 0.0050, 0.0573 ];
NumPorts = 10;
TargetReturn = [ 0.05; 0.06; 0.07; 0.08; 0.09; 0.10 ];
[PortRisk, PortReturn, PortWts] = frontcon(ExpReturn, ExpCovariance, [], TargetReturn);
disp(' Efficient Target');
disp([PortReturn, TargetReturn]);
Error using frontcon (line 89)
In a future release, frontcon will be removed. Use the Portfolio object instead.
See the release notes for details, including examples to make the conversion.
```

To migrate a frontcon syntax for target returns outside of the range of efficient portfolio returns to a Portfolio object:

```
ExpReturn = [ 0.0054; 0.0531; 0.0779; 0.0934; 0.0130 ];
ExpCovariance = [ 0.0569, 0.0092, 0.0039, 0.0070, 0.0022;
    0.0092, 0.0380, 0.0035, 0.0197, 0.0028;
    0.0039, 0.0035, 0.0997, 0.0100, 0.0070;
    0.0070, 0.0197, 0.0100, 0.0461, 0.0050;
    0.0022, 0.0028, 0.0070, 0.0050, 0.0573 ];
NumPorts = 10;
TargetReturn = [ 0.05; 0.06; 0.07; 0.08; 0.09; 0.10 ];
p = Portfolio;
p = setAssetMoments(p, ExpReturn, ExpCovariance);
p = setDefaultConstraints(p);
PortWts = estimateFrontierByReturn(p, TargetReturn);
[PortRisk, PortReturn] = estimatePortMoments(p, PortWts);
disp(' Efficient Target');
```

```
disp([PortReturn, TargetReturn]);
Warning: One or more target return values are outside the feasible range [
0.0427391, 0.0934 ].
    Will return portfolios associated with endpoints of the range for these
        values.

## Migrate frontcon Syntax When Using Bounds

This example shows how to migrate frontcon syntax for AssetBounds to a Portfolio object.

Use frontcon with an input specification for AssetBounds that contains the lower and upper bounds on the weight allocated to each asset in the portfolio:

```
ExpReturn = [ 0.0054; 0.0531; 0.0779; 0.0934; 0.0130 ];
ExpCovariance = [ 0.0569, 0.0092, 0.0039, 0.0070, 0.0022;
    0.0092, 0.0380, 0.0035, 0.0197, 0.0028;
    0.0039, 0.0035, 0.0997, 0.0100, 0.0070;
    0.0070, 0.0197, 0.0100, 0.0461, 0.0050;
    0.0022, 0.0028, 0.0070, 0.0050, 0.0573 ];
NumPorts = 10
AssetBounds = [ 0.1, 0.1, 0.1, 0.1, 0.1; 0.5, 0.5, 0.5, 0.5, 0.5 ];
[PortRisk, PortReturn, PortWts] = frontcon(ExpReturn, ExpCovariance, NumPorts, [], AssetBounds);
disp([PortRisk, PortReturn]);
Error using frontcon (line 89)
In a future release, frontcon will be removed. Use the Portfolio object instead.
See the release notes for details, including examples to make the conversion.
```

To migrate a frontcon syntax using AssetBounds to a Portfolio object:

```
ExpReturn = [ 0.0054; 0.0531; 0.0779; 0.0934; 0.0130 ];
ExpCovariance = [ 0.0569, 0.0092, 0.0039, 0.0070, 0.0022;
    0.0092, 0.0380, 0.0035, 0.0197, 0.0028;

## Migrate frontcon Syntax When Using Groups

This example shows how to migrate frontcon syntax for Groups and GroupBounds to a Portfolio object.

Use frontcon with an input specification for Groups (asset groups or classes.) and GroupBounds (the lower and upper bounds of the total weights of all assets in a group). Consider three groups: Assets 2, 3, and 4 can constitute up to $80 \%$ of a portfolio, Assets 1 and 2 can constitute up to $70 \%$ of a portfolio, and Assets 3, 4, and 5 can constitute up to $90 \%$ of a portfolio.

```
ExpReturn = [ 0.0054; 0.0531; 0.0779; 0.0934; 0.0130 ];
ExpCovariance = [ 0.0569, 0.0092, 0.0039, 0.0070, 0.0022;
    0.0092, 0.0380, 0.0035, 0.0197, 0.0028;
    0.0039, 0.0035, 0.0997, 0.0100, 0.0070;
    0.0070, 0.0197, 0.0100, 0.0461, 0.0050;
    0.0022, 0.0028, 0.0070, 0.0050, 0.0573 ];
NumPorts = 10;
```

```
Groups = [ 0 1 1 1 0; 1 1 0 0 0; 0 0 1 1 1 ];
GroupBounds = [ 0, 0.8; 0, 0.7; 0, 0.9 ];
[PortRisk, PortReturn, PortWgts] = frontcon(ExpReturn, ExpCovariance, NumPorts, [], [], ...
Groups, GroupBounds);
disp([PortRisk, PortReturn]);
Error using frontcon (line 89)
In a future release, frontcon will be removed. Use the Portfolio object instead.
See the release notes for details, including examples to make the conversion.
```

To migrate a frontcon syntax using Groups and GroupBounds to a Portfolio object:

```
ExpReturn = [ 0.0054; 0.0531; 0.0779; 0.0934; 0.0130 ];
ExpCovariance = [ 0.0569, 0.0092, 0.0039, 0.0070, 0.0022;
    0.0092, 0.0380, 0.0035, 0.0197, 0.0028;
    0.0039, 0.0035, 0.0997, 0.0100, 0.0070;
    0.0070, 0.0197, 0.0100, 0.0461, 0.0050;
    0.0022, 0.0028, 0.0070, 0.0050, 0.0573 ];
NumPorts = 10;
Groups = [ 0 1 1 1 0; 1 1 0 0 0; 0 0 1 1 1 ];
GroupBounds = [ 0, 0.8; 0, 0.7; 0, 0.9 ];
LowerGroup = GroupBounds(:,1);
UpperGroup = GroupBounds(:,2);
p = Portfolio;
p = setAssetMoments(p, ExpReturn, ExpCovariance);
p = setDefaultConstraints(p);
p = setGroups(p, Groups, LowerGroup, UpperGroup);
PortWts = estimateFrontier(p, NumPorts);
[PortRisk, PortReturn] = estimatePortMoments(p, PortWts);
disp([PortRisk, PortReturn]);

## Constraint Specification Using a Portfolio Object

In this section...<br>"Constraints for Efficient Frontier" on page 3-34<br>"Linear Constraint Equations" on page 3-36<br>"Specifying Group Constraints" on page 3-39

## Constraints for Efficient Frontier

This example computes the efficient frontier of portfolios consisting of three different assets, INTC, XON, and RD, given a list of constraints. The expected returns for INTC, XON, and RD are respectively as follows:

```
ExpReturn = [0.1 0.2 0.15];
```

The covariance matrix is

- Constraint 1
- Allow short selling up to $10 \%$ of the portfolio value in any asset, but limit the investment in any one asset to $110 \%$ of the portfolio value.
- Constraint 2
- Consider two different sectors, technology and energy, with the following table indicating the sector each asset belongs to.

| Asset | INTC | XON | RD |
| :--- | :--- | :--- | :--- |
| Sector | Technology | Energy | Energy |

Constrain the investment in the Energy sector to $80 \%$ of the portfolio value, and the investment in the Technology sector to $70 \%$.

To solve this problem, use Portfolio, passing in a list of asset constraints. Consider eight different portfolios along the efficient frontier:

```
NumPorts = 8;
```

To introduce the asset bounds constraints specified in Constraint 1, create the matrix AssetBounds, where each column represents an asset. The upper row represents the lower bounds, and the lower row represents the upper bounds. Since the bounds are the same for each asset, only one pair of bounds is needed because of scalar expansion.

```
AssetBounds = [-0.1, 1.1];
```

Constraint 2 must be entered in two parts, the first part defining the groups, and the second part defining the constraints for each group. Given the information above, you can build a matrix of 1 s and 0 s indicating whether a specific asset belongs to a group. Each column represents an asset, and each row represents a group. This example has two groups: the technology group, and the energy group. Create the matrix Groups as follows.

```
Groups = [\begin{array}{ccc}{0}&{1}&{1;}\\{1}&{0}&{0}\end{array}]
```

The GroupBounds matrix allows you to specify an upper and lower bound for each group. Each row in this matrix represents a group. The first column represents the minimum allocation, and the second column represents the maximum allocation to each group. Since the investment in the Energy sector is capped at $80 \%$ of the portfolio value, and the investment in the Technology sector is capped at $70 \%$, create the GroupBounds matrix using this information.

```
GroupBounds = [0 0.80;
    0 0.70];
```

Now use Portfolio to obtain the vectors and arrays representing the risk, return, and weights for each of the eight portfolios computed along the efficient frontier. A budget constraint is added to ensure that the portfolio weights sum to 1.

```
p = Portfolio('AssetMean', ExpReturn, 'AssetCovar', ExpCovariance);
p = setBounds(p, AssetBounds(1), AssetBounds(2));
p = setBudget(p, 1, 1);
p = setGroups(p, Groups, GroupBounds(:,1), GroupBounds(:,2));
PortWts = estimateFrontier(p, NumPorts);
[PortRisk, PortReturn] = estimatePortMoments(p, PortWts);
PortRisk
PortReturn
PortWts
```

```
PortRisk =
    0.0416
    0.0499
    0.0624
    0.0767
    0.0920
    0.1100
    0.1378
    0.1716
```

PortReturn =
0.1279
0.1361
0.1442
0.1524
0.1605
0.1687
0.1768
0.1850

PortWts =

| 0.7000 | 0.6031 | 0.4864 | 0.3696 | 0.2529 | 0.2000 | 0.2000 | 0.2000 |
| ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| 0.2582 | 0.3244 | 0.3708 | 0.4172 | 0.4636 | 0.5738 | 0.7369 | 0.9000 |
| 0.0418 | 0.0725 | 0.1428 | 0.2132 | 0.2835 | 0.2262 | 0.0631 | -0.1000 |

The outputs are represented as columns for the portfolio's risk and return. Portfolio weights are identified as corresponding column vectors in a matrix.

## Linear Constraint Equations

While the Portfolio object allows you to enter a fixed set of constraints related to minimum and maximum values for groups and individual assets, you often need to specify a larger and more general set of constraints when finding the optimal risky portfolio. Portfolio also addresses this need, by accepting an arbitrary set of constraints.

This example requires specifying the minimum and maximum investment in various groups.

Maximum and Minimum Group Exposure

| Group | Minimum Exposure | Maximum Exposure |
| :--- | :--- | :--- |
| North America | 0.30 | 0.75 |
| Europe | 0.10 | 0.55 |
| Latin America | 0.20 | 0.50 |
| Asia | 0.50 | 0.50 |

The minimum and maximum exposure in Asia is the same. This means that you require a fixed exposure for this group.

Also assume that the portfolio consists of three different funds. The correspondence between funds and groups is shown in the table below.

## Group Membership

| Group | Fund 1 | Fund 2 | Fund 3 |
| :--- | :--- | :--- | :--- |
| North America | X | X |  |
| Europe |  |  | X |
| Latin America | X |  |  |
| Asia |  | X | X |

Using the information in these two tables, build a mathematical representation of the constraints represented. Assume that the vector of weights representing the exposure of each asset in a portfolio is called Wts $=\left[\begin{array}{l}\text { W1 W2 W3]. }\end{array}\right.$

Specifically

| 1. | $W 1+W 2$ | $\geq$ | 0.30 |
| :--- | :--- | :--- | :--- |
| 2. | $W 1+W 2$ | $\leq$ | 0.75 |
| 3. | $W 3$ | $\geq$ | 0.10 |
| 4. | $W 3$ | $\leq$ | 0.55 |
| 5. | $W 1$ | $\geq$ | 0.20 |
| 6. | $W 1$ | $\leq$ | 0.50 |

| 7. | $W 2+W 3$ | $=$ | 0.50 |
| :--- | :--- | :--- | :--- |

Since you must represent the information in the form $A * W t s<=b$, multiply equations 1 , 3 and 5 by -1 . Also turn equation 7 into a set of two inequalities: $W 2+W 3 \geq 0.50$ and $W 2$ $+W 3 \leq 0.50$. (The intersection of these two inequalities is the equality itself.) Thus

| 1. | $-W 1-W 2$ | $\leq$ | -0.30 |
| :--- | :--- | :--- | :--- |
| 2. | $W 1+W 2$ | $\leq$ | 0.75 |
| 3. | $-W 3$ | $\leq$ | -0.10 |
| 4. | $W 3$ | $\leq$ | 0.55 |
| 5. | $-W 1$ | $\leq$ | -0.20 |
| 6. | $W 1$ | 0.50 |  |
| 7. | $-W 2-W 3$ | $\leq$ | -0.50 |
| 8. | $W 2+W 3$ | $\leq$ | 0.50 |

Bringing these equations into matrix notation gives
$A=\left[\begin{array}{rrr}-1 & -1 & 0 ; \\ 1 & 1 & 0 ; \\ 0 & 0 & -1 ; \\ 0 & 0 & 1 ; \\ -1 & 0 & 0 ; \\ 1 & 0 & 0 ; \\ 0 & -1 & -1 ; \\ 0 & 1 & 1]\end{array}\right.$
b = [-0.30;
0.75 ;
-0.10;
0.55 ;
-0.20;
0.50;
-0.50;
$0.50]$
One approach to solving this portfolio problem is to explicitly use the setInequality function:

```
p = Portfolio('AssetMean', ExpReturn, 'AssetCovar', ExpCovariance);
p = setBounds(p, AssetBounds(1), AssetBounds(2));
```

```
p = setBudget(p, 1, 1);
p = setInequality(p, A, b);
PortWts = estimateFrontier(p, NumPorts);
[PortRisk, PortReturn] = estimatePortMoments(p, PortWts);
PortRisk
PortReturn
PortWts
PortRisk =
    0.0586
    0.0586
    0.0586
    0.0586
    0.0586
    0.0586
    0.0586
    0.0586
PortReturn =
    0.1375
    0.1375
    0.1375
    0.1375
    0.1375
    0.1375
    0.1375
    0.1375
PortWts =
\begin{tabular}{llllllll}
0.5000 & 0.5000 & 0.5000 & 0.5000 & 0.5000 & 0.5000 & 0.5000 & 0.5000 \\
0.2500 & 0.2500 & 0.2500 & 0.2500 & 0.2500 & 0.2500 & 0.2500 & 0.2500 \\
0.2500 & 0.2500 & 0.2500 & 0.2500 & 0.2500 & 0.2500 & 0.2500 & 0.2500
\end{tabular}
```

In this case, the constraints allow only one optimum portfolio. Since eight portfolios were requested, all eight portfolios are the same. Note that the solution to this portfolio problem using the setInequality function is the same as using the setGroups function in the next example ("Specifying Group Constraints" on page 3-39).

## Specifying Group Constraints

The example above ("Linear Constraint Equations" on page 3-36) defines a constraint matrix that specifies a set of typical scenarios. It defines groups of assets, specifies upper and lower bounds for total allocation in each of these groups, and it sets the total allocation of one group to a fixed value. Constraints like these are common occurrences. Portfolio enables you to simplify the creation of the constraint matrix for these and other common portfolio requirements.

An alternative approach for solving the portfolio problem is to use the Portfolio object to define:

- A Group matrix, indicating the assets that belong to each group.
- A GroupMin vector, indicating the minimum bounds for each group.
- A GroupMax vector, indicating the maximum bounds for each group.

Based on the table Group Membership, build the Group matrix, with each row representing a group, and each column representing an asset.

```
Group = [\begin{array}{lll}{1}&{1}&{0;}\end{array}]
    0 0 1;
    1 0 0;
    0 1 1];
```

The table Maximum and Minimum Group Exposure has the information to build GroupMin and GroupMax.

```
GroupMin = [lllll}0.30\mathrm{ 0.10 0.20 0.50];
GroupMax = [llllll}0.75 0.55 0.50 0.50];'
```

Now use Portfolio and the setInequality function to obtain the vectors and arrays representing the risk, return, and weights for the portfolios computed along the efficient frontier.

```
p = Portfolio('AssetMean', ExpReturn, 'AssetCovar', ExpCovariance);
p = setBounds(p, AssetBounds(1), AssetBounds(2));
p = setBudget(p, 1, 1);
p = setGroups(p, Group, GroupMin, GroupMax);
PortWts = estimateFrontier(p, NumPorts);
[PortRisk, PortReturn] = estimatePortMoments(p, PortWts);
```

PortRisk
PortReturn
PortWts
PortRisk $=$
0.0586
0.0586
0.0586
0.0586
0.0586
0.0586
0.0586
0.0586

```
PortReturn =
    0.1375
    0.1375
    0.1375
    0.1375
    0.1375
    0.1375
    0.1375
    0.1375
PortWts =
\begin{tabular}{llllllll}
0.5000 & 0.5000 & 0.5000 & 0.5000 & 0.5000 & 0.5000 & 0.5000 & 0.5000 \\
0.2500 & 0.2500 & 0.2500 & 0.2500 & 0.2500 & 0.2500 & 0.2500 & 0.2500 \\
0.2500 & 0.2500 & 0.2500 & 0.2500 & 0.2500 & 0.2500 & 0.2500 & 0.2500
\end{tabular}
```

In this case, the constraints allow only one optimum portfolio. Since eight portfolios were requested, all eight portfolios are the same. Note that the solution to this portfolio problem using the setGroups function is the same as using the setInequality function in the previous example ("Linear Constraint Equations" on page 3-36).

## Active Returns and Tracking Error Efficient Frontier

Suppose that you want to identify an efficient set of portfolios that minimize the variance of the difference in returns with respect to a given target portfolio, subject to a given expected excess return. The mean and standard deviation of this excess return are often called the active return and active risk, respectively. Active risk is sometimes referred to as the tracking error. Since the objective is to track a given target portfolio as closely as possible, the resulting set of portfolios is sometimes referred to as the tracking error efficient frontier.

Specifically, assume that the target portfolio is expressed as an index weight vector, such that the index return series may be expressed as a linear combination of the available assets. This example illustrates how to construct a frontier that minimizes the active risk (tracking error) subject to attaining a given level of return. That is, it computes the tracking error efficient frontier.

One way to construct the tracking error efficient frontier is to explicitly form the target return series and subtract it from the return series of the individual assets. In this manner, you specify the expected mean and covariance of the active returns, and compute the efficient frontier subject to the usual portfolio constraints.

This example works directly with the mean and covariance of the absolute (unadjusted) returns but converts the constraints from the usual absolute weight format to active weight format.

Consider a portfolio of five assets with the following expected returns, standard deviations, and correlation matrix based on absolute weekly asset returns.

| NumAssets | $=$ | $5 ;$ |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| ExpReturn | $=$ | [0.2074 | 0.1971 | 0.2669 | 0.1323 | 0.2535]/100; |
| Sigmas | $=$ | [2.6570 | 3.6297 | 3.9916 | 2.7145 | 2.6133]/100; |
| Correlations | $=$ | [1.0000 | 0.6092 | 0.6321 | 0.5833 | 0.7304 |
|  |  | 0.6092 | 1.0000 | 0.8504 | 0.8038 | 0.7176 |
|  |  | 0.6321 | 0.8504 | 1.0000 | 0.7723 | 0.7236 |
|  |  | 0.5833 | 0.8038 | 0.7723 | 1.0000 | 0.7225 |
|  |  | 0.7304 | 0.7176 | 0.7236 | 0.7225 | 1.0000]; |

Convert the correlations and standard deviations to a covariance matrix using corr2cov.

```
ExpCovariance = corr2cov(Sigmas, Correlations);
```

Next, assume that the target index portfolio is an equally weighted portfolio formed from the five assets. The sum of index weights equals 1 , satisfying the standard full investment budget equality constraint.

```
Index = ones(NumAssets, 1)/NumAssets;
```

Generate an asset constraint matrix using portcons. The constraint matrix AbsConSet is expressed in absolute format (unadjusted for the index), and is formatted as [A b], corresponding to constraints of the form $A * W$ <= b. Each row of AbsConSet corresponds to a constraint, and each column corresponds to an asset. Allow no short-selling and full investment in each asset (lower and upper bounds of each asset are 0 and 1, respectively). In particular, note that the first two rows correspond to the budget equality constraint; the remaining rows correspond to the upper/lower investment bounds.

```
AbsConSet = portcons('PortValue', 1, NumAssets, ...
'AssetLims', zeros(NumAssets,1), ones(NumAssets,1));
```

Now transform the absolute constraints to active constraints with abs2active.

```
ActiveConSet = abs2active(AbsConSet, Index);
```

An examination of the absolute and active constraint matrices reveals that they differ only in the last column (the columns corresponding to the b in $\mathrm{A} * \mathrm{w}<=\mathrm{b}$ ).

```
[AbsConSet(:,end) ActiveConSet(:,end)]
ans =
    1.0000 0
    -1.0000 0
    1.0000 0.8000
    1.0000 0.8000
    1.0000 0.8000
    1.0000 0.8000
    1.0000 0.8000
        0 0.2000
        0 0.2000
        0 0.2000
        0 0.2000
        0 0.2000
```

In particular, note that the sum-to-one absolute budget constraint becomes a sum-to-zero active budget constraint. The general transformation is as follows:

$$
b_{\text {active }}=b_{\text {absolute }}-A \times \text { Index. }
$$

Now construct the Portfolio object and plot the tracking error efficient frontier with 21 portfolios.

```
p = Portfolio('AssetMean', ExpReturn, 'AssetCovar', ExpCovariance);
p = p.setInequality(ActiveConSet(:,1:end-1), ActiveConSet(:,end));
[ActiveRisk, ActiveReturn] = p.plotFrontier(21);
plot(ActiveRisk*100, ActiveReturn*100, 'blue')
grid('on')
xlabel('Active Risk (Standard Deviation in Percent)')
ylabel('Active Return (Percent)')
title('Tracking Error Efficient Frontier')
```

Of particular interest is the lower-left portfolio along the frontier. This zero-risk/zeroreturn portfolio has a practical economic significance. It represents a full investment in the index portfolio itself. Each tracking error efficient portfolio (each row in the array ActiveWeights) satisfies the active budget constraint, and thus represents portfolio investment allocations with respect to the index portfolio. To convert these allocations to absolute investment allocations, add the index to each efficient portfolio.

ActiveWeights = p.estimateFrontier(21);
AbsoluteWeights = ActiveWeights + repmat(Index, 1, 21);

## Porffolio Optimization Theory

In this section...<br>"Portfolio Optimization Problems" on page 4-2<br>"Portfolio Problem Specification" on page 4-2<br>"Return Proxy" on page 4-3<br>"Risk Proxy" on page 4-5<br>"Portfolio Set for Optimization Using Portfolio Object" on page 4-7<br>"Default Portfolio Problem" on page 4-15

## Portfolio Optimization Problems

Portfolio optimization problems involve identifying portfolios that satisfy three criteria:

- Minimize a proxy for risk.
- Match or exceed a proxy for return.
- Satisfy basic feasibility requirements.

Portfolios are points from a feasible set of assets that constitute an asset universe. A portfolio specifies either holdings or weights in each individual asset in the asset universe. The convention is to specify portfolios in terms of weights, although the portfolio optimization tools work with holdings as well.

The set of feasible portfolios is necessarily a nonempty, closed, and bounded set. The proxy for risk is a function that characterizes either the variability or losses associated with portfolio choices. The proxy for return is a function that characterizes either the gross or net benefits associated with portfolio choices. The terms "risk" and "risk proxy" and "return" and "return proxy" are interchangeable. The fundamental insight of Markowitz (see "Portfolio Optimization" on page A-10) is that the goal of the portfolio choice problem is to seek minimum risk for a given level of return and to seek maximum return for a given level of risk. Portfolios satisfying these criteria are efficient portfolios and the graph of the risks and returns of these portfolios forms a curve called the efficient frontier.

## Porffolio Problem Specification

To specify a portfolio optimization problem, you need the following:

- Proxy for portfolio return ( $\mu$ )
- Proxy for portfolio risk ( $\Sigma$ )
- Set of feasible portfolios ( $X$ ), called a portfolio set

Financial Toolbox has three objects to solve specific types of portfolio optimization problems:

- The Portfolio object (Using Portfolio Objects) supports mean-variance portfolio optimization (see Markowitz [46], [47] at "Portfolio Optimization" on page A-10). This object has either gross or net portfolio returns as the return proxy, the variance of portfolio returns as the risk proxy, and a portfolio set that is any combination of the specified constraints to form a portfolio set.
- The PortfolioCVaR object (Using PortfolioCVaR Objects) implements what is known as conditional value-at-risk portfolio optimization (see Rockafellar and Uryasev [48], [49] at "Portfolio Optimization" on page A-10), which is generally referred to as CVaR portfolio optimization. CVaR portfolio optimization works with the same return proxies and portfolio sets as mean-variance portfolio optimization but uses conditional value-at-risk of portfolio returns as the risk proxy.
- The PortfolioMAD object (Using PortfolioMAD Objects) implements what is known as mean-absolute deviation portfolio optimization (see Konno and Yamazaki [50] at "Portfolio Optimization" on page A-10), which is generally referred to as MAD portfolio optimization. MAD portfolio optimization works with the same return proxies and portfolio sets as mean-variance portfolio optimization but uses meanabsolute deviation portfolio returns as the risk proxy.

## Return Proxy

The proxy for portfolio return is a function $\mu: X \rightarrow R$ on a portfolio set $X \subset R^{n}$ that characterizes the rewards associated with portfolio choices. In most cases, the proxy for portfolio return has two general forms, gross and net portfolio returns. Both portfolio return forms separate the risk-free rate $r_{0}$ so that the portfolio $x \in X$ contains only risky assets.

Regardless of the underlying distribution of asset returns, a collection of $S$ asset returns $y_{1}, \ldots, y_{S}$ has a mean of asset returns

$$
m=\frac{1}{S} \sum_{s=1}^{S} y_{s}
$$

and (sample) covariance of asset returns

$$
C=\frac{1}{S-1} \sum_{s=1}^{S}\left(y_{s}-m\right)\left(y_{s}-m\right)^{T}
$$

These moments (or alternative estimators that characterize these moments) are used directly in mean-variance portfolio optimization to form proxies for portfolio risk and return.

## Gross Porifolio Returns

The gross portfolio return for a portfolio $x \in X$ is

$$
\mu(x)=r_{0}+\left(m-r_{0} 1\right)^{T} x,
$$

where:
$r_{0}$ is the risk-free rate (scalar).
$m$ is the mean of asset returns ( $n$ vector).
If the portfolio weights sum to 1 , the risk-free rate is irrelevant. The properties in the Portfolio object to specify gross portfolio returns are:

- RiskFreeRate for $r_{0}$
- AssetMean for $m$

## Net Portfolio Returns

The net portfolio return for a portfolio $x \in X$ is

$$
\mu(x)=r_{0}+\left(m-r_{0} 1\right)^{T} x-b^{T} \max \left\{0, x-x_{0}\right\}-s^{T} \max \left\{0, x_{0}-x\right\},
$$

where:
$r_{0}$ is the risk-free rate (scalar).
$m$ is the mean of asset returns ( $n$ vector).
$b$ is the proportional cost to purchase assets ( $n$ vector).
$s$ is the proportional cost to sell assets ( $n$ vector).
You can incorporate fixed transaction costs in this model also. Though in this case, it is necessary to incorporate prices into such costs. The properties in the Portfolio object to specify net portfolio returns are:

- RiskFreeRate for $r_{0}$
- AssetMean for $m$
- InitPort for $x_{0}$
- BuyCost for $b$
- SellCost for $s$

## Risk Proxy

The proxy for portfolio risk is a function $\Sigma: X \rightarrow R$ on a portfolio set $X \subset R^{n}$ that characterizes the risks associated with portfolio choices.

## Variance

The variance of portfolio returns for a portfolio $x \in X$ is

$$
\Sigma(x)=x^{T} C x
$$

where $C$ is the covariance of asset returns (n-by-n positive-semidefinite matrix).
The property in the Portfolio object to specify the variance of portfolio returns is AssetCovar for $C$.

Although the risk proxy in mean-variance portfolio optimization is the variance of portfolio returns, the square root, which is the standard deviation of portfolio returns, is often reported and displayed. Moreover, this quantity is often called the "risk" of the portfolio. For details, see Markowitz ("Portfolio Optimization" on page A-10).

## Conditional Value-at-Risk

The conditional value-at-risk for a portfolio $x \in X$, which is also known as expected shortfall, is defined as

$$
C V a R_{\alpha}(x)=\frac{1}{1-\alpha} \int_{f(x, y) \geq \operatorname{VaR}_{\alpha}(x)} f(x, y) p(y) d y,
$$

where:
$\alpha$ is the probability level such that $0<\alpha<1$.
$f(x, y)$ is the loss function for a portfolio $x$ and asset return $y$.
$p(y)$ is the probability density function for asset return $y$.
$V a R_{a}$ is the value-at-risk of portfolio $x$ at probability level $a$.
The value-at-risk is defined as

$$
\operatorname{Va}_{\alpha}(x)=\min \{\gamma: \operatorname{Pr}[f(x, Y) \leq \gamma] \geq \alpha\} .
$$

An alternative formulation for CVaR has the form:

$$
C V a R_{\alpha}(x)=V a R_{\alpha}(x)+\frac{1}{1-\alpha} \int_{R^{n}} \max \left\{0,\left(f(x, y)-V a R_{\alpha}(x)\right)\right\} p(y) d y
$$

The choice for the probability level $a$ is typically 0.9 or 0.95 . Choosing $a$ implies that the value-at-risk $\operatorname{VaR}_{a}(x)$ for portfolio $x$ is the portfolio return such that the probability of portfolio returns falling below this level is $(1-\alpha)$. Given $V a R_{a}(x)$ for a portfolio $x$, the conditional value-at-risk of the portfolio is the expected loss of portfolio returns above the value-at-risk return.

Note: Value-at-risk is a positive value for losses so that the probability level $\alpha$ indicates the probability that portfolio returns are below the negative of the value-at-risk.

The risk proxy for CVaR portfolio optimization is $C \operatorname{Va} R_{a}(x)$ for a given portfolio $x \in X$ and $\alpha \in(0,1)$. The value-at-risk, or VaR, for a given probability level is estimated whenever CVaR is estimated.

In addition, keep in mind that VaR and CVaR are sample estimators for VaR and CVaR based on the given scenarios. Better scenario samples yield more reliable estimates of VaR and CVaR.

For more information, see Rockafellar and Uryasev [48], [49] at "Portfolio Optimization" on page A-10.

## Mean Absolute-Deviation

The mean-absolute-deviation (MAD) for a portfolio $x \in X$ is defined as

$$
\sum(x)=\frac{1}{S} \sum_{s=1}^{S}\left|\left(y_{s}-m\right)^{T} x\right|
$$

where:
$y_{s}$ are asset returns with scenarios $s=1, \ldots S$ ( $S$ collection of $n$ vectors).
$f(x, y)$ is the loss function for a portfolio $x$ and asset return $y$.
$m$ is the mean of asset returns ( $n$ vector).
such that

$$
m=\frac{1}{S} \sum_{s=1}^{S} y_{s}
$$

For more information, see Konno and Yamazaki [50] at "Portfolio Optimization" on page A-10.

## Porffolio Set for Optimization Using Porffolio Object

The final element for a complete specification of a portfolio optimization problem is the set of feasible portfolios, which is called a portfolio set. A portfolio set $X \subset R^{n}$ is specified by construction as the intersection of sets formed by a collection of constraints on portfolio weights. A portfolio set necessarily and sufficiently must be a nonempty, closed, and bounded set.

When setting up your portfolio set, ensure that the portfolio set satisfies these conditions. The most basic or "default" portfolio set requires portfolio weights to be nonnegative (using the lower-bound constraint) and to sum to 1 (using the budget constraint). The most general portfolio set handled by the portfolio optimization tools can have any of these constraints:

- Linear inequality constraints
- Linear equality constraints
- Bound constraints
- Budget constraints
- Group constraints
- Group ratio constraints
- Average turnover constraints
- One-way turnover constraints
- Tracking error constraints

## Linear Inequality Constraints

Linear inequality constraints are general linear constraints that model relationships among portfolio weights that satisfy a system of inequalities. Linear inequality constraints take the form

$$
A_{I} x \leq b_{I}
$$

where:
$x$ is the portfolio ( $n$ vector).
$A_{I}$ is the linear inequality constraint matrix ( $n_{I}$-by- $n$ matrix).
$b_{I}$ is the linear inequality constraint vector ( $n_{I}$ vector).
$n$ is the number of assets in the universe and $n_{I}$ is the number of constraints.
Portfolio object properties to specify linear inequality constraints are:

- AInequality for $A_{I}$
- bInequality for $b_{I}$
- NumAssets for $n$

The default is to ignore these constraints.

## Linear Equality Constraints

Linear equality constraints are general linear constraints that model relationships among portfolio weights that satisfy a system of equalities. Linear equality constraints take the form

$$
A_{E} x=b_{E}
$$

where:
$x$ is the portfolio ( $n$ vector).
$A_{E}$ is the linear equality constraint matrix ( $n_{E}$-by- $n$ matrix).
$b_{E}$ is the linear equality constraint vector ( $n_{E}$ vector).
$n$ is the number of assets in the universe and $n_{E}$ is the number of constraints.
Portfolio object properties to specify linear equality constraints are:

- AEquality for $A_{E}$
- bEquality for $b_{E}$
- NumAssets for $n$

The default is to ignore these constraints.

## Bound Constraints

Bound constraints are specialized linear constraints that confine portfolio weights to fall either above or below specific bounds. Since every portfolio set must be bounded, it is often a good practice, albeit not necessary, to set explicit bounds for the portfolio problem. To obtain explicit bounds for a given portfolio set, use the estimateBounds function. Bound constraints take the form

$$
l_{B} \leq x \leq u_{B}
$$

where:
$x$ is the portfolio ( $n$ vector).
$l_{B}$ is the lower-bound constraint ( $n$ vector).
$u_{B}$ is the upper-bound constraint ( $n$ vector).
$n$ is the number of assets in the universe.
Portfolio object properties to specify bound constraints are:

- LowerBound for $l_{B}$
- UpperBound for $u_{B}$
- NumAssets for $n$

The default is to ignore these constraints.
The default portfolio optimization problem (see "Default Portfolio Problem" on page $4-15$ ) has $l_{B}=0$ with $u_{B}$ set implicitly through a budget constraint.

## Budget Constraints

Budget constraints are specialized linear constraints that confine the sum of portfolio weights to fall either above or below specific bounds. The constraints take the form

$$
l_{S} \leq 1^{T} x \leq u_{S}
$$

where:
$x$ is the portfolio ( $n$ vector).
1 is the vector of ones ( $n$ vector).
$l_{S}$ is the lower-bound budget constraint (scalar).
$u_{S}$ is the upper-bound budget constraint (scalar).
$n$ is the number of assets in the universe.
Portfolio object properties to specify budget constraints are:

- LowerBudget for $l_{S}$
- UpperBudget for $u_{S}$
- NumAssets for $n$

The default is to ignore this constraint.
The default portfolio optimization problem (see "Default Portfolio Problem" on page $4-15$ ) has $l_{S}=u_{S}=1$, which means that the portfolio weights sum to 1 . If the portfolio optimization problem includes possible movements in and out of cash, the budget constraint specifies how far portfolios can go into cash. For example, if $l_{S}=0$ and $u_{S}=1$, then the portfolio can have $0-100 \%$ invested in cash. If cash is to be a portfolio choice, set RiskFreeRate ( $r_{0}$ ) to a suitable value (see "Return Proxy" on page 4-3 and "Working with a Riskless Asset" on page 4-51).

## Group Constraints

Group constraints are specialized linear constraints that enforce "membership" among groups of assets. The constraints take the form

$$
l_{G} \leq G x \leq u_{G}
$$

where:
$x$ is the portfolio ( $n$ vector).
$l_{G}$ is the lower-bound group constraint ( $n_{G}$ vector).
$u_{G}$ is the upper-bound group constraint ( $n_{G}$ vector).
$G$ is the matrix of group membership indexes ( $n_{G}$-by- $n$ matrix).
Each row of $G$ identifies which assets belong to a group associated with that row. Each row contains either 0 s or 1 s with 1 indicating that an asset is part of the group or 0 indicating that the asset is not part of the group.

Portfolio object properties to specify group constraints are:

- GroupMatrix for $G$
- LowerGroup for $l_{G}$
- UpperGroup for $u_{G}$
- NumAssets for $n$

The default is to ignore these constraints.

## Group Ratio Constraints

Group ratio constraints are specialized linear constraints that enforce relationships among groups of assets. The constraints take the form

$$
l_{R i}\left(G_{B} x\right)_{i} \leq\left(G_{A} x\right)_{i} \leq u_{R i}\left(G_{B} x\right)_{i}
$$

for $i=1, \ldots, n_{R}$ where:
$x$ is the portfolio ( $n$ vector).
$l_{R}$ is the vector of lower-bound group ratio constraints ( $n_{R}$ vector).
$u_{R}$ is the vector matrix of upper-bound group ratio constraints ( $n_{R}$ vector).
$G_{A}$ is the matrix of base group membership indexes ( $n_{R}$-by- $n$ matrix).
$G_{B}$ is the matrix of comparison group membership indexes ( $n_{R}$-by- $n$ matrix).
$n$ is the number of assets in the universe and $n_{R}$ is the number of constraints.
Each row of $G_{A}$ and $G_{B}$ identifies which assets belong to a base and comparison group associated with that row.

Each row contains either 0s or 1 s with 1 indicating that an asset is part of the group or 0 indicating that the asset is not part of the group.

Portfolio object properties to specify group ratio constraints are:

- GroupA for $G_{A}$
- GroupB for $G_{B}$
- LowerRatio for $l_{R}$
- UpperRatio for $u_{R}$
- NumAssets for $n$

The default is to ignore these constraints.

## Average Turnover Constraints

Turnover constraint is a linear absolute value constraint that ensures estimated optimal portfolios differ from an initial portfolio by no more than a specified amount. Although
portfolio turnover is defined in many ways, the turnover constraints implemented in Financial Toolbox computes portfolio turnover as the average of purchases and sales. Average turnover constraints take the form

$$
\frac{1}{2} 1^{T}\left|x-x_{0}\right| \leq \tau
$$

where:
$x$ is the portfolio ( $n$ vector).
1 is the vector of ones ( $n$ vector).
$x_{0}$ is the initial portfolio ( $n$ vector).
$\tau$ is the upper bound for turnover (scalar).
$n$ is the number of assets in the universe.
Portfolio object properties to specify the average turnover constraint are:

- Turnover for $\tau$
- InitPort for $x_{0}$
- NumAssets for $n$

The default is to ignore this constraint.

## One-way Turnover Constraints

One-way turnover constraints ensure that estimated optimal portfolios differ from an initial portfolio by no more than specified amounts according to whether the differences are purchases or sales. The constraints take the forms

$$
\begin{aligned}
& 1^{T} \max \left\{0, x-x_{0}\right\} \leq \tau_{B} \\
& 1^{T} \max \left\{0, x_{0}-x\right\} \leq \tau_{S}
\end{aligned}
$$

where:
$x$ is the portfolio ( $n$ vector)
1 is the vector of ones ( $n$ vector).
$x_{0}$ is the Initial portfolio ( $n$ vector).
$\tau_{B}$ is the upper bound for turnover constraint on purchases (scalar).
$\tau_{S}$ is the upper bound for turnover constraint on sales (scalar).

To specify one-way turnover constraints, use the following properties in the Portfolio or PortfolioCVaR object:

- BuyTurnover for $\tau_{B}$
- SellTurnover for $\tau_{S}$
- InitPort for $x_{0}$

The default is to ignore this constraint.

Note: The average turnover constraint (see "Working with Average Turnover Constraints Using Portfolio Object" on page 4-73) with $\tau$ is not a combination of the one-way turnover constraints with $\tau=\tau_{B}=\tau_{S}$.

## Tracking Error Constraints

Tracking error constraint, within a portfolio optimization framework, is an additional constraint to specify the set of feasible portfolios known as a portfolio set. The trackingerror constraint has the form

$$
\left(x-x_{T}\right)^{T} C\left(x-x_{T}\right) \leq \tau_{T}{ }^{2}
$$

where:
$x$ is the portfolio ( $n$ vector).
$x_{T}$ is the tracking portfolio against which risk is to be measured ( $n$ vector).
$\tau_{T}$ is the upper bound for tracking error (scalar).
$n$ is the number of assets in the universe.
Portfolio object properties to specify the average turnover constraint are:

- TrackingPort for $x_{T}$
- TrackingError for $\tau_{T}$

The default is to ignore this constraint.

Note: The tracking error constraints can be used with any of the other supported constraints in the Portfolio object without restrictions. However, since the portfolio set necessarily and sufficiently must be a non-empty compact set, the application of a tracking error constraint may result in an empty portfolio set. Use estimateBounds to confirm that the portfolio set is non-empty and compact.

## Default Portfolio Problem

The default portfolio optimization problem has a risk and return proxy associated with a given problem, and a portfolio set that specifies portfolio weights to be nonnegative and to sum to 1 . The lower bound combined with the budget constraint is sufficient to ensure that the portfolio set is nonempty, closed, and bounded. The default portfolio optimization problem characterizes a long-only investor who is fully invested in a collection of assets.

- For mean-variance portfolio optimization, it is sufficient to set up the default problem. After setting up the problem, data in the form of a mean and covariance of asset returns are then used to solve portfolio optimization problems.
- For conditional value-at-risk portfolio optimization, the default problem requires the additional specification of a probability level that must be set explicitly. Generally, "typical" values for this level are 0.90 or 0.95 . After setting up the problem, data in the form of scenarios of asset returns are then used to solve portfolio optimization problems.
- For MAD portfolio optimization, it is sufficient to set up the default problem. After setting up the problem, data in the form of scenarios of asset returns are then used to solve portfolio optimization problems.

## Porifolio Object Workflow

The Portfolio object workflow for creating and modeling a mean-variance portfolio is:
1 Create a Portfolio.
Create a Portfolio object for mean-variance portfolio optimization. For more information, see "Creating the Portfolio Object" on page 4-24.
2 Estimate the mean and covariance for returns.
Evaluate the mean and covariance for portfolio asset returns, including assets with missing data and financial time series data. For more information, see "Asset Returns and Moments of Asset Returns Using Portfolio Object" on page 4-41.
3 Specify the Portfolio Constraints.
Define the constraints for portfolio assets such as linear equality and inequality, bound, budget, group, group ratio, turnover, and tracking error constraints. For more information, see "Working with Portfolio Constraints" on page 4-57.
4 Validate the Portfolio.
Identify errors for the portfolio specification. For more information, see "Validate the Portfolio Problem for Portfolio Object" on page 4-82.
5 Estimate the efficient portfolios and frontiers.
Analyze the efficient portfolios and efficient frontiers for a portfolio. For more information, see "Estimate Efficient Portfolios for Portfolio Object" on page 4-87 and "Estimate Efficient Frontiers for Portfolio Object" on page 4-99.
6 Postprocess the results.
Use the efficient portfolios and efficient frontiers results to set up trades. For more information, see "Postprocessing Results" on page 4-107.

For an example of this workflow, see "Asset Allocation Case Study" on page 4-142 and "Portfolio Optimization Examples" on page 4-114.

## Porffolio Object Properties and Functions

The Portfolio object implements mean-variance portfolio optimization. Every property and function of the Portfolio object is public, although some properties and functions are hidden. See Using Portfolio Objects for the properties and functions of the Portfolio object. The Portfolio object is a value object where every instance of the object is a distinct version of the object. Since the Portfolio object is also a MATLAB object, it inherits the default functions associated with MATLAB objects.

## Working with Porffolio Objects

The Portfolio object and its functions are an interface for mean-variance portfolio optimization. So, almost everything you do with the Portfolio object can be done using the associated functions. The basic workflow is:

1 Design your portfolio problem.
2 Use the Portfolio function to create the Portfolio object or use the various set functions to set up your portfolio problem.
3 Use estimate functions to solve your portfolio problem.
In addition, functions are available to help you view intermediate results and to diagnose your computations. Since MATLAB features are part of a Portfolio object, you can save and load objects from your workspace and create and manipulate arrays of objects. After
settling on a problem, which, in the case of mean-variance portfolio optimization, means that you have either data or moments for asset returns and a collection of constraints on your portfolios, use the Portfolio function to set the properties for the Portfolio object. The Portfolio function lets you create an object from scratch or update an existing object. Since the Portfolio object is a value object, it is easy to create a basic object, then use functions to build upon the basic object to create new versions of the basic object. This is useful to compare a basic problem with alternatives derived from the basic problem. For details, see "Creating the Portfolio Object" on page 4-24.

## Setting and Getting Properties

You can set properties of a Portfolio object using either the Portfolio function or various set functions.

Note: Although you can also set properties directly, it is not recommended since errorchecking is not performed when you set a property directly.

The Portfolio function supports setting properties with name-value pair arguments such that each argument name is a property and each value is the value to assign to that property. For example, to set the AssetMean and AssetCovar properties in an existing Portfolio object $p$ with the values $m$ and $C$, use the syntax:

```
p = Portfolio(p, 'AssetMean', m, 'AssetCovar', C);
```

In addition to the Portfolio function, which lets you set individual properties one at a time, groups of properties are set in a Portfolio object with various "set" and "add" functions. For example, to set up an average turnover constraint, use the setTurnover function to specify the bound on portfolio average turnover and the initial portfolio. To get individual properties from a Portfolio object, obtain properties directly or use an assortment of "get" functions that obtain groups of properties from a Portfolio object. The Portfolio function and set functions have several useful features:

- The Portfolio function and set functions try to determine the dimensions of your problem with either explicit or implicit inputs.
- The Portfolio function and set functions try to resolve ambiguities with default choices.
- The Portfolio function and set functions perform scalar expansion on arrays when possible.
- The associated Portfolio object functions try to diagnose and warn about problems.

## Displaying Portfolio Objects

The Portfolio object uses the default display functions provided by MATLAB, where display and disp display a Portfolio object and its properties with or without the object variable name.

## Saving and Loading Porffolio Objects

Save and load Portfolio objects using the MATLAB save and load commands.

## Estimating Efficient Portfolios and Frontiers

Estimating efficient portfolios and efficient frontiers is the primary purpose of the portfolio optimization tools. A collection of "estimate" and "plot" functions provide ways to explore the efficient frontier. The "estimate" functions obtain either efficient portfolios or risk and return proxies to form efficient frontiers. At the portfolio level, a collection of functions estimates efficient portfolios on the efficient frontier with functions to obtain efficient portfolios:

- At the endpoints of the efficient frontier
- That attain targeted values for return proxies
- That attain targeted values for risk proxies
- Along the entire efficient frontier

These functions also provide purchases and sales needed to shift from an initial or current portfolio to each efficient portfolio. At the efficient frontier level, a collection of functions plot the efficient frontier and estimate either risk or return proxies for efficient portfolios on the efficient frontier. You can use the resultant efficient portfolios or risk and return proxies in subsequent analyses.

## Arrays of Portfolio Objects

Although all functions associated with a Portfolio object are designed to work on a scalar Portfolio object, the array capabilities of MATLAB enables you to set up and work with arrays of Portfolio objects. The easiest way to do this is with the repmat function. For example, to create a 3-by-2 array of Portfolio objects:

```
p = repmat(Portfolio, 3, 2);
disp(p)
```

After setting up an array of Portfolio objects, you can work on individual Portfolio objects in the array by indexing. For example:
p(i,j) = Portfolio(p(i,j), ... );
This example calls the Portfolio function for the $(i, j)$ element of a matrix of Portfolio objects in the variable $p$.

If you set up an array of Portfolio objects, you can access properties of a particular Portfolio object in the array by indexing so that you can set the lower and upper bounds lb and ub for the (i,j,k) element of a 3-D array of Portfolio objects with
$p(i, j, k)=$ setBounds (p(i,j,k),lb, ub);
and, once set, you can access these bounds with
[lb, ub] = getBounds(p(i,j,k));
Portfolio object functions work on only one Portfolio object at a time.

## Subclassing Porffolio Objects

You can subclass the Portfolio object to override existing functions or to add new properties or functions. To do so, create a derived class from the Portfolio class. This gives you all the properties and functions of the Portfolio class along with any new features that you choose to add to your subclassed object. The Portfolio class is derived from an abstract class called AbstractPortfolio. Because of this, you can also create a derived class from AbstractPortfolio that implements an entirely different form of portfolio optimization using properties and functions of the AbstractPortfolio class.

## Conventions for Representation of Data

The portfolio optimization tools follow these conventions regarding the representation of different quantities associated with portfolio optimization:

- Asset returns or prices are in matrix form with samples for a given asset going down the rows and assets going across the columns. In the case of prices, the earliest dates must be at the top of the matrix, with increasing dates going down.
- The mean and covariance of asset returns are stored in a vector and a matrix and the tools have no requirement that the mean must be either a column or row vector.
- Portfolios are in vector or matrix form with weights for a given portfolio going down the rows and distinct portfolios going across the columns.
- Constraints on portfolios are formed in such a way that a portfolio is a column vector.
- Portfolio risks and returns are either scalars or column vectors (for multiple portfolio risks and returns).

| "Portfolio Function Examples" on page 4-25 |

To create a fully specified mean-variance portfolio optimization problem, instantiate the Portfolio object using the Portfolio function. For information on the workflow when using Portfolio objects, see "Portfolio Object Workflow" on page 4-17.

## Syntax

Use the Portfolio function to create an instance of an object of the Portfolio class. You can use the Portfolio function in several ways. To set up a portfolio optimization problem in a Portfolio object, the simplest syntax is:

```
p = Portfolio;
```

This syntax creates a Portfolio object, p, such that all object properties are empty.
The Portfolio function also accepts collections of argument name-value pair arguments for properties and their values. The Portfolio function accepts inputs for public properties with the general syntax:

```
p = Portfolio('property1', value1, 'property2', value2, ... );
```

If a Portfolio object already exists, the syntax permits the first (and only the first argument) of the Portfolio function to be an existing object with subsequent argument name-value pair arguments for properties to be added or modified. For example, given an existing Portfolio object in $\mathbf{p}$, the general syntax is:

```
p = Portfolio(p, 'property1', value1, 'property2', value2, ... );
```

Input argument names are not case-sensitive, but must be completely specified. In addition, several properties can be specified with alternative argument names (see "Shortcuts for Property Names" on page 4-29). The Portfolio function tries to detect problem dimensions from the inputs and, once set, subsequent inputs can undergo various scalar or matrix expansion operations that simplify the overall process to formulate a problem. In addition, a Portfolio object is a value object so that, given portfolio p , the following code creates two objects, p and q , that are distinct:

```
q = Portfolio(p, ...)
```

## Portfolio Problem Sufficiency

A mean-variance portfolio optimization is completely specified with the Portfolio object if these two conditions are met:

- The moments of asset returns must be specified such that the property AssetMean contains a valid finite mean vector of asset returns and the property AssetCovar contains a valid symmetric positive-semidefinite matrix for the covariance of asset returns.

The first condition is satisfied by setting the properties associated with the moments of asset returns.

- The set of feasible portfolios must be a nonempty compact set, where a compact set is closed and bounded.

The second condition is satisfied by an extensive collection of properties that define different types of constraints to form a set of feasible portfolios. Since such sets must be bounded, either explicit or implicit constraints can be imposed, and several functions, such as estimateBounds, provide ways to ensure that your problem is properly formulated.

Although the general sufficiency conditions for mean-variance portfolio optimization go beyond these two conditions, the Portfolio object implemented in Financial Toolbox implicitly handles all these additional conditions. For more information on the Markowitz model for mean-variance portfolio optimization, see "Portfolio Optimization" on page A-10.

## Porffolio Function Examples

If you create a Portfolio object, p, with no input arguments, you can display it using disp:
p = Portfolio;
disp(p) ; Portfolio
Portfolio with properties:
BuyCost: []
SellCost: []

```
    RiskFreeRate: []
        AssetMean: []
        AssetCovar: []
TrackingError: []
    TrackingPort: []
            Turnover: []
        BuyTurnover: []
    SellTurnover: []
            Name: []
        NumAssets: []
        AssetList: []
            InitPort: []
        AInequality: []
        bInequality: []
        AEquality: []
        bEquality: []
        LowerBound: []
        UpperBound: []
        LowerBudget: []
        UpperBudget: []
        GroupMatrix: []
            LowerGroup: []
            UpperGroup: []
            GroupA: []
            GroupB: []
    LowerRatio: []
    UpperRatio: []
```

The approaches listed provide a way to set up a portfolio optimization problem with the Portfolio function. The set functions offer additional ways to set and modify collections of properties in the Portfolio object.

## Using the Portfolio Function for a Single-Step Setup

You can use the Portfolio function to directly set up a "standard" portfolio optimization problem, given a mean and covariance of asset returns in the variables $m$ and C :

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
    0.00408 0.0289 0.0204 0.0119;
    0.00192 0.0204 0.0576 0.0336;
    0 0.0119 0.0336 0.1225 ];
```

p = Portfolio('assetmean', m, 'assetcovar', C, ...
'lowerbudget', 1, 'upperbudget', 1, 'lowerbound', 0);
The LowerBound property value undergoes scalar expansion since AssetMean and AssetCovar provide the dimensions of the problem.

You can use dot notation with the function plotFrontier.
p.plotFrontier;

## Using the Porifolio Function with a Sequence of Steps

An alternative way to accomplish the same task of setting up a "standard" portfolio optimization problem, given a mean and covariance of asset returns in the variables $m$ and C (which also illustrates that argument names are not case-sensitive):

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
    0.00408 0.0289 0.0204 0.0119;
    0.00192 0.0204 0.0576 0.0336;
    0 0.0119 0.0336 0.1225 ];
```

```
p = Portfolio;
p = Portfolio(p, 'assetmean', m, 'assetcovar', C);
p = Portfolio(p, 'lowerbudget', 1, 'upperbudget', 1);
p = Portfolio(p, 'lowerbound', 0);
plotFrontier(p);
```

This way works because the calls to the Portfolio function are in this particular order. In this case, the call to initialize AssetMean and AssetCovar provides the dimensions for the problem. If you were to do this step last, you would have to explicitly dimension the LowerBound property as follows:

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
    0.00408 0.0289 0.0204 0.0119;
    0.00192 0.0204 0.0576 0.0336;
    0 0.0119 0.0336 0.1225 ];
p = Portfolio;
```

```
p = Portfolio(p, 'LowerBound', zeros(size(m)));
p = Portfolio(p, 'LowerBudget', 1, 'UpperBudget', 1);
p = Portfolio(p, 'AssetMean', m, 'AssetCovar', C);
plotFrontier(p);
```

If you did not specify the size of LowerBound but, instead, input a scalar argument, the Portfolio function assumes that you are defining a single-asset problem and produces an error at the call to set asset moments with four assets.

## Shortcuts for Property Names

The Portfolio function has shorter argument names that replace longer argument names associated with specific properties of the Portfolio object. For example, rather than enter 'assetcovar', the Portfolio function accepts the case-insensitive name 'covar' to set the AssetCovar property in a Portfolio object. Every shorter argument name corresponds with a single property in the Portfolio function. The one exception is the alternative argument name 'budget ', which signifies both the LowerBudget and UpperBudget properties. When 'budget' is used, then the LowerBudget and UpperBudget properties are set to the same value to form an equality budget constraint.

## Shortcuts for Property Names

| Shortcut Argument Name | Equivalent Argument / Property Name |
| :--- | :--- |
| ae | AEquality |
| ai | AInequality |
| covar | AssetCovar |
| assetnames or assets | AssetList |
| mean | AssetMean |
| be | bEquality |
| bi | bInequality |
| group | GroupMatrix |
| lb | LowerBound |
| n or num | NumAssets |
| rfr | RiskFreeRate |
| ub | UpperBound |
| budget | UpperBudget and LowerBudget |

For example, this call to the Portfolio function uses these shortcuts for properties and is equivalent to the previous examples:

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
    0.00408 0.0289 0.0204 0.0119;
    0.00192 0.0204 0.0576 0.0336;
    0 0.0119 0.0336 0.1225 ];
p = Portfolio('mean', m, 'covar', C, 'budget', 1, 'lb', 0);
plotFrontier(p);
```

## Direct Setting of Portfolio Object Properties

Although not recommended, you can set properties directly, however no error-checking is done on your inputs:

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
    0.00408 0.0289 0.0204 0.0119;
```

```
    0.00192 0.0204 0.0576 0.0336;
    0 0.0119 0.0336 0.1225 ];
p = Portfolio;
p.NumAssets = numel(m);
p.AssetMean = m;
p.AssetCovar = C;
p.LowerBudget = 1;
p.UpperBudget = 1;
p.LowerBound = zeros(size(m));
plotFrontier(p);
```

## Common Operations on the Porffolio Object

```
In this section...
"Naming a Portfolio Object" on page 4-32
"Configuring the Assets in the Asset Universe" on page 4-32
"Setting Up a List of Asset Identifiers" on page 4-33
"Truncating and Padding Asset Lists" on page 4-34
"Setting Up an Initial or Current Portfolio" on page 4-35
"Setting Up a Tracking Portfolio" on page 4-37
```

## Naming a Porffolio Object

To name a Portfolio object, use the Name property. Name is informational and has no effect on any portfolio calculations. If the Name property is nonempty, Name is the title for the efficient frontier plot generated by plotFrontier. For example, if you set up an asset allocation fund, you could name the Portfolio object Asset Allocation Fund:

```
p = Portfolio('Name','Asset Allocation Fund');
disp(p.Name);
Asset Allocation Fund
```

## Configuring the Assets in the Asset Universe

The fundamental quantity in the Portfolio object is the number of assets in the asset universe. This quantity is maintained in the NumAssets property. Although you can set this property directly, it is usually derived from other properties such as the mean of asset returns and the initial portfolio. In some instances, the number of assets may need to be set directly. This example shows how to set up a Portfolio object that has four assets:

```
p = Portfolio('NumAssets', 4);
disp(p.NumAssets);
```

4

After setting the NumAssets property, you cannot modify it (unless no other properties are set that depend on NumAssets). The only way to change the number of assets in an existing Portfolio object with a known number of assets is to create a new Portfolio object.

## Setting Up a List of Asset Identifiers

When working with portfolios, you must specify a universe of assets. Although you can perform a complete analysis without naming the assets in your universe, it is helpful to have an identifier associated with each asset as you create and work with portfolios. You can create a list of asset identifiers as a cell vector of strings in the property AssetList. You can set up the list using the next two functions.

## Setting Up Asset Lists Using the Porffolio Function

Suppose that you have a Portfolio object, p, with assets with symbols 'AA '', 'BA', 'CAT', 'DD', and 'ETR'. You can create a list of these asset symbols in the object using the Portfolio function:

```
p = Portfolio('assetlist', { 'AA', 'BA', 'CAT', 'DD', 'ETR' });
disp(p.AssetList);
'AA' 'BA' 'CAT' 'DD' 'ETR'
```

Notice that the property AssetList is maintained as a cell array that contains strings, and that it is necessary to pass a cell array into the Portfolio function to set AssetList. In addition, notice that the property NumAssets is set to 5 based on the number of symbols used to create the asset list:

```
disp(p.NumAssets);
```

5

## Setting Up Asset Lists Using the setAssetList Function

You can also specify a list of assets using the setAssetList function. Given the list of asset symbols 'AA', 'BA', 'CAT', 'DD', and 'ETR', you can use setAssetList with:

```
p = Portfolio;
p = setAssetList(p, { 'AA', 'BA', 'CAT', 'DD', 'ETR' });
disp(p.AssetList);
    'AA' 'BA' 'CAT' 'DD' 'ETR'
```

setAssetList also enables you to enter symbols directly as a comma-separated list without creating a cell array of strings. For example, given the list of assets symbols 'AA', 'BA', 'CAT', 'DD', and 'ETR', use setAssetList:
p = Portfolio;
p = setAssetList(p,'AA', 'BA', 'CAT', 'DD', 'ETR');

```
disp(p.AssetList);
'AA' 'BA' 'CAT' 'DD' 'ETR'
```

setAssetList has many additional features to create lists of asset identifiers. If you use setAssetList with just a Portfolio object, it creates a default asset list according to the name specified in the hidden public property defaultforAssetList (which is 'Asset' by default). The number of asset names created depends on the number of assets in the property NumAssets. If NumAssets is not set, then NumAssets is assumed to be 1 .

For example, if a Portfolio object $p$ is created with NumAssets $=5$, then this code fragment shows the default naming behavior:

```
p = Portfolio('numassets',5);
p = setAssetList(p);
disp(p.AssetList);
'Asset1' 'Asset2' 'Asset3' 'Asset4' 'Asset5'
```

Suppose that your assets are, for example, ETFs and you change the hidden property defaultforAssetList to 'ETF', you can then create a default list for ETFs:

```
p = Portfolio('numassets',5);
p.defaultforAssetList = 'ETF';
p = setAssetList(p);
disp(p.AssetList);
```

'ETF1' 'ETF2' 'ETF3' 'ETF4' 'ETF5'

## Truncating and Padding Asset Lists

If the NumAssets property is already set and you pass in too many or too few identifiers, the Portfolio function, and the setAssetList function truncate or pad the list with numbered default asset names that use the name specified in the hidden public property defaultforAssetList. If the list is truncated or padded, a warning message indicates the discrepancy. For example, assume that you have a Portfolio object with five ETFs and you only know the first three CUSIPs '921937835', '922908769', and '922042775'. Use this syntax to create an asset list that pads the remaining asset identifiers with numbered 'UnknownCUSIP' placeholders:

```
p = Portfolio('numassets',5);
p.defaultforAssetList = 'UnknownCUSIP';
p = setAssetList(p,'921937835', '922908769', '922042775');
disp(p.AssetList);
Warning: Input list of assets has 2 too few identifiers. Padding with numbered assets.
```

'921937835' '922908769' '922042775' 'UnknownCUSIP4' 'UnknownCUSIP5'
Alternatively, suppose that you have too many identifiers and need only the first four assets. This example illustrates truncation of the asset list using the Portfolio function:

```
p = Portfolio('numassets',4);
p = Portfolio(p, 'assetlist', { 'AGG', 'EEM', 'MDY', 'SPY', 'VEU' });
disp(p.AssetList);
Warning: AssetList has 1 too many identifiers. Using first 4 assets.
> In Portfolio.checkarguments at 434
    In Portfolio.Portfolio>Portfolio.Portfolio at 171
        'AGG' 'EEM' 'MDY' 'SPY'
```

The hidden public property uppercaseAssetList is a Boolean flag to specify whether to convert asset names to uppercase letters. The default value for uppercaseAssetList is false. This example shows how to use the uppercaseAssetList flag to force identifiers to be uppercase letters:

```
p = Portfolio;
p.uppercaseAssetList = true;
p = setAssetList(p,{ 'aa', 'ba', 'cat', 'dd', 'etr' });
disp(p.AssetList);
'AA' 'BA' 'CAT' 'DD' 'ETR'
```

## Setting Up an Initial or Current Portfolio

In many applications, creating a new optimal portfolio requires comparing the new portfolio with an initial or current portfolio to form lists of purchases and sales. The Portfolio object property InitPort lets you identify an initial or current portfolio. The initial portfolio also plays an essential role if you have either transaction costs or turnover constraints. The initial portfolio need not be feasible within the constraints of the problem. This can happen if the weights in a portfolio have shifted such that some constraints become violated. To check if your initial portfolio is feasible, use the checkFeasibility function described in "Validating Portfolios" on page 4-84. Suppose that you have an initial portfolio in xO , then use the Portfolio function to set up an initial portfolio:

```
x0 = [ 0.3; 0.2; 0.2; 0.0 ];
p = Portfolio('InitPort', x0);
disp(p.InitPort);
```

0.3000
0.2000
0.2000

0
As with all array properties, you can set InitPort with scalar expansion. This is helpful to set up an equally weighted initial portfolio of, for example, 10 assets:

```
p = Portfolio('NumAssets', 10, 'InitPort', 1/10);
disp(p.InitPort);
    0.1000
    0.1000
    0.1000
    0.1000
    0.1000
    0.1000
    0.1000
    0.1000
    0.1000
    0.1000
```

To clear an initial portfolio from your Portfolio object, use either the Portfolio or the setInitPort function with an empty input for the InitPort property. If transaction costs or turnover constraints are set, it is not possible to clear the InitPort property in this way. In this case, to clear InitPort, first clear the dependent properties and then clear theInitPort property.

The InitPort property can also be set with setInitPort which lets you specify the number of assets if you want to use scalar expansion. For example, given an initial portfolio in xO , use setInitPort to set the InitPort property:

```
p = Portfolio;
x0 = [ 0.3; 0.2; 0.2; 0.0 ];
p = setInitPort(p, x0);
disp(p.InitPort);
0.3000
0.2000
0.2000
0
```

To create an equally weighted portfolio of four assets, use setInitPort:
p = Portfolio;

```
p = setInitPort(p, 1/4, 4);
disp(p.InitPort);
```

0.2500
0.2500
0.2500
0.2500

Portfolio object functions that work with either transaction costs or turnover constraints also depend on the InitPort property. So, the set functions for transaction costs or turnover constraints permit the assignment of a value for the InitPort property as part of their implementation. For details, see "Working with Average Turnover Constraints Using Portfolio Object" on page 4-73, "Working with One-way Turnover Constraints Using Portfolio Object" on page 4-75, and "Working with Transaction Costs" on page 4-52 for details. If either transaction costs or turnover constraints are used, then the InitPort property must have a nonempty value. Absent a specific value assigned through the Portfolio function or various set functions, the Portfolio object sets InitPort to 0 and warns if BuyCost, SellCost, or Turnover properties are set. The following example illustrates what happens if an average turnover constraint is specified with an initial portfolio:

```
p = Portfolio('Turnover', 0.3, 'InitPort', [ 0.3; 0.2; 0.2; 0.0 ]);
disp(p.InitPort);
    0.3000
    0.2000
    0.2000
        0
```

In contrast, this example shows what happens if an average turnover constraint is specified without an initial portfolio:

```
p = Portfolio('Turnover', 0.3);
disp(p.InitPort);
Warning: InitPort and NumAssets are empty and either transaction costs or turnover constraints specified.
Will set NumAssets = 1 and InitPort = 0.
> In Portfolio.checkarguments at 367
    In Portfolio.Portfolio>Portfolio.Portfolio at 171
        0
```

## Setting Up a Tracking Porffolio

Given a benchmark or tracking portfolio, you can ensure that the risk of a portfolio relative to the benchmark portfolio is no greater than a specified amount. The Portfolio object property TrackingPort lets you identify a tracking portfolio. For more
information on using a tracking portfolio with tracking error constraints, see "Working with Tracking Error Constraints Using Portfolio Object" on page 4-78.

The tracking error constraints can be used with any of the other supported constraints in the Portfolio object without restrictions. However, since the portfolio set necessarily and sufficiently must be a non-empty compact set, the application of a tracking error constraint can result in an empty portfolio set. Use estimateBounds to confirm that the portfolio set is non-empty and compact.

Suppose that you have an initial portfolio in $\times 0$, then use the Portfolio function to set up a tracking portfolio:

```
x0 = [ 0.3; 0.2; 0.2; 0.0 ];
p = Portfolio('TrackingPort', x0);
disp(p.TrackingPort);
0.3000
    0.2000
    0.2000
        0
```

As with all array properties, you can set TrackingPort with scalar expansion. This is helpful to set up an equally weighted tracking portfolio of, for example, 10 assets:

```
p = Portfolio('NumAssets', 10, 'TrackingPort', 1/10);
disp(p.TrackingPort);
0.1000
    0.1000
    0.1000
    0.1000
    0.1000
    0.1000
    0.1000
    0.1000
    0.1000
    0.1000
```

To clear a tracking portfolio from your Portfolio object, use either the Portfolio or the setTrackingPort function with an empty input for the TrackingPort property. If transaction costs or turnover constraints are set, it is not possible to clear the TrackingPort property in this way. In this case, to clear TrackingPort, first clear the dependent properties and then clear theTrackingPort property.

The TrackingPort property can also be set with setTrackingPort which lets you specify the number of assets if you want to use scalar expansion. For example, given an initial portfolio in x 0 , use setTrackingPort to set the TrackingPort property:

```
p = Portfolio;
x0 = [ 0.3; 0.2; 0.2; 0.0 ];
p = setTrackingPort(p, x0);
disp(p.TrackingPort);
```

0.3000
0.2000
0.2000

0
To create an equally weighted portfolio of four assets, use setTrackingPort:

```
p = Portfolio;
p = setTrackingPort(p, 1/4, 4);
disp(p.TrackingPort);
    0.2500
    0.2500
    0.2500
    0.2500
```

## Asset Returns and Moments of Asset Returns Using Porifolio Object

```
In this section...
"Assignment Using the Portfolio Function" on page 4-41
"Assignment Using the setAssetMoments Function" on page 4-43
"Scalar Expansion of Arguments" on page 4-43
"Estimating Asset Moments from Prices or Returns" on page 4-45
"Estimating Asset Moments with Missing Data" on page 4-48
"Estimating Asset Moments from Time Series Data" on page 4-50
"Working with a Riskless Asset" on page 4-51
"Working with Transaction Costs" on page 4-52
```

Since mean-variance portfolio optimization problems require estimates for the mean and covariance of asset returns, the Portfolio object has several ways to set and get the properties AssetMean (for the mean) and AssetCovar (for the covariance). In addition, the return for a riskless asset is kept in the property RiskFreeRate so that all assets in AssetMean and AssetCovar are risky assets. For information on the workflow when using Portfolio objects, see "Portfolio Object Workflow" on page 4-17.

## Assignment Using the Portfolio Function

Suppose that you have a mean and covariance of asset returns in variables $m$ and $C$. The properties for the moments of asset returns are set using the Portfolio function:

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
    0.00408 0.0289 0.0204 0.0119;
    0.00192 0.0204 0.0576 0.0336;
    0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;
p = Portfolio('AssetMean', m, 'AssetCovar', C);
disp(p.NumAssets);
disp(p.AssetMean);
disp(p.AssetCovar);
```

4

```
0.0042
0.0083
0.0100
0.0150
\begin{tabular}{rrrr}
0.0005 & 0.0003 & 0.0002 & 0 \\
0.0003 & 0.0024 & 0.0017 & 0.0010 \\
0.0002 & 0.0017 & 0.0048 & 0.0028 \\
0 & 0.0010 & 0.0028 & 0.0102
\end{tabular}
```

Notice that the Portfolio object determines the number of assets in NumAssets from the moments. The Portfolio function enables separate initialization of the moments, for example:

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
    0.00408 0.0289 0.0204 0.0119;
    0.00192 0.0204 0.0576 0.0336;
    0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;
p = Portfolio;
p = Portfolio(p, 'AssetMean', m);
p = Portfolio(p, 'AssetCovar', C);
[assetmean, assetcovar] = p.getAssetMoments
```

assetmean =
0.0042
0.0083
0.0100
0.0150
assetcovar =

| 0.0005 | 0.0003 | 0.0002 | 0 |
| ---: | ---: | ---: | ---: |
| 0.0003 | 0.0024 | 0.0017 | 0.0010 |
| 0.0002 | 0.0017 | 0.0048 | 0.0028 |
| 0 | 0.0010 | 0.0028 | 0.0102 |

The getAssetMoments function lets you get the values for AssetMean and AssetCovar properties at the same time.

## Assignment Using the setAssetMoments Function

You can also set asset moment properties using the setAssetMoments function. For example, given the mean and covariance of asset returns in the variables $m$ and $C$, the asset moment properties can be set:

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
    0.00408 0.0289 0.0204 0.0119;
    0.00192 0.0204 0.0576 0.0336;
    0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;
p = Portfolio;
p = setAssetMoments(p, m, C);
[assetmean, assetcovar] = getAssetMoments(p)
assetmean =
    0.0042
    0.0083
    0.0100
    0.0150
assetcovar =
\begin{tabular}{rrrr}
0.0005 & 0.0003 & 0.0002 & 0 \\
0.0003 & 0.0024 & 0.0017 & 0.0010 \\
0.0002 & 0.0017 & 0.0048 & 0.0028 \\
0 & 0.0010 & 0.0028 & 0.0102
\end{tabular}
```

## Scalar Expansion of Arguments

Both the Portfolio function and the setAssetMoments function perform scalar expansion on arguments for the moments of asset returns. When using the Portfolio function, the number of assets must be already specified in the variable NumAssets. If NumAssets has not already been set, a scalar argument is interpreted as a scalar with NumAssets set to 1 . setAssetMoments provides an additional optional argument to specify the number of assets so that scalar expansion works with the correct number of assets. In addition, if either a scalar or vector is input for the covariance of asset returns, a diagonal matrix is formed such that a scalar expands along the diagonal and a vector
becomes the diagonal. This example demonstrates scalar expansion for four jointly independent assets with a common mean 0.1 and common variance 0.03 :

```
p = Portfolio;
p = setAssetMoments(p, 0.1, 0.03, 4);
[assetmean, assetcovar] = getAssetMoments(p)
assetmean =
    0.1000
    0.1000
    0.1000
    0.1000
assetcovar =
\begin{tabular}{rrrr}
0.0300 & 0 & 0 & 0 \\
0 & 0.0300 & 0 & 0 \\
0 & 0 & 0.0300 & 0 \\
0 & 0 & 0 & 0.0300
\end{tabular}
```

If at least one argument is properly dimensioned, you do not need to include the additional NumAssets argument. This example illustrates a constant-diagonal covariance matrix and a mean of asset returns for four assets:

```
p = Portfolio;
p = setAssetMoments(p, [ 0.05; 0.06; 0.04; 0.03 ], 0.03);
[assetmean, assetcovar] = getAssetMoments(p)
assetmean =
```

0.0500
0.0600
0.0400
0.0300
assetcovar =

| 0.0300 | 0 | 0 | 0 |
| ---: | ---: | ---: | ---: |
| 0 | 0.0300 | 0 | 0 |
| 0 | 0 | 0.0300 | 0 |
| 0 | 0 | 0 | 0.0300 |

In addition, scalar expansion works with the Portfolio function if NumAssets is known, or is deduced from the inputs.

## Estimating Asset Moments from Prices or Returns

Another way to set the moments of asset returns is to use the estimateAssetMoments function which accepts either prices or returns and estimates the mean and covariance of asset returns. Either prices or returns are stored as matrices with samples going down the rows and assets going across the columns. In addition, prices or returns can be stored in a financial time series (fints) object (see "Estimating Asset Moments from Time Series Data" on page 4-50). To illustrate using estimateAssetMoments, generate random samples of 120 observations of asset returns for four assets from the mean and covariance of asset returns in the variables $m$ and $C$ with portsim. The default behavior of portsim creates simulated data with estimated mean and covariance identical to the input moments m and C . In addition to a return series created by portsim in the variable X , a price series is created in the variable Y :

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
    0.00408 0.0289 0.0204 0.0119;
    0.00192 0.0204 0.0576 0.0336;
    0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;
X = portsim(m', C, 120);
Y = ret2tick(X);
```

Note: Portfolio optimization requires that you use total returns and not just price returns. So, "returns" should be total returns and "prices" should be total return prices.

Given asset returns and prices in variables $X$ and $Y$ from above, this sequence of examples demonstrates equivalent ways to estimate asset moments for the Portfolio object. A Portfolio object is created in p with the moments of asset returns set directly in the Portfolio function, and a second Portfolio object is created in $q$ to obtain the mean and covariance of asset returns from asset return data in X using estimateAssetMoments:

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
    0.00408 0.0289 0.0204 0.0119;
    0.00192 0.0204 0.0576 0.0336;
    0 0.0119 0.0336 0.1225 ];
m = m/12;
```

```
C = C/12;
X = portsim(m', C, 120);
p = Portfolio('mean', m, 'covar', C);
q = Portfolio;
q = estimateAssetMoments(q, X);
[passetmean, passetcovar] = getAssetMoments(p)
[qassetmean, qassetcovar] = getAssetMoments(q)
passetmean =
    0.0042
    0.0083
    0.0100
    0.0150
passetcovar =
\begin{tabular}{rrrr}
0.0005 & 0.0003 & 0.0002 & 0 \\
0.0003 & 0.0024 & 0.0017 & 0.0010 \\
0.0002 & 0.0017 & 0.0048 & 0.0028 \\
0 & 0.0010 & 0.0028 & 0.0102
\end{tabular}
qassetmean =
    0.0042
    0.0083
    0.0100
    0.0150
qassetcovar =
\begin{tabular}{llll}
0.0005 & 0.0003 & 0.0002 & 0.0000 \\
0.0003 & 0.0024 & 0.0017 & 0.0010 \\
0.0002 & 0.0017 & 0.0048 & 0.0028 \\
0.0000 & 0.0010 & 0.0028 & 0.0102
\end{tabular}
```

Notice how either approach has the same moments. The default behavior of estimateAssetMoments is to work with asset returns. If, instead, you have asset prices in the variable $Y$, estimateAssetMoments accepts a name-value pair argument name 'DataFormat' with a corresponding value set to 'prices' to indicate that the input to the function is in the form of asset prices and not returns (the default value for the 'DataFormat ' argument is 'returns '). This example compares direct assignment of
moments in the Portfolio object p with estimated moments from asset price data in Y in the Portfolio object q :

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
    0.00408 0.0289 0.0204 0.0119;
    0.00192 0.0204 0.0576 0.0336;
    0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;
X = portsim(m', C, 120);
Y = ret2tick(X);
p = Portfolio('mean',m,'covar',C);
q = Portfolio;
q = estimateAssetMoments(q, Y, 'dataformat', 'prices');
[passetmean, passetcovar] = getAssetMoments(p)
[qassetmean, qassetcovar] = getAssetMoments(q)
passetmean =
    0.0042
    0.0083
    0.0100
    0.0150
passetcovar =
\begin{tabular}{rrrr}
0.0005 & 0.0003 & 0.0002 & 0 \\
0.0003 & 0.0024 & 0.0017 & 0.0010 \\
0.0002 & 0.0017 & 0.0048 & 0.0028 \\
0 & 0.0010 & 0.0028 & 0.0102
\end{tabular}
qassetmean =
    0.0042
    0.0083
    0 . 0 1 0 0
    0.0150
qassetcovar =
```

| 0.0005 | 0.0003 | 0.0002 | 0.0000 |

## Estimating Asset Moments with Missing Data

Often when working with multiple assets, you have missing data indicated by NaN values in your return or price data. Although "Multivariate Normal Regression" on page 9-2 goes into detail about regression with missing data, the estimateAssetMoments function has a name-value pair argument name 'MissingData' that indicates with a Boolean value whether to use the missing data capabilities of Financial Toolbox software. The default value for 'MissingData' is false which removes all samples with NaN values. If, however, 'MissingData' is set to true, estimateAssetMoments uses the ECM algorithm to estimate asset moments. This example illustrates how this works on price data with missing values:

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
    0.00408 0.0289 0.0204 0.0119;
    0.00192 0.0204 0.0576 0.0336;
    0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;
X = portsim(m', C, 120);
Y = ret2tick(X);
Y(1:20,1) = NaN;
Y(1:12,4) = NaN;
p = Portfolio('mean',m,'covar',C);
q = Portfolio;
q = estimateAssetMoments(q, Y, 'dataformat', 'prices');
r = Portfolio;
r = estimateAssetMoments(r, Y, 'dataformat', 'prices', 'missingdata', true);
[passetmean, passetcovar] = getAssetMoments(p)
[qassetmean, qassetcovar] = getAssetMoments(q)
[rassetmean, rassetcovar] = getAssetMoments(r)
passetmean =
```

0.0042
0.0083
0.0100
0.0150

```
passetcovar =
\begin{tabular}{rrrr}
0.0005 & 0.0003 & 0.0002 & 0 \\
0.0003 & 0.0024 & 0.0017 & 0.0010 \\
0.0002 & 0.0017 & 0.0048 & 0.0028 \\
0 & 0.0010 & 0.0028 & 0.0102
\end{tabular}
qassetmean =
    0.0045
    0.0082
    0.0101
    0.0091
qassetcovar =

0.0008 & 0.0005 & 0.0001 & -0.0001 \\
0.0005 & 0.0032 & 0.0022 & 0.0015 \\
0.0001 & 0.0022 & 0.0063 & 0.0040 \\
-0.0001 & 0.0015 & 0.0040 & 0.0144
\end{tabular}
```

The Portfolio object p contains raw moments, the object q contains estimated moments in which NaN values are discarded, and the object $r$ contains raw moments that accommodate missing values. Each time you run this example, you will get different estimates for the moments in $q$ and $r$, and these will also differ from the moments in $p$.

## Estimating Asset Moments from Time Series Data

The estimateAssetMoments function also accepts asset returns or prices stored in financial time series (fints) objects. estimateAssetMoments implicitly works with matrices of data or data in a fints object using the same rules for whether the data are returns or prices.

To illustrate, use fints to create a fints objects Xfts that contains asset returns generated with portsim (see "Estimating Asset Moments from Prices or Returns" on page 4-45) and add series labels:

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
    0.00408 0.0289 0.0204 0.0119;
    0.00192 0.0204 0.0576 0.0336;
    0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;
X = portsim(m', C, 120);
d = (datenum('31-jan-2001'):datenum('31-dec-2010'))';
Xfts = fints(d, zeros(numel(d),4), {'Bonds', 'LargeCap', 'SmallCap', 'Emerging'});
Xfts = tomonthly(Xfts);
Xfts.Bonds = X(:,1);
Xfts.LargeCap = X(:,2);
Xfts.SmallCap = X(:,3);
Xfts.Emerging = X(:,4);
p = Portfolio('mean',m,'covar',C);
q = Portfolio;
q = estimateAssetMoments(q, Xfts);
[passetmean, passetcovar] = getAssetMoments(p)
[qassetmean, qassetcovar] = getAssetMoments(q)
passetmean =
    0.0042
    0.0083
    0.0100
    0.0150
passetcovar =
\begin{tabular}{rrrr}
0.0005 & 0.0003 & 0.0002 & 0 \\
0.0003 & 0.0024 & 0.0017 & 0.0010 \\
0.0002 & 0.0017 & 0.0048 & 0.0028 \\
0 & 0.0010 & 0.0028 & 0.0102
\end{tabular}
```

qassetmean =
0.0042
0.0083
0.0100
0.0150
qassetcovar =

| 0.0005 | 0.0003 | 0.0002 | 0.0000 |
| :--- | :--- | :--- | :--- |
| 0.0003 | 0.0024 | 0.0017 | 0.0010 |
| 0.0002 | 0.0017 | 0.0048 | 0.0028 |
| 0.0000 | 0.0010 | 0.0028 | 0.0102 |

As you can see, the moments match. The argument name-value inputs 'DataFormat' to handle return or price data and 'MissingData' to ignore or use samples with missing values also work for fints data. In addition, estimateAssetMoments also extracts asset names or identifiers from a fints object with the argument name 'GetAssetList' set to true (its default value is false). If the 'GetAssetList' value is true, the identifiers are used to set the AssetList property of the object. Thus, repeating the formation of the Portfolio object q from the previous example with the 'GetAssetList' flag set to true extracts the series labels from the fints object:

```
q = estimateAssetMoments(q, Xfts, 'getassetlist', true);
disp(q.AssetList)
```

'Bonds' 'LargeCap' 'SmallCap' 'Emerging'
Note if you set the 'GetAssetList' flag set to true and your input data is in a matrix, estimateAssetMoments uses the default labeling scheme from setAssetList described in "Setting Up a List of Asset Identifiers" on page 4-33.

## Working with a Riskless Asset

You can specify a riskless asset with the mean and covariance of asset returns in the AssetMean and AssetCovar properties such that the riskless asset has variance of 0 and is completely uncorrelated with all other assets. In this case, the Portfolio object uses a separate RiskFreeRate property that stores the rate of return of a riskless asset. Thus, you can separate your universe into a riskless asset and a collection of risky assets. For example, assume that your riskless asset has a return in the scalar variable r0, then the property for the RiskFreeRate is set using the Portfolio function:

```
rO = 0.01/12;
m = [ 0.05; 0.1; 0.12; 0.18 ];
```

```
C = [ 0.0064 0.00408 0.00192 0;
    0.00408 0.0289 0.0204 0.0119;
    0.00192 0.0204 0.0576 0.0336;
    0 0.0119 0.0336 0.1225 ];
p = Portfolio('RiskFreeRate', r0, 'AssetMean', m, 'AssetCovar', C);
disp(p.RiskFreeRate);
    8.3333e-004
```

Note: If your problem has a budget constraint such that your portfolio weights must sum to 1 , then the riskless asset is irrelevant.

## Working with Transaction Costs

The difference between net and gross portfolio returns is transaction costs. The net portfolio return proxy has distinct proportional costs to purchase and to sell assets which are maintained in the Portfolio object properties BuyCost and SellCost. Transaction costs are in units of total return and, as such, are proportional to the price of an asset so that they enter the model for net portfolio returns in return form. For example, suppose that you have a stock currently priced $\$ 40$ and your usual transaction costs are 5 cents per share. Then the transaction cost for the stock is $0.05 / 40=0.00125$ (as defined in "Net Portfolio Returns" on page 4-4). Costs are entered as positive values and credits are entered as negative values.

## Setting Transaction Costs Using the Portfolio Function

To set up transaction costs, you must specify an initial or current portfolio in the InitPort property. If the initial portfolio is not set when you set up the transaction cost properties, InitPort is 0 . The properties for transaction costs can be set using thePortfolio function. For example, assume that purchase and sale transaction costs are in the variables bc and Sc and an initial portfolio is in the variable $\times 0$, then transaction costs are set:

```
bc = [ 0.00125; 0.00125; 0.00125; 0.00125; 0.00125 ];
sc = [ 0.00125; 0.007; 0.00125; 0.00125; 0.0024 ];
x0 = [ 0.4; 0.2; 0.2; 0.1; 0.1 ];
p = Portfolio('BuyCost', bc, 'SellCost', sc, 'InitPort', x0);
disp(p.NumAssets);
disp(p.BuyCost);
disp(p.SellCost);
disp(p.InitPort);
```

0.4000
0.2000
0.2000
0.1000
0.1000

## Setting Transaction Costs Using the setCosts Function

You can also set the properties for transaction costs using setCosts. Assume that you have the same costs and initial portfolio as in the previous example. Given a Portfolio object $p$ with an initial portfolio already set, use setCosts to set up transaction costs:

```
bc = [ 0.00125; 0.00125; 0.00125; 0.00125; 0.00125 ];
sc = [ 0.00125; 0.007; 0.00125; 0.00125; 0.0024 ];
x0 = [ 0.4; 0.2; 0.2; 0.1; 0.1 ];
p = Portfolio('InitPort', x0);
p = setCosts(p, bc, sc);
disp(p.NumAssets);
disp(p.BuyCost);
disp(p.SellCost);
disp(p.InitPort);
5
0.0013
0.0013
0.0013
0.0013
0.0013
```

```
0.0013
0.0070
0.0013
0.0013
0.0024
0.4000
0.2000
0.2000
0.1000
0.1000
```

You can also set up the initial portfolio's InitPort value as an optional argument to setCosts so that the following is an equivalent way to set up transaction costs:

```
bc = [ 0.00125; 0.00125; 0.00125; 0.00125; 0.00125 ];
sc = [ 0.00125; 0.007; 0.00125; 0.00125; 0.0024 ];
x0 = [ 0.4; 0.2; 0.2; 0.1; 0.1 ];
p = Portfolio;
p = setCosts(p, bc, sc, x0);
disp(p.NumAssets);
disp(p.BuyCost);
disp(p.SellCost);
disp(p.InitPort);
    5
    0.0013
    0.0013
    0.0013
    0.0013
    0.0013
    0.0013
    0.0070
    0.0013
    0.0013
    0.0024
    0.4000
    0.2000
    0.2000
```

### 0.1000

0.1000

## Setting Transaction Costs with Scalar Expansion

Both the Portfolio function and the setCosts function implement scalar expansion on the arguments for transaction costs and the initial portfolio. If the NumAssets property is already set in the Portfolio object, scalar arguments for these properties are expanded to have the same value across all dimensions. In addition, setCosts lets you specify NumAssets as an optional final argument. For example, assume that you have an initial portfolio xO and you want to set common transaction costs on all assets in your universe. You can set these costs in any of these equivalent ways:

```
x0 = [ 0.4; 0.2; 0.2; 0.1; 0.1 ];
p = Portfolio('InitPort', x0, 'BuyCost', 0.002, 'SellCost', 0.002);
or
x0 = [ 0.4; 0.2; 0.2; 0.1; 0.1 ];
p = Portfolio('InitPort', x0);
p = setCosts(p, 0.002, 0.002);
or
x0 = [ 0.4; 0.2; 0.2; 0.1; 0.1 ];
p = Portfolio;
p = setCosts(p, 0.002, 0.002, x0);
```

To clear costs from your Portfolio object, use either the Portfolio function or setCosts with empty inputs for the properties to be cleared. For example, you can clear sales costs from the Portfolio object $p$ in the previous example:

```
p = Portfolio(p, 'SellCost', []);
```

The final element for a complete specification of a portfolio optimization problem is the set of feasible portfolios, which is called a portfolio set. A portfolio set $X \subset R^{n}$ is specified by construction as the intersection of sets formed by a collection of constraints on portfolio weights. A portfolio set necessarily and sufficiently must be a nonempty, closed, and bounded set.

When setting up your portfolio set, ensure that the portfolio set satisfies these conditions. The most basic or "default" portfolio set requires portfolio weights to be nonnegative (using the lower-bound constraint) and to sum to 1 (using the budget constraint). For information on the workflow when using Portfolio objects, see "Portfolio Object Workflow" on page $4-17$.

## Setting Default Constraints for Portfolio Weights Using Portfolio Object

The "default" portfolio problem has two constraints on portfolio weights:

- Portfolio weights must be nonnegative.
- Portfolio weights must sum to 1 .

Implicitly, these constraints imply that portfolio weights are no greater than 1, although this is a superfluous constraint to impose on the problem.

## Setting Default Constraints Using the Portfolio Function

Given a portfolio optimization problem with NumAssets = 20 assets, use the Portfolio function to set up a default problem and explicitly set bounds and budget constraints:

```
p = Portfolio('NumAssets', 20, 'LowerBound', 0, 'Budget', 1);
disp(p);
Portfolio with properties:
```

            BuyCost: []
            SellCost: []
        RiskFreeRate: []
            AssetMean: []
            AssetCovar: []
    TrackingError: []
    TrackingPort: []
            Turnover: []
        BuyTurnover: []
    SellTurnover: []
        Name: []
        NumAssets: 20
        AssetList: []
            InitPort: []
        AInequality: []
        bInequality: []
            AEquality: []
            bEquality: []
            LowerBound: [20x1 double]
            UpperBound: []
            LowerBudget: 1
            UpperBudget: 1
            GroupMatrix: []
            LowerGroup: []
            UpperGroup: []
            GroupA: []
            GroupB: []
            LowerRatio: []
            UpperRatio: []
    
## Setting Default Constraints Using the setDefaultConstraints Function

An alternative approach is to use the setDefaultConstraints function. If the number of assets is already known in a Portfolio object, use setDefaultConstraints with no
arguments to set up the necessary bound and budget constraints. Suppose that you have 20 assets to set up the portfolio set for a default problem:

```
p = Portfolio('NumAssets', 20);
p = setDefaultConstraints(p);
disp(p);
    Portfolio with properties:
            BuyCost: []
            SellCost: []
        RiskFreeRate: []
            AssetMean: []
            AssetCovar: []
    TrackingError: []
    TrackingPort: []
            Turnover: []
        BuyTurnover: []
    SellTurnover: []
            Name: []
        NumAssets: 20
        AssetList: []
            InitPort: []
        AInequality: []
        bInequality: []
            AEquality: []
            bEquality: []
        LowerBound: [20x1 double]
        UpperBound: []
            LowerBudget: 1
            UpperBudget: 1
            GroupMatrix: []
            LowerGroup: []
            UpperGroup: []
            GroupA: []
            GroupB: []
            LowerRatio: []
            UpperRatio: []
```

If the number of assets is unknown, setDefaultConstraints accepts NumAssets as an optional argument to form a portfolio set for a default problem. Suppose that you have 20 assets:

```
p = Portfolio;
p = setDefaultConstraints(p, 20);
```

```
disp(p);
Portfolio with properties:
            BuyCost: []
            SellCost: []
        RiskFreeRate: []
            AssetMean: []
            AssetCovar: []
            TrackingError: []
            TrackingPort: []
            Turnover: []
        BuyTurnover: []
    SellTurnover: []
            Name: []
        NumAssets: 20
        AssetList: []
            InitPort: []
        AInequality: []
        bInequality: []
            AEquality: []
            bEquality: []
        LowerBound: [20x1 double]
        UpperBound: []
        LowerBudget: 1
        UpperBudget: 1
        GroupMatrix: []
        LowerGroup: []
        UpperGroup: []
            GroupA: []
            GroupB: []
        LowerRatio: []
        UpperRatio: []
```

## Working with Bound Constraints Using Portfolio Object

Bound constraints are optional linear constraints that maintain upper and lower bounds on portfolio weights (see "Bound Constraints" on page 4-9). Although every portfolio set must be bounded, it is not necessary to specify a portfolio set with explicit bound constraints. For example, you can create a portfolio set with an implicit upper bound constraint or a portfolio set with average turnover constraints. The bound constraints have properties LowerBound for the lower-bound constraint and UpperBound for the upper-bound constraint. Set default values for these constraints using the
setDefaultConstraints function (see "Setting Default Constraints for Portfolio Weights Using Portfolio Object" on page 4-57).

## Setting Bounds Using the Portfolio Function

The properties for bound constraints are set through the Portfolio function. Suppose that you have a balanced fund with stocks that can range from $50 \%$ to $75 \%$ of your portfolio and bonds that can range from $25 \%$ to $50 \%$ of your portfolio. The bound constraints for a balanced fund are set with:

```
lb = [ 0.5; 0.25 ];
ub = [ 0.75; 0.5 ];
p = Portfolio('LowerBound', lb, 'UpperBound', ub);
disp(p.NumAssets);
disp(p.LowerBound);
disp(p.UpperBound);
2
0.5000
0.2500
0.7500
0.5000
```

To continue with this example, you must set up a budget constraint. For details, see "Working with Budget Constraints Using Portfolio Object" on page 4-62.

## Setting Bounds Using the setBounds Function

You can also set the properties for bound constraints using setBounds. Suppose that you have a balanced fund with stocks that can range from $50 \%$ to $75 \%$ of your portfolio and bonds that can range from $25 \%$ to $50 \%$ of your portfolio. Given a Portfolio object p, use setBounds to set the bound constraints:

```
lb = [ 0.5; 0.25 ];
ub = [ 0.75; 0.5 ];
p = Portfolio;
p = setBounds(p, lb, ub);
disp(p.NumAssets);
disp(p.LowerBound);
disp(p.UpperBound);
```

0.5000
0.2500
0.7500
0.5000

## Setting Bounds Using the Portfolio Function or setBounds Function

Both the Portfolio function and setBounds function implement scalar expansion on either the LowerBound or UpperBound properties. If the NumAssets property is already set in the Portfolio object, scalar arguments for either property expand to have the same value across all dimensions. In addition, setBounds lets you specify NumAssets as an optional argument. Suppose that you have a universe of 500 assets and you want to set common bound constraints on all assets in your universe. Specifically, you are a long-only investor and want to hold no more than $5 \%$ of your portfolio in any single asset. You can set these bound constraints in any of these equivalent ways:

```
p = Portfolio('NumAssets', 500, 'LowerBound', 0, 'UpperBound', 0.05);
or
p = Portfolio('NumAssets', 500);
p = setBounds(p, 0, 0.05);
or
p = Portfolio;
p = setBounds(p, 0, 0.05, 500);
```

To clear bound constraints from your Portfolio object, use either the Portfolio function or setBounds with empty inputs for the properties to be cleared. For example, to clear the upper-bound constraint from the Portfolio object $p$ in the previous example:
p = Portfolio(p, 'UpperBound', []);

## Working with Budget Constraints Using Porifolio Object

The budget constraint is an optional linear constraint that maintains upper and lower bounds on the sum of portfolio weights (see "Budget Constraints" on page 4-10). Budget constraints have properties LowerBudget for the lower budget constraint and UpperBudget for the upper budget constraint. If you set up a portfolio optimization
problem that requires portfolios to be fully invested in your universe of assets, you can set LowerBudget to be equal to UpperBudget. These budget constraints can be set with default values equal to 1 using setDefaultConstraints (see "Setting Default Constraints for Portfolio Weights Using Portfolio Object" on page 4-57).

## Setting Budget Constraints Using the Portfolio Function

The properties for the budget constraint can also be set using the Portfolio function. Suppose that you have an asset universe with many risky assets and a riskless asset and you want to ensure that your portfolio never holds more than $1 \%$ cash, that is, you want to ensure that you are $99-100 \%$ invested in risky assets. The budget constraint for this portfolio can be set with:

```
p = Portfolio('LowerBudget', 0.99, 'UpperBudget', 1);
disp(p.LowerBudget);
disp(p.UpperBudget);
```

0.9900

1

## Setting Budget Constraints Using the setBudget Function

You can also set the properties for a budget constraint using setBudget. Suppose that you have a fund that permits up to $10 \%$ leverage which means that your portfolio can be from $100 \%$ to $110 \%$ invested in risky assets. Given a Portfolio object $p$, use setBudget to set the budget constraints:

```
p = Portfolio;
p = setBudget(p, 1, 1.1);
disp(p.LowerBudget);
disp(p.UpperBudget);
1
```

### 1.1000

If you were to continue with this example, then set the RiskFreeRate property to the borrowing rate to finance possible leveraged positions. For details on the RiskFreeRate property, see "Working with a Riskless Asset" on page 4-51. To clear either bound for the budget constraint from your Portfolio object, use either the Portfolio function or setBudget with empty inputs for the properties to be cleared. For example, clear the upper-budget constraint from the Portfolio object $p$ in the previous example with:

```
p = Portfolio(p, 'UpperBudget', []);
```

## Working with Group Constraints Using Portfolio Object

Group constraints are optional linear constraints that group assets together and enforce bounds on the group weights (see "Group Constraints" on page 4-11). Although the constraints are implemented as general constraints, the usual convention is to form a group matrix that identifies membership of each asset within a specific group with Boolean indicators (either true or false or with 1 or 0) for each element in the group matrix. Group constraints have properties GroupMatrix for the group membership matrix, LowerGroup for the lower-bound constraint on groups, and UpperGroup for the upper-bound constraint on groups.

## Setting Group Constraints Using the Portfolio Function

The properties for group constraints are set through the Portfolio function. Suppose that you have a portfolio of five assets and want to ensure that the first three assets constitute no more than $30 \%$ of your portfolio, then you can set group constraints:

```
G = [ [11 1 1 1 0 0 ];
p = Portfolio('GroupMatrix', G, 'UpperGroup', 0.3);
disp(p.NumAssets);
disp(p.GroupMatrix);
disp(p.UpperGroup);
5
1
0.3000
```

The group matrix $G$ can also be a logical matrix so that the following code achieves the same result.

```
G = [ true true true false false ];
p = Portfolio('GroupMatrix', G, 'UpperGroup', 0.3);
disp(p.NumAssets);
disp(p.GroupMatrix);
disp(p.UpperGroup);
```

5
$\begin{array}{lllll}1 & 1 & 1 & 0 & 0\end{array}$

### 0.3000

## Setting Group Constraints Using the setGroups and addGroups Functions

You can also set the properties for group constraints using setGroups. Suppose that you have a portfolio of five assets and want to ensure that the first three assets constitute no more than $30 \%$ of your portfolio. Given a Portfolio object p, use setGroups to set the group constraints:

```
G = [ true true true false false ];
p = Portfolio;
p = setGroups(p, G, [], 0.3);
disp(p.NumAssets);
disp(p.GroupMatrix);
disp(p.UpperGroup);
```

5
$\begin{array}{lllll}1 & 1 & 1 & 0 & 0\end{array}$
0.3000

In this example, you would set the LowerGroup property to be empty ([ ]).
Suppose you want to add another group constraint to make odd-numbered assets constitute at least $20 \%$ of your portfolio. Set up an augmented group matrix and introduce infinite bounds for unconstrained group bounds or use the addGroups function to build up group constraints. For this example, create another group matrix for the second group constraint:

```
p = Portfolio;
G = [ true true true false false ]; % group matrix for first group constraint
p = setGroups(p, G, [], 0.3);
G = [ true false true false true ]; % group matrix for second group constraint
p = addGroups(p, G, 0.2);
disp(p.NumAssets)
disp(p.GroupMatrix)
disp(p.LowerGroup);
disp(p.UpperGroup);
5
1
1 0
- Inf
```

### 0.2000

### 0.3000

Inf
addGroups determines which bounds are unbounded so you only need to focus on the constraints that you want to set.

The Portfolio function and setGroups and addGroups implement scalar expansion on either the LowerGroup or UpperGroup properties based on the dimension of the group matrix in the property GroupMatrix. Suppose that you have a universe of 30 assets with 6 asset classes such that assets $1-5$, assets $6-12$, assets $13-18$, assets 19-22, assets 23-27, and assets $28-30$ constitute each of your 6 asset classes and you want each asset class to fall from $0 \%$ to $25 \%$ of your portfolio. Let the following group matrix define your groups and scalar expansion define the common bounds on each group:

```
p = Portfolio;
G = blkdiag(true(1,5), true(1,7), true(1,6), true(1,4), true(1,5), true(1,3));
p = setGroups(p, G, 0, 0.25);
disp(p.NumAssets);
disp(p.GroupMatrix);
disp(p.LowerGroup);
disp(p.UpperGroup);
30
    Columns 1 through 16

    0.2500
    0.2500
```

## Working with Group Ratio Constraints Using Portfolio Object

Group ratio constraints are optional linear constraints that maintain bounds on proportional relationships among groups of assets (see "Group Ratio Constraints" on page 4-12). Although the constraints are implemented as general constraints, the usual convention is to specify a pair of group matrices that identify membership of each asset within specific groups with Boolean indicators (either true or false or with 1 or 0 ) for each element in each of the group matrices. The goal is to ensure that the ratio of a base group compared to a comparison group fall within specified bounds. Group ratio constraints have properties:

- GroupA for the base membership matrix
- GroupB for the comparison membership matrix
- LowerRatio for the lower-bound constraint on the ratio of groups
- UpperRatio for the upper-bound constraint on the ratio of groups

## Setting Group Ratio Constraints Using the Portfolio Function

The properties for group ratio constraints are set using the Portfolio function. For example, assume that you want the ratio of financial to nonfinancial companies in your portfolios to never go above $50 \%$. Suppose that you have six assets with three financial companies (assets 1-3) and three nonfinanical companies (assets 4-6). To set group ratio constraints:

```
GA = [ 1 1 1 1 0 0 0 ]; % financial companies
GB = [ 0 0 0 1 1 1 ]; % nonfinancial companies
p = Portfolio('GroupA', GA, 'GroupB', GB, 'UpperRatio', 0.5);
disp(p.NumAssets);
disp(p.GroupA);
disp(p.GroupB);
disp(p.UpperRatio);
6
\begin{tabular}{llllll}
1 & 1 & 1 & 0 & 0 & 0 \\
0 & 0 & 0 & 1 & 1 & 1
\end{tabular}
0.5000
```

Group matrices GA and GB in this example can be logical matrices with true and false elements that yield the same result:

```
GA = [ true true true false false false ]; % financial companies
GB = [ false false false true true true ]; % nonfinancial companies
```

```
p = Portfolio('GroupA', GA, 'GroupB', GB, 'UpperRatio', 0.5);
disp(p.NumAssets);
disp(p.GroupA);
disp(p.GroupB);
disp(p.UpperRatio);
6
1
0
0.5000
```

## Setting Group Ratio Constraints Using the setGroupRatio and addGroupRatio Functions

You can also set the properties for group ratio constraints using setGroupRatio. For example, assume that you want the ratio of financial to nonfinancial companies in your portfolios to never go above $50 \%$. Suppose that you have six assets with three financial companies (assets $1-3$ ) and three nonfinanical companies (assets 4-6). Given a Portfolio object $p$, use setGroupRatio to set the group constraints:

```
GA = [ true true true false false false ]; % financial companies
GB = [ false false false true true true ]; % nonfinancial companies
p = Portfolio;
p = setGroupRatio(p, GA, GB, [], 0.5);
disp(p.NumAssets);
disp(p.GroupA);
disp(p.GroupB);
disp(p.UpperRatio);
6
1 1 1 1 1 0
0
```

0.5000

In this example, you would set the LowerRatio property to be empty ([ ]).
Suppose that you want to add another group ratio constraint to ensure that the weights in odd-numbered assets constitute at least $20 \%$ of the weights in nonfinancial assets your portfolio. You can set up augmented group ratio matrices and introduce infinite bounds for unconstrained group ratio bounds, or you can use the addGroupRatio function to build up group ratio constraints. For this example, create another group matrix for the second group constraint:

```
p = Portfolio;
```

```
GA = [ true true true false false false ]; % financial companies
GB = [ false false false true true true ]; % nonfinancial companies
p = setGroupRatio(p, GA, GB, [], 0.5);
GA = [ true false true false true false ]; % odd-numbered companies
GB = [ false false false true true true ]; % nonfinancial companies
p = addGroupRatio(p, GA, GB, 0.2);
disp(p.NumAssets);
disp(p.GroupA);
disp(p.GroupB);
disp(p.LowerRatio);
disp(p.UpperRatio);
    6
\begin{tabular}{llllll}
1 & 1 & 1 & 0 & 0 & 0 \\
1 & 0 & 1 & 0 & 1 & 0 \\
0 & 0 & 0 & 1 & 1 & 1 \\
0 & 0 & 0 & 1 & 1 & 1
\end{tabular}
    - Inf
0.2000
0.5000
    Inf
```

Notice that addGroupRatio determines which bounds are unbounded so you only need to focus on the constraints you want to set.

The Portfolio function, setGroupRatio, and addGroupRatio implement scalar expansion on either the LowerRatio or UpperRatio properties based on the dimension of the group matrices in GroupA and GroupB properties.

## Working with Linear Equality Constraints Using Portfolio Object

Linear equality constraints are optional linear constraints that impose systems of equalities on portfolio weights (see "Linear Equality Constraints" on page 4-9). Linear equality constraints have properties AEquality, for the equality constraint matrix, and bEquality, for the equality constraint vector.

## Setting Linear Equality Constraints Using the Portfolio Function

The properties for linear equality constraints are set using the Portfolio function. Suppose that you have a portfolio of five assets and want to ensure that the first three assets are $50 \%$ of your portfolio. To set this constraint:

```
A = [ 1 1 1 1 0 0 l];
b = 0.5;
p = Portfolio('AEquality', A, 'bEquality', b);
disp(p.NumAssets);
disp(p.AEquality);
disp(p.bEquality);
5
1
0.5000
```

## Setting Linear Equality Constraints Using the setEquality and addEquality Functions

You can also set the properties for linear equality constraints using setEquality.
Suppose that you have a portfolio of five assets and want to ensure that the first three assets are $50 \%$ of your portfolio. Given a Portfolio object p, use setEquality to set the linear equality constraints:

```
A = [ 1 1 1 0 0 ];
b = 0.5;
p = Portfolio;
p = setEquality(p, A, b);
disp(p.NumAssets);
disp(p.AEquality);
disp(p.bEquality);
5
1 
0.5000
```

Suppose that you want to add another linear equality constraint to ensure that the last three assets also constitute $50 \%$ of your portfolio. You can set up an augmented system of linear equalities or use addEquality to build up linear equality constraints. For this example, create another system of equalities:

```
p = Portfolio;
A = [ 1 1 1 1 0 0 ]; % first equality constraint
b = 0.5;
p = setEquality(p, A, b);
```

```
A = [ 0 0 1 1 1 1 ]; % second equality constraint
b = 0.5;
p = addEquality(p, A, b);
disp(p.NumAssets);
disp(p.AEquality);
disp(p.bEquality);
5
1
0.5000
0.5000
```

The Portfolio function, setEquality, and addEquality implement scalar expansion on the bEquality property based on the dimension of the matrix in the AEquality property.

## Working with Linear Inequality Constraints Using Porffolio Object

Linear inequality constraints are optional linear constraints that impose systems of inequalities on portfolio weights (see "Linear Inequality Constraints" on page 4-8).
Linear inequality constraints have properties AInequality for the inequality constraint matrix, and bInequality for the inequality constraint vector.

## Setting Linear Inequality Constraints Using the Portfolio Function

The properties for linear inequality constraints are set using the Portfolio function. Suppose that you have a portfolio of five assets and you want to ensure that the first three assets are no more than $50 \%$ of your portfolio. To set up these constraints:

```
A = [ [14ccllll
b = 0.5;
p = Portfolio('AInequality', A, 'bInequality', b);
disp(p.NumAssets);
disp(p.AInequality);
disp(p.bInequality);
```

5
$\begin{array}{lllll}1 & 1 & 1 & 0 & 0\end{array}$

### 0.5000

## Setting Linear Inequality Constraints Using the setInequality and addInequality Functions

You can also set the properties for linear inequality constraints using set Inequality. Suppose that you have a portfolio of five assets and you want to ensure that the first three assets constitute no more than $50 \%$ of your portfolio. Given a Portfolio object p, use setInequality to set the linear inequality constraints:

```
A = [[\begin{array}{llllll}{1}&{1}&{1}&{0}&{0}\end{array}];
b = 0.5;
p = Portfolio;
p = setInequality(p, A, b);
disp(p.NumAssets);
disp(p.AInequality);
disp(p.bInequality);
5
1 1 1 1 1 0
0.5000
```

Suppose that you want to add another linear inequality constraint to ensure that the last three assets constitute at least $50 \%$ of your portfolio. You can set up an augmented system of linear inequalities or use the addInequality function to build up linear inequality constraints. For this example, create another system of inequalities:

```
p = Portfolio;
A = [ 1 1 1 0 0 ]; % first inequality constraint
b = 0.5;
p = setInequality(p, A, b);
A = [ 0 0 -1 -1 -1 ]; % second inequality constraint
b = -0.5;
p = addInequality(p, A, b);
disp(p.NumAssets);
disp(p.AInequality);
disp(p.bInequality);
```

5

| 1 | 1 | 1 | 0 | 0 |
| ---: | ---: | ---: | ---: | ---: |

The Portfolio function, setInequality, and addInequality implement scalar expansion on the bInequality property based on the dimension of the matrix in the AInequality property.

## Working with Average Turnover Constraints Using Portfolio Object

The turnover constraint is an optional linear absolute value constraint (see "Average Turnover Constraints" on page 4-12) that enforces an upper bound on the average of purchases and sales. The turnover constraint can be set using the Portfolio function or the setTurnover function. The turnover constraint depends on an initial or current portfolio, which is assumed to be zero if not set when the turnover constraint is set. The turnover constraint has properties Turnover, for the upper bound on average turnover, and InitPort, for the portfolio against which turnover is computed.

## Setting Average Turnover Constraints Using the Porffolio Function

The properties for the turnover constraints are set using the Portfolio function. Suppose that you have an initial portfolio of 10 assets in a variable x 0 and you want to ensure that average turnover is no more than $30 \%$. To set this turnover constraint:

```
x0 = [ 0.12; 0.09; 0.08; 0.07; 0.1; 0.1; 0.15; 0.11; 0.08; 0.1 ];
p = Portfolio('Turnover', 0.3, 'InitPort', x0);
disp(p.NumAssets);
disp(p.Turnover);
disp(p.InitPort);
```

10

### 0.0800

0.1000

Note if the NumAssets or InitPort properties are not set before or when the turnover constraint is set, various rules are applied to assign default values to these properties (see "Setting Up an Initial or Current Portfolio" on page 4-35).

## Setting Average Turnover Constraints Using the setTurnover Function

You can also set properties for portfolio turnover using setTurnover to specify both the upper bound for average turnover and an initial portfolio. Suppose that you have an initial portfolio of 10 assets in a variable $x 0$ and want to ensure that average turnover is no more than $30 \%$. Given a Portfolio object p, use setTurnover to set the turnover constraint with and without the initial portfolio being set previously:

```
x0 = [ 0.12; 0.09; 0.08; 0.07; 0.1; 0.1; 0.15; 0.11; 0.08; 0.1 ];
p = Portfolio('InitPort', x0);
p = setTurnover(p, 0.3);
disp(p.NumAssets);
disp(p.Turnover);
disp(p.InitPort);

setTurnover implements scalar expansion on the argument for the initial portfolio. If the NumAssets property is already set in the Portfolio object, a scalar argument for InitPort expands to have the same value across all dimensions. In addition, setTurnover lets you specify NumAssets as an optional argument. To clear turnover from your Portfolio object, use the Portfolio function or setTurnover with empty inputs for the properties to be cleared.

## Working with One-way Turnover Constraints Using Portfolio Object

One-way turnover constraints are optional constraints (see "One-way Turnover Constraints" on page 4-13) that enforce upper bounds on net purchases or net sales. One-way turnover constraints can be set using the Portfolio function or the setOneWayTurnover function. One-way turnover constraints depend upon an initial or current portfolio, which is assumed to be zero if not set when the turnover constraints are set. One-way turnover constraints have properties BuyTurnover, for the upper bound on net purchases, SellTurnover, for the upper bound on net sales, and InitPort, for the portfolio against which turnover is computed.

## Setting One-way Turnover Constraints Using the Portfolio Function

The Properties for the one-way turnover constraints are set using the Portfolio function. Suppose that you have an initial portfolio with 10 assets in a variable x 0 and you want to ensure that turnover on purchases is no more than $30 \%$ and turnover on sales is no more than $20 \%$ of the initial portfolio. To set these turnover constraints:

```
x0 = [ 0.12; 0.09; 0.08; 0.07; 0.1; 0.1; 0.15; 0.11; 0.08; 0.1 ];
p = Portfolio('BuyTurnover', 0.3, 'SellTurnover', 0.2, 'InitPort', x0);
disp(p.NumAssets);
disp(p.BuyTurnover);
```

```
disp(p.SellTurnover);
disp(p.InitPort);
    1 0
    0.3000
    0.2000
    0.1200
    0.0900
    0.0800
    0.0700
    0.1000
    0.1000
    0.1500
    0.1100
    0.0800
    0.1000
```

If the NumAssets or InitPort properties are not set before or when the turnover constraint is set, various rules are applied to assign default values to these properties (see "Setting Up an Initial or Current Portfolio" on page 4-35).

## Setting Turnover Constraints Using the setOneWayTurnover Function

You can also set properties for portfolio turnover using setOneWayTurnover to specify the upper bounds for turnover on purchases (BuyTurnover) and sales (SellTurnover) and an initial portfolio. Suppose that you have an initial portfolio of 10 assets in a variable x 0 and want to ensure that turnover on purchases is no more than $30 \%$ and that turnover on sales is no more than $20 \%$ of the initial portfolio. Given a Portfolio object p, use setOneWayTurnover to set the turnover constraints with and without the initial portfolio being set previously:

```
x0 = [ 0.12; 0.09; 0.08; 0.07; 0.1; 0.1; 0.15; 0.11; 0.08; 0.1 ];
p = Portfolio('InitPort', x0);
p = setOneWayTurnover(p, 0.3, 0.2);
disp(p.NumAssets);
disp(p.BuyTurnover);
disp(p.SellTurnover);
disp(p.InitPort);
    1 0
    0.3000
```

```

    0.1000
    0.1500
    0.1100
    0.0800
    0.1000
```

setOneWayTurnover implements scalar expansion on the argument for the initial portfolio. If the NumAssets property is already set in the Portfolio object, a scalar argument for InitPort expands to have the same value across all dimensions. In addition, setOneWayTurnover lets you specify NumAssets as an optional argument. To remove one-way turnover from your Portfolio object, use the Portfolio function or setOneWayTurnover with empty inputs for the properties to be cleared.

## Working with Tracking Error Constraints Using Portfolio Object

Tracking error constraints are optional constraints (see "Tracking Error Constraints" on page 4-14) that measure the risk relative to a portfolio called a tracking portfolio. Tracking error constraints can be set using the Portfolio function or the setTrackingError function.

The tracking error constraint is an optional quadratic constraint that enforces an upper bound on tracking error, which is the relative risk between a portfolio and a designated tracking portfolio. For more information, see "Tracking Error Constraints" on page 4-14.

The tracking error constraint can be set using the Portfolio function or the setTrackingPort and setTrackingError functions. The tracking error constraint depends on a tracking portfolio, which is assumed to be zero if not set when the tracking error constraint is set. The tracking error constraint has properties TrackingError, for the upper bound on tracking error, and TrackingPort, for the portfolio against which tracking error is computed.

Note: The initial portfolio in the Portfolio object property InitPort is distinct from the tracking portfolio in the Portfolio object property TrackingPort.

## Setting Tracking Error Constraints Using the Poriffolio Function

The properties for the tracking error constraints are set using the Portfolio function. Suppose that you have a tracking portfolio of 10 assets in a variable $x 0$ and you want to ensure that the tracking error of any portfolio on the efficient frontier is no more than $8 \%$ relative to this portfolio. To set this constraint:

```
x0 = [ 0.12; 0.09; 0.08; 0.07; 0.1; 0.1; 0.15; 0.11; 0.08; 0.1 ];
p = Portfolio('TrackingError', 0.08, 'TrackingPort', x0);
disp(p.NumAssets);
disp(p.TrackingError);
disp(p.TrackingPort);
```

0.0700
0.1000
0.1000
0.1500
0.1100
0.0800
0.1000

Note that if the NumAssets or TrackingPort properties are not set before or when the tracking error constraint is set, various rules are applied to assign default values to these properties (see "Setting Up a Tracking Portfolio" on page 4-37).

## Setting Tracking Error Constraints Using the setTrackingError Function

You can also set properties for portfolio tracking error using the setTrackingError function to specify both the upper bound for tracking error and a designated tracking portfolio. Suppose that you have a tracking portfolio of 10 assets in a variable $x 0$ and want to ensure that tracking error is no more than $8 \%$. Given a Portfolio object $p$, use setTrackingError to set the tracking error constraint with and without the initial portfolio being set previously:

```
x0 = [ 0.12; 0.09; 0.08; 0.07; 0.1; 0.1; 0.15; 0.11; 0.08; 0.1 ];
p = Portfolio('TrackingPort', x0);
p = setTrackingError(p, 0.08);
disp(p.NumAssets);
disp(p.TrackingError);
disp(p.TrackingPort);
    1 0
    0.0800
    0.1200
    0.0900
    0.0800
    0.0700
    0.1000
    0.1000
    0.1500
    0.1100
    0.0800
    0.1000
or
x0 = [ 0.12; 0.09; 0.08; 0.07; 0.1; 0.1; 0.15; 0.11; 0.08; 0.1 ];
```

```
p = Portfolio('TrackingPort', x0);
p = setTrackingError(p, 0.08, x0);
disp(p.NumAssets);
disp(p.TrackingError);
disp(p.TrackingPort);

## Validate the Portfolio Problem for Portfolio Object

```
In this section...
"Validating a Portfolio Set" on page 4-82
"Validating Portfolios" on page 4-84
```

In some cases, you may want to validate either your inputs to, or outputs from, a portfolio optimization problem. Although most error checking that occurs during the problem setup phase catches most difficulties with a portfolio optimization problem, the processes to validate portfolio sets and portfolios are time consuming and are best done offline. So, the portfolio optimization tools have specialized functions to validate portfolio sets and portfolios. For information on the workflow when using Portfolio objects, see "Portfolio Object Workflow" on page 4-17.

## Validating a Portfolio Set

Since it is necessary and sufficient that your portfolio set must be a nonempty, closed, and bounded set to have a valid portfolio optimization problem, the estimateBounds function lets you examine your portfolio set to determine if it is nonempty and, if nonempty, whether it is bounded. Suppose that you have the following portfolio set which is an empty set because the initial portfolio at 0 is too far from a portfolio that satisfies the budget and turnover constraint:

```
p = Portfolio('NumAssets', 3, 'Budget', 1);
p = setTurnover(p, 0.3, 0);
```

If a portfolio set is empty, estimateBounds returns NaN bounds and sets the isbounded flag to []:
[lb, ub, isbounded] = estimateBounds(p)
lb =
NaN
NaN
NaN
$u b=$
NaN

```
    NaN
    NaN
isbounded =
    []
```

Suppose that you create an unbounded portfolio set as follows:

```
p = Portfolio('AInequality', [1 -1; 1 1 ], 'bInequality', 0);
[lb, ub, isbounded] = estimateBounds(p)
```

lb $=$
- Inf
- Inf
ub $=$
1.0e-008 *
$-0.3712$
Inf
isbounded =
0

In this case, estimateBounds returns (possibly infinite) bounds and sets the isbounded flag to false. The result shows which assets are unbounded so that you can apply bound constraints as necessary.

Finally, suppose that you created a portfolio set that is both nonempty and bounded. estimateBounds not only validates the set, but also obtains tighter bounds which are useful if you are concerned with the actual range of portfolio choices for individual assets in your portfolio set:

```
p = Portfolio;
p = setBudget(p, 1,1);
p = setBounds(p, [ -0.1; 0.2; 0.3; 0.2 ], [ 0.5; 0.3; 0.9; 0.8 ]);
[lb, ub, isbounded] = estimateBounds(p)
lb =
```

    \(-0.1000\)
    0.2000
    ```
    0.3000
    0.2000
ub =
    0.3000
    0.3000
    0.7000
    0.6000
isbounded =
    1
```

In this example, all but the second asset has tighter upper bounds than the input upper bound implies.

## Validating Porffolios

Given a portfolio set specified in a Portfolio object, you often want to check if specific portfolios are feasible with respect to the portfolio set. This can occur with, for example, initial portfolios and with portfolios obtained from other procedures. The checkFeasibility function determines whether a collection of portfolios is feasible. Suppose that you perform the following portfolio optimization and want to determine if the resultant efficient portfolios are feasible relative to a modified problem.

First, set up a problem in the Portfolio object p, estimate efficient portfolios in pwgt, and then confirm that these portfolios are feasible relative to the initial problem:

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
    0.00408 0.0289 0.0204 0.0119;
    0.00192 0.0204 0.0576 0.0336;
    0 0.0119 0.0336 0.1225 ];
p = Portfolio;
p = setAssetMoments(p, m, C);
p = setDefaultConstraints(p);
pwgt = estimateFrontier(p);
checkFeasibility(p, pwgt)
ans =
```

Next, set up a different portfolio problem that starts with the initial problem with an additional a turnover constraint and an equally weighted initial portfolio:

```
q = setTurnover(p, 0.3, 0.25);
checkFeasibility(q, pwgt)
ans =
\begin{tabular}{llllllllll}
0 & 0 & 0 & 1 & 1 & 0 & 0 & 0 & 0 & 0
\end{tabular}
```

In this case, only two of the 10 efficient portfolios from the initial problem are feasible relative to the new problem in Portfolio object q. Solving the second problem using checkFeasibility demonstrates that the efficient portfolio for Portfolio object q is feasible relative to the initial problem:

```
qwgt = estimateFrontier(q);
checkFeasibility(p, qwgt)
ans =
```

    \(\begin{array}{llllllllll}1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1\end{array}\)

# Estimate Efficient Portfolios for Portfolio Object 

In this section...<br>"Obtaining Portfolios Along the Entire Efficient Frontier" on page 4-87<br>"Obtaining Endpoints of the Efficient Frontier" on page 4-88<br>"Obtaining Efficient Portfolios for Target Returns" on page 4-90<br>"Obtaining Efficient Portfolios for Target Risks" on page 4-93<br>"Efficient Portfolio That Maximizes Sharpe Ratio" on page 4-95<br>"Choosing and Controlling the Solver" on page 4-97

There are two ways to look at a portfolio optimization problem that depends on what you are trying to do. One goal is to estimate efficient portfolios and the other is to estimate efficient frontiers. This section focuses on the former goal and "Estimate Efficient Frontiers for Portfolio Object" on page 4-99 focuses on the latter goal. For information on the workflow when using Portfolio objects, see "Portfolio Object Workflow" on page 4-17.

## Obtaining Porffolios Along the Entire Efficient Frontier

The most basic way to obtain optimal portfolios is to obtain points over the entire range of the efficient frontier. Given a portfolio optimization problem in a Portfolio object, the estimateFrontier function computes efficient portfolios spaced evenly according to the return proxy from the minimum to maximum return efficient portfolios. The number of portfolios estimated is controlled by the hidden property defaultNumPorts which is set to 10. A different value for the number of portfolios estimated is specified as input to estimateFrontier. This example shows the default number of efficient portfolios over the entire range of the efficient frontier:

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
    0.00408 0.0289 0.0204 0.0119;
    0.00192 0.0204 0.0576 0.0336;
    0 0.0119 0.0336 0.1225 ];
p = Portfolio;
p = setAssetMoments(p, m, C);
p = setDefaultConstraints(p);
pwgt = estimateFrontier(p);
disp(pwgt);
\begin{tabular}{rrrrrrrrr}
0.8891 & 0.7215 & 0.5540 & 0.3865 & 0.2190 & 0.0515 & 0 & 0 & 0 \\
0.0369 & 0.1289 & 0.2209 & 0.3129 & 0.4049 & 0.4969 & 0.4049 & 0.2314 & 0.0579
\end{tabular}
```

| 0.0404 | 0.0567 | 0.0730 | 0.0893 | 0.1056 | 0.1219 | 0.1320 | 0.1394 | 0.1468 |
| ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| 0.0336 | 0.0929 | 0.1521 | 0.2113 | 0.2705 | 0.3297 | 0.4630 | 0.6292 | 0.7953 |

If you want only four portfolios in the previous example:

```
pwgt = estimateFrontier(p, 4);
disp(pwgt);
\begin{tabular}{rrrr}
0.8891 & 0.3865 & 0 & 0 \\
0.0369 & 0.3129 & 0.4049 & 0 \\
0.0404 & 0.0893 & 0.1320 & 0 \\
0.0336 & 0.2113 & 0.4630 & 1.0000
\end{tabular}
```

Starting from the initial portfolio, estimateFrontier also returns purchases and sales to get from your initial portfolio to each efficient portfolio on the efficient frontier. For example, given an initial portfolio in pwgt0, you can obtain purchases and sales:

```
pwgt0 = [ 0.3; 0.3; 0.2; 0.1 ];
p = setInitPort(p, pwgt0);
[pwgt, pbuy, psell] = estimateFrontier(p);
display(pwgt);
display(pbuy);
display(psell);
pwgt =
\begin{tabular}{rrrrrrrrr}
0.8891 & 0.7215 & 0.5540 & 0.3865 & 0.2190 & 0.0515 & 0 & 0 & 0 \\
0.0369 & 0.1289 & 0.2209 & 0.3129 & 0.4049 & 0.4969 & 0.4049 & 0.2314 & 0.0579 \\
0.0404 & 0.0567 & 0.0730 & 0.0893 & 0.1056 & 0.1219 & 0.1320 & 0.1394 & 0.1468 \\
0.0336 & 0.0929 & 0.1521 & 0.2113 & 0.2705 & 0.3297 & 0.4630 & 0.6292 & 0.7953
\end{tabular}
pbuy =
\begin{tabular}{rrrrrrrrrr}
0.5891 & 0.4215 & 0.2540 & 0.0865 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0.0129 & 0.1049 & 0.1969 & 0.1049 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0.0521 & 0.1113 & 0.1705 & 0.2297 & 0.3630 & 0.5292 & 0.6953 & 0.9000
\end{tabular}
psell =
\begin{tabular}{llllllllrrr}
0 & 0 & 0 & 0 & 0.0810 & 0.2485 & 0.3000 & 0.3000 & 0.3000 & 0.3000 \\
0.2631 & 0.1711 & 0.0791 & 0 & 0 & 0 & 0 & 0.0686 & 0.2421 & 0.3000 \\
0.1596 & 0.1433 & 0.1270 & 0.1107 & 0.0944 & 0.0781 & 0.0680 & 0.0606 & 0.0532 & 0.2000 \\
0.0664 & 0.0071 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0
\end{tabular}
```

If you do not specify an initial portfolio, the purchase and sale weights assume that your initial portfolio is 0 .

## Obtaining Endpoints of the Efficient Frontier

In many cases, you might be interested in the endpoint portfolios for the efficient frontier. Suppose that you want to determine the range of returns from minimum
to maximum to refine a search for a portfolio with a specific target return. Use the estimateFrontierLimits function to obtain the endpoint portfolios:

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
    0.00408 0.0289 0.0204 0.0119;
    0.00192 0.0204 0.0576 0.0336;
    0 0.0119 0.0336 0.1225 ];
p = Portfolio;
p = setAssetMoments(p, m, C);
p = setDefaultConstraints(p);
pwgt = estimateFrontierLimits(p);
disp(pwgt);
\begin{tabular}{lr}
0.8891 & 0 \\
0.0369 & 0 \\
0.0404 & 0 \\
0.0336 & 1.0000
\end{tabular}
```

The estimatePortMoments function shows the range of risks and returns for efficient portfolios:

```
[prsk, pret] = estimatePortMoments(p, pwgt);
disp([prsk, pret]);
0.0769 0.0590
```

Starting from an initial portfolio, estimateFrontierLimits also returns purchases and sales to get from the initial portfolio to the endpoint portfolios on the efficient frontier. For example, given an initial portfolio in pwgt0, you can obtain purchases and sales:

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
    0.00408 0.0289 0.0204 0.0119;
    0.00192 0.0204 0.0576 0.0336;
    0 0.0119 0.0336 0.1225 ];
p = Portfolio;
p = setAssetMoments(p, m, C);
p = setDefaultConstraints(p);
```

```
pwgt0 = [ 0.3; 0.3; 0.2; 0.1 ];
p = setInitPort(p, pwgt0);
[pwgt, pbuy, psell] = estimateFrontierLimits(p);
display(pwgt);
display(pbuy);
display(psell);
pwgt =
    0.8891 0
    0.0369 0
    0.0404 0
    0.0336 1.0000
pbuy =
    0.5891 0
        0 0
        0
        0.9000
psell =
\begin{tabular}{rr}
0 & 0.3000 \\
0.2631 & 0.3000 \\
0.1596 & 0.2000 \\
0.0664 & 0
\end{tabular}
```

If you do not specify an initial portfolio, the purchase and sale weights assume that your initial portfolio is 0 .

## Obtaining Efficient Porffolios for Target Returns

To obtain efficient portfolios that have targeted portfolio returns, the estimateFrontierByReturn function accepts one or more target portfolios returns and obtains efficient portfolios with the specified returns. For example, assume that you have a universe of four assets where you want to obtain efficient portfolios with target portfolio returns of $6 \%, 9 \%$, and $12 \%$ :

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
    0.00408 0.0289 0.0204 0.0119;
    0.00192 0.0204 0.0576 0.0336;
```

```
    0 0.0119 0.0336 0.1225 ];
p = Portfolio;
p = setAssetMoments(p, m, C);
p = setDefaultConstraints(p);
pwgt = estimateFrontierByReturn(p, [0.06, 0.09, 0.12]);
display(pwgt);
pwgt =
\begin{tabular}{lll}
0.8772 & 0.5032 & 0.1293 \\
0.0434 & 0.2488 & 0.4541 \\
0.0416 & 0.0780 & 0.1143 \\
0.0378 & 0.1700 & 0.3022
\end{tabular}
```

In some cases, you can request a return for which no efficient portfolio exists. Based on the previous example, suppose that you want a portfolio with a $5 \%$ return (which is the return of the first asset). A portfolio that is fully invested in the first asset, however, is inefficient. estimateFrontierByReturn warns if your target returns are outside the range of efficient portfolio returns and replaces it with the endpoint portfolio of the efficient frontier closest to your target return:

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
    0.00408 0.0289 0.0204 0.0119;
    0.00192 0.0204 0.0576 0.0336;
    0 0.0119 0.0336 0.1225 ];
p = Portfolio;
p = setAssetMoments(p, m, C);
p = setDefaultConstraints(p);
pwgt = estimateFrontierByReturn(p, [0.05, 0.09, 0.12]);
display(pwgt);
Warning: One or more target return values are outside the feasible range [ 0.0590468, 0.18 ].
Will return portfolios associated with endpoints of the range for these values.
> In Portfolio.estimateFrontierByReturn at 70
pwgt =
    0.8891 0.5032 0.1293
    0.0369 0.2488 0.4541
    0.0404 0.0780 0.1143
    0.0336 0.1700 0.3022
```

The best way to avoid this situation is to bracket your target portfolio returns with estimateFrontierLimits and estimatePortReturn (see "Obtaining Endpoints of the Efficient Frontier" on page 4-88 and "Obtaining Portfolio Risks and Returns" on page 4-99).

```
pret = estimatePortReturn(p, p.estimateFrontierLimits);
display(pret);
pret =
    0.0590
    0.1800
```

This result indicates that efficient portfolios have returns that range between $5.9 \%$ and 18\%.

If you have an initial portfolio, estimateFrontierByReturn also returns purchases and sales to get from your initial portfolio to the target portfolios on the efficient frontier. For example, given an initial portfolio in pwgt0, to obtain purchases and sales with target returns of $6 \%, 9 \%$, and $12 \%$ :

```
pwgt0 = [ 0.3; 0.3; 0.2; 0.1 ];
p = setInitPort(p, pwgt0);
[pwgt, pbuy, psell] = estimateFrontierByReturn(p, [0.06, 0.09, 0.12]);
display(pwgt);
display(pbuy);
display(psell);
pwgt =
\begin{tabular}{lll}
0.8772 & 0.5032 & 0.1293 \\
0.0434 & 0.2488 & 0.4541 \\
0.0416 & 0.0780 & 0.1143 \\
0.0378 & 0.1700 & 0.3022
\end{tabular}
pbuy =
\begin{tabular}{rrr}
0.5772 & 0.2032 & 0 \\
0 & 0 & 0.1541 \\
0 & 0 & 0 \\
0 & 0.0700 & 0.2022
\end{tabular}
psell =
\begin{tabular}{rrr}
0 & 0 & 0.1707 \\
0.2566 & 0.0512 & 0 \\
0.1584 & 0.1220 & 0.0857 \\
0.0622 & 0 & 0
\end{tabular}
```

If you do not have an initial portfolio, the purchase and sale weights assume that your initial portfolio is 0 .

## Obtaining Efficient Porffolios for Target Risks

To obtain efficient portfolios that have targeted portfolio risks, the estimateFrontierByRisk function accepts one or more target portfolio risks and obtains efficient portfolios with the specified risks. Suppose that you have a universe of four assets where you want to obtain efficient portfolios with target portfolio risks of $12 \%$, $14 \%$, and $16 \%$.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
    0.00408 0.0289 0.0204 0.0119;
    0.00192 0.0204 0.0576 0.0336;
    0 0.0119 0.0336 0.1225 ];
p = Portfolio;
p = setAssetMoments(p, m, C);
p = setDefaultConstraints(p);
pwgt = estimateFrontierByRisk(p, [0.12, 0.14, 0.16]);
display(pwgt);
pwgt =
\begin{tabular}{lll}
0.3984 & 0.2659 & 0.1416 \\
0.3064 & 0.3791 & 0.4474 \\
0.0882 & 0.1010 & 0.1131 \\
0.2071 & 0.2540 & 0.2979
\end{tabular}
```

In some cases, you can request a risk for which no efficient portfolio exists. Based on the previous example, suppose that you want a portfolio with $7 \%$ risk (individual assets in this universe have risks ranging from $8 \%$ to $35 \%$ ). It turns out that a portfolio with $7 \%$ risk cannot be formed with these four assets. estimateFrontierByRisk warns if your target risks are outside the range of efficient portfolio risks and replaces it with the endpoint of the efficient frontier closest to your target risk:

```
pwgt = estimateFrontierByRisk(p, 0.07)
Warning: One or more target risk values are outside the feasible range [ 0.0769288, 0.35 ].
Will return portfolios associated with endpoints of the range for these values.
> In Portfolio.estimateFrontierByRisk at }8
pwgt =
    0.8891
    0.0369
    0.0404
    0.0336
```

The best way to avoid this situation is to bracket your target portfolio risks with estimateFrontierLimits and estimatePortRisk (see "Obtaining Endpoints of the Efficient Frontier" on page 4-88 and "Obtaining Portfolio Risks and Returns" on page 4-99).

```
prsk = estimatePortRisk(p, p.estimateFrontierLimits);
display(prsk);
prsk =
    0.0769
    0.3500
```

This result indicates that efficient portfolios have risks that range from $7.7 \%$ to $35 \%$.
Starting with an initial portfolio, estimateFrontierByRisk also returns purchases and sales to get from your initial portfolio to the target portfolios on the efficient frontier. For example, given an initial portfolio in pwgt0, you can obtain purchases and sales from the example with target risks of $12 \%, 14 \%$, and $16 \%$ :

```
pwgt0 = [ 0.3; 0.3; 0.2; 0.1 ];
p = setInitPort(p, pwgt0);
[pwgt, pbuy, psell] = estimateFrontierByRisk(p, [0.12, 0.14, 0.16]);
display(pwgt);
display(pbuy);
display(psell);
pwgt =
\begin{tabular}{lll}
0.3984 & 0.2659 & 0.1416 \\
0.3064 & 0.3791 & 0.4474 \\
0.0882 & 0.1010 & 0.1131 \\
0.2071 & 0.2540 & 0.2979
\end{tabular}
pbuy =
\begin{tabular}{rrr}
0.0984 & 0 & 0 \\
0.0064 & 0.0791 & 0.1474 \\
0 & 0 & 0 \\
0.1071 & 0.1540 & 0.1979
\end{tabular}
psell =
```

| 0 | 0.0341 | 0.1584 |
| ---: | ---: | ---: |
| 0 | 0 | 0 |
| 0.118 | 0.0990 | 0.0869 |
| 0 | 0 | 0 |

If you do not specify an initial portfolio, the purchase and sale weights assume that your initial portfolio is 0 .

## Efficient Portfolio That Maximizes Sharpe Ratio

The Sharpe ratio is defined as the ratio

$$
\frac{\mu(x)-r_{0}}{\sqrt{\sum(x)}}
$$

where $x \in R^{n}$ and $r_{0}$ is the risk-free rate ( $\mu$ and $\Sigma$ proxies for portfolio return and risk). For more information, see "Portfolio Optimization Theory" on page 4-2.

Portfolios that maximize the Sharpe ratio are portfolios on the efficient frontier that satisfy a number of theoretical conditions in finance. For example, such portfolios are called tangency portfolios since the tangent line from the risk-free rate to the efficient frontier touches the efficient frontier at portfolios that maximize the Sharpe ratio.

To obtain efficient portfolios that maximizes the Sharpe ratio, the estimateMaxSharpeRatio function accepts a Portfolio object and obtains efficient portfolios that maximize the Sharpe Ratio.

Suppose that you have a universe with four risky assets and a riskless asset and you want to obtain a portfolio that maximizes the Sharpe ratio, where, in this example, $r_{0}$ is the return for the riskless asset.

```
r0 = 0.03;
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
    0.00408 0.0289 0.0204 0.0119;
    0.00192 0.0204 0.0576 0.0336;
    0 0.0119 0.0336 0.1225 ];
p = Portfolio('RiskFreeRate', ro);
p = setAssetMoments(p, m, C);
p = setDefaultConstraints(p);
```

```
pwgt = estimateMaxSharpeRatio(p);
display(pwgt);
pwgt =
    0.4251
    0.2917
    0.0856
    0.1977
```

If you start with an initial portfolio, estimateMaxSharpeRatio also returns purchases and sales to get from your initial portfolio to the portfolio that maximizes the Sharpe ratio. For example, given an initial portfolio in pwgt0, you can obtain purchases and sales from the previous example:

```
pwgtO = [ 0.3; 0.3; 0.2; 0.1 ];
```

$\mathrm{p}=$ setInitPort(p, pwgt0);
[pwgt, pbuy, psell] = estimateMaxSharpeRatio(p);
display(pwgt);
display(pbuy);
display(psell);
pwgt =
0.4251
0.2917
0.0856
0.1977
pbuy =
0.1251

0
0
0.0977
psell =
0
0.0083
0.1144

0
If you do not specify an initial portfolio, the purchase and sale weights assume that you initial portfolio is 0 .

## Choosing and Controlling the Solver

The default solver for mean-variance portfolio optimization is lcprog, which implements a linear complementarity programming (LCP) algorithm. Although lcprog works for most problems, you can adjust arguments to control the algorithm. Alternatively, the mean-variance portfolio optimization tools let you use any of the variations of quadprog from Optimization Toolbox ${ }^{\mathrm{TM}}$ software. Unlike Optimization Toolbox which uses the trust-region-reflective algorithm as the default algorithm for quadprog, the portfolio optimization tools use the interior-point-convex algorithm. For details about quadprog and quadratic programming algorithms and options, see "Quadratic Programming Algorithms".

To modify either lcprog or to specify quadprog as your solver, use the setSolver function to set the hidden properties solverType and solverOptions that specify and control the solver. Since the solver properties are hidden, you cannot set these using the Portfolio function. The default solver is lcprog so you do not need to use setSolver to specify this solver. To use quadprog, you must set up the interior-point-convex version of quadprog using:

```
p = Portfolio;
p = setSolver(p, 'quadprog');
display(p.solverType);
quadprog
and you can switch back tolcprog with:
```

```
p = setSolver(p, 'lcprog');
display(p.solverType);
```

## lcprog

In both cases, setSolver sets up default options associated with either solver. If you want to specify additional options associated with a given solver, setSolver accepts these options with argument name-value pair arguments in the function call. For example, if you intend to use quadprog and want to use the active-set algorithm, call setSolver with:

```
p = setSolver(p, 'quadprog', 'Algorithm', 'active-set');
display(p.solverOptions.Algorithm);
```

## active-set

In addition, if you want to specify any of the options for quadprog that are normally set through optimoptions, setSolver accepts an optimoptions object as the second argument. For example, you can start with the default options for quadprog set by setSolver and then change the algorithm to 'trust-region-reflective' with no displayed output:

```
p = Portfolio;
options = optimoptions('quadprog', 'Algorithm', 'trust-region-reflective', 'Display', 'off');
p = setSolver(p, 'quadprog', options);
display(p.solverOptions.Algorithm);
display(p.solverOptions.Display);
trust-region-reflective
off
```

# Estimate Efficient Frontiers for Portfolio Object 

In this section...<br>"Obtaining Portfolio Risks and Returns" on page 4-99<br>"Plotting the Efficient Frontier for a Portfolio Object" on page 4-101

Whereas "Estimate Efficient Portfolios for Portfolio Object" on page 4-87 focused on estimation of efficient portfolios, this section focuses on the estimation of efficient frontiers. For information on the workflow when using Portfolio objects, see "Portfolio Object Workflow" on page 4-17.

## Obtaining Porffolio Risks and Returns

Given any portfolio and, in particular, efficient portfolios, the function estimatePortReturn, estimatePortRisk, and estimatePortMoments provide estimates for the return (or return proxy), risk (or the risk proxy), and, in the case of mean-variance portfolio optimization, the moments of expected portfolio returns. Each function has the same input syntax but with different combinations of outputs. Suppose that you have this following portfolio optimization problem that gave you a collection of portfolios along the efficient frontier in pwgt:

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
    0.00408 0.0289 0.0204 0.0119;
    0.00192 0.0204 0.0576 0.0336;
    0 0.0119 0.0336 0.1225 ];
pwgt0 = [ 0.3; 0.3; 0.2; 0.1 ];
p = Portfolio('AssetMean', m, 'AssetCovar', C, 'InitPort', pwgt0);
p = setDefaultConstraints(p);
pwgt = estimateFrontier(p);
```

Given pwgt0 and pwgt, use the portfolio risk and return estimation functions to obtain
risks and returns for your initial portfolio and the portfolios on the efficient frontier:

```
[prskO, pretO] = estimatePortMoments(p, pwgt0);
[prsk, pret] = estimatePortMoments(p, pwgt);
or
prskO = estimatePortRisk(p, pwgt0);
pret0 = estimatePortReturn(p, pwgt0);
prsk = estimatePortRisk(p, pwgt);
pret = estimatePortReturn(p, pwgt);
```

In either case, you obtain these risks and returns:

```
display(prskO);
display(pret0);
display(prsk);
display(pret);
prsk0 =
    0.1103
pret0 =
    0.0870
prsk =
    0.0769
    0.0831
    0.0994
    0.1217
    0.1474
    0.1750
    0.2068
    0.2487
    0.2968
    0.3500
pret =
    0.0590
    0.0725
    0.0859
    0.0994
    0.1128
    0.1262
    0.1397
    0.1531
    0.1666
    0.1800
```

Note that the returns and risks are at the periodicity of the moments of asset returns so that, if you have values for AssetMean and AssetCovar in terms of monthly returns, the estimates for portfolio risk and return are in terms of monthly returns as well.

In addition, the estimate for portfolio risk in the mean-variance case is the standard deviation of portfolio returns, not the variance of portfolio returns.

## Plotting the Efficient Frontier for a Portfolio Object

The plotFrontier function creates a plot of the efficient frontier for a given portfolio optimization problem. This function accepts several types of inputs and generates a plot with an optional possibility to output the estimates for portfolio risks and returns along the efficient frontier. plotFrontier has four different ways that it can be used. In addition to a plot of the efficient frontier, if you have an initial portfolio in the InitPort property, plotFrontier also displays the return versus risk of the initial portfolio on the same plot. If you have a well-posed portfolio optimization problem set up in a Portfolio object and you use plotFrontier, you will get a plot of the efficient frontier with the default number of portfolios on the frontier (the default number is currently 10 and is maintained in the hidden property defaultNumPorts). This example illustrates a typical use of plotFrontier to create a new plot:

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
    0.00408 0.0289 0.0204 0.0119;
    0.00192 0.0204 0.0576 0.0336;
    0 0.0119 0.0336 0.1225 ];
pwgt0 = [ 0.3; 0.3; 0.2; 0.1 ];
p = Portfolio('Name', 'Asset Allocation Portfolio', 'InitPort', pwgt0);
p = setAssetMoments(p, m, C);
p = setDefaultConstraints(p);
plotFrontier(p);
```

The Name property appears as the title of the efficient frontier plot if you set it in the Portfolio object. Without an explicit name, the title on the plot would be "Efficient Frontier." If you want to obtain a specific number of portfolios along the efficient frontier, use plotFrontier with the number of portfolios that you want. Suppose that you have the Portfolio object from the previous example and you want to plot 20 portfolios along the efficient frontier and to obtain 20 risk and return values for each portfolio:

```
[prsk, pret] = plotFrontier(p, 20);
display([pret, prsk]);
ans =
\begin{tabular}{ll}
0.0590 & 0.0769 \\
0.0654 & 0.0784 \\
0.0718 & 0.0825 \\
0.0781 & 0.0890 \\
0.0845 & 0.0973 \\
0.0909 & 0.1071 \\
0.0972 & 0.1179 \\
0.1036 & 0.1296
\end{tabular}
```

| 0.1100 | 0.1418 |
| :--- | :--- |
| 0.1163 | 0.1545 |
| 0.1227 | 0.1676 |
| 0.1291 | 0.1810 |
| 0.1354 | 0.1955 |
| 0.1418 | 0.2128 |
| 0.1482 | 0.2323 |
| 0.1545 | 0.2535 |
| 0.1609 | 0.2760 |
| 0.1673 | 0.2995 |
| 0.1736 | 0.3239 |
| 0.1800 | 0.3500 |

## Plotting Existing Efficient Portfolios

If you already have efficient portfolios from any of the "estimateFrontier" functions (see "Estimate Efficient Portfolios for Portfolio Object" on page 4-87), pass them into plotFrontier directly to plot the efficient frontier:

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
```

```
C = [ 0.0064 0.00408 0.00192 0;
    0.00408 0.0289 0.0204 0.0119;
    0.00192 0.0204 0.0576 0.0336
    0 0.0119 0.0336 0.1225 ]
pwgt0 = [ 0.3; 0.3; 0.2; 0.1 ];
p = Portfolio('Name', 'Asset Allocation Portfolio', 'InitPort', pwgt0);
p = setAssetMoments(p, m, C);
p = setDefaultConstraints(p);
pwgt = estimateFrontier(p, 20);
plotFrontier(p, pwgt);
```

Plotting Existing Efficient Portfolio Risks and Returns
If you already have efficient portfolio risks and returns, you can use the interface to plotFrontier to pass them into plotFrontier to obtain a plot of the efficient frontier:

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
    0.00408 0.0289 0.0204 0.0119;
    0.00192 0.0204 0.0576 0.0336
    0 0.0119 0.0336 0.1225 ];
pwgt0 = [ 0.3; 0.3; 0.2; 0.1 ];
```

```
p = Portfolio('Name', 'Asset Allocation Portfolio', 'InitPort', pwgt0);
p = setAssetMoments(p, m, C);
p = setDefaultConstraints(p);
[prsk, pret] = estimatePortMoments(p, p.estimateFrontier(20));
plotFrontier(p, prsk, pret);
```

## Postprocessing Results

In this section...<br>"Setting Up Tradable Portfolios" on page 4-107<br>"Troubleshooting Portfolio Optimization Results" on page 4-108

After obtaining efficient portfolios or estimates for expected portfolio risks and returns, use your results to set up trades to move toward an efficient portfolio. For information on the workflow when using Portfolio objects, see "Portfolio Object Workflow" on page 4-17.

## Setting Up Tradable Portfolios

Suppose that you set up a portfolio optimization problem and obtained portfolios on the efficient frontier. Use the dataset object from Statistics and Machine Learning Toolbox ${ }^{\mathrm{TM}}$ to form a blotter that lists your portfolios with the names for each asset. For example, suppose that you want to obtain five portfolios along the efficient frontier. You can set up a blotter with weights multiplied by 100 to view the allocations for each portfolio:

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
    0.00408 0.0289 0.0204 0.0119;
        0.00192 0.0204 0.0576 0.0336;
        0 0.0119 0.0336 0.1225 ];
pwgt0 = [ 0.3; 0.3; 0.2; 0.1 ];
p = Portfolio('InitPort', pwgt0);
p = setAssetList(p, 'Bonds','Large-Cap Equities','Small-Cap Equities','Emerging Equities');
p = setAssetMoments(p, m, C);
p = setDefaultConstraints(p);
pwgt = estimateFrontier(p, 5);
pnames = cell(1,5);
    for i = 1:5
        pnames{i} = sprintf('Port%d',i);
    end
Blotter = dataset([{100*pwgt},pnames],'obsnames',p.AssetList);
display(Blotter);
Blotter =
```

|  | Port1 | Port2 | Port3 | Port4 | Port5 |
| :--- | ---: | :--- | :--- | ---: | ---: |
| Bonds | 88.906 | 51.216 | 13.525 | 0 | 0 |
| Large-Cap Equities | 3.6875 | 24.387 | 45.086 | 27.479 | 0 |
| Small-Cap Equities | 4.0425 | 7.7088 | 11.375 | 13.759 | 0 |
| Emerging Equities | 3.364 | 16.689 | 30.014 | 58.762 | 100 |

This result indicates that you would invest primarily in bonds at the minimum-risk/ minimum-return end of the efficient frontier (Port1), and that you would invest completely in emerging equity at the maximum-risk/maximum-return end of the efficient frontier (Port5). You can also select a particular efficient portfolio, for example, suppose that you want a portfolio with $15 \%$ risk and you add purchase and sale weights outputs obtained from the "estimateFrontier" functions to set up a trade blotter:

```
m}=[0.05;0.1;0.12;0.18]
C = [ 0.0064 0.00408 0.00192 0;
    0.00408 0.0289 0.0204 0.0119;
    0.00192 0.0204 0.0576 0.0336;
    0 0.0119 0.0336 0.1225 ];
pwgt0 = [ 0.3; 0.3; 0.2; 0.1 ];
p = Portfolio('InitPort', pwgt0);
p = setAssetList(p, 'Bonds','Large-Cap Equities','Small-Cap Equities','Emerging Equities');
p = setAssetMoments(p,m,C);
p = setDefaultConstraints(p);
[pwgt, pbuy, psell] = estimateFrontierByRisk(p, 0.15);
Blotter = dataset [{100% [pyt0, puyt, pouy, psell1}, ...
    {'Initial','Weight', 'Purchases','Sales'}],'obsnames',p.AssetList);
display(Blotter);
```

Blotter =

|  | Initial | Weight | Purchases | Sales |
| :--- | :--- | ---: | :---: | ---: |
| Bonds | 30 | 20.299 | 0 | 9.7007 |
| Large-Cap Equities | 30 | 41.366 | 11.366 | 0 |
| Small-Cap Equities | 20 | 10.716 | 0 | 9.2838 |
| Emerging Equities | 10 | 27.619 | 17.619 | 0 |

If you have prices for each asset (in this example, they can be ETFs), add them to your blotter and then use the tools of the dataset object to obtain shares and shares to be traded. For an example, see "Asset Allocation Case Study" on page 4-142.

## Troubleshooting Porifolio Optimization Results

## Portfolio Object Destroyed When Modifying

If a Portfolio object is destroyed when modifying, remember to pass an existing object into the Portfolio function if you want to modify it, otherwise it creates a new object. See "Creating the Portfolio Object" on page 4-24 for details.

## Optimization Fails with "Bad Pivot" Message

If the optimization fails with a "bad pivot" message from lcprog, try a larger value for tolpiv which is a tolerance for pivot selection in the lcprog algorithm (try 1.0e-7,
for example) or try the interior-point-convex version of quadprog. For details, see "Choosing and Controlling the Solver" on page 4-97, the help header for lcprog, and the quadprog documentation.

## Speed of Optimization

Although it is difficult to characterize when one algorithm is faster than the other, the default solver, lcprog is generally faster for smaller problems and the quadprog solver is generally faster for larger problems. If one solver seems to take too much time, try the other solver. To change solvers, use setSolver.

## Matrix Incompatibility and "Non-Conformable" Errors

If you get matrix incompatibility or "non-conformable" errors, the representation of data in the tools follows a specific set of basic rules described in "Conventions for Representation of Data" on page 4-22.

## Missing Data Estimation Fails

If asset return data has missing or NaN values, the estimateAssetMoments function with the 'missingdata' flag set to true may fail with either too many iterations or a singular covariance. To correct this problem, consider this:

- If you have asset return data with no missing or NaN values, you can compute a covariance matrix that may be singular without difficulties. If you have missing or NaN values in your data, the supported missing data feature requires that your covariance matrix must be positive-definite, that is, nonsingular.
- estimateAssetMoments uses default settings for the missing data estimation procedure that might not be appropriate for all problems.

In either case, you might want to estimate the moments of asset returns separately with either the ECM estimation functions such as ecmnmle or with your own functions.

## mv_optim_transform Errors

If you obtain optimization errors such as:

```
Error using mv_optim_transform (line 233)
Portfolio set \overline{appears to be either empty or unbounded. Check constraints.}
Error in Portfolio/estimateFrontier (line 63)
    [A, b, fO, f, H, g, lb] = mv_optim_transform(obj);
Or
Error using mv_optim_transform (line 238)
Cannot obtain finite lower bounds for specified portfolio set.
```

```
Error in Portfolio/estimateFrontier (line 63)
    [A, b, fO, f, H, g, lb] = mv_optim_transform(obj);
```

Since the portfolio optimization tools require a bounded portfolio set, these errors (and similar errors) can occur if your portfolio set is either empty and, if nonempty, unbounded. Specifically, the portfolio optimization algorithm requires that your portfolio set have at least a finite lower bound. The best way to deal with these problems is to use the validation functions in "Validate the Portfolio Problem for Portfolio Object" on page 4-82. Specifically, use estimateBounds to examine your portfolio set, and use checkFeasibility to ensure that your initial portfolio is either feasible and, if infeasible, that you have sufficient turnover to get from your initial portfolio to the portfolio set.

Tip To correct this problem, try solving your problem with larger values for turnover or tracking-error and gradually reduce to the value that you want.

## Efficient Porffolios Do Not Make Sense

If you obtain efficient portfolios that do not seem to make sense, this can happen if you forget to set specific constraints or you set incorrect constraints. For example, if you allow portfolio weights to fall between 0 and 1 and do not set a budget constraint, you can get portfolios that are $100 \%$ invested in every asset. Although it may be hard to detect, the best thing to do is to review the constraints you have set with display of the object. If you get portfolios with $100 \%$ invested in each asset, you can review the display of your object and quickly see that no budget constraint is set. Also, you can use estimateBounds and checkFeasibility to determine if the bounds for your portfolio set make sense and to determine if the portfolios you obtained are feasible relative to an independent formulation of your portfolio set.

## Efficient Frontiers Do Not Make Sense

If you obtain efficient frontiers that do not seem to make sense, this can happen for some cases of mean and covariance of asset returns. It is possible for some mean-variance portfolio optimization problems to have difficulties at the endpoints of the efficient frontier. It is generally rare for standard problems but can occur with, for example, unusual combinations of turnover constraints and transaction costs. In most cases, the workaround of setting the hidden property enforcePareto produces a single portfolio for the entire efficient frontier, where any other solutions are not Pareto optimal (which is what efficient portfolios must be).

An example of a portfolio optimization problem that has difficulties at the endpoints of the efficient frontier is this standard mean-variance portfolio problem (long-only with a budget constraint) with the following mean and covariance of asset returns:

```
m = [ 1; 2; 3 ];
C=[[14 1 0; 1 1 0; 0 0 1 1];
p = Portfolio;
p = Portfolio(p, 'assetmean', m, 'assetcovar', C);
p = Portfolio(p, 'lowerbudget', 1, 'upperbudget', 1);
p = Portfolio(p, 'lowerbound', 0);
plotFrontier(p);
```

To workaround this problem, set the hidden Portfolio object property for enforcePareto. This property instructs the optimizer to perform extra steps to ensure a Pareto-optimal solution. This slows down the solver, but guarantees a Pareto-optimal solution.

```
p.enforcePareto = true;
plotFrontier(p);
```

## Portfolio Optimization Examples

The following sequence of examples highlights features of the Portfolio object in the Financial Toolbox ${ }^{\mathrm{TM}}$. Specifically, the examples show how to set up mean-variance portfolio optimization problems that focus on the two-fund theorem, the impact of transaction costs and turnover constraints, how to obtain portfolios that maximize the Sharpe ratio, and how to set up two popular hedge-fund strategies - dollar-neutral and 130-30 portfolios.

## Set up the Data

Every example works with moments for monthly total returns of a universe of 30 "bluechip" stocks. Although derived from real data, these data are for illustrative purposes and are not meant to be representative of specific assets or of market performance. The data are contained in the file BlueChipStockMoments. mat with a list of asset identifiers in the variable AssetList, a mean and covariance of asset returns in the variables AssetMean and AssetCovar, and the mean and variance of cash and market returns in the variables CashMean, CashVar, MarketMean, and MarketVar. Since most of the analysis requires the use of the standard deviation of asset returns as the proxy for risk, cash and market variances are converted into standard deviations.
load BlueChipStockMoments

```
mret = MarketMean;
mrsk = sqrt(MarketVar);
cret = CashMean;
crsk = sqrt(CashVar);
```

## Create a Portfolio Object

The first step is to create a "standard" Portfolio object with the Portfolio constructor and to incorporate the list of assets, the risk-free rate, and the moments of asset returns into the object.
p = Portfolio('AssetList', AssetList, 'RiskFreeRate', CashMean);
p = setAssetMoments(p, AssetMean, AssetCovar);
To provide a basis for comparison, set up an equal-weight portfolio and make it the initial portfolio in the Portfolio object. Keep in mind that the hedged portfolios to be constructed later will require a different initial portfolio. Once the initial portfolio is created, the estimatePortMoments method estimates the mean and standard deviation of equalweight portfolio returns.

```
p = setInitPort(p, 1/p.NumAssets);
[ersk, eret] = estimatePortMoments(p, p.InitPort);
```

A specialized "helper" function portfolioexamples_plot makes it possible to plot all results to be developed here. This first plot shows the distribution of individual assets according to their means and standard deviations of returns. In addition, the equalweight, market, and cash portfolios are plotted on the same plot. Note that the plot function converts monthly total returns into annualized total returns.

```
clf;
portfolioexamples_plot('Asset Risks and Returns', ...
    {'scatter', mrsk, mret, {'Market'}}, ...
    {'scatter', crsk, cret, {'Cash'}}, ...
    {'scatter', ersk, eret, {'Equal'}}, ...
    {'scatter', sqrt(diag(p.AssetCovar)), p.AssetMean, p.AssetList, '.r'});
```

## Set up a Portfolio Optimization Problem

Set up a "standard" or default mean-variance portfolio optimization problem with the setDefaultConstraints method that requires fully-invested long-only portfolios (non-negative weights that must sum to 1). Given this initial problem, estimate the efficient frontier with the methods estimateFrontier and estimatePortMoments, where estimateFrontier estimates efficient portfolios and estimatePortMoments estimates risks and returns for portfolios. The next figure overlays the efficient frontier on the previous plot.

```
p = setDefaultConstraints(p);
pwgt = estimateFrontier(p, 20);
```

```
[prsk, pret] = estimatePortMoments(p, pwgt);
% Plot efficient frontier
clf;
portfolioexamples_plot('Efficient Frontier', ...
    {'line', prsk, pret}, ...
    {'scatter', [mrsk, crsk, ersk], [mret, cret, eret], {'Market', 'Cash', 'Equal'}}, ...
    {'scatter', sqrt(diag(p.AssetCovar)), p.AssetMean, p.AssetList, '.r'});
```

## Illustrate the Tangent Line to the Efficient Frontier

Tobin's mutual fund theorem (Tobin 1958) says that the portfolio allocation problem can be viewed as a decision to allocate between a riskless asset and a risky portfolio.

In the mean-variance framework, cash can serve as a proxy for a riskless asset and an efficient portfolio on the efficient frontier serves as the risky portfolio such that any allocation between cash and this portfolio dominates all other portfolios on the efficient frontier. This portfolio is called a tangency portfolio because it is located at the point on the efficient frontier where a tangent line that originates at the riskless asset touches the efficient frontier.

Given that the Portfolio object already has the risk-free rate, obtain the tangent line by creating a copy of the Portfolio object with a budget constraint that permits allocation between $0 \%$ and $100 \%$ in cash. Since the Portfolio object is a value object, it is easy to create a copy by assigning the output of either the constructor or set methods to a new instance of the object. The plot shows the efficient frontier with Tobin's allocations that form the tangent line to the efficient frontier.

```
q = setBudget(p, 0, 1);
```

qwgt $=$ estimateFrontier (q, 20);
[qrsk, qret] = estimatePortMoments(q, qwgt);

```
% Plot efficient frontier with tangent line (0 to 1 cash)
```

clf;
portfolioexamples_plot('Efficient Frontier with Tangent Line', ...
\{'line', prsk, pret\}, ...
\{'line', qrsk, qret, [], [], 1\}, ...
\{'scatter', [mrsk, crsk, ersk], [mret, cret, eret], \{'Market', 'Cash', 'Equal'\}\}, ...
\{'scatter', sqrt(diag(p.AssetCovar)), p.AssetMean, p.AssetList, '.r'\});

Note that cash actually has a small risk so that the tangent line does not pass through the cash asset.

## Obtain Range of Risks and Returns

To obtain efficient portfolios with target values of either risk or return, it is necessary to obtain the range of risks and returns among all portfolios on the efficient frontier. This can be accomplished with the estimateFrontierLimits method.

```
[rsk, ret] = estimatePortMoments(p, estimateFrontierLimits(p));
display(rsk);
display(ret);
```

```
rsk =
    0.0348
    0.0903
ret =
    0.0094
    0.0179
```

The range of monthly portfolio returns is between $0.9 \%$ and $1.8 \%$ and the range for portfolio risks is between $3.5 \%$ and $9.0 \%$. In annualized terms, the range of portfolio returns is $11.2 \%$ to $21.5 \%$ and the range of portfolio risks is $12.1 \%$ to $31.3 \%$.

## Find a Portfolio with a Targeted Return and Targeted Risk

Given the range of risks and returns, it is possible to locate specific portfolios on the efficient frontier that have target values for return and risk using the methods estimateFrontierByReturn and estimateFrontierByRisk.

```
TargetReturn = 0.20; % input target annualized return and risk here
TargetRisk = 0.15;
% Obtain portfolios with targeted return and risk
awgt = estimateFrontierByReturn(p, TargetReturn/12);
[arsk, aret] = estimatePortMoments(p, awgt);
bwgt = estimateFrontierByRisk(p, TargetRisk/sqrt(12));
[brsk, bret] = estimatePortMoments(p, bwgt);
% Plot efficient frontier with targeted portfolios
clf;
portfolioexamples plot('Efficient Frontier with Targeted Portfolios', ...
    {'line', prsk, pret}, ...
    {'scatter', [mrsk, crsk, ersk], [mret, cret, eret], {'Market', 'Cash', 'Equal'}}, ...
    {'scatter', arsk, aret, {sprintf('%g%% Return',100*TargetReturn)}}, ...
    {'scatter', brsk, bret, {sprintf('%g%% Risk',100*TargetRisk)}}, ...
    {'scatter', sqrt(diag(p.AssetCovar)), p.AssetMean, p.AssetList, '.r'});
```

## Efficient Frontier with Targeted Portfolios

To see what these targeted portfolios look like, use the dataset object to set up "blotters" that contain the portfolio weights and asset names (which are obtained from the Portfolio object).

```
aBlotter = dataset({100*awgt(awgt > 0),'Weight'}, 'obsnames', p.AssetList(awgt > 0));
fprintf('Portfolio with %g%% Target Return\n', 100*TargetReturn);
disp(aBlotter);
bBlotter = dataset({100*bwgt(bwgt > 0),'Weight'}, 'obsnames', p.AssetList(bwgt > 0));
fprintf('Portfolio with %g%% Target Risk\n', 100*TargetRisk);
disp(bBlotter);
```

```
Portfolio with 20% Target Return

    PG 4.086
    UTX 10.281
    WMT 25.031
    XOM 12.69
```

## Transactions Costs

The Portfolio object makes it possible to account for transaction costs as part of the optimization problem. Although individual costs can be set for each asset, use the scalar expansion features of the Portfolio object's methods to set up uniform transaction costs across all assets and compare efficient frontiers with gross versus net portfolio returns.

```
BuyCost = 0.0020;
SellCost = 0.0020;
q = setCosts(p, BuyCost, SellCost);
qwgt = estimateFrontier(q, 20);
[qrsk, qret] = estimatePortMoments(q, qwgt);
% Plot efficient frontiers with gross and net returns
clf;
portfolioexamples_plot('Efficient Frontier with and without Transaction Costs', ...
    {'line', prsk, pret, {'Gross'}, ':b'}, ...
    {'line', qrsk, qret, {'Net'}}, ...
    {'scatter', [mrsk, crsk, ersk], [mret, cret, eret], {'Market', 'Cash', 'Equal'}}, ...
```

```
{'scatter', sqrt(diag(p.AssetCovar)), p.AssetMean, p.AssetList, '.r'});
```

## Turnover Constraint

In addition to transaction costs, the Portfolio object can handle turnover constraints. The following example demonstrates that a turnover constraint produces an efficient frontier in the neighborhood of an initial portfolio that may restrict trading. Moreover, the introduction of a turnover constraint often implies that multiple trades may be necessary to shift from an initial portfolio to an unconstrained efficient frontier. Consequently, the turnover constraint introduces a form of time diversification that can spread trades out over multiple time periods. In this example, note that the sum of purchases and sales from the estimateFrontier method confirms that the turnover constraint has been satisfied.

```
BuyCost = 0.0020;
SellCost = 0.0020;
Turnover = 0.2;
q = setCosts(p, BuyCost, SellCost);
q = setTurnover(q, Turnover);
[qwgt, qbuy, qsell] = estimateFrontier(q, 20);
[qrsk, qret] = estimatePortMoments(q, qwgt);
% Plot efficient frontier with turnover constraint
clf;
portfolioexamples_plot('Efficient Frontier with Turnover Constraint', ...
    {'line', prsk, pret, {'Unconstrained'}, ':b'}, ...
    {'line', qrsk, qret, {sprintf('%g%% Turnover', 100*Turnover)}}, ...
    {'scatter', [mrsk, crsk, ersk], [mret, cret, eret], {'Market', 'Cash', 'Equal'}}, ...
    {'scatter', sqrt(diag(p.AssetCovar)), p.AssetMean, p.AssetList, '.r'});
fprintf('Sum of Purchases by Portfolio along Efficient Frontier (Max. Turnover %g%%)\n
        100*Turnover);
disp(100*sum(qbuy));
fprintf('Sum of Sales by Portfolio along Efficient Frontier (Max. Turnover %g%%)\n', .
        100*Turnover);
disp(100*sum(qsell));

Columns 15 through 20
$20.0000 \quad 20.0000 \quad 20.0000 \quad 20.0000 \quad 20.0000 \quad 20.0000$

## Tracking-Error Constraint

The Portfolio object can handle tracking-error constraints, where tracking-error is the relative risk of a portfolio compared with a tracking portfolio. In this example, a sub-
collection of nine assets forms an equally-weighted tracking portfolio. The goal is to find efficient portfolios with tracking errors that are within 5\% of this tracking portfolio.

```
ii = [15, 16, 20, 21, 23, 25, 27, 29, 30]; % indexes of assets to include in tracking
TrackingError = 0.05/sqrt(12);
TrackingPort = zeros(30, 1);
TrackingPort(ii) = 1;
TrackingPort = (1/sum(TrackingPort))*TrackingPort;
q = setTrackingError(p, TrackingError, TrackingPort);
qwgt = estimateFrontier(q, 20);
[qrsk, qret] = estimatePortMoments(q, qwgt);
[trsk, tret] = estimatePortMoments(q, TrackingPort);
% Plot efficient frontier with tracking-error constraint
clf;
portfolioexamples_plot('Efficient Frontier with 5% Tracking-Error Constraint', ...
    {'line', prsk, pret, {'Unconstrained'}, ':b'}, ...
    {'line', qrsk, qret, {'Tracking'}}, ...
    {'scatter', [mrsk, crsk], [mret, cret], {'Market', 'Cash'}}, ...
    {'scatter', trsk, tret, {'Tracking'}, 'r'});
```

## Combined Turnover and Tracking-Error Constraints

This example illustrates the interactions that can occur with combined constraints. In this case, both a turnover constraint relative to an initial equal-weight portfolio and a tracking-error constraint relative to a tracking portfolio must be satisfied. The turnover constraint has maximum $30 \%$ turnover and the tracking-error constraint has maximum $5 \%$ tracking error. Note that the turnover to get from the initial portfolio to the tracking portfolio is $70 \%$ so that an upper bound of $30 \%$ turnover means that the efficient frontier will lie somewhere between the initial portfolio and the tracking portfolio.

```
Turnover = 0.3;
InitPort = (1/q.NumAssets)*ones(q.NumAssets, 1);
ii = [15, 16, 20, 21, 23, 25, 27, 29, 30]; % indexes of assets to include in tracking
```

```
TrackingError = 0.05/sqrt(12);
TrackingPort = zeros(30, 1);
TrackingPort(ii) = 1;
TrackingPort = (1/sum(TrackingPort))*TrackingPort;
q = setTurnover(q, Turnover, InitPort);
qwgt = estimateFrontier(q, 20);
[qrsk, qret] = estimatePortMoments(q, qwgt);
[trsk, tret] = estimatePortMoments(q, TrackingPort);
[ersk, eret] = estimatePortMoments(q, InitPort);
% Plot efficient frontier with combined turnover and tracking-error constraint
clf;
portfolioexamples_plot('Efficient Frontier with Turnover and Tracking-Error Constraint
    {'line', prsk, pret, {'Unconstrained'}, ':b'}, ...
    {'line', qrsk, qret, {'Turnover & Tracking'}}, ...
    {'scatter', [mrsk, crsk], [mret, cret], {'Market', 'Cash'}}, ...
    {'scatter', trsk, tret, {'Tracking'}, 'r'}, ...
    {'scatter', ersk, eret, {'Initial'}, 'b'});
```

## Maximize the Sharpe Ratio

The Sharpe ratio (Sharpe 1966) is a measure of return-to-risk that plays an important role in portfolio analysis. Specifically, a portfolio that maximizes the Sharpe ratio is also the tangency portfolio on the efficient frontier from the mutual fund theorem. The maximum Sharpe ratio portfolio is located on the efficient frontier with the method estimateMaxSharpeRatio and the dataset object is used to list the assets in this portfolio.

```
p = setInitPort(p, 0);
swgt = estimateMaxSharpeRatio(p);
[srsk, sret] = estimatePortMoments(p, swgt);
```

```
% Plot efficient frontier with portfolio that attains maximum Sharpe ratio
clf;
portfolioexamples_plot('Efficient Frontier with Maximum Sharpe Ratio Portfolio', ...
    {'line', prsk, pret}, ...
    {'scatter', srsk, sret, {'Sharpe'}}, ...
    {'scatter', [mrsk, crsk, ersk], [mret, cret, eret], {'Market', 'Cash', 'Equal'}}, ...
    {'scatter', sqrt(diag(p.AssetCovar)), p.AssetMean, p.AssetList, '.r'});
% Set up a dataset object that contains the portfolio that maximizes the Sharpe ratio
Blotter = dataset({100*swgt(swgt > 0),'Weight'}, 'obsnames', AssetList(swgt > 0));
fprintf('Portfolio with Maximum Sharpe Ratio\n');
disp(Blotter);

## Confirm that Maximum Sharpe Ratio is a Maximum

The following plot demonstrates that this portfolio (which is located at the dot on the plots) indeed maximizes the Sharpe ratio among all portfolios on the efficient frontier.

```
psratio = (pret - p.RiskFreeRate) ./ prsk;

\{'scatter', srsk, sret, \{'Sharpe'\}\}, ...
$\left\{{ }^{\prime}\right.$ scatter', [mrsk, crsk, ersk], [mret, cret, eret], \{'Market', 'Cash', 'Equal'\}\}, ... \{'scatter', sqrt(diag(p.AssetCovar)), p.AssetMean, p.AssetList, '.r'\});

## Dollar-Neutral Hedge-Fund Structure

To illustrate how to use the portfolio optimization tools in hedge fund management, two popular strategies with dollar-neutral and 130-30 portfolios are examined. The dollarneutral strategy invests equally in long and short positions such that the net portfolio position is 0 . Such a portfolio is said to be dollar-neutral.

To set up a dollar-neutral portfolio, start with the "standard" portfolio problem and set the maximum exposure in long and short positions in the variable Exposure. The bounds for individual asset weights are plus or minus Exposure. Since the net position must be dollar-neutral, the budget constraint is 0 and the initial portfolio must be 0 . Finally, the one-way turnover constraints provide the necessary long and short restrictions to prevent "double-counting" of long and short positions. The blotter shows
the portfolio weights for the dollar-neutral portfolio that maximizes the Sharpe ratio. The long and short positions are obtained from the buy and sell trades relative to the initial portfolio.

```
Exposure = 1;
q = setBounds(p, -Exposure, Exposure);
q = setBudget(q, 0, 0);
q = setOneWayTurnover(q, Exposure, Exposure, 0);
[qwgt, qlong, qshort] = estimateFrontier(q, 20);
[qrsk, qret] = estimatePortMoments(q, qwgt);
[qswgt, qslong, qsshort] = estimateMaxSharpeRatio(q);
[qsrsk, qsret] = estimatePortMoments(q, qswgt);
% Plot efficient frontier for a dollar-neutral fund structure with tangency portfolio

## 130/30 Fund Structure

Finally, the turnover constraints can be used to set up a 130-30 portfolio structure, which is a structure with a net long position but permits leverage with long and short positions up to a maximum amount of leverage. In the case of a 130-30 portfolio, the leverage is $30 \%$.

To set up a 130-30 portfolio, start with the "standard" portfolio problem and set the maximum value for leverage in the variable Leverage. The bounds for individual asset weights range between -Leverage and $1+$ Leverage. Since the net position must be long, the budget constraint is 1 and, once again, the initial portfolio is 0. Finally, the oneway turnover constraints provide the necessary long and short restrictions to prevent "double-counting" of long and short positions. The blotter shows the portfolio weights for
the 130-30 portfolio that maximizes the Sharpe ratio. The long and short positions are obtained from the buy and sell trades relative to the initial portfolio.

```
Leverage = 0.3;
q = setBounds(p, -Leverage, 1 + Leverage);
q = setBudget(q, 1, 1);
q = setOneWayTurnover(q, 1 + Leverage, Leverage);
[qwgt, qbuy, qsell] = estimateFrontier(q, 20);
[qrsk, qret] = estimatePortMoments(q, qwgt);
[qswgt, qslong, qsshort] = estimateMaxSharpeRatio(q);
[qsrsk, qsret] = estimatePortMoments(q, qswgt);

\section*{Asset Allocation Case Study}

This example shows how to set up a basic asset allocation problem that uses meanvariance portfolio optimization to estimate efficient portfolios.

Step 1. Defining the portfolio problem.
Suppose that you want to manage an asset allocation fund with four asset classes: bonds, large-cap equities, small-cap equities, and emerging equities. The fund is long-only with no borrowing or leverage, should have no more than \(85 \%\) of the portfolio in equities, and no more than \(35 \%\) of the portfolio in emerging equities. The cost to trade the first three assets is 10 basis points annualized and the cost to trade emerging equities is four times higher. Finally, you want to ensure that average turnover is no more than \(15 \%\). To solve this problem, you will set up a basic mean-variance portfolio optimization problem and then slowly introduce the various constraints on the problem to get to a solution.

To set up the portfolio optimization problem, start with basic definitions of known quantities associated with the structure of this problem. Each asset class is assumed to have a tradeable asset with a real-time price. Such assets can be, for example, exchangetraded funds (ETFs). The initial portfolio with holdings in each asset that has a total of \(\$ 7.5\) million along with an additional cash position of \(\$ 60,000\). These basic quantities and the costs to trade are set up in the following variables with asset names in the cell array Asset, current prices in the vector Price, current portfolio holdings in the vector Holding, and transaction costs in the vector UnitCost.

To analyze this portfolio, you can set up a blotter in a dataset object to help track prices, holdings, weights, and so forth. In particular, you can compute the initial portfolio weights and maintain them in a new blotter field called InitPort.
```

Asset = { 'Bonds', 'Large-Cap Equities', 'Small-Cap Equities', 'Emerging Equities' };
Price = [ 52.4; 122.7; 35.2; 46.9 ];
Holding = [ 42938; 24449; 42612; 15991 ];
UnitCost = [ 0.001; 0.001; 0.001; 0.004 ];
Blotter = dataset({Price, 'Price'}, {Holding, 'InitHolding'},'obsnames',Asset);
Wealth = sum(Blotter.Price .* Blotter.InitHolding);
Blotter.InitPort = (1/Wealth)*(Blotter.Price .* Blotter.InitHolding);
Blotter.UnitCost = UnitCost;
disp(Blotter);

|  | Price | InitHolding | InitPort | UnitCost |
| :--- | ---: | :--- | :--- | :--- |
| Bonds | 52.4 | 42938 | 0.3 | 0.001 |

```
\begin{tabular}{lrrrr} 
Large-Cap Equities & 122.7 & 24449 & 0.4 & 0.001 \\
Small-Cap Equities & 35.2 & 42612 & 0.2 & 0.001 \\
Emerging Equities & 46.9 & 15991 & 0.1 & 0.004
\end{tabular}

\section*{Step 2. Simulating asset prices.}

Since this is a hypothetical example, to simulate asset prices from a given mean and covariance of annual asset total returns for the asset classes, the portsim fuction is used to create asset returns with the desired mean and covariance. Specifically, portsim is used to simulate five years of monthly total returns and then plotted to show the log of the simulated total return prices

The mean and covariance of annual asset total returns are maintained in the variables AssetMean and AssetCovar. The simulated asset total return prices (which are compounded total returns) are maintained in the variable Y. All initial asset total return prices are normalized to 1 in this example.
```

AssetMean = [ 0.05; 0.1; 0.12; 0.18 ];
AssetCovar = [ 0.0064 0.00408 0.00192 0;
0.00408 0.0289 0.0204 0.0119;
0.00192 0.0204 0.0576 0.0336;
0 0.0119 0.0336 0.1225 ];
X = portsim(AssetMean'/12, AssetCovar/12, 60); % monthly total returns for 5 years (60
[Y, T] = ret2tick(X, [], 1/12); % form total return prices
plot(T, log(Y));
title('\bfSimulated Asset Class Total Return Prices');
xlabel('Year');
ylabel('Log Total Return Price');
legend(Asset,'Location','best');

```

\section*{Step 3. Setting up the Porffolio object.}

To explore portfolios on the efficient frontier, set up a Portfolio object using these specifications:
- Portfolio weights are nonnegative and sum to 1.
- Equity allocation is no more than \(85 \%\) of the portfolio.
- Emerging equity is no more than \(35 \%\) of the portfolio.

These specifications are incorporated into the Portfolio object p in the following sequence of using functions that starts with using the Portfolio function.

1 The specification of the initial portfolio from Blotter gives the number of assets in your universe so you do not need to specify the NumAssets property directly. Next, set up default constraints (long-only with a budget constraint). In addition, set up the group constraint that imposes an upper bound on equities in the portfolio (equities are identified in the group matrix with 1 's) and the upper bound constraint on emerging equities. Although you could have set the upper bound on emerging equities using the setBounds function, notice how the addGroups function is used to set up this constraint.
2 To have a fully specified mean-variance portfolio optimization problem, you must specify the mean and covariance of asset returns. Since starting with these moments in the variables AssetMean and AssetCovar, you can use the setAssetMoments function to enter these variables into your Portfolio object (remember that you are assuming that your raw data are monthly returns which is why you divide your annual input moments by 12 to get monthly returns).
3 Use the total return prices with the estimateAssetMoments function with a specification that your data in Y are prices, and not returns, to estimate asset return moments for your Portfolio object.
4 Although the returns in your Portfolio object are in units of monthly returns, and since subsequent costs are annualized, it is convenient to specify them as annualized total returns with this direct transformation of the AssetMean and AssetCovar properties of your Portfolio object p.
5 Display the Portfolio object p.
```

p = Portfolio('Name', 'Asset Allocation Portfolio', ...
'AssetList', Asset, 'InitPort', Blotter.InitPort);
p = setDefaultConstraints(p);
p = setGroups(p, [ 0, 1, 1, 1 ], [], 0.85);
p = addGroups(p, [ 0, 0, 0, 1 ], [], 0.35);
p = setAssetMoments(p, AssetMean/12, AssetCovar/12);
p = estimateAssetMoments(p, Y, 'DataFormat', 'Prices');
p.AssetMean = 12*p.AssetMean;
p.AssetCovar = 12*p.AssetCovar;
display(p);
p =

```
```

```

\section*{Step 4. Validate the portfolio problenm.}

An important step in portfolio optimization is to validate that the portfolio problem is feasible and the main test is to ensure that the set of portfolios is nonempty and bounded. Use the estimateBounds function to determine the bounds for the portfolio set. In this case, Since both lb and ub are finite, the set is bounded.
```

[lb, ub] = estimateBounds(p);
display([lb, ub]);
ans =

```
\begin{tabular}{ll}
0.1500 & 1.0000 \\
0.0000 & 0.8500 \\
0.0000 & 0.8500 \\
0.0000 & 0.3500
\end{tabular}

\section*{Step 5. Plotting the efficient frontier.}

Given the constructed Portfolio object, use the plotFrontier function to view the efficient frontier. Instead of using the default of 10 portfolios along the frontier, you can display the frontier with 40 portfolios. Notice gross efficient portfolio returns fall between approximately \(6 \%\) and \(16 \%\) per years.
```

plotFrontier(p, 40);

```

Step 6. Evaluating gross vs. net portfolio returns.
The Portfolio object \(p\) does not include transaction costs so that the portfolio optimization problem specified in \(p\) uses gross portfolio return as the return proxy. To handle net returns, create a second Portfolio object q that includes transaction costs.
```

q = setCosts(p, UnitCost, UnitCost);

```
display(q);
\(q=\)
Portfolio with properties:
```

```

\section*{Step 7. Analyzing descriptive properties of the Porffolio structures.}

To be more concrete about the ranges of efficient portfolio returns and risks, use the estimateFrontierLimits function to obtain portfolios at the endpoints of the efficient frontier. Given these portfolios, compute their moments using the estimatePortMoments function. The following code generates a table that lists the risk and return of the initial portfolio as well as the gross and net moments of portfolio returns for the portfolios at the endpoints of the efficient frontier:
```

[prsk0, pret0] = estimatePortMoments(p, p.InitPort);
pret = estimatePortReturn(p, p.estimateFrontierLimits);
qret = estimatePortReturn(q, q.estimateFrontierLimits);

```
```

fprintf('Annualized Portfolio Returns ...\n');
fprintf(' %6s %6s\n','Gross','Net');
fprintf('Initial Portfolio Return %6.2f %% %6.2f %%\n',100*pret0,100*pret0)
fprintf('Minimum Efficient Portfolio Return %6.2f %% %6.2f %%\n',100*pret(1),100*qret
fprintf('Maximum Efficient Portfolio Return %6.2f %% %6.2f %%\n',100*pret(2),100*qret
%
% The results shows that the cost to trade ranges from 14 to 19 basis
% points to get from the current portfolio to the efficient portfolios at
% the endpoints of the efficient frontier (these costs are the difference
% between gross and net portfolio returns.) In addition, notice that the
% maximum efficient portfolio return (13%) is less than the maximum asset
% return (18%) due to the constraints on equity allocations.

```

Annualized Portfolio Returns ...
\begin{tabular}{lrr} 
& Gross & Net \\
Initial Portfolio Return & \(9.70 \%\) & \(9.70 \%\) \\
Minimum Efficient Portfolio Return & \(5.90 \%\) & \(5.77 \%\) \\
Maximum Efficient Portfolio Return & \(13.05 \%\) & \(12.86 \%\)
\end{tabular}

Step 8. Obtaining a Portfolio at the specified return level on the efficient frontier.
A common approach to select efficient portfolios is to pick a portfolio that has a desired fraction of the range of expected portfolio returns. To obtain the portfolio that is \(30 \%\) of the range from the minimum to maximum return on the efficient frontier, obtain the range of net returns in qret using the Portfolio object q and interpolate to obtain a \(30 \%\) level with the interp1 function to obtain a portfolio qwgt.
```

Level = 0.3;
qret = estimatePortReturn(q, q.estimateFrontierLimits);
qwgt = estimateFrontierByReturn(q, interp1([0, 1], qret, Level));
[qrsk, qret] = estimatePortMoments(q, qwgt);
fprintf('Portfolio at %g%% return level on efficient frontier ...\n',100*Level);
fprintf('%10s %10s\n','Return','Risk');
fprintf('%10.2f %10.2f\n',100*qret,100*qrsk);
display(qwgt);
% The target portfolio that is 30% of the range from minimum to maximum net
% returns has a return of 7.9% and a risk of 9.1%.
Portfolio at 30% return level on efficient frontier ...
Return Risk
7.90 9.09

```
qwgt =
0.6252
0.1856
0.0695
0.1198

\section*{Step 9. Obtaining a Porffolio at the specified risk levels on the efficient frontier.}

Although you could accept this result, suppose that you want to target values for portfolio risk. Specifically, suppose that you have a conservative target risk of \(10 \%\), a moderate target risk of \(15 \%\), and an aggressive target risk of \(20 \%\) and you want to obtain portfolios that satisfy each risk target. Use the estimateFrontierByRisk function to obtain targeted risks specified in the variable TargetRisk. The resultant three efficient portfolios are obtained in qwgt.
```

TargetRisk = [ 0.10; 0.15; 0.20 ];
qwgt = estimateFrontierByRisk(q, TargetRisk);
display(qwgt);
%
% Use the estimatePortRisk function to compute
% the portfolio risks for the three portfolios to confirm that the target
% risks have been attained:
display(estimatePortRisk(q, qwgt));
% Suppose that you want to shift from the current portfolio to the moderate
% portfolio. You can estimate the purchases and sales to get to this
% portfolio:
[qwgt, qbuy, qsell] = estimateFrontierByRisk(q, 0.15);
% If you average the purchases and sales for this portfolio, you can see
% that the average turnover is 17%, which is greater than the target of
% 15%:
disp(sum(qbuy + qsell)/2)
% Since you also want to ensure that average turnover is no more than 15%,
% you can add the average turnover constraint to the Portfolio object:
q = setTurnover(q, 0.15);

```
```

[qwgt, qbuy, qsell] = estimateFrontierByRisk(q, 0.15);
\% You can enter the estimated efficient portfolio with purchases and sales into the Bld
qbuy (abs (qbuy) < 1.0e-5) = 0;
qsell(abs(qsell) < $1.0 \mathrm{e}-5)=0$; \% zero out near 0 trade weights
Blotter.Port = qwgt;
Blotter. Buy = qbuy;
Blotter.Sell = qsell;
display(Blotter);
\% The Buy and Sell elements of the Blotter are changes in portfolio weights that
\% must be converted into changes in portfolio holdings to determine
\% the trades. Since you are working with net portfolio returns, you
\% must first compute the cost to trade from your initial portfolio to
\% the new portfolio. This can be accomplished as follows:
TotalCost $=$ Wealth * sum(Blotter.UnitCost .* (Blotter.Buy + Blotter.Sell))
\% The cost to trade is $\$ 5,625$, so that, in general, you would have to
\% adjust your initial wealth accordingly before setting up your new
\% portfolio weights. However, to keep the analysis simple, note that you
$\%$ have sufficient cash $(\$ 60,0000)$ set aside to pay the trading costs and
\% that you will not touch the cash position to build up any positions in
\% your portfolio. Thus, you can populate your blotter with the new
\% portfolio holdings and the trades to get to the new portfolio without
\% making any changes in your total invested wealth. First, compute portfolio holding:
Blotter. Holding = Wealth * (Blotter.Port ./ Blotter.Price);
\% Compute number of shares to Buy and Sell in your Blotter:
Blotter.BuyShare = Wealth * (Blotter.Buy ./ Blotter.Price);
Blotter.SellShare = Wealth * (Blotter.Sell ./ Blotter.Price);
\% Notice how you used an add-hoc truncation rule to obtain unit numbers of
\% shares to buy and sell. Clean up the blotter by removing the unit costs
\% and the buy and sell portfolio weights:
Blotter. Buy = [];
Blotter.Sell = [];
Blotter.UnitCost = [];

\section*{Portfolio Optimization Against a Benchmark}

Required products: MATLAB, Financial Toolbox, Optimization Toolbox, and Statistics and Machine Learning Toolbox.

This example shows how to perform portfolio optimization using the Portfolio object in Financial Toolbox. The example, in particular, demonstrates optimizing a portfolio to maximize the information ratio relative to a market benchmark.

Step 1. Import historical data using MATLAB.
Import historical prices for the asset universe and the Dow Jones Industrial Average (DJI) market benchmark. The data is imported into a dataset array from an Microsoft \({ }^{\text {® }}\) Excel spreadsheet using the MATLAB xlsread function.
```

data = dataset('xlsfile', 'dowPortfolio.xlsx');
data(1:10,:)
ans =

| Dates | DJI | AA | AIG | AXP | BA | C | CAT | DD | DIS | GE |

\hline
\end{tabular}

Separate the asset names, asset prices, and DJI benchmark prices from the dataset array. The visualization shows the evolution of all the asset prices normalized to start at unity.
```

dates = datenum(data.Dates);
benchPrice = data.DJI;
assetNames = data.Properties.VarNames(3:2:end);
assetPrice = double( data(:,3:2:end) );
assetP = bsxfun( @rdivide, assetPrice, assetPrice(1,:) );
benchmarkP = benchPrice / benchPrice(1);
plot(dates, assetP);
hold on;
plot(dates, benchmarkP, 'LineWidth', 3, 'Color', 'k');
hold off;
xlabel('Date');
ylabel('Normalized Price');
title('Normalized Asset Prices and Benchmark');
datetick('x');
grid on;

```

The bold line indicates the DJIA market benchmark.

\section*{Step 2. Compute returns and risk-adjusted returns.}

Calculate the return series from the price series and compute asset moments (historical returns and standard deviations). The visualization shows a scatter plot of the riskreturn characteristics of all the assets and the DJI market benchmark.
```

benchReturn = tick2ret(benchPrice);
assetReturn = tick2ret(assetPrice);
activReturn = assetReturn - repmat(benchReturn, 1, size(assetReturn,2));

```

Calculate historical statistics and plot the risk returns.
```

benchRetn = mean(benchReturn);
benchRisk = std(benchReturn);
assetRetn = mean(assetReturn);
assetRisk = std(assetReturn);
scale = 252;
assetRiskR = sqrt(scale) * assetRisk;
benchRiskR = sqrt(scale) * benchRisk;
assetReturnR = scale * assetRetn;
benchReturnR = scale * benchRetn;

```
```

scatter(assetRiskR, assetReturnR, 6, 'm', 'Filled');
hold on
scatter(benchRiskR, benchReturnR, 6, 'g', 'Filled');
for k = 1:length(assetNames)
text(assetRiskR(k) + 0.005, assetReturnR(k), assetNames{k}, 'FontSize', 8);
end
text(benchRiskR + 0.005, benchReturnR, 'Benchmark', 'Fontsize', 8);
hold off;
xlabel('Risk (Std Dev of Return)');
ylabel('Expected Return');
grid on;

```

\section*{Step 3. Set up a porifolio optimization.}

Set up a portfolio optimization problem by populating the Portfolio object. In this example, the expected returns and covariances of the assets in the portfolio are set to their historical values.
p = Portfolio('AssetList', assetNames)
\(p=\)

\section*{Step 4. Compute the efficient frontier using the Portfolio object.}

Compute the mean-variance efficient frontier of 20 optimal portfolios. Visualize the frontier over the risk-return characteristics of the individual assets. Furthermore, calculate and visualize the information ratio for each portfolio along the frontier.
```

wAct = estimateFrontier(pAct, 20); % Estimate weights
[portRiskAct, portRetnAct] = estimatePortMoments(pAct, wAct); % Get risk and return
if isa(p,'Portfolio')
% Extract asset moments \& names
[assetReturnP, assetCovarP] = getAssetMoments(p);
assetRiskP = sqrt(diag(assetCovarP));
assetNames = p.AssetList;
else
assetNames = p;
end
if isa(p,'Portfolio')
% Extract asset moments \& names
[assetReturnP, assetCovarP] = getAssetMoments(p);
assetRiskP = sqrt(diag(assetCovarP));
assetNamesP = p.AssetList;
else
assetNamesP = p
end
% Rescale
assetRiskT = sqrt(scale) * assetRiskP;
portRiskT = sqrt(scale) * portRiskAct;
assetReturnT = scale * assetReturnP;
portReturnT = scale * portRetnAct;

```
```

subplot(2,1,1);
scatter(assetRiskT, assetReturnT, 6, 'm', 'Filled');
hold on
for k = 1:length(assetNames)
text(assetRisk(k) + 0.005, assetReturn(k), assetNames{k}, 'FontSize', 8);
end
plot(portRiskT, portReturnT, 'bo-', 'MarkerFaceColor', 'b');
hold off;
xlabel('Risk (Std Dev of Active Return)');
ylabel('Expected Active Return');
grid on;
subplot(2,1,2);
plot(portRiskT, portReturnT./portRiskT, 'bo-', 'MarkerFaceColor', 'b');
xlabel('Risk (Std Dev of Active Return)');
ylabel('Information Ratio');
grid on;

```

\section*{Step 5. Perform information ratio maximization using Optimization Toolbox.}

Run a hybrid optimization to find the portfolio along the frontier with the maximum information ratio. The information ratio is the ratio of relative return to relative risk (known as "tracking error"). Whereas the Sharpe ratio looks at returns relative to a
riskless asset, the information ratio is based on returns relative to a risky benchmark, in this case the DJI benchmark. This is done by running an optimization that finds the optimal return constraint for which the portfolio optimization problem returns the maximum information ratio portfolio. The portfolio optimization functions are called from an objective function infoRatioTargetReturn that is optimized by the Optimization Toolbox function fminbnd. The function infoRatioTargetReturn calculates a minimum (active) risk portfolio given a target active return.
```

type infoRatioTargetReturn
function [infoRatio, wts] = infoRatioTargetReturn(targetReturn, portObj)
% Calculate information ratio for a target-return portfolio along the
% efficient frontier
wts = estimateFrontierByReturn(portObj, targetReturn);
portRiskAct = estimatePortRisk(portObj, wts);
infoRatio = targetReturn/portRiskAct;

```

The infoRatioTargetReturn function is called as an objective function in an optimization routine (fminbnd) that seeks to find the target return that maximizes the information ratio and minimizes a negative information ratio.
```

objFun = @(targetReturn) -infoRatioTargetReturn(targetReturn, pAct);
options = optimset('TolX', 1.Oe-8);
[optPortRetn, ~, exitflag] = fminbnd(objFun, 0, max(portRetnAct), options);

```

Get weights, information ratio, and risk return for the optimal portfolio
```

[optInfoRatio, optWts] = infoRatioTargetReturn(optPortRetn, pAct);
optPortRisk = estimatePortRisk(pAct, optWts)
optPortRisk =

```
    0.0040

\section*{Step 6. Plot the optimal porifolio.}

Verify that the portfolio found is indeed the maximum information-ratio portfolio.
```

if isa(p,'Portfolio')
% Extract asset moments \& names
[assetReturnQ, assetCovarQ] = getAssetMoments(p);
assetRiskQ = sqrt(diag(assetCovarQ));
assetNamesQ = p.AssetList;
else
assetNamesQ = p;
end
% Rescale
assetRiskS = sqrt(scale) * assetRiskQ;
portRiskS = sqrt(scale) * portRiskAct;
optPortRiskS = sqrt(scale) * optPortRisk;
assetReturnS = scale * assetReturnQ;

```
```

    portReturnS = scale * portRetnAct;
    optPortReturnS = scale * optPortRetn;
subplot(2,1,1);
scatter(assetRiskS, assetReturnS, 6, 'm', 'Filled');
hold on
for k = 1:length(assetNames)
text(assetRisk(k) + 0.005, assetReturn(k), assetNames{k}, 'FontSize', 8);
end
plot(portRiskS, portReturnS, 'bo-', 'MarkerSize', 4, 'MarkerFaceColor', 'b');
plot(optPortRiskS, optPortReturnS, 'ro-', 'MarkerFaceColor', 'r');
hold off;
xlabel('Risk (Std Dev of Active Return)');
ylabel('Expected Active Return');
grid on;
subplot(2,1,2);
plot(portRiskS, portReturnS./portRiskS, 'bo-', 'MarkerSize', 4, 'MarkerFaceColor', 'b');
hold on
plot(optPortRiskS, optPortReturnS./optPortRiskS, 'ro-', 'MarkerFaceColor', 'r');
hold off;
xlabel('Risk (Std Dev of Active Return)');
ylabel('Information Ratio');
title('Information Ratio with Optimal Portfolio');
grid on;

```

\section*{Step 7. Display the porifolio optimization solution.}

Display the portfolio optimization solution.
```

assetIndx = optWts > .001;
results = dataset({assetNames(assetIndx)', 'Asset'}, {optWts(assetIndx)*100, 'Weights'});
disp('Maximum Information Ratio Portfolio:');
disp(results);
fprintf('Max. Info Ratio portfolio has expected active return %0.2f%%\n', optPortRetn*25200);
fprintf('Max. Info Ratio portfolio has expected tracking error of %0.2f%%\n', optPortRisk*sqrt(252)*100);
Maximum Information Ratio Portfolio:

| Asset | Weights |
| :--- | :--- |
| 'AA' | 1.539 |
| 'AXP' | 0.3555 |
| 'C' | 9.6533 |
| 'DD' | 4.0684 |
| 'HPQ' | 17.698 |
| 'JPM ' | 21.565 |
| 'MCD' | 26.736 |
| 'MO' | 13.648 |
| 'MSFT' | 2.6858 |
| 'UTX' | 2.0509 |

```

Max. Info Ratio portfolio has expected active return 12.14\%
Max. Info Ratio portfolio has expected tracking error of \(6.32 \%\)

\section*{Portfolio Optimization Problems}

Portfolio optimization problems involve identifying portfolios that satisfy three criteria:
- Minimize a proxy for risk.
- Match or exceed a proxy for return.
- Satisfy basic feasibility requirements.

Portfolios are points from a feasible set of assets that constitute an asset universe. A portfolio specifies either holdings or weights in each individual asset in the asset universe. The convention is to specify portfolios in terms of weights, although the portfolio optimization tools work with holdings as well.

The set of feasible portfolios is necessarily a nonempty, closed, and bounded set. The proxy for risk is a function that characterizes either the variability or losses associated with portfolio choices. The proxy for return is a function that characterizes either the gross or net benefits associated with portfolio choices. The terms "risk" and "risk proxy" and "return" and "return proxy" are interchangeable. The fundamental insight of Markowitz (see "Portfolio Optimization" on page A-10) is that the goal of the portfolio choice problem is to seek minimum risk for a given level of return and to seek maximum return for a given level of risk. Portfolios satisfying these criteria are efficient portfolios and the graph of the risks and returns of these portfolios forms a curve called the efficient frontier.

\section*{Porffolio Problem Specification}

To specify a portfolio optimization problem, you need the following:
- Proxy for portfolio return ( \(\mu\) )
- Proxy for portfolio risk ( \(\Sigma\) )
- Set of feasible portfolios ( \(X\) ), called a portfolio set

Financial Toolbox has three objects to solve specific types of portfolio optimization problems:
- The Portfolio object (Using Portfolio Objects) supports mean-variance portfolio optimization (see Markowitz [46], [47] at "Portfolio Optimization" on page A-10). This object has either gross or net portfolio returns as the return proxy, the variance of portfolio returns as the risk proxy, and a portfolio set that is any combination of the specified constraints to form a portfolio set.
- The PortfolioCVaR object (Using PortfolioCVaR Objects) implements what is known as conditional value-at-risk portfolio optimization (see Rockafellar and Uryasev [48], [49] at "Portfolio Optimization" on page A-10), which is generally referred to as CVaR portfolio optimization. CVaR portfolio optimization works with the same return proxies and portfolio sets as mean-variance portfolio optimization but uses conditional value-at-risk of portfolio returns as the risk proxy.
- The PortfolioMAD object (Using PortfolioMAD Objects) implements what is known as mean-absolute deviation portfolio optimization (see Konno and Yamazaki [50] at "Portfolio Optimization" on page A-10), which is generally referred to as MAD portfolio optimization. MAD portfolio optimization works with the same return proxies and portfolio sets as mean-variance portfolio optimization but uses meanabsolute deviation portfolio returns as the risk proxy.

\section*{Return Proxy}

The proxy for portfolio return is a function \(\mu: X \rightarrow R\) on a portfolio set \(X \subset R^{n}\) that characterizes the rewards associated with portfolio choices. In most cases, the proxy for portfolio return has two general forms, gross and net portfolio returns. Both portfolio return forms separate the risk-free rate \(r_{0}\) so that the portfolio \(x \in X\) contains only risky assets.

Regardless of the underlying distribution of asset returns, a collection of \(S\) asset returns \(y_{1}, \ldots, y_{S}\) has a mean of asset returns
\[
m=\frac{1}{S} \sum_{s=1}^{S} y_{s}
\]
and (sample) covariance of asset returns
\[
C=\frac{1}{S-1} \sum_{s=1}^{S}\left(y_{s}-m\right)\left(y_{s}-m\right)^{T}
\]

These moments (or alternative estimators that characterize these moments) are used directly in mean-variance portfolio optimization to form proxies for portfolio risk and return.

\section*{Gross Portfolio Returns}

The gross portfolio return for a portfolio \(x \in X\) is
\[
\mu(x)=r_{0}+\left(m-r_{0} 1\right)^{T} x,
\]
where:
\(r_{0}\) is the risk-free rate (scalar).
\(m\) is the mean of asset returns ( \(n\) vector).
If the portfolio weights sum to 1 , the risk-free rate is irrelevant. The properties in the Portfolio object to specify gross portfolio returns are:
- RiskFreeRate for \(r_{0}\)
- AssetMean for \(m\)

\section*{Net Porifolio Returns}

The net portfolio return for a portfolio \(x \in X\) is
\[
\mu(x)=r_{0}+\left(m-r_{0} 1\right)^{T} x-b^{T} \max \left\{0, x-x_{0}\right\}-s^{T} \max \left\{0, x_{0}-x\right\},
\]
where:
\(r_{0}\) is the risk-free rate (scalar).
\(m\) is the mean of asset returns ( \(n\) vector).
\(b\) is the proportional cost to purchase assets ( \(n\) vector).
\(s\) is the proportional cost to sell assets ( \(n\) vector).
You can incorporate fixed transaction costs in this model also. Though in this case, it is necessary to incorporate prices into such costs. The properties in the Portfolio object to specify net portfolio returns are:
- RiskFreeRate for \(r_{0}\)
- AssetMean for \(m\)
- InitPort for \(x_{0}\)
- BuyCost for \(b\)
- SellCost for \(s\)

\section*{Risk Proxy}

The proxy for portfolio risk is a function \(\Sigma: X \rightarrow R\) on a portfolio set \(X \subset R^{n}\) that characterizes the risks associated with portfolio choices.

\section*{Variance}

The variance of portfolio returns for a portfolio \(x \in X\) is
\[
\Sigma(x)=x^{T} C x
\]
where \(C\) is the covariance of asset returns (n-by-n positive-semidefinite matrix).
The property in the Portfolio object to specify the variance of portfolio returns is AssetCovar for \(C\).

Although the risk proxy in mean-variance portfolio optimization is the variance of portfolio returns, the square root, which is the standard deviation of portfolio returns, is often reported and displayed. Moreover, this quantity is often called the "risk" of the portfolio. For details, see Markowitz ("Portfolio Optimization" on page A-10).

\section*{Conditional Value-at-Risk}

The conditional value-at-risk for a portfolio \(x \in X\), which is also known as expected shortfall, is defined as
\[
C V a R_{\alpha}(x)=\frac{1}{1-\alpha} \int_{f(x, y) \geq V a R_{\alpha}(x)} f(x, y) p(y) d y
\]
where:
\(\alpha\) is the probability level such that \(0<\alpha<1\).
\(f(x, y)\) is the loss function for a portfolio \(x\) and asset return \(y\).
\(p(y)\) is the probability density function for asset return \(y\).
\(V a R_{a}\) is the value-at-risk of portfolio \(x\) at probability level \(a\)
The value-at-risk is defined as
\[
\operatorname{VaR}_{\alpha}(x)=\min \{\gamma: \operatorname{Pr}[f(x, Y) \leq \gamma] \geq \alpha\} .
\]

An alternative formulation for CVaR has the form:
\[
C V a R_{\alpha}(x)=\operatorname{VaR}_{\alpha}(x)+\frac{1}{1-\alpha} \int_{R^{n}} \max \left\{0,\left(f(x, y)-\operatorname{Va} R_{\alpha}(x)\right)\right\} p(y) d y
\]

The choice for the probability level \(a\) is typically 0.9 or 0.95 . Choosing \(a\) implies that the value-at-risk \(\operatorname{Va} R_{a}(x)\) for portfolio \(x\) is the portfolio return such that the probability of portfolio returns falling below this level is \((1-\alpha)\). Given \(V a R_{a}(x)\) for a portfolio \(x\), the conditional value-at-risk of the portfolio is the expected loss of portfolio returns above the value-at-risk return.

Note: Value-at-risk is a positive value for losses so that the probability level \(\alpha\) indicates the probability that portfolio returns are below the negative of the value-at-risk.

The risk proxy for CVaR portfolio optimization is \(C \operatorname{Va} R_{a}(x)\) for a given portfolio \(x \in X\) and \(\alpha \in(0,1)\). The value-at-risk, or VaR , for a given probability level is estimated whenever CVaR is estimated.

In addition, keep in mind that VaR and CVaR are sample estimators for VaR and CVaR based on the given scenarios. Better scenario samples yield more reliable estimates of VaR and CVaR.

For more information, see Rockafellar and Uryasev [48], [49] at "Portfolio Optimization" on page A-10.

\section*{Mean Absolute-Deviation}

The mean-absolute deviation (MAD) for a portfolio \(x \in X\) is defined as
\[
\sum(x)=\frac{1}{S} \sum_{s=1}^{S}\left|\left(y_{s}-m\right)^{T} x\right|
\]
where:
\(y_{s}\) are asset returns with scenarios \(s=1, \ldots S\) ( \(S\) collection of \(n\) vectors).
\(f(x, y)\) is the loss function for a portfolio \(x\) and asset return \(y\).
\(m\) is the mean of asset returns ( \(n\) vector).
such that
\[
m=\frac{1}{S} \sum_{s=1}^{S} y_{s}
\]

For more information, see Konno and Yamazaki [50] at "Portfolio Optimization" on page A-10.

\section*{Porffolio Set for Optimization Using PorffolioCVaR Object}

The final element for a complete specification of a portfolio optimization problem is the set of feasible portfolios, which is called a portfolio set. A portfolio set \(X \subset R^{n}\) is specified by construction as the intersection of sets formed by a collection of constraints on portfolio weights. A portfolio set necessarily and sufficiently must be a nonempty, closed, and bounded set.

When setting up your portfolio set, ensure that the portfolio set satisfies these conditions. The most basic or "default" portfolio set requires portfolio weights to be nonnegative (using the lower-bound constraint) and to sum to 1 (using the budget constraint). The most general portfolio set handled by the portfolio optimization tools can have any of these constraints:
- Linear inequality constraints
- Linear equality constraints
- Bound constraints
- Budget constraints
- Group constraints
- Group ratio constraints
- Average turnover constraints
- One-way turnover constraints

\section*{Linear Inequality Constraints}

Linear inequality constraints are general linear constraints that model relationships among portfolio weights that satisfy a system of inequalities. Linear inequality constraints take the form
\[
A_{I} x \leq b_{I}
\]
where:
\(x\) is the portfolio ( \(n\) vector).
\(A_{I}\) is the linear inequality constraint matrix ( \(n_{I}\)-by- \(n\) matrix).
\(b_{I}\) is the linear inequality constraint vector ( \(n_{I}\) vector).
\(n\) is the number of assets in the universe and \(n_{I}\) is the number of constraints.
Portfolio object properties to specify linear inequality constraints are:
- AInequality for \(A_{I}\)
- bInequality for \(b_{I}\)
- NumAssets for \(n\)

The default is to ignore these constraints.

\section*{Linear Equality Constraints}

Linear equality constraints are general linear constraints that model relationships among portfolio weights that satisfy a system of equalities. Linear equality constraints take the form
\[
A_{E} x=b_{E}
\]
where:
\(x\) is the portfolio ( \(n\) vector).
\(A_{E}\) is the linear equality constraint matrix ( \(n_{E}\)-by- \(n\) matrix).
\(b_{E}\) is the linear equality constraint vector ( \(n_{E}\) vector).
\(n\) is the number of assets in the universe and \(n_{E}\) is the number of constraints.
Portfolio object properties to specify linear equality constraints are:
- AEquality for \(A_{E}\)
- bEquality for \(b_{E}\)
- NumAssets for \(n\)

The default is to ignore these constraints.

\section*{Bound Constraints}

Bound constraints are specialized linear constraints that confine portfolio weights to fall either above or below specific bounds. Since every portfolio set must be bounded, it is often a good practice, albeit not necessary, to set explicit bounds for the portfolio problem. To obtain explicit bounds for a given portfolio set, use the estimateBounds function. Bound constraints take the form
\[
l_{B} \leq x \leq u_{B}
\]
where:
\(x\) is the portfolio ( \(n\) vector).
\(l_{B}\) is the lower-bound constraint ( \(n\) vector).
\(u_{B}\) is the upper-bound constraint ( \(n\) vector).
\(n\) is the number of assets in the universe.
Portfolio object properties to specify bound constraints are:
- LowerBound for \(l_{B}\)
- UpperBound for \(u_{B}\)
- NumAssets for \(n\)

The default is to ignore these constraints.
The default portfolio optimization problem (see "Default Portfolio Problem" on page \(5-14)\) has \(l_{B}=0\) with \(u_{B}\) set implicitly through a budget constraint.

\section*{Budget Constraints}

Budget constraints are specialized linear constraints that confine the sum of portfolio weights to fall either above or below specific bounds. The constraints take the form
\[
l_{S} \leq 1^{T} x \leq u_{S}
\]
where:
\(x\) is the portfolio ( \(n\) vector).
1 is the vector of ones ( \(n\) vector).
\(l_{S}\) is the lower-bound budget constraint (scalar).
\(u_{S}\) is the upper-bound budget constraint (scalar).
\(n\) is the number of assets in the universe.
Portfolio object properties to specify budget constraints are:
- LowerBudget for \(l_{S}\)
- UpperBudget for \(u_{S}\)
- NumAssets for \(n\)

The default is to ignore this constraint.
The default portfolio optimization problem (see "Default Portfolio Problem" on page \(5-14\) ) has \(l_{S}=u_{S}=1\), which means that the portfolio weights sum to 1 . If the portfolio optimization problem includes possible movements in and out of cash, the budget constraint specifies how far portfolios can go into cash. For example, if \(l_{S}=0\) and \(u_{S}=1\), then the portfolio can have \(0-100 \%\) invested in cash. If cash is to be a portfolio choice, set RiskFreeRate ( \(r_{0}\) ) to a suitable value (see "Portfolio Problem Specification" on page \(5-2\) and "Working with a Riskless Asset" on page 5-48).

\section*{Group Constraints}

Group constraints are specialized linear constraints that enforce "membership" among groups of assets. The constraints take the form
\[
l_{G} \leq G x \leq u_{G}
\]
where:
\(x\) is the portfolio ( \(n\) vector).
\(l_{G}\) is the lower-bound group constraint ( \(n_{G}\) vector).
\(u_{G}\) is the upper-bound group constraint ( \(n_{G}\) vector).
\(G\) is the matrix of group membership indexes ( \(n_{G}\)-by- \(n\) matrix).
Each row of \(G\) identifies which assets belong to a group associated with that row. Each row contains either 0 s or 1 s with 1 indicating that an asset is part of the group or 0 indicating that the asset is not part of the group.

Portfolio object properties to specify group constraints are:
- GroupMatrix for \(G\)
- LowerGroup for \(l_{G}\)
- UpperGroup for \(u_{G}\)
- NumAssets for \(n\)

The default is to ignore these constraints.

\section*{Group Ratio Constraints}

Group ratio constraints are specialized linear constraints that enforce relationships among groups of assets. The constraints take the form
\[
l_{R i}\left(G_{B} x\right)_{i} \leq\left(G_{A} x\right)_{i} \leq u_{R i}\left(G_{B} x\right)_{i}
\]
for \(i=1, \ldots, n_{R}\) where:
\(x\) is the portfolio ( \(n\) vector).
\(l_{R}\) is the vector of lower-bound group ratio constraints ( \(n_{R}\) vector).
\(u_{R}\) is the vector matrix of upper-bound group ratio constraints ( \(n_{R}\) vector).
\(G_{A}\) is the matrix of base group membership indexes ( \(n_{R}\)-by- \(n\) matrix).
\(G_{B}\) is the matrix of comparison group membership indexes ( \(n_{R}\)-by- \(n\) matrix).
\(n\) is the number of assets in the universe and \(n_{R}\) is the number of constraints.
Each row of \(G_{A}\) and \(G_{B}\) identifies which assets belong to a base and comparison group associated with that row.

Each row contains either 0 s or 1 s with 1 indicating that an asset is part of the group or 0 indicating that the asset is not part of the group.

Portfolio object properties to specify group ratio constraints are:
- GroupA for \(G_{A}\)
- GroupB for \(G_{B}\)
- LowerRatio for \(l_{R}\)
- UpperRatio for \(u_{R}\)
- NumAssets for \(n\)

The default is to ignore these constraints.

\section*{Average Turnover Constraints}

Turnover constraint is a linear absolute value constraint that ensures estimated optimal portfolios differ from an initial portfolio by no more than a specified amount. Although
portfolio turnover is defined in many ways, the turnover constraints implemented in Financial Toolbox computes portfolio turnover as the average of purchases and sales. Average turnover constraints take the form
\[
\frac{1}{2} 1^{T}\left|x-x_{0}\right| \leq \tau
\]
where:
\(x\) is the portfolio ( \(n\) vector).
1 is the vector of ones ( \(n\) vector).
\(x_{0}\) is the initial portfolio ( \(n\) vector).
\(\tau\) is the upper bound for turnover (scalar).
\(n\) is the number of assets in the universe.
Portfolio object properties to specify the average turnover constraint are:
- Turnover for \(\tau\)
- InitPort for \(x_{0}\)
- NumAssets for \(n\)

The default is to ignore this constraint.

\section*{One-way Turnover Constraints}

One-way turnover constraints ensure that estimated optimal portfolios differ from an initial portfolio by no more than specified amounts according to whether the differences are purchases or sales. The constraints take the forms
\[
\begin{aligned}
& 1^{T} \times \max \left\{0, x-x_{0}\right\} \leq \tau_{B} \\
& 1^{T} \times \max \left\{0, x_{0}-x\right\} \leq \tau_{S}
\end{aligned}
\]
where:
\(x\) is the portfolio ( \(n\) vector)

1 is the vector of ones ( \(n\) vector).
\(x_{0}\) is the Initial portfolio ( \(n\) vector).
\(\tau_{B}\) is the upper bound for turnover constraint on purchases (scalar).
\(\tau_{S}\) is the upper bound for turnover constraint on sales (scalar).
To specify one-way turnover constraints, use the following properties in the Portfolio or PortfolioCVaR object:
- BuyTurnover for \(\tau_{B}\)
- SellTurnover for \(\tau_{S}\)
- InitPort for \(x_{0}\)

The default is to ignore this constraint.

Note: The average turnover constraint (see "Average Turnover Constraints" on page \(5-12\) ) with \(\tau\) is not a combination of the one-way turnover constraints with \(\tau=\tau_{B}=\tau_{S}\).

\section*{Default Portfolio Problem}

The default portfolio optimization problem has a risk and return proxy associated with a given problem, and a portfolio set that specifies portfolio weights to be nonnegative and to sum to 1 . The lower bound combined with the budget constraint is sufficient to ensure that the portfolio set is nonempty, closed, and bounded. The default portfolio optimization problem characterizes a long-only investor who is fully invested in a collection of assets.
- For mean-variance portfolio optimization, it is sufficient to set up the default problem. After setting up the problem, data in the form of a mean and covariance of asset returns are then used to solve portfolio optimization problems.
- For conditional value-at-risk portfolio optimization, the default problem requires the additional specification of a probability level that must be set explicitly. Generally, "typical" values for this level are 0.90 or 0.95 . After setting up the problem, data in the form of scenarios of asset returns are then used to solve portfolio optimization problems.
- For MAD portfolio optimization, it is sufficient to set up the default problem. After setting up the problem, data in the form of scenarios of asset returns are then used to solve portfolio optimization problems.

\section*{PortfolioCVaR Object Workflow}

The PortfolioCVaR object workflow for creating and modeling a mean-variance portfolio is:

1 Create a CVaR Portfolio.
Create a PortfolioCVaR object for conditional value-at-risk (CVaR) portfolio optimization. For more information, see "Creating the PortfolioCVaR Object" on page 5-23.

2 Define asset returns and scenarios.
Evaluate scenarios for portfolio asset returns, including assets with missing data and financial time series data. For more information, see "Asset Returns and Scenarios Using PortfolioCVaR Object" on page 5-38.
3 Specify the CVaR Portfolio Constraints.
Define the constraints for portfolio assets such as linear equality and inequality, bound, budget, group, group ratio, and turnover constraints. For more information, see "Working with CVaR Portfolio Constraints" on page 5-53.
4 Validate the CVaR Portfolio.
Identify errors for the portfolio specification. For more information, see "Validate the CVaR Portfolio Problem" on page 5-75.
5 Estimate the efficient portfolios and frontiers.
Analyze the efficient portfolios and efficient frontiers for a CVaR portfolio. For more information, see "Estimate Efficient Portfolios for PortfolioCVaR Object" on page 5-80 and "Estimate Efficient Frontiers for PortfolioCVaR Object" on page 5-92.

6 Postprocess the results.
Use the efficient portfolios and efficient frontiers results to set up trades. For more information, see "Postprocessing Results" on page 5-101.

\section*{PorifolioCVaR Object Properties and Functions}

The PortfolioCVaR object implements conditional value-at-risk (CVaR) portfolio optimization. Every property and function of the PortfolioCVaR object is public, although some properties and functions are hidden. SeePortfolioCVaR for the properties and functions of a PortfolioCVaR object. The PortfolioCVaR object is a value object where every instance of the object is a distinct version of the object. Since the PortfolioCVaR object is also a MATLAB object, it inherits the default functions associated with MATLAB objects.

\section*{Working with PortfolioCVaR Objects}

The PortfolioCVaR object and its functions are an interface for conditional value-at-risk portfolio optimization. So, almost everything you do with the PortfolioCVaR object can be done using the functions. The basic workflow is:

1 Design your portfolio problem.
2 Use the PortfolioCVaR function to create the PortfolioCVaR object or use the various set functions to set up your portfolio problem.
3 Use estimate functions to solve your portfolio problem.
In addition, functions are available to help you view intermediate results and to diagnose your computations. Since MATLAB features are part of a PortfolioCVaR object, you can
save and load objects from your workspace and create and manipulate arrays of objects. After settling on a problem, which, in the case of CVaR portfolio optimization, means that you have either scenarios, data, or moments for asset returns, a probability level, and a collection of constraints on your portfolios, use the PortfolioCVaR function to set the properties for the PortfolioCVaR object.

ThePortfolioCVaR function lets you create an object from scratch or update an existing object. Since the PortfolioCVaR object is a value object, it is easy to create a basic object, then use functions to build upon the basic object to create new versions of the basic object. This is useful to compare a basic problem with alternatives derived from the basic problem. For details, see "Creating the PortfolioCVaR Object" on page 5-23.

\section*{Setting and Getting Properties}

You can set properties of a PortfolioCVaR object using either the PortfolioCVaR function or various set functions.

Note: Although you can also set properties directly, it is not recommended since errorchecking is not performed when you set a property directly.

The PortfolioCVaR function supports setting properties with name-value pair arguments such that each argument name is a property and each value is the value to assign to that property. For example, to set the LowerBound, Budget, and ProbabilityLevel properties in an existing PortfolioCVaR object p, use the syntax:
```

p = PortfolioCVaR(p,'LowerBound', 0, 'Budget', 'ProbabilityLevel', 0.95);

```

In addition to the PortfolioCVaR function, which lets you set individual properties one at a time, groups of properties are set in a PortfolioCVaR object with various "set" and "add" functions. For example, to set up an average turnover constraint, use the setTurnover function to specify the bound on portfolio turnover and the initial portfolio. To get individual properties from a PortfolioCVaR object, obtain properties directly or use an assortment of "get" functions that obtain groups of properties from a PortfolioCVaR object. The PortfolioCVaR function and set functions have several useful features:
- The PortfolioCVaR function and set functions try to determine the dimensions of your problem with either explicit or implicit inputs.
- The PortfolioCVaR function and set functions try to resolve ambiguities with default choices.
- The PortfolioCVaR function and set functions perform scalar expansion on arrays when possible.
- The CVaR functions try to diagnose and warn about problems.

\section*{Displaying PorffolioCVaR Objects}

The PortfolioCVaR object uses the default display functions provided by MATLAB, where display and disp display a PortfolioCVaR object and its properties with or without the object variable name.

\section*{Saving and Loading PorifolioCVaR Objects}

Save and load PortfolioCVaR objects using the MATLAB save and load commands.

\section*{Estimating Efficient Porffolios and Frontiers}

Estimating efficient portfolios and efficient frontiers is the primary purpose of the CVaR portfolio optimization tools. A collection of "estimate" and "plot" functions provide ways to explore the efficient frontier. The "estimate" functions obtain either efficient portfolios or risk and return proxies to form efficient frontiers. At the portfolio level, a collection of functions estimates efficient portfolios on the efficient frontier with functions to obtain efficient portfolios:
- At the endpoints of the efficient frontier
- That attain targeted values for return proxies
- That attain targeted values for risk proxies
- Along the entire efficient frontier

These functions also provide purchases and sales needed to shift from an initial or current portfolio to each efficient portfolio. At the efficient frontier level, a collection of functions plot the efficient frontier and estimate either risk or return proxies for efficient portfolios on the efficient frontier. You can use the resultant efficient portfolios or risk and return proxies in subsequent analyses.

\section*{Arrays of PorffolioCVaR Objects}

Although all functions associated with a PortfolioCVaR object are designed to work on a scalar PortfolioCVaR object, the array capabilities of MATLAB enables you to set up and
work with arrays of PortfolioCVaR objects. The easiest way to do this is with the repmat function. For example, to create a 3-by-2 array of PortfolioCVaR objects:
```

p = repmat(PortfolioCVaR, 3, 2);
disp(p)

```

After setting up an array of PortfolioCVaR objects, you can work on individual PortfolioCVaR objects in the array by indexing. For example:
```

p(i,j) = PortfolioCVaR(p(i,j), ... );

```

This example calls the PortfolioCVaR function for the ( \(i, j\) ) element of a matrix of PortfolioCVaR objects in the variable p .

If you set up an array of PortfolioCVaR objects, you can access properties of a particular PortfolioCVaR object in the array by indexing so that you can set the lower and upper bounds lb and ub for the ( \(\mathrm{i}, \mathrm{j}, \mathrm{k}\) ) element of a 3-D array of PortfolioCVaR objects with
```

p(i,j,k) = setBounds(p(i,j,k), lb, ub);

```
and, once set, you can access these bounds with
[lb, ub] = getBounds \((\mathrm{p}(\mathrm{i}, \mathrm{j}, \mathrm{k}))\);
PortfolioCVaR object functions work on only one PortfolioCVaR object at a time.

\section*{Subclassing PorffolioCVaR Objects}

You can subclass the PortfolioCVaR object to override existing functions or to add new properties or functions. To do so, create a derived class from the PortfolioCVaR class. This gives you all the properties and functions of thePortfolioCVaR class along with any new features that you choose to add to your subclassed object. ThePortfolioCVaR class is derived from an abstract class called AbstractPortfolio. Because of this, you can also create a derived class from AbstractPortfolio that implements an entirely different form of portfolio optimization using properties and functions of theAbstractPortfolio class.

\section*{Conventions for Representation of Data}

The CVaR portfolio optimization tools follow these conventions regarding the representation of different quantities associated with portfolio optimization:
- Asset returns or prices for scenarios are in matrix form with samples for a given asset going down the rows and assets going across the columns. In the case of prices, the earliest dates must be at the top of the matrix, with increasing dates going down.
- Portfolios are in vector or matrix form with weights for a given portfolio going down the rows and distinct portfolios going across the columns.
- Constraints on portfolios are formed in such a way that a portfolio is a column vector.
- Portfolio risks and returns are either scalars or column vectors (for multiple portfolio risks and returns).

"PortfolioCVaR Function Examples" on page 5-24

```

To create a fully specified CVaR portfolio optimization problem, instantiate the PortfolioCVaR object using the PortfolioCVaR function. For information on the workflow when using PortfolioCVaR objects, see "PortfolioCVaR Object Workflow" on page 5-16.

\section*{Syntax}

Use the PortfolioCVaR function to create an instance of an object of the PortfolioCVaR class. You can use the PortfolioCVaR function in several ways. To set up a portfolio optimization problem in a PortfolioCVaR object, the simplest syntax is:
```

p = PortfolioCVaR;

```

This syntax creates a PortfolioCVaR object, p, such that all object properties are empty.
The PortfolioCVaR function also accepts collections of argument name-value pair arguments for properties and their values. The PortfolioCVaR function accepts inputs for public properties with the general syntax:
```

p = PortfolioCVaR('property1', value1, 'property2', value2, ... );

```

If a PortfolioCVaR object already exists, the syntax permits the first (and only the first argument) of the PortfolioCVaR function to be an existing object with subsequent argument name-value pair arguments for properties to be added or modified. For example, given an existing PortfolioCVaR object in \(p\), the general syntax is:
```

p = PortfolioCVaR(p, 'property1', value1, 'property2', value2, ... );

```

Input argument names are not case-sensitive, but must be completely specified. In addition, several properties can be specified with alternative argument names (see "Shortcuts for Property Names" on page 5-28). The PortfolioCVaR function tries to detect problem dimensions from the inputs and, once set, subsequent inputs can
undergo various scalar or matrix expansion operations that simplify the overall process to formulate a problem. In addition, a PortfolioCVaR object is a value object so that, given portfolio \(p\), the following code creates two objects, \(p\) and \(q\), that are distinct:
```

q = PortfolioCVaR(p, ...)

```

\section*{PorffolioCVaR Problem Sufficiency}

A CVaR portfolio optimization problem is completely specified with the PortfolioCVaR object if the following three conditions are met:
- You must specify a collection of asset returns or prices known as scenarios such that all scenarios are finite asset returns or prices. These scenarios are meant to be samples from the underlying probability distribution of asset returns. This condition can be satisfied by the setScenarios function or with several canned scenario simulation functions.
- The set of feasible portfolios must be a nonempty compact set, where a compact set is closed and bounded. You can satisfy this condition using an extensive collection of properties that define different types of constraints to form a set of feasible portfolios. Since such sets must be bounded, either explicit or implicit constraints can be imposed and several tools, such as the estimateBounds function, provide ways to ensure that your problem is properly formulated.
- You must specify a probability level to locate the level of tail loss above which the conditional value-at-risk is to be minimized. This condition can be satisfied by the setProbabilityLevel function.

Although the general sufficient conditions for CVaR portfolio optimization go beyond the first three conditions, the PortfolioCVaR object handles all these additional conditions.

\section*{PorifolioCVaR Function Examples}

If you create a PortfolioCVaR object, p , with no input arguments, you can display it using disp:
p = PortfolioCVaR;
disp(p);
PortfolioCVaR with properties:
```

            BuyCost: []
            SellCost: []
        RiskFreeRate: []
    ProbabilityLevel: []
Turnover: []
BuyTurnover: []
SellTurnover: []
NumScenarios: []
Name: []
NumAssets: []
AssetList: []
InitPort: []
AInequality: []
bInequality: []
AEquality: []
bEquality: []
LowerBound: []
UpperBound: []
LowerBudget: []
UpperBudget: []
GroupMatrix: []
LowerGroup: []
UpperGroup: []
GroupA: []
GroupB: []
LowerRatio: []
UpperRatio: []

```

The approaches listed provide a way to set up a portfolio optimization problem with the PortfolioCVaR function. The custom set functions offer additional ways to set and modify collections of properties in the PortfolioCVaR object.

\section*{Using the PorifolioCVaR Function for a Single-Step Setup}

You can use thePortfolioCVaR function to directly set up a "standard" portfolio optimization problem. Given scenarios of asset returns in the variable AssetScenarios, this problem is completely specified as follows:
```

m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
0.00408 0.0289 0.0204 0.0119;
0.00192 0.0204 0.0576 0.0336;
0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;
AssetScenarios = mvnrnd(m, C, 20000);

```
p = PortfolioCVaR('Scenarios', AssetScenarios, ...
'LowerBound', 0, 'LowerBudget', 1, 'UpperBudget', 1, ...
'ProbabilityLevel', 0.95);
The LowerBound property value undergoes scalar expansion since AssetScenarios provides the dimensions of the problem.

You can use dot notation with the function plotFrontier.
p.plotFrontier;

\section*{Using the PorffolioCVaR Function with a Sequence of Steps}

An alternative way to accomplish the same task of setting up a "standard" CVaR portfolio optimization problem, given AssetScenarios variable is:
```

m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
0.00408 0.0289 0.0204 0.0119;
0.00192 0.0204 0.0576 0.0336;
0 0.0119 0.0336 0.1225 ];

```
```

m = m/12;
C = C/12;

```
AssetScenarios \(=\) mvnrnd(m, C, 20000);
p = PortfolioCVaR;
p = setScenarios(p, AssetScenarios);
p = PortfolioCVaR(p, 'LowerBound', 0);
p = PortfolioCVaR(p, 'LowerBudget', 1, 'UpperBudget', 1);
\(p=\operatorname{setProbabilityLevel(p,~0.95);~}\)
plotFrontier (p);

This way works because the calls to the are in this particular order. In this case, the call to initialize AssetScenarios provides the dimensions for the problem. If you were to do this step last, you would have to explicitly dimension the LowerBound property as follows:
```

m = [ 0.05; 0.1; 0.12; 0.18 ];

```
```

C = [ 0.0064 0.00408 0.00192 0;
0.00408 0.0289 0.0204 0.0119;
0.00192 0.0204 0.0576 0.0336;
0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;
AssetScenarios = mvnrnd(m, C, 20000);
p = PortfolioCVaR;
p = PortfolioCVaR(p, 'LowerBound', zeros(size(m)));
p = PortfolioCVaR(p, 'LowerBudget', 1, 'UpperBudget', 1);
p = setProbabilityLevel(p, 0.95);
p = setScenarios(p, AssetScenarios);

```

Note: If you did not specify the size of LowerBound but, instead, input a scalar argument, the PortfolioCVaR function assumes that you are defining a single-asset problem and produces an error at the call to set asset scenarios with four assets.

\section*{Shortcuts for Property Names}

The PortfolioCVaR function has shorter argument names that replace longer argument names associated with specific properties of the PortfolioCVaR object. For example, rather than enter 'ProbabilityLevel', the PortfolioCVaR function accepts the case-insensitive name 'plevel' to set the ProbabilityLevel property in a PortfolioCVaR object. Every shorter argument name corresponds with a single property in the PortfolioCVaR function. The one exception is the alternative argument name ' budget ', which signifies both the LowerBudget and UpperBudget properties. When 'budget ' is used, then the LowerBudget and UpperBudget properties are set to the same value to form an equality budget constraint.

\section*{Shortcuts for Property Names}
\begin{tabular}{|l|l|}
\hline Shortcut Argument Name & Equivalent Argument/Property Name \\
\hline ae & AEquality \\
\hline ai & AInequality \\
\hline assetnames or assets & AssetList \\
\hline be & bEquality \\
\hline
\end{tabular}
\begin{tabular}{|l|l|}
\hline Shortcut Argument Name & Equivalent Argument / Property Name \\
\hline bi & bInequality \\
\hline budget & UpperBudget and LowerBudget \\
\hline group & GroupMatrix \\
\hline lb & LowerBound \\
\hline n or num & NumAssets \\
\hline level, problevel, or plevel & ProbabilityLevel \\
\hline rfr & RiskFreeRate \\
\hline \begin{tabular}{l} 
scenario or \\
assetscenarios
\end{tabular} & Scenarios \\
\hline ub & UpperBound \\
\hline
\end{tabular}

For example, this call to the PortfolioCVaR function uses these shortcuts for properties:
```

m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
0.00408 0.0289 0.0204 0.0119;
0.00192 0.0204 0.0576 0.0336;
0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;
AssetScenarios = mvnrnd(m, C, 20000);
p = PortfolioCVaR('scenario', AssetScenarios, 'lb', 0, 'budget', 1, 'plevel', 0.95);
plotFrontier(p);

```

\section*{Direct Setting of Portfolio Object Properties}

Although not recommended, you can set properties directly using dot notation, however no error-checking is done on your inputs:
```

m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
0.00408 0.0289 0.0204 0.0119;
0.00192 0.0204 0.0576 0.0336;
0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;

```
AssetScenarios = mvnrnd(m, C, 20000);
```

p = PortfolioCVaR;
p = setScenarios(p, AssetScenarios);
p.ProbabilityLevel = 0.95;
p.LowerBudget = 1;
p.UpperBudget = 1;
p.LowerBound = zeros(size(m));
plotFrontier(p);

```

Note: Scenarios cannot be assigned directly to a PortfolioCVaR object. Scenarios must always be set through either the PortfolioCVaR function, the setScenarios function, or any of the scenario simulation functions.

\section*{Common Operations on the PorifolioCVaR Object}

\author{
In this section... \\ "Naming a PortfolioCVaR Object" on page 5-31 \\ "Configuring the Assets in the Asset Universe" on page 5-31 \\ "Setting Up a List of Asset Identifiers" on page 5-32 \\ "Truncating and Padding Asset Lists" on page 5-33 \\ "Setting Up an Initial or Current Portfolio" on page 5-34
}

\section*{Naming a PorffolioCVaR Object}

To name a PortfolioCVaR object, use the Name property. Name is informational and has no effect on any portfolio calculations. If the Name property is nonempty, Name is the title for the efficient frontier plot generated by plotFrontier. For example, if you set up an asset allocation fund, you could name the PortfolioCVaR object Asset Allocation Fund:
```

p = PortfolioCVaR('Name','Asset Allocation Fund');
disp(p.Name);
Asset Allocation Fund

```

\section*{Configuring the Assets in the Asset Universe}

The fundamental quantity in the PortfolioCVaR object is the number of assets in the asset universe. This quantity is maintained in the NumAssets property. Although you can set this property directly, it is usually derived from other properties such as the number of assets in the scenarios or the initial portfolio. In some instances, the number of assets may need to be set directly. This example shows how to set up a PortfolioCVaR object that has four assets:
```

p = PortfolioCVaR('NumAssets', 4);
disp(p.NumAssets);
4

```

After setting the NumAssets property, you cannot modify it (unless no other properties are set that depend on NumAssets). The only way to change the number of assets in an existing PortfolioCVaR object with a known number of assets is to create a new PortfolioCVaR object.

\section*{Setting Up a List of Asset Identifiers}

When working with portfolios, you must specify a universe of assets. Although you can perform a complete analysis without naming the assets in your universe, it is helpful to have an identifier associated with each asset as you create and work with portfolios. You can create a list of asset identifiers as a cell vector of strings in the property AssetList. You can set up the list using the next two methods.

\section*{Setting up Asset Lists Using the PortfolioCVaR Function}

Suppose that you have a PortfolioCVaR object, p, with assets with symbols 'AA ' ', 'BA', 'CAT', 'DD', and 'ETR'. You can create a list of these asset symbols in the object using the PortfolioCVaR function:
```

p = PortfolioCVaR('assetlist', { 'AA', 'BA', 'CAT', 'DD', 'ETR' });
disp(p.AssetList);
'AA' 'BA' 'CAT' 'DD' 'ETR'

```

Notice that the property AssetList is maintained as a cell array that contains strings, and that it is necessary to pass a cell array into the PortfolioCVaR function to set AssetList. In addition, notice that the property NumAssets is set to 5 based on the number of symbols used to create the asset list:
```

disp(p.NumAssets);

```

5

\section*{Setting Up Asset Lists Using the setAssetList Function}

You can also specify a list of assets using the setAssetList function. Given the list of asset symbols 'AA', 'BA', 'CAT', 'DD', and 'ETR', you can use setAssetList with:
```

p = PortfolioCVaR;
p = setAssetList(p, { 'AA', 'BA', 'CAT', 'DD', 'ETR' });
disp(p.AssetList);
'AA' 'BA' 'CAT' 'DD' 'ETR'

```
setAssetList also enables you to enter symbols directly as a comma-separated list without creating a cell array of strings. For example, given the list of assets symbols 'AA', 'BA', 'CAT', 'DD', and 'ETR', use setAssetList:
p = PortfolioCVaR;
```

p = setAssetList(p, 'AA', 'BA', 'CAT', 'DD', 'ETR');
disp(p.AssetList);
'AA' 'BA' 'CAT' 'DD' 'ETR'

```
setAssetList has many additional features to create lists of asset identifiers. If you use setAssetList with just a PortfolioCVaR object, it creates a default asset list according to the name specified in the hidden public property defaultforAssetList (which is 'Asset ' by default). The number of asset names created depends on the number of assets in the property NumAssets. If NumAssets is not set, then NumAssets is assumed to be 1 .

For example, if a PortfolioCVaR object \(p\) is created with NumAssets \(=5\), then this code fragment shows the default naming behavior:
```

p = PortfolioCVaR('numassets',5);
p = setAssetList(p);
disp(p.AssetList);
'Asset1' 'Asset2' 'Asset3' 'Asset4' 'Asset5'

```

Suppose that your assets are, for example, ETFs and you change the hidden property defaultforAssetList to 'ETF ', you can then create a default list for ETFs:
```

p = PortfolioCVaR('numassets',5);
p.defaultforAssetList = 'ETF';
p = setAssetList(p);
disp(p.AssetList);
'ETF1' 'ETF2' 'ETF3' 'ETF4' 'ETF5'

```

\section*{Truncating and Padding Asset Lists}

If the NumAssets property is already set and you pass in too many or too few identifiers, the PortfolioCVaR function, and the setAssetList function truncate or pad the list with numbered default asset names that use the name specified in the hidden public property defaultforAssetList. If the list is truncated or padded, a warning message indicates the discrepancy. For example, assume that you have a PortfolioCVaR object with five ETFs and you only know the first three CUSIPs '921937835', '922908769', and ' 922042775 '. Use this syntax to create an asset list that pads the remaining asset identifiers with numbered 'UnknownCUSIP' placeholders:
```

p = PortfolioCVaR('numassets',5);
p.defaultforAssetList = 'UnknownCUSIP';
p = setAssetList(p, '921937835', '922908769', '922042775');

```
```

disp(p.AssetList);
Warning: Input list of assets has 2 too few identifiers. Padding with numbered assets.
> In PortfolioCVaR.setAssetList at }11
921937835' '922908769' '922042775' 'UnknownCUSIP4' 'UnknownCUSIP5'

```

Alternatively, suppose that you have too many identifiers and need only the first four assets. This example illustrates truncation of the asset list using the PortfolioCVaR function:
```

p = PortfolioCVaR('numassets',4);
p = PortfolioCVaR(p, 'assetlist', { 'AGG', 'EEM', 'MDY', 'SPY', 'VEU' });
disp(p.AssetList);
Warning: AssetList has 1 too many identifiers. Using first 4 assets.
> In PortfolioCVaR.checkarguments at 399
In PortfolioCVaR.PortfolioCVaR>PortfolioCVaR.PortfolioCVaR at 195
'AGG' 'EEM' 'MDY' 'SPY

```

The hidden public property uppercaseAssetList is a Boolean flag to specify whether to convert asset names to uppercase letters. The default value for uppercaseAssetList is false. This example shows how to use the uppercaseAssetList flag to force identifiers to be uppercase letters:
```

p = PortfolioCVaR;
p.uppercaseAssetList = true;
p = setAssetList(p, { 'aa', 'ba', 'cat', 'dd', 'etr' });
disp(p.AssetList);
'AA' 'BA' 'CAT' 'DD' 'ETR'

```

\section*{Setting Up an Initial or Current Portfolio}

In many applications, creating a new optimal portfolio requires comparing the new portfolio with an initial or current portfolio to form lists of purchases and sales. The PortfolioCVaR object property InitPort lets you identify an initial or current portfolio. The initial portfolio also plays an essential role if you have either transaction costs or turnover constraints. The initial portfolio need not be feasible within the constraints of the problem. This can happen if the weights in a portfolio have shifted such that some constraints become violated. To check if your initial portfolio is feasible, use the checkFeasibility function described in "Validating CVaR Portfolios" on page 5-77. Suppose that you have an initial portfolio in \(\mathrm{x0}\), then use the PortfolioCVaR function to set up an initial portfolio:
```

x0 = [ 0.3; 0.2; 0.2; 0.0 ];
p = PortfolioCVaR('InitPort', x0);

```
```

disp(p.InitPort);

```
    0.3000
    0.2000
    0.2000
    0

As with all array properties, you can set InitPort with scalar expansion. This is helpful to set up an equally weighted initial portfolio of, for example, 10 assets:
```

p = PortfolioCVaR('NumAssets', 10, 'InitPort', 1/10);
disp(p.InitPort);
0.1000
0.1000
0.1000
0.1000
0.1000
0.1000
0.1000
0.1000
0.1000
0.1000

```

To clear an initial portfolio from your PortfolioCVaR object, use either the PortfolioCVaR function or the setInitPort function with an empty input for the InitPort property. If transaction costs or turnover constraints are set, it is not possible to clear the InitPort property in this way. In this case, to clear InitPort, first clear the dependent properties and then clear theInitPort property.

The InitPort property can also be set with setInitPort which lets you specify the number of assets if you want to use scalar expansion. For example, given an initial portfolio in xO , use setInitPort to set the InitPort property:
```

p = PortfolioCVaR;
x0 = [ 0.3; 0.2; 0.2; 0.0 ];
p = setInitPort(p, x0);
disp(p.InitPort);
0.3000
0.2000
0.2000
0

```

To create an equally weighted portfolio of four assets, use setInitPort:
```

p = PortfolioCVaR;
p = setInitPort(p, 1/4, 4);
disp(p.InitPort);
0.2500
0.2500
0.2500
0.2500

```

PortfolioCVaR object functions that work with either transaction costs or turnover constraints also depend on the InitPort property. So, the set functions for transaction costs or turnover constraints permit the assignment of a value for the InitPort property as part of their implementation. For details, see "Working with Average Turnover Constraints Using PortfolioCVaR Object" on page 5-69, "Working with One-way Turnover Constraints Using PortfolioCVaR Object" on page 5-71, and "Working with Transaction Costs" on page 5-48. If either transaction costs or turnover constraints are used, then the InitPort property must have a nonempty value. Absent a specific value assigned through the PortfolioCVaR function or various set functions, the PortfolioCVaR object sets InitPort to 0 and warns if BuyCost, SellCost, or Turnover properties are set. This example shows what happens if you specify an average turnover constraint with an initial portfolio:
```

p = PortfolioCVaR('Turnover', 0.3, 'InitPort', [ 0.3; 0.2; 0.2; 0.0 ]);
disp(p.InitPort);

```
0.3000
0.2000
0.2000

0
In contrast, this example shows what happens if an average turnover constraint is specified without an initial portfolio:
```

p = PortfolioCVaR('Turnover', 0.3);
disp(p.InitPort);
Warning: InitPort and NumAssets are empty and either transaction costs or turnover constraints specified.
Will set NumAssets = 1 and InitPort = 0.
> In PortfolioCVaR.checkarguments at 322
In PortfolioCVaR.PortfolioCVaR>PortfolioCVaR.PortfolioCVaR at 195
0

```

\section*{How Stochastic Optimization Works}

The CVaR of a portfolio is a conditional expectation. (For the definition of the CVaR function, see "Risk Proxy" on page 5-5.) Therefore, the CVaR portfolio optimization problem is a stochastic optimization problem. Given a sample of scenarios, the conditional expectation that defines the sample CVaR of the portfolio can be expressed as a finite sum, a weighted average of losses. The weights of the losses depend on their relative magnitude; for a confidence level \(\alpha\), only the worst \((1-\alpha) \times 100 \%\) losses get a positive weight. As a function of the portfolio weights, the CVaR of the portfolio is a convex function (see [48], [49] Rockafellar \& Uryasev at "Portfolio Optimization" on page A-10). It is also a nonsmooth function, but its edges are less sharp as the sample size increases.

There are reformulations of the CVaR portfolio optimization problem (see [48], [49] at Rockafellar \& Uryasev) that result in a linear programming problem, which can be solved either with standard linear programming techniques or with stochastic programming solvers. The PortfolioCVaR object, however, does not reformulate the problem in such a manner. The PortfolioCVaR object computes the CVaR as a nonlinear function. The
convexity of the CVaR, as a function of the portfolio weights and the dull edges when the number of scenarios is large, make the CVaR portfolio optimization problem tractable, in practice, for certain nonlinear programming solvers, such as fmincon from Optimization Toolbox. The problem can also be solved using a cutting-plane method (see Kelley [45] at "Portfolio Optimization" on page A-10). For more information, see Algorithms section of setSolver. To learn more about the workflow when using PortfolioCVaR objects, see "PortfolioCVaR Object Workflow" on page 5-16.

\section*{What Are Scenarios?}

Since conditional value-at-risk portfolio optimization works with scenarios of asset returns to perform the optimization, several ways exist to specify and simulate scenarios. In many applications with CVaR portfolio optimization, asset returns may have distinctly nonnormal probability distributions with either multiple modes, binning of returns, truncation of distributions, and so forth. In other applications, asset returns are modeled as the result of various simulation methods that might include MonteCarlo simulation, quasi-random simulation, and so forth. In many cases, the underlying probability distribution for risk factors may be multivariate normal but the resultant transformations are sufficiently nonlinear to result in distinctively nonnormal asset returns.

For example, this occurs with bonds and derivatives. In the case of bonds with a nonzero probability of default, such scenarios would likely include asset returns that are \(-100 \%\) to indicate default and some values slightly greater than \(-100 \%\) to indicate recovery rates.

Although the PortfolioCVaR object has functions to simulate multivariate normal scenarios from either data or moments (simulateNormalScenariosByData and simulateNormalScenariosByMoments), the usual approach is to specify scenarios directly from your own simulation functions. These scenarios are entered directly as a matrix with a sample for all assets across each row of the matrix and with samples for an asset down each column of the matrix. The architecture of the CVaR portfolio optimization tools references the scenarios through a function handle so scenarios that have been set cannot be accessed directly as a property of the PortfolioCVaR object.

\section*{Setting Scenarios Using the PorifolioCVaR Function}

Suppose that you have a matrix of scenarios in the AssetScenarios variable. The scenarios are set through the PortfolioCVaR function with:
```

m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
0.00408 0.0289 0.0204 0.0119;
0.00192 0.0204 0.0576 0.0336;
0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;
AssetScenarios = mvnrnd(m, C, 20000);
p = PortfolioCVaR('Scenarios', AssetScenarios);
disp(p.NumAssets);
disp(p.NumScenarios);
4

```

\section*{20000}

Notice that the PortfolioCVaR object determines and fixes the number of assets in NumAssets and the number of scenarios in NumScenarios based on the scenario's matrix. You can change the number of scenarios by calling the PortfolioCVaR function with a different scenario matrix. However, once the NumAssets property has been set in the object, you cannot enter a scenario matrix with a different number of assets. The getScenarios function lets you recover scenarios from a PortfolioCVaR object. You can also obtain the mean and covariance of your scenarios using estimateScenarioMoments.

Although not recommended for the casual user, an alternative way exists to recover scenarios by working with the function handle that points to scenarios in the PortfolioCVaR object. To access some or all of the scenarios from a PortfolioCVaR object, the hidden property localScenarioHandle is a function handle that points to a function to obtain scenarios that have already been set. To get scenarios directly from a PortfolioCVaR object p, use
scenarios = p.localScenarioHandle([], []);
and to obtain a subset of scenarios from rows startrow to endrow, use
scenarios = p.localScenarioHandle(startrow, endrow); where \(1 \leq\) startrow \(\leq\) endrow \(\leq\) numScenarios.

\section*{Setting Scenarios Using the setScenarios Function}

You can also set scenarios using setScenarios. For example, given the mean and covariance of asset returns in the variables m and C , the asset moment properties can be set:
```

m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
0.00408 0.0289 0.0204 0.0119;
0.00192 0.0204 0.0576 0.0336;
0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;

```
AssetScenarios = mvnrnd(m, C, 20000);
p = PortfolioCVaR;
p = setScenarios(p, AssetScenarios);
disp(p.NumAssets);
disp(p.NumScenarios);

4

\section*{20000}

\section*{Estimating the Mean and Covariance of Scenarios}

The estimateScenarioMoments function obtains estimates for the mean and covariance of scenarios in a PortfolioCVaR object.
```

m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
0.00408 0.0289 0.0204 0.0119;
0.00192 0.0204 0.0576 0.0336;
0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;
AssetScenarios = mvnrnd(m, C, 20000);
p = PortfolioCVaR;

```
```

p = setScenarios(p, AssetScenarios);
[mean, covar] = estimateScenarioMoments(p)
mean =
0.0043
0.0085
0.0098
0.0153
covar =

| 0.0005 | 0.0003 | 0.0002 | 0.0000 |
| :--- | :--- | :--- | :--- |
| 0.0003 | 0.0024 | 0.0017 | 0.0010 |
| 0.0002 | 0.0017 | 0.0049 | 0.0029 |
| 0.0000 | 0.0010 | 0.0029 | 0.0102 |

```

\section*{Simulating Normal Scenarios}

As a convenience, the two functions (simulateNormalScenariosByData and simulateNormalScenariosByMoments) exist to simulate scenarios from data or moments under an assumption that they are distributed as multivariate normal random asset returns.

\section*{Simulating Normal Scenarios from Returns or Prices}

Given either return or price data, use the function simulateNormalScenariosByData to simulate multivariate normal scenarios. Either returns or prices are stored as matrices with samples going down the rows and assets going across the columns. In addition, returns or prices can be stored in a financial time series fints object (see "Simulating Normal Scenarios from Time Series Data" on page 5-45). To illustrate using simulateNormalScenariosByData, generate random samples of 120 observations of asset returns for four assets from the mean and covariance of asset returns in the variables \(m\) and \(C\) with portsim. The default behavior of portsim creates simulated data with estimated mean and covariance identical to the input moments \(m\) and C . In addition to a return series created by portsim in the variable \(X\), a price series is created in the variable \(Y\) :
```

m = [ 0.0042; 0.0083; 0.01; 0.15 ];
C = [ 0.005333 0.00034 0.00016 0;
0.00034 0.002408 0.0017 0.000992;

```
```

0.00016 0.0017 0.0048 0.0028;
0 0.000992 0.0028 0.010208 ];
X = portsim(m', C, 120);
Y = ret2tick(X);

```

Note: Portfolio optimization requires that you use total returns and not just price returns. So, "returns" should be total returns and "prices" should be total return prices.

Given asset returns and prices in variables \(X\) and \(Y\) from above, this sequence of examples demonstrates equivalent ways to simulate multivariate normal scenarios for the PortfolioCVaR object. Assume a PortfolioCVaR object created in \(p\) that uses the asset returns in \(X\) uses simulateNormalScenariosByData:
```

p = PortfolioCVaR;
p = simulateNormalScenariosByData(p, X, 20000);
[passetmean, passetcovar] = estimateScenarioMoments(p)
passetmean =
0.0043
0.0083
0.0102
0.1507

```
passetcovar =
\begin{tabular}{llll}
0.0053 & 0.0003 & 0.0002 & 0.0000 \\
0.0003 & 0.0024 & 0.0017 & 0.0010 \\
0.0002 & 0.0017 & 0.0049 & 0.0028 \\
0.0000 & 0.0010 & 0.0028 & 0.0101
\end{tabular}

The moments that you obtain from this simulation will likely differ from the moments listed here because the scenarios are random samples from the estimated multivariate normal probability distribution of the input returns \(X\).

The default behavior of simulateNormalScenariosByData is to work with asset returns. If, instead, you have asset prices as in the variable \(Y\), simulateNormalScenariosByData accepts a name-value pair argument name 'DataFormat ' with a corresponding value set to 'prices' to indicate that the input to the function is in the form of asset prices and not returns (the default value for the
'DataFormat' argument is 'returns'). This example simulates scenarios with the asset price data in \(Y\) for the PortfolioCVaR object q :
```

p = PortfolioCVaR;
p = simulateNormalScenariosByData(p, Y, 20000, 'dataformat', 'prices');
[passetmean, passetcovar] = estimateScenarioMoments(p)
passetmean =

```
0.0043
0.0084
0.0094
0.1490

\section*{passetcovar =}
\begin{tabular}{rrrr}
0.0054 & 0.0004 & 0.0001 & -0.0000 \\
0.0004 & 0.0024 & 0.0016 & 0.0009 \\
0.0001 & 0.0016 & 0.0048 & 0.0028 \\
-0.0000 & 0.0009 & 0.0028 & 0.0100
\end{tabular}

\section*{Simulating Normal Scenarios with Missing Data}

Often when working with multiple assets, you have missing data indicated by NaN values in your return or price data. Although "Multivariate Normal Regression" on page 9-2 goes into detail about regression with missing data, the simulateNormalScenariosByData function has a name-value pair argument name 'MissingData' that indicates with a Boolean value whether to use the missing data capabilities of Financial Toolbox. The default value for 'MissingData' is false which removes all samples with NaN values. If, however, 'MissingData' is set to true, simulateNormalScenariosByData uses the ECM algorithm to estimate asset moments. This example shows how this works on price data with missing values:
```

m = [ 0.0042; 0.0083; 0.01; 0.15 ];
C = [ 0.005333 0.00034 0.00016 0;
0.00034 0.002408 0.0017 0.000992;
0.00016 0.0017 0.0048 0.0028;
0 0.000992 0.0028 0.010208 ];
X = portsim(m', C, 120);
Y = ret2tick(X);
Y(1:20,1) = NaN;

```
```

Y(1:12,4) = NaN;

```

Notice that the prices above in \(Y\) have missing values in the first and fourth series.
```

p = PortfolioCVaR;
p = simulateNormalScenariosByData(p, Y, 20000, 'dataformat', 'prices');
q = PortfolioCVaR;
q = simulateNormalScenariosByData(q, Y, 20000, 'dataformat', 'prices', 'missingdata', true);

```
[passetmean, passetcovar] = estimateScenarioMoments(p)
[qassetmean, qassetcovar] = estimateScenarioMoments(q)
passetmean =
    0.0020
    0.0074
    0.0078
    0.1476
passetcovar =
\begin{tabular}{rrrr}
0.0055 & 0.0003 & -0.0001 & -0.0003 \\
0.0003 & 0.0024 & 0.0019 & 0.0012 \\
-0.0001 & 0.0019 & 0.0050 & 0.0028 \\
-0.0003 & 0.0012 & 0.0028 & 0.0101
\end{tabular}
qassetmean \(=\)
    0.0024
    0.0085
    0.0106
    0.1482
qassetcovar =
\begin{tabular}{rrrr}
0.0071 & 0.0004 & -0.0001 & -0.0004 \\
0.0004 & 0.0032 & 0.0022 & 0.0012 \\
-0.0001 & 0.0022 & 0.0063 & 0.0034 \\
-0.0004 & 0.0012 & 0.0034 & 0.0127
\end{tabular}

The first PortfolioCVaR object, p , contains scenarios obtained from price data in Y where NaN values are discarded and the second PortfolioCVaR object, q, contains scenarios obtained from price data in \(Y\) that accommodate missing values. Each time you run this example, you get different estimates for the moments in \(p\) and \(q\).

\section*{Simulating Normal Scenarios from Time Series Data}

The simulateNormalScenariosByData function also accepts asset returns or prices stored in financial time series (fints) objects. The function implicitly works with
matrices of data or data in a fints object using the same rules for whether the data are returns or prices. To illustrate, use fints to create the fints object Xfts that contains asset returns generated with fints (see "Estimating Asset Moments from Prices or Returns" on page 4-45) and add series labels:
```

m = [ 0.0042; 0.0083; 0.01; 0.15 ];
C=[ [ 0.005333 0.00034 0.00016 0;
0.00034 0.002408 0.0017 0.000992;
0.00016 0.0017 0.0048 0.0028;
0 0.000992 0.0028 0.010208 ];
X = portsim(m', C, 120);
d = (datenum('31-jan-2001'):datenum('31-dec-2010'))';
Xfts = fints(d, zeros(numel(d),4), {'Bonds', 'LargeCap', 'SmallCap', 'Emerging'});
Xfts = tomonthly(Xfts);
Xfts.Bonds = X(:,1);
Xfts.LargeCap = X(:,2);
Xfts.SmallCap = X(:,3);
Xfts.Emerging = X(:,4);
p = PortfolioCVaR;
p = simulateNormalScenariosByData(p, Xfts, 20000);
[passetmean, passetcovar] = estimateScenarioMoments(p)
passetmean =
0.0044
0.0082
0.0102
0.1504
passetcovar =

| 0.0054 | 0.0004 | 0.0002 | -0.0000 |
| ---: | ---: | ---: | ---: |
| 0.0004 | 0.0024 | 0.0017 | 0.0010 |
| 0.0002 | 0.0017 | 0.0047 | 0.0027 |
| -0.0000 | 0.0010 | 0.0027 | 0.0102 |

```

The name-value inputs 'DataFormat' to handle return or price data and 'MissingData' to ignore or use samples with missing values also work for fints data. In addition, simulateNormalScenariosByData extracts asset names or identifiers from a fints object if the argument name 'GetAssetList' is set to true (the default value is false). If the 'GetAssetList' value is true, the identifiers are used to set the AssetList property of the PortfolioCVaR object. Thus, repeating the formation of the PortfolioCVaR object q from the previous example with the 'GetAssetList' flag set to true extracts the series labels from the fints object:
```

p = simulateNormalScenariosByData(p, Xfts, 20000, 'getassetlist', true);
disp(p.AssetList)
'Bonds' 'LargeCap' 'SmallCap' 'Emerging'

```

If you set the 'GetAssetList' flag set to true and your input data is in a matrix, simulateNormalScenariosByData uses the default labeling scheme from setAssetList as described in "Setting Up a List of Asset Identifiers" on page 5-32.

\section*{Simulating Normal Scenarios with Mean and Covariance}

Given the mean and covariance of asset returns, use the simulateNormalScenariosByMoments function to simulate multivariate normal scenarios. The mean can be either a row or column vector and the covariance matrix must be a symmetric positive-semidefinite matrix. Various rules for scalar expansion apply. To illustrate using simulateNormalScenariosByMoments, start with moments in m and C and generate 20,000 scenarios:
```

m = [ 0.0042; 0.0083; 0.01; 0.15 ];
C = [ 0.005333 0.00034 0.00016 0;
0.00034 0.002408 0.0017 0.000992;
0.00016 0.0017 0.0048 0.0028;
0 0.000992 0.0028 0.010208 ];
p = PortfolioCVaR;
p = simulateNormalScenariosByMoments(p, m, C, 20000);
[passetmean, passetcovar] = estimateScenarioMoments(p)
passetmean =

```
0.0049
0.0083
0.0101
0.1503
```

passetcovar =

```
\begin{tabular}{rrrr}
0.0053 & 0.0003 & 0.0002 & -0.0000 \\
0.0003 & 0.0024 & 0.0017 & 0.0010 \\
0.0002 & 0.0017 & 0.0047 & 0.0028 \\
-0.0000 & 0.0010 & 0.0028 & 0.0101
\end{tabular}
simulateNormalScenariosByMoments performs scalar expansion on arguments for the moments of asset returns. If NumAssets has not already been set, a scalar argument is interpreted as a scalar with NumAssets set to 1. simulateNormalScenariosByMoments provides an additional optional argument to specify the number of assets so that scalar expansion works with the correct number of assets. In addition, if either a scalar or vector is input for the covariance of asset returns, a diagonal matrix is formed such that a scalar expands along the diagonal and a vector becomes the diagonal.

\section*{Working with a Riskless Asset}

The PortfolioCVaR object has a separate RiskFreeRate property that stores the rate of return of a riskless asset. Thus, you can separate your universe into a riskless asset and a collection of risky assets. For example, assume that your riskless asset has a return in the scalar variable r 0 , then the property for the RiskFreeRate is set using the PortfolioCVaR function:
```

r0 = 0.01/12;
p = PortfolioCVaR;
p = PortfolioCVaR('RiskFreeRate', rO);
disp(p.RiskFreeRate);
8.3333e-04

```

Note: If your portfolio problem has a budget constraint such that your portfolio weights must sum to 1 , then the riskless asset is irrelevant.

\section*{Working with Transaction Costs}

The difference between net and gross portfolio returns is transaction costs. The net portfolio return proxy has distinct proportional costs to purchase and to sell assets which are maintained in the PortfolioCVaR object properties BuyCost and SellCost. Transaction costs are in units of total return and, as such, are proportional to the price of an asset so that they enter the model for net portfolio returns in return form. For example, suppose that you have a stock currently priced \(\$ 40\) and your usual transaction costs are 5 cents per share. Then the transaction cost for the stock is \(0.05 / 40=0.00125\) (as defined in "Net Portfolio Returns" on page 5-4). Costs are entered as positive values and credits are entered as negative values.

\section*{Setting Transaction Costs Using the PorffolioCVaR Function}

To set up transaction costs, you must specify an initial or current portfolio in the InitPort property. If the initial portfolio is not set when you set up the transaction cost properties, InitPort is 0 . The properties for transaction costs can be set using the PortfolioCVaR function. For example, assume that purchase and sale transaction costs are in the variables bc and Sc and an initial portfolio is in the variable xO , then transaction costs are set:
```

bc = [ 0.00125; 0.00125; 0.00125; 0.00125; 0.00125 ];
sc = [ 0.00125; 0.007; 0.00125; 0.00125; 0.0024 ];
x0 = [ 0.4; 0.2; 0.2; 0.1; 0.1 ];
p = PortfolioCVaR('BuyCost', bc, 'SellCost', sc, 'InitPort', x0);
disp(p.NumAssets);
disp(p.BuyCost);
disp(p.SellCost);
disp(p.InitPort);
5

0.4000
0.2000
0.2000
0.1000
0.1000

```

\section*{Setting Transaction Costs Using the setCosts Function}

You can also set the properties for transaction costs using setCosts. Assume that you have the same costs and initial portfolio as in the previous example. Given a PortfolioCVaR object \(p\) with an initial portfolio already set, use setCosts to set up transaction costs:
```

bc = [ 0.00125; 0.00125; 0.00125; 0.00125; 0.00125 ];
sc = [ 0.00125; 0.007; 0.00125; 0.00125; 0.0024 ];
x0 = [ 0.4; 0.2; 0.2; 0.1; 0.1 ];
p = PortfolioCVaR('InitPort', x0);
p = setCosts(p, bc, sc);
disp(p.NumAssets);
disp(p.BuyCost);
disp(p.SellCost);
disp(p.InitPort);
5

0.2000
0.2000
0.1000
0.1000

```

You can also set up the initial portfolio's InitPort value as an optional argument to setCosts so that the following is an equivalent way to set up transaction costs:
```

bc = [ 0.00125; 0.00125; 0.00125; 0.00125; 0.00125 ];
sc = [ 0.00125; 0.007; 0.00125; 0.00125; 0.0024 ];
x0 = [ 0.4; 0.2; 0.2; 0.1; 0.1 ];
p = PortfolioCVaR;
p = setCosts(p, bc, sc, x0);
disp(p.NumAssets);
disp(p.BuyCost);
disp(p.SellCost);

```
```

disp(p.InitPort);

0.1000

```

\section*{Setting Transaction Costs with Scalar Expansion}

Both the PortfolioCVaR function and setCosts function implement scalar expansion on the arguments for transaction costs and the initial portfolio. If the NumAssets property is already set in the PortfolioCVaR object, scalar arguments for these properties are expanded to have the same value across all dimensions. In addition, setCosts lets you specify NumAssets as an optional final argument. For example, assume that you have an initial portfolio xO and you want to set common transaction costs on all assets in your universe. You can set these costs in any of these equivalent ways:
```

x0 = [ 0.4; 0.2; 0.2; 0.1; 0.1 ];
p = PortfolioCVaR('InitPort', x0, 'BuyCost', 0.002, 'SellCost', 0.002);
or
xO = [ 0.4; 0.2; 0.2; 0.1; 0.1 ];
p = PortfolioCVaR('InitPort', x0);
p = setCosts(p, 0.002, 0.002);
or
x0 = [ 0.4; 0.2; 0.2; 0.1; 0.1 ];
p = PortfolioCVaR;

```
```

p = setCosts(p, 0.002, 0.002, x0);

```

To clear costs from your PortfolioCVaR object, use either the PortfolioCVaR function or setCosts with empty inputs for the properties to be cleared. For example, you can clear sales costs from the PortfolioCVaR object \(p\) in the previous example:
```

p = PortfolioCVaR(p, 'SellCost', []);

```

```

The final element for a complete specification of a portfolio optimization problem is the set of feasible portfolios, which is called a portfolio set. A portfolio set \(X \subset R^{n}\) is specified by construction as the intersection of sets formed by a collection of constraints on portfolio weights. A portfolio set necessarily and sufficiently must be a nonempty, closed, and bounded set.

When setting up your portfolio set, ensure that the portfolio set satisfies these conditions. The most basic or "default" portfolio set requires portfolio weights to be nonnegative (using the lower-bound constraint) and to sum to 1 (using the budget constraint). For information on the workflow when using PortfolioCVaR objects, see "PortfolioCVaR Object Workflow" on page 5-16.

\section*{Setting Default Constraints for Portfolio Weights Using PortfolioCVaR Object}

The "default" CVaR portfolio problem has two constraints on portfolio weights:
- Portfolio weights must be nonnegative.
- Portfolio weights must sum to 1 .

Implicitly, these constraints imply that portfolio weights are no greater than 1, although this is a superfluous constraint to impose on the problem.

\section*{Setting Default Constraints Using the PorffolioCVaR Function}

Given a portfolio optimization problem with NumAssets = 20 assets, use the PortfolioCVaR function to set up a default problem and explicitly set bounds and budget constraints:
```

p = PortfolioCVaR('NumAssets', 20, 'LowerBound', 0, 'Budget', 1);
disp(p);
PortfolioCVaR with properties:
BuyCost: []
SellCost: []
RiskFreeRate: []
ProbabilityLevel: []
Turnover: []
BuyTurnover: []
SellTurnover: []
NumScenarios: []
Name: []
NumAssets: 20
AssetList: []
InitPort: []
AInequality: []
bInequality: []
AEquality: []
bEquality: []
LowerBound: [20x1 double]
UpperBound: []
LowerBudget: 1
UpperBudget: 1
GroupMatrix: []
LowerGroup: []
UpperGroup: []
GroupA: []
GroupB: []
LowerRatio: []
UpperRatio: []

```

\section*{Setting Default Constraints Using the setDefaultConstraints Function}

An alternative approach is to use the setDefaultConstraints function. If the number of assets is already known in a PortfolioCVaR object, use setDefaultConstraints with no arguments to set up the necessary bound and budget constraints. Suppose that you have 20 assets to set up the portfolio set for a default problem:
```

p = PortfolioCVaR('NumAssets', 20);
p = setDefaultConstraints(p);
disp(p);
PortfolioCVaR with properties:
BuyCost: []
SellCost: []
RiskFreeRate: []
ProbabilityLevel: []
Turnover: []
BuyTurnover: []
SellTurnover: []
NumScenarios: []
Name: []
NumAssets: 20
AssetList: []
InitPort: []
AInequality: []
bInequality: []
AEquality: []
bEquality: []
LowerBound: [20x1 double]
UpperBound: []
LowerBudget: 1
UpperBudget: 1
GroupMatrix: []
LowerGroup: []
UpperGroup: []
GroupA: []
GroupB: []
LowerRatio: []
UpperRatio: []

```

If the number of assets is unknown, setDefaultConstraints accepts NumAssets as an optional argument to form a portfolio set for a default problem. Suppose that you have 20 assets:
```

p = PortfolioCVaR;
p = setDefaultConstraints(p, 20);
disp(p);

\section*{Working with Bound Constraints Using PortfolioCVaR Object}

Bound constraints are optional linear constraints that maintain upper and lower bounds on portfolio weights (see "Bound Constraints" on page 5-9). Although every CVaR portfolio set must be bounded, it is not necessary to specify a CVaR portfolio set with explicit bound constraints. For example, you can create a CVaR portfolio set with an implicit upper bound constraint or a CVaR portfolio set with average turnover constraints. The bound constraints have properties LowerBound for the lower-bound constraint and UpperBound for the upper-bound constraint. Set default values for
these constraints using the setDefaultConstraints function (see "Setting Default Constraints for Portfolio Weights Using PortfolioCVaR Object" on page 5-53).

\section*{Setting Bounds Using the PortfolioCVaR Function}

The properties for bound constraints are set through the PortfolioCVaR function. Suppose that you have a balanced fund with stocks that can range from \(50 \%\) to \(75 \%\) of your portfolio and bonds that can range from \(25 \%\) to \(50 \%\) of your portfolio. The bound constraints for a balanced fund are set with:
```

lb = [ 0.5; 0.25 ];
ub = [ 0.75; 0.5 ];
p = PortfolioCVaR('LowerBound', lb, 'UpperBound', ub);
disp(p.NumAssets);
disp(p.LowerBound);
disp(p.UpperBound);
2
0.5000
0.2500
0.7500
0.5000

```

To continue with this example, you must set up a budget constraint. For details, see "Working with Budget Constraints Using PortfolioCVaR Object" on page 5-58.

\section*{Setting Bounds Using the setBounds Function}

You can also set the properties for bound constraints using setBounds. Suppose that you have a balanced fund with stocks that can range from \(50 \%\) to \(75 \%\) of your portfolio and bonds that can range from \(25 \%\) to \(50 \%\) of your portfolio. Given a PortfolioCVaR object p, use setBounds to set the bound constraints:
```

lb = [ 0.5; 0.25 ];
ub = [ 0.75; 0.5 ];
p = PortfolioCVaR;
p = setBounds(p, lb, ub);
disp(p.NumAssets);
disp(p.LowerBound);
disp(p.UpperBound);

```
0.5000
0.2500
0.7500
0.5000

\section*{Setting Bounds Using the PortfolioCVaR Function or setBounds Function}

Both the PortfolioCVaR function and setBounds function implement scalar expansion on either the LowerBound or UpperBound properties. If the NumAssets property is already set in the PortfolioCVaR object, scalar arguments for either property expand to have the same value across all dimensions. In addition, setBounds lets you specify NumAssets as an optional argument. Suppose that you have a universe of 500 assets and you want to set common bound constraints on all assets in your universe. Specifically, you are a long-only investor and want to hold no more than \(5 \%\) of your portfolio in any single asset. You can set these bound constraints in any of these equivalent ways:
```

p = PortfolioCVaR('NumAssets', 500, 'LowerBound', 0, 'UpperBound', 0.05);
or
p = PortfolioCVaR('NumAssets', 500);
p = setBounds(p, 0, 0.05);
or
p = PortfolioCVaR;
p = setBounds(p, 0, 0.05, 500);

```

To clear bound constraints from your PortfolioCVaR object, use either the PortfolioCVaR function or setBounds with empty inputs for the properties to be cleared. For example, to clear the upper-bound constraint from the PortfolioCVaR object p in the previous example:
```

p = PortfolioCVaR(p, 'UpperBound', []);

```

\section*{Working with Budget Constraints Using PorffolioCVaR Object}

The budget constraint is an optional linear constraint that maintains upper and lower bounds on the sum of portfolio weights (see "Budget Constraints" on page 5-10). Budget constraints have properties LowerBudget for the lower budget constraint and UpperBudget for the upper budget constraint. If you set up a CVaR portfolio
optimization problem that requires portfolios to be fully invested in your universe of assets, you can set LowerBudget to be equal to UpperBudget. These budget constraints can be set with default values equal to 1 using setDefaultConstraints (see "Setting Default Constraints Using the PortfolioCVaR Function" on page 5-54).

\section*{Setting Budget Constraints Using the PortfolioCVaR Function}

The properties for the budget constraint can also be set using the PortfolioCVaR function. Suppose that you have an asset universe with many risky assets and a riskless asset and you want to ensure that your portfolio never holds more than \(1 \%\) cash, that is, you want to ensure that you are \(99-100 \%\) invested in risky assets. The budget constraint for this portfolio can be set with:
```

p = PortfolioCVaR('LowerBudget', 0.99, 'UpperBudget', 1);
disp(p.LowerBudget);
disp(p.UpperBudget);

```
0.9900

1

\section*{Setting Budget Constraints Using the setBudget Function}

You can also set the properties for a budget constraint using setBudget. Suppose that you have a fund that permits up to \(10 \%\) leverage which means that your portfolio can be from \(100 \%\) to \(110 \%\) invested in risky assets. Given a PortfolioCVaR object p, use setBudget to set the budget constraints:
```

p = PortfolioCVaR;
p = setBudget(p, 1, 1.1);
disp(p.LowerBudget);
disp(p.UpperBudget);

```

1
1.1000

If you were to continue with this example, then set the RiskFreeRate property to the borrowing rate to finance possible leveraged positions. For details on the RiskFreeRate property, see "Working with a Riskless Asset" on page 5-48. To clear either bound for the budget constraint from your PortfolioCVaR object, use either the PortfolioCVaR function or setBudget with empty inputs for the properties to be cleared. For example, clear the upper-budget constraint from the PortfolioCVaR object \(p\) in the previous example with:
```

p = PortfolioCVaR(p, 'UpperBudget', []);

```

\section*{Working with Group Constraints Using PorifolioCVaR Object}

Group constraints are optional linear constraints that group assets together and enforce bounds on the group weights (see "Group Constraints" on page 5-11). Although the constraints are implemented as general constraints, the usual convention is to form a group matrix that identifies membership of each asset within a specific group with Boolean indicators (either true or false or with 1 or 0 ) for each element in the group matrix. Group constraints have properties GroupMatrix for the group membership matrix, LowerGroup for the lower-bound constraint on groups, and UpperGroup for the upper-bound constraint on groups.

\section*{Setting Group Constraints Using the PortfolioCVaR Function}

The properties for group constraints are set through the PortfolioCVaR function. Suppose that you have a portfolio of five assets and want to ensure that the first three assets constitute no more than \(30 \%\) of your portfolio, then you can set group constraints:
```

G = [ [10cclll
p = PortfolioCVaR('GroupMatrix', G, 'UpperGroup', 0.3);
disp(p.NumAssets);
disp(p.GroupMatrix);
disp(p.UpperGroup);
5
1
0.3000

```

The group matrix \(G\) can also be a logical matrix so that the following code achieves the same result.
\(G=[\) true true true false false ];
p = PortfolioCVaR('GroupMatrix', G, 'UpperGroup', 0.3);
disp(p.NumAssets);
disp(p.GroupMatrix);
disp(p.UpperGroup);
5
\(\begin{array}{lllll}1 & 1 & 1 & 0 & 0\end{array}\)

\subsection*{0.3000}

\section*{Setting Group Constraints Using the setGroups and addGroups Functions}

You can also set the properties for group constraints using setGroups. Suppose that you have a portfolio of five assets and want to ensure that the first three assets constitute no more than \(30 \%\) of your portfolio. Given a PortfolioCVaR object p, use setGroups to set the group constraints:
```

G = [ true true true false false ];
p = PortfolioCVaR;
p = setGroups(p, G, [], 0.3);
disp(p.NumAssets);
disp(p.GroupMatrix);
disp(p.UpperGroup);
5
1 1 1 1 1 0
0.3000

```

In this example, you would set the LowerGroup property to be empty ([ ]).
Suppose that you want to add another group constraint to make odd-numbered assets constitute at least \(20 \%\) of your portfolio. Set up an augmented group matrix and introduce infinite bounds for unconstrained group bounds or use the addGroups function to build up group constraints. For this example, create another group matrix for the second group constraint:
```

p = PortfolioCVaR;
G = [ true true true false false ]; % group matrix for first group constraint
p = setGroups(p, G, [], 0.3);
G = [ true false true false true ]; % group matrix for second group constraint
p = addGroups(p, G, 0.2);
disp(p.NumAssets);
disp(p.GroupMatrix);
disp(p.LowerGroup);
disp(p.UpperGroup);
5
1
1 0

- Inf

```

\subsection*{0.2000}

\subsection*{0.3000}

Inf
addGroups determines which bounds are unbounded so you only need to focus on the constraints that you want to set.

The PortfolioCVaR function, setGroups, and addGroups implement scalar expansion on either the LowerGroup or UpperGroup properties based on the dimension of the group matrix in the property GroupMatrix. Suppose that you have a universe of 30 assets with 6 asset classes such that assets \(1-5\), assets \(6-12\), assets \(13-18\), assets \(19-22\), assets 23-27, and assets 28-30 constitute each of your asset classes and you want each asset class to fall from \(0 \%\) to \(25 \%\) of your portfolio. Let the following group matrix define your groups and scalar expansion define the common bounds on each group:
```

p = PortfolioCVaR;
G = blkdiag(true(1,5), true(1,7), true(1,6), true(1,4), true(1,5), true(1,3));
p = setGroups(p, G, 0, 0.25);
disp(p.NumAssets);
disp(p.GroupMatrix);
disp(p.LowerGroup);
disp(p.UpperGroup);
30

\section*{Working with Group Ratio Constraints Using PortfolioCVaR Object}

Group ratio constraints are optional linear constraints that maintain bounds on proportional relationships among groups of assets (see "Group Ratio Constraints" on page \(5-12\) ). Although the constraints are implemented as general constraints, the usual convention is to specify a pair of group matrices that identify membership of each asset within specific groups with Boolean indicators (either true or false or with 1 or 0 ) for each element in each of the group matrices. The goal is to ensure that the ratio of a base group compared to a comparison group fall within specified bounds. Group ratio constraints have properties:
- GroupA for the base membership matrix
- GroupB for the comparison membership matrix
- LowerRatio for the lower-bound constraint on the ratio of groups
- UpperRatio for the upper-bound constraint on the ratio of groups

\section*{Setting Group Ratio Constraints Using the PortfolioCVaR Function}

The properties for group ratio constraints are set using PortfolioCVaR function. For example, assume that you want the ratio of financial to nonfinancial companies in your portfolios to never go above \(50 \%\). Suppose that you have six assets with three financial companies (assets 1-3) and three nonfinanical companies (assets 4-6). To set group ratio constraints:
```

GA = [ 1 1 1 1 0 0 0 ]; % financial companies
GB = [ 0 0 0 1 1 1 ]; % nonfinancial companies
p = PortfolioCVaR('GroupA', GA, 'GroupB', GB, 'UpperRatio', 0.5);
disp(p.NumAssets);
disp(p.GroupA);
disp(p.GroupB);
disp(p.UpperRatio);
6
1 1}1
0
0.5000

```

Group matrices GA and GB in this example can be logical matrices with true and false elements that yield the same result:
```

GA = [ true true true false false false ]; % financial companies
GB = [ false false false true true true ]; % nonfinancial companies

```
```

p = PortfolioCVaR('GroupA', GA, 'GroupB', GB, 'UpperRatio', 0.5);
disp(p.NumAssets);
disp(p.GroupA);
disp(p.GroupB);
disp(p.UpperRatio);
6
1
0
0.5000

```

\section*{Setting Group Ratio Constraints Using the setGroupRatio and addGroupRatio Functions}

You can also set the properties for group ratio constraints using setGroupRatio. For example, assume that you want the ratio of financial to nonfinancial companies in your portfolios to never go above \(50 \%\). Suppose that you have six assets with three financial companies (assets 1-3) and three nonfinanical companies (assets 4-6). Given a PortfolioCVaR object \(p\), use setGroupRatio to set the group constraints:
```

GA = [ true true true false false false ]; % financial companies
GB = [ false false false true true true ]; % nonfinancial companies
p = PortfolioCVaR;
p = setGroupRatio(p, GA, GB, [], 0.5);
disp(p.NumAssets);
disp(p.GroupA);
disp(p.GroupB);
disp(p.UpperRatio);
6
1 1}1
0
0.5000

```

In this example, you would set the LowerRatio property to be empty ([ ]).
Suppose that you want to add another group ratio constraint to ensure that the weights in odd-numbered assets constitute at least \(20 \%\) of the weights in nonfinancial assets your portfolio. You can set up augmented group ratio matrices and introduce infinite bounds for unconstrained group ratio bounds, or you can use the addGroupRatio function to build up group ratio constraints. For this example, create another group matrix for the second group constraint:
```

p = PortfolioCVaR;

```
```

GA = [ true true true false false false ]; % financial companies
GB = [ false false false true true true ]; % nonfinancial companies
p = setGroupRatio(p, GA, GB, [], 0.5);
GA = [ true false true false true false ]; % odd-numbered companies
GB = [ false false false true true true ]; % nonfinancial companies
p = addGroupRatio(p, GA, GB, O.2);
disp(p.NumAssets);
disp(p.GroupA);
disp(p.GroupB);
disp(p.LowerRatio);
disp(p.UpperRatio);
6

| 1 | 1 | 1 | 0 | 0 | 0 |
| :--- | :--- | :--- | :--- | :--- | :--- |
| 1 | 0 | 1 | 0 | 1 | 0 |
| 0 | 0 | 0 | 1 | 1 | 1 |
| 0 | 0 | 0 | 1 | 1 | 1 |

    - Inf
    0.2000
0.5000
Inf

```

Notice that addGroupRatio determines which bounds are unbounded so you only need to focus on the constraints you want to set.

The PortfolioCVaR function, setGroupRatio, and addGroupRatio implement scalar expansion on either the LowerRatio or UpperRatio properties based on the dimension of the group matrices in GroupA and GroupB properties.

\section*{Working with Linear Equality Constraints Using PortfolioCVaR Object}

Linear equality constraints are optional linear constraints that impose systems of equalities on portfolio weights (see "Linear Equality Constraints" on page 5-9). Linear equality constraints have properties AEquality, for the equality constraint matrix, and bEquality, for the equality constraint vector.

\section*{Setting Linear Equality Constraints Using the PortfolioCVaR Function}

The properties for linear equality constraints are set using the PortfolioCVaR function. Suppose that you have a portfolio of five assets and want to ensure that the first three assets are \(50 \%\) of your portfolio. To set this constraint:
```

A = [ 1 1 1 1 0 0 ];
b = 0.5;
p = PortfolioCVaR('AEquality', A, 'bEquality', b);
disp(p.NumAssets);
disp(p.AEquality);
disp(p.bEquality);
5
1
0.5000

```

\section*{Setting Linear Equality Constraints Using the setEquality and addEquality Functions}

You can also set the properties for linear equality constraints using setEquality. Suppose that you have a portfolio of five assets and want to ensure that the first three assets are \(50 \%\) of your portfolio. Given a PortfolioCVaR object p, use setEquality to set the linear equality constraints:
```

A = [ 1 1 1 0 0 ];
b = 0.5;
p = PortfolioCVaR;
p = setEquality(p, A, b);
disp(p.NumAssets);
disp(p.AEquality);
disp(p.bEquality);
5
1
0.5000

```

Suppose that you want to add another linear equality constraint to ensure that the last three assets also constitute \(50 \%\) of your portfolio. You can set up an augmented system of linear equalities or use addEquality to build up linear equality constraints. For this example, create another system of equalities:
```

p = PortfolioCVaR;
A = [ 1 1 1 1 0 0 ]; % first equality constraint
b = 0.5;
p = setEquality(p, A, b);

```
```

A = [ 0 0 1 1 1 ]; % second equality constraint
b = 0.5;
p = addEquality(p, A, b);
disp(p.NumAssets);
disp(p.AEquality);
disp(p.bEquality);
5
1
0.5000
0.5000

```

The PortfolioCVaR function, setEquality, and addEquality implement scalar expansion on the bEquality property based on the dimension of the matrix in the AEquality property.

\section*{Working with Linear Inequality Constraints Using PortfolioCVaR Object}

Linear inequality constraints are optional linear constraints that impose systems of inequalities on portfolio weights (see "Linear Inequality Constraints" on page 5-8).
Linear inequality constraints have properties AInequality for the inequality constraint matrix, and bInequality for the inequality constraint vector.

\section*{Setting Linear Inequality Constraints Using the PorffolioCVaR Function}

The properties for linear inequality constraints are set using the PortfolioCVaR function. Suppose that you have a portfolio of five assets and you want to ensure that the first three assets are no more than \(50 \%\) of your portfolio. To set up these constraints:
```

A = [ 1 1 1 0 0 ];
b = 0.5;
p = PortfolioCVaR('AInequality', A, 'bInequality', b);
disp(p.NumAssets);
disp(p.AInequality);
disp(p.bInequality);

```
5
\(\begin{array}{lllll}1 & 1 & 1 & 0 & 0\end{array}\)

\subsection*{0.5000}

\section*{Setting Linear Inequality Constraints Using the setInequality and addInequality Functions}

You can also set the properties for linear inequality constraints using setInequality. Suppose that you have a portfolio of five assets and you want to ensure that the first three assets constitute no more than \(50 \%\) of your portfolio. Given a PortfolioCVaR object p , use set Inequality to set the linear inequality constraints:
```

A = [ [$$
\begin{array}{llllll}{1}&{1}&{1}&{0}&{0}\end{array}
$$];
b = 0.5;
p = PortfolioCVaR;
p = setInequality(p, A, b);
disp(p.NumAssets);
disp(p.AInequality);
disp(p.bInequality);
5
1 1 1 1 1 0
0.5000

```

Suppose that you want to add another linear inequality constraint to ensure that the last three assets constitute at least \(50 \%\) of your portfolio. You can set up an augmented system of linear inequalities or use the addInequality function to build up linear inequality constraints. For this example, create another system of inequalities:
```

p = PortfolioCVaR;
A = [ 1 1 1 0 0 ]; % first inequality constraint
b = 0.5;
p = setInequality(p, A, b);
A = [ 0 0 -1 -1 -1 ]; % second inequality constraint
b = -0.5;
p = addInequality(p, A, b);
disp(p.NumAssets);
disp(p.AInequality);
disp(p.bInequality);

```
5
\begin{tabular}{rrrrr}
1 & 1 & 1 & 0 & 0 \\
0 & 0 & -1 & -1 & -1
\end{tabular}
0.5000
-0. 5000
The PortfolioCVaR function, setInequality, and addInequality implement scalar expansion on the bInequality property based on the dimension of the matrix in the AInequality property.

\section*{Working with Average Turnover Constraints Using PorffolioCVaR Object}

The turnover constraint is an optional linear absolute value constraint (see "Average Turnover Constraints" on page 5-12) that enforces an upper bound on the average of purchases and sales. The turnover constraint can be set using the PortfolioCVaR function or the setTurnover function. The turnover constraint depends on an initial or current portfolio, which is assumed to be zero if not set when the turnover constraint is set. The turnover constraint has properties Turnover, for the upper bound on average turnover, and InitPort, for the portfolio against which turnover is computed.

\section*{Setting Average Turnover Constraints Using the PorffolioCVaR Function}

The properties for the turnover constraints are set using the PortfolioCVaR function. Suppose that you have an initial portfolio of 10 assets in a variable x 0 and you want to ensure that average turnover is no more than \(30 \%\). To set this turnover constraint:
```

x0 = [ 0.12; 0.09; 0.08; 0.07; 0.1; 0.1; 0.15; 0.11; 0.08; 0.1 ];
p = PortfolioCVaR('Turnover', 0.3, 'InitPort', x0);
disp(p.NumAssets);
disp(p.Turnover);
disp(p.InitPort);

```

0.1000
0.1000
0.1500
0.1100

\subsection*{0.0800}
0.1000

Note if the NumAssets or InitPort properties are not set before or when the turnover constraint is set, various rules are applied to assign default values to these properties (see "Setting Up an Initial or Current Portfolio" on page 5-34).

\section*{Setting Average Turnover Constraints Using the setTurnover Function}

You can also set properties for portfolio turnover using setTurnover to specify both the upper bound for average turnover and an initial portfolio. Suppose that you have an initial portfolio of 10 assets in a variable \(x 0\) and want to ensure that average turnover is no more than \(30 \%\). Given a PortfolioCVaR object p, use setTurnover to set the turnover constraint with and without the initial portfolio being set previously:
```

x0 = [ 0.12; 0.09; 0.08; 0.07; 0.1; 0.1; 0.15; 0.11; 0.08; 0.1 ];
p = PortfolioCVaR('InitPort', x0);
p = setTurnover(p, 0.3);
disp(p.NumAssets);
disp(p.Turnover);
disp(p.InitPort);

0.1100
0.0800
0.1000
setTurnover implements scalar expansion on the argument for the initial portfolio. If the NumAssets property is already set in the PortfolioCVaR object, a scalar argument for InitPort expands to have the same value across all dimensions. In addition, setTurnover lets you specify NumAssets as an optional argument. To clear turnover from your PortfolioCVaR object, use the PortfolioCVaR function or setTurnover with empty inputs for the properties to be cleared.

\section*{Working with One-way Turnover Constraints Using PortfolioCVaR Object}

One-way turnover constraints are optional constraints (see "One-way Turnover Constraints" on page 5-13) that enforce upper bounds on net purchases or net sales. One-way turnover constraints can be set using the PortfolioCVaR function or the setOneWayTurnover function. One-way turnover constraints depend upon an initial or current portfolio, which is assumed to be zero if not set when the turnover constraints are set. One-way turnover constraints have properties BuyTurnover, for the upper bound on net purchases, SellTurnover, for the upper bound on net sales, and InitPort, for the portfolio against which turnover is computed.

\section*{Setting One-way Turnover Constraints Using the PortfolioCVaR Function}

The Properties for the one-way turnover constraints are set using the PortfolioCVaR function. Suppose that you have an initial portfolio with 10 assets in a variable x 0 and you want to ensure that turnover on purchases is no more than \(30 \%\) and turnover on sales is no more than \(20 \%\) of the initial portfolio. To set these turnover constraints:
```

x0 = [ 0.12; 0.09; 0.08; 0.07; 0.1; 0.1; 0.15; 0.11; 0.08; 0.1 ];
p = PortfolioCVaR('BuyTurnover', 0.3, 'SellTurnover', 0.2, 'InitPort', x0);
disp(p.NumAssets);
disp(p.BuyTurnover);

```

0.1000

```

If the NumAssets or InitPort properties are not set before or when the turnover constraint is set, various rules are applied to assign default values to these properties (see "Setting Up an Initial or Current Portfolio" on page 5-34).

\section*{Setting Turnover Constraints Using the setOneWayTurnover Function}

You can also set properties for portfolio turnover using setOneWayTurnover to specify to the upper bounds for turnover on purchases (BuyTurnover) and sales (SellTurnover) and an initial portfolio. Suppose that you have an initial portfolio of 10 assets in a variable x 0 and want to ensure that turnover on purchases is no more than \(30 \%\) and that turnover on sales is no more than \(20 \%\) of the initial portfolio. Given a PortfolioCVaR object \(p\), use setOneWayTurnover to set the turnover constraints with and without the initial portfolio being set previously:
```

x0 = [ 0.12; 0.09; 0.08; 0.07; 0.1; 0.1; 0.15; 0.11; 0.08; 0.1 ];
p = PortfolioCVaR('InitPort', x0);
p = setOneWayTurnover(p, 0.3, 0.2);
disp(p.NumAssets);
disp(p.BuyTurnover);
disp(p.SellTurnover);
disp(p.InitPort);
1 0
0.3000

```
```

    0.2000
    0.1200
    0.0900
    0.0800
    0.0700
    0.1000
    0.1000
    0.1500
    0.1100
    0.0800
    0.1000
    Or
x0 = [ 0.12; 0.09; 0.08; 0.07; 0.1; 0.1; 0.15; 0.11; 0.08; 0.1 ];
p = PortfolioCVaR;
p = setOneWayTurnover(p, 0.3, 0.2, x0);
disp(p.NumAssets);
disp(p.BuyTurnover);
disp(p.SellTurnover);
disp(p.InitPort);

0.3000
0.2000
0.1200
0.0900
0.0800
0.0700
0.1000
0.1000
0.1500
0.1100
0.0800
0.1000

```
setOneWayTurnover implements scalar expansion on the argument for the initial portfolio. If the NumAssets property is already set in the PortfolioCVaR object, a scalar argument for InitPort expands to have the same value across all dimensions. In addition, setOneWayTurnover lets you specify NumAssets as an optional argument. To remove one-way turnover from your PortfolioCVaR object, use thePortfolioCVaR function or setOneWayTurnover with empty inputs for the properties to be cleared.

\section*{Validate the CVaR Portfolio Problem}
```

In this section...
"Validating a CVaR Portfolio Set" on page 5-75
"Validating CVaR Portfolios" on page 5-77

```

In some cases, you may want to validate either your inputs to, or outputs from, a portfolio optimization problem. Although most error checking that occurs during the problem setup phase catches most difficulties with a portfolio optimization problem, the processes to validate CVaR portfolio sets and portfolios are time consuming and are best done offline. So, the portfolio optimization tools have specialized functions to validate CVaR portfolio sets and portfolios. For information on the workflow when using PortfolioCVaR objects, see "PortfolioCVaR Object Workflow" on page 5-16.

\section*{Validating a CVaR Porffolio Set}

Since it is necessary and sufficient that your CVaR portfolio set must be a nonempty, closed, and bounded set to have a valid portfolio optimization problem, the estimateBounds function lets you examine your portfolio set to determine if it is nonempty and, if nonempty, whether it is bounded. Suppose that you have the following CVaR portfolio set which is an empty set because the initial portfolio at 0 is too far from a portfolio that satisfies the budget and turnover constraint:
```

p = PortfolioCVaR('NumAssets', 3, 'Budget', 1);
p = setTurnover(p, 0.3, 0);

```

If a CVaR portfolio set is empty, estimateBounds returns NaN bounds and sets the isbounded flag to []:
```

[lb, ub, isbounded] = estimateBounds(p)

```
lb \(=\)
    NaN
    NaN
    NaN
\(u b=\)
```

    NaN
    NaN
    NaN
    isbounded =
[]

```

Suppose that you create an unbounded CVaR portfolio set as follows:
```

p = PortfolioCVaR('AInequality', [1 -1; 1 1 ], 'bInequality', 0);

```
[lb, ub, isbounded] = estimateBounds(p)
lb =
    - Inf
    - Inf
ub =
    1.0e-008
    \(-0.3712\)
        Inf
isbounded =

0
In this case, estimateBounds returns (possibly infinite) bounds and sets the isbounded flag to false. The result shows which assets are unbounded so that you can apply bound constraints as necessary.

Finally, suppose that you created a CVaR portfolio set that is both nonempty and bounded. estimateBounds not only validates the set, but also obtains tighter bounds which are useful if you are concerned with the actual range of portfolio choices for individual assets in your portfolio set:
```

p = PortfolioCVaR;
p = setBudget(p, 1,1);
p = setBounds(p, [ -0.1; 0.2; 0.3; 0.2 ], [ 0.5; 0.3; 0.9; 0.8 ]);
[lb, ub, isbounded] = estimateBounds(p)
lb =

```
    0.2000
    0.3000
    0.2000
ub =
    0.3000
    0.3000
    0.7000
    0.6000
isbounded =
    1
```

In this example, all but the second asset has tighter upper bounds than the input upper bound implies.

## Validating CVaR Porffolios

Given a CVaR portfolio set specified in a PortfolioCVaR object, you often want to check if specific portfolios are feasible with respect to the portfolio set. This can occur with, for example, initial portfolios and with portfolios obtained from other procedures. The checkFeasibility function determines whether a collection of portfolios is feasible. Suppose that you perform the following portfolio optimization and want to determine if the resultant efficient portfolios are feasible relative to a modified problem.

First, set up a problem in the PortfolioCVaR object p, estimate efficient portfolios in pwgt, and then confirm that these portfolios are feasible relative to the initial problem:

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
    0.00408 0.0289 0.0204 0.0119;
    0.00192 0.0204 0.0576 0.0336;
    0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;
AssetScenarios = mvnrnd(m, C, 20000);
p = PortfolioCVaR;
p = setScenarios(p, AssetScenarios);
p = setDefaultConstraints(p);
```

```
p = setProbabilityLevel(p, 0.95);
pwgt = estimateFrontier(p);
checkFeasibility(p, pwgt)
ans =
```

Next, set up a different portfolio problem that starts with the initial problem with an additional a turnover constraint and an equally weighted initial portfolio:

```
q = setTurnover(p, 0.3, 0.25);
checkFeasibility(q, pwgt)
ans =
```

$\begin{array}{llllllllll}0 & 0 & 0 & 1 & 1 & 0 & 0 & 0 & 0 & 0\end{array}$
In this case, only two of the 10 efficient portfolios from the initial problem are feasible relative to the new problem in PortfolioCVaR object q. Solving the second problem using checkFeasibility demonstrates that the efficient portfolio for PortfolioCVaR object q is feasible relative to the initial problem:

```
qwgt = estimateFrontier(q);
checkFeasibility(p, qwgt)
ans =
\begin{tabular}{llllllllll}
1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1
\end{tabular}
```

# Estimate Efficient Portfolios for PortfolioCVaR Object 

In this section...<br>"Obtaining Portfolios Along the Entire Efficient Frontier" on page 5-80<br>"Obtaining Endpoints of the Efficient Frontier" on page 5-82<br>"Obtaining Efficient Portfolios for Target Returns" on page 5-84<br>"Obtaining Efficient Portfolios for Target Risks" on page 5-86<br>"Choosing and Controlling the Solver" on page 5-89

There are two ways to look at a portfolio optimization problem that depends on what you are trying to do. One goal is to estimate efficient portfolios and the other is to estimate efficient frontiers. This section focuses on the former goal and "Estimate Efficient Frontiers for PortfolioCVaR Object" on page 5-92 focuses on the latter goal. For information on the workflow when using PortfolioCVaR objects, see "PortfolioCVaR Object Workflow" on page 5-16.

## Obtaining Porffolios Along the Entire Efficient Frontier

The most basic way to obtain optimal portfolios is to obtain points over the entire range of the efficient frontier. Given a portfolio optimization problem in a PortfolioCVaR object, the estimateFrontier function computes efficient portfolios spaced evenly according to the return proxy from the minimum to maximum return efficient portfolios. The number of portfolios estimated is controlled by the hidden property defaultNumPorts which is set to 10. A different value for the number of portfolios estimated is specified as input to estimateFrontier. This example shows the default number of efficient portfolios over the entire range of the efficient frontier:

```
m}=[0.05;0.1;0.12;0.18]
C = [ 0.0064 0.00408 0.00192 0;
    0.00408 0.0289 0.0204 0.0119;
    0.00192 0.0204 0.0576 0.0336;
    0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;
AssetScenarios = mvnrnd(m, C, 20000);
p = PortfolioCVaR;
p = setScenarios(p, AssetScenarios);
p = setDefaultConstraints(p);
p = setProbabilityLevel(p, 0.95);
pwgt = estimateFrontier(p);
disp(pwgt);
```

Columns 1 through 8

| 0.8670 | 0.7046 | 0.5421 | 0.3825 | 0.2236 | 0.0570 | 0.0000 | 0.0000 |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| 0.0413 | 0.1193 | 0.1963 | 0.2667 | 0.3392 | 0.4159 | 0.3392 | 0.1753 |
| 0.0488 | 0.0640 | 0.0811 | 0.1012 | 0.1169 | 0.1427 | 0.1568 | 0.1754 |
| 0.0429 | 0.1120 | 0.1806 | 0.2496 | 0.3203 | 0.3844 | 0.5040 | 0.6493 |

Columns 9 through 10

| 0.0000 | 0.0000 |
| :--- | :--- |
| 0.0230 | 0.0000 |
| 0.1777 | 0.0000 |
| 0.7993 | 1.0000 |

If you want only four portfolios in the previous example:

```
pwgt = estimateFrontier(p, 4);
```

disp(pwgt);

| 0.8670 | 0.3825 | 0.0000 | 0.0000 |
| :--- | :--- | :--- | :--- |
| 0.0413 | 0.2667 | 0.3392 | 0.0000 |
| 0.0488 | 0.1012 | 0.1568 | 0.0000 |
| 0.0429 | 0.2496 | 0.5040 | 1.0000 |

Starting from the initial portfolio, estimateFrontier also returns purchases and sales to get from your initial portfolio to each efficient portfolio on the efficient frontier. For example, given an initial portfolio in pwgt0, you can obtain purchases and sales:

```
pwgt0 = [ 0.3; 0.3; 0.2; 0.1 ];
p = setInitPort(p, pwgt0);
[pwgt, pbuy, psell] = estimateFrontier(p);
display(pwgt);
display(pbuy);
display(psell);
pwgt =
    Columns 1 through 8
\begin{tabular}{llllllll}
0.8670 & 0.7046 & 0.5421 & 0.3825 & 0.2236 & 0.0570 & 0.0000 & 0.0000 \\
0.0413 & 0.1193 & 0.1963 & 0.2667 & 0.3392 & 0.4159 & 0.3392 & 0.1753 \\
0.0488 & 0.0640 & 0.0811 & 0.1012 & 0.1169 & 0.1427 & 0.1568 & 0.1754 \\
0.0429 & 0.1120 & 0.1806 & 0.2496 & 0.3203 & 0.3844 & 0.5040 & 0.6493
\end{tabular}
Columns 9 through 10
        0.0000 0.0000
        0.0230 0.0000
        0.1777 0.0000
        0.7993 1.0000
pbuy =
    Columns 1 through 8
\begin{tabular}{llllllll}
0.5670 & 0.4046 & 0.2421 & 0.0825 & 0 & 0 & 0 & 0
\end{tabular}
```

If you do not specify an initial portfolio, the purchase and sale weights assume that your initial portfolio is 0 .

## Obtaining Endpoints of the Efficient Frontier

In many cases, you might be interested in the endpoint portfolios for the efficient frontier. Suppose that you want to determine the range of returns from minimum to maximum to refine a search for a portfolio with a specific target return. Use the estimateFrontierLimits function to obtain the endpoint portfolios:

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
    0.00408 0.0289 0.0204 0.0119;
    0.00192 0.0204 0.0576 0.0336;
    0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;
AssetScenarios = mvnrnd(m, C, 20000);
p = PortfolioCVaR;
p = setScenarios(p, AssetScenarios);
p = setDefaultConstraints(p);
p = setProbabilityLevel(p, 0.95);
```

```
pwgt = estimateFrontierLimits(p);
disp(pwgt);
0.8646 0.0000
0.0470 0.0000
0.0414 0.0000
0.0470 1.0000
```

Note: The endpoints of the efficient frontier depend upon the Scenarios in the PortfolioCVaR object. If you change the Scenarios, you are likely to obtain different endpoints.

Starting from an initial portfolio, estimateFrontierLimits also returns purchases and sales to get from the initial portfolio to the endpoint portfolios on the efficient frontier. For example, given an initial portfolio in pwgt0, you can obtain purchases and sales:

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
    0.00408 0.0289 0.0204 0.0119;
    0.00192 0.0204 0.0576 0.0336;
    0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;
AssetScenarios = mvnrnd(m, C, 20000);
p = PortfolioCVaR;
p = setScenarios(p, AssetScenarios);
p = setDefaultConstraints(p);
p = setProbabilityLevel(p, 0.95);
pwgt0 = [ 0.3; 0.3; 0.2; 0.1 ];
p = setInitPort(p, pwgt0);
[pwgt, pbuy, psell] = estimateFrontierLimits(p);
display(pwgt);
display(pbuy);
display(psell);
```

pwgt =

| 0.8624 | 0.0000 |
| :--- | :--- |
| 0.0513 | 0.0000 |
| 0.0452 | 0.0000 |
| 0.0411 | 1.0000 |

pbuy =

| 0.5624 | 0 |
| ---: | ---: |
| 0 | 0 |
| 0 | 0 |
| 0 | 0.9000 |

psell =

| 0 | 0.3000 |
| ---: | ---: |
| 0.2487 | 0.3000 |
| 0.1548 | 0.2000 |
| 0.0589 | 0 |

If you do not specify an initial portfolio, the purchase and sale weights assume that your initial portfolio is 0 .

## Obtaining Efficient Portfolios for Target Returns

To obtain efficient portfolios that have targeted portfolio returns, the estimateFrontierByReturn function accepts one or more target portfolio returns and obtains efficient portfolios with the specified returns. For example, assume that you have a universe of four assets where you want to obtain efficient portfolios with target portfolio returns of $7 \%, 10 \%$, and $12 \%$ :

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
    0.00408 0.0289 0.0204 0.0119;
    0.00192 0.0204 0.0576 0.0336;
    0 0.0119 0.0336 0.1225 ];
AssetScenarios = mvnrnd(m, C, 20000);
p = PortfolioCVaR;
p = setScenarios(p, AssetScenarios);
p = setDefaultConstraints(p);
```

```
p = setProbabilityLevel(p, 0.95);
pwgt = estimateFrontierByReturn(p, [0.07, 0.10, .12]);
display(pwgt);
pwgt =
\begin{tabular}{lll}
0.7526 & 0.3773 & 0.1306 \\
0.1047 & 0.3079 & 0.4348 \\
0.0662 & 0.1097 & 0.1426 \\
0.0765 & 0.2051 & 0.2920
\end{tabular}
```

In some cases, you can request a return for which no efficient portfolio exists. Based on the previous example, suppose that you want a portfolio with a $4 \%$ return (which is the return of the first asset). A portfolio that is fully invested in the first asset, however, is inefficient. estimateFrontierByReturn warns if your target returns are outside the range of efficient portfolio returns and replaces it with the endpoint portfolio of the efficient frontier closest to your target return:

```
pwgt = estimateFrontierByReturn(p, [0.04]);
Warning: One or more target return values are outside the feasible range [
0.066388, 0.178834 ]
Will return portfolios associated with endpoints of the range for these values.
> In PortfolioCVaR.estimateFrontierByReturn at 93
The best way to avoid this situation is to bracket your target portfolio returns with
estimateFrontierLimits and estimatePortReturn (see "Obtaining Endpoints
of the Efficient Frontier" on page 5-82 and "Obtaining CVaR Portfolio Risks and
Returns" on page 5-92).
```

```
pret = estimatePortReturn(p, p.estimateFrontierLimits);
```

display(pret);
pret =
0.0664
0.1788

This result indicates that efficient portfolios have returns that range from $6.5 \%$ to $17.8 \%$. Note, your results for these examples may be different due to the random generation of scenarios.

If you have an initial portfolio, estimateFrontierByReturn also returns purchases and sales to get from your initial portfolio to the target portfolios on the efficient frontier. For example, given an initial portfolio in pwgt0, to obtain purchases and sales with target returns of $7 \%, 10 \%$, and $12 \%$ :

```
pwgt0 = [ 0.3; 0.3; 0.2; 0.1 ];
p = setInitPort(p, pwgt0);
[pwgt, pbuy, psell] = estimateFrontierByReturn(p, [0.07, 0.10, .12]);
display(pwgt);
display(pbuy);
display(psell);
pwgt =
\begin{tabular}{lll}
0.7526 & 0.3773 & 0.1306 \\
0.1047 & 0.3079 & 0.4348 \\
0.0662 & 0.1097 & 0.1426 \\
0.0765 & 0.2051 & 0.2920
\end{tabular}
pbuy =
\begin{tabular}{rrr}
0.4526 & 0.0773 & 0 \\
0 & 0.0079 & 0.1348 \\
0 & 0 & 0 \\
0 & 0.1051 & 0.1920
\end{tabular}
psell =
\begin{tabular}{rrr}
0 & 0 & 0.1694 \\
0.1953 & 0 & 0 \\
0.1338 & 0.0903 & 0.0574 \\
0.0235 & 0 & 0
\end{tabular}
```

If you do not have an initial portfolio, the purchase and sale weights assume that your initial portfolio is 0 .

## Obtaining Efficient Portfolios for Target Risks

To obtain efficient portfolios that have targeted portfolio risks, the estimateFrontierByRisk function accepts one or more target portfolio risks and obtains efficient portfolios with the specified risks. Suppose that you have a universe of four assets where you want to obtain efficient portfolios with target portfolio risks of $12 \%$, $14 \%$, and $16 \%$.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
    0.00408 0.0289 0.0204 0.0119;
    0.00192 0.0204 0.0576 0.0336;
```

```
    0 0.0119 0.0336 0.1225 ];
AssetScenarios = mvnrnd(m, C, 20000);
p = PortfolioCVaR;
p = setScenarios(p, AssetScenarios);
p = setDefaultConstraints(p);
p = setProbabilityLevel(p, 0.9);
pwgt = estimateFrontierByRisk(p, [0.12, 0.14, 0.16]);
display(pwgt);
pwgt =
\begin{tabular}{lll}
0.3594 & 0.2524 & 0.1543 \\
0.3164 & 0.3721 & 0.4248 \\
0.1044 & 0.1193 & 0.1298 \\
0.2199 & 0.2563 & 0.2910
\end{tabular}
```

In some cases, you can request a risk for which no efficient portfolio exists. Based on the previous example, suppose that you want a portfolio with $6 \%$ risk (individual assets in this universe have risks ranging from $7 \%$ to $42.5 \%$ ). It turns out that a portfolio with $6 \%$ risk cannot be formed with these four assets. estimateFrontierByRisk warns if your target risks are outside the range of efficient portfolio risks and replaces it with the endpoint of the efficient frontier closest to your target risk:

```
pwgt = estimateFrontierByRisk(p, 0.06)
Warning: One or more target risk values are outside the feasible range [
0.0735749, 0.436667 ].
Will return portfolios associated with endpoints of the range for these values.
> In PortfolioCVaR.estimateFrontierByRisk at 80
pwgt =
    0.7899
    0.0856
    0.0545
    0.0700
```

The best way to avoid this situation is to bracket your target portfolio risks with estimateFrontierLimits and estimatePortRisk (see "Obtaining Endpoints of the Efficient Frontier" on page 5-82 and "Obtaining CVaR Portfolio Risks and Returns" on page 5-92).

```
prsk = estimatePortRisk(p, p.estimateFrontierLimits);
```

```
display(prsk);
prsk =
    0.0736
    0.4367
```

This result indicates that efficient portfolios have risks that range from $7 \%$ to $42.5 \%$. Note, your results for these examples may be different due to the random generation of scenarios.

Starting with an initial portfolio, estimateFrontierByRisk also returns purchases and sales to get from your initial portfolio to the target portfolios on the efficient frontier. For example, given an initial portfolio in pwgt0, you can obtain purchases and sales from the example with target risks of $12 \%, 14 \%$, and $16 \%$ :

```
pwgt0 = [ 0.3; 0.3; 0.2; 0.1 ];
```

p = setInitPort(p, pwgt0);
[pwgt, pbuy, psell] = estimateFrontierByRisk(p, [0.12, 0.14, 0.16]);
display(pwgt);
display(pbuy);
display(psell);
pwgt =

| 0.3594 | 0.2524 | 0.1543 |
| :--- | :--- | :--- |
| 0.3164 | 0.3721 | 0.4248 |
| 0.1044 | 0.1193 | 0.1298 |
| 0.2199 | 0.2563 | 0.2910 |

pbuy =

| 0.0594 | 0 | 0 |
| ---: | ---: | ---: |
| 0.0164 | 0.0721 | 0.1248 |
| 0 | 0 | 0 |
| 0.1199 | 0.1563 | 0.1910 |

psell =

| 0 | 0.0476 | 0.1457 |
| ---: | ---: | ---: |
| 0 | 0 | 0 |
| 0.0956 | 0.0807 | 0.0702 |

$\begin{array}{lll}0 & 0 & 0\end{array}$
If you do not specify an initial portfolio, the purchase and sale weights assume that your initial portfolio is 0 .

## Choosing and Controlling the Solver

When solving portfolio optimizations for a PortfolioCVaR object, all variations of fmincon from Optimization Toolbox are supported. Alternatively, you can use ' cuttingplane ', a solver that implements Kelley's cutting plane method (see Kelley [45] at "Portfolio Optimization" on page A-10).

Unlike Optimization Toolbox which uses the interior-point algorithm as the default algorithm for fmincon, the portfolio optimization for a PortfolioCVaR object uses the sqp algorithm. For details about fmincon and constrained nonlinear optimization algorithms and options, see "Constrained Nonlinear Optimization Algorithms".

To modify fmincon options for CVaR portfolio optimizations, use setSolver to set the hidden properties solverType and solverOptions to specify and control the solver. (Note that you can see the default options by creating a dummyPortfolioCVaR object, using $p=$ PortfolioCVaR and then type $p$.solverOptions.) Since these solver properties are hidden, you cannot set them using the PortfolioCVaR function. The default solver is fmincon with the sqp algorithm objective function, gradients turned on, and no displayed output, so you do not need to use setSolver to specify this.

If you want to specify additional options associated with the fmincon solver, setSolver accepts these options as name-value pair arguments. For example, if you want to use fmincon with the trust-region-reflective algorithm and with no displayed output, use setSolver with:

```
p = PortfolioCVaR;
= setSolver(p, 'fmincon', 'Algorithm', 'trust-region-reflective', 'Display', 'on');
display(p.solverOptions.Algorithm);
display(p.solverOptions.Display);
trust-region-reflective
on
```

Alternatively, setSolver accepts an optimoptions object as the second argument. For example, you can change the algorithm to trust-region-reflective with no displayed output as follows:

```
p = PortfolioCVaR;
options = optimoptions('fmincon','Algorithm', 'trust-region-reflective', 'Display', 'off');
p = setSolver(p, 'fmincon', options);
display(p.solverOptions.Algorithm);
display(p.solverOptions.Display);
```

```
trust-region-reflective
off
```

The 'cuttingplane' solver has options to control the number iterations and stopping tolerances. Moreover, this solver uses linprog as the master solver, and all linprog options are supported using optimoptions structures. All these options are set using setSolver.

For example, you can use setSolver to increase the number of iterations for 'cuttingplane':

```
p = PortfolioCVaR;
p = setSolver(p, 'cuttingplane', 'MaxIter', 2000);
display(p.solverType);
display(p.solverOptions);
```

cuttingplane
MaxIter: 2000
AbsTol: 1.0000e-06
RelTol: 1.0000e-05
MasterSolverOptions: [1x1 optim.options.Linprog]

To change the master solver algorithm to 'interior-point ', with no display, use setSolver to modify 'MasterSolverOptions':
p = PortfoliocVaR;
options = optimoptions('linprog','Algorithm','interior-point','Display','off');
$\mathrm{p}=$ setSolver(p,'cuttingplane','MasterSolverOptions',options);
display(p.solverType)
display(p.solverOptions)
display(p.solverOptions.MasterSolverOptions.Algorithm)
display(p.solverOptions.MasterSolverOptions.Display)
cuttingplane
MaxIter: 1000
AbsTol: 1.0000e-06
RelTol: 1.0000e-05
MasterSolverOptions: [1x1 optim.options.Linprog]
interior-point
off

# Estimate Efficient Frontiers for PortfolioCVaR Object 

In this section...<br>"Obtaining CVaR Portfolio Risks and Returns" on page 5-92<br>"Obtaining Portfolio Standard Deviation and VaR" on page 5-94<br>"Plotting the Efficient Frontier for a PortfolioCVaR Object" on page 5-95

Whereas "Estimate Efficient Portfolios for PortfolioCVaR Object" on page 5-80 focused on estimation of efficient portfolios, this section focuses on the estimation of efficient frontiers. For information on the workflow when using PortfolioCVaR objects, see "PortfolioCVaR Object Workflow" on page 5-16.

## Obtaining CVaR Poriffolio Risks and Returns

Given any portfolio and, in particular, efficient portfolios, the functions estimatePortReturn and estimatePortRisk provide estimates for the return (or return proxy), risk (or the risk proxy). Each function has the same input syntax but with different combinations of outputs. Suppose that you have this following portfolio optimization problem that gave you a collection of portfolios along the efficient frontier in pwgt:

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
0.00408 0.0289 0.0204 0.0119;
0.00192 0.0204 0.0576 0.0336;
0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;
AssetScenarios = mvnrnd(m, C, 20000);
p = PortfolioCVaR;
p = setScenarios(p, AssetScenarios);
p = setDefaultConstraints(p);
p = setProbabilityLevel(p, 0.95);
pwgt0 = [ 0.3; 0.3; 0.2; 0.1 ];
p = setInitPort(p, pwgt0);
```

```
pwgt = estimateFrontier(p);
```

Note: Remember that the risk proxy for CVaR portfolio optimization is CVaR.

Given pwgt0 and pwgt, use the portfolio risk and return estimation functions to obtain risks and returns for your initial portfolio and the portfolios on the efficient frontier:

```
prsk0 = estimatePortRisk(p, pwgt0);
pret0 = estimatePortReturn(p, pwgt0);
prsk = estimatePortRisk(p, pwgt);
pret = estimatePortReturn(p, pwgt);
You obtain these risks and returns:
display(prsk0);
display(pret0);
display(prsk);
display(pret);
prsk0 =
    0.0591
pret0 =
    0.0067

0.0129
0.0139

## Obtaining Portfolio Standard Deviation and VaR

The PortfolioCVaR object has functions to compute standard deviations of portfolio returns and the value-at-risk of portfolios with the functions estimatePortStd and estimatePortVaR. These functions work with any portfolios, not necessarily efficient portfolios. For example, the following example obtains five portfolios (pwgt) on the efficient frontier and also has an initial portfolio in pwgt0. Various portfolio statistics are computed that include the return, risk, standard deviation, and value-at-risk. The listed estimates are for the initial portfolio in the first row followed by estimates for each of the five efficient portfolios in subsequent rows.

```
m = [ 0.0042; 0.0083; 0.01; 0.15 ];
C = [ 0.005333 0.00034 0.00016 0;
0.00034 0.002408 0.0017 0.000992;
0.00016 0.0017 0.0048 0.0028;
0 0.000992 0.0028 0.010208 ];
pwgt0 = [ 0.3; 0.3; 0.2; 0.1 ];
p = PortfolioCVaR('initport', pwgt0);
p = simulateNormalScenariosByMoments(p, m, C, 20000);
p = setDefaultConstraints(p);
p = setProbabilityLevel(p, 0.9);
pwgt = estimateFrontier(p, 5);
pret = estimatePortReturn(p, [pwgt0, pwgt]);
prsk = estimatePortRisk(p, [pwgt0, pwgt]);
pstd = estimatePortStd(p, [pwgt0, pwgt]);
pvar = estimatePortVaR(p, [pwgt0, pwgt]);
```

```
[pret, prsk, pstd, pvar]
ans =
\begin{tabular}{lllr}
0.0207 & 0.0464 & 0.0381 & 0.0283 \\
0.1009 & 0.0214 & 0.0699 & -0.0109 \\
0.1133 & 0.0217 & 0.0772 & -0.0137 \\
0.1256 & 0.0226 & 0.0849 & -0.0164 \\
0.1380 & 0.0240 & 0.0928 & -0.0182 \\
0.1503 & 0.0262 & 0.1011 & -0.0197
\end{tabular}
```

## Plotting the Efficient Frontier for a PorffolioCVaR Object

The plotFrontier function creates a plot of the efficient frontier for a given portfolio optimization problem. This function accepts several types of inputs and generates a plot with an optional possibility to output the estimates for portfolio risks and returns along the efficient frontier. plotFrontier has four different ways that it can be used. In addition to a plot of the efficient frontier, if you have an initial portfolio in the InitPort property, plotFrontier also displays the return versus risk of the initial portfolio on the same plot. If you have a well-posed portfolio optimization problem set up in a PortfolioCVaR object and you use plotFrontier, you get a plot of the efficient frontier with the default number of portfolios on the frontier (the default number is currently 10 and is maintained in the hidden property defaultNumPorts). This example illustrates a typical use of plotFrontier to create a new plot:

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
    0.00408 0.0289 0.0204 0.0119;
    0.00192 0.0204 0.0576 0.0336;
    0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;
AssetScenarios = mvnrnd(m, C, 20000);
p = PortfolioCVaR;
p = setScenarios(p, AssetScenarios);
p = setDefaultConstraints(p);
p = setProbabilityLevel(p, 0.95);
plotFrontier(p);
```

The Name property appears as the title of the efficient frontier plot if you set it in the PortfolioCVaR object. Without an explicit name, the title on the plot would be "Efficient Frontier." If you want to obtain a specific number of portfolios along the efficient frontier, use plotFrontier with the number of portfolios that you want. Suppose that you have the PortfolioCVaR object from the previous example and you want to plot 20 portfolios along the efficient frontier and to obtain 20 risk and return values for each portfolio:

```
[prsk, pret] = plotFrontier(p, 20);
display([pret, prsk]);
ans =
\begin{tabular}{ll}
0.0051 & 0.0406 \\
0.0056 & 0.0414 \\
0.0061 & 0.0437 \\
0.0066 & 0.0471 \\
0.0071 & 0.0515 \\
0.0076 & 0.0567 \\
0.0082 & 0.0624 \\
0.0087 & 0.0687
\end{tabular}
```

| 0.0092 | 0.0753 |
| :--- | :--- |
| 0.0097 | 0.0821 |
| 0.0102 | 0.0891 |
| 0.0107 | 0.0962 |
| 0.0112 | 0.1044 |
| 0.0117 | 0.1142 |
| 0.0122 | 0.1251 |
| 0.0127 | 0.1369 |
| 0.0133 | 0.1496 |
| 0.0138 | 0.1628 |
| 0.0143 | 0.1766 |
| 0.0148 | 0.1907 |

## Plotting Existing Efficient Portfolios

If you already have efficient portfolios from any of the "estimateFrontier" functions (see "Estimate Efficient Portfolios for PortfolioCVaR Object" on page 5-80), pass them into plotFrontier directly to plot the efficient frontier:

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
```

```
C = [ 0.0064 0.00408 0.00192 0;
    0.00408 0.0289 0.0204 0.0119;
    0.00192 0.0204 0.0576 0.0336;
    0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;
AssetScenarios = mvnrnd(m, C, 20000);
pwgt0 = [ 0.3; 0.3; 0.2; 0.1 ];
p = PortfolioCVaR('Name', 'Asset Allocation Portfolio', 'InitPort', pwgt0);
p = setScenarios(p, AssetScenarios);
p = setDefaultConstraints(p);
p = setProbabilityLevel(p, 0.95);
pwgt = estimateFrontier(p, 20);
plotFrontier(p, pwgt);
```

## Plotting Existing Efficient Portfolio Risks and Returns

If you already have efficient portfolio risks and returns, you can use the interface to plotFrontier to pass them into plotFrontier to obtain a plot of the efficient frontier:

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
    0.00408 0.0289 0.0204 0.0119;
    0.00192 0.0204 0.0576 0.0336;
    0 0.0119 0.0336 0.1225 ];
AssetScenarios = mvnrnd(m, C, 20000);
pwgt0 = [ 0.3; 0.3; 0.2; 0.1 ];
p = PortfolioCVaR('Name', 'Asset Allocation Portfolio', 'InitPort', pwgt0);
p = setScenarios(p, AssetScenarios);
p = setDefaultConstraints(p);
p = setProbabilityLevel(p, 0.95);
pwgt = estimateFrontier(p);
pret= estimatePortReturn(p, pwgt);
prsk = estimatePortRisk(p, pwgt);
plotFrontier(p, prsk, pret);
```

## Postprocessing Results

```
In this section...
"Setting Up Tradable Portfolios" on page 5-101
"Working with Other Portfolio Objects" on page 5-102
"Troubleshooting CVaR Portfolio Optimization Results" on page 5-105
```

After obtaining efficient portfolios or estimates for expected portfolio risks and returns, use your results to set up trades to move toward an efficient portfolio. For information on the workflow when using PortfolioCVaR objects, see "PortfolioCVaR Object Workflow" on page 5-16.

## Setting Up Tradable Porffolios

Suppose that you set up a portfolio optimization problem and obtained portfolios on the efficient frontier. Use the dataset object from Statistics and Machine Learning Toolbox to form a blotter that lists your portfolios with the names for each asset. For example, suppose that you want to obtain five portfolios along the efficient frontier. You can set up a blotter with weights multiplied by 100 to view the allocations for each portfolio:

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
0.00408 0.0289 0.0204 0.0119;
0.00192 0.0204 0.0576 0.0336;
0 0.0119 0.0336 0.1225 ];
pwgt0 = [ 0.3; 0.3; 0.2; 0.1 ];
p = PortfolioCVaR;
p = setAssetList(p, 'Bonds','Large-Cap Equities','Small-Cap Equities','Emerging Equities');
p = setInitPort(p, pwgt0);
p = simulateNormalScenariosByMoments(p, m, C, 20000);
p = setDefaultConstraints(p);
p = setProbabilityLevel(p, 0.9);
pwgt = estimateFrontier(p, 5);
pnames = cell(1,5);
for i = 1:5
pnames{i} = sprintf('Port%d',i);
end
Blotter = dataset([{100*pwgt},pnames],'obsnames',p.AssetList);
display(Blotter);
Blotter =
\begin{tabular}{lcllrl} 
& Port1 & Port2 & Port3 & Port4 & Port5 \\
Bonds & 78.84 & 43.688 & 8.3448 & 0 & \(1.2501 e-12\)
\end{tabular}
```

| Large-Cap Equities | 9.3338 | 29.131 | 48.467 | 23.602 | $9.4219 \mathrm{e}-13$ |
| :--- | :--- | :--- | :--- | :--- | ---: |
| Small-Cap Equities | 4.8843 | 8.1284 | 12.419 | 16.357 | $8.281 \mathrm{e}-14$ |
| Emerging Equities | 6.9419 | 19.053 | 30.769 | 60.041 | 100 |

Note: Your results may differ from this result due to the simulation of scenarios.

This result indicates that you would invest primarily in bonds at the minimum-risk/ minimum-return end of the efficient frontier (Port1), and that you would invest completely in emerging equity at the maximum-risk/maximum-return end of the efficient frontier (Port5). You can also select a particular efficient portfolio, for example, suppose that you want a portfolio with $15 \%$ risk and you add purchase and sale weights outputs obtained from the "estimateFrontier" functions to set up a trade blotter:

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
0.00408 0.0289 0.0204 0.0119;
0.00192 0.0204 0.0576 0.0336;
0 0.0119 0.0336 0.1225 ];
pwgt0 = [ 0.3; 0.3; 0.2; 0.1 ];
p = PortfolioCVaR;
p = setAssetList(p, 'Bonds','Large-Cap Equities','Small-Cap Equities','Emerging Equities');
p = setInitPort(p, pwgt0);
p = simulateNormalScenariosByMoments(p, m, C, 20000);
p = setDefaultConstraints(p);
p = setProbabilityLevel(p, 0.9);
[pwgt, pbuy, psell] = estimateFrontierByRisk(p, 0.15);
Blotter = dataset([{100*[pwgt0, pwgt, pbuy, psell]},
{'Initial','Weight', 'Purchases','Sales'}],'obsnames',p.AssetList);
display(Blotter);
Blotter =
\begin{tabular}{llrcr} 
& Initial & Weight & Purchases & Sales \\
Bonds & 30 & 15.036 & 0 & 14.964 \\
Large-Cap Equities & 30 & 45.357 & 15.357 & 0 \\
Small-Cap Equities & 20 & 12.102 & 0 & 7.8982 \\
Emerging Equities & 10 & 27.505 & 17.505 & 0
\end{tabular}
```

If you have prices for each asset (in this example, they can be ETFs), add them to your blotter and then use the tools of the dataset object to obtain shares and shares to be traded.

## Working with Other Portfolio Objects

The PortfolioCVaR object is for CVaR portfolio optimization. The Portfolio object is for mean-variance portfolio optimization. In some cases, you might want to examine portfolio
optimization problems according to different combinations of return and risk proxies. A common example is that you want to do a CVaR portfolio optimization and then want to work primarily with moments of portfolio returns. Suppose that you set up a CVaR portfolio optimization problem with:

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
0.00408 0.0289 0.0204 0.0119;
0.00192 0.0204 0.0576 0.0336;
0 0.0119 0.0336 0.1225 ];
pwgt0 = [ 0.3; 0.3; 0.2; 0.1 ];
p = PortfolioCVaR;
p = setAssetList(p, 'Bonds','Large-Cap Equities','Small-Cap Equities','Emerging Equities');
p = setInitPort(p, pwgt0);
p = simulateNormalScenariosByMoments(p, m, C, 20000);
p = setDefaultConstraints(p);
p = setProbabilityLevel(p, 0.9);
```

To work with the same problem in a mean-variance framework, you can use the scenarios from the PortfolioCVaR object to set up a Portfolio object so that p contains a CVaR optimization problem and q contains a mean-variance optimization problem based on the same data.

```
q = Portfolio('AssetList', p.AssetList);
q = estimateAssetMoments(q, p.getScenarios);
q = setDefaultConstraints(q);
pwgt = estimateFrontier(p);
qwgt = estimateFrontier(q);
```

Since each object has a different risk proxy, it is not possible to compare results side by side. To obtain means and standard deviations of portfolio returns, you can use the functions associated with each object to obtain:

```
pret = estimatePortReturn(p, pwgt);
pstd = estimatePortStd(p, pwgt);
qret = estimatePortReturn(q, qwgt);
qstd = estimatePortStd(q, qwgt);
[pret, qret]
[pstd, qstd]
ans =
    0.0665 0.0585
    0.0787 0.0716
```

| 0.0910 | 0.0848 |
| :---: | :---: |
| 0.1033 | 0.0979 |
| 0.1155 | 0.1111 |
| 0.1278 | 0.1243 |
| 0.1401 | 0.1374 |
| 0.1523 | 0.1506 |
| 0.1646 | 0.1637 |
| 0.1769 | 0.1769 |
| ans $=$ |  |
|  |  |
| 0.0797 | 0.0774 |
| 0.0912 | 0.0835 |
| 0.1095 | 0.0995 |
| 0.1317 | 0.1217 |
| 0.1563 | 0.1472 |
| 0.1823 | 0.1746 |
| 0.2135 | 0.2059 |
| 0.2534 | 0.2472 |
| 0.2985 | 0.2951 |
| 0.3499 | 0.3499 |

To produce comparable results, you can use the returns or risks from one portfolio optimization as target returns or risks for the other portfolio optimization.

```
qwgt = estimateFrontierByReturn(q, pret);
qret = estimatePortReturn(q, qwgt);
qstd = estimatePortStd(q, qwgt);
[pret, qret]
[pstd, qstd]
ans =

\end{tabular}
```

```
ans =
0.0797 0.0797
0.0912 0.0912
0.1095 0.1095
0.1317 0.1317
0.1563 0.1563
0.1823 0.1823
0.2135 0.2135
0.2534 0.2534
0.2985 0.2985
0.3499 0.3499
```

Now it is possible to compare standard deviations of portfolio returns from either type of portfolio optimization.

## Troubleshooting CVaR Portfolio Optimization Results

## PorffolioCVaR Object Destroyed When Modifying

If a PortfolioCVaR object is destroyed when modifying, remember to pass an existing object into the PortfolioCVaR function if you want to modify it, otherwise it creates a new object. See "Creating the PortfolioCVaR Object" on page 5-23 for details.

## Matrix Incompatibility and "Non-Conformable" Errors

If you get matrix incompatibility or "non-conformable" errors, the representation of data in the tools follows a specific set of basic rules described in "Conventions for Representation of Data" on page 5-21.

## CVaR Portfolio Optimization Warns About "Max Iterations"

If the 'cuttingplane' solver displays the following warning:

```
Warning: Max iterations reached. Consider modifying the solver options, or using fmincon.
> In @PortfolioCVaR\private\cvar cuttingplane solver at 255
    In @PortfolioCVaR\private\cvar_optim_min_risk at }8
    In PortfolioCVaR.estimateFrontier at }6
this warning indicates that some of the reported efficient portfolios may not be accurate enough.
```

This warning is usually related to portfolios in the lower-left end of the efficient frontier. The cutting plane solver may have gotten very close to the solution, but there may be too
many portfolios with very similar risks and returns in that neighborhood, and the solver runs out of iterations before reaching the desired accuracy.

To correct this problem, you can use setSolver to make any of these changes:

- Increase the maximum number of iterations ('MaxIter').
- Relax the stopping tolerances ('AbsTol' and/or 'RelTol').
- Use a different master solver algorithm ('MasterSolverOptions').
- Alternatively, you can try the 'fmincon ' solver.

When the default maximum number of iterations of the 'cuttingplane' solver is reached, the solver usually needs many more iterations to reach the accuracy required by the default stopping tolerances. You may want to combine increasing the number of iterations (e.g., multiply by 5) with relaxing the stopping tolerances (e.g., multiply by 10 or 100). Since the CVaR is a stochastic optimization problem, the accuracy of the solution is relative to the scenario sample, so a looser stopping tolerance may be acceptable. Keep in mind that the solution time may increase significantly when you increase the number of iterations. For example, doubling the number of iterations more than doubles the solution time. Sometimes using a different master solver (e.g., switching to 'interiorpoint ' if you are using the default 'simplex') can get the 'cuttingplane' solver to converge without changing the maximum number of iterations.

Alternatively, the 'fmincon' solver may be faster than the 'cuttingplane' solver for problems where cutting plane reaches the maximum number of iterations.

## CVaR Porifolio Optimization Errors with "Could Not Solve" Message

If the 'cuttingplane' solver generates the following error:

```
Error using cvar_cuttingplane_solver (line 251)
Could not solve the problem. Consider modifying the solver options, or using fmincon.
Error in cvar_optim_by_return (line 100)
    [x,~,~,exitfllag] = cvar_cuttingplane_solver(...
Error in PortfolioCVaR/estimateFrontier (line 80)
pwgt = cvar_optim_by_return(obj, r(2:end-1), obj.NumAssets, ...
```

this error means that the master solver failed to solve one of the master problems. The error may be due to numerical instability or other problem-specific situation.

To correct this problem, you can use setSolver to make any of these changes:

- Modify the master solver options ('MasterSolverOptions'), for example, change the algorithm ('Algorithm') or the termination tolerance ('TolFun').
- Alternatively, you can try the 'fmincon' solver.

## Missing Data Estimation Fails

If asset return data has missing or NaN values, the simulateNormalScenariosByData function with the 'missingdata' flag set to true may fail with either too many iterations or a singular covariance. To correct this problem, consider this:

- If you have asset return data with no missing or NaN values, you can compute a covariance matrix that may be singular without difficulties. If you have missing or NaN values in your data, the supported missing data feature requires that your covariance matrix must be positive-definite, that is, nonsingular.
- simulateNormalScenariosByData uses default settings for the missing data estimation procedure that might not be appropriate for all problems.

In either case, you might want to estimate the moments of asset returns separately with either the ECM estimation functions such as ecmnmle or with your own functions.

## cvar_optim_transform Errors

If you obtain optimization errors such as:

```
Error using cvar optim transform (line 276)
Portfolio set ap\overline{p}ears \overline{to be either empty or unbounded. Check constraints.}
Error in PortfolioCVaR/estimateFrontier (line 64)
    [AI, bI, AE, bE, lB, uB, f0, f, x0] = cvar_optim_transform(obj);
Or
Error using cvar_optim_transform (line 281)
Cannot obtain fin̄ite lōwer bounds for specified portfolio set.
Error in PortfolioCVaR/estimateFrontier (line 64)
    [AI, bI, AE, bE, lB, uB, f0, f, x0] = cvar_optim_transform(obj);
```

Since the portfolio optimization tools require a bounded portfolio set, these errors
(and similar errors) can occur if your portfolio set is either empty and, if nonempty,
unbounded. Specifically, the portfolio optimization algorithm requires that your
portfolio set have at least a finite lower bound. The best way to deal with these problems is to use the validation functions in "Validate the CVaR Portfolio Problem" on page 5-75. Specifically, use estimateBounds to examine your portfolio set, and use checkFeasibility to ensure that your initial portfolio is either feasible and, if infeasible, that you have sufficient turnover to get from your initial portfolio to the portfolio set.

Tip To correct this problem, try solving your problem with larger values for turnover and gradually reduce to the value that you want.

## Efficient Portfolios Do Not Make Sense

If you obtain efficient portfolios that, do not seem to make sense, this can happen if you forget to set specific constraints or you set incorrect constraints. For example, if you allow portfolio weights to fall between 0 and 1 and do not set a budget constraint, you can get portfolios that are $100 \%$ invested in every asset. Although it may be hard to detect, the best thing to do is to review the constraints you have set with display of the PortfolioCVaR object. If you get portfolios with $100 \%$ invested in each asset, you can review the display of your object and quickly see that no budget constraint is set. Also, you can use estimateBounds and checkFeasibility to determine if the bounds for your portfolio set make sense and to determine if the portfolios you obtained are feasible relative to an independent formulation of your portfolio set.

## Porffolio Optimization Theory

In this section...<br>"Portfolio Optimization Problems" on page 6-2<br>"Portfolio Problem Specification" on page 6-2<br>"Return Proxy" on page 6-3<br>"Risk Proxy" on page 6-5<br>"Portfolio Set for Optimization Using PortfolioMAD Object" on page 6-7<br>"Default Portfolio Problem" on page 6-14

## Porffolio Optimization Problems

Portfolio optimization problems involve identifying portfolios that satisfy three criteria:

- Minimize a proxy for risk.
- Match or exceed a proxy for return.
- Satisfy basic feasibility requirements.

Portfolios are points from a feasible set of assets that constitute an asset universe. A portfolio specifies either holdings or weights in each individual asset in the asset universe. The convention is to specify portfolios in terms of weights, although the portfolio optimization tools work with holdings as well.

The set of feasible portfolios is necessarily a nonempty, closed, and bounded set. The proxy for risk is a function that characterizes either the variability or losses associated with portfolio choices. The proxy for return is a function that characterizes either the gross or net benefits associated with portfolio choices. The terms "risk" and "risk proxy" and "return" and "return proxy" are interchangeable. The fundamental insight of Markowitz (see "Portfolio Optimization" on page A-10) is that the goal of the portfolio choice problem is to seek minimum risk for a given level of return and to seek maximum return for a given level of risk. Portfolios satisfying these criteria are efficient portfolios and the graph of the risks and returns of these portfolios forms a curve called the efficient frontier.

## Porffolio Problem Specification

To specify a portfolio optimization problem, you need the following:

- Proxy for portfolio return ( $\mu$ )
- Proxy for portfolio risk ( $\Sigma$ )
- Set of feasible portfolios ( $X$ ), called a portfolio set

Financial Toolbox has three objects to solve specific types of portfolio optimization problems:

- The Portfolio object (Using Portfolio Objects) supports mean-variance portfolio optimization (see Markowitz [46], [47] at "Portfolio Optimization" on page A-10). This object has either gross or net portfolio returns as the return proxy, the variance of portfolio returns as the risk proxy, and a portfolio set that is any combination of the specified constraints to form a portfolio set.
- The PortfolioCVaR object (Using PortfolioCVaR Objects) implements what is known as conditional value-at-risk portfolio optimization (see Rockafellar and Uryasev [48], [49] at "Portfolio Optimization" on page A-10), which is generally referred to as CVaR portfolio optimization. CVaR portfolio optimization works with the same return proxies and portfolio sets as mean-variance portfolio optimization but uses conditional value-at-risk of portfolio returns as the risk proxy.
- The PortfolioMAD object (Using PortfolioMAD Objects) implements what is known as mean-absolute deviation portfolio optimization (see Konno and Yamazaki [50] at "Portfolio Optimization" on page A-10), which is generally referred to as MAD portfolio optimization. MAD portfolio optimization works with the same return proxies and portfolio sets as mean-variance portfolio optimization but uses meanabsolute deviation portfolio returns as the risk proxy.

## Return Proxy

The proxy for portfolio return is a function $\mu: X \rightarrow R$ on a portfolio set $X \subset R^{n}$ that characterizes the rewards associated with portfolio choices. In most cases, the proxy for portfolio return has two general forms, gross and net portfolio returns. Both portfolio return forms separate the risk-free rate $r_{0}$ so that the portfolio $x \in X$ contains only risky assets.

Regardless of the underlying distribution of asset returns, a collection of $S$ asset returns $y_{1}, \ldots, y_{S}$ has a mean of asset returns

$$
m=\frac{1}{S} \sum_{s=1}^{S} y_{s}
$$

and (sample) covariance of asset returns

$$
C=\frac{1}{S-1} \sum_{s=1}^{S}\left(y_{s}-m\right)\left(y_{s}-m\right)^{T}
$$

These moments (or alternative estimators that characterize these moments) are used directly in mean-variance portfolio optimization to form proxies for portfolio risk and return.

## Gross Porifolio Returns

The gross portfolio return for a portfolio $x \in X$ is

$$
\mu(x)=r_{0}+\left(m-r_{0} 1\right)^{T} x,
$$

where:
$r_{0}$ is the risk-free rate (scalar).
$m$ is the mean of asset returns ( $n$ vector).
If the portfolio weights sum to 1 , the risk-free rate is irrelevant. The properties in the Portfolio object to specify gross portfolio returns are:

- RiskFreeRate for $r_{0}$
- AssetMean for $m$

## Net Portfolio Returns

The net portfolio return for a portfolio $x \in X$ is

$$
\mu(x)=r_{0}+\left(m-r_{0} 1\right)^{T} x-b^{T} \max \left\{0, x-x_{0}\right\}-s^{T} \max \left\{0, x_{0}-x\right\}
$$

where:
$r_{0}$ is the risk-free rate (scalar).
$m$ is the mean of asset returns ( $n$ vector).
$b$ is the proportional cost to purchase assets ( $n$ vector).
$s$ is the proportional cost to sell assets ( $n$ vector).
You can incorporate fixed transaction costs in this model also. Though in this case, it is necessary to incorporate prices into such costs. The properties in the Portfolio object to specify net portfolio returns are:

- RiskFreeRate for $r_{0}$
- AssetMean for $m$
- InitPort for $x_{0}$
- BuyCost for $b$
- SellCost for $s$

## Risk Proxy

The proxy for portfolio risk is a function $\Sigma: X \rightarrow R$ on a portfolio set $X \subset R^{n}$ that characterizes the risks associated with portfolio choices.

## Variance

The variance of portfolio returns for a portfolio $x \in X$ is

$$
\Sigma(x)=x^{T} C x
$$

where $C$ is the covariance of asset returns ( n -by-n positive-semidefinite matrix).
The property in the Portfolio object to specify the variance of portfolio returns is AssetCovar for $C$.

Although the risk proxy in mean-variance portfolio optimization is the variance of portfolio returns, the square root, which is the standard deviation of portfolio returns, is often reported and displayed. Moreover, this quantity is often called the "risk" of the portfolio. For details, see Markowitz [46], [47] at ("Portfolio Optimization" on page A-10).

## Conditional Value-at-Risk

The conditional value-at-risk for a portfolio $x \in X$, which is also known as expected shortfall, is defined as

$$
C V a R_{\alpha}(x)=\frac{1}{1-\alpha} \int_{f(x, y) \geq V a R_{\alpha}(x)} f(x, y) p(y) d y
$$

where:
$a$ is the probability level such that $0<\alpha<1$.
$f(x, y)$ is the loss function for a portfolio $x$ and asset return $y$.
$p(y)$ is the probability density function for asset return $y$.
$V a R_{\alpha}$ is the value-at-risk of portfolio $x$ at probability level $\alpha$.
The value-at-risk is defined as

$$
\operatorname{VaR}_{\alpha}(x)=\min \{\gamma: \operatorname{Pr}[f(x, Y) \leq \gamma] \geq \alpha\} .
$$

An alternative formulation for CVaR has the form:

$$
C V a R_{\alpha}(x)=\operatorname{VaR}_{\alpha}(x)+\frac{1}{1-\alpha} \int_{R^{n}} \max \left\{0,\left(f(x, y)-\operatorname{Va} R_{\alpha}(x)\right)\right\} p(y) d y
$$

The choice for the probability level $\alpha$ is typically 0.9 or 0.95 . Choosing $\alpha$ implies that the value-at-risk $\operatorname{VaR}_{a}(x)$ for portfolio $x$ is the portfolio return such that the probability of portfolio returns falling below this level is $(1-\alpha)$. Given $V a R_{a}(x)$ for a portfolio $x$, the conditional value-at-risk of the portfolio is the expected loss of portfolio returns above the value-at-risk return.

Note: Value-at-risk is a positive value for losses so that the probability level $a$ indicates the probability that portfolio returns are below the negative of the value-at-risk.

The risk proxy for CVaR portfolio optimization is $C \operatorname{Va} R_{a}(x)$ for a given portfolio $x \in X$ and $\alpha \in(0,1)$. The value-at-risk, or VaR, for a given probability level is estimated whenever CVaR is estimated.

In addition, keep in mind that VaR and CVaR are sample estimators for VaR and CVaR based on the given scenarios. Better scenario samples yield more reliable estimates of VaR and CVaR.

For more information, see Rockafellar and Uryasev [48], [49] at "Portfolio Optimization" on page A-10.

## Mean Absolute-Deviation

The mean-absolute deviation (MAD) for a portfolio $x \in X$ is defined as

$$
\sum(x)=\frac{1}{S} \sum_{s=1}^{S}\left|\left(y_{s}-m\right)^{T} x\right|
$$

where:
$y_{s}$ are asset returns with scenarios $s=1, \ldots S$ ( $S$ collection of $n$ vectors).
$f(x, y)$ is the loss function for a portfolio $x$ and asset return $y$.
$m$ is the mean of asset returns ( $n$ vector).
such that

$$
m=\frac{1}{S} \sum_{s=1}^{S} y_{s}
$$

For more information, see Konno and Yamazaki [50] at "Portfolio Optimization" on page A-10.

## Porffolio Set for Optimization Using PorffolioMAD Object

The final element for a complete specification of a portfolio optimization problem is the set of feasible portfolios, which is called a portfolio set. A portfolio set $X \subset R^{n}$ is specified by construction as the intersection of sets formed by a collection of constraints on portfolio weights. A portfolio set necessarily and sufficiently must be a nonempty, closed, and bounded set.

When setting up your portfolio set, ensure that the portfolio set satisfies these conditions. The most basic or "default" portfolio set requires portfolio weights to be nonnegative (using the lower-bound constraint) and to sum to 1 (using the budget constraint). The most general portfolio set handled by the portfolio optimization tools can have any of these constraints:

- Linear inequality constraints
- Linear equality constraints
- Bound constraints
- Budget constraints
- Group constraints
- Group ratio constraints
- Average turnover constraints
- One-way turnover constraints

## Linear Inequality Constraints

Linear inequality constraints are general linear constraints that model relationships among portfolio weights that satisfy a system of inequalities. Linear inequality constraints take the form

$$
A_{I} x \leq b_{I}
$$

where:
$x$ is the portfolio ( $n$ vector).
$A_{I}$ is the linear inequality constraint matrix ( $n_{I}$-by- $n$ matrix).
$b_{I}$ is the linear inequality constraint vector ( $n_{I}$ vector).
$n$ is the number of assets in the universe and $n_{I}$ is the number of constraints.
Portfolio object properties to specify linear inequality constraints are:

- AInequality for $A_{I}$
- bInequality for $b_{I}$
- NumAssets for $n$

The default is to ignore these constraints.

## Linear Equality Constraints

Linear equality constraints are general linear constraints that model relationships among portfolio weights that satisfy a system of equalities. Linear equality constraints take the form

$$
A_{E} x=b_{E}
$$

where:
$x$ is the portfolio ( $n$ vector).
$A_{E}$ is the linear equality constraint matrix ( $n_{E}$-by- $n$ matrix).
$b_{E}$ is the linear equality constraint vector ( $n_{E}$ vector).
$n$ is the number of assets in the universe and $n_{E}$ is the number of constraints.
Portfolio object properties to specify linear equality constraints are:

- AEquality for $A_{E}$
- bEquality for $b_{E}$
- NumAssets for $n$

The default is to ignore these constraints.

## Bound Constraints

Bound constraints are specialized linear constraints that confine portfolio weights to fall either above or below specific bounds. Since every portfolio set must be bounded, it is often a good practice, albeit not necessary, to set explicit bounds for the portfolio problem. To obtain explicit bounds for a given portfolio set, use the estimateBounds function. Bound constraints take the form

$$
l_{B} \leq x \leq u_{B}
$$

where:
$x$ is the portfolio ( $n$ vector).
$l_{B}$ is the lower-bound constraint ( $n$ vector).
$u_{B}$ is the upper-bound constraint ( $n$ vector).
$n$ is the number of assets in the universe.
Portfolio object properties to specify bound constraints are:

- LowerBound for $l_{B}$
- UpperBound for $u_{B}$
- NumAssets for $n$

The default is to ignore these constraints.
The default portfolio optimization problem (see "Default Portfolio Problem" on page $6-14)$ has $l_{B}=0$ with $u_{B}$ set implicitly through a budget constraint.

## Budget Constraints

Budget constraints are specialized linear constraints that confine the sum of portfolio weights to fall either above or below specific bounds. The constraints take the form

$$
l_{S} \leq 1^{T} x \leq u_{S}
$$

where:
$x$ is the portfolio ( $n$ vector).
1 is the vector of ones ( $n$ vector).
$l_{S}$ is the lower-bound budget constraint (scalar).
$u_{S}$ is the upper-bound budget constraint (scalar).
$n$ is the number of assets in the universe.
Portfolio object properties to specify budget constraints are:

- LowerBudget for $l_{S}$
- UpperBudget for $u_{S}$
- NumAssets for $n$

The default is to ignore this constraint.
The default portfolio optimization problem (see "Default Portfolio Problem" on page $6-14)$ has $l_{S}=u_{S}=1$, which means that the portfolio weights sum to 1 . If the portfolio optimization problem includes possible movements in and out of cash, the budget constraint specifies how far portfolios can go into cash. For example, if $l_{S}=0$ and $u_{S}=1$, then the portfolio can have $0-100 \%$ invested in cash. If cash is to be a portfolio choice, set RiskFreeRate ( $r_{0}$ ) to a suitable value (see "Return Proxy" on page 6-3 and "Working with a Riskless Asset" on page 6-47).

## Group Constraints

Group constraints are specialized linear constraints that enforce "membership" among groups of assets. The constraints take the form

$$
l_{G} \leq G x \leq u_{G}
$$

where:
$x$ is the portfolio ( $n$ vector).
$l_{G}$ is the lower-bound group constraint ( $n_{G}$ vector).
$u_{G}$ is the upper-bound group constraint ( $n_{G}$ vector).
$G$ is the matrix of group membership indexes ( $n_{G}$-by- $n$ matrix).
Each row of $G$ identifies which assets belong to a group associated with that row. Each row contains either 0 s or 1 s with 1 indicating that an asset is part of the group or 0 indicating that the asset is not part of the group.

Portfolio object properties to specify group constraints are:

- GroupMatrix for $G$
- LowerGroup for $l_{G}$
- UpperGroup for $u_{G}$
- NumAssets for $n$

The default is to ignore these constraints.

## Group Ratio Constraints

Group ratio constraints are specialized linear constraints that enforce relationships among groups of assets. The constraints take the form

$$
l_{R i}\left(G_{B} x\right)_{i} \leq\left(G_{A} x\right)_{i} \leq u_{R i}\left(G_{B} x\right)_{i}
$$

for $i=1, \ldots, n_{R}$ where:
$x$ is the portfolio ( $n$ vector).
$l_{R}$ is the vector of lower-bound group ratio constraints ( $n_{R}$ vector).
$u_{R}$ is the vector matrix of upper-bound group ratio constraints ( $n_{R}$ vector).
$G_{A}$ is the matrix of base group membership indexes ( $n_{R}$-by- $n$ matrix).
$G_{B}$ is the matrix of comparison group membership indexes ( $n_{R}$-by- $n$ matrix).
$n$ is the number of assets in the universe and $n_{R}$ is the number of constraints.
Each row of $G_{A}$ and $G_{B}$ identifies which assets belong to a base and comparison group associated with that row.

Each row contains either 0s or 1 s with 1 indicating that an asset is part of the group or 0 indicating that the asset is not part of the group.

Portfolio object properties to specify group ratio constraints are:

- GroupA for $G_{A}$
- GroupB for $G_{B}$
- LowerRatio for $l_{R}$
- UpperRatio for $u_{R}$
- NumAssets for $n$

The default is to ignore these constraints.

## Average Turnover Constraints

Turnover constraint is a linear absolute value constraint that ensures estimated optimal portfolios differ from an initial portfolio by no more than a specified amount. Although
portfolio turnover is defined in many ways, the turnover constraints implemented in Financial Toolbox computes portfolio turnover as the average of purchases and sales. Average turnover constraints take the form

$$
\frac{1}{2} 1^{T}\left|x-x_{0}\right| \leq \tau
$$

where:
$x$ is the portfolio ( $n$ vector).
1 is the vector of ones ( $n$ vector).
$x_{0}$ is the initial portfolio ( $n$ vector).
$\tau$ is the upper bound for turnover (scalar).
$n$ is the number of assets in the universe.
Portfolio object properties to specify the average turnover constraint are:

- Turnover for $\tau$
- InitPort for $x_{0}$
- NumAssets for $n$

The default is to ignore this constraint.

## One-way Turnover Constraints

One-way turnover constraints ensure that estimated optimal portfolios differ from an initial portfolio by no more than specified amounts according to whether the differences are purchases or sales. The constraints take the forms

$$
\begin{aligned}
& 1^{T} \times \max \left\{0, x-x_{0}\right\} \leq \tau_{B} \\
& 1^{T} \times \max \left\{0, x_{0}-x\right\} \leq \tau_{S}
\end{aligned}
$$

where:
$x$ is the portfolio ( $n$ vector)
1 is the vector of ones ( $n$ vector).
$x_{0}$ is the Initial portfolio ( $n$ vector).
$\tau_{B}$ is the upper bound for turnover constraint on purchases (scalar).
$\tau_{S}$ is the upper bound for turnover constraint on sales (scalar).
To specify one-way turnover constraints, use the following properties in the Portfolio, PortfolioCVaR, or PotfolioMAD object:

- BuyTurnover for $\tau_{B}$
- SellTurnover for $\tau_{S}$
- InitPort for $x_{0}$

The default is to ignore this constraint.

Note: The average turnover constraint (see "Working with Average Turnover Constraints Using PortfolioMAD Object" on page 6-68) with $\tau$ is not a combination of the one-way turnover constraints with $\tau=\tau_{B}=\tau_{S}$.

## Default Portfolio Problem

The default portfolio optimization problem has a risk and return proxy associated with a given problem, and a portfolio set that specifies portfolio weights to be nonnegative and to sum to 1 . The lower bound combined with the budget constraint is sufficient to ensure that the portfolio set is nonempty, closed, and bounded. The default portfolio optimization problem characterizes a long-only investor who is fully invested in a collection of assets.

- For mean-variance portfolio optimization, it is sufficient to set up the default problem. After setting up the problem, data in the form of a mean and covariance of asset returns are then used to solve portfolio optimization problems.
- For conditional value-at-risk portfolio optimization, the default problem requires the additional specification of a probability level that must be set explicitly. Generally, "typical" values for this level are 0.90 or 0.95 . After setting up the problem, data in
the form of scenarios of asset returns are then used to solve portfolio optimization problems.
- For MAD portfolio optimization, it is sufficient to set up the default problem. After setting up the problem, data in the form of scenarios of asset returns are then used to solve portfolio optimization problems.

## PorffolioMAD Object Workflow

The PortfolioMAD object workflow for creating and modeling a mean-variance portfolio is:

1 Create a MAD Portfolio.
Create a PortfolioMAD object for mean-absolute deviation (MAD) portfolio optimization. "Creating the PortfolioMAD Object" on page 6-22.
2 Define asset returns and scenarios.
Evaluate scenarios for portfolio asset returns, including assets with missing data and financial time series data. For more information, see "Asset Returns and Scenarios Using PortfolioMAD Object" on page 6-37.
3 Specify the MAD Portfolio Constraints.
Define the constraints for portfolio assets such as linear equality and inequality, bound, budget, group, group ratio, and turnover constraints. For more information, see "Working with MAD Portfolio Constraints" on page 6-52.
4 Validate the MAD Portfolio.
Identify errors for the portfolio specification. For more information, see "Validate the MAD Portfolio Problem" on page 6-74.
5 Estimate the efficient portfolios and frontiers.
Analyze the efficient portfolios and efficient frontiers for a portfolio. For more information, see "Estimate Efficient Portfolios for PortfolioMAD Object" on page 6-79 and "Estimate Efficient Frontiers for PortfolioMAD Object" on page 6-90.

6 Postprocess the results.
Use the efficient portfolios and efficient frontiers results to set up trades. For more information, see "Postprocessing Results" on page 6-100.

## PortfolioMAD Object Properties and Functions

The PortfolioMAD object implements mean absolute-deviation (MAD) portfolio optimization and is derived from the abstract class AbstractPortfolio. Every property and function of the PortfolioMAD object is public, although some properties and functions are hidden. The PortfolioMAD object is a value object where every instance of the object is a distinct version of the object. Since the PortfolioMAD object is also a MATLAB object, it inherits the default functions associated with MATLAB objects.

## Working with PortfolioMAD Objects

The PortfolioMAD object and its functions are an interface for mean absolute-deviation portfolio optimization. So, almost everything you do with the PortfolioMAD object can be done using the functions. The basic workflow is:

1 Design your portfolio problem.
2 Use the PortfolioMAD function to create the PortfolioMAD object or use the various set functions to set up your portfolio problem.
3 Use estimate functions to solve your portfolio problem.
In addition, functions are available to help you view intermediate results and to diagnose your computations. Since MATLAB features are part of a PortfolioMAD object, you can
save and load objects from your workspace and create and manipulate arrays of objects. After settling on a problem, which, in the case of MAD portfolio optimization, means that you have either scenarios, data, or moments for asset returns, and a collection of constraints on your portfolios, use the PortfolioMAD function to set the properties for the PortfolioMAD object.

The PortfolioMAD function lets you create an object from scratch or update an existing object. Since the PortfolioMAD object is a value object, it is easy to create a basic object, then use functions to build upon the basic object to create new versions of the basic object. This is useful to compare a basic problem with alternatives derived from the basic problem. For details, see "Creating the PortfolioMAD Object" on page 6-22.

## Setting and Getting Properties

You can set properties of a PortfolioMAD object using either thePortfolioMAD function or various set functions.

Note: Although you can also set properties directly, it is not recommended since errorchecking is not performed when you set a property directly.

The PortfolioMAD function supports setting properties with name-value pair arguments such that each argument name is a property and each value is the value to assign to that property. For example, to set the LowerBound and Budget properties in an existing PortfolioMAD object $p$, use the syntax:
p = PortfolioMAD(p,'LowerBound', 0,'Budget', 1);
In addition to the PortfolioMAD function, which lets you set individual properties one at a time, groups of properties are set in a PortfolioMAD object with various "set" and "add" functions. For example, to set up an average turnover constraint, use the setTurnover function to specify the bound on portfolio turnover and the initial portfolio. To get individual properties from a PortfolioMAD object, obtain properties directly or use an assortment of "get" functions that obtain groups of properties from a PortfolioMAD object. The PortfolioMAD function and set functions have several useful features:

- The PortfolioMAD function and set functions try to determine the dimensions of your problem with either explicit or implicit inputs.
- The PortfolioMAD function and set functions try to resolve ambiguities with default choices.
- The PortfolioMAD function and set functions perform scalar expansion on arrays when possible.
- The PortfolioMAD functions try to diagnose and warn about problems.

## Displaying PorffolioMAD Objects

The PortfolioMAD object uses the default display function provided by MATLAB, where display and disp display a PortfolioMAD object and its properties with or without the object variable name.

## Saving and Loading PorffolioMAD Objects

Save and load PortfolioMAD objects using the MATLAB save and load commands.

## Estimating Efficient Porffolios and Frontiers

Estimating efficient portfolios and efficient frontiers is the primary purpose of the MAD portfolio optimization tools. A collection of "estimate" and "plot" functions provide ways to explore the efficient frontier. The "estimate" functions obtain either efficient portfolios or risk and return proxies to form efficient frontiers. At the portfolio level, a collection of functions estimates efficient portfolios on the efficient frontier with functions to obtain efficient portfolios:

- At the endpoints of the efficient frontier
- That attain targeted values for return proxies
- That attain targeted values for risk proxies
- Along the entire efficient frontier

These functions also provide purchases and sales needed to shift from an initial or current portfolio to each efficient portfolio. At the efficient frontier level, a collection of functions plot the efficient frontier and estimate either risk or return proxies for efficient portfolios on the efficient frontier. You can use the resultant efficient portfolios or risk and return proxies in subsequent analyses.

## Arrays of PortfolioMAD Objects

Although all functions associated with a PortfolioMAD object are designed to work on a scalar PortfolioMAD object, the array capabilities of MATLAB enables you to set up and
work with arrays of PortfolioMAD objects. The easiest way to do this is with the repmat function. For example, to create a 3-by-2 array of PortfolioMAD objects:

```
p = repmat(PortfolioMAD, 3, 2);
disp(p)
```

After setting up an array of PortfolioMAD objects, you can work on individual PortfolioMAD objects in the array by indexing. For example:

```
p(i,j) = PortfolioMAD(p(i,j), ... );
```

This example calls the PortfolioMAD function for the (i,j) element of a matrix of PortfolioMAD objects in the variable $p$.

If you set up an array of PortfolioMAD objects, you can access properties of a particular PortfolioMAD object in the array by indexing so that you can set the lower and upper bounds lb and ub for the ( $\mathrm{i}, \mathrm{j}, \mathrm{k}$ ) element of a 3-D array of PortfolioMAD objects with
$p(i, j, k)=\operatorname{setBounds}(p(i, j, k), l b, u b)$;
and, once set, you can access these bounds with
[lb, ub] = getBounds $(\mathrm{p}(\mathrm{i}, \mathrm{j}, \mathrm{k}))$;
PortfolioMAD object functions work on only one PortfolioMAD object at a time.

## Subclassing PortfolioMAD Objects

You can subclass the PortfolioMAD object to override existing functions or to add new properties or functions. To do so, create a derived class from the PortfolioMAD class. This gives you all the properties and functions of the PortfolioMAD class along with any new features that you choose to add to your subclassed object. ThePortfolioMAD class is derived from an abstract class called AbstractPortfolio. Because of this, you can also create a derived class from AbstractPortfolio that implements an entirely different form of portfolio optimization using properties and functions of theAbstractPortfolio class.

## Conventions for Representation of Data

The MAD portfolio optimization tools follow these conventions regarding the representation of different quantities associated with portfolio optimization:

- Asset returns or prices for scenarios are in matrix form with samples for a given asset going down the rows and assets going across the columns. In the case of prices, the earliest dates must be at the top of the matrix, with increasing dates going down.
- Portfolios are in vector or matrix form with weights for a given portfolio going down the rows and distinct portfolios going across the columns.
- Constraints on portfolios are formed in such a way that a portfolio is a column vector.
- Portfolio risks and returns are either scalars or column vectors (for multiple portfolio risks and returns).

## Creating the PortfolioMAD Object

```
In this section...
"Syntax" on page 6-22
"PortfolioMAD Problem Sufficiency" on page 6-23
"PortfolioMAD Function Examples" on page 6-23
```

To create a fully specified MAD portfolio optimization problem, instantiate the PortfolioMAD object using the PortfolioMAD function. For information on the workflow when using PortfolioMAD objects, see "PortfolioMAD Object Workflow" on page 6-16.

## Syntax

Use the PortfolioMAD function to create an instance of an object of the PortfolioMAD class. You can use the PortfolioMAD function in several ways. To set up a portfolio optimization problem in a PortfolioMAD object, the simplest syntax is:

```
p = PortfolioMAD;
```

This syntax creates a PortfolioMAD object, p , such that all object properties are empty.
The PortfolioMAD function also accepts collections of argument name-value pair arguments for properties and their values. The PortfolioMAD function accepts inputs for public properties with the general syntax:

```
p = PortfolioMAD('property1', value1, 'property2', value2, ... );
```

If a PortfolioMAD object already exists, the syntax permits the first (and only the first argument) of the PortfolioMAD function to be an existing object with subsequent argument name-value pair arguments for properties to be added or modified. For example, given an existing PortfolioMAD object in $p$, the general syntax is:

```
p = PortfolioMAD(p, 'property1', value1, 'property2', value2, ... );
```

Input argument names are not case-sensitive, but must be completely specified. In addition, several properties can be specified with alternative argument names (see "Shortcuts for Property Names" on page 6-27). The PortfolioMAD function tries to detect problem dimensions from the inputs and, once set, subsequent inputs can undergo various scalar or matrix expansion operations that simplify the overall process
to formulate a problem. In addition, a PortfolioMAD object is a value object so that, given portfolio p , the following code creates two objects, p and q , that are distinct:
$q=\operatorname{PortfolioMAD(p,~...)~}$

## PortfolioMAD Problem Sufficiency

A MAD portfolio optimization problem is completely specified with the PortfolioMAD object if the following three conditions are met:

- You must specify a collection of asset returns or prices known as scenarios such that all scenarios are finite asset returns or prices. These scenarios are meant to be samples from the underlying probability distribution of asset returns. This condition can be satisfied by the setScenarios function or with several canned scenario simulation functions.
- The set of feasible portfolios must be a nonempty compact set, where a compact set is closed and bounded. You can satisfy this condition using an extensive collection of properties that define different types of constraints to form a set of feasible portfolios. Since such sets must be bounded, either explicit or implicit constraints can be imposed and several tools, such as the estimateBounds function, provide ways to ensure that your problem is properly formulated.

Although the general sufficient conditions for MAD portfolio optimization go beyond these conditions, the PortfolioMAD object handles all these additional conditions.

## PortfolioMAD Function Examples

If you create a PortfolioMAD object, p , with no input arguments, you can display it using disp:

```
p = PortfolioMAD;
```

disp(p);
PortfolioMAD with properties:

BuyCost: []
SellCost: []
RiskFreeRate: []
Turnover: []
BuyTurnover: []
SellTurnover: []

```
NumScenarios: []
            Name: []
    NumAssets: []
    AssetList: []
        InitPort: []
AInequality: []
bInequality: []
    AEquality: []
        bEquality: []
    LowerBound: []
    UpperBound: []
LowerBudget: []
UpperBudget: []
GroupMatrix: []
    LowerGroup: []
    UpperGroup: []
        GroupA: []
    GroupB: []
    LowerRatio: []
    UpperRatio: []
```

The approaches listed provide a way to set up a portfolio optimization problem with the PortfolioMAD function. The custom set functions offer additional ways to set and modify collections of properties in the PortfolioMAD object.

## Using the PorffolioMAD Function for a Single-Step Setup

You can use the PortfolioMAD function to directly set up a "standard" portfolio optimization problem. Given scenarios of asset returns in the variable AssetScenarios, this problem is completely specified as follows:

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
    0.00408 0.0289 0.0204 0.0119
    0.00192 0.0204 0.0576 0.0336;
    0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;
AssetScenarios = mvnrnd(m, C, 20000);
p = PortfolioMAD('Scenarios', AssetScenarios, ...
'LowerBound', 0, 'LowerBudget', 1, 'UpperBudget', 1);
The LowerBound property value undergoes scalar expansion since AssetScenarios
provides the dimensions of the problem.
```

You can use dot notation with the function plotFrontier.
p.plotFrontier;

## Using the PorffolioMAD Function with a Sequence of Steps

An alternative way to accomplish the same task of setting up a "standard" MAD portfolio optimization problem, given AssetScenarios variable is:

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
0.00408 0.0289 0.0204 0.0119;
0.00192 0.0204 0.0576 0.0336;
0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;
```

AssetScenarios = mvnrnd(m, C, 20000);
p = PortfolioMAD;
$p=$ setScenarios( $p$, AssetScenarios);
p = PortfolioMAD(p, 'LowerBound', 0);

```
p = PortfolioMAD(p, 'LowerBudget', 1, 'UpperBudget', 1);
plotFrontier(p);
```

This way works because the calls to the PortfolioMAD function are in this particular order. In this case, the call to initialize AssetScenarios provides the dimensions for the problem. If you were to do this step last, you would have to explicitly dimension the LowerBound property as follows:

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
0.00408 0.0289 0.0204 0.0119;
0.00192 0.0204 0.0576 0.0336;
0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;
```

AssetScenarios = mvnrnd(m, C, 20000);
p = PortfolioMAD;

```
p = PortfolioMAD(p, 'LowerBound', zeros(size(m)));
p = PortfolioMAD(p, 'LowerBudget', 1, 'UpperBudget', 1);
p = setScenarios(p, AssetScenarios);
```

Note: If you did not specify the size of LowerBound but, instead, input a scalar argument, the PortfolioMAD function assumes that you are defining a single-asset problem and produces an error at the call to set asset scenarios with four assets.

## Shortcuts for Property Names

The PortfolioMAD function has shorter argument names that replace longer argument names associated with specific properties of the PortfolioMAD object. For example, rather than enter 'AInequality', the PortfolioMAD function accepts the caseinsensitive name 'ai' to set the AInequality property in a PortfolioMAD object. Every shorter argument name corresponds with a single property in the PortfolioMAD function. The one exception is the alternative argument name 'budget ', which signifies both the LowerBudget and UpperBudget properties. When 'budget' is used, then the LowerBudget and UpperBudget properties are set to the same value to form an equality budget constraint.

## Shortcuts for Property Names

| Shortcut Argument Name | Equivalent Argument / Property Name |
| :--- | :--- |
| ae | AEquality |
| ai | AInequality |
| assetnames or assets | AssetList |
| be | bEquality |
| bi | bInequality |
| budget | UpperBudget and LowerBudget |
| group | GroupMatrix |
| lb | LowerBound |
| n or num | NumAssets |
| rfr | RiskFreeRate |
| scenario or <br> assetscenarios | Scenarios |

| Shortcut Argument Name | Equivalent Argument / Property Name |
| :--- | :--- |
| ub | UpperBound |

For example, this call to the PortfolioMAD function uses these shortcuts for properties:

```
m = [ 0.05; 0.1; 0.12; 0.18];
C=[ 0.0064 0.00408 0.00192 0;
0.00408 0.0289 0.0204 0.0119;
0.00192 0.0204 0.0576 0.0336;
0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;
AssetScenarios = mvnrnd(m, C, 20000);
```

```
p = PortfolioMAD('scenario', AssetScenarios, 'lb', 0, 'budget', 1);
```

p = PortfolioMAD('scenario', AssetScenarios, 'lb', 0, 'budget', 1);
plotFrontier(p);

```

\section*{Direct Setting of Portfolio Object Properties}

Although not recommended, you can set properties directly using dot notation, however no error-checking is done on your inputs:
```

m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
0.00408 0.0289 0.0204 0.0119;
0.00192 0.0204 0.0576 0.0336;
0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;
AssetScenarios = mvnrnd(m, C, 20000);
p = PortfolioMAD;
p = setScenarios(p, AssetScenarios);
p.LowerBudget = 1;
p.UpperBudget = 1;
p.LowerBound = zeros(size(m));
plotFrontier(p);

```

Note: Scenarios cannot be assigned directly to a PortfolioMAD object. Scenarios must always be set through either the PortfolioMAD function, the setScenarios function, or any of the scenario simulation functions.

}

\section*{Naming a PorifolioMAD Object}

To name a PortfolioMAD object, use the Name property. Name is informational and has no effect on any portfolio calculations. If the Name property is nonempty, Name is the title for the efficient frontier plot generated by plotFrontier. For example, if you set up an asset allocation fund, you could name the PortfolioMAD object Asset Allocation Fund:
```

p = PortfolioMAD('Name','Asset Allocation Fund');

```
disp(p.Name);

Asset Allocation Fund

\section*{Configuring the Assets in the Asset Universe}

The fundamental quantity in the PortfolioMAD object is the number of assets in the asset universe. This quantity is maintained in the NumAssets property. Although you can set this property directly, it is usually derived from other properties such as the number of assets in the scenarios or the initial portfolio. In some instances, the number of assets may need to be set directly. This example shows how to set up a PortfolioMAD object that has four assets:
```

p = PortfolioMAD('NumAssets', 4);
disp(p.NumAssets);
4

```

After setting the NumAssets property, you cannot modify it (unless no other properties are set that depend on NumAssets). The only way to change the number of assets in an existing PortfolioMAD object with a known number of assets is to create a new PortfolioMAD object.

\section*{Setting Up a List of Asset Identifiers}

When working with portfolios, you must specify a universe of assets. Although you can perform a complete analysis without naming the assets in your universe, it is helpful to have an identifier associated with each asset as you create and work with portfolios. You can create a list of asset identifiers as a cell vector of strings in the property AssetList. You can set up the list using the next two methods.

\section*{Setting Up Asset Lists Using the PortfolioMAD Function}

Suppose that you have a PortfolioMAD object, p, with assets with symbols 'AA '', 'BA', 'CAT', 'DD', and 'ETR'. You can create a list of these asset symbols in the object using the PortfolioMAD function:
```

p = PortfolioMAD('assetlist', { 'AA', 'BA', 'CAT', 'DD', 'ETR' });
disp(p.AssetList);
'AA' 'BA' 'CAT' 'DD' 'ETR'

```

Notice that the property AssetList is maintained as a cell array that contains strings, and that it is necessary to pass a cell array into the PortfolioMAD function to set AssetList. In addition, notice that the property NumAssets is set to 5 based on the number of symbols used to create the asset list:
```

disp(p.NumAssets);

```

5

\section*{Setting Up Asset Lists Using the setAssetList Function}

You can also specify a list of assets using the setAssetList function. Given the list of asset symbols 'AA', 'BA', 'CAT', 'DD', and 'ETR', you can use setAssetList with:
```

p = PortfolioMAD;
p = setAssetList(p, { 'AA', 'BA', 'CAT', 'DD', 'ETR' });
disp(p.AssetList);
'AA' 'BA' 'CAT' 'DD' 'ETR'

```
setAssetList also enables you to enter symbols directly as a comma-separated list without creating a cell array of strings. For example, given the list of assets symbols 'AA', 'BA', 'CAT', 'DD', and 'ETR', use setAssetList:
p = PortfolioMAD;
```

p = setAssetList(p, 'AA', 'BA', 'CAT', 'DD', 'ETR');
disp(p.AssetList);
'AA' 'BA' 'CAT' 'DD' 'ETR'

```
setAssetList has many additional features to create lists of asset identifiers. If you use setAssetList with just a PortfolioMAD object, it creates a default asset list according to the name specified in the hidden public property defaultforAssetList (which is 'Asset' by default). The number of asset names created depends on the number of assets in the property NumAssets. If NumAssets is not set, then NumAssets is assumed to be 1 .

For example, if a PortfolioMAD object \(p\) is created with NumAssets \(=5\), then this code fragment shows the default naming behavior:
```

p = PortfolioMAD('numassets',5);
p = setAssetList(p);
disp(p.AssetList);
'Asset1' 'Asset2' 'Asset3' 'Asset4' 'Asset5'

```

Suppose that your assets are, for example, ETFs and you change the hidden property defaultforAssetList to 'ETF ', you can then create a default list for ETFs:
```

p = PortfolioMAD('numassets',5);
p.defaultforAssetList = 'ETF';
p = setAssetList(p);
disp(p.AssetList);
'ETF1' 'ETF2' 'ETF3' 'ETF4' 'ETF5'

```

\section*{Truncating and Padding Asset Lists}

If the NumAssets property is already set and you pass in too many or too few identifiers, the PortfolioMAD function, and the setAssetList function truncate or pad the list with numbered default asset names that use the name specified in the hidden public property defaultforAssetList. If the list is truncated or padded, a warning message indicates the discrepancy. For example, assume that you have a PortfolioMAD object with five ETFs and you only know the first three CUSIPs '921937835', '922908769', and ' 922042775 '. Use this syntax to create an asset list that pads the remaining asset identifiers with numbered 'UnknownCUSIP' placeholders:
```

p = PortfolioMAD('numassets',5);
p.defaultforAssetList = 'UnknownCUSIP';
p = setAssetList(p, '921937835', '922908769', '922042775');

```
```

disp(p.AssetList);
Warning: Input list of assets has 2 too few identifiers. Padding with numbered
assets.
> In PortfolioMAD.setAssetList at 121
Columns 1 through 4
921937835' '922908769' '922042775' 'UnknownCUSIP4'
Column 5

```
    UnknownCUSIP5

Alternatively, suppose that you have too many identifiers and need only the first four assets. This example illustrates truncation of the asset list using the PortfolioMAD function:
```

p = PortfolioMAD('numassets',4);
p = PortfolioMAD(p, 'assetlist', { 'AGG', 'EEM', 'MDY', 'SPY', 'VEU' });
disp(p.AssetList);
Warning: AssetList has 1 too many identifiers. Using first 4 assets.
> In PortfolioMAD.checkarguments at 410
In PortfolioMAD.PortfolioMAD>PortfolioMAD.PortfolioMAD at 187
AGG' 'EEM' 'MDY' 'SPY'

```

The hidden public property uppercaseAssetList is a Boolean flag to specify whether to convert asset names to uppercase letters. The default value for uppercaseAssetList is false. This example shows how to use the uppercaseAssetList flag to force identifiers to be uppercase letters:
```

p = PortfolioMAD;
p.uppercaseAssetList = true;
p = setAssetList(p, { 'aa', 'ba', 'cat', 'dd', 'etr' });
disp(p.AssetList);
'AA' 'BA' 'CAT' 'DD' 'ETR'

```

\section*{Setting Up an Initial or Current Portfolio}

In many applications, creating a new optimal portfolio requires comparing the new portfolio with an initial or current portfolio to form lists of purchases and sales. The PortfolioMAD object property InitPort lets you identify an initial or current portfolio. The initial portfolio also plays an essential role if you have either transaction costs or turnover constraints. The initial portfolio need not be feasible within the constraints of the problem. This can happen if the weights in a portfolio have shifted such that some constraints become violated. To check if your initial portfolio is feasible, use
thecheckFeasibility function described in "Validating MAD Portfolios" on page 6-76. Suppose that you have an initial portfolio in \(\times 0\), then use the PortfolioMAD function to set up an initial portfolio:
```

x0 = [ 0.3; 0.2; 0.2; 0.0 ];
p = PortfolioMAD('InitPort', x0);
disp(p.InitPort);
0.3000
0.2000
0.2000
0

```

As with all array properties, you can set InitPort with scalar expansion. This is helpful to set up an equally weighted initial portfolio of, for example, 10 assets:
```

p = PortfolioMAD('NumAssets', 10, 'InitPort', 1/10);
disp(p.InitPort);
0.1000
0.1000
0.1000
0.1000
0.1000
0.1000
0.1000
0.1000
0.1000
0.1000

```

To clear an initial portfolio from your PortfolioMAD object, use either the PortfolioMAD function or the setInitPort function with an empty input for the InitPort property. If transaction costs or turnover constraints are set, it is not possible to clear the InitPort property in this way. In this case, to clear InitPort, first clear the dependent properties and then clear theInitPort property.

The InitPort property can also be set with setInitPort which lets you specify the number of assets if you want to use scalar expansion. For example, given an initial portfolio in xO , use setInitPort to set the InitPort property:
```

p = PortfolioMAD;
x0 = [ 0.3; 0.2; 0.2; 0.0 ];
p = setInitPort(p, x0);
disp(p.InitPort);

```
0.3000
0.2000
0.2000

0
To create an equally weighted portfolio of four assets, use setInitPort:
```

p = PortfolioMAD;
p = setInitPort(p, 1/4, 4);
disp(p.InitPort);
0.2500
0.2500
0.2500
0.2500

```

PortfolioMAD object functions that work with either transaction costs or turnover constraints also depend on the InitPort property. So, the set functions for transaction costs or turnover constraints permit the assignment of a value for the InitPort property as part of their implementation. For details, see "Working with Average Turnover Constraints Using PortfolioMAD Object" on page 6-68, "Working with Oneway Turnover Constraints Using PortfolioMAD Object" on page 6-70, and "Working with Transaction Costs" on page 6-47. If either transaction costs or turnover constraints are used, then the InitPort property must have a nonempty value. Absent a specific value assigned through the PortfolioMAD function or various set functions, the PortfolioMAD object sets InitPort to 0 and warns if BuyCost, SellCost, or Turnover properties are set. This example shows what happens if you specify an average turnover constraint with an initial portfolio:
```

p = PortfolioMAD('Turnover', 0.3, 'InitPort', [ 0.3; 0.2; 0.2; 0.0 ]);
disp(p.InitPort);

```
0.3000
0.2000
0.2000

0
In contrast, this example shows what happens if an average turnover constraint is specified without an initial portfolio:
```

p = PortfolioMAD('Turnover', 0.3);
disp(p.InitPort);
Warning: InitPort and NumAssets are empty and either transaction costs or
turnover constraints specified. Will set NumAssets = 1 and InitPort = 0.
> In PortfolioMAD.checkarguments at 446
In PortfolioMAD.PortfolioMAD>PortfolioMAD.PortfolioMAD at 190

```

\section*{How Stochastic Optimization Works}

The MAD of a portfolio is mean-absolute deviation. For the definition of the MAD function, see "Risk Proxy" on page 6-5. Although analytic solutions for MAD exist for a few probability distributions, an alternative is to compute the expectation for MAD with samples from the probability distribution of asset returns. These samples are called scenarios and, given a collection of scenarios, the portfolio optimization problem becomes a stochastic optimization problem.

As a function of the portfolio weights, the MAD of the portfolio is a convex non-smooth function (see Konno and Yamazaki [50] at "Portfolio Optimization" on page A-10). The PortfolioMAD object computes MAD as this nonlinear function which can be handled by the solver fmincon Optimization Toolbox. The nonlinear programming solver fmincon has several algorithms that can be selected with the setSolver function, the two algorithms that work best in practice are 'sqp' and 'active-set'.

There are reformulations of the MAD portfolio optimization problem (see Konno and Yamazaki [50] at "Portfolio Optimization" on page A-10) that result in a linear programming problem, which can be solved either with standard linear programming
techniques or with stochastic programming solvers. The PortfolioMAD object, however, does not reformulate the problem in such a manner. The PortfolioMAD object computes the MAD as a nonlinear function. The convexity of the MAD, as a function of the portfolio weights and the dull edges when the number of scenarios is large, make the MAD portfolio optimization problem tractable, in practice, for certain nonlinear programming solvers, such as fmincon from Optimization Toolbox. To learn more about the workflow when using PortfolioMAD objects, see "PortfolioMAD Object Workflow" on page 6-16.

\section*{What Are Scenarios?}

Since mean absolute deviation portfolio optimization works with scenarios of asset returns to perform the optimization, several ways exist to specify and simulate scenarios. In many applications with MAD portfolio optimization, asset returns may have distinctly nonnormal probability distributions with either multiple modes, binning of returns, truncation of distributions, and so forth. In other applications, asset returns are modeled as the result of various simulation methods that might include Monte-Carlo simulation, quasi-random simulation, and so forth. In many cases, the underlying probability distribution for risk factors may be multivariate normal but the resultant transformations are sufficiently nonlinear to result in distinctively nonnormal asset returns.

For example, this occurs with bonds and derivatives. In the case of bonds with a nonzero probability of default, such scenarios would likely include asset returns that are \(-100 \%\) to indicate default and some values slightly greater than \(-100 \%\) to indicate recovery rates.

Although the PortfolioMAD object has functions to simulate multivariate normal scenarios from either data or moments (simulateNormalScenariosByData and simulateNormalScenariosByMoments), the usual approach is to specify scenarios directly from your own simulation functions. These scenarios are entered directly as a matrix with a sample for all assets across each row of the matrix and with samples for an asset down each column of the matrix. The architecture of the MAD portfolio optimization tools references the scenarios through a function handle so scenarios that have been set cannot be accessed directly as a property of the PortfolioMAD object.

\section*{Setting Scenarios Using the PortfolioMAD Function}

Suppose that you have a matrix of scenarios in the AssetScenarios variable. The scenarios are set through the PortfolioMAD function with:
```

m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
0.00408 0.0289 0.0204 0.0119;
0.00192 0.0204 0.0576 0.0336;
0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;

```
AssetScenarios = mvnrnd(m, C, 20000);
p = PortfolioMAD('Scenarios', AssetScenarios);
disp(p.NumAssets);
disp(p.NumScenarios);
4

\section*{20000}

Notice that the PortfolioMAD object determines and fixes the number of assets in NumAssets and the number of scenarios in NumScenarios based on the scenario's matrix. You can change the number of scenarios by calling the PortfolioMAD function with a different scenario matrix. However, once the NumAssets property has been set in the object, you cannot enter a scenario matrix with a different number of assets. The getScenarios function lets you recover scenarios from a PortfolioMAD object. You can also obtain the mean and covariance of your scenarios using estimateScenarioMoments.

Although not recommended for the casual user, an alternative way exists to recover scenarios by working with the function handle that points to scenarios in the PortfolioMAD object. To access some or all of the scenarios from a PortfolioMAD object, the hidden property localScenarioHandle is a function handle that points to a function to obtain scenarios that have already been set. To get scenarios directly from a PortfolioMAD object p , use
scenarios = p.localScenarioHandle([], []);
and to obtain a subset of scenarios from rows startrow to endrow, use
scenarios = p.localScenarioHandle(startrow, endrow); where \(1 \leq\) startrow \(\leq\) endrow \(\leq\) numScenarios.

\section*{Setting Scenarios Using the setScenarios Function}

You can also set scenarios using setScenarios. For example, given the mean and covariance of asset returns in the variables \(m\) and \(C\), the asset moment properties can be set:
```

m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
0.00408 0.0289 0.0204 0.0119;
0.00192 0.0204 0.0576 0.0336;
0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;

```
AssetScenarios = mvnrnd(m, C, 20000);
p = PortfolioMAD;
p = setScenarios(p, AssetScenarios);
disp(p.NumAssets);
disp(p.NumScenarios);

4

\section*{20000}

\section*{Estimating the Mean and Covariance of Scenarios}

The estimateScenarioMoments function obtains estimates for the mean and covariance of scenarios in a PortfolioMAD object.
```

m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
0.00408 0.0289 0.0204 0.0119;
0.00192 0.0204 0.0576 0.0336;
0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;
AssetScenarios = mvnrnd(m, C, 20000);
p = PortfolioMAD;

```
```

p = setScenarios(p, AssetScenarios);
[mean, covar] = estimateScenarioMoments(p)
mean =
0.0044
0.0084
0.0108
0.0155
covar =

| 0.0005 | 0.0003 | 0.0002 | -0.0000 |
| ---: | ---: | ---: | ---: |
| 0.0003 | 0.0024 | 0.0017 | 0.0010 |
| 0.0002 | 0.0017 | 0.0047 | 0.0028 |
| -0.0000 | 0.0010 | 0.0028 | 0.0103 |

```

\section*{Simulating Normal Scenarios}

As a convenience, the two functions (simulateNormalScenariosByData and simulateNormalScenariosByMoments) exist to simulate scenarios from data or moments under an assumption that they are distributed as multivariate normal random asset returns.

\section*{Simulating Normal Scenarios from Returns or Prices}

Given either return or price data, use the simulateNormalScenariosByData function to simulate multivariate normal scenarios. Either returns or prices are stored as matrices with samples going down the rows and assets going across the columns. In addition, returns or prices can be stored in a financial time series fints object (see "Simulating Normal Scenarios from Time Series Data" on page 6-45). To illustrate using simulateNormalScenariosByData, generate random samples of 120 observations of asset returns for four assets from the mean and covariance of asset returns in the variables \(m\) and \(C\) with portsim. The default behavior of portsim creates simulated data with estimated mean and covariance identical to the input moments m and C . In addition to a return series created by portsim in the variable \(X\), a price series is created in the variable \(Y\) :
```

m = [ 0.0042; 0.0083; 0.01; 0.15 ];
C = [ 0.005333 0.00034 0.00016 0;
0.00034 0.002408 0.0017 0.000992;

```
```

0.00016 0.0017 0.0048 0.0028;
0 0.000992 0.0028 0.010208 ];
X = portsim(m', C, 120);
Y = ret2tick(X);

```

Note: Portfolio optimization requires that you use total returns and not just price returns. So, "returns" should be total returns and "prices" should be total return prices.

Given asset returns and prices in variables \(X\) and \(Y\) from above, this sequence of examples demonstrates equivalent ways to simulate multivariate normal scenarios for the PortfolioMAD object. Assume a PortfolioMAD object created in p that uses the asset returns in \(X\) uses simulateNormalScenariosByData:
```

p = PortfolioMAD;
p = simulateNormalScenariosByData(p, X, 20000);
[passetmean, passetcovar] = estimateScenarioMoments(p)
passetmean =
0.0033
0.0085
0.0095
0.1503
passetcovar =

| 0.0055 | 0.0004 | 0.0002 | 0.0001 |
| :--- | :--- | :--- | :--- |
| 0.0004 | 0.0024 | 0.0017 | 0.0010 |
| 0.0002 | 0.0017 | 0.0049 | 0.0028 |
| 0.0001 | 0.0010 | 0.0028 | 0.0102 |

```

The moments that you obtain from this simulation will likely differ from the moments listed here because the scenarios are random samples from the estimated multivariate normal probability distribution of the input returns \(X\).

The default behavior of simulateNormalScenariosByData is to work with asset returns. If, instead, you have asset prices as in the variable \(Y\), simulateNormalScenariosByData accepts a name-value pair argument name 'DataFormat ' with a corresponding value set to 'prices' to indicate that the input to the function is in the form of asset prices and not returns (the default value for the
'DataFormat ' argument is 'returns'). This example simulates scenarios with the asset price data in \(Y\) for the PortfolioMAD object q:
```

p = PortfolioMAD;
p = simulateNormalScenariosByData(p, Y, 20000, 'dataformat', 'prices');
[passetmean, passetcovar] = estimateScenarioMoments(p)
passetmean =

```
0.0043
0.0083
0.0099
0.1500

\section*{passetcovar =}
\begin{tabular}{llll}
0.0053 & 0.0003 & 0.0001 & 0.0002 \\
0.0003 & 0.0024 & 0.0017 & 0.0010 \\
0.0001 & 0.0017 & 0.0047 & 0.0027 \\
0.0002 & 0.0010 & 0.0027 & 0.0100
\end{tabular}

\section*{Simulating Normal Scenarios with Missing Data}

Often when working with multiple assets, you have missing data indicated by NaN values in your return or price data. Although "Multivariate Normal Regression" on page 9-2 goes into detail about regression with missing data, the simulateNormalScenariosByData function has a name-value pair argument name 'MissingData' that indicates with a Boolean value whether to use the missing data capabilities of Financial Toolbox. The default value for 'MissingData' is false which removes all samples with NaN values. If, however, 'MissingData' is set to true, simulateNormalScenariosByData uses the ECM algorithm to estimate asset moments. This example shows how this works on price data with missing values:
```

m = [ 0.0042; 0.0083; 0.01; 0.15 ];
C = [ 0.005333 0.00034 0.00016 0;
0.00034 0.002408 0.0017 0.000992;
0.00016 0.0017 0.0048 0.0028;
0 0.000992 0.0028 0.010208 ];
X = portsim(m', C, 120);
Y = ret2tick(X);
Y(1:20,1) = NaN;

```
```

Y(1:12,4) = NaN;

```

Notice that the prices above in \(Y\) have missing values in the first and fourth series.
```

p = PortfolioMAD;
p = simulateNormalScenariosByData(p, Y, 20000, 'dataformat', 'prices');
q = PortfolioMAD;
q = simulateNormalScenariosByData(q, Y, 20000, 'dataformat', 'prices', 'missingdata', true);
[passetmean, passetcovar] = estimateScenarioMoments(p)
[qassetmean, qassetcovar] = estimateScenarioMoments(q)
passetmean =
0.0095
0.0103
0.0124
0.1505
passetcovar =

| 0.0054 | 0.0000 | -0.0005 | -0.0006 |
| ---: | ---: | ---: | ---: |
| 0.0000 | 0.0021 | 0.0015 | 0.0010 |
| -0.0005 | 0.0015 | 0.0046 | 0.0026 |
| -0.0006 | 0.0010 | 0.0026 | 0.0100 |

qassetmean =
0.0092
0.0082
0.0094
0.1463
qassetcovar =

| 0.0071 | -0.0000 | -0.0006 | -0.0006 |
| ---: | ---: | ---: | ---: |
| -0.0000 | 0.0032 | 0.0023 | 0.0015 |
| -0.0006 | 0.0023 | 0.0064 | 0.0036 |
| -0.0006 | 0.0015 | 0.0036 | 0.0133 |

```

The first PortfolioMAD object, \(p\), contains scenarios obtained from price data in \(Y\) where NaN values are discarded and the second PortfolioMAD object, q, contains scenarios obtained from price data in \(Y\) that accommodate missing values. Each time you run this example, you get different estimates for the moments in \(p\) and \(q\).

\section*{Simulating Normal Scenarios from Time Series Data}

The simulateNormalScenariosByData function also accepts asset returns or prices stored in financial time series (fints) objects. The function implicitly works with matrices of data or data in a fints object using the same rules for whether the data are returns or prices. To illustrate, use fints to create the fints object Xfts that contains asset returns generated with fints (see "Simulating Normal Scenarios from Returns or Prices" on page 6-41) and add series labels:
```

m = [ 0.0042; 0.0083; 0.01; 0.15 ];
C = [ 0.005333 0.00034 0.00016 0;
0.00034 0.002408 0.0017 0.000992;
0.00016 0.0017 0.0048 0.0028;
0 0.000992 0.0028 0.010208 ];
X = portsim(m', C, 120);
d = (datenum('31-jan-2001'):datenum('31-dec-2010'))';
Xfts = fints(d, zeros(numel(d),4), {'Bonds', 'LargeCap', 'SmallCap', 'Emerging'});
Xfts = tomonthly(Xfts);
Xfts.Bonds = X(:,1);
Xfts.LargeCap = X(:,2);
Xfts.SmallCap = X(:,3);
Xfts.Emerging = X(:,4);
p = PortfolioMAD;
p = simulateNormalScenariosByData(p, Xfts, 20000);
[passetmean, passetcovar] = estimateScenarioMoments(p)
passetmean =
0.0038
0.0078
0.0102
0.1492
passetcovar =

| 0.0053 | 0.0004 | 0.0001 | -0.0000 |
| ---: | ---: | ---: | ---: |
| 0.0004 | 0.0024 | 0.0017 | 0.0010 |
| 0.0001 | 0.0017 | 0.0048 | 0.0028 |
| -0.0000 | 0.0010 | 0.0028 | 0.0103 |

```

The name-value inputs 'DataFormat' to handle return or price data and 'MissingData' to ignore or use samples with missing values also work for fints data. In addition, simulateNormalScenariosByData extracts asset names or identifiers from a fints object if the argument name 'GetAssetList' is set
to true (the default value is false). If the 'GetAssetList' value is true, the identifiers are used to set the AssetList property of the PortfolioMAD object. Thus, repeating the formation of the PortfolioMAD object q from the previous example with the 'GetAssetList ' flag set to true extracts the series labels from the fints object:
```

p = simulateNormalScenariosByData(p, Xfts, 20000, 'getassetlist', true);

```
disp(p.AssetList)
'Bonds' 'LargeCap' 'SmallCap' 'Emerging'
If you set the 'GetAssetList ' flag set to true and your input data is in a matrix, simulateNormalScenariosByData uses the default labeling scheme from setAssetList as described in "Setting Up a List of Asset Identifiers" on page 6-31.

\section*{Simulating Normal Scenarios for Mean and Covariance}

Given the mean and covariance of asset returns, use the simulateNormalScenariosByMoments function to simulate multivariate normal scenarios. The mean can be either a row or column vector and the covariance matrix must be a symmetric positive-semidefinite matrix. Various rules for scalar expansion apply. To illustrate using simulateNormalScenariosByMoments, start with moments in \(m\) and \(C\) and generate 20,000 scenarios:
```

m = [ 0.0042; 0.0083; 0.01; 0.15 ];
C = [ 0.005333 0.00034 0.00016 0;
0.00034 0.002408 0.0017 0.000992;
0.00016 0.0017 0.0048 0.0028;
0 0.000992 0.0028 0.010208 ];
p = PortfolioMAD;
p = simulateNormalScenariosByMoments(p, m, C, 20000);
[passetmean, passetcovar] = estimateScenarioMoments(p)
passetmean =
0.0040
0.0084
0.0105
0.1513

```
passetcovar =
\begin{tabular}{llll}
0.0053 & 0.0003 & 0.0002 & 0.0001 \\
0.0003 & 0.0024 & 0.0017 & 0.0009 \\
0.0002 & 0.0017 & 0.0048 & 0.0028 \\
0.0001 & 0.0009 & 0.0028 & 0.0102
\end{tabular}
simulateNormalScenariosByMoments performs scalar expansion on arguments for the moments of asset returns. If NumAssets has not already been set, a scalar argument is interpreted as a scalar with NumAssets set to 1. simulateNormalScenariosByMoments provides an additional optional argument to specify the number of assets so that scalar expansion works with the correct number of assets. In addition, if either a scalar or vector is input for the covariance of asset returns, a diagonal matrix is formed such that a scalar expands along the diagonal and a vector becomes the diagonal.

\section*{Working with a Riskless Asset}

The PortfolioMAD object has a separate RiskFreeRate property that stores the rate of return of a riskless asset. Thus, you can separate your universe into a riskless asset and a collection of risky assets. For example, assume that your riskless asset has a return in the scalar variable r0, then the property for the RiskFreeRate is set using the PortfolioMAD function:
```

rO = 0.01/12;
p = PortfolioMAD;
p = PortfolioMAD('RiskFreeRate', r0);
disp(p.RiskFreeRate);

```
8.3333e-04

Note: If your portfolio problem has a budget constraint such that your portfolio weights must sum to 1 , then the riskless asset is irrelevant.

\section*{Working with Transaction Costs}

The difference between net and gross portfolio returns is transaction costs. The net portfolio return proxy has distinct proportional costs to purchase and to sell assets which are maintained in the PortfolioMAD object properties BuyCost and SellCost. Transaction costs are in units of total return and, as such, are proportional to the price
of an asset so that they enter the model for net portfolio returns in return form. For example, suppose that you have a stock currently priced \(\$ 40\) and your usual transaction costs are 5 cents per share. Then the transaction cost for the stock is \(0.05 / 40=0.00125\) (as defined in "Net Portfolio Returns" on page 6-4). Costs are entered as positive values and credits are entered as negative values.

\section*{Setting Transaction Costs Using the PorifolioMAD Function}

To set up transaction costs, you must specify an initial or current portfolio in the InitPort property. If the initial portfolio is not set when you set up the transaction cost properties, InitPort is 0 . The properties for transaction costs can be set using the PortfolioMAD function. For example, assume that purchase and sale transaction costs are in the variables bc and Sc and an initial portfolio is in the variable \(\times 0\), then transaction costs are set:
```

bc = [ 0.00125; 0.00125; 0.00125; 0.00125; 0.00125 ];
sc = [ 0.00125; 0.007; 0.00125; 0.00125; 0.0024 ];
x0 = [ 0.4; 0.2; 0.2; 0.1; 0.1 ];
p = PortfolioMAD('BuyCost', bc, 'SellCost', sc, 'InitPort', x0);
disp(p.NumAssets);
disp(p.BuyCost);
disp(p.SellCost);
disp(p.InitPort);

```
    5
    0.0013
    0.0013
    0.0013
    0.0013
    0.0013
    0.0013
    0.0070
    0.0013
    0.0013
    0.0024
    0.4000
    0.2000
    0.2000
    0.1000
    0.1000

\section*{Setting Transaction Costs Using the setCosts Function}

You can also set the properties for transaction costs using setCosts. Assume that you have the same costs and initial portfolio as in the previous example. Given a PortfolioMAD object p with an initial portfolio already set, use setCosts to set up transaction costs:
```

bc = [ 0.00125; 0.00125; 0.00125; 0.00125; 0.00125 ];
sc = [ 0.00125; 0.007; 0.00125; 0.00125; 0.0024 ];
x0 = [ 0.4; 0.2; 0.2; 0.1; 0.1 ];
p = PortfolioMAD('InitPort', x0);
p = setCosts(p, bc, sc);
disp(p.NumAssets);
disp(p.BuyCost);
disp(p.SellCost);
disp(p.InitPort);
5
0.0013
0.0013
0.0013
0.0013
0.0013
0.0013
0.0070

0.0024
0.4000
0.2000
0.2000
0.1000
0.1000

```

You can also set up the initial portfolio's InitPort value as an optional argument to setCosts so that the following is an equivalent way to set up transaction costs:
```

bc = [ 0.00125; 0.00125; 0.00125; 0.00125; 0.00125 ];
sc = [ 0.00125; 0.007; 0.00125; 0.00125; 0.0024 ];
x0 = [ 0.4; 0.2; 0.2; 0.1; 0.1 ];

```
```

p = PortfolioMAD;
p = setCosts(p, bc, sc, x0);
disp(p.NumAssets);
disp(p.BuyCost);
disp(p.SellCost);
disp(p.InitPort);
5
0.0013
0.0013

0.2000
0.2000
0.1000
0.1000

```

\section*{Setting Transaction Costs with Scalar Expansion}

Both the PortfolioMAD function and setCosts function implement scalar expansion on the arguments for transaction costs and the initial portfolio. If the NumAssets property is already set in the PortfolioMAD object, scalar arguments for these properties are expanded to have the same value across all dimensions. In addition, setCosts lets you specify NumAssets as an optional final argument. For example, assume that you have an initial portfolio x 0 and you want to set common transaction costs on all assets in your universe. You can set these costs in any of these equivalent ways:
```

x0 = [ 0.4; 0.2; 0.2; 0.1; 0.1 ];
p = PortfolioMAD('InitPort', x0, 'BuyCost', 0.002, 'SellCost', 0.002);
or
x0 = [ 0.4; 0.2; 0.2; 0.1; 0.1 ];

```
```

p = PortfolioMAD('InitPort', x0);
p = setCosts(p, 0.002, 0.002);
or
x0 = [ 0.4; 0.2; 0.2; 0.1; 0.1 ];
p = PortfolioMAD;
p = setCosts(p, 0.002, 0.002, x0);

```

To clear costs from your PortfolioMAD object, use either thePortfolioMAD function or setCosts with empty inputs for the properties to be cleared. For example, you can clear sales costs from the PortfolioMAD object \(p\) in the previous example:
```

p = PortfolioMAD(p, 'SellCost', []);

```

6-70

```

The final element for a complete specification of a portfolio optimization problem is the set of feasible portfolios, which is called a portfolio set. A portfolio set \(X \subset R^{n}\) is specified by construction as the intersection of sets formed by a collection of constraints on portfolio weights. A portfolio set necessarily and sufficiently must be a nonempty, closed, and bounded set.

When setting up your portfolio set, ensure that the portfolio set satisfies these conditions. The most basic or "default" portfolio set requires portfolio weights to be nonnegative (using the lower-bound constraint) and to sum to 1 (using the budget constraint). For information on the workflow when using PortfolioMAD objects, see "PortfolioMAD Object Workflow" on page 6-16.

\section*{Setting Default Constraints for Portfolio Weights Using PortfolioMAD Object}

The "default" MAD portfolio problem has two constraints on portfolio weights:
- Portfolio weights must be nonnegative.
- Portfolio weights must sum to 1 .

Implicitly, these constraints imply that portfolio weights are no greater than 1, although this is a superfluous constraint to impose on the problem.

\section*{Setting Default Constraints Using the PortfolioMAD Function}

Given a portfolio optimization problem with NumAssets \(=20\) assets, use the PortfolioMAD function to set up a default problem and explicitly set bounds and budget constraints:
```

p = PortfolioMAD('NumAssets', 20, 'LowerBound', 0, 'Budget', 1);
disp(p);

```
    PortfolioMAD with properties:
        BuyCost: []
        SellCost: []
    RiskFreeRate: []
        Turnover: []
        BuyTurnover: []
    SellTurnover: []
    NumScenarios: []
        Name: []
        NumAssets: 20
        AssetList: []
            InitPort: []
        AInequality: []
        bInequality: []
            AEquality: []
            bEquality: []
        LowerBound: [20x1 double]
        UpperBound: []
    LowerBudget: 1
    UpperBudget: 1
    GroupMatrix: []
        LowerGroup: []
        UpperGroup: []
            GroupA: []
            GroupB: []
            LowerRatio: []
            UpperRatio: []

\section*{Setting Default Constraints Using the setDefaultConstraints Function}

An alternative approach is to use the setDefaultConstraints function. If the number of assets is already known in a PortfolioMAD object, use setDefaultConstraints with no arguments to set up the necessary bound and budget constraints. Suppose that you have 20 assets to set up the portfolio set for a default problem:
```

p = PortfolioMAD('NumAssets', 20);
p = setDefaultConstraints(p);
disp(p);
PortfolioMAD with properties:
BuyCost: []
SellCost: []
RiskFreeRate: []
Turnover: []
BuyTurnover: []
SellTurnover: []
NumScenarios: []
Name: []
NumAssets: 20
AssetList: []
InitPort: []
AInequality: []
bInequality: []
AEquality: []
bEquality: []
LowerBound: [20x1 double]
UpperBound: []
LowerBudget: 1
UpperBudget: 1
GroupMatrix: []
LowerGroup: []
UpperGroup: []
GroupA: []
GroupB: []
LowerRatio: []
UpperRatio: []

```

If the number of assets is unknown, setDefaultConstraints accepts NumAssets as an optional argument to form a portfolio set for a default problem. Suppose that you have 20 assets:
```

p = PortfolioMAD;

```
```

p = setDefaultConstraints(p, 20);
disp(p);
PortfolioMAD with properties:
BuyCost: []
SellCost: []
RiskFreeRate: []
Turnover: []
BuyTurnover: []
SellTurnover: []
NumScenarios: []
Name: []
NumAssets: 20
AssetList: []
InitPort: []
AInequality: []
bInequality: []
AEquality: []
bEquality: []
LowerBound: [20x1 double]
UpperBound: []
LowerBudget: 1
UpperBudget: 1
GroupMatrix: []
LowerGroup: []
UpperGroup: []
GroupA: []
GroupB: []
LowerRatio: []
UpperRatio: []

```

\section*{Working with Bound Constraints Using PortfolioMAD Object}

Bound constraints are optional linear constraints that maintain upper and lower bounds on portfolio weights (see "Bound Constraints" on page 6-9). Although every MAD portfolio set must be bounded, it is not necessary to specify a MAD portfolio set with explicit bound constraints. For example, you can create a MAD portfolio set with an implicit upper bound constraint or a MAD portfolio set with average turnover constraints. The bound constraints have properties LowerBound for the lower-bound constraint and UpperBound for the upper-bound constraint. Set default values for these constraints using the setDefaultConstraints function (see "Setting Default Constraints for Portfolio Weights Using PortfolioMAD Object" on page 6-52).

\section*{Setting Bounds Using the PoriffolioMAD Function}

The properties for bound constraints are set through the PortfolioMAD function. Suppose that you have a balanced fund with stocks that can range from \(50 \%\) to \(75 \%\) of your portfolio and bonds that can range from \(25 \%\) to \(50 \%\) of your portfolio. The bound constraints for a balanced fund are set with:
```

lb = [ 0.5; 0.25 ];
ub = [ 0.75; 0.5 ];
p = PortfolioMAD('LowerBound', lb, 'UpperBound', ub);
disp(p.NumAssets);
disp(p.LowerBound);
disp(p.UpperBound);
2
0.5000
0.2500
0.7500
0.5000

```

To continue with this example, you must set up a budget constraint. For details, see "Budget Constraints" on page 6-10.

\section*{Setting Bounds Using the setBounds Function}

You can also set the properties for bound constraints using setBounds. Suppose that you have a balanced fund with stocks that can range from \(50 \%\) to \(75 \%\) of your portfolio and bonds that can range from \(25 \%\) to \(50 \%\) of your portfolio. Given a PortfolioMAD object \(p\), use setBounds to set the bound constraints:
```

lb = [ 0.5; 0.25 ];
ub = [ 0.75; 0.5 ];
p = PortfolioMAD;
p = setBounds(p, lb, ub);
disp(p.NumAssets);
disp(p.LowerBound);
disp(p.UpperBound);

```
    2
    0.5000
0.2500
0.7500
0.5000

\section*{Setting Bounds Using the PorifolioMAD Function or setBounds Function}

Both the PortfolioMAD function and setBounds function implement scalar expansion on either the LowerBound or UpperBound properties. If the NumAssets property is already set in the PortfolioMAD object, scalar arguments for either property expand to have the same value across all dimensions. In addition, setBounds lets you specify NumAssets as an optional argument. Suppose that you have a universe of 500 assets and you want to set common bound constraints on all assets in your universe. Specifically, you are a long-only investor and want to hold no more than \(5 \%\) of your portfolio in any single asset. You can set these bound constraints in any of these equivalent ways:
```

p = PortfolioMAD('NumAssets', 500, 'LowerBound', 0, 'UpperBound', 0.05);

```
or
```

p = PortfolioMAD('NumAssets', 500);

```
\(p=\) setBounds(p, 0, 0.05);
or
p = PortfolioMAD;
\(p=\operatorname{setBounds}(p, 0,0.05,500) ;\)
To clear bound constraints from your PortfolioMAD object, use either the PortfolioMAD function or setBounds with empty inputs for the properties to be cleared. For example, to clear the upper-bound constraint from the PortfolioMAD object \(p\) in the previous example:
p = PortfolioMAD(p, 'UpperBound', []);

\section*{Working with Budget Constraints Using PorffolioMAD Object}

The budget constraint is an optional linear constraint that maintains upper and lower bounds on the sum of portfolio weights (see "Budget Constraints" on page 5-10). Budget constraints have properties LowerBudget for the lower budget constraint and UpperBudget for the upper budget constraint. If you set up a MAD portfolio optimization problem that requires portfolios to be fully invested in your universe of
assets, you can set LowerBudget to be equal to UpperBudget. These budget constraints can be set with default values equal to 1 using setDefaultConstraints (see "Setting Default Constraints for Portfolio Weights Using PortfolioMAD Object" on page 6-52).

\section*{Setting Budget Constraints Using the PortfolioMAD Function}

The properties for the budget constraint can also be set using the PortfolioMAD function. Suppose that you have an asset universe with many risky assets and a riskless asset and you want to ensure that your portfolio never holds more than \(1 \%\) cash, that is, you want to ensure that you are 99-100\% invested in risky assets. The budget constraint for this portfolio can be set with:
```

p = PortfolioMAD('LowerBudget', 0.99, 'UpperBudget', 1);
disp(p.LowerBudget);
disp(p.UpperBudget);
0.9900
1

```

\section*{Setting Budget Constraints Using the setBudget Function}

You can also set the properties for a budget constraint using setBudget. Suppose that you have a fund that permits up to \(10 \%\) leverage which means that your portfolio can be from \(100 \%\) to \(110 \%\) invested in risky assets. Given a PortfolioMAD object p, use setBudget to set the budget constraints:
```

p = PortfolioMAD;
p = setBudget(p, 1, 1.1);
disp(p.LowerBudget);
disp(p.UpperBudget);

```
1
1.1000

If you were to continue with this example, then set the RiskFreeRate property to the borrowing rate to finance possible leveraged positions. For details on the RiskFreeRate property, see "Working with a Riskless Asset" on page 6-47. To clear either bound for the budget constraint from your PortfolioMAD object, use either the PortfolioMAD function or setBudget with empty inputs for the properties to be cleared. For example, clear the upper-budget constraint from the PortfolioMAD object \(p\) in the previous example with:
```

p = PortfolioMAD(p, 'UpperBudget', []);

```

\section*{Working with Group Constraints Using PortfolioMAD Object}

Group constraints are optional linear constraints that group assets together and enforce bounds on the group weights (see "Group Constraints" on page 6-11). Although the constraints are implemented as general constraints, the usual convention is to form a group matrix that identifies membership of each asset within a specific group with Boolean indicators (either true or false or with 1 or 0) for each element in the group matrix. Group constraints have properties GroupMatrix for the group membership matrix, LowerGroup for the lower-bound constraint on groups, and UpperGroup for the upper-bound constraint on groups.

\section*{Setting Group Constraints Using the PortfolioMAD Function}

The properties for group constraints are set through the PortfolioMAD function. Suppose that you have a portfolio of five assets and want to ensure that the first three assets constitute no more than \(30 \%\) of your portfolio, then you can set group constraints:
```

G = [ [1 1 1 1 0 0 ] ];
p = PortfolioMAD('GroupMatrix', G, 'UpperGroup', 0.3);
disp(p.NumAssets);
disp(p.GroupMatrix);
disp(p.UpperGroup);
5
1 1}1
0.3000

```

The group matrix \(G\) can also be a logical matrix so that the following code achieves the same result.
```

G = [ true true true false false ];
p = PortfolioMAD('GroupMatrix', G, 'UpperGroup', 0.3);
disp(p.NumAssets);
disp(p.GroupMatrix);
disp(p.UpperGroup);

```
5
\(\begin{array}{lllll}1 & 1 & 1 & 0 & 0\end{array}\)
0.3000

\section*{Setting Group Constraints Using the setGroups and addGroups Functions}

You can also set the properties for group constraints using setGroups. Suppose that you have a portfolio of five assets and want to ensure that the first three assets constitute no more than \(30 \%\) of your portfolio. Given a PortfolioMAD object p, use setGroups to set the group constraints:
```

G = [ true true true false false ];
p = PortfolioMAD;
p = setGroups(p, G, [], 0.3);
disp(p.NumAssets);
disp(p.GroupMatrix);
disp(p.UpperGroup);

```
5
\(\begin{array}{lllll}1 & 1 & 1 & 0 & 0\end{array}\)

\subsection*{0.3000}

In this example, you would set the LowerGroup property to be empty ([ ]).
Suppose that you want to add another group constraint to make odd-numbered assets constitute at least \(20 \%\) of your portfolio. Set up an augmented group matrix and introduce infinite bounds for unconstrained group bounds or use the addGroups function to build up group constraints. For this example, create another group matrix for the second group constraint:
```

p = PortfolioMAD;
G = [ true true true false false ]; % group matrix for first group constraint
p = setGroups(p, G, [], 0.3);
G = [ true false true false true ]; % group matrix for second group constraint
p = addGroups(p, G, 0.2);
disp(p.NumAssets);
disp(p.GroupMatrix);
disp(p.LowerGroup);
disp(p.UpperGroup);
5

| 1 | 1 | 1 | 0 | 0 |
| :--- | :--- | :--- | :--- | :--- |
| 1 | 0 | 1 | 0 | 1 |

    -Inf
    0.2000

```

\section*{Inf}
addGroups determines which bounds are unbounded so you only need to focus on the constraints that you want to set.

The PortfolioMAD function, setGroups, and addGroups implement scalar expansion on either the LowerGroup or UpperGroup properties based on the dimension of the group matrix in the property GroupMatrix. Suppose that you have a universe of 30 assets with 6 asset classes such that assets \(1-5\), assets \(6-12\), assets \(13-18\), assets \(19-22\), assets 23-27, and assets \(28-30\) constitute each of your asset classes and you want each asset class to fall from \(0 \%\) to \(25 \%\) of your portfolio. Let the following group matrix define your groups and scalar expansion define the common bounds on each group:
```

p = PortfolioMAD;
G = blkdiag(true(1,5), true(1,7), true(1,6), true(1,4), true(1,5), true(1,3));
p = setGroups(p, G, 0, 0.25);
disp(p.NumAssets);
disp(p.GroupMatrix);
disp(p.LowerGroup);
disp(p.UpperGroup);
30

```

\title{
Working with Group Ratio Constraints Using PortfolioMAD Object
}

Group ratio constraints are optional linear constraints that maintain bounds on proportional relationships among groups of assets (see "Group Ratio Constraints" on page 6-12). Although the constraints are implemented as general constraints, the usual convention is to specify a pair of group matrices that identify membership of each asset within specific groups with Boolean indicators (either true or false or with 1 or 0 ) for each element in each of the group matrices. The goal is to ensure that the ratio of a base group compared to a comparison group fall within specified bounds. Group ratio constraints have properties:
- GroupA for the base membership matrix
- GroupB for the comparison membership matrix
- LowerRatio for the lower-bound constraint on the ratio of groups
- UpperRatio for the upper-bound constraint on the ratio of groups

\section*{Setting Group Ratio Constraints Using the PortfolioMAD Function}

The properties for group ratio constraints are set using PortfolioMAD function. For example, assume that you want the ratio of financial to nonfinancial companies in your portfolios to never go above \(50 \%\). Suppose that you have six assets with three financial companies (assets 1-3) and three nonfinanical companies (assets 4-6). To set group ratio constraints:
```

GA = [ 1 1 1 1 0 0 0 ]; % financial companies
GB = [lllllllll}0000; % % nonfinancial companies
p = PortfolioMAD('GroupA', GA, 'GroupB', GB, 'UpperRatio', 0.5);
disp(p.NumAssets);
disp(p.GroupA);
disp(p.GroupB);
disp(p.UpperRatio);
6
1 1
0
0.5000

```

Group matrices GA and GB in this example can be logical matrices with true and false elements that yield the same result:
```

GA = [ true true true false false false ]; % financial companies
GB = [ false false false true true true ]; % nonfinancial companies
p = PortfolioMAD('GroupA', GA, 'GroupB', GB, 'UpperRatio', 0.5);
disp(p.NumAssets);
disp(p.GroupA);
disp(p.GroupB);
disp(p.UpperRatio);
6
1
0
0.5000

```

\section*{Setting Group Ratio Constraints Using the setGroupRatio and addGroupRatio Functions}

You can also set the properties for group ratio constraints using setGroupRatio. For example, assume that you want the ratio of financial to nonfinancial companies in your portfolios to never go above \(50 \%\). Suppose that you have six assets with three financial companies (assets 1-3) and three nonfinanical companies (assets 4-6). Given a PortfolioMAD object p, use setGroupRatio to set the group constraints:
```

GA = [ true true true false false false ]; % financial companies
GB = [ false false false true true true ]; % nonfinancial companies
p = PortfolioMAD;
p = setGroupRatio(p, GA, GB, [], 0.5);
disp(p.NumAssets);
disp(p.GroupA);
disp(p.GroupB);
disp(p.UpperRatio);

```
6
\begin{tabular}{llllll}
1 & 1 & 1 & 0 & 0 & 0 \\
0 & 0 & 0 & 1 & 1 & 1
\end{tabular}

\subsection*{0.5000}

In this example, you would set the LowerRatio property to be empty ([ ]).
Suppose that you want to add another group ratio constraint to ensure that the weights in odd-numbered assets constitute at least \(20 \%\) of the weights in nonfinancial assets your
portfolio. You can set up augmented group ratio matrices and introduce infinite bounds for unconstrained group ratio bounds, or you can use the addGroupRatio function to build up group ratio constraints. For this example, create another group matrix for the second group constraint:
```

p = PortfolioMAD;
GA = [ true true true false false false ]; % financial companies
GB = [ false false false true true true ]; % nonfinancial companies
p = setGroupRatio(p, GA, GB, [], 0.5);
GA = [ true false true false true false ]; % odd-numbered companies
GB = [ false false false true true true ]; % nonfinancial companies
p = addGroupRatio(p, GA, GB, 0.2);
disp(p.NumAssets);
disp(p.GroupA);
disp(p.GroupB);
disp(p.LowerRatio);
disp(p.UpperRatio);
6
1
1
0
Inf
0.2000
0.5000
Inf

```

Notice that addGroupRatio determines which bounds are unbounded so you only need to focus on the constraints you want to set.

ThePortfolioMAD function, setGroupRatio, and addGroupRatio implement scalar expansion on either the LowerRatio or UpperRatio properties based on the dimension of the group matrices in GroupA and GroupB properties.

\section*{Working with Linear Equality Constraints Using PortfolioMAD Object}

Linear equality constraints are optional linear constraints that impose systems of equalities on portfolio weights (see "Linear Equality Constraints" on page 6-9). Linear equality constraints have properties AEquality, for the equality constraint matrix, and bEquality, for the equality constraint vector.

\section*{Setting Linear Equality Constraints Using the PortfolioMAD Function}

The properties for linear equality constraints are set using the PortfolioMAD function. Suppose that you have a portfolio of five assets and want to ensure that the first three assets are \(50 \%\) of your portfolio. To set this constraint:
```

A = [ [10ccllll
b = 0.5;
p = PortfolioMAD('AEquality', A, 'bEquality', b);
disp(p.NumAssets);
disp(p.AEquality);
disp(p.bEquality);
5
1 1 1 1 1 0
0.5000

```

\section*{Setting Linear Equality Constraints Using the setEquality and addEquality Functions}

You can also set the properties for linear equality constraints using setEquality. Suppose that you have a portfolio of five assets and want to ensure that the first three assets are \(50 \%\) of your portfolio. Given a PortfolioMAD object p, use setEquality to set the linear equality constraints:
\(A=\left[\begin{array}{lllll}1 & 1 & 1 & 0 & 0\end{array}\right] ;\)
b \(=0.5\);
p = PortfolioMAD;
\(\mathrm{p}=\operatorname{setEquality}(\mathrm{p}, \mathrm{A}, \mathrm{b})\);
disp(p.NumAssets);
disp(p.AEquality);
disp(p.bEquality);
5
\(\begin{array}{lllll}1 & 1 & 1 & 0 & 0\end{array}\)
0.5000

Suppose that you want to add another linear equality constraint to ensure that the last three assets also constitute \(50 \%\) of your portfolio. You can set up an augmented system of linear equalities or use addEquality to build up linear equality constraints. For this example, create another system of equalities:
```

p = PortfolioMAD;
A = [ 11 1 1 0 0 ] ; % first equality constraint
b = 0.5;
p = setEquality(p, A, b);
A = [ 0 0 1 1 1 1 ]; % second equality constraint
b = 0.5;
p = addEquality(p, A, b);
disp(p.NumAssets);
disp(p.AEquality);
disp(p.bEquality);
5
1
0
0.5000
0.5000

```

The PortfolioMAD function, setEquality, and addEquality implement scalar expansion on the bEquality property based on the dimension of the matrix in the AEquality property.

\section*{Working with Linear Inequality Constraints Using PortfolioMAD Object}

Linear inequality constraints are optional linear constraints that impose systems of inequalities on portfolio weights (see "Linear Inequality Constraints" on page 6-8). Linear inequality constraints have properties AInequality for the inequality constraint matrix, and bInequality for the inequality constraint vector.

\section*{Setting Linear Inequality Constraints Using the PorffolioMAD Function}

The properties for linear inequality constraints are set using the PortfolioMAD function. Suppose that you have a portfolio of five assets and you want to ensure that the first three assets are no more than \(50 \%\) of your portfolio. To set up these constraints:
```

A = [ 1 1 1 1 0 0 ];
b = 0.5;
p = PortfolioMAD('AInequality', A, 'bInequality', b);
disp(p.NumAssets);
disp(p.AInequality);

```
```

disp(p.bInequality);

```

5
0.5000

\section*{Setting Linear Inequality Constraints Using the setlnequality and addlnequality Functions}

You can also set the properties for linear inequality constraints using set Inequality. Suppose that you have a portfolio of five assets and you want to ensure that the first three assets constitute no more than \(50 \%\) of your portfolio. Given a PortfolioMAD object p, use set Inequality to set the linear inequality constraints:
```

A = [ 1 1 1 1 1 0 0 ];
b = 0.5;
p = PortfolioMAD;
p = setInequality(p, A, b);
disp(p.NumAssets);
disp(p.AInequality);
disp(p.bInequality);
5
1 1 1 1 1 0
0.5000

```

Suppose that you want to add another linear inequality constraint to ensure that the last three assets constitute at least \(50 \%\) of your portfolio. You can set up an augmented system of linear inequalities or use the addInequality function to build up linear inequality constraints. For this example, create another system of inequalities:
```

p = PortfolioMAD;
A = [ 1 1 1 1 0 0 ]; % first inequality constraint
b = 0.5;
p = setInequality(p, A, b);
A = [ 0 0 -1 -1 -1 ]; % second inequality constraint
b = -0.5;
p = addInequality(p, A, b);
disp(p.NumAssets);
disp(p.AInequality);

```
```

disp(p.bInequality);
5
1
0
0.5000
-0.5000

```

The PortfolioMAD function, setInequality, and addInequality implement scalar expansion on the bInequality property based on the dimension of the matrix in the AInequality property.

\section*{Working with Average Turnover Constraints Using PortfolioMAD Object}

The turnover constraint is an optional linear absolute value constraint (see "Average Turnover Constraints" on page 6-12) that enforces an upper bound on the average of purchases and sales. The turnover constraint can be set using the PortfolioMAD function or the setTurnover function. The turnover constraint depends on an initial or current portfolio, which is assumed to be zero if not set when the turnover constraint is set. The turnover constraint has properties Turnover, for the upper bound on average turnover, and InitPort, for the portfolio against which turnover is computed.

\section*{Setting Average Turnover Constraints Using the PorffolioMAD Function}

The properties for the turnover constraints are set using the PortfolioMAD function. Suppose that you have an initial portfolio of 10 assets in a variable \(x 0\) and you want to ensure that average turnover is no more than \(30 \%\). To set this turnover constraint:
```

x0 = [ 0.12; 0.09; 0.08; 0.07; 0.1; 0.1; 0.15; 0.11; 0.08; 0.1 ];
p = PortfolioMAD('Turnover', 0.3, 'InitPort', x0);
disp(p.NumAssets);
disp(p.Turnover);
disp(p.InitPort);
1 0
0.3000
0.1200
0.0900
0.0800
0.0700

```
0.1000
0.1000
0.1500
0.1100
0.0800
0.1000

Note if the NumAssets or InitPort properties are not set before or when the turnover constraint is set, various rules are applied to assign default values to these properties (see "Setting Up an Initial or Current Portfolio" on page 6-33).

\section*{Setting Average Turnover Constraints Using the setTurnover Function}

You can also set properties for portfolio turnover using setTurnover to specify both the upper bound for average turnover and an initial portfolio. Suppose that you have an initial portfolio of 10 assets in a variable \(\mathrm{x0}\) and want to ensure that average turnover is no more than \(30 \%\). Given a PortfolioMAD object p, use setTurnover to set the turnover constraint with and without the initial portfolio being set previously:
```

x0 = [ 0.12; 0.09; 0.08; 0.07; 0.1; 0.1; 0.15; 0.11; 0.08; 0.1 ];
p = PortfolioMAD('InitPort', x0);
p = setTurnover(p, 0.3);
disp(p.NumAssets);
disp(p.Turnover);
disp(p.InitPort);
1 0
0.3000
0.1200
0.0900
0.0800
0.0700
0.1000
0.1000
0.1500
0.1100
0.0800
0.1000
or
x0 = [ 0.12; 0.09; 0.08; 0.07; 0.1; 0.1; 0.15; 0.11; 0.08; 0.1 ];
p = PortfolioMAD;
p = setTurnover(p, 0.3, x0);
disp(p.NumAssets);

```
```

disp(p.Turnover);

```
disp(p.InitPort);

setTurnover implements scalar expansion on the argument for the initial portfolio. If the NumAssets property is already set in the PortfolioMAD object, a scalar argument for InitPort expands to have the same value across all dimensions. In addition, setTurnover lets you specify NumAssets as an optional argument. To clear turnover from your PortfolioMAD object, use the PortfolioMAD function or setTurnover with empty inputs for the properties to be cleared.

\section*{Working with One-way Turnover Constraints Using PortfolioMAD Object}

One-way turnover constraints are optional constraints (see "One-way Turnover Constraints" on page 6-13) that enforce upper bounds on net purchases or net sales. One-way turnover constraints can be set using the PortfolioMAD function or the setOneWayTurnover function. One-way turnover constraints depend upon an initial or current portfolio, which is assumed to be zero if not set when the turnover constraints are set. One-way turnover constraints have properties BuyTurnover, for the upper bound on net purchases, SellTurnover, for the upper bound on net sales, and InitPort, for the portfolio against which turnover is computed.

\section*{Setting One-way Turnover Constraints Using the PortfolioMAD Function}

The Properties for the one-way turnover constraints are set using the PortfolioMAD function. Suppose that you have an initial portfolio with 10 assets in a variable x 0 and you want to ensure that turnover on purchases is no more than \(30 \%\) and turnover on sales is no more than \(20 \%\) of the initial portfolio. To set these turnover constraints:
```

x0 = [ 0.12; 0.09; 0.08; 0.07; 0.1; 0.1; 0.15; 0.11; 0.08; 0.1 ];
p = PortfolioMAD('BuyTurnover', 0.3, 'SellTurnover', 0.2, 'InitPort', x0);
disp(p.NumAssets);
disp(p.BuyTurnover);
disp(p.SellTurnover);
disp(p.InitPort);

0.1000

```

If the NumAssets or InitPort properties are not set before or when the turnover constraint is set, various rules are applied to assign default values to these properties (see "Setting Up an Initial or Current Portfolio" on page 6-33).

\section*{Setting Turnover Constraints Using the setOneWayTurnover Function}

You can also set properties for portfolio turnover using setOneWayTurnover to specify to the upper bounds for turnover on purchases (BuyTurnover) and sales (SellTurnover) and an initial portfolio. Suppose that you have an initial portfolio of 10 assets in a variable x 0 and want to ensure that turnover on purchases is no more than \(30 \%\) and that turnover on sales is no more than \(20 \%\) of the initial portfolio. Given a PortfolioMAD object p, use setOneWayTurnover to set the turnover constraints with and without the initial portfolio being set previously:
```

x0 = [ 0.12; 0.09; 0.08; 0.07; 0.1; 0.1; 0.15; 0.11; 0.08; 0.1 ];
p = PortfolioMAD('InitPort', x0);
p = setOneWayTurnover(p, 0.3, 0.2);
disp(p.NumAssets);
disp(p.BuyTurnover);
disp(p.SellTurnover);
disp(p.InitPort);
or

```
```

x0 = [ 0.12; 0.09; 0.08; 0.07; 0.1; 0.1; 0.15; 0.11; 0.08; 0.1 ];
p = PortfolioMAD;
p = setOneWayTurnover(p, 0.3, 0.2, x0);
disp(p.NumAssets);
disp(p.BuyTurnover);
disp(p.SellTurnover);
disp(p.InitPort);

\section*{Validate the MAD Portfolio Problem}

\author{
In this section... \\ "Validating a MAD Portfolio Set" on page 6-74 \\ "Validating MAD Portfolios" on page 6-76
}

In some cases, you may want to validate either your inputs to, or outputs from, a portfolio optimization problem. Although most error checking that occurs during the problem setup phase catches most difficulties with a portfolio optimization problem, the processes to validate MAD portfolio sets and portfolios are time consuming and are best done offline. So, the portfolio optimization tools have specialized functions to validate MAD portfolio sets and portfolios. For information on the workflow when using PortfolioMAD objects, see "PortfolioMAD Object Workflow" on page 6-16.

\section*{Validating a MAD Portfolio Set}

Since it is necessary and sufficient that your MAD portfolio set must be a nonempty, closed, and bounded set to have a valid portfolio optimization problem, the estimateBounds function lets you examine your portfolio set to determine if it is nonempty and, if nonempty, whether it is bounded. Suppose that you have the following MAD portfolio set which is an empty set because the initial portfolio at 0 is too far from a portfolio that satisfies the budget and turnover constraint:
```

p = PortfolioMAD('NumAssets', 3, 'Budget', 1);
p = setTurnover(p, 0.3, 0);

```

If a MAD portfolio set is empty, estimateBounds returns NaN bounds and sets the isbounded flag to []:
```

[lb, ub, isbounded] = estimateBounds(p)

```
lb =
    NaN
    NaN
    NaN
ub \(=\)
    NaN
    NaN

NaN
isbounded =
[]
Suppose that you create an unbounded MAD portfolio set as follows:
```

p = PortfolioMAD('AInequality', [1 -1; 1 1 ], 'bInequality', 0);
[lb, ub, isbounded] = estimateBounds(p)
lb =
-Inf
-Inf
ub =
1.0e-008 *
-0.3712
Inf
isbounded =
0

```

In this case, estimateBounds returns (possibly infinite) bounds and sets the isbounded flag to false. The result shows which assets are unbounded so that you can apply bound constraints as necessary.

Finally, suppose that you created a MAD object that is both nonempty and bounded. estimateBounds not only validates the set, but also obtains tighter bounds which are useful if you are concerned with the actual range of portfolio choices for individual assets in your portfolio:
```

p = PortfolioMAD;
p = setBudget(p, 1,1);
p = setBounds(p, [ -0.1; 0.2; 0.3; 0.2 ], [ 0.5; 0.3; 0.9; 0.8 ]);
[lb, ub, isbounded] = estimateBounds(p)
lb =
-0.1000
0.2000
0.3000

```
```

    0.2000
    ub =
0.3000
0.3000
0.7000
0.6000
isbounded =
1

```

In this example, all but the second asset has tighter upper bounds than the input upper bound implies.

\section*{Validating MAD Porifolios}

Given a MAD portfolio set specified in a PortfolioMAD object, you often want to check if specific portfolios are feasible with respect to the portfolio set. This can occur with, for example, initial portfolios and with portfolios obtained from other procedures. The checkFeasibility function determines whether a collection of portfolios is feasible. Suppose that you perform the following portfolio optimization and want to determine if the resultant efficient portfolios are feasible relative to a modified problem.

First, set up a problem in the PortfolioMAD object p, estimate efficient portfolios in pwgt, and then confirm that these portfolios are feasible relative to the initial problem:
```

m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
0.00408 0.0289 0.0204 0.0119;
0.00192 0.0204 0.0576 0.0336;
0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;
AssetScenarios = mvnrnd(m, C, 20000);
p = PortfolioMAD;
p = setScenarios(p, AssetScenarios);
p = setDefaultConstraints(p);
pwgt = estimateFrontier(p);

```
```

checkFeasibility(p, pwgt)
ans =
1

```

Next, set up a different portfolio problem that starts with the initial problem with an additional a turnover constraint and an equally weighted initial portfolio:
```

q = setTurnover(p, 0.3, 0.25);
checkFeasibility(q, pwgt)
ans =
0

```

In this case, only two of the 10 efficient portfolios from the initial problem are feasible relative to the new problem in PortfolioMAD object q. Solving the second problem using checkFeasibility demonstrates that the efficient portfolio for PortfolioMAD object q is feasible relative to the initial problem:
```

qwgt = estimateFrontier(q);
checkFeasibility(p, qwgt)
ans =

| 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |

```

\title{
Estimate Efficient Portfolios for PortfolioMAD Object
}

\author{
In this section... \\ "Obtaining Portfolios Along the Entire Efficient Frontier" on page 6-79 \\ "Obtaining Endpoints of the Efficient Frontier" on page 6-81 \\ "Obtaining Efficient Portfolios for Target Returns" on page 6-83 \\ "Obtaining Efficient Portfolios for Target Risks" on page 6-85 \\ "Choosing and Controlling the Solver" on page 6-88
}

There are two ways to look at a portfolio optimization problem that depends on what you are trying to do. One goal is to estimate efficient portfolios and the other is to estimate efficient frontiers. This section focuses on the former goal and "Estimate Efficient Frontiers for PortfolioMAD Object" on page 6-90 focuses on the latter goal. For information on the workflow when using PortfolioMAD objects, see "PortfolioMAD Object Workflow" on page 6-16.

\section*{Obtaining Portfolios Along the Entire Efficient Frontier}

The most basic way to obtain optimal portfolios is to obtain points over the entire range of the efficient frontier. Given a portfolio optimization problem in a PortfolioMAD object, the estimateFrontier function computes efficient portfolios spaced evenly according to the return proxy from the minimum to maximum return efficient portfolios. The number of portfolios estimated is controlled by the hidden property defaultNumPorts which is set to 10. A different value for the number of portfolios estimated is specified as input to estimateFrontier. This example shows the default number of efficient portfolios over the entire range of the efficient frontier:
```

m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
0.00408 0.0289 0.0204 0.0119;
0.00192 0.0204 0.0576 0.0336;
0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;
AssetScenarios = mvnrnd(m, C, 20000);
p = PortfolioMAD;
p = setScenarios(p, AssetScenarios);
p = setDefaultConstraints(p);
pwgt = estimateFrontier(p);
disp(pwgt);

| 0.8907 | 0.7289 | 0.5614 | 0.3946 | 0.2257 | 0.0612 | 0 | 0.0000 |

| 0.0330 | 0.1163 | 0.2119 | 0.3042 | 0.3998 | 0.4876 | 0.4400 | 0.3125 |
| 0.0420 | 0.0469 | 0.0472 | 0.0505 | 0.0534 | 0.0580 | 0.0374 | 0.0018 |
| 0.0343 | 0.1079 | 0.1794 | 0.2507 | 0.3211 | 0.3933 | 0.5226 | 0.6857 |

Columns 9 through 10
$0.0000 \quad 0.0000$
$0.1570 \quad 0.0000$
$0.0000 \quad 0.0000$
$0.8430 \quad 1.0000$
If you want only four portfolios in the previous example:

```
pwgt = estimateFrontier(p, 4);
disp(pwgt);
\begin{tabular}{rrrr}
0.8907 & 0.3946 & 0 & 0.0000 \\
0.0330 & 0.3042 & 0.4401 & 0.0000 \\
0.0420 & 0.0505 & 0.0373 & 0.0000 \\
0.0343 & 0.2507 & 0.5227 & 1.0000
\end{tabular}
```

Starting from the initial portfolio, estimateFrontier also returns purchases and sales to get from your initial portfolio to each efficient portfolio on the efficient frontier. For example, given an initial portfolio in pwgt0, you can obtain purchases and sales:

```
pwgt0 = [ 0.3; 0.3; 0.2; 0.1 ];
p = setInitPort(p, pwgt0);
[pwgt, pbuy, psell] = estimateFrontier(p);
display(pwgt);
display(pbuy);
display(psell);

If you do not specify an initial portfolio, the purchase and sale weights assume that your initial portfolio is 0 .

## Obtaining Endpoints of the Efficient Frontier

In many cases, you might be interested in the endpoint portfolios for the efficient frontier. Suppose that you want to determine the range of returns from minimum to maximum to refine a search for a portfolio with a specific target return. Use the estimateFrontierLimits function to obtain the endpoint portfolios:

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
    0.00408 0.0289 0.0204 0.0119;
    0.00192 0.0204 0.0576 0.0336;
    0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;
AssetScenarios = mvnrnd(m, C, 20000);
p = PortfolioMAD;
p = setScenarios(p, AssetScenarios);
p = setDefaultConstraints(p);
pwgt = estimateFrontierLimits(p);
```

```
disp(pwgt);
    0.8875 0.0000
    0.0373 0.0000
    0.0386 0.0000
    0.0366 1.0000
```

Note: The endpoints of the efficient frontier depend upon the Scenarios in the PortfolioMAD object. If you change the Scenarios, you are likely to obtain different endpoints.

Starting from an initial portfolio, estimateFrontierLimits also returns purchases and sales to get from the initial portfolio to the endpoint portfolios on the efficient frontier. For example, given an initial portfolio in pwgt0, you can obtain purchases and sales:

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
    0.00408 0.0289 0.0204 0.0119;
    0.00192 0.0204 0.0576 0.0336;
    0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;
AssetScenarios = mvnrnd(m, C, 20000);
p = PortfolioMAD;
p = setScenarios(p, AssetScenarios);
p = setDefaultConstraints(p);
pwgt0 = [ 0.3; 0.3; 0.2; 0.1 ];
p = setInitPort(p, pwgt0);
[pwgt, pbuy, psell] = estimateFrontierLimits(p);
display(pwgt);
display(pbuy);
display(psell);
pwgt =
    0.8927 0.0000
```

| 0.0334 | 0.0000 |
| ---: | ---: |
| 0.0422 | 0.0000 |
| 0.0317 | 1.0000 |
| pbuy $=$ |  |
| 0.5927 | 0 |
| 0 | 0 |
| 0 | 0 |
| 0 | 0.9000 |

psell =

| 0 | 0.3000 |
| ---: | ---: |
| 0.2666 | 0.3000 |
| 0.1578 | 0.2000 |
| 0.0683 | 0 |

If you do not specify an initial portfolio, the purchase and sale weights assume that your initial portfolio is 0 .

## Obtaining Efficient Portfolios for Target Returns

To obtain efficient portfolios that have targeted portfolio returns, the estimateFrontierByReturn function accepts one or more target portfolio returns and obtains efficient portfolios with the specified returns. For example, assume that you have a universe of four assets where you want to obtain efficient portfolios with target portfolio returns of $7 \%, 10 \%$, and $12 \%$ :

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
    0.00408 0.0289 0.0204 0.0119;
    0.00192 0.0204 0.0576 0.0336;
    0 0.0119 0.0336 0.1225 ];
AssetScenarios = mvnrnd(m, C, 20000);
p = PortfolioMAD;
p = setScenarios(p, AssetScenarios);
p = setDefaultConstraints(p);
pwgt = estimateFrontierByReturn(p, [0.07, 0.10, .12]);
```

```
display(pwgt);
pwgt =
\begin{tabular}{lll}
0.7537 & 0.3899 & 0.1478 \\
0.1113 & 0.2934 & 0.4136 \\
0.0545 & 0.1006 & 0.1319 \\
0.0805 & 0.2161 & 0.3066
\end{tabular}
```

In some cases, you can request a return for which no efficient portfolio exists. Based on the previous example, suppose that you want a portfolio with a $4 \%$ return (which is the return of the first asset). A portfolio that is fully invested in the first asset, however, is inefficient. estimateFrontierByReturn warns if your target returns are outside the range of efficient portfolio returns and replaces it with the endpoint portfolio of the efficient frontier closest to your target return:

```
pwgt = estimateFrontierByReturn(p, [0.04]);
Warning: One or more target return values are outside the feasible range [
0.0591121, 0.182542 ].
Will return portfolios associated with endpoints of the range for these values.
> In PortfolioMAD.estimateFrontierByReturn at 90
```

The best way to avoid this situation is to bracket your target portfolio returns with estimateFrontierLimits and estimatePortReturn (see "Obtaining Endpoints of the Efficient Frontier" on page 6-81 and "Obtaining MAD Portfolio Risks and Returns" on page 6-90).

```
pret = estimatePortReturn(p, p.estimateFrontierLimits);
display(pret);
pret =
    0.0591
    0.1825
```

This result indicates that efficient portfolios have returns that range from $6.5 \%$ to $17.8 \%$. Note, your results for these examples may be different due to the random generation of scenarios.

If you have an initial portfolio, estimateFrontierByReturn also returns purchases and sales to get from your initial portfolio to the target portfolios on the efficient frontier. For example, given an initial portfolio in pwgt0, to obtain purchases and sales with target returns of $7 \%, 10 \%$, and $12 \%$ :

```
pwgt0 = [ 0.3; 0.3; 0.2; 0.1 ];
p = setInitPort(p, pwgt0);
[pwgt, pbuy, psell] = estimateFrontierByReturn(p, [0.07, 0.10, .12]);
```

```
display(pwgt);
display(pbuy);
display(psell);
pwgt =
\begin{tabular}{lll}

\end{tabular}
```

If you do not have an initial portfolio, the purchase and sale weights assume that your initial portfolio is 0 .

## Obtaining Efficient Portfolios for Target Risks

To obtain efficient portfolios that have targeted portfolio risks, the estimateFrontierByRisk function accepts one or more target portfolio risks and obtains efficient portfolios with the specified risks. Suppose that you have a universe of four assets where you want to obtain efficient portfolios with target portfolio risks of $12 \%$, $14 \%$, and $16 \%$.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
    0.00408 0.0289 0.0204 0.0119;
    0.00192 0.0204 0.0576 0.0336;
    0 0.0119 0.0336 0.1225 ];
```

```
AssetScenarios = mvnrnd(m, C, 20000);
p = PortfolioMAD;
p = setScenarios(p, AssetScenarios);
p = setDefaultConstraints(p);
pwgt = estimateFrontierByRisk(p, [0.12, 0.14, 0.16]);
display(pwgt);
pwgt =
\begin{tabular}{rrr}
0.2102 & 0.0621 & 0 \\
0.3957 & 0.4723 & 0.4305 \\
0.1051 & 0.1204 & 0.1291 \\
0.2889 & 0.3452 & 0.4404
\end{tabular}
```

In some cases, you can request a risk for which no efficient portfolio exists. Based on the previous example, suppose that you want a portfolio with $6 \%$ risk (individual assets in this universe have risks ranging from $7 \%$ to $42.5 \%$ ). It turns out that a portfolio with $6 \%$ risk cannot be formed with these four assets. estimateFrontierByRisk warns if your target risks are outside the range of efficient portfolio risks and replaces it with the endpoint of the efficient frontier closest to your target risk:

```
pwgt = estimateFrontierByRisk(p, 0.06)
Warning: One or more target risk values are outside the feasible range [
0.0610574, 0.278711 ].
Will return portfolios associated with endpoints of the range for these values.
> In PortfolioMAD.estimateFrontierByRisk at 82
pwgt =
    0.8867
    0.0396
    0.0404
    0.0332
```

The best way to avoid this situation is to bracket your target portfolio risks with estimateFrontierLimits and estimatePortRisk (see "Obtaining Endpoints of the Efficient Frontier" on page 6-81 and "Estimate Efficient Frontiers for PortfolioMAD Object" on page 6-90).

```
prsk = estimatePortRisk(p, p.estimateFrontierLimits);
```

display(prsk);
prsk =

### 0.0611 <br> 0.2787

This result indicates that efficient portfolios have risks that range from $7 \%$ to $42.5 \%$. Note, your results for these examples may be different due to the random generation of scenarios.

Starting with an initial portfolio, estimateFrontierByRisk also returns purchases and sales to get from your initial portfolio to the target portfolios on the efficient frontier. For example, given an initial portfolio in pwgt0, you can obtain purchases and sales from the example with target risks of $12 \%, 14 \%$, and $16 \%$ :

```
pwgt0 = [ 0.3; 0.3; 0.2; 0.1 ];
p = setInitPort(p, pwgt0);
[pwgt, pbuy, psell] = estimateFrontierByRisk(p, [0.12, 0.14, 0.16]);
display(pwgt);
display(pbuy);
display(psell);
pwgt =
\begin{tabular}{rrr}
0.2102 & 0.0621 & 0 \\
0.3957 & 0.4723 & 0.4305 \\
0.1051 & 0.1204 & 0.1291 \\
0.2889 & 0.3452 & 0.4404
\end{tabular}
pbuy =
\begin{tabular}{rrr}
0 & 0 & 0 \\
0.0957 & 0.1723 & 0.1305 \\
0 & 0 & 0 \\
0.1889 & 0.2452 & 0.3404
\end{tabular}
```

psell =

| 0.0898 | 0.2379 | 0.3000 |
| ---: | ---: | ---: |
| 0 | 0 | 0 |
| 0.0949 | 0.0796 | 0.0709 |
| 0 | 0 | 0 |

If you do not specify an initial portfolio, the purchase and sale weights assume that your initial portfolio is 0 .

## Choosing and Controlling the Solver

When solving portfolio optimizations for a PortfolioMAD object, while all variations of fmincon from Optimization Toolbox are supported, using 'sqp' and 'active-set' algorithms for fmincon is recommended and the use of 'interior-point' algorithm is not recommended for MAD portfolio optimization.

Unlike Optimization Toolbox which uses the 'trust-region-reflective' algorithm as the default algorithm for fmincon, the portfolio optimization for a PortfolioMAD object uses the 'active-set' algorithm. For details about fmincon and constrained nonlinear optimization algorithms and options, see "Constrained Nonlinear Optimization Algorithms".

To modify fmincon options for MAD portfolio optimizations, use setSolver to set the hidden properties solverType and solverOptions to specify and control the solver. Since these solver properties are hidden, you cannot set them using the PortfolioMAD function. The default solver is fmincon with the 'sqb ' algorithm and no displayed output, so you do not need to use setSolver to specify this.

If you want to specify additional options associated with the fmincon solver, setSolver accepts these options as name-value pair arguments. For example, if you want to use fmincon with the sqp algorithm and with displayed output, use setSolver with:

```
p = PortfolioMAD;
p = setSolver(p, 'fmincon', 'Algorithm', 'sqp', 'Display', 'final');
display(p.solverOptions.Algorithm);
display(p.solverOptions.Display);
sqp
final
```

Alternatively, the setSolver function accepts an optimoptions object as the second argument. For example, you can change the algorithm to trust-region-reflective with no displayed output as follows:

```
p = PortfolioMAD;
options = optimoptions('fmincon', 'Algorithm', 'trust-region-reflective', 'Display', 'off');
p = setSolver(p, 'fmincon', options);
display(p.solverOptions.Algorithm);
display(p.solverOptions.Display);
trust-region-reflective
off
```

```

# Estimate Efficient Frontiers for PortfolioMAD Object 

In this section...<br>"Obtaining MAD Portfolio Risks and Returns" on page 6-90<br>"Obtaining the PortfolioMAD Standard Deviation" on page 6-92<br>"Plotting the Efficient Frontier for a PortfolioMAD Object" on page 6-93

Whereas "Estimate Efficient Portfolios for PortfolioMAD Object" on page 6-79 focused on estimation of efficient portfolios, this section focuses on the estimation of efficient frontiers. For information on the workflow when using PortfolioMAD objects, see "PortfolioMAD Object Workflow" on page 6-16.

## Obtaining MAD Porffolio Risks and Returns

Given any portfolio and, in particular, efficient portfolios, the functions estimatePortReturn and estimatePortRisk provide estimates for the return (or return proxy), risk (or the risk proxy). Each function has the same input syntax but with different combinations of outputs. Suppose that you have this following portfolio optimization problem that gave you a collection of portfolios along the efficient frontier in pwgt:

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
0.00408 0.0289 0.0204 0.0119;
0.00192 0.0204 0.0576 0.0336;
0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;
AssetScenarios = mvnrnd(m, C, 20000);
p = PortfolioMAD;
p = setScenarios(p, AssetScenarios);
p = setDefaultConstraints(p);
pwgt0 = [ 0.3; 0.3; 0.2; 0.1 ];
p = setInitPort(p, pwgt0);
pwgt = estimateFrontier(p)
pwgt =
```

Columns 1 through 8

| 0.8954 | 0.7264 | 0.5573 | 0.3877 | 0.2176 | 0.0495 | 0.0000 | 0 |
| :--- | ---: | :--- | :--- | :--- | :--- | ---: | ---: |
| 0.0310 | 0.1239 | 0.2154 | 0.3081 | 0.4028 | 0.4924 | 0.4069 | 0.2386 |

| 0.0694 | 0.0000 |
| 0.1221 | 0.0000 |
| 0.8084 | 1.0000 |

Note: Remember that the risk proxy for MAD portfolio optimization is mean-absolute deviation.

Given pwgt0 and pwgt, use the portfolio risk and return estimation functions to obtain risks and returns for your initial portfolio and the portfolios on the efficient frontier:

```
prsk0 = estimatePortRisk(p, pwgt0);
pret0 = estimatePortReturn(p, pwgtO);
prsk = estimatePortRisk(p, pwgt);
pret = estimatePortReturn(p, pwgt);
display(prskO);
display(pret0);
display(prsk);
display(pret);
You obtain these risks and returns:
prsk0 =
    0.0256
pret0 =
    0.0072
prsk =
    0.0178
    0.0193
    0.0233
    0.0286
```

0.0348

0.0145
0.0157

## Obtaining the PorffolioMAD Standard Deviation

The PortfolioMAD object has a function to compute standard deviations of portfolio returns, estimatePortStd. This function works with any portfolios, not necessarily efficient portfolios. For example, the following example obtains five portfolios (pwgt) on the efficient frontier and also has an initial portfolio in pwgt0. Various portfolio statistics are computed that include the return, risk, and standard deviation. The listed estimates are for the initial portfolio in the first row followed by estimates for each of the five efficient portfolios in subsequent rows.

```
m = [ 0.0042; 0.0083; 0.01; 0.15 ];
C = [ 0.005333 0.00034 0.00016 0;
0.00034 0.002408 0.0017 0.000992;
0.00016 0.0017 0.0048 0.0028;
0 0.000992 0.0028 0.010208 ];
pwgt0 = [ 0.3; 0.3; 0.2; 0.1 ];
p = PortfolioMAD('initport', pwgt0);
p = simulateNormalScenariosByMoments(p, m, C, 20000);
p = setDefaultConstraints(p);
```

```
pwgt = estimateFrontier(p, 5);
pret = estimatePortReturn(p, [pwgt0, pwgt]);
prsk = estimatePortRisk(p, [pwgt0, pwgt]);
pstd = estimatePortStd(p, [pwgt0, pwgt]);
[pret, prsk, pstd]
ans =
\begin{tabular}{lll}
0.0212 & 0.0305 & 0.0381 \\
0.0187 & 0.0326 & 0.0407 \\
0.0514 & 0.0369 & 0.0462 \\
0.0841 & 0.0484 & 0.0607 \\
0.1168 & 0.0637 & 0.0796 \\
0.1495 & 0.0807 & 0.1009
\end{tabular}
```

## Plotting the Efficient Frontier for a PorffolioMAD Object

The plotFrontier function creates a plot of the efficient frontier for a given portfolio optimization problem. This function accepts several types of inputs and generates a plot with an optional possibility to output the estimates for portfolio risks and returns along the efficient frontier. plotFrontier has four different ways that it can be used. In addition to a plot of the efficient frontier, if you have an initial portfolio in the InitPort property, plotFrontier also displays the return versus risk of the initial portfolio on the same plot. If you have a well-posed portfolio optimization problem set up in a PortfolioMAD object and you use plotFrontier, you get a plot of the efficient frontier with the default number of portfolios on the frontier (the default number is currently 10 and is maintained in the hidden property defaultNumPorts). This example illustrates a typical use of plotFrontier to create a new plot:

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
    0.00408 0.0289 0.0204 0.0119;
    0.00192 0.0204 0.0576 0.0336;
    0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;
AssetScenarios = mvnrnd(m, C, 20000);
p = PortfolioMAD;
p = setScenarios(p, AssetScenarios);
p = setDefaultConstraints(p);
plotFrontier(p);
```

The Name property appears as the title of the efficient frontier plot if you set it in the PortfolioMAD object. Without an explicit name, the title on the plot would be "Efficient Frontier." If you want to obtain a specific number of portfolios along the efficient frontier, use plotFrontier with the number of portfolios that you want. Suppose that you have the PortfolioMAD object from the previous example and you want to plot 20 portfolios along the efficient frontier and to obtain 20 risk and return values for each portfolio:

```
[prsk, pret] = plotFrontier(p, 20);
display([pret, prsk]);
ans =
\begin{tabular}{ll}
0.0049 & 0.0176 \\
0.0054 & 0.0179 \\
0.0058 & 0.0189 \\
0.0063 & 0.0205 \\
0.0068 & 0.0225 \\
0.0073 & 0.0248 \\
0.0078 & 0.0274 \\
0.0083 & 0.0302
\end{tabular}
```

| 0.0088 | 0.0331 |
| :--- | :--- |
| 0.0093 | 0.0361 |
| 0.0098 | 0.0392 |
| 0.0103 | 0.0423 |
| 0.0108 | 0.0457 |
| 0.0112 | 0.0496 |
| 0.0117 | 0.0539 |
| 0.0122 | 0.0586 |
| 0.0127 | 0.0635 |
| 0.0132 | 0.0687 |
| 0.0137 | 0.0744 |
| 0.0142 | 0.0806 |

## Plotting Existing Efficient Portfolios

If you already have efficient portfolios from any of the "estimateFrontier" functions (see "Estimate Efficient Frontiers for PortfolioMAD Object" on page 6-90), pass them into plotFrontier directly to plot the efficient frontier:

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
```

```
C = [ 0.0064 0.00408 0.00192 0;
    0.00408 0.0289 0.0204 0.0119;
    0.00192 0.0204 0.0576 0.0336;
    0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;
AssetScenarios = mvnrnd(m, C, 20000);
pwgt0 = [ 0.3; 0.3; 0.2; 0.1 ];
p = PortfolioMAD('Name', 'Asset Allocation Portfolio', 'InitPort', pwgt0);
p = setScenarios(p, AssetScenarios);
p = setDefaultConstraints(p);
pwgt = estimateFrontier(p, 20);
plotFrontier(p, pwgt)
```

## Plotting Existing Efficient Portfolio Risks and Returns

If you already have efficient portfolio risks and returns, you can use the interface to plotFrontier to pass them into plotFrontier to obtain a plot of the efficient frontier:

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
    0.00408 0.0289 0.0204 0.0119;
    0.00192 0.0204 0.0576 0.0336;
    0 0.0119 0.0336 0.1225 ];
AssetScenarios = mvnrnd(m, C, 20000);
pwgt0 = [ 0.3; 0.3; 0.2; 0.1 ];
p = PortfolioMAD('Name', 'Asset Allocation Portfolio', 'InitPort', pwgt0);
p = setScenarios(p, AssetScenarios);
p = setDefaultConstraints(p);
pwgt = estimateFrontier(p);
pret= estimatePortReturn(p, pwgt)
prsk = estimatePortRisk(p, pwgt)
plotFrontier(p, prsk, pret)
pret =
    0.0590
    0.0723
    0.0857
    0.0991
    0.1124
    0.1258
    0.1391
    0.1525
    0.1658
    0.1792
prsk =
    0.0615
    0.0664
    0.0795
    0.0976
    0.1184
    0.1408
    0.1663
    0.1992
    0.2368
    0.2787
```

## Postprocessing Results

```
In this section...
"Setting Up Tradable Portfolios" on page 6-100
"Working with Other Portfolio Objects" on page 6-101
"Troubleshooting MAD Portfolio Optimization Results" on page 6-104
```

After obtaining efficient portfolios or estimates for expected portfolio risks and returns, use your results to set up trades to move toward an efficient portfolio. For information on the workflow when using PortfolioMAD objects, see "PortfolioMAD Object Workflow" on page 6-16.

## Setting Up Tradable Portfolios

Suppose that you set up a portfolio optimization problem and obtained portfolios on the efficient frontier. Use the dataset object from Statistics and Machine Learning Toolbox to form a blotter that lists your portfolios with the names for each asset. For example, suppose that you want to obtain five portfolios along the efficient frontier. You can set up a blotter with weights multiplied by 100 to view the allocations for each portfolio:

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
0.00408 0.0289 0.0204 0.0119;
0.00192 0.0204 0.0576 0.0336;
0 0.0119 0.0336 0.1225 ];
pwgt0 = [ 0.3; 0.3; 0.2; 0.1 ];
p = PortfolioMAD;
p = setAssetList(p, 'Bonds','Large-Cap Equities','Small-Cap Equities','Emerging Equities');
p = setInitPort(p, pwgt0);
p = simulateNormalScenariosByMoments(p, m, C, 20000);
p = setDefaultConstraints(p);
pwgt = estimateFrontier(p, 5);
pnames = cell(1,5);
for i = 1:5
pnames{i} = sprintf('Port%d',i);
end
Blotter = dataset([{100*pwgt},pnames],'obsnames',p.AssetList);
display(Blotter);
Blotter =
\begin{tabular}{llllrl} 
& Port1 & Port2 & Port3 & Port4 & Port5 \\
Bonds & 88.154 & 50.867 & 13.611 & 0 & \(1.0609 \mathrm{e}-12\)
\end{tabular}
```

| Large-Cap Equities | 4.0454 | 22.571 | 41.276 | 23.38 | $7.9362 \mathrm{e}-13$ |
| :--- | ---: | ---: | ---: | ---: | ---: |
| Small-Cap Equities | 4.2804 | 9.3108 | 14.028 | 17.878 | $6.4823 \mathrm{e}-14$ |
| Emerging Equities | 3.5202 | 17.252 | 31.084 | 58.743 | 100 |

Note: Your results may differ from this result due to the simulation of scenarios.

This result indicates that you would invest primarily in bonds at the minimum-risk/ minimum-return end of the efficient frontier (Port1), and that you would invest completely in emerging equity at the maximum-risk/maximum-return end of the efficient frontier (Port5). You can also select a particular efficient portfolio, for example, suppose that you want a portfolio with $15 \%$ risk and you add purchase and sale weights outputs obtained from the "estimateFrontier" functions to set up a trade blotter:

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
0.00408 0.0289 0.0204 0.0119;
0.00192 0.0204 0.0576 0.0336;
0 0.0119 0.0336 0.1225 ];
pwgt0 = [ 0.3; 0.3; 0.2; 0.1 ];
p = PortfolioMAD;
p = setAssetList(p, 'Bonds','Large-Cap Equities','Small-Cap Equities','Emerging Equities');
p = setInitPort(p, pwgt0);
p = simulateNormalScenariosByMoments(p, m, C, 20000);
p = p.setDefaultConstraints;
[pwgt, pbuy, psell] = estimateFrontierByRisk(p, 0.15);
Blotter = dataset([{100*[pwgt0, pwgt, pbuy, psell]}, ...
{'Initial','Weight', 'Purchases','Sales'}],'obsnames',p.AssetList);
display(Blotter);
Blotter =
\begin{tabular}{llrrr} 
& Initial & Weight & Purchases & Sales \\
Bonds & 30 & \(6.0364 \mathrm{e}-18\) & 0 & 30 \\
Large-Cap Equities & 30 & 50.179 & 20.179 & 0 \\
Small-Cap Equities & 20 & 13.43 & 0 & 6.5696 \\
Emerging Equities & 10 & 36.391 & 26.391 & 0
\end{tabular}
```

If you have prices for each asset (in this example, they can be ETFs), add them to your blotter and then use the tools of the dataset object to obtain shares and shares to be traded.

## Working with Other Portfolio Objects

The PortfolioMAD object is for MAD portfolio optimization. The PortfolioCVaR object is for CVaR portfolio optimization. The Portfolio object is for mean-variance portfolio optimization. In some cases, you might want to examine portfolio optimization problems
according to different combinations of return and risk proxies. A common example is that you want to do a MAD portfolio optimization and then want to work primarily with moments of portfolio returns. Suppose that you set up a MAD portfolio optimization problem with:

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
0.00408 0.0289 0.0204 0.0119;
0.00192 0.0204 0.0576 0.0336;
0 0.0119 0.0336 0.1225 ];
pwgt0 = [ 0.3;0.3; 0.2;0.1 ];
p = PortfolioMAD;
p = setAssetList(p, 'Bonds','Large-Cap Equities','Small-Cap Equities','Emerging Equities');
p = setInitPort(p, pwgt0);
p = simulateNormalScenariosByMoments(p, m, C, 20000);
p = setDefaultConstraints(p);
```

To work with the same problem in a mean-variance framework, you can use the scenarios from the PortfolioMAD object to set up a Portfolio object so that $p$ contains a MAD optimization problem and q contains a mean-variance optimization problem based on the same data.

```
q = Portfolio('AssetList', p.AssetList);
q = estimateAssetMoments(q, p.getScenarios);
q = setDefaultConstraints(q);
pwgt = estimateFrontier(p);
qwgt = estimateFrontier(q);
```

Since each object has a different risk proxy, it is not possible to compare results side by side. To obtain means and standard deviations of portfolio returns, you can use the functions associated with each object to obtain:

```
pret = estimatePortReturn(p, pwgt);
pstd = estimatePortStd(p, pwgt);
qret = estimatePortReturn(q, qwgt);
qstd = estimatePortStd(q, qwgt);
[pret, qret]
[pstd, qstd]
ans =
    0.0592 0.0590
    0.0730 0.0728
    0.0868 0.0867
```

| 0.1006 | 0.1005 |
| :---: | :---: |
| 0.1145 | 0.1143 |
| 0.1283 | 0.1282 |
| 0.1421 | 0.1420 |
| 0.1559 | 0.1558 |
| 0.1697 | 0.1697 |
| 0.1835 | 0.1835 |
|  |  |
| ans $=$ |  |
|  |  |
| 0.0767 | 0.0767 |
| 0.0829 | 0.0828 |
| 0.0989 | 0.0987 |
| 0.1208 | 0.1206 |
| 0.1461 | 0.1459 |
| 0.1732 | 0.1730 |
| 0.2042 | 0.2040 |
| 0.2453 | 0.2452 |
| 0.2929 | 0.2928 |
| 0.3458 | 0.3458 |

To produce comparable results, you can use the returns or risks from one portfolio optimization as target returns or risks for the other portfolio optimization.

```
qwgt = estimateFrontierByReturn(q, pret);
qret = estimatePortReturn(q, qwgt);
qstd = estimatePortStd(q, qwgt);
[pret, qret]
[pstd, qstd]
ans =
\begin{tabular}{ll}
0.0592 & 0.0592 \\
0.0730 & 0.0730 \\
0.0868 & 0.0868 \\
0.1006 & 0.1006 \\
0.1145 & 0.1145 \\
0.1283 & 0.1283 \\
0.1421 & 0.1421 \\
0.1559 & 0.1559 \\
0.1697 & 0.1697 \\
0.1835 & 0.1835
\end{tabular}
```

| 0.0767 | 0.0767 |
| :--- | :--- |
| 0.0829 | 0.0829 |
| 0.0989 | 0.0989 |
| 0.1208 | 0.1208 |
| 0.1461 | 0.1461 |
| 0.1732 | 0.1732 |
| 0.2042 | 0.2042 |
| 0.2453 | 0.2453 |
| 0.2929 | 0.2929 |
| 0.3458 | 0.3458 |

Now it is possible to compare standard deviations of portfolio returns from either type of portfolio optimization.

## Troubleshooting MAD Portfolio Optimization Results

## PorffolioMAD Object Destroyed When Modifying

If a PortfolioMAD object is destroyed when modifying, remember to pass an existing object into the PortfolioMAD function if you want to modify it, otherwise it creates a new object. See "Creating the PortfolioMAD Object" on page 6-22 for details.

## Matrix Incompatibility and "Non-Conformable" Errors

If you get matrix incompatibility or "non-conformable" errors, the representation of data in the tools follows a specific set of basic rules described in "Conventions for Representation of Data" on page 6-20.

## Missing Data Estimation Fails

If asset return data has missing or NaN values, the simulateNormalScenariosByData function with the 'missingdata' flag set to true may fail with either too many iterations or a singular covariance. To correct this problem, consider this:

- If you have asset return data with no missing or NaN values, you can compute a covariance matrix that may be singular without difficulties. If you have missing or NaN values in your data, the supported missing data feature requires that your covariance matrix must be positive-definite, that is, nonsingular.
- simulateNormalScenariosByData uses default settings for the missing data estimation procedure that might not be appropriate for all problems.

In either case, you might want to estimate the moments of asset returns separately with either the ECM estimation functions such as ecmnmle or with your own functions.

## mad_optim_transform Errors

If you obtain optimization errors such as:

```
Error using mad_optim_transform (line 276)
Portfolio set appears to be either empty or unbounded. Check constraints.
Error in PortfolioMAD/estimateFrontier (line 64)
    [AI, bI, AE, bE, lB, uB, fO, f, x0] = mad_optim_transform(obj);
Or
Error using mad_optim_transform (line 281)
Cannot obtain finite lower bounds for specified portfolio set.
Error in PortfolioMAD/estimateFrontier (line 64)
    [AI, bI, AE, bE, 1B, uB, f0, f, x0] = mad_optim_transform(obj);
Since the portfolio optimization tools require a bounded portfolio set, these errors
(and similar errors) can occur if your portfolio set is either empty and, if nonempty,
unbounded. Specifically, the portfolio optimization algorithm requires that your
portfolio set have at least a finite lower bound. The best way to deal with these
problems is to use the validation methods in "Validate the MAD Portfolio Problem"
on page 6-74. Specifically, use estimateBounds to examine your portfolio set, and
use checkFeasibility to ensure that your initial portfolio is either feasible and, if
infeasible, that you have sufficient turnover to get from your initial portfolio to the
portfolio set.
```

Tip To correct this problem, try solving your problem with larger values for turnover and gradually reduce to the value that you want.

## Efficient Portfolios Do Not Make Sense

If you obtain efficient portfolios that, do not seem to make sense, this can happen if you forget to set specific constraints or you set incorrect constraints. For example, if you allow portfolio weights to fall between 0 and 1 and do not set a budget constraint, you can get portfolios that are $100 \%$ invested in every asset. Although it may be hard to detect, the best thing to do is to review the constraints you have set with display of the PortfolioMAD object. If you get portfolios with $100 \%$ invested in each asset, you can review the display of your object and quickly see that no budget constraint is set. Also, you can use estimateBounds and checkFeasibility to determine if the bounds for your portfolio set make sense and to determine if the portfolios you obtained are feasible relative to an independent formulation of your portfolio set.

## Overview of Performance Metrics

```
In this section...
"Performance Metrics Types" on page 7-2
"Performance Metrics" on page 7-2
```

## Performance Metrics Types

Sharpe first proposed a ratio of excess return to total risk as an investment performance metric. Subsequent work by Sharpe, Lintner, and Mossin extended these ideas to entire asset markets in what is called the Capital Asset Pricing Model (CAPM). Since the development of the CAPM, a variety of investment performance metrics has evolved.

This section presents four types of investment performance metrics:

- The first type of metrics is absolute investment performance metrics that are called "classic" metrics since they are based on the CAPM. They include the Sharpe ratio, the information ratio, and tracking error. To compute the Sharpe ratio from data, use sharpe to calculate the ratio for one or more asset return series. To compute the information ratio and associated tracking error, use inforatio to calculate these quantities for one or more asset return series.
- The second type of metrics is relative investment performance metrics to compute risk-adjusted returns. These metrics are also based on the CAPM and include Beta, Jensen's Alpha, the Security Market Line (SML), Modigliani and Modigliani RiskAdjusted Return, and the Graham-Harvey measures. To calculate risk-adjusted alpha and return, use portalpha.
- The third type of metrics is alternative investment performance metrics based on lower partial moments. To calculate lower partial moments, use lpm for sample lower partial moments and elpm for expected lower partial moments.
- The fourth type of metrics is performance metrics based on maximum drawdown and expected maximum drawdown. To calculate maximum or expected maximum drawdowns, use maxdrawdown and emaxdrawdown.

## Performance Metrics

To illustrate the functions for investment performance metrics, you work with three financial time series objects using performance data for:

- An actively managed, large-cap value mutual fund
- A large-cap market index
- 90-day Treasury bills

The data is monthly total return prices that cover a span of five years.
The following plot illustrates the performance of each series in terms of total returns to an initial $\$ 1$ invested at the start of this 5 -year period:

```
load FundMarketCash
plot(TestData)
hold on
title('\bfFive-Year Total Return Performance');
legend('Fund','Market','Cash','Location','SouthEast');
hold off
```

The mean (Mean) and standard deviation (Sigma) of returns for each series are

```
Returns = tick2ret(TestData);
```

Assets

```
Mean = mean(Returns)
Sigma = std(Returns, 1)
```

which gives the following result:

```
Assets =
    Fund' 'Market' 'Cash'
Mean =
    0.0038 0.0030 0.0017
Sigma =
    0.0229 0.0389 0.0009
```

Note: Functions for investment performance metrics use total return price and total returns. To convert between total return price and total returns, use ret2tick and tick2ret.

## Using the Sharpe Ratio

```
In this section...
"Introduction" on page 7-5
"Sharpe Ratio" on page 7-5
```

## Introduction

The Sharpe ratio is the ratio of the excess return of an asset divided by the asset's standard deviation of returns. The Sharpe ratio has the form:
(Mean - Riskless) / Sigma
Here Mean is the mean of asset returns, Riskless is the return of a riskless asset, and Sigma is the standard deviation of asset returns. A higher Sharpe ratio is better than a lower Sharpe ratio. A negative Sharpe ratio indicates "anti-skill" since the performance of the riskless asset is superior. For more information, see sharpe.

## Sharpe Ratio

To compute the Sharpe ratio, the mean return of the cash asset is used as the return for the riskless asset. Thus, given asset return data and the riskless asset return, the Sharpe ratio is calculated with

```
load FundMarketCash
Returns = tick2ret(TestData);
Riskless = mean(Returns(:,3))
Sharpe = sharpe(Returns, Riskless)
```

which gives the following result:

## Riskless =

0.0017

Sharpe =
0.08860 .03150

The Sharpe ratio of the example fund is significantly higher than the Sharpe ratio of the market. As is demonstrated with portalpha, this translates into a strong risk-adjusted return. Since the Cash asset is the same as Riskless, it makes sense that its Sharpe
ratio is 0 . The Sharpe ratio was calculated with the mean of cash returns. It can also be calculated with the cash return series as input for the riskless asset

Sharpe = sharpe(Returns, Returns(:,3))
which gives the following result:

## Sharpe =

$0.0886 \quad 0.0315 \quad 0$
When using the Portfolio object, you can use the estimateMaxSharpeRatio function to estimate an efficient portfolio that maximizes the Sharpe ratio. For more information, see "Efficient Portfolio That Maximizes Sharpe Ratio" on page 4-95.

## Using the Information Ratio

```
In this section...
"Introduction" on page 7-7
"Information Ratio" on page 7-7
```

## Introduction

Although originally called the "appraisal ratio" by Treynor and Black, the information ratio is the ratio of relative return to relative risk (known as "tracking error"). Whereas the Sharpe ratio looks at returns relative to a riskless asset, the information ratio is based on returns relative to a risky benchmark which is known colloquially as a "bogey." Given an asset or portfolio of assets with random returns designated by Asset and a benchmark with random returns designated by Benchmark, the information ratio has the form:

Mean(Asset - Benchmark) / Sigma (Asset - Benchmark)
Here Mean (Asset - Benchmark) is the mean of Asset minus Benchmark returns, and Sigma(Asset - Benchmark) is the standard deviation of Asset minus Benchmark returns. A higher information ratio is considered better than a lower information ratio. For more information, see inforatio.

## Information Ratio

To calculate the information ratio using the example data, the mean return of the market series is used as the return of the benchmark. Thus, given asset return data and the riskless asset return, compute the information ratio with

```
load FundMarketCash
Returns = tick2ret(TestData);
Benchmark = Returns(:,2);
InfoRatio = inforatio(Returns, Benchmark)
```

which gives the following result:
InfoRatio =
0.0432
NaN -0.0315

Since the market series has no risk relative to itself, the information ratio for the second series is undefined (which is represented as NaN in MATLAB software). Its standard deviation of relative returns in the denominator is 0 .

- "Tracking Error" on page 7-9
- "Risk-Adjusted Return" on page 7-11
- "Sample and Expected Lower Partial Moments" on page 7-14
- "Maximum and Expected Maximum Drawdown" on page 7-17

## Tracking Error

```
In this section...
"Introduction" on page 7-9
"Tracking Error" on page 7-9
```

## Introduction

Given an asset or portfolio of assets and a benchmark, the relative standard deviation of returns between the asset or portfolio of assets and the benchmark is called tracking error.

## Tracking Error

The function inforatio computes tracking error and returns it as a second argument

```
load FundMarketCash
Returns = tick2ret(TestData);
Benchmark = Returns(:,2);
[InfoRatio, TrackingError] = inforatio(Returns, Benchmark)
```

which gives the following results:

```
InfoRatio =
    0.0432 NaN -0.0315
TrackingError =
    0.0187 0 0.0390
```

Tracking error is a useful measure of performance relative to a benchmark since it is in units of asset returns. For example, the tracking error of $1.87 \%$ for the fund relative to the market in this example is reasonable for an actively managed, large-cap value fund.

## Risk-Adjusted Return

## In this section...

"Introduction" on page 7-11
"Risk-Adjusted Return" on page 7-11

## Introduction

Risk-adjusted return either shifts the risk (which is the standard deviation of returns) of a portfolio to match the risk of a market portfolio or shifts the risk of a market portfolio to match the risk of a fund. According to the Capital Asset Pricing Model (CAPM), the market portfolio and a riskless asset are points on a Security Market Line (SML). The return of the resultant shifted portfolio, levered or unlevered, to match the risk of the market portfolio, is the risk-adjusted return. The SML provides another measure of riskadjusted return, since the difference in return between the fund and the SML, return at the same level of risk.

## Risk-Adjusted Return

Given our example data with a fund, a market, and a cash series, you can calculate the risk-adjusted return and compare it with the fund and market's mean returns

```
load FundMarketCash
Returns = tick2ret(TestData);
Fund = Returns(:,1);
Market = Returns(:,2);
Cash = Returns(:,3);
MeanFund = mean(Fund)
MeanMarket = mean(Market)
[MM, aMM] = portalpha(Fund, Market, Cash, 'MM')
[GH1, aGH1] = portalpha(Fund, Market, Cash, 'gh1')
[GH2, aGH2] = portalpha(Fund, Market, Cash, 'gh2')
[SML, aSML] = portalpha(Fund, Market, Cash, 'sml')
```

which gives the following results:
MeanFund $=$
0.0038

```
MeanMarket =
    0.0030
MM =
    0.0022
aMM =
    0.0052
GH1 =
    0.0013
aGH1 =
    0.0025
GH2 =
    0.0022
aGH2 =
    0.0052
SML =
    0.0013
aSML =
    0.0025
```

Since the fund's risk is much less than the market's risk, the risk-adjusted return of the fund is much higher than both the nominal fund and market returns.

- "Using the Information Ratio" on page 7-7
- "Tracking Error" on page 7-9
- "Sample and Expected Lower Partial Moments" on page 7-14
- "Maximum and Expected Maximum Drawdown" on page 7-17

## Sample and Expected Lower Partial Moments

```
In this section...
"Introduction" on page 7-14
"Sample Lower Partial Moments" on page 7-14
"Expected Lower Partial Moments" on page 7-15
```

## Introduction

Use lower partial moments to examine what is colloquially known as "downside risk." The main idea of the lower partial moment framework is to model moments of asset returns that fall below a minimum acceptable level of return. To compute lower partial moments from data, use lpm to calculate lower partial moments for multiple asset return series and for multiple moment orders. To compute expected values for lower partial moments under several assumptions about the distribution of asset returns, use elpm to calculate lower partial moments for multiple assets and for multiple orders.

## Sample Lower Partial Moments

The following example demonstrates lpm to compute the zero-order, first-order, and second-order lower partial moments for the three time series, where the mean of the third time series is used to compute MAR (with the so-called risk-free rate).

```
load FundMarketCash
Returns = tick2ret(TestData);
Assets
MAR = mean(Returns(:,3))
LPM = lpm(Returns, MAR, [0 1 2])
```

which gives the following results:

```
Assets =
    Fund' 'Market' 'Cash
MAR =
    0.0017
LPM =
\(0.4333 \quad 0.4167 \quad 0.6167\)
\(0.0075 \quad 0.0140 \quad 0.0004\)
```

$0.0003 \quad 0.0008 \quad 0.0000$
The first row of LPM contains zero-order lower partial moments of the three series. The fund and market index fall below MAR about $40 \%$ of the time and cash returns fall below its own mean about $60 \%$ of the time.

The second row contains first-order lower partial moments of the three series. The fund and market have large expected shortfall returns relative to MAR by 75 and 140 basis points per month. On the other hand, cash underperforms MAR by about only four basis points per month on the downside.

The third row contains second-order lower partial moments of the three series. The square root of these quantities provides an idea of the dispersion of returns that fall below the MAR. The market index has a much larger variation on the downside when compared to the fund.

## Expected Lower Partial Moments

To compare realized values with expected values, use elpm to compute expected lower partial moments based on the mean and standard deviations of normally distributed asset returns. The elpm function works with the mean and standard deviations for multiple assets and multiple orders.

```
load FundMarketCash
Returns = tick2ret(TestData);
MAR = mean(Returns(:,3))
Mean = mean(Returns)
Sigma = std(Returns, 1)
Assets
ELPM = elpm(Mean, Sigma, MAR, [0 1 2])
```

which gives the following results:

```
Assets =
    Fund' 'Market' 'Cash'
ELPM =
\begin{tabular}{lll}
0.4647 & 0.4874 & 0.5000 \\
0.0082 & 0.0149 & 0.0004 \\
0.0002 & 0.0007 & 0.0000
\end{tabular}
```

Based on the moments of each asset, the expected values for lower partial moments imply better than expected performance for the fund and market and worse than
expected performance for cash. This function works with either degenerate or nondegenerate normal random variables. For example, if cash were truly riskless, its standard deviation would be 0 . You can examine the difference in expected shortfall.

RisklessCash $=$ elpm(Mean(3), 0, MAR, 1)
which gives the following result:

```
RisklessCash =
```

0

# Maximum and Expected Maximum Drawdown 

```
In this section...
"Introduction" on page 7-17
"Maximum Drawdown" on page 7-17
"Expected Maximum Drawdown" on page 7-20
```

## Introduction

Maximum drawdown is the maximum decline of a series, measured as return, from a peak to a nadir over a period of time. Although additional metrics exist that are used in the hedge fund and commodity trading communities (see Pederson and Rudholm-Alfvin [20] in Appendix A), the original definition and subsequent implementation of these metrics is not yet standardized.

It is possible to compute analytically the expected maximum drawdown for a Brownian motion with drift (see Magdon-Ismail, Atiya, Pratap, and Abu-Mostafa [16] Appendix A). These results are used to estimate the expected maximum drawdown for a series that approximately follows a geometric Brownian motion.

Use maxdrawdown and emaxdrawdown to calculate the maximum and expected maximum drawdowns.

## Maximum Drawdown

This example demonstrates how to compute the maximum drawdown (MaxDD) using our example data with a fund, a market, and a cash series:

```
load FundMarketCash
MaxDD = maxdrawdown(TestData)
```

which gives the following results:
MaxDD =
$0.1658 \quad 0.3381 \quad 0$
The maximum drop in the given time period was of $16.58 \%$ for the fund series, and $33.81 \%$ for the market. There was no decline in the cash series, as expected, because the cash account never loses value.
maxdrawdown can also return the indices (MaxDDIndex) of the maximum drawdown intervals for each series in an optional output argument:

```
[MaxDD, MaxDDIndex] = maxdrawdown(TestData)
```

which gives the following results:

```
MaxDD =
```

    \(0.1658 \quad 0.3381 \quad 0\)
    
## MaxDDIndex =

| 2 | 2 | NaN |
| ---: | ---: | ---: |
| 18 | 18 | NaN |

The first two series experience their maximum drawdowns from the second to the 18th month in the data. The indices for the third series are NaNs because it never has a drawdown.

The $16.58 \%$ value loss from month 2 to month 18 for the fund series is verified using the reported indices:

```
Start = MaxDDIndex(1,:);
End = MaxDDIndex(2,:);
(TestData(Start(1),1) - TestData(End(1),1))/TestData(Start(1),1)
ans =
0.1658
```

Although the maximum drawdown is measured in terms of returns, maxdrawdown can measure the drawdown in terms of absolute drop in value, or in terms of log-returns. To contrast these alternatives more clearly, we work with the fund series assuming, an initial investment of 50 dollars:

```
Fund50 = 50*TestData(:,1);
plot(Fund50);
title('\bfFive-Year Fund Performance, Initial Investment 50 usd');
xlabel('Months');
ylabel('Value of Investment');
```

First, we compute the standard maximum drawdown, which coincides with the results above because returns are independent of the initial amounts invested:

MaxDD50Ret $=$ maxdrawdown(Fund50)
MaxDD50Ret $=$
0.1658

Next, we compute the maximum drop in value, using the arithmetic argument:
[MaxDD50Arith, Ind50Arith] = maxdrawdown(Fund50,'arithmetic')
MaxDD50Arith =
8.4285

Ind50Arith =

The value of this investment was $\$ 50.84$ in month 2 , but by month 18 the value was down to $\$ 42.41$, a drop of $\$ 8.43$. This is the largest loss in dollar value from a previous high in the given time period. In this case, the maximum drawdown period, 2 nd to 18 th month, is the same independently of whether drawdown is measured as return or as dollar value loss.

Last, we compute the maximum decline based on log-returns using the geometric argument. In this example, the log-returns result in a maximum drop of $18.13 \%$, again from the second to the 18th month, not far from the $16.58 \%$ obtained using standard returns.
[MaxDD50LogRet, Ind50LogRet] = maxdrawdown(Fund50,'geometric')
MaxDD50LogRet =
0.1813

Ind50LogRet =
2
18
Note, the last measure is equivalent to finding the arithmetic maximum drawdown for the log of the series:

MaxDD50LogRet2 = maxdrawdown(log(Fund50),'arithmetic')
MaxDD50LogRet2 =
0.1813

## Expected Maximum Drawdown

This example demonstrates using the log-return moments of the fund to compute the expected maximum drawdown (EMaxDD) and then compare it with the realized maximum drawdown (MaxDD).
load FundMarketCash
logReturns $=\log ($ TestData(2:end,:).$/$ TestData(1:end - 1,:)); Mu = mean(logReturns(:,1));

```
Sigma = std(logReturns(:,1),1);
T = size(logReturns,1);
MaxDD = maxdrawdown(TestData(:,1),'geometric')
EMaxDD = emaxdrawdown(Mu-0.5*Sigma^2, Sigma, T)
```

which gives the following results:

## MaxDD =

0.1813

## EMaxDD =

0.1588

The drawdown observed in this time period is above the expected maximum drawdown. There is no contradiction here. The expected maximum drawdown is not an upper bound on the maximum losses from a peak, but an estimate of their average, based on a geometric Brownian motion assumption.

## Credit Rating by Bagging Decision Trees

This example shows how to build an automated credit rating tool.
One of the fundamental tasks in credit risk management is to assign a credit grade to a borrower. Grades are used to rank customers according to their perceived creditworthiness: better grades mean less risky customers; similar grades mean similar level of risk. Grades come in two categories: credit ratings and credit scores. Credit ratings are a small number of discrete classes, usually labeled with letters, such as 'AAA', 'BB-', etc. Credit scores are numeric grades such as '640' or '720'. Credit grades are one of the key elements in regulatory frameworks, such as Basel II (see Basel Committee on Banking Supervision [3]).

Assigning a credit grade involves analyzing information on the borrower. If the borrower is an individual, information of interest could be the individual's income, outstanding debt (mortgage, credit cards), household size, residential status, etc. For corporate borrowers, one may consider certain financial ratios (e.g., sales divided by total assets), industry, etc. Here, we refer to these pieces of information about a borrower as features or predictors. Different institutions use different predictors, and they may also have different rating classes or score ranges to rank their customers. For relatively small loans offered to a large market of potential borrowers (e.g., credit cards), it is common to use credit scores, and the process of grading a borrower is usually automated. For larger loans, accessible to small- to medium-sized companies and larger corporations, credit ratings are usually used, and the grading process may involve a combination of automated algorithms and expert analysis.

There are rating agencies that keep track of the creditworthiness of companies. Yet, most banks develop an internal methodology to assign credit grades for their customers. Rating a customer internally can be a necessity if the customer has not been rated by a rating agency, but even if a third-party rating exists, an internal rating offers a complementary assessment of a customer's risk profile.

This example shows how MATLAB® can help with the automated stage of a credit rating process. In particular, we take advantage of one of the statistical learning tools readily available in Statistics and Machine Learning Toolbox ${ }^{\mathrm{TM}}$, a classification algorithm known as a bagged decision tree.

We assume that historical information is available in the form of a data set where each record contains the features of a borrower and the credit rating that was assigned to it. These may be internal ratings, assigned by a committee that followed policies and
procedures already in place. Alternatively, the ratings may come from a rating agency, whose ratings are being used to "jump start" a new internal credit rating system.

The existing historical data is the starting point, and it is used to train the bagged decision tree that will automate the credit rating. In the vocabulary of statistical learning, this training process falls in the category of supervised learning. The classifier is then used to assign ratings to new customers. In practice, these automated or predicted ratings would most likely be regarded as tentative, until a credit committee of experts reviews them. The type of classifier we use here can also facilitate the revision of these ratings, because it provides a measure of certainty for the predicted ratings, a classification score.

In practice, one needs to train a classifier first, then use it to assign a credit rating to new customers, and finally one also needs to profile or evaluate the quality or accuracy of the classifier, a process also known as validation or back-testing. We discuss some readily available back-testing tools, as well.

## Loading the Existing Credit Rating Data

We load the historical data from the comma-delimited text file CreditRating_Historical.dat. We choose to work with text files here, but users with access to Database Toolbox ${ }^{\mathrm{TM}}$ can certainly load this information directly from a database.

The data set contains financial ratios, industry sector, and credit ratings for a list of corporate customers. This is simulated, not real data. The first column is a customer ID. Then we have five columns of financial ratios. These are the same ratios used in Altman's z-score (see Altman [1]; see also Loeffler and Posch [4] for a related analysis).

- Working capital / Total Assets (WC_TA)
- Retained Earnings / Total Assets (RE_TA)
- Earnings Before Interests and Taxes / Total Assets (EBIT_TA)
- Market Value of Equity / Book Value of Total Debt (MVE_BVTD)
- Sales / Total Assets (S_TA)

Next, we have an industry sector label, an integer value ranging from 1 to 12 . The last column has the credit rating assigned to the customer. We load the data into a table array.

```
creditDS = readtable('CreditRating Historical.dat');
```

We copy the features into a matrix X , and the corresponding classes, the ratings, into a vector $Y$. This is not a required step, since we could access this information directly from the dataset or table array, but we do it here to simplify some repeated function calls below.

The features to be stored in the matrix $X$ are the five financial ratios, and the industry label. Industry is a categorical variable, nominal in fact, because there is no ordering in the industry sectors. The response variable, the credit ratings, is also categorical, though this is an ordinal variable, because, by definition, ratings imply a ranking of creditworthiness. We can use this variable "as is" to train our classifier. Here we choose to copy it into an ordinal array because this way the outputs come out in the natural order of the ratings and are easier to read. The ordering of the ratings is established by the cell array we pass as a third argument in the definition of Y . The credit ratings can also be mapped into numeric values, which can be useful to try alternative methods to analyze the data (e.g., regression). It is always recommended to try different methods in practice.

```
X = [creditDS.WC_TA creditDS.RE_TA creditDS.EBIT_TA creditDS.MVE_BVTD...
    creditDS.S_TA creditDS.Industry];
Y = ordinal(creditDS.Rating);
```

We use the predictors $X$ and the response $Y$ to fit a particular type of classification ensemble called a bagged decision tree. "Bagging," in this context, stands for "bootstrap aggregation." The methodology consists in generating a number of sub-samples, or bootstrap replicas, from the data set. These sub-samples are randomly generated, sampling with replacement from the list of customers in the data set. For each replica, a decision tree is grown. Each decision tree is a trained classifier on its own, and could be used in isolation to classify new customers. The predictions of two trees grown from two different bootstrap replicas may be different, though. The ensemble aggregates the predictions of all the decision trees that are grown for all the bootstrap replicas. If the majority of the trees predict one particular class for a new customer, it is reasonable to consider that prediction to be more robust than the prediction of any single tree alone. Moreover, if a different class is predicted by a smaller set of trees, that information is useful, too. In fact, the proportion of trees that predict different classes is the basis for the classification scores that are reported by the ensemble when classifying new data.

## Constructing the Tree Bagger

The first step to construct our classification ensemble will be to find a good leaf size for the individual trees; here we try sizes of 1,5 and 10. (See Statistics and Machine

Learning Toolbox documentation for more on TreeBagger.) We start with a small number of trees, 25 only, because we mostly want to compare the initial trend in the classification error for different leaf sizes. For reproducibility and fair comparisons, we reinitialize the random number generator, which is used to sample with replacement from the data, each time we build a classifier.

```
leaf = [1 5 10];
nTrees = 25;
rng(9876,'twister');
savedRng = rng; % save the current RNG settings
color = 'bgr';
for ii = 1:length(leaf)
    % Reinitialize the random number generator, so that the
    % random samples are the same for each leaf size
    rng(savedRng);
    % Create a bagged decision tree for each leaf size and plot out-of-bag
    % error 'oobError'
    b = TreeBagger(nTrees,X,Y,'OOBPred','on',...
                                    'CategoricalPredictors',6,...
                                    'MinLeaf',leaf(ii));
        plot(b.oobError,color(ii));
        hold on;
end
xlabel('Number of grown trees');
ylabel('Out-of-bag classification error');
legend({'1', '5', '10'},'Location','NorthEast');
title('Classification Error for Different Leaf Sizes');
hold off;
```

The errors are comparable for the three leaf-size options. We will therefore work with a leaf size of 10 , because it results in leaner trees and more efficient computations.

Note that we did not have to split the data into training and test subsets. This is done internally, it is implicit in the sampling procedure that underlies the method. At each bootstrap iteration, the bootstrap replica is the training set, and any customers left out ("out-of-bag") are used as test points to estimate the out-of-bag classification error reported above.

Next, we want to find out whether all the features are important for the accuracy of our classifier. We do this by turning on the feature importance measure (oobvarimp), and plot the results to visually find the most important features. We also try a larger number of trees now, and store the classification error, for further comparisons below.

```
nTrees = 50;
leaf = 10;
rng(savedRng);
b = TreeBagger(nTrees,X,Y,'OOBVarImp','on',...
                        'MinLeaf',leaf);
bar(b.00BPermutedVarDeltaError);
xlabel('Feature number');
ylabel('Out-of-bag feature importance');
title('Feature importance results');
oobErrorFullX = b.oobError;
```

                        'CategoricalPredictors',6,...
    Feature importance results

Features 2, 4 and 6 stand out from the rest. Feature 4, market value of equity / book value of total debt (MVE_BVTD), is the most important predictor for this data set. This ratio is closely related to the predictors of creditworthiness in structural models, such as Merton's model [5], where the value of the firm's equity is compared to its outstanding debt to determine the default probability.

Information on the industry sector, feature 6 (Industry), is also relatively more important than other variables to assess the creditworthiness of a firm for this data set.

Although not as important as MVE_BVTD, feature 2, retained earnings / total assets (RE_TA), stands out from the rest. There is a correlation between retained earnings and the age of a firm (the longer a firm has existed, the more earnings it can accumulate, in general), and in turn the age of a firm is correlated to its creditworthiness (older firms tend to be more likely to survive in tough times).

Let us fit a new classification ensemble using only predictors RE_TA, MVE_BVTD, and Industry. We compare its classification error with the previous classifier, which uses all features.

```
X = [creditDS.RE_TA creditDS.MVE_BVTD creditDS.Industry];
rng(savedRng);
b = TreeBagger(nTrees,X,Y,'OOBPred','on',...
    'CategoricalPredictors',3,...
    'MinLeaf',leaf);
oobErrorX246 = b.oobError;
plot(oobErrorFullX,'b');
hold on;
plot(oobErrorX246,'r');
xlabel('Number of grown trees');
ylabel('Out-of-bag classification error');
legend({'All features', 'Features 2, 4, 6'},'Location','NorthEast');
title('Classification Error for Different Sets of Predictors');
hold off;
```

The accuracy of the classification does not deteriorate significantly when we remove the features with relatively low importance ( 1,3 , and 5 ), so we will use the more parsimonious classification ensemble for our predictions.

In this example, we have started with a set of six features only, and used the feature importance measure of the classifier, and the out-of-bag classification error as criteria to screen out three of the variables. Feature selection can be a time consuming process when the initial set of potential predictors contains dozens of variables. Besides the tools we have used here (variable importance and a "visual" comparison of out-of-bag errors), other variable selection tools in Statistics and Machine Learning Toolbox can be helpful for these types of analyses (see documentation). However, in the end, a successful feature selection process requires a combination of quantitative tools and an analyst's judgement.

For example, the variable importance measure we used here is a ranking mechanism that estimates the relative impact of a feature by measuring how much the predictive accuracy of the classifier deteriorates when this feature's values are randomly permuted. The idea is that when the feature in question adds little to the predictive power of the classifier, using altered (in this case permuted) values should not impact the classification results. Relevant information, on the other hand, cannot be randomly swapped without degrading the predictions. Now, if two highly correlated features are important, they will both rank high in this analysis. In that case, keeping one of these features should suffice for accurate classifications, but one would not know that from the ranking results alone. One would have to check the correlations separately, or use an expert's judgement. That is to say, tools like variable importance or sequentialfs can greatly help for feature selection, but an analyst's judgment is a key piece in this process.

At this point, the classifier could be saved (e.g., save classifier.mat b), to be loaded in a future session (load classifier) to classify new customers. For efficiency, it is recommended to keep a compact version of the classifier once the training process is finished.
b = b.compact;

## Classifying New Data

Here we use the previously constructed classification ensemble to assign credit ratings to new customers. Because the ratings of existing customers need to be reviewed, too, on a regular basis, especially when their financial information has substantially changed, the data set could also contain a list of existing customers under review. We start by loading the new data.

```
newDS = readtable('CreditRating_NewCompanies.dat');
```

To predict the credit rating for this new data, we call the predict method on the classifier. The method returns two arguments, the predicted class and the classification score. We certainly want to get both output arguments, since the classification scores contain information on how certain the predicted ratings seem to be. We could copy variables RE_TA, MVE_BVTD and Industry into a matrix X, as before, but since we will make only one call to predict, we can skip this step and use newDS directly.

```
[predClass,classifScore] = b.predict([newDS.RE_TA newDS.MVE_BVTD...
    newDS.Industry]);
```

At this point, we can create a report. Here we only display on the screen a small report for the first three customers, for illustration purposes, but MATLAB's deployment tools could greatly improve the workflow here. For example, credit analysts could run this
classification remotely, using a web browser, and get a report, without even having MATLAB on their desktops.

```
for i = 1:3
    fprintf('Customer %d:\n',newDS.ID(i));
    fprintf(' RE/TA = %5.2f\n',newDS.RE_TA(i));
    fprintf(' MVE/BVTD = %5.2f\n',newDS.MVE_BVTD(i));
    fprintf(' Industry = %2d\n',newDS.Industry(i));
    fprintf(' Predicted Rating : %s\n',predClass{i});
    fprintf(' Classification score : \n');
    for j = 1:length(b.ClassNames)
        if (classifScore(i,j)>0)
            fprintf(' %s : %5.4f \n',b.ClassNames{j},classifScore(i,j));
        end
    end
end
Customer 60644:
    RE/TA = 0.22
    MVE/BVTD = 2.40
    Industry = 6
    Predicted Rating : AA
    Classification score :
        A : 0.3030
        AA : 0.6970
Customer 33083:
    RE/TA = 0.24
    MVE/BVTD = 1.51
    Industry = 4
    Predicted Rating : BBB
    Classification score :
        A : 0.0821
        BB : 0.0013
        BBB : 0.9166
Customer 63830:
    RE/TA = 0.18
    MVE/BVTD = 1.69
    Industry = 7
    Predicted Rating : A
    Classification score :
        A : 0.6453
        AA : 0.0167
        B : 0.0022
        BB : 0.0002
        BBB : 0.3356
```

Keeping records of the predicted ratings and corresponding scores can be useful for periodic assessments of the quality of the classifier. We store this information here in the table array predDS.

```
classnames = b.ClassNames;
predDS = [table(newDS.ID,predClass),array2table(classifScore)];
predDS.Properties.VariableNames = {'ID','PredRating',classnames{:}};
```

This information could be saved, for example, to a comma-delimited text file PredictedRatings.dat using the command

```
export(predDS,'file','PredictedRatings.dat','delimiter',',')
```

or written directly to a database using Database Toolbox.

## Back-Testing: Profiling the Classification Process

Validation or back-testing is the process of profiling or assessing the quality of the credit ratings. There are many different measures and tests related to this task (see, for example, Basel Committee on Banking Supervision [2]). Here, we focus on the following two questions:

- How accurate are the predicted ratings, as compared to the actual ratings? Here "predicted ratings" refers to those obtained from the automated classification process, and "actual ratings" to those assigned by a credit committee that puts together the predicted ratings and their classification scores, and other pieces of information, such as news and the state of the economy to determine a final rating.
- How well do the actual ratings rank customers according to their creditworthiness? This is done in an ex-post analysis performed, for example, one year later, when it is known which companies defaulted during the year.

The file CreditRating_ExPost.dat contains "follow up" data on the same companies considered in the previous section. It contains the actual ratings that the committee assigned to these companies, as well as a "default flag" that indicates whether the corresponding company defaulted within one year of the rating process (if 1 ) or not (if 0 ).

```
exPostDS = readtable('CreditRating_ExPost.dat');
```

If this were a new MATLAB session, besides reading the follow up data from CreditRating_ExPost.dat we would need to load the predicted ratings information stored in predDS, for example, with the command

```
predDS = readtable('PredictedRatings.dat')
```

Comparing predicted ratings vs. actual ratings. The rationale to train an automated classifier is to expedite the work of the credit committee. The more accurate the predicted ratings are, the less time the committee has to spend reviewing the predicted ratings. So it is conceivable that the committee wants to have regular checks on how closely the predicted ratings match the final ratings they assign, and to recommend re-training the automated classifier (and maybe include new features, for example) if the mismatch seems concerning.

The first tool we can use to compare predicted vs. actual ratings is a confusion matrix, readily available in Statistics and Machine Learning Toolbox:

```
C = confusionmat(exPostDS.Rating,predDS.PredRating,...
    order',{'AAA' 'AA' 'A' 'BBB' 'BB' 'B' 'CCC'})
C =
\begin{tabular}{rrrrrrr}
203 & 13 & 0 & 0 & 0 & 0 & 0 \\
8 & 110 & 20 & 0 & 0 & 0 & 0 \\
0 & 18 & 154 & 32 & 0 & 0 & 0 \\
0 & 1 & 26 & 248 & 48 & 0 & 0 \\
0 & 0 & 0 & 39 & 229 & 17 & 0 \\
0 & 0 & 0 & 1 & 46 & 44 & 2 \\
0 & 0 & 0 & 0 & 0 & 9 & 43
\end{tabular}
```

The rows in C correspond to the actual ratings, and the columns to the predicted ratings. The amount in the position ( $i, j$ ) in this matrix indicates how many customers received an actual rating $i$ and were predicted as rating j. For example, position $(3,2)$ tells us how many customers received a rating of 'A' by the credit committee, but were predicted as 'AA' with the automated classifier. One can also present this matrix in percentage form with a simple transformation:

```
Cperc = diag(sum(C,2))\C
```

Cperc =

| 0.9398 | 0.0602 | 0 | 0 | 0 | 0 |
| ---: | ---: | ---: | ---: | ---: | ---: |
| 0.0580 | 0.7971 | 0.1449 | 0 | 0 | 0 |
| 0 | 0.0882 | 0.7549 | 0.1569 | 0 | 0 |

| 0 | 0.0031 | 0.0805 | 0.7678 | 0.1486 | 0 | 0 |
| ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| 0 | 0 | 0 | 0.1368 | 0.8035 | 0.0596 | 0 |
| 0 | 0 | 0 | 0.0108 | 0.4946 | 0.4731 | 0.0215 |
| 0 | 0 | 0 | 0 | 0 | 0.1731 | 0.8269 |

Good agreement between the predicted and the actual ratings would result in values in the main diagonal that dominate the rest of the values in a row, ideally values close to 1. In this case, we actually see an important disagreement for 'B,' since about half of the customers that were rated as ' B ' by the credit committee had been predicted as ' BB ' by the automated classifier. On the other hand, it is good to see that ratings differ in at most one notch in most cases, with the only exception of 'BBB.'

A confusion matrix could also be used to compare the internal ratings assigned by the institution against third-party ratings; this is often done in practice.

For each specific rating, we can compute yet another measure of agreement between predicted and actual ratings. We can build a Receiver Operating Characteristic (ROC) curve using the perfcurve function from Statistics and Machine Learning Toolbox, and check the area under the curve (AUC). The perfcurve function takes as an argument the actual ratings, which are our benchmark, the standard we are comparing against, and the 'BBB' classification scores determined by the automated process. Let us build a ROC and calculate the AUC for rating 'BBB' in our example.

```
[xVal,yVal,~,auc] = perfcurve(exPostDS.Rating,predDS.BBB,'BBB');
plot(xVal,yVal);
xlabel('False positive rate');
ylabel('True positive rate');
text(0.5,0.25,strcat('AUC=',num2str(auc)),'EdgeColor','k');
title('ROC curve BBB, predicted vs. actual rating');
```

Here is an explanation of how the ROC is built. Recall that for each customer the automated classifier returns a classification score for each of the credit ratings, in particular, for 'BBB,' which can be interpreted as how likely it is that this particular customer should be rated 'BBB.' In order to build the ROC curve, one needs to vary the classification threshold. That is, the minimum score to classify a customer as 'BBB.' In other words, if the threshold is t , we only classify customers as 'BBB' if their 'BBB' score is greater than or equal to $t$. For example, suppose that company $X Y Z$ had a 'BBB' score of 0.87 . If the actual rating of $X Y Z$ (the information in exPostDS. Rating) is 'BBB,' then $X Y Z$ would be correctly classified as 'BBB' for any threshold of up to 0.87 . This would be a true positive, and it would increase what is call the sensitivity of the classifier. For any threshold greater than 0.87 , this company would not receive a 'BBB' rating, and we would have a false negative case. To complete the description, suppose now that XYZ's
actual rating is 'BB.' Then it would be correctly rejected as a 'BBB' for thresholds of more than 0.87 , becoming a true negative, and thus increasing the so called specificity of the classifier. However, for thresholds of up to 0.87 , it would become a false positive (it would be classified as 'BBB,' when it actually is a 'BB'). The ROC curve is constructed by plotting the proportion of true positives (sensitivity), versus false positives ( 1 -specificity), as the threshold varies from 0 to 1 .

The AUC, as its name indicates, is the area under the ROC curve. The closer the AUC is to 1 , the more accurate the classifier (a perfect classifier would have an AUC of 1). In this example, the AUC seems high enough, but it would be up to the committee to decide which level of AUC for the ratings should trigger a recommendation to improve the automated classifier.

Comparing actual ratings vs. defaults in the following year. A common tool used to assess the ranking of customers implicit in the credit ratings is the Cumulative Accuracy Profile (CAP), and the associated accuracy ratio measure. The idea is to measure the relationship between the credit ratings assigned and the number of defaults observed in the following year. One would expect that fewer defaults are observed for better rating classes. If the default rate were the same for all ratings, the rating system would be no different from a naive (and useless) classification system in which customers were randomly assigned a rating, independently of their creditworthiness.

It is not hard to see that the perfcurve function can also be used to construct the CAP. The standard we compare against is not a rating, as before, but the default flag that we loaded from the CreditRating_ExPost.dat file. The score we use is a "dummy score" that indicates the ranking in creditworthiness implicit in the list of ratings. The dummy score only needs to satisfy that better ratings get lower dummy scores (they are "less likely to have a default flag of 1 "), and that any two customers with the same rating get the same dummy score. A default probability could be passed as a score, of course, but we do not have default probabilities here, and in fact we do not need to have estimates of the default probabilities to construct the CAP, because we are not validating default probabilities. All we are assessing with this tool is how well the ratings rank customers according to their creditworthiness.

Usually, the CAP of the rating system under consideration is plotted together with the CAP of the "perfect rating system." The latter is a hypothetical credit rating system for which the lowest rating includes all the defaulters, and no other customers. The area under this perfect curve is the maximum possible AUC attainable by a rating system. By convention, the AUC is adjusted for CAPs to subtract the area under the naive system's CAP, that is, the CAP of the system that randomly assigns ratings to customers. The naive system's CAP is simply a straight line from the origin to $(1,1)$, with an AUC of 0.5.

The accuracy ratio for a rating system is then defined as the ratio of the adjusted AUC (AUC of the system in consideration minus AUC of the naive system) to the maximum accuracy (AUC of the perfect system minus AUC of the naive system).

```
ratingsList = {'AAA' 'AA' 'A' 'BBB' 'BB' 'B' 'CCC'};
Nratings = length(ratingsList);
dummyDelta = 1/(Nratings+1);
dummyRank = linspace(dummyDelta,1-dummyDelta,Nratings)';
D = exPostDS.Def_tplus1;
fracTotDef = sum(D)/length(D);
maxAcc = 0.5 - 0.5 * fracTotDef;
R = double(ordinal(exPostDS.Rating,[],ratingsList));
S = dummyRank(R);
[xVal,yVal,~,auc] = perfcurve(D,S,1);
accRatio = (auc-0.5)/maxAcc;
fprintf('Accuracy ratio for actual ratings: %5.3f\n',accRatio);
xPerfect(1) = 0; xPerfect(2) = fracTotDef; xPerfect(3) = 1;
yPerfect(1) = 0; yPerfect(2) = 1; yPerfect(3) = 1;
xNaive(1) = 0; xNaive(2) = 1;
yNaive(1) = 0; yNaive(2) = 1;
plot(xPerfect,yPerfect,'--k',xVal,yVal,'b',xNaive,yNaive,'-.k');
xlabel('Fraction of all companies');
ylabel('Fraction of defaulted companies');
title('Cumulative Accuracy Profile');
legend({'Perfect','Actual','Naive'},'Location','SouthEast');
text(xVal(2)+0.01,yVal(2)-0.01,'CCC')
text(xVal(3)+0.01,yVal(3)-0.02,'B')
text(xVal(4)+0.01,yVal(4)-0.03,'BB')
Accuracy ratio for actual ratings: 0.850
```

The key to reading the information of the CAP is in the "kinks," labeled in the plot for ratings 'CCC,' 'B,' and 'BB.' For example, the second kink is associated with the second lowest rating, 'B,' and it is located at ( $0.097,0.714$ ). This means that $9.7 \%$ of the customers were ranked 'B' or lower, and they account for $71.4 \%$ of the defaults observed.

In general, the accuracy ratio should be treated as a relative, rather than an absolute measure. For example, we can add the CAP of the predicted ratings in the same plot, and compute its accuracy ratio to compare it with the accuracy ratio of the actual ratings.

```
Rpred = double(ordinal(predDS.PredRating,[],ratingsList));
Spred = dummyRank(Rpred);
[xValPred,yValPred,~,aucPred] = perfcurve(D,Spred,1);
accRatioPred = (aucPred-0.5)/maxAcc;
```

```
fprintf('Accuracy ratio for predicted ratings: %5.3f\n',accRatioPred);
plot(xPerfect,yPerfect,'--k',xVal,yVal,'b',xNaive,yNaive,'-.k',...
    xValPred,yValPred,':r');
xlabel('Fraction of all companies');
ylabel('Fraction of defaulted companies');
title('Cumulative Accuracy Profile');
legend({'Perfect','Actual','Naive','Predicted'},'Location','SouthEast');
Accuracy ratio for predicted ratings: 0.812
```

The accuracy ratio of the predicted rating is smaller, and its CAP is mostly below the CAP of the actual rating. This is reasonable, since the actual ratings are assigned by
the credit committees that take into consideration the predicted ratings and extra information that can be important to fine-tune the ratings.

## Final Remarks

MATLAB offers a wide range of machine learning tools, besides bagged decision trees, that can be used in the context of credit rating. In Statistics and Machine Learning Toolbox you can find classification tools such as discriminant analysis and naive Bayes classifiers. MATLAB also offers Neural Networks Toolbox ${ }^{\text {TM }}$. Also, Database Toolbox and MATLAB's deployment tools may provide you with more flexibility to adapt the workflow presented here to your own preferences and needs.

No probabilities of default have been computed here. For credit ratings, the probabilities of default are usually computed based on credit-rating migration history. See the transprob reference page in Financial Toolbox ${ }^{\text {TM }}$ for more information.

## Estimation of Transition Probabilities

In this section...<br>"Introduction" on page 8-21<br>"Estimate Transition Probabilities" on page 8-21<br>"Estimate Transition Probabilities for Different Rating Scales" on page 8-24<br>"Estimate Point-in-Time and Through-the-Cycle Probabilities" on page 8-25<br>"Estimate $t$-Year Default Probabilities" on page 8-28<br>"Estimate Bootstrap Confidence Intervals" on page 8-29<br>"Group Credit Ratings" on page 8-30<br>"Work with Nonsquare Matrices" on page 8-32<br>"Remove Outliers" on page 8-34<br>"Estimate Probabilities for Different Segments" on page 8-35<br>"Work with Large Datasets" on page 8-36

## Introduction

Credit ratings rank borrowers according to their credit worthiness. Though this ranking is, in itself, useful, institutions are also interested in knowing how likely it is that borrowers in a particular rating category will be upgraded or downgraded to a different rating, and especially, how likely it is that they will default.

Transition probabilities offer one way to characterize the past changes in credit quality of obligors (typically firms), and are cardinal inputs to many risk management applications. Financial Toolbox software supports the estimation of transition probabilities using both cohort and duration (also known as hazard rate or intensity) approaches using transprob and related functions.

Note: The sample dataset used throughout this section is simulated using a single transition matrix. No attempt is made to match historical trends in transition rates.

## Estimate Transition Probabilities

The Data_TransProb.mat file contains sample credit ratings data.
load Data_TransProb
load Data_TransProb
data(1:10,:)
data(1:10,:)
ans =
ans =

| ID | Date | Rating |
| :---: | :---: | :---: |
| '00010283' | '10-Nov-1984' | ' CCC ' |
| '00010283' | '12-May-1986' | 'B' |
| '00010283' | '29-Jun-1988' | 'CCC' |
| '00010283' | '12-Dec-1991' | ' D' |

| '00014413' | '16-Jan-1998' | ' ${ }^{\prime}$ |

The sample data is formatted as a cell array with three columns. Each row contains an ID (column 1), a date (column 2), and a credit rating (column 3). The assigned credit rating corresponds to the associated ID on the associated date. All information corresponding to the same ID must be stored in contiguous rows. In this example, IDs, dates, and ratings are stored in string format, but you also can enter them in numeric format.

In this example, the simplest calling syntax for transprob passes the nRecords-by-3 cell array as the only input argument. The default startDate and endDate are the earliest and latest dates in the data. The default estimation algorithm is the duration method and 1 -year transition probabilities are estimated:

| transMat0 $=$ transprob(data) |  |  |  |  |  |  |  |
| ---: | :--- | ---: | ---: | ---: | ---: | ---: | ---: |
| transMat0 $=$ |  |  |  |  |  |  |  |
| 93.1170 | 5.8428 | 0.8232 | 0.1763 | 0.0376 | 0.0012 | 0.0001 | 0.0017 |
| 1.6166 | 93.1518 | 4.3632 | 0.6602 | 0.1626 | 0.0055 | 0.0004 | 0.0396 |
| 0.1237 | 2.9003 | 92.2197 | 4.0756 | 0.5365 | 0.0661 | 0.0028 | 0.0753 |
| 0.0236 | 0.2312 | 5.0059 | 90.1846 | 3.7979 | 0.4733 | 0.0642 | 0.2193 |
| 0.0216 | 0.1134 | 0.6357 | 5.7960 | 88.9866 | 3.4497 | 0.2919 | 0.7050 |
| 0.0010 | 0.0062 | 0.1081 | 0.8697 | 7.3366 | 86.7215 | 2.5169 | 2.4399 |
| 0.0002 | 0.0011 | 0.0120 | 0.2582 | 1.4294 | 4.2898 | 81.2927 | 12.7167 |
| 0 | 0 | 0 | 0 | 0 | 0 | 0 | 100.0000 |

It is recommended to provide explicit start and end dates. Otherwise the estimation window for two different datasets can differ, and the estimates might not be comparable. From this point, assume that the time window of interest is the 5 -year period from the end of 1995 to the end of 2000 . For comparisons, compute the estimates for this
time window. First use the duration algorithm (default option), and then the cohort algorithm explicitly set.

By default, the cohort algorithm internally gets yearly snapshots of the credit ratings, but the number of snapshots per year is definable using the parameter/value pair snapsPerYear. To get the estimates using quarterly snapshots:

Both duration and cohort compute 1-year transition probabilities by default, but the time interval for the transitions is definable using the parameter/value pair transInterval. For example, to get the 2 -year transition probabilities using the cohort algorithm with the same snapshot periodicity and estimation window:

```
transMat4 = transprob(data,'startDate',startDate,'endDate',endDate,...
'algorithm','cohort','snapsPerYear',4,'transInterval',2)
transMat4 =
```

## Estimate Transition Probabilities for Different Rating Scales

The dataset data from Data_TransProb.mat contains sample credit ratings using the default rating scale \{'AAA', 'AA','A', 'BBB', 'BB', 'B', 'CCC', 'D'\}. It also contains the dataset dataIGSG with ratings investment grade ('IG'), speculative grade ('SG'), and default ('D'). To estimate the transition matrix for this dataset, use the labels argument.

```
load Data_TransProb
startDate = '31-Dec-1995';
endDate = '31-Dec-2000';
dataIGSG(1:10,:)
transMatIGSG = transprob(dataIGSG,'labels',{'IG','SG','D'},...
'startDate',startDate,'endDate',endDate)
ans =
\begin{tabular}{|c|c|c|}
\hline 00011253 \({ }^{\prime}\) & '04-Apr-1983' & 'IG' \\
\hline 00012751' & '17-Feb-1985' & 'SG' \\
\hline 00012751' & '19-May-1986' & 'D' \\
\hline 00014690' & '17-Jan-1983' & 'IG' \\
\hline '00012144' & '21-Nov-1984' & 'IG' \\
\hline '00012144' & '25-Mar-1992' & 'SG' \\
\hline '00012144' & '07-May-1994' & 'IG' \\
\hline '00012144' & '23-Jan-2000' & 'SG' \\
\hline '00012144' & '20-Aug-2001' & 'IG' \\
\hline 00012937 \({ }^{\prime}\) & '07-Feb-1984' & IG' \\
\hline
\end{tabular}
```

transMatIGSG =

| 98.1986 | 1.5179 | 0.2835 |
| ---: | ---: | ---: |
| 8.5396 | 89.4891 | 1.9713 |
| 0 | 0 | 100.0000 |

There is another dataset, dataIGSGnum, with the same information as dataIGSG, except the ratings are mapped to a numeric scale where 'IG'=1, 'SG'=2, and 'D'=3.

To estimate the transition matrix, use the labels optional argument specifying the numeric scale as a cell array.

```
dataIGSGnum(1:10,:)
% Note {1,2,3} and num2cell(1:3) are equivalent; num2cell is convenient
% when the number of ratings is larger
transMatIGSGnum = transprob(dataIGSGnum,'labels',{1,2,3},...
'startDate',startDate,'endDate',endDate)
ans =
    '00011253' '04-Apr-1983' [1]
    '00012751' '17-Feb-1985' [2]
    '00012751' '19-May-1986' [ 3]
    '00014690' '17-Jan-1983' [1]
    '00012144' '21-Nov-1984' [1]
    '00012144' '25-Mar-1992' [2]
    '00012144' '07-May-1994' [1]
    '00012144' '23-Jan-2000' [2]
    '00012144' '20-Aug-2001' [1]
    '00012937' '07-Feb-1984' [1]
transMatIGSGnum =
\begin{tabular}{rrr}
98.1986 & 1.5179 & 0.2835 \\
8.5396 & 89.4891 & 1.9713 \\
0 & 0 & 100.0000
\end{tabular}
```

Any time the input dataset contains ratings not included in the default rating scale \{'AAA', 'AA', 'A', 'BBB', 'BB', 'B', 'CCC', 'D'\}, the full rating scale must be specified using the labels optional argument. For example, if the dataset contains ratings 'AAA', ..., 'CCC, 'D', and 'NR' (not rated), use labels with this cell array \{'AAA', 'AA', 'A','BBB','BB','B','CCC','D','NR'\}.

## Estimate Point-in-Time and Through-the-Cycle Probabilities

Transition probability estimates are sensitive to the length of the estimation window. When the estimation window is small, the estimates only capture recent credit events, and these can change significantly from one year to the next. These are called point-intime (PIT) estimates. In contrast, a large time window yields fairly stable estimates that average transition rates over a longer period of time. These are called through-the-cycle (TTC) estimates.

The estimation of PIT probabilities requires repeated calls to transprob with a rolling estimation window. Use transprobprep every time repeated calls to transprob are required. transprobprep performs a preprocessing step on the raw dataset that is independent of the estimation window. The benefits of transprobprep are greater as the number of repeated calls to transprob increases. Also, the performance gains from transprobprep are more significant for the cohort algorithm.

```
load Data_TransProb
prepData = transprobprep(data);
Years = 1991:2000;
nYears = length(Years);
nRatings = length(prepData.ratingsLabels);
transMatPIT = zeros(nRatings,nRatings,nYears);
algorithm = 'duration';
sampleTotals(nYears,1) = struct('totalsVec',[],'totalsMat',[],...
'algorithm',algorithm);
for t = 1:nYears
    startDate = ['31-Dec-' num2str(Years(t)-1)];
    endDate = ['31-Dec-' num2str(Years(t))];
    [transMatPIT(:,:,t),sampleTotals(t)] = transprob(prepData,...
        'startDate',startDate,'endDate',endDate,' algorithm',algorithm);
end
```

Here is the PIT transition matrix for 1993. Recall that the sample dataset contains simulated credit migrations so the PIT estimates in this example do not match actual historical transition rates.

A structure array stores the sampleTotals optional output from transprob. The sampleTotals structure contains summary information on the total time spent on each rating, and the number of transitions out of each rating, for each year under consideration. For more information on the sampleTotals structure, see "Algorithms" on page 18-1397.

As an example, the sampleTotals structure for 1993 is used here. The total time spent on each rating is stored in the totalsVec field of the structure. The total transitions out of each rating are stored in the totalsMat field. A third field, algorithm, indicates the algorithm used to generate the structure.
sampleTotals(Years==1993).totalsVec sampleTotals(Years==1993).totalsMat
sampleTotals(Years==1993).algorithm

ans =

| 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

ans =
duration
To get the TTC transition matrix, pass the sampleTotals structure array to transprobbytotals. Internally, transprobbytotals aggregates the information in the sampleTotals structures to get the total time spent on each rating over the 10 years considered in this example, and the total number of transitions out of each rating during the same period. transprobbytotals uses the aggregated information to get the TTC matrix, or average 1-year transition matrix.

The same TTC matrix could be obtained with a direct call to transprob, setting the estimation window to the 10 years under consideration. But it is much more efficient to use the sampleTotals structures, whenever they are available. (Note, for the duration algorithm, these alternative workflows can result in small numerical differences in the estimates whenever leap years are part of the sample.)

In "Estimate Transition Probabilities" on page 8-21, a 1-year transition matrix is estimated using the 5 -year time window from 1996 through 2000. This is another example of a TTC matrix and this can also be computed using the sampleTotals structure array.

## Estimate $\dagger$ Year Default Probabilities

By varying the start and end dates, the amount of data considered for the estimation is changed, but the output still contains, by default, 1-year transition probabilities. You can change the default behavior by specifying the transInterval argument, as illustrated in "Estimate Transition Probabilities" on page 8-21.

However, when $t$-year transition probabilities are required for a whole range of values of $t$, for example, 1 -year, 2 -year, 3 -year, 4 -year, and 5 -year transition probabilities, it is more efficient to call transprob once to get the optional output sampleTotals. You can use the same sampleTotals structure can be used to get the $t$-year transition matrix for any transition interval $t$. Given a sampleTotals structure and a transition interval, you can get the corresponding transition matrix by using transprobbytotals.

```
load Data_TransProb
startDate = '31-Dec-1995';
endDate = '31-Dec-2000';
[~,sampleTotals] = transprob(data,'startDate', ...
startDate, 'endDate',endDate);
DefProb = zeros(7,5);
for t = 1:5
    transMatTemp = transprobbytotals(sampleTotals,'transInterval',t);
    DefProb(:,t) = transMatTemp(1:7,8);
end
DefProb
DefProb =

```

## Estimate Bootstrap Confidence Intervals

transprob also returns the idTotals structure array which contains, for each ID, or company, the total time spent on each rating, and the total transitions out of each rating. For more information on the idTotals structure, see "Algorithms" on page 18-1397. The idTotals structure is similar to the sampleTotals structures (see "Estimate Point-in-Time and Through-the-Cycle Probabilities" on page 8-25), but idTotals has the information at an ID level. Because most companies only migrate between very few ratings, the numeric arrays in idTotals are stored as sparse arrays to reduce memory requirements.

You can use the idTotals structure array to estimate confidence intervals for the transition probabilities using a bootstrapping procedure, as the following example demonstrates. To do this, call transprob and keep the third output argument, idTotals. The idTotals fields are displayed for the last company in the sample. Within the estimation window, this company spends almost a year as 'AA' and it is then upgraded to 'AAA'.

```
load Data_TransProb
startDate = '31-Dec-1995';
endDate = '31-Dec-2000';
[transMat,~,idTotals] = transprob(data,...
    'startDate',startDate,'endDate',endDate);
% Total time spent on each rating
full(idTotals(end).totalsVec)
% Total transitions out of each rating
full(idTotals(end).totalsMat)
% Algorithm
idTotals(end).algorithm
ans =
ans =
\begin{tabular}{llllllll}
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0
\end{tabular}
```

| 4.0820 | 0.9180 | 0 | 0 | 0 | 0 | 0 | 0 |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |

Next, use bootstrp from Statistics and Machine Learning Toolbox with transprobbytotals as the bootstrap function and idTotals as the data to sample from. Each bootstrap sample corresponds to a dataset made of companies sampled with replacement from the original data. However, you do not have to draw companies from the original data, because a bootstrap idTotals sample contains all the information required to compute the transition probabilities. transprobbytotals aggregates all structures in each bootstrap idTotals sample and finds the corresponding transition matrix.

To estimate $95 \%$ confidence intervals for the transition matrix and display the probabilities of default together with its upper and lower confidence bounds:

```
PD = transMat(1:7,8);
bootstat = bootstrp(100,@(totals)transprobbytotals(totals),idTotals);
ci = prctile(bootstat,[2.5 97.5]); % 95% confidence
CIlower = reshape(ci(1,:),8,8);
CIupper = reshape(ci(2,:),8,8);
PD_LB = CIlower(1:7,8);
PD_UB = CIupper(1:7,8);
[PD_LB PD PD_UB]
ans =
\begin{tabular}{lll}
0.0004 & 0.0043 & 0.0106 \\
0.0028 & 0.0754 & 0.2192 \\
0.0126 & 0.0832 & 0.2180 \\
0.1659 & 0.3992 & 0.6617 \\
0.5703 & 1.0980 & 1.7260 \\
1.7264 & 3.0860 & 4.7602 \\
1.7678 & 5.3484 & 9.5055
\end{tabular}
```

## Group Credit Ratings

Credit rating scales can be more or less granular. For example, there are ratings with qualifiers (such as, 'AA+', 'BB-', etc.), whole ratings ('AA', 'BB', etc.), and investment or speculative grade (' IG ', 'SG') categories. Given a dataset with credit ratings at a more granular level, transition probabilities for less granular categories can be of interest. For example, you might be interested in a transition matrix for investment and speculative grades given a dataset with whole ratings. Use transprobgrouptotals for
this evaluation, as illustrated in the following examples. The sample dataset data has whole credit ratings:

```
load Data_TransProb
startDate = '31-Dec-1995';
endDate = '31-Dec-2000';
data(1:5,:)
ans =
    '00010283' '10-Nov-1984' 'CCC'
    '00010283' '12-May-1986' 'B'
    '00010283' '29-Jun-1988' 'CCC'
    '00010283' '12-Dec-1991' 'D'
    '00013326' '09-Feb-1985' 'A'
```

A call to transprob returns the transition matrix and totals structures for the eight ('AAA' to 'D') whole credit ratings. The array with number of transitions out of each credit rating is displayed after the call to transprob:
[transMat, sampleTotals,idTotals] = transprob(data,'startDate',startDate,...
'endDate', endDate);
sampleTotals.totalsMat
ans =

| 0 | 67 | 7 | 3 | 0 | 0 | 0 | 0 |
| ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| 67 | 0 | 68 | 15 | 3 | 0 | 0 | 1 |
| 4 | 101 | 0 | 93 | 11 | 1 | 0 | 1 |
| 1 | 7 | 163 | 0 | 62 | 10 | 2 | 5 |
| 1 | 3 | 16 | 168 | 0 | 37 | 0 | 11 |
| 0 | 0 | 2 | 10 | 83 | 0 | 10 | 14 |
| 0 | 0 | 0 | 2 | 8 | 16 | 0 | 7 |
| 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

Next, use transprobgrouptotals to group whole ratings into investment and speculative grades. This function takes a totals structure as the first argument. The second argument indicates the edges between rating categories. In this case, ratings 1 through 4 ('AAA' through 'BBB') correspond to the first category ('IG'), ratings 5 through 7 ('BB' through 'CCC') to the second category ('SG'), and rating 8 (' $\mathrm{D}^{\prime}$ ) is a category of its own. transprobgrouptotals adds up the total time spent on ratings that belong to the same category. For example, total times spent on 'AAA' through 'BBB' are added up as the total time spent on 'IG'. transprobgrouptotals also adds up the total number of transitions between any ' IG' rating and any 'SG ' rating, for example, a credit migration from 'BBB' to ' BB '.

The grouped totals can then be passed to transprobbytotals to obtain the transition matrix for investment and speculative grades. Both totalsMat and the new transition matrix are both 3-by-3, corresponding to the grouped categories 'IG', 'SG', and 'D'.

```
sampleTotalsIGSG = transprobgrouptotals(sampleTotals,[\begin{array}{lll}{7}&{7}\end{array}])
transMatIGSG = transprobbytotals(sampleTotalsIGSG)
sampleTotalsIGSG =
    totalsVec: [4.8591e+003 1.5034e+003 1.1621e+003]
totalsMat: [3x3 double]
algorithm: 'duration'
transMatIGSG =
\begin{tabular}{rrr}
98.1591 & 1.6798 & 0.1611 \\
12.3228 & 85.6961 & 1.9811 \\
0 & 0 & 100.0000
\end{tabular}
```

When a totals structure array is passed to transprobgrouptotals, this function groups each structure in the array individually and preserves sparsity, if the fields in the input structures are sparse. One way to exploit this feature is to compute confidence intervals for the investment grade default rate and the speculative grade default rate (see also "Estimate Bootstrap Confidence Intervals" on page 8-29).

```
PDIGSG = transMatIGSG(1:2,3);
idTotalsIGSG = transprobgrouptotals(idTotals,[4 7 8]);
bootstat = bootstrp(100,@(totals)transprobbytotals(totals),idTotalsIGSG);
ci = prctile(bootstat,[2.5 97.5]); % 95% confidence
CIlower = reshape(ci(1,:),3,3);
CIupper = reshape(ci(2,:),3,3);
PDIGSG_LB = CIlower(1:2,3);
PDIGSG_UB = CIupper(1:2,3);
[PDIGSG_LB PDIGSG PDIGSG_UB]
ans =
\(0.0603 \quad 0.1611 \quad 0.2538\)
    1.3470 1.9811 2.6195
```

## Work with Nonsquare Matrices

Transition probabilities and the number of transitions between ratings are usually reported without the 'D' ('Default') row. For example, a credit report can contain the
following table, indicating the number of issuers starting in each rating (first column), and the number of transitions between ratings (remaining columns):

| Initial |  | AAA | AA | A | BBB | BB | B | CCC | D |
| ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| AAA | 98 | 88 | 9 | 1 | 0 | 0 | 0 | 0 | 0 |
| AA | 389 | 0 | 368 | 19 | 2 | 0 | 0 | 0 | 0 |
| A | 1165 | 1 | 21 | 1087 | 56 | 0 | 0 | 0 | 0 |
| BBB | 1435 | 0 | 2 | 89 | 1289 | 45 | 8 | 0 | 2 |
| BB | 915 | 0 | 0 | 1 | 60 | 776 | 73 | 2 | 3 |
| B | 867 | 0 | 0 | 1 | 7 | 88 | 715 | 39 | 17 |
| CCC | 112 | 0 | 0 | 0 | 1 | 3 | 34 | 61 | 13 |

You can store the information in this table in a totals structure compatible with the cohort algorithm. For more information on the cohort algorithm and the totals structure, see "Algorithms" on page 18-1397. The totalsMat field is a nonsquare array in this case.

```
% Define totals structure
totals.totalsVec = [98 389 1165 1435 915 867 112];
totals.totalsMat = [
\begin{tabular}{rrrrrrrr}
88 & 9 & 1 & 0 & 0 & 0 & 0 & \(0 ;\) \\
0 & 368 & 19 & 2 & 0 & 0 & 0 & \(0 ;\) \\
1 & 21 & 1087 & 56 & 0 & 0 & 0 & \(0 ;\) \\
0 & 2 & 89 & 1289 & 45 & 8 & 0 & \(2 ;\) \\
0 & 0 & 1 & 60 & 776 & 73 & 2 & \(3 ;\) \\
0 & 0 & 1 & 7 & 88 & 715 & 39 & \(17 ;\) \\
0 & 0 & 0 & 1 & 3 & 34 & 61 & \(13] ;\) \\
totals.algorithm \(=\) & cohort' \(;\)
\end{tabular}
```

transprobbytotals and transprobgrouptotals accept totals inputs with nonsquare totalsMat fields. To get the transition matrix corresponding to the previous table, and to group ratings into investment and speculative grade with the corresponding matrix:

```
transMat = transprobbytotals(totals)
% Group into IG/SG and get IG/SG transition matrix
totalsIGSG = transprobgrouptotals(totals,[4 7]);
transMatIGSG = transprobbytotals(totalsIGSG)
transMat =
\begin{tabular}{rrrrrrrr}
89.7959 & 9.1837 & 1.0204 & 0 & 0 & 0 & 0 & 0 \\
0 & 94.6015 & 4.8843 & 0.5141 & 0 & 0 & 0 & 0 \\
0.0858 & 1.8026 & 93.3047 & 4.8069 & 0 & 0 & 0 & 0 \\
0 & 0.1394 & 6.2021 & 89.8258 & 3.1359 & 0.5575 & 0 & 0.1394 \\
0 & 0 & 0.1093 & 6.5574 & 84.8087 & 7.9781 & 0.2186 & 0.3279 \\
0 & 0 & 0.1153 & 0.8074 & 10.1499 & 82.4683 & 4.4983 & 1.9608 \\
0 & 0 & 0 & 0.8929 & 2.6786 & 30.3571 & 54.4643 & 11.6071
\end{tabular}
```

```
transMatIGSG =
\begin{tabular}{rrr}
98.2183 & 1.7169 & 0.0648
\end{tabular}
```

## Remove Outliers

The idTotals output from transprob can also be exploited to update the transition probability estimates after removing some outlier information. For more information on idTotals, see "Algorithms" on page 18-1397. For example, if you know that the credit rating migration information for the 4th and 27th companies in the data have problems, you can remove those companies and efficiently update the transition probabilities as follows:

```
load Data_TransProb
startDate = '31-Dec-1995';
endDate = '31-Dec-2000';
[transMat,~,idTotals] = transprob(data,'startDate', ...
startDate, 'endDate',endDate);
transMat
transMat =
\begin{tabular}{rrrrrrrr}
90.6236 & 7.9051 & 1.0314 & 0.4123 & 0.0210 & 0.0020 & 0.0003 & 0.0043 \\
4.4780 & 89.5558 & 4.5298 & 1.1225 & 0.2284 & 0.0094 & 0.0009 & 0.0754 \\
0.3983 & 6.1164 & 87.0641 & 5.4801 & 0.7637 & 0.0892 & 0.0050 & 0.0832 \\
0.1029 & 0.8572 & 10.7918 & 83.0204 & 3.9971 & 0.7001 & 0.1313 & 0.3992 \\
0.1043 & 0.3745 & 2.2962 & 14.0954 & 78.9840 & 3.0013 & 0.0463 & 1.0980 \\
0.0113 & 0.0544 & 0.7055 & 3.2925 & 15.4350 & 75.5988 & 1.8166 & 3.0860 \\
0.0044 & 0.0189 & 0.1903 & 1.9743 & 6.2320 & 10.2334 & 75.9983 & 5.3484 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 100.0000
\end{tabular}
nIDs = length(idTotals);
keepInd = setdiff(1:nIDs,[4 27]);
transMatNoOutlier \(=\) transprobbytotals(idTotals(keepInd))
transMatNoOutlier \(=\)
\begin{tabular}{rrrrrrrr}
90.6241 & 7.9067 & 1.0290 & 0.4124 & 0.0211 & 0.0020 & 0.0003 & 0.0043 \\
4.4917 & 89.5918 & 4.4779 & 1.1240 & 0.2288 & 0.0094 & 0.0009 & 0.0756 \\
0.3990 & 6.1220 & 87.0530 & 5.4841 & 0.7643 & 0.0893 & 0.0050 & 0.0833 \\
0.1030 & 0.8576 & 10.7909 & 83.0207 & 3.9971 & 0.7001 & 0.1313 & 0.3992 \\
0.1043 & 0.3746 & 2.2960 & 14.0955 & 78.9840 & 3.0013 & 0.0463 & 1.0980 \\
0.0113 & 0.0544 & 0.7054 & 3.2925 & 15.4350 & 75.5988 & 1.8166 & 3.0860 \\
0.0044 & 0.0189 & 0.1903 & 1.9743 & 6.2320 & 10.2334 & 75.9983 & 5.3484 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 100.0000
\end{tabular}
```

Deciding which companies to remove is a case-by-case situation. Reasons to remove a company can include a typo in one of the ratings histories, or an unusual migration between ratings whose impact on the transition probability estimates must be measured. transprob does not reorder the companies in any way. The ordering of companies in the input data is the same as the ordering in the idTotals array.

## Estimate Probabilities for Different Segments

You can use idTotals efficiently to get estimates over different segments of the sample. For more information on idTotals, see "Algorithms" on page 18-1397. For example, assume that the companies in the example are grouped into three geographic regions and that the companies were grouped by geographic regions previously, so that the first 340 companies correspond to the first region, the next 572 companies to the second region, and the rest to the third region. You can efficiently get transition probabilities for each region as follows:

```
load Data_TransProb
startDate = '31-Dec-1995';
endDate = '31-Dec-2000';
[~,~,idTotals] = transprob(data,'startDate', ...
startDate, 'endDate',endDate);
n1 = 340;
n2 = 572;
transMatG1 = transprobbytotals(idTotals(1:n1))
transMatG2 = transprobbytotals(idTotals(n1+1:n1+n2))
transMatG3 = transprobbytotals(idTotals(n1+n2+1:end))
transMatG1 =
```

| 90.8299 | 7.6501 | 0.3178 | 1.1700 | 0.0255 | 0.0044 | 0.0021 | 0.0002 |

## Work with Large Datasets

This example shows how to aggregate estimates from two (or more) datasets. It is possible that two datasets, coming from two different databases, must be considered for the estimation of the transition probabilities. Also, if a dataset is too large and cannot be loaded into memory, the dataset can be split into two (or more) datasets. In these cases, it is simple to apply transprob to each individual dataset, and then get the final estimates corresponding to the aggregated data with a call to transprobbytotals at the end.

For example, the dataset data is artificially split into two sections in this example. In practice the two datasets would come from different files or databases. When aggregating multiple datasets, the history of a company cannot be split across datasets. You can verify that this condition is satisfied for the arbitrarily chosen cut-off point.

```
load Data_TransProb
```

cutoff = 2099;
data(cutoff-5:cutoff,:)
data(cutoff+1:cutoff+6,:)
ans =

| '00011166' | '24-Aug-1995' | 'BBB' |
| :--- | :--- | :--- |
| '00011166' | '25-Jan-1997' | 'A' |
| '00011166' | '01-Feb-1998' | 'AA' |
| '00014878' | '15-Mar-1983' | 'B' |
| '00014878' | '21-Sep-1986' | 'BB' |
| $00014878 '$ | '17-Jan-1998' | 'BBB' |

| ans $=$ |  |  |
| :--- | :--- | :--- |
| '00012043' | '09-Feb-1985' | 'BBB' |
| '00012043' | '03-Jan-1988' | 'A' |
| '00012043' | '15-Jan-1994' | 'AAA' |
| '00011157' | '24-Jun-1984' | 'A' |
| '00011157' | '09-Dec-1999' | 'BBB' |
| '00011157' | '28-Mar-2001' | 'A' |

When working with multiple datasets, it is important to set the start and end dates explicitly. Otherwise, the estimation window differs for each dataset because the default
start and end dates used by transprob are the earliest and latest dates found in the input data.

```
startDate = '31-Dec-1995';
endDate = '31-Dec-2000';
```

In practice, this is the point where you can read in the first dataset. Now, the dataset is already obtained. Call transprob with the first dataset and the explicit start and end dates. Keep only the sampleTotals output. For details on sampleTotals, see"Algorithms" on page 18-1397.

```
[~,sampleTotals(1)] = transprob(data(1:cutoff,:),...
    'startDate',startDate,'endDate',endDate);
```

Repeat for the remaining datasets. Note the different sampleTotals structures are stored in a structured array.

```
[~,sampleTotals(2)] = transprob(data(cutoff+1:end,:),...
    'startDate',startDate,'endDate',endDate);
```

To get the transition matrix corresponding to the aggregated dataset, use transprobbytotals. When the totals input is a structure array, transprobbytotals aggregates the information over all structures, and returns a single transition matrix.

```
transMatAggr = transprobbytotals(sampleTotals)
transMatAggr =
```

| 90.6236 | 7.9051 | 1.0314 | 0.4123 | 0.0210 | 0.0020 | 0.0003 | 0.0043 |
| ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| 4.4780 | 89.5558 | 4.5298 | 1.1225 | 0.2284 | 0.0094 | 0.0009 | 0.0754 |
| 0.3983 | 6.1164 | 87.0641 | 5.4801 | 0.7637 | 0.0892 | 0.0050 | 0.0832 |
| 0.1029 | 0.8572 | 10.7918 | 83.0204 | 3.9971 | 0.7001 | 0.1313 | 0.3992 |
| 0.1043 | 0.3745 | 2.2962 | 14.0954 | 78.9840 | 3.0013 | 0.0463 | 1.0980 |
| 0.0113 | 0.0544 | 0.7055 | 3.2925 | 15.4350 | 75.5988 | 1.8166 | 3.0860 |

## Forecasting Corporate Default Rates

This example shows how to build a forecasting model for corporate default rates.
Risk parameters are dynamic in nature, and understanding how these parameters change in time is a fundamental task for risk management.

In the first part, we work with historical credit migrations data to construct some time series of interest, and to visualize default rates dynamics. In the second part, we use some of the series constructed in the first part, and some additional data, to fit a forecasting model for corporate default rates, and to show some backtesting and stress testing concepts. A linear regression model for corporate default rates is studied there, but the tools and concepts described can be used in combination with other forecasting methodologies. The appendix at the end touches on the handling of models for full transition matrices.

People interested in forecasting, backtesting and stress testing may go directly to the second part. The first part is more relevant for people who work with credit migration data.

## Part I: Working with Credit Migrations Data

We work with historical transition probabilities for corporate issuers (variable TransMat). This is yearly data for the period 1981-2005, from [10]. The data includes, for each year, the number of issuers per rating at the beginning of the year (variable nIssuers), and the number of new issuers per rating per year (variable nNewIssuers). There is also a corporate profits forecast, from [9], and a corporate spread, from [4] (variables CPF and SPR). A variable indicating recession years (Recession), consistent with recession dates from [7], is used mainly for visualizations.

Example_LoadData

## Getting Default Rates for Different Ratings Categories

We start by performing some aggregations to get corporate default rates for Investment Grade (IG) and Speculative Grade (SG) issuers, and the overall corporate default rate.

Aggregation and segmentation are relative terms. IG is an aggregate with respect to credit ratings, but a segment from the perspective of the overall corporate portfolio. Other segments are of interest in practice, for example, economic sectors, industries, or geographic regions. The data we use, however, is aggregated by credit ratings, so further
segmentation is not possible. Nonetheless, the tools and workflow discussed here may be useful to work with other segment-specific models.

We use existing functionality in Financial Toolbox ${ }^{\text {TM }}$, specifically, functions transprobgrouptotals and transprobbytotals, to perform the aggregation. These functions take as inputs structures with credit migration information in a particular format. We set up the inputs here, and visualize them below to understand their information and format.

```
% Pre-allocate the struct array
totalsByRtg(nYears,1) = struct('totalsVec',[],'totalsMat',[],...
    'algorithm','cohort');
for t = 1:nYears
    % Number of issuers per rating at the beginning of the year
    totalsByRtg(t).totalsVec = nIssuers(t,:);
    % Number of transitions between ratings during the year
    totalsByRtg(t).totalsMat = round(diag(nIssuers(t,:))*...
            (0.01*TransMat(:,:,t)));
        % Algorithm
    totalsByRtg(t).algorithm = 'cohort';
end
```

It is useful to see both the original data and the data stored in these totals structures side to side. The original data contains number of issuers and transition probabilities for each year. For example, for 2005

```
fprintf('\nTransition matrix for 2005:\n\n')
Example_DisplayTransitions(squeeze(TransMat(:,:,end)),nIssuers(end,:),...
    {'AAA', 'AA','A','BBB','BB','B','CCC'},...
    {'AAA','AA','A','BBB','BB','B', 'CCC', 'D', 'NR'})
Transition matrix for 2005:
```

|  | Init | AAA | AA | A | BBB | BB | B | CCC | D | NR |
| ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| AAA | 98 | 88.78 | 9.18 | 1.02 | 0 | 0 | 0 | 0 | 0 | 1.02 |
| AA | 407 | 0 | 90.66 | 4.91 | 0.49 | 0 | 0 | 0 | 0 | 3.93 |
| A | 1224 | 0.08 | 1.63 | 88.89 | 4.41 | 0 | 0 | 0 | 0 | 4.98 |
| BBB | 1535 | 0 | 0.2 | 5.93 | 84.04 | 3.06 | 0.46 | 0 | 0.07 | 6.25 |
| BB | 1015 | 0 | 0 | 0 | 5.71 | 76.75 | 6.9 | 0.2 | 0.2 | 10.25 |
| B | 1010 | 0 | 0 | 0.1 | 0.59 | 8.51 | 70.59 | 3.76 | 1.58 | 14.85 |
| CCC | 126 | 0 | 0 | 0 | 0.79 | 0.79 | 25.4 | 46.83 | 8.73 | 17.46 |

The totals structure stores the total number of issuers per rating at the beginning of the year in the totalsVec field, and the total number of migrations between ratings
(instead of transition probabilities) in the totalsMat field. Here is the information for 2005

```
fprintf('\nTransition counts (totals struct) for 2005:\n\n')
Example_DisplayTransitions(totalsByRtg(end).totalsMat,...
    totalsByRtg(end).totalsVec,...
    {'AAA','AA','A','BBB','BB','B','CCC'},...
    {'AAA','AA','A','BBB','BB','B','CCC','D','NR'})
Transition counts (totals struct) for 2005:
```

|  | Init | AAA | AA | A | BBB | BB | B | CCC | D | NR |
| ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| AAA | 98 | 87 | 9 | 1 | 0 | 0 | 0 | 0 | 0 | 1 |
| AA | 407 | 0 | 369 | 20 | 2 | 0 | 0 | 0 | 0 | 16 |
| A | 1224 | 1 | 20 | 1088 | 54 | 0 | 0 | 0 | 0 | 61 |
| BBB | 1535 | 0 | 3 | 91 | 1290 | 47 | 7 | 0 | 1 | 96 |
| BB | 1015 | 0 | 0 | 0 | 58 | 779 | 70 | 2 | 2 | 104 |
| B | 1010 | 0 | 0 | 1 | 6 | 86 | 713 | 38 | 16 | 150 |
| CCC | 126 | 0 | 0 | 0 | 1 | 1 | 32 | 59 | 11 | 22 |

The third field in the totals structure, algorithm, indicates that we are working with the 'cohort' method ('duration' is also supported, although the information in totalsVec and totalsMat would be different). These structures are usually obtained as optional outputs from transprob, but this example shows how a user can define these structures directly.

We now group ratings 'AAA' to 'BBB' (ratings 1 to 4 ) into the IG category and ratings 'BB' to 'CCC' (ratings 5 to 7) into the SG category. We use transprobgrouptotals for this. The 'edges' argument tells the function which ratings are to be grouped together ( 1 to 4 , and 5 to 7 ). We also group all non-default ratings into one category. These are preliminary steps to get the IG, SG and overall default rates for each year.

```
edgesIGSG = [4 7];
totalsIGSG = transprobgrouptotals(totalsByRtg,edgesIGSG);
edgesAll = 7; % could also use edgesAll = 2 with totalsIGSG
totalsAll = transprobgrouptotals(totalsByRtg,edgesAll);
```

Here are the 2005 totals grouped at IG/SG level, and the corresponding transition matrix, recovered using transprobbytotals.

```
fprintf('\nTransition counts for 2005 at IG/SG level:\n\n')
Example_DisplayTransitions(totalsIGSG(end).totalsMat,...
```

```
    totalsIGSG(end).totalsVec,...
    {'IG','SG'},...
    {'IG','SG','D','NR'})
fprintf('\nTransition matrix for 2005 at IG/SG level:\n\n')
Example_DisplayTransitions(transprobbytotals(totalsIGSG(end)),[],...
    {'IG','SG'},...
    {'IG','SG','D','NR'})
Transition counts for 2005 at IG/SG level:
\begin{tabular}{llrrrr} 
& Init & IG & SG & D & NR \\
IG & 3264 & 3035 & 54 & 1 & 174 \\
SG & 2151 & 66 & 1780 & 29 & 276
\end{tabular}
Transition matrix for 2005 at IG/SG level:
\begin{tabular}{lrrrr} 
& IG & SG & D & NR \\
IG & 92.98 & 1.65 & 0.03 & 5.33 \\
SG & 3.07 & 82.75 & 1.35 & 12.83
\end{tabular}
```

We now get transition matrices for every year both at IG/SG and non-default/default levels and store the default rates only (we do not use the rest of the transition probabilities).

```
DefRateIG = zeros(nYears,1);
DefRateSG = zeros(nYears,1);
DefRate = zeros(nYears,1);
for t=1:nYears
    % Get transition matrix at IG/SG level and extract IG default rate and
    % SG default rate for year t
    tmIGSG = transprobbytotals(totalsIGSG(t));
    DefRateIG(t) = tmIGSG(1,3);
    DefRateSG(t) = tmIGSG(2,3);
    % Get transition matrix at most aggregate level and extract overall
    % corporate default rate for year t
    tmAll = transprobbytotals(totalsAll(t));
    DefRate(t) = tmAll(1,2);
end
```

Here is a visualization of the dynamics of IG, SG and overall corporate default rates together. To emphasize their patterns, rather than their magnitudes, a log scale is used. The shaded bands indicate recession years. The patterns of SG and IG are slightly
different. For example, the IG rate is higher in 1994 than in 1995, but the opposite is true for SG. More noticeably, the IG default rate peaked after the 2001 recession, in 2002, whereas the peak for SG is in 2001. This suggests that models for the dynamics of the IG and SG default rates could have important differences, a common situation when working with different segments. The overall corporate default rate is by construction a combination of the other two, and its pattern is closer to SG, most likely due to the relative magnitude of $S G$ versus IG.

```
minIG = min(DefRateIG(DefRateIG~=0));
figure
plot(Years,log(DefRateSG),'m-*')
hold on
plot(Years,log(DefRate),'b-o')
plot(Years,log(max(DefRateIG,minIG-0.001)),'r-+')
Example_RecessionBands
hold off
grid on
title('{\bf Default Rates (log scale)}')
ylabel('log %')
legend({'SG','Overall','IG'},'location','NW')
```

## Getting Default Rates for Different Time Periods

The default rates just obtained are examples of point-in-time (PIT) rates, only the most recent information is used to estimate them. On the other extreme, we can use all the migrations observed in the 25 years spanned by the dataset to estimate long-term, or through-the-cycle (TTC) default rates. Other rates of interest are the average default rates over recession or expansion years.

All of these are easy to estimate with the data we have and the same tools. For example, to estimate the average transition probabilities over recession years, pass to transprobbytotals the totals structures corresponding to the recession years only. We use logical indexing below, taking advantage of the Recession
variable. transprobbytotals aggregates the information over time and returns the corresponding transition matrix.

```
tmAllRec = transprobbytotals(totalsAll(Recession));
DefRateRec = tmAllRec(1,2);
tmAllExp = transprobbytotals(totalsAll(~Recession));
DefRateExp = tmAllExp(1,2);
tmAllTTC = transprobbytotals(totalsAll);
DefRateTTC = tmAllTTC(1,2);
```

The following figure shows the estimated PIT rates, TTC rates and recession and expansion rates.

```
DefRateTwoValues = DefRateExp*ones(nYears,1);
```

DefRateTwoValues(Recession) = DefRateRec;

```
figure
plot(Years,DefRate,'bo:','LineWidth',1.2)
hold on
stairs(Years-0.5,DefRateTwoValues,'m-',''LineWidth',1.5)
plot(Years,DefRateTTC*ones(nYears,1),'r-.','LineWidth',1.5)
Example_RecessionBands
hold off
grid on
title('{\bf Default Rate}')
ylabel('%')
legend({'Point-in-time (PIT)','Recession/Expansion Avg',...
    'Through-the-cycle (TTC)'},'location','NW')
```

Some analyses (see, for example, [11]) use simulations where the default rate is conditional on the general state of the economy, e.g., recession v. expansion. The recession and expansion estimates just obtained can be useful in such a framework. These are all historical averages, however, and may not work well if used as predictions for the actual default rates expected on any particular year. In the second part, we revisit the use these types of historical averages as forecasting tools in a backtesting exercise.

## Building Predictors Using Credit Ratings Data

Using the credit data one can build new time series of interest. We start with an age proxy that is used as predictor in the forecasting model in the second part.

Age is known to be an important factor in predicting default rates; see, e.g., [1] and [5]. Age here means the number of years since a bond was issued. By extension, the age of a portfolio is the average age of its bonds. Certain patterns have been observed historically. Many low quality borrowers default just a few years after issuing a bond. When troubled companies issue bonds, the amount borrowed helps them make payments for a year or two. Beyond that point, their only source of money is their cash flows, and if they are insufficient, default occurs.

We cannot calculate the exact age of the portfolio, because there is no information at issuer level in the dataset. We follow [6], however, and use the number of new issuers in year $t-3$ divided by the total number of issuers at the end of year $t$ as an age proxy. Because of the lag, the age proxy starts in 1984. For the numerator, we have explicit information on the number of new issuers. For the denominator, the number of issuers at the end of a year equals the number of issuers at the beginning of next year. This is known for all years but the last one, which is set to the total transitions into a nondefault rating plus the number of new issuers on that year.

```
% Total number of issuers at the end of the year
nEOY = zeros(nYears,1);
% nIssuers is number of issuers per ratings at the beginning of the year
% nEOY ( 1981 ) = sum nIssuers ( 1982 ), etc until 2004
nEOY(1:end-1) = sum(nIssuers(2:end,:),2);
% nEOY ( 2005 ) = issuers in non-default state at end of 2005 plus
% new issuers in 2005
nEOY(end) = totalsAll(end).totalsMat(1,1) + sum(nNewIssuers(end,:));
% Age proxy
AGE = 100*[nan(3,1); sum(nNewIssuers(1:end-3,:),2)./nEOY(4:end)];
```

Examples of other time series of interest are the proportion of SG issuers at the end of each year, or an age proxy for SG.

```
% nSGEOY: Number of SG issuers at the end of the year
% nSGEOY is similar to nEOY, but for SG only, from 5 ('BB') to 7 ('CCC')
indSG = 5:7;
nSGEOY = zeros(nYears,1);
nSGEOY(1:end-1) = sum(nIssuers(2:end,indSG),2);
nSGEOY(end) = sum(totalsIGSG(end).totalsMat(:,2)) +...
    sum(nNewIssuers(end,indSG));
% Proportion of SG issuers
SG = 100*nSGEOY./nEOY;
% SG age proxy: new SG issuers in t-3 / total issuers at the end of year t
AGESG = 100*[nan(3,1); sum(nNewIssuers(1:end-3,indSG),2)./nEOY(4:end)];
```

## Part II: A Forecasting Model for Default Rates

We work with the following linear regression model for corporate default rates

$$
\text { DefRate }=\beta_{0}+\beta_{\text {age }} A G E+\beta_{\text {cpf } f} C P F+\beta_{\text {spr }} S P R
$$

where

- AGE: Age proxy defined above
- CPF: Corporate profits forecast
- SPR: Corporate spread over treasuries

This is the same model as in [6], except the model in [6] is for IG only.
As discussed above, age is known to be an important factor regarding default rates. The corporate profits provide information on the economic environment. The corporate spread is a proxy for credit quality. Age, environment and quality are three dimensions frequently found in credit analysis models.

```
inSample = 4:nYears-1;
T = length(inSample);
varNames = {'AGE','CPF','SPR'};
X = [AGE CPF SPR];
X = X(inSample,:);
y = DefRate(inSample+1); % DefaultRate, year t+1
stats = regstats(y,X);
fprintf('\nConst AGE CPF SPR adjR^2\n')
fprintf('%1.2f %1.2f %1.2f %1.2f %1.4f\n',...
    [stats.beta;stats.adjrsquare])
Const AGE CPF SPR adjR^2
-1.19 0.15 -0.10 0.71 0.7424
```

The coefficients have the expected sign: default rates tend to increase with a higher proportion of 3 -year issuers, decrease with good corporate profits, and increase when the corporate yields are higher. The adjusted R square shows a good fit.

The in-sample fit, or how close the model predictions are from the sample points used to fit the model, is shown in the following figure.

```
bHat = stats.beta;
yHat = [ones(T,1),X]*bHat;
figure
plot(Years(inSample+1),DefRate(inSample+1),'ko','LineWidth',1.5,...
    'MarkerSize', 10, 'MarkerFaceColor', 'g')
hold on
plot(Years(inSample+1),yHat,'b-s','LineWidth',1.2,'MarkerSize', 10)
hold off
grid on
legend({'Actual','Model'},'location', 'NW')
title('{\bf Corporate Default Rate Models: In-Sample Fit}')
xlabel('Year')
ylabel('Percent')
```

It can be shown that there is no strong statistical evidence to conclude that the linear regression assumptions are violated. It is apparent that default rates are not normally distributed. The model, however, does not make that assumption. The only normality assumption in the model is that, given the predictors values, the error between the predicted and the observed default rates is normally distributed. By looking at the insample fit, this does not seem unreasonable. The magnitude of the errors certainly seems independent of whether the default rates are high or low. Year 2001 has a high default rate and a high error, but years 1991 or 2002 also have high rates and yet very small errors. Likewise, low default rate years like 1996 and 1997 show considerable errors, but years 2004 or 2005 have similarly low rates and tiny errors.

A thorough statistical analysis of the model is out of scope here, but there are several detailed examples in Statistics and Machine Learning Toolbox ${ }^{\mathrm{TM}}$ and Econometrics Toolbox ${ }^{\mathrm{TM}}$.

## Backtesting

To evaluate how this model performs out-of-sample, we set up a backtesting exercise. Starting at the end of 1995, we fit the linear regression model with the information available up to that date, and compare the model prediction to the actual default rate observed the following year. We repeat the same for all subsequent years until the end of the sample.

For backtesting, relative performance of a model, when compared to alternatives, is easier to assess than the performance of a model in isolation. Here we include two alternatives to determine next year's default rate, both likely candidates in practice. One is the TTC default rate, estimated with data from the beginning of the sample to the current year, a very stable default rate estimate. The other is the PIT rate, estimated using data from the most recent year only, much more sensitive to recent events.

```
XBT = [AGE,CPF,SPR];
yBT = DefRate;
iYear0 = find(Years==1984); % index of first year in sample, 1984
T = find(Years==1995); % ind "current" year, start at 1995, updated in loop
YearsBT = 1996:2005; % years predicted in BT exercise
iYearsBT = find(Years==1996):find(Years==2005); % corresponding indices
nYearsBT = length(YearsBT); % number of years in BT exercise
MethodTags = {'Model','PIT','TTC'};
nMethods = length(MethodTags);
PredDefRate = zeros(nYearsBT,nMethods);
```

```
ErrorBT = zeros(nYearsBT,nMethods);
alpha = 0.05;
PredDefLoBnd = zeros(nYearsBT,1);
PredDefUpBnd = zeros(nYearsBT,1);
for k=1:nYearsBT
    % In sample years for predictors, from 1984 to "last" year (T-1)
    inSampleBT = iYear0:T-1;
    % Method 1: Linear regression model
    % Fit regression model with data up to "current" year (T)
    s = regstats(yBT(inSampleBT+1),XBT(inSampleBT,:));
    % Predict default rate for "next" year (T+1)
    PredDefRate(k,1) = [1 XBT(T,:)]*s.beta;
    % Compute prediction intervals
    tCrit = tinv(1-alpha/2,s.tstat.dfe);
    PredStd = sqrt([1 XBT(T,:)]*s.covb*[1 XBT(T,:)]'+s.mse);
    PredDefLoBnd(k) = max(0,PredDefRate(k,1) - tCrit*PredStd);
    PredDefUpBnd(k) = PredDefRate(k,1) + tCrit*PredStd;
    % Method 2: Point-in-time (PIT) default rate
    PredDefRate(k,2) = DefRate(T);
    % Method 3: Through-the-cycle (TTC) default rate
    tmAll = transprobbytotals(totalsAll(iYear0:T));
    PredDefRate(k,3) = tmAll(1,2);
    % Update error
    ErrorBT(k,:) = PredDefRate(k,:) - DefRate(T+1);
    % Move to next year
    T = T + 1;
end
```

Here are the predictions of the three alternative approaches, compared to the actual default rates observed. Unsurprisingly, TTC shows a very poor predictive power. However, it is not obvious whether PIT or the linear regression model makes better predictions in this 10 -year time span.

Example_BacktestPlot(YearsBT, DefRate(iYearsBT), PredDefRate, 'Year', '\%', ... \{\bf Default Rate Estimation Methods: Backtesting\}',... ['Actual' MethodTags],'NW')

The following plot keeps track of cumulative square error, a measure often used for comparisons in backtesting exercises. This confirms TTC as a poor alternative. PIT shows lower cumulative error than the linear regression model in the late nineties, but after the 2001 recession the situation is reversed. Cumulative square error, however, is not an intuitive measure, it is hard to get a sense of what the difference between these alternatives means in practical terms.

```
CumSqError = cumsum(ErrorBT.^2);
Example_BacktestPlot(YearsBT,[],CumSqError,'Year','Cum Sq Error',...
        '{\bf Cumulative Square Error in Backtesting Exercise}',...
    MethodTags,'NW')
```

It makes sense to translate the prediction errors into a monetary measure. Here we measure the impact of the prediction error on a simplified framework for generating loss reserves in an institution.

We assume a homogeneous portfolio, where all credits have the same probability of default, the same loss given default (LGD), and the same exposure at default (EAD). Both LGD and EAD are assumed to be known. For simplicity, we keep these values constant for the 10 years of the exercise. We set LGD at $45 \%$, and EAD per bond at 100 million. The portfolio is assumed to have a thousand bonds, so the total value of the portfolio, the total EAD, is 100 billion.

The predicted default rate for year $t$, determined at the end of year $t-1$, is used to calculate the expected loss for year t

```
\(E L_{t}=E A D_{t} \times L G D_{t} \times\) PredictedDefaultRate \(_{t}\)
```

This is the amount added to the loss reserves at the start of year $t$. At the end of the year, the actual losses are known

$$
A L_{t}=E A D_{t} \times L G D_{t} \times \text { ObservedDefault Rate }_{t}
$$

We assume that unused loss reserves remain in the reserves fund. The starting balance in reserves at the beginning of the exercise is set to zero. If the actual losses surpass the expected loss, unused reserves accumulated over the years are used first, and only if these run out, capital is used to cover a shortfall. All this translates into the following formula

$$
\text { Reserves }_{t}=\text { Reserves }_{t-1}+\left(E L_{t}-A L_{t}\right)
$$

or equivalently

$$
\text { Reserves }_{t}=\sum_{s=1}^{t}\left(E L_{t}-A L_{t}\right)
$$

The following figure shows the loss reserves balance for each of the three alternatives in the backtesting exercise.

```
EAD = 100*ones(nYearsBT,1); % in billions
LGD = 0.45*ones(nYearsBT,1); % Loss given default, 45%
% Reserves excess or shortfall for each year, in billions
ReservesExcessShortfall = bsxfun(@times,EAD.*LGD,ErrorBT/100);
% Cumulative reserve balance for each year, in billions
ReservesBalanceEOY = cumsum(ReservesExcessShortfall);
Example_BacktestPlot(YearsBT,[],ReservesBalanceEOY,'Year',...
    'Billions of Dollars',...
    '{\bf Reserves Balance (EOY): Backtesting}',...
    MethodTags,'SW')
grid on
```

Using the linear regression model we only observe a deficit in reserves in two out of ten years, and the maximum deficit, in 2001, is 0.09 billion, only nine basis points of the portfolio value.

In contrast, both TTC and PIT reach a deficit of 1.2 billion by 2001. Things get worse for TTC in the next two years, reaching a deficit of 2.1 billion by 2003. PIT does make a correction quickly after 2001, and by 2004 the reserves have a surplus. Yet, both TTC and PIT lead to more deficit years than surplus years in this exercise.

The linear regression model shows more of a counter-cyclical effect than the alternatives in this exercise. The money set aside using the linear regression model reaches close to a billion in 1997 and 1998. High levels of unused reserves translate into a slower pace of lending (not reflected in the exercise, because we exogenously impose the portfolio
value). Moreover, capital is only slightly impacted during the 2001 recession thanks to the reserves accumulated over the previous expansion. This translates into more capital available to back up further lending, if desired, during the economic recovery.

The last backtesting tool we discuss is the use of prediction intervals. Linear regression models provide standard formulas to compute confidence intervals for the values of new observations. These intervals are shown in the next figure for the 10 years spanned in the backtesting exercise.

```
figure
plot(YearsBT,DefRate(iYearsBT),'ko','LineWidth',1.5,'MarkerSize',10,...
    MarkerFaceColor','g')
hold on
plot(YearsBT,PredDefRate(:,1),'b-s','LineWidth',1.2,'MarkerSize',10)
plot(YearsBT,[PredDefLoBnd PredDefUpBnd],'b:','LineWidth',1.2)
hold off
strConf = num2str((1-alpha)*100);
title(['{\bf Backtesting Results with ' strConf '% Prediction Intervals}'])
xlabel('Year');
ylabel('%');
legend({'Actual','Predicted','Conf Bounds'},'location','NW');
```

The observed default rates fall outside the prediction intervals for two years, 1996 and 1997, where very low default rates are observed. For a $95 \%$ confidence level, two out of ten seems high. Yet, the observed values in these cases fall barely outside the prediction interval, which is a positive sign for the model. It is also positive that the prediction intervals contain the observed values around the 2001 recession.

## Stress Testing

Stress testing is a broad area that reaches far beyond computational tools; see, for example, [3]. We show here some tools that can be incorporated into a comprehensive stress testing framework. We build on the linear regression model presented above, but the concepts and tools are compatible with other forecasting methodologies.

The first tool is the use of prediction intervals to define a worst-case scenario forecasts. This is to account for uncertainty in the model only, not in the value of the predictors.

We take a baseline scenario of predictors, in our case, the latest known values of our age proxy AGE, corporate profits forecast CPF and corporate spread SPR. We then use the linear regression model to compute a $95 \%$ confidence upper bound for the predicted default rate. The motivation for this is illustrated in the last plot of the backtesting section, where the $95 \%$ confidence upper limit acts as a conservative bound when the prediction underestimates the actual default rates.

```
tCrit = tinv(1-alpha/2,stats.tstat.dfe);
XLast = [AGE(end),CPF(end),SPR(end)];
yPred = [1 XLast]*stats.beta;
PredStd = sqrt([1 XLast]*stats.covb*[1 XLast]'+stats.mse);
yPredUB = yPred + tCrit*PredStd;
fprintf('\nPredicted default rate:\n');
fprintf(' Baseline: %4.2f%%\n',yPred);
fprintf(' %g%% Upper Bound: %4.2f%%\n',(1-alpha)*100,yPredUB);
Predicted default rate:
    Baseline: 1.18%
    95% Upper Bound: 2.31%
```

The next step is to incorporate stressed scenarios of the predictors in the analysis. CPF and SPR can change in the short term, whereas AGE cannot. This is important. The corporate profits forecast and the corporate spread are influenced by world events, including, for example, natural disasters. These predictors can significantly change overnight. On the other hand, AGE depends on managerial decisions that can alter the proportion of old and new loans in time, but these decisions take months, if not years, to reflect in the AGE time series. Scenarios for AGE are compatible with longer term analyses. Here we look at one year ahead only, and keep AGE fixed for the remainder of this section.

It is convenient to define the predicted default rate and the confidence bounds as functions of CPF and SPR to simplify the scenario analysis.

```
yPredFn = @(cpf,spr) [1 AGE(end) cpf spr]*stats.beta;
PredStdFn = @(cpf,spr) sqrt([1 AGE(end) cpf spr]*stats.covb*...
    [1 AGE(end) cpf spr]'+stats.mse);
yPredUBFn = @(cpf,spr) (yPredFn(cpf,spr) + tCrit*PredStdFn(cpf,spr));
yPredLBFn = @(cpf,spr) (yPredFn(cpf,spr) - tCrit*PredStdFn(cpf,spr));
```

Two extreme scenarios of interest can be a drop in the corporate profits forecast of $4 \%$ relative to the baseline, and an increase in the corporate spread of 100 basis points over the baseline.

Moving one predictor at a time is not unreasonable in this case, because the correlation between CPF and SPR is very low. Moderate correlation levels may require perturbing predictors together to get more reliable results. Highly correlated predictors usually do not coexist in the same model, since they offer redundant information.

```
fprintf('\n\n What-if Analysis\n');
fprintf('Scenario LB Pred UB\n');
cpf = CPF(end)-4;
spr = SPR(end);
yPredRange = [yPredLBFn(cpf,spr),yPredFn(cpf,spr),yPredUBFn(cpf,spr)];
fprintf('CPF drops 4%% %4.2f%%% %4.2f%% %4.2f%%\n',yPredRange);
cpf = CPF(end);
spr = SPR(end)+1;
yPredRange = [yPredLBFn(cpf,spr),yPredFn(cpf,spr),yPredUBFn(cpf,spr)];
fprintf('SPR rises 1%% %4.2f%%% %4.2f%% %4.2f%%\n',yPredRange);
cpf = CPF(end);
spr = SPR(end);
yPredRange = [yPredLBFn(cpf,spr),yPredFn(cpf,spr),yPredUBFn(cpf,spr)];
fprintf(' Baseline %4.2f%% %4.2f%%% %4.2f%%\n',yPredRange);
fprintf('\nCorrelation between CPF and SPR: %4.3f\n',corr(CPF,SPR));
```

| What-if Analysis |  |  |  |
| :--- | :---: | :--- | :---: |
| Scenario | LB | Pred | UB |
| CPF drops 4\% | $0.42 \%$ | $1.57 \%$ | $2.71 \%$ |
| SPR rises 1\% | $0.71 \%$ | $1.88 \%$ | $3.05 \%$ |
| Baseline | $0.04 \%$ | $1.18 \%$ | $2.31 \%$ |

Correlation between CPF and SPR: 0.012
We now take a more global view of the scenario analysis. Instead of analyzing one scenario at a time, we visualize the default rate forecasts as a function of CPF and SPR. More precisely, we plot default rate contours over a whole grid of CPF and SPR values. We use the conservative $95 \%$ upper bound.

If we assumed a particular bivariate distribution for the values of CPF and SPR, we could plot the contours of their distribution in the same figure. That would give visual
information on the probability of falling on each region. Lacking such a distribution, we simply add to the plot the CPF - SPR pairs observed in our sample, as a historical, empirical distribution. The last observation in the sample, the baseline scenario, is marked in red.

```
gridCPF = 2*min(CPF):0.1:max(CPF);
gridSPR = min(SPR):0.1:2*max(SPR);
nGridCPF = length(gridCPF);
nGridSPR = length(gridSPR);
DefRateUB = zeros(nGridCPF,nGridSPR);
for i=1:nGridCPF
    for j=1:nGridSPR
        DefRateUB(i,j) = yPredUBFn(gridCPF(i),gridSPR(j));
    end
end
Example_StressTestPlot(gridCPF,gridSPR,DefRateUB,CPF,SPR,...
    'Corporate Profits Forecast (%)','Corporate Spread (%)',...
    ['{\bf ' strConf '% UB Default Rate Regions (in %)}'])
```

95\% UB Default Rate Regions (in \%)

Very different predictor values result in similar default rate levels. For example, consider a profits forecast around $10 \%$ with a spread of $3.5 \%$, and a profits forecast of $-2.5 \%$ with a spread of $2 \%$, they both result in a default rate slightly above $3 \%$. Also, only one point in the available history yields a default rate higher than $4 \%$.

Monetary terms, once again, may be more meaningful. We use Basel II's capital requirements formula (see [2]) to translate the default rates into a monetary measure. Basel II's formula is convenient because it is analytic (there is no need to simulate to estimate the capital requirements), but also because it depends only on the probabilities of default. We define Basel II's capital requirements as a function K .

```
% Correlation as a function of PD
w = @(pd) (1-\operatorname{exp}(-50*pd))/(1-\operatorname{exp}(-50)); % weight
```

```
R = @(pd) (0.12*w(pd)+0.24*(1-w(pd))); % correlation
% Vasicek formula
V = @(pd) normcdf(norminv(pd)+R(pd).*norminv(0.999)./sqrt(1-R(pd)));
% Parameter b for maturity adjustment
b = @(pd) (0.11852-0.05478*log(pd)).^2;
% Basel II capital requirement with LGD=45% and maturity M=2.5 (numerator
% in maturity adjustment term becomes 1)
K = @(pd) 0.45*(V(pd)-pd).*(1./(1-1.5*b(pd)));
```

Worst-case default rates for a whole grid of CPF - SPR pairs are stored in DefRateUB. By applying the function $K$ to DefRateUB we can visualize the capital requirements over the same grid.

```
CapReq = 100*K(DefRateUB/100);
Example_StressTestPlot(gridCPF,gridSPR,CapReq,CPF,SPR,...
    'Corporate Profits Forecast (%)','Corporate Spread (%)',...
    {'{\bf Capital Requirement Regions (% of value)}';...
    ['{\bf using ' strConf '% UB Default Rate}']})
```

## Capital Requirement Regions (\% of value) using 95\% UB Default Rate

The contour levels now indicate capital requirements as a percentage of portfolio value. The two scenarios above, profits of $10 \%$ with spread of $3.5 \%$, and profits of $-2.5 \%$ and spread of $2 \%$, result in capital requirements near $2.75 \%$. The worst-case point from the historical data yields a capital requirement of about $3 \%$.

This visualization can also be used, for example, as part of a reverse stress test analysis. Critical levels of capital can be determined first, and the figure can be used to determine regions of risk factor values (in this case CPF and SPR) that lead to those critical levels.

Instead of historical observations of CPF and SPR, an empirical distribution for the risk factors can be simulated using, for example, a vector autoregressive (VAR) model from Econometrics Toolbox ${ }^{\mathrm{TM}}$. The capital requirements corresponding to each default probability level can be found by simulation if a closed form formula is not available,
and the same plots can be generated. For large simulations, a distributed computing implementation using Parallel Computing Toolbox ${ }^{\text {TM }}$ or MATLAB Distributed Computing Server ${ }^{\mathrm{TM}}$ can make the process more efficient.

## Appendix: Modeling Full Transition Matrices

Transition matrices change in time, and a full description of their dynamics requires working with multi-dimensional time series. There are, however, techniques that exploit the particular structure of transition matrices to reduce the dimensionality of the problem. In [8], for example, a single parameter related to the proportion of downgrades is used, and both [6] and [8] describe a method to shift transition probabilities using a single parameter. The latter approach is shown in this appendix.

The method takes the TTC transition matrix as a baseline.

An equivalent way to represent this matrix is by transforming it into credit quality thresholds, that is, critical values of a standard normal distribution that yield the same transition probabilities (row by row).

```
thresholdMat = transprobtothresholds(tmTTC);
Example_DisplayTransitions(thresholdMat,[],...
    {'AAA','AA','A','BBB','BB','B','CCC'},...
    {'AAA','AA','A','BBB','BB','B','CCC','D','NR'})
\begin{tabular}{rrrrrrrrrr} 
& AAA & AA & A & BBB & BB & B & CCC & D & NR \\
AAA & Inf & -1.19 & -1.74 & -1.8 & -1.81 & -1.81 & -1.81 & -1.81 & -1.81 \\
AA & Inf & 2.52 & -1.16 & -1.68 & -1.75 & -1.75 & -1.76 & -1.77 & -1.77 \\
A & Inf & 3.31 & 2.07 & -1.24 & -1.62 & -1.66 & -1.68 & -1.68 & -1.69 \\
BBB & Inf & 3.57 & 2.91 & 1.75 & -1.18 & -1.43 & -1.49 & -1.5 & -1.52
\end{tabular}
```

| BB | Inf | 3.39 | 3.16 | 2.72 | 1.59 | -0.89 | -1.21 | -1.26 |
| ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| -1.32 |  |  |  |  |  |  |  |  |
| B | Inf | Inf | 3.28 | 2.82 | 2.54 | 1.55 | -0.8 | -0.95 |
| CCC | Inf | Inf | Inf | 2.77 | 2.46 | 2.07 | 1.13 | -0.25 |

Credit quality thresholds are illustrated in the following figure. The segments in the vertical axis represent transition probabilities, and the boundaries between them determine the critical values in the horizontal axis, via the standard normal distribution. Each row in the transition matrix determines a set of thresholds. The figure shows the thresholds for the ' CCC ' rating.

```
xliml = -5;
xlimr = 5;
step = 0.1;
x=xliml:step:xlimr;
thresCCC = thresholdMat(7,:);
centersY = (normcdf([thresCCC(2:end) xliml])+...
    normcdf([xlimr thresCCC(2:end)]))/2;
labels = {'AAA','AA','A','BBB','BB','B','CCC','D','NR'};
figure
plot(x,normcdf(x),'m','LineWidth',1.5)
for i=2:length(labels)
    val = thresCCC(i);
    line([val val],[0 normcdf(val)],'LineStyle',':');
    line([x(1) val],[normcdf(val) normcdf(val)],'LineStyle',':');
    if (centersY(i-1)-centersY(i))>0.05
        text(-4.5,centersY(i),labels{i});
    end
end
xlabel('Credit Quality Thresholds')
ylabel('Cumulative Probability')
title('{\bf Visualization of Credit Quality Thresholds}')
legend('Std Normal CDF','Location','E')
```

Shifting the critical values to the right or left changes the transition probabilities. For example, here is the transition matrix obtained by shifting the TTC thresholds by 0.5 to the right. Note that default probabilities increase.

```
shiftedThresholds = thresholdMat+0.5;
Example_DisplayTransitions(transprobfromthresholds(shiftedThresholds),...
    [],{'AAA', 'AA', 'A', 'BBB', 'BB','B', 'CCC'},...
    {'AAA','AA','A','BBB','BB','B','CCC','D', 'NR'})
\begin{tabular}{rrrrrrrrrr} 
& AAA & AA & A & BBB & BB & B & CCC & D & NR \\
AAA & 75.34 & 13.84 & 1.05 & 0.19 & 0.13 & 0 & 0 & 0 & 9.45 \\
AA & 0.13 & 74.49 & 13.53 & 1.21 & 0.12 & 0.22 & 0.04 & 0.02 & 10.24 \\
A & 0.01 & 0.51 & 76.4 & 10.02 & 0.83 & 0.31 & 0.06 & 0.08 & 11.77 \\
BBB & 0 & 0.03 & 1.2 & 74.03 & 7.22 & 1.39 & 0.32 & 0.51 & 15.29
\end{tabular}
```

| BB | 0 | 0.01 | 0.05 | 1.77 | 63.35 | 10.94 | 1.47 | 1.88 |
| ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| 20.52 |  |  |  |  |  |  |  |  |
| B | 0 | 0.01 | 0.04 | 0.07 | 1.91 | 59.67 | 5.74 | 8.1 |
| 24.46 |  |  |  |  |  |  |  |  |
| CCC | 0 | 0 | 0.05 | 0.1 | 0.36 | 4.61 | 35.06 | 33.18 |

Given a particular PIT matrix, the idea in [6] and [8] is to vary the shifting parameter applied to the TTC thresholds so that the resulting transition matrix is as close as possible to the PIT matrix. Closeness is measured as the sum of squares of differences between corresponding transition probabilities. The optimal shifting value is called credit index. A credit index is determined for every PIT transition matrix in the sample.

Here we use fminunc from Optimization Toolbox ${ }^{\mathrm{TM}}$ to find the credit indices.

```
CreditIndex = zeros(nYears,1);
ExitFlag = zeros(nYears,1);
options = optimset('LargeScale','Off','Display','Off');
for i=1:nYears
    errorfun = @(z)norm(squeeze(TransMat(:,:,i))-...
        transprobfromthresholds(...
        transprobtothresholds(tmTTC)+z),'fro');
    [CreditIndex(i),~,ExitFlag(i)] = fminunc(errorfun,0,options);
end
```

In general, one expects that higher credit indices correspond to riskier years. The series of credit indices found does not entirely match this pattern. There may be different reasons for this. First, transition probabilities may deviate from their long-term averages in different ways that may lead to confounding effects in the single parameter trying to capture these difference, the credit index. Having separate credit indices for IG and SG, for example, may help separate confounding effects. Second, a difference of five basis points may be very significant for the 'BBB' default rate, but not as important for the 'CCC' default rate, yet the norm used weights them equally. Other norms can be considered. Also, it is always a good idea to check the exit flags of optimization solvers, in case the algorithm could not find a solution. Here we get valid solutions for each year (all exit flags are 1).

```
figure
plot(Years,CreditIndex,'-d')
hold on
Example_RecessionBands
hold off
grid on
xlabel('Year')
ylabel('Shift')
title('{\bf Credit Index}')
```

The workflow above can be adapted to work with the series of credit indices instead of the series of corporate default rates. A model can be fit to predict a credit index for the following year, and a predicted transition matrix can be inferred and used for risk analyses.

## Credit Quality Thresholds

```
In this section...
"Introduction" on page 8-70
"Compute Credit Quality Thresholds" on page 8-70
"Visualize Credit Quality Thresholds" on page 8-71
```

## Introduction

An equivalent way to represent transition probabilities is by transforming them into credit quality thresholds. These are critical values of a standard normal distribution that yield the same transition probabilities.

An M-by-N matrix of transition probabilities TRANS and the corresponding M-by-N matrix of credit quality thresholds THRESH are related as follows. The thresholds THRESH $(i, j)$ are critical values of a standard normal distribution $z$, such that

```
TRANS(i,N) = P[z < THRESH(i,N)],
TRANS(i,j) = P[z< THRESH(i,j)] - P[z < THRESH(i,j+1)], for 1<=j<N
```

Financial Toolbox supports the transformation between transition probabilities and credit quality thresholds with the functions transprobtothresholds and transprobfromthresholds.

## Compute Credit Quality Thresholds

To compute credit quality thresholds, transition probabilities are required as input. Here is a transition matrix estimated from credit ratings data:

| ```load Data_TransProb trans = transprob(data)``` |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| trans $=$ |  |  |  |  |  |  |  |
| 93.1170 | 5.8428 | 0.8232 | 0.1763 | 0.0376 | 0.0012 | 0.0001 | 0.0017 |
| 1.6166 | 93.1518 | 4.3632 | 0.6602 | 0.1626 | 0.0055 | 0.0004 | 0.0396 |
| 0.1237 | 2.9003 | 92.2197 | 4.0756 | 0.5365 | 0.0661 | 0.0028 | 0.0753 |
| 0.0236 | 0.2312 | 5.0059 | 90.1846 | 3.7979 | 0.4733 | 0.0642 | 0.2193 |
| 0.0216 | 0.1134 | 0.6357 | 5.7960 | 88.9866 | 3.4497 | 0.2919 | 0.7050 |
| 0.0010 | 0.0062 | 0.1081 | 0.8697 | 7.3366 | 86.7215 | 2.5169 | 2.4399 |
| 0.0002 | 0.0011 | 0.0120 | 0.2582 | 1.4294 | 4.2898 | 81.2927 | 12.7167 |
| 0 | 0 | 0 | 0 | 0 | 0 | 0 | 100.0000 |

Convert the transition matrix to credit quality thresholds using transprobtothresholds:
thresh $=$ transprobtothresholds(trans)
thresh =

| Inf | -1.4846 | -2.3115 | -2.8523 | -3.3480 | -4.0083 | -4.1276 | -4.1413 |
| ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| Inf | 2.1403 | -1.6228 | -2.3788 | -2.8655 | -3.3166 | -3.3523 | -3.3554 |
| Inf | 3.0264 | 1.8773 | -1.6690 | -2.4673 | -2.9800 | -3.1631 | -3.1736 |
| Inf | 3.4963 | 2.8009 | 1.6201 | -1.6897 | -2.4291 | -2.7663 | -2.8490 |
| Inf | 3.5195 | 2.9999 | 2.4225 | 1.5089 | -1.7010 | -2.3275 | -2.4547 |
| Inf | 4.2696 | 3.8015 | 3.0477 | 2.3320 | 1.3838 | -1.6491 | -1.9703 |
| Inf | 4.6241 | 4.2097 | 3.6472 | 2.7803 | 2.1199 | 1.5556 | -1.1399 |
| Inf | Inf | Inf | Inf | Inf | Inf | Inf | Inf |

Conversely, given a matrix of thresholds, you can compute transition probabilities using transprobfromthresholds. For example, take the thresholds computed previously as input to recover the original transition probabilities:

```
trans1 = transprobfromthresholds(thresh)
trans1
\begin{tabular}{rrrrrrrr}
93.1170 & 5.8428 & 0.8232 & 0.1763 & 0.0376 & 0.0012 & 0.0001 & 0.0017 \\
1.6166 & 93.1518 & 4.3632 & 0.6602 & 0.1626 & 0.0055 & 0.0004 & 0.0396 \\

## Visualize Credit Quality Thresholds

You can graphically represent the relationship between credit quality thresholds and transition probabilities. Here, this example shows the relationship for the 'CCC' credit rating. In the plot, the thresholds are marked by the vertical lines and the transition probabilities are the area below the standard normal density curve:

```
load Data_TransProb
trans = transprob(data);
thresh = transprobtothresholds(trans);
xliml = -5;
xlimr = 5;
step = 0.1;
x=xliml:step:xlimr;
thresCCC = thresh(7,:);
labels = {'AAA','AA','A','BBB','BB','B','CCC','D'};
centersX = ([5 thresCCC(2:end)]+[thresCCC(2:end) -5])*0.5;
omag = round(log10(trans(7,:)));
omag (omag>0) =omag (omag>0) .^2;
```

```
fs = 14+2*omag;
```

```
figure
plot(x,normpdf(x),'LineWidth',1.5)
text(centersX(1),0.2,labels{1},'FontSize',fs(1),...
    'HorizontalAlignment','center')
for i=2:length(labels)
    val = thresCCC(i);
    line([val val],[0 0.4],'LineStyle',':')
    text(centersX(i),0.2,labels{i},'FontSize',fs(i),...
        'HorizontalAlignment','center')
end
xlabel('Credit Quality Thresholds')
ylabel('Probability Density Function')
title('{\bf Visualization of Credit Quality Thresholds}')
legend('Std Normal PDF','Location','S')
```

The second plot uses the cumulative density function instead. The thresholds are represented by vertical lines. The transition probabilities are given by the distance between horizontal lines.

```
figure
plot(x,normcdf(x),'m','LineWidth',1.5)
text(centersX(1),0.2,labels{1},'FontSize',fs(1),...
    HorizontalAlignment','center')
for i=2:length(labels)
    val = thresCCC(i);
    line([val val],[0 normcdf(val)],'LineStyle',':');
    line([x(1) val],[normcdf(val) normcdf(val)],'LineStyle',':');
    text(centersX(i),0.2,labels{i},'FontSize',fs(i),...
        'HorizontalAlignment','center')
end
xlabel('Credit Quality Thresholds')
ylabel('Cumulative Probability')
title('{\bf Visualization of Credit Quality Thresholds}')
legend('Std Normal CDF','Location','W')
```

## About Credit Scorecards

In this section...<br>"What Is a Credit Scorecard?" on page 8-75<br>"Credit Scorecard Development Process" on page 8-78

## What Is a Credit Scorecard?

Credit scoring is one of the most widely used credit risk analysis tools. The goal of credit scoring is ranking borrowers by their credit worthiness. In the context of retail credit (credit cards, mortgages, car loans, etc.), credit scoring is performed using a credit scorecard. Credit scorecards represent different characteristics of a customer (age, residential status, time at current address, time at current job, and so on) translated into points and the total number of points becomes the credit score. The credit worthiness of customers is summarized by their credit score; high scores usually correspond to low-risk customers, and conversely. Scores are also used for corporate credit analysis of small and medium enterprises, and, large corporations.

A credit scorecard is a lookup table that maps specific characteristics of a borrower into points. The total number of points becomes the credit score. Credit scorecards are a widely used type of credit scoring model. As such, the goal of a credit scorecard is to distinguish between customers who repay their loans ("good" customers), and customers who will not ("bad" customers). Like other credit scoring models, credit scorecards quantify the risk that a borrower will not repay a loan in the form of a score and a probability of default.

For example, a credit scorecard can give individual borrowers points for their age and income according to the following table. Other characteristics such as residential status, employment status, might also be included, although, for brevity, they are not shown in this table.
Age Points
Up to 25
26 to 4010
41 to 65 ..... 38
66 and up ..... 43
Income
Up to 40 k ..... 16
40k to 70k ..... 28
...
Total score
(Sum of Points)

Using the credit scorecard in this example, a particular customer who is 31 and has an income of $\$ 52,000$ a year, is placed into the second age group (26-40) and receives 25 points for their age, and similarly, receives 28 points for their income. Other characteristics (not shown here) might contribute additional points to their score. The total score is the sum of all points, which in this example is assumed to give the customer a total of 238 points (this is a fictitious example on an arbitrary scoring scale).

| Age | Points |  |
| :---: | :---: | :---: |
| Up to 25 | 10 | John: |
| 26 to 40 | 25 |  |
| 41 to 65 | 38 | - 31 years old |
| 66 and up | 43 | - 52k a year |
| Income |  | - Single |
| Up to 40k | 16 | " ... |
| 40k to 70k | 28 | Score 238 |
|  |  |  |
| Total score | 238 |  |

Technically, to determine the credit scorecard points, start out by selecting a set of potential predictors (column 1 in the next figure). Then, bin data into groups (for example, ages 'Up to 25 ', ' 25 to 40 ' (column 2 in the figure). This grouping helps to distinguish between "good" and "bad" customers. The Weight of Evidence (WOE) is a way to measure how well the distribution of "good" and "bad" are separated across bins or groups for each individual predictor (column 3 in the figure). By fitting a logistic regression model, you can identify which predictors, when put together, do a better job distinguishing between "good" and "bad" customers. The model is summarized by its coefficients (column 4 in the figure). Finally, the combination of WOE's and model coefficients (commonly scaled, shifted, and rounded) make up the scorecard points (column 5 in the figure).

| Predictor | Bin | WOE | Model | Points* |
| :---: | :---: | :---: | :---: | :---: |
| Age |  |  | $\beta_{\text {age }}$ |  |
|  | 'Up to $25{ }^{\prime}$ | WOE $\mathrm{E}_{\text {ago }}$ ('Up to 25') |  | $\beta_{\text {agp }}{ }^{*} W^{*} \mathrm{WE}_{\text {ape }}$ ('Up to $25^{\prime}$ ) |
|  | ' 26 to 40' | WOE $_{\text {cgo }}(26$ to 40 ) |  | $\beta_{\text {age }}{ }^{*}$ WOE $_{\text {ape }}$ ( 26 to 40 ') |
|  | '41 to 65' | WOE $_{\text {spe }}$ ( 41 to $65{ }^{\text {') }}$ |  | $\beta_{\text {sge }}{ }^{*} \mathrm{WOE}_{\text {age }}\left(41\right.$ to $65^{\prime}$ ) |
|  | '66 and up' | WOE ${ }_{\text {age }}$ ( 66 and up') |  | $\beta_{\text {age }}{ }^{*}$ WOEE $\mathrm{agpe}(66$ and up') |
| Income |  |  | $\beta_{\text {income }}$ |  |
|  | 'Up to 40k' | WOE income $^{\text {('Up to }} 40 \mathrm{k}$ ') |  |  |
|  | '40k to 70 k ' | WOE income $(40 \mathrm{k}$ to 70 k ) |  | $\beta_{\text {ncome }}{ }^{\text {* }}$ WOE $\mathrm{Emcome}(40 \mathrm{k}$ to 70 k ') |
|  | ... |  |  |  |

* Points may include a constant and may be scaled and rounded.

## Credit Scorecard Development Process

1 Data gathering and preparation phase
This includes data gathering and integration, such as querying, merging, aligning. It also includes treatment of missing information and outliers. There is a prescreening step based on reports of association measures between the predictors and the response variable. Finally, there is a sampling step, to produce a training set, sometimes called the modeling view, and usually a validation set, too. The training set, in the form of a table, is the required data input to the creditscorecard object, and this training set table must be prepared before creating a creditscorecard object in the Modeling phase.
2 Modeling phase
Use the creditscorecard object and associated object functions to develop a credit scorecard model. You can bin the data, apply the Weight of Evidence (WOE) transformation, and compute other statistics, such as the Information Value. You can fit a logistic regression model and also review the resulting scorecard points and format their scaling and rounding. For details on using the creditscorecard object, see Using creditscorecard Objects.
3 Deployment phase

Deployment entails integrating a credit scorecard model into an IT production environment and keeping tracking logs, performance reports, and so on.

The creditscorecard object is designed for the Modeling phase of the credit scorecard workflow. Support for all three phases requires other MathWorks ${ }^{\circledR}$ products.

## Credit Scorecard Modeling Workflow

Create, model, and analyze credit scorecards as follows.
1 Create a creditscorecard object.
Create a creditscorecard object for credit scorecard analysis by specifying "training" data in table format. The training data, sometimes called the modeling view, is the result of multiple data preparation tasks (see "About Credit Scorecards" on page 8-75) that must be performed before creating a creditscorecard object.

You can use optional input arguments for creditscorecard to specify scorecard properties such as the response variable and the GoodLabel. Perform some initial data exploration when the creditscorecard object is created, although data analysis is usually done in combination with data binning (see step 2). For more information and examples, see creditscorecard and step 1 in "Case Study for a Credit Scorecard Analysis" on page 8-93.
2 Bin the data.
Perform manual or automatic binning of the data loaded into the creditscorecard object.

A common starting point is to apply automatic binning to all or selected variables using autobinning, report using bininfo, and visualize bin information with respect to bin counts and statistics or association measures such as Weight of Evidence (WOE) using plotbins. The bins can be modified or fine-tuned either manually using modifybins or with a different automatic binning algorithm using autobinning. Bins that show a close-to-linear trend in the WOE are frequently desired in the credit scorecard context. For more information and examples, see autobinning, modifybins, bininfo, and plotbins and step 2 in "Case Study for a Credit Scorecard Analysis" on page 8-93.
3 Fit a logistic regression model.
Fit a logistic regression model to the WOE data from the creditscorecard object. The fitmodel function internally bins the training data, transforms it into WOE values, maps the response variable so that 'Good ' is 1, and fits a linear logistic regression model.

By default, fitmodel uses a stepwise procedure to determine which predictors should be in the model, but optional input arguments can also be used, for example,
to fit a full model. For more information and examples, see fitmodel and step 3 in "Case Study for a Credit Scorecard Analysis" on page 8-93.
4 Review and format credit scorecard points.
After fitting the logistic model, use displaypoints to summarize the scorecard points. By default, the points are unscaled and come directly from the combination of Weight of Evidence (WOE) values and model coefficients.

The formatpoints function lets you control scaling and rounding of scorecard points. For more information and examples, see displaypoints and formatpoints and step 4 in "Case Study for a Credit Scorecard Analysis" on page 8-93.
5 Score the data.
The score function computes the scores for the training data.
An optional data input can also be passed to score, for example, validation data. The points per predictor for each customer are also provided as an optional output. For more information and examples, see score and step 5 in "Case Study for a Credit Scorecard Analysis" on page 8-93.
6 Calculate the probability of default for credit scorecard scores.
The probdefault function to calculate the probability of default for training data.
In addition, you can compute likelihood of default for a different dataset (for example, a validation data set) using the probdefault function. For more information and examples, see probdefault and step 6 in "Case Study for a Credit Scorecard Analysis" on page 8-93.
7 Validate the credit scorecard model.
Use the validatemodel function to validate the quality of the credit scorecard model.

You can obtain the Cumulative Accuracy Profile (CAP), Receiver Operating Characteristic (ROC), and Kolmogorov-Smirnov (KS) plots and statistics for a given dataset using the validatemodel function. For more information and examples, see validatemodel and step 7 in "Case Study for a Credit Scorecard Analysis" on page 8-93.

For an example of this workflow, see "Case Study for a Credit Scorecard Analysis" on page 8-93.

## Troubleshooting Credit Scorecard Results

```
In this section...
"Predictor Name Is Unspecified and the Parser Returns an Error" on page 8-83
"Using bininfo or plotbins Before Binning" on page 8-83
"If Categorical Data Is Given as Numeric" on page 8-86
"NaNs Returned When Scoring a "Test" Dataset" on page 8-89
```

This topic shows some of the results when using credit scorecards that need troubleshooting. These examples cover the full range of the credit score card workflow. For details on the overall process of creating and developing credit scorecards, see "Credit Scorecard Modeling Workflow" on page 8-80.

## Predictor Name Is Unspecified and the Parser Returns an Error

If you attempt to use modifybins, bininfo, or plotbins and omit the predictor's name, the parser returns an error.

```
load CreditCardData
sc = creditscorecard(data,'IDVar','CustID','GoodLabel',0);
modifybins(sc,'CutPoints',[20 30 50 65])
```

Error using creditscorecard/modifybins (line 79)
Expected a string for the parameter name, instead the input type was 'double'.

Solution: Make sure to include the predictor's name when using these functions. Use this syntax to specify the PredictorName when using modifybins.

```
load CreditCardData
sc = creditscorecard(data,'IDVar','CustID','GoodLabel',0);
modifybins(sc,'CustIncome','CutPoints',[20 30 50 65]);
```

## Using bininfo or plotbins Before Binning

If you use bininfo or plotbins before binning, the results might be unusable.

```
load CreditCardData
sc = creditscorecard(data,'IDVar','CustID','GoodLabel',0);
```

## bininfo(sc, 'CustAge') <br> plotbins(sc,'CustAge')

ans $=$

| '73' | 3 | 0 | Inf | Inf | Inf |
| '74' | 1 | 0 | Inf | Inf | Inf |

The plot for CustAge is not readable because it has too many bins. Additionally, bininfo returns data that have Inf values for the WOE due to zero observations for either Good or Bad.

Solution: Bin the data using autobinning or modifybins before plotting or inquiring about the bin statistics, to avoid having too many bins or having NaNs and Infs. For example, you can use the name-value pair argument for AlgoOptions with the autobinning function to define the number of bins.

```
load CreditCardData
sc = creditscorecard(data,'IDVar','CustID','GoodLabel',0);
AlgoOptions = {'NumBins',4};
sc = autobinning(sc,'CustAge','Algorithm','EqualFrequency', ...
'AlgorithmOptions',AlgoOptions);
bininfo(sc,'CustAge','Totals','off')
plotbins(sc,'CustAge')
ans =
```

## If Categorical Data Is Given as Numeric

Categorical data is often recorded using numeric values, and can be stored in a numeric array. Although you know that the data should be interpreted as categorical information, for creditscorecard this predictor looks like a numeric array.

To show the case where categorical data is given as numeric data, the data for the variable ResStatus is intentionally converted to numeric values.

```
load CreditCardData
data.ResStatus = double(data.ResStatus);
sc = creditscorecard(data,'IDVar','CustID')
sc =
```

    creditscorecard with properties:
    ```
    GoodLabel: 0
    ResponseVar: 'status
        VarNames: {1x11 cell}
    NumericPredictors: {1x7 cell}
CategoricalPredictors: {'EmpStatus' 'OtherCC'}
    IDVar: 'CustID'
PredictorVars: {1x9 cell}
```

Note that 'ResStatus' appears as part of the NumericPredictors property. If we applied automatic binning, the resulting bin information raises flags regarding the predictor type.

```
sc = autobinning(sc,'ResStatus');
[bi,cg] = bininfo(sc,'ResStatus')
bi =
\begin{tabular}{lllllll} 
Bin & Good & Bad & \multicolumn{2}{c}{ Odds } & & \multicolumn{1}{c}{ WOE }
\end{tabular}
cg =
2
```

The numeric ranges in the bin labels show that 'ResStatus ' is being treated as a numeric variable. This is also confirmed by the fact that the optional output from bininfo is a numeric array of cut points, as opposed to a table with category groupings. Moreover, the output from predictorinfo confirms that the credit scorecard is treating the data as numeric.

```
[T,Stats] = predictorinfo(sc,'ResStatus')
```

$T=$

| ResStatus 'Num |  |
| :---: | :---: |
| Stats = |  |
|  | Value |
| Min | 1 |
| Max | 3 |
| Mean | 1.7017 |

Solution: For creditscorecard, 'Categorical' means a MATLAB categorical data type. For more information, see categorical. To treat'ResStatus' as categorical, change the 'PredictorType' of the PredictorName 'ResStatus' from 'Numeric' to 'Categorical' using modifypredictor.

```
sc = modifypredictor(sc,'ResStatus','PredictorType','Categorical')
```

[T,Stats] = predictorinfo(sc,'ResStatus')
sc $=$
creditscorecard with properties:
GoodLabel: 0
ResponseVar: 'status
VarNames: \{1×11 cell\}
NumericPredictors: \{1x6 cell\}
CategoricalPredictors: \{'ResStatus' 'EmpStatus' 'OtherCC'\}
IDVar: 'CustID'
PredictorVars: \{1x9 cell\}
$T=$

|  | PredictorType <br> ResStatus |  |
| :--- | :--- | :--- |
| 'Categorical' | false |  |

| Stats $=$ |  |
| :--- | :--- |
|  | Count |
| C1 | 542 |
| C2 | 474 |
| C3 | 184 |

Note that 'ResStatus ' now appears as part of the Categorical predictors. Also, predictorinfo now describes 'ResStatus' as categorical and displays the category counts.

If you apply autobinning, the categories are now reordered, as shown by calling bininfo, which also shows the category labels, as opposed to numeric ranges. The optional output of bininfo is now a category grouping table.

```
sc = autobinning(sc,'ResStatus');
[bi,cg] = bininfo(sc,'ResStatus')
bi =
\begin{tabular}{lrrrrr} 
& & & \\
'C2' & 307 & 167 & 1.8383 & -0.095564 & 0.0036638 \\
'C1' & 365 & 177 & 2.0621 & 0.019329 & 0.0001682 \\

\section*{NaNs Returned When Scoring a "Test" Dataset}

When applying a creditscorecard model to a "test" dataset using the score function, if an observation in the "test" dataset has a NaN or <undefined> value, a NaN total score is returned for each of these observations. For example, a creditscorecard object is created using "training" data.
```

load CreditCardData
sc = creditscorecard(data,'IDVar','CustID');
sc = autobinning(sc);
sc = fitmodel(sc);

1. Adding CustIncome, Deviance = 1490.8527, Chi2Stat = 32.588614, PValue = 1.1387992e-08
2. Adding TmWBank, Deviance = 1467.1415, Chi2Stat = 23.711203, PValue = 1.1192909e-06
3. Adding AMBalance, Deviance = 1455.5715, Chi2Stat = 11.569967, PValue = 0.00067025601
4. Adding EmpStatus, Deviance = 1447.3451, Chi2Stat = 8.2264038, PValue = 0.0041285257
5. Adding CustAge, Deviance = 1441.994, Chi2Stat = 5.3511754, PValue = 0.020708306
6. Adding ResStatus, Deviance = 1437.8756, Chi2Stat = 4.118404, PValue = 0.042419078
7. Adding OtherCC, Deviance = 1433.707, Chi2Stat = 4.1686018, PValue = 0.041179769
Generalized Linear regression model:
logit(status) ~ 1 + CustAge + ResStatus + EmpStatus + CustIncome + TmWBank + OtherCC + AMBalance
Distribution = Binomial
Estimated Coefficients:

|  | Estimate | SE |  | tStat |  |
| :--- | ---: | ---: | ---: | ---: | ---: | pValue

```

\footnotetext{
1200 observations, 1192 error degrees of freedom
Dispersion: 1
Chi^2-statistic vs. constant model: 89.7, p-value = 1.4e-16
}

Suppose that a missing observation (Nan) is added to the data and then newdata is scored using the score function. By default, the points and score assigned to the missing value is NaN .
```

newdata = data(1:10,:);
newdata.CustAge(1) = NaN;
[Scores,Points] = score(sc,newdata)

```
```

Scores =

```
Scores =
    NaN

    1.0399
    0.8252
```

Points =

| CustAge | ResStatus | EmpStatus | CustIncome | TmWBank | Othercc | AMBalance |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| NaN | -0.031252 | -0.076317 | 0.43693 | 0.39607 | 0.15842 | -0.017472 |
| 0.479 | 0.12696 | 0.31449 | 0.43693 | -0.033752 | 0.15842 | -0.017472 |
| 0.21445 | -0.031252 | 0.31449 | 0.081611 | 0.39607 | -0.19168 | -0.017472 |
| 0.23039 | 0.12696 | 0.31449 | 0.43693 | -0.044811 | 0.15842 | 0.35551 |
| 0.479 | 0.12696 | 0.31449 | 0.43693 | -0.044811 | 0.15842 | -0.017472 |
| 0.479 | 0.12696 | 0.31449 | 0.43693 | 0.39607 | 0.15842 | -0.017472 |
| -0.14036 | 0.12696 | -0.076317 | -0.10466 | -0.033752 | 0.15842 | -0.017472 |
| 0.23039 | 0.37641 | 0.31449 | 0.43693 | -0.033752 | -0.19168 | -0.21206 |
| 0.23039 | -0.031252 | -0.076317 | 0.43693 | -0.033752 | 0.15842 | 0.35551 |
| 0.23039 | 0.12696 | -0.076317 | 0.43693 | -0.033752 | 0.15842 | -0.0174 |

Additionally, notice that because the CustAge predictor for the first observation is NaN , the corresponding Scores output is NaN also.

Solution: To resolve this issue, use the formatpoints function with the name-value pair argument Missing. When using Missing, you can replace a predictor's NaN value according to three alternative criteria ('ZeroWoe', 'MinPoints', or 'MaxPoints').

For example, use Missing to replace the missing value with the 'MinPoints ' option. The row with the missing data now has a score corresponding to assigning it the minimum possible points for CustAge.

```
sc = formatpoints(sc,'Missing','MinPoints');
[Scores,Points] = score(sc,newdata)
PointsTable = displaypoints(sc);
PointsTable(1:7,:)
```

```
Scores =
    0.7074
    1.4646
    0.7662
    1.5779
    1.4535
    1.8944
    0.0872
    0.9207
    1.0399
    0.8252
```

Points =

| CustAge | ResStatus | EmpStatus | CustIncome | TmWBank | Othercc | AMBalance |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| -0.15894 | -0.031252 | -0.076317 | 0.43693 | 0.39607 | 0.15842 | -0.017472 |
| 0.479 | 0.12696 | 0.31449 | 0.43693 | -0.033752 | 0.15842 | -0.017472 |

## Case Study for a Credit Scorecard Analysis

This example shows how to create a creditscorecard object, bin data, display and plot binned data information, fit a logistic regression model, obtain a score for the scorecard model, determine the probabilities of default, and validate the credit scorecard model using three different metrics.

## Step 1. Create a creditscorecard object.

Use the CreditCardData.mat file to load the data (using a dataset from Refaat 2011). By default, 'ResponseVar' is set to the last column in the data ('status ' in this example) and the 'GoodLabel' to the response value with the highest count ( 0 in this example). The syntax for creditscorecard indicates that 'CustID' is the 'IDVar' to remove from the list of predictors.

```
load CreditCardData
sc = creditscorecard(data,'IDVar','CustID')
SC =
    creditscorecard with properties:
            IDVar: 'CustID'
            GoodLabel: 0
        ResponseVar: 'status'
        VarNames: {1x11 cell}
        PredictorVars: {1x9 cell}
```

Perform some initial data exploration. Inquire about predictor statistics for the categorical variable 'ResStatus' and plot the bin information for 'ResStatus'.

```
bininfo(sc,'ResStatus')
plotbins(sc,'ResStatus')
```

ans =

| Bin | Good | Bad | Odds | WOE | InfoValue |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 'Home Owner' | 365 | 177 | 2.0621 | 0.019329 | 0.0001682 |
| 'Tenant' | 307 | 167 | 1.8383 | -0.095564 | 0.0036638 |
| 'Other' | 131 | 53 | 2.4717 | 0.20049 | 0.0059418 |
| 'Totals' | 803 | 397 | 2.0227 | NaN | 0.0097738 |

This bin information contains the frequencies of "Good" and "Bad," and bin statistics. Avoid having bins with frequencies of zero because they lead to infinite or undefined ( NaN ) statistics. Use the modifybins or autobinning functions to bin the data accordingly.

For numeric data, a common first step is "fine classing." This means binning the data into several bins, defined with a regular grid. To illustrate this point, use the predictor 'CustIncome'.
cp = 20000:5000:60000;
$s c=$ modifybins(sc,'CustIncome','CutPoints', cp);

```
bininfo(sc,'CustIncome')
```

plotbins(sc,'CustIncome')

## Step 2a. Automatically bin the data.

Use the autobinning function to perform automatic binning for every predictor variable, using the default 'Monotone' algorithm with default algorithm options.
sc = autobinning(sc);
After the automatic binning step, every predictor bin must be reviewed using the bininfo and plotbins functions and fine-tuned. A monotonic, ideally linear trend in the Weight of Evidence (WOE) is desirable for credit scorecards because this translates
into linear points for a given predictor. The WOE trends can be visualized using plotbins.
plotbins(sc,sc.PredictorVars)

Unlike the initial plot of 'ResStatus ' when the scorecard was created, the new plot for 'ResStatus' shows an increasing WOE trend. This is because the autobinning function, by default, sorts the order of the categories by increasing odds.

These plots show that the 'Monotone ' algorithm does a good job finding monotone WOE trends for this dataset. To complete the binning process, it is necessary to make only a few manual adjustments for some predictors using the modifybins function.

## Step 2b. Fine-tune the bins using manual binning.

Common steps to manually modify bins are:

- Use the bininfo function with two output arguments where the second argument contains binning rules.
- Manually modify the binning rules using the second output argument from bininfo.
- Set the updated binning rules with modifybins and then use plotbins or bininfo to review the updated bins.

For example, based on the plot for 'CustAge ', bins number 1 and 2 have similar WOE's as do bins number 5 and 6 . To merge these bins, using the steps outlined above:

```
[bi,cp] = bininfo(sc,'CustAge');
cp([1 5]) = []; % To merge bins 1 and 2, and bins 5 and 6
sc = modifybins(sc,'CustAge','CutPoints',cp);
plotbins(sc,'CustAge')
```

For 'Cust Income', based on the plot above, it is best to merge bins 3, 4 and 5 because they have similar WOE's. To merge these bins:

```
[bi,cp] = bininfo(sc,'CustIncome');
cp([3 4]) = [];
sc = modifybins(sc,'CustIncome','CutPoints',cp);
plotbins(sc,'CustIncome')
```

For 'TmWBank', based on the plot above, it is best to merge bins 2 and 3 because they have similar WOE's. To merge these bins:

```
[bi,cp] = bininfo(sc,'TmWBank');
cp(2) = [];
sc = modifybins(sc,'TmWBank','CutPoints',cp);
plotbins(sc,'TmWBank')
```

For 'AMBalance', based on the plot above, it is best to merge bins 2 and 3 because they have similar WOE's. To merge these bins:

```
[bi,cp] = bininfo(sc,'AMBalance');
cp(2) = [];
sc = modifybins(sc,'AMBalance','CutPoints',cp);
plotbins(sc,'AMBalance')
```

Now that the binning fine-tuning is completed, the bins for all predictors have close-tolinear WOE trends.

## Step 3. Fit a logistic regression model.

The fitmodel function fits a logistic regression model to the WOE data. fitmodel internally bins the training data, transforms it into WOE values, maps the response variable so that 'Good ' is 1, and fits a linear logistic regression model. By default, fitmodel uses a stepwise procedure to determine which predictors should be in the model.

```
sc = fitmodel(sc);
1. Adding CustIncome, Deviance = 1490.8954, Chi2Stat = 32.545914, PValue = 1.1640961e-08
2. Adding TmWBank, Deviance = 1467.3249, Chi2Stat = 23.570535, PValue = 1.2041739e-06
3. Adding AMBalance, Deviance = 1455.858, Chi2Stat = 11.466846, PValue = 0.00070848829
4. Adding EmpStatus, Deviance = 1447.6148, Chi2Stat = 8.2432677, PValue = 0.0040903428
5. Adding CustAge, Deviance = 1442.06, Chi2Stat = 5.5547849, PValue = 0.018430237
6. Adding ResStatus, Deviance = 1437.9435, Chi2Stat = 4.1164321, PValue = 0.042468555
7. Adding OtherCC, Deviance = 1433.7372, Chi2Stat = 4.2063597, PValue = 0.040272676
Generalized Linear regression model:
    logit(status) ~ 1 + CustAge + ResStatus + EmpStatus + CustIncome + TmWBank + OtherCC + AMBalance
    Distribution = Binomial
```

Estimated Coefficients:

| Estimate | SE | tStat | pValue |
| :---: | :---: | :---: | :---: |
| 0.7024 | 0.064 | 10.975 | 5.0407e-28 |
| 0.61562 | 0.24783 | 2.4841 | 0.012988 |
| 1.3776 | 0.65266 | 2.1107 | 0.034799 |
| 0.88592 | 0.29296 | 3.024 | 0.0024946 |
| 0.69836 | 0.21715 | 3.216 | 0.0013001 |
| 1.106 | 0.23266 | 4.7538 | 1.9958e-06 |
| 1.0933 | 0.52911 | 2.0662 | 0.038806 |
| 1.0437 | 0.32292 | 3.2322 | 0.0012285 |

1200 observations, 1192 error degrees of freedom
Dispersion: 1
Chi^2-statistic vs. constant model: 89.7, $p$-value $=1.42 \mathrm{e}-16$

## Step 4. Review and format scorecard points.

After fitting the logistic model, by default the points are unscaled and come directly from the combination of WOE values and model coefficients. The displaypoints function summarizes the scorecard points.

```
p1 = displaypoints(sc);
disp(p1)
```

'AMBalance' '558.88 to 1597.43' -0.026797
'AMBalance' '1597.44 and up' -0.21168
```

Points are usually scaled and also often rounded. To do this, use the formatpoints function. For example, you can set a target level of points corresponding to a target odds level and also set the required points-to-double-the-odds (PDO).

```
TargetPoints = 500;
TargetOdds = 2;
PDO = 50; % Points to double the odds
sc = formatpoints(sc,'PointsOddsAndPDO',[TargetPoints TargetOdds PDO],'Round','AllPoints');
p2 = displaypoints(sc);
disp(p2)
```

## Step 5. Score the data.

The score function computes the scores for the training data. An optional data input can also be passed to score, for example, validation data. The points per predictor for each customer are provided as an optional output.

## Step 6. Calculate the probability of default.

To calculate the probability of default, use the probdefault function.
pd = probdefault(sc);
Define the probability of being "Good" and plot the predicted odds versus the formatted scores. Visually verify that the target points and target odds match and that the points-to-double-the-odds (PDO) relationship holds.

```
ProbGood = 1-pd;
PredictedOdds = ProbGood./pd;
figure
scatter(Scores,PredictedOdds)
title('Predicted Odds vs. Score')
xlabel('Score')
ylabel('Predicted Odds')
hold on
```

```
xLimits = xlim;
yLimits = ylim;
% Target points and odds
plot([TargetPoints TargetPoints],[yLimits(1) TargetOdds],'k:')
plot([xLimits(1) TargetPoints],[TargetOdds Target0dds],'k:')
% Target points plus PDO
plot([TargetPoints+PDO TargetPoints+PDO],[yLimits(1) 2*TargetOdds],'k:')
plot([xLimits(1) TargetPoints+PDO],[2*TargetOdds 2*TargetOdds],'k:')
% Target points minus PDO
plot([TargetPoints-PDO TargetPoints-PDO],[yLimits(1) TargetOdds/2],'k:')
plot([xLimits(1) TargetPoints-PDO],[TargetOdds/2 TargetOdds/2],'k:')
hold off
```

## Step 7. Validate the credit scorecard model using the CAP, ROC, and Kolmogorov-Smirnov statistic

The creditscorecard class supports three validation methods, the Cumulative Accuracy Profile (CAP), the Receiver Operating Characteristic (ROC), and the KolmogorovSmirnov (K-S) statistic. For more information on CAP, ROC, and KS, see "Cumulative

Accuracy Profile (CAP)" on page 18-1718, "Receiver Operating Characteristic (ROC)" on page 18-1719, and "Kolmogorov-Smirnov statistic (KS) " on page 18-1719.

```
[Stats,T] = validatemodel(sc,'Plot',{'CAP','ROC', 'KS'});
disp(Stats)
disp(T(1:15,:))
```

| Measure |  | Value |
| :--- | :--- | :--- |
| 'Accuracy Ratio' |  |  |
| 'Area under ROC curve' | 0.32257 |  |
| 'KS statistic' | 0.66128 |  |
| 'KS score' | 515 |  |

| Scores | ProbDefault | TrueBads | FalseBads | TrueGoods | FalseGoods | Sensitivity | FalseAlarm | Pct0bs |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 368 | 0.7535 | 0 | 1 | 802 | 397 | 0 | 0.0012453 | 0.00083333 |
| 377 | 0.73107 | 1 | 1 | 802 | 396 | 0.0025189 | 0.0012453 | 0.0016667 |

## Introduction

This section focuses on using likelihood-based methods for multivariate normal regression. The parameters of the regression model are estimated via maximum likelihood estimation. For multiple series, this requires iteration until convergence. The complication due to the possibility of missing data is incorporated into the analysis with a variant of the EM algorithm known as the ECM algorithm.

The underlying theory of maximum likelihood estimation and the definition and significance of the Fisher information matrix can be found in Caines [1] and Cramér [2]. The underlying theory of the ECM algorithm can be found in Meng and Rubin [8] and Sexton and Swensen [9].

In addition, these two examples of maximum likelihood estimation are presented:

- "Portfolios with Missing Data" on page 9-26
- "Estimation of Some Technology Stock Betas" on page 9-35

## Multivariate Normal Linear Regression

Suppose that you have a multivariate normal linear regression model in the form

$$
\left[\begin{array}{c}
Z_{1} \\
\vdots \\
Z_{m}
\end{array}\right] \sim N\left(\left[\begin{array}{c}
H_{1} b \\
\vdots \\
H_{m} b
\end{array}\right],\left[\begin{array}{ccc}
C & & 0 \\
& \ddots & \\
0 & & C
\end{array}\right]\right)
$$

where the model has $m$ observations of $n$-dimensional random variables $\mathbf{Z}_{1}, \ldots, \mathbf{Z}_{m}$ with a linear regression model that has a $p$-dimensional model parameter vector $\mathbf{b}$. In addition, the model has a sequence of $m$ design matrices $\mathbf{H}_{1}, \ldots, \mathbf{H}_{m}$, where each design matrix is a known $n$-by- $p$ matrix.

Given a parameter vector $\mathbf{b}$ and a collection of design matrices, the collection of $m$ independent variables $\mathbf{Z}_{k}$ is assumed to have independent identically distributed multivariate normal residual errors $\mathbf{Z}_{k}-\mathbf{H}_{k} \mathbf{b}$ with $n$-vector mean $\mathbf{0}$ and n-by-n covariance matrix $\mathbf{C}$ for each $k=1, \ldots, m$.

A concise way to write this model is

$$
Z_{k} \sim N\left(H_{k} b, C\right)
$$

for $k=1, \ldots, m$.
The goal of multivariate normal regression is to obtain maximum likelihood estimates for $\mathbf{b}$ and $\mathbf{C}$ given a collection of $m$ observations $\mathbf{z}_{1}, \ldots, \mathbf{z}_{m}$ of the random variables $\mathbf{Z}_{1}, \ldots$, $\mathbf{Z}_{m}$. The estimated parameters are the $p$ distinct elements of $\mathbf{b}$ and the $n(n+1) / 2$ distinct elements of $\mathbf{C}$ (the lower-triangular elements of $\mathbf{C}$ ).

Note: Quasi-maximum likelihood estimation works with the same models but with a relaxation of the assumption of normally distributed residuals. In this case, however, the parameter estimates are asymptotically optimal.

## Maximum Likelihood Estimation

To estimate the parameters of the multivariate normal linear regression model using maximum likelihood estimation, it is necessary to maximize the log-likelihood function over the estimation parameters given observations $\mathbf{z}_{1}, \ldots, \mathbf{z}_{m}$.

Given the multivariate normal model to characterize residual errors in the regression model, the log-likelihood function is

$$
\begin{aligned}
L\left(z_{1}, \ldots, z_{m} ; b, C\right)= & \frac{1}{2} m n \log (2 \pi)+\frac{1}{2} m \log (\operatorname{det}(C)) \\
& +\frac{1}{2} \sum_{k=1}^{m}\left(z_{k}-H_{k} b\right)^{T} C^{-1}\left(z_{k}-H_{k} b\right) .
\end{aligned}
$$

Although the cross-sectional residuals must be independent, you can use this loglikelihood function for quasi-maximum likelihood estimation. In this case, the estimates for the parameters $\mathbf{b}$ and $\mathbf{C}$ provide estimates to characterize the first and second moments of the residuals. See Caines [1] for details.

Except for a special case (see "Special Case of Multiple Linear Regression Model" on page $9-4$ ), if both the model parameters in $\mathbf{b}$ and the covariance parameters in $\mathbf{C}$ are to be estimated, the estimation problem is intractably nonlinear and a solution must use iterative methods. Denote estimates for the parameters $\mathbf{b}$ and $\mathbf{C}$ for iteration $t=0,1, \ldots$ with the superscript notation $\mathbf{b}^{(t)}$ and $\mathbf{C}^{(t)}$.

Given initial estimates $\mathbf{b}^{(0)}$ and $\mathbf{C}^{(0)}$ for the parameters, the maximum likelihood estimates for $\mathbf{b}$ and $\mathbf{C}$ are obtained using a two-stage iterative process with

$$
b^{(t+1)}=\left(\sum_{k=1}^{m} H_{k}^{T}\left(C^{(t)}\right)^{-1} H_{k}\right)^{-1}\left(\sum_{k=1}^{m} H_{k}^{T}\left(C^{(t)}\right)^{-1} z_{k}\right)
$$

and

$$
C^{(t+1)}=\frac{1}{m} \sum_{k=1}^{m}\left(z_{k}-H_{k} b^{(t+1)}\right)\left(z_{k}-H_{k} b^{(t+1)}\right)^{T}
$$

for $t=0,1, \ldots$.

## Special Case of Multiple Linear Regression Model

The special case mentioned in "Maximum Likelihood Estimation" on page 9-3 occurs if $n=1$ so that the sequence of observations is a sequence of scalar observations. This model is known as a multiple linear regression model. In this case, the covariance matrix $\mathbf{C}$ is a 1-by-1 matrix that drops out of the maximum likelihood iterates so that a singlestep estimate for $\mathbf{b}$ and $\mathbf{C}$ can be obtained with converged estimates $\mathbf{b}^{(1)}$ and $\mathbf{C}^{(1)}$.

## Least-Squares Regression

Another simplification of the general model is called least-squares regression. If $\mathbf{b}^{(0)}=$ $\mathbf{0}$ and $\mathbf{C}^{(0)}=\mathbf{I}$, then $\mathbf{b}^{(1)}$ and $\mathbf{C}^{(1)}$ from the two-stage iterative process are least-squares estimates for $\mathbf{b}$ and $\mathbf{C}$, where

$$
b^{L S}=\left(\sum_{k=1}^{m} H_{k}^{T} H_{k}\right)^{-1}\left(\sum_{k=1}^{m} H_{k}^{T} z_{k}\right)
$$

and

$$
C^{L S}=\frac{1}{m} \sum_{k=1}^{m}\left(z_{k}-H_{k} b^{L S}\right)\left(z_{k}-H_{k} b^{L S}\right)^{T} .
$$

## Mean and Covariance Estimation

A final simplification of the general model is to estimate the mean and covariance of a sequence of $n$-dimensional observations $\mathbf{z}_{1}, \ldots, \mathbf{z}_{m}$. In this case, the number of series is equal to the number of model parameters with $n=p$ and the design matrices are identity matrices with $\mathbf{H}_{k}=\mathbf{I}$ for $i=1, \ldots, m$ so that $\mathbf{b}$ is an estimate for the mean and $\mathbf{C}$ is an estimate of the covariance of the collection of observations $\mathbf{z}_{1}, \ldots, \mathbf{z}_{m}$.

## Convergence

If the iterative process continues until the log-likelihood function increases by no more than a specified amount, the resultant estimates are said to be maximum likelihood estimates $\mathbf{b}^{M L}$ and $\mathbf{C}^{M L}$.

If $n=1$ (which implies a single data series), convergence occurs after only one iterative step, which, in turn, implies that the least-squares and maximum likelihood estimates are identical. If, however, $n>1$, the least-squares and maximum likelihood estimates are usually distinct.

In Financial Toolbox software, both the changes in the log-likelihood function and the norm of the change in parameter estimates are monitored. Whenever both changes fall
below specified tolerances (which should be something between machine precision and its square root), the toolbox functions terminate under an assumption that convergence has been achieved.

## Fisher Information

Since maximum likelihood estimates are formed from samples of random variables, their estimators are random variables; an estimate derived from such samples has an uncertainty associated with it. To characterize these uncertainties, which are called standard errors, two quantities are derived from the total log-likelihood function.

The Hessian of the total log-likelihood function is

$$
\nabla^{2} L\left(z_{1}, \ldots, z_{m} ; \theta\right)
$$

and the Fisher information matrix is

$$
I(\theta)=-E\left[\nabla^{2} L\left(z_{1}, \ldots, z_{m} ; \theta\right)\right]
$$

where the partial derivatives of the $\nabla^{2}$ operator are taken with respect to the combined parameter vector $\Theta$ that contains the distinct components of $\mathbf{b}$ and $\mathbf{C}$ with a total of $q=p$ $+n(n+1) / 2$ parameters.

Since maximum likelihood estimation is concerned with large-sample estimates, the central limit theorem applies to the estimates and the Fisher information matrix plays a key role in the sampling distribution of the parameter estimates. Specifically, maximum likelihood parameter estimates are asymptotically normally distributed such that

$$
\left(\theta^{(t)}-\theta\right) \sim N\left(0, I^{-1},\left(\theta^{(t)}\right)\right) \text { as } t \rightarrow \infty,
$$

where $\Theta$ is the combined parameter vector and $\Theta^{(t)}$ is the estimate for the combined parameter vector at iteration $t=0,1, \ldots$.

The Fisher information matrix provides a lower bound, called a Cramér-Rao lower bound, for the standard errors of estimates of the model parameters.

## Statistical Tests

Given an estimate for the combined parameter vector $\Theta$, the squared standard errors are the diagonal elements of the inverse of the Fisher information matrix

$$
s^{2}\left(\hat{\theta}_{i}\right)=\left(I^{-1}\left(\hat{\theta}_{i}\right)\right)_{i i}
$$

for $i=1, \ldots, q$.
Since the standard errors are estimates for the standard deviations of the parameter estimates, you can construct confidence intervals so that, for example, a $95 \%$ interval for each parameter estimate is approximately

$$
\hat{\theta}_{i} \pm 1.96 s\left(\hat{\theta}_{i}\right)
$$

for $i=1, \ldots, q$.
Error ellipses at a level-of-significance $\alpha \varepsilon[0,1]$ for the parameter estimates satisfy the inequality

$$
(\theta-\hat{\theta})^{T} I(\hat{\theta})(\theta-\hat{\theta}) \leq \chi_{1-\alpha, q}^{2}
$$

and follow a $\chi^{2}$ distribution with $q$ degrees-of-freedom. Similar inequalities can be formed for any subcollection of the parameters.

In general, given parameter estimates, the computed Fisher information matrix, and the log-likelihood function, you can perform numerous statistical tests on the parameters, the model, and the regression.

# Maximum Likelihood Estimation with Missing Data 

In this section...<br>"Introduction" on page 9-9<br>"ECM Algorithm" on page 9-10<br>"Standard Errors" on page 9-10<br>"Data Augmentation" on page 9-11<br>"Multivariate Normal Regression Functions" on page 9-12<br>"Multivariate Normal Regression Without Missing Data" on page 9-13<br>"Multivariate Normal Regression with Missing Data" on page 9-14<br>"Least-Squares Regression with Missing Data" on page 9-14<br>"Multivariate Normal Parameter Estimation with Missing Data" on page 9-15<br>"Support Functions" on page 9-15

## Introduction

Suppose that a portion of the sample data is missing, where missing values are represented as NaNs. If the missing values are missing-at-random and ignorable, where Little and Rubin [7] have precise definitions for these terms, it is possible to use a version of the Expectation Maximization, or EM, algorithm of Dempster, Laird, and Rubin [3] to estimate the parameters of the multivariate normal regression model. The algorithm used in Financial Toolbox software is the ECM (Expectation Conditional Maximization) algorithm of Meng and Rubin [8] with enhancements by Sexton and Swensen [9].

Each sample $\mathbf{z}_{k}$ for $k=1, \ldots, m$, is either complete with no missing values, empty with no observed values, or incomplete with both observed and missing values. Empty samples are ignored since they contribute no information.

To understand the missing-at-random and ignorabable conditions, consider an example of stock price data before an IPO. For a counterexample, censored data, in which all values greater than some cutoff are replaced with NaNs , does not satisfy these conditions.

In sample $k$, let $\mathbf{x}_{k}$ represent the missing values in $\mathbf{z}_{k}$, and $\mathbf{y}_{k}$ represent the observed values. Define a permutation matrix $\mathbf{P}_{\mathrm{k}}$ so that

$$
z_{k}=P_{k}\left[\begin{array}{c}
x_{k} \\
y_{k}
\end{array}\right]
$$

for $k=1, \ldots, m$.

## ECM Algorithm

The ECM algorithm has two steps - an E, or expectation step, and a CM, or conditional maximization, step. As with maximum likelihood estimation, the parameter estimates evolve according to an iterative process, where estimates for the parameters after $t$ iterations are denoted as $\mathbf{b}^{(t)}$ and $\mathbf{C}^{(t)}$.

The E step forms conditional expectations for the elements of missing data with

$$
\begin{aligned}
& E\left[X_{k} \mid Y_{k}=y_{k} ; b^{(t)}, C^{(t)}\right] \\
& \operatorname{cov}\left[X_{k} \mid Y_{k}=y_{k} ; b^{(t)}, C^{(t)}\right]
\end{aligned}
$$

for each sample $k \in\{1, \ldots, m\}$ that has missing data.
The CM step proceeds in the same manner as the maximum likelihood procedure without missing data. The main difference is that missing data moments are imputed from the conditional expectations obtained in the E step.

The E and CM steps are repeated until the log-likelihood function ceases to increase. One of the important properties of the ECM algorithm is that it is always guaranteed to find a maximum of the log-likelihood function and, under suitable conditions, this maximum can be a global maximum.

## Standard Errors

The negative of the expected Hessian of the log-likelihood function and the Fisher information matrix are identical if no data is missing. However, if data is missing, the Hessian, which is computed over available samples, accounts for the loss of information due to missing data. So, the Fisher information matrix provides standard errors that are a Cramér-Rao lower bound whereas the Hessian matrix provides standard errors that may be greater if there is missing data.

## Data Augmentation

The ECM functions do not "fill in" missing values as they estimate model parameters. In some cases, you may want to fill in the missing values. Although you can fill in the missing values in your data with conditional expectations, you would get optimistic and unrealistic estimates because conditional estimates are not random realizations.

Several approaches are possible, including resampling methods and multiple imputation (see Little and Rubin [7] and Shafer [10] for details). A somewhat informal sampling method for data augmentation is to form random samples for missing values based on the conditional distribution for the missing values. Given parameter estimates for $X \subset R^{n}$ and $\hat{C}$, each observation has moments

$$
E\left[Z_{k}\right]=H_{k} \hat{b}
$$

and

$$
\operatorname{cov}\left(Z_{k}\right)=H_{k} \hat{C} H_{k}^{T}
$$

for $k=1, \ldots, m$, where you have dropped the parameter dependence on the left sides for notational convenience.

For observations with missing values partitioned into missing values $\mathbf{X}_{k}$ and observed values $\mathbf{Y}_{k}=\mathbf{y}_{k}$, you can form conditional estimates for any subcollection of random variables within a given observation. Thus, given estimates $\boldsymbol{E}\left[\mathbf{Z}_{k}\right]$ and $\operatorname{cov}\left(\mathbf{Z}_{k}\right)$ based on the parameter estimates, you can create conditional estimates

$$
E\left[X_{k} \mid y_{k}\right]
$$

and

$$
\operatorname{cov}\left(X_{k} \mid y_{k}\right)
$$

using standard multivariate normal distribution theory. Given these conditional estimates, you can simulate random samples for the missing values from the conditional distribution

$$
X_{k} \sim N\left(E\left[X_{k} \mid y_{k}\right], \operatorname{cov}\left(X_{k} \mid y_{k}\right)\right)
$$

The samples from this distribution reflect the pattern of missing and nonmissing values for observations $k=1, \ldots, m$. You must sample from conditional distributions for each observation to preserve the correlation structure with the nonmissing values at each observation.

If you follow this procedure, the resultant filled-in values are random and generate mean and covariance estimates that are asymptotically equivalent to the ECM-derived mean and covariance estimates. Note, however, that the filled-in values are random and reflect likely samples from the distribution estimated over all the data and may not reflect "true" values for a particular observation.

## Multivariate Normal Regression Functions

Financial Toolbox software has a number of functions for multivariate normal regression with or without missing data. The toolbox functions solve four classes of regression problems with functions to estimate parameters, standard errors, log-likelihood functions, and Fisher information matrices. The four classes of regression problems are:

- "Multivariate Normal Regression Without Missing Data" on page 9-13
- "Multivariate Normal Regression with Missing Data" on page 9-14
- "Least-Squares Regression with Missing Data" on page 9-14
- "Multivariate Normal Parameter Estimation with Missing Data" on page 9-15

Additional support functions are also provided, see "Support Functions" on page 9-15.
In all functions, the MATLAB representation for the number of observations (or samples) is NumSamples $=m$, the number of data series is NumSeries $=n$, and the number of model parameters is NumParams $=p$. The moment estimation functions have NumSeries $=$ NumParams.

The collection of observations (or samples) is stored in a MATLAB matrix Data such that

$$
\operatorname{Data}(\mathrm{k},:)=z_{k}^{T}
$$

for k = 1, ..., NumSamples, where Data is a NumSamples-by-NumSeries matrix.

For the multivariate normal regression or least-squares functions, an additional required input is the collection of design matrices that is stored as either a MATLAB matrix or a vector of cell arrays denoted as Design.

If Numseries = 1, Design can be a NumSamples-by-NumParams matrix. This is the "standard" form for regression on a single data series.

If Numseries $=1$, Design can be either a cell array with a single cell or a cell array with NumSamples cells. Each cell in the cell array contains a NumSeries-by-NumParams matrix such that

$$
\operatorname{Design}\{\mathrm{k}\}=H_{k}
$$

for $k=1$, ..., NumSamples. If Design has a single cell, it is assumed to be the same Design matrix for each sample such that

$$
\operatorname{Design}\{1\}=H_{1}=\ldots=H_{m}
$$

Otherwise, Design must contain individual design matrices for each sample.
The main distinction among the four classes of regression problems depends upon how missing values are handled and where missing values are represented as the MATLAB value NaN . If a sample is to be ignored given any missing values in the sample, the problem is said to be a problem "without missing data." If a sample is to be ignored if and only if every element of the sample is missing, the problem is said to be a problem "with missing data" since the estimation must account for possible NaN values in the data.

In general, Data may or may not have missing values and Design should have no missing values. In some cases, however, if an observation in Data is to be ignored, the corresponding elements in Design are also ignored. Consult the function reference pages for details.

## Multivariate Normal Regression Without Missing Data

You can use the following functions for multivariate normal regression without missing data.
mvnrmle

Estimate model parameters, residuals, and the residual covariance.

| mvnrstd | Estimate standard errors of model and covariance <br> parameters. |
| :--- | :--- |
| mvnrfish | Estimate the Fisher information matrix. |
| mvnrobj | Calculate the log-likelihood function. |

The first two functions are the main estimation functions. The second two are supporting functions that can be used for more detailed analyses.

## Multivariate Normal Regression with Missing Data

You can use the following functions for multivariate normal regression with missing data.

| ecmmvnrmle | Estimate model parameters, residuals, and the residual <br> covariance. |
| :--- | :--- |
| ecmmvnrstd | Estimate standard errors of model and covariance <br> parameters. |
| ecmmvnrfish | Estimate the Fisher information matrix. <br> ecmmvnrobj |
| Calculate the log-likelihood function. |  |

The first two functions are the main estimation functions. The second two are supporting functions used for more detailed analyses.

## Least-Squares Regression with Missing Data

You can use the following functions for least-squares regression with missing data or for covariance-weighted least-squares regression with a fixed covariance matrix.

```
ecmlsrmle
ecmlsrobj
```

Estimate model parameters, residuals, and the residual covariance.
Calculate the least-squares objective function (pseudo log-likelihood).

To compute standard errors and estimates for the Fisher information matrix, the multivariate normal regression functions with missing data are used.
ecmmvnrstd
Estimate standard errors of model and covariance parameters.

## Multivariate Normal Parameter Estimation with Missing Data

You can use the following functions to estimate the mean and covariance of multivariate normal data.

```
ecmnmle Estimate the mean and covariance of the data.
ecmnstd
ecmnfish
ecmnhess
ecmnobj Calculate the log-likelihood function.
```

These functions behave slightly differently from the more general regression functions since they solve a specialized problem. Consult the function reference pages for details.

## Support Functions

Two support functions are included.

```
convert2sur Convert a multivariate normal regression model into an SUR model.
ecmninit Obtain initial estimates for the mean and covariance of a Data matrix.
```

The convert2sur function converts a multivariate normal regression model into a seemingly unrelated regression, or SUR, model. The second function ecmninit is a specialized function to obtain initial ad hoc estimates for the mean and covariance of a Data matrix with missing data. (If there are no missing values, the estimates are the maximum likelihood estimates for the mean and covariance.)

## Regressions

Each regression function has a specific operation. This section shows how to use these functions to perform specific types of regressions. To illustrate use of the functions for various regressions, "typical" usage is shown with optional arguments kept to a minimum. For a typical regression, you estimate model parameters and residual
covariance matrices with the mle functions and estimate the standard errors of model parameters with the std functions. The regressions "without missing data" essentially ignore samples with any missing values, and the regressions "with missing data" ignore samples with every value missing.

## Multivariate Normal Regression

Multivariate normal regression, or MVNR, is the "standard" implementation of the regression functions in Financial Toolbox software.

## Multivariate Normal Regression Without Missing Data

## Estimate Parameters

```
[Parameters, Covariance] = mvnrmle(Data, Design);
```

## Estimate Standard Errors

```
StdParameters = mvnrstd(Data, Design, Covariance);
```

## Multivariate Normal Regression with Missing Data

## Estimate Parameters

[Parameters, Covariance] = ecmmvnrmle(Data, Design);
Estimate Standard Errors
StdParameters = ecmmvnrstd(Data, Design, Covariance);

## Least-Squares Regression

Least-squares regression, or LSR, sometimes called ordinary least-squares or multiple linear regression, is the simplest linear regression model. It also enjoys the property that, independent of the underlying distribution, it is a best linear unbiased estimator (BLUE).

Given $m=$ NumSamples observations, the typical least-squares regression model seeks to minimize the objective function

$$
\sum_{k=1}^{m}\left(Z_{k}-H_{k} b\right)^{T}\left(Z_{k}-H_{k} b\right),
$$

which, within the maximum likelihood framework of the multivariate normal regression routine mvnrmle, is equivalent to a single-iteration estimation of just the parameters to obtain Parameters with the initial covariance matrix Covariance held fixed as the identity matrix. In the case of missing data, however, the internal algorithm to handle missing data requires a separate routine ecmlsrmle to do least-squares instead of multivariate normal regression.

## Least-Squares Regression Without Missing Data

Estimate Parameters

```
[Parameters, Covariance] = mvnrmle(Data, Design, 1);
```

Estimate Standard Errors
StdParameters = mvnrstd(Data, Design, Covariance);

## Least-Squares Regression with Missing Data

## Estimate Parameters

[Parameters, Covariance] = ecmlsrmle(Data, Design);
Estimate Standard Errors

```
StdParameters = ecmmvnrstd(Data, Design, Covariance);
```

## Covariance-Weighted Least Squares

Given $m=$ NUMSAMPLES observations, the typical covariance-weighted least squares, or CWLS, regression model seeks to minimize the objective function

$$
\sum_{k=1}^{m}\left(Z_{k}-H_{k} b\right)^{T} C_{0}\left(Z_{k}-H_{k} b\right)
$$

with fixed covariance $C_{0}$.
In most cases, $C_{0}$ is a diagonal matrix. The inverse matrix $W=C_{0}^{-1}$ has diagonal elements that can be considered relative "weights" for each series. Thus, CWLS is a form of weighted least squares with the weights applied across series.

## Covariance-Weighted Least Squares Without Missing Data

## Estimate Parameters

```
[Parameters, Covariance] = mvnrmle(Data, Design, 1, [], [], [], Covar0);
```

Estimate Standard Errors
StdParameters = mvnrstd(Data, Design, Covariance);

## Covariance-Weighted Least Squares with Missing Data

## Estimate Parameters

```
[Parameters, Covariance] = ecmlsrmle(Data, Design, [], [], [], [], Covar0);
```

## Estimate Standard Errors

```
StdParameters = ecmmvnrstd(Data, Design, Covariance);
```

## Feasible Generalized Least Squares

An ad hoc form of least squares that has surprisingly good properties for misspecified or nonnormal models is known as feasible generalized least squares, or FGLS. The basic procedure is to do least-squares regression and then to do covariance-weighted leastsquares regression with the resultant residual covariance from the first regression.

## Feasible Generalized Least Squares Without Missing Data

## Estimate Parameters

```
[Parameters, Covariance] = mvnrmle(Data, Design, 2, 0, 0);
```

or (to illustrate the FGLS process explicitly)
[Parameters, Covar0] = mvnrmle(Data, Design, 1);
[Parameters, Covariance] = mvnrmle(Data, Design, 1, [], [], [], Covaro)

Estimate Standard Errors

```
StdParameters = mvnrstd(Data, Design, Covariance);
```

# Feasible Generalized Least Squares with Missing Data 

Estimate Parameters<br>[Parameters, Covar0] = ecmlsrmle(Data, Design);<br>[Parameters, Covariance] = ecmlsrmle(Data, Design, [], [], [], [], Covar0)

Estimate Standard Errors
StdParameters = ecmmvnrstd(Data, Design, Covariance);

## Seemingly Unrelated Regression

Given a multivariate normal regression model in standard form with a Data matrix and a Design array, it is possible to convert the problem into a seemingly unrelated regression (SUR) problem by a simple transformation of the Design array. The main idea of SUR is that instead of having a common parameter vector over all data series, you have a separate parameter vector associated with each separate series or with distinct groups of series that, nevertheless, share a common residual covariance. It is this ability to aggregate and disaggregate series and to perform comparative tests on each design that is the power of SUR.

To make the transformation, use the function convert2sur, which converts a standardform design array into an equivalent design array to do SUR with a specified mapping of the series into NUMGROUPS groups. The regression functions are used in the usual manner, but with the SUR design array instead of the original design array. Instead of having NUMPARAMS elements, the SUR output parameter vector has NUMGROUPS of stacked parameter estimates, where the first NUMPARAMS elements of Parameters contain parameter estimates associated with the first group of series, the next NUMPARAMS elements of Parameters contain parameter estimates associated with the second group of series, and so on. If the model has only one series, for example, NUMSERIES $=1$, then the SUR design array is the same as the original design array since SUR requires two or more series to generate distinct parameter estimates.

Given NUMPARAMS parameters and NUMGROUPS groups with a parameter vector (Parameters) with NUMGROUPS * NUMPARAMS elements from any of the regression routines, the following MATLAB code fragment shows how to print a table of SUR parameter estimates with rows that correspond to each parameter and columns that correspond to each group or series:

```
fprintf(1,'Seemingly Unrelated Regression Parameter
    Estimates\n');
fprintf(1,' %7s ',' ');
fprintf(1,' Group(%3d) ',1:NumGroups);
fprintf(1,'\n');
for i = 1:NumParams
    fprintf(1,' %7d ',i);
    ii = i;
        for j = 1:NumGroups
            fprintf(1,'%12g ',Param(ii));
            ii = ii + NumParams;
            end
        fprintf(1,'\n');
end
fprintf(1,'\n');
```

## Seemingly Unrelated Regression Without Missing Data

Form an SUR Design
DesignSUR = convert2sur(Design, Group);
Estimate Parameters
[Parameters, Covariance] = mvnrmle(Data, DesignSUR);
Estimate Standard Errors
StdParameters = mvnrstd(Data, DesignSUR, Covariance);

## Seemingly Unrelated Regression with Missing Data

Form a SUR Design
DesignSUR = convert2sur(Design, Group);
Estimate Parameters
[Parameters, Covariance] = ecmmvnrmle(Data, DesignSUR);
Estimate Standard Errors
StdParameters = ecmmvnrstd(Data, DesignSUR, Covariance);

## Mean and Covariance Parameter Estimation

Without missing data, you can estimate the mean of your Data with the function mean and the covariance with the function cov. Nevertheless, the function ecmnmle does this for you if it detects an absence of missing values. Otherwise, it uses the ECM algorithm to handle missing values.

## Estimate Parameters

[Mean, Covariance] = ecmnmle(Data);
Estimate Standard Errors

```
StdMean = ecmnstd(Data, Mean, Covariance);
```

## Troubleshooting Multivariate Normal Regression

This section provides a few pointers to handle various technical and operational difficulties that might occur.

## Biased Estimates

If samples are ignored, the number of samples used in the estimation is less than NumSamples. Clearly the actual number of samples used must be sufficient to obtain estimates. In addition, although the model parameters Parameters (or mean estimates Mean) are unbiased maximum likelihood estimates, the residual covariance estimate Covariance is biased. To convert to an unbiased covariance estimate, multiply Covariance by
Count/(Count-1),
where Count is the actual number of samples used in the estimation with Count $\leq$ NumSamples. None of the regression functions perform this adjustment.

## Requirements

The regression functions, particularly the estimation functions, have several requirements. First, they must have consistent values for NumSamples, NumSeries, and NumParams. As a rule, the multivariate normal regression functions require

# Count $\times$ NumSeries $\leq \max \{$ NumParams, NumSeries $\times($ NumSeries +1$) / 2\}$ 

and the least-squares regression functions require
Count $\times$ NumSeries $\leq$ NumParams,
where Count is the actual number of samples used in the estimation with

Count $\leq$ NumSamples.

Second, they must have enough nonmissing values to converge. Third, they must have a nondegenerate covariance matrix.

Although some necessary and sufficient conditions can be found in the references, general conditions for existence and uniqueness of solutions in the missing-data case, do not exist. Nonconvergence is usually due to an ill-conditioned covariance matrix estimate, which is discussed in greater detail in "Nonconvergence" on page 9-25.

## Slow Convergence

Since worst-case convergence of the ECM algorithm is linear, it is possible to execute hundreds and even thousands of iterations before termination of the algorithm. If you are estimating with the ECM algorithm regularly with regular updates, you can use prior estimates as initial guesses for the next period's estimation. This approach often speeds up things since the default initialization in the regression functions sets the initial parameters $\mathbf{b}$ to zero and the initial covariance $\mathbf{C}$ to be the identity matrix.

Other ad hoc approaches are possible although most approaches are problem-dependent. In particular, for mean and covariance estimation, the estimation function ecmnmle uses a function ecmninit to obtain an initial estimate.

## Nonrandom Residuals

Simultaneous estimates for parameters $\mathbf{b}$ and covariances $\mathbf{C}$ require $\mathbf{C}$ to be positivedefinite. So, the general multivariate normal regression routines require nondegenerate residual errors. If you are faced with a model that has exact results, the least-squares routine ecmlsrmle still works, although it provides a least-squares estimate with a singular residual covariance matrix. The other regression functions fail.

## Nonconvergence

Although the regression functions are robust and work for most "typical" cases, they can fail to converge. The main failure mode is an ill-conditioned covariance matrix, where failures are either soft or hard. A soft failure wanders endlessly toward a nearly singular covariance matrix and can be spotted if the algorithm fails to converge after about 100 iterations. If MaxIterations is increased to 500 and display mode is initiated (with no output arguments), a typical soft failure looks like this.

This case, which is based on 20 observations of five assets with $30 \%$ of data missing, shows that the log-likelihood goes linearly to infinity as the likelihood function goes to 0 . In this case, the function converges but the covariance matrix is effectively singular with a smallest eigenvalue on the order of machine precision (eps).

For the function ecmnmle, a hard error looks like this:

[^0]```
    In ecmnmle at 140
??? Error using ==> ecmnmle
Full covariance not positive-definite in iteration 218.
```

From a practical standpoint, if in doubt, test your residual covariance matrix from the regression routines to ensure that it is positive-definite. This is important because a soft error has a matrix that appears to be positive-definite but actually has a near-zerovalued eigenvalue to within machine precision. To do this with a covariance estimate Covariance, use cond (Covariance), where any value greater than 1 /eps should be considered suspect.

If either type of failure occurs, however, note that the regression routine is indicating that something is probably wrong with the data. (Even with no missing data, two time series that are proportional to one another produce a singular covariance matrix.)

## Porffolios with Missing Data

This example illustrates how to use the missing data algorithms for portfolio optimization and for valuation. This example works with five years of daily total return data for 12 computer technology stocks, with 6 hardware and 6 software companies. The example estimates the mean and covariance matrix for these stocks, forms efficient frontiers with both a naïve approach and the ECM approach, and compares results.

You can run the example directly with ecmtechdemo.m.
1 Load the following data file:
load ecmtechdemo
This file contains these three quantities:

- Assets is a cell array of the tickers for the 12 stocks in the example.
- Data is a 1254 -by- 12 matrix of 1254 daily total returns for each of the 12 stocks.
- Dates is a 1254 -by- 1 column vector of the dates associated with the data.

The time period for the data extends from April 19, 2000 to April 18, 2005.
The sixth stock in Assets is Google (GOOG), which started trading on August 19, 2004. So, all returns before August 20, 2004 are missing and represented as NaNs. Also, Amazon (AMZN) had a few days with missing values scattered throughout the past five years.

2 A naïve approach to the estimation of the mean and covariance for these 12 assets is to eliminate all days that have missing values for any of the 12 assets. Use the function ecmninit with the nanskip option to do this.
[NaNMean, NaNCovar] = ecmninit(Data,'nanskip');
3 Contrast the result of this approach with using all available data and the function ecmnmle to compute the mean and covariance. First, call ecmnmle with no output arguments to establish that enough data is available to obtain meaningful estimates.
ecmnmle(Data);
The following figure shows that, even with almost $87 \%$ of the Google data being NaN values, the algorithm converges after only four iterations.

4 Estimate the mean and covariance as computed by ecmnmle.
[ECMMean, ECMCovar] = ecmnmle(Data)

5 Given estimates for the mean and covariance of asset returns derived from the naïve and ECM approaches, estimate portfolios, and associated expected returns and risks on the efficient frontier for both approaches.

```
[ECMRisk, ECMReturn, ECMWts] = portopt(ECMMean',ECMCovar,10);
[NaNRisk, NaNReturn, NaNWts] = portopt(NaNMean',NaNCovar,10);
```

6 Plot the results on the same graph to illustrate the differences.

```
figure(gcf)
plot(ECMRisk,ECMReturn,'-bo','MarkerFaceColor','b','MarkerSize', 3);
hold on
```

```
plot(NaNRisk,NaNReturn,'-ro','MarkerFaceColor','r','MarkerSize', 3);
title('\bfMean-Variance Efficient Frontiers under Various Assumptions');
legend('ECM','NaN','Location','SouthEast');
xlabel('\bfStd. Dev. of Returns');
ylabel('\bfMean of Returns');
hold off
```

7 Clearly, the naïve approach is optimistic about the risk-return trade-offs for this universe of 12 technology stocks. The proof, however, lies in the portfolio weights. To view the weights, enter

Assets
ECMWts
NaNWts
which generates

The naïve portfolios in NaNWts tend to favor Apple Computer (AAPL), which happened to do well over the period from the Google IPO to the end of the estimation period, while the ECM portfolios in ECMWts tend to underweight Apple Computer and to recommend increased weights in Google relative to the naïve weights.
8 To evaluate the impact of estimation error and, in particular, the effect of missing data, use ecmnstd to calculate standard errors. Although it is possible to estimate the standard errors for both the mean and covariance, the standard errors for the mean estimates alone are usually the main quantities of interest.
```

StdMeanF = ecmnstd(Data,ECMMean,ECMCovar,'fisher');

```

9 Calculate standard errors that use the data-generated Hessian matrix (which accounts for the possible loss of information due to missing data) with the option HESSIAN.

StdMeanH = ecmnstd(Data,ECMMean,ECMCovar,'hessian');
The difference in the standard errors shows the increase in uncertainty of estimation of asset expected returns due to missing data. This can be viewed by entering:

Assets
StdMeanH \({ }^{\prime}\)
StdMeanF'
StdMeanH' - StdMeanF'
The two assets with missing data, AMZN and GOOG, are the only assets to have differences due to missing information.

\section*{Introduction}

The Capital Asset Pricing Model (CAPM) is a venerable but often maligned tool to characterize comovements between asset and market prices. Although many issues arise in CAPM implementation and interpretation, one problem that practitioners face is to estimate the coefficients of the CAPM with incomplete stock price data.

This example shows how to use the missing data regression functions to estimate the coefficients of the CAPM. You can run the example directly using CAPMdemo.m located at matlabroot/toolbox/finance/findemos.

\section*{Capital Asset Pricing Model}

Given a host of assumptions that can be found in the references (see Sharpe [11], Lintner [6], Jarrow [5], and Sharpe, et. al. [12]), the CAPM concludes that asset returns have a linear relationship with market returns. Specifically, given the return of all stocks that constitute a market denoted as \(M\) and the return of a riskless asset denoted as \(C\), the CAPM states that the return of each asset \(R_{\mathrm{i}}\) in the market has the expectational form
\[
E\left[R_{i}\right]=\alpha_{i}+C+\beta_{i}(E[M]-C)
\]
for assets \(i=1, \ldots, n\), where \(\beta_{i}\) is a parameter that specifies the degree of comovement between a given asset and the underlying market. In other words, the expected return of each asset is equal to the return on a riskless asset plus a risk-adjusted expected market return net of riskless asset returns. The collection of parameters \(\beta_{1}, \ldots, \beta_{n}\) is called asset betas.

The beta of an asset has the form
\[
\beta_{i}=\frac{\operatorname{cov}\left(R_{i}, M\right)}{\operatorname{var}(M)},
\]
which is the ratio of the covariance between asset and market returns divided by the variance of market returns. If an asset has a beta \(=1\), the asset is said to move with the market; if an asset has a beta \(>1\), the asset is said to be more volatile than the market. Conversely, if an asset has a beta \(<1\), the asset is said to be less volatile than the market.

\section*{Estimation of the CAPM}

The standard CAPM model is a linear model with additional parameters for each asset to characterize residual errors. For each of \(n\) assets with \(m\) samples of observed asset returns \(R_{k, i}\), market returns \(M_{k}\), and riskless asset returns \(C_{k}\), the estimation model has the form
\[
R_{k, i}=\alpha_{i}+C_{k}+\beta_{i}\left(M_{k}-C_{k}\right)+V_{k, i}
\]
for samples \(k=1, \ldots, m\) and assets \(i=1, \ldots, n\), where \(\alpha_{i}\) is a parameter that specifies the nonsystematic return of an asset, \(\beta_{i}\) is the asset beta, and \(V_{k, i}\) is the residual error for each asset with associated random variable \(V_{i}\).

The collection of parameters \(a_{1}, \ldots, a_{n}\) are called asset alphas. The strict form of the CAPM specifies that alphas must be zero and that deviations from zero are the result of temporary disequilibria. In practice, however, assets may have nonzero alphas, where much of active investment management is devoted to the search for assets with exploitable nonzero alphas.

To allow for the possibility of nonzero alphas, the estimation model generally seeks to estimate alphas and to perform tests to determine if the alphas are statistically equal to zero.

The residual errors \(V_{i}\) are assumed to have moments
\[
E\left[V_{i}\right]=0
\]
and
\[
E\left[V_{i} V_{j}\right]=S_{i j}
\]
for assets \(i, j=1, \ldots, n\), where the parameters \(S_{11}, \ldots, S_{n n}\) are called residual or nonsystematic variances/covariances.

The square root of the residual variance of each asset, for example, \(\operatorname{sqrt}\left(S_{i i}\right)\) for \(i=1, \ldots, n\), is said to be the residual or nonsystematic risk of the asset since it characterizes the residual variation in asset prices that are not explained by variations in market prices.

\section*{Estimation with Missing Data}

Although betas can be estimated for companies with sufficiently long histories of asset returns, it is difficult to estimate betas for recent IPOs. However, if a collection of sufficiently observable companies exists that can be expected to have some degree of correlation with the new company's stock price movements, that is, companies within the same industry as the new company, it is possible to obtain imputed estimates for new company betas with the missing-data regression routines.

\section*{Estimation of Some Technology Stock Betas}

To illustrate how to use the missing-data regression routines, estimate betas for 12 technology stocks, where a single stock (GOOG) is an IPO.

1 Load dates, total returns, and ticker symbols for the 12 stocks from the MAT-file CAPMuniverse.
```

load CAPMuniverse
whos Assets Data Dates

| Name | Size | Bytes | Class |
| :--- | ---: | ---: | :--- |
|  |  |  |  |
| Assets | $1 \times 14$ | 952 | cell array |
| Data | $1471 \times 14$ | 164752 | double array |
| Dates | $1471 \times 1$ | 11768 | double array |

Grand total is 22135 elements using 177472 bytes

```

The assets in the model have the following symbols, where the last two series are proxies for the market and the riskless asset:
```

Assets(1:7)
Assets(8:14)

```

The data covers the period from January 1, 2000 to November 7, 2005 with daily total returns. Two stocks in this universe have missing values that are represented by NaNs. One of the two stocks had an IPO during this period and, so, has significantly less data than the other stocks.
2 Compute separate regressions for each stock, where the stocks with missing data have estimates that reflect their reduced observability.
```

[NumSamples, NumSeries] = size(Data);
NumAssets = NumSeries - 2;
StartDate = Dates(1);
EndDate = Dates(end);
fprintf(1,'Separate regressions with ');
fprintf(1,'daily total return data from %s to %S ...\n', ...
datestr(StartDate,1), datestr(EndDate,1));
fprintf(1,' %4s %-20s %-20s %-20s\n','','Alpha','Beta','Sigma');
fprintf(1,' ---- ------------------- ');
fprintf(1, '------------------ -------------------------- n');
for i = 1:NumAssets
% Set up separate asset data and design matrices
TestData = zeros(NumSamples,1);
TestDesign = zeros(NumSamples,2);
TestData(:) = Data(:,i) - Data(:,14);
TestDesign(:,1) = 1.0;
TestDesign(:,2) = Data(:,13) - Data(:,14);
% Estimate CAPM for each asset separately
[Param, Covar] = ecmmvnrmle(TestData, TestDesign);
% Estimate ideal standard errors for covariance parameters
[StdParam, StdCovar] = ecmmvnrstd(TestData, TestDesign, ...
Covar, 'fisher');
% Estimate sample standard errors for model parameters
StdParam = ecmmvnrstd(TestData, TestDesign, Covar, 'hessian');
% Set up results for output
Alpha = Param(1);
Beta = Param(2);
Sigma = sqrt(Covar);
StdAlpha = StdParam(1);

```
```

    StdBeta = StdParam(2);
    StdSigma = sqrt(StdCovar);
    % Display estimates
fprintf(' %4s %9.4f (%8.4f) %9.4f (%8.4f) %9.4f (%8.4f)\n', ...
Assets{i},Alpha(1),abs(Alpha(1)/StdAlpha(1)), ...
Beta(1),abs(Beta(1)/StdBeta(1)),Sigma(1),StdSigma(1));
end

```

This code fragment generates the following table.
\begin{tabular}{|c|c|c|c|c|c|c|}
\hline & Alpha & & Beta & & Sigma & \\
\hline AAPL & 0.0012 & ( 1.3882) & 1.2294 & ( 17.1839) & 0.0322 & \(0.0062)\) \\
\hline AMZN & 0.0006 & ( 0.5326) & 1.3661 & ( 13.6579) & 0.0449 & \(0.0086)\) \\
\hline CSCO & -0.0002 & ( 0.2878) & 1.5653 & ( 23.6085) & 0.0298 & \(0.0057)\) \\

\hline IBM & -0.0000 & ( 0.0312) & 1.0807 & ( 28.7576) & 0.0169 & \(0.0032)\) \\
\hline INTC & 0.0001 & ( 0.1608) & 1.6002 & ( 27.3684) & 0.0263 & \(0.0050)\) \\
\hline MSFT & -0.0002 & ( 0.4871) & 1.1765 & ( 27.4554) & 0.0193 & \(0.0037)\) \\
\hline ORCL & 0.0000 & ( 0.0389) & 1.5010 & ( 21.1855) & 0.0319 & \(0.0061)\) \\
\hline YHOO & 0.0001 & ( 0.1282) & 1.6543 & ( 19.3838) & 0.0384 & ( 0.0074) \\
\hline
\end{tabular}

The Alpha column contains alpha estimates for each stock that are near zero as expected. In addition, the \(t\)-statistics (which are enclosed in parentheses) generally reject the hypothesis that the alphas are nonzero at the \(99.5 \%\) level of significance.

The Beta column contains beta estimates for each stock that also have t-statistics enclosed in parentheses. For all stocks but GOOG, the hypothesis that the betas are nonzero is accepted at the \(99.5 \%\) level of significance. It seems, however, that GOOG does not have enough data to obtain a meaningful estimate for beta since its \(t\)-statistic would imply rejection of the hypothesis of a nonzero beta.

The Sigma column contains residual standard deviations, that is, estimates for nonsystematic risks. Instead of t-statistics, the associated standard errors for the residual standard deviations are enclosed in parentheses.

\section*{Grouped Estimation of Some Technology Stock Betas}

To estimate stock betas for all 12 stocks, set up a joint regression model that groups all 12 stocks within a single design. (Since each stock has the same design matrix, this model is actually an example of seemingly unrelated regression.) The routine to
estimate model parameters is ecmmvnrmle, and the routine to estimate standard errors is ecmmvnrstd.

Because GOOG has a significant number of missing values, a direct use of the missing data routine ecmmvnrmle takes 482 iterations to converge. This can take a long time to compute. For the sake of brevity, the parameter and covariance estimates after the first 480 iterations are contained in a MAT-file and are used as initial estimates to compute stock betas.
```

load CAPMgroupparam
whos Param0 Covar0

| Name | Size | Bytes | Class |
| :--- | :--- | ---: | :--- |
| Covaro | $12 \times 12$ | 1152 | double array |
| Param0 | $24 \times 1$ | 192 | double array |
| Grand total is 168 elements using | 1344 bytes |  |  |

```

Now estimate the parameters for the collection of 12 stocks.
```

fprintf(1,'\n');
fprintf(1,'Grouped regression with ');
fprintf(1,'daily total return data from %s to %s ...\n', ...
datestr(StartDate,1), datestr(EndDate,1));
fprintf(1,' %4s %-20s %-20s %-20s\n','','Alpha','Beta','Sigma');
fprintf(1,' ---- -------------------' ');
fprintf(1,'-----------------------------------------------
NumParams = 2 * NumAssets;
% Set up grouped asset data and design matrices
TestData = zeros(NumSamples, NumAssets);
TestDesign = cell(NumSamples, 1);
Design = zeros(NumAssets, NumParams);
for k = 1:NumSamples
for i = 1:NumAssets

\hline IBM & -0.0000 & ( 0.0312) & 1.0807 & ( 28.7576) & 0.0169 & \(0.0032)\) \\
\hline INTC & 0.0001 & ( 0.1608) & 1.6002 & ( 27.3684) & 0.0263 & \(0.0050)\) \\
\hline MSFT & -0.0002 & ( 0.4871) & 1.1765 & ( 27.4554) & 0.0193 & \(0.0037)\) \\
\hline ORCL & 0.0000 & ( 0.0389) & 1.5010 & ( 21.1855) & 0.0319 & \(0.0061)\) \\
\hline YHOO & 0.0001 & ( 0.1282) & 1.6543 & ( 19.3838) & 0.0384 & ( 0.0074) \\
\hline
\end{tabular}

Although the results for complete-data stocks are the same, the beta estimates for AMZN and GOOG (the two stocks with missing values) are different from the estimates derived for each stock separately. Since AMZN has few missing values, the differences in the estimates are small. With GOOG, however, the differences are more pronounced.

The t-statistic for the beta estimate of GOOG is now significant at the \(99.5 \%\) level of significance. However, the t-statistics for beta estimates are based on standard errors from the sample Hessian which, in contrast to the Fisher information matrix, accounts for the increased uncertainty in an estimate due to missing values. If the \(t\)-statistic is obtained from the more optimistic Fisher information matrix, the t-statistic for GOOG is 8.25. Thus, despite the increase in uncertainty due to missing data, GOOG nonetheless has a statistically significant estimate for beta.

Finally, note that the beta estimate for GOOG is 0.62 - a value that may require some explanation. Although the market has been volatile over this period with sideways price movements, GOOG has steadily appreciated in value. So, it is less tightly correlated with the market, implying that it is less volatile than the market (beta < 1).

\section*{Introduction}

This section shows how Financial Toolbox functions solve real-world problems. The examples ship with the toolbox as MATLAB files. Try them by entering the commands directly or by executing the code.

This section contains two major topics:
- A demonstration of how Financial Toolbox solves real-world financial problems, specifically:
- "Sensitivity of Bond Prices to Interest Rates" on page 10-3
- "Bond Portfolio for Hedging Duration and Convexity" on page 10-7
- "Bond Prices and Yield Curve Parallel Shifts" on page 10-10
- "Greek-Neutral Portfolios of European Stock Options" on page 10-18
- "Term Structure Analysis and Interest-Rate Swaps" on page 10-22
- "Producing Graphics with the Toolbox" on page 10-26

Shows how the toolbox produces presentation-quality graphics by solving these problems:
- "Plotting an Efficient Frontier" on page 10-26
- "Plotting Sensitivities of an Option" on page 10-30
- "Plotting Sensitivities of a Portfolio of Options" on page 10-31

\section*{Sensitivity of Bond Prices to Interest Rates}

Macaulay and modified duration measure the sensitivity of a bond's price to changes in the level of interest rates. Convexity measures the change in duration for small shifts in the yield curve, and thus measures the second-order price sensitivity of a bond. Both measures can gauge the vulnerability of a bond portfolio's value to changes in the level of interest rates.

Alternatively, analysts can use duration and convexity to construct a bond portfolio that is partly hedged against small shifts in the term structure. If you combine bonds in a portfolio whose duration is zero, the portfolio is insulated, to some extent, against interest rate changes. If the portfolio convexity is also zero, this insulation is even better. However, since hedging costs money or reduces expected return, you must know how much protection results from hedging duration alone compared to hedging both duration and convexity.

This example demonstrates a way to analyze the relative importance of duration and convexity for a bond portfolio using some of the SIA-compliant bond functions in Financial Toolbox software. Using duration, it constructs a first-order approximation of the change in portfolio price to a level shift in interest rates. Then, using convexity, it calculates a second-order approximation. Finally, it compares the two approximations with the true price change resulting from a change in the yield curve.

\section*{Step 1}

Define three bonds using values for the settlement date, maturity date, face value, and coupon rate. For simplicity, accept default values for the coupon payment periodicity (semiannual), end-of-month payment rule (rule in effect), and day-count basis (actual/ actual). Also, synchronize the coupon payment structure to the maturity date (no odd first or last coupon dates). Any inputs for which defaults are accepted are set to empty matrices ([ ]) as placeholders where appropriate.
```

Settle = '19-Aug-1999';
Maturity = ['17-Jun-2010'; '09-Jun-2015'; '14-May-2025'];
Face = [100; 100; 1000];
CouponRate = [0.07; 0.06; 0.045];

```

Also, specify the yield curve information.
```

Yields = [0.05; 0.06; 0.065];

```

\section*{Step 2}

Use Financial Toolbox functions to calculate the price, modified duration in years, and convexity in years of each bond.

The true price is quoted (clean) price plus accrued interest.
```

[CleanPrice, AccruedInterest] = bndprice(Yields, CouponRate,...
Settle, Maturity, 2, 0, [], [], [], [], [], Face);
Durations = bnddury(Yields, CouponRate, Settle, Maturity, 2, 0,...
[], [], [], [], [], Face);
Convexities = bndconvy(Yields, CouponRate, Settle, Maturity, 2, 0,...
[], [], [], [], [], Face);
Prices = CleanPrice + AccruedInterest;

```

\section*{Step 3}

Choose a hypothetical amount by which to shift the yield curve (here, 0.2 percentage point or 20 basis points).
```

dY = 0.002;

```

Weight the three bonds equally, and calculate the actual quantity of each bond in the portfolio, which has a total value of \(\$ 100,000\).
```

PortfolioPrice = 100000;
PortfolioWeights = ones(3,1)/3;
PortfolioAmounts = PortfolioPrice * PortfolioWeights ./ Prices;

```

\section*{Step 4}

Calculate the modified duration and convexity of the portfolio. The portfolio duration or convextity is a weighted average of the durations or convexities of the individual bonds. Calculate the first- and second-order approximations of the percent price change as a function of the change in the level of interest rates.
```

PortfolioDuration = PortfolioWeights' * Durations;
PortfolioConvexity = PortfolioWeights' * Convexities;
PercentApprox1 = -PortfolioDuration * dY * 100;
PercentApprox2 = PercentApprox1 + ...
PortfolioConvexity*dY^2*100/2.0;

```

\section*{Step 5}

Estimate the new portfolio price using the two estimates for the percent price change.
```

PriceApprox1 = PortfolioPrice + ...
PercentApprox1 * PortfolioPrice/100;
PriceApprox2 = PortfolioPrice + ...
PercentApprox2 * PortfolioPrice/100;

```

\section*{Step 6}

Calculate the true new portfolio price by shifting the yield curve.
```

[CleanPrice, AccruedInterest] = bndprice(Yields + dY,...
CouponRate, Settle, Maturity, 2, 0, [], [], [], [], [],...
Face);
NewPrice = PortfolioAmounts' * (CleanPrice + AccruedInterest);

```

\section*{Step 7}

Compare the results. The analysis results are as follows:
- The original portfolio price was \(\$ 100,000\).
- The yield curve shifted up by 0.2 percentage point or 20 basis points.
- The portfolio duration and convexity are 10.3181 and 157.6346 , respectively. These are needed for "Bond Portfolio for Hedging Duration and Convexity" on page 10-7.
- The first-order approximation, based on modified duration, predicts the new portfolio price (PriceApprox1), which is \(\$ 97,936.37\).
- The second-order approximation, based on duration and convexity, predicts the new portfolio price (PriceApprox2), which is \(\$ 97,967.90\).
- The true new portfolio price (NewPrice) for this yield curve shift is \(\$ 97,967.51\).
- The estimate using duration and convexity is good (at least for this fairly small shift in the yield curve), but only slightly better than the estimate using duration alone. The importance of convexity increases as the magnitude of the yield curve shift increases. Try a larger shift (dY) to see this effect.

The approximation formulas in this example consider only parallel shifts in the term structure, because both formulas are functions of dY , the change in yield. The formulas are not well-defined unless each yield changes by the same amount. In actual financial markets, changes in yield curve level typically explain a substantial portion of bond price movements. However, other changes in the yield curve, such as slope, may also be important and are not captured here. Also, both formulas give local approximations whose accuracy deteriorates as dY increases in size. You can demonstrate this by running the program with larger values of \(d Y\).

\section*{Bond Portfolio for Hedging Duration and Convexity}

This example constructs a bond portfolio to hedge the portfolio of "Sensitivity of Bond Prices to Interest Rates" on page 10-3. It assumes a long position in (holding) the portfolio, and that three other bonds are available for hedging. It chooses weights for these three other bonds in a new portfolio so that the duration and convexity of the new portfolio match those of the original portfolio. Taking a short position in the new portfolio, in an amount equal to the value of the first portfolio, partially hedges against parallel shifts in the yield curve.

Recall that portfolio duration or convexity is a weighted average of the durations or convexities of the individual bonds in a portfolio. As in the previous example, this example uses modified duration in years and convexity in years. The hedging problem therefore becomes one of solving a system of linear equations, which is an easy to do in MATLAB software.

\section*{Step 1}

Define three bonds available for hedging the original portfolio. Specify values for the settlement date, maturity date, face value, and coupon rate. For simplicity, accept default values for the coupon payment periodicity (semiannual), end-of-month payment rule (rule in effect), and day-count basis (actual/actual). Also, synchronize the coupon payment structure to the maturity date (that is, no odd first or last coupon dates). Set any inputs for which defaults are accepted to empty matrices ([ ]) as placeholders where appropriate. The intent is to hedge against duration and convexity and constrain total portfolio price.
```

Settle = '19-Aug-1999';
Maturity = ['15-Jun-2005'; '02-Oct-2010'; '01-Mar-2025'];
Face = [500; 1000; 250];
CouponRate = [0.07; 0.066; 0.08];

```

Also, specify the yield curve for each bond.
```

Yields = [0.06; 0.07; 0.075];

```

\section*{Step 2}

Use Financial Toolbox functions to calculate the price, modified duration in years, and convexity in years of each bond.

The true price is quoted (clean price plus accrued interest.
```

[CleanPrice, AccruedInterest] = bndprice(Yields,CouponRate,...
Settle, Maturity, 2, 0, [], [], [], [], [], Face);
Durations = bnddury(Yields, CouponRate, Settle, Maturity,...
2, 0, [], [], [], [], [], Face);
Convexities = bndconvy(Yields, CouponRate, Settle,...
Maturity, 2, 0, [], [], [], [], [], Face);
Prices = CleanPrice + AccruedInterest;

```

\section*{Step 3}

Set up and solve the system of linear equations whose solution is the weights of the new bonds in a new portfolio with the same duration and convexity as the original portfolio. In addition, scale the weights to sum to 1 ; that is, force them to be portfolio weights. You can then scale this unit portfolio to have the same price as the original portfolio. Recall that the original portfolio duration and convexity are 10.3181 and 157.6346, respectively. Also, note that the last row of the linear system ensures that the sum of the weights is unity.

A = [Durations'
Convexities'
1 1];
b \(=\) [ 10.3181
157.6346

1];
Weights = \(\mathrm{A} \backslash \mathrm{b}\);

\section*{Step 4}

Compute the duration and convexity of the hedge portfolio, which should now match the original portfolio.
```

PortfolioDuration = Weights' * Durations;
PortfolioConvexity = Weights' * Convexities;

```

\section*{Step 5}

Finally, scale the unit portfolio to match the value of the original portfolio and find the number of bonds required to insulate against small parallel shifts in the yield curve.

PortfolioValue = 100000;
HedgeAmounts = Weights ./ Prices * PortfolioValue;

\section*{Step 6}

Compare the results.
- As required, the duration and convexity of the new portfolio are 10.3181 and 157.6346, respectively.
- The hedge amounts for bonds 1,2 , and 3 are \(-57.37,71.70\), and 216.27, respectively.

Notice that the hedge matches the duration, convexity, and value \((\$ 100,000)\) of the original portfolio. If you are holding that first portfolio, you can hedge by taking a short position in the new portfolio.

Just as the approximations of the first example are appropriate only for small parallel shifts in the yield curve, the hedge portfolio is appropriate only for reducing the impact of small level changes in the term structure.

\section*{Bond Prices and Yield Curve Parallel Shifts}

Often bond portfolio managers want to consider more than just the sensitivity of a portfolio's price to a small shift in the yield curve, particularly if the investment horizon is long. This example shows how MATLAB software can help you to visualize the price behavior of a portfolio of bonds over a wide range of yield curve scenarios, and as time progresses toward maturity.

This example uses Financial Toolbox bond pricing functions to evaluate the impact of time-to-maturity and yield variation on the price of a bond portfolio. It plots the portfolio value and shows the behavior of bond prices as yield and time vary.

\section*{Step 1}

Specify values for the settlement date, maturity date, face value, coupon rate, and coupon payment periodicity of a four-bond portfolio. For simplicity, accept default values for the end-of-month payment rule (rule in effect) and day-count basis (actual/actual). Also, synchronize the coupon payment structure to the maturity date (no odd first or last coupon dates). Any inputs for which defaults are accepted are set to empty matrices ([ ]) as placeholders where appropriate.
```

Settle = '15-Jan-1995';
Maturity = datenum(['03-Apr-2020'; '14-May-2025'; ...
'09-Jun-2019'; '25-Feb-2019']);
Face = [1000; 1000; 1000; 1000];
CouponRate = [0; 0.05; 0; 0.055];
Periods = [0; 2; 0; 2];

```

Also, specify the points on the yield curve for each bond.
```

Yields = [0.078; 0.09; 0.075; 0.085];

```

\section*{Step 2}

Use Financial Toolbox functions to calculate the true bond prices as the sum of the quoted price plus accrued interest.
```

[CleanPrice, AccruedInterest] = bndprice(Yields,...
CouponRate,Settle, Maturity, Periods,...
[], [], [], [], [], [], Face);

```
```

Prices = CleanPrice + AccruedInterest;

```

\section*{Step 3}

Assume that the value of each bond is \(\$ 25,000\), and determine the quantity of each bond such that the portfolio value is \(\$ 100,000\).

BondAmounts = 25000 ./ Prices;

\section*{Step 4}

Compute the portfolio price for a rolling series of settlement dates over a range of yields. The evaluation dates occur annually on January 15, beginning on 15-Jan-1995 (settlement) and extending out to \(15-\mathrm{Jan}-2018\). Thus, this step evaluates portfolio price on a grid of time of progression (dT) and interest rates (dY).
```

dy = -0.05:0.005:0.05; % Yield changes
D = datevec(Settle); % Get date components
dt = datenum(D(1):2018, D(2), D(3)); % Get evaluation dates
[dT, dY] = meshgrid(dt, dy); % Create grid
NumTimes = length(dt); % Number of time steps
NumYields = length(dy); % Number of yield changes
NumBonds = length(Maturity); % Number of bonds
% Preallocate vector
Prices = zeros(NumTimes*NumYields, NumBonds);

```

Now that the grid and price vectors have been created, compute the price of each bond in the portfolio on the grid one bond at a time.
```

for i = 1:NumBonds
[CleanPrice, AccruedInterest] = bndprice(Yields(i)+...
dY(:), CouponRate(i), dT(:), Maturity(i), Periods(i),...
[], [], [], [], [], [], Face(i));
Prices(:,i) = CleanPrice + AccruedInterest;
end

```

Scale the bond prices by the quantity of bonds.
```

Prices = Prices * BondAmounts;

```

Reshape the bond values to conform to the underlying evaluation grid.
```

Prices = reshape(Prices, NumYields, NumTimes);

```

\section*{Step 5}

Plot the price of the portfolio as a function of settlement date and a range of yields, and as a function of the change in yield (dY). This plot illustrates the interest rate sensitivity of the portfolio as time progresses (dT), under a range of interest rate scenarios. With the following graphics commands, you can visualize the three-dimensional surface relative to the current portfolio value (that is, \(\$ 100,000\) ).
```

figure % Open a new figure window
surf(dt, dy, Prices) % Draw the surface

```

Add the base portfolio value to the existing surface plot.
```

hold on % Add the current value for reference
basemesh = mesh(dt, dy, 100000*ones(NumYields, NumTimes));

```

Make it transparent, plot it so the price surface shows through, and draw a box around the plot.
```

set(basemesh, 'facecolor', 'none');
set(basemesh, 'edgecolor', 'm');
set(gca, 'box', 'on');

```

Plot the \(x\)-axis using two-digit year (YY format) labels for ticks.
```

dateaxis('x', 11);

```

Add axis labels and set the three-dimensional viewpoint. MATLAB produces the figure.
```

xlabel('Evaluation Date (YY Format)');
ylabel('Change in Yield');
zlabel('Portfolio Price');
hold off
view(-25,25);

```

MATLAB three-dimensional graphics allow you to visualize the interest rate risk experienced by a bond portfolio over time. This example assumed parallel shifts in the term structure, but it might similarly have allowed other components to vary, such as the level and slope.

\section*{Bond Prices and Yield Curve Nonparallel Shifts}

Key rate duration enables you to determine the sensitivity of the price of a bond to nonparallel shifts in the yield curve. This example uses bndkrdur to construct a portfolio to hedge the interest rate risk of a U.S. Treasury bond maturing in 20 years.
```

Settle = datenum('2-Dec-2008');
CouponRate = 5.500/100;
Maturity = datenum('15-Aug-2028');
Price = 128.68;

```

The interest rate risk of this bond is hedged with the following four on-the-run Treasury bonds:

The 30-year bond.
```

Maturity_30 = datenum('15-May-2038');
Coupon_30 = .045;
Price_30 = 124.69;

```

The 10-year note.
```

Maturity_10 = datenum('15-Nov-2018');
Coupon_10 = .0375;
Price_10 = 109.35;

```

The five-year note.
```

Maturity_05 = datenum('30-Nov-2013');
Coupon_05 = .02;
Price_05 = 101.67;

```

The two-year note.
```

Maturity 02 = datenum('30-Nov-2010');
Coupon_02 = .01250;
Price_02 = 100.72;

```

You can get the Treasury spot or zero curve from: http://www.treas.gov/offices/domestic-finance/debt-management/interest-rate/yield.shtml.
```

ZeroDates = daysadd(Settle,[30 90 180 360 360*2 360*3 360*5 ...
360*7 360*10 360*20 360*30]);
ZeroRates = ([0.09 0.07 0.44 0.81 0.90 1.16 1.71 2.13 2.72 3.51 3.22]/100)';

```

\section*{Step 1}

Compute the key rate durations for both the bond and the hedging portfolio:
```

BondKRD = bndkrdur([ZeroDates ZeroRates], CouponRate, Settle,...
Maturity,'keyrates',[2 5 10 20]);
HedgeMaturity = [Maturity_02;Maturity_05;Maturity_10;Maturity_30];
HedgeCoupon = [Coupon_02;Coupon_05;Coupon_10;Coupon_30];
HedgeKRD = bndkrdur([\overline{ZeroDates ŻeroRates], HedgeCoupon,...}
Settle, HedgeMaturity, 'keyrates',[2 5 10 20]);

```

\section*{Step 2}

Compute the dollar durations for each of the instruments and each of the key rates (assuming holding 100 bonds):
```

PortfolioDD = 100*Price* BondKRD;
HedgeDD = bsxfun(@times, HedgeKRD,[Price_30;Price_10;Price_05;Price_02]);

```

\section*{Step 3}

Compute the number of bonds to sell short to obtain a key rate duration that is 0 for the entire portfolio:
```

NumBonds = PortfolioDD/HedgeDD;

```

NumBonds =
\(\begin{array}{llll}3.8973 & 6.1596 & 23.0282 \quad 80.0522\end{array}\)
These results indicate selling 4, 6, 23 and 80 bonds respectively of the \(2-, 5-, 10-\), and \(30-\) year bonds achieves a portfolio that is neutral with respect to the 2 -, 5 -, 10 -, and 30 -year spot rates.

\section*{Greek-Neutral Portfolios of European Stock Options}

The option sensitivity measures familiar to most option traders are often referred to as the greeks: delta, gamma, vega, lambda, rho, and theta. Delta is the price sensitivity of an option with respect to changes in the price of the underlying asset. It represents a first-order sensitivity measure analogous to duration in fixed income markets. Gamma is the sensitivity of an option's delta to changes in the price of the underlying asset, and represents a second-order price sensitivity analogous to convexity in fixed income markets. Vega is the price sensitivity of an option with respect to changes in the volatility of the underlying asset. See "Pricing and Analyzing Equity Derivatives" on page 2-42 or the Glossary for other definitions.

The greeks of a particular option are a function of the model used to price the option. However, given enough different options to work with, a trader can construct a portfolio with any desired values for its greeks. For example, to insulate the value of an option portfolio from small changes in the price of the underlying asset, one trader might construct an option portfolio whose delta is zero. Such a portfolio is then said to be "delta neutral." Another trader may want to protect an option portfolio from larger changes in the price of the underlying asset, and so might construct a portfolio whose delta and gamma are both zero. Such a portfolio is both delta and gamma neutral. A third trader may want to construct a portfolio insulated from small changes in the volatility of the underlying asset in addition to delta and gamma neutrality. Such a portfolio is then delta, gamma, and vega neutral.

Using the Black-Scholes model for European options, this example creates an equity option portfolio that is simultaneously delta, gamma, and vega neutral. The value of a particular greek of an option portfolio is a weighted average of the corresponding greek of each individual option. The weights are the quantity of each option in the portfolio. Hedging an option portfolio thus involves solving a system of linear equations, an easy process in MATLAB.

\section*{Step 1}

Create an input data matrix to summarize the relevant information. Each row of the matrix contains the standard inputs to Financial Toolbox Black-Scholes suite of functions: column 1 contains the current price of the underlying stock; column 2 the strike price of each option; column 3 the time to-expiry of each option in years; column 4 the annualized stock price volatility; and column 5 the annualized dividend rate of the underlying asset. Rows 1 and 3 are data related to call options, while rows 2 and 4 are data related to put options.
\begin{tabular}{rlrllll} 
DataMatrix \(=[100.000\) & 100 & 0.2 & 0.3 & 0 & \% Call \\
119.100 & 125 & 0.2 & 0.2 & 0.025 & \% Put \\
87.200 & 85 & 0.1 & 0.23 & 0 & \% Call \\
& 301.125 & 315 & 0.5 & 0.25 & \(0.0333]\) & \% Put
\end{tabular}

Also, assume that the annualized risk-free rate is \(10 \%\) and is constant for all maturities of interest.
```

RiskFreeRate = 0.10;

```

For clarity, assign each column of DataMatrix to a column vector whose name reflects the type of financial data in the column.
```

StockPrice = DataMatrix(:,1);
StrikePrice = DataMatrix(:,2);
ExpiryTime = DataMatrix(:,3);
Volatility = DataMatrix(:,4);
DividendRate = DataMatrix(:,5);

```

\section*{Step 2}

Based on the Black-Scholes model, compute the prices, and the delta, gamma, and vega sensitivity greeks of each of the four options. The functions blsprice and blsdelta have two outputs, while blsgamma and blsvega have only one. The price and delta of a call option differ from the price and delta of an otherwise equivalent put option, in contrast to the gamma and vega sensitivities, which are valid for both calls and puts.
```

[CallPrices, PutPrices] = blsprice(StockPrice, StrikePrice,...
RiskFreeRate, ExpiryTime, Volatility, DividendRate);
[CallDeltas, PutDeltas] = blsdelta(StockPrice,...
StrikePrice, RiskFreeRate, ExpiryTime, Volatility,...
DividendRate);
Gammas = blsgamma(StockPrice, StrikePrice, RiskFreeRate,...
ExpiryTime, Volatility , DividendRate)';
Vegas = blsvega(StockPrice, StrikePrice, RiskFreeRate,...
ExpiryTime, Volatility , DividendRate)';

```

Extract the prices and deltas of interest to account for the distinction between call and puts.

Prices \(=\) [CallPrices(1) PutPrices(2) CallPrices(3)...
PutPrices(4)];

Deltas \(=[\) CallDeltas(1) PutDeltas(2) CallDeltas(3)...
PutDeltas(4)];

\section*{Step 3}

Now, assuming an arbitrary portfolio value of \(\$ 17,000\), set up and solve the linear system of equations such that the overall option portfolio is simultaneously delta, gamma, and vega-neutral. The solution computes the value of a particular greek of a portfolio of options as a weighted average of the corresponding greek of each individual option in the portfolio. The system of equations is solved using the back slash ( \(\backslash\) ) operator discussed in "Solving Simultaneous Linear Equations" on page 1-13.
```

A = [Deltas; Gammas; Vegas; Prices];
b = [0; 0; 0; 17000];
OptionQuantities = A\b; % Quantity (number) of each option.

```

\section*{Step 4}

Finally, compute the market value, delta, gamma, and vega of the overall portfolio as a weighted average of the corresponding parameters of the component options. The weighted average is computed as an inner product of two vectors.
```

PortfolioValue = Prices * OptionQuantities;
PortfolioDelta = Deltas * OptionQuantities;
PortfolioGamma = Gammas * OptionQuantities;
PortfolioVega = Vegas * OptionQuantities;

```

The output for these computations is:
\begin{tabular}{crrrrr} 
Option & Price & Delta & Gamma & Vega & \multicolumn{1}{c}{ Quantity } \\
1 & 6.3441 & 0.5856 & 0.0290 & 17.4293 & 22332.6131 \\
2 & 6.6035 & -0.6255 & 0.0353 & 20.0347 & 6864.0731 \\
3 & 4.2993 & 0.7003 & 0.0548 & 9.5837 & -15654.8657 \\
4 & 22.7694 & -0.4830 & 0.0074 & 83.5225 & -4510.5153
\end{tabular}

Portfolio Value: \$17000.00
Portfolio Delta: 0.00
Portfolio Gamma: \(\quad-0.00\)
Portfolio Vega : 0.00
You can verify that the portfolio value is \(\$ 17,000\) and that the option portfolio is indeed delta, gamma, and vega neutral, as desired. Hedges based on these measures are effective only for small changes in the underlying variables.

\section*{Term Structure Analysis and Interest-Rate Swaps}

This example illustrates some of the term-structure analysis functions found in Financial Toolbox software. Specifically, it illustrates how to derive implied zero (spot) and forward curves from the observed market prices of coupon-bearing bonds. The zero and forward curves implied from the market data are then used to price an interest rate swap agreement.

In an interest rate swap, two parties agree to a periodic exchange of cash flows. One of the cash flows is based on a fixed interest rate held constant throughout the life of the swap. The other cash flow stream is tied to some variable index rate. Pricing a swap at inception amounts to finding the fixed rate of the swap agreement. This fixed rate, appropriately scaled by the notional principal of the swap agreement, determines the periodic sequence of fixed cash flows.

In general, interest rate swaps are priced from the forward curve such that the variable cash flows implied from the series of forward rates and the periodic sequence of fixedrate cash flows have the same current value. Thus, interest rate swap pricing and term structure analysis are intimately related.

\section*{Step 1}

Specify values for the settlement date, maturity dates, coupon rates, and market prices for 10 U.S. Treasury Bonds. This data allows you to price a five-year swap with net cash flow payments exchanged every six months. For simplicity, accept default values for the end-of-month payment rule (rule in effect) and day-count basis (actual/actual). To avoid issues of accrued interest, assume that all Treasury Bonds pay semiannual coupons and that settlement occurs on a coupon payment date.
```

Settle = datenum('15-Jan-1999');
BondData = {'15-Jul-1999' 0.06000 99.93
'15-Jan-2000' 0.06125 99.72
'15-Jul-2000' 0.06375 99.70
'15-Jan-2001' 0.06500 99.40
'15-Jul-2001' 0.06875 99.73
'15-Jan-2002' 0.07000 99.42
'15-Jul-2002' 0.07250 99.32
'15-Jan-2003' 0.07375 98.45
'15-Jul-2003' 0.07500 97.71

```
```

'15-Jan-2004' 0.08000 98.15};

```

BondData is an instance of a MATLAB cell array, indicated by the curly braces (\{\}).

Next assign the date stored in the cell array to Maturity, CouponRate, and Prices vectors for further processing.
```

Maturity = datenum(char(BondData{:,1}));
CouponRate = [BondData{:,2}]';
Prices = [BondData{:,3}]';
Period = 2; % semiannual coupons

```

\section*{Step 2}

Now that the data has been specified, use the term structure function zbtprice to bootstrap the zero curve implied from the prices of the coupon-bearing bonds. This implied zero curve represents the series of zero-coupon Treasury rates consistent with the prices of the coupon-bearing bonds such that arbitrage opportunities will not exist.
```

ZeroRates = zbtprice([Maturity CouponRate], Prices, Settle);

```

The zero curve, stored in ZeroRates, is quoted on a semiannual bond basis (the periodic, six-month, interest rate is doubled to annualize). The first element of ZeroRates is the annualized rate over the next six months, the second element is the annualized rate over the next 12 months, and so on.

\section*{Step 3}

From the implied zero curve, find the corresponding series of implied forward rates using the term structure function zero2fwd.
```

ForwardRates = zero2fwd(ZeroRates, Maturity, Settle);

```

The forward curve, stored in ForwardRates, is also quoted on a semiannual bond basis. The first element of ForwardRates is the annualized rate applied to the interval between settlement and six months after settlement, the second element is the annualized rate applied to the interval from six months to 12 months after settlement, and so on. This implied forward curve is also consistent with the observed market prices such that arbitrage activities will be unprofitable. Since the first forward rate is also a zero rate, the first element of ZeroRates and ForwardRates are the same.

\section*{Step 4}

Now that you have derived the zero curve, convert it to a sequence of discount factors with the term structure function zero2disc.
```

DiscountFactors = zero2disc(ZeroRates, Maturity, Settle);

```

\section*{Step 5}

From the discount factors, compute the present value of the variable cash flows derived from the implied forward rates. For plain interest rate swaps, the notional principle remains constant for each payment date and cancels out of each side of the present value equation. The next line assumes unit notional principle.
```

PresentValue = sum((ForwardRates/Period) .* DiscountFactors);

```

\section*{Step 6}

Compute the swap's price (the fixed rate) by equating the present value of the fixed cash flows with the present value of the cash flows derived from the implied forward rates. Again, since the notional principle cancels out of each side of the equation, it is assumed to be 1 .
```

SwapFixedRate = Period * PresentValue / sum(DiscountFactors);

```

The output for these computations is:
```

Zero Rates Forward Rates
0.0614 0.0614
0.0642 0.0670
0.0660 0.0695
0.0684 0.0758
0.0702 0.0774
0.0726 0.0846
0.0754 0.0925
0.0795 0.1077
0.0827 0.1089
0.0868 0.1239
Swap Price (Fixed Rate) = 0.0845

```

All rates are in decimal format. The swap price, \(8.45 \%\), would likely be the mid-point between a market-maker's bid/ask quotes.

\section*{Introduction}

Financial Toolbox and MATLAB graphics functions work together to produce presentation quality graphics, as these examples show. The examples ship with the toolbox as MATLAB files. Try them by entering the commands directly or by executing the code. For help using MATLAB plotting functions, see "Creating Line Plots" in the MATLAB documentation.

\section*{Plotting an Efficient Frontier}

This example plots the efficient frontier of a hypothetical portfolio of three assets. It illustrates how to specify the expected returns, standard deviations, and correlations of a portfolio of assets, how to convert standard deviations and correlations into a covariance matrix, and how to compute and plot the efficient frontier from the returns and covariance matrix. The example also illustrates how to randomly generate a set of portfolio weights, and how to add the random portfolios to an existing plot for comparison with the efficient frontier.

First, specify the expected returns, standard deviations, and correlation matrix for a hypothetical portfolio of three assets.
```

Returns = [0.1 0.15 0.12];
STDs = [0.2 0.25 0.18];

```

```

    0.3 1 0.3
    0.4 0.3 1 ];
    ```

Convert the standard deviations and correlation matrix into a variance-covariance matrix with the Financial Toolbox function corr2cov.
```

Covariances = corr2cov(STDs, Correlations);

```

Evaluate and plot the efficient frontier at 20 points along the frontier, using the function portopt and the expected returns and corresponding covariance matrix. Although rather elaborate constraints can be placed on the assets in a portfolio, for simplicity accept the default constraints and scale the total value of the portfolio to 1 and constrain the weights to be positive (no short-selling).

Note: portopt has been partially removed and will no longer accept ConSet or varargin arguments. Use Portfolio instead to solve portfolio problems that are more than a long-only fully-invested portfolio. For information on the workflow when using Portfolio objects, see "Portfolio Object Workflow" on page 4-17. For more information on migrating portopt code to Portfolio, see "portopt Migration to Portfolio Object" on page 3-14.
portopt(Returns, Covariances, 20)

Now that the efficient frontier is displayed, randomly generate the asset weights for 1000 portfolios starting from the MATLAB initial state.
```

rng('default')
Weights = rand(1000, 3);

```

The previous line of code generates three columns of uniformly distributed random weights, but does not guarantee they sum to 1 . The following code segment normalizes the weights of each portfolio so that the total of the three weights represent a valid portfolio.
```

Total = sum(Weights, 2); % Add the weights
Total = Total(:,ones(3,1)); % Make size-compatible matrix
Weights = Weights./Total; % Normalize so sum = 1

```

Given the 1000 random portfolios created, compute the expected return and risk of each portfolio associated with the weights.
```

[PortRisk, PortReturn] = portstats(Returns, Covariances, ...
Weights);

```

Finally, hold the current graph, and plot the returns and risks of each portfolio on top of the existing efficient frontier for comparison. After plotting, annotate the graph with a title and return the graph to default holding status (any subsequent plots will erase the existing data). The efficient frontier appears in blue, while the 1000 random portfolios appear as a set of red dots on or below the frontier.
```

hold on
plot (PortRisk, PortReturn, '.r')
title('Mean-Variance Efficient Frontier and Random Portfolios')
hold off

```

\section*{Plotting Sensitivities of an Option}

This example creates a three-dimensional plot showing how gamma changes relative to price for a Black-Scholes option.

Recall that gamma is the second derivative of the option price relative to the underlying security price. The plot in this example shows a three-dimensional surface whose \(z\)-value is the gamma of an option as price ( \(x\)-axis) and time ( \(y\)-axis) vary. The plot adds yet a fourth dimension by showing option delta (the first derivative of option price to security price) as the color of the surface. First set the price range of the options, and set the time range to one year divided into half-months and expressed as fractions of a year.
```

Range = 10:70;
Span = length(Range);
j = 1:0.5:12;
Newj = j(ones(Span,1),:)'/12;

```

For each time period, create a vector of prices from 10 to 70 and create a matrix of all ones.
```

JSpan = ones(length(j),1);
NewRange = Range(JSpan,:);
Pad = ones(size(Newj));

```

Calculate the gamma and delta sensitivities (greeks) using the blsgamma and blsdelta functions. Gamma is the second derivative of the option price with respect to the stock price, and delta is the first derivative of the option price with respect to the stock price. The exercise price is \(\$ 40\), the risk-free interest rate is \(10 \%\), and volatility is 0.35 for all prices and periods.
```

ZVal = blsgamma(NewRange, 40*Pad, 0.1*Pad, Newj, 0.35*Pad);
Color = blsdelta(NewRange, 40*Pad, 0.1*Pad, Newj, 0.35*Pad);

```

Display the greeks as a function of price and time. Gamma is the \(z\)-axis; delta is the color.
```

mesh(Range, j, ZVal, Color);
xlabel('Stock Price (\$)');
ylabel('Time (months)');
zlabel('Gamma');
title('Call Option Price Sensitivity');
axis([[10 70 1 1 12 -inf inf]);
view(-40, 50);
colorbar('horiz');

```

\section*{Plotting Sensitivities of a Porffolio of Options}

This example plots gamma as a function of price and time for a portfolio of 10 BlackScholes options.

The plot in this example shows a three-dimensional surface. For each point on the surface, the height ( \(z\)-value) represents the sum of the gammas for each option in the portfolio weighted by the amount of each option. The \(x\)-axis represents changing price, and the \(y\)-axis represents time. The plot adds a fourth dimension by showing delta as surface color. This example has applications in hedging. First set up the portfolio with arbitrary data. Current prices range from \(\$ 20\) to \(\$ 90\) for each option. Then, set the corresponding exercise prices for each option.
```

Range = 20:90;
PLen = length(Range);
ExPrice = [lllllllllllll

```

Set all risk-free interest rates to \(10 \%\), and set times to maturity in days. Set all volatilities to 0.35 . Set the number of options of each instrument, and allocate space for matrices.
```

Rate = 0.1*ones(10,1);
Time =[[$$
\begin{array}{lllllllllll}{36}&{36}&{36}&{27}&{18}&{18}&{18}&{9}&{9}&{9}\end{array}
$$];
Sigma = 0.35*ones(10,1);
NumOpt = 1000*[[4 8 3 5 5.5 2 4.8 3 4.8 2.5];
ZVal = zeros(36, PLen);
Color = zeros(36, PLen);

```

For each instrument, create a matrix (of size Time by PLen) of prices for each period.
```

for i = 1:10
Pad = ones(Time(i),PLen);
NewR = Range(ones(Time(i),1),:);

```

Create a vector of time periods 1 to Time and a matrix of times, one column for each price.
```

T = (1:Time(i))';
NewT = T(:,ones(PLen,1));

```

Use the Black-Scholes gamma and delta sensitivity functions blsgamma and blsdelta to compute gamma and delta.
```

ZVal(36-Time(i)+1:36,:) = ZVal(36-Time(i)+1:36,:) ...
+ NumOpt(i) * blsgamma(NewR, ExPrice(i)*Pad, ...
Rate(i)*Pad, NewT/36, Sigma(i)*Pad);
Color(36-Time(i)+1:36,:) = Color(36-Time(i)+1:36,:) ...
+ NumOpt(i) * blsdelta(NewR, ExPrice(i)*Pad, ...
Rate(i)*Pad, NewT/36, Sigma(i)*Pad);

```
end
Draw the surface as a mesh, set the viewpoint, and reverse the \(x\)-axis because of the viewpoint. The axes range from 20 to 90,0 to 36 , and \(-\infty\) to \(\infty\).
```

mesh(Range, 1:36, ZVal, Color);

```
```

view(60,60);
set(gca, 'xdir','reverse', 'tag', 'mesh_axes_3');
axis([20 90 0 36 -inf inf]);

```

Add a title and axis labels and draw a box around the plot. Annotate the colors with a bar and label the color bar.
```

title('Call Option Portfolio Sensitivity');
xlabel('Stock Price (\$)');
ylabel('Time (months)');
zlabel('Gamma');
set(gca, 'box', 'on');
colorbar('horiz');

```

\section*{Analyzing Financial Time Series}

Financial Toolbox software provides a collection of tools for the analysis of time series data in the financial markets. The toolbox contains a financial time series object constructor and several methods that operate on and analyze the object. Financial engineers working with time series data, such as equity prices or daily interest fluctuations, can use these tools for more intuitive data management than by using regular vectors or matrices.

This section discusses how to create a financial time series object in one of two ways:
- "Using the Constructor" on page 11-3
- "Transforming a Text File" on page 11-13
chartfts is a graphical tool for visualizing financial time series objects. You can find this discussion in "Visualizing Financial Time Series Objects" on page 11-16.

\section*{Creating Financial Time Series Objects}

In this section...
"Introduction" on page 11-3
"Using the Constructor" on page 11-3
"Transforming a Text File" on page 11-13

\section*{Introduction}

Financial Toolbox software provides two ways to create a financial time series object:
- At the command line using the object constructor fints
- From a text data file through the function ascii2fts

The structure of the object minimally consists of a description field, a frequency indicator field, the date vector field, and at least one data series vector. The names for the fields are fixed for the first three fields: desc, freq, and dates. You can specify names of your choice for any data series vectors. If you do not specify names, the object uses the default names series1, series2, series3, and so on.

If time-of-day information is incorporated in the date vector, the object contains an additional field named times.

\section*{Using the Constructor}

The object constructor function fints has five different syntaxes. These forms exist to simplify object construction. The syntaxes vary according to the types of input arguments presented to the constructor. The syntaxes are
- Single Matrix Input
- See "Time-of-Day Information Excluded" on page 11-4.
- See "Time-of-Day Information Included" on page 11-6.
- Separate Vector Input
- See "Time-of-Day Information Excluded" on page 11-7.
- See "Time-of-Day Information Included" on page 11-8.
- See "Data Name Input" on page 11-9.
- See "Frequency Indicator Input" on page 11-11.
- See "Description Field Input" on page 11-12.

\section*{Single Matrix Input}

The date information provided with this syntax must be in serial date number format. The date number may or may not include time-of-day information.

Note If you are unfamiliar with the concepts of date strings and serial date numbers, consult "Handle and Convert Dates" on page 2-4.

\section*{Time-of-Day Information Excluded}
```

fts = fints(dates_and_data)

```

In this simplest form of syntax, the input must be at least a two-column matrix. The first column contains the dates in serial date format; the second column is the data series. The input matrix can have more than two columns, each additional column representing a different data series or set of observations.

If the input is a two-column matrix, the output object contains four fields: desc, freq, dates, and series1. The description field, desc, defaults to blanks ' ', and the frequency indicator field, freq, defaults to 0 . The dates field, dates, contains the serial dates from the first column of the input matrix, while the data series field, series1, has the data from the second column of the input matrix.

The first example makes two financial time series objects. The first one has only one data series, while the other has more than one. A random vector provides the values for the data series. The range of dates is arbitrarily chosen using the today function:
```

date_series = (today:today+100)';
data_series = exp(randn(1, 101))';
dates_and_data = [date_series data_series];
fts1 = fints(dates_and_data);

```

Examine the contents of the object fts 1 create. The actual date series you observe will vary according to the day when you run the example (the value of today). Also, your
values in series1 will differ from those shown, depending upon the sequence of random numbers generated:
```

fts1 =
desc: (none)
freq: Unknown (0)
'dates: (101)' 'series1: (101)
'12-Jul-1999' [ 0.3124]
13-Jul-1999' [ 3.2665]
'14-Jul-1999' [ 0.9847]
'15-Jul-1999' [ 1.7095]
'16-Jul-1999' [ 0.4885]
'17-Jul-1999' [ 0.5192]
'18-Jul-1999' [ 1.3694]
19-Jul-1999' [ 1.1127]
'20-Jul-1999' [ 6.3485]
21-Jul-1999' [ 0.7595]
'22-Jul-1999' [ 9.1390]
'23-Jul-1999' [ 4.5201]
'24-Jul-1999' [ 0.1430]
25-Jul-1999' [ 0.1863
'26-Jul-1999' [ 0.5635]
'27-Jul-1999' [ 0.8304]
'28-Jul-1999 ' [ 1.0090]...

```

The output is truncated for brevity. There are actually 101 data points in the object.
The desc field displays as (none) instead of ' ' , and that the contents of the object display as cell array elements. Although the object displays as such, it should be thought of as a MATLAB structure containing the default field names for a single data series object: desc, freq, dates, and series1.

Now create an object with more than one data series in it:
```

date_series = (today:today+100)';
data_series1 = exp(randn(1, 101))';
data_series2 = exp(randn(1, 101))';
dates_and_data = [date_series data_series1 data_series2];
fts2 = fints(dates_and_data);

```

Now look at the object created (again in abbreviated form):
```

fts2 =
desc: (none)
freq: Unknown (0)
'dates: (101)' 'series1: (101)' 'series2: (101)

```
\begin{tabular}{|c|c|c|c|}
\hline '13-Jul-1999' & \(5.1253]\) & [ & 0.9262] \\
\hline '14-Jul-1999' & [ 2.2824] & [ & 5.6869] \\
\hline '15-Jul-1999' & [ 1.2596] & [ & \(5.0631]\) \\
\hline '16-Jul-1999' & [ 1.9574] & [ & 1.8709] \\
\hline '17-Jul-1999' & [ 0.6017] & [ & 1.0962] \\
\hline '18-Jul-1999' & [ 2.3546] & [ & \(0.4459]\) \\
\hline '19-Jul-1999' & [ 1.3080] & [ & 0.6304 ] \\
\hline '20-Jul-1999' & [ 1.8682] & [ & 0.2451] \\
\hline '21-Jul-1999' & [ 0.3509] & [ & \(0.6876]\) \\
\hline '22-Jul-1999' & [ 4.6444] & [ & \(0.6244]\) \\
\hline '23-Jul-1999' & [ 1.5441] & [ & 5.7621] \\
\hline '24-Jul-1999' & [ 0.1470] & [ & 2.1238] \\
\hline '25-Jul-1999' & [ 1.5999] & [ & 1.0671] \\
\hline '26-Jul-1999' & [ 3.5764] & [ & \(0.7462]\) \\
\hline '27-Jul-1999' & [ 1.8937] & [ & 1.0863] \\
\hline '28-Jul-1999' & [ 3.9780] & [ & \(2.1516]\) \\
\hline
\end{tabular}

The second data series name defaults to series2, as expected.
Before you can perform any operations on the object, you must set the frequency indicator field freq to the valid frequency of the data series contained in the object. You can leave the description field desc blank.

To set the frequency indicator field to a daily frequency, enter
fts2.freq \(=1\), or
fts2.freq = 'daily'.
For more information, see fints.

\section*{Time-of-Day Information Included}

The serial date number used with this form of the fints function can incorporate time-of-day information. When time-of-day information is present, the output of the function contains a field times that indicates the time of day.

If you recode the previous example to include time-of-day information, you can see the additional column present in the output object:
```

time_series = (now:now+100)';
data_series = exp(randn(1, 101))';
times__and_data = [time_series data_series];
fts1 = fints(times_and_data);
fts1 =
desc: (none)
freq: Unknown (0)

```
\begin{tabular}{lllll} 
'dates: (101)' & 'times: & (101)' & 'series1: (101)' \\
'29-Nov-2001' & '14:57' & & [ & \(0.5816]\) \\
'30-Nov-2001' & '14:57' & [ & \(5.1253]\) \\
'01-Dec-2001' & '14:57' & [ & \(2.2824]\) \\
'02-Dec-2001' & '14:57' & [ & \(1.2596] . .\).
\end{tabular}

\section*{Separate Vector Input}

The date information provided with this syntax can be in serial date number or date string format. The date information may or may not include time-of-day information.

\section*{Time-of-Day Information Excluded}
```

fts = fints(dates, data)

```

In this second syntax the dates and data series are entered as separate vectors to fints, the financial time series object constructor function. The dates vector must be a column vector, while the data series data can be a column vector (if there is only one data series) or a column-oriented matrix (for multiple data series). A column-oriented matrix, in this context, indicates that each column is a set of observations. Different columns are different sets of data series.

Here is an example:
```

dates = (today:today+100)';
data_series1 = exp(randn(1, 101))';
data_series2 = exp(randn(1, 101))';
data = [data_series1 data_series2];
fts = fints(\overline{dates, data)}
fts =
desc: (none)
freq: Unknown (0)

| dates: (101)' | 'series1: (101) | 'series2: | (101) |
| :---: | :---: | :---: | :---: |
| '12-Jul-1999' | [ 0.5816] | [ | $1.2816]$ |
| '13-Jul-1999' | [ 5.1253] | [ | $0.9262]$ |
| '14-Jul-1999' | [ 2.2824] | [ | $5.6869]$ |
| '15-Jul-1999' | $1.2596]$ | [ | 5.0631 ] |
| '16-Jul-1999' | [ 1.9574] | [ | 1.8709 |
| '17-Jul-1999' | $0.6017]$ | [ | 1.0962 |
| '18-Jul-1999' | [ 2.3546] | [ | $0.4459]$ |
| '19-Jul-1999' | $1.3080]$ | [ | 0.6304 |
| '20-Jul-1999' | $1.8682]$ | [ | 0.2451 ] |
| '21-Jul-1999' | $0.3509]$ | [ | $0.6876]$ |
| '22-Jul-1999' | $4.6444]$ | [ | 0.6244 |
| '23-Jul-1999' | $1.5441]$ | [ | 5.7621 ] |
| '24-Jul-1999' | 0.1470 ] | [ | 2.1238 |
| '25-Jul-1999' | $1.5999]$ | [ | 1.0671 |
| '26-Jul-1999' | $3.5764]$ | [ | $0.7462]$ |
| '27-Jul-1999' | 1.8937] |  | $1.0863]$ |

```
'28-Jul-1999' [ 3.9780 ] \([\) 2.1516]...
The result is exactly the same as the first syntax. The only difference between the first and second syntax is the way the inputs are entered into the constructor function.

\section*{Time-of-Day Information Included}

With this form of the function you can enter the time-of-day information either as a serial date number or as a date string. If more than one serial date and time are present, the entry must be in the form of a column-oriented matrix. If more than one string date and time are present, the entry must be a column-oriented cell array of dates and times.

With date string input, the dates and times can initially be separate column-oriented date and time series, but you must concatenate them into a single column-oriented cell array before entering them as the first input to fints.

For date string input the allowable formats are
- 'ddmmmyy hh:mm' or 'ddmmmyyyy hh:mm'
- 'mm/dd/yy hh:mm' or 'mm/dd/yyyy hh:mm'
- 'dd-mmm-yy hh:mm' or 'dd-mmm-yyyy hh:mm'
- 'mmm.dd,yy hh:mm' or 'mmm.dd,yyyy hh:mm'

The next example shows time-of-day information input as serial date numbers in a column-oriented matrix:
```

f = fints([now;now+1],(1:2)')
f =
desc: (none)
freq: Unknown (0)
'dates: (2)' 'times: (2)' 'series1: (2)
'29-Nov-2001' '15:22' [ 1]
'30-Nov-2001' '15:22' [ 2]

```

If the time-of-day information is in date string format, you must provide it to fints as a column-oriented cell array:
```

f = fints({'01-Jan-2001 12:00';'02-Jan-2001 12:00'},(1:2)')
f =

```
```

desc: (none)

```
freq: Unknown (0)
\begin{tabular}{lllll} 
'dates: (2)' & 'times: & (2)' & 'series1: & (2)' \\
'01-Jan-2001' & '12:00' & {\([\)} & \(1]\) \\
'02-Jan-2001' & \(12: 00 '\) & {\([\)} & \(2]\)
\end{tabular}

If the dates and times are in date string format and contained in separate matrices, you must concatenate them before using the date and time information as input to fints:
```

dates = ['01-Jan-2001'; '02-Jan-2001'; '03-Jan-2001'];
times = ['12:00';'12:00';'12:00'];
dates_time = cellstr([dates,repmat(' ',size(dates,1),1),times]);
f = fints(dates_time,(1:3)')
f =
desc: (none)
freq: Unknown (0)
'dates: (3)' 'times: (3)' 'series1: (3)
'01-Jan-2001' '12:00' [ 1]
'02-Jan-2001' '12:00' [ 2]
'03-Jan-2001' '12:00' [ 3]

```

\section*{Data Name Input}
```

fts = fints(dates, data, datanames)

```

The third syntax lets you specify the names for the data series with the argument datanames. The datanames argument can be a MATLAB string for a single data series. For multiple data series names, it must be a cell array of strings.

Look at two examples, one with a single data series and a second with two. The first example sets the data series name to the specified name First:
```

dates = (today:today+100)';
data = exp(randn(1, 101))';
fts1 = fints(dates, data, 'First')
fts1 =
desc: (none)
freq: Unknown (0)

```
\begin{tabular}{|c|c|}
\hline 'dates: (101)' & 'First: (101)' \\
\hline '12-Jul-1999' & [ 0.4615] \\
\hline '13-Jul-1999' & [ 1.1640] \\
\hline '14-Jul-1999' & [ 0.7140] \\
\hline '15-Jul-1999' & [ 2.6400] \\
\hline '16-Jul-1999' & [ 0.8983] \\
\hline '17-Jul-1999' & [ 2.7552] \\
\hline '18-Jul-1999' & [ 0.6217] \\
\hline '19-Jul-1999' & [ 1.0714] \\
\hline '20-Jul-1999' & [ 1.4897] \\
\hline '21-Jul-1999' & [ 3.0536] \\
\hline '22-Jul-1999' & [ 1.8598] \\
\hline '23-Jul-1999' & [ 0.7500] \\
\hline '24-Jul-1999' & [ 0.2537] \\
\hline '25-Jul-1999' & [ 0.5037] \\
\hline '26-Jul-1999' & [ 1.3933] \\
\hline '27-Jul-1999' & 0.3687 ] \\
\hline
\end{tabular}

The second example provides two data series named First and Second:
```

dates = (today:today+100)';
data_series1 = exp(randn(1, 101))';
data_series2 = exp(randn(1, 101))';
data = [data_series1 data_series2];
fts2 = fints(dates, data, {'First', 'Second'})
fts2 =
desc: (none)
freq: Unknown (0)
'dates: (101)'

| irst: (101)' | Second: (101)' |
| :---: | :---: |
| 1.2305] | $0.7396]$ |
| $1.2473]$ | 2.6038 ] |
| $0.3657]$ | $0.5866]$ |
| $0.6357]$ | $0.4061]$ |
| $4.0530]$ | $0.4096]$ |
| $0.6300]$ | $1.3214]$ |
| $1.0333]$ | $0.4744]$ |
| $2.2228]$ | $4.9702]$ |
| [ 2.4518] | 1.7758 ] |
| [ 1.1479] | $1.3780]$ |
| [ 0.1981] | $0.8595]$ |
| [ 0.1927] | $1.3713]$ |
| [ 1.5353] | $3.8332]$ |
| $0.4784]$ | 0.1067 ] |

```
\begin{tabular}{lllll} 
'26-Jul-1999' & {\([\)} & \(1.7593]\) & {\([\)} & \(3.6434]\) \\
'27-Jul-1999' & {\([\)} & \(0.2505]\) & {\([\)} & \(0.6849]\) \\
'28-Jul-1999' & {\([\)} & \(1.5845]\) & {\([\)} & \(1.0025] \ldots\)
\end{tabular}

Note Data series names must be valid MATLAB variable names. The only allowed nonalphanumeric character is the underscore ( \(\_\)) character.

Because freq for fts2 has not been explicitly indicated, the frequency indicator for fts2 is set to Unknown. Set the frequency indicator field freq before you attempt any operations on the object. You will not be able to use the object until the frequency indicator field is set to a valid indicator.

\section*{Frequency Indicator Input}
fts \(=\) fints(dates, data, datanames, freq)
With the fourth syntax you can set the frequency indicator field when you create the financial time series object. The frequency indicator field freq is set as the fourth input argument. You will not be able to use the financial time series object until freq is set to a valid indicator. Valid frequency indicators are
```

UNKNOWN, Unknown, unknown, U, u,0
DAILY, Daily, daily, D, d,1
WEEKLY, Weekly, weekly, W, w,2
MONTHLY, Monthly, monthly, M, m,3
QUARTERLY, Quarterly, quarterly, Q, q,4
SEMIANNUAL, Semiannual, semiannual, S, s,5
ANNUAL, Annual, annual, A, a,6

```

The previous example contained sets of daily data. The freq field displayed as Unknown (0) because the frequency indicator was not explicitly set. The command
```

fts = fints(dates, data, {'First', 'Second'}, 1);

```
sets the freq indicator to Daily (1) when creating the financial time series object:
```

fts =
desc: (none)
freq: Daily (1)
'dates: (101)' 'First: (101)' 'Second: (101)'

```
\begin{tabular}{|c|c|c|c|c|}
\hline '12-Jul-1999' & & \(1.2305]\) & & \(0.7396]\) \\
\hline '13-Jul-1999' & [ & 1.2473 ] & [ & 2.6038 ] \\
\hline '14-Jul-1999' & [ & \(0.3657]\) & & \(0.5866]\) \\
\hline '15-Jul-1999' & [ & \(0.6357]\) & & 0.4061 ] \\
\hline '16-Jul-1999' & & \(4.0530]\) & & \(0.4096]\) \\
\hline '17-Jul-1999' & & \(0.6300]\) & & \(1.3214]\) \\
\hline '18-Jul-1999' & & \(1.0333]\) & & 0.4744 ] \\
\hline
\end{tabular}

When you create the object using this syntax, you can use the other valid frequency indicators for a particular frequency. For a daily data set you can use DAILY, Daily, daily, D, or d. Similarly, with the other frequencies, you can use the valid string indicators or their numeric counterparts.

\section*{Description Field Input}
```

fts = fints(dates, data, datanames, freq, desc)

```

With the fifth syntax, you can explicitly set the description field as the fifth input argument. The description can be anything you want. It is not used in any operations performed on the object.

This example sets the desc field to 'Test TS'.
```

dates = (today:today+100)';
data_series1 = exp(randn(1, 101))';
data_series2 = exp(randn(1, 101))';
data = [data_series1 data_series2];
fts = fints(dates, data, {'First', 'Second'}, 1, 'Test TS')
fts =
desc: Test TS
freq: Daily (1)
'dates: (101)' 'First: (101)' 'Second: (101)'
'12-Jul-1999' [ 0.5428] [ 1.2491]
'13-Jul-1999' [ 0.6649] [ 6.4969]
'14-Jul-1999' [ 0.2428] [ 1.1163]
'15-Jul-1999' [ 1.2550] [ 0.6628]
'16-Jul-1999' [ 1.2312] [ 1.6674]
'17-Jul-1999' [ 0.4869] [ 0.3015]
'18-Jul-1999' [ 2.1335] [ 0.9081]...

```

Now the description field is filled with the specified string 'Test TS ' when the constructor is called.

\section*{Transforming a Text File}

The function ascii2fts creates a financial time series object from a text (ASCII) data file if the data file conforms to a general format. The general format of the text data file is as follows:
- Can contain header text lines.
- Can contain column header information. The column header information must immediately precede the data series columns unless the skiprows argument (see below) is specified.
- Leftmost column must be the date column.
- Dates must be in a valid date string format.
```

- 'ddmmmyy' or 'ddmmmyyyy'
- 'mm/dd/yy' or 'mm/dd/yyyy'
- 'dd-mmm-yy' or 'dd-mmm-yyyy'
- 'mmm.dd,yy' or 'mmm.dd,yyyy'

```
- Each column must be separated either by spaces or a tab.

Several example text data files are included with the toolbox. These files are in the ftsdata subfolder within the folder matlabroot/toolbox/finance.

The syntax of the function
fts = ascii2fts(filename, descrow, colheadrow, skiprows);
takes in the data file name (filename), the row number where the text for the description field is (descrow), the row number of the column header information (colheadrow), and the row numbers of rows to be skipped (skiprows). For example, rows need to be skipped when there are intervening rows between the column head row and the start of the time series data.

Look at the beginning of the ASCII file disney. dat in the ftsdata subfolder:
\begin{tabular}{llllll} 
Walt Disney Company (DIS) & & & \\
Daily prices \((3 / 29 / 96\) to & \(3 / 29 / 99)\) & & \\
DATE & OPEN & HIGH & LOW & CLOSE & VOLUME \\
\(3 / 29 / 99\) & 33.0625 & 33.188 & 32.75 & 33.063 & 6320500 \\
\(3 / 26 / 99\) & 33.3125 & 33.375 & 32.75 & 32.938 & 5552800
\end{tabular}
\begin{tabular}{llllll}
\(3 / 25 / 99\) & 33.5 & 33.625 & 32.875 & 33.375 & 7936000 \\
\(3 / 24 / 99\) & 33.0625 & 33.25 & 32.625 & 33.188 & \(6025400 \ldots\)
\end{tabular}

The command-line
disfts = ascii2fts('disney.dat', 1, 3, 2)
uses disney.dat to create time series object disfts. This example
- Reads the text data file disney. dat
- Uses the first line in the file as the content of the description field
- Skips the second line
- Parses the third line in the file for column header (or data series names)
- Parses the rest of the file for the date vector and the data series values

The resulting financial time series object looks like this.
disfts =

There are 782 data points in this object. Only the first few lines are shown here. Also, this object has two other data series, the CLOSE and VOLUME data series, that are not shown here. In creating the financial time series object, ascii2fts sorts the data into ascending chronological order.

The frequency indicator field, freq, is set to 0 for Unknown frequency. You can manually reset it to the appropriate frequency using structure syntax disfts.freq \(=1\) for Daily frequency.

With a slightly different syntax, the function ascii2fts can create a financial time series object when time-of-day data is present in the ASCII file. The new syntax has the form
fts = ascii2fts(filename, timedata, descrow, colheadrow, skiprows);

Set timedata to ' \(T\) ' when time-of-day data is present and to ' \(N T\) ' when there is no time data. For an example using this function with time-of-day data, see the reference page for ascii2fts.

\section*{Visualizing Financial Time Series Objects}
```

In this section...
"Introduction" on page 11-16
"Using chartfts" on page 11-16
"Zoom Tool" on page 11-19
"Combine Axes Tool" on page 11-22

```

\section*{Introduction}

Financial Toolbox software contains the function chartfts, which provides a visual representation of a financial time series object. chartfts is an interactive charting and graphing utility for financial time series objects. With this function, you can observe time series values on the entire range of dates covered by the time series.

Note Interactive charting is also available from the Graphs menu of the user interface. See "Interactive Chart" on page 14-16 for additional information.

\section*{Using charifts}
chartfts requires a single input argument, tsobj, where tsobj is the name of the financial time series object you want to explore. Most equity financial time series objects contain four price series, such as opening, closing, highest, and lowest prices, plus an additional series containing the volume traded. However, chartfts is not limited to a time series of equity prices and volume traded. It can be used to display any time series data you may have.

To illustrate the use of chartfts, use the equity price and volume traded data for the Walt Disney Corporation (NYSE: DIS) provided in the file disney . mat:
```

load disney.mat
whos

| Name | Size | Bytes | Class |
| :--- | :---: | :--- | :--- |
| dis | $782 \times 5$ | 39290 | fints object |

```
\begin{tabular}{lrrl} 
dis_CLOSE & \(782 \times 1\) & 6256 & double array \\
dis_HIGH & \(782 \times 1\) & 6256 & double array \\
dis_LOW & \(782 \times 1\) & 6256 & double array \\
dis_OPEN & \(782 \times 1\) & 6256 & double array \\
dis_VOLUME & \(782 \times 1\) & 6256 & double array \\
dis_nv & \(782 \times 4\) & 32930 & fints object \\
q_dis & \(13 \times 4\) & 2196 & fints object
\end{tabular}

For charting purposes look only at the objects dis (daily equity data including volume traded) and dis_nv (daily data without volume traded). Both objects contain the series OPEN, HIGH, LOW, and CLOSE, but only dis contains the additional VOLUME series.

Use chartfts(dis) to observe the values.

The chart contains five plots, each representing one of the series in the time series object. Boxes indicate the value of each individual plot. The date box is always on the left. The number of data boxes on the right depends upon the number of data series in the time series object, five in this case. The order in which these boxes are arranged (left to right) matches the plots from top to bottom. With more than eight data series in the object, the
scroll bar on the right is activated so that additional data from the other series can be brought into view.

Slide the mouse cursor over the chart. A vertical bar appears across all plots. This bar selects the set of data shown in the boxes below. Move this bar horizontally and the data changes accordingly.

Click the plot. A small information box displays the data at the point where you click the mouse button.

\section*{Zoom Tool}

The zoom feature of chartfts enables a more detailed look at the data during a selected time frame. The Zoom tool is found under the Chart Tools menu.

Note Due to the specialized nature of this feature, do not use the MATLAB zoom command or Zoom In and Zoom Out from the Tools menu.

When the feature is turned on, you will see two inactive buttons (ZOOM In and Reset ZOOM) above the boxes. The buttons become active later after certain actions have been performed.

The window title bar displays the status of the chart tool that you are using. With the Zoom tool turned on, you see Zoom ON in the title bar in addition to the name of the time series you are working with. When the tool is off, no status is displayed.

To zoom into the chart, you need to define the starting and ending dates. Define the starting date by moving the cursor over the chart until the desired date appears at the bottom-left box and click the mouse button. A blue vertical line indicates the starting date that you have selected. Next, again move the cursor over the chart until the desired ending date appears in the box and click the mouse once again. This time, a red vertical line appears and the ZOOM In button is activated.

To zoom into the chart, click the ZOOM In button.

The chart is zoomed in. The Reset ZOOM button now becomes active while the ZOOM In button becomes inactive again. To return the chart to its original state (not zoomed),
click the Reset ZOOM button. To zoom into the chart even further, repeat the steps above for zooming into the chart.

Turn off the Zoom tool by going back to the Chart Tools menu and choosing Zoom Off.

With the tool turned off, the chart stays at the last state that it was in. If you turn it off when the chart is zoomed in, the chart stays zoomed in. If you reset the zoom before turning it off, the chart becomes the original (not zoomed).

\section*{Combine Axes Tool}

The Combine Axes tool allows you to combine all axes or specific axes into one. With axes combined, you can visually spot any trends that can occur among the data series in a financial time series object.

To illustrate this tool, use dis_nv, the financial time series object that does not contain volume traded data:
chartfts(dis_nv)

To combine axes, choose the Chart Tools menu, followed by Combine Axes and On.

When the Combine Axes tool is on, check boxes appear beside each individual plot. An additional check box enables the combination of all plots.

\section*{Combining All Axes}

To combine all plots, select the Select all plots check box.

Now click the Combine Selected Graphs button to combine the chosen plots. In this case, all plots are combined.

The combined plots have a single plot axis with all data series traced. The background of each data box has changed to the color corresponding to the color of the trace that represents the data series. After the axes are combined, the tool is turned off.

\section*{Combining Selected Axes}

You can choose any combination of the available axes to combine. For example, combine the HIGH and LOW price series of the Disney time series. Click the check boxes next to the corresponding plots. The Combine Selected Graphs button appears and is active.

Click the Combine Selected Graphs button. The chart with the combined plots looks like the next figure.

The plot with the combined axes is located at the top of the chart while the remaining plots follow it. The data boxes have also been changed. The boxes that correspond to the combined axes are relocated to the beginning, and the background colors are set to the color of the respective traces. The data boxes for the remaining axes retain their original formats.

\section*{Resetting Axes}

If you have altered the chart by combining axes, you must reset the axes before you can visualize additional combinations. Reset the axes with the Reset Axes menu item under Chart Tools > Combine Axes. Now the On and Off features are turned off.

With axes reset, the interactive chart appears in its original format, and you can proceed with additional axes combinations.

}

\section*{Introduction}

A financial time series object is used as if it were a MATLAB structure. (See the MATLAB documentation for a description of MATLAB structures or how to use MATLAB in general.)

This part of the tutorial assumes that you know how to use MATLAB and are familiar with MATLAB structures. The terminology is similar to that of a MATLAB structure. The financial time series object term component is interchangeable with the MATLAB structure term field.

\section*{Financial Time Series Object Structure}

A financial time series object always contains three component names: desc (description field), freq (frequency indicator field), and dates (date vector). If you build the object using the constructor fints, the default value for the description field is a blank string (' '). If you build the object from a text data file using ascii2fts, the default is the name of the text data file. The default for the frequency indicator field is 0 (Unknown frequency). Objects created from operations can default the setting to 0 . For example, if you decide to pick out values selectively from an object, the frequency of the new object might not be the same as that of the object from which it came.

The date vector dates does not have a default set of values. When you create an object, you have to supply the date vector. You can change the date vector afterward but, at object creation time, you must provide a set of dates.

The final component of a financial time series object is one or more data series vectors. If you do not supply a name for the data series, the default name is series1. If you have multiple data series in an object and do not supply the names, the default is the name series followed by a number, for example, series1, series2, and series3.

\section*{Data Extraction}

Here is an exercise on how to extract data from a financial time series object. As mentioned before, you can think of the object as a MATLAB structure. Highlight each line in the exercise in the MATLAB Help browser, press the right mouse button, and select Evaluate Selection to execute it.

To begin, create a financial time series object called myfts:
```

dates = (datenum('05/11/99'):datenum('05/11/99')+100)';
data_series1 = exp(randn(1, 101))';
data_series2 = exp(randn(1, 101))';
data = [data_series1 data_series2];
myfts = fints(dates, data);

```

The myfts object looks like this:
```

myfts =
desc: (none)
freq: Unknown (0)

| s: (101)' | series1: (101)' | 'series2: (101)' |
| :---: | :---: | :---: |
| '11-May-1999 | 2.8108] | $0.9323]$ |
| '12-May-1999 | $0.2454]$ | $0.5608]$ |
| '13-May-1999 | $0.3568]$ | 1.5989 ] |
| '14-May-1999 | $0.5255]$ | 3.6682 ] |
| '15-May-1999 | 1.1862] | $5.1284]$ |
| '16-May-1999 | 3.8376] | $0.4952]$ |
| '17-May-1999' | 6.9329] | $2.2417]$ |
| '18-May-1999 | $2.0987]$ | 0.3579 ] |
| '19-May-1999 | $2.2524]$ | $3.6492]$ |
| '20-May-1999 | $0.8669]$ | $1.0150]$ |
| '21-May-1999 | $0.9050]$ | $1.2445]$ |
| '22-May-1999 | $0.4493]$ | $5.5466]$ |
| '23-May-1999 | 1.6376] | $0.1251]$ |
| '24-May-1999 | 3.4472] | $1.1195]$ |
| '25-May-1999 | $3.6545]$ | $0.3374]$ |

```

There are more dates in the object; only the first few lines are shown here.

Note The actual data in your series1 and series2 differs from the above because of the use of random numbers.

Now create another object with only the values for series2:
```

srs2 = myfts.series2
srs2 =
desc: (none)
freq: Unknown (0)
'dates: (101)' 'series2: (101)'
'11-May-1999' [ 0.9323]
'12-May-1999' [ 0.5608]
'13-May-1999' [ 1.5989]
'14-May-1999' [ 3.6682]
'15-May-1999' [ 5.1284]
'16-May-1999' [ 0.4952]
'17-May-1999' [ 2.2417]
'18-May-1999' [ 0.3579]
'19-May-1999' [ 3.6492]
'20-May-1999' [ 1.0150]
'21-May-1999' [ 1.2445]
'22-May-1999' [ 5.5466]
'23-May-1999' [ 0.1251]
'24-May-1999' [ 1.1195]
'25-May-1999' [ 0.3374]...

```

The new object srs2 contains all the dates in myfts, but the only data series is series2. The name of the data series retains its name from the original object, myfts.

Note The output from referencing a data series field or indexing a financial time series object is always another financial time series object. The exceptions are referencing the description, frequency indicator, and dates fields, and indexing into the dates field.

\section*{Object-to-Matrix Conversion}

The function fts2mat extracts the dates and/or the data series values from an object and places them into a vector or a matrix. The default behavior extracts just the values into a vector or a matrix. Look at the next example:
```

srs2_vec = fts2mat(myfts.series2)
srs2_vec =
0.9323
0.5608
1.5989
3.6682
5.1284
0.4952
2.2417
0.3579
3.6492
1.0150
1.2445
5.5466
0.1251
1.1195
0.3374...

```

If you want to include the dates in the output matrix, provide a second input argument and set it to 1 . This results in a matrix whose first column is a vector of serial date numbers:
```

format long g
srs2_mtx = fts2mat(myfts.series2, 1)
srs2_mtx =

```
    \(730251 \quad 0.932251754559576\)
    7302520.560845677519876
    \(730253 \quad 1.59888712183914\)
    \(730254 \quad 3.6681500883527\)
    \(730255 \quad 5.12842215360269\)
    \(730256 \quad 0.49519254119977\)
    \(730257 \quad 2.24174134286213\)
    \(730258 \quad 0.357918065917634\)
```

730259 3.64915665824198
730260 1.01504236943148
730261 1.24446420606078
730262 5.54661849025711
730263 0.12507959735904
730264 1.11953883096805
730265 0.337398214166607

```

The vector srs2_vec contains series2 values. The matrix srs2_mtx contains dates in the first column and the values of the series2 data series in the second. Dates in the first column are in serial date format. Serial date format is a representation of the date string format (for example, serial date \(=1\) is equivalent to \(01-J a n-0000\) ). (The serial date vector can include time-of-day information.)

The long g display format displays the numbers without exponentiation. (To revert to the default display format, use format short. (See the format command in the MATLAB documentation for a description of MATLAB display formats.) Remember that both the vector and the matrix have 101 rows of data as in the original object myfts but are shown truncated here.

\section*{Indexing a Financial Time Series Object}

You can also index into the object as with any other MATLAB variable or structure. A financial time series object lets you use a date string, a cell array of date strings, a date string range, or normal integer indexing. You cannot, however, index into the object using serial dates. If you have serial dates, you must first use the MATLAB datestr command to convert them into date strings.

When indexing by date string, note that
- Each date string must contain the day, month, and year. Valid formats are
```

- 'ddmmmyy hh:mm' or 'ddmmmyyyy hh:mm'
- 'mm/dd/yy hh:mm' or 'mm/dd/yyyy hh:mm'
- 'dd-mmm-yy hh:mm' or 'dd-mmm-yyyy hh:mm'
- 'mmm.dd,yy hh:mm' or 'mmm.dd,yyyy hh:mm'

```
- All data falls at the end of the indicated time period, that is, weekly data falls on Fridays, monthly data falls on the end of each month, and so on, whenever the data has gone through a frequency conversion.

\section*{Indexing with Date Strings}

With date string indexing, you get the values in a financial time series object for a specific date using a date string as the index into the object. Similarly, if you want values for multiple dates in the object, you can put those date strings into a cell array and use the cell array as the index to the object. Here are some examples.

This example extracts all values for May 11, 1999 from myfts:
```

format short
myfts('05/11/99')
ans =
desc: (none)
freq: Unknown (0)

```
```

'dates: (1)' 'series1: (1)' 'series2: (1)
'11-May-1999' [ 2.8108] [ 0.9323]

```

The next example extracts only series2 values for May 11, 1999 from myfts:
```

myfts.series2('05/11/99')
ans =
desc: (none)
freq: Unknown (0)
'dates: (1)' 'series2: (1)'
'11-May-1999' [ 0.9323]

```

The third example extracts all values for three different dates:
```

myfts({'05/11/99', '05/21/99', '05/31/99'})
ans =
desc: (none)
freq: Unknown (0)
'dates: (3)' 'series1: (3)' 'series2: (3)
'11-May-1999' [ 2.8108] [ 0.9323]
'21-May-1999' [ 0.9050] [ 1.2445]
'31-May-1999' [ 1.4266] [ 0.6470]

```

The next example extracts only series2 values for the same three dates:
```

myfts.series2({'05/11/99', '05/21/99', '05/31/99'})
ans =
desc: (none)
freq: Unknown (0)

| s: (3) ${ }^{\prime}$ | series2: (3)' |
| :---: | :---: |
| '11-May-1999' | $0.9323]$ |
| '21-May-1999' | $1.2445]$ |
| '31-May-1999 ' | 0.6470 ] |

```

\section*{Indexing with Date String Range}

A financial time series is unique because it allows you to index into the object using a date string range. A date string range consists of two date strings separated by two colons (: :). In MATLAB this separator is called the double-colon operator. An example of a MATLAB date string range is '05/11/99: :05/31/99'. The operator gives you all data points available between those dates, including the start and end dates.

Here are some date string range examples:
```

myfts ('05/11/99::05/15/99')
ans =
desc: (none)
freq: Unknown (0)

| ates: (5)' | 'series1: (5)' | series2: (5)' |
| :---: | :---: | :---: |
| '11-May-1999' | $2.8108]$ | [ 0.9323] |
| '12-May-1999' | $0.2454]$ | [ 0.5608] |
| '13-May-1999' | 0.3568 ] | [ 1.5989] |
| '14-May-1999' | $0.5255]$ | [ 3.6682] |
| '15-May-1999' | 1.1862] | $5.1284]$ |

myfts.series2('05/11/99::05/15/99')
ans =
desc: (none)
freq: Unknown (0)

```
\begin{tabular}{lll} 
'dates: (5)' & \multicolumn{1}{l}{ 'series2: (5)' } \\
'11-May-1999' & [r & \(0.9323]\) \\
'12-May-1999' & [ & \(0.5608]\) \\
'13-May-1999' & [ & \(1.5989]\) \\
'14-May-1999' & [ & \(3.6682]\) \\
'15-May-1999' & [ & \(5.1284]\)
\end{tabular}

As with any other MATLAB variable or structure, you can assign the output to another object variable:
```

nfts = myfts.series2('05/11/99::05/20/99');

```
nfts is the same as ans in the second example.
If one of the dates does not exist in the object, an error message indicates that one or both date indexes are out of the range of the available dates in the object. You can either display the contents of the object or use the command ftsbound to determine the first and last dates in the object.

\section*{Indexing with Integers}

Integer indexing is the normal form of indexing in MATLAB. Indexing starts at 1 (not 0 ); index \(=1\) corresponds to the first element, index \(=2\) to the second element, index \(=\) 3 to the third element, and so on. Here are some examples with and without data series reference.

Get the first item in series2:
```

myfts.series2(1)
ans =
desc: (none)
freq: Unknown (0)
'dates: (1)' 'series2: (1)
'11-May-1999' [ 0.9323]

```

Get the first, third, and fifth items in series2:
```

myfts.series2([1, 3, 5])
ans =

```
```

desc: (none)
freq: Unknown (0)

```
\begin{tabular}{|c|c|}
\hline 'dates: (3)' & 'series2: (3) \\
\hline '11-May-1999' & \(0.9323]\) \\
\hline '13-May-1999' & [ 1.5989] \\
\hline '15-May-1999' & \(5.1284]\) \\
\hline
\end{tabular}

Get items 16 through 20 in series2:
```

myfts.series2(16:20)

```
ans \(=\)

Get items 16 through 20 in the financial time series object myfts:
```

myfts(16:20)
ans =
desc: (none)
freq: Unknown (0)

| 'dates: (5)' | 'series1: (5)' | 'series2: (5)' |  |
| :--- | :--- | :--- | :--- |
| '26-May-1999' | [ | $0.7571]$ | $[$ |

```

Get the last item in myfts:
myfts(end)
ans \(=\)
```

desc: (none)
freq: Unknown (0)

```
```

dates: (1)' 'series1: (1)' 'series2: (1)'
'19-Aug-1999' [ 1.4692] [ 3.4238]

```

This example uses the MATLAB special variable end, which points to the last element of the object when used as an index. The example returns an object whose contents are the values in the object myfts on the last date entry.

\section*{Indexing When Time-of-Day Data Is Present}

Both integer and date string indexing are permitted when time-of-day information is present in the financial time series object. You can index into the object with both date and time specifications, but not with time of day alone. To show how indexing works with time-of-day data present, create a financial time series object called timeday containing a time specification:
```

dates = ['01-Jan-2001';'01-Jan-2001'; '02-Jan-2001'; ...
'02-Jan-2001'; '03-Jan-2001';'03-Jan-2001'];
times = ['11:00';'12:00';'11:00';'12:00';'11:00';'12:00'];
dates_times = cellstr([dates, repmat(' ',size(dates,1),1),...
times]);
timeday = fints(dates_times,(1:6)',{'Data1'},1,'My first FINTS')
timeday =
desc: My first FINTS
freq: Daily (1)

| dates: (6)' | times: | (6) ' | 'Data1: (6)' |
| :---: | :---: | :---: | :---: |
| '01-Jan-2001' | '11:00' |  | 1] |
| " ' | '12:00' |  | 2] |
| '02-Jan-2001' | '11:00' |  | $3]$ |
| " ' | '12:00' |  | $4]$ |
| '03-Jan-2001' | '11:00' |  | $5]$ |
| ' " ' | '12:00' |  | $6]$ |

```

Use integer indexing to extract the second and third data items from timeday:
```

timeday(2:3)

```
ans =
```

desc: My first FINTS
freq: Daily (1)

| 'dates: (2)' | 'times: | (2)' | 'Data1: | (2)' |
| :--- | :--- | :--- | :--- | :--- |
| '01-Jan-2001' | $' 12: 00$ |  | $[$ | $2]$ |
| '02-Jan-2001' | $11: 00$ | $[$ | $3]$ |  |

```

For date string indexing, enclose the date and time string in one pair of quotation marks. If there is one date with multiple times, indexing with only the date returns the data for all the times for that specific date. For example, the command timeday ('01-Jan-2001' ) returns the data for all times on January 1, 2001:
```

ans =
desc: My first FINTS
freq: Daily (1)

| dates: (2) | 'times: | $(2){ }^{\prime}$ | Data1: (2) |
| :---: | :---: | :---: | :---: |
| 01-Jan-2001' | '11:00' |  | [ 1 |
| , | '12:00' |  | $2]$ |

```

You can also indicate a specific date and time:
```

timeday('01-Jan-2001 12:00')
ans =
desc: My first FINTS
freq: Daily (1)
'dates: (1)' 'times: (1)' 'Data1: (1)'

```

Use the double-colon operator : : to specify a range of dates and times:
```

timeday('01-Jan-2001 12:00::03-Jan-2001 11:00')

```
ans =
desc: My first FINTS
freq: Daily (1)
\begin{tabular}{lllll} 
'dates: (4)' & 'times: & (4)' & 'Data1: & (4)' \\
'01-Jan-2001' & '12:00' & & {\([\)} & \(2]\) \\
'02-Jan-2001' & '11:00' & {\([\)} & \(3]\)
\end{tabular}
\begin{tabular}{ccc}
\(\prime \prime\) & \(' 12: 00 '\) & {\([\)} \\
'03-Jan-2001' & \(' 11: 00 '\) & {\([\)}
\end{tabular}

Treat timeday as a MATLAB structure if you want to obtain the contents of a specific field. For example, to find the times of day included in this object, enter
```

datestr(timeday.times)
ans =
11:00 AM
12:00 PM
11:00 AM
12:00 PM
11:00 AM
12:00 PM

```

\section*{Financial Time Series Operations}

Several MATLAB functions have been overloaded to work with financial time series objects. The overloaded functions include basic arithmetic functions such as addition, subtraction, multiplication, and division and other functions such as arithmetic average, filter, and difference. Also, specific methods have been designed to work with the financial time series object. For a list of functions grouped by type, enter
help ftseries
at the MATLAB command prompt.

\section*{Basic Arithmetic}

Financial time series objects permit you to do addition, subtraction, multiplication, and division, either on the entire object or on specific object fields. This is a feature that MATLAB structures do not allow. You cannot do arithmetic operations on entire MATLAB structures, only on specific fields of a structure.

You can perform arithmetic operations on two financial time series objects as long as they are compatible. (All contents are the same except for the description and the values associated with the data series.)

Note Compatible time series are not the same as equal time series. Two time series objects are equal when everything but the description fields are the same.

Here are some examples of arithmetic operations on financial time series objects.
Load a MAT-file that contains some sample financial time series objects:
load dji3Oshort
One of the objects in dji30short is called myfts1:
```

myfts1 =
desc: DJI30MAR94.dat
freq: Daily (1)

| 'dates: (20)' | Open: (20) | 'High: (20) | Low: (20) | Close: (20)' |
| :--- | :--- | :--- | :--- | :--- |
| '04-Mar-1994' | $[3830.90]$ | $[3868.04]$ | $[3800.50]$ | $[3832.30]$ |
| '07-Mar-1994' | $[3851.72]$ | $[3882.40]$ | $[3824.71]$ | $[3856.22]$ |
| '08-Mar-1994' | $[3858.48]$ | $[3881.55]$ | $[3822.45]$ | $[3851.72]$ |
| '09-Mar-1994' | $[3853.97]$ | $[3874.52]$ | $[3817.95]$ | $[3853.41]$ |
| '10-Mar-1994' | $[3852.57]$ | $[3865.51]$ | $[3801.63]$ | $[3830.62] \ldots$ |

```

Create another financial time series object that is identical to myfts1:
```

newfts = fints(myfts1.dates, fts2mat(myfts1)/100,...
{'Open','High','Low', 'Close'}, 1, 'New FTS')
newfts =
desc: New FTS
freq: Daily (1)
'dates: (20)' 'Open: (20)' 'High: (20)' 'Low: (20)' 'Close:(20)'
'O4-Mar-1994' [ 38.31] [ 38.68] [ 38.01] [ 38.32]
'07-Mar-1994' [ 38.52] [ 38.82] [ 38.25] [ 38.56]
'08-Mar-1994' [ 38.58] [ 38.82] [ 38.22] [ 38.52]
'09-Mar-1994' [ 38.54] [ 38.75] [ 38.18] [ 38.53]
'10-Mar-1994' [ 38.53] [ 38.66] [ 38.02] [ 38.31]...

```

Perform an addition operation on both time series objects:
```

addup = myfts1 + newfts
addup =
desc: DJI30MAR94.dat
freq: Daily (1)

| s: (20) ${ }^{\text {d }}$ | Open: (20)' | 'High: (20)' | 'Low: (20)' | Close: (20)' |
| :---: | :---: | :---: | :---: | :---: |
| '04-Mar-1994' | [3869.21] | [ 3906.72] | [ 3838.51] | [ 3870.62] |
| '07-Mar-1994' | $3890.24]$ | [ 3921.22] | $3862.96]$ | [ 3894.78] |

```
```

'08-Mar-1994' [ 3897.06] [ 3920.37] [ 3860.67] [ 3890.24]
'09-Mar-1994' [ 3892.51] [ 3913.27] [ 3856.13] [ 3891.94]
'10-Mar-1994' [ 3891.10] [ 3904.17] [ 3839.65] [ 3868.93]...

```

Now, perform a subtraction operation on both time series objects:
```

subout = myfts1 - newfts
subout =
desc: DJI30MAR94.dat
freq: Daily (1)

| ${ }^{\prime}$ dates: (20)' | ${ }^{\prime}$ Open: (20) | 'High: (20) |  | ${ }^{\prime}$ Low: (20) |
| :--- | :--- | :--- | :--- | :--- |${ }^{\prime}$ Close: (20)'

```

\section*{Operations with Objects and Matrices}

You can also perform operations involving a financial time series object and a matrix or scalar:
```

addscalar = myfts1 + 10000
addscalar =
desc: DJI30MAR94.dat
freq: Daily (1)
'dates: (20)' 'Open: (20)' 'High: (20)' 'Low: (20)' 'Close: (20)'
'04-Mar-1994' [ 13830.90] [ 13868.04] [ 13800.50] [ 13832.30]
07-Mar-1994' [ 13851.72] [ 13882.40] [ 13824.71] [ 13856.22]
'08-Mar-1994' [ 13858.48] [ 13881.55] [ 13822.45] [ 13851.72]
'09-Mar-1994' [ 13853.97] [ 13874.52] [ 13817.95] [ 13853.41]
'10-Mar-1994' [ 13852.57] [ 13865.51] [ 13801.63] [ 13862.70]...

```

For operations with both an object and a matrix, the size of the matrix must match the size of the object. For example, a matrix to be subtracted from myfts 1 must be 20 -by- 4 , since myfts 1 has 20 dates and 4 data series:
```

submtx = myfts1 - randn(20, 4)
submtx =

```
```

desc: DJI30MAR94.dat
freq: Daily (1)

| 'dates: (20)' | 'Open: (20) | 'High: (20)' | 'Low: (20)' | 'Close: (20)' |
| :--- | :--- | :--- | :--- | :--- |
| '04-Mar-1994' | $[3831.33]$ | $[3867.75]$ | $[3802.10]$ | $[3832.63]$ |
| '07-Mar-1994' | $[3853.39]$ | $[3883.74]$ | $[3824.45]$ | $[3857.06]$ |
| '08-Mar-1994' | $[3858.35]$ | $[3880.84]$ | $[3823.51]$ | $[3851.22]$ |
| '09-Mar-1994' | $[3853.68]$ | $[3872.90]$ | $[3816.53]$ | $[3851.92]$ |
| ${ }^{\prime} 10-M a r-1994^{\prime}$ | $[3853.72]$ | $[3866.20]$ | $[3802.44]$ | $[3831.17] . .$. |

```

\section*{Arithmetic Operations with Differing Data Series Names}

Arithmetic operations on two objects that have the same size but contain different data series names require the function fts2mat. This function extracts the values in an object and puts them into a matrix or vector, whichever is appropriate.

To see an example, create another financial time series object the same size as myfts1 but with different values and data series names:
```

newfts2 = fints(myfts1.dates, fts2mat(myfts1/10000),...
{'Rat1','Rat2', 'Rat3','Rat4'}, 1, 'New FTS')

```

If you attempt to add (or subtract, and so on) this new object to myfts1, an error indicates that the objects are not identical. Although they contain the same dates, number of dates, number of data series, and frequency, the two time series objects do not have the same data series names. Use fts2mat to bypass this problem:
```

addother = myfts1 + fts2mat(newfts2);

```

This operation adds the matrix that contains the contents of the data series in the object newfts2 to myfts1. You should carefully consider the effects on your data before deciding to combine financial time series objects in this manner.

\section*{Other Arithmetic Operations}

In addition to the basic arithmetic operations, several other mathematical functions operate directly on financial time series objects. These functions include exponential (exp), natural logarithm (log), common logarithm (log10), and many more.

\section*{Data Transformation and Frequency Conversion}

The data transformation and the frequency conversion functions convert a data series into a different format.

\section*{Data Transformation Functions}
\begin{tabular}{ll} 
Function & Purpose \\
boxcox & Box-Cox transformation \\
diff & Differencing \\
fillts & Fill missing values \\
filter & Filter \\
lagts & Lag time series object \\
leadts & Lead time series object \\
peravg & Periodic average \\
smoothts & Smooth data \\
tsmovavg & Moving average \\
\hline Frequency Conversion Functions & \\
Function & \\
\hline convertto & New Frequency \\
resamplets & As specified \\
toannual & As specified \\
todaily & Annual \\
tomonthly & Daily \\
toquarterly & Monthly \\
tosemi & Quarterly \\
toweekly & Semiannually \\
\hline
\end{tabular}

As an example look at boxcox, the Box-Cox transformation function. This function transforms the data series contained in a financial time series object into another set of data series with relatively normal distributions.

First create a financial time series object from the supplied whirlpool. dat data file.
```

whrl = ascii2fts('whirlpool.dat', 1, 2, []);

```

Fill any missing values denoted with NaNs in whrl with values calculated using the linear method:
```

f whrl = fillts(whrl);

```

Transform the nonnormally distributed filled data series f_whrl into a normally distributed one using Box-Cox transformation:
```

bc_whrl = boxcox(f_whrl);

```

Compare the result of the Close data series with a normal (Gaussian) probability distribution function and the nonnormally distributed f_whrl:
```

subplot(2, 1, 1);
hist(f_whrl.Close);
grid; title('Nonnormally Distributed Data');
subplot(2, 1, 2);
hist(bc whrl.Close);
grid; títle('Box-Cox Transformed Data');

```

\section*{Box-Cox Transformation}

The bar chart on the top represents the probability distribution function of the filled data series, \(f\) _whrl, which is the original data series whrl with the missing values
interpolated using the linear method. The distribution is skewed toward the left (not normally distributed). The bar chart on the bottom is less skewed to the left. If you plot a Gaussian probability distribution function (PDF) with similar mean and standard deviation, the distribution of the transformed data is very close to normal (Gaussian).

When you examine the contents of the resulting object bc_whrl, you find an identical object to the original object whrl but the contents are the transformed data series. If you have the Statistics and Machine Learning Toolbox software, you can generate a Gaussian PDF with mean and standard deviation equal to those of the transformed data series and plot it as an overlay to the second bar chart. In the next figure, you can see that it is an approximately normal distribution.

\section*{Overlay of Gaussian PDF}

The next example uses the smoothts function to smooth a time series.
To begin, transform ibm9599. dat, a supplied data file, into a financial time series object:
```

ibm = ascii2fts('ibm9599.dat', 1, 3, 2);

```

Fill the missing data for holidays with data interpolated using the fillts function and the Spline fill method:
```

f_ibm = fillts(ibm, 'Spline');

```

Smooth the filled data series using the default Box (rectangular window) method:
```

sm_ibm = smoothts(f_ibm);

```

Now, plot the original and smoothed closing price series for IBM stock:
```

plot(f_ibm.CLOSE('11/01/97::02/28/98'), 'r')
datetick('x', 'mmmyy')
hold on
plot(sm_ibm.CLOSE('11/01/97::02/28/98'), 'b')
hold off
datetick('x', 'mmmyy')
legend('Filled', 'Smoothed')
title('Filled IBM Close Price vs. Smoothed Series')

```

\section*{Smoothed Data Series}

These examples give you an idea of what you can do with a financial time series object. This toolbox provides some MATLAB functions that have been overloaded to work directly with these objects. The overloaded functions are those most commonly needed to work with time series data.
```

```

\section*{Related Examples}
- "Creating Financial Time Series Objects" on page 11-3
- "Visualizing Financial Time Series Objects" on page 11-16
- "Using the Financial Time Series App" on page 13-13
- "Using Time Series to Predict Equity Return" on page 12-23

\section*{Using Time Series to Predict Equity Return}

This example shows a practical use of financial time series objects, predicting the return of a stock from a given set of data. The data is a series of closing stock prices, a series of dividend payments from the stock, and an explanatory series (in this case a market index). Additionally, the example calculates the dividend rate from the stock data provided.

\section*{Step 1. Load the data.}

The data for this demonstration is found in the MAT-file predict_ret_data.mat. The MAT-file contains six vectors:
- Dates corresponding to the closing stock prices, sdates
- Closing stock prices, sdata
- Dividend dates, divdates
- Dividend paid, divdata
- Dates corresponding to the metric data, expdates
- Metric data, expdata
load predict_ret_data.mat

\section*{Step 2. Create Financial Time Series objects.}

It is useful to work with financial time series objects rather than with the vectors now in the workspace. By using objects, you can easily keep track of the dates. Also, you can manipulate the data series based on dates because a time series object keeps track of the administration of a time series for you. Use the object constructor fints to construct three financial time series objects.
```

t0 = fints(sdates, sdata, {'Close'}, 'd', 'Inc');
dO = fints(divdates, divdata, {'Dividends'}, 'u', 'Inc');
x0 = fints(expdates, expdata, {'Metric'}, 'w', 'Index');

```

The variables \(\mathrm{t} 0, \mathrm{dO}\), and x 0 are financial time series objects containing the stock closing prices, dividend payments, and the explanatory data, respectively.

\section*{Step 3. Create closing prices adjustment series.}

The price of a stock is affected by the dividend payment. On the day before the dividend payment date, the stock price reflects the amount of dividend to be paid the next day. On
the dividend payment date, the stock price is decreased by the amount of dividend paid. Create a time series (dadj1) that reflects this adjustment factor. Then create the series (dadj2) that adjusts the prices at the day of dividend payment; this is an adjustment of 0 . You also need to add the previous dividend payment date since the stock price data reflect the period subsequent to that day; the previous dividend date was December 31, 1998. Combining the two objects (dadj1 and dadj2) gives the data needed to adjust the prices. However, since the stock price data is daily data and the effect of the dividend is linearly divided during the period, use the fillts function to make a daily time series ( \(\operatorname{dadj} 3\) ) from the adjustment data. Use the dates from the stock price data to make the dates of the adjustment the same.
```

dadj1 = d0;
dadj1.dates = dadj1.dates-1;
dadj2 = d0;
dadj2.Dividends = 0;
dadj2 = fillts(dadj2,'linear','12/31/98');
dadj2('12/31/98') = 0;
dadj3 = [dadj1; dadj2];
dadj3 = fillts(dadj3, 'linear', to.dates);

```

\section*{Step 4. Adjust closing prices and make them spot prices.}

The stock price recorded already reflects the dividend effect. To obtain the "correct" price, subtract the dividend amount from the closing prices. Put the result inside the same object t0 with the data series name Spot. To make sure that adjustments correspond, index into the adjustment series using the dates from the stock price series t0. Use the datestr command because t0. dates returns the dates in serial date format. Also, since the data series name in the adjustment series dadj3 does not match the one in t0, use the function fts2mat.
```

t0.Spot = t0.Close - fts2mat(dadj3(datestr(t0.dates)));

```

\section*{Step 5. Create return series.}

Calculate the return series from the stock price data. A stock return is calculated by dividing the difference between the current closing price and the previous closing price by the previous closing price.
```

tret = (t0.Spot - lagts(t0.Spot, 1)) ./ lagts(t0.Spot, 1);
tret = chfield(tret, 'Spot', 'Return');

```

Ignore any warnings you receive during this sequence. Since the operation on the first line above preserves the data series name Spot, it has to be changed with the chfield command to reflect the contents correctly.

\section*{Step 6. Regress return series against metric data.}

The explanatory (metric) data set is a weekly data set while the stock price data is a daily data set. The frequency needs to be the same. Use todaily to convert the weekly series into a daily series. The constant needs to be included here to get the constant factor from the regression. Get all the dates common to the return series calculated and the explanatory (metric) data and then combine the contents of the two series that have dates in common into a new time series (regts0). Remove the contents of the new time series that are not finite to create time series (regts1).

Place the data to be regressed into a matrix using the function fts2mat. The first column of the matrix corresponds to the values of the first data series in the object, the second column to the second data series, and so on. In this case, the first column is regressed against the second and third column. Using the regression coefficients, calculate the predicted return from the stock price data. Put the result into the return time series tret as the data series PredReturn.
```

x1 = todaily(x0);
x1.Const = 1;
dcommon = intersect(tret.dates, x1.dates);
regts0 = [tret(datestr(dcommon)), x1(datestr(dcommon))];
finite_regts0 = find(all(isfinite( fts2mat(regts0)), 2));
regts1 = regts0( finite_regts0 );
DataMatrix = fts2mat(regts1);
XCoeff = DataMatrix(:, 2:3) \ DataMatrix(:, 1);
RetPred = DataMatrix(:,2:3) * XCoeff;
tret.PredReturn(datestr(regts1.dates)) = RetPred;

```

\section*{Step 7. Plot the results.}

Plot the results in a single window. The top plot in the window has the actual closing stock prices and the dividend-adjusted stock prices (spot prices). The bottom plot shows the actual return of the stock and the predicted stock return through regression.
```

subplot(2, 1, 1);

```
    plot(t0);
    plot(t0);
    title('Spot and Closing Prices of Stock');
    title('Spot and Closing Prices of Stock');
    subplot(2, 1, 2);
    subplot(2, 1, 2);
    plot(tret);
    plot(tret);
    title('Actual and Predicted Return of Stock');
    title('Actual and Predicted Return of Stock');
Spot and Closing Prices of Stock

Actual and Predicted Return of Stock

\section*{Step 8. Calculate the dividend rate.}

Calculate the dividend rate from the stock price data by dividing the dividend payments by the corresponding closing stock prices. Stock price data for October 2, 1999 does not exist. The fillts function can overcome this situation; fillts allows you to insert a date and interpolate a value for the date from the existing values in the series. There are a number of interpolation methods. Use fillts to create a new time series
(t1) containing the missing date from the original data series. Then set the frequency indicator to daily.
```

datestr(d0.dates, 2)
t1 = fillts(t0,'nearest',d0.dates);
t1.freq = 'd';
tdr = do./fts2mat(t1.Close(datestr(do.dates))) % Calculate the dividend rate
ans =
04/15/99
06/30/99
10/02/99
12/30/99
tdr =
desc: Inc
freq: Unknown (0)
'dates: (4)' 'Dividends: (4)
'15-Apr-1999' [ 0.0193]
'30-Jun-1999' [ 0.0305]
'02-Oct-1999' [ 0.0166]
'30-Dec-1999' [ 0.0134]

```

You can find a file for this example program in the folder matlabroot/toolbox/ finance/findemos on your MATLAB® path. The file is predict_ret.m.

- "Using the Financial Time Series App with GUIs" on page 13-21

\section*{What Is the Financial Time Series App?}

The Financial Time Series app enables you to create and manage financial time series (fints) objects. The Financial Time Series app interoperates with the Financial Time Series Graphical User Interface (ftsgui) and Interactive Chart (chartfts). In addition, you can use Datafeed Toolbox \({ }^{\mathrm{TM}}\) or Database Toolbox \({ }^{\mathrm{TM}}\) software to connect to external data sources.

A financial time series object minimally consists of:
- Desc, which is the description field.
- Freq, which is a frequency indicator field.
- Dates, which is a date vector field. If the date vector incorporates time-of-day information, the object contains an additional field named times.
- In addition, you can have at least one data series vector. You can specify names for any data series vectors. If you do not specify names, the object uses the default names series1, series2, series3, and so on.

In general, the workflow for using the Financial Time Series app is:
1 Acquire data.
2 Create a variable.
3 Convert the variable to fints.
4 Convert fints to a MATLAB double object.
To obtain the data for the Financial Time Series app, you need to use a MATLAB double object or a financial time series (fints) object. You can use previously stored internal data on your computer or you can connect to external data sources using Datafeed Toolbox or Database Toolbox software.

Note: You must obtain a license for these products from MathWorks before you can use either of these toolboxes.

After creating a financial time series object, you can use the Financial Time Series app to change the characteristics of the time series object, including merging with other financial time series objects, removing rows or columns, and changing the frequency. You can also use the Financial Time Series app to generate various forms of plotted output and you can reconvert a fints object to a MATLAB double-precision matrix.

\section*{Getting Started with the Financial Time Series App}

To start the Financial Time Series app:
1 On the MATLAB desktop toolstrip, click the Apps tab and in the apps gallery, under Computational Finance, click Financial Time Series.

The Financial Time Series app opens. For an overview of the Financial Time Series app, see "What Is the Financial Time Series App?" on page 13-2.
2 To load data with the Financial Time Series app, see "Loading Data with the Financial Time Series App" on page 13-7.

If you plan to load data from Database Toolbox or Datafeed Toolbox software, ensure that you have a license. For more information on using these toolboxes, see the Database Toolbox and Datafeed Toolbox documentation.
3 For more information on the tasks supported by the Financial Time Series app, see "Using the Financial Time Series App" on page 13-13 and "Using the Financial Time Series App with GUIs" on page 13-21.

\section*{Loading Data with the Financial Time Series App}
```

In this section...
"Overview" on page 13-7
"Obtaining External Data" on page 13-7
"Obtaining Internal Data" on page 13-9
"Viewing the MATLAB Workspace" on page 13-10

```

\section*{Overview}

The Data source pane in the Financial Time Series app lets you do the following:
- Obtain live data from various external data servers using either Datafeed Toolbox or Database Toolbox software.
- Load data you previously obtained and stored in a file.
- View data contained within the MATLAB workspace.

\section*{Obtaining External Data}

You can obtain external data using Datafeed Toolbox or Database Toolbox software. Datafeed Toolbox software lets you obtain data from several financial data servers, including:
- Bloomberg \({ }^{\circledR}\)
- \(e_{\text {eSignal }}{ }^{\circledR}\)
- FactSet \({ }^{\circledR}\)
- Federal Reserve Economic Data (FRED \({ }^{\circledR}\) )
- Haver Analytics \({ }^{\circledR}\) financial data
- Interactive Data \({ }^{\mathrm{TM}}\)
- IQFEED \(^{\circledR}\)
- Kx Systems \({ }^{\circledR}\), Inc. kdb+ database
- Thomson Reuters \({ }^{\mathrm{TM}}\)
- SIX Financial Information
- Yahoo! \({ }^{\circledR}\)

Except for Federal Reserve Economic Data (FRED) and Yahoo!, these data servers require that you obtain a license from the vendor before you can access their data.

Tip If you open Datafeed Toolbox or Database Toolbox software before starting the Financial Time Series app, the Financial Time Series app is unable to recognize the toolboxes. When working with the Financial Time Series app, select File > Load to open these toolboxes.

\section*{Obtaining External Data with Datafeed Toolbox Software}

1 From the Financial Time Series app, select File \(>\) Load \(>\) Datafeed Toolbox to open the toolbox.

2 Click the Connection tab in Datafeed Toolbox software to select the data source you want to load into the Financial Time Series app.

3 Click the Data tab in Datafeed Toolbox software to select the security and the associated data that you want to load into the Financial Time Series app.

4 After using Datafeed Toolbox software to define the connection, security, data, and MATLAB variable name, click Get Data and then, using the Financial Time Series app, click Refresh variable list. The Data source field in the Financial Time Series app displays the name of the security you selected from the Data tab in Datafeed Toolbox software. The Financial Time Series app Active variable field indicates the name of the MATLAB workspace variable you chose for this security.
5 Click Close to exit Datafeed Toolbox software. The Financial Time Series app clears the Data source and Active variable fields.

\section*{Obtaining External Data with Database Toolbox Software}

1 From the Financial Time Series app, select File > Load > Database Toolbox to open the toolbox.

2 From the Visual Query Builder window, select the data you want to load into the Financial Time Series app.

3 After using Database Toolbox software to select data and name the MATLAB workspace variable, click Execute and then, using the Financial Time Series app, click Refresh variable list. The Data source field in the Financial Time Series app displays the name of the highlighted data source that you selected from the Data list box in the Visual Query Builder window. The Financial Time Series app Active variable field indicates the name of the MATLAB workspace variable you chose for the security in the Visual Query Builder window.
4 From the Database Toolbox software, select Query > Close Visual Query Builder, the Financial Time Series app clears the Data source and Active variable fields.

\section*{Obtaining Internal Data}

You can use the Financial Time Series app to load data from files previously stored on your computer. The types of data files you can load are as follows:
- MATLAB .mat files, with or without fints objects
- ASCII text files (.dat or .txt suffixes)
- Excel .xls files

To obtain internal data:
1 From the Financial Time Series app, select File \(>\) Load \(>\) File to open the Load a MAT, ASCII, .XLS File dialog box.
2 Select the data you want to load into the Financial Time Series app.
- If you load a MATLAB MAT-file, the variables in the file are placed into the MATLAB workspace. The MATLAB Workspace Variables list box shows the variables that have been added to the workspace. For example, if you load the file disney.mat, which is distributed with the toolbox, the MATLAB Workspace Variables list box displays the variables in that MAT-file.

Note: The Financial Time Series app automatically generates a line plot for each workspace variable unless you disable this feature by resetting the default action under File > Preferences > Generate line plot on load.
- If you load a . dat or an ASCII . txt file, the ASCII File Parameters dialog box opens. Use this dialog box to transform a text data file into a MATLAB financial time series fints object. The format for the ascii data must be:
- Dates must be in a valid date string format:
- 'ddmmmyy' or 'ddmmmyyyy'
- 'mm/dd/yy' or 'mm/dd/yyyy'
- 'dd-mmm-yy' or 'dd-mmm-yyyy'
- 'mmm.dd, yy' or 'mmm.dd, yyyy'
- Time information must be in 'hh:mm' format.
- Each column must be separated either by spaces or a tab.

For more information on converting ascii data to a fints object, see ascii2fts.
- If you load an Excel .xls file, the Excel File Parameters dialog box opens. Use this dialog box to transform Excel worksheet data into a MATLAB financial time series (fints) object.
3 From the Financial Time Series app, select File \(>\) Save to save the data you loaded from an internal file.

\section*{Viewing the MATLAB Workspace}

The MATLAB Workspace Variables list box displays all existing MATLAB workspace variables. Double-click any variable to display the data in the Data Table. You can only display financial time series (fints) objects, MATLAB doubles, and cell arrays of double data in the Data Table.

In addition, you can click Refresh variable list to refresh the MATLAB Workspace Variables list box. You need to refresh this list periodically because it is refreshed automatically only for operations performed with the Financial Time Series app, not for operations performed within MATLAB itself.

Click Remove variable(s) to remove variable from the MATLAB Workspace Variables list and from the MATLAB workspace.
```

"Modifying Data for a Financial Time Series Object in the Data Table" on page 13-17
"Viewing and Modifying the Properties for a FINTS Object" on page 13-19

```

\section*{Creating a Financial Time Series Object}

Using the Create tab in the FINTS Objects and Outputs pane for the Financial Time Series app, you can create a financial time series (fints) object from one or more selected variables.

Note: When you first start the Financial Time Series app, the Create tab appears on top, unless you reset the default using File > Preferences > Show Create tab when ftstool starts.

To create a financial time series (fints) object from one or more selected variables:
1 Load data into the Financial Time Series app from either an external data source using Datafeed Toolbox or Database Toolbox software or an internal data source using File \(>\) Load \(>\) File.

2 Select one or more variables from the MATLAB Workspace Variables list.
3 Click the Create tab and then click Active variable.
When combining multiple variables, you can type a new variable name for the combined variables in the MATLAB workspace variable box. The new variable name is added to the MATLAB Workspace Variables list. (If you do not choose a name for the MATLAB workspace variable, the Financial Time Series app uses the default name myFts.)

4 Click Create FINTS object to display the result in the Data Table.

\section*{Merge Financial Time Series Objects}

Using the Create tab in the FINTS Objects and Outputs pane for the Financial Time Series app, you can create a new financial time series object by merging (joining) multiple existing financial time series objects.

Note: When you first start the Financial Time Series app, the Create tab appears on top, unless you reset the default using File \(>\) Preferences.

To create a financial time series (fints) object by merging multiple existing financial time series objects:

1 Load data into the Financial Time Series app from either an external data source using Datafeed Toolbox or Database Toolbox software or an internal data source using File \(>\) Load \(>\) File.
2 To merge multiple existing financial time series objects, click the Create tab, click Components, and then select a value for the Time vector source and one or more items from the Data sources list.

Note: You can merge at once multiple financial time series objects. For more information on merging fints objects, see merge.
3 Click Create FINTS object to display the result in the Data Table.

\section*{Converting a Financial Time Series Object to a MATLAB Double-Precision Matrix}

Using the Convert tab in the FINTS Objects and Outputs pane for the Financial Time Series app, you can convert a financial time series (fints) object to a MATLAB double-precision matrix.

To create a financial time series object from one or more selected variables:
1 Load data into the Financial Time Series app from either an external data source using Datafeed Toolbox or Database Toolbox software or an internal data source using File \(>\) Load \(>\) File.

2 Select a variable from the MATLAB Workspace Variables list box.
3 Click the Convert tab and then determine whether to include or exclude dates in the conversion by clicking Include dates or Exclude dates.
4 Type a variable name in the Output variable name box. (If you do not choose a variable name, the Financial Time Series app uses the default name myDbl.)
5 Click Convert FINTS to double matrix. (This operation is equivalent to performing fts2mat on a financial time series object.)

\section*{Plotting the Output in Several Formats}

Using the Plot tab in the FINTS Objects and Outputs pane for the Financial Time Series app, you can create several forms of plotted output by using a selection list. You can create four types of bar charts, candle plots, high-low plots, line plots, and interactive charts (the latter is created by using the interoperation of the Financial Time Series app with the function chartfts).

The set of plots supported by the Financial Time Series app are identical to the set provided by the Graphs menu of the Financial Time Series GUI. (See "Graphs Menu" on page 14-14.) You can find more detailed information for the supported plots by consulting the reference page for each individual type of plot.

To create a plotted output:
1 Load data into the Financial Time Series app from either an external data source using Datafeed Toolbox or Database Toolbox software or an internal data source using File \(>\) Load \(>\) File.
2 Select a variable from the MATLAB Workspace Variables list box or select data from the Data Table.
3 Click the Plot tab and indicate whether you are plotting based on a workspace variable or data from the Data Table.
4 From the Type drop-down list, select the type of plot.
5 Click Plot. The plot is displayed.

\footnotetext{
Note: If the selected workspace variable that you are plotting is not a fints object, a fints object is created when you click Plot. The new fints object uses the name designated by the MATLAB workspace variable box on the Create tab.
}

\section*{Viewing Data for a Financial Time Series Object in the Data Table}

Once a financial time series (fints) object is created, the Financial Time Series app Data Table displays user-designated data, including financial time series objects, MATLAB double-precision variables, and cell arrays of doubles. (Cell arrays of doubles are often the resulting format when using Database Toolbox software.)

When displaying double variables (or a cell array of doubles) in the Data Table, the column headings for a double variable or cell array of doubles displayed in the Data Table are labeled A, B, C, and so on.

\section*{Overwriting Data in the Data Table Display}

If you use the command line to overwrite data previously retrieved using Datafeed Toolbox or Database Toolbox software, two events could occur:
- If the new data contains the same number of columns as before, the headers remain unchanged when you attempt to create a financial time series (fints) object using the modified data.
- If the data contains a different number of columns, a warning dialog box appears.

For example, assume that you use Datafeed Toolbox software to obtain Close, Date, High, Low, Open, and Volume data for the equity GOOG. You store the data in the MATLAB workspace with the variable name cur1. From the command line, if you redefine the variable cur1, eliminating the second column (Close)
```

cur1(:,2) = [ ]

```
and then return to the Financial Time Series app and attempt to create a financial time series object, a warning dialog box appears.

\section*{Modifying Data for a Financial Time Series Object in the Data Table}

The Financial Time Series app lets you update your data displayed in the Data Table by adding or removing rows or columns.

Note: Modifying data in the Data Table will not update the MATLAB workspace variable. To update the workspace variable after modifying the Data Table, click Update workspace variable.

\section*{Adding and Removing Rows}

To add a row of data displayed in the Data Table:
1 Select a row from the Data Table display where you want to add a row. Click Additional options to open the Data Table Options dialog box.
2 Click Add row. The default is to add up the row. To add a row down, select Insertion option and then click Add down. In addition, you can select the Insertion option of Date to designate a specific date. (If a date is not specified, the
added row contains a date that is chronologically in order with respect to the initial row.)

When you add rows, the Data Table display is immediately updated.
To remove a row of data from the Data Table:
1 Select one or more rows in the Data Table display that you want to remove. Click Additional options to open the Data Table Options dialog box.
2 Click Remove row(s). The default is to remove the selected rows. In addition, to remove selected rows, select Removal options and then select other options for row removal from the Remove rows list box. You can specify a Start and End date or you can click the Non-uniform range setting option to designate a range.

When you remove rows, the Data Table display is updated immediately.

\section*{Adding and Removing Columns}

To add a column of data displayed in the Data Table:
1 Select a column from the Data Table display where you want to add a column. Click Additional options to open the Data Table Options dialog box.
2 Click Add column. The default is to add the column to the left of the selected column.

Note: For time series objects, you cannot add a column to the left of the Date/Times column; there is no restriction for double data.

To add a column to the right, select Insertion option and then click Add right. In addition, you can use the Insertion option of New Column Name to designate a specific column name. (If a New Column Name is not specified, an added column contains a column name of series1, series2, and so on.)

When you add columns, the Data Table display is updated immediately.
To remove a column of data displayed in the Data Table:
1 Select one or more columns in the Data Table display that you want to remove. Click Additional options to open the Data Table Options dialog box.

2 Click Remove column(s). The default is to remove the selected rows. In addition, to remove selected columns, select Removal options and then select columns for removal from the Remove columns list box.

When you remove columns, the Data Table display is updated immediately.

\section*{Viewing and Modifying the Properties for a FINTS Object}

The FINTS Object Properties pane in the Financial Time Series app lets you modify financial time series (fints) object properties. This area becomes active whenever the Data Table displays a financial time series object.

To modify the properties for a fints object:
1 After you create a fints object, double-click the object name in the MATLAB Workspace Variables list box to open the Data Table and display the fints object properties.
2 Click to modify the Description, Frequency, or Series Names fields.
The Frequency drop-down list supports the following conversion functions:
\begin{tabular}{ll} 
Function & New Frequency \\
toannual & Annual \\
todaily & Daily \\
tomonthy & Monthly \\
toquarterly & Quarterly \\
tosemi & Semiannually \\
toweekly & Weekly
\end{tabular}

3 Click Update properties to save the changes. This action also updates the associated workspace variable.

\section*{Using the Financial Time Series App with GUls}

\begin{abstract}
The Financial Time Series app works with Datafeed Toolbox and Database Toolbox software to load data. In addition, the Financial Time Series app interoperates with chartfts to display an interactive plot and ftsgui to perform further time series data analysis.
\end{abstract}

The workflow for using the Financial Time Series app with chartfts is:
1 After loading data from either Datafeed Toolbox or Database Toolbox software or an internal file, select a variable from the MATLAB Workspace Variables list box.
2 Click the Plot tab, click Type, and then select Interactive Chart.
3 Click Plot. The interactive plot is displayed in chartfts. You can then use chartfts menu items for further display options.

For more information on chartfts, select Help > Graphics Help.
The workflow for using the Financial Time Series app with the Financial Time Series GUI (ftsgui) is:

1 After loading data from either Datafeed Toolbox or Database Toolbox software or an internal file, select a variable from the MATLAB Workspace Variables list box.
2 Select Tools > FTSGUI to open the Financial Time Series GUI window.
3 Select a variable from the MATLAB Workspace Variables list box. Click the Plot tab and then select one of the following from the Type drop-down list: Line Plot, High-Low Plot, or Candlestick Plot.
4 Click Plot. The plot is displayed in a MATLAB graphic window. In addition, the Financial Time Series GUI window displays an entry for the plotted fints object. You can then use the menu items in the Financial Time Series GUI window to perform further analysis.

For more information on ftsgui, select Help > Help on Financial Time Series GUI.

\footnotetext{
Note: If the selected workspace variable that you are plotting is not a fints object, a fints object is created when you click Plot. The new fints object uses the name designated by the MATLAB workspace variable box on the Create tab.
}

\hline
\end{tabular}

The title bar acts as an active time series object indicator (indicates the currently active financial time series object). For example, if you load the file disney.mat and want to use the time series data in the file dis, the title bar on the main GUI would read as shown.

The menu bar consists of six menu items: File, Data, Analysis, Graphs, Window, and Help. Under the menu bar is a status box that displays the steps you are doing.

\section*{File Menu}

The File menu contains the commands for input and output. You can read and save (Load, Save, and Save As) MATLAB MAT-files, ASCII (text) data files. To load MATLAB MAT-files, the MAT-file must contain a fints object. You can also import (Import) Excel XLS files.

The File menu also contains the printing suite (Page Setup, Print Preview, and Print). Lastly, from this menu you can close the GUI itself (Close FTS GUI) and quit MATLAB (Exit MATLAB).

\section*{Data Menu}

The Data menu provides a collection of data manipulation functions and data conversion functions.
\begin{tabular}{|l|l|}
\hline Resample data & \\
\hline \multicolumn{1}{|c|}{ Convert Data Frequency To } & To Daily \\
\hline & To Weekly \\
& To Monthly \\
& To Quarterly \\
& To Semi-annual \\
& To Annual \\
\hline
\end{tabular}

To use any of the functions here, make sure that the correct financial time series object is displayed in the title bar of the main GUI window.

Analysis Menu

The Analysis menu provides
- A set of exponentiation and logarithmic functions.
- Statistical tools (Basic Statistics), which calculate and display the minimum, maximum, average (mean), standard deviation, and variance of the current (active) time series object; these basic statistics numbers are displayed in a dialog box.
- Data difference (Difference) and periodic average (Periodic Average) calculations. Data difference generates a vector of data that is the difference between the first data point and the second, the second, and the third, and so on. The periodic average function calculates the average per defined length period, for example, averages of every five days.
- Technical analysis functions. See "Chart Technical Indicators" for a list of the technical analysis functions.

As with the Data menu, to use any of the Analysis menu functions, make sure that the correct financial time series object is displayed in the title bar of the main GUI window.

\section*{Graphs Menu}

The Graphs menu contains functions that graphically display the current (active) financial time series object. You can also start up the interactive charting function (chartfts) from this menu.

\section*{Window Menu}

The Window menu lists open windows under the current MATLAB session.

\section*{Help Menu}
\begin{tabular}{|c|c|c|}
\hline \multicolumn{2}{|l|}{- Financial Time Series GUl, Active: Walt Disney Company (DIS)} & -|回| \\
\hline File Data Analysis Graphs Window & Help & \\
\hline \multirow[t]{4}{*}{\begin{tabular}{l}
Started: Main FTS GUI Window \\
Loaded file: J:\disney.mat \\
Displaying: Walt Disney Company (DIS) \\
Displaying: TOQUARTERLY: Walt Disney Company (DIS \\
Displaying: Walt Disney Company (DIS) - No VOLUMME
\end{tabular}} & Help on Financial Time Series GUI & \(\square\) \\
\hline & Help on Financial Time Series Toolbox & \\
\hline & Help on MATLAB & \\
\hline & MATLAB Demos & \(\checkmark\) \\
\hline \multicolumn{2}{|r|}{About Financial Time Series GUI} & \\
\hline & About MATLAB & \\
\hline
\end{tabular}

The Help menu provides a standard set of Help menu links.

- "Working with Financial Time Series Objects" on page 12-3

\section*{Using the Financial Time Series GUI}
```

In this section...
"Getting Started" on page 14-7
"Data Menu" on page 14-9
"Analysis Menu" on page 14-13
"Graphs Menu" on page 14-14
"Saving Time Series Data" on page 14-18

```

\section*{Getting Started}

To use the Financial Time Series GUI, first start the financial time series GUI with the command ftsgui. Then load (or import) the time series data.

For example, if your data is in a MATLAB MAT-file, select Load from the File menu.

For illustration purposes, choose the file ftsdata.mat from the dialog box presented.
If you do not see the MAT-file, look in the folder matlabroot \(\backslash\) toolbox \(\backslash\) finance \findemos, where matlabroot is the MATLAB root folder (the folder where MATLAB is installed).

Note Data loaded through the Financial Time Series GUI is not available in the MATLAB workspace. You can access this data only through the GUI itself, not with any MATLAB command-line functions.

Each financial time series object inside the MAT-file is presented as a line plot in a separate window. The status window is updated accordingly.

Whirlpool (WHR) is the last plot displayed, as indicated on the title bar of the main window.

\section*{Data Menu}

The Data menu provides functions that manipulate time series data.

Here are some example tasks that illustrate the use of the functions on this menu.

\section*{Fill Missing Data}

First, look at filling missing data. The Fill Missing Data item uses the toolbox function fillts. With the data loaded from the file ftsdata, you have three time series: IBM

Corp. (IBM), Walt Disney Co. (DIS), and Whirlpool (WHR). Click the window that shows the time series data for Walt Disney Co. (DIS).

To view any missing data in this time series data set, zoom into the plot using the Zoom tool (the magnifying glass icon with the plus sign) from the toolbar and select a region.

The gaps represent the missing data in the series. To fill these gaps, select Data \(>\) Fill Missing Data. This selection automatically fills the gaps and generates a new plot that displays the filled time series data.

You cannot see the filled gaps when you display the entire data set. However, when you zoom into the plot, you see that the gaps have been eliminated. The title bar has
changed; the title has been prefixed with the word Filled to reflect the filled time series data.

\section*{Frequency Conversion}

The Data menu also provides access to frequency conversion functions.
\begin{tabular}{|l|l|}
\hline Resample data & \\
\hline \multicolumn{1}{|c|}{ Convert Data Frequency To } & To Daily \\
& To Weekly \\
& To Monthly \\
& To Quarterly \\
& To Semi-annual \\
& To Annual \\
\hline
\end{tabular}

This example changes the DIS time series data frequency from daily to monthly. Close the Filled Walt Disney Company (DIS) window, and click the Walt Disney Company (DIS) window to make it active (current) again. Then, from the Data menu, select Convert Data Frequency To and To Monthly.

A new figure window displays the result of this conversion.

The title reflects that the data displayed had its frequency changed to monthly.

\section*{Analysis Menu}

The Analysis menu provides functions that analyze time series data, including the technical analysis functions. (See "Chart Technical Indicators" for a complete list of the technical analysis functions and several usage examples.)

For example, you can use the Analysis menu to calculate the natural logarithm (log) of the data contained within the data set ftsdata.mat. This data file provides time series data for IBM (IBM), Walt Disney (DIS), and Whirlpool (WHR). Click the window displaying the data for IBM Corporation (IBM) to make it active (current). Then select the Analysis menu, followed by \(\log (. .\).\() . The result appears in its own window.\)

Close the above window and click again on the IBM data window to make it active (current).

Note Before proceeding with any time series analysis, make certain that the title bar confirms that the active data series is the correct one.

From the Analysis menu on the main window, select Technical Analysis and MACD. The result, again, is displayed in its own window.

Other analysis functions work similarly.

\section*{Graphs Menu}

The Graphs menu displays time series data using the provided graphics functions. Included in the Graphs menu are several types of bar charts (bar, barh and bar3, bar3h), line plot (plot), candle plot (candle), and High-Low plot (highlow). The Graphs menu also provides access to the interactive charting function, chartfts.

\section*{Candle Plot}

For example, you can display the candle plot of a set of time series data and start up the interactive chart on the same data set.

Load the ftsdata.mat data set, and click the window that displays the Whirlpool (WHR) time series data to make it active (current). From the main window, select the Graphs menu and then Candle Plot.

The result is shown below.

This does not look much like a candle plot because there are too many data points in the data set. All the candles are too compressed for effective viewing. However, when you zoom into a region of this plot, the candles become apparent.

\section*{Interactive Chart}

To create an interactive chart (chartfts) on the Whirlpool data, click the window that displays the Whirlpool (WHR) data to make it active (current). Then, go to the Graphs menu and select Interactive Chart.

The chart that results is shown below.

You can use this interactive chart as if you had invoked it with the chartfts command from the MATLAB command line. For a tutorial on the use of chartfts, see "Visualizing Financial Time Series Objects" on page 11-16.

\section*{Saving Time Series Data}

The Save and Save As items on the main window File menu let you save the time series data that results from your analyses and computations. These items save all time series data that has been loaded or processed during the current session, even if the window displaying the results of a computation has previously been dismissed.

Note The Save and Save As items on the File menu of the individual plot windows will not save the time series data, but will save the actual plot.

You can save your time series data in two ways:
- Into the latest MAT-file loaded (Save)
- Into a MAT-file chosen (or named) from the window (Save As)

To illustrate this, start by loading the data file testftsdata.mat (located in matlabroot/toolbox/finance/findemos). Then, convert the Disney (DIS) data from daily (the original frequency) to monthly data. Next, run the MACD analysis on the Whirlpool (WHR) data. You now have a set of five open figure windows.

\section*{Saving into the Original File (Save)}

To save the data back into the original file (testftsdata.mat), select Save from the File menu.

A confirmation window appears. It confirms that the data has been saved in the latest MAT-file loaded (testftsdata.mat in this example).

\section*{Saving into a New File (Save As)}

To save the data in a different file, choose Save As from the File menu.
The dialog box that appears lets you choose an existing MAT-file from a list or type in the name of a new MAT-file you want to create.

After you click the Save button, another confirmation window appears.

This confirmation window indicates that the data has been saved in a new file named myftstestdata.mat.

\section*{Related Examples}
- "Working with Financial Time Series Objects" on page 12-3

\section*{More About}
- "Financial Time Series User Interface" on page 14-2

\section*{Trading Date Utilities}
- "Trading Calendars User Interface" on page 15-2
- "UICalendar User Interface" on page 15-4

\section*{Trading Calendars User Interface}

Use the createholidays function to open the Trading Calendars user interface.

The createholidays function supports http://www.FinancialCalendar.com trading calendars. This function can be used from the command line or from the Trading Calendars user interface. To use createholidays or the Trading Calendars user interface, you must obtain data, codes, and info files from http: / / www. FinancialCalendar. com trading calendars. For more information on using the command line to programmatically generate the market-specific holidays.m files without displaying the interface, see createholidays.

To use the Trading Calendars user interface:
1 From the command line, type the following command to open the Trading Calendars user interface.
```

createholidays

```

2 Click Choose data file to select the data file.
3 Click Choose codes file to select the codes file.
4 Click Choose info file to select the info file.
5 Click Choose directory for writing holiday files to select the output folder.
6 Select Include weekends to include weekends in the holiday list and click Prompt for target directory to be prompted for the file location for each holidays.m file that is created.
7 Click Create holiday files to convert FinancialCalendar. com financial center holiday data into market-specific holidays.m files.

The market-specific holidays.m files can be used in place of the standard holidays.m that ships with Financial Toolbox software.

\section*{Related Examples}
- "Handle and Convert Dates" on page 2-4
- "UICalendar User Interface" on page 15-4

\section*{UICalendar User Interface}
```

In this section...
"Using UICalendar in Standalone Mode" on page 15-4
"Using UICalendar with an Application" on page 15-4

```

\section*{Using UICalendar in Standalone Mode}

You can use the UICalendar user interface in standalone mode to look up any date. To use the standalone mode:

1 Type the following command to open the UICalendar GUI:
uicalendar
The UICalendar interface is displayed:
\begin{tabular}{|c|c|c|c|c|c|c|}
\hline \multicolumn{5}{|l|}{- \(\lambda\) UICalendar} & \multicolumn{2}{|l|}{\(\underline{-} \square\)} \\
\hline - \({ }^{\text {N }}\) & May & & & 07 & \(\nabla\) & \(\bullet\) \\
\hline Su & Mo & Tu & Lye & Th & Fr & Sa \\
\hline 29 & 30 & 1 & 2 & 3 & 4 & 5 \\
\hline 6 & 7 & 8 & 9 & 10 & 11 & 12 \\
\hline 13 & 14 & 15 & 16 & 17 & 18 & 19 \\
\hline 20 & 21 & 22 & 23 & 24 & 25 & 26 \\
\hline 27 & 28 & 29 & 30 & 31 & & 2 \\
\hline 3 & 4 & 5 & 6 & 7 & 18 & 9 \\
\hline \multicolumn{2}{|l|}{Clear all} & & & OK & & ncel \\
\hline
\end{tabular}

2 Click the date and year controls to locate any date.

\section*{Using UICalendar with an Application}

You can use the UICalendar user interface with an application to look up any date. To use the UICalendar graphical interface with an application, use the following command:
```

uicalendar('PARAM1', VALUE1, 'PARAM2', VALUE2', ...)

```

For more information, see uicalendar.

\section*{Example of Using UICalendar with an Application}

The UICalendar example creates a function that displays a user interface that lets you select a date from the UICalendar user interface and fill in a text field with that date.

1 Create a figure.
function uicalendarGUIExample
f = figure('Name', 'uicalendarGUIExample');
2 Add a text control field.
```

dateTextHandle = uicontrol(f, 'Style', 'Text', ...
'String', 'Date:', ...
'Horizontalalignment', 'left', ...
'Position', [100 200 50 20]);

```

3 Add an uicontrol editable text field to display the selected date.
```

dateEditBoxHandle = uicontrol(f, 'Style', 'Edit', ...
'Position', [140 200 100 20], ...
'BackgroundColor', 'w');

```

4 Create a push button that startups the UICalendar.
```

calendarButtonHandle = uicontrol(f, 'Style', 'PushButton', ...

```
'String', 'Select a single date', ...
'Position', [275 200200 20], ...
'callback', @pushbutton_cb);

5 To start up UICalendar, create a nested function (callback function) for the push button.
```

function pushbutton_cb(hcbo, eventStruct)
% Create a UICALENDA}R\mathrm{ with the following properties:
% 1) Highlight weekend dates.
% 2) Only allow a single date to be selected at a time.
% 3) Send the selected date to the edit box uicontrol.
uicalendar('Weekend', [1 0 0 0 0 0 1], ...
'SelectionType', 1, ...
'DestinationUI', dateEditBoxHandle);
end
end

```

6 Run the function uicalendarGUIExample to display the application interface:

7 Click Select a single date to display the UICalendar user interface:

8 Select a date and click OK to display the date in the text field:

\section*{Technical Analysis}
- "Technical Indicators" on page 16-2
- "Technical Analysis Examples" on page 16-4

\section*{Technical Indicators}

Technical analysis (or charting) is used by some investment managers to help manage portfolios. Technical analysis relies heavily on the availability of historical data.
Investment managers calculate different indicators from available data and plot them as charts. Observations of price, direction, and volume on the charts assist managers in making decisions on their investment portfolios.

The technical analysis functions in Financial Toolbox are tools to help analyze your investments. The functions in themselves will not make any suggestions or perform any qualitative analysis of your investment.

\section*{Technical Analysis Examples}
```

In this section...
"Overview" on page 16-4
"Moving Average Convergence/Divergence (MACD)" on page 16-4
"Williams %R" on page 16-6
"Relative Strength Index (RSI)" on page 16-8
"On-Balance Volume (OBV)" on page 16-10

```

\section*{Overview}

To illustrate some of the technical analysis functions, this section uses the IBM stock price data contained in the supplied file ibm9599. dat. First create a financial time series object from the data using ascii2fts:
```

ibm = ascii2fts('ibm9599.dat', 1, 3, 2);

```

The time series data contains the open, close, high, and low prices, and the volume traded on each day. The time series dates start on January 3, 1995, and end on April 1, 1999, with some values missing for weekday holidays; weekend dates are not included.

\section*{Moving Average Convergence/Divergence (MACD)}

Moving Average Convergence/Divergence (MACD) is an oscillator function used by technical analysts to spot overbought and oversold conditions. Use the IBM® stock price data contained in the supplied file ibm9599. dat. First, create a financial time series object from the data using ascii2fts. Look at the portion of the time series covering the 3 -month period between October 1, 1995 and December 31, 1995. At the same time fill any missing values due to holidays within the time period specified:
```

ibm = ascii2fts('ibm9599.dat', 1, 3, 2);
part_ibm = fillts(ibm('10/01/95::12/31/95'));

```

Calculate the MACD, which when plotted produces two lines; the first line is the MACD line itself and the second is the nine-period moving average line:
```

macd_ibm = macd(part_ibm);

```

When you call macd without giving it a second input argument to specify a particular data series name, it searches for a closing price series named Close (in all combinations of letter cases).

Plot the MACD lines and the High-Low plot of the IBM stock prices in two separate plots in one window.
```

subplot(2, 1, 1);
plot(macd_ibm);
title('MACD of IBM Close Stock Prices, 10/01/95-12/31/95');
datetick('x', 'mm/dd/yy');
subplot(2, 1, 2);
highlow(part_ibm);
title('IBM Stock Prices, 10/01/95-12/31/95');
datetick('x', 'mm/dd/yy')

```

\section*{Williams \%R}

Williams \(\% \mathrm{R}\) is an indicator that measures overbought and oversold levels. The function willpctr is from the stochastics category. All the technical analysis functions can accept a different name for a required data series. If, for example, a function needs the high, low, and closing price series but your time series object does not have the data series names exactly as High, Low, and Close, you can specify the correct names as follows:
```

wpr =
willpctr(tsobj,14,'HighName','Hi','LowName','Lo','CloseName','Closing').

```

The function willpctr now assumes that your high price series is named Hi , low price series is named Lo, and closing price series is named Closing. Use the IBM® stock price data contained in the supplied file ibm9599. dat. First, create a financial time series object from the data using ascii2fts. Look at the portion of the time series covering the 3 -month period between October 1, 1995 and December 31, 1995. At the same time fill any missing values due to holidays within the time period specified:
```

ibm = ascii2fts('ibm9599.dat', 1, 3, 2);
part_ibm = fillts(ibm('10/01/95::12/31/95'));

```

Since the time series object part_ibm has its data series names identical to the required names, name adjustments are not needed. The input argument to the function is only the name of the time series object itself.

Calculate and plot the Williams \%R indicator for IBM stock along with the price range using these commands:
```

wpctr_ibm = willpctr(part_ibm);
subplot(2, 1, 1);
plot(wpctr_ibm);
title('Williams %R of IBM stock, 10/01/95-12/31/95');
datetick('x', 'mm/dd/yy');
hold on;
plot(wpctr_ibm.dates, -80*ones(1, length(wpctr_ibm)),...
'color', [0.5 0 0], 'linewidth', 2)
plot(wpctr_ibm.dates, -20*ones(1, length(wpctr_ibm)),...
'color', [0 0.5 0], 'linewidth', 2)
subplot(2, 1, 2);
highlow(part_ibm);
title('IBM Stock Prices, 10/01/95-12/31/95');
datetick('x', 'mm/dd/yy');

```

The top plot has the Williams \%R line plus two lines at \(-20 \%\) and \(-80 \%\). The bottom plot is the High-Low plot of the IBM stock price for the corresponding time period.

\section*{Relative Strength Index (RSI)}

The Relative Strength Index (RSI) is a momentum indicator that measures an equity's price relative to itself and its past performance. The function name is rsindex. The rsindex function needs a series that contains the closing price of a stock. The default period length for the RSI calculation is 14 periods. This length can be changed by providing a second input argument to the function. First, create a financial time series object from the data using ascii2fts. Look at the portion of the time series covering the

3 -month period between October 1, 1995 and December 31, 1995. At the same time fill any missing values due to holidays within the time period specified:
```

ibm = ascii2fts('ibm9599.dat', 1, 3, 2);
part_ibm = fillts(ibm('10/01/95::12/31/95'));

```

Calculate and plot the RSI for IBM® stock along with the price range using these commands:
```

rsi_ibm = rsindex(part_ibm);
subplot(2, 1, 1);
plot(rsi_ibm);
title('RSI of IBM stock, 10/01/95-12/31/95');
datetick('x', 'mm/dd/yy');
hold on;
wpctr_ibm = willpctr(part_ibm);
plot(rsi_ibm.dates, 30*ones(1, length(wpctr_ibm)),...
'color', [0.5 0 0], 'linewidth', 2)
plot(rsi_ibm.dates, 70*ones(1, length(wpctr_ibm)),...
'color',[0 0.5 0], 'linewidth', 2)
subplot(2, 1, 2);
highlow(part_ibm);
title('IBM Stock Prices, 10/01/95-12/31/95');
datetick('x', 'mm/dd/yy');

```

\section*{On-Balance Volume (OBV)}

On-Balance Volume (OBV) relates volume to price change. The function onbalvol requires you to have the closing price (Close) series and the volume traded (Volume) series. First, create a financial time series object from the data using ascii2fts. Look at the portion of the time series covering the 3 -month period between October 1, 1995 and December 31, 1995. At the same time fill any missing values due to holidays within the time period specified:
```

ibm = ascii2fts('ibm9599.dat', 1, 3, 2);
part_ibm = fillts(ibm('10/01/95::12/31/95'));

```

Calculate and plot the OBV for IBM® stock along with the price range using these commands:
```

obv_ibm = onbalvol(part_ibm);
subplot(2, 1, 1);
plot(obv_ibm);
title('On-Balance Volume of IBM Stock, 10/01/95-12/31/95');
datetick('x', 'mm/dd/yy');
subplot(2, 1, 2);
highlow(part_ibm);
title('IBM Stock Prices, 10/01/95-12/31/95');
datetick('x', 'mm/dd/yy');

```

\section*{SDE Modeling}

Financial Toolbox software enables you to model dependent financial and economic variables, such as interest rates and equity prices, by performing Monte Carlo simulation of stochastic differential equations (SDEs). The flexible architecture of the SDE engine provides efficient simulation methods that allow you to create new simulation and derivative pricing methods.

The following table lists tasks you can perform using the SDE functionality.
\begin{tabular}{|c|c|}

\section*{Trials vs. Paths}

Monte Carlo simulation literature often uses different terminology for the evolution of the simulated variables of interest, such as trials and paths. The following sections use the terms trial and path interchangeably.

However, there are situations where you should distinguish between these terms. Specifically, the term trial often implies the result of an independent random experiment (for example, the evolution of the price of a single stock or portfolio of stocks). Such an experiment computes the average or expected value of a variable of interest (for example, the price of a derivative security) and its associated confidence interval.

By contrast, the term path implies the result of a random experiment that is different or unique from other results, but that may or may not be independent.

The distinction between these terms is usually unimportant. It may, however, be useful when applied to variance reduction techniques that attempt to increase the efficiency of Monte Carlo simulation by inducing dependence across sample paths. A classic example involves pairwise dependence induced by antithetic sampling, and applies to more sophisticated variance reduction techniques, such as stratified sampling.

\section*{NTRIALS, NPERIODS, and NSTEPS}

SDE methods in the Financial Toolbox software use the parameters NTRIALS, NPERIODS, and NSTEPS as follows:
- The input argument NTRIALS specifies the number of simulated trials or sample paths to generate. This argument always determines the size of the third dimension (the number of pages) of the output three-dimensional time series array Paths. Indeed, in a traditional Monte Carlo simulation of one or more variables, each sample path is independent and represents an independent trial.
- The parameters NPERIODS and NSTEPS represent the number of simulation periods and time steps, respectively. Both periods and time steps are related to
time increments that determine the exact sequence of observed sample times. The distinction between these terms applies only to issues of accuracy and memory management. For more information, see "Optimizing Accuracy: About Solution Precision and Error" on page 17-81 and "Managing Memory" on page 17-79.

\section*{SDE Class Hierarchy}

TheFinancial Toolbox SDE class structure represents a generalization and specialization hierarchy. The top-level class provides the most general model interface and offers the default Monte Carlo simulation and interpolation methods. In turn, derived classes offer restricted interfaces that simplify model creation and manipulation while providing detail regarding model structure.

The following table lists the SDE classes. The introductory examples in "Available Models" on page 17-13 show how to use these classes to create objects associated with univariate models. Although the Financial Toolbox SDE engine supports multivariate models, univariate models facilitate object creation and display, and allow you to easily associate inputs with object parameters.

```

\section*{Introduction}

Most models and utilities available with Monte Carlo Simulation of SDEs are represented as MATLAB objects. Therefore, this documentation often uses the terms model and object interchangeably.

However, although all models are represented as objects, not all objects represent models. In particular, drift and diffusion objects are used in model specification, but neither of these types of objects in and of themselves makes up a complete model. In most cases, you do not need to create drift and diffusion objects directly, so you do not need to differentiate between objects and models. It is important, however, to understand the distinction between these terms.

In many of the following examples, most model parameters are evaluated or invoked like any MATLAB function. Although it is helpful to examine and access model parameters as you would data structures, think of these parameters as functions that perform actions.

For more information about MATLAB objects, see "Class to Manage Writable Files" in the MATLAB documentation.

\section*{Creating SDE Objects}
- "Constructing Objects" on page 17-8
- "Displaying Objects" on page 17-8
- "Assigning and Referencing Object Parameters" on page 17-8
- "Constructing and Evaluating Models" on page 17-8
- "Specifying SDE Simulation Parameters" on page 17-9

\section*{Constructing Objects}

You use constructors to create SDE objects.
For examples and more information, see:
- "Available Models" on page 17-13
- "Simulating Equity Prices" on page 17-33
- "Simulating Interest Rates" on page 17-61

\section*{Displaying Objects}
- Objects display like traditional MATLAB data structures.
- Displayed object parameters appear as nouns that begin with capital letters. In contrast, parameters such as simulate and interpolate appear as verbs that begin with lowercase letters, which indicate tasks to perform.

\section*{Assigning and Referencing Object Parameters}
- Objects support referencing similar to data structures. For example, statements like the following are generally valid:
\(A=o b j . A\)
- Objects support complete parameter assignment similar to data structures. For example, statements like the following are generally valid:
obj. \(A=3\)
- Objects do not support partial parameter assignment as data structures do. Therefore, statements like the following are generally invalid:
\[
\text { obj.A(i,j) }=0.3
\]

\section*{Constructing and Evaluating Models}
- You can construct objects of any model class only if enough information is available to determine unambiguously the dimensionality of the model. Because various class constructors offer unique input interfaces, some models require additional information to resolve model dimensionality.
- You need only enter required input parameters in placeholder format, where a given input argument is associated with a specific position in an argument list. You can enter optional inputs in any order as parameter name-value pairs, where the name of
a given parameter appears in single quotation marks and precedes its corresponding value.
- Association of dynamic (time-variable) behavior with function evaluation, where time and state ( \(t, X_{t}\) ) are passed to a common, published interface, is pervasive throughout the SDE class system. You can use this function evaluation approach to model or construct powerful analytics. For a simple example, see "Example: Univariate GBM Models" on page 17-27.

\section*{Specifying SDE Simulation Parameters}

The SDE engine allows the simulation of generalized multivariate stochastic processes, and provides a flexible and powerful simulation architecture. The framework also provides you with utilities and model classes that offer various parametric specifications and interfaces. The architecture is fully multidimensional in both the state vector and the Brownian motion, and offers both linear and mean-reverting drift-rate specifications.

You can specify most parameters as MATLAB arrays or as functions accessible by a common interface, that supports general dynamic/nonlinear relationships common in SDE simulation. Specifically, you can simulate correlated paths of any number of state variables driven by a vector-valued Brownian motion of arbitrary dimensionality. This simulation approximates the underlying multivariate continuous-time process using a vector-valued stochastic difference equation.

Consider the following general stochastic differential equation:
\(d X_{t}=F\left(t, X_{t}\right) d t+G\left(t, X_{t}\right) d W_{t}\)
where:
- \(X\) is an NVARS-by- 1 state vector of process variables (for example, short rates or equity prices) to simulate.
- \(W\) is an NBROWNS-by-1 Brownian motion vector.
- \(F\) is an \(N V A R S\)-by-1 vector-valued drift-rate function.
- \(G\) is an \(N V A R S\)-by- \(N B R O W N S\) matrix-valued diffusion-rate function.

The drift and diffusion rates, \(F\) and \(G\), respectively, are general functions of a real-valued scalar sample time \(t\) and state vector \(X_{t}\). Also, static (non-time-variable) coefficients are simply a special case of the more general dynamic (time-variable) situation, just as a function can be a trivial constant; for example, \(f\left(t, X_{t}\right)=4\). The SDE in Equation 17-1 is
useful in implementing derived classes that impose additional structure on the drift and diffusion-rate functions.

\section*{Specifying User-Defined Functions as Model Parameters}

Several examples in this documentation emphasize the evaluation of object parameters as functions accessible by a common interface. In fact, you can evaluate object parameters by passing to them time and state, regardless of whether the underlying user-specified parameter is a function. However, it is helpful to compare the behavior of object parameters that are specified as functions to that of user-specified noise and end-of-period processing functions.

Model parameters that are specified as functions are evaluated in the same way as user-specified random number (noise) generation functions. (For more information, see "Evaluating Different Types of Functions" on page 17-11.) Model parameters that are specified as functions are inputs to remove object constructors. User-specified noise and processing functions are optional inputs to simulation methods.

Because class constructors offer unique interfaces, and simulation methods of any given model have different implementation details, models often call parameter functions for validation purposes a different number of times, or in a different order, during object creation, simulation, and interpolation.

Therefore, although parameter functions, user-specified noise generation functions, and end-of-period processing functions all share the same interface and are validated at the same initial time and state (obj.StartTime and obj.StartState), parameter functions are not guaranteed to be invoked only once before simulation as noise generation and end-of-period processing functions are. In fact, parameter functions might not even be invoked the same number of times during a given Monte Carlo simulation process.

In most applications in which you specify parameters as functions, they are simple, deterministic functions of time and/or state. There is no need to count periods, count trials, or otherwise accumulate information or synchronize time.

However, if parameter functions require more sophisticated bookkeeping, the correct way to determine when a simulation has begun (or equivalently, to determine when model validation is complete) is to determine when the input time and/or state differs from the initial time and state (obj.StartTime and obj.StartState, respectively). Because the input time is a known scalar, detecting a change from the initial time is likely the best choice in most situations. This is a general mechanism that you can apply to any type of user-defined function.

\section*{Evaluating Different Types of Functions}

It is useful to compare the evaluation rules of user-specified noise generation functions to those of end-of-period processing functions. These functions have the following in common:
- They both share the same general interface, returning a column vector of appropriate length when evaluated at the current time and state:
\[
\begin{aligned}
& X_{t}=f\left(t, X_{t}\right) \\
& z_{t}=Z\left(t, X_{t}\right)
\end{aligned}
\]
- Before simulation, the simulation method itself calls each function once to validate the size of the output at the initial time and state, obj. StartTime, and obj. StartState, respectively.
- During simulation, the simulation method calls each function the same number of times: NPERIODS * NSTEPS.

However, there is an important distinction regarding the timing between these two types of functions. It is most clearly drawn directly from the generic SDE model:
\[
d X_{t}=F\left(t, X_{t}\right) d t+G\left(t, X_{t}\right) d W_{t}
\]

This equation is expressed in continuous time, but the simulation methods approximate the model in discrete time as:
\[
X_{t+\Delta t}=X_{t}+F\left(t, X_{t}\right) \Delta t+G\left(t, X_{t}\right) \sqrt{\Delta t} Z\left(t, X_{t}\right)
\]
where \(\Delta t>0\) is a small (and not necessarily equal) period or time increment into the future. This equation is often referred to as a Euler approximation. All functions on the right-hand side are evaluated at the current time and state \(\left(t, X_{t}\right)\).

In other words, over the next small time increment, the simulation evolves the state vector based only on information available at the current time and state. In this sense, you can think of the noise function as a beginning-of-period function, or as a function evaluated from the left. This is also true for any user-supplied drift or diffusion function.

In contrast, user-specified end-of-period processing functions are applied only at the end of each simulation period or time increment. For more information about processing functions, see "Pricing Equity Options" on page 17-56.

Therefore, all simulation methods evaluate noise generation functions as:
\[
z_{t}=Z\left(t, X_{t}\right)
\]
for \(t=t_{0}, t_{0}+\Delta t, t_{0}+2 \Delta t, \ldots, T-\Delta t\).
Yet simulation methods evaluate end-of-period processing functions as:
\[
\begin{gathered}
X_{t}=f\left(t, X_{t}\right) \\
\text { for } t=t_{0}+\Delta t, t_{0}+2 \Delta t, \ldots, T .
\end{gathered}
\]
where \(t_{0}\) and \(T\) are the initial time (taken from the object) and the terminal time (derived from inputs to the simulation method), respectively. These evaluations occur on all sample paths. Therefore, during simulation, noise functions are never evaluated at the final (terminal) time, and end-of-period processing functions are never evaluated at the initial (starting) time.

\section*{Drift and Diffusion}

For example, an SDE with a linear drift rate has the form:
\(F\left(t, X_{t}\right)=A(t)+B(t) X_{t}\)
where \(A\) is an \(N V A R S\)-by- 1 vector-valued function and \(B\) is an \(N V A R S\)-by- \(N V A R S\) matrix-valued function.

As an alternative, consider a drift-rate specification expressed in mean-reverting form:
\[
F\left(t, X_{t}\right)=S(t)\left[L(t)-X_{t}\right]
\]
where \(S\) is an \(N V A R S\)-by-NVARS matrix-valued function of mean reversion speeds (that is, rates of mean reversion), and \(L\) is an NVARS-by-1 vector-valued function of mean reversion levels (that is, long run average level).

Similarly, consider the following diffusion-rate specification:
\(G\left(t, X_{t}\right)=D\left(t, X_{t}^{\alpha(t)}\right) V(t)\)
where \(D\) is an \(N V A R S\)-by- \(N V A R S\) diagonal matrix-valued function. Each diagonal element of \(D\) is the corresponding element of the state vector raised to the corresponding
element of an exponent \(A l p h a\), which is also an \(N V A R S\)-by- 1 vector-valued function. \(V\) is an NVARS-by-NBROWNS matrix-valued function of instantaneous volatility rates. Each row of \(V\) corresponds to a particular state variable, and each column corresponds to a particular Brownian source of uncertainty. \(V\) associates the exposure of state variables with sources of risk.

The parametric specifications for the drift and diffusion-rate functions associate parametric restrictions with familiar models derived from the general SDE class, and provide coverage for many popular models.

As discussed in the following sections, the class system and hierarchy of the SDE engine use industry-standard terminology to provide simplified interfaces for many models by placing user-transparent restrictions on drift and diffusion specifications. This design allows you to mix and match existing models, and customize drift or diffusion-rate functions.

\section*{Available Models}

For example, the following models are special cases of the general SDE model.

\section*{SDE Models}
\begin{tabular}{|l|l|}
\hline Model Name & Specification \\
\hline Brownian Motion (BM) & \(d X_{t}=A(t) d t+V(t) d W_{t}\) \\
\hline Geometric Brownian Motion (GBM) & \(d X_{t}=B(t) X_{t} d t+V(t) X_{t} d W_{t}\) \\
\hline Constant Elasticity of Variance (CEV) & \(d X_{t}=B(t) X_{t} d t+V(t) X_{t}^{\alpha(t)} d W_{t}\) \\
\hline Cox-Ingersoll-Ross (CIR) & \(d X_{t}=S(t)\left(L(t)-X_{t}\right) d t+V(t) X_{t}^{\frac{1}{2}} d W_{t}\) \\
\hline Hull-White/Vasicek (HWV) & \(d X_{t}=S(t)\left(L(t)-X_{t}\right) d t+V(t) d W_{t}\) \\
\hline Heston & \(d X_{1 t}=B(t) X_{1 t} d t+\sqrt{X_{2 t}} X_{1 t} d W_{1 t}\) \\
& \(d X_{2 t}=S(t)\left[L(t)-X_{2 t}\right] d t+V(t) \sqrt{X_{2 t}} d W_{2 t}\) \\
\hline
\end{tabular}

\section*{SDE Methods}

The SDE class provides default simulation and interpolation methods for all derived classes:
- simulate: High-level wrapper around the user-specified simulation method stored in the Simulation property
- simByEuler: Default Euler approximation simulation method
- interpolate: Stochastic interpolation method (that is, Brownian bridge)

The HWV and GBM classes feature an additional method, simBySolution, that simulates approximate solutions of diagonal-drift processes.

\section*{Base SDE Models}
```

In this section...
"Overview" on page 17-15
"Example: Base SDE Models" on page 17-15

```

\section*{Overview}

The base SDE class:
\[
d X_{t}=F\left(t, X_{t}\right) d t+G\left(t, X_{t}\right) d W_{t}
\]
represents the most general model.

Tip The SDE class is not an abstract class. You can instantiate SDE objects directly to extend the set of core models.

Constructing an SDE object requires the following inputs:
- A drift-rate function F. This function returns an NVARS-by-1 drift-rate vector when run with the following inputs:
- A real-valued scalar observation time \(t\).
- An NVARS-by- 1 state vector \(X_{t}\).
- A diffusion-rate function G. This function returns an NVARS-by-NBROWNS diffusionrate matrix when run with the inputs \(t\) and \(X_{t}\).

Evaluating object parameters by passing \(\left(t, X_{t}\right)\) to a common, published interface allows most parameters to be referenced by a common input argument list that reinforces common method programming. You can use this simple function evaluation approach to model or construct powerful analytics, as in the following example.

\section*{Example: Base SDE Models}

Construct an SDE object obj to represent a univariate geometric Brownian Motion model of the form:
\[
d X_{t}=0.1 X_{t} d t+0.3 X_{t} d W_{t}
\]

1 Create drift and diffusion functions that are accessible by the common \(\left(t, X_{t}\right)\) interface:
```

F = @(t,X) 0.1 * X;
G = @(t,X) 0.3 * X;

```

2 Pass the functions to the SDE constructor to create an object obj of class SDE:
```

obj = sde(F, G) % dX = F(t,X)dt + G(t,X)dW
obj =
Class SDE: Stochastic Differential Equation
Dimensions: State = 1, Brownian = 1
StartTime: 0
StartState: 1
Correlation: 1
Drift: drift rate function F(t,X(t))
Diffusion: diffusion rate function G(t,X(t))
Simulation: simulation method/function simByEuler

```
obj displays like a MATLAB structure, with the following information:
- The object's class
- A brief description of the object
- A summary of the dimensionality of the model

The object's displayed parameters are as follows:
- StartTime: The initial observation time (real-valued scalar)
- StartState: The initial state vector (NVARS-by-1 column vector)
- Correlation: The correlation structure between Brownian process
- Drift: The drift-rate function \(F\left(t, X_{t}\right)\)
- Diffusion: The diffusion-rate function \(G\left(t, X_{t}\right)\)
- Simulation: The simulation method or function.

Of these displayed parameters, only Drift and Diffusion are required inputs.

The only exception to the \(\left(t, X_{t}\right)\) evaluation interface is Correlation. Specifically, when you enter Correlation as a function, the SDE engine assumes that it is a deterministic function of time, \(C(t)\). This restriction on Correlation as a deterministic function of time allows Cholesky factors to be computed and stored before the formal simulation. This inconsistency dramatically improves run-time performance for dynamic correlation structures. If Correlation is stochastic, you can also include it within the simulation architecture as part of a more general random number generation function.

In this section... \\ "Overview" on page 17-18 \\ "Example: Drift and Diffusion Rates" on page 17-19 \\ "Example: SDEDDO Models" on page 17-20
}

\section*{Overview}

Because base-level SDE objects accept drift and diffusion objects in lieu of functions accessible by \(\left(t, X_{t}\right)\), you can create SDE objects with combinations of customized drift or diffusion functions and objects. The drift and diffusion rate classes encapsulate the details of input parameters to optimize run-time efficiency for any given combination of input parameters.

Although drift and diffusion objects differ in the details of their representation, they are identical in their basic implementation and interface. They look, feel like, and are evaluated as functions:
- The drift class allows you to create drift-rate objects of the form:
\[
F\left(t, X_{t}\right)=A(t)+B(t) X_{t}
\]
where:
- A is an NVARS-by- 1 vector-valued function accessible using the \(\left(t, X_{t}\right)\) interface.
- B is an NVARS-by-NVARS matrix-valued function accessible using the \(\left(t, X_{t}\right)\) interface.
- Similarly, the diffusion class allows you to create diffusion-rate objects:
\[
G\left(t, X_{t}\right)=D\left(t, X_{t}^{\alpha(t)}\right) V(t)
\]
where:
- Each diagonal element of \(D\) is the corresponding element of the state vector raised to the corresponding element of an exponent Alpha, which is an NVARS-by-1 vector-valued function.
- V is an NVARS-by-NBROWNS matrix-valued volatility rate function Sigma.
- Alpha and Sigma are also accessible using the \(\left(t, X_{t}\right)\) interface.

Note: You can express drift and diffusion classes in the most general form to emphasize the functional \(\left(t, X_{t}\right)\) interface. However, you can specify the components A and B as functions that adhere to the common \(\left(t, X_{t}\right)\) interface, or as MATLAB arrays of appropriate dimension.

\section*{Example: Drift and Diffusion Rates}

In this example, you create drift and diffusion rate objects to create the same model as in "Example: Base SDE Models" on page 17-15.

Create a drift-rate function \(F\) and a diffusion-rate function \(G\) :
```

F = drift(0, 0.1) % Drift rate function F(t,X)
G = diffusion(1, 0.3) % Diffusion rate function G(t,X)
F =
Class DRIFT: Drift Rate Specification
Rate: drift rate function F(t,X(t))
A: 0
B: 0.1
G =
Class DIFFUSION: Diffusion Rate Specification
Rate: diffusion rate function G(t,X(t))
Alpha: 1
Sigma: 0.3

```

Each object displays like a MATLAB structure and contains supplemental information, namely, the object's class and a brief description. However, in contrast to the SDE
representation, a summary of the dimensionality of the model does not appear, because drift and diffusion classes create model components rather than models. Neither F nor \(G\) contains enough information to characterize the dimensionality of a problem.

The drift object's displayed parameters are:
- Rate: The drift-rate function, \(F\left(t, X_{t}\right)\)
- A: The intercept term, \(A\left(t, X_{t}\right)\), of \(F\left(t, X_{t}\right)\)
- B: The first order term, \(B\left(t, X_{t}\right)\), of \(F\left(t, X_{t}\right)\)
\(A\) and \(B\) enable you to query the original inputs. The function stored in Rate fully encapsulates the combined effect of \(A\) and \(B\).

The diffusion object's displayed parameters are:
- Rate: The diffusion-rate function, \(G\left(t, X_{t}\right)\).
- Alpha: The state vector exponent, which determines the format of \(D\left(t, X_{t}\right)\) of \(G\left(t, X_{t}\right)\).
- Sigma: The volatility rate, \(V\left(t, X_{t}\right)\), of \(G\left(t, X_{t}\right)\).

Again, Alpha and Sigma enable you to query the original inputs. (The combined effect of the individual Alpha and Sigma parameters is fully encapsulated by the function stored in Rate.) The Rate functions are the calculation engines for the drift and diffusion objects, and are the only parameters required for simulation.

\section*{Example: SDEDDO Models}

The SDEDDO class derives from the base SDE class. To use this class, you must pass drift and diffusion-rate objects to the SDEDDO constructor.

1 Create drift and diffusion rate objects:
```

F = drift(0, 0.1); % Drift rate function F(t,X)
G = diffusion(1, 0.3); % Diffusion rate function G(t,X)

```

2 Pass these objects to the SDEDDO constructor:
```

obj = sdeddo(F, G) % dX = F(t,X)dt + G(t,X)dW
obj =

```
```

Class SDEDDO: SDE from Drift and Diffusion Objects
Dimensions: State = 1, Brownian = 1
StartTime: 0
StartState: 1
Correlation: 1
Drift: drift rate function F(t,X(t))
Diffusion: diffusion rate function G(t,X(t))
Simulation: simulation method/function simByEuler
A: 0
B: 0.1
Alpha: 1
Sigma: 0.3

```

In this example, the object displays the additional parameters associated with input drift and diffusion objects.

\section*{Linear Drift Models}

\section*{In this section...}
"Overview" on page 17-22
"Example: SDELD Models" on page 17-22

\section*{Overview}

The SDELD class derives from the SDEDDO class. These objects allow you to simulate correlated paths of NVARS state variables expressed in linear drift-rate form:
\[
d X_{t}=\left(A(t)+B(t) X_{t}\right) d t+D\left(t, X_{t}^{\alpha(t)}\right) V(t) d W_{t}
\]

SDELD objects provide a parametric alternative to the mean-reverting drift form, as discussed in "Example: SDEMRD Models" on page 17-28. They also provide an alternative interface to the SDEDDO parent class, because you can create an object without first having to create its drift and diffusion-rate components.

\section*{Example: SDELD Models}

Create the same model as in "Example: Base SDE Models" on page 17-15:
```

obj = sdeld(0, 0.1, 1, 0.3) % (A, B, Alpha, Sigma)
obj =
Class SDELD: SDE with Linear Drift
Dimensions: State = 1, Brownian = 1
StartTime: 0
StartState: 1
Correlation: 1
Drift: drift rate function F(t,X(t))
Diffusion: diffusion rate function G(t,X(t))
Simulation: simulation method/function simByEuler
A: 0
B: 0.1

```
```

Alpha: 1
Sigma: 0.3

```

\section*{Creating Brownian Motion (BM) Models}

The Brownian Motion (BM) model derives directly from the linear drift (SDELD) class:
\[
d X_{t}=\mu(t) d t+V(t) d W_{t}
\]

\section*{Example: BM Models}

Create a univariate Brownian motion (BM) object to represent the model:
```

    dXt}=0.3d\mp@subsup{W}{t}{}
    obj = bm(0, 0.3) % (A = Mu, Sigma)
obj =

```
    Class BM: Brownian Motion
    Dimensions: State = 1, Brownian = 1
    StartTime: 0
    StartState: 0
```

Correlation: 1
Drift: drift rate function F(t,X(t))
Diffusion: diffusion rate function G(t,X(t))
Simulation: simulation method/function simByEuler
Mu: 0
Sigma: 0.3

```

BM objects display the parameter A as the more familiar Mu.
The BM class also provides an overloaded Euler simulation method that improves runtime performance in certain common situations. This specialized method is invoked automatically only if all the following conditions are met:
- The expected drift, or trend, rate Mu is a column vector.
- The volatility rate, Sigma, is a matrix.
- No end-of-period adjustments and/or processes are made.
- If specified, the random noise process \(Z\) is a three-dimensional array.
- If \(Z\) is unspecified, the assumed Gaussian correlation structure is a double matrix.

\section*{Creating Constant Elasticity of Variance (CEV) Models}

The Constant Elasticity of Variance (CEV) model also derives directly from the linear drift (SDELD) class:
\[
d X_{t}=\mu(t) X_{t} d t+D\left(t, X_{t}^{\alpha(t)}\right) V(t) d W_{t}
\]

The CEV class constrains \(A\) to an NVARS-by- 1 vector of zeros. \(D\) is a diagonal matrix whose elements are the corresponding element of the state vector \(X\), raised to an exponent \(\alpha(t)\).

\section*{Example: Univariate CEV Models}

Create a univariate CEV object to represent the model:
```

    dX t}=0.25\mp@subsup{X}{t}{}+0.3\mp@subsup{X}{t}{\frac{1}{2}}d\mp@subsup{W}{t}{}
    obj = cev(0.25, 0.5, 0.3) % (B = Return, Alpha, Sigma)

```
```

obj =
Class CEV: Constant Elasticity of Variance
Dimensions: State = 1, Brownian = 1
StartTime: 0
StartState: 1
Correlation: 1
Drift: drift rate function F(t,X(t))
Diffusion: diffusion rate function G(t,X(t))
Simulation: simulation method/function simByEuler
Return: 0.25
Alpha: 0.5
Sigma: 0.3

```

CEV and GBM objects display the parameter B as the more familiar Return.

\section*{Creating Geometric Brownian Motion (GBM) Models}

The Geometric Brownian Motion (GBM) model derives directly from the CEV model:
\[
d X_{t}=\mu(t) X_{t} d t+D\left(t, X_{t}\right) V(t) d W_{t}
\]

Compared to CEV, GBM constrains all elements of the alpha exponent vector to one such that \(D\) is now a diagonal matrix with the state vector \(X\) along the main diagonal.

The GBM class also provides two simulation methods that can be used by separable models:
- An overloaded Euler simulation method that improves run-time performance in certain common situations. This specialized method is invoked automatically only if all the following conditions are true:
- The expected rate of return (Return) is a diagonal matrix.
- The volatility rate (Sigma) is a matrix.
- No end-of-period adjustments/processes are made.
- If specified, the random noise process \(Z\) is a three-dimensional array.
- If \(Z\) is unspecified, the assumed Gaussian correlation structure is a double matrix.
- An approximate analytic solution (simBySolution) obtained by applying a Euler approach to the transformed (using Ito's formula) logarithmic process. In general, this is not the exact solution to this GBM model, as the probability distributions of the simulated and true state vectors are identical only for piecewise constant parameters. If the model parameters are piecewise constant over each observation period, the state vector \(X_{t}\) is lognormally distributed and the simulated process is exact for the observation times at which \(X_{t}\) is sampled.

\section*{Example: Univariate GBM Models}

Create a univariate GBM object to represent the model:
```

    dX t}=0.25\mp@subsup{X}{t}{}dt+0.3\mp@subsup{X}{t}{}d\mp@subsup{W}{t}{
    obj = gbm(0.25, 0.3) % (B = Return, Sigma)
obj =
Class GBM: Generalized Geometric Brownian Motion
Dimensions: State = 1, Brownian = 1
StartTime: O
StartState: 1
Correlation: 1
Drift: drift rate function F(t,X(t))
Diffusion: diffusion rate function G(t,X(t))
Simulation: simulation method/function simByEuler
Return: 0.25
Sigma: 0.3

```

\section*{Creating Stochastic Differential Equations from Mean-Reverting Drift (SDEMRD) Models}

The SDEMRD class derives directly from the SDEDDO class. It provides an interface in which the drift-rate function is expressed in mean-reverting drift form:
\[
d X_{t}=S(t)\left[L(t)-X_{t}\right] d t+D\left(t, X_{t}^{\alpha(t)}\right) V(t) d W_{t}
\]

SDEMRD objects provide a parametric alternative to the linear drift form by reparameterizing the general linear drift such that:
\[
A(t)=S(t) L(t), B(t)=-S(t)
\]

\section*{Example: SDEMRD Models}

Create an SDEMRD object obj with a square root exponent to represent the model:
```

    dX 
    obj = sdemrd(0.2, 0.1, 0.5, 0.05)
% (Speed, Level, Alpha, Sigma)
obj =
Class SDEMRD: SDE with Mean-Reverting Drift
Dimensions: State = 1, Brownian = 1
StartTime: 0
StartState: 1
Correlation: 1
Drift: drift rate function F(t,X(t))
Diffusion: diffusion rate function G(t,X(t))
Simulation: simulation method/function simByEuler
Alpha: 0.5
Sigma: 0.05
Level: 0.1
Speed: 0.2

```

SDEMRD objects display the familiar Speed and Level parameters instead of A and B.

\section*{Creating Cox-Ingersoll-Ross (CIR) Square Root Diffusion Models}

The Cox-Ingersoll-Ross (CIR) short rate class derives directly from SDE with meanreverting drift (SDEMRD):
\[
d X_{t}=S(t)\left[L(t)-X_{t}\right] d t+D\left(t, X_{t}^{\frac{1}{2}}\right) V(t) d W_{t}
\]
where \(D\) is a diagonal matrix whose elements are the square root of the corresponding element of the state vector.

\section*{Example: CIR Models}

Create a CIR object to represent the same model as in "Example: SDEMRD Models" on page 17-28:
```

obj = cir(0.2, 0.1, 0.05) % (Speed, Level, Sigma)
obj =
Class CIR: Cox-Ingersoll-Ross
Dimensions: State = 1, Brownian = 1
StartTime: 0
StartState: 1
Correlation: 1
Drift: drift rate function F(t,X(t))
Diffusion: diffusion rate function G(t,X(t))
Simulation: simulation method/function simByEuler
Sigma: 0.05
Level: 0.1
Speed: 0.2

```

Although the last two objects are of different classes, they represent the same mathematical model. They differ in that you create the CIR object by specifying only three input arguments. This distinction is reinforced by the fact that the Alpha parameter does not display - it is defined to be \(1 / 2\).

\section*{Creating Hull-White/Vasicek (HWV) Gaussian Diffusion Models}

The Hull-White/Vasicek(HWV) short rate class derives directly from SDE with meanreverting drift (that is, SDEMRD):
\[
d X_{t}=S(t)\left[L(t)-X_{t}\right] d t+V(t) d W_{t}
\]

\section*{Example: HWV Models}

Using the same parameters as in the previous example, create an HWV object to represent the model:
```

    dX 
    obj = hwv(0.2, 0.1, 0.05) % (Speed, Level, Sigma)
obj =
Class HWV: Hull-White/Vasicek
Dimensions: State = 1, Brownian = 1
StartTime: 0
StartState: 1
Correlation: 1
Drift: drift rate function F(t,X(t))
Diffusion: diffusion rate function G(t,X(t))
Simulation: simulation method/function simByEuler
Sigma: 0.05
Level: 0.1
Speed: 0.2

```

CIR and HWV constructors share the same interface and display methods. The only distinction is that CIR and HWV models constrain Alpha exponents to \(1 / 2\) and 0 , respectively. Furthermore, the HWV class also provides an additional method that simulates approximate analytic solutions (simBySolution) of separable models. This method simulates the state vector \(X_{t}\) using an approximation of the closed-form solution of diagonal drift HWV models. Each element of the state vector \(X_{t}\) is expressed as the sum of NBROWNS correlated Gaussian random draws added to a deterministic time-variable drift.

When evaluating expressions, all model parameters are assumed piecewise constant over each simulation period. In general, this is not the exact solution to this HWV model, because the probability distributions of the simulated and true state vectors are identical only for piecewise constant parameters. If \(S\left(t, X_{t}\right), L\left(t, X_{t}\right)\), and \(V\left(t, X_{t}\right)\) are piecewise constant over each observation period, the state vector \(X_{t}\) is normally distributed, and the simulated process is exact for the observation times at which \(X_{t}\) is sampled.

\section*{Hull-White vs. Vasicek Models}

Many references differentiate between Vasicek models and Hull-White models. Where such distinctions are made, Vasicek parameters are constrained to be constants, while Hull-White parameters vary deterministically with time. Think of Vasicek models in
this context as constant-coefficient Hull-White models and equivalently, Hull-White models as time-varying Vasicek models. However, from an architectural perspective, the distinction between static and dynamic parameters is trivial. Since both models share the same general parametric specification as previously described, a single HWV class encompasses the models.

\section*{Creating Heston Stochastic Volatility Models}

The Heston (heston) class derives directly from SDE from Drift and Diffusion (SDEDDO). Each Heston model is a bivariate composite model, consisting of two coupled univariate models:
\[
\begin{aligned}
& d X_{1 t}=B(t) X_{1 t} d t+\sqrt{X_{2 t}} X_{1 t} d W_{1 t} \\
& d X_{2 t}=S(t)\left[L(t)-X_{2 t}\right] d t+V(t) \sqrt{X_{2 t}} d W_{2 t}
\end{aligned}
\]

Equation \(17-5\) is typically associated with a price process. Equation \(17-6\) represents the evolution of the price process' variance. Models of type heston are typically used to price equity options.

\section*{Example: Heston Models}

Create a heston object to represent the model:
```

    d\mp@subsup{X}{1t}{}=0.1\mp@subsup{X}{1t}{}dt+\sqrt{}{\mp@subsup{X}{2t}{}}\mp@subsup{X}{1t}{}d\mp@subsup{W}{1t}{}
    dX 2t}=0.2[0.1-\mp@subsup{X}{2t}{}]dt+0.05\sqrt{}{\mp@subsup{X}{2t}{}}d\mp@subsup{W}{2t}{
    obj = heston (0.1, 0.2, 0.1, 0.05)
obj =
Class HESTON: Heston Bivariate Stochastic Volatility
Dimensions: State = 2, Brownian = 2
StartTime: 0
StartState: 1 (2x1 double array)
Correlation: 2x2 diagonal double array

```
```

        Drift: drift rate function F(t,X(t))
    Diffusion: diffusion rate function G(t,X(t))
    Simulation: simulation method/function simByEuler
Return: 0.1
Speed: 0.2
Level: 0.1
Volatility: 0.05

```

```

\section*{Simulating Multidimensional Market Models}

This example compares alternative implementations of a separable multivariate geometric Brownian motion process that is often referred to as a multidimensional market model. It simulates sample paths of an equity index portfolio using SDE, SDEDDO, SDELD, CEV, and GBM objects.

The market model to simulate is:
\[
d X_{t}=\mu X_{t} d t+D\left(X_{t}\right) \sigma d W_{t}
\]

\section*{where:}
- \(\mu\) is a diagonal matrix of expected index returns.
- \(D\) is a diagonal matrix with \(X_{t}\) along the diagonal.
- \(\sigma\) is a diagonal matrix of standard deviations of index returns.

\section*{Representing Market Models Using SDE Objects}

Create an SDE object to represent the equity market model.
1 Load the Data_GlobalIdx2 data set:
```

load Data_GlobalIdx2
prices = [Dataset.TSX Dataset.CAC Dataset.DAX ...
Dataset.NIK Dataset.FTSE Dataset.SP];

```

2 Convert daily prices to returns:
returns \(=\) tick2ret(prices);

3 Compute data statistics to input to simulation methods:
```

nVariables = size(returns, 2);
expReturn = mean(returns);
sigma = std(returns);
correlation = corrcoef(returns);
t = 0;
X = 100;
X = X(ones(nVariables,1));

```

4 Create simple anonymous drift and diffusion functions accessible by \(\left(t, X_{t}\right)\) :
```

F = @(t,X) diag(expReturn) * X;
G = @(t,X) diag(X) * diag(sigma);

```

5 Use these functions to create an SDE object to represent the market model in Equation 17-7:
```

SDE = sde(F, G, 'Correlation', correlation, 'StartState', X)
SDE =

```
    Class SDE: Stochastic Differential Equation
        Dimensions: State \(=6\), Brownian \(=6\)
        StartTime: 0
        StartState: 100 (6x1 double array)
        Correlation: 6x6 double array
            Drift: drift rate function \(F(t, X(t))\)
        Diffusion: diffusion rate function \(G(t, X(t))\)
        Simulation: simulation method/function simByEuler

The SDE constructor requires additional information to determine the dimensionality of the model, because the functions passed to the SDE constructor are known only by their \(\left(t, X_{t}\right)\) interface. In other words, the SDE constructor requires only two inputs: a drift-rate function and a diffusion-rate function, both accessible by passing the sample time and the corresponding state vector \(\left(t, X_{t}\right)\).

In this case, this information is insufficient to determine unambiguously the dimensionality of the state vector and Brownian motion. You resolve the dimensionality by specifying an initial state vector, StartState. The SDE engine has assigned the default simulation method, simByEuler, to the Simulation parameter.

\section*{Representing Market Models Using SDEDDO Objects}

Create an SDEDDO object to represent the market model in Equation 17-7:
1 Load the Data_GlobalIdx2 data set:
```

load Data_GlobalIdx2
prices =- [Dataset.TSX Dataset.CAC Dataset.DAX ...
Dataset.NIK Dataset.FTSE Dataset.SP];

```

2 Convert daily prices to returns:
```

returns = tick2ret(prices);

```

3 Compute data statistics to input to simulation methods:
```

nVariables = size(returns, 2);
expReturn = mean(returns);
sigma = std(returns);
correlation = corrcoef(returns);

```

4 Create drift and diffusion objects:
```

F = drift(zeros(nVariables,1), diag(expReturn))
G = diffusion(ones(nVariables,1), diag(sigma))
F =
Class DRIFT: Drift Rate Specification
Rate: drift rate function F(t,X(t))
A: 6x1 double array
B: 6x6 diagonal double array
G =
Class DIFFUSION: Diffusion Rate Specification
Rate: diffusion rate function G(t,X(t))
Alpha: 6x1 double array
Sigma: 6x6 diagonal double array

```

5 Pass the drift and diffusion objects to the SDEDDO constructor:
SDEDDO = sdeddo(F, G, 'Correlation', correlation, ...
'StartState', 100)
```

SDEDDO =
Class SDEDDO: SDE from Drift and Diffusion Objects
Dimensions: State = 6, Brownian = 6
StartTime: 0
StartState: 100 (6x1 double array)
Correlation: 6x6 double array
Drift: drift rate function F(t,X(t))
Diffusion: diffusion rate function G(t,X(t))
Simulation: simulation method/function simByEuler
A: 6x1 double array
B: 6x6 diagonal double array
Alpha: 6x1 double array
Sigma: 6x6 diagonal double array

```

The SDEDDO constructor requires two input objects that provide more information than the two functions from step 4 of "Representing Market Models Using SDE Objects" on page 17-33. Thus, the dimensionality is more easily resolved. In fact, the initial price of each index is as a scalar (StartState \(=100\) ). This is in contrast to the SDE constructor, which required an explicit state vector to uniquely determine the dimensionality of the problem.

Once again, the class of each object is clearly identified, and parameters display like fields of a structure. In particular, the Rate parameter of drift and diffusion objects is identified as a callable function of time and state, \(F\left(t, X_{t}\right)\) and \(G\left(t, X_{t}\right)\), respectively. The additional parameters, A, B, Alpha, and Sigma, are arrays of appropriate dimension, indicating static (non-time-varying) parameters. In other words, \(A\left(t, X_{t}\right)\), \(B\left(t, X_{t}\right), \operatorname{Alph} \alpha\left(t, X_{t}\right)\), and \(\operatorname{Sigma}\left(t, X_{t}\right)\) are constant functions of time and state.

\section*{Representing Market Models Using SDELD, CEV, and GBM Objects}

Create SDELD, CEV, and GBM objects to represent the market model in Equation 17-7.
1 Load the Data_GlobalIdx2 data set:
```

load Data_GlobalIdx2
prices = [Dataset.TSX Dataset.CAC Dataset.DAX ...
Dataset.NIK Dataset.FTSE Dataset.SP];

```

2 Convert daily prices to returns:
```

returns = tick2ret(prices);

```

3 Compute data statistics to input to simulation methods:
```

nVariables = size(returns, 2);
expReturn = mean(returns);
sigma = std(returns);
correlation = corrcoef(returns);
t = 0;
X = 100;
X = X(ones(nVariables,1));

```

4 Create an SDELD object:
```

SDELD = sdeld(zeros(nVariables,1), diag(expReturn), ...

```
    ones(nVariables,1), diag(sigma),'Correlation', ...
    correlation, 'StartState', X)
SDELD =
    Class SDELD: SDE with Linear Drift
    Dimensions: State = 6, Brownian \(=6\)
        StartTime: 0
    StartState: 100 (6x1 double array)
    Correlation: 6x6 double array
            Drift: drift rate function \(F(t, X(t))\)
        Diffusion: diffusion rate function \(G(t, X(t))\)
    Simulation: simulation method/function simByEuler
            A: \(6 \times 1\) double array
            B: 6x6 diagonal double array
            Alpha: \(6 \times 1\) double array
            Sigma: 6x6 diagonal double array

5 Create a CEV object:
CEV = cev(diag(expReturn), ones(nVariables,1), ...
    diag(sigma), 'Correlation', correlation, ...
    'StartState', X)
CEV =
    Class CEV: Constant Elasticity of Variance
```

    Dimensions: State = 6, Brownian = 6
        StartTime: 0
    StartState: 100 (6x1 double array)
    Correlation: 6x6 double array
Drift: drift rate function F(t,X(t))
Diffusion: diffusion rate function G(t,X(t))
Simulation: simulation method/function simByEuler
Return: 6x6 diagonal double array
Alpha: 6x1 double array
Sigma: 6x6 diagonal double array

```

6 Create a GBM object:
```

GBM = gbm(diag(expReturn), diag(sigma), 'Correlation', ...
correlation, 'StartState', X)
GBM =
Class GBM: Generalized Geometric Brownian Motion
Dimensions: State = 6, Brownian = 6
StartTime: 0
StartState: 100 (6x1 double array)
Correlation: 6x6 double array
Drift: drift rate function F(t,X(t))
Diffusion: diffusion rate function G(t,X(t))
Simulation: simulation method/function simByEuler
Return: 6x6 diagonal double array
Sigma: 6x6 diagonal double array

```

Note the succession of interface restrictions:
- SDELD objects require you to specify A, B, Alpha, and Sigma.
- CEV objects require you to specify Return, Alpha, and Sigma.
- GBM objects require you to specify only Return and Sigma.

However, all three objects represent the same multidimensional market model.

Also, CEV and GBM objects display the underlying parameter B derived from the SDELD class as Return. This is an intuitive name commonly associated with equity models.

\section*{Simulating Equity Markets Using the Default Simulate Method}

1 Load the Data_GlobalIdx2 data set and specify the SDE model as in "Representing Market Models Using SDE Objects" on page 17-33.
```

load Data_GlobalIdx2
prices = [Dataset.TSX Dataset.CAC Dataset.DAX ...
Dataset.NIK Dataset.FTSE Dataset.SP];
returns = tick2ret(prices);
nVariables = size(returns,2);
expReturn = mean(returns);
sigma = std(returns);
correlation = corrcoef(returns);
t = 0;
X = 100;
X = X(ones(nVariables,1));
F = @(t,X) diag(expReturn)* X;
G = @(t,X) diag(X) * diag(sigma);
SDE = sde(F, G, 'Correlation', ...
correlation, 'StartState', X);

```

2 Simulate a single path of correlated equity index prices over one calendar year (defined as approximately 250 trading days) using the default simulate method:
```

nPeriods = 249; % \# of simulated observations
dt = 1; % time increment = 1 day
rng(142857,'twister')
[S,T] = simulate(SDE, nPeriods, 'DeltaTime', dt);

```
whos S
\begin{tabular}{lrrlr} 
Name & Size & Bytes & Class & Attributes \\
S & \(250 \times 6\) & 12000 & double &
\end{tabular}

The output array S is a 250 -by- \(6=(\) NPERIODS +1 -by-nVariables-by- 1 ) array with the same initial value, 100, for all indices. Each row of \(S\) is an observation of the state vector \(X_{t}\) at time \(t\).

3 Plot the simulated paths.
```

plot(T, S), xlabel('Trading Day'), ylabel('Price')
title('Single Path of Multi-Dimensional Market Model')
legend({'Canada' 'France' 'Germany' 'Japan' 'UK' 'US'}, ...
'Location', 'Best')

```

\section*{Simulating Equity Markets Using the SimByEuler Method}

Because simByEuler is a valid simulation method, you can call it directly, overriding the Simulation parameter's current method or function (which in this case is simByEuler). The following statements produce the same price paths as generated in "Simulating Equity Markets Using the Default Simulate Method" on page 17-39:

1 Load the Data_GlobalIdx2 data set and specify the SDE model as in "Representing Market Models Using SDE Objects" on page 17-33.
```

load Data_GlobalIdx2
prices = [Dataset.TSX Dataset.CAC Dataset.DAX ...
Dataset.NIK Dataset.FTSE Dataset.SP];
returns = tick2ret(prices);
nVariables = size(returns,2);
expReturn = mean(returns);
sigma = std(returns);
correlation = corrcoef(returns);
t = 0;
X = 100;
X = X(ones(nVariables,1));
F = @(t,X) diag(expReturn)* X;
G = @(t,X) diag(X) * diag(sigma);
SDE = sde(F, G, 'Correlation', ...
correlation, 'StartState', X);

```

2 Simulate a single path using simByEuler.
```

nPeriods = 249; % \# of simulated observations
dt = 1; % time increment = 1 day
rng(142857,'twister')
[S,T] = simByEuler(SDE, nPeriods, 'DeltaTime', dt);

```

3 Simulate 10 trials with the same initial conditions, and examine S :
```

rng(142857,'twister')
[S,T] = simulate(SDE, nPeriods, 'DeltaTime', dt, 'nTrials', 10);
whos S

```
Name Size Bytes Class Attributes

Now the output array \(S\) is an NPERIODS + 1-by-nVariables-by-nTrials time series array.
4 Plot the first paths.
```

plot(T, S(:,:,1)), xlabel('Trading Day'), ylabel('Price')
title('First Path of Multi-Dimensional Market Model')
legend({'Canada' 'France' 'Germany' 'Japan' 'UK' 'US'},...
'Location', 'Best')

```

The first realization of S is identical to the paths in the plot.

\section*{Simulating Equity Markets Using GBM Simulation Methods}

Finally, consider simulation using GBM simulation methods. Separable GBM models have two specific simulation methods:
- An overloaded Euler simulation method, designed for optimal performance
- A method that provides an approximate solution of the underlying stochastic differential equation, designed for accuracy

1 Load the Data_GlobalIdx2 data set and specify the SDE model as in "Representing Market Models Using SDE Objects" on page 17-33, and the GBM model as in "Representing Market Models Using SDELD, CEV, and GBM Objects" on page 17-36.
```

load Data GlobalIdx2
prices = [Dataset.TSX Dataset.CAC Dataset.DAX ...
Dataset.NIK Dataset.FTSE Dataset.SP];
returns = tick2ret(prices);
nVariables = size(returns,2);
expReturn = mean(returns);
sigma = std(returns);
correlation = corrcoef(returns);
t = 0;
X = 100;
X = X(ones(nVariables,1));
F = @(t,X) diag(expReturn)* X;
G = @(t,X) diag(X) * diag(sigma);
SDE = sde(F, G, 'Correlation', ...
correlation, 'StartState', X);
GBM = gbm(diag(expReturn),diag(sigma), 'Correlation', ...
correlation, 'StartState', X);

```

2 To illustrate the performance benefit of the overloaded Euler approximation method, increase the number of trials to 10000 .
```

nPeriods = 249; % \# of simulated observations
dt = 1; % time increment = 1 day
rng(142857,'twister')
[X,T] = simulate(GBM, nPeriods, 'DeltaTime', dt, ...

```
```

        'nTrials', 10000);
    whos X

| Name | Size | Bytes Class | Attributes |
| :--- | :---: | ---: | :--- |
| X | $250 \times 6 \times 10000$ | 120000000 double |  |

```

The output \(X\) is a much larger time series array.
3 Using this sample size, examine the terminal distribution of Canada's TSX Composite to verify qualitatively the lognormal character of the data.
```

histogram(squeeze(X(end,1,:)), 30), xlabel('Price'), ylabel('Frequency')
title('Histogram of Prices after One Year: Canada (TSX Composite)')

```

4 Simulate 10 trials of the solution and plot the first trial:
```

rng(142857,'twister')
[S,T] = simulate(SDE, nPeriods, 'DeltaTime', dt, 'nTrials', 10);
rng(142857,'twister')
[X,T] = simBySolution(GBM, nPeriods,...
'DeltaTime', dt, 'nTrials', 10);
subplot(2,1,1)
plot(T, S(:,:,1)), xlabel('Trading Day'),ylabel('Price')
title('1st Path of Multi-Dim Market Model:Euler Approximation')
subplot(2,1,2)
plot(T, X(:,:,1)), xlabel('Trading Day'),ylabel('Price')
title('1st Path of Multi-Dim Market Model:Analytic Solution')

```

In this example, all parameters are constants, and simBySolution does indeed sample the exact solution. The details of a single index for any given trial show that the price paths of the Euler approximation and the exact solution are close, but not identical.

5 The following plot illustrates the difference between the two methods:
```

subplot(1,1,1)
plot(T, S(:,1,1) - X(:,1,1), 'blue'), grid('on')
xlabel('Trading Day'), ylabel('Price Difference')
title('Euler Approx Minus Exact Solution:Canada(TSX Composite)')

```

The simByEuler Euler approximation literally evaluates the stochastic differential equation directly from the equation of motion, for some suitable value of the \(d t\) time increment. This simple approximation suffers from discretization error. This error can be attributed to the discrepancy between the choice of the dt time increment and what in theory is a continuous-time parameter.

The discrete-time approximation improves as DeltaTime approaches zero. The Euler method is often the least accurate and most general method available. All models shipped in the simulation suite have this method.

In contrast, the simBySolution method provides a more accurate description of the underlying model. This method simulates the price paths by an approximation of the
closed-form solution of separable models. Specifically, it applies a Euler approach to a transformed process, which in general is not the exact solution to this GBM model. This is because the probability distributions of the simulated and true state vectors are identical only for piecewise constant parameters.

When all model parameters are piecewise constant over each observation period, the simulated process is exact for the observation times at which the state vector is sampled. Since all parameters are constants in this example, simBySolution does indeed sample the exact solution.

For an example of how to use simBySolution to optimize the accuracy of solutions, see "Optimizing Accuracy: About Solution Precision and Error" on page 17-81.

\section*{Inducing Dependence and Correlation}

This example illustrates two techniques that induce dependence between individual elements of a state vector. It also illustrates the interaction between Sigma and Correlation.

The first technique generates correlated Gaussian variates to form a Brownian motion process with dependent components. These components are then weighted by a diagonal volatility or exposure matrix Sigma.

The second technique generates independent Gaussian variates to form a standard Brownian motion process, which is then weighted by the lower Cholesky factor of the desired covariance matrix. Although these techniques can be used on many models, the relationship between them is most easily illustrated by working with a separable GBM model (see Simulating Equity Prices Using GBM Simulation Methods). The market model to simulate is:
\[
d X_{t}=\mu X_{t} d t+\sigma X_{t} d W_{t}
\]
where \(\mu\) is a diagonal matrix.
1 Load the data set:
```

load Data_GlobalIdx2
prices =- [Dataset.TSX Dataset.CAC Dataset.DAX ...
Dataset.NIK Dataset.FTSE Dataset.SP];

```

2 Convert the daily prices to returns:
```

returns = tick2ret(prices);

```

3 Specify Sigma and Correlation using the first technique:
a Using the first technique, specify Sigma as a diagonal matrix of asset return standard deviations:
```

expReturn = diag(mean(returns)); % expected return vector
sigma = diag(std(returns)); % volatility of returns

```
b Specify Correlation as the sample correlation matrix of those returns. In this case, the components of the Brownian motion are dependent:
```

correlation = corrcoef(returns);
GBM1 = gbm(expReturn,sigma,'Correlation',...
correlation);

```

4 Specify Sigma and Correlation using the second technique:
a Using the second technique, specify Sigma as the lower Cholesky factor of the asset return covariance matrix:
```

covariance = cov(returns);
sigma = cholcov(covariance)';

```
b Set Correlation to an identity matrix:
GBM2 \(\quad=\operatorname{gbm}(\operatorname{expReturn}\), sigma \()\);
Here, sigma captures both the correlation and magnitude of the asset return uncertainty. In contrast to the first technique, the components of the Brownian motion are independent. Also, this technique accepts the default assignment of an identity matrix to Correlation, and is more straightforward.
5 Simulate a single trial of 1000 observations (roughly four years of daily data) using both techniques. By default, all state variables start at 1:
```

rng(22814,'twister')
[X1,T] = simByEuler(GBM1,1000); % correlated Brownian motion
rng(22814,'twister')
[X2,T] = simByEuler(GBM2,1000); % standard Brownian motion

```

When based on the same initial random number state, each technique generates identical asset price paths:
```

subplot(2,1,1)

```
```

plot(T, X1)
title('Sample Paths from Correlated Brownian Motion')
ylabel('Asset Price')
subplot(2,1,2)
plot(T, X2)
title('Sample Paths from Standard Brownian Motion')
xlabel('Trading Day')
ylabel('Asset Price')

```

\section*{Dynamic Behavior of Market Parameters}

As discussed in "Creating SDE Objects" on page 17-7, object parameters may be evaluated as if they are MATLAB functions accessible by a common interface. This
accessibility provides the impression of dynamic behavior regardless of whether the underlying parameters are truly time-varying. Furthermore, because parameters are accessible by a common interface, seemingly simple linear constructs may in fact represent complex, nonlinear designs.

For example, consider a univariate geometric Brownian motion (GBM) model of the form:
\[
d X_{t}=\mu(t) X_{t} d t+\sigma(t) X_{t} d W_{t}
\]

In this model, the return, \(\mu(t)\), and volatility, \(\sigma(t)\), are generally dynamic parameters of time alone. However, when creating a GBM object to represent the underlying model, such dynamic behavior must be accessible by the common \(\left(t, X_{t}\right)\) interface. This reflects the fact that GBM models (and others) are restricted parameterizations that derive from the general SDE class.

As a convenience, you can specify parameters of restricted models, such as GBM models, as traditional MATLAB arrays of appropriate dimension. In this case, such arrays represent a static special case of the more general dynamic situation accessible by the ( \(t\), \(X_{t}\) ) interface.

Moreover, when you enter parameters as functions, object constructors can verify that they return arrays of correct size by evaluating them at the initial time and state. Otherwise, object constructors have no knowledge of any particular functional form.

The following example illustrates a technique that includes dynamic behavior by mapping a traditional MATLAB time series array to a callable function with a \(\left(t, X_{t}\right)\) interface. It also compares the function with an otherwise identical model with constant parameters.

Because time series arrays represent dynamic behavior that must be captured by functions accessible by the \(\left(t, X_{t}\right)\) interface, you need utilities to convert traditional time series arrays into callable functions of time and state. The following example shows how to do this using the conversion function ts2func (time series to function).

1 Load the data. Load a daily historical data set containing 3-month Euribor rates and closing index levels of France's CAC 40 spanning the time interval February 7, 2001 to April 24, 2006:
load Data_GlobalIdx2
2 Simulate risk-neutral sample paths. Simulate risk-neutral sample paths of the CAC 40 index using a geometric Brownian motion (GBM) model:
\[
d X_{t}=r(t) X_{t} d t+\sigma X_{t} d W_{t}
\]
where \(r(t)\) represents evolution of the risk-free rate of return.
Furthermore, assume that you need to annualize the relevant information derived from the daily data (annualizing the data is optional, but is useful for comparison to other examples), and that each calendar year comprises 250 trading days:
```

dt = 1/250;
returns = tick2ret(Dataset.CAC);
sigma = std(returns)*sqrt(250);
yields = Dataset.EB3M;
yields = 360*log(1 + yields);

```

3 Compare the sample paths from two risk-neutral historical simulation approaches. Compare the resulting sample paths obtained from two risk-neutral historical simulation approaches, where the daily Euribor yields serve as a proxy for the risk-free rate of return.
a The first approach specifies the risk-neutral return as the sample average of Euribor yields, and therefore assumes a constant (non-dynamic) risk-free return:
```

nPeriods = length(yields); % Simulated observations
rng(5713,'twister')
obj = gbm(mean(yields),diag(sigma),'StartState',100)
[X1,T] = simulate(obj,nPeriods,'DeltaTime',dt);
obj =
Class GBM: Generalized Geometric Brownian Motion
Dimensions: State = 1, Brownian = 1
StartTime: O
StartState: 100
Correlation: 1
Drift: drift rate function F(t,X(t))
Diffusion: diffusion rate function G(t,X(t))
Simulation: simulation method/function simByEuler
Return: 0.0278117
Sigma: 0.231906

```
b In contrast, the second approach specifies the risk-neutral return as the historical time series of Euribor yields. It therefore assumes a dynamic, yet deterministic, rate of return; this example does not illustrate stochastic interest rates. To illustrate this dynamic effect, use the ts2func utility:
\(r=t s 2 f u n c(y i e l d s, ' T i m e s ',(0: n P e r i o d s-1) ') ;\)
ts2func packages a specified time series array inside a callable function of time and state, and synchronizes it with an optional time vector. For instance:
\(r(0,100)\)
ans =
0.0470
evaluates the function at ( \(t=0, X_{t}=100\) ) and returns the first observed Euribor yield. However, you can also evaluate the resulting function at any intermediate time \(t\) and state \(X_{t}\) :
\(r(7.5,200)\)
ans =
0.0472

Furthermore, the following command produces the same result when called with time alone:
\(r(7.5)\)
ans =
0.0472

The equivalence of these last two commands highlights some important features.

When you specify parameters as functions, they must evaluate properly when passed a scalar, real-valued sample time ( \(t\) ), and an NVARS-by-1 state vector \(\left(X_{t}\right)\). They must also generate an array of appropriate dimensions, which in the first case is a scalar constant, and in the second case is a scalar, piecewise constant function of time alone.

You are not required to use either time \((t)\) or state \(\left(X_{t}\right)\). In the current example, the function evaluates properly when passed time followed by state, thereby satisfying the minimal requirements. The fact that it also evaluates correctly when passed only time simply indicates that the function does not require the state vector \(X_{t}\). The important point to make is that it works when you pass it ( \(t\), \(\left.X_{t}\right)\).

Furthermore, the ts2func function performs a zero-order-hold (ZOH) piecewise constant interpolation. The notion of piecewise constant parameters is pervasive throughout the SDE architecture, and is discussed in more detail in "Optimizing Accuracy: About Solution Precision and Error" on page 17-81.
4 Perform a second simulation using the same initial random number state. Complete the comparison by performing the second simulation using the same initial random number state:
```

rng(5713,'twister')
obj = gbm(r, diag(sigma),'StartState',100)
X2 = simulate(obj,nPeriods,'DeltaTime',dt);
obj =
Class GBM: Generalized Geometric Brownian Motion
Dimensions: State = 1, Brownian = 1
StartTime: 0
StartState: 100
Correlation: 1
Drift: drift rate function F(t,X(t))
Diffusion: diffusion rate function G(t,X(t))
Simulation: simulation method/function simByEuler
Return: function ts2func/vector2Function
Sigma: 0.231906

```

5 Compare the two simulation trials. Plot the series of risk-free reference rates to compare the two simulation trials:
```

subplot(2,1,1)
plot(dates,100*yields)
datetick('x')
xlabel('Date')
ylabel('Annualized Yield (%)')
title('Risk Free Rate(3-Mo Euribor Continuously-Compounded)')
subplot(2,1,2)
plot(T,X1,'red',T,X2,'blue')
xlabel('Time (Years)')
ylabel('Index Level')
title('Constant vs. Dynamic Rate of Return: CAC 40')
legend({'Constant Interest Rates' 'Dynamic Interest Rates'},...
'Location', 'Best')

```

The paths are close but not exact. The blue line in the last plot uses all the historical Euribor data, and illustrates a single trial of a historical simulation.

\section*{Pricing Equity Options}

As discussed in "Ensuring Positive Interest Rates" on page 17-68, all simulation and interpolation methods allow you to specify one or more functions of the form:
\[
X_{t}=f\left(t, X_{t}\right)
\]
to evaluate at the end of every sample time.

The related example illustrates a simple, common end-of-period processing function to ensure nonnegative interest rates. This example illustrates a processing function that allows you to avoid simulation outputs altogether.

Consider pricing European stock options by Monte Carlo simulation within a Black-Scholes-Merton framework. Assume that the stock has the following characteristics:
- The stock currently trades at 100.
- The stock pays no dividends.
- The stock's volatility is \(50 \%\) per annum.
- The option strike price is 95 .
- The option expires in three months.
- The risk-free rate is constant at \(10 \%\) per annum.

To solve this problem, model the evolution of the underlying stock by a univariate geometric Brownian motion (GBM) model with constant parameters:
\[
d X_{t}=0.1 X_{t} d t+0.5 X_{t} d W_{t}
\]

Furthermore, assume that the stock price is simulated daily, and that each calendar month comprises 21 trading days:
```

strike = 95;
rate = 0.1;
sigma = 0.5;
dt = 1/252;
nPeriods = 63;
T = nPeriods*dt;
obj = gbm(rate,sigma,'StartState',100);

```

The goal is to simulate independent paths of daily stock prices, and calculate the price of European options as the risk-neutral sample average of the discounted terminal option payoff at expiration 63 days from now. This example calculates option prices by two approaches:
- A Monte Carlo simulation that explicitly requests the simulated stock paths as an output. The output paths are then used to price the options.
- An end-of-period processing function, accessible by time and state, that records the terminal stock price of each sample path. This processing function is implemented
as a nested function with access to shared information. For more information, see Example_BlackScholes.m.

1 Before simulation, invoke the example file to access the end-of-period processing function:
```

nTrials = 10000; % Number of independent trials (i.e., paths)
f = Example_BlackScholes(nPeriods,nTrials)
f =
BlackScholes: @Example_BlackScholes/saveTerminalStockPrice
CallPrice: @Example_BlackScholes/getCallPrice
PutPrice: @Example_BlackScholes/getPutPrice

```

2 Simulate 10000 independent trials (sample paths). Request the simulated stock price paths as an output, and specify an end-of-period processing function:
```

rng(88161,'twister')
X = simBySolution(obj,nPeriods,'DeltaTime',dt,...
'nTrials',nTrials,'Processes',f.BlackScholes);

```

3 Calculate the option prices directly from the simulated stock price paths. Because these are European options, ignore all intermediate stock prices:
```

call = mean(exp(-rate*T)*max(squeeze(X(end,:,:)) - strike, 0))
put = mean(exp(-rate*T)*max(strike - squeeze(X(end,:,:)), 0))
call =
13.9342
put =
6.4166

```

4 Price the options indirectly by invoking the nested functions:
```

f.CallPrice(strike,rate)
f.PutPrice(strike,rate)

```
13.9342
ans \(=\)
6.4166

For reference, the theoretical call and put prices computed from the Black-Scholes option formulas are 13.6953 and 6.3497 , respectively.

5 Although steps 3 and 4 produce the same option prices, the latter approach works directly with the terminal stock prices of each sample path. Therefore, it is much more memory efficient. In this example, there is no compelling reason to request an output.

}

\section*{Simulating Interest Rates}

All simulation methods require that you specify a time grid by specifying the number of periods (NPERIODS). You can also optionally specify a scalar or vector of strictly positive time increments (DeltaTime) and intermediate time steps (NSTEPS). These parameters, along with an initial sample time associated with the object (StartTime), uniquely determine the sequence of times at which the state vector is sampled. Thus, simulation methods allow you to traverse the time grid from beginning to end (that is, from left to right).

In contrast, interpolation methods allow you to traverse the time grid in any order, allowing both forward and backward movements in time. They allow you to specify a vector of interpolation times whose elements do not have to be unique.

Many references define the Brownian Bridge as a conditional simulation combined with a scheme for traversing the time grid, effectively merging two distinct algorithms. In contrast, the interpolation method offered here provides additional flexibility by intentionally separating the algorithms. In this method for moving about a time grid, you perform an initial Monte Carlo simulation to sample the state at the terminal time, and then successively sample intermediate states by stochastic interpolation. The first few samples determine the overall behavior of the paths, while later samples progressively refine the structure. Such algorithms are often called variance reduction techniques. This algorithm is simple when the number of interpolation times is a power of 2 . In this case, each interpolation falls midway between two known states, refining the interpolation using a method like bisection. This example highlights the flexibility of refined interpolation by implementing this power-of-two algorithm.

1 Load the data. Load a historical data set of three-month Euribor rates, observed daily, and corresponding trading dates spanning the time interval from February 7, 2001 through April 24, 2006:
load Data_GlobalIdx2
plot(dates, 100 * Dataset.EB3M)
```

datetick('x'), xlabel('Date'), ylabel('Daily Yield (%)')
title('3-Month Euribor as a Daily Effective Yield')

```

2 Fit a model to the data. Now fit a simple univariate Vasicek model to the daily equivalent yields of the three-month Euribor data:
\[
d X_{t}=S\left(L-X_{t}\right) d t+\sigma d W_{t}
\]

Given initial conditions, the distribution of the short rate at some time \(T\) in the future is Gaussian with mean:
\[
E\left(X_{T}\right)=X_{0} e^{-S T}+L\left(1-e^{-S T}\right)
\]
and variance:
\[
\operatorname{Var}\left(X_{T}\right)=\sigma^{2}\left(1-e^{-S T}\right) / 2 S
\]

To calibrate this simple short rate model, rewrite it in more familiar regression format:
\[
y_{t}=\alpha+\beta x_{t}+\varepsilon_{t}
\]
where:
\[
y_{t}=d X_{t}, \alpha=S L d t, \beta=-S d t
\]
perform an ordinary linear regression where the model volatility is proportional to the standard error of the residuals:
```

\sigma=\sqrt{}{\operatorname{Var}(\mp@subsup{\varepsilon}{t}{})/dt}
yields = Dataset.EB3M;
regressors = [ones(length(yields) - 1, 1) yields(1:end-1)];
[coefficients, intervals, residuals] = ...
regress(diff(yields), regressors);
dt = 1; % time increment = 1 day
speed = -coefficients(2)/dt;
level = -coefficients(1)/coefficients(2);
sigma = std(residuals)/sqrt(dt);

```

3 Create an object and set its initial StartState. Create an HWV object with an initial StartState set to the most recently observed short rate:
```

obj = hwv(speed, level, sigma, 'StartState', yields(end))
obj =
Class HWV: Hull-White/Vasicek
Dimensions: State = 1, Brownian = 1
StartTime: 0

```
    StartState: 7.70408e-05
Correlation: 1
    Drift: drift rate function F(t,X(t))
    Diffusion: diffusion rate function G(t,X(t))
Simulation: simulation method/function simByEuler
    Sigma: 4.77637e-07
    Level: 6.00424e-05
    Speed: 0.00228854
```

4 Simulate the fitted model. Assume, for example, that you simulate the fitted model over $64\left(2^{6}\right)$ trading days, using a refined Brownian bridge with the power-of-two algorithm instead of the usual beginning-to-end Monte Carlo simulation approach. Furthermore, assume that the initial time and state coincide with those of the last available observation of the historical data, and that the terminal state is the expected value of the Vasicek model 64 days into the future. In this case, you can assess the behavior of various paths that all share the same initial and terminal states, perhaps to support pricing path-dependent interest rate options over a threemonth interval.

Create a vector of interpolation times to traverse the time grid by moving both forward and backward in time. Specifically, the first interpolation time is set to the most recent short rate observation time, the second interpolation time is set to the terminal time, and subsequent interpolation times successively sample intermediate states:

```
T = 64;
times = (1:T)';
t = NaN(length(times) + 1, 1);
t(1) = obj.StartTime;
t(2) = T;
delta = T;
jMax = 1;
iCount = 3;
for k = 1:log2(T)
    i = delta / 2;
    for j = 1:jMax
        t(iCount) = times(i);
        i = i + delta;
        iCount = iCount + 1;
    end
    jMax = 2 * jMax;
    delta = delta / 2;
```

end
5 Plot the interpolation times. Examine the sequence of interpolation times generated by this algorithm:

```
stem(1:length(t), t, 'filled')
xlabel('Index'), ylabel('Interpolation Time (Days)')
title ('Sampling Scheme for the Power-of-Two Algorithm')
```

The first few samples are widely separated in time and determine the course structure of the paths. Later samples are closely spaced and progressively refine the detailed structure.

6 Initialize the time series grid. Now that you have generated the sequence of interpolation times, initialize a course time series grid to begin the interpolation.

The sampling process begins at the last observed time and state taken from the historical short rate series, and ends 64 days into the future at the expected value of the Vasicek model derived from the calibrated parameters:

```
average = obj.StartState * exp(-speed * T) + level * ...
(1 - exp(-speed * T));
X = [obj.StartState ; average];
```

7 Generate five sample paths. Generate five sample paths, setting the Refine input flag to TRUE to insert each new interpolated state into the time series grid as it becomes available. Perform interpolation on a trial-by-trial basis. Because the input time series X has five trials (where each page of the three-dimensional time series represents an independent trial), the interpolated output series Y also has five pages:

```
nTrials = 5;
rng(63349,'twister')
Y = obj.interpolate(t, X(:,:,ones(nTrials,1)), ...
'Times',[obj.StartTime T], 'Refine', true);
```

8 Plot the resulting sample paths. Because the interpolation times do not monotonically increase, sort the times and reorder the corresponding short rates:

```
[t,i] = sort(t);
Y = squeeze(Y);
Y = Y(i,:);
plot(t, 100 * Y), hold('on')
plot(t([1 end]), 100 * Y([1 end],1),'. black','MarkerSize', 20)
xlabel('Interpolation Time (Days into the Future)')
ylabel('Yield (%)'), hold('off')
title ('Euribor Yields from Brownian Bridge Interpolation')
```

The short rates in this plot represent alternative sample paths that share the same initial and terminal values. They illustrate a special, though simplistic, case of a broader sampling technique known as stratified sampling. For a more sophisticated example of stratified sampling, see "Stratified Sampling" on page 17-73.

Although this simple example simulated a univariate Vasicek interest rate model, it applies to problems of any dimensionality.

Tip Brownian-bridge methods also apply more general variance-reduction techniques. For more information, see "Stratified Sampling" on page 17-73.

## Ensuring Positive Interest Rates

All simulation and interpolation methods allow you to specify a sequence of functions, or background processes, to evaluate at the end of every sample time period. This period includes any intermediate time steps determined by the optional NSTEPS input, as discussed in "Optimizing Accuracy: About Solution Precision and Error" on page 17-81. These functions are specified as callable functions of time and state, and must return an updated state vector $X_{t}$ :

$$
X_{t}=f\left(t, X_{t}\right)
$$

You must specify multiple processing functions as a cell array of functions. These functions are invoked in the order in which they appear in the cell array.

Processing functions are not required to use time $(t)$ or state $\left(X_{t}\right)$. They are also not required to update or change the input state vector. In fact, simulation and interpolation methods have no knowledge of any implementation details, and in this respect, they only adhere to a published interface.

Such processing functions provide a powerful modeling tool that can solve various problems. Such functions allow you to, for example, specify boundary conditions, accumulate statistics, plot graphs, and price path-dependent options.

Except for Brownian motion (BM) models, the individual components of the simulated state vector typically represent variables whose real-world counterparts are inherently positive quantities, such as asset prices or interest rates. However, by default, most of the simulation and interpolation methods provided here model the transition between successive sample times as a scaled (possibly multivariate) Gaussian draw. So, when approximating a continuous-time process in discrete time, the state vector may not remain positive. The only exception is the simBySolution logarithmic transform of separable geometric Brownian motion models. Moreover, by default, none of the simulation and interpolation methods make adjustments to the state vector. Therefore, you are responsible for ensuring that all components of the state vector remain positive as appropriate.

Fortunately, specifying nonnegative states ensures a simple end-of-period processing adjustment. Although this adjustment is widely applicable, it is revealing when applied to a univariate CIR square-root diffusion model:

$$
d X_{t}=0.25\left(0.1-X_{t}\right) d t+0.2 X_{t}^{\frac{1}{2}} d W_{t}=S\left(L-X_{t}\right) d t+\sigma X_{t}^{\frac{1}{2}} d W_{t}
$$

Perhaps the primary appeal of univariate CIR models where:

$$
2 S L \geq \sigma^{2}
$$

is that the short rate remains positive. However, the positivity of short rates only holds for the underlying continuous-time model.

1 Simulate daily short rates of the CIR model. To illustrate the latter statement, simulate daily short rates of the CIR model over one calendar year (approximately 250 trading days):

```
rng(14151617,'twister')
obj = cir(0.25,@(t,X)0.1,0.2,'StartState',0.02);
[X,T] = simByEuler(obj,250,'DeltaTime',1/250,'nTrials',5);
sprintf('%0.4f\t%0.4f+i%0.4f\n',[T(195:205)';...
        real(X(195:205,1,4))'; imag(X(195:205,1,4))'])
ans =
0.7760 0.0003+i0.0000
0.7800 0.0004+i0.0000
0.7840 0.0002+i0.0000
0.7880-0.0000+i0.0000
0.7920 0.0001+i0.0000
0.7960 0.0002+i0.0000
0.8000 0.0002+i0.0000
0.8040 0.0008+i0.0001
0.8080 0.0004+i0.0001
0.8120 0.0008+i0.0001
0.8160 0.0008+i0.0001
```

Interest rates can become negative if the resulting paths are simulated in discrete time. Moreover, since CIR models incorporate a square root diffusion term, the short rates might even become complex.
2 Repeat the simulation with a processing function. Repeat the simulation, this time specifying a processing function that takes the absolute magnitude of the short rate at the end of each period. You can access the processing function by time and state $\left(t, X_{t}\right)$, but it only uses the state vector of short rates $X_{t}$ :

```
rng(14151617,'twister')
```

```
[Y,T] = simByEuler(obj,250,'DeltaTime',1/250,...
    'nTrials',5,'Processes',@(t,X)abs(X));
```

3 Compare the adjusted and non-adjusted paths. Graphically compare the magnitude of the unadjusted path (with negative and complex numbers!) to the corresponding path kept positive by using an end-of-period processing function over the time span of interest:

```
clf
plot(T,100*abs(X(:, 1,4)),'red',T,100*Y(:, 1,4),'blue')
axis([0.75 1 0 0.4])
xlabel('Time (Years)'), ylabel('Short Rate (%)')
title('Univariate CIR Short Rates')
legend({'Negative/Complex Rates' 'Positive Rates'}, ...
    'Location', 'Best')
```

Tip You can use this method to obtain more accurate SDE solutions. For more information, see "Performance Considerations" on page 17-79.

## Stratified Sampling

Simulation methods allow you to specify a noise process directly, as a callable function of time and state:

$$
z_{t}=Z\left(t, X_{t}\right)
$$

Stratified sampling is a variance reduction technique that constrains a proportion of sample paths to specific subsets (or strata) of the sample space.

This example specifies a noise function to stratify the terminal value of a univariate equity price series. Starting from known initial conditions, the function first stratifies the terminal value of a standard Brownian motion, and then samples the process from beginning to end by drawing conditional Gaussian samples using a Brownian bridge.

The stratification process assumes that each path is associated with a single stratified terminal value such that the number of paths is equal to the number of strata. This technique is called proportional sampling. This example is similar to, yet more sophisticated than, the one discussed in "Simulating Interest Rates" on page 17-61. Since stratified sampling requires knowledge of the future, it also requires more sophisticated time synchronization; specifically, the function in this example requires knowledge of the entire sequence of sample times. For more information, see the example stratifiedExample.m.

The function implements proportional sampling by partitioning the unit interval into bins of equal probability by first drawing a random number uniformly distributed in each bin. The inverse cumulative distribution function of a standard $N(0,1)$ Gaussian distribution then transforms these stratified uniform draws. Finally, the resulting stratified Gaussian draws are scaled by the square root of the terminal time to stratify the terminal value of the Brownian motion.

The noise function does not return the actual Brownian paths, but rather the Gaussian draws $Z\left(t, X_{t}\right)$ that drive it.

This example first stratifies the terminal value of a univariate, zero-drift, unit-variancerate Brownian motion (BM) model:

$$
d X_{t}=d W_{t}
$$

1 Assume that 10 paths of the process are simulated daily over a three-month period. Also assume that each calendar month and year consist of 21 and 252 trading days, respectively:

```
rng(10203,'twister')
dt = 1 / 252; % 1 day = 1/252 years
nPeriods = 63; % % months = 63 trading days
T = nPeriods * dt; % 3 months = 0.25 years
nPaths = 10; % # of simulated paths
obj = bm(0, 1, 'StartState', 0);
sampleTimes = cumsum([obj.StartTime; ...
        dt(ones(nPeriods,1))]);
z = Example_StratifiedRNG(nPaths, sampleTimes);
```

2 Simulate the standard Brownian paths by explicitly passing the stratified sampling function to the simulation method:

```
X = obj.simulate(nPeriods, 'DeltaTime', dt, ...
    'nTrials', nPaths, 'Z', z);
```

3 For convenience, reorder the output sample paths by reordering the threedimensional output to a 2 -dimensional equivalent array:

X = squeeze( X );
4 Verify the stratification:
a Recreate the uniform draws with proportional sampling:

```
rng(10203,'twister')
U = ((1:nPaths)' - 1 + rand(nPaths,1))/nPaths;
```

b Transform them to obtain the terminal values of standard Brownian motion:

```
WT = norminv(U) * sqrt(T); % Stratified Brownian motion.
```

c Plot the terminal values and output paths on the same figure:

```
plot(sampleTimes, X), hold('on')
xlabel('Time (Years)'), ylabel('Brownian State')
title('Terminal Stratification: Standard Brownian Motion')
plot(T, WT, '. black', T, WT, 'o black')
hold('off')
```

The last value of each sample path (the last row of the output array $X$ ) coincides with the corresponding element of the stratified terminal value of the Brownian motion. This occurs because the simulated model and the noise generation function both represent the same standard Brownian motion.

However, you can use the same stratified sampling function to stratify the terminal price of constant-parameter geometric Brownian motion models. In fact, you can use the stratified sampling function to stratify the terminal value of any constantparameter model driven by Brownian motion if the model's terminal value is a monotonic transformation of the terminal value of the Brownian motion.

To illustrate this, load the data set and simulate risk-neutral sample paths of the FTSE 100 index using a geometric Brownian motion (GBM) model with constant parameters:

$$
d X_{t}=r X_{t} d t+\sigma X_{t} d W_{t}
$$

where the average Euribor yield represents the risk-free rate of return.
1 Assume that the relevant information derived from the daily data is annualized, and that each calendar year comprises 252 trading days:

```
load Data_GlobalIdx2
returns = tick2ret(Dataset.FTSE);
sigma = std(returns) * sqrt(252);
rate = Dataset.EB3M;
rate = mean(360 * log(1 + rate));
```

2 Create the GBM model, assuming the FTSE 100 starts at 100:
obj = gbm(rate, sigma, 'StartState', 100);
3 Determine the sample time and simulate the price paths.
In what follows, NSTEPS specifies the number of intermediate time steps within each time increment DeltaTime. Each increment DeltaTime is partitioned into NSTEPS subintervals of length DeltaTime/nSteps each, refining the simulation by evaluating the simulated state vector at NSTEPS-1 intermediate points. This refinement improves accuracy by allowing the simulation to more closely approximate the underlying continuous-time process without storing the intermediate information:

```
nSteps = 1;
sampleTimes = cumsum([obj.StartTime ; ...
dt(ones(nPeriods * nSteps,1))/nSteps]);
z = Example_StratifiedRNG(nPaths, sampleTimes);
rng(10203,'twister')
[Y, Times] = obj.simBySolution(nPeriods, 'nTrials', nPaths,...
'DeltaTime', dt, 'nSteps', nSteps, 'Z', z);
Y = squeeze(Y); % Reorder to a 2-D array
plot(Times, Y)
xlabel('Time (Years)'), ylabel('Index Level')
title('FTSE 100 Terminal Stratification:Geometric Brownian Motion')
```

Although the terminal value of the Brownian motion shown in the latter plot is normally distributed, and the terminal price in the previous plot is lognormally distributed, the corresponding paths of each graph are similar.

Tip For another example of variance reduction techniques, see "Simulating Interest Rates" on page 17-61.

## Performance Considerations

In this section...<br>"Managing Memory" on page 17-79<br>"Enhancing Performance" on page 17-80<br>"Optimizing Accuracy: About Solution Precision and Error" on page 17-81

## Managing Memory

There are two general approaches for managing memory when solving most problems supported by the SDE engine:

- "Managing Memory with Outputs" on page 17-79
- "Managing Memory Using End-of-Period Processing Functions" on page 17-80

## Managing Memory with Outputs

Perform a traditional simulation to simulate the underlying variables of interest, specifically requesting and then manipulating the output arrays.

This approach is straightforward and the best choice for small or medium-sized problems. Since its outputs are arrays, it is convenient to manipulate simulated results in the MATLAB matrix-based language. However, as the scale of the problem increases, the benefit of this approach decreases, because the output arrays must store large quantities of possibly extraneous information.

For example, consider pricing a European option in which the terminal price of the underlying asset is the only value of interest. To ease the memory burden of the traditional approach, reduce the number of simulated periods specified by the required input NPERIODS and specify the optional input NSTEPS. This enables you to manage memory without sacrificing accuracy (see "Optimizing Accuracy: About Solution Precision and Error" on page 17-81).

In addition, simulation methods can determine the number of output arguments and allocate memory accordingly. Specifically, all simulation methods support the same output argument list:
[Paths,Times, Z]
where Paths and $Z$ can be large, three-dimensional time series arrays. However, the underlying noise array is typically unnecessary, and is only stored if requested as an
output. In other words, Z is stored only at your request; do not request it if you do not need it.

If you need the output noise array Z, but do not need the Paths time series array, then you can avoid storing Paths two ways:

- It is best practice to use the $\sim$ output argument placeholder. For example, use the following output argument list to store $Z$ and Times, but not Paths:

```
[~,Times,Z]
```

- Use the optional input flag StorePaths, which all simulation methods support. By default, Paths is stored (StorePaths = true). However, setting StorePaths to false returns Paths as an empty matrix.

## Managing Memory Using End-of-Period Processing Functions

Specify one or more end-of-period processing functions to manage and store only the information of interest, avoiding simulation outputs altogether.

This approach requires you to specify one or more end-of-period processing functions, and is often the preferred approach for large-scale problems. This approach allows you to avoid simulation outputs altogether. Since no outputs are requested, the threedimensional time series arrays Paths and $Z$ are not stored.

This approach often requires more effort, but is far more elegant and allows you to customize tasks and dramatically reduce memory usage. See "Pricing Equity Options" on page 17-56.

## Enhancing Performance

The following approaches improve performance when solving SDE problems:

- Specifying model parameters as traditional MATLAB arrays and functions, in various combinations. This provides a flexible interface that can support virtually any general nonlinear relationship. However, while functions offer a convenient and elegant solution for many problems, simulations typically run faster when you specify parameters as double-precision vectors or matrices. Thus, it is a good practice to specify model parameters as arrays when possible.
- Use models that have overloaded Euler simulation methods, when possible. Using Brownian motion (BM) and geometric Brownian motion (GBM) models that
provide overloaded Euler simulation methods take advantage of separable, constantparameter models. These specialized methods are exceptionally fast, but are only available to models with constant parameters that are simulated without specifying end-of-period processing and noise generation functions.
- Replace the simulation of a constant-parameter, univariate model derived from the SDEDDO class with that of a diagonal multivariate model. Treat the multivariate model as a portfolio of univariate models. This increases the dimensionality of the model and enhances performance by decreasing the effective number of simulation trials.

Note: This technique is applicable only to constant-parameter univariate models without specifying end-of-period processing and noise generation functions.

- Take advantage of the fact that simulation methods are designed to detect the presence of NaN (not a number) conditions returned from end-of-period processing functions. A NaN represents the result of an undefined numerical calculation, and any subsequent calculation based on a NaN produces another NaN. This helps improve performance in certain situations. For example, consider simulating paths of the underlier of a knock-out barrier option (that is, an option that becomes worthless when the price of the underlying asset crosses some prescribed barrier). Your end-of-period function could detect a barrier crossing and return a NaN to signal early termination of the current trial.

## Optimizing Accuracy: About Solution Precision and Error

The simulation architecture does not, in general, simulate exact solutions to any SDE. Instead, the simulation architecture provides a discrete-time approximation of the underlying continuous-time process, a simulation technique often known as a Euler approximation.

In the most general case, a given simulation derives directly from an SDE. Therefore, the simulated discrete-time process approaches the underlying continuous-time process only in the limit as the time increment $d t$ approaches zero. In other words, the simulation architecture places more importance on ensuring that the probability distributions of the discrete-time and continuous-time processes are close, than on the pathwise proximity of the processes.

Before illustrating techniques to improve the approximation of solutions, it is helpful to understand the source of error. Throughout this architecture, all simulation methods
assume that model parameters are piecewise constant over any time interval of length $d t$. In fact, the methods even evaluate dynamic parameters at the beginning of each time interval and hold them fixed for the duration of the interval. This sampling approach introduces discretization error.

However, there are certain models for which the piecewise constant approach provides exact solutions:

- "Creating Brownian Motion (BM) Models" on page 17-24 with constant parameters, simulated by Euler approximation (simByEuler).
- "Creating Geometric Brownian Motion (GBM) Models" on page 17-26 with constant parameters, simulated by closed-form solution (simBySolution).
- "Creating Hull-White/Vasicek (HWV) Gaussian Diffusion Models" on page 17-29 with constant parameters, simulated by closed-form solution (simBySolution)

More generally, you can simulate the exact solutions for these models even if the parameters vary with time, if they vary in a piecewise constant way such that parameter changes coincide with the specified sampling times. However, such exact coincidence is unlikely; therefore, the previously discussed constant parameter condition is commonly used in practice.

One obvious way to improve accuracy involves sampling the discrete-time process more frequently. This decreases the time increment ( $d t$ ), causing the sampled process to more closely approximate the underlying continuous-time process. Although decreasing the time increment is universally applicable, however, there is a tradeoff among accuracy, run-time performance, and memory usage.

To manage this tradeoff, specify an optional input argument, NSTEPS, for all simulation methods. NSTEPS indicates the number of intermediate time steps within each time increment $d t$, at which the process is sampled but not reported.

It is important and convenient at this point to emphasize the relationship of the inputs NSTEPS, NPERIODS, and DeltaTime to the output vector Times, which represents the actual observation times at which the simulated paths are reported.

- NPERIODS, a required input, indicates the number of simulation periods of length DeltaTime, and determines the number of rows in the simulated three-dimensional Paths time series array (if an output is requested).
- DeltaTime is optional, and indicates the corresponding NPERIODS-length vector of positive time increments between successive samples. It represents the familiar $d t$
found in stochastic differential equations. If DeltaTime is unspecified, the default value of 1 is used.
- NSTEPS is also optional, and is only loosely related to NPERIODS and DeltaTime. NSTEPS specifies the number of intermediate time steps within each time increment DeltaTime.

Specifically, each time increment DeltaTime is partitioned into NSTEPS subintervals of length DeltaTime/NSTEPS each, and refines the simulation by evaluating the simulated state vector at (NSTEPS - 1) intermediate times. Although the output state vector (if requested) is not reported at these intermediate times, this refinement improves accuracy by causing the simulation to more closely approximate the underlying continuous-time process. If NSTEPS is unspecified, the default is 1 (to indicate no intermediate evaluation).

- The output Times is an NPERIODS + 1-length column vector of observation times associated with the simulated paths. Each element of Times is associated with a corresponding row of Paths.

The following example illustrates this intermediate sampling by comparing the difference between a closed-form solution and a sequence of Euler approximations derived from various values of NSTEPS.

## Example: Improving Solution Accuracy

Consider a univariate geometric Brownian motion (GBM) model with constant parameters:

$$
d X_{t}=0.1 X_{t} d t+0.4 X_{t} d W_{t}
$$

Assume that the expected rate of return and volatility parameters are annualized, and that a calendar year comprises 250 trading days.

1 Simulate approximately four years of univariate prices for both the exact solution and the Euler approximation for various values of NSTEPS:

```
nPeriods = 1000;
dt = 1/250;
obj = gbm(0.1,0.4,'StartState',100);
rng(575,'twister')
[X1,T1] = simBySolution(obj,nPeriods,'DeltaTime',dt);
```

```
rng(575,'twister')
[Y1,T1] = simByEuler(obj,nPeriods,'DeltaTime',dt);
rng(575,'twister')
[X2,T2] = simBySolution(obj,nPeriods,'DeltaTime',...
    dt,'nSteps',2);
rng(575,'twister')
[Y2,T2] = simByEuler(obj,nPeriods,'DeltaTime',...
    dt,'nSteps',2);
rng(575,'twister')
[X3,T3] = simBySolution(obj,nPeriods, 'DeltaTime',...
    dt,'nSteps',10);
rng(575,'twister')
[Y3,T3] = simByEuler(obj,nPeriods,'DeltaTime',...
    dt,'nSteps',10);
rng(575,'twister')
[X4,T4] = simBySolution(obj,nPeriods,'DeltaTime',...
    dt,'nSteps',100);
rng(575,'twister')
[Y4,T4] = simByEuler(obj,nPeriods,'DeltaTime',...
    dt,'nSteps',100);
```

2 Compare the error (the difference between the exact solution and the Euler approximation) graphically:

```
clf;
plot(T1,X1 - Y1,'red')
hold on;
plot(T2,X2 - Y2,'blue')
plot(T3,X3 - Y3,'green')
plot(T4,X4 - Y4,'black')
hold off
xlabel('Time (Years)')
ylabel('Price Difference')
title('Exact Solution Minus Euler Approximation')
legend({'# of Steps = 1' '# of Steps = 2' ...
    '# of Steps = 10' '# of Steps = 100'},...
    'Location', 'Best')
hold off
whos T X Y
```

As expected, the simulation error decreases as the number of intermediate time steps increases. Because the intermediate states are not reported, all simulated time series have the same number of observations regardless of the actual value of NSTEPS.

Furthermore, since the previously simulated exact solutions are correct for any number of intermediate time steps, additional computations are not needed for this example.
In fact, this assessment is generally correct. The exact solutions are sampled at intermediate times to ensure that the simulation uses the same sequence of Gaussian random variates in the same order. Without this assurance, there is no way to compare simulated prices on a pathwise basis. However, there might be valid reasons for sampling exact solutions at closely spaced intervals, such as pricing path-dependent options.

## Pricing American Basket Options by Monte Carlo Simulation

This example shows how to model the fat-tailed behavior of asset returns and assess the impact of alternative joint distributions on basket option prices. Using various implementations of a separable multivariate Geometric Brownian Motion (GBM) process, often referred to as a multi-dimensional market model, the example simulates riskneutral sample paths of an equity index portfolio and prices basket put options using the technique of Longstaff \& Schwartz.

In addition, this example also illustrates salient features of the Stochastic Differential Equation (SDE) architecture, including

- Customized random number generation functions that compare Brownian motion and Brownian copulas
- End-of-period processing functions that form an equity index basket and price American options on the underlying basket based on the least squares method of Longstaff \& Schwartz
- Piecewise probability distributions and Extreme Value Theory (EVT)

This example also highlights important issues of volatility and interest rate scaling. It illustrates how equivalent results can be achieved by working with daily or annualized data. For more information about EVT and copulas, see Using Extreme Value Theory and Copulas to Evaluate Market Risk.

## Overview of the Modeling Framework

The ultimate objective of this example is to compare basket option prices derived from different noise processes. The first noise process is a traditional Brownian motion model whose index portfolio price process is driven by correlated Gaussian random draws. As alternatives, the Brownian motion benchmark is compared to noise processes driven by Gaussian and Student's t copulas, referred to collectively as a Brownian copula.

A copula is a multivariate cumulative distribution function (CDF) with uniformlydistributed margins. Although the theoretical foundations were established decades ago, copulas have experienced a tremendous surge in popularity over the last few years, primarily as a technique for modeling non-Gaussian portfolio risks.

Although numerous families exist, all copulas represent a statistical device for modeling the dependence structure between 2 or more random variables. In addition, important statistics, such as rank correlation and tail dependence, are properties of a given copula and are unchanged by monotonic transforms of its margins.

These copula draws produce dependent random variables, which are subsequently transformed to individual variables (margins). This transformation is achieved with a semi-parametric probability distribution with generalized Pareto tails.

The risk-neutral market model to simulate is

$$
d X_{t}=r X_{t} d t+\sigma X_{t} d W_{t}
$$

where the risk-free rate, $r$, is assumed constant over the life of the option. Because this is a separable multivariate model, the risk-free return is a diagonal matrix in which the same riskless return is applied to all indices. Dividend yields are ignored to simplify the model its associated data collection.

In contrast, the specification of the exposure matrix, sigma, depends on how the driving source of uncertainty is modeled. You can model it directly as a Brownian motion (correlated Gaussian random numbers implicitly mapped to Gaussian margins) or model it as a Brownian copula (correlated Gaussian or t random numbers explicitly mapped to semi-parametric margins).

Because the CDF and inverse CDF (quantile function) of univariate distributions are both monotonic transforms, a copula provides a convenient way to simulate dependent random variables whose margins are dissimilar and arbitrarily distributed. Moreover, because a copula defines a given dependence structure regardless of its margins, copula parameter calibration is typically easier than estimation of the joint distribution function.

Once you have simulated sample paths, options are priced by the least squares regression method of Longstaff \& Schwartz (see Valuing American Options by Simulation: A Simple Least-Squares Approach, The Review of Financial Studies, Spring 2001). This approach uses least squares to estimate the expected payoff of an option if it is not immediately exercised. It does so by regressing the discounted option cash flows received in the future on the current price of the underlier associated with all in-themoney sample paths. The continuation function is estimated by a simple third-order polynomial, in which all cash flows and prices in the regression are normalized by the option strike price, improving numerical stability.

## Import the Supporting Historical Dataset

Load a daily historical dataset of 3 -month Euribor, the trading dates spanning the interval 07-Feb-2001 to 24-Apr-2006, and the closing index levels of the following representative large-cap equity indices:

- TSX Composite (Canada)
- CAC 40 (France)
- DAX (Germany)
- Nikkei 225 (Japan)
- FTSE 100 (UK)
- S\&P 500 (US)

```
clear
load Data_GlobalIdx2
```

The following plots illustrate this data. Specifically, the plots show the relative price movements of each index and the Euribor risk-free rate proxy. The initial level of each index has been normalized to unity to facilitate the comparison of relative performance over the historical record.

```
nIndices = size(Data,2)-1; % # of indices
prices = Data(:,1:end-1);
yields = Data(:,end); % daily effective yields
yields = 360 * log(1 + yields); % continuously-compounded, annualized yield
plot(dates, ret2tick(tick2ret(prices,[],'continuous'),[],[],[],'continuous'))
datetick('x')
xlabel('Date')
ylabel('Index Value')
title ('Normalized Daily Index Closings')
legend(series{1:end-1}, 'Location', 'NorthWest')
```

## Extreme Value Theory \& Piecewise Probability Distributions

To prepare for copula modeling, characterize individually the distribution of returns of each index. Although the distribution of each return series may be characterized parametrically, it is useful to fit a semi-parametric model using a piecewise distribution with generalized Pareto tails. This uses Extreme Value Theory to better characterize the behavior in each tail.

The Statistics and Machine Learning Toolbox ${ }^{\mathrm{TM}}$ software currently supports two univariate probability distributions related to EVT, a statistical tool for modeling the fattailed behavior of financial data such as asset returns and insurance losses:

- Generalized Extreme Value (GEV) distribution, which uses a modeling technique known as the block maxima or minima method. This approach, divides a historical
dataset into a set of sub-intervals, or blocks, and the largest or smallest observation in each block is recorded and fitted to a GEV distribution.
- Generalized Pareto (GP) distribution, uses a modeling technique known as the distribution of exceedances or peaks over threshold method. This approach sorts a historical dataset, and fits the amount by which those observations that exceed a specified threshold to a GP distribution.

The following analysis highlights the Pareto distribution, which is more widely used in risk management applications.

Suppose we wish to create a complete statistical description of the probability distribution of daily asset returns of any one of the equity indices. Assume that this description is provided by a piecewise semi-parametric distribution, where the asymptotic behavior in each tail is characterized by a generalized Pareto distribution.

Ultimately, a copula will be used to generate random numbers to drive the simulations. The CDF and inverse CDF transforms will capture the volatility of simulated returns as part of the diffusion term of the SDE. The mean return of each index is governed by the riskless rate and incorporated in the drift term of the SDE. The following code segment centers the returns (that is, extracts the mean) of each index.

Because the following analysis uses extreme value theory to characterize the distribution of each equity index return series, it is helpful to examine details for a particular country:

```
returns = tick2ret(prices,[],'continuous'); % convert prices to returns
returns = bsxfun(@minus, returns, mean(returns)); % center the returns
index = 3; % Germany stored in column 3
plot(dates(2:end), returns(:,index))
datetick('x')
xlabel('Date')
ylabel('Return')
title(['Daily Logarithmic Centered Returns: ' series{index}])
```

Note that this code segment can be changed to examine details for any country.
Using these centered returns, estimate the empirical, or non-parametric, CDF of each index with a Gaussian kernel. This smoothes the CDF estimates, eliminating the staircase pattern of unsmoothed sample CDFs. Although non-parametric kernel CDF estimates are well-suited for the interior of the distribution, where most of the data is found, they tend to perform poorly when applied to the upper and lower tails. To better estimate the tails of the distribution, apply EVT to the returns that fall in each tail.

Specifically, find upper and lower thresholds such that $10 \%$ of the returns is reserved for each tail. Then fit the amount by which the extreme returns in each tail fall beyond the associated threshold to a Pareto distribution by maximum likelihood.

The following code segment creates one object of type paretotails for each index return series. These Pareto tail objects encapsulate the estimates of the parametric Pareto lower tail, the non-parametric kernel-smoothed interior, and the parametric Pareto upper tail to construct a composite semi-parametric CDF for each index.

```
tailFraction = 0.1; % decimal fraction allocated to each tail
tails = cell(nIndices,1); % cell array of Pareto tail objects
for i = 1:nIndices
    tails{i} = paretotails(returns(:,i), tailFraction, 1 - tailFraction, 'kernel');
end
```

The resulting piecewise distribution object allows interpolation within the interior of the CDF and extrapolation (function evaluation) in each tail. Extrapolation allows estimation of quantiles outside the historical record, which is invaluable for risk management applications.

Pareto tail objects also provide methods to evaluate the CDF and inverse CDF (quantile function), and to query the cumulative probabilities and quantiles of the boundaries between each segment of the piecewise distribution.

Now that three distinct regions of the piecewise distribution have been estimated, graphically concatenate and display the result.

The following code calls the CDF and inverse CDF methods of the Pareto tails object of interest with data other than that upon which the fit is based. The referenced methods have access to the fitted state. They are now invoked to select and analyze specific regions of the probability curve, acting as a powerful data filtering mechanism.

For reference, the plot also includes a zero-mean Gaussian CDF of the same standard deviation. To a degree, the variation in options prices reflect the extent to which the distribution of each asset differs from this normal curve.

```
minProbability = cdf(tails{index}, (min(returns(:,index))));
maxProbability = cdf(tails{index}, (max(returns(:,index))));
pLowerTail = linspace(minProbability , tailFraction , 200); % lower tail
pUpperTail = linspace(1 - tailFraction, maxProbability , 200); % upper tail
pInterior = linspace(tailFraction , 1 - tailFraction, 200); % interior
plot(icdf(tails{index}, pLowerTail), pLowerTail, 'red' , 'LineWidth', 2)
hold on
grid on
plot(icdf(tails{index}, pInterior) , pInterior , 'black', 'LineWidth', 2)
```

```
plot(icdf(tails{index}, pUpperTail), pUpperTail, 'blue' , 'LineWidth', 2)
limits = axis;
x = linspace(limits(1), limits(2));
plot(x, normcdf(x, 0, std(returns(:,index))), 'green', 'LineWidth', 2)
fig = gcf;
fig.Color = [1 1 1 1];
hold off
xlabel('Centered Return')
ylabel('Probability')
title (['Semi-Parametric/Piecewise CDF: ' series{index}])
legend({'Pareto Lower Tail' 'Kernel Smoothed Interior' ...
'Pareto Upper Tail' 'Gaussian with Same \sigma'}, 'Location', 'NorthWest')
```

The lower and upper tail regions, displayed in red and blue, respectively, are suitable for extrapolation, while the kernel-smoothed interior, in black, is suitable for interpolation.

## Copula Calibration

The Statistics and Machine Learning Toolbox software includes functionality that calibrates and simulates Gaussian and t copulas.

Using the daily index returns, estimate the parameters of the Gaussian and $t$ copulas using the function copulafit. Since a t copula becomes a Gaussian copula as the scalar degrees of freedom parameter ( DoF ) becomes infinitely large, the two copulas are really of the same family, and therefore share a linear correlation matrix as a fundamental parameter.

Although calibration of the linear correlation matrix of a Gaussian copula is straightforward, the calibration of a $t$ copula is not. For this reason, the Statistics and Machine Learning Toolbox software offers two techniques to calibrate at copula:

- The first technique performs maximum likelihood estimation (MLE) in a two-step process. The inner step maximizes the log-likelihood with respect to the linear correlation matrix, given a fixed value for the degrees of freedom. This conditional maximization is placed within a 1-D maximization with respect to the degrees of freedom, thus maximizing the log-likelihood over all parameters. The function being maximized in this outer step is known as the profile log-likelihood for the degrees of freedom.
- The second technique is derived by differentiating the log-likelihood function with respect to the linear correlation matrix, assuming the degrees of freedom is a fixed constant. The resulting expression is a non-linear equation that can be solved iteratively for the correlation matrix. This technique approximates the profile loglikelihood for the degrees of freedom parameter for large sample sizes. This technique is usually significantly faster than the true maximum likelihood technique outlined above; however, you should not use it with small or moderate sample sizes as the estimates and confidence limits may not be accurate.

When the uniform variates are transformed by the empirical CDF of each margin, the calibration method is often known as canonical maximum likelihood (CML). The following code segment first transforms the daily centered returns to uniform variates by the piecewise, semi-parametric CDFs derived above. It then fits the Gaussian and t copulas to the transformed data:
$U=z e r o s(s i z e(r e t u r n s)) ;$

```
for i = 1:nIndices
    U(:,i) = cdf(tails{i}, returns(:,i)); % transform each margin to uniform
end
options = statset('Display', 'off', 'TolX', 1e-4);
[rhoT, DoF] = copulafit('t', U, 'Method', 'ApproximateML', 'Options', options);
rhoG = copulafit('Gaussian', U);
```

The estimated correlation matrices are quite similar but not identical.
corrcoef(returns) \% linear correlation matrix of daily returns

| 0.6521 | 0.5122 | 0.5877 | 0.1539 | 0.4769 | 1.0000 |

Note the relatively low degrees of freedom parameter obtained from the $t$ copula calibration, indicating a significant departure from a Gaussian situation.

```
DoF % scalar degrees of freedom parameter of the optimized t copula
```

DoF =
4.8613

## Copula Simulation

Now that the copula parameters have been estimated, simulate jointly-dependent uniform variates using the function copularnd.

Then, by extrapolating the Pareto tails and interpolating the smoothed interior, transform the uniform variates derived from copularnd to daily centered returns via the inverse CDF of each index. These simulated centered returns are consistent with those obtained from the historical dataset. The returns are assumed to be independent in time, but at any point in time possess the dependence and rank correlation induced by the given copula.

The following code segment illustrates the dependence structure by simulating centered returns using the $t$ copula. It then plots a 2-D scatter plot with marginal histograms for the French CAC 40 and German DAX using the Statistics and Machine Learning Toolbox scatterhist function. The French and German indices were chosen simply because they have the highest correlation of the available data.

```
nPoints = 10000; % # of simulated observations
s = RandStream.getGlobalStream();
reset(s)
R = zeros(nPoints, nIndices); % pre-allocate simulated returns array
U = copularnd('t', rhoT, DoF, nPoints); % simulate U(0,1) from t copula
for j = 1:nIndices
    R(:,j) = icdf(tails{j}, U(:,j));
```

## end

```
h = scatterhist(R(:,2), R(:,3),'Color','r','Marker','.','MarkerSize',1);
fig = gcf;
fig.Color = [1 1 1];
y1 = ylim(h(1));
y3 = ylim(h(3));
xlim(h(1), [-.1 .1])
ylim(h(1), [-.1 .1])
xlim(h(2), [-.1 .1])
ylim(h(3), [(y3(1) + (-0.1 - y1(1))) (y3(2) + (0.1 - y1(2)))])
xlabel('France')
ylabel('Germany')
title(['t Copula (\nu = ' num2str(DoF,2) ')'])
```

Now simulate and plot centered returns using the Gaussian copula.

```
reset(s)
R = zeros(nPoints, nIndices); % pre-allocate simulated returns array
U = copularnd('Gaussian', rhoG, nPoints); % simulate U(0,1) from Gaussian copula
for j = 1:nIndices
    R(:,j) = icdf(tails{j}, U(:,j));
end
h = scatterhist(R(:,2), R(:,3),'Color','r','Marker','.','MarkerSize',1);
fig = gcf;
fig.Color = [11 1 1];
y1 = ylim(h(1));
y3 = ylim(h(3));
xlim(h(1), [-.1 .1])
ylim(h(1), [-.1 .1])
xlim(h(2), [-.1 .1])
ylim(h(3), [(y3(1) + (-0.1 - y1(1))) (y3(2) + (0.1 - y1(2)))])
xlabel('France')
ylabel('Germany')
title('Gaussian Copula')
```

Examine these two figures. There is a strong similarity between the miniature histograms on the corresponding axes of each figure. This similarity is not coincidental.

Both copulas simulate uniform random variables, which are then transformed to daily centered returns by the inverse CDF of the piecewise distribution of each index. Therefore, the simulated returns of any given index are identically distributed regardless of the copula.

However, the scatter graph of each figure indicates the dependence structure associated with the given copula, and in contrast to the univariate margins shown in the histograms, the scatter graphs are distinct.

Once again, the copula defines a dependence structure regardless of its margins, and therefore offers many features not limited to calibration alone.

For reference, simulate and plot centered returns using the Gaussian distribution, which underlies the traditional Brownian motion model.

```
reset(s)
R = mvnrnd(zeros(1,nIndices), cov(returns), nPoints);
h = scatterhist(R(:,2), R(:,3),'Color','r','Marker','.','MarkerSize',1);
fig = gcf;
fig.Color = [1 1 1];
y1 = ylim(h(1));
y3 = ylim(h(3));
xlim(h(1), [-.1 .1])
ylim(h(1), [-.1 .1])
xlim(h(2), [-.11 .1])
ylim(h(3), [(y3(1) + (-0.1 - y1(1))) (y3(2) + (0.1 - y1(2)))])
xlabel('France')
ylabel('Germany')
title('Gaussian Distribution')
```

## American Option Pricing Using the Longstaff \& Schwartz Approach

Now that the copulas have been calibrated, compare the prices of at-the-money American basket options derived from various approaches. To simply the analysis, assume that:

- All indices begin at 100 .
- The portfolio holds a single unit, or share, of each index such that the value of the portfolio at any time is the sum of the values of the individual indices.
- The option expires in 3 months.
- The information derived from the daily data is annualized.
- Each calendar year is composed of 252 trading days.
- Index levels are simulated daily.
- The option may be exercised at the end of every trading day and approximates the American option as a Bermudan option.

Now compute the parameters common to all simulation methods:

```
dt = 1 252; % time increment = 1 day = 1/252 years
yields = Data(:,end); % daily effective yields
yields = 360 * log(1 + yields); % continuously-compounded, annualized yields
r = mean(yields); % historical 3M Euribor average
X = repmat(100, nIndices, 1); % initial state vector
strike = sum(X); % initialize an at-the-money basket
nTrials = 100; % # of independent trials
nPeriods = 63; % # of simulation periods: 63/252 = 0.25 years = 3 months
```

Now create two separable multi-dimensional market models in which the riskless return and volatility exposure matrices are both diagonal.

While both are diagonal GBM models with identical risk-neutral returns, the first is driven by a correlated Brownian motion and explicitly specifies the sample linear correlation matrix of centered returns. This correlated Brownian motion process is then weighted by a diagonal matrix of annualized index volatilities or standard deviations.

As an alternative, the same model could be driven by an uncorrelated Brownian motion (standard Brownian motion) by specifying correlation as an identity matrix, or by simply accepting the default value. In this case, the exposure matrix sigma is specified as the lower Cholesky factor of the index return covariance matrix. Because the copulabased approaches simulate dependent random numbers, the diagonal exposure form is chosen for consistency. For further details, see Alternatives for Inducing Dependence \& Correlation.

```
sigma = std(returns) * sqrt(252); % annualized volatility
correlation = corrcoef(returns); % correlated Gaussian disturbances
GBM1 = gbm(diag(r(ones(1,nIndices))), diag(sigma), 'StartState', X, ...
    'Correlation' , correlation);
```

Now create the second model driven by the Brownian copula with an identity matrix sigma.

```
GBM2 = gbm(diag(r(ones(1,nIndices))), eye(nIndices), 'StartState', X);
```

The newly created model may seem unusual, but it highlights the flexibility of the SDE architecture.

When working with copulas, it is often convenient to allow the random number generator function $\mathrm{Z}(\mathrm{t}, \mathrm{X})$ to induce dependence (of which the traditional notion of linear correlation is a special case) with the copula, and to induce magnitude or scale of variation (similar to volatility or standard deviation) with the semi-parametric CDF and inverse CDF transforms. Since the CDF and inverse CDF transforms of each index inherit the characteristics of historical returns, this also explains why the returns are now centered.

In the following sections, statements like:

```
z = Example_CopulaRNG(returns * sqrt(252), nPeriods, 'Gaussian');
```

or
z = Example_CopulaRNG(returns * sqrt(252), nPeriods, 't');
fit the Gaussian and $t$ copula dependence structures, respectively, and the semiparametric margins to the centered returns scaled by the square root of the number of trading days per year (252). This scaling does not annualize the daily centered returns. Instead, it scales them such that the volatility remains consistent with the diagonal annualized exposure matrix sigma of the traditional Brownian motion model (GBM1) created previously.

In this example, you also specify an end-of-period processing function that accepts time followed by state ( $\mathrm{t}, \mathrm{X}$ ), and records the sample times and value of the portfolio as the single-unit weighted average of all indices. This function also shares this information with other functions designed to price American options with a constant riskless rate using the least squares regression approach of Longstaff \& Schwartz.

```
f = Example_LongstaffSchwartz(nPeriods, nTrials)
```

```
f =
    LongstaffSchwartz: @Example_LongstaffSchwartz/saveBasketPrices
        CallPrice: @Example_LongstaffSchwartz/getCallPrice
            PutPrice: @Example_LongstaffSchwartz/getPutPrice
                Prices: @Example_LongstaffSchwartz/getBasketPrices
```

Now simulate independent trials of equity index prices over 3 calendar months using the default simByEuler method. No outputs are requested from the simulation methods; in fact the simulated prices of the individual indices which comprise the basket are unnecessary. Call option prices are reported for convenience:

```
reset(s)
simByEuler(GBM1, nPeriods, 'nTrials' , nTrials, 'DeltaTime', dt, ...
    'Processes', f.LongstaffSchwartz);
BrownianMotionCallPrice = f.CallPrice(strike, r);
BrownianMotionPutPrice = f.PutPrice (strike, r);
reset(s)
z = Example_CopulaRNG(returns * sqrt(252), nPeriods, 'Gaussian');
f = Example_LongstaffSchwartz(nPeriods, nTrials);
simByEuler(GBM2, nPeriods, 'nTrials' , nTrials, 'DeltaTime', dt, ...
    'Processes', f.LongstaffSchwartz, 'Z', z);
GaussianCopulaCallPrice = f.CallPrice(strike, r);
GaussianCopulaPutPrice = f.PutPrice (strike, r);
```

Now repeat the copula simulation with the $t$ copula dependence structure. You use the same model object for both copulas; only the random number generator and option pricing functions need to be re-initialized.

```
reset(s)
z = Example_CopulaRNG(returns * sqrt(252), nPeriods, 't');
f = Example_LongstaffSchwartz(nPeriods, nTrials);
simByEuler(GBM2, nPeriods, 'nTrials' , nTrials, 'DeltaTime', dt, ...
    'Processes', f.LongstaffSchwartz, 'Z', z);
tCopulaCallPrice = f.CallPrice(strike, r);
tCopulaPutPrice = f.PutPrice (strike, r);
```

Finally, compare the American put and call option prices obtained from all models.

```
disp(' ')
fprintf(' # of Monte Carlo Trials: %8d\n' , nTrials)
fprintf(' # of Time Periods/Trial: %8d\n\n' , nPeriods)
fprintf(' Brownian Motion American Call Basket Price: %8.4f\n' , BrownianMotionCallPr:
fprintf(' Brownian Motion American Put Basket Price: %8.4f\n\n', BrownianMotionPutPri
fprintf(' Gaussian Copula American Call Basket Price: %8.4f\n', GaussianCopulaCallPr
fprintf(' Gaussian Copula American Put Basket Price: %8.4f\n\n', GaussianCopulaPutPri
fprintf(' t Copula American Call Basket Price: %8.4f\n' , tCopulaCallPrice)
fprintf(' t Copula American Put Basket Price: %8.4f\n' , tCopulaPutPrice)
```

| \# of Monte Carlo Trials: | 100 |  |
| ---: | ---: | ---: |
| \# of Time Periods/Trial: | 63 |  |
| Brownian Motion American Call Basket Price: | 25.9456 |  |
| Brownian Motion American Put | Basket Price: | 16.4132 |
| Gaussian Copula American Call Basket Price: | 24.5711 |  |
| Gaussian Copula American Put | Basket Price: | 17.4229 |
| t Copula American Call Basket Price: | 22.6220 |  |
| t Copula American Put | Basket Price: | 20.9983 |

This analysis represents only a small-scale simulation. If the simulation is repeated with 100,000 trials, the following results are obtained:

```
# of Monte Carlo Trials: 100000
# of Time Periods/Trial: 63
```

Brownian Motion American Call Basket Price: 20.2214
Brownian Motion American Put Basket Price: 16.5355
Gaussian Copula American Call Basket Price: 20.6097
Gaussian Copula American Put Basket Price: 16.5539
t Copula American Call Basket Price: 21.1273
t Copula American Put Basket Price: 16.6873
Interestingly, the results agree closely. Put option prices obtained from copulas exceed those of Brownian motion by less than $1 \%$.

## A Note on Volatility and Interest Rate Scaling

The same option prices could also be obtained by working with unannualized (in this case, daily) centered returns and riskless rates, where the time increment $d t=1$ day rather than $1 / 252$ years. In other words, portfolio prices would still be simulated every trading day; the data is simply scaled differently.

Although not executed, and by first resetting the random stream to its initial internal state, the following code segments work with daily centered returns and riskless rates and produce the same option prices.

## Gaussian Distribution/Brownian Motion \& Daily Data:

reset(s)

```
f = Example LongstaffSchwartz(nPeriods, nTrials);
GBM1 = gbm(diag}(r(ones(1,nIndices))/252), diag(std(returns)), 'StartState', X, ...
    'Correlation', correlation);
simByEuler(GBM1, nPeriods, 'nTrials', nTrials, 'DeltaTime', 1, ...
    'Processes', f.LongstaffSchwartz);
BrownianMotionCallPrice = f.CallPrice(strike, r/252)
BrownianMotionPutPrice = f.PutPrice (strike, r/252)
```

## Gaussian Copula \& Daily Data:

```
reset(s)
```

```
z = Example_CopulaRNG(returns, nPeriods, 'Gaussian');
```

$\mathrm{f}=$ Example_LongstaffSchwartz(nPeriods, nTrials);
GBM2 $=\operatorname{gbm}(\operatorname{diag}(r($ ones $(1, n I n d i c e s)) / 252)$, eye(nIndices), 'StartState', X);
simByEuler(GBM2, nPeriods, 'nTrials' , nTrials, 'DeltaTime', 1, ...
'Processes', f.LongstaffSchwartz , 'Z', z);
GaussianCopulaCallPrice $=\mathrm{f}$. CallPrice(strike, $\mathrm{r} / 252$ )
GaussianCopulaPutPrice $=$ f.PutPrice (strike, r/252)

## t Copula \& Daily Data:

```
reset(s)
```

z = Example_CopulaRNG(returns, nPeriods, 't');
f = Example_LongstaffSchwartz(nPeriods, nTrials);
simByEuler(GBM2, nPeriods, 'nTrials' , nTrials, 'DeltaTime', 1, ...
'Processes', f.LongstaffSchwartz , 'Z', z);
tCopulaCallPrice $=$ f.CallPrice(strike, r/252)
tCopulaPutPrice $=$ f.PutPrice (strike, r/252)

## Improving Performance of Monte Carlo Simulation with Parallel Computing

This example shows how to improve the performance of a Monte Carlo simulation using Parallel Computing Toolbox ${ }^{\mathrm{TM}}$.

Consider a geometric Brownian motion (GBM) process in which you want to incorporate alternative asset price dynamics. Specifically, suppose you want to include a timevarying short rate as well as a volatility surface. The process to simulate is written as

$$
d S(t)=r(t) S(t) d t+V(t, S(t)) S(t) d W(t)
$$

for stock price $S(t)$, rate of return $r(t)$, volatility $V(t, S(t))$, and Brownian motion $W(t)$. In this example, the rate of return is a deterministic function of time and the volatility is a function of both time and current stock price. Both the return and volatility are defined on a discrete grid such that intermediate values is obtained by linear interpolation. For example, such a simulation could be used to support the pricing of thinly traded options.

To include a time series of riskless short rates, suppose that you derive the following deterministic short rate process as a function of time.

```
times = [0 0.25 0.5 1 2 3 4 5 6 7 8 9 10]; % in years
rates =[[0.1 0.2 0.3 0.4 0.5 0.8 1.25 1.75 2.0 2.2 2.25 2.50 2.75]/100;
```

Suppose that you then derive the following volatility surface whose columns correspond to simple relative moneyness, or the ratio of the spot price to strike price, and whose rows correspond to time to maturity, or tenor.

```
surface = [lllllllllllllll
```

```
    21.7 17.6 13.7 11.5 9.4 7.3 7.3 5.7 5.4 5.4 5.4 5.4 5.4 5.4
    19.8 16.4 12.9 11.1 9.3 7.6 6.6 6.2 5.6 5.6 5.6 5.6 5.6 5.6
    18.6 15.6 12.5 10.8 9.3 7. 7.8 6.6.6
    17.4 13.8 11.7 10.8 9.9 9.1 
    17.1 13.7 12.0 11.2 10.6 10.0 9.5 9.1 8.8 8.6 8.4 8.0
    17.5 13.9 12.5 11.9 11.4 10.9 10.5 10.2 9.9 9.9 9.6 9.4 
    18.3 14.9 13.7 13.2 12.8 12.4 12.0 11.7 11.4 4 11.2 11.0 10.8
    19.2 19.6 14.2 13.9 13.4 13.0 13.2 12.5 12.1 11.9 11.8 11.4]/100;
tenor = [0 0.25 0.50 0.75 1 2 3 5 7 10]; % in years
```

```
moneyness = [l0.25 0.5 0.75 0.8 0.9 1 1.10 1.25 1.50 2 3 5];
```

Set the simulation parameters. The following assumes that the price of the underlying asset is initially equal to the strike price and that the price of the underlying asset is simulated monthly for 10 years, or 120 months. As a simple illustration, 100 sample paths are simulated.

```
price = 100;
strike = 100;
dt = 1/12;
nPeriods = 120;
nTrials = 100;
```

For reproducibility, set the random number generator to its default, and draw the Gaussian random variates that drive the simulation. Generating the random variates is not necessary to incur the performance improvement of parallel computation, but doing so allows the resulting simulated paths to match those of the conventional (that is, nonparallelized) simulation. Moreover, generating independent Gaussian random variates as inputs also guarantees that all simulated paths are independent.

```
rng default
Z = randn(nPeriods,1,nTrials);
```

Create the return and volatility functions and the GBM model. Notice that the rate of return is a deterministic function of time, and therefore accepts simulation time as its only input argument. In contrast, the volatility must account for the moneyness and is a function of both time and stock price. Moreover, since the volatility surface is defined as a function of time to maturity rather than simulation time, the volatility function subtracts the current simulation time from the last time at which the price process is simulated (10 years). This ensures that as the simulation time approaches its terminal value, the time to maturity of the volatility surface approaches zero. Although far more elaborate return and volatility functions could be used if desired, the following assumes simple linear interpolation.

```
mu = @(t) interp1(times,rates,t);
sigma = @(t,S) interp2(moneyness,tenor,surface,S/strike,tenor(end)-t);
mdl = gbm(mu,sigma,'StartState',price);
```

Simulate the paths of the underlying geometric Brownian motion without parallelization.

```
tStart = tic;
paths = simBySolution(mdl,nPeriods,'nTrials',nTrials,'DeltaTime',dt,'Z',Z);
time1 = toc(tStart);
```

Simulate the paths in parallel using a parfor loop. For users licensed to access the Parallel Computing Toolbox, the following code segment automatically creates a parallel pool using the default local profile. If desired, this behavior can be changed by first calling the parpool function. If a parallel pool is not already created, the following simulation will likely be slower than the previous simulation without parallelization. In this case, rerun the following simulation to assess the true benefits of parallelization.

```
tStart = tic;
parPaths = zeros(nPeriods+1,1,nTrials);
parfor i = 1:nTrials
    parPaths(:,:,i) = simBySolution(mdl,nPeriods,'DeltaTime',dt,'Z',Z(:,:,i));
end
time2 = toc(tStart);
```

If you examine any given path obtained without parallelization to the corresponding path with parallelization, you see that they are identical. Moreover, although relative performance varies, the results obtained with parallelization will generally incur a significant improvement. To assess the performance improvement, examine the runtime of each approach in seconds and speedup gained from simulating the paths in parallel.

```
time1 % elapsed time of conventional simulation, in seconds
time2 % elapsed time of parallel simulation, in seconds
speedup = time1/time2 % speedup factor
time1 =
    6.1329
time2 =
    2.5918
speedup =
    2.3663
```

## Functions - Alphabetical List

## abs2active

Convert constraints from absolute to active format

## Syntax

ActiveConSet $=$ abs2active(AbsConSet, Index)

## Description

ActiveConSet = abs2active(AbsConSet, Index) transforms a constraint matrix to an equivalent matrix expressed in active weight format (relative to the index).

## Input Arguments

#### Abstract

AbsConSet Portfolio linear inequality constraint matrix expressed in absolute weight format. AbsConSet is formatted as [A b] such that $A * W<=b$, where $A$ is a number of constraints (NCONSTRAINTS) by number of assets (NASSETS) weight coefficient matrix, and $b$ and $w$ are column vectors of length NASSETS. The value $w$ represents a vector of absolute asset weights whose elements sum to the total portfolio value. See the output ConSet from portcons for additional details about constraint matrices.

## Index

NASSETS-by-1 vector of index portfolio weights. The sum of the index weights must equal the total portfolio value (for example, a standard portfolio optimization imposes a sum-toone budget constraint).

## Output Arguments

## ActiveConSet

The transformed portfolio linear inequality constraint matrix expressed in active weight format, also of the form [A b] such that $A * W<=b$. The value $w$ represents a vector of active asset weights (relative to the index portfolio) whose elements sum to zero.

## Definitions

abs2active transforms a constraint matrix to an equivalent matrix expressed in active weight format (relative to the index). The transformation equation is

$$
A w_{\text {absolute }}=A\left(w_{\text {active }}+w_{\text {index }}\right) \leq b_{\text {absolute }} .
$$

Therefore

$$
A w_{\text {active }} \leq b_{\text {absolute }}-A w_{\text {index }}=b_{\text {active }}
$$

The initial constraint matrix consists of NCONSTRAINTS portfolio linear inequality constraints expressed in absolute weight format. The index portfolio vector contains NASSETS assets.

## Examples

Set up constraints for a portfolio optimization for portfolio w0 with constraints in the form $A * W$ <= $b$, where $w$ is absolute portfolio weights. (Absolute weights do not depend on the tracking portfolio.) Use abs2active to convert constraints in terms of absolute weights into constraints in terms of active portfolio weights, defined relative to the tracking portfolio w0. Assume three assets with the following mean and covariance of asset returns:

```
m = [ 0.14; 0.10; 0.05 ];
C = [ 0.29^2 0.4*0.29*0.17 0.1*0.29*0.08; 0.4*0.29*0.17 0.17^2 0.3*0.17*0.08; ...
0.1*0.29*0.08 0.3*0.17*0.08 0.08^2 ];
```

Absolute portfolio constraints are the typical ones (weights sum to 1 and fall from 0 through 1), create the A and b matrices using portcons:

```
AbsCons = portcons('PortValue',1,3,'AssetLims', [0; 0; 0], [1; 1; 1;]);
```

Use the Portfolio object to determine the efficient frontier:

```
p = Portfolio('AssetMean', m, 'AssetCovar', C);
p = p.setInequality(AbsCons(:,1:end-1), AbsCons(:,end));
p.plotFrontier;
```

The tracking portfolio w0 is:
wO = [ 0.1; 0.55; 0.35 ];
Use abs2active to compute the constraints for active portfolio weights:
ActCons = abs2active(AbsCons, wO)
This returns:
ActCons =

| 1.0000 | 1.0000 | 1.0000 | 0 |
| ---: | ---: | ---: | ---: |
| -1.0000 | -1.0000 | -1.0000 | 0 |
| 1.0000 | 0 | 0 | 0.9000 |
| 0 | 1.0000 | 0 | 0.4500 |
| 0 | 0 | 1.0000 | 0.6500 |

| -1.0000 | 0 | 0 | 0.1000 |
| ---: | ---: | ---: | ---: |
| 0 | -1.0000 | 0 | 0.5500 |
| 0 | 0 | -1.0000 | 0.3500 |

Use the Portfolio object $p$ and its efficient frontier to demonstrate expected returns and risk relative to the tracking portfolio wO:
$p=p . s e t I n e q u a l i t y(A c t C o n s(:, 1: e n d-1)$, ActCons(:,end));
p.plotFrontier;

## Introduced before R2006a

## accrfrac

Fraction of coupon period before settlement

## Syntax

Fraction = accrfrac(Settle, Maturity)
Fraction = accrfrac(Settle, Maturity, Period, Basis, EndMonthRule, IssueDate, FirstCouponDate, LastCouponDate, StartDate)

## Description

Fraction = accrfrac(Settle, Maturity) returns the fraction of the coupon period before settlement.

Fraction = accrfrac(Settle, Maturity, Period, Basis, EndMonthRule, IssueDate, FirstCouponDate, LastCouponDate, StartDate) returns the fraction of the coupon period before settlement with optional inputs.

Use accrfrac for computing accrued interest. accrfrac calculates accrued interest for bonds with regular or odd first or last coupon periods.

## Input Arguments

## Settle

Settlement date. A vector of serial date numbers or date strings. Settle must be earlier than Maturity.

## Maturity

Maturity date. A vector of serial date numbers or date strings.

## Period

Coupons per year of the bond. A vector of integers. Values are 0, 1, 2, 3, 4, 6, and 12.

## Default: 2

## Basis

Day-count basis of the instrument. A vector of integers.

- $0=$ actual/actual (default)
- $1=30 / 360$ (SIA)
- 2 = actual/360
- 3 = actual $/ 365$
- $4=30 / 360$ (BMA)
- $5=30 / 360$ (ISDA)
- $6=30 / 360$ (European)
- $7=$ actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- $10=$ actual/365 (ICMA)
- $11=30 / 360 \mathrm{E}$ (ICMA)
- $12=\mathrm{actual} / 365$ (ISDA)
- 13 = BUS/252

For more information, see basis.
Default: 0

## EndMonthRule

End-of-month rule. A vector. This rule applies only when Maturity is an end-of-month date for a month having 30 or fewer days. $0=$ ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month. $1=$ set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

Default: 1

## IssueDate

Issue date for a bond.

## FirstCouponDate

Date when a bond makes its first coupon payment; used when bond has an irregular first coupon period. When FirstCouponDate and LastCouponDate are both specified, FirstCouponDate takes precedence in determining the coupon payment structure.

Default: If you do not specify a FirstCouponDate, the cash flow payment dates are determined from other inputs.

## LastCouponDate

Last coupon date of a bond before the maturity date; used when bond has an irregular last coupon period. In the absence of a specified FirstCouponDate, a specified LastCouponDate determines the coupon structure of the bond. The coupon structure of a bond is truncated at the LastCouponDate, regardless of where it falls, and is followed only by the bond's maturity cash flow date.

Default: If you do not specify a LastCouponDate, the cash flow payment dates are determined from other inputs.

## StartDate

Future implementation.

## Output Arguments

## Fraction

NBONDS-by- 1 vector of accrued interest fractions.

## Examples

## Find Accrued Interest for a Bond

This example shows how to find the accrued interest for given bond data.

```
Settle = '14-Mar-1997';
Maturity = ['30-Nov-2000'
    '31-Dec-2000'
    '31-Jan-2001'];
```

```
Period = 2;
Basis = 0;
EndMonthRule = 1;
Fraction = accrfrac(Settle, Maturity, Period, Basis,...
EndMonthRule)
Fraction =
    0.5714
    0.4033
    0.2320
```

## acrubond

Accrued interest of security with periodic interest payments

## Syntax

AccruInterest = acrubond(IssueDate, Settle, FirstCouponDate, Face, CouponRate, Period, Basis)

## Arguments

| IssueDate | Enter as serial date number or date string. |
| :---: | :---: |
| Settle | Enter as serial date number or date string. |
| FirstCouponDate | Enter as serial date number or date string. |
| Face | Redemption (par, face) value. |
| CouponRate | Enter as decimal fraction. |
| Period | (Optional) Coupons per year of the bond. A vector of integers. Allowed values are 0, 1, 2 (default), 3, 4, 6, and 12. |
| Basis | (Optional) Day-count basis of the instrument. A vector of integers. <br> - $0=$ actual/actual (default) <br> - $1=30 / 360$ (SIA) <br> - 2 = actual $/ 360$ <br> - 3 = actual $/ 365$ <br> - $4=30 / 360$ (BMA) <br> - $5=30 / 360$ (ISDA) <br> - $6=30 / 360$ (European) <br> - $7=$ actual/365 (Japanese) <br> - $8=$ actual/actual (ICMA) <br> - 9 = actual/360 (ICMA) <br> - $10=$ actual/365 (ICMA) |

(ICMA)
For more information, see basis.

## Description

AccruInterest = acrubond(IssueDate, Settle, FirstCouponDate, Face, CouponRate, Period, Basis) returns the accrued interest for a security with periodic interest payments. This function computes the accrued interest for securities with standard, short, and long first coupon periods.

Note cfamounts or accrfrac is recommended when calculating accrued interest beyond the first period.

## Examples

## Find Accrued Interest of a Bond with Periodic Interest Payments

This example shows how to find the accrued interest for a bond with semiannual interest payments.

```
AccruInterest = acrubond('31-jan-1983', '1-mar-1993', ...
    '31-jul-1983', 100, 0.1, 2, 0)
```

AccruInterest =
0.8011

## acrudisc

Accrued interest of discount security paying at maturity

## Syntax

AccruInterest = acrudisc(Settle, Maturity, Face, Discount, Period, Basis)

## Arguments

| Settle | Enter as serial date number or date string. Settle must be earlier than Maturity. |
| :---: | :---: |
| Maturity | Enter as serial date number or date string. |
| Face | Redemption (par, face) value. |
| Discount | Discount rate of the security. Enter as decimal fraction. |
| Period | (Optional) Coupons per year of the bond. A vector of integers. Allowed values are 0, 1, 2 (default), 3, 4, 6, and 12. |
| Basis | (Optional) Day-count basis of the instrument. A vector of integers. <br> - $0=$ actual/actual (default) <br> - $1=30 / 360$ (SIA) <br> - 2 = actual/360 <br> - $3=$ actual/ 365 <br> - $4=30 / 360$ (BMA) <br> - $5=30 / 360$ (ISDA) <br> - $6=30 / 360$ (European) <br> - 7 = actual/365 (Japanese) <br> - $8=$ actual/actual (ICMA) <br> - 9 = actual/360 (ICMA) <br> - 10 = actual/365 (ICMA) <br> - $11=30 / 360 \mathrm{E}$ (ICMA) |

| $\bullet \quad 12=$ actual $/ 365$ (ISDA) |
| :--- | :--- |
| $\cdot \quad 13=$ BUS $/ 252$ |
| For more information, see basis. |

## Description

AccruInterest = acrudisc(Settle, Maturity, Face, Discount, Period, Basis) returns the accrued interest of a discount security paid at maturity.

## Examples

## Find Accrued Interest of a Discount Security Paid at Maturity

This example shows how to find the accrued interest of a discount security paid at maturity.

```
AccruInterest = acrudisc('05/01/1992', '07/15/1992', ...
    100, 0.1, 2, 0)
```

AccruInterest =

## active2abs

Convert constraints from active to absolute format

## Syntax

AbsConSet = active2abs(ActiveConSet, Index)

## Arguments

\(\left.$$
\begin{array}{|l|l|}\hline \text { ActiveConSet } & \begin{array}{l}\text { Portfolio linear inequality constraint matrix expressed in } \\
\text { active weight format. ActiveConSet is formatted as [A b] } \\
\text { such that } A * w<=~ b, ~ w h e r e ~ A ~ i s ~ a ~ n u m b e r ~ o f ~ c o n s t r a i n t s ~\end{array}
$$ <br>
(NCONSTRAINTS) by number of assets (NASSETS) weight <br>
coefficient matrix, and b and ware column vectors of length <br>
NASSETS. The value wrepresents a vector of active asset <br>
weights (relative to the index portfolio) whose elements sum <br>
to 0. <br>
See the output ConSet from portcons for additional details <br>

about constraint matrices.\end{array}\right\}\)| NASSETS-by-1 vector of index portfolio weights. The sum of |
| :--- |
| the index weights must equal the total portfolio value (for |
| example, a standard portfolio optimization imposes a sum-to- |
| one budget constraint). |

## Description

AbsConSet = active2abs(ActiveConSet, Index) transforms a constraint matrix to an equivalent matrix expressed in absolute weight format. The transformation equation is

$$
A w_{\text {active }}=A\left(w_{\text {absolute }}-w_{\text {index }}\right) \leq b_{\text {active }}
$$

Therefore

$$
A w_{\text {absolute }} \leq b_{\text {active }}+A w_{\text {index }}=b_{\text {absolute }}
$$

The initial constraint matrix consists of NCONSTRAINTS portfolio linear inequality constraints expressed in active weight format (relative to the index portfolio). The index portfolio vector contains NASSETS assets.

AbsConSet is the transformed portfolio linear inequality constraint matrix expressed in absolute weight format, also of the form [A b] such that $A * w<=b$. The value $w$ represents a vector of active asset weights (relative to the index portfolio) whose elements sum to the total portfolio value.

## addEquality

Add linear equality constraints for portfolio weights to existing constraints
Use the addEquality function with a Portfolio, PortfolioCVaR, or PortfolioMAD object to add linear equality constraints for portfolio weights to existing constraints.

For details on the respective workflows when using these different objects, see "Portfolio Object Workflow" on page 4-17, "PortfolioCVaR Object Workflow" on page 5-16, and "PortfolioMAD Object Workflow" on page 6-16.

## Syntax

```
obj = addEquality(obj,AEquality,bEquality)
```

## Description

obj = addEquality(obj,AEquality,bEquality) adds linear equality constraints for portfolio weights to existing constraints.

Given a linear equality constraint matrix AEquality and vector bEquality, every weight in a portfolio Port must satisfy the following:

AEquality * Port = bEquality
This function "stacks" additional linear equality constraints onto any existing linear equality constraints that exist in the input portfolio object. If no constraints exist, this method is the same as setEquality.

## Examples

## Add a Linear Equality Constraint for a Portfolio Object

Use the addEquality method to create linear equality constraints. Add another linear equality constraint to ensure that the last three assets constitute $50 \%$ of a portfolio.

```
p = Portfolio;
```

```
A = [ 1 1 1 1 0 0 ]; % First equality constraint
b = 0.5;
p = setEquality(p, A, b);
A = [ 0 0 1 1 1 1 ]; % Second equality constraint
b = 0.5;
p = addEquality(p, A, b);
disp(p.NumAssets);
disp(p.AEquality);
disp(p.bEquality);
    5
    1 1
    0
    0.5000
    0.5000
```

## Add a Linear Equality Constraint for a PorifolioCVaR Object

Use the addEquality method to create linear equality constraints. Add another linear equality constraint to ensure that the last three assets constitute $50 \%$ of a portfolio.

```
p = PortfolioCVaR;
A = [ 1 1 1 1 0 0 ]; % First equality constraint
b = 0.5;
p = setEquality(p, A, b);
A = [ 0 0 1 1 1 1 ]; % Second equality constraint
b = 0.5;
p = addEquality(p, A, b);
disp(p.NumAssets);
disp(p.AEquality);
disp(p.bEquality);
    5
    1
    0
    0.5000
```

### 0.5000

## Add a Linear Equality Constraint for a PorifolioMAD Object

Use the addEquality method to create linear equality constraints. Add another linear equality constraint to ensure that the last three assets constitute $50 \%$ of a portfolio.

```
p = PortfolioMAD;
A = [ 1 1 1 1 0 0 ]; % First equality constraint
b = 0.5;
p = setEquality(p, A, b);
A = [ 0 0 0 1 1 1 ]; % Second equality constraint
b = 0.5;
p = addEquality(p, A, b);
disp(p.NumAssets);
disp(p.AEquality);
disp(p.bEquality);
    5
    1
    0.5000
    0.5000
```

- "Portfolio Optimization Examples" on page 4-114

## Input Arguments

obj - Object for porifolio
object

Object for portfolio, specified using Portfolio, PortfolioCVaR, or PortfolioMAD object. For more information on creating a portfolio object, see

- Using Portfolio Objects
- Using PortfolioCVaR Objects
- Using PortfolioMAD Objects

## AEquality - Linear equality constraints formed from matrix matrix

Linear equality constraints, specified as a matrix.

Note: An error results if AEquality is empty and bEquality is nonempty.

## Data Types: double

## bEquality - Linear equality constraints formed from vector vector

Linear equality constraints, specified as a vector.

Note: An error results if bEquality is empty and AEquality is nonempty.

## Data Types: double

## Output Arguments

## obj - Updated porifolio object

object for portfolio
Updated portfolio object, returned as a Portfolio, PortfolioCVaR, or PortfolioMAD object. For more information on creating a portfolio object, see

- Using Portfolio Objects
- Using PortfolioCVaR Objects
- Using PortfolioMAD Objects

## More About

## Tips

- You can also use dot notation to add the linear equality constraints for portfolio weights.
obj = obj.addEquality(AEquality, bEquality)
- You can also remove linear equality constraints from a portfolio object using dot notation.
obj = obj.setEquality([ ], [ ])

## See Also <br> setEquality

Introduced in R2011a

## addGroupRatio

Add group ratio constraints for portfolio weights to existing group ratio constraints
Use the addGroupratio function with a Portfolio, PortfolioCVaR, or PortfolioMAD object to add group ratio constraints for portfolio weights to existing group ratio constraints.

For details on the respective workflows when using these different objects, see "Portfolio Object Workflow" on page 4-17, "PortfolioCVaR Object Workflow" on page 5-16, and "PortfolioMAD Object Workflow" on page 6-16.

## Syntax

```
obj = addGroupRatio(obj,GroupA,GroupB,LowerRatio)
obj = addGroupRatio(obj,GroupA,GroupB,LowerRatio,UpperRatio)
```

## Description

obj = addGroupRatio(obj,GroupA,GroupB,LowerRatio) adds group ratio constraints for portfolio weights to existing group ratio constraints.

Given base and comparison group matrices GroupA and GroupB and, either LowerRatio, or UpperRatio bounds, group ratio constraints require any portfolio in Port to satisfy the following:

```
(GroupB * Port) .* LowerRatio <= GroupA * Port <= (GroupB * Port) .* UpperRatio
```

Note: This collection of constraints usually requires that portfolio weights be nonnegative and that the products GroupA * Port and GroupB * Port are always nonnegative. Although negative portfolio weights and non-Boolean group ratio matrices are supported, use with caution.
obj = addGroupRatio(obj,GroupA,GroupB, LowerRatio,UpperRatio) adds group ratio constraints for portfolio weights to existing group ratio constraints with an additional option for UpperRatio.

Given base and comparison group matrices GroupA and GroupB and, either LowerRatio, or UpperRatio bounds, group ratio constraints require any portfolio in Port to satisfy the following:
(GroupB * Port) . * LowerRatio <= GroupA * Port <= (GroupB * Port) . * UpperRatio

Note: This collection of constraints usually requires that portfolio weights be nonnegative and that the products GroupA * Port and GroupB * Port are always nonnegative. Although negative portfolio weights and non-Boolean group ratio matrices are supported, use with caution.

## Examples

## Add Group Ratio Constraints to a Porifolio Object

Set a group ratio constraint to ensure that the weight in financial assets does not exceed $50 \%$ of the weight in nonfinancial assets. Then add another group ratio constraint to ensure that the weight in financial assets constitute at least $20 \%$ of the weight in nonfinancial assets of the portfolio.

```
p = Portfolio;
GA = [ true true true false false false ]; % financial companies
GB = [ false false false true true true ]; % nonfinancial companies
p = setGroupRatio(p, GA, GB, [], 0.5);
GA = [ true false true false true false ]; % odd-numbered companies
GB = [ false false false true true true ]; % nonfinancial companies
p = addGroupRatio(p, GA, GB, 0.2);
disp(p.NumAssets);
disp(p.GroupA);
disp(p.GroupB);
disp(p.LowerRatio);
disp(p.UpperRatio);

## Input Arguments

## obj - Object for portfolio

object
Object for portfolio, specified using Portfolio, PortfolioCVaR, or PortfolioMAD object. For more information on creating a portfolio object, see

- Using Portfolio Objects
- Using PortfolioCVaR Objects
- Using PortfolioMAD Objects

## GroupA - Base groups for comparison

matrix of logical or numerical arrays
Base groups for comparison, specified as a matrix of logical or numerical arrays.

Note: The group matrices GroupA and GroupB are usually indicators of membership in groups, which means that their elements are usually either 0 or 1 . Because of this interpretation, the GroupA and GroupB matrices can be logical or numerical arrays.

## Data Types: double

## GroupB - Comparison group

matrix of logical or numerical arrays
Comparison group, specified as a matrix of logical or numerical arrays.

Note: The group matrices GroupA and GroupB are usually indicators of membership in groups, which means that their elements are usually either 0 or 1 . Because of this interpretation, the GroupA and GroupB matrices can be logical or numerical arrays.

## Data Types: double

## LowerRatio - Lower-bound for ratio of GroupB groups to GroupA groups vector

Lower-bound for ratio of GroupB groups to GroupA groups, specified as a vector.

Note: If input is scalar, LowerRatio undergoes scalar expansion to be conformable with the group matrices.

## Data Types: double

## UpperRatio - Upper-bound for ratio of GroupB groups to GroupA groups

 vectorUpper-bound for ratio of GroupB groups to GroupA groups, specified as a vector.

Note: If input is scalar, UpperRatio undergoes scalar expansion to be conformable with the group matrices.

## Data Types: double

## Output Arguments

## obj - Updated porifolio object

object for portfolio
Updated portfolio object, returned as a Portfolio, PortfolioCVaR, or PortfolioMAD object. For more information on creating a portfolio object, see

- Using Portfolio Objects
- Using PortfolioCVaR Objects
- Using PortfolioMAD Objects

## More About

## Tips

- You can also use dot notation to add group ratio constraints for the portfolio weights to existing group ratio constraints.
obj = obj.addGroupRatio(GroupA, GroupB, LowerRatio, UpperRatio)
- To remove group ratio constraints from any of the portfolio objects using dot notation, enter empty arrays for the corresponding arrays.

## addGroups

Add group constraints for portfolio weights to existing group constraints
Use the addGroups function with a Portfolio, PortfolioCVaR, or PortfolioMAD object to add group constraints for portfolio weights to existing group constraints.

For details on the respective workflows when using these different objects, see "Portfolio Object Workflow" on page 4-17, "PortfolioCVaR Object Workflow" on page 5-16, and "PortfolioMAD Object Workflow" on page 6-16.

## Syntax

```
obj = addGroups(obj,GroupMatrix,LowerGroup)
obj = addGroups(obj,GroupMatrix,LowerGroup,UpperGroup)
```

## Description

obj = addGroups(obj, GroupMatrix, LowerGroup) adds group constraints for portfolio weights to existing group constraints.

Given GroupMatrix and either LowerGroup or UpperGroup, a portfolio Port must satisfy the following:

LowerGroup <= GroupMatrix * Port <= UpperGroup
obj = addGroups(obj,GroupMatrix,LowerGroup,UpperGroup) adds group constraints for portfolio weights to existing group constraints with an additional option for UpperGroup.

Given GroupMatrix and either LowerGroup or UpperGroup, a portfolio Port must satisfy the following:

LowerGroup <= GroupMatrix * Port <= UpperGroup

## Examples

## Add Group Constraints to a Portfolio Object

Set a group constraint to ensure that the first three assets constitute at most $30 \%$ of a portfolio. Then add another group constraint to ensure that the odd-numbered assets constitute at least $20 \%$ of a portfolio.

```
p = Portfolio;
G = [ true true true false false ]; % group matrix for first group constraint
p = setGroups(p, G, [], 0.3);
G = [ true false true false true ]; % group matrix for second group constraint
p = addGroups(p, G, 0.2);
disp(p.NumAssets);
disp(p.GroupMatrix);
disp(p.LowerGroup);
disp(p.UpperGroup);
    5
    1
    1 0
    -Inf
    0.2000
    0.3000
    Inf
```

## Add Group Constraints to a PortfolioCVaR Object

Set a group constraint to ensure that the first three assets constitute at most $30 \%$ of a portfolio. Then add another group constraint to ensure that the odd-numbered assets constitute at least $20 \%$ of a portfolio.

```
p = PortfolioCVaR;
G = [ true true true false false ]; % group matrix for first group constraint
p = setGroups(p, G, [], 0.3);
G = [ true false true false true ]; % group matrix for second group constraint
p = addGroups(p, G, 0.2);
disp(p.NumAssets);
disp(p.GroupMatrix);
disp(p.LowerGroup);
```

```
disp(p.UpperGroup);
    5
    1
    1 0
    -Inf
    0.2000
    0.3000
    Inf
```

## Add Group Constraints to a PortfolioMAD Object

Set a group constraint to ensure that the first three assets constitute at most $30 \%$ of a portfolio. Then add another group constraint to ensure that the odd-numbered assets constitute at least $20 \%$ of a portfolio.

```
p = PortfolioMAD;
G = [ true true true false false ]; % group matrix for first group constraint
p = setGroups(p, G, [], 0.3);
G = [ true false true false true ]; % group matrix for second group constraint
p = addGroups(p, G, 0.2);
disp(p.NumAssets);
disp(p.GroupMatrix);
disp(p.LowerGroup);
disp(p.UpperGroup);
    5
    1
    1 0
    -Inf
    0.2000
    0.3000
    Inf

## addInequality

Add linear inequality constraints for portfolio weights to existing constraints
Use the addInequality function with a Portfolio, PortfolioCVaR, or PortfolioMAD object to add linear inequality constraints for portfolio weights to existing constraints.

For details on the respective workflows when using these different objects, see "Portfolio Object Workflow" on page 4-17, "PortfolioCVaR Object Workflow" on page 5-16, and "PortfolioMAD Object Workflow" on page 6-16.

## Syntax

```
obj = addInequality(obj,AInequality,bInequality)
```

## Description

obj = addInequality(obj,AInequality,bInequality) adds linear inequality constraints for portfolio weights to existing constraints.

Given a linear equality constraint matrix AInequality and vector bInequality, every weight in a portfolio Port must satisfy the following:

```
AInequality * Port = bInequality
```

This function "stacks" additional linear inequality constraints onto any existing linear inequality constraints that exist in the input portfolio object. If no constraints exist, this function is the same as setInequality.

## Examples

## Add Linear Inequality Constraint to a Portfolio Object

Set a linear inequality constraint to ensure that the first three assets constitute at most $50 \%$ of a portfolio. Then add another linear inequality constraint to ensure that the last three assets constitute at least $50 \%$ of a portfolio.

```
p = Portfolio;
A = [ 1 1 1 1 0 0 ] ; % first inequality constraint
b = 0.5;
p = setInequality(p, A, b);
A = [ 0 0 -1 -1 -1 ]; % second inequality constraint
b = -0.5;
p = addInequality(p, A, b);
disp(p.NumAssets);
disp(p.AInequality);
disp(p.bInequality);
    5
    1
    0
    0.5000
    -0.5000
```

## Add Linear Inequality Constraint to a PorffolioCVaR Object

Set a linear inequality constraint to ensure that the first three assets constitute at most $50 \%$ of a portfolio. Then add another linear inequality constraint to ensure that the last three assets constitute at least $50 \%$ of a portfolio.

```
p = PortfolioCVaR;
A = [ 1 1 1 1 0 0 ]; % first inequality constraint
b = 0.5;
p = setInequality(p, A, b);
A = [ 0 0 -1 -1 -1 ]; % second inequality constraint
b = -0.5;
p = addInequality(p, A, b);
disp(p.NumAssets);
disp(p.AInequality);
disp(p.bInequality);
    5
    1 1 1 1 1 0
```

```
    0
    0.5000
-0.5000
```

## Add Linear Inequality Constraint to a PorifolioMAD Object

Set a linear inequality constraint to ensure that the first three assets constitute at most $50 \%$ of a portfolio. Then add another linear inequality constraint to ensure that the last three assets constitute at least $50 \%$ of a portfolio.

```
p = PortfolioMAD;
A = [ 1 1 1 1 0 0 ]; % first inequality constraint
b = 0.5;
p = setInequality(p, A, b);
A = [ 0 0 -1 -1 -1 ]; % second inequality constraint
b = -0.5;
p = addInequality(p, A, b);
disp(p.NumAssets);
disp(p.AInequality);
disp(p.bInequality);
    5
    1
    0
    0.5000
    -0.5000
```

## adline

Accumulation/Distribution line

## Syntax

```
adln = adline(highp, lowp, closep, tvolume)
adln = adline([highp lowp closep tvolume])
adlnts = adline(tsobj)
adlnts = adline(tsobj, 'ParameterName', ParameterValue, ...)
```

## Arguments

| highp | High price (vector) |
| :--- | :--- |
| lowp | Low price (vector) |
| closep | Closing price (vector) |
| tvolume | Volume traded (vector) |
| tsobj | Time series object |

## Description

adln = adline(highp, lowp, closep, tvolume) computes the Accumulation/ Distribution line for a set of stock price and volume traded data. The prices required for this function are the high (highp), low (lowp), and closing (closep) prices.
adln = adline([highp lowp closep tvolume]) accepts a four-column matrix as input. The first column contains the high prices, the second contains the low prices, the third contains the closing prices, and the fourth contains the volume traded.
adlnts = adline(tsobj) computes the Williams Accumulation/Distribution line for a set of stock price data contained in the financial time series object tsobj. The object
must contain the high, low, and closing prices plus the volume traded. The function assumes that the series are named High, Low, Close, and Volume. All are required. adlnts is a financial time series object with the same dates as tsobj but with a single series named ADLine.
adlnts = adline(tsobj, 'ParameterName', ParameterValue, ...) accepts parameter name/parameter value pairs as input. These pairs specify the name(s) for the required data series if it is different from the expected default name(s). Valid parameter names are

- HighName: high prices series name
- LowName: low prices series name
- CloseName: closing prices series name
- VolumeName: volume traded series name

Parameter values are the strings that represent the valid parameter names.

## Examples

## Calculate the Accumulation/Distribution Line for a Stock

This example shows how to compute the Accumulation/Distribution line for Disney stock and plot the results.
load disney.mat
dis_ADLine = adline(dis);
plot(dis_ADLine)
title('Açcumulation/Distribution Line for Disney')

## adosc

Accumulation/Distribution oscillator

## Syntax

```
ado = adosc(highp, lowp, openp, closep)
ado = adosc([highp lowp openp closep])
adots = adosc(tsobj)
adots = adosc(tsojb, 'ParameterName', ParameterValue, ...)
```

## Arguments

| highp | High price (vector) |
| :--- | :--- |
| lowp | Low price (vector) |
| openp | Opening price (vector) |
| closep | Closing price (vector) |
| tsobj | Time series object |

## Description

ado $=$ adosc(highp, lowp, openp, closep) returns a vector, ado, that represents the Accumulation/Distribution (A/D) oscillator. The A/D oscillator is calculated based on the high, low, opening, and closing prices of each period. Each period is treated individually.
ado $=$ adosc([highp lowp openp closep]) accepts a four-column matrix as input. The order of the columns must be high, low, opening, and closing prices.
adots $=$ adosc(tsobj) calculates the Accumulation/Distribution (A/D) oscillator, adots, for the set of stock price data contained in the financial time series object tsobj.

The object must contain the high, low, opening, and closing prices. The function assumes that the series are named High, Low, Open, and Close. All are required. adots is a financial time series object with similar dates to tsobj and only one series named ADOsc.
adots $=$ adosc(tsobj, 'ParameterName', ParameterValue, ...) accepts parameter name-parameter value pairs as input. These pairs specify the name(s) for the required data series if it is different from the expected default name(s). Valid parameter names are

- HighName: high prices series name
- LowName: low prices series name
- OpenName: opening prices series name
- CloseName: closing prices series name

Parameter values are the strings that represent the valid parameter names.

## Examples

## Calculate the Accumulation/Distribution Oscillator for a Stock

This example shows how to find the Accumulation/Distribution oscillator for Disney stock and plot the results.

```
load disney.mat
dis_ADOsc = adosc(dis);
plot(dis_ADOsc)
title('A/D Oscillator for Disney')
```

## amortize

Amortization schedule

## Syntax

[Principal, Interest, Balance, Payment] = amortize(Rate, NumPeriods, PresentValue, FutureValue, Due)

## Arguments

| Rate | Interest rate per period, as a decimal fraction. |
| :--- | :--- |
| NumPeriods | Number of payment periods. |
| PresentValue | Present value of the loan. |
| FutureValue | (Optional) Future value of the loan. Default $=0$. |
| Due | (Optional) When payments are due: $0=$ end of period <br> (default), or $1=$ beginning of period. |

## Description

[Principal, Interest, Balance, Payment] = amortize(Rate, NumPeriods, PresentValue, FutureValue, Due) returns the principal and interest payments of a loan, the remaining balance of the original loan amount, and the periodic payment.

| Principal | Principal paid in each period. A 1-by-NumPeriods vector. |
| :--- | :--- |
| Interest | Interest paid in each period. A 1-by-NumPeriods vector. |
| Balance | Remaining balance of the loan in each payment period. A 1- <br> by-NumPeriods vector. |
| Payment | Payment per period. A scalar. |

## Examples

## Compute an Amortization Schedule for a Conventional 30-Year, Fixed-Rate Mortgage With Fixed Monthly Payments

Compute an amortization schedule for a conventional 30-year, fixed-rate mortgage with fixed monthly payments and assume a fixed rate of $12 \%$ APR and an initial loan amount of $\$ 100,000$.

```
Rate = 0.12/12; % 12 percent APR = 1 percent per month
NumPeriods = 30*12; % 30 years = 360 months
PresentValue = 100000;
[Principal, Interest, Balance, Payment] = amortize(Rate, ...
NumPeriods, PresentValue);
```

The output argument Payment contains the fixed monthly payment.

```
format bank
```

Payment

```
Payment =
```

1028.61

Summarize the amortization schedule graphically by plotting the current outstanding loan balance, the cumulative principal, and the interest payments over the life of the mortgage. In particular, note that total interest paid over the life of the mortgage exceeds $\$ 270,000$, far in excess of the original loan amount.

```
plot(Balance,'b'), hold('on')
plot(cumsum(Principal),'--k')
plot(cumsum(Interest),':r')
xlabel('Payment Month')
ylabel('Dollars')
grid('on')
title('Outstanding Balance, Cumulative Principal & Interest')
legend('Outstanding Balance', 'Cumulative Principal', ...
'Cumulative Interest')
```

The solid blue line represents the declining principal over the 30 -year period. The dotted red line indicates the increasing cumulative interest payments. Finally, the dashed black line represents the cumulative principal payments, reaching $\$ 100,000$ after 30 years.

- "Analyzing and Computing Cash Flows" on page 2-17

## See Also

annurate | annuterm | payadv | payodd | payper

Introduced before R2006a

## annurate

Periodic interest rate of annuity

## Syntax

Rate = annurate(NumPeriods, Payment, PresentValue, FutureValue, Due)

## Arguments

| NumPeriods | Number of payment periods. |
| :--- | :--- |
| Payment | Payment per period. |
| PresentValue | Present value of the loan or annuity. |
| FutureValue | (Optional) Future value of the loan or annuity. Default $=0$. |
| Due | (Optional) When payments are due: $0=$ end of period <br> (default), or $1=$ beginning of period. |

## Description

Rate = annurate(NumPeriods, Payment, PresentValue, FutureValue, Due) returns the periodic interest rate paid on a loan or annuity.

## Examples

## Calculate the Periodic Interest Rate Paid on a Loan or Annuity

This example shows how to find the periodic interest rate of a four-year, $\$ 5000$ loan with a $\$ 130$ monthly payment made at the end of each month.

```
Rate = annurate(4*12, 130, 5000, 0, 0)
```

Rate =

### 0.0094

Rate multiplied by 12 gives an annual interest rate of $11.32 \%$ on the loan.

- "Analyzing and Computing Cash Flows" on page 2-17

## See Also

amortize | annuterm | bndyield | irr

Introduced before R2006a

## annuterm

Number of periods to obtain value

## Syntax

NumPeriods = annuterm(Rate, Payment, PresentValue, FutureValue, Due)

## Arguments

| Rate | Interest rate per period, as a decimal fraction. |
| :--- | :--- |
| Payment | Payment per period. |
| PresentValue | Present value. |
| FutureValue | (Optional) Future value. Default $=0$. |
| Due | (Optional) When payments are due: $0=$ end of period <br> (default), or $1=$ beginning of period. |

## Description

NumPeriods = annuterm(Rate, Payment, PresentValue, FutureValue, Due) calculates the number of periods needed to obtain a future value. To calculate the number of periods needed to pay off a loan, enter the payment or the present value as a negative value.

## Examples

## Calculate the Number of Periods Needed to Obtain a Future Value

This example shows a savings account with a starting balance of $\$ 1500 . \$ 200$ is added at the end of each month and the account pays $9 \%$ interest, compounded monthly. How many years will it take to save $\$ 5,000$ ?

NumPeriods $=$ annuterm(0.09/12, 200, 1500, 5000, 0)

NumPeriods =
15.6752

- "Analyzing and Computing Cash Flows" on page 2-17

See Also<br>amortize | annurate | fvfix | pvfix<br>Introduced before R2006a

## arith2geom

Arithmetic to geometric moments of asset returns

## Syntax

[mg, Cg] = arith2geom(ma, Ca)
[mg, Cg] = arith2geom(ma, Ca, t)

## Arguments

| ma | Arithmetic mean of asset-return data (n-vector). |
| :--- | :--- |
| Ca | Arithmetic covariance of asset-return data, an n -by-n symmetric, <br> positive-semidefinite matrix. |
| t | (Optional) Target period of geometric moments in terms of <br> periodicity of arithmetic moments with default value 1 (scalar). |

## Description

arith2geom transforms moments associated with a simple Brownian motion into equivalent continuously compounded moments associated with a geometric Brownian motion with a possible change in periodicity.
[mg, Cg] = arith2geom(ma, Ca, t) returns mg, continuously compounded or "geometric" mean of asset returns over the target period (n-vector), and Cg, which is a continuously compounded or "geometric" covariance of asset returns over the target period ( $n$-by-n matrix).

Arithmetic returns over period $t_{A}$ are modeled as multivariate normal random variables with moments

$$
E[\mathrm{X}]=\mathrm{m}_{A}
$$

and

$$
\operatorname{cov}(\mathrm{X})=\mathrm{C}_{A}
$$

Geometric returns over period $t_{G}$ are modeled as multivariate lognormal random variables with moments

$$
\begin{aligned}
& E[\mathrm{Y}]=1+\mathrm{m}_{G} \\
& \operatorname{cov}(\mathrm{Y})=\mathrm{C}_{G}
\end{aligned}
$$

Given $t=t_{G} / t_{A}$, the transformation from geometric to arithmetic moments is

$$
\begin{aligned}
& 1+\mathrm{m}_{G_{i}}=\exp \left(t \mathrm{~m}_{A_{i}}+\frac{1}{2} t \mathrm{C}_{A_{i i}}\right) \\
& \mathrm{C}_{G_{i j}}=\left(1+\mathrm{m}_{G_{i}}\right)\left(1+\mathrm{m}_{G_{\mathrm{j}}}\right)\left(\exp \left(t \mathrm{C}_{A i j}\right)-1\right)
\end{aligned}
$$

For $i, j=1, \ldots, n$.

Note: If $t=1$, then $\mathbf{Y}=\exp (\mathbf{X})$.

This function has no restriction on the input mean ma but requires the input covariance Ca to be a symmetric positive-semidefinite matrix.

The functions arith2geom and geom2arith are complementary so that, given m, C, and $t$, the sequence

```
[mg, Cg] = arith2geom(m, C, t);
[ma, Ca] = geom2arith(mg, Cg, 1/t);
yields ma =m and Ca=C.
```

## Examples

Example 1. Given arithmetic mean $m$ and covariance C of monthly total returns, obtain annual geometric mean mg and covariance Cg . In this case, the output period (1 year) is 12 times the input period ( 1 month) so that $t=12$ with

```
[mg, Cg] = arith2geom(m, C, 12);
```

Example 2. Given annual arithmetic mean $m$ and covariance $C$ of asset returns, obtain monthly geometric mean mg and covariance Cg . In this case, the output period (1 month) is $1 / 12$ times the input period ( 1 year) so that $\mathrm{t}=1 / 12$ with

```
[mg, Cg] = arith2geom(m, C, 1/12);
```

Example 3. Given arithmetic means m and standard deviations S of daily total returns (derived from 260 business days per year), obtain annualized continuously compounded mean mg and standard deviations sg with

```
[mg, Cg] = arith2geom(m, diag(s .^2), 260);
```

sg $=\operatorname{sqrt}(\operatorname{diag}(\mathrm{Cg}))$;

Example 4. Given arithmetic mean $m$ and covariance $C$ of monthly total returns, obtain quarterly continuously compounded return moments. In this case, the output is 3 of the input periods so that $t=3$ with

```
[mg, Cg] = arith2geom(m, C, 3);
```

Example 5. Given arithmetic mean m and covariance C of 1254 observations of daily total returns over a 5 -year period, obtain annualized continuously compounded return moments. Since the periodicity of the arithmetic data is based on 1254 observations for a 5 -year period, a 1-year period for geometric returns implies a target period of $\mathrm{t}=$ $1254 / 5$ so that
[mg, Cg] = arith2geom(m, C, 1254/5);

## ascii2fts

Create financial time series object from ASCII file

## Syntax

```
tsobj = ascii2fts(filename, descrow, colheadrow, skiprows)
```

tsobj = ascii2fts(filename, timedata, descrow, colheadrow,
skiprows)

## Arguments

| filename | ASCII data file |
| :--- | :--- |
| descrow | (Optional) Row number in the data file that contains the <br> description to be used for the description field of the financial time <br> series object |
| colheadrow | (Optional) Row number that has the column headers/names |
| skiprows | (Optional) Scalar or vector of row numbers to be skipped in the data <br> file |
| timedata | Set to ' $T^{\prime}$ ' if time-of-day data is present in the ASCII data file or to <br> 'NT' if no time-of-day data is present. |

## Description

tsobj = ascii2fts(filename, descrow, colheadrow, skiprows) creates a financial time series object tsobj from the ASCII file named filename. This form of the function can only read a data file without time-of-day information and create a financial time series object without time information. If time information is present in the ASCII file, an error message appears.

The general format of the text data file is

- Can contain header text lines.
- Can contain column header information. The column header information must immediately precede the data series columns unless skiprows is specified.
- Leftmost column must be the date column.
- Dates must be in a valid date string format:
- 'ddmmmyy' or 'ddmmmyyyy'
- 'mm/dd/yy' or 'mm/dd/yyyy'
- 'dd-mmm-yy' or 'dd-mmm-yyyy'
- 'mmm.dd,yy' or 'mmm.dd,yyyy'
- Time information must be in 'hh:mm' format.
- Each column must be separated either by spaces or a tab.
tsobj = ascii2fts(filename, timedata, descrow, colheadrow, skiprows) creates a financial time series object containing time-of-day data. Set timedata to ' $T$ ' to create a financial time series object containing time-of-day data. The ascii time information must be in 'hh: mm' format for ascii2fts.

## Examples

Example 1. If your data file contains no description or column header rows,

| $1 / 3 / 95$ | 36.75 | 36.9063 | 36.6563 | 36.875 | 1167900 |  |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| $1 / 4 / 95$ | 37 | 37.2813 | 36.625 | 37.1563 | 1994700 | $\ldots$ |

you can create a financial time series object from it with the simplest form of the ascii2fts function:

```
myinc = ascii2fts('my_inc.dat');
myinc =
desc: my_inc.dat
freq: Unknown (0)
'dates: (2)' 'series1: (2)' 'series2: (2)' 'series3: (2)'...
'03-Jan-1995' [ 36.7500] [ 36.9063] [ 36.6563]
'04-Jan-1995' [ 37] [ 37.2813] [ 36.6250]
```

Example 2: If your data file contains description and column header information with the data series immediately following the column header row,

```
International Business Machines Corporation (IBM)
Daily prices (1/3/95 to 4/5/99)
DATE OPEN HIGH LOW CLOSE VOLUME
1/3/95 36.75 36.9063 36.6563 36.875 1167900
1/4/95 37 37.2813 36.625 37.1563 1994700 ...
```

you must specify the row numbers containing the description and column headers:

```
ibm = ascii2fts('ibm9599.dat', 1, 3);
ibm =
desc: International Business Machines Corporation (IBM)
freq: Unknown (0)
'dates: (2)' 'OPEN: (2)' 'HIGH: (2)' 'LOW: (2)' ...
```

Example 3: If your data file contains rows between the column headers and the data series, for example,

```
Staples, Inc. (SPLS)
Daily prices
DATE OPEN HIGH LOW CLOSE VOLUME
Starting date: 04/08/1996
Ending date: 04/07/1999
4/8/96 19.50 19.75 19.25 19.375 548500
4/9/96 19.75 20.125 19.375 20 1135900 ...
```

you need to indicate to ascii2fts the rows in the file that must be skipped. Assume that you have called the data file containing the Staples data above staples.dat. The command

```
spls = ascii2fts('staples.dat', 1, 3, [4 5]);
```

indicates that the fourth and fifth rows in the file should be skipped in creating the financial time series object:

```
spls =
desc: Staples, Inc. (SPLS)
freq: Unknown (0)
\begin{tabular}{|c|c|c|c|}
\hline dates: (2)' & 'OPEN: (2) \({ }^{\prime}\) & 'HIGH: (2)' & 'LOW: (2) \\
\hline '08-Apr-1996' & \(19.5000]\) & [ 19.7500] & [19.2500] \\
\hline
\end{tabular}
```

```
'09-Apr-1996' [ 19.7500] [ 20.1250] [19.3750]
```

Example 4: Create a financial time series object containing time-of-day information.
First create a data file with time information:

```
dates = ['01-Jan-2001';'01-Jan-2001'; '02-Jan-2001'; ...
'02-Jan-2001'; '03-Jan-2001';'03-Jan-2001'];
times = ['11:00';'12:00';'11:00';'12:00';'11:00';'12:00'];
serial_dates_times = [datenum(dates), datenum(times)];
data ='round(10*rand (6,2));
stat = fts2ascii('myfts_file2.txt',serial_dates_times,data, ...
{'dates';'times';'Data1';'Data2'},'My FTS with Time');
```

Now read the data file back and create a financial time series object:

```
MyFts = ascii2fts('myfts_file2.txt','t',1,2,1)
MyFts =
    desc: My FTS with Time
    freq: Unknown (0)
\begin{tabular}{|c|c|c|c|c|c|}
\hline dates: (6)' & 'times: & (6) \({ }^{\prime}\) & 'Data1: (6)' & 'Data2: & (6) \\
\hline 01-Jan-2001' & '11:00' & & \(9]\) & [ & 4] \\
\hline & '12:00' & & [ 7] & [ & 9] \\
\hline '02-Jan-2001' & '11:00' & & [ 2] & [ & 1] \\
\hline " ' & '12:00' & & [ 4] & [ & 4] \\
\hline '03-Jan-2001' & '11:00' & & [ 9] & [ & 8] \\
\hline & '12:00' & & [ 9] & [ & 0] \\
\hline
\end{tabular}
```

## bar, barh

Bar chart

## Syntax

```
bar(tsobj)
bar(tsobj, width)
bar(..., 'style')
hbar = bar(...)
barh(...)
hbarh = barh(...)
```

## Arguments

| tsobj | Financial time series object. |
| :--- | :--- |
| width | Width of the bars and separation of bars within a group. (Default <br> = 0.8.) If width is 1, the bars within a group touch one another. <br> Values > 1 produce overlapping bars. |
| style | 'grouped ' (default) or 'stacked '. |

## Description

bar, barh draw vertical and horizontal bar charts.
bar(tsobj) draws the columns of data series of the object tsobj. The number of data series dictates the number of vertical bars per group. Each group is the data for one particular date.
bar(tsobj, width) specifies the width of the bars.
$\operatorname{bar}(. . .$, 'style') changes the style of the bar chart.
hbar $=\operatorname{bar}(. .$.$) returns a vector of bar handles.$
Use the MATLAB command shading faceted to put edges on the bars. Use shading flat to turn edges off.

## Examples

## Create a Bar Chart for a Stock

This example shows how to create a bar chart for Disney stock showing high, low, opening, and closing prices.
load disney
bar(q_dis)
title('Bar Chart of Disney Prices')

Bar Chart of Disney Prices

## Create a Horizontal Bar Chart for a Stock

This example shows how to create a horizontal bar chart for Disney stock showing high, low, opening, and closing prices.

```
load disney
barh(q_dis)
title('Horizontal Bar Chart of Disney Prices')
```

## Syntax

```
bar3(tsobj)
bar3(tsobj, width)
bar3(..., 'style')
hbar3 = bar3(...)
bar3h(...)
hbar3h = bar3h(...)
```

## Arguments

| tsobj | Financial time series object. |
| :--- | :--- |
| width | Width of the bars and separation of bars within a group. (Default <br> = 0.8.) If width is 1, the bars within a group touch one another. <br> Values > 1 produce overlapping bars. |
| style | 'detached ' (default), 'grouped ', or 'stacked '. |

## Description

bar3, bar3h draw three-dimensional vertical and horizontal bar charts.
bar3(tsobj) draws the columns of data series of the object tsobj. The number of data series dictates the number of vertical bars per group. Each group is the data for one particular date.
bar3(tsobj, width) specifies the width of the bars.
bar3(..., 'style') changes the style of the bar chart.
hbar3 $=\operatorname{bar} 3(. .$.$) returns a vector of bar handles.$
Use the MATLAB command shading faceted to put edges on the bars. Use shading flat to turn edges off.

## Examples

## Create a Three-Dimensional Bar Chart

This example shows how to create a three-dimensional bar chart for Disney stock showing high, low, opening, and closing prices.
load disney
bar3(q_dis, 'stacked')
title('Three-Dimensional Bar Chart of Disney Prices')

## Create a Three-Dimensional (Stacked) Bar Chart

This example shows how to create a three-dimensional, stacked bar chart for Disney stock showing high, low, opening, and closing prices.

```
load disney
bar3(q_dis, 'stacked')
title('Three-Dimensional Bar Chart of Disney Prices (Stacked)')
```

Three-Dimensional Bar Chart of Disney Prices (Stacked)

## beytbill

Bond equivalent yield for Treasury bill

## Syntax

```
Yield = beytbill(Settle, Maturity, Discount)
```

## Arguments

| Settle | Enter as serial date numbers or date strings. Settle must be <br> earlier than Maturity. |
| :--- | :--- |
| Maturity | Enter as serial date numbers or date strings. |
| Discount | Discount rate of the Treasury bill. Enter as decimal fraction. |

## Description

Yield = beytbill(Settle, Maturity, Discount) returns the bond equivalent yield for a Treasury bill.

## Examples

## Find the Bond Equivalent Yield for a Treasury Bill

This example shows how to find the bond equivalent yield for a Treasury bill that has a settlement date of February 11, 2000, a maturity date of August 7, 2000, and a discount rate is 5.77.

Yield = beytbill('2/11/2000', '8/7/2000', 0.0577)

Yield =
0.0602

## binprice

Binomial put and call pricing

## Syntax

[AssetPrice, OptionValue] = binprice(Price, Strike, Rate, Time, Increment, Volatility, Flag, DividendRate, Dividend, ExDiv)

## Arguments

| Price | Underlying asset price. A scalar. |
| :--- | :--- |
| Strike | Option exercise price. A scalar. |
| Rate | Risk-free interest rate. A scalar. Enter as a decimal fraction. |
| Time | Option time until maturity in years. A scalar. |
| Increment | Time increment. A scalar. Increment is adjusted so that the <br> length of each interval is consistent with the maturity time of <br> the option. (Increment is adjusted so that Time divided by <br> Increment equals an integer number of increments.) |
| Volatility | Asset volatility. A scalar. |
| Flag | Specifies whether the option is a call (Flag = 1) or a put <br> (Flag = 0). A scalar. |
| DividendRate | (Optional) The dividend rate, as a decimal fraction. A scalar. <br> Default = 0. If you enter a value for DividendRate, set <br> Dividend and ExDiv = 0 or do not enter them. If you enter <br> values for Dividend and ExDiv, set DividendRate = 0. |
| Dividend | (Optional) The dividend payment at an ex-dividend date, <br> ExDiv. A row vector. For each dividend payment, there must <br> be a corresponding ex-dividend date. Default = 0. If you enter <br> values for Dividend and ExDiv, set DividendRate = 0. |
| ExDiv | (Optional) Ex-dividend date, specified in number of periods. <br> A row vector. Default = 0. |

## Description

[AssetPrice, OptionValue] = binprice(Price, Strike, Rate, Time, Increment, Volatility, Flag, DividendRate, Dividend, ExDiv) prices an American option using the Cox-Ross-Rubinstein binomial pricing model.

## Examples

## Price an American Option Using the Cox-Ross-Rubinstein Binomial Pricing Model

This example shows how to price an American put option with an exercise price of $\$ 50$ that matures in 5 months. The current asset price is $\$ 52$, the risk-free interest rate is $10 \%$, and the volatility is $40 \%$. There is one dividend payment of $\$ 2.06$ in $3-1 / 2$ months. When specifying the input argument ExDiv in terms of number of periods, divide the exdividend date, specified in years, by the time Increment.

```
ExDiv = (3.5/12) / (1/12) = 3.5
[Price, Option] = binprice(52, 50, 0.1, 5/12, 1/12, 0.4, 0, 0, 2.06, 3.5)
Price =
\begin{tabular}{rrrrrr}
52.0000 & 58.1367 & 65.0226 & 72.7494 & 79.3515 & 89.0642 \\
0 & 46.5642 & 52.0336 & 58.1706 & 62.9882 & 70.6980 \\
0 & 0 & 41.7231 & 46.5981 & 49.9992 & 56.1192 \\
0 & 0 & 0 & 37.4120 & 39.6887 & 44.5467 \\
0 & 0 & 0 & 0 & 31.5044 & 35.3606 \\
0 & 0 & 0 & 0 & 0 & 28.0688
\end{tabular}
```

## Option =

```
\begin{tabular}{rrrrrr}
4.4404 & 2.1627 & 0.6361 & 0 & 0 & 0 \\
0 & 6.8611 & 3.7715 & 1.3018 & 0 & 0 \\
0 & 0 & 10.1591 & 6.3785 & 2.6645 & 0 \\
0 & 0 & 0 & 14.2245 & 10.3113 & 5.4533 \\
0 & 0 & 0 & 0 & 18.4956 & 14.6394 \\
0 & 0 & 0 & 0 & 0 & 21.9312
\end{tabular}
```

The output returned is the asset price and American option value at each node of the binary tree.

blkprice | blsprice

## Introduced before R2006a

## blkimpv

Implied volatility for futures options from Black model

## Syntax

Volatility = blkimpv(Price, Strike, Rate, Time, Value, Limit, Tolerance, Class)

## Arguments

| Price | Current price of the underlying asset (a futures contract). |
| :--- | :--- |
| Strike | Exercise price of the futures option. |
| Rate | Annualized, continuously compounded risk-free rate of return over <br> the life of the option, expressed as a positive decimal number. |
| Time | Time to expiration of the option, expressed in years. |
| Value | Price of a European futures option from which the implied volatility <br> of the underlying asset is derived. |
| Limit | (Optional) Positive scalar representing the upper bound of the <br> implied volatility search interval. If Limit is empty or unspecified, <br> the default = 10, or 1000\% per annum. |
| Tolerance | (Optional) Implied volatility termination tolerance. A positive <br> scalar. Default = 1e-6. |
| Class | (Optional) Option class (call or put) indicating the option type from <br> which the implied volatility is derived.Class may be a logical <br> indicator or a cell array of characters. To specify call options, set <br> Class = true or Class = \{ call ' \}; to specify put options, <br> set Class = false or Class = \{ ' put ' \}. If Class is empty or <br> unspecified, the default is a call option. |

## Description

Volatility = blkimpv(Price, Strike, Rate, Time, CallPrice, MaxIterations, Tolerance) computes the implied volatility of a futures price from the market value of European futures options using Black's model.

Volatility is the implied volatility of the underlying asset derived from European futures option prices, expressed as a decimal number. If no solution is found, blkimpv returns NaN .

Any input argument can be a scalar, vector, or matrix. When a value is a scalar, that value is used to compute the implied volatility of all the options. If more than one input is a vector or matrix, the dimensions of all nonscalar inputs must be identical.

Rate and Time must be expressed in consistent units of time.

## Examples

## Find Implied Volatility for Futures Options from Black's Model

This example shows how to find the implied volatility for a European call futures option that expires in four months, trades at $\$ 1.1166$, and has an exercise price of $\$ 20$. Assume that the current underlying futures price is also $\$ 20$ and that the risk-free rate is $9 \%$ per annum. Furthermore, assume that you are interested in implied volatilities no greater than 0.5 ( $50 \%$ per annum). Under these conditions, the following commands all return an implied volatility of 0.25 , or $25 \%$ per annum.

```
Volatility = blkimpv(20, 20, 0.09, 4/12, 1.1166, 0.5);
Volatility = blkimpv(20, 20, 0.09, 4/12, 1.1166, 0.5, [], {'Call'});
Volatility = blkimpv(20, 20, 0.09, 4/12, 1.1166, 0.5, [], true)
Volatility =
    0.2500
```

## blkprice

Black model for pricing futures options

## Syntax

[Call, Put] = blkprice(Price, Strike, Rate, Time, Volatility)

## Arguments

| Price | Current price of the underlying asset (a futures contract). |
| :--- | :--- |
| Strike | Strike or exercise price of the futures option. |
| Rate | Annualized, continuously compounded, risk-free rate of return over <br> the life of the option, expressed as a positive decimal number. |
| Time | Time until expiration of the option, expressed in years. Must be <br> greater than 0. |
| Volatility | Annualized futures price volatility, expressed as a positive decimal <br> number. |

## Description

[Call, Put] = blkprice(ForwardPrice, Strike, Rate, Time, Volatility) uses Black's model to compute European put and call futures option prices.

Any input argument can be a scalar, vector, or matrix. When a value is a scalar, that value is used to compute the implied volatility from all options. If more than one input is a vector or matrix, the dimensions of all non-scalar inputs must be identical.

Rate, Time, and Volatility must be expressed in consistent units of time.

## Examples

## Compute European Put and Call Futures Option Prices Using Black's Model

This example shows how to price European futures options with exercise prices of $\$ 20$ that expire in four months. Assume that the current underlying futures price is also $\$ 20$ with a volatility of $25 \%$ per annum. The risk-free rate is $9 \%$ per annum.

```
[Call, Put] = blkprice(20, 20, 0.09, 4/12, 0.25)
```

Call $=$
1.1166

Put =
1.1166

## blsdelta

Black-Scholes sensitivity to underlying price change

## Syntax

[CallDelta, PutDelta] = blsdelta(Price, Strike, Rate, Time, Volatility, Yield)

## Arguments

| Price | Current price of the underlying asset. |
| :--- | :--- |
| Strike | Exercise price of the option. |
| Rate | Annualized, continuously compounded risk-free rate of return over <br> the life of the option, expressed as a positive decimal number. |
| Time | Time to expiration of the option, expressed in years. |
| Volatility | Annualized asset price volatility (annualized standard deviation of <br> the continuously compounded asset return), expressed as a positive <br> decimal number. |
| Yield | (Optional) Annualized, continuously compounded yield of the <br> underlying asset over the life of the option, expressed as a decimal <br> number. (Default = 0.) For example, for options written on stock <br> indices, Yield could represent the dividend yield. For currency <br> options, Yield could be the foreign risk-free interest rate. |

## Description

[CallDelta, PutDelta] = blsdelta(Price, Strike, Rate, Time, Volatility, Yield) returns delta, the sensitivity in option value to change in the underlying asset price. Delta is also known as the hedge ratio. blsdelta uses normcdf, the normal cumulative distribution function in the Statistics and Machine Learning Toolbox.

Note: blsdelta can handle other types of underlies like Futures and Currencies. When pricing Futures (Black model), enter the input argument Yield as:

```
Yield = Rate
```

When pricing currencies (Garman-Kohlhagen model), enter the input argument Yield as:

Yield = ForeignRate
where ForeignRate is the continuously compounded, annualized risk free interest rate in the foreign country.

## Examples

## Find the Sensitivity in Option Value to Change in the Underlying Asset Price

This example shows how to find the Black-Scholes delta sensitivity for an underlying asset price change.
[CallDelta, PutDelta] = blsdelta(50, 50, 0.1, 0.25, 0.3, 0)

## CallDelta =

0.5955

## PutDelta =

$-0.4045$

## blsgamma

Black-Scholes sensitivity to underlying delta change

## Syntax

Gamma = blsgamma(Price, Strike, Rate, Time, Volatility, Yield)

## Arguments

| Price | Current price of the underlying asset. |
| :--- | :--- |
| Strike | Exercise price of the option. |
| Rate | Annualized, continuously compounded risk-free rate of return over <br> the life of the option, expressed as a positive decimal number. |
| Time | Time to expiration of the option, expressed in years. |
| Volatility | Annualized asset price volatility (annualized standard deviation of <br> the continuously compounded asset return), expressed as a positive <br> decimal number. |
| Yield | (Optional) Annualized, continuously compounded yield of the <br> underlying asset over the life of the option, expressed as a decimal <br> number. (Default = 0.) For example, for options written on stock <br> indices, Yield could represent the dividend yield. For currency <br> options, Yield could be the foreign risk-free interest rate. |

## Description

Gamma = blsgamma(Price, Strike, Rate, Time, Volatility, Yield) returns gamma, the sensitivity of delta to change in the underlying asset price. blsgamma uses normpdf, the probability density function in the Statistics and Machine Learning Toolbox.

Note: blsgamma can handle other types of underlies like Futures and Currencies. When pricing Futures (Black model), enter the input argument Yield as:

Yield = Rate
When pricing currencies (Garman-Kohlhagen model), enter the input argument Yield as:

Yield = ForeignRate
where ForeignRate is the continuously compounded, annualized risk free interest rate in the foreign country.

## Examples

## Find Gamma for a Change in the Underlying Asset Price

This example shows how to find the gamma, the sensitivity of delta to a change in the underlying asset price.

```
Gamma = blsgamma(50, 50, 0.12, 0.25, 0.3, 0)
```

Gamma =

$$

## blsimpv

Black-Scholes implied volatility

## Syntax

Volatility = blsimpv(Price, Strike, Rate, Time, Value, Limit, Yield, Tolerance, Class)

## Arguments

| Price | Current price of the underlying asset. |
| :--- | :--- |
| Strike | Exercise price of the option. |
| Rate | Annualized, continuously compounded risk-free rate of return over <br> the life of the option, expressed as a positive decimal number. |
| Time | Time to expiration of the option, expressed in years. |
| Value | Price of a European option from which the implied volatility of the <br> underlying asset is derived. |
| Limit | (Optional) Positive scalar representing the upper bound of the <br> implied volatility search interval. If Limit is empty or unspecified, <br> the default = 10, or 1000\% per annum. |
| Yield | (Optional) Annualized, continuously compounded yield of the <br> underlying asset over the life of the option, expressed as a decimal <br> number. (Default = 0.) For example, for options written on stock <br> indices, Yield could represent the dividend yield. For currency <br> options, Yield could be the foreign risk-free interest rate. |
| Tolerance | (Optional) Implied volatility termination tolerance. A positive <br> scalar. Default = 1e-6. |
| Class | (Optional) Option class (call or put) indicating the option type <br> from which the implied volatility is derived. Class can be a logical <br> indicator or a cell array of characters. To specify call options, set <br> Class = true or Class = \{ call ' \}; to specify put options, <br> set Class = false or Class = \{ ' put ' $\}$. If Class is empty or <br> unspecified, the default is a call option. |

## Description

Volatility = blsimpv(Price, Strike, Rate, Time, Value, Limit, Yield, Tolerance, Class) using a Black-Scholes model computes the implied volatility of an underlying asset from the market value of European call and put options.

Volatility is the implied volatility of the underlying asset derived from European option prices, expressed as a decimal number. If no solution is found, blsimpv returns NaN .

Any input argument can be a scalar, vector, or matrix. When a value is a scalar, that value is used to price all the options. If more than one input is a vector or matrix, the dimensions of all non-scalar inputs must be identical.

Rate, Time, and Yield must be expressed in consistent units of time.

## Examples

## Compute the Implied Volatility of an Underlying Asset Using a Black-Scholes Model

This example shows how to compute the implied volatility for a European call option trading at $\$ 10$ with an exercise price of $\$ 95$ and three months until expiration. Assume that the underlying stock pays no dividend and trades at $\$ 100$. The risk-free rate is $7.5 \%$ per annum. Furthermore, assume that you are interested in implied volatilities no greater than 0.5 ( $50 \%$ per annum). Under these conditions, the following statements all compute an implied volatility of 0.3130 , or $31.30 \%$ per annum.

```
Volatility = blsimpv(100, 95, 0.075, 0.25, 10, 0.5);
Volatility = blsimpv(100, 95, 0.075, 0.25, 10, 0.5, 0, [], {'Call'});
Volatility = blsimpv(100, 95, 0.075, 0.25, 10, 0.5, 0, [], true)
Volatility =
```

    0.3130

## blslambda

Black-Scholes elasticity

## Syntax

[CallEl, PutEl] = blslambda(Price, Strike, Rate, Time, Volatility, Yield)

## Arguments

| Price | Current price of the underlying asset. |
| :--- | :--- |
| Strike | Exercise price of the option. |
| Rate | Annualized, continuously compounded risk-free rate of return over <br> the life of the option, expressed as a positive decimal number. |
| Time | Time to expiration of the option, expressed in years. |
| Volatility | Annualized asset price volatility (annualized standard deviation of <br> the continuously compounded asset return), expressed as a positive <br> decimal number. |
| Yield | (Optional) Annualized, continuously compounded yield of the <br> underlying asset over the life of the option, expressed as a decimal <br> number. (Default = 0.) For example, for options written on stock <br> indices, Yield could represent the dividend yield. For currency <br> options, Yield could be the foreign risk-free interest rate. |

## Description

[CallEl, PutEl] = blslambda(Price, Strike, Rate, Time, Volatility, Yield) returns the elasticity of an option. CallEl is the call option elasticity or leverage factor, and PutEl is the put option elasticity or leverage factor. Elasticity (the leverage of an option position) measures the percent change in an option price per 1 percent change in the underlying asset price. blslambda uses normcdf, the normal cumulative distribution function in the Statistics and Machine Learning Toolbox.

Note: blslambda can handle other types of underlies like Futures and Currencies. When pricing Futures (Black model), enter the input argument Yield as:

```
Yield = Rate
```

When pricing currencies (Garman-Kohlhagen model), enter the input argument Yield as:

Yield = ForeignRate
where ForeignRate is the continuously compounded, annualized risk free interest rate in the foreign country.

## Examples

## Find the Black-Scholes Elasticity (Lambda) for an Option

This example shows how to find the Black-Scholes elasticity, or leverage, of an option positon.
[CallEl, PutEl] = blslambda(50, 50, 0.12, 0.25, 0.3)

CallEl =
8.1274

## PutEl =

$-8.6466$

## blsprice

Black-Scholes put and call option pricing

## Syntax

[Call, Put] = blsprice(Price, Strike, Rate, Time, Volatility, Yield)

## Arguments

| Price | Current price of the underlying asset. |
| :--- | :--- |
| Strike | Exercise price of the option. |
| Rate | Annualized, continuously compounded risk-free rate of return over <br> the life of the option, expressed as a positive decimal number. |
| Time | Time to expiration of the option, expressed in years. |
| Volatility | Annualized asset price volatility (annualized standard deviation of <br> the continuously compounded asset return), expressed as a positive <br> decimal number. |
| Yield | (Optional) Annualized, continuously compounded yield of the <br> underlying asset over the life of the option, expressed as a decimal <br> number. (Default = 0.) For example, for options written on stock <br> indices, Yield could represent the dividend yield. For currency <br> options, Yield could be the foreign risk-free interest rate. |

## Description

[Call, Put] = blsprice(Price, Strike, Rate, Time, Volatility, Yield) computes European put and call option prices using a Black-Scholes model.

Any input argument can be a scalar, vector, or matrix. When a value is a scalar, that value is used to price all the options. If more than one input is a vector or matrix, the dimensions of all non-scalar inputs must be identical.

Rate, Time, Volatility, and Yield must be expressed in consistent units of time.

Note: blsprice can handle other types of underlies like Futures and Currencies. When pricing Futures (Black model), enter the input argument Yield as:

## Yield = Rate

When pricing currencies (Garman-Kohlhagen model), enter the input argument Yield as:

Yield = ForeignRate
where ForeignRate is the continuously compounded, annualized risk free interest rate in the foreign country.

## Examples

## Compute European Put and Call Option Prices Using a Black-Scholes Model

This example shows how to price European stock options that expire in three months with an exercise price of $\$ 95$. Assume that the underlying stock pays no dividend, trades at $\$ 100$, and has a volatility of $50 \%$ per annum. The risk-free rate is $10 \%$ per annum.

```
[Call, Put] = blsprice(100, 95, 0.1, 0.25, 0.5)
```

## Call =

13.6953

Put =
6.3497

## blsho

Black-Scholes sensitivity to interest rate change

## Syntax

[CallRho, PutRho]= blsrho(Price, Strike, Rate, Time, Volatility, Yield)

## Arguments

| Price | Current price of the underlying asset. |
| :--- | :--- |
| Strike | Exercise price of the option. |
| Rate | Annualized, continuously compounded risk-free rate of return over <br> the life of the option, expressed as a positive decimal number. |
| Time | Time to expiration of the option, expressed in years. |
| Volatility | Annualized asset price volatility (annualized standard deviation of <br> the continuously compounded asset return), expressed as a positive <br> decimal number. |
| Yield | (Optional) Annualized, continuously compounded yield of the <br> underlying asset over the life of the option, expressed as a decimal <br> number. (Default = 0.) For example, for options written on stock <br> indices, Yield could represent the dividend yield. For currency <br> options, Yield could be the foreign risk-free interest rate. |

## Description

[CallRho, PutRho]= blsrho(Price, Strike, Rate, Time, Volatility, Yield) returns the call option rho CallRho, and the put option rho PutRho. Rho is the rate of change in value of derivative securities with respect to interest rates. blsrho uses normcdf, the normal cumulative distribution function in the Statistics and Machine Learning Toolbox

Note: blsrho can handle other types of underlies like Futures and Currencies. When pricing Futures (Black model), enter the input argument Yield as:

```
Yield = Rate
```

When pricing currencies (Garman-Kohlhagen model), enter the input argument Yield as:

Yield = ForeignRate
where ForeignRate is the continuously compounded, annualized risk free interest rate in the foreign country.

## Examples

## Find the Black-Scholes Sensitivity (Rho) to Interest-Rate Change

This example shows how to find the Black-Scholes sensitivity, rho, to interest-rate change.
[CallRho, PutRho] = blsrho(50, 50, 0.12, 0.25, 0.3, 0)

CallRho =
6.6686

## PutRho =

$-5.4619$

- "Pricing and Analyzing Equity Derivatives" on page 2-42
- "Greek-Neutral Portfolios of European Stock Options" on page 10-18
- "Plotting Sensitivities of an Option" on page 10-30
- "Plotting Sensitivities of a Portfolio of Options" on page 10-31

## blstheta

Black-Scholes sensitivity to time-until-maturity change

## Syntax

[CallTheta, PutTheta] = blstheta(Price, Strike, Rate, Time, Volatility, Yield)

## Arguments

| Price | Current price of the underlying asset. |
| :--- | :--- |
| Strike | Exercise price of the option. |
| Rate | Annualized, continuously compounded risk-free rate of return over <br> the life of the option, expressed as a positive decimal number. |
| Time | Time to expiration of the option, expressed in years. |
| Volatility | Annualized asset price volatility (annualized standard deviation of <br> the continuously compounded asset return), expressed as a positive <br> decimal number. |
| Yield | (Optional) Annualized, continuously compounded yield of the <br> underlying asset over the life of the option, expressed as a decimal <br> number. (Default = 0.) For example, for options written on stock <br> indices, Yield could represent the dividend yield. For currency <br> options, Yield could be the foreign risk-free interest rate. |

## Description

[CallTheta, PutTheta] = blstheta(Price, Strike, Rate, Time, Volatility, Yield) returns the call option theta CallTheta, and the put option theta PutTheta.

Theta is the sensitivity in option value with respect to time and is measured in years. CallTheta or PutTheta can be divided by 365 to get Theta per calendar day or by 252 to get Theta by trading day.
blstheta uses normcdf, the normal cumulative distribution function in the Statistics and Machine Learning Toolbox.

Note: blstheta can handle other types of underlies like Futures and Currencies. When pricing Futures (Black model), enter the input argument Yield as:

```
Yield = Rate
```

When pricing currencies (Garman-Kohlhagen model), enter the input argument Yield as:

Yield = ForeignRate
where ForeignRate is the continuously compounded, annualized risk free interest rate in the foreign country.

## Examples

## Compute the Black-Scholes Sensitivity to Time-Until-Maturity Change (Theta)

This example shows how to compute theta, the sensitivity in option value with respect to time.
[CallTheta, PutTheta] = blstheta(50, 50, 0.12, 0.25, 0.3, 0)

CallTheta =
$-8.9630$

PutTheta =
$-3.1404$

## blsvega

Black-Scholes sensitivity to underlying price volatility

## Syntax

Vega = blsvega(Price, Strike, Rate, Time, Volatility, Yield)

## Arguments

| Price | Current price of the underlying asset. |
| :--- | :--- |
| Strike | Exercise price of the option. |
| Rate | Annualized, continuously compounded risk-free rate of return over <br> the life of the option, expressed as a positive decimal number. |
| Time | Time to expiration of the option, expressed in years. |
| Volatility | Annualized asset price volatility (annualized standard deviation of <br> the continuously compounded asset return), expressed as a positive <br> decimal number. |
| Yield | (Optional) Annualized, continuously compounded yield of the <br> underlying asset over the life of the option, expressed as a decimal <br> number. (Default = 0.) For example, for options written on stock <br> indices, Yield could represent the dividend yield. For currency <br> options, Yield could be the foreign risk-free interest rate. |

## Description

Vega = blsvega(Price, Strike, Rate, Time, Volatility, Yield) returns Vega, the rate of change of the option value with respect to the volatility of the underlying asset. blsvega uses normpdf, the normal probability density function in the Statistics and Machine Learning Toolbox.

Note: blsvega can handle other types of underlies like Futures and Currencies. When pricing Futures (Black model), enter the input argument Yield as:

```
Yield = Rate
```

When pricing currencies (Garman-Kohlhagen model), enter the input argument Yield as:

Yield = ForeignRate
where ForeignRate is the continuously compounded, annualized risk free interest rate in the foreign country.

## Examples

## Compute Black-Scholes Sensitivity to Underlying Price Volatility (Vega)

This example shows how to compute vega, the rate of change of the option value with respect to the volatility of the underlying asset.

```
Vega = blsvega(50, 50, 0.12, 0.25, 0.3, 0)
```

## bm

Brownian motion models

## Syntax

$B M=b m(M u$, Sigma)
BM = bm(Mu, Sigma, 'Name1', Value1, 'Name2', Value2, ...)

## Class

## BM

## Description

This constructor creates and displays Brownian motion (sometimes called arithmetic Brownian motion or generalized Wiener process) objects that derive from the SDELD (SDE with drift rate expressed in linear form) class. Use BM objects to simulate sample paths of NVARS state variables driven by NBROWNS sources of risk over NPERIODS consecutive observation periods, approximating continuous-time Brownian motion stochastic processes. This enables you to transform a vector of NBROWNS uncorrelated, zero-drift, unit-variance rate Brownian components into a vector of NVARS Brownian components with arbitrary drift, variance rate, and correlation structure.

The bm method allows you to simulate any vector-valued BM process of the form:

$$
d X_{t}=\mu(t) d t+V(t) d W_{t}
$$

where:

- $X_{t}$ is an NVARS-by- 1 state vector of process variables.
- $\mu$ is an NVARS-by- 1 drift-rate vector.
- $V$ is an NVARS-by-NBROWNS instantaneous volatility rate matrix.
- $d W_{t}$ is an NBROWNS-by-1 vector of (possibly) correlated zero-drift/unit-variance rate Brownian components.

## Input Arguments

Specify required input parameters as one of the following types:

- A MATLAB array. Specifying an array indicates a static (non-time-varying) parametric specification. This array fully captures all implementation details, which are clearly associated with a parametric form.
- A MATLAB function. Specifying a function provides indirect support for virtually any static, dynamic, linear, or nonlinear model. This parameter is supported via an interface, because all implementation details are hidden and fully encapsulated by the function.

Note: You can specify combinations of array and function input parameters as needed.
Moreover, a parameter is identified as a deterministic function of time if the function accepts a scalar time $t$ as its only input argument. Otherwise, a parameter is assumed to be a function of time $t$ and state $X(t)$ and is invoked with both input arguments.

The required input parameters are:

| Mu | Mu represents $\mu$. If you specify Mu as an array, it must be an NVARS-by-1 <br> column vector representing the drift rate (the expected instantaneous <br> rate of drift, or time trend). As a deterministic function of time, when <br> Mu is called with a real-valued scalar time t as its only input, Mu must <br> produce an NVARS-by-NVARS matrix. If you specify Mu as a function of <br> time and state, it calculates the expected instantaneous rate of drift. This <br> function must generate an NVARS-by-1 column vector when invoked with <br> two inputs: |
| :--- | :--- |
| - A real-valued scalar observation time $t$. |  |
| - An NVARS-by-1 state vector $X_{t}$. |  |

$|$| Sigma must produce an NVARS-by-NBROWNS matrix. If you specify Sigma <br> as a function of time and state, it must generate an NVARS-by-NBROWNS <br> matrix of volatility rates when invoked with two inputs: |
| :--- |
| A real-valued scalar observation time $t$. <br> $\quad$ An NVARS-by-1 state vector $X_{t}$. |
| Although the constructor does not enforce restrictions on the sign of this <br> argument, Sigma is usually specified as a positive value. |

## Optional Input Arguments

Specify optional inputs as matching parameter name/value pairs as follows:

- Specify the parameter name as a character string, followed by its corresponding value.
- You can specify parameter name/value pairs in any order.
- Parameter names are case insensitive.
- You can specify unambiguous partial string matches.

Valid parameter names are:

| StartTime | Scalar starting time of the first observation, applied to all state <br> variables. If you do not specify a value for StartTime, the default <br> is 0. |
| :--- | :--- |
| StartState | Scalar, NVARS-by-1 column vector, or NVARS-by-NTRIALS matrix of <br> initial values of the state variables. <br> If StartState is a scalar, bm applies the same initial value to all <br> state variables on all trials. <br> If StartState is a column vector, bm applies a unique initial value <br> to each state variable on all trials. <br> If StartState is a matrix, bm applies a unique initial value to each <br> state variable on each trial. <br> If you do not specify a value for StartState, all variables start at <br> 1. |

| Correlation | Correlation between Gaussian random variates drawn to <br> generate the Brownian motion vector (Wiener processes). Specify <br> Correlation as an NBROWNS-by-NBROWNS positive semidefinite <br> matrix, or as a deterministic function $C(t)$ that accepts the current <br> time $t$ and returns an NBROWNS-by-NBROWNS positive semidefinite <br> correlation matrix. <br> A Correlation matrix represents a static condition. <br> As a deterministic function of time, Correlation allows you to <br> specify a dynamic correlation structure. |
| :--- | :--- |
|  | If you do not specify a value for Correlation, the default is an <br> NBROWNS-by-NBROWNS identity matrix representing independent <br> Gaussian processes. |
| Simulation | A user-defined simulation function or SDE simulation method. If <br> you do not specify a value for Simulation, the default method is <br> simulation by Euler approximation (simByEuler). |

## Output Arguments

| BM | Object of class BM with the following displayed parameters: <br> - StartTime: Initial observation time <br> - StartState: Initial state at time StartTime <br> - Correlation: Access function for the Correlation input argument, callable as a function of time <br> - Drift: Composite drift-rate function, callable as a function of time and state <br> - Diffusion: Composite diffusion-rate function, callable as a function of time and state <br> - Simulation: A simulation function or method <br> - Mu: Access function for the input argument Mu, callable as a function of time and state <br> - Sigma: Access function for the input argument Sigma, callable as a function of time and state |
| :---: | :---: |

## Algorithm

When you specify the required input parameters as arrays, they are associated with a specific parametric form. By contrast, when you specify either required input parameter as a function, you can customize virtually any specification.

Accessing the output parameters with no inputs simply returns the original input specification. Thus, when you invoke these parameters with no inputs, they behave like simple properties and allow you to test the data type (double vs. function, or equivalently, static vs. dynamic) of the original input specification. This is useful for validating and designing methods.

When you invoke these parameters with inputs, they behave like functions, giving the impression of dynamic behavior. The parameters accept the observation time $t$ and a state vector $X_{t}$, and return an array of appropriate dimension. Even if you originally specified an input as an array, bm treats it as a static function of time and state, by that means guaranteeing that all parameters are accessible by the same interface.

## bndconvp

Bond convexity given price

## Syntax

```
[YearConvexity, PerConvexity] = bndconvp(Price, CouponRate,
Settle, Maturity)
[YearConvexity, PerConvexity] = bndconvp(Price,
CouponRate, Settle, Maturity, Period, Basis, EndMonthRule,
IssueDate, FirstCouponDate, LastCouponDate, StartDate,
Face)
[YearConvexity, PerConvexity] = bndconvp(Price,
CouponRate, Settle, Maturity,
'ParameterName', ParameterValue, ...)
```

## Description

[YearConvexity, PerConvexity] = bndconvp(Price, CouponRate, Settle, Maturity) computes the convexity of NUMBONDS fixed income securities given a clean price for each bond.
[YearConvexity, PerConvexity] = bndconvp(Price, CouponRate, Settle, Maturity, Period, Basis, EndMonthRule, IssueDate, FirstCouponDate, LastCouponDate, StartDate, Face) computes the convexity of NUMBONDS fixed income securities given a clean price for each bond using optional arguments.
[YearConvexity, PerConvexity] = bndconvp(Price, CouponRate, Settle, Maturity,
'ParameterName', ParameterValue, ...) computes the convexity of NUMBONDS fixed income securities given a clean price for each bond and accepts optional inputs as one or more comma-separated parameter/value pairs. 'ParameterName' is the name of the parameter inside single quotes. ParameterValue is the value corresponding to 'ParameterName '. Specify parameter/value pairs in any order. Names are caseinsensitive.

## Input Arguments

## Price

Clean price (excludes accrued interest).

## CouponRate

Decimal number indicating the annual percentage rate used to determine the coupons payable on a bond.

## Settle

Settlement date. A vector of serial date numbers or date strings. Settle must be earlier than Maturity.

## Maturity

Maturity date. A vector of serial date numbers or date strings.

## Ordered Input or Parameter-Value Pairs

Enter the following inputs using an ordered syntax or as parameter/value pairs. You cannot mix ordered syntax with parameter/value pairs.

## Period

Coupons per year of the bond. A vector of integers. Values are $0,1,2,3,4,6$, and 12 .

## Default: 2

## Basis

Day-count basis of the instrument. A vector of integers.

- $0=$ actual/actual
- $1=30 / 360$ (SIA)
- 2 = actual $/ 360$
- $3=$ actual $/ 365$
- $4=30 / 360$ (PSA)
- $5=30 / 360$ (ISDA)
- $6=30 / 360$ (European)
- $7=$ actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- $10=$ actual/365 (ICMA)
- $11=30 / 360 \mathrm{E}$ (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see basis.
Default: 0

## EndMonthRule

End-of-month rule. A vector. This rule applies only when Maturity is an end-of-month date for a month having 30 or fewer days. $0=$ ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month. $1=$ set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

## Default: 1

## IssueDate

Issue date for a bond.

## FirstCouponDate

Date when a bond makes its first coupon payment; used when bond has an irregular first coupon period. When FirstCouponDate and LastCouponDate are both specified, FirstCouponDate takes precedence in determining the coupon payment structure.

Default: If you do not specify a FirstCouponDate, the cash flow payment dates are determined from other inputs.

## LastCouponDate

Last coupon date of a bond before the maturity date; used when bond has an irregular last coupon period. In the absence of a specified FirstCouponDate, a specified

LastCouponDate determines the coupon structure of the bond. The coupon structure of a bond is truncated at the LastCouponDate, regardless of where it falls, and is followed only by the bond's maturity cash flow date.

Default: If you do not specify a LastCouponDate, the cash flow payment dates are determined from other inputs.

## StartDate

Date when a bond actually starts (the date from which a bond cash flow is considered). To make an instrument forward-starting, specify this date as a future date. If you do not specify StartDate, the effective start date is the Settle date.

## Face

Face or par value.
Default: 100

## Parameter-Value Pairs

Enter the following inputs only as parameter/value pairs.

## CompoundingFrequency

Compounding frequency for yield calculation. By default, SIA bases (0-7) and BUS/252 use a semiannual compounding convention and ICMA bases (8-12) use an annual compounding convention.

## DiscountBasis

Basis used to compute the discount factors for computing the yield. The default behavior is for SIA bases to use the actual/actual day count to compute discount factors. If you use ICMA day counts and BUS/252, the specified bases are used.

## Output Arguments

## YearConvexity

NUMBONDS-by- 1 vector for the yearly (annualized) convexity.

## PerConvexity

NUMBONDS-by-1 vector for the periodic convexity reported on a semiannual bond basis (in accordance with SIA convention).

## Definitions

bndconvp determines the convexity for a bond whether the first or last coupon periods in the coupon structure are short or long (that is, whether the coupon structure is synchronized to maturity). This function also determines the convexity of a zero coupon bond.

All specified arguments must be number of bonds (NUMBONDS)-by-1 or 1-by-NUMBONDS conforming vectors or scalar arguments. Use an empty matrix ([ ]) as a placeholder for an optional argument. Fill in unspecified entries input vectors with NaNs. Dates can be serial date numbers or date strings.

## Examples

## Find Bond Convexity Given Price

This example shows how to compute the convexity of three bonds given their prices.

```
Price = [106; 100; 98];
CouponRate = 0.055;
Settle = '02-Aug-1999';
Maturity = '15-Jun-2004';
Period = 2;
Basis = 0;
[YearConvexity, PerConvexity] = bndconvp(Price,...
CouponRate,Settle, Maturity, Period, Basis)
YearConvexity =
    21.4447
    21.0363
    20.8951
```

PerConvexity =
85.7788
84.1454
83.5803

## bndconvy

Bond convexity given yield

## Syntax

[YearConvexity, PerConvexity] = bndconvy(Yield, CouponRate, Settle, Maturity)
[YearConvexity, PerConvexity] = bndconvy(Yield, CouponRate, Settle, Maturity, Period, Basis, EndMonthRule, IssueDate, FirstCouponDate, LastCouponDate, StartDate, Face)
[YearConvexity, PerConvexity] = bndconvy(Yield, CouponRate, Settle, Maturity,
'ParameterName', ParameterValue, ...)

## Description

[YearConvexity, PerConvexity] = bndconvy(Yield, CouponRate, Settle, Maturity) computes the convexity of NUMBONDS fixed income securities given the yield to maturity for each bond.
[YearConvexity, PerConvexity] = bndconvy(Yield, CouponRate, Settle, Maturity, Period, Basis, EndMonthRule, IssueDate, FirstCouponDate, LastCouponDate, StartDate, Face) computes the convexity of NUMBONDS fixed income securities given the yield to maturity for each bond using optional arguments.
[YearConvexity, PerConvexity] = bndconvy(Yield, CouponRate, Settle, Maturity,
'ParameterName', ParameterValue, ...) computes the convexity of NUMBONDS fixed income securities given the yield to maturity for each bond and accepts optional inputs as one or more comma-separated parameter/value pairs. 'ParameterName' is the name of the parameter inside single quotes. ParameterValue is the value corresponding to 'ParameterName '. Specify parameter/value pairs in any order. Names are caseinsensitive.

## Input Arguments

## Yield

Yield to maturity on a semiannual basis.

## CouponRate

Decimal number indicating the annual percentage rate used to determine the coupons payable on a bond.

## Settle

Settlement date. A vector of serial date numbers or date strings. Settle must be earlier than Maturity.

## Maturity

Maturity date. A vector of serial date numbers or date strings.

## Ordered Input or Parameter-Value Pairs

Enter the following inputs using an ordered syntax or as parameter/value pairs. You cannot mix ordered syntax with parameter/value pairs.

## Period

Coupons per year of the bond. A vector of integers. Values are $0,1,2,3,4,6$, and 12 .

## Default: 2

## Basis

Day-count basis of the instrument. A vector of integers.

- $0=$ actual/actual
- $1=30 / 360$ (SIA)
- $2=$ actual/360
- 3 = actual/365
- $4=30 / 360$ (PSA)
- $5=30 / 360$ (ISDA)
- $6=30 / 360$ (European)
- $7=$ actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- $10=$ actual/365 (ICMA)
- $11=30 / 360 \mathrm{E}$ (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see basis.
Default: 0

## EndMonthRule

End-of-month rule. A vector. This rule applies only when Maturity is an end-of-month date for a month having 30 or fewer days. $0=$ ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month. $1=$ set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

## Default: 1

## IssueDate

Issue date for a bond.

## FirstCouponDate

Date when a bond makes its first coupon payment; used when bond has an irregular first coupon period. When FirstCouponDate and LastCouponDate are both specified, FirstCouponDate takes precedence in determining the coupon payment structure.

Default: If you do not specify a FirstCouponDate, the cash flow payment dates are determined from other inputs.

## LastCouponDate

Last coupon date of a bond before the maturity date; used when bond has an irregular last coupon period. In the absence of a specified FirstCouponDate, a specified

LastCouponDate determines the coupon structure of the bond. The coupon structure of a bond is truncated at the LastCouponDate, regardless of where it falls, and is followed only by the bond's maturity cash flow date.

Default: If you do not specify a LastCouponDate, the cash flow payment dates are determined from other inputs.

## StartDate

Date when a bond actually starts (the date from which a bond cash flow is considered). To make an instrument forward-starting, specify this date as a future date. If you do not specify StartDate, the effective start date is the Settle date.

## Face

Face or par value.
Default: 100

## Parameter-Value Pairs

Enter the following inputs only as parameter/value pairs.

## CompoundingFrequency

Compounding frequency for yield calculation. By default, SIA bases (0-7) and BUS/252 use a semiannual compounding convention and ICMA bases (8-12) use an annual compounding convention.

## DiscountBasis

Basis used to compute the discount factors for computing the yield. The default behavior is for SIA bases to use the actual/actual day count to compute discount factors. If you use ICMA day counts and BUS/252, the specified bases are used.

## Output Arguments

## YearConvexity

NUMBONDS-by- 1 vector for the yearly (annualized) convexity.

## PerConvexity

NUMBONDS-by- 1 vector for the periodic convexity reported on a semiannual bond basis (in accordance with SIA convention).

## Definitions

bndconvy determines the convexity for a bond whether the first or last coupon periods in the coupon structure are short or long (that is, whether the coupon structure is synchronized to maturity). This function also determines the convexity of a zero coupon bond.

All specified arguments must be number of bonds (NUMBONDS)-by-1 or 1-by-NUMBONDS conforming vectors or scalar arguments. Use an empty matrix ([ ]) as a placeholder for an optional argument. Fill in unspecified entries input vectors with NaNs. Dates can be serial date numbers or date strings.

## Examples

## Find Bond Convexity Given Yield

This example shows how to compute the convexity of a bond at three different yield values.

```
Yield = [0.04; 0.055; 0.06];
CouponRate = 0.055;
Settle = '02-Aug-1999';
Maturity = '15-Jun-2004';
Period = 2;
Basis = 0;
[YearConvexity, PerConvexity]=bndconvy(Yield, CouponRate,...
Settle, Maturity, Period, Basis)
YearConvexity =
    21.4825
    21.0358
    20.8885
```

PerConvexity =
85.9298
84.1434
83.5541

## bnddurp

Bond duration given price

## Syntax

[ModDuration, YearDuration, PerDuration] = bnddurp(Price, CouponRate, Settle, Maturity)
[ModDuration, YearDuration, PerDuration] = bnddurp(Price, CouponRate, Settle, Maturity, Period, Basis, EndMonthRule, IssueDate, FirstCouponDate, LastCouponDate, StartDate, Face)
[ModDuration, YearDuration, PerDuration] = bnddurp(Price, CouponRate, Settle, Maturity, 'ParameterName', ParameterValue, ...)

## Description

[ModDuration, YearDuration, PerDuration] = bnddurp(Price, CouponRate, Settle, Maturity) computes the Macaulay and modified duration of NUMBONDS fixed-income securities given a clean price for each bond.
[ModDuration, YearDuration, PerDuration] = bnddurp(Price, CouponRate, Settle, Maturity, Period, Basis, EndMonthRule, IssueDate, FirstCouponDate, LastCouponDate, StartDate, Face) computes the Macaulay and modified duration of NUMBONDS fixed-income securities given a clean price for each bond using optional arguments.
[ModDuration, YearDuration, PerDuration] = bnddurp(Price, CouponRate, Settle, Maturity, 'ParameterName', ParameterValue, ...) computes the Macaulay and modified duration of NUMBONDS fixed-income securities given a clean price for each bond and accepts optional inputs as one or more comma-separated parameter/value pairs.
'ParameterName ' is the name of the parameter inside single quotes. ParameterValue is the value corresponding to 'ParameterName'. Specify parameter/value pairs in any order. Names are case-insensitive.

## Input Arguments

## Price

Clean price (excludes accrued interest).

## CouponRate

Decimal number indicating the annual percentage rate used to determine the coupons payable on a bond.

## Settle

Settlement date. A vector of serial date numbers or date strings. Settle must be earlier than Maturity.

## Maturity

Maturity date. A vector of serial date numbers or date strings.

## Ordered Input or Parameter-Value Pairs

Enter the following inputs using an ordered syntax or as parameter/value pairs. You cannot mix ordered syntax with parameter/value pairs.

## Period

Coupons per year of the bond. A vector of integers. Values are 0, 1, 2, 3, 4, 6, and 12.

## Default: 2

## Basis

Day-count basis of the instrument. A vector of integers.

- $0=$ actual/actual
- $1=30 / 360$ (SIA)
- 2 = actual/360
- 3 = actual/ 365
- $4=30 / 360$ (PSA)
- $5=30 / 360$ (ISDA)
- $6=30 / 360$ (European)
- $7=$ actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- $10=$ actual/365 (ICMA)
- $11=30 / 360 \mathrm{E}$ (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see basis.
Default: 0

## EndMonthRule

End-of-month rule. A vector. This rule applies only when Maturity is an end-of-month date for a month having 30 or fewer days. $0=$ ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month. $1=$ set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

## Default: 1

## IssueDate

Issue date for a bond.

## FirstCouponDate

Date when a bond makes its first coupon payment; used when bond has an irregular first coupon period. When FirstCouponDate and LastCouponDate are both specified, FirstCouponDate takes precedence in determining the coupon payment structure.

Default: If you do not specify a FirstCouponDate, the cash flow payment dates are determined from other inputs.

## LastCouponDate

Last coupon date of a bond before the maturity date; used when bond has an irregular last coupon period. In the absence of a specified FirstCouponDate, a specified

LastCouponDate determines the coupon structure of the bond. The coupon structure of a bond is truncated at the LastCouponDate, regardless of where it falls, and is followed only by the bond's maturity cash flow date.

Default: If you do not specify a LastCouponDate, the cash flow payment dates are determined from other inputs.

## StartDate

Date when a bond actually starts (the date from which a bond cash flow is considered). To make an instrument forward-starting, specify this date as a future date. If you do not specify StartDate, the effective start date is the Settle date.

## Face

Face or par value.
Default: 100

## Parameter-Value Pairs

Enter the following inputs only as parameter/value pairs.

## CompoundingFrequency

Compounding frequency for yield calculation. By default, SIA bases (0-7) and BUS/252 use a semiannual compounding convention and ICMA bases ( $8-12$ ) use an annual compounding convention.

## DiscountBasis

Basis used to compute the discount factors for computing the yield. The default behavior is for SIA bases to use the actual/actual day count to compute discount factors. If you use ICMA day counts and BUS/252, the specified bases are used.

## Output Arguments

ModDuration
NUMBONDS-by-1 vector for the modified duration in years, reported on a semiannual bond basis (in accordance with SIA convention).

## YearDuration

NUMBONDS-by-1 vector for the Macaulay duration in years.

## PerDuration

NUMBONDS-by-1 vector for the periodic Macaulay duration reported on a semiannual bond basis (in accordance with SIA convention).

## Definitions

bnddurp determines the Macaulay and modified duration for a bond whether the first or last coupon periods in the coupon structure are short or long (that is, whether the coupon structure is synchronized to maturity). This function also determines the Macaulay and modified duration for a zero coupon bond.

All specified arguments must be number of bonds (NUMBONDS)-by-1 or 1-by-NUMBONDS conforming vectors or scalar arguments. Use an empty matrix ([ ]) as a placeholder for an optional argument. Fill in unspecified entries input vectors with NaNs. Dates can be serial date numbers or date strings.

## Examples

## Find Bond Duration Given Price

This example shows how to compute the duration of three bonds given their prices.

```
Price = [106; 100; 98];
CouponRate = 0.055;
Settle = '02-Aug-1999';
Maturity = '15-Jun-2004';
Period = 2;
Basis = 0;
[ModDuration, YearDuration, PerDuration] = bnddurp(Price,...
CouponRate, Settle, Maturity, Period, Basis)
ModDuration =
```

## bndkrdur

Bond key rate duration given zero curve

## Syntax

KRDUR = bndkrdur(ZeroData, CouponRate, Settle, Maturity)

KRDUR = bndkrdur(ZeroData, CouponRate, Settle, Maturity, 'Parameter1', Value1, 'Parameter2', Value2, ...)

## Arguments

| ZeroData | Zero curve represented as a numRates-by-2 matrix where <br> the first column is a MATLAB date number and the second <br> column is accompanying zero rates. |
| :--- | :--- |
| CouponRate | numBonds-by-1 vector of coupon rates in decimal form. |
| Settle | Scalar MATLAB date number for the settlement date for <br> all the bonds and the zero data. Settle must be the same <br> settlement date for all the bonds and the zero curve. |
| Maturity | numBonds-by-1 vector of maturity dates. |
| Period | (Optional) Coupons per year of the bond. A vector of <br> integers. Acceptable values are 0, 1, 2 (default), 3, 4, 6, and <br> 12. |
| InterpMethod | (Optional) Interpolation method used to obtain points from <br> the zero curve. Acceptable values are: <br> $-\quad$ ' linear' (default) <br> $-\quad$ ' cubic ' <br> - 'pchip' |
| ShiftValue | (Optional) Scalar value that zero curve is shifted up and <br> down to compute duration. Default is .01 (100 basis points). |

| KeyRates | (Optional) Rates to perform the duration calculation, specified as a time to maturity. By default, KeyRates is set to each of the zero dates. |
| :---: | :---: |
| CurveCompounding | (Optional) Compounding frequency of the curve. Default is semiannual. |
| CurveBasis | (Optional) Basis of the curve, where the choices are identical to Basis below. Default is 0 (actual/actual). |
| Basis | (Optional) Day-count basis of the bond instrument. A vector of integers: <br> - $0=$ actual/actual (default) <br> - $1=30 / 360$ (SIA) <br> - 2 = actual $/ 360$ <br> - $3=$ actual $/ 365$ <br> - $4=30 / 360$ (PSA) <br> - $5=30 / 360$ (ISDA) <br> - $6=30 / 360$ (European) <br> - 7 = actual/365 (Japanese) <br> - $8=$ actual/actual (ICMA) <br> - $9=$ actual/360 (ICMA) <br> - $10=$ actual/365 (ICMA) <br> - $11=30 / 360 \mathrm{E}$ (ICMA) <br> - 12 = actual/365 (ISDA) <br> - 13 = BUS/252 <br> For more information, see basis. |
| EndMonthRule | (Optional) End-of-month rule. This rule applies only when Maturity is an end-of-month date for a month having 30 or fewer days. The values are: <br> - 0 = ignore rule, meaning that a bond's coupon payment date is always the same numerical day of the month. <br> - 1 = set rule on (default), meaning that a bond's coupon payment date is always the last actual day of the month. |

| IssueDate | (Optional) Date when a bond was issued. |
| :--- | :--- |
| FirstCouponDate | (Optional) Date when a bond makes its first coupon <br> payment; used when bond has an irregular first coupon <br> period. When FirstCouponDate and LastCouponDate <br> are both specified, FirstCouponDate takes precedence in <br> determining the coupon payment structure. If you do not <br> specify a FirstCouponDate, the cash flow payment dates <br> are determined from other inputs. |
| LastCouponDate | (Optional) Last coupon date of a bond before the maturity <br> date; used when bond has an irregular last coupon period. <br> In the absence of a specified FirstCouponDate, a specified <br> LastCouponDate determines the coupon structure of <br> the bond. The coupon structure of a bond is truncated at <br> the LastCouponDate, regardless of where it falls, and is <br> followed only by the bond's maturity cash flow date. If you <br> do not specify a LastCouponDate, the cash flow payment <br> dates are determined from other inputs. |
| StartDate | (Optional) Date when a bond actually starts (the date <br> from which a bond cash flow is considered). To make an <br> instrument forward-starting, specify this date as a future <br> date. If you do not specify StartDate, the effective start <br> date is the Settle date. |
| Face | (Optional) Face or par value. Default = 100. Face has no <br> impact on key rate duration. |

Note: You must enter the optional arguments as parameter/value pairs.

## Description

KRDUR = bndkrdur(ZeroData, CouponRate, Settle, Maturity)
KRDUR = bndkrdur(ZeroData, CouponRate, Settle, Maturity,
'Parameter1', Value1, 'Parameter2', Value2, ...)
The output argument KRDUR is a numBonds-by-numRates matrix of key rate durations.
bndkrdur computes the key rate durations for one or more bonds given a zero curve and a set of key rates. By default, the key rates are each of the zero curve rates. For each key rate, the duration is computed by shifting the zero curve up and down by a specified amount (ShiftValue) at that particular key rate, computing the present value of the bond in each case with the new zero curves, and then evaluating the following:

$$
k r d u r_{i}=\frac{\left(P V_{\text {down }}-P V_{u p}\right)}{(P V \times \text { ShiftValue } \times 2)}
$$

Note: The shift to the curve is computed by shifting the particular key rate by the ShiftValue and then interpolating the values of the curve in the interval between the previous and next key rates. For the first key rate, any curve values before the date are equal to the ShiftValue; likewise, for the last key rate, any curve values after the date are equal to the ShiftValue.

## Examples

## Find the Bond Key Rate Duration Given the Zero Curve

This example shows how to compute the key rate duration of a bond for key rate times of $2,5,10$, and 30 years.

```
ZeroRates = [0.0476 .0466 . 0465 .0468 .0473 .0478 ...
.0493 .0539 .0572 .0553 .0530]';
ZeroDates = daysadd('31-Dec-1998',[30 360 360*2 360*3 360*5 ...
360*7 360*10 360*15 360*20 360*25 360*30],1);
ZeroData = [ZeroDates ZeroRates];
krdur = bndkrdur(ZeroData,.0525,'12/31/1998',...
'11/15/2028','KeyRates',[2 5 10 30])
```

krdur =
$0.2986 \quad 0.8791 \quad 4.1353 \quad 9.5814$

## bndprice

Price fixed-income security from yield to maturity

## Syntax

```
[Price, AccruedInt] = bndprice(Yield, CouponRate, Settle,
Maturity)
[Price, AccruedInt] = bndprice(Yield, CouponRate, Settle,
Maturity, Period, Basis, EndMonthRule, IssueDate,
FirstCouponDate, LastCouponDate, StartDate, Face)
[Price, AccruedInt] = bndprice(Yield, CouponRate, Settle,
Maturity, 'ParameterName', ParameterValue, ...)
```

## Description

[Price, AccruedInt] = bndprice(Yield, CouponRate, Settle, Maturity) given bonds with SIA date parameters and semiannual yields to maturity, returns the clean prices and accrued interest due.
[Price, AccruedInt] = bndprice(Yield, CouponRate, Settle, Maturity, Period, Basis, EndMonthRule, IssueDate, FirstCouponDate, LastCouponDate, StartDate, Face) given bonds with SIA date parameters and semiannual yields to maturity and optional inputs, returns the clean prices and accrued interest due.
[Price, AccruedInt] = bndprice(Yield, CouponRate, Settle, Maturity, 'ParameterName', ParameterValue, ...) accepts optional inputs as one or more comma-separated parameter/value pairs. 'ParameterName' is the name of the parameter inside single quotes. ParameterValue is the value corresponding to 'ParameterName'. Specify parameter/value pairs in any order. Names are caseinsensitive.

Note: Given NBONDS with date parameters and yields to maturity, bndprice returns the clean prices and the accrued interest due.

All nonscalar or empty matrix input arguments must be either NUMBONDS-by-1 or 1 -by-NUMBONDS conforming vectors. Fill in unspecified entries input vectors with NaNs. $\underline{\text { Dates can be serial date numbers or date strings. }}$

## Input Arguments

## Yield

Bond yield to maturity is on a semiannual basis for basis values 0 through 7 and an annual basis for basis values 8 through 12.

## CouponRate

Decimal number indicating the annual percentage rate used to determine the coupons payable on a bond.

## Settle

Settlement date. A vector of serial date numbers or date strings. Settle must be earlier than Maturity.

## Maturity

Maturity date. A vector of serial date numbers or date strings.

## Ordered Input or Parameter-Value Pairs

Enter the following inputs using an ordered syntax or as parameter value pairs. You cannot mix ordered syntax with parameter value pairs.

## Period

Coupons per year of the bond. A vector of integers. Values are 0, 1, 2, 3, 4, 6, and 12.

## Default: 2

## Basis

Day-count basis of the instrument. A vector of integers.

- $0=$ actual/actual
- $1=30 / 360$ (SIA)
- 2 = actual/360
- 3 = actual/365
- $4=30 / 360$ (PSA)
- $5=30 / 360$ (ISDA)
- $6=30 / 360$ (European)
- 7 = actual/365 (Japanese)
- $8=$ actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- $10=\mathrm{actual} / 365$ (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see basis.

## Default: 0

## EndMonthRule

End-of-month rule. A vector. This rule applies only when Maturity is an end-of-month date for a month having 30 or fewer days. $0=$ ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month. $1=$ set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

## Default: 1

## IssueDate

Issue date for a bond.
Default: If you do not specify an IssueDate, the cash flow payment dates are determined from other inputs.

## FirstCouponDate

Date when a bond makes its first coupon payment; used when bond has an irregular first coupon period. When FirstCouponDate and LastCouponDate are both specified, FirstCouponDate takes precedence in determining the coupon payment structure.

Default: If you do not specify a FirstCouponDate, the cash flow payment dates are determined from other inputs.

## LastCouponDate

Last coupon date of a bond before the maturity date; used when bond has an irregular last coupon period. In the absence of a specified FirstCouponDate, a specified LastCouponDate determines the coupon structure of the bond. The coupon structure of a bond is truncated at the LastCouponDate, regardless of where it falls, and is followed only by the bond's maturity cash flow date.

Default: If you do not specify a LastCouponDate, the cash flow payment dates are determined from other inputs.

## StartDate

Date when a bond actually starts (the date from which a bond cash flow is considered). To make an instrument forward-starting, specify this date as a future date. If you do not specify StartDate, the effective start date is the Settle date.

Default: If you do not specify StartDate, the effective start date is the Settle date.

## Face

Face or par value.
Default: 100

## Parameter-Value Pairs

Enter the following inputs only as parameter/value pairs.

## CompoundingFrequency

Compounding frequency for yield calculation. By default, SIA bases (0-7) and BUS/252 use a semiannual compounding convention and ICMA bases (8-12) use an annual compounding convention.

Default: SIA bases (0-7) and BUS/252 use a semiannual compounding convention and ICMA bases ( $8-12$ ) use an annual compounding convention.

## DiscountBasis

Basis used to compute the discount factors for computing the yield. The default behavior is for SIA bases to use the actual/actual day count to compute discount factors. If you use ICMA day counts and BUS/252, the specified bases are used.

Default: SIA bases use the actual/actual day count to compute discount factors.

## LastCouponInterest

Compounding convention for computing the yield of a bond in the last coupon period. This is based on only the last coupon and the face value to be repaid. Acceptable values are simple or compound.

Default: compound

## Output Arguments

## Price

NUMBONDS-by- 1 vector for the clean price of the bond. The dirty price of the bond is the clean price plus the accrued interest. It equals the present value of the bond cash flows of the yield to maturity with semiannual compounding.

## AccruedInt

NUMBONDS-by- 1 vector for the accrued interest payable at settlement.

## Examples

## Price a Treasury Bond from Yield to Maturity

This example shows how to price a treasury bond at three different yield values.

```
Yield = [0.04; 0.05; 0.06];
CouponRate = 0.05;
Settle = '20-Jan-1997';
Maturity = '15-Jun-2002';
Period = 2;
Basis = 0;
```

```
[Price, AccruedInt] = bndprice(Yield, CouponRate, Settle,...
Maturity, Period, Basis)
Price =
    104.8106
        99.9951
        95.4384
AccruedInt =
    0.4945
    0.4945
    0.4945
```

## Price a Treasury Bond with Different Yield Values

This example shows how to price a Treasury bond at two different yield values that include parameter/value pairs for CompoundingFrequency, DiscountBasis, and LastCouponPeriodInterest.

```
bndprice(.04,0.08,'5/25/2004','4/21/2005','Period',1,'Basis',8, ...
'LastCouponInterest','simple')
ans =
```

    103.4743
    - "Bond Portfolio for Hedging Duration and Convexity" on page 10-7
- "Pricing Functions" on page 2-29
- "Sensitivity of Bond Prices to Interest Rates" on page 10-3

## More About

## Algorithms

For SIA conventions, the Price and Yield are related by the formula:

```
Price + Accrued Interest = sum(Cash_Flow*(1+Yield/2)^(-Time))
```

where the sum is over the bond's cash flows and corresponding times in units of semiannual coupon periods.

For ICMA conventions, the Price and Yield are related by the formula:

```
Price + Accrued Interest = sum(Cash_Flow*(1+Yield)^(-Time))
```

## Algorithms

For SIA conventions, the following formula defines bond price and yield:

$$
P V=\sum_{i=1}^{n}\left(\frac{C F}{\left(1+\frac{z}{f}\right)^{T F}}\right)
$$

where:

| $P V=$ | Present value of a cash flow. |
| :--- | :--- |
| $C F=$ | Cash flow amount. |
| $z=$ | Risk-adjusted annualized rate or yield corresponding to a given cash <br> flow. The yield is quoted on a semiannual basis. |
| $f=$ | Frequency of quotes for the yield. Default is 2 for Basis values 0 to 7 <br> and 13 and 1 for Basis values 8 to 12. The default can be overridden <br> by specifying the CompoundingFrequency name/value pair. |
| $T F=$ | Time factor for a given cash flow. The time factor is computed using the <br> compounding frequency and the discount basis. If these values are not <br> specified, then the defaults are as follows: CompoundingFrequency <br> default is 2 for Basis values 0 to 7 and 13 and 1 for Basis values 8 to <br> 12. DiscountBasis is 0 for Basis values 0 to 7 and 13 and the input <br> Basis for Basis values 8 to 12. |

Note: The Basis is always used to compute accrued interest.

For ICMA conventions, the frequency of annual coupon payments determines bond price and yield.

## Introduced before R2006a

## bndspread

Static spread over spot curve

## Syntax

Spread = bndspread(SpotInfo, Price, Coupon, Settle, Maturity) Spread = bndspread(SpotInfo, Price, Coupon, Settle, Maturity, Period, Basis, EndMonthRule, IssueDate, FirstCouponDate, LastCouponDate, StartDate, Face) Spread = bndspread(SpotInfo, Price, Coupon, Settle, Maturity, 'ParameterName', ParameterValue, ...)

## Description

Spread = bndspread(SpotInfo, Price, Coupon, Settle, Maturity) computes the static spread (Z-spread) to benchmark in basis points.

Spread = bndspread(SpotInfo, Price, Coupon, Settle, Maturity, Period, Basis, EndMonthRule, IssueDate, FirstCouponDate, LastCouponDate, StartDate, Face) computes the static spread (Z-spread) to benchmark in basis points including optional inputs.

Spread = bndspread(SpotInfo, Price, Coupon, Settle, Maturity, 'ParameterName', ParameterValue, ...) accepts optional inputs as one or more comma-separated parameter/value pairs. 'ParameterName' is the name of the parameter inside single quotes. ParameterValue is the value corresponding to 'ParameterName'. Specify parameter/value pairs in any order. Names are caseinsensitive.

## Input Arguments

## SpotInfo

This input can either be a matrix of two columns, or an annualized term structure created by intenvset.

- Matrix of two columns- The first column is the SpotDate, and the second column, ZeroRates, is the zero-rate corresponding to maturities on the SpotDate. It is recommended that the spot-rates are spaced as evenly apart as possible, perhaps one that is built from 3-months deposit rates. For example, using the 3-month deposit rates:

```
SpotInfo = ...
[datenum('2-Jan-2004') , 0.03840;
datenum('2-Jan-2005') , 0.04512;
datenum('2-Jan-2006') , 0.05086];
```

- Annualized term structure - Refer to intenvset to create an annualized term structure. For example:

```
Settle = datenum('1-Jan-2004');
Rates = [0.03840; 0.04512; 0.05086];
EndDates = [datenum('2-Jan-2004'); datenum('2-Jan-2005');...
    datenum('2-Jan-2006')];
SpotInfo = intenvset('StartDates' , Settle ,...
    'Rates' , Rates ,...
    'EndDates' , EndDates,...
    'Compounding', 2 ,...
    'Basis' , 0);
```

## Price

Price for every $\$ 100$ notional amount of bonds whose spreads are computed. This is the clean price of the bond (current price without accrued interest).

## Coupon

Annual coupon rate of bonds whose spreads are computed.

## Settle

Settlement date. A vector of serial date numbers or date strings. Settle must be earlier than Maturity.

## Maturity

Maturity date. A vector of serial date numbers or date strings.

## Ordered Input or Parameter-Value Pairs

Enter the following inputs using an ordered syntax or as parameter/value pairs. You cannot mix ordered syntax with parameter/value pairs.

## Period

Coupons per year of the bond. A vector of integers. Values are 0, 1, 2, 3, 4, 6, and 12.

## Default: 2

## Basis

Day-count basis of the instrument. A vector of integers.

- $0=$ actual/actual
- $1=30 / 360$ (SIA)
- 2 = actual/360
- 3 = actual/365
- $4=30 / 360$ (PSA)
- $5=30 / 360$ (ISDA)
- $6=30 / 360$ (European)
- $7=$ actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- $10=\mathrm{actual} / 365$ (ICMA)
- $11=30 / 360 \mathrm{E}$ (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see basis.
Default: 0

## EndMonthRule

End-of-month rule. A vector. This rule applies only when Maturity is an end-of-month date for a month having 30 or fewer days. $0=$ ignore rule, meaning that a bond coupon
payment date is always the same numerical day of the month. $1=$ set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

## Default: 1

## IssueDate

Issue date for a bond.

## FirstCouponDate

Date when a bond makes its first coupon payment; used when bond has an irregular first coupon period. When FirstCouponDate and LastCouponDate are both specified, FirstCouponDate takes precedence in determining the coupon payment structure.

Default: If you do not specify a FirstCouponDate, the cash flow payment dates are determined from other inputs.

## LastCouponDate

Last coupon date of a bond before the maturity date; used when bond has an irregular last coupon period. In the absence of a specified FirstCouponDate, a specified LastCouponDate determines the coupon structure of the bond. The coupon structure of a bond is truncated at the LastCouponDate, regardless of where it falls, and is followed only by the bond's maturity cash flow date.

Default: If you do not specify a LastCouponDate, the cash flow payment dates are determined from other inputs.

## StartDate

Date when a bond actually starts (the date from which a bond cash flow is considered). To make an instrument forward-starting, specify this date as a future date. If you do not specify StartDate, the effective start date is the Settle date.

## Face

Face or par value.
Default: 100

## Parameter-Value Pairs

Enter the following inputs only as parameter/value pairs.

## CompoundingFrequency

Compounding frequency for yield calculation. By default, SIA bases (0-7) and BUS/252 use a semiannual compounding convention and ICMA bases ( $8-12$ ) use an annual compounding convention.

## DiscountBasis

Basis used to compute the discount factors for computing the yield. The default behavior is for SIA bases to use the actual/actual day count to compute discount factors. If you use ICMA day counts and BUS/252, the specified bases are used.

## Output Arguments

## Spread

Static spread to benchmark, in basis points.

## Examples

## Compute the Static Spread Over a Spot Curve

This example shows how to compute a Federal National Mortgage Association (FNMA) 4 $3 / 8$ spread over a Treasury spot curve and plot the results.

```
RefMaturity = [datenum('02/27/2003');
    datenum('05/29/2003');
    datenum('10/31/2004');
    datenum('11/15/2007');
    datenum('11/15/2012');
    datenum('02/15/2031')];
RefCpn = [0;
    0;
    2.125;
    3;
    4;
    5.375] / 100;
RefPrices = [99.6964;
    99.3572;
    100.3662;
```

```
            99.4511;
            99.4299;
            106.5756];
RefBonds = [RefPrices, RefMaturity, RefCpn];
Settle = datenum('26-Nov-2002');
[ZeroRates, CurveDates] = zbtprice(RefBonds(:, 2:end), ...
RefPrices, Settle)
% FNMA 4 3/8 maturing 10/06 at 4.30 pm Tuesday
Price = 105.484;
Coupon = 0.04375;
Maturity = datenum('15-Oct-2006');
% All optional inputs are supposed to be accounted by default,
% except the accrued interest under 30/360 (SIA), so:
Period = 2;
Basis = 1;
SpotInfo = [CurveDates, ZeroRates];
% Compute static spread over treasury curve, taking into account
% the shape of curve as derived by bootstrapping method embedded
% within bndspread.
SpreadInBP = bndspread(SpotInfo, Price, Coupon, Settle, ...
Maturity, Period, Basis)
plot(CurveDates, ZeroRates*100, 'b', CurveDates, ...

## bndtotalreturn

Total return of fixed-coupon bond

## Syntax

[BondEquiv,EffectiveRate] = bndtotalreturn(Price, CouponRate, Settle, Maturity, ReinvestRate) [BondEquiv,EffectiveRate] = bndtotalreturn(Price, CouponRate, Settle,Maturity, ReinvestRate, Name, Value)

## Description

[BondEquiv,EffectiveRate] = bndtotalreturn(Price, CouponRate, Settle, Maturity, ReinvestRate) calculates the total return for fixed-coupon bonds to maturity or to a specific investment horizon.
[BondEquiv,EffectiveRate] = bndtotalreturn(Price, CouponRate,Settle, Maturity, ReinvestRate, Name, Value) calculates the total return for fixed-coupon bonds to maturity or to a specific investment horizon with additional options specified by one or more Name, Value pair arguments.

## Input Arguments

## Price

NINST-by- 1 matrix for the clean price at the settlement date.

## CouponRate

NINST-by-1 matrix for the coupon rate in decimal form.

## Settle

NINST-by-1 vector for the settlement date of the fixed-coupon bond.

## Maturity

NINST-by- 1 vector of dates representing the maturity date of the fixed-coupon bond.

## ReinvestRate

NINST-by-1 vector for the reinvestment rate in decimal form. This is the rate earned by reinvesting the coupons.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

## 'HorizonDate'

Investment horizon date. If unspecified, the total return is calculated to maturity.

## Default:

## 'HorizonPrice'

Price at investment horizon date. If unspecified, the price at horizon is calculated based on the reinvestment rate. If the horizon date equals the maturity date, this price is ignored and the total return to maturity is calculated based on the face value.

## Default:

## 'Period'

Number of coupon payments per year. Values are: 0, 1, 2, 3, 4, 6, 12.

## Default: 2

## 'Basis'

NINST-by- 1 vector representing day-count basis:

- $0=$ actual/actual
- 1 = 30/360 (SIA)
- 2 = actual $/ 360$
- $3=$ actual/365
- $4=30 / 360$ (BMA)
- $5=30 / 360$ (ISDA)
- $6=30 / 360$ (European)
- $7=$ actual/365 (Japanese)
- $8=$ actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- $10=\mathrm{actual} / 365$ (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see basis.
Default: 0 (actual/actual)

## 'EndMonthRule'

Value for the end-of-month rule.

- 0 - Rule is not in effect for the bond(s).
- 1 - Rule is in effect for the bond(s). This means that a security that pays coupon interest on the last day of the month will always make payment on the last day of the month.

Default: 1 (in effect)

## 'IssueDate'

Bond issue date.
Default: If you do not specify an IssueDate, the cash flow payment dates are determined from other inputs.

## 'FirstCouponDate'

Irregular or normal first coupon date.

Default: If you do not specify a FirstCouponDate, the cash flow payment dates are determined from other inputs.

## 'LastCouponDate'

Irregular or normal last coupon date.
Default: If you do not specify a LastCouponDate, the cash flow payment dates are determined from other inputs.

## 'StartDate'

Forward starting date of payments.
Default: If you do not specify a StartDate, the effective start date is the Settle date.

```
'Face'
```

Face value of the bond.
Default: 100

## 'CompoundingFrequency '

Compounding frequency for yield calculation. By default, SIA bases (0-7) and BUS/252 use a semi-annual compounding convention and ICMA bases (8-12) use an annual compounding convention.

## Default:

## 'DiscountBasis'

Basis used to compute the discount factors for computing the yield. The default behavior is for SIA bases to use the actual/actual day count to compute discount factors, and for ICMA day counts $(8-12)$ and BUS / 252 to use the specified basis.

## Default:

## Output Arguments

## BondEquiv

NUMBONDS-by- 1 vector for the total return in bond equivalent basis.

## EffectiveRate

NUMBONDS-by- 1 vector for the total return in effective rate basis.

## Examples

## Compute the Total Return of a Fixed-Coupon Bond

Use bndtotalreturn to compute the total return for a fixed-coupon bond, given an investment horizon date.

Define fixed-coupon bond.

```
Price = 101;
CouponRate = 0.05;
Settle = '15-Nov-2011';
Maturity = '15-Nov-2031';
ReinvestRate = 0.04;
```

Calculate the total return to maturity.

```
[BondEquiv, EffectiveRate] = bndtotalreturn(Price, CouponRate, ...
```

Settle, Maturity, ReinvestRate)

## BondEquiv =

0.0460

EffectiveRate =
0.0466

Specify an investment horizon.

```
HorizonDate = '15-Nov-2021';
[BondEquiv, EffectiveRate] = bndtotalreturn(Price, CouponRate, ...
Settle, Maturity, ReinvestRate, 'HorizonDate', HorizonDate)
```

BondEquiv =
0.0521

## EffectiveRate =

0.0528

Perform scenario analysis on the reinvestment rate.
ReinvestRate $=$ [0.03; 0.035; 0.04; 0.045; 0.05];
[BondEquiv, EffectiveRate] = bndtotalreturn(Price, CouponRate, ... Settle, Maturity, ReinvestRate, 'HorizonDate', HorizonDate)

BondEquiv =
0.0557
0.0538
0.0521
0.0505
0.0490

EffectiveRate =
0.0565
0.0546
0.0528
0.0511
0.0496

## bndyield

Yield to maturity for fixed-income security

## Syntax

```
Yield = bndyield(Price, CouponRate, Settle, Maturity)
Yield = bndyield(Price, CouponRate, Settle, Maturity,
Period, Basis, EndMonthRule, IssueDate, FirstCouponDate,
LastCouponDate, StartDate, Face)
Yield = bndyield(Price, CouponRate, Settle, Maturity,
'ParameterName', ParameterValue, ...)
```

## Description

Yield = bndyield(Price, CouponRate, Settle, Maturity), given NUMBONDS bonds with SIA date parameters and clean prices (excludes accrued interest), returns the bond equivalent yields to maturity.

Yield = bndyield(Price, CouponRate, Settle, Maturity, Period, Basis, EndMonthRule, IssueDate, FirstCouponDate, LastCouponDate, StartDate, Face) bonds with SIA date parameters and clean prices (excludes accrued interest) and optional inputs, returns the bond equivalent yields to maturity.

```
Yield = bndyield(Price, CouponRate, Settle, Maturity,
'ParameterName', ParameterValue, ...) accepts optional inputs as one or
more comma-separated parameter/value pairs. 'ParameterName' is the name of
the parameter inside single quotes. ParameterValue is the value corresponding to
'ParameterName '. Specify parameter/value pairs in any order. Names are case-
insensitive.
```

Note: All nonscalar or empty matrix input arguments must be either NUMBONDS-by-1 or 1-by-NUMBONDS conforming vectors. Fill in unspecified entries input vectors with NaNs. Dates can be serial date numbers or date strings.

## Input Arguments

## Price

Clean price of the bond (current price without accrued interest).

## CouponRate

Decimal number indicating the annual percentage rate used to determine the coupons payable on a bond.

## Settle

Settlement date. A vector of serial date numbers or date strings. Settle must be earlier than Maturity.

## Maturity

Maturity date. A vector of serial date numbers or date strings.

## Ordered Input or Parameter-Value Pairs

Enter the following inputs using an ordered syntax or as parameter/value pairs. You cannot mix ordered syntax with parameter/value pairs.

## Period

Coupons per year of the bond. A vector of integers. Values are 0, 1, 2, 3, 4, 6, and 12.

## Default: 2

## Basis

Day-count basis of the instrument. A vector of integers.

- $0=$ actual/actual
- $1=30 / 360$ (SIA)
- 2 = actual/360
- 3 = actual/365
- $4=30 / 360$ (PSA)
- $5=30 / 360$ (ISDA)
- $6=30 / 360$ (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- $10=$ actual/365 (ICMA)
- $11=30 / 360 \mathrm{E}$ (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see basis.
Default: 0

## EndMonthRule

End-of-month rule. A vector. This rule applies only when Maturity is an end-of-month date for a month having 30 or fewer days. $0=$ ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month. $1=$ set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

Default: 1

## IssueDate

Issue date for a bond.
Default: If you do not specify an IssueDate, the cash flow payment dates are determined from other inputs.

## FirstCouponDate

Date when a bond makes its first coupon payment; used when bond has an irregular first coupon period. When FirstCouponDate and LastCouponDate are both specified, FirstCouponDate takes precedence in determining the coupon payment structure.

Default: If you do not specify a FirstCouponDate, the cash flow payment dates are determined from other inputs.

## LastCouponDate

Last coupon date of a bond before the maturity date; used when bond has an irregular last coupon period. In the absence of a specified FirstCouponDate, a specified LastCouponDate determines the coupon structure of the bond. The coupon structure of a bond is truncated at the LastCouponDate, regardless of where it falls, and is followed only by the bond's maturity cash flow date.

Default: If you do not specify a LastCouponDate, the cash flow payment dates are determined from other inputs.

## StartDate

Date when a bond actually starts (the date from which a bond cash flow is considered). To make an instrument forward-starting, specify this date as a future date. If you do not specify StartDate, the effective start date is the Settle date.

Default: If you do not specify StartDate, the effective start date is the Settle date.

## Face

Face or par value.
Default: 100

## Parameter-Value Pairs

Enter the following inputs only as parameter/value pairs.

## CompoundingFrequency

Compounding frequency for yield calculation. By default, SIA bases (0-7) and BUS/252 use a semiannual compounding convention and ICMA bases (8-12) use an annual compounding convention.

Default: SIA bases (0-7) and BUS/252 use a semiannual compounding convention and ICMA bases ( $8-12$ ) use an annual compounding convention.

## DiscountBasis

Basis used to compute the discount factors for computing the yield. The default behavior is for SIA bases to use the actual/actual day count to compute discount factors. If you use ICMA day counts and BUS/252, the specified bases are used.

Default: SIA bases use the actual/actual day count to compute discount factors.

## LastCouponInterest

Compounding convention for computing the yield of a bond in the last coupon period. This computation is based on only the last coupon and the face value to be repaid. Acceptable values are simple or compound.

Default: compound

## Output Arguments

## Yield

NUMBONDS-by- 1 vector of the yield to maturity with semiannual compounding.

## Examples

## Compute Yield to Maturity for a Treasury Bond

This example shows how to compute the yield of a Treasury bond at three different price values.

```
Price = [95; 100; 105];
CouponRate = 0.05;
Settle = '20-Jan-1997';
Maturity = '15-Jun-2002';
Period = 2;
Basis = 0;
Yield = bndyield(Price, CouponRate, Settle,...
Maturity, Period, Basis)
Yield =
    0.0610
    0.0500
    0.0396
```

- "Bond Portfolio for Hedging Duration and Convexity" on page 10-7
- "Pricing Functions" on page 2-29
- "Sensitivity of Bond Prices to Interest Rates" on page 10-3

## More About

## Algorithms

For SIA conventions, the Price and Yield are related by the formula:

```
Price + Accrued Interest = sum(Cash_Flow*(1+Yield/2)^(-Time))
```

where the sum is over the bond's cash flows and corresponding times in units of semiannual coupon periods.

For ICMA conventions, the Price and Yield are related by the formula:

```
Price + Accrued Interest = sum(Cash_Flow*(1+Yield)^(-Time))
```

## Algorithms

For SIA conventions, the following formula defines bond price and yield:

$$
P V=\frac{C F}{\left(1+\frac{z}{f}\right)^{T F}},
$$

where:

| $P V=$ | Present value of a cash flow. |
| :--- | :--- |
| $C F=$ | The cash flow amount. |
| $z=$ | The risk-adjusted annualized rate or yield corresponding to a given <br> cash flow. The yield is quoted on a semiannual basis. |
| $f=$ | The frequency of quotes for the yield. |
| $T F=$ | Time factor for a given cash flow. Time is measured in semiannual <br> periods from the settlement date to the cash flow date. In computing <br> time factors, use SIA actual/actual day count conventions for all time <br> factor calculations. |

For ICMA conventions, the frequency of annual coupon payments determines bond price and yield.

## Introduced before R2006a

## bolling

Bollinger band chart

## Syntax

```
bolling(Asset, Samples, Alpha, Width)
[Movavgv, UpperBand, LowerBand] = bolling(Asset, Samples, Alpha,
Width)
```

## Arguments

| Asset | Vector of asset data. |
| :--- | :--- |
| Samples | Number of samples to use in computing the moving average. |
| Alpha | (Optional) Exponent used to compute the element weights of the <br> moving average. Default $=0$ (simple moving average). |
| Width | (Optional) Number of standard deviations to include in the <br> envelope. A multiplicative factor specifying how tight the bands <br> should be around the simple moving average. Default $=2$. |

## Description

bolling(Asset, Samples, Alpha, Width) plots Bollinger bands for given Asset data. This form of the function does not return any data.
[Movavgv, UpperBand, LowerBand] = bolling(Asset, Samples, Alpha, Width) returns Movavgv with the moving average of the Asset data, UpperBand with the upper band data, and LowerBand with the lower band data. This form of the function does not plot any data.

Note The standard deviations are normalized by $\mathrm{N}-1$, where $\mathrm{N}=$ the sequence length.

## Examples

If Asset is a column vector of closing stock prices
bolling(Asset, 20, 1)
plots linear 20-day moving average Bollinger bands based on the stock prices.
[Movavgv, UpperBand, LowerBand] = bolling(Asset, 20, 1)
returns Movavgv, UpperBand, and LowerBand as vectors containing the moving average, upper band, and lower band data, without plotting the data.

## More About

- "Technical Indicators" on page 16-2

## bollinger

Time series Bollinger band

## Syntax

[mid, uppr, lowr] = bollinger(data, wsize, wts, nstd)

```
[midfts, upprfts, lowrfts] = bollinger(tsobj, wsize, wts, nstd)
```

## Arguments

| data | Data vector. |
| :--- | :--- |
| wsize | (Optional) Window size. Default = 20. |
| wts | (Optional) Weight factor. Determines the type of moving average <br> used. Default = 0 (box). $1=$ linear. |
| nstd | (Optional) Number of standard deviations for upper and lower <br> bands. Default $=2$. |
| tsobj | Financial time series object. |

## Description

[mid, uppr, lowr] = bollinger(data, wsize, wts, nstd) calculates the middle (mid), upper (uppr), and lower (lowr) bands that make up the Bollinger bands from the vector data.
mid is the vector that represents the middle band, a simple moving average with a window size of wsize. uppr and lowr are vectors that represent the upper and lower bands. uppr is a vector representing the upper band that is +nstd times. lowr is a vector representing the lower band that is -nstd times.
[midfts, upprfts, lowrfts] = bollinger(tsobj, wsize, wts, nstd) calculates the middle, upper, and lower bands that make up the Bollinger bands from a financial time series object tsobj.
midfts is a financial time series object that represents the middle band for all series in tsobj. Both upprfts and lowrfts are financial time series objects that represent the upper and lower bands of all series, which are +nstd times and -nstd times moving standard deviations away from the middle band.

## Examples

## Create a Bollinger Bands Plot

This example shows how to compute the Bollinger bands for Disney stock closing prices and plot the results.

```
load disney.mat
[dis_Mid,dis_Uppr,dis_Lowr]= bollinger(dis);
dis_CloseBolling = [dis_Mid.CLOSE, dis_Uppr.CLOSE,...
dis_Lowr.CLOSE];
plot(dis_CloseBolling)
title('Bōllinger Bands for Disney Closing Prices')
```

Introduced before R2006a

## boxcox

Box-Cox transformation

## Syntax

```
[transdat, lambda] = boxcox(data)
[transfts, lambda] = boxcox(tsobj)
transdat = boxcox(lambda, data)
transfts = boxcox(lambda, tsobj)
```

## Arguments

| data | Data vector. Must be positive and specified as a column data vector. |
| :--- | :--- |
| tsobj | Financial time series object. |

## Description

boxcox transforms nonnormally distributed data to a set of data that has approximately normal distribution. The Box-Cox transformation is a family of power transformations.

If $\lambda$ is not $=0$, then

$$
\operatorname{data}(\lambda)=\frac{d a t a^{\lambda}-1}{\lambda}
$$

If $\lambda$ is $=0$, then

$$
\operatorname{data}(\lambda)=\log (d a t a)
$$

The logarithm is the natural logarithm (log base e). The algorithm calls for finding the $\lambda$ value that maximizes the Log-Likelihood Function (LLF). The search is conducted using fminsearch.
[transdat, lambda] = boxcox(data) transforms the data vector data using the Box-Cox transformation method into transdat. It also estimates the transformation parameter $\lambda$.
[transfts, lambda] = boxcox(tsojb) transforms the financial time series object tsobj using the Box-Cox transformation method into transfts. It also estimates the transformation parameter $\lambda$.

If the input data is a vector, lambda is a scalar. If the input is a financial time series object, lambda is a structure with fields similar to the components of the object; for example, if the object contains series names Open and Close, lambda has fields lambda. Open and lambda.Close.
transdat = boxcox(lambda, data) and transfts = boxcox(lambda, tsobj) transform the data using a certain specified $\lambda$ for the Box-Cox transformation. This syntax does not find the optimum $\lambda$ that maximizes the LLF.

## Introduced before R2006a

## busdate

Next or previous business day

## Syntax

Busday = busdate(Date, DirFlag, Holiday, Weekend)

## Arguments

| Date | Reference date. Enter scalar, vector, or matrix of reference business <br> dates as serial date numbers or date strings. |
| :--- | :--- |
| DirFlag | (Optional) String or cell array of strings of business day convention <br> with possible values: follow (default), modifiedfollow, <br> previous, modifiedprevious. Also, DirFlag can be a scalar, <br> vector, or matrix of search directions, where Next is DIREC = 1 <br> (default) or Previous is DIREC $=-1$. |
| Holiday | (Optional) Vector of holidays and nontrading-day dates. All dates <br> in Holiday must be the same format: either serial date numbers or <br> date strings. (Using serial date numbers improves performance.) <br> If Holiday is not specified, the non-trading day default vector is <br> determined by the routine holidays function. |
| Weekend | (Optional) Vector of length 7, containing 0 and 1, the value <br> 1 indicating weekend days. The first element of this vector <br> corresponds to Sunday. Thus, when Saturday and Sunday form the <br> weekend (default), Weekend = [1 0 0 0 0 0 1]. |

## Description

Busday = busdate(Date, DirFlag, Holiday, Weekend) returns the scalar, vector, or matrix of the next or previous business day(s), depending on Holiday.

Use the function datestr to convert serial date numbers to formatted date strings.

## Examples

```
Example 1.
Busday = busdate('3-Jul-2001', 1)
Busday =
    731037
datestr(Busday)
ans =
05-Jul-2001
```

Example 2. You can indicate that Saturday is a business day by appropriately setting the Weekend argument.

```
Weekend = [1 0 0 0 0 0 0];
```

July 4, 2003 falls on a Friday. Use busdate to verify that Saturday, July 5, is actually a business day.

```
Date = datestr(busdate('3-Jul-2003', 1, [], Weekend))
```

## More About

- "Trading Calendars User Interface" on page 15-2

## See Also

holidays
Introduced before R2006a

## busdays

Business days in serial date format

## Syntax

```
bdates = busdays(sdate, edate, bdmode)
bdates = busdays(sdate, edate, bdmode, holvec)
```

## Arguments

| sdate | Start date in string or serial date format. |
| :---: | :---: |
| edate | End date in string or serial date format. |
| bdmode | (Optional) Frequency of business days: <br> - DAILY, Daily, daily, D, d, 1 (default) <br> - WEEKLY, Weekly, weekly, W, w, 2 <br> - MONTHLY, Monthly, monthly, M, m, 3 <br> - QUARTERLY, Quarterly, quarterly, Q, q, 4 <br> - SEMIANNUAL, Semiannual, semiannual, S, s, 5 <br> - ANNUAL, Annual, annual, A, a, 6 <br> Strings must be enclosed in single quotation marks. |
| holvec | (Optional) Holiday dates vector in string or serial date format. Using a holvec value of NaN uses a holiday list that has no dates. |

## Description

bdates = busdays(sdate, edate, bdmode) generates a vector of business days, bdates, in serial date format between the last business date of the period that contains the start date, and the last business date of period that contains the end date. If holvec is not supplied, the dates are generated based on United States holidays. If you do not supply bdmode, busdays generates a daily vector.

For example:

```
vec = datestr(busdays('1/2/01','1/9/01','weekly'))
```

vec =
05-Jan-2001
12-Jan-2001
The end of the week is considered to be a Friday. Between 1/2/01 (Monday) and 1/9/01 (Tuesday), there is only one end-of-week day, 1/5/01 (Friday).

Because $1 / 9 / 01$ is part of the following week, the following Friday ( $1 / 12 / 01$ ) is also reported.
bdates = busdays(sdate, edate, bdmode, holvec) lets you supply a vector of holidays, holvec, used to generate business days. holvec can either be in serial date format or date string format. If you use this syntax, you must supply the frequency bdmode.

The output, bdates, is a column vector of business dates in serial date format.
Setting holvec to ' ' (empty string) or [] (empty vector) results in BUSDAYS using a default holiday schedule. The default holiday schedule is the NYSE holiday schedule.

## candle

Candlestick chart

## Syntax

```
candle(HighPrices, LowPrices, ClosePrices, OpenPrices)
candle(HighPrices, LowPrices, ClosePrices, OpenPrices,
Color, Dates, Dateform)
```

## Arguments

| HighPrices | High prices for a security. A column vector. |
| :--- | :--- |
| LowPrices | Low prices for a security. A column vector. |
| ClosePrices | Closing prices for a security. A column vector. |
| OpenPrices | Opening prices for a security. A column vector. |
| Color | (Optional) Candlestick color. A string. MATLAB software supplies a <br> default color if none is specified. The default color differs depending <br> on the background color of the figure window. See ColorSpec in <br> the MATLAB documentation for color names. |
| Dates | (Optional) Column vector of dates for user specified X-axis tick <br> labels. |
| Dateform | (Optional) Date string format used as the $x$-axis tick labels. (See <br> datetick in the MATLAB documentation.) You can specify a <br> dateform only when tsobj does not contain time-of-day data. If <br> tsobj contains time-of-day data, dateform is restricted to 'dd - <br> mmm-yyyy HH: MM '. |

## Description

candle(HighPrices, LowPrices, ClosePrices, OpenPrices) plots a candlestick chart given column vectors with the high, low, closing, and opening prices of a security.

If the closing price is greater than the opening price, the body (the region between the opening and closing price) is unfilled.

If the opening price is greater than the closing price, the body is filled.
candle(HighPrices, LowPrices, ClosePrices, OpenPrices, Color, Dates, Dateform) plots a candlestick chart given column vectors with the high, low, closing, and opening prices of a security. In addition, the optional arguments Color, Dates, and Dateform specify the color of the candle box and the date string format used as the $x$ axis tick labels.

## Examples

## Create a Candlestick Chart

This example shows how to create a candlestick chart, with blue candles, for the most recent 21 days in disney.mat.

```
load disney;
candle(dis_HIGH(end-20:end), dis_LOW(end-20:end), dis_CLOSE(end-20:end),...
dis_OPEN(end-20:end), 'b');
```

- "Charting Financial Data" on page 2-12

## See Also

bolling | candle | dateaxis | highlow | movavg | pointfig

Introduced before R2006a

## candle (fts)

Time series candle plot

## Syntax

```
candle(tsobj)
candle(tsobj, color)
candle(tsobj, color, dateform)
candle(tsobj, color, dateform, 'ParameterName', ParameterValue, ...)
hcdl = candle(tsobj, color, dateform, 'ParameterName',
ParameterValue, ...)
```

## Arguments

| tsobj | Financial time series object |
| :--- | :--- |
| color | (Optional) A three-element row vector representing RGB or a color <br> identifier. (See plot in the MATLAB documentation.) |
| dateform | (Optional) Date string format used as the $x$-axis tick labels. (See <br> datetick in the MATLAB documentation.) You can specify a <br> dateform only when tsobj does not contain time-of-day data. If <br> tsobj contains time-of-day data, dateform is restricted to ' dd- <br> mmm-yyyy HH:MM ' |

## Description

candle(tsobj) generates a candle plot of the data in the financial time series object tsobj. tsobj must contain at least four data series representing the high, low, open, and closing prices. These series must have the names High, Low, Open, and Close (caseinsensitive).
candle(tsobj, color) additionally specifies the color of the candle box.
candle(tsobj, color, dateform) additionally specifies the date string format used as the $x$-axis tick labels. See datestr for a list of date string formats.
candle(tsobj, color, dateform, 'ParameterName', ParameterValue, ...) indicates the actual names of the required data series if the data series do not have the default names. 'ParameterName' can be

- HighName: high prices series name
- LowName: low prices series name
- OpenName: open prices series name
- CloseName: closing prices series name
hcdl = candle(tsobj, color, dateform, 'ParameterName',
ParameterValue, ...) returns the handle to the patch objects and the line object that make up the candle plot. hdcl is a three-element column vector representing the handles to the two patches and one line that forms the candle plot.

## Examples

## Create a Candle Plot for a Financial Time Series Object

This example shows how to create a candle plot for Disney stock for the dates March 31, 1998 through April 30, 1998.

```
load disney.mat
candle(dis('3/31/98::4/30/98'))
title('Disney 3/31/98 to 4/30/98')
```

## cdai

Accrued interest on certificate of deposit

## Syntax

AccrInt = cdai(CouponRate, Settle, Maturity, IssueDate, Basis)

## Arguments

| CouponRate | Annual interest rate in decimal. |
| :---: | :---: |
| Settle | Settlement date. Settle must be earlier than Maturity. |
| Maturity | Maturity date. |
| IssueDate | Issue date. |
| Basis | (Optional) Day-count basis of the instrument. <br> - $0=$ actual/actual (default) <br> - $1=30 / 360$ (SIA) <br> - 2 = actual/ 360 <br> - 3 = actual $/ 365$ <br> - $4=30 / 360$ (BMA) <br> - $5=30 / 360$ (ISDA) <br> - $6=30 / 360$ (European) <br> - 7 = actual/365 (Japanese) <br> - $8=$ actual/actual (ICMA) <br> - 9 = actual/360 (ICMA) <br> - $10=\mathrm{actual} / 365$ (ICMA) <br> - $11=30 / 360 \mathrm{E}$ (ICMA) <br> - 12 = actual/365 (ISDA) <br> - 13 = BUS/252 <br> For more information, see basis. |

Each required input must be some certificates of deposit (NCDS)-by-1 or 1-by-NCDS conforming vector or scalar. The optional Basis argument may be either a NCDS-by- 1 or a 1 -by-NCDS vector, a scalar, or the empty matrix ([ ]).

## Description

AccrInt = cdai(CouponRate, Settle, Maturity, IssueDate, Basis) computes the accrued interest on a certificate of deposit.

Accrint represents the accrued interest per $\$ 100$ of face value.
This function assumes that the certificates of deposit pay interest at maturity. Because of the simple interest treatment of these securities, the function is best used for short-term maturities (less than 1 year). The default simple interest calculation is the actual/360 convention (SIA).

## Examples

## Find the Accrued Interest on a Certificate of Deposit

This example shows how to compute the accrued interest due, given a certificate of deposit with the following characteristics.

```
CouponRate = 0.05;
Settle = '02-Jan-02';
Maturity = '31-Mar-02';
IssueDate = '1-Oct-01';
AccrInt = cdai(CouponRate, Settle, Maturity, IssueDate)
AccrInt =

## cdprice

Price of certificate of deposit

## Syntax

[Price, AccrInt] = cdprice(Yield, CouponRate, Settle, Maturity, IssueDate, Basis)

## Arguments

| Yield | Simple yield to maturity over the basis denominator. |
| :---: | :---: |
| CouponRate | Coupon interest rate in decimal. |
| Settle | Settlement date. Settle must be earlier than Maturity. |
| Maturity | Maturity date. |
| IssueDate | Issue date. |
| Basis | (Optional) Day-count basis of the instrument. <br> - $0=$ actual/actual (default) <br> - $1=30 / 360$ (SIA) <br> - 2 = actual $/ 360$ <br> - 3 = actual $/ 365$ <br> - $4=30 / 360$ (BMA) <br> - $5=30 / 360$ (ISDA) <br> - $6=30 / 360$ (European) <br> - 7 = actual/365 (Japanese) <br> - $8=$ actual/actual (ICMA) <br> - $9=$ actual/360 (ICMA) <br> - $10=$ actual/365 (ICMA) <br> - $11=30 / 360 \mathrm{E}$ (ICMA) <br> - 12 = actual/365 (ISDA) |

## - 13 = BUS/252

For more information, see basis.
Each required input must be some certificates of deposit (NCDS)-by-1 or 1-by-NCDS conforming vector or scalar. The optional Basis argument may be either a NCDS-by- 1 or a 1 -by-NCDS vector, a scalar, or the empty matrix ([ ]).

## Description

[Price, AccrInt] = cdprice(Yield, CouponRate, Settle, Maturity, IssueDate, Basis) computes the price of a certificate of deposit given its yield.

Price is the clean price of the certificate of deposit per $\$ 100$ of face value.
AccruedInt is the accrued interest payable at settlement per unit of face value.
This function assumes that the certificates of deposit pay interest at maturity. Because of the simple interest treatment of these securities, the function is best used for short-term maturities (less than 1 year). The default simple interest calculation is the actual/360 convention.

## Examples

## Compute the Price and Accrued Interest for a Certificate of Deposit

This example shows how to compute the price and the accrued interest due on the settlement date, given a certificate of deposit with the following characteristics.

```
Yield = 0.0525;
CouponRate = 0.05;
Settle = '02-Jan-02';
Maturity = '31-Mar-02';
IssueDate = '1-Oct-01';
[Price, AccruedInt] = cdprice(Yield, CouponRate, Settle, ...
Maturity, IssueDate)
```

## cev

Construct constant elasticity of variance models (objects of class CEV)

## Syntax

CEV $=\operatorname{cev}($ Return, Alpha, Sigma)
CEV = cev(Return, Alpha, Sigma, 'Name1', Value1, 'Name2', Value2, ...)

## Class

CEV

## Description

This constructor creates and displays CEV objects, which derive from the SDELD (SDE with drift rate expressed in linear form) class. Use CEV objects to simulate sample paths of NVARS state variables driven by NBROWNS Brownian motion sources of risk over NPERIODS consecutive observation periods, approximating continuous-time stochastic processes.

This method allows you to simulate any vector-valued SDE of the form:

$$
d X_{t}=\mu(t) X_{t} d t+D\left(t, X_{t}^{\alpha(t)}\right) V(t) d W_{t}
$$

where:

- $X_{t}$ is an NVARS-by- 1 state vector of process variables.
- $\mu$ is an NVARS-by-NVARS (generalized) expected instantaneous rate of return matrix.
- $D$ is an NVARS-by-NVARS diagonal matrix, where each element along the main diagonal is the corresponding element of the state vector raised to the corresponding power of $a$.
- $V$ is an NVARS-by-NBROWNS instantaneous volatility rate matrix.
- $d W_{t}$ is an NBROWNS-by-1 Brownian motion vector.

## Input Arguments

Specify required input parameters as one of the following types:

- A MATLAB array. Specifying an array indicates a static (non-time-varying) parametric specification. This array fully captures all implementation details, which are clearly associated with a parametric form.
- A MATLAB function. Specifying a function provides indirect support for virtually any static, dynamic, linear, or nonlinear model. This parameter is supported via an interface, because all implementation details are hidden and fully encapsulated by the function.

Note: You can specify combinations of array and function input parameters as needed.
Moreover, a parameter is identified as a deterministic function of time if the function accepts a scalar time $t$ as its only input argument. Otherwise, a parameter is assumed to be a function of time $t$ and state $X(t)$ and is invoked with both input arguments.

The required input parameters are:

| Return | Return represents the parameter $\mu$. <br> If you specify Return as an array, it is a NVARS-by-NVARS <br> 2-dimensional matrix that represents the expected (mean) <br> instantaneous rate of return. As a deterministic function of time, <br> when Return is called with a real-valued scalar time $t$ as its only <br> input, Return must produce an NVARS-by-NVARS matrix. <br> If you specify Return as a function of time and state, it calculates the <br> expected instantaneous rate of return. This function must generate an <br> NVARS-by-NVARS matrix when invoked with two inputs: |
| :--- | :--- |
|  | - A real-valued scalar observation time $t$. <br> $-\quad$ An NVARS-by-1 state vector $X_{t}$. |
| Alpha | Alpha determines the format of the parameter $D$. <br> If you specify Alpha as an array, it represents an NVARS-by-1 column <br> vector of exponents. As a deterministic function of time, when Alpha |

|  | is called with a real-valued scalar time $t$ as its only input, Alpha <br> must produce an NVARS-by-1 matrix. <br> If you specify it as a function of time and state, Alpha must return <br> an NVARS-by-1 column vector of exponents when invoked with two <br> inputs: <br> $-\quad$ A real-valued scalar observation time $t$. <br> $-\quad$ An NVARS-by-1 state vector $X_{t}$. |
| :--- | :--- |
| Sigma | Sigma represents the parameter $V$. <br> If you specify Sigma as an array, it represents an NVARS-by-NBROWNS <br> 2-dimensional matrix of instantaneous volatility rates. In this case, <br> each row of Sigma corresponds to a particular state variable. Each <br> column of Sigma corresponds to a particular Brownian source of <br> uncertainty, and associates the magnitude of the exposure of state <br> variables with sources of uncertainty. As a deterministic function of <br> time, when Sigma is called with a real-valued scalar time t as its only <br> input, Sigma must produce an NVARS-by-NBROWNS matrix. <br> If you specify it as a function of time and state, Sigma must generate |
| an NVARS-by-NBROWNS matrix of volatility rates when invoked with |  |
| two inputs: |  |
| - A real-valued scalar observation time $t$. |  |
| $-\quad$ An NVARS-by-1 state vector $X_{t}$. |  |

Note: Although the constructor does not enforce restrictions on the signs of these input arguments, each argument is usually specified as a positive value.

## Optional Input Arguments

Specify optional inputs as matching parameter name/value pairs as follows:

- Specify the parameter name as a character string, followed by its corresponding value.
- You can specify parameter name/value pairs in any order.
- Parameter names are case insensitive.
- You can specify unambiguous partial string matches.

Valid parameter names are:
\(\left.\left.$$
\begin{array}{|l|l|}\hline \text { StartTime } & \begin{array}{l}\text { Scalar starting time of the first observation, applied to all state } \\
\text { variables. If you do not specify a value for StartTime, the default } \\
\text { is 0. }\end{array} \\
\hline \text { StartState } & \begin{array}{l}\text { Scalar, NVARS-by-1 column vector, or NVARS-by-NTRIALS matrix of } \\
\text { initial values of the state variables. } \\
\text { If StartState is a scalar, cev applies the same initial value to all } \\
\text { state variables on all trials. } \\
\text { If StartState is a column vector, cev applies a unique initial } \\
\text { value to each state variable on all trials. } \\
\text { If StartState is a matrix, cev applies a unique initial value to } \\
\text { each state variable on each trial. } \\
\text { If you do not specify a value for StartState, all variables start at } \\
1 .\end{array} \\
\hline \text { Correlation } & \begin{array}{l}\text { Correlation between Gaussian random variates drawn to } \\
\text { generate the Brownian motion vector (Wiener processes). Specify } \\
\text { Correlation as an NBROWNS-by-NBROWNS positive semidefinite } \\
\text { matrix, or as a deterministic function C( } t \text { ) that accepts the current } \\
\text { time } t \text { and returns an NBROWNS-by-NBROWNS positive semidefinite } \\
\text { correlation matrix. }\end{array} \\
\text { A Correlation matrix represents a static condition. }\end{array}
$$\right\} \begin{array}{l}As a deterministic function of time, Correlation allows you to <br>

specify a dynamic correlation structure.\end{array}\right\}\)| If you do not specify a value for Correlation, the default is an |
| :--- |
| NBROWNS-by-NBROWNS identity matrix representing independent |
| Gaussian processes. |

## Output Arguments

| CEV | Object of class CEV with the following displayed parameters: <br> - StartTime: Initial observation time <br> - StartState: Initial state at time StartTime <br> - Correlation: Access function for the Correlation input argument, callable as a function of time <br> - Drift: Composite drift-rate function, callable as a function of time and state <br> - Diffusion: Composite diffusion-rate function, callable as a function of time and state <br> - Simulation: A simulation function or method <br> - Return: Access function for the input argument Return, callable as a function of time and state <br> - Alpha: Access function for the input argument Alpha, callable as a function of time and state <br> - Sigma: Access function for the input argument Sigma, callable as a function of time and state |
| :---: | :---: |

## More About

## Algorithms

When you specify the required input parameters as arrays, they are associated with a specific parametric form. By contrast, when you specify either required input parameter as a function, you can customize virtually any specification.

Accessing the output parameters with no inputs simply returns the original input specification. Thus, when you invoke these parameters with no inputs, they behave like simple properties and allow you to test the data type (double vs. function, or equivalently, static vs. dynamic) of the original input specification. This is useful for validating and designing methods.

When you invoke these parameters with inputs, they behave like functions, giving the impression of dynamic behavior. The parameters accept the observation time $t$ and a state vector $X_{t}$, and return an array of appropriate dimension. Even if you originally specified an input as an array, cev treats it as a static function of time and state, by that means guaranteeing that all parameters are accessible by the same interface.

## cfamounts

Cash flow and time mapping for bond portfolio

## Syntax

```
[CFlowAmounts, CFlowDates, TFactors, CFlowFlags,
CFPrincipal] = cfamounts(CouponRate, Settle, Maturity)
[CFlowAmounts, CFlowDates, TFactors, CFlowFlags,
CFPrincipal] = cfamounts(CouponRate, Settle, Maturity, Period,
Basis, EndMonthRule, IssueDate, FirstCouponDate,
LastCouponDate, StartDate, Face)
[CFlowAmounts, CFlowDates, TFactors, CFlowFlags,
CFPrincipal] = cfamounts(CouponRate, Settle, Maturity,
'ParameterName', ParameterValue, ...)
```

## Description

[CFlowAmounts, CFlowDates, TFactors, CFlowFlags, CFPrincipal] = cfamounts(CouponRate, Settle, Maturity) returns matrices of cash flow amounts, cash flow dates, time factors, and cash flow flags for a portfolio of NUMBONDS fixed-income securities.
[CFlowAmounts, CFlowDates, TFactors, CFlowFlags, CFPrincipal] = cfamounts(CouponRate, Settle, Maturity, Period, Basis, EndMonthRule, IssueDate, FirstCouponDate, LastCouponDate, StartDate, Face) returns matrices of cash flow amounts, cash flow dates, time factors, and cash flow flags for a portfolio of NUMBONDS fixed-income securities defined using required and optional inputs.
[CFlowAmounts, CFlowDates, TFactors, CFlowFlags, CFPrincipal] = cfamounts(CouponRate, Settle, Maturity, 'ParameterName', ParameterValue, ...) accepts optional inputs as one or more comma-separated parameter/value pairs. 'ParameterName' is the name of the parameter inside single quotes. ParameterValue is the value corresponding to 'ParameterName '. Specify parameter/value pairs in any order. Names are caseinsensitive.

## Input Arguments

## CouponRate

Decimal number indicating the annual percentage rate used to determine the coupons payable on a bond. CouponRate is 0 for zero coupon bonds.

Note: CouponRate and Face can change over the life of the bond. Schedules for CouponRate and Face can be specified with an NINST-by-1 cell array, where each element is a NumDates-by-2 matrix or cell array, where the first column is dates and the second column is associated rates. The date indicates the last day that the coupon rate or face value is valid.

## Settle

Settlement date. A vector of serial date numbers or date strings. Settle must be earlier than Maturity.

## Maturity

Maturity date. A vector of serial date numbers or date strings.

## Ordered Input or Parameter-Value Pairs

Enter the following inputs using an ordered syntax or as parameter/value pairs. You cannot mix ordered syntax with parameter/value pairs.

## Period

Coupons per year of the bond. A vector of integers. Values are 0, 1, 2, 3, 4, 6, and 12.

## Default: 2

## Basis

Day-count basis of the instrument. A vector of integers.

- $0=$ actual/actual
- $1=30 / 360$ (SIA)
- 2 = actual/360
- 3 = actual/ 365
- $4=30 / 360$ (PSA)
- $5=30 / 360$ (ISDA)
- $6=30 / 360$ (European)
- $7=$ actual/365 (Japanese)
- $8=$ actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- $10=$ actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see basis.
Default: 0

## EndMonthRule

End-of-month rule. A vector. This rule applies only when Maturity is an end-of-month date for a month having 30 or fewer days.

- $0=$ ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month.
- 1 = set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

## Default: 1

## IssueDate

Issue date for a bond.
Default: If you do not specify an IssueDate, the cash flow payment dates are determined from other inputs.

## FirstCouponDate

Date when a bond makes its first coupon payment; used when bond has an irregular first coupon period. When FirstCouponDate and LastCouponDate are both specified, FirstCouponDate takes precedence in determining the coupon payment structure.

Default: If you do not specify a FirstCouponDate, the cash flow payment dates are determined from other inputs.

## LastCouponDate

Last coupon date of a bond before the maturity date; used when bond has an irregular last coupon period. In the absence of a specified FirstCouponDate, a specified LastCouponDate determines the coupon structure of the bond. The coupon structure of a bond is truncated at the LastCouponDate, regardless of where it falls, and is followed only by the bond's maturity cash flow date.

Default: If you do not specify a LastCouponDate, the cash flow payment dates are determined from other inputs.

## StartDate

Date when a bond actually starts (the date from which a bond cash flow is considered). To make an instrument forward-starting, specify this date as a future date.

Default: If you do not specify StartDate, the effective start date is the Settle date.

## Face

Face or par value.

Note: CouponRate and Face can change over the life of the bond. Schedules for CouponRate and Face can be specified with an NINST-by-1 cell array where each element is a NumDates-by-2 matrix or cell array, where the first column is dates and the second column is associated rates. The date indicates the last day that the coupon rate or face value is valid.

Default: 100

## Parameter-Value Pairs

Enter the following inputs only as parameter/value pairs.

## AdjustCashFlowsBasis

Adjust the cash flows based on the actual period day count. NINST-by-1 of logicals.

## Default: False

## BusinessDayConvention

Require payment dates to be business dates. NINST-by-1 cell array with possible choices of business day convention:

- actual
- follow
- modifiedfollow
- previous
- modifiedprevious

## Default: actual

## CompoundingFrequency

Compounding frequency for yield calculation.
Default: SIA bases (0-7) and BUS/252 use a semiannual compounding convention and ICMA bases (8-12) use an annual compounding convention.

## DiscountBasis

Basis used to compute the discount factors for computing the yield. The default behavior is for SIA bases to use the actual/actual day count to compute discount factors, and for ICMA day counts and BUS/252 to use the specified Basis.

Default: SIA bases use the actual/actual day count to compute discount factors.

## Holidays

Holidays used for business day convention. NHOLIDAYS-by-1 of MATLAB date numbers.
Default: If no dates are specified, holidays.m is used.

## PrincipalType

Type of principal for case when a Face schedule is specified. The principal type is either sinking or bullet. If sinking, principal cash flows are returned throughout the life of the bond. If bullet, principal cash flow is only returned at maturity.

Default: sinking

## Output Arguments

## CFIowAmounts

Cash flow amounts. First entry in each row vector is the accrued interest due at settlement. This amount could be zero, positive or negative. If no accrued interest is due, the first column is zero. If the bond is trading ex-coupon then the accrued interest is negative.

## CFlowDates

Cash flow date matrix of a portfolio of bonds. Each row represents a single bond in the portfolio. Each element in a column represents a cash flow date of that bond.

## TFactors

Matrix of time factors for a portfolio of bonds. Each row corresponds to the vector of time factors for each bond. Each element in a column corresponds to the specific time factor associated with each cash flow of a bond. Time factors help determine the present value of a stream of cash flows. The term time factor refers to the exponent TF in the discounting equation

$$
P V=\sum_{i=1}^{n}\left(\frac{C F}{\left(1+\frac{z}{f}\right)^{T F}}\right)
$$

where:

| $P V=$ | Present value of a cash flow. |
| :--- | :--- |
| $C F=$ | Cash flow amount. |
| $z=$ | Risk-adjusted annualized rate or yield corresponding to a given cash <br> flow. The yield is quoted on a semiannual basis. |
| $f=$ | Frequency of quotes for the yield. Default is 2 for Basis values 0 to 7 <br> and 13 and 1 for Basis values 8 to 12. The default can be overridden <br> by specifying the CompoundingFrequency name/value pair. |

| $T F=$ | Time factor for a given cash flow. The time factor is computed using the <br> compounding frequency and the discount basis. If these values are not <br> specified, then the defaults are as follows: CompoundingFrequency <br> default is 2 for Basis values 0 to 7 and 13 and 1 for Basis values 8 to <br> 12. DiscountBasis is 0 for Basis values 0 to 7 and 13 and the input <br> Basis for Basis values 8 to 12. |
| :--- | :--- |

Note: The Basis is always used to compute accrued interest.

## CFlowFlags

Matrix of cash flow flags for a portfolio of bonds. Each row corresponds to the vector of cash flow flags for each bond. Each element in a column corresponds to the specific flag associated with each cash flow of a bond. Flags identify the type of each cash flow (for example, nominal coupon cash flow, front, or end partial, or "stub" coupon, maturity cash flow).

| Flag | Cash Flow Type |
| :--- | :--- |
| 0 | Accrued interest due on a bond at settlement. |
| 1 | Initial cash flow amount smaller than normal due to a "stub" coupon <br> period. A stub period is created when the time from issue date to first <br> coupon date is shorter than normal. |
| 2 | Larger than normal initial cash flow amount because the first coupon <br> period is longer than normal. |
| 3 | Nominal coupon cash flow amount. |
| 4 | Normal maturity cash flow amount (face value plus the nominal <br> coupon amount). |
| 5 | End "stub" coupon amount (last coupon period is abnormally short and <br> actual maturity cash flow is smaller than normal). |
| 6 | Larger than normal maturity cash flow because the last coupon period <br> longer than normal. |
| 7 | Maturity cash flow on a coupon bond when the bond has less than one <br> coupon period to maturity. |
| 8 | Smaller than normal maturity cash flow when the bond has less than <br> one coupon period to maturity. |

| Flag | Cash Flow Type |
| :--- | :--- |
| 9 | Larger than normal maturity cash flow when the bond has less than <br> one coupon period to maturity. |
| 10 | Maturity cash flow on a zero coupon bond. |
| 11 | Sinking principal and initial cash flow amount smaller than normal <br> due to a "stub" coupon period. A stub period is created when the time <br> from issue date to first coupon date is shorter than normal. |
| 12 | Sinking principal and larger than normal initial cash flow amount <br> because the first coupon period is longer than normal. |
| 13 | Sinking principal and nominal coupon cash flow amount. |

## CFPrincipal

CFPrincipal contains the principal cash flows. If PrincipalType is bullet, CFPrincipal is all zeros and, at Maturity, the appropriate Face value.

## Definitions

The elements contained in the cfamounts cash flow matrix, time factor matrix, and cash flow flag matrix correspond to the cash flow dates for each security. The first element of each row in the cash flow matrix is the accrued interest payable on each bond. This accrued interest is zero in the case of all zero coupon bonds. cfamounts determines all cash flows and time mappings for a bond whether or not the coupon structure contains odd first or last periods. All output matrices are padded with NaNs as necessary to ensure that all rows have the same number of elements.

## Examples

## Compute the Cash Flow Structure and Time Factors for a Bond Porifolio

This example shows how to compute the cash flow structure and time factors for a bond portfolio that contains a corporate bond paying interest quarterly and a Treasury bond paying interest semiannually.

```
Settle = '01-Nov-1993';
Maturity = ['15-Dec-1994';'15-Jun-1995'];
```

```
CouponRate= [0.06; 0.05];
Period = [4; 2];
Basis = [1; 0];
[CFlowAmounts, CFlowDates, TFactors, CFlowFlags] = ...
cfamounts(CouponRate,Settle, Maturity, Period, Basis)
```

CFlowAmounts =

| -0.7667 | 1.5000 | 1.5000 | 1.5000 | 1.5000 | 101.5000 |
| ---: | ---: | ---: | ---: | ---: | ---: |
| -1.8989 | 2.5000 | 2.5000 | 2.5000 | 102.5000 | NaN |

CFlowDates =

| 728234 | 728278 | 728368 | 728460 | 728552 | 728643 |
| ---: | ---: | ---: | ---: | ---: | ---: |

| ---: | ---: | ---: | ---: | ---: | ---: |
| 0 | 3 | 3 | 3 | 4 | NaN |

## Compute the Cash Flow Structure and Time Factors for a Bond Portfolio Using Optional NameValue Pairs

This example shows how to compute the cash flow structure and time factors for a bond portfolio that contains a corporate bond paying interest quarterly and a Treasury bond paying interest semiannually. This example uses the following Name-Value pairs for Period, Basis, BusinessDayConvention, and AdjustCashFlowsBasis.

```
Settle = '01-Jun-2010';
Maturity = ['15-Dec-2011';'15-Jun-2012'];
CouponRate= [0.06; 0.05];
Period = [4; 2];
Basis = [1; 0];
```

```
[CFlowAmounts, CFlowDates, TFactors, CFlowFlags] = ...
cfamounts(CouponRate,Settle, Maturity, 'Period',Period, ...
    'Basis', Basis, 'AdjustCashFlowsBasis', true,...
    'BusinessDayConvention','modifiedfollow')
CFlowAmounts =

## Use cfamounts With a CouponRate Schedule

This example shows how to use cfamounts with a CouponRate schedule. For CouponRate and Face that change over the life of the bond, schedules for CouponRate and Face can be specified with an NINST-by- 1 cell array, where each element is a NumDates-by-2 matrix where the first column is dates and the second column is associated rates.

```
CouponSchedule = {[datenum('15-Mar-2012') .04;datenum('15- Mar -2013') .05;...
datenum('15- Mar -2015') .06]}
cfamounts(CouponSchedule,'01-Mar-2011','15-Mar-2015' )
CouponSchedule =
    [3x2 double]
ans =
    Columns 1 through 7
    llllllll}\begin{array}{llllll}{1.8453 2.0000 2.0000 2.0000 2.5000 2.5000 3.0000}
    Columns 8 through 10
```

    \(3.0000 \quad 3.0000 \quad 103.0000\)
    
## Use cfamounts With a Face Schedule

This example shows how to use cfamounts with a Face schedule. For CouponRate and Face that change over the life of the bond, schedules for CouponRate and Face can be specified with an NINST-by- 1 cell array, where each element is a NumDates-by-2 matrix where the first column is dates and the second column is associated rates.

FaceSchedule $=\{[$ datenum('15-Mar-2012') 100; datenum('15- Mar-2013') 90;... datenum('15- Mar -2015') 80]\}

```
cfamounts(.05,'01-Mar-2011','15-Mar-2015', 'Face', FaceSchedule)
FaceSchedule =
    [3x2 double]
ans =
    Columns 1 through 7
        -2.3066 2.5000 2.5000 12.5000 2.2500 12.2500 2.0000
    Columns 8 through 10
        2.0000 2.0000 82.0000

## Introduced before R2006a

## cfconv

Cash flow convexity

## Syntax

CFlowConvexity $=$ cfconv(CashFlow, Yield)

## Arguments

| CashFlow | A vector of real numbers. |
| :--- | :--- |
| Yield | Periodic yield. A scalar. Enter as a decimal fraction. |

## Description

CFlowConvexity $=$ cfconv(CashFlow, Yield) returns the convexity of a cash flow in periods.

## Examples

## Compute the Convexity of a Cash Flow

This example shows how to return the convexity of a cash flow, given a cash flow of nine payments of $\$ 2.50$ and a final payment $\$ 102.50$, with a periodic yield of $2.5 \%$.

```
CashFlow = [2.5 2.5 2.5 2.5 2.5 2.5 2.5 2.5 2.5 102.5];
Convex = cfconv(CashFlow, 0.025)
Convex =
```

## cfdates

Cash flow dates for fixed-income security

## Syntax

CFlowDates = cfdates(Settle, Maturity, Period, Basis, EndMonthRule, IssueDate, FirstCouponDate, LastCouponDate, StartDate)

## Arguments

| Settle | Settlement date. A vector of serial date numbers or date strings. Settle must be earlier than Maturity. |
| :---: | :---: |
| Maturity | Maturity date. A vector of serial date numbers or date strings. |
| Period | (Optional) Coupons per year of the bond. A vector of integers. Allowed values are 0, 1, 2 (default), 3, 4, 6, and 12. |
| Basis | (Optional) Day-count basis of the instrument. A vector of integers. <br> - $0=$ actual/actual (default) <br> - $1=30 / 360$ (SIA) <br> - 2 = actual/360 <br> - $3=$ actual $/ 365$ <br> - $4=30 / 360$ (PSA) <br> - $5=30 / 360$ (ISDA) <br> - $6=30 / 360$ (European) <br> - $7=$ actual/365 (Japanese) <br> - 8 = actual/actual (ICMA) <br> - 9 = actual/360 (ICMA) <br> - $10=\mathrm{actual} / 365$ (ICMA) <br> - $11=30 / 360 \mathrm{E}$ (ICMA) |

|  | • $\quad 12=$ actual/365 (ISDA) <br> For more information, see basis. |
| :--- | :--- |
| EndMonthRule | (Optional) End-of-month rule. A vector. This rule applies <br> only when Maturity is an end-of-month date for a month <br> having 30 or fewer days. 0 = ignore rule, meaning that a <br> bond's coupon payment date is always the same numerical <br> day of the month. 1 = set rule on (default), meaning that a <br> bond's coupon payment date is always the last actual day of <br> the month. |
| IssueDate | (Optional) Date when a bond was issued. |
| FirstCouponDate | (Optional) Date when a bond makes its first coupon <br> payment; used when bond has an irregular first coupon <br> period. When FirstCouponDate and LastCouponDate <br> are both specified, FirstCouponDate takes precedence in <br> determining the coupon payment structure. If you do not <br> specify a FirstCouponDate, the cash flow payment dates <br> are determined from other inputs. |
| LastCouponDate | (Optional) Last coupon date of a bond before the maturity <br> date; used when bond has an irregular last coupon period. <br> In the absence of a specified FirstCouponDate, a specified <br> LastCouponDate determines the coupon structure of <br> the bond. The coupon structure of a bond is truncated at <br> the LastCouponDate, regardless of where it falls, and is <br> followed only by the bond's maturity cash flow date. If you <br> do not specify a LastCouponDate, the cash flow payment <br> dates are determined from other inputs. |
| StartDate | (Optional) Date when a bond actually starts (the date <br> from which a bond cash flow is considered). To make an <br> instrument forward-starting, specify this date as a future <br> date. If you do not specify StartDate, the effective start <br> date is the Settle date. |

Required arguments must be number of bonds (NUMBONDS)-by-1 or 1-by-NUMBONDS conforming vectors or scalars. Optional arguments must be either NUMBONDS-by-1 or 1-by-NUMBONDS conforming vectors, scalars, or empty matrices.

Any input can contain multiple values, but if so, all other inputs must contain the same number of values or a single value that applies to all. For example, if Maturity contains N dates, then Settle must contain N dates or a single date.

## Description

CFlowDates = cfdates(Settle, Maturity, Period, Basis, EndMonthRule, IssueDate, FirstCouponDate, LastCouponDate, StartDate) returns a matrix of cash flow dates for a bond or set of bonds. cfdates determines all cash flow dates for a bond whether or not the coupon payment structure is normal or the first and/or last coupon period is long or short.

CFlowDates is an N-row matrix of serial date numbers, padded with NaNs as necessary to ensure that all rows have the same number of elements. Use the function datestr to convert serial date numbers to formatted date strings.

Note The cash flow flags for a portfolio of bonds were formerly available as the cfdates second output argument, CFlowFlags. You can now use cfamounts to get these flags. If you specify a CFlowFlags argument, cfdates displays a message directing you to use cfamounts.

## Examples

```
CFlowDates = cfdates('14 Mar 1997', '30 Nov 1998', 2, 0, 1)
CFlowDates =
    729541 729724 729906 730089
datestr(CFlowDates)
ans =
31-May-1997
30-Nov-1997
31-May-1998
30-Nov-1998
```

Given three securities with different maturity dates and the same default arguments

```
Maturity = ['30-Sep-1997'; '31-Oct-1998'; '30-Nov-1998'];
CFlowDates = cfdates('14-Mar-1997', Maturity)
CFlowDates =
```

| 729480 | 729663 | NaN | NaN |
| ---: | ---: | ---: | ---: |
| 729510 | 729694 | 729875 | 730059 |
| 729541 | 729724 | 729906 | 730089 |

Look at the cash-flow dates for the last security.
datestr(CFlowDates(3,:))
ans =
31-May-1997
30-Nov-1997
31-May-1998
30-Nov-1998

```

Introduced before R2006a

## cfdur

Cash-flow duration and modified duration

## Syntax

[Duration, ModDuration] = cfdur(CashFlow, Yield)

## Arguments

| CashFlow | A vector or matrix of real numbers. When using a matrix, each <br> column of the matrix is a separate CashFlow. |
| :--- | :--- |
| Yield | Periodic yield. A scalar or vector. Enter as a decimal fraction. |

## Description

[Duration, ModDuration] = cfdur(CashFlow, Yield) calculates the duration and modified duration of a cash flow in periods.

## Examples

## Compute the Duration and Modified Duration of a Cash Flow

This example shows how to calculate the duration and modified duration of a cash flow, given a cash flow of nine payments of $\$ 2.50$ and a final payment $\$ 102.50$, with a periodic yield of $2.5 \%$.

```
CashFlow=[2.5 2.5 2.5 2.5 2.5 2.5 2.5 2.5 2.5 102.5];
[Duration, ModDuration] = cfdur(CashFlow, 0.025)
```

Duration =
8.9709

## cfplot

Visualize cash flows of financial instruments

## Syntax

```
cfplot(CFlowDates,CFlowAmounts)
```

h = cfplot (__, Name, Value)
[h,axes_handle] = cfplot (__ , Name, Value)

## Description

cfplot(CFlowDates, CFlowAmounts) plots a cash flow diagram for the specified cash flow amounts (CFlowAmounts) and dates (CFlowDates). The length and orientation of each arrow correspond to the cash flow amount.
cfplot (__ , Name, Value) plots a cash flow diagram for the specified cash flow amounts (CFlowAmounts), dates (CFlowDates), and optional name-value pair arguments.
h = cfplot (__ , Name, Value) returns the handle to the line objects used in the cash flow diagram.
[h,axes_handle] = cfplot (__ , Name, Value) returns the handles to the line objects and the axes using optional name-value pair arguments.

## Examples

## Plot Cash Flows

Define CFlowAmounts and CFlowDates using the cfamounts function.
CouponRate = [0.06; 0.05; 0.03];
Settle = '03-Jun-1999';

```
Maturity = ['15-Aug-2000';'15-Dec-2000';'15-Jun-2000'];
Period = [1; 2; 2]; Basis = [1; 0; 0];
[CFlowAmounts, CFlowDates] = cfamounts(...
CouponRate, Settle, Maturity, Period, Basis)
```

CFlowAmounts =

| -4.8000 | 6.0000 | 106.0000 | NaN | NaN |
| ---: | ---: | ---: | ---: | ---: |
| -2.3352 | 2.5000 | 2.5000 | 2.5000 | 102.5000 |
| -1.4011 | 1.5000 | 1.5000 | 101.5000 | NaN |

CFlowDates =

| 730274 | 730347 | 730713 | NaN | NaN |
| ---: | ---: | ---: | ---: | ---: |
| 730274 | 730286 | 730469 | 730652 | 730835 |
| 730274 | 730286 | 730469 | 730652 | NaN |

Plot all cash flows on the same axes, and label the first two.
cfplot(CFlowDates, CFlowAmounts, 'ShowAmnt', [1 2])

Group the second and third cash flows.
figure;
cfplot(CFlowDates, CFlowAmounts, 'Groups', \{[2 3]\}, 'ShowAmnt', 1);

Format the date axis and place ticks on actual cash flow dates.
figure;
cfplot(CFlowDates, CFlowAmounts, 'Groups', \{[2 3]\}, 'ShowAmnt', 1, ... 'DateFormat', 6, 'DateSpacing', 100);

Stack the cash flow arrows occurring on the same dates.
figure; cfplot(CFlowDates, CFlowAmounts, 'Groups', \{[2 3]\}, 'ShowAmnt', 1, ... 'DateFormat', 6, 'DateSpacing', 100, 'Stacked', 1);

Form subplots of multiple groups and add titles using axes handles.
figure;
[h, axes_handle] = cfplot(CFlowDates, CFlowAmounts, ... 'Groups', \{[1] [2 3]\}, 'ShowAmnt', 1, 'Stacked', 2, ... 'DateSpacing', [1 602 100], 'DateFormat', [1 12 2 6]); title(axes_handle(1), 'Group 1', 'FontWeight', 'bold'); title(axes_handle(2), 'Group 2', 'FontWeight', 'bold');

## Group 1

## Group 2

## Plot Cash Flows for Swap

Define the swap using the swapbyzero function.

```
Settle = datenum('08-Jun-2010');
RateSpec = intenvset('Rates', [.005 .0075 .01 . 014 .02 .025 .03]',...
'StartDates',Settle, 'EndDates',{'08-Dec-2010','08-Jun-2011',...
'08-Jun-2012','08-Jun-2013','08-Jun-2015','08-Jun-2017', ...
'08-Jun-2020'}');
Maturity = datenum('15-Sep-2020');
LegRate = [.025 50];
LegType = [1 0]; % fixed/floating
LatestFloatingRate = .005;
[Price, SwapRate, AI, RecCF, RecCFDates, PayCF,PayCFDates] = ...
```

```
swapbyzero(RateSpec, LegRate, Settle, Maturity,'LegType',LegType,...
'LatestFloatingRate', LatestFloatingRate)
Price =
    -6.7258
SwapRate =
    NaN
AI =
    1.4575
RecCF =
    Columns 1 through 7
    -1.8219 2.5000 2.5000 2.5000 2.5000 2.5000 2.5000
    Columns 8 through 12
    2.5000 2.5000 2.5000 2.5000 102.5000
RecCFDates =
    Columns 1 through 6
            734297 734396 
    Columns 7 through 12
            736222 736588 736953 737318 737683 738049
PayCF =
    Columns 1 through 7
```

```
    lllllll
    Columns 8 through 12
    4.1733 4.5164 4.4666 4.8068 104.6743
PayCFDates =
    Columns 1 through 6
        734297 734396 
    Columns 7 through 12
        736222 736588 7
Define CFlowDates and CFlowAmounts for the swap and generate a cash flow plot using cfplot.
CFlowDates = [PayCFDates;RecCFDates];
CFlowAmounts = [-PayCF;RecCF];
cfplot(CFlowDates, CFlowAmounts, 'Groups', \{[1 2]\});
xlabel('Numeric Cash Flow Dates');
```

- "Analyzing and Computing Cash Flows" on page 2-17

## Input Arguments

## CFlowDates - Matrix of serial date numbers for cash flows

vector
Matrix of serial date numbers for cash flows, specified as a NINST-by- (Number of cash flows) matrix of cash flow dates in date numbers, with empty entries padded with NaNs.

Each row of the CFlowDates matrix represents an instrument so that CFlowDates ( $\mathrm{k},:$ ) is the vector of cash flow dates for the kth instrument. Rows are padded with trailing NaNs if the number of cash flows is not the same for all instruments.
cfamounts can be used to generate CFlowDates.
Data Types: double
CFlowAmounts - Matrix of cash flow amounts
vector
Matrix of cash flow amounts, specified as a NINST-by-(Number of cash flows) matrix of cash flow amounts, with empty entries padded with NaNs. The CFlowAmounts matrix must be the same size as CFlowDates.
cfamounts can be used to generate CFlowAmounts.
Data Types: double

## Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.
Example: cfplot(CFlowDates, CFlowAmounts, 'Groups ' , \{[2 3]\},'ShowAmnt',1, 'DateFormat',6,'DateSpacing', 100)

## 'Groups ' - Group cash flows

'off' (default) | string with value 'off' or 'individual' | cell array of vectors
Group cash flows specified using the following values:

- 'off' - Show all instruments in one set of axes, arranged from top to bottom.
- 'individual' - Generate subplots and plot each instrument in its own axis.
- GRP - Cell array of instrument groups, \{Group1, Group2, ... \}. This generates subplots and plots each group in each axis. When specifying \{Group1, Group2, . . \}, each Group must be mutually exclusive vectors of INSTIndex. Unspecified instruments are not shown in the grouped plot.

Data Types: double

## 'Stacked ' - Stack arrows if cash flows are in same direction on same day <br> Ignored when 'Groups' is 'off', otherwise 'off' (default) | string with value 'off', 'all', or 'GRPIndex'

Stack arrows if the cash flows are in the same direction on the same day specified using the following values:

- 'off' - For all groups, all arrows originate from the horizontal line.
- 'all' - For all groups, arrows are stacked if the cash flows are in the same direction on the same day.
- 'GRPIndex ' - For specified groups, arrows are stacked if the cash flows are in the same direction on the same day.

## Data Types: double

```
'ShowAmnt' - Show amount on arrows
'off' (default)| string with value 'off' or 'individual' | cell array of vectors |
```

Show amount on the arrows specified using the following values:

- 'off' - Hide cash flow amounts on arrows.
- 'all' - Show cash flow amounts on arrows.
- [INSTIndex or GRPIndex] - Show cash flow amounts for the specified vector of instruments (when 'Groups' is 'off') or groups.

## Data Types: double

## 'DateSpacing' - Control for date axis tick spacing <br> 'off' (default) | string with value 'off' or string TickDateSpace | numeric value for TickDateSpace

Control for data spacing specified by the following values:

- 'off' - The date axis ticks are spaced regularly.
- TickDateSpace - The date axis ticks are placed on actual cash flow dates. The ticks skip some cash flows if they are less than TickDateSpace apart.

## Data Types: double

[^1]Date format is specified by the following values:

- 'off' - The date axis tick labels are in date numbers.
- DateFormNum - The date format number (2 = 'mm/dd/yy', $6={ }^{\prime} \mathrm{mm} / \mathrm{dd}{ }^{\prime}$, and $10=$ ' yyyy '). Additional values for DateFormNum are as follows:

| DateFormNum | Example |
| :--- | :--- |
| 2 | $03 / 01 / 00$ |
| 3 | Mar |
| 5 | 03 |
| 6 | $03 / 01$ |
| 7 | 01 |
| 8 | Wed |
| 9 | W |
| 10 | 2000 |
| 11 | 00 |
| 12 | Mar00 |
| 17 | Q1-00 |
| 18 | Q1 |
| 19 | $01 / 03$ |
| 20 | $01 / 03 / 00$ |
| 27 | Q1-2000 |
| 28 | Mar2000 |
| 29 | $2000-03-01$ |

Data Types: double

## Output Arguments

h - Handles to line objects

vector

Handles to line objects, returned as a NINST-by-3 matrix of handles to line objects, containing [hLines, hUArrowHead, hDArrowHead] where:

- hLines - Horizontal and vertical lines used in the cash flow diagram
- hUArrowHead - "Up" arrowheads
- hDArrowHead - "Down" arrowheads

## axes_handle - Handles to axes for plot or subplots

vector
Handles to axes for the plot or subplots, returned as a (Number of axes)-by-1 vector of handles to axes.

## See Also <br> cfamounts | cfdates | swapbyzero

Introduced in R2013a

## cfport

Portfolio form of cash flow amounts

## Syntax

[CFBondDate, AllDates, AllTF, IndByBond] = cfport(CFlowAmounts, CFlowDates, TFactors)

## Arguments

| CFlowAmounts | Number of bonds (NUMBONDS) by number of cash flows <br> (NUMCFS) matrix with entries listing cash flow amounts <br> corresponding to each date in CFlowDates. |
| :--- | :--- |
| CFlowDates | NUMBONDS-by-NUMCFS matrix with rows listing cash flow <br> dates for each bond and padded with NaNs. |
| TFactors | (Optional) NUMBONDS-by-NUMCFS matrix with entries <br> listing the time between settlement and the cash flow date <br> measured in semiannual coupon periods. |

## Description

[CFBondDate, AllDates, AllTF, IndByBond] = cfport(CFlowAmounts, CFlowDates, TFactors) computes a vector of all cash flow dates of a bond portfolio, and a matrix mapping the cash flows of each bond to those dates. Use the matrix for pricing the bonds against a curve of discount factors.

CFBondDate is a NUMBONDS by number of dates (NUMDATES) matrix of cash flows indexed by bond and by date in AllDates. Each row contains a bond's cash flow values at the indices corresponding to entries in AllDates. Other indices in the row contain zeros.

AllDates is a NUMDATES-by-1 list of all dates that have any cash flow from the bond portfolio.

AllTF is a NUMDATES-by- 1 list of time factors corresponding to the dates in AllDates. If TFactors is not entered, AllTF contains the number of days from the first date in AllDates.

IndByBond is a NUMBONDS-by-NUMCFS matrix of indices. The $i$ th row contains a list of indices into AllDates where the $i$ th bond has cash flows. Since some bonds have more cash flows than others, the matrix is padded with NaNs .

## Examples

## Calculate the Cash Flow Amounts, Cash Flow Dates, and Time Factors for Each of Two Bonds

Use the function cfamounts to calculate the cash flow amounts, cash flow dates, and time factors for each of two bonds. Then use the function cfplot to plot the cash flow diagram.

```
Settle = '03-Aug-1999';
Maturity = ['15-Aug-2000';'15-Dec-2000'];
CouponRate= [0.06; 0.05];
Period = [3;2];
Basis = [1;0];
[CFlowAmounts, CFlowDates, TFactors] = cfamounts(CouponRate,...
Settle, Maturity, Period, Basis);
cfplot(CFlowDates,CFlowAmounts)
xlabel('Numeric Cash Flow Dates')
ylabel('Bonds')
title('Cash Flow Diagram')
```

## Cash Flow Diagram

Call the function cfport to map the cash flow amounts to the cash flow dates. Each row in the resultant CFBondDate matrix represents a bond. Each column represents a date on which one or more of the bonds has a cash flow. A 0 means the bond did not have a cash flow on that date. The dates associated with the columns are listed in AllDates. For example, the first bond had a cash flow of 2.000 on 730347. The second bond had no cash flow on this date For each bond, IndByBond indicates the columns of CFBondDate, or dates in AllDates, for which a bond has a cash flow.
[CFBondDate, AllDates, AllTF, IndByBond] = ...
cfport(CFlowAmounts, CFlowDates, TFactors)

CFBondDate =

```
        -1.8000 2.0000 2.0000 2.0000 0
        -0.6694 0
AllDates =
    7 3 0 3 3 5
    730347
    7 3 0 4 6 9
    7 3 0 5 9 1
    7 3 0 6 5 2
    7 3 0 7 1 3
    7 3 0 8 3 5
AllTF =
        0
        0.0663
        0.7322
        1.3989
        1.7322
        2.0663
        2.7322
IndByBond =
    1
    1 3
```

- "Analyzing and Computing Cash Flows" on page 2-17

## See Also

cfamounts | cfplot

## Introduced before R2006a

## cfprice

Compute price for cash flow given yield to maturity

## Syntax

Price = cfprice(CFAmounts, CFDates, Yield, Settle) Price = cfprice(CFAmounts, CFDates, Yield, Settle, Name, Value)

## Description

Price = cfprice(CFAmounts, CFDates, Yield, Settle) computes a price given yield for a cash flow.

Price = cfprice(CFAmounts, CFDates, Yield, Settle, Name, Value) computes a price for a cash flow given yield to maturity with additional options specified by one or more Name, Value pair arguments.

## Input Arguments

## CFlowAmounts

NINST-by-MOSTCFS matrix of cash flow amounts. Each row is a list of cash flow values for one instrument. If an instrument has fewer than MOSTCFS cash flows, the end of the row is padded with NaNs .

## CFlowDates

NINST-by-MOSTCFS matrix of cash flow dates. Each entry contains the serial date of the corresponding cash flow in CFlowAmounts.

Yield
NINST-by-1 vector of yields.

## Settle

Settlement date is a serial date number or date string. Settlement date is the date on which the cash flows are priced.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, . . , NameN, ValueN.

Note: Any optional input of size N -by- 1 is also acceptable as an array of size 1 -by- N , or as a single value applicable to all contracts. Single values are internally expanded to an array of size N -by- 1 .

## 'Basis'

N-by-1 vector of day-count basis:

- $0=$ actual/actual
- $1=30 / 360$ (SIA)
- 2 = actual/360
- $3=$ actual/ 365
- $4=30 / 360$ (BMA)
- $5=30 / 360$ (ISDA)
- $6=30 / 360$ (European)
- $7=$ actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- $10=$ actual/365 (ICMA)
- $11=30 / 360 \mathrm{E}$ (ICMA)
- $12=$ actual/365 (ISDA)
- 13 = BUS/252

For more information, see basis.
Default: 0 (actual/actual)

## 'CompoundingFrequency '

NINST-by-1 vector of Compounding Frequency. By default, SIA bases (0-7) and BUS/252 use a semiannual compounding convention and ICMA bases (8-12) use an annual compounding convention.

Default: 2

## Output Arguments

Price
Price of cash flows.

## Examples

## Compute the Price for a Cash Flow Given Yield to Maturity

Use cfprice to compute: price for a cash flow given yield to maturity.
Define data for the yield curve.

```
Settle = datenum('01-Jul-2003');
Yield = .05;
CFAmounts = [30;40;30];
CFDates = datenum({'15-Jul-2004', '15-Jul-2005', '15-Jul-2006'});
```

Compute the Price.

```
Price = cfprice(CFAmounts, CFDates, Yield, Settle)
```

Price =
28.4999
36.1689
25.8195

- "Analyzing and Computing Cash Flows" on page 2-17

See Also<br>cfbyzero | cfspread | cfyield

Introduced in R2012a

## cfspread

Compute spread over yield curve for cash flow

## Syntax

```
Spread = cfspread(RateSpec, Price, CFAmounts,
CFDates, Settle)
Spread = cfspread(RateSpec, Price, CFAmounts,
CFDates, Settle, Name,Value)
```

## Description

Spread = cfspread(RateSpec, Price, CFAmounts, CFDates, Settle) computes spread over a yield curve for a cash flow.

Spread = cfspread(RateSpec, Price, CFAmounts, CFDates, Settle, Name, Value) computes spread over a yield curve for a cash flow with additional options specified by one or more Name, Value pair arguments.

## Input Arguments

## RateSpec

Interest-rate specification for the initial risk free rate curve. See intenvset for information on declaring an interest-rate variable.

## Price

Price of cash flows.

## CFlowAmounts

NINST-by-MOSTCFS matrix of cash flow amounts. Each row is a list of cash flow values for one instrument. If an instrument has fewer than MOSTCFS cash flows, the end of the row is padded with NaNs.

## CFlowDates

NINST-by-MOSTCFS matrix of cash flow dates. Each entry contains the serial date of the corresponding cash flow in CFlowAmounts.

## Settle

Settlement date is a serial date number or date string. Settlement date is the date on which the cash flows are priced.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, . . , NameN, ValueN.

Note: Any optional input of size N -by- 1 is also acceptable as an array of size 1-by-N, or as a single value applicable to all contracts. Single values are internally expanded to an array of size N -by- 1 .

## 'Basis'

N -by-1 vector of day-count basis:

- $0=$ actual/actual
- $1=30 / 360$ (SIA)
- 2 = actual/360
- $3=$ actual $/ 365$
- $4=30 / 360$ (BMA)
- $5=30 / 360$ (ISDA)
- $6=30 / 360$ (European)
- $7=$ actual/365 (Japanese)
- $8=$ actual/actual (ICMA)
- $9=$ actual/360 (ICMA)
- $10=$ actual/365 (ICMA)
- $11=30 / 360 \mathrm{E}$ (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see basis.
Default: 0 (actual/actual)

## 'CompFreq'

Compounding frequency. By default, SIA bases (0-7) and BUS/252 use a semi-annual compounding convention and ICMA bases (8-12) use an annual compounding convention.

Default: actual

## Output Arguments

## Spread

Spread of cash flows over a zero curve.

## Examples

## Compute Spread Over a Yield Curve for a Cash Flow

Use cfspread to compute the spread over a yield curve for a cash flow.
Define data for the yield curve.

```
Settle = datenum('01-Jul-2003');
CurveDates = daysadd(Settle,360*[.25 .5 1 2 3 5 7 10 20],1);
ZeroRates = [.0089 .0096 .0107 .0130 .0166 .0248 .0306 .0356 .0454]';
```

Compute the RateSpec.

```
RateSpec = intenvset('StartDates', Settle, 'EndDates', CurveDates,...
```

'Rates', ZeroRates)

```
            FinObj: 'RateSpec'
    Compounding: 2
                Disc: [9\times1 double]
            Rates: [9\times1 double]
        EndTimes: [9x1 double]
    StartTimes: [9x1 double]
        EndDates: [9\times1 double]
    StartDates: 731763
ValuationDate: 731763
    Basis: 0
EndMonthRule: 1
```

Compute the spread.

```
Price = 98;
CFAmounts = [30;40;30];
CFDates = datenum({'15-Jul-2004', '15-Jul-2005', '15-Jul-2006'});
Spread = cfspread(RateSpec, Price, CFAmounts, CFDates, Settle)
Spread =
    1.0e+03 *
    -8.7956
    -4.0774
    -3.7073
```

- "Analyzing and Computing Cash Flows" on page 2-17

## See Also

## cfyield

Compute yield to maturity for cash flow given price

## Syntax

```
Yield = cfyield(CFAmounts, CFDates, Price, Settle)
Yield = cfyield(CFAmounts, CFDates, Price, Settle,
Name,Value)
```

## Description

Yield = cfyield(CFAmounts, CFDates, Price, Settle) computes yield to maturity for a cash flow given price.

Yield = cfyield(CFAmounts, CFDates, Price, Settle, Name, Value) computes yield to maturity for a cash flow given price with additional options specified by one or more Name, Value pair arguments.

## Input Arguments

## CFlowAmounts

NINST-by-MOSTCFS matrix of cash flow amounts. Each row is a list of cash flow values for one instrument. If an instrument has fewer than MOSTCFS cash flows, the end of the row is padded with NaNs .

## CFlowDates

NINST-by-MOSTCFS matrix of cash flow dates. Each entry contains the serial date of the corresponding cash flow in CFlowAmounts.

## Price

Price.

## Settle

Settlement date is a serial date number or date string. Settlement date is the date on which the cash flows are priced.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, . . , NameN, ValueN.

Note: Any optional input of size N -by- 1 is also acceptable as an array of size 1 -by-N, or as a single value applicable to all contracts. Single values are internally expanded to an array of size N -by- 1 .

## 'Basis'

N-by-1 vector of day-count basis:

- $0=$ actual/actual
- $1=30 / 360$ (SIA)
- 2 = actual/360
- $3=$ actual/ 365
- $4=30 / 360$ (BMA)
- $5=30 / 360$ (ISDA)
- $6=30 / 360$ (European)
- $7=$ actual/365 (Japanese)
- $8=$ actual/actual (ICMA)
- $9=$ actual/360 (ICMA)
- $10=\mathrm{actual} / 365$ (ICMA)
- $11=30 / 360 \mathrm{E}$ (ICMA)
- $12=$ actual/365 (ISDA)
- 13 = BUS/252

For more information, see basis.
Default: 0 (actual/actual)

## 'CompFreq'

Compounding frequency. By default, SIA bases (0-7) and BUS/252 use a semi-annual compounding convention and ICMA bases ( $8-12$ ) use an annual compounding convention.

Default: actual

## Output Arguments

## Yield

Yield for cash flows.

## Examples

## Compute the Yield to Maturity for a Cash Flow When Given a Price

Use cfyield to compute yield to maturity for a cash flow when given a price.
Define data for the yield curve and price.

```
Settle = datenum('01-Jul-2003');
Price = 98;
CFlowAmounts = [30 40 30];
CFlowDates = datenum({'15-Jul-2004', '15-Jul-2005', '15-Jul-2006'})';
Compute the Yield.
    Yield = cfyield(CFlowAmounts, CFlowDates, Price, Settle)
Yield =
    0.0099
```

- "Analyzing and Computing Cash Flows" on page 2-17

See Also cfbyzero | cfprice | cfspread<br>Introduced in R2012a

## cftimes

Time factors corresponding to bond cash flow dates

## Syntax

```
[TFactors] = cftimes(Settle, Maturity)
[TFactors] = cftimes(Settle, Maturity,
Period, Basis, EndMonthRule,
IssueDate, FirstCouponDate, LastCouponDate, StartDate)
[TFactors] = cftimes(Settle, Maturity,
'ParameterName', ParameterValue, ...)
```

## Description

[TFactors] = cftimes(Settle, Maturity) determines the time factors corresponding to the cash flows of a bond or set of bonds.
[TFactors] = cftimes(Settle, Maturity, Period, Basis, EndMonthRule, IssueDate, FirstCouponDate, LastCouponDate, StartDate) determines the time factors corresponding to the cash flows of a bond or set of bonds, including optional inputs.
[TFactors] = cftimes(Settle, Maturity, 'ParameterName', ParameterValue, ...) accepts optional inputs as one or more comma-separated parameter/value pairs. 'ParameterName' is the name of the parameter inside single quotes. ParameterValue is the value corresponding to 'ParameterName '. Specify parameter/value pairs in any order. Names are caseinsensitive.

## Input Arguments

## Settle

Settlement date. A vector of serial date numbers or date strings. Settle must be earlier than Maturity.

## Maturity

Maturity date. A vector of serial date numbers or date strings.

## Ordered Input or Parameter-Value Pairs

Enter the following inputs using an ordered syntax or as parameter/value pairs. You cannot mix ordered syntax with parameter/value pairs.

## Period

Coupons per year of the bond. A vector of integers. Values are 0, 1, 2, 3, 4, 6, and 12.

## Default: 2

## Basis

Day-count basis of the instrument. A vector of integers.

- $0=$ actual/actual
- $1=30 / 360$ (SIA)
- 2 = actual/360
- $3=$ actual $/ 365$
- $4=30 / 360$ (PSA)
- $5=30 / 360$ (ISDA)
- $6=30 / 360$ (European)
- $7=$ actual/365 (Japanese)
- $8=$ actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- $10=\mathrm{actual} / 365$ (ICMA)
- 11 = 30/360E (ICMA)
- $12=\mathrm{actual} / 365$ (ISDA)
- 13 = BUS/252

For more information, see basis.
Default: 0

## EndMonthRule

End-of-month rule. A vector. This rule applies only when Maturity is an end-of-month date for a month having 30 or fewer days. $0=$ ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month. $1=$ set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

## Default: 1

## IssueDate

Issue date for a bond.

## FirstCouponDate

Date when a bond makes its first coupon payment; used when bond has an irregular first coupon period. When FirstCouponDate and LastCouponDate are both specified, FirstCouponDate takes precedence in determining the coupon payment structure.

Default: If you do not specify a FirstCouponDate, the cash flow payment dates are determined from other inputs.

## LastCouponDate

Last coupon date of a bond before the maturity date; used when bond has an irregular last coupon period. In the absence of a specified FirstCouponDate, a specified LastCouponDate determines the coupon structure of the bond. The coupon structure of a bond is truncated at the LastCouponDate, regardless of where it falls, and is followed only by the bond's maturity cash flow date.

Default: If you do not specify a LastCouponDate, the cash flow payment dates are determined from other inputs.

## StartDate

Date when a bond actually starts (the date from which a bond cash flow is considered). To make an instrument forward-starting, specify this date as a future date. If you do not specify StartDate, the effective start date is the Settle date.

## Parameter-Value Pairs

Enter the following inputs only as parameter/value pairs.

## CompoundingFrequency

Compounding frequency for yield calculation. By default, SIA bases (0-7) and BUS/252 use a semiannual compounding convention and ICMA bases (8-12) use an annual compounding convention.

## DiscountBasis

Basis used to compute the discount factors for computing the yield. The default behavior is for SIA bases to use the actual/actual day count to compute discount factors. If you use ICMA day counts and BUS/252, the specified bases are used.

## Output Arguments

## TFactors

TFactors has NUMBONDS rows and the number of columns is determined by the maximum number of cash flow payment dates required to hold the bond portfolio. NaNs are padded for bonds which have less than the maximum number of cash flow payment dates.

## Definitions

cftimes computes the time factor of a cash flow, which is the difference between the settlement date and the cash flow date, in units of semiannual coupon periods. In computing time factors, use SIA actual/actual day count conventions for all time factor calculations.

## Examples

## Compute the Time Factor of a Cash Flow

This example shows how to calculate a cash flow time factor.

```
Settle = '15-Mar-1997';
Maturity = '01-Sep-1999';
Period = 2;
TFactors = cftimes(Settle, Maturity, Period)
```

TFactors $=$

| 0.9239 | 1.9239 | 2.9239 | 3.9239 | 4.9239 |

## Introduced before R2006a

## chaikosc

Chaikin oscillator

## Syntax

```
chosc = chaikosc(highp, lowp, closep, tvolume)
chosc = chaikosc([highp lowp closep tvolume])
choscts = chaikosc(tsobj)
choscts = chaikosc(tsobj, 'ParameterName', ParameterValue, ... )
```

## Arguments

| highp | High price (vector) |
| :--- | :--- |
| lowp | Low price (vector) |
| closep | Closing price (vector) |
| tvolume | Volume traded (vector) |
| tsobj | Financial time series object |

## Description

The Chaikin oscillator is calculated by subtracting the 10-period exponential moving average of the Accumulation/Distribution (A/D) line from the three-period exponential moving average of the A/D line.
chosc $=$ chaikosc(highp, lowp, closep, tvolume) calculates the Chaikin oscillator (vector), chosc, for the set of stock price and volume traded data (tvolume). The required inputs are the prices for the high (highp), low (lowp), and closing (closep) prices and the volume traded data (tvolume).
chosc = chaikosc([highp lowp closep tvolume]) accepts a four-column matrix as input.
choscts $=$ chaikosc(tsobj) calculates the Chaikin Oscillator, choscts, from the data contained in the financial time series object tsobj. tsobj must at least contain data series with names High, Low, Close, and Volume. These series must represent the high, low, and closing prices, plus the volume traded. choscts is a financial time series object with the same dates as tsobj but only one series named ChaikOsc.
choscts = chaikosc(tsobj, 'ParameterName', ParameterValue, ...) accepts parameter name/parameter value pairs as input. These pairs specify the name(s) for the required data series if it is different from the expected default name(s). Valid parameter names are

- HighName: high prices series name
- LowName: low prices series name
- CloseName: closing prices series name
- VolumeName: volume traded series name

Parameter values are the strings that represent the valid parameter names.

## Examples

## Compute the Chaikin Oscillator

This example shows how to compute the Chaikin oscillator for Disney stock and plot the results.

```
load disney.mat
dis_CHAIKosc = chaikosc(dis);
plot(dis_CHAIKosc)
title('Chaikin Oscillator for Disney')
```

## chaikvolat

Chaikin volatility

## Syntax

```
chvol = chaikvolat(highp, lowp)
chvol = chaikvolat([highp lowp])
chvol = chaikvolat(high, lowp, nperdiff, manper)
chvol = chaikvolat([high lowp], nperdiff, manper)
chvts = chaikvolat(tsobj)
chvts = chaikvolat(tsobj, nperdiff, manper, 'ParameterName',
ParameterValue, ...)
```

## Arguments

| highp | High price (vector). |
| :--- | :--- |
| lowp | Low price (vector). |
| nperdiff | Period difference (vector). Default = 10. |
| manper | Length of exponential moving average in periods (vector). Default $=$ <br> 10. |
| tsobj | Financial time series object. |

## Description

chvol = chaikvolat (highp, lowp) calculates the Chaikin volatility from the series of stock prices, highp and lowp. The vector chvol contains the Chaikin volatility values, calculated on a 10 -period exponential moving average and 10-period difference.
chvol = chaikvolat([highp lowp]) accepts a two-column matrix as the input.
chvol $=$ chaikvolat(high, lowp, nperdiff, manper) manually sets the period difference nperdiff and the length of the exponential moving average manper in periods.
chvol = chaikvolat([high lowp], nperdiff, manper) accepts a two-column matrix as the first input.
chvts = chaikvolat(tsobj) calculates the Chaikin volatility from the financial time series object tsobj. The object must contain at least two series named High and Low, representing the high and low prices per period. chvts is a financial time series object containing the Chaikin volatility values, based on a 10-period exponential moving average and 10-period difference. chvts has the same dates as tsobj and a series called ChaikVol.
chvts = chaikvolat (tsobj, nperdiff, manper, 'ParameterName', ParameterValue, ...) accepts parameter name/parameter value pairs as input. These pairs specify the name(s) for the required data series if it is different from the expected default name(s). Valid parameter names are

- HighName: high prices series name
- LowName: low prices series name

Parameter values are the strings that represent the valid parameter names.
nperdiff, the period difference, and manper, the length of the exponential moving average in periods, can also be set with this form of chaikvolat.

## Examples

## Compute the Chaikin Volatility

This example shows how to compute the Chaikin volatility for Disney stock and plot the results.

```
load disney.mat
dis_CHAIKvol = chaikvolat(dis);
plot(dis_CHAIKvol)
title('Chaikin Volatility for Disney')
```

## charifts

Interactive display

## Syntax

```
chartfts(tsobj)
```

## Description

chartfts(tsobj) produces a figure window that contains one or more plots. You can use the mouse to observe the data at a particular time point of the plot.

## Examples

Create a financial time series object from the supplied data file ibm9599. dat:
ibmfts = ascii2fts('ibm9599.dat', 1, 3, 2);
Chart the financial time series object ibmfts:
chartfts(ibmfts)
With the Zoom feature set off, a mouse click on the indicator line displays object data in a pop-up box.

With the Zoom feature set on, mouse clicks indicate the area of the chart to zoom.

You can find a tutorial on using chartfts in "Visualizing Financial Time Series Objects" on page 11-16. See "Zoom Tool" on page 11-19 for details on performing the zoom.

Also see "Combine Axes Tool" on page 11-22 for information about combining axes for specified plots.

## checkFeasibility

Check feasibility of input portfolios against portfolio object
Use the checkFeasibility function with a Portfolio, PortfolioCVaR, or PortfolioMAD object to check the feasibility of input portfolios against a portfolio object.

For details on the respective workflows when using these different objects, see "Portfolio Object Workflow" on page 4-17, "PortfolioCVaR Object Workflow" on page 5-16, and "PortfolioMAD Object Workflow" on page 6-16.

## Syntax

```
status = checkFeasibility(obj,pwgt)
```

## Description

status = checkFeasibility(obj, pwgt) checks the feasibility of input portfolios against a portfolio object.

## Examples

## Determine if the Portfolio Is Feasible for a Portfolio Object

Given portfolio $p$, determine if $p$ is feasible.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
    0.00408 0.0289 0.0204 0.0119;
    0.00192 0.0204 0.0576 0.0336;
    0 0.0119 0.0336 0.1225 ];
p = Portfolio;
p = setAssetMoments(p, m, C);
p = setDefaultConstraints(p);
pwgt = estimateFrontier(p);
```

```
checkFeasibility(p, pwgt)
```

ans =

## Determine if the Portfolio Is Feasible for a PorffolioCVaR Object

Given portfolio $p$, determine if $p$ is feasible.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
    0.00408 0.0289 0.0204 0.0119;
    0.00192 0.0204 0.0576 0.0336;
    0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;
AssetScenarios = mvnrnd(m, C, 20000);
p = PortfolioCVaR;
p = setScenarios(p, AssetScenarios);
p = setDefaultConstraints(p);
p = setProbabilityLevel(p, 0.95);
pwgt = estimateFrontier(p);
checkFeasibility(p, pwgt)
```

ans =

## Determine if the Portfolio Is Feasible for a PorffolioMAD Object

Given portfolio $p$, determine if $p$ is feasible.

```

- "Validate the Portfolio Problem for Portfolio Object" on page 4-82
- "Validate the CVaR Portfolio Problem" on page 5-75
- "Validate the MAD Portfolio Problem" on page 6-74
- "Portfolio Optimization Examples" on page 4-114

## Input Arguments

## obj - Object for portfolio

object
Object for portfolio, specified using Portfolio, PortfolioCVaR, or PortfolioMAD object. For more information on creating a portfolio object, see

- Using Portfolio Objects
- Using PortfolioCVaR Objects
- Using PortfolioMAD Objects

## pwgt - Porifolios to check

matrix

Portfolios to check, specified as a NumAssets-by-NumPorts matrix.
Data Types: double

## Output Arguments

## status - Indicator if portfolio is feasible

row vector
Indicator if portfolio is feasible, returned as a row vector of NumPorts indicators that are true if portfolio is feasible and false otherwise.

Note: By definition, any portfolio set must be nonempty and bounded. If the set is empty, no portfolios can be feasible. Use estimateBounds to test for nonempty and bounded sets.

Feasibility status is returned for Portfolio, PortfolioCVaR, or PortfolioMAD objects. For more information on creating a portfolio object, see

- Using Portfolio Objects
- Using PortfolioCVaR Objects
- Using PortfolioMAD Objects

## More About

## Tips

- You can also use dot notation to check the feasibility of input portfolios against a portfolio object.

```
status = obj.checkFeasibility(pwgt);
```

- The constraint tolerance to assess whether a constraint is satisfied is obtained from the hidden property obj.defaultTolCon.
- "Portfolio Optimization Theory" on page 4-2
- Getting Started with Portfolio Optimization (13 min 31 sec )

See Also<br>estimateBounds<br>Introduced in R201 la

## chfield

Change data series name

## Syntax

newfts $=$ chfield(oldfts, oldname, newname)

## Arguments

| oldfts | Name of an existing financial time series object. |
| :--- | :--- |
| oldname | Name of the existing component in oldfts. A MATLAB string or <br> column cell array. |
| newname | New name for the component in oldfts. A MATLAB string or <br> column cell array. |

## Description

newfts = chfield(oldfts, oldname, newname) changes the name of the financial time series object component from oldname to newname.

Set newfts = oldfts to change the name of an existing component without changing the name of the financial time series object.

To change the names of several components at once, specify the series of old and new component names in corresponding column cell arrays.

You cannot change the names of the object components desc, freq, and dates.

Group <br>
If NUMSERIES > 1, Design is a cell array with NUMSAMPLES <br>
cells, where each cell contains a NUMSERIES-by-NUMPARAMS <br>

matrix of known values.\end{array}\right]\)| Contains information about how data series are to be grouped, with |
| :--- |
| separate parameters for each group. Specify groups either by series |
| or by groups: |
| -To identify groups by series, construct an index vector that has <br> NUMSERIES elements. Element i $=1, \ldots$, NUMSERIES in <br> the vector, and has the index $j=1, \ldots$, NUMGROUPS of the <br> group in which series $i$ is a member. <br> To identify groups by groups, construct a cell array with <br> NUMGROUPS elements. Each cell contains a vector with the <br> indexes of the series that populate a given group. |
| In either case, the number of series is NUMSERIES and the <br> number of groups is NUMGROUPS, with $1 \leq$ NUMGROUPS $\leq$ <br> NUMSERIES. |

## Description

DesignSUR = convert2sur(Design, Group) converts a multivariate normal regression model into a seemingly unrelated regression model with a specified grouping of the data series. DesignSUR is either a matrix or a cell array that depends on the value of NUMSERIES:

- If NUMSERIES = 1, DesignSUR = Design, which is a NUMSAMPLES-by-NUMPARAMS matrix.
- If NUMSERIES > 1 and NUMGROUPS groups are to be formed, Design is a cell array with NUMSAMPLES cells, where each cell contains a NUMSERIES-by-(NUMGROUPS * NUMPARAMS) matrix of known values.

The original collection of parameters that are common to all series are replicated to form collections of parameters for each group.

## Examples

## Use convert2sur to Estimate Stock Alpha and Beta Values

This example shows a CAPM demonstration using 6 stocks and 60 months of simulated asset returns, where the model for each stock is AssetReturn = Alpha * 1 + CashReturn + Beta * (MarketReturn - CashReturn) + Noise and the parameters to estimate are Alpha and Beta.

Using simulated data, where the Alpha estimate(s) are displayed in the first row(s) and the Beta estimate(s) are display in the second row(s).

```
Market = (0.1 - 0.04) + 0.17*randn (60, 1);
Asset = (0.1 - 0.04) + 0.35*randn (60, 6);
Design = cell(60, 1);
for i = 1:60
    Design{i} = repmat([ 1, Market(i) ], 6, 1);
end
```

Obtain the aggregate estimates for all stocks.

```
[Param, Covar] = mvnrmle(Asset, Design);
```

disp(\{'All 6 Assets Combined'\});
disp(Param);

## 'All 6 Assets Combined

## cir

Cox-Ingersoll-Ross mean-reverting square root diffusion models

## Syntax

```
CIR = cir(Speed, Level, Sigma)
```

CIR = cir(Speed, Level, Sigma, 'Name1', Value1, 'Name2', Value2, ...)

## Class

## CIR

## Description

This constructor creates and displays CIR objects, which derive from the SDEMRD (SDE with drift rate expressed in mean-reverting form) class. Use CIR objects to simulate sample paths of NVARS state variables expressed in mean-reverting drift-rate form. These state variables are driven by NBROWNS Brownian motion sources of risk over NPERIODS consecutive observation periods, approximating continuous-time CIR stochastic processes with square root diffusions.

This method allows you to simulate any vector-valued SDE of the form:

$$
d X_{t}=S(t)\left[L(t)-X_{t}\right] d t+D\left(t, X_{t}^{\frac{1}{2}}\right) V(t) d W_{t}
$$

where:

- $X_{t}$ is an NVARS-by- 1 state vector of process variables.
- $S$ is an NVARS-by-NVARS matrix of mean reversion speeds (the rate of mean reversion).
- $L$ is an NVARS-by- 1 vector of mean reversion levels (long-run mean or level).
- $D$ is an NVARS-by-NVARS diagonal matrix, where each element along the main diagonal is the square root of the corresponding element of the state vector.
- $V$ is an NVARS-by-NBROWNS instantaneous volatility rate matrix.
- $d W_{t}$ is an NBROWNS-by- 1 Brownian motion vector.

## Input Arguments

Specify required input parameters as one of the following types:

- A MATLAB array. Specifying an array indicates a static (non-time-varying) parametric specification. This array fully captures all implementation details, which are clearly associated with a parametric form.
- A MATLAB function. Specifying a function provides indirect support for virtually any static, dynamic, linear, or nonlinear model. This parameter is supported via an interface, because all implementation details are hidden and fully encapsulated by the function.

Note: You can specify combinations of array and function input parameters as needed.
Moreover, a parameter is identified as a deterministic function of time if the function accepts a scalar time $t$ as its only input argument. Otherwise, a parameter is assumed to be a function of time $t$ and state $X(t)$ and is invoked with both input arguments.

The required input parameters are:

| Speed | Speed represents S. If you specify Speed as an array, it must be an <br> NVARS-by-NVARS matrix of mean-reversion speeds (the rate or speed <br> at which the state vector reverts to its long-run average Level). As a <br> deterministic function of time, when Speed is called with a real-valued <br> scalar time t as its only input, Speed must produce an NVARS-by-NVARS <br> matrix. <br> If you specify Speed as a function of time and state, it must generate <br> an NVARS-by-NVARS matrix of reversion rates when invoked with two <br> inputs: <br> - A real-valued scalar observation time $t$. <br>  |
| :--- | :--- |
|  | An NVARS-by-1 state vector $X_{t}$. |

| Level | Level represents $L$. If you specify Level as an array, it must be <br> an NVARS-by-1 column vector of reversion levels. As a deterministic <br> function of time, when Level is called with a real-valued scalar time t <br> as its only input, Level must produce an NVARS-by-1 matrix. |
| :--- | :--- |
| If you specify Level as a function of time and state, it must generate <br> an NVARS-by-1 column vector of reversion levels when invoked with two <br> inputs: <br> $-\quad$ A real-valued scalar observation time $t$. <br> $-\quad$ An NVARS-by-1 state vector $X_{t}$. |  |
| Sigma | Sigma represents the parameter $V$. If you specify Sigma as an <br> array, it must be an NVARS-by-NBROWNS 2-dimensional matrix <br> of instantaneous volatility rates. In this case, each row of Sigma <br> corresponds to a particular state variable. Each column of Sigma <br> corresponds to a particular Brownian source of uncertainty, and <br> associates the magnitude of the exposure of state variables with sources <br> of uncertainty. As a deterministic function of time, when Sigma is called <br> with a real-valued scalar time $t$ as its only input, Sigma must produce <br> an NVARS-by-NBROWNS matrix. |
| If you specify Sigma as a function of time and state, it must generate <br> an NVARS-by-NBROWNS matrix of volatility rates when invoked with two <br> inputs: <br> $-\quad$ A real-valued scalar observation time $t$. <br> • An NVARS-by-1 state vector $X_{t}$. |  |

Note: Although the constructor does not enforce restrictions on the signs of these input arguments, each argument is usually specified as a positive value.

## Optional Input Arguments

Specify optional inputs as matching parameter name/value pairs as follows:

- Specify the parameter name as a character string, followed by its corresponding value.
- You can specify parameter name/value pairs in any order.
- Parameter names are case insensitive.
- You can specify unambiguous partial string matches.

Valid parameter names are:

| StartTime | Scalar starting time of the first observation, applied to all state <br> variables. If you do not specify a value for StartTime, the default <br> is 0. |
| :--- | :--- |
| StartState | Scalar, NVARS-by-1 column vector, or NVARS-by-NTRIALS matrix of <br> initial values of the state variables. <br> If StartState is a scalar, cir applies the same initial value to all <br> state variables on all trials. <br> If StartState is a column vector, cir applies a unique initial <br> value to each state variable on all trials. |
| If StartState is a matrix, cir applies a unique initial value to |  |
| each state variable on each trial. |  |
| Correlation | If you do not specify a value for StartState, all variables start at <br> 1. |
| Correlation between Gaussian random variates drawn to <br> generate the Brownian motion vector (Wiener processes). Specify <br> Correlation as an NBROWNS-by-NBROWNS positive semidefinite <br> matrix, or as a deterministic function $C(t)$ that accepts the current <br> time $t$ and returns an NBROWNS-by-NBROWNS positive semidefinite <br> correlation matrix. |  |

|  | A Correlation matrix represents a static condition. <br> As a deterministic function of time, Correlation allows you to <br> specify a dynamic correlation structure. |
| :--- | :--- |
|  | If you do not specify a value for Correlation, the default is an <br> NBROWNS-by-NBROWNS identity matrix representing independent <br> Gaussian processes. |
| Simulation | A user-defined simulation function or SDE simulation method. If <br> you do not specify a value for Simulation, the default method is <br> simulation by Euler approximation (simByEuler). |

## Output Arguments

| CIR | Object of class CIR with the following displayed parameters: <br> - StartTime: Initial observation time <br> - StartState: Initial state at time StartTime <br> - Correlation: Access function for the Correlation input argument, callable as a function of time <br> - Drift: Composite drift-rate function, callable as a function of time and state <br> - Diffusion: Composite diffusion-rate function, callable as a function of time and state <br> - Simulation: A simulation function or method <br> - Speed: Access function for the input argument Speed, callable as a function of time and state <br> - Level: Access function for the input argument Level, callable as a function of time and state <br> - Sigma: Access function for the input argument Sigma, callable as a function of time and state |
| :---: | :---: |

## Examples

## More About

## Algorithms

When you specify the required input parameters as arrays, they are associated with a specific parametric form. By contrast, when you specify either required input parameter as a function, you can customize virtually any specification.

Accessing the output parameters with no inputs simply returns the original input specification. Thus, when you invoke these parameters with no inputs, they behave like simple properties and allow you to test the data type (double vs. function, or equivalently, static vs. dynamic) of the original input specification. This is useful for validating and designing methods.

When you invoke these parameters with inputs, they behave like functions, giving the impression of dynamic behavior. The parameters accept the observation time $t$ followed by a state vector $X_{t}$, and return an array of appropriate dimension. Even if you originally specified an input as an array, cir treats it as a static function of time and state, by that means guaranteeing that all parameters are accessible by the same interface.

## convertto

Convert to specified frequency

## Syntax

```
newfts = convertto(oldfts, newfreq)
newfts = convertto(oldfts, newfreq, 'param1','value1','param2',
'value2', ... )
```

## Arguments

| oldfts | Name of an existing financial time series object. |
| :--- | :--- |
| newfreq | 1, DAILY, Daily, daily, D, d |
|  | 2, WEEKLY, Weekly, weekly, W, w |
|  | 3, MONTHLY, Monthly, monthly, M, m |
|  | 4, QUARTERLY, Quarterly, quarterly, Q, q |
|  | 5, SEMIANNUAL, Semiannual, semiannual, S, s |
|  | 6, ANNUAL, Annual, annual, A, a |

## Description

convertto converts a financial time series of any frequency to one of a specified frequency.
newfts = convertto(oldfts, newfreq) converts the object oldfts to the new time series object newfts with the frequency newfreq.

Refer to the documentation for each frequency conversion function to determine the valid parameter/value pairs.

## Introduced before R2006a

## corrcoef

Correlation coefficients

## Syntax

```
r = corrcoef(X)
r = corrcoef(X,Y)
```

## Arguments

| X | Matrix where each row is an observation and each column is a <br> variable. |
| :--- | :--- |
| Y | Matrix where each row is an observation and each column is a <br> variable. |

## Description

corrcoef for financial time series objects is based on the MATLAB corrcoef function. See corrcoef in the MATLAB documentation.
$r=\operatorname{corrcoef}(X)$ calculates a matrix $r$ of correlation coefficients for an array $X$, in which each row is an observation, and each column is a variable.
$r=\operatorname{corrcoef}(X, Y)$, where $X$ and $Y$ are column vectors, is the same as $r=\operatorname{corrcoef}$ ( $[X$ $Y]$ ). corrcoef converts $X$ and $Y$ to column vectors if they are not; that is, $r=$ $\operatorname{corrcoef}(X, Y)$ is equivalent to $r=\operatorname{corrcoef}([X(:) Y(:)])$ in that case.

If $c$ is the covariance matrix, $c=\operatorname{cov}(X)$, then $\operatorname{corrcoef}(X)$ is the matrix whose $(i, j)$ 'th element is ci, $j / \operatorname{sqrt}\left(\mathrm{ci}, i^{*} \mathrm{c}(j, j)\right.$ ).
$[r, p]=\operatorname{corrcoef}(\ldots)$ also returns $p$, a matrix of $p$-values for testing the hypothesis of no correlation. Each $p$-value is the probability of getting a correlation as large as the
observed value by random chance, when the true correlation is zero. If $p(i, j)$ is less than 0.05 , then the correlation $r(i, j)$ is significant.
[r,p,rlo, rup]=corrcoef (. . .) also returns matrices rlo and rup, of the same size as $r$, containing lower and upper bounds for a $95 \%$ confidence interval for each coefficient.
[...]=corrcoef(..., 'PARAM1', VAL1, 'PARAM2' ,VAL2, ...) specifies additional parameters and their values. Valid parameters are:

- 'alpha' - A number from 0 through 1 to specify a confidence level of $100^{*}(1-$ ALPHA) \%. Default is 0.05 for $95 \%$ confidence intervals.
- 'rows ' - Either 'all' (default) to use all rows, 'complete' to use rows with no NaN values, or 'pairwise' to compute $\mathrm{r}(i, j)$ using rows with no NaN values in column $i$ or $j$.

The $p$-value is computed by transforming the correlation to create a t-statistic having $N-2$ degrees of freedom, where $N$ is the number of rows of $X$. The confidence bounds are based on an asymptotic normal distribution of $0.5^{*} \log ((1+r) /(1-r))$, with an approximate variance equal to $1 /(\mathrm{N}-3)$. These bounds are accurate for large samples when $X$ has a multivariate normal distribution. The 'pairwise' option can produce an $r$ matrix that is not positive definite.

## Examples

## Compute Correlation Coefficients

This example shows how to generate random data having correlation between column 4 and the other columns.

```
x = randn(30,4); % uncorrelated data
x(:,4) = sum(x,2); % introduce correlation
f = fints((today:today+29)', x); % create a fints object using x
[r,p] = corrcoef(x); % compute sample correlation and p-values
[i,j] = find(p<0.05); % find significant correlations
[i,j] % display their (row,col) indices
ans =
```

## corr2cov

Convert standard deviation and correlation to covariance

## Syntax

ExpCovariance = corr2cov(ExpSigma, ExpCorrC)

## Arguments

| ExpSigma | Vector of length $n$ with the standard deviations of each process. $n$ is <br> the number of random processes. |
| :--- | :--- |
| ExpCorrC | (Optional) $n$-by- $n$ correlation coefficient matrix. If ExpCorrC is not <br> specified, the processes are assumed to be uncorrelated, and the <br> identity matrix is used. |

## Description

corr2cov converts standard deviation and correlation to covariance.
ExpCovariance is an $n$-by- $n$ covariance matrix, where $n$ is the number of processes.
$\operatorname{ExpCov}(i, j)=\operatorname{ExpCorrC}(i, j) * E x p S i g m a(i) * E x p S i g m a(j)$

## Examples

## Convert Standard Deviation and Correlation to Covariance

This example shows how to convert standard deviation and correlation to covariance.

```
ExpSigma = [0.5 2.0];
ExpCorrC = [1.0 -0.5
    -0.5 1.0];
ExpCovariance = corr2cov(ExpSigma, ExpCorrC)
```

ExpCovariance =
$0.2500-0.5000$
-0.5000 4.0000

- "Data Transformation and Frequency Conversion" on page 12-17

See Also<br>corrcoef | cov | cov2corr | ewstats | std<br>Introduced before R2006a

## COV

Covariance matrix

## Syntax

$\operatorname{cov}(X)$
$\operatorname{cov}(X, Y)$

## Arguments

| X | Financial times series object. |
| :--- | :--- |
| Y | Financial times series object. |

## Description

cov for financial time series objects is based on the MATLAB cov function. See cov in the MATLAB documentation.

If $X$ is a financial time series object with one series, $\operatorname{cov}(X)$ returns the variance. For a financial time series object containing multiple series, where each row is an observation, and each series a variable, $\operatorname{cov}(X)$ is the covariance matrix.
$\operatorname{diag}(\operatorname{cov}(X))$ is a vector of variances for each series and sqrt $(\operatorname{diag}(\operatorname{cov}(X)))$ is a vector of standard deviations.
$\operatorname{cov}(X, Y)$, where $X$ and $Y$ are financial time series objects with the same number of elements, is equivalent to $\operatorname{cov}([X(:) Y(:)])$.
$\operatorname{cov}(X)$ or $\operatorname{cov}(X, Y)$ normalizes by $(N-1)$ if $N>1$, where $N$ is the number of observations. This makes $\operatorname{cov}(X)$ the best unbiased estimate of the covariance matrix if the observations are from a normal distribution. For $N=1$, cov normalizes by $N$.
$\operatorname{cov}(X, 1)$ or $\operatorname{cov}(X, Y, 1)$ normalizes by $N$ and produces the second moment matrix of the observations about their mean. $\operatorname{cov}(\mathrm{X}, \mathrm{Y}, \mathrm{O})$ is the same as $\operatorname{cov}(\mathrm{X}, \mathrm{Y})$ and
$\operatorname{cov}(X, 0)$ is the same as $\operatorname{cov}(X)$. The mean is removed from each column before calculating the result.

## Examples

## Create a Covariance Matrix

This example shows how to create a covariance matrix for the following dates.

```
dates = {'01-Jan-2007';'02-Jan-2007';'03-Jan-2007'};
A = [-1 1 2 ; -2 3 1 ; 4 0 3];
f = fints(dates, A);
c = cov(f)
c =
\begin{tabular}{rrr}
10.3333 & -4.1667 & 3.0000 \\
-4.1667 & 2.3333 & -1.5000 \\
3.0000 & -1.5000 & 1.0000
\end{tabular}
```

## cov2corr

Convert covariance to standard deviation and correlation coefficient

## Syntax

[ExpSigma, ExpCorrC] = cov2corr(ExpCovariance)

## Arguments

| ExpCovariance | $n$-by- $n$ covariance matrix; for example, from cov or <br> ewstats. $n$ is the number of random processes. |
| :--- | :--- |

## Description

[ExpSigma, ExpCorrC] = cov2corr (ExpCovariance) converts covariance to standard deviations and correlation coefficients.

ExpSigma is a 1-by- $n$ vector with the standard deviation of each process.
ExpCorrC is an $n$-by- $n$ matrix of correlation coefficients.
ExpSigma(i) = sqrt(ExpCovariance(i,i))
$\operatorname{ExpCorrC}(i, j)=\operatorname{ExpCovariance}(i, j) /(E x p S i g m a(i) * E x p S i g m a(j))$

## Examples

## Convert Covariance to Standard Deviations and Correlation Coefficients

This example shows how to convert a covariance matrix to standard deviations and correlation coefficients.

```
ExpCovariance = [0.25 -0.5
    -0.5 4.0];
```

[ExpSigma, ExpCorrC] = cov2corr(ExpCovariance)

```
ExpSigma =
    0.5000 2.0000
ExpCorrC =
    1.0000 -0.5000
    -0.5000 1.0000

## cpncount

Coupon payments remaining until maturity

## Syntax

NumCouponsRemaining = cpncount(Settle, Maturity, Period, Basis, EndMonthRule, IssueDate, FirstCouponDate, LastCouponDate, StartDate)

## Arguments

| Settle | Settlement date. A vector of serial date numbers or date strings. Settle must be earlier than Maturity. |
| :---: | :---: |
| Maturity | Maturity date. A vector of serial date numbers or date strings. |
| Period | (Optional) Coupons per year of the bond. A vector of integers. Allowed values are 0, 1, 2 (default), 3, 4, 6, and 12. |
| Basis | (Optional) Day-count basis of the instrument. A vector of integers. <br> - $0=$ actual/actual (default) <br> - $1=30 / 360$ (SIA) <br> - $2=$ actual $/ 360$ <br> - $3=$ actual $/ 365$ <br> - $4=30 / 360$ (PSA) <br> - $5=30 / 360$ (ISDA) <br> - $6=30 / 360$ (European) <br> - $7=$ actual/365 (Japanese) <br> - $8=$ actual/actual (ICMA) <br> - $9=$ actual/360 (ICMA) <br> - $10=$ actual $/ 365$ (ICMA) |

|  | • $11=30 / 360 \mathrm{E}$ (ICMA) <br> $-12=$ actual/365 (ISDA) <br> For more information, see basis. |
| :--- | :--- |
| EndMonthRule | (Optional) End-of-month rule. A vector. This rule applies <br> only when Maturity is an end-of-month date for a month <br> having 30 or fewer days. $0=$ ignore rule, meaning that a <br> bond's coupon payment date is always the same numerical <br> day of the month. 1 = set rule on (default), meaning that a <br> bond's coupon payment date is always the last actual day of <br> the month. |
| IssueDate | Optional) Date when a bond was issued. |
| FirstCouponDate | (Optional) Date when a bond makes its first coupon <br> payment; used when bond has an irregular first coupon <br> period. When FirstCouponDate and LastCouponDate <br> are both specified, FirstCouponDate takes precedence in <br> determining the coupon payment structure. If you do not <br> specify a FirstCouponDate, the cash flow payment dates <br> are determined from other inputs. |
| LastCouponDate | (Optional) Last coupon date of a bond before the maturity <br> date; used when bond has an irregular last coupon period. <br> In the absence of a specified FirstCouponDate, a specified <br> LastCouponDate determines the coupon structure of <br> the bond. The coupon structure of a bond is truncated at <br> the LastCouponDate, regardless of where it falls, and is <br> followed only by the bond's maturity cash flow date. If you <br> do not specify a LastCouponDate, the cash flow payment <br> dates are determined from other inputs. |
| StartDate | (Future implementation) |

Required arguments must be number of bonds, NUMBONDS)-by-1 or 1-by-NUMBONDS, conforming vectors or scalars. Optional arguments must be either NUMBONDS-by-1 or 1-by-NUMBONDS conforming vectors, scalars, or empty matrices.

## Description

NumCouponsRemaining = cpncount(Settle, Maturity, Period, Basis, EndMonthRule) returns the whole number of coupon payments between the settlement and maturity dates for a coupon bond or set of bonds. Coupons falling on or before settlement are not counted, except for the maturity payment which is always counted.

## Examples

## Find Coupon Payments Remaining Until Maturity

This example shows how to find the coupon payments remaining until maturity.

```
NumCouponsRemaining = cpncount('14 Mar 1997', '30 Nov 2000',...
```

2, 0, 0)

## NumCouponsRemaining =

8

## Find Coupon Payments Remaining Until Maturity for Different Maturity Dates

This example shows how to find the coupon payments remaining until maturity, given three coupon bonds with different maturity dates and the same default arguments.

```
Maturity = ['30 Sep 2000'; '31 Oct 2001'; '30 Nov 2002'];
NumCouponsRemaining = cpncount('14 Sep 1997', Maturity)
NumCouponsRemaining =
    7
    9
    1 1
```

## cpndaten

Next coupon date for fixed-income security

## Syntax

NextCouponDate = cpndaten(Settle, Maturity, Period, Basis, EndMonthRule, IssueDate, FirstCouponDate, LastCouponDate)

## Arguments

| Settle | Settlement date. A vector of serial date numbers or date strings. Settle must be earlier than Maturity. |
| :---: | :---: |
| Maturity | Maturity date. A vector of serial date numbers or date strings. |
| Period | (Optional) Coupons per year of the bond. A vector of integers. Allowed values are 0, 1, 2 (default), 3, 4, 6, and 12. |
| Basis | (Optional) Day-count basis of the instrument. A vector of integers. <br> - $0=$ actual/actual (default) <br> - $1=30 / 360$ (SIA) <br> - 2 = actual/360 <br> - 3 = actual/ 365 <br> - $4=30 / 360$ (PSA) <br> - $5=30 / 360$ (ISDA) <br> - $6=30 / 360$ (European) <br> - 7 = actual/365 (Japanese) <br> - $8=$ actual/actual (ICMA) <br> - 9 = actual/360 (ICMA) <br> - $10=$ actual/365 (ICMA) <br> - $11=30 / 360 \mathrm{E}$ (ICMA) |

|  | • $12=$ actual/365 (ISDA) <br> For more information, see basis. |
| :--- | :--- |
| EndMonthRule | (Optional) End-of-month rule. A vector. This rule applies <br> only when Maturity is an end-of-month date for a month <br> having 30 or fewer days. 0 = ignore rule, meaning that a <br> bond's coupon payment date is always the same numerical <br> day of the month. 1 = set rule on (default), meaning that a <br> bond's coupon payment date is always the last actual day of <br> the month. |
| IssueDate | Optional) Date when a bond was issued. |
| FirstCouponDate | (Optional) Date when a bond makes its first coupon <br> payment; used when bond has an irregular first coupon <br> period. When FirstCouponDate and LastCouponDate <br> are both specified, FirstCouponDate takes precedence in <br> determining the coupon payment structure. If you do not <br> specify a FirstCouponDate, the cash flow payment dates <br> are determined from other inputs. |
| LastCouponDate | (Optional) Last coupon date of a bond before the maturity <br> date; used when bond has an irregular last coupon period. <br> In the absence of a specified FirstCouponDate, a specified <br> LastCouponDate determines the coupon structure of <br> the bond. The coupon structure of a bond is truncated at <br> the LastCouponDate, regardless of where it falls, and is <br> followed only by the bond's maturity cash flow date. If you <br> do not specify a LastCouponDate, the cash flow payment <br> dates are determined from other inputs. |

Required arguments must be number of bonds, NUMBONDS)-by-1 or 1-by-NUMBONDS, conforming vectors or scalars. Optional arguments must be either NUMBONDS-by-1 or 1-by-NUMBONDS conforming vectors, scalars, or empty matrices.

## Description

NextCouponDate = cpndaten(Settle, Maturity, Period, Basis, EndMonthRule, IssueDate, FirstCouponDate, LastCouponDate) returns the
next coupon date after the settlement date. This function finds the next coupon date whether or not the coupon structure is synchronized with the maturity date.

NextCouponDate is returned as a serial date number. The function datestr converts a serial date number to a formatted date string.

## Examples

```
NextCouponDate = cpndaten('14 Mar 1997', '30 Nov 2000', 2, 0, 0);
datestr(NextCouponDate)
ans =
30-May-1997
NextCouponDate = cpndaten('14 Mar 1997', '30 Nov 2000', 2, 0, 1);
datestr(NextCouponDate)
ans =
31-May-1997
```

```
Maturity = ['30 Sep 2000'; '31 Oct 2000'; '30 Nov 2000'];
```

Maturity = ['30 Sep 2000'; '31 Oct 2000'; '30 Nov 2000'];
NextCouponDate = cpndaten('14 Mar 1997', Maturity);
datestr(NextCouponDate)
ans =
31-Mar-1997
30-Apr-1997
31-May-1997

```

For more information, see basis.
\end{tabular} \\
\hline EndMonthRule & \begin{tabular}{l} 
(Optional) End-of-month rule. A vector. This rule applies \\
only when Maturity is an end-of-month date for a month \\
having 30 or fewer days. 0 = ignore rule, meaning that a \\
bond's coupon payment date is always the same numerical \\
day of the month. 1 = set rule on (default), meaning that a \\
bond's coupon payment date is always the last actual day of \\
the month.
\end{tabular} \\
\hline IssueDate & (Optional) Date when a bond was issued. \\
\hline FirstCouponDate & \begin{tabular}{l} 
(Optional) Date when a bond makes its first coupon \\
payment; used when bond has an irregular first coupon \\
period. When FirstCouponDate and LastCouponDate \\
are both specified, FirstCouponDate takes precedence in \\
determining the coupon payment structure. If you do not \\
specify a FirstCouponDate, the cash flow payment dates \\
are determined from other inputs.
\end{tabular} \\
\hline LastCouponDate & \begin{tabular}{l} 
(Optional) Last coupon date of a bond before the maturity \\
date; used when bond has an irregular last coupon period. \\
In the absence of a specified FirstCouponDate, a specified \\
LastCouponDate determines the coupon structure of \\
the bond. The coupon structure of a bond is truncated at \\
the LastCouponDate, regardless of where it falls, and is \\
followed only by the bond's maturity cash flow date. If you \\
do not specify a LastCouponDate, the cash flow payment \\
dates are determined from other inputs.
\end{tabular} \\
\hline
\end{tabular}

Required arguments must be number of bonds, NUMBONDS)-by-1 or 1-by-NUMBONDS, conforming vectors or scalars. Optional arguments must be either NUMBONDS-by-1 or 1-by-NUMBONDS conforming vectors, scalars, or empty matrices. Fill unspecified entries in input vectors with the value NaN. Dates can be serial date numbers or date strings.

\section*{Description}

NextQuasiCouponDate = cpndatenq(Settle, Maturity, Period, Basis, EndMonthRule, IssueDate, FirstCouponDate, LastCouponDate) determines
the next quasi coupon date for a portfolio of NUMBONDS fixed income securities whether or not the first or last coupon is normal, short, or long. For zero coupon bonds cpndatenq returns quasi coupon dates as if the bond had a semiannual coupon structure. Successive quasi coupon dates determine the length of the standard coupon period for the fixed income security of interest and do not necessarily coincide with actual coupon payment dates.

Outputs are NUMBONDS-by-1 vectors.
If Settle is a coupon date, this function never returns the settlement date. It returns the quasi coupon date strictly after settlement.

NextQuasiCouponDate is returned as a serial date number. The function datestr converts a serial date number to a formatted date string.

\section*{Examples}

\section*{Determine the Next Quasi Coupon Date for a Porffolio of Fixed-Income Securities}

Given a pair of bonds with the following characteristics:
```

Settle = char('30-May-1997','10-Dec-1997');
Maturity = char('30-Nov-2002','10-Jun-2004');

```

Compute NextCouponDate for this pair of bonds.
```

NextCouponDate = cpndaten(Settle, Maturity);

```
datestr(NextCouponDate)
ans =
31-May-1997
10-Jun-1998

Compute the next quasi coupon dates for these two bonds.
NextQuasiCouponDate = cpndatenq(Settle, Maturity); datestr(NextQuasiCouponDate)

\section*{ans =}

31-May-1997
10-Jun-1998

Because no FirstCouponDate has been specified, the results are identical.
Now supply an explicit FirstCouponDate for each bond.
```

FirstCouponDate = char('30-Nov-1997','10-Dec-1998');

```

Compute the next coupon dates.
```

NextCouponDate = cpndaten(Settle, Maturity, 2, 0, 1, [],...
FirstCouponDate);
datestr(NextCouponDate)

```
```

ans =

```
30-Nov-1997
10-Dec-1998

The next coupon dates are identical to the specified first coupon dates.
Now recompute the next quasi coupon dates.
```

NextQuasiCouponDate = cpndatenq(Settle, Maturity, 2, 0, 1, [],...
FirstCouponDate);
datestr(NextQuasiCouponDate)
ans =
31-May-1997
10-Jun-1998

```

These results illustrate the distinction between actual coupon payment dates and quasi coupon dates. FirstCouponDate (and LastCouponDate, as well), when specified, is associated with an actual coupon payment and also serves as the synchronization date for determining all quasi coupon dates. Since each bond in this example pays semiannual coupons, and the first coupon date occurs more than six months after settlement, each
will have an intermediate quasi coupon date before the actual first coupon payment occurs.

\begin{tabular}{|l|l|} 
& \begin{tabular}{l} 
- \(12=\) actual/365 (ISDA) \\
For more information, see basis.
\end{tabular} \\
\hline EndMonthRule & \begin{tabular}{l} 
(Optional) End-of-month rule. A vector. This rule applies \\
only when Maturity is an end-of-month date for a month \\
having 30 or fewer days. \(0=\) ignore rule, meaning that a \\
bond's coupon payment date is always the same numerical \\
day of the month. 1 = set rule on (default), meaning that a \\
bond's coupon payment date is always the last actual day of \\
the month.
\end{tabular} \\
\hline IssueDate & \begin{tabular}{l} 
Optional) Date when a bond was issued.
\end{tabular} \\
\hline FirstCouponDate & \begin{tabular}{l} 
(Optional) Date when a bond makes its first coupon \\
payment; used when bond has an irregular first coupon \\
period. When FirstCouponDate and LastCouponDate \\
are both specified, FirstCouponDate takes precedence in \\
determining the coupon payment structure. If you do not \\
specify a FirstCouponDate, the cash flow payment dates \\
are determined from other inputs.
\end{tabular} \\
\hline LastCouponDate & \begin{tabular}{l} 
(Optional) Last coupon date of a bond before the maturity \\
date; used when bond has an irregular last coupon period. \\
In the absence of a specified FirstCouponDate, a specified \\
LastCouponDate determines the coupon structure of \\
the bond. The coupon structure of a bond is truncated at \\
the LastCouponDate, regardless of where it falls, and is \\
followed only by the bond's maturity cash flow date. If you \\
do not specify a LastCouponDate, the cash flow payment \\
dates are determined from other inputs.
\end{tabular} \\
\hline
\end{tabular}

Required arguments must be number of bonds, NUMBONDS)-by-1 or 1-by-NUMBONDS, conforming vectors or scalars. Optional arguments must be either NUMBONDS-by-1 or 1-by-NUMBONDS conforming vectors, scalars, or empty matrices.

\section*{Description}

PreviousCouponDate = cpndatep(Settle, Maturity, Period, Basis, EndMonthRule, IssueDate, FirstCouponDate, LastCouponDate) returns the
previous coupon date on or before settlement for a portfolio of bonds. This function finds the previous coupon date whether or not the coupon structure is synchronized with the maturity date.

For zero coupon bonds the previous coupon date is the issue date, if available. However, if the issue date is not supplied, the previous coupon date for zero coupon bonds is the previous quasi coupon date calculated as if the frequency is semiannual.

PreviousCouponDate is returned as a serial date number. The function datestr converts a serial date number to a formatted date string.

\section*{Examples}
```

PreviousCouponDate = cpndatep('14 Mar 1997', '30 Jun 2000',...
2, 0, 0);
datestr(PreviousCouponDate)
ans =
30-Dec-1996
PreviousCouponDate = cpndatep('14 Mar 1997', '30 Jun 2000',...
2, 0, 1);
datestr(PreviousCouponDate)
ans =
31-Dec-1996
Maturity = ['30 Apr 2000'; '31 May 2000'; '30 Jun 2000'];
PreviousCouponDate = cpndatep('14 Mar 1997', Maturity);
datestr(PreviousCouponDate)
ans =
31-Oct-1996
30-Nov-1996
31-Dec-1996

```

If you do } \\ \text { not specify a LastCouponDate, the cash flow payment dates } \\ \text { are determined from other inputs. }\end{array}\right\}\)

Required arguments must be number of bonds, NUMBONDS-by-1 or 1-by-NUMBONDS, conforming vectors or scalars. Optional arguments must be either NUMBONDS-by-1 or 1-by-NUMBONDS conforming vectors, scalars, or empty matrices. Fill in unspecified entries for input vectors with the value NaN. Dates can be serial date numbers or date strings.

\section*{Description}

PreviousQuasiCouponDate = cpndatepq(Settle, Maturity, Period, Basis, EndMonthRule, IssueDate, FirstCouponDate, LastCouponDate) determines
the previous quasi coupon date on or before settlement for a set of NUMBONDS fixed income securities. This function finds the previous quasi coupon date for a bond with a coupon structure in which the first or last period is either normal, short, or long (whether or not the coupon structure is synchronized to maturity). For zero coupon bonds this function returns quasi coupon dates as if the bond had a semiannual coupon structure.

The term "previous quasi coupon date" refers to the previous coupon date for a bond calculated as if no issue date were specified. Although the issue date is not actually a coupon date, when issue date is specified, the previous actual coupon date for a bond is normally calculated as being either the previous coupon date or the issue date, whichever is greater. This function always returns the previous quasi coupon date regardless of issue date. If the settlement date is a coupon date, this function returns the settlement date.

PreviousQuasiCouponDate is returned as a serial date number. The function datestr converts a serial date number to a formatted date string.

\section*{Examples}

\section*{Determine the Previous Quasi Coupon Date for a Porffolio of Fixed-Income Securities}

Given a pair of bonds with the following characteristics:
```

Settle = char('30-May-1997','10-Dec-1997');
Maturity = char('30-Nov-2002','10-Jun-2004');

```

With no FirstCouponDate explicitly supplied, compute the PreviousCouponDate for this pair of bonds.
```

PreviousCouponDate = cpndatep(Settle, Maturity);

```
datestr(PreviousCouponDate)
ans =

30-Nov-1996
10-Dec-1997

Note that since the settlement date for the second bond is also a coupon date, cpndatep returns this date as the previous coupon date.

Now establish a FirstCouponDate and IssueDate for this pair of bonds.
```

FirstCouponDate = char('30-Nov-1997','10-Dec-1998');
IssueDate = char('30-May-1996', '10-Dec-1996');

```

Recompute the PreviousCouponDate for this pair of bonds.
```

PreviousCouponDate = cpndatep(Settle, Maturity, 2, 0, 1, ...
IssueDate, FirstCouponDate);
datestr(PreviousCouponDate)

```
ans =
30-May-1996
10-Dec-1996

Since both of these bonds settled before the first coupon had been paid, cpndatep returns the IssueDate as the PreviousCouponDate.

Using the same data, compute PreviousQuasiCouponDate.
```

PreviousQuasiCouponDate = cpndatepq(Settle, Maturity, 2, 0, 1,···.
IssueDate, FirstCouponDate);

```
datestr(PreviousQuasiCouponDate)
ans =
\(30-\) Nov-1996
10-Dec-1997

For the first bond the settlement date is not a normal coupon date. The PreviousQuasiCouponDate is the coupon date before or on the settlement date. Since the coupon structure is synchronized to FirstCouponDate, the previous quasi coupon date is 30 -Nov-1996. PreviousQuasiCouponDate disregards IssueDate and FirstCouponDate in this case. For the second bond the settlement date (10-Dec-1997) occurs on a date when a coupon would normally be paid in the absence of an explicit FirstCouponDate. cpndatepq returns this date as PreviousQuasiCouponDate.
- "Pricing and Computing Yields for Fixed-Income Securities" on page 2-21

• \(11=30 / 360 \mathrm{E}\) (ICMA) \\
\(-12=\) actual/365 (ISDA) \\
For more information, see basis.
\end{tabular} \\
\hline EndMonthRule & \begin{tabular}{l} 
(Optional) End-of-month rule. A vector. This rule applies \\
only when Maturity is an end-of-month date for a month \\
having 30 or fewer days. \(0=\) ignore rule, meaning that a \\
bond's coupon payment date is always the same numerical \\
day of the month. 1 = set rule on (default), meaning that a \\
bond's coupon payment date is always the last actual day of \\
the month.
\end{tabular} \\
\hline IssueDate & \begin{tabular}{l} 
Optional) Date when a bond was issued.
\end{tabular} \\
\hline FirstCouponDate & \begin{tabular}{l} 
(Optional) Date when a bond makes its first coupon \\
payment; used when bond has an irregular first coupon \\
period. When FirstCouponDate and LastCouponDate \\
are both specified, FirstCouponDate takes precedence in \\
determining the coupon payment structure. If you do not \\
specify a FirstCouponDate, the cash flow payment dates \\
are determined from other inputs.
\end{tabular} \\
\hline LastCouponDate & \begin{tabular}{l} 
(Optional) Last coupon date of a bond before the maturity \\
date; used when bond has an irregular last coupon period. \\
In the absence of a specified FirstCouponDate, a specified \\
LastCouponDate determines the coupon structure of \\
the bond. The coupon structure of a bond is truncated at \\
the LastCouponDate, regardless of where it falls, and is \\
followed only by the bond's maturity cash flow date. If you \\
do not specify a LastCouponDate, the cash flow payment \\
dates are determined from other inputs.
\end{tabular} \\
\hline StartDate & (Future implementation) \\
\hline
\end{tabular}

Required arguments must be number of bonds, NUMBONDS-by-1 or 1-by-NUMBONDS, conforming vectors or scalars. Optional arguments must be either NUMBONDS-by-1 or 1-by-NUMBONDS conforming vectors, scalars, or empty matrices.

\section*{Description}

NumDaysNext = cpndaysn(Settle, Maturity, Period, Basis, EndMonthRule, IssueDate, FirstCouponDate, LastCouponDate, StartDate) returns the number of days from the settlement date to the next coupon date for a bond or set of bonds. For zero coupon bonds coupon dates are computed as if the bonds have a semiannual coupon structure.

\section*{Examples}

NumDaysNext \(=\) cpndaysn('14 Sep 2000', '30 Jun 2001', 2, 0, 0)
NumDaysNext =
107
NumDaysNext \(=\) cpndaysn('14 Sep 2000', '30 Jun 2001', 2, 0, 1)
NumDaysNext =
108
Maturity = ['30 Apr 2001'; '31 May 2001'; '30 Jun 2001'];
NumDaysNext \(=\) cpndaysn('14 Sep 2000', Maturity)
NumDaysNext =
47
77
108

\hline Basis & \begin{tabular}{l}
(Optional) Day-count basis of the instrument. A vector of integers. \\
- \(0=\) actual/actual (default) \\
- \(1=30 / 360\) (SIA) \\
- 2 = actual \(/ 360\) \\
- 3 = actual/365 \\
- \(4=30 / 360\) (PSA) \\
- \(5=30 / 360\) (ISDA) \\
- \(6=30 / 360\) (European) \\
- \(7=\) actual/365 (Japanese) \\
- \(8=\) actual/actual (ICMA) \\
- \(9=\mathrm{actual} / 360\) (ICMA) \\
- \(10=\) actual/365 (ICMA)
\end{tabular} \\
\hline
\end{tabular}
\begin{tabular}{|l|l|} 
& \begin{tabular}{l} 
• \(11=30 / 360 \mathrm{E}\) (ICMA) \\
\(-12=\) actual/365 (ISDA) \\
For more information, see basis.
\end{tabular} \\
\hline EndMonthRule & \begin{tabular}{l} 
(Optional) End-of-month rule. A vector. This rule applies \\
only when Maturity is an end-of-month date for a month \\
having 30 or fewer days. 0 = ignore rule, meaning that a \\
bond's coupon payment date is always the same numerical \\
day of the month. 1 = set rule on (default), meaning that a \\
bond's coupon payment date is always the last actual day of \\
the month.
\end{tabular} \\
\hline IssueDate & \begin{tabular}{l} 
Optional) Date when a bond was issued.
\end{tabular} \\
\hline FirstCouponDate & \begin{tabular}{l} 
(Optional) Date when a bond makes its first coupon \\
payment; used when bond has an irregular first coupon \\
period. When FirstCouponDate and LastCouponDate \\
are both specified, FirstCouponDate takes precedence in \\
determining the coupon payment structure. If you do not \\
specify a FirstCouponDate, the cash flow payment dates \\
are determined from other inputs.
\end{tabular} \\
\hline LastCouponDate & \begin{tabular}{l} 
(Optional) Last coupon date of a bond before the maturity \\
date; used when bond has an irregular last coupon period. \\
In the absence of a specified FirstCouponDate, a specified \\
LastCouponDate determines the coupon structure of \\
the bond. The coupon structure of a bond is truncated at \\
the LastCouponDate, regardless of where it falls, and is \\
followed only by the bond's maturity cash flow date. If you \\
do not specify a LastCouponDate, the cash flow payment \\
dates are determined from other inputs.
\end{tabular} \\
\hline StartDate & (Future implementation) \\
\hline
\end{tabular}

Required arguments must be a number of bonds, NUMBONDS-by-1 or 1-by-NUMBONDS, conforming vectors or scalars. Optional arguments must be either NUMBONDS-by-1 or 1 -by-NUMBONDS conforming vectors, scalars, or empty matrices.

\section*{Description}

NumDaysPrevious = cpndaysp(Settle, Maturity, Period, Basis, EndMonthRule, IssueDate, FirstCouponDate, LastCouponDate, StartDate) returns the number of days between the previous coupon date and the settlement date for a bond or set of bonds. When the coupon frequency is 0 (a zero coupon bond), the previous coupon date is calculated as if the frequency were semiannual.

\section*{Examples}
```

NumDaysPrevious = cpndaysp('14 Mar 2000', '30 Jun 2001', 2, 0, 0)

```
NumDaysPrevious =
    75
NumDaysPrevious = cpndaysp('14 Mar 2000', '30 Jun 2001', 2, 0, 1)
NumDaysPrevious =
    74
Maturity = ['30 Apr 2001'; '31 May 2001'; '30 Jun 2001'];
NumDaysPrevious = cpndaysp('14 Mar 2000', Maturity)
NumDaysPrevious =
    135
    105
    74

\section*{Introduced before R2006a}

\section*{createholidays}

Create trading calendars

\section*{Syntax}
createholidays(Filename, Codefile, InfoFile, TargetDir, IncludeWkds, Wprompt, NoGUI)

\section*{Arguments}
\begin{tabular}{|l|l|}
\hline Filename & The data file name. \\
\hline Codefile & The code file name. \\
\hline InfoFile & The info file name. \\
\hline TargetDir & The target folder where to write the new holidays.m files. \\
\hline IncludeWkds & \begin{tabular}{l} 
Option to include weekends in the holiday list. Values are: \\
- 0 - Do not include weekends in the holiday list. \\
- 1 - Include weekends in the holiday list.
\end{tabular} \\
\hline Wprompt & \begin{tabular}{l} 
Option to prompt for the file location for each holiday .m \\
file that is created. Values are:
\end{tabular} \\
\hline NoGUI \(\quad 0\) - Do not prompt for the file location. \\
- 1 - Prompt for the file location.
\end{tabular}

\section*{Description}
createholidays(Filename, Codefile, InfoFile, TargetDir, IncludeWkds, Wprompt, NoGUI ) programmatically generates the market-specific holidays.m files without displaying the interface.

Note: To use createholidays, you must obtain data, codes, and info files from http://www.FinancialCalendar.com trading calendars.

\section*{Examples}
createholidays('FinancialCalendar\My_datafile.csv',...
'FinancialCalendar\My_codesfile.csv', ...
'FinancialCalendar\My_infofile.csv', 'c:\work',1,1,1)
creates holidays*.m files from My_datafile.csv in the folder c: \work. Weekends are included in the holidays list based on the input flag INCLUDEWDKS \(=1\).

\section*{cumsum}

Cumulative sum

\section*{Syntax}
```

newfts = cumsum(oldfts)

```

\section*{Description}
newfts = cumsum(oldfts) calculates the cumulative sum of each individual time series data series in the financial time series object oldfts and returns the result in another financial time series object newfts. newfts contains the same data series names as oldfts.

\section*{Examples}

\section*{Compute the Cumulative Sum}

This example shows how to compute the cumulative sum for Disney stock and plot the results.
load disney.mat
cs_dis = cumsum(fillts(dis));
plot(cs_dis)
title('Cumulative Sum for Disney')

\section*{cur2frac}

Decimal currency values to fractional values

\section*{Syntax}

Fraction = cur2frac(Decimal, Denominator)

\section*{Description}

Fraction = cur2frac(Decimal, Denominator) converts decimal currency values to fractional values. Fraction is returned as a string.

\section*{Examples}

\section*{Convert Decimal Currency Values to Fractional Values}

This example shows how to convert decimal currency values to fractional values.
Fraction \(=\) cur2frac(12.125, 8)

Fraction =
12.1
- "Format Currency" on page 2-11

\section*{See Also}
cur2str | frac2cur
Introduced before R2006a

\section*{cur2str}

Bank-formatted text

\section*{Syntax}

String = cur2str(Value, Digits)

\section*{Description}

String = cur2str(Value, Digits) returns the given value in bank format. By default, Digits = 2. A negative Digits rounds the value to the left of the decimal point. String is returned as a string with a leading dollar sign (\$). Negative numbers are displayed in parentheses.

\section*{See Also \\ cur2frac | frac2cur}

\section*{Related Examples}
- "Format Currency" on page 2-11

Introduced before R2006a

\section*{date2time}

Time and frequency from dates

\section*{Syntax}
[TFactors, F] = date2time(Settle, Maturity, Compounding, Basis, EndMonthRule)

\section*{Arguments}
\begin{tabular}{|c|c|}
\hline Settle & Settlement date. A vector of serial date numbers or date strings. \\
\hline Maturity & A vector of serial maturity dates. \\
\hline Compounding & \begin{tabular}{l}
(Optional) Scalar value representing the rate at which the input zero rates were compounded when annualized. The default Compounding value is 2 . This argument determines the formula for the discount factors (Disc): \\
- Compounding \(=0\) for simple interest \\
- Disc \(=1 /(1+Z * T)\), where \(T\) is time in years and simple interest assumes annual times \(F=1\). \\
- Compounding \(=1,2,3,4,6,12\) \\
- Disc \(=(1+Z / F)^{\wedge}(-T)\), where \(F\) is the compounding frequency, \(Z\) is the zero rate, and \(T\) is the time in periodic units, for example, \(\mathrm{T}=\mathrm{F}\) is one year. \\
- Compounding \(=365\) \\
- Disc \(=(1+Z / F)^{\wedge}(-T)\), where \(F\) is the number of days in the basis year and \(T\) is a number of days elapsed computed by basis. \\
- Compounding \(=-1\) \\
- Disc \(=\exp \left(-T^{*} Z\right)\), where \(T\) is time in years.
\end{tabular} \\
\hline
\end{tabular}
\begin{tabular}{|c|c|}
\hline Basis & \begin{tabular}{l}
(Optional) Day-count basis of the instrument. A vector of integers. \\
- \(0=\) actual/actual (default) \\
- \(1=30 / 360\) (SIA) \\
- \(2=\) actual/ 360 \\
- 3 = actual/ 365 \\
- \(4=30 / 360\) (PSA) \\
- \(5=30 / 360\) (ISDA) \\
- \(6=30 / 360\) (European) \\
- 7 = actual/365 (Japanese) \\
- \(8=\) actual/actual (ICMA) \\
- \(9=\) actual/360 (ICMA) \\
- \(10=\) actual/365 (ICMA) \\
- \(11=30 / 360 \mathrm{E}\) (ICMA) \\
- 12 = actual/365 (ISDA) \\
- 13 = BUS/252 \\
For more information, see basis.
\end{tabular} \\
\hline EndMonthRule & (Optional) End-of-month rule. A vector. This rule applies only when Maturity is an end-of-month date for a month having 30 or fewer days. \(0=\) ignore rule, meaning that a bond's coupon payment date is always the same numerical day of the month. \(1=\) set rule on (default), meaning that a bond's coupon payment date is always the last actual day of the month. \\
\hline
\end{tabular}

\section*{Description}
[TFactors, F] = date2time(Settle, Maturity, Compounding, Basis, EndMonthRule) computes time factors appropriate to compounded rate quotes between the settlement and maturity dates.

TFactors is a vector of time factors.
\(F\) is a scalar of related compounding frequencies.
date2time is the inverse of time2date.

\section*{Definitions}

The difference between yearfrac and date2time is that date2time counts full periods as a whole integer, even if the number of actual days in the periods are different. yearfrac does not count full periods. For example,
```

yearfrac('1/1/2000', '1/1/2001', 9)

```
ans =

\subsection*{1.0167}
yearfrac for Basis 9 (ACT/360 ICMA) calculates \(366 / 360=1.0167\). So, even if the dates have the same month and date, with a difference of 1 in the year, the returned value may not be exactly 1 . On the other hand, date2time calculates one full year period:
```

date2time('1/1/2000', '1/1/2001', 1, 9)

```
ans \(=\)
    1

\section*{See Also}
cftimes | disc2rate | rate2disc | time2date | yearfrac

\section*{Related Examples}
- "Handle and Convert Dates" on page 2-4

\section*{Introduced before R2006a}

\section*{dateaxis}

Convert serial-date axis labels to calendar-date axis labels

\section*{Syntax}
dateaxis(Tickaxis, DateForm, StartDate)

\section*{Arguments}
\begin{tabular}{|l|l|}
\hline Tickaxis & \begin{tabular}{l} 
(Optional) Determines which axis tick labels- \(x, y\), or \(z\)-to replace. \\
Enter as a string. Default \(=\) ' x '.
\end{tabular} \\
\hline DateForm & \begin{tabular}{l} 
(Optional) Specifies which date format to use. Enter as an integer \\
from 0 to 17. If no DateForm argument is entered, this function \\
determines the date format based on the span of the axis limits. \\
For example, if the difference between the axis minimum and \\
maximum is less than 15, the tick labels are converted to three- \\
letter day-of-the-week abbreviations (DateForm = 8). See \\
DateForm format descriptions below.
\end{tabular} \\
\hline StartDate & \begin{tabular}{l} 
(Optional) Assigns the date to the first axis tick value. Enter \\
as a string. The tick values are treated as serial date numbers. \\
The default StartDate is the lower axis limit converted to \\
the appropriate date number. For example, a tick value of 1 is \\
converted to the date 01-Jan-0000. Entering StartDate as '06- \\
apr-1999' assigns the date April 6, 1999 to the first tick value and \\
the axis tick labels are set accordingly.
\end{tabular} \\
\hline
\end{tabular}

\section*{Description}
dateaxis(Tickaxis, DateForm, StartDate) replaces axis tick labels with date labels on a graphic figure.

See the MATLAB set command for information on modifying the axis tick values and other axis parameters.
\begin{tabular}{lll} 
DateForm & Format & Description \\
0 & \(01-\) Mar-1999 15:45:17 & day-month-year hour:minute:second \\
1 & \(01-\) mar-1999 & day-month-year \\
2 & \(03 / 01 / 99\) & month/day/year \\
3 & Mar & month, three letters \\
4 & M & month, single letter \\
5 & 3 & month \\
6 & \(03 / 01\) & month/day \\
7 & 1 & day of month \\
8 & Wed & day of week, three letters \\
9 & W & day of week, single letter \\
10 & 1999 & year, four digits \\
11 & 99 & year, two digits \\
12 & Mar99 & month year \\
13 & \(15: 45: 17\) & hour:minute:second \\
14 & \(03: 45: 17\) PM & hour:minute:second AM or PM \\
15 & \(15: 45\) & hour:minute \\
16 & \(03: 45\) PM & hour:minute AM or PM \\
17 & \(95 / 03 / 01\) & year month day
\end{tabular}

\section*{Examples}
```

dateaxis('x') or dateaxis

```
converts the \(x\)-axis labels to an automatically determined date format.
```

dateaxis('y', 6)

```
converts the \(y\)-axis labels to the month/day format.
dateaxis('x', 2, '03/03/1999')
converts the \(x\)-axis labels to the month/day/year format. The minimum \(x\)-tick value is treated as March 3, 1999.
```

Introduced before R2006a

```

\section*{datedisp}

Display date entries

\section*{Syntax}
datedisp(NumMat, DateForm)
CharMat = datedisp(NumMat, DateForm)

\section*{Arguments}
\begin{tabular}{|l|l|}
\hline NumMat & Numeric matrix to display. \\
\hline DateForm & \begin{tabular}{l} 
(Optional) Date format. See datestr for available and default \\
format flags.
\end{tabular} \\
\hline
\end{tabular}

\section*{Description}
datedisp(NumMat, DateForm) displays a matrix with the serial dates formatted as date strings, using a matrix with mixed numeric entries and serial date number entries. Integers between datenum ('01-Jan-1900') and datenum ('01-Jan-2200') are assumed to be serial date numbers, while all other values are treated as numeric entries.

CharMat is a character array representing NumMat. If no output variable is assigned, the function prints the array to the display.

\section*{Examples}

\section*{Display a Matrix with the Serial Dates Formatted as Date Strings}

This example shows how to display a matrix with the serial dates formatted as date strings.
```

NumMat = [730730, 0.03, 1200 730100;
730731, 0.05, 1000 NaN];

```
```

datedisp(NumMat)

| $01-$ Sep-2000 | 0.03 | 1200 | $11-$ Dec-1998 |
| :---: | :---: | :---: | :---: |
| $02-$ Sep-2000 | 0.05 | 1000 | NaN |

02-Sep-2000 0.05 1000 NaN

```
- "Handle and Convert Dates" on page 2-4

\section*{See Also}
datenum | datestr

Introduced before R2006a

\section*{datefind}

Indices of date numbers in matrix

\section*{Syntax}

Indices = datefind(Subset, Superset, Tolerance)

\section*{Arguments}
\begin{tabular}{|l|l|}
\hline Subset & \begin{tabular}{l} 
Subset matrix of date numbers used to find matching date numbers \\
in Superset. These date numbers must be a nonrepeating subset \\
of those in Superset.
\end{tabular} \\
\hline Superset & \begin{tabular}{l} 
Superset matrix of nonrepeating date numbers whose elements are \\
sought.
\end{tabular} \\
\hline Tolerance & \begin{tabular}{l} 
(Optional) Tolerance \((+/-)\) for matching the date numbers in \\
Superset. A positive integer. Default \(=0\).
\end{tabular} \\
\hline
\end{tabular}

\section*{Description}

Indices = datefind(Subset, Superset, Tolerance) returns a vector of indices to the date numbers in Superset that are present in Subset, plus or minus the Tolerance. If no date numbers match, Indices = [].

Although this function was designed for use with sequential date numbers, you can use it with any nonrepeating integers.

\section*{Examples}

\section*{Return a Vector of Indices to Date Numbers}

This example shows how to return a vector of indices to date numbers.
```

Superset = datenum(1999, 7, 1:31);

```
```

Subset = [datenum(1999, 7, 10); datenum(1999, 7, 20)];
Indices = datefind(Subset, Superset, 1)
Indices =
9
10
11
1 9
20
21

```
- "Handle and Convert Dates" on page 2-4

datenum

Introduced before R2006a

\section*{datemnth}

Date of day in future or past month

\section*{Syntax}

TargetDate = datemnth(StartDate, NumberMonths, DayFlag, Basis, EndMonthRule)

\section*{Arguments}
\begin{tabular}{|c|c|}
\hline StartDate & Enter as serial date numbers or date strings. \\
\hline NumberMonths & Vector containing number of months in future (positive) or past (negative). Values must be in integer form. \\
\hline DayFlag & \begin{tabular}{l}
(Optional) Vector containing values that specify how the actual day number for the target date in future or past month is determined. 0 (default) = day number should be the day in the future or past month corresponding to the actual day number of the start date. 1 = day number should be the first day of the future or past month. \(2=\) day number should be the last day of the future or past month. \\
This flag has no effect if EndMonthRule is set to 1.
\end{tabular} \\
\hline Basis & \begin{tabular}{l}
(Optional) Day-count basis of the instrument. A vector of integers. \\
- \(0=\) actual/actual (default) \\
- \(1=30 / 360\) (SIA) \\
- 2 = actual/360 \\
- 3 = actual \(/ 365\) \\
- \(4=30 / 360\) (PSA) \\
- \(5=30 / 360\) (ISDA) \\
- \(6=30 / 360\) (European) \\
- \(7=\) actual/365 (Japanese)
\end{tabular} \\
\hline
\end{tabular}
\begin{tabular}{|c|c|}
\hline & \begin{tabular}{l}
- \(8=\) actual/actual (ICMA) \\
- \(9=\) actual/360 (ICMA) \\
- \(10=\) actual/365 (ICMA) \\
- \(11=30 / 360 \mathrm{E}\) (ICMA) \\
- 12 = actual/365 (ISDA) \\
- 13 = BUS/252 \\
For more information, see basis.
\end{tabular} \\
\hline EndMonthRule & \begin{tabular}{l}
(Optional) End-of-month rule. A vector. 1 = rule in effect, meaning that if you are beginning on the last day of a month, and the month has 30 or fewer days, you will end on the last actual day of the future or past month regardless of whether that month has \(28,29,30\) or 31 days. \\
\(0=\) rule off (default), meaning that the rule is not in effect.
\end{tabular} \\
\hline
\end{tabular}

Any input can contain multiple values, but if so, all other inputs must contain the same number of values or a single value that applies to all. For example, if StartDate is an n-row character array of date strings, then NumberMonths must be an \(n\)-by- 1 vector of integers or a single integer. TargetDate is then an \(n\)-by- 1 vector of date numbers.

\section*{Description}

TargetDate = datemnth(StartDate, NumberMonths, DayFlag, Basis, EndMonthRule) returns the serial date number of the target date in the future or past.

Use datestr to convert serial date numbers to formatted date strings.

\section*{Examples}

Day = datemnth('3 jun 2001', 6, 0, 0, 0)
Day =
731188
datestr(Day)
ans \(=\)

03-Dec-2001
Day = datemnth('3 jun 2001', 6, 1, 0, 1); datestr(Day)
ans =
01 -Dec-2001
```

Day = datemnth('31 jan 2001', 5, 0, 0, 0); datestr(Day)

```
ans =
30-Jun-2001
Day \(=\) datemnth('31 jan 2001', 5, 1, 0, 0); datestr(Day)
ans =
01 -Jun-2001
Day \(=\) datemnth('31 jan 2001', 5, 1, 0, 1); datestr(Day)
ans \(=\)
30-Jun-2001
Day = datemnth('31 jan 2001', 5, 2, 0, 1); datestr(Day)
ans \(=\)
30-Jun-2001
Months = [1; 3; 5; 7; 9];
Day = datemnth('31 jan 2001', Months); datestr(Day)
ans =

```

18 Functions - Alphabetical List

Introduced before R2006a

\section*{datewrkdy}

Date of future or past workday

\section*{Syntax}

EndDate = datewrkdy(StartDate, NumberWorkDays, NumberHolidays)

\section*{Arguments}
\begin{tabular}{|l|l|}
\hline StartDate & \begin{tabular}{l} 
Start date vector. Enter as serial date numbers or date \\
strings.
\end{tabular} \\
\hline NumberWorkDays & \begin{tabular}{l} 
Vector containing number of work or business days in future \\
(positive) or past (negative), including the starting date.
\end{tabular} \\
\hline NumberHolidays & \begin{tabular}{l} 
Vector containing values for the number of holidays \\
within NumberWorkDays. NumberHolidays and \\
NumberWorkDays must have the same sign.
\end{tabular} \\
\hline
\end{tabular}

Any input can contain multiple values, but if so, all other inputs must contain the same number of values or a single value that applies to all. For example, if StartDate is an nrow character array of date strings, then NumberWorkDays must be an \(n\)-by- 1 vector of integers or a single integer. EndDate is then an \(n\)-by- 1 vector of date numbers.

\section*{Description}

EndDate = datewrkdy(StartDate, NumberWorkDays, NumberHolidays) returns the serial number of the date a given number of workdays before or after the start date.

Use datestr to convert serial date numbers to formatted date strings.

\section*{Examples}

Workday = datewrkdy('12-dec-2000', 16, 2); datestr(Workday)
```

ans =
04-Jan-2001
NumDays = [16; 20; 44];
Workdays = datewrkdy('12-dec-2000', NumDays, 2);
datestr(Workdays)
ans =
4-Jan-2001
10-Jan-2001
13-Feb-2001

```

\section*{More About}
- "Trading Calendars User Interface" on page 15-2
- "UICalendar User Interface" on page 15-4

\author{
See Also \\ busdate | holidays | isbusday | wrkdydif
}

Introduced before R2006a

\section*{day}

Day of month

\section*{Syntax}

DayMonth \(=\operatorname{day}(\) Date \()\)
DayMonth \(=\operatorname{day}(\) Date, F)

\section*{Description}

DayMonth = day (Date) returns the day of the month given a serial date number or date string.

DayMonth = day (Date, F) returns the day of the of the month, given a serial date number or date string, in a specified date format.

\section*{Examples}

DayMonth \(=\operatorname{day}(730544)\)
or
DayMonth \(=\operatorname{day}\left({ }^{\prime} 2 / 28 / 00 '\right)\)
DayMonth \(=\)
28.00

You can also use the \(F\) argument to designate a country-specific date format:
DayMonth \(=\operatorname{day}\left({ }^{\prime} 28 / 02 / 00 ', ' d d / m m / y y y y '\right)\)
DayMonth \(=\)
28.00

\author{
See Also \\ datevec | eomday | month | year \\ Introduced before R2006a
}

\section*{days252bus}

Number of business days between dates

\section*{Syntax}
```

NumberDays = days252bus(StartDate, EndDate)
NumberDays = days252bus(StartDate, EndDate, HolidayVector)

```

\section*{Arguments}
\begin{tabular}{|l|l|}
\hline StartDate & \begin{tabular}{l}
N -by-1 or 1-by-N vector or scalar value, in either serial date number \\
or date string form, representing the start date.
\end{tabular} \\
\hline EndDate & \begin{tabular}{l}
N -by-1 or 1-by-N vector or scalar value, in either serial date number \\
or date string form, representing the end date.
\end{tabular} \\
\hline HolidayVector & \begin{tabular}{l} 
(Optional) N -by-1 or 1-by-N vector, in either serial date number or \\
date string form, representing holidays.
\end{tabular} \\
\hline
\end{tabular}

\section*{Description}

NumberDays = days252bus(StartDate, EndDate, HolidayVector) computes the number of business days (that is, non-holiday or non-weekend) between the two input dates. Note that a holiday vector may be optionally specified; if it is not, then the holidays.m file is used to determine the holidays.
days252bus returns NumberDays, a N -by-1 or 1-by-N vector or scalar value for the number of days between two dates.

\section*{Examples}

\section*{Computes the Number of Business Days Between Two Input Dates}

This example shows how to compute the number of business days (i.e. non-holiday or non-weekend) between two dates using the days252bus convention.
```

NumberDays = days252bus('1/1/2009', '8/1/2009')
NumberDays =
145
. "Handle and Convert Dates" on page 2-4

```

## days 360

Days between dates based on 360-day year

## Syntax

NumDays = days360(StartDate, EndDate)

## Arguments

| StartDate | Enter as serial date numbers or date strings. |
| :--- | :--- |
| EndDate | Enter as serial date numbers or date strings. |

Either input can contain multiple values, but if so, the other must contain the same number of values or a single value that applies to all. For example, if StartDate is an nrow character array of date strings, then EndDate must be an $n$-by- 1 vector of integers or a single integer. NumDays is then an $n$-by- 1 vector of date numbers.

## Description

NumDays = days360(StartDate, EndDate) returns the number of days between StartDate and EndDate based on a 360 -day year (that is, all months contain 30 days). If EndDate is earlier than StartDate, NumDays is negative.

## Examples

```
NumDays = days360('15-jan-2000', '15-mar-2000')
NumDays =
    6 0
MoreDays = ['15-mar-2000'; '15-apr-2000'; '15-jun-2000'];
NumDays = days360('15-jan-2000', MoreDays)
NumDays =
```

## days360e

Days between dates based on 360-day year (European)

## Syntax

```
NumDays = days360e(StartDate, EndDate)
```

## Arguments

| StartDate | Row vector, column vector, or scalar value in serial date number or <br> date string format. |
| :--- | :--- |
| EndDate | Row vector, column vector, or scalar value in serial date number or <br> date string format. |

Either input can contain multiple values, but if so, the other must contain the same number of values or a single value that applies to all.

## Description

NumDays = days360e(StartDate, EndDate) returns a vector or scalar value representing the number of days between StartDate and EndDate based on a 360day year (that is, all months contain 30 days). If EndDate is earlier than StartDate, NumDays is negative.

This day count convention is used primarily in Europe. Under this convention all months contain 30 days.

## Examples

Example 1. Use this convention to find the number of days in the month of January.

```
StartDate = '1-Jan-2002';
EndDate = '1-Feb-2002';
```

```
NumDays = days360e(StartDate, EndDate)
NumDays =
    30
```

Example 2. Use this convention to find the number of days in February during a leap year.

```
StartDate = '1-Feb-2000';
EndDate = '1-Mar-2000';
NumDays = days360e(StartDate, EndDate)
NumDays =
```

    30
    Example 3. Use this convention to find the number of days in February of a non-leap year.

```
StartDate = '1-Feb-2002';
EndDate = '1-Mar-2002';
NumDays = days360e(StartDate, EndDate)
NumDays =
    3 0
```

```
See Also
days360 | days360isda | days360psa
```

Introduced before R2006a

## days360isda

Days between dates based on 360-day year (International Swap Dealer Association (ISDA) compliant)

## Syntax

```
NumDays = days360isda(StartDate, EndDate)
```

## Arguments

| StartDate | Row vector, column vector, or scalar value in serial date number or <br> date string format. |
| :--- | :--- |
| EndDate | Row vector, column vector, or scalar value in serial date number or <br> date string format. |

Either input can contain multiple values, but if so, the other must contain the same number of values or a single value that applies to all.

## Description

NumDays = days360isda(StartDate, EndDate) returns a vector or scalar value representing the number of days between StartDate and EndDate based on a 360day year (that is, all months contain 30 days). If EndDate is earlier than StartDate, NumDays is negative.

Under this convention, all months contain 30 days.

## Examples

Example 1. Use this convention to find the number of days in the month of January.

```
StartDate = '1-Jan-2002';
EndDate = '1-Feb-2002';
```

```
NumDays = days360isda(StartDate, EndDate)
NumDays =
    30
```

Example 2. Use this convention to find the number of days in February during a leap year.

```
StartDate = '1-Feb-2000';
EndDate = '1-Mar-2000';
NumDays = days360isda(StartDate, EndDate)
NumDays =
```

    30
    Example 3. Use this convention to find the number of days in February of a non-leap year.

```
StartDate = '1-Feb-2002';
EndDate = '1-Mar-2002';
NumDays = days360isda(StartDate, EndDate)
NumDays =
    3 0
```

```
See Also
days360 | days360e
```

Introduced before R2006a

## days 360 psa

Days between dates based on 360-day year (Public Securities Association (PSA) compliant)

## Syntax

NumDays = days360psa(StartDate, EndDate)

## Arguments

| StartDate | Row vector, column vector, or scalar value in serial date number or <br> date string format. |
| :--- | :--- |
| EndDate | Row vector, column vector, or scalar value in serial date number or <br> date string format. |

Either input can contain multiple values, but if so, the other must contain the same number of values or a single value that applies to all.

## Description

NumDays = days360psa(StartDate, EndDate) returns a vector or scalar value representing the number of days between StartDate and EndDate based on a 360day year (that is, all months contain 30 days). If EndDate is earlier than StartDate, NumDays is negative.

Under this payment convention, all months contain 30 days. In both leap and non-leap years, if the StartDate is the last day of February, this day is considered to be day 30 of the month.

## Examples

Example 1. Use this convention to find the number of days in between the last day of February and the first day of March during a leap year.

```
StartDate = '29-Feb-2000';
EndDate = '1-Mar-2000';
NumDays = days360psa(StartDate, EndDate)
NumDays =
    1
```

Example 2. Use this convention to find the number of days in between the last day of February and the first day of March during a non-leap year.

```
StartDate = '28-Feb-2002';
EndDate = '1-Mar-2002';
NumDays = days360psa(StartDate, EndDate)
NumDays =
```

    1
    As expected, the number of days in both cases is the same. The convention always assumes that the last day of February is the 30th day.

See Also<br>days360 | days360e | days360isda<br>Introduced before R2006a

## days365

Days between dates based on 365-day year

## Syntax

NumDays = days365(StartDate, EndDate)

## Arguments

| StartDate | Enter as serial date numbers or date strings. |
| :--- | :--- |
| EndDate | Enter as serial date numbers or date strings. |

Either input can contain multiple values, but if so, the other must contain the same number of values or a single value that applies to all. For example, if StartDate is an nrow character array of date strings, then EndDate must be an $n$-by- 1 vector of integers or a single integer. NumDays is then an $n$-by- 1 vector of date numbers.

## Description

NumDays = days365(StartDate, EndDate) returns the number of days between dates StartDate and EndDate based on a 365-day year. (All months contain their actual number of days. February always contains 28 days.) If EndDate is earlier than StartDate, NumDays is negative. Enter dates as serial date numbers or date strings.

## Examples

NumDays = days365('15-jan-2000', '15-mar-2000')
NumDays =
59
MoreDays = ['15-mar-2000'; '15-apr-2000'; '15-jun-2000'];
NumDays = days365('15-jan-2000', MoreDays)

```
NumDays =
    5 9
    90
151
```

## See Also

```
days360 | daysact | daysdif | wrkdydif | yearfrac
Introduced before R2006a
```

## daysact

Actual number of days between dates

## Syntax

```
NumDays = daysact(StartDate, EndDate)
```

## Arguments

| StartDate | Enter as serial date numbers or date strings. |
| :--- | :--- |
| EndDate | (Optional) Enter as serial date numbers or date strings. |

Either input can contain multiple values, but if so, the other must contain the same number of values or a single value that applies to all. For example, if StartDate is an $n$ row character array of date strings, then EndDate must be an $n$-row character array of date strings or a single date. NumDays is then an $n$-by- 1 vector of numbers.

## Description

NumDays = daysact(StartDate, EndDate) returns the actual number of days between two dates. Enter dates as serial date numbers or date strings. NumDays is negative if EndDate is earlier than StartDate.

NumDays = daysact(StartDate) returns the actual number of days between the MATLAB base date and StartDate. In MATLAB software, the base date 1 is 1 -Jan-0000 A.D. See datenum for a similar function.

## Examples

NumDays = daysact('7-sep-2002', '25-dec-2002')
NumDays = 109

```
NumDays = daysact('9/7/2002')
NumDays =
    731466
MoreDays = ['09/07/2002'; '10/22/2002'; '11/05/2002'];
NumDays = daysact(MoreDays, '12/25/2002')
NumDays =
    109
        6 4
        50
```

## More About

## daysadd

Date away from starting date for any day-count basis

## Syntax

```
NewDate = daysadd(StartDate, NumDays, Basis)
```

## Arguments

| StartDate | Start date. Enter as serial date numbers or date strings. |
| :---: | :---: |
| NumDays | Integer number of days from start date. Enter a negative integer for dates before start date. |
| Basis | (Optional) Day-count basis of the instrument. A vector of integers. <br> - $0=$ actual/actual (default) <br> - $1=30 / 360$ (SIA) <br> - 2 = actual/360 <br> - 3 = actual/365 <br> - $4=30 / 360$ (PSA) <br> - $5=30 / 360$ (ISDA) <br> - $6=30 / 360$ (European) <br> - 7 = actual/365 (Japanese) <br> - $8=$ actual/actual (ICMA) <br> - 9 = actual/360 (ICMA) <br> - $10=$ actual/365 (ICMA) <br> - $11=30 / 360 \mathrm{E}$ (ICMA) <br> - 12 = actual/365 (ISDA) <br> - 13 = BUS/252 <br> For more information, see basis. |

Note When using the 30/360 day-count basis, it is not always possible to find the exact date NewDate number of days away because of a known discontinuity in the method of counting days. A warning is displayed if this occurs.

## Description

NewDate = daysadd(StartDate, NumDays, Basis) returns a date NewDate number of days away from StartDate, using the given day-count basis.

## Examples

```
NewDate = daysadd('01-Feb-2004', 31)
NewDate =
    7 3 2 0 0 9
datestr(NewDate)
ans =
03-Mar-2004
NewDate = daysadd('01-Feb-2004', 31, 1)
NewDate =
    7 3 2 0 0 8
datestr(NewDate)
ans =
02-Mar-2004
```

## More About

## See Also

daysdif

Introduced before R2006a

## daysdif

Days between dates for any day-count basis

## Syntax

NumDays = daysdif(StartDate, EndDate, Basis)

## Arguments

| StartDate | Enter as serial date numbers or date strings. |
| :---: | :---: |
| EndDate | Enter as serial date numbers or date strings. |
| Basis | (Optional) Day-count basis of the instrument. A vector of integers. <br> - $0=$ actual/actual (default) <br> - $1=30 / 360$ (SIA) <br> - 2 = actual/360 <br> - $3=$ actual $/ 365$ <br> - $4=30 / 360$ (PSA) <br> - $5=30 / 360$ (ISDA) <br> - $6=30 / 360$ (European) <br> - 7 = actual/365 (Japanese) <br> - $8=$ actual/actual (ICMA) <br> - $9=$ actual/360 (ICMA) <br> - 10 = actual/365 (ICMA) <br> - $11=30 / 360 \mathrm{E}$ (ICMA) <br> - 12 = actual/365 (ISDA) <br> - 13 = BUS/252 <br> For more information, see basis. |

Any input argument can contain multiple values, but if so, the other inputs must contain the same number of values or a single value that applies to all. For example, if

StartDate is an n-row character array of date strings, then EndDate must be an nrow character array of date strings or a single date. NumDays is then an $n$-by- 1 vector of numbers.

## Description

NumDays = daysdif(StartDate, EndDate, Basis) returns the number of days between dates StartDate and EndDate using the given day-count basis. Enter dates as serial date numbers or date strings. Enter dates as serial date numbers or date strings. The first date (StartDate) is not included when determining the number of days between first and last date.

This function is a helper function for the bond pricing and yield functions. It is designed to make the code more readable and to eliminate redundant calls within if statements.

## Examples

```
NumDays = daysdif('3/1/99', '3/1/00', 1)
NumDays =
    360
MoreDays = ['3/1/2001'; '3/1/2002'; '3/1/2003'];
NumDays = daysdif('3/1/98', MoreDays)
NumDays =
    1096
    1461
    1 8 2 6
```

Introduced before R2006a

## dec2thirtytwo

Decimal to thirty-second quotation

## Syntax

[OutNumber, Fractions] = dec2thirtytwo(InNumber, Accuracy)

## Arguments

| InNumber | Input number as a decimal fraction. |
| :--- | :--- |
| Accuracy | (Optional) Rounding. Default = 1, round down to nearest thirty <br> second. Other values are 2 (nearest half), 4 (nearest quarter) and <br> 10 (nearest decile). |

## Description

[OutNumber, Fractions] = dec2thirtytwo(InNumber, Accuracy) changes a decimal price quotation for a bond or bond future to a fraction with a denominator of 32 .

OutNumber is InNumber rounded downward to the closest integer.
Fractions is the fractional part in units of thirty-second with accuracy as prescribed by the input Accuracy.

## Examples

## Convert Decimal to Thirty-Second Quotation

This example shows two bonds that are quoted with decimal prices of 101.78 and 102.96. These prices are converted to fractions with a denominator of 32 .

```
InNumber = [101.78; 102.96];
[OutNumber, Fractions] = dec2thirtytwo(InNumber)
```

OutNumber =101102
Fractions =
2531- "Format Currency" on page 2-11

## depfixdb

Fixed declining-balance depreciation schedule

## Syntax

Depreciation = depfixdb(Cost, Salvage, Life, Period, Month)

## Arguments

| Cost | Scalar for the initial value of the asset. |
| :--- | :--- |
| Salvage | Scalar for the salvage value of the asset. |
| Life | Scalar value for the life of the asset in years. |
| Period | Scalar integer for the number of years to calculate. |
| Month | (Optional) Scalar value for the number of months in the first year of <br> asset life. Default $=12$. |

## Description

Depreciation = depfixdb(Cost, Salvage, Life, Period, Month) calculates the fixed declining-balance depreciation for each period.

## Examples

## Compute the Fixed Declining-Balance Depreciation

This example shows how to calculate the depreciation for the first five years for a car is purchased for $\$ 11,000$, with a salvage value of $\$ 1500$, and a lifetime of eight years.

Depreciation $=$ depfixdb(11000, 1500, 8, 5)

Depreciation =

```
    1.0e+03 *
    2.4251 1.8904 1.4737 1.1488 0.8955
```

- "Analyzing and Computing Cash Flows" on page 2-17

## See Also

depgendb | deprdv | depsoyd | depstln

Introduced before R2006a

## depgendb

General declining-balance depreciation schedule

## Syntax

Depreciation = depgendb(Cost, Salvage, Life, Factor)

## Arguments

| Cost | Cost of the asset. |
| :--- | :--- |
| Salvage | Estimated salvage value of the asset. |
| Life | Number of periods over which the asset is depreciated. |
| Factor | Depreciation factor. Factor $=2$ uses the double-declining-balance <br> method. |

## Description

Depreciation = depgendb(Cost, Salvage, Life, Factor) calculates the declining-balance depreciation for each period.

## Examples

## Calculate the Declining-Balance Depreciation

A car is purchased for $\$ 10,000$ and is to be depreciated over five years. The estimated salvage value is $\$ 1000$. Using the double-declining-balance method, the function calculates the depreciation for each year and returns the remaining depreciable value at the end of the life of the car.

Define the depreciation.
Life = 5;
Salvage = 0;

```
Cost = 10000;
Factor=2;
```

Use depgendb to calculate the depreciation.
Depreciation $=$ depgendb $(10000,1000,5,2)$

## Depreciation =

$1.0 e+03$ *
$\begin{array}{lllll}4.0000 & 2.4000 & 1.4400 & 0.8640 & 0.2960\end{array}$

The large value returned at the final year is the sum of the depreciation over the life time and is equal to the difference between the Cost and Salvage. The value of the asset in the final year is computed as (Cost - Salvage) = Sum_Depreciation_Upto_Final_Year.

- "Analyzing and Computing Cash Flows" on page 2-17

## See Also

depfixdb | deprdv | depsoyd | depstln
Introduced before R2006a

## deprdv

Remaining depreciable value

## Syntax

Value = deprdv(Cost, Salvage, Accum)

## Arguments

| Cost | Cost of the asset. |
| :--- | :--- |
| Salvage | Salvage value of the asset. |
| Accum | Accumulated depreciation of the asset for prior periods. |

## Description

Value $=$ deprdv(Cost, Salvage, Accum) returns the remaining depreciable value for an asset.

## Examples

## Compute the Remaining Depreciable Value for an Asset

This example shows how to find the remaining depreciable value after six years for the cost of an asset for $\$ 13,000$ with a life of 10 years. The salvage value is $\$ 1000$.

Accum $=\operatorname{depstln}(13000,1000,10)$ * 6
Value $=\operatorname{deprdv}(13000,1000,7200)$

Accum $=$

## Value =

4800

- "Analyzing and Computing Cash Flows" on page 2-17

## See Also

depfixdb | depgendb | depsoyd | depstln

## depsoyd

Sum of years' digits depreciation

## Syntax

```
Sum = depsoyd(Cost, Salvage, Life)
```

## Arguments

| Cost | Cost of the asset. |
| :--- | :--- |
| Salvage | Salvage value of the asset. |
| Life | Depreciable life of the asset in years. |

## Description

Sum = depsoyd(Cost, Salvage, Life) calculates the depreciation for an asset using the sum of years' digits method. Sum is a 1 -by-Life vector of depreciation values with each element corresponding to a year of the asset's life.

## Examples

## Compute the Depreciation for an Asset Using the Sum of Years' Digits Method

This example shows how to calculate the depreciation for an asset using the sum of years' digits method where the asset is $\$ 13,000$ with a life of 10 years. The salvage value of the asset is $\$ 1000$.

```
Sum = depsoyd(13000, 1000, 10)'
```

Sum =
$1.0 \mathrm{e}+03$

## depstln

Straight-line depreciation schedule

## Syntax

Depreciation = depstln(Cost, Salvage, Life)

## Arguments

| Cost | Cost of the asset. |
| :--- | :--- |
| Salvage | Salvage value of the asset. |
| Life | Depreciable life of the asset in years. |

## Description

Depreciation = depstln(Cost, Salvage, Life) calculates straight-line depreciation for an asset.

## Examples

## Compute the Straight-Line Depreciation for an Asset

This example shows how to calculate the straight-line depreciation for an asset that costs $\$ 13,000$ with a life of 10 years. The salvage value of the asset is $\$ 1000$.

Depreciation $=$ depstln(13000, 1000, 10)

## Depreciation =

1200

## diff

Differencing

## Syntax

```
newfts = diff(oldfts)
```

## Description

diff computes the differences of the data series in a financial time series object. It returns another time series object containing the difference.
newfts = diff(oldfts) computes the difference of all the data in the data series of the object oldfts and returns the result in the object newfts. newfts is a financial time series object containing the same data series (names) as the input oldfts.

## diffusion

Construct diffusion-rate model components

## Syntax

DiffusionRate = diffusion(Alpha, Sigma)

## Class

Diffusion

## Description

The diffusion constructor specifies the diffusion-rate component of continuous-time stochastic differential equations (SDEs). The diffusion-rate specification supports the simulation of sample paths of NVARS state variables driven by NBROWNS Brownian motion sources of risk over NPERIODS consecutive observation periods, approximating continuous-time stochastic processes.

The diffusion-rate specification can be any NVARS-by-NBROWNS matrix-valued function $G$ of the general form:

$$
G\left(t, X_{t}\right)=D\left(t, X_{t}^{\alpha(t)}\right) V(t)
$$

associated with a vector-valued SDE of the form:

$$
d X_{t}=F\left(t, X_{t}\right) d t+G\left(t, X_{t}\right) d W_{t}
$$

where:

- $X_{t}$ is an NVARS-by- 1 state vector of process variables.
- $d W_{t}$ is an NBROWNS-by-1 Brownian motion vector.
- $D$ is an NVARS-by-NVARS diagonal matrix, in which each element along the main diagonal is the corresponding element of the state vector raised to the corresponding power of $a$.
- $V$ is an NVARS-by-NBROWNS matrix-valued volatility rate function Sigma.

The diffusion-rate specification is flexible, and provides direct parametric support for static volatilities and state vector exponents. It is also extensible, and provides indirect support for dynamic/nonlinear models via an interface. This enables you to specify virtually any diffusion-rate specification.

## Input Arguments

Specify required input parameters as one of the following types:

- A MATLAB array. Specifying an array indicates a static (non-time-varying) parametric specification. This array fully captures all implementation details, which are clearly associated with a parametric form.
- A MATLAB function. Specifying a function provides indirect support for virtually any static, dynamic, linear, or nonlinear model. This parameter is supported via an interface, because all implementation details are hidden and fully encapsulated by the function.

Note: You can specify combinations of array and function input parameters as needed.
Moreover, a parameter is identified as a deterministic function of time if the function accepts a scalar time $t$ as its only input argument. Otherwise, a parameter is assumed to be a function of time $t$ and state $X(t)$ and is invoked with both input arguments.

The required input parameters are:

| Alpha | Alpha determines the format of the parameter $D$. If you specify Alpha <br> as an array, it must be an NVARS-by-1 column vector of exponents. As a <br> deterministic function of time, when Alpha is called with a real-valued <br> scalar time t as its only input, Alpha must produce an NVARS-by-1 column <br> vector. If you specify Alpha as a function of time and state, it must return <br> an NVARS-by-1 column vector of exponents when invoked with two inputs: |
| :--- | :--- |
| $-\quad$ A real-valued scalar observation time $t$.  <br>  An NVARS-by-1 state vector $X_{t}$. |  |

| Sigma | Sigma represents the parameter $V$. <br> If you specify Sigma as an array, it must be an NVARS-by-NBROWNS <br> 2-dimensional matrix of instantaneous volatility rates. In this case, <br> each row of Sigma corresponds to a particular state variable. Each <br> column corresponds to a particular Brownian source of uncertainty, and <br> associates the magnitude of the exposure of state variables with sources <br> of uncertainty. As a deterministic function of time, when Sigma is called <br> with a real-valued scalar time $t$ as its only input, Sigma must produce an <br> NVARS-by-NBROWNS matrix. If you specify Sigma as a function of time and <br> state, it must return an NVARS-by-NBROWNS matrix of volatility rates when <br> invoked with two inputs: <br> $-\quad$ A real-valued scalar observation time $t$. <br> $-\quad$ An NVARS-by-1 state vector $X_{t}$. |
| :--- | :--- |

Note: Although the constructor enforces no restrictions on the signs of these volatility parameters, each parameter is usually specified as a positive value.

## Output Arguments

| DiffusionRate | Object of class diffusion that encapsulates the composite <br> diffusion-rate specification, with the following displayed <br> parameters: |
| :--- | :--- |
|  | Rate: The diffusion-rate function, $G$. Rate is the diffusion- <br> rate calculation engine. It accepts the current time $t$ and an <br> NVARS-by-1 state vector $X_{t}$ as inputs, and returns an NVARS- <br> by-1 diffusion-rate vector. |
|  | Alpha: Access function for the input argument Alpha. |
|  | - $\quad$ Sigma: Access function for the input argument Sigma. |

## Examples

"Overview" on page 17-18

## More About

## Algorithms

When you specify the input arguments Alpha and Sigma as MATLAB arrays, they are associated with a specific parametric form. By contrast, when you specify either Alpha or Sigma as a function, you can customize virtually any diffusion-rate specification.

Accessing the output diffusion-rate parameters Alpha and Sigma with no inputs simply returns the original input specification. Thus, when you invoke diffusion-rate parameters with no inputs, they behave like simple properties and allow you to test the data type (double vs. function, or equivalently, static vs. dynamic) of the original input specification. This is useful for validating and designing methods.

When you invoke diffusion-rate parameters with inputs, they behave like functions, giving the impression of dynamic behavior. The parameters Alpha and Sigma accept the observation time $t$ and a state vector $X_{t}$, and return an array of appropriate dimension. Specifically, parameters Alpha and Sigma evaluate the corresponding diffusion-rate component. Even if you originally specified an input as an array, diffusion treats it as a static function of time and state, by that means guaranteeing that all parameters are accessible by the same interface.

## disc2zero

Zero curve given discount curve

## Syntax

[ZeroRates, CurveDates] = disc2zero(DiscRates, CurveDates, Settle, Compounding, Basis)
[ZeroRates, CurveDates] = disc2zero(DiscRates, CurveDates, Settle, Name, Value)

## Arguments

| DiscRates | Column vector of discount factors, as decimal fractions. In <br> aggregate, the factors in DiscRates constitute a discount curve for <br> the investment horizon represented by CurveDates. |
| :--- | :--- |
| CurveDates | Column vector of maturity dates (as serial date numbers) that <br> correspond to the discount factors in DiscRates. |
| Settle | Serial date number or date string that is the common settlement <br> date for the discount rates in DiscRates. |

## Ordered Input or Name-Value Pair Arguments

Enter the following inputs using an ordered syntax or as name-value pair arguments. You cannot mix ordered syntax with name-value pairs.

## Compounding

Scalar value representing the rate at which the output zero rates are compounded when annualized. Allowed values are:

- 0 - Simple interest (no compounding)
- 1 - Annual compounding
- 2 - Semiannual compounding (default)
- 3 - Compounding three times per year
- 4 - Quarterly compounding
- 6 - Bimonthly compounding
- 12 - Monthly compounding
- 365 - Daily compounding
-     - 1 - Continuous compounding

Default: 2 (default)

## Basis

Day-count basis used for annualizing the output zero rates. A vector of integers.

- $0=$ actual/actual
- $1=30 / 360$ (SIA)
- $2=$ actual $/ 360$
- 3 = actual/365
- $4=30 / 360$ (PSA)
- $5=30 / 360$ (ISDA)
- $6=30 / 360$ (European)
- $7=$ actual/365 (Japanese)
- $8=$ actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- $10=$ actual/365 (ICMA)
- $11=30 / 360 \mathrm{E}$ (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see basis.
Default: 0

## Description

[ZeroRates, CurveDates] = disc2zero(DiscRates, CurveDates, Settle, Compounding, Basis) returns a zero curve given a discount curve and its maturity dates.
[ZeroRates, CurveDates] = disc2zero(DiscRates, CurveDates, Settle, Name, Value) returns a zero curve given a discount curve and its maturity dates using optional name-value pair arguments. Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

| ZeroRates | Column vector of decimal fractions. In aggregate, the rates in <br> ZeroRates constitute a zero curve for the investment horizon <br> represented by CurveDates. The zero rates are the yields to <br> maturity on theoretical zero-coupon bonds. |
| :--- | :--- |
| CurveDates | Column vector of maturity dates (as serial date numbers) that <br> correspond to the zero rates. This vector is the same as the input <br> vector CurveDates, but is sorted by ascending maturity. |

## Examples

## Determine the Zero Curve Given a Discount Curve and Maturity Dates

Given the following discount factors DiscRates over a set of maturity dates CurveDates, and a settlement date Settle:

```
DiscRates = [0.9996
    0.9947
    0.9896
    0.9866
    0.9826
    0.9786
    0.9745
    0.9665
    0.9552
    0.9466];
CurveDates = [datenum('06-Nov-2000')
    datenum('11-Dec-2000')
    datenum('15-Jan-2001')
    datenum('05-Feb-2001')
    datenum('04-Mar-2001')
    datenum('02-Apr-2001')
    datenum('30-Apr-2001')
```

```
    datenum('25-Jun-2001')
    datenum('04-Sep-2001')
    datenum('12-Nov-2001')];
```

Settle = datenum('03-Nov-2000');

Set daily compounding for the output zero curve, on an actual/365 basis.
Compounding = 365;
Basis = 3;
Execute the function disc2zero which returns the zero curve ZeroRates at the maturity dates CurveDates.
[ZeroRates, CurveDates] = disc2zero(DiscRates, CurveDates,... Settle, Compounding, Basis)

ZeroRates =
0.0487
0.0510
0.0523
0.0524
0.0530
0.0526
0.0530
0.0532
0.0549
0.0536

CurveDates =
730796
730831
730866
730887
730914
730943
730971
731027
731098
731167

For readability, DiscRates and ZeroRates are shown here only to the basis point. However, MATLAB® software computed them at full precision. If you enter DiscRates as shown, ZeroRates may differ due to rounding.

## discrate

Bank discount rate of money market security

## Syntax

DiscRate = discrate(Settle, Maturity, Face, Price, Basis)

## Arguments

| Settle | Enter as serial date numbers or date strings. Settle must be earlier than Maturity. |
| :---: | :---: |
| Maturity | Enter as serial date numbers or date strings. |
| Face | Redemption (par, face) value. |
| Price | Price of the security. |
| Basis | (Optional) Day-count basis of the instrument. A vector of integers. <br> - $0=$ actual/actual (default) <br> - $1=30 / 360$ (SIA) <br> - 2 = actual/360 <br> - 3 = actual $/ 365$ <br> - $4=30 / 360$ (PSA) <br> - $5=30 / 360$ (ISDA) <br> - $6=30 / 360$ (European) <br> - 7 = actual/365 (Japanese) <br> - $8=$ actual/actual (ICMA) <br> - $9=$ actual/360 (ICMA) <br> - $10=$ actual/365 (ICMA) <br> - $11=30 / 360 \mathrm{E}$ (ICMA) <br> - 12 = actual/365 (ISDA) <br> - 13 = BUS/252 |

## Description

DiscRate = discrate(Settle, Maturity, Face, Price, Basis) finds the bank discount rate of a security. The bank discount rate normalizes by the face value of the security (for example, U. S. Treasury Bills) and understates the true yield earned by investors.

## Examples

## Compute the Bank Discount Rate of a Security

This example shows how to find the bank discount rate of a security.
DiscRate = discrate('12-jan-2000', '25-jun-2000', 100, 97.74, 0)

DiscRate =
0.0501

## drift

Construct drift-rate model components

## Syntax

DriftRate = drift(A, B)

## Class

Drift

## Description

This constructor specifies the drift-rate component of continuous-time stochastic differential equations (SDEs). The drift-rate specification supports the simulation of sample paths of NVARS state variables driven by NBROWNS Brownian motion sources of risk over NPERIODS consecutive observation periods, approximating continuous-time stochastic processes.

The drift-rate specification can be any NVARS-by-1 vector-valued function $F$ of the general form:

$$
F\left(t, X_{t}\right)=A(t)+B(t) X_{t}
$$

associated with a vector-valued SDE of the form

$$
d X_{t}=F\left(t, X_{t}\right) d t+G\left(t, X_{t}\right) d W_{t}
$$

where:

- $X_{t}$ is an NVARS-by- 1 state vector of process variables.
- $d W_{t}$ is an NBROWNS-by-1 Brownian motion vector.
- $A$ and $B$ are model parameters.

The drift-rate specification is flexible, and provides direct parametric support for static/ linear drift models. It is also extensible, and provides indirect support for dynamic/ nonlinear models via an interface. This enables you to specify virtually any drift-rate specification.

## Input Arguments

Specify required input parameters as one of the following types:

- A MATLAB array. Specifying an array indicates a static (non-time-varying) parametric specification. This array fully captures all implementation details, which are clearly associated with a parametric form.
- A MATLAB function. Specifying a function provides indirect support for virtually any static, dynamic, linear, or nonlinear model. This parameter is supported via an interface, because all implementation details are hidden and fully encapsulated by the function.

Note: You can specify combinations of array and function input parameters as needed.
Moreover, a parameter is identified as a deterministic function of time if the function accepts a scalar time $t$ as its only input argument. Otherwise, a parameter is assumed to be a function of time $t$ and state $X(t)$ and is invoked with both input arguments.

The required input parameters are:
A This argument represents the parameter $A$. If you specify A as an array, it must be an NVARS-by- 1 column vector. As a deterministic function of time, when A is called with a real-valued scalar time $t$ as its only input, A must produce an NVARS-by- 1 column vector. If you specify A as a function of time and state, it must return an NVARS-by- 1 column vector when invoked with two inputs:

- A real-valued scalar observation time $t$.
- An NVARS-by- 1 state vector $X_{t}$.

| B | This argument represents the parameter $B$. If you specify B as an array, <br> it must be an NVARS-by-NVARS 2-dimensional matrix. As a deterministic <br> function of time, when B is called with a real-valued scalar time t as its <br> only input, B must produce an NVARS-by-NVARS matrix. If you specify B as <br> a function of time and state, it must return an NVARS-by-NVARS column <br> vector when invoked with two inputs: |
| :--- | :--- |
| - A real-valued scalar observation time $t$. |  |
|  | An NVARS-by-1 state vector $X_{t}$. |

## Output Arguments

| DriftRate | Object of class drift that encapsulates the composite drift-rate <br> specification, with the following displayed parameters: |
| :--- | :--- |
|  | Rate: The drift-rate function, $F$. Rate is the drift-rate calculation <br> engine. It accepts the current time $t$ and an NVARS-by-1 state vector <br>  <br> $X_{t}$ as inputs, and returns an NVARS-by-1 drift-rate vector. <br> - <br> A: Access function for the input argument A. |
|  | B: Access function for the input argument B. |

## Examples

"Overview" on page 17-18

## More About

## Algorithms

When you specify the input arguments $A$ and $B$ as MATLAB arrays, they are associated with a linear drift parametric form. By contrast, when you specify either A or B as a function, you can customize virtually any drift-rate specification.

Accessing the output drift-rate parameters $A$ and $B$ with no inputs simply returns the original input specification. Thus, when you invoke drift-rate parameters with no
inputs, they behave like simple properties and allow you to test the data type (double vs. function, or equivalently, static vs. dynamic) of the original input specification. This is useful for validating and designing methods.

When you invoke drift-rate parameters with inputs, they behave like functions, giving the impression of dynamic behavior. The parameters A and B accept the observation time $t$ and a state vector $X_{t}$, and return an array of appropriate dimension. Specifically, parameters A and B evaluate the corresponding drift-rate component. Even if you originally specified an input as an array, drift treats it as a static function of time and state, by that means guaranteeing that all parameters are accessible by the same interface.

## Introduced in R2008a

## ecmlsrmle

Least-squares regression with missing data

## Syntax

[Parameters, Covariance, Resid, Info] = ecmlsrmle(Data, Design, MaxIterations, TolParam, TolObj, Param0, Covar0, CovarFormat)

## Arguments

\(\left.$$
\begin{array}{|l|l|}\hline \text { Data } & \begin{array}{l}\text { NUMSAMPLES-by-NUMSERIES matrix with NUMSAMPLES } \\
\text { samples of a NUMSERIES-dimensional random vector. } \\
\text { Missing values are represented as NaNs. Only samples that } \\
\text { are entirely NaNs are ignored. (To ignore samples with at } \\
\text { least one NaN, use mvnrmle.) }\end{array} \\
\hline \text { Design } & \begin{array}{l}\text { A matrix or a cell array that handles two model structures: } \\
\text { - If NUMSERIES = 1, Design is a NUMSAMPLES- } \\
\text { by-NUMPARAMS matrix with known values. This structure } \\
\text { is the standard form for regression on a single series. } \\
\text { If NUMSERIES } \geq 1, \text { Design is a cell array. The cell array } \\
\text { contains either one or NUMSAMPLES cells. Each cell } \\
\text { contains a NUMSERIES-by-NUMPARAMS matrix of known } \\
\text { values. }\end{array}
$$ <br>
If Design has a single cell, it is assumed to have the <br>
same Design matrix for each sample. If Design has <br>
more than one cell, each cell contains a Design matrix <br>

for each sample.\end{array}\right\}\)| (Optional) Maximum number of iterations for the estimation |
| :--- |
| algorithm. Default value is 100. |$|$| (Optional) Convergence tolerance for estimation algorithm |
| :--- |
| based on changes in model parameter estimates. Default |
| value is sqrt (eps) which is about 1.0e-8 for double |

|  | precision. The convergence test for changes in model parameters is |
| :---: | :---: |
|  | $\\|$ Param $_{k}-$ Param $_{k-1} \\|<$ TolParam $\times\left(1+\left\\|\operatorname{Param}_{k}\right\\|\right)$ |
|  | where Param represents the output Parameters, and iteration $k=2,3, \ldots$. Convergence is assumed when both the TolParam and TolObj conditions are satisfied. If both TolParam $\leq 0$ and TolObj $\leq 0$, do the maximum number of iterations (MaxIterations), whatever the results of the convergence tests. |
| Tol0bj | (Optional) Convergence tolerance for estimation algorithm based on changes in the objective function. Default value is eps $\wedge 3 / 4$ which is about $1.0 \mathrm{e}-12$ for double precision. The convergence test for changes in the objective function is $\mid O b j_{k}-\text { Obj }_{k-1} \mid<T o l O b j \times\left(1+\left\|\mathrm{Obj}_{k}\right\|\right)$ <br> for iteration $k=2,3, \ldots$. Convergence is assumed when both the TolParam and TolObj conditions are satisfied. If both TolParam $\leq 0$ and TolObj $\leq 0$, do the maximum number of iterations (MaxIterations), whatever the results of the convergence tests. |
| Param0 | (Optional) NUMPARAMS-by-1 column vector that contains a user-supplied initial estimate for the parameters of the regression model. Default is a zero vector. |
| Covar0 | (Optional) NUMSERIES-by-NUMSERIES matrix that contains a user-supplied initial or known estimate for the covariance matrix of the regression residuals. Default is an identity matrix. <br> For covariance-weighted least-squares calculations, this matrix corresponds with weights for each series in the regression. The matrix also serves as an initial guess for the residual covariance in the expectation conditional maximization (ECM) algorithm. |

| CovarFormat | Optional) String that specifies the format for the covariance <br> matrix. The choices are: <br> $-\quad$ ' full' - Default method. Compute the full covariance <br> matrix. <br> $-\quad$'diagonal' - Force the covariance matrix to be a <br> diagonal matrix. |
| :---: | :--- |

## Description

[Parameters, Covariance, Resid, Info] = ecmlsrmle(Data, Design, MaxIterations, TolParam, TolObj, Param0, Covar0, CovarFormat) estimates a least-squares regression model with missing data. The model has the form

$$
\text { Data }_{k} \sim N\left(\text { Design }_{k} \times \text { Parameters, Covariance }\right)
$$

for samples $k=1, \ldots$, NUMSAMPLES.
ecmlsrmle estimates a NUMPARAMS-by-1 column vector of model parameters called Parameters, and a NUMSERIES-by-NUMSERIES matrix of covariance parameters called Covariance.
ecmlsrmle(Data, Design) with no output arguments plots the log-likelihood function for each iteration of the algorithm.

To summarize the outputs of ecmlsrmle:

- Parameters is a NUMPARAMS-by- 1 column vector of estimates for the parameters of the regression model.
- Covariance is a NUMSERIES-by-NUMSERIES matrix of estimates for the covariance of the regression model's residuals. For least-squares models, this estimate may not be a maximum likelihood estimate except under special circumstances.
- Resid is a NUMSAMPLES-by-NUMSERIES matrix of residuals from the regression.

Another output, Info, is a structure that contains additional information from the regression. The structure has these fields:

- Info. Obj - A variable-extent column vector, with no more than MaxIterations elements, that contain each value of the objective function at each iteration of the estimation algorithm. The last value in this vector, Obj (end), is the terminal estimate of the objective function. If you do least-squares, the objective function is the least-squares objective function.
- Info. PrevParameters - NUMPARAMS-by-1 column vector of estimates for the model parameters from the iteration just prior to the terminal iteration.
- Info. PrevCovariance - NUMSERIES-by-NUMSERIES matrix of estimates for the covariance parameters from the iteration just prior to the terminal iteration.

## Notes

If doing covariance-weighted least-squares, Covar0 should usually be a diagonal matrix. Series with greater influence should have smaller diagonal elements in Covar0 and series with lesser influence should have larger diagonal elements. Note that if doing CWLS, Covar0 do not need to be a diagonal matrix even if CovarFormat = 'diagonal'.

You can configure Design as a matrix if NUMSERIES $=1$ or as a cell array if NUMSERIES $\geq 1$.

- If Design is a cell array and NUMSERIES = 1, each cell contains a NUMPARAMS row vector.
- If Design is a cell array and NUMSERIES > 1, each cell contains a NUMSERIES-by-NUMPARAMS matrix.

These points concern how Design handles missing data:

- Although Design should not have NaN values, ignored samples due to NaN values in Data are also ignored in the corresponding Design array.
- If Design is a 1-by-1 cell array, which has a single Design matrix for each sample, no NaN values are permitted in the array. A model with this structure must have NUMSERIES $\geq$ NUMPARAMS with rank (Design\{1\}) $=$ NUMPARAMS.
- ecmlsrmle is more strict than mvnrmle about the presence of NaN values in the Design array.

Use the estimates in the optional output structure Info for diagnostic purposes.

## ecmlsrobj

Log-likelihood function for least-squares regression with missing data

## Syntax

Objective = ecmlsrobj(Data, Design, Parameters, Covariance)

## Arguments

| Data | NUMSAMPLES-by-NUMSERIES matrix with NUMSAMPLES samples <br> of a NUMSERIES-dimensional random vector. Missing values are <br> represented as NaNs. Only samples that are entirely NaNs are <br> ignored. (To ignore samples with at least one NaN, use mvnrmle.) |
| :--- | :--- |
| Design | A matrix or a cell array that handles two model structures: <br> If NUMSERIES = 1, Design is a NUMSAMPLES-by-NUMPARAMS <br> matrix with known values. This structure is the standard form <br> for regression on a single series. <br> If NUMSERIES $\geq 1$, Design is a cell array. The cell array <br> contains either one or NUMSAMPLES cells. Each cell contains a <br> NUMSERIES-by-NUMPARAMS matrix of known values. |
| If Design has a single cell, it is assumed to have the same <br> Design matrix for each sample. If Design has more than one <br> cell, each cell contains a Design matrix for each sample. |  |
| Parameters | NUMPARAMS-by-1 column vector of estimates for the parameters of <br> the regression model. |
| Covariance | (Optional) NUMSERIES-by-NUMSERIES matrix that contains a user- <br> supplied estimate for the covariance matrix of the residuals of the <br> regression. Default is an identity matrix. |

## Description

Objective = ecmlsrobj(Data, Design, Parameters, Covariance) computesa least-squares objective function based on current parameter estimates with missing data. Objective is a scalar that contains the least-squares objective function.

## Notes

ecmlsrobj requires that Covariance be positive-definite.

## Note that

ecmlsrobj(Data, Design, Parameters) = ecmmvnrobj(Data, ...
Design, Parameters, IdentityMatrix)
where IdentityMatrix is a NUMSERIES-by-NUMSERIES identity matrix.
You can configure Design as a matrix if NUMSERIES = 1 or as a cell array if NUMSERIES $\geq 1$.

- If Design is a cell array and NUMSERIES $=1$, each cell contains a NUMPARAMS row vector.
- If Design is a cell array and NUMSERIES > 1, each cell contains a NUMSERIES-by-NUMPARAMS matrix.

## Examples

## ecmmvnrfish

Fisher information matrix for multivariate normal regression model

## Syntax

Fisher = ecmmvnrfish(Data, Design, Covariance, Method, MatrixFormat, CovarFormat)

## Arguments

$\left.\left.\begin{array}{|l|l|}\hline \text { Data } & \begin{array}{l}\text { NUMSAMPLES-by-NUMSERIES matrix with NUMSAMPLES } \\ \text { samples of a NUMSERIES-dimensional random vector. } \\ \text { Missing values are represented as NaNs. Only samples that } \\ \text { are entirely NaNs are ignored. (To ignore samples with at } \\ \text { least one NaN, use mvnrfish.) }\end{array} \\ \hline \text { Design } & \begin{array}{l}\text { A matrix or a cell array that handles two model structures: } \\ \text { If NUMSERIES = 1, Design is a NUMSAMPLES- } \\ \text { by-NUMPARAMS matrix with known values. This structure } \\ \text { is the standard form for regression on a single series. } \\ \text { If NUMSERIES } \geq \text { 1, Design is a cell array. The cell array } \\ \text { contains either one or NUMSAMPLES cells. Each cell } \\ \text { contains a NUMSERIES-by-NUMPARAMS matrix of known } \\ \text { values. }\end{array} \\ \text { If Design has a single cell, it is assumed to have the } \\ \text { same Design matrix for each sample. If Design has } \\ \text { more than one cell, each cell contains a Design matrix } \\ \text { for each sample. }\end{array}\right\} \begin{array}{l}\text { NUMSERIES-by-NUMSERIES matrix of estimates for the } \\ \text { covariance of the residuals of the regression. }\end{array}\right\}$

|  | method is recommended since the resultant standard errors incorporate the increased uncertainties due to missing data. <br> - fisher - Use the Fisher information matrix. |
| :---: | :---: |
| MatrixFormat | (Optional) String that identifies parameters to be included in the Fisher information matrix: <br> - full - Default format. Compute the full Fisher information matrix for both model and covariance parameter estimates. <br> - paramonly - Compute only components of the Fisher information matrix associated with the model parameter estimates. |
| CovarFormat | (Optional) String that specifies the format for the covariance matrix. The choices are: <br> - 'full' - Default method. The covariance matrix is a full matrix. <br> - 'diagonal' - The covariance matrix is a diagonal matrix. |

## Description

Fisher = ecmmvnrfish(Data, Design, Covariance, Method, MatrixFormat, CovarFormat) computes a Fisher information matrix based on current maximum likelihood or least-squares parameter estimates that account for missing data.

Fisher is a NUMPARAMS-by-NUMPARAMS Fisher information matrix or Hessian matrix. The size of NUMPARAMS depends on MatrixFormat and on current parameter estimates. If MatrixFormat = 'full',

NUMPARAMS $=$ NUMSERIES * (NUMSERIES + 3)/2
If MatrixFormat = 'paramonly',
NUMPARAMS = NUMSERIES

Note ecmmvnrfish operates slowly if you calculate the full Fisher information matrix.

## ecmmvnrmle

Multivariate normal regression with missing data

## Syntax

[Parameters, Covariance, Resid, Info] = ecmmvnrmle(Data, Design, MaxIterations, TolParam, TolObj, Param0, Covar0, CovarFormat)

## Arguments

| Data | NUMSAMPLES-by-NUMSERIES matrix with NUMSAMPLES <br> samples of a NUMSERIES-dimensional random vector. Missing <br> values are represented as NaNs. Only samples that are <br> entirely NaNs are ignored. (To ignore samples with at least <br> one NaN, use mvnrmle.) |
| :--- | :--- |
| Design | A matrix or a cell array that handles two model structures: <br> - If NUMSERIES = 1, Design is a NUMSAMPLES- <br> by-NUMPARAMS matrix with known values. This structure <br> is the standard form for regression on a single series. <br> If NUMSERIES $\geq 1$, Design is a cell array. The cell array <br> contains either one or NUMSAMPLES cells. Each cell <br> contains a NUMSERIES-by-NUMPARAMS matrix of known <br> values. |
| If Design has a single cell, it is assumed to have the |  |
| same Design matrix for each sample. If Design has more |  |
| than one cell, each cell contains a Design matrix for each |  |
| sample. |  |$|$

|  | precision. The convergence test for changes in model parameters is $\\| \text { Param }_{k}-\text { Param }_{k-1} \\|<\text { TolParam } \times\left(1+\\| \text { Param }_{k} \\|\right)$ <br> where Param represents the output Parameters, and iteration $k=2,3, \ldots$. Convergence is assumed when both the TolParam and TolObj conditions are satisfied. If both TolParam $\leq 0$ and TolObj $\leq 0$, do the maximum number of iterations (MaxIterations), whatever the results of the convergence tests. |
| :---: | :---: |
| Tol0bj | (Optional) Convergence tolerance for estimation algorithm based on changes in the objective function. Default value is eps $\wedge 3 / 4$ which is about $1.0 \mathrm{e}-12$ for double precision. The convergence test for changes in the objective function is $\left\|O b j_{k}-O b j_{k-1}\right\|<T o l O b j \times\left(1+\left\|O b j_{k}\right\|\right)$ <br> for iteration $k=2,3, \ldots$. Convergence is assumed when both the TolParam and TolObj conditions are satisfied. If both TolParam $\leq 0$ and TolObj $\leq 0$, do the maximum number of iterations (MaxIterations), whatever the results of the convergence tests. |
| Param0 | (Optional) NUMPARAMS-by- 1 column vector that contains a user-supplied initial estimate for the parameters of the regression model. |
| Covar0 | (Optional) NUMSERIES-by-NUMSERIES matrix that contains a user-supplied initial or known estimate for the covariance matrix of the regression residuals. |
| CovarFormat | (Optional) String that specifies the format for the covariance matrix. The choices are: <br> - 'full' — Default method. Compute the full covariance matrix. <br> - 'diagonal' - Force the covariance matrix to be a diagonal matrix. |

## Description

[Parameters, Covariance, Resid, Info] = ecmmvnrmle(Data, Design, MaxIterations, TolParam, TolObj, Param0, Covar0, CovarFormat) estimates a multivariate normal regression model with missing data. The model has the form

$$
\text { Data }_{k} \sim N\left(\text { Design }_{k} \times \text { Parameters, Covariance }\right)
$$

for samples $k=1, \ldots$, NUMSAMPLES.
ecmmvnrmle estimates a NUMPARAMS-by-1 column vector of model parameters called Parameters, and a NUMSERIES-by-NUMSERIES matrix of covariance parameters called Covariance.
ecmmvnrmle(Data, Design) with no output arguments plots the log-likelihood function for each iteration of the algorithm.

To summarize the outputs of ecmmvnrmle:

- Parameters is a NUMPARAMS-by- 1 column vector of estimates for the parameters of the regression model.
- Covariance is a NUMSERIES-by-NUMSERIES matrix of estimates for the covariance of the regression model's residuals.
- Resid is a NUMSAMPLES-by-NUMSERIES matrix of residuals from the regression. For any missing values in Data, the corresponding residual is the difference between the conditionally imputed value for Data and the model, that is, the imputed residual.

Note: The covariance estimate Covariance cannot be derived from the residuals.
Another output, Info, is a structure that contains additional information from the regression. The structure has these fields:

- Info. Obj - A variable-extent column vector, with no more than MaxIterations elements, that contain each value of the objective function at each iteration of the estimation algorithm. The last value in this vector, Obj (end), is the terminal estimate of the objective function. If you do maximum likelihood estimation, the objective function is the log-likelihood function.
- Info. PrevParameters - NUMPARAMS-by-1 column vector of estimates for the model parameters from the iteration just prior to the terminal
iteration.nfo. PrevCovariance - NUMSERIES-by-NUMSERIES matrix of estimates for the covariance parameters from the iteration just prior to the terminal iteration.

## Notes

ecmmvnrmle does not accept an initial parameter vector, since the parameters are estimated directly from the first iteration onward.

You can configure Design as a matrix if NUMSERIES $=1$ or as a cell array if NUMSERIES $\geq 1$.

- If Design is a cell array and NUMSERIES $=1$, each cell contains a NUMPARAMS row vector.
- If Design is a cell array and NUMSERIES > 1, each cell contains a NUMSERIES-by-NUMPARAMS matrix.

These points concern how Design handles missing data:

- Although Design should not have NaN values, ignored samples due to NaN values in Data are also ignored in the corresponding Design array.
- If Design is a 1-by- 1 cell array, which has a single Design matrix for each sample, no NaN values are permitted in the array. A model with this structure must have NUMSERIES $\geq$ NUMPARAMS with rank (Design\{1\}) $=$ NUMPARAMS.
- ecmmvnrmle is more strict than mvnrmle about the presence of NaN values in the Design array.

Use the estimates in the optional output structure Info for diagnostic purposes.

## ecmmvnrstd

Evaluate standard errors for multivariate normal regression model

## Syntax

[StdParameters, StdCovariance] = ecmmvnrstd(Data, Design, Covariance, Method, CovarFormat)

## Arguments

| Data | NUMSAMPLES-by-NUMSERIES matrix with NUMSAMPLES samples <br> of a NUMSERIES-dimensional random vector. Missing values are <br> represented as NaNs. Only samples that are entirely NaNs are <br> ignored. (To ignore samples with at least one NaN, use mvnrstd.) |
| :--- | :--- |
| Design | A matrix or a cell array that handles two model structures: <br> If NUMSERIES = 1, Design is a NUMSAMPLES-by-NUMPARAMS <br> matrix with known values. This structure is the standard form <br> for regression on a single series. <br> If NUMSERIES $\geq 1$, Design is a cell array. The cell array <br> contains either one or NUMSAMPLES cells. Each cell contains a <br> NUMSERIES-by-NUMPARAMS matrix of known values. <br> If Design has a single cell, it is assumed to have the same <br> Design matrix for each sample. If Design has more than one <br> cell, each cell contains a Design matrix for each sample. |
| Covariance | NUMSERIES-by-NUMSERIES matrix of estimates for the covariance <br> of the regression residuals. |
| Method | (Optional) String that identifies method of calculation for the <br> information matrix: |
| - hessian - Default method. Use the expected Hessian |  |
| matrix of the observed log-likelihood function. This method is |  |
| recommended since the resultant standard errors incorporate |  |
| the increased uncertainties due to missing data. |  |

|  | $\cdot \quad$ fisher - Use the Fisher information matrix. |
| :--- | :--- |
| CovarFormat | (Optional) String that specifies the format for the covariance <br> matrix. The choices are: |
|  | 'full' — Default method. The covariance matrix is a full <br> matrix. <br> 'diagonal' - The covariance matrix is a diagonal matrix. |

## Description

[StdParameters, StdCovariance] = ecmmvnrstd(Data, Design, Covariance, Method, CovarFormat) evaluates standard errors for a multivariate normal regression model with missing data. The model has the form

$$
\text { Data }_{k} \sim N\left(\text { Design }_{k} \times \text { Parameters, Covariance }\right)
$$

for samples $k=1, \ldots$, NUMSAMPLES.
ecmmvnrstd computes two outputs:

- StdParameters is a NUMPARAMS-by-1 column vector of standard errors for each element of Parameters, the vector of estimated model parameters.
- StdCovariance is a NUMSERIES-by-NUMSERIES matrix of standard errors for each element of Covariance, the matrix of estimated covariance parameters.

Note ecmmvnrstd operates slowly when you calculate the standard errors associated with the covariance matrix Covariance.

## Notes

You can configure Design as a matrix if NUMSERIES = 1 or as a cell array if NUMSERIES $\geq 1$.

- If Design is a cell array and NUMSERIES = 1, each cell contains a NUMPARAMS row vector.
- If Design is a cell array and NUMSERIES > 1, each cell contains a NUMSERIES-by-NUMPARAMS matrix.

## Examples

See "Multivariate Normal Regression" on page 9-18, "Least-Squares Regression" on page 9-18, "Covariance-Weighted Least Squares" on page 9-19, "Feasible Generalized Least Squares" on page 9-20, and "Seemingly Unrelated Regression" on page 9-21.

## ecmnfish

Fisher information matrix

## Syntax

Fisher = ecmnfish(Data, Covariance, InvCovariance, MatrixFormat)

## Arguments

| Data | NUMSAMPLES-by-NUMSERIES matrix of observed <br> multivariate normal data |
| :--- | :--- |
| Covariance | NUMSERIES-by-NUMSERIES matrix with covariance estimate <br> of Data |
| InvCovariance | (Optional) Inverse of covariance matrix: inv (Covariance) |
| MatrixFormat | (Optional) String that identifies parameters included in the <br> Fisher information matrix. If MatrixFormat $=[]$ or ' ', the <br> default method full is used. The parameter choices are |
| - full - (Default) Compute full Fisher information |  |
| matrix. |  |
| meanonly - Compute only components of the Fisher |  |
| information matrix associated with the mean. |  |

## Description

```
Fisher = ecmnfish(Data, Covariance, InvCovariance, MatrixFormat)
computes a NUMPARAMS-by-NUMPARAMS Fisher information matrix based on current
parameter estimates, where
NUMPARAMS = NUMSERIES*(NUMSERIES + 3)/2
if MatrixFormat = 'full' and
NUMPARAMS = NUMSERIES
```

```
if MatrixFormat = 'meanonly'.
```

The data matrix has NaNs for missing observations. The multivariate normal model has

```
NUMPARAMS = NUMSERIES + NUMSERIES*(NUMSERIES + 1)/2
```

distinct parameters. Therefore, the full Fisher information matrix is of size NUMPARAMS-by-NUMPARAMS. The first NUMSERIES parameters are estimates for the mean of the data in Mean and the remaining NUMSERIES* (NUMSERIES + 1)/2 parameters are estimates for the lower-triangular portion of the covariance of the data in Covariance, in row-major order.

If MatrixFormat = 'meanonly', the number of parameters is reduced to NUMPARAMS $=$ NUMSERIES, where the Fisher information matrix is computed for the mean parameters only. In this format, the routine executes fastest.

This routine expects the inverse of the covariance matrix as an input. If you do not pass in the inverse, the routine computes it. You can obtain an approximation for the lowerbound standard errors of estimation of the parameters from

```
Stderr = (1.0/sqrt(NumSamples)) .* sqrt(diag(inv(Fisher)));
```

Because of missing information, these standard errors can be smaller than the estimated standard errors derived from the expected Hessian matrix. To see the difference, compare to standard errors calculated with ecmnhess.

## More About

- "Fisher Information" on page 9-6

## See Also

ecmnhess | ecmnmle

## Related Examples

Introduced before R2006a

## ecmnhess

Hessian of negative log-likelihood function

## Syntax

Hessian = ecmnhess(Data, Covariance, InvCovariance, MatrixFormat)

## Arguments

| Data | NUMSAMPLES-by-NUMSERIES matrix of observed <br> multivariate normal data |
| :--- | :--- |
| Covariance | NUMSERIES-by-NUMSERIES matrix with covariance estimate <br> of Data |
| InvCovariance | (Optional) Inverse of covariance matrix: inv (Covariance) |
| MatrixFormat | (Optional) String that identifies parameters included in the <br> Hessian matrix. If MatrixFormat $=[$ ] or ' ' , the default <br> method full is used. The parameter choices are: |
| - full - (Default) Compute full Hessian matrix. |  |
| - meanonly - Compute only components of the Hessian |  |
| matrix associated with the mean. |  |

## Description

Hessian = ecmnhess(Data, Covariance, InvCovariance, MatrixFormat) computes a NUMPARAMS -by-NUMPARAMS Hessian matrix of the observed negative loglikelihood function based on current parameter estimates, where

```
NUMPARAMS = NUMSERIES*(NUMSERIES + 3)/2
if MatrixFormat = 'full' and
NUMPARAMS = NUMSERIES
if MatrixFormat = 'meanonly'.
```

This routine is slow for NUMSERIES > 10 or NUMSAMPLES > 1000.
The data matrix has NaNs for missing observations. The multivariate normal model has

```
NUMPARAMS = NUMSERIES + NUMSERIES*(NUMSERIES + 1)/2
```

distinct parameters. Therefore, the full Hessian is a NUMPARAMS-by-NUMPARAMS matrix.
The first NUMSERIES parameters are estimates for the mean of the data in Mean and the remaining NUMSERIES* (NUMSERIES + 1)/2 parameters are estimates for the lowertriangular portion of the covariance of the data in Covariance, in row-major order.

If MatrixFormat = 'meanonly', the number of parameters is reduced to NUMPARAMS $=$ NUMSERIES, where the Hessian is computed for the mean parameters only. In this format, the routine executes fastest.

This routine expects the inverse of the covariance matrix as an input. If you do not pass in the inverse, the routine computes it.

The equation

```
Stderr = (1.0/sqrt(NumSamples)) .* sqrt(diag(inv(Hessian)));
```

provides an approximation for the observed standard errors of estimation of the parameters.

Because of the additional uncertainties introduced by missing information, these standard errors can be larger than the estimated standard errors derived from the Fisher information matrix. To see the difference, compare to standard errors calculated from ecmnfish.

## ecmninit

Initial mean and covariance

## Syntax

[Mean, Covariance] = ecmninit(Data, InitMethod)

## Arguments

| Data | NUMSAMPLES-by-NUMSERIES matrix with NUMSAMPLES samples <br> of a NUMSERIES-dimensional random vector. Missing values are <br> indicated by NaNs. |
| :--- | :--- |
| InitMethod | (Optional) String that identifies one of three defined initialization <br> methods to compute initial estimates for the mean and covariance <br> of the data. If InitMethod = [] or ' ' the default method <br> nanskip is used. The initialization methods are |
|  | - nanskip - (Default) Skip all records with NaNs. <br> twostage - Estimate mean. Fill NaNs with the mean. Then <br> estimate the covariance. |
| diagonal - Form a diagonal covariance. |  |

## Description

[Mean, Covariance] = ecmninit(Data, InitMethod) creates initial mean and covariance estimates for the function ecmnmle. Mean is a NUMSERIES-by- 1 column vector estimate for the mean of Data. Covariance is a NUMSERIES-by-NUMSERIES matrix estimate for the covariance of Data.

## More About

## Algorithms

## Model

The general model is

$$
Z \sim N(\text { Mean, Covariance }),
$$

where each row of Data is an observation of $Z$.
Each observation of $Z$ is assumed to be iid (independent, identically distributed) multivariate normal, and missing values are assumed to be missing at random (MAR).

## Initialization Methods

This routine has three initialization methods that cover most cases, each with its advantages and disadvantages.

## nanskip

The nanskip method works well with small problems (fewer than 10 series or with monotone missing data patterns). It skips over any records with NaNs and estimates initial values from complete-data records only. This initialization method tends to yield fastest convergence of the ECM algorithm. This routine switches to the twostage method if it determines that significant numbers of records contain NaN.

## twostage

The twostage method is the best choice for large problems (more than 10 series). It estimates the mean for each series using all available data for each series. It then estimates the covariance matrix with missing values treated as equal to the mean rather than as NaNs. This initialization method is robust but tends to result in slower convergence of the ECM algorithm.

## diagonal

The diagonal method is a worst-case approach that deals with problematic data, such as disjoint series and excessive missing data (more than $33 \%$ missing data). Of the three initialization methods, this method causes the slowest convergence of the ECM algorithm.

- "Mean and Covariance Estimation" on page 9-5

ecmnmle
Introduced before R2006a

## ecmnmle

Mean and covariance of incomplete multivariate normal data

## Syntax

[Mean, Covariance] = ecmnmle(Data, InitMethod, MaxIterations, Tolerance, Mean0, Covar0)

## Arguments

| Data | NUMSAMPLES-by-NUMSERIES matrix with NUMSAMPLES samples of a NUMSERIES-dimensional random vector. Missing values are indicated by NaNs. A sample is also called an observation or a record. |
| :---: | :---: |
| InitMethod | (Optional) String that identifies one of three defined initialization methods to compute initial estimates for the mean and covariance of the data. If InitMethod = [ ] or ' ' , the default method nanskip is used. The initialization methods are: <br> - nanskip - (Default) Skip all records with NaNs. <br> - twostage - Estimate mean. Fill NaNs with mean. Then estimate covariance. <br> - diagonal - Form a diagonal covariance. |
|  | Note If you supply Mean0 and Covar0, InitMethod is not executed. |
| MaxIterations | (Optional) Maximum number of iterations for the expectation conditional maximization (ECM) algorithm. Default $=50$. |
| Tolerance | (Optional) Convergence tolerance for the ECM algorithm (Default $=1.0 \mathrm{e}-8$.) If Tolerance $\leq 0$, perform maximum iterations specified by MaxIterations and do not evaluate |

| Mean0 | the objective function at each step unless in display mode, as <br> described below. |
| :--- | :--- |
| Covar0 | (Optional) Initial NUMSERIES-by-1 column vector estimate <br> for the mean. If you leave Mean0 unspecified ([ ]), the <br> method specified by InitMethod is used. If you specify <br> Mean0, you must also specify Covar0. |
|  | (Optional) Initial NUMSERIES-by-NUMSERIES matrix <br> estimate for the covariance, where the input matrix must <br> be positive-definite. If you leave Covar0 unspecified ([ ]), <br> the method specified by InitMethod is used. If you specify <br> Covar0, you must also specify Mean0. |

## Description

[Mean, Covariance] = ecmnmle(Data, InitMethod, MaxIterations, Tolerance, Mean0, Covar0) estimates the mean and covariance of a data set. If the data set has missing values, this routine implements the ECM algorithm of Meng and Rubin [2] with enhancements by Sexton and Swensen [3]. ECM stands for expectation conditional maximization, a conditional maximization form of the EM algorithm of Dempster, Laird, and Rubin [4].

This routine has two operational modes.

## Display Mode

With no output arguments, this mode displays the convergence of the ECM algorithm. It estimates and plots objective function values for each iteration of the ECM algorithm until termination, as shown in the following plot.

Display mode can determine MaxIter and Tolerance values or serve as a diagnostic tool. The objective function is the negative log-likelihood function of the observed data and convergence to a maximum likelihood estimate corresponds with minimization of the objective.

## Estimation Mode

With output arguments, this mode estimates the mean and covariance via the ECM algorithm.

## Examples

To see an example of how to use ecmnmle, run the program ecmguidemo.

## More About

## Algorithms

## Model

The general model is

$$
Z \sim N(\text { Mean, Covariance }),
$$

where each row of Data is an observation of $Z$.
Each observation of $Z$ is assumed to be iid (independent, identically distributed) multivariate normal, and missing values are assumed to be missing at random (MAR). See Little and Rubin [1] for a precise definition of MAR.

This routine estimates the mean and covariance from given data. If data values are missing, the routine implements the ECM algorithm of Meng and Rubin [2] with enhancements by Sexton and Swensen [3].

If a record is empty (every value in a sample is NaN ), this routine ignores the record because it contributes no information. If such records exist in the data, the number of nonempty samples used in the estimation is $\leq$ NumSamples.

The estimate for the covariance is a biased maximum likelihood estimate (MLE). To convert to an unbiased estimate, multiply the covariance by Count/(Count - 1 ), where Count is the number of nonempty samples used in the estimation.

## Requirements

This routine requires consistent values for NUMSAMPLES and NUMSERIES with NUMSAMPLES > NUMSERIES. It must have enough nonmissing values to converge. Finally, it must have a positive-definite covariance matrix. Although the references provide some necessary and sufficient conditions, general conditions for existence and uniqueness of solutions in the missing-data case, do not exist. The main failure mode is an illconditioned covariance matrix estimate. Nonetheless, this routine works for most cases that have less than $15 \%$ missing data (a typical upper bound for financial data).

## Initialization Methods

This routine has three initialization methods that cover most cases, each with its advantages and disadvantages. The ECM algorithm always converges to a minimum of the observed negative log-likelihood function. If you override the initialization methods, you must ensure that the initial estimate for the covariance matrix is positive-definite.

The following is a guide to the supported initialization methods.

## nanskip

The nanskip method works well with small problems (fewer than 10 series or with monotone missing data patterns). It skips over any records with NaNs and estimates initial values from complete-data records only. This initialization method tends to yield fastest convergence of the ECM algorithm. This routine switches to the twostage method if it determines that significant numbers of records contain NaN.

## twostage

The twostage method is the best choice for large problems (more than 10 series). It estimates the mean for each series using all available data for each series. It then estimates the covariance matrix with missing values treated as equal to the mean rather than as NaNs. This initialization method is robust but tends to result in slower convergence of the ECM algorithm.

## diagonal

The diagonal method is a worst-case approach that deals with problematic data, such as disjoint series and excessive missing data (more than $33 \%$ of data missing). Of the three initialization methods, this method causes the slowest convergence of the ECM algorithm. If problems occur with this method, use display mode to examine convergence and modify either MaxIterations or Tolerance, or try alternative initial estimates with Mean0 and Covar0. If all else fails, try

```
MeanO = zeros(NumSeries);
CovarO = eye(NumSeries,NumSeries);
```

Given estimates for mean and covariance from this routine, you can estimate standard errors with the companion routine ecmnstd.

## Convergence

The ECM algorithm does not work for all patterns of missing values. Although it works in most cases, it can fail to converge if the covariance becomes singular. If this occurs, plots of the log-likelihood function tend to have a constant upward slope over many iterations as the log of the negative determinant of the covariance goes to zero. In some cases, the objective fails to converge due to machine precision errors. No general theory of missing data patterns exists to determine these cases. An example of a known failure occurs when two time series are proportional wherever both series contain nonmissing values.

## Introduced before R2006a

## ecmnobi

Multivariate normal negative log-likelihood function

## Syntax

Objective = ecmnobj(Data, Mean, Covariance, CholCovariance)

## Arguments

| Data | NUMSAMPLES-by-NUMSERIES matrix of observed <br> multivariate normal data |
| :--- | :--- |
| Mean | NUMSERIES-by-1 column vector with mean estimate of Data |
| Covariance | NUMSERIES-by-NUMSERIES matrix with covariance estimate <br> of Data |
| CholCovariance | (Optional) Cholesky decomposition of covariance matrix: <br> chol(Covariance) |

## Description

Objective = ecmnobj(Data, Mean, Covariance, CholCovariance) computes the value of the observed negative log-likelihood function over the data given current estimates for the mean and covariance of the data.

The data matrix has NaNs for missing observations. The inputs Mean and Covariance are current estimates for model parameters.

This routine expects the Cholesky decomposition of the covariance matrix as an input. The routine computes the Cholesky decomposition if you do not explicitly specify it.

## ecmnstd

Standard errors for mean and covariance of incomplete data

## Syntax

[StdMean, StdCovariance] = ecmnstd(Data, Mean, Covariance, Method)

## Arguments

| Data | NUMSAMPLES-by-NUMSERIES matrix with NUMSAMPLES samples <br> of a NUMSERIES-dimensional random vector. Missing values are <br> indicated by NaNs. |
| :--- | :--- |
| Mean | NUMSERIES-by-1 column vector of maximum-likelihood parameter <br> estimates for the mean of Data using the expectation conditional <br> maximization (ECM) algorithm |
| Covariance | NUMSERIES-by-NUMSERIES matrix of maximum-likelihood <br> covariance estimates for the covariance of Data using the ECM <br> algorithm |
| Method | (Optional) String indicating method of estimation for standard <br> error calculations. The methods are: |
| - hessian - (Default) Hessian of the observed negative log- |  |
| likelihood function. |  |
| fisher - Fisher information matrix. |  |

## Description

[StdMean, StdCovariance] = ecmnstd(Data, Mean, Covariance, Method) computes standard errors for mean and covariance of incomplete data.

StdMean is a NUMSERIES-by-1 column vector of standard errors of estimates for each element of the mean vector Mean.

StdCovariance is a NUMSERIES-by-NUMSERIES matrix of standard errors of estimates for each element of the covariance matrix Covariance.

Use this routine after estimating the mean and covariance of Data with ecmnmle. If the mean and distinct covariance elements are treated as the parameter $\theta$ in a completedata maximum-likelihood estimation, then as the number of samples increases, $\theta$ attains asymptotic normality such that

$$
\theta-E[\theta] \sim N\left(0, I^{-1}(\theta)\right)
$$

where $E[\theta]$ is the mean and $I(\theta)$ is the Fisher information matrix.
With missing data, the Hessian $H(\theta)$ is a good approximation for the Fisher information (which can only be approximated when data is missing).

It is usually advisable to use the default Method since the resultant standard errors incorporate the increased uncertainty due to missing data. In particular, standard errors calculated with the Hessian are generally larger than standard errors calculated with the Fisher information matrix.

Note This routine is slow for NUMSERIES > 10 or NUMSAMPLES $>1000$.

## elpm

Compute expected lower partial moments for normal asset returns

## Syntax

```
elpm(Mean, Sigma)
elpm(Mean, Sigma, MAR)
elpm(Mean, Sigma, MAR, Order)
oment = elpm(Mean, Sigma, MAR, Order)
```

## Arguments

| Mean | NUMSERIES vector with mean returns for a collection of NUMSERIES <br> assets. |
| :--- | :--- |
| Sigma | NUMSERIES vector with standard deviation of returns for a <br> collection of NUMSERIES assets. |
| MAR | (Optional) Scalar minimum acceptable return (default MAR $=0$ ). <br> This is a cutoff level of return such that all returns above MAR <br> contribute nothing to the lower partial moment. |
| Order | (Optional) Either a scalar or a NUMORDERS vector of nonnegative <br> integer moment orders. If no order specified, default Order $=0$, <br> which is the shortfall probability. This function will not work for <br> negative or noninteger orders. |

## Description

Given NUMSERIES asset returns with a vector of mean returns in a NUMSERIES vector Mean, a vector of standard deviations of returns in a NUMSERIES vector Sigma, a scalar minimum acceptable return MAR, and one or more nonnegative integer moment orders in a NUMORDERS vector Order, compute expected lower partial moments (elpm) relative to MAR for each asset in a NUMORDERS-by-NUMSERIES matrix Moment.

The output, Moment, is a NUMORDERS-by-NUMSERIES matrix of expected lower partial moments with NUMORDERS Orders and NUMSERIES series, that is, each row contains expected lower partial moments for a given order.

Note: To compute upper partial moments, reverse the signs of both the input Mean and MAR (do not reverse the signs of either Sigma or the output). This function computes expected lower partial moments with the mean and standard deviation of normally distributed asset returns. To compute sample lower partial moments from asset returns which have no distributional assumptions, use lpm.

## Examples

See "Expected Lower Partial Moments" on page 7-15.

## emaxdrawdown

Compute expected maximum drawdown for Brownian motion

## Syntax

EDD = emaxdrawdown(Mu, Sigma, T)

## Arguments

| Mu | Scalar. Drift term of a Brownian motion with drift. |
| :--- | :--- |
| Sigma | Scalar. Diffusion term of a Brownian motion with drift. |
| T | A time period of interest or a vector of times. |

## Description

EDD = emaxdrawdown(Mu, Sigma, T) computes the expected maximum drawdown for a Brownian motion for each time period in T using the following equation:

$$
d X(t)=\mu d t+\sigma d W(t)
$$

If the Brownian motion is geometric with the stochastic differential equation

$$
d S(t)=\mu_{0} S(t) d t+\sigma_{0} S(t) d W(t)
$$

then use Ito's lemma with $X(t)=\log (S(t))$ such that

$$
\begin{aligned}
\mu & =\mu_{0}-0.5 \sigma_{0}{ }^{2}, \\
\sigma & =\sigma_{0}
\end{aligned}
$$

converts it to the form used here.

The output argument ExpDrawdown is computed using an interpolation method. Values are accurate to a fraction of a basis point. Maximum drawdown is nonnegative since it is the change from a peak to a trough.

Note To compare the actual results from maxdrawdown with the expected results of emaxdrawdown, set the Format input argument of maxdrawdown to either of the nondefault values ('arithmetic' or 'geometric'). These are the only two formats emaxdrawdown supports.

## Examples

See "Expected Maximum Drawdown" on page 7-20.

## eomdate

Last date of month

## Syntax

DayMonth = eomdate(Date)
DayMonth = eomdate(Year, Month)

## Description

DayMonth = eomdate(Date) returns the serial date number of the last date of the month for the given Date. Enter Date as a four-digit integer or a date string.

DayMonth = eomdate(Year, Month) returns the serial date number of the last date of the month for the given year and month. Enter Year as a four-digit integer; enter Month as an integer from 1 through 12.

Either input argument can contain multiple values, but if so, the other input must contain the same number of values or a single value that applies to all. For example, if Year is a 1 -by- $n$ vector of integers, then Month must be a 1 -by- $n$ vector of integers or a single integer. DayMonth is then a 1 -by- $n$ vector of date numbers.

Use the function datestr to convert serial date numbers to formatted date strings or datenum to convert date and time to serial date number.

## Examples

```
DayMonth = eomdate(2001, 2)
```

DayMonth =
730910
datestr(DayMonth)
ans =
28-Feb-2001
Year = [2002 20032004 2005];

```
DayMonth = eomdate(Year, 2)
DayMonth =
    731275 731640 732006 732371
datestr(DayMonth)
ans =
28-Feb-2002
28-Feb-2003
29-Feb-2004
28-Feb-2005
```

## eq (fts)

Multiple financial times series object equality

## Syntax

```
tsobj_1 == tsobj_2
iseq = eq(tsobj_1, tsobj_2)
```

## Arguments

| tsobj_1 | Financial time series object. |
| :--- | :--- |
| tsobj_2 | Financial time series object. |

## Description

tsobj_1 == tsobj_2 returns True (1) if both financial time series objects have the same dates, frequencies, data series names, and data values. Otherwise, eq returns False (0).

Note: The data series names are case-sensitive, but do not have to be in the same order within each object.

## Examples

## Determine Multiple Financial Times Series Object Equality

This example shows how to determine if multiple financial times series objects are equal.

## estimateAssetMoments

Estimate mean and covariance of asset returns from data
Use the estimateAssetMoments function with a Portfolio object to estimate mean and covariance of asset returns from data.

For details on the workflow, see "Portfolio Object Workflow" on page 4-17.

## Syntax

obj = estimateAssetMoments(obj,AssetReturns)
obj] = estimateAssetMoments(obj,AssetReturns,Name,Value)

## Description

obj = estimateAssetMoments(obj,AssetReturns) estimates mean and covariance of asset returns from data for a Portfolio object.
obj] = estimateAssetMoments(obj,AssetReturns,Name,Value) estimates mean and covariance of asset returns from data for a Portfolio object with additional options for one or more Name, Value pair arguments.

## Examples

## Estimate Mean and Covariance of Asset Returns from Data for a Portfolio Object

To illustrate using the estimateAssetMoments function, generate random samples of 120 observations of asset returns for four assets from the mean and covariance of asset returns in the variables $m$ and $C$ with the portsim function. The default behavior portsim creates simulated data with estimated mean and covariance identical to the input moments $m$ and $C$. In addition to a return series created by the portsim function in the variable X , a price series is created in the variable Y :

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
    0.00408 0.0289 0.0204 0.0119;
    0.00192 0.0204 0.0576 0.0336;
```

```
    0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;
X = portsim(m', C, 120);
Y = ret2tick(X);
```

Given asset returns and prices in the variables $X$ and $Y$ from above, the following examples demonstrate equivalent ways to estimate asset moments for the Portfolio object. A Portfolio object is created in p with the moments of asset returns set directly in the Portfolio function and a second Portfolio object is created in $q$ to obtain the mean and covariance of asset returns from asset return data in $X$ using the estimateAssetMoments function.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
    0.00408 0.0289 0.0204 0.0119;
    0.00192 0.0204 0.0576 0.0336;
    0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;
X = portsim(m', C, 120);
p = Portfolio('mean',m,'covar',C);
q = Portfolio;
q = estimateAssetMoments(q, X);
```

[passetmean, passetcovar] = getAssetMoments(p)
[qassetmean, qassetcovar] = getAssetMoments(q)
passetmean =
0.0042
0.0083
0.0100
0.0150
passetcovar =

| 0.0005 | 0.0003 | 0.0002 | 0 |
| ---: | ---: | ---: | ---: |
| 0.0003 | 0.0024 | 0.0017 | 0.0010 |
| 0.0002 | 0.0017 | 0.0048 | 0.0028 |
| 0 | 0.0010 | 0.0028 | 0.0102 |

```
qassetmean =
    0.0042
    0.0083
    0.0100
    0.0150
qassetcovar =
\begin{tabular}{llll}
0.0005 & 0.0003 & 0.0002 & 0.0000 \\
0.0003 & 0.0024 & 0.0017 & 0.0010 \\
0.0002 & 0.0017 & 0.0048 & 0.0028 \\
0.0000 & 0.0010 & 0.0028 & 0.0102
\end{tabular}
```

Notice how either approach yields the same moments. The default behavior of the estimateAssetMoments function is to work with asset returns. If, instead, you have asset prices, such as in the variable Y , the estimateAssetMoments function accepts a parameter name 'DataFormat' with a corresponding value set to 'prices' to indicate that the input to the method is in the form of asset prices and not returns (the default parameter value for 'DataFormat' is 'returns'). The following example compares direct assignment of moments in the Portfolio object p with estimated moments from asset price data in $Y$ in the Portfolio object $q$ :

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
    0.00408 0.0289 0.0204 0.0119;
    0.00192 0.0204 0.0576 0.0336;
    0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;
X = portsim(m', C, 120);
Y = ret2tick(X);
p = Portfolio('mean',m,'covar',C);
q = Portfolio;
q = estimateAssetMoments(q, Y, 'dataformat', 'prices');
[passetmean, passetcovar] = getAssetMoments(p)
```

```
[qassetmean, qassetcovar] = getAssetMoments(q)
```

passetmean =
0.0042
0.0083
0.0100
0.0150
passetcovar =

| 0.0005 | 0.0003 | 0.0002 | 0 |
| ---: | ---: | ---: | ---: |
| 0.0003 | 0.0024 | 0.0017 | 0.0010 |
| 0.0002 | 0.0017 | 0.0048 | 0.0028 |
| 0 | 0.0010 | 0.0028 | 0.0102 |

qassetmean =
0.0042
0.0083
0.0100
0.0150
qassetcovar =

| 0.0005 | 0.0003 | 0.0002 | 0.0000 |

- "Asset Returns and Moments of Asset Returns Using Portfolio Object" on page 4-41
- "Portfolio Optimization Examples" on page 4-114

## Input Arguments

## obj - Object for portfolio

object

Object for portfolio, specified using a Portfolio object. For more information on creating a portfolio object, see

- Using Portfolio Objects

AssetReturns - Matrix or fints object that contains asset price data that can be converted to asset returns
matrix | fints object
Matrix or fints object that contains asset price data that can be converted to asset returns, specified by a fints object or NumSamples-by-NumAssets matrix for asset returns. Use the optional 'DataFormat ' argument to convert AssetReturns input data that is asset prices into asset returns. Be careful when using asset price data because portfolio optimization usually requires total returns and not simply price returns.
Data Types: double

## Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, . . , NameN, ValueN.

Example: $\mathrm{p}=$ estimateAssetMoments(p, Y, 'dataformat', 'prices')
'DataFormat ' - Flag to convert input data as prices into returns
'Returns ' (default) $\mid$ string with values 'Returns ' or 'Prices '
Flag to convert input data as prices into returns, specified using a string with the values:

- 'Returns' - Data in AssetReturns contains asset total returns.
- 'Prices ' - Data in AssetReturns contains asset total return prices.

## Data Types: char

## 'MissingData ' - Flag indicating whether to use ECM algorithm or exclude samples with NaN values <br> false (default) | logical with value true or false

Flag indicating whether to use ECM algorithm or excludes samples with NaN values, specified as a logical with a value of true or false.

To handle time series with missing data (indicated with NaN values), the MissingData flag either uses the ECM algorithm to obtain maximum likelihood estimates in the presences of NaN values or excludes samples with NaN values. Since the default is false, it is necessary to specify MissingData as true to use the ECM algorithm.

Acceptable values for MissingData are:

- false - Do not use ECM algorithm to handle NaN values (exclude NaN values).
- true - Use ECM algorithm to handle NaN values.

For more information on the ECM algorithm, see ecmnmle and "Multivariate Normal Regression" on page 9-2.

## Data Types: logical

## 'GetAssetList ' - Flag indicating which asset names to use for asset list <br> false (default) | logical with value true or false

Flag indicating which asset names to use for the asset list, specified as a logical with a value of true or false. Acceptable values for GetAssetList are:

- false - Do not extract or create asset names.
- true - Extract or create asset names from fints object.

If a fints object is passed into this function and the GetAssetList flag is true, the series names from the fints object are used as asset names in obj. AssetList.

If a matrix is passed and the GetAssetList flag is true, default asset names are created based on the AbstractPortfolio property defaultforAssetList, which is 'Asset'.

If the GetAssetList flag is false, no action occurs, which is the default behavior.
Data Types: logical

## Output Arguments

obj - Updated porifolio object<br>object for portfolio

Updated portfolio object, returned as a Portfolio object. For more information on creating a portfolio object, see

- Using Portfolio Objects

## More About

## Tips

You can also use dot notation to estimate the mean and covariance of asset returns from data.

```
obj = obj.estimateAssetMoments(AssetReturns);
```

## estimateBounds

Estimate global lower and upper bounds for set of portfolios
Use the estimateBounds function with a Portfolio, PortfolioCVaR, or PortfolioMAD object to estimate global lower and upper bounds for a set of portfolios.

For details on the respective workflows when using these different objects, see "Portfolio Object Workflow" on page 4-17, "PortfolioCVaR Object Workflow" on page 5-16, and "PortfolioMAD Object Workflow" on page 6-16.

## Syntax

[glb,gub,isbounded] = estimateBounds(obj)
[glb,gub,isbounded] = estimateBounds(obj,obtainExactBounds)

## Description

[glb,gub,isbounded] = estimateBounds(obj) estimates global lower and upper bounds for set of portfolios.
[glb,gub,isbounded] = estimateBounds(obj,obtainExactBounds) estimates global lower and upper bounds for set of portfolios with an additional option specified for obtainExactBounds.

## Examples

## Create an Unbounded Porffolio for a Porffolio Object

Create an unbounded portfolio set.

```
p = Portfolio('AInequality', [1 -1; 1 1 ], 'bInequality', 0);
```

[lb, ub, isbounded] = estimateBounds(p)

```
    - Inf
    - Inf
ub =
    1.0e-08 *
    -0.3712
        Inf
isbounded =
    0
```

The estimateBounds function returns (possibly infinite) bounds and sets the isbounded flag to false. The result shows which assets are unbounded so that you can apply bound constraints as necessary.

## Create an Unbounded Porifolio for a PorifolioCVaR Object

Create an unbounded portfolio set.

```
p = PortfolioCVaR('AInequality', [1 -1; 1 1 ], 'bInequality', 0);
[lb, ub, isbounded] = estimateBounds(p)
lb =
    - Inf
    - Inf
ub =
    1.0e-08 *
    -0.3712
        Inf
isbounded =
```

The estimateBounds function returns (possibly infinite) bounds and sets the isbounded flag to false. The result shows which assets are unbounded so that you can apply bound constraints as necessary.

## Create an Unbounded Portfolio for a PortfolioMAD Object

Create an unbounded portfolio set.

```
p = PortfolioMAD('AInequality', [1 -1; 1 1 ], 'bInequality', 0);
[lb, ub, isbounded] = estimateBounds(p)
lb =
    - Inf
    - Inf
ub =
    1.0e-08
    -0.3712
        Inf
isbounded =
```

    0
    The estimateBounds function returns (possibly infinite) bounds and sets the isbounded flag to false. The result shows which assets are unbounded so that you can apply bound constraints as necessary.

## Input Arguments

## obj - Object for portfolio

object
Object for portfolio, specified using Portfolio, PortfolioCVaR, or PortfolioMAD object. For more information on creating a portfolio object, see

- Using Portfolio Objects
- Using PortfolioCVaR Objects
- Using PortfolioMAD Objects

## obtainExactBounds - Flag to specify whether to solve for all bounds or to accept specified bounds whenever available

true (default) | logical
Flag to specify whether to solve for all bounds or to accept specified bounds whenever available, specified as a logical with values of true or false. If bounds are known, set obtainExactBounds to false to accept known bounds. The default for obtainExactBounds is true.

Data Types: logical

## Output Arguments

glb - Global lower bounds for portfolio set
vector
Global lower bounds for portfolio set, returned as vector for a Portfolio, PortfolioCVaR, or PortfolioMAD input object (obj).
gub - Global upper bounds for portfolio set vector

Global upper bounds for portfolio set, returned as vector for a Portfolio, PortfolioCVaR, or PortfolioMAD input object (obj).
isbounded - Indicator for whether portfolio set is empty, bounded, or unbounded logical

Indicator for whether portfolio set is empty ([ ]), bounded (true), or unbounded (false), returned as a logical.

Note: By definition, any portfolio set must be nonempty and bounded:

- If the set is empty, isbounded = [ ].
- If the set is nonempty and unbounded, isbounded = false.
- If the set is nonempty and bounded, isbounded = true.
- If the set is empty, glb and gub are set to NaN vectors.

An isbounded value is returned for Portfolio, PortfolioCVaR, or PortfolioMAD input object (obj).

## More About

## Tips

- You can also use dot notation to estimate the global lower and upper bounds for a given set of portfolios.
[glb, gub, isbounded] = obj.estimateBounds;
- Estimated bounds are accurate in most cases to within $1.0 e-8$. If you intend to use these bounds directly in a portfolio object, ensure that if you impose such bound constraints, a lower bound of 0 is probably preferable to a lower bound of, for example, $1.0 \mathrm{e}-10$ for portfolio weights.

Introduced in R201 la

## estimateFrontier

Estimate specified number of optimal portfolios on the efficient frontier
Use the estimateFrontier function with a Portfolio, PortfolioCVaR, or PortfolioMAD object to estimate specified number of optimal portfolios on the efficient frontier.

For details on the respective workflows when using these different objects, see "Portfolio Object Workflow" on page 4-17, "PortfolioCVaR Object Workflow" on page 5-16, and "PortfolioMAD Object Workflow" on page 6-16.

## Syntax

```
[pwgt,pbuy,psell] = estimateFrontier(obj)
[pwgt,pbuy,psell] = estimateFrontier(obj,NumPorts)
```

## Description

[pwgt, pbuy, psell] = estimateFrontier(obj) estimates the specified number of optimal portfolios on the efficient frontier.
[pwgt,pbuy,psell] = estimateFrontier(obj,NumPorts) estimates the specified number of optimal portfolios on the efficient frontier with an additional option specified for NumPorts.

## Examples

## Obtain the Default Number of Efficient Portfolios for a Porifolio Object

Obtain the default number of efficient portfolios over the entire range of the efficient frontier.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
    0.00408 0.0289 0.0204 0.0119;
```

```
    0.00192 0.0204 0.0576 0.0336
    0 0.0119 0.0336 0.1225 ];
p = Portfolio;
p = setAssetMoments(p, m, C);
p = setDefaultConstraints(p);
pwgt = estimateFrontier(p);
disp(pwgt);
```

## Input Arguments

obj - Object for porifolio
object
Object for portfolio, specified using Portfolio, PortfolioCVaR, or PortfolioMAD object. For more information on creating a portfolio object, see

- Using Portfolio Objects
- Using PortfolioCVaR Objects
- Using PortfolioMAD Objects

## NumPorts - Number of points to obtain on efficient frontier <br> value from hidden property defaultNumPorts (default value is 10 ) (default) | scalar integer

Number of points to obtain on the efficient frontier, specified as a scalar integer.

Note: If no value is specified for NumPorts, the default value is obtained from the hidden property defaultNumPorts (default value is 10 ). If NumPorts $=1$, this function returns the portfolio specified by the hidden property defaultFrontierLimit (current default value is 'min').

## Data Types: double

## Output Arguments

pwgt - Optimal portfolios on efficient frontier with specified number of portfolios spaced equally from minimum to maximum portfolio return

matrix

Optimal portfolios on the efficient frontier with specified number of portfolios spaced equally from minimum to maximum portfolio return, returned as a NumAssets-by-NumPorts matrix. pwgt is returned for a Portfolio, PortfolioCVaR, or PortfolioMAD input object (obj).

## pbuy - Purchases relative to initial portfolio for optimal portfolios on efficient frontier

 matrixPurchases relative to an initial portfolio for optimal portfolios on the efficient frontier, returned as NumAssets-by-NumPorts matrix.

Note: If no initial portfolio is specified in obj. InitPort, that value is assumed to be 0 such that pbuy $=\max (0$, pwgt) and psell $=\max (0,-$ pwgt).
pbuy is returned for a Portfolio, PortfolioCVaR, or PortfolioMAD input object (obj).
psell - Sales relative to initial portfolio for optimal portfolios on efficient frontier matrix

Sales relative to an initial portfolio for optimal portfolios on the efficient frontier, returned as a NumAssets-by-NumPorts matrix.

Note: If no initial portfolio is specified in obj. InitPort, that value is assumed to be 0 such that pbuy $=\max (0, \mathrm{pwgt})$ and psell $=\max (0,-\mathrm{pwgt})$.
psell is returned for Portfolio, PortfolioCVaR, or PortfolioMAD input object (obj).

## More About

## Tips

- You can also use dot notation to estimate the specified number of optimal portfolios over the entire efficient frontier.

```
[pwgt, pbuy, psell] = obj.estimateFrontier(NumPorts);
```

- When introducing transaction costs and turnover constraints to the Portfolio, PortfolioCVaR, or PortfolioMAD object, the portfolio optimization objective contains a term with an absolute value. For more information on how Financial Toolbox handles such cases algorithmically, see Bibliography.

## Introduced in R201la

## estimateFrontierByReturn

Estimate optimal portfolios with targeted portfolio returns
Use the estimateFrontierByReturn function with a Portfolio, PortfolioCVaR, or PortfolioMAD object to estimate optimal portfolios with targeted portfolio returns.

For details on the respective workflows when using these different objects, see "Portfolio Object Workflow" on page 4-17, "PortfolioCVaR Object Workflow" on page 5-16, and "PortfolioMAD Object Workflow" on page 6-16.

## Syntax

```
[pwgt,pbuy,psell] = estimateFrontierByReturn(obj,TargetReturn)
```

## Description

[pwgt,pbuy,psell] = estimateFrontierByReturn(obj,TargetReturn) estimates optimal portfolios with targeted portfolio returns.

## Examples

## Obtain the Portfolio for Targeted Portfolio Returns for a Porffolio Object

To obtain efficient portfolios that have targeted portfolio returns, the estimateFrontierByReturn function accepts one or more target portfolio returns and obtains efficient portfolios with the specified returns. Assume you have a universe of four assets where you want to obtain efficient portfolios with target portfolio returns of $6 \%$, $9 \%$, and $12 \%$.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
    0.00408 0.0289 0.0204 0.0119;
    0.00192 0.0204 0.0576 0.0336;
    0 0.0119 0.0336 0.1225 ];
p = Portfolio;
p = setAssetMoments(p, m, C);
p = setDefaultConstraints(p);
```

```
pwgt = estimateFrontierByReturn(p, [0.06, 0.09, 0.12]);
display(pwgt);
```

## pwgt =

| 0.8772 | 0.5032 | 0.1293 |
| :--- | :--- | :--- |
| 0.0434 | 0.2488 | 0.4541 |
| 0.0416 | 0.0780 | 0.1143 |
| 0.0378 | 0.1700 | 0.3022 |

## Obtain the Portfolio for Targeted Porffolio Returns for a PorffolioCVaR Object

To obtain efficient portfolios that have targeted portfolio returns, the estimateFrontierByReturn function accepts one or more target portfolio returns and obtains efficient portfolios with the specified returns. Assume you have a universe of four assets where you want to obtain efficient portfolios with target portfolio returns of $7 \%$, $10 \%$, and $13 \%$.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
    0.00408 0.0289 0.0204 0.0119;
    0.00192 0.0204 0.0576 0.0336;
    0 0.0119 0.0336 0.1225 ];
rng(11);
p = PortfolioCVaR;
p = simulateNormalScenariosByMoments(p, m, C, 2000);
p = setDefaultConstraints(p);
p = setProbabilityLevel(p, 0.95);
pwgt = estimateFrontierByReturn(p, [0.07 0.10, 0.13]);
display(pwgt);
pwgt =
\begin{tabular}{lrr}
0.7371 & 0.3071 & 0 \\
0.1504 & 0.3919 & 0.4396 \\
0.0286 & 0.1011 & 0.1360 \\
0.0839 & 0.1999 & 0.4244
\end{tabular}
```

The function rng(seed) is used to reset the random number generator to produce the documented results. It is not necessary to reset the random number generator to simulate scenarios.

## Obtain the Portfolio for Targeted Portfolio Returns for a PortfolioMAD Object

To obtain efficient portfolios that have targeted portfolio returns, the estimateFrontierByReturn function accepts one or more target portfolio returns and obtains efficient portfolios with the specified returns. Assume you have a universe of four assets where you want to obtain efficient portfolios with target portfolio returns of $7 \%$, $10 \%$, and $13 \%$.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
    0.00408 0.0289 0.0204 0.0119;
    0.00192 0.0204 0.0576 0.0336;
    0 0.0119 0.0336 0.1225 ];
rng(11);
p = PortfolioMAD;
p = simulateNormalScenariosByMoments(p, m, C, 2000);
p = setDefaultConstraints(p);
pwgt = estimateFrontierByReturn(p, [0.07 0.10, 0.13]);
display(pwgt);
pwgt =
\begin{tabular}{lll}
0.7436 & 0.3147 & 0.0000 \\
0.1357 & 0.3835 & 0.4422 \\
0.0328 & 0.0939 & 0.1324 \\
0.0879 & 0.2079 & 0.4254
\end{tabular}
```

The function rng (seed) is used to reset the random number generator to produce the documented results. It is not necessary to reset the random number generator to simulate scenarios.

## Input Arguments

## obj - Object for portfolio

object
Object for portfolio, specified using Portfolio, PortfolioCVaR, or PortfolioMAD object. For more information on creating a portfolio object, see

- Using Portfolio Objects
- Using PortfolioCVaR Objects
- Using PortfolioMAD Objects

## TargetReturn - Target values for porffolio return

 vectorTarget values for portfolio return, specified as a NumPorts vector.

Note: TargetReturn specifies target returns for portfolios on the efficient frontier. If any TargetReturn values are outside the range of returns for efficient portfolios, the TargetReturn is replaced with the minimum or maximum efficient portfolio return, depending upon whether the target return is below or above the range of efficient portfolio returns.

## Data Types: double

## Output Arguments

## pwgt - Optimal porffolios on efficient frontier with specified target returns

 matrixOptimal portfolios on the efficient frontier with specified target returns from TargetReturn, returned as a NumAssets-by-NumPorts matrix. pwgt is returned for a Portfolio, PortfolioCVaR, or PortfolioMAD input object (obj).

## pbuy - Purchases relative to initial portfolio for optimal portfolios on efficient frontier matrix

Purchases relative to an initial portfolio for optimal portfolios on the efficient frontier, returned as NumAssets-by-NumPorts matrix.

Note: If no initial portfolio is specified in obj. InitPort, that value is assumed to be 0 such that pbuy $=\max (0$, pwgt $)$ and psell $=\max (0,-$ pwgt $)$.
pbuy is returned for a Portfolio, PortfolioCVaR, or PortfolioMAD input object (obj).
psell - Sales relative to initial portfolio for optimal portfolios on efficient frontier matrix

Sales relative to an initial portfolio for optimal portfolios on the efficient frontier, returned as a NumAssets-by-NumPorts matrix.

Note: If no initial portfolio is specified in obj. InitPort, that value is assumed to be 0 such that pbuy $=\max (0$, pwgt $)$ and psell $=\max (0,-$ pwgt $)$.
psell is returned for Portfolio, PortfolioCVaR, or PortfolioMAD input object (obj).

## More About

## Tips

You can also use dot notation to estimate optimal portfolios with targeted portfolio returns.
[pwgt, pbuy, psell] = obj.estimateFrontierByReturn(TargetReturn);

- "Portfolio Optimization Theory" on page 4-2
See AlsoestimateFrontier | estimateFrontierByRisk | estimateFrontierLimitsIntroduced in R2011a

## estimateFrontierByRisk

Estimate optimal portfolios with targeted portfolio risks
Use the estimateFrontierByRisk function with a Portfolio, PortfolioCVaR, or PortfolioMAD object to estimate optimal portfolios with targeted portfolio risks.

For details on the respective workflows when using these different objects, see "Portfolio Object Workflow" on page 4-17, "PortfolioCVaR Object Workflow" on page 5-16, and "PortfolioMAD Object Workflow" on page 6-16.

## Syntax

[pwgt, pbuy,psell] = estimateFrontierByReturn(obj,TargetRisk)

## Description

[pwgt,pbuy,psell] = estimateFrontierByReturn(obj,TargetRisk) estimates optimal portfolios with targeted portfolio risks.

## Examples

## Obtain Porffolios with Targeted Porffolio Risks for a Porffolio Object

To obtain efficient portfolios that have targeted portfolio risks, the estimateFrontierByRisk function accepts one or more target portfolio risks and obtains efficient portfolios with the specified risks. Assume you have a universe of four assets where you want to obtain efficient portfolios with target portfolio risks of $12 \%$, $14 \%$, and $16 \%$.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
    0.00408 0.0289 0.0204 0.0119;
    0.00192 0.0204 0.0576 0.0336;
    0 0.0119 0.0336 0.1225 ];
p = Portfolio;
```

```
p = setAssetMoments(p, m, C);
p = setDefaultConstraints(p);
pwgt = estimateFrontierByRisk(p, [0.12, 0.14, 0.16]);
display(pwgt);

## Input Arguments

obj - Object for porifolio
object
Object for portfolio, specified using Portfolio, PortfolioCVaR, or PortfolioMAD object. For more information on creating a portfolio object, see

- Using Portfolio Objects
- Using PortfolioCVaR Objects
- Using PortfolioMAD Objects

## TargetRisk - Target values for porffolio risk vector

Target values for portfolio risk, specified as a NumPorts vector.

Note: If any TargetRisk values are outside the range of risks for efficient portfolios, the target risk is replaced with the minimum or maximum efficient portfolio risk, depending on whether the target risk is below or above the range of efficient portfolio risks.

## Data Types: double

## Output Arguments

pwgt - Optimal porffolios on efficient frontier with specified target risks matrix

Optimal portfolios on the efficient frontier with specified target returns from TargetRisk, returned as a NumAssets-by-NumPorts matrix. pwgt is returned for a Portfolio, PortfolioCVaR, or PortfolioMAD input object (obj).

## pbuy - Purchases relative to initial portfolio for optimal portfolios on efficient frontier

 matrixPurchases relative to an initial portfolio for optimal portfolios on the efficient frontier, returned as NumAssets-by-NumPorts matrix.

Note: If no initial portfolio is specified in obj. InitPort, that value is assumed to be 0 such that pbuy $=\max (0$, pwgt $)$ and psell $=\max (0,-$ pwgt).
pbuy is returned for a Portfolio, PortfolioCVaR, or PortfolioMAD input object (obj).
psell - Sales relative to initial porifolio for optimal portfolios on efficient frontier matrix

Sales relative to an initial portfolio for optimal portfolios on the efficient frontier, returned as a NumAssets-by-NumPorts matrix.

Note: If no initial portfolio is specified in obj. InitPort, that value is assumed to be 0 such that pbuy $=\max (0$, pwgt $)$ and psell $=\max (0,-$ pwgt $)$.
psell is returned for Portfolio, PortfolioCVaR, or PortfolioMAD input object (obj).

## estimateFrontierLimits

Estimate optimal portfolios at endpoints of efficient frontier
Use the estimateFrontierLimits function with a Portfolio, PortfolioCVaR, or PortfolioMAD object to estimate optimal portfolios at endpoints of efficient frontier.

For details on the respective workflows when using these different objects, see "Portfolio Object Workflow" on page 4-17, "PortfolioCVaR Object Workflow" on page 5-16, and "PortfolioMAD Object Workflow" on page 6-16.

## Syntax

[pwgt,pbuy,psell] = estimateFrontierLimits(obj)
[pwgt, pbuy,psell] = estimateFrontierLimits(obj,Choice)

## Description

[pwgt, pbuy, psell] = estimateFrontierLimits(obj) estimates optimal portfolios at endpoints of efficient frontier.
[pwgt,pbuy,psell] = estimateFrontierLimits(obj, Choice) estimates optimal portfolios at endpoints of efficient frontier with an additional option specified for the Choice argument.

## Examples

## Obtain Endpoint Porffolios for a Portfolio Object

Given portfolio p, the estimateFrontierLimits function obtains the endpoint portfolios.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
    0.00408 0.0289 0.0204 0.0119;
    0.00192 0.0204 0.0576 0.0336;
    0 0.0119 0.0336 0.1225 ];
```

```
p = Portfolio;
p = setAssetMoments(p, m, C);
p = setDefaultConstraints(p);
pwgt = estimateFrontierLimits(p);
disp(pwgt);
```

| 0.8891 | 0 |

## Input Arguments

## obj - Object for portfolio

object
Object for portfolio, specified using Portfolio, PortfolioCVaR, or PortfolioMAD object. For more information on creating a portfolio object, see

- Using Portfolio Objects
- Using PortfolioCVaR Objects
- Using PortfolioMAD Objects

## Choice - Indicator for which portfolios to obtain at extreme ends of efficient frontier

[] (default) | string with values [], 'Both', 'Min', 'Max'
Indicator which portfolios to obtain at the extreme ends of the efficient frontier, specified as a string with values [ ], 'Both', 'Min', or 'Max'. Choice specifies various actions with default value []. The options for a Choice action are:

- [] - Compute both minimum-risk and maximum-return portfolios.
- 'Both ' - Compute both minimum-risk and maximum-return portfolios.
- 'Min' - Compute minimum-risk portfolio only.
- 'Max' - Compute maximum-return portfolio only.

## Data Types: char

## Output Arguments

## pwgt - Optimal portfolios at endpoints of efficient frontier

matrix
Optimal portfolios at the endpoints of the efficient frontier TargetReturn, returned as a NumAssets-by-NumPorts matrix. pwgt is returned for a Portfolio, PortfolioCVaR, or PortfolioMAD input object (obj).

## pbuy - Purchases relative to an initial portfolio for optimal portfolios at endpoints of efficient frontier

matrix
Purchases relative to an initial portfolio for optimal portfolios at the endpoints of the efficient frontier, returned as NumAssets-by-NumPorts matrix.

Note: If no initial portfolio is specified in obj. InitPort, that value is assumed to be 0 such that pbuy $=\max (0$, pwgt $)$ and psell $=\max (0,-$ pwgt $)$.
pbuy is returned for a Portfolio, PortfolioCVaR, or PortfolioMAD input object (obj).

## psell - Sales relative to an initial portfolio for optimal portfolios at endpoints of efficient frontier

matrix
Sales relative to an initial portfolio for optimal portfolios on the efficient frontier, returned as a NumAssets-by-NumPorts matrix.

Note: If no initial portfolio is specified in obj. InitPort, that value is assumed to be 0 such that pbuy $=\max (0$, pwgt) and psell $=\max (0,-$ pwgt $)$.
psell is returned for Portfolio, PortfolioCVaR, or PortfolioMAD input object (obj).

## More About

## Tips

You can also use dot notation to estimate the optimal portfolios at the endpoints of the efficient frontier.

## estimateMaxSharpeRatio

Estimate efficient portfolio to maximize Sharpe ratio for Portfolio object
Use the estimateMaxSharpeRatio function with a Portfolio object to estimate moments of portfolio returns.

For details on the workflow, see "Portfolio Object Workflow" on page 4-17.

## Syntax

[pwgt,pbuy,psell] = estimateMaxSharpeRatio(obj)

## Description

[pwgt,pbuy,psell] = estimateMaxSharpeRatio(obj) estimates efficient portfolio to maximize Sharpe ratio for Portfolio object.

## Examples

## Estimate Efficient Porffolio that Maximizes the Sharpe Ratio for a Porffolio Object

Estimate the efficient portfolio that maximizes the Sharpe ratio.

```
p = Portfolio('AssetMean',[0.3, 0.1, 0.5], 'AssetCovar',...
[0.01, -0.010, 0.004; -0.010, 0.040, -0.002; 0.004, -0.002, 0.023]);
p = setDefaultConstraints(p);
plotFrontier(p, 20);
weights = estimateMaxSharpeRatio(p);
[risk, ret] = estimatePortMoments(p, weights);
hold on
plot(risk,ret,'*r');
```

- "Estimate Efficient Portfolios for Portfolio Object" on page 4-87
- "Portfolio Optimization Examples" on page 4-114

## Input Arguments

## obj - Object for portfolio <br> object

Object for portfolio, specified using a Portfolio object.

Note: The risk-free rate is obtained from the property RiskFreeRate in the Portfolio object. If you leave the RiskFreeRate unset, it is assumed to be 0 .

For more information on creating a portfolio object, see

- Using Portfolio Objects

## Output Arguments

pwgt - Porffolio on efficient frontier with maximum Sharpe ratio
vector
Portfolio on the efficient frontier with a maximum Sharpe ratio, returned as a NumAssets vector.

## pbuy - Purchases relative to initial portfolio for portfolio on efficient frontier with maximum Sharpe ratio <br> vector

Purchases relative to an initial portfolio for a portfolio on the efficient frontier with a maximum Sharpe ratio, returned as a NumAssets vector.
pbuy is returned for a Portfolio input object (obj).
psell - Sales relative to initial portfolio for portfolio on efficient frontier with maximum Sharpe ratio
vector
Sales relative to an initial portfolio for a portfolio on the efficient frontier with maximum Sharpe ratio, returned as a NumAssets vector.
psell is returned for a Portfolio input object (obj).

## More About

## Sharpe Ratio

The Sharpe ratio is the ratio of the difference between the mean of portfolio returns and the risk-free rate divided by the standard deviation of portfolio returns. The
estimateMaxSharpeRation function maximizes the Sharpe ratio among portfolios on the efficient frontier.

## Tips

You can also use dot notation to estimate an efficient portfolio that maximizes the Sharpe ratio.

```
[pwgt,pbuy,psell] = obj.estimateMaxSharpeRatio;
```

## Algorithms

The maximization of the Sharpe ratio is accomplished by a one-dimensional optimization using fminbnd to find the portfolio that minimizes the negative of the Sharpe ratio. The estimateMaxSharpeRation function takes only a fully qualified Portfolio object as its input and uses all information in the object to solve the problem.

- "Portfolio Optimization Theory" on page 4-2
- Getting Started with Portfolio Optimization (13 min 31 sec )

```

## estimatePortMoments

Estimate moments of portfolio returns for Portfolio object
Use the estimatePortMoments function with a Portfolio object to estimate moments of portfolio returns.

For details on the workflow, see "Portfolio Object Workflow" on page 4-17.

## Syntax

[prsk, pret = estimatePortMoments(obj,pwgt)

## Description

[prsk, pret = estimatePortMoments(obj, pwgt) estimate moments of portfolio returns for a Portfolio object.

The estimate of port moments is specific to mean-variance portfolio optimization and computes the mean and standard deviation (which is the square-root of variance) of portfolio returns.

## Examples

Identify the Range of Risks and Returns for Efficient Portfolios for a Portfolio Object
Given portfolio $p$, use the estimatePortMoments function to show the range of risks and returns for efficient portfolios.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
    0.00408 0.0289 0.0204 0.0119;
    0.00192 0.0204 0.0576 0.0336;
    0 0.0119 0.0336 0.1225 ];
p = Portfolio;
p = setAssetMoments(p, m, C);
p = setDefaultConstraints(p);
```

```
pwgt = estimateFrontierLimits(p);
[prsk, pret] = estimatePortMoments(p, pwgt);
disp([prsk, pret]);
\begin{tabular}{ll}
0.0769 & 0.0590 \\
0.3500 & 0.1800
\end{tabular}
```

- "Estimate Efficient Portfolios for Portfolio Object" on page 4-87
- "Portfolio Optimization Examples" on page 4-114

## Input Arguments

## obj - Object for portfolio

object
Object for portfolio, specified using a Portfolio object. For more information on creating a portfolio object, see

- Using Portfolio Objects

## pwgt - Collection of portfolios

## matrix

Collection of portfolios, specified as a NumAssets-by-NumPorts matrix where NumAssets is the number of assets in the universe and NumPorts is the number of portfolios in the collection of portfolios.

Data Types: double

## Output Arguments

## prsk - Estimates for standard deviations of porffolio returns for each porffolio in pwgt vector

Estimates for standard deviations of portfolio returns for each portfolio in pwgt, returned as a NumPorts vector.
prsk is returned for a Portfolio input object (obj).

## pret - Estimates for means of porffolio returns for each portfolio in pwgt

vector
Estimates for means of portfolio returns for each portfolio in pwgt, returned as a NumPorts vector.
pret is returned for a Portfolio input object (obj).

## More About

## Tips

You can also use dot notation to estimate the moments of portfolio returns.
[prsk, pret] = obj.estimatePortMoments(pwgt);

- "Portfolio Optimization Theory" on page 4-2
- Getting Started with Portfolio Optimization (13 min 31 sec )

See Also<br>estimatePortReturn | estimatePortRisk<br>Introduced in R201 la

## estimatePortReturn

Estimate mean of portfolio returns
Use the estimatePortReturn function with a Portfolio, PortfolioCVaR, or PortfolioMAD object to estimate mean of portfolio returns.

For details on the respective workflows when using these different objects, see "Portfolio Object Workflow" on page 4-17, "PortfolioCVaR Object Workflow" on page 5-16, and "PortfolioMAD Object Workflow" on page 6-16.

## Syntax

pret = estimatePortReturn(obj,pwgt)

## Description

pret $=$ estimatePortReturn(obj, pwgt) estimates the mean of portfolio returns (as the proxy for portfolio return).

Note: Depending on whether costs have been set, the portfolio return is either gross or net portfolio returns.

## Examples

## Estimate the Mean of Porifolio Returns for a Porifolio Object

Given portfolio p , use the estimatePortReturn function to estimate the mean of portfolio returns.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
    0.00408 0.0289 0.0204 0.0119;
    0.00192 0.0204 0.0576 0.0336;
```

```
        0 0.0119 0.0336 0.1225 ];
p = Portfolio;
p = setAssetMoments(p, m, C);
p = setDefaultConstraints(p);
pwgt = estimateFrontierLimits(p);
pret = estimatePortReturn(p, pwgt);
disp(pret)
```

0.0590
0.1800

## Estimate the Mean of Portfolio Returns for a PortfolioCVaR Object

Given portfolio p, use the estimatePortReturn function to estimate the mean of portfolio returns.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
    0.00408 0.0289 0.0204 0.0119;
    0.00192 0.0204 0.0576 0.0336;
    0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;
rng(11);
AssetScenarios = mvnrnd(m, C, 20000);
p = PortfolioCVaR;
p = setScenarios(p, AssetScenarios);
p = setDefaultConstraints(p);
p = setProbabilityLevel(p, 0.95);
pwgt = estimateFrontierLimits(p);
pret = estimatePortReturn(p, pwgt);
disp(pret)
```

0.0050
0.0154

The function rng(seed) resets the random number generator to produce the documented results. It is not necessary to reset the random number generator to simulate scenarios.

## Estimate the Mean of Porifolio Returns for a PorifolioMAD Object

Given portfolio $p$, use the estimatePortReturn function to estimate the mean of portfolio returns.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
    0.00408 0.0289 0.0204 0.0119;
    0.00192 0.0204 0.0576 0.0336;
    0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;
rng(11);
AssetScenarios = mvnrnd(m, C, 20000);
p = PortfolioMAD;
p = setScenarios(p, AssetScenarios);
p = setDefaultConstraints(p);
pwgt = estimateFrontierLimits(p);
pret = estimatePortReturn(p, pwgt);
disp(pret)
    0.0048
    0.0154
```

The function rng(seed) resets the random number generator to produce the documented results. It is not necessary to reset the random number generator to simulate scenarios.

## estimatePortRisk

Estimate standard deviation of portfolio returns (portfolio risk)
Use the estimatePortRisk function with a Portfolio, PortfolioCVaR, or PortfolioMAD object to estimate standard deviation of portfolio returns (portfolio risk).

For details on the respective workflows when using these different objects, see "Portfolio Object Workflow" on page 4-17, "PortfolioCVaR Object Workflow" on page 5-16, and "PortfolioMAD Object Workflow" on page 6-16.

## Syntax

prsk = estimatePortRisk(obj,pwgt)

## Description

prsk = estimatePortRisk(obj, pwgt) estimates standard deviation of portfolio returns (portfolio risk).

## Examples

## Standard Deviation of Portfolio Returns as the Proxy for Porifolio Risk for a Porifolio Object

Given portfolio $p$, use the estimatePortRisk function to show the standard deviation of portfolio returns for each portfolio in pwgt.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
    0.00408 0.0289 0.0204 0.0119;
    0.00192 0.0204 0.0576 0.0336;
    0 0.0119 0.0336 0.1225 ];
p = Portfolio;
p = setAssetMoments(p, m, C);
p = setDefaultConstraints(p);
pwgt = estimateFrontierLimits(p);
prsk = estimatePortRisk(p, pwgt);
```

## disp(prsk)

0.0769
0.3500

## Conditional Value-at-Risk of Porffolio Returns as the Proxy for Portfolio Risk for a PorffolioCVaR Object

Given a portfolio pwgt, use the estimatePortRisk function to show the conditional value-at-risk (CVaR) of portfolio returns for each portfolio.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
    0.00408 0.0289 0.0204 0.0119;
    0.00192 0.0204 0.0576 0.0336;
    0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;
rng(11);
AssetScenarios = mvnrnd(m, C, 20000);
p = PortfolioCVaR;
p = setScenarios(p, AssetScenarios);
p = setDefaultConstraints(p);
p = setProbabilityLevel(p, 0.95);
pwgt = estimateFrontierLimits(p);
prsk = estimatePortRisk(p, pwgt);
disp(prsk)
0.0407
0.1911
```

The function rng(seed) resets the random number generator to produce the documented results. It is not necessary to reset the random number generator to simulate scenarios.

## Mean-Absolute Deviation Returns as the Proxy for Porffolio Risk for a PorffolioMAD Object

Given a portfolio pwgt, use the estimatePortRisk function to show the mean-absolute deviation of portfolio returns for each portfolio.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
        0.00408 0.0289 0.0204 0.0119;
        0.00192 0.0204 0.0576 0.0336;
        0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;
rng(11);
AssetScenarios = mvnrnd(m, C, 20000);
p = PortfolioMAD;
p = setScenarios(p, AssetScenarios);
p = setDefaultConstraints(p);
pwgt = estimateFrontierLimits(p);
prsk = estimatePortRisk(p, pwgt);
disp(prsk)
    0.0177
    0.0809
```

The function rng(seed) resets the random number generator to produce the documented results. It is not necessary to reset the random number generator to simulate scenarios.

## estimateScenarioMoments

Estimate mean and covariance of asset return scenarios
Use the estimateScenarioMoments function with a PortfolioCVaR or PortfolioMAD objects to estimate mean and covariance of asset return scenarios.

For details on the workflows, see "PortfolioCVaR Object Workflow" on page 5-16, and "PortfolioMAD Object Workflow" on page 6-16.

## Syntax

[ScenarioMean,ScenarioCovar] = estimateScenarioMoments(obj)

## Description

[ScenarioMean,ScenarioCovar] = estimateScenarioMoments(obj) estimates mean and covariance of asset return scenarios for PortfolioCVaR or PortfolioMAD objects.

## Examples

## Estimate Mean and Covariance of Asset Return Scenarios for a PorffolioCVaR Object

Given PortfolioCVaR object $p$, use the estimatePortRisk function to estimate mean and covariance of asset return scenarios.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
    0.00408 0.0289 0.0204 0.0119;
    0.00192 0.0204 0.0576 0.0336;
    0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;
rng(11);
```

```
AssetScenarios = mvnrnd(m, C, 20000);
p = PortfolioCVaR;
p = setScenarios(p, AssetScenarios);
p = setDefaultConstraints(p);
p = setProbabilityLevel(p, 0.95);
[ScenarioMean, ScenarioCovar] = estimateScenarioMoments(p)
ScenarioMean =
    0.0039
    0.0082
    0.0102
    0.0154
ScenarioCovar =
\begin{tabular}{rrrr}

## ewstats

Expected return and covariance from return time series

## Syntax

[ExpReturn, ExpCovariance, NumEffObs] = ewstats(RetSeries, DecayFactor, WindowLength)

## Arguments

| RetSeries | Return Series: number of observations (NUMOBS) by number of <br> assets (NASSETS) matrix of equally spaced incremental return <br> observations. The first row is the oldest observation, and the last <br> row is the most recent. |
| :--- | :--- |
| DecayFactor | (Optional) Controls how much less each observation is weighted <br> than its successor. The $k$ th observation back in time has <br> weight DecayFactor^k. DecayFactor must lie in the range: <br> $0<$ DecayFactor $<=1$. |
|  | Default = 1, the equally weighted linear moving average model <br> (BIS). |
| WindowLength | (Optional) Number of recent observations in the computation. <br> Default = NUMOBS. |

## Description

[ExpReturn, ExpCovariance, NumEffObs] = ewstats(RetSeries, DecayFactor, WindowLength) computes estimated expected returns, estimated covariance matrix, and the number of effective observations. These are maximum likelihood estimates which are generally biased.

ExpReturn is a 1-by-NASSETS vector of estimated expected returns.
ExpCovariance is an NASSETS-by-NASSETS estimated covariance matrix. The standard deviations of the asset return processes are given by

```
STDVec = sqrt(diag(ExpCovariance))
```

The correlation matrix is

```
CorrMat = ExpCovariance./( STDVec*STDVec' )
```

NumEffObs is the number of effective observations $=(1-$ DecayFactor^WindowLength)/(1-DecayFactor).

A smaller DecayFactor or WindowLength emphasizes recent data more strongly but uses less of the available data set.

## Examples

## Compute Estimated Expected Returns and Estimated Covariance Matrix

This example shows how to compute the estimated expected returns and the estimated covariance matrix.

```
RetSeries = [ 0.24 0.08
    0.15 0.13
    0.27 0.06
    0.14 0.13 ];
DecayFactor = 0.98;
[ExpReturn, ExpCovariance] = ewstats(RetSeries, DecayFactor)
ExpReturn =
    0.1995 0.1002
ExpCovariance =
    0.0032 -0.0017
    0.0017 0.0010
```

## More About

- "Portfolio Optimization Functions" on page 3-4

See Also<br>cov \| mean<br>Introduced before R2006a

## exp

Exponential values

## Syntax

```
newfts = exp(tsobj)
```

## Description

newfts $=\exp (t s o b j)$ calculates the natural exponential (base e) of all the data in the data series of the financial time series object tsobj and returns the result in the object newfts.

## See Also

log | log10 | log2

## Related Examples

Introduced before R2006a

## extfield

Data series extraction

## Syntax

```
ftse = extfield(tsobj, fieldnames)
```

## Arguments

| tsobj | Financial time series object |
| :--- | :--- |
| fieldnames | Data series to be extracted. A cell array if a list of data series <br> names (fieldnames) is supplied. A string if only one is wanted. |

## Description

ftse $=$ extfield(tsobj, fieldnames) extracts from tsobj the dates and data series specified by fieldnames into a new financial time series object ftse. ftse has all the dates in tsobj but contains a smaller number of data series.

## Examples

extfield is identical to referencing a field in the object. For example,

```
ftse = extfield(fts, 'Close')
```

is the same as
ftse $=$ fts.Close
This function is the complement of the function rmfield.

## fanplot

Plot combined historical and forecast data to visualize possible outcomes

## Syntax

fanplot(historical,forecast)
h = fanplot(historical,forecast)

## Description

fanplot (historical, forecast) generates a fan chart. In time series analysis, a fan chart is a chart that joins a simple line chart for observed past data with ranges for possible values of future data. The historical data and possible future data are joined with a line showing a central estimate or most likely value for the future outcomes.
fanplot supports three plotting scenarios:

- Matching - This scenario occurs when the time period perfectly matches for historicall and forecast data.
- Backtest - This scenario occurs when there are overlaps between historical and forecast data.
- Gap - This scenario occurs when there are NaN values in the historical or forecast data.
h = fanplot(historical,forecast) generates a fan chart and returns the figure handle $h$. In time series analysis, a fan chart is a chart that joins a simple line chart for observed past data with ranges for possible values of future data. The historical data and possible future data are joined with a line showing a central estimate or most likely value for the future outcomes.
fanplot supports three plotting scenarios:
- Matching - This scenario occurs when the time period perfectly matches for historicall and forecast data.
- Backtest - This scenario occurs when there are overlaps between historical and forecast data.
- Gap - This scenario occurs when there are NaN values in the historical or forecast data.

## Examples

## Create a Fan Plot Using Cell Array Data

Define the data inputs for historical as a 5-by-2 cell array and forecast as a 5-by-21 cell array with 20 observations.
$\left.\left.\begin{array}{rl}\text { historical }= & \{[2006] \\ {[2007]} & {[-0.0110]} \\ {[2008]} & {[0.0120]} \\ & {[2009]} \\ & {[2010]}\end{array}\right][0.0090]\right\}$ [0.0150]\};

| forecast $=$ | \{[2011] | [0.0203] | [-0.0155] | [0.0311] | [-0.0026] | [0.0035] |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | [0.0533] | [0.0139] | [0.0037] | [-0.0727] | [-0.0291] |
|  | [2012] | [0.0430] | [-0.0094] | [0.0587] | [ 0.0095] | [0.0185] |
|  |  | [0.0141] | [0.0337] | [0.0187] | [0.0132] | [-0.0292] |
|  | [2013] | [0.0518] | [-0.0116] | [0.0708] | [0.0112] | [0.0221] |
|  |  | [0.0168] | [0.0405] | [0.0224] | [0.0157] | [-0.0356] |
|  | [2014] | [0.0546] | [-0.0171] | [0.0762] | [0.0088] | [0.0210] |
|  |  | [0.0151] | [0.0419] | [0.0214] | [0.0139] | [-0.0442] |
|  | [2015] | [0.0565] | [-0.0207] | [0.0797] | [0.0072] | [0.0203] |
|  |  | [0.0139] | [0.0428] | [0.0207] | [0.0126] | [-0.0499] |

Generate the fan plot.
fanplot (historical, forecast);

The dotted points are the historical lines and the filled lines indicate the mean for the forecasts. This fanplot represents a matching scenario where the time period perfectly matches for the historical and forcast data.

## Create a Fan Plot Using Matrix Data

Define the data inputs for historical as a 5-by-2 matrix and forecast as a 5-by-21 matrix with 20 observations.

$$
\left.\begin{array}{rrr}
\text { historical }=\left[\begin{array}{rr}
{[1.0000} & 2.8046 ; \\
2.0000 & 4.1040 ; \\
3.0000 & 6.7292 \\
& 4.0000 \\
& 8.6486
\end{array} ;\right. \\
& 5.0000 & 10.4747
\end{array}\right]
$$

| forecast | 3.0000 | 28.9874 | 18.3958 | 19.6376 | 29.5627 | 8.3462 | 7.1502 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | 20.8557 | 27.0691 | 23.0803 | 20.7885 | 18.0205 | 17.2294 |
|  | 4.0000 | 4.8933 | 27.2659 | 7.2206 | 24.4703 | 10.5895 | 15.0212 |
|  |  | 8.0007 | 18.7114 | 19.1691 | 24.5963 | 4.2835 | 4.0676 |
|  | 5.0000 | 20.9732 | 19.7069 | 11.6862 | 25.7018 | 31.8940 | 7.2664 |
|  |  | 31.7996 | 3.6419 | 3.2695 | 27.1422 | 10.5487 | 32.6529 |
|  | 6.0000 | 11.0069 | 29.1965 | 4.5551 | 20.2627 | 10.9209 | 15.2675 |
|  |  | 23.9532 | 18.4804 | 25.5484 | 4.8747 | 8.0036 | 11.5329 |
|  | 7.0000 | 5.9699 | 11.1486 | 26.0449 | 13.4619 | 21.1196 | 28.8068 |
|  |  | 21.2390 | 29.2396 | 18.4828 | 28.3945 | 21.9342 | 14.4642 |

Generate the fan plot and return the figure handle.

```
h = fanplot(historical, forecast)
```

$\mathrm{h}=$

Figure (1) with properties:
Number: 1

Use GET to show all properties

Financial Forecast Chart

The dotted points are the historical lines and the filled lines indicate the mean for the forecasts. This fanplot represents a backtest scenario where there is an overlap between the historical and forecast data.

- "Charting Financial Data" on page 2-12

## Input Arguments

historical - Historical dates and data
matrix | cell array

Historical dates and data, specified as an N -by-2 matrix or cell array, where the first column is the date, and the second column is the data associated for that date. N indicates the number of dates.

Data Types: cell | double

## forecast - Forecast dates and data

matrix | cell array
Forecast dates and data, specified as an N-by-M matrix or cell array, where the first column is the date, and the second to the last columns are the data observations. N indicates the number of the dates and $(M-1)$ is the number for data observations.

## Data Types: cell | double

## Output Arguments

## h - Figure handle for fanplot

handle object
Figure handle for the fanplot, returned as handle object.

Introduced in R2014b

## fbusdate

First business date of month

## Syntax

Date = fbusdate(Year, Month, Holiday, Weekend)

## Arguments

| Year | Enter as four-digit integer. |
| :--- | :--- |
| Month | Enter as integer from 1 to 12. |
| Holiday | (Optional) Vector of holidays and nontrading-day dates. All dates <br> in Holiday must be the same format: either serial date numbers <br> or date strings. (Using date numbers improves performance.) The <br> holidays function supplies the default vector. |
| Weekend | $\left.\begin{array}{l}\text { (Optional) Vector of length 7, containing } 0 \text { and 1, the value } \\ 1 \text { indicating weekend days. The first element of this vector } \\ \text { corresponds to Sunday. Thus, when Saturday and Sunday form the } \\ \text { weekend (default), then Weekend }=\left[\begin{array}{llll}1 & 0 & 0 & 0\end{array} 0001\right.\end{array}\right]$. |

## Description

Date = fbusdate(Year, Month, Holiday, Weekend) returns the serial date number for the first business date of the given year and month. Holiday specifies nontrading days.

Year and Month can contain multiple values. If one contains multiple values, the other must contain the same number of values or a single value that applies to all. For example, if Year is a 1-by-n vector of integers, then Month must be a 1 -by-n vector of integers or a single integer. Date is then a 1-by- $n$ vector of date numbers.

Use the function datestr to convert serial date numbers to formatted date strings.

## Examples

## Return a Serial Date Number for the First Business Date

This example shows how to return serial date numbers for the first business date, given year and month.

```
Date = fbusdate(2001, 11)
datestr(Date)
Year = [2002 2003 2004];
Date = fbusdate(Year, 11)
datestr(Date)
```

Date $=$
731156
ans $=$
01 -Nov-2001
Date =
$731521 \quad 731888 \quad 732252$
ans $=$
01 - Nov-2002
03-Nov-2003
01 -Nov-2004

- "Handle and Convert Dates" on page 2-4

# Return a Serial Date Number for the First Business Date Using the Weekend Argument 

This example shows how to return serial date numbers for the first business date, given year and month, and also indicate that Saturday is a business day by setting the Weekend argument. March 1, 2003, is a Saturday. Use fbusdate to check that this Saturday is actually the first business day of the month.

```
Weekend = [1 0 0 0 0 0 0];
Date = datestr(fbusdate(2003, 3, [], Weekend))
```

Date =
01-Mar-2003

## fetch

Data from financial time series object

## Syntax

newfts = fetch(oldfts, StartDate, StartTime, EndDate, EndTime, delta, dmy_specifier, time_ref)

## Arguments

| oldfts | Existing financial time series object. |
| :--- | :--- |
| StartDate | First date in the range from which data is to be extracted. |
| StartTime | Beginning time on each day. If you do not require specific <br> times or oldfts does not contain time information, use [ ]. <br> If you specify StartTime, you must also specify EndTime. |
| EndDate | Last date in the range from which data is to be extracted. |
| EndTime | Ending time on each day. If you do not require specific times <br> or oldfts does not contain time information, use [ ]. If you <br> specify EndTime, you must also specify StartTime. <br> Skip interval. Can be any positive integer. Units for the skip |
| delta | interval specified by dmy_specifier. |
| dmy_specifier | Specifies the units for delta. Can be <br> - $\quad$ M, m (Days) (Months) <br> - Y, y (Years) |
| time_ref | Time reference intervals or specific times. Valid time <br> reference intervals are 1, 5, 15, or 60 minutes. Enter specific <br> times as 'hh:mm '. |

## Description

newfts = fetch(oldfts, StartDate, StartTime, EndDate, EndTime, delta, dmy_specifier, time_ref) requests data from a financial time series object beginning from the start date and/or start time to the end date and/or end time, skipping a specified number of days, months, or years.

Note If time information is present in oldfts, using [ ] for start or end times results in fetch returning all instances of a specific date.

## Examples

Example 1. Create a financial time series object containing both dates and times:

```
dates = ['01-Jan-2001';'01-Jan-2001'; '02-Jan-2001'; ...
    '02-Jan-2001'; '03-Jan-2001';'03-Jan-2001'];
times = ['11:00';'12:00';'11:00';'12:00';'11:00';'12:00'];
dates_times = cellstr([dates, repmat(' ',size(dates,1),1),...
times]);
myFts = fints(dates_times,(1:6)',{'Data1'},1,'My first FINTS')
myFts =
    desc: My first FINTS
    freq: Daily (1)
    'dates: (6)',
```

To fetch all dates and times from this financial time series, enter

```
fetch(myFts,'01-Jan-2001',[],'03-Jan-2001',[],1,'d')
or
fetch(myFts,'01-Jan-2001','11:00','03-Jan-2001','12:00',1, 'd')
```

These commands reproduce the entire time series shown above.

To fetch every other day's data, enter

```
fetch(myFts,'01-Jan-2001',[],'03-Jan-2001',[],2,'d')
```

This returns:

```
ans =
    desc: My first FINTS
    freq: Daily (1)
\begin{tabular}{|c|c|c|}
\hline tes: (4)' & 'times: (4)' & 'Data1: (4) \\
\hline 01-Jan-2001' & '11:00' & [ 1] \\
\hline " & '12:00' & 2] \\
\hline '03-Jan-2001' & '11:00' & 5] \\
\hline & '12:00' & \\
\hline
\end{tabular}
```

Example 2. Create a financial time series object with time intervals of less than 1 hour:

```
dates2 = ['01-Jan-2001';'01-Jan-2001'; '01-Jan-2001';...
    '02-Jan-2001'; '02-Jan-2001';'02-Jan-2001'];
times2 = ['11:00';'11:05';'11:06';'12:00';'12:05';'12:06'];
dates_times2 = cellstr([dates2, repmat(' ',size(dates2,1),1),...
times2]);
myFts2 = fints(dates_times2,(1:6)',{'Data1'},1,'My second
FINTS')
myFts2 =
desc: My second FINTS
freq: Daily (1)
\begin{tabular}{|c|c|c|c|}
\hline dates: (6)' & 'times: & (6) ' & 'Data1: (6) \\
\hline '01-Jan-2001' & '11:00' & & 1] \\
\hline ' " ' & '11:05' & & \(2]\) \\
\hline ' " ' & '11:06' & & \(3]\) \\
\hline '02-Jan-2001' & '12:00' & & [ 4] \\
\hline ' " ' & '12:05' & & 5] \\
\hline ' " ' & '12:06' & & 6] \\
\hline
\end{tabular}
```

Use fetch to extract data from this time series object at 5 -minute intervals for each day starting at 11:00 o'clock on January 1, 2001.

```
fetch(myFts2,'01-Jan-2001',[],'02-Jan-2001',[],1,'d',5)
    desc: My second FINTS
    freq: Daily (1)
```

You can use this version of fetch to extract data at specific times. For example, to fetch data only at 11:06 and 12:06 from myFts2, enter

```
fetch(myFts2,'01-Jan-2001',[],'02-Jan-2001',[],1,'d',...
{'11:06';'12:06'})
ans =
    desc: My second FINTS
    freq: Daily (1)
\begin{tabular}{lllll} 
'dates: (2)' & 'times: & (2)' & 'Data1: & (2)' \\
'01-Jan-2001' & '11:06' & & {\([\)} & \(3]\) \\
'02-Jan-2001' & \(' 12: 06 '\) & {\([\)} & \(6]\)
\end{tabular}
```

## More About

- "What Is the Financial Time Series App?" on page 13-2

See Also<br>extfield | ftsbound | getfield | subsref<br>Introduced before R2006a

## fieldnames

Get names of fields

## Syntax

```
fnames = fieldnames(tsobj)
fnames = fieldnames(tsobj, srsnameonly)
```

## Arguments

| tsobj | Financial time series object |
| :--- | :--- |
| srsnameonly | Field names returned: |
|  | $0=$ All field names (default). |
|  | $1=$ Data series names only. |

## Description

fieldnames gets field names in a financial time series object.
fnames = fieldnames(tsobj) returns the field names associated with the financial time series object tsobj as a cell array of strings, including the common fields: desc, freq, dates (and times if present).
fnames = fieldnames(tsobj, srsnameonly) returns field names depending upon the setting of srsnameonly. If srsnameonly is 0 , the function returns all field names, including the common fields: desc, freq, dates, and times. If srsnameonly is set to 1 , fieldnames returns only the data series in fnames.

## More About

- "What Is the Financial Time Series App?" on page 13-2

Introduced before R2006a

## fills

Fill missing values in time series

## Syntax

```
newfts = fillts(oldfts, fill_method)
newfts = fillts(oldfts, fill_method, newdates)
newfts = fillts(oldfts, fill_method,
newdates, {'T1','T2',...})
newfts = fillts(oldfts, fill_method, newdates,
'SPAN', {'TS','TE'}, delta)
newfts = fillts(... sortmode)
```

## Arguments

| oldfts | Financial time series object. |
| :---: | :---: |
| fill_method | (Optional) Replaces missing values ( NaN ) in oldfts using an interpolation process, a constant, or a zero-order hold. <br> Valid fill methods (interpolation methods) are: <br> - linear - 'linear ' - 'l' (default) <br> - linear with extrapolation - 'linearExtrap' - 'le' <br> - cubic - 'cubic' - 'c' <br> - cubic with extrapolation - 'cubicExtrap' - 'ce' <br> - spline - 'spline' - 's' <br> - spline with extrapolation - 'splineExtrap' - 'se' <br> - nearest - 'nearest' - 'n' <br> - nearest with extrapolation - 'nearestExtrap' - 'ne' <br> - pchip - 'pchip' - 'p' <br> - pchip with extrapolation - 'pchipExtrap' - 'pe' |

|  | (See interp1 for a discussion of extrapolation.) <br> To fill with a constant, enter that constant. <br> A zero-order hold (' zero ') fills a missing value with the <br> value immediately preceding it. If the first value in the time <br> series is missing, it remains a NaN. |
| :--- | :--- |
| newdates | (Optional) Column vector of serial dates, a date string, or a <br> column cell array of date strings. If oldfts contains time <br> of day information, newdates must be accompanied by a <br> time vector (newtimes). Otherwise, newdates is assumed <br> to have times of '00:00 ' |
| T1, T2, TS, TE | First time, second time, start time, end time |
| delta | Time interval in minutes to span between the start time and <br> end time |
| sortmode | (Optional) Default = 0 (unsorted). 1 = sorted. |

## Description

newfts = fillts(oldfts, fill_method) replaces missing values (represented by NaN ) in the financial time series object oldfts with real values, using either a constant or the interpolation process indicated by fill_method.
newfts = fillts(oldfts, fill_method, newdates) replaces all the missing values on the specified dates newdates added to the financial time series oldfts with new values. The values can be a single constant or values obtained through the interpolation process designated by fill_method. If any of the dates in newdates exists in oldfts, the existing one has precedence.
newfts $=$ fillts(oldfts, fill_method, newdates, $\{$ 'T1', 'T2',...\}) additionally allows the designation of specific times of day for addition or replacement of data.
newfts $=$ fillts(oldfts, fill_method, newdates, 'SPAN', \{'TS','TE'\}, delta) is similar to the previous format except that you designate only a start time and an end time. You follow these times with a spanning time interval, delta.

If you specify only one date for newdates, specifying a start and end time generates only times for that specific date.
newfts $=$ fillts (... sortmode) additionally denotes whether you want the order of the dates in the output object to stay the same as in the input object or to be sorted chronologically.
sortmode $=0$ (unsorted) appends any new dates to the end. The interpolation and zeroorder processes that calculate the values for the new dates work on a sorted object. Upon completion, the existing dates are reordered as they were originally, and the new dates are appended to the end.
sortmode $=1$ sorts the output. After interpolation, no reordering of the date sequence occurs.

## Examples

Example 1. Create a financial time series object with missing data in the fourth and fifth rows.

```
dates = ['01-Jan-2001';'01-Jan-2001'; '02-Jan-2001';....
    '02-Jan-2001'; '03-Jan-2001';'03-Jan-2001'];
times = ['11:00';'12:00';'11:00';'12:00';'11:00';'12:00'];
dates_times = cellstr([dates, repmat(' ',size(dates,1),1),...
    times]);
OpenFts = fints(dates_times,[(1:3)'; nan; nan; 6],{'Data1'},1,\ldots
'Open Financial Time Series');
```

OpenFts looks like this:

```
OpenFts =
    desc: Open Financial Time Series
    freq: Daily (1)
\begin{tabular}{|c|c|c|c|}
\hline dates: (6)' & 'times: & (6) ' & 'Data1: (6)' \\
\hline 01-Jan-2001' & '11:00' & & \(1]\) \\
\hline & '12:00' & & 2] \\
\hline '02-Jan-2001' & '11:00' & & \(3]\) \\
\hline & '12:00' & & \(\mathrm{NaN}]\) \\
\hline '03-Jan-2001' & '11:00' & & \(\mathrm{NaN}]\) \\
\hline & '12:00' & & \(6]\) \\
\hline
\end{tabular}
```

Example 2. Fill the missing data in OpenFts using cubic interpolation.

```
FilledFts = fillts(OpenFts,'cubic')
FilledFts =
    desc: Filled Open Financial Time Series
    freq: Unknown (0)
    'dates: (6)' 'times: (6)' 'Data1: (6)
'01-Jan-2001' '11:00'
    '12:00
'02-Jan-2001' '11:00'
' " ' '12:00
'03-Jan-2001' '11:00
    12:00'
```

Example 3. Fill the missing data in OpenFts with a constant value.

```
FilledFts = fillts(OpenFts,0.3)
```

FilledFts =
desc: Filled Open Financial Time Series
freq: Unknown (0)

| dates: (6)' | 'times: | (6) ${ }^{\prime}$ | 'Data1: (6)' |
| :---: | :---: | :---: | :---: |
| '01-Jan-2001' | '11:00' |  | [ 1] |
|  | '12:00' |  | [ 2] |
| '02-Jan-2001' | '11:00' |  | [ 3] |
| ' " ' | '12:00' |  | [ 0.3000] |
| '03-Jan-2001' | '11:00' |  | [ 0.3000] |
|  | '12:00' |  | $6]$ |

Example 4. You can use fillts to identify a specific time on a specific day for the replacement of missing data. This example shows how to replace missing data at 12:00 on January 2 and 11:00 on January 3.

FilltimeFts $=$ fillts (OpenFts, 'c', ..
\{'02-Jan-2001'; '03-Jan-2001'\}, \{'12:00';'11:00'\},0)
FilltimeFts =
desc: Filled Open Financial Time Series
freq: Unknown (0)
'dates: (6)' 'times: (6)' 'Data1: (6)

| '01-Jan-2001' | '11:00' | [ | 1] |
| :---: | :---: | :---: | :---: |
| ' " ' | '12:00' | [ | 2] |
| '02-Jan-2001' | '11:00' | [ | $3]$ |
| ' " ' | '12:00' | [ | 3.0663 ] |
| '03-Jan-2001' | '11:00' | [ | $5.8411]$ |
| ' " ' | '12:00' |  | $6.0000]$ |

Example 5. Use a spanning time interval to add an additional day to OpenFts.

```
SpanFts = fillts(OpenFts,'c','04-Jan-2001','span',...
            {'11:00';'12:00'},60,0)
```

## SpanFts =

desc: Filled Open Financial Time Series
freq: Unknown (0)
freq: Unknown (0)

| 'dates: (8)' | 'times: | (8) ${ }^{\prime}$ | 'Data1: (8)' |
| :---: | :---: | :---: | :---: |
| '01-Jan-2001' | '11:00' |  | [ 1] |
|  | '12:00' |  | [ 2] |
| '02-Jan-2001' | '11:00' |  | [ 3] |
|  | '12:00' |  | [ 3.0663] |
| '03-Jan-2001' | '11:00' |  | [ 5.8411] |
|  | '12:00' |  | [ 6.0000] |
| '04-Jan-2001' | '11:00' |  | [ 9.8404] |
|  | '12:00' |  | [ 9.9994] |

## See Also

interp1
Introduced before R2006a

## filter

Linear filtering

## Syntax

```
newfts = filter(B, A, oldfts)
```

## Description

filter filters an entire financial time series object with certain filter specifications. The filter is specified in a transfer function expression.
newfts $=$ filter $(B, A$, oldfts) filters the data in the financial time series object oldfts with the filter described by vectors A and B to create the new financial time series object newfts. The filter is a "Direct Form II Transposed" implementation of the standard difference equation. newfts is a financial time series object containing the same data series (names) as the input oldfts.

## fints

Construct financial time series object

## Syntax

```
tsobj = fints(dates_and_data)
tsobj = fints(dates, data)
tsobj = fints(dates, data, datanames)
tsobj = fints(dates, data, datanames, freq)
tsobj = fints(dates, data, datanames, freq, desc)
```

## Arguments

| dates_and_data | Column-oriented matrix containing one column of dates <br> and a single column for each series of data. In this format, <br> dates must be entered in serial date number format. If the <br> input serial date numbers encode time-of-day information, <br> the output object contains a column labeled ' dates ' <br> containing the date information and another labeled <br> 'times ' containing the time information. <br> You can use the MATLAB function today to enter date |
| :--- | :--- |
| information or the MATLAB function now to enter date with |  |
| time information. |  |$|$

|  | - 'ddmmmyy hh:mm' or 'ddmmmyyyy hh:mm' <br> - 'mm/dd/yy hh:mm' or 'mm/dd/yyyy hh:mm' <br> - 'dd-mmm-yy hh:mm' or 'dd-mmm-yyyy hh:mm' <br> - 'mmm.dd,yy hh:mm' or 'mmm.dd,yyyy hh:mm' <br> Dates and times can initially be separate column-oriented vectors, but they must be concatenated into a single columnoriented matrix before being passed to fints. You can use the MATLAB functions today and now to help with entering date and time information. |
| :---: | :---: |
| data | Column-oriented matrix containing a column for each series of data. The number of values in each data series must match the number of dates. If a mismatch occurs, MATLAB does not generate the financial time series object, and you receive an error message. |
| datanames | Cell array of data series names. Overrides the default data series names. Default data series names are series1, series2, and so on. |
|  | Note: Not all strings are accepted as datanames parameters. Supported data series names cannot start with a number and must contain only these characters: <br> - Lowercase Latin alphabet, a to z <br> - Uppercase Latin alphabet, A to Z <br> - Underscore, |

| freq | Frequency indicator. Allowed values are: |
| :--- | :--- |
|  | UNKNOWN, Unknown, unknown, U, u, 0 |
| DAILY, Daily, daily, D, d, 1 |  |
| WEEKLY, Weekly, weekly, W, w, 2 |  |
| MONTHLY, Monthly, monthly, M, m, 3 |  |
| QUARTERLY, Quarterly, quarterly, Q, q, 4 |  |
| SEMIANNUAL, Semiannual, semiannual, S, s, 5 |  |
| ANNUAL, Annual, annual, A, a, 6 |  |
| Default = Unknown. |  |
| desc | String providing descriptive name for financial time series <br> object. Default = ' '. |

## Description

fints constructs a financial time series object. A financial time series object is a MATLAB object that contains a series of dates and one or more series of data. Before you perform an operation on the data, you must set the frequency indicator (freq). You can optionally provide a description (desc) for the time series.
tsobj = fints(dates_and_data) creates a financial time series object containing the dates and data from the matrix dates_and_data. If the dates contain time-of-day information, the object contains an additional series of times. The date series and each data series must each be a column in the input matrix. The names of the data series default to series1, ..., seriesn. The desc and freq fields are set to their defaults.
tsobj = fints(dates, data) generates a financial time series object containing dates from the dates column vector of dates and data from the matrix data. If the dates contain time-of-day information, the object contains an additional series of times. The data matrix must be column-oriented, that is, each column in the matrix is a data series. The names of the series default to series $1, \ldots$, seriesn, where $n$ is the total number of columns in data. The desc and freq fields are set to their defaults.
tsobj $=$ fints(dates, data, datanames) also allows you to rename the data series. The names are specified in the datanames cell array. The number of strings in datanames must correspond to the number of columns in data. The desc and freq fields are set to their defaults.
tsobj = fints(dates, data, datanames, freq) also sets the frequency when you create the object. The desc field is set to its default ' ' .
tsobj = fints(dates, data, datanames, freq, desc) provides a description string for the financial time series object.

Note: fints only supports hourly and minute time series. Seconds are not supported and will be disregarded when the fints object is created (that is, 01 -jan-2001 12:00:01 will be considered as 01-jan-2001 12:00). If there are duplicate dates and times, the fints constructor sorts the dates and times and chooses the first instance of the duplicate dates and times. The other duplicate dates and times are removed from the object along with their corresponding data.

## Examples

## Create a Financial Time Series Object Containing Days and Data

Define the data:

```
data = [1:6]'
data =
    1
    2
    3
    4
    5
    6
```

Define the dates:
dates $=[\text { today:today }+5]^{\prime}$

```
dates =
    7 3 6 2 0 0
    7 3 6 2 0 1
    7 3 6 2 0 2
    7 3 6 2 0 3
    7 3 6 2 0 4
    7 3 6 2 0 5
```

Create the financial times series object:

```
tsobjkt = fints(dates, data)
```

tsobjkt =
desc: (none)
freq: Unknown (0)
'dates: (6)' 'series1: (6)
'24-Aug-2015' [ 1]
'25-Aug-2015' [ 2]
'26-Aug-2015' [ 3]
'27-Aug-2015' [ 4]
'28-Aug-2015' [ 5]
'29-Aug-2015 ' [ 6]

## Create a Financial Time Series Object Containing Days, Time of Day, and Data

Define the data:

```
data = [1:6]
```

data =
1
2
3
4
5
6

Define the dates:

```
dates = [now:now+5]'
dates =
    1.0e+05
    7.3620
    7.3620
    7.3620
    7.3620
    7.3620
    7.3621
```

Create the financial times series object:

```
tsobjkt = fints(dates, data)
```

tsobjkt =
desc: (none)
freq: Unknown (0)

| dates: (6)' | 'times: (6)' | 'series1: (6) |
| :---: | :---: | :---: |
| 24-Aug-2015' | '17:40' | 1] |
| '25-Aug-2015' | '17:40' | 2] |
| '26-Aug-2015' | '17:40' | $3]$ |
| '27-Aug-2015' | '17:40' | 4] |
| '28-Aug-2015' | '17:40' | 5] |
| 29-Aug-2015' | '17:40' | $6]$ |

## Create a Financial Time Series Object From a Single Input for Dates and Times

Define the dates and times:

```
dates_and_times = (now:now+5)'
dates_and_times =
    1.0e+05 *
```

7.3620
7.3620
7.3620
7.3620
7.3620
7.3621

Create the financial times series object:

```
f = fints(dates_and_times, randn(6,1))
```

$f=$
desc: (none)
freq: Unknown (0)

| 'dates: (6)' | 'times: | $(6)^{\prime}$ | 'series1: (6)' |
| :---: | :---: | :---: | :---: |
| ' 24 - Aug-2015' | '17:39' |  | 0.5377 ] |
| '25-Aug-2015' | '17:39' |  | $1.8339]$ |
| ' 26-Aug-2015' | '17:39' |  | -2.2588] |
| '27-Aug-2015' | '17:39' |  | $0.8622]$ |
| ' 28 -Aug-2015' | '17:39' |  | $0.3188]$ |
| '29-Aug-2015' | '17:39' |  | -1.3077] |

This generates a financial time series object, $f$, and obtains the dates and data from the matrix dates_and_times. The dates and times in the input matrix must be oriented column-wise (i.e. the date series and each time series are columns in the input matrix). In addition, the dates entered must be in the serial date format (i.e. 01-Jan-2001 is 730852). You can also use the function now to enter in date information. The names of the series will default to 'series1', ..., '| seriesN'| where $N$ is the total number of columns in dates_and_times less 1 (that is the number of data columns). The default contents of the desc and freq fields are|"| and | 'Unknown'| (0), respectively.

## floardiscmargin

Discount margin for floating-rate bond

## Syntax

```
Margin = floatdiscmargin(Price,Spread,Settle,Maturity,
RateInfo,LatestFloatingRate)
Margin = floatdiscmargin(Price,Spread,Settle,Maturity,
RateInfo,LatestFloatingRate,Name,Value)
```

## Description

Margin = floatdiscmargin(Price,Spread,Settle,Maturity, RateInfo, LatestFloatingRate) calculates the discount margin or zero discount margin for a floating-rate bond.

Margin = floatdiscmargin(Price,Spread,Settle, Maturity, RateInfo, LatestFloatingRate, Name, Value) calculates the discount margin or zero discount margin for a floating-rate bond with additional options specified by one or more Name, Value pair arguments.

## Input Arguments

## Price

NINST-by-1 matrix of bond prices where the discount margin is to be computed. The spread is calculated against the clean price (the function internally does not add the accrued interest to the price specified by the Price input). If the spread is required against the dirty price, you must supply the dirty price to this input.

## Spread

NINST-by-1 matrix for the number of basis points over the reference rate.

## Settle

Settlement date of the floating-rate bond(s). If supplied as a NINST-by- 1 vector of dates, all settlement dates must be the same (only a single settlement date is supported).

## Maturity

NINST-by- 1 vector of dates representing the maturity date of the floating-rate bond.

## RateInfo

Interest-rate information. This argument determines if the discount margin or zero discount margin is calculated. If this input is a NINST-by-2 vector, the discount margin is calculated where the:

- First column is the stub rate between the settlement date and the first coupon rate.
- Second column is the reference rate for the term of the floating coupons (for example, the 3-month LIBOR from the settlement date for a bond with a Reset of 4).

Note: If this argument is an annualized zero-rate term structure created by intenvset, the zero discount margin is calculated.

## LatestFloatingRate

NINST-by-1 vector representing the rate for the next floating payment set at the last reset date.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.
'Reset'
NINST-by-1 vector representing the frequency of payments per year.
Default: 1

## 'Basis'

NINST-by-1 vector representing the basis used for time factor calculations:

- $0=$ actual/actual
- $1=30 / 360$ (SIA)
- 2 = actual/360
- $3=$ actual $/ 365$
- $4=30 / 360$ (BMA)
- $5=30 / 360$ (ISDA)
- $6=30 / 360$ (European)
- $7=$ actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- $10=\mathrm{actual} / 365$ (ICMA)
- $11=30 / 360 \mathrm{E}$ (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

## For more information, see basis.

Default: 0 (actual/actual)

## 'Principal'

NINST-by-1 of notional principal amounts or NINST-by-1 cell array where each element is a NUMDATES-by-2 cell array where the first column is dates and the second column is the associated principal amount. The date indicates the last day that the principal value is valid.

Default: 100

## 'EndMonthRule'

NINST-by- 1 vector representing the end-of-month rule.
Default: 1 (in effect)

## 'AdjustCashFlowsBasis'

NINST-by- 1 vector of logicals. Adjusts cash flows according to the accrual amount.

> Note: Usually you want to set AdjustCashFlowsBasis to true, so cash flows are calculated with adjustments on accrual amounts. The default is set to false to be consistent with floatbyzero.

## Default: false

## 'Holidays'

NHOLIDAYS-by-1 vector of MATLAB date numbers. Holidays are used in computing business days.

Default: holidays.m used

## 'BusinessDayConvention'

NINST-by- 1 cell array of business day convention to be used in computing payment dates. Values are:

- actual
- follow
- modifiedfollow
- previous
- modifiedprevious

Default: actual

## Output Arguments

## Margin

NINST-by-1 vector of the discount margin if RateInfo is specified as a NINST-by-2 vector of stub and spot rates. NINST-by-NCURVES matrix of the zero discount margin if RateInfo is specified as an annualized zero rate term structure created by intenvset.

## Examples

## Compute the Zero Discount Margin Using a Yield Curve

Use floatdiscmargin to compute the discount margin and zero discount margin for a floating-rate note.

Define data for the floating-rate note.

```
Price = 99.99;
Spread = 50;
Settle = '20-Jan-2011';
Maturity = '15-Jan-2012';
LatestFloatingRate = 0.05;
StubRate = 0.049;
SpotRate = 0.05;
Reset = 4;
Basis = 2;
```

Compute the discount margin.
dMargin = floatdiscmargin(Price, Spread, Settle, Maturity, ...
[StubRate, SpotRate], LatestFloatingRate,'Reset', Reset, 'Basis', Basis, ...
'AdjustCashFlowsBasis', true)

## dMargin =

48.4810

Usually you want to set AdjustCashFlowsBasis to true, so cash flows are calculated with adjustments on accrual amounts.

Create an annualized zero-rate term structure to calculate the zero discount margin.

```
Rates = [0.0500;
    0.0505;
    0.0510;
    0.0520];
StartDates = ['20-Jan-2011';
        '15-Apr-2011';
        '15-Jul-2011';
        '15-Oct-2011'];
```

```
EndDates = ['15-Apr-2011';
    '15-Jul-2011';
    '15-0ct-2011';
    '15-Jan-2012'];
ValuationDate = '20-Jan-2011';
RateSpec = intenvset('Compounding', Reset, 'Rates', Rates,...
'StartDates', StartDates, 'EndDates', EndDates,...
'ValuationDate', ValuationDate, 'Basis', Basis);
```

Calculate the zero discount margin using the previous yield curve.

```
dMargin = floatdiscmargin(Price, Spread, Settle, Maturity, ...
RateSpec, LatestFloatingRate,'Reset', Reset, 'Basis', Basis, ...
'AdjustCashFlowsBasis', true)
```

dMargin =
46.0688

## floatmargin

Margin measures for floating-rate bond

## Syntax

[Margin,AdjPrice] = floatmargin(Price,Spread,Settle, Maturity)
[Margin,AdjPrice] = floatmargin(Price,Spread,Settle, Maturity, Name, Value)

## Description

[Margin,AdjPrice] = floatmargin(Price,Spread,Settle, Maturity) calculates margin measures for a floating-rate bond.
[Margin,AdjPrice] = floatmargin(Price,Spread,Settle, Maturity, Name, Value) calculates margin measures for a floating-rate bond with additional options specified by one or more Name, Value pair arguments.

Use floatmargin to calculate the following types of margin measures for a floating-rate bond:

- Spread for life
- Adjusted simple margin
- Adjusted total margin

To calculate the discount margin or zero discount margin, see floatdiscmargin.

## Input Arguments

## Price

NINST-by- 1 matrix of bond prices where spreads are to be computed.

## Spread

NINST-by- 1 matrix for the number of basis points over the reference rate.

## Settle

Settlement date of the floating-rate bond(s). If supplied as a NINST-by- 1 vector of dates, all settlement dates must be the same (only a single settlement date is supported).

## Maturity

NINST-by- 1 vector of dates representing the maturity date of the floating-rate bond.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, . . . NameN, ValueN.

## 'SpreadType'

The type of spread to calculate. Values are:

- spreadforlife
- adjustedsimple
- adjustedtotal

Only single SpreadType values are supported.
If the SpreadType is spreadforlife (default), then the Name-Value arguments LatestFloatingRate and RateInfo are not used. If the SpreadType is adjustedsimple or adjustedtotal, then the Name-Value arguments LatestFloatingRate and RateInfo must be specified.

Default: spreadforlife
'LatestFloatingRate'
NINST-by-1 vector representing the rate for the next floating payment set at the last reset date. This rate must be specified for SpreadType of adjustedsimple and adjustedtotal.

Default:

## 'RateInfo'

NINST-by-2 vector representing the interest-rate information where the:

- First column is the stub rate between the settlement date and the first coupon rate.
- Second column is the reference rate for the term of the floating coupons (for example, the 3 -month LIBOR from settlement date for a bond with a Reset of 4).

Note: The RateInfo must be specified for SpreadType of adjustedsimple and adjustedtotal.

## Default:

## 'Reset'

NINST-by-1 vector representing the frequency of payments per year.

## Default: 1

## 'Basis'

NINST-by-1 vector representing the basis used for time factor calculations:

- $0=$ actual/actual
- $1=30 / 360$ (SIA)
- 2 = actual/360
- $3=$ actual $/ 365$
- $4=30 / 360$ (BMA)
- $5=30 / 360$ (ISDA)
- $6=30 / 360$ (European)
- $7=$ actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- $9=$ actual/360 (ICMA)
- $10=$ actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- $12=$ actual/365 (ISDA)
- 13 = BUS/252

For more information, see basis.
Default: 0 (actual/actual)

## 'Principal'

NINST-by-1 of notional principal amounts.
Default: 100

## 'EndMonthRule'

NINST-by-1 vector representing the end-of-month rule.
Default: 1 (in effect)

## 'Holidays'

NHOLIDAYS-by-1 vector of MATLAB date numbers. Holidays are used in computing business days.

Default: holidays.m used

## 'BusinessDayConvention'

NINST-by- 1 cell array of business day conventions to be used in computing payment dates. Values are:

- actual
- follow
- modifiedfollow
- previous
- modifiedprevious

Default: actual

## Output Arguments

## Margin

NINST-by-1 vector of spreads for the floating-rate bond.

## AdjPrice

NINST-by-1 vector of the adjusted price used to calculate spreads for SpreadType of adjustedsimple and adjustedtotal.

## Examples

## Compute Margin Measures for a Floating-Rate Bond

Use floatmargin to compute margin measures for spreadforlife, adjustedsimple, and adjustedtotal for a floating-rate note.

Define data for the floating-rate note.

```
Price = 99.99;
Spread = 50;
Settle = '20-Jan-2011';
Maturity = '15-Jan-2012';
LatestFloatingRate = 0.05;
StubRate = 0.049;
SpotRate = 0.05;
Reset = 4;
Basis = 2;
```

Calculate spreadforlife.

```
Margin = floatmargin(Price, Spread, Settle, Maturity, 'Reset', ...
Reset, 'Basis', Basis)
```

## Margin =

```
51.0051
```

Calculate adjustedsimple margin.
[Margin, AdjPrice] = floatmargin(Price, Spread, Settle, Maturity, ... 'SpreadType', 'adjustedsimple', 'RateInfo', [StubRate, SpotRate], ... 'LatestFloatingRate', LatestFloatingRate, 'Reset', Reset, 'Basis', Basis)

Calculate adjustedtotal margin.
[Margin, AdjPrice] = floatmargin(Price, Spread, Settle, Maturity, ... 'SpreadType', 'adjustedtotal', 'RateInfo', [StubRate, SpotRate], ... 'LatestFloatingRate', LatestFloatingRate, 'Reset', Reset, 'Basis', Basis)

Margin =
53.4463

AdjPrice =
99.9673

Introduced in R2012b

## fpctkd

## Fast stochastics

## Syntax

```
[pctk, pctd] = fpctkd(highp, lowp, closep)
[pctk, pctd] = fpctkd([highp lowp closep])
[pctk, pctd] = fpctkd(highp, lowp, closep, kperiods, dperiods,
    dmamethod)
[pctk, pctd] = fpctkd([highp lowp closep], kperiods, dperiods,
dmamethod)
pkdts = fpctkd(tsobj, kperiods, dperiods, dmamethod)
pkdts = fpctkd(tsobj, kperiods, dperiods, dmamethod, 'ParameterName',
ParameterValue, ...)
```

## Arguments

| highp | High price (vector). |
| :--- | :--- |
| lowp | Low price (vector). |
| closep | Closing price (vector). |
| kperiods | (Optional) \%K periods. Default = 10. |
| dperiods | (Optional) \%D periods. Default = 3. |
| damethod | (Optional) \%D moving average method. Default = ' e' <br> (exponential). |
| tsobj | Financial time series object. |
| 'ParameterName ' | Valid parameter names are: <br> $-\quad$ HighName: high prices series name <br> LowName: low prices series name <br> CloseName: closing prices series name |

| ParameterValue | Parameter values are the strings that represent the valid <br> parameter names. |
| :--- | :--- |

## Description

fpctkd calculates the stochastic oscillator.
[pctk, pctd] = fpctkd(highp, lowp, closep) calculates the fast stochastics F\%K and F\%D from the stock price data highp (high prices), lowp (low prices), and closep (closing prices).
[pctk, pctd] = fpctkd([highp lowp closep]) accepts a three-column matrix of high (highp), low (lowp), and closing prices (closep), in that order.
[pctk, pctd] = fpctkd(highp, lowp, closep, kperiods, dperiods, dmamethod) calculates the fast stochastics F\%K and F\%D from the stock price data highp (high prices), lowp (low prices), and closep (closing prices). kperiods sets the \%K period. dperiods sets the \%D period.
damethod specifies the \%D moving average method. Valid moving average methods for $\% \mathrm{D}$ are Exponential ('e') and Triangular ('t'). See tsmovavg for explanations of these methods.
[pctk, pctd]= fpctkd([highp lowp closep], kperiods, dperiods, dmamethod) accepts a three-column matrix of high (highp), low (lowp), and closing prices (closep), in that order.
pkdts = fpctkd(tsobj, kperiods, dperiods, dmamethod) calculates the fast stochastics F\%K and F\%D from the stock price data in the financial time series object tsobj. tsobj must minimally contain the series High (high prices), Low (low prices), and Close (closing prices). pkdts is a financial time series object with similar dates to tsobj and two data series named PercentK and PercentD.
pkdts = fpctkd(tsobj, kperiods, dperiods, dmamethod, 'ParameterName', ParameterValue, ...) accepts parameter name/parameter value pairs as input. These pairs specify the name(s) for the required data series if it is different from the expected default name(s). Parameter values are the strings that represent the valid parameter names.

## Examples

## Compute the Stochastic Oscillator

This example shows how to compute the stochastic oscillator for Disney stock and plot the results.

```
load disney.mat
dis_FastStoc = fpctkd(dis);
plot(dis_FastStoc)
title('Stochastic Oscillator for Disney')
```

## frac2cur

Fractional currency value to decimal value

## Syntax

Decimal = frac2cur(Fraction, Denominator)

## Description

Decimal = frac2cur(Fraction, Denominator) converts a fractional currency value to a decimal value. Fraction is the fractional currency value input as a string, and Denominator is the denominator of the fraction.

## Examples

## Convert a Fractional Currency Value to a Decimal Value

This example shows how to convert a fractional currency value to a decimal value.

```
Decimal = frac2cur('12.1', 8)
```

Decimal =
12.1250

## freqnum

Convert string frequency indicator to numeric frequency indicator

## Syntax

```
nfreq = freqnum(sfreq)
```

## Arguments

```
sfreq UNKNOWN, Unknown, unknown, U, u
DAILY, Daily, daily, D, d
WEEKLY, Weekly, weekly, W, w
MONTHLY, Monthly, monthly, M, m
QUARTERLY, Quarterly, quarterly, Q, q
SEMIANNUAL, Semiannual, semiannual, S, s
ANNUAL, Annual, annual, A, a
```

## Description

$n f r e q=f r e q n u m(s f r e q)$ converts a string frequency indicator into a numeric value.

| String Frequency Indicator | Numeric Representation |
| :--- | :--- |
| UNKNOWN, Unknown, unknown, U, u | 0 |
| DAILY, Daily, daily, D, d | 1 |
| WEEKLY, Weekly, weekly, W, w | 2 |
| MONTHLY, Monthly, monthly, M, m | 3 |
| QUARTERLY, Quarterly, quarterly, Q, q | 4 |

## frontcon

Mean-variance efficient frontier

## Compatibility

frontcon has been removed. Use Portfolio instead. The Portfolio object supports gross or net portfolio returns as the return proxy, the variance of portfolio returns as the risk proxy, and a portfolio set that is any combination of the specified constraints to form a portfolio set. For information on the workflow when using Portfolio objects, see "Portfolio Object Workflow" on page 4-17. For more information on migrating frontcon code to Portfolio, see "frontcon Migration to Portfolio Object" on page 3-25.

## Syntax

[PortRisk, PortReturn, PortWts] = frontcon(ExpReturn, ExpCovariance, NumPorts, PortReturn, AssetBounds, Groups, GroupBounds, varargin)

## Arguments

| ExpReturn | 1 by number of assets (NASSETS) vector specifying the <br> expected (mean) return of each asset. |
| :--- | :--- |
| ExpCovariance | NASSETS-by-NASSETS matrix specifying the covariance of <br> asset returns. |
| NumPorts | (Optional) Number of portfolios generated along the efficient <br> frontier. Returns are equally spaced between the maximum <br> possible return and the minimum risk point. If NumPorts <br> is empty (entered as [ ], frontcon computes 10 equally <br> spaced points. When entering a target rate of return <br> (PortReturn), enter NumPorts as an empty matrix [ ]. |
| PortReturn | (Optional) Vector of length equal to the number of portfolios <br> (NPORTS) containing the target return values on the frontier. <br> If PortReturn is not entered or [ ], NumPorts equally |

|  | spaced returns between the minimum and maximum <br> possible values are used. |
| :--- | :--- |
| AssetBounds | (Optional) 2-by-NASSETS matrix containing the lower and <br> upper bounds on the weight allocated to each asset in the <br> portfolio. Default lower bound = all 0s (no short-selling). <br> Default upper bound = all 1s (any asset may constitute the <br> entire portfolio). |
| Groups | (Optional) Number of groups (NGROUPS-by-NASSETS) matrix <br> specifying NGROUPS asset groups or classes. Each row <br> specifies a group. Groups (i, j) = 1 ( jth asset belongs in <br> the ith group). Groups (i, j) = 0 ( $j$ th asset not a member <br> of the ith group). |
| GroupBounds | (Optional) NGROUPS-by-2 matrix specifying, for each group, <br> the lower and upper bounds of the total weights of all assets <br> in that group. Default lower bound = all 0s. Default upper <br> bound = all 1s. |

| varargin | (Optional) varargin supports the following parametervalue pairs: <br> - 'algorithm' - Defines which algorithm to use with frontcon. Use either a value of 'lcprog' or 'quadprog' to indicate the algorithm to use. The default is 'lcprog'. <br> - 'maxiter' - Maximum number of iterations before termination of algorithm. The default is 100000 . <br> - 'tiebreak ' - Method to break ties for pivot selection. This value pair applies only to 'lcprog' algorithm. The default is 'first'. Options are: <br> - 'first' - Selects pivot with lowest index. <br> - 'last' - Selects pivot with highest index. <br> - 'random' - Selects pivot at random. <br> - 'tolcon' - Tolerance for constraint violations. This value pair applies only to 'lcprog' algorithm. The default is $1.0 \mathrm{e}-6$. <br> - 'tolpiv' - Pivot value below which a number is considered to be zero. This value pair applies only to 'lcprog ' algorithm. The default is $1.0 \mathrm{e}-9$. |
| :---: | :---: |

## Description

[PortRisk, PortReturn, PortWts] = frontcon(ExpReturn, ExpCovariance, NumPorts, PortReturn, AssetBounds, Groups, GroupBounds, varargin) returns the mean-variance efficient frontier with user-specified asset constraints, covariance, and returns. For a collection of NASSETS risky assets, computes a portfolio of asset investment weights that minimize the risk for given values of the expected return. The portfolio risk is minimized subject to constraints on the asset weights or on groups of asset weights.

PortRisk is an NPORTS-by-1 vector of the standard deviation of each portfolio.
PortReturn is a NPORTS-by-1 vector of the expected return of each portfolio.

PortWts is an NPORTS-by-NASSETS matrix of weights allocated to each asset. Each row represents a portfolio. The total of all weights in a portfolio is 1.
frontcon generates a plot of the efficient frontier if you invoke it without output arguments.

The asset returns are assumed to be jointly normal, with expected mean returns of ExpReturn and return covariance ExpCovariance. The variance of a portfolio with 1-by-NASSETS weights PortWts is given by PortVar = PortWts*ExpCovariance*PortWts'. The portfolio expected return is PortReturn $=\operatorname{dot}(E x p R e t u r n$, PortWts).

## Examples

## Compute the Mean-Variance Efficient Frontier

This example shows how to compute the mean-variance efficient frontier for four points, given three assets with expected returns and expected covariance.

ExpReturn $=\left[\begin{array}{lll}0.1 & 0.2 & 0.15\end{array}\right] ;$
ExpCovariance $=\left[\begin{array}{rrc}0.0100 & -0.0061 & 0.0042 \\ & -0.0061 & 0.0400 \\ & 0.0042 & -0.0252 \\ & 0.0252 & 0.0225] ;\end{array}\right.$
NumPorts $=4$;
[PortRisk, PortReturn, PortWts] = frontcon(ExpReturn,... ExpCovariance, NumPorts)

Error using frontcon (line 89)
In a future release, frontcon will be removed. Use the Portfolio object instead.
See the release notes for details, including examples to make the conversion.

## frontier

Rolling efficient frontier

## Syntax

[PortWts, AllMean, AllCovariance] = frontier(Universe, Window, Offset, NumPorts, ActiveMap, ConSet, NumNonNan)

## Arguments

| Universe | Number of observations (NUMOBS) by number of assets plus one <br> (NASSETS + 1) time series array containing total return data for <br> a group of securities. Each row represents an observation. Column <br> 1 contains MATLAB serial date numbers. The remaining columns <br> contain the total return data for each security. |
| :--- | :--- |
| Window | Number of data periods used to calculate each frontier. |
| Offset | Increment in number of periods between each frontier. |
| NumPorts | Number of portfolios to calculate on each frontier. |
| ActiveMap | (Optional) Number of observations (NUMOBS) by number of <br> assets (NASSETS) matrix with Boolean elements corresponding <br> to the Universe. Each element indicates if the asset is part of <br> the Universe on the corresponding date. Default = NUMOBS- <br> by-NASSETS matrix of 1's (all assets active on all dates). |
| Conset | (Optional) Constraint matrix for a portfolio of asset investments, <br> created using portcons with the 'Default constraint type. This <br> single constraint matrix is applied to each frontier. |
| NumNonNan | (Optional) Minimum number of non-NaN points for each active asset <br> in each window of data needed to perform the optimization. The <br> default value is Window - NASSETS. |

## Description

[PortWts, AllMean, AllCovariance] = frontier(Universe, Window, Offset, NumPorts, ActiveMap, ConSet, NumNonNan) generates a surface of efficient frontiers showing how asset allocation influences risk and return over time.

PortWts is a number of curves (NCURVES)-by- 1 cell array, where each element is a NPORTS-by-NASSETS matrix of weights allocated to each asset.

AllMean is a NCURVES-by- 1 cell array, where each element is a 1-by-NASSETS vector of the expected asset returns used to generate each curve on the surface.

AllCovariance is a NCURVES-by- 1 cell array, where each element is a NASSETS-by-NASSETS vector of the covariance matrix used to generate each curve on the surface.

## Introduced before R2006a

## fts2ascii

Write elements of time series data into ASCII file

## Syntax

```
stat = fts2ascii(filename, tsobj, exttext)
stat = fts2ascii(filename, dates, data, colheads, desc, exttext)
```

## Arguments

| filename | Name of an ASCII file |
| :--- | :--- |
| tsobj | Financial time series object |
| exttext | (Optional) Extra text. A string written after the description line <br> (line 2 in the file). |
| dates | Column vector containing dates. Dates must be in serial date <br> number format and can specify time of day. |
| data | Column-oriented matrix. Each column is a series. |
| colheads | (Optional) Cell array of column headers (names); first cell must <br> always be the one for the dates column. colheads is written to the <br> file just before the data. |
| desc | (Optional) Description string, which is the first line in the file. |

## Description

stat = fts2ascii(filename, tsobj, exttext) writes the financial time series object tsobj into an ASCII file filename. The data in the file is tab delimited.
stat $=f t s 2 a s c i i(f i l e n a m e, ~ d a t e s, ~ d a t a, ~ c o l h e a d s, ~ d e s c, ~ e x t t e x t) ~$ writes into an ASCII file filename the dates, times, and data contained in the column vector dates and the column-oriented matrix data. The first column in filename contains the dates, followed by times (if specified). Subsequent columns contain the data. The data in the file is tab delimited.
stat indicates whether file creation is successful (1) or not (0).

## Examples

## Use fts2ascii to Write a Time Series to an ASCII File

Create a data file with time information.

```
dates = ['01-Jan-2001';'01-Jan-2001'; '02-Jan-2001'; ...
'02-Jan-2001'; '03-Jan-2001';'03-Jan-2001'];
times = ['11:00';'12:00';'11:00';'12:00';'11:00';'12:00'];
serial_dates_times = [datenum(dates), datenum(times)];
data = round(10*rand (6,2));
```

Use fts2ascii to write the time series to an ascii file.

```
stat = fts2ascii('myfts_file2.txt',serial_dates_times,data, ...
{'dates';'times';'Data1';'Data2'},'My FTS with Time')
stat =
    1
```

Read the data file back and create a financial time series object using ascii2fts.

```
MyFts = ascii2fts('myfts_file2.txt','t',1,2,1)
```

MyFts =
desc: My FTS with Time
freq: Unknown (0)

| dates: (6)' | 'times: | (6) ' | 'Data1: (6) | 'Data2: (6) |
| :---: | :---: | :---: | :---: | :---: |
| 01-Jan-2001' | '11:00' |  | 8] | $3]$ |
| " ' | '12:00' |  | $9]$ | 5] |
| 02-Jan-2001 ${ }^{\prime}$ | '11:00' |  | 1] | $10]$ |
| " ' | '12:00' |  | 9] | $10]$ |
| '03-Jan-2001' | '11:00' |  | 6] | 2] |
|  | '12:00' |  | 1] | 10] |

- "Working with Financial Time Series Objects" on page 12-3

## fts2mat

Convert to matrix

## Syntax

```
tsmat = fts2mat(tsobj)
tsmat = fts2mat(tsobj, datesflag)
tsmat = fts2mat(tsobj, seriesnames)
tsmat = fts2mat(tsobj, datesflag, seriesnames)
```

## Arguments

| tsobj | Financial time series object |
| :--- | :--- |
| datesflag | (Optional) Specifies inclusion of dates vector: <br> datesflag $=0$ (default) excludes dates. <br> datesflag $=1$ includes dates vector. |
| seriesnames | (Optional) Specifies the data series to be included in the matrix. <br> Can be a cell array of strings. |

## Description

tsmat $=$ fts2mat(tsobj) takes the data series in the financial time series object tsobj and puts them into the matrix tsmat as columns. The order of the columns is the same as the order of the data series in the object tsobj.
tsmat = fts2mat(tsobj, datesflag) specifies whether you want the dates vector included. The dates vector is the first column. The dates are represented as serial date numbers. Dates can include time-of-day information.
tsmat $=$ fts2mat(tsobj, seriesnames) extracts the data series named in seriesnames and puts its values into tsmat. The seriesnames argument can be a cell array of strings.
tsmat = fts2mat(tsobj, datesflag, seriesnames) puts into tsmat the specific data series named in seriesnames. The datesflag argument must be specified. If datesflag is set to 1 , the dates vector is included. If you specify an empty matrix ([ ]) for datesflag, the default behavior is adopted.

## ftsbound

Start and end dates

## Syntax

```
datesbound = ftsbound(tsobj)
datesbound = ftsbound(tsobj, dateform)
```

## Arguments

| tsobj | Financial time series object |
| :--- | :--- |
| dateform | dateform is an integer representing the format of a date string. <br> See datestr for a description of these formats. |

## Description

ftsbound returns the start and end dates of a financial time series object. If the object contains time-of-day data, ftsbound also returns the starting time on the first date and the ending time on the last date.
datesbound $=$ ftsbound(tsobj) returns the start and end dates contained in tsobj as serial dates in the column matrix datesbound. The first row in datesbound corresponds to the start date, and the second corresponds to the end date.
datesbound $=$ ftsbound(tsobj, dateform) returns the starting and ending dates contained in the object, tsobj, as date strings in the column matrix, datesbound. The first row in datesbound corresponds to the start date, and the second corresponds to the end date. The dateform argument controls the format of the output dates.

Introduced before R2006a

## ftsinfo

Financial time series object information

## Syntax

```
ftsinfo(tsobj)
infofts = ftsinfo(tsobj)
```

## Arguments

| tsobj | Financial time series object. |
| :--- | :--- |

## Description

ftsinfo(tsobj) displays information about the financial time series object tsobj.
infofts = ftsinfo(tsobj) stores information about the financial time series object tsobj in the structure infofts.
infofts has these fields.

| Field | Contents |
| :--- | :--- |
| version | Financial time series object version. |
| desc | Description of the time series object (tsobj. desc). <br> freq |
|  | Numeric representation of the time series data frequency <br> (tsobj.freq). See freqstr for list of numeric frequencies and <br> what they represent. |
| startdate | Earliest date in the time series. |
| enddate | Latest date in the time series. <br> seriesnames <br> ndata |
|  | Cell array containing the time series data column names. |
|  | Number of data points in the time series. |

| Field | Contents |
| :--- | :--- |
| nseries | Number of columns of time series data. |

## Examples

Convert the supplied file disney. dat into a financial time series object named dis:

```
dis = ascii2fts('disney.dat', 1, 3);
```

Now use ftsinfo to obtain information about dis:

```
ftsinfo(dis)
```

```
FINTS version: 2.0
```

    Description: Walt Disney Company (DIS)
            Frequency: Unknown
        Start date: 29-Mar-1996
            End date: 29-Mar-1999
    Series names: OPEN
                                HIGH
                                LOW
                                CLOSE
                                VOLUME
            \# of data: 782
    \# of series: 5
    Then, executing

```
infodis = ftsinfo(dis)
```

creates the structure infodis containing the values

```
infodis =
```

```
            ver: '2.0'
            desc: 'Walt Disney Company (DIS)'
            freq: 0
    startdate: '29-Mar-1996'
        enddate: '29-Mar-1999'
        seriesnames: {5x1 cell}
            ndata: 782
    nseries: 5
```

## Financial Time Series

Create and manage Financial Time Series objects

## Description

The Financial Time Series app enables you to create and manage Financial Time Series (fints) objects.

## Open the Financial Time Series App

- MATLAB Toolstrip: Open the Apps tab, under Financial Time Series, click the app icon.
- MATLAB command prompt: Enter ftstool.

## Examples

- "Loading Data with the Financial Time Series App" on page 13-7
- "Using the Financial Time Series App" on page 13-13
- "Using the Financial Time Series App with GUIs" on page 13-21

## Programmatic Use

ftstool

## See Also

Functions
ftsgui

## ftstool

Financial Time Series app

## Syntax

ftstool

## Description

ftstool creates and manages Financial Time Series objects. ftstool allows the creation and management of Financial Time Series objects via the Financial Time Series app. ftstool can interface with ftsgui, meaning Line Plots generated with ftstool can be analyzed with ftsgui. However, ftsgui must be running prior to the generation of any Line Plots.

The use of the Financial Time Series app is described in "Getting Started with the Financial Time Series App" on page 13-4.

## Examples

ftstool

Alternatively, on the MATLAB desktop toolstrip, click the Apps tab and in the apps gallery, under Computational Finance, click Financial Time Series. The Financial Time Series app opens. For an overview of the Financial Time Series app, see "What Is the Financial Time Series App?" on page 13-2.

## More About

- "What Is the Financial Time Series App?" on page 13-2

See Also<br>ftsgui<br>Introduced in R2006b

## ftsuniq

Determine uniqueness

## Syntax

uniq = ftsuniq(dates_and_times)
[uniq, dup] = ftsuniq(dates_and_times)

## Arguments

| dates_and_times | A single column vector of serial date numbers. The serial <br> date numbers can include time-of-day information. |
| :--- | :--- |

## Description

uniq $=$ ftsuniq(dates_and_times) returns 1 if the dates and times within the financial time series object are unique and 0 if duplicates exist.
[uniq, dup] = ftsuniq(dates_and_times) additionally returns a structure dup. In the structure

- dup.DT contains the strings of the duplicate dates and times and their locations in the object.
- dup.intIdx contains the integer indices of duplicate dates and times in the object.

## fudisc

Future value of discounted security

## Syntax

FutureVal = fvdisc(Settle, Maturity, Price, Discount, Basis)

## Arguments

| Settle | Settlement date. Enter as serial date number or date string. Settle must be earlier than Maturity. |
| :---: | :---: |
| Maturity | Maturity date. Enter as serial date number or date string. |
| Price | Price (present value) of the security. |
| Discount | Bank discount rate of the security. Enter as decimal fraction. |
| Basis | (Optional) Day-count basis of the instrument. A vector of integers. <br> - $0=$ actual/actual (default) <br> - $1=30 / 360$ (SIA) <br> - 2 = actual/360 <br> - 3 = actual/365 <br> - $4=30 / 360$ (PSA) <br> - $5=30 / 360$ (ISDA) <br> - $6=30 / 360$ (European) <br> - 7 = actual/365 (Japanese) <br> - $8=$ actual/actual (ICMA) <br> - $9=$ actual/360 (ICMA) <br> - $10=$ actual/365 (ICMA) <br> - $11=30 / 360 \mathrm{E}$ (ICMA) <br> - 12 = actual/365 (ISDA) <br> - 13 = BUS/252 |

## For more information, see basis.

## Description

FutureVal = fvdisc(Settle, Maturity, Price, Discount, Basis) finds the amount received at maturity for a fully vested security.

## Examples

## Find the Amount Received at Maturity for a Fully-Vested Security

This example shows how to find the amount received at maturity for a fully-vested security, using the following data.

```
Settle = '02/15/2001';
Maturity = '05/15/2001';
Price = 100;
Discount = 0.0575;
Basis = 2;
FutureVal = fvdisc(Settle, Maturity, Price, Discount, Basis)
```

FutureVal =
101.4420

## fufix

Future value with fixed periodic payments

## Syntax

FutureVal = fvfix(Rate, NumPeriods, Payment, PresentVal, Due)

## Arguments

| Rate | Periodic interest rate, as a decimal fraction. |
| :--- | :--- |
| NumPeriods | Number of periods. |
| Payment | Periodic payment. |
| PresentVal | (Optional) Initial value. Default $=0$. |
| Due | (Optional) When payments are due or made: $0=$ end of period <br> (default), or $1=$ beginning of period. |

## Description

FutureVal = fvfix(Rate, NumPeriods, Payment, PresentVal, Due) returns the future value of a series of equal payments.

## Examples

## Return the Future Value of a Series of Equal Payments

This example shows how to compute the future value of a series of equal payments using a savings account that has a starting balance of $\$ 1500$. $\$ 200$ is added at the end of each month for 10 years and the account pays $9 \%$ interest compounded monthly.

FutureVal $=$ fvfix(0.09/12, 12*10, 200, 1500, 0)

## $4.2380 \mathrm{e}+04$

- "Analyzing and Computing Cash Flows" on page 2-17

## See Also

## Introduced before R2006a

## fuvar

Future value of varying cash flow

## Syntax

FutureVal = fvvar(CashFlow, Rate, CFDates)

## Arguments

| CashFlow | A vector of varying cash flows. Include the initial investment as the <br> initial cash flow value (a negative number). |
| :--- | :--- |
| Rate | Periodic interest rate. Enter as a decimal fraction. |
| CFDates | (Optional) For irregular (nonperiodic) cash flows, a vector of dates <br> on which the cash flows occur. Enter dates as serial date numbers <br> or date strings. Default assumes CashFlow contains regular <br> (periodic) cash flows. |

## Description

FutureVal = fvvar(CashFlow, Rate, CFDates) returns the future value of a varying cash flow.

## Examples

This cash flow represents the yearly income from an initial investment of $\$ 10,000$. The annual interest rate is $8 \%$.

| Year 1 | $\$ 2000$ |
| :--- | :--- |
| Year 2 | $\$ 1500$ |
| Year 3 | $\$ 3000$ |

| Year 4 | $\$ 3800$ |
| :--- | :--- |
| Year 5 | $\$ 5000$ |

For the future value of this regular (periodic) cash flow
FutureVal = fvvar([-10000 2000150030003800 5000], 0.08)
returns
FutureVal =

### 2520.47

An investment of $\$ 10,000$ returns this irregular cash flow. The original investment and its date are included. The periodic interest rate is $9 \%$.

| Cash Flow | Dates |
| :--- | :--- |
| $(\$ 10000)$ | January 12, 2000 |
| $\$ 2500$ | February 14, 2001 |
| $\$ 2000$ | March 3, 2001 |
| $\$ 3000$ | June 14, 2001 |
| $\$ 4000$ | December 1, 2001 |

To calculate the future value of this irregular (nonperiodic) cash flow
CashFlow = [-10000, 2500, 2000, 3000, 4000];
CFDates $=[$ '01/12/2000'
'02/14/2001'
'03/03/2001'
'06/14/2001'
'12/01/2001'];
FutureVal = fvvar(CashFlow, 0.09, CFDates)
returns
FutureVal =
170.66

See Also<br>fvfix | irr | payuni | pvfix | pvvar<br>Introduced before R2006a

## fwd2zero

Zero curve given forward curve

## Syntax

[ZeroRates, CurveDates] = fwd2zero(ForwardRates, CurveDates, Settle)
[ZeroRates, CurveDates] = fwd2zero(ForwardRates, CurveDates, Settle, Name, Value)

## Compatibility

In R2015b, the specification of optional input arguments has changed. While the previous ordered inputs syntax is still supported, it may no longer be supported in a future release. Use the new optional name-value pair inputs: InputCompounding, InputBasis, OutputCompounding, and OutputBasis.

## Input Arguments

| ForwardRates | A number of bonds (NUMBONDS)-by-1 vector of annualized implied <br> forward rates, as decimal fractions. In aggregate, the rates in <br> ForwardRates constitute an implied forward curve for the <br> investment horizon represented by CurveDates. The first element <br> pertains to forward rates from the settlement date to the first curve <br> date. |
| :--- | :--- |
| CurveDates | A NUMBONDS-by-1 vector of maturity dates (as serial date numbers) <br> that correspond to the forward rates. |
| Settle | A serial date number or date string that is the common settlement <br> date for the forward rates. |

## Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single
quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, . . ., NameN, ValueN.
Example: [ZeroRates,CurveDates] =
fwd2zero(ForwardRates, CurveDates,Settle, 'InputCompounding' , 3, 'InputBasis' ,5, '0

## ' InputCompounding ' - Compounding frequency of input forward rates

if InputCompounding is not specified, it is assigned the value specified for OutputCompounding. If neither InputCompounding nor OutputCompounding are specified, the default is 2 (semiannual) for both. (default) | scalar

Compounding frequency of the input forward rates, specified as a scalar with allowed values:

- 0 - Simple interest (no compounding)
- 1 - Annual compounding
- 2 - Semiannual compounding (default)
- 3-Compounding three times per year
- 4 - Quarterly compounding
- 6 - Bimonthly compounding
- 12 - Monthly compounding
- 365 - Daily compounding
-     - 1 - Continuous compounding

Data Types: single | double

## 'InputBasis ' - Day count basis of input forward rates

if InputBasis is not specified, it is assigned the value specified for OutputBasis. If neither InputBasis nor OutputBasis are specified, the default is 0 (actual/actual) for both. (default) | scalar

Day count basis of input forward rates, specified as a scalar with possible values:

- $0=$ actual/actual
- $1=30 / 360$ (SIA)
- 2 = actual/360
- $3=$ actual $/ 365$
- $4=30 / 360$ (PSA)
- $5=30 / 360$ (ISDA)
- $6=30 / 360$ (European)
- $7=$ actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- $10=$ actual/365 (ICMA)
- $11=30 / 360 \mathrm{E}$ (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

Data Types: single | double

## ' OutputCompounding' - Compounding frequency of output zero rates

if OutputCompounding is not specified, it is assigned the value specified for InputCompounding. If neither InputCompounding nor OutputCompounding are specified, the default is 2 (semiannual) for both. (default) | scalar

Compounding frequency of the output zero rates, specified as a scalar with allowed values:

- 0 - Simple interest (no compounding)
- 1 -Annual compounding
- 2 -Semiannual compounding (default)
- 3 - Compounding three times per year
- 4 - Quarterly compounding
- 6 - Bimonthly compounding
- 12 - Monthly compounding
- 365 - Daily compounding
-     - 1 - Continuous compounding

Data Types: single | double

## 'OutputBasis' - Day count basis of output zero rates

if OutputBasis is not specified, it is assigned the value specified for InputBasis. If neither InputBasis nor OutputBasis are specified, the default is 0 (actual/actual) for both. (default) | scalar

Day count basis of output zero rates, specified as a scalar with possible values:

- $0=$ actual/actual
- $1=30 / 360$ (SIA)
- 2 = actual/360
- 3 = actual/365
- $4=30 / 360$ (PSA)
- $5=30 / 360$ (ISDA)
- $6=30 / 360$ (European)
- $7=$ actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- $10=\mathrm{actual} / 365$ (ICMA)
- $11=30 / 360 \mathrm{E}$ (ICMA)
- $12=$ actual/365 (ISDA)
- 13 = BUS/252

## Data Types: single | double

## Description

[ZeroRates, CurveDates] = fwd2zero(ForwardRates, CurveDates, Settle) returns a zero curve given an implied forward rate curve and its maturity dates.
[ZeroRates, CurveDates] = fwd2zero(ForwardRates, CurveDates, Settle, Name, Value) returns a zero curve given an implied forward rate curve and its maturity dates using optional name-value arguments for InputCompounding, InputBasis, OutputCompounding, and OutputBasis.

| ZeroRates | A NUMBONDS-by-1 vector of decimal fractions. In aggregate, the <br> rates in ZeroRates constitute a zero curve for the investment <br> horizon represented by CurveDates. |
| :--- | :--- |
| CurveDates | A NUMBONDS-by-1 vector of maturity dates (as serial date numbers) <br> that correspond to the zero rates in ZeroRates. This vector is the <br> same as the input vector CurveDates, but is sorted by ascending <br> maturity. |

## Examples

## Compute the Zero Curve Given the Forward Curve

This example shows how to compute the zero curve, given an implied forward rate curve over a set of maturity dates, a settlement date, and a compounding rate.

```
ForwardRates = [0.0469
    0.0519
    0.0549
    0.0535
    0.0558
    0.0508
    0.0560
    0.0545
        0.0615
        0.0486];
CurveDates = [datenum('06-Nov-2000')
    datenum('11-Dec-2000')
    datenum('15-Jan-2001')
    datenum('05-Feb-2001')
    datenum('04-Mar-2001')
    datenum('02-Apr-2001')
    datenum('30-Apr-2001')
    datenum('25-Jun-2001')
    datenum('04-Sep-2001')
    datenum('12-Nov-2001')];
Settle = datenum('03-Nov-2000');
InputCompounding = 1;
InputBasis = 2;
OutputCompounding = 1;
OutputBasis = 2;
```

Execute the function fwd2zero to return the zero-rate curve ZeroRates at the maturity dates CurveDates.
[ZeroRates, CurveDates] = fwd2zero(ForwardRates, CurveDates,...
Settle,'InputCompounding',1,'InputBasis',2,'OutputCompounding',1,'OutputBasis',2)
ZeroRates =

## gbm

Create GBM model

## Syntax

GBM $=$ gbm(Return, Sigma)
GBM $=$ gbm(Return, Sigma, 'Name1', Value1, 'Name2', Value2, ...)

## Class

GBM

## Description

This function creates and displays geometric Brownian motion (GBM) models, which derive from the CEV (constant elasticity of variance) class. Use GBM models to simulate sample paths of NVARS state variables driven by NBROWNS Brownian motion sources of risk over NPERIODS consecutive observation periods, approximating continuous-time GBM stochastic processes.

This function allows simulation of vector-valued GBM processes of the form:

$$
d X_{t}=\mu(t) X_{t} d t+D\left(t, X_{t}\right) V(t) d W_{t}
$$

where:

- $X_{t}$ is an NVARS-by- 1 state vector of process variables.
- $\mu$ is an NVARS-by-NVARS generalized expected instantaneous rate of return matrix.
- $D$ is an NVARS-by-NVARS diagonal matrix, where each element along the main diagonal is the corresponding element of the state vector $X_{t}$.
- $V$ is an NVARS-by-NBROWNS instantaneous volatility rate matrix.
- $d W_{t}$ is an NBROWNS-by- 1 Brownian motion vector.

## Input Arguments

Specify required input parameters as one of the following types:

- A MATLAB array. Specifying an array indicates a static (non-time-varying) parametric specification. This array fully captures all implementation details, which are clearly associated with a parametric form.
- A MATLAB function. Specifying a function provides indirect support for virtually any static, dynamic, linear, or nonlinear model. This parameter is supported via an interface, because all implementation details are hidden and fully encapsulated by the function.

Note: You can specify combinations of array and function input parameters as needed.
Moreover, a parameter is identified as a deterministic function of time if the function accepts a scalar time $t$ as its only input argument. Otherwise, a parameter is assumed to be a function of time $t$ and state $X(t)$ and is invoked with both input arguments.

The required input parameters are:

| Return | Return represents the parameter $\mu$. If you specify Return as an array <br> and it must be an NVARS-by-NVARS matrix representing the expected <br> (mean) instantaneous rate of return. As a deterministic function of <br> time, when Return is called with a real-valued scalar time t as its only <br> input, Return must produce an NVARS-by-NVARS matrix. If you specify <br> Return as a function of time and state, it must return an NVARS- <br> by-NVARS matrix when invoked with two inputs: <br> - A real-valued scalar observation time $t$. <br> $-\quad$ An NVARS-by-1 state vector $X_{t}$. |
| :--- | :--- |
| Sigma | Sigma represents the parameter $V$. If you specify Sigma as an array, <br> it must be an NVARS-by-NBROWNS matrix of instantaneous volatility <br> rates or as a deterministic function of time. In this case, each row <br> of Sigma corresponds to a particular state variable. Each column <br> corresponds to a particular Brownian source of uncertainty, and |

associates the magnitude of the exposure of state variables with
sources of uncertainty. As a deterministic function of time, when
Sigma is called with a real-valued scalar time t as its only input,
Sigma must produce an NVARS-by-NBROWNS matrix. If you specify
Sigma as a function of time and state, it must return an NVARS-
by-NBROWNS matrix of volatility rates when invoked with two inputs:

- A real-valued scalar observation time $t$.
- An NVARS-by-1 state vector $X_{t}$.

| Although the gbm function enforces no restrictions on the sign of Sigma |
| :--- |
| volatilities, they are usually specified as positive values. |

## Optional Input Arguments

Specify optional input arguments as variable-length lists of matching parameter name/ value pairs: 'Name1', Value1, 'Name2', Value2, ... and so on. The following rules apply when specifying parameter-name pairs:

- Specify the parameter name as a character string, followed by its corresponding parameter value.
- You can specify parameter name/value pairs in any order.
- Parameter names are case insensitive.
- You can specify unambiguous partial string matches.

Valid parameter names are:

| StartTime | Scalar starting time of the first observation, applied to all state <br> variables. If you do not specify a value for StartTime, the default <br> is 0. |
| :--- | :--- |
| StartState | Scalar, NVARS-by-1 column vector, or NVARS-by-NTRIALS matrix of <br> initial values of the state variables. <br> If StartState is a scalar, gbm applies the same initial value to all <br> state variables on all trials. <br> If StartState is a column vector, gbm applies a unique initial <br> value to each state variable on all trials. |

|  | If StartState is a matrix, gbm applies a unique initial value to <br> each state variable on each trial. <br> If you do not specify a value for StartState, all variables start at <br> 1. |
| :--- | :--- |
| Correlation | Correlation between Gaussian random variates drawn to <br> generate the Brownian motion vector (Wiener processes). Specify <br> Correlation as an NBROWNS-by-NBROWNS positive semidefinite <br> matrix, or as a deterministic function C( $t$ ) that accepts the current <br> time $t$ and returns an NBROWNS-by-NBROWNS positive semidefinite <br> correlation matrix. |
| A Correlation matrix represents a static condition. |  |
| As a deterministic function of time, Correlation allows you to |  |
| specify a dynamic correlation structure. |  |

## Output Arguments

| GBM | Geometric Brownian motion model with the following displayed <br> parameters: |
| :--- | :--- |
|  | -StartTime: Initial observation time <br> - <br> - <br>  <br> CtartState: Initial state at StartTime <br> as a function of time function for the Correlation input, callable <br> Drift: Composite drift-rate function, callable as a function of time <br> and state <br> Diffusion: Composite diffusion-rate function, callable as a function <br> of time and state |

| •Simulation: A simulation function or method <br> - <br> Return: Access function for the input argument Return, callable as a <br> function of time and state |
| :--- | :--- |
| Sigma: Access function for the input argument Sigma, callable as a <br> function of time and state |

## Examples

## More About

## Algorithms

When you specify the required input parameters as arrays, they are associated with a specific parametric form. By contrast, when you specify either required input parameter as a function, you can customize virtually any specification.

Accessing the output parameters with no inputs simply returns the original input specification. Thus, when you invoke these parameters with no inputs, they behave like simple properties and allow you to test the data type (double vs. function, or equivalently, static vs. dynamic) of the original input specification. This is useful for validating and designing methods.

When you invoke these parameters with inputs, they behave like functions, giving the impression of dynamic behavior. The parameters accept the observation time $t$ and a state vector $X_{t}$, and return an array of appropriate dimension. Even if you originally specified an input as an array, gbm treats it as a static function of time and state, by that means guaranteeing that all parameters are accessible by the same interface.

## geom2arith

Geometric to arithmetic moments of asset returns

## Syntax

[ma, Ca] = geom2arith(mg, Cg)
[ma, Ca] = geom2arith(mg, Cg, t)

## Arguments

| mg | Continuously compounded or "geometric" mean of asset returns <br> (positive n-vector). |
| :--- | :--- |
| Cg | Continuously compounded or "geometric" covariance of asset <br> returns, a n-by-n symmetric, positive-semidefinite matrix. |
| t | (Optional) Target period of arithmetic moments in terms of <br> periodicity of geometric moments with default value 1 (positive <br> scalar). |

## Description

geom2arith transforms moments associated with a continuously compounded geometric Brownian motion into equivalent moments associated with a simple Brownian motion with a possible change in periodicity.
[ma, Ca] = geom2arith(mg, Cg, t) returns ma, arithmetic mean of asset returns over the target period ( n -vector), andCa, which is an arithmetric covariance of asset returns over the target period (n-by-n matrix).

Geometric returns over period $t_{G}$ are modeled as multivariate lognormal random variables with moments

$$
E[\mathrm{Y}]=1+\mathrm{m}_{G}
$$

and

$$
\operatorname{cov}(\mathrm{Y})=\mathrm{C}_{G}
$$

Arithmetic returns over period $t_{A}$ are modeled as multivariate normal random variables with moments

$$
\begin{aligned}
& E[\mathrm{X}]=\mathrm{m}_{A} \\
& \operatorname{cov}(\mathrm{X})=\mathrm{C}_{A}
\end{aligned}
$$

Given $t=t_{A} / t_{G}$, the transformation from geometric to arithmetic moments is

$$
\begin{aligned}
& \mathrm{C}_{A_{i j}}=t \log \left(1+\frac{\mathrm{C}_{G_{i j}}}{\left(1+\mathrm{m}_{G_{i}}\right)\left(1+\mathrm{m}_{G_{j}}\right)}\right) \\
& \mathrm{m}_{A_{i}}=t \log \left(1+\mathrm{m}_{G_{i}}\right)-\frac{1}{2} \mathrm{C}_{A_{i i}}
\end{aligned}
$$

For $i, j=1, \ldots, n$.

Note: If $t=1$, then $\mathbf{X}=\log (\mathbf{Y})$.

This function requires that the input mean must satisfy $1+\mathrm{mg}>0$ and that the input covariance Cg must be a symmetric, positive, semidefinite matrix.

The functions geom2arith and arith2geom are complementary so that, given $\mathrm{m}, \mathrm{C}$, and $t$, the sequence
[ma, Ca] = geom2arith(m, C, t);
[mg, Cg] = arith2geom(ma, Ca, 1/t);
yields $\mathrm{mg}=\mathrm{m}$ and $\mathrm{Cg}=\mathrm{C}$.

## Examples

Example 1. Given geometric mean $m$ and covariance $C$ of monthly total returns, obtain annual arithmetic mean ma and covariance Ca. In this case, the output period ( 1 year) is 12 times the input period ( 1 month) so that $t=12$ with
[ma, Ca] = geom2arith(m, C, 12);
Example 2. Given annual geometric mean $m$ and covariance $C$ of asset returns, obtain monthly arithmetic mean ma and covariance Ca. In this case, the output period (1 month) is $1 / 12$ times the input period ( 1 year) so that $t=1 / 12$ with

```
[ma, Ca] = geom2arith(m, C, 1/12);
```

Example 3. Given geometric means m and standard deviations s of daily total returns (derived from 260 business days per year), obtain annualized arithmetic mean ma and standard deviations sa with

```
[ma, Ca] = geom2arith(m, diag(s .^2), 260);
sa = sqrt(diag(Ca));
```

Example 4. Given geometric mean $m$ and covariance $C$ of monthly total returns, obtain quarterly arithmetic return moments. In this case, the output is 3 of the input periods so that $\mathrm{t}=3$ with [ma, Ca] = geom2arith(m, C, 3);

Example 5. Given geometric mean $m$ and covariance $C$ of 1254 observations of daily total returns over a 5 -year period, obtain annualized arithmetic return moments. Since the periodicity of the geometric data is based on 1254 observations for a 5 -year period, a 1 year period for arithmetic returns implies a target period of $t=1254 / 5$ so that
[ma, Ca] = geom2arith(m, C, 1254/5);

## getAssetMoments

Obtain mean and covariance of asset returns from Portfolio object
Use the getAssetMoments function with a Portfolio object to obtain mean and covariance of asset returns.

For details on the workflow, see "Portfolio Object Workflow" on page 4-17.

## Syntax

[AssetMean,AssetCovar] = getAssetMoments(obj)

## Description

[AssetMean,AssetCovar] = getAssetMoments(obj) obtains mean and covariance of asset returns for a Portfolio object.

## Examples

## Obtain Asset Moment Properties for a Porffolio Object

Given the mean and covariance of asset returns in the variables $m$ and $C$, the asset moment properties can be set and then obtained using the getAssetMoments function:

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
    0.00408 0.0289 0.0204 0.0119;
    0.00192 0.0204 0.0576 0.0336;
    0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;
p = Portfolio;
p = setAssetMoments(p, m, C);
[assetmean, assetcovar] = getAssetMoments(p)
```

- "Portfolio Optimization Examples" on page 4-114

## Input Arguments

## obj - Object for portfolio

object
Object for portfolio, specified using a Portfolio object. For more information on creating a portfolio object, see

- Using Portfolio Objects

## Output Arguments

## AssetMean - Mean of asset returns

vector
Mean of asset returns, returned as a vector.

## AssetCovar - Covariance of asset returns

matrix
Covariance of asset returns, returned as a matrix.

## More About

## Tips

You can also use dot notation to obtain the mean and covariance of asset returns from a Portfolio object:
[AssetMean, AssetCovar] = obj.getAssetMoments;

- "Portfolio Optimization Theory" on page 4-2
- Getting Started with Portfolio Optimization (13 min 31 sec )

## Obtain Values for Lower and Upper Bounds for a PorffolioMAD Object

```
Given a PortfolioMAD object p with the default constraints set, obtain the values for LowerBound and UpperBound.
p = PortfolioMAD;
p = setDefaultConstraints(p, 5);
[LowerBound, UpperBound] = getBounds(p)

\section*{UpperBound =}

\section*{getBudget}

Obtain budget constraint bounds from portfolio object
Use the getBudget function with a Portfolio, PortfolioCVaR, or PortfolioMAD object to obtain budget constraint bounds from portfolio objects.

For details on the respective workflows when using these different objects, see "Portfolio Object Workflow" on page 4-17, "PortfolioCVaR Object Workflow" on page 5-16, and "PortfolioMAD Object Workflow" on page 6-16.

\section*{Syntax}
[LowerBudget,UpperBudget] = getBudget(obj)

\section*{Description}
[LowerBudget,UpperBudget] = getBudget(obj) obtains budget constraint bounds from portfolio objects.

\section*{Examples}

\section*{Obtain Values for Lower and Upper Budgets for a Porffolio Object}

Given portfolio \(p\) with the default constraints set, obtain the values for LowerBudget and UpperBudget.
p = Portfolio;
\(\mathrm{p}=\) setDefaultConstraints(p, 5);

\section*{getEquality}

Obtain equality constraint arrays from portfolio object
Use the getEquality function with a Portfolio, PortfolioCVaR, or PortfolioMAD object to obtain equality constraint arrays from portfolio objects.

For details on the respective workflows when using these different objects, see "Portfolio Object Workflow" on page 4-17, "PortfolioCVaR Object Workflow" on page 5-16, and "PortfolioMAD Object Workflow" on page 6-16.

\section*{Syntax}
[AEquality,bEquality] = getEquality(obj)

\section*{Description}
[AEquality,bEquality] = getEquality(obj) obtains equality constraint arrays from portfolio objects.

\section*{Examples}

\section*{Obtain Equality Constraints for a Portfolio Object}

Suppose you have a portfolio of five assets and you want to ensure that the first three assets are exactly \(50 \%\) of your portfolio. Given a Portfolio object p, set the linear equality constraints and obtain the values for AEquality and bEquality:
\(A=\left[\begin{array}{lllll}1 & 1 & 1 & 0 & 0\end{array}\right] ;\)
b \(=0.5\);
p = Portfolio;
\(p=\operatorname{setEquality}(p, A, b)\);
[AEquality, bEquality] = getEquality(p)

AEquality =
```

    1
    bEquality =
0.5000

```

\section*{Obtain Equality Constraints for a PorffolioCVaR Object}

Suppose you have a portfolio of five assets and you want to ensure that the first three assets are \(50 \%\) of your portfolio. Given a PortfolioCVaR object p, set the linear equality constraints and obtain the values for AEquality and bEquality:
```

A = [ 1 1 1 0 0 ];
b = 0.5;
p = PortfolioCVaR;
p = setEquality(p, A, b);
[AEquality, bEquality] = getEquality(p)
AEquality =
1 1 1 1 1 0
bEquality =
0.5000

```

\section*{Obtain Equality Contraintsfor a PortfolioMAD Object}

Suppose you have a portfolio of five assets and you want to ensure that the first three assets are \(50 \%\) of your portfolio. Given a PortfolioMAD object \(p\), set the linear equality constraints and obtain the values for AEquality and bEquality:
\(A=\left[\begin{array}{ccccc}1 & 1 & 1 & 0 & 0\end{array}\right] ;\)
b \(=0.5\);
p = PortfolioMAD;
\(p=\) setEquality (p, A, b);
[AEquality, bEquality] = getEquality(p)
```

\section*{getScenarios}

Obtain scenarios from portfolio object
Use the getScenarios function with a PortfolioCVaR or PortfolioMAD objects to obtain scenarios.

For details on the workflows, see "PortfolioCVaR Object Workflow" on page 5-16, and "PortfolioMAD Object Workflow" on page 6-16.

\section*{Syntax}
```

Y = getScenarios(obj)

```

\section*{Description}

Y = getScenarios(obj) obtains scenarios for PortfolioCVaR or PortfolioMAD objects.

\section*{Examples}

\section*{Obtain Scenarios for a CVaR Portfolio Object}

For a given PortfolioCVaR object p, display the defined scenarios.
```

m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
0.00408 0.0289 0.0204 0.0119;
0.00192 0.0204 0.0576 0.0336;
0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;
rng(11);
rng(11);
AssetScenarios = mvnrnd(m, C, 10);

```
```

p = PortfolioCVaR;
p = setScenarios(p, AssetScenarios);
p = setDefaultConstraints(p);
p = setProbabilityLevel(p, 0.95);
Y = getScenarios(p)
Y =

| -0.0056 | 0.0440 | 0.1186 | 0.0488 |
| ---: | ---: | ---: | ---: |
| -0.0368 | -0.0753 | 0.0087 | 0.1124 |

\section*{geffield}

Content of specific field

\section*{Syntax}
```

fieldval = getfield(tsobj, field)

```
fieldval = getfield(tsobj, field, \{dates\})

\section*{Arguments}
\begin{tabular}{|l|l|}
\hline tsobj & Financial time series object. \\
\hline field & Field name within tsobj. \\
\hline dates & \begin{tabular}{l} 
Date range. Dates can be expanded to include time-of-day \\
information.
\end{tabular} \\
\hline
\end{tabular}

\section*{Description}
getfield treats the contents of a financial times series object tsobj as fields in a structure.
fieldval = getfield(tsobj, field) returns the contents of the specified field. This is equivalent to the syntax fieldval = tsobj field.
fieldval = getfield(tsobj, field, \{dates\}) returns the contents of the specified field for the specified dates. dates can be individual cells of date strings or a cell of a date string range using the : : operator, such as '03/01/99::03/31/99'.

\section*{Examples}

Create a financial time series object containing both date and time-of-day information:
```

dates = ['01-Jan-2001';'01-Jan-2001'; '02-Jan-2001'; ...
'02-Jan-2001'; '03-Jan-2001';'03-Jan-2001'];
times = ['11:00';'12:00';'11:00';'12:00';'11:00';'12:00'];

```
```

dates_times = cellstr([dates, repmat(' ',size(dates,1),1),···.
times]);
AnFts = fints(dates_times,[(1:4)'; nan; 6],{'Data1'},1,···.
'Yet Another Financial Time Series')
AnFts =
desc: Yet Another Financial Time Series
freq: Daily (1)

| 'dates: (6)' | 'times: | $(6)^{\prime}$ | 'Data1: (6)' |
| :---: | :---: | :---: | :---: |
| '01-Jan-2001' | '11:00' |  | $1]$ |
| ' " ' | '12:00' |  | $2]$ |
| '02-Jan-2001' | '11:00' |  | 3 ] |
| ' " ' | '12:00' |  | $4]$ |
| '03-Jan-2001' | '11:00' |  | NaN ] |
| ' ${ }^{\text {a }}$ | '12:00' |  | $6]$ |

```

Example 1. Get the contents of the times field in AnFts:
```

F = datestr(getfield(AnFts, 'times'))
F =

```
11:00 AM
12:00 PM
11:00 AM
12:00 PM
11:00 AM
12:00 PM

Example 2. Extract the contents of specific data fields within AnFts:
```

FF = getfield(AnFts,'Data1',...
'01-Jan-2001 12:00::02-Jan-2001 12:00')
FF =

```
    2
    3
    4

\section*{getInequality}

Obtain inequality constraint arrays from portfolio object
Use the getInequality function with a Portfolio, PortfolioCVaR, or PortfolioMAD object to obtain inequality constraint arrays from portfolio objects.

For details on the respective workflows when using these different objects, see "Portfolio Object Workflow" on page 4-17, "PortfolioCVaR Object Workflow" on page 5-16, and "PortfolioMAD Object Workflow" on page 6-16.

\section*{Syntax}
[AInequality,bInequality] = getInequality(obj)

\section*{Description}
[AInequality,bInequality] = getInequality(obj) obtains equality constraint arrays from portfolio objects.

\section*{Examples}

\section*{Obtain Inequality Constraints for a Portfolio Object}

Suppose you have a portfolio of five assets and you want to ensure that the first three assets are no more than \(50 \%\) of your portfolio. Given a Portfolio object p, set the linear inequality constraints and then obtain values for AInequality and bInequality.
\(A=\left[\begin{array}{lllll}1 & 1 & 1 & 0 & 0\end{array}\right] ;\)
b \(=0.5\);
p = Portfolio;
\(\mathrm{p}=\) setInequality \((\mathrm{p}, \mathrm{A}, \mathrm{b})\);
[AInequality, bInequality] = getInequality(p)

AInequality =
```

    1 1
    bInequality =
0.5000

```

\section*{Obtain Inequality Constraints for a PortfolioCVaR Object}

Suppose you have a portfolio of five assets and you want to ensure that the first three assets constitute at most \(50 \%\) of your portfolio. Given a PortfolioCVaR object p , set the linear inequality constraints and then obtain values for AInequality and bInequality.
```

A = [ [1 1 1 1 0 0 0 ];

```
\(b=0.5\);
p = PortfolioCVaR;
\(p=\operatorname{setInequality(p,~A,~b);~}\)
[AInequality, bInequality] = getInequality(p)

\section*{AInequality =}
bInequality =
0.5000

\section*{Obtain Inequality Constraints for a PortfolioMAD Object}

Suppose you have a portfolio of five assets and you want to ensure that the first three assets constitute at most \(50 \%\) of your portfolio. Given a PortfolioMAD object \(p\), set the linear inequality constraints and then obtain values for AInequality and bInequality.
\(A=\left[\begin{array}{ccccc}1 & 1 & 1 & 0 & 0\end{array}\right] ;\)
b \(=0.5\);
p = PortfolioMAD;
\(p=\) setInequality ( \(\mathrm{p}, \mathrm{A}, \mathrm{b}\) );
[AInequality, bInequality] = getInequality(p)

\section*{Input Arguments}

\section*{obj - Object for porifolio}
object
Object for portfolio, specified using Portfolio, PortfolioCVaR, or PortfolioMAD object. For more information on creating a portfolio object, see
- Using Portfolio Objects
- Using PortfolioCVaR Objects
- Using PortfolioMAD Objects

\section*{Output Arguments}

\section*{BuyTurnover - Turnover constraint on purchases}
scalar
Turnover constraint on purchases, returned as a scalar for a Portfolio, PortfolioCVaR, or PortfolioMAD input object (obj).

\section*{SellTurnover - Turnover constraint on sales \\ scalar}

Turnover constraint on sales, returned as a scalar for a Portfolio, PortfolioCVaR, or PortfolioMAD input object (obj).

\section*{More About}

\section*{One-way Turnover Constraint}

One-way turnover constraints ensure that estimated optimal portfolios differ from an initial portfolio by no more than specified amounts according to whether the differences are purchases or sales.

The constraints take the form
\[
\begin{aligned}
& 1^{T} \max \left\{0, x-x_{0}\right\} \leq \tau_{B} \\
& 1^{T} \max \left\{0, x_{0}-x\right\} \leq \tau_{S}
\end{aligned}
\]
with
- x — The portfolio (NumAssets vector)
- \(\mathrm{x}_{0}\) - Initial portfolio (NumAssets vector)
- \(\tau_{B}\) - Upper-bound for turnover constraint on purchases (scalar)
- \(\tau_{S}\) - Upper-bound for turnover constraint on sales (scalar)

Specify one-way turnover constraints using the following properties in a supported portfolio object: BuyTurnover for \(\tau_{B}\), SellTurnover for \(\tau_{S}\), and InitPort for \(\mathrm{x}_{0}\).

Note: The average turnover constraint (which is set using setTurnover) is not just the combination of the one-way turnover constraints with the same value for the constraint.

\section*{Tips}

You can also use dot notation to get the one-way turnover constraint for portfolio objects.
[BuyTurnover,SellTurnover] = obj.getOneWayTurnover

\section*{getnameidx}

Find name in list

\section*{Syntax}
```

nameidx = getnameidx(list, name)

```

\section*{Arguments}
\begin{tabular}{|l|l|}
\hline list & Cell array of name strings. \\
\hline name & String or cell array of name strings. \\
\hline
\end{tabular}

\section*{Description}
nameidx = getnameidx(list, name) finds the occurrence of a name or set of names in a list. It returns an index (order number) indicating where the specified names are located within the list. If name is not found, nameidx returns 0 .

If name is a cell array of names, getnameidx returns a vector containing the indices (order number) of the name strings within list. If none of the names in the name cell array is in list, it returns zero. If some of the names in name are not found, the indices for these names are zeros.
getnameidx finds only the first occurrence of the name in the list of names. This function is meant to be used on a list of unique names (strings) only. It does not find multiple occurrences of a name or a list of names within list.

\section*{Examples}

Given
```

poultry = {'duck', 'chicken'}
animals = {'duck', 'cow', 'sheep', 'horse', 'chicken'}
nameidx = getnameidx(animals, poultry)

```

\section*{ans =}

15
```

Given
poultry = {'duck', 'goose', 'chicken'}
animals = {'duck', 'cow', 'sheep', 'horse', 'chicken'}
nameidx = getnameidx(animals, poultry)
ans =
1 0 5

```

\section*{heston}

\section*{Create Heston model}

\section*{Syntax}
```

heston = heston(Return, Speed, Level, Volatility)
heston = heston(Return, Speed, Level, Volatility, 'Name1', Value1,
'Name2', Value2, ...)

```

\section*{Class}

\section*{Heston}

\section*{Description}

This constructor creates and displays heston objects, which derive from the SDEDDO (SDE from drift and diffusion objects) class. Use heston objects to simulate sample paths of two state variables. Each state variable is driven by a single Brownian motion source of risk over NPERIODS consecutive observation periods, approximating continuoustime stochastic volatility processes.

Heston models are bivariate composite models. Each Heston model consists of two coupled univariate models:
- A geometric Brownian motion (GBM) model with a stochastic volatility function.
\[
d X_{1 t}=B(t) X_{1 t} d t+\sqrt{X_{2 t}} X_{1 t} d W_{1 t}
\]

This model usually corresponds to a price process whose volatility (variance rate) is governed by the second univariate model.
- A Cox-Ingersoll-Ross (CIR) square root diffusion model.
\[
d X_{2 t}=S(t)\left[L(t)-X_{2 t}\right] d t+V(t) \sqrt{X_{2 t}} d W_{2 t}
\]

This model describes the evolution of the variance rate of the coupled GBM price process.

\section*{Input Arguments}

Specify required input parameters as one of the following types:
- A MATLAB array. Specifying an array indicates a static (non-time-varying) parametric specification. This array fully captures all implementation details, which are clearly associated with a parametric form.
- A MATLAB function. Specifying a function provides indirect support for virtually any static, dynamic, linear, or nonlinear model. This parameter is supported via an interface, because all implementation details are hidden and fully encapsulated by the function.

Note: You can specify combinations of array and function input parameters as needed.
Moreover, a parameter is identified as a deterministic function of time if the function accepts a scalar time \(t\) as its only input argument. Otherwise, a parameter is assumed to be a function of time \(t\) and state \(X(t)\) and is invoked with both input arguments.

The required input parameters are:
\begin{tabular}{|l|l|}
\hline Return & \begin{tabular}{l} 
If you specify Return as a scalar, it represents the expected (mean) \\
instantaneous rate of return of the univariate GBM price model. As \\
a deterministic function of time, when Return is called with a real- \\
valued scalar time t as its only input, Return must produce a scalar. \\
If you specify it as a function of time and state, Return calculates the \\
instantaneous rate of return of the GBM price model. This function \\
generates a scalar when invoked with two inputs:
\end{tabular} \\
& \begin{tabular}{l} 
- A real-valued scalar observation time \(t\). \\
\(-\quad\) A 2-by-1 bivariate state vector \(X_{t}\).
\end{tabular} \\
\hline Speed & \begin{tabular}{l} 
If you specify Speed as a scalar, it represents the mean-reversion speed \\
of the univariate CIR stochastic variance model (the speed at which the \\
CIR variance reverts to its long-run average level). As a deterministic
\end{tabular}
\end{tabular}
\begin{tabular}{|l|l|} 
& \begin{tabular}{l} 
function of time, when Speed is called with a real-valued scalar time \\
t as its only input, Speed must produce a scalar. If you specify it as a \\
function time and state, Speed calculates the speed of mean reversion of \\
the CIR variance model. This function generates a scalar when invoked \\
with two inputs:
\end{tabular} \\
\hline - A real-valued scalar observation time \(t\). \\
\(-\quad\) A 2-by-1 state vector \(X_{t}\).
\end{tabular}

Note: Although the constructor does not enforce restrictions on the signs of any of these input arguments, each argument is usually specified as a positive value.

\section*{Optional Input Arguments}

Specify optional input arguments as variable-length lists of matching parameter name/ value pairs: 'Name1', Value1, 'Name2', Value2, ... and so on. The following rules apply when specifying parameter-name pairs:
- Specify the parameter name as a character string, followed by its corresponding parameter value.
- You can specify parameter name/value pairs in any order.
- Parameter names are case insensitive.
- You can specify unambiguous partial string matches.

The following table lists valid parameter names.
\(\left.\left.\begin{array}{|l|l|}\hline \text { StartTime } & \begin{array}{l}\text { Scalar starting time of the first observation, applied to all state } \\ \text { variables. If you do not specify a value for StartTime, the default } \\ \text { is 0. }\end{array} \\ \hline \text { StartState } & \begin{array}{l}\text { Scalar, 2-by-1 column vector, or 2-by-NTRIALS matrix of initial } \\ \text { values of the state variables. } \\ \text { If StartState is a scalar, heston applies the same initial value to } \\ \text { both state variables on all trials. } \\ \text { If StartState is a bivariate column vector, heston applies a } \\ \text { unique initial value to each state variable on all trials. }\end{array} \\ \hline \text { If StartState is a matrix, heston applies a unique initial value to } \\ \text { each state variable on each trial. } \\ \text { Correlation } & \begin{array}{l}\text { If you do not specify a value for StartState, all variables start at } \\ 1 .\end{array} \\ \begin{array}{l}\text { Correlation between Gaussian random variates drawn to } \\ \text { generate the Brownian motion vector (Wiener processes). Specify } \\ \text { Correlation as a scalar, a 2-by-2 positive semidefinite matrix, or } \\ \text { as a deterministic function } C(t) \text { that accepts the current time } t \text { and } \\ \text { returns a 2-by-2 positive semidefinite correlation matrix. }\end{array} \\ \text { A Correlation matrix represents a static condition. } \\ \text { As a deterministic function of time, Correlation allows you to } \\ \text { specify a dynamic correlation structure. }\end{array}\right\} \begin{array}{l}\text { If you do not specify a value for Correlation, the default is a 2- } \\ \text { by-2 identity matrix representing independent Gaussian processes. }\end{array}\right\}\)
\begin{tabular}{|l|l|}
\hline Simulation & \begin{tabular}{l} 
A user-defined simulation function or SDE simulation method. If \\
you do not specify a value for Simulation, the default method is \\
simulation by Euler approximation (simByEuler).
\end{tabular} \\
\hline
\end{tabular}

\section*{Output Arguments}
\begin{tabular}{|c|c|}
\hline heston & \begin{tabular}{l}
Object of class heston with the following displayed parameters: \\
- StartTime: Initial observation time \\
- StartState: Initial state at StartTime \\
- Correlation: Access function for the Correlation input, callable as a function of time \\
- Drift: Composite drift-rate function, callable as a function of time and state \\
- Diffusion: Composite diffusion-rate function, callable as a function of time and state \\
- Simulation: A simulation function or method \\
- Return: Access function for the input argument Return, callable as a function of time and state \\
- Speed: Access function for the input argument Speed, callable as a function of time and state \\
- Level: Access function for the input argument Level, callable as a function of time and state \\
- Volatility: Access function for the input argument Volatility, callable as a function of time and state
\end{tabular} \\
\hline

\section*{hhigh}

Highest high

\section*{Syntax}
```

hhv = hhigh(data)
hhv = hhigh(data, nperiods, dim)
hhvts = hhigh(tsobj, nperiods)
hhvts = hhigh(tsobj, nperiods, 'ParameterName', ParameterValue, ...)

```

\section*{Arguments}
\begin{tabular}{|l|l|}
\hline data & Data series matrix. \\
\hline nperiods & (Optional) Number of periods. Default \(=14\). \\
\hline dim & (Optional) Dimension. \\
\hline tsobj & Financial time series object. \\
\hline 'ParameterName' & \begin{tabular}{l} 
The valid parameter name is: \\
\\
ParameterValue
\end{tabular} \\
\hline \begin{tabular}{l} 
The parameter value is a string that represents the valid \\
parameter name.
\end{tabular} \\
\hline
\end{tabular}

\section*{Description}
hhv = hhigh(data) generates a vector of highest high values for the past 14 periods from the matrix data.
hhv = hhigh(data, nperiods, dim) generates a vector of highest high values for the past nperiods periods. dim indicates the direction in which the highest high is to be searched. If you input [ ] for nperiods, the default is 14.
hhvts = hhigh(tsobj, nperiods) generates a vector of highest high values from tsobj, a financial time series object. tsobj must include at least the series High. The output hhvts is a financial time series object with the same dates as tsobj and data series named HighestHigh. If nperiods is specified, hhigh generates a financial time series object of highest high values for the past nperiods periods.
hhvts = hhigh(tsobj, nperiods, 'ParameterName', ParameterValue, ...) specifies the name for the required data series when it is different from the default name. The valid parameter name isHighName. The parameter value is a string that represents the valid parameter name.

\section*{Examples}

\section*{Compute the Highest High Price}

This example shows how to compute the highest high price for Disney stock and plot the results.
```

load disney.mat
dis_HHigh = hhigh(dis);
plot(dis_HHigh)
title('Highest High for Disney')

```

Introduced before R2006a

\section*{highlow (fts)}

Time series High-Low plot

\section*{Syntax}
```

highlow(tsobj)
highlow(tsobj, color)
highlow(tsobj, color, dateform)
highlow(tsobj, color, dateform, 'ParameterName', ParameterValue, ...)
hll = highlow(tsobj, color, dateform, 'ParameterName',
ParameterValue, ...)

```

\section*{Arguments}
\begin{tabular}{|l|l|}
\hline tsobj & Financial time series object. \\
\hline color & \begin{tabular}{l} 
(Optional) A three-element row vector representing RGB or a \\
color identifier. (See plot in the MATLAB documentation.)
\end{tabular} \\
\hline dateform & \begin{tabular}{l} 
(Optional) Date string format used as the \(x\)-axis tick labels. \\
(See datetick in the MATLAB documentation.) You can \\
specify a dateform only when tsobj does not contain time- \\
of-day data. If tsobj contains time-of-day data, dateform is \\
restricted to 'dd-mmm-yyyy HH:MM '.
\end{tabular} \\
\hline 'ParameterName ' & \begin{tabular}{l} 
'ParameterName ' can be: \\
- HighName: high prices series name \\
- LowName: low prices series name
\end{tabular} \\
\hline ParameterValue & \begin{tabular}{l} 
OpenName: open prices series name \\
- CloseName: closing prices series name
\end{tabular} \\
\hline parameter name.
\end{tabular}

\section*{Description}
highlow (tsobj) generates a High-Low plot of the data in the financial time series object tsobj. tsobj must contain at least four data series representing the high, low, open, and closing prices. These series must have the names High, Low, Open, and Close (case-insensitive).
highlow(tsobj, color) additionally specifies the color of the plot.
highlow(tsobj, color, dateform) additionally specifies the date string format used as the \(x\)-axis tick labels. See datestr for a list of date string formats.
highlow(tsobj, color, dateform, 'ParameterName', ParameterValue, ...) indicates the actual names of the required data series if the data series do not have the default names.

You can specify open prices as optional by providing the parameter name 'OpenName ' and the parameter value ' ' (empty string).
```

highlow(tsobj, color, dateform, 'OpenName', '')

```
hhll = highlow(tsobj, color, dateform, 'ParameterName', ParameterValue, ...) returns the handle to the line object that makes up the HighLow plot.

\section*{Examples}

\section*{Generate a High-Low Plot}

This example shows how to generate a High-Low plot for Disney stock for the dates May 28 to June 18, 1998.
```

load disney.mat
highlow(dis('28-May-1998::18-Jun-1998'))
title('High-Low Plot for Disney')

```

\hline High & High prices for a security. A column vector. \\
\hline Low & Low prices for a security. A column vector. \\
\hline Close & Closing prices for a security. A column vector. \\
\hline Open & \begin{tabular}{l} 
(Optional) Opening prices for a security. A column vector. To \\
specify Color when Open is unknown, enter Open as an empty \\
matrix [ ].
\end{tabular} \\
\hline Color & \begin{tabular}{l} 
(Optional) Vertical line color. A string. MATLAB software supplies \\
a default color if none is specified. The default color differs \\
depending on the background color of the figure window. See \\
ColorSpec in the MATLAB documentation for color names.
\end{tabular} \\
\hline Dates & (Optional) User-defined dates. A column vector. \\
\hline Dateform & \begin{tabular}{l} 
(Optional) Format of the date string as tick labels. For more \\
information on date string formats, see dateaxis.
\end{tabular} \\
\hline
\end{tabular}

\section*{Description}
highlow(High, Low, Close, Open, Color) plots the high, low, opening, and closing prices of an asset. Plots are vertical lines whose top is the high, bottom is the low, open is a short horizontal tick to the left, and close is a short horizontal tick to the right.
highlow(High, Low, Close, Open, Color, Dates, Dateform) plots the high, low, opening, and closing prices of an asset. Plots are vertical lines whose top is the high, bottom is the low, open is a short horizontal tick to the left, and close is a short horizontal tick to the right. The plot also contains user-defined dates and date string format for tick labels.

Handles = highlow(High, Low, Close, Open, Color, Dates, Dateform) plots the figure and returns the handles of the lines.

\section*{Examples}

\section*{Create a HighLow Chart}

The high, low, open, and closing prices for the equity DIS are stored in equal-length vectors dis_HIGH, dis_LOW, dis_OPEN, and dis_CLOSE respectively and highlow plots the price data using blue lines.
```

load disney.mat
range = 1:25;
highlow(dis_HIGH(range), dis_LOW(range), dis_CLOSE(range),...
dis_OPEN(range), 'blue',dis.dates(range));

```

\section*{hist}

Histogram

\section*{Syntax}
```

hist(tsobj, numbins)

```
ftshist \(=\) hist(tsobj, numbins)
[ftshist, binpos] = hist(tsobj, numbins)

\section*{Arguments}
\begin{tabular}{|l|l|}
\hline tsobj & Financial time series object. \\
\hline numbins & (Optional) Number of histogram bins. Default \(=10\). \\
\hline
\end{tabular}

\section*{Description}
hist(tsobj, numbins) calculates and displays the histogram of the data series contained in the financial time series object tsobj.
ftshist = hist(tsobj, numbins) calculates, but does not display, the histogram of the data series contained in the financial time series object tsobj. The output ftshist is a structure with field names similar to the data series names of tsobj.
[ftshist, binpos] = hist(tsobj, numbins) additionally returns the bin positions binpos. The positions are the centers of each bin. binpos is a column vector.

\section*{Examples}

\section*{Create a Histogram}

This example shows how to generate a histogram of Disney open, high, low, and close prices.
```

load disney.mat
dis = rmfield(dis,'VOLUME'); % Remove VOLUME field
hist(dis)
title('Disney Histogram')

```

Disney Histogram

\section*{hwv}

\section*{Create HWV model}

\section*{Syntax}
```

HWV = hwv(Speed, Level, Sigma)
HWV = hwv(Speed, Level, Sigma, 'Name1', Value1, 'Name2',
Value2, ...)

```

\section*{Class}

\section*{HWV}

\section*{Description}

This constructor creates and displays HWV objects, which derive from the SDEMRD (SDE with drift rate expressed in mean-reverting form) class. Use HWV objects to simulate sample paths of NVARS state variables expressed in mean-reverting drift-rate form. These state variables are driven by NBROWNS Brownian motion sources of risk over NPERIODS consecutive observation periods, approximating continuous-time HWV stochastic processes with Gaussian diffusions.

This method allows you to simulate vector-valued HWV processes of the form:
\[
d X_{t}=S(t)\left[L(t)-X_{t}\right] d t+V(t) d W_{t}
\]
where:
- \(X_{t}\) is an NVARS-by-1 state vector of process variables.
- \(S\) is an NVARS-by-NVARS of mean reversion speeds (the rate of mean reversion).
- \(L\) is an NVARS-by-1 vector of mean reversion levels (long-run mean or level).
- \(V\) is an NVARS-by-NBROWNS instantaneous volatility rate matrix.
- \(d W_{t}\) is an NBROWNS-by-1 Brownian motion vector.

\section*{Input Arguments}

Specify required input parameters as one of the following types:
- A MATLAB array. Specifying an array indicates a static (non-time-varying) parametric specification. This array fully captures all implementation details, which are clearly associated with a parametric form.
- A MATLAB function. Specifying a function provides indirect support for virtually any static, dynamic, linear, or nonlinear model. This parameter is supported via an interface, because all implementation details are hidden and fully encapsulated by the function.

Note: You can specify combinations of array and function input parameters as needed.
Moreover, a parameter is identified as a deterministic function of time if the function accepts a scalar time \(t\) as its only input argument. Otherwise, a parameter is assumed to be a function of time \(t\) and state \(X(t)\) and is invoked with both input arguments.

The required input parameters are:
\begin{tabular}{|ll|}
\hline Speed & \begin{tabular}{l} 
Speed represents the function \(S\). If you specify Speed as an array, it \\
must be an NVARS-by-NVARS matrix of mean-reversion speeds (the rate \\
at which the state vector reverts to its long-run average Level). As a \\
deterministic function of time, when Speed is called with a real-valued \\
scalar time \(t\) as its only input, Speed must produce an NVARS-by-NVARS \\
matrix. If you specify Speed as a function of time and state, it calculates \\
the speed of mean reversion. This function must generate an NVARS- \\
by-NVARS matrix of reversion rates when called with two inputs:
\end{tabular} \\
& - A real-valued scalar observation time \(t\). \\
& - An NVARS-by-1 state vector \(X_{t}\).
\end{tabular}
\begin{tabular}{|l|l|} 
& - A real-valued scalar observation time \(t\). \\
& - An NVARS-by-1 state vector \(X_{t}\).
\end{tabular}

Note: Although the constructor does not enforce restrictions on the signs of any of these input arguments, each argument is usually specified as a positive value.

\section*{Optional Input Arguments}

Specify optional input arguments as variable-length lists of matching parameter name/ value pairs: 'Name1', Value1, 'Name2', Value2, ... and so on. The following rules apply when specifying parameter-name pairs:
- Specify the parameter name as a character string, followed by its corresponding parameter value.
- You can specify parameter name/value pairs in any order.
- Parameter names are case insensitive.
- You can specify unambiguous partial string matches.

Valid parameter names are:
\begin{tabular}{|l|l|}
\hline StartTime & \begin{tabular}{l} 
Scalar starting time of the first observation, applied to all state \\
variables. If you do not specify a value for StartTime, the default \\
is 0.
\end{tabular} \\
\hline
\end{tabular}
\(\left.\begin{array}{|l|l|}\hline \text { StartState } & \begin{array}{l}\text { Scalar, NVARS-by-1 column vector, or NVARS-by-NTRIALS matrix of } \\
\text { initial values of the state variables. } \\
\text { If StartState is a scalar, hwv applies the same initial value to all } \\
\text { state variables on all trials. } \\
\text { If StartState is a column vector, hwv applies a unique initial } \\
\text { value to each state variable on all trials. } \\
\text { If StartState is a matrix, hwv applies a unique initial value to } \\
\text { each state variable on each trial. } \\
\text { If you do not specify a value for StartState, all variables start at } \\
1 .\end{array} \\
\hline \text { Correlation } & \begin{array}{l}\text { Correlation between Gaussian random variates drawn to } \\
\text { generate the Brownian motion vector (Wiener processes). Specify } \\
\text { Correlation as an NBROWNS-by-NBROWNS positive semidefinite } \\
\text { matrix, or as a deterministic function C( } t \text { ) that accepts the current } \\
\text { time } t \text { and returns an NBROWNS-by-NBROWNS positive semidefinite } \\
\text { correlation matrix. }\end{array} \\
\text { A Correlation matrix represents a static condition. } \\
\text { As a deterministic function of time, Correlation allows you to }\end{array}\right\}\)\begin{tabular}{l} 
specify a dynamic correlation structure.
\end{tabular}

\section*{Output Arguments}
\begin{tabular}{|l|l|}
\hline HWV & Object of class hwv with the following displayed parameters: \\
& - StartTime: Initial observation time
\end{tabular}

\section*{- StartState: Initial state at StartTime}
- Correlation: Access function for the Correlation input, callable as a function of time
- Drift: Composite drift-rate function, callable as a function of time and state
- Diffusion: Composite diffusion-rate function, callable as a function of time and state
- Simulation: A simulation function or method
- Speed: Access function for the input argument Speed, callable as a function of time and state
- Level: Access function for the input argument Level, callable as a function of time and state
- Sigma: Access function for the input argument Sigma, callable as a function of time and state

\section*{Examples}
"Creating Hull-White/Vasicek (HWV) Gaussian Diffusion Models" on page 17-29

\section*{More About}

\section*{Algorithms}

When you specify the required input parameters as arrays, they are associated with a specific parametric form. By contrast, when you specify either required input parameter as a function, you can customize virtually any specification.

Accessing the output parameters with no inputs simply returns the original input specification. Thus, when you invoke these parameters with no inputs, they behave like simple properties and allow you to test the data type (double vs. function, or equivalently, static vs. dynamic) of the original input specification. This is useful for validating and designing methods.

When you invoke these parameters with inputs, they behave like functions, giving the impression of dynamic behavior. The parameters accept the observation time \(t\) and a
state vector \(X_{t}\), and return an array of appropriate dimension. Even if you originally specified an input as an array, hwv treats it as a static function of time and state, by that means guaranteeing that all parameters are accessible by the same interface.

\section*{holdings2weights}

Portfolio holdings into weights

\section*{Syntax}

Weights = holdings2weights(Holdings, Prices, Budget)

\section*{Arguments}
\begin{tabular}{|l|l|}
\hline Holdings & \begin{tabular}{l} 
Number of portfolios (NPORTS) by number of assets (NASSETS) \\
matrix with the holdings of NPORTS portfolios containing NASSETS \\
assets.
\end{tabular} \\
\hline Prices & NASSETS vector of asset prices. \\
\hline Budget & \begin{tabular}{l} 
(Optional) Scalar or NPORTS vector of nonzero budget constraints. \\
Default \(=1\).
\end{tabular} \\
\hline
\end{tabular}

\section*{Description}

Weights = holdings2weights(Holdings, Prices, Budget) converts portfolio holdings into portfolio weights. The weights must satisfy a budget constraint such that the weights sum to Budget for each portfolio.

Weights is a NPORTS by NASSETS matrix containing the normalized weights of NPORTS portfolios containing NASSETS assets.

\section*{Notes}
- Holdings may be negative to indicate a short position, but the overall portfolio weights must satisfy a nonzero budget constraint.
- The weights in each portfolio sum to the Budget value (which is 1 if Budget is unspecified.)

\section*{holidays}

Holidays and nontrading days

\section*{Syntax}
```

H = holidays
H = holidays(StartDate, EndDate)
H = holidays(StartDate, EndDate, AltHolidays)

```

\section*{Description}
\(\mathrm{H}=\) holidays returns a vector of serial date numbers corresponding to all holidays and nontrading days.

H = holidays(StartDate, EndDate) returns a vector of serial date numbers corresponding to the holidays and nontrading days between StartDate and EndDate, inclusive.

H = holidays(StartDate, EndDate, AltHolidays) returns a vector of serial date numbers corresponding to the alternate list of holidays and nontrading days.

\section*{Input Arguments}

\section*{StartDate}

Start date. Enter as a serial date number or date string.

\section*{EndDate}

End date. Enter as a serial date number or date string.

\section*{AltHolidays}

Alternate list of holidays and nontrading days stored as serial date numbers.

\section*{Output Arguments}

\section*{H}

Returns a vector of serial date numbers corresponding to all holidays and nontrading days.

\section*{Definitions}
holidays is based on a modern 5-day workweek. This function contains all holidays and special nontrading days for the New York Stock Exchange from January 1, 1885 to December 31, 2050. Since the New York Stock Exchange was open on Saturdays before September 29, 1952, exact closures from 1885 to 2050 should include Saturday trading days. To capture these dates, use the function nyseclosures. The results from holidays and nyseclosures are identical if the WorkWeekFormat in nyseclosures is 'Modern'.

\section*{Examples}

Create a vector of serial date numbers corresponding to all holidays and nontrading dates between a specified StartDate and EndDate:
```

H = holidays('jan 1 2001', 'jun 23 2001')

```

This returns:
H =
730852
730866
730901
730954
730999
The serial date numbers for these values are:
```

01-Jan-2001 (New Year's Day)
15-Jan-2001 (Martin Luther King Day)
19-Feb-2001 (President's Day)
13-Apr-2001 (Good Friday)

```

\section*{28-May-2001 (Memorial Day)}

\section*{horzcat}

Concatenate financial time series objects horizontally

\section*{Syntax}
horzcat

\section*{Description}
horzcat implements horizontal concatenation of financial time series objects. horzcat essentially merges the data columns of the financial time series objects. The time series objects must contain the exact same dates and times.

When multiple instances of a data series name occur, concatenation adds a suffix to the current names of the data series. The suffix has the format _objectname<n>, where n is a number indicating the position of the time series, from left to right, in the concatenation command. The n part of the suffix appears only when there is more than one instance of a particular data series name.

The description fields are concatenated as well. They are separated by two forward slashes (//).

\section*{Examples}

Construct three financial time series, each containing a data series named DataSeries:
```

firstfts = fints((today:today+4)', (1:5)','DataSeries','d');
secondfts = fints((today:today+4)', (11:15)','DataSeries','d');
thirdfts = fints((today:today+4)', (21:25)','DataSeries','d');

```

Concatenate the time series horizontally into a new financial time series newfts:
```

newfts = [firstfts secondfts thirdfts secondfts];

```

The resulting object newfts has data series names DataSeries_firstfts, DataSeries_secondfts2, DataSeries_thirdfts, and DataSeries_secondfts4.

Verify this with the command
```

fieldnames(newfts)
ans =
'desc
'freq
'dates'
'DataSeries_firstfts'
'DataSeries_secondfts2'
'DataSeries_thirdfts'
'DataSeries_secondfts4'
'times

```

Use chfield to change the data series names.

Note If all input objects have the same frequency, the new object has that frequency as well. However, if one of the objects concatenated has a different frequency from the others, the frequency indicator of the resulting object is set to Unknown (0).

\section*{inforatio}

Calculate information ratio for one or more assets

\section*{Syntax}
```

inforatio(Asset, Benchmark)

```
Ratio = inforatio(Asset, Benchmark)
[Ratio, TE] = inforatio(Asset, Benchmark)

\section*{Arguments}
\begin{tabular}{|l|l|}
\hline Asset & \begin{tabular}{l} 
NUMSAMPLES-by-NUMSERIES matrix with NUMSAMPLES observations \\
of asset returns for NUMSERIES asset return series.
\end{tabular} \\
\hline Benchmark & \begin{tabular}{l} 
NUMSAMPLES vector of returns for a benchmark asset. The \\
periodicity must be the same as the periodicity of Asset. For \\
example, if Asset is monthly data, then Benchmark must be \\
monthly returns.
\end{tabular} \\
\hline
\end{tabular}

\section*{Description}

Given NUMSERIES assets with NUMSAMPLES returns for each asset in a NUMSAMPLES x NUMSERIES matrix Asset and given a NUMSAMPLES vector of benchmark returns in Benchmark, inforatio computes the information ratio and tracking error for each asset relative to the Benchmark.

To summarize the outputs of inforatio:
- Ratio is a \(1 \times\) NUMSERIES row vector of information ratios for each series in Asset. Any series in Asset with a tracking error of 0 has a NaN value for its information ratio.
- TE is a \(1 \times\) NUMSERIES row vector of tracking errors, that is, the standard deviation of Asset relative to Benchmark returns, for each series.

Note: NaN values in the data are ignored. If the Asset and Benchmark series are identical, the information ratio is NaN since the tracking error is 0 . The information ratio and the Sharpe ratio of an Asset versus a riskless Benchmark (a Benchmark with standard deviation of returns equal to 0 ) are equivalent. This equivalence is not necessarily true if the Benchmark is risky.

\section*{Examples}

See "Information Ratio" on page 7-7.

\section*{interpolate}

Brownian interpolation of stochastic differential equations

\section*{Syntax}
[XT, T] = interpolate(MDL, T, Paths)
[XT, T] = interpolate(MDL, Paths, 'Name1', Value1, 'Name2', Value2, ...)

\section*{Classes}

All classes in "SDE Class Hierarchy" on page 17-5.

\section*{Description}

This method performs a Brownian interpolation into a user-specified time series array, based on a piecewise-constant Euler sampling approach.

Consider a vector-valued SDE of the form:
\[
d X_{t}=F\left(t, X_{t}\right) d t+G\left(t, X_{t}\right) d W_{t}
\]
where:
- \(X\) is an NVARS-by-1 state vector.
- \(F\) is an \(N V A R S\)-by-1 drift-rate vector-valued function.
- \(G\) is an \(N V A R S\)-by-NBROWNS diffusion-rate matrix-valued function.
- \(W\) is an NBROWNS-by-1 Brownian motion vector.

Given a user-specified time series array associated with this equation, this method performs a Brownian (stochastic) interpolation by sampling from a conditional Gaussian distribution. This sampling technique is sometimes called a Brownian bridge.

Note: Unlike simulation methods, the interpolate method does not support userspecified noise processes.

\section*{Input Arguments}
\begin{tabular}{|ll|}
\hline MDL & Stochastic differential equation model. \\
\hline T & \begin{tabular}{l} 
NTIMES element vector of interpolation times. The length of this vector \\
determines the number of rows in the interpolated output time series XT.
\end{tabular} \\
\hline Paths & \begin{tabular}{l} 
NPERIODS-by-NVARS-by-NTRIALS time series array of sample paths of \\
correlated state variables. For a given trial, each row of this array is the \\
transpose of the state vector \(X_{t}\) at time \(t\). Paths is the initial time series \\
array into which interpolate performs the Brownian interpolation.
\end{tabular} \\
\hline
\end{tabular}

\section*{Optional Input Arguments}

Specify optional input arguments as variable-length lists of matching parameter name/ value pairs: 'Name1', Value1, 'Name2', Value2, ... and so on. The following rules apply when specifying parameter-name pairs:
- Specify the parameter name as a character string, followed by its corresponding parameter value.
- You can specify parameter name/value pairs in any order.
- Parameter names are case insensitive.
- You can specify unambiguous partial string matches.

Valid parameter names are:
\begin{tabular}{|l|l|}
\hline Times & \begin{tabular}{l} 
Vector of monotonically increasing observation times associated with \\
the time series input Paths. If you do not specify a value for this \\
parameter, Times is a zero-based, unit-increment column vector of \\
length NPERIODS.
\end{tabular} \\
\hline Refine & \begin{tabular}{l} 
Scalar logical flag that indicates whether interpolate uses the \\
interpolation times you request (see T) to refine the interpolation as \\
new information becomes available. If you do not specify a value for this \\
argument or set it to FALSE (the default value), interpolate bases the \\
interpolation only on the state information specified in Paths. If you \\
set Refine to TRUE, interpolate inserts all new interpolated states \\
into the existing Paths array as they become available. This refines the \\
interpolation grid available to subsequent interpolation times during \\
the current trial.
\end{tabular} \\
\hline
\end{tabular}
\begin{tabular}{|l|l|}
\hline Processes & \begin{tabular}{l} 
Function or cell array of functions that indicates a sequence of \\
background processes or state vector adjustments of the form
\end{tabular} \\
\(\quad X_{t}=P\left(t, X_{t}\right)\) \\
The interpolate method runs processing functions at each \\
interpolation time. They must accept the current interpolation time \(t\), \\
and the current state vector \(X_{t}\), and return a state vector that may be an \\
adjustment to the input state.
\end{tabular}

\section*{Output Arguments}
\begin{tabular}{|l|l|}
\hline XT & \begin{tabular}{l} 
NTIMES-by-NVARS-by-NTRIALS time series array of interpolated state \\
variables. For a given trial, each row of this array is the transpose of the \\
interpolated state vector \(X_{t}\) at time \(t\). XT is the interpolated time series \\
formed by interpolating into the input Paths time series array.
\end{tabular} \\
\hline T & \begin{tabular}{l} 
NTIMES-by-1 column vector of interpolation times associated with the \\
output time series XT. If the input interpolation time vector T contains \\
no missing observations (NaNs), this output is the same time vector \\
as T, but with the NaNs removed. This reduces the length of T and the \\
number of rows of XT.
\end{tabular} \\
\hline
\end{tabular}

\section*{Examples}

\section*{Stochastic Interpolation Without Refinement}

Many applications require knowledge of the state vector at intermediate sample times that are initially unavailable. One way to approximate these intermediate states is to
perform a deterministic interpolation. However, deterministic interpolation techniques fail to capture the correct probability distribution at these intermediate times. Brownian (or stochastic) interpolation captures the correct joint distribution by sampling from a conditional Gaussian distribution. This sampling technique is sometimes referred to as a Brownian Bridge.

The default stochastic interpolation technique is designed to interpolate into an existing time series and ignore new interpolated states as additional information becomes available. This technique is the usual notion of interpolation, which is called Interpolation without refinement.

Alternatively, the interpolation technique may insert new interpolated states into the existing time series upon which subsequent interpolation is based, by that means refining information available at subsequent interpolation times. This technique is called interpolation with refinement.

Interpolation without refinement is a more traditional technique, and is most useful when the input series is closely spaced in time. In this situation, interpolation without refinement is a good technique for inferring data in the presence of missing information, but is inappropriate for extrapolation. Interpolation with refinement is more suitable when the input series is widely spaced in time, and is useful for extrapolation.

The stochastic interpolation method is available to any model. It is best illustrated, however, by way of a constant-parameter Brownian motion process. Consider a correlated, bivariate Brownian motion (BM) model of the form:
\[
\begin{aligned}
& d X_{1 t}=0.3 d t+0.2 d W_{1 t}-0.1 d W_{2 t} \\
& d X_{2 t}=0.4 d t+0.1 d W_{1 t}-0.2 d W_{2 t} \\
& E\left[d W_{1 t} d W_{2 t}\right]=\rho d t=0.5 d t
\end{aligned}
\]

1 Create a BM object to represent the bivariate model:
```

mu = [0.3; 0.4];
sigma = [0.2 -0.1; 0.1 -0.2];
rho = [1 0.5; 0.5 1];
obj = bm(mu,sigma,'Correlation',rho);

```

2 Assuming that the drift (Mu) and diffusion (Sigma) parameters are annualized, simulate a single Monte Carlo trial of daily observations for one calendar year (250 trading days):
```

rng default % make output reproducible
dt = 1/250; % 1 trading day = 1/250 years
[X,T] = simulate(obj,250,'DeltaTime',dt);

```

3 It is helpful to examine a small interval in detail.
a Interpolate into the simulated time series with a Brownian bridge:
```

t = ((T(1) + dt/2):(dt/2):(T(end) - dt/2));
x = interpolate(obj,t,X,'Times',T);

```
b Plot both the simulated and interpolated values:
```

plot(T,X(:, 1),'.-r',T,X(:, 2),' .-b')
grid on;
hold on;
plot(t,x(:, 1),'or',t,x(:,2),'ob')
hold off;
xlabel('Time (Years)')
ylabel('State')
title('Bi-Variate Brownian Motion: \rho = 0.5')
axis([0.4999 0.6001 0.25 0.4])

```

In this plot:
- The solid red and blue dots indicate the simulated states of the bivariate model.
- The straight lines that connect the solid dots indicate intermediate states that would be obtained from a deterministic linear interpolation.
- Open circles indicate interpolated states.
- Open circles associated with every other interpolated state encircle solid dots associated with the corresponding simulated state. However, interpolated states at the midpoint of each time increment typically deviate from the straight line connecting each solid dot.

\section*{Simulation of Conditional Gaussian Distributions}

You can gain additional insight into the behavior of stochastic interpolation by regarding a Brownian bridge as a Monte Carlo simulation of a conditional Gaussian distribution.

This example examines the behavior of a Brownian bridge over a single time increment.
1 Divide a single time increment of length dt into 10 subintervals:
```

mu = [0.3; 0.4];
sigma = [0.2 -0.1; 0.1 -0.2];
rho = [1 0.5; 0.5 1];
obj = bm(mu,sigma,'Correlation',rho);
rng default; % make output reproducible
dt = 1/250; % 1 trading day = 1/250 years
[X,T] = simulate(obj,250,'DeltaTime',dt);
n = 125; % index of simulated state near middle
times = (T(n):(dt/10):T(n + 1));
nTrials = 25000; % \# of Trials at each time

```

2 In each subinterval, take 25000 independent draws from a Gaussian distribution, conditioned on the simulated states to the left, and right:
```

average = zeros(length(times),1);
variance = zeros(length(times),1);
for i = 1:length(times)
t = times(i);
x = interpolate(obj,t(ones(nTrials,1)),...
X,'Times',T);
average(i) = mean(x(:,1));
variance(i) = var(x(:,1));
end

```

3 Plot the sample mean and variance of each state variable:
```

Note: The following graph plots the sample statistics of the first state variable only,
but similar results hold for any state variable.
subplot(2,1,1);
hold on;
grid on;

```
```

plot([T(n) T(n + 1)],[X(n,1) X(n + 1,1)],'.-b')
plot(times, average, 'or')
hold off;
title('Brownian Bridge without Refinement: Sample Mean')
ylabel('Mean')
limits = axis;
axis([T(n) T(n + 1) limits(3:4)]);
subplot(2,1,2)
hold on;
grid on;
plot(T(n),0,'.-b',T(n + 1),0,'.-b')
plot(times, variance, '.-r')
hold('off');
title('Brownian Bridge without Refinement: Sample Variance')
xlabel('Time (Years)')
ylabel('Variance')
limits = axis;
axis([T(n) T(n + 1) limits(3:4)]);

```

The Brownian interpolation within the chosen interval, \(d t\), illustrates the following:
- The conditional mean of each state variable lies on a straight-line segment between the original simulated states at each endpoint.
- The conditional variance of each state variable is a quadratic function. This function attains its maximum midway between the interval endpoints, and is zero at each endpoint.
- The maximum variance, although dependent upon the actual model diffusionrate function \(G(t, X)\), is the variance of the sum of NBROWNS correlated Gaussian variates scaled by the factor \(d t / 4\).

The previous plot highlights interpolation without refinement, in that none of the interpolated states take into account new information as it becomes available. If you had performed interpolation with refinement, new interpolated states would have been inserted into the time series and made available to subsequent interpolations on a trial-by-trial basis. In this case, all random draws for any given interpolation time would be identical. Also, the plot of the sample mean would exhibit greater variability, but would still cluster around the straight-line segment between the original simulated states at each endpoint. The plot of the sample variance, however, would be zero for all interpolation times, exhibiting no variability.

\section*{More About}

\section*{Algorithms}
- The interpolate method assumes that all model parameters are piecewiseconstant, and evaluates them from the most recent observation time in Times that precedes a specified interpolation time in T. This is consistent with the Euler approach of Monte Carlo simulation.
- When an interpolation time falls outside the interval specified by Times, a Euler simulation extrapolates the time series by using the nearest available observation.
- The user-defined time series Paths and corresponding observation Times must be fully observed (no missing observations denoted by NaNs ).
- The interpolate method assumes that the user-specified time series array Paths is associated with the SDE object. For example, the Times/Paths input pair is the result of an initial course-grained simulation. However, the interpolation ignores the initial conditions of the SDE object (StartTime and StartState), allowing the userspecified Times/Paths input series to take precedence.

\section*{irr}

Internal rate of return

\section*{Syntax}

Return = irr(CashFlow)
[Return, AllRates] = irr(CashFlow)

\section*{Description}

Return = irr(CashFlow) calculates the internal rate of return for a series of periodic cash flows.
[Return, AllRates] = irr(CashFlow) calculates the internal rate of return and a vector of all internal rates for a series of periodic cash flows.

\section*{Input Arguments}

\section*{CashFlow}

A vector containing a stream of periodic cash flows. The first entry in CashFlow is the initial investment. If CashFlow is a matrix, irr handles each column of CashFlow as a separate cash-flow stream.

\section*{Output Arguments}

\section*{Return}

An internal rate of return associated to CashFlow. If CashFlow is a matrix, then Return is a vector whose entry \(j\) is an internal rate of return for column \(j\) in CashFlow.

\section*{AllRates}

A vector containing all the internal rates of return associated with CashFlow. If CashFlow is a matrix, then AllRates is also a matrix, with the same number of
columns as CashFlow and one less row. Also, column \(j\) in AllRates contains all the rates of return associated to column \(j\) in CashFlow (including complex-valued rates).

\section*{Definitions}
irr uses the following conventions:
- If one or more internal rates of returns (warning if multiple) are strictly positive rates, Return sets to the minimum.
- If there is no strictly positive rate of returns, but one or multiple (warning if multiple) returns are nonpositive rates, Return sets to the maximum.
- If no real-valued rates exist, Return sets to NaN (no warnings).

\section*{Examples}

Find the internal rate of return for a simple investment with a unique positive rate of return. The initial investment is \(\$ 100,000\) and the following cash flows represent the yearly income from the investment.
- Year 1 - \(\$ 10,000\)
- Year 2 - \$20,000
- Year 3 - \(\$ 30,000\)
- Year 4 - \(\$ 40,000\)
- Year 5 - \(\$ 50,000\)

Calculate the internal rate of return on the investment:
Return \(=\operatorname{irr}([-10000010000200003000040000\) 50000])
This returns:
Return =
0.1201

If the cash flow payments were monthly, then the resulting rate of return is multiplied by 12 for the annual rate of return.

Find the internal rate of return for multiple rates of return. The project has the following cash flows and a market rate of \(10 \%\).
```

CashFlow = [-1000 6000 -10900 5800]

```

Use irr with a single output argument:
```

Return = irr(CashFlow)

```

A warning appears and irr returns a \(100 \%\) rate of return. The \(100 \%\) rate on the project looks attractive:
```

Warning: Multiple rates of return

```
> In irr at 166

Return =
1.0000

Use irr with two output arguments:
```

[Return, AllRates] = irr(CashFlow)

```

This returns:
```

>> [Return, AllRates] = irr(CashFlow)

```

Return =
1.0000

\section*{AllRates =}
\(-0.0488\)
1.0000
2.0488

The rates of return in AllRates are \(-4.88 \%, 100 \%\), and \(204.88 \%\). Though some rates are lower and some higher than the market rate, based on the work of Hazen, any rate gives a consistent recommendation on the project. However, you can use a present value analysis in these kinds of situations. To check the present value of the project, use pvvar:
```

PV = pvvar(CashFlow,0.10)

```

\section*{This returns:}

PV =
-196.0932
The second argument is the \(10 \%\) market rate. The present value is -196.0932 , negative, so the project is undesirable.

Introduced before R2006a

\section*{isbusday}

True for dates that are business days

\section*{Syntax}

Busday = isbusday(Date, Holiday, Weekend)

\section*{Arguments}
\begin{tabular}{|l|l|}
\hline Date & \begin{tabular}{l} 
Date(s) being checked. Enter as a vector of serial date numbers or \\
date strings. Date can contain multiple dates, but they must all be \\
in the same format. Dates are assumed to be whole date numbers \\
or date stamps with no fractional or time values.
\end{tabular} \\
\hline Holiday & \begin{tabular}{l} 
(Optional) Vector of holidays and nontrading-day dates. All dates \\
in Holiday must be the same format: either serial date numbers \\
or date strings. (Using date numbers improves performance.) The \\
holidays function supplies the default vector.
\end{tabular} \\
\hline Weekend & \begin{tabular}{l} 
(Optional) Vector of length 7, containing 0 and 1, the value \\
1 indicating weekend days. The first element of this vector \\
corresponds to Sunday. Thus, when Saturday and Sunday form the \\
weekend (default), then Weekend \(=\left[\begin{array}{lllll}1 & 0 & 0 & 0 & 0\end{array}\right]\). \\
\hline
\end{tabular} \\
\hline
\end{tabular}

\section*{Description}

Busday = isbusday (Date, Holiday, Weekend) returns logical true (1) if Date is a business day and logical false (0) otherwise.

\section*{Examples}

Example 1:
Busday = isbusday('16 jun 2001')
Busday =
```

    0
    Date = ['15 feb 2001'; '16 feb 2001'; '17 feb 2001'];
Busday = isbusday(Date)
Busday =
1
1
O

```

Example 2: Set June 21, 2003 (a Saturday) as a business day.
```

Weekend = [11 0 0 0 0 0 0];
isbusday('June 21, 2003', [], Weekend)
ans =

```
    1

Note: If the second argument, Holiday, is empty ([ ]), the default Holidays vector (generated with holidays and then associated to the NYSE calendar) is used. To consider a calendar without holidays (except for weekends as controlled by third input), use a serial (or text date) out of your range. For example, \(0-\) Jan-0 or the value 0 are with high probabilities out of the range. This value overwrites the default calendar allowing you to remove any specific country holiday:
```

isbusday(datenum('06092010','ddmmyyyy '),0)

```
ans \(=\)
    1

18 Functions - Alphabetical List

Introduced before R2006a

\section*{iscompatible}

Structural equality

\section*{Syntax}
iscomp = iscompatible(tsobj_1, tsobj_2)

\section*{Arguments}

> \begin{tabular}{|l|l} \hline tsobj_1, tsobj_2 & A pair of financial time series objects. \end{tabular}

\section*{Description}
iscomp = iscompatible(tsobj_1, tsobj_2) returns 1 if both financial time series objects tsobj_1 and tsobj_2 have the same dates and data series names. It returns 0 if any component is different.
iscomp \(=1\) indicates that the two objects contain the same number of data points and equal number of data series. However, the values contained in the data series can be different.

Note Data series names are case-sensitive.

\section*{isequal}

Multiple object equality

\section*{Syntax}
iseq \(=\) isequal(tsobj_1, tsobj_2, ...)

\section*{Arguments}
\begin{tabular}{|l|l}
\hline tsobj_1 ... & A list of financial time series objects.
\end{tabular}

\section*{Description}
iseq = isequal(tsobj_1, tsobj_2, ...) returns 1 if all listed financial time series objects have the same dates, data series names, and values contained in the data series. It returns 0 if any of those components is different.

Note Data series names are case-sensitive.
iseq \(=1\) implies that each object contains the same number of dates and the same data. Only the descriptions can differ.

\section*{isempty}

True for empty financial time series objects

\section*{Syntax}
tf = isempty(fts)

\section*{Arguments}
fts \(\quad\) Financial time series object.

\section*{Description}
isempty for financial times series objects is based on the MATLAB isempty function.
See isempty in the MATLAB documentation.
\(\mathrm{tf}=\) isempty (fts) returns true (1) if fts is an empty financial time series object and false (0) otherwise. An empty financial times series object has no elements, that is, length \((f t s)=0\).

\section*{lagts}

Lag time series object

\section*{Syntax}
```

newfts = lagts(oldfts)
newfts = lagts(oldfts, lagperiod)
newfts = lagts(oldfts, lagperiod, padmode)

```

\section*{Arguments}
\begin{tabular}{|l|l|}
\hline oldfts & Financial time series object \\
\hline lagperiod & \begin{tabular}{l} 
Number of lag periods expressed in the frequency of the time series \\
object
\end{tabular} \\
\hline padmode & Data padding value \\
\hline
\end{tabular}

\section*{Description}
lagts delays a financial time series object by a specified time step.
newfts = lagts(oldfts) delays the data series in oldfts by one time series date entry and returns the result in the object newfts. The end is padded with zeros, by default.
newfts \(=\) lagts (oldfts, lagperiod) shifts time series values to the right on an increasing time scale. lagts delays the data series to happen later. lagperiod is the number of lag periods expressed in the frequency of the time series object oldfts. For example, if oldfts is a daily time series, lagperiod is specified in days. lagts pads the data with zeros (default).
newfts = lagts(oldfts, lagperiod, padmode) lets you pad the data with an arbitrary value, NaN, or Inf rather than zeros by setting padmode to the desired value.

\section*{See Also \\ leadts \\ Related Examples}
- "Data Transformation and Frequency Conversion" on page 12-17
- "Using Time Series to Predict Equity Return" on page 12-23

Introduced before R2006a

\section*{Ibusdate}

Last business date of month

\section*{Syntax}

Date = lbusdate(Year, Month, Holiday, Weekend)

\section*{Arguments}
\begin{tabular}{|l|l|}
\hline Year & Enter as four-digit integer. \\
\hline Month & Enter as integer from 1 through 12. \\
\hline Holiday & \begin{tabular}{l} 
(Optional) Vector of holidays and nontrading-day dates. All dates \\
in Holiday must be the same format: either serial date numbers \\
or date strings. (Using date numbers improves performance.) The \\
holidays function supplies the default vector.
\end{tabular} \\
\hline Weekend & \(\left.\begin{array}{l}\text { (Optional) Vector of length 7, containing } 0 \text { and 1, the value } \\
1 \text { indicating weekend days. The first element of this vector } \\
\text { corresponds to Sunday. Thus, when Saturday and Sunday form the } \\
\text { weekend (default), then Weekend }=\left[\begin{array}{llll}1 & 0 & 0 & 0\end{array} 0001\right.\end{array}\right]\). \\
\hline
\end{tabular}

\section*{Description}

Date \(=\) lbusdate(Year, Month, Holiday, Weekend) returns the serial date number for the last business date of the given year and month. Holiday specifies nontrading days.

Year and Month can contain multiple values. If one contains multiple values, the other must contain the same number of values or a single value that applies to all. For example, if Year is a 1-by-n vector of integers, then Month must be a 1-by-n vector of integers or a single integer. Date is then a 1-by- \(n\) vector of date numbers.

Use the function datestr to convert serial date numbers to formatted date strings.

\section*{Examples}

\section*{Example 1.}
```

Date = lbusdate(2001, 5)
Date =
7 3 1 0 0 2
datestr(Date)
ans =
31-May-2001

```

Example 2. You can indicate that Saturday is a business day by appropriately setting the Weekend argument.
```

Weekend = [1 0 0 0 0 0 0 0];

```

May 31, 2003, is a Saturday. Use lbusdate to check that this Saturday is actually the last business day of the month.
```

Date = datestr(lbusdate(2003, 5, [], Weekend))
Date =

```
31-May-2003

\section*{More About}

\section*{leadts}

Lead time series object

\section*{Syntax}
```

newfts = leadts(oldfts)
newfts = leadts(oldfts, leadperiod)
newfts = leadts(oldfts, leadperiod, padmode)

```

\section*{Arguments}
\begin{tabular}{|l|l|}
\hline oldfts & Financial time series object. \\
\hline leadperiod & \begin{tabular}{l} 
Number of lead periods expressed in the frequency of the time \\
series object.
\end{tabular} \\
\hline padmode & Data padding value. \\
\hline
\end{tabular}

\section*{Description}
leadts advances a financial time series object by a specified time step.
newfts = leadts(oldfts) advances the data series in oldfts by one time series date entry and returns the result in the object newfts. The end will be padded with zeros, by default.
newfts = leadts(oldfts, leadperiod) shifts time series values to the left on an increasing time scale. leadts advances the data series to happen at an earlier time. leadperiod is the number of lead periods expressed in the frequency of the time series object oldfts. For example, if oldfts is a daily time series, leadperiod is specified in days. leadts pads the data with zeros (default).
newfts = leadts(oldfts, leadperiod, padmode) lets you pad the data with an arbitrary value, NaN, or Inf rather than zeros by setting padmode to the desired value.

- "Case Study for Life Tables Analysis" on page 2-50

\section*{Input Arguments}

\section*{x0 - Increasing ages for raw data}
vector of nonnegative integer values
Increasing ages for raw data, specified as nonnegative integer values in an NO vector.
The vector of ages \(x\) must contain nonnegative integer values. If the input series is the discrete survival function \(l x\), then the starting age need only be nonnegative. Otherwise, the starting age must be 0 .

\section*{Data Types: double}

\section*{\(1 \times 0\) - Collection of num standardized survivor series matrix}

Collection of num standardized survivor series, specified as an NO-by-num matrix. The input \(1 \times 0\) series is the number of people alive at age \(x\), given 100,000 alive at birth. Values of 0 or NaN in the input table \(1 \times 0\) are ignored.
Data Types: double

\section*{y0 - Collection of num life table series to be converted matrix}

Collection of num life table series to be converted, specified as an NO-by-num matrix. The default y 0 series is lx 0 .

Data Types: double

\section*{y0type - (Optional) Type of mortality series for input y0 with default ' \(1 x\) '}
'lx' (default) | string with values ' qx ', ' lx ', ' dx '
(Optional) Type of mortality series for input y0, specified as a string with one of the following values:
- ' \(q x\) ' - Input is a table of discrete hazards (qx).
- ' \(1 x\) ' - Input is a table of discrete survival counts (lx).
- ' dx ' - Input is a table of discrete decrements (dx).

Whereas the output series have forced termination, the input series (y0) can have one of several types of termination:
- Natural termination runs out to the last person so that \(1 x\) goes to 0 , \(q \times\) goes to 1 , and dx goes to 0 . For more information, see "Natural Termination" on page 18-750.
- Truncated termination stops at a terminal age so that \(l x\) is positive, \(q x\) is less than 1 , and \(d x\) is positive. Any ages after the terminal age are NaN values. For more information, see "Truncated Termination" on page 18-751.

\section*{Data Types: char}

\section*{Output Arguments}

\author{
qx - Discrete hazard function \\ matrix
}

Discrete hazard function, returned as an NO-by-num matrix with forced termination. For more information, see "Forced Termination" on page 18-749.

The series qx is the conditional probability that a person at age x will die between age \(x\) and the next age in the series.

\section*{lx - Discrete survival function \\ matrix}

Discrete survival function, returned as an NO-by-num matrix with forced termination. For more information, see "Forced Termination" on page 18-749.

The series \(1 x\) is the number of people alive at age \(x\), given 100,000 alive at birth.

\section*{dx - Discrete decrements function}
matrix
Discrete decrements function, returned as an NO-by-num matrix with forced termination. For more information, see "Forced Termination" on page 18-749.

The series dx is the number of people who die out of 100,000 alive at birth, between age \(x\) and the next age in the series.

\section*{More About}

\section*{Forced Termination}

Most modern life tables have "forced" termination. Forced termination means that the last row of the life table applies for all persons with ages on or after the last age in the life table. This sample illustrates forced termination.

\section*{United States Life Tables 2009}
\begin{tabular}{|c|c|c|c|c|c|c|c|c|}
\hline & \(1 \times \mathrm{WM}\) & \(1 \times\) WF & \(l_{x} \mathrm{BM}\) & \(1 \times \mathrm{BF}\) & \(q_{x}\) WM & \(q_{x}\) WF & \(q_{\times} \mathrm{BM}\) & \(q_{x} \mathrm{BF}\) \\
\hline 93 & 9533 & 18368 & 6615 & 15685 & 0.219553 & 0.177156 & 0.200605 & 0.157858 \\
\hline 94 & 7440 & 15114 & 5288 & 13209 & 0.23871 & 0.194852 & 0.214448 & 0.170868 \\
\hline 95 & 5664 & 12169 & 4154 & 10952 & 0.258475 & 0.213411 & 0.229177 & 0.184624 \\
\hline 96 & 4200 & 9572 & 3202 & 8930 & 0.27881 & 0.232971 & 0.24391 & 0.198992 \\
\hline 97 & 3029 & 7342 & 2421 & 7153 & 0.299439 & 0.253337 & 0.259397 & 0.214036 \\
\hline 98 & 2122 & 5482 & 1793 & 5622 & 0.320452 & 0.27417 & 0.274958 & 0.229634 \\
\hline 99 & 1442 & 3979 & 1300 & 4331 & 0.341886 & 0.295803 & 0.291538 & 0.245671 \\
\hline 100+ & 949 & 2802 & 921 & 3267 & 1 & 1 & 1 & 1 \\
\hline
\end{tabular}

In this case, the last row of the life table applies for all persons aged 100 or older. Specifically, \(q_{x}\) probabilities are \({ }_{1} q_{x}\) for ages less than 100 and, technically, \({ }_{\infty} q_{x}\) for age 100.

Forced termination has terminal age values that apply to all ages after the terminal age so that \(l \mathrm{x}\) is positive, qx is 1 , and \(d x\) is positive. Ages after the terminal age are NaN values, although \(l x\) and \(d x\) can be 0 and \(q x\) can be 1 for input series. Forced termination is triggered by a naturally terminating series, the last age in a truncated series, or the first NaN value in a series.

\section*{Natural Termination}

Before 1970, life tables were often published with data that included all ages for which persons associated with a given series were still alive. Tables in this form have "natural" termination. In natural termination, the last row of the life table for each series counts the deaths or probabilities of deaths of the last remaining person at the corresponding age. Tables in this form can be problematic due to the granularity of the data and the fact that groups of series can terminate at distinct ages. Natural termination is illustrated in the following sample of the last few years of a life table.

\section*{United States Life Tables 1940}
\begin{tabular}{rrrrrrrrr}
\(x\) & \(I_{x} \mathrm{WM}\) & \(I_{x} \mathrm{WF}\) & \(l_{x} \mathrm{BM}\) & \(l_{x} \mathrm{BF}\) & \(q_{x} \mathrm{WM}\) & \(q_{x} \mathrm{WF}\) & \(q_{x} \mathrm{BM}\) & \(q_{x} \mathrm{BF}\) \\
103 & 14 & 29 & 59 & 234 & 0.428571 & 0.413793 & 0.389831 & 0.333333 \\
104 & 8 & 17 & 36 & 156 & 0.5 & 0.470588 & 0.416667 & 0.358974 \\
105 & 4 & 9 & 21 & 100 & 0.5 & 0.444444 & 0.47619 & 0.38 \\
106 & 2 & 5 & 11 & 62 & 0.5 & 0.4 & 0.454545 & 0.403226 \\
107 & 1 & 3 & 6 & 37 & 0 & 0.666667 & 0.5 & 0.432432 \\
108 & 1 & 1 & 3 & 21 & 1 & 0 & 0.666667 & 0.47619 \\
109 & & 1 & 1 & 11 & & 1 & 1 & 0.454545 \\
110 & & & & 6 & & & & 0.5 \\
111 & & & & 3 & & & & 0.666667 \\
112 & & & & 1 & & & & 0 \\
113 & & & & 1 & & & & 1 \\
114 & & & & & & & &
\end{tabular}

This form for life tables poses a number of issues that go beyond the obvious statistical issues. First, the \(l_{x}\) table on the left terminates at ages 108, 109, 109, and 113 for the four series in the table. Technically, the numbers after these ages are 0 , but can also be NaN values because no person is alive after these terminating ages. Second, the probabilities \(q_{x}\) on the right terminate with fluctuating probabilities that go from 0 to 1 in some cases. In this case, however, all probabilities are \({ }_{1} q_{x}\) probabilities (unlike the forced termination probabilities). You can argue that the probabilities after the ages of termination can be 1 (anyone alive at this age is expected to die in the next year), 0 (the age lies outside the support of the probability distribution), or NaN values.

\section*{Truncated Termination}

Truncated termination occurs with truncation of life tables at an arbitrary age. For example, from 1970-1990, United States life tables truncated at age 85. This format is problematic because life table probabilities must either terminate with probability 1 (forced termination) or discard data that exceeds the terminating age. This sample of the last few years of a life table illustrates truncated termination. The raw data for this table is the \(l_{x}\) series. The \(q_{x}\) series is derived from this series.

\section*{United States Life Tables 1980}
\begin{tabular}{rrrrrrrrr}
\(x\) & \(l_{x} \mathrm{WM}\) & \(l_{x} \mathrm{WF}\) & \(l_{x} \mathrm{BM}\) & \(l_{x} \mathrm{BF}\) & \(q_{x} \mathrm{WM}\) & \(q_{x} \mathrm{WF}\) & \(q_{x} \mathrm{BM}\) & \(q_{x} \mathrm{BF}\) \\
78 & 38558 & 61100 & 25481 & 45776 & 0.078064 & 0.045221 & 0.082689 & 0.054789 \\
79 & 35548 & 58337 & 23374 & 43268 & 0.084477 & 0.050037 & 0.088303 & 0.059351 \\
80 & 32545 & 55418 & 21310 & 40700 & 0.091504 & 0.055542 & 0.094603 & 0.064619 \\
81 & 29567 & 52340 & 19294 & 38070 & 0.099165 & 0.061922 & 0.101741 & 0.070607 \\
82 & 26635 & 49099 & 17331 & 35382 & 0.107528 & 0.06935 & 0.109746 & 0.077356 \\
83 & 23771 & 45694 & 15429 & 32645 & 0.116613 & 0.078194 & 0.118608 & 0.084822 \\
84 & 20999 & 42121 & 13599 & 29876 & 0.126339 & 0.081788 & 0.128392 & 0.093018 \\
85 & 18346 & 38676 & 11853 & 27097 & & & &
\end{tabular}

This life table format poses problems for termination because, for example, over 27\% of the population for the fourth \(l_{x}\) series is still alive at age 85 . To claim that the probability of dying for all ages after age 85 is \(100 \%\) might be true but is uninformative. Notwithstanding the statistical issues, however, tables in this form are completed by forced termination.

\section*{lifetablefit}

Calibrate life table from survival data with parametric models

\section*{Syntax}
```

[a,elx] = lifetablefit(x,lx)
[a,elx] = lifetablefit(___,
,lifemodel,objtype,interpmethod,a0)

```

\section*{Description}
[a,elx] = lifetablefit(x,lx) calibrates a life table, x, from survival data, lx, using parametric models.
```

[a,elx] = lifetablefit( ___,lifemodel,objtype,interpmethod,a0)

```
calibrates a life table, \(x\), from survival data, \(l x\), using parametric models using optional arguments for lifemodel, objtype, interpmethod, and a0.

\section*{Examples}

Calibrate Life Table from Survival Data Using a Heligman-Pollard Parametric Model
Load the life table data file.
```

load us_lifetable_2009

```

Calibrate the life table from survival data using the default heligman-pollard parametric model.

Plot the qx series and display the legend. The series qx is the conditional probability that a person at age \(x\) will die between age \(x\) and the next age in the series
```

plot(x,log(qx))
legend(series)

```

- "Case Study for Life Tables Analysis" on page 2-50

\section*{Input Arguments}
x - Increasing ages for raw data
vector of nonnegative integers
Increasing ages for raw data, specified as a N vector for nonnegative integers.
Data Types: double
\(1 x-\) Collection of num discrete survival counts
matrix

Collection of num discrete survival counts, specified as an \(N\)-by-num matrix. The input \(1 x\) series is the number of people alive at age \(x\), given 100,000 alive at birth. Values of 0 or NaN in the input table 1 x are ignored.

\section*{Data Types: double}

\section*{lifemodel - (Optional) Parametric mortality model type}
```

'heligman-pollard' (default) | string with values 'heligman-pollard ',
'heligman-pollard-2''heligman-pollard-3', 'gompertz', 'makeham', 'siler'

```
(Optional) Parametric mortality model type, specified as a string with one of the following values:
- 'heligman-pollard ' - Eight-parameter Heligman-Pollard model (version 1), specified in terms of the discrete hazard function:
\[
\frac{q(x)}{1-q(x)}=A^{(x+B)^{c}}+D \exp \left(-E\left(\log \frac{x}{F}\right)^{2}\right)+G H^{X}
\]
for ages \(x \geq 0\), with parameters \(A, B, C, D, E, F, G, H \geq 0\).
- 'heligman-pollard-2' - Eight-parameter Heligman-Pollard model (version 2), specified in terms of the discrete hazard function:
\[
\frac{q(x)}{1-q(x)}=A^{(x+B)^{c}}+D \exp \left(-E\left(\log \frac{x}{F}\right)^{2}\right)+\frac{G H^{X}}{1+G H^{X}}
\]
for ages \(x \geq 0\), with parameters \(A, B, C, D, E, F, G, H \geq 0\).
- 'heligman-pollard-3' — Eight-parameter Heligman-Pollard model (version 3), specified in terms of the discrete hazard function:
\[
q(x)=A^{(x+B)^{c}}+D \exp \left(-E\left(\log \frac{x}{F}\right)^{2}\right)+G H^{X}
\]
for ages \(x \geq 0\), with parameters \(A, B, C, D, E, F, G, H \geq 0\).
- 'gompertz' - Two-parameter Gompertz model, specified in terms of the continuous hazard function:
\(h(x)=A \exp (B x)\)
for ages \(x \geq 0\), with parameters \(A, B \geq 0\).
- 'makeham ' - Three-parameter Gompertz-Makeham model, specified in terms of the continuous hazard function:
\(h(x)=A \exp (B x)+C\)
for ages \(x \geq 0\), with parameters \(A, B, C \geq 0\).
- 'siler' - Five-parameter Siler model, specified in terms of the continuous hazard function:
\(\mathrm{h}(\mathrm{x})=\mathrm{A} \exp (\mathrm{Bx})+\mathrm{C}+\mathrm{D} \exp (-\mathrm{Ex})\)
for ages \(x \geq 0\), with parameters \(A, B, C, D, E \geq 0\).

\section*{Data Types: char}

\section*{objtype - (Optional) Objective for nonlinear least-squares estimation}
'ratio' (default) | string with values 'ratio' 'logratio'
(Optional) Objective for nonlinear least-squares estimation, specified as a string with the following values:
- 'ratio' - Given raw data \(q_{\mathrm{x}}\) and model estimates \(\hat{q}_{x}\) for \(x=1, \ldots, N\), the first objective (which is the preferred objective) has the form
\[
\Phi=\sum_{x=1}^{N}\left(1-\frac{\hat{q}_{x}}{q_{x}}\right)^{2}
\]
- 'logratio' - Given raw data \(q_{\mathrm{x}}\) and model estimates \(\hat{q}_{x}\) for \(x=1, \ldots, N\), the second objective has the form
\[
\Phi=\sum_{x=1}^{N}\left(\log \left(q_{x}\right)-\log \left(q_{x}\right)\right)^{2}
\]

\section*{Data Types: char}

\section*{interpmethod - (Optional) Interpolation method to use for abridged life table inputs}
'cubic' (default) | string with values 'cubic', 'linear', 'none'
(Optional) Interpolation method to use for abridged life table inputs, specified as a string with the following values:
- 'cubic' - Cubic interpolation that uses 'pchip' method in interp1.
- 'linear' - Linear interpolation.
- 'none ' - No interpolation.

Note: If the ages in \(x\) are not consecutive years and interpolation is set to 'none ', then the estimates for the parameters are suitable only for the age vector \(x\).

If you use the parameter estimates to compute life table values for arbitrary years, interpolate using the default 'cubic' method.

Interpolation with abridged life tables forms internal interpolated full life tables, which usually improves model fits.

\section*{Data Types: char}

\section*{a0 - (Optional) Initial parameter estimate to be applied to all series vector}
(Optional) Initial parameter estimate to be applied to all series, specified as a numparam vector. This vector must conform to the number of parameters in the model specified using the lifemodel argument.
Data Types: double

\section*{Output Arguments}
a - Parameter estimates for each num series
matrix
Parameter estimates for each num series, returned as a numparam-by-num matrix.

\section*{elx - Estimated collection of num standardized survivor series}
matrix
Estimated collection of num standardized survivor series, returned as an N -by-num matrix. The elx output series is the number of people alive at age \(x\), given 100,000 alive at birth. Values of 0 or NaN in the input table 1 x are ignored.

Introduced in R2015a

\section*{lifetablegen}

Generate life table series from calibrated mortality model

\section*{Syntax}
```

[qx,lx,dx] = lifetablegen(x,a)
[qx,lx,dx] = lifetablegen(x,a,lifemodel)

```

\section*{Description}
[ \(q x, l x, d x\) ] = lifetablegen( \(x, a)\) generates a life table series from a calibrated mortality model.
\([q x, l x, d x]=\) lifetablegen \((x, a, l i f e m o d e l)\) generates a life table series from a calibrated mortality model using the optional argument for lifemodel.

\section*{Examples}

\section*{Generate Life Table Series from a Calibrated Mortality Model for Heligman-Pollard}

Load the life table data file.
```

load us_lifetable_2009

```

Calibrate the life table from survival data using the default heligman-pollard parametric model.
```

a = lifetablefit(x, lx)

```
a =
\begin{tabular}{lll}

Plot the qx series and display the legend. The series \(q x\) is the conditional probability that a person at age \(x\) will die between age \(x\) and the next age in the series.
plot((0:100), \(\log (q x))\);
legend(series, 'location', 'southeast');
title('Conditional Probability of Dying within One Year of Current Age'); xlabel('Age');
ylabel('Log Probability');

- "Case Study for Life Tables Analysis" on page 2-50

\section*{Input Arguments}
x - Increasing ages for raw data
vector of nonnegative integers
Increasing ages for raw data, specified as a \(N\) vector of nonnegative integer values. The ages must start at 0 (birth).

Data Types: double

\section*{a - Model parameters for num models}

\section*{matrix}

Model parameters for num models, specified as a numparam-by-num matrix, where the number of parameters (numparam) depends on the model specified using the lifemodel argument.

\section*{Data Types: double}

\section*{lifemodel - (Optional) Parametric mortality model type}
'heligman-pollard' (default) | string with values 'heligman-pollard', 'heligman-pollard-2''heligman-pollard-3', 'gompertz', 'makeham', 'siler'
(Optional) Parametric mortality model type, specified as a string with one of the following values:
- 'heligman-pollard ' - Eight-parameter Heligman-Pollard model (version 1), specified in terms of the discrete hazard function:
\[
\frac{q(x)}{1-q(x)}=A^{(x+B)^{C}}+D \exp \left(-E\left(\log \frac{x}{F}\right)^{2}\right)+G H^{X}
\]
for ages \(x \geq 0\), with parameters \(A, B, C, D, E, F, G, H \geq 0\).
- 'heligman-pollard-2' — Eight-parameter Heligman-Pollard model (version 2), specified in terms of the discrete hazard function:
\[
\frac{q(x)}{1-q(x)}=A^{(x+B)^{c}}+D \exp \left(-E\left(\log \frac{x}{F}\right)^{2}\right)+\frac{G H^{X}}{1+G H^{X}}
\]
for ages \(x \geq 0\), with parameters \(A, B, C, D, E, F, G, H \geq 0\).
- 'heligman-pollard-3' - Eight-parameter Heligman-Pollard model (version 3), specified in terms of the discrete hazard function:
\[
q(x)=A^{(x+B)^{c}}+D \exp \left(-E\left(\log \frac{x}{F}\right)^{2}\right)+G H^{X}
\]
for ages \(x \geq 0\), with parameters \(A, B, C, D, E, F, G, H \geq 0\).
- 'gompertz' — Two-parameter Gompertz model, specified in terms of the continuous hazard function:
\(h(x)=A \exp (B x)\)
for ages \(x \geq 0\), with parameters \(A, B \geq 0\).
- 'makeham ' - Three-parameter Gompertz-Makeham model, specified in terms of the continuous hazard function:
\(h(x)=A \exp (B x)+C\)
for ages \(x \geq 0\), with parameters \(A, B, C \geq 0\).
- 'siler' - Five-parameter Siler model, specified in terms of the continuous hazard function:
\(h(x)=A \exp (B x)+C+D \exp (-E x)\)
for ages \(x \geq 0\), with parameters \(A, B, C, D, E \geq 0\).

\section*{Data Types: char}

\section*{Output Arguments}

\section*{\(q x\) - Conditional probabilities of dying for \(N\) ages and num series} matrix

Conditional probabilities of dying for N ages and num series, returned as an N -by-num matrix. The series qx is the conditional probability that a person at age \(x\) will die between age \(x\) and the next age in the series. For the last age, \(\mathrm{q} \times\) represents probabilities or counts for all ages after the last age.

The last row of the N -by-num output for qx is the values for all ages on or after the last age in \(x\) (due to "Forced Termination" on page 18-769). Therefore, the last row of qx contains 1 ( \(100 \%\) probability of dying on or after the last age).

\section*{lx - Survival counts for N ages and num series} matrix

Survival counts for \(N\) ages and num series, returned as an \(N\)-by-num matrix. The series 1 x is the number of people alive at age \(x\), given 100,000 alive at birth.

\section*{dx - Decrement counts for N ages and num series matrix}

Decrement counts for N ages and num series, returned as an N -by-num matrix. The series \(d x\) is the number of people out of 100,000 alive at birth who die between age \(x\) and the
next age in the series. For the last age, dx represent probabilities or counts for all ages after the last age.

The last row of the N -by-num output for dx are values for all ages on or after the last age in \(x\) (due to "Forced Termination" on page 18-769). Therefore, the last row of dx contains the remaining count of 100,000 people alive at birth who have not died by the last age.

\section*{More About}

\section*{Forced Termination}

Most modern life tables have "forced" termination. Forced termination means that the last row of the life table applies for all persons with ages on or after the last age in the life table. This sample illustrates forced termination.

United States Life Tables 2009
\begin{tabular}{|c|c|c|c|c|c|c|c|c|}
\hline & \(1 \times\) WM & \(l_{x}\) WF & \(I_{x} \mathrm{BM}\) & \(1 \times \mathrm{BF}\) & \(q_{\times}\)WM & \(q_{\times}\)WF & \(q_{\times} \mathrm{BM}\) & \(q_{\times} \mathrm{BF}\) \\
\hline 93 & 9533 & 18368 & 6615 & 15685 & 0.219553 & 0.177156 & 0.200605 & 0.157858 \\
\hline 94 & 7440 & 15114 & 5288 & 13209 & 0.23871 & 0.194852 & 0.214448 & 0.170868 \\
\hline 95 & 5664 & 12169 & 4154 & 10952 & 0.258475 & 0.213411 & 0.229177 & 0.184624 \\
\hline 96 & 4200 & 9572 & 3202 & 8930 & 0.27881 & 0.232971 & 0.24391 & 0.198992 \\
\hline 97 & 3029 & 7342 & 2421 & 7153 & 0.299439 & 0.253337 & 0.259397 & 0.214036 \\
\hline 98 & 2122 & 5482 & 1793 & 5622 & 0.320452 & 0.27417 & 0.274958 & 0.229634 \\
\hline 99 & 1442 & 3979 & 1300 & 4331 & 0.341886 & 0.295803 & 0.291538 & 0.245671 \\
\hline 100+ & 949 & 2802 & 921 & 3267 & 1 & 1 & 1 & 1 \\
\hline
\end{tabular}

In this case, the last row of the life table applies for all persons aged 100 or older. Specifically, \(q_{x}\) probabilities are \({ }_{1} q_{x}\) for ages less than 100 and, technically, \({ }_{\infty} q_{x}\) for age 100.

Forced termination has terminal age values that apply to all ages after the terminal age so that \(l \mathrm{x}\) is positive, qx is 1 , and dx is positive. Ages after the terminal age are NaN values, although \(l x\) and \(d x\) can be 0 and \(q x\) can be 1 for input series. Forced termination is triggered by a naturally terminating series, the last age in a truncated series, or the first NaN value in a series.

\section*{linebreak}

Line break chart

\section*{Syntax}
linebreak(X)

\section*{Arguments}
\begin{tabular}{|l|l|}
\hline\(X\) & \begin{tabular}{l} 
M -by-2 matrix where the first column contains date numbers and \\
the second column is the asset price.
\end{tabular} \\
\hline
\end{tabular}

\section*{Description}
linebreak (X) plots asset price with respect to dates.

\section*{Examples}

\section*{Create a Line Break Chart}

This example shows how to generate a line break chart for asset X that is an M-by-2 matrix of date numbers and asset prices.
```

X = [...

```
\begin{tabular}{ll}
733299.00 & \(41.99 ; \ldots\) \\
733300.00 & \(42.14 ; \ldots\) \\
733303.00 & \(41.93 ; \ldots\) \\
733304.00 & \(41.98 ; \ldots\) \\
733305.00 & \(41.75 ; \ldots\) \\
733306.00 & \(41.61 ; \ldots\) \\
733307.00 & \(42.29 ; \ldots\) \\
733310.00 & \(42.19 ; \ldots\)
\end{tabular}
\begin{tabular}{rr}
733311.00 & 41.82 \\
733312.00 & 41.9 \\
733313.00 & 41.81 \\
733314.00 & 41.3 \\
733317.00 & 41.1 \\
733318.00 & 42.02 \\
linebreak(X) & \\
& \\
\(X\) & \\
& \\
\(1.0 e+05\) * & \\
7.3330 & 0.0004 \\
7.3330 & 0.0004 \\
7.3330 & 0.0004 \\
7.3330 & 0.0004 \\
7.3331 & 0.0004 \\
7.3331 & 0.0004 \\
7.3331 & 0.0004 \\
7.3331 & 0.0004 \\
7.3331 & 0.0004 \\
7.3331 & 0.0004 \\
7.3331 & 0.0004 \\
7.3331 & 0.0004 \\
7.3332 & 0.0004 \\
7.3332 & 0.0004
\end{tabular}

Introduced in R2008a

\section*{llow}

Lowest low

\section*{Syntax}
```

llv = llow(data)
llv = llow(data, nperiods, dim)
llvts = llow(tsobj, nperiods)
llvts = llow(tsobj, nperiods, 'ParameterName', ParameterValue, ...)

```

\section*{Arguments}
\begin{tabular}{|l|l|}
\hline data & Data series matrix. \\
\hline nperiods & (Optional) Number of periods. Default \(=14\). \\
\hline dim & Dimension. \\
\hline tsobj & Financial time series object. \\
\hline 'ParameterName' & \begin{tabular}{l} 
The valid parameter name is: \\
- LowName: low prices series name
\end{tabular} \\
\hline ParameterValue & \begin{tabular}{l} 
The parameter value is a string that represents the valid \\
parameter name.
\end{tabular} \\
\hline
\end{tabular}

\section*{Description}
llv = llow(data) generates a vector of lowest low values for the past 14 periods from the matrix data.
llv = llow(data, nperiods, dim) generates a vector of lowest low values for the past nperiods periods. dim indicates the direction in which the lowest low is to be searched. If you input [ ] for nperiods, the default is 14.
llvts = llow(tsobj, nperiods) generates a vector of lowest low values from tsobj, a financial time series object. tsobj must include at least the series Low. The output llvts is a financial time series object with the same dates as tsobj and data series named LowestLow. If nperiods is specified, llow generates a financial time series object of lowest low values for the past nperiods periods.
llvts = llow(tsobj, nperiods, 'ParameterName', ParameterValue, ...) specifies the name for the required data series when it is different from the default name. The parameter value is a string that represents the valid parameter name.

\section*{Examples}

\section*{Compute the Lowest Low Price}

This example shows how to compute the lowest low price for Disney stock and plot the results.
```

load disney.mat
dis_LLow = llow(dis);
plot(dis_LLow)
title('Lōwest Low for Disney')

```

\section*{lpm}

Compute sample lower partial moments of data

\section*{Syntax}
```

lpm(Data)
lpm(Data, MAR)
lpm(Data, MAR, Order)
Moment = lpm(Data, MAR, Order)

```

\section*{Arguments}
\begin{tabular}{|l|l|}
\hline Data & \begin{tabular}{l} 
NUMSAMPLES-by-NUMSERIES matrix with NUMSAMPLES observations \\
of NUMSERIES asset returns.
\end{tabular} \\
\hline MAR & \begin{tabular}{l} 
(Optional) Scalar minimum acceptable return (default MAR \(=0\) ). \\
This is a cutoff level of return such that all returns above MAR \\
contribute nothing to the lower partial moment.
\end{tabular} \\
\hline Order & \begin{tabular}{l} 
(Optional) Either a scalar or a NUMORDERS vector of nonnegative \\
integer moment orders. If no order specified, default Order \(=0\), \\
which is the shortfall probability. Although this function works for \\
noninteger orders and, in some cases, for negative orders, this falls \\
outside customary usage.
\end{tabular} \\
\hline
\end{tabular}

\section*{Description}

Given NUMSERIES assets with NUMSAMPLES returns in a NUMSAMPLES-by-NUMSERIES matrix Data, a scalar minimum acceptable return MAR, and one or more nonnegative moment orders in a NUMORDERS vector Order, lpm computes lower partial moments relative to MAR for each asset in a NUMORDERS x NUMSERIES matrix Moment.

The output Moment is a NUMORDERS x NUMSERIES matrix of lower partial moments with NUMORDERS Orders and NUMSERIES series, that is, each row contains lower partial moments for a given order.

Note: To compute upper partial moments, reverse the signs of both Data and MAR (do not reverse the sign of the output). This function computes sample lower partial moments from data. To compute expected lower partial moments for multivariate normal asset returns with a specified mean and covariance, use elpm. With lpm, you can compute various investment ratios such as Omega ratio, Sortino ratio, and Upside Potential ratio, where:
- Omega = lpm(-Data, -MAR, 1) / lpm(Data, MAR, 1)
- Sortino \(=(\) mean (Data) - MAR) \(/ \operatorname{sqrt(lpm(Data,~MAR,~2))~}\)
- Upside = lpm(-Data, -MAR, 1) / sqrt(lpm(Data, MAR, 2))

\section*{Examples}

See "Sample Lower Partial Moments" on page 7-14.

\section*{More About}
- "Overview of Performance Metrics" on page 7-2

\section*{References}

18 Functions - Alphabetical List

Introduced in R2006b

\section*{Iweekdate}

Date of last occurrence of weekday in month

\section*{Syntax}

LastDate = lweekdate(Weekday, Year, Month, NextDay)

\section*{Arguments}
\begin{tabular}{|l|l|l|}
\hline Weekday & \multicolumn{2}{|l|}{ Weekday whose date you seek. Enter as an integer from 1 through } \\
& \(7:\) & Sunday \\
\hline & 1 & Monday \\
\hline & 2 & Tuesday \\
\hline & 3 & Wednesday \\
\hline & 4 & Thursday \\
\hline & 5 & Friday \\
\hline Year & 6 & Saturday \\
\hline Month & 7 & Year. Enter as a four-digit integer. \\
\hline NextDay & \begin{tabular}{l} 
Month. Enter as an integer from 1 through 12. \\
(Optional) Weekday that must occur after Weekday in the same \\
week. Enter as an integer from 0 through 7, where 0 = ignore \\
(default) and 1 through 7 are the same as for Weekday.
\end{tabular} \\
\hline
\end{tabular}

Any input can contain multiple values, but if so, all other inputs must contain the same number of values or a single value that applies to all. For example, if Year is a 1-by-n vector of integers, then Month must be a 1-by-n vector of integers or a single integer. LastDate is then a 1 -by-n vector of date numbers.

\section*{Description}

LastDate = lweekdate (Weekday, Year, Month, NextDay) returns the serial date number for the last occurrence of Weekday in the given year and month and in a week that also contains NextDay.

Use the function datestr to convert serial date numbers to formatted date strings.

\section*{Examples}

Example 1. To find the last Monday in June 2001
LastDate \(=\) lweekdate (2, 2001, 6); datestr(LastDate)
ans \(=\)
25-Jun-2001
Example 2. To find the last Monday in a week that also contains a Friday in June 2001
```

LastDate = lweekdate(2, 2001, 6, 6); datestr(LastDate)

```
ans \(=\)
25-Jun-2001
Example 3. To find the last Monday in May for 2001, 2002, and 2003
```

Year = [2001:2003];
LastDate = lweekdate(2, Year, 5)
LastDate =
730999 731363 731727
datestr(LastDate)
ans =
28-May-2001
27-May-2002
26-May-2003

```

\author{
See Also \\ eomdate | lbusdate | nweekdate \\ Introduced before R2006a
}

\section*{m2xdate}

MATLAB serial date number to Excel serial date number

\section*{Syntax}

DateNum = m2xdate(MATLABDateNumber, Convention)

\section*{Arguments}
\begin{tabular}{|c|c|}
\hline MATLABDateNumber & A vector or scalar of MATLAB serial date numbers. \\
\hline Convention & \begin{tabular}{l}
(Optional) Excel date system. A vector or scalar. When Convention = 0 (default), the Excel 1900 date system is in effect. When Convention = 1, the Excel 1904 date system in used. \\
In the Excel 1900 date system, the Excel serial date number 1 corresponds to January 1, 1900 A.D. In the Excel 1904 date system, date number 0 is January 1, 1904 A.D. \\
Due to a software limitation in Excel software, the year 1900 is considered a leap year. As a result, all DATEVALUE's reported by Excel software between Jan. 1, 1900 and Feb. 28,1900 (inclusive) differs from the values reported by 1. For example: \\
- In Excel software, Jan. 1, \(1900=1\) \\
- In MATLAB, Jan. 1, 1900 - 693960 (for 1900 date system) \(=2\) \\
datenum('Jan 1, 1900') - 693960 \\
ans \(=\) \\
2
\end{tabular} \\
\hline
\end{tabular}

Vector arguments must have consistent dimensions.

\section*{Description}

DateNum = m2xdate(MATLABDateNumber, Convention) converts MATLAB serial date numbers to Excel serial date numbers. MATLAB date numbers start with 1 = January 1, 0000 A.D., hence there is a difference of 693960 relative to the 1900 date system, or 695422 relative to the 1904 date system. This function is useful with Spreadsheet Link \({ }^{\text {TM }}\) EX software.

\section*{Examples}

\section*{Convert MATLAB Serial Date Numbers Using 1900 Date System}

This example shows how to convert MATLAB serial date numbers using the 1900 date system. Given MATLAB date numbers for Christmas 2001 through 2004, convert them to Excel date numbers in the 1900 system.
```

DateNum = datenum(2001:2004, 12, 25);

```
ExDate = m2xdate (DateNum)

\section*{ExDate =}
\(\begin{array}{llll}37250 & 37615 & 37980 & 38346\end{array}\)

\section*{Convert MATLAB Serial Date Numbers Using 1904 Date System}

This example shows how to convert MATLAB serial date numbers using the 1904 date system. Given MATLAB date numbers for Christmas 2001 through 2004, convert them to Excel date numbers in the 1904 system.

DateNum = datenum(2001:2004, 12, 25);
ExDate = m2xdate (DateNum, 1)

ExDate =
\(35788 \quad 36153 \quad 36518 \quad 3684\)
- "Handle and Convert Dates" on page 2-4

\author{
See Also \\ datenum | datestr | x2mdate \\ Introduced before R2006a
}

\section*{macd}

Moving Average Convergence/Divergence (MACD)

\section*{Syntax}
```

[macdvec, nineperma] = macd(data)

```
[macdvec, nineperma] = macd(data, dim)
macdts = macd(tsobj, series_name)

\section*{Arguments}
\begin{tabular}{|l|l|}
\hline data & Data matrix \\
\hline dim & Dimension. Default = 1 (column orientation). \\
\hline tsobj & Financial time series object \\
\hline series_name & Data series name \\
\hline
\end{tabular}

\section*{Description}
[macdvec, nineperma] = macd(data) calculates the Moving Average Convergence/ Divergence (MACD) line, macdvec, from the data matrix, data, and the nine-period exponential moving average, nineperma, from the MACD line.

When the two lines are plotted, they can give you an indication of whether to buy or sell a stock, when an overbought or oversold condition is occurring, and when the end of a trend might occur.

The MACD is calculated by subtracting the 26-period (7.5\%) exponential moving average from the 12 -period ( \(15 \%\) ) moving average. The 9 -day ( \(20 \%\) ) exponential moving average of the MACD line is used as the signal line. For example, when the MACD and the \(20 \%\) moving average line have just crossed and the MACD line falls below the other line, it is time to sell.
[macdvec, nineperma] = macd(data, dim) lets you specify the orientation direction for the input. If the input data is a matrix, you must indicate whether each row is a set of observations ( \(\mathrm{dim}=2\) ) or each column is a set of observations (dim \(=1\), the default).
macdts = macd(tsobj, series_name) calculates the MACD line from the financial time series tsobj, and the nine-period exponential moving average from the MACD line. The MACD is calculated for the closing price series in tsobj, presumed to have been named Close. The result is stored in the financial time series object macdts. The macdts object has the same dates as the input object tsobj and contains only two series, named MACDLine and NinePerMA. The first series contains the values representing the MACD line and the second is the nine-period exponential moving average of the MACD line.

\section*{Examples}

\section*{Compute the Moving Average Convergence/Divergence (MACD)}

This example shows how to compute the MACD for Disney stock and plot the results.
```

load disney.mat
dis_CloseMACD = macd(dis);
dis_OpenMACD = macd(dis, 'OPEN');
plot(dis_CloseMACD);
plot(dis_OpenMACD);
title('MA\overline{CD for Disney')}

```

\section*{max}

Maximum value

\section*{Syntax}
```

tsmax = max(tsobj)

```

\section*{Description}
tsmax = max(tsobj) finds the maximum value in each data series in the financial time series object ( tsobj ) and returns it in a structure tsmax. The tsmax structure contains field name(s) identical to the data series name(s).

Note tsmax returns only the values and does not return the dates associated with the values. The maximum values are not necessarily from the same date.

\section*{See Also}
min

\section*{Related Examples}

\section*{maxdrawdown}

Compute maximum drawdown for one or more price series

\section*{Syntax}
```

MaxDD = maxdrawdown(Data)
MaxDD = maxdrawdown(Data, Format)
[MaxDD, MaxDDIndex] = maxdrawdown(Data, Format)

```

\section*{Arguments}
\begin{tabular}{|l|l|}
\hline Data & \begin{tabular}{l} 
T-by-N matrix with T samples of N total return price series (also \\
known as total equity).
\end{tabular} \\
\hline Format & \begin{tabular}{l} 
(Optional) MATLAB string indicating format of data. Possible \\
values are:
\end{tabular} \\
\hline & \begin{tabular}{l} 
'return ' (default) - Maximum drawdown in terms of maximum \\
percentage drop from a peak.
\end{tabular} \\
\hline & \begin{tabular}{l} 
'arithmetic ' - Maximum drawdown of an arithmetic Brownian \\
motion with drift (differences of data from peak to trough) using the \\
equation
\end{tabular} \\
\(d X(t)=\mu d t+\sigma d W(t)\). \\
'geometric ' - Maximum drawdown of a geometric Brownian \\
motion with drift (differences of log of data from peak to trough) \\
using the equation
\end{tabular}\(\quad\)\begin{tabular}{l}
\(d S(t)=\mu_{0} S(t) d t+\sigma_{0} S(t) d W(t)\)
\end{tabular}

\section*{Description}

MaxDD = maxdrawdown(Data, Format) computes maximum drawdown for each series in an N -vector MaxDD and identifies start and end indexes of maximum drawdown periods for each series in a 2-by-N matrix MaxDDIndex.

To summarize the outputs of maxdrawdown:
- MaxDD is a 1 -by- N vector with maximum drawdown for each of N time series.
- MaxDDIndex is a 2-by-N vector of start and end indexes for each maximum drawdown period for each total equity time series, where the first row contains the start indexes and the second row contains the end indexes of each maximum drawdown period.

\section*{Notes}
- Drawdown is the percentage drop in total returns from the start to the end of a period. If the total equity time series is increasing over an entire period, drawdown
is 0 . Otherwise, it is a positive number. Maximum drawdown is an ex-ante proxy for downside risk that computes the largest drawdown over all intervals of time that can be formed within a specified interval of time.
- Maximum drawdown is sensitive to quantization error.

\section*{Examples}

See "Maximum Drawdown" on page 7-17.

\section*{More About}
- "Overview of Performance Metrics" on page 7-2

\section*{References}

Introduced before R2006a

\section*{medprice}

Median price

\section*{Syntax}
```

mprc = medprice(highp, lowp)
mprc = medprice([highp lowp])
mprcts = medprice(tsobj)
mprcts = medprice(tsobj, 'ParameterName', ParameterValue, ...)

```

\section*{Arguments}
\begin{tabular}{|l|l|}
\hline highp & High price (vector) \\
\hline lowp & Low price (vector) \\
\hline tsobj & Financial time series object \\
\hline 'ParameterName' & \begin{tabular}{l} 
Valid parameter names are: \\
\\
- HighName - high prices series name \\
- LowName - low prices series name
\end{tabular} \\
\hline ParameterValue & \begin{tabular}{l} 
Parameter values are the strings that represent the valid \\
parameter names.
\end{tabular} \\
\hline
\end{tabular}

\section*{Description}
mprc \(=\) medprice (highp, lowp) calculates the median prices mprc from the high (highp) and low (lowp) prices. The median price is the average of the high and low price for each period.
mprc = medprice ([highp lowp]) accepts a two-column matrix as the input rather than two individual vectors. The columns of the matrix represent the high and low prices, in that order.
mprcts \(=\) medprice(tsobj) calculates the median prices of a financial time series object tsobj. The object must minimally contain the series High and Low. The median price is the average of the high and low price each period. mprcts is a financial time series object with the same dates as tsobj and the data series MedPrice.
mprcts = medprice(tsobj, 'ParameterName', ParameterValue, ...) accepts parameter name/parameter value pairs as input. These pairs specify the name(s) for the required data series if it is different from the expected default name(s). Parameter values are the strings that represent the valid parameter names.

\section*{Examples}

\section*{Compute the Median Price}

This example shows how to compute the median price for Disney stock and plot the results.
load disney.mat
dis_MedPrice = medprice(dis);
plot(dis_MedPrice)
title('Median Price for Disney')

\section*{merge}

Merge multiple financial time series objects

\section*{Syntax}
```

newfts = merge(fts1, fts2)
newfts = merge(fts1, fts2, ..., ftsx)
newfts = merge(fts1, fts2, ..., ftsx, 'PARAM1', VALUE1, 'PARAM2',
VALUE2, ...)

```

\section*{Arguments}
\begin{tabular}{|ll|}
\hline \begin{tabular}{l} 
fts1, \\
fts2, \(\ldots\)
\end{tabular} & Comma-separated list of financial time series objects to merge. \\
& \begin{tabular}{l} 
Note Multiple Financial Time Series objects can be merged at \\
once. The merged objects must appear in a comma separated \\
list before the optional inputs. The order of the inputs is \\
significant.
\end{tabular} \\
\hline 'DateSetMethod' & \begin{tabular}{l} 
(Optional) Merge method. Valid merge values are: \\
'union' — (Default) Returns the combined values of all \\
merged objects. \\
'intersection ' — Returns the values common to all merged \\
objects.
\end{tabular} \\
\hline \begin{tabular}{l} 
Ref0bj — Maps all values to a reference time contained in \\
a Financial Time Series object (RefObj) or vector of date \\
numbers.
\end{tabular} \\
\hline 'DataSetMethod' & \begin{tabular}{l} 
(Optional) Merge method. Valid merge values are: \\
'closest ' - (Default) Returns data based on the order of \\
the inputs. However, the first missing data point (NaN value) of
\end{tabular}
\end{tabular}
\begin{tabular}{|l|l|} 
& \begin{tabular}{l} 
a date will be replaced by the closest non-NaN data point that \\
appears on the same date of subsequent merged objects. \\
'order' — Returns data based strictly on the order of the \\
inputs.
\end{tabular} \\
\hline 'SortColumns' & \begin{tabular}{l} 
(Optional) Sorts columns. Valid merge values are: \\
True \(/ 1\) - (Default) Sorts the columns based on the headers \\
(series names). The headers are sorted in alphabetical order.
\end{tabular} \\
False/0 - Columns are not sorted.
\end{tabular}

\section*{Description}
newfts = merge(fts1, fts2, ..., ftsx, 'PARAM1', VALUE1, 'PARAM2', VALUE2', ...) merges multiple financial time series objects. The optional parameter and value pair argument specifies the values contained in the output financial time series object ftsout.

\section*{Examples}

\section*{Create Three Financial Time Series Objects and Merge into a Single Object}

Create three financial time series objects and merged into a new time series object t123.
```

dates = {'jan-01-2001'; 'jan-02-2001'; 'jan-03-2001'; ...
' jan-04-2001'; ' jan-06-2001'};
data = [1; 1; 1; 1; 1];
t1 = fints(dates, data);
dates = {'jan-02-2001'; 'jan-03-2001'; 'jan-04-2001';
jan-05-2001'};
data = [2; 2; 2; 2];
t2 = fints(dates, data);
dates = {'jan-03-2001'; 'jan-04-2001'; 'jan-05-2001';
jan-06-2001'};
data = [3; 3; 3; 3];

```
```

t3 = fints(dates, data);
t123 = merge(t1, t2, t3)
t123 =
desc: || ||
freq: Unknown (0)
'dates: (6)' 'series1: (6)
'01-Jan-2001' [ 1]
'02-Jan-2001' [ 1]
'03-Jan-2001' [ 1]
'04-Jan-2001' [ 1]
'05-Jan-2001' [ 2]
'06-Jan-2001' [ 1]

```

If you change the order of input time series, the output may contain different data when duplicate dates exist. Here, for example, is the result of using the same three time series defined above but with the order changed.
```

merge(t3, t2, t1)

```
ans \(=\)
desc: || ||
freq: Unknown (0)
\begin{tabular}{lll} 
'dates: (6)' & 'series1: & (6)' \\
'01-Jan-2001' & {\([\)} & \(1]\) \\
'02-Jan-2001' & {\([\)} & \(2]\) \\
'03-Jan-2001' & {\([\)} & \(3]\) \\
'04-Jan-2001' & {\([\)} & \(3]\) \\
'05-Jan-2001' & {\([\)} & \(3]\) \\
'06-Jan-2001' & {\([\)} & \(3]\)
\end{tabular}
t123 contains all 1's except on '05-Jan-2001' because t1 appears first in the list of inputs and takes precedence. The same logic can be applied to t 321 . By changing the
order of inputs, you can overwrite old financial time series data with new data by placing the new time series ahead of the old one in the list of inputs to the merge function.

\section*{Merge Financial Time Series Objects with Different Headers (Series Names)}

Merge time series objects with different headers into a new time series object t45.
```

dates = {'jan-01-2001'; 'jan-02-2001'; 'jan-03-2001'; ...
'jan-04-2001'; 'jan-06-2001'};
data = [1; 1; 1; 1; 1];
t4 = fints(dates, data, 'ts4');
dates = {'jan-02-2001'; 'jan-03-2001'; 'jan-04-2001'; 'jan-05-2001'};
data = [2; 2; 2; 2];
t5 = fints(dates, data, 'ts5');
t45 = merge(t4, t5)
t45 =
desc: ||
freq: Unknown (0)

| ates: (6) | ts4: (6) | 'ts5: (6) |
| :---: | :---: | :---: |
| '01-Jan-2001' | [ 1] | NaN] |
| '02-Jan-2001' | [ 1] | $2]$ |
| '03-Jan-2001' | $1]$ | $2]$ |
| '04-Jan-2001' | $1]$ | $2]$ |
| '05-Jan-2001' | NaN] | 2] |
| '06-Jan-2001' | $1]$ | NaN ] |

```

\section*{Merge Two Financial Index Series and Keep Intersecting Dates}

Merge two index series into the final merged object (t12) and keep the intersecting dates.
```

dates = {'jan-01-2001'; 'jan-02-2001'; 'jan-03-2001'; 'jan-04-2001'; 'jan-06-2001'};
data = [1; 1; 1; 1; 1];
t1 = fints(dates, data,'A')
dates = {'jan-02-2001'; 'jan-03-2001'; 'jan-04-2001'; 'jan-05-2001'};
data = [2; 2; 2; 2];
t2 = fints(dates, data,'B')

```
```

t12 = merge(t1, t2,'DateSetMethod','Intersection')
t1 =
desc: (none)
freq: Unknown (0)
'dates: (5)' 'A: (5)
'01-Jan-2001' [ 1]
'02-Jan-2001' [ 1]
'03-Jan-2001' [ 1]
'04-Jan-2001' [ 1]
'06-Jan-2001' [ 1]
t2 =
desc: (none)
freq: Unknown (0)
'dates: (4)' 'B: (4)
'02-Jan-2001' [ 2]
'03-Jan-2001' [ 2]
'04-Jan-2001' [ 2]
'05-Jan-2001' [ 2]
t12 =
desc: ||
freq: Unknown (0)
'dates: (3)' 'A: (3)' 'B: (3)'
'02-Jan-2001' [ 1] [ 2]
'03-Jan-2001' [ 1] [ 2]
'04-Jan-2001' [ 1] [ 2]

\section*{min}

Minimum value

\section*{Syntax}
```

tsmin = min(tsobj)

```

\section*{Description}
tsmin \(=\min (t s o b j)\) finds the minimum value in each data series in the financial time series object (tsobj) and returns it in the structure tsmin. The tsmin structure contains field name(s) identical to the data series name(s).

Note tsmin returns only the values and does not return the dates associated with the values. The minimum values are not necessarily from the same date.

Introduced before R2006a

\section*{minus}

Financial time series subtraction

\section*{Syntax}
```

newfts = tsobj_1 - tsobj_2
newfts = tsobj - array
newfts = array - tsobj

```

\section*{Arguments}
\begin{tabular}{|l|l|}
\hline tsobj_1, tsobj_2 & A pair of financial time series objects . \\
\hline array & \begin{tabular}{l} 
A scalar value or array with the number of rows equal to the \\
number of dates in tsobj and the number of columns equal \\
to the number of data series in tsobj.
\end{tabular} \\
\hline
\end{tabular}

\section*{Description}
minus is an element-by-element subtraction of the components.
newfts = tsobj_1 - tsobj_2 subtracts financial time series objects. If an object is to be subtracted from another object, both objects must have the same dates and data series names, although the order need not be the same. The order of the data series, when one financial time series object is subtracted from another, follows the order of the first object.
newfts = tsobj - array subtracts an array element by element from a financial time series object.
newfts = array - tsobj subtracts a financial time series object element by element from an array.

\section*{minute}

Minute of date or time

\section*{Syntax}

Minute = minute(Date)

\section*{Description}

Minute = minute(Date) returns the minute given a serial date number or a date string.

\section*{Examples}

Minute \(=\) minute(731204.5591223380)
or
Minute = minute('19-dec-2001, 13:25:08.17')
returns
Minute =
25

\author{
See Also \\ datevec | hour | second \\ Introduced before R2006a
}

\section*{mirr}

Modified internal rate of return

\section*{Syntax}

Return = mirr(CashFlow, FinRate, Reinvest)

\section*{Arguments}
\begin{tabular}{|l|l|}
\hline CashFlow & Vector of cash flows. The first entry is the initial investment. \\
\hline FinRate & \begin{tabular}{l} 
Finance rate for negative cash flow values. Enter as a decimal \\
fraction.
\end{tabular} \\
\hline Reinvest & \begin{tabular}{l} 
Reinvestment rate for positive cash flow values, as a decimal \\
fraction.
\end{tabular} \\
\hline
\end{tabular}

\section*{Description}

Return = mirr(CashFlow, FinRate, Reinvest) calculates the modified internal rate of return for a series of periodic cash flows. This function calculates only positive rates of return; for nonpositive rates of return, Return \(=0\).

\section*{Examples}

This cash flow represents the yearly income from an initial investment of \(\$ 100,000\). The finance rate is \(9 \%\) and the reinvestment rate is \(12 \%\).
\begin{tabular}{|l|l|}
\hline Year 1 & \(\$ 20,000\) \\
\hline Year 2 & \((\$ 10,000)\) \\
\hline Year 3 & \(\$ 30,000\) \\
\hline Year 4 & \(\$ 38,000\) \\
\hline Year 5 & \(\$ 50,000\) \\
\hline
\end{tabular}
```

To calculate the modified internal rate of return on the investment
Return = mirr([-100000 20000 -10000 30000 38000 50000], 0.09,...
0.12)
returns
Return =
0.0832 (8.32%)

```

\section*{month}

Month of date

\section*{Syntax}
[MonthNum, MonthString] = month(Date)
[MonthNum, MonthString] = month(Date, F)

\section*{Description}
[MonthNum, MonthString] = month(Date) returns the month in numeric and string form given a serial date number or a date string.
[MonthNum, MonthString] = month(Date, F) returns the day of the of the month, given a serial date number or date string, in a specified date format.

\section*{Examples}
[MonthNum, MonthString] \(=\) month(730368)
or
[MonthNum, MonthString] = month('05-Sep-1999')
returns
MonthNum =

9

MonthString =
Sep
You can also use the \(F\) argument to designate a country-specific date format:
[MonthNum, MonthString] = month('1999/05/09', 'yyyy/dd/mm')
returns
hmiMonthNum =

9

MonthString =
Sep

\section*{See Also}
datevec | day | year
Introduced before R2006a

\section*{months}

Number of whole months between dates

\section*{Syntax}

MyMonths = months(StartDate, EndDate, EndMonthFlag)

\section*{Arguments}
\begin{tabular}{|l|l|}
\hline StartDate & Enter as serial date numbers or date strings. \\
\hline EndDate & Enter as serial date numbers or date strings. \\
\hline EndMonthFlag & \begin{tabular}{l} 
(Optional) end-of-month flag. If StartDate and EndDate \\
are end-of-month dates and EndDate has fewer days than \\
StartDate, EndMonthFlag = 1 (default) treats EndDate \\
as the end of a whole month, while EndMonthFlag = 0 \\
does not.
\end{tabular} \\
\hline
\end{tabular}

\section*{Description}

MyMonths = months(StartDate, EndDate, EndMonthFlag) returns the number of whole months between StartDate and EndDate. If EndDate is earlier than StartDate, MyMonths is negative. Enter dates as serial date numbers or date strings.

Any input argument can contain multiple values, but if so, all other inputs must contain the same number of values or a single value that applies to all. For example, if StartDate is an \(n\)-row character array of date strings, then EndDate must be an \(n\)-row character array of date strings or a single date. MyMonths is then an \(n\)-by- 1 vector of numbers.

\section*{Examples}

MyMonths = months('may \(312000^{\prime}, \quad\) 'jun \(\left.302000^{\prime}, 1\right)\)
```

MyMonths =
1
MyMonths = months('may 31 2000','jun 30 2000', 0)
MyMonths =
0
Dates = ['mar 31 2002'; 'apr 30 2002'; 'may 31 2002'];
MyMonths = months(Dates, 'jun 30 2002')
MyMonths =
3
2
1

```

\author{
See Also yearfrac
}
```

Introduced before R2006a

```

\section*{movavg}

Leading and lagging moving averages chart

\section*{Syntax}
```

movavg(Asset, Lead, Lag, Alpha)
[Short, Long] = movavg(Asset, Lead, Lag, Alpha)

```

\section*{Arguments}
\begin{tabular}{|l|l|}
\hline Asset & Security data, a vector of time-series prices. \\
\hline Lead & \begin{tabular}{l} 
Number of samples to use in leading average calculation. A positive \\
integer. Lead must be less than or equal to Lag.
\end{tabular} \\
\hline Lag & \begin{tabular}{l} 
Number of samples to use in the lagging average calculation. A \\
positive integer.
\end{tabular} \\
\hline Alpha & \begin{tabular}{l} 
(Optional) Control parameter that determines the type of moving \\
averages. \(0=\) simple moving average (default), \(0.5=\) square root \\
weighted moving average, \(1=\) linear moving average, \(2=\) square \\
weighted moving average, and so on. To calculate the exponential \\
moving average, set Alpha \(=\) ' e '.
\end{tabular} \\
\begin{tabular}{l} 
Note: When Alpha = 'e ' , the value of the moving average depends \\
on all previous data points (due to the iterative calculation). In \\
this case, the Lead and Lag parameters are used to calculate the \\
weighting factor for their respective averages (which is different \\
from the number of samples).
\end{tabular} \\
\hline
\end{tabular}

\section*{Description}
movavg(Asset, Lead, Lag, Alpha) plots leading and lagging moving averages.
[Short, Long] = movavg(Asset, Lead, Lag, Alpha) returns the leading Short and lagging Long moving average data without plotting it.

Note: m, When using movavg syntax with output arguments, zero padding is used at the edges of the data. If you use movavg without output arguments, there is no zero padding in the data for the plot.

\section*{Examples}

\section*{Compute the Moving Average for DIS Closing Prices}

Load the DIS closing prices using disney. mat.
load disney.mat
Use movavg to plot the leading and lagging moving averages for DIS.
```

movavg(dis_CLOSE,3,20,1);ylabel('Price')
legend('Asset Price','Lagging Long','Leading Short')

```

Introduced before R2006a

\section*{mrdivide}

Financial time series matrix division

\section*{Syntax}
```

newfts = tsobj_1 / tsobj_2
newfts = tsobj / array
newfts = array / tsobj

```

\section*{Arguments}
\begin{tabular}{|l|l|}
\hline tsobj_1, tsobj_2 & A pair of financial time series objects. \\
\hline array & \begin{tabular}{l} 
A scalar value or array with number of rows equal to the \\
number of dates in tsobj and number of columns equal to \\
the number of data series in tsobj.
\end{tabular} \\
\hline
\end{tabular}

\section*{Description}

The mrdivide method divides element by element the components of one financial time series object ( tsobj ) by the components of the other. You can also divide the whole object by an array or divide a financial time series object into an array.

If an object is to be divided by another object, both objects must have the same dates and data series names, although the order need not be the same. The order of the data series, when an object is divided by another object, follows the order of the first object.
newfts = tsobj_1 / tsobj_2 divides financial time series objects element by element.
newfts = tsobj / array divides a financial time series object element by element by an array.
newfts = array / tsobj divides an array element by element by a financial time series object.

For financial time series objects, the mrdivide operation is identical to the rdivide operation.

\section*{See Also}
minus | plus | rdivide | times

\section*{Related Examples}

- "Using Time Series to Predict Equity Return" on page 12-23

\section*{Introduced before R2006a}

\section*{mtimes}

Financial time series matrix multiplication

\section*{Syntax}
```

newfts = tsobj_1 * tsobj_2
newfts = tsobj * array
newfts = array * tsobj

```

\section*{Arguments}
\begin{tabular}{|l|l|}
\hline tsobj_1, tsobj_2 & A pair of financial time series objects. \\
\hline array & \begin{tabular}{l} 
A scalar value or array with number of rows equal to the \\
number of dates in tsobj and number of columns equal to \\
the number of data series in tsobj.
\end{tabular} \\
\hline
\end{tabular}

\section*{Description}

The mtimes method multiplies element by element the components of one financial time series object (tsobj) by the components of the other. You can also multiply the entire object by an array.

If an object is to be multiplied by another object, both objects must have the same dates and data series names, although the order need not be the same. The order of the data series, when an object is multiplied by another object, follows the order of the first object.
newfts = tsobj_1 * tsobj_2 multiplies financial time series objects element by element.
newfts = tsobj * array multiplies a financial time series object element by element by an array.
newfts = array * tsobj and newfts = array / tsobj multiplies an array element by element by a financial time series object.

For financial time series objects, the mtimes operation is identical to the times operation.

\section*{mvnrfish}

Fisher information matrix for multivariate normal or least-squares regression

\section*{Syntax}

Fisher = mvnrfish(Data, Design, Covariance, MatrixFormat, CovarFormat)

\section*{Arguments}
\(\left.\begin{array}{|l|l|}\hline \text { Data } & \begin{array}{l}\text { NUMSAMPLES-by-NUMSERIES matrix with NUMSAMPLES } \\
\text { samples of a NUMSERIES-dimensional random vector. If a } \\
\text { data sample has missing values, represented as NaNs, the } \\
\text { sample is ignored. }\end{array} \\
\hline \text { Design } & \begin{array}{l}\text { A matrix or a cell array that handles two model structures: } \\
\text { If NUMSERIES = 1, Design is a NUMSAMPLES- } \\
\text { by-NUMPARAMS matrix with known values. This structure } \\
\text { is the standard form for regression on a single series. } \\
\text { If NUMSERIES } \geq \text { 1, Design is a cell array. The cell array } \\
\text { contains either one or NUMSAMPLES cells. Each cell } \\
\text { contains a NUMSERIES-by-NUMPARAMS matrix of known } \\
\text { values. }\end{array} \\
\text { If Design has a single cell, it is assumed to have the } \\
\text { same Design matrix for each sample. If Design has } \\
\text { more than one cell, each cell contains a Design matrix } \\
\text { for each sample. }\end{array}\right\}\)\begin{tabular}{l} 
NUMSERIES-by-NUMSERIES matrix of estimates for the \\
covariance of the residuals of the regression.
\end{tabular}
\begin{tabular}{|l|l|}
\hline CovarFormat & \begin{tabular}{l} 
e paramonly — Compute only components of the Fisher \\
information matrix associated with the model parameter \\
estimates.
\end{tabular} \\
\hline \begin{tabular}{l} 
(Optional) String that specifies the format for the covariance \\
matrix. The choices are:
\end{tabular} \\
\begin{tabular}{l} 
- full'—Default method. The covariance matrix is a \\
full matrix. \\
'diagonal' - The covariance matrix is a diagonal \\
matrix.
\end{tabular} \\
\hline
\end{tabular}

\section*{Description}

Fisher = mvnrfish(Data, Design, Covariance, MatrixFormat, CovarFormat) computes a Fisher information matrix based on current maximum likelihood or least-squares parameter estimates.

Fisher is a TOTALPARAMS-by-TOTALPARAMS Fisher information matrix. The size of TOTALPARAMS depends on MatrixFormat and on current parameter estimates. If MatrixFormat = 'full',

TOTALPARAMS \(=\) NUMPARAMS + NUMSERIES * (NUMSERIES + 1)/2
If MatrixFormat = 'paramonly',
TOTALPARAMS = NUMPARAMS

Note mvnrfish operates slowly if you calculate the full Fisher information matrix.

\section*{Examples}

See "Multivariate Normal Linear Regression" on page 9-2.

more than one cell, each cell contains a Design matrix \\
for each sample.
\end{tabular}
\begin{tabular}{|c|c|}
\hline & precision. The convergence test for changes in model parameters is \\
\hline & \(\|\) Param \(_{k}-\) Param \(_{k-1} \|<\) TolParam \(\times\left(1+\left\|\operatorname{Param}_{k}\right\|\right)\) \\
\hline & where Param represents the output Parameters, and iteration \(k=2,3, \ldots\). Convergence is assumed when both the TolParam and TolObj conditions are satisfied. If both TolParam \(\leq 0\) and TolObj \(\leq 0\), do the maximum number of iterations (MaxIterations), whatever the results of the convergence tests. \\
\hline Tol0bj & \begin{tabular}{l}
(Optional) Convergence tolerance for estimation algorithm based on changes in the objective function. Default value is eps \(\wedge 3 / 4\) which is about \(1.0 \mathrm{e}-12\) for double precision. The convergence test for changes in the objective function is
\[
\left|\mathrm{Obj}_{k}-\mathrm{Obj}_{k-1}\right|<\operatorname{TolObj} \times\left(1+\left|\mathrm{Obj}_{k}\right|\right)
\] \\
for iteration \(k=2,3, \ldots\). Convergence is assumed when both the TolParam and TolObj conditions are satisfied. If both TolParam \(\leq 0\) and TolObj \(\leq 0\), do the maximum number of iterations (MaxIterations), whatever the results of the convergence tests.
\end{tabular} \\
\hline Covar0 & (Optional) NUMSERIES-by-NUMSERIES matrix that contains a user-supplied initial or known estimate for the covariance matrix of the regression residuals. \\
\hline CovarFormat & \begin{tabular}{l}
(Optional) String that specifies the format for the covariance matrix. The choices are: \\
- 'full' — Default method. Compute the full covariance matrix. \\
- 'diagonal' - Force the covariance matrix to be a diagonal matrix.
\end{tabular} \\
\hline
\end{tabular}

\section*{Description}
[Parameters, Covariance, Resid, Info] = mvnrmle(Data, Design, MaxIterations, TolParam, TolObj, CovarO, CovarFormat) estimates a multivariate normal regression model without missing data. The model has the form
\[
\text { Data }_{k} \sim N\left(\text { Design }_{k} \times \text { Parameters, Covariance }\right)
\]
for samples \(k=1, \ldots\), NUMSAMPLES.
mvnrmle estimates a NUMPARAMS-by-1 column vector of model parameters called Parameters, and a NUMSERIES-by-NUMSERIES matrix of covariance parameters called Covariance.
mvnrmle(Data, Design) with no output arguments plots the log-likelihood function for each iteration of the algorithm.

To summarize the outputs of mvnrmle:
- Parameters is a NUMPARAMS-by-1 column vector of estimates for the parameters of the regression model.
- Covariance is a NUMSERIES-by-NUMSERIES matrix of estimates for the covariance of the regression model's residuals.
- Resid is a NUMSAMPLES-by-NUMSERIES matrix of residuals from the regression. For any row with missing values in Data, the corresponding row of residuals is represented as all NaN missing values, since this routine ignores rows with NaN values.

Another output, Info, is a structure that contains additional information from the regression. The structure has these fields:
- Info. Obj - A variable-extent column vector, with no more than MaxIterations elements, that contain each value of the objective function at each iteration of the estimation algorithm. The last value in this vector, Obj (end), is the terminal estimate of the objective function. If you do maximum likelihood estimation, the objective function is the log-likelihood function.
- Info. PrevParameters - NUMPARAMS-by-1 column vector of estimates for the model parameters from the iteration just before the terminal iteration.
- Info. PrevCovariance - NUMSERIES-by-NUMSERIES matrix of estimates for the covariance parameters from the iteration just before the terminal iteration.

\section*{Notes}
mvnrmle does not accept an initial parameter vector, because the parameters are estimated directly from the first iteration onward.

You can configure Design as a matrix if NUMSERIES \(=1\) or as a cell array if NUMSERIES \(\geq 1\).
- If Design is a cell array and NUMSERIES \(=1\), each cell contains a NUMPARAMS row vector.
- If Design is a cell array and NUMSERIES > 1, each cell contains a NUMSERIES-by-NUMPARAMS matrix.

These points concern how Design handles missing data:
- Although Design should not have NaN values, ignored samples due to NaN values in Data are also ignored in the corresponding Design array.
- If Design is a 1-by-1 cell array, which has a single Design matrix for each sample, no NaN values are permitted in the array. A model with this structure must have NUMSERIES \(\geq\) NUMPARAMS with rank (Design\{1\}) \(=\) NUMPARAMS.
- Two functions for handling missing data, ecmmvnrmle and ecmlsrmle, are stricter about the presence of NaN values in Design.

Use the estimates in the optional output structure Info for diagnostic purposes.

\section*{Examples}

\section*{mvnrobi}

Log-likelihood function for multivariate normal regression without missing data

\section*{Syntax}

Objective = mvnrobj(Data, Design, Parameters, Covariance, CovarFormat)

\section*{Arguments}
\begin{tabular}{|l|l|}
\hline Data & \begin{tabular}{l} 
NUMSAMPLES-by-NUMSERIES matrix with NUMSAMPLES samples \\
of a NUMSERIES-dimensional random vector. If a data sample has \\
missing values, represented as NaNs, the sample is ignored. (Use \\
ecmmvnrmle to handle missing data.)
\end{tabular} \\
\hline Design & \begin{tabular}{l} 
A matrix or a cell array that handles two model structures: \\
If NUMSERIES \(=1\), Design is a NUMSAMPLES-by-NUMPARAMS \\
matrix with known values. This structure is the standard form \\
for regression on a single series. \\
If NUMSERIES 1, Design is a cell array. The cell array \\
contains either one or NUMSAMPLES cells. Each cell contains a \\
NUMSERIES-by-NUMPARAMS matrix of known values. \\
If Design has a single cell, it is assumed to have the same \\
Design matrix for each sample. If Design has more than one \\
cell, each cell contains a Design matrix for each sample.
\end{tabular} \\
\hline Parameters & \begin{tabular}{l} 
NUMPARAMS-by-1 column vector of estimates for the parameters of \\
the regression model.
\end{tabular} \\
\hline Covariance & \begin{tabular}{l} 
NUMSERIES-by-NUMSERIES matrix of estimates for the covariance \\
of the residuals of the regression.
\end{tabular} \\
\hline CovarFormat & \begin{tabular}{l} 
(Optional) String that specifies the format for the covariance \\
matrix. The choices are:
\end{tabular} \\
- 'full ' - Default method. The covariance matrix is a full \\
matrix.
\end{tabular}
\(\square\)

\section*{Description}

Objective = mvnrobj(Data, Design, Parameters, Covariance, CovarFormat) computes the log-likelihood function based on current maximum likelihood parameter estimates without missing data. Objective is a scalar that contains the log-likelihood function.

\section*{Notes}

You can configure Design as a matrix if NUMSERIES \(=1\) or as a cell array if NUMSERIES \(\geq 1\).
- If Design is a cell array and NUMSERIES = 1, each cell contains a NUMPARAMS row vector.
- If Design is a cell array and NUMSERIES > 1, each cell contains a NUMSERIES-by-NUMPARAMS matrix.

Although Design should not have NaN values, ignored samples due to NaN values in Data are also ignored in the corresponding Design array.

\section*{Examples}

See "Multivariate Normal Regression" on page 9-18, "Least-Squares Regression" on page 9-18, "Covariance-Weighted Least Squares" on page 9-19, "Feasible Generalized Least Squares" on page 9-20, and "Seemingly Unrelated Regression" on page 9-21.

Introduced in R2006a

\section*{mvnrstd}

Evaluate standard errors for multivariate normal regression model

\section*{Syntax}
[StdParameters, StdCovariance] = mvnrstd(Data, Design, Covariance, CovarFormat)

\section*{Arguments}
\begin{tabular}{|c|c|}
\hline Data & NUMSAMPLES-by-NUMSERIES matrix with NUMSAMPLES samples of a NUMSERIES-dimensional random vector. If a data sample has missing values, represented as NaNs , the sample is ignored. (Use ecmmvnrmle to handle missing data.) \\
\hline Design & \begin{tabular}{l}
A matrix or a cell array that handles two model structures: \\
- If NUMSERIES = 1, Design is a NUMSAMPLES-by-NUMPARAMS matrix with known values. This structure is the standard form for regression on a single series. \\
- If NUMSERIES \(\geq 1\), Design is a cell array. The cell array contains either one or NUMSAMPLES cells. Each cell contains a NUMSERIES-by-NUMPARAMS matrix of known values. \\
If Design has a single cell, it is assumed to have the same Design matrix for each sample. If Design has more than one cell, each cell contains a Design matrix for each sample.
\end{tabular} \\
\hline Covariance & NUMSERIES-by-NUMSERIES matrix of estimates for the covariance of the regression residuals. \\
\hline CovarFormat & \begin{tabular}{l}
(Optional) String that specifies the format for the covariance matrix. The choices are: \\
- 'full' - Default method. The covariance matrix is a full matrix. \\
- 'diagonal ' - The covariance matrix is a diagonal matrix.
\end{tabular} \\
\hline
\end{tabular}

\section*{Description}
[StdParameters, StdCovariance] = mvnrstd(Data, Design, Covariance, CovarFormat) evaluates standard errors for a multivariate normal regression model without missing data. The model has the form
\[
\text { Data }_{k} \sim N\left(\text { Design }_{k} \times \text { Parameters, Covariance }\right)
\]
for samples \(k=1, \ldots\), NUMSAMPLES.
mvnrstd computes two outputs:
- StdParameters is a NUMPARAMS-by-1 column vector of standard errors for each element of Parameters, the vector of estimated model parameters.
- StdCovariance is a NUMSERIES-by-NUMSERIES matrix of standard errors for each element of Covariance, the matrix of estimated covariance parameters.

Note mvnrstd operates slowly when you calculate the standard errors associated with the covariance matrix Covariance.

\section*{Notes}

You can configure Design as a matrix if NUMSERIES = 1 or as a cell array if NUMSERIES \(\geq 1\).
- If Design is a cell array and NUMSERIES = 1, each cell contains a NUMPARAMS row vector.
- If Design is a cell array and NUMSERIES > 1, each cell contains a NUMSERIES-by-NUMPARAMS matrix.

\section*{Examples}

See "Multivariate Normal Regression" on page 9-18, "Least-Squares Regression" on page 9-18, "Covariance-Weighted Least Squares" on page 9-19, "Feasible Generalized Least Squares" on page 9-20, and "Seemingly Unrelated Regression" on page 9-21.

\section*{More About}
- "Multivariate Normal Linear Regression" on page 9-2

Introduced in R2006a

\section*{nancov}

Covariance ignoring NaNs

\section*{Syntax}
\(c=n a n c o v(X)\)
c = nancov(..., 'pairwise')

\section*{Arguments}
\begin{tabular}{|l|l|}
\hline X & Financial times series object. \\
\hline Y & Financial times series object. \\
\hline
\end{tabular}

\section*{Description}
nancov for financial times series objects is based on the Statistics and Machine Learning Toolbox function nancov. See nancov in the Statistics and Machine Learning Toolbox documentation.
\(c=\operatorname{nancov}(X)\), if \(X\) is a financial time series object with one series and returns the sample variance of the values in X , treating NaNs as missing values. For a financial time series object containing more than one series, where each row is an observation and each series a variable, \(\operatorname{nancov}(X)\) is the covariance matrix computing using rows of \(X\) that do not contain any NaN values. \(\operatorname{nancov}(\mathrm{X}, \mathrm{Y})\), where X and Y are financial time series objects with the same number of elements, is equivalent to nancov([X(:) Y(: )]).
nancov \((X)\) or nancov \((X, Y)\) normalizes by \((N-1)\) if \(N>1\), where \(N\) is the number of observations after removing missing values. This makes nancov the best unbiased estimate of the covariance matrix if the observations are from a normal distribution. For \(N=1\), cov normalizes by \(N\).
nancov \((X, 1)\) or \(\operatorname{nancov}(X, Y, 1)\) normalizes by \(N\) and produces the second moment matrix of the observations about their mean. nancov \((X, Y, 0)\) is the same as \(\operatorname{nancov}(X, Y)\), and nancov \((X, 0)\) is the same as nancov \((X)\).
\(c=\) nancov(..., 'pairwise') computes \(c(i, j)\) using rows with no NaN values in columns ior \(j\). The result may not be a positive definite matrix. \(c=\) nancov (..., 'complete') is the default, and it omits rows with any NaN values, even if they are not in column \(i\) or \(j\). The mean is removed from each column before calculating the result.

\section*{Examples}

To generate random data having nonzero covariance between column 4 and the other columns:
```

x = randn(30, 4); % uncorrelated data
x(:, 4) = sum(x, 2); % introduce correlation
x(2, 3) = NaN; % introduce one missing value
f = fints((today:today+29)', x); % create a fints object using x
c = nancov(f) % compute sample covariance
C =

| 1.6898 | -0.0005 | 0.3612 | 1.9143 |
| ---: | ---: | ---: | ---: |
| -0.0005 | 1.0833 | -0.5513 | 0.6059 |
| 0.3612 | -0.5513 | 1.0369 | 0.7570 |
| 1.9143 | 0.6059 | 0.7570 | 4.4895 |

```

\section*{nanmax}

Maximum ignoring NaNs

\section*{Syntax}
```

m = nanmax(X)
[m,ndx] = nanmax(X)
m = nanmax(X,Y)
[m,ndx] = nanmax(X,[],DIM)

```

\section*{Arguments}
\begin{tabular}{|l|l|}
\hline\(X\) & Financial times series object. \\
\hline\(Y\) & Financial times series object or scalar. \\
\hline DIM & Dimension of \(X\). \\
\hline
\end{tabular}

\section*{Description}
nanmax for financial times series objects is based on the Statistics and Machine Learning Toolbox function nanmax. See nanmax in the Statistics and Machine Learning Toolbox documentation.
\(m=\operatorname{nanmax}(X)\) returns the maximum of a financial time series object \(X\) with NaNs treated as missing. \(m\) is the largest non-NaN element in \(X\).
\([m, n d x]=\operatorname{nanmax}(X)\) returns the indices of the maximum values in \(X\). If the values along the first nonsingleton dimension contain multiple maximal elements, the index of the first one is returned.
\(m=n a n m a x(X, Y)\) returns an array the same size as \(X\) and \(Y\) with the largest elements taken from \(X\) or \(Y\). Only \(Y\) can be a scalar double.
[m,ndx] = nanmax(X,[],DIM) operates along the dimension DIM.

\section*{Examples}

To compute nanmax for the following dates:
```

dates = {'01-Jan-2007';'02-Jan-2007';'03-Jan-2007'};
f = fints(dates, magic(3));
f.series1(1) = nan;
f.series2(3) = nan;
f.series3(2) = nan;
[nmax, maxidx] = nanmax(f)
nmax =
4 5 6
maxidx =
3 2 1

```
```

See Also

```
Introduced before R2006a

\section*{nanmean}

Mean ignoring NaNs

\section*{Syntax}
```

m = nanmean(X)
m = nanmean(X,DIM)

```

\section*{Arguments}
\begin{tabular}{|l|l|}
\hline X & Financial times series object. \\
\hline DIM & Dimension along which the operation is conducted. \\
\hline
\end{tabular}

\section*{Description}
nanmean for financial times series objects is based on the Statistics and Machine Learning Toolbox function nanmean. See nanmean in the Statistics and Machine Learning Toolbox documentation.
\(m=\) nanmean \((X)\) returns the sample mean of a financial time series object \(X\), treating NaNs as missing values. m is a row vector containing the mean value of the non- NaN elements in each series.
\(m=\) nanmean (X,DIM) takes the mean along dimension DIM of \(X\).

\section*{Examples}

To compute nanmean for the following dates:
```

dates = {'01-Jan-2007';'02-Jan-2007';'03-Jan-2007'};
f = fints(dates, magic(3));
f.series1(1) = nan;
f.series2(3) = nan;

```
```

f.series3(2) = nan;
nmean = nanmean(f)
nmean =
3.5000 3.0000 4.0000

```

\section*{See Also}
```

mean | nanmax | nanmin | nanstd | nansum | nanvar
Introduced before R2006a

```

\section*{nanmedian}

Median ignoring NaNs

\section*{Syntax}
\(\mathrm{m}=\) nanmedian(X)
m = nanmedian(X,DIM)

\section*{Arguments}
\begin{tabular}{|l|l|}
\hline X & Financial times series object. \\
\hline DIM & Dimension along which the operation is condcuted. \\
\hline
\end{tabular}

\section*{Description}
nanmedian for financial times series objects is based on the Statistics and Machine Learning Toolbox function nanmedian. See nanmedian in the Statistics and Machine Learning Toolbox documentation.
\(m=\) nanmedian \((X)\) returns the sample median of a financial time series object \(X\), treating NaNs as missing values. m is a row vector containing the median value of non-NaN elements in each column.
\(m=\) nanmedian (X,DIM) takes the median along the dimension DIM of \(X\).

\section*{Examples}

To compute nanmedian for the following dates:
```

dates = {'01-Jan-2007';'02-Jan-2007';'03-Jan-2007';'04-Jan-2007'};
f = fints(dates, magic(4));
f.series1(1) = nan;
f.series2(2) = nan;
f.series3([1 3]) = nan;

```
```

nmedian = nanmedian(f)
nmedian =
5.0000 7.0000 12.5000 10.0000

```

\section*{See Also}
```

mean | nanmax | nanmin | nanstd | nansum | nanvar
Introduced before R2006a

```

\section*{nanmin}

Minimum ignoring NaNs

\section*{Syntax}
```

m = nanmin(X)
[m,ndx] = nanmin(X)
m = nanmin(X,Y)
[m,ndx] = nanmin(X,[],DIM)

```

\section*{Arguments}
\begin{tabular}{|l|l|}
\hline\(X\) & Financial times series object. \\
\hline\(Y\) & Financial times series object or scalar. \\
\hline DIM & Dimension along which the operation is conducted. \\
\hline
\end{tabular}

\section*{Description}
nanmin for financial times series objects is based on the Statistics and Machine Learning Toolbox function nanmin. See nanmin in the Statistics and Machine Learning Toolbox documentation.
\(m=\) nanmin \((X)\) returns the minimum of a financial time series object \(X\) with NaNs treated as missing. m is the smallest non-NaN element in X .
[ \(m, n d x\) ] \(=\) nanmin( \(X\) ) returns the indices of the minimum values in \(X\). If the values along the first nonsingleton dimension contain multiple elements, the index of the first one is returned.
\(m=\) nanmin \((X, Y)\) returns an array the same size as \(X\) and \(Y\) with the smallest elements taken from \(X\) or \(Y\). Only \(Y\) can be a scalar double.
[m,ndx] = nanmin(X, [], DIM) operates along the dimension DIM.

\section*{Examples}

To compute nanmin for the following dates:
```

dates = {'01-Jan-2007';'02-Jan-2007';'03-Jan-2007'};
f = fints(dates, magic(3));
f.series1(1) = nan;
f.series2(3) = nan;
f.series3(2) = nan;
[nmin, minidx] = nanmin(f)
nmin =
3 1 2
minidx =
2 1 3

```

\section*{See Also}
mean | nanmax | nanstd | nanvar

Introduced before R2006a

\section*{nanstd}

Standard deviation ignoring NaNs

\section*{Syntax}
```

y = nanstd(X)
y = nanstd(X,1)
y = nanstd(X,FLAG,DIM)

```

\section*{Arguments}
\begin{tabular}{|l|l|}
\hline\(X\) & Financial times series object. \\
\hline FLAG & Normalization flag. \\
\hline DIM & Dimension along which the operation is conducted. \\
\hline
\end{tabular}

\section*{Description}
nanstd for financial times series objects is based on the Statistics and Machine Learning Toolbox function nanstd. See nanstd in the Statistics and Machine Learning Toolbox documentation.
\(y=\) nanstd \((X)\) returns the sample standard deviation of the values in a financial time series object \(X\), treating NaNs as missing values. \(y\) is the standard deviation of the non-NaN elements of \(X\).
nanstd normalizes \(y\) by \((N-1)\), where \(N\) is the sample size. This is the square root of an unbiased estimator of the variance of the population from which \(X\) is drawn, as long as \(X\) consists of independent, identically distributed samples and data are missing at random.
\(y=\) nanstd \((X, 1)\) normalizes by \(N\) and produces the square root of the second moment of the sample about its mean. nanstd \((X, 0)\) is the same as nanstd \((X)\).
\(\mathrm{y}=\) nanstd( \(\mathrm{X}, \mathrm{flag}, \mathrm{dim})\) takes the standard deviation along the dimension dim of X . Set the value of flag to 0 to normalize the result by \(n-1\); set the value of flag to 1 to normalize the result by \(n\).

\section*{Examples}

To compute nanstd for the following dates:
```

dates = {'01-Jan-2007';'02-Jan-2007';'03-Jan-2007'};
f = fints(dates, magic(3));
f.series1(1) = nan;
f.series2(3) = nan;
f.series3(2) = nan;

\section*{nansum}

\section*{Sum ignoring NaNs}

\section*{Syntax}
```

y = nansum(X)
y = nansum(X,DIM)

```

\section*{Arguments}
\begin{tabular}{|l|l|}
\hline X & Financial time series object. \\
\hline DIM & Dimension along which the operation is conducted. \\
\hline
\end{tabular}

\section*{Description}
nansum for financial times series objects is based on the Statistics and Machine Learning Toolbox function nansum. See nansum in the Statistics and Machine Learning Toolbox documentation.
\(y=\) nansum (X) returns the sum of a financial time series object \(X\), treating NaNs as missing values. y is the sum of the non- NaN elements in X .
\(\mathrm{y}=\) nansum(X,DIM) takes the sum along dimension DIM of X .

\section*{Examples}

To compute nansum for the following dates:
```

dates = {'01-Jan-2007';'02-Jan-2007';'03-Jan-2007'};
f = fints(dates, magic(3));
f.series1(1) = nan;
f.series2(3) = nan;
f.series3(2) = nan;

```
```

nsum = nansum(f)
nsum =
7 6 8

```

\section*{See Also}
nanmax | nanmean | nanmedian | nanmin | nanstd | nanvar

\section*{nanvar}

Variance ignoring NaNs

\section*{Syntax}
```

y = nanvar(X)
y = nanvar(X,1)
y = nanvar(X,W)
y = nanvar(X,W,DIM)

```

\section*{Arguments}
\begin{tabular}{|l|l|}
\hline\(X\) & Financial times series object. \\
\hline W & Weight vector. \\
\hline DIM & Dimension along which the operation is conducted. \\
\hline
\end{tabular}

\section*{Description}
nanvar for financial times series objects is based on the Statistics and Machine Learning Toolbox function nanvar. See nanvar in the Statistics and Machine Learning Toolbox documentation.
\(y=\) nanvar \((X)\) returns the sample variance of the values in a financial time series object \(X\), treating NaNs as missing values. y is the variance of the non-NaN elements of each series in \(X\).
nanvar normalizes \(y\) by \(N-1\) if \(N>1\), where \(N\) is the sample size of the non- NaN elements. This is an unbiased estimator of the variance of the population from which X is drawn, as long as X consists of independent, identically distributed samples, and data are missing at random. For \(N=1, y\) is normalized by \(N\).
\(y=\) nanvar \((X, 1)\) normalizes by \(N\) and produces the second moment of the sample about its mean. nanvar \((X, 0)\) is the same as nanvar \((X)\).
\(y=\) nanvar \((X, W)\) computes the variance using the weight vector \(W\). The length of \(W\) must equal the length of the dimension over which nanvar operates, and its non-NaN elements must be nonnegative. Elements of X corresponding to NaN elements of Ware ignored.
\(\mathrm{y}=\) nanvar( \(\mathrm{X}, \mathrm{W}, \mathrm{DIM})\) takes the variance along dimension DIM of X .

\section*{Examples}

To compute nanvar:
```

f = fints((today:today+1)', [4 -2 1; 9 5 7])
f.series1(1) = nan;
f.series3(2) = nan;
nvar = nanvar(f)
nvar =
0 24.5000 0

```

\section*{See Also}
nanmax | nanmean | nanmedian | nanmin | nanstd | var

\section*{negvolidx}

Negative volume index

\section*{Syntax}
```

nvi = negvolidx(closep, tvolume, initnvi)
nvi = negvolidx([closep tvolume], initnvi)
nvits = negvolidx(tsobj)
vits = negvolidx(tsobj, initnvi, 'ParameterName', ParameterValue,
...)

```

\section*{Arguments}
\begin{tabular}{|l|l|}
\hline closep & Closing price (vector). \\
\hline tvolume & Volume traded (vector). \\
\hline initnvi & \begin{tabular}{l} 
(Optional) Initial value for negative volume index (Default \\
\(=100)\).
\end{tabular} \\
\hline tsobj & Financial time series object. \\
\hline 'ParameterName ' & \begin{tabular}{l} 
Valid parameter names are: \\
- CloseName: closing prices series name \\
- VolumeName: volume traded series name
\end{tabular} \\
\hline ParameterValue & \begin{tabular}{l} 
Parameter values are the strings that represent the valid \\
parameter names.
\end{tabular} \\
\hline
\end{tabular}

\section*{Description}
nvi = negvolidx(closep, tvolume, initnvi) calculates the negative volume index from a set of stock closing prices (closep) and volume traded (tvolume) data. nvi
is a vector representing the negative volume index. If initnvi is specified, negvolidx uses that value instead of the default (100).
nvi = negvolidx([closep tvolume], initnvi) accepts a two-column matrix, the first column representing the closing prices (closep), and the second representing the volume traded (tvolume). If initnvi is specified, negvolidx uses that value instead of the default (100).
nvits = negvolidx(tsobj) calculates the negative volume index from the financial time series object tsobj. The object must contain, at least, the series Close and Volume. The nvits output is a financial time series object with dates similar to tsobj and a data series named NVI. The initial value for the negative volume index is arbitrarily set to 100.
nvits = negvolidx(tsobj, initnvi, 'ParameterName', ParameterValue, ...) accepts parameter name/ parameter value pairs as input. These pairs specify the name(s) for the required data series if it is different from the expected default name(s). Parameter values are the strings that represent the valid parameter names.

\section*{Examples}

\section*{Compute the Negative Volume Index}

This example shows how to compute the negative volume index for Disney stock and plot the results.
```

load disney.mat
dis_NegVol = negvolidx(dis);
plōt(dis_NegVol)
title('Negative Volume Index for Disney')

```

Introduced before R2006a

\section*{nweekdate}

Date of specific occurrence of weekday in month

\section*{Syntax}
```

Date = nweekdate(n, Weekday, Year, Month, Same)

```

\section*{Arguments}
\begin{tabular}{|l|l|l|}
\hline n & \begin{tabular}{l} 
Nth occurrence of the weekday in a month. Enter as integer from 1 \\
through 5.
\end{tabular} \\
\hline Weekday & Weekday whose date you seek. Enter as integer from 1 through 7. \\
\hline & 1 & Sunday \\
\hline & 2 & Monday \\
\hline & 3 & Tuesday \\
\hline & 4 & Wednesday \\
\hline & 5 & Thursday \\
\hline & 6 & Friday \\
\hline Year & 7 & Saturday \\
\hline Month & Year. Enter as a four-digit integer. \\
\hline Same & Month. Enter as an integer from 1 through 12. \\
\hline & \begin{tabular}{l} 
(Optional) Weekday that must occur in the same week with \\
Weekday. Enter as an integer from 0 through 7, where 0 \\
(default) and 1 through 7 are as for Weekday.
\end{tabular} \\
\hline
\end{tabular}

\section*{Description}

Date \(=\) nweekdate(n, Weekday, Year, Month, Same) returns the serial date number for the specific occurrence of the weekday in the given year and month, and in a week that also contains the weekday Same.

If n is larger than the last occurrence of Weekday, Date \(=0\).
Any input can contain multiple values, but if so, all other inputs must contain the same number of values or a single value that applies to all. For example, if Year is a 1-by-n vector of integers, then Month must be a 1-by-n vector of integers or a single integer. Date is then a 1 -by- n vector of date numbers.

Use the function datestr to convert serial date numbers to formatted date strings.

\section*{Examples}

To find the first Thursday in May 2001
```

Date = nweekdate(1, 5, 2001, 5); datestr(Date)

```
ans \(=\)

03-May-2001
To find the first Thursday in a week that also contains a Wednesday in May 2001
```

Date = nweekdate(2, 5, 2001, 5, 4); datestr(Date)
ans =

\section*{nyseclosures}

New York Stock Exchange closures from 1885 to 2050

\section*{Syntax}
[Closures, SatTransition] = nyseclosures(StartDate, EndDate, WorkWeekFormat)

\section*{Description}
[Closures, SatTransition] = nyseclosures(StartDate, EndDate, WorkWeekFormat) returns a vector of serial date numbers corresponding to market closures between StartDate and EndDate, inclusive. If you do not specify StartDate and EndDate,

Closures output contains all known or anticipated closures from January 1, 1885 to December 31, 2050. By default, WorkWeekFormat argument uses the 'Implicit' value.

SatTransition output is the date of transition for the New York Stock Exchange from a 6 -day workweek to a 5 -day workweek. The date for this transition is September 29, 1952 and this date returns the serial date number 713226 .

Since the New York Stock Exchange was open on Saturdays before September 29, 1952, exact closures from 1885 to 1952 are based on a 6 -day workweek. nyseclosures contains all holiday and special non-trading days for the New York Stock Exchange from 1885 through 2050 based on a six-day work week (always closed on Sundays). Use WorkWeekFormat to modify the list of dates.

\section*{Input Arguments}

\section*{StartDate}

First date of a specified date range that is a date string or a serial date number.
Default: January 1, 1885 (start of the default date range)

\section*{EndDate}

Last date of a specified date range that is a date string or a serial date number. If specified, the EndDate must be a date after the StartDate.

Default: December 31, 2050 (end of the default date range)
WorkWeekFormat
Specifies method to handle the workweek. The default is 'Implicit'. This function accepts the first letter for each method as input and is not case sensitive. Acceptable values are:
- 'Modern' - 5-day workweek with all Saturday trading days removed
- 'Implicit' - 6-day workweek until 1952 and 5-day week afterward (no need to exclude Saturdays)
- 'Archaic ' - 6-day workweek throughout and Saturdays treated as closures after 1952

\section*{Output Arguments}

\section*{Closures}

A vector of serial date numbers corresponding to market closures between the dates StartDate and EndDate, inclusive

\section*{SatTransition}

The date of transition for the New York Stock Exchange from a 6-day workweek to a 5day workweek.

\section*{Definitions}
holidays is based on a modern 5-day workweek and contains all holidays and special nontrading days for the New York Stock Exchange from January 1, 1885 to December 31, 2050. Since the New York Stock Exchange was open on Saturdays before September 29, 1952, exact closures for the period from 1885 to 2050 should include Saturday trading days. To capture these dates, use the function nyseclosures. The results from
holidays and nyseclosures are identical if the WorkWeekFormat in nyseclosures is 'modern'.

\section*{Examples}

Find the NYSE closures for 1899:
```

datestr(nyseclosures('1-jan-1899','31-dec-1899'),'dd-mmm-yyyy ddd')

```

This returns:
ans =
02-Jan-1899 Mon
11-Feb-1899 Sat
13-Feb-1899 Mon
22-Feb-1899 Wed
31-Mar-1899 Fri
29-May-1899 Mon
30-May-1899 Tue
03-Jul-1899 Mon
04-Jul-1899 Tue
04-Sep-1899 Mon
29-Sep-1899 Fri
30-Sep-1899 Sat
07-Nov-1899 Tue
25-Nov-1899 Sat
30-Nov-1899 Thu
25-Dec-1899 Mon
Find the NYSE closure dates using the 'Archaic ' value for WorkWeekFormat:
datestr(nyseclosures('1-sep-1952', '31-oct-1952', 'a'), 1)
This returns:
ans =
01-Sep-1952
06-Sep-1952
13-Sep-1952
20-Sep-1952
27-Sep-1952

04-Oct-1952
11-0ct-1952
13-0ct-1952
18-Oct-1952
25-0ct-1952
The exchange was closed on Saturdays for much of 1952 before the official transition to a 5-day workweek.

}

\section*{onbalvol}

On-Balance Volume (OBV)

\section*{Syntax}
```

obv = onbalvol(closep, tvolume)
obv = onbalvol([closep tvolume])
obvts = onbalvol(tsobj)
obvts = onbalvol(tsobj, 'ParameterName', ParameterValue, ...)

```

\section*{Arguments}
\begin{tabular}{|l|l|}
\hline closep & Closing price (vector) \\
\hline tvolume & Volume traded \\
\hline tsobj & Financial time series object \\
\hline
\end{tabular}

\section*{Description}
obv = onbalvol(closep, tvolume) calculates the On-Balance Volume (OBV) from the stock closing price (closep) and volume traded (tvolume) data.
obv = onbalvol([closep tvolume]) accepts a two-column matrix representing the closing price (closep) and volume traded (tvolume), in that order.
obvts \(=\) onbalvol(tsobj) calculates the OBV from the stock data in the financial time series object tsobj. The object must minimally contain series names Close and Volume. The obvts output is a financial time series object with the same dates as tsobj and a series named OnBalVol.
obvts = onbalvol(tsobj, 'ParameterName', ParameterValue, ...) accepts parameter name/ parameter value pairs as input. These pairs specify the name(s) for the
required data series if it is different from the expected default name(s). Valid parameter names are
- CloseName: closing prices series name
- VolumeName: volume traded series name

Parameter values are the strings that represent the valid parameter names.

\section*{Examples}

\section*{Calculate the On-Balance Volume (OBV)}

This example shows how to calculate the OBV for Disney stock and plot the results.
load disney.mat
dis_OnBalVol = onbalvol(dis);
plot(dis_OnBalVol)
title('Ōn-Balance Volume for Disney')

\section*{opprofit}

Option profit

\section*{Syntax}

Profit = opprofit(AssetPrice, Strike, Cost, PosFlag, OptType)

\section*{Arguments}
\begin{tabular}{|l|l|}
\hline AssetPrice & Asset price. \\
\hline Strike & Strike or exercise price. \\
\hline Cost & Cost of the option. \\
\hline PosFlag & Option position. \(0=\) long, \(1=\) short. \\
\hline OptType & Option type. \(0=\) call option, \(1=\) put option. \\
\hline
\end{tabular}

\section*{Description}

Profit = opprofit(AssetPrice, Strike, Cost, PosFlag, OptType) returns the profit of an option.

\section*{Examples}

\section*{Calcualte the Profit of an Option}

This example shows how to return the profit of an option. For example, consider buying (going long on) a call option with a strike price of \(\$ 90\) on an underlying asset with a current price of \(\$ 100\) for a cost of \(\$ 4\).
```

Profit = opprofit(100, 90, 4, 0, 0)

```

Profit =

\section*{payadv}

Periodic payment given number of advance payments

\section*{Syntax}

Payment = payadv(Rate, NumPeriods, PresentValue, FutureValue, Advance)

\section*{Arguments}
\begin{tabular}{|l|l|}
\hline Rate & \begin{tabular}{l} 
Lending or borrowing rate per period. Enter as a decimal \\
fraction. Must be greater than or equal to 0.
\end{tabular} \\
\hline NumPeriods & Number of periods in the life of the instrument. \\
\hline PresentValue & Present value of the instrument. \\
\hline FutureValue & \begin{tabular}{l} 
Future value or target value to be attained after \\
NumPeriods periods.
\end{tabular} \\
\hline Advance & \begin{tabular}{l} 
Number of advance payments. If the payments are made at \\
the beginning of the period, add 1 to Advance.
\end{tabular} \\
\hline
\end{tabular}

\section*{Description}

Payment = payadv(Rate, NumPeriods, PresentValue, FutureValue, Advance) returns the periodic payment given a number of advance payments.

\section*{Examples}

\section*{Compute the Periodic Payment}

This example shows how to compute the periodic payment, given a number of advance payments. For example, the present value of a loan is \(\$ 1000.00\) and it will be paid in full in 12 months. The annual interest rate is \(10 \%\) and three payments are made at closing time.

Payment \(=\) payadv(0.1/12, 12, 1000, 0, 3)

Payment =
85.9389
- "Analyzing and Computing Cash Flows" on page 2-17

\author{
See Also \\ amortize \| payodd | payper \\ Introduced before R2006a
}

\section*{payodd}

Payment of loan or annuity with odd first period

\section*{Syntax}

Payment \(=\) payodd(Rate, NumPeriods, PresentValue, FutureValue, Days)

\section*{Arguments}
\begin{tabular}{|l|l|}
\hline rate & Interest rate per period. Enter as a decimal fraction. \\
\hline NumPeriods & Number of periods in the life of the instrument. \\
\hline PresentValue & Present value of the instrument. \\
\hline FutureValue & \begin{tabular}{l} 
Future value or target value to be attained after \\
NumPeriods periods.
\end{tabular} \\
\hline Days & Actual number of days until the first payment is made. \\
\hline
\end{tabular}

\section*{Description}

Payment = payodd(Rate, NumPeriods, PresentValue, FutureValue, Days) returns the payment for a loan or annuity with an odd first period.

\section*{Examples}

\section*{Compute the Payment for a Loan or Annuity With an Odd First Period}

This example shows how to return the payment for a loan or annuity with an odd first period. For example, consider a two-year loan for \(\$ 4000\) that has an annual interest rate of \(11 \%\) and the first payment will be made in 36 days.
```

Payment = payodd(0.11/12, 24, 4000, 0, 36)

```

\subsection*{186.7731}
- "Analyzing and Computing Cash Flows" on page 2-17

\section*{See Also \\ amortize | payadv | payper \\ Introduced before R2006a}

\section*{payper}

Periodic payment of loan or annuity

\section*{Syntax}

Payment = payper(Rate, NumPeriods, PresentValue, FutureValue, Due)

\section*{Arguments}
\begin{tabular}{|l|l|}
\hline Rate & Interest rate per period. Enter as a decimal fraction. \\
\hline NumPeriods & Number of payment periods in the life of the instrument. \\
\hline PresentValue & Present value of the instrument. \\
\hline FutureValue & \begin{tabular}{l} 
(Optional) Future value or target value to be attained after \\
NumPeriods periods. Default \(=0\).
\end{tabular} \\
\hline Due & \begin{tabular}{l} 
(Optional) When payments are due: \(0=\) end of period \\
(default), or \(1=\) beginning of period.
\end{tabular} \\
\hline
\end{tabular}

\section*{Description}

Payment = payper(Rate, NumPeriods, PresentValue, FutureValue, Due) returns the periodic payment of a loan or annuity.

\section*{Examples}

\section*{Compute the Periodic Payment of a Loan or Annuity}

This example shows how to find the monthly payment for a three-year loan of \(\$ 9000\) with an annual interest rate of \(11.75 \%\).

Payment = payper \((0.1175 / 12,36,9000,0,0)\)

Payment =

\subsection*{297.8553}

\section*{payuni}

Uniform payment equal to varying cash flow

\section*{Syntax}

Series = payuni(CashFlow, Rate)

\section*{Arguments}
\begin{tabular}{|l|l|}
\hline CashFlow & \begin{tabular}{l} 
A vector of varying cash flows. Include the initial investment as the \\
initial cash flow value (a negative number).
\end{tabular} \\
\hline Rate & Periodic interest rate. Enter as a decimal fraction. \\
\hline
\end{tabular}

\section*{Description}

Series = payuni(CashFlow, Rate) returns the uniform series value of a varying cash flow.

\section*{Examples}

This cash flow represents the yearly income from an initial investment of \(\$ 10,000\). The annual interest rate is \(8 \%\).
\begin{tabular}{|l|l|}
\hline Year 1 & \(\$ 2000\) \\
\hline Year 2 & \(\$ 1500\) \\
\hline Year 3 & \(\$ 3000\) \\
\hline Year 4 & \(\$ 3800\) \\
\hline Year 5 & \(\$ 5000\) \\
\hline
\end{tabular}

To calculate the uniform series value
Series = payuni([-10000 2000150030003800 5000], 0.08)
returns

Series =
429.63

\section*{pcalims}

Linear inequalities for individual asset allocation
As an alternative to pcalims, use the Portfolio object (Portfolio) for mean-variance portfolio optimization. This object supports gross or net portfolio returns as the return proxy, the variance of portfolio returns as the risk proxy, and a portfolio set that is any combination of the specified constraints to form a portfolio set. For information on the workflow when using Portfolio objects, see "Portfolio Object Workflow" on page 4-17.

\section*{Syntax}
[A,b] = pcalims(AssetMin, AssetMax, NumAssets)

\section*{Arguments}
\begin{tabular}{|l|l|}
\hline AssetMin & \begin{tabular}{l} 
Scalar or NASSETS vector of minimum allocations in each asset. \\
NaN indicates no constraint.
\end{tabular} \\
\hline AssetMax & \begin{tabular}{l} 
Scalar or NASSETS vector of maximum allocations in each asset. \\
NaN indicates no constraint.
\end{tabular} \\
\hline NumAssets & \begin{tabular}{l} 
(Optional) Number of assets. Default = length of AssetMin or \\
AssetMax.
\end{tabular} \\
\hline
\end{tabular}

\section*{Description}
[A,b] = pcalims(AssetMin, AssetMax, NumAssets) specifies the lower and upper bounds of portfolio allocations in each of NumAssets available asset investments.
\(A\) is a matrix and \(b\) is a vector such that \(A * P o r t W t s^{\prime}<=b\), where PortWts is a 1 -by-NASSETS vector of asset allocations.

If pcalims is called with fewer than two output arguments, the function returns \(A\) concatenated with \(b[A, b]\).

\section*{Examples}

Set the minimum weight in every asset to 0 (no short-selling), and set the maximum weight of IBM stock to 0.5 and CSCO to 0.8 , while letting the maximum weight in INTC float.

Portfolio weights of \(50 \%\) in IBM and \(50 \%\) in INTC satisfy the constraints.
Set the minimum weight in every asset to 0 and the maximum weight to 1 .
\begin{tabular}{llll} 
Asset & IBM & INTC & CSCO \\
Minimum Weight & 0 & 0 & 0 \\
Maximum Weight & 1 & 1 & 1
\end{tabular}

AssetMin \(=0\)
AssetMax = 1
NumAssets \(=3\)
```

[A,b] = pcalims(AssetMin, AssetMax, NumAssets)
A =

| 1 | 0 | 0 |
| ---: | ---: | ---: |
| 0 | 1 | 0 |
| 0 | 0 | 1 |
| -1 | 0 | 0 |
| 0 | -1 | 0 |
| 0 | 0 | -1 |

b =
1
1
1
0
0
0

```

Portfolio weights of \(50 \%\) in IBM and \(50 \%\) in INTC satisfy the constraints.

\section*{More About}
- "Analyzing Portfolios" on page 3-2
- "Portfolio Optimization Functions" on page 3-4
- Getting Started with Portfolio Optimization (13 min 31 sec )

\section*{See Also \\ pcgcomp | pcglims | pcpval | portcons | portopt | portstats \\ Introduced before R2006a}

\section*{pcgcomp}

Linear inequalities for asset group comparison constraints
As an alternative to pcgcomp, use the Portfolio object (Portfolio) for mean-variance portfolio optimization. This object supports gross or net portfolio returns as the return proxy, the variance of portfolio returns as the risk proxy, and a portfolio set that is any combination of the specified constraints to form a portfolio set. For information on the workflow when using Portfolio objects, see "Portfolio Object Workflow" on page 4-17.

\section*{Syntax}
[A,b] = pcgcomp(GroupA, AtoBmin, AtoBmax, GroupB)

\section*{Arguments}
\begin{tabular}{|l|l|}
\hline GroupA & \begin{tabular}{l} 
Number of groups (NGROUPS) by number of assets (NASSETS) \\
Gpecifications of groups to compare. Each row specifies a group. For
\end{tabular} \\
\hline \begin{tabular}{l} 
a specific group, Group \((i, j)=1\) if the group contains asset \(j ;\) \\
otherwise, Group \((i, j)=0\).
\end{tabular} \\
\hline AtoBmin & \begin{tabular}{l} 
Scalar or NGROUPS-long vectors of minimum and maximum ratios \\
of allocations in GroupA to allocations in GroupB. NaN indicates no \\
constraint between the two groups. Scalar bounds are applied to all \\
group pairs. The total number of assets allocated to GroupA divided \\
by the total number of assets allocated to GroupB is >=AtoBmin \\
and <= AtoBmax.
\end{tabular} \\
\hline
\end{tabular}

\section*{Description}
[A,b] = pcgcomp(GroupA, AtoBmin, AtoBmax, GroupB) specifies that the ratio of allocations in one group to allocations in another group is at least AtoBmin to 1 and at most AtoBmax to 1 . Comparisons can be made between an arbitrary number of group pairs NGROUPS comprising subsets of NASSETS available investments.

A is a matrix and \(b\) a vector such that \(A * P o r t W t s{ }^{\prime}<=b\), where PortWts is a 1 -by-NASSETS vector of asset allocations.

If pcgcomp is called with fewer than two output arguments, the function returns \(A\) concatenated with \(b[A, b]\).

\section*{Examples}
\begin{tabular}{llll} 
Asset & INTC & XOM & RD \\
Region & North America & North America & Europe \\
Sector & Technology & Energy & Energy
\end{tabular}
\begin{tabular}{lll} 
Group & Min. Exposure & Max. Exposure \\
North America & 0.30 & 0.75 \\
Europe & 0.10 & 0.55 \\
Technology & 0.20 & 0.50 \\
Energy & 0.20 & 0.80
\end{tabular}

Make the North American energy sector compose exactly 20\% of the North American investment.
```

% INTC XOM RD
GroupA = [ 0 1 0 ]; % North American Energy
GroupB = [ 1 1 1 0 ]; % North America
AtoBmin = 0.20;
AtoBmax = 0.20;
[A,b] = pcgcomp(GroupA, AtoBmin, AtoBmax, GroupB)
A =
0.2000 -0.8000 0
b =
0
0

```

Portfolio weights of \(40 \%\) for INTC, \(10 \%\) for XOM, and \(50 \%\) for RD satisfy the constraints.

}

\section*{pcglims}

Linear inequalities for asset group minimum and maximum allocation
As an alternative to pcglims, use the Portfolio object (Portfolio) for mean-variance portfolio optimization. This object supports gross or net portfolio returns as the return proxy, the variance of portfolio returns as the risk proxy, and a portfolio set that is any combination of the specified constraints to form a portfolio set. For information on the workflow when using Portfolio objects, see "Portfolio Object Workflow" on page 4-17.

\section*{Syntax}
[A,b] = pcglims(Groups, GroupMin, GroupMax)

\section*{Arguments}
\begin{tabular}{|l|l|}
\hline Groups & \begin{tabular}{l} 
Number of groups (NGROUPS) by number of assets (NASSETS) \\
specification of which assets belong to which group. Each row \\
specifies a group. For a specific group, Group \((i, j)=1\) if the \\
group contains asset j; otherwise, Group \((i, j)=0\).
\end{tabular} \\
\hline GroupMin & \begin{tabular}{l} 
Scalar or NGROUPS-long vectors of minimum and maximum \\
combined allocations in each group. NaN indicates no constraint. \\
Scalar bounds are applied to all groups.
\end{tabular} \\
\hline
\end{tabular}

\section*{Description}
[A,b] = pcglims(Groups, GroupMin, GroupMax) specifies minimum and maximum allocations to groups of assets. An arbitrary number of groups, NGROUPS, comprising subsets of NASSETS investments, is allowed.
\(A\) is a matrix and \(b\) a vector such that \(A * P o r t W t s{ }^{\prime}<=b\), where PortWts is a 1-by-NASSETS vector of asset allocations.

If pcglims is called with fewer than two output arguments, the function returns \(A\) concatenated with \(b[A, b]\).

\section*{Examples}
\begin{tabular}{llll} 
Asset & INTC & XOM & RD \\
Region & North America & North America & Europe \\
Sector & Technology & Energy & Energy
\end{tabular}
\begin{tabular}{lll} 
Group & Min. Exposure & Max. Exposure \\
North America & 0.30 & 0.75 \\
Europe & 0.10 & 0.55 \\
Technology & 0.20 & 0.50 \\
Energy & 0.50 & 0.50
\end{tabular}

Set the minimum and maximum investment in various groups.
```

% INTC XOM RD
Groups = [ 1 1 1 0 ; % North America
0 0 1 ; % Europe
1 0 0 ; % Technology
0 1 1 ]; % Energy
GroupMin = [0.30
0.10
0.20
0.50];
GroupMax = [0.75
0.55
0.50
0.50];
[A,b] = pcglims(Groups, GroupMin, GroupMax)
A =

| -1 | -1 | 0 |
| ---: | ---: | ---: |
| 0 | 0 | -1 |
| -1 | 0 | 0 |
| 0 | -1 | -1 |
| 1 | 1 | 0 |
| 0 | 0 | 1 |

```
```

        10
    b =
-0.3000
-0.1000
-0.2000
-0.5000
0.7500
0.5500
0.5000
0.5000

```
    \(\begin{array}{lll}0 & 1 & 1\end{array}\)

Portfolio weights of \(50 \%\) in INTC, \(25 \%\) in XOM, and \(25 \%\) in RD satisfy the constraints.

\section*{More About}
- "Analyzing Portfolios" on page 3-2
- "Portfolio Optimization Functions" on page 3-4
- Getting Started with Portfolio Optimization (13 min 31 sec )

\author{
See Also \\ pcalims | pcgcomp | pcpval | portcons | portopt \\ Introduced before R2006a
}

\section*{pcpval}

Linear inequalities for fixing total portfolio value
As an alternative to pcpval, use the Portfolio object (Portfolio) for mean-variance portfolio optimization. This object supports gross or net portfolio returns as the return proxy, the variance of portfolio returns as the risk proxy, and a portfolio set that is any combination of the specified constraints to form a portfolio set. For information on the workflow when using Portfolio objects, see "Portfolio Object Workflow" on page 4-17.

\section*{Syntax}
[A,b] = pcpval(PortValue, NumAssets)

\section*{Arguments}
\begin{tabular}{|l|l|}
\hline PortValue & \begin{tabular}{l} 
Scalar total value of asset portfolio (sum of the allocations in \\
all assets). PortValue = 1 specifies weights as fractions of \\
the portfolio and return and risk numbers as rates instead of \\
value.
\end{tabular} \\
\hline NumAssets & Number of available asset investments. \\
\hline
\end{tabular}

\section*{Description}
\([A, b]=p c p v a l(P o r t V a l u e, N u m A s s e t s)\) scales the total value of a portfolio of NumAssets assets to PortValue. All portfolio weights, bounds, return, and risk values except ExpReturn and ExpCovariance (see portopt) are in terms of PortValue.
\(A\) is a matrix and \(b\) a vector such that \(A * P o r t W t s{ }^{\prime}<=b\), where PortWts is a 1-by-NASSETS vector of asset allocations.

If pcpval is called with fewer than two output arguments, the function returns \(A\) concatenated with \(b[A, b]\).

\section*{Examples}

Scale the value of a portfolio of three assets \(=1\), so all return values are rates and all weight values are in fractions of the portfolio.
```

PortValue = 1;
NumAssets = 3;
[A,b] = pcpval(PortValue, NumAssets)
A =
1 1 1
-1
b =
1
-1

```

Portfolio weights of \(40 \%, 10 \%\), and \(50 \%\) in the three assets satisfy the constraints.

\section*{peravg}

Periodic average of FINTS object

\section*{Syntax}
```

avgfts = peravg(tsobj)
avgfts = peravg(tsobj, numperiod)
avgfts = peravg(tsobj, daterange)

```

\section*{Arguments}
\begin{tabular}{|l|l|}
\hline tsobj & Financial time series object \\
\hline numperiod & \begin{tabular}{l} 
(Optional) Integer specifying the number of data points over which \\
each periodic average should be averaged
\end{tabular} \\
\hline daterange & (Optional) Time period over which the data is averaged \\
\hline
\end{tabular}

\section*{Description}
peravg calculates periodic averages of a financial time series object. Periodic averages are calculated from the values per period defined. If the period supplied is a string, it is assumed as a range of date string. If the period is entered as numeric, the number represents the number of data points (financial time series periods) to be included in a period for the calculation. For example, if you enter '01/01/98: :01/01/99' as the period input argument, peravg returns the average of the time series between those dates, inclusive. However, if you enter the number 5 as the period input, peravg returns a series of averages from the time series data taken 5 date points (financial time series periods) at a time.
avgfts = peravg(tsobj, numperiod) returns a structure avgfts that contains the periodic (per numperiod periods) average of the financial time series object. avgfts has field names identical to the data series names of tsobj.
avgfts = peravg(tsobj, daterange) returns a structure avgfts that contains the periodic (as specified by daterange) average of the financial time series object. avgfts has field names identical to the data series names of tsobj.

Note: peravg calculates periodic averages of a FINTS object. Periodic averages are calculated from the values per period defined. If the period supplied is a string, it is assumed as a range of date strings. If the period is entered as numeric, the number represents the number of data points to be included in a period for the calculation.

\section*{Examples}

If you enter 01-Jan-2001::03-Jan-2001 as the period input argument, peravg returns the average of the time series between those dates, inclusive. However, if you enter the number 5 as the period input, peravg returns a series of averages from the time series data, taken 5 date points at a time.
```

%% Create the FINTS object %%
dates = ['01-Jan-2001';'01-Jan-2001'; '02-Jan-2001'; ...
'02-Jan-2001'; '03-Jan-2001';'03-Jan-2001'];
times = ['11:00';'12:00';'11:00';'12:00';'11:00';'12:00'];
dates_times = cellstr([dates, repmat(' ', size(dates, 1), 1), times]);
data = [(1:6)', 2*(1:6)'];
myFts = fints(dates_times, data, {'Data1', 'Data2'}, 1, 'My first FINTS')
%% Create the FINTS object %%
[p, pFts] = peravg(myFts, 3)
p =
Data1: [2 5]
Data2: [4 10]
pFts =
desc: My first FINTS
freq: Daily (1)
'dates: (2)' 'times: (2)' 'Data1: (2)' 'Data2: (2)'

```

```

[p, pFts] = peravg(myFts,'01-Jan-2001 12:00::03-Jan-2001 11:00')
p =

```
```

    Data1: 3.5000
    Data2: 7
    pFts =
desc: My first FINTS
freq: Daily (1)

```

\section*{periodicreturns}

Periodic total returns from total return prices

\section*{Syntax}

TotalReturn = periodicreturns(TotalReturnPrices)
TotalReturn = periodicreturns(TotalReturnPrices, Period)

\section*{Arguments}
\begin{tabular}{|c|c|}
\hline TotalReturnPrices & Number of observations (NUMOBS) by number of assets (NASSETS +1 ) matrix of total return prices for a given security. Column 1 contains MATLAB serial date numbers. The remaining columns contain total return price data. \\
\hline Period & ```
(Optional) Periodicity flag used to compute total returns:
'd' = daily values (default)
' w' = weekly values
' m ' = monthly values
\(n=\) rolling return periodic values, where \(n\) is an integer
``` \\
\hline
\end{tabular}

\section*{Description}

TotalReturn = periodicreturns(TotalReturnPrices) calculates the daily total returns from a daily total return price series.

TotalReturn = periodicreturns(TotalReturnPrices, Period) calculates the total returns for a periodicity that you specify from a daily total return price series.

TotalReturn is a NUMOBS-by-NASSETS +1 matrix containing month-end dates and return values. Each row represents an observation. Column 1 contains month-end dates in MATLAB serial date number format. The remaining columns contain monthly return values.

Note: Although input returns can have dates in either ascending or descending order, output total returns in TotalReturn have dates in ascending order, with the earliest date in the first row TotalReturn, and the most recent date in the last row of TotalReturn.

\section*{Introduced before R2006a}

\section*{plot}

Plot data series

\section*{Syntax}
```

plot(tsobj)
hp = plot(tsobj)
plot(tsobj, linefmt)
hp = plot(tsobj, linefmt)
plot(..., volumename, bar)
hp = plot(..., volumename, bar)

```

\section*{Arguments}
\begin{tabular}{|l|l|}
\hline tsobj & Financial time series object. \\
\hline linefmt & (Optional) Line format. \\
\hline volumename & \begin{tabular}{l} 
(Optional) Specifies which data series is the volume series. \\
volumename must be the exact data series name for the volume \\
column (case sensitive).
\end{tabular} \\
\hline bar & \begin{tabular}{l} 
(Optional) \\
bar \(=0-\) (Default) Plot volume as a line. \\
bar \(=1-\) Plot volume as a bar chart. The width of each bar is \\
the same as the default in bar, barh.
\end{tabular} \\
\hline
\end{tabular}

\section*{Description}
plot (tsobj) plots the data series contained in the object tsobj. Each data series is a line. plot automatically generates a legend and dates on the \(x\)-axis. Grid is turned on by default. plot uses the default color order as if plotting a matrix.

The plot command automatically creates subplots when multiple time series are encountered, and they differ greatly on their decimal scales. For example, subplots are generated if one time series data set is in the 10 s and another is in the \(10,000 \mathrm{~s}\).
\(\mathrm{hp}=\mathrm{plot}(\mathrm{tsobj})\) also returns the handle(s) to the object(s) inside the plot figure. If there are multiple lines in the plot, hp is a vector of multiple handles.
plot (tsobj, linefmt) plots the data series in tsobj using the line format specified. For a list of possible line formats, see plot in the MATLAB documentation. The plot legend is not generated, but the dates on the \(x\)-axis and the plot grid are. The specified line format is applied to all data series; that is, all data series have the same line type.
hp \(=\) plot(tsobj, linefmt) plots the data series in tsobj using the format specified. The plot legend is not generated, but the dates on the \(x\)-axis and the plot grid are. The specified line format is applied to all data series, that is, all data series can have the same line type. If there are multiple lines in the plot, hp is a vector of multiple handles.
plot(..., volumename, bar) also specifies which data series is the volume. The volume is plotted in a subplot below the other data series. If bar \(=1\), the volume is plotted as a bar chart. Otherwise, a line plot is used.
\(\mathrm{hp}=\operatorname{plot}(. . .\), volumename, bar) returns handles for each line. If bar \(=1\), the handle to the patch for the bars is also returned.

Note To turn off the legend, enter legend off at the MATLAB command line. Once you turn it off, the legend is deleted. To turn it back on, recreate it using the legend command as if you are creating it for the first time. To turn off the grid, enter grid off. To turn it back on, enter grid on.

\section*{Introduced before R2006a}

\section*{plotFrontier}

Plot efficient frontier
Use the plotFrontier function with a Portfolio, PortfolioCVaR, or PortfolioMAD object to plot the efficient frontier for a portfolio object.

For details on the respective workflows when using these different objects, see "Portfolio Object Workflow" on page 4-17, "PortfolioCVaR Object Workflow" on page 5-16, and "PortfolioMAD Object Workflow" on page 6-16.

\section*{Syntax}
```

[prsk,pret] = plotFrontier(obj)
[prsk,pret] = plotFrontier(obj,varargin)

```

\section*{Description}
[prsk, pret] = plotFrontier(obj) plots the efficient frontier for a portfolio object.
[prsk, pret] = plotFrontier(obj, varargin) plot the efficient frontier for a portfolio object with multiple types of input methods. There are four ways to use plotFrontier:
- Method 1 - Given a portfolio object obj, estimate the efficient frontier with default number of 10 portfolios on the frontier.
- Method 2 - Given a portfolio object obj, estimate the efficient frontier with a specified number of portfolios NumPorts on the frontier.
- Method 3 - Given a portfolio object obj with estimated efficient portfolios in PortWeights, plot the efficient frontier with those portfolios. This method assumes that you provide valid efficient portfolios as input.
- Method 4 - Given a portfolio object obj with estimated portfolio risks (PortRisk) and returns (PortReturn), plot the efficient frontier. This method assumes that you provide valid inputs for efficient portfolio risks and returns.

Note: plotFrontier handles multiple input formats as described above. Given an asset universe with NumAssets assets and an efficient frontier with NumPorts portfolios, remember that portfolio weights are NumAsset-by-NumPorts matrices and that portfolio risks and returns are NumPorts column vectors.

\section*{Examples}

\section*{Plot the Efficient Frontier for the Portfolio Object}

Given a portfolio p, plot the efficient frontier.
load CAPMuniverse
p = Portfolio('AssetList',Assets(1:12));
\(p\) = estimateAssetMoments(p, Data(:,1:12),'missingdata',true);
p = setDefaultConstraints(p);
plotFrontier(p);

Plot the Efficient Frontier for the PortfolioCVaR Object
Given a PortfolioCVaR p, plot the efficient frontier.
```

m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
0.00408 0.0289 0.0204 0.0119;
0.00192 0.0204 0.0576 0.0336;
0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;

```

AssetScenarios = mvnrnd(m, C, 20000);
```

p = PortfolioCVaR;
p = setScenarios(p, AssetScenarios);
p = setDefaultConstraints(p);
p = setProbabilityLevel(p, 0.95);
plotFrontier(p);

```

\section*{Plot Efficient Frontier for PorifolioMAD Object}

Given a PortfolioMAD p, plot the efficient frontier.
```

m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
0.00408 0.0289 0.0204 0.0119;

```
```

            0.00192 0.0204 0.0576 0.0336;
            0 0.0119 0.0336 0.1225 ];
        m = m/12;
        C = C/12;
        AssetScenarios = mvnrnd(m, C, 20000);
        p = PortfolioMAD;
        p = setScenarios(p, AssetScenarios);
        p = setDefaultConstraints(p);
        plotFrontier(p);
    ```

Efficient Frontier

- "Plotting the Efficient Frontier for a Portfolio Object" on page 4-101
- "Plotting the Efficient Frontier for a PortfolioCVaR Object" on page 5-95
- "Plotting the Efficient Frontier for a PortfolioMAD Object" on page 6-93
- "Portfolio Optimization Examples" on page 4-114

\section*{Input Arguments}

\section*{obj - Object for portfolio}
object
Object for portfolio, specified using Portfolio, PortfolioCVaR, or PortfolioMAD object. For more information on creating a portfolio object, see
- Using Portfolio Objects
- Using PortfolioCVaR Objects
- Using PortfolioMAD Objects

\section*{varargin - Optional input methods}
vector for NumPorts, PortRisk, PortReturn, or PortWeights
Optional input methods, specified as varargin can be NumPorts, PortRisk, PortReturn, or PortWeights depending on which of these four input methods you use:
- Method 1 - Given a portfolio object obj, estimate the efficient frontier with the default number of 10 portfolios on the frontier:
```

[prsk, pret] = plotFrontier(obj)

```
- Method 2 - Given a portfolio object obj, estimate the efficient frontier with a specified number of portfolios NumPorts on the frontier:
```

[prsk, pret] = plotFrontier(obj,NumPorts)

```
- Method 3 - Given a portfolio object obj with estimated efficient portfolios in PortWeights, plot the efficient frontier with those portfolios:
[prsk, pret] = plotFrontier(obj,PortWeights)
The plotFrontier function assumes that you provide valid efficient portfolios as inputs.
- Method 4 - Given a portfolio object obj with estimated portfolio risks (PortRisk) and returns (PortReturn), plot the efficient frontier:
[prsk, pret] = plotFrontier(obj,PortRisk,PortReturn)
The plotFrontier function assumes that you provide valid efficient portfolio risks and returns as inputs.

\section*{Data Types: double}

\section*{Output Arguments}

\section*{prsk - Estimated efficient portfolio risks (standard deviation of returns}
vector
Estimated efficient portfolio risks (standard deviation of returns, returned as a vector for a Portfolio, PortfolioCVaR, or PortfolioMAD input object (obj).

\section*{Note:}
- If the portfolio object has a name in the Name property, the name is displayed as the title of the plot. Otherwise, the plot is just labeled "Efficient Frontier."
- If the portfolio object has an initial portfolio in the InitPort property, the initial portfolio is plotted and labeled.
- If portfolio risks and returns are inputs, make sure that risks come first in the calling sequence. In addition, if portfolio risks and returns are not sorted in ascending order, this method performs the sort. On output, the sorted moments are returned.

\section*{pret - Estimated efficient porifolio returns}

\section*{vector}

Estimated efficient portfolio returns, returned as a vector for a Portfolio, PortfolioCVaR, or PortfolioMAD input object (obj).

\section*{Note:}
- If the portfolio object has a name in the Name property, the name is displayed as the title of the plot. Otherwise, the plot is labeled "Efficient Frontier."
- If the portfolio object has an initial portfolio in the InitPort property, the initial portfolio is plotted and labeled.
- If portfolio risks and returns are inputs, make sure that risks come first in the calling sequence. In addition, if portfolio risks and returns are not sorted in ascending order, this method performs the sort. On output, the sorted moments are returned.

\section*{More About}

\section*{Tips}

You can also use dot notation to plot the efficient frontier.
[prsk, pret] = obj.plotFrontier;

\section*{Introduced in R201 la}

\section*{plus}

Financial time series addition

\section*{Syntax}
```

newfts = tsobj_1 + tsobj_2
newfts = tsobj + array
newfts = array + tsobj

```

\section*{Arguments}
\begin{tabular}{|l|l|}
\hline tsobj_1, tsobj_2 & A pair of financial time series objects. \\
\hline array & \begin{tabular}{l} 
A scalar value or array with the number of rows equal to the \\
number of dates in tsobj and the number of columns equal \\
to the number of data series in tsobj.
\end{tabular} \\
\hline
\end{tabular}

\section*{Description}
plus is an element-by-element addition of the components.
newfts = tsobj_1 + tsobj_2 adds financial time series objects. If an object is to be added to another object, both objects must have the same dates and data series names, although the order need not be the same. The order of the data series, when one financial time series object is added to another, follows the order of the first object.
newfts \(=\) tsobj + array adds an array element by element to a financial time series object.
newfts = array + tsobj adds a financial time series object element by element to an array.

\section*{pointfig}

Point and figure chart

\section*{Syntax}
```

pointfig(Asset)

```

\section*{Description}
pointfig(Asset) plots a point and figure chart for a vector of price data Asset. Upward price movements are plotted as X's and downward price movements are plotted as O's.

\section*{Examples}

\section*{Create a Point and Figure Chart for an Equity's Closing Prices}

Using the price data for the equity DIS, plot a point and figure chart for the closing prices.
load disney;
pointfig(dis_CLOSE)

- "Charting Financial Data" on page 2-12

\section*{See Also}
bolling | candle | dateaxis | highlow | movavg

Introduced before R2006a

\section*{portalloc}

Optimal capital allocation to efficient frontier portfolios

\section*{Syntax}
[RiskyRisk, RiskyReturn, RiskyWts, RiskyFraction, OverallRisk, OverallReturn] = portalloc(PortRisk, PortReturn, PortWts, RisklessRate, BorrowRate, RiskAversion)

\section*{Arguments}
\begin{tabular}{|l|l|}
\hline PortRisk & \begin{tabular}{l} 
Standard deviation of each risky asset efficient frontier \\
portfolio. A number of portfolios (NPORTS-by-1 vector).
\end{tabular} \\
\hline PortReturn & \begin{tabular}{l} 
Expected return of each risky asset efficient frontier \\
portfolio. An NPORTS-by-1 vector.
\end{tabular} \\
\hline PortWts & \begin{tabular}{l} 
Weights allocated to each asset. An NPORTS by number of \\
assets (NASSETS) matrix of weights allocated to each asset. \\
Each row represents an efficient frontier portfolio of risky \\
assets. Total of all weights in a portfolio is 1.
\end{tabular} \\
\hline RisklessRate & Risk-free lending rate. A decimal number. \\
\hline BorrowRate & \begin{tabular}{l} 
(Optional) Borrowing rate. A decimal number. If borrowing \\
is not desired, or not an option, set to NaN (default).
\end{tabular} \\
\hline RiskAversion & \begin{tabular}{l} 
(Optional) Coefficient of investor's degree of risk aversion. \\
Higher numbers indicate greater risk aversion. Typical \\
coefficients range from 2.0 through 4.0 (Default = 3).
\end{tabular} \\
\hline & \begin{tabular}{l} 
Note: Consider that a less risk-averse investor would be \\
expected to accept much greater risk and, consequently, \\
a more risk-averse investor would accept less risk \\
for a given level of return. Therefore, making the \\
RiskAversionargument higher reflects the risk-return \\
tradeoff in the data.
\end{tabular} \\
\hline
\end{tabular}

\section*{Description}
[RiskyRisk, RiskyReturn, RiskyWts, RiskyFraction, OverallRisk, OverallReturn] = portalloc(PortRisk, PortReturn, PortWts, RisklessRate, BorrowRate, RiskAversion) computes the optimal risky portfolio, and the optimal allocation of funds between the risky portfolio and the risk-free asset.

RiskyRisk is the standard deviation of the optimal risky portfolio.
RiskyReturn is the expected return of the optimal risky portfolio.
RiskyWts is a 1-by-NASSETS vector of weights allocated to the optimal risky portfolio. The total of all weights in the portfolio is 1 .

RiskyFraction is the fraction of the complete portfolio allocated to the risky portfolio.
OverallRisk is the standard deviation of the optimal overall portfolio.
OverallReturn is the expected rate of return of the optimal overall portfolio.
portalloc generates a plot of the optimal capital allocation if you invoke it without output arguments.

\section*{Examples}

\section*{Compute the Optimal Risky Portfolio}

This example shows how to compute the optimal risky portfolio by generating the efficient frontier from the asset data and then finding the optimal risky portfolio and allocate capital. The risk-free investment return is \(8 \%\), and the borrowing rate is \(12 \%\).
```

ExpReturn = [0.1 0.2 0.15];
ExpCovariance = [0.005 -0.010 0.004
-0.010 0.040 -0.002
[PortRisk, PortReturn, PortWts] = portopt(ExpReturn,...
ExpCovariance);
RisklessRate = 0.08;
BorrowRate = 0.12;

```
```

RiskAversion = 3;

}

\section*{portalpha}

Compute risk-adjusted alphas and returns for one or more assets

\section*{Syntax}
```

portalpha(Asset, Benchmark)
portalpha(Asset, Benchmark, Cash)
portalpha(Asset, Benchmark, Cash, Choice)
Alpha = portalpha(Asset, Benchmark, Cash, Choice)
[Alpha, RAReturn] = portalpha(Asset, Benchmark, Cash, Choice)

```

\section*{Arguments}
\begin{tabular}{|l|l|}
\hline Asset & \begin{tabular}{l} 
NUMSAMPLES x NUMSERIES matrix with NUMSAMPLES \\
observations of asset returns for NUMSERIES asset return \\
series.
\end{tabular} \\
\hline Benchmark & \begin{tabular}{l} 
NUMSAMPLES vector of returns for a benchmark asset. The \\
periodicity must be the same as the periodicity of Asset. \\
For example, if Asset is monthly data, then Benchmark \\
should be monthly returns.
\end{tabular} \\
\hline Cash & \begin{tabular}{l} 
(Optional) Either a scalar return for a riskless asset or a \\
vector of asset returns to be a proxy for a "riskless" asset. \\
In either case, the periodicity must be the same as the \\
periodicity of Asset. For example, if Asset is monthly data, \\
then Cash must be monthly returns. If no value is supplied, \\
the default value for Cash returns is 0.
\end{tabular} \\
\hline Choice & \begin{tabular}{l} 
(Optional) A number, string, or cell array of numbers or \\
strings to indicate one or more measures to be computed \\
from among a number of risk-adjusted alphas and return \\
measures. The number of choices selected in Choice is
\end{tabular} \\
NUMCHOICES. The current list of choices is given in the \\
following table:
\end{tabular}

\section*{Description}

Given NUMSERIES assets with NUMSAMPLES returns in a NUMSAMPLES-by-NUMSERIES matrix Asset, a NUMSAMPLES vector of Benchmark returns, and either a scalar Cash return or a NUMSAMPLES vector of Cash returns, compute risk-adjusted alphas and returns for one or more methods specified by Choice.

To summarize the outputs of portalpha:
- Alpha is a NUMCHOICES-by-NUMSERIES matrix of risk-adjusted alphas for each series in Asset with each row corresponding to a specified measure in Choice.
- RAReturn is a NUMCHOICES-by-NUMSERIES matrix of risk-adjusted returns for each series in Asset with each row corresponding to a specified measure in Choice.

Note: NaN values in the data are ignored and, if NaNs are present, some results could be unpredictable. Although the alphas are comparable across measures, risk-adjusted returns depend on whether the Asset or Benchmark is levered or unlevered to match its risk with the alternative. If Choice = 'all', the order of rows in Alpha and RAReturn follows the order in the table. In addition, Choice \(=\) 'all' overrides all other choices.

\section*{Examples}

See "Risk-Adjusted Return" on page 7-11.

\section*{portcons}

\section*{Portfolio constraints}

As an alternative to portcons, use the Portfolio object (Portfolio) for mean-variance portfolio optimization. This object supports gross or net portfolio returns as the return proxy, the variance of portfolio returns as the risk proxy, and a portfolio set that is any combination of the specified constraints to form a portfolio set. For information on the workflow when using Portfolio objects, see "Portfolio Object Workflow" on page 4-17.

\section*{Syntax}

ConSet = portcons(varargin)

\section*{Description}

Using linear inequalities, portcons generates a matrix of constraints for a portfolio of asset investments. The matrix ConSet is defined as ConSet \(=[A \mathrm{~b}] . \mathrm{A}\) is a matrix and b a vector such that \(A * P o r t W t s{ }^{\prime}<=b\) sets the value, where PortWts is a 1-by-number of assets (NASSETS) vector of asset allocations.

ConSet \(=\) portcons('ConstType', Data1, ..., DataN) creates a matrix ConSet, based on the constraint type ConstType, and the constraint parameters Data1, ..., DataN.

ConSet = portcons('ConstType1', Data11, ..., Data21, ..., Data2N, ...) creates a matrix ConSet, based on the constraint types ConstTypeN, and the corresponding constraint parameters DataN1, ..., DataNN.

\section*{Examples}

Constrain a portfolio of three assets:
\begin{tabular}{llll} 
Asset & IBM & HPQ & XOM \\
Group & A & A & B \\
Minimum Weight & 0 & 0 & 0 \\
Maximum Weight & 0.5 & 0.9 & 0.8
\end{tabular}
```

NumAssets = 3;
PVal = 1; % Scale portfolio value to 1.

```
```

AssetMin = 0;
AssetMax = [0.5 0.9 0.8];
GroupA = [llll}1100]
GroupB = [0 0 1];
AtoBmax = 1.5 % Value of assets in Group A at most 1.5 times value
% in group B.
ConSet = portcons('PortValue', PVal, NumAssets,'AssetLims',...
AssetMin, AssetMax, NumAssets, 'GroupComparison',GroupA, NaN,...
AtoBmax, GroupB)
ConSet =

| 1.0000 | 1.0000 | 1.0000 | 1.0000 |
| ---: | ---: | ---: | ---: |
| -1.0000 | -1.0000 | -1.0000 | -1.0000 |
| 1.0000 | 0 | 0 | 0.5000 |
| 0 | 1.0000 | 0 | 0.9000 |
| 0 | 0 | 1.0000 | 0.8000 |
| -1.0000 | 0 | 0 | 0 |
| 0 | -1.0000 | 0 | 0 |
| 0 | 0 | -1.0000 | 0 |
| 1.0000 | 1.0000 | -1.5000 | 0 |

```

For instance, one possible solution for portfolio weights that satisfy the constraints is \(30 \%\) in IBM, \(30 \%\) in HPQ, and \(40 \%\) in XOM.

\section*{Using Portfolio Objects}

Portfolio object for mean-variance portfolio optimization and analysis

\section*{Description}

The Portfolio object implements mean-variance portfolio optimization. Portfolio objects support functions that are specific to mean-variance portfolio optimization.

The main workflow for portfolio optimization is to create an instance of a Portfolio object that completely specifies a portfolio optimization problem and to operate on the Portfolio object using supported functions to obtain and analyze efficient portfolios. A mean-variance optimization problem is completely specified with the following three elements:
- A universe of assets with estimates for the prospective mean and covariance of asset total returns for a period of interest.
- A portfolio set that specifies the set of portfolio choices in terms of a collection of constraints.
- A model for portfolio return and risk, which, for mean-variance optimization, is either the gross or net mean of portfolio returns and the standard deviation of portfolio returns.

After you specify these three elements in an unambiguous way, you can solve and analyze portfolio optimization problems. The simplest mean-variance portfolio optimization problem has:
- A mean and covariance of asset total returns
- Nonnegative weights for all portfolios that sum to 1 (the summation constraint is known as a budget constraint)
- Built-in models for portfolio return and risk that use the mean and covariance of asset total returns

Given mean and covariance of asset returns in the variables AssetMean and AssetCovar, this problem is completely specified by:
```

p = Portfolio('AssetMean', AssetMean, 'AssetCovar', AssetCovar,...
'LowerBound', 0, 'UpperBudget',1, 'LowerBudget', 1)

```
or equivalently by:
p = Portfolio;
p = setAssetMoments(p, AssetMean, AssetCovar);
p = setDefaultConstraints(p);
For more information on the workflow when using Portfolio objects, see "Portfolio Object Workflow" on page 4-17 and for more detailed information on the theoretical basis for mean-variance optimization, see "Portfolio Optimization Theory" on page 4-2.

\section*{Examples}

\section*{Construct a Poriffolio Object and Determine Efficient Portfolios}

Create efficient portfolios:
```

load CAPMuniverse

```
p = Portfolio('AssetList',Assets(1:12));
p = estimateAssetMoments(p, Data(:,1:12),'missingdata',true);
p = setDefaultConstraints(p);
plotFrontier(p);
pwgt = estimateFrontier(p, 5);
pnames \(=\operatorname{cell}(1,5)\);
for \(i=1: 5\)
    pnames\{i\} = sprintf('Port\%d',i);
end
Blotter = dataset([\{pwgt\},pnames],'obsnames',p.AssetList);
disp(Blotter);
\begin{tabular}{lrrrrl}

\section*{Introduced in R201 la}

\section*{Portfolio}

Create Portfolio object for mean-variance portfolio optimization
Use the Portfolio function to create a Portfolio object for mean-variance portfolio optimization. For more information, see Using Portfolio Objects.

You can use the Portfolio function in several ways. To set up a portfolio optimization problem in a Portfolio object, the simplest syntax is:
```

p = Portfolio;

```

This syntax creates a Portfolio object, p, such that all object properties are empty.
The Portfolio function also accepts collections of argument name-value pair arguments for properties and their values. The Portfolio function accepts inputs for properties with the general syntax:
```

p = Portfolio('property1', value1, 'property2', value2, ... );

```

If a Portfolio object exists, the syntax permits the first (and only the first argument) of the Portfolio function to be an existing object with subsequent argument name-value pair arguments for properties to be added or modified. For example, given an existing Portfolio object in \(p\), the general syntax is:
\(p=\) Portfolio( \(p, \quad\) 'property1', value1, 'property2', value2, ... );
Input argument names are not case-sensitive, but must be completely specified. In addition, several properties can be specified with alternative argument names (see "Shortcuts for Property Names" on page 18-946). The Portfolio function tries to detect problem dimensions from the inputs and, once set, subsequent inputs can undergo various scalar or matrix expansion operations that simplify the overall process to formulate a problem. In addition, a Portfolio object is a value object so that, given portfolio p , the following code creates two objects, p and q , that are distinct:
q = Portfolio(p, ...)
After creating a Portfolio object, you can use the associated object functions to set portfolio constraints, analyze the efficient frontier, and validate the portfolio model.

For details on this workflow, see "Portfolio Object Workflow" on page 4-17 and for more detailed information on the theoretical basis for mean-variance optimization, see "Portfolio Optimization Theory" on page 4-2.

\section*{Syntax}
```

p = Portfolio
p = Portfolio(Name,Value)
p = Portfolio(p,Name,Value)

```

\section*{Description}
p = Portfolio constructs an empty Portfolio object for mean-variance portfolio optimization and analysis. You can then add elements to the Portfolio object using the supported add and set functions. For more information, see "Creating the Portfolio Object" on page 4-24..
p = Portfolio(Name, Value) constructs a Portfolio object for mean-variance portfolio optimization and analysis with additional options specified by one or more Name, Value arguments.
p = Portfolio( \(p\), Name, Value) constructs a Portfolio object for mean-variance portfolio optimization and analysis using a previously constructed Portfolio object p with additional options specified by one or more Name, Value arguments.

\section*{Examples}

\section*{Create an Empty Portfolio Object}

You can create a Portfolio object, p , with no input arguments and display it using disp.
```

p = Portfolio;
disp(p);
Portfolio with properties:
BuyCost: []
SellCost: []
RiskFreeRate: []
AssetMean: []
AssetCovar: []
TrackingError: []
TrackingPort: []

```
Turnover: []
BuyTurnover: []
SellTurnover: []
Name: []
NumAssets: []
AssetList: []
InitPort: []
AInequality: []
bInequality: []
AEquality: []
bEquality: []
LowerBound: []
UpperBound: []
LowerBudget: []
UpperBudget: []
GroupMatrix: []
LowerGroup: []
UpperGroup: []
GroupA: []
GroupB: []
LowerRatio: []
UpperRatio: []

This approach provides a way to set up a portfolio optimization problem with the Portfolio function. You can then use the associated set functions to set and modify collections of properties in the Portfolio object.

\section*{Create a Portfolio Object Using a Single-Step Setup}

You can use the Portfolio function directly set up a "standard" portfolio optimization problem, given a mean and covariance of asset returns in the variables \(m\) and \(C\).
```

m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
0.00408 0.0289 0.0204 0.0119;
0.00192 0.0204 0.0576 0.0336;
0 0.0119 0.0336 0.1225 ];
p = Portfolio('assetmean', m, 'assetcovar', C, ...
'lowerbudget', 1, 'upperbudget', 1, 'lowerbound', 0)

```
\(\mathrm{p}=\)
```

Portfolio with properties:
BuyCost: []
SellCost: []
RiskFreeRate: []
AssetMean: [4x1 double]
AssetCovar: [4x4 double]
TrackingError: []
TrackingPort: []
Turnover: []
BuyTurnover: []
SellTurnover: []
Name: []
NumAssets: 4
AssetList: []
InitPort: []
AInequality: []
bInequality: []
AEquality: []
bEquality: []
LowerBound: [4x1 double]
UpperBound: []
LowerBudget: 1
UpperBudget: 1
GroupMatrix: []
LowerGroup: []
UpperGroup: []
GroupA: []
GroupB: []
LowerRatio: []
UpperRatio: []

```

Note that the LowerBound property value undergoes scalar expansion since AssetMean and AssetCovar provide the dimensions of the problem.

\section*{Create a Porffolio Object Using a Sequence of Steps}

Using a sequence of steps is an alternative way to accomplish the same task of setting up a "standard" portfolio optimization problem, given a mean and covariance of asset returns in the variables \(m\) and \(C\) (which also illustrates that argument names are not case sensitive).
```

m = [ 0.05; 0.1; 0.12; 0.18 ];

```
```

C = [ 0.0064 0.00408 0.00192 0;
0.00408 0.0289 0.0204 0.0119;
0.00192 0.0204 0.0576 0.0336;
0 0.0119 0.0336 0.1225 ];
p = Portfolio;
p = Portfolio(p, 'assetmean', m, 'assetcovar', C);
p = Portfolio(p, 'lowerbudget', 1, 'upperbudget', 1);
p = Portfolio(p, 'lowerbound', 0);
plotFrontier(p);

```

This way works because the calls to the Portfolio function are in this particular order. In this case, the call to initialize AssetMean and AssetCovar provides the dimensions
for the problem. If you were to do this step last, you would have to explicitly dimension the LowerBound property as follows:
```

m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
0.00408 0.0289 0.0204 0.0119;
0.00192 0.0204 0.0576 0.0336;
0 0.0119 0.0336 0.1225 ];
p = Portfolio;
p = Portfolio(p, 'LowerBound', zeros(size(m)));
p = Portfolio(p, 'LowerBudget', 1, 'UpperBudget', 1);
p = Portfolio(p, 'AssetMean', m, 'AssetCovar', C);
plotFrontier(p);

```

If you did not specify the size of LowerBound but, instead, input a scalar argument, the Portfolio function assumes that you are defining a single-asset problem and produces an error at the call to set asset moments with four assets.

\section*{Create a Porifolio Object Using Shortcuts for Property Names}

You can create a Portfolio object, p with the Portfolio function using shortcuts for property names.
```

m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
0.00408 0.0289 0.0204 0.0119;
0.00192 0.0204 0.0576 0.0336;
0 0.0119 0.0336 0.1225 ];

```
```

p = Portfolio('mean', m, 'covar', C, 'budget', 1, 'lb', 0)
p =
Portfolio with properties:
BuyCost: []
SellCost: []
RiskFreeRate: []
AssetMean: [4x1 double]
AssetCovar: [4x4 double]
TrackingError: []
TrackingPort: []
Turnover: []
BuyTurnover: []
SellTurnover: []
Name: []
NumAssets: 4
AssetList: []
InitPort: []
AInequality: []
bInequality: []
AEquality: []
bEquality: []
LowerBound: [4x1 double]
UpperBound: []
LowerBudget: 1
UpperBudget: 1
GroupMatrix: []
LowerGroup: []
UpperGroup: []
GroupA: []
GroupB: []
LowerRatio: []
UpperRatio: []

```

\section*{Direct Setting of Portfolio Object Properties}

Although not recommended, you can set properties directly, however no error-checking is done on your inputs.
```

m = [ 0.05; 0.1; 0.12; 0.18 ];

```
```

C = [ 0.0064 0.00408 0.00192 0;
0.00408 0.0289 0.0204 0.0119;
0.00192 0.0204 0.0576 0.0336;
0 0.0119 0.0336 0.1225 ];
p = Portfolio;
p.NumAssets = numel(m);
p.AssetMean = m;
p.AssetCovar = C;
p.LowerBudget = 1;
p.UpperBudget = 1;
p.LowerBound = zeros(size(m));
disp(p)

```
    Portfolio with properties:
            BuyCost: []
            SellCost: []
    RiskFreeRate: []
            AssetMean: [4x1 double]
            AssetCovar: [4x4 double]
        TrackingError: []
        TrackingPort: []
            Turnover: []
        BuyTurnover: []
        SellTurnover: []
            Name: []
        NumAssets: 4
        AssetList: []
            InitPort: []
        AInequality: []
        bInequality: []
            AEquality: []
            bEquality: []
        LowerBound: [4x1 double]
        UpperBound: []
            LowerBudget: 1
            UpperBudget: 1
            GroupMatrix: []
            LowerGroup: []
            UpperGroup: []
            GroupA: []

\section*{More About}

\section*{Mean-Variance Porifolio Optimization}

For more information on the theory and definition of mean-variance optimization supported by portfolio optimization tools in Financial Toolbox, see "Portfolio Optimization Theory" on page 4-2.

\section*{Portfolio Problem Sufficiency}

A mean-variance portfolio optimization is completely specified with the Portfolio object if these two conditions are met:
- The moments of asset returns must be specified such that the property AssetMean contains a valid finite mean vector of asset returns and the property AssetMean contains a valid symmetric positive-semidefinite matrix for the covariance of asset returns.

The first condition is satisfied by setting the properties associated with the moments of asset returns.
- The set of feasible portfolios must be a nonempty compact set, where a compact set is closed and bounded.

The second condition is satisfied by an extensive collection of properties that define different types of constraints to form a set of feasible portfolios. Since such sets must be bounded, either explicit or implicit constraints can be imposed, and several functions, such as estimateBounds, provide ways to ensure that your problem is properly formulated.

Although the general sufficiency conditions for mean-variance portfolio optimization go beyond these two conditions, the Portfolio object implemented in Financial Toolbox implicitly handles all these additional conditions. For more information on the Markowitz model for mean-variance portfolio optimization, see "Portfolio Optimization" on page A-10.

\section*{Shortcuts for Property Names}

The Portfolio function has shorter argument names that replace longer argument names associated with specific properties of the Portfolio object.

For example, rather than enter 'assetcovar', the Portfolio function accepts the case-insensitive name 'covar' to set the AssetCovar property in a Portfolio object.

Every shorter argument name corresponds with a single property in the Portfolio function. The one exception is the alternative argument name 'budget', which signifies both the LowerBudget and UpperBudget properties. When 'budget' is used, then the LowerBudget and UpperBudget properties are set to the same value to form an equality budget constraint.

\section*{Shortcuts for Property Names}
\begin{tabular}{|l|l|}
\hline Shortcut Argument Name & Equivalent Argument / Property Name \\
\hline ae & AEquality \\
\hline ai & AInequality \\
\hline covar & AssetCovar \\
\hline assetnames or assets & AssetList \\

\section*{Portfolio Properties}

Manage Portfolio object for mean-variance portfolio optimization and analysis
The main workflow for portfolio optimization is to create an instance of a Portfolio object that completely specifies a portfolio optimization problem and to operate on the Portfolio object using the supported object functions to obtain and analyze efficient portfolios.

The Portfolio object and its associated functions are an interface for mean-variance portfolio optimization. So, almost everything you do with the Portfolio object can be done using the associated functions. The basic workflow is:

1 Design your portfolio problem.
2 Use the Portfolio function to create the Portfolio object or use the various set functions to set up your portfolio problem.
3 Use estimate functions to solve your portfolio problem.
In addition, functions are available to help you view intermediate results and to diagnose your computations. Since MATLAB features are part of a Portfolio object, you can save and load objects from your workspace and create and manipulate arrays of objects. After settling on a problem, which, in the case of mean-variance portfolio optimization, means that you have either data or moments for asset returns and a collection of constraints on your portfolios, use the Portfolio function to set the properties for the Portfolio object. The Portfolio function lets you create an object from scratch or update an existing object. Since the Portfolio object is a value object, it is easy to create a basic object, then use functions to build upon the basic object to create new versions of the basic object. This is useful to compare a basic problem with alternatives derived from the basic problem. For details, see "Creating the Portfolio Object" on page 4-24.

For more information on the workflow when using Portfolio objects, see "Portfolio Object Workflow" on page 4-17.

\section*{Setting Up the Object}

AssetList - cell array of strings
[] (default) | square matrix
Names or symbols of assets in the universe, specified as a cell array of strings

\section*{Data Types: cell}

\section*{InitPort - Initial porffolio}
[] (default) | vector
Initial portfolio, specified as a vector.
Data Types: double
Name - Name for instance of Porifolio object
[] (default) | string
Name for instance of the Portfolio object, specified as a string.
Data Types: char

\section*{NumAssets - Number of assets in the universe}
[ ] (default) | integer scalar
Number of assets in the universe, specified as an integer scalar.
Data Types: double

\section*{Portfolio Object Constraints}

\section*{AEquality - Linear equality constraint matrix}
[] (default) | matrix
Linear equality constraint matrix, specified as a matrix.
Data Types: double

\section*{AInequality - Linear inequality constraint matrix [] (default) | matrix}

Linear inequality constraint matrix, specified as a matrix.
Data Types: double

\section*{bEquality - Linear equality constraint vector}
[] (default) | vector
Linear equality constraint vector, specified as a vector.
Data Types: double

\section*{bInequality - Linear inequality constraint \\ [] (default) | vector}

Linear inequality constraint vector, specified as a vector.

\section*{Using PorffolioCVaR Objects}

PortfolioCVaR object for conditional value-at-risk portfolio optimization and analysis

\section*{Description}

The PortfolioCVaR object implements conditional value-at-risk (CVaR) portfolio optimization. PortfolioCVaR objects support functions that are specific to conditional value-at-risk (CVaR) portfolio optimization.

The main workflow for CVaR portfolio optimization is to create an instance of a PortfolioCVaR object that completely specifies a portfolio optimization problem and to operate on the PortfolioCVaR object using supported functions to obtain and analyze efficient portfolios. A CVaR optimization problem is completely specified with the following four elements:
- A universe of assets with scenarios of asset total returns for a period of interest, where scenarios comprise a collection of samples from the underlying probability distribution for asset total returns. This collection must be sufficiently large for asymptotic convergence of sample statistics. Asset return moments and related statistics are derived exclusively from the scenarios.
- A portfolio set that specifies the set of portfolio choices in terms of a collection of constraints.
- A model for portfolio return and risk proxies, which, for CVaR optimization, is either the gross or net mean of portfolio returns and the conditional value-at-risk of portfolio returns.
- A probability level that specifies the probability that a loss is less than or equal to the value-at-risk. Typical values are 0.9 and 0.95 , which indicate \(10 \%\) and \(5 \%\) loss probabilities.

After these four elements have been specified in an unambiguous way, it is possible to solve and analyze CVaR portfolio optimization problems.

The simplest CVaR portfolio optimization problem has:
- Scenarios of asset total returns
- A requirement that all portfolios have nonnegative weights that sum to 1 (the summation constraint is known as a budget constraint)
- Built-in models for portfolio return and risk proxies that use scenarios of asset total returns
- A probability level of 0.95

Given scenarios of asset returns in the variable AssetScenarios, this problem is completely specified by:
```

p = PortfolioCVaR('Scenarios', AssetScenarios, 'LowerBound', 0, 'Budget', 1, ...
'ProbabilityLevel', 0.95);
or equivalently by:
p = PortfolioCVaR;
p = setScenarios(p, AssetScenarios);
p = setDefaultConstraints(p);
p = setProbabilityLevel(p, 0.95);

```

To confirm that this is a valid portfolio optimization problem, the following function determines whether the set of PortfolioCVaR choices is bounded (a necessary condition for portfolio optimization).
```

[lb, ub, isbounded] = estimateBounds(p);

```

Given the problem specified in the PortfolioCVaR object \(p\), the efficient frontier for this problem can be displayed with:
```

plotFrontier(p);

```
and efficient portfolios can be obtained with:
```

pwgt = estimateFrontier(p);

```

For more information on the workflow when using PortfolioCVaR objects, see "PortfolioCVaR Object Workflow" on page 5-16 and for more detailed information on the theoretical basis for conditional value-at-risk optimization, see "Portfolio Optimization Theory" on page 5-2.

\section*{PorffolioCVaR}

Create PortfolioCVaR object for conditional value-at-risk portfolio optimization
Use the PortfolioCVaR function to create a PortfolioCVaR object for conditional value-at-risk portfolio optimization. For more information, see Using PortfolioCVaR Objects

You can use the PortfolioCVaR function in several ways. To set up a portfolio optimization problem in a PortfolioCVaR object, the simplest syntax is:
p = PortfolioCVaR;
This syntax creates a PortfolioCVaR object, p, such that all object properties are empty.
The PortfolioCVaR function also accepts collections of argument name-value pair arguments for properties and their values. The PortfolioCVaR function accepts inputs for properties with the general syntax:
```

p = PortfolioCVaR('property1', value1, 'property2', value2, ... );

```

If a PortfolioCVaR object already exists, the syntax permits the first (and only the first argument) of the PortfolioCVaR function to be an existing object with subsequent argument name-value pair arguments for properties to be added or modified. For example, given an existing PortfolioCVaR object in p , the general syntax is:
```

p = PortfolioCVaR(p, 'property1', value1, 'property2', value2, ... );

```

Input argument names are not case sensitive, but must be completely specified. In addition, several properties can be specified with alternative argument names (see "Shortcuts for Property Names" on page 18-980). The PortfolioCVaR function tries to detect problem dimensions from the inputs and, once set, subsequent inputs can undergo various scalar or matrix expansion operations that simplify the overall process to formulate a problem. In addition, a PortfolioCVaR object is a value object so that, given portfolio \(p\), the following code creates two objects, \(p\) and \(q\), that are distinct:
```

q = PortfolioCVaR(p, ...)

```

After creating a PortfolioCVaR object, you can use the associated object functions to set portfolio constraints, analyze the efficient frontier, and validate the portfolio model.

For details on this workflow, see "PortfolioCVaR Object Workflow" on page 5-16 and for more detailed information on the theoretical basis for conditional value-at-risk portfolio optimization, see "Portfolio Optimization Theory" on page 5-2.

\section*{Syntax}
```

p = PortfolioCVaR
p = PortfolioCVaR(Name,Value)
p = PortfolioCVaR(p,Name,Value)

```

\section*{Description}
p = PortfolioCVaR constructs an empty PortfolioCVaR object for conditional value-atrisk portfolio optimization and analysis. You can then add elements to the PortfolioCVaR object using the supported add and set functions. For more information, see "Creating the PortfolioCVaR Object" on page 5-23..
p = PortfolioCVaR(Name, Value) constructs a PortfolioCVaR object for conditional value-at-risk portfolio optimization and analysis with additional options specified by one or more Name, Value arguments.
p = PortfolioCVaR(p,Name, Value) constructs a PortfolioCVaR object for conditional value-at-risk portfolio optimization and analysis using a previously constructed PortfolioCVaR object \(p\) with additional options specified by one or more Name, Value arguments.

\section*{Examples}

\section*{Create an Empty PorifolioCVaR Object}

You can create a PortfolioCVaR object, p , with no input arguments and display it using disp.
```

p = PortfolioCVaR;
disp(p);

```
    PortfolioCVaR with properties:
            BuyCost: []
            SellCost: []
        RiskFreeRate: []
    ProbabilityLevel: []
            Turnover: []
```

    BuyTurnover: []
    SellTurnover: []
NumScenarios: []
Name: []
NumAssets: []
AssetList: []
InitPort: []
AInequality: []
bInequality: []
AEquality: []
bEquality: []
LowerBound: []
UpperBound: []
LowerBudget: []
UpperBudget: []
GroupMatrix: []
LowerGroup: []
UpperGroup: []
GroupA: []
GroupB: []
LowerRatio: []
UpperRatio: []

```

This approach provides a way to set up a portfolio optimization problem with the PortfolioCVaR function. You can then use the associated set functions to set and modify collections of properties in the PortfolioCVaR object.

\section*{Create a PorifolioCVaR Object Using a Single-Step Setup}

You can use the PortfolioCVaR function directly set up a "standard" portfolio optimization problem. Given scenarios of asset returns in the variable AssetScenarios, this problem is completely specified as follows:
```

m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
0.00408 0.0289 0.0204 0.0119;
0.00192 0.0204 0.0576 0.0336;
0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;
AssetScenarios = mvnrnd(m, C, 20000);

```
```

p = PortfolioCVaR('Scenarios', AssetScenarios, ...
'LowerBound', 0, 'LowerBudget', 1, 'UpperBudget', 1, ...
'ProbabilityLevel', 0.95)
p =
PortfolioCVaR with properties:
BuyCost: []
SellCost: []
RiskFreeRate: []
ProbabilityLevel: 0.9500
Turnover: []
BuyTurnover: []
SellTurnover: []
NumScenarios: 20000
Name: []
NumAssets: 4
AssetList: []
InitPort: []
AInequality: []
bInequality: []
AEquality: []
bEquality: []
LowerBound: [4x1 double]
UpperBound: []
LowerBudget: 1
UpperBudget: 1
GroupMatrix: []
LowerGroup: []
UpperGroup: []
GroupA: []
GroupB: []
LowerRatio: []
UpperRatio: []

```

Note that the LowerBound property value undergoes scalar expansion since AssetScenarios provides the dimensions of the problem.

\section*{Create a PorffolioCVaR Object Using a Sequence of Steps}

Using a sequence of steps is an alternative way to accomplish the same task of setting up a "standard" CVaR portfolio optimization problem, given AssetScenarios variable is:
```

m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
0.00408 0.0289 0.0204 0.0119;
0.00192 0.0204 0.0576 0.0336;
0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;

```
AssetScenarios = mvnrnd(m, C, 20000);
p = PortfolioCVaR;
p = setScenarios(p, AssetScenarios);
\(p\) = PortfolioCVaR(p, 'LowerBound', 0);
p = PortfolioCVaR(p, 'LowerBudget', 1, 'UpperBudget', 1);
p = setProbabilityLevel(p, 0.95);
plotFrontier(p);

This way works because the calls to the PortfolioCVaR function are in this particular order. In this case, the call to initialize AssetScenarios provides the dimensions for the problem. If you were to do this step last, you would have to explicitly dimension the LowerBound property as follows:
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.00640 .004080 .001920 ;
0.004080 .02890 .02040 .0119 ;
0.001920 .02040 .05760 .0336 ;
00.01190 .03360 .1225 ];
\(\mathrm{m}=\mathrm{m} / 12\);
\(C=C / 12 ;\)
```

AssetScenarios = mvnrnd(m, C, 20000);
p = PortfolioCVaR;
p = PortfolioCVaR(p, 'LowerBound', zeros(size(m)));
p = PortfolioCVaR(p, 'LowerBudget', 1, 'UpperBudget', 1);
p = setProbabilityLevel(p, 0.95);
p = setScenarios(p, AssetScenarios);
plotFrontier(p);

```

If you did not specify the size of LowerBound but, instead, input a scalar argument, the PortfolioCVaR function assumes that you are defining a single-asset problem and produces an error at the call to set asset scenarios with four assets.

\section*{Create a PortfolioCVaR Object Using Shortcuts for Property Names}

You can create a PortfolioCVaR object, p with the PortfolioCVaR function using shortcuts for property names.
```

m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
0.00408 0.0289 0.0204 0.0119;
0.00192 0.0204 0.0576 0.0336;
0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;
AssetScenarios = mvnrnd(m, C, 20000);
p = PortfolioCVaR('scenario', AssetScenarios, 'lb', 0, 'budget', 1, 'plevel', 0.95)
p =

object for CVaR portfolio
Updated CVaR portfolio object, returned as a PortfolioCVaR object, For more information on using the PortfolioCVaR object, see Using PortfolioCVaR Objects.

\section*{More About}

\section*{Conditional Value-at-Risk Portfolio Optimization}

For more information on the theory and definition of conditional value-at-risk optimization supported by portfolio optimization tools in Financial Toolbox, see "Portfolio Optimization Theory" on page 5-2.

\section*{PortfolioCVaR Problem Sufficiency}

A CVaR portfolio optimization problem is completely specified with the PortfolioCVaR object if the following three conditions are met:
- You must specify a collection of asset returns or prices known as scenarios such that all scenarios are finite asset returns or prices. These scenarios are meant to be samples from the underlying probability distribution of asset returns. This condition can be satisfied by the setScenarios function or with several canned scenario simulation functions.
- The set of feasible portfolios must be a nonempty compact set, where a compact set is closed and bounded. You can satisfy this condition using an extensive collection of properties that define different types of constraints to form a set of feasible portfolios. Since such sets must be bounded, either explicit or implicit constraints can be imposed and several tools, such as the estimateBounds function, provide ways to ensure that your problem is properly formulated.
- You must specify a probability level to locate the level of tail loss above which the conditional value-at-risk is to be minimized. This condition can be satisfied by the setProbabilityLevel function.

Although the general sufficient conditions for CVaR portfolio optimization go beyond the first three conditions, the PortfolioCVaR object handles all these additional conditions.

\section*{Shortcuts for Property Names}

The PortfolioCVaR function has shorter argument names that replace longer argument names associated with specific properties of the PortfolioCVaR object.

For example, rather than enter 'ProbabilityLevel', the PortfolioCVaR function accepts the case-insensitive name 'plevel' to set the ProbabilityLevel property in a PortfolioCVaR object. Every shorter argument name corresponds with a single property in the PortfolioCVaR function. The one exception is the alternative argument name 'budget ', which signifies both the LowerBudget and UpperBudget properties. When 'budget ' is used, then the LowerBudget and UpperBudget properties are set to the same value to form an equality budget constraint.

\section*{Shortcuts for Property Names}

\section*{PoriffolioCVaR Properties}

Manage Portfolio object for conditional value-at-risk portfolio optimization and analysis
The main workflow for CVaR portfolio optimization is to create an instance of a PortfolioCVaR object that completely specifies a conditional value-at-risk optimization problem and to operate on the PortfolioCVaR object using the supported object functions to obtain and analyze efficient portfolios.

The PortfolioCVaR object and its associated functions are an interface for conditional value-at-risk optimization. So, almost everything you do with the PortfolioCVaR object can be done using the associated functions. The basic workflow is:

1 Design your portfolio problem.
2 Use the PortfolioCVaR function to create the PortfolioCVaR object or use the various set functions to set up your portfolio problem.
3 Use estimate functions to solve your portfolio problem.
In addition, functions are available to help you view intermediate results and to diagnose your computations. Since MATLAB features are part of a PortfolioCVaR object, you can save and load objects from your workspace and create and manipulate arrays of objects. After settling on a problem, which, in the case of CVaR portfolio optimization, means that you have either scenarios, data, or moments for asset returns, a probability level, and a collection of constraints on your portfolios, use the PortfolioCVaR function to set the properties for the PortfolioCVaR object.

The PortfolioCVaR function lets you create an object from scratch or update an existing object. Since the PortfolioCVaR object is a value object, it is easy to create a basic object, then use methods to build upon the basic object to create new versions of the basic object. This is useful to compare a basic problem with alternatives derived from the basic problem. For details, see "Creating the PortfolioCVaR Object" on page 5-23

For more information on the workflow when using PortfolioCVaR objects, see "PortfolioCVaR Object Workflow" on page 5-16.

\section*{Using PorffolioMAD Objects}

PortfolioMAD object for mean-absolute deviation portfolio optimization and analysis

\section*{Description}

The PortfolioMAD object implements mean-absolute deviation portfolio optimization, where MAD stands for "mean-absolute deviation." PortfolioMAD objects support functions that are specific to MAD portfolio optimization.

The main workflow for MAD portfolio optimization is to create an instance of a PortfolioMAD object that completely specifies a portfolio optimization problem and to operate on the PortfolioMAD object to obtain and analyze efficient portfolios. A MAD optimization problem is completely specified with these three elements:
- A universe of assets with scenarios of asset total returns for a period of interest, where scenarios comprise a collection of samples from the underlying probability distribution for asset total returns. This collection must be sufficiently large for asymptotic convergence of sample statistics. Asset return moments and related statistics are derived exclusively from the scenarios.
- A portfolio set that specifies the set of portfolio choices in terms of a collection of constraints.
- A model for portfolio return and risk proxies, which, for MAD optimization, is either the gross or net mean of portfolio returns and the mean-absolute deviation of portfolio returns.

After these three elements have been specified unambiguously, it is possible to solve and analyze MAD portfolio optimization problems.

The simplest MAD portfolio optimization problem has:
- Scenarios of asset total returns
- A requirement that all portfolios have nonnegative weights that sum to 1 (the summation constraint is known as a budget constraint)
- Built-in models for portfolio return and risk proxies that use scenarios of asset total returns

Given scenarios of asset returns in the variable AssetScenarios, this problem is completely specified by:
```

p = PortfolioMAD('Scenarios', AssetScenarios, 'LowerBound', 0, 'Budget', 1);
or equivalently by:
p = PortfolioMAD;
p = setScenarios(p, AssetScenarios);
p = setDefaultConstraints(p);

```

To confirm that this is a valid portfolio optimization problem, the following function determines whether the set of PortfolioMAD choices is bounded (a necessary condition for portfolio optimization).
```

[lb, ub, isbounded] = estimateBounds(p);

```

Given the problem specified in the PortfolioMAD object \(p\), the efficient frontier for this problem can be displayed with:
```

plotFrontier(p);

```
and efficient portfolios can be obtained with:
```

pwgt = estimateFrontier(p);

```

For more information on the workflow when using PortfolioMAD objects, see"PortfolioMAD Object Workflow" on page 6-16 and for more detailed information on the theoretical basis for mean-absolute deviation optimization, see "Portfolio Optimization Theory" on page 6-2.

\section*{Examples}

\section*{Construct a PorffolioMAD Object and Determine Efficient Portfolios}

Create efficient portfolios:
load CAPMuniverse
```

p = PortfolioMAD('AssetList',Assets(1:12));
p = simulateNormalScenariosByData(p, Data(:,1:12), 20000 ,'missingdata',true);
p = setDefaultConstraints(p);

```
```

plotFrontier(p);
pwgt = estimateFrontier(p, 5);
pnames = cell(1,5);
for i = 1:5
pnames{i} = sprintf('Port%d',i);
end
Blotter = dataset([{pwgt},pnames],'obsnames',p.AssetList);
disp(Blotter);

Set up group constraints for portfolio weights
Set up linear inequality constraints for portfolio weights
Set up bounds for portfolio weights
Set up budget constraints
Set up proportional transaction costs
Set up portfolio constraints with nonnegative weights that sum to 1
Set up linear equality constraints for portfolio weights
Set up group ratio constraints for portfolio weights
Set up initial or current portfolio
Set up one-way portfolio turnover constraints
Set up maximum portfolio turnover constraint
Check feasibility of input portfolios against portfolio object
Estimate global lower and upper bounds for set of portfolios
Estimate specified number of optimal portfolios on the efficient frontier Estimate optimal portfolios with targeted portfolio returns
Estimate optimal portfolios with targeted portfolio risks
Estimate optimal portfolios at endpoints of efficient frontier
Plot efficient frontier
Estimate mean of portfolio returns
Estimate standard deviation of portfolio returns (portfolio risk)
Choose main solver and specify associated solver options for portfolio optimization Set probability level for VaR and CVaR calculations
Set asset returns scenarios by direct matrix Obtain scenarios from portfolio object

\section*{Introduced in R2013b}

\section*{PorffolioMAD}

Create PortfolioMAD object for mean-absolute deviation portfolio optimization
Use the PortfolioMAD function to create a PortfolioMAD object for mean-absolute deviation portfolio optimization. For more information, see Using PortfolioMAD Objects.

You can use the PortfolioMAD function in several ways. To set up a portfolio optimization problem in a PortfolioMAD object, the simplest syntax is:

\section*{p = PortfolioMAD;}

This syntax creates a PortfolioMAD object, p, such that all object properties are empty.
The PortfolioMAD function also accepts collections of argument name-value pair arguments for properties and their values. The PortfolioMAD function accepts inputs for properties with the general syntax:
```

p = PortfolioMAD('property1', value1, 'property2', value2, ... );

```

If a PortfolioMAD object exists, the syntax permits the first (and only the first argument) of the PortfolioMAD function to be an existing object with subsequent argument namevalue pair arguments for properties to be added or modified. For example, given an existing PortfolioMAD object in \(p\), the general syntax is:
p = PortfolioMAD(p, 'property1', value1, 'property2', value2, ... );
Input argument names are not case-sensitive, but must be completely specified. In addition, several properties can be specified with alternative argument names (see "Shortcuts for Property Names" on page 18-1011). The PortfolioMAD function tries to detect problem dimensions from the inputs and, once set, subsequent inputs can undergo various scalar or matrix expansion operations that simplify the overall process to formulate a problem. In addition, a PortfolioMAD object is a value object so that, given portfolio p , the following code creates two objects, p and q , that are distinct:
\(\mathrm{q}=\operatorname{PortfolioMAD(p,...)~}\)
After creating a PortfolioMAD object, you can use the associated object functions to set portfolio constraints, analyze the efficient frontier, and validate the portfolio model.

For details on this workflow, see"PortfolioMAD Object Workflow" on page 6-16 and for more detailed information on the theoretical basis for conditional value-at-risk portfolio optimization, see "Portfolio Optimization Theory" on page 6-2.

\section*{Syntax}
p = PortfolioMAD
p = PortfolioMAD(Name, Value)
p = PortfolioMAD( p, Name, Value)

\section*{Description}
p = PortfolioMAD constructs an empty PortfolioMAD object for mean-absolute deviation portfolio optimization and analysis. You can then add elements to the PortfolioMAD object using the supported add and set functions. For more information, see "Creating the PortfolioMAD Object" on page 6-22.
p = PortfolioMAD(Name, Value) constructs a PortfolioMAD object for mean-absolute deviation portfolio optimization and analysis with additional options specified by one or more Name, Value arguments.
p = PortfolioMAD( \(p\), Name, Value) constructs a PortfolioMAD object for meanabsolute deviation portfolio optimization and analysis using a previously constructed PortfolioMAD object p with additional options specified by one or more Name, Value arguments.

\section*{Examples}

\section*{Create an Empty PortfolioMAD Object}

You can create a PortfolioMAD object, p , with no input arguments and display it using disp.
p = PortfolioMAD;
disp(p);
PortfolioMAD with properties:
BuyCost: []
SellCost: []
RiskFreeRate: []
Turnover: []
BuyTurnover: []
SellTurnover: []
```

NumScenarios: []
Name: []
NumAssets: []
AssetList: []
InitPort: []
AInequality: []
bInequality: []
AEquality: []
bEquality: []
LowerBound: []
UpperBound: []
LowerBudget: []
UpperBudget: []
GroupMatrix: []
LowerGroup: []
UpperGroup: []
GroupA: []
GroupB: []
LowerRatio: []
UpperRatio: []

```

This approach provides a way to set up a portfolio optimization problem with the PortfolioMAD function. You can then use the associated set functions to set and modify collections of properties in the PortfolioMAD object.

\section*{Create a PorifolioMAD Object Using a Single-Step Setup}

You can use the PortfolioMAD function directly set up a "standard" portfolio optimization problem. Given scenarios of asset returns in the variable AssetScenarios, this problem is completely specified as follows:
```

m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
0.00408 0.0289 0.0204 0.0119;
0.00192 0.0204 0.0576 0.0336;
0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;

```
AssetScenarios = mvnrnd(m, C, 20000);
p = PortfolioMAD('Scenarios', AssetScenarios, ...
'LowerBound', 0, 'LowerBudget', 1, 'UpperBudget', 1)
```

p =
PortfolioMAD with properties:
BuyCost: []
SellCost: []
RiskFreeRate: []
Turnover: []
BuyTurnover: []
SellTurnover: []
NumScenarios: 20000
Name: []
NumAssets: 4
AssetList: []
InitPort: []
AInequality: []
bInequality: []
AEquality: []
bEquality: []
LowerBound: [4x1 double]
UpperBound: []
LowerBudget: 1
UpperBudget: 1
GroupMatrix: []
LowerGroup: []
UpperGroup: []
GroupA: []
GroupB: []
LowerRatio: []
UpperRatio: []

```

Note that the LowerBound property value undergoes scalar expansion since AssetScenarios provides the dimensions of the problem.

\section*{Create a PorffolioMAD Object Using a Sequence of Steps}

Using a sequence of steps is an alternative way to accomplish the same task of setting up a "standard" MAD portfolio optimization problem, given AssetScenarios variable is:
\(\mathrm{m}=\mathrm{[ } 0.05 ; 0.1 ; 0.12 ; 0.18\) ];
\(C=[0.00640 .004080 .001920\);
0.004080 .02890 .02040 .0119 ;
\(0.001920 .02040 .05760 .0336 ;\)
\(00.01190 .03360 .1225 \mathrm{]}\);
\(\mathrm{m}=\mathrm{m} / 12\);
C = C/12;
AssetScenarios = mvnrnd(m, C, 20000);
p = PortfolioMAD;
p = setScenarios(p, AssetScenarios);
\(\mathrm{p}=\) PortfolioMAD(p, 'LowerBound', 0 );
\(\mathrm{p}=\) PortfolioMAD(p, 'LowerBudget', 1, 'UpperBudget', 1);
plotFrontier(p);

This way works because the calls to the PortfolioMAD function are in this particular order. In this case, the call to initialize AssetScenarios provides the dimensions for the problem. If you were to do this step last, you would have to explicitly dimension the LowerBound property as follows:
```

m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
0.00408 0.0289 0.0204 0.0119;
0.00192 0.0204 0.0576 0.0336;
0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;
AssetScenarios = mvnrnd(m, C, 20000);
p = PortfolioMAD;
p = PortfolioMAD(p, 'LowerBound', zeros(size(m)));
p = PortfolioMAD(p, 'LowerBudget', 1, 'UpperBudget', 1);
p = setScenarios(p, AssetScenarios);
plotFrontier(p);

```

If you did not specify the size of LowerBound but, instead, input a scalar argument, the PortfolioMAD function assumes that you are defining a single-asset problem and produces an error at the call to set asset scenarios with four assets.

\section*{Create a PortfolioMAD Object Using Shortcuts for Property Names}

You can create a PortfolioMAD object, p with the PortfolioMAD function using shortcuts for property names.
```

m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
0.00408 0.0289 0.0204 0.0119;
0.00192 0.0204 0.0576 0.0336;
0 0.0119 0.0336 0.1225 ];

```
```

m = m/12;
C = C/12;
AssetScenarios = mvnrnd(m, C, 20000);
p = PortfolioMAD('scenario', AssetScenarios, 'lb', 0, 'budget', 1)
p =
PortfolioMAD with properties:
BuyCost: []
SellCost: []
RiskFreeRate: []
Turnover: []
BuyTurnover: []
SellTurnover: []
NumScenarios: 20000
Name: []
NumAssets: 4
AssetList: []
InitPort: []
AInequality: []
bInequality: []
AEquality: []
bEquality: []
LowerBound: [4x1 double]
UpperBound: []
LowerBudget: 1
UpperBudget: 1
GroupMatrix: []
LowerGroup: []
UpperGroup: []
GroupA: []
GroupB: []
LowerRatio: []
UpperRatio: []

```

\section*{Direct Setting of PortfolioMAD Object Properties}

Although not recommended, you can set properties directly, however no error-checking is done on your inputs.
```

m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
0.00408 0.0289 0.0204 0.0119;
0.00192 0.0204 0.0576 0.0336;
0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;
AssetScenarios = mvnrnd(m, C, 20000);
p = PortfolioMAD;
p = setScenarios(p, AssetScenarios);
p.LowerBudget = 1;
p.UpperBudget = 1;
p.LowerBound = zeros(size(m));
disp(p);
PortfolioMAD with properties:
BuyCost: []
SellCost: []
RiskFreeRate: []
Turnover: []
BuyTurnover: []
SellTurnover: []
NumScenarios: 20000
Name: []
NumAssets: 4
AssetList: []
InitPort: []
AInequality: []
bInequality: []
AEquality: []
bEquality: []
LowerBound: [4x1 double]
UpperBound: []
LowerBudget: 1
UpperBudget: 1
GroupMatrix: []
LowerGroup: []
UpperGroup: []
GroupA: []
GroupB: []

```

LowerRatio: []
UpperRatio: []

Scenarios cannot be assigned directly to a PortfolioMAD object. Scenarios must always be set through either the PortfolioMAD function, the setScenarios function, or any of the scenario simulation functions.

\section*{Construct a PortfolioMAD Object and Determine Efficient Portfolios}

Create efficient portfolios:
```

load CAPMuniverse

```
\(\mathrm{p}=\) PortfolioMAD('AssetList', Assets(1:12));
p = simulateNormalScenariosByData(p, Data(:,1:12), 20000 ,'missingdata',true);
\(p=\) setDefaultConstraints(p);
plotFrontier(p);
pwgt = estimateFrontier(p, 5);
pnames \(=\operatorname{cell}(1,5)\);
for \(i=1: 5\)
    pnames\{i\} = sprintf('Port\%d',i);
end
Blotter = dataset([\{pwgt\}, pnames],'obsnames', p.AssetList);
disp(Blotter);
\begin{tabular}{lrrrrr} 
& \multicolumn{1}{l}{ Port1 } & \multicolumn{1}{l}{ Port2 } & Port3 & Port4 & Port5 \\

\section*{More About}

\section*{Mean-Absolute Deviation Porffolio Optimization}

For more information on the theory and definition of mean-absolute deviation (MAD) optimization supported by portfolio optimization tools in Financial Toolbox, see "Portfolio Optimization Theory" on page 5-2.

\section*{PortfolioMAD Problem Sufficiency}

A MAD portfolio optimization problem is completely specified with the PortfolioMAD object if the following three conditions are met:
- You must specify a collection of asset returns or prices known as scenarios such that all scenarios are finite asset returns or prices. These scenarios are meant to be samples from the underlying probability distribution of asset returns. This condition
can be satisfied by the setScenarios function or with several canned scenario simulation functions.
- The set of feasible portfolios must be a nonempty compact set, where a compact set is closed and bounded. You can satisfy this condition using an extensive collection of properties that define different types of constraints to form a set of feasible portfolios. Since such sets must be bounded, either explicit or implicit constraints can be imposed and several tools, such as the estimateBounds function, provide ways to ensure that your problem is properly formulated.

Although the general sufficient conditions for MAD portfolio optimization go beyond these conditions, the PortfolioMAD object handles all these additional conditions.

\section*{Shortcuts for Property Names}

The PortfolioMAD function has shorter argument names that replace longer argument names associated with specific properties of the PortfolioMAD object.

For example, rather than enter 'AInequality', the PortfolioMAD function. accepts the case-insensitive name 'ai' to set the AInequality property in a PortfolioMAD object. Every shorter argument name corresponds with a single property in the PortfolioMAD function. The one exception is the alternative argument name 'budget', which signifies both the LowerBudget and UpperBudget properties. When 'budget ' is used, then the LowerBudget and UpperBudget properties are set to the same value to form an equality budget constraint.

\section*{Shortcuts for Property Names}
\begin{tabular}{|l|l|}
\hline Shortcut Argument Name & Equivalent Argument / Property Name \\

\section*{PortfolioMAD Properties}

Manage PortfolioMAD object for mean-absolute deviation portfolio optimization and analysis

The main workflow for MAD portfolio optimization is to create an instance of a PortfolioMAD object that completely specifies a mean-absolute deviation optimization problem and to operate on the PortfolioMAD object using the supported object functions to obtain and analyze efficient portfolios.

The PortfolioMAD object and its associated functions are an interface for mean-absolute deviation optimization. So, almost everything you do with the PortfolioMAD object can be done using the associated functions. The basic workflow is:

1 Design your portfolio problem.
2 Use the PortfolioMAD function to create the PortfolioMAD object or use the various set functions to set up your portfolio problem.
3 Use estimate functions to solve your portfolio problem.
In addition, methods are available to help you view intermediate results and to diagnose your computations. Since MATLAB features are part of a PortfolioMAD object, you can save and load objects from your workspace and create and manipulate arrays of objects. After settling on a problem, which, in the case of MAD portfolio optimization, means that you have either scenarios, data, or moments for asset returns, and a collection of constraints on your portfolios, use the PortfolioMAD function to set the properties for the PortfolioMAD object.

The PortfolioMAD function lets you create an object from scratch or update an existing object. Since the PortfolioMAD object is a value object, it is easy to create a basic object, then use methods to build upon the basic object to create new versions of the basic object. This is useful to compare a basic problem with alternatives derived from the basic problem. For details, see "Creating the PortfolioMAD Object" on page 6-22.

For more information on the workflow when using PortfolioMAD objects, see "PortfolioMAD Object Workflow" on page 6-16 and for more detailed information on the theoretical basis for mean-absolute deviation optimization, see "Portfolio Optimization Theory" on page 6-2.

\section*{portopt}

Portfolios on constrained efficient frontier

\section*{Compatibility}
portopt has been partially removed and will no longer accept ConSet or varargin arguments. Use Portfolio instead to solve portfolio problems that are more than a long-only fully-invested portfolio. For information on the workflow when using Portfolio objects, see "Portfolio Object Workflow" on page 4-17. For more information on migrating portopt code to Portfolio, see "portopt Migration to Portfolio Object" on page 3-14.

\section*{Syntax}
[PortRisk, PortReturn, PortWts] = portopt(ExpReturn, ExpCovariance)
[PortRisk, PortReturn, PortWts] = portopt(ExpReturn, ExpCovariance, NumPorts)
[PortRisk, PortReturn, PortWts] = portopt(ExpReturn, ExpCovariance, NumPorts, PortReturn)

\section*{Arguments}
\begin{tabular}{|l|l|}
\hline ExpReturn & \begin{tabular}{l}
1 by number of assets (NASSETS) vector specifying the \\
expected (mean) return of each asset.
\end{tabular} \\
\hline ExpCovariance & \begin{tabular}{l} 
NASSETS-by-NASSETS matrix specifying the covariance of \\
the asset returns.
\end{tabular} \\
\hline NumPorts & \begin{tabular}{l} 
(Optional) Number of portfolios generated along the efficient \\
frontier. Returns are equally spaced between the maximum \\
possible return and the minimum risk point. If NumPorts is \\
empty (entered as [ ]), computes 10 equally spaced points.
\end{tabular} \\
\hline PortReturn & \begin{tabular}{l} 
(Optional) Expected return of each portfolio. A number of \\
portfolios (NPORTS-by-1 vector). If not entered or empty, \\
NumPorts equally spaced returns between the minimum \\
and maximum possible values are used.
\end{tabular} \\
\hline
\end{tabular}

\section*{Description}
[PortRisk, PortReturn, PortWts] = portopt(ExpReturn, ExpCovariance) sets up the most basic portfolio problem with weights greater than or equal to 0 that must sum to 1 . All that is necessary to solve this problem is the mean and covariance of asset returns. The problem returns 10 equally-spaced points on the efficient frontier by return.
[PortRisk, PortReturn, PortWts] = portopt(ExpReturn, ExpCovariance, NumPorts) sets up the basic portfolio problem but lets you specify how many equallyspaced points on the efficient frontier that you want in NumPorts. If you specify 1, it returns the minimum-risk portfolio.
[PortRisk, PortReturn, PortWts] = portopt(ExpReturn, ExpCovariance, NumPorts, PortReturn) sets up the basic portfolio problem but lets you specify target returns on the efficient frontier in the vector PortReturn. This functionality requires that if you set PortReturn, NumPorts should be empty.

Note: portopt generates a warning if have returns outside the range and returns the portfolios at the endpoints of the efficient frontier.

The outputs for portopt are:
PortRisk is an NPORTS-by-1 vector of the standard deviation of each portfolio.
PortReturn is an NPORTS-by-1 vector of the expected return of each portfolio.
PortWts is an NPORTS-by-NASSETS matrix of weights allocated to each asset. Each row represents a portfolio. The total of all weights in a portfolio is 1 .

If portopt is invoked without output arguments, it writes to the current figure window.

\section*{Examples}

\section*{Plot the Risk-Return Efficient Frontier}

This example shows how to plot the risk-return efficient frontier of portfolios allocated among three assets.

Connect 20 portfolios along the frontier having evenly spaced returns. By default, choose among portfolios without short-selling and scale the value of the portfolio to 1 .

ExpReturn \(=\left[\begin{array}{lll}0.1 & 0.2 & 0.15\end{array}\right] ;\)
\begin{tabular}{rrrc} 
ExpCovariance \(=\) & {\([0.005\)} & -0.010 & 0.004 \\
& -0.010 & 0.040 & -0.002 \\
& 0.004 & -0.002 & \(0.023] ;\)
\end{tabular}

NumPorts = 20;
portopt(ExpReturn, ExpCovariance, NumPorts)

Return the two efficient portfolios that have returns of \(16 \%\) and \(17 \%\). Limit to portfolios that have at least \(20 \%\) of the allocation in the first asset, and cap the total value in the first and third assets at \(50 \%\) of the portfolio.

ExpReturn = [0.1 0.2 0.15];
\(\begin{array}{rlrc}\text { ExpCovariance }= & {[0.005} & -0.010 & 0.004 \\ & -0.010 & 0.040 & -0.002 \\ & 0.004 & -0.002 & 0.023] ;\end{array}\)
```

PortReturn = [0.16
0.17];
NumAssets = 3;
AssetMin = [0.20 NaN NaN];
Group = [$$
\begin{array}{llll}{1}&{0}&{1}\end{array}
$$];
GroupMax = 0.50;
ConSet = portcons('Default', NumAssets, 'AssetLims', AssetMin,...
NaN,'GroupLims', Group, NaN, GroupMax);
[PortRisk, PortReturn, PortWts] = portopt(ExpReturn,...
ExpCovariance, [], PortReturn, ConSet)

```

\section*{Error using portopt (line 83)}

In the current and future releases, portopt will no longer accept ConSet or varargin arguments.
'It will only solve the portfolio problem for long-only fully-invested portfolios.
To solve more general problems, use the Portfolio object.
See the release notes for details, including examples to make the conversion.

\section*{portrand}

Randomized portfolio risks, returns, and weights

\section*{Syntax}
[PortRisk, PortReturn, PortWts] = portrand(Asset, Return, Points, Method)
portrand(Asset, Return, Points, Method)

\section*{Arguments}
\begin{tabular}{|l|l|}
\hline Asset & \begin{tabular}{l} 
Matrix of time series data. Each row is an observation and each \\
column represents a single security.
\end{tabular} \\
\hline Return & \begin{tabular}{l} 
(Optional) Row vector where each column represents the rate of \\
return for the corresponding security in Asset. By default, Return \\
is computed by taking the average value of each column of Asset.
\end{tabular} \\
\hline Points & \begin{tabular}{l} 
(Optional) Scalar that specifies how many random points should be \\
generated. Default = 1000.
\end{tabular} \\
\hline Method & \begin{tabular}{l} 
(Optional) A string that specifies how to generate random portfolios \\
from the set of portfolios with two possible methods: \\
' uniform ' - Uniformly distributed portfolio weights (default \\
method). The ' uniform ' method generates portfolio weights \\
that are uniformly distributed on the set of portfolio weights. \\
'geometric ' - Concentrated portfolio weights around the \\
geometric center of the set of portfolios. The 'geometric' \\
method generates portfolio weights that are concentrated \\
around the geometric center of the set of portfolio weights.
\end{tabular} \\
\hline Note: The ' uniform ' and 'geometric' methods generate \\
weights that are distributed symmetrically around the geometric \\
center of the set of weights.
\end{tabular}

\section*{Description}
[PortRisk, PortReturn, PortWts] = portrand(Asset, Return, Points, Method) returns the risks, rates of return, and weights of random portfolio configurations.
\begin{tabular}{|l|l|}
\hline PortRisk & Points-by-1 vector of standard deviations. \\
\hline PortReturn & Points-by-1 vector of expected rates of return. \\
\hline PortWts & \begin{tabular}{l} 
Points by number of securities matrix of asset weights. Each row \\
of PortWts is a different portfolio configuration.
\end{tabular} \\
\hline
\end{tabular}
portrand(Asset, Return, Points, Method) plots the points representing each portfolio configuration. It does not return any data to the MATLAB workspace.

Note: Portfolios are selected at random from a set of portfolios such that portfolio weights are nonnegative and sum to 1 . The sample mean and covariance of asset returns are used to compute portfolio returns for each random portfolio.

\section*{portror}

Portfolio expected rate of return

\section*{Syntax}
```

R = portror(Return, Weight)

```

\section*{Arguments}
\begin{tabular}{|l|l|}
\hline Return & \begin{tabular}{l} 
1-by-N matrix of rates of return. Each column of Return represents \\
the rate of return for a single security
\end{tabular} \\
\hline Weight & \begin{tabular}{l} 
M-by-N matrix of weights. Each row of Weight represents a \\
different weighting combination of the assets in the portfolio.
\end{tabular} \\
\hline
\end{tabular}

\section*{Description}
\(R=\) portror(Return, Weight) returns a 1-by-M vector for the expected rate of return.

\section*{Examples}

\section*{Portfolio Expected Rate of Return}

This example shows a portfolio that is made up of two assets ABC and XYZ having expected rates of return of \(10 \%\) and \(14 \%\), respectively. If \(40 \%\) percent of the portfolio's funds are allocated to asset ABC and the remaining funds are allocated to asset XYZ, the portfolio's expected rate of return is:
```

r = portror([.1 .14],[.4 .6])

```

\section*{portsim}

Monte Carlo simulation of correlated asset returns

\section*{Syntax}

RetSeries = portsim(ExpReturn, ExpCovariance, NumObs, RetIntervals, NumSim, Method)

\section*{Arguments}
\begin{tabular}{|l|l|}
\hline ExpReturn & \begin{tabular}{l}
1 by number of assets (NASSETS) vector specifying the \\
expected (mean) return of each asset.
\end{tabular} \\
\hline ExpCovariance & \begin{tabular}{l} 
NASSETS-by-NASSETS matrix of asset return \\
covariances. ExpCovariance must be symmetric \\
and positive semidefinite (no negative eigenvalues). \\
The standard deviations of the returns are \\
ExpSigma = sqrt (diag (ExpCovariance) ).
\end{tabular} \\
\hline NumObs & \begin{tabular}{l} 
Positive scalar integer indicating the number of consecutive \\
observations in the return time series. If NumObs is entered \\
as the empty matrix [ ], the length of Ret Intervals is \\
used.
\end{tabular} \\
\hline Ret Intervals & \begin{tabular}{l} 
(Optional) Positive scalar or number of observations \\
(NUMOBS)-by-1 vector of interval times between observations. \\
If RetIntervals is not specified, all intervals are assumed \\
to have length 1.
\end{tabular} \\
\hline NumSim & \begin{tabular}{l} 
(Optional) Positive scalar integer indicating the number \\
of simulated sample paths (realizations) of NUMOBS \\
observations. Default = 1 (single realization of NUMOBS \\
correlated asset returns).
\end{tabular} \\
\hline Method & \begin{tabular}{l} 
(Optional) String indicating the type of Monte Carlo \\
simulation:
\end{tabular} \\
\hline & \begin{tabular}{l} 
'Exact ' (default) generates correlated asset returns in \\
which the sample mean and covariance match the input
\end{tabular} \\
\hline
\end{tabular}
\begin{tabular}{|l|l|} 
& \begin{tabular}{l} 
mean (ExpReturn) and covariance (ExpCovariance) \\
specifications. \\
'Expected ' generates correlated asset returns in which \\
the sample mean and covariance are statistically equal to \\
the input mean and covariance specifications. (The expected \\
value of the sample mean and covariance are equal to the \\
input mean (ExpReturn) and covariance (ExpCovariance) \\
specifications.)
\end{tabular} \\
\begin{tabular}{l} 
For either method, the sample mean and covariance \\
returned are appropriately scaled by Ret Intervals.
\end{tabular} \\
\hline
\end{tabular}

\section*{Description}
portsim simulates correlated returns of NASSETS assets over NUMOBS consecutive observation intervals. Asset returns are simulated as the proportional increments of constant drift, constant volatility stochastic processes, thereby approximating continuous-time geometric Brownian motion.

RetSeries is a NUMOBS-by-NASSETS-by-NUMSIM three-dimensional array of correlated, normally distributed, proportional asset returns. Asset returns over an interval of length \(d t\) are given by
\[
\frac{d S}{S}=\mu d t+\sigma d z=\mu d t+\sigma \varepsilon \sqrt{d t}
\]
where \(S\) is the asset price, \(\mu\) is the expected rate of return, \(\sigma\) is the volatility of the asset price, and \(\varepsilon\) represents a random drawing from a standardized normal distribution.

\section*{Notes}
- When Method is 'Exact', the sample mean and covariance of all realizations (scaled by RetIntervals) match the input mean and covariance. When the returns are then converted to asset prices, all terminal prices for a given asset are in close agreement. Although all realizations are drawn independently, they produce similar terminal asset prices. Set Method to 'Expected' to avoid this behavior.
- The returns from the portfolios in PortWts are given by PortReturn = PortWts * RetSeries(:,:,1)', where PortWts is a matrix in which each row contains the asset allocations of a portfolio. Each row of PortReturn corresponds to one of the portfolios identified in PortWts, and each column corresponds to one of the observations taken from the first realization (the first plane) in RetSeries. See portopt and portstats for portfolio specification and optimization.

\section*{Examples}

\section*{Distinction Bełween Simulation Methods}

This example shows the distinction between the Exact and Expected methods of simulation.

Consider a portfolio of five assets with the following expected returns, standard deviations, and correlation matrix based on daily asset returns (where ExpReturn and Sigmas are divided by 100 to convert percentages to returns).
\begin{tabular}{|c|c|c|c|c|c|}
\hline ExpReturn & \(=[0.0246\) & 0.0189 & 0.0273 & 0.0141 & 0.0311]/100; \\
\hline Sigmas & \(=[0.9509\) & 1.4259 & 1.5227 & 1.1062 & 1.0877]/100; \\
\hline Correlations & \(=[1.0000\) & 0.4403 & 0.4735 & 0.4334 & 0.6855 \\
\hline & 0.4403 & 1.0000 & 0.7597 & 0.7809 & 0.4343 \\
\hline & 0.4735 & 0.7597 & 1.0000 & 0.6978 & 0.4926 \\
\hline & 0.4334 & 0.7809 & 0.6978 & 1.0000 & 0.4289 \\
\hline & 0.6855 & 0.4343 & 0.4926 & 0.4289 & 1.0000]; \\
\hline
\end{tabular}

Convert the correlations and standard deviations to a covariance matrix.
ExpCovariance \(=\) corr2cov(Sigmas, Correlations)

ExpCovariance =
1.0e-03 *
\begin{tabular}{lllll}
0.0904 & 0.0597 & 0.0686 & 0.0456 & 0.0709 \\
0.0597 & 0.2033 & 0.1649 & 0.1232 & 0.0674 \\
0.0686 & 0.1649 & 0.2319 & 0.1175 & 0.0816 \\
0.0456 & 0.1232 & 0.1175 & 0.1224 & 0.0516
\end{tabular}

\section*{\(\begin{array}{lllll}0.0709 & 0.0674 & 0.0816 & 0.0516 & 0.1183\end{array}\)}

Assume that there are 252 trading days in a calendar year, and simulate two sample paths (realizations) of daily returns over a two-year period. Since ExpReturn and ExpCovariance are expressed daily, set RetIntervals \(=1\).
```

StartPrice = 100;
NumObs = 504; % two calendar years of daily returns
NumSim = 2;
RetIntervals = 1; % one trading day
NumAssets = 5;

```

To illustrate the distinction between methods, simulate two paths by each method, starting with the same random number state.
```

rng('default');
RetExact = portsim(ExpReturn, ExpCovariance, NumObs, ...
RetIntervals, NumSim, 'Exact');
randn('state',0);
RetExpected = portsim(ExpReturn, ExpCovariance, NumObs, ...
RetIntervals, NumSim, 'Expected');

```

Compare the mean and covariance of RetExact with the inputs (ExpReturn and ExpCovariance), you will observe that they are almost identical.

At this point, RetExact and RetExpected are both 504-by-5-by-2 arrays. Now assume an equally weighted portfolio formed from the five assets and create arrays of portfolio returns in which each column represents the portfolio return of the corresponding sample path of the simulated returns of the five assets. The portfolio arrays PortRetExact and PortRetExpected are 504-by-2 matrices.
```

Weights = ones(NumAssets, 1)/NumAssets;
PortRetExact = zeros(NumObs, NumSim);
PortRetExpected = zeros(NumObs, NumSim);
for i = 1:NumSim
PortRetExact(:,i) = RetExact(:,:,i) * Weights;
PortRetExpected(:,i) = RetExpected(:,:,i) * Weights;
end

```

Finally, convert the simulated portfolio returns to prices and plot the data. In particular, note that since the Exact method matches expected return and covariance, the terminal
portfolio prices are virtually identical for each sample path. This is not true for the Expected simulation method. Although this example examines portfolios, the same methods apply to individual assets as well. Thus, Exact simulation is most appropriate when unique paths are required to reach the same terminal prices.
```

PortExact = ret2tick(PortRetExact, ...
repmat(StartPrice,1,NumSim));
PortExpected = ret2tick(PortRetExpected, ...
repmat(StartPrice,1,NumSim));
subplot(2,1,1), plot(PortExact, '-r')
ylabel('Portfolio Prices')
title('Exact Method')
subplot(2,1,2), plot(PortExpected, '-b')
ylabel('Portfolio Prices')
title('Expected Method')

```

\section*{Interaction Between ExpReturn, ExpCovariance, and RetIntervals}

This example shows the interplay among ExpReturn, ExpCovariance, and RetIntervals. Recall that portsim simulates correlated asset returns over an interval of length \(d t\), given by the equation
\[
\frac{d S}{S}=\mu d t+\sigma d z=\mu d t+\sigma \varepsilon \sqrt{d t}
\]
where \(S\) is the asset price, \(\mu\) is the expected rate of return, \(\sigma\) is the volatility of the asset price, and \(\varepsilon\) represents a random drawing from a standardized normal distribution.

The time increment \(d t\) is determined by the optional input RetIntervals, either as an explicit input argument or as a unit time increment by default. Regardless, the periodicity of ExpReturn, ExpCovariance, and RetIntervals must be consistent. For example, if ExpReturn and ExpCovariance are annualized, then RetIntervals must be in years. This point is often misunderstood.

To illustrate the interplay among ExpReturn, ExpCovariance, and RetIntervals, consider a portfolio of five assets with the following expected returns, standard deviations, and correlation matrix based on daily asset returns.
\(\left.\begin{array}{llllll}\text { ExpReturn } & =\left[\begin{array}{lllll}0.0246 & 0.0189 & 0.0273 & 0.0141 & 0.0311\end{array}\right] / 100 ; \\ \text { Sigmas }= & {\left[\begin{array}{lllll}0.9509 & 1.4259 & 1.5227 & 1.1062 & 1.0877\end{array}\right] / 100 ;} \\ \text { Correlations }= & {[1.0000} & 0.4403 & 0.4735 & 0.4334 & 0.6855 \\ & 0.4403 & 1.0000 & 0.7597 & 0.7809 & 0.4343 \\ & 0.4735 & 0.7597 & 1.0000 & 0.6978 & 0.4926 \\ & 0.4334 & 0.7809 & 0.6978 & 1.0000 & 0.4289 \\ & 0.6855 & 0.4343 & 0.4926 & 0.4289 & 1.0000\end{array}\right] ;\)

Convert the correlations and standard deviations to a covariance matrix of daily returns.
```

ExpCovariance = corr2cov(Sigmas, Correlations);

```

Assume 252 trading days per calendar year, and simulate a single sample path of daily returns over a four-year period. Since the ExpReturn and ExpCovariance inputs are expressed daily, set RetIntervals \(=1\).
```

StartPrice = 100;
NumObs = 1008; % four calendar years of daily returns
RetIntervals = 1; % one trading day
NumAssets = length(ExpReturn);
randn('state',0);
RetSeries1 = portsim(ExpReturn, ExpCovariance, NumObs, ...
RetIntervals, 1, 'Expected');

```

Now annualize the daily data, thereby changing the periodicity of the data, by multiplying ExpReturn and ExpCovariance by 252 and dividing RetIntervals by 252 (RetIntervals = 1/252 of a year). Resetting the random number generator to its initial state, you can reproduce the results.
rng('default');
RetSeries2 \(=\) portsim(ExpReturn*252, ExpCovariance*252, ...
NumObs, RetIntervals/252, 1, 'Expected');
Assume an equally weighted portfolio and compute portfolio returns associated with each simulated return series.
```

Weights = ones(NumAssets, 1)/NumAssets;
PortRet1 = RetSeries2 * Weights;
PortRet2 = RetSeries2 * Weights;

```

Comparison of the data reveals that PortRet1 and PortRet2 are identical.

\section*{Univariate Geometric Brownian Motion}

This example shows how to simulates a univariate geometric Brownian motion process. It is based on an example found in Hull, Options, Futures, and Other Derivatives, 5th Edition (see example 12.2 on page 236). In addition to verifying Hull's example, it also graphically illustrates the lognormal property of terminal stock prices by a rather large Monte Carlo simulation.

Assume that you own a stock with an initial price of \(\$ 20\), an annualized expected return of \(20 \%\) and volatility of \(40 \%\). Simulate the daily price process for this stock over the course of one full calendar year ( 252 trading days).
```

StartPrice = 20;
ExpReturn = 0.2;
ExpCovariance = 0.4^2;
NumObs = 252;
NumSim = 10000;
RetIntervals = 1/252;

```

Note that RetIntervals is expressed in years, consistent with the fact that ExpReturn and ExpCovariance are annualized. Also, note that ExpCovariance is entered as a variance rather than the more familiar standard deviation (volatility).

Set the random number generator state, and simulate 10,000 trials (realizations) of stock returns over a full calendar year of 252 trading days.
```

rng('default');
RetSeries = squeeze(portsim(ExpReturn, ExpCovariance, Num0bs, ...
RetIntervals, NumSim, 'Expected'));

```

The squeeze function reformats the output array of simulated returns from a 252 -by- 1 -by- 10000 array to more convenient 252 -by- 10000 array. (Recall that portsim is fundamentally a multivariate simulation engine).

In accordance with Hull's equations 12.4 and 12.5 on page 236
\[
\begin{aligned}
E\left(S_{T}\right) & =S_{0} e^{\mu T} \\
\operatorname{var}\left(S_{T}\right) & =S_{0}{ }^{2} e^{2 \mu T}\left(e^{\sigma^{2} T}-1\right)
\end{aligned}
\]
convert the simulated return series to a price series and compute the sample mean and the variance of the terminal stock prices.
```

StockPrices = ret2tick(RetSeries, repmat(StartPrice, 1, NumSim));
SampMean = mean(StockPrices(end,:))
SampVar = var(StockPrices(end,:))
SampMean =
24.4489
SampVar =
101.4243

```

Compare these values with the values you obtain by using Hull's equations.
```

ExpValue = StartPrice*exp(ExpReturn)
ExpVar = ...
StartPrice*StartPrice*exp(2*ExpReturn)*(exp((ExpCovariance)) - 1)

```

ExpValue =
24.4281

ExpVar =
103.5391

These results are very close to the results shown in Hull's example 12.2.
Display the sample density function of the terminal stock price after one calendar year. From the sample density function, the lognormal distribution of terminal stock prices is apparent.
```

[count, BinCenter] = hist(StockPrices(end,:), 30);
figure
bar(BinCenter, count/sum(count), 1, 'r')
xlabel('Terminal Stock Price')
ylabel('Probability')
title('Lognormal Terminal Stock Prices')

```

\section*{Description}
[PortRisk, PortReturn] = portstats(ExpReturn, ExpCovariance, PortWts) computes the expected rate of return and risk for a portfolio of assets.

PortRisk is an NPORTS-by- 1 vector of the standard deviation of each portfolio.
PortReturn is an NPORTS-by-1 vector of the expected return of each portfolio.

\section*{Examples}

\section*{Computes the Expected Rate of Return and Risk for a Porifolio of Assets}

This example shows how to calculate the expected rate of return and risk for a portfolio of assets.
```

ExpReturn = [0.1 0.2 0.15];
ExpCovariance = [0.0100 -0.0061 0.0042
-0.0061 0.0400 -0.0252
0.0042 -0.0252 0.0225 ];
PortWts=[0.4 0.2 0.4; 0.2 0.4 0.2];
[PortRisk, PortReturn] = portstats(ExpReturn, ExpCovariance,...
PortWts)
PortRisk =
0.0560
0.0550
PortReturn =
0.1400
0.1300

\section*{portvar}

Variance for portfolio of assets

\section*{Syntax}

V = portvar(Asset, Weight)

\section*{Arguments}
\begin{tabular}{|l|l|}
\hline Asset & M-by-N matrix of \(M\) asset returns for \(N\) securities. \\
\hline Weight & \begin{tabular}{l} 
R-by-N matrix of \(R\) portfolio weights for \(N\) securities. Each row of \\
Weight constitutes a portfolio of securities in Asset.
\end{tabular} \\
\hline
\end{tabular}

\section*{Description}
\(\mathrm{V}=\) portvar(Asset, Weight) returns the portfolio variance as an R-by-1vector (assuming Weight is a matrix of size R -by- N ) with each row representing a variance calculation for each row of Weight.
\(\mathrm{V}=\) portvar(Asset) assigns each security an equal weight when calculating the portfolio variance.

\section*{portvrisk}

Portfolio value at risk (VaR)

\section*{Syntax}
```

ValueAtRisk = portvrisk(PortReturn, PortRisk, RiskThreshold,
PortValue)

```

\section*{Arguments}
\begin{tabular}{|l|l|}
\hline PortReturn & \begin{tabular}{l} 
Number of portfolios (NPORTS)-by-1 vector or scalar of the \\
expected return of each portfolio over the period.
\end{tabular} \\
\hline PortRisk & \begin{tabular}{l} 
NPORTS-by-1 vector or scalar of the standard deviation of \\
each portfolio over the period.
\end{tabular} \\
\hline RiskThreshold & \begin{tabular}{l} 
(Optional) NPORTS-by-1 vector or scalar specifying the loss \\
probability. Default = 0.05 (5\%).
\end{tabular} \\
\hline PortValue & \begin{tabular}{l} 
(Optional) NPORTS-by-1 vector or scalar specifying the total \\
value of asset portfolio. Default = 1.
\end{tabular} \\
\hline
\end{tabular}

\section*{Description}

ValueAtRisk = portvrisk(PortReturn, PortRisk, RiskThreshold, PortValue) returns the maximum potential loss in the value of a portfolio over one period of time (that is, monthly, quarterly, yearly, etc.) given the loss probability level RiskThreshold.

ValueAtRisk is an NPORTS-by-1 vector of the estimated maximum loss in the portfolio, predicted with a confidence probability of 1 - RiskThreshold. portvrisk calculates ValueAtRisk using a normal distribution.

If PortValue is not given, ValueAtRisk is presented on a per-unit basis. A value of 0 indicates no losses.

\section*{Examples}

\section*{Compute the Maximum Potential Loss in the Value of a Porffolio Over One Period of Time}

This example shows how to return the maximum potential loss in the value of a portfolio over one period of time, where ValueAtRisk is computed on a per-unit basis.
```

PortReturn = 0.29/100;
PortRisk = 3.08/100;
RiskThreshold = [0.01;0.05;0.10];
PortValue = 1;
ValueAtRisk = portvrisk(PortReturn,PortRisk,...
RiskThreshold,PortValue)

```
ValueAtRisk =
0.0688
0.0478
0.0366

\section*{Compute the Maximum Potential Loss in the Value of a Portfolio Over One Period of Time Using Actual Values}

This example shows how to return the maximum potential loss in the value of a portfolio over one period of time, where ValueAtRisk is computed with actual values.
```

PortReturn = [0.29/100;0.30/100];
PortRisk = [3.08/100;3.15/100];
RiskThreshold = 0.10;
PortValue = [1000000000;500000000];
ValueAtRisk = portvrisk(PortReturn,PortRisk,...
RiskThreshold,PortValue)
ValueAtRisk =
1.0e+07
3.6572
1.8684

```

\section*{posvolidx}

Positive volume index

\section*{Syntax}
```

pvi = posvolidx(closep, tvolume, initpvi)
pvi = posvolidx([closep tvolume], initpvi)
pvits = posvolidx(tsobj)
pvits = posvolidx(tsobj, initpvi, 'ParameterName', ParameterValue, ...)

```

\section*{Arguments}
\begin{tabular}{|l|l|}
\hline closep & Closing price (vector). \\
\hline tvolume & Volume traded (vector). \\
\hline initpvi & (Optional) Initial value for positive volume index. Default =100. \\
\hline tsobj & Financial time series object. \\
\hline
\end{tabular}

\section*{Description}
pvi = posvolidx(closep, tvolume, initpvi) calculates the positive volume index from a set of stock closing prices (closep) and volume traded (tvolume) data. pvi is a vector representing the positive volume index. If initpvi is specified, posvolidx uses that value instead of the default (100).
pvi = posvolidx([closep tvolume], initpvi) accepts a two-column matrix, the first column representing the closing prices (closep) and the second representing the volume traded (tvolume). If initpvi is specified, posvolidx uses that value instead of the default (100).
pvits = posvolidx(tsobj) calculates the positive volume index from the financial time series object tsobj. The object must contain, at least, the series Close and Volume.

The pvits output is a financial time series object with dates similar to tsobj and a data series named PVI. The initial value for the positive volume index is arbitrarily set to 100.
pvits = posvolidx(tsobj, initpvi, 'ParameterName', ParameterValue, ...) accepts parameter name/parameter value pairs as input. These pairs specify the name(s) for the required data series if it is different from the expected default name(s). Valid parameter names are
- CloseName: closing prices series name
- VolumeName: volume traded series name

Parameter values are the strings that represent the valid parameter names.

\section*{Examples}

\section*{Compute the Positive Volume Index}

This example shows how to compute the positive volume index for Disney stock and plot the results.
```

load disney.mat
dis_PosVol = posvolidx(dis);
plot}(dis_PosVol
title('Positive Volume Index for Disney')

```

\section*{power}

\section*{Financial time series power}

\section*{Syntax}
```

newfts = tsobj .^ array
newfts = array .^tsobj
newfts = tsobj_1 .^ tsobj_2

```

\section*{Arguments}
\begin{tabular}{|l|l|}
\hline tsobj & Financial time series object. \\
\hline array & \begin{tabular}{l} 
Scalar value or array with the number of rows equal to the \\
number of dates in tsobj and the number of columns equal \\
to the number of data series in tsobj.
\end{tabular} \\
\hline tsobj_1, tsobj_2 & Pair of financial time series objects. \\
\hline
\end{tabular}

\section*{Description}
newfts \(=\) tsobj .^ array raises all values in the data series of the financial time series object tsobj element by element to the power indicated by the array value. The results are stored in another financial time series object newfts. The newfts object contains the same data series names as tsobj.
newfts = array .^ tsobj raises the array values element by element to the values contained in the data series of the financial time series object tsobj. The results are stored in another financial time series object newfts. The newfts object contains the same data series names as tsobj.
newfts = tsobj_1 .^ tsobj_2 raises the values in the object tsobj_1 element by element to the values in the object tsobj_2. The data series names, the dates, and the number of data points in both series must be identical. newfts contains the same data series names as the original time series objects.

\section*{prbyzero}

Price bonds in portfolio by set of zero curves

\section*{Syntax}

BondPrices = prbyzero(Bonds, Settle, ZeroRates, ZeroDates, Compounding)

\section*{Arguments}
\begin{tabular}{|c|c|c|}
\hline Bonds & \multicolumn{2}{|l|}{Coupon bond information used to compute prices. A number of bonds (NUMBONDS)-by-6 matrix where each row describes a bond. The first two columns are required; the rest are optional but must be added in order. All rows in Bonds must have the same number of columns. Columns are [Maturity CouponRate Face Period Basis EndMonthRule] where:} \\
\hline & Maturity & Maturity date of the bond, as a serial date number. Use datenum to convert date strings to serial date numbers. \\
\hline & CouponRate & Decimal number indicating the annual percentage rate used to determine the coupons payable on a bond. \\
\hline & Face & (Optional) Face or par value of the bond. Default \(=100\). \\
\hline & Period & (Optional) Coupons per year of the bond. Allowed values are 0, 1, 2 (default), 3, 4, 6, and 12. \\
\hline & Basis & \begin{tabular}{l}
(Optional) Day-count basis of the instrument. A vector of integers. \\
- \(0=\) actual/actual (default) \\
- \(1=30 / 360\) (SIA) \\
- \(2=\) actual/ 360
\end{tabular} \\
\hline
\end{tabular}
\begin{tabular}{|c|c|c|}
\hline & & \begin{tabular}{l}
- 3 = actual/365 \\
- \(4=30 / 360\) (BMA) \\
- \(5=30 / 360\) (ISDA) \\
- \(6=30 / 360\) (European) \\
- \(7=\) actual/365 (Japanese) \\
- \(8=\) actual/actual (ICMA) \\
- 9 = actual/360 (ICMA) \\
- 10 = actual/365 (ICMA) \\
- \(11=30 / 360 \mathrm{E}\) (ICMA) \\
- 12 = actual/365 (ISDA) \\
- 13 = BUS/252 \\
For more information, see basis.
\end{tabular} \\
\hline & EndMonthRule & (Optional) End-of-month rule. This rule applies only when Maturity is an end-of-month date for a month having 30 or fewer days. \(0=\) ignore rule, meaning that a bond's coupon payment date is always the same numerical day of the month. \(1=\) set rule on (default), meaning that a bond's coupon payment date is always the last actual day of the month. \\
\hline Settle & \multicolumn{2}{|l|}{Serial date number of the settlement date.} \\
\hline ZeroRates & \multicolumn{2}{|l|}{NUMDATES-by-NUMCURVES matrix of observed zero rates, as decimal fractions. Each column represents a rate curve. Each row represents an observation date.} \\
\hline ZeroDates & \multicolumn{2}{|l|}{NUMDATES-by-1 column of dates for observed zeros} \\
\hline Compounding & \multicolumn{2}{|l|}{Scalar value representing the rate at which the input zero rates were compounded when annualized. This argument determines the formula for the discount factors. Compounding values are: 1, 2, 3, 4, 6, 12.} \\
\hline
\end{tabular}

\section*{Description}

BondPrices = prbyzero(Bonds, Settle, ZeroRates, ZeroDates, Compounding) computes the bond prices in a portfolio using a set of zero curves.

BondPrices is a NUMBONDS-by-NUMCURVES matrix of clean bond prices. Each column is derived from the corresponding zero curve in ZeroRates.

In addition, you can use the Financial Instruments Toolbox \({ }^{\mathrm{TM}}\) method getZeroRates for an IRDataCurve object with a Dates property to create a vector of dates and data acceptable for prbyzero. For more information, see "Converting an IRDataCurve or IRFunctionCurve Object".

\section*{Examples}

\section*{Compute the Bond Prices in a Portfolio Using a Set of Zero Curves}

This example uses the function zbtprice to compute a zero curve given a portfolio of coupon bonds and their prices. It then reverses the process, using the zero curve as input to the function prbyzero to compute the prices.
```

Bonds = [datenum('6/1/1998') 0.0475 100 2 0 0;
datenum('7/1/2000') 0.06 100 2 0 0;
datenum('7/1/2000') 0.09375 100 6 1 0;
datenum('6/30/2001') 0.05125 100 1 3 1;
datenum('4/15/2002') 0.07125 100 4 1 0;
datenum('1/15/2000') 0.065 100 2 0 0;
datenum('9/1/1999') 0.08 100 3 3 0;
datenum('4/30/2001') 0.05875 100 2 0 0;
datenum('11/15/1999') 0.07125 100 2 0 0;
datenum('6/30/2000') 0.07 100 2 3 1;
datenum('7/1/2001') 0.0525 100 2 3 0;
datenum('4/30/2002') 0.07 100 2 0 0];
Prices = [ 99.375;
99.875;
105.75;
96.875;
103.625;
101.125;
103.125;

```
```

    99.375;
    101.0 ;
    101.25;
    96.375;
    102.75 ];
    Settle = datenum('12/18/1997');

```

Set semiannual compounding for the zero curve, on an actual/365 basis.
OutputCompounding = 2;
Execute the function zbtprice which returns the zero curve at the maturity dates.
[ZeroRates, ZeroDates] = zbtprice(Bonds, Prices, Settle,... OutputCompounding)

ZeroRates =
0.0616
0.0609
0.0658
0.0590
0.0647
0.0655
0.0606
0.0601
0.0642
0.0621
0.0627

ZeroDates =
729907
730364
730439
730500
730667
730668
730971
731032
731033
731321

Execute the function prbyzero.
BondPrices = prbyzero(Bonds, Settle, ZeroRates, ZeroDates)

BondPrices =
99.3750
98.7980
106.8270
96.8750
103.6249
101.1250
103.1250
99.3637
101.0000
101.2500
96.3750
102.7384

In this example zbtprice and prbyzero do not exactly reverse each other. Many of the bonds have the end-of-month rule off (EndMonthRule \(=0\) ). The rule subtly affects the time factor computation. If you set the rule on (EndMonthRule \(=1\) ) everywhere in the Bonds matrix, then prbyzero returns the original prices, except when the two incompatible prices fall on the same maturity date.

\section*{prcroc}

Price rate of change

\section*{Syntax}
```

proc = prcroc(closep, nTimes)
procts = prcroc(tsobj, nTimes)
procts = prcroc(tsobj, nTimes, 'ParameterName', ParameterValue, ...)

```

\section*{Arguments}
\begin{tabular}{|l|l|}
\hline closep & Closing price \\
\hline nTimes & (Optional) Time difference. Default \(=12\). \\
\hline tsobj & Financial time series object \\
\hline
\end{tabular}

\section*{Description}
proc \(=\) prcroc(closep, \(n\) Times) calculates the price rate of change proc from the closing price closep. If nTimes time is specified, the price rate of change is calculated between the current closing price and the closing price nTimes ago.
procts \(=\) prcroc (tsobj, nTimes) calculates the price rate of change procts from the financial time series object tsobj. tsobj must contain a data series named Close. The output procts is a financial time series object with similar dates as tsobj and a data series named PriceROC. If nTimes is specified, the price rate of change is calculated between the current closing price and the closing price nTimes ago.
procts = prcroc(tsobj, nTimes, 'ParameterName', ParameterValue, ...) specifies the name for the required data series when it is different from the default name. The valid parameter name is
- CloseName: closing price series name

The parameter value is a string that represents the valid parameter name.
Note, to compute a quantity over \(n\) periods, you must specify \(n+1\) for \(n T i m e s\). If you specify \(n\) Times \(=0\), the function returns your original time series.

\section*{Examples}

\section*{Compute the Price Rate of Change}

This example shows how to compute the price rate of change for Disney stock and plot the results.
```

load disney.mat
dis_PriceRoc = prcroc(dis);
plot(dis_PriceRoc)
title('Price Rate of Change for Disney')

```

\end{tabular}

\section*{Description}
[Price, AccruInterest] = prmat(Settle, Maturity, Issue, Face, CouponRate, Yield, Basis) returns the price and accrued interest of a security that pays interest at maturity. This function also applies to zero-coupon bonds or pure discount securities by setting CouponRate \(=0\).

\section*{Examples}

\section*{Compute the Price and Accrued Interest of a Security That Pays Interest at Maturity}

This example shows how to compute the price and accrued interest of a security that pays interest at maturity.
```

Settle = '02/07/2002';
Maturity = '04/13/2002';
Issue = '10/11/2001';
Face = 100;
CouponRate = 0.0608;
Yield = 0.0608;
Basis = 1;
[Price, AccruInterest] = prmat(Settle, Maturity, Issue, Face,...
CouponRate, Yield, Basis)

```

\section*{Price =}
99.9784

\section*{prtbill}

Price of Treasury bill

\section*{Syntax}

Price = prtbill(Settle, Maturity, Face, Discount)

\section*{Arguments}
\begin{tabular}{|l|l|}
\hline Settle & \begin{tabular}{l} 
Enter as serial date number or date string. Settle must be earlier \\
than Maturity.
\end{tabular} \\
\hline Maturity & Enter as serial date number or date string. \\
\hline Face & Redemption (par, face) value. \\
\hline Discount & Discount rate of the Treasury bill. Enter as decimal fraction. \\
\hline
\end{tabular}

\section*{Description}

Price = prtbill(Settle, Maturity, Face, Discount) returns the price for a Treasury bill.

\section*{Examples}

\section*{Calculate the Price for a Treasury Bill}

This example shows how to return the price for a Treasury bill, where the settlement date of a Treasury bill is February 10, 2002, the maturity date is August 6, 2002, the discount rate is \(3.77 \%\), and the par value is \(\$ 1000\).
```

Price = prtbill('2/10/2002', '8/6/2002', 1000, 0.0377)

```

\section*{pvfix}

Present value with fixed periodic payments

\section*{Syntax}

PresentVal = pvfix(Rate, NumPeriods, Payment, ExtraPayment, Due)

\section*{Arguments}
\begin{tabular}{|l|l|}
\hline rate & Periodic interest rate, as a decimal fraction. \\
\hline NumPeriods & Number of periods. \\
\hline Payment & Periodic payment. \\
\hline ExtraPayment & \begin{tabular}{l} 
(Optional) Payment received other than Payment in the last \\
period. Default \(=0\).
\end{tabular} \\
\hline Due & \begin{tabular}{l} 
(Optional) When payments are due or made: \(0=\) end of \\
period (default), or \(1=\) beginning of period.
\end{tabular} \\
\hline
\end{tabular}

\section*{Description}

PresentVal = pvfix(Rate, NumPeriods, Payment, ExtraPayment, Due) returns the present value of a series of equal payments.

\section*{Examples}

\section*{Calculate the Present Value of a Series of Equal Payments}

This example shows how to return the present value of a series of equal payments, where \(\$ 200\) is paid monthly into a savings account earning \(6 \%\). The payments are made at the end of the month for five years.
```

PresentVal = pvfix(0.06/12, 5*12, 200, 0, 0)

```

PresentVal =
\(1.0345 e+04\)
- "Analyzing and Computing Cash Flows" on page 2-17

\section*{See Also}
fvfix | fvvar | payper | pvvar

Introduced before R2006a

\section*{pvtrend}

Price and Volume Trend (PVT)

\section*{Syntax}
```

pvt = pvtrend(closep, tvolume)
pvt = pvtrend([closep tvolume])
pvtts = pvtrend(tsobj)
pvtts = pvtrend(tsobj, 'ParameterName', ParameterValue, ...)

```

\section*{Arguments}
\begin{tabular}{|l|l|}
\hline closep & Closing price. \\
\hline tvolume & Volume traded. \\
\hline tsobj & Financial time series object. \\
\hline 'ParameterName' & \begin{tabular}{l} 
Valid parameter names are: \\
- CloseName - closing prices series name \\
\\
- VolumeName - volume traded series name
\end{tabular} \\
\hline ParameterValue & \begin{tabular}{l} 
Parameter values are the strings that represent the \\
valid parameter names.
\end{tabular} \\
\hline
\end{tabular}

\section*{Description}
pvt = pvtrend(closep, tvolume) calculates the Price and Volume Trend (PVT) from the stock closing price (closep) data and the volume traded (tvolume) data.
pvt = pvtrend([closep tvolume]) accepts a two-column matrix in which the first column contains the closing prices (closep) and the second contains the volume traded (tvolume).
pvtts = pvtrend(tsobj) calculates the PVT from the stock data contained in the financial time series object tsobj. The object tsobj must contain the closing price series Close and the volume traded series Volume. The output pvtts is a financial time series object with dates similar to tsobj and a data series named PVT.
pvtts = pvtrend(tsobj, 'ParameterName', ParameterValue, ...) accepts parameter name/ parameter value pairs as input. These pairs specify the name(s) for the required data series if it is different from the expected default name(s). Parameter values are the strings that represent the valid parameter names.

\section*{Examples}

\section*{Calculate the Price and Volume Trend (PVT)}

This example shows how to calculate the PVT for Disney stock and plot the results.
```

load disney.mat
dis_PVTrend = pvtrend(dis);
plot(dis_PVTrend)
title('Price and Volume Trend for Disney')

```

\section*{pvvar}

Present value of varying cash flow

\section*{Syntax}

PresentVal = pvvar(CashFlow, Rate, CFDates)

\section*{Arguments}
\begin{tabular}{|l|l|}
\hline CashFlow & \begin{tabular}{l} 
A vector of varying cash flows. Include the initial investment as \\
the initial cash flow value (a negative number). If CashFlow is a \\
matrix, each column is treated as a separate cash-flow stream.
\end{tabular} \\
\hline Rate & \begin{tabular}{l} 
Periodic interest rate. Enter as a decimal fraction. If CashFlow \\
is a matrix, a scalar Rate is allowed when the same rate applies \\
to all cash-flow streams in CashFlow. When multiple cash-flow \\
streams require different discount rates, Rate must be a vector \\
whose length equals the number of columns in CashFlow.
\end{tabular} \\
\hline CFDates & \begin{tabular}{l} 
(Optional) A vector of serial date numbers or date strings on which \\
the cash flows occur. Specify CFDates when there are irregular \\
(nonperiodic) cash flows. The default assumes that CashFlow \\
contains regular (periodic) cash flows. If CashFlow is a matrix, \\
and all cash-flow streams share the same dates, CFDates can be \\
a vector whose length matches the number of rows in CashFlow. \\
When different cash-flow streams have different payment dates, \\
specify CFDates as a matrix the same size as CashFlow.
\end{tabular} \\
\hline
\end{tabular}

\section*{Description}

PresentVal = pvvar(CashFlow, Rate, CFDates) returns the net present value of a varying cash flow. Present value is calculated at the time the first cash flow occurs.

\section*{Examples}

This cash flow represents the yearly income from an initial investment of \(\$ 10,000\). The annual interest rate is \(8 \%\).
\begin{tabular}{|l|l|}
\hline Year 1 & \(\$ 2000\) \\
\hline Year 2 & \(\$ 1500\) \\
\hline Year 3 & \(\$ 3000\) \\
\hline Year 4 & \(\$ 3800\) \\
\hline Year 5 & \(\$ 5000\) \\
\hline
\end{tabular}

To calculate the net present value of this regular cash flow
PresentVal \(=\) pvvar \(([-10000 \quad 2000 \quad 150030003800\) 5000], 0.08)
returns
PresentVal =
1715.39

An investment of \(\$ 10,000\) returns this irregular cash flow. The original investment and its date are included. The periodic interest rate is \(9 \%\).
\begin{tabular}{|l|l|}
\hline Cash Flow & Dates \\
\hline\((\$ 10000)\) & January 12,1987 \\
\hline\(\$ 2500\) & February 14,1988 \\
\hline\(\$ 2000\) & March 3,1988 \\
\hline\(\$ 3000\) & June 14, 1988 \\
\hline\(\$ 4000\) & December 1, 1988 \\
\hline
\end{tabular}
```

To calculate the net present value of this irregular cash flow

```
```

CashFlow = [-10000, 2500, 2000, 3000, 4000];

```
CashFlow = [-10000, 2500, 2000, 3000, 4000];
CFDates = ['01/12/1987'
    '02/14/1988'
    '03/03/1988'
    '06/14/1988'
```

```
    '12/01/1988'];
PresentVal = pvvar(CashFlow, 0.09, CFDates)
returns
PresentVal =
    142.16
The net present value of the same investment under different discount rates of 7%, 9%,
and 11% is obtained in a single call:
```

```
PresentVal = pvvar(repmat(CashFlow,3,1)', [.07 .09 .11], CFDates)
```

PresentVal = pvvar(repmat(CashFlow,3,1)', [.07 .09 .11], CFDates)
pv =
419.0136 142.1648 -122.1275

```

\section*{Introduced before R2006a}

\section*{pyld2zero}

Zero curve given par yield curve

\section*{Syntax}
[ZeroRates, CurveDates] = pyld2zero(ParRates, CurveDates, Settle)
[ZeroRates, CurveDates] = pyld2zero(ParRates, CurveDates, Settle, Name, Value)

\section*{Compatibility}

In R2015b, the specification of optional input arguments has changed. While the previous ordered inputs syntax is still supported, it may no longer be supported in a future release. Use the new optional name-value pair inputs: InputCompounding, InputBasis, OutputCompounding, and OutputBasis.

\section*{Input Arguments}
\begin{tabular}{|l|l|}
\hline ParRates & \begin{tabular}{l} 
Column vector of annualized implied par yield rates, as \\
decimal fractions. (Par yields = coupon rates.) In aggregate, \\
the yield rates in ParRates constitute an implied par \\
yield curve for the investment horizon represented by \\
CurveDates.
\end{tabular} \\
\hline CurveDates & \begin{tabular}{l} 
Column vector of maturity dates (as serial date numbers) \\
that correspond to the par rates.
\end{tabular} \\
\hline Settle & \begin{tabular}{l} 
Serial date number or date string that is the common \\
settlement date for the par rates.
\end{tabular} \\
\hline
\end{tabular}

\section*{Name-Value Pair Arguments}

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single
quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.
Example: [ZeroRates,CurveDates] = pyld2zero(ParRates, CurveDates, Settle, 'OutputCompounding', 3, 'OutputBasis' ,5,'InputCompounding', 4, 'InputBasis'

\section*{' OutputCompounding' - Compounding frequency of output zero rates}
if OutputCompounding is 0 (simple), - 1 (continuous), or 365 (daily), the par rate InputCompounding must also be specified a valid value. If OutputCompounding is not specified, it is assigned the value specified for InputCompounding. If neither InputCompounding nor OutputCompounding are specified, the default is 2 (semiannual) for both. (default) | scalar

Compounding frequency of the output zero rates, specified as a scalar with allowed values:
- 0 - Simple interest (no compounding, zero rates only)
- 1 - Annual compounding
- 2 - Semiannual compounding (default)
- 3 - Compounding three times per year
- 4-Quarterly compounding
- 6 - Bimonthly compounding
- 12 - Monthly compounding
- 365 - Daily compounding (zero rates only)
- - 1 - Continuous compounding (zero rates only)

Data Types: single | double

\section*{' OutputBasis ' - Day count basis of output zero rates}
if OutputBasis is not specified, it is assigned the value specified for InputBasis. If neither InputBasis nor OutputBasis are specified, the default is 0 (actual/actual) for both. (default) | scalar

Day count basis of output zero rates, specified as a scalar with possible values:
- \(0=\) actual/actual
- \(1=30 / 360\) (SIA)
- \(2=\) actual \(/ 360\)
- 3 = actual \(/ 365\)
- \(4=30 / 360\) (PSA)
- \(5=30 / 360\) (ISDA)
- \(6=30 / 360\) (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- \(10=\) actual/365 (ICMA)
- \(11=30 / 360 \mathrm{E}\) (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

Data Types: single | double

\section*{' InputCompounding ' - Compounding frequency of input par rates}
if OutputCompounding is \(1,2,3,4,6\), or 12 , and InputCompounding is not specified, it is assigned the value of OutputCompounding. If OutputCompounding is 0 (simple), - 1 (continuous), or 365 (daily), a valid InputCompounding value must also be specified. If neither InputCompounding nor OutputCompounding are specified, the default is 2 (semiannual) for both. (default) | scalar

Compounding frequency of the input par rates, specified as a scalar with allowed values:
- 1 - Annual compounding
- 2 -Semiannual compounding (default)
- 3 - Compounding three times per year
- 4 - Quarterly compounding
- 6 - Bimonthly compounding
- 12 - Monthly compounding

Data Types: single | double

\section*{' InputBasis ' - Day count basis of input par rates}
if InputBasis is not specified, it is assigned the value specified for OutputBasis. If neither InputBasis nor OutputBasis are specified, the default is 0 (actual/actual) for both. (default) | scalar

Day count basis of input par rates, specified as a scalar with possible values:
- \(0=\) actual/actual
- \(1=30 / 360\) (SIA)
- 2 = actual/360
- 3 = actual/365
- \(4=30 / 360\) (PSA)
- \(5=30 / 360\) (ISDA)
- \(6=30 / 360\) (European)
- \(7=\) actual/365 (Japanese)
- \(8=\) actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- \(10=\) actual/365 (ICMA)
- \(11=30 / 360 \mathrm{E}\) (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

\section*{Data Types: single | double}

\section*{Description}
[ZeroRates, CurveDates] = pyld2zero(ParRates, CurveDates, Settle) returns a zero curve given a par yield curve and its maturity dates.
[ZeroRates, CurveDates] = pyld2zero(ParRates, CurveDates, Settle, Name, Value) returns a zero curve given a par yield curve and its maturity dates using optional name-value pair arguments for InputCompounding, InputBasis, OutputCompounding, and OutputBasis.
\begin{tabular}{|l|l|}
\hline ZeroRates & \begin{tabular}{l} 
Column vector of decimal fractions. In aggregate, the rates in \\
ZeroRates constitute a zero curve for the investment horizon \\
represented by CurveDates.
\end{tabular} \\
\hline CurveDates & \begin{tabular}{l} 
Column vector of maturity dates (as serial date numbers) \\
corresponding to the zero rates. This vector is the same as the input \\
vector CurveDates, but is sorted by ascending maturity.
\end{tabular} \\
\hline
\end{tabular}

\section*{Examples}

\section*{Compute Zero Curve Given Par Yield Curve}

Define the settlement date, maturity, and zero rates.
```

Settle = datenum('01-Feb-2013');
CurveDates = datemnth(Settle,12*[11 2 3 5 7 10 20 30]');
ZeroRates = [l.11 0.30 0.64 1.44 2.07 2.61 3.29 3.55]'/100;
InputCompounding = 2;
InputBasis = 1;
OutputCompounding = 2;
OutputBasis = 1;

```

Compute par yield curve from zero rates.
ParRates = zero2pyld(ZeroRates, CurveDates, Settle,'InputCompounding',2,...
'InputBasis',1,'OutputCompounding',2,'OutputBasis',1)
ParRates =
0.0011
0.0030
0.0064
0.0142
0.0201
0.0251
0.0309
0.0330

Compute zero curve from the par yield curve.
ZeroRates = pyld2zero(ParRates, CurveDates, Settle,'InputCompounding',2,... 'InputBasis',1,'OutputCompounding',2,'OutputBasis',1)

ZeroRates =
0.0011
0.0030
0.0064
0.0144
0.0207
0.0261
0.0329

\subsection*{0.0355}

\section*{Demonstrate a Roundtrip From pyld2zero to zero2pyld}

Given the following a par yield curve and its maturity dates, return the ZeroRates.
```

Settle = datenum('01-Feb-2013');
CurveDates = [datenum('01-Feb-2014')
datenum('01-Feb-2015')
datenum('01-Feb-2016')
datenum('01-Feb-2018')
datenum('01-Feb-2020')
datenum('01-Feb-2023')
datenum('01-Feb-2033')
datenum('01-Feb-2043')];
OriginalParRates =[[0.11 0.30 0.64 1.42 2.02 2.51 3.10 3.31]'/100;
InputCompounding = 1;
InputBasis = 0;
OutputCompounding = 1;
OutputBasis = 0;
ZeroRates = pyld2zero(OriginalParRates, CurveDates, Settle, ...
'OutputCompounding', OutputCompounding, 'OutputBasis', OutputBasis, ...
'InputCompounding', InputCompounding, 'InputBasis', InputBasis)
ZeroRates =
0.0011
0.0030
0.0064
0.0144
0.0207
0.0261
0.0329
0.0356

```

Using the ZeroRates, use the zero2pyld function to return the ParRatesOut and determine the roundtrip error.
```

ParRatesOut = zero2pyld(ZeroRates, CurveDates, Settle, ...
'OutputCompounding', OutputCompounding, 'OutputBasis', OutputBasis, ...
'InputCompounding', InputCompounding, 'InputBasis', InputBasis)

```
\(\max (a b s(O r i g i n a l P a r R a t e s ~-~ P a r R a t e s O u t)) ~ \% ~ R o u n d t r i p ~ e r r o r ~\)

Introduced before R2006a

\section*{rdivide}

Financial time series division

\section*{Syntax}
```

newfts = tsobj_1 ./ tsobj_2
newfts = tsobj ./ array
newfts = array ./ tsobj

```

\section*{Arguments}
\begin{tabular}{|l|l|}
\hline tsobj_1, tsobj_2 & Pair of financial time series objects. \\
\hline array & \begin{tabular}{l} 
Scalar value or array with the number of rows equal to the \\
number of dates in tsobj and the number of columns equal \\
to the number of data series in tsobj.
\end{tabular} \\
\hline
\end{tabular}

\section*{Description}

The rdivide method divides, element by element, the components of one financial time series object by the components of the other. You can also divide the whole object by an array or divide a financial time series object into an array.

If an object is to be divided by another object, both objects must have the same dates and data series names, although the order need not be the same. The order of the data series, when an object is divided by another object, follows the order of the first object.
newfts = tsobj_1 ./ tsobj_2 divides financial time series objects element by element.
newfts = tsobj ./ array divides a financial time series object element by element by an array.
newfts = array ./ tsobj divides an array element by element by a financial time series object.

For financial time series objects, the rdivide operation is identical to the mrdivide operation.

\section*{See Also}
minus | mrdivide | plus | times

\section*{Introduced before R2006a}

\section*{renko}

Renko chart

\section*{Syntax}
```

renko(X)
renko(X, threshold)

```

\section*{Arguments}
\begin{tabular}{|l|l|}
\hline X & \begin{tabular}{l} 
M-by-2 matrix where the first column contains date numbers and \\
the second column is the asset price.
\end{tabular} \\
\hline threshold & \begin{tabular}{l} 
(Optional) Specifies a threshold value for asset price. By default, \\
threshold is set to 1.
\end{tabular} \\
\hline
\end{tabular}

\section*{Description}
renko ( X ) plots asset price with respect to dates.
renko ( X , threshold) plots the asset data, X , adding a new box only when the price has changed but at least the value specified by threshold.

\section*{Examples}

\section*{Plot Asset Price With Respect to Dates}

This example shows how to plot asset price with respect to dates, given asset X as an M -by- 2 matrix of date numbers and asset prices, generate a Renko chart.
```

X = [...

```

\section*{resamplets}

Downsample data

\section*{Syntax}
```

newfts = resamplets(oldfts, samplestep)

```

\section*{Description}
newfts = resamplets(oldfts, samplestep) downsamples the data contained in the financial time series object oldfts every samplestep periods. For example, to have the new financial time series object contain every other data element from oldfts, set samplestep to 2.
newfts is a financial time series object containing the same data series (names) as the input oldfts.

\section*{Introduced before R2006a}

\section*{ret2tick}

Convert return series to price series

\section*{Syntax}
[TickSeries, TickTimes] = ret2tick(RetSeries, StartPrice, RetIntervals, StartTime, Method)

\section*{Arguments}
\begin{tabular}{|l|l|}
\hline RetSeries & \begin{tabular}{l} 
Number of observations (NUMOBS) by number of assets \\
(NASSETS) time series array of asset returns associated \\
with the prices in TickSeries. The ith return is quoted for \\
the period TickTimes (i) to TickTimes (i+1) and is not \\
normalized by the time increment between successive price \\
observations.
\end{tabular} \\
\hline StartPrice & \begin{tabular}{l} 
(Optional) 1-by-NASSETS vector of initial asset prices or a \\
single scalar initial price applied to all assets. Prices start at \\
1 if StartPrice is not specified.
\end{tabular} \\
\hline Ret Intervals & \begin{tabular}{l} 
(Optional) Scalar or NUMOBS-by-1 vector of interval times \\
between observations. If this argument is not specified, all \\
intervals are assumed to have length 1.
\end{tabular} \\
\hline StartTime & \begin{tabular}{l} 
(Optional) Starting time for first observation, applied to the \\
price series of all assets. The default is 0.
\end{tabular} \\
\hline Method & \begin{tabular}{l} 
(Optional) Character string indicating the method to convert \\
asset returns to prices. Must be 'Simple ' (default) or \\
'Continuous '. If Method is 'Simple', ret2tick uses \\
simple periodic returns. If Method is 'Continuous', the \\
function uses continuously compounded returns. Case is \\
ignored for Method.
\end{tabular} \\
\hline
\end{tabular}

\section*{Description}
[TickSeries, TickTimes] = ret2tick(RetSeries, StartPrice, RetIntervals, StartTime, Method) generates price values from the starting prices of NASSETS investments and NUMOBS incremental return observations.

TickSeries is a NUMOBS+1-by-NASSETS times series array of equity prices. The first row contains the oldest observations and the last row the most recent. Observations across a given row occur at the same time for all columns. Each column is a price series of an individual asset. If Method is unspecified or 'Simple', the prices are
```

TickSeries(i+1) = TickSeries(i)*[1 + RetSeries(i)]

```

If Method is 'Continuous ', the prices are
```

TickSeries(i+1) = TickSeries(i)*exp[RetSeries(i)]

```

TickTimes is a NUMOBS+1 column vector of monotonically increasing observation times associated with the prices in TickSeries. The initial time is zero unless specified in StartTime, and sequential observation times occur at unit increments unless specified in RetIntervals.

\section*{Examples}

\section*{Convert a Return Series to a Price Series}

This example shows how to compute the price increase of two stocks over a year's time based on three incremental return observations.
```

RetSeries = [0.10 0.12
0.05 0.04
-0.05 0.05];
RetIntervals = [182
91
92];
StartTime = datenum('18-Dec-2000');
[TickSeries,TickTimes] = ret2tick(RetSeries,[],RetIntervals,...
StartTime)

```
```

datestr(TickTimes)
TickSeries =
1.0000 1.0000
1.1000 1.1200
1.1550 1.1648
1.0973 1.2230
TickTimes =
730838
7 3 1 0 2 0
7 3 1 1 1 1
7 3 1 2 0 3
ans =
18-Dec-2000
18-Jun-2001
17-Sep-2001
18-Dec-2001

\section*{ret2tick (fts)}

Convert return series to price series for time series object

\section*{Syntax}
```

priceFts = ret2tick(returnFts)
priceFts = ret2tick(returnFts, 'PARAM1', VALUE1,
'PARAM2', VALUE2', ...)

```

\section*{Arguments}
\begin{tabular}{|l|l|}
\hline returnFts & Financial time series object of returns. \\
\hline 'PARAM1' & \begin{tabular}{l} 
(Optional) StartPrice is a Numeric value and is a \\
scalar or 1-by-N vector of initial prices for each asset. If \\
StartPrice is unspecified or empty, the initial price of all \\
assets is 1.
\end{tabular} \\
\hline 'PARAM2' & \begin{tabular}{l} 
(Optional) StartTime is Date value for a scalar date \\
number or a single date string specifying the starting time \\
for the first observation. This date is applied to the price \\
series of all assets.
\end{tabular} \\
\hline \begin{tabular}{l} 
Note: The first period price value of the resulting price \\
series will not be reported if StartTime is not specified. The \\
resulting price series are scaled based on the StartPrice, \\
even if StartTime is not supplied.
\end{tabular} \\
\hline 'PARAM3' & \begin{tabular}{l} 
(Optional) Method is a character string indicating the \\
method to convert asset returns to prices. The value must be \\
defined as 'Simple ' (default) or 'Continuous '. If Method \\
is 'Simple ' ret2tick uses simple periodic returns. If \\
Method is 'Continuous ', the function uses continuously \\
compounded returns. Case is ignored for Method.
\end{tabular} \\
\hline
\end{tabular}

\section*{Description}
priceFts = ret2tick(returnFts, 'PARAM1', VALUE1, 'PARAM2', VALUE2', ...) generates a financial time series object of prices.

If Method is unspecified or 'Simple', the prices are
PriceSeries(i+1) = PriceSeries(i)*[1 + ReturnSeries(i)]
If Method is 'Continuous ', the prices are
```

PriceSeries(i+1) = PriceSeries(i)*exp[ReturnSeries(i)]

```

\section*{Examples}

Compute the price series from the following return series:
```

RetSeries = [0.10 0.12
0.05 0.04
-0.05 0.05]

```

Use the following dates:
```

Dates = {'18-Jun-2001'; '17-Sep-2001'; '18-Dec-2001'}

```
where
```

ret = fints(Dates, RetSeries)
ret =
desc: (none)
freq: Unknown (0)

```
\begin{tabular}{llll} 
'dates: (3)' & 'series1: (3)' & 'series2: (3)' \\
'18-Jun-2001' & [ & \(0.1000]\) & {\([\)}
\end{tabular}

PriceFtS is computed as:
```

PriceFts = ret2tick(ret, 'StartPrice', 100, 'StartTime', '18-Dec-2000')

```
PriceFts =
desc: (none)
freq: Unknown (0)
\begin{tabular}{|c|c|c|}
\hline es: (4) & 'series1: (4) & series2: (4) \\
\hline '18-Dec-2000' & [ 100] & 100] \\
\hline '18-Jun-2001' & [ 110.0000] & \(112.0000]\) \\
\hline '17-Sep-2001' & [ 115.5000] & \(116.4800]\) \\
\hline '18-Dec-2001' & [ 109.7250] & 122.3040] \\
\hline
\end{tabular}

\section*{rmfield}

Remove data series

\section*{Syntax}
```

fts = rmfield(tsobj, fieldname)

```

\section*{Arguments}
\begin{tabular}{|l|l|}
\hline tsobj & Financial time series object. \\
\hline fieldname & \begin{tabular}{l} 
String array containing the data series name to remove a single \\
series from the object. Cell array of data series names to remove \\
multiple data series from the object at the same time.
\end{tabular} \\
\hline
\end{tabular}

\section*{Description}
fts = rmfield(tsobj, fieldname) removes the data series fieldname and its contents from the financial time series object tsobj.

\section*{rsindex}

Relative Strength Index (RSI)

\section*{Syntax}
```

rsi = rsindex(closep, nperiods)
rsits = rsindex(tsobj, nperiods)
rsits = rsindex(tsobj, nperiods, 'ParameterName', ParameterValue, ...)

```

\section*{Arguments}
\begin{tabular}{|l|l|}
\hline closep & Vector of closing prices. \\
\hline nperiods & (Optional) Number of periods. Default \(=14\). \\
\hline tsobj & Financial time series object. \\
\hline
\end{tabular}

\section*{Description}
rsi \(=\) rsindex(closep, nperiods) calculates the Relative Strength Index (RSI) from the closing price vector closep.
rsits = rsindex(tsobj, nperiods) calculates the RSI from the closing price series in the financial time series object tsobj. The object tsobj must contain at least the series Close, representing the closing prices. The output rsits is a financial time series object whose dates are the same as tsobj and whose data series name is RSI.
rsits = rsindex(tsobj, nperiods, 'ParameterName',
ParameterValue, ...) accepts a parameter name/parameter value pair as input. This pair specifies the name for the required data series if it is different from the expected default name. The valid parameter name is

CloseName: closing prices series name

The parameter value is the string that represents the valid parameter name.
1 The relative strength factor is calculated by dividing the average of the gains by the average of the losses within a specified time period:
RS = (average gains)/(average losses).
2 The first value of RSI, RISI (1), is set as NaN to preserve the dimensions of CLOSEP.

\section*{Examples}

\section*{Calculate the Relative Strength Index (RSI)}

This example shows how to calculate the RSI for Disney stock and plot the results.
load disney.mat
dis_RSI = rsindex(dis);
plot(dis_RSI)
title('Relative Strength Index for Disney')

\section*{sde}

Create SDE model from user-specified functions

\section*{Syntax}
```

SDE = sde(DriftRate, DiffusionRate)
SDE = sde(DriftRate, DiffusionRate, 'Name1', Value1, 'Name2',
Value2, ...)

```

\section*{Class}

Stochastic Differential Equations

\section*{Description}

This function creates and displays general stochastic differential equation (SDE) models from user-defined drift and diffusion rate functions. Use SDE models to simulate sample paths of NVARS state variables driven by NBROWNS Brownian motion sources of risk over NPERIODS consecutive observation periods, approximating continuous-time stochastic processes.

This function enables you to simulate any vector-valued SDE of the form:
\[
d X_{t}=F\left(t, X_{t}\right) d t+G\left(t, X_{t}\right) d W_{t}
\]
where:
- \(X_{t}\) is an NVARS-by- 1 state vector of process variables.
- \(d W_{t}\) is an NBROWNS-by- 1 Brownian motion vector.
- \(F\) is an NVARS-by-1 vector-valued drift-rate function.
- \(G\) is an NVARS-by-NBROWNS matrix-valued diffusion-rate function.

\section*{Input Arguments}
\begin{tabular}{|l|l|}
\hline DriftRate & \begin{tabular}{l} 
User-defined drift-rate function, denoted by \(F\). DriftRate is a \\
function that returns an NVARS-by-1 drift-rate vector when called \\
with two inputs:
\end{tabular} \\
& \begin{tabular}{l} 
- A real-valued scalar observation time \(t\). \\
- An NVARS-by-1 state vector \(X_{t}\).
\end{tabular} \\
\hline \begin{tabular}{l} 
Alternatively, DriftRate may also be an object of class Drift that \\
encapsulates the drift-rate specification. In this case, however, sde \\
uses only the Rate parameter of the object.
\end{tabular} \\
\hline DiffusionRate & \begin{tabular}{l} 
User-defined diffusion-rate function, denoted by \(G\). \\
DiffusionRate is a function that returns an NVARS-by-NBRowNS \\
diffusion-rate matrix when called with two inputs:
\end{tabular} \\
& \begin{tabular}{l} 
A real-valued scalar observation time \(t\). \\
- An NVARS-by-1 state vector \(X_{t}\).
\end{tabular} \\
\begin{tabular}{l} 
Alternatively, DiffusionRate may also be an object of class \\
Diffusion that encapsulates the diffusion-rate specification. In \\
this case, however, sde uses only the Rate parameter of the object.
\end{tabular} \\
\hline
\end{tabular}

\section*{Optional Input Arguments}

Specify optional inputs as matching parameter name/value pairs as follows:
- Specify the parameter name as a character string, followed by its corresponding value.
- You can specify parameter name/value pairs in any order.
- Parameter names are case insensitive.
- You can specify unambiguous partial string matches.

Valid parameter names are:
\begin{tabular}{|l|l|}
\hline StartTime & \begin{tabular}{l} 
Scalar starting time of the first observation, applied to all state \\
variables. If you do not specify a value for StartTime, the default \\
is 0.
\end{tabular} \\
\hline
\end{tabular}
\(\left.\begin{array}{|l|l|}\hline \text { StartState } & \begin{array}{l}\text { Scalar, NVARS-by-1 column vector, or NVARS-by-NTRIALS matrix of } \\
\text { initial values of the state variables. } \\
\text { If StartState is a scalar, sde applies the same initial value to all } \\
\text { state variables on all trials. } \\
\text { If StartState is a column vector, sde applies a unique initial } \\
\text { value to each state variable on all trials. } \\
\text { If StartState is a matrix, sde applies a unique initial value to } \\
\text { each state variable on each trial. } \\
\text { If you do not specify a value for StartState, all variables start at } \\
1 .\end{array} \\
\hline \text { Correlation } & \begin{array}{l}\text { Correlation between Gaussian random variates drawn to } \\
\text { generate the Brownian motion vector (Wiener processes). Specify } \\
\text { Correlation as an NBROWNS-by-NBROWNS positive semidefinite } \\
\text { matrix, or as a deterministic function C( } t \text { ) that accepts the current } \\
\text { time } t \text { and returns an NBROWNS-by-NBROWNS positive semidefinite } \\
\text { correlation matrix. }\end{array} \\
\text { A Correlation matrix represents a static condition. } \\
\text { As a deterministic function of time, Correlation allows you to }\end{array}\right\}\)\begin{tabular}{l} 
specify a dynamic correlation structure.
\end{tabular}

\section*{Output Arguments}
\begin{tabular}{|l|l|}
\hline SDE & \begin{tabular}{l} 
Stochastic differential equation model (SDE) with the following \\
parameters: \\
\(\cdot \quad\) StartTime: Initial observation time
\end{tabular}
\end{tabular}
\begin{tabular}{l} 
• \begin{tabular}{l} 
StartState: Initial state at time StartTime \\
Correlation: Access function for the Correlation input argument, \\
callable as a function of time
\end{tabular} \\
\begin{tabular}{l} 
Drift: Composite drift-rate function, callable as a function of time and \\
state
\end{tabular} \\
\begin{tabular}{l} 
Diffusion: Composite diffusion-rate function, callable as a function of \\
time and state \\
Simulation: A simulation function or method
\end{tabular} \\
\hline
\end{tabular}

\section*{Examples}

- Implementing Multidimensional Equity Market Models, Implementation 1: Using SDE Objects

\section*{More About}

\section*{Algorithms}

When you specify the required input parameters as arrays, they are associated with a specific parametric form. By contrast, when you specify either required input parameter as a function, you can customize virtually any specification.

Accessing the output parameters with no inputs simply returns the original input specification. Thus, when you invoke these parameters with no inputs, they behave like simple properties and allow you to test the data type (double vs. function, or equivalently, static vs. dynamic) of the original input specification. This is useful for validating and designing methods.

When you invoke these parameters with inputs, they behave like functions, giving the impression of dynamic behavior. The parameters accept the observation time \(t\) and a state vector \(X_{t}\), and return an array of appropriate dimension. Even if you originally specified an input as an array, sde treats it as a static function of time and state, by that means guaranteeing that all parameters are accessible by the same interface.

\section*{sdeddo}

Create sdeddo model from Drift and Diffusion objects

\section*{Syntax}
```

SDE = sdeddo(DriftRate, DiffusionRate)

```

SDE = sdeddo(DriftRate, DiffusionRate, 'Name1', Value1, 'Name2', Value2, ...)

\section*{Class}

SDEDDO

\section*{Description}

This constructor creates and displays SDEDDO objects, specifically instantiated with objects of class drift and diffusion. These restricted SDEDDO objects contain the input drift and diffusion objects; therefore, you can directly access their displayed parameters.

This abstraction also generalizes the notion of drift and diffusion-rate objects as functions that sdeddo evaluates for specific values of time \(t\) and state \(X_{t}\). Like SDE objects, SDEDDO objects allow you to simulate sample paths of NVARS state variables driven by NBROWNS Brownian motion sources of risk over NPERIODS consecutive observation periods, approximating continuous-time stochastic processes.

This method enables you to simulate any vector-valued SDE of the form:
\[
d X_{t}=F\left(t, X_{t}\right) d t+G\left(t, X_{t}\right) d W_{t}
\]
where:
- \(X_{t}\) is an NVARS-by- 1 state vector of process variables.
- \(d W_{t}\) is an NBROWNS-by- 1 Brownian motion vector.
- \(F\) is an NVARS-by-1 vector-valued drift-rate function.
- \(G\) is an NVARS-by-NBROWNS matrix-valued diffusion-rate function.

\section*{Input Arguments}
\begin{tabular}{|l|l|}
\hline DriftRate & \begin{tabular}{l} 
Object of class drift that encapsulates a user-defined drift-rate \\
specification, represented as \(F\).
\end{tabular} \\
\hline DiffusionRate & \begin{tabular}{l} 
Object of class diffusion that encapsulates a user-defined \\
diffusion-rate specification, represented as \(G\).
\end{tabular} \\
\hline
\end{tabular}

\section*{Optional Input Arguments}

Specify optional inputs as matching parameter name/value pairs as follows:
- Specify the parameter name as a character string, followed by its corresponding value.
- You can specify parameter name/value pairs in any order.
- Parameter names are case insensitive.
- You can specify unambiguous partial string matches.

Valid parameter names are:
\begin{tabular}{|l|l|}
\hline StartTime & \begin{tabular}{l} 
Scalar starting time of the first observation, applied to all state \\
variables. If you do not specify a value for StartTime, the default \\
is 0.
\end{tabular} \\
\hline StartState & \begin{tabular}{l} 
Scalar, NVARS-by-1 column vector, or NVARS-by-NTRIALS matrix of \\
initial values of the state variables. \\
If StartState is a scalar, sdeddo applies the same initial value to \\
all state variables on all trials.
\end{tabular}
\end{tabular}
\begin{tabular}{|l|l|} 
& \begin{tabular}{l} 
If StartState is a column vector, sdeddo applies a unique initial \\
value to each state variable on all trials. \\
If StartState is a matrix, sdeddo applies a unique initial value to \\
each state variable on each trial. \\
If you do not specify a value for StartState, all variables start at \\
1.
\end{tabular} \\
\hline Correlation & \begin{tabular}{l} 
Correlation between Gaussian random variates drawn to \\
generate the Brownian motion vector (Wiener processes). Specify \\
Correlation as an NBROWNS-by-NBROWNS positive semidefinite \\
matrix, or as a deterministic function C( \(t\) ) that accepts the current \\
time \(t\) and returns an NBROWNS-by-NBROWNS positive semidefinite \\
correlation matrix. \\
A Correlation matrix represents a static condition. \\
As a deterministic function of time, Correlation allows you to \\
specify a dynamic correlation structure.
\end{tabular} \\
\hline \begin{tabular}{l} 
If you do not specify a value for Correlation, the default is an \\
NBROWNS-by-NBROWNS identity matrix representing independent \\
Gaussian processes.
\end{tabular} \\
\hline \begin{tabular}{l} 
A user-defined simulation function or SDE simulation method. If \\
you do not specify a value for Simulation, the default method is \\
simulation by Euler approximation (simByEuler).
\end{tabular} \\
\hline
\end{tabular}

\section*{Output Arguments}
\begin{tabular}{|c|c|}
\hline SDE & \begin{tabular}{l}
Object of class sdeddo with the following parameters: \\
- StartTime: Initial observation time \\
- StartState: Initial state at time StartTime \\

\section*{sdeld}

Construct stochastic differential equation from linear drift-rate models

\section*{Syntax}
```

SDE = sdeld(A, B, Alpha, Sigma)
SDE = sdeld(A, B, Alpha, Sigma, 'Name1', Value1, 'Name2',
Value2, ...)

```

\section*{Class}

\section*{SDELD}

\section*{Description}

This constructor creates and displays SDE objects whose drift rate is expressed in linear drift-rate form and that derive from the SDEDDO (SDE from drift and diffusion objects class).

Use SDELD objects to simulate sample paths of NVARS state variables expressed in linear drift-rate form. They provide a parametric alternative to the mean-reverting drift form (see sdemrd).

These state variables are driven by NBROWNS Brownian motion sources of risk over NPERIODS consecutive observation periods, approximating continuous-time stochastic processes with linear drift-rate functions.

This method allows you to simulate any vector-valued SDE of the form:
\(d X_{t}=\left(A(t)+B(t) X_{t}\right) d t+D\left(t, X_{t}^{\alpha(t)}\right) V(t) d W_{t}\)
where:
- \(X_{t}\) is an NVARS-by- 1 state vector of process variables.
- \(A\) is an NVARS-by- 1 vector.
- \(B\) is an NVARS-by-NVARS matrix.
- \(D\) is an NVARS-by-NVARS diagonal matrix, where each element along the main diagonal is the corresponding element of the state vector raised to the corresponding power of \(a\).
- \(V\) is an NVARS-by-NBROWNS instantaneous volatility rate matrix.
- \(d W_{t}\) is an NBROWNS-by- 1 Brownian motion vector.

\section*{Input Arguments}

Specify required input parameters as one of the following types:
- A MATLAB array. Specifying an array indicates a static (non-time-varying) parametric specification. This array fully captures all implementation details, which are clearly associated with a parametric form.
- A MATLAB function. Specifying a function provides indirect support for virtually any static, dynamic, linear, or nonlinear model. This parameter is supported via an interface, because all implementation details are hidden and fully encapsulated by the function.

Note: You can specify combinations of array and function input parameters as needed.
Moreover, a parameter is identified as a deterministic function of time if the function accepts a scalar time \(t\) as its only input argument. Otherwise, a parameter is assumed to be a function of time \(t\) and state \(X(t)\) and is invoked with both input arguments.

The required input parameters are:
A \(\quad\) A represents the parameter \(A\). If you specify \(A\) as an array, it must be an NVARS-by- 1 column vector of intercepts. As a deterministic function of time, when \(A\) is called with a real-valued scalar time \(t\) as its only input, A must produce an NVARS-by- 1 column vector. If you specify \(A\) as a function of time and state, it must generate an NVARS-by- 1 column vector of intercepts when invoked with two inputs:
- A real-valued scalar observation time \(t\).
- An NVARS-by- 1 state vector \(X_{t}\).
\begin{tabular}{|c|c|}
\hline B & \begin{tabular}{l}
\(B\) represents the parameter \(B\). If you specify \(B\) as an array, it must be an NVARS-by-NVARS matrix of state vector coefficients. As a deterministic function of time, when \(B\) is called with a real-valued scalar time \(t\) as its only input, \(B\) must produce an NVARS-by-NVARS matrix. If you specify \(B\) as a function of time and state, it must generate an NVARS-by-NVARS matrix of state vector coefficients when invoked with two inputs: \\
- A real-valued scalar observation time \(t\). \\
- An NVARS-by- 1 state vector \(X_{t}\).
\end{tabular} \\
\hline Alpha & \begin{tabular}{l}
Alpha determines the format of the parameter \(D\). If you specify Alpha as an array, it represents an NVARS-by- 1 column vector of exponents. As a deterministic function of time, when Alpha is called with a real-valued scalar time \(t\) as its only input, Alpha must produce an NVARS-by- 1 column vector. If you specify it as a function of time and state, it must return an NVARS-by- 1 column vector of exponents when invoked with two inputs: \\
- A real-valued scalar observation time \(t\). \\
- An NVARS-by- 1 state vector \(X_{t}\).
\end{tabular} \\
\hline Sigma & \begin{tabular}{l}
Sigma represents the parameter \(V\). If you specify Sigma as an array, it represents is an NVARS-by-NBROWNS 2-dimensional matrix of instantaneous volatility rates. In this case, each row of Sigma corresponds to a particular state variable. Each column of Sigma corresponds to a particular Brownian source of uncertainty, and associates the magnitude of the exposure of state variables with sources of uncertainty. As a deterministic function of time, when Sigma is called with a real-valued scalar time \(t\) as its only input, Sigma must produce an NVARS-by-NBROWNS matrix. If you specify it as a function of time and state, it must generate an NVARS-by-NBROWNS matrix of volatility rates when invoked with two inputs: \\
- A real-valued scalar observation time \(t\). \\
- An NVARS-by- 1 state vector \(X_{t}\).
\end{tabular} \\
\hline
\end{tabular}

Note: Although the constructor does not enforce restrictions on the signs of Alpha or Sigma, each parameter is usually specified as a positive value.

\section*{Optional Input Arguments}

Specify optional inputs as matching parameter name/value pairs as follows:
- Specify the parameter name as a character string, followed by its corresponding value.
- You can specify parameter name/value pairs in any order.
- Parameter names are case insensitive.
- You can specify unambiguous partial string matches.

Valid parameter names are:
\begin{tabular}{|l|l|}
\hline StartTime & \begin{tabular}{l} 
Scalar starting time of the first observation, applied to all state \\
variables. If you do not specify a value for StartTime, the default \\
is 0.
\end{tabular} \\
\hline StartState & \begin{tabular}{l} 
Scalar, NVARS-by-1 column vector, or NVARS-by-NTRIALS matrix of \\
initial values of the state variables. \\
If StartState is a scalar, sdeld applies the same initial value to \\
all state variables on all trials. \\
If StartState is a column vector, sdeld applies a unique initial \\
value to each state variable on all trials. \\
If StartState is a matrix, sdeld applies a unique initial value to
\end{tabular} \\
each state variable on each trial. \\
If you do not specify a value for StartState, all variables start at \\
1. & \begin{tabular}{l} 
Correlation between Gaussian random variates drawn to \\
generate the Brownian motion vector (Wiener processes). Specify \\
Correlation as an NBROWNS-by-NBROWNS positive semidefinite \\
matrix, or as a deterministic function C(t) that accepts the current \\
time \(t\) and returns an NBROWNS-by-NBROWNS positive semidefinite \\
correlation matrix. \\
A Correlation matrix represents a static condition.
\end{tabular} \\
\hline As a deterministic function of time, Correlation allows you to \\
specify a dynamic correlation structure.
\end{tabular}
\begin{tabular}{|l|l|} 
& \begin{tabular}{l} 
If you do not specify a value for Correlation, the default is an \\
NBROWNS-by-NBROWNS identity matrix representing independent \\
Gaussian processes.
\end{tabular} \\
\hline Simulation & \begin{tabular}{l} 
A user-defined simulation function or SDE simulation method. If \\
you do not specify a value for Simulation, the default method is \\
simulation by Euler approximation (simByEuler).
\end{tabular} \\
\hline
\end{tabular}

\section*{Output Arguments}
\begin{tabular}{|c|c|}
\hline SDE & \begin{tabular}{l}
Object of class sdeld with the following parameters: \\
- StartTime: Initial observation time \\
- StartState: Initial state at time StartTime \\
- Correlation: Access function for the Correlation input argument, callable as a function of time \\
- Drift: Composite drift-rate function, callable as a function of time and state \\
- Diffusion: Composite diffusion-rate function, callable as a function of time and state \\
- A: Access function for the input argument A, callable as a function of time and state \\
- B: Access function for the input argument B, callable as a function of time and state \\
- Alpha: Access function for the input argument Alpha, callable as a function of time and state \\
- Sigma: Access function for the input argument Sigma, callable as a function of time and state \\
- Simulation: A simulation function or method
\end{tabular} \\
\hline

\section*{More About}

\section*{Algorithms}

When you specify the required input parameters as arrays, they are associated with a specific parametric form. By contrast, when you specify either required input parameter as a function, you can customize virtually any specification.

Accessing the output parameters with no inputs simply returns the original input specification. Thus, when you invoke these parameters with no inputs, they behave like simple properties and allow you to test the data type (double vs. function, or equivalently, static vs. dynamic) of the original input specification. This is useful for validating and designing methods.

When you invoke these parameters with inputs, they behave like functions, giving the impression of dynamic behavior. The parameters accept the observation time \(t\) and a state vector \(X_{t}\), and return an array of appropriate dimension. Even if you originally specified an input as an array, sdeld treats it as a static function of time and state, by that means guaranteeing that all parameters are accessible by the same interface.

\section*{sdemrd}

Construct stochastic differential equation from mean-reverting drift-rate models

\section*{Syntax}
```

SDE = sdemrd(Speed, Level, Alpha, Sigma)
SDE = sdemrd(Speed, Level, Alpha, Sigma, 'Name1', Value1, 'Name2',
Value2, ...)

```

\section*{Class}

\section*{SDEMRD}

\section*{Description}

This constructor creates and displays SDE objects whose drift rate is expressed in mean-reverting drift-rate form and which derive from the SDEDDO class (SDE from drift and diffusion objects). Use SDEMRD objects to simulate of sample paths of NVARS state variables expressed in mean-reverting drift-rate form, and provide a parametric alternative to the linear drift form (see sdeld). These state variables are driven by NBROWNS Brownian motion sources of risk over NPERIODS consecutive observation periods, approximating continuous-time stochastic processes with mean-reverting driftrate functions.

This method allows you to simulate any vector-valued SDE of the form:
\[
d X_{t}=S(t)\left[L(t)-X_{t}\right] d t+D\left(t, X_{t}^{\alpha(t)}\right) V(t) d W_{t}
\]
where:
- \(X_{t}\) is an NVARS-by- 1 state vector of process variables.
- \(S\) is an NVARS-by-NVARS matrix of mean reversion speeds.
- \(L\) is an NVARS-by- 1 vector of mean reversion levels.
- \(D\) is an NVARS-by-NVARS diagonal matrix, where each element along the main diagonal is the corresponding element of the state vector raised to the corresponding power of \(a\).
- \(\quad V\) is an NVARS-by-NBROWNS instantaneous volatility rate matrix.
- \(d W_{t}\) is an NBROWNS-by-1 Brownian motion vector.

\section*{Input Arguments}

Specify required input parameters as one of the following types:
- A MATLAB array. Specifying an array indicates a static (non-time-varying) parametric specification. This array fully captures all implementation details, which are clearly associated with a parametric form.
- A MATLAB function. Specifying a function provides indirect support for virtually any static, dynamic, linear, or nonlinear model. This parameter is supported via an interface, because all implementation details are hidden and fully encapsulated by the function.

Note: You can specify combinations of array and function input parameters as needed.
Moreover, a parameter is identified as a deterministic function of time if the function accepts a scalar time \(t\) as its only input argument. Otherwise, a parameter is assumed to be a function of time \(t\) and state \(X(t)\) and is invoked with both input arguments.

The required input parameters are:
\begin{tabular}{|l|l|}
\hline Speed & \begin{tabular}{l} 
Speed represents the parameter S. If you specify Speed as an \\
array, it represents an NVARS-by-NVARS 2-dimensional matrix of \\
mean-reversion speeds (the rate or speed at which the state vector \\
reverts to its long-run average Level). As a deterministic function \\
of time, when Speed is called with a real-valued scalar time t as \\
its only input, Speed must produce an NVARS-by-NVARS matrix. If \\
you specify Speed as a function time and state, Speed calculates \\
the speed of mean reversion. This function must generate an NVARS- \\
by-NVARS matrix of reversion rates when called with two inputs:
\end{tabular} \\
\(-\quad\) A real-valued scalar observation time \(t\).
\end{tabular}
\begin{tabular}{|c|c|}
\hline & An NVARS-by- 1 state vector \(X_{t}\). \\
\hline Level & \begin{tabular}{l}
Level represents the parameter \(L\). If you specify Level as an array, it must be an NVARS-by- 1 column vector of reversion levels. As a deterministic function of time, when Level is called with a real-valued scalar time \(t\) as its only input, Level must produce an NVARS-by-1 column vector. If you specify Level as a function of time and state, must generate an NVARS-by- 1 column vector of reversion levels when invoked with two inputs: \\
- A real-valued scalar observation time \(t\). \\
- An NVARS-by- 1 state vector \(X_{t}\).
\end{tabular} \\
\hline Alpha & \begin{tabular}{l}
Alpha determines the format of the parameter \(D\). If you specify Alpha as an array, it must be an NVARS-by- 1 column vector of exponents. As a deterministic function of time, when Alpha is called with a real-valued scalar time \(t\) as its only input, Alpha must produce an NVARS-by- 1 column vector. If you specify it as a function of time and state, it must return an NVARS-by- 1 column vector of exponents when invoked with two inputs: \\
- A real-valued scalar observation time \(t\). \\
- An NVARS-by- 1 state vector \(X_{t}\).
\end{tabular} \\
\hline Sigma & \begin{tabular}{l}
Sigma represents the parameter \(V\). If you specify Sigma as an array, it must be an NVARS-by-NBROWNS 2 -dimensional matrix of instantaneous volatility rates. In this case, each row of Sigma corresponds to a particular state variable. Each column of Sigma corresponds to a particular Brownian source of uncertainty, and associates the magnitude of the exposure of state variables with sources of uncertainty. As a deterministic function of time, when Sigma is called with a real-valued scalar time \(t\) as its only input, Sigma must produce an NVARS-by-NBROWNS matrix. If you specify it as a function of time and state, it must generate an NVARS-by-NBROWNS matrix of volatility rates when invoked with two inputs: \\
- A real-valued scalar observation time \(t\). \\
- An NVARS-by- 1 state vector \(X_{t}\).
\end{tabular} \\
\hline
\end{tabular}

Note: Although the constructor does not enforce restrictions on the signs of these input arguments, each argument is usually specified as a positive value.

\section*{Optional Input Arguments}

Specify optional inputs as matching parameter name/value pairs as follows:
- Specify the parameter name as a character string, followed by its corresponding value.
- You can specify parameter name/value pairs in any order.
- Parameter names are case insensitive.
- You can specify unambiguous partial string matches.

Valid parameter names are:
\begin{tabular}{|l|l|}
\hline StartTime & \begin{tabular}{l} 
Scalar starting time of the first observation, applied to all state \\
variables. If you do not specify a value for StartTime, the default \\
is 0.
\end{tabular} \\
\hline StartState & \begin{tabular}{l} 
Scalar, NVARS-by-1 column vector, or NVARS-by-NTRIALS matrix of \\
initial values of the state variables. \\
If StartState is a scalar, sdemrd applies the same initial value to \\
all state variables on all trials. \\
If StartState is a column vector, sdemrd applies a unique initial \\
value to each state variable on all trials.
\end{tabular} \\
If StartState is a matrix, sdemrd applies a unique initial value to \\
each state variable on each trial. \\
If you do not specify a value for StartState, all variables start at \\
1.
\end{tabular} \begin{tabular}{l} 
Correlation between Gaussian random variates drawn to \\
generate the Brownian motion vector (Wiener processes). Specify \\
Correlation as an NBROWNS-by-NBROWNS positive semidefinite \\
matrix, or as a deterministic function C(t) that accepts the current \\
time \(t\) and returns an NBROWNS-by-NBROWNS positive semidefinite \\
correlation matrix.
\end{tabular}
\begin{tabular}{|l|l|} 
& \begin{tabular}{l} 
A Correlation matrix represents a static condition. \\
As a deterministic function of time, Correlation allows you to \\
specify a dynamic correlation structure.
\end{tabular} \\
& \begin{tabular}{l} 
If you do not specify a value for Correlation, the default is an \\
NBROWNS-by-NBROWNS identity matrix representing independent \\
Gaussian processes.
\end{tabular} \\
\hline Simulation & \begin{tabular}{l} 
A user-defined simulation function or SDE simulation method. If \\
you do not specify a value for Simulation, the default method is \\
simulation by Euler approximation (simByEuler).
\end{tabular} \\
\hline
\end{tabular}

\section*{simByEuler}

Euler simulation of stochastic differential equations (SDEs)

\section*{Syntax}
[Paths, Times, Z] = simByEuler(MDL, NPERIODS)
[Paths, Times, Z] = simByEuler(MDL, NPERIODS, 'Name1', Value1, 'Name2', Value2, ...)

\section*{Classes}

All classes in the "SDE Class Hierarchy" on page 17-5.

\section*{Description}

This method simulates any vector-valued SDE of the form
\[
d X_{t}=F\left(t, X_{t}\right) d t+G\left(t, X_{t}\right) d W_{t}
\]
where:
- \(X\) is an NVARS-by- 1 state vector of process variables (for example, short rates or equity prices) to simulate.
- \(W\) is an NBROWNS-by- 1 Brownian motion vector.
- \(F\) is an \(N V A R S\)-by-1 vector-valued drift-rate function.
- \(G\) is an \(N V A R S\)-by-NBROWNS matrix-valued diffusion-rate function.
simByEuler simulates NTRIALS sample paths of NVARS correlated state variables driven by NBROWNS Brownian motion sources of risk over NPERIODS consecutive observation periods, using the Euler approach to approximate continuous-time stochastic processes.

\section*{Input Arguments}
\begin{tabular}{|l|l|}
\hline MDL & \begin{tabular}{l} 
Stochastic differential equation object created with the sdeddo \\
constructor.
\end{tabular} \\
\hline NPERIODS & \begin{tabular}{l} 
Positive scalar integer number of simulation periods. The value of \\
NPERIODS determines the number of rows of the simulated output \\
series.
\end{tabular} \\
\hline
\end{tabular}

\section*{Optional Input Arguments}

Specify optional inputs as matching parameter name/value pairs as follows:
- Specify the parameter name as a character string, followed by its corresponding value.
- You can specify parameter name/value pairs in any order.
- Parameter names are case insensitive.
- You can specify unambiguous partial string matches.

Valid parameter names are:
\begin{tabular}{|l|l|}
\hline NTRIALS & \begin{tabular}{l} 
Positive scalar integer number of simulated trials (sample paths) of \\
NPERIODS observations each. If you do not specify a value for this \\
argument, the default is 1, indicating a single path of correlated state \\
variables.
\end{tabular} \\
\hline DeltaTime & \begin{tabular}{l} 
Scalar or NPERIODS-by-1 column vector of positive time increments \\
between observations. DeltaTime represents the familiar \(d t\) found in \\
stochastic differential equations, and determines the times at which \\
the simulated paths of the output state variables are reported. If you \\
do not specify a value for this argument, the default is 1.
\end{tabular} \\
\hline NSTEPS & \begin{tabular}{l} 
Positive scalar integer number of intermediate time steps within \\
each time increment \(d t\) (specified as DeltaTime). The simByEuler \\
method partitions each time increment \(d t\) into NSTEPS subintervals \\
of length \(d t /\) NSTEPS, and refines the simulation by evaluating \\
the simulated state vector at NSTEPS - 1 intermediate points. \\
Although simByEuler does not report the output state vector at \\
these intermediate points, the refinement improves accuracy by \\
allowing the simulation to more closely approximate the underlying
\end{tabular} \\
\hline
\end{tabular}
\(\left.\left.\begin{array}{|l|l|} & \begin{array}{l}\text { continuous-time process. If you do not specify a value for NSTEPS, the } \\
\text { default is 1, indicating no intermediate evaluation. }\end{array} \\
\hline \text { Antithetic } & \begin{array}{l}\text { Scalar logical flag that indicates whether simByEuler uses antithetic } \\
\text { sampling to generate the Gaussian random variates that drive the } \\
\text { Brownian motion vector (Wiener processes). } \\
\text { When Antithetic is TRUE (logical 1), simByEuler performs } \\
\text { sampling such that all primary and antithetic paths are simulated } \\
\text { and stored in successive matching pairs: }\end{array} \\
\text { - Odd trials (1,3,5, . . ) correspond to the primary Gaussian } \\
\text { paths. } \\
\text { - Even trials (2, 4, 6, . . ) are the matching antithetic paths } \\
\text { of each pair derived by negating the Gaussian draws of the } \\
\text { corresponding primary (odd) trial. }\end{array}\right\} \begin{array}{l}\text { If you specify Antithetic to be any value other than TRUE, } \\
\text { simByEuler assumes that it is FALSE (logical 0) by default, and does } \\
\text { not perform antithetic sampling. When you specify an input noise } \\
\text { process (see Z), simByEuler ignores the value of Antithetic. }\end{array}\right\}\)\begin{tabular}{l} 
Direct specification of the dependent random noise process used to \\
generate the Brownian motion vector (Wiener process) that drives the \\
simulation. Specify this argument as a function, or as an (NPERIODS \\
* NSTEPS)-by-NBROWNS-by-NTRIALS three-dimensional array of \\
dependent random variates. If you specify Z as a function, it must \\
return an NBROWNS-by-1 column vector, and you must call it with two \\
inputs: \\
- A real-valued scalar observation time \(t\).
\end{tabular}
\(\left.\begin{array}{|c|l|}\hline \text { Processes } & \begin{array}{l}\text { Function or cell array of functions that indicates a sequence of end-of- } \\ \text { period processes or state vector adjustments of the form }\end{array} \\ \quad X_{t}=P\left(t, X_{t}\right) \\ \text { simByEuler applies processing functions at the end of each } \\ \text { observation period. These functions must accept the current } \\ \text { observation time } t \text { and the current state vector } X_{t} \text {, and return a state } \\ \text { vector that may be an adjustment to the input state. } \\ \text { If you specify more than one processing function, simByEuler invokes } \\ \text { the functions in the order in which they appear in the cell array. } \\ \text { You can use this argument to specify boundary conditions, prevent } \\ \text { negative prices, accumulate statistics, plot graphs, and more. } \\ \text { If you do not specify a processing function, simByEuler makes no } \\ \text { adjustments and performs no processing. }\end{array}\right]\)

\section*{Output Arguments}
\begin{tabular}{|l|l|}
\hline Paths & \begin{tabular}{l} 
(NPERIODS + 1)-by-NVARS-by-NTRIALS three-dimensional time \\
series array, consisting of simulated paths of correlated state \\
variables. For a given trial, each row of Paths is the transpose of the \\
state vector \(X_{t}\) at time \(t\). When the input flag StorePaths = FALSE, \\
simByEuler returns Paths as an empty matrix.
\end{tabular} \\
\hline Times & \begin{tabular}{l} 
(NPERIODS + 1)-by-1 column vector of observation times associated \\
with the simulated paths. Each element of Times is associated with \\
the corresponding row of Paths.
\end{tabular} \\
\hline Z & \begin{tabular}{l} 
(NPERIODS * NSTEPS) -by-NBROWNS-by-NTRIALS three-dimensional \\
time series array of dependent random variates used to generate the \\
Brownian motion vector (Wiener processes) that drive the simulation.
\end{tabular} \\
\hline
\end{tabular}

\section*{Examples}

Implementing Multidimensional Equity Market Models, Implementation 5: Using the simByEuler Method

\section*{More About}

\section*{Algorithms}
- This simulation engine provides a discrete-time approximation of the underlying generalized continuous-time process. The simulation is derived directly from the stochastic differential equation of motion. Thus, the discrete-time process approaches the true continuous-time process only as DeltaTime approaches zero.
- The input argument \(Z\) allows you to directly specify the noise-generation process. This process takes precedence over the Correlation parameter of the SDE object and the value of the Antithetic input flag. If you do not specify a value for \(Z\), simByEuler generates correlated Gaussian variates, with or without antithetic sampling as requested.
- The end-of-period Processes argument allows you to terminate a given trial early. At the end of each time step, simByEuler tests the state vector \(X_{t}\) for an all- NaN condition. Thus, to signal an early termination of a given trial, all elements of the state vector \(X_{t}\) must be NaN. This test enables a user-defined Processes function to signal early termination of a trial, and offers significant performance benefits in some situations (for example, pricing down-and-out barrier options).

}

\section*{simBySolution}

Simulate approximate solution of diagonal-drift HWV and GBM processes

\section*{Syntax}
[Paths, Times, Z] = simBySolution(MDL, NPERIODS)
[Paths, Times, Z] = simBySolution(MDL, NPERIODS, 'Name1', Value1,'Name2', Value2, ...)

\section*{Classes}
- GBM
- HWV

\section*{Description}

The simBySolution method simulates NTRIALS sample paths of NVARS correlated state variables, driven by NBROWNS Brownian motion sources of risk over NPERIODS consecutive observation periods, approximating continuous-time Hull-White/Vasicek (HWV), and geometric Brownian motion (GBM) short-rate models by an approximation of the closed-form solution.

Consider a separable, vector-valued HWV model of the form:
\[
d X_{t}=S(t)\left[L(t)-X_{t}\right] d t+V(t) d W_{t}
\]

\section*{where:}
- \(X\) is an NVARS-by- 1 state vector of process variables.
- \(S\) is an NVARS-by-NVARS matrix of mean reversion speeds (the rate of mean reversion).
- \(L\) is an NVARS-by-1 vector of mean reversion levels (long-run mean or level).
- \(V\) is an \(N V A R S\)-by- \(N B R O W N S\) instantaneous volatility rate matrix.
- \(W\) is an NBROWNS-by-1 Brownian motion vector.
or a separable, vector-valued GBM model of the form:
\[
d X_{t}=\mu(t) X_{t} d t+D\left(t, X_{t}\right) V(t) d W_{t}
\]
where:
- \(X_{t}\) is an NVARS-by- 1 state vector of process variables.
- \(\mu\) is an NVARS-by-NVARS generalized expected instantaneous rate of return matrix.
- \(V\) is an NVARS-by-NBROWNS instantaneous volatility rate matrix.
- \(d W_{t}\) is an NBROWNS-by- 1 Brownian motion vector.

The simBySolution method simulates the state vector \(X_{t}\) using an approximation of the closed-form solution of diagonal-drift models.

When evaluating the expressions, simBySolution assumes that all model parameters are piecewise-constant over each simulation period.

In general, this is not the exact solution to the models, because the probability distributions of the simulated and true state vectors are identical only for piecewiseconstant parameters.

When parameters are piecewise-constant over each observation period, the simulated process is exact for the observation times at which \(X_{t}\) is sampled.

\section*{Input Arguments}
\begin{tabular}{|l|l|}
\hline MDL & Hull-White/Vasicek (HWV) or geometric Brownian motion (GBM) model. \\
\hline NPERIODS & \begin{tabular}{l} 
Positive scalar integer number of simulation periods. The value of \\
this argument determines the number of rows of the simulated output \\
series.
\end{tabular} \\
\hline
\end{tabular}

\section*{Optional Input Arguments}

Specify optional input arguments as variable-length lists of matching parameter name/ value pairs: 'Name1', Value1, 'Name2', Value2, ... and so on. The following rules apply when specifying parameter-name pairs:
- Specify the parameter name as a character string, followed by its corresponding parameter value.
- You can specify parameter name/value pairs in any order.
- Parameter names are case insensitive.
- You can specify unambiguous partial string matches.

Valid parameter names are:
\begin{tabular}{|l|l|}
\hline NTRIALS & \begin{tabular}{l} 
Positive scalar integer number of simulated trials (sample paths) of \\
NPERIODS observations each. If you do not specify a value for this \\
argument, the default is 1, indicating a single path of correlated state \\
variables.
\end{tabular} \\
\hline DeltaTime & \begin{tabular}{l} 
Scalar or NPERIODS-by-1 column vector of positive time increments \\
between observations. DeltaTime represents the familiar \(d t\) found in \\
stochastic differential equations, and determines the times at which \\
simBySolution reports the simulated paths of the output state \\
variables. If you do not specify a value for this argument, the default \\
is 1.
\end{tabular} \\
\hline NSTEPS & \begin{tabular}{l} 
Positive scalar integer number of intermediate time steps within \\
each time increment dt (specified as DeltaTime). simBySolution \\
partitions each time increment dt into NSTEPS subintervals \\
of length dt/NSTEPS, and refines the simulation by evaluating \\
the simulated state vector at NSTEPS - 1 intermediate points. \\
Although simBySolution does not report the output state vector \\
at these intermediate points, the refinement improves accuracy by \\
allowing the simulation to more closely approximate the underlying \\
continuous-time process. If you do not specify a value for NSTEPS, the \\
default is 1, indicating no intermediate evaluation.
\end{tabular} \\
\hline Antithetic & \begin{tabular}{l} 
Scalar logical flag that indicates whether antithetic sampling is used \\
to generate the Gaussian random variates that drive the Brownian \\
motion vector (Wiener processes). When Antithetic is TRUE (logical \\
1), simBySolution performs sampling such that all primary and \\
antithetic paths are simulated and stored in successive matching \\
pairs:
\end{tabular} \\
- Odd trials (1, 3, 5, . .) correspond to the primary Gaussian
\end{tabular}\(|\)
\begin{tabular}{|l|l|} 
& \begin{tabular}{l} 
If you specify Antithetic to be any value other than \\
TRUE,simBySolution assumes that it is FALSE (logical 0) by default, \\
and does not perform antithetic sampling. When you specify an \\
input noise process (see Z), simBySolution ignores the value of \\
Antithetic.
\end{tabular} \\
\hline Z & \begin{tabular}{l} 
Direct specification of the dependent random noise process used to \\
generate the Brownian motion vector (Wiener process) that drives the \\
simulation. Specify this argument as a function, or as an (NPERIODS \\
* NSTEPS)-by-NBROWNS-by-NTRIALS array of dependent random \\
variates. If you specify Z as a function, it must return an NBROWNS- \\
by-1 column vector, and you must call it with two inputs: \\
- A real-valued scalar observation time \(t\). \\
- An NVARS-by-1 state vector \(X_{t}\).
\end{tabular} \\
\begin{tabular}{l} 
If you do not specify a value for Z, simBySolution generates \\
correlated Gaussian variates based on the Correlation member of \\
the SDE object.
\end{tabular} \\
\hline StorePaths & \begin{tabular}{l} 
Scalar logical flag that indicates how simBySolution stores the \\
output array Paths and returns it to the caller. If StorePaths is \\
TRUE(the default value) or is unspecified, simBySolution returns \\
Paths as a three-dimensional time series array. If StorePaths is \\
FALSE (logical 0), simBySolution returns the Paths output array as \\
an empty matrix.
\end{tabular} \\
\hline
\end{tabular}
\(\left.\begin{array}{|c|l|}\hline \text { Processes } & \begin{array}{l}\text { Function or cell array of functions that indicates a sequence of end-of- } \\ \text { period processes or state vector adjustments of the form }\end{array} \\ \quad X_{t}=P\left(t, X_{t}\right) \\ \text { simBySolution applies processing functions at the end of each } \\ \text { observation period. These functions must accept the current } \\ \text { observation time } t \text { and the current state vector } X_{t} \text {, and return a state } \\ \text { vector that may be an adjustment to the input state. } \\ \text { If you specify more than one processing function, simBySolution } \\ \text { invokes the functions in the order in which they appear in the cell } \\ \text { array. You can use this argument to specify boundary conditions, } \\ \text { prevent negative prices, accumulate statistics, plot graphs, and more. } \\ \text { If you do not specify a processing function, simBySolution makes no } \\ \text { adjustments and performs no processing. }\end{array}\right]\)

\section*{Output Arguments}
\begin{tabular}{|l|l|}
\hline Paths & \begin{tabular}{l} 
(NPERIODS + 1)-by-NVARS-by-NTRIALS three-dimensional time \\
series array, consisting of simulated paths of correlated state variables. \\
For a given trial, each row of Paths is the transpose of the state \\
vector \(X_{t}\) at time \(t\). When the input flag StorePaths = FALSE, \\
simBySolution returns Paths as an empty matrix.
\end{tabular} \\
\hline Times & \begin{tabular}{l} 
(NPERIODS + 1)-by-1 column vector of observation times associated \\
with the simulated paths. Each element of Times is associated with \\
the corresponding row of Paths.
\end{tabular} \\
\hline Z & \begin{tabular}{l} 
(NPERIODS * NSTEPS) -by-NBROWNS-by-NTRIALS three-dimensional \\
time series array of dependent random variates used to generate the \\
Brownian motion vector (Wiener processes) that drive the simulation.
\end{tabular} \\
\hline
\end{tabular}

\section*{Examples}

Implementing Multidimensional Equity Market Models, Implementation 6: Using GBM Simulation Methods

\section*{More About}

\section*{Algorithms}
- The input argument \(Z\) allows you to directly specify the noise generation process. This process takes precedence over the Correlation parameter of the SDE object and the value of the Antithetic input flag. If you do not specify a value for \(Z\), simBySolution generates correlated Gaussian variates, with or without antithetic sampling as requested.
- Gaussian diffusion models, such as HWV, allow negative states. By default, simBySolution does nothing to prevent negative states, nor does it guarantee that the model be strictly mean-reverting. Thus, the model may exhibit erratic or explosive growth.
- The end-of-period Processes argument allows you to terminate a given trial early. At the end of each time step, simBySolution tests the state vector \(X_{t}\) for an all-NaN condition. Thus, to signal an early termination of a given trial, all elements of the state vector \(X_{t}\) must be NaN. This test enables a user-defined Processes function to signal early termination of a trial, and offers significant performance benefits in some situations (for example, pricing down-and-out barrier options).

\section*{simulate}

Simulate multivariate stochastic differential equations (SDEs)

\section*{Syntax}
[Paths, Times, Z] = simulate(MDL, ...)

\section*{Classes}

All classes in the "SDE Class Hierarchy" on page 17-5.

\section*{Description}

This method simulates any vector-valued SDE of the form:
\[
d X_{t}=F\left(t, X_{t}\right) d t+G\left(t, X_{t}\right) d W_{t}
\]
where:
- \(X\) is an NVARS-by- 1 state vector of process variables (for example, short rates or equity prices) to simulate.
- \(W\) is an NBROWNS-by-1 Brownian motion vector.
- \(F\) is an \(N V A R S\)-by- 1 vector-valued drift-rate function.
- \(G\) is an \(N V A R S\)-by- \(N B R O W N S\) matrix-valued diffusion-rate function.
[Paths, Times, Z] = simulate(MDL, ...) simulates NTRIALS sample paths of NVARS correlated state variables, driven by NBROWNS Brownian motion sources of risk over NPERIODS consecutive observation periods, approximating continuous-time stochastic processes.

\section*{Input Arguments}
\begin{tabular}{|l|l}
\hline MDL & Stochastic differential equation model.
\end{tabular}

\section*{Optional Input Arguments}

The simulate method accepts any variable-length list of input arguments that the simulation method or function referenced by the SDE. Simulation parameter requires or accepts. It passes this input list directly to the appropriate SDE simulation method or user-defined simulation function.

\section*{Output Arguments}
\begin{tabular}{|l|l|}
\hline Paths & \begin{tabular}{l} 
(NPERIODS + 1)-by-NVARS-by-NTRIALS three-dimensional time series \\
array, consisting of simulated paths of correlated state variables. For a \\
given trial, each row of Paths is the transpose of the state vector \(X_{t}\) at \\
time \(t\).
\end{tabular} \\
\hline Times & \begin{tabular}{l} 
(NPERIODS + 1)-by-1 column vector of observation times associated \\
with the simulated paths. Each element of Times is associated with a \\
corresponding row of Paths.
\end{tabular} \\
\hline Z & \begin{tabular}{l} 
NTIMES-by-NBROWNS-by-NTRIALS three-dimensional time series array of \\
dependent random variates used to generate the Brownian motion vector \\
(Wiener processes) that drove the simulated results found in Paths.
\end{tabular} \\
\begin{tabular}{l} 
NTIMES is the number of time steps at which simulate samples the \\
state vector. NTIMES includes intermediate times designed to improve \\
accuracy, which simulate does not necessarily report in the Paths \\
output time series.
\end{tabular} \\
\hline
\end{tabular}

\section*{Examples}

\section*{Antithetic Sampling}

Simulation methods allow you to specify a popular variance reduction technique called antithetic sampling. This technique attempts to replace one sequence of random observations with another of the same expected value, but smaller variance.

In a typical Monte Carlo simulation, each sample path is independent and represents an independent trial. However, antithetic sampling generates sample paths in pairs. The
first path of the pair is referred to as the primary path, and the second as the antithetic path. Any given pair is independent of any other pair, but the two paths within each pair are highly correlated. Antithetic sampling literature often recommends averaging the discounted payoffs of each pair, effectively halving the number of Monte Carlo trials.

This technique attempts to reduce variance by inducing negative dependence between paired input samples, ideally resulting in negative dependence between paired output samples. The greater the extent of negative dependence, the more effective antithetic sampling is.

This example applies antithetic sampling to a path-dependent barrier option. Consider a European up-and-in call option on a single underlying stock. The evolution of this stock's price is governed by a Geometric Brownian Motion (GBM) model with constant parameters:
\[
d X_{t}=0.05 X_{t} d t+0.3 X_{t} d W_{t}
\]

Assume the following characteristics:
- The stock currently trades at 105.
- The stock pays no dividends.
- The stock volatility is \(30 \%\) per annum.
- The option strike price is 100 .
- The option expires in three months.
- The option barrier is 120 .
- The risk-free rate is constant at \(5 \%\) per annum.

The goal is to simulate various paths of daily stock prices, and calculate the price of the barrier option as the risk-neutral sample average of the discounted terminal option payoff. Since this is a barrier option, you must also determine if and when the barrier is crossed.

This example performs antithetic sampling by explicitly setting the Antithetic flag to true, and then specifies an end-of-period processing function to record the maximum and terminal stock prices on a path-by-path basis.

1 Create a GBM model:
```

barrier = 120; % barrier
strike = 100; % exercise price
rate = 0.05; % annualized risk-free rate
sigma = 0.3; % annualized volatility
nPeriods = 63; % 63 trading days
dt = 1 / 252; % time increment = 252 days
T = nPeriods * dt; % expiration time = 0.25 years
obj = gbm(rate, sigma, 'StartState', 105);

```

2 Perform a small-scale simulation that explicitly returns two simulated paths:
```

rng('default') % make output reproducible
[X, T] = obj.simBySolution(nPeriods, 'DeltaTime', dt, ...
'nTrials', 2, 'Antithetic', true);

```

3 Perform antithetic sampling such that all primary and antithetic paths are simulated and stored in successive matching pairs. Odd paths ( \(1,3,5, \ldots\) ) correspond to the primary Gaussian paths. Even paths \((2,4,6, \ldots)\) are the matching antithetic paths of each pair, derived by negating the Gaussian draws of the corresponding primary (odd) path.

Verify this by examining the matching paths of the primary/antithetic pair:
```

plot(T, X(:,:,1), 'blue', T, X(:,:,2), 'red')
xlabel('Time (Years)'), ylabel('Stock Price'), ...
title('Antithetic Sampling')
legend({'Primary Path' 'Antithetic Path'}, ...
'Location', 'Best')

```

To price the European barrier option, specify an end-of-period processing function to record the maximum and terminal stock prices. This processing function is accessible by time and state, and is implemented as a nested function with access to shared information that allows the option price and corresponding standard error to be calculated. For more information on using an end-of-period processing function, see "Pricing Equity Options" on page 17-56.

1 Simulate 200 paths using the processing function method:
```

rng('default') % make output reproducible
barrier = 120; %barrier
strike = 100; % exercise price
rate = 0.05; % annualized risk-free rate

```
```

sigma = 0.3; % annualized volatility
nPeriods = 63; % 63 trading days
dt = 1 252; % time increment = 252 days
T = nPeriods * dt; % expiration time = 0.25 years
obj = gbm(rate, sigma, 'StartState', 105);
nPaths = 200; % \# of paths = 100 sets of pairs
f = Example_BarrierOption(nPeriods, nPaths);
simulate(obj, nPeriods, 'DeltaTime' , dt, ...
'nTrials', nPaths, 'Antithetic', true, ...
'Processes', f.SaveMaxLast);

```

2 Approximate the option price with a \(95 \%\) confidence interval:
```

optionPrice = f.OptionPrice (strike, rate, barrier);
standardError = f.StandardError(strike, rate, barrier,...
true);
lowerBound = optionPrice - 1.96 * standardError;
upperBound = optionPrice + 1.96 * standardError;
fprintf(' Up-and-In Barrier Option Price: %8.4f\n', ...
optionPrice)
fprintf(' Standard Error of Price: %8.4f\n', ...
standardError)
fprintf(' Confidence Interval Lower Bound: %8.4f\n', ...
lowerBound)
fprintf(' Confidence Interval Upper Bound: %8.4f\n', ...
upperBound)

```
\begin{tabular}{rr} 
Up-and-In Barrier Option Price: & 6.6572 \\
Standard Error of Price: & 0.7292 \\
Confidence Interval Lower Bound: & 5.2280 \\
Confidence Interval Upper Bound: & \(\mathbf{8 . 0 8 6 4}\)
\end{tabular}

\section*{selectreturn}

Portfolio configurations from 3-D efficient frontier

\section*{Syntax}

PortConfigs = selectreturn(AllMean, All Covariance, Target)

\section*{Arguments}
\begin{tabular}{|l|l|}
\hline AllMean & \begin{tabular}{l} 
Number of curves (NCURVES-by-1 cell array), where each \\
element is a 1-by-NASSETS (number of assets) vector of the \\
expected asset returns used to generate each curve on the \\
surface.
\end{tabular} \\
\hline AllCovariance & \begin{tabular}{l} 
NCURVES-by-1 cell array where each element is an NASSETS- \\
by-NASSETS vector of the covariance matrix used to generate \\
each curve on the surface.
\end{tabular} \\
\hline Target & Target return value for each curve in the frontier. \\
\hline
\end{tabular}

\section*{Description}

PortConfigs = selectreturn(AllMean, All Covariance, Target) returns the portfolio configurations for a target return given the average return and covariance for a rolling efficient frontier.

PortConfigs is a NASSETS-by-NCURVES matrix of asset allocation weights needed to obtain the target rate of return.

\section*{setAssetList}

Set up list of identifiers for assets
Use the setAssetList function with a Portfolio, PortfolioCVaR, or PorfolioMAD object to set up list of identifiers for assets for a portfolio object.

For details on the respective workflows when using these different objects, see "Portfolio Object Workflow" on page 4-17, "PortfolioCVaR Object Workflow" on page 5-16, and "PortfolioMAD Object Workflow" on page 6-16.

\section*{Syntax}
```

obj = setAssetList(obj,varargin)

```

\section*{Description}
obj = setAssetList (obj, varargin) sets up the list of identifiers for assets for a portfolio object.

\section*{Examples}

\section*{Create a Default List of Asset Names with Three Assets for a Portfolio Object}

Create a default list of asset names with three assets.
```

p = Portfolio('NumAssets',3);
p = setAssetList(p);
disp(p.AssetList);
'Asset1' 'Asset2' 'Asset3'

```

\section*{Create an Explicitly Named List of Asset Names with Three Assets for a Portfolio Object}

Create a list of asset names for three equities AGG, EEM, and VEU.
```

p = Portfolio;

```
```

p = setAssetList(p, 'AGG', 'EEM', 'VEU');
disp(p.AssetList);
AGG' 'EEM' 'VEU'

```

\section*{Create a Default List of Asset Names with Three Assets for a PorffolioCVaR Object}

Create a default list of asset names with three assets.
```

p = PortfolioCVaR('NumAssets',3);
p = setAssetList(p);
disp(p.AssetList);
'Asset1' 'Asset2' 'Asset3'

```

\section*{Create an Explicitly Named List of Asset Names with Three Assets for a PortfolioCVaR Object}

Create a list of asset names for three equities AGG, EEM, and VEU.
```

p = PortfolioCVaR;
p = setAssetList(p, 'AGG', 'EEM', 'VEU');
disp(p.AssetList);
AGG' 'EEM' 'VEU'

```

\section*{Create a Default List of Asset Names with Three Assets for a PorifolioMAD Object}

Create a default list of asset names with three assets.
```

p = PortfolioMAD('NumAssets',3);
p = setAssetList(p);

- "Common Operations on the PortfolioCVaR Object" on page 5-31
- "Common Operations on the PortfolioMAD Object" on page 6-30
- "Portfolio Optimization Examples" on page 4-114

\section*{Input Arguments}

\section*{obj - Object for portfolio}
object
Object for portfolio, specified using Portfolio, PortfolioCVaR, or PortfolioMAD object. For more information on creating a portfolio object, see
- Using Portfolio Objects
- Using PortfolioCVaR Objects
- Using PortfolioMAD Objects

\section*{varargin - Asset identifiers}
comma-separated list of strings | vector cell array of strings
Asset identifiers, specified as a comma-separated list of strings or a vector cell array of strings where each string is an asset identifier.

If an asset list is entered as an input, this function overwrites an existing asset list in the object if one exists.

If no asset list is entered as an input, three actions can occur:
- If NumAssets is nonempty and AssetList is empty, AssetList becomes a numbered list of assets with default names according to the hidden property in defaultforAssetList ('Asset').
- If NumAssets is nonempty and AssetList is nonempty, nothing happens.
- If NumAssets is empty and AssetList is empty, the default NumAssets \(=1\) is set and a default asset list is created ('Asset1').

\section*{Data Types: char | cell}

\section*{Output Arguments}

\section*{obj - Updated portfolio object}
object for portfolio
Updated portfolio object, returned as a Portfolio, PortfolioCVaR, or PortfolioMAD object. For more information on creating a portfolio object, see
- Using Portfolio Objects
- Using PortfolioCVaR Objects
- Using PortfolioMAD Objects

The underlying object ( obj ) has a number of public hidden properties to format the asset list:
- defaultforAssetList - Default name for assets ('Asset '). Change this name to create default asset names such as 'ETF', 'Bond'.
- sortAssetList - Reserved for future implementation.
- uppercaseAssetList - If true, make all asset identifiers uppercase strings. Otherwise do nothing. Default is false.

\section*{More About}

\section*{Tips}
- You can also use dot notation to set up list of identifiers for assets.
obj = obj.setAssetList(varargin);
- To clear an AssetList, call this method with[ ] or \{[]\}.
- Getting Started with Portfolio Optimization (13 min 31 sec )

\section*{setAssetMoments}

Set moments (mean and covariance) of asset returns for Portfolio object
Use the setAssetMoments function with a Portfolio object to set moments (mean and covariance) of asset returns.

For details on the workflow, see "Portfolio Object Workflow" on page 4-17.

\section*{Syntax}
```

obj = setAssetMoments(obj,AssetMean)

```
obj = setAssetMoments(obj,AssetMean,AssetCovar,NumAssets)

\section*{Description}
obj = setAssetMoments(obj,AssetMean) obtains mean and covariance of asset returns for a Portfolio object.
obj = setAssetMoments(obj,AssetMean,AssetCovar,NumAssets) obtains mean and covariance of asset returns for a Portfolio object with additional options for AssetCovar and NumAssets.

\section*{Examples}

\section*{Set Asset Moments for a Portfolio Object}

Set the asset moment properties, given the mean and covariance of asset returns in the variables m and C .
```

m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
0.00408 0.0289 0.0204 0.0119;
0.00192 0.0204 0.0576 0.0336;
0 0.0119 0.0336 0.1225 ];

```
\(\mathrm{m}=\mathrm{m} / 12\);
\(C=C / 12\);
p = Portfolio;
\(p=\operatorname{setAssetMoments(p,m,C);~}\)
[assetmean, assetcovar] = getAssetMoments(p)
assetmean =
0.0042
0.0083
0.0100
0.0150

\section*{Input Arguments}

\section*{obj - Object for portfolio}
object
Object for portfolio, specified using a Portfolio object. For more information on creating a portfolio object, see
- Using Portfolio Objects

\section*{AssetMean - Mean of asset returns}
vector
Mean of asset returns, specified as a vector.

Note: If AssetMean is a scalar and the number of assets is known, scalar expansion occurs. If the number of assets cannot be determined, this method assumes that NumAssets \(=1\).

\section*{Data Types: double}

\section*{AssetCovar - Covariance of asset returns}
symmetric positive-semidefinite matrix
Covariance of asset returns, specified as a symmetric positive-semidefinite matrix.

Note: If AssetCovar is a scalar and the number of assets is known, a diagonal matrix is formed with the scalar value along the diagonals. If it is not possible to determine the number of assets, this method assumes that NumAssets \(=1\).

If AssetCovar is a vector, a diagonal matrix is formed with the vector along the diagonal.

\section*{Data Types: double}

\section*{NumAssets - Number of assets \\ integer}

Number of assets, specified as an integer.

Note: If NumAssets is not already set in the object, NumAssets can be entered to resolve array expansions with AssetMean or AssetCovar.

\section*{Data Types: double}

\section*{Output Arguments}

\section*{obj - Updated porifolio object}
object for portfolio
Updated portfolio object, returned as a Portfolio object. For more information on creating a portfolio object, see
- Using Portfolio Objects

\section*{More About}

\section*{Tips}
- You can also use dot notation to set moments (mean and covariance) of the asset returns.
obj = obj.setAssetMoments(obj, AssetMean, AssetCovar, NumAssets);
- To clear NumAssets and AssetCovar, use this function to set these respective inputs to [].

\section*{setBounds}

Set up bounds for portfolio weights
Use the setBounds function with a Portfolio, PortfolioCVaR, or PortfolioMAD object to set up bounds for portfolio weights for portfolio objects.

For details on the respective workflows when using these different objects, see "Portfolio Object Workflow" on page 4-17, "PortfolioCVaR Object Workflow" on page 5-16, and "PortfolioMAD Object Workflow" on page 6-16.

\section*{Syntax}
obj = setBounds(obj, LowerBound)
obj = setBounds(obj,LowerBound,UpperBound,NumAssets)

\section*{Description}
obj = setBounds(obj, LowerBound) sets up bounds for portfolio weights for portfolio objects.
obj = setBounds(obj, LowerBound,UpperBound,NumAssets) sets up bounds for portfolio weights for portfolio objects with additional options for UpperBound and NumAssets.

Given bound constraints LowerBound and UpperBound, every weight in a portfolio Port must satisfy the following:
```

LowerBound <= Port <= UpperBound

```

\section*{Examples}

\section*{Set Bound Constraints for a Porffolio Object}

Suppose you have a balanced fund with stocks that can range from \(50 \%\) to \(75 \%\) of your portfolio and bonds that can range from \(25 \%\) to \(50 \%\) of your portfolio. To set the bound constraints for a balanced fund.
```

lb = [ 0.5; 0.25 ];
ub = [ 0.75; 0.5 ];
p = Portfolio;
p = setBounds(p, lb, ub);
disp(p.NumAssets);
disp(p.LowerBound);
disp(p.UpperBound);
2
0.5000
0.2500
0.7500
0.5000

```

\section*{Set Bound Constraints for a PorffolioCVaR Object}

Suppose you have a balanced fund with stocks that can range from \(50 \%\) to \(75 \%\) of your portfolio and bonds that can range from \(25 \%\) to \(50 \%\) of your portfolio. To set the bound constraints for a balanced fund.
```

lb = [ 0.5; 0.25 ];
ub = [ 0.75; 0.5 ];
p = PortfolioCVaR;
p = setBounds(p, lb, ub);
disp(p.NumAssets);
disp(p.LowerBound);
disp(p.UpperBound);
2
0.5000
0.2500
0.7500
0.5000

```

\section*{Set Bound Constraints for a PorifolioMAD Object}

Suppose you have a balanced fund with stocks that can range from \(50 \%\) to \(75 \%\) of your portfolio and bonds that can range from \(25 \%\) to \(50 \%\) of your portfolio. To set the bound constraints for a balanced fund.
```

lb = [ 0.5; 0.25 ];
ub = [ 0.75; 0.5 ];
p = PortfolioMAD;
p = setBounds(p, lb, ub);
disp(p.NumAssets);
disp(p.LowerBound);
disp(p.UpperBound);
2
0.5000
0.2500
0.7500
0.5000

\section*{Input Arguments}

\section*{obj - Object for portfolio}
object
Object for portfolio, specified using Portfolio, PortfolioCVaR, or PortfolioMAD object. For more information on creating a portfolio object, see
- Using Portfolio Objects
- Using PortfolioCVaR Objects
- Using PortfolioMAD Objects

\section*{LowerBound - Lower-bound weight for each asset}
vector
Lower-bound weight for each asset, specified as a vector for a Portfolio, PortfolioCVaR, or PortfolioMAD input object (obj).

\section*{Note:}
- If either LowerBound or UpperBound are input as empties with [ ], the corresponding attributes in the portfolio object are cleared and set to [ ].
- If LowerBound or UpperBound are specified as scalars and NumAssets exists or can be imputed, then they undergo scalar expansion. The default value for NumAssets is 1.
- If both LowerBound and UpperBound exist and they are not ordered correctly, the setBounds function switches bounds if necessary.

\section*{Data Types: double}

\section*{UpperBound - Upper-bound weight for each asset}

\section*{vector}

Upper-bound weight for each asset, specified as a vector for a Portfolio, PortfolioCVaR, or PortfolioMAD input object (obj).

\section*{Note:}
- If either LowerBound or UpperBound are input as empties with [ ], the corresponding attributes in the portfolio object are cleared and set to [ ].
- If LowerBound or UpperBound are specified as scalars and NumAssets exists or can be imputed, then they undergo scalar expansion. The default value for NumAssets is 1.
- If both LowerBound and UpperBound exist and they are not ordered correctly, the setBounds function switches bounds if necessary.

\section*{Data Types: double}

\section*{NumAssets - Number of assets in portfolio}
scalar
Number of assets in portfolio, specified as a scalar for a Portfolio, PortfolioCVaR, or PortfolioMAD input object (obj).

Note: NumAssets cannot be used to change the dimension of a portfolio object.
- If either LowerBound or UpperBound are input as empties with [ ], the corresponding attributes in the portfolio object are cleared and set to [].
- If LowerBound or UpperBound are specified as scalars and NumAssets exists or can be imputed, then they undergo scalar expansion. The default value for NumAssets is 1.
- If both LowerBound and UpperBound exist and they are not ordered correctly, the setBounds function switches bounds if necessary.

\section*{Data Types: double}

\section*{Output Arguments}

\section*{obj - Updated porifolio object}
object for portfolio
Updated portfolio object, returned as a Portfolio, PortfolioCVaR, or PortfolioMAD object. For more information on creating a portfolio object, see
- Using Portfolio Objects
- Using PortfolioCVaR Objects
- Using PortfolioMAD Objects

\section*{More About}

\section*{Tips}

You can also use dot notation to set up the bounds for portfolio weights.
```

obj = obj.setBounds(LowerBound, UpperBound, NumAssets);

```

\section*{See Also \\ getBounds}

Introduced in R2011a

\section*{setBudget}

Set up budget constraints
Use the setBudget function with a Portfolio, PortfolioCVaR, or PortfolioMAD object to set up budget constraints for portfolio objects.

For details on the respective workflows when using these different objects, see "Portfolio Object Workflow" on page 4-17, "PortfolioCVaR Object Workflow" on page 5-16, and "PortfolioMAD Object Workflow" on page 6-16.

\section*{Syntax}
```

obj = setBudget(obj,LowerBudget)
obj = setBudget(obj,LowerBudget,UpperBudget)

```

\section*{Description}
obj = setBudget (obj, LowerBudget) sets up budget constraints for portfolio objects.
obj = setBudget(obj, LowerBudget, UpperBudget) sets up budget constraints for portfolio objects with an additional option for UpperBudget.

\section*{Examples}

\section*{Set Budget Constraint for a Portfolio Object}

Assume you have a fund that permits up to \(10 \%\) leverage, which means that your portfolio can be from \(100 \%\) to \(110 \%\) invested in risky assets. Given a Portfolio object p, set the budget constraint.
```

p = Portfolio;
p = setBudget(p, 1, 1.1);
disp(p.LowerBudget);
disp(p.UpperBudget);
1

```
    1.1000

\section*{Set Budget Constraint for a PorffolioCVaR Object}

Assume you have a fund that permits up to \(10 \%\) leverage, which means that your portfolio can be from \(100 \%\) to \(110 \%\) invested in risky assets. Given a CVaR portfolio object p , set the budget constraint.
```

p = PortfolioCVaR;
p = setBudget(p, 1, 1.1);
disp(p.LowerBudget);
disp(p.UpperBudget);
1

```
1.1000

\section*{Set Budget Constraint for a PorffolioMAD Object}

Assume you have a fund that permits up to \(10 \%\) leverage, which means that your portfolio can be from \(100 \%\) to \(110 \%\) invested in risky assets. Given PortfolioMAD object p , set the budget constraint.
```

p = PortfolioMAD;
p = setBudget(p, 1, 1.1);
disp(p.LowerBudget);
disp(p.UpperBudget);
1

```

\section*{Input Arguments}

\section*{obj - Object for portfolio}
object

Object for portfolio, specified using Portfolio, PortfolioCVaR, or PortfolioMAD object. For more information on creating a portfolio object, see
- Using Portfolio Objects
- Using PortfolioCVaR Objects
- Using PortfolioMAD Objects

\section*{LowerBudget - Lower-bound for budget constraint}
scalar
Lower-bound for budget constraint, specified as a scalar for a Portfolio, PortfolioCVaR, or PortfolioMAD input object (obj).

Note: Given bounds for a budget constraint in either LowerBudget or UpperBudget, budget constraints require any portfolio in Port to satisfy:

LowerBudget <= sum(Port) <= UpperBudget

One or both constraints may be specified. The usual budget constraint for a fully invested portfolio is to have LowerBudget = UpperBudget = 1. However, if the portfolio has allocations in cash, the budget constraints can be used to specify the cash constraints. For example, if the portfolio can hold between \(0 \%\) and \(10 \%\) in cash, the budget constraint would be set up with
```

obj = setBudget(obj, 0.9, 1)

```

\section*{Data Types: double}

\section*{UpperBudget - Upper-bound for budget constraint scalar}

Upper-bound for budget constraint, specified as a scalar for a Portfolio, PortfolioCVaR, or PortfolioMAD input object (obj).

Note: Given bounds for a budget constraint in either LowerBudget or UpperBudget, budget constraints require any portfolio in Port to satisfy:
```

LowerBudget <= sum(Port) <= UpperBudget

```

One or both constraints may be specified. The usual budget constraint for a fully invested portfolio is to have LowerBudget \(=\) UpperBudget \(=1\). However, if the portfolio has allocations in cash, the budget constraints can be used to specify the cash constraints. For example, if the portfolio can hold between \(0 \%\) and \(10 \%\) in cash, the budget constraint would be set up with
```

obj = setBudget(obj, 0.9, 1)

```

\section*{Data Types: double}

\section*{Output Arguments}

\section*{obj - Updated porffolio object}
object for portfolio
Updated portfolio object, returned as a Portfolio, PortfolioCVaR, or PortfolioMAD object. For more information on creating a portfolio object, see
- Using Portfolio Objects
- Using PortfolioCVaR Objects
- Using PortfolioMAD Objects

\section*{More About}

\section*{Tips}

You can also use dot notation to set up the budget constraints.
obj = obj.setBudget(LowerBudget, UpperBudget);

18 Functions - Alphabetical List

Introduced in R201 la

\section*{setCosts}

Set up proportional transaction costs
Use the setCosts function with a Portfolio, PortfolioCVaR, or PortfolioMAD object to set up proportional transaction costs for portfolio objects.

For details on the respective workflows when using these different objects, see "Portfolio Object Workflow" on page 4-17, "PortfolioCVaR Object Workflow" on page 5-16, and "PortfolioMAD Object Workflow" on page 6-16.

\section*{Syntax}
```

obj = setCosts(obj,BuyCost)

```
obj = setCosts(obj, BuyCost,SellCost,InitPort,NumAssets)

\section*{Description}
obj = setCosts(obj, BuyCost) sets up proportional transaction costs for portfolio objects.
obj = setCosts(obj,BuyCost,SellCost, InitPort,NumAssets) sets up proportional transaction costs for portfolio objects with additional options specified for SellCost, InitPort, and NumAssets.

Given proportional transaction costs and an initial portfolio in the variables BuyCost, SellCost, and InitPort, the transaction costs for any portfolio Port reduce expected portfolio return by:
```

BuyCost' * max{0, Port - InitPort} + SellCost' * max{0, InitPort - Port}

```

\section*{Examples}

\section*{Set Up Transaction Costs for a Porifolio Object}

Assume you have the same costs and initial portfolio as in the previous example. Given a Portfolio object \(p\) with an initial portfolio already set, use the setCosts function to set up transaction costs.
```

bc = [ 0.00125; 0.00125; 0.00125; 0.00125; 0.00125 ];
sc = [ 0.00125; 0.007; 0.00125; 0.00125; 0.0024 ];
x0 = [ 0.4; 0.2; 0.2; 0.1; 0.1 ];
p = Portfolio('InitPort', x0);
p = setCosts(p, bc, sc);
disp(p.NumAssets);
disp(p.BuyCost);
disp(p.SellCost);
disp(p.InitPort);

\section*{Input Arguments}

\section*{obj - Object for portfolio}
object
Object for portfolio, specified using Portfolio, PortfolioCVaR, or PortfolioMAD object. For more information on creating a portfolio object, see
- Using Portfolio Objects
- Using PortfolioCVaR Objects
- Using PortfolioMAD Objects

\section*{BuyCost - Proportional transaction cost to purchase each asset} vector

Proportional transaction cost to purchase each asset, specified as a vector for a Portfolio, PortfolioCVaR, or PortfolioMAD input object (obj).

\section*{Note:}
- If BuyCost, SellCost, or InitPort are specified as scalars and NumAssets exists or can be imputed, then these values undergo scalar expansion. The default value for NumAssets is 1 .
- Transaction costs in BuyCost and SellCost are positive valued if they introduce a cost to trade. In some cases, they can be negative valued, which implies trade credits.

\section*{Data Types: double}

\section*{SellCost - Proportional transaction cost to sell each asset}

\section*{vector}

Proportional transaction cost to sell each asset, specified as a vector for a Portfolio, PortfolioCVaR, or PortfolioMAD input object (obj).

\section*{Note:}
- If BuyCost, SellCost, or InitPort are specified as scalars and NumAssets exists or can be imputed, then these values undergo scalar expansion. The default value for NumAssets is 1 .
- Transaction costs in BuyCost and SellCost are positive valued if they introduce a cost to trade. In some cases, they can be negative valued, which implies trade credits.

\section*{Data Types: double}

\section*{InitPort - Initial or current portfolio weights}
vector
Initial or current portfolio weights, specified as a vector for a Portfolio, PortfolioCVaR, or PortfolioMAD input object (obj).

Note: If no InitPort is specified, that value is assumed to be 0 .
- If BuyCost, SellCost, or InitPort are specified as scalars and NumAssets exists or can be imputed, then these values undergo scalar expansion. The default value for NumAssets is 1 .
- Transaction costs in BuyCost and SellCost are positive valued if they introduce a cost to trade. In some cases, they can be negative valued, which implies trade credits.

\section*{Data Types: double}

\section*{NumAssets - Number of assets in porffolio \\ scalar}

Number of assets in portfolio, specified as a scalar for a Portfolio, PortfolioCVaR, or PortfolioMAD input object (obj).

Note: NumAssets cannot be used to change the dimension of a portfolio object.
- If BuyCost, SellCost, or InitPort are specified as scalars and NumAssets exists or can be imputed, then these values undergo scalar expansion. The default value for NumAssets is 1.
- Transaction costs in BuyCost and SellCost are positive valued if they introduce a cost to trade. In some cases, they can be negative valued, which implies trade credits.

\section*{Data Types: double}

\section*{Output Arguments}

\section*{obj - Updated porifolio object}
object for portfolio
Updated portfolio object, returned as a Portfolio, PortfolioCVaR, or PortfolioMAD object. For more information on creating a portfolio object, see
- Using Portfolio Objects
- Using PortfolioCVaR Objects
- Using PortfolioMAD Objects

\section*{More About}

\section*{Tips}
- You can also use dot notation to set up proportional transaction costs.
obj = obj.setCosts(BuyCost, SellCost, InitPort, NumAssets);
- If BuyCost or SellCost are input as empties with [ ], the corresponding attributes in the portfolio object are cleared and set to [ ]. If InitPort is set to empty with [ ], it will only be cleared and set to [ ] if BuyCost, SellCost, and Turnover are also empty. Otherwise, it is an error.

\section*{setDefaultConstraints}

Set up portfolio constraints with nonnegative weights that sum to 1
Use the setDefaultConstraints function with a Portfolio, PortfolioCVaR, or PortfolioMAD object to set up portfolio constraints with nonnegative weights that sum to 1 for portfolio objects.

For details on the respective workflows when using these different objects, see "Portfolio Object Workflow" on page 4-17, "PortfolioCVaR Object Workflow" on page 5-16, and "PortfolioMAD Object Workflow" on page 6-16.

\section*{Syntax}
```

obj = setDefaultConstraints(obj)
obj = setDefaultConstraints(obj,NumAssets)

```

\section*{Description}
obj = setDefaultConstraints(obj) sets up portfolio constraints with nonnegative weights that sum to 1 .
obj = setDefaultConstraints(obj,NumAssets) sets up portfolio constraints with nonnegative weights that sum to 1 with an additional option for NumAssets.

A "default" portfolio set has LowerBound = 0 and LowerBudget = UpperBudget = 1 such that a portfolio Port must satisfy sum(Port) \(=1\) with Port \(>=0\).

\section*{Examples}

\section*{Define Default Constraints for the Portfolio Object}

Assuming you have 20 assets, you can define the "default" portfolio set.
```

p = Portfolio('NumAssets', 20);

```
\(\mathrm{p}=\) setDefaultConstraints(p);
```

disp(p);

\section*{setEquality}

Set up linear equality constraints for portfolio weights
Use the setEquality function with a Portfolio, PortfolioCVaR, or PortfolioMAD object to set up linear equality constraints for portfolio weights for portfolio objects.

For details on the respective workflows when using these different objects, see "Portfolio Object Workflow" on page 4-17, "PortfolioCVaR Object Workflow" on page 5-16, and "PortfolioMAD Object Workflow" on page 6-16.

\section*{Syntax}
```

obj= setEquality(obj,AEquality,bEquality)

```

\section*{Description}
obj= setEquality(obj,AEquality,bEquality) sets up linear equality constraints for portfolio weights for portfolio objects.

Given linear equality constraint matrix AEquality and vector bEquality, every weight in a portfolio Port must satisfy the following:
```

AEquality * Port = bEquality

```

\section*{Examples}

\section*{Set Linear Equality Constraints for a Porffolio Object}

Suppose you have a portfolio of five assets, and you want to ensure that the first three assets are \(50 \%\) of your portfolio. Given a Portfolio object p, set the linear equality constraints with the following.
```

A = [ [1 1 1 1 0 0 ];
b = 0.5;
p = Portfolio;
p = setEquality(p, A, b);

```
```

disp(p.NumAssets);
disp(p.AEquality);
disp(p.bEquality);
5
1
0.5000

```

\section*{Set Linear Equality Constraints for a PorffolioCVaR Object}

Suppose you have a portfolio of five assets and you want to ensure that the first three assets are \(50 \%\) of your portfolio. Given a PortfolioCVaR object p, set the linear equality constraints and obtain the values for AEquality and bEquality:
```

A = [ [1 1 1 1 0 0 ];
b = 0.5;
p = PortfolioCVaR;
p = setEquality(p, A, b);
disp(p.NumAssets);
disp(p.AEquality);
disp(p.bEquality);
5
1
0.5000

```

\section*{Set Linear Equality Constraints for a PorifolioMAD Object}

Suppose you have a portfolio of five assets and you want to ensure that the first three assets are \(50 \%\) of your portfolio. Given a PortfolioMAD object \(p\), set the linear equality constraints and obtain the values for AEquality and bEquality:
\(A=\left[\begin{array}{lllll}1 & 1 & 1 & 0 & 0\end{array}\right] ;\)
b \(=0.5\);
p = PortfolioMAD;
\(p\) = setEquality (p, A, b);
[AEquality, bEquality] = getEquality(p)

AEquality =
\(\begin{array}{lllll}1 & 1 & 1 & 0 & 0\end{array}\)
bEquality =
0.5000

\section*{Input Arguments}

\section*{obj - Object for portfolio}
object
Object for portfolio, specified using Portfolio, PortfolioCVaR, or PortfolioMAD object. For more information on creating a portfolio object, see
- Using Portfolio Objects
- Using PortfolioCVaR Objects
- Using PortfolioMAD Objects

\section*{AEquality - Matrix to form linear equality constraints \\ matrix}

Matrix to form linear equality constraints, returned as a matrix for a Portfolio, PortfolioCVaR, or PortfolioMAD input object (obj).

Note: An error results if AEquality is empty and bEquality is nonempty.

\section*{bEquality - Vector to form linear equality constraints \\ vector}

Vector to form linear equality constraints, returned as a vector for a Portfolio, PortfolioCVaR, or PortfolioMAD input object (obj).

Note: An error results if AEquality is nonempty and bEquality is empty.

\section*{Data Types: double}

\section*{Output Arguments}

\section*{obj - Updated portfolio object}
object for portfolio
Updated portfolio object, returned as a Portfolio, PortfolioCVaR, or PortfolioMAD object. For more information on creating a portfolio object, see
- Using Portfolio Objects
- Using PortfolioCVaR Objects
- Using PortfolioMAD Objects

\section*{More About}

\section*{Tips}
- You can also use dot notation to set up linear equality constraints for portfolio weights.
obj = obj.setEquality(AEquality, bEquality);
- Linear equality constraints can be removed from a portfolio object by entering [ ] for each property you want to remove.

\section*{setGroupRatio}

Set up group ratio constraints for portfolio weights
Use the setGroupRatio function with a Portfolio, PortfolioCVaR, or PortfolioMAD object to set up group ratio constraints for portfolio weights for portfolio objects.

For details on the respective workflows when using these different objects, see "Portfolio Object Workflow" on page 4-17, "PortfolioCVaR Object Workflow" on page 5-16, and "PortfolioMAD Object Workflow" on page 6-16.

\section*{Syntax}
```

obj = setGroupRatio(obj,GroupA)
obj = setGroupRatio(obj,GroupA,GroupB,LowerRatio,UpperRatio)

```

\section*{Description}
obj = setGroupRatio(obj,GroupA) sets up group ratio constraints for portfolio weights for portfolio objects
obj = setGroupRatio(obj,GroupA, GroupB, LowerRatio,UpperRatio) sets up group ratio constraints for portfolio weights for portfolio objects with additional options specified for GroupB, LowerRatio, and UpperRatio.

Given base and comparison group matrices GroupA and GroupB and LowerRatio or UpperRatio bounds, group ratio constraints require any portfolio in Port to satisfy the following:
(GroupB * Port) . * LowerRatio <= GroupA * Port <= (GroupB * Port) . * UpperRatio

Caution This collection of constraints usually requires that portfolio weights be nonnegative and that the products GroupA * Port and GroupB * Port are always nonnegative. Although negative portfolio weights and non-Boolean group ratio matrices are supported, use with caution.

\section*{Examples}

\section*{Set Group Ratio Constraints for a Porifolio Object}

Suppose you want to ensure that the ratio of financial to nonfinancial companies in your portfolio never exceeds \(50 \%\). Assume you have six assets with three financial companies (assets 1-3) and three nonfinanical companies (assets 4-6). Group ratio constraints can be set with:
```

GA = [ true true true false false false ]; % financial companies
GB = [ false false false true true true ]; % nonfinancial companies
p = Portfolio;
p = setGroupRatio(p, GA, GB, [], 0.5);
disp(p.NumAssets);
disp(p.GroupA);
disp(p.GroupB);
disp(p.UpperRatio);

```
    6
    \(\begin{array}{llllll}1 & 1 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 1 & 1\end{array}\)
    0.5000

\section*{Set Group Ratio Constraints for a PorifolioCVaR Object}

Suppose you want to ensure that the ratio of financial to nonfinancial companies in your portfolio never exceeds \(50 \%\). Assume you have six assets with three financial companies (assets 1-3) and three nonfinanical companies (assets 4-6). Group ratio constraints can be set with:
```

GA = [ true true true false false false ]; % financial companies
GB = [ false false false true true true ]; % nonfinancial companies
p = PortfolioCVaR;
p = setGroupRatio(p, GA, GB, [], 0.5);
disp(p.NumAssets);
disp(p.GroupA);
disp(p.GroupB);

```
```

disp(p.UpperRatio);
6
1
0
0.5000

```

\section*{Set Group Ratio Constraints for a PorffolioMAD Object}

Suppose you want to ensure that the ratio of financial to nonfinancial companies in your portfolio never exceeds \(50 \%\). Assume you have six assets with three financial companies (assets 1-3) and three nonfinanical companies (assets 4-6). Group ratio constraints can be set with:
```

GA = [ true true true false false false ]; % financial companies
GB = [ false false false true true true ]; % nonfinancial companies
p = PortfolioMAD;
p = setGroupRatio(p, GA, GB, [], 0.5);
disp(p.NumAssets);
disp(p.GroupA);
disp(p.GroupB);
disp(p.UpperRatio);

```

\section*{Input Arguments}

\section*{obj - Object for porffolio}
object
Object for portfolio, specified using Portfolio, PortfolioCVaR, or PortfolioMAD object. For more information on creating a portfolio object, see
- Using Portfolio Objects
- Using PortfolioCVaR Objects
- Using PortfolioMAD Objects

\section*{GroupA - Matrix that forms base groups for comparison}
matrix
Matrix that forms base groups for comparison, specified as a matrix for a Portfolio, PortfolioCVaR, or PortfolioMAD input object (obj).

Note: The group matrices GroupA and GroupB are usually indicators of membership in groups, which means that their elements are usually either 0 or 1 . Because of this interpretation, GroupA and GroupB matrices can be either logical or numerical arrays.

\section*{Data Types: double}

\section*{GroupB - Matrix that forms comparison groups}
matrix
Matrix that forms comparison groups, specified as a matrix Portfolio, PortfolioCVaR, or PortfolioMAD input object (obj).

Note: The group matrices GroupA and GroupB are usually indicators of membership in groups, which means that their elements are usually either 0 or 1 . Because of this interpretation, GroupA and GroupB matrices can be either logical or numerical arrays.

\section*{Data Types: double}

\section*{LowerRatio - Lower bound for ratio of GroupB groups to GroupA groups}
vector

Lower bound for ratio of GroupB groups to GroupA groups, specified as a vector for a Portfolio, PortfolioCVaR, or PortfolioMAD input object (obj).

Note: If input is scalar, LowerRatio undergoes scalar expansion to be conformable with the group matrices.

\section*{Data Types: double}

\section*{UpperRatio - Upper bound for ratio of GroupB groups to GroupA groups vector}

Upper bound for ratio of GroupB groups to GroupA groups, specified as a vector for a Portfolio, PortfolioCVaR, or PortfolioMAD input object (obj).

Note: If input is scalar, UpperRatio undergoes scalar expansion to be conformable with the group matrices.

\section*{Data Types: double}

\section*{Output Arguments}

\section*{obj - Updated porifolio object}
object for portfolio
Updated portfolio object, returned as a Portfolio, PortfolioCVaR, or PortfolioMAD object. For more information on creating a portfolio object, see
- Using Portfolio Objects
- Using PortfolioCVaR Objects
- Using PortfolioMAD Objects

\section*{More About}

\section*{Tips}
- You can also use dot notation to set up group ratio constraints for portfolio weight.
```

obj = obj.setGroupRatio(GroupA, GroupB, LowerRatio, UpperRatio);

```
- To remove group ratio constraints, enter empty arrays for the corresponding arrays. To add to existing group ratio constraints, use addGroupRatio.

\section*{Introduced in R2011a}

\section*{setGroups}

Set up group constraints for portfolio weights
Use the setGroups function with a Portfolio, PortfolioCVaR, or PortfolioMAD object to set up group constraints for portfolio weights for portfolio objects.

For details on the respective workflows when using these different objects, see "Portfolio Object Workflow" on page 4-17, "PortfolioCVaR Object Workflow" on page 5-16, and "PortfolioMAD Object Workflow" on page 6-16.

\section*{Syntax}
```

obj = setGroups(obj,GroupMatrix,LowerGroup)

```
obj = setGroups(obj,GroupMatrix,LowerGroup,UpperGroup)

\section*{Description}
obj = setGroups(obj,GroupMatrix,LowerGroup) sets up group constraints for portfolio weights for portfolio objects.
obj = setGroups(obj,GroupMatrix,LowerGroup,UpperGroup) sets up group constraints for portfolio weights for portfolio objects with an additional option specified for UpperGroup.

Given GroupMatrix and either LowerGroup or UpperGroup, a portfolio Port must satisfy the following:
```

LowerGroup <= GroupMatrix * Port <= UpperGroup

```

\section*{Examples}

\section*{Set Group Constraints for a Porffolio Object}

Suppose you have a portfolio of five assets and you want to ensure that the first three assets constitute at most \(30 \%\) of your portfolio. Given a Portfolio object p, set the group constraints with the following.
```

G = [ true true true false false ];
p = Portfolio;
p = setGroups(p, G, [], 0.3);
disp(p.NumAssets);
disp(p.GroupMatrix);
disp(p.UpperGroup);
5
1 1
0.3000

```

\section*{Set Group Constraints for a PorffolioCVaR Object}

Suppose you have a portfolio of five assets and you want to ensure that the first three assets constitute at most \(30 \%\) of your portfolio. Given a CVaR portfolio object p , set the group constraints with the following.
```

G = [ true true true false false ];
p = PortfolioCVaR;
p = setGroups(p, G, [], 0.3);
disp(p.NumAssets);
disp(p.GroupMatrix);
disp(p.UpperGroup);

```

\section*{setInequality}

Set up linear inequality constraints for portfolio weights
Use the setInequality function with a Portfolio, PortfolioCVaR, or PortfolioMAD object to set up linear inequality constraints for portfolio weights for portfolio objects.

For details on the respective workflows when using these different objects, see "Portfolio Object Workflow" on page 4-17, "PortfolioCVaR Object Workflow" on page 5-16, and "PortfolioMAD Object Workflow" on page 6-16.

\section*{Syntax}
obj = setInequality(obj,AInequality,bInequality)

\section*{Description}
obj = setInequality(obj,AInequality,bInequality) sets up linear inequality constraints for portfolio weights for portfolio objects.

Given a linear inequality constraint matrix AInequality and vector bInequality, every weight in a portfolio Port must satisfy the following:
```

AInequality * Port <= bInequality

```

\section*{Examples}

\section*{Set Linear Inequality Constraints for a Portfolio Object}

Suppose you have a portfolio of five assets and you want to ensure that the first three assets are no more than \(50 \%\) of your portfolio. Given a Portfolio object p, set the linear inequality constraints with the following.
```

A = [ 1 1 1 1 0 0 ];
b = 0.5;
p = Portfolio;

```
```

p = setInequality(p, A, b);
disp(p.NumAssets);
disp(p.AInequality);
disp(p.bInequality);
5
1 1
0.5000

```

\section*{Set Linear Inequality Constraints for a PortfolioCVaR Object}

Suppose you have a portfolio of five assets and you want to ensure that the first three assets are no more than \(50 \%\) of your portfolio. Given a CVaR portfolio object p , set the linear inequality constraints with the following.
```

A = [ [10cclll
b = 0.5;
p = PortfolioCVaR;
p = setInequality(p, A, b);

}

\section*{setOneWayTurnover}

Set up one-way portfolio turnover constraints
Use the setOneWayTurnover function with a Portfolio, PortfolioCVaR, or PortfolioMAD object to set up one-way portfolio turnover constraints for portfolio objects.

For details on the respective workflows when using these different objects, see "Portfolio Object Workflow" on page 4-17, "PortfolioCVaR Object Workflow" on page 5-16, and "PortfolioMAD Object Workflow" on page 6-16.

\section*{Syntax}
obj = setOneWayTurnover(obj,BuyTurnover)
obj = setOneWayTurnover(obj,BuyTurnover,SellTurnover,InitPort, NumAssets)

\section*{Description}
obj = setOneWayTurnover(obj, BuyTurnover) sets up one-way portfolio turnover constraints for portfolio objects.
obj = setOneWayTurnover(obj,BuyTurnover,SellTurnover, InitPort, NumAssets) sets up one-way portfolio turnover constraints for portfolio objects with additional options specified for SellTurnover, InitPort, and NumAssets.

Given an initial portfolio in InitPort and an upper bound for portfolio turnover on purchases in BuyTurnover or sales in SellTurnover, the one-way turnover constraints require any portfolio Port to satisfy the following:
```

1' * max{0, Port - InitPort} <= BuyTurnover
1' * max{0, InitPort - Port} <= SellTurnover

```

Note: If Turnover =BuyTurnover = SellTurnover, the constraint is not equivalent to:
```

1' * | Port - InitPort | <= Turnover

```

To set this constraint, use setTurnover.

\section*{Examples}

\section*{Set One-Way Turnover Constraints for a Portfolio Object}

Set one-way turnover constraints.
```

p = Portfolio('AssetMean',[0.1, 0.2, 0.15], 'AssetCovar',...
[ 0.005, -0.010, 0.004; -0.010, 0.040, -0.002; 0.004, -0.002, 0.023]);
p = setBudget(p, 1, 1);
p = setOneWayTurnover(p, 1.3, 0.3, 0); %130-30 portfolio
plotFrontier(p);

## Input Arguments

## obj - Object for portfolio

object
Object for portfolio, specified using Portfolio, PortfolioCVaR, or PortfolioMAD object. For more information on creating a portfolio object, see

- Using Portfolio Objects
- Using PortfolioCVaR Objects
- Using PortfolioMAD Objects

## BuyTurnover - Turnover constraint on purchases

nonnegative and finite scalar
Turnover constraint on purchases, specified as a nonnegative and finite scalar for a Portfolio, PortfolioCVaR, or PortfolioMAD input object (obj).

## SellTurnover - Turnover constraint on sales <br> nonnegative and finite scalar

Turnover constraint on sales, specified as a nonnegative and finite scalar for a Portfolio, PortfolioCVaR, or PortfolioMAD input object (obj).

## InitPort - Initial or current portfolio weights <br> 0 (default) | finite vector with NumAssets > 0 elements

Initial or current portfolio weights, specified as a finite vector with NumAssets $>0$ elements for a Portfolio, PortfolioCVaR, PortfolioMAD input object (obj).

Note: If no InitPort is specified, that value is assumed to be 0 .
If InitPort is specified as a scalar and NumAssets exists, then InitPort undergoes scalar expansion.

## Data Types: double

## NumAssets - Number of assets in porifolio <br> 1 (default) | scalar

Number of assets in portfolio, specified as a scalar for a Portfolio, PortfolioCVaR, or PortfolioMAD input object (obj).

Note: If it is not possible to obtain a value for NumAssets, it is assumed that NumAssets is 1 .

## Data Types: double

## Output Arguments

## obj - Updated porifolio object

object for portfolio
Updated portfolio object, returned as a Portfolio, PortfolioCVaR, or PortfolioMAD object. For more information on creating a portfolio object, see

- Using Portfolio Objects
- Using PortfolioCVaR Objects
- Using PortfolioMAD Objects

## More About

## One-way Turnover Constraint

One-way turnover constraints ensure that estimated optimal portfolios differ from an initial portfolio by no more than specified amounts according to whether the differences are purchases or sales.

The constraints take the form

$$
\begin{aligned}
& 1^{T} \max \left\{0, x-x_{0}\right\} \leq \tau_{B} \\
& 1^{T} \max \left\{0, x_{0}-x\right\} \leq \tau_{S}
\end{aligned}
$$

with

- x - The portfolio (NumAssets vector)
- $\mathrm{x}_{0}$ - Initial portfolio (NumAssets vector)
- $\tau_{B}$ - Upper-bound for turnover constraint on purchases (scalar)
- $\tau_{S}$ - Upper-bound for turnover constraint on sales (scalar)

Specify one-way turnover constraints using the following properties in a supported portfolio object: BuyTurnover for $\tau_{B}$, SellTurnover for $\tau_{S}$, and InitPort for $\mathrm{x}_{0}$.

Note: The average turnover constraint (which is set using setTurnover) is not just the combination of the one-way turnover constraints with the same value for the constraint.

## Tips

You can also use dot notation to set up one-way portfolio turnover constraints.
obj = obj.setOneWayTurnover(BuyTurnover,SellTurnover, InitPort,NumAssets)

- "Portfolio Set for Optimization Using Portfolio Object" on page 4-7

## setProbabilityLevel

Set probability level for VaR and CVaR calculations
Use the setProbabilityLevel function with a PortfolioCVaR object to set probability level for VaR and CVaR calculations.

For details on the workflow, see "PortfolioCVaR Object Workflow" on page 5-16.

## Syntax

```
obj = setProbabilityLevel(obj,ProbabilityLevel)
```

## Description

obj = setProbabilityLevel(obj,ProbabilityLevel) sets probability level for VaR and CVaR calculations for a PortfolioCVaR object.

## Examples

## Set Probability Level for a PorffolioCVaR Object

Set the ProbabilityLevel for a CVaR portfolio object.

```
p = PortfolioCVaR;
p = setProbabilityLevel(p, 0.95);
disp(p.ProbabilityLevel)
```

0.9500

- "What Are Scenarios?" on page 5-39

## Input Arguments

obj - Object for portfolio
object

Object for portfolio, specified using a PortfolioCVaR object.
For more information on creating a PortfolioCVaR object, see

- Using PortfolioCVaR Objects

## ProbabilityLevel - Probability level which is 1 minus the probability of losses greater than the value-at-risk

scalar with value from 0 to 1
Probability level which is 1 minus the probability of losses greater than the value-at-risk, specified as a scalar with value from 0 to 1 .

Note: ProbabilityLevel must be a value from 0 to 1 and, in most cases, should be a value from 0.9 to 0.99 .

## Data Types: double

## Output Arguments

obj - Updated portfolio object
object for portfolio
Updated portfolio object, returned as a PortfolioCVaR object. For more information on creating a portfolio object, see

- Using PortfolioCVaR Objects

## More About

## Tips

You can also use dot notation to set the probability level for VaR and CVaR calculations:
obj = obj.setProbabilityLevel(ProbabilityLevel)

- "Conditional Value-at-Risk" on page 5-5
- CVaR Portfolio Optimization (5 min 33 sec )
- Analyzing Investment Strategies with CVaR Portfolio Optimization in MATLAB (50 $\min 42 \mathrm{sec}$ )

See Also<br>setScenarios

Introduced in R2012b

## setSolver

Choose main solver and specify associated solver options for portfolio optimization
Use the setSolver function with a Portfolio, PortfolioCVaR, or PortfolioMAD object to choose main solver and specify associated solver options for portfolio optimization for portfolio objects.

For details on the respective workflows when using these different objects, see "Portfolio Object Workflow" on page 4-17, "PortfolioCVaR Object Workflow" on page 5-16, and "PortfolioMAD Object Workflow" on page 6-16.

## Syntax

```
obj = setSolver(obj,solverType)
obj = setSolver(obj,solverType,varargin)
```

## Description

obj = setSolver(obj, solverType) chooses main solver and specify associated solver options for portfolio optimization for portfolio objects.
obj = setSolver(obj, solverType, varargin) chooses main solver and specify associated solver options for portfolio optimization for portfolio objects with additional options specified for varargin by using one or more Name, Value pair arguments, or an optimoptions object.

After you specify a solver, the varargin argument accepts either name-value pair arguments to set options or, for the case of solvers from Optimization Toolbox software, a structure created by optimoptions.

## Examples

## Set Solver Type for a Porifolio Object

If you use the quadprog function as the solverType, the default is the interior-point-convex version of quadprog.

```
load CAPMuniverse
p = Portfolio('AssetList',Assets(1:12));
p = setDefaultConstraints(p);
p = setSolver(p, 'quadprog');
display(p.solverType);
quadprog
```

You can switch back to lcprog with:

```
p = setSolver(p, 'lcprog');
display(p.solverType);
```

lcprog

## Set the Solver Type as 'fmincon'for a PortfolioCVaR Object

Use 'fmincon' as the solverType.
p = PortfolioCVaR;
p = setSolver(p, 'fmincon');
display(p.solverType);
fmincon

## Set the Solver Type as 'fmincon' and Use Name-Value Pair Arguments to Set the Algorithm for a PortfolioCVaR Object

Use 'fmincon' as the solverType and use name-value pair arguments to set the algorithm to 'trust-region-reflective' and to turn off the display.

```
p = PortfolioCVaR;
p = setSolver(p, 'fmincon', 'Algorithm', 'trust-region-reflective', 'Display', 'off');
display(p.solverOptions.Algorithm);
display(p.solverOptions.Display);
trust-region-reflective
off
```

## Set the Solver Type as 'fmincon' and Use an optimoptions Object to Set the Algorithm for a PortfolioCVaR Object

Use 'fmincon' as the solverType and use an optimoptions object to set the algorithm to 'trust-region-reflective' and to turn off the display.

```
p = PortfolioCVaR;
options = optimoptions('fmincon', 'Algorithm', 'trust-region-reflective', 'Display',
```

```
p = setSolver(p, 'fmincon', options);
display(p.solverOptions.Algorithm);
display(p.solverOptions.Display);
trust-region-reflective
off
```

## Set 'cuttingplane' as the Solver Type with Default Options for a PortfolioCVaR Object

Use 'cuttingplane' as the solverType with default options.

```
p = PortfolioCVaR;
```

p = setSolver( p, 'cuttingplane');
display(p.solverType);
cuttingplane

## Set 'cuttingplane' as the Solver Type with Maximum Iterations for a PorffolioCVaR Object

Use the Name-Value pair 'MaxIter' to set the maximum number of iterations to 1500.

```
p = PortfolioCVaR;
p = setSolver(p,'cuttingplane','MaxIter',1500);
display(p.solverType);
display(p.solverOptions);
```

cuttingplane
MaxIter: 1500
AbsTol: 1.0000e-06
RelTol: 1.0000e-05
MasterSolverOptions: [1x1 optim.options.Linprog]

## Set 'cuttingplane' as the Solver Type and Change the Master Solver Option for a PortfolioCVaR Object

For the master solver, continue using the dual-simplex algorithm with no display, but tighten its termination tolerance to 1e-8.

```
p = PortfolioCVaR;
options = optimoptions('linprog','Algorithm', 'Dual-Simplex', 'Display','off', 'TolFun
p = setSolver(p,'cuttingplane','MasterSolverOptions',options);
display(p.solverType)
display(p.solverOptions)
display(p.solverOptions.MasterSolverOptions.Algorithm)
display(p.solverOptions.MasterSolverOptions.Display)
```

```
display(p.solverOptions.MasterSolverOptions.TolFun)
cuttingplane
    MaxIter: 1000
    AbsTol: 1.0000e-06
    RelTol: 1.0000e-05
    MasterSolverOptions: [1x1 optim.options.Linprog]
dual-simplex
off
ans =
    1.0000e-08
```

For the master solver, use the interior-point algorithm with no display, and with a termination tolerance of $1 \mathrm{e}-7$.

```
p = PortfolioCVaR;
options = optimoptions('linprog','Algorithm','interior-point','Display','off', 'TolFun
p = setSolver(p,'cuttingplane','MasterSolverOptions',options);
display(p.solverType)
display(p.solverOptions)
display(p.solverOptions.MasterSolverOptions.Algorithm)
display(p.solverOptions.MasterSolverOptions.Display)
display(p.solverOptions.MasterSolverOptions.TolFun)
cuttingplane
                                    MaxIter: 1000
                            AbsTol: 1.0000e-06
                            RelTol: 1.0000e-05
    MasterSolverOptions: [1x1 optim.options.Linprog]
interior-point
off
ans =
    1.0000e-07
```

## Set Solver Type as 'fmincon' for a PortfolioMAD Object

Use 'fmincon' as the solverType.

```
p = PortfolioMAD;
p = setSolver(p, 'fmincon');
display(p.solverType);
fmincon
```

## Set the Solver Type as 'fmincon' and Use Name-Value Pair Arguments to Set the Algorithm for a PortfolioMAD Object

Use 'fmincon' as the solverType and use name-value pair arguments to set the algorithm to|'sqp'| and to turn on the display.

```
p = PortfolioMAD;
p = setSolver(p, 'fmincon', 'Algorithm', 'sqp', 'Display', 'final');
display(p.solverOptions.Algorithm);
display(p.solverOptions.Display);
sqp
final
```

## Set Solver Type as 'fmincon' and Use an optimoptions Structure to Set the Algorithm for a PortfolioMAD Object

Use 'fmincon' as the solverType and use an optimoptions object to set the algorithm to 'trust-region-reflective' and to turn off the display.

```
p = PortfolioMAD;
options = optimoptions('fmincon', 'Algorithm', 'trust-region-reflective', 'Display',
p = setSolver(p, 'fmincon', options);
display(p.solverOptions.Algorithm);
display(p.solverOptions.Display);
trust-region-reflective
off
```

## Set the Solver Type as 'fmincon' and Use an optimoptions Structure to Set the Algorithm and Use of Gradients for a PortfolioMAD Object

Use 'fmincon' as the solverType and use an optimoptions object to set the algorithm to 'active-set' and to set the gradients flag 'on' for 'GradObj' and turn off the display.

```
p = PortfolioMAD;
options = optimoptions('fmincon','algorithm','active-set','display','off','gradobj','or
```

```
p = setSolver(p, 'fmincon', options);
display(p.solverOptions.Algorithm);
display(p.solverOptions.Display);
active-set
off
```

- "Working with One-way Turnover Constraints Using PortfolioCVaR Object" on page 5-71
- "Working with One-way Turnover Constraints Using PortfolioMAD Object" on page 6-70
- "Portfolio Optimization Examples" on page 4-114

## Input Arguments

## obj - Object for portfolio

object
Object for portfolio, specified using Portfolio, PortfolioCVaR, or PortfolioMAD object. For more information on creating a portfolio object, see

- Using Portfolio Objects
- Using PortfolioCVaR Objects
- Using PortfolioMAD Objects

## Name-Value Pair Arguments for varargin or optimoptions Object

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, . . ., NameN, ValueN.

Example: $p$ = setSolver(p,'cuttingplane','MasterSolverOptions',options)

## ' solverType ' - Solver to use for portfolio optimization <br> string

Solver to use for portfolio optimization, specified using a string, or optimoptions object.

The SolverType input argument depends on which type of object (obj) is being used for a portfolio optimization.

For a Portfolio object:

- The default solverType for the Portfolio object is 'lcprog' with the control variables 'maxiter', 'tiebreak', 'tolpiv'
- The Portfolio object can also use 'quadprog ', which has several different options that can be set with optimoptions. Like Optimization Toolbox software which uses the interior-point-convex algorithm as the default algorithm for quadprog, the portfolio optimization tools also uses the interior-point-convex algorithm. For more information about quadprog and quadratic programming algorithms and options, see "Quadratic Programming Algorithms".

For a PortfolioCVaR object:

- The supported solverType are:
- 'fmincon'
- 'cuttingplane'
- The default is 'fmincon' using the 'sqp ' algorithm.

For a PortfolioMAD object:

- The supported solverType is:
- 'fmincon'
- The default is 'fmincon' using the 'sqb' algorithm and 'GradObj' set to 'on'

## 'varargin' - Options to control the solver specified in solverType as name-value pair arguments or an optimoptions object

optimoptions object | string
Options to control the solver specified in solverType as name-value pair arguments or an optimoptions object. Note, optimoptions is the default and recommended method to set solver options, however optimset is also supported.

The varargin input argument depends on which type of object (obj) is being used for a portfolio optimization

For a Portfolio object:

- The default solverType for the Portfolio object is 'lcprog' with the control variables 'maxiter', 'tiebreak', 'tolpiv'
- The Portfolio object can also use a solverType of 'quadprog', which has several different options that can be set with optimoptions. Like Optimization Toolbox software which uses the interior-point-convex algorithm as the default algorithm for quadprog, the portfolio optimization tools also uses the interior-point-convex algorithm. For more information about quadprog and quadratic programming algorithms and options, see "Quadratic Programming Algorithms".

## For a PortfolioCVaR object:

- For the default solverType, ' fmincon', PortfolioCVaR by default sets the algorithm to 'sqp ', uses objective function gradients, and turns off the display. All fmincon options are supported, either as name-value pair arguments or using an optimoptions object. For more information about fmincon and quadratic programming algorithms and options, see "Quadratic Programming Algorithms".
- For the cuttingplane solver, the following solver options are available as namevalue pair arguments:
- MaxIter
- AbsTol
- RelTol
- MasterSolverOptions

For a PortfolioMAD object:

- For the default solverType 'fmincon', PortfolioMAD, by default, sets the algorithm to 'sqp ' and turns off the display. While all variations of fmincon from Optimization Toolbox are accepted, use of 'sqp' and 'active-set' algorithms for fmincon are recommended and the use of 'interior-point' and 'trust-region-reflective' algorithms are not recommended for MAD portfolio optimization.
- All fmincon options are supported either as name-value pair arguments or using an optimoptions object.
- optimoptions is the default and recommended method to set solver options, however optimset is also supported. For details about fmincon and constrained nonlinear optimization algorithms and options, see "Constrained Nonlinear Optimization Algorithms".

## Data Types: char

'MaxIter ' - Maximum number of iterations<br>1000 (default) | positive integer

Maximum number of iterations, specified as a positive integer when using a PortfolioCVaR object.

Data Types: char | double

'AbsTol' - Absolute stopping tolerance<br>1e-6 (default) | positive scalar

Absolute stopping tolerance, specified as a positive scalar when using a PortfolioCVaR object.

Data Types: char | double

## 'RelTol' - Relative stopping tolerance <br> 1e-5 (default) | positive scalar

Relative stopping tolerance, specified as a positive scalar when using a PortfolioCVaR object.

## Data Types: char | double

```
'MasterSolverOptions' - Options for the master solver
optimoptions('linprog','Algorithm','Dual-Simplex','Display','off')
(default) | optimoptions object
```

Options for the master solver linprog, specified as an optimoptions object when using a PortfolioCVaR object. For more information about linprog and linear programming algorithms and options, see "Linear Programming Algorithms".

Data Types: double

## Output Arguments

## obj - Updated porifolio object

object for portfolio
Updated portfolio object, returned as a Portfolio, PortfolioCVaR, or PortfolioMAD object. For more information on creating a portfolio object, see

- Using Portfolio Objects
- Using PortfolioCVaR Objects
- Using PortfolioMAD Objects

## More About

## Tips

You can also use dot notation to choose the solver and specify associated solver options.

```
obj = obj.setSolver(solverType, varargin);
```

## Algorithms

One version of the CVaR portfolio optimization problem minimizes risk, measured as the CVaR of the portfolio, subject to a target return and other linear constraints on the portfolio. For the definition of the CVaR function, see "Risk Proxy" on page 5-5.

```
minimize}\mp@subsup{x}{~}{CVaR
subject to }\mp@subsup{\overline{y}}{}{T}x\geq\mathrm{ TargetReturn
Ax \leqb
A Aq
lb\leqx\lequb
```

Vector $\bar{y}$ is the mean return vector (the column-wise mean of the scenario matrix $Y$ ), so that $\bar{y}^{T} x$ is the expected return of portfolio $x$. The first constraint says that the expected return must be at least as good as a target return.

An alternative version of the CVaR portfolio optimization problem maximizes the expected return of the portfolio, subject to a target risk and other linear constraints on the portfolio.

```
\(\operatorname{maximize}_{x} \bar{y}^{T} x\)
subject to \(C V a R_{\alpha}(x) \leq C V a R L i m i t\)
\(A x \leq b\)
\(A_{e q} x=b_{e q}\)
\(l b \leq x \leq u b\)
```

The first constraint in this case says that the portfolio CVaR cannot exceed a given CVaR limit.

By default, the CVaR portfolio object uses fmincon to solve the CVaR portfolio optimization problems. For information about fmincon and quadratic programming algorithms and options, see "Quadratic Programming Algorithms".

Alternatively, the CVaR portfolio optimization problems can be solved with 'cuttingplane', an implementation of Kelley's cutting-plane method. For more information, see Kelley [45] at "Portfolio Optimization" on page A-10.

## setScenarios

Set asset returns scenarios by direct matrix
Use the setScenarios function with a PortfolioCVaR or PortfolioMAD objects to set asset returns scenarios by direct matrix.

For details on the workflows, see "PortfolioCVaR Object Workflow" on page 5-16, and "PortfolioMAD Object Workflow" on page 6-16.

## Syntax

```
obj = setScenarios(obj,AssetScenarios)
obj = setScenarios(obj,AssetScenarios,Name,Value)
```

## Description

obj = setScenarios(obj,AssetScenarios) sets asset returns scenarios by direct matrix for PortfolioCVaR or PortfolioMAD objects.
obj = setScenarios(obj,AssetScenarios,Name,Value) set asset returns scenarios by direct matrix for PortfolioCVaR or PortfolioMAD objects using additional options specified by one or more Name, Value pair arguments.

## Examples

## Set Asset Returns Scenarios for a PorifolioCVaR Object

Given a PortfolioCVaR object p, use the setScenarios function to set asset return scenarios.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
    0.00408 0.0289 0.0204 0.0119;
    0.00192 0.0204 0.0576 0.0336;
    0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;
```

```
AssetScenarios = mvnrnd(m, C, 20000);
p = PortfolioCVaR;
p = setScenarios(p, AssetScenarios);
p = setDefaultConstraints(p);
p = setProbabilityLevel(p, 0.95);

```

- "Asset Returns and Scenarios Using PortfolioCVaR Object" on page 5-38
- "Asset Returns and Scenarios Using PortfolioMAD Object" on page 6-37

## Input Arguments

## obj - Object for portfolio

object
Object for portfolio, specified using a PortfolioCVaR or PortfolioMAD object.
For more information on creating a PortfolioCVaR or PortfolioMAD object, see

- Using PortfolioCVaR Objects
- Using PortfolioMAD Objects

## AssetScenarios - Scenarios for asset returns or prices

matrix
Scenarios for asset returns or prices, specified as a matrix. If the input data are prices, they can be converted into returns with the 'DataFormat' name-value argument, where the default format is assumed to be 'Returns'. Be careful using price data because portfolio optimization usually requires total returns and not simply price returns.

This function sets up a function handle to indirectly access input AssetScenarios without needing to make a copy of the data.

## Data Types: double

## Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, . . , NameN, ValueN.

Example: $p$ = setScenarios(p,
AssetScenarios, 'DataFormat', 'Returns', 'GetAssetList', false);

## 'DataFormat ' - Flag to convert input data as prices into returns <br> 'Returns' (default) | string with values 'Returns' or 'Prices'

Flag to convert input data as prices into returns, specified using a string with the values:

- 'Returns ' - Data in AssetReturns contains asset total returns.
- 'Prices ' - Data in AssetReturns contains asset total return prices.

## Data Types: char

## 'GetAssetList ' - Flag indicating which asset names to use for the asset list false (default) | logical with value true or false

Flag indicating which asset names to use for the asset list, specified as a logical with a value of true or false. Acceptable values for GetAssetList are:

- false - Do not extract or create asset names.
- true - Extract or create asset names from fints object.

If a fints object is passed into this function and the GetAssetList flag is true, the series names from the fints object are used as asset names in obj. AssetList.

If a matrix is passed and the GetAssetList flag is true, default asset names are created based on the AbstractPortfolio property defaultforAssetList, which is currently 'Asset'.

If the GetAssetList flag is false, no action occurs, which is the default behavior.
Data Types: logical

## Output Arguments

## obj - Updated porifolio object

object for portfolio
Updated portfolio object, returned as a PortfolioCVaR or PortfolioMAD object. For more information on creating a portfolio object, see

- Using PortfolioCVaR Objects
- Using PortfolioMAD Objects

## setTrackingError

Set up maximum portfolio tracking error constraint

## Syntax

```
obj = setTrackingPort(obj,TrackingError)
obj = setTrackingPort(
```

$\qquad$

``` ,TrackingPort,NumAssets)
```

## Description

obj = setTrackingPort(obj,TrackingError) sets up a maximum portfolio tracking error constraint.
obj = setTrackingPort( $\qquad$ , TrackingPort, NumAssets) sets up a maximum portfolio tracking error constraint using optional arguments for TrackingPort and NumAssets.

## Examples

## Set up a Tracking Error Constraint

Create a Portfolio object.
AssetMean = [ 0.05; 0.1; 0.12; 0.18 ];
AssetCovar = [ 0.00640 .004080 .001920 ;
0.004080 .02890 .0204 0.0119;
0.001920 .02040 .05760 .0336 ;
$00.01190 .03360 .1225 \mathrm{]}$;
p = Portfolio('mean', AssetMean, 'covar', AssetCovar, 'lb', 0, 'budget', 1)
$p=$

- "Working with Tracking Error Constraints Using Portfolio Object" on page 4-78
- "Portfolio Optimization Examples" on page 4-114

## Input Arguments

## obj - Object for portfolio

object
Object for portfolio, specified using a Portfolio object. For more information on creating a portfolio object, see Using Portfolio Objects.

## TrackingError - Upper bound for porffolio tracking error nonnegative and finite scalar

Upper bound for portfolio tracking error, specified using a nonnegative and finite scalar.
Given an upper bound for portfolio tracking error in TrackingError and a tracking portfolio in TrackingPort, the tracking error constraint requires any portfolio in Port to satisfy

```
Port - TrackingPort)'*AssetCovar*(Port - TrackingPort) <= TrackingError^2 .
```

Data Types: double

## TrackingPort - Tracking portfolio weights

finite vector
Tracking portfolio weights, specified using a vector. TrackingPort must be a finite vector with NumAssets > 0 elements.

If no TrackingPort is specified, it is assumed to be 0 . If TrackingPort is specified as a scalar and NumAssets exists, then TrackingPort undergoes scalar expansion.

## Data Types: double

## NumAssets - Number of assets in porifolio

 scalarNumber of assets in portfolio, specified using a scalar. If it is not possible to obtain a value for NumAssets, it is assumed that NumAssets is 1.

Data Types: double

## Output Arguments

## obj - Updated porffolio object

object for portfolio
Updated portfolio object, returned as a Portfolio object. For more information on creating a portfolio object, see Using Portfolio Objects.

Note: The tracking error constraints can be used with any of the other supported constraints in the Portfolio object without restrictions. However, since the portfolio set necessarily and sufficiently must be a non-empty compact set, the application of a tracking error constraint can result in an empty portfolio set. Use estimateBounds to confirm that the portfolio set is non-empty and compact.

## More About

## Tips

You can also use dot notation to set up a maximum portfolio tracking error constraint.

```
obj = obj.setTrackingError(TrackingError, NumAssets);
```

To remove a tracking portfolio, call this function with an empty argument ([ ]) for TrackingError.

```
obj = setTrackingError(obj, [ ]);
```

## setTurnover

Set up maximum portfolio turnover constraint
Use the setTurnover function with a Portfolio, PortfolioCVaR, or PortfolioMAD object to set up maximum portfolio turnover constraint for portfolio objects.

For details on the respective workflows when using these different objects, see "Portfolio Object Workflow" on page 4-17, "PortfolioCVaR Object Workflow" on page 5-16, and "PortfolioMAD Object Workflow" on page 6-16.

## Syntax

obj = setTurnover(obj,Turnover)
obj = setTurnover(obj,Turnover, InitPort,NumAssets)

## Description

obj = setTurnover(obj, Turnover) sets up maximum portfolio turnover constraint for portfolio objects.
obj = setTurnover(obj,Turnover, InitPort, NumAssets) sets up maximum portfolio turnover constraint for portfolio objects with additional options specified for Turnover, InitPort, and NumAssets.

Given an upper bound for portfolio turnover in Turnover and an initial portfolio in InitPort, the turnover constraint requires any portfolio in Port to satisfy the following:

```
1' * | Port - InitPort | <= Turnover
```

## Examples

## Set Turnover Constraint for a Porffolio Object

Given a Portfolio object p, to ensure that average turnover is no more than $30 \%$ with an initial portfolio of 10 assets in a variable x 0 , use the setTurnover method to set the turnover constraint.

```
x0 = [ 0.12; 0.09; 0.08; 0.07; 0.1; 0.1; 0.15; 0.11; 0.08; 0.1 ];
p = Portfolio('InitPort', x0);
p = setTurnover(p, 0.3);
disp(p.NumAssets);
disp(p.Turnover);
disp(p.InitPort);

## Input Arguments

## obj - Object for porffolio

object
Object for portfolio, specified using Portfolio, PortfolioCVaR, or PortfolioMAD object. For more information on creating a portfolio object, see

- Using Portfolio Objects
- Using PortfolioCVaR Objects
- Using PortfolioMAD Objects

## Turnover - Portfolio turnover constraint

nonnegative and finite scalar
Portfolio turnover constraint, specified as a nonnegative and finite scalar for a Portfolio, PortfolioCVaR, or PortfolioMADinput object (obj).

## InitPort - Initial or current porffolio weights

0 (default) | finite vector with NumAssets $>0$ elements.
Initial or current portfolio weights, specified as a finite vector with NumAssets $>0$ elements for a Portfolio, PortfolioCVaR, or PortfolioMAD input object (obj).

Note: If no InitPort is specified, that value is assumed to be 0 .
If InitPort is specified as a scalar and NumAssets exists, then InitPort undergoes scalar expansion.

## Data Types: double

## NumAssets - Number of assets in portfolio

```
1 (default) | scalar
```

Number of assets in portfolio, specified as a scalar for a Portfolio, PortfolioCVaR, or PortfolioMAD input object (obj).

Note: If it is not possible to obtain a value for NumAssets, it is assumed that NumAssets is 1.

## Data Types: double

## Output Arguments

## obj - Updated porifolio object

object for portfolio
Updated portfolio object, returned as a Portfolio, PortfolioCVaR, or PortfolioMAD object. For more information on creating a portfolio object, see

- Using Portfolio Objects

## simulateNormalScenariosByData

Simulate multivariate normal asset return scenarios from data
Use the simulateNormalScenariosByData function with a PortfolioCVaR or PortfolioMAD objects to simulate multivariate normal asset return scenarios from data.

For details on the workflows, see "PortfolioCVaR Object Workflow" on page 5-16, and "PortfolioMAD Object Workflow" on page 6-16.

## Syntax

```
obj = simulateNormalScenariosByData(obj,AssetReturns)
```

obj = simulateNormalScenariosByData(obj,AssetReturns,NumScenarios,
Name, Value)

## Description

obj = simulateNormalScenariosByData(obj,AssetReturns) simulates multivariate normal asset return scenarios from data for portfolio object for PortfolioCVaR or PortfolioMAD objects.
obj = simulateNormalScenariosByData(obj,AssetReturns,NumScenarios, Name, Value) simulates multivariate normal asset return scenarios from data for portfolio object for PortfolioCVaR or PortfolioMAD objects using additional options specified by one or more Name, Value pair arguments.

This function estimates the mean and covariance of asset returns from either price or return data and then uses these estimates to generate the specified number of scenarios with the function mvnrnd.

Data can in be either a NumSamples-by-NumAssets matrix of NumSamples prices or returns at a given periodicity for a collection of NumAssets assets or a fints object with NumSamples observations and NumAssets time series.

Note: If you want to use the method multiple times and you want to simulate identical scenarios each time the function is called, precede each function call with rng(seed) using a specified integer seed.

## Examples

## Simulate Multivariate Normal Asset Return Scenarios from Data for a PortfolioCVaR Object

Given a PortfolioCVaR object p, use the simulateNormalScenariosByData function to simulate multivariate normal asset return scenarios from data.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
    0.00408 0.0289 0.0204 0.0119;
    0.00192 0.0204 0.0576 0.0336;
    0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;
RawData = mvnrnd(m, C, 240);
NumScenarios = 2000;
p = PortfolioCVaR;
p = simulateNormalScenariosByData(p, RawData, NumScenarios)
p = setDefaultConstraints(p);
p = setProbabilityLevel(p, 0.9);
disp(p);

Simulate the scenarios from the data for each of the 12 assets from CAPMuniverse.mat.
p = simulateNormalScenariosByData(p, Data(:,1:12), 20000 ,'missingdata',true);

- "Asset Returns and Scenarios Using PortfolioCVaR Object" on page 5-38
- "Asset Returns and Scenarios Using PortfolioMAD Object" on page 6-37

## Input Arguments

## obj - Object for portfolio

object
Object for portfolio, specified using a PortfolioCVaR or PortfolioMAD object.
For more information on creating a PortfolioCVaR or PortfolioMAD object, see

- Using PortfolioCVaR Objects
- Using PortfolioMAD Objects

## AssetReturns - Asset data that can be converted into asset returns

 fints object | matrixAsset data that can be converted into asset returns, specified as a fints object or NumSamples-by-NumAssets matrix

Data Types: double

## NumScenarios - Number of scenarios to simulate

positive integer
Number of scenarios to simulate, specified as a positive integer.

## Data Types: double

## Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.
Example: p =
simulateNormalScenariosByData(p,RawData,NumScenarios,'DataFormat', 'Returns', '

## 'DataFromat ' - Flag to convert input data as prices into returns <br> 'Returns' (default) | string with values 'Returns' or 'Prices'

Flag to convert input data as prices into returns, specified using a string with the values:

- 'Returns' - Data in AssetReturns contains asset total returns.
- 'Prices ' - Data in AssetReturns contains asset total return prices.

Data Types: char

## 'MissingData' - Flag to use ECM algorithm to handle NaN values

false (default) | logical with values true or false
Flag to use ECM algorithm to handle NaN values, as a logical with a value of true or false.

- false - Do not use ECM algorithm to handle NaN values (exclude NaN values).
- true - Use ECM algorithm to handle NaN values.

Data Types: logical

## 'GetAssetList ' - Flag indicating which asset names to use for the asset list <br> false (default) | logical with values true or false

Flag indicating which asset names to use for the asset list, specified as a logical with a value of true or false.

- false - Do not extract or create asset names.
- true - Extract or create asset names from fints object.

If a fints object is passed into this function and the GetAssetList flag is true, the series names from the fints object are used as asset names in obj. AssetList.

If a matrix is passed and the GetAssetList flag is true, default asset names are created based on the AbstractPortfolio property defaultforAssetList, which is 'Asset'.

If the GetAssetList flag is false, no action occurs, which is the default behavior.

## Data Types: logical

## Output Arguments

## obj - Updated porifolio object

object for portfolio
Updated portfolio object, returned as a PortfolioCVaR or PortfolioMAD object. For more information on creating a portfolio object, see

- Using PortfolioCVaR Objects
- Using PortfolioMAD Objects

## More About

## Tips

You can also use dot notation to simulate multivariate normal asset return scenarios from data for a PortfolioCVaR or PortfolioMAD object.
obj = obj.simulateNormalScenariosByData(AssetReturns, NumScenarios, varargin);

- $\quad$ CVaR Portfolio Optimization (5 min 33 sec )

## simulateNormalScenariosByMoments

Simulate multivariate normal asset return scenarios from mean and covariance of asset returns

Use the simulateNormalScenariosByMoments function with a PortfolioCVaR or PortfolioMAD objects to simulate multivariate normal asset return scenarios from mean and covariance of asset returns.

For details on the workflows, see "PortfolioCVaR Object Workflow" on page 5-16, and "PortfolioMAD Object Workflow" on page 6-16.

## Syntax

obj = simulateNormalScenariosByMoments(obj,AssetMean,AssetCovar, NumScenarios)
obj = simulateNormalScenariosByMoments(obj,AssetMean, AssetCovarNumScenarios, NumAssets)

## Description

obj = simulateNormalScenariosByMoments(obj,AssetMean,AssetCovar, NumScenarios) simulates multivariate normal asset return scenarios from mean and covariance of asset returns for PortfolioCVaR or PortfolioMAD objects.
obj = simulateNormalScenariosByMoments(obj,AssetMean, AssetCovarNumScenarios, NumAssets) simulates multivariate normal asset return scenarios from mean and covariance of asset returns for PortfolioCVaR or PortfolioMAD objects using the optional input NumScenarios.

Note: This function overwrites existing scenarios associated with PortfolioCVaR or PortfolioMAD objects, and also, possibly, NumScenarios.

If you want to use the function multiple times and you want to simulate identical scenarios each time the function is called, precede each function call with rng(seed) using a specified integer seed.

## Examples

## Simulate Multivariate Normal Asset Return Scenarios from Moments for a PorifolioCVaR Object

Given PortfolioCVaR object p, use the simulateNormalScenariosByMoments function to simulate multivariate normal asset return scenarios from moments.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
    0.00408 0.0289 0.0204 0.0119;
    0.00192 0.0204 0.0576 0.0336;
    0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;
AssetScenarios = mvnrnd(m, C, 20000);
p = PortfolioCVaR;
p = setScenarios(p, AssetScenarios);
p = setDefaultConstraints(p);
p = setProbabilityLevel(p, 0.95);
AssetMean = [.5]
AssetCovar = [.5]
NumScenarios = 100
```

## Simulate Multivariate Normal Asset Return Scenarios from Moments for a PorifolioMAD Object

Given PortfolioMAD object p , use the simulateNormalScenariosByMoments function to simulate multivariate normal asset return scenarios from moments.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
    0.00408 0.0289 0.0204 0.0119;
    0.00192 0.0204 0.0576 0.0336;
    0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;
```

```
AssetScenarios = mvnrnd(m, C, 20000);
p = PortfolioMAD;
p = setScenarios(p, AssetScenarios);
p = setDefaultConstraints(p);

- "Asset Returns and Scenarios Using PortfolioCVaR Object" on page 5-38
- "Asset Returns and Scenarios Using PortfolioMAD Object" on page 6-37

## Input Arguments

## obj - Object for portfolio

object
Object for portfolio, specified using a PortfolioCVaR or PortfolioMAD object.
For more information on creating a PortfolioCVaR or PortfolioMAD object, see

- Using PortfolioCVaR Objects
- Using PortfolioMAD Objects

## AssetMean - Mean of asset returns

vector
Mean of asset returns, specified as a vector.

Note: If AssetMean is a scalar and the number of assets is known, scalar expansion occurs. If the number of assets cannot be determined, this function assumes that NumAssets $=1$.

## Data Types: double

## AssetCovar - Covariance of asset returns

symmetric positive-semidefinite matrix
Covariance of asset returns, specified as a symmetric positive-semidefinite matrix.

## Note:

- If AssetCovar is a scalar and the number of assets is known, a diagonal matrix is formed with the scalar value along the diagonals. If it is not possible to determine the number of assets, this method assumes that NumAssets $=1$.
- If AssetCovar is a vector, a diagonal matrix is formed with the vector along the diagonal.

## Data Types: double

## NumScenarios - Number of scenarios to simulate

positive integer
Number of scenarios to simulate, specified as a positive integer.
Data Types: double

## NumAssets - Number of assets

scalar
Number of assets, specified as a scalar.
Data Types: double

## Output Arguments

## obj - Updated portfolio object

object for portfolio
Updated portfolio object, returned as a PortfolioCVaR or PortfolioMAD object. For more information on creating a portfolio object, see

- Using PortfolioCVaR Objects
- Using PortfolioMAD Objects

## More About

## Tips

You can also use dot notation to simulate multivariate normal asset return scenarios from a mean and covariance of asset returns for a PortfolioCVaR or PortfolioMAD object.
obj = obj.simulateNormalScenariosByMoments(AssetMean, AssetCovar, NumScenarios, NumAssets);

- CVaR Portfolio Optimization (5 min 33 sec )
- Analyzing Investment Strategies with CVaR Portfolio Optimization in MATLAB (50 min 42 sec )

rng | simulateNormalScenariosByData

Introduced in R2012b

## setfield

Set content of specific field

## Syntax

```
newfts = setfield(tsobj, field, V)
newfts = setfield(tsobj, field, {dates}, V)
```

## Description

setfield treats the contents of fields in a time series object ( tsobj ) as fields in a structure.
newfts = setfield(tsobj, field, $V$ ) sets the contents of the specified field to the value $V$. This is equivalent to the syntax S.field $=V$.
newfts = setfield(tsobj, field, \{dates\}, V) sets the contents of the specified field for the specified dates. dates can be individual cells of date strings or a cell of a date string range using the : : operator, for example, '03/01/99::03/31/99'. Dates can contain time-of-day information.

## Examples

Example 1. Set the closing value for all days to 3890.

```
load dji30short
format bank
myfts1 = setfield(myfts1, 'Close', 3890)
myfts1 =
    desc: DJI30MAR94.dat
    freq: Daily (1)
\begin{tabular}{|c|c|c|c|c|}
\hline s: (20)' & 'Open: (20) ' & 'High: (20) & 'Low: (20) \({ }^{\text {' }}\) & Close: (20)' \\
\hline '04-Mar-1994' & [ 3830.90] & \(3868.04]\) & \(3800.50]\) & \(3890.00]\) \\

| '31-Mar-1994' | [ | 3639.71 ] | [ | 3673.10 ] |  | $3544.12]$ | [ | $3890.00]$ |

Example 2. Set values for specific times on specific days.
First create a financial time series containing time-of-day data.

```
dates = ['01-Jan-2001';'01-Jan-2001'; '02-Jan-2001'; ...
    '02-Jan-2001'; '03-Jan-2001';'03-Jan-2001'];
times = ['11:00';'12:00';'11:00';'12:00';'11:00';'12:00'];
dates_times = cellstr([dates, repmat(' ',size(dates,1),1),...
    times]);
myfts = fints(dates_times,[(1:4)'; nan; 6],{'Data1'},1,\ldots.
    'My FINTS')
myfts =
    desc: My FINTS
    freq: Daily (1)
\begin{tabular}{|c|c|c|}
\hline dates: (6)' & 'times: (6)' & 'Data1: (6)' \\
\hline '01-Jan-2001' & '11:00' & \(1]\) \\
\hline & '12:00' & [ 2] \\
\hline '02-Jan-2001' & '11:00' & [ 3] \\
\hline & '12:00' & [ 4] \\
\hline '03-Jan-2001' & '11:00' & [ NaN ] \\
\hline & '12:00' & \(6]\) \\
\hline
\end{tabular}
```

Now use setfield to replace the data in myfts with new data starting at 12:00 on January 1, 2001 and ending at 11:00 on January 3, 2001.

```
S = setfield(myfts,'Data1',...
    {'01-Jan-2001 12:00::03-Jan-2001 11:00'},(102:105)')
S =
    desc: My FINTS
    freq: Daily (1)
```

| 'dates: (6)' | 'times: | $(6)^{\prime}$ | 'Data1: | (6) ${ }^{\prime}$ |
| :---: | :---: | :---: | :---: | :---: |
| '01-Jan-2001' | '11:00' |  | [ | $1.00]$ |
| ' " ' | '12:00' |  | 10 | 02.00] |
| '02-Jan-2001' | '11:00' |  | 10 | 03.00] |
| ' | '12:00' |  | 10 | 04.00] |
| '03-Jan-2001' | '11:00' |  | 10 | 05.00] |
| ' " ' | '12:00' |  | [ | $6.00]$ |

## More About

## sharpe

Compute Sharpe ratio for one or more assets

## Syntax

```
sharpe(Asset)
sharpe(Asset, Cash)
Ratio = sharpe(Asset, Cash)
```

## Arguments

| Asset | NUMSAMPLES-by-NUMSERIES matrix with NUMSAMPLES <br> observations of asset returns for NUMSERIES asset return <br> series. |
| :--- | :--- |
| Cash | (Optional) Either a scalar return for a riskless asset or a <br> vector of asset returns to be a proxy for a riskless asset. In <br> either case, the return periodicity must be the same as the <br> periodicity of Asset. For example, if Asset is monthly data, <br> then Cash must be monthly returns. If no value is supplied, <br> the default value for Cash returns is 0. |

## Description

Given NUMSERIES assets with NUMSAMPLES returns for each asset in a NUMSAMPLES-by-NUMSERIES matrix Asset and given either a scalar Cash asset return or a vector of Cash asset returns, the Sharpe ratio is computed for each asset.

The output is Ratio, a 1-by-NUMSERIES row vector of Sharpe ratios for each series in Asset. Any series in Asset with standard deviation of returns equal to 0 has a NaN value for its Sharpe ratio.

Note: If Cash is a vector, Asset and Cash need not have the same number of returns but must have the same periodicity of returns. The classic Sharpe ratio assumes that Cash
is riskless. In reality, a short-term cash rate is not necessarily riskless. NaN values in the data are ignored.

## Examples

See "Sharpe Ratio" on page 7-5.

Introduced in R2006b

## size

Number of dates and data series

## Syntax

```
szfts = size(tsobj, dim)
[numRows, numCols] = size(tsobj)
```

## Arguments

| tsobj | Financial time series object. |
| :--- | :--- |
| dim | (Optional) A scalar that specifies the following dimension: |
|  | dim $=1$ returns number of dates (rows). |
|  | dim $=2$ returns number of data series (columns). |

## Description

szfts = size(tsobj) returns the number of dates (rows) and the number of data series (columns) in the financial time series object tsobj. The result is returned in the vector szfts, whose first element is the number of dates and second is the number of data series.
szfts $=$ size(tsobj, dim) specifies the dimension you want to extract.
numRows returns a scalar representing the number of dates (rows).
numCols returns a scalar representing the number of data series (columns).

## See Also <br> length | size

## Related Examples

Introduced before R2006a

## smoothts

Smooth data

## Syntax

```
output = smoothts(input)
output = smoothts(input, 'b', wsize)
output = smoothts(input, 'g', wsize, stdev)
output = smoothts(input, 'e', n)
```

## Arguments

| input | Financial time series object or a row-oriented matrix. In a row-oriented matrix, each row represents an individual set of observations. |
| :---: | :---: |
| 'b', 'g', or 'e' | Smoothing method (essentially the type of filter used). Can be Exponential (e), Gaussian (g), or Box (b). Default = b. |
| wsize | Window size (scalar). Default = 5 . |
| stdev | Scalar that represents the standard deviation of the Gaussian window. Default $=0.65$. |
| n | For Exponential method, specifies window size or exponential factor, depending upon value. <br> - $\mathrm{n}>1$ (window size) or period length <br> - $\mathrm{n}<1$ and $>0$ (exponential factor: alpha) <br> - $\mathrm{n}=1$ (either window size or alpha) <br> If n is not supplied, the defaults are wsize = 5 and alpha $=$ 0.3333. |

## Description

smoothts smooths the input data using the specified method.
output $=$ smoothts(input) smooths the input data using the default Box method with window size, wsize, of 5 .
output = smoothts(input, 'b', wsize) smooths the input data using the Box (simple, linear) method. wsize specifies the width of the box to be used.
output = smoothts(input, 'g', wsize, stdev) smooths the input data using the Gaussian window method.
output $=$ smoothts(input, $\left.{ }^{\prime} e^{\prime}, n\right)$ smooths the input data using the Exponential method. n can represent the window size (period length) or alpha. If $\mathrm{n}>1, \mathrm{n}$ represents the window size. If $0<n<1$, $n$ represents alpha, where

$$
\alpha=\frac{2}{w s i z e+1}
$$

If input is a financial time series object, output is a financial time series object identical to input except for contents. If input is a row-oriented matrix, output is a row-oriented matrix of the same length.

## sorifts

Sort financial time series

## Syntax

```
sfts = sortfts(tsobj)
sfts = sortfts(tsobj, flag)
sfts = sortfts(tsobj, seriesnames, flag)
[sfts, sidx] = sortfts(...)
```

## Arguments

| tsobj | Financial time series object. |
| :--- | :--- |
| flag | (Optional) Sort order: <br> flag $=1 ;$ increasing order (default) <br> flag $=-1 ;$ decreasing order |
| seriesnames | (Optional) String containing a data series name or cell array <br> containing a list of data series names. |

## Description

sfts = sortfts(tsobj) sorts the financial time series object tsobj in increasing order based only upon the 'dates' vector if tsobj does not contain time-of-day information. If the object includes time-of-day information, the sort is based upon a combination of the 'dates' and 'times' vectors. The 'times' vector cannot be sorted individually.
sfts = sortfts(tsobj, flag) sets the order of the sort. flag = 1: increasing date and time order. flag $=-1$ : decreasing date and time order.
sfts $=$ sortfts(tsobj, seriesnames, flag) sorts the financial time series object tsobj based upon the data series name(s) seriesnames. The seriesnames argument can be a single string containing a data series name or a cell array containing a list of data series names. If the optional flag is set to -1 , the sort is in decreasing order.
[sfts, sidx] = sortfts(...) also returns the index of the original object tsobj sorted based on 'dates ' or specified data series name(s).

## spctkd

Slow stochastics

## Syntax

```
[spctk, spctd] = spctkd(fastpctk, fastpctd)
[spctk, spctd] = spctkd([fastpctk fastpctd])
[spctk, spctd] = spctkd(fastpctk, fastpctd, dperiods, dmamethod)
[spctk, spctd] = spctkd([fastpctk fastpctd], dperiods, dmamethod)
skdts = spctkd(tsobj)
skdts = spctkd(tsobj, dperiods, dmamethod)
skdts = spctkd(tsobj, dperiods, dmamethod, 'ParameterName',
ParameterValue, ...)
```

## Arguments

| fastpctk | Fast stochastic F\%K (vector). |
| :--- | :--- |
| fastpctd | Fast stochastic F\%D (vector). |
| dperiods | (Optional) \%D periods. Default = 3. |
| dmamethod | (Optional) \%D moving average method. Default = ' e' <br> (exponential). |
| tsobj | Financial time series object. |

## Description

[spctk, spctd] = spctkd(fastpctk, fastpctd) calculates the slow stochastics $\mathrm{S} \% \mathrm{~K}$ and $\mathrm{S} \% \mathrm{D}$. spctk and spctd are column vectors representing the respective slow stochastics. The inputs must be single column-oriented vectors containing the fast stochastics F\%K and F\%D.
[spctk, spctd] = spctkd([fastpctk fastpctd]) accepts a two-column matrix as input. The first column contains the fast stochastic F\%K values, and the second contains the fast stochastic F\%D values.
[spctk, spctd] = spctkd(fastpctk, fastpctd, dperiods, dmamethod) calculates the slow stochastics, $\mathrm{S} \% \mathrm{~K}$ and $\mathrm{S} \% \mathrm{D}$, using the value of dperiods to set the number of periods and dmamethod to indicate the moving average method. The inputs fastpctk and fastpctk must contain the fast stochastics, F\%K and F\%D, in column orientation. spctk and spctd are column vectors representing the respective slow stochastics.

Valid moving average methods for \%D are exponential ('e'), triangular ('t'), and modified ('m'). See tsmovavg for explanations of these methods.
[spctk, spctd] = spctkd([fastpctk fastpctd], dperiods, dmamethod) accepts a two-column matrix rather than two separate vectors. The first column contains the $\mathrm{F} \% \mathrm{~K}$ values, and the second contains the $\mathrm{F} \% \mathrm{D}$ values.
skdts = spctkd(tsobj) calculates the slow stochastics, $\mathrm{S} \% \mathrm{~K}$ and $\mathrm{S} \% \mathrm{D} . \mathrm{tsobj}$ must contain the fast stochastics, F\%K and F\%D, in data series named PercentK and PercentD. The skdts output is a financial time series object with the same dates as tsobj. Within tsobj the two series SlowPctK and SlowPctD represent the respective slow stochastics.
skdts = spctkd(tsobj, dperiods, dmamethod) lets you specify the length and the method of the moving average used to calculate $\mathrm{S} \% \mathrm{D}$ values.
skdts = spctkd(tsobj, dperiods, dmamethod, 'ParameterName', ParameterValue, ...) accepts parameter name/parameter value pairs as input. These pairs specify the name(s) for the required data series if it is different from the expected default name(s). Valid parameter names are

- KName: F\%K series name
- DName: F\%D series name

Parameter values are the strings that represent the valid parameter names.

## Examples

## Calculate the Slow Stochastics

This example shows how to calculate the slow stochastics for Disney stock and plot the results.

```
load disney.mat
dis_FastStoch = fpctkd(dis);
dis_SlowStoch = spctkd(dis_FastStoch);
plot(dis_SlowStoch)
title('Slow Stochastics for Disney')
```

## std

Standard deviation

## Syntax

```
tsstd = std(tsobj)
tsstd = std(tsobj, flag)
```

## Arguments

| tsobj | Financial time series object. |
| :--- | :--- |
| flag | (Optional) Normalization factor: |
|  | flag $=1$ normalizes by n (number of observations). |
|  | flag $=0$ normalizes by n-1. |

## Description

tsstd $=s t d(t s o b j)$ computes the standard deviation of each data series in the financial time series object tsobj and returns the results in tsstd. The tsstd output is a structure with field name(s) identical to the data series name(s).
tsstd = std(tsobj, flag) normalizes the data as indicated by flag.

## stochosc

Stochastic oscillator

## Syntax

```
stosc = stochosc(highp, lowp, closep)
stosc = stochosc([highp lowp closep])
stosc = stochosc(highp, lowp, closep, kperiods, dperiods, dmamethod)
stosc = stochosc([highp lowp closep], kperiods, dperiods, dmamethod)
stoscts = stochosc(tsobj, kperiods, dperiods, dmamethod)
stoscts = stochosc(tsobj, kperiods, dperiods, dmamethod,
'ParameterName', ParameterValue, ...)
```

## Arguments

| highp | High price (vector). |
| :--- | :--- |
| lowp | Low price (vector). |
| closep | Closing price (vector). |
| kperiods | (Optional) \%K periods. Default $=10$. |
| dperiods | (Optional) \%D periods. Default = 3. |
| damethod | (Optional) \%D moving average method. Default $=$ ' ${ }^{\prime}$ ' <br> (exponential). |
| tsobj | Financial time series object. |

## Description

stosc = stochosc(highp, lowp, closep) calculates the fast stochastics F\%K and F\%D from the stock price data highp (high prices), lowp (low prices), and closep (closing prices). stosc is a two-column matrix whose first column is the $\mathrm{F} \% \mathrm{~K}$ values and second is the $\mathrm{F} \% \mathrm{D}$ values.
stosc $=$ stochosc([highp lowp closep]) accepts a three-column matrix of high (highp), low (lowp), and closing prices (closep), in that order.
stosc $=$ stochosc(highp, lowp, closep, kperiods, dperiods, dmamethod) calculates the fast stochastics F\%K and F\%D from the stock price data highp (high prices), lowp (low prices), and closep (closing prices). kperiods sets the $\% \mathrm{~K}$ period. dperiods sets the \%D period. damethod specifies the \%D moving average method. Valid moving average methods for $\% \mathrm{D}$ are exponential ('e') and triangular ('t'). See tsmovavg for explanations of these methods.
stosc= stochosc([highp lowp closep], kperiods, dperiods, dmamethod) accepts a three-column matrix of high (highp), low (lowp), and closing prices (closep), in that order.
stoscts = stochosc(tsobj, kperiods, dperiods, dmamethod) calculates the fast stochastics F\%K and F\%D from the stock price data in the financial time series object tsobj. tsobj must minimally contain the series High (high prices), Low (low prices), and Close (closing prices). stoscts is a financial time series object with similar dates to tsobj and two data series named SOK and SOD.
stoscts = stochosc(tsobj, kperiods, dperiods, dmamethod, 'ParameterName', ParameterValue, ...) accepts parameter name/parameter value pairs as input. These pairs specify the name(s) for the required data series if it is different from the expected default name(s). Valid parameter names are

- HighName: high prices series name
- LowName: low prices series name
- CloseName: closing prices series name

Parameter values are the strings that represent the valid parameter names.

## Examples

## Compute the Stochastic Oscillator

This example shows how to compute the stochastic oscillator for Disney stock and plot the results.
load disney.mat
dis_StochOsc = stochosc(dis);
plot(dis_StochOsc)

## subsasgn

Content assignment

## Syntax

subasgn

## Description

subasgn assigns content to a component within a financial time series object. subasgn supports integer indexing or date string indexing into the time series object with values assigned to the designated components. Serial date numbers cannot be used as indices. To use date string indexing, enclose the date string(s) in a pair of single quotation marks ' '.

You can use integer indexing on the object as in any other MATLAB matrix. It will return the appropriate entry(ies) from the object.

You must specify the component to which you want to assign values. An assigned value must be either a scalar or a column vector.

## Examples

Given a time series myfts with a default data series name of series1, myfts.series1('07/01/98::07/03/98') = [1 2 3]';
assigns the values 1, 2, and 3 corresponding to the first three days of July, 1998.

```
myfts('07/01/98::07/05/98')
```

ans =
desc: Data Assignment
freq: Daily (1)
'dates: (5)' 'series1:
(5)

| '01-Jul-1998' | $[$ | $1]$ |
| :---: | :---: | ---: |
| '02-Jul-1998' | $[$ | $2]$ |
| '03-Jul-1998' | $[$ | $3]$ |
| '04-Jul-1998' | $[$ | $4561.2]$ |
| '05-Jul-1998' | $[$ | $5612.3]$ |

When the financial time series object contains a time-of-day specification, you can assign data to a specific time on a specific day. For example, create a financial time series object called timeday containing both dates and times:

```
dates = ['01-Jan-2001';'01-Jan-2001'; '02-Jan-2001'; ...
'02-Jan-2001'; '03-Jan-2001';'03-Jan-2001'];
times = ['11:00';'12:00';'11:00';'12:00';'11:00';'12:00'];
dates_times = cellstr([dates, repmat(' ',size(dates,1),1),...
times]);
timeday = fints(dates_times,(1:6)',{'Data1'},1,'My first FINTS')
timeday =
    desc: My first FINTS
    freq: Daily (1)
\begin{tabular}{|c|c|c|c|}
\hline dates: (6)' & 'times: & (6) ' & 'Data1: (6) \\
\hline 01-Jan-2001' & '11:00' & & [ 1] \\
\hline " ' & '12:00' & & [ 2] \\
\hline 02-Jan-2001' & '11:00' & & [ 3] \\
\hline " ' & '12:00' & & \(4]\) \\
\hline '03-Jan-2001' & '11:00' & & [ 5] \\
\hline & '12:00' & & 6] \\
\hline
\end{tabular}
```

Use integer indexing to assign the value 999 to the first item in the object.

```
timeday(1) = 999
```

timeday $=$
desc: My first FINTS
freq: Daily (1)

| dates: (6)' | 'times: | (6) ${ }^{\prime}$ | 'Data1: (6) |
| :---: | :---: | :---: | :---: |
| 01-Jan-2001' | '11:00' |  | [ 999] |
| " ' | '12:00' |  | [ 2] |
| '02-Jan-2001' | '11:00' |  | [ 3] |
| " ' | '12:00' |  | 4] |
| 03-Jan-2001 ${ }^{\prime}$ | '11:00' |  | 5] |
|  | '12:00' |  | [ 6] |

For value assignment using date strings, enclose the string in single quotation marks. If a date has multiple times, designating only the date and assigning a value results in every element of that date taking on the assigned value. For example, to assign the value 0.5 to all times-of-day on January 1, 2001, enter

```
timedata('01-Jan-2001') = 0.5
```

The result is

```
timedata =
    desc: My first FINTS
    freq: Daily (1)
\begin{tabular}{|c|c|c|c|}
\hline dates: (6) & 'times: & (6) \({ }^{\prime}\) & 'Data1: (6)' \\
\hline 01-Jan-2001 & '11:00' & & \(0.5000]\) \\
\hline & '12:00' & & [ 0.5000] \\
\hline '02-Jan-2001 & '11:00' & & [ 3] \\
\hline " & '12:00' & & 4] \\
\hline '03-Jan-2001 & '11:00' & & [ 5] \\
\hline & '12:00' & & 6] \\
\hline
\end{tabular}
```

To access the individual components of the financial time series object, use the structure syntax. For example, to assign a range of data to all the data items in the series Data1, you can use

```
timedata.Data1 = (0: .1 : .5)'
timedata =
    desc: My first FINTS
    freq: Daily (1)
```

## See Also <br> datestr | subsref

18 Functions - Alphabetical List

Introduced before R2006a

## subsref

Subscripted reference

## Syntax

subref

## Description

subsref implements indexing for a financial time series object. Integer indexing or date (and time) string indexing is allowed. Serial date numbers cannot be used as indices.

To use date string indexing, enclose the date string(s) in a pair of single quotation marks ${ }^{\prime}{ }^{\prime}$

You can use integer indexing on the object as in any other MATLAB matrix. It returns the appropriate entry(ies) from the object.

Additionally, subsref lets you access the individual components of the object using the structure syntax.

## Examples

Create a time series named myfts:

```
myfts = fints((datenum('07/01/98'):datenum('07/01/98')+4)',...
[1234.56; 2345.61; 3456.12; 4561.23; 5612.34], [], 'Daily',...
'Data Reference');
```

Extract the data for the single day July 1, 1998:

```
myfts('07/01/98')
```

```
ans =
```

    desc: Data Reference
    freq: Daily (1)
    ```
'dates: (1)' 'series1: (1)'
'01-Jul-1998' [ 1234.6]
```

Now, extract the data for the range of dates July 1, 1998, through July 5, 1998:

```
myfts('07/01/98::07/03/98')
ans =
    desc: Data Reference
    freq: Daily (1)
    'dates: (3)' 'series1: (3)
    '01-Jul-1998' [ 1234.6]
    '02-Jul-1998' [ 2345.6]
    '03-Jul-1998' [ 3456.1]
```

You can use the MATLAB structure syntax to access the individual components of a financial time series object. To get the description field of myfts, enter

```
myfts.desc
```

at the command line, which returns

```
ans =
Data Reference
```

Similarly
myfts.series1
returns
ans =
desc: Data Reference
freq: Daily (1)
'dates: (5)' 'series1: (5)'
'01-Jul-1998' [ 1234.6]
'02-Jul-1998' [ 2345.6]
'03-Jul-1998' [ 3456.1]
'04-Jul-1998' [ 4561.2]
'05-Jul-1998' [ 5612.3]

The syntax for integer indexing is the same as for any other MATLAB matrix. Create a new financial time series object containing both dates and times:

```
dates = ['01-Jan-2001';'01-Jan-2001'; '02-Jan-2001'; ...
```

```
    02-Jan-2001'; '03-Jan-2001';'03-Jan-2001'];
times = ['11:00';'12:00';'11:00';'12:00';'11:00';'12:00'];
dates_times = cellstr([dates, repmat(' ',size(dates,1),1),\ldots
    times]);
anewfts = fints(dates_times,(1:6)',{'Data1'},1,'Another FinTs');
```

Use integer indexing to extract the second and third data items from the object.

```
anewfts(2:3)
ans =
    desc: Another FinTs
    freq: Daily (1)
    'dates: (2)' 'times: (2)' 'Data1: (2)
    '01-Jan-2001' '12:00' [ 2]
    '02-Jan-2001' '11:00' [ 3]
```

For date or string enclose the indexing string in a pair of single quotation marks.
If there is one date with multiple times, indexing with only the date returns all the times for that specific date:

```
anewfts('01-Jan-2001')
ans =
    desc: Another FinTs
    freq: Daily (1)
    'dates: (2)' 'times: (2)' 'Data1: (2)
    '01-Jan-2001', '11:00' [12.00' [ [ [ ]
```

To specify one specific date and time, index with that date and time:

```
anewfts('01-Jan-2001 12:00')
ans =
    desc: Another FinTs
    freq: Daily (1)
    'dates: (1)' 'times: (1)' 'Data1: (1)
    '01-Jan-2001' '12:00' [ 2]
```

To specify a range of dates and times, use the double colon (: :) operator:

```
anewfts('01-Jan-2001 12:00::03-Jan-2001 11:00')
ans =
    desc: Another FinTs
    freq: Daily (1)
\begin{tabular}{llll} 
'dates: (4)' & 'times: & \((4)^{\prime}\) & \\
'01-Jan-2001' & \(' 12: 00 '\) & & [
\end{tabular}
```

To request all the dates, times, and data, use the : : operator without specifying any specific date or time:
anewfts('::')

## targetreturn

Portfolio weight accuracy

## Syntax

return $=$ targetreturn(Universe, Window, Offset, Weights)

## Arguments

| Universe | Number of observations (NUMOBS) by number of assets plus one <br> (NASSETS + 1) array containing total return data for a group of <br> securities. Each row represents an observation. Column 1 contains <br> MATLAB serial date numbers. The remaining columns contain the <br> total return data for each security. |
| :--- | :--- |
| Window | Number of data periods used to calculate frontier. |
| Offset | Increment in number of periods at which each frontier is generated. |
| Weights | Number of assets (NASSETS) by number of curves (NCURVES) matrix <br> of asset allocation weights needed to obtain the target rate of <br> return. |

## Description

return = targetreturn(Universe, Window, Offset, Weights) computes target return values for each window of data and given portfolio weights. These values should match the input target return used with selectreturn.

## taxedrr

After-tax rate of return

## Syntax

Return = taxedrr(PreTaxReturn, TaxRate)

## Arguments

| PreTaxReturn | Nominal rate of return. Enter as a decimal fraction. |
| :--- | :--- |
| TaxRate | Tax rate. Enter as a decimal fraction. |

## Description

Return = taxedrr(PreTaxReturn, TaxRate) calculates the after-tax rate of return.

## Examples

## Calculate the After-Tax Rate of Return

This example shows how to calculate the after-tax rate of return, given an investment that has a $12 \%$ nominal rate of return and is taxed at a $30 \%$ rate.

```
Return = taxedrr(0.12, 0.30)
```

Return =
0.0840

## tbilldisc2yield

Convert Treasury bill discount to equivalent yield

## Syntax

[BEYield MMYield] = tbilldisc2yield(Discount, Settle, Maturity)

## Arguments

| Discount | Discount rate of Treasury bills in decimal. The discount rate basis is <br> actual/360. |
| :--- | :--- |
| Settle | Settlement date. Settle must be earlier than Maturity. |
| Maturity | Maturity date. |

Inputs must either be a scalar or a vector of size equal to the number of Treasury bills (NTBILLS) by 1 or 1 -by-NTBILLS.

## Description

[BEYield MMYield] = tbilldisc2yield(Yield, Settle, Maturity) converts the discount rate on Treasury bills into their respective money-market or bondequivalent yields.

BEYield is an NTBILLS-by- 1 vector of bond-equivalent yields. The bond-equivalent yield basis is actual/365.

MMYield is an NTBILLS-by-1 vector of money-market yields. The money-market yield basis is actual/360.

## Examples

## Convert the Discount Rate on Treasury Bills

This example shows how to convert the discount rate on Treasury bills into their respective money-market or bond-equivalent yields, given a Treasury bill with the following characteristics.

```
Discount = 0.0497;
Settle = '01-Oct-02';
Maturity = '31-Mar-03';
[BEYield MMYield] = tbilldisc2yield(Discount, Settle, Maturity)
```

BEYield =
0.0517
MMYield =
0.0510

## tbillprice

Price Treasury bill

## Syntax

```
Price = tbillprice(Rate, Settle, Maturity, Type)
```

## Arguments

| Rate | Bond-equivalent yield, money-market yield, or discount rate in <br> decimal. |
| :--- | :--- |
| Settle | Settlement date. Settle must be earlier than Maturity. |
| Maturity | Maturity date. |
| Type | (Optional) Rate type. Determines how to interpret values entered in <br> Rate. 1 = money market (default). $2=$ bond-equivalent. 3 = discount <br> rate. |

All arguments must be a scalar or some Treasury bills (NTBILLS-by-1) or (1-by-NTBILLS) vector.

Note The bond-equivalent yield basis is actual/365. The money-market yield basis is actual $/ 360$. The discount rate basis is actual $/ 360$.

## Description

Price = tbillprice(Rate, Settle, Maturity, Type) computes the price of a Treasury bill given a yield or discount rate.

Price is an NTBILLS-by-1 vector of T-bill prices for every $\$ 100$ face.

## Examples

Example 1. Given a Treasury bill with these characteristics, compute the price of the Treasury bill using the bond-equivalent yield as input.

```
Rate = 0.045;
Settle = '01-Oct-02';
Maturity = '31-Mar-03';
Type = 2;
Price = tbillprice(Rate, Settle, Maturity, Type)
Price =
```

    97.8172
    Example 2. Use tbillprice to price a portfolio of Treasury bills.
Rate $=$ [0.045; 0.046];
Settle = \{'02-Jan-02'; '01-Mar-02'\};
Maturity = \{'30-June-02'; '30-June-02'\};
Type = [2 3];
Price = tbillprice(Rate, Settle, Maturity, Type)
Price =
97.8408
98.4539

## tbillrepo

Break-even discount of repurchase agreement

## Syntax

TBEDiscount = tbillrepo(RepoRate, InitialDiscount, PurchaseDate, SaleDate, Maturity)

## Arguments

| RepoRate | The annualized, 360-day based repurchase rate, in decimal. |
| :--- | :--- |
| InitialDiscount | Discount on the Treasury bill on the day of purchase, in <br> decimal. |
| PurchaseDate | Date the Treasury bill is purchased. |
| SaleDate | Date the Treasury bill repurchase term is due. |
| Maturity | Treasury bill maturity date. |

All arguments must be a scalar or some Treasury bills (NTBILLS-by-1) or a (1-by-NTBILLS) vector.

All dates must be in serial date number format.

## Description

TBEDiscount = tbillrepo(RepoRate, InitialDiscount, PurchaseDate, SaleDate, Maturity) computes the true break-even discount of a repurchase agreement. TBEDiscount can be a scalar or vector of size NTBills-by-1.

## Examples

## Compute the True Break-Even Discount

This example shows how to compute the true break-even discount of a Treasury bill repurchase agreement.

```
RepoRate = [0.045; 0.0475];
InitialDiscount = 0.0475;
PurchaseDate = '3-Jan-2002';
SaleDate = '3-Feb-2002';
Maturity = '3-Apr-2002';
TBEDiscount = tbillrepo(RepoRate, InitialDiscount,...
PurchaseDate, SaleDate, Maturity)
TBEDiscount =
    0.0491
    0.0478
```

Introduced before R2006a

## tbillval01

Value of one basis point

## Syntax

[Val01Disc, Val01mMY, Val01BEY] = tbillval01(Settle, Maturity)

## Arguments

| Settle | Settlement date of Treasury bills. Settle must be earlier than <br> Maturity. |
| :--- | :--- |
| Maturity | Maturity date of Treasury bills. |

## Description

[Val01Disc, Val01MMY, Val01BEY] = tbillval01(Settle, Maturity) calculates the value of one basis point of $\$ 100$ Treasury bill face value on the discount rate, money-market yield, or bond-equivalent yield.

Val01Disc is the value of one basis point of discount rate.
Val01MMY is the value of one basis point of money-market yield.
Val01BEY is the value of one basis point of bond-equivalent yield.
All outputs are of size equal to the number of Treasury bills (NTBILLS) by 1.

## Examples

## Compute the Value of One Basis Point

This example shows how to compute the value of one basis point, given a Treasury bill with the following settle and maturity dates.

```
Settle = '01-Mar-03';
Maturity = '30-June-03';
[Val01Disc, Val01MMY, Val01BEY] = tbillvalO1(Settle, Maturity)
Val01Disc =
    0.0034
Val01MMY =
    0.0034
Val01BEY =
    0.0033
```

- "Treasury Bills Defined" on page 2-34

## References

This function adheres to SIA Fixed Income Securities Formulas for Price, Yield, and Accrued Interest, Volume 1, 3rd edition, pp 108-115, on zero coupon instrument pricing.

## See Also <br> tbilldisc2yield | tbillprice | tbillyield | tbillyield2disc

Introduced before R2006a

## tbillyield

Yield on Treasury bill

## Syntax

[MMYield, BEYield, Discount] = tbillyield(Price, Settle, Maturity)

## Arguments

| Price | Price of Treasury bills for every $\$ 100$ face value. |
| :--- | :--- |
| Settle | Settlement date. Settle must be earlier than Maturity. |
| Maturity | Maturity date. |

All arguments must be a scalar or some Treasury bills (NTBILLS-by-1) or (1-by-NTBILLS) vector.

## Description

[MMYield, BEYield, Discount] = tbillyield(Price, Settle, Maturity) computes the yield of U.S. Treasury bills given Price, Settle, and Maturity. MMYield is the money-market yields of the Treasury bills. BEYield is the bond equivalent yields of the Treasury bills. Discount is the discount rates of the Treasury bills.

All outputs are NTBILLS-by-1 vectors.

Note The money-market yield basis is actual/360. The bond-equivalent yield basis is actual/365. The discount rate basis is actual/360.

## Examples

## Compute the Yield of U.S. Treasury Bills

This example shows how to compute the yield of U.S. Treasury bills, given a Treasury bill with the following characteristics.

```
Price = 98.75;
Settle = '01-0ct-02';
Maturity = '31-Mar-03';
[MMYield, BEYield, Discount] = tbillyield(Price, Settle,...
Maturity)
MMYield =
    0.0252
BEYield =
    0.0255
Discount =
    0.0249
- "Computing Treasury Bill Price and Yield" on page 2-35
```

## More About

- "Treasury Bills Defined" on page 2-34

## References

This function adheres to SIA Fixed Income Securities Formulas for Price, Yield, and Accrued Interest, Volume 1, 3rd edition, pp. 44-45 (on Treasury bills), and Money Market and Bond Calculation by Stigum and Robinson.

See Also<br>tbilldisc2yield | tbillprice | tbillyield2disc | zeroyield<br>Introduced before R2006a

## tbillyield2disc

Convert Treasury bill yield to equivalent discount

## Syntax

Discount = tbillyield2disc(Yield, Settle, Maturity, Type)

## Arguments

| Yield | Yield of Treasury bills in decimal. |
| :--- | :--- |
| Settle | Settlement date. Settle must be earlier than Maturity. |
| Maturity | Maturity date. |
| Type | (Optional) Yield type. Determines how to interpret values entered in <br> Yield. 1 = money market (default). 2 = bond-equivalent. |

Inputs must either be a scalar or a vector of size equal to the number of Treasury bills (NTBILLS-by-1) or (1-by-NTBILLS).

Note The money-market yield basis is actual/360. The bond-equivalent yield basis is actual $/ 365$. The discount rate basis is actual/360.

## Description

Discount = tbillyield2disc(Yield, Settle, Maturity, Type) converts the yield on some Treasury bills into their respective discount rates.

Discount is a NTBILLS-by-1 vector of T-bill discount rates.

## Examples

Given a Treasury bill with these characteristics, compute the discount rate on a moneymarket basis.

```
Yield = 0.0497;
Settle = '01-0ct-02';
Maturity = '31-Mar-03';
Discount = tbillyield2disc(Yield, Settle, Maturity)
Discount =
    0.0485
```

Now recompute the discount on a bond-equivalent basis.
Discount = tbillyield2disc(Yield, Settle, Maturity, 2)
Discount =
0.0478

tbilldisc2yield

Introduced before R2006a

## tbl2bond

Treasury bond parameters given Treasury bill parameters

## Syntax

[TBondMatrix, Settle] = tbl2bond(TBillMatrix)

## Arguments

| TBillMatrix | Treasury bill parameters. An n-by-5 matrix <br> where each row describes a Treasury bill. n <br> is the number of Treasury bills. Columns are <br> [Maturity DaysMaturity Bid Asked AskYield] where: |
| :--- | :--- |
| Maturity | Maturity date, as a serial date number. Use datenum to convert <br> date strings to serial date numbers. |
| DaysMaturity | Days to maturity, as an integer. Days to maturity is quoted on <br> a skip-day basis; the actual number of days from settlement to <br> maturity is DaysMaturity + 1. |
| Bid | Bid bank-discount rate: the percentage discount from face value <br> at which the bill could be bought, annualized on a simple-interest <br> basis. A decimal fraction. |
| Asked | Asked bank-discount rate, as a decimal fraction. <br> AskYieldAsked yield: the bond-equivalent yield from holding the bill to <br> maturity, annualized on a simple-interest basis and assuming a <br> $365-$ day year. A decimal fraction. |

## Description

[TBondMatrix, Settle] = tbl2bond(TBillMatrix) restates U.S. Treasury bill market parameters in U.S. Treasury bond form as zero-coupon bonds. This function makes Treasury bills directly comparable to Treasury bonds and notes.

| TBondMatrix | Treasury bond parameters. An N-by-5 matrix where each row <br> describes an equivalent Treasury (zero-coupon) bond. Columns are <br> [CouponRate Maturity Bid Asked AskYield] where |
| :--- | :--- |
| CouponRate | Coupon rate, which is always 0. |
| Maturity | Maturity date, as a serial date number. This date is the same as the <br> Treasury bill Maturity date. |
| Bid | Bid price based on $\$ 100$ face value. |
| Asked | Asked price based on $\$ 100$ face value. |
| AskYield | Asked yield to maturity: the effective return from holding the bond <br> to maturity, annualized on a compound-interest basis. |

## Examples

## Restate U.S. Treasury Bill in U.S. Treasury Bond Form

This example shows how to restate U.S. Treasury bill market parameters in U.S.
Treasury bond form, given published Treasury bill market parameters for December 22, 1997.

```
TBill = [datenum('jan 02 1998') 10 0.0526 0.0522 0.0530
    datenum('feb 05 1998') 44 0.0537}00.0533 0.054
    datenum('mar 05 1998') 72 0.0529 0.0527 0.0540];
```

TBond $=$ tbl2bond(TBill)

TBond =
$1.0 \mathrm{e}+05$ *

# thirdwednesday 

Find third Wednesday of month

## Syntax

[BeginDates, EndDates] = thirdwednesday(Month, Year)

## Arguments

| Month | Month of delivery for Eurodollar futures. |
| :--- | :--- |
| Year | Four-digit year of delivery for Eurodollar futures, in sequence <br> corresponding to a month in the Month input argument. |

Inputs can be scalars or $n$-by- 1 vectors.

## Description

[BeginDates, EndDates] = thirdwednesday(Month, Year) computes the beginning and end period date for a LIBOR contract (third Wednesdays of delivery months).

BeginDates is the beginning of three-month period contract as specified by Month and Year.

EndDates is the end of three-month period contract as specified by Month and Year.

## Notes

- All dates are returned as serial date numbers. Convert to strings using datestr.
- The function returns duplicates if you supply identical months and years.
- The function supports dates from January 2000 to December 2099.

## Examples

Find the third Wednesday dates for swaps commencing in the month of October in the years 2002, 2003, and 2004.

```
Months = [10; 10; 10];
Year = [2002; 2003; 2004];
[BeginDates, EndDates] = thirdwednesday(Months, Year);
datestr(BeginDates)
ans =
16-0ct-2002
15-0ct-2003
20-0ct-2004
datestr(EndDates)
ans =
16-Jan-2003
15-Jan-2004
20-Jan-2005
```

## thirtytwo2dec

Thirty-second quotation to decimal

## Syntax

```
OutNumber = thirtytwo2dec(InNumber, InFraction)
```

## Arguments

| InNumber | Scalar or vector of input numbers without fractional component. |
| :--- | :--- |
| InFraction | Scalar or vector of fractional portions of each element in InNumber. |

## Description

OutNumber = thirtytwo2dec(InNumber, InFraction) changes the price quotation for a bond or bond future from a fraction with a denominator of 32 to a decimal.

OutNumber represents the sum of InNumber and InFraction expressed as a decimal.

## Examples

## Change the Price Quotation for a Bond or Bond Future From a Fraction

This example shows how to change the price quotation for a bond or bond future from a fraction with a denominator of 32 to a decimal, given two bonds that are quoted as 101-25 and 102-31.

```
InNumber = [101; 102];
InFraction = [25; 31];
OutNumber = thirtytwo2dec(InNumber, InFraction)
OutNumber =
```

101.7813

## tick2ret

Convert price series to return series

## Syntax

[RetSeries, RetIntervals] = tick2ret(TickSeries, TickTimes, Method)

## Arguments

| TickSeries | Number of observations (NUMOBS) by number of assets (NASSETS) <br> matrix of prices of equity assets. Each column is a price series of an <br> individual asset. First row is oldest observation. Last row is most <br> recent. Observations across a given row occur at the same time for <br> all columns. |
| :--- | :--- |
| TickTimes | (Optional) NUMOBS-by-1 increasing vector of observation times <br> associated with the prices in TickSeries. Times are serial date <br> numbers (day units) or decimal numbers in arbitrary units (for <br> example, yearly). If TickTimes is empty or missing, sequential <br> observation times from 1, 2, ... NUMOBS are assumed. |
| Method | (Optional) Character string indicating the method to convert prices <br> to asset returns. Must be 'Simple ' (default) or 'Continuous '. <br> If Method is 'Simple ', tick2ret computes simple periodic <br> returns. If Method is 'Continuous', returns are continuously <br> compounded. Case is ignored for Method. |

## Description

[RetSeries, RetIntervals] = tick2ret(TickSeries, TickTimes, Method) computes the asset returns realized between NUMOBS observations of prices of NASSETS assets.

RetSeries is a (NUMOBS-1)-by-NASSETS time series array of asset returns associated with the prices in TickSeries. The $i$ th return is quoted for the period TickTimes(i) to

TickTimes (i+1) and is not normalized by the time increment between successive price observations. If Method is unspecified or 'Simple ', the returns are:

RetSeries(i) $=$ TickSeries(i+1)/TickSeries(i) - 1
If Method is 'Continuous ', the returns are:
RetSeries(i) $=\log [$ TickSeries(i+1)/TickSeries(i)]
RetIntervals is a (NUMOBS-1)-by-1 column vector of interval times between observations. If TickTimes is empty or unspecified, all intervals are assumed to have length 1.

## Examples

## Convert Price Series to Return Series

This example shows how to convert price series to return series, given periodic returns of two stocks observed in the first, second, third, and fourth quarters.

```
TickSeries = [100 80
    110 90
    11588
    110 91];
```

TickTimes $=[0$
6
9
12];
[RetSeries, RetIntervals] = tick2ret(TickSeries, TickTimes)
RetSeries =
$0.1000 \quad 0.1250$
$0.0455-0.0222$
$-0.0435 \quad 0.0341$
RetIntervals =
6

- "Data Transformation and Frequency Conversion" on page 12-17

## tick2ret (fts)

Convert price series to return series for time series object

## Syntax

```
returnFts = tick2ret(priceFts)
returnFts = tick2ret(priceFts, 'PARAM1', VALUE1,
'PARAM2', VALUE2', ...)
```

## Arguments

| priceFts | Financial time series object of prices. |
| :--- | :--- |
| 'PARAM1' | (Optional) Method is a character string indicating the <br> method to convert asset returns to prices. The value must be <br> defined as 'Simple ' (default) or 'Continuous '. If Method <br> is 'Simple' ', tick2ret uses simple periodic returns. If <br> Method is 'Continuous ' the function uses continuously <br> compounded returns. Case is ignored for Method. |

## Description

```
returnFts = tick2ret(priceFts, 'PARAM1', VALUE1, 'PARAM2',
```

VALUE2', ...) generates a financial time series object of returns.

Note: The $i$ 'th return is quoted for the period PriceSeries $(i)$ to PriceSeries $(i+1)$ and is not normalized by the time increment between successive price observations.

If Method is unspecified or 'Simple ', the prices are
ReturnSeries(i) = PriceSeries(i+1)/PriceSeries(i)-1
If Method is 'Continuous ', the prices are

```
ReturnSeries(i) = log[PriceSeries(i+1)/PriceSeries(i)]
```

## Examples

## Convert Price Series to Return Series for a fints Object

Compute the return series from the following price series:

```
PriceSeries = [100.0000 100.0000
110.0000 112.0000
115.5000 116.4800
109.7250 122.3040]
PriceSeries =
    100.0000 100.0000
    110.0000 112.0000
    115.5000 116.4800
    109.7250 122.3040
```

Use the following dates:

```
Dates = {'18-Dec-2000'
'18-Jun-2001'
'17-Sep-2001'
'18-Dec-2001'}
Dates =
    '18-Dec-2000'
    '18-Jun-2001'
    '17-Sep-2001'
    '18-Dec-2001'
```

The fints object is:

```
p = fints(Dates, PriceSeries)
p =
```

```
desc: (none)
freq: Unknown (0)
\begin{tabular}{|c|c|c|}
\hline es: (4)' & 'series1: (4) & series2: (4) \\
\hline '18-Dec-2000' & [ 100] & 100] \\
\hline '18-Jun-2001' & [ 110] & [ 112] \\
\hline '17-Sep-2001' & \(115.5000]\) & [ 116.4800] \\
\hline '18-Dec-2001' & 109.7250] & 122.3040 ] \\
\hline
\end{tabular}
returnFts is computed as:
    tick2ret(p)
ans =
    desc: (none)
    freq: Unknown (0)
    'dates: (3)' 'series1: (3)' 'series2: (3)
    '18-Jun-2001' [ 0.1000] [ 0.1200]
    17-Sep-2001' [ 0.0500] [ 0.0400]
    18-Dec-2001' [ -0.0500] [ 0.0500]
```

Note that for n dates in the original time series, there are ( $\mathrm{n}-1$ ) dates returned for returnFts from tick2ret. The formula for the date output dates is described as: RetDate(i) $=$ PriceDate (i+1).

## Introduced before R2006a

## time2date

Dates from time and frequency

## Syntax

Dates = time2date(Settle, TFactors, Compounding, Basis, EndMonthRule)

## Arguments

| Settle | Settlement date. A vector of serial date numbers or date strings. |
| :---: | :---: |
| TFactors | A vector of time factors corresponding to the compounding value. TFactors must be equal to or greater than zero. |
| Compounding | (Optional) Scalar value representing the rate at which the input zero rates were compounded when annualized. Default $=2$. This argument determines the formula for the discount factors: <br> Compounding $=1,2,3,4,6,12$ <br> Disc $=(1+Z / F)^{\wedge}(-T)$, where $F$ is the compounding frequency, $Z$ is the zero rate, and $T$ is the time in periodic units; for example, $T=F$ is one year. <br> Compounding $=365$ <br> Disc $=(1+Z / F)^{\wedge}(-T)$, where $F$ is the number of days in the basis year and $T$ is a number of days elapsed computed by basis. <br> Compounding $=-1$ <br> Disc $=\exp (-T * Z)$, where $T$ is time in years. |
| Basis | (Optional) Day-count basis of the instrument. A vector of integers. |

|  | - $0=$ actual/actual (default) <br> - $1=30 / 360$ (SIA) <br> - 2 = actual/360 <br> - 3 = actual $/ 365$ <br> - $4=30 / 360$ (BMA) <br> - $5=30 / 360$ (ISDA) <br> - $6=30 / 360$ (European) <br> - $7=$ actual/365 (Japanese) <br> - $8=$ actual/actual (ICMA) <br> - $9=$ actual/360 (ICMA) <br> - 10 = actual/365 (ICMA) <br> - $11=30 / 360 \mathrm{E}$ (ICMA) <br> - 12 = actual/365 (ISDA) <br> - 13 = BUS/252 <br> For more information, see basis. |
| :---: | :---: |
| EndMonthRule | (Optional) End-of-month rule. A vector. This rule applies only when Maturity is an end-of-month date for a month having 30 or fewer days. $0=$ ignore rule, meaning that a bond's coupon payment date is always the same numerical day of the month. $1=$ set rule on (default), meaning that a bond's coupon payment date is always the last actual day of the month. |

## Description

Dates = time2date(Settle, TFactors, Compounding, Basis, EndMonthRule) computes dates corresponding to the times occurring beyond the settlement date.

The time2date function is the inverse of date2time.

## Examples

Show that date2time and time2date are the inverse of each other. First compute the time factors using date2time.

```
Settle = '1-Sep-2002';
Dates = datenum(['31-Aug-2005'; '28-Feb-2006'; '15-Jun-2006';
Compounding = 2;
Basis = 0;
EndMonthRule = 1;
TFactors = date2time(Settle, Dates, Compounding, Basis,...
    EndMonthRule)
TFactors =
    5.9945
    6.9945
    7.5738
    8.6576
```

Now use the calculated TFactors in time2date and compare the calculated dates with the original set.

```
Dates_calc = time2date(Settle, TFactors, Compounding, Basis,...
                                    EndMonthRule)
Dates_calc =
    7 3 2 5 5 5
    7 3 2 7 3 6
    7 3 2 8 4 3
    733042
datestr(Dates_calc)
ans =
31-Aug-2005
28-Feb-2006
15-Jun-2006
31-Dec-2006
```

```
See Also
cftimes | date2time
```

Introduced before R2006a

## times

## Financial time series multiplication

## Syntax

```
newfts = tsobj_1 .* tsobj_2
newfts = tsobj .* array
newfts = array .* tsobj
```

## Arguments

| tsobj_1, tsobj_2 | Pair of financial time series objects. |
| :--- | :--- |
| array | A scalar value or array with the number of rows equal to the <br> number of dates in tsobj and the number of columns equal <br> to the number of data series in tsobj. |

## Description

The times method multiplies element by element the components of one financial time series object by the components of the other. You can also multiply the entire object by an array.

If an object is to be multiplied by another object, both objects must have the same dates and data series names, although the order need not be the same. The order of the data series, when an object is multiplied by another object, follows the order of the first object.
newfts = tsobj_1 .* tsobj_2 multiplies financial time series objects element by element.
newfts = tsobj .* array multiplies a financial time series object element by element by an array.
newfts = array .* tsobj and newfts = array / tsobj multiplies an array element by element by a financial time series object.

For financial time series objects, the times operation is identical to the mtimes operation.

## toannual

Convert to annual

## Syntax

```
newfts = toannual(oldfts)
newfts = toannual(oldfts, 'ParameterName', ParameterValue, ...)
```

## Arguments

| oldfts | Financial time series object. |
| :--- | :--- |

## Description

newfts = toannual(oldfts) converts a financial time series of any frequency to one of an annual frequency. The default end-of-year is the last business day of the December. toannual uses holidays.m to determine valid trading days.

Note If oldfts contains time-of-day information, newfts displays the time-of-day as '00:00' for those days that did not previously exist in oldfts.

Empty ([ ]) passed as inputs for parameter pair values for toannual triggers the use of the defaults.
newfts = toannual(oldfts, 'ParameterName', ParameterValue, ...) accepts parameter name/parameter value pairs as input, as specified in the following table.

## Parameter Name Parameter Value Description

| CalcMethod | CumSum | Returns the cumulative sum of the values within each <br> year. Data for missing dates are given the value 0. |
| :--- | :--- | :--- |
| CalcMethod | Exact | Returns the exact value at the end-of-year date. No <br> data manipulation occurs. |

## Parameter Name Parameter Value Description

| CalcMethod | Nearest | (Default) Returns the values located at the end-of-year <br> dates. If there is missing data, Nearest returns the <br> nearest data point preceding the end-of-year date. |
| :--- | :--- | :--- |
| CalcMethod | SimpAvg | Returns an averaged annual value that only takes <br> into account dates with data (non-NaN) within each |
| CalcMethod | year. |  |

Note If you set CalcMethod to v21x, settings for all the following parameter name/ parameter value pairs are not supported.

| BusDays | 0 | Returns a financial time series that ranges from (or <br> between) the first date to the last date in oldfts <br> (includes NYSE nonbusiness days and holidays). |
| :--- | :---: | :--- |
| BusDays | (Default) Generates a monthly financial time series <br> that ranges from the first date to the last date in <br> oldfts (excludes NYSE nonbusiness days and <br> holidays and weekends based on AltHolidays <br> and Weekend). If an end-of-month date falls on a <br> nonbusiness day or NYSE holiday, returns the last <br> business day of the month. |  |
| NYSE market closures, holidays, and weekends <br> are observed if AltHolidays and Weekend are not <br> supplied or empty ([ ]). |  |  |

| Parameter Name Parameter Value | Description <br> DateFilter <br> Absolute <br> (Default) Returns all annual dates between the <br> start and end dates of oldfts. Some dates may be <br> disregarded if BusDays $=1$. |  |
| :--- | :--- | :--- |
|  | Note: The default is to create a time series with <br> every date at the specified periodicity, which is with <br> DateFilter = Absolute. If you use DateFilter $=$ <br> Relative, the endpoint effects do not apply since only <br> your data defines which dates appear in the output <br> time series object. |  |
| DateFilter | Relative | Returns only the annual dates that exist in oldfts. <br> Some dates may be disregarded if BusDays = 1. |
| ED | 0 | Annual period ends on the last day or last business <br> day of the month. |
| ED | $1-31$ | Specifies a particular annual day. Months that do not <br> contain the specified day return the last day (or last <br> business day) of the month (for example, ED = 31 <br> does not exist for February.) |
| EM | $1-12$ | (Default) The annual period ends on the last day <br> (or last business day) of the specified month. All <br> subsequent annual dates are calculated from this <br> month. Default annual month is December (12). |

## Parameter Name Parameter Value Description

EndPtTol [Begin, End] Denotes the minimum number of days that constitute an odd annual period at the endpoints of the time series (before the first-time series date and after the last end-of-year date).

Begin and End must be -1 or any positive integer greater than or equal to 0 .

A single value input for 'EndPtTol' is the same as specifying that single value for Begin and End.
-1 Exclude odd annual period dates and data from calculations.

0 (Default) Include odd annual period dates and data in calculations.
n Number of days (any positive integer) that constitute an odd annual period. If there are insufficient days for a complete year, the endpoint data is ignored.
The following diagram is a general depiction of the factors involved in the determination of endpoints for this function.

[^2]| Parameter Name | Parameter Value | Description |
| :---: | :---: | :---: |
| TimeSpec | Last | (Default) Returns only the observation that occurs at the last (latest) time for a specific date. |
| AltHolidays |  | Vector of dates specifying an alternate set of market closure dates. |
| AltHolidays | -1 | Excludes all holidays. |
| Weekend |  | Vector of length 7 containing 0 's and 1's. The value 1 indicates a weekend day. The first element of this vector corresponds to Sunday. For example, when Saturday and Sunday are weekend days (default) then Weekend $=\left[\begin{array}{lllllll}1 & 0 & 0 & 0 & 0 & 0 & 1\end{array}\right]$. |

## Examples

## Transform Time Series Object from Weekly to Annual Values

This example shows how to transform a time series object from weekly to annual values.
Load the data from the file predict_ret_data.mat and use the fints function to create a time series object with a weekly frequency.

```
load predict_ret_data.mat
x0 = fints(exppdātes, expdata, {'Metric'}, 'w', 'Index')
x0 =
    desc: Index
    freq: Weekly (2)
    'dates: (53)' 'Metric: (53)'
    '01-Jan-1999' [ 97.8872]
    '08-Jan-1999' [ 97.0847]
    '15-Jan-1999' [ 109.6312]
    '22-Jan-1999' [ 105.5743]
    '29-Jan-1999' [ 108.4028]
    '05-Feb-1999' [ 134.4882]
    '12-Feb-1999' [ 117.5581]
    19-Feb-1999' [ 106.6683]
    '26-Feb-1999 ' [ 118.2912]
```

## todaily

Convert to daily

## Syntax

```
newfts = todaily(oldfts)
newfts = todaily(oldfts, 'ParameterName', ParameterValue, ...)
```

## Arguments

| oldfts | Financial time series object |
| :--- | :--- |

## Description

newfts = todaily(oldfts) converts a financial time series of any frequency to a daily frequency. todaily uses holidays.m to determine valid trading days.

Note If oldfts contains time-of-day information, newfts displays the time-of-day as '00:00' for those days that did not previously exist in oldfts.

Empty ([ ]) passed as inputs for parameter pair values for todaily trigger the use of the defaults.
newfts = todaily(oldfts, 'ParameterName', ParameterValue, ...) accepts parameter name/parameter value pairs as input, as specified in the following table.

| Parameter Name Parameter Value | Description |  |
| :--- | :--- | :--- |
| CalcMethod | Exact | Returns the value at specific dates/times. No data <br> manipulation occurs. |
| CalcMethod | v21x | This mode is compatible with previous versions of this <br> function (Version 2.1.x and earlier). It returns a five- <br> day business week that starts on Monday and ends on |
|  |  | Friday. |

| Parameter Name Parameter Value Description |  |  |
| :---: | :---: | :---: |
| Note If you set CalcMethod to v21x, settings for all the following parameter name/ parameter value pairs are not supported. |  |  |
| BusDays | 0 | Generates a financial time series that ranges from (or between) the first date to the last date in oldfts (includes NYSE nonbusiness days and holidays). |
| BusDays | 1 | (Default) Generates a daily financial time series that ranges from the first date to the last date in oldfts (excludes NYSE nonbusiness days and holidays and weekends based on AltHolidays and Weekend). |
|  |  | NYSE market closures, holidays, and weekends are observed if AltHolidays and Weekend are not supplied or empty ([]). |
| DateFilter | Absolute | (Default) Displays all daily dates between the start and end dates of oldfts. Some dates may be disregarded if BusDays $=1$. |
|  |  | Note: The default is to create a time series with every date at the specified periodicity, which is with DateFilter = Absolute. If you use DateFilter = Relative, the endpoint effects do not apply since only your data defines which dates appear in the output time series object. |
| DateFilter | Relative | Displays only dates that exist in oldfts. Some dates may be disregarded if BusDays $=1$. |
| TimeSpec | First | Returns only the observation that occurs at the first (earliest) time for a specific date. |
| TimeSpec | Last | (Default) Returns only the observation that occurs at the last (latest) time for a specific date. |
| AltHolidays |  | Vector of dates specifying an alternate set of market closure dates. |
| AltHolidays | -1 | Excludes all holidays. |

## Parameter Name Parameter Value Description <br> Weekend <br> Vector of length 7 containing 0's and 1's. The value 1 indicates a weekend day. The first element of this vector corresponds to Sunday. For example, when Saturday and Sunday are weekend days (default) then Weekend = [1 0 0 O O O 1].

## Examples

## Transform Time Series Object from Weekly to Daily Values

Load the data from the file predict_ret_data.mat and use the fints function to create a time series object with a weekly frequency.

```
load predict_ret_data.mat
x0 = fints(expdates, expdata, {'Metric'}, 'w', 'Index')
x0 =
    desc: Index
    freq: Weekly (2)
    'dates: (53)' 'Metric
                                7.

## today

Current date

## Syntax

## Datenum = today

## Description

Datenum = today returns the current date as a serial date number.

## Examples

Datenum = today
returns
Datenum =
730695

See Also<br>datenum | datestr | now<br>Introduced before R2006a

## todecimal

Fractional to decimal conversion

## Syntax

```
usddec = todecimal(quote, fracpart)
```

## Description

usddec = todecimal(quote, fracpart) returns the decimal equivalent, usddec, of a security whose price is normally quoted as a whole number and a fraction (quote). fracpart indicates the fractional base (denominator) with which the security is normally quoted $($ default $=32)$.

## Examples

In the Wall Street Journal, bond prices are quoted in fractional form based on a denominator of 32 . For example, if you see the quoted price is 100:05 it means $1005 / 32$. To find the equivalent decimal value, enter

```
usddec = todecimal(100.05)
usddec =
    100.1563
usddec = todecimal(97.04, 16)
usddec =
    97.2500
```

Note The convention of using . (period) as a substitute for : (colon) in the input is adopted from Excel software.

## tomonthly

Convert to monthly

## Syntax

```
newfts = tomonthly(oldfts)
newfts = tomonthly(oldfts, 'ParameterName', ParameterValue, ...)
```

## Arguments

| oldfts | Financial time series object. |
| :--- | :--- |

## Description

newfts = tomonthly (oldfts) converts a financial time series of any frequency to a monthly frequency. The default end-of-month day is the last business day of the month. tomonthly uses holidays.m to determine valid trading days.

Note If oldfts contains time-of-day information, newfts displays the time-of-day as 00:00 for those days that did not previously exist in oldfts.

Empty ([ ]) passed as inputs for parameter pair values for tomonthly triggers the use of the defaults.
newfts = tomonthly(oldfts, 'ParameterName', ParameterValue, ...) accepts parameter name/parameter value pairs as input, as specified in the following table.

## Parameter Name Parameter Value Description

| CalcMethod | CumSum |
| :---: | :---: |
| Exact | Returns the cumulative sum of the values within each <br> month. Data for missing dates are given the value 0. |
| Returns the exact value at the end-of-month date. No <br> data manipulation occurs. |  |

| Parameter Name | Parameter Value | Description |
| :---: | :---: | :---: |
| DateFilter | Absolute | (Default) Returns all monthly dates between the start and end dates of oldfts. Some dates may be disregarded if BusDays $=1$. |
|  |  | Note: The default is to create a time series with every date at the specified periodicity, which is with DateFilter = Absolute. If you use DateFilter = Relative, the endpoint effects do not apply since only your data defines which dates appear in the output time series object. |
|  | Relative | Returns only monthly dates that exist in oldfts. Some dates may be disregarded if BusDays $=1$. |
| ED | 0 | (Default) The end-of-month date is the last day (or last business day) of the month. |
|  | 1-31 | Returns values on the specified end-of-month day. Months that do not contain the specified end-of-month day return the last day of the month instead (for example, ED = 31 does not exist for February). |
|  |  | If end-of-month falls on a NYSE non-business day or holiday, the previous business day is returned if BusDays $=1$. |

## Parameter Name Parameter Value Description

EndPtTol [Begin, End] Denotes the minimum number of days that constitute an odd month at the end points of the time series (before the first whole period and after the last whole period).

Begin and End must be -1 or any positive integer greater than or equal to 0 .

A single value input for EndPtTol is the same as specifying that single value for Begin and End.
-1 Do not include odd month dates and data in calculations.

0 (Default) Include all odd month dates and data in calculations.
n Number of days that constitute an odd month. If the minimum number of days is not met, the odd month dates and data are ignored.
The following diagram is a general depiction of the factors involved in the determination of end points for this function.

| TimeSpec | First | Returns only the observation that occurs at the first <br> (earliest) time for a specific date. |
| :---: | :---: | :--- |
| Last | (Default) Returns only the observation that occurs at <br> the last (latest) time for a specific date. |  |

| Parameter Name | Parameter Value | Description |
| :---: | :---: | :---: |
| AltHolidays |  | Vector of dates specifying an alternate set of market closure dates. |
|  | -1 | Excludes all holidays. |
| Weekend |  | Vector of length 7 containing 0 's and 1's. The value 1 indicates a weekend day. The first element of this vector corresponds to Sunday. For example, when Saturday and Sunday are weekend days (default) then Weekend $=\left[\begin{array}{lllllll}1 & 0 & 0 & 0 & 0 & 0 & 1\end{array}\right]$. |

## Examples

## Transform Time Series Object from Weekly to Monthly Values

This example shows how to transform a time series object from weekly to monthly values.

Load the data from the file predict ret_data.mat and use the fints function to create a time series object with a weekly frequency.

```
load predict_ret_data.mat
x0 = fints(expdates, expdata, {'Metric'}, 'w', 'Index')
x0 =
```

    desc: Index
    freq: Weekly (2)
    'dates: (53)' 'Metric: (53)
    '01-Jan-1999' [ 97.8872]
    '08-Jan-1999' [ 97.0847]
    '15-Jan-1999' [ 109.6312]
    '22-Jan-1999' [ 105.5743]
    '29-Jan-1999' [ 108.4028]
    05-Feb-1999' [ 134.4882]
    '12-Feb-1999' [ 117.5581]
    19-Feb-1999' [ 106.6683]
    '26-Feb-1999' [ 118.2912]
    '05-Mar-1999' [ 105.6835]
    12-Mar-1999' [ 128.5836]
    

Use tomonthly to obtain the monthly aggregate for the x 0 times series.

```
x1 = tomonthly(x0)
x1 =
    desc: TOMONTHLY: Index
    freq: Monthly (3)
    'dates: (12)' 'Metric: (12)
    '29-Jan-1999' [ 108.4028]
    '26-Feb-1999' [ 118.2912]
    '31-Mar-1999' [ 131.2854]
    '30-Apr-1999' [ 78.5738]
    '28-May-1999' [ 72.9190]
    '30-Jun-1999' [ 49.4032]
    '30-Jul-1999' [ 53.9584]
    '31-Aug-1999' [ 56.4897]
    '30-Sep-1999' [ 46.5143]
    '29-Oct-1999' [ 36.9287]
    '30-Nov-1999' [ 36.9495]
    '31-Dec-1999' [ 28.5665]
```

## toquarterly

Convert to quarterly

## Syntax

```
newfts = toquarterly(oldfts)
newfts = toquarterly(oldfts, 'ParameterName', ParameterValue, ...)
```

## Arguments

| oldfts | Financial time series object |
| :--- | :--- |

## Description

newfts = toquarterly(oldfts) converts a financial time series of any frequency to a quarterly frequency. The default quarterly days are the last business day of March, June, September, and December. toquarterly uses holidays.m to determine valid trading days.

Note If oldfts contains time-of-day information, newfts displays the time-of-day as 00:00 for those days that did not previously exist in oldfts.

Empty ([ ]) passed as inputs for parameter pair values for toquarterly triggers the use of the defaults.
newfts = toquarterly(oldfts, 'ParameterName', ParameterValue, ...) accepts parameter name/parameter value pairs as input, as specified in the following table.

| Parameter Name | Parameter Value | Description |
| :---: | :---: | :---: |
| CalcMethod | CumSum | Returns the cumulative sum of the values between each quarter. Data for missing dates are given the value 0 . |

| Parameter Name | Parameter Value | Description |
| :---: | :---: | :---: |
| DateFilter | Absolute | (Default) Returns all quarterly dates between the start and end dates of oldfts. Some dates may be disregarded if BusDays $=1$. |
|  |  | Note: The default is to create a time series with every date at the specified periodicity, which is with DateFilter = Absolute. If you use DateFilter = Relative, the endpoint effects do not apply since only your data defines which dates appear in the output time series object. |
|  | Relative | Returns only quarterly dates that exist in oldfts. Some dates may be disregarded if BusDays $=1$. |
| ED | 0 | (Default) The end-of-quarter date is the last day (or last business day) of the quarter. |
|  | 1-31 | Specifies a particular end-of-quarter day. Months that do not contain the specified end-of-quarter day return the last day of the quarter instead (for example, ED = 31 does not exist for February). |
| EM | 1-12 | Last month of the first quarter. All subsequent quarterly dates are based on this month. The default end-of-first-quarter month is March (3). |

## Parameter Name Parameter Value Description

EndPtTol [Begin, End] Denotes the minimum number of days that constitute an odd quarter at the endpoints of the time series (before the first whole period and after the last whole period).

Begin and End must be -1 or any positive integer greater than or equal to 0 .

A single value input for EndPtTol is the same as specifying that single value for Begin and End.
-1 Do not include odd quarter dates and data in calculations.

0 (Default) Include all odd quarter dates and data in calculations.
n Number of days (any positive integer) that constitute an odd quarter. If there are insufficient days for a complete quarter, the odd quarter dates and data are ignored.

The following diagram is a general depiction of the factors involved in the determination of endpoints for this function.

[^3]| Parameter Name Parameter ValueLast | Description <br> (Default) Returns only the observation that occurs at <br> the last (latest) time for a specific date. |
| :--- | :--- |
| AltHolidays | Vector of dates specifying an alternate set of market <br> closure dates. |
| Weekend | Excludes all holidays. <br>  <br> Vector of length 7 containing 0's and 1's. The value <br> 1 indicates a weekend day. The first element of this <br> vector corresponds to Sunday. For example, when <br> Saturday and Sunday are weekend days (default) then <br> Weekend $=\left[\begin{array}{lllll}1 & 0 & 0 & 0 & 0\end{array}\right]$. |

```

Introduced before R2006a

## toquoted

Decimal to fractional conversion

## Syntax

```
quote = toquoted(usddec, fracpart)
```

## Description

quote $=$ toquoted(usddec, fracpart) returns the fractional equivalent, quote, of the decimal figure, usddec, based on the fractional base (denominator), fracpart. The fractional bases are the ones used for quoting equity prices in the United States (denominator $2,4,8,16$, or 32 ). If fracpart is not entered, the denominator 32 is assumed.

## Examples

A United States equity price in decimal form is 101.625 . To convert this to fractional form in eighths of a dollar:

```
quote = toquoted(101.625, 8)
quote =
    101.05
```

The answer is interpreted as $1015 / 8$.

Note The convention of using . (period) as a substitute for : (colon) in the output is adopted from Excel software.

See Also<br>todecimal<br>Introduced before R2006a

## tosemi

Convert to semiannual

## Syntax

```
newfts = tosemi(oldfts)
newfts = tosemi(oldfts, 'ParameterName', ParameterValue, ...)
```

## Arguments

| oldfts | Financial time series object. |
| :--- | :--- |

## Description

newfts $=$ tosemi(oldfts) converts a financial time series of any frequency to a semiannual frequency. The default semiannual days are the last business day of June and December. tosemi uses holidays.m to determine valid trading days.

Note If oldfts contains time-of-day information, newfts displays the time-of-day as 00:00 for those days that did not previously exist in oldfts.

Empty ([ ]) passed as inputs for parameter pair values for tosemi triggers the use of the defaults.
newfts = tosemi(oldfts, 'ParameterName', ParameterValue, ...) accepts parameter name/parameter value pairs as input, as specified in the following table.

| Parameter Name Parameter Value | Description |
| :---: | :--- | :--- |
| CalcMethod $\quad$ CumSum | Returns the cumulative sum of the values within each <br> semiannual period. Data for missing dates are given <br> the value 0. |
| Exact | Returns the exact value at the end-of-period date. No <br> data manipulation occurs. |

| Parameter Name | Parameter Value | Description |
| :---: | :---: | :---: |
| DateFilter | Absolute | (Default) Returns all semiannual dates between the start and end dates of oldfts. Some dates may be disregarded if BusDays $=1$. |
|  |  | Note: The default is to create a time series with every date at the specified periodicity, which is with DateFilter = Absolute. If you use DateFilter = Relative, the endpoint effects do not apply since only your data defines which dates appear in the output time series object. |
|  | Relative | Returns only semiannual dates that exist in oldfts. Some dates may be disregarded if BusDays $=1$. |
| ED | 0 | (Default) The end-of-period date is the last day (or last business day) of the semiannual period. |
|  | 1-31 | Specifies a particular end-of-period day. Months that do not contain the specified end-of-period day return the last day of the semiannual period instead (for example, ED = 31 does not exist for February). |
| EM | 1-12 | End month of the first semiannual period. All subsequent period dates are based on this month. The default end-of-period months are June (6) and December (12). |

## Parameter Name Parameter Value Description

EndPtTol [Begin, End] Denotes the minimum number of days that constitute an odd semiannual period at the endpoints of the time series (before the first whole period and after the last whole period).

Begin and End must be -1 or any positive integer greater than or equal to 0 .

A single value input for EndPtTol is the same as specifying that single value for Begin and End.
-1 Do not include odd period dates and data in calculations.

0 (Default) Include all odd period dates and data in calculations.
n Number of days (any positive integer) that constitute an odd period. If there are insufficient days for a complete semiannual period, the odd period dates and data are ignored.

The following diagram is a general depiction of the factors involved in the determination of endpoints for this function.

[^4]| Parameter Name | Parameter Value | Description |
| :---: | :---: | :---: |
| AltHolidays | Last | (Default) Returns only the observation that occurs at the last (latest) time for a specific date. |
|  |  | Vector of dates specifying an alternate set of market closure dates. |
|  | -1 | Excludes all holidays. |
| Weekend |  | Vector of length 7 containing 0 's and 1's. The value 1 indicates a weekend day. The first element of this vector corresponds to Sunday. For example, when Saturday and Sunday are weekend days (default) then Weekend $=\left[\begin{array}{lllllll}1 & 0 & 0 & 0 & 0 & 0 & 1\end{array}\right]$. |

## totalreturnprice

Total return price time series

## Syntax

```
Return = totalreturnprice(Price, Action, Dividend)
```

## Arguments

| Price | Number of observations (NUMOBS)-by-2 matrix of price data. <br> Column 1 contains MATLAB serial date numbers. Column 2 <br> contains price values. |
| :--- | :--- |
| Action | NUMOBS-by-2 matrix of price data. Column 1 contains MATLAB <br> serial date numbers. Column 2 contains split ratios. |
| Dividend | NUMOBS-by-2 matrix of price data. Column 1 contains MATLAB <br> serial date numbers. Column 2 contains dividend payouts. |

The number of observations (NUMOBS) for the three input arguments differ from each other.

## Description

Return = totalreturnprice(Price, Action, Dividend) generates a total return price time series given price data, action or split data, and dividend data.

Return is NUMOBS-by-2 array of price data, where NUMOBS reflects the number of observations of price data. Column 1 contains MATLAB serial date numbers. Column 2 contains total return price values.

## toweekly

Convert to weekly

## Syntax

```
newfts = toweekly(oldfts)
newfts = toweekly(oldfts, 'ParameterName', ParameterValue, ...)
```

## Arguments

| oldfts | Financial time series object. |
| :--- | :--- |

## Description

newfts = toweekly (oldfts) converts a financial time series of any frequency to a weekly frequency. The default weekly days are Fridays or the last business day of the week. toweekly uses holidays.m to determine valid trading days.

Note If oldfts contains time-of-day information, newfts displays the time-of-day as 00:00 for those days that did not previously exist in oldfts.

Empty ([ ]) passed as inputs for parameter pair values for toweekly triggers the use of the defaults.
newfts = toweekly(oldfts, 'ParameterName', ParameterValue, ...) accepts parameter name/parameter value pairs as input, as specified in the following table.

## Parameter Name Parameter Value Description

| CalcMethod | CumSum |
| :---: | :---: |
| Exact | Returns the cumulative sum of the values within each <br> week. Data for missing dates are given the value 0. |
| Returns the exact value at the end-of-week dates. No <br> data manipulation occurs. |  |

## Parameter Name Parameter Value Description

| DateFilter | Absolute | (Default) Returns all weekly dates between the start and end dates of oldfts. Some dates may be disregarded if BusDays $=1$. |
| :---: | :---: | :---: |
|  |  | Note: The default is to create a time series with every date at the specified periodicity, which is with DateFilter = Absolute. If you use DateFilter = Relative, the endpoint effects do not apply since only your data defines which dates appear in the output time series object. |
|  | Relative | Returns only end-of-week dates that exist in oldfts. Some dates may be disregarded if BusDays $=1$. |
| EndPtTol | [Begin, End] | Denotes the minimum number of days that constitute an odd week at the endpoints of the time series (before the first whole period and after the last whole period). |
|  |  | Begin and End must be -1 or any positive integer greater than or equal to 0 . |
|  |  | A single value input for EndPtTol is the same as specifying that single value for Begin and End. |
|  |  | -1 Do not include odd week dates and data in calculations. |
|  |  | 0 (Default) Include all odd week dates and data in calculations. |
|  |  | n Number of days (any positive integer) that constitute an odd week. If there are insufficient days for a complete week, the odd week dates and data are ignored. |

## Parameter Name Parameter Value Description

The following diagram is a general depiction of the factors involved in the determination of endpoints for this function.

## Examples

## Transform Time Series Object from Quarterly to Weekly Values

This example shows how to transform a time series object from quarterly to weekly values.

Load the data from the file predict_ret_data.mat and use the fints function to create a time series object with a quarterly frequency.

```
load predict_ret_data.mat
x0 = fints(expdates, expdata, {'Metric'}, 'q', 'Index')
```

$x 0=$

## tr2bonds

Term-structure parameters given Treasury bond parameters

## Syntax

[Bonds, Prices, Yields] = tr2bonds(TreasuryMatrix, Settle)

## Arguments

| TreasuryMatrix | Treasury bond parameters. An n-by-5 matrix, where <br> each row describes a Treasury bond. Columns are <br> [CouponRate Maturity Bid Asked AskYield ] where: |
| :--- | :--- |
| CouponRate | Coupon rate, as a decimal fraction. |
| Maturity | Maturity date, as a serial date number. Use datenum to <br> convert date strings to serial date numbers. |
| Bid | Bid price based on $\$ 100$ face value. |
| Asked | Asked price based on $\$ 100$ face value. |
| AskYield | Asked yield to maturity, as a decimal fraction. |
| Settle | (Optional) Date string or serial date number of the <br> settlement date for the analysis. |

## Description

[Bonds, Prices, Yields] = tr2bonds(TreasuryMatrix, Settle) returns term-structure parameters (bond information, prices, and yields) sorted by ascending maturity date, given Treasury bond parameters. The formats of the output matrix and vectors meet requirements for input to the zbtprice and zbtyield zero-curve bootstrapping functions.

| Bonds | Coupon bond information. An n-by-6 matrix where each row <br> describes a bond. Columns are [Maturity CouponRate <br> Face Period Basis EndMonthRule] where: |
| :--- | :--- |

| Maturity | Maturity date of the bond, as a serial date number. Use datestr to convert serial date numbers to date strings. |
| :---: | :---: |
| CouponRate | Coupon rate of the bond, as a decimal fraction. |
| Face | Redemption or face value of the bond, always 100. |
| Period | Coupons per year of the bond, always 2. |
| Basis | Day-count basis of the bond, possible values include: <br> - $0=$ actual/actual (default) <br> - $1=30 / 360$ (SIA) <br> - $2=$ actual/360 <br> - $3=$ actual $/ 365$ <br> For more information, see basis. |
| EndMonthRule | End-of-month flag, always 1, meaning that a bond's coupon payment date is always the last day of the month. |
| Prices | Prices. Column vector containing the price of each bond in bonds, respectively. The number of rows ( $n$ ) matches the number of rows in bonds. |
| Yields | Yields. Column vector containing the yield to maturity of each bond in bonds, respectively. The number of rows ( $n$ ) matches the number of rows in bonds. If Settle is input, Yields is computed as a semiannual yield to maturity. If Settle is not input, the quoted input yields are used. |

## Examples

## Return Term-Structure Parameters Given Treasury Bond Parameters

This example shows how to return term-structure parameters (bond information, prices, and yields) sorted by ascending maturity date, given Treasury bond market parameters for December 22, 1997.

```
Matrix =[0.0650 datenum('15-apr-1999') 101.03125 101.09375 0.0564
    0.05125 datenum('17-dec-1998') 99.4375 99.5 0.0563
    0.0625 datenum('30-jul-1998') 100.3125 100.375 0.0560
    0.06125 datenum('26-mar-1998') 100.09375 100.15625 0.0546];
```

```
[Bonds, Prices, Yields] = tr2bonds(Matrix)
Bonds =
    1.0e+05 *

## transprob

Estimate transition probabilities from credit ratings data

## Syntax

```
[transMat, sampleTotals, idTotals] = transprob(data)
[transMat, sampleTotals, idTotals] = transprob(data,
Name, Value)
```

## Description

[transMat, sampleTotals, idTotals] = transprob(data) constructs a transition matrix from historical data of credit ratings.
[transMat, sampleTotals, idTotals] = transprob(data,
Name, Value) constructs a transition matrix from historical data of credit ratings with additional options specified by one or more Name, Value pair arguments.

## Input Arguments

## data

Using transprob to estimate transition probabilities given credit ratings historical data (that is, credit migration data), the data input can be one of the following:

- An nRecords-by-3 MATLAB table containing the historical credit ratings data of the form:

| ID | Date | Rating |
| :---: | :---: | :---: |
| '00010283' | '10-Nov-1984' | 'CCC' |
| '00010283' | '12-May-1986' | B' |
| '00010283' | '29-Jun-1988' | CCC ${ }^{\prime}$ |
| '00010283' | '12-Dec-1991' | $\mathrm{D}^{\prime}$ |
| '00013326' | '09-Feb-1985' | A' |
| '00013326' | '24-Feb-1994' | AA' |

```
'00013326' '10-Nov-2000' 'BBB'
'00014413' '23-Dec-1982' 'B'
```

where each row contains an ID (column 1), a date (column 2), and a credit rating (column 3). Column 3 is the rating assigned to the corresponding ID on the corresponding date. All information corresponding to the same ID must be stored in contiguous rows. Sorting this information by date is not required, but recommended for efficiency. When using a MATLAB table input, the names of the columns are irrelevant, but the ID, date and rating information are assumed to be in the first, second and third columns, respectively. Also, when using a table input, the first and third columns can be categorical arrays, and the second can be a datetime array. The following summarizes the supported data types for table input:

| Data Input Type | ID (1 st Column) | Date (2nd Column) | Rating (3rd Column) |
| :---: | :---: | :---: | :---: |
| Table | - Numeric array | - Numeric array | - Numeric array |
|  | - Cell array of strings | - Cell array of strings | - Cell array of strings |
|  | - Categorical array | - Datetime array | - Categorical array |

- An nRecords-by-3 cell array containing the historical credit ratings data of the form:

```
'00010283' '10-Nov-1984' 'CCC'
'00010283' '12-May-1986' 'В'
'00010283' '29-Jun-1988' 'CCC'
'00010283' '12-Dec-1991' 'D'
'00013326' '09-Feb-1985' 'A'
'00013326' '24-Feb-1994' 'AA'
'00013326' '10-Nov-2000' 'BBB'
'00014413' '23-Dec-1982' 'B'
```

where each row contains an ID (column 1), a date (column 2), and a credit rating (column 3). Column 3 is the rating assigned to the corresponding ID on the corresponding date. All information corresponding to the same ID must be stored in contiguous rows. Sorting this information by date is not required, but recommended for efficiency. IDs, dates, and ratings are usually stored in string format, but they can also be entered in numeric format. The following summarizes the supported data types for cell array input:

| Data Input Type | ID (1st Column) | Date (2nd Column) | Rating (3rd Column) |
| :--- | :--- | :--- | :--- |
| Cell | Numeric <br> elements | Numeric <br> elements | Numeric <br> elements |

| Data Input Type | ID (1 st Column) | Date (2nd Column) | Rating (3rd Column) |
| :--- | :--- | :--- | :--- |
|  | $\cdot$ String elements | $\cdot$ | String elements | • String elements | ( |
| :--- |

- A preprocessed data structure obtained using transprobprep. This data structure contains the fields'idStart', 'numericDates', 'numericRatings', and 'ratingsLabels'.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

```
'algorithm'
```

Estimation algorithm, in string format. Valid values are duration or cohort.
Default: duration

## 'endDate'

End date of the estimation time window, in string or numeric format. The endDate cannot be a date before the startDate.

Default: Latest date in data

## 'labels'

Cell array of size nRatings-by-1, or 1-by-nRatings, containing the credit-rating scale. It must be consistent with the ratings labels used in the third column of data. Use a cell array of numbers for numeric ratings, and a cell array of strings for string or categorical ratings.

Note: When the input argument data is a preprocessed data structure obtained from a previous call to transprobprep, this optional input for ' labels is unused because the labels in the 'ratingsLabels' field of transprobprep take priority.

Default: \{'AAA', 'AA', 'A','BBB', 'BB', 'B', $C C C ', ' D '\}$

## 'snapsPerYear'

Integer indicating the number of credit-rating snapshots per year to be considered for the estimation. Valid values are $1,2,3,4,6,12$. This parameter is only used with the cohort algorithm.

Default: 1 - One snapshot per year

## 'startDate'

Start date of the estimation time window, in string or numeric format.
Default: Earliest date in data

## 'transInterval'

Length of the transition interval, in years.
Default: 1 - One year transition probability

## Output Arguments

## transMat

Matrix of transition probabilities in percent. The size of the transition matrix is nRatings-by-nRatings.

## sampleTotals

Structure with fields:

- totalsVec - A vector of size 1-by-nRatings.
- totalsMat - A matrix of size nRatings-by-nRatings.
- algorithm - A string with values 'duration' or 'cohort'.

For the 'duration' algorithm, totalsMat $(i, j)$ contains the total transitions observed out of rating $i$ into rating (all the diagonal elements are zero). The total time spent on rating $i$ is stored in totalsVec $(i)$. For example, if there are three rating categories, Investment Grade (IG), Speculative Grade (SG), and Default (D), and the following information:

```
Total time spent IG SG D
```

```
in rating: 4859.09 1503.36 1162.05
```

| Transitions |  | IG | SG | D |
| :--- | ---: | ---: | ---: | ---: |
| out of (row) | IG | 0 | 89 | 7 |
| into (column): | SG | 202 | 0 | 32 |
|  | D | 0 | 0 | 0 |

Then

```
totals.totalsVec = [\begin{array}{llll}{4859.09 1503.36 1162.05]}\end{array}]
```

totals.totalsMat $=\left[\begin{array}{ccc}0 & 89 & 7\end{array}\right.$
202032
$\left.\begin{array}{lll}0 & 0 & 0\end{array}\right]$
totals.algorithm = 'duration'

For the ' cohort ' algorithm, totalsMat $(i, j)$ contains the total transitions observed from rating $i$ to rating $j$, and totalsVec $(i)$ is the initial count in rating $i$. For example, given the following information:

| Initial count | IG | SG | D |
| :--- | ---: | ---: | ---: |
| in rating: | 4808 | 1572 | 1145 |
|  |  |  |  |
| Transitions |  | IG | SG |
| from (row) | IG | 4721 | 80 |
| to (column): | SG | 193 | 1347 |
|  | D | 0 | 0 |
|  |  |  |  |
|  |  |  | 1145 |

Then

```
totals.totalsVec = [4808 1572 1145]
totals.totalsMat = [4721 80 7
    193 1347 32
        0 0 1145
totals.algorithm = 'cohort'
```

## idTotals

Struct array of size nIDs-by-1, where $n$ IDs is the number of distinct IDs in column 1 of data when this is a table or cell array or, equivalently, equal to the length of the idStart field minus 1 when data is a preprocessed data structure from transprobprep. For each ID in the sample, idTotals contains one structure with the following fields:

- totalsVec - A sparse vector of size 1-by-nRatings.
- totalsMat - A sparse matrix of size nRatings-by-nRatings.
- algorithm - A string with values 'duration' or 'cohort'.

These fields contain the same information described for the output sampleTotals, but at an ID level. For example, for 'duration', idTotals $(k)$.totalsVec contains the total time that the $k$-th company spent on each rating.

## Examples

## Construct a Transition Matrix From a Table of Historical Data of Credit Ratings

Using the historical credit rating table as input data from Data_TransProb.mat display the first ten rows and compute the transition matrix:

```
load Data_TransProb
data(1:10,:)
% Estimate transition probabilities with default settings
transMat = transprob(data)
ans =
\begin{tabular}{|c|c|c|}
\hline ID & Date & Rating \\
\hline '00010283 ' & '10-Nov-1984' & ' CCC ' \\
\hline '00010283 ' & '12-May-1986' & B' \\
\hline '00010283' & '29-Jun-1988' & CCC' \\
\hline '00010283' & '12-Dec-1991' & D' \\

- "Estimation of Transition Probabilities" on page 8-21
- "Estimate Transition Probabilities for Different Rating Scales" on page 8-24

## More About

## Cohort Estimation

The cohort algorithm estimates the transition probabilities based on a sequence of snapshots of credit ratings at regularly spaced points in time. If the credit rating of a company changes twice between two snapshot dates, the intermediate rating is overlooked and only the initial and final ratings influence the estimates.

## Duration Estimation

Unlike the cohort method, the duration algorithm estimates the transition probabilities based on the full credit ratings history, looking at the exact dates on which the credit rating migrations occur. There is no concept of snapshots in this method, and all credit rating migrations influence the estimates, even when a company's rating changes twice within a short time.

## Algorithms

## Cohort Estimation

The algorithm first determines a sequence $t_{0, \ldots, t_{K}}$ of snapshot dates. The elapsed time, in years, between two consecutive snapshot dates $t_{k-1}$ and $t_{k}$ is equal to $1 / n s$, where $n s$ is the number of snapshots per year. These $K+1$ dates determine $K$ transition periods.

The algorithm computes $N_{i}^{n}$, the number of transition periods in which obligor $n$ starts at rating $i$. These are added up over all obligors to get $N_{i}$, the number of obligors in the sample that start a period at rating $i$. The number periods in which obligor $n$ starts at
rating $i$ and ends at rating $j$, or migrates from $i$ to $j$, denoted by $N_{i j}^{n}$, is also computed.
These are also added up to get $N_{i j}$, the total number of migrations from $i$ to $j$ in the sample.

The estimate of the transition probability from $i$ to $j$ in one period, denoted by $P_{i j}$, is given by:

$$
P_{i j}=\frac{N_{i j}}{N i}
$$

These probabilities are arranged in a one-period transition matrix $P_{0}$, where the $i, j$ entry in $P_{o}$ is $P_{i j}$.

If the number of snapshots per year $n s$ is 4 (quarterly snapshots), the probabilities in $P_{0}$ are 3 -month (or 0.25 -year) transition probabilities. You may, however, be interested in 1 -year or 2 -year transition probabilities. The latter time interval is called the transition interval, $\Delta t$, and it is used to convert $P_{0}$ into the final transition matrix, $P$, according to the formula:

$$
P=P_{0}^{n s \Delta t}
$$

For example, if $n s=4$ and $\Delta t=2, P$ contains the 2 -year transition probabilities estimated from quarterly snapshots.

Note: For the cohort algorithm, optional output arguments idTotals and sampleTotals from transprob contain the following information:

- idTotals(n).totalsVec $=\left(N_{i}^{n}\right) \forall i$
- 

idTotals(n).totalsMat $=\left(N_{i, j}^{n}\right) \forall i j$

- idTotals(n).algoritm = 'cohort'
- sampleTotals.totalsVec $=\left(N_{i}\right) \forall i$
- sampleTotals.totalsMat $=\left(N_{i, j}\right) \forall i j$
- sampleTotals.algoritm = 'cohort'

For efficiency, the vectors and matrices in idTotals are stored as sparse arrays.

## Duration Estimation

The algorithm computes $T_{i}^{n}$, the total time that obligor $n$ spends in rating $i$ within the estimation time window. These quantities are added up over all obligors to get $T_{i}$, the total time spent in rating $i$, collectively, by all obligors in the sample. The algorithm also computes $T_{i j}^{n}$, the number times that obligor $n$ migrates from rating $i$ to rating $j$, with $i$ not equal to $j$, within the estimation time window. And it also adds them up to get $T_{i j}$, the total number of migrations, by all obligors in the sample, from the rating $i$ to $j$, with $i$ not equal to $j$.

To estimate the transition probabilities, the duration algorithm first needs to compute a generator matrix $\Lambda$. Each off-diagonal entry of this matrix is an estimate of the transition rate out of rating $i$ into rating $j$, and is given by:

$$
\lambda_{i j}=\frac{T_{i j}}{T_{i}}, i \neq j
$$

The diagonal entries are computed as:

$$
\lambda_{i i}=-\sum_{j \neq i} \lambda_{i j}
$$

With the generator matrix and the transition interval $\Delta t$ (e.g., $\Delta t=2$ corresponds to 2 year transition probabilities), the transition matrix is obtained as $P=\exp (\Delta t \Lambda)$, where exp denotes matrix exponentiation (expm in MATLAB).

Note: For the duration algorithm, optional output arguments idTotals and sampleTotals from transprob contain the following information:

```
idTotals(n).totalsVec = (T
    idTotals(n).totalsMat = (Ti,j)\forallij
- idTotals(n).algoritm = 'duration'
s sampleTotals.totalsVec = (Ti)\foralli
.
    sampleTotals.totalsMat = (Ti,j)\forallij
- sampleTotals.algoritm = 'duration'
For efficiency, the vectors and matrices in idTotals are stored as sparse arrays.

## transprobbytotals

Estimate transition probabilities using totals structure input

## Syntax

[transMat,sampleTotals] = transprobbytotals(totals) [transMat,sampleTotals] = transprobbytotals(totals, Name, Value)

## Description

[transMat, sampleTotals] = transprobbytotals(totals) estimates transition probabilities using a totals structure input.
[transMat,sampleTotals] = transprobbytotals(totals, Name, Value) estimates transition probabilities using a totals structure input with additional options specified by one or more Name, Value pair arguments.
transprobbytotals is useful for removing outlier information, obtaining bootstrapped confidence intervals, or computing transition probability estimates for different periodicity parameters (1-year transitions, 2 -year transitions, etc.) efficiently.

## Input Arguments

## totals

This can be:

- totalsVec - A sparse vector of size 1-by-nRatings1.
- totalsMat - A sparse matrix of size nRatings1-by-nRatings2 with nRatings1 $\leq$ nRatings2.
- algorithm - A string with values 'duration' or 'cohort'.

For the 'duration' algorithm, totalsMat $(i, j)$ contains the total transitions observed out of rating $i$ into rating $j$ (all the diagonal elements are 0 ). The total time spent on
rating $i$ is stored in totalsVec $(i)$. For example, you have three rating categories, Investment Grade (IG), Speculative Grade (SG), and Default (D), and the following information:

| Total time spent in rating: | $\begin{gathered} \text { IG } \\ 4859.09 \end{gathered}$ |  | SG | D |
| :---: | :---: | :---: | :---: | :---: |
|  |  |  | 1503.36 | 1162.05 |
| Transitions |  | IG | SG | D |
| out of (row) | IG | 0 | 89 | 7 |
| into (column) : | SG | 202 | 0 | 32 |
|  | D | 0 | 0 | 0 |

Then:

```
totals.totalsVec = [4859.09 1503.36 1162.05]
totals.totalsMat = [ 0 89 7
    202 0 32
        0 0 0]
totals.algorithm = 'duration'
```

For the ' cohort ' algorithm, totalsMat $(i, j)$ contains the total transitions observed from rating $i$ to rating $j$, and totals $\operatorname{Vec}(i)$ is the initial count in rating $i$. For example, given the following information:

| Initial count | IG | SG | D |
| :--- | ---: | ---: | :---: |
| in rating: | 4808 | 1572 | 1145 |
|  |  |  |  |
| Transitions |  | IG | SG |
| from (row) | IG | 4721 | 80 |
| to (column): | SG | 193 | 1347 |
|  | D | 0 | 0 |
|  |  |  | 32 |
|  |  |  |  |

Then:

```
totals.totalsVec = [\begin{array}{lll}{4808}&{1572 1145}\end{array}]
totals.totalsMat = [4721 80 7
    193 1347 32
        0 0 1145
```

totals.algorithm = 'cohort'

Common totals structures are the optional output arguments from transprob:

- sampleTotals - A single structure summarizing the totals information for the whole dataset.
- idTotals - A struct array with the totals information at the ID level.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

## 'snapsPerYear'

Integer indicating the number of credit-rating snapshots per year to be considered for the estimation. Values are $1,2,3,4,6$, or 12 . This argument is only used with the cohort algorithm.

Default: 1 - One snapshot per year

## 'transInterval'

Length of the transition interval, in years.
Default: 1 - One-year transition probabilities

## Output Arguments

## transMat

Matrix of transition probabilities in percent. The size of the transition matrix is nRatings1-by-nRatings2.

## sampleTotals

Structure with fields:

- totalsVec - A vector of size 1-by-nRatings1.
- totalsMat - A matrix of size nRatings1-by-nRatings2 with nRatings1 $\leq$ nRatings2.
- algorithm - A string with values 'duration' or 'cohort'.

If totals is a struct array, sampleTotals contains the aggregated information. That is, sampleTotals.totalsVec is the sum of totals $(k)$.totalsVec over all $k$, and similarly for totalsMat. When totals is itself a single structure, sampleTotals and totals are the same.

## Examples

## Estimate Transition Probabilities Using a totals Structure Input

Use historical credit rating input data from Data_TransProb.mat and transprob to generate input for transprobbytotals:

```
load Data_TransProb
```

```
% Call TRANSPROB with three output arguments
[transMat, sampleTotals, idTotals] = transprob(data);
transMat
```

transMat =

## More About

## Cohort Estimation

The cohort algorithm estimates the transition probabilities based on a sequence of snapshots of credit ratings at regularly spaced points in time. If the credit rating of a company changes twice between two snapshot dates, the intermediate rating is overlooked and only the initial and final ratings influence the estimates. For more information, see "Algorithms" on page 18-1397.

## Duration Estimation

Unlike the cohort algorithm, the duration algorithm estimates the transition probabilities based on the full credit ratings history, looking at the exact dates on which the credit rating migrations occur. There is no concept of snapshots in this method, and all credit rating migrations influence the estimates, even when a company's rating changes twice within a short time. For more information, see "Algorithms" on page 18-1397.

## transprobfromthresholds

Convert from credit quality thresholds to transition probabilities

## Syntax

trans = transprobfromthresholds(thresh)

## Description

trans = transprobfromthresholds(thresh) transforms credit quality thresholds into transition probabilities.

## Input Arguments

## thresh

M-by-N matrix of credit quality thresholds. In each row, the first element must be Inf and the entries must satisfy the following monotonicity condition:

```
thresh(i,j) >= thresh(i,j+1), for 1<=j<N
```

The M-by-N input thresh and the M-by-N output trans are related as follows. The thresholds thresh $(i, j)$ are critical values of a standard normal distribution $z$, such that:

```
trans(i,N) = P[z< thresh(i,N)],
trans(i,j) = P[z<thresh(i,j)] - P[z < thresh(i,j+1)], for 1<=j<N
```

Any given row in the output matrix TRANS determines a probability distribution over a discrete set of N ratings ' R 1 ', ..., 'RN', so that for any row $i \operatorname{TRANS}(i, j)$ is the probability of migrating into 'Rj'. TRANS can be a standard transition matrix, with $\mathrm{M} \leq \mathrm{N}$, in which case row $i$ contains the transition probabilities for issuers with rating 'Ri'. But TRANS does not have to be a standard transition matrix. TRANS can contain individual transition probabilities for a set of $M$-specific issuers, with $M>N$.

For example, suppose that there are only N=3 ratings, 'High ', 'Low', and 'Default', with these credit quality thresholds:

|  | High | Low | Default |
| :--- | :--- | ---: | ---: |
| High | Inf | -2.0814 | -3.1214 |
| Low | Inf | 2.4044 | -1.7530 |

The matrix of transition probabilities is then:

|  | High | Low | Default |
| :--- | ---: | :---: | :---: |
| High | 98.13 | 1.78 | 0.09 |
| Low | 0.81 | 95.21 | 3.98 |

This means the probability of default for 'High' is equivalent to drawing a standard normal random number smaller than -3.1214 , or $0.09 \%$. The probability that a 'High' ends up the period with a rating of 'Low' or lower is equivalent to drawing a standard normal random number smaller than -2.0814 , or $1.87 \%$. From here, the probability of ending with a 'Low' rating is:

```
P[z<-2.0814] - P[z<-3.1214] = 1.87% - 0.09% = 1.78%
```

And the probability of ending with a 'High ' rating is:

```
100%-1.87% = 98.13%
```

where $100 \%$ is the same as:
$\mathrm{P}[z<\operatorname{Inf}]$

## Output Arguments

## trans

M-by-N matrix with transition probabilities, in percent.

## Examples

## Transform Credit Quality Thresholds Into Transition Probabilities

Use historical credit rating input data from Data_TransProb.mat, estimate transition probabilities with default settings.

```
load Data_TransProb
% Estimate transition probabilities with default settings
transMat = transprob(data)
```

## transMat =

## transprobgrouptotals

Aggregate credit ratings information into fewer rating categories

## Syntax

totalsGrouped = transprobgrouptotals(totals,groupingEdges)

## Description

totalsGrouped = transprobgrouptotals(totals,groupingEdges) aggregates the credit ratings information stored in the totals input into fewer ratings categories, which are defined by the groupingEdges argument.

## Input Arguments

## totals

Structure, or a struct array of length nTotals, with fields:

- totalsVeC - A vector of size 1-by-nRatings1.
- totalsMat - A matrix of size nRatings1-by-nRatings2, with nRatings1 $\leq$ nRatings2.
- algorithm - A string with values 'duration' or 'cohort'.

For the 'duration ' algorithm, totalsMat $(i, j)$ contains the total transitions observed out of rating $i$ into rating $j$ (all the diagonal elements are 0 ). The total time spent on rating $i$ is stored in totalsVec $(i)$. For example, if there are three rating categories, Investment Grade (IG), Speculative Grade (SG), and Default (D), and the following information:

| Total time spent | IG | SG | D |  |
| :--- | ---: | ---: | ---: | ---: |
| in rating: | 4859.09 | 1503.36 | 1162.05 |  |
|  |  | IG | SG | D |
| Transitions |  | 0 | 89 | 7 |
| out of (row) | IG | 0 | 0 | 32 |

D 000
Then:

```
totals.totalsVec = [4859.09 1503.36 1162.05]
totals.totalsMat = [ 0 89 7
    202 0 32
    0 0 0]
```

totals.algorithm = 'duration'
For the 'cohort' algorithm, totalsMat $(i, j)$ contains the total transitions observed
from rating $i$ to rating $j$, and totalsVec $(i)$ is the initial count in rating $i$. For
example, given the following information:

| Initial count | IG | SG | D |  |
| :--- | ---: | ---: | ---: | :---: |
| in rating: | 4808 | 1572 | 1145 |  |
|  |  |  |  |  |
| Transitions |  | IG | SG | D |
| from (row) | IG | 4721 | 80 | 7 |
| to (column): | SG | 193 | 1347 | 32 |
|  | D | 0 | 0 | 1145 |

Then:
$\begin{array}{lrr}\text { totals.totalsVec }=[4808 & 1572 & 1145] \\ \text { totals.totalsMat }=[4721 & 80 & 7 \\ 193 & 1347 & 32 \\ 0 & 0 & 1145]\end{array}$
totals.algorithm = 'cohort'

Note: Common totals structures are the optional output arguments from transprob:

- sampleTotals - A single structure summarizing the totals information for the whole dataset.
- idTotals - A struct array with the totals information at the ID level.

For more information, see "Algorithms" on page 18-1397.

## groupingEdges

Numeric array with increasing, positive integers to indicate how to group credit ratings into categories.

This table illustrates how to group a list of whole ratings into investment grade (IG) and speculative grade (SG) categories. Eight ratings are in the original list. Ratings 1 to 4 are

IG, ratings 5 to 7 are SG, and rating 8 is a category of its own. In this example, the array of grouping edges is [lllll 478 .

| Original ratings: 'AAA | A ${ }^{\prime}$ | A' | BBB | BB' | B' | CCC | 'D' |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Relative ordering: (1) | (2) | (3) | (4) | (5) | (6) | (7) | (8) |
| Grouped ratings: |  |  |  |  | SG' |  | 'D' |
| Grouping edges: |  |  | (4) |  |  | (7) | (8) |

In general, if groupingEdges has $K$ elements edge $1<$ edge2 $<\ldots$ edge $K$, ratings 1 to edge1 (inclusive) are grouped in the first category, ratings edge $1+1$ to edge 2 in the second category, and so forth.

Regarding the last element, edge $K$ :

- If $n$ Ratings1 equals $n$ Ratings2, then edge $K$ must equal $n$ Ratings1. This leads to $K$ groups, and $n$ RatingsGrouped $1=n$ RatingsGrouped2 $=K$.
- If $n$ Ratings $1<n$ Ratings2, then either:
- edge $K$ equals $n$ Ratings1, in which case ratings edge $K+1, \ldots, n$ natings2 are treated as categories of their own. This results in $K+($ nRatings2-edge $K$ ) groups, with nRatingsGrouped1 $=K$ and nRatingsGrouped2 $=K+$ (nRatings2 edge $K$ ); or
- edge $K$ equals nRatings2, in which case there must be a $j$ th edge element, edgej, such that edge $j$ equals nRatings1. This leads to $K$ groups, and nRatingsGrouped1 $=j$ and nRatingsGrouped2 $=K$.

## Output Arguments

## totalsGrouped

Structure, or a struct array of length nTotals, with fields:

- totalsVec - A vector of size 1-by-nRatingsGrouped1.
- totalsMat - A matrix of size nRatingsGrouped1-by-nRatingsGrouped2.
- algorithm - A string, 'duration' or 'cohort'.
nRatingsGrouped1 and nRatingsGrouped2 are defined in the description of groupingEdges. Each structure contains aggregated information by categories, based
on the information provided in the corresponding structure in totals, according to the grouping of ratings defined by groupingEdges and consistent with the algorithm choice.

Following the examples in the description of the totals input, suppose IG and SG are grouped into a single ND (Not-Defaulted) category, using the edges[2 3]. For the ' cohort ' algorithm, the output is:

```
totalsGrouped.totalsVec = [6380 1145]
totalsGrouped.totalsMat = [6341 39
    0 1145]
totalsGrouped.algorithm = 'cohort'
and for the 'duration' algorithm:
totalsGrouped.totalsVec = [l6362.45 1162.05]
totalsGrouped.totalsMat = [l0 39
    0 0]
totalsGrouped.algorithm = 'duration'
```

## Examples

## Aggregate the Credit Ratings Information Stored in the totals Input

Use historical credit rating input data from Data_TransProb.mat. Load input data from file Data_TransProb.mat.

```
load Data_TransProb
```

```
% Call TRANSPROB with two output arguments
[transMat, sampleTotals] = transprob(data);
transMat
```

## transMat =

## transprobprep

Preprocess credit ratings data to estimate transition probabilities

## Syntax

```
[prepData] = transprobprep(data)
[prepData] = transprobprep(data, Name,Value)
```

## Description

[prepData] = transprobprep(data) preprocesses credit ratings historical data (that is, credit migration data) for the subsequent estimation of transition probabilities.
[prepData] = transprobprep(data, Name, Value) preprocesses credit ratings historical data (that is, credit migration data) for the subsequent estimation of transition probabilities with additional options specified by one or more Name, Value pair arguments.

## Input Arguments

data
Historical input data for credit ratings. the data input can be one of the following:

- A MATLAB table of size nRecords-by-3 containing the credit ratings. Each row contains an ID (column 1), a date (column 2), and a credit rating (column 3). The assigned credit rating corresponds to the associated ID on the associated date. All information corresponding to the same ID must be stored in contiguous rows. Sorting this information by date is not required, but recommended for efficiency.When using a MATLAB table input, the names of the columns are irrelevant, but the ID, date and rating information are assumed to be in the first, second and third columns, respectively. Also, when using a table input, the first and third columns can be categorical arrays, and the second can be a datetime array. Here is an example with all of the information in table format:

| ID | Date | Rating |
| :---: | :---: | :---: |
| '00010283' | '10-Nov-1984' | 'CCC' |
| '00010283' | '12-May-1986' | 'B' |
| '00010283' | ' 29-Jun-1988' | 'CCC' |
| '00010283' | '12-Dec-1991' | 'D' |
| '00013326' | '09-Feb-1985' | ' ${ }^{\prime}$ ' |
| '00013326' | ' 24-Feb-1994' | ' AA ' |

The following summarizes the supported data types for table input:

| Data Input Type | ID (1 st Column) | Date (2nd Column) | Rating (3rd Column) |
| :---: | :---: | :---: | :---: |
| Table | - Numeric array | - Numeric array | - Numeric array |
|  | - Cell array of strings | - Cell array of strings | - Cell array of strings |
|  | - Categorical array | - Datetime array | - Categorical array |

- A cell array of size nRecords-by-3 containing the credit ratings. Each row contains an ID (column 1), a date (column 2), and a credit rating (column 3). The assigned credit rating corresponds to the associated ID on the associated date. All information corresponding to the same ID must be stored in contiguous rows. Sorting this information by date is not required but is recommended. IDs, dates, and ratings are usually stored in string format, but they can also be entered in numeric format. Here is an example with all of the information in string format:

| '00010283' | $' 10-$ Nov-1984' | 'CCC ' |
| :--- | :--- | :--- |
| '00010283' | '12-May-1986' | 'B' |
| '00010283' | '29-Jun-1988' | 'CCC ' |
| '00010283' | $12-$ Dec-1991' | 'D' |
| '00013326' | '09-Feb-1985' | 'A' |
| '00013326' | $' 24-$ Feb-1994' | 'AA' |

The following summarizes the supported data types for cell array input:

| Data Input Type | ID (1 st Column) | Date (2nd Column) | Rating (3rd Column) |
| :---: | :---: | :---: | :---: |
| Cell | - Numeric elements <br> - String elements | - Numeric elements <br> - String elements | - Numeric elements <br> - String elements |

## Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, . . . NameN, ValueN.

## 'labels'

Cell array of size nRatings-by-1, or 1-by-nRatings, containing the credit-rating scale. It must be consistent with type of the ratings in the third column of data. Use a cell array of numbers for numeric ratings, and a cell array of strings for string or categorical ratings.

Default: \{'AAA','AA', 'A','BBB', 'BB','B', CCC', 'D'\}

## Output Arguments

## prepData

Structure with the following fields:

- idStart - Array of size ( $n$ IDs +1 )-by- 1 , where $n$ IDs is the number of distinct IDs in column 1 of data. This array summarizes where the credit ratings information corresponding to each company starts and ends. The dates and ratings corresponding to company $j$ in data are stored from row idStart $(j)$ to row idStart $(j+1)-1$ of numericDates and numericRatings.
- numericDates - Array of size $n$ Records-by-1, containing the dates in column 2 of data, in numeric format.
- numericRatings - Array of size $n$ Records-by-1, containing the ratings in column 3 of data, mapped into numeric format.
- ratingsLabels - Cell array of size1-by-nRatings, containing the credit rating scale.

## Examples

## Aggregate the Credit Ratings Information Stored in the totals Input

Load input data from the file Data_TransProb.mat and display the first ten rows. In this example, the inputs are provided in string format.

```
load Data_TransProb
% Preprocess credit ratings data.
prepData = transprobprep(data)
prepData =
    idStart: [1506x1 double]
        numericDates: [4315x1 double]
    numericRatings: [4315\times1 double]

## transprobtothresholds

Convert from transition probabilities to credit quality thresholds

## Syntax

```
thresh = transprobtothresholds(trans)
```

## Description

thresh = transprobtothresholds(trans) transforms transition probabilities into credit quality thresholds.

## Input Arguments

## trans

M-by-N matrix with transition probabilities, in percent. Entries cannot be negative and cannot exceed 100, and all rows must add up to 100 .

Any given row in the M -by- N input matrix trans determines a probability distribution over a discrete set of $N$ ratings. If the ratings are 'R1', .., 'RN', then for any row $i$ trans $(i, j)$ is the probability of migrating into ' $R j^{\prime}$. If trans is a standard transition matrix, then $M \leqq N$ and row $i$ contains the transition probabilities for issuers with rating 'Ri'. But trans does not have to be a standard transition matrix. trans can contain individual transition probabilities for a set of $M$-specific issuers, with $M>N$.

The credit quality thresholds thresh $(i, j)$ are critical values of a standard normal distribution $z$, such that:

```
trans(i,N) = P[z< thresh(i,N)],
trans(i,j) = P[z< thresh(i,j)] - P[z<thresh(i,j+1)], for 1<=j<N
```

This implies that thresh $(i, 1)=$ Inf, for all $i$. For example, suppose that there are only $\mathrm{N}=3$ ratings, 'High ', 'Low', and 'Default', with the following transition probabilities:

```
High Low Default
```

| High | 98.13 | 1.78 | 0.09 |
| :--- | ---: | ---: | ---: |
| Low | 0.81 | 95.21 | 3.98 |

The matrix of credit quality thresholds is:

|  | High | Low | Default |
| :--- | :--- | ---: | :---: |
| High | Inf | -2.0814 | -3.1214 |
| Low | Inf | 2.4044 | -1.7530 |

This means the probability of default for 'High' is equivalent to drawing a standard normal random number smaller than -3.1214 , or $0.09 \%$. The probability that a 'High ' ends up the period with a rating of 'Low' or lower is equivalent to drawing a standard normal random number smaller than -2.0814 , or $1.87 \%$. From here, the probability of ending with a 'Low' rating is:
$P[z<-2.0814]-P[z<-3.1214]=1.87 \%-0.09 \%=1.78 \%$
And the probability of ending with a 'High ' rating is:
$100 \%-1.87 \%=98.13 \%$
where $100 \%$ is the same as:
$\mathrm{P}[z<\operatorname{Inf}]$

## Output Arguments

## thresh

M-by-N matrix of credit quality thresholds.

## Examples

## Transform Transition Probabilities Into Credit Quality Thresholds

Use historical credit rating input data from Data_TransProb. mat. Load input data from file Data_TransProb.mat.

```
load Data_TransProb
% Estimate transition probabilities with default settings
transMat = transprob(data)
```

## ts2func

Convert time series arrays to functions of time and state

## Syntax

F = ts2func (Array)
F = ts2func(Array, 'Name1', Value1, 'Name2', Value2, ...)

## Description

The ts2func function encapsulates a time series array associated with a vector of realvalued observation times within a MATLAB function suitable for Monte Carlo simulation of an NVARS-by- 1 state vector $X_{t}$.

## Input Arguments

| Array | Time series array to encapsulate within a callable function of time and <br> state. Array may be a vector, 2-dimensional matrix, or three-dimensional <br> array. |
| :--- | :--- |

## Optional Input Arguments

Specify optional input arguments as variable-length lists of matching parameter name/ value pairs: 'Name1', Value1, 'Name2', Value2, ... and so on. The following rules apply when specifying parameter-name pairs:

- Specify the parameter name as a character string, followed by its corresponding parameter value.
- You can specify parameter name/value pairs in any order.
- Parameter names are case insensitive.
- You can specify unambiguous partial string matches.

Valid parameter names are:

| Times | Vector of monotonically increasing observation times associated <br> with the time series input array Array. If you do not specify a <br> value for this argument, Times is a zero-based, unit-increment <br> vector of the same length as that of the dimension of Array <br> associated with time (see TimeDimension). |
| :--- | :--- |
| TimeDimension | Positive scalar integer that specifies which dimension of the <br> input time series array Array is associated with time. The <br> value of this argument cannot be greater than the number <br> of dimensions of Array. If you do not specify a value for this <br> argument, the default is 1, indicating that time is associated <br> with the rows of Array. |
| StateDimension | Positive scalar integer that specifies which dimension of the <br> input time series array Array is associated with the NVARS <br> state variables. StateDimension cannot be greater than the <br> number of dimensions of Array. If you do not specify a value <br> for this argument, ts2func assigns StateDimension the first <br> dimension of Array that is not already associated with time (the <br> state vector $X_{t}$ is associated with the first available dimension of <br> Array not already assigned to TimeDimension). |
| Deterministic | A scalar, logical flag to indicate whether the output function <br> is a deterministic function of time alone. If Deterministic is <br> true, the output function F is a deterministic function of time, <br> $F(t)$, and the only input it accepts is a scalar, real-valued time <br> $t$ If Deterministic is false, the output function F accepts two <br> inputs, a scalar, real-valued time $t$ followed by an NVARS-by-1 <br> state vector $X(t)$. The default is false, and F is a callable function <br> of time and state, $F(t, X)$. |

## Output Arguments

| F | Callable function $F(t)$ of a real-valued scalar observation time $t$. <br> You can invoke $F$ with a second input (such as an NVARS-by-1 state <br> vector $X$ ), which is a placeholder that ts2func ignores. For example, <br> while $F(t)$ and $F(t, X)$ produce identical results, the latter directly <br> supports SDE simulation methods. If the optional input argument <br> Deterministic is true, F is a deterministic function of time, $F(t)$, and <br> the only input it accepts is a scalar, real-valued time $t$. Otherwise, if |
| :--- | :--- |

Deterministic is false (the default), F accepts a scalar, real-valued time $t$ followed by an NVARS-by- 1 state vector $X(t)$.

## More About

## Algorithms

- When you specify Array as a trivial scalar or a vector (row or column), ts2func assumes that it represents a univariate time series.
- F returns an array with one fewer dimension than the input time series array Array with which F is associated. Thus, when Array is a vector, a 2 -dimensional matrix, or a three-dimensional array, $F$ returns a scalar, vector, or 2 -dimensional matrix, respectively.
- When the scalar time $t$ at which ts2func evaluates the function $F$ does not coincide with an observation time in Times, F performs a zero-order-hold interpolation. The only exception is if $t$ precedes the first element of Times, in which case $F(t)=$ $F($ Times(1)).
- To support Monte Carlo simulation methods, the output function F returns an NVARS-by-1 column vector or a 2-dimensional matrix with NVARS rows.
- The output function F is always a deterministic function of time, $F(t)$, and may always be called with a single input regardless of the Deterministic flag. The distinction is that when Deterministic is false, the function $F$ may also be called with a second input, an NVARS-by- 1 state vector $X(t)$, which is a placeholder and ignored. While $F(t)$ and $F(t, X)$ produce identical results, the former specifically indicates that the function is a deterministic function of time, and may offer significant performance benefits in some situations.

## Introduced in R2008a

## tsaccel

Acceleration between times

## Syntax

```
acc = tsaccel(data, nTimes, datatype)
```

accts $=$ tsaccel(tsobj, nTimes, datatype)

## Arguments

| data | Data series. |
| :--- | :--- |
| nTimes | (Optional) Number of times. Default = 12. |
| datatype | (Optional) Indicates whether data contains the data itself or the <br> momentum of the data: <br> $0=$ Data contains the data itself (default). <br> $1=$ Data contains the momentum of the data. |
| tsobj | Name of an existing financial time series object. |

## Description

Acceleration is the difference of two momentums separated by some number of periods.
acc $=$ tsaccel(data, nTimes, datatype) calculates the acceleration of a data series, essentially the difference of the current momentum with the momentum some number of periods ago. If $n$ Times is specified, tsaccel calculates the acceleration of a data series data with time distance of nTimes times.
accts = tsaccel(tsobj, nTimes, datatype) calculates the acceleration of the data series in the financial time series object tsobj, essentially the difference of the current momentum with the momentum some number of periods ago. Each data series in
tsobj is treated individually. accts is a financial time series object with similar dates and data series names as tsobj.

Note, to compute a quantity over n periods, you must specify $\mathrm{n}+1$ for nTimes . If you specify nTimes $=0$, the function returns your original time series.

## Examples

## Calculate the Acceleration of a Data Series

This example shows how to calculate the acceleration of a data series for Disney stock and plot the results.

```
load disney.mat
dis = rmfield(dis,'VOLUME'); % remove VOLUME field
dis_Accel = tsaccel(dis);
plot(dis_Accel)
title('Acceleration for Disney')
```

tsmom

Introduced before R2006a

## tsmom

Momentum between times

## Syntax

```
mom = tsmom(data, nTimes)
momts = tsmom(tsobj, nTimes)
```

## Arguments

| data | Data series. Column-oriented vector or matrix. |
| :--- | :--- |
| nTimes | (Optional) Number of times. Default $=12$. |
| tsobj | Financial time series object. |

## Description

Momentum is the difference between two prices (data points) separated by a number of times.
mom = tsmom(data, nTimes) calculates the momentum of a data series data. If nTimes is specified, tsmom uses that value instead of the default 12.
momts $=$ tsmom(tsobj, nTimes) calculates the momentum of all data series in the financial time series object tsobj. Each data series in tsobj is treated individually. momts is a financial time series object with similar dates and data series names as tsobj. If nTimes is specified, tsmom uses that value instead of the default 12.

Note, to compute a quantity over n periods, you must specify $\mathrm{n}+1$ for nTimes. If you specify $n$ Times $=0$, the function returns your original time series.

## Examples

## Calculate the Momentum of a Data Series

This example shows how to calculate the momentum of a data series for Disney stock and plot the results.

```
load disney.mat
dis = rmfield(dis,'VOLUME'); % remOve VOLUME field
dis_Mom = tsmom(dis);
plot(dis_Mom)
title('Mömentum for Disney')
```

Momentum for Disney

See Also<br>tsaccel<br>Introduced before R2006a

## tsmovavg

Moving average
tsmovavg calculates the simple, exponential, triangular, weighted, and modified moving average of a vector or fints object of data. For information on working with financial time series (fints objects) data, see "Working with Financial Time Series Objects" on page 12-3.

## Syntax

```
output = tsmovavg(tsobj,'s',lag,dim)
output = tsmovavg(vector,'s',lag,dim)
output = tsmovavg(tsobj,'e',timeperiod,dim)
output = tsmovavg(vector,'e',timeperiod,dim)
output = tsmovavg(tsobj,'t',numperiod,dim)
output = tsmovavg(vector,'t',numperiod,dim)
output = tsmovavg(tsobj,'w',weights,dim)
output = tsmovavg(vector,'w',weights,dim)
output = tsmovavg(tsobj,'m',numperiod,dim)
output = tsmovavg(vector,'m',numperiod,dim)
```

## Description

output = tsmovavg(tsobj,'s',lag, dim) returns the simple moving average for financial time series object, tsobj. lag indicates the number of previous data points used with the current data point when calculating the moving average.
output = tsmovavg(vector,'s',lag,dim) returns the simple moving average for a vector. lag indicates the number of previous data points used with the current data point when calculating the moving average.
output = tsmovavg(tsobj, 'e',timeperiod, dim) returns the exponential weighted moving average for financial time series object, tsobj. The exponential moving
average is a weighted moving average, where timeperiod specifies the time period. Exponential moving averages reduce the lag by applying more weight to recent prices. For example, a 10 -period exponential moving average weights the most recent price by 18.18\%. (2/(timeperiod + 1)).
output = tsmovavg(vector,'e',timeperiod, dim) returns the exponential weighted moving average for a vector. The exponential moving average is a weighted moving average, where timeperiod specifies the time period. Exponential moving averages reduce the lag by applying more weight to recent prices. For example, a 10 -period exponential moving average weights the most recent price by $18.18 \%$. ( 2 / (timeperiod + 1)).
output = tsmovavg(tsobj,'t', numperiod, dim) returns the triangular moving average for financial time series object, tsobj. The triangular moving average doublesmooths the data. tsmovavg calculates the first simple moving average with window width of ceil (numperiod +1 )/2. Then it calculates a second simple moving average on the first moving average with the same window size.
output = tsmovavg(vector,'t', numperiod, dim) returns the triangular moving average for a vector. The triangular moving average double-smooths the data. tsmovavg calculates the first simple moving average with window width of ceil(numperiod + 1) /2. Then it calculates a second simple moving average on the first moving average with the same window size.
output = tsmovavg(tsobj, 'w', weights, dim) returns the weighted moving average for the financial time series object, tsobj, by supplying weights for each element in the moving window. The length of the weight vector determines the size of the window. If larger weight factors are used for more recent prices and smaller factors for previous prices, the trend is more responsive to recent changes.
output = tsmovavg(vector,'w',weights, dim) returns the weighted moving average for the vector by supplying weights for each element in the moving window. The length of the weight vector determines the size of the window. If larger weight factors are used for more recent prices and smaller factors for previous prices, the trend is more responsive to recent changes.
output = tsmovavg(tsobj, 'm', numperiod, dim) returns the modified moving average for the financial time series object, tsobj. The modified moving average is similar to the simple moving average. Consider the argument numperiod to be the lag of the simple moving average. The first modified moving average is calculated like a
simple moving average. Subsequent values are calculated by adding the new price and subtracting the last average from the resulting sum.
output = tsmovavg(vector,'m', numperiod,dim) returns the modified moving average for the vector. The modified moving average is similar to the simple moving average. Consider the argument numperiod to be the lag of the simple moving average. The first modified moving average is calculated like a simple moving average. Subsequent values are calculated by adding the new price and subtracting the last average from the resulting sum.

## Examples

## Compute Five Forms of Moving Averages Using a Financial Time Series Object

Load the financial time series object, dis for Disney stock and look at the weekly data for this time series.

```
load disney.mat
weekly = toweekly(dis);
dates = (weekly.dates);
price = fts2mat(weekly.CLOSE);
```

Set the |lag| input argument for the window size for the moving average.

```
window_size = 12;
```

Calculate the simple moving average.

```
simple = tsmovavg(price,'s',window_size,1);
```

Calculate the simple moving average.

```
simple = tsmovavg(price,'s',window_size,1);
```

Calculate the exponential weighted moving average moving average.

```
exp = tsmovavg(price,'e',window_size,1);
```

Calculate the triangular moving average moving average.
tri = tsmovavg(price,'t',window_size,1);

Calculate the weighted moving average moving average.

```
semi_gaussian = [0.026 0.045 0.071 0.1 0.12 0.138];
semi_gaussian = [semi_gaussian fliplr(semi_gaussian)];
weighted = tsmovavg(price,'w',semi_gaussian,1);
```

Calculate the modified moving average moving average.

```
modif = tsmovavg(price,'m',window_size,1);
```

Plot the results for the five moving average calculations for Disney stock.

```
plot(dates,price,...
    dates,simple,...
    dates,exp,...
    dates,tri,...
    dates,weighted,...
    dates,modif)
datetick
legend('Stock Price','Simple','Exponential','Triangular','Weighted',...
    'Modified','Location','NorthWest')
title('Disney Weekly Price & Moving Averages')

## Input Arguments

## tsobj - Financial time series object

object
Financial time series object specified using a time series object created using fints.

## lag - Number of previous data points <br> nonnegative integer

Number of previous data points specified as a nonnegative integer. Lag indicates the window size or number of periods of the moving average.

## vector - Set of observations

vector or matrix
Set of observations specified as a vector or matrix.

## dim - dimension to operate along <br> positive integer with value 1 or 2

Dimension to operate along, specified as a positive integer with a value of 1 or 2 . dim is an optional input argument, and if it is not included as an input, the default value 2 is assumed. The default of dim = 2 indicates a row-oriented matrix, where each row is a variable and each column is an observation.

If $\operatorname{dim}=1$, the input is assumed to be a column vector or column-oriented matrix, where each column is a variable and each row an observation.

## timeperiod - Length of time period

nonnegative integer
Length of time period specified as a nonnegative integer.

## numperiod - Number of periods considered

nonnegative integer
Number of periods considered specified as a nonnegative integer.
weights - Weights for each element in the moving window
vector of weights

Weights for each element in the window specified as a vector of weights.

## Output Arguments

## output - Moving average calculation

vector or matrix
Moving average calculation returned as a vector or matrix. The output returned from tsmovavg is identical in format to the input.

## typprice

Typical price

## Syntax

```
tprc = typprice(highp, lowp, closep)
tprc = typprice([highp lowp closep])
tprcts = typprice(tsobj)
tprcts = typprice(tsobj, 'ParameterName', ParameterValue, ...)
```

## Arguments

| highp | High price (vector). |
| :--- | :--- |
| lowp | Low price (vector). |
| closep | Closing price (vector). |
| tsobj | Financial time series object. |

## Description

tprc = typprice(highp, lowp, closep) calculates the typical prices tprc from the high (highp), low (lowp), and closing (closep) prices. The typical price is the average of the high, low, and closing prices for each period.
tprc = typprice([highp lowp closep]) accepts a three-column matrix as the input rather than two individual vectors. The columns of the matrix represent the high, low, and closing prices, in that order.
tprcts = typprice(tsobj) calculates the typical prices from the stock data contained in the financial time series object tsobj. The object must contain, at least, the High, Low, and Close data series. The typical price is the average of the closing price
plus the high and low prices. tprcts is a financial time series object of the same dates as tsobj containing the data series TypPrice.
tprcts = typprice(tsobj, 'ParameterName', ParameterValue, ...) accepts parameter name/parameter value pairs as input. These pairs specify the name(s) for the required data series if it is different from the expected default name(s). Valid parameter names are

- HighName: high prices series name
- LowName: low prices series name
- CloseName: closing prices series name

Parameter values are the strings that represent the valid parameter names.

## Examples

## Compute the Typical Price

This example shows how to compute the typical price for Disney stock and plot the results.

```
load disney.mat
dis_Typ = typprice(dis);
plot}(dis_Typ
title('Typical Price for Disney')
```

## ugarch

Univariate GARCH $(\mathrm{P}, \mathrm{Q})$ parameter estimation with Gaussian innovations
As an alternative to ugarch, use the garch object to create conditional variance models. For more information, see "Specify GARCH Models Using garch".

## Compatibility

ugarch will be removed in a future release. Use the garch object to create conditional variance models and the estimate function to fit conditional variance models to data. For more information, see "Likelihood Ratio Test for Conditional Variance Models".

## Syntax

[Kappa, Alpha, Beta] = ugarch(U, P, Q)

## Arguments

| U | Single column vector of random disturbances, that is, the residuals or <br> innovations $\left(\varepsilon_{\mathrm{t}}\right)$, of an econometric model representing a mean-zero, <br> discrete-time stochastic process. The innovations time series $U$ is assumed <br> to follow a GARCH(P,Q) process. |
| :--- | :--- |
|  | Note: The latest value of residuals is the last element of vector U. |
| P | Nonnegative, scalar integer representing a model order of the GARCH <br> process. $P$ is the number of lags of the conditional variance. P can be zero; <br> when $P=0$, a GARCH $(0, Q)$ process is actually an ARCH(Q) process. |
| Q | Positive, scalar integer representing a model order of the GARCH process. <br> Q is the number of lags of the squared innovations. |

## Description

[Kappa, Alpha, Beta] = ugarch(U, P, Q) computes estimated univariate GARCH $(\mathrm{P}, \mathrm{Q})$ parameters with Gaussian innovations.

Kappa is the estimated scalar constant term ([[KAPPA]]) of the GARCH process.
Alpha is a P-by- 1 vector of estimated coefficients, where $P$ is the number of lags of the conditional variance included in the GARCH process.

Beta is a $Q$-by- 1 vector of estimated coefficients, where $Q$ is the number of lags of the squared innovations included in the GARCH process.

The time-conditional variance, $\sigma_{t}^{2}$, of a $\operatorname{GARCH}(\mathrm{P}, \mathrm{Q})$ process is modeled as

$$
\sigma_{t}^{2}=K+\sum_{i=1}^{P} \alpha_{i} \sigma_{t-i}^{2}+\sum_{j=1}^{Q} \beta_{j} \varepsilon_{t-j}^{2}
$$

where $\alpha$ represents the argument Alpha, $\beta$ represents Beta, and the GARCH(P, Q) coefficients $\{K, \alpha, \beta\}$ are subject to the following constraints.

$$
\begin{aligned}
& \sum_{i=1}^{P} \alpha_{i}+\sum_{j=1}^{Q} \beta_{j}<1 \\
& K>0 \\
& \alpha_{i} \geq 0 \quad i=1,2, \ldots, P \\
& \beta_{j} \geq 0 \quad j=1,2, \ldots, Q .
\end{aligned}
$$

Note that U is a vector of residuals or innovations $\left(\varepsilon_{t}\right)$ of an econometric model, representing a mean-zero, discrete-time stochastic process.

Although $\sigma_{t}^{2}$ is generated using the equation above, $\varepsilon^{t}$ and $\sigma_{t}^{2}$ are related as

$$
\varepsilon_{t}=\sigma_{t} v_{t}
$$

where $\left\{v_{t}\right\}$ is an independent, identically distributed (iid) sequence $\sim \mathrm{N}(0,1)$.

Note The Econometrics Toolbox software provides a comprehensive and integrated computing environment for the analysis of volatility in time series. For information, see the Econometrics Toolbox documentation or the financial products Web page at http:// www.mathworks.com/products/finprod/.

## Examples

See ugarchsim for an example of a $\operatorname{GARCH}(\mathrm{P}, \mathrm{Q})$ process.

## ugarchllf

Log-likelihood objective function of univariate $\operatorname{GARCH}(\mathrm{P}, \mathrm{Q})$ processes with Gaussian innovations

## Compatibility

ugarchllf will be removed in a future release. Use the garch object to create conditional variance models. For more information, see "Specify GARCH Models Using garch".

## Syntax

LogLikelihood = ugarchllf(Parameters, U, P, Q)

## Arguments

| Parameters | $(1+P+Q)$-by-1 column vector of GARCH(P,Q) process <br> parameters. The first element is the scalar constant term <br> $[[K A P P A]]$ of the GARCH process; the next P elements are <br> coefficients associated with the P lags of the conditional variance <br> terms; the next Q elements are coefficients associated with the Q <br> lags of the squared innovations terms. |
| :--- | :--- |
| U | Single column vector of random disturbances, that is, the residuals <br> or innovations $\left(\varepsilon_{t}\right)$ of an econometric model representing a mean- <br> zero, discrete-time stochastic process. The innovations time series U <br> is assumed to follow a GARCH $(P, Q)$ process. |
| P | Note: The latest value of residuals is the last element of vector U. |
| Nonnegative, scalar integer representing a model order of the <br> GARCH process. P is the number of lags of the conditional variance. <br> P can be zero; when P = 0, a GARCH(0,Q) process is actually an <br> ARCH(Q) process. |  |

```
Q Positive, scalar integer representing a model order of the GARCH process. \(Q\) is the number of lags of the squared innovations.
```

## Description

LogLikelihood = ugarchllf(Parameters, U, P, Q) computes the log-likelihood objective function of univariate $\operatorname{GARCH}(\mathrm{P}, \mathrm{Q})$ processes with Gaussian innovations.

LogLikelihood is a scalar value of the $\operatorname{GARCH}(\mathrm{P}, \mathrm{Q})$ log-likelihood objective function given the input arguments. This function is meant to be optimized via the fmincon function of the Optimization Toolbox software.
fmincon is a minimization routine. To maximize the log-likelihood function, the LogLikelihood output parameter is actually the negative of what is formally presented in most time series or econometrics references.

The time-conditional variance, $\sigma_{t}^{2}$, of a $\operatorname{GARCH}(\mathrm{P}, \mathrm{Q})$ process is modeled as

$$
\sigma_{t}^{2}=K+\sum_{i=1}^{P} \alpha_{i} \sigma_{t-i}^{2}+\sum_{j=1}^{Q} \beta_{j} \varepsilon_{t-j}^{2}
$$

where $\alpha$ represents the argument Alpha, and $\beta$ represents Beta.
U is a vector of residuals or innovations $\left(\varepsilon_{t}\right)$ representing a mean-zero, discrete time stochastic process. Although $\sigma_{t}^{2}$ is generated via the equation above, $\varepsilon^{t}$ and $\sigma_{t}^{2}$ are related as

$$
\varepsilon_{t}=\sigma_{t} v_{t}
$$

where $\left\{v_{t}\right\}$ is an independent, identically distributed (iid) sequence $\sim \mathrm{N}(0,1)$.
Since ugarchllf is really just a helper function, no argument checking is performed. This function is not meant to be called directly from the command line.

Note The Econometrics Toolbox software provides a comprehensive and integrated computing environment for the analysis of volatility in time series. For information, see
the Econometrics Toolbox documentation or the financial products Web page at http:// www.mathworks.com/products/finprod/.

## ugarchpred

Forecast conditional variance of univariate $\operatorname{GARCH}(\mathrm{P}, \mathrm{Q})$ processes
As an alternative to ugarchpred, use the garch object to create conditional variance models. For more information, see "Specify GARCH Models Using garch".

## Compatibility

ugarchpred will be removed in a future release. Use garch object to create conditional variance models and the forecast function to generate minimum mean square error forecasts. For more information, see "Forecast a Conditional Variance Model".

## Syntax

[VarianceForecast, H] = ugarchpred(U, Kappa, Alpha, Beta, NumPeriods)

## Arguments

| U | Single column vector of random disturbances, that is, the residuals <br> or innovations $\left(\varepsilon_{t}\right)$ of an econometric model representing a mean- <br> zero, discrete-time stochastic process. The innovations time series U <br> is assumed to follow a GARCH(P,Q) process. |
| :--- | :--- |
| Note: The latest value of residuals is the last element of vector U. |  |
| Kappa | Scalar constant term [[KAPPA]] of the GARCH process. |
| Alpha | P-by-1 vector of coefficients, where P is the number of lags of the <br> conditional variance included in the GARCH process. Alpha can <br> be an empty matrix, in which case P is assumed 0; when P $=0$, a <br> GARCH $(0, Q)$ process is actually an ARCH(Q) process. |
| Beta | Q-by-1 vector of coefficients, where Q is the number of lags of the <br> squared innovations included in the GARCH process. |

| NumPeriods | Positive, scalar integer representing the forecast horizon of interest, <br> expressed in periods compatible with the sampling frequency of the <br> input innovations column vector $U$. |
| :--- | :--- |

## Description

[VarianceForecast, H] = ugarchpred(U, Kappa, Alpha, Beta, NumPeriods) forecasts the conditional variance of univariate GARCH (P,Q) processes.

VarianceForecast is a number of periods (NUMPERIODS-by-1) vector of the minimum mean-square error forecast of the conditional variance of the innovations time series vector $U\left(\right.$ that is, $\left.\varepsilon_{t}\right)$. The first element contains the 1-period-ahead forecast, the second element contains the 2-period-ahead forecast, and so on. Thus, if a forecast horizon greater than 1 is specified (NUMPERIODS > 1), the forecasts of all intermediate horizons are returned as well. In this case, the last element contains the variance forecast of the specified horizon, NumPeriods from the most recent observation in $U$.

H is a vector of the conditional variances $\left(\sigma_{\mathrm{t}}^{2}\right)$ corresponding to the innovations vector $U$. It is inferred from the innovations $U$, and is a reconstruction of the "past" conditional variances, whereas the VarianceForecast output represents the projection of conditional variances into the "future." This sequence is based on setting pre-sample values of $\sigma_{t}{ }^{2}$ to the unconditional variance of the $\left\{\varepsilon_{t}\right\}$ process. $H$ is a single column vector of the same length as the input innovations vector $U$.

The time-conditional variance, $\sigma_{t}^{2}$, of a $\operatorname{GARCH}(\mathrm{P}, \mathrm{Q})$ process is modeled as

$$
\sigma_{t}^{2}=K+\sum_{i=1}^{P} \alpha_{i} \sigma_{t-i}^{2}+\sum_{j=1}^{Q} \beta_{j} \varepsilon_{t-j}^{2}
$$

where $\alpha$ represents the argument Alpha, $\beta$ represents Beta, and the GARCH $(\mathrm{P}, \mathrm{Q})$ coefficients $\{K, \alpha, \beta\}$ are subject to the following constraints.

$$
\begin{array}{ll}
\sum_{i=1}^{P} \alpha_{i}+\sum_{j=1}^{Q} \beta_{j}<1 \\
K>0 & \\
\alpha_{i} \geq 0 & \quad i=1,2, \ldots, P \\
\beta_{j} \geq 0 & j=1,2, \ldots, Q .
\end{array}
$$

Note that U is a vector of residuals or innovations $\left(\varepsilon_{t}\right)$ of an econometric model, representing a mean-zero, discrete-time stochastic process.

Although $\sigma_{t}^{2}$ is generated using the equation above, $\varepsilon^{t}$ and $\sigma_{t}^{2}$ are related as

$$
\varepsilon_{t}=\sigma_{t} v_{t}
$$

where $\left\{v_{t}\right\}$ is an independent, identically distributed (iid) sequence $\sim \mathrm{N}(0,1)$.

Note The Econometrics Toolbox software provides a comprehensive and integrated computing environment for the analysis of volatility in time series. For information, see the Econometrics Toolbox documentation or the financial products Web page at http:// www.mathworks.com/products/finprod/.

## Compatibility

ugarchsim will be removed in a future release. Use garch object to create conditional variance models and the simulate function to generate Monte Carlo simulations from conditional variance models. For more information, see "Simulate Conditional Variance Model".

## Syntax

[U, H] = ugarchsim(Kappa, Alpha, Beta, NumSamples)

## Arguments

| Kappa | Scalar constant term [[KAPPA]] of the GARCH process. |
| :--- | :--- |
| Alpha | P-by-1 vector of coefficients, where P is the number of lags of the <br> conditional variance included in the GARCH process. Alpha can <br> be an empty matrix, in which case P is assumed 0; when $P=0, a$ <br> GARCH $(0, Q)$ process is actually an ARCH(Q) process. |
| Beta | Q-by-1 vector of coefficients, where Q is the number of lags of the <br> squared innovations included in the GARCH process. |
| NumSamples | Positive, scalar integer indicating the number of samples of the <br> innovations U and conditional variance H (see below) to simulate. |

## Description

[U, H] = ugarchsim(Kappa, Alpha, Beta, NumSamples) simulates a univariate GARCH $(\mathrm{P}, \mathrm{Q})$ process with Gaussian innovations.

U is a number of samples (NUMSAMPLES)-by- 1 vector of innovations $\left(\varepsilon_{t}\right)$, representing a mean-zero, discrete-time stochastic process. The innovations time series $U$ is designed to follow the $\operatorname{GARCH}(\mathrm{P}, \mathrm{Q})$ process specified by the inputs Kappa, Alpha, and Beta.

H is a NUMSAMPLES-by- 1 vector of the conditional variances ( $\sigma_{t}^{2}$ ) corresponding to the innovations vector $U$. Note that $U$ and $H$ are the same length, and form a "matching" pair of vectors. As shown in the following equation, $\sigma_{t}^{2}$ (that is, $\mathrm{H}(\mathrm{t})$ ) represents the time series inferred from the innovations time series $\left\{\varepsilon_{t}\right\}$ (that is, U ).

The time-conditional variance, $\sigma_{t}^{2}$, of a $\operatorname{GARCH}(\mathrm{P}, \mathrm{Q})$ process is modeled as

$$
\sigma_{t}^{2}=K+\sum_{i=1}^{P} \alpha_{i} \sigma_{t-i}^{2}+\sum_{j=1}^{Q} \beta_{j} \varepsilon_{t-j}^{2}
$$

where a represents the argument Alpha, $B$ represents Beta, and the GARCH $(\mathrm{P}, \mathrm{Q})$ coefficients $\{K, a, \beta\}$ are subject to the following constraints.

$$
\begin{aligned}
& \sum_{i=1}^{P} \alpha_{i}+\sum_{j=1}^{Q} \beta_{j}<1 \\
& K>0 \\
& \alpha_{i} \geq 0 \quad i=1,2, \ldots, P \\
& \beta_{j} \geq 0 \quad j=1,2, \ldots, Q .
\end{aligned}
$$

Note that U is a vector of residuals or innovations $\left(\varepsilon_{t}\right)$ of an econometric model, representing a mean-zero, discrete-time stochastic process.

Although $\sigma_{t}^{2}$ is generated using the equation above, $\varepsilon^{t}$ and $\sigma_{t}^{2}$ are related as

$$
\varepsilon_{t}=\sigma_{t} v_{t}
$$

where $\left\{v_{t}\right\}$ is an independent, identically distributed (iid) sequence $\sim \mathrm{N}(0,1)$.
The output vectors U and H are designed to be steady-state sequences in which transients have arbitrarily small effect. The (arbitrary) metric used by ugarchsim strips the first N
samples of U and H such that the sum of the GARCH coefficients, excluding Kappa, raised to the Nth power, does not exceed 0.01 .

```
0.01 = (sum(Alpha) + sum(Beta) )^N
```

Thus

$$
N=\log (0.01) / \log ((\text { sum(Alpha) }+\operatorname{sum}(\text { Beta })))
$$

Note The Econometrics Toolbox software provides a comprehensive and integrated computing environment for the analysis of volatility in time series. For information see the Econometrics Toolbox documentation or the financial products Web page at http:// www.mathworks.com/products/finprod/.

## Examples

```
This example simulates a GARCH(P,Q) process with P = 2 and Q = 1.
% Set the random number generator seed for reproducability.
rng('default')
% Set the simulation parameters of GARCH(P,Q) = GARCH(2,1) process.
Kappa = 0.25; %a positive scalar.
Alpha = [0.2 0.1]'; %a column vector of nonnegative numbers (P = 2).
Beta = 0.4; %Q = 1.
NumSamples = 500; % number of samples to simulate.
% Now simulate the process.
[U , H] = ugarchsim(Kappa, Alpha, Beta, NumSamples);
% Estimate the process parameters.
P = 2; % Model order P (P = length of Alpha).
Q = 1; % Model order Q (Q = length of Beta).
[k, a, b] = ugarch(U , P , Q);
disp(' ')
disp(' Estimated Coefficients:')
disp(' ----------------------')
disp([k; a; b])
disp(' ')
% Forecast the conditional variance using the estimated
% coefficients.
NumPeriods = 10; % Forecast out to 10 periods.
[VarianceForecast, H1] = ugarchpred(U, k, a, b, NumPeriods);
disp(' Variance Forecasts:')
disp(' -----------------'')
```

## disp(VarianceForecast) <br> disp(' ')

When the above code is executed, the screen output looks like the display shown.

## vicalendar

Graphical calendar

## Syntax

```
uicalendar('PARAM1', VALUE1, 'PARAM2', VALUE2', ...)
```

## Arguments

| 'BusDays' | Values are: <br> - 0 - (Default) Standard calendar without nonbusiness day indicators. <br> - 1 - Marks NYSE nonbusiness days in red. |
| :---: | :---: |
| 'BusDaySelect' | Values are: <br> - 0 - Only allow selection of business days. Nonbusiness days are determined from the following parameters: <br> - 'BusDays' <br> - 'Holiday' <br> - 'Weekend' <br> - 1 - (Default) Allows selections of business and nonbusiness days. |
| 'DateBoxColor' | [date R G B] : Sets the color of the date squares to the specified [R G B] color. |
| 'DateStrColor' | [date R G B] : Sets the color of the numeric date number in the date square to the specified [R G B] color. |
| 'DestinationUI' | Values are: <br> - H - Scalar or vector of the destination object's handles. The default UI property that is populated with the date(s) is 'string'. |

|  | - \{H, \{Prop\}\} - Cell array of handles and the destination object's UI properties. H must be a scalar or vector and Prop must be a single property string or a cell array of property strings. |
| :---: | :---: |
| 'Holiday' | Sets the specified holiday dates into the calendar. The corresponding date string of the holiday will appear Red. The Date(s) must be a scalar or vector of datenums. |
| 'InitDate' | Values are: <br> - Datenum - Numeric date value specifying the initial start date when the calendar is initialized. The default date is TODAY. <br> - Datestr - Date string value specifying the initial start date when the calendar is initialized. Datestr must include a Year, Month, and Day (for example, 01-Jan-2006). |
| 'InputDateFormat' | Format - Sets the format of initial start date, InitDate. See 'help datestr' for date format values. |
| 'OutputDateFormat' | Format - Sets the format of output date string. See 'help datestr' for date format values. |
| 'OutputDateStyle' | Values are: <br> - 0 - (Default) Returns a single date string or a cell array (row) of date string. For example, \{'01-Jan-2001, 02-Jan-2001, ...'\}. <br> - 1 - Returns a single date string or a cell (column) array of date strings. For example, \{ '01-Jan-2001; 02-Jan-2001; ...'\}. <br> - 2 - Returns a string representation of a row vector of datenums. For example, ' [732758, 732759, 732760, 732761]'. <br> - 3 - Returns a string representation of a column vector of datenums. For example, ' [732758; 732759; 732760; 732761]'. |

| 'SelectionType' | Values are: <br> - 0 - Allows multiple date selections. <br> - 1 - (Default) Allows only a single date selection. |
| :---: | :---: |
| 'Weekend ' | DayOfWeek - Sets the specified days of the week as weekend days. Weekend days are marked in red. DayOfWeek can be a vector containing the following numeric values: <br> - 1 -Sunday <br> - 2 -Monday <br> - 3 -Tuesday <br> - 4 -Wednesday <br> - 5 -Thursday <br> - 6 - Friday <br> - 7 - Saturday <br> Also this value can be a vector of length 7 containing 0's and 1 's. The value 1 indicates a weekend day. The first element of this vector corresponds to Sunday. For example, when Saturday and Sunday are weekend days then WEEKEND = [ 10 $00001]$. |
| 'WindowStyle' | Values are: <br> - Normal - (Default) Standard figure properties. <br> - Modal - Modal figures remain stacked above all normal figures and the MATLAB Command Window. |

## Description

uicalendar('PARAM1', VALUE1, 'PARAM2', VALUE2', ...) supports a customizable graphical calendar that interfaces with uicontrols. uicalendar populates uicontrols with user-selected dates.

## Examples

Create a uicontrol:

```
textH1 = uicontrol('style', 'edit', 'position', [10 10 100 20]);
```

Call UICalendar:

```
uicalendar('DestinationUI', {textH1, 'string'})
```

Select a date and click ' $O K$ '.

| - U UICalendar |  |  |  | - $\square \times$ |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  |  |  | 07 | $\checkmark$ | - |
| Su | Mo | Tu | ave | Th | Fr | Sa |
| 29 | 30 | 1 | 2 | 3 | 4 | 5 |
| 6 | 7 | 8 | 9 | 10 | 11 | 12 |
| 13 | 14 | 15 | 16 | 17 | 18 | 19 |
| 20 | 21 | 22 | 23 | 24 | 25 | 26 |
| 27 | 28 | 29 | 30 | 31 |  | 2 |
| 3 | 4 | 5 | E | 7 | 8 | 9 |
| Clear all |  |  |  | OK | Can | ncel |

For more information on using uicalendar with an application, see "Example of Using UICalendar with an Application" on page 15-5.

## var

## Variance

## Syntax

```
y = var(X)
y = var(X, 1)
y = var(X, W)
y = var(X, W, DIM)
```

## Arguments

| $X$ | Financial times series object. |
| :--- | :--- |
| W | Weight vector used in calculating variance. |
| DIM | Dimension of $X$ used in calculating variance. |

## Description

var supports financial time series objects based on the MATLAB var function. See var in the MATLAB documentation.
$y=\operatorname{var}(X)$, if $X$ is a financial time series object and returns the variance of each series.
var normalizes y by $N-1$ if $N>1$, where $N$ is the sample size. This is an unbiased estimator of the variance of the population from which $X$ is drawn, as long as $X$ consists of independent, identically distributed samples. For $N=1$, y is normalized by $N$.
$y=\operatorname{var}(X, 1)$ normalizes by $N$ and produces the second moment of the sample about its mean. $\operatorname{var}(X, 0)$ is the same as $\operatorname{var}(X)$.
$y=\operatorname{var}(X, W)$ computes the variance using the weight vector $W$. The length of W must equal the length of the dimension over which var operates, and its elements must be
nonnegative. var normalizes $W$ to sum to 1 . Use a value of 0 for $W$ to use the default normalization by $\mathrm{N}-1$, or use a value of 1 to use N .
$y=\operatorname{var}(X, W, D I M)$ takes the variance along the dimension DIM of $X$.

## Examples

The variance is the square of the standard deviation. Consider if

```
f = fints((today:today+1)', [4 -2 1; 9 5 7])
```

then

```
var(f, 0, 1)
```

is
[12.5 24.5 18.0]
and
var(f, 0, 2)
is
[9.0; 4.0]

```

Introduced before R2006a
```

## vertcat

Concatenate financial time series objects vertically

## Syntax

vertcat

## Description

vertcat implements vertical concatenation of financial time series objects. vertcat essentially adds data points to a time series object. Objects to be vertically concatenated must not have any duplicate dates and/or times or any overlapping dates and/or times. The description fields are concatenated as well. They are separated by ||.

## Examples

Create two financial time series objects with daily frequencies:

```
myfts = fints((today:today+4)', (1:5)', 'DataSeries', 'd');
yourfts = fints((today+5:today+9)', (11:15)', 'DataSeries', 'd');
```

Use vertcat to concatenate them vertically:

```
newfts1 = [myfts; yourfts]
newfts1 =
```

| ${ }^{\prime} 18-$-Dec-2001' | $[$ | $13]$ |
| :---: | :---: | :---: |
| '19-Dec-2001' | $[$ | $14]$ |
| '20-Dec-2001' | $[$ | $15]$ |

Create two financial time series objects with different frequencies:

```
myfts = fints((today:today+4)', (1:5)', 'DataSeries', 'd');
hisfts = fints((today+5:7:today+34)', (11:15)', 'DataSeries',...
'w');
```

Concatenate these two objects vertically:

```
newfts2 = [myfts; hisfts]
newfts2 =
    desc: ||
    freq: Unknown (0)
    'dates: (10)' 'DataSeries: (10)
    '11-Dec-2001' [ 1]
    '12-Dec-2001' [ 2]
    '13-Dec-2001' [ 3]
    '14-Dec-2001' [ 4]
    '15-Dec-2001' [ 5]
    '16-Dec-2001' [ 11]
    '23-Dec-2001' [ 12]
    '30-Dec-2001' [ 13]
    '06-Jan-2002' [ 14]
    '13-Jan-2002' [ 15]
```

If all frequency indicators are the same, the new object has the same frequency indicator. However, if one of the concatenated objects has a different freq from the other(s), the frequency of the resulting object is set to Unknown (0). In these examples, newfts1 has Daily frequency, while newfts2 has Unknown (0) frequency.

## volarea

Price and volume chart

## Syntax

volarea(X)

## Arguments

| $X$ | M-by-3 matrix where the first column contains date numbers, <br> the second column is the asset price, and the third column is the <br> volume. |
| :--- | :--- |

## Description

volarea( X ) plots asset date, price, and volume on a single axis.

## Examples

## Plot Asset Date, Price, and Volume on a Single Axis

This example shows how to plot asset date, price, and volume on a single axis, given asset X as an M-by-3 matrix of date numbers, asset price, and volume.

```
X = [...

## volroc

Volume rate of change

## Syntax

```
vroc = volroc(tvolume nTimes)
vrocts = volroc(tsobj, nTimes)
vrocts = volroc(tsobj, nTimes, 'ParameterName', ParameterValue, ...)
```

## Arguments

| tvolume | Volume traded. |
| :--- | :--- |
| nTimes | (Optional) Time difference. Default $=12$. |
| tsobj | Financial time series object. |

## Description

vroc $=$ volroc(tvolume nTimes) calculates the volume rate of change, vroc, from the volume traded data tvolume. If nTimes is specified, the volume rate of change is calculated between the current volume and the volume nTimes ago.
vrocts = volroc(tsobj, nTimes) calculates the volume rate of change, vrocts, from the financial time series object tsobj. The vrocts output is a financial time series object with similar dates as tsobj and a data series named VolumeROC. If nTimes is specified, the volume rate of change is calculated between the current volume and the volume nTimes ago.
vrocts = volroc(tsobj, nTimes, 'ParameterName', ParameterValue, ...) specifies the name for the required data series when it is different from the default name. The valid parameter name is

- VolumeName: volume traded series name

The parameter value is a string that represents the valid parameter name.
Note, to compute a quantity over n periods, you must specify $\mathrm{n}+1$ for nTimes. If you specify $n$ Times $=0$, the function returns your original time series.

## Examples

## Compute the Volume Rate of Change

This example shows how to compute the volume rate of change for Disney stock and plot the results.

```
load disney.mat
dis_VolRoc = volroc(dis);
plot(dis_VolRoc)
title('Volume Rate of Change for Disney')
```

## wclose

Weighted close

## Syntax

```
wcls = wclose(highp, lowp, closep)
wcls = wclose([highp lowp closep])
wclsts = wclose(tsobj)
wclsts = wclose(tsobj, 'ParameterName', ParameterValue, ...)
```

## Arguments

| highp | High price (vector). |
| :--- | :--- |
| lowp | Low price (vector). |
| closep | Closing price (vector). |
| tsobj | Financial time series object. |

## Description

The weighted close price is the average of twice the closing price plus the high and low prices.
wcls = wclose(highp, lowp, closep) calculates the weighted close prices wcls based on the high (highp), low (lowp), and closing (closep) prices per period.
wcls = wclose([highp lowp closep]) accepts a three-column matrix consisting of the high, low, and closing prices, in that order.
wclsts = wclose(tsobj) computes the weighted close prices for a set of stock price data contained in the financial time series object tsobj. The object must contain the
high, low, and closing prices needed for this function. The function assumes that the series are named High, Low, and Close. All three are required. wclsts is a financial time series object of the same dates as tsobj and contains the data series named WClose.
wclsts = wclose(tsobj, 'ParameterName', ParameterValue, ...) accepts parameter name/parameter value pairs as input. These pairs specify the name(s) for the required data series if it is different from the expected default name(s). Valid parameter names are

- HighName: high prices series name
- LowName: low prices series name
- CloseName: closing prices series name

Parameter values are the strings that represent the valid parameter names.

## Examples

## Compute the Weighted Closing Prices

This example shows how to compute the weighted closing prices for Disney stock and plot the results.
load disney.mat
dis_Wclose = wclose(dis);
plot(dis_Wclose)
title('Weighted Closing Prices for Disney')

## weeknum

Week in year

## Syntax

```
[N]= weeknum(D)
[N] = weeknum(D, W, E)
```

## Arguments

| D | Serial date number or a serial date string. Serial date numbers can be a matrix. Date strings can be specified as a one-dimensional cell array of strings. All of the date strings must have the same format. |
| :---: | :---: |
| W | (Optional) A numeric representation of the day a week begins. The week start values and their corresponding day are: <br> - 1 (default) - Sunday <br> - 2 - Monday <br> - 3 -Tuesday <br> - 4 -Wednesday <br> - 5 -Thursday <br> - 6 - Friday <br> - 7 -Saturday |
| E | (Optional) Indicates if the week of the year display is in the European standard. The European standard considers first week of year to be first week longer than three days, offset by the given week's start day. Set to 1 to use the European standard. The default setting is 0 . |

## Description

[ $N$ ] = weeknum ( D ) returns the week number of the year, given D , a serial date number, or a serial date string. If $D$ is a one-dimensional cell array of strings, then weeknum returns a column vector of $M$ week numbers, where $M$ is the number of strings in D .
[ N ] = weeknum(D, W, E) returns the week number of the year, given D, a serial date number, or a date string, W, a numeric representation of the day a week begins, and when $E$ is set to 1 , the week of the year is in the European standard.

The weeknum function considers the week containing January 1 to be the first week of the year.

## Examples

You can determine the week of the year using a serial date number
$\mathrm{N}=$ weeknum(728647)
$\mathrm{N}=$
52
or a date string
$\mathrm{N}=$ weeknum('19-Dec-1994')
$N=$
52
The first week of the year must have at least four days in it. For example, January 8, 2004 was a Thursday. The European standard is used because the first week of the year is the first week longer than three days.

```
weeknum('08-jan-2004',1,1)
ans =
```

2
You can use weeknum with datenum:

```
weeknum(datenum('01-Jan-2004'):datenum('08-Jan-2004'))
ans =
```

    \(\begin{array}{llllllll}1 & 1 & 1 & 2 & 2 & 2 & 2 & 2\end{array}\)
    The default start day of the week is Sunday. Every day after, and including the first Sunday of the year (04-Jan-2004), returns 2 denoting the second week. In this case, the first of week of the year started before January 1, 2004.

You can also use weeknum with datenum and specify a $W$ value of 5 to indicate that the weeks start on Thursday:

```
weeknum(datenum('01-Jan-2004'):datenum('08-Jan-2004'),5)
ans =
    1
```

The first week of the year that has four or more days, based on the specified start day, is considered week one (even if this is not the first week in the calendar). Any day falling in (or before) this week is given a week number of 1 .

See Also<br>datenum | datestr | datevec | day<br>Introduced before R2006a

## weights2holdings

Portfolio values and weights into holdings

## Syntax

Holdings = weights2holdings(Values, Weights, Prices)

## Arguments

| Values | Scalar or number of portfolios (NPORTS) vector containing portfolio <br> values. |
| :--- | :--- |
| Weights | NPORTS by number of assets (NASSETS) matrix with portfolio <br> weights. The weights sum to the value of a Budget constraint, <br> which is usually 1. (See holdings2weights for information about <br> budget constraints.) |
| Prices | NASSETS vector of prices. |

## Description

Holdings = weights2holdings(Values, Weights, Prices) converts portfolio values and weights into portfolio holdings.

Holdings is a NPORTS-by-NASSETS matrix containing the holdings of NPORTS portfolios that contain NASSETS assets.

Note This function does not create round-lot positions. Holdings are floating-point values.

See Also<br>holdings2weights

## Related Examples

## willad

Williams Accumulation/Distribution line

## Syntax

```
wadl = willad(highp, lowp, closep)
wadl = willad([highp lowp closep])
wadlts = willad(tsobj)
wadlts = willad(tsobj, 'ParameterName', ParameterValue, ...)
```

## Arguments

| highp | High price (vector) |
| :--- | :--- |
| lowp | Low price (vector) |
| closep | Closing price (vector) |
| tsobj | Time series object |

## Description

wadl = willad(highp, lowp, closep) computes the Williams Accumulation/ Distribution line for a set of stock price data. The prices needed for this function are the high (highp), low (lowp), and closing (closep) prices. All three are required.
wadl = willad([highp lowp closep]) accepts a three-column matrix of prices as input. The first column contains the high prices, the second contains the low prices, and the third contains the closing prices.
wadlts = willad(tsobj) computes the Williams Accumulation/Distribution line for a set of stock price data contained in the financial time series object tsobj. The object must contain the high, low, and closing prices needed for this function. The function
assumes that the series are named High, Low, and Close. All three are required. wadlts is a financial time series object with the same dates as tsobj and a single data series named WillAD.
wadlts = willad(tsobj, 'ParameterName', ParameterValue, ...) accepts parameter name/parameter value pairs as input. These pairs specify the name(s) for the required data series if it is different from the expected default name(s). Valid parameter names are

- HighName: high prices series name
- LowName: low prices series name
- CloseName: closing prices series name

Parameter values are the strings that represent the valid parameter names.

## Examples

## Compute the Williams A/D Line

This example shows how to compute the Williams A/D line for Disney stock and plot the results.
load disney.mat
dis_Willad = willad(dis);
plot(dis_Willad)
title('Williams A/D Line for Disney')

## willpctr

Williams \%R

## Syntax

```
wpctr = willpctr(highp, lowp, closep, nperiods)
wpctr = willpctr([highp, lowp, closep], nperiods)
wpctrts = willpctr(tsobj)
wpctrts = willpctr(tsobj, nperiods)
wpctrts = willpctr(tsobj, nperiods, 'ParameterName', ParameterValue,
... )
```

## Arguments

| highp | High price (vector) |
| :--- | :--- |
| lowp | Low price (vector) |
| closep | Closing price (vector) |
| nperiods | Number of periods (scalar). Default $=14$. |
| tsobj | Financial time series object |

## Description

wpctr = willpctr(highp, lowp, closep, nperiods) calculates the Williams \%R values for the given set of stock prices for a specified number of periods nperiods. The stock prices needed are the high (highp), low (lowp), and closing (closep) prices. wpctr is a vector that represents the Williams \%R values from the stock data.
wpctr = willpctr([highp, lowp, closep], nperiods) accepts the price input as a three-column matrix representing the high, low, and closing prices, in that order.
wpctrts = willpctr(tsobj) calculates the Williams \%R values for the financial time series object tsobj. The object must contain at least three data series named High (high prices), Low (low prices), and Close (closing prices). wpctrts is a financial time series object with the same dates as tsobj and a single data series named WillPctR.
wpctrts = willpctr(tsobj, nperiods) calculates the Williams \%R values for the financial time series object tsobj for nperiods periods.
wpctrts = willpctr(tsobj, nperiods, 'ParameterName', ParameterValue, ...) accepts parameter name/parameter value pairs as input. These pairs specify the name(s) for the required data series if it is different from the expected default name(s). Valid parameter names are

- HighName: high prices series name
- LowName: low prices series name
- CloseName: closing prices series name

Parameter values are the strings that represent the valid parameter names.

## Examples

## Compute the Williams \%R Values

This example shows how to compute the Williams \%R values for Disney stock and plot the results.

```
load disney.mat
dis_Wpctr = willpctr(dis);
plot(dis_Wpctr)
title('Williams %R for Disney')
```

## wrkdydif

Number of working days between dates

## Syntax

Days = wrkdydif(StartDate, EndDate, Holidays)

## Arguments

| StartDate | Enter as serial date numbers or date strings. |
| :--- | :--- |
| EndDate | Enter as serial date numbers or date strings. |
| Holidays | A vector containing values for the number of Holidays between the <br> two dates. |

## Description

Days = wrkdydif(StartDate, EndDate, Holidays) returns the number of working days between dates StartDate and EndDate inclusive. Holidays is the number of holidays between the given dates, an integer. Enter dates as serial date numbers or date strings.

## Examples

```
Days = wrkdydif('9/1/2000', '9/11/2000', 1)
```

or
Days = wrkdydif(730730, 730740, 1)
returns
Days =

## x2mdate

Excel serial date number to MATLAB serial date number

## Syntax

MATLABDate $=$ x2mdate(ExcelDateNumber, Convention)

## Arguments

| ExcelDateNumber | A vector or scalar of Excel serial date numbers. |
| :--- | :--- |
| Convention | (Optional) Excel date system. A vector or scalar. When <br> Convention = 0 (default), the Excel 1900 date system <br> is in effect. When Convention = 1, the Excel 1904 date <br> system is used. <br> In the Excel 1900 date system, the Excel serial date number <br> 1 corresponds to January 1, 1900 A.D. In the Excel 1904 <br> date system, date number 0 is January 1, 1904 A.D. |
|  | Due to a software limitation in Excel software, the year 1900 <br> is considered a leap year. As a result, all DATEVALUEs <br> reported by Excel software between Jan. 1, 1900 and Feb. <br> 28,1900 (inclusive) differ from the values reported by 1. For <br> example: <br> $-\quad$ In Excel software, Jan. 1, 1900 =1 <br> $-\quad$ In MATLAB, Jan. 1, 1900 = 2 |

Vector arguments must have consistent dimensions.

## Description

DateNumber = x2mdate(ExcelDateNumber, Convention) converts Excel serial date numbers to MATLAB serial date numbers. MATLAB date numbers start with

1 = January 1, 0000 A.D., hence there is a difference of 693960 relative to the 1900 date system, or 695422 relative to the 1904 date system. This function is useful with Spreadsheet Link EX software.

## Examples

Given Excel date numbers in the 1904 system

```
ExDates = [lllll}35423 35788 36153];'
```

convert them to MATLAB date numbers

```
MATLABDate = x2mdate(ExDates, 1)
```

MATLABDate $=$
$730845 \quad 731210 \quad 731575$
and then to date strings.

```
datestr(MATLABDate)
```

ans $=$
25-Dec-2000
25-Dec-2001
25-Dec-2002

## xirr

Internal rate of return for nonperiodic cash flow

## Syntax

```
Return = xirr(CashFlow, CashFlowDates)
Return = xirr(CashFlow, CashFlowDates, Guess, MaxIterations,
Basis)
```

## Description

Return = xirr(CashFlow, CashFlowDates) returns the internal rate of return for a schedule of nonperiodic cash flows.

Return = xirr(CashFlow, CashFlowDates, Guess, MaxIterations, Basis) returns the internal rate of return for a schedule of nonperiodic cash flows with optional inputs.

## Input Arguments

## CashFlow

A vector or matrix of cash flows. If CashFlow is a matrix, each column represents a separate stream of cash flows whose internal rate of return is calculated. The first cash flow of each stream is the initial investment, entered as a negative number.

## CashFlowDates

(Required) A vector or matrix of serial date numbers the same size as CashFlow, or a cell array of date strings the same size as CashFlow. Each column of CashFlowDate represents the dates of the corresponding column of CashFlow.

## Guess

The initial estimate of the internal rate of return. Guess is a scalar applied to all streams, or a vector the same length as the number of streams.

Default: 0.1 (10\%)

## MaxIterations

The positive integer number of iterations used by Newton's method to solve the internal rate of return. MaxIterations is a scalar applied to all streams, or a vector the same length as the number of streams.

## Default: 50

## Basis

Day-count basis of the instrument. A vector of integers.

- $0=$ actual/actual (default)
- $1=30 / 360$ (SIA)
- 2 = actual/360
- $3=$ actual/365
- $4=30 / 360$ (BMA)
- $5=30 / 360$ (ISDA)
- $6=30 / 360$ (European)
- $7=$ actual/365 (Japanese)
- $8=$ actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- $10=$ actual/365 (ICMA)
- $11=30 / 360 \mathrm{E}$ (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see basis.
Default: 0

## Output Arguments

## Return

Vector of the annualized internal rate of return of each cash flow stream. A NaN indicates that a solution is not found.

## Examples

Find the internal rate of return for an investment of $\$ 10,000$ that returns the following nonperiodic cash flow. The original investment is the first cash flow and is a negative number.

| Cash Flow | Dates |
| :--- | :--- |
| $(\$ 10000)$ | January 12, 2007 |
| $\$ 2500$ | February 14, 2008 |
| $\$ 2000$ | March 3, 2008 |
| $\$ 3000$ | June 14, 2008 |
| $\$ 4000$ | December 1, 2008 |

Calculate the internal rate of return for this nonperiodic cash flow:

```
CashFlow = [-10000, 2500, 2000, 3000, 4000];
CashFlowDates = ['01/12/2007'
    '02/14/2008'
    '03/03/2008'
    '06/14/2008'
    '12/01/2008'];
Return = xirr(CashFlow, CashFlowDates)
```

This returns:
Return $=$

## year

Year of date

## Syntax

```
Year = year(Date)
Year = year(Date, F)
```

## Description

Year $=$ year(Date) returns the year of a serial date number or a date string.
Year = year(Date, F) returns the year, given a serial date number or date string, in a specified date format.

## Examples

```
Year = year(731798.776)
```

or

```
Year = year('05-Aug-2003')
```

returns
Year =
2003
You can also use the $F$ argument to designate a country-specific date format:

```
Year = year('2003/08/05','yyyy/mm/dd')
Year =
```

    2003.00
    See Also<br>datevec | day | month | yeardays<br>Introduced before R2006a

## yeardays

Number of days in year

## Syntax

```
Days = yeardays(Year, Basis)
```

## Arguments

| Year | Enter as a four-digit integer. |
| :---: | :---: |
| Basis | (Optional) Day-count basis of the instrument. A vector of integers. <br> - $0=$ actual/actual (default) <br> - $1=30 / 360$ (SIA) <br> - $2=$ actual/ 360 <br> - 3 = actual $/ 365$ <br> - $4=30 / 360$ (BMA) <br> - $5=30 / 360$ (ISDA) <br> - $6=30 / 360$ (European) <br> - 7 = actual/365 (Japanese) <br> - $8=$ actual/actual (ICMA) <br> - $9=$ actual/360 (ICMA) <br> - $10=$ actual/365 (ICMA) <br> - $11=30 / 360 \mathrm{E}$ (ICMA) <br> - 12 = actual/365 (ISDA) <br> - 13 = BUS/252 <br> For more information, see basis. |

## Description

Days = yeardays(Year, Basis) returns the number of days in the given year, based on the day-count basis.

## Examples

Days = yeardays(2000)
Days =
366
Days = yeardays(2000, 1)
Days =
360

See Also<br>days360 | days365 | daysact | year | yearfrac<br>Introduced before R2006a

## yearfrac

Fraction of year between dates

## Syntax

YearFraction = yearfrac(StartDate, EndDate, Basis)

## Arguments

| StartDate | Enter as serial date numbers or date strings. |
| :---: | :---: |
| EndDate | Enter as serial date numbers or date strings. |
| Basis | (Optional) Day-count basis of the instrument. A vector of integers. <br> - $0=$ actual/actual (default) <br> - $1=30 / 360$ (SIA) <br> - 2 = actual/360 <br> - 3 = actual/365 <br> - $4=30 / 360$ (BMA) <br> - $5=30 / 360$ (ISDA) <br> - $6=30 / 360$ (European) <br> - $7=$ actual/365 (Japanese) <br> - 8 = actual/actual (ICMA) <br> - 9 = actual/360 (ICMA) <br> - 10 = actual/365 (ICMA) <br> - $11=30 / 360 \mathrm{E}$ (ICMA) <br> - 12 = actual/365 (ISDA) <br> - 13 = BUS/252 <br> For more information, see basis. |

All specified arguments must be number of instruments (NUMINST-by-1) or (1-by-NUMINST) conforming vectors or scalar arguments.

## Description

YearFraction = yearfrac(StartDate, EndDate, Basis) returns a fraction based on the number of days between dates StartDate and EndDate using the given day-count basis. Note, the number of days in a year (365 or 366) is equal to the number of days in the calendar year after the StartDate. If EndDate is earlier than StartDate, Fraction is negative.

## Definitions

The difference between yearfrac and date2time is that date2time counts full periods as a whole integer, even if the number of actual days in the periods are different. yearfrac does not count full periods. For example,

```
yearfrac('1/1/2000', '1/1/2001', 9)
ans =
    1.0167
```

yearfrac for Basis 9 (ACT/360 ICMA) calculates $366 / 360=1.0167$. So, even if the dates have the same month and date, with a difference of 1 in the year, the returned value may not be exactly 1 . On the other hand, date2time calculates one full year period:

```
date2time('1/1/2000', '1/1/2001', 1, 9)
```

ans $=$

## Examples

## Compute yearfrac When the Calendar Year After the StartDate is Not a Leap Year

Given a Basis of 0 and a Basis of 1, compute yearfrac.
Define the StartDate and EndDate using a Basis of 0.

```
YearFraction = yearfrac('14 mar 01', '14 sep 01', 0)
YearFraction =
    0.5041
Define the StartDate and EndDate using a Basis of 1.
YearFraction = yearfrac('14 mar 01', '14 sep 01', 1)
YearFraction =
    0.5000
```

## Compute yearfrac When the Calendar Year After the StartDate is a Leap Year

Given a Basis of 0, compute yearfrac when the calendar after StartDate is in a leap year.

Define the StartDate and EndDate using a Basis of 0.

```
yearFraction = yearfrac(' 14 mar 03', '14 sep 03', 0)
```

yearFraction =
0.5027

There are 184 days between March 14 and September 14, and the calendar year after the StartDate is a leap year, so yearfrac returns $184 / 366=0.5027$.

## Introduced before R2006a

## ylddisc

Yield of discounted security

## Syntax

```
Yield = ylddisc(Settle, Maturity, Face, Price, Basis)
```

## Arguments

| Settle | Settlement date. Enter as serial date number or date string. Settle must be earlier than Maturity. |
| :---: | :---: |
| Maturity | Maturity date. Enter as serial date number or date string. |
| Face | Redemption (par, face) value. |
| Price | Discounted price of the security. |
| Basis | (Optional) Day-count basis of the instrument. A vector of integers. <br> - $0=$ actual/actual (default) <br> - $1=30 / 360$ (SIA) <br> - 2 = actual/360 <br> - 3 = actual $/ 365$ <br> - $4=30 / 360$ (BMA) <br> - $5=30 / 360$ (ISDA) <br> - $6=30 / 360$ (European) <br> - $7=$ actual/365 (Japanese) <br> - $8=$ actual/actual (ICMA) <br> - $9=$ actual/360 (ICMA) <br> - $10=$ actual/365 (ICMA) <br> - $11=30 / 360 \mathrm{E}$ (ICMA) <br> - 12 = actual/365 (ISDA) <br> - 13 = BUS/252 |

## Description

Yield = ylddisc(Settle, Maturity, Face, Price, Basis) finds the yield of a discounted security.

## Examples

## Find the Yield of a Discounted Security

This example shows how to find the yield of the following discounted security.

```
Settle = '10/14/2000';
Maturity = '03/17/2001';
Face = 100;
Price = 96.28;
Basis = 2;
Yield = ylddisc(Settle, Maturity, Face, Price, Basis)
Yield =
    0.0903

## yldmat

Yield with interest at maturity

## Syntax

Yield = yldmat(Settle, Maturity, Issue, Face, Price, CouponRate, Basis)

## Arguments

| Settle | Settlement date. Enter as serial date number or date string. Settle must be earlier than Maturity. |
| :---: | :---: |
| Maturity | Maturity date. Enter as serial date number or date string. |
| Issue | Issue date. Enter as serial date number or date string. |
| Face | Redemption (par, face) value. |
| Price | Price of the security. |
| CouponRate | Coupon rate. Enter as decimal fraction. |
| Basis | (Optional) Day-count basis of the instrument. A vector of integers. <br> - $0=$ actual/actual (default) <br> - $1=30 / 360$ (SIA) <br> - 2 = actual/360 <br> - 3 = actual/365 <br> - $4=30 / 360$ (BMA) <br> - $5=30 / 360$ (ISDA) <br> - $6=30 / 360$ (European) <br> - $7=$ actual/365 (Japanese) <br> - $8=$ actual/actual (ICMA) <br> - $9=$ actual/360 (ICMA) <br> - $10=$ actual/365 (ICMA) |

```
- \(11=30 / 360 \mathrm{E}\) (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252
For more information, see basis.
```

## Description

Yield = yldmat(Settle, Maturity, Issue, Face, Price, CouponRate, Basis) returns the yield of a security paying interest at maturity.

## Examples

## Find the Yield of a Security Paying Interest at Maturity

This example shows how to find the yield of a security paying interest at maturity for the following.

```
Settle = '02/07/2000';
Maturity = '04/13/2000';
Issue = '10/11/1999';
Face = 100;
Price = 99.98;
CouponRate = 0.0608;
Basis = 1;
Yield = yldmat(Settle, Maturity, Issue, Face, Price,...
CouponRate, Basis)
```

Yield =
0.0607

## yldtbill

Yield of Treasury bill

## Syntax

Yield = yldtbill(Settle, Maturity, Face, Price)

## Arguments

| Settle | Settlement date. Enter as serial date number or date string. <br> Settle must be earlier than Maturity. |
| :--- | :--- |
| Maturity | Maturity date. Enter as serial date number or date string. |
| Face | Redemption (par, face) value. |
| Price | Price of the Treasury bill. |

## Description

Yield = yldtbill(Settle, Maturity, Face, Price) returns the yield for a Treasury bill.

## Examples

## Find the Yield for a Treasury Bill

This example shows how to return the yield for a Treasury bill, given the settlement date of a Treasury bill is February 10, 2000, the maturity date is August 6, 2000, the par value is $\$ 1000$, and the price is $\$ 981.36$.

Yield = yldtbill('2/10/2000', '8/6/2000', 1000, 981.36)

Yield =

## Introduced before R2006a

## zbtprice

Zero curve bootstrapping from coupon bond data given price

## Syntax

[ZeroRates, CurveDates] = zbtprice(Bonds, Prices, Settle, OutputCompounding)

## Arguments

| Bonds | Coupon bond information used to generate the zero curve. An n-by-2 to n-by-6 matrix where each row describes a bond. The first two columns are required; the remainder are optional but must be added in order. All rows in Bonds must have the same number of columns. <br> Columns are <br> [Maturity CouponRate Face Period Basis <br> EndMonthRule] where |  |
| :---: | :---: | :---: |
|  | Maturity | Maturity date of the bond, as a serial date number. Use datenum to convert date strings to serial date numbers. |
|  | CouponRate | Coupon rate of the bond, as a decimal fraction. |
|  | Face | (Optional) Redemption or face value of the bond. Default $=100$. |
|  | Period | (Optional) Coupons per year of the bond, as an integer. Allowed values are $0,1,2$ (default), 3, 4, 6, and 12. |
|  | Basis | (Optional) Day-count basis of the bond: <br> - $0=$ actual/actual (default) <br> - $1=30 / 360$ (SIA) <br> - 2 = actual/360 |

|  |  | - 3 = actual/365 <br> - $4=30 / 360$ (BMA) <br> - $5=30 / 360$ (ISDA) <br> - $6=30 / 360$ (European) <br> - 7 = actual/365 (Japanese) <br> - $8=$ actual/actual (ICMA) <br> - $9=$ actual/360 (ICMA) <br> - $10=$ actual/365 (ICMA) <br> - $11=30 / 360 \mathrm{E}$ (ICMA) <br> - 12 = actual/365 (ISDA) <br> - 13 = BUS/252 <br> For more information, see basis. |
| :---: | :---: | :---: |
|  | EndMonthRule | (Optional) End-of-month flag. This flag applies only when Maturity is an end-of-month date for a month having 30 or fewer days. $0=$ ignore flag, meaning that a bond's coupon payment date is always the same day of the month. $1=$ set flag (default), meaning that a bond's coupon payment date is always the last day of the month. |
| Prices | Column vector containing the clean price (price without accrued interest) of each bond in Bonds, respectively. The number of rows ( n ) must match the number of rows in Bonds. |  |
| Settle | Settlement date, as a scalar serial date number. This represents time zero for deriving the zero curve, and it is normally the common settlement date for all the bonds. |  |
| OutputCompounding | (Optional) Scalar value representing the period by which the output zero rates are compounded. The default OutputCompounding value is semiannual compounding (that is 2). Allowed values are: |  |
|  | 0 | Simple interest (no compounding) |

|  | 1 | Annual compounding |
| :--- | :--- | :--- |
|  | 2 | Semiannual compounding (default) |
|  | 3 | Compounding three times per year |
|  | 4 | Quarterly compounding |
|  | 6 | Bimonthly compounding |
|  | 12 | Monthly compounding |
|  | -1 | Continuous compounding |

## Description

[ZeroRates, CurveDates] = zbtprice(Bonds, Prices, Settle, OutputCompounding) uses the bootstrap method to return a zero curve given a portfolio of coupon bonds and their prices. A zero curve consists of the yields to maturity for a portfolio of theoretical zero-coupon bonds that are derived from the input Bonds portfolio. The bootstrap method that this function uses does not require alignment among the cashflow dates of the bonds in the input portfolio. It uses theoretical par bond arbitrage and yield interpolation to derive all zero rates; specifically, the interest rates for cash flows are determined using linear interpolation. For best results, use a portfolio of at least 30 bonds evenly spaced across the investment horizon.
$\left.\left.\begin{array}{|l|l|}\hline \text { ZeroRates } & \begin{array}{l}\text { An m-by-1 vector of decimal fractions that are the implied } \\ \text { zero rates for each point along the investment horizon } \\ \text { represented by CurveDates; } m \text { is the number of bonds } \\ \text { of unique maturity dates. In aggregate, the rates in } \\ \text { ZeroRates constitute a zero curve. } \\ \text { If more than one bond has the same maturity date, }\end{array} \\ \text { zbtprice returns the mean zero rate for that maturity. } \\ \text { Any rates before the first maturity are assumed to be } \\ \text { equal to the rate at the first maturity, that is, the curve is } \\ \text { assumed to be flat before the first maturity. }\end{array} \right\rvert\, \begin{array}{l}\text { An m-by-1 vector of unique maturity dates (as serial date } \\ \text { numbers) that correspond to the zero rates in ZeroRates; } \\ \text { m is the number of bonds of different maturity dates. These } \\ \text { dates begin with the earliest maturity date and end with the } \\ \text { latest maturity date Maturity in the Bonds matrix. }\end{array}\right]$

## Examples

## Compute a Zero Curve Given a Porifolio of Coupon Bonds and Their Prices

Given data and prices for 12 coupon bonds, two with the same maturity date, and given the common settlement date.

| Bonds = [datenum( $6 / 1 / 1998$ ') | 0.0475 | 100 | 2 | 0 | 0 |

## zero2disc

Discount curve given zero curve

## Syntax

[DiscRates, CurveDates] = zero2disc(ZeroRates, CurveDates, Settle, Compounding, Basis)
[DiscRates, CurveDates] = zero2disc(ZeroRates, CurveDates, Settle, Name, Value)

## Arguments

| ZeroRates | Number of bonds (NUMBONDS)-by-1 vector of annualized zero rates, <br> as decimal fractions. In aggregate, the rates constitute an implied <br> zero curve for the investment horizon represented by CurveDates. |
| :--- | :--- |
| CurveDates | NUMBONDS-by-1 vector of maturity dates (as serial date numbers) <br> that correspond to the zero rates. |
| Settle | Serial date number or date string that is the common settlement <br> date for the zero rates; that is, the settlement date for the bonds <br> from which the zero curve was bootstrapped. |

## Ordered Input or Name-Value Pair Arguments

Enter the following inputs using an ordered syntax or as name-value pair arguments. You cannot mix ordered syntax with name-value pairs.

## Compounding

Scalar value representing the rate at which the input ZeroRates were compounded when annualized. Allowed values are:

- 0 - Simple interest (no compounding)
- 1 -Annual compounding
- 2 - Semiannual compounding (default)
- 3 - Compounding three times per year
- 4 - Quarterly compounding
- 6 - Bimonthly compounding
- 12 - Monthly compounding
- 365 - Daily compounding
-     - 1 - Continuous compounding

Default: 2 (default)

## Basis

Day-count basis used for annualizing the input zero rates. A vector of integers.

- $0=$ actual/actual
- $1=30 / 360$ (SIA)
- $2=$ actual $/ 360$
- 3 = actual/365
- $4=30 / 360$ (PSA)
- $5=30 / 360$ (ISDA)
- $6=30 / 360$ (European)
- $7=$ actual/365 (Japanese)
- $8=$ actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- $10=$ actual/365 (ICMA)
- $11=30 / 360 \mathrm{E}$ (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see basis.
Default: 0

## Description

[DiscRates, CurveDates] = zero2disc(ZeroRates, CurveDates, Settle, Compounding, Basis) returns a discount curve given a zero curve and its maturity dates.
[DiscRates, CurveDates] = zero2disc(ZeroRates, CurveDates, Settle, Name, Value) returns a discount curve given a zero curve and its maturity dates using optional name-value pair arguments. Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

| DiscRates | A NUMBONDS-by-1 vector of discount factors, as decimal fractions. <br> In aggregate, the factors constitute a discount curve for the <br> investment horizon represented by CurveDates. |
| :--- | :--- |
| CurveDates | A NUMBONDS-by-1 vector of maturity dates (as serial date numbers) <br> that correspond to the discount rates. This vector is the same as the <br> input vector CurveDates, but is sorted by ascending maturity. |

## Examples

## Compute a Discount Curve Given a Zero Curve and Maturity Dates

Given a zero curve over a set of maturity dates and a settlement date.

```
ZeroRates = [0.0464
    0.0509
    0.0524
    0.0525
    0.0531
    0.0525
    0.0530
    0.0531
    0.0549
        0.0536];
CurveDates = [datenum('06-Nov-2000')
    datenum('11-Dec-2000')
    datenum('15-Jan-2001')
    datenum('05-Feb-2001')
    datenum('04-Mar-2001')
    datenum('02-Apr-2001')
    datenum('30-Apr-2001')
    datenum('25-Jun-2001')
    datenum('04-Sep-2001')
```

```
    datenum('12-Nov-2001')];
Settle = datenum('03-Nov-2000');
The zero curve is compounded daily on an actual/365 basis.
Compounding = 365;
Basis = 3;
```

Execute the function zero2disc which returns the discount curve DiscRates at the maturity dates CurveDates.
[DiscRates, CurveDates] = zero2disc(ZeroRates, CurveDates,... Settle, Compounding, Basis)

## DiscRates =

0.9996
0.9947
0.9896
0.9866
0.9826
0.9787
0.9745
0.9665
0.9552
0.9466

## CurveDates =

730796
730831
730866
730887
730914
730943
730971
731027
731098
731167

For readability, ZeroRates and DiscRates are shown here only to the basis point. However, MATLAB® software computed them at full precision. If you enter ZeroRates as shown, DiscRates may differ due to rounding.

Introduced before R2006a

## zero2fwd

Forward curve given zero curve

## Syntax

[ForwardRates, CurveDates] = zero2fwd(ZeroRates, CurveDates, Settle)
[ForwardRates, CurveDates] = zero2fwd(ZeroRates, CurveDates, Settle, Name, Value)

## Compatibility

In R2015b, the specification of optional input arguments has changed. While the previous ordered inputs syntax is still supported, it may no longer be supported in a future release. Use the new optional name-value pair inputs: InputCompounding, InputBasis, OutputCompounding, and OutputBasis.

## Input Arguments

| ZeroRates | Number of bonds (NUMBONDS)-by-1 vector of annualized zero rates, <br> as decimal fractions. In aggregate, the rates constitute an implied <br> zero curve for the investment horizon represented by CurveDates. <br> The first element pertains to forward rates from the settlement <br> date to the first curve date. |
| :--- | :--- |
| CurveDates | NUMBONDS-by-1 vector of maturity dates (as serial date numbers) <br> that correspond to the zero rates. |
| Settle | Serial date number or date string that is the common settlement <br> date for the zero rates. |

## Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single
quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, . . . NameN, ValueN.
Example: [ForwardRates,CurveDates] = zero2fwd(ZeroRates, CurveDates, Settle, 'InputCompounding' , 3, 'InputBasis' , 5, 'Outp

## 'InputCompounding' - Compounding frequency of input zero rates

if InputCompounding is not specified, it is assigned the value specified for OutputCompounding. If neither InputCompounding nor OutputCompounding are specified, the default is 2 (semiannual) for both. (default) | scalar

Compounding frequency of the input zero rates, specified as a scalar with allowed values:

- 0 - Simple interest (no compounding)
- 1 -Annual compounding
- 2 - Semiannual compounding (default)
- 3-Compounding three times per year
- 4 - Quarterly compounding
- 6 - Bimonthly compounding
- 12 - Monthly compounding
- 365 - Daily compounding
-     - 1 - Continuous compounding

## Data Types: single | double

## 'InputBasis' - Day count basis of input zero rates

if InputBasis is not specified, it is assigned the value specified for OutputBasis. If neither InputBasis nor OutputBasis are specified, the default is 0 (actual/actual) for both. (default) | scalar

Day count basis of input zero rates, specified as a scalar with possible values:

- $0=$ actual/actual
- $1=30 / 360$ (SIA)
- 2 = actual/360
- 3 = actual/365
- $4=30 / 360$ (PSA)
- $5=30 / 360$ (ISDA)
- $6=30 / 360$ (European)
- $7=$ actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- $10=$ actual/365 (ICMA)
- $11=30 / 360 E$ (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

## Data Types: single | double

## ' OutputCompounding ' - Compounding frequency of output forward rates

if OutputCompounding is not specified, it is assigned the value specified for InputCompounding. If neither InputCompounding nor OutputCompounding are specified, the default is 2 (semiannual) for both. (default) | scalar

Compounding frequency of the output forward rates, specified as a scalar with allowed values:

- 0 - Simple interest (no compounding)
- 1 -Annual compounding
- 2 - Semiannual compounding (default)
- 3 - Compounding three times per year
- 4 - Quarterly compounding
- 6 - Bimonthly compounding
- 12 - Monthly compounding
- 365 - Daily compounding
-     - 1 - Continuous compounding

Data Types: single | double

## ' OutputBasis ' - Day count basis of output forward rates

if OutputBasis is not specified, it is assigned the value specified for InputBasis. If neither InputBasis nor OutputBasis are specified, the default is 0 (actual/actual) for both. (default) | scalar

Day count basis of output forward rates, specified as a scalar with possible values:

- $0=$ actual/actual
- $1=30 / 360$ (SIA)
- 2 = actual/360
- $3=$ actual $/ 365$
- $4=30 / 360$ (PSA)
- $5=30 / 360$ (ISDA)
- $6=30 / 360$ (European)
- $7=$ actual/365 (Japanese)
- $8=$ actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

## Data Types: single | double

## Description

[ForwardRates, CurveDates] = zero2fwd(ZeroRates, CurveDates, Settle) returns an implied forward rate curve given a zero curve and its maturity dates.
[ForwardRates, CurveDates] = zero2fwd(ZeroRates, CurveDates, Settle, Name, Value) returns an implied forward rate curve given a zero curve and its maturity dates using optional name-value arguments for InputCompounding, InputBasis, OutputCompounding, and OutputBasis.

| ForwardRates | A NUMBONDS-by-1 vector of decimal fractions. In aggregate, the <br> rates in ForwardRates constitute a forward curve over the dates <br> in CurveDates. |
| :--- | :--- |
| CurveDates | A NUMBONDS-by-1 vector of maturity dates (as serial date numbers) <br> that correspond to the forward rates. This vector is the same as the <br> input vector CurveDates, but is sorted by ascending maturity. |

## Examples

## Compute an Implied Forward Rate Curve Given a Zero Curve and Maturity Dates

Given a zero curve over a set of maturity dates, a settlement date, and a compounding rate, compute the forward rate curve.

```
ZeroRates = [0.0458
    0.0502
    0.0518
    0.0519
    0.0524
    0.0519
    0.0523
    0.0525
    0.0541
    0.0529];
CurveDates = [datenum('06-Nov-2000')
    datenum('11-Dec-2000')
    datenum('15-Jan-2001')
    datenum('05-Feb-2001')
    datenum('04-Mar-2001')
    datenum('02-Apr-2001')
    datenum('30-Apr-2001')
    datenum('25-Jun-2001')
    datenum('04-Sep-2001')
    datenum('12-Nov-2001')];
```

Settle = datenum('03-Nov-2000');
InputCompounding = 1;
InputBasis = 2;
OutputCompounding = 1;
OutputBasis = 2;

Execute the function zero2fwd to return the forward rate curve ForwardRates at the maturity dates CurveDates.

```
[ForwardRates, CurveDates] = zero2fwd(ZeroRates, CurveDates,...
Settle, 'InputCompounding',1,'InputBasis',2,'OutputCompounding',1,'OutputBasis',2)
```

ForwardRates =
0.0458
0.0506

## zero2pyld

Par yield curve given zero curve

## Syntax

[ParRates, CurveDates] = zero2pyld(ZeroRates, CurveDates, Settle)
[ParRates, CurveDates] = zero2pyld(ZeroRates, CurveDates, Settle, Name, Value)

## Compatibility

In R2015b, the specification of optional input arguments has changed. While the previous ordered inputs syntax is still supported, it may no longer be supported in a future release. Use the new optional name-value pair inputs: InputCompounding, InputBasis, OutputCompounding, and OutputBasis.

## Input Arguments

| ZeroRates | A number of bonds (NUMBONDS)-by-1 vector of annualized <br> zero rates, as decimal fractions. In aggregate, the rates <br> constitute an implied zero curve for the investment horizon <br> represented by CurveDates. |
| :--- | :--- |
| CurveDates | A NUMBONDS-by-1 vector of maturity dates (as serial date <br> numbers) that correspond to the zero rates. |
| Settle | A serial date number or date string that is the common <br> settlement date for the zero rates. |

## Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, . . ., NameN, ValueN.

Example: [ParRates,CurveDates] = zero2pyld(ZeroRates,CurveDates, Settle, 'OutputCompounding' ,3,'OutputBasis' ,5,'InputCompounding' , 4, 'InputBasis'

## 'OutputCompounding ' - Compounding frequency of output par rates

if InputCompounding is $1,2,3,4,6$, or 12 and OutputCompounding is not specified, the value of InputCompounding is used. If InputCompounding is 0 (simple), - 1 (continuous), or 365 (daily), a valid OutputCompounding value must also be specified. If neither InputCompounding nor OutputCompounding are specified, the default is 2 (semiannual) for both. (default) | scalar

Compounding frequency of the output par rates, specified as a scalar with allowed values:

- 1 - Annual compounding
- 2 - Semiannual compounding (default)
- 3 - Compounding three times per year
- 4-Quarterly compounding
- 6 - Bimonthly compounding
- 12 - Monthly compounding

Data Types: single | double

## ' OutputBasis ' - Day count basis of output par rates

if OutputBasis is not specified, it is assigned the value specified for InputBasis. If neither InputBasis nor OutputBasis are specified, the default is 0 (actual/actual) for both. (default) | scalar

Day count basis of output zero rates, specified as a scalar with possible values:

- $0=$ actual/actual
- $1=30 / 360$ (SIA)
- 2 = actual/360
- 3 = actual/365
- $4=30 / 360$ (PSA)
- $5=30 / 360$ (ISDA)
- $6=30 / 360$ (European)
- $7=$ actual/365 (Japanese)
- $8=$ actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- $10=\mathrm{actual} / 365$ (ICMA)
- $11=30 / 360 \mathrm{E}$ (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

Data Types: single | double

## ' InputCompounding' - Compounding frequency of input zero rates

if InputCompounding is 0 (simple), - 1 (continuous), or 365 (daily), the par rate OutputCompounding must also be specified a valid value. If InputCompounding is not specified, it is assigned the value specified for OutputCompounding. If neither InputCompounding nor OutputCompounding are specified, the default is 2 (semiannual) for both. (default) | scalar

Compounding frequency of the input forward rates, specified as a scalar with allowed values:

- 0 - Simple interest (no compounding, zero rates only)
- 1 - Annual compounding
- 2 - Semiannual compounding (default)
- 3 - Compounding three times per year
- 4 -Quarterly compounding
- 6 - Bimonthly compounding
- 12 - Monthly compounding
- 365 - Daily compounding (zero rates only)
-     - 1 - Continuous compounding (zero rates only)

Data Types: single | double

## 'InputBasis' - Day count basis of input zero rates

if InputBasis is not specified, it is assigned the value specified for OutputBasis. If neither InputBasis nor OutputBasis are specified, the default is 0 (actual/actual) for both. (default) | scalar

Day count basis of input zero rates, specified as a scalar with possible values:

- $0=$ actual/actual
- $1=30 / 360$ (SIA)
- 2 = actual/360
- 3 = actual/365
- $4=30 / 360$ (PSA)
- $5=30 / 360$ (ISDA)
- $6=30 / 360$ (European)
- $7=$ actual/365 (Japanese)
- $8=$ actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- $10=\mathrm{actual} / 365$ (ICMA)
- $11=30 / 360 \mathrm{E}$ (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

Data Types: single | double

## Description

[ParRates, CurveDates] = zero2pyld(ZeroRates, CurveDates, Settle) returns a par yield curve given a zero curve and its maturity dates.
[ParRates, CurveDates] = zero2pyld(ZeroRates, CurveDates, Settle, Name, Value) returns a par yield curve given a zero curve and its maturity dates using optional name-value pair arguments for InputCompounding, InputBasis, OutputCompounding, and OutputBasis.

| ParRates | A NUMBONDS-by-1 vector of annualized par yields, as decimal <br> fractions. (Par yields = coupon rates.) In aggregate, the yield <br> rates in ParRates constitute a par yield curve for the investment <br> horizon represented by CurveDates. |
| :--- | :--- |
| CurveDates | A NUMBONDS-by-1 vector of maturity dates (as serial date numbers) <br> that correspond to the par yield rates. This vector is the same as <br> the input vector CurveDates, but is sorted by ascending maturity. |

## Examples

## Compute Par Yield Curve Given a Zero Curve and Maturity Dates

Given a zero curve over a set of maturity dates, a settlement date, and annual compounding for the input zero curve and monthly compounding for the output par rates, compute a par yield curve.

```
ZeroRates = [0.0457
    0.0487
    0.0506
    0.0507
    0.0505
    0.0504
    0.0506
    0.0516
    0.0539
    0.0530];
CurveDates = [datenum('06-Nov-2000')
    datenum('11-Dec-2000')
    datenum('15-Jan-2001')
    datenum('05-Feb-2001')
    datenum('04-Mar-2001')
    datenum('02-Apr-2001')
    datenum('30-Apr-2001')
    datenum('25-Jun-2001')
    datenum('04-Sep-2001')
    datenum('12-Nov-2001')];
Settle = datenum('03-Nov-2000');
InputCompounding = 12;
InputBasis = 2;
OutputCompounding = 1;
OutputBasis = 2;
[ParRates, CurveDates] = zero2pyld(ZeroRates, CurveDates,...
Settle, 'InputCompounding',12,'InputBasis',2,'OutputCompounding',1,'OutputBasis',2)
ParRates =
-0.0436
    0.0611
    0.0579
    0.0567
    0.0550
    0.0543
    0.0541
    0.0546
    0.0565
    0.0561
```

## Demonstrate a Roundtrip From zero2pyld to pyld2zero

Given the following zero curve and its maturity dates, return the ParRates.

```
Settle = datenum('01-Feb-2013');
CurveDates = [datenum('01-Feb-2014')
    datenum('01-Feb-2015')
    datenum('01-Feb-2016')
    datenum('01-Feb-2018')
    datenum('01-Feb-2020')
    datenum('01-Feb-2023')
    datenum('01-Feb-2033')
    datenum('01-Feb-2043')];
OriginalZeroRates = [lllllllll
OutputCompounding = 1;
OutputBasis = 0;
InputCompounding = 1;
InputBasis = 0;
ParRates = zero2pyld(OriginalZeroRates, CurveDates, Settle, ...
'OutputCompounding', OutputCompounding, 'OutputBasis', OutputBasis, ...
'InputCompounding', InputCompounding, 'InputBasis', InputBasis)
ParRates =
0.0011
0.0030
0.0064
0.0142
```

0.0202
0.0251
0.0310
0.0331

Using the ParRates, use the pyld2zero function to return the ZeroRatesOut and determine the roundtrip error.

ZeroRatesOut = pyld2zero(ParRates, CurveDates, Settle, ...
'OutputCompounding', OutputCompounding, 'OutputBasis', OutputBasis, ... 'InputCompounding', InputCompounding, 'InputBasis', InputBasis)
$\max (a b s(O r i g i n a l Z e r o R a t e s ~-~ Z e r o R a t e s O u t)) ~ \% ~ R o u n d t r i p ~ e r r o r ~$
ZeroRatesOut =

## score

Compute credit scores for given data

## Syntax

```
Scores = score(sc)
Scores = score(sc, data)
[Scores,Points] = score(sc)
[Scores,Points] = score(sc,data)
```

## Description

Scores $=$ score (sc) computes the credit scores for the creditscorecard object's training data. This data can be a "training" or a "live" dataset. If the data input argument is not explicitly provided, the score function determines scores for the existing creditscorecard object's data.
formatpoints supports multiple alternatives to modify the scaling of the scores and can also be used to control the rounding of points and scores, and whether the base points are reported separately or spread across predictors. Missing data translates into NaN values for the corresponding points, and therefore for the total score. Use formatpoints to modify the score behavior for rows with missing data.

Scores $=$ score(sc, data) computes the credit scores for the given input data. This data can be a "training" or a "live" dataset.
formatpoints supports multiple alternatives to modify the scaling of the scores and can also be used to control the rounding of points and scores, and whether the base points are reported separately or spread across predictors. Missing data translates into NaN values for the corresponding points, and therefore for the total score. Use formatpoints to modify the score behavior for rows with missing data.
[Scores,Points] = score(sc) computes the credit scores and points for the given data. If the data input argument is not explicitly provided, the score function determines scores for the existing creditscorecard object's data.
formatpoints supports multiple alternatives to modify the scaling of the scores and can also be used to control the rounding of points and scores, and whether the base points are reported separately or spread across predictors. Missing data translates into NaN values for the corresponding points, and therefore for the total score. Use formatpoints to modify the score behavior for rows with missing data.
[Scores,Points] = score(sc,data) computes the credit scores and points for the given input data. This data can be a "training" or a "live" dataset.
formatpoints supports multiple alternatives to modify the scaling of the scores and can also be used to control the rounding of points and scores, and whether the base points are reported separately or spread across predictors. Missing data translates into NaN values for the corresponding points, and therefore for the total score. Use formatpoints to modify the score behavior for rows with missing data.

## Examples

## Obtain Scores for Training Data

This example shows how to use score to obtain scores for the training data.
Create a creditscorecard object using the CreditCardData.mat file to load the data (using a dataset from Refaat 2011). Use the 'IDVar' argument in the creditscorecard function to indicate that 'CustID' contains ID information and should not be included as a predictor variable.

```
load CreditCardData
sc = creditscorecard(data,'IDVar','CustID');
```

Perform automatic binning to bin for all predictors.

```
sc = autobinning(sc);
```

Fit a linear regression model using default parameters.

```
sc = fitmodel(sc);
1. Adding CustIncome, Deviance = 1490.8527, Chi2Stat = 32.588614, PValue = 1.1387992e-(
2. Adding TmWBank, Deviance = 1467.1415, Chi2Stat = 23.711203, PValue = 1.1192909e-06
3. Adding AMBalance, Deviance = 1455.5715, Chi2Stat = 11.569967, PValue = 0.0006702560
4. Adding EmpStatus, Deviance = 1447.3451, Chi2Stat = 8.2264038, PValue = 0.0041285257
5. Adding CustAge, Deviance = 1441.994, Chi2Stat = 5.3511754, PValue = 0.020708306
6. Adding ResStatus, Deviance = 1437.8756, Chi2Stat = 4.118404, PValue = 0.042419078
```

```
7. Adding OtherCC, Deviance = 1433.707, Chi2Stat = 4.1686018, PValue = 0.041179769
Generalized Linear regression model:

## Score a New Dataset

This example shows how to use score to obtain scores for a new dataset (for example, a validation or a test dataset) using the optional 'data' input in the score function.

Create a creditscorecard object using the CreditCardData.mat file to load the data (using a dataset from Refaat 2011). Use the 'IDVar' argument in the creditscorecard function to indicate that 'CustID' contains ID information and should not be included as a predictor variable.

```
load CreditCardData
sc = creditscorecard(data,'IDVar','CustID');
```

Perform automatic binning to bin for all predictors.

```
sc = autobinning(sc);
```

Fit a linear regression model using default parameters.

```
sc = fitmodel(sc);
```

1. Adding CustIncome, Deviance $=1490.8527$, Chi2Stat $=32.588614$, PValue $=1.1387992 \mathrm{e}-\mathrm{C}$
2. Adding TmWBank, Deviance $=1467.1415$, Chi2Stat $=23.711203$, PValue $=1.1192909 \mathrm{e}-06$
3. Adding AMBalance, Deviance $=1455.5715$, Chi2Stat $=11.569967$, PValue $=0.0006702560$
4. Adding EmpStatus, Deviance $=1447.3451$, Chi2Stat $=8.2264038$, PValue $=0.0041285257$
5. Adding CustAge, Deviance $=1441.994$, Chi2Stat $=5.3511754$, PValue $=0.020708306$
6. Adding ResStatus, Deviance $=1437.8756$, Chi2Stat $=4.118404$, PValue $=0.042419078$
7. Adding OtherCC, Deviance $=1433.707$, Chi2Stat $=4.1686018$, PValue $=0.041179769$
Generalized Linear regression model:
status ~ [Linear formula with 8 terms in 7 predictors]

## Input Arguments

sc - Credit scorecard model
creditscorecard object
Credit scorecard model, specified as a creditscorecard object. The creditscorecard function must be used to create a creditscorecard object.

## data - (Optional) Dataset to be scored <br> table

(Optional) Dataset to be scored, specified as a MATLAB table where each row corresponds to individual observations. The data must contain columns for each of the predictors in the creditscorecard object.

## Output Arguments

## Scores - Scores for each observation

vector
Scores for each observation, returned as a vector.

## Points - Points per predictor for each observation

table

Points per predictor for each observation, returned as a table.

## More About

## Algorithms

The score of an individual $i$ is given by the formula

```
Score(i) = Shift + Slope*(bO + b1*WOE1(i) + b2*WOE2(i) + ... +bp*WOEp(i))
```

where $b j$ is the coefficient of the $j$-th variable in the model, and $\operatorname{WOEj}(i)$ is the Weight of Evidence (WOE) value for the $i$-th individual corresponding to the $j$-th model variable. Shift and Slope are scaling constants further discussed below. The scaling constant can be controlled with formatpoints.

If the data for individual $i$ is in the $i$-th row of a given dataset, to compute a score, the data $(i, j)$ is binned using existing binning maps, and converted into a corresponding Weight of Evidence value WOE $j(i)$. Using the model coefficients, the unscaled score is computed as

```
s = bO + b1*WOE1(i) + ... +bp*WOEp(i).
```

For simplicity, assume in the description above that the $j$-th variable in the model is the $j$-th column in the data input, although, in general, the order of variables in a given dataset does not have to match the order of variables in the model, and the dataset could have additional variables that are not used in the model.

The formatting options can be controlled using formatpoints.

## formatpoints

Format scorecard points and scaling

## Syntax

sc = formatpoints(sc,Name,Value)

## Description

sc = formatpoints(sc, Name, Value) modifies the scorecard points and scaling using optional name-value pair arguments. For example, use optional name-value pair arguments to change the scaling of the scores or the rounding of the points.

## Examples

## Scale Points Using Worst and Best Scores

This example shows how to use formatpoints to scale by providing the Worst and Best score values. By using formatpoints to scale, you can put points and scores in a desired range that is more meaningful for practical purposes. Technically, this involves a linear transformation from the unscaled to the scaled points.

Create a creditscorecard object using the CreditCardData.mat file to load the data (using a dataset from Refaat 2011). Use the 'IDVar' argument in the creditscorecard function to indicate that 'CustID' contains ID information and should not be included as a predictor variable.

```
load CreditCardData
sc = creditscorecard(data,'IDVar','CustID');
```

Perform automatic binning to bin for all predictors.

```
sc = autobinning(sc);
```

Fit a linear regression model using default parameters.

```
sc = fitmodel(sc);
```

## Scale Points Using Points, Odds Levels, and PDO

This example shows how to use formatpoints to scale by providing the points, odds levels, and PDO (points to double the odds). By using formatpoints to scale, you can put points and scores in a desired range that is more meaningful for practical purposes. Technically, this involves a linear transformation from the unscaled to the scaled points by the formatpoints function.

Create a creditscorecard object using the CreditCardData.mat file to load the data (using a dataset from Refaat 2011). Use the 'IDVar ' argument in the
creditscorecard function to indicate that 'CustID' contains ID information and should not be included as a predictor variable.

```
load CreditCardData
sc = creditscorecard(data,'IDVar','CustID');
```

Perform automatic binning to bin for all predictors.

```
sc = autobinning(sc);
```

Fit a linear regression model using default parameters.

```
sc = fitmodel(sc);
```

1. Adding CustIncome, Deviance $=1490.8527$, Chi2Stat $=32.588614$, PValue $=1.1387992 \mathrm{e}-0$
2. Adding TmWBank, Deviance $=1467.1415$, Chi2Stat $=23.711203$, PValue $=1.1192909 \mathrm{e}-06$
3. Adding AMBalance, Deviance $=1455.5715$, Chi2Stat $=11.569967$, PValue $=0.0006702560$
4. Adding EmpStatus, Deviance $=1447.3451$, Chi2Stat $=8.2264038$, PValue $=0.0041285257$
5. Adding CustAge, Deviance $=1441.994$, Chi2Stat $=5.3511754$, PValue $=0.020708306$
6. Adding ResStatus, Deviance $=1437.8756$, Chi2Stat $=4.118404$, PValue $=0.042419078$
7. Adding OtherCC, Deviance $=1433.707$, Chi2Stat $=4.1686018$, PValue $=0.041179769$

Generalized Linear regression model:
status ~ [Linear formula with 8 terms in 7 predictors]
Distribution = Binomial

Estimated Coefficients:

| Estimate | SE |  | tStat |  |
| ---: | ---: | ---: | ---: | ---: | pValue

1200 observations, 1192 error degrees of freedom
Dispersion: 1
Chi^2-statistic vs. constant model: 89.7, p-value $=1.4 \mathrm{e}-16$
Display unscaled points for predictors retained in the fitting model and display the minimum and maximum possible unscaled scores.

\section*{Round Points}

This example shows how to use formatpoints to round points. Rounding is usually applied after scaling, otherwise, if the points for a particular predictor are all in a small
range, rounding could cause the rounded points for different bins to be the same. Also, rounding all the points may slightly change the minimum and maximum total points.

Create a creditscorecard object using the CreditCardData.mat file to load the data (using a dataset from Refaat 2011). Use the 'IDVar' argument in the creditscorecard function to indicate that 'CustID' contains ID information and should not be included as a predictor variable.
```

load CreditCardData
sc = creditscorecard(data,'IDVar','CustID');

```

Perform automatic binning to bin for all predictors.
```

sc = autobinning(sc);

```

Fit a linear regression model using default parameters.
```

sc = fitmodel(sc);

\section*{Scores for Missing or Out-of-Range Data}

This example shows how to use formatpoints to score missing or out-of-range data. When data is scored, some observations can be either missing (NaN, or undefined) or out of range. You need to decide whether or not points are assigned to these cases. Use the name-value pair argument Missing to do so.

Create a creditscorecard object using the CreditCardData.mat file to load the data (using a dataset from Refaat 2011). Use the 'IDVar' argument in the creditscorecard function to indicate that 'CustID' contains ID information and should not be included as a predictor variable.
```

load CreditCardData
sc = creditscorecard(data,'IDVar','CustID');

```

Perform automatic binning to bin for all predictors
```

sc = autobinning(sc);

```

Fit a linear regression model using default parameters.
```

sc = fitmodel(sc);

1. Adding CustIncome, Deviance = 1490.8527, Chi2Stat = 32.588614, PValue = 1.1387992e-08
2. Adding TmWBank, Deviance = 1467.1415, Chi2Stat = 23.711203, PValue = 1.1192909e-06
3. Adding AMBalance, Deviance = 1455.5715, Chi2Stat = 11.569967, PValue = 0.00067025601
4. Adding EmpStatus, Deviance = 1447.3451, Chi2Stat = 8.2264038, PValue = 0.0041285257
5. Adding CustAge, Deviance = 1441.994, Chi2Stat = 5.3511754, PValue = 0.020708306
Generalized Linear regression model:
logit(status) ~ 1 + CustAge + EmpStatus + CustIncome + TmWBank + AMBalance
Distribution = Binomial
Estimated Coefficients:
```

\begin{tabular}{lrrrr} 
CustAge & 0.57265 & 0.2482 & 2.3072 & 0.021043 \\

- "Troubleshooting Credit Scorecard Results" on page 8-83

\section*{Input Arguments}

\section*{sc - Credit scorecard model}
creditscorecard object
Credit scorecard model, specified as a creditscorecard object. The creditscorecard function must be used to create a creditscorecard object.

\section*{Name-Value Pair Arguments}

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

Example: SC =
formatpoints(sc, 'BasePoints',true,'Round ', 'AllPoints', 'WorstAndBestScores', [100, 700])

Note: ShiftAndSlope, PointsOddsAndPDO, and WorstAndBestScores are scaling methods and you can use only one of these name-value pair arguments at one time. The
other three name-value pair arguments (BasePoints, Missing, and Round) are not scaling methods and can be used together or with any one of the three scaling methods.

\section*{'BasePoints' - Indicator for separating base points}
false (default) | logical scalar
Indicator for separating base points, specified as a logical scalar. If true, the scorecard explicitly separates base points. If false, the base points are spread across all variables in the creditscorecard object.

Data Types: char

\section*{'Missing' - Indicator for points assigned to missing or out-of-range information when scoring}

NoScore (default) | string with values NoScore, ZeroWOE, MinPoints, and MaxPoints
Indicator for points assigned to missing or out-of-range information when scoring, specified as a string with a value for NoScore, ZeroPoints, MinPoints, or MaxPoints, where:
- NoScore - Missing and out-of-range data do not get points assigned and points are set to NaN . Also, the total score is set to NaN .
- ZeroWOE - Missing or out-of-range data get assigned a zero Weight-of-Evidence (WOE) value.
- MinPoints - Missing or out-of-range data get the minimum possible points for that predictor. This penalizes the score if higher scores are better.
- MaxPoints - Missing or out-of-range data get the maximum possible points for that predictor. This penalizes the score if lower scores are better.

\section*{Data Types: char}

\section*{'Round ' - Indicator whether to round points or scores \\ 'None' (default) | string with values 'AllPoints', 'FinalScore'}

Indicator whether to round points or scores, specified as a string with values
'AllPoints', 'FinalScore' or 'None', where:
- None - No rounding is applied.
- AllPoints - Apply rounding to each predictor's points before adding up the total score.
- FinalScore - Round the final score only (rounding is applied after all points are added up).

Data Types: char
'ShiftAndSlope' - Indicator for shift and slope scaling parameters
[0,1] (default) | numeric array with two elements [Shift,Slope]
Indicator for shift and slope scaling parameters for the credit scorecard, specified using numeric array with two elements [Shift, Slope]. Slope cannot be zero. The ShiftAndSlope values are used scale the scoring model.

Note: ShiftAndSlope, PointsOddsAndPDO, and WorstAndBestScores are scaling methods and you can use only one of these name-value pair arguments at one time. The other three name-value pair arguments (BasePoints, Missing, and Round) are not scaling methods and can be used together or with any one of the three scaling methods.

To remove a previous scaling and revert to unscaled scores, set ShiftAndSlope to \([0,1]\).

\section*{Data Types: double}

\section*{' Points0ddsAndPDO ' - Indicator for target points for given odds and double odds level numeric array with three elements [Points, Odds, PDO]}

Indicator for target points (Points) for a given odds level (Odds) and the desired number of points to double the odds (PDO), specified using numeric array with three elements [Points, Odds, PDO]. Odds must be a positive number. The PointsOddsAndPDO values are used to find scaling parameters for the scoring model.

Note: The points to double the odds (PDO) may be positive or negative, depending on whether higher scores mean lower risk, or vice versa.

ShiftAndSlope, PointsOddsAndPDO, and WorstAndBestScores are scaling methods and you can use only one of these name-value pair arguments at one time. The other three name-value pair arguments (BasePoints, Missing, and Round) are not scaling methods and can be used together or with any one of the three scaling methods.

To remove a previous scaling and revert to unscaled scores, set ShiftAndSlope to \([0,1]\).

\section*{Data Types: double}

\section*{'WorstAndBestScores ' - Indicator for worst (highest risk) and best (lowest risk) scores in scorecard \\ numeric array with two elements [WorstScore, BestScore]}

Indicator for worst (highest risk) and best (lowest risk) scores in the scorecard, specified as a numeric array with two elements [WorstScore, BestScore]. WorstScore and BestScore must be different values. These WorstAndBestScores values are used to find scaling parameters for the scoring model.

Note: WorstScore means the riskiest score, and its value could be lower or higher than the 'best' score. In other words, the 'minimum' score may be the 'worst' score or the 'best' score, depending on the desired scoring scale.

ShiftAndSlope, PointsOddsAndPDO, and WorstAndBestScores are scaling methods and you can use only one of these name-value pair arguments at one time. The other three name-value pair arguments (BasePoints, Missing, and Round) are not scaling methods and can be used together or with any one of the three scaling methods.

To remove a previous scaling and revert to unscaled scores, set ShiftAndSlope to \([0,1]\).

\section*{Data Types: double}

\section*{Output Arguments}

\section*{sc - Credit scorecard model}
creditscorecard object
Credit scorecard model returned as an updated creditscorecard object. For more information on using the creditscorecard object, see Using creditscorecard Objects.

\section*{More About}

\section*{Algorithms}

The score of an individual \(i\) is given by the formula

Score(i) \(=\) Shift + Slope*(b0 + b1*WOE1(i) + b2*WOE2(i) \(+\ldots+\) bp*WOEp(i))
where \(b j\) is the coefficient of the \(j\) th variable in the model, and \(\operatorname{WOEj}(i)\) is the Weight of Evidence (WOE) value for the \(i\) th individual corresponding to the \(j\) th model variable. Shift and Slope are scaling constants further discussed below. The scaling constant can be controlled with formatpoints.

If the data for individual \(i\) is in the \(i\)-th row of a given dataset, to compute a score, the data \((i, j)\) is binned using existing binning maps, and converted into a corresponding Weight of Evidence value WOE \(j(i)\). Using the model coefficients, the unscaled score is computed as
```

s = bO + b1*WOE1(i) + ... +bp*WOEp(i).

```

For simplicity, assume in the description above that the \(j\)-th variable in the model is the \(j\)-th column in the data input, although, in general, the order of variables in a given dataset does not have to match the order of variables in the model, and the dataset could have additional variables that are not used in the model.

The formatting options can be controlled using formatpoints. When the base points are reported separately (see the formatpoints parameter BasePoints), the base points are given by

Base Points = Shift + Slope*b0, and the points for the \(j\)-th predictor, \(i\)-th row are given by
```

Points_ji = Slope*(bj*WOEj(i))).

```

By default, the base points are not reported separately, in which case
Points_ji = (Shift + Slope*b0)/p + Slope*(bj*WOEj(i)), where \(\bar{p}\) is the number of predictors in the scorecard model.

By default, no rounding is applied to the points by the score function (Round is None). If Round is set to AllPoints using formatpoints, then the points for individual \(i\) for variable \(j\) are given by
points if rounding is 'AllPoints': round( Points_ji )
and, if base points are reported separately, the are also rounded. This yields integervalued points per predictor, hence also integer-valued scores. If Round is set to FinalScore using formatpoints, then the points per predictor are not rounded, and only the final score is rounded
```

score if rounding is 'FinalScore': round(Score(i)).

```

Regarding the scaling parameters, the Shift parameter, and the Slope parameter can be set directly with the ShiftAndSlope parameter of formatpoints. Alternatively, you can use the formatpoints parameter for WorstAndBestScores. In this case, the parameters Shift and Slope are found internally by solving the system

Shift + Slope*smin = WorstScore, Shift + Slope*smax = BestScore, where WorstScore and BestScore are the first and second elements in the formatpoints parameter for WorstAndBestScores and smin and smax are the minimum and maximum possible unscaled scores:
```

smin = b0 + min(b1*WOE1) + ... +min(bp*WOEp),
smax = b0 + max(b1*WOE1) + ... +max(bp*WOEp).

```

A third alternative to scale scores is the PointsOddsAndPDO parameter in formatpoints. In this case, assume that the unscaled score \(s\) gives the log-odds for a row, and the Shift and Slope parameters are found by solving the following system
```

Points = Shift + Slope*log(Odds)
Points + PDO = Shift + Slope*log(2*Odds)

```
where Points, Odds, and PDO ("points to double the odds") are the first, second, and
third elements in the PointsOddsAndPDO parameter.

Whenever a given dataset has a missing or out-of-range value data \((i, j)\), the points for predictor \(j\), for individual \(i\), are set to NaN by default, which results in a missing score for that row (a NaN score). Using the Missing parameter for formatpoints, you can modify this behavior and set the corresponding Weight-of-Evidence (WOE) value to zero, or set the points to the minimum points, or the maximum points for that predictor.

\section*{displaypoints}

Return points per predictor per bin

\section*{Syntax}

PointsInfo = displaypoints(sc)
[PointsInfo,MinScore, MaxScore] = displaypoints(sc)

\section*{Description}

PointsInfo = displaypoints(sc) returns a table of points for all bins of all predictor variables used in the creditscorecard object after a linear logistic regression model is fit using fitmodel to the Weight of Evidence data. The Points Info table displays information on the predictor name, bin labels, and the corresponding points per bin.
[PointsInfo,MinScore, MaxScore] = displaypoints(sc) returns a table of points for all bins of all predictor variables used in the creditscorecard object after a linear logistic regression model is fit (fitmodel) to the Weight of Evidence data. The PointsInfo table displays information on the predictor name, bin labels, and the corresponding points per bin and displaypoints. In addition, the optional MinScore and MaxScore values are returned.

\section*{Examples}

\section*{Display Unscaled Points}

This example shows how to use displaypoints after a model is fitted to compute the unscaled points per bin, for a given predictor in the creditscorecard model.

Create a creditscorecard object using the CreditCardData.mat file to load the data (using a dataset from Refaat 2011). Use the 'IDVar' argument in the creditscorecard function to indicate that 'CustID' contains ID information and should not be included as a predictor variable.
```

load CreditCardData
sc = creditscorecard(data,'IDVar','CustID');

```

Perform automatic binning to bin for all predictors.
```

sc = autobinning(sc);

```

Fit a linear regression model using default parameters.
```

sc = fitmodel(sc);

```

\section*{Display Scaled Points}

This example shows how to use formatpoints after a model is fitted to format scaled points, and then use displaypoints to display the scaled points per bin, for a given predictor in the creditscorecard model.

Points become scaled when a range is defined. Specifically, a linear transformation from the unscaled to the scaled points is necessary. This transformation is defined either by supplying a shift and slope or by specifying the worst and best scores possible. (For more information, see formatpoints.)

Create a creditscorecard object using the CreditCardData.mat file to load the data (using a dataset from Refaat 2011). Use the 'IDVar' argument in the creditscorecard function to indicate that 'CustID' contains ID information and should not be included as a predictor variable.
load CreditCardData
```

sc = creditscorecard(data,'IDVar','CustID');

```

Perform automatic binning to bin for all predictors.
```

sc = autobinning(sc);

```

Fit a linear regression model using default parameters.
```

sC = fitmodel(SC);

```
1. Adding CustIncome, Deviance \(=1490.8527\), Chi2Stat \(=32.588614\), PValue \(=1.1387992 e-1\)
2. Adding TmWBank, Deviance \(=1467.1415\), Chi2Stat \(=23.711203\), \(\mathrm{PValue}=1.1192909 \mathrm{e}-06\)
3. Adding AMBalance, Deviance \(=1455.5715\), Chi2Stat \(=11.569967\), PValue \(=0.0006702560\)
4. Adding EmpStatus, Deviance \(=1447.3451\), Chi2Stat \(=8.2264038\), PValue \(=0.0041285257\)
5. Adding CustAge, Deviance \(=1441.994\), Chi2Stat \(=5.3511754\), PValue \(=0.020708306\)
6. Adding ResStatus, Deviance \(=1437.8756\), Chi2Stat \(=4.118404\), PValue \(=0.042419078\)
7. Adding OtherCC, Deviance \(=1433.707\), Chi2Stat \(=4.1686018\), PValue \(=0.041179769\)
Generalized Linear regression model:
    status ~ [Linear formula with 8 terms in 7 predictors]
    Distribution = Binomial

Estimated Coefficients:

\hline
\end{tabular}
```

'AMBalance' '[1254.28,1597.44)' 58.231
AMBalance' '[1597.44,Inf]' 39.729
MinScore =
300.0000
MaxScore =

```
    850.0000

Notice that, as expected, the values of MinScore and MaxScore correspond to the worst and best possible scores.

\section*{Separate the Base Points From the Total Points}

This example shows how to use displaypoints after a model is fitted to separate the base points from the rest of the points assigned to each predictor variable. The namevalue pair argument 'BasePoints' in the formatpoints function is a boolean that serves this purpose. By default, the base points are spread across all variables in the scorecard.

Create a creditscorecard object using the CreditCardData.mat file to load the data (using a dataset from Refaat 2011). Use the 'IDVar' argument in the creditscorecard function to indicate that 'CustID' contains ID information and should not be included as a predictor variable.
```

load CreditCardData
sc = creditscorecard(data,'IDVar','CustID');

```

Perform automatic binning to bin for all predictors.
```

sc = autobinning(sc);

```

Fit a linear regression model using default parameters.
\(s c=\) fitmodel(sc);
1. Adding CustIncome, Deviance \(=1490.8527\), Chi2Stat \(=32.588614\), PValue \(=1.1387992 \mathrm{e}-(\)
2. Adding TmWBank, Deviance \(=1467.1415\), Chi2Stat \(=23.711203\), PValue \(=1.1192909 \mathrm{e}-06\)
3. Adding AMBalance, Deviance \(=1455.5715\), Chi2Stat \(=11.569967\), PValue \(=0.0006702560\)
4. Adding EmpStatus, Deviance \(=1447.3451\), Chi2Stat \(=8.2264038\), PValue \(=0.0041285257\)
5. Adding CustAge, Deviance \(=1441.994\), Chi2Stat \(=5.3511754\), PValue \(=0.020708306\)
6. Adding ResStatus, Deviance \(=1437.8756\), Chi2Stat \(=4.118404\), PValue \(=0.042419078\)
7. Adding OtherCC, Deviance \(=1433.707\), Chi2Stat \(=4.1686018\), PValue \(=0.041179769\)

\hline 'AMBalance' & '[-Inf, 558.88) & 0.25517 \\
\hline 'AMBalance' & ' [558.88, 1254.28) ' & -0.11781 \\
\hline 'AMBalance' & '[1254.28, 1597.44) ' & -0.16498 \\
\hline 'AMBalance' & '[1597.44, Inf]' & -0.3124 \\
\hline
\end{tabular}

\section*{Display Points After Modifying Bin Labels}

This example shows how to use displaypoints after a model is fitted and the modifybins function is used to provide user-defined bin labels for a numeric predictor.

Create a creditscorecard object using the CreditCardData.mat file to load the data (using a dataset from Refaat 2011). Use the 'IDVar' argument in the creditscorecard function to indicate that 'CustID' contains ID information and should not be included as a predictor variable.
```

load CreditCardData
sc = creditscorecard(data,'IDVar','CustID');

```

Perform automatic binning to bin for all predictors.
```

sc = autobinning(sc);

```

Fit a linear regression model using default parameters.
```

sc = fitmodel(sc);

```

Use the displaypoints function to display point information.
[PointsInfo,MinScore,MaxScore] = displaypoints(sc)
Use the modifybins function to specify user-defined bin labels for 'CustAge' so that the bin ranges are described in natural language.
```

labels = {'Up to 32','33 to 36','37 to 39','40 to 45','46 to 47','48 to 57','At least
sc = modifybins(sc,'CustAge','BinLabels',labels);

```

Rerun displaypoints to verify the updated bin labels.
[PointsInfo,MinScore, MaxScore] = displaypoints(sc)
- "Case Study for a Credit Scorecard Analysis" on page 8-93
- "Troubleshooting Credit Scorecard Results" on page 8-83

\section*{Input Arguments}

\section*{sc - Credit scorecard model \\ creditscorecard object}

Credit scorecard model, specified as a creditscorecard object. The creditscorecard function must be used to create a creditscorecard object.

\section*{Output Arguments}

PointsInfo - One row per bin, per predictor, with the corresponding points table

One row per bin, per predictor, with the corresponding points, returned as a table. For example:
\begin{tabular}{|l|l|l|}
\hline Predictors & Bin & Points \\
\hline Predictor_1 & Bin_11 & Points_11 \\
\hline
\end{tabular}
\begin{tabular}{|l|l|l|}
\hline Predictors & Bin & Points \\
\hline & \(\ldots\) & \(\ldots\) \\
\hline Predictor_2 & Bin_21 & Points_21 \\
\hline & \(\ldots\) & \(\ldots\) \\
\hline Predictor_ \(j\) & Bin_ji & Points_ji \\
\hline & \(\ldots\) & \(\ldots\) \\
\hline
\end{tabular}

When base points are reported separately (see formatpoints), the first row of the returned PointsInfo table contains the base points.

\section*{MinScore - Minimum possible total score}
scalar
Minimum possible total score, returned as a scalar.

Note: Minimum score is the lowest possible total score in the mathematical sense, independently of whether a low score means high risk or low risk.

\section*{MaxScore - Maximum possible total score}
scalar
Maximum possible total score, returned as a scalar.

Note: Maximum score is the highest possible total score in the mathematical sense, independently of whether a high score means high risk or low risk.

\section*{More About}

\section*{Algorithms}

The points for predictor \(j\) and bin \(i\) are, by default, given by
Points_ji = (Shift + Slope*bO)/p + Slope*(bj*WOEj(i))
where \(b j\) is the model coefficient of predictor \(j, p\) is the number of predictors in the model, and \(\operatorname{WOEj}(i)\) is the Weight of Evidence (WOE) value for the \(i\)-th bin corresponding to the j-th model predictor. Shift and Slope are scaling constants.

When the base points are reported separately (see the formatpoints name-value pair argument BasePoints), the base points are given by

Base Points = Shift + Slope*b0, and the points for the \(j\)-th predictor, \(i\)-th row are given by
```

Points_ji = Slope*(bj*WOEj(i))).

```

By default, the base points are not reported separately.
The minimum and maximum scores are:
```

MinScore = Shift + Slope*b0 + min(Slope*b1*WOE1) + ... +min(Slope*bp*WOEp)),
MaxScore = Shift + Slope*bO + max(Slope*b1*WOE1) + ... +max(Slope*bp*WOEp)).

```

Use formatpoints to control the way points are scaled, rounded, and whether the base points are reported separately. See formatpoints for more information on format parameters and for details and formulas on these formatting options.

\section*{fitmodel}

Fit logistic regression model to Weight of Evidence (WOE) data

\section*{Syntax}
```

sc = fitmodel(sc)

```
[sc,mdl] = fitmodel(sc)
[sc,mdl] = fitmodel(__, Name, Value)

\section*{Description}
sc = fitmodel(sc) fits a logistic regression model to the Weight of Evidence (WOE) data and stores the model predictor names and corresponding coefficients in the creditscorecard object.
fitmodel internally transforms all the predictor variables into WOE values, using the bins found with the automatic or manual binning process. The response variable is mapped so that "Good" is 1 , and "Bad" is 0 . This implies that higher (unscaled) scores correspond to better (less risky) individuals (smaller probability of default).

Alternatively, you can use setmodel to provide names of the predictors that you want in the logistic regression model, along with their corresponding coefficients.
[sc,mdl] = fitmodel(sc) fits a logistic regression model to the Weight of Evidence (WOE) data and stores the model predictor names and corresponding coefficients in the creditscorecard object. fitmodel returns an updated creditscorecard object and a GeneralizedLinearModel object containing the fitted model.
fitmodel internally transforms all the predictor variables into WOE values, using the bins found with the automatic or manual binning process. The response variable is mapped so that "Good" is 1 , and "Bad" is 0 . This implies that higher (unscaled) scores correspond to better (less risky) individuals (smaller probability of default).

Alternatively, you can use setmodel to provide names of the predictors that you want in the logistic regression model, along with their corresponding coefficients.
[sc,mdl] = fitmodel(__ , Name, Value) fits a logistic regression model to the Weight of Evidence (WOE) data using optional name-value pair arguments and stores the model predictor names and corresponding coefficients in the creditscorecard object. Using name-value pair arguments, you can select which Generalized Linear Model to fit the data. fitmodel returns an updated creditscorecard object and a GeneralizedLinearModel object containing the fitted model.
fitmodel internally transforms all the predictor variables into WOE values, using the bins found with the automatic or manual binning process. The response variable is mapped so that "Good" is 1 , and "Bad" is 0 . This implies that higher (unscaled) scores correspond to better (less risky) individuals (smaller probability of default).

Alternatively, you can use setmodel to provide names of the predictors that you want in the logistic regression model, along with their corresponding coefficients.

\section*{Examples}

\section*{Fit a Stepwise Logistic Model}

Create a creditscorecard object using the CreditCardData.mat file to load the data (using a dataset from Refaat 2011).
```

load CreditCardData
sc = creditscorecard(data,'IDVar','CustID')
sc =

```
    creditscorecard with properties:
            GoodLabel: 0
            ResponseVar: 'status'
                            VarNames: \(\{1 \times 11\) cell\}
            NumericPredictors: \{1x6 cell\}
        CategoricalPredictors: \{'ResStatus' 'EmpStatus' 'OtherCC'\}
                            IDVar: 'CustID'
                PredictorVars: \{1x9 cell\}
Perform automatic binning.
sc = autobinning(sc)

SC =
creditscorecard with properties:
```

                        GoodLabel: 0
            ResponseVar: 'status'
                            VarNames: {1x11 cell}
        NumericPredictors: {1x6 cell}
        CategoricalPredictors: {'ResStatus' 'EmpStatus' 'OtherCC'}
            IDVar: 'CustID'
            PredictorVars: {1x9 cell}
    ```

Use fitmodel to fit a logistic regression model using Weight of Evidence (WOE) data. fitmodel internally transforms all the predictor variables into WOE values, using the bins found with the automatic binning process. fitmodel then fits a logistic regression model using a stepwise method (by default).
```

sc = fitmodel(sc);

```

```

\section*{Fit a Logistic Model with All Predictors}

Create a creditscorecard object using the CreditCardData.mat file to load the data (using a dataset from Refaat 2011).
load CreditCardData
sc = creditscorecard(data,'IDVar', 'CustID')
SC =
    creditscorecard with properties:
                    GoodLabel: 0
                    ResponseVar: 'status'
                            VarNames: \{1x11 cell\}
            NumericPredictors: \(\{1 \times 6\) cell\}
        CategoricalPredictors: \{'ResStatus' 'EmpStatus' 'OtherCC'\}
                        IDVar: 'CustID'
                            PredictorVars: \{1x9 cell\}

Perform automatic binning.
```

sc = autobinning(sc,'Algorithm','EqualFrequency')

```
sc =
    creditscorecard with properties:

GoodLabel: 0
ResponseVar: 'status'
VarNames: \{1x11 cell\}
NumericPredictors: \(\{1 \times 6\) cell\} CategoricalPredictors: \{'ResStatus' 'EmpStatus' 'OtherCC'\} IDVar: 'CustID'
PredictorVars: \{1x9 cell\}

Use fitmodel to fit a logistic regression model using Weight of Evidence (WOE) data. fitmodel internally transforms all the predictor variables into WOE values, using the bins found with the automatic binning process. Set the VariableSelection namevalue pair argument to FullModel to specify that all predictors must be included in the fitted logistic regression model.
```

sc = fitmodel(sc,'VariableSelection','FullModel');
Generalized Linear regression model:
status ~ [Linear formula with 10 terms in 9 predictors]
Distribution = Binomial
Estimated Coefficients:

| Estimate | SE |  | tStat |  |
| ---: | ---: | ---: | ---: | ---: | pValue

```

1200 observations, 1190 error degrees of freedom
Dispersion: 1
Chi^2-statistic vs. constant model: 85.6, p-value \(=1.25 e-14\)
- "Case Study for a Credit Scorecard Analysis" on page 8-93
- "Troubleshooting Credit Scorecard Results" on page 8-83

\section*{Input Arguments}

\section*{sc - Credit scorecard model}
creditscorecard object

Credit scorecard model, specified as a creditscorecard object. The creditscorecard function must be used to create a creditscorecard object.

\section*{Name-Value Pair Arguments}

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, . . , NameN, ValueN.
```

Example:[sc,mdl] = fitmodel(sc,'VariableSelection','FullModel')

```

\section*{'PredictorVars ' - Predictor variables for fitting creditscorecard object \\ all predictors in the creditscorecard object (default) | cell array of strings}

Predictor variables for fitting the creditscorecard object, specified when using a cell array of strings. When provided, the creditscorecard object property PredictorsVars is updated. When not provided, the predictors used to create the creditscorecard object (by using the creditscorecard function) are used.
'VariableSelection' - Variable selection method to fit logistic regression model
'Stepwise' (default) | string with values 'Stepwise', 'FullModel'
The variable selection method to fit the logistic regression model, specified as a string with values 'Stepwise' or 'FullModel':
- Stepwise - Uses a stepwise selection method which calls the Statistics and Machine Learning Toolbox function stepwiseglm. Only variables in PredictorVars can potentially become part of the model and uses the StartingModel name-value pair argument to select the starting model.
- FullModel - Fits a model with all predictor variables in the PredictorVars namevalue pair argument and calls fitglm.

Note: Only variables in the PredictorVars property of the creditscorecard object can potentially become part of the logistic regression model and only linear terms are included in this model with no interactions or any other higher-order terms.

The response variable is mapped so that "Good" is 1 and " Bad " is 0 .

\footnotetext{
Data Types: char
}

\section*{'StartingModel' - Initial model for Stepwise variable selection \\ 'Constant' (default) | string with values 'Constant', 'Linear'}

Initial model for the Stepwise variable selection method, specified using a string with values 'Constant' or 'Linear'. This option determines the initial model (constant or linear) that the Statistics and Machine Learning Toolbox function stepwiseglm starts with.
- Constant - Starts the stepwise method with an empty (constant only) model.
- Linear - Starts the stepwise method from a full (all predictors in) model.

Note: StartingModel is used only for the Stepwise option of VariableSelection and has no effect for the FullModel option of VariableSelection.

\section*{Data Types: char}

\section*{' Display ' - Indicator to display model information at command line \\ 'On' (default) | string with values 'On ', 'Off'}

Indicator to display model information at command line, specified using a string with value 'On' or 'Off'.

Data Types: char

\section*{Output Arguments}

\section*{sc - Credit scorecard model}
creditscorecard object
Credit scorecard model, returned as an updated creditscorecard object. The creditscorecard object contains information about the model predictors and coefficients used to fit the WOE data. For more information on using the creditscorecard object, see Using creditscorecard Objects.

\section*{mdl - Fitted logistic model}

GeneralizedLinearModel object
Fitted logistic model, retuned as an object of type GeneralizedLinearModel containing the fitted model. For more information on a GeneralizedLinearModel object, see GeneralizedLinearModel.

\section*{More About}

\section*{Algorithms}

For the logistic regression model used in the creditscorecard object, the probability of being "Bad" is given by

ProbBad \(=\exp (-s) /(1+\exp (-s))\).
- "Credit Scorecard Modeling Workflow" on page 8-80
- "About Credit Scorecards" on page 8-75
- Using creditscorecard Objects
- "What Are Generalized Linear Models?"

\section*{References}

autobinning | bindata | bininfo | creditscorecard | displaypoints | fitglm | formatpoints | GeneralizedLinearModel | modifybins | modifypredictor | plotbins | predictorinfo | probdefault | score | setmodel | stepwiseglm | validatemodel

Introduced in R2014b

\section*{setmodel}

Set model predictors and coefficients

\section*{Syntax}
```

sc = setmodel(sc,ModelPredictors,ModelCoefficients)

```

\section*{Description}
sc = setmodel(sc,ModelPredictors,ModelCoefficients) sets the predictors and coefficients of a linear logistic regression model fitted outside the creditscorecard object and returns an updated creditscorecard object. The predictors and coefficients are used for the computation of scorecard points. Use setmodel in lieu of fitmodel, which fits a linear logistic regression model, because setmodel offers increased flexibility. For example, when a model fitted with fitmodel needs to be modified, you can use setmodel. For more information, see "Workflows for Using setmodel" on page 18-1622.

Note: When using setmodel, the following assumptions apply:
- The model coefficients correspond to a linear logistic regression model (where only linear terms are included in the model and there are no interactions or any other higher-order terms).
- The model was previously fitted using Weight of Evidence (WOE) data with the response mapped so that 'Good' is 1 and 'Bad' is 0 .

\section*{Examples}

\section*{Modify a GLM Model Fitted with fitmodel}

This example shows how to use setmodel to make modifications to a logistic regression model initially fitted using the fitmodel function, and then set the new logistic regression model predictors and coefficients back into the creditscorecard object.

Create a creditscorecard object using the CreditCardData.mat file to load the data (using a dataset from Refaat 2011).
```

load CreditCardData
sc = creditscorecard(data,'IDVar','CustID')
SC =
creditscorecard with properties:
GoodLabel: 0
ResponseVar: 'status'
VarNames: {1\times11 cell}
NumericPredictors: {1x6 cell}
CategoricalPredictors: {'ResStatus' 'EmpStatus' 'OtherCC'}
IDVar: 'CustID'
PredictorVars: {1x9 cell}

```

Perform automatic binning.
```

sc = autobinning(sc);

```

The standard workflow is to use the fitmodel function to fit a logistic regression model using a stepwise method. However, fitmodel only supports limited options regarding the stepwise procedure. You can use the optional mdl output argument from fitmodel to get a copy of the fitted GeneralizedLinearModel object, to later modify.
```

[sc,mdl] = fitmodel(sc);

1. Adding CustIncome, Deviance = 1490.8527, Chi2Stat = 32.588614, PValue = 1.1387992e-(
2. Adding TmWBank, Deviance = 1467.1415, Chi2Stat = 23.711203, PValue = 1.1192909e-06
3. Adding AMBalance, Deviance = 1455.5715, Chi2Stat = 11.569967, PValue = 0.0006702560
4. Adding EmpStatus, Deviance = 1447.3451, Chi2Stat = 8.2264038, PValue = 0.0041285257
5. Adding CustAge, Deviance = 1441.994, Chi2Stat = 5.3511754, PValue = 0.020708306
6. Adding ResStatus, Deviance = 1437.8756, Chi2Stat = 4.118404, PValue = 0.042419078
7. Adding OtherCC, Deviance = 1433.707, Chi2Stat = 4.1686018, PValue = 0.041179769
Generalized Linear regression model:
status ~ [Linear formula with 8 terms in 7 predictors]
Distribution = Binomial
Estimated Coefficients:
```
\begin{tabular}{lrrrrrr} 
& \multicolumn{2}{c}{ Estimate } & \multicolumn{1}{c}{ SE } & & \multicolumn{1}{c}{ tStat } &
\end{tabular} pValue
```

1200 observations, 1192 error degrees of freedom
Dispersion: 1
Chi^2-statistic vs. constant model: 89.7, p-value = 1.4e-16

```

Suppose you want to include, or "force," the predictor 'UtilRate' in the logistic regression model, even though the stepwise method did not include it in the fitted model. You can add 'UtilRate' to the logistic regression model using the GeneralizedLinearModel object mdl directly.
```

mdl = mdl.addTerms('UtilRate')
mdl =
Generalized Linear regression model:
status ~ [Linear formula with 9 terms in 8 predictors]
Distribution = Binomial
Estimated Coefficients:
Estimate

| SE | tStat | pValue |
| :---: | :---: | :---: |

| 0.23307 | 4.7503 | 2.0316e-06 |
| 0.52918 | 2.0563 | 0.03975 |
| 0.36557 | 2.8483 | 0.004395 |
| 0.60864 | 0.021618 | 0.9827 |

```
```

1 2 0 0 observations, 1191 error degrees of freedom
Dispersion: 1
Chi^2-statistic vs. constant model: 89.7, p-value = 5.26e-16

```

Use setmodel to update the model predictors and model coefficients in the creditscorecard object. The ModelPredictors input argument does not explicitly include a string for the intercept. However, the ModelCoefficients input argument does have the intercept information as its first element.
```

ModelPredictors =
CustAge
'ResStatus'
'EmpStatus'
'CustIncome'
'TmWBank'
'OtherCC'
'AMBalance'
'UtilRate'

```
ModelPredictors = mdl.PredictorNames
ModelCoefficients = mdl.Coefficients.Estimate
sc = setmodel(sc,ModelPredictors,ModelCoefficients);
ModelCoefficients =
    0.7024
    0.6084
    1.3773
    0.8856
    0.7015
    1.1071
    1.0882
    1.0413
    0.0132

Verify that 'UtilRate' is part of the scorecard predictors by displaying the scorecard points.
```

pi = displaypoints(sc)

```
pi =
\begin{tabular}{|c|c|c|}

\section*{Fit a Logistic Regression Model Outside of the creditscorecard Object}

This example shows how to use setmodel to fit a logistic regression model directly, without using the fitmodel function, and then set the new model predictors and coefficients back into the creditscorecard object. This approach gives more flexibility regarding options to control the stepwise procedure. This example fits a logistic regression model with a nondefault value for the 'PEnter' parameter, the criterion to admit a new predictor in the logistic regression model during the stepwise procedure.

Create a creditscorecard object using the CreditCardData.mat file to load the data (using a dataset from Refaat 2011). Use the 'IDVar' argument to indicate that 'CustID' contains ID information and should not be included as a predictor variable.
```

load CreditCardData
sc = creditscorecard(data,'IDVar','CustID')
sc =

```
    creditscorecard with properties:
            GoodLabel: 0
            ResponseVar: 'status'
                            VarNames: \{1×11 cell\}
        NumericPredictors: \{1x6 cell\}
        CategoricalPredictors: \{'ResStatus' 'EmpStatus' 'OtherCC'\}
                    IDVar: 'CustID'
            PredictorVars: \{1x9 cell\}

Perform automatic binning.
```

sc = autobinning(sc);

```

The logistic regression model needs to be fit with Weight of Evidence (WOE) data. The WOE transformation is a special case of binning, since the data first needs to be binned, and then the binned information is mapped to the corresponding WOE values. This transformation is done using the bindata function. bindata has an argument that prepares the data for the model fitting step. By setting the bindata name-value pair argument for 'OutputType' to WOEModelInput':
- All predictors are converted to WOE values.
- The output contains only predictors and response (no 'IDVar ' or any unused variables).
- Predictors with infinite or undefined (NaN) WOE values are discarded.
- The response values are mapped so that "Good" is 1 and "Bad" is 0 (this implies that higher unscaled scores correspond to better, less risky customers).
```

bd = bindata(sc,'OutputType','WOEModelInput');

```

Use a sample of four variables (including the response) in the original data.
```

data(1:10,{'CustAge' 'ResStatus' 'CustIncome' 'status'})

```
ans =
\begin{tabular}{|c|c|c|c|}
\hline CustAge & ResStatus & CustIncome & status \\
\hline 53 & Tenant & 50000 & 0 \\
\hline 61 & Home Owner & 52000 & 0 \\
\hline 47 & Tenant & 37000 & 0 \\
\hline 50 & Home Owner & 53000 & 0 \\
\hline 68 & Home Owner & 53000 & 0 \\
\hline 65 & Home Owner & 48000 & 0 \\
\hline 34 & Home Owner & 32000 & 1 \\

\section*{Input Arguments}

\author{
sc - Credit scorecard model
}
creditscorecard object
Credit scorecard model, specified as a creditscorecard object. The creditscorecard function must be used to create a creditscorecard object.

\section*{ModelPredictors - Predictor names included in fitted model}
cell array of strings with predictor values
\{'PredictorName1','PredictorName2',...\}
Predictor names included in the fitted model, specified as a cell array of strings as \{'PredictorName1','PredictorName2', ...\}. The predictor names must match predictor variable names in the creditscorecard object.

Note: Do not include a string for the constant term in ModelPredictors, setmodel internally handles the ' (Intercept)' term based on the number of model coefficients (see ModelCoefficients).

\section*{Data Types: cell}

\section*{ModelCoefficients - Model coefficients corresponding to model predictors numeric array with values [coeff1, coeff2,...]}

Model coefficients corresponding to the model predictors, specified as a numeric array of model coefficients, [coeff1, coeff2, . .]. If \(N\) is the number of predictor names provided in ModelPredictors, the size of ModelCoefficients can be \(N\) or \(N+1\). If ModelCoefficients has \(N+1\) elements, then the first coefficient is used as the ' (Intercept)' of the fitted model. Otherwise, the ' (Intercept)' is set to 0 .

Data Types: double

\section*{Output Arguments}

\section*{sc - Credit scorecard model}
creditscorecard object

Credit scorecard model, returned as an updated creditscorecard object. The creditscorecard object contains information about the model predictors and coefficients of the fitted model. For more information on using the creditscorecard object, see Using creditscorecard Objects.

\section*{More About}

\section*{Workflows for Using setmodel}

When using setmodel, there are two possible workflows to set the final model predictors and model coefficients into a creditscorecard object.

The first workflow is:
- Use fitmodel to get the optional output argument mdl. This is a GeneralizedLinearModel object and you can add and remove terms, or modify the parameters of the stepwise procedure. Only linear terms can be in the model (no interactions or any other higher-order terms).
- Once the GeneralizedLinearModel object is satisfactory, set the final model predictors and model coefficients into the creditscorecard object using the setmodel input arguments for ModelPredictors and ModelCoefficients.

An alternate workflow is:
- Obtain the Weight of Evidence (WOE) data using bindata. Use the 'WOEModelInput ' option for the 'OutputType ' name-value pair argument in bindata to ensure that:
- The predictors data is transformed to WOE.
- Only predictors whose bins have finite WOE values are included.
- The response variable is placed in the last column.
- The response variable is mapped ("Good" is 1 and "Bad" is 0 ).
- Use the data from the previous step to fit a linear logistic regression model (only linear terms in the model, no interactions, or any other higher-order terms). See, for example, stepwiseglm.
- Once the GeneralizedLinearModel object is satisfactory, set the final model predictors and model coefficients into the creditscorecard object using the setmodel input arguments for ModelPredictors and ModelCoefficients.
- "Credit Scorecard Modeling Workflow" on page 8-80
- "About Credit Scorecards" on page 8-75

\section*{bindata}

Binned predictor variables

\section*{Syntax}
```

bdata = bindata(sc)
bdata = bindata(sc,data)
bdata = bindata(sc,Name,Value)

```

\section*{Description}
bdata = bindata(sc) binned predictor variables returned as a table. This is a table of the same size (see exception in the following Note) as the data input, but only the predictors specified in the creditscorecard object's PredictorVars property are binned and the remaining ones are unchanged.
bdata \(=\) bindata(sc, data) returns a table of binned predictor variables. bindata returns a table of the same size as the creditscorecard data, but only the predictors specified in the creditscorecard object's PredictorVars property are binned and the remaining ones are unchanged.
bdata \(=\) bindata(sc, Name, Value) binned predictor variables returned as a table using optional name-value pair arguments. This is a table of the same size (see exception in the following Note) as the data input, but only the predictors specified in the creditscorecard object's PredictorVars property are binned and the remaining ones are unchanged.

\footnotetext{
Note: When the bindata name-value pair argument 'OutputType' is set to 'WOEModelInput ', the bdata output only contains the columns corresponding to predictors whose bins do not have Inf or NaN Weight of Evidence (WOE) values, and bdata includes the mapped response as the last column.

Missing data (if any) are included in the bdata output as missing data as well, and do not influence the rules to discard predictors when 'OutputType' is set to 'WOEModelInput'.
}

\section*{Examples}

\section*{Bin creditscorecard Data as Bin Numbers, Categories, or WOE Values}

This example shows how to use the bindata function to simply bin or discretize data.
Suppose bin ranges of
- '0 to 30'
- '31 to 50'
- '51 and up'
are determined for the age variable (via manual or automatic binning). If a data point with age 41 is given, binning this data point means placing it in the bin for 41 years old, which is the second bin, or the ' 31 to 50 ' bin. Binning is then the mapping from the original data, into discrete groups or bins. In this example, you can say that a 41-year old is mapped into bin number 2, or that it is binned into the ' 31 to 50 ' category. If you know the Weight of Evidence (WOE) value for each of the three bins, you could also replace the data point 41 with the WOE value corresponding to the second bin. bindata supports the three binning formats just mentioned:
- Bin number (where the 'OutputType' name-value pair argument is set to 'BinNumber '); this is the default option, and in this case, 41 is mapped to bin 2.
- Categorical (where the 'OutputType' name-value pair argument is set to 'Categorical'); in this case, 41 is mapped to the ' 31 to 50 ' bin.
- WOE value (where the 'OutputType' name-value pair argument is set to 'WOE '); in this case, 41 is mapped to the WOE value of bin number 2.

Create a creditscorecard object using the CreditCardData.mat file to load the data (using a dataset from Refaat 2011). Use the 'IDVar' argument to indicate that 'CustID' contains ID information and should not be included as a predictor variable.
```

load CreditCardData
sc = creditscorecard(data,'IDVar','CustID')
sc =
creditscorecard with properties:

```
```

                        GoodLabel: 0
            ResponseVar: 'status'
            VarNames: {1x11 cell}
    NumericPredictors: {1x6 cell}
    CategoricalPredictors: {'ResStatus' 'EmpStatus' 'OtherCC'}
IDVar: 'CustID'
PredictorVars: {1x9 cell}

```

Perform automatic binning.
```

sc = autobinning(sc);

```

Show the bin information for 'CustAge'.
```

bininfo(sc,'CustAge')

```
ans =
\begin{tabular}{|c|c|c|c|c|c|}

\section*{Apply a Weight of Evidence (WOE) Transformation to Data}
bindata supports the following types of WOE transformation:
- When the 'OutputType' name-value argument is set to 'WOE ', bindata simply applies the WOE transformation to all predictors and keeps the rest of the variables in the original data in place and unchanged.
- When the 'OutputType' name-value pair argument is set to 'WOEModelInput ', bindata returns a table that can be used directly as an input for fitting a logistic regression model for the scorecard. In this case, bindata:
- Applies WOE transformation to all predictors.
- Returns predictor variables, but no IDVar or unused variables are included in the output.
- Includes the mapped response variable as the last column.
- The fitmodel function calls bindata internally using the 'WOEModelInput ' option to fit the logistic regression model for the creditscorecard model.

Create a creditscorecard object using the CreditCardData.mat file to load the data (using a dataset from Refaat 2011). Use the 'IDVar' argument to indicate that 'CustID' contains ID information and should not be included as a predictor variable.
```

sc =

```
load CreditCardData
sc = creditscorecard(data,'IDVar','CustID')
    creditscorecard with properties:
                    GoodLabel: 0
            ResponseVar: 'status'
                    VarNames: \(\{1 \times 11\) cell\}
            NumericPredictors: \{1x6 cell\}
        CategoricalPredictors: \{'ResStatus' 'EmpStatus' 'OtherCC'\}
                                    IDVar: 'CustID'
                PredictorVars: \{1x9 cell\}

Perform automatic binning.
sc = autobinning(sc);
Show the bin information for 'CustAge'.
```

bininfo(sc,'CustAge')

```
ans =
\begin{tabular}{|c|c|c|c|c|c|}
\hline Bin & Good & Bad & Odds & WOE & InfoValue \\
\hline [ [-Inf, 33) ' & 70 & 53 & 1.3208 & -0.42622 & 0.019746 \\
\hline ' \([33,37)\) ' & 64 & 47 & 1.3617 & -0.39568 & 0.015308 \\
\hline '[37,40)' & 73 & 47 & 1.5532 & -0.26411 & 0.0072573 \\
\hline '[40,46)' & 174 & 94 & 1.8511 & -0.088658 & 0.001781 \\
\hline '[46,48)' & 61 & 25 & 2.44 & 0.18758 & 0.0024372 \\
\hline ' \([48,58\) )' & 263 & 105 & 2.5048 & 0.21378 & 0.013476 \\
\hline '[58,Inf]' & 98 & 26 & 3.7692 & 0.62245 & 0.0352 \\
\hline 'Totals' & 803 & 397 & 2.0227 & NaN & 0.095205 \\
\hline
\end{tabular}

These are the first 10 age values in the original data, used to create the creditscorecard object.
```

data(1:10,'CustAge')
ans =
CustAge
5 3
6 1
4 7
50
6 8
65
34
50
50
4 9

```

Convert the test data to WOE values. To do this, set the bindata name-value pair argument for 'OutputType' to 'WOE'.
bdata = bindata(sc,'OutputType','WOE');
These are the first 10 binned ages, in WOE format. The ages are mapped to the WOE values displayed internally by bininfo.
```

bdata(1:10,'CustAge')
ans =
CustAge
0.21378
0.62245
0.18758
0.21378
0.62245
0.62245
0.39568
0.21378
0.21378
0.21378

```

These are the first 10 binned ages, in WOE format. The ages are mapped to the WOE values displayed internally by bininfo.
```

bdata(1:10,'CustAge')

```
ans =
CustAge
0.21378
0.62245
0.18758
0.21378
0.62245
0.62245
\(-0.39568\)
0.21378
0.21378
0.21378

The size of the original data and the size of bdata output are the same because bindata leaves unused variables (such as 'IDVar') unchanged and in place.

\section*{whos data bdata}
\begin{tabular}{lrrlr} 
Name & Size & Bytes & Class & Attributes \\
bdata & \(1200 \times 11\) & 109650 & table & \\
data & \(1200 \times 11\) & 85634 & table
\end{tabular}

The response values are the same in the original data and in the binned data because, by default, bindata does not modify response values.
```

disp([data.status(1:10) bdata.status(1:10)])

```
\begin{tabular}{ll}
0 & 0 \\
0 & 0 \\
0 & 0 \\
0 & 0 \\
0 & 0 \\
0 & 0 \\
1 & 1 \\
0 & 0 \\
1 & 1 \\
1 & 1
\end{tabular}

When fitting a logistic regression model with WOE data, set the 'OutputType ' namevalue pair argument to 'WOEModelInput'.
```

bdata = bindata(sc,'OutputType','WOEModelInput');

```

The binned predictor data is the same as when the 'OutputType' name-value pair argument is set to 'WOE '.
```

bdata(1:10,'CustAge')

```
ans =

CustAge
0.21378
0.62245
0.18758
0.21378
0.62245
0.62245
\(-0.39568\)
0.21378
0.21378
0.21378

However, the size of the original data and the size of bdata output are different. This is because bindata removes unused variables (such as 'IDVar').
```

whos data bdata

```
\begin{tabular}{lrlll} 
Name & Size & Bytes & Class & Attributes \\
bdata & \(1200 \times 10\) & 99814 & table \\
data & \(1200 \times 11\) & 85634 & table
\end{tabular}

The response values are also modified in this case and are mapped so that "Good" is 1 and "Bad" is 0 .
disp([data.status(1:10) bdata.status(1:10)])
\begin{tabular}{ll}
0 & 1 \\
0 & 1 \\

0 & 1 \\
1 & 0 \\
1 & 0
\end{tabular}
- "Case Study for a Credit Scorecard Analysis" on page 8-93
- "Troubleshooting Credit Scorecard Results" on page 8-83

\section*{Input Arguments}

\section*{sc - Credit scorecard model}
creditscorecard object

Credit scorecard model, specified as a creditscorecard object. The creditscorecard function must be used to create a creditscorecard object.

\section*{data - Data to bin given the rules set in creditscorecard object}
table
Data to bin given the rules set in the creditscorecard object, specified using a table. By default, data is set to the creditscorecard object's raw data.

Before creating a creditscorecard object, perform a data preparation task to have an appropriately structured data as input to a creditscorecard object.
Data Types: table

\section*{Name-Value Pair Arguments}

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

Example: bdata =
bindata(sc,'OutputType', 'WOE', 'ResponseFormat', 'Mapped')

\section*{'OutputType' - Output format}
'BinNumber' (default) | string with values 'BinNumber', 'Categorical', 'WOE'
Output format, specified as a string with the following values:
- BinNumber - Returns the bin numbers corresponding to each observation.
- Categorical - Returns the bin label corresponding to each observation.
- WOE - Returns the Weight of Evidence (WOE) corresponding to each observation.
- WOEModelInput - Use this option when fitting a model. This option:
- Returns the Weight of Evidence (WOE) corresponding to each observation.
- Returns predictor variables, but no IDVar or unused variables are included in the output.
- Discards any predictors whose bins have Inf or NaN WOE values.
- Includes the mapped response variable as the last column.

\section*{Data Types: char}

\section*{'ResponseFormat ' - Response values format}
'RawData' (default) | string with values 'RawData', 'Mapped'
Response values format, specified using a string with the following values:
- RawData - The response variable is copied unchanged into the bdata output.
- Mapped - The response values are modified (if necessary) so that "Good" is mapped to 1 , and "Bad" is mapped to 0 .

Data Types: char

\section*{Output Arguments}

\section*{bdata - Binned predictor variables}
table
Binned predictor variables, returned as a table. This is a table of the same size (see exception in the following Note) as the data input, but only the predictors specified in the creditscorecard object's PredictorVars property are binned and the remaining ones are unchanged.

Note: When the bindata name-value pair argument 'OutputType' is set to 'WOEModelInput', the bdata output only contains the columns corresponding to predictors whose bins do not have Inf or NaN Weight of Evidence (WOE) values, and bdata includes the mapped response as the last column.

Missing data (if any) are included in the bdata output as missing data as well, and do not influence the rules to discard predictors when 'OutputType' is set to 'WOEModelInput'.

\section*{plotbins}

Plot histogram counts for predictor variables

\section*{Syntax}
plotbins(sc, PredictorName)
hFigure = plotbins(sc, PredictorName)
hFigure \(=\) plotbins( \(\qquad\) , Name, Value)

\section*{Description}
plotbins(sc, PredictorName) plots histogram counts for given predictor variables. When a predictor's bins are modified using modifybins or autobinning, rerun plotbins to update the figure to reflect the change.
hFigure \(=\) plotbins(sc, PredictorName) returns a handle to the figure. plotbins plots histogram counts for given predictor variables. When a predictor's bins are modified using modifybins or autobinning, rerun plotbins to update the figure to reflect the change.
hFigure = plotbins( \(\qquad\) , Name, Value) returns a handle to the figure. plotbins plots histogram counts for given predictor variables using optional name-value pair arguments. When a predictor's bins are modified using modifybins or autobinning, rerun plotbins to update the figure to reflect the change.

\section*{Examples}

\section*{Plot a Histogram for Bin Information}

Create a creditscorecard object using the CreditCardData.mat file to load the data (using a dataset from Refaat 2011).
load CreditCardData
sc = creditscorecard(data);
Perform automatic binning for the PredictorName input argument for CustIncome using the defaults for the algorithm Monotone.
```

sc = autobinning(sc, 'CustIncome')
Sc =
creditscorecard with properties:
GoodLabel: 0
ResponseVar: 'status
VarNames: {1x11 cell}
NumericPredictors: {1x7 cell}
CategoricalPredictors: {'ResStatus' 'EmpStatus' 'OtherCC'}
IDVar: ''
PredictorVars: {1x10 cell}

```

Use bininfo to display the autobinned data.
```

[bi, cp] = bininfo(sc, 'CustIncome')

```
bi =
\begin{tabular}{|c|c|c|c|c|c|}
\hline Bin & Good & Bad & Odds & WOE & InfoValue \\
\hline ' [-Inf, 29000) ' & 53 & 58 & 0.91379 & -0.79457 & 0.06364 \\
\hline '[29000, 33000) ' & 74 & 49 & 1.5102 & -0.29217 & 0.0091366 \\
\hline '[33000, 35000) ' & 68 & 36 & 1.8889 & -0.06843 & 0.00041042 \\
\hline '[35000, 40000) ' & 193 & 98 & 1.9694 & -0.026696 & 0.00017359 \\
\hline ' [40000, 42000) ' & 68 & 34 & 2 & -0.011271 & 1.0819e-05 \\
\hline ' [42000, 47000) ' & 164 & 66 & 2.4848 & 0.20579 & 0.0078175 \\
\hline '[47000, Inf] & 183 & 56 & 3.2679 & 0.47972 & 0.041657 \\
\hline 'Totals' & 803 & 397 & 2.0227 & NaN & 0.12285 \\
\hline
\end{tabular}
cp =2900033000
        35000
        40000
        42000
        47000

Manually remove the second cut point (the boundary between the second and third bins) to merge bins two and three. Use the modifybins function to update the scorecard and then display updated bin information.
```

cp(2) = [];

```
sc = modifybins(sc,'CustIncome','CutPoints', cp);
bi = bininfo(sc,'CustIncome')
bi =
\begin{tabular}{|c|c|c|c|c|c|}

\hline '[47000,Inf]' & 183 & 56 & 3.2679 & 0.47972 & 0.041657 \\
\hline 'Totals' & 803 & 397 & 2.0227 & NaN & 0.12043 \\
\hline
\end{tabular}

Plot the histogram count for updated bin information for the PredictorName called CustIncome.
```

plotbins(sc,'CustIncome');

```

\section*{CustIncome}

\(\square\)

Plot a Histogram for Bin Information Using Name-Value Pair Arguments
Create a creditscorecard object using the CreditCardData.mat file to load the data (using a dataset from Refaat 2011).
```

load CreditCardData
sc = creditscorecard(data);

```

Perform automatic binning for the PredictorName input argument for CustIncome using the defaults for the algorithm Monotone.
```

sc = autobinning(sc, 'CustIncome')
Sc =

```
```

creditscorecard with properties:
GoodLabel: 0
ResponseVar: 'status'
VarNames: {1x11 cell}
NumericPredictors: {1x7 cell}
CategoricalPredictors: {'ResStatus' 'EmpStatus' 'OtherCC'}
IDVar:
PredictorVars: {1x10 cell}

```

Use bininfo to display the autobinned data.
[bi, cp] = bininfo(sc, 'CustIncome')
bi =
\(\qquad\)

\end{tabular}
\(c p=\)
29000
33000
35000
40000
42000
47000

Plot the bin information for Cust Income without the Weight of Evidence (WOE) line and without a legend by setting the 'WOE' and 'Legend ' name-value arguments to 'Off'. Also, set the 'BinText' name-value pair argument to 'PercentRows' to show as text
over the plot bars for the proportion of "Good" and "Bad" within each bin, that is, the probability of "Good" and "Bad" within each bin.
plotbins(sc,'CustIncome','WOE','Off','Legend','Off','BinText','PercentRows');
CustIncome

- "Case Study for a Credit Scorecard Analysis" on page 8-93
- "Troubleshooting Credit Scorecard Results" on page 8-83

\section*{Input Arguments}

\section*{sc - Credit scorecard model}
creditscorecard object

Credit scorecard model, specified as a creditscorecard object. The creditscorecard function must be used to create a creditscorecard object.

\section*{PredictorName - Name of one or more predictors to plot}
string with predicator name | cell array of strings with predictor names
Name of one or more predictors to plot, specified using a string or cell array of strings containing one or more names of the predictors.

Data Types: char | cell

\section*{Name-Value Pair Arguments}

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, . . . NameN, ValueN.
Example: plotbins(sc, PredictorName, 'BinText', 'Count', 'WOE', 'On')

\section*{'BinText ' - Information to display on top of plotted bin counts}
'None' (default) | string with values 'None', 'Count', 'PercentRows',
'PercentCols', 'PercentTotal'
Information to display on top of plotted bin counts, specified using a string with values:
- None - No text is displayed on top of the bins.
- Count - For each bin, displays the count for "Good" and "Bad."
- PercentRows - For each bin, displays the count for "Good" and "Bad" as a percentage of the number of observations in the bin.
- PercentCols - For each bin, displays the count for "Good" and "Bad" as a percentage of the total "Good" and total "Bad" in the entire sample.
- PercentTotal - For each bin, displays the count for "Good" and "Bad" as a percentage of the total number of observations in the entire sample.

\section*{Data Types: char}

\author{
'WOE ' - Indicator for Weight of Evidence (WOE) \\ 'On' (default) | string with values 'On', 'Off'
}

Indicator for Weight of Evidence (WOE) line, specified using a string with values On or Off. When set to On, the WOE line is plotted on top of the histogram.

\section*{Data Types: char}

\section*{'Legend ' - Indicator for legend on plot \\ 'On' (default) | string with values 'On', 'Off'}

Indicator for legend on the plot, specified using a string with values On or Off.

\section*{Data Types: char}

\section*{Output Arguments}

\section*{hFigure - Figure handle for histogram plot for predictor variables}
figure object
Figure handle for histogram plot for predictor variables, returned as figure object or array of figure objects if more than one PredictorName is specified as an input.

\section*{Introduced in R2014b}

\section*{modifybins}

Modify predictor's bins

\section*{Syntax}
sc = modifybins(sc,PredictorName,Name,Value)

\section*{Description}
sc = modifybins(sc, PredictorName, Name, Value) manually modifies predictor bins for numeric predictors or categorical predictors using optional name-value pair arguments. For numeric predictors, minimum value, maximum value, and cut points can be specified. For categorical predictors, category groupings can be specified. Bin labels can be specified for both types of predictors.

\section*{Examples}

\section*{Modify Predictor Bins for Numeric Data}

Create a creditscorecard object using the CreditCardData.mat file to load the data (using a dataset from Refaat 2011).
```

load CreditCardData
sc = creditscorecard(data);

```

The predictor CustIncome is numeric. By default, each value of a predictor is placed in a separate bin.
```

bi = bininfo(sc,'CustIncome')

```
bi \(=\)
\begin{tabular}{|c|c|c|c|c|c|}
\hline Bin & Good & Bad & Odds & WOE & InfoValue \\
\hline '18000' & 2 & 3 & 0.66667 & -1.1099 & 0.0056227 \\
\hline ' 19000 ' & 1 & 2 & 0.5 & -1.3976 & 0.0053002 \\

\section*{Modify Predictor Bins for Categorical Data}

Create a creditscorecard object using the CreditCardData.mat file to load the data (using a dataset from Refaat 2011).
load CreditCardData
sc = creditscorecard(data);
The binning map or rules for categorical data are summarized in a "category grouping" table, returned as an optional output. By default, each category is placed in a separate bin. Here is the information for the predictor ResStatus.
```

[bi,cg] = bininfo(sc,'ResStatus')
bi =

| Bin | Good | Bad | Odds | WOE | InfoValue |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 'Home Owner' | 365 | 177 | 2.0621 | 0.019329 | 0.0001682 |
| 'Tenant' | 307 | 167 | 1.8383 | -0.095564 | 0.0036638 |
| 'Other' | 131 | 53 | 2.4717 | 0.20049 | 0.0059418 |
| 'Totals' | 803 | 397 | 2.0227 | NaN | 0.0097738 |

cg =
Category BinNumber
'Home Owner' 1
'Tenant' 2
'Other' 3

```

To group categories 'Tenant' and 'Other', modify the category grouping table cg, so the bin number for 'Other' is the same as the bin number for 'Tenant'. Then use modifybins to update the scorecard.
```

cg.BinNumber(3) = 2;
sc = modifybins(sc,'ResStatus','CatGrouping',cg);

```

Display the updated bin information. Note that the bin labels has been updated and that the bin membership information is contained in the category grouping cg .
```

[bi,cg] = bininfo(sc,'ResStatus')

```
bi =
\begin{tabular}{lllllll} 
Bin & Good & \multicolumn{2}{c}{ Bad } & \multicolumn{1}{c}{ Odds } & & \multicolumn{1}{c}{ WOE }
\end{tabular}
cg \(=\)
Category BinNumber
'Home Owner' 1
'Tenant' 2
'Other' 2

\section*{Merge Bins for Numerical and Categorical Predictors}

Create a creditscorecard object (using a dataset from Refaat 2011).
load CreditCardData
sc = creditscorecard(data,'IDVar','CustID', 'GoodLabel', 0);
For the numerical predictor CustAge, use the modifybins function to set the following cut points:
```

cp = [25 37 49 65];

```
```

sc = modifybins(sc,'CustAge','CutPoints',cp,'MinValue',0,'MaxValue',75);
bininfo(sc,'CustAge')

```
ans =
\begin{tabular}{lrrrrrr} 
Bin & Good & Bad & \multicolumn{2}{c}{ Odds } & & \multicolumn{1}{c}{ WOE }
\end{tabular}

Use the modifybins function to merge the 2nd and 3rd bins.
```

sc = modifybins(sc,'CustAge','CutPoints',cp([1 1 3 4]));
bininfo(sc,'CustAge')

```
ans =
\begin{tabular}{|c|c|c|c|c|c|}

| 'Group2 ' | 438 | 220 | 1.9909 | -0.015827 | 0.00013772 |
| 'Totals' | 803 | 397 | 2.0227 | NaN | 0.00030592 |

```

\section*{Split Bins for Numerical and Categorical Predictors}

Create a creditscorecard object (using a dataset from Refaat 2011).
load CreditCardData
sc = creditscorecard(data,'IDVar','CustID', 'GoodLabel', 0)
sc \(=\)
creditscorecard with properties:
GoodLabel: 0
ResponseVar: 'status'
VarNames: \{1×11 cell\}
NumericPredictors: \(\{1 \times 6\) cell\}
CategoricalPredictors: \{'ResStatus' 'EmpStatus' 'OtherCC'\}
IDVar: 'CustID'
PredictorVars: \{1x9 cell\}

For the numerical predictor TmAtAddress, use the modifybins function to set the following cut points:
```

cp = [30 80 120];
sc = modifybins(sc,'TmAtAddress','CutPoints',cp,'MinValue',0,'MaxValue',210);
bininfo(sc,'TmAtAddress')

```
ans =
\begin{tabular}{|c|c|c|c|c|c|}
\hline Bin & Good & Bad & Odds & WOE & InfoValue \\
\hline ' \([0,30\) ) ' & 330 & 154 & 2.1429 & 0.057722 & 0.0013305 \\
\hline '[30,80) & 379 & 201 & 1.8856 & -0.070187 & 0.0024086 \\
\hline '[80,120)' & 78 & 36 & 2.1667 & 0.068771 & 0.00044396 \\

cg =
Category BinNumber
'Home Owner' 1
'Tenant' 2
'Other' 3

```

\section*{Modify Bin Labels}

Create a creditscorecard object using the CreditCardData.mat file to load the data (using a dataset from Refaat 2011).
```

load CreditCardData
sc = creditscorecard(data);

```

Use modifybins to reset the minimum value and create three bins for the predictor Cust Income and display updated bin information.
```

sc = modifybins(sc,'CustIncome','MinValue',0,'CutPoints',[30000 50000]);
bi = bininfo(sc,'CustIncome')
bi =

| Bin | Good | Bad | Odds | WOE | InfoValue |
| :---: | :---: | :---: | :---: | :---: | :---: |
| ' [0, 30000)' | 64 | 68 | 0.94118 | -0.76504 | 0.070065 |
| '[30000, 50000) ' | 628 | 296 | 2.1216 | 0.047762 | 0.0017421 |
| '[50000, Inf]' | 111 | 33 | 3.3636 | 0.5086 | 0.028028 |
| 'Totals' | 803 | 397 | 2.0227 | NaN | 0.099836 |

```

Modify the bin labels and display updated bin information.
```

NewLabels = {'Up to 30k','30k to 50k','50k and more'};
sc = modifybins(sc,'CustIncome','BinLabels',NewLabels);
bi = bininfo(sc,'CustIncome')
bi =

| Bin | Good | Bad | Odds | WOE | InfoValue |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 'Up to 30k' | 64 | 68 | 0.94118 | -0.76504 | 0.070065 |
| '30k to 50k' | 628 | 296 | 2.1216 | 0.047762 | 0.0017421 |
| '50k and more' | 111 | 33 | 3.3636 | 0.5086 | 0.028028 |
| 'Totals' | 803 | 397 | 2.0227 | NaN | 0.099836 |

```

Bin labels should be the last bin-modification step. As in this example, user-defined bin labels often contain information about the cut points, minimum, or maximum values for numeric data, or information about category groupings for categorical data. To prevent situations where user-defined labels and cut points are inconsistent (and labels are misleading), the creditscorecard object overrides user-defined labels every time the bins are modified using modifybins.

To illustrate modifybins overriding user-defined labels every time the bins are modified, reset the first cut point to 31000 and display updated bin information. Note that the bin labels are reset to their default format and accurately reflect the change in the cut points.
```

sc = modifybins(sc,'CustIncome','CutPoints',[31000 50000]);
bi = bininfo(sc,'CustIncome')
bi =

```
\begin{tabular}{|c|c|c|c|c|c|}
\hline Bin & Good & Bad & Odds & WOE & InfoValue \\
\hline ' [0,31000)' & 82 & 84 & 0.97619 & -0.72852 & 0.079751 \\
\hline '[31000,50000) \({ }^{\prime}\) & 610 & 280 & 2.1786 & 0.074251 & 0.0040364 \\
\hline '[50000, Inf]' & 111 & 33 & 3.3636 & 0.5086 & 0.028028 \\
\hline 'Totals' & 803 & 397 & 2.0227 & NaN & 0.11182 \\
\hline
\end{tabular}
- "Case Study for a Credit Scorecard Analysis" on page 8-93
- "Troubleshooting Credit Scorecard Results" on page 8-83

\section*{Input Arguments}

\section*{sc - Credit scorecard model}
creditscorecard object
Credit scorecard model, specified as a creditscorecard object. The creditscorecard function must be used to create a creditscorecard object.

\section*{PredictorName - Name of predictor}
string
Name of predictor, specified as a string containing the name of the predictor.
PredictorName is case-sensitive.
Data Types: char

\section*{Name-Value Pair Arguments}

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Example: sc = modifybins(sc,PredictorName,'MinValue',10,'CutPoints', [23, 44, 66, 88])
'MinValue ' - Minimum acceptable value (numeric predictors only)
- Inf (default) | numeric

Minimum acceptable value, specified as a numeric value (for numeric predictors only). Values below this number are considered out of range.

Data Types: double

\section*{'MaxValue' - Maximum acceptable value (numeric predictors only) Inf (default) | numeric}

Maximum acceptable value, specified as a numeric value (for numeric predictors only). Values above this number are considered out of range.

\section*{Data Types: double}

\section*{'CutPoints ' - Split points between bins}
each observed value of the predictor is placed in a separate bin (default) | nondecreasing numeric array

Split points between bins, specified using a nondecreasing numeric array. If there are NumBins bins, there are \(n=\) NumBins -1 cut points so that C1, C2,..., C \(n\) describe the bin boundaries with the following convention:
- The first bin includes any values \(>=\) MinValue, but \(<\mathrm{C} 1\).
- The second bin includes any values \(>=\mathrm{C} 1\), but \(<\mathrm{C} 2\).
- The last bin includes any values \(>=\mathrm{C} n\), and \(<=\) MaxValue.

Note: Cut points do not include MinValue or MaxValue.

By default, cut points are defined so that each observed value of the predictor is placed in a separate bin. If the sorted observed values are \(\mathrm{V} 1, \ldots, \mathrm{~V} M\), the default cut points are V2, ..., VM, which define \(M\) bins.

Data Types: double
'CatGrouping ' - Table with two columns named Category and BinNumber
each category is placed in a separate bin (default) | table with two columns named Category and BinNumber

Table with two columns named Category and BinNumber specified using a table, where the first column contains an exhaustive list of categories for the predictor, and the second column contains the bin number to which each category belongs.

By default, each category is placed in a separate bin. If the observed categories are 'Cat1 '..., ' \(\operatorname{Cat} M\) ', the default category grouping is as follows.
\begin{tabular}{|l|l|}
\hline Category & BinNumber \\
\hline ' Cat1' & 1 \\
\hline ' Cat2' & 2 \\
\hline\(\ldots\) & \(\ldots\) \\
\hline ' Cat \(M^{\prime \prime}\) & \(M\) \\
\hline
\end{tabular}

\section*{Data Types: double}

\section*{'BinLabels ' - Bin labels for each bin \\ automatically generated bin labels depending on the predictor's type (default) | cell array of strings}

Bin labels for each bin, specified using a cell array of strings with bin label names. Bin labels are used to tag the bins in different object functions such as bininfo, plotbins, and displaypoints. A creditscorecard object automatically sets default bins whenever bins are modified. The default format for bin labels depends on the predictor's type.

The format for BinLabels is:
- Numeric data - Before any manual or automatic modification of the predictor bins, there is a bin for each observed predictor value by default. In that case, the bin labels simply show the predictor values. Once the predictor bins have been modified, there are nondefault values for MinValue or MaxValue, or nondefault cut points \(\mathrm{C} 1, \mathrm{C} 2, \ldots\), \(\mathrm{C} n\). In that case, the bin labels are:
- Bin 1 label: ' [MinValue, C1)'
- Bin 2 label: ' [C1, C2)'
- Last bin label: ' [Cn, MaxValue]'

For example, if there are three bins, MinValue is 0 and MaxValue is 40, and cut point 1 is 20 and cut point 2 is 30 , then the corresponding three bin labels are:
'[0,20)'
' \([20,30\) ) '
'[30,40]'
- Categorical data - For categorical data, before any modification of the predictor bins, there is one bin per category. In that case, the bin labels simply show the predictor categories. Once the bins have been modified, the labels are set to 'Group1',
'Group2 ', etc., for bin 1, bin 2, etc., respectively. For example, suppose that we have the following category grouping
\begin{tabular}{|l|l|}
\hline Category & BinNumber \\
\hline 'Cat1' & 1 \\
\hline 'Cat2' & 2 \\
\hline 'Cat3' & 2 \\
\hline
\end{tabular}

Bin 1 contains 'Cat1' only and its bin label is set to 'Group1 '. Bin 2 contains 'Cat2' and 'Cat3' and its bin label is set to 'Group2'.

Tip Using BinLabels should be the last step (if needed) in modifying bins. BinLabels definitions are overridden each time that the bins are modified using the modifybins or autobinning functions.

\section*{Data Types: cell}

\section*{Output Arguments}

\section*{sc - Credit scorecard model}
creditscorecard object
Credit scorecard model, returned as an updated creditscorecard object. For more information on using the creditscorecard object, see Using creditscorecard Objects.

\section*{modifypredictor}

Set properties of credit scorecard predictors

\section*{Syntax}
```

sc = modifypredictor(sc,PredictorName)
sc = modifypredictor(

```
\(\qquad\)
``` , Name, Value)
```

## Description

sc = modifypredictor(sc,PredictorName) sets the properties of the credit scorecard predictors.
sc = modifypredictor( $\qquad$ , Name, Value) sets the properties of the credit scorecard predictors using optional name-value pair arguments.

## Examples

## Modify a Predictor to Change the Predictor Type from Numeric to Categorical

Create a creditscorecard object using the CreditCardData.mat file to load the data (using a dataset from Refaat 2011). In practice, categorical data many times is represented with numeric values. To show the case where categorical data is given as numeric data, the data for the variable 'ResStatus ' is intentionally converted to numeric values.

```
load CreditCardData
data.ResStatus = double(data.ResStatus);
sc = creditscorecard(data,'IDVar','CustID')
[T,Stats] = predictorinfo(sc,'ResStatus')
Sc =
    creditscorecard with properties:
```

```
                GoodLabel: 0
            ResponseVar: 'status'
            VarNames: {1x11 cell}
            NumericPredictors: {1x7 cell}
        CategoricalPredictors: {'EmpStatus' 'OtherCC'}
                        IDVar: 'CustID'
            PredictorVars: {1x9 cell}
T =
                    PredictorType
    ResStatus 'Numeric'
Stats =
                    Value
    Min 1
    Max 3
    Mean 1.7017
    Std 0.71863
```

Note that 'ResStatus ' appears as part of the NumericPredictors property. Assume that you want 'ResStatus' to be treated as categorical data. For example, you may want to allow automatic binning algorithms to reorder the categories. Use modifypredictor to change the 'PredictorType' of the PredictorName 'ResStatus ' from numeric to categorical.

```
sc = modifypredictor(sc,'ResStatus','PredictorType','Categorical')
[T,Stats] = predictorinfo(sc,'ResStatus')
SC =
    creditscorecard with properties:
```

                        GoodLabel: 0
                    ResponseVar: 'status'
    ```
    VarNames: {1x11 cell}
        NumericPredictors: {1x6 cell}
CategoricalPredictors: {'ResStatus' 'EmpStatus' 'OtherCC'}
                                    IDVar: 'CustID'
            PredictorVars: {1x9 cell}
T =
\begin{tabular}{lll} 
& \begin{tabular}{l} 
PredictorType \\
\\
ResStatus \\
\end{tabular} & \begin{tabular}{l} 
Ordinal \\
'Categorical'
\end{tabular} \\
false
\end{tabular}
Stats =
Count
    C1 542
    C2 474
    C3 184
```

Notice that 'ResStatus ' now appears as part of the 'Categorical' predictors.

## Input Arguments

## sc - Credit scorecard model

creditscorecard object
Credit scorecard model, specified as a creditscorecard object. The creditscorecard function must be used to create a creditscorecard object.

## PredictorName - Predictor name

string | cell array
Predictor name, specified using a string or cell array containing the names of the credit scorecard predictors. PredictorName is case-sensitive.

Data Types: char | cell

## Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, . . ., NameN, ValueN.
Example: sc = modifypredictor(sc, \{'CustAge','CustIncome'\},'PredictorType','Categorical', 'Ordinal', true)
'PredictorType ' - Predictor type that one or more predictors are converted to
' no conversion occurs (default) | strings with values 'Numeric', 'Categorical'
Predictor type that one or more predictors are converted to, specified as a string. Possible values are:

- ' ' - No conversion occurs.
- 'Numeric' - The predictor data specified by PredictorName is converted to numeric.
- 'Categorical' - The predictor data specified by PredictorName is converted to categorical.

## Data Types: char

## 'Ordinal' - Indicator for whether predictors being converted to categorical are ordinal false (default) | logical with values true, false

Indicator for whether predictors being converted to categorical or existing categorical predictors are treated as ordinal data, specified as a logical with values true or false.

Note: This optional input parameter is only used for predictors of type 'Categorical'.

## Data Types: logical

## Output Arguments

## sc - Credit scorecard model

creditscorecard object

Credit scorecard model, returned as an updated creditscorecard object.

See Also<br>bininfo | modifybins | predictorinfo<br>Introduced in R2015b

## predictorinfo

Summary of credit scorecard predictor properties

## Syntax

[T,Stats] = predictorinfo(sc,PredictorName)

## Description

[T,Stats] = predictorinfo(sc,PredictorName) returns a summary of credit scorecard predictor properties and some basic predictor statistics.

## Examples

Obtain Information for a Specified PredictorName
Create a creditscorecard object using the CreditCardData.mat file to load the data (using a dataset from Refaat 2011).

```
load CreditCardData
sc = creditscorecard(data,'IDVar','CustID')
sc =
    creditscorecard with properties:
                            GoodLabel: 0
                            ResponseVar: 'status'
                            VarNames: {1x11 cell}
            NumericPredictors: {1x6 cell}
        CategoricalPredictors: {'ResStatus' 'EmpStatus' 'OtherCC'}
                            IDVar: 'CustID'
                            PredictorVars: {1x9 cell}
```

Obtain the predictor statistics for the PredictorName of CustAge.

```
[T,Stats] = predictorinfo(sc,'CustAge')
```

$\mathrm{T}=$

PredictorType

CustAge 'Numeric'

Stats =

|  | Value |
| :--- | ---: |
|  |  |
| Min | 21 |
| Max | 74 |
| Mean | 45.174 |
| Std | 9.8343 |

Obtain the predictor statistics for the PredictorName of ResStatus.
[T,Stats] = predictorinfo(sc,'ResStatus')

T =

|  | PredictorType <br> ResStatus | Ordinal <br> 'Categorical' |
| :--- | :--- | :--- |
| false |  |  |

## Stats =

## Count

Home Owner 542
Tenant 474
Other 184

## Input Arguments

## sc - Credit scorecard model <br> creditscorecard object

Credit scorecard model, specified as a creditscorecard object. The creditscorecard function must be used to create a creditscorecard object.

## PredictorName - Predictor name

string
Predictor name, specified using a string containing the names of the credit scorecard predictor of interest. PredictorName is case-sensitive.

Data Types: char

## Output Arguments

## T - Summary information for specified predictor table

Summary information for specified predictor, returned as table with the following columns:

- 'PredictorType' - 'Numeric' or 'Categorical'.
- 'Ordinal' - For categorical predictors, a boolean indicating whether it is ordinal.

The predictor's name is used as a row name in the table that is returned.

## Stats - Summary statistics for the input PredictorName table

Summary statistics for the input PredictorName, returned as a table.
The table's row names indicate the relevant statistics for numeric predictors:

- 'Min' - Minimum value in the sample.
- 'Max' - Maximum value in the sample.
- 'Mean ' - Mean value in the sample.
- 'Std ' - Standard deviation of the sample.

Note: For data types other than 'double' or 'single', numeric precision may be lost for the standard deviation. Data types other than 'double' or 'single' are cast as 'double' before computing the standard deviation.

For categorical predictors, the row names contain the names of the categories, with corresponding total count in the 'Count ' column.

See Also<br>bininfo | modifybins | modifypredictor<br>Introduced in R2015b

## bininfo

Return predictor's bin information

## Syntax

```
bi = bininfo(sc,PredictorName)
```

bi = bininfo( __, ,Name,Value)

```
[bi,bm] = bininfo(sc,PredictorName,Name,Value)
```

## Description

bi = bininfo(sc,PredictorName) returns information at bin level, such as frequencies of "Good," "Bad," and bin statistics for the predictor specified in PredictorName.
bi = bininfo( __ , Name, Value) returns information at bin level, such as frequencies of "Good," "Bad," and bin statistics for the predictor specified in PredictorName using optional name-value pair arguments.
[bi,bm] = bininfo(sc,PredictorName,Name,Value) returns information at bin level, such as frequencies of "Good," "Bad," and bin statistics for the predictor specified in PredictorName using optional name-value pair arguments. bininfo also optionally returns the binning map or bin rules in the form of a vector of cut points for numeric predictors, or a table of category groupings for categorical predictors.

## Examples

## Display Bin Information Using Default Options

Create a creditscorecard object using the CreditCardData.mat file to load the data (using a dataset from Refaat 2011).
load CreditCardData

```
sc = creditscorecard(data);
```

Display bin information for the categorical predictor ResStatus.

```
bi = bininfo(sc,'ResStatus')
```

bi =

| Bin | Good | Bad | Odds | WOE | InfoValue |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 'Home Owner' | 365 | 177 | 2.0621 | 0.019329 | 0.0001682 |
| 'Tenant' | 307 | 167 | 1.8383 | -0.095564 | 0.0036638 |
| Other ${ }^{\text {' }}$ | 131 | 53 | 2.4717 | 0.20049 | 0.0059418 |
| 'Totals' | 803 | 397 | 2.0227 | NaN | 0.0097738 |

## Display Bin Information Using Name-Value Arguments

Create a creditscorecard object using the CreditCardData.mat file to load the data (using a dataset from Refaat 2011).

```
load CreditCardData
```

sc = creditscorecard(data);

Display customized bin information for the categorical predictor ResStatus, keeping only the WOE column.

```
bi = bininfo(sc,'ResStatus','Statistics','WOE')
```

bi =

| Bin | Good | Bad | WOE |
| :---: | :---: | :---: | :---: |
| 'Home Owner' | 365 | 177 | 0.019329 |
| 'Tenant' | 307 | 167 | -0.095564 |
| 'Other' | 131 | 53 | 0.20049 |
| 'Totals' | 803 | 397 | NaN |

Display customized bin information for the categorical predictor ResStatus, keeping only the Odds and WOE columns, without the Totals row.

```
bi = bininfo(sc,'ResStatus','Statistics',{'Odds','WOE'},'Totals','Off')
bi =
\begin{tabular}{|c|c|c|c|c|}
\hline Bin & Good & Bad & Odds & WOE \\
\hline 'Home Owner' & 365 & 177 & 2.0621 & 0.019329 \\
\hline 'Tenant' & 307 & 167 & 1.8383 & -0.095564 \\
\hline 'Other' & 131 & 53 & 2.4717 & 0.20049 \\
\hline
\end{tabular}
```

## Display Bin Information and Binning Map for Categorical Data

Create a creditscorecard object using the CreditCardData.mat file to load the data (using a dataset from Refaat 2011).

```
load CreditCardData
sc = creditscorecard(data);
```

The binning map or rules for categorical data are summarized in a "category grouping" table, returned as an optional output. By default, each category is placed in a separate bin. Here is the information for the predictor ResStatus.

```
[bi,cg] = bininfo(sc,'ResStatus')
bi =
\begin{tabular}{|c|c|c|c|c|c|}
\hline Bin & Good & Bad & Odds & WOE & InfoValue \\
\hline 'Home Owner' & 365 & 177 & 2.0621 & 0.019329 & 0.0001682 \\
\hline 'Tenant' & 307 & 167 & 1.8383 & -0.095564 & 0.0036638 \\
\hline 'Other' & 131 & 53 & 2.4717 & 0.20049 & 0.0059418 \\
\hline 'Totals' & 803 & 397 & 2.0227 & NaN & 0.009773 \\
\hline
\end{tabular}
```

cg $=$
Category BinNumber
'Home Owner'
1

```
'Tenant'
2
'Other' 3
```

To group categories Tenant and Other, modify the category grouping table cg so that the bin number for Other is the same as the bin number for Tenant. Then use the modifybins function to update the scorecard.

```
cg.BinNumber(3) = 2;
sc = modifybins(sc,'ResStatus','CatGrouping',cg);
```

Display the updated bin information. The bin labels have been updated and that the bin membership information is contained in the category grouping cg .

```
[bi,cg] = bininfo(sc,'ResStatus')
```

bi =

| Bin | Good | Bad | Odds | WOE | InfoValue |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 'Group1 ${ }^{\text {' }}$ | 365 | 177 | 2.0621 | 0.019329 | 0.0001682 |
| 'Group2 ' | 438 | 220 | 1.9909 | -0.015827 | 0.00013772 |
| 'Totals' | 803 | 397 | 2.0227 | NaN | 0.00030592 |

cg $=$

| Category |  | BinNumber |  |
| :--- | :--- | :--- | :---: |
| 'Home Owner'  <br> 'Tenant'  <br> 'Other' 2 | 2 |  |  |

## Display Bin Information and Binning Map for Numeric Data

Create a creditscorecard object using the CreditCardData.mat file to load the data (using a dataset from Refaat 2011).

```
load CreditCardData
sc = creditscorecard(data);
```

The predictor Cust Income is numeric. By default, each value of the predictor is placed in a separate bin.

```
bi = bininfo(sc,'CustIncome')
```

bi =

Reduce the number of bins using the autobinning function (the modifybins function can also be used).

```
sc = autobinning(sc,'CustIncome');
```

Display the updated bin information. The binning map or rules for numeric data are summarized as "cut points," returned as an optional output (cp).

```
[bi,cp] = bininfo(sc,'CustIncome')
```

bi =

29000
35000
40000
42000
47000

Note, it is recommended to avoid having bins with frequencies of zero because they lead to infinite or undefined ( NaN ) statistics. Use the modifybins or autobinning functions to modify bins.

- "Case Study for a Credit Scorecard Analysis" on page 8-93
- "Troubleshooting Credit Scorecard Results" on page 8-83

## Input Arguments

## sc - Credit scorecard model

creditscorecard object
Credit scorecard model, specified as a creditscorecard object. The creditscorecard function must be used to create a creditscorecard object.

## PredictorName - Predictor name

string
Predictor name, specified using a string containing the name of the predictor. PredictorName is case-sensitive.

Data Types: char

## Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Example: bi = bininfo(sc, PredictorName, 'Statistics', 'WOE', 'Totals', 'On')

## 'Statistics ' - List of statistics to include for bin information

\{'Odds', 'WOE', 'InfoValue'\} (default) | strings with values 'Odds', 'WOE',
'InfoValue','Entropy' | cell array of strings with values 'Odds', 'WOE ',
'InfoValue', 'Entropy'
List of statistics to include in the bin information, specified as a string or a cell array of strings. For more information, see "Statistics for a Credit Scorecard" on page 18-1682. Possible values are:

- 'Odds ' — Odds information is the ratio of "Goods" over "Bads."
- 'WOE ' - Weight of Evidence. The WOE Statistic measures the deviation between the distribution of "Goods" and "Bads."
- 'InfoValue' - Information value. Closely tied to the WOE, it is a statistic used to determine how strong a predictor is to use in the fitting model. It measures how strong the deviation is between the distributions of "Goods" and "Bads." However, bins with only "Good" or only "Bad" observations do lead to an infinite Information Value. Consider modifying the bins in those cases by using modifybins or autobinning.
- 'Entropy ' - Entropy is a measure of unpredictability contained in the bins. The more the number of "Goods" and "Bads" differ within the bins, the lower the entropy.

Note: Avoid having bins with frequencies of zero because they lead to infinite or undefined ( NaN ) statistics. Use modifybins or autobinning to modify bins.

Data Types: char | cell

## ' Totals ' - Indicator to include row of totals at bottom information table 'On' (default) | string with values 'On', 'Off'

Indicator to include a row of totals at the bottom of the information table, specified as a string with values On or Off.

Data Types: char

## Output Arguments

## bi - Bin information

table
Bin information, returned as a table. The bin information table contains one row per bin and a row of totals. The columns contain bin descriptions, frequencies of "Good" and "Bad," and bin statistics. Avoid having bins with frequencies of zero because they lead to infinite or undefined ( NaN ) statistics. Use modifybins or autobinning to modify bins.

## bm - Binning map or rules

vector of cut points for numeric predictors | table of category groupings for categorical predictors

Binning map or rules, returned as a vector of cut points for numeric predictors, or a table of category groupings for categorical predictors. For more information, see modifybins.

## More About

## Statistics for a Credit Scorecard

Weight of Evidence (WOE) is a measure of the difference of the distribution of "Goods" and "Bads" within a bin.

Suppose the predictor's data takes on $M$ possible values b1, $\ldots$, b $M$. For binned data, $M$ is a small number. The response takes on two values, "Good" and "Bad." The frequency table of the data is given by:

|  | Good | Bad | Total |
| :--- | :--- | :--- | :--- |
| b1: | n11 | n12 | n1 |
| b2: | n21 | n22 | n2 |
| bM: | nM1 | nM2 | n $M$ |
| Total: | nGood | nBad | nTotal |

The Weight of Evidence (WOE) is defined for each data value bi as

```
WOE(i) = log((ni1/nGood)/(ni2/nBad)).
```

If you define

```
pGood(i) = ni1/nGood, pBad(i) = ni2/nBad
```

then $\operatorname{pGood}(i)$ is the proportion of "Good" observations that take on the value bi, and similarly for $\mathrm{pBad}(i)$. In other words, $\mathrm{pGood}(i)$ gives the distribution of good observations over the $M$ observed values of the predictor, and similarly for $\mathrm{pBad}(i)$. With this, an equivalent formula for the WOE is

```
WOE(i) = log(pGood(i)/pBad(i)).
```

Using the same frequency table, the odds for row $i$ are defined as
Odds(i) = ni1 / ni2,
and the odds for the sample are defined as

```
OddsTotal = nGood / nBad.
```

For each row $i$, you can also compute its contribution to the total Information Value, given by

InfoValue(i) $=(\operatorname{pGood}(i)-\operatorname{pBad}(i)) * \operatorname{WOE}(i)$,
and the total Information Value is simply the sum of all the InfoValuel $(i)$ terms. (A nansum is returned to discard contributions from rows with no observations at all.)

Likewise, for each row $i$, we can compute its contribution to the total Entropy, given by

```
Entropy(i) = -1/log(2)*(ni1/ni*log(ni1/ni)+ni2/ni*log(ni2/ni),
``` and the total Entropy is simply the weighted sum of the row entropies,

Entropy \(=\) sum(ni/nTotal * Entropy(i)), \(i=1 \ldots M\)

\section*{autobinning}

Perform automatic binning of given predictors

\section*{Syntax}
```

sc = autobinning(sc)
sc = autobinning(sc,PredictorNames)
sc = autobinning( ___,Name,Value)

```

\section*{Description}
sc = autobinning(sc) performs automatic binning of all predictors.
Automatic binning finds binning maps or rules to bin numeric data and to group categories of categorical data. The binning rules are stored in the creditscorecard object. To apply the binning rules to the creditscorecard object data, or to a new dataset, use bindata.
sc = autobinning(sc,PredictorNames) performs automatic binning of the predictors given in PredictorNames.

Automatic binning finds binning maps or rules to bin numeric data and to group categories of categorical data. The binning rules are stored in the creditscorecard object. To apply the binning rules to the creditscorecard object data, or to a new dataset, use bindata.
sc = autobinning(__ , Name, Value) performs automatic binning of the predictors given in PredictorNames using optional name-value pair arguments. See the namevalue argument Algorithm for a description of the supported binning algorithms.

Automatic binning finds binning maps or rules to bin numeric data and to group categories of categorical data. The binning rules are stored in the creditscorecard object. To apply the binning rules to the creditscorecard object data, or to a new dataset, use bindata.

\section*{Examples}

\section*{Perform Automatic Binning Using the Defaults}

Create a creditscorecard object using the CreditCardData.mat file to load the data (using a dataset from Refaat 2011).
```

load CreditCardData
sc = creditscorecard(data,'IDVar','CustID');

```

Perform automatic binning using the default options. By default, autobinning bins all predictors and uses the Monotone algorithm.
sc = autobinning(sc);
Use bininfo to display the binned data for the predictor Cust Income.
bi = bininfo(sc, 'CustIncome')
bi =
\begin{tabular}{lrrrrrr}
\multicolumn{1}{c}{ Bin } & Good & Bad & \multicolumn{2}{l}{ Odds } & & \multicolumn{1}{c}{ WOE }
\end{tabular}

Use plotbins to display the histogram and WOE curve for the predictor Cust Income. plotbins(sc,'CustIncome')

\section*{Perform Automatic Binning with a Named Predictor Using the Defaults}

Create a creditscorecard object using the CreditCardData.mat file to load the data (using a dataset from Refaat 2011).
```

load CreditCardData
sc = creditscorecard(data);

```

Perform automatic binning for the predictor Cust Income using the default options. By default, autobinning uses the Monotone algorithm.
sc = autobinning(sc,'CustIncome');
Use bininfo to display the binned data.
```

bi = bininfo(sc, 'CustIncome')
bi =

```
\begin{tabular}{|c|c|c|c|c|c|}
\hline Bin & Good & Bad & Odds & WOE & InfoValue \\

\end{tabular}

\section*{Perform Automatic Binning Using Two Name-Value Pair Arguments}

Create a creditscorecard object using the CreditCardData.mat file to load the data (using a dataset from Refaat 2011).
```

load CreditCardData
sc = creditscorecard(data);

```

Perform automatic binning for the predictor CustIncome using the Monotone algorithm with the initial number of bins set to 20 . This example explicitly sets both the Algorithm and the AlgorithmOptions name-value arguments.
```

AlgoOptions = {'InitialNumBins',20};
sc = autobinning(sc,'CustIncome','Algorithm','Monotone','AlgorithmOptions',...
AlgoOptions);

```

Use bininfo to display the binned data. Here, the cut points, which delimit the bins, are also displayed.
```

[bi,cp] = bininfo(sc,'CustIncome')

```

\section*{Perform Automatic Binning for Multiple Predictors}

Create a creditscorecard object using the CreditCardData.mat file to load the data (using a dataset from Refaat 2011).
```

load CreditCardData
sc = creditscorecard(data,'IDVar','CustID');

```

Perform automatic binning for the predictor CustIncome and CustAge using the default Monotone algorithm with AlgorithmOptions for InitialNumBins and Trend.
```

AlgoOptions = {'InitialNumBins',20,'Trend','Increasing'};
sc = autobinning(sc,{'CustAge','CustIncome'},'Algorithm','Monotone',...
AlgorithmOptions',AlgoOptions);

```

Use bininfo to display the binned data.
```

bi1 = bininfo(sc, 'CustIncome')
bi2 = bininfo(sc, 'CustAge')
bi1 =

```

\section*{Perform Automatic Binning for a Categorical Predictor Using the Defaults}

Create a creditscorecard object using the CreditCardData.mat file to load the data (using a dataset from Refaat 2011).
load CreditCardData
```

sc = creditscorecard(data);

```

Perform automatic binning for the predictor that is a categorical predictor called ResStatus using the default options. By default, autobinning uses the Monotone algorithm.
```

sc = autobinning(sc,'ResStatus');

```

Use bininfo to display the binned data.
```

bi = bininfo(sc, 'ResStatus')

```
bi =
\begin{tabular}{|c|c|c|c|c|c|}
\hline Bin & Good & Bad & Odds & WOE & InfoValue \\
\hline 'Tenant \({ }^{\text {' }}\) & 307 & 167 & 1.8383 & -0.095564 & 0.0036638 \\
\hline 'Home Owner' & 365 & 177 & 2.0621 & 0.019329 & 0.0001682 \\
\hline 'Other' & 131 & 53 & 2.4717 & 0.20049 & 0.0059418 \\
\hline 'Totals' & 803 & 397 & 2.0227 & NaN & 0.0097738 \\
\hline
\end{tabular}

\section*{Perform Automatic Binning for a Categorical Predictor Using Name-Value Pair Arguments}

This example shows how to modify the data (for this example only) to illustrate binning categorical predictors using the Monotone algorithm.

Create a creditscorecard object using the CreditCardData.mat file to load the data (using a dataset from Refaat 2011).
```

load CreditCardData

```

Add two new categories and updating the response variable.
```

newdata = data;
rng('default'); %for reproducibility
Predictor = 'ResStatus';
Status = newdata.status;
NumObs = length(newdata.(Predictor));
Ind1 = randi(NumObs,100,1);
Ind2 = randi(NumObs,100,1);
newdata.(Predictor)(Ind1) = 'Subtenant';
newdata.(Predictor)(Ind2) = 'CoOwner';

```
```

Status(Ind1) = randi(2,100,1)-1;
Status(Ind2) = randi(2,100,1)-1;
newdata.status = Status;

```

Update the creditscorecard object using the newdata and plot the bins for a later comparison.
```

scnew = creditscorecard(newdata,'IDVar','CustID');
[bi,cg] = bininfo(scnew,Predictor)
plotbins(scnew,Predictor)
bi =

| Bin | Good | Bad | Odds | WOE | InfoValue |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 'Home Owner' | 308 | 154 | 2 | 0.092373 | 0.0032392 |
| 'Tenant' | 264 | 136 | 1.9412 | 0.06252 | 0.0012907 |
| 'Other' | 109 | 49 | 2.2245 | 0.19875 | 0.0050386 |
| 'Subtenant' | 42 | 42 | 1 | -0.60077 | 0.026813 |
| ' CoOwner ${ }^{\text {' }}$ | 52 | 44 | 1.1818 | -0.43372 | 0.015802 |
| 'Totals' | 775 | 425 | 1.8235 | NaN | 0.052183 |

```
\(\mathrm{cg}=\)
    Category BinNumber
    'Home Owner' 1
    'Tenant' 2
    'Other' 3
    'Subtenant' 4
    'CoOwner' 5

Perform automatic binning for the categorical Predictor using the default Monotone algorithm with the AlgorithmOptions name-value pair arguments for 'SortCategories' and 'Trend'.
```

AlgoOptions = {'SortCategories','Goods','Trend','Increasing'};

```
scnew = autobinning(scnew,Predictor,'Algorithm','Monotone', ...
    'AlgorithmOptions',AlgoOptions);

Use bininfo to display the bin information. The second output parameter ' cg ' captures the bin membership, which is the bin number that each group belongs to.
[bi,cg] = bininfo(scnew,Predictor)
bi =
\begin{tabular}{lrrrrrr} 
Bin & Good & Bad & \multicolumn{2}{c}{ Odds } & & \multicolumn{1}{c}{ WOE }
\end{tabular}
\(\mathrm{cg}=\)
\begin{tabular}{|c|c|}
\hline Category & BinNumber \\
\hline 'Subtenant' & 1 \\
\hline 'CoOwner' & 2 \\
\hline 'Other' & 3 \\
\hline 'Tenant' & 3 \\
\hline 'Home Owner' & 3 \\
\hline
\end{tabular}

Plot bins and compare with the histogram plotted pre-binning.
plotbins(scnew, Predictor)

- "Case Study for a Credit Scorecard Analysis" on page 8-93
- "Troubleshooting Credit Scorecard Results" on page 8-83

\section*{Input Arguments}

\section*{sc - Credit scorecard model}

\section*{creditscorecard object}

Credit scorecard model, specified as a creditscorecard object. The creditscorecard function must be used to create a creditscorecard object.

\section*{PredictorNames - Predictor or predictors names to automatically bin} string | cell array of strings

Predictor or predictors names to automatically bin, specified as a string or a cell array of strings containing the name of the predictor or predictors. PredictorNames are case-sensitive and when no PredictorNames are defined, all predictors in the PredictorVars property of the creditscorecard object are binned.

Data Types: char | cell

\section*{Name-Value Pair Arguments}

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, . . . NameN, ValueN.
Example: sc = autobinning(sc,'Algorithm','EqualFrequency')

\section*{'Algorithm' - Algorithm selection}
'Monotone' (default) | string with values 'Monotone', 'EqualFrequency ', 'EqualWidth'

Algorithm selection, specified using a string indicating which algorithm to use. The same algorithm is used for all predictors in PredictorNames. Possible values are:
- 'Monotone ' - (default) Monotone Adjacent Pooling Algorithm (MAPA), also known as Maximum Likelihood Monotone Coarse Classifier (MLMCC). Supervised optimal binning algorithm that aims to find bins with a monotone Weight-Of-Evidence (WOE) trend. This algorithm assumes that only neighboring attributes can be grouped. Thus, for categorical predictors, categories are sorted before applying the algorithm (see 'SortCategories'). For more information, see "Monotone" on page 18-1700.
- 'EqualFrequency ' - Unsupervised algorithm that divides the data into a predetermined number of bins that contain approximately the same number of observations. This algorithm is also known as "equal height" or "equal depth." For categorical predictors, categories are sorted before applying the algorithm (see 'SortCategories '). For more information, see "Equal Frequency" on page 18-1702.
- 'EqualWidth ' - Unsupervised algorithm that divides the range of values in the domain of the predictor variable into a predetermined number of bins of "equal width." For numeric data, the width is measured as the distance between bin edges.

For categorical data, width is measured as the number of categories within a bin. For categorical predictors, categories are sorted before applying the algorithm (see 'SortCategories '). For more information, see "Equal Width" on page 18-1703.

\section*{Data Types: char}

\section*{'Algorithm0ptions' - Algorithm options for selected Algorithm}
\{'InitialNumBins',10,'Trend','Auto','SortCategories', 'Odds'\} for Monotone (default) | cell array with \{'OptionName',OptionValue\} for Algorithm options

Algorithm options for the selected Algorithm, specified using a cell array. Possible values are:
- For Monotone algorithm:
- \{'InitialNumBins ',\(n\}\) - Initial number ( \(n\) ) of bins (default is 10 ). ' InitialNumBins ' must be an integer > 2. Used for numeric predictors only.
- \{'Trend', 'TrendOption'\} - Determines whether the Weight-Of-Evidence (WOE) monotonic trend is expected to be increasing or decreasing. The values for 'TrendOption' are:
- 'Auto ' - (Default) Automatically determines if the WOE trend is increasing or decreasing.
- 'Increasing' - Look for an increasing WOE trend.
- 'Decreasing' - Look for a decreasing WOE trend.

The value of the optional input parameter 'Trend ' does not necessarily reflect that of the resulting WOE curve. The parameter 'Trend ' tells the algorithm to "look for" an increasing or decreasing trend, but the outcome may not show the desired trend. For example, the algorithm cannot find a decreasing trend when the data actually has an increasing WOE trend. For more information on the 'Trend ' option, see "Monotone" on page 18-1700.
- \{'SortCategories', 'SortOption'\} - Used for categorical predictors only. Used to determine how the predictor categories are sorted as a preprocessing step before applying the algorithm. The values of 'SortOption' are:
- 'Odds ' - (default) The categories are sorted by order of increasing values of odds, defined as the ratio of "Good" to "Bad" observations, for the given category.
- 'Goods ' - The categories are sorted by order of increasing values of "Good."
- 'Bads ' - The categories are sorted by order of increasing values of "Bad."
- 'Totals' - The categories are sorted by order of increasing values of total number of observations ("Good" plus "Bad").
- 'None' - No sorting is applied. The existing order of the categories is unchanged before applying the algorithm. (The existing order of the categories can be seen in the category grouping optional output from bininfo.)

For more information, see "Sort Categories" on page 18-1703
- For EqualFrequency algorithm:
- \{ 'NumBins ' , \(n\}\) - Specifies the desired number ( \(n\) ) of bins. The default is \{ 'NumBins', 5\(\}\) and the number of bins must be a positive number.
- \{'SortCategories', 'SortOption'\} - Used for categorical predictors only. Used to determine how the predictor categories are sorted as a preprocessing step before applying the algorithm. The values of 'SortOption' are:
- 'Odds ' - (default) The categories are sorted by order of increasing values of odds, defined as the ratio of "Good" to "Bad" observations, for the given category.
- 'Goods ' — The categories are sorted by order of increasing values of "Good."
- 'Bads ' — The categories are sorted by order of increasing values of "Bad."
- 'Totals ' - The categories are sorted by order of increasing values of total number of observations ("Good" plus "Bad").
- 'None' - No sorting is applied. The existing order of the categories is unchanged before applying the algorithm. (The existing order of the categories can be seen in the category grouping optional output from bininfo.)

For more information, see "Sort Categories" on page 18-1703
- For EqualWidth algorithm:
- \{ 'NumBins ' , \(n\}\) - Specifies the desired number ( \(n\) ) of bins. The default is \{'NumBins',5\} and the number of bins must be a positive number.
- \{'SortCategories', 'SortOption'\} — Used for categorical predictors only. Used to determine how the predictor categories are sorted as a preprocessing step before applying the algorithm. The values of 'SortOption' are:
- 'Odds ' - (default) The categories are sorted by order of increasing values of odds, defined as the ratio of "Good" to "Bad" observations, for the given category.
- 'Goods ' — The categories are sorted by order of increasing values of "Good."
- 'Bads ' — The categories are sorted by order of increasing values of "Bad."
- 'Totals ' - The categories are sorted by order of increasing values of total number of observations ("Good" plus "Bad").
- 'None' - No sorting is applied. The existing order of the categories is unchanged before applying the algorithm. (The existing order of the categories can be seen in the category grouping optional output from bininfo.)

For more information, see "Sort Categories" on page 18-1703
```

Example: sc =
autobinning(sc,'CustAge','Algorithm','Monotone','AlgorithmOptions',
{'Trend','Increasing'})
Data Types: cell

```

\section*{'Display ' - Indicator to display information on status of the binning process at command line}
```

'Off' (default)| string with values 'On', 'Off'

```

Indicator to display the information on status of the binning process at command line, specified using a string with value 'On' or 'Off'.

Data Types: char

\section*{Output Arguments}

\section*{sc - Credit scorecard model \\ creditscorecard object}

Credit scorecard model, returned as an updated creditscorecard object containing the automatically determined binning maps or rules (cut points or category groupings) for one or more predictors. For more information on using the creditscorecard object, see Using creditscorecard Objects.

Note: If you have previously used the modifybins function to manually modify bins, these changes are lost when running autobinning because all the data is automatically binned based on internal autobinning rules.

\section*{More About}

\section*{Monotone}

The 'Monotone' algorithm is an implementation of the Monotone Adjacent Pooling Algorithm (MAPA), also known as Maximum Likelihood Monotone Coarse Classifier (MLMCC); see Anderson or Thomas in the Bibliography.

\section*{Preprocessing}

During the preprocessing phase, preprocessing of numeric predictors consists in applying equal frequency binning, with the number of bins determined by the 'InitialNumBins ' parameter (the default is 10 bins). The preprocessing of categorical predictors consists in sorting the categories according to the 'SortCategories' criterion (the default is to sort by odds in increasing order). Sorting is not applied to ordinal predictors. See the "Sort Categories" on page 18-1703 definition or the description of AlgorithmOptions option for 'SortCategories' for more information.

\section*{Main Algorithm}

The following example illustrates how the 'Monotone' algorithm arrives at cut points for numeric data.
\begin{tabular}{|c|c|c|c|c|c|c|}
\hline Bin & Good & Bad & Iteration 1 & Iteration2 & Iteration3 & Iteration4 \\
\hline \[
\begin{aligned}
& \hline \text { ' }[- \\
& \text { Inf , } 33000
\end{aligned}
\] & 127 & 107 & 0.543 & & & \\
\hline ' [33000, 31 & ¢194 & 90 & 0.620 & 0.683 & & \\
\hline ' [38000, 4: & 135 & 78 & 0.624 & 0.662 & & \\
\hline ' [42000, 4 ' & 164 & 66 & 0.645 & 0.678 & 0.713 & \\
\hline '[47000, It & 183 & 56 & 0.669 & 0.700 & 0.740 & 0.766 \\
\hline
\end{tabular}

Initially, the numeric data is preprocessed with an equal frequency binning. In this example, for simplicity, only the five initial bins are used. The first column indicates
the equal frequency bin ranges, and the second and third columns have the "Good" and "Bad" counts per bin. (The number of observations is 1,200 , so a perfect equal frequency binning would result in five bins with 240 observations each. In this case, the observations per bin do not match 240 exactly. This is a common situation when the data has repeated values.)

Monotone finds break points based on the cumulative proportion of "Good" observations. In the ' Iteration1' column, the first value (0.543) is the number of "Good" observations in the first bin (127), divided by the total number of observations in the bin \((127+107)\). The second value ( 0.620 ) is the number of "Good" observations in bins 1 and 2 , divided by the total number of observations in bins 1 and 2 . And so forth. The first cut point is set where the minimum of this cumulative ratio is found, which is in the first bin in this example. This is the end of iteration 1.

Starting from the second bin (the first bin after the location of the minimum value in the previous iteration), cumulative proportions of "Good" observations are computed again. The second cut point is set where the minimum of this cumulative ratio is found. In this case, it happens to be in bin number 3, therefore bins 2 and 3 are merged.

The algorithm proceeds the same way for two more iterations. In this particular example, in the end it only merges bins 2 and 3 . The final binning has four bins with cut points at \(33,000,42,000\), and 47,000 .

For categorical data, the only difference is that the preprocessing step consists in reordering the categories. Consider the following categorical data:
\begin{tabular}{|l|l|ll|}
\hline Bin & Good & Bad & Odds \\
\hline 'Home Owner' & 365 & 177 & 2.062 \\
\hline 'Tenant' & 307 & 167 & 1.838 \\
\hline 'Other' & 131 & 53 & 2.474 \\
\hline
\end{tabular}

The preprocessing step, by default, sorts the categories by 'Odds'. (See the "Sort Categories" on page 18-1703 definition or the description of AlgorithmOptions option for 'SortCategories' for more information.) Then, it applies the same steps described above, shown in the following table:
\begin{tabular}{|l|l|l|l|l|l|l|}
\hline Bin & Good & Bad & Odds & Iteration 1 & Iteration2 & Iteration3 \\
\hline 'Tenant' & 307 & 167 & 1.838 & 0.648 & & \\
\hline
\end{tabular}
\begin{tabular}{|l|l|l|l|l|l|l|}
\hline Bin & Good & Bad & Odds & Iteration 1 & Iteration2 & Iteration3 \\
\hline \begin{tabular}{l} 
'Home \\
Owner'
\end{tabular} & 365 & 177 & 2.062 & 0.661 & 0.673 & \\
\hline 'Other' & 131 & 53 & 2.472 & 0.669 & 0.683 & 0.712 \\
\hline
\end{tabular}

In this case, the Monotone algorithm would not merge any categories. The only difference, compared with the data before the application of the algorithm, is that the categories are now sorted by 'Odds '.

In both the numeric and categorical examples above, the implicit 'Trend ' choice is 'Increasing '. (See the description of AlgorithmOptions option for the 'Monotone' 'Trend ' option.) If you set the trend to 'Decreasing ', the algorithm looks for the maximum (instead of the minimum) cumulative ratios to determine the cut points. In that case, at iteration 1, the maximum would be in the last bin, which would imply that all bins should be merged into a single bin. Binning into a single bin is a total loss of information and has no practical use. Therefore, when the chosen trend leads to a single bin, the Monotone implementation rejects it, and the algorithm returns the bins found after the preprocessing step. This state is the initial equal frequency binning for numeric data and the sorted categories for categorical data. The implementation of the Monotone algorithm by default uses a heuristic to identify the trend ('Auto' option for 'Trend ').

\section*{Equal Frequency}

Unsupervised algorithm that divides the data into a predetermined number of bins that contain approximately the same number of observations.

EqualFrequency is defined as:
Let \(\mathrm{v}[1], \mathrm{v}[2], \ldots, \mathrm{v}[\mathrm{N}]\) be the sorted list of different values or categories observed in the data. Let \(\mathrm{f}[i]\) be the frequency of \(\mathrm{v}[i]\). Let \(\mathrm{F}[k]=\mathrm{f}[1]+\ldots+\mathrm{f}[k]\) be the cumulative sum of frequencies up to the \(k\) th sorted value. Then \(\mathrm{F}[N]\) is the same as the total number of observations.

Define AvgFreq = F[N]/ NumBins, which is the ideal average frequency per bin after binning. The \(n\)th cut point index is the index \(k\) such that the distance \(\operatorname{abs}(\mathrm{F}[k]\) \(n^{*}\) AvgFreq) is minimized.

This rule attempts to match the cumulative frequency up to the \(n\)th bin. If a single value contains too many observations, equal frequency bins are not possible, and the above rule yields less than NumBins total bins. In that case, the algorithm determines NumBins bins by breaking up bins, in the order in which the bins were constructed.

The preprocessing of categorical predictors consists in sorting the categories according to the 'SortCategories ' criterion (the default is to sort by odds in increasing order). Sorting is not applied to ordinal predictors. See the "Sort Categories" on page 18-1703 definition or the description of AlgorithmOptions option for 'SortCategories' for more information.

\section*{Equal Width}

Unsupervised algorithm that divides the range of values in the domain of the predictor variable into a predetermined number of bins of "equal width." For numeric data, the width is measured as the distance between bin edges. For categorical data, width is measured as the number of categories within a bin.

The EqualWidth option is defined as:
For numeric data, if MinValue and MaxValue are the minimum and maximum data values, then

Width = (MaxValue - MinValue)/NumBins
and the CutPoints are set to MinValue + Width, MinValue \(+2^{*}\) Width, ... MaxValue
- Width. If a MinValue or MaxValue have not been specified using the modifybins function, the EqualWidth option sets MinValue and MaxValue to the minimum and maximum values observed in the data.

For categorical data, if there are NumCats numbers of original categories, then
Width \(=\) NumCats / NumBins,
and set cut point indices to the rounded values of Width, \(2^{*}\) Width, ..., NumCats - Width, plus 1 .

The preprocessing of categorical predictors consists in sorting the categories according to the 'SortCategories ' criterion (the default is to sort by odds in increasing order). Sorting is not applied to ordinal predictors. See the "Sort Categories" on page 18-1703 definition or the description of AlgorithmOptions option for 'SortCategories' for more information.

\section*{Sort Categories}

As a preprocessing step for categorical data, 'Monotone', 'EqualFrequency ', and 'EqualWidth' support the 'SortCategories' input. This serves the purpose of reordering the categories before applying the main algorithm. The default sorting
criterion is to sort by ' Odds '. For example, suppose that the data originally looks like this:
\begin{tabular}{|l|l|ll|}
\hline Bin & Good & Bad & Odds \\
\hline 'Home Owner' & 365 & 177 & 2.062 \\
\hline 'Tenant' & 307 & 167 & 1.838 \\
\hline 'Other \(^{\prime}\) & 131 & 53 & 2.472 \\
\hline
\end{tabular}

After the preprocessing step, the rows would be sorted by 'Odds ' and the table looks like this:
\begin{tabular}{|l|l|ll|}
\hline Bin & Good & Bad & Odds \\
\hline 'Tenant' & 307 & 167 & 1.838 \\
\hline 'Home Owner' & 365 & 177 & 2.062 \\
\hline 'Other' & 131 & 53 & 2.472 \\
\hline
\end{tabular}

The three algorithms only merge adjacent bins, so the initial order of the categories makes a difference for the final binning. The 'None ' option for 'SortCategories ' would leave the original table unchanged. For a description of the sorting criteria supported, see the description of the AlgorithmOptions option for 'SortCategories'.

Upon the construction of a scorecard, the initial order of the categories, before any algorithm or any binning modifications are applied, is the order shown in the first output of bininfo. If the bins have been modified (either manually with modifybins or automatically with autobinning), use the optional output (cg, 'category grouping') from bininfo to get the current order of the categories.

The 'SortCategories' option has no effect on categorical predictors for which the 'Ordinal' parameter is set to true (see the 'Ordinal' input parameter in MATLAB categorical arrays for categorical. Ordinal data has a natural order, which is honored in the preprocessing step of the algorithms by leaving the order of the categories unchanged. Only categorical predictors whose 'Ordinal' parameter is false (default option) are subject to reordering of categories according to the 'SortCategories ' criterion.

\section*{probdefault}

Likelihood of default for given data set

\section*{Syntax}
pd = probdefault(sc)
pd = probdefault(sc,data)

\section*{Description}
pd = probdefault(sc) computes the probability of default for sc, the data used to build the creditscorecard object.
pd = probdefault(sc, data) computes the probability of default for a given data set specified using the optional argument data.

By default, the data used to build the creditscorecard object are used. You can also supply input data, to which the same computation of probability of default is applied.

\section*{Examples}

\section*{Compute Probability for Default Using Credit ScoreCard Data}

Create a creditscorecard object using the CreditCardData.mat file to load the data (using a dataset from Refaat 2011).
load CreditCardData
sc = creditscorecard(data,'IDVar','CustID')

SC =
creditscorecard with properties:
GoodLabel: 0
```

        ResponseVar: 'status'
            VarNames: {1x11 cell}
        NumericPredictors: {1x6 cell}
    CategoricalPredictors: {'ResStatus' 'EmpStatus' 'OtherCC'}
IDVar: 'CustID'
PredictorVars: {1x9 cell}

```

Perform automatic binning using the default options. By default, autobinning uses the Monotone algorithm.
```

sc = autobinning(sc);

```

Fit the model.
```

sc = fitmodel(sc);

\section*{Input Arguments}

\section*{sc - Credit scorecard model}
creditscorecard object
Credit scorecard model, specified as a creditscorecard object. To create this object, use the creditscorecard function.

\section*{data - (Optional) Validation data}
table
(Optional) Validation data, specified as a MATLAB table, where each table row corresponds to individual observations. The data must contain columns for each of the predictors in the credit scorecard model. The columns of data can be any one of the following data types:
- Numeric
- Logical
- Cell array of strings
- Character array
- Categorical

In addition, the table must contain a binary response variable.
Data Types: table

\section*{Name-Value Pair Arguments}

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

Example: SC = validatemodel(sc,data,'AnalysisLevel', 'Deciles','Plot', 'CAP')

\section*{'AnalysisLevel' - Type of analysis level}
'Scores' (default) | string with values 'Deciles', 'Scores'
Type of analysis level, specified as string with one of the following values:
- 'Scores' - Returns the statistics (Stats) at the observation level. Scores are sorted from riskiest to safest, and duplicates are removed.
- 'Deciles ' - Returns the statistics (Stats) at decile level. Scores are sorted from riskiest to safest and binned with their corresponding statistics into 10 deciles ( \(10 \%\), \(20 \%, \ldots, 100 \%)\).

Data Types: char

\section*{'Plot ' - Type of plot}
'None' (default) | string with values 'None', 'CAP', 'ROC','KS' | cell array of string with values 'None', 'CAP', 'ROC','KS'

Type of plot, specified as string with one of the following values:
- 'None' - No plot is displayed.
- 'CAP' - Cumulative Accuracy Profile. Plots the fraction of borrowers up to score " \(s\) " versus the fraction of defaulters up to score "s" ('PctObs ' versus 'Sensitivity' columns of T optional output argument). For more details, see "Cumulative Accuracy Profile (CAP)" on page 18-1718.
- 'ROC ' - Receiver Operating Characteristic. Plots the fraction of non-defaulters up to score " \(s\) " versus the fraction of defaulters up to score " \(s\) " ( ' FalseAlarm' versus 'Sensitivity ' columns of T optional output argument). For more details, see "Receiver Operating Characteristic (ROC)" on page 18-1719.
- 'KS ' - Kolmogorov-Smirnov. Plots each score "s" versus the fraction of defaulters up to score "s," and also versus the fraction of non-defaulters up to score "s" ('Scores ' versus both 'Sensitivity' and 'FalseAlarm' columns of the optional output argument T). For more details, see "Kolmogorov-Smirnov statistic (KS)" on page 18-1719.

Tip For the Kolmogorov-Smirnov statistic option, you can enter 'KS' or 'K-S'.
Data Types: char | cell

\section*{Output Arguments}

\section*{Stats - Validation measures}
table
Validation measures, returned as a 4-by-2 table. The first column, 'Measure ', contains the names of the following measures:
- Accuracy ratio (AR)
- Area under the ROC curve (AUROC)
- The KS statistic
- KS score

The second column, 'Value', contains the values corresponding to these measures.

\section*{T - Validation statistics data \\ array}

Validation statistics data, returned as an N-by-9 table of validation statistics data, sorted, by score, from riskiest to safest. When AnalysisLevel is set to 'Deciles', N
is equal to 10 . Otherwise, N is equal to the total number of unique scores, that is, scores without duplicates.

The table T contains the following nine columns, in this order:
- 'Scores ' - Scores sorted from riskiest to safest. The data in this row corresponds to all observations up to, and including the score in this row.
- 'ProbDefault' - Probability of default for observations in this row. For deciles, the average probability of default for all observations in the given decile is reported.
- 'TrueBads ' — Cumulative number of "bads" up to, and including, the corresponding score.
- 'FalseBads ' - Cumulative number of "goods" up to, and including, the corresponding score.
- 'TrueGoods ' - Cumulative number of "goods" above the corresponding score.
- 'FalseGoods ' - Cumulative number of "bads" above the corresponding score.
- 'Sensitivity ' - Fraction of defaulters (or the cumulative number of "bads" divided by total number of "bads"). This is the distribution of "bads" up to and including the corresponding score.
- 'FalseAlarm' - Fraction of non-defaulters (or the cumulative number of "goods" divided by total number of "goods"). This is the distribution of "goods" up to and including the corresponding score.
- 'PctObs' - Fraction of borrowers, or the cumulative number of observations, divided by total number of observations up to and including the corresponding score.

\section*{hf - Handle to the plotted measures}
figure handle
Figure handle to plotted measures, returned as a figure handle or array of handles. When Plot is set to 'None', hf is an empty array.

\section*{More About}

\section*{Cumulative Accuracy Profile (CAP)}

CAP is generally a concave curve and is also known as the Gini curve, Power curve, or Lorenz curve. The scores of given observations are sorted from riskiest to safest. For a given fraction M ( \(0 \%\) to \(100 \%\) ) of the total borrowers, the height of the CAP curve is the
fraction of defaulters whose scores are less than or equal to the maximum score of the fraction M, also known as "Sensitivity."

The area under the CAP curve, known as the AUCAP, is then compared to that of the perfect or "ideal" model, leading to the definition of a summary index known as the accuracy ratio \((A R)\) or the Gini coefficient:
\[
A R=\frac{A_{R}}{A_{P}}
\]
where \(A_{R}\) is the area between the CAP curve and the diagonal, and \(A_{P}\) is the area between the perfect model and the diagonal. The diagonal represents a "random" model, where scores are assigned randomly and therefore the proportion of defaulters and non-defaulters is independent of the score. The perfect model is the model for which all defaulters are assigned the lowest scores, and therefore, perfectly discriminates between defaulters and nondefaulters. Thus, the closer to unity \(A R\) is, the better the scoring model.

\section*{Receiver Operating Characteristic (ROC)}

To find the receiver operating characteristic (ROC) curve, the proportion of defaulters up to a given score "s," or "Sensitivity," is computed. This proportion is known as the true positive rate (TPR). Additionally, the proportion of nondefaulters up to score "s," or "False Alarm Rate," is also computed. This proportion is also known as the false positive rate (FPR). The ROC curve is the plot of the "Sensitivity" vs. the "False Alarm Rate." Computing the ROC curve is similar to computing the equivalent of a confusion matrix at each score level.

Similar to the CAP, the ROC has a summary statistic known as the area under the ROC curve (AUROC). The closer to unity, the better the scoring model. The accuracy ratio \((A R)\) is related to the area under the curve by the following formula:
\[
A R=2(A U R O C)-1
\]

\section*{Kolmogorov-Smirnov statistic (KS)}

The Kolmogorov-Smirnov (KS) plot, also known as the fish-eye graph, is a common statistic used to measure the predictive power of scorecards.

The KS plot shows the distribution of defaulters and the distribution of non-defaulters on the same plot. For the distribution of defaulters, each score "s" is plotted versus the
proportion of defaulters up to "s," or "Sensitivity." For the distribution of non-defaulters, each score "s" is plotted versus the proportion of non-defaulters up to "s," or "False Alarm." The statistic of interest is called the KS statistic and is the maximum difference between these two distributions ("Sensitivity" minus "False Alarm"). The score at which this maximum is attained is also of interest.

\section*{Introduced in R2015a}

\section*{creditscorecard}

Create creditscorecard object
Build a credit scorecard model by creating a creditscorecard object and specifying input data in a table format. For more information on using a creditscorecard object, see Using creditscorecard Objects.

After creating a creditscorecard object, you can use the associated object functions to bin the data and perform logistic regression analysis to develop a credit scorecard model to guide credit decisions. This workflow shows how to develop a credit scorecard model.

1 Create a creditscorecard object.
2 Bin the data.
3 Fit a logistic regression model.
4 Review and format the credit scorecard points.
5 Score the data.
6 Calculate the probabilities of default for data.
7 Validate the quality of the credit scorecard model.
For details on this workflow, see "Credit Scorecard Modeling Workflow" on page 8-80.

\section*{Syntax}
sc = creditscorecard(data)
sc = creditscorecard( \(\qquad\) , Name, Value)

\section*{Description}
sc = creditscorecard(data) creates a creditscorecard object by specifying data.
sc = creditscorecard( \(\qquad\) , Name, Value) creates a creditscorecard object by specifying data and using optional name-value pair arguments.

\section*{Examples}

\section*{Create a creditscorecard Object}

Create a creditscorecard object using the CreditCardData.mat file to load the data (using a dataset from Refaat 2011).
```

load CreditCardData

```
sc = creditscorecard(data)
sc =
    creditscorecard with properties:
            GoodLabel: 0
            ResponseVar: 'status'
                            VarNames: \{1×11 cell\}
            NumericPredictors: \{1x7 cell\}
        CategoricalPredictors: \{'ResStatus' 'EmpStatus' 'OtherCC'\}
                            IDVar:
                            PredictorVars: \{1x10 cell\}

In this example, the default values for the properties ResponseVar, PredictorVars and GoodLabel are assigned when this object is created. By default, the property ResponseVar is set to the variable name that is in the last column of the input data ('status ' in this example). The property PredictorVars contains the names of all the variables that are in VarNames, but excludes IDVar and ResponseVar. Also, by default in the previous example, GoodLabel is set to 0 , since it is the value in the response variable (ResponseVar) with the highest count.

Display the creditscorecard object properties using dot notation.
```

sc.PredictorVars
sc.VarNames
ans =
Columns 1 through 5
'CustID' 'CustAge' 'TmAtAddress' 'ResStatus' 'EmpStatus'

```
```

    Columns 6 through 10
    CustIncome' 'TmWBank' 'OtherCC' 'AMBalance' 'UtilRate'
    ans =
Columns 1 through 5
'CustID' 'CustAge' 'TmAtAddress' 'ResStatus' 'EmpStatus'
Columns 6 through 10
'CustIncome' 'TmWBank' 'OtherCC' 'AMBalance' 'UtilRate'
Column 11
'status'

```

Since IDVar and PredictorVars have public access, you can change their values at the command line.
```

sc.IDVar = 'CustID'
sc.PredictorVars = {'CustIncome','ResStatus','AMBalance'}
disp(sc)
SC =
creditscorecard with properties:
GoodLabel: 0
ResponseVar: 'status'
VarNames: {1x11 cell}
NumericPredictors: {1x6 cell}
CategoricalPredictors: {'ResStatus' 'EmpStatus' 'OtherCC'}
IDVar: 'CustID'
PredictorVars: {1x9 cell}
SC =
creditscorecard with properties:

```
```

                        GoodLabel: 0
            ResponseVar: 'status'
                            VarNames: {1x11 cell}
        NumericPredictors: {'CustIncome' 'AMBalance'}
    CategoricalPredictors: {'ResStatus'}
                            IDVar: 'CustID'
                PredictorVars: {'CustIncome' 'ResStatus' 'AMBalance'}
    creditscorecard with properties:

```
            GoodLabel: 0
            ResponseVar: 'status'
            VarNames: \{1x11 cell\}
        NumericPredictors: \{'CustIncome' 'AMBalance'\}
    CategoricalPredictors: \{'ResStatus'\}
                            IDVar: 'CustID'
            PredictorVars: \{'CustIncome' 'ResStatus' 'AMBalance'\}

\section*{Create a creditscorecard Object and Set GoodLabel and ResponseVar}

Create a creditscorecard object using the CreditCardData.mat file to load the data (using a dataset from Refaat 2011). Then use name-value pair arguments for the creditscorecard function to define GoodLabel and ResponseVar.
```

load CreditCardData
sc = creditscorecard(data,'IDVar','CustID','GoodLabel',0,'ResponseVar','status')
SC =
creditscorecard with properties:

```
                    GoodLabel: 0
                    ResponseVar: 'status'
                            VarNames: \{1x11 cell\}
            NumericPredictors: \{1x6 cell\}
        CategoricalPredictors: \{'ResStatus' 'EmpStatus' 'OthercC'\}
                            IDVar: 'CustID'
                            PredictorVars: \{1x9 cell\}

GoodLabel and ResponseVar can only be set (enforced) when creating a creditscorecard object using the creditscorecard function.
- "Case Study for a Credit Scorecard Analysis" on page 8-93
- "Troubleshooting Credit Scorecard Results" on page 8-83

\section*{Input Arguments}
data - Data for creditscorecard object
table
Data for the creditscorecard object, specified as a MATLAB table, where each column of data can be any one of the following data types:
- Numeric
- Logical
- Cell array of strings
- Character array
- Categorical

In addition, the table must contain a binary response variable. Before creating a creditscorecard object, perform a data preparation task to have appropriately structured data as input to a creditscorecard object.

\section*{Data Types: table}

\section*{Name-Value Pair Arguments}

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.
Example: sc =
creditscorecard(data, 'GoodLabel',0,'IDVar', 'CustID', 'ResponseVar', 'status', 'Pr \{'CustID','CustIncome'\})

\section*{'GoodLabel ' - Indicator for which of two possible values in response variable correspond to "Good" observations}
set to the response value with the highest count (default) | string | numeric scalar | logical

Indicator for which of the two possible values in the response variable correspond to "Good" observations, specified as a numeric scalar, logical, or string. When specifying GoodLabel, follow these guidelines.
\begin{tabular}{|l|l|}
\hline If Response Is... & GoodLabel Must be... \\
\hline numeric & numeric \\
\hline logical & logical or numeric \\
\hline cell array of strings & string \\
\hline character array & string \\
\hline categorical & string \\
\hline
\end{tabular}

If not specified, GoodLabel is set to the response value with the highest count. GoodLabel can only be set when creating the creditscorecard object. This parameter cannot be set using dot notation.
Data Types: char | double

\section*{' IDVar ' - Variable name used as ID or tag for observations empty string ' ' (default) | string}

Variable name used as ID or tag for the observations, specified as a string. The IDVar data could be an ordinal number (for example, 1,2,3...), a Social Security number. This is provided as a convenience to remove this column from the predictor variables. IDVar is case-sensitive. You can set this optional parameter using the creditscorecard function or by using dot notation at the command line, as follows.
Example: sc.IDVar = 'CustID'
Data Types: char
```

'ResponseVar ' - Response variable name for "Good" or "Bad" indicator last column of the data input (default) | string

```

Response variable name for the "Good" or "Bad" indicator, specified as a string. The response variable data must be binary. If not specified, ResponseVar is set to the last column of the data input. ResponseVar can only be set when creating the
creditscorecard object using the creditscorecard function. ResponseVar is casesensitive.

\section*{Data Types: char}

\section*{'PredictorVars ' - Predictor variable names set difference between VarNames and \{IDVar, ResponseVar\} (default) | cell array of strings containing names}

Predictor variable names, specified using a cell array of strings containing names. By default, when you create a credit scorecard using creditscorecard, all variables are predictors except for IDVar and ResponseVar. This property can be modified by using dot notation or by using a name-value pair argument for the fitmodel function. PredictorVars is case-sensitive and the predictor variable name cannot be the same as the IDVar or ResponseVar.

Data Types: cell

\section*{Output Arguments}

\section*{sc - Credit scorecard model}
creditscorecard object
Credit scorecard model, returned as a creditscorecard object that contains the binning maps or rules (cut points or category groupings) for one or more predictors. For more information on using the creditscorecard object, see Using creditscorecard Objects.

\section*{Using creditscorecard Objects}

Build credit scorecard model

\section*{Description}

Build a credit scorecard model by creating a creditscorecard object and specify input data in a table format.

After creating a creditscorecard object, you can use the associated object functions to bin the data and perform logistic regression analysis to develop a credit scorecard model to guide credit decisions. This workflow shows how to develop a credit scorecard model.

1 Create a creditscorecard object.
2 Bin the data.
3 Fit a logistic regression model.
4 Review and format the credit scorecard points.
5 Score the data.
6 Calculate the probabilities of default for the data.
7 Validate the quality of the credit scorecard model.
For more detailed information on this workflow, see "Credit Scorecard Modeling Workflow" on page 8-80.

\section*{Examples}

\section*{Create a creditscorecard Object}

Create a creditscorecard object using the CreditCardData.mat file to load the data (using a dataset from Refaat 2011).
load CreditCardData
sc = creditscorecard(data)

SC =
creditscorecard with properties:
```

    GoodLabel: 0
    ResponseVar: 'status'
    VarNames: {1x11 cell}
    NumericPredictors: {1x7 cell}
    CategoricalPredictors: {'ResStatus' 'EmpStatus' 'OtherCC'}
IDVar:
PredictorVars: {1x10 cell}

```

\section*{Display creditscorecard Object Properties}

Create a creditscorecard object using the CreditCardData.mat file to load the data (using a dataset from Refaat 2011).
```

load CreditCardData

```
sc = creditscorecard(data)
sc =
    creditscorecard with properties:
                    GoodLabel: 0
                    ResponseVar: 'status'
                    VarNames: \{1×11 cell\}
            NumericPredictors: \(\{1 \times 7\) cell\}
        CategoricalPredictors: \{'ResStatus' 'EmpStatus' 'OtherCC'\}
                        IDVar:
                            PredictorVars: \{1x10 cell\}

To display the creditscorecard object properties, use dot notation.

\section*{sc.PredictorVars}
sc.VarNames

\section*{ans =}

Columns 1 through 5
'CustID' 'CustAge' 'TmAtAddress' 'ResStatus' 'EmpStatus' Columns 6 through 10
```

    CustIncome' 'TmWBank' 'OtherCC' 'AMBalance' 'UtilRate'
    ans =
Columns 1 through 5
CustID' 'CustAge' 'TmAtAddress' 'ResStatus' 'EmpStatus
Columns 6 through 10
'CustIncome' 'TmWBank' 'OtherCC' 'AMBalance' 'UtilRate'
Column 11
'status'

```

\section*{Change a Property Value for a creditscorecard Object}

Create a creditscorecard object using the CreditCardData.mat file to load the data (using a dataset from Refaat 2011).
load CreditCardData
sc = creditscorecard(data)
sc =
    creditscorecard with properties:
            GoodLabel: 0
            ResponseVar: 'status'
                    VarNames: \{1x11 cell\}
            NumericPredictors: \{1x7 cell\}
        CategoricalPredictors: \{'ResStatus' 'EmpStatus' 'OtherCC'\}
                        IDVar:
            PredictorVars: \{1x10 cell\}

Since the IDVar property has public access, you can change its value at the command line.
sc.IDVar = 'CustID'
```

SC =
creditscorecard with properties:
GoodLabel: 0
ResponseVar: 'status'
VarNames: {1x11 cell}
NumericPredictors: {1x6 cell}
CategoricalPredictors: {'ResStatus' 'EmpStatus' 'OtherCC'}
IDVar: 'CustID'
PredictorVars: {1x9 cell}

```
- "Case Study for a Credit Scorecard Analysis" on page 8-93
- "Troubleshooting Credit Scorecard Results" on page 8-83

\section*{Properties}

\section*{IDVar - Name of the variable used as ID or tag for the observations}
empty string ' ' (default) | string
Name of the variable used as ID or tag for the observations, specified as a string. This property can be set as an optional parameter using the creditscorecard function or by using dot notation at the command line. IDVar is case-sensitive.

Example: sc.IDVar = 'CustID'
Data Types: char
VarNames - All variable names from the data input
VarNames come directly from data input to creditscorecard object (default)
This property is read only.
VarNames is a cell array of strings containing the names of all variables in the data. The VarNames come directly from the data input to the creditscorecard object. VarNames is case-sensitive.

Example:
Data Types: cell
ResponseVar - Name of the response variable, "Good" or "Bad" indicator last column of the data input (default) | string

Name of the response variable, "Good" or "Bad" indicator, specified as a string. The response variable data must be binary. If not specified, ResponseVar is set to the last column of the data input. This property can only be set with an optional parameter when using the creditscorecard function. ResponseVar is case-sensitive.

\section*{Data Types: char}

\section*{GoodLabel - Indicator for which of the two possible values in the response variable correspond to "Good" observations}
set to the response value with the highest count (default) | string | numeric scalar | logical

Indicator for which of the two possible values in the response variable correspond to "Good" observations. When specifying GoodLabel, follow these guidelines:
\begin{tabular}{|l|l|}
\hline If Response is... & GoodLabel must be: \\
\hline numeric & numeric \\
\hline logical & logical or numeric \\
\hline cell array of strings & string \\
\hline character array & string \\
\hline categorical & string \\
\hline
\end{tabular}

If not specified, GoodLabel is set to the response value with the highest count. This property can only be set with an optional parameter when using the creditscorecard function. This property cannot be set using dot notation.
Data Types: char | double

\section*{PredictorVars - Predictor variable names}
set difference between VarNames and \{IDVar,ResponseVar\} (default) | cell array of strings containing names

Predictor variable names, specified using a cell array of strings containing names. By default, when you create a credit scorecard using creditscorecard, all variables are predictors except for IDVar and ResponseVar. This property can be modified using a name-value pair argument for the fitmodel function or by using dot notation. PredictorVars is case-sensitive and the predictor variable name cannot be the same as the IDVar or ResponseVar.

Example: sc.PredictorVars = \{'CustID', 'CustIncome'\}
Data Types: cell

\section*{NumericPredictors - Name of numeric predictors}

\section*{empty string ' ' (default) | string}

Name of numeric predictors, specified as a string. This property cannot be set by using dot notation at the command line. It can only be modified using the modifypredictor function.

Data Types: char
CategoricalPredictors - Name of categorical predictors
empty string ' ' (default) | string
Name of categorical predictors, specified as a string. This property cannot be set by using dot notation at the command line. It can only be modified using the modifypredictor function.

Data Types: char

Note: For the well-known algorithms and formulas used in Financial Toolbox software (such as how to compute a loan payment given principal, interest rate, and length of the loan), no references are given here. The references here pertain to less common formulas.

\section*{Bond Pricing and Yields}

The pricing and yield formulas for fixed-income securities come from:
[1] Golub, B.W. and L.M. Tilman, Risk Management: Approaches for Fixed Income Markets Wiley, 2000.
[2] Martellini, L., P. Priaulet, and S. Priaulet Fixed Income Securities Wiley, 2003.
[3] Mayle, Jan, Standard Securities Calculation Methods New York: Securities Industry Association, Inc. Vol. 1, 3rd ed., 1993, ISBN 1-882936-01-9. Vol. 2, 1994, ISBN 1-882936-02-7.
[4] Tuckman, B. Fixed Income Securities: Tools for Today's Markets Wiley, 2002.
In many cases these formulas compute the price of a security given yield, dates, rates, and other data. These formulas are nonlinear, however; so when solving for an independent variable within a formula, Financial Toolbox software uses Newton's method. See any elementary numerical methods textbook for the mathematics underlying Newton's method.

\section*{Term Structure of Interest Rates}

The formulas and methodology for term structure functions come from:
[5] Fabozzi, Frank J., "The Structure of Interest Rates." Ch. 6 in Fabozzi, Frank J. and T. Dessa Fabozzi, eds. The Handbook of Fixed Income Securities. 4th ed. New York: Irwin Professional Publishing, 1995, ISBN 0-7863-0001-9.
[6] McEnally, Richard W. and James V. Jordan, "The Term Structure of Interest Rates." Ch. 37 in Fabozzi and Fabozzi, ibid.
[7] Das, Satyajit, "Calculating Zero Coupon Rates." Swap and Derivative Financing. Appendix to Ch. 8, pp. 219-225, New York: Irwin Professional Publishing., 1994, ISBN 1-55738-542-4.

\section*{Derivatives Pricing and Yields}

The pricing and yield formulas for derivative securities come from:
[8] Chriss, Neil A., "Black-Scholes and Beyond: Option Pricing Models," Chicago: Irwin Professional Publishing, 1997, ISBN 0-7863-1025-1.
[9] Cox, J., S. Ross, and M. Rubenstein, "Option Pricing: A Simplified Approach", Journal of Financial Economics 7, Sept. 1979, pp. 229-263.
[10] Hull, John C., Options, Futures, and Other Derivatives, Prentice Hall, 5th edition, 2003, ISBN 0-13-009056-5.

\section*{Portfolio Analysis}

The Markowitz model is used for portfolio analysis computations. For a discussion of this model see Chapter 7 of:
[11] Bodie, Zvi, Alex Kane, and Alan J. Marcus, Investments, Burr Ridge, IL: Irwin. 2nd. ed., 1993, ISBN 0-256-08342-8.

\section*{Investment Performance Metrics}

The risk and ratio formulas for investment performance metrics come from:
[12] Daniel Bernoulli, "Exposition of a New Theory on the Measurement of Risk," Econometrica, Vol. 22, No 1, January 1954, pp. 23-36 (English translation of "Specimen Theoriae Novae de Mensura Sortis," Commentarii Academiae Scientiarum Imperialis Petropolitanae, Tomus V, 1738, pp. 175-192).
[13] Martin Eling and Frank Schuhmacher, Does the Choice of Performance Measure Influence the Evaluation of Hedge Funds?, Working Paper, November 2005.
[14] John Lintner, "The Valuation of Risk Assets and the Selection of Risky Investments in Stocks Portfolios and Capital Budgets," Review of Economics and Statistics, Vol. 47, No. 1, February 1965, pp. 13-37.
[15] Malik Magdon-Ismail, Amir F. Atiya, Amrit Pratap, and Yaser S. Abu-Mostafa, "On the Maximum Drawdown of a Brownian Motion," Journal of Applied Probability, Volume 41, Number 1, March 2004, pp. 147-161.

\(\left.\left.\begin{array}{ll}\text { active return } & \begin{array}{l}\text { Amount of return achieved in excess of the return } \\ \text { produced by an appropriate benchmark (for example, an } \\ \text { index portfolio). }\end{array} \\ \text { active risk } & \begin{array}{l}\text { Standard deviation of the active return. Also known as } \\ \text { the tracking error. }\end{array} \\ \text { American option } & \begin{array}{l}\text { An option that can be exercised any time until its } \\ \text { expiration date. Contrast with European option. }\end{array} \\ \text { amortization } & \begin{array}{l}\text { Reduction in value of an asset over some period for } \\ \text { accounting purposes. Generally used with intangible }\end{array} \\ \text { assets. Depreciation is the term used with fixed or } \\ \text { tangible assets. }\end{array}\right\} \begin{array}{l}\text { A series of payments over a period of time. The payments } \\ \text { are usually in equal amounts and usually at regular } \\ \text { intervals such as quarterly, semiannually, or annually. }\end{array}\right\}\)
\begin{tabular}{|l|l|}
\hline \begin{tabular}{l} 
Basis \\
Value
\end{tabular} & Day Count Convention \\
\hline \(\mathbf{0}\) & \begin{tabular}{l} 
actual/actual (default) - Number of days in both \\
a period and a year is the actual number of days.
\end{tabular} \\
\hline \(\mathbf{1}\) & \begin{tabular}{l}
\(30 / 360\) SIA - Year fraction is calculated based \\
on a 360 day year with 30-day months, after \\
applying the following rules: If the first date and \\
the second date are the last day of February, \\
the second date is changed to the 30th. If the \\
first date falls on the 31st or is the last day of \\
February, it is changed to the 30th. If after the \\
preceding test, the first day is the 30th and the \\
second day is the 31st, then the second day is \\
changed to the 30th.
\end{tabular} \\
\hline \(\mathbf{2}\) & \begin{tabular}{l} 
actual/360 - Number of days in a period is equal \\
to the actual number of days, however the number \\
of days in a year is 360.
\end{tabular} \\
\hline \(\mathbf{3}\) & \begin{tabular}{l} 
actual/365 - Number of days in a period is equal \\
to the actual number of days, however the number \\
of days in a year is 365 (even in a leap year).
\end{tabular} \\
\hline 4 & \begin{tabular}{l}
\(30 / 360\) PSA - Number of days in every month is \\
set to 30 (including February). If the start date of \\
the period is either the 31st of a month or the last \\
day of February, the start date is set to the 30th, \\
while if the start date is the 30th of a month and \\
the end date is the 31st, the end date is set to the \\
\(30 t h . ~ T h e ~ n u m b e r ~ o f ~ d a y s ~ i n ~ a ~ y e a r ~ i s ~ 360 . ~\)
\end{tabular} \\
\hline 5 & \begin{tabular}{l}
\(30 / 360\) ISDA - Number of days in every month \\
is set to 30, except for February where it is the \\
actual number of days. If the start date of the \\
period is the 31st of a month, the start date is set \\
to the 30th while if the start date is the 30th of a \\
month and the end date is the 31st, the end date \\
is set to the 30th. The number of days in a year is \\
360.
\end{tabular} \\
\hline
\end{tabular}

\begin{tabular}{|c|c|}
\hline \begin{tabular}{l}
Basis \\
Value
\end{tabular} & Day Count Convention \\
\hline 6 & \(30 \mathrm{E} / 360\) - Number of days in every month is set to 30 except for February where it is equal to the actual number of days. If the start date or the end date of the period is the 31st of a month, that date is set to the 30th. The number of days in a year is 360. \\
\hline 7 & actual/365 Japanese - Number of days in a period is equal to the actual number of days, except for leap days (29th February) which are ignored. The number of days in a year is 365 (even in a leap year). \\
\hline 8 & actual/actual ICMA - Number of days in both a period and a year is the actual number of days and the compounding frequency is annual. \\
\hline 9 & actual/360 ICMA - Number of days in a period is equal to the actual number of days, however the number of days in a year is 360 and the compounding frequency is annual. \\
\hline 10 & actual/365 ICMA - Number of days in a period is equal to the actual number of days, however the number of days in a year is 365 (even in a leap year) and the compounding frequency is annual. \\
\hline 11 & 30/360 ICMA - Number of days in every month is set to 30 , except for February where it is equal to the actual number of days. If the start date or the end date of the period is the 31st of a month, that date is set to the 30th. The number of days in a year is 360 and the compounding frequency is annual. \\
\hline 12 & actual/365 ISDA - The day count fraction is calculated using the following formula: (Actual number of days in period that fall in a leap year / 366) + (Actual number of days in period that fall in a normal year / 365 ). \\
\hline
\end{tabular}

Glossary-3
\begin{tabular}{ll|l|}
\hline \begin{tabular}{l} 
Basis \\
Value
\end{tabular} & Day Count Convention \\
\hline 13 & \begin{tabular}{l} 
bus/252 - The number of days in a period is \\
equal to the actual number of business days. The \\
number of business days in a year is 252.
\end{tabular} \\
beta & \begin{tabular}{l} 
The price volatility of a financial instrument relative to \\
the price volatility of a market or index as a whole. Beta \\
is commonly used with respect to equities. A high-beta \\
instrument is riskier than a low-beta instrument.
\end{tabular} \\
binomial model & \begin{tabular}{l} 
A method of pricing options or other equity derivatives \\
in which the probability over time of each possible price \\
follows a binomial distribution. The basic assumption is \\
that prices can move to only two values (one higher and \\
one lower) over any short time period.
\end{tabular} \\
Black-Scholes model & \begin{tabular}{l} 
The first complete mathematical model for pricing \\
options, developed by Fischer Black and Myron Scholes. \\
It examines market price, strike price, volatility, time to \\
expiration, and interest rates. It is limited to only certain \\
kinds of options.
\end{tabular} \\
Bollinger band chart & \begin{tabular}{l} 
A financial chart that plots actual asset data along with \\
three other bands of data: the upper band is two standard \\
deviations above a user-specified moving average; the \\
lower band is two standard deviations below that moving \\
average; and the middle band is the moving average itself.
\end{tabular} \\
bootstrapping, bootstrap & \begin{tabular}{l} 
An arithmetic method for backing an implied zero curve \\
out of the par yield curve.
\end{tabular} \\
method & \begin{tabular}{l} 
A zero-mean continuous-time stochastic process with \\
independent increments (also known as a Wiener process).
\end{tabular} \\
Brownian motion a binomial tree & \begin{tabular}{l} 
For a binomial option model: plotting the two possible \\
short-term price-changes values, and then the subsequent \\
two values each, and then the subsequent two values \\
each, and so on over time, is known as "building a \\
binomial tree." See also binomial model.
\end{tabular} \\
\hline
\end{tabular}
\(\left.\begin{array}{ll}\text { call } & \begin{array}{l}\text { a. An option to buy a certain quantity of a stock or } \\
\text { commodity for a specified price within a specified time. } \\
\text { See also put. b. A demand to submit bonds to the issuer } \\
\text { for redemption before the maturity date. c. A demand for } \\
\text { payment of a debt. d. A demand for payment due on stock } \\
\text { bought on margin. }\end{array} \\
\text { callable bond } & \begin{array}{l}\text { A bond that allows the issuer to buy back the bond at a } \\
\text { predetermined price at specified future dates. The bond } \\
\text { contains an embedded call option; that is, the holder has } \\
\text { sold a call option to the issuer. See also puttable bond. }\end{array} \\
\text { candlestick chart } & \begin{array}{l}\text { A financial chart usually used to plot the high, low, open, } \\
\text { and close price of a security over time. The body of the } \\
\text { "candle" is the region between the open and close price of } \\
\text { the security. Thin vertical lines extend up to the high and } \\
\text { down to the low, respectively. If the open price is greater } \\
\text { than the close price, the body is empty. If the close price } \\
\text { is greater than the open price, the body is filled. See also } \\
\text { high-low-close chart. }\end{array} \\
\text { cap } & \begin{array}{l}\text { Interest-rate option that guarantees that the rate on a } \\
\text { floating-rate loan will not exceed a certain level. }\end{array} \\
\text { cash flow } \\
\text { clean price } & \begin{array}{l}\text { Cash received and paid over time. }\end{array} \\
\text { collar } & \begin{array}{l}\text { The price of a bond excluding any interest that has } \\
\text { accrued since issue or the most recent coupon payment. }\end{array} \\
\text { correlation } & \begin{array}{l}\text { Interest-rate option that guarantees that the rate on a } \\
\text { floating-rate loan will not exceed a certain upper level } \\
\text { nor fall below a lower level. It is designed to protect an } \\
\text { investor against wide fluctuations in interest rates. }\end{array} \\
\text { A measure of the rate of change in duration; measured } \\
\text { in time. The greater the rate of change, the more the } \\
\text { duration changes as yield changes. }\end{array}\right\}\)\begin{tabular}{l} 
The simultaneous change in value of two random numeric \\
variables.
\end{tabular}
\begin{tabular}{ll} 
correlation coefficient & \begin{tabular}{l} 
A statistic in which the covariance is scaled to a value \\
between minus one (perfect negative correlation) and plus \\
one (perfect positive correlation).
\end{tabular} \\
coupon & \begin{tabular}{l} 
Detachable certificate attached to a bond that shows the \\
amount of interest payable at regular intervals, usually \\
semiannually. Originally coupons were actually attached \\
to the bonds and had to be cut off or "clipped" to redeem \\
them and receive the interest payment.
\end{tabular} \\
coupon dates & \begin{tabular}{l} 
The dates when the coupons are paid. Typically a bond \\
pays coupons annually or semiannually.
\end{tabular} \\
coupon rate & \begin{tabular}{l} 
The nominal interest rate that the issuer promises to pay \\
the buyer of a bond.
\end{tabular} \\
covariance & \begin{tabular}{l} 
A measure of the degree to which returns on two assets \\
move in tandem. A positive covariance means that asset \\
returns move together; a negative covariance means they \\
vary inversely.
\end{tabular} \\
credit rating & \begin{tabular}{l} 
A credit rating evaluates a potential borrower's ability to \\
repay debt.
\end{tabular} \\
day count convention & \begin{tabular}{l} 
A convention used to determine the number of days \\
between two coupon dates, which is important in \\
calculating accrued interest and present value when the \\
next coupon payment is less than a full coupon period
\end{tabular} \\
away. See also basis
\end{tabular}

Glossary-6
\begin{tabular}{ll} 
diffusion & \begin{tabular}{l} 
The function that characterizes the random (stochastic) \\
portion of a stochastic differential equation. See also \\
stochastic differential equation.
\end{tabular} \\
dirty price & \begin{tabular}{l} 
The price of a bond including the accrued interest.
\end{tabular} \\
discount curve & \begin{tabular}{l} 
The curve of discount rates versus maturity dates for \\
bonds.
\end{tabular} \\
discretization error & \begin{tabular}{l} 
Errors that may arise due to discrete-time sampling of \\
continuous stochastic processes.
\end{tabular} \\
drawdown & \begin{tabular}{l} 
The peak to trough decline during a specific record period \\
of an investment or fund.
\end{tabular} \\
drift & \begin{tabular}{l} 
The function that characterizes the deterministic portion \\
of a stochastic differential equation. See also stochastic \\
differential equation.
\end{tabular} \\
duration & \begin{tabular}{l} 
The expected life of a fixed-income security considering \\
its coupon yield, interest payments, maturity, and call \\
features. As market interest rates rise, the duration of \\
a financial instrument decreases. See also Macaulay \\
duration .
\end{tabular} \\
efficient frontier & \begin{tabular}{l} 
A graph representing a set of portfolios that maximizes \\
expected return at each level of portfolio risk. See also \\
Markowitz model .
\end{tabular} \\
efficient porffolio & \begin{tabular}{l} 
Portfolios satisfying the criteria of minimum risk for a \\
given level of return and maximum return for a given \\
level of risk. See also Markowitz model .
\end{tabular} \\
elasticity & \begin{tabular}{l} 
See Lambda
\end{tabular} \\
Euler approximation & \begin{tabular}{l} 
A simulation technique that provides a discrete-time \\
approximation of a continuous-time stochastic process.
\end{tabular} \\
An option that can be exercised only on its expiration \\
date. Contrast with American option.
\end{tabular}
\(\left.\begin{array}{ll}\text { ex-post } & \begin{array}{l}\text { Referring to past events, when uncertainty of the result } \\
\text { has been eliminated. }\end{array} \\
\text { exercise price } & \begin{array}{l}\text { The price set for buying an asset (call) or selling an asset } \\
\text { (put). The strike price. }\end{array} \\
\text { face value } & \begin{array}{l}\text { The maturity value of a security. Also known as par } \\
\text { value, principal value, or redemption value. }\end{array} \\
\text { fixed-income security } & \begin{array}{l}\text { A security that pays a specified cash flow over a specific } \\
\text { period. Bonds are typical fixed-income securities. }\end{array} \\
\text { floor } & \begin{array}{l}\text { Interest-rate option that guarantees that the rate on a } \\
\text { floating-rate loan will not fall below a certain level. }\end{array} \\
\text { forward curve } & \begin{array}{l}\text { The curve of forward interest rates versus maturity dates } \\
\text { for bonds. }\end{array} \\
\text { forward rate } & \begin{array}{l}\text { The future interest rate of a bond inferred from the term } \\
\text { structure, especially from the yield curve of zero-coupon } \\
\text { bonds, calculated from the growth factor of an investment } \\
\text { in a zero held until maturity. }\end{array} \\
\text { future value } & \begin{array}{l}\text { The value that a sum of money (the present value) } \\
\text { earning compound interest will have in the future. }\end{array} \\
\text { gamma } & \begin{array}{l}\text { The rate of change of delta for a derivative security } \\
\text { relative to the price of the underlying asset; that is, } \\
\text { the second derivative of the option price relative to the } \\
\text { security price. }\end{array} \\
\text { greeks } & \begin{array}{l}\text { Collectively, "greeks" refer to the financial measures beta, }\end{array} \\
\text { ISDA } \\
\text { delta, gamma, lambda, rho, theta, and vega, which are } \\
\text { sensitivity measures used in evaluating derivatives. }\end{array}\right\}\)\begin{tabular}{l} 
International Swaps and Derivatives Association.
\end{tabular}

Glossary-8
\begin{tabular}{ll} 
high-low-close chart & \begin{tabular}{l} 
A financial chart usually used to plot the high, low, open, \\
and close price of a security over time. Plots are vertical \\
lines whose top is the high, bottom is the low, open is \\
a short horizontal tick to the left, and close is a short \\
horizontal tick to the right.
\end{tabular} \\
implied volatility & \begin{tabular}{l} 
For an option, the variance that makes a call option \\
price equal to the market price. Given the option price, \\
strike price, and other factors, the Black-Scholes model \\
computes implied volatility.
\end{tabular} \\
information ratio & \begin{tabular}{l} 
The ratio of relative return to relative risk.
\end{tabular} \\
internal rate of return & \begin{tabular}{l} 
a. The average annual yield earned by an investment \\
during the period held. b. The effective rate of interest \\
on a loan. c. The discount rate in discounted cash flow \\
analysis. d. The rate that adjusts the value of future cash \\
receipts earned by an investment so that interest earned \\
equals the original cost. See also yield
\end{tabular} \\
issue date & \begin{tabular}{l} 
The date a security is first offered for sale. That date \\
usually determines when interest payments, known as \\
coupons, are made.
\end{tabular} \\
Ito process & \begin{tabular}{l} 
Statistical assumptions about the behavior of security \\
prices. For details, see the book by Hull in "Derivatives \\
Pricing and Yields" on page A-4.
\end{tabular} \\
key rate duration & \begin{tabular}{l} 
Key rate duration measures the sensitivity of a portfolio's \\
(or security's) value in relation to changes in specific \\
maturities of the zero or spot curve.
\end{tabular} \\
lamb position & \begin{tabular}{l} 
The percentage change in the price of an option relative to
\end{tabular} \\
a 1\% change in the price of the underlying security. Also \\
known as elasticity.
\end{tabular}
lower partial moment

\section*{Macaulay duration}

\section*{Markowitz model}
maturity date
mean
modified duration

Monte-Carlo simulation
moving average

A model for the moments of asset returns that fall below a minimum acceptable level of return.

A widely used measure of price sensitivity to yield changes developed by Frederick Macaulay in 1938. It is measured in years and is a weighted average-time-to-maturity of an instrument. The Macaulay duration of an income stream, such as a coupon bond, measures how long, on average, the owner waits before receiving a payment. It is the weighted average of the times payments are made, with the weights at time \(T\) equal to the present value of the money received at time T.

A model for selecting an optimum investment portfolio, devised by H. M. Markowitz. It uses a discrete-time, continuous-outcome approach for modeling investment problems, often called the mean-variance paradigm. See also efficient portfolio and efficient frontier.

The date when the issuer returns the final face value of a bond to the buyer.
a. A number that typifies a set of numbers, such as a geometric mean or an arithmetic mean. \(\mathbf{b}\). The average value of a set of numbers.

The Macaulay duration discounted by the per-period interest rate; that is, divided by (1+rate/frequency).

A mathematical modeling process. For a model that has several parameters with statistical properties, pick a set of random values for the parameters and run a simulation. Then pick another set of values, and run it again. Run it many times (often 10,000 times) and build up a statistical distribution of outcomes of the simulation. This distribution of outcomes is then used to answer whatever question you are asking.

A price average that is adjusted by adding other parametrically determined prices over some time period.
\(\left.\left.\begin{array}{ll}\text { moving-averages chart } & \begin{array}{l}\text { A financial chart that plots leading and lagging moving } \\
\text { averages for prices or values of an asset. }\end{array} \\
\begin{array}{l}\text { normal (bell-shaped) } \\
\text { distribution }\end{array} & \begin{array}{l}\text { In statistics, a theoretical frequency distribution for a } \\
\text { set of variable data, usually represented by a bell-shaped } \\
\text { curve symmetrical about the mean. }\end{array} \\
\text { odd first or last period } & \begin{array}{l}\text { Fixed-income securities may be purchased on dates that } \\
\text { do not coincide with coupon or payment dates. The length } \\
\text { of the first and last periods may differ from the regular } \\
\text { period between coupons, and thus the bond owner is not } \\
\text { entitled to the full value of the coupon for that period. }\end{array} \\
\text { Instead, the coupon is prorated according to how long the } \\
\text { bond is held during that period. }\end{array}\right\} \begin{array}{l}\text { The most recently auctioned issue of a U.S. Treasury bond } \\
\text { or note of a particular maturity. }\end{array}\right\}\)\begin{tabular}{l} 
A right to buy or sell specific securities or commodities at \\
a stated price (exercise or strike price) within a specified \\
time. An option is a type of derivative.
\end{tabular}

Glossary-11
\(\left.\left.\left.\begin{array}{ll} & \begin{array}{l}\text { proportional sampling involves stratifying the terminal } \\ \text { value of a price process in which each sample path is } \\ \text { associated with a single stratified terminal value such } \\ \text { that the number of paths equals the number of strata. }\end{array} \\ \text { PSA } & \text { See also stratified sampling. } \\ \text { purchase price } & \begin{array}{l}\text { Public Securities Association. }\end{array} \\ \text { Price actually paid for a security. Typically the purchase } \\ \text { price of a bond is not the same as the redemption value. }\end{array}\right\} \begin{array}{l}\text { An option to sell a stipulated amount of stock or securities } \\ \text { within a specified time and at a fixed exercise price. See } \\ \text { also call. }\end{array}\right\} \begin{array}{l}\text { A bond that allows the holder to redeem the bond at a } \\ \text { predetermined price at specified future dates. The bond } \\ \text { contains an embedded put option; that is, the holder has } \\ \text { bought a put option. See also callable bond. }\end{array}\right\}\)
\begin{tabular}{ll} 
sensitivity & \begin{tabular}{l} 
The "what if" relationship between variables; the degree \\
to which changes in one variable cause changes in another \\
variable. A specific synonym is volatility.
\end{tabular} \\
settlement date & \begin{tabular}{l} 
The date when money first changes hands; that is, when \\
a buyer actually pays for a security. It need not coincide \\
with the issue date.
\end{tabular} \\
Sharpe ratio & \begin{tabular}{l} 
The ratio of the excess return of an asset divided by the \\
asset's standard deviation of returns.
\end{tabular} \\
short rate & \begin{tabular}{l} 
The annualized one-period interest rate.
\end{tabular} \\
short sale, short position & \begin{tabular}{l} 
The sale of a security or financial instrument not owned, \\
in anticipation of a price decline and making a profit by \\
purchasing the instrument later at a lower price, and \\
then delivering the instrument to complete the sale. See \\
also long position.
\end{tabular} \\
SIA \\
spot curve, spot yield curve & \begin{tabular}{l} 
Securities Industry Association.
\end{tabular} \\
spot rate & \begin{tabular}{l} 
See zero curve, zero-coupon yield curve .
\end{tabular} \\
spread & \begin{tabular}{l} 
The current interest rate appropriate for discounting a \\
cash flow of some given maturity.
\end{tabular} \\
standard deviation & \begin{tabular}{l} 
For options, a combination of call or put options on the \\
same stock with differing exercise prices or maturity \\
dates.
\end{tabular} \\
stochastic & \begin{tabular}{l} 
A measure of the variation in a distribution, equal to the \\
square root of the arithmetic mean of the squares of the \\
deviations from the arithmetic mean; the square root of \\
the variance.
\end{tabular} \\
equation & \begin{tabular}{l} 
Involving or containing a random variable or variables; \\
involving chance or probability.
\end{tabular} \\
a generalization of an ordinary differential equation, \\
variables as solutions.
\end{tabular}
\begin{tabular}{ll} 
straddle & \begin{tabular}{l} 
A strategy used in trading options or futures. It involves \\
simultaneously purchasing put and call options with the \\
same exercise price and expiration date, and it is most \\
profitable when the price of the underlying security is \\
very volatile.
\end{tabular} \\
strata & \begin{tabular}{l} 
See stratified sampling.
\end{tabular} \\
stratified sampling & \begin{tabular}{l} 
A variance reduction technique that constrains a \\
proportion of sample paths to specific subsets (or strata) of \\
the sample space.
\end{tabular} \\
strike & \begin{tabular}{l} 
Exercise a put or call option.
\end{tabular} \\
strike price & \begin{tabular}{l} 
See exercise price.
\end{tabular} \\
swap & \begin{tabular}{l} 
A contract between two parties to exchange cash flows in \\
the future according to some formula.
\end{tabular} \\
swaption & \begin{tabular}{l} 
A swap option; an option on an interest-rate swap. The \\
option gives the holder the right to enter into a contracted \\
interest-rate swap at a specified future date. See also \\
swap.
\end{tabular} \\
term structure & \begin{tabular}{l} 
The relationship between the yields on fixed-interest \\
securities and their maturity dates. Expectation of \\
changes in interest rates affects term structure, as do
\end{tabular} \\
liquidity preferences and hedging pressure. A yield curve
\end{tabular}
\begin{tabular}{ll} 
variance & \begin{tabular}{l} 
The dispersion of a variable. The square of the standard \\
deviation.
\end{tabular} \\
vega & \begin{tabular}{l} 
The rate of change in the price of a derivative security \\
relative to the volatility of the underlying security. When \\
vega is large, the security is sensitive to small changes in \\
volatility.
\end{tabular} \\
volatility & \begin{tabular}{l} 
a. Another general term for sensitivity. b. The standard \\
deviation of the annualized continuously compounded rate \\
of return of an asset. c. A measure of uncertainty or risk.
\end{tabular} \\
Wiener process & \begin{tabular}{l} 
See Brownian motion.
\end{tabular} \\
yield & \begin{tabular}{l} 
a. Measure of return on an investment, stated as a \\
percentage of price. Yield can be computed by dividing \\
return by purchase price, current market value, or other \\
measure of value. b. Income from a bond expressed as \\
an annualized percentage rate. c. The nominal annual \\
interest rate that gives a future value of the purchase \\
price equal to the redemption value of the security. Any \\
coupon payments determine part of that yield.
\end{tabular} \\
yield curve & \begin{tabular}{l} 
Graph of yields (vertical axis) of a particular type \\
of security versus the time to maturity (horizontal \\
axis). This curve usually slopes upward, indicating \\
that investors usually expect to receive a premium for \\
securities that have a longer time to maturity. The \\
benchmark yield curve is for U.S. Treasury securities with \\
maturities ranging from three months to 30 years. See \\
also term structure.
\end{tabular} \\
yield to maturity & \begin{tabular}{l} 
A measure of the average rate of return that will be
\end{tabular} \\
earned on a bond if held to maturity.
\end{tabular}
near par value in \(\$ 1000\) denominations or higher. Face value is paid at maturity.

The dispersion of a variable. The square of the standard deviation.

The rate of change in the price of a derivative security relative to the volatility of the underlying security. When vega is large, the security is sensitive to small changes in volatility.
a. Another general term for sensitivity. b. The standard deviation of the annualized continuously compounded rate of return of an asset. c. A measure of uncertainty or risk.

\section*{See Brownian motion.}
a. Measure of return on an investment, stated as a percentage of price. Yield can be computed by dividing return by purchase price, current market value, or other measure of value. \(\mathbf{b}\). Income from a bond expressed as an annualized percentage rate. c. The nominal annual interest rate that gives a future value of the purchase price equal to the redemption value of the security. Any coupon payments determine part of that yield.

Graph of yields (vertical axis) of a particular type of security versus the time to maturity (horizontal axis). This curve usually slopes upward, indicating that investors usually expect to receive a premium for securities that have a longer time to maturity. The benchmark yield curve is for U.S. Treasury securities with maturities ranging from three months to 30 years. See also term structure.

A measure of the average rate of return that will be earned on a bond if held to maturity.

A yield curve for zero-coupon bonds; zero rates versus maturity dates. Since the maturity and duration (Macaulay duration) are identical for zeros, the zero curve is a pure depiction of supply/demand conditions
for loanable funds across a continuum of durations and maturities. Also known as spot curve or spot yield curve.

\section*{zero-coupon bond, or zero}

A bond that, instead of carrying a coupon, is sold at a discount from its face value, pays no interest during its life, and pays the principal only at maturity.```

[^0]:    > In ecmninit at 60

[^1]:    'DateFormat' - Date format
    'off' (default) | string with value 'off' or string DateFormNum | numeric value for DateFormNum

[^2]:    TimeSpec First
    Returns only the observation that occurs at the first (earliest) time for a specific date.

[^3]:    TimeSpec First
    Returns only the observation that occurs at the first (earliest) time for a specific date.

[^4]:    TimeSpec First
    Returns only the observation that occurs at the first (earliest) time for a specific date.
