If you assign values to this property, then MATLAB sets the associated mode property to 'manual'. When the associated mode property is set to 'auto', MATLAB chooses the minor tick values.

**MinorTickValuesMode — Selection mode for MinorTickValues property**

'auto' (default) | 'manual'

Selection mode for the `MinorTickValues` property, specified as one of these values:

- 'auto' — Automatically select the minor tick values.
- 'manual' — Use manually specified minor tick values. To specify the minor tick values, set the `MinorTickValues` property.

**Font****FontName — Text character style**

'Helvetica' (default) | 'FixedWidth' | system-supported font name

Font name, specified as the name of the font to use or the string 'FixedWidth'. To display and print properly, the font name must be a font that your system supports.

To use a fixed-width font that renders well, use the case-sensitive string 'FixedWidth'. The 'FixedWidth' value relies on the root `FixedWidthFontName` property. Setting the root `FixedWidthFontName` property causes an immediate update of the display to use the new font.

---

**Note:** Setting the `FontName` property for the parent axes sets the `FontName` property for the ruler to the same value. However, setting the ruler property does not set the axes property. To prevent the axes property value from overriding the ruler property value, set the axes value first, and then set the ruler value.

---

Example: `ax.XAxis.FontName = 'Cambria';`

### **FontSize** — Text character size

10 (default) | scalar numeric value

Font size, specified as a scalar numeric value.

---

**Note:** Setting the `FontSize` property for the parent axes sets the `FontSize` property for the ruler to the same value. However, setting the ruler property does not set the axes property. To prevent the axes property value from overriding the ruler property value, set the axes value first, and then set the ruler value.

---

Example: `ax.XAxis.FontSize = 12;`

### **FontWeight** — Thickness of text characters

'normal' (default) | 'bold'

Thickness of the text characters, specified as one of these values:

- 'normal' — Default weight as defined by the particular font
- 'bold' — Thicker character outlines than normal

MATLAB uses the `FontWeight` property to select a font from those available on your system. Not all fonts have a bold font weight. Therefore, specifying a bold font weight still can result in the normal font weight.

---

**Note:** Setting the `FontWeight` property for the parent axes sets the `FontWeight` property for the ruler to the same value. However, setting the ruler property does not set the axes property. To prevent the axes property value from overriding the ruler property value, set the axes value first, and then set the ruler value.

---

Example: `ax.XAxis.FontWeight = 'bold';`

### **FontAngle — Text character slant**

'normal' (default) | 'italic'

Character slant, specified as 'normal' or 'italic'. Not all fonts have both font styles. Therefore, setting the italic font can look the same as the normal font.

---

**Note:** Setting the `FontAngle` property for the parent axes sets the `FontAngle` property for the ruler to the same value. However, setting the ruler property does not set the axes property. To prevent the axes property value from overriding the ruler property value, set the axes value first, and then set the ruler value.

---

Example: `ax.XAxis.FontAngle = 'italic';`

### **FontSmoothing — Text smoothing**

'on' (default) | 'off'

Text smoothing, specified as one of these values:

- 'on' — Apply font smoothing to reduce the jagged appearance of text characters and make the text easier to read. In certain cases, smoothed text blends against the background color and can make the text appear blurry.
- 'off' — Do not use antialiasing. Use this setting if the text seems blurry.

---

**Note:** Setting the `FontSmoothing` property for the parent axes sets the `FontSmoothing` property for the ruler to the same value. However, setting the ruler property does not set the axes property. To prevent the axes property value from overriding the ruler property value, set the axes value first, and then set the ruler value.

---

Example: `ax.XAxis.FontSmoothing = 'off';`

## **Parent/Child**

### **Parent — Parent of numeric ruler**

axes object

Parent of numeric ruler, specified as an axes object. However, ruler objects are not listed as children of the axes.

### **Children — Children of numeric ruler**

empty GraphicsPlaceholder array

The numeric ruler has no children. You cannot set this property.

## **See Also**

Axes Properties

**Introduced in R2015b**

## **nzmax**

Amount of storage allocated for nonzero matrix elements

### **Syntax**

`n = nzmax(S)`

### **Description**

`n = nzmax(S)` returns the amount of storage allocated for nonzero elements.

If <code>S</code> is a sparse matrix...	<code>nzmax(S)</code> is the number of storage locations allocated for the nonzero elements in <code>S</code> .
If <code>S</code> is a full matrix...	<code>nzmax(S) = prod(size(S))</code> .

Often, `nnz(S)` and `nzmax(S)` are the same. But if `S` is created by an operation which produces fill-in matrix elements, such as sparse matrix multiplication or sparse LU factorization, more storage may be allocated than is actually required, and `nzmax(S)` reflects this. Alternatively, `sparse(i, j, s, m, n, nzmax)` or its simpler form, `spalloc(m, n, nzmax)`, can set `nzmax` in anticipation of later fill-in.

## ode15i

Solve fully implicit differential equations, variable order method

### Syntax

```
[T,Y] = ode15i(odefun,tspan,y0,yp0)
[T,Y] = ode15i(odefun,tspan,y0,yp0,options)
[T,Y,TE,YE,IE] = ode15i(odefun,tspan,y0,yp0,options...)
sol = ode15i(odefun,[t0 tfinal],y0,yp0,...)
```

### Arguments

The following table lists the input arguments for `ode15i`.

<code>odefun</code>	A function handle that evaluates the left side of the differential equations, which are of the form $f(t,y,y') = 0$ .
<code>tspan</code>	A vector specifying the interval of integration, $[t_0, t_f]$ . To obtain solutions at specific times (all increasing or all decreasing), use <code>tspan = [t0,t1,...,tf]</code> .
<code>y0, yp0</code>	Vectors of initial conditions for $y$ and $y'$ respectively.
<code>options</code>	Optional integration argument created using the <code>odeset</code> function. See <code>odeset</code> for details.

The following table lists the output arguments for `ode15i`.

<code>T</code>	Column vector of time points
<code>Y</code>	Solution array. Each row in $y$ corresponds to the solution at a time returned in the corresponding row of $t$ .

### Description

`[T,Y] = ode15i(odefun,tspan,y0,yp0)` with `tspan = [t0 tf]` integrates the system of differential equations  $f(t,y,y') = 0$  from time  $t_0$  to  $t_f$  with initial conditions  $y_0$  and  $yp_0$ . `odefun` is a function handle. Function `ode15i` solves ODEs and DAEs of index 1. The initial conditions must be consistent, meaning that  $f(t_0,y_0,yp_0) = 0$ . You

can use the function `decic` to compute consistent initial conditions close to guessed values. Function `odefun(t,y,yp)`, for a scalar `t` and column vectors `y` and `yp`, must return a column vector corresponding to  $f(t,y,y')$ . Each row in the solution array `Y` corresponds to a time returned in the column vector `T`. To obtain solutions at specific times `t0,t1,...,tf` (all increasing or all decreasing), use `tspan = [t0,t1,...,tf]`.

“Parameterizing Functions” explains how to provide additional parameters to the function `odefun`, if necessary.

`[T,Y] = ode15i(odefun,tspan,y0,yp0,options)` solves as above with default integration parameters replaced by property values specified in `options`, an argument created with the `odeset` function. Commonly used options include a scalar relative error tolerance `RelTol` ( $1e-3$  by default) and a vector of absolute error tolerances `AbsTol` (all components  $1e-6$  by default). See `odeset` for details.

`[T,Y,TE,YE,IE] = ode15i(odefun,tspan,y0,yp0,options...)` with the 'Events' property in `options` set to a function `events`, solves as above while also finding where functions of  $(t,y,y')$ , called event functions, are zero. The function `events` is of the form `[value,isterminal,direction] = events(t,y,yp)` and includes the necessary event functions. Code the function `events` so that the `i`th element of each output vector corresponds to the `i`th event. For the `i`th event function in `events`:

- `value(i)` is the value of the function.
- `isterminal(i) = 1` if the integration is to terminate at a zero of this event function and 0 otherwise.
- `direction(i) = 0` if all zeros are to be computed (the default), `+1` if only the zeros where the event function increases, and `-1` if only the zeros where the event function decreases.

Output `TE` is a column vector of times at which events occur. Rows of `YE` are the corresponding solutions, and indices in vector `IE` specify which event occurred. See “Integrator Options” in the MATLAB Mathematics documentation for more information.

`sol = ode15i(odefun,[t0 tfinal],y0,yp0,...)` returns a structure that can be used with `deval` to evaluate the solution at any point between `t0` and `tfinal`. The structure `sol` always includes these fields:

<code>sol.x</code>	Steps chosen by the solver. If you specify the <code>Events</code> option and a terminal event is detected, <code>sol.x(end)</code> contains the end of the step at which the event occurred.
<code>sol.y</code>	Each column <code>sol.y(:,i)</code> contains the solution at <code>sol.x(i)</code> .

If you specify the **Events** option and events are detected, **sol** also includes these fields:

<b>sol.xe</b>	Points at which events, if any, occurred. <b>sol.xe(end)</b> contains the exact point of a terminal event, if any.
<b>sol.ye</b>	Solutions that correspond to events in <b>sol.xe</b> .
<b>sol.ie</b>	Indices into the vector returned by the function specified in the <b>Events</b> option. The values indicate which event the solver detected.

## Options

**ode15i** accepts the following parameters in **options**. For more information, see **odeset** and **Changing ODE Integration Properties** in the MATLAB Mathematics documentation.

Error control	<b>RelTol, AbsTol, NormControl</b>
Solver output	<b>OutputFcn, OutputSel, Refine, Stats</b>
Event location	<b>Events</b>
Step size	<b>MaxStep, InitialStep</b>
Jacobian matrix	<b>Jacobian, JPattern, Vectorized</b>

## Solver Output

If you specify an output function as the value of the **OutputFcn** property, the solver calls it with the computed solution after each time step. Four output functions are provided: **odeplot**, **odephas2**, **odephas3**, **odeprint**. When you call the solver with no output arguments, it calls the default **odeplot** to plot the solution as it is computed. **odephas2** and **odephas3** produce two- and three-dimensional phase plane plots, respectively. **odeprint** displays the solution components on the screen. By default, the ODE solver passes all components of the solution to the output function. You can pass only specific components by providing a vector of indices as the value of the **OutputSel** property. For example, if you call the solver with no output arguments and set the value of **OutputSel** to **[1,3]**, the solver plots solution components 1 and 3 as they are computed.

## Jacobian Matrices

The Jacobian matrices  $\partial f/\partial y$  and  $\partial f/\partial y'$  are critical to reliability and efficiency. You can provide these matrices as one of the following:

- Function of the form  $[dfdy, dfdyp] = FJAC(t, y, yp)$  that computes the Jacobian matrices. If FJAC returns an empty matrix  $[\ ]$  for either  $dfdy$  or  $dfdyp$ , then `ode15i` approximates that matrix by finite differences.
- Cell array of two constant matrices  $\{dfdy, dfdyp\}$ , either of which could be empty.

Use `odeset` to set the `Jacobian` option to the function or cell array. If you do not set the `Jacobian` option, `ode15i` approximates both Jacobian matrices by finite differences.

For `ode15i`, `Vectorized` is a two-element cell array. Set the first element to 'on' if `odefun(t, [y1, y2, ...], yp)` returns `[odefun(t, y1, yp), odefun(t, y2, yp), ...]`. Set the second element to 'on' if `odefun(t, y, [yp1, yp2, ...])` returns `[odefun(t, y, yp1), odefun(t, y, yp2), ...]`. The default value of `Vectorized` is `{'off', 'off'}`.

For `ode15i`, `JPattern` is also a two-element sparse matrix cell array. If  $\partial f/\partial y$  or  $\partial f/\partial y'$  is a sparse matrix, set `JPattern` to the sparsity patterns, `{SPDY, SPDYP}`. A sparsity pattern of  $\partial f/\partial y$  is a sparse matrix `SPDY` with `SPDY(i, j) = 1` if component `i` of  $f(t, y, yp)$  depends on component `j` of `y`, and 0 otherwise. Use `SPDY = []` to indicate that  $\partial f/\partial y$  is a full matrix. Similarly for  $\partial f/\partial y'$  and `SPDYP`. The default value of `JPattern` is `{[], []}`.

## Examples

### Solve Weissinger Implicit ODE

This example uses a helper function, `decic`, to hold fixed the initial value for  $y(t_0)$  and compute a consistent initial value for  $y'(t_0)$  for the Weissinger implicit ODE. The Weissinger function evaluates the residual of the implicit ODE.

```
t0 = 1;
y0 = sqrt(3/2);
yp0 = 0;
[y0, yp0] = decic(@weissinger, t0, y0, 1, yp0, 0);
```

Use `ode15i` to solve the ODE, and then plot the numerical solution, `y`, against the analytical solution, `ytrue`.

```
[t, y] = ode15i(@weissinger, [1 10], y0, yp0);
ytrue = sqrt(t.^2 + 0.5);
plot(t, y, t, ytrue, 'o')
```

## Other Examples

The files, `ihb1dae.m` and `iburgersode.m`, are examples of implicit ODEs.

## ode15s

Solve stiff differential equations and DAEs; variable order method

### Syntax

```
[T,Y] = solver(odefun,tspan,y0)
[T,Y] = solver(odefun,tspan,y0,options)
[T,Y,TE,YE,IE] = solver(odefun,tspan,y0,options)
sol = solver(odefun,[t0 tf],y0...)
```

This page contains an overview of the solver functions: `ode23`, `ode45`, `ode113`, `ode15s`, `ode23s`, `ode23t`, and `ode23tb`. You can call any of these solvers by substituting the placeholder, `solver`, with any of the function names.

### Arguments

The following table describes the input arguments to the solvers.

<code>odefun</code>	A function handle that evaluates the right side of the differential equations. All solvers solve systems of equations in the form $y' = f(t,y)$ or problems that involve a mass matrix, $M(t,y)y' = f(t,y)$ . The <code>ode23s</code> solver can solve only equations with constant mass matrices. <code>ode15s</code> and <code>ode23t</code> can solve problems with a mass matrix that is singular, i.e., differential-algebraic equations (DAEs).
<code>tspan</code>	A vector specifying the interval of integration, <code>[t0,tf]</code> . The solver imposes the initial conditions at <code>tspan(1)</code> , and integrates from <code>tspan(1)</code> to <code>tspan(end)</code> . To obtain solutions at specific times (all increasing or all decreasing), use <code>tspan = [t0,t1,...,tf]</code> .  For <code>tspan</code> vectors with two elements <code>[t0 tf]</code> , the solver returns the solution evaluated at every integration step. For <code>tspan</code> vectors with more than two elements, the solver returns solutions evaluated at the given time points. The time values must be in order, either increasing or decreasing.

	<p>Specifying <code>tspan</code> with more than two elements does not affect the internal time steps that the solver uses to traverse the interval from <code>tspan(1)</code> to <code>tspan(end)</code>. All solvers in the ODE suite obtain output values by means of continuous extensions of the basic formulas. Although a solver does not necessarily step precisely to a time point specified in <code>tspan</code>, the solutions produced at the specified time points are of the same order of accuracy as the solutions computed at the internal time points.</p> <p>Specifying <code>tspan</code> with more than two elements has little effect on the efficiency of computation, but for large systems, affects memory management.</p>
<code>y0</code>	A vector of initial conditions.
<code>options</code>	<p>Structure of optional parameters that change the default integration properties. This is the fourth input argument.</p> <p><code>[t,y] = solver(odefun,tspan,y0,options)</code></p> <p>You can create options using the <code>odeset</code> function. See <code>odeset</code> for details.</p>

The following table lists the output arguments for the solvers.

<code>T</code>	Column vector of time points.
<code>Y</code>	Solution array. Each row in <code>Y</code> corresponds to the solution at a time returned in the corresponding row of <code>T</code> .
<code>TE</code>	The time at which an event occurs.
<code>YE</code>	The solution at the time of the event.
<code>IE</code>	The index <code>i</code> of the event function that vanishes.
<code>sol</code>	Structure to evaluate the solution.

## Description

`[T,Y] = solver(odefun,tspan,y0)` with `tspan = [t0 tf]` integrates the system of differential equations  $y' = f(t,y)$  from time `t0` to `tf` with initial conditions `y0`. The first

input argument, `odefun`, is a function handle. The function,  $f = \text{odefun}(t, y)$ , for a scalar  $t$  and a column vector  $y$ , must return a column vector  $f$  corresponding to  $f(t, y)$ . Each row in the solution array  $Y$  corresponds to a time returned in column vector  $T$ . To obtain solutions at the specific times  $t_0, t_1, \dots, t_f$  (all increasing or all decreasing), use `tspan = [t0, t1, ..., tf]`.

“Parameterizing Functions” explains how to provide additional parameters to the function `fun`, if necessary.

`[T, Y] = solver(odefun, tspan, y0, options)` solves as above with default integration parameters replaced by property values specified in `options`, an argument created with the `odeset` function. Commonly used properties include a scalar relative error tolerance `RelTol` ( $1e-3$  by default) and a vector of absolute error tolerances `Abstol` (all components are  $1e-6$  by default). If certain components of the solution must be nonnegative, use the `odeset` function to set the `NonNegative` property to the indices of these components. See `odeset` for details.

`[T, Y, TE, YE, IE] = solver(odefun, tspan, y0, options)` solves as above while also finding where functions of  $(t, y)$ , called event functions, are zero. For each event function, you specify whether the integration is to terminate at a zero and whether the direction of the zero crossing matters. Do this by setting the 'Events' property to a function, e.g., `events` or `@events`, and creating a function `[value, isterminal, direction] = events(t, y)`. For the  $i$ th event function in `events`,

- `value(i)` is the value of the function.
- `isterminal(i) = 1`, if the integration is to terminate at a zero of this event function and 0 otherwise.
- `direction(i) = 0` if all zeros are to be computed (the default), +1 if only the zeros where the event function increases, and -1 if only the zeros where the event function decreases.

Corresponding entries in `TE`, `YE`, and `IE` return, respectively, the time at which an event occurs, the solution at the time of the event, and the index  $i$  of the event function that vanishes.

`sol = solver(odefun, [t0 tf], y0...)` returns a structure that you can use with `deval` to evaluate the solution at any point on the interval `[t0, tf]`. You must pass `odefun` as a function handle. The structure `sol` always includes these fields:

<code>sol.x</code>	Steps chosen by the solver.
--------------------	-----------------------------

<code>sol.y</code>	Each column <code>sol.y(:,i)</code> contains the solution at <code>sol.x(i)</code> .
<code>sol.solver</code>	Solver name.

If you specify the `Events` option and events are detected, `sol` also includes these fields:

<code>sol.xe</code>	Points at which events, if any, occurred. <code>sol.xe(end)</code> contains the exact point of a terminal event, if any.
<code>sol.ye</code>	Solutions that correspond to events in <code>sol.xe</code> .
<code>sol.ie</code>	Indices into the vector returned by the function specified in the <code>Events</code> option. The values indicate which event the solver detected.

If you specify an output function as the value of the `OutputFcn` property, the solver calls it with the computed solution after each time step. Four output functions are provided: `odeplot`, `odephas2`, `odephas3`, `odeprint`. When you call the solver with no output arguments, it calls the default `odeplot` to plot the solution as it is computed. `odephas2` and `odephas3` produce two- and three-dimensional phase plane plots, respectively. `odeprint` displays the solution components on the screen. By default, the ODE solver passes all components of the solution to the output function. You can pass only specific components by providing a vector of indices as the value of the `OutputSel` property. For example, if you call the solver with no output arguments and set the value of `OutputSel` to `[1,3]`, the solver plots solution components 1 and 3 as they are computed.

For the stiff solvers `ode15s`, `ode23s`, `ode23t`, and `ode23tb`, the Jacobian matrix  $\partial f/\partial y$  is critical to reliability and efficiency. Use `odeset` to set `Jacobian` to `@FJAC` if `FJAC(T,Y)` returns the Jacobian  $\partial f/\partial y$  or to the matrix  $\partial f/\partial y$  if the Jacobian is constant. If the `Jacobian` property is not set (the default),  $\partial f/\partial y$  is approximated by finite differences. Set the `Vectorized` property 'on' if the ODE function is coded so that `odefun(T,[Y1,Y2 ...])` returns `[odefun(T,Y1),odefun(T,Y2),...]`. If  $\partial f/\partial y$  is a sparse matrix, set the `JPattern` property to the sparsity pattern of  $\partial f/\partial y$ , i.e., a sparse matrix `S` with `S(i,j) = 1` if the *i*th component of  $f(t,y)$  depends on the *j*th component of  $y$ , and 0 otherwise.

The solvers of the ODE suite can solve problems of the form  $M(t,y)y' = f(t,y)$ , with time- and state-dependent mass matrix  $M$ . (The `ode23s` solver can solve only equations with constant mass matrices.) If a problem has a mass matrix, create a function `M = MASS(t,y)` that returns the value of the mass matrix, and use `odeset` to set the `Mass` property to `@MASS`. If the mass matrix is constant, the matrix should be used as the value of the `Mass` property. Problems with state-dependent mass matrices are more difficult:

- If the mass matrix does not depend on the state variable  $y$  and the function `MASS` is to be called with one input argument,  $t$ , set the `MStateDependence` property to 'none'.
- If the mass matrix depends weakly on  $y$ , set `MStateDependence` to 'weak' (the default); otherwise, set it to 'strong'. In either case, the function `MASS` is called with the two arguments  $(t,y)$ .

If there are many differential equations, it is important to exploit sparsity:

- Return a sparse  $M(t,y)$ .
- Supply the sparsity pattern of  $\partial f/\partial y$  using the `JPattern` property or a sparse  $\partial f/\partial y$  using the `Jacobian` property.
- For strongly state-dependent  $M(t,y)$ , set `MvPattern` to a sparse matrix  $S$  with  $S(i,j) = 1$  if for any  $k$ , the  $(i,k)$  component of  $M(t,y)$  depends on component  $j$  of  $y$ , and 0 otherwise.

If the mass matrix  $M$  is singular, then  $M(t,y)y' = f(t,y)$  is a system of differential algebraic equations. DAEs have solutions only when  $y_0$  is consistent, that is, if there is a vector  $yp_0$  such that  $M(t_0,y_0)yp_0 = f(t_0,y_0)$ . The `ode15s` and `ode23t` solvers can solve DAEs of index 1 provided that  $y_0$  is sufficiently close to being consistent. If there is a mass matrix, you can use `odeset` to set the `MassSingular` property to 'yes', 'no', or 'maybe'. The default value of 'maybe' causes the solver to test whether the problem is a DAE. You can provide  $yp_0$  as the value of the `InitialSlope` property. The default is the zero vector. If a problem is a DAE, and  $y_0$  and  $yp_0$  are not consistent, the solver treats them as guesses, attempts to compute consistent values that are close to the guesses, and continues to solve the problem. When solving DAEs, it is very advantageous to formulate the problem so that  $M$  is a diagonal matrix (a semi-explicit DAE).

Solver	Problem Type	Order of Accuracy	When to Use
ode45	Nonstiff	Medium	Most of the time. This should be the first solver you try.
ode23	Nonstiff	Low	For problems with crude error tolerances or for solving moderately stiff problems.
ode113	Nonstiff	Low to high	For problems with stringent error tolerances or for solving computationally intensive problems.

Solver	Problem Type	Order of Accuracy	When to Use
ode15s	Stiff	Low to medium	If ode45 is slow because the problem is stiff.
ode23s	Stiff	Low	If using crude error tolerances to solve stiff systems and the mass matrix is constant.
ode23t	Moderately Stiff	Low	For moderately stiff problems if you need a solution without numerical damping.
ode23tb	Stiff	Low	If using crude error tolerances to solve stiff systems.

The algorithms used in the ODE solvers vary according to order of accuracy [6] and the type of systems (stiff or nonstiff) they are designed to solve. See “Algorithms” on page 1-6089 for more details.

## Options

Different solvers accept different parameters in the options list. For more information, see `odeset` and “Integrator Options” in the MATLAB Mathematics documentation.

Parameters	ode45	ode23	ode113	ode15s	ode23s	ode23t	ode23tb
RelTol, AbsTol, NormControl	√	√	√	√	√	√	√
OutputFcn, OutputSel, Refine, Stats	√	√	√	√	√	√	√
NonNegative	√	√	√	√ *	—	√ *	√ *
Events	√	√	√	√	√	√	√
MaxStep, InitialStep	√	√	√	√	√	√	√

Parameters	ode45	ode23	ode113	ode15s	ode23s	ode23t	ode23tb
Jacobian, JPattern, Vectorized	—	—	—	√	√	√	√
Mass	√	√	√	√	√	√	√
MStateDependence	√	√	√	√	—	√	√
MvPattern	—	—	—	√	—	√	√
MassSingular	—	—	—	√	—	√	—
InitialSlope	—	—	—	√	—	√	—
MaxOrder, BDF	—	—	—	√	—	—	—

---

**Note** You can use the `NonNegative` parameter with `ode15s`, `ode23t`, and `ode23tb` only for those problems for which there is no mass matrix.

---

## Examples

### Example 1

An example of a nonstiff system is the system of equations describing the motion of a rigid body without external forces.

$$\begin{aligned}
 y_1' &= y_2 y_3 & y_1(0) &= 0 \\
 y_2' &= -y_1 y_3 & y_2(0) &= 1 \\
 y_3' &= -0.51 y_1 y_2 & y_3(0) &= 1
 \end{aligned}$$

To simulate this system, create a function `rigid` containing the equations

```
function dy = rigid(t,y)
dy = zeros(3,1); % a column vector
dy(1) = y(2) * y(3);
dy(2) = -y(1) * y(3);
dy(3) = -0.51 * y(1) * y(2);
```

In this example we change the error tolerances using the `odeset` command and solve on a time interval `[0 12]` with an initial condition vector `[0 1 1]` at time 0.

```
options = odeset('RelTol',1e-4,'AbsTol',[1e-4 1e-4 1e-5]);
[T,Y] = ode45(@rigid,[0 12],[0 1 1],options);
```

Plotting the columns of the returned array Y versus T shows the solution

```
plot(T,Y(:,1),'-',T,Y(:,2),'-.',T,Y(:,3),'-.')
```

## Example 2

An example of a stiff system is provided by the van der Pol equations in relaxation oscillation. The limit cycle has portions where the solution components change slowly and the problem is quite stiff, alternating with regions of very sharp change where it is not stiff.

$$\begin{aligned}y_1' &= y_2 & y_1(0) &= 2 \\y_2' &= 1000(1 - y_1^2)y_2 - y_1 & y_2(0) &= 0\end{aligned}$$

To simulate this system, create a function `vdp1000` containing the equations

```
function dy = vdp1000(t,y)
dy = zeros(2,1); % a column vector
dy(1) = y(2);
dy(2) = 1000*(1 - y(1)^2)*y(2) - y(1);
```

For this problem, we will use the default relative and absolute tolerances ( $1e-3$  and  $1e-6$ , respectively) and solve on a time interval of `[0 3000]` with initial condition vector `[2 0]` at time 0.

```
[T,Y] = ode15s(@vdp1000,[0 3000],[2 0]);
```

Plotting the first column of the returned matrix `Y` versus `T` shows the solution

```
plot(T,Y(:,1),'-o')
```

### Example 3

This example solves an ordinary differential equation with time-dependent terms.

Consider the following ODE, with time-dependent parameters defined only through the set of data points given in two vectors:

$$y'(t) + f(t)y(t) = g(t)$$

The initial condition is  $y(1) = 1$ , where the function  $f(t)$  is defined by the  $n$ -by-1 vector  $f$  evaluated at times  $ft$ , and the function  $g(t)$  is defined by the  $m$ -by-1 vector  $g$  evaluated at times  $gt$ .

First, define the time-dependent parameters  $f(t)$  and  $g(t)$  as the following:

```
ft = linspace(0,5,25); % Generate t for f
f = ft.^2 - ft - 3; % Generate f(t)
gt = linspace(1,6,25); % Generate t for g
g = 3*sin(gt-0.25); % Generate g(t)
```

Write a function to interpolate the data sets specified above to obtain the value of the time-dependent terms at the specified time:

```
function dydt = myode(t,y,ft,f,gt,g)
f = interp1(ft,f,t); % Interpolate the data set (ft,f) at time t
g = interp1(gt,g,t); % Interpolate the data set (gt,g) at time t
dydt = -f.*y + g; % Evaluate ODE at time t
```

Call the derivative function `myode.m` within the MATLAB `ode45` function specifying time as the first input argument :

```
Tspan = [1 5]; % Solve from t=1 to t=5
IC = 1; % y(t=1) = 1
[T Y] = ode45(@(t,y) myode(t,y,ft,f,gt,g),Tspan,IC); % Solve ODE
Plot the solution y (t) as a function of time:
```

```
plot(T, Y);
title('Plot of y as a function of time');
xlabel('Time');
ylabel('Y(t)');
```

## More About

### Algorithms

`ode45` is based on an explicit Runge-Kutta (4,5) formula, the Dormand-Prince pair. It is a *one-step* solver – in computing  $y(t_n)$ , it needs only the solution at the immediately preceding time point,  $y(t_{n-1})$ . In general, `ode45` is the best function to apply as a *first try* for most problems. [3]

`ode23` is an implementation of an explicit Runge-Kutta (2,3) pair of Bogacki and Shampine. It may be more efficient than `ode45` at crude tolerances and in the presence of moderate stiffness. Like `ode45`, `ode23` is a one-step solver. [2]

**ode113** is a variable order Adams-Bashforth-Moulton PECE solver. It may be more efficient than **ode45** at stringent tolerances and when the ODE file function is particularly expensive to evaluate. **ode113** is a *multistep* solver — it normally needs the solutions at several preceding time points to compute the current solution. [7]

The above algorithms are intended to solve nonstiff systems. If they appear to be unduly slow, try using one of the stiff solvers below.

**ode15s** is a variable order solver based on the numerical differentiation formulas (NDFs). Optionally, it uses the backward differentiation formulas (BDFs, also known as Gear's method) that are usually less efficient. Like **ode113**, **ode15s** is a multistep solver. Try **ode15s** when **ode45** fails, or is very inefficient, and you suspect that the problem is stiff, or when solving a differential-algebraic problem. [9], [10]

**ode23s** is based on a modified Rosenbrock formula of order 2. Because it is a one-step solver, it may be more efficient than **ode15s** at crude tolerances. It can solve some kinds of stiff problems for which **ode15s** is not effective. [9]

**ode23t** is an implementation of the trapezoidal rule using a “free” interpolant. Use this solver if the problem is only moderately stiff and you need a solution without numerical damping. **ode23t** can solve DAEs. [10]

**ode23tb** is an implementation of TR-BDF2, an implicit Runge-Kutta formula with a first stage that is a trapezoidal rule step and a second stage that is a backward differentiation formula of order two. By construction, the same iteration matrix is used in evaluating both stages. Like **ode23s**, this solver may be more efficient than **ode15s** at crude tolerances. [8], [1]

## ode23

Solve nonstiff differential equations; low order method

### Syntax

```
[T,Y] = solver(odefun,tspan,y0)
[T,Y] = solver(odefun,tspan,y0,options)
[T,Y,TE,YE,IE] = solver(odefun,tspan,y0,options)
sol = solver(odefun,[t0 tf],y0...)
```

This page contains an overview of the solver functions: `ode23`, `ode45`, `ode113`, `ode15s`, `ode23s`, `ode23t`, and `ode23tb`. You can call any of these solvers by substituting the placeholder, `solver`, with any of the function names.

### Arguments

The following table describes the input arguments to the solvers.

<code>odefun</code>	A function handle that evaluates the right side of the differential equations. All solvers solve systems of equations in the form $y' = f(t,y)$ or problems that involve a mass matrix, $M(t,y)y' = f(t,y)$ . The <code>ode23s</code> solver can solve only equations with constant mass matrices. <code>ode15s</code> and <code>ode23t</code> can solve problems with a mass matrix that is singular, i.e., differential-algebraic equations (DAEs).
<code>tspan</code>	A vector specifying the interval of integration, <code>[t0,tf]</code> . The solver imposes the initial conditions at <code>tspan(1)</code> , and integrates from <code>tspan(1)</code> to <code>tspan(end)</code> . To obtain solutions at specific times (all increasing or all decreasing), use <code>tspan = [t0,t1,...,tf]</code> .  For <code>tspan</code> vectors with two elements <code>[t0 tf]</code> , the solver returns the solution evaluated at every integration step. For <code>tspan</code> vectors with more than two elements, the solver returns solutions evaluated at the given time points. The time values must be in order, either increasing or decreasing.

	<p>Specifying <code>tspan</code> with more than two elements does not affect the internal time steps that the solver uses to traverse the interval from <code>tspan(1)</code> to <code>tspan(end)</code>. All solvers in the ODE suite obtain output values by means of continuous extensions of the basic formulas. Although a solver does not necessarily step precisely to a time point specified in <code>tspan</code>, the solutions produced at the specified time points are of the same order of accuracy as the solutions computed at the internal time points.</p> <p>Specifying <code>tspan</code> with more than two elements has little effect on the efficiency of computation, but for large systems, affects memory management.</p>
<code>y0</code>	A vector of initial conditions.
<code>options</code>	<p>Structure of optional parameters that change the default integration properties. This is the fourth input argument.</p> <p><code>[t,y] = solver(odefun,tspan,y0,options)</code></p> <p>You can create options using the <code>odeset</code> function. See <code>odeset</code> for details.</p>

The following table lists the output arguments for the solvers.

<code>T</code>	Column vector of time points.
<code>Y</code>	Solution array. Each row in <code>Y</code> corresponds to the solution at a time returned in the corresponding row of <code>T</code> .
<code>TE</code>	The time at which an event occurs.
<code>YE</code>	The solution at the time of the event.
<code>IE</code>	The index <code>i</code> of the event function that vanishes.
<code>sol</code>	Structure to evaluate the solution.

## Description

`[T,Y] = solver(odefun,tspan,y0)` with `tspan = [t0 tf]` integrates the system of differential equations  $y' = f(t,y)$  from time `t0` to `tf` with initial conditions `y0`. The first

input argument, `odefun`, is a function handle. The function,  $f = \text{odefun}(t, y)$ , for a scalar  $t$  and a column vector  $y$ , must return a column vector  $f$  corresponding to  $f(t, y)$ . Each row in the solution array  $Y$  corresponds to a time returned in column vector  $T$ . To obtain solutions at the specific times  $t_0, t_1, \dots, t_f$  (all increasing or all decreasing), use `tspan = [t0, t1, ..., tf]`.

“Parameterizing Functions” explains how to provide additional parameters to the function `fun`, if necessary.

`[T, Y] = solver(odefun, tspan, y0, options)` solves as above with default integration parameters replaced by property values specified in `options`, an argument created with the `odeset` function. Commonly used properties include a scalar relative error tolerance `RelTol` ( $1e-3$  by default) and a vector of absolute error tolerances `Abstol` (all components are  $1e-6$  by default). If certain components of the solution must be nonnegative, use the `odeset` function to set the `NonNegative` property to the indices of these components. See `odeset` for details.

`[T, Y, TE, YE, IE] = solver(odefun, tspan, y0, options)` solves as above while also finding where functions of  $(t, y)$ , called event functions, are zero. For each event function, you specify whether the integration is to terminate at a zero and whether the direction of the zero crossing matters. Do this by setting the 'Events' property to a function, e.g., `events` or `@events`, and creating a function `[value, isterminal, direction] = events(t, y)`. For the  $i$ th event function in `events`,

- `value(i)` is the value of the function.
- `isterminal(i) = 1`, if the integration is to terminate at a zero of this event function and 0 otherwise.
- `direction(i) = 0` if all zeros are to be computed (the default), +1 if only the zeros where the event function increases, and -1 if only the zeros where the event function decreases.

Corresponding entries in `TE`, `YE`, and `IE` return, respectively, the time at which an event occurs, the solution at the time of the event, and the index  $i$  of the event function that vanishes.

`sol = solver(odefun, [t0 tf], y0...)` returns a structure that you can use with `deval` to evaluate the solution at any point on the interval `[t0, tf]`. You must pass `odefun` as a function handle. The structure `sol` always includes these fields:

<code>sol.x</code>	Steps chosen by the solver.
--------------------	-----------------------------

<code>sol.y</code>	Each column <code>sol.y(:,i)</code> contains the solution at <code>sol.x(i)</code> .
<code>sol.solver</code>	Solver name.

If you specify the `Events` option and events are detected, `sol` also includes these fields:

<code>sol.xe</code>	Points at which events, if any, occurred. <code>sol.xe(end)</code> contains the exact point of a terminal event, if any.
<code>sol.ye</code>	Solutions that correspond to events in <code>sol.xe</code> .
<code>sol.ie</code>	Indices into the vector returned by the function specified in the <code>Events</code> option. The values indicate which event the solver detected.

If you specify an output function as the value of the `OutputFcn` property, the solver calls it with the computed solution after each time step. Four output functions are provided: `odeplot`, `odephas2`, `odephas3`, `odeprint`. When you call the solver with no output arguments, it calls the default `odeplot` to plot the solution as it is computed. `odephas2` and `odephas3` produce two- and three-dimensional phase plane plots, respectively. `odeprint` displays the solution components on the screen. By default, the ODE solver passes all components of the solution to the output function. You can pass only specific components by providing a vector of indices as the value of the `OutputSel` property. For example, if you call the solver with no output arguments and set the value of `OutputSel` to `[1,3]`, the solver plots solution components 1 and 3 as they are computed.

For the stiff solvers `ode15s`, `ode23s`, `ode23t`, and `ode23tb`, the Jacobian matrix  $\partial f/\partial y$  is critical to reliability and efficiency. Use `odeset` to set `Jacobian` to `@FJAC` if `FJAC(T,Y)` returns the Jacobian  $\partial f/\partial y$  or to the matrix  $\partial f/\partial y$  if the Jacobian is constant. If the `Jacobian` property is not set (the default),  $\partial f/\partial y$  is approximated by finite differences. Set the `Vectorized` property 'on' if the ODE function is coded so that `odefun(T,[Y1,Y2 ...])` returns `[odefun(T,Y1),odefun(T,Y2),...]`. If  $\partial f/\partial y$  is a sparse matrix, set the `JPattern` property to the sparsity pattern of  $\partial f/\partial y$ , i.e., a sparse matrix `S` with `S(i,j) = 1` if the *i*th component of  $f(t,y)$  depends on the *j*th component of  $y$ , and 0 otherwise.

The solvers of the ODE suite can solve problems of the form  $M(t,y)y' = f(t,y)$ , with time- and state-dependent mass matrix  $M$ . (The `ode23s` solver can solve only equations with constant mass matrices.) If a problem has a mass matrix, create a function `M = MASS(t,y)` that returns the value of the mass matrix, and use `odeset` to set the `Mass` property to `@MASS`. If the mass matrix is constant, the matrix should be used as the value of the `Mass` property. Problems with state-dependent mass matrices are more difficult:

- If the mass matrix does not depend on the state variable  $y$  and the function `MASS` is to be called with one input argument,  $t$ , set the `MStateDependence` property to 'none'.
- If the mass matrix depends weakly on  $y$ , set `MStateDependence` to 'weak' (the default); otherwise, set it to 'strong'. In either case, the function `MASS` is called with the two arguments  $(t,y)$ .

If there are many differential equations, it is important to exploit sparsity:

- Return a sparse  $M(t,y)$ .
- Supply the sparsity pattern of  $\partial f/\partial y$  using the `JPattern` property or a sparse  $\partial f/\partial y$  using the `Jacobian` property.
- For strongly state-dependent  $M(t,y)$ , set `MvPattern` to a sparse matrix  $S$  with  $S(i,j) = 1$  if for any  $k$ , the  $(i,k)$  component of  $M(t,y)$  depends on component  $j$  of  $y$ , and  $0$  otherwise.

If the mass matrix  $M$  is singular, then  $M(t,y)y' = f(t,y)$  is a system of differential algebraic equations. DAEs have solutions only when  $y_0$  is consistent, that is, if there is a vector  $yp_0$  such that  $M(t_0,y_0)yp_0 = f(t_0,y_0)$ . The `ode15s` and `ode23t` solvers can solve DAEs of index 1 provided that  $y_0$  is sufficiently close to being consistent. If there is a mass matrix, you can use `odeset` to set the `MassSingular` property to 'yes', 'no', or 'maybe'. The default value of 'maybe' causes the solver to test whether the problem is a DAE. You can provide  $yp_0$  as the value of the `InitialSlope` property. The default is the zero vector. If a problem is a DAE, and  $y_0$  and  $yp_0$  are not consistent, the solver treats them as guesses, attempts to compute consistent values that are close to the guesses, and continues to solve the problem. When solving DAEs, it is very advantageous to formulate the problem so that  $M$  is a diagonal matrix (a semi-explicit DAE).

Solver	Problem Type	Order of Accuracy	When to Use
ode45	Nonstiff	Medium	Most of the time. This should be the first solver you try.
ode23	Nonstiff	Low	For problems with crude error tolerances or for solving moderately stiff problems.
ode113	Nonstiff	Low to high	For problems with stringent error tolerances or for solving computationally intensive problems.

Solver	Problem Type	Order of Accuracy	When to Use
ode15s	Stiff	Low to medium	If ode45 is slow because the problem is stiff.
ode23s	Stiff	Low	If using crude error tolerances to solve stiff systems and the mass matrix is constant.
ode23t	Moderately Stiff	Low	For moderately stiff problems if you need a solution without numerical damping.
ode23tb	Stiff	Low	If using crude error tolerances to solve stiff systems.

The algorithms used in the ODE solvers vary according to order of accuracy [6] and the type of systems (stiff or nonstiff) they are designed to solve. See “Algorithms” on page 1-6103 for more details.

## Options

Different solvers accept different parameters in the options list. For more information, see `odeset` and “Integrator Options” in the MATLAB Mathematics documentation.

Parameters	ode45	ode23	ode113	ode15s	ode23s	ode23t	ode23tb
RelTol, AbsTol, NormControl	√	√	√	√	√	√	√
OutputFcn, OutputSel, Refine, Stats	√	√	√	√	√	√	√
NonNegative	√	√	√	√ *	—	√ *	√ *
Events	√	√	√	√	√	√	√
MaxStep, InitialStep	√	√	√	√	√	√	√

Parameters	ode45	ode23	ode113	ode15s	ode23s	ode23t	ode23tb
Jacobian, JPattern, Vectorized	—	—	—	√	√	√	√
Mass	√	√	√	√	√	√	√
MStateDependence	√	√	√	√	—	√	√
MvPattern	—	—	—	√	—	√	√
MassSingular	—	—	—	√	—	√	—
InitialSlope	—	—	—	√	—	√	—
MaxOrder, BDF	—	—	—	√	—	—	—

---

**Note** You can use the `NonNegative` parameter with `ode15s`, `ode23t`, and `ode23tb` only for those problems for which there is no mass matrix.

---

## Examples

### Example 1

An example of a nonstiff system is the system of equations describing the motion of a rigid body without external forces.

$$\begin{aligned}
 y_1' &= y_2 y_3 & y_1(0) &= 0 \\
 y_2' &= -y_1 y_3 & y_2(0) &= 1 \\
 y_3' &= -0.51 y_1 y_2 & y_3(0) &= 1
 \end{aligned}$$

To simulate this system, create a function `rigid` containing the equations

```
function dy = rigid(t,y)
dy = zeros(3,1); % a column vector
dy(1) = y(2) * y(3);
dy(2) = -y(1) * y(3);
dy(3) = -0.51 * y(1) * y(2);
```

In this example we change the error tolerances using the `odeset` command and solve on a time interval `[0 12]` with an initial condition vector `[0 1 1]` at time `0`.

```
options = odeset('RelTol',1e-4,'AbsTol',[1e-4 1e-4 1e-5]);
[T,Y] = ode45(@rigid,[0 12],[0 1 1],options);
```

Plotting the columns of the returned array Y versus T shows the solution

```
plot(T,Y(:,1),'-',T,Y(:,2),'-.',T,Y(:,3),'.'
```

## Example 2

An example of a stiff system is provided by the van der Pol equations in relaxation oscillation. The limit cycle has portions where the solution components change slowly and the problem is quite stiff, alternating with regions of very sharp change where it is not stiff.

$$\begin{aligned}y_1' &= y_2 & y_1(0) &= 2 \\y_2' &= 1000(1 - y_1^2)y_2 - y_1 & y_2(0) &= 0\end{aligned}$$

To simulate this system, create a function `vdp1000` containing the equations

```
function dy = vdp1000(t,y)
dy = zeros(2,1); % a column vector
dy(1) = y(2);
dy(2) = 1000*(1 - y(1)^2)*y(2) - y(1);
```

For this problem, we will use the default relative and absolute tolerances ( $1e-3$  and  $1e-6$ , respectively) and solve on a time interval of `[0 3000]` with initial condition vector `[2 0]` at time 0.

```
[T,Y] = ode15s(@vdp1000,[0 3000],[2 0]);
```

Plotting the first column of the returned matrix `Y` versus `T` shows the solution

```
plot(T,Y(:,1),'-o')
```

### Example 3

This example solves an ordinary differential equation with time-dependent terms.

Consider the following ODE, with time-dependent parameters defined only through the set of data points given in two vectors:

$$y'(t) + f(t)y(t) = g(t)$$

The initial condition is  $y(1) = 1$ , where the function  $f(t)$  is defined by the  $n$ -by-1 vector  $f$  evaluated at times  $ft$ , and the function  $g(t)$  is defined by the  $m$ -by-1 vector  $g$  evaluated at times  $gt$ .

First, define the time-dependent parameters  $f(t)$  and  $g(t)$  as the following:

```
ft = linspace(0,5,25); % Generate t for f
f = ft.^2 - ft - 3; % Generate f(t)
gt = linspace(1,6,25); % Generate t for g
g = 3*sin(gt-0.25); % Generate g(t)
```

Write a function to interpolate the data sets specified above to obtain the value of the time-dependent terms at the specified time:

```
function dydt = myode(t,y,ft,f,gt,g)
f = interp1(ft,f,t); % Interpolate the data set (ft,f) at time t
g = interp1(gt,g,t); % Interpolate the data set (gt,g) at time t
dydt = -f.*y + g; % Evaluate ODE at time t
```

Call the derivative function `myode.m` within the MATLAB `ode45` function specifying time as the first input argument :

```
Tspan = [1 5]; % Solve from t=1 to t=5
IC = 1; % y(t=1) = 1
[T Y] = ode45(@(t,y) myode(t,y,ft,f,gt,g),Tspan,IC); % Solve ODE
Plot the solution y (t) as a function of time:
```

```
plot(T, Y);
title('Plot of y as a function of time');
xlabel('Time');
ylabel('Y(t)');
```

## More About

### Algorithms

`ode45` is based on an explicit Runge-Kutta (4,5) formula, the Dormand-Prince pair. It is a *one-step* solver – in computing  $y(t_n)$ , it needs only the solution at the immediately preceding time point,  $y(t_{n-1})$ . In general, `ode45` is the best function to apply as a *first try* for most problems. [3]

`ode23` is an implementation of an explicit Runge-Kutta (2,3) pair of Bogacki and Shampine. It may be more efficient than `ode45` at crude tolerances and in the presence of moderate stiffness. Like `ode45`, `ode23` is a one-step solver. [2]

`ode113` is a variable order Adams-Bashforth-Moulton PECE solver. It may be more efficient than `ode45` at stringent tolerances and when the ODE file function is particularly expensive to evaluate. `ode113` is a *multistep* solver — it normally needs the solutions at several preceding time points to compute the current solution. [7]

The above algorithms are intended to solve nonstiff systems. If they appear to be unduly slow, try using one of the stiff solvers below.

`ode15s` is a variable order solver based on the numerical differentiation formulas (NDFs). Optionally, it uses the backward differentiation formulas (BDFs, also known as Gear's method) that are usually less efficient. Like `ode113`, `ode15s` is a multistep solver. Try `ode15s` when `ode45` fails, or is very inefficient, and you suspect that the problem is stiff, or when solving a differential-algebraic problem. [9], [10]

`ode23s` is based on a modified Rosenbrock formula of order 2. Because it is a one-step solver, it may be more efficient than `ode15s` at crude tolerances. It can solve some kinds of stiff problems for which `ode15s` is not effective. [9]

`ode23t` is an implementation of the trapezoidal rule using a “free” interpolant. Use this solver if the problem is only moderately stiff and you need a solution without numerical damping. `ode23t` can solve DAEs. [10]

`ode23tb` is an implementation of TR-BDF2, an implicit Runge-Kutta formula with a first stage that is a trapezoidal rule step and a second stage that is a backward differentiation formula of order two. By construction, the same iteration matrix is used in evaluating both stages. Like `ode23s`, this solver may be more efficient than `ode15s` at crude tolerances. [8], [1]

## ode23s

Solve stiff differential equations; low order method

### Syntax

```
[T,Y] = solver(odefun,tspan,y0)
[T,Y] = solver(odefun,tspan,y0,options)
[T,Y,TE,YE,IE] = solver(odefun,tspan,y0,options)
sol = solver(odefun,[t0 tf],y0...)
```

This page contains an overview of the solver functions: `ode23`, `ode45`, `ode113`, `ode15s`, `ode23s`, `ode23t`, and `ode23tb`. You can call any of these solvers by substituting the placeholder, `solver`, with any of the function names.

### Arguments

The following table describes the input arguments to the solvers.

<code>odefun</code>	A function handle that evaluates the right side of the differential equations. All solvers solve systems of equations in the form $y' = f(t,y)$ or problems that involve a mass matrix, $M(t,y)y' = f(t,y)$ . The <code>ode23s</code> solver can solve only equations with constant mass matrices. <code>ode15s</code> and <code>ode23t</code> can solve problems with a mass matrix that is singular, i.e., differential-algebraic equations (DAEs).
<code>tspan</code>	A vector specifying the interval of integration, <code>[t0,tf]</code> . The solver imposes the initial conditions at <code>tspan(1)</code> , and integrates from <code>tspan(1)</code> to <code>tspan(end)</code> . To obtain solutions at specific times (all increasing or all decreasing), use <code>tspan = [t0,t1,...,tf]</code> .  For <code>tspan</code> vectors with two elements <code>[t0 tf]</code> , the solver returns the solution evaluated at every integration step. For <code>tspan</code> vectors with more than two elements, the solver returns solutions evaluated at the given time points. The time values must be in order, either increasing or decreasing.

	<p>Specifying <code>tspan</code> with more than two elements does not affect the internal time steps that the solver uses to traverse the interval from <code>tspan(1)</code> to <code>tspan(end)</code>. All solvers in the ODE suite obtain output values by means of continuous extensions of the basic formulas. Although a solver does not necessarily step precisely to a time point specified in <code>tspan</code>, the solutions produced at the specified time points are of the same order of accuracy as the solutions computed at the internal time points.</p> <p>Specifying <code>tspan</code> with more than two elements has little effect on the efficiency of computation, but for large systems, affects memory management.</p>
<code>y0</code>	A vector of initial conditions.
<code>options</code>	<p>Structure of optional parameters that change the default integration properties. This is the fourth input argument.</p> <p><code>[t,y] = solver(odefun,tspan,y0,options)</code></p> <p>You can create options using the <code>odeset</code> function. See <code>odeset</code> for details.</p>

The following table lists the output arguments for the solvers.

<code>T</code>	Column vector of time points.
<code>Y</code>	Solution array. Each row in <code>Y</code> corresponds to the solution at a time returned in the corresponding row of <code>T</code> .
<code>TE</code>	The time at which an event occurs.
<code>YE</code>	The solution at the time of the event.
<code>IE</code>	The index <code>i</code> of the event function that vanishes.
<code>sol</code>	Structure to evaluate the solution.

## Description

`[T,Y] = solver(odefun,tspan,y0)` with `tspan = [t0 tf]` integrates the system of differential equations  $y' = f(t,y)$  from time `t0` to `tf` with initial conditions `y0`. The first

input argument, `odefun`, is a function handle. The function,  $f = \text{odefun}(t, y)$ , for a scalar  $t$  and a column vector  $y$ , must return a column vector  $f$  corresponding to  $f(t, y)$ . Each row in the solution array  $Y$  corresponds to a time returned in column vector  $T$ . To obtain solutions at the specific times  $t_0, t_1, \dots, t_f$  (all increasing or all decreasing), use `tspan = [t0,t1,...,tf]`.

“Parameterizing Functions” explains how to provide additional parameters to the function `fun`, if necessary.

`[T,Y] = solver(odefun,tspan,y0,options)` solves as above with default integration parameters replaced by property values specified in `options`, an argument created with the `odeset` function. Commonly used properties include a scalar relative error tolerance `RelTol` ( $1e-3$  by default) and a vector of absolute error tolerances `Abstol` (all components are  $1e-6$  by default). If certain components of the solution must be nonnegative, use the `odeset` function to set the `NonNegative` property to the indices of these components. See `odeset` for details.

`[T,Y,TE,YE,IE] = solver(odefun,tspan,y0,options)` solves as above while also finding where functions of  $(t,y)$ , called event functions, are zero. For each event function, you specify whether the integration is to terminate at a zero and whether the direction of the zero crossing matters. Do this by setting the 'Events' property to a function, e.g., `events` or `@events`, and creating a function `[value,isterminal,direction] = events(t,y)`. For the  $i$ th event function in `events`,

- `value(i)` is the value of the function.
- `isterminal(i) = 1`, if the integration is to terminate at a zero of this event function and 0 otherwise.
- `direction(i) = 0` if all zeros are to be computed (the default), +1 if only the zeros where the event function increases, and -1 if only the zeros where the event function decreases.

Corresponding entries in `TE`, `YE`, and `IE` return, respectively, the time at which an event occurs, the solution at the time of the event, and the index  $i$  of the event function that vanishes.

`sol = solver(odefun,[t0 tf],y0...)` returns a structure that you can use with `deval` to evaluate the solution at any point on the interval `[t0,tf]`. You must pass `odefun` as a function handle. The structure `sol` always includes these fields:

<code>sol.x</code>	Steps chosen by the solver.
--------------------	-----------------------------

<code>sol.y</code>	Each column <code>sol.y(:,i)</code> contains the solution at <code>sol.x(i)</code> .
<code>sol.solver</code>	Solver name.

If you specify the `Events` option and events are detected, `sol` also includes these fields:

<code>sol.xe</code>	Points at which events, if any, occurred. <code>sol.xe(end)</code> contains the exact point of a terminal event, if any.
<code>sol.ye</code>	Solutions that correspond to events in <code>sol.xe</code> .
<code>sol.ie</code>	Indices into the vector returned by the function specified in the <code>Events</code> option. The values indicate which event the solver detected.

If you specify an output function as the value of the `OutputFcn` property, the solver calls it with the computed solution after each time step. Four output functions are provided: `odeplot`, `odephas2`, `odephas3`, `odeprint`. When you call the solver with no output arguments, it calls the default `odeplot` to plot the solution as it is computed. `odephas2` and `odephas3` produce two- and three-dimensional phase plane plots, respectively. `odeprint` displays the solution components on the screen. By default, the ODE solver passes all components of the solution to the output function. You can pass only specific components by providing a vector of indices as the value of the `OutputSel` property. For example, if you call the solver with no output arguments and set the value of `OutputSel` to `[1,3]`, the solver plots solution components 1 and 3 as they are computed.

For the stiff solvers `ode15s`, `ode23s`, `ode23t`, and `ode23tb`, the Jacobian matrix  $\partial f/\partial y$  is critical to reliability and efficiency. Use `odeset` to set `Jacobian` to `@FJAC` if `FJAC(T,Y)` returns the Jacobian  $\partial f/\partial y$  or to the matrix  $\partial f/\partial y$  if the Jacobian is constant. If the `Jacobian` property is not set (the default),  $\partial f/\partial y$  is approximated by finite differences. Set the `Vectorized` property 'on' if the ODE function is coded so that `odefun(T,[Y1,Y2 ...])` returns `[odefun(T,Y1),odefun(T,Y2),...]`. If  $\partial f/\partial y$  is a sparse matrix, set the `JPattern` property to the sparsity pattern of  $\partial f/\partial y$ , i.e., a sparse matrix `S` with `S(i,j) = 1` if the *i*th component of  $f(t,y)$  depends on the *j*th component of  $y$ , and 0 otherwise.

The solvers of the ODE suite can solve problems of the form  $M(t,y)y' = f(t,y)$ , with time- and state-dependent mass matrix  $M$ . (The `ode23s` solver can solve only equations with constant mass matrices.) If a problem has a mass matrix, create a function `M = MASS(t,y)` that returns the value of the mass matrix, and use `odeset` to set the `Mass` property to `@MASS`. If the mass matrix is constant, the matrix should be used as the value of the `Mass` property. Problems with state-dependent mass matrices are more difficult:

- If the mass matrix does not depend on the state variable  $y$  and the function `MASS` is to be called with one input argument,  $t$ , set the `MStateDependence` property to 'none'.
- If the mass matrix depends weakly on  $y$ , set `MStateDependence` to 'weak' (the default); otherwise, set it to 'strong'. In either case, the function `MASS` is called with the two arguments  $(t,y)$ .

If there are many differential equations, it is important to exploit sparsity:

- Return a sparse  $M(t,y)$ .
- Supply the sparsity pattern of  $\partial f/\partial y$  using the `JPattern` property or a sparse  $\partial f/\partial y$  using the `Jacobian` property.
- For strongly state-dependent  $M(t,y)$ , set `MvPattern` to a sparse matrix  $S$  with  $S(i,j) = 1$  if for any  $k$ , the  $(i,k)$  component of  $M(t,y)$  depends on component  $j$  of  $y$ , and  $0$  otherwise.

If the mass matrix  $M$  is singular, then  $M(t,y)y' = f(t,y)$  is a system of differential algebraic equations. DAEs have solutions only when  $y_0$  is consistent, that is, if there is a vector  $yp_0$  such that  $M(t_0,y_0)yp_0 = f(t_0,y_0)$ . The `ode15s` and `ode23t` solvers can solve DAEs of index 1 provided that  $y_0$  is sufficiently close to being consistent. If there is a mass matrix, you can use `odeset` to set the `MassSingular` property to 'yes', 'no', or 'maybe'. The default value of 'maybe' causes the solver to test whether the problem is a DAE. You can provide  $yp_0$  as the value of the `InitialSlope` property. The default is the zero vector. If a problem is a DAE, and  $y_0$  and  $yp_0$  are not consistent, the solver treats them as guesses, attempts to compute consistent values that are close to the guesses, and continues to solve the problem. When solving DAEs, it is very advantageous to formulate the problem so that  $M$  is a diagonal matrix (a semi-explicit DAE).

Solver	Problem Type	Order of Accuracy	When to Use
ode45	Nonstiff	Medium	Most of the time. This should be the first solver you try.
ode23	Nonstiff	Low	For problems with crude error tolerances or for solving moderately stiff problems.
ode113	Nonstiff	Low to high	For problems with stringent error tolerances or for solving computationally intensive problems.

Solver	Problem Type	Order of Accuracy	When to Use
ode15s	Stiff	Low to medium	If ode45 is slow because the problem is stiff.
ode23s	Stiff	Low	If using crude error tolerances to solve stiff systems and the mass matrix is constant.
ode23t	Moderately Stiff	Low	For moderately stiff problems if you need a solution without numerical damping.
ode23tb	Stiff	Low	If using crude error tolerances to solve stiff systems.

The algorithms used in the ODE solvers vary according to order of accuracy [6] and the type of systems (stiff or nonstiff) they are designed to solve. See “Algorithms” on page 1-6117 for more details.

## Options

Different solvers accept different parameters in the options list. For more information, see `odeset` and “Integrator Options” in the MATLAB Mathematics documentation.

Parameters	ode45	ode23	ode113	ode15s	ode23s	ode23t	ode23tb
RelTol, AbsTol, NormControl	√	√	√	√	√	√	√
OutputFcn, OutputSel, Refine, Stats	√	√	√	√	√	√	√
NonNegative	√	√	√	√ *	—	√ *	√ *
Events	√	√	√	√	√	√	√
MaxStep, InitialStep	√	√	√	√	√	√	√

Parameters	ode45	ode23	ode113	ode15s	ode23s	ode23t	ode23tb
Jacobian, JPattern, Vectorized	—	—	—	√	√	√	√
Mass	√	√	√	√	√	√	√
MStateDependence	√	√	√	√	—	√	√
MvPattern	—	—	—	√	—	√	√
MassSingular	—	—	—	√	—	√	—
InitialSlope	—	—	—	√	—	√	—
MaxOrder, BDF	—	—	—	√	—	—	—

---

**Note** You can use the `NonNegative` parameter with `ode15s`, `ode23t`, and `ode23tb` only for those problems for which there is no mass matrix.

---

## Examples

### Example 1

An example of a nonstiff system is the system of equations describing the motion of a rigid body without external forces.

$$\begin{aligned}
 y_1' &= y_2 y_3 & y_1(0) &= 0 \\
 y_2' &= -y_1 y_3 & y_2(0) &= 1 \\
 y_3' &= -0.51 y_1 y_2 & y_3(0) &= 1
 \end{aligned}$$

To simulate this system, create a function `rigid` containing the equations

```
function dy = rigid(t,y)
dy = zeros(3,1); % a column vector
dy(1) = y(2) * y(3);
dy(2) = -y(1) * y(3);
dy(3) = -0.51 * y(1) * y(2);
```

In this example we change the error tolerances using the `odeset` command and solve on a time interval `[0 12]` with an initial condition vector `[0 1 1]` at time `0`.

```
options = odeset('RelTol',1e-4,'AbsTol',[1e-4 1e-4 1e-5]);
[T,Y] = ode45(@rigid,[0 12],[0 1 1],options);
```

Plotting the columns of the returned array Y versus T shows the solution

```
plot(T,Y(:,1),'-',T,Y(:,2),'-.',T,Y(:,3),'-.')
```

## Example 2

An example of a stiff system is provided by the van der Pol equations in relaxation oscillation. The limit cycle has portions where the solution components change slowly and the problem is quite stiff, alternating with regions of very sharp change where it is not stiff.

$$\begin{aligned}y_1' &= y_2 & y_1(0) &= 2 \\y_2' &= 1000(1 - y_1^2)y_2 - y_1 & y_2(0) &= 0\end{aligned}$$

To simulate this system, create a function `vdp1000` containing the equations

```
function dy = vdp1000(t,y)
dy = zeros(2,1); % a column vector
dy(1) = y(2);
dy(2) = 1000*(1 - y(1)^2)*y(2) - y(1);
```

For this problem, we will use the default relative and absolute tolerances ( $1\text{e-}3$  and  $1\text{e-}6$ , respectively) and solve on a time interval of `[0 3000]` with initial condition vector `[2 0]` at time 0.

```
[T,Y] = ode15s(@vdp1000,[0 3000],[2 0]);
```

Plotting the first column of the returned matrix `Y` versus `T` shows the solution

```
plot(T,Y(:,1),'-o')
```

### Example 3

This example solves an ordinary differential equation with time-dependent terms.

Consider the following ODE, with time-dependent parameters defined only through the set of data points given in two vectors:

$$y'(t) + f(t)y(t) = g(t)$$

The initial condition is  $y(1) = 1$ , where the function  $f(t)$  is defined by the  $n$ -by-1 vector  $f$  evaluated at times  $ft$ , and the function  $g(t)$  is defined by the  $m$ -by-1 vector  $g$  evaluated at times  $gt$ .

First, define the time-dependent parameters  $f(t)$  and  $g(t)$  as the following:

```
ft = linspace(0,5,25); % Generate t for f
f = ft.^2 - ft - 3; % Generate f(t)
gt = linspace(1,6,25); % Generate t for g
g = 3*sin(gt-0.25); % Generate g(t)
```

Write a function to interpolate the data sets specified above to obtain the value of the time-dependent terms at the specified time:

```
function dydt = myode(t,y,ft,f,gt,g)
f = interp1(ft,f,t); % Interpolate the data set (ft,f) at time t
g = interp1(gt,g,t); % Interpolate the data set (gt,g) at time t
dydt = -f.*y + g; % Evaluate ODE at time t
```

Call the derivative function `myode.m` within the MATLAB `ode45` function specifying time as the first input argument :

```
Tspan = [1 5]; % Solve from t=1 to t=5
IC = 1; % y(t=1) = 1
[T Y] = ode45(@(t,y) myode(t,y,ft,f,gt,g),Tspan,IC); % Solve ODE
Plot the solution y (t) as a function of time:
```

```
plot(T, Y);
title('Plot of y as a function of time');
xlabel('Time');
ylabel('Y(t)');
```

## More About

### Algorithms

`ode45` is based on an explicit Runge-Kutta (4,5) formula, the Dormand-Prince pair. It is a *one-step* solver – in computing  $y(t_n)$ , it needs only the solution at the immediately preceding time point,  $y(t_{n-1})$ . In general, `ode45` is the best function to apply as a *first try* for most problems. [3]

`ode23` is an implementation of an explicit Runge-Kutta (2,3) pair of Bogacki and Shampine. It may be more efficient than `ode45` at crude tolerances and in the presence of moderate stiffness. Like `ode45`, `ode23` is a one-step solver. [2]

`ode113` is a variable order Adams-Bashforth-Moulton PECE solver. It may be more efficient than `ode45` at stringent tolerances and when the ODE file function is particularly expensive to evaluate. `ode113` is a *multistep* solver — it normally needs the solutions at several preceding time points to compute the current solution. [7]

The above algorithms are intended to solve nonstiff systems. If they appear to be unduly slow, try using one of the stiff solvers below.

`ode15s` is a variable order solver based on the numerical differentiation formulas (NDFs). Optionally, it uses the backward differentiation formulas (BDFs, also known as Gear's method) that are usually less efficient. Like `ode113`, `ode15s` is a multistep solver. Try `ode15s` when `ode45` fails, or is very inefficient, and you suspect that the problem is stiff, or when solving a differential-algebraic problem. [9], [10]

`ode23s` is based on a modified Rosenbrock formula of order 2. Because it is a one-step solver, it may be more efficient than `ode15s` at crude tolerances. It can solve some kinds of stiff problems for which `ode15s` is not effective. [9]

`ode23t` is an implementation of the trapezoidal rule using a “free” interpolant. Use this solver if the problem is only moderately stiff and you need a solution without numerical damping. `ode23t` can solve DAEs. [10]

`ode23tb` is an implementation of TR-BDF2, an implicit Runge-Kutta formula with a first stage that is a trapezoidal rule step and a second stage that is a backward differentiation formula of order two. By construction, the same iteration matrix is used in evaluating both stages. Like `ode23s`, this solver may be more efficient than `ode15s` at crude tolerances. [8], [1]

## ode23t

Solve moderately stiff ODEs and DAEs; trapezoidal rule

### Syntax

```
[T,Y] = solver(odefun,tspan,y0)
[T,Y] = solver(odefun,tspan,y0,options)
[T,Y,TE,YE,IE] = solver(odefun,tspan,y0,options)
sol = solver(odefun,[t0 tf],y0...)
```

This page contains an overview of the solver functions: `ode23`, `ode45`, `ode113`, `ode15s`, `ode23s`, `ode23t`, and `ode23tb`. You can call any of these solvers by substituting the placeholder, `solver`, with any of the function names.

### Arguments

The following table describes the input arguments to the solvers.

<code>odefun</code>	A function handle that evaluates the right side of the differential equations. All solvers solve systems of equations in the form $y' = f(t,y)$ or problems that involve a mass matrix, $M(t,y)y' = f(t,y)$ . The <code>ode23s</code> solver can solve only equations with constant mass matrices. <code>ode15s</code> and <code>ode23t</code> can solve problems with a mass matrix that is singular, i.e., differential-algebraic equations (DAEs).
<code>tspan</code>	A vector specifying the interval of integration, <code>[t0,tf]</code> . The solver imposes the initial conditions at <code>tspan(1)</code> , and integrates from <code>tspan(1)</code> to <code>tspan(end)</code> . To obtain solutions at specific times (all increasing or all decreasing), use <code>tspan = [t0,t1,...,tf]</code> .  For <code>tspan</code> vectors with two elements <code>[t0 tf]</code> , the solver returns the solution evaluated at every integration step. For <code>tspan</code> vectors with more than two elements, the solver returns solutions evaluated at the given time points. The time values must be in order, either increasing or decreasing.

	<p>Specifying <code>tspan</code> with more than two elements does not affect the internal time steps that the solver uses to traverse the interval from <code>tspan(1)</code> to <code>tspan(end)</code>. All solvers in the ODE suite obtain output values by means of continuous extensions of the basic formulas. Although a solver does not necessarily step precisely to a time point specified in <code>tspan</code>, the solutions produced at the specified time points are of the same order of accuracy as the solutions computed at the internal time points.</p> <p>Specifying <code>tspan</code> with more than two elements has little effect on the efficiency of computation, but for large systems, affects memory management.</p>
<code>y0</code>	A vector of initial conditions.
<code>options</code>	<p>Structure of optional parameters that change the default integration properties. This is the fourth input argument.</p> <p><code>[t,y] = solver(odefun,tspan,y0,options)</code></p> <p>You can create options using the <code>odeset</code> function. See <code>odeset</code> for details.</p>

The following table lists the output arguments for the solvers.

<code>T</code>	Column vector of time points.
<code>Y</code>	Solution array. Each row in <code>Y</code> corresponds to the solution at a time returned in the corresponding row of <code>T</code> .
<code>TE</code>	The time at which an event occurs.
<code>YE</code>	The solution at the time of the event.
<code>IE</code>	The index <code>i</code> of the event function that vanishes.
<code>sol</code>	Structure to evaluate the solution.

## Description

`[T,Y] = solver(odefun,tspan,y0)` with `tspan = [t0 tf]` integrates the system of differential equations  $y' = f(t,y)$  from time `t0` to `tf` with initial conditions `y0`. The first

input argument, `odefun`, is a function handle. The function,  $f = \text{odefun}(t, y)$ , for a scalar  $t$  and a column vector  $y$ , must return a column vector  $f$  corresponding to  $f(t, y)$ . Each row in the solution array  $Y$  corresponds to a time returned in column vector  $T$ . To obtain solutions at the specific times  $t_0, t_1, \dots, t_f$  (all increasing or all decreasing), use `tspan = [t0, t1, ..., tf]`.

“Parameterizing Functions” explains how to provide additional parameters to the function `fun`, if necessary.

`[T, Y] = solver(odefun, tspan, y0, options)` solves as above with default integration parameters replaced by property values specified in `options`, an argument created with the `odeset` function. Commonly used properties include a scalar relative error tolerance `RelTol` ( $1e-3$  by default) and a vector of absolute error tolerances `Abstol` (all components are  $1e-6$  by default). If certain components of the solution must be nonnegative, use the `odeset` function to set the `NonNegative` property to the indices of these components. See `odeset` for details.

`[T, Y, TE, YE, IE] = solver(odefun, tspan, y0, options)` solves as above while also finding where functions of  $(t, y)$ , called event functions, are zero. For each event function, you specify whether the integration is to terminate at a zero and whether the direction of the zero crossing matters. Do this by setting the 'Events' property to a function, e.g., `events` or `@events`, and creating a function `[value, isterminal, direction] = events(t, y)`. For the  $i$ th event function in `events`,

- `value(i)` is the value of the function.
- `isterminal(i) = 1`, if the integration is to terminate at a zero of this event function and 0 otherwise.
- `direction(i) = 0` if all zeros are to be computed (the default), +1 if only the zeros where the event function increases, and -1 if only the zeros where the event function decreases.

Corresponding entries in `TE`, `YE`, and `IE` return, respectively, the time at which an event occurs, the solution at the time of the event, and the index  $i$  of the event function that vanishes.

`sol = solver(odefun, [t0 tf], y0...)` returns a structure that you can use with `deval` to evaluate the solution at any point on the interval `[t0, tf]`. You must pass `odefun` as a function handle. The structure `sol` always includes these fields:

<code>sol.x</code>	Steps chosen by the solver.
--------------------	-----------------------------

<code>sol.y</code>	Each column <code>sol.y(:,i)</code> contains the solution at <code>sol.x(i)</code> .
<code>sol.solver</code>	Solver name.

If you specify the `Events` option and events are detected, `sol` also includes these fields:

<code>sol.xe</code>	Points at which events, if any, occurred. <code>sol.xe(end)</code> contains the exact point of a terminal event, if any.
<code>sol.ye</code>	Solutions that correspond to events in <code>sol.xe</code> .
<code>sol.ie</code>	Indices into the vector returned by the function specified in the <code>Events</code> option. The values indicate which event the solver detected.

If you specify an output function as the value of the `OutputFcn` property, the solver calls it with the computed solution after each time step. Four output functions are provided: `odeplot`, `odephas2`, `odephas3`, `odeprint`. When you call the solver with no output arguments, it calls the default `odeplot` to plot the solution as it is computed. `odephas2` and `odephas3` produce two- and three-dimensional phase plane plots, respectively. `odeprint` displays the solution components on the screen. By default, the ODE solver passes all components of the solution to the output function. You can pass only specific components by providing a vector of indices as the value of the `OutputSel` property. For example, if you call the solver with no output arguments and set the value of `OutputSel` to `[1,3]`, the solver plots solution components 1 and 3 as they are computed.

For the stiff solvers `ode15s`, `ode23s`, `ode23t`, and `ode23tb`, the Jacobian matrix  $\partial f/\partial y$  is critical to reliability and efficiency. Use `odeset` to set `Jacobian` to `@FJAC` if `FJAC(T,Y)` returns the Jacobian  $\partial f/\partial y$  or to the matrix  $\partial f/\partial y$  if the Jacobian is constant. If the `Jacobian` property is not set (the default),  $\partial f/\partial y$  is approximated by finite differences. Set the `Vectorized` property 'on' if the ODE function is coded so that `odefun(T,[Y1,Y2 ...])` returns `[odefun(T,Y1),odefun(T,Y2),...]`. If  $\partial f/\partial y$  is a sparse matrix, set the `JPattern` property to the sparsity pattern of  $\partial f/\partial y$ , i.e., a sparse matrix `S` with `S(i,j) = 1` if the *i*th component of  $f(t,y)$  depends on the *j*th component of  $y$ , and 0 otherwise.

The solvers of the ODE suite can solve problems of the form  $M(t,y)y' = f(t,y)$ , with time- and state-dependent mass matrix  $M$ . (The `ode23s` solver can solve only equations with constant mass matrices.) If a problem has a mass matrix, create a function `M = MASS(t,y)` that returns the value of the mass matrix, and use `odeset` to set the `Mass` property to `@MASS`. If the mass matrix is constant, the matrix should be used as the value of the `Mass` property. Problems with state-dependent mass matrices are more difficult:

- If the mass matrix does not depend on the state variable  $y$  and the function `MASS` is to be called with one input argument,  $t$ , set the `MStateDependence` property to 'none'.
- If the mass matrix depends weakly on  $y$ , set `MStateDependence` to 'weak' (the default); otherwise, set it to 'strong'. In either case, the function `MASS` is called with the two arguments  $(t,y)$ .

If there are many differential equations, it is important to exploit sparsity:

- Return a sparse  $M(t,y)$ .
- Supply the sparsity pattern of  $\partial f/\partial y$  using the `JPattern` property or a sparse  $\partial f/\partial y$  using the `Jacobian` property.
- For strongly state-dependent  $M(t,y)$ , set `MvPattern` to a sparse matrix  $S$  with  $S(i, j) = 1$  if for any  $k$ , the  $(i, k)$  component of  $M(t,y)$  depends on component  $j$  of  $y$ , and  $0$  otherwise.

If the mass matrix  $M$  is singular, then  $M(t,y)y' = f(t,y)$  is a system of differential algebraic equations. DAEs have solutions only when  $y_0$  is consistent, that is, if there is a vector  $yp_0$  such that  $M(t_0,y_0)yp_0 = f(t_0,y_0)$ . The `ode15s` and `ode23t` solvers can solve DAEs of index 1 provided that  $y_0$  is sufficiently close to being consistent. If there is a mass matrix, you can use `odeset` to set the `MassSingular` property to 'yes', 'no', or 'maybe'. The default value of 'maybe' causes the solver to test whether the problem is a DAE. You can provide  $yp_0$  as the value of the `InitialSlope` property. The default is the zero vector. If a problem is a DAE, and  $y_0$  and  $yp_0$  are not consistent, the solver treats them as guesses, attempts to compute consistent values that are close to the guesses, and continues to solve the problem. When solving DAEs, it is very advantageous to formulate the problem so that  $M$  is a diagonal matrix (a semi-explicit DAE).

Solver	Problem Type	Order of Accuracy	When to Use
ode45	Nonstiff	Medium	Most of the time. This should be the first solver you try.
ode23	Nonstiff	Low	For problems with crude error tolerances or for solving moderately stiff problems.
ode113	Nonstiff	Low to high	For problems with stringent error tolerances or for solving computationally intensive problems.

Solver	Problem Type	Order of Accuracy	When to Use
ode15s	Stiff	Low to medium	If ode45 is slow because the problem is stiff.
ode23s	Stiff	Low	If using crude error tolerances to solve stiff systems and the mass matrix is constant.
ode23t	Moderately Stiff	Low	For moderately stiff problems if you need a solution without numerical damping.
ode23tb	Stiff	Low	If using crude error tolerances to solve stiff systems.

The algorithms used in the ODE solvers vary according to order of accuracy [6] and the type of systems (stiff or nonstiff) they are designed to solve. See “Algorithms” on page 1-6131 for more details.

## Options

Different solvers accept different parameters in the options list. For more information, see `odeset` and “Integrator Options” in the MATLAB Mathematics documentation.

Parameters	ode45	ode23	ode113	ode15s	ode23s	ode23t	ode23tb
RelTol, AbsTol, NormControl	√	√	√	√	√	√	√
OutputFcn, OutputSel, Refine, Stats	√	√	√	√	√	√	√
NonNegative	√	√	√	√ *	—	√ *	√ *
Events	√	√	√	√	√	√	√
MaxStep, InitialStep	√	√	√	√	√	√	√

Parameters	ode45	ode23	ode113	ode15s	ode23s	ode23t	ode23tb
Jacobian, JPattern, Vectorized	—	—	—	√	√	√	√
Mass	√	√	√	√	√	√	√
MStateDependence	√	√	√	√	—	√	√
MvPattern	—	—	—	√	—	√	√
MassSingular	—	—	—	√	—	√	—
InitialSlope	—	—	—	√	—	√	—
MaxOrder, BDF	—	—	—	√	—	—	—

---

**Note** You can use the `NonNegative` parameter with `ode15s`, `ode23t`, and `ode23tb` only for those problems for which there is no mass matrix.

---

## Examples

### Example 1

An example of a nonstiff system is the system of equations describing the motion of a rigid body without external forces.

$$\begin{aligned}
 y_1' &= y_2 y_3 & y_1(0) &= 0 \\
 y_2' &= -y_1 y_3 & y_2(0) &= 1 \\
 y_3' &= -0.51 y_1 y_2 & y_3(0) &= 1
 \end{aligned}$$

To simulate this system, create a function `rigid` containing the equations

```
function dy = rigid(t,y)
dy = zeros(3,1); % a column vector
dy(1) = y(2) * y(3);
dy(2) = -y(1) * y(3);
dy(3) = -0.51 * y(1) * y(2);
```

In this example we change the error tolerances using the `odeset` command and solve on a time interval `[0 12]` with an initial condition vector `[0 1 1]` at time 0.

```
options = odeset('RelTol',1e-4,'AbsTol',[1e-4 1e-4 1e-5]);
[T,Y] = ode45(@rigid,[0 12],[0 1 1],options);
```

Plotting the columns of the returned array Y versus T shows the solution

```
plot(T,Y(:,1),'-',T,Y(:,2),'-.',T,Y(:,3),'-.')
```

## Example 2

An example of a stiff system is provided by the van der Pol equations in relaxation oscillation. The limit cycle has portions where the solution components change slowly and the problem is quite stiff, alternating with regions of very sharp change where it is not stiff.

$$\begin{aligned}y_1' &= y_2 & y_1(0) &= 2 \\y_2' &= 1000(1 - y_1^2)y_2 - y_1 & y_2(0) &= 0\end{aligned}$$

To simulate this system, create a function `vdp1000` containing the equations

```
function dy = vdp1000(t,y)
dy = zeros(2,1); % a column vector
dy(1) = y(2);
dy(2) = 1000*(1 - y(1)^2)*y(2) - y(1);
```

For this problem, we will use the default relative and absolute tolerances ( $1e-3$  and  $1e-6$ , respectively) and solve on a time interval of `[0 3000]` with initial condition vector `[2 0]` at time 0.

```
[T,Y] = ode15s(@vdp1000,[0 3000],[2 0]);
```

Plotting the first column of the returned matrix `Y` versus `T` shows the solution

```
plot(T,Y(:,1),'-o')
```

### Example 3

This example solves an ordinary differential equation with time-dependent terms.

Consider the following ODE, with time-dependent parameters defined only through the set of data points given in two vectors:

$$y'(t) + f(t)y(t) = g(t)$$

The initial condition is  $y(1) = 1$ , where the function  $f(t)$  is defined by the  $n$ -by-1 vector  $f$  evaluated at times  $ft$ , and the function  $g(t)$  is defined by the  $m$ -by-1 vector  $g$  evaluated at times  $gt$ .

First, define the time-dependent parameters  $f(t)$  and  $g(t)$  as the following:

```
ft = linspace(0,5,25); % Generate t for f
f = ft.^2 - ft - 3; % Generate f(t)
gt = linspace(1,6,25); % Generate t for g
g = 3*sin(gt-0.25); % Generate g(t)
```

Write a function to interpolate the data sets specified above to obtain the value of the time-dependent terms at the specified time:

```
function dydt = myode(t,y,ft,f,gt,g)
f = interp1(ft,f,t); % Interpolate the data set (ft,f) at time t
g = interp1(gt,g,t); % Interpolate the data set (gt,g) at time t
dydt = -f.*y + g; % Evaluate ODE at time t
```

Call the derivative function `myode.m` within the MATLAB `ode45` function specifying time as the first input argument :

```
Tspan = [1 5]; % Solve from t=1 to t=5
IC = 1; % y(t=1) = 1
[T Y] = ode45(@(t,y) myode(t,y,ft,f,gt,g),Tspan,IC); % Solve ODE
Plot the solution $y(t)$ as a function of time:
```

```
plot(T, Y);
title('Plot of y as a function of time');
xlabel('Time');
ylabel('Y(t)');
```

## More About

### Algorithms

`ode45` is based on an explicit Runge-Kutta (4,5) formula, the Dormand-Prince pair. It is a *one-step* solver – in computing  $y(t_n)$ , it needs only the solution at the immediately preceding time point,  $y(t_{n-1})$ . In general, `ode45` is the best function to apply as a *first try* for most problems. [3]

`ode23` is an implementation of an explicit Runge-Kutta (2,3) pair of Bogacki and Shampine. It may be more efficient than `ode45` at crude tolerances and in the presence of moderate stiffness. Like `ode45`, `ode23` is a one-step solver. [2]

`ode113` is a variable order Adams-Bashforth-Moulton PECE solver. It may be more efficient than `ode45` at stringent tolerances and when the ODE file function is particularly expensive to evaluate. `ode113` is a *multistep* solver — it normally needs the solutions at several preceding time points to compute the current solution. [7]

The above algorithms are intended to solve nonstiff systems. If they appear to be unduly slow, try using one of the stiff solvers below.

`ode15s` is a variable order solver based on the numerical differentiation formulas (NDFs). Optionally, it uses the backward differentiation formulas (BDFs, also known as Gear's method) that are usually less efficient. Like `ode113`, `ode15s` is a multistep solver. Try `ode15s` when `ode45` fails, or is very inefficient, and you suspect that the problem is stiff, or when solving a differential-algebraic problem. [9], [10]

`ode23s` is based on a modified Rosenbrock formula of order 2. Because it is a one-step solver, it may be more efficient than `ode15s` at crude tolerances. It can solve some kinds of stiff problems for which `ode15s` is not effective. [9]

`ode23t` is an implementation of the trapezoidal rule using a “free” interpolant. Use this solver if the problem is only moderately stiff and you need a solution without numerical damping. `ode23t` can solve DAEs. [10]

`ode23tb` is an implementation of TR-BDF2, an implicit Runge-Kutta formula with a first stage that is a trapezoidal rule step and a second stage that is a backward differentiation formula of order two. By construction, the same iteration matrix is used in evaluating both stages. Like `ode23s`, this solver may be more efficient than `ode15s` at crude tolerances. [8], [1]

## ode23tb

Solve stiff differential equations; low order method

### Syntax

```
[T,Y] = solver(odefun,tspan,y0)
[T,Y] = solver(odefun,tspan,y0,options)
[T,Y,TE,YE,IE] = solver(odefun,tspan,y0,options)
sol = solver(odefun,[t0 tf],y0...)
```

This page contains an overview of the solver functions: `ode23`, `ode45`, `ode113`, `ode15s`, `ode23s`, `ode23t`, and `ode23tb`. You can call any of these solvers by substituting the placeholder, `solver`, with any of the function names.

### Arguments

The following table describes the input arguments to the solvers.

<code>odefun</code>	A function handle that evaluates the right side of the differential equations. All solvers solve systems of equations in the form $y' = f(t,y)$ or problems that involve a mass matrix, $M(t,y)y' = f(t,y)$ . The <code>ode23s</code> solver can solve only equations with constant mass matrices. <code>ode15s</code> and <code>ode23t</code> can solve problems with a mass matrix that is singular, i.e., differential-algebraic equations (DAEs).
<code>tspan</code>	A vector specifying the interval of integration, <code>[t0,tf]</code> . The solver imposes the initial conditions at <code>tspan(1)</code> , and integrates from <code>tspan(1)</code> to <code>tspan(end)</code> . To obtain solutions at specific times (all increasing or all decreasing), use <code>tspan = [t0,t1,...,tf]</code> .  For <code>tspan</code> vectors with two elements <code>[t0 tf]</code> , the solver returns the solution evaluated at every integration step. For <code>tspan</code> vectors with more than two elements, the solver returns solutions evaluated at the given time points. The time values must be in order, either increasing or decreasing.

	<p>Specifying <code>tspan</code> with more than two elements does not affect the internal time steps that the solver uses to traverse the interval from <code>tspan(1)</code> to <code>tspan(end)</code>. All solvers in the ODE suite obtain output values by means of continuous extensions of the basic formulas. Although a solver does not necessarily step precisely to a time point specified in <code>tspan</code>, the solutions produced at the specified time points are of the same order of accuracy as the solutions computed at the internal time points.</p> <p>Specifying <code>tspan</code> with more than two elements has little effect on the efficiency of computation, but for large systems, affects memory management.</p>
<code>y0</code>	A vector of initial conditions.
<code>options</code>	<p>Structure of optional parameters that change the default integration properties. This is the fourth input argument.</p> <p><code>[t,y] = solver(odefun,tspan,y0,options)</code></p> <p>You can create options using the <code>odeset</code> function. See <code>odeset</code> for details.</p>

The following table lists the output arguments for the solvers.

<code>T</code>	Column vector of time points.
<code>Y</code>	Solution array. Each row in <code>Y</code> corresponds to the solution at a time returned in the corresponding row of <code>T</code> .
<code>TE</code>	The time at which an event occurs.
<code>YE</code>	The solution at the time of the event.
<code>IE</code>	The index <code>i</code> of the event function that vanishes.
<code>sol</code>	Structure to evaluate the solution.

## Description

`[T,Y] = solver(odefun,tspan,y0)` with `tspan = [t0 tf]` integrates the system of differential equations  $y' = f(t,y)$  from time `t0` to `tf` with initial conditions `y0`. The first

input argument, `odefun`, is a function handle. The function,  $f = \text{odefun}(t, y)$ , for a scalar  $t$  and a column vector  $y$ , must return a column vector  $f$  corresponding to  $f(t, y)$ . Each row in the solution array  $Y$  corresponds to a time returned in column vector  $T$ . To obtain solutions at the specific times  $t_0, t_1, \dots, t_f$  (all increasing or all decreasing), use `tspan = [t0, t1, ..., tf]`.

“Parameterizing Functions” explains how to provide additional parameters to the function `fun`, if necessary.

`[T, Y] = solver(odefun, tspan, y0, options)` solves as above with default integration parameters replaced by property values specified in `options`, an argument created with the `odeset` function. Commonly used properties include a scalar relative error tolerance `RelTol` ( $1e-3$  by default) and a vector of absolute error tolerances `Abstol` (all components are  $1e-6$  by default). If certain components of the solution must be nonnegative, use the `odeset` function to set the `NonNegative` property to the indices of these components. See `odeset` for details.

`[T, Y, TE, YE, IE] = solver(odefun, tspan, y0, options)` solves as above while also finding where functions of  $(t, y)$ , called event functions, are zero. For each event function, you specify whether the integration is to terminate at a zero and whether the direction of the zero crossing matters. Do this by setting the 'Events' property to a function, e.g., `events` or `@events`, and creating a function `[value, isterminal, direction] = events(t, y)`. For the  $i$ th event function in `events`,

- `value(i)` is the value of the function.
- `isterminal(i) = 1`, if the integration is to terminate at a zero of this event function and 0 otherwise.
- `direction(i) = 0` if all zeros are to be computed (the default), +1 if only the zeros where the event function increases, and -1 if only the zeros where the event function decreases.

Corresponding entries in `TE`, `YE`, and `IE` return, respectively, the time at which an event occurs, the solution at the time of the event, and the index  $i$  of the event function that vanishes.

`sol = solver(odefun, [t0 tf], y0...)` returns a structure that you can use with `deval` to evaluate the solution at any point on the interval `[t0, tf]`. You must pass `odefun` as a function handle. The structure `sol` always includes these fields:

<code>sol.x</code>	Steps chosen by the solver.
--------------------	-----------------------------

<code>sol.y</code>	Each column <code>sol.y(:,i)</code> contains the solution at <code>sol.x(i)</code> .
<code>sol.solver</code>	Solver name.

If you specify the `Events` option and events are detected, `sol` also includes these fields:

<code>sol.xe</code>	Points at which events, if any, occurred. <code>sol.xe(end)</code> contains the exact point of a terminal event, if any.
<code>sol.ye</code>	Solutions that correspond to events in <code>sol.xe</code> .
<code>sol.ie</code>	Indices into the vector returned by the function specified in the <code>Events</code> option. The values indicate which event the solver detected.

If you specify an output function as the value of the `OutputFcn` property, the solver calls it with the computed solution after each time step. Four output functions are provided: `odeplot`, `odephas2`, `odephas3`, `odeprint`. When you call the solver with no output arguments, it calls the default `odeplot` to plot the solution as it is computed. `odephas2` and `odephas3` produce two- and three-dimensional phase plane plots, respectively. `odeprint` displays the solution components on the screen. By default, the ODE solver passes all components of the solution to the output function. You can pass only specific components by providing a vector of indices as the value of the `OutputSel` property. For example, if you call the solver with no output arguments and set the value of `OutputSel` to `[1,3]`, the solver plots solution components 1 and 3 as they are computed.

For the stiff solvers `ode15s`, `ode23s`, `ode23t`, and `ode23tb`, the Jacobian matrix  $\partial f/\partial y$  is critical to reliability and efficiency. Use `odeset` to set `Jacobian` to `@FJAC` if `FJAC(T,Y)` returns the Jacobian  $\partial f/\partial y$  or to the matrix  $\partial f/\partial y$  if the Jacobian is constant. If the `Jacobian` property is not set (the default),  $\partial f/\partial y$  is approximated by finite differences. Set the `Vectorized` property 'on' if the ODE function is coded so that `odefun(T,[Y1,Y2 ...])` returns `[odefun(T,Y1),odefun(T,Y2),...]`. If  $\partial f/\partial y$  is a sparse matrix, set the `JPattern` property to the sparsity pattern of  $\partial f/\partial y$ , i.e., a sparse matrix `S` with `S(i,j) = 1` if the *i*th component of  $f(t,y)$  depends on the *j*th component of  $y$ , and 0 otherwise.

The solvers of the ODE suite can solve problems of the form  $M(t,y)y' = f(t,y)$ , with time- and state-dependent mass matrix  $M$ . (The `ode23s` solver can solve only equations with constant mass matrices.) If a problem has a mass matrix, create a function `M = MASS(t,y)` that returns the value of the mass matrix, and use `odeset` to set the `Mass` property to `@MASS`. If the mass matrix is constant, the matrix should be used as the value of the `Mass` property. Problems with state-dependent mass matrices are more difficult:

- If the mass matrix does not depend on the state variable  $y$  and the function `MASS` is to be called with one input argument,  $t$ , set the `MStateDependence` property to 'none'.
- If the mass matrix depends weakly on  $y$ , set `MStateDependence` to 'weak' (the default); otherwise, set it to 'strong'. In either case, the function `MASS` is called with the two arguments  $(t,y)$ .

If there are many differential equations, it is important to exploit sparsity:

- Return a sparse  $M(t,y)$ .
- Supply the sparsity pattern of  $\partial f/\partial y$  using the `JPattern` property or a sparse  $\partial f/\partial y$  using the `Jacobian` property.
- For strongly state-dependent  $M(t,y)$ , set `MvPattern` to a sparse matrix  $S$  with  $S(i, j) = 1$  if for any  $k$ , the  $(i, k)$  component of  $M(t,y)$  depends on component  $j$  of  $y$ , and  $0$  otherwise.

If the mass matrix  $M$  is singular, then  $M(t,y)y' = f(t,y)$  is a system of differential algebraic equations. DAEs have solutions only when  $y_0$  is consistent, that is, if there is a vector  $yp_0$  such that  $M(t_0,y_0)yp_0 = f(t_0,y_0)$ . The `ode15s` and `ode23t` solvers can solve DAEs of index 1 provided that  $y_0$  is sufficiently close to being consistent. If there is a mass matrix, you can use `odeset` to set the `MassSingular` property to 'yes', 'no', or 'maybe'. The default value of 'maybe' causes the solver to test whether the problem is a DAE. You can provide  $yp_0$  as the value of the `InitialSlope` property. The default is the zero vector. If a problem is a DAE, and  $y_0$  and  $yp_0$  are not consistent, the solver treats them as guesses, attempts to compute consistent values that are close to the guesses, and continues to solve the problem. When solving DAEs, it is very advantageous to formulate the problem so that  $M$  is a diagonal matrix (a semi-explicit DAE).

Solver	Problem Type	Order of Accuracy	When to Use
ode45	Nonstiff	Medium	Most of the time. This should be the first solver you try.
ode23	Nonstiff	Low	For problems with crude error tolerances or for solving moderately stiff problems.
ode113	Nonstiff	Low to high	For problems with stringent error tolerances or for solving computationally intensive problems.

Solver	Problem Type	Order of Accuracy	When to Use
ode15s	Stiff	Low to medium	If ode45 is slow because the problem is stiff.
ode23s	Stiff	Low	If using crude error tolerances to solve stiff systems and the mass matrix is constant.
ode23t	Moderately Stiff	Low	For moderately stiff problems if you need a solution without numerical damping.
ode23tb	Stiff	Low	If using crude error tolerances to solve stiff systems.

The algorithms used in the ODE solvers vary according to order of accuracy [6] and the type of systems (stiff or nonstiff) they are designed to solve. See “Algorithms” on page 1-6145 for more details.

## Options

Different solvers accept different parameters in the options list. For more information, see `odeset` and “Integrator Options” in the MATLAB Mathematics documentation.

Parameters	ode45	ode23	ode113	ode15s	ode23s	ode23t	ode23tb
RelTol, AbsTol, NormControl	√	√	√	√	√	√	√
OutputFcn, OutputSel, Refine, Stats	√	√	√	√	√	√	√
NonNegative	√	√	√	√ *	—	√ *	√ *
Events	√	√	√	√	√	√	√
MaxStep, InitialStep	√	√	√	√	√	√	√

Parameters	ode45	ode23	ode113	ode15s	ode23s	ode23t	ode23tb
Jacobian, JPattern, Vectorized	—	—	—	√	√	√	√
Mass	√	√	√	√	√	√	√
MStateDependence	√	√	√	√	—	√	√
MvPattern	—	—	—	√	—	√	√
MassSingular	—	—	—	√	—	√	—
InitialSlope	—	—	—	√	—	√	—
MaxOrder, BDF	—	—	—	√	—	—	—

---

**Note** You can use the `NonNegative` parameter with `ode15s`, `ode23t`, and `ode23tb` only for those problems for which there is no mass matrix.

---

## Examples

### Example 1

An example of a nonstiff system is the system of equations describing the motion of a rigid body without external forces.

$$\begin{aligned}
 y_1' &= y_2 y_3 & y_1(0) &= 0 \\
 y_2' &= -y_1 y_3 & y_2(0) &= 1 \\
 y_3' &= -0.51 y_1 y_2 & y_3(0) &= 1
 \end{aligned}$$

To simulate this system, create a function `rigid` containing the equations

```
function dy = rigid(t,y)
dy = zeros(3,1); % a column vector
dy(1) = y(2) * y(3);
dy(2) = -y(1) * y(3);
dy(3) = -0.51 * y(1) * y(2);
```

In this example we change the error tolerances using the `odeset` command and solve on a time interval `[0 12]` with an initial condition vector `[0 1 1]` at time `0`.

```
options = odeset('RelTol',1e-4,'AbsTol',[1e-4 1e-4 1e-5]);
[T,Y] = ode45(@rigid,[0 12],[0 1 1],options);
```

Plotting the columns of the returned array Y versus T shows the solution

```
plot(T,Y(:,1),'-',T,Y(:,2),'-.',T,Y(:,3),'-.')
```

## Example 2

An example of a stiff system is provided by the van der Pol equations in relaxation oscillation. The limit cycle has portions where the solution components change slowly and the problem is quite stiff, alternating with regions of very sharp change where it is not stiff.

$$\begin{aligned}y_1' &= y_2 & y_1(0) &= 2 \\y_2' &= 1000(1 - y_1^2)y_2 - y_1 & y_2(0) &= 0\end{aligned}$$

To simulate this system, create a function `vdp1000` containing the equations

```
function dy = vdp1000(t,y)
dy = zeros(2,1); % a column vector
dy(1) = y(2);
dy(2) = 1000*(1 - y(1)^2)*y(2) - y(1);
```

For this problem, we will use the default relative and absolute tolerances ( $1e-3$  and  $1e-6$ , respectively) and solve on a time interval of `[0 3000]` with initial condition vector `[2 0]` at time 0.

```
[T,Y] = ode15s(@vdp1000,[0 3000],[2 0]);
```

Plotting the first column of the returned matrix `Y` versus `T` shows the solution

```
plot(T,Y(:,1),'-o')
```

### Example 3

This example solves an ordinary differential equation with time-dependent terms.

Consider the following ODE, with time-dependent parameters defined only through the set of data points given in two vectors:

$$y'(t) + f(t)y(t) = g(t)$$

The initial condition is  $y(1) = 1$ , where the function  $f(t)$  is defined by the  $n$ -by-1 vector  $f$  evaluated at times  $ft$ , and the function  $g(t)$  is defined by the  $m$ -by-1 vector  $g$  evaluated at times  $gt$ .

First, define the time-dependent parameters  $f(t)$  and  $g(t)$  as the following:

```
ft = linspace(0,5,25); % Generate t for f
f = ft.^2 - ft - 3; % Generate f(t)
gt = linspace(1,6,25); % Generate t for g
g = 3*sin(gt-0.25); % Generate g(t)
```

Write a function to interpolate the data sets specified above to obtain the value of the time-dependent terms at the specified time:

```
function dydt = myode(t,y,ft,f,gt,g)
f = interp1(ft,f,t); % Interpolate the data set (ft,f) at time t
g = interp1(gt,g,t); % Interpolate the data set (gt,g) at time t
dydt = -f.*y + g; % Evaluate ODE at time t
```

Call the derivative function `myode.m` within the MATLAB `ode45` function specifying time as the first input argument :

```
Tspan = [1 5]; % Solve from t=1 to t=5
IC = 1; % y(t=1) = 1
[T Y] = ode45(@(t,y) myode(t,y,ft,f,gt,g),Tspan,IC); % Solve ODE
Plot the solution y (t) as a function of time:
```

```
plot(T, Y);
title('Plot of y as a function of time');
xlabel('Time');
ylabel('Y(t)');
```

## More About

### Algorithms

`ode45` is based on an explicit Runge-Kutta (4,5) formula, the Dormand-Prince pair. It is a *one-step* solver – in computing  $y(t_n)$ , it needs only the solution at the immediately preceding time point,  $y(t_{n-1})$ . In general, `ode45` is the best function to apply as a *first try* for most problems. [3]

`ode23` is an implementation of an explicit Runge-Kutta (2,3) pair of Bogacki and Shampine. It may be more efficient than `ode45` at crude tolerances and in the presence of moderate stiffness. Like `ode45`, `ode23` is a one-step solver. [2]

**ode113** is a variable order Adams-Bashforth-Moulton PECE solver. It may be more efficient than **ode45** at stringent tolerances and when the ODE file function is particularly expensive to evaluate. **ode113** is a *multistep* solver — it normally needs the solutions at several preceding time points to compute the current solution. [7]

The above algorithms are intended to solve nonstiff systems. If they appear to be unduly slow, try using one of the stiff solvers below.

**ode15s** is a variable order solver based on the numerical differentiation formulas (NDFs). Optionally, it uses the backward differentiation formulas (BDFs, also known as Gear's method) that are usually less efficient. Like **ode113**, **ode15s** is a multistep solver. Try **ode15s** when **ode45** fails, or is very inefficient, and you suspect that the problem is stiff, or when solving a differential-algebraic problem. [9], [10]

**ode23s** is based on a modified Rosenbrock formula of order 2. Because it is a one-step solver, it may be more efficient than **ode15s** at crude tolerances. It can solve some kinds of stiff problems for which **ode15s** is not effective. [9]

**ode23t** is an implementation of the trapezoidal rule using a “free” interpolant. Use this solver if the problem is only moderately stiff and you need a solution without numerical damping. **ode23t** can solve DAEs. [10]

**ode23tb** is an implementation of TR-BDF2, an implicit Runge-Kutta formula with a first stage that is a trapezoidal rule step and a second stage that is a backward differentiation formula of order two. By construction, the same iteration matrix is used in evaluating both stages. Like **ode23s**, this solver may be more efficient than **ode15s** at crude tolerances. [8], [1]

## ode45

Solve nonstiff differential equations; medium order method

### Syntax

```
[T,Y] = solver(odefun,tspan,y0)
[T,Y] = solver(odefun,tspan,y0,options)
[T,Y,TE,YE,IE] = solver(odefun,tspan,y0,options)
sol = solver(odefun,[t0 tf],y0...)
```

This page contains an overview of the solver functions: `ode23`, `ode45`, `ode113`, `ode15s`, `ode23s`, `ode23t`, and `ode23tb`. You can call any of these solvers by substituting the placeholder, `solver`, with any of the function names.

### Arguments

The following table describes the input arguments to the solvers.

<code>odefun</code>	A function handle that evaluates the right side of the differential equations. All solvers solve systems of equations in the form $y' = f(t,y)$ or problems that involve a mass matrix, $M(t,y)y' = f(t,y)$ . The <code>ode23s</code> solver can solve only equations with constant mass matrices. <code>ode15s</code> and <code>ode23t</code> can solve problems with a mass matrix that is singular, i.e., differential-algebraic equations (DAEs).
<code>tspan</code>	A vector specifying the interval of integration, <code>[t0,tf]</code> . The solver imposes the initial conditions at <code>tspan(1)</code> , and integrates from <code>tspan(1)</code> to <code>tspan(end)</code> . To obtain solutions at specific times (all increasing or all decreasing), use <code>tspan = [t0,t1,...,tf]</code> .  For <code>tspan</code> vectors with two elements <code>[t0 tf]</code> , the solver returns the solution evaluated at every integration step. For <code>tspan</code> vectors with more than two elements, the solver returns solutions evaluated at the given time points. The time values must be in order, either increasing or decreasing.

	<p>Specifying <code>tspan</code> with more than two elements does not affect the internal time steps that the solver uses to traverse the interval from <code>tspan(1)</code> to <code>tspan(end)</code>. All solvers in the ODE suite obtain output values by means of continuous extensions of the basic formulas. Although a solver does not necessarily step precisely to a time point specified in <code>tspan</code>, the solutions produced at the specified time points are of the same order of accuracy as the solutions computed at the internal time points.</p> <p>Specifying <code>tspan</code> with more than two elements has little effect on the efficiency of computation, but for large systems, affects memory management.</p>
<code>y0</code>	A vector of initial conditions.
<code>options</code>	<p>Structure of optional parameters that change the default integration properties. This is the fourth input argument.</p> <p><code>[t,y] = solver(odefun,tspan,y0,options)</code></p> <p>You can create options using the <code>odeset</code> function. See <code>odeset</code> for details.</p>

The following table lists the output arguments for the solvers.

<code>T</code>	Column vector of time points.
<code>Y</code>	Solution array. Each row in <code>Y</code> corresponds to the solution at a time returned in the corresponding row of <code>T</code> .
<code>TE</code>	The time at which an event occurs.
<code>YE</code>	The solution at the time of the event.
<code>IE</code>	The index <code>i</code> of the event function that vanishes.
<code>sol</code>	Structure to evaluate the solution.

## Description

`[T,Y] = solver(odefun,tspan,y0)` with `tspan = [t0 tf]` integrates the system of differential equations  $y' = f(t,y)$  from time `t0` to `tf` with initial conditions `y0`. The first

input argument, `odefun`, is a function handle. The function, `f = odefun(t,y)`, for a scalar `t` and a column vector `y`, must return a column vector `f` corresponding to  $f(t,y)$ . Each row in the solution array `Y` corresponds to a time returned in column vector `T`. To obtain solutions at the specific times `t0, t1, ..., tf` (all increasing or all decreasing), use `tspan = [t0,t1, ..., tf]`.

“Parameterizing Functions” explains how to provide additional parameters to the function `fun`, if necessary.

`[T,Y] = solver(odefun,tspan,y0,options)` solves as above with default integration parameters replaced by property values specified in `options`, an argument created with the `odeset` function. Commonly used properties include a scalar relative error tolerance `RelTol` (`1e-3` by default) and a vector of absolute error tolerances `Abstol` (all components are `1e-6` by default). If certain components of the solution must be nonnegative, use the `odeset` function to set the `NonNegative` property to the indices of these components. See `odeset` for details.

`[T,Y,TE,YE,IE] = solver(odefun,tspan,y0,options)` solves as above while also finding where functions of  $(t,y)$ , called event functions, are zero. For each event function, you specify whether the integration is to terminate at a zero and whether the direction of the zero crossing matters. Do this by setting the 'Events' property to a function, e.g., `events` or `@events`, and creating a function `[value,isterminal,direction] = events(t,y)`. For the `i`th event function in `events`,

- `value(i)` is the value of the function.
- `isterminal(i) = 1`, if the integration is to terminate at a zero of this event function and `0` otherwise.
- `direction(i) = 0` if all zeros are to be computed (the default), `+1` if only the zeros where the event function increases, and `-1` if only the zeros where the event function decreases.

Corresponding entries in `TE`, `YE`, and `IE` return, respectively, the time at which an event occurs, the solution at the time of the event, and the index `i` of the event function that vanishes.

`sol = solver(odefun,[t0 tf],y0...)` returns a structure that you can use with `deval` to evaluate the solution at any point on the interval `[t0,tf]`. You must pass `odefun` as a function handle. The structure `sol` always includes these fields:

<code>sol.x</code>	Steps chosen by the solver.
--------------------	-----------------------------

<code>sol.y</code>	Each column <code>sol.y(:,i)</code> contains the solution at <code>sol.x(i)</code> .
<code>sol.solver</code>	Solver name.

If you specify the `Events` option and events are detected, `sol` also includes these fields:

<code>sol.xe</code>	Points at which events, if any, occurred. <code>sol.xe(end)</code> contains the exact point of a terminal event, if any.
<code>sol.ye</code>	Solutions that correspond to events in <code>sol.xe</code> .
<code>sol.ie</code>	Indices into the vector returned by the function specified in the <code>Events</code> option. The values indicate which event the solver detected.

If you specify an output function as the value of the `OutputFcn` property, the solver calls it with the computed solution after each time step. Four output functions are provided: `odeplot`, `odephas2`, `odephas3`, `odeprint`. When you call the solver with no output arguments, it calls the default `odeplot` to plot the solution as it is computed. `odephas2` and `odephas3` produce two- and three-dimensional phase plane plots, respectively. `odeprint` displays the solution components on the screen. By default, the ODE solver passes all components of the solution to the output function. You can pass only specific components by providing a vector of indices as the value of the `OutputSel` property. For example, if you call the solver with no output arguments and set the value of `OutputSel` to `[1,3]`, the solver plots solution components 1 and 3 as they are computed.

For the stiff solvers `ode15s`, `ode23s`, `ode23t`, and `ode23tb`, the Jacobian matrix  $\partial f/\partial y$  is critical to reliability and efficiency. Use `odeset` to set `Jacobian` to `@FJAC` if `FJAC(T,Y)` returns the Jacobian  $\partial f/\partial y$  or to the matrix  $\partial f/\partial y$  if the Jacobian is constant. If the `Jacobian` property is not set (the default),  $\partial f/\partial y$  is approximated by finite differences. Set the `Vectorized` property 'on' if the ODE function is coded so that `odefun(T,[Y1,Y2 ...])` returns `[odefun(T,Y1),odefun(T,Y2),...]`. If  $\partial f/\partial y$  is a sparse matrix, set the `JPattern` property to the sparsity pattern of  $\partial f/\partial y$ , i.e., a sparse matrix `S` with `S(i,j) = 1` if the *i*th component of  $f(t,y)$  depends on the *j*th component of  $y$ , and 0 otherwise.

The solvers of the ODE suite can solve problems of the form  $M(t,y)y' = f(t,y)$ , with time- and state-dependent mass matrix  $M$ . (The `ode23s` solver can solve only equations with constant mass matrices.) If a problem has a mass matrix, create a function `M = MASS(t,y)` that returns the value of the mass matrix, and use `odeset` to set the `Mass` property to `@MASS`. If the mass matrix is constant, the matrix should be used as the value of the `Mass` property. Problems with state-dependent mass matrices are more difficult:

- If the mass matrix does not depend on the state variable  $y$  and the function `MASS` is to be called with one input argument,  $t$ , set the `MStateDependence` property to 'none'.
- If the mass matrix depends weakly on  $y$ , set `MStateDependence` to 'weak' (the default); otherwise, set it to 'strong'. In either case, the function `MASS` is called with the two arguments  $(t,y)$ .

If there are many differential equations, it is important to exploit sparsity:

- Return a sparse  $M(t,y)$ .
- Supply the sparsity pattern of  $\partial f/\partial y$  using the `JPattern` property or a sparse  $\partial f/\partial y$  using the `Jacobian` property.
- For strongly state-dependent  $M(t,y)$ , set `MvPattern` to a sparse matrix  $S$  with  $S(i, j) = 1$  if for any  $k$ , the  $(i, k)$  component of  $M(t,y)$  depends on component  $j$  of  $y$ , and  $0$  otherwise.

If the mass matrix  $M$  is singular, then  $M(t,y)y' = f(t,y)$  is a system of differential algebraic equations. DAEs have solutions only when  $y_0$  is consistent, that is, if there is a vector  $yp_0$  such that  $M(t_0,y_0)yp_0 = f(t_0,y_0)$ . The `ode15s` and `ode23t` solvers can solve DAEs of index 1 provided that  $y_0$  is sufficiently close to being consistent. If there is a mass matrix, you can use `odeset` to set the `MassSingular` property to 'yes', 'no', or 'maybe'. The default value of 'maybe' causes the solver to test whether the problem is a DAE. You can provide  $yp_0$  as the value of the `InitialSlope` property. The default is the zero vector. If a problem is a DAE, and  $y_0$  and  $yp_0$  are not consistent, the solver treats them as guesses, attempts to compute consistent values that are close to the guesses, and continues to solve the problem. When solving DAEs, it is very advantageous to formulate the problem so that  $M$  is a diagonal matrix (a semi-explicit DAE).

Solver	Problem Type	Order of Accuracy	When to Use
ode45	Nonstiff	Medium	Most of the time. This should be the first solver you try.
ode23	Nonstiff	Low	For problems with crude error tolerances or for solving moderately stiff problems.
ode113	Nonstiff	Low to high	For problems with stringent error tolerances or for solving computationally intensive problems.

Solver	Problem Type	Order of Accuracy	When to Use
ode15s	Stiff	Low to medium	If ode45 is slow because the problem is stiff.
ode23s	Stiff	Low	If using crude error tolerances to solve stiff systems and the mass matrix is constant.
ode23t	Moderately Stiff	Low	For moderately stiff problems if you need a solution without numerical damping.
ode23tb	Stiff	Low	If using crude error tolerances to solve stiff systems.

The algorithms used in the ODE solvers vary according to order of accuracy [6] and the type of systems (stiff or nonstiff) they are designed to solve. See “Algorithms” on page 1-6159 for more details.

## Options

Different solvers accept different parameters in the options list. For more information, see `odeset` and “Integrator Options” in the MATLAB Mathematics documentation.

Parameters	ode45	ode23	ode113	ode15s	ode23s	ode23t	ode23tb
RelTol, AbsTol, NormControl	√	√	√	√	√	√	√
OutputFcn, OutputSel, Refine, Stats	√	√	√	√	√	√	√
NonNegative	√	√	√	√ *	—	√ *	√ *
Events	√	√	√	√	√	√	√
MaxStep, InitialStep	√	√	√	√	√	√	√

Parameters	ode45	ode23	ode113	ode15s	ode23s	ode23t	ode23tb
Jacobian, JPattern, Vectorized	—	—	—	√	√	√	√
Mass	√	√	√	√	√	√	√
MStateDependence	√	√	√	√	—	√	√
MvPattern	—	—	—	√	—	√	√
MassSingular	—	—	—	√	—	√	—
InitialSlope	—	—	—	√	—	√	—
MaxOrder, BDF	—	—	—	√	—	—	—

**Note** You can use the `NonNegative` parameter with `ode15s`, `ode23t`, and `ode23tb` only for those problems for which there is no mass matrix.

## Examples

### Example 1

An example of a nonstiff system is the system of equations describing the motion of a rigid body without external forces.

$$\begin{aligned}
 y_1' &= y_2 y_3 & y_1(0) &= 0 \\
 y_2' &= -y_1 y_3 & y_2(0) &= 1 \\
 y_3' &= -0.51 y_1 y_2 & y_3(0) &= 1
 \end{aligned}$$

To simulate this system, create a function `rigid` containing the equations

```
function dy = rigid(t,y)
dy = zeros(3,1); % a column vector
dy(1) = y(2) * y(3);
dy(2) = -y(1) * y(3);
dy(3) = -0.51 * y(1) * y(2);
```

In this example we change the error tolerances using the `odeset` command and solve on a time interval `[0 12]` with an initial condition vector `[0 1 1]` at time 0.

```
options = odeset('RelTol',1e-4,'AbsTol',[1e-4 1e-4 1e-5]);
[T,Y] = ode45(@rigid,[0 12],[0 1 1],options);
```

Plotting the columns of the returned array Y versus T shows the solution

```
plot(T,Y(:,1),'-',T,Y(:,2),'-.',T,Y(:,3),'-.')
```

## Example 2

An example of a stiff system is provided by the van der Pol equations in relaxation oscillation. The limit cycle has portions where the solution components change slowly and the problem is quite stiff, alternating with regions of very sharp change where it is not stiff.

$$\begin{aligned}y_1' &= y_2 & y_1(0) &= 2 \\y_2' &= 1000(1 - y_1^2)y_2 - y_1 & y_2(0) &= 0\end{aligned}$$

To simulate this system, create a function `vdp1000` containing the equations

```
function dy = vdp1000(t,y)
dy = zeros(2,1); % a column vector
dy(1) = y(2);
dy(2) = 1000*(1 - y(1)^2)*y(2) - y(1);
```

For this problem, we will use the default relative and absolute tolerances ( $1e-3$  and  $1e-6$ , respectively) and solve on a time interval of `[0 3000]` with initial condition vector `[2 0]` at time 0.

```
[T,Y] = ode15s(@vdp1000,[0 3000],[2 0]);
```

Plotting the first column of the returned matrix `Y` versus `T` shows the solution

```
plot(T,Y(:,1),'-o')
```

### Example 3

This example solves an ordinary differential equation with time-dependent terms.

Consider the following ODE, with time-dependent parameters defined only through the set of data points given in two vectors:

$$y'(t) + f(t)y(t) = g(t)$$

The initial condition is  $y(1) = 1$ , where the function  $f(t)$  is defined by the  $n$ -by-1 vector  $f$  evaluated at times  $ft$ , and the function  $g(t)$  is defined by the  $m$ -by-1 vector  $g$  evaluated at times  $gt$ .

First, define the time-dependent parameters  $f(t)$  and  $g(t)$  as the following:

```
ft = linspace(0,5,25); % Generate t for f
f = ft.^2 - ft - 3; % Generate f(t)
gt = linspace(1,6,25); % Generate t for g
g = 3*sin(gt-0.25); % Generate g(t)
```

Write a function to interpolate the data sets specified above to obtain the value of the time-dependent terms at the specified time:

```
function dydt = myode(t,y,ft,f,gt,g)
f = interp1(ft,f,t); % Interpolate the data set (ft,f) at time t
g = interp1(gt,g,t); % Interpolate the data set (gt,g) at time t
dydt = -f.*y + g; % Evaluate ODE at time t
```

Call the derivative function `myode.m` within the MATLAB `ode45` function specifying time as the first input argument :

```
Tspan = [1 5]; % Solve from t=1 to t=5
IC = 1; % y(t=1) = 1
[T Y] = ode45(@(t,y) myode(t,y,ft,f,gt,g),Tspan,IC); % Solve ODE
Plot the solution y (t) as a function of time:

## More About

### Algorithms

`ode45` is based on an explicit Runge-Kutta (4,5) formula, the Dormand-Prince pair. It is a *one-step* solver – in computing  $y(t_n)$ , it needs only the solution at the immediately preceding time point,  $y(t_{n-1})$ . In general, `ode45` is the best function to apply as a *first try* for most problems. [3]

`ode23` is an implementation of an explicit Runge-Kutta (2,3) pair of Bogacki and Shampine. It may be more efficient than `ode45` at crude tolerances and in the presence of moderate stiffness. Like `ode45`, `ode23` is a one-step solver. [2]

`ode113` is a variable order Adams-Bashforth-Moulton PECE solver. It may be more efficient than `ode45` at stringent tolerances and when the ODE file function is particularly expensive to evaluate. `ode113` is a *multistep* solver — it normally needs the solutions at several preceding time points to compute the current solution. [7]

The above algorithms are intended to solve nonstiff systems. If they appear to be unduly slow, try using one of the stiff solvers below.

`ode15s` is a variable order solver based on the numerical differentiation formulas (NDFs). Optionally, it uses the backward differentiation formulas (BDFs, also known as Gear's method) that are usually less efficient. Like `ode113`, `ode15s` is a multistep solver. Try `ode15s` when `ode45` fails, or is very inefficient, and you suspect that the problem is stiff, or when solving a differential-algebraic problem. [9], [10]

`ode23s` is based on a modified Rosenbrock formula of order 2. Because it is a one-step solver, it may be more efficient than `ode15s` at crude tolerances. It can solve some kinds of stiff problems for which `ode15s` is not effective. [9]

`ode23t` is an implementation of the trapezoidal rule using a “free” interpolant. Use this solver if the problem is only moderately stiff and you need a solution without numerical damping. `ode23t` can solve DAEs. [10]

`ode23tb` is an implementation of TR-BDF2, an implicit Runge-Kutta formula with a first stage that is a trapezoidal rule step and a second stage that is a backward differentiation formula of order two. By construction, the same iteration matrix is used in evaluating both stages. Like `ode23s`, this solver may be more efficient than `ode15s` at crude tolerances. [8], [1]

## ode113

Solve nonstiff differential equations; variable order method

### Syntax

```
[T,Y] = solver(odefun,tspan,y0)
[T,Y] = solver(odefun,tspan,y0,options)
[T,Y,TE,YE,IE] = solver(odefun,tspan,y0,options)
sol = solver(odefun,[t0 tf],y0...)
```

This page contains an overview of the solver functions: `ode23`, `ode45`, `ode113`, `ode15s`, `ode23s`, `ode23t`, and `ode23tb`. You can call any of these solvers by substituting the placeholder, `solver`, with any of the function names.

### Arguments

The following table describes the input arguments to the solvers.

<code>odefun</code>	A function handle that evaluates the right side of the differential equations. All solvers solve systems of equations in the form $y' = f(t,y)$ or problems that involve a mass matrix, $M(t,y)y' = f(t,y)$ . The <code>ode23s</code> solver can solve only equations with constant mass matrices. <code>ode15s</code> and <code>ode23t</code> can solve problems with a mass matrix that is singular, i.e., differential-algebraic equations (DAEs).
<code>tspan</code>	<p>A vector specifying the interval of integration, <code>[t0,tf]</code>. The solver imposes the initial conditions at <code>tspan(1)</code>, and integrates from <code>tspan(1)</code> to <code>tspan(end)</code>. To obtain solutions at specific times (all increasing or all decreasing), use <code>tspan = [t0,t1,...,tf]</code>.</p> <p>For <code>tspan</code> vectors with two elements <code>[t0 tf]</code>, the solver returns the solution evaluated at every integration step. For <code>tspan</code> vectors with more than two elements, the solver returns solutions evaluated at the given time points. The time values must be in order, either increasing or decreasing.</p>

	<p>Specifying <code>tspan</code> with more than two elements does not affect the internal time steps that the solver uses to traverse the interval from <code>tspan(1)</code> to <code>tspan(end)</code>. All solvers in the ODE suite obtain output values by means of continuous extensions of the basic formulas. Although a solver does not necessarily step precisely to a time point specified in <code>tspan</code>, the solutions produced at the specified time points are of the same order of accuracy as the solutions computed at the internal time points.</p> <p>Specifying <code>tspan</code> with more than two elements has little effect on the efficiency of computation, but for large systems, affects memory management.</p>
<code>y0</code>	A vector of initial conditions.
<code>options</code>	<p>Structure of optional parameters that change the default integration properties. This is the fourth input argument.</p> <p><code>[t,y] = solver(odefun,tspan,y0,options)</code></p> <p>You can create options using the <code>odeset</code> function. See <code>odeset</code> for details.</p>

The following table lists the output arguments for the solvers.

<code>T</code>	Column vector of time points.
<code>Y</code>	Solution array. Each row in <code>Y</code> corresponds to the solution at a time returned in the corresponding row of <code>T</code> .
<code>TE</code>	The time at which an event occurs.
<code>YE</code>	The solution at the time of the event.
<code>IE</code>	The index <code>i</code> of the event function that vanishes.
<code>sol</code>	Structure to evaluate the solution.

## Description

`[T,Y] = solver(odefun,tspan,y0)` with `tspan = [t0 tf]` integrates the system of differential equations  $y' = f(t,y)$  from time `t0` to `tf` with initial conditions `y0`. The first

input argument, `odefun`, is a function handle. The function,  $f = \text{odefun}(t, y)$ , for a scalar  $t$  and a column vector  $y$ , must return a column vector  $f$  corresponding to  $f(t, y)$ . Each row in the solution array  $Y$  corresponds to a time returned in column vector  $T$ . To obtain solutions at the specific times  $t_0, t_1, \dots, t_f$  (all increasing or all decreasing), use `tspan = [t0, t1, ..., tf]`.

“Parameterizing Functions” explains how to provide additional parameters to the function `fun`, if necessary.

`[T, Y] = solver(odefun, tspan, y0, options)` solves as above with default integration parameters replaced by property values specified in `options`, an argument created with the `odeset` function. Commonly used properties include a scalar relative error tolerance `RelTol` ( $1e-3$  by default) and a vector of absolute error tolerances `Abstol` (all components are  $1e-6$  by default). If certain components of the solution must be nonnegative, use the `odeset` function to set the `NonNegative` property to the indices of these components. See `odeset` for details.

`[T, Y, TE, YE, IE] = solver(odefun, tspan, y0, options)` solves as above while also finding where functions of  $(t, y)$ , called event functions, are zero. For each event function, you specify whether the integration is to terminate at a zero and whether the direction of the zero crossing matters. Do this by setting the 'Events' property to a function, e.g., `events` or `@events`, and creating a function `[value, isterminal, direction] = events(t, y)`. For the  $i$ th event function in `events`,

- `value(i)` is the value of the function.
- `isterminal(i) = 1`, if the integration is to terminate at a zero of this event function and 0 otherwise.
- `direction(i) = 0` if all zeros are to be computed (the default), +1 if only the zeros where the event function increases, and -1 if only the zeros where the event function decreases.

Corresponding entries in `TE`, `YE`, and `IE` return, respectively, the time at which an event occurs, the solution at the time of the event, and the index  $i$  of the event function that vanishes.

`sol = solver(odefun, [t0 tf], y0...)` returns a structure that you can use with `deval` to evaluate the solution at any point on the interval `[t0, tf]`. You must pass `odefun` as a function handle. The structure `sol` always includes these fields:

<code>sol.x</code>	Steps chosen by the solver.
--------------------	-----------------------------

<code>sol.y</code>	Each column <code>sol.y(:,i)</code> contains the solution at <code>sol.x(i)</code> .
<code>sol.solver</code>	Solver name.

If you specify the `Events` option and events are detected, `sol` also includes these fields:

<code>sol.xe</code>	Points at which events, if any, occurred. <code>sol.xe(end)</code> contains the exact point of a terminal event, if any.
<code>sol.ye</code>	Solutions that correspond to events in <code>sol.xe</code> .
<code>sol.ie</code>	Indices into the vector returned by the function specified in the <code>Events</code> option. The values indicate which event the solver detected.

If you specify an output function as the value of the `OutputFcn` property, the solver calls it with the computed solution after each time step. Four output functions are provided: `odeplot`, `odephas2`, `odephas3`, `odeprint`. When you call the solver with no output arguments, it calls the default `odeplot` to plot the solution as it is computed. `odephas2` and `odephas3` produce two- and three-dimensional phase plane plots, respectively. `odeprint` displays the solution components on the screen. By default, the ODE solver passes all components of the solution to the output function. You can pass only specific components by providing a vector of indices as the value of the `OutputSel` property. For example, if you call the solver with no output arguments and set the value of `OutputSel` to `[1,3]`, the solver plots solution components 1 and 3 as they are computed.

For the stiff solvers `ode15s`, `ode23s`, `ode23t`, and `ode23tb`, the Jacobian matrix  $\partial f/\partial y$  is critical to reliability and efficiency. Use `odeset` to set `Jacobian` to `@FJAC` if `FJAC(T,Y)` returns the Jacobian  $\partial f/\partial y$  or to the matrix  $\partial f/\partial y$  if the Jacobian is constant. If the `Jacobian` property is not set (the default),  $\partial f/\partial y$  is approximated by finite differences. Set the `Vectorized` property 'on' if the ODE function is coded so that `odefun(T,[Y1,Y2 ...])` returns `[odefun(T,Y1),odefun(T,Y2),...]`. If  $\partial f/\partial y$  is a sparse matrix, set the `JPattern` property to the sparsity pattern of  $\partial f/\partial y$ , i.e., a sparse matrix `S` with `S(i,j) = 1` if the *i*th component of  $f(t,y)$  depends on the *j*th component of  $y$ , and 0 otherwise.

The solvers of the ODE suite can solve problems of the form  $M(t,y)y' = f(t,y)$ , with time- and state-dependent mass matrix  $M$ . (The `ode23s` solver can solve only equations with constant mass matrices.) If a problem has a mass matrix, create a function `M = MASS(t,y)` that returns the value of the mass matrix, and use `odeset` to set the `Mass` property to `@MASS`. If the mass matrix is constant, the matrix should be used as the value of the `Mass` property. Problems with state-dependent mass matrices are more difficult:

- If the mass matrix does not depend on the state variable  $y$  and the function `MASS` is to be called with one input argument,  $t$ , set the `MStateDependence` property to 'none'.
- If the mass matrix depends weakly on  $y$ , set `MStateDependence` to 'weak' (the default); otherwise, set it to 'strong'. In either case, the function `MASS` is called with the two arguments  $(t,y)$ .

If there are many differential equations, it is important to exploit sparsity:

- Return a sparse  $M(t,y)$ .
- Supply the sparsity pattern of  $\partial f/\partial y$  using the `JPattern` property or a sparse  $\partial f/\partial y$  using the `Jacobian` property.
- For strongly state-dependent  $M(t,y)$ , set `MvPattern` to a sparse matrix  $S$  with  $S(i,j) = 1$  if for any  $k$ , the  $(i,k)$  component of  $M(t,y)$  depends on component  $j$  of  $y$ , and  $0$  otherwise.

If the mass matrix  $M$  is singular, then  $M(t,y)y' = f(t,y)$  is a system of differential algebraic equations. DAEs have solutions only when  $y_0$  is consistent, that is, if there is a vector  $yp_0$  such that  $M(t_0,y_0)yp_0 = f(t_0,y_0)$ . The `ode15s` and `ode23t` solvers can solve DAEs of index 1 provided that  $y_0$  is sufficiently close to being consistent. If there is a mass matrix, you can use `odeset` to set the `MassSingular` property to 'yes', 'no', or 'maybe'. The default value of 'maybe' causes the solver to test whether the problem is a DAE. You can provide  $yp_0$  as the value of the `InitialSlope` property. The default is the zero vector. If a problem is a DAE, and  $y_0$  and  $yp_0$  are not consistent, the solver treats them as guesses, attempts to compute consistent values that are close to the guesses, and continues to solve the problem. When solving DAEs, it is very advantageous to formulate the problem so that  $M$  is a diagonal matrix (a semi-explicit DAE).

Solver	Problem Type	Order of Accuracy	When to Use
ode45	Nonstiff	Medium	Most of the time. This should be the first solver you try.
ode23	Nonstiff	Low	For problems with crude error tolerances or for solving moderately stiff problems.
ode113	Nonstiff	Low to high	For problems with stringent error tolerances or for solving computationally intensive problems.

Solver	Problem Type	Order of Accuracy	When to Use
ode15s	Stiff	Low to medium	If ode45 is slow because the problem is stiff.
ode23s	Stiff	Low	If using crude error tolerances to solve stiff systems and the mass matrix is constant.
ode23t	Moderately Stiff	Low	For moderately stiff problems if you need a solution without numerical damping.
ode23tb	Stiff	Low	If using crude error tolerances to solve stiff systems.

The algorithms used in the ODE solvers vary according to order of accuracy [6] and the type of systems (stiff or nonstiff) they are designed to solve. See “Algorithms” on page 1-6173 for more details.

## Options

Different solvers accept different parameters in the options list. For more information, see `odeset` and “Integrator Options” in the MATLAB Mathematics documentation.

Parameters	ode45	ode23	ode113	ode15s	ode23s	ode23t	ode23tb
RelTol, AbsTol, NormControl	√	√	√	√	√	√	√
OutputFcn, OutputSel, Refine, Stats	√	√	√	√	√	√	√
NonNegative	√	√	√	√ *	—	√ *	√ *
Events	√	√	√	√	√	√	√
MaxStep, InitialStep	√	√	√	√	√	√	√

Parameters	ode45	ode23	ode113	ode15s	ode23s	ode23t	ode23tb
Jacobian, JPattern, Vectorized	—	—	—	√	√	√	√
Mass	√	√	√	√	√	√	√
MStateDependence	√	√	√	√	—	√	√
MvPattern	—	—	—	√	—	√	√
MassSingular	—	—	—	√	—	√	—
InitialSlope	—	—	—	√	—	√	—
MaxOrder, BDF	—	—	—	√	—	—	—

---

**Note** You can use the `NonNegative` parameter with `ode15s`, `ode23t`, and `ode23tb` only for those problems for which there is no mass matrix.

---

## Examples

### Example 1

An example of a nonstiff system is the system of equations describing the motion of a rigid body without external forces.

$$\begin{aligned}
 y_1' &= y_2 y_3 & y_1(0) &= 0 \\
 y_2' &= -y_1 y_3 & y_2(0) &= 1 \\
 y_3' &= -0.51 y_1 y_2 & y_3(0) &= 1
 \end{aligned}$$

To simulate this system, create a function `rigid` containing the equations

```
function dy = rigid(t,y)
dy = zeros(3,1); % a column vector
dy(1) = y(2) * y(3);
dy(2) = -y(1) * y(3);
dy(3) = -0.51 * y(1) * y(2);
```

In this example we change the error tolerances using the `odeset` command and solve on a time interval `[0 12]` with an initial condition vector `[0 1 1]` at time `0`.

```
options = odeset('RelTol',1e-4,'AbsTol',[1e-4 1e-4 1e-5]);
[T,Y] = ode45(@rigid,[0 12],[0 1 1],options);
```

Plotting the columns of the returned array Y versus T shows the solution

```
plot(T,Y(:,1),'-',T,Y(:,2),'-.',T,Y(:,3),'-.')
```

## Example 2

An example of a stiff system is provided by the van der Pol equations in relaxation oscillation. The limit cycle has portions where the solution components change slowly and the problem is quite stiff, alternating with regions of very sharp change where it is not stiff.

$$\begin{aligned}y_1' &= y_2 & y_1(0) &= 2 \\y_2' &= 1000(1 - y_1^2)y_2 - y_1 & y_2(0) &= 0\end{aligned}$$

To simulate this system, create a function `vdp1000` containing the equations

```
function dy = vdp1000(t,y)
dy = zeros(2,1); % a column vector
dy(1) = y(2);
dy(2) = 1000*(1 - y(1)^2)*y(2) - y(1);
```

For this problem, we will use the default relative and absolute tolerances ( $1e-3$  and  $1e-6$ , respectively) and solve on a time interval of `[0 3000]` with initial condition vector `[2 0]` at time 0.

```
[T,Y] = ode15s(@vdp1000,[0 3000],[2 0]);
```

Plotting the first column of the returned matrix `Y` versus `T` shows the solution

```
plot(T,Y(:,1),'-o')
```

### Example 3

This example solves an ordinary differential equation with time-dependent terms.

Consider the following ODE, with time-dependent parameters defined only through the set of data points given in two vectors:

$$y'(t) + f(t)y(t) = g(t)$$

The initial condition is  $y(1) = 1$ , where the function  $f(t)$  is defined by the  $n$ -by-1 vector  $f$  evaluated at times  $ft$ , and the function  $g(t)$  is defined by the  $m$ -by-1 vector  $g$  evaluated at times  $gt$ .

First, define the time-dependent parameters  $f(t)$  and  $g(t)$  as the following:

```
ft = linspace(0,5,25); % Generate t for f
f = ft.^2 - ft - 3; % Generate f(t)
gt = linspace(1,6,25); % Generate t for g
g = 3*sin(gt-0.25); % Generate g(t)
```

Write a function to interpolate the data sets specified above to obtain the value of the time-dependent terms at the specified time:

```
function dydt = myode(t,y,ft,f,gt,g)
f = interp1(ft,f,t); % Interpolate the data set (ft,f) at time t
g = interp1(gt,g,t); % Interpolate the data set (gt,g) at time t
dydt = -f.*y + g; % Evaluate ODE at time t
```

Call the derivative function `myode.m` within the MATLAB `ode45` function specifying time as the first input argument :

```
Tspan = [1 5]; % Solve from t=1 to t=5
IC = 1; % y(t=1) = 1
[T Y] = ode45(@(t,y) myode(t,y,ft,f,gt,g),Tspan,IC); % Solve ODE
Plot the solution y (t) as a function of time:
```

```
plot(T, Y);
title('Plot of y as a function of time');
xlabel('Time');
ylabel('Y(t)');
```

## More About

### Algorithms

`ode45` is based on an explicit Runge-Kutta (4,5) formula, the Dormand-Prince pair. It is a *one-step* solver – in computing  $y(t_n)$ , it needs only the solution at the immediately preceding time point,  $y(t_{n-1})$ . In general, `ode45` is the best function to apply as a *first try* for most problems. [3]

`ode23` is an implementation of an explicit Runge-Kutta (2,3) pair of Bogacki and Shampine. It may be more efficient than `ode45` at crude tolerances and in the presence of moderate stiffness. Like `ode45`, `ode23` is a one-step solver. [2]

`ode113` is a variable order Adams-Bashforth-Moulton PECE solver. It may be more efficient than `ode45` at stringent tolerances and when the ODE file function is particularly expensive to evaluate. `ode113` is a *multistep* solver — it normally needs the solutions at several preceding time points to compute the current solution. [7]

The above algorithms are intended to solve nonstiff systems. If they appear to be unduly slow, try using one of the stiff solvers below.

`ode15s` is a variable order solver based on the numerical differentiation formulas (NDFs). Optionally, it uses the backward differentiation formulas (BDFs, also known as Gear's method) that are usually less efficient. Like `ode113`, `ode15s` is a multistep solver. Try `ode15s` when `ode45` fails, or is very inefficient, and you suspect that the problem is stiff, or when solving a differential-algebraic problem. [9], [10]

`ode23s` is based on a modified Rosenbrock formula of order 2. Because it is a one-step solver, it may be more efficient than `ode15s` at crude tolerances. It can solve some kinds of stiff problems for which `ode15s` is not effective. [9]

`ode23t` is an implementation of the trapezoidal rule using a “free” interpolant. Use this solver if the problem is only moderately stiff and you need a solution without numerical damping. `ode23t` can solve DAEs. [10]

`ode23tb` is an implementation of TR-BDF2, an implicit Runge-Kutta formula with a first stage that is a trapezoidal rule step and a second stage that is a backward differentiation formula of order two. By construction, the same iteration matrix is used in evaluating both stages. Like `ode23s`, this solver may be more efficient than `ode15s` at crude tolerances. [8], [1]

## odeget

Ordinary differential equation options parameters

### Syntax

```
o = odeget(options,'name')
o = odeget(options,'name',default)
```

### Description

`o = odeget(options,'name')` extracts the value of the property specified by string 'name' from integrator options structure `options`, returning an empty matrix if the property value is not specified in `options`. It is only necessary to type the leading characters that uniquely identify the property name. Case is ignored for property names.

`o = odeget(options,'name',default)` returns `o = default` if the named property is not specified in `options`.

The empty matrix `[]` is a valid `options` argument, and the syntax `odeget([], 'name', default)` always returns `default`.

### Examples

Having constructed an ODE options structure,

```
options = odeset('RelTol',1e-4,'AbsTol',[1e-3 2e-3 3e-3]);
```

you can view these property settings with `odeget`.

```
odeget(options,'RelTol')
ans =
```

```
1.0000e-04
```

```
odeget(options,'AbsTol')
ans =
```

0.0010    0.0020    0.0030

```
odeget([], 'RelTol', 1e-3)
ans =
```

1.0000e-03

options = odeset(olddopts,newopts)
odeset
```

### Description

The `odeset` function lets you adjust the integration parameters of the following ODE solvers.

For solving fully implicit differential equations:  
`ode15i`

For solving initial value problems:  
`ode23`, `ode45`, `ode113`, `ode15s`, `ode23s`, `ode23t`, `ode23tb`

See below for information about the integration parameters.

`options = odeset('name1',value1,'name2',value2,...)` creates an options structure that you can pass as an argument to any of the ODE solvers. In the resulting structure, `options`, the named properties have the specified values. For example, `'name1'` has the value `value1`. Any unspecified properties have default values. It is sufficient to type only the leading characters that uniquely identify a property name. Case is ignored for property names.

`options = odeset(olddopts,'name1',value1,...)` alters an existing options structure `olddopts`. This sets `options` equal to the existing structure `olddopts`, overwrites any values in `olddopts` that are respecified using name/value pairs, and adds any new pairs to the structure. The modified structure is returned as an output argument.

`options = odeset(oldopts,newopts)` alters an existing `options` structure `oldopts` by combining it with a new options structure `newopts`. Any new options not equal to the empty matrix overwrite corresponding options in `oldopts`.

`odeset` with no input arguments displays all property names as well as their possible and default values.

## ODE Properties

The following sections describe the properties that you can set using `odeset`. The available properties depend on the ODE solver you are using. There are several categories of properties:

- “Error Control Properties” on page 1-6179
- “Solver Output Properties” on page 1-6181
- “Step-Size Properties” on page 1-6184
- “Event Location Property” on page 1-6185
- “Jacobian Matrix Properties” on page 1-6186
- “Mass Matrix and DAE Properties” on page 1-6189
- “ode15s and ode15i-Specific Properties” on page 1-6191

---

**Note** This reference page describes the ODE properties for MATLAB, Version 7. The Version 5 properties are supported only for backward compatibility. For information on the Version 5 properties, type at the MATLAB command line: `more on`, `type odeset`, `more off`.

---

## Error Control Properties

At each step, the solver estimates the local error  $e$  in the  $i$ th component of the solution. This error must be less than or equal to the acceptable error, which is a function of the specified relative tolerance, `RelTol`, and the specified absolute tolerance, `AbsTol`.

$$|e(i)| \leq \max(\text{RelTol} * \text{abs}(y(i)), \text{AbsTol}(i))$$

For routine problems, the ODE solvers deliver accuracy roughly equivalent to the accuracy you request. They deliver less accuracy for problems integrated over "long" intervals and problems that are moderately unstable. Difficult problems may require

tighter tolerances than the default values. For relative accuracy, adjust **RelTol**. For the absolute error tolerance, the scaling of the solution components is important: if  $|y|$  is somewhat smaller than **AbsTol**, the solver is not constrained to obtain any correct digits in  $y$ . You might have to solve a problem more than once to discover the scale of solution components.

Roughly speaking, this means that you want **RelTol** correct digits in all solution components except those smaller than thresholds **AbsTol**( $i$ ). Even if you are not interested in a component  $y(i)$  when it is small, you may have to specify **AbsTol**( $i$ ) small enough to get some correct digits in  $y(i)$  so that you can accurately compute more interesting components.

The following table describes the error control properties. Further information on each property is given following the table.

Property	Value	Description
<b>RelTol</b>	Positive scalar {1e-3}	Relative error tolerance that applies to all components of the solution vector $y$ .
<b>AbsTol</b>	Positive scalar or vector {1e-6}	Absolute error tolerances that apply to the individual components of the solution vector.
<b>NormControl</b>	on   {off}	Control error relative to norm of solution.

## Description of Error Control Properties

**RelTol** — This tolerance is a measure of the error relative to the size of each solution component. Roughly, it controls the number of correct digits in all solution components, except those smaller than thresholds **AbsTol**( $i$ ).

The default,  $1e-3$ , corresponds to 0.1% accuracy.

**AbsTol** — **AbsTol**( $i$ ) is a threshold below which the value of the  $i$ th solution component is unimportant. The absolute error tolerances determine the accuracy when the solution approaches zero.

If **AbsTol** is a vector, the length of **AbsTol** must be the same as the length of the solution vector  $y$ . If **AbsTol** is a scalar, the value applies to all components of  $y$ .

**NormControl** — Set this property **on** to request that the solvers control the error in each integration step with  $\text{norm}(e) \leq \max(\text{RelTol} * \text{norm}(y), \text{AbsTol})$ . By default the solvers use a more stringent componentwise error control.

## Solver Output Properties

The following table lists the solver output properties that control the output that the solvers generate. Further information on each property is given following the table.

Property	Value	Description
NonNegative	Vector of integers	Specifies which components of the solution vector must be nonnegative. The default value is <code>[]</code> .
OutputFcn	Function handle	A function for the solver to call after every successful integration step.
OutputSel	Vector of indices	Specifies which components of the solution vector are to be passed to the output function.
Refine	Positive integer	Increases the number of output points by a factor of <code>Refine</code> .
Stats	on   {off}	Determines whether the solver should display statistics about its computations. By default, <code>Stats</code> is off.

### Description of Solver Output Properties

**NonNegative** — The `NonNegative` property is not available in `ode23s`, `ode15i`. In `ode15s`, `ode23t`, and `ode23tb`, `NonNegative` is not available for problems where there is a mass matrix.

**OutputFcn** — To specify an output function, set `'OutputFcn'` to a function handle. For example,

```
options = odeset('OutputFcn',@myfun)
```

sets `'OutputFcn'` to `@myfun`, a handle to the function `myfun`. See “Create Function Handle” for more information.

The output function must be of the form

```
status = myfun(t,y,flag)
```

“Parameterizing Functions” explains how to provide additional parameters to `myfun`, if necessary.

The solver calls the specified output function with the following flags. Note that the syntax of the call differs with the flag. The function must respond appropriately:

Flag	Description
<code>init</code>	The solver calls <code>myfun(tspan,y0,'init')</code> before beginning the integration to allow the output function to initialize. <code>tspan</code> and <code>y0</code> are the input arguments to the ODE solver.
<code>{[]}</code>	<p>The solver calls <code>status = myfun(t,y,[])</code> after each integration step on which output is requested. <code>t</code> contains points where output was generated during the step, and <code>y</code> is the numerical solution at the points in <code>t</code>. If <code>t</code> is a vector, the <code>i</code>th column of <code>y</code> corresponds to the <code>i</code>th element of <code>t</code>.</p> <p>When <code>length(tspan) &gt; 2</code> the output is produced at every point in <code>tspan</code>. When <code>length(tspan) = 2</code> the output is produced according to the <code>Refine</code> option.</p> <p><code>myfun</code> must return a <code>status</code> output value of 0 or 1. If <code>status = 1</code>, the solver halts integration. You can use this mechanism, for instance, to implement a <b>Stop</b> button.</p>
<code>done</code>	The solver calls <code>myfun([],[],'done')</code> when integration is complete to allow the output function to perform any cleanup chores.

You can use these general purpose output functions or you can edit them to create your own. Type `help function` at the command line for more information.

- `odeplot` — Time series plotting (default when you call the solver with no output arguments and you have not specified an output function)
- `odephas2` — Two-dimensional phase plane plotting
- `odephas3` — Three-dimensional phase plane plotting
- `odeprint` — Print solution as it is computed

---

**Note** If you call the solver with no output arguments, the solver does not allocate storage to hold the entire solution history.

---

**OutputSel** — Use `OutputSel` to specify which components of the solution vector you want passed to the output function. For example, if you want to use the `odeplot` output

function, but you want to plot only the first and third components of the solution, you can do this using

```
options = ...
odeset('OutputFcn',@odeplot,'OutputSel',[1 3]);
```

By default, the solver passes all components of the solution to the output function.

**Refine** — If **Refine** is 1, the solver returns solutions only at the end of each time step. If **Refine** is  $n > 1$ , the solver subdivides each time step into  $n$  smaller intervals and returns solutions at each time point. **Refine** does not apply when  $\text{length}(\text{tspan}) > 2$  or the ODE solver returns the solution as a structure.

---

**Note** In all the solvers, the default value of **Refine** is 1. Within **ode45**, however, the default is 4 to compensate for the solver's large step sizes. To override this and see only the time steps chosen by **ode45**, set **Refine** to 1.

---

The extra values produced for **Refine** are computed by means of continuous extension formulas. These are specialized formulas used by the ODE solvers to obtain accurate solutions between computed time steps without significant increase in computation time.

**Stats** — By default, **Stats** is off. If it is on, after solving the problem the solver displays

- Number of successful steps
- Number of failed attempts
- Number of times the ODE function was called to evaluate  $f(t,y)$

Solvers based on implicit methods, including **ode23s**, **ode23t**, **ode15s**, and **ode15i**, also display

- Number of times that the partial derivatives matrix  $\partial f/\partial x$  was formed
- Number of LU decompositions
- Number of solutions of linear systems

## Step-Size Properties

The step-size properties specify the size of the first step the solver tries, potentially helping it to better recognize the scale of the problem. In addition, you can specify bounds on the sizes of subsequent time steps.

The following table describes the step-size properties. Further information on each property is given following the table.

Property	Value	Description
<code>InitialStep</code>	Positive scalar	Suggested initial step size.
<code>MaxStep</code>	Positive scalar { $0.1 * \text{abs}(t_0 - t_f)$ }	Upper bound on solver step size.

### Description of Step-Size Properties

**InitialStep** — `InitialStep` sets an upper bound on the magnitude of the first step size the solver tries. If you do not set `InitialStep`, the initial step size is based on the slope of the solution at the initial time `tspan(1)`, and if the slope of all solution components is zero, the procedure might try a step size that is much too large. If you know this is happening or you want to be sure that the solver resolves important behavior at the start of the integration, help the code start by providing a suitable `InitialStep`.

**MaxStep** — If the differential equation has periodic coefficients or solutions, it might be a good idea to set `MaxStep` to some fraction (such as 1/4) of the period. This guarantees that the solver does not enlarge the time step too much and step over a period of interest. Do *not* reduce `MaxStep` for any of the following purposes:

- To produce more output points. This can significantly slow down solution time. Instead, use `Refine` to compute additional outputs by continuous extension at very low cost.
- When the solution does not appear to be accurate enough. Instead, reduce the relative error tolerance `RelTol`, and use the solution you just computed to determine appropriate values for the absolute error tolerance vector `AbsTol`. See “Error Control Properties” on page 1-6179 for a description of the error tolerance properties.
- To make sure that the solver doesn't step over some behavior that occurs only once during the simulation interval. If you know the time at which the change occurs,

break the simulation interval into two pieces and call the solver twice. If you do not know the time at which the change occurs, try reducing the error tolerances `RelTol` and `Abstol`. Use `MaxStep` as a last resort.

## Event Location Property

In some ODE problems the times of specific events are important, such as the time at which a ball hits the ground, or the time at which a spaceship returns to the earth. While solving a problem, the ODE solvers can detect such events by locating transitions to, from, or through zeros of user-defined functions.

The following table describes the `Events` property. Further information on each property is given following the table.

### ODE Events Property

String	Value	Description
Events	Function handle	Handle to a function that includes one or more event functions.

## Description of Event Location Properties

**Events** — The function is of the form

```
[value, isterminal, direction] = events(t,y)
```

`value`, `isterminal`, and `direction` are vectors for which the `i`th element corresponds to the `i`th event function:

- `value(i)` is the value of the `i`th event function.
- `isterminal(i) = 1` if the integration is to terminate at a zero of this event function, otherwise, `0`.
- `direction(i) = 0` if all zeros are to be located (the default), `+1` if only zeros where the event function is increasing, and `-1` if only zeros where the event function is decreasing.

If you specify an events function and events are detected, the solver returns three additional outputs:

- A column vector of times at which events occur

- Solution values corresponding to these times
- Indices into the vector returned by the events function. The values indicate which event the solver detected.

If you call the solver as

```
[T,Y,TE,YE,IE] = solver(odefun,tspan,y0,options)
```

the solver returns these outputs as TE, YE, and IE respectively. If you call the solver as

```
sol = solver(odefun,tspan,y0,options)
```

the solver returns these outputs as `sol.xe`, `sol.ye`, and `sol.ie`, respectively.

For examples that use an event function, see “Event Location” and “Advanced Event Location” in the MATLAB Mathematics documentation.

## Jacobian Matrix Properties

The stiff ODE solvers often execute faster if you provide additional information about the Jacobian matrix  $\partial f/\partial y$ , a matrix of partial derivatives of the function that defines the differential equations.

$$\frac{\partial f}{\partial y} = \begin{bmatrix} \frac{\partial f_1}{\partial y_1} & \frac{\partial f_1}{\partial y_2} & \cdots \\ \frac{\partial f_2}{\partial y_1} & \frac{\partial f_2}{\partial y_2} & \cdots \\ \vdots & \vdots & \ddots \end{bmatrix}$$

The Jacobian matrix properties pertain only to those solvers for stiff problems (`ode15s`, `ode23s`, `ode23t`, `ode23tb`, and `ode15i`) for which the Jacobian matrix  $\partial f/\partial y$  can be critical to reliability and efficiency. If you do not provide a function to calculate the Jacobian, these solvers approximate the Jacobian numerically using finite differences. In this case, you might want to use the `Vectorized` or `JPattern` properties.

The following table describes the Jacobian matrix properties for all implicit solvers except `ode15i`. Further information on each property is given following the table. See [Jacobian Properties for ode15i](#) for `ode15i`-specific information.

### Jacobian Properties for All Implicit Solvers Except ode15i

Property	Value	Description
Jacobian	Function handle   constant matrix	Matrix or function that evaluates the Jacobian.
JPattern	Sparse matrix of {0,1}	Generates a sparse Jacobian matrix numerically.
Vectorized	on   {off}	Allows the solver to reduce the number of function evaluations required.

### Description of Jacobian Properties

**Jacobian** — Supplying an analytical Jacobian often increases the speed and reliability of the solution for stiff problems. Set this property to a function `FJac`, where `FJac(t,y)` computes  $\partial f/\partial y$ , or to the constant value of  $\partial f/\partial y$ .

The Jacobian for the “van der Pol Equation (Stiff)”, described in the MATLAB Mathematics documentation, can be coded as

```
function J = vdp1000jac(t,y)
J = [0 1
 (-2000*y(1)*y(2)-1) (1000*(1-y(1)^2))];
```

**JPattern** — `JPattern` is a sparsity pattern with 1s where there might be nonzero entries in the Jacobian.

---

**Note** If you specify `Jacobian`, the solver ignores any setting for `JPattern`.

---

Set this property to a sparse matrix  $S$  with  $S(i,j) = 1$  if component  $i$  of  $f(t,y)$  depends on component  $j$  of  $y$ , and 0 otherwise. The solver uses this sparsity pattern to generate a sparse Jacobian matrix numerically. If the Jacobian matrix is large and sparse, this can greatly accelerate execution. For an example using the `JPattern` property, see Example: Large, Stiff, Sparse Problem in the MATLAB Mathematics documentation.

**Vectorized** — The `Vectorized` property allows the solver to reduce the number of function evaluations required to compute all the columns of the Jacobian matrix, and might significantly reduce solution time.

Set `on` to inform the solver that you have coded the ODE function `F` so that `F(t, [y1 y2 ...])` returns `[F(t,y1) F(t,y2) ...]`. This allows the solver to reduce the number of function evaluations required to compute all the columns of the Jacobian matrix, and might significantly reduce solution time.

---

**Note** If you specify `Jacobian`, the solver ignores a setting of `'on'` for `'Vectorized'`.

---

With the MATLAB array notation, it is typically an easy matter to vectorize an ODE function. For example, you can vectorize the “van der Pol Equation (Stiff)”, described in the MATLAB Mathematics documentation, by introducing colon notation into the subscripts and by using the array power (`.^`) and array multiplication (`.*`) operators.

```
function dydt = vdp1000(t,y)
dydt = [y(2,:); 1000*(1-y(1,:).^2).*y(2,:)-y(1,:)];
```

---

**Note** Vectorization of the ODE function used by the ODE solvers differs from the vectorization used by the boundary value problem (BVP) solver, `bvp4c`. For the ODE solvers, the ODE function is vectorized only with respect to the second argument, while `bvp4c` requires vectorization with respect to the first and second arguments.

---

The following table describes the Jacobian matrix properties for `ode15i`.

### Jacobian Properties for `ode15i`

Property	Value	Description
Jacobian	Function handle   Cell array of constant values	Function that evaluates the Jacobian or a cell array of constant values.
JPattern	Sparse matrices of {0,1}	Generates a sparse Jacobian matrix numerically.
Vectorized	on   {off}	Vectorized ODE function

### Description of Jacobian Properties for `ode15i`

**Jacobian** — Supplying an analytical Jacobian often increases the speed and reliability of the solution for stiff problems. Set this property to a function

```
[dFdy,dFdp] = Fjac(t,y,yp)
```

or to a cell array of constant values  $[\partial F/\partial y, (\partial F/\partial y)']$ .

**JPattern** — JPattern is a sparsity pattern with 1's where there might be nonzero entries in the Jacobian.

Set this property to {dFdyPattern, dFdypPattern}, the sparsity patterns of  $\partial F/\partial y$  and  $\partial F/\partial y'$ , respectively.

**Vectorized** —

Set this property to {yVect, ypVect}. Setting yVect to 'on' indicates that

$F(t, [y1\ y2\ \dots], yp)$

returns

$[F(t, y1, yp), F(t, y2, yp)\ \dots]$

Setting ypVect to 'on' indicates that

$F(t, y, [yp1\ yp2\ \dots])$

returns

$[F(t, y, yp1)\ F(t, y, yp2)\ \dots]$

## Mass Matrix and DAE Properties

This section describes mass matrix and differential-algebraic equation (DAE) properties, which apply to all the solvers except ode15i. These properties are not applicable to ode15i and their settings do not affect its behavior.

The solvers of the ODE suite can solve ODEs of the form

$$M(t, y)y' = f(t, y)$$

with a mass matrix  $M(t, y)$  that can be sparse.

When  $M(t, y)$  is nonsingular, the equation above is equivalent to  $y' = M^{-1} f(t, y)$  and the ODE has a solution for any initial values  $y_0$  at  $t_0$ . The more general form (Equation 1-3)

is convenient when you express a model naturally in terms of a mass matrix. For large, sparse  $M(t,y)$ , solving Equation 1-3 directly reduces the storage and run-time needed to solve the problem.

When  $M(t,y)$  is singular, then  $M(t,y)$  times  $M(t,y)y' = f(t,y)$  is a DAE. A DAE has a solution only when  $y_0$  is consistent; that is, there exists an initial slope  $yp_0$  such that  $M(t_0,y_0)yp_0 = f(t_0,y_0)$ . If  $y_0$  and  $yp_0$  are not consistent, the solver treats them as guesses, attempts to compute consistent values that are close to the guesses, and continues to solve the problem. For DAEs of index 1, solving an initial value problem with consistent initial conditions is much like solving an ODE.

The `ode15s` and `ode23t` solvers can solve DAEs of index 1. For examples of DAE problems, see Example: Differential-Algebraic Problem, in the MATLAB Mathematics documentation, and the examples `amp1dae` and `hb1dae`.

The following table describes the mass matrix and DAE properties. Further information on each property is given following the table.

### Mass Matrix and DAE Properties (Solvers Other Than `ode15i`)

Property	Value	Description
Mass	Matrix   function handle	Mass matrix or a function that evaluates the mass matrix $M(t,y)$ .
MStateDependence	none   {weak}   strong	Dependence of the mass matrix on $y$ .
MvPattern	Sparse matrix	$\partial(M(t,y)v)/\partial y$ sparsity pattern.
MassSingular	yes   no   {maybe}	Indicates whether the mass matrix is singular.
InitialSlope	Vector {zero vector}	Vector representing the consistent initial slope $yp_0$ .

### Description of Mass Matrix and DAE Properties

**Mass** — For problems of the form  $M(t)y' = f(t,y)$ , set 'Mass' to a mass matrix  $M$ .

For problems of the form  $M(t)y' = f(t,y)$ , set 'Mass' to a function handle `@Mfun`, where `Mfun(t,y)` evaluates the mass matrix  $M(t,y)$ . The `ode23s` solver can only solve problems with a constant mass matrix  $M$ . When solving DAEs, using `ode15s` or `ode23t`, it is advantageous to formulate the problem so that  $M$  is a diagonal matrix (a semiexplicit DAE).

For example problems, see “Finite Element Discretization” in the MATLAB Mathematics documentation, or the examples `fem2ode` or `batonode`.

**MStateDependence** — Set this property to `none` for problems  $M(t)y' = f(t, y)$ .

Both `weak` and `strong` indicate  $M(t, y)$ , but `weak` results in implicit solvers using approximations when solving algebraic equations.

**MvPattern** — Set this property to a sparse matrix  $S$  with  $S(i, j) = 1$  if, for any  $k$ , the  $(i, k)$  component of  $M(t, y)$  depends on component  $j$  of  $y$ , and 0 otherwise. For use with the `ode15s`, `ode23t`, and `ode23tb` solvers when `MStateDependence` is `strong`. See `burgersode` as an example.

**MassSingular** — Set this property to `no` if the mass matrix is not singular and you are using either the `ode15s` or `ode23t` solver. The default value of `maybe` causes the solver to test whether the problem is a DAE, by testing whether  $M(t_0, y_0)$  is singular.

**InitialSlope** — Vector representing the consistent initial slope  $yp_0$ , where  $yp_0$  satisfies  $M(t_0, y_0) \cdot yp_0 = f(t_0, y_0)$ . The default is the zero vector.

This property is for use with the `ode15s` and `ode23t` solvers when solving DAEs.

## ode15s and ode15i-Specific Properties

`ode15s` is a variable-order solver for stiff problems. It is based on the numerical differentiation formulas (NDFs). The NDFs are generally more efficient than the closely related family of backward differentiation formulas (BDFs), also known as Gear's methods. The `ode15s` properties let you choose among these formulas, as well as specifying the maximum order for the formula used.

`ode15i` solves fully implicit differential equations of the form

$$f(t, y, y') = 0$$

using the variable order BDF method.

The following table describes the `ode15s` and `ode15i`-specific properties. Further information on each property is given following the table. Use `odeset` to set these properties.

**ode15s and ode15i-Specific Properties**

Property	Value	Description
MaxOrder	1   2   3   4   {5}	Maximum order formula used to compute the solution.
BDF (ode15s only)	on   {off}	Specifies whether you want to use the BDFs instead of the default NDFs.

**Description of ode15s and ode15i-Specific Properties**

**MaxOrder** — Maximum order formula used to compute the solution.

**BDF** (ode15s only) — Set BDF on to have ode15s use the BDFs.

For both the NDFs and BDFs, the formulas of orders 1 and 2 are A-stable (the stability region includes the entire left half complex plane). The higher order formulas are not as stable, and the higher the order the worse the stability. There is a class of stiff problems (stiff oscillatory) that is solved more efficiently if MaxOrder is reduced (for example to 2) so that only the most stable formulas are used.

# odextend

Extend solution of initial value problem for ordinary differential equation

## Syntax

```
solext = odextend(sol, odefun, tfinal)
solext = odextend(sol, [], tfinal)
solext = odextend(sol, odefun, tfinal, yinit)
solext = odextend(sol, odefun, tfinal, [yinit, ypinit])
solext = odextend(sol, odefun, tfinal, yinit, options)
```

## Description

`solext = odextend(sol, odefun, tfinal)` extends the solution stored in `sol` to an interval with upper bound `tfinal` for the independent variable. Specify `odefun` as a function handle. Specify `sol` as an ODE solution structure created using an ODE solver. The lower bound for the independent variable in `solext` is the same as in `sol`. If you created `sol` with an ODE solver other than `ode15i`, the function `odefun` computes the right-hand side of the ODE equation, which is of the form  $y' = f(t,y)$ . If you created `sol` using `ode15i`, the function `odefun` computes the left-hand side of the ODE equation, which is of the form  $f(t,y,y') = 0$ .

“Parameterizing Functions” explains how to provide additional parameters to the function `odefun`, if necessary.

`odextend` extends the solution by integrating `odefun` from the upper bound for the independent variable in `sol` to `tfinal`, using the same ODE solver that created `sol`. By default, `odextend` uses

- The initial conditions `y = sol.y(:,end)` for the subsequent integration
- The same integration properties and additional input arguments the ODE solver originally used to compute `sol`. This information is stored as part of the solution structure `sol` and is subsequently passed to `solext`. Unless you want to change these values, you do not need to pass them to `odextend`.

`solext = odextend(sol, [], tfinal)` uses the same ODE function that the ODE solver uses to compute `sol` to extend the solution. It is not necessary to pass in `odefun` explicitly unless it differs from the original ODE function.

`solext = odextend(sol, odefun, tfinal, yinit)` uses the column vector `yinit` as new initial conditions for the subsequent integration, instead of the vector `sol.y(end)`.

---

**Note** `solext = odextend(sol, odefun, tfinal, [yinit, ypinit])` extends solutions obtained with `ode15i` by using the column vector `ypinit` to specify the initial derivative of the solution.

---

`solext = odextend(sol, odefun, tfinal, yinit, options)` uses the integration properties specified in `options` instead of the options the ODE solver originally used to compute `sol`. The new options are then stored within the structure `solext`. See `odeset` for details on setting `options` properties. Set `yinit = []` as a placeholder to specify the default initial conditions.

## Examples

The following command

```
sol=ode45(@vdp1,[0 10],[2 0]);
```

uses `ode45` to solve the system  $y' = \text{vdp1}(t, y)$ , where `vdp1` is an example of an ODE function provided with MATLAB software, on the interval `[0 10]`. Then, the commands

```
sol=odextend(sol,@vdp1,20);
plot(sol.x,sol.y(1,:));
```

extend the solution to the interval `[0 20]` and plot the first component of the solution on `[0 20]`.

## onCleanup

Cleanup tasks upon function completion

### Syntax

```
cleanupObj = onCleanup(cleanupFun)
```

### Description

`cleanupObj = onCleanup(cleanupFun)` creates an object that, when destroyed, executes the function `cleanupFun`. MATLAB implicitly clears all local variables at the termination of a function, whether by normal completion, or a forced exit, such as an error, or **Ctrl+C**.

If you reference or pass `cleanupObj` outside your function, then `cleanupFun` does not run when that function terminates. Instead, it runs whenever MATLAB destroys the object.

### Examples

#### Close a Figure After Executing Function

Save the following code in `action.m` and type `action` in the Command Window.

```
function [] = action()
f = figure;
finishup = onCleanup(@() myCleanupFun(f));
disp('Display Figure')
end
```

```
function myCleanupFun(f)
close(f)
disp('Close Figure')
end
```

```
Display Figure
```

Close Figure

### Switch Directories After Executing Function

Pass your own script to the `onCleanup` object so that it executes when MATLAB destroys the cleanup object.

Save the following code in `cleanup.m`.

```
cd(tempdir)
disp('You are now in the temporary folder')
```

Save the following code in `youraction.m` and type `youraction` in the Command Window.

```
function [] = youraction
 changeup = onCleanup(@cleanup);
 disp('Execute Code')
end
```

Execute Code

You are now in the temporary folder

## Input Arguments

### `cleanupFun` — Clean-up task

function handle

Clean-up task, specified as a handle to a function.

You can declare any number of `onCleanup` objects in a program file. However, if the clean-up tasks depend on the order of execution, then you should define only one object that calls a script or function, containing the relevant clean-up commands.

You should use an anonymous function handle to call your clean-up task. This allows you to pass arguments to your clean-up function.

Example: `@() fclose('file.m')`

Example: `@() user_script`

Example: `@() function(input)`

Data Types: `function_handle`

## More About

### Tips

- Avoid using nested functions during cleanup. MATLAB can clear variables used in nested functions before the clean-up function tries to read from them.
- If your program contains multiple cleanup objects, MATLAB does not guarantee the order that it destroys these objects.
- If the order of your cleanup functions matters, define one `onCleanup` object for all the tasks.
  - “Clean Up When Functions Complete”
  - “Object Lifecycle”
  - “Function Handles”
  - “What Are Anonymous Functions?”

**Introduced in R2008a**

## ones

Create array of all ones

### Syntax

```
X = ones
X = ones(n)
X = ones(sz1, ..., szN)
X = ones(sz)

X = ones(classname)
X = ones(n, classname)
X = ones(sz1, ..., szN, classname)
X = ones(sz, classname)

X = ones('like', p)
X = ones(n, 'like', p)
X = ones(sz1, ..., szN, 'like', p)
X = ones(sz, 'like', p)
```

### Description

`X = ones` returns the scalar 1.

`X = ones(n)` returns an  $n$ -by- $n$  matrix of ones.

`X = ones(sz1, ..., szN)` returns an  $sz1$ -by-...-by- $szN$  array of ones where  $sz1, \dots, szN$  indicates the size of each dimension. For example, `ones(2,3)` returns a 2-by-3 array of ones.

`X = ones(sz)` returns an array of ones where the size vector, `SZ`, defines `size(X)`. For example, `ones([2,3])` returns a 2-by-3 array of ones.

`X = ones(classname)` returns a scalar 1 where the string, `classname`, specifies the data type. For example, `ones('int8')` returns a scalar, 8-bit integer 1.

`X = ones(n, classname)` returns an  $n$ -by- $n$  array of ones of data type `classname`.

`X = ones(sz1, ..., szN, classname)` returns an `sz1`-by-...-by-`szN` array of ones of data type `classname`.

`X = ones(sz, classname)` returns an array of ones where the size vector, `SZ`, defines `size(X)` and `classname` defines `class(X)`.

`X = ones('like', p)` returns a scalar 1 with the same data type, sparsity, and complexity (real or complex) as the numeric variable, `p`.

`X = ones(n, 'like', p)` returns an `n`-by-`n` array of ones like `p`.

`X = ones(sz1, ..., szN, 'like', p)` returns an `sz1`-by-...-by-`szN` array of ones like `p`.

`X = ones(sz, 'like', p)` returns an array of ones like `p` where the size vector, `SZ`, defines `size(X)`.

## Examples

### Square Array of Ones

Create a 4-by-4 array of ones.

```
X = ones(4)
```

```
X =
```

```
 1 1 1 1
 1 1 1 1
 1 1 1 1
 1 1 1 1
```

### 3-D Array of Ones

Create a 2-by-3-by-4 array of ones.

```
X = ones(2,3,4);
```

```
size(X)
```

```
ans =
```

```

 2 3 4

```

### Size Defined by Existing Array

Define a 3-by-2 array A.

```
A = [1 4 ; 2 5 ; 3 6];
```

```
sz = size(A)
```

```
sz =
```

```

 3 2

```

Create an array of ones that is the same size as A

```
X = ones(sz)
```

```
X =
```

```

 1 1
 1 1
 1 1

```

### Nondefault Numeric Data Type

Create a 1-by-3 vector of ones whose elements are 16-bit unsigned integers.

```
X = ones(1,3,'uint16'),
class(X)
```

```
X =
```

```

 1 1 1

```

```
ans =
```

```
uint16
```

### Complex One

Create a scalar 1 that is not real valued, but instead is complex like an existing array.

Define a complex vector.

```
p = [1+2i 3i];
```

Create a scalar `1` that is complex like `p`.

```
X = ones('like',p)
X =
 1.0000 + 0.0000i
```

### Size and Numeric Data Type of Defined by Existing Array

Define a 2-by-3 array of 8-bit unsigned integers.

```
p = uint8([1 3 5 ; 2 4 6]);
```

Create an array of ones that is the same size and data type as `p`.

```
X = ones(size(p), 'like', p),
class(X)
X =
 1 1 1
 1 1 1
```

```
ans =
```

```
uint8
```

## Input Arguments

### **n** — Size of square matrix

integer value

Size of square matrix, specified as an integer value, defines the output as a square, n-by-n matrix of ones.

- If `n` is 0, then `X` is an empty matrix.
- If `n` is negative, then it is treated as 0.

Data Types: `double` | `single` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**sz1, . . . , szN — Size of each dimension**

two or more integer values

Size of each dimension, specified as two or more integer values, defines X as a sz1-by...-by-szN array.

- If the size of any dimension is 0, then X is an empty array.
- If the size of any dimension is negative, then it is treated as 0.
- If any trailing dimensions greater than 2 have a size of 1, then the output, X, does not include those dimensions.

Data Types: double | single | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**sz — Output size**

row vector of integer values

Output size, specified as a row vector of integer values. Each element of this vector indicates the size of the corresponding dimension.

- If the size of any dimension is 0, then X is an empty array.
- If the size of any dimension is negative, then it is treated as 0.
- If any trailing dimensions greater than 2 have a size of 1, then the output, X, does not include those dimensions.

Example: `sz = [2,3,4]` defines X as a 2-by-3-by-4 array.

Data Types: double | single | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**classname — Output class**

'double' (default) | 'single' | 'int8' | 'uint8' | ...

Output class, specified as 'double', 'single', 'int8', 'uint8', 'int16', 'uint16', 'int32', 'uint32', 'int64', or 'uint64'.

Data Types: char

**p — Prototype**

numeric variable

Prototype, specified as a numeric variable.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Complex Number Support: Yes

## **More About**

- “Class Support for Array-Creation Functions”
- “Preallocation”

## **See Also**

`complex` | `eye` | `false` | `rand` | `randn` | `size` | `zeros`

**Introduced before R2006a**

## open

Open file in appropriate application

### Syntax

```
open(name)
output = open(name)
```

### Description

`open(name)` opens the specified file or variable in the appropriate application.

`output = open(name)` returns an empty *output* (`[]`) for most cases. If opening a MAT-file, *output* is a structure that contains the variables in the file. If opening a figure, *output* is a handle to that figure.

### Input Arguments

#### **name**

Name of file or variable to open. If *name* does not include an extension, the `open` function:

- 1 Searches for a variable named *name*. If the variable exists, `open` opens it in the Variables editor.
- 2 Searches the MATLAB path for *name*.mdl, *name*.slx, or *name*.m. If *name*.mdl or *name*.slx exists, then `open` opens the model in Simulink. If only *name*.m exists, `open` opens the file in the MATLAB Editor.

If more than one file named *name* exists on the MATLAB path, the `open` function opens the file returned by `which(name)`.

The `open` function performs the following actions based on the file extension:

.m                      Open in MATLAB Editor.

<code>.mat</code>	Return variables in structure <code>st</code> when called with the syntax:  <code>st = open(name)</code>
<code>.fig</code>	Open figure in Handle Graphics.
<code>.mdl</code> or <code>.slx</code>	Open model in Simulink.
<code>.prj</code>	Open project in the MATLAB Compiler Deployment Tool.
<code>.doc*</code>	Open document in Microsoft Word.
<code>.exe</code>	Run executable file (only on Windows systems).
<code>.pdf</code>	Open document in Adobe® Acrobat®.
<code>.ppt*</code>	Open document in Microsoft PowerPoint.
<code>.xls*</code>	Start MATLAB Import Wizard.
<code>.htm</code> or <code>.html</code>	Open document in MATLAB browser.
<code>.url</code>	Open file in your default Web browser.

## Examples

Open `Contents.m` in the MATLAB Editor by typing:

```
open Contents.m
```

Generally, MATLAB opens `matlabroot\toolbox\matlab\general\Contents.m`. However, if you have a file called `Contents.m` in a directory that is before `toolbox\matlab\general` on the MATLAB path, then `open` opens that file instead.

Open a file not on the MATLAB path by including the complete file specification:

```
open('D:\temp\data.mat')
```

If the file does not exist, MATLAB displays an error message.

Create a function called `opentxt` to handle files with extension `.txt`:

```
function opentxt(filename)

 fprintf('You have requested file: %s\n', filename);

 wh = which(filename);
```

```
if exist(filename, 'file') == 2
 fprintf('Opening in MATLAB Editor: %s\n', filename);
 edit(filename);
elseif ~isempty(wh)
 fprintf('Opening in MATLAB Editor: %s\n', wh);
 edit(wh);
else
 warning('MATLAB:fileNotFound', ...
 'File was not found: %s', filename);
end
```

end

Open the file `ngc6543a.txt` (a description of `ngc6543a.jpg`, located in `matlabroot\toolbox\matlab\demos`):

```
photo_text = 'ngc6543a.txt';
open(photo_text)
```

`open` calls your function with the following syntax:

```
opentxt(photo_text)
```

## More About

### Tips

The `open` function opens files based on their extension. You can extend the functionality of `open` by defining your own file handling function of the form `openxxx`, where `xxx` is a file extension. For example, if you create a function `openlog`, the `open` function calls `openlog` to process any files with the `.log` extension. The `open` function returns any single *output* defined by your function.

**Introduced before R2006a**

## openfig

Open figure saved in FIG-file

### Syntax

```
openfig(filename)
openfig(filename,copies)
openfig(__ ,visibility)

fig = openfig(__)
```

### Description

`openfig(filename)` opens the figure saved in the MATLAB figure file (FIG-file) called `filename`.

`openfig(filename,copies)` specifies whether to open a new copy of the figure in the case that a copy is already open. If you do not want to create a new copy, set `copies` to `'reuse'`. The `'reuse'` option brings the existing figure to the front of the screen. To open a new copy of the figure regardless of whether a copy is already open, set `copies` to `'new'`. The `'new'` option is the default behavior.

`openfig( __ ,visibility)` specifies whether to open the figure in a visible or invisible state. To display the figure, set `visibility` to `'visible'`. If you do not want to display the figure, use the `'invisible'` setting. You can use this option with any of the input argument combinations in the previous syntaxes.

`fig = openfig( __ )` returns the figure object. Set properties of the figure object to modify its appearance or behavior. For a list of properties, see [Figure Properties](#).

### Examples

#### Open Figure Saved in MATLAB Figure File

Create a surface plot and save the figure as a MATLAB figure file. Then, close the figure.

```
surf(peaks)
savefig('MySavedPlot.fig')
close(gcf)
```

Open the saved figure.

```
openfig('MySavedPlot.fig')
```

### Open Invisible Figure in Visible State

Create a surface plot and make the figure invisible. Then, save the figure as a MATLAB figure file. Close the invisible figure.

```
surf(peaks)
set(gcf, 'Visible', 'off')
savefig('MySavedPlot.fig')
close(gcf)
```

Open the saved figure and make it visible on the screen.

```
openfig('MySavedPlot.fig', 'visible')
```

## Input Arguments

### **filename** — File name of saved figure

string

File name of saved figure, specified as a string. You do not have to specify the full file path, as long as it is on your MATLAB path. Including `.fig` in the file name is optional.

Example: `openfig('MySavedFigure.fig')`

### **copies** — Control for opening multiple copies of figure

'new' (default) | 'reuse'

Control for opening multiple copies of the figure, specified as one of these values:

- 'new' — Open a new copy of the figure, even if a copy already exists on the screen.
- 'reuse' — Open a new copy of the figure only if one does not exist. If a copy exists, then bring the existing copy to the front of the screen. If the figure is off the screen, then 'reuse' repositions the figure so that it is completely on the screen. This option helps provide compatibility with different screen sizes and resolutions by ensuring that the figure displays on screen.

Example: `openfig('MySavedFigure.fig','reuse')`

**visibility** — Figure visibility

'visible' | 'invisible'

Figure visibility, specified as one of these values:

- 'visible' — Open the saved figure in a visible state. If the MATLAB figure file contains an invisible figure, then you can use this option to make the figure visible when it opens.
- 'invisible' — Open the saved figure in an invisible state.

Example: `openfig('MySavedFigure.fig','invisible')`

## Output Arguments

**fig** — Figure object

figure object

Figure object. Set properties of the figure to change the appearance or behavior of the opened figure. For a list of properties, see Figure Properties.

## Limitations

- Do not use `openfig` to open FIG-files created with GUIDE. Use the `guide` function instead.

## More About

- “Save Figure to Reopen in MATLAB Later”

**See Also**

`open` | `saveas` | `savefig`

**Introduced before R2006a**

# opengl

Control OpenGL rendering

## Compatibility

The `autoselect`, `neverselect`, `advise`, `quiet`, `verbose`, and `DriverBugWorkaround` inputs have been removed in R2014b. For more information about the behavior of these syntaxes in previous releases, see `opengl` for R2014a.

## Syntax

```
opengl info
d = opengl('data')

opengl software
opengl hardware
opengl hardwarebasic

opengl('save',pref)
```

## Description

`opengl info` prints information about the OpenGL implementation currently in use by MATLAB, such as the version, vendor, and graphics features that it supports. The returned fields might change in future releases as graphics features change. Using this command loads OpenGL.

`d = opengl('data')` returns the same data provided with `opengl info`, but stores it in a structure.

`opengl software` uses a software version of OpenGL to render subsequent graphics for the current MATLAB session. This command works only on Windows systems.

`opengl hardware` uses a hardware-accelerated version of OpenGL to render subsequent graphics. If your graphics hardware does not support hardware-accelerated OpenGL, then MATLAB uses a software version instead.

`opengl hardwarebasic` uses a hardware-accelerated version of OpenGL, but disables some advanced graphics features that are unstable with certain graphics drivers. If your graphics hardware does not support hardware-accelerated OpenGL, then MATLAB uses a software version instead.

`opengl('save',pref)` sets your preferences so that future sessions of MATLAB on this computer use the preferred version of OpenGL. Specify `pref` as `'software'`, `'hardware'`, `'hardwarebasic'`, or `'none'`. This command does not affect the current session.

## Examples

### Display Information About OpenGL

Using the `opengl info` command, display information about the OpenGL implementation currently in use by MATLAB. For example, display the vendor, the version, and the supported graphics features. Also display whether MATLAB is using a hardware-accelerated implementation or a software implementation of OpenGL.

```
opengl info
```

```
Version: '3.3.0'
Vendor: 'NVIDIA Corporation'
Renderer: 'Quadro 400/PCIe/SSE2'
RendererDriverVersion: '9.18.13.679'
RendererDriverReleaseDate: '22-Sep-2012'
MaxTextureSize: 8192
Visual: 'Visual 0x07, (RGBA 32 bits (8 8 8 8), ...'
Software: 'false'
HardwareSupportLevel: 'full'
SupportsGraphicsSmoothing: 1
SupportsDepthPeelTransparency: 1
SupportsAlignVertexCenters: 1
Extensions: {251x1 cell}
MaxFrameBufferSize: 8192
```

### Determine Graphics Hardware

Using the `opengl info` command, determine your graphics hardware by checking the `Vendor` and `Renderer` fields.

```
opengl info
```

```
Version: '3.3.0'
Vendor: 'NVIDIA Corporation'
Renderer: 'Quadro 400/PCIe/SSE2'
RendererDriverVersion: '9.18.13.3182'
RendererDriverReleaseDate: '11-Nov-2013'
MaxTextureSize: 8192
Visual: 'Visual 0x07, (RGBA 32 bits (8 8 8 8...'
Software: 'false'
HardwareSupportLevel: 'full'
SupportsGraphicsSmoothing: 1
SupportsDepthPeelTransparency: 1
SupportsAlignVertexCenters: 1
Extensions: {248x1 cell}
MaxFrameBufferSize: 8192
```

---

**Note:** If the returned fields contain the line `Software: 'true'`, then you are using software OpenGL and the name listed in the `Vendor` field is not your graphics hardware vendor. Instead, the `Vendor` field indicates the manufacturer of the software OpenGL implementation.

---

## Determine Graphics Hardware When Using Software OpenGL (Windows)

Close all figures, switch to hardware OpenGL, and issue the `opengl info` command. Then, switch back to software OpenGL.

```
close all
opengl hardware
opengl info
opengl software
```

## Determine Graphics Hardware When Using Software OpenGL (Linux)

Start MATLAB with the `-nosoftwareopengl` flag. Then, issue the `opengl info` command.

## Use Software OpenGL for Current Session

Switch to using software OpenGL to render graphics in the current session.

```
opengl software
```

This command works only on Windows systems.

## Use Software OpenGL for Future Sessions

Set your preferences so that MATLAB uses software OpenGL to render graphics in all future sessions. This command does not affect the current session.

```
opengl('save','software')
```

## Input Arguments

### **info** — Information about OpenGL implementation

`info`

Information about the OpenGL implementation currently in use by MATLAB, specified as `info`. The `opengl info` command returns the fields listed in this table.

Field	Description
Version	Version of the OpenGL implementation.
Vendor	Manufacturer of the OpenGL implementation.
RendererDriverVersion	Version of the OpenGL driver (Windows systems with hardware-accelerated OpenGL only). This field does not display on virtual machines.
RendererDriverReleaseDate	Release date of the OpenGL driver (Windows systems with hardware-accelerated OpenGL only). This field does not display on virtual machines.
Renderer	Description of the OpenGL renderer. If you are using hardware-accelerated OpenGL, this field is the graphics card model name.
MaxTextureSize	Maximum texture size supported by the OpenGL implementation.

Field	Description
Visual	Display properties of the OpenGL implementation.
Software	Software OpenGL enabled, returned as 'true' or 'false'.
HardwareSupportLevel	Hardware support level, returned as one of these values: <ul style="list-style-type: none"> <li>'full' — Hardware-accelerated OpenGL (all graphics features enabled)</li> <li>'basic' — Basic hardware-accelerated OpenGL (some graphics features disabled)</li> <li>'none' — Software OpenGL</li> </ul> If MATLAB detects an unsupported driver, this field also contains 'known graphics driver issues'.
SupportsGraphicsSmoothing	Graphics smoothing feature support, returned as 1 if supported or 0 otherwise.
SupportsDepthPeelTransparency	Depth peel transparency feature support, returned as 1 if supported or 0 otherwise.
SupportsAlignVertexCenters	Align vertex centers feature support, returned as 1 if supported or 0 otherwise.
Extensions	Extended capabilities supported by the OpenGL implementation.
MaxFrameBufferSize	Maximum frame buffer size supported by the OpenGL implementation.

For more information about the graphics smoothing, depth peel transparency, and align vertex centers features, see “Advanced Graphics Features” on page 1-6217.

### **software — Software OpenGL**

software

Software OpenGL, specified as `software`.

To switch to software OpenGL:

- On Windows systems, execute `opengl software`.
- On Linux systems, start MATLAB with the `-softwareopengl` flag.
- Macintosh systems do not support software OpenGL.

Software OpenGL can be slower than hardware-accelerated OpenGL and does not support all graphics features. For a table of supported features, see “Advanced Graphics Features” on page 1-6217.

### **hardware — Hardware-accelerated OpenGL**

`hardware`

Hardware-accelerated OpenGL, specified as `hardware`. All systems support using the `opengl hardware` command to switch from basic hardware to hardware OpenGL. However, only Windows systems support using the `opengl hardware` command to switch from software to hardware OpenGL. To switch from software to hardware on Linux systems, start MATLAB with the `-nosoftwareopengl` flag.

### **hardwarebasic — Basic version of hardware-accelerated OpenGL**

`hardwarebasic`

Basic version of hardware-accelerated OpenGL, specified as `hardwarebasic`. This version of hardware-accelerated OpenGL uses your graphics hardware, but disables graphics features that are unstable with some graphics drivers. The disabled features might change in future releases as graphics features change and graphics hardware evolves. For a table of supported features, see “Advanced Graphics Features” on page 1-6217.

### **pref — OpenGL version preference for future sessions**

`'software' | 'hardware' | 'hardwarebasic' | 'none'`

OpenGL version preference for future sessions, specified as one of these options:

- `'software'` — Software OpenGL. This option is not available on Macintosh systems.
- `'hardware'` — Hardware-accelerated OpenGL.
- `'hardwarebasic'` — Hardware-accelerated OpenGL with some advanced graphics features disabled. For more information, see “Advanced Graphics Features” on page 1-6217.
- `'none'` — Default value for your system.

## More About

### Advanced Graphics Features

Advanced graphics features are features that require certain implementations of OpenGL. These features are graphics smoothing, depth peel transparency, and align vertex centers. Support for these features depends on:

- Whether you are using hardware, basic hardware, or software OpenGL. To determine which implementation you are using, check the `HardwareSupportLevel` field returned by `opengl info`.
- The version of the OpenGL implementation. To determine the version in use, check the `Version` field returned by `opengl info`. To get the latest version available for your graphics hardware, upgrade your graphics drivers from your computer manufacturer website. For more information on upgrading graphics drivers, see “System Requirements for Graphics”.

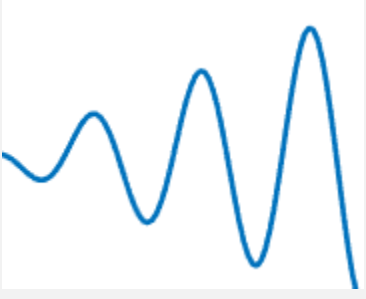

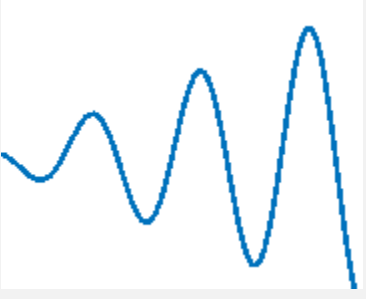

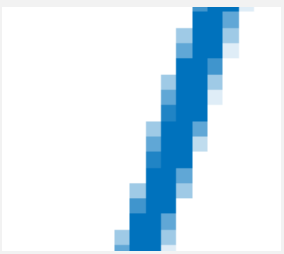

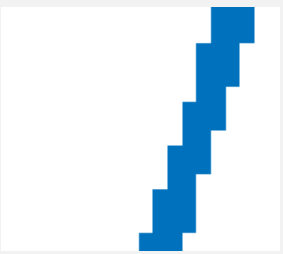

This table lists the advanced graphics features and the circumstances under which they are supported.

Graphics Feature	Hardware OpenGL	Basic Hardware OpenGL	Software OpenGL on Windows (Uses OpenGL 1.1)	Software OpenGL on Linux (Uses OpenGL 2.1)
Graphics Smoothing	Supported for OpenGL 2.1 or later	Supported for OpenGL 2.1 or later	Not supported	Not supported
Depth Peel Transparency	Supported for OpenGL 2.1 or later	Disabled	Not supported	Supported
Align Vertex Centers	Supported for OpenGL 2.1 or later	Disabled	Not supported	Not supported

### Graphics Smoothing

Graphics smoothing is a technique to improve the appearance of plots by reducing the appearance of jagged lines. By default, this feature is enabled if your system supports it.

This table shows the difference when the feature is enabled versus disabled.

When Supported and Enabled	When Not Supported or Disabled
	
 <p data-bbox="244 980 452 1015">(Zoomed-in view)</p>	 <p data-bbox="795 980 1003 1015">(Zoomed-in view)</p>

To turn it off, set the GraphicsSmoothing property of the figure to 'off'.

### Depth Peel Transparency

Depth peel transparency is a feature for correctly drawing transparent 3-D objects or complex plots that contain intersecting transparent objects. In the table, the left image shows the result of using transparency on a sphere when the depth peel transparency feature is supported. The right image shows the same sphere with unexpected shaded areas that occur when the feature is not supported.

### Align Vertex Centers

Align vertex centers is a feature for sharp vertical and horizontal lines. If graphics smoothing is enabled, it can cause horizontal and vertical lines to appear uneven in thickness or color. The align vertex centers feature eliminates the uneven appearance. By default, the align vertex centers feature is not enabled. However, if your system supports this feature, then you can turn it on for objects that have an `AlignVertexCenters` property by setting the property to 'on'.

This table shows the difference when the feature is enabled versus disabled.

## Tips

- Painters is an alternate rendering method for screen display and printing. For more information, see the figure's `Renderer` property.
- By default, MATLAB uses hardware-accelerated OpenGL if your graphics hardware supports it. However, in some cases, MATLAB automatically switches to software OpenGL, for example, if it detects:
  - You are using a graphics driver with known issues or graphics virtualization.
  - A previous MATLAB session crashed due to a graphics issue.
  - You do not have graphics hardware or your graphics hardware does not support hardware OpenGL.
- “System Requirements for Graphics”
- “Resolving Low-Level Graphics Issues”

## See Also

`matlablinux` | `matlabmac` | `matlabwindows`

**Introduced before R2006a**

## openvar

Open workspace variable in Variables editor or other graphical editing tool

### Syntax

```
openvar(varname)
```

### Description

`openvar(varname)` opens the workspace variable named by the string, `varname`, in the Variables editor for graphical editing. Changes that you make to variables in the Variables editor occur in the workspace as soon as you enter them.

In some toolboxes, `openvar` opens a tool appropriate for viewing or editing objects indicated by `varname` instead of opening the Variables editor.

MATLAB does not impose any limitation on the size of a variable that you can open in the Variables editor. However, your operating system or the amount of physical memory installed on your computer can impose such limits.

### Examples

#### Identify Outliers in a Linked Graph

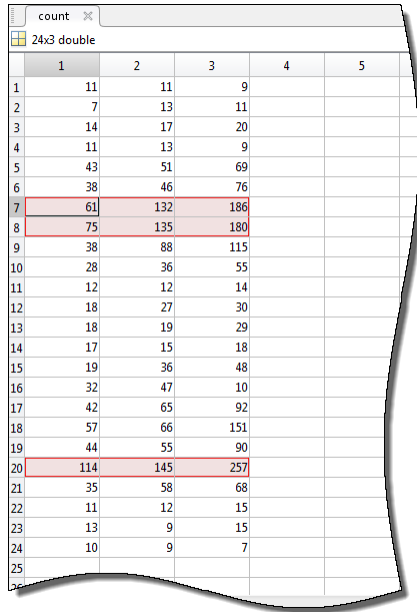

Use data brushing to identify observations in a vector or matrix that might warrant further analysis.

Make a scatter plot of data in the sample MAT-file `count.dat`, and open the variable `count` in the Variables editor.

```
load count.dat
scatter(count(:,1),count(:,2))
openvar('count')
```

Right-click a cell in the Variables editor and select **Brushing > Brushing On**. This turns on data brushing in the Variables editor.

Select the rows 7, 8, and 20. (Select noncontiguous rows by holding down the **Ctrl** key and clicking in each row.)

	1	2	3	4	5
1	11	11	9		
2	7	13	11		
3	14	17	20		
4	11	13	9		
5	43	51	69		
6	38	46	76		
7	61	132	186		
8	75	135	180		
9	38	88	115		
10	28	36	55		
11	12	12	14		
12	18	27	30		
13	18	19	29		
14	17	15	18

25					
26					

In the Figure window with the scatter plot, click **Brush/Select Data**  to enable data brushing, and **Link Plot**  to enable data linking.

The data observations you brushed in the Variables editor appear highlighted in the scatter plot.

As long as data linking is enabled in the figure, observations that you brush in the scatter plot are highlighted in the Variables editor. When a figure is not linked to its data sources, you can still brush its graphs and you can brush the same data in the Variables editor, but only the display that you brush responds by highlighting.

## Input Arguments

**varname** — Variable name

string

Variable name, specified as a string. The named variable can be an array, character string, cell array, structure, or an object and its properties. If the named variable is a multidimensional array, then you can only view the array in the Variables editor, and not edit it.

Example: 'myVariable'

Example: 'A'

## More About

### Tips

- As an alternative to the `openvar` function, double-click a variable in the Workspace browser.
- “View, Edit, and Copy Variables”
- “Making Graphs Responsive with Data Linking”

# optimget

Optimization options values

## Syntax

```
val = optimget(options, 'param')
val = optimget(options, 'param', default)
```

## Description

`val = optimget(options, 'param')` returns the value of the specified parameter in the optimization options structure `options`. You need to type only enough leading characters to define the parameter name uniquely. Case is ignored for parameter names.

`val = optimget(options, 'param', default)` returns `default` if the specified parameter is not defined in the optimization options structure `options`. Note that this form of the function is used primarily by other optimization functions.

## Examples

This statement returns the value of the `Display` optimization options parameter in the structure called `my_options`.

```
val = optimget(my_options, 'Display')
```

This statement returns the value of the `Display` optimization options parameter in the structure called `my_options` (as in the previous example) except that if the `Display` parameter is not defined, it returns the value `'final'`.

```
optnew = optimget(my_options, 'Display', 'final');
```

## See Also

`optimset` | `fminbnd` | `fminsearch` | `fzero` | `lsqnonneg`

Introduced before R2006a

## optimset

Create or edit optimization options structure

### Syntax

```
options = optimset('param1',value1,'param2',value2,...)
optimset
options = optimset
options = optimset(optimfun)
options = optimset(olddopts,'param1',value1,...)
options = optimset(olddopts,newopts)
```

### Description

The function `optimset` creates an `options` structure that you can pass as an input argument to the following four MATLAB optimization functions:

- `fminbnd`
- `fminsearch`
- `fzero`
- `lsqnonneg`

You can use the `options` structure to change the default parameters for these functions.

---

**Note** If you have an Optimization Toolbox license, you can also use `optimset` to create an expanded `options` structure containing additional options specifically designed for the functions provided in that toolbox. For more information about these additional options, see the reference page for the enhanced Optimization Toolbox `optimset` function.

---

`options = optimset('param1',value1,'param2',value2,...)` creates an optimization options structure called `options`, in which the specified parameters (`param`) have specified values. Any unspecified parameters are set to `[]` (parameters with value `[]` indicate to use the default value for that parameter when `options`

is passed to the optimization function). It is sufficient to type only enough leading characters to define the parameter name uniquely. Case is ignored for parameter names.

`optimset` with no input or output arguments displays a complete list of parameters with their valid values.

`options = optimset` (with no input arguments) creates an options structure `options` where all fields are set to `[]`.

`options = optimset(optimfun)` creates an options structure `options` with all parameter names and default values relevant to the optimization function `optimfun`.

`options = optimset(olddopts, 'param1', value1, ...)` creates a copy of `olddopts`, modifying the specified parameters with the specified values.

`options = optimset(olddopts, newopts)` combines an existing options structure `olddopts` with a new options structure `newopts`. Any parameters in `newopts` with nonempty values overwrite the corresponding old parameters in `olddopts`.

## Options

The following table lists the available options for the MATLAB optimization functions.

Option	Value	Description	Solvers
Display	'off'   'iter'   {'final'}   'notify'	Level of display. 'off' displays no output; 'iter' displays output at each iteration (not available for <code>lsqnonneg</code> ); 'final' displays just the final output; 'notify' displays output only if the function does not converge.	fminbnd, fminsearch,fzero, lsqnonneg
FunValChec	{'off'}   'on'	Check whether objective function values are valid. 'on' displays an error when the objective function returns a value that is <code>complex</code> or <code>NaN</code> . 'off' displays no error.	fminbnd, fminsearch,fzero

Option	Value	Description	Solvers
MaxFunEval	positive integer	Maximum number of function evaluations allowed.	fminbnd, fminsearch
MaxIter	positive integer	Maximum number of iterations allowed.	fminbnd, fminsearch
OutputFcn	function   {[ ]}	User-defined function that an optimization function calls at each iteration. See “Output Functions”.	fminbnd, fminsearch, fzero
PlotFcns	function   {[ ]}	User-defined or built-in plot function that an optimization function calls at each iteration. Built-in functions: <ul style="list-style-type: none"> <li>• @optimplotx plots the current point</li> <li>• @optimplotfval plots the function value</li> <li>• @optimplotfunccount plots the function count (not available for fzero)</li> </ul> See “Plot Functions”.	fminbnd, fminsearch, fzero
TolFun	positive scalar	Termination tolerance on the function value. See “Tolerances and Stopping Criteria”.	fminsearch
TolX	positive scalar	Termination tolerance on $x$ , the current point. See “Tolerances and Stopping Criteria”.	fminbnd, fminsearch, fzero, lsqnonneg

## Examples

This statement creates an optimization options structure called `options` in which the `Display` parameter is set to `'iter'` and the `TolFun` parameter is set to `1e-8`.

```
options = optimset('Display','iter','TolFun',1e-8)
```

This statement makes a copy of the options structure called `options`, changing the value of the `TolX` parameter and storing new values in `optnew`.

```
optnew = optimset(options,'TolX',1e-4);
```

This statement returns an optimization options structure that contains all the parameter names and default values relevant to the function `fminbnd`.

```
optimset('fminbnd')
```

## or, |

Find logical OR

### Syntax

A | B | ...  
or(A, B)

### Description

A | B | ... performs a logical OR of all input arrays A, B, etc., and returns an array containing elements set to either logical 1 (**true**) or logical 0 (**false**). An element of the output array is set to 1 if any input arrays contain a nonzero element at that same array location. Otherwise, that element is set to 0.

Each input of the expression can be an array or can be a scalar value. All nonscalar input arrays must have equal dimensions. If one or more inputs are an array, then the output is an array of the same dimensions. If all inputs are scalar, then the output is scalar.

If the expression contains both scalar and nonscalar inputs, then each scalar input is treated as if it were an array having the same dimensions as the other input arrays. In other words, if input A is a 3-by-5 matrix and input B is the number 1, then B is treated as if it were a 3-by-5 matrix of ones.

or(A, B) is called for the syntax A | B when either A or B is an object.

---

**Note** The symbols | and || perform different operations in a MATLAB application. The element-wise OR operator described here is |. The short-circuit OR operator is ||.

---

### Examples

If matrix A is

0.4235	0.5798	0	0.7942	0
0.5155	0	0	0	0.8744

	0	0	0	0.4451	0.0150
0.4329		0.6405	0.6808	0	0

and matrix B is

0	1	0	1	0
1	1	0	0	1
0	0	0	1	0
0	1	0	0	1

then

A   B					
ans =					
	1	1	0	1	0
	1	1	0	0	1
	0	0	0	1	1
	1	1	1	0	1

## ordeig

Eigenvalues of quasitriangular matrices

### Syntax

```
E = ordeig(T)
E = ordeig(AA, BB)
```

### Description

`E = ordeig(T)` takes a quasitriangular Schur matrix `T`, typically produced by `schur`, and returns the vector `E` of eigenvalues in their order of appearance down the diagonal of `T`.

`E = ordeig(AA, BB)` takes a quasitriangular matrix pair `AA` and `BB`, typically produced by `qz`, and returns the generalized eigenvalues in their order of appearance down the diagonal of  $AA - \lambda * BB$ .

`ordeig` is an order-preserving version of `eig` for use with `ordschur` and `ordqz`. It is also faster than `eig` for quasitriangular matrices.

### Examples

#### Example 1

```
T=diag([1 -1 3 -5 2]);
```

`ordeig(T)` returns the eigenvalues of `T` in the same order they appear on the diagonal.

```
ordeig(T)
```

```
ans =
```

```
 1
 -1
 3
```

```
-5
 2
```

`eig(T)`, on the other hand, returns the eigenvalues in order of increasing magnitude.

```
eig(T)
```

```
ans =
```

```
-5
-1
 1
 2
 3
```

## Example 2

```
A = rand(10);
[U, T] = schur(A);
abs(ordeig(T))
```

```
ans =
```

```
5.3786
0.7564

# orderfields

Order fields of structure array

## Syntax

```
s = orderfields(s1)
s = orderfields(s1, s2)
s = orderfields(s1, c)
s = orderfields(s1, perm)
[s, perm] = orderfields(...)
```

## Description

`s = orderfields(s1)` orders the fields in `s1` so that the new structure array `s` has field names in ASCII dictionary order.

`s = orderfields(s1, s2)` orders the fields in `s1` so that the new structure array `s` has field names in the same order as those in `s2`. Structures `s1` and `s2` must have the same fields.

`s = orderfields(s1, c)` orders the fields in `s1` so that the new structure array `s` has field names in the same order as those in the cell array of field name strings `c`. Structure `s1` and cell array `c` must contain the same field names.

`s = orderfields(s1, perm)` orders the fields in `s1` so that the new structure array `s` has fieldnames in the order specified by the indices in permutation vector `perm`.

If `s1` has `N` fieldnames, the elements of `perm` must be an arrangement of the numbers from 1 to `N`. This is particularly useful if you have more than one structure array that you would like to reorder in the same way.

`[s, perm] = orderfields(...)` returns a permutation vector representing the change in order performed on the fields of the structure array that results in `s`.

## Examples

Create a structure `s`. Then create a new structure from `s`, but with the fields ordered alphabetically:

```
s = struct('b', 2, 'c', 3, 'a', 1)
s =
 b: 2
 c: 3
 a: 1
```

```
snew = orderfields(s)
snew =
 a: 1
 b: 2
 c: 3
```

Arrange the fields of `s` in the order specified by the second (cell array) argument of `orderfields`. Return the new structure in `snew` and the permutation vector used to create it in `perm`:

```
[snew, perm] = orderfields(s, {'b', 'a', 'c'})
snew =
 b: 2
 a: 1
 c: 3
perm =
 1
 3
 2
```

Now create a new structure, `s2`, having the same fieldnames as `s`. Reorder the fields using the permutation vector returned in the previous operation:

```
s2 = struct('b', 3, 'c', 7, 'a', 4)
s2 =
 b: 3
 c: 7
 a: 4

snew = orderfields(s2, perm)
snew =
 b: 3
 a: 4
```

c: 7

## More About

### Tips

`orderfields` only orders top-level fields. It is not recursive.

## ordqz

Reorder eigenvalues in QZ factorization

### Syntax

```
[AAS,BBS,QS,ZS] = ordqz(AA,BB,Q,Z,select)
[...] = ordqz(AA,BB,Q,Z,keyword)
[...] = ordqz(AA,BB,Q,Z,clusters)
```

### Description

[AAS,BBS,QS,ZS] = ordqz(AA,BB,Q,Z,select) reorders the QZ factorizations  $Q^*A^*Z = AA$  and  $Q^*B^*Z = BB$  produced by the qz function for a matrix pair (A,B). It returns the reordered pair (AAS,BBS) and the cumulative orthogonal transformations QS and ZS such that  $QS^*A^*ZS = AAS$  and  $QS^*B^*ZS = BBS$ . In this reordering, the selected cluster of eigenvalues appears in the leading (upper left) diagonal blocks of the quasitriangular pair (AAS,BBS), and the corresponding invariant subspace is spanned by the leading columns of ZS. The logical vector `select` specifies the selected cluster as  $E(\text{select})$  where E is the vector of eigenvalues as they appear along the diagonal of  $AA - \lambda^*BB$ .

---

**Note** To extract E from AA and BB, use `ordeig(BB)`, instead of `eig`. This ensures that the eigenvalues in E occur in the same order as they appear on the diagonal of  $AA - \lambda^*BB$ .

---

[...] = ordqz(AA,BB,Q,Z,keyword) sets the selected cluster to include all eigenvalues in the region specified by keyword:

keyword	Selected Region
'lhp'	Left-half plane ( $\text{real}(E) < 0$ )
'rhp'	Right-half plane ( $\text{real}(E) > 0$ )
'udi'	Interior of unit disk ( $\text{abs}(E) < 1$ )
'udo'	Exterior of unit disk ( $\text{abs}(E) > 1$ )

[...] = `ordqz(AA, BB, Q, Z, clusters)` reorders multiple clusters at once. Given a vector `clusters` of cluster indices commensurate with `E = ordeig(AA, BB)`, such that all eigenvalues with the same `clusters` value form one cluster, `ordqz` sorts the specified clusters in descending order along the diagonal of `(AAS, BBS)`. The cluster with highest index appears in the upper left corner.

## See Also

`ordeig` | `ordschur` | `qz`

**Introduced before R2006a**

## ordschur

Reorder eigenvalues in Schur factorization

### Syntax

```
[US,TS] = ordschur(U,T,select)
[US,TS] = ordschur(U,T,keyword)
[US,TS] = ordschur(U,T,clusters)
```

### Description

`[US,TS] = ordschur(U,T,select)` reorders the Schur factorization  $X = U*TS*U'$  produced by the `schur` function and returns the reordered Schur matrix `TS` and the cumulative orthogonal transformation `US` such that  $X = US*TS*US'$ . In this reordering, the selected cluster of eigenvalues appears in the leading (upper left) diagonal blocks of the quasitriangular Schur matrix `TS`, and the corresponding invariant subspace is spanned by the leading columns of `US`. The logical vector `select` specifies the selected cluster as `E(select)` where `E` is the vector of eigenvalues as they appear along `T`'s diagonal.

---

**Note** To extract `E` from `T`, use `E = ordeig(T)`, instead of `eig`. This ensures that the eigenvalues in `E` occur in the same order as they appear on the diagonal of `TS`.

---

`[US,TS] = ordschur(U,T,keyword)` sets the selected cluster to include all eigenvalues in one of the following regions:

keyword	Selected Region
'lhp'	Left-half plane ( $\text{real}(E) < 0$ )
'rhp'	Right-half plane ( $\text{real}(E) > 0$ )
'udi'	Interior of unit disk ( $\text{abs}(E) < 1$ )
'udo'	Exterior of unit disk ( $\text{abs}(E) > 1$ )

`[US,TS] = ordschur(U,T,clusters)` reorders multiple clusters at once. Given a vector `clusters` of cluster indices, commensurate with `E = ordeig(T)`, and such that all eigenvalues with the same `clusters` value form one cluster, `ordschur` sorts the specified clusters in descending order along the diagonal of `TS`, the cluster with highest index appearing in the upper left corner.

## orient

Hardcopy paper orientation

### Alternatives

Use **File** → **Print Preview** on the figure window menu to directly manipulate print layout, paper size, headers, fonts and other properties when printing figures. For details, see “Print Figure from File Menu” in the MATLAB Graphics documentation.

### Syntax

```
orient
orient landscape
orient portrait
orient tall
orient(fig_handle)
orient(simulink_model)
orient(fig_handle,orientation)
orient(simulink_model,orientation)
```

### Description

`orient` returns a string with the current paper orientation: `portrait`, `landscape`, or `tall`.

`orient landscape` sets the paper orientation of the current figure to full-page landscape, orienting the longest page dimension horizontally. The figure is centered on the page and scaled to fit the page with a 0.25 inch border.

`orient portrait` sets the paper orientation of the current figure to portrait, orienting the longest page dimension vertically. The `portrait` option returns the page orientation to the MATLAB default. (Note that the result of using the `portrait` option is affected by changes you make to figure properties. See the "Algorithm" section for more specific information.)

`orient tall` maps the current figure to the entire page in portrait orientation, leaving a 0.25 inch border.

`orient(fig_handle)` returns the current orientation of the specified figure.

`orient(simulink_model)` returns the current orientation of the Simulink model.

`orient(fig_handle,orientation)` sets the orientation for the specified figure to the specified orientation (`landscape`, `portrait`, or `tall`).

`orient(simulink_model,orientation)` sets the orientation for the Simulink model.

## More About

### Algorithms

`orient` sets the `PaperOrientation`, `PaperPosition`, and `PaperUnits` properties of the current figure. Subsequent print operations use these properties. The result of using the `portrait` option can be affected by default property values as follows:

- If the current figure `PaperType` is the same as the default figure `PaperType` and the default figure `PaperOrientation` has been set to `landscape`, then the `orient portrait` command uses the current values of `PaperOrientation` and `PaperPosition` to place the figure on the page.
- If the current figure `PaperType` is the same as the default figure `PaperType` and the default figure `PaperOrientation` has been set to `landscape`, then the `orient portrait` command uses the default figure `PaperPosition` with the `x`, `y` and `width`, `height` values reversed (i.e., `[y,x,height,width]`) to position the figure on the page.
- If the current figure `PaperType` is different from the default figure `PaperType`, then the `orient portrait` command uses the current figure `PaperPosition` with the `x`, `y` and `width`, `height` values reversed (i.e., `[y,x,height,width]`) to position the figure on the page.

`print` | `printpreview` | `set`

Introduced before R2006a

## orth

Orthonormal basis for range of matrix

### Syntax

```
Q = orth(A)
```

### Description

`Q = orth(A)` returns an orthonormal basis for the range of **A**. The columns of **Q** are vectors, which span the range of **A**. The number of columns in **Q** is equal to the rank of **A**.

### Examples

#### Basis for Full Rank Matrix

Calculate and verify the orthonormal basis vectors for the range of a full rank matrix.

Define a matrix and find the rank.

```
A = [1 0 1; -1 -2 0; 0 1 -1];
```

```
r = rank(A)
```

```
r =
```

```
3
```

Since **A** is a square matrix of full rank, the orthonormal basis calculated by `orth(A)` matches the matrix **U** calculated in the singular value decomposition, `[U,S] = svd(A, 'econ')`. This is because the singular values of **A** are all nonzero.

Calculate the orthonormal basis for the range of **A** using `orth`.

```
Q = orth(A)
```

```
Q =
```

```
-0.1200 -0.8097 0.5744
 0.9018 0.1531 0.4042
-0.4153 0.5665 0.7118
```

The number of columns in  $Q$  is equal to  $\text{rank}(A)$ . Since  $A$  is of full rank,  $Q$  and  $A$  are the same size.

Verify that the basis,  $Q$ , is orthogonal and normalized within a reasonable error range.

```
E = norm(eye(r) - Q' * Q, 'fro')
```

```
E =
```

```
9.6228e-16
```

The error is on the order of `eps`.

### Basis for Rank Deficient Matrix

Calculate and verify the orthonormal basis vectors for the range of a rank deficient matrix.

Define a singular matrix and find the rank.

```
A = [1 0 1; 0 1 0; 1 0 1];
r = rank(A)
```

```
r =
```

```
2
```

Since  $A$  is rank deficient, the orthonormal basis calculated by `orth(A)` matches only the first  $r = 2$  columns of matrix  $U$  calculated in the singular value decomposition,  $[U, S] = \text{svd}(A, 'econ')$ . This is because the singular values of  $A$  are *not* all nonzero.

Calculate the orthonormal basis for the range of  $A$  using `orth`.

```
Q = orth(A)
```

```
Q =
```

```
-0.7071 0
 0 1.0000
-0.7071 0
```

Since  $A$  is rank deficient,  $Q$  contains one fewer column than  $A$ .

## Input Arguments

### **A** — Input matrix

scalar | vector | matrix

Input matrix, specified as a scalar, vector, or matrix.

Data Types: `single` | `double`

Complex Number Support: Yes

## More About

### Range

The column space, or *range*, of a matrix  $A$  is the collection of all linear combinations of the columns of  $A$ . Any vector,  $\mathbf{b}$ , that is a solution to the linear equation,  $A\mathbf{x} = \mathbf{b}$ , is included in the range of  $A$  since you can also write it as a linear combination of the columns of  $A$ .

### Rank

The rank of a matrix is equal to the dimension of the range.

### Algorithms

`orth` is obtained from  $U$  in the singular value decomposition,  $[U,S] = \text{svd}(A, 'econ')$ .

If  $r = \text{rank}(A)$ , the first  $r$  columns of  $U$  form an orthonormal basis for the range of  $A$ .

### See Also

`null` | `rank` | `svd`

Introduced before R2006a

# outerjoin

Outer join between two tables

## Syntax

```
C = outerjoin(A,B)
C = outerjoin(A,B,Name,Value)
[C,ia,ib] = outerjoin(___)
```

## Description

`C = outerjoin(A,B)` creates the table, `C`, as the outer join between the tables `A` and `B` by matching up rows using all the variables with the same name as key variables.

The outer join includes the rows that match between `A` and `B`, and also unmatched rows from either `A` or `B`, all with respect to the key variables. `C` contains all variables from both `A` and `B`, including the key variables.

`C = outerjoin(A,B,Name,Value)` performs the outer-join operation with additional options specified by one or more `Name,Value` pair arguments.

`[C,ia,ib] = outerjoin( ___ )` also returns index vectors, `ia` and `ib`, indicating the correspondence between rows in `C` and those in `A` and `B` respectively. You can use this syntax with any of the input arguments in the previous syntaxes.

## Examples

### Outer-Join Operation of Tables with One Variable in Common

Create a table, `A`.

```
A = table([5;12;23;2;15;6],...
 {'cheerios';'pizza';'salmon';'oreos';'lobster';'pizza'},...
 'VariableNames',{'Age','FavoriteFood'},...
 'RowNames',{'Amy','Bobby','Holly','Harry','Marty','Sally'})
```

A =

	Age	FavoriteFood
Amy	5	'cheerios'
Bobby	12	'pizza'
Holly	23	'salmon'
Harry	2	'oreos'
Marty	15	'lobster'
Sally	6	'pizza'

Create a table, B, with one variable in common with A, called FavoriteFood.

```
B = table({'cheerios';'oreos';'pizza';'salmon';'cake'},...
[110;160;140;367;243],...
{'A-';'D';'B';'B';'C-'},...
'VariableNames',{'FavoriteFood','Calories','NutritionGrade'})
```

B =

FavoriteFood	Calories	NutritionGrade
'cheerios'	110	'A-'
'oreos'	160	'D'
'pizza'	140	'B'
'salmon'	367	'B'
'cake'	243	'C-'

Use the `outerjoin` function to create a new table, C, with data from tables A and B.

```
C = outerjoin(A,B)
```

C =

Age	FavoriteFood_A	FavoriteFood_B	Calories	NutritionGrade
NaN	' '	'cake'	243	'C-'
5	'cheerios'	'cheerios'	110	'A-'
15	'lobster'	' '	NaN	' '
2	'oreos'	'oreos'	160	'D'
12	'pizza'	'pizza'	140	'B'
6	'pizza'	'pizza'	140	'B'

```
23 'salmon' 'salmon' 367 'B'
```

Table C contains a separate variable for the key variable from A, called `FavoriteFood_A`, and the key variable from B, called `FavoriteFood_B`.

### Merge Key Variable Pair to Single Variable

Create a table, A.

```
A = table({'a' 'b' 'c' 'e' 'h'},[1 2 3 11 17]',...
 'VariableNames',{ 'Key1' 'Var1'})
```

A =

Key1	Var1
'a'	1
'b'	2
'c'	3
'e'	11
'h'	17

Create a table, B, with common values in the variable `Key1` between tables A and B, but also containing rows with values of `Key1` not present in A.

```
B = table({'a' 'b' 'd' 'e'},[4;5;6;7]',...
 'VariableNames',{ 'Key1' 'Var2'})
```

B =

Key1	Var2
'a'	4
'b'	5
'd'	6
'e'	7

Use the `outerjoin` function to create a new table, C, with data from tables A and B. Merge the key values into a single variable in the output table, C.

```
C = outerjoin(A,B, 'MergeKeys', true)
```

C =

Key1	Var1	Var2
'a'	1	4
'b'	2	5
'c'	3	NaN
'd'	NaN	6
'e'	11	7
'h'	17	NaN

Variables in table C that came from A contain null values in the rows that have no match from B. Similarly, variables in C that came from B contain null values in those rows that had no match from A.

## Outer-Join Operation of Tables and Indices to Values

Create a table, A.

```
A = table({'a' 'b' 'c' 'e' 'h'},[1 2 3 11 17]',...
 'VariableNames',{ 'Key1' 'Var1'})
```

A =

Key1	Var1
'a'	1
'b'	2
'c'	3
'e'	11
'h'	17

Create a table, B, with common values in the variable Key1 between tables A and B, but also containing rows with values of Key1 not present in A.

```
B = table({'a' 'b' 'd' 'e'},[4;5;6;7],...
 'VariableNames',{ 'Key1' 'Var2'})
```

B =

Key1	Var2
------	------

```
'a' 4
'b' 5
'd' 6
'e' 7
```

Use the `outerjoin` function to create a new table, **C**, with data from tables **A** and **B**. Match up rows with common values in the key variable, **Key1**, but also retain rows whose key values don't have a match.

Also, return index vectors, **ia** and **ib** indicating the correspondence between rows in **C** and rows in **A** and **B** respectively.

```
[C,ia,ib] = outerjoin(A,B)
```

```
C =
```

Key1_A	Var1	Key1_B	Var2
'a'	1	'a'	4
'b'	2	'b'	5
'c'	3	''	NaN
''	NaN	'd'	6
'e'	11	'e'	7
'h'	17	''	NaN

```
ia =
```

```
1
2
3
0
4
5
```

```
ib =
```

```
1
2
0
3
4
0
```

The index vectors `ia` and `ib` contain zeros to indicate the rows in table `C` that do not correspond to rows in tables `A` or `B`, respectively.

### Left Outer-Join Operation of Tables and Indices to Values

Create a table, `A`.

```
A = table({'a' 'b' 'c' 'e' 'h'},[1 2 3 11 17]',...
 'VariableNames',{ 'Key1' 'Var1'})
```

`A =`

Key1	Var1
'a'	1
'b'	2
'c'	3
'e'	11
'h'	17

Create a table, `B`, with common values in the variable `Key1` between tables `A` and `B`, but also containing rows with values of `Key1` not present in `A`.

```
B = table({'a' 'b' 'd' 'e'},[4;5;6;7],...
 'VariableNames',{ 'Key1' 'Var2'})
```

`B =`

Key1	Var2
'a'	4
'b'	5
'd'	6
'e'	7

Use the `outerjoin` function to create a new table, `C`, with data from tables `A` and `B`. Ignore rows in `B` whose key values do not match any rows in `A`.

Also, return index vectors, `ia` and `ib` indicating the correspondence between rows in `C` and rows in `A` and `B` respectively.

```
[C,ia,ib] = outerjoin(A,B,'Type','left')
```

```
C =
```

Key1_A	Var1	Key1_B	Var2
'a'	1	'a'	4
'b'	2	'b'	5
'c'	3	''	NaN
'e'	11	'e'	7
'h'	17	''	NaN

```
ia =
```

```
1
2
3
4
5
```

```
ib =
```

```
1
2
0
4
0
```

All values of `ia` are nonzero indicating that all rows in `C` have corresponding rows in `A`.

## Input Arguments

**A, B** — Input tables  
tables

Input tables, specified as tables.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single

quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'Keys',2` uses the second variable in A and the second variable in B as key variables.

### **'Keys' — Variables to use as keys**

positive integer | vector of positive integers | variable name | cell array of variable names | logical vector

Variables to use as keys, specified as the comma-separated pair consisting of `'Keys'` and a positive integer, vector of positive integers, variable name, cell array of variable names, or logical vector.

You cannot use the `'Keys'` name-value pair argument with the `'LeftKeys'` and `'RightKeys'` name-value pair arguments.

Example: `'Keys',[1 3]` uses the first and third variables in A and B as a key variables.

### **'LeftKeys' — Variables to use as keys in A**

positive integer | vector of positive integers | variable name | cell array of variable names | logical vector

Variables to use as keys in A, specified as the comma-separated pair consisting of `'LeftKeys'` and a positive integer, vector of positive integers, variable name, cell array of variable names, or logical vector.

You must use the `'LeftKeys'` name-value pair argument in conjunction with the `'RightKeys'` name-value pair argument. `'LeftKeys'` and `'RightKeys'` both must specify the same number of key variables. `outerjoin` pairs key values based on their order.

Example: `'LeftKeys',1` uses only the first variable in A as a key variable.

### **'RightKeys' — Variables to use as keys in B**

positive integer | vector of positive integers | variable name | cell array of variable names | logical vector

Variables to use as keys in B, specified as the comma-separated pair consisting of `'RightKeys'` and a positive integer, vector of positive integers, variable name, cell array of variable names, or logical vector.

You must use the `'RightKeys'` name-value pair argument in conjunction with the `'LeftKeys'` name-value pair argument. `'LeftKeys'` and `'RightKeys'` both must

specify the same number of key variables. `outerjoin` pairs key values based on their order.

Example: `'RightKeys', 3` uses only the third variable in B as a key variable.

### 'MergeKeys' — Merge keys flag

false (default) | true | 0 | 1

Merge keys flag, specified as the comma-separated pair consisting of `'MergeKeys'` and either `false`, `true`, 0 or 1.

false	<p><code>outerjoin</code> includes two separate variables in the output table, C, for each key variable pair from tables A and B.</p> <p>This is the default behavior.</p>
true	<p><code>outerjoin</code> includes a single variable in the output table, C, for each key variable pair from tables A and B.</p> <p><code>outerjoin</code> creates the single variable by merging the key values from A and B, taking values from A where a corresponding row exists in A, and taking values from B otherwise.</p> <p>If you specify, <code>'MergeKeys', true</code>, then <code>outerjoin</code> includes all key variables in the output table, C, and overrides the inclusion or exclusion of key variables specified via the <code>'LeftVariables'</code> and <code>'RightVariables'</code> name-value pair arguments.</p>

### 'LeftVariables' — Variables from A to include in C

positive integer | vector of positive integers | variable name | cell array containing one or more variable names | logical vector

Variables from A to include in C, specified as the comma-separated pair consisting of `'LeftVariables'` and a positive integer, vector of positive integers, variable name, cell array of variable names, or logical vector.

You can use `'LeftVariables'` to include or exclude key variables as well as nonkey variables from the output, C.

By default, `outerjoin` includes all variables from A.

### 'RightVariables' — Variables from B to include in C

positive integer | vector of positive integers | variable name | cell array containing one or more variable names | logical vector

Variables from **B** to include in **C**, specified as the comma-separated pair consisting of `'RightVariables'` and a positive integer, vector of positive integers, variable name, cell array of variable names, or logical vector.

You can use `'RightVariables'` to include or exclude key variables as well as nonkey variables from the output, **C**.

By default, `outerjoin` includes all the variables from **B**.

### **'Type' — Type of outer join operation**

`'full'` (default) | `'left'` | `'right'`

Type of outer-join operation, specified as the comma-separated pair consisting of `'Type'` and either `'full'`, `'left'`, or `'right'`.

- For a left outer join, **C** contains rows corresponding to key values in **A** that do not match any values in **B**, but not vice-versa.
- For a right outer join, **C** contains rows corresponding to key values in **B** that do not match any values in **A**, but not vice-versa.

By default, `outerjoin` does a full outer join and includes unmatched rows from both **A** and **B**.

## **Output Arguments**

### **C — Outer join from A and B**

table

Outer join from **A** and **B**, returned as a table. The output table, **C**, contains one row for each pair of rows in tables **A** and **B** that share the same combination of key values. If **A** and **B** contain variables with the same name, `outerjoin` adds a unique suffix to the corresponding variable names in **C**. Variables in **C** that came from **A** contain null values in those rows that had no match from **B**. Similarly, variables in **C** that came from **B** contain null values in those rows that had no match from **A**.

In general, if there are  $m$  rows in table **A** and  $n$  rows in table **B** that all contain the same combination of values in the key variables, table **C** contains  $m*n$  rows for that combination. **C** also contains rows corresponding to key value combinations in one input table that do not match any row the other input table.

**C** contains the horizontal concatenation of **A(ia,LeftVars)** and **B(ib,RightVars)** sorted by the values in the key variables. By default, **LeftVars** consists of all the variables of **A**, and **RightVars** consists of all the from **B**. Otherwise, **LeftVars** consists of the variables specified by the '**LeftVariables**' name-value pair argument, and **RightVars** consists of the variables specified by the '**RightVariables**' name-value pair argument.

You can store additional metadata such as descriptions, variable units, variable names, and row names in the table. For more information, see [Table Properties](#).

**ia — Index to A**

column vector

Index to **A**, returned as a column vector. Each element of **ia** identifies the row in table **A** that corresponds to that row in the output table, **C**. The vector **ia** contains zeros to indicate the rows in **C** that do not correspond to rows in **A**.

**ib — Index to B**

column vector

Index to **B**, returned as a column vector. Each element of **ib** identifies the row in table **B** that corresponds to that row in the output table, **C**. The vector **ib** contains zeros to indicate the rows in **C** that do not correspond to rows in **B**.

## More About

**Key Variable**

Variable used to match and combine data between the input tables, **A** and **B**.

**Introduced in R2013b**

# pack

Consolidate workspace memory

## Syntax

```
pack
pack filename
pack('filename')
```

## Description

`pack` frees up needed space by reorganizing information so that it only uses the minimum memory required. All variables from your base and global workspaces are preserved. Any persistent variables that are defined at the time are set to their default value (the empty matrix, `[]`).

The MATLAB software temporarily stores your workspace data in a file called `tp#####.mat` (where `#####` is a numeric value) that is located in your temporary folder. (You can use the command `dir(tempdir)` to see the files in this folder).

`pack filename` frees space in memory, temporarily storing workspace data in a file specified by `filename`. This file resides in your current working folder and, unless specified otherwise, has a `.mat` file extension.

`pack('filename')` is the function form of `pack`.

## Examples

Change the current folder to one that is writable, run `pack`, and return to the previous folder.

```
cwd = pwd;
cd(tempdir);
pack
cd(cwd)
```

## More About

### Tips

You can only run `pack` from the MATLAB command line.

If you specify a `filename` argument, that file must reside in a folder for which you have write permission.

The `pack` function does not affect the amount of memory allocated to the MATLAB process. You must quit MATLAB to free up this memory.

Since MATLAB uses a heap method of memory management, extended MATLAB sessions may cause memory to become fragmented. When memory is fragmented, there may be plenty of free space, but not enough contiguous memory to store a new large variable.

If you get the `Out of memory` message from MATLAB, the `pack` function may find you some free memory without forcing you to delete variables.

The `pack` function frees space by

- Saving all variables in the base and global workspaces to a temporary file.
- Clearing all variables and functions from memory.
- Reloading the base and global workspace variables back from the temporary file and then deleting the file.

If you use `pack` and there is still not enough free memory to proceed, you must clear some variables. If you run out of memory often, you can allocate larger matrices earlier in the MATLAB session and use these system-specific tips:

- When running MATLAB on The Open Group UNIX platforms, ask your system manager to increase your swap space.
- On Microsoft Windows platforms, increase virtual memory using the Windows Control Panel.

To maintain persistent variables when you run `pack`, use `mlock` in the function.

# padecoeff

Padé approximation of time delays

## Syntax

```
[num,den] = padecoeff(T,N)
```

## Description

`[num,den] = padecoeff(T,N)` returns the Nth-order Padé approximation of the continuous-time delay  $T$  in transfer function form. The row vectors `num` and `den` contain the numerator and denominator coefficients in descending powers of  $s$ . Both are Nth-order polynomials.

Class support for input  $T$ :

float: double, single

## Class Support

Input  $T$  support floating-point values of type `single` or `double`.

## pagesetupdlg

Page setup dialog box

### Syntax

```
dlg = pagesetupdlg(fig)
```

---

**Note:** pagesetupdlg is no longer supported. Use `printpreview` instead.

---

### Description

`dlg = pagesetupdlg(fig)` creates a dialog box from which a set of page layout properties for the figure window, `fig`, can be set.

`pagesetupdlg` implements the "Page Setup..." option in the **Figure File Menu**.

`pagesetupdlg` supports setting the layout for a single figure. `fig` must be a single figure handle, not a vector of figures or a Simulink diagram.

## pan

Pan view of graph interactively

### Syntax

```
pan on
pan xon
pan yon
pan off
pan
pan(figure_handle, ...)
h = pan(figure_handle)
```

### Description

`pan on` turns on mouse-based panning in the current figure.

`pan xon` turns on panning only in the *x* direction in the current figure.

`pan yon` turns on panning only in the *y* direction in the current figure.

`pan off` turns panning off in the current figure.

`pan` toggles the pan state in the current figure `on` or `off`.

`pan(figure_handle, ...)` sets the pan state in the specified figure.

`h = pan(figure_handle)` returns the figure's pan *mode object* for the figure `figure_handle` for you to customize the mode's behavior.

### Using Pan Mode Objects

Access the following properties of pan mode objects.

- *Enable* 'on' | 'off' — Specifies whether this figure mode is currently enabled on the figure
- *Motion* 'horizontal' | 'vertical' | 'both' — The type of panning enabled for the figure

- **FigureHandle** <handle> — The associated figure handle, a read-only property that cannot be set

## Pan Mode Callbacks

You can program the following callbacks for pan mode operations.

- **ButtonDownFilter** <function\_handle> — Function to intercept **ButtonDown** events

The application can inhibit the panning operation under circumstances the programmer defines, depending on what the callback returns. The input function handle should reference a function with two implicit arguments (similar to Handle Graphics object callbacks):

```
function [res] = myfunction(obj,event_obj)
% obj handle to the object clicked on
% event_obj event data (empty in this release)
% res [output] a logical flag to determine whether the pan
% operation should take place(for 'res' set to 'false')
% or the 'ButtonDownFcn' property of the object should
% take precedence (when 'res' is 'true')
```

- **ActionPreCallback** <function\_handle> — Function to execute before panning

Set this callback to if you need to execute code when a pan operation begins. The function handle should reference a function with two implicit arguments (similar to Handle Graphics object callbacks):

```
function myfunction(obj,event_obj)
% obj handle to the figure that has been clicked on
% event_obj object containing struct of event data
```

The event data struct has the following field:

<b>Axes</b>	The handle of the axes that is being panned
-------------	---------------------------------------------

- **ActionPostCallback** <function\_handle> — Function to execute after panning

Set this callback if you need to execute code when a pan operation ends. The function handle should reference a function with two implicit arguments (similar to Handle Graphics object callbacks):

```
function myfunction(obj,event_obj)
```

```
% obj handle to the figure that has been clicked on
% event_obj object containing struct of event data
% (same as the event data of the
% 'ActionPreCallback' callback)
```

## Pan Mode Utility Functions

The following functions in pan mode query and set certain of its properties.

- `flags = isAllowAxesPan(h, axes)` — Function querying permission to pan axes

Calling the function `isAllowAxesPan` on the pan object, `h`, with a vector of axes handles, `axes`, as input returns a logical array of the same dimension as the axes handle vector, which indicates whether a pan operation is permitted on the axes objects.

- `setAllowAxesPan(h, axes, flag)` — Function to set permission to pan axes

Calling the function `setAllowAxesPan` on the pan object, `h`, with a vector of axes handles, `axes`, and a logical scalar, `flag`, either allows or disallows a pan operation on the axes objects.

- `info = getAxesPanMotion(h, axes)` — Function to get style of pan operations

Calling the function `getAxesPanMotion` on the pan object, `h`, with a vector of axes handles, `axes`, as input will return a character cell array of the same dimension as the axes handle vector, which indicates the type of pan operation for each axes. Possible values for the type of operation are 'horizontal', 'vertical' or 'both'.

- `setAxesPanMotion(h, axes, style)` — Function to set style of pan operations

Calling the function `setAxesPanMotion` on the pan object, `h`, with a vector of axes handles, `axes`, and a character array, `style`, sets the style of panning on each axes.

## Examples

### Example 1 — Entering Pan Mode

Plot a graph and turn on Pan mode:

```
plot(magic(10));
pan on
```

```
% pan on the plot
```

## Example 2 — Constrained Pan

Constrain pan to *x*-axis using `set`:

```
plot(magic(10));
h = pan;
h.Motion = 'horizontal';
h.Enable = 'on';
% pan on the plot in the horizontal direction.
```

## Example 3 — Constrained Pan in Subplots

Create four axes as subplots and give each one a different panning behavior:

```
ax1 = subplot(2,2,1);
plot(1:10);
h = pan;
ax2 = subplot(2,2,2);
plot(rand(3));
setAllowAxesPan(h,ax2,false);
ax3 = subplot(2,2,3);
plot(peaks);
setAxesPanMotion(h,ax3,'horizontal');
ax4 = subplot(2,2,4);
contour(peaks);
setAxesPanMotion(h,ax4,'vertical');
% pan on the plots.
```

## Example 4 — Coding a ButtonDown Callback

Create a `buttonDown` callback for pan mode objects to trigger. Copy the following code to a new file, execute it, and observe panning behavior:

```
function demo
% Allow a line to have its own 'ButtonDownFcn' callback.
hLine = plot(rand(1,10));
hLine.ButtonDownFcn = 'disp(''This executes'')';
hLine.Tag = 'DoNotIgnore';
h = pan;
h.ButtonDownFilter = @mycallback;
h.Enable = 'on';
```

```

% mouse click on the line
%
function [flag] = mycallback(obj,event_obj)
% If the tag of the object is 'DoNotIgnore', then
% return true.

% Indicate what the target is.
disp(['Clicked ' obj.Type ' object'])
objTag = obj.Tag;
if strcmpi(objTag,'DoNotIgnore')
 flag = true;
else
 flag = false;
end

```

## Example 5 — Coding Pre- and Post-Callback Behavior

Create callbacks for pre- and post-ButtonDown events for pan mode objects to trigger. Copy the following code to a new file, execute it, and observe panning behavior:

```

function demo
% Listen to pan events
plot(1:10);
h = pan;
h.ActionPreCallback = @myprecallback;
h.ActionPostCallback = @mypostcallback;
h.Enable = 'on';
%
function myprecallback(obj, evd)
disp('A pan is about to occur. ');
%
function mypostcallback(obj, evd)
newLim = evd.Axes.XLim;
msgbox(sprintf('The new X-Limits are [%f,%f].',newLim));

```

## Example 6 — Creating a Context Menu for Pan Mode

Coding a context menu that lets the user to switch to Zoom mode by right-clicking:

```

figure
plot(magic(10));
hCM = uicontextmenu;
hMenu = uimenu('Parent',hCM,'Label','Switch to zoom',...

```

```
 'Callback', 'zoom(gcf, 'on')');
hPan = pan(gcf);
hPan.UIContextMenu = hCM;
pan('on')
```

You cannot add items to the built-in pan context menu, but you can replace it with your own.

## Alternatives

Use the Pan tool  on the figure toolbar to enable and disable pan mode on a plot, or select **Pan** from the figure's **Tools** menu. For details, see “Panning — Shifting Your View of the Graph”.

## More About

### Tips

You can create a pan mode object once and use it to customize the behavior of different axes, as Example 3 illustrates. You can also change its callback functions on the fly.

---

**Note: Do not change figure callbacks within an interactive mode.** While a mode is active (when panning, zooming, etc.), you will receive a warning if you attempt to change any of the figure's callbacks and the operation will not succeed. The one exception to this rule is the figure `WindowButtonMotionFcn` callback, which can be changed from within a mode. Therefore, if you are creating a UI that updates a figure's callbacks, the UI should some keep track of which interactive mode is active, if any, before attempting to do this.

---

When you assign different pan behaviors to different `subplot` axes via a mode object and then link them using the `linkaxes` function, the behavior of the axes you manipulate with the mouse carries over to the linked axes, regardless of the behavior you previously set for the other axes.

## matlab.unittest.parameters

Summary of classes associated with MATLAB Unit Test parameters

### Description

The `matlab.unittest.parameters` package consists of the following classes used in parameterized testing.

<code>matlab.unittest.parameters.EmptyParameter</code>	Empty parameter implementation
<code>matlab.unittest.parameters.ClassSetupParameter</code>	Specification of Class Setup Parameter
<code>matlab.unittest.parameters.TestParameter</code>	Specification of Test Parameter
<code>matlab.unittest.parameters.MethodSetupParameter</code>	Specification of Method Setup Parameter

### See Also

`matlab.unittest.TestSuite.selectIf`

### Related Examples

- “Create Advanced Parameterized Test”

# matlab.unittest.parameters.EmptyParameter class

**Package:** matlab.unittest.parameters

Empty parameter implementation

## Description

The `matlab.unittest.parameters.EmptyParameter` class is a `Parameter` implementation that provides no parameter information. There is no need for test authors to interact with this `Parameter` directly. This class provides an empty parameter instance to the `Parameterization` property of a nonparameterized test element.

## Properties

### Property

String indicating the name of the property that defines the Empty Parameter.

### Name

String indicating the name that uniquely identifies a particular value for a Empty Parameter.

### Value

Value of the Empty Parameter. The `Value` property holds the data that the Test Runner uses for parameterized testing.

## Copy Semantics

Value. To learn how value classes affect copy operations, see [Copying Objects in the MATLAB documentation](#).

## See Also

`matlab.unittest.TestCase`

## pareto

Pareto chart

## Syntax

```
pareto(Y)
pareto(Y, names)
pareto(Y, X)
H = pareto(...)
```

## Description

Pareto charts display the values in the vector `Y` as bars drawn in descending order. Values in `Y` must be nonnegative and not include NaNs. Only the first 95% of the cumulative distribution is displayed.

`pareto(Y)` labels each bar with its element index in `Y` and also plots a line displaying the cumulative sum of `Y`.

`pareto(Y, names)` labels each bar with the associated name in the string matrix or cell array `names`.

`pareto(Y, X)` labels each bar with the associated value from `X`.

`pareto(ax, ...)` plots into the axes `ax` rather than the current axes, `gca`.

`H = pareto(...)` returns handles to the primitive line and bar series objects created.

## Examples

### Create Pareto Chart

Create a Pareto chart of vector `y`.

```
y = [90,75,30,60,5,40,40,5];
figure
pareto(y)
```

`pareto` displays the elements in `y` as bars in descending order and labels each bar with its index in `y`. Since `pareto` displays only the first 95% of the cumulative distribution, some elements in `y` are not displayed.

### Label Bars in Pareto Chart

Examine the cumulative productivity of a group of programmers to see how normal its distribution is. Label each bar with the name of the programmer.

```
codelines = [200 120 555 608 1024 101 57 687];
```

```
coders = {'Fred', 'Ginger', 'Norman', 'Max', 'Julia', 'Wally', 'Heidi', 'Pat'};

figure
pareto(codelines, coders)
title('Lines of Code by Programmer')
```

## More About

### Tips

You cannot place datatips (use the Datacursor tool) on graphs created with pareto.

# parfor

Parallel for loop

## Syntax

```
parfor loopvar = initval:endval; statements; end
parfor (loopvar = initval:endval, M); statements; end
```

## Description

`parfor loopvar = initval:endval; statements; end` executes a series of MATLAB statements for values of `loopvar` between `initval` and `endval`, inclusive, which specify a vector of increasing integer values. The loop runs in parallel when you have the Parallel Computing Toolbox or when you create a MEX function or standalone code with MATLAB Coder. Unlike a traditional `for`-loop, iterations are not executed in a guaranteed order. You cannot call scripts directly in a `parfor`-loop. However, you can call functions that call scripts.

`parfor (loopvar = initval:endval, M); statements; end` executes statements in a loop using a maximum of `M` workers or threads, where `M` is a nonnegative integer.

## Examples

Perform three large eigenvalue computations using three workers or cores with Parallel Computing Toolbox software:

```
parpool(3)
parfor i=1:3, c(:,i) = eig(rand(1000)); end
```

## More About

### Tips

- If you have Parallel Computing Toolbox software, see the function reference pages for `parfor` and `parpool` for additional information.

- If you have MATLAB Coder software, see the `parfor` function reference page for additional information.

## parse

**Class:** inputParser

Parse function inputs

## Syntax

```
parse(p, argList)
```

## Description

`parse(p, argList)` parses and validates the inputs in `argList`.

## Input Arguments

**p**

Object of class `inputParser`.

**argList**

Comma separated list of inputs to parse and validate for your custom function. The class of each input depends upon your function definition.

## Examples

### Input Parsing

Parse and validate required and optional function inputs.

Create a custom function with required and optional inputs in the file `findArea.m`.

```
function a = findArea(width,varargin)
 p = inputParser;
 defaultHeight = 1;
```

```
defaultUnits = 'inches';
defaultShape = 'rectangle';
expectedShapes = {'square', 'rectangle', 'parallelogram'};

addRequired(p, 'width', @isnumeric);
addOptional(p, 'height', defaultHeight, @isnumeric);
addParameter(p, 'units', defaultUnits);
addParameter(p, 'shape', defaultShape, ...
 @(x) any(validatestring(x, expectedShapes)));

parse(p, width, varargin{:});
a = p.Results.width .* p.Results.height;
```

The input parser checks whether `width` and `height` are numeric, and whether the `shape` matches a string in cell array `expectedShapes`. `@` indicates a function handle, and the syntax `@(x)` creates an anonymous function with input `x`.

Call the function with inputs that do not match the scheme. For example, specify a nonnumeric value for the `width` input:

```
findArea('text')
```

```
Error using findArea (line 14)
The value of 'width' is invalid. It must satisfy the function: isnumeric.
```

Specify an unsupported value for `shape`:

```
findArea(4, 'shape', 'circle')
```

```
Error using findArea (line 14)
The value of 'shape' is invalid. Expected input to match one of these strings:
```

```
square, rectangle, parallelogram
```

```
The input, 'circle', did not match any of the valid strings.
```

# parseSoapResponse

Convert response string from SOAP (Simple Object Access Protocol) server into MATLAB types

## Compatibility

parseSoapResponse will be removed in a future release. Use `matlab.wsd1.createWSDLClient` instead.

## Syntax

```
data = parseSoapResponse(response)
```

## Description

`data = parseSoapResponse(response)` extracts data from SOAP server response and converts to MATLAB types.

## Examples

### Retrieve Book Information from Library Database

This example assumes the library is on a local intranet and does not use an actual endpoint; therefore, you cannot run it.

Retrieve the name of the author of a book titled “In the Fall.” The relative path of the library service is `urn:LibraryCatalog`. To get the author's name, use the `getAuthor` function, which takes the book name as the input value. The `getAuthor` parameter is `nameToLookUp`. The XML data type for title is `{http://www.w3.org/2001/XMLSchema}string`. The SOAP message style is `rpc` by default.

Create the SOAP message.

```
message = createSoapMessage(...
```

```
'urn:LibraryCatalog',...
'getAuthor',...
{'In the Fall'},...
{'nameToLookUp'},...
{'{http://www.w3.org/2001/XMLSchema}string'})
```

```
message =
```

```
[#document: null]
```

This response does not necessarily indicate that the message is valid, although certain input problems produce error messages.

Send the message to the server for processing, and get the author's name back. The server endpoint is `http://test/soap/services/LibraryCatalog`. The server method is `urn:LibraryCatalog#getAuthor`.

```
response = callSoapService(...
 'http://test/soap/services/LibraryCatalog',...
 'urn:LibraryCatalog#getAuthor',...
 message)
```

```
<?xml version="1.0" encoding="utf-8"?>
<soapenv:Envelope
xmlns:soapenv="http://schemas.xmlsoap.org/soap/envelope/"
xmlns:xsd="http://www.w3.org/2001/XMLSchema"
xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
<soapenv:Body>
<getAuthorResponse xmlns="urn:LibraryCatalog">
<ns1:getAuthorReturn xmlns:ns1="http://latestversion.soap.test">
Kate Alvin
</ns1:getAuthorReturn>
</getAuthorResponse>
</soapenv:Body>
</soapenv:Envelope>
```

MATLAB returns the message in a single line, displayed here on separate lines for legibility.

Extract the author's name.

```
author = parseSoapResponse(response)
```

```
author = Kate Alvin
```

MATLAB automatically converted the XML string data type to `char`.

## Input Arguments

### **response** — Data from SOAP server

string

Data from SOAP server, specified as a string. `response` is the output from the `callSoapService` function.

## Output Arguments

### **data** — Output of SOAP service call

cell array of any valid MATLAB type

Output of SOAP service call, returned as a cell array of any valid MATLAB type. For information about `data`, see the documentation for the SOAP service used in the `callSoapService` function.

# pascal

Pascal matrix

## Syntax

```
A = pascal(n)
A = pascal(n,1)
A = pascal(n,2)
```

## Description

`A = pascal(n)` returns a “Pascal’s Matrix” on page 1-6291 of order  $n$ : a symmetric positive definite matrix with integer entries taken from Pascal's triangle. The inverse of  $A$  has integer entries.

`A = pascal(n,1)` returns the lower triangular Cholesky factor (up to the signs of the columns) of the Pascal matrix. It is *involutary*, that is, it is its own inverse.

`A = pascal(n,2)` returns a transposed and permuted version of `pascal(n,1)`.  $A$  is a cube root of the identity matrix.

## Examples

`pascal(4)` returns

```
1 1 1 1
1 2 3 4
1 3 6 10
1 4 10 20
```

`A = pascal(3,2)` produces

```
A =
 1 1 1
 -2 -1 0
 1 0 0
```

## More About

### Pascal's Matrix

Pascal's triangle is a triangle formed by rows of numbers. The first row has entry 1. Each succeeding row is formed by adding adjacent entries of the previous row, substituting a 0 where there is no adjacent entry. Pascal's matrix is generated by selecting the portion of Pascal's triangle that corresponds to the specified matrix dimensions, as outlined in the graphic. The matrix outlined corresponds to the MATLAB command `pascal(4)`.

Introduced before R2006a

## patch

Create one or more filled polygons

### Syntax

```
patch(X,Y,C)
patch(X,Y,Z,C)
patch('XData',X,'YData',Y)
patch('XData',X,'YData',Y,'ZData',Z)

patch('Face',F,'Vertices',V)

patch(S)

patch(____,Name,Value)

p = patch(____)
```

### Description

`patch(X,Y,C)` creates one or more filled polygons using the elements of `X` and `Y` as the coordinates for each vertex. `patch` connects the vertices in the order that you specify them. To create one polygon, specify `X` and `Y` as vectors. To create multiple polygons, specify `X` and `Y` as matrices where each column corresponds to a polygon. `C` determines the polygon colors.

`patch(X,Y,Z,C)` creates the polygons in 3-D coordinates using `X`, `Y`, and `Z`. To view the polygons in a 3-D view, use the `view(3)` command. `C` determines the polygon colors.

`patch('XData',X,'YData',Y)` is similar to `patch(X,Y,C)`, except that you do not have to specify color data for the 2-D coordinates.

`patch('XData',X,'YData',Y,'ZData',Z)` is similar to `patch(X,Y,Z,C)`, except that you do not have to specify color data for the 3-D coordinates.

`patch('Face',F,'Vertices',V)` creates one or more polygons where `V` specifies vertex values and `F` defines which vertices to connect. Specifying only unique vertices

and their connection matrix can reduce the size of the data when there are many polygons. Specify one vertex per row in *V*. To create one polygon, specify *F* as a vector. To create multiple polygons, specify *F* as a matrix with one row per polygon. Each face does not have to have the same number of vertices. To specify different numbers of vertices, pad *F* with NaN values.

`patch(S)` creates one or more polygons using structure *S*. The structure fields correspond to patch property names and the field values corresponding to property values. For example, *S* can contain the fields `Faces` and `Vertices`.

`patch( ____, Name, Value)` creates polygons and specifies one or more patch properties using name-value pair arguments. A patch is the object that contains the data for all of the polygons created. You can specify patch properties with any of the input argument combinations in the previous syntaxes. For example, `'LineWidth', 2` sets the outline width for all of the polygons to 2 points.

`p = patch( ____ )` returns the patch object that contains the data for all the polygons. Use *p* to query and modify properties of the patch object after it is created. For a list of properties and descriptions, see Patch Properties.

## Examples

### Specifying Coordinates

Create a single polygon by specifying the  $(x,y)$  coordinates of each vertex. Then, add two more polygons to the figure.

Create a red square with vertices at  $(0,0)$ ,  $(1,0)$ ,  $(1,1)$ , and  $(0,1)$ . Specify *x* as the *x*-coordinates of the vertices and *y* as the *y*-coordinates. `patch` automatically connects the last  $(x,y)$  coordinate with the first  $(x,y)$  coordinate.

```
x = [0 1 1 0];
y = [0 0 1 1];
patch(x,y, 'red')
```

Create two polygons by specifying  $x$  and  $y$  as two-column matrices. Each column defines the coordinates for one of the polygons. `patch` adds the polygons to the current axes without clearing the axes.

```
x2 = [2 5; 2 5; 8 8];
y2 = [4 0; 8 2; 4 0];
patch(x2,y2, 'green')
```

### Specifying Faces and Vertices

Create a single polygon by specifying the coordinates of each unique vertex and a matrix that defines how to connect them. Then, add two more polygons to the figure.

Create a red square with corners at  $(0,0)$ ,  $(1,0)$ ,  $(1,1)$ , and  $(0,1)$ . Specify  $v$  so that each row defines the  $(x,y)$  coordinates for one vertex. Then, specify  $f$  as the vertices to connect. Set the color by specifying the `FaceColor` property.

```
v = [0 0; 1 0; 1 1; 0 1];
f = [1 2 3 4];
patch('Faces',f,'Vertices',v,'FaceColor','red')
```

Create two polygons by specifying `f` as a two-row matrix. Each row defines the face for one patch.

```
v2 = [2 4; 2 8; 8 4; 5 0; 5 2; 8 0];
f2 = [1 2 3;
 4 5 6];
patch('Faces',f2,'Vertices',v2,'FaceColor','green')
```

### Different Polygon Face Colors

Create two polygons and use a different color for each polygon face. Use a colorbar to show how the colors map into the colormap.

Create the polygons using matrices `x` and `y`. Specify `c` as a column vector with two elements since there are two polygon faces, and add a colorbar.

```
x = [2 5; 2 5; 8 8];
y = [4 0; 8 2; 4 0];
c = [0; 1];
figure
patch(x,y,c)
colorbar
```

Alternatively, you can get the same result when using `f` and `v` instead. When you create the polygons, set `FaceVertexCData` to a column vector with two elements since there are two polygon faces. Set `FaceColor` to `'flat'`.

```
v = [2 4; 2 8; 8 4; 5 0; 5 2; 8 0];
f = [1 2 3; 4 5 6];
col = [0; 1];
figure
patch('Faces',f,'Vertices',v,'FaceVertexCData',col,'FaceColor','flat');
colorbar
```

### Interpolated Polygon Face Colors

Interpolate colors across polygon faces by specifying a color at each polygon vertex, and use a colorbar to show how the colors map into the colormap.

Create the polygons using matrices `x` and `y`. Specify `c` as a matrix the same size as `x` and `y` defining one color per vertex, and add a colorbar.

```
x = [2 5; 2 5; 8 8];
y = [4 0; 8 2; 4 0];
c = [0 3; 6 4; 4 6];
figure
patch(x,y,c)
colorbar
```

Alternatively, you can get the same result using `f` and `v` instead. When you create the polygons, set `FaceVertexCData` to a column vector with one value per vertex and set `FaceColor` to `'interp'`.

```
v = [2 4; 2 8; 8 4; 5 0; 5 2; 8 0];
f = [1 2 3; 4 5 6];
col = [0; 6; 4; 3; 4; 6];
figure
patch('Faces',f,'Vertices',v,'FaceVertexCData',col,'FaceColor','interp');
colorbar
```

### Polygon Edges Without Faces

Create a polygon with green edges and do not display the face. Then, create a second polygon with a different color for each edge.

```
v = [0 0; 1 0; 1 1];
f = [1 2 3];
figure
patch('Faces',f,'Vertices',v,...
 'EdgeColor','green','FaceColor','none','LineWidth',2);
```

Use a different color for each edge by specifying a color for each vertex and setting `EdgeColor` to `'flat'`.

```
v = [2 0; 3 0; 3 1];
f = [1 2 3];
c = [1 0 0; % red
 0 1 0; % green
 0 0 1]; % blue
patch('Faces',f,'Vertices',v,'FaceVertexCData',c,...
 'EdgeColor','flat','FaceColor','none','LineWidth',2);
```

### Polygons Using Structure

Use a structure to create two polygons. First, create a structure with fields names that match patch property names. Then, use the structure to create the polygons.

```
clear S
S.Vertices = [2 4; 2 8; 8 4; 5 0; 5 2; 8 0];
S.Faces = [1 2 3; 4 5 6];
S.FaceVertexCData = [0; 1];
S.FaceColor = 'flat';
S.EdgeColor = 'red';
S.LineWidth = 2;
figure
patch(S)
```

### Semitransparent Polygons

Create two semitransparent polygons by setting the `FaceAlpha` property to a value between 0 and 1.

```
v1 = [2 4; 2 8; 8 4];
f1 = [1 2 3];
figure
patch('Faces',f1,'Vertices',v1,'FaceColor','red','FaceAlpha',.3);

v2 = [2 4; 2 8; 8 8];
f2 = [1 2 3];
patch('Faces',f2,'Vertices',v2,'FaceColor','blue','FaceAlpha',.5);
```

### Create Multicolored Line

Create a multicolored line with markers at each vertex. Interpolate the colors and use a colorbar to show how the values map to the colormap.

Create the data. Set the last entry of `y` to `NaN` so that `patch` creates a line instead of a closed polygon. Define a color for each vertex using the `y` values. The values in `c` map to colors in the colormap.

```
x = linspace(1,10,15);
y = sin(x);
y(end) = NaN;
c = y;
```

Create the line. Show markers at each vertex and set the EdgeColor to 'interp' to interpolate the colors between vertices. Add a colorbar.

```
figure
patch(x,y,c,'EdgeColor','interp','Marker','o','MarkerFaceColor','flat');
colorbar;
```

- “Multifaceted Patches”

## Input Arguments

**X** — x-coordinates for vertices

vector | matrix

*x*-coordinates for the vertices, specified in one of these forms:

- **Vector** — Create one polygon.
- **Matrix** — Create *n* polygons with *m* vertices each, where `[m,n] = size(X)`. Each column in the matrix corresponds to one polygon.

If the data does not define closed polygons, then `patch` closes the polygons. If the edges of an individual polygon intersect themselves, the resulting polygons might be partly filled. In that case, it is better to divide the patch object into smaller polygons.

When you specify *X*, the `patch` function sets the `XData` property for the patch object to the same value. The patch object automatically calculates the face and vertex data and sets the `Faces` and `Vertices` properties to the appropriate values.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **Y — y-coordinates for vertices**

`vector` | `matrix`

*y*-coordinates for the vertices, specified in one of these forms:

- **Vector** — Create one polygon.
- **Matrix** — Create *n* polygons with *m* vertices each, where `[m,n] = size(Y)`. Each column in the matrix corresponds to one polygon.

If the data does not define closed polygons, then `patch` closes the polygons. If the edges of an individual polygon intersect themselves, the resulting polygons might be partly filled. In that case, it is better to divide the patch object into smaller polygons.

When you specify *Y*, the `patch` function sets the `YData` property for the patch object to the same value. The patch object automatically calculates the face and vertex data and sets the `Faces` and `Vertices` properties to the appropriate values.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **Z — z-coordinates for vertices**

`vector` | `matrix`

*z*-coordinates for the vertices, specified in one of these forms:

- Vector — Create one polygon.
- Matrix — Create  $m$  polygons with  $n$  vertices each, where  $[m, n] = \text{size}(Z)$ . Each column in the matrix corresponds to one polygon.

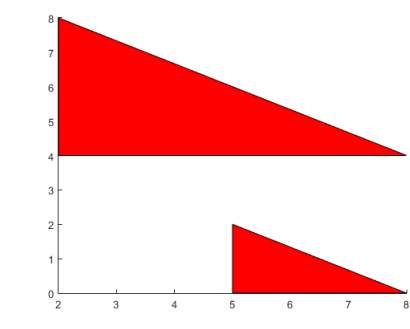

When you specify  $Z$ , the `patch` function sets the `ZData` property for the patch object to the same value. The patch object automatically calculates the face and vertex data and sets the `Faces` and `Vertices` properties to the appropriate values.

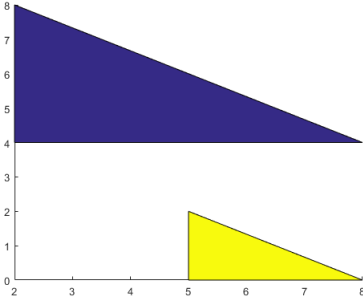

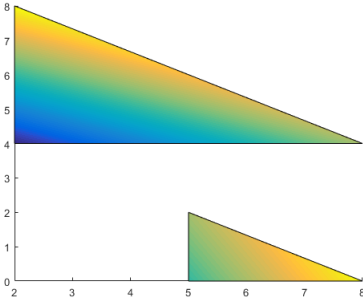

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### C — Polygon colors

`scalar` | `vector` | `matrix` | `color string`

Polygon colors, specified as a scalar, vector, matrix, or color string. The format of the input determines whether all polygons have the same color, one color per face, or interpolated face colors.

Desired Effect	Use One of These Formats	Results
Single color for all faces	<ul style="list-style-type: none"> <li>• Color string, for example, 'r' for red.</li> <li>• RGB triplet, for example, [0 .5 .5].</li> <li>• Scalar value, for example, 2. The <code>CDataMapping</code> property determines how the value maps into the <code>colormap</code>.</li> </ul> <p>For an example, see “Specifying Coordinates” on page 1-6293.</p>	 <ul style="list-style-type: none"> <li>• Sets the <code>FaceColor</code> property to the specified color.</li> </ul>

Desired Effect	Use One of These Formats	Results
<p>One color per face</p>	<ul style="list-style-type: none"> <li>• <math>n</math>-by-1 vector of colormap colors, where <math>n</math> is the number of faces. The <code>CDataMapping</code> property determines how the values map into the colormap.</li> <li>• <math>n</math>-by-1-by-3 array of RGB values. The first page of the array defines the red components of the colors, the second page defines the blue, and the third page defines the green.</li> </ul> <p>For an example, see “Different Polygon Face Colors” on page 1-6297.</p>	 <ul style="list-style-type: none"> <li>• Sets the <code>FaceColor</code> property to <code>'flat'</code>.</li> <li>• Sets the <code>CData</code> and <code>FaceVertexCData</code> properties using the specified color values.</li> </ul>
<p>Interpolated face colors</p>	<ul style="list-style-type: none"> <li>• <math>m</math>-by-<math>n</math> matrix of colormap values, where <math>[m,n] = \text{size}(X)</math>. Specify one color per vertex.</li> <li>• <math>m</math>-by-<math>n</math>-by-3 array of RGB values.</li> </ul> <p>For an example, see “Interpolated Polygon Face Colors” on page 1-6299.</p>	 <ul style="list-style-type: none"> <li>• Sets the <code>FaceColor</code> property to <code>'interp'</code>.</li> <li>• Sets the <code>CData</code> and <code>FaceVertexCData</code> properties using the specified color values.</li> </ul>

**V — Polygon vertices**

two-column or three-column matrix

Polygon vertices, specified in one of these forms:

- Two-column matrix — Each row contains the  $(x,y)$  coordinates for a vertex.
- Three-column matrix — Each row contains the  $(x,y,Z)$  coordinates for a vertex.

Specify only unique vertices. You can refer to a vertex more than once when defining the face definitions in **F**.

When you specify **V**, the `patch` function sets the `Vertices` property for the patch object to the same value. The patch object automatically calculates the coordinate data and sets the `XData`, `YData`, and `ZData` to the appropriate values.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**F — Face definitions**

row vector | matrix

Face definitions, specified in one of these forms:

- Row vector — Create a single polygon.
- Matrix — Create multiple polygons where each row corresponds to a polygon.

For example, this code defines three vertices in **V** and creates one polygon by connecting vertex 1 to 2, 2 to 3, and 3 to 1.

```
V = [1 1; 2 1; 2 2];
F = [1 2 3 1];
patch('Faces',F,'Vertices',V)
```

When you specify **F**, the `patch` function sets the `Faces` property for the patch object to the same value. The patch object automatically calculates the coordinate data and sets the `XData`, `YData`, and `ZData` to the appropriate values.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**S — Patch definition**

structure

Patch definition, specified as a structure with fields that correspond patch property names and field values that correspond to patch property values.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as **Name1**, **Value1**, . . . , **NameN**, **ValueN**.

Example: `patch(x,y,c,'FaceAlpha',.5,'LineStyle',':')` creates semitransparent polygons with dotted edges.

The properties listed here are only a subset of patch properties. For a complete list, see Patch Properties.

### 'FaceColor' — Face color

[0 0 0] (default) | RGB triplet or color string | 'flat' | 'interp' | 'none'

Face color, specified as one of these values:

- RGB triplet or color string — Single color for all of the faces. See the following table for more details.
- 'flat' — Uniform face colors. First, specify **CData** or **FaceVertexCData** as an array containing one color per face or one color per vertex. If you specify a color for each vertex, then the color of the first vertex specified determines the face color.
- 'interp' — Interpolate the color across each face. First, specify **CData** or **FaceVertexCData** as an array containing one value per vertex. Determine the face colors by using a bilinear interpolation of the values at each vertex.
- 'none' — No faces displayed.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0, 1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[1 1 0]

Long Name	Short Name	RGB Triplet
'magenta'	'm'	[ 1 0 1 ]
'cyan'	'c'	[ 0 1 1 ]
'red'	'r'	[ 1 0 0 ]
'green'	'g'	[ 0 1 0 ]
'blue'	'b'	[ 0 0 1 ]
'white'	'w'	[ 1 1 1 ]
'black'	'k'	[ 0 0 0 ]

**'FaceAlpha' — Face transparency**

1 (default) | scalar in range [0,1] | 'flat' | 'interp'

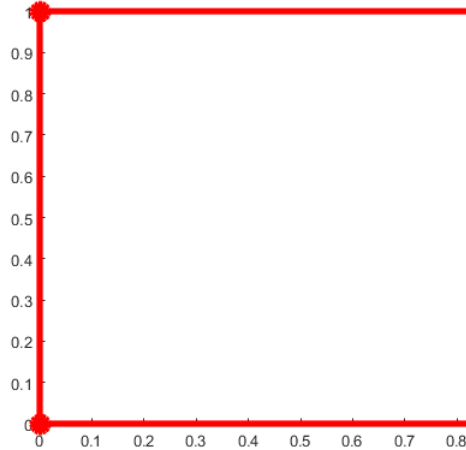

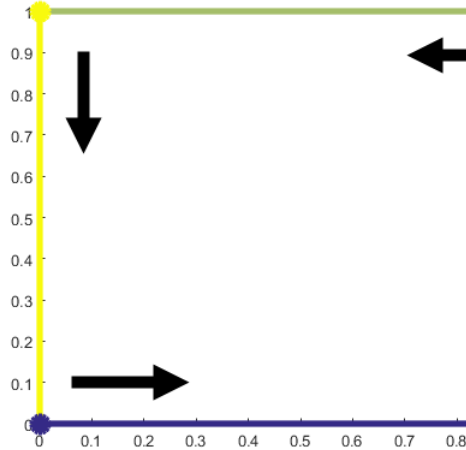

Face transparency, specified as one of these values:

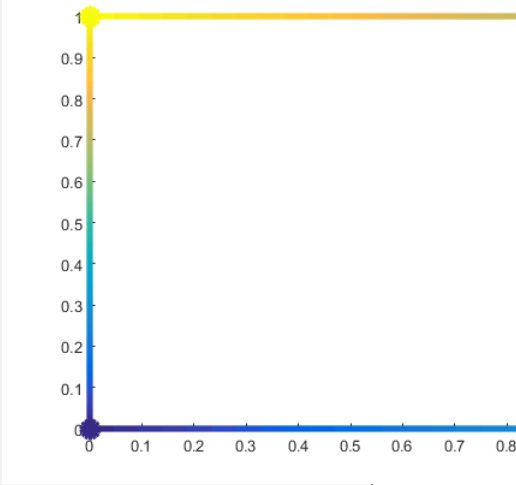

- Scalar in range [0, 1] — Use uniform transparency across all of the faces. A value of 1 is fully opaque and 0 is completely transparent. This option does not use the transparency values in the `FaceVertexAlphaData` property.
- 'flat' — Use a different transparency for each face based on the values in the `FaceVertexAlphaData` property. First you must specify the `FaceVertexAlphaData` property as a vector containing one transparency value per face or vertex. The transparency value at the first vertex determines the transparency for the entire face.
- 'interp' — Use interpolated transparency for each face based on the values in `FaceVertexAlphaData` property. First you must specify the `FaceVertexAlphaData` property as a vector containing one transparency value per vertex. The transparency varies across each face by interpolating the values at the vertices.

**'EdgeColor' — Edge colors**

[ 0 0 0 ] (default) | 'none' | 'flat' | 'interp' | RGB triplet or color string

Edge colors, specified as one of the values in this table. The default edge color is black with an RGB triplet value of [ 0 0 0 ]. If multiple polygons share an edge, then the most recently drawn polygon controls the displayed edge color.

Value	Description	Result
RGB triplet or a color string	Single color for all of the edges. See the following table for more details.	
'flat'	Different color for each edge. Use the vertex colors to set the color of the edge that follows it. You must first specify <code>CData</code> or <code>FaceVertexCData</code> as an array containing one color per vertex. The edge color depends on the order in which you specify the vertices.	

Value	Description	Result
'interp'	Interpolated edge color. You must first specify <code>CData</code> or <code>FaceVertexCData</code> as an array containing one color per vertex. Determine the edge color by linearly interpolating the values at the two bounding vertices.	
'none'	No edges displayed.	No edges displayed.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0, 1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[1 1 0]
'magenta'	'm'	[1 0 1]
'cyan'	'c'	[0 1 1]
'red'	'r'	[1 0 0]
'green'	'g'	[0 1 0]
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]
'black'	'k'	[0 0 0]

**'LineStyle' — Line style**

'-' (default) | '--' | ':' | '-.' | 'none'

Line style, specified as one of the line style strings listed in this table.

String	Line Style	Resulting Line
' _ '	Solid line	
' _ _ '	Dashed line	
' : '	Dotted line	
' - . '	Dash-dotted line	
' none '	No line	No line

## Output Arguments

**p** — patch object

scalar

Patch object, returned as a scalar. Each patch object can consist of one or more polygons. Use **p** to query or change properties of the patch object after it is created.

## More About

- “Specifying Patch Coloring”
- “Interpreting Indexed and Truecolor Data”

## See Also

### Functions

area | fill | fill3

### Properties

Patch Properties

Introduced before R2006a

## Patch Properties

Control patch appearance and behavior

Patch properties control the appearance and behavior of patch objects. By changing property values, you can modify certain aspects of the patch.

Starting in R2014b, you can use dot notation to query and set properties.

```
p = patch;
c = p.CData;
p.CDataMapping = 'scaled';
```

If you are using an earlier release, use the `get` and `set` functions instead.

## Faces

### FaceColor — Face color

[0 0 0] (default) | RGB triplet or color string | 'flat' | 'interp' | 'none'

Face color, specified as one of these values:

- RGB triplet or color string — Single color for all of the faces. See the following table for more details.
- 'flat' — Uniform face colors. First, specify `CData` or `FaceVertexCData` as an array containing one color per face or one color per vertex. If you specify a color for each vertex, then the color of the first vertex specified determines the face color.
- 'interp' — Interpolate the color across each face. First, specify `CData` or `FaceVertexCData` as an array containing one value per vertex. Determine the face colors by using a bilinear interpolation of the values at each vertex.
- 'none' — No faces displayed.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0,1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[1 1 0]
'magenta'	'm'	[1 0 1]

Long Name	Short Name	RGB Triplet
'cyan'	'c'	[ 0 1 1 ]
'red'	'r'	[ 1 0 0 ]
'green'	'g'	[ 0 1 0 ]
'blue'	'b'	[ 0 0 1 ]
'white'	'w'	[ 1 1 1 ]
'black'	'k'	[ 0 0 0 ]

### FaceAlpha — Face transparency

1 (default) | scalar in range [0,1] | 'flat' | 'interp'

Face transparency, specified as one of these values:

- Scalar in range [0, 1] — Use uniform transparency across all of the faces. A value of 1 is fully opaque and 0 is completely transparent. This option does not use the transparency values in the `FaceVertexAlphaData` property.
- 'flat' — Use a different transparency for each face based on the values in the `FaceVertexAlphaData` property. First you must specify the `FaceVertexAlphaData` property as a vector containing one transparency value per face or vertex. The transparency value at the first vertex determines the transparency for the entire face.
- 'interp' — Use interpolated transparency for each face based on the values in `FaceVertexAlphaData` property. First you must specify the `FaceVertexAlphaData` property as a vector containing one transparency value per vertex. The transparency varies across each face by interpolating the values at the vertices.

### FaceLighting — Effect of light objects on faces

'flat' (default) | 'gouraud' | 'none'

Effect of light objects on faces, specified as one of these values:

- 'flat' — Apply light uniformly across the faces. Use this value to view faceted objects.
- 'gouraud' — Vary the light across the faces. Calculate the light at the vertices and then linearly interpolate the light across the faces. Use this value to view curved surfaces.

- 'none' — Do not apply light from light objects to the faces.

---

**Note:** The 'phong' value has been removed. Use 'gouraud' instead.

---

### **BackFaceLighting** — Face lighting when normals point away from camera

'reverselit' (default) | 'unlit' | 'lit'

Face lighting when the vertex normals point away from camera, specified as one of these values:

- 'reverselit' — Light the face as if the vertex normal pointed towards the camera.
- 'unlit' — Do not light the face.
- 'lit' — Light the face according to the vertex normal.

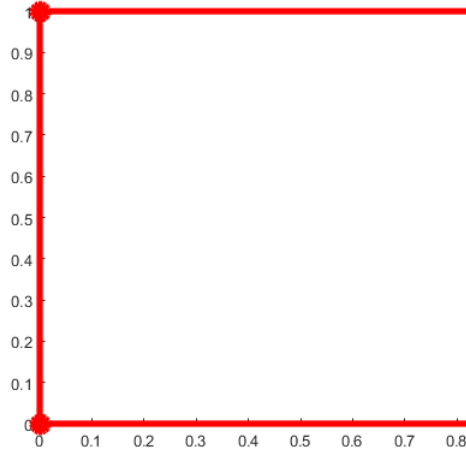

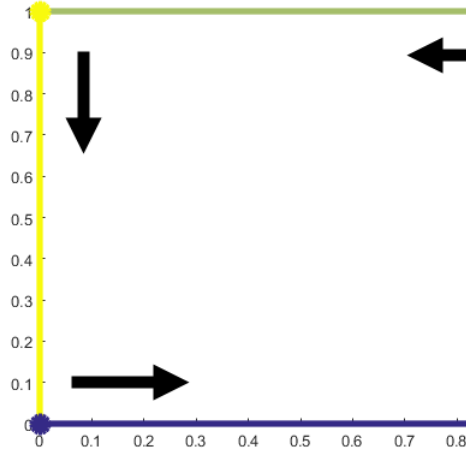

Use this property to discriminate between the internal and external surfaces of an object. For an example, see “Back Face Lighting”.

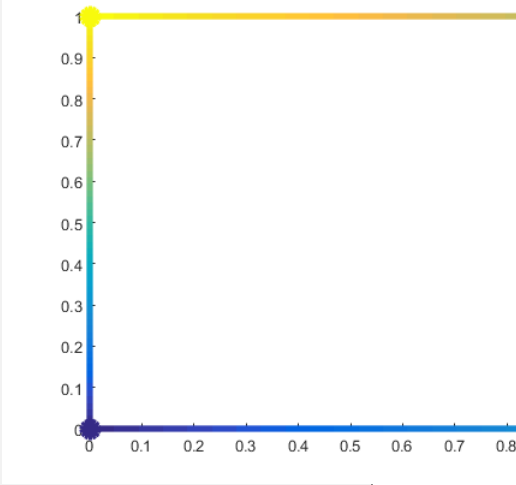

## **Edges**

### **EdgeColor** — Edge colors

[0 0 0] (default) | 'none' | 'flat' | 'interp' | RGB triplet or color string

Edge colors, specified as one of the values in this table. The default edge color is black with an RGB triplet value of [0 0 0]. If multiple polygons share an edge, then the most recently drawn polygon controls the displayed edge color.

Value	Description	Result
RGB triplet or a color string	Single color for all of the edges. See the following table for more details.	
'flat'	Different color for each edge. Use the vertex colors to set the color of the edge that follows it. You must first specify <code>CData</code> or <code>FaceVertexCData</code> as an array containing one color per vertex. The edge color depends on the order in which you specify the vertices.	

Value	Description	Result
'interp'	Interpolated edge color. You must first specify <code>CData</code> or <code>FaceVertexCData</code> as an array containing one color per vertex. Determine the edge color by linearly interpolating the values at the two bounding vertices.	
'none'	No edges displayed.	No edges displayed.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range  $[0, 1]$ , for example,  $[0.4 \ 0.6 \ 0.7]$ . This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	$[1 \ 1 \ 0]$
'magenta'	'm'	$[1 \ 0 \ 1]$
'cyan'	'c'	$[0 \ 1 \ 1]$
'red'	'r'	$[1 \ 0 \ 0]$
'green'	'g'	$[0 \ 1 \ 0]$
'blue'	'b'	$[0 \ 0 \ 1]$
'white'	'w'	$[1 \ 1 \ 1]$
'black'	'k'	$[0 \ 0 \ 0]$

**EdgeAlpha — Edge line transparency**

1 (default) | scalar value in range  $[0, 1]$  | 'flat' | 'interp'

Edge line transparency, specified as one of these values:

- Scalar value in range `[0, 1]` — Use uniform transparency across all of the edges. A value of `1` is fully opaque and `0` is completely transparent. This option does not use the transparency values in the `FaceVertexAlphaData` property.
- `'flat'` — Use a different transparency for each edge based on the values in the `FaceVertexAlphaData` property. First you must specify the `FaceVertexAlphaData` property as a vector containing one transparency value per face or vertex. The transparency value at the first vertex determines the transparency for the edge.
- `'interp'` — Use interpolated transparency for each edge based on the values in `FaceVertexAlphaData` property. First you must specify the `FaceVertexAlphaData` property as a vector containing one transparency value per vertex. Vary the transparency across each edge by interpolating the values at the vertices.

### LineStyle — Line style

`'-'` (default) | `'--'` | `':'` | `'-.'` | `'none'`

Line style, specified as one of the line style strings listed in this table.

String	Line Style	Resulting Line
<code>'-'</code>	Solid line	
<code>'--'</code>	Dashed line	
<code>':'</code>	Dotted line	
<code>'-.'</code>	Dash-dotted line	
<code>'none'</code>	No line	No line

### LineWidth — Line width

`0.5` (default) | positive value

Line width, specified as a positive value in point units. If the line has markers, then the line width also affects the marker edges.

Example: `0.75`

## **EdgeLighting** — Effect of light objects on edges

'none' (default) | 'flat' | 'gouraud'

Effect of light objects on edges, specified as one of these values:

- 'flat' — Apply light uniformly across the each edges.
- 'none' — Do not apply lights from light objects to the edges.
- 'gouraud' — Calculate the light at the vertices, and then linearly interpolate across the edges.

---

**Note:** The 'phong' value has been removed. Use 'gouraud' instead.

---

## **AlignVertexCenters** — Sharp vertical and horizontal lines

'off' (default) | 'on'

Sharp vertical and horizontal lines, specified as 'off' or 'on'.

If the associated figure has a GraphicsSmoothing property set to 'on' and a Renderer property set to 'opengl', then the figure applies a smoothing technique to plots. In some cases, this smoothing technique can cause vertical and horizontal lines to appear uneven in thickness or color. Use the `AlignVertexCenters` property to eliminate the uneven appearance.

- 'off' — Do not sharpen vertical or horizontal lines. The lines might appear uneven in thickness or color.
- 'on' — Sharpen vertical and horizontal lines to eliminate an uneven appearance.

---

**Note:** You must have a graphics card that supports this feature. To see if the feature is supported, type `opengl info`. If it is supported, then the returned fields contain the line `SupportsAlignVertexCenters: 1`.

---

## **Markers**

### **Marker** — Marker symbol

'none' (default) | marker string

Marker symbol, specified as one of the marker strings listed in this table. By default, the patch object does not display markers. Specifying a marker symbol adds markers at each data point or vertex.

String	Marker Symbol
'o'	Circle
'+'	Plus sign
'*'	Asterisk
'.'	Point
'x'	Cross
'square' or 's'	Square
'diamond' or 'd'	Diamond
'^'	Upward-pointing triangle
'v'	Downward-pointing triangle
'>'	Right-pointing triangle
'<'	Left-pointing triangle
'pentagram' or 'p'	Five-pointed star (pentagram)
'hexagram' or 'h'	Six-pointed star (hexagram)
'none'	No markers

Example: '+'

Example: 'diamond'

### **MarkerEdgeColor** — Marker outline color

'auto' (default) | 'none' | 'flat' | RGB triplet or color string

Marker outline color, specified as specified as one of these values:

- 'auto' — Use the same color as the `EdgeColor` property.
- 'none' — Use no color, which makes unfilled markers invisible.
- 'flat' — Use the `CData` value at the vertex to set the color.
- RGB triplet or color string — Use the specified color.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range

[0, 1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[1 1 0]
'magenta'	'm'	[1 0 1]
'cyan'	'c'	[0 1 1]
'red'	'r'	[1 0 0]
'green'	'g'	[0 1 0]
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]
'black'	'k'	[0 0 0]

Example: [0.5 0.5 0.5]

Example: 'blue'

**MarkerFaceColor** — Marker fill color

'none' (default) | 'auto' | 'flat' | RGB triplet or color string

Marker fill color, specified as one of these values:

- 'none' — Use no color, which allows the background to show through.
- 'auto' — Use the same color as the Color property for the axes.
- 'flat' — Use the CData value of the vertex to set the color.
- RGB triplet or color string — Use the specified color.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0, 1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[1 1 0]
'magenta'	'm'	[1 0 1]
'cyan'	'c'	[0 1 1]
'red'	'r'	[1 0 0]

Long Name	Short Name	RGB Triplet
'green'	'g'	[ 0 1 0 ]
'blue'	'b'	[ 0 0 1 ]
'white'	'w'	[ 1 1 1 ]
'black'	'k'	[ 0 0 0 ]

This property affects only the circle, square, diamond, pentagram, hexagram, and the four triangle marker types.

Example: [0.3 0.2 0.1]

Example: 'green'

Example:

### **MarkerSize** — Marker size

6 (default) | positive value

Marker size, specified as a positive value in point units.

Example: 10

## **Color and Transparency Mapping**

### **FaceVertexCData** — Face and vertex colors

[ ] (default) | single color for entire patch | one color per face | one color per vertex

Face and vertex colors, specified as a single color for the entire patch, one color per face, or one color per vertex for interpolated face color.

If you want to use indexed colors, then specify **FaceVertexCData** in one of these forms:

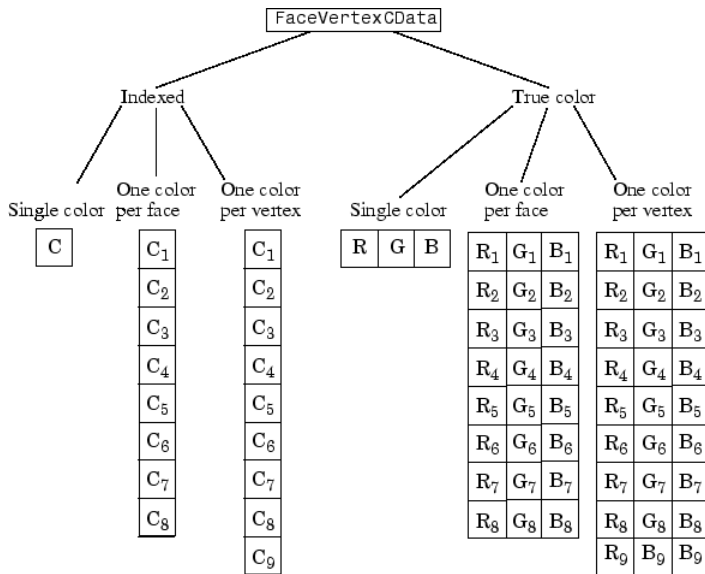

- For one color for the entire patch, use a single value.
- For one color per face, use an m-by-1 column vector, where m is the number of rows in the **Faces** property.
- For interpolated face color, use an m-by-1 column vector where m is the number of rows in the **Vertices** property.

If you want to use true colors, then specify **FaceVertexCData** in one of these forms:

- For one color for the entire patch, use a three-element row vector defining an RGB triplet.

- For one color per face, use an m-by-3 array of RGB triplets, where m is the number of rows in the `Faces` property.
- For interpolated face color, use an m-by-3 array, where m is the number of rows in the `Vertices` property.

The following diagram illustrates the various forms of the `FaceVertexCData` property for a patch having eight faces and nine vertices. The `CDataMapping` property determines how MATLAB interprets the `FaceVertexCData` property when you specify indexed colors.

**CData – Patch color data**

single color for entire patch | one color per face | one color per vertex

Patch color data, specified as a single color for the entire patch, one color per face, or one color per vertex.

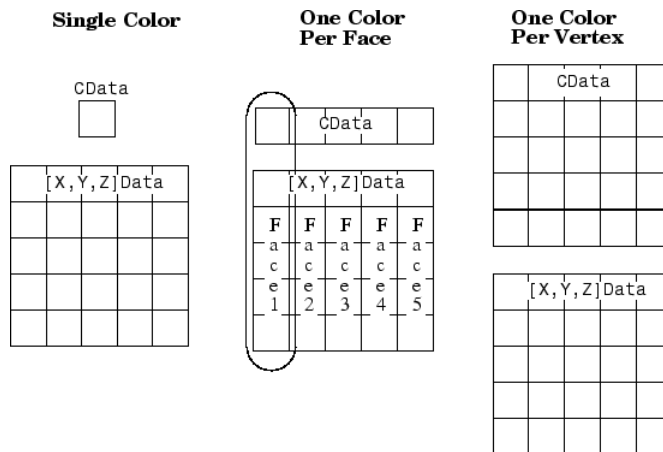

The way the `patch` function interprets `CData` depends on the type of data supplied. Specify `CData` in one of these forms:

- Numeric values that are scaled to map linearly into the current colormap.
- Integer values that are used directly as indices into the current colormap.

- Arrays of RGB triplets. RGB triplets are not mapped into the current colormap, but interpreted as the colors defined.

The following diagrams illustrate the dimensions of CData with respect to the arrays in the XData, YData, and ZData properties.

These diagrams illustrates the use of indexed color.

These diagrams illustrates the use of true color. True color requires either a single RGB triplet or an array of RGB triplets.

If `CData` contains NaNs, then `patch` does not color the faces.

An alternative method for defining patches uses the `Faces`, `Vertices`, and `FaceVertexCData` properties.

Example: `[1,0,0]`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **CDataMapping** — Direct or scaled color data mapping

'scaled' (default) | 'direct'

Direct or scaled color data mapping, specified as 'scaled' (the default) or 'direct'. The `CData` and `FaceVertexCData` properties contains color data. If you use true color specification for `CData` or `FaceVertexCData`, then this property has no effect.

- 'direct' — Interpret the values as indices into the current colormap. Values with a decimal portion are fixed to the nearest lower integer.
  - If the values are of type `double` or `single`, then values of 1 or less map to the first color in the colormap. Values equal to or greater than the length of the colormap map to the last color in the colormap.
  - If the values are of type `uint8`, `uint16`, `uint32`, `uint64`, `int8`, `int16`, `int32`, or `int64`, then values of 0 or less map to the first color in the colormap. Values

equal to or greater than the length of the colormap map to the last color in the colormap (or up to the range limits of the type).

- If the values are of type `logical`, then values of 0 map to the first color in the colormap and values of 1 map to the second color in the colormap.
- `'scaled'` — Scale the values to range between the minimum and maximum color limits. The `CLim` property of the axes contains the color limits.

### FaceVertexAlphaData — Face and vertex transparency values

`[]` (default) | scalar | vector with one value per face | vector with one value per vertex

Face and vertex transparency values, specified as a scalar, a vector with one value per face, or a vector with one value per vertex.

- For uniform transparency across all of the faces or edges, specify a scalar value. Then, set the `FaceAlpha` or `EdgeAlpha` property to `'flat'`.
- For a different transparency for each face or edge, specify an `m`-by-1 vector, where `m` is the number of faces. Then, set the `FaceAlpha` or `EdgeAlpha` property to `'flat'`. To determine the number of faces, query the number of rows in the `Faces` property.
- For interpolated transparency across each face or edge, specify an `n`-by-1 vector, where `n` is the number of vertices. Then, set the `FaceAlpha` or `EdgeAlpha` property to `'interp'`. To determine the number of faces, query the number of rows in the `Vertices` property.

The `AlphaDataMapping` property determines how the patch interprets the `FaceVertexAlphaData` property values.

---

**Note:** If the `FaceAlpha` and `EdgeAlpha` properties are both set to scalar values, then the patch does not use the `FaceVertexAlphaData` values.

---

### AlphaDataMapping — Interpretation of FaceVertexAlphaData values

`'scaled'` (default) | `'direct'` | `'none'`

Interpretation of `FaceVertexAlphaData` values, specified as one of these values:

- `'none'` — Interpret the values as transparency values. A value of 1 or greater is completely opaque, a value of 0 or less is completely transparent, and a value between 0 and 1 is semitransparent.
- `'scaled'` — Map the values into the figure's alphamap. The minimum and maximum alpha limits of the axes determine the alpha data values that map to the

first and last elements in the alphamap, respectively. For example, if the alpha limits are [3 5], then alpha data values less than or equal to 3 map to the first element in the alphamap. Alpha data values greater than or equal to 5 map to the last element in the alphamap. The `ALim` property of the axes contains the alpha limits. The `Alphamap` property of the figure contains the alphamap.

- `'direct'` — Interpret the values as indices into the figure's alphamap. Values with a decimal portion are fixed to the nearest lower integer.
  - If the values are of type `double` or `single`, then values of 1 or less map to the first element in the alphamap. Values equal to or greater than the length of the alphamap map to the last element in the alphamap.
  - If the values are of integer type, then values of 0 or less map to the first element in the alphamap. Values equal to or greater than the length of the alphamap map to the last element in the alphamap (or up to the range limits of the type). The integer types are `uint8`, `uint16`, `uint32`, `uint64`, `int8`, `int16`, `int32`, and `int64`.
  - If the values are of type `logical`, then values of 0 map to the first element in the alphamap and values of 1 map to the second element in the alphamap.

## Face and Vertex Normals

### **FaceNormals** — Face normal vectors

m-by-n-by-3 array (default) | array of normal vectors

Face normal vectors, specified as an array of normal vectors with one normal vector one per patch face. Define one normal per patch face, as determined by the size of the `Faces` property value. Face normals determine the orientation of each patch face. This data is used for lighting calculations.

Specifying values for this property sets the associated mode to manual. If you do not specify normal vectors, then the patch generates this data when the axes contains light objects. The patch computes face normals using Newell's method.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **VertexNormals** — Vertex normal vectors

m-by-n-by-3 array (default) | array of normal vectors

Vertex normal vectors, specified as an array of normal vectors with one normal vector one per patch vertex. Define one normal per patch vertex, as determined by the size of

the `Vertices` property value. Vertex normals determine the shape and orientation of the patch. This data is used for lighting calculations.

Specifying values for this property sets the associated mode to manual. If you do not specify normal vectors, then the patch generates this data when the axes contains light objects.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **FaceNormalsMode** — Selection mode for FaceNormals

'auto' (default) | 'manual'

Selection mode for `FaceNormals`, specified as one of these values:

- 'auto' — The `patch` function calculates face normals when you add a light to the scene.
- 'manual' — Use the face normal data specified by the `FaceNormals` property. Assigning values to the `FaceNormals` property sets `FaceNormalsMode` to 'manual'.

### **VertexNormalsMode** — Selection mode for VertexNormals

'auto' (default) | 'manual'

Selection mode for `VertexNormals`, specified as one of these values:

- 'auto' — The `patch` function calculates vertex normals when you add a light to the scene.
- 'manual' — Use the vertex normal data specified by the `VertexNormals` property. Assigning values to the `VertexNormals` property sets `VertexNormalsMode` to 'manual'.

## **Ambient Lighting**

### **AmbientStrength** — Strength of ambient light

0.3 (default) | scalar in range [0, 1]

Strength of ambient light, specified as a scalar value in the range [0, 1]. Ambient light is a nondirectional light that illuminates the entire scene. There must be at least one visible light object in the axes for the ambient light to be visible.

The `AmbientLightColor` property for the axes sets the color of the ambient light. The color is the same for all objects in the axes.

Example: 0.5

Data Types: double

## **DiffuseStrength — Strength of diffuse light**

0.6 (default) | scalar in range [0, 1]

Strength of diffuse light, specified as a scalar value in the range [0, 1]. Diffuse light is the nonspecular reflectance from light objects in the axes.

Example: 0.3

Data Types: double

## **SpecularStrength — Strength of specular reflection**

0.9 (default) | scalar in range [0, 1]

Strength of specular reflection, specified as a scalar value in the range [0, 1]. Specular reflections are the bright spots on the surface from light objects in the axes.

Example: 0.3

Data Types: double

## **SpecularColorReflectance — Color of specular reflections**

1 (default) | scalar between 0 and 1 inclusive

Color of specular reflections, specified as a scalar between 0 and 1 inclusive.

- 0 — The color of the specular reflection depends on both the color of the object from which it reflects and the color of the light source.
- 1 — The color of the specular reflection depends only on the color of the light source (that is, the light object Color property).

The contributions from the light source color and the patch color to the specular reflection color vary linearly for values between 0 and 1.

Example: 0.5

Data Types: single | double

## **SpecularExponent — Expansiveness of specular reflection**

10 (default) | scalar value greater than 0

Expansiveness of specular reflection, specified as a scalar value greater than 0. `SpecularExponent` controls the size of the specular reflection spot. Greater values produce less specular reflection.

Most materials have exponents in the range of 5 to 20.

Example: 17

Data Types: double

## Data

### **XData** — x-coordinates of the patch vertices

vector | matrix

The *x*-coordinates of the patch vertices, specified as a vector or a matrix. If `XData` is a matrix, then each column represents the *x*-coordinates of a single face of the patch. In this case, `XData`, `YData`, and `ZData` must have the same dimensions.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

### **YData** — y-coordinates of the patch vertices

vector | matrix

The *y*-coordinates defining the patch, specified as a vector or a matrix. If `YData` is a matrix, then each column represents the *y*-coordinates of a single face of the patch. In this case, `XData`, `YData`, and `ZData` must have the same dimensions.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

### **ZData** — z-coordinates of the patch vertices

vector | matrix

The *z*-coordinates of the patch vertices, specified as a vector or a matrix. If `ZData` is a matrix, then each column represents the *z*-coordinates of a single face of the patch. In this case, `XData`, `YData`, and `ZData` must have the same dimensions.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

### **Faces** — Vertex connection defining each face

vector | matrix

Vertex connection defining each face, specified as a vector or a matrix defining the vertices in the **Vertices** property that are to be connected to form each face. The **Faces** and **Vertices** properties provide an alternative way to specify a patch that can be more efficient than using **XData**, **YData**, and **ZData** coordinates in most cases.

Each row in the faces array designates the connections for a single face, and the number of elements in that row that are not NaN defines the number of vertices for that face. Therefore, an m-by-n **Faces** array defines m faces with up to n vertices each.

For example, consider the following patch. It is composed of eight triangular faces defined by nine vertices. The corresponding **Faces** and **Vertices** properties are shown to the right of the patch. Note how some faces share vertices with other faces. For example, the fifth vertex (**V5**) is used six times, once each by faces one, two, three, six, seven, and eight. Without sharing vertices, this same patch requires 24 vertex definitions.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**Vertices – Vertex coordinates**

vector | matrix

Vertex coordinates, specified as a vector or a matrix defining the (x,y,z) coordinates of each vertex. The **Faces** and **Vertices** properties provide an alternative way to specify a patch that can be more efficient than using **XData**, **YData**, and **ZData** coordinates in most cases. See the **Faces** property for a description of how the vertex data is used.

---

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

## Visibility

### Visible — State of visibility

`'on'` (default) | `'off'`

State of visibility, specified as one of these values:

- `'on'` — Display the patch.
- `'off'` — Hide the patch without deleting it. You still can access the properties of an invisible patch object.

### Clipping — Clipping of patch object to axes limits

`'on'` (default) | `'off'`

Clipping of the patch object to the axes limits, specified as one of these values:

- `'on'` — Do not display parts of the patch object that are outside the axes limits.
- `'off'` — Display the entire patch object, even if parts of it appear outside the axes limits. Parts of the patch object might appear outside the axes limits if you create a plot, set `hold on`, freeze the axis scaling, and then create the patch object so that it is larger than the original plot.

The `Clipping` property of the axes that contains the patch object must be set to `'on'`, otherwise this property has no effect. For more information about the clipping behavior, see the `Clipping` property of the axes.

### EraseMode — (removed) Technique to draw and erase objects

`'normal'` (default) | `'none'` | `'xor'` | `'background'`

---

**Note:** `EraseMode` has been removed. You can delete code that accesses the `EraseMode` property with minimal impact. If you were using `EraseMode` to create line animations, use the `animatedline` function instead.

---

Technique to draw and erase objects, specified as one of these values:

- `'normal'` — Redraw the affected region of the display, performing the three-dimensional analysis necessary to correctly render all objects. This mode produces

the most accurate picture, but is the slowest. The other modes are faster, but do not perform a complete redraw and, therefore, are less accurate.

- 'none' — Do not erase the object when it is moved or destroyed. After you erase the object with `EraseMode`, 'none', it is still visible on the screen. However, you cannot print the object because MATLAB does not store any information on its former location.
- 'xor' — Draw and erase the object by performing an exclusive OR (XOR) with the color of the screen beneath it. This mode does not damage the color of the objects beneath it. However, the object color depends on the color of whatever is beneath it on the display.
- 'background' — Erase the object by redrawing it in the axes background color, or the figure background color if the axes `Color` property is 'none'. This damages objects that are behind the erased object, but properly colors the erased object.

MATLAB always prints figures as if the `EraseMode` property of all objects is set to 'normal'. This means graphics objects created with `EraseMode` set to 'none', 'xor', or 'background' can look different on screen than on paper. On screen, MATLAB mathematically combines layers of colors and ignores three-dimensional sorting to obtain greater rendering speed. However, MATLAB does not apply these techniques to the printed output. Use the `getframe` command or other screen capture applications to create an image of a figure containing nonnormal mode objects.

## Identifiers

### Type — Type of graphics object

'patch'

This property is read only.

Type of graphics object, returned as 'patch'. Use this property to find all objects of a given type within a plotting hierarchy, for example, searching for the type using `findobj`.

### Tag — User-specified tag

'' (default) | string

Tag to associate with the patch, specified as a string. Tags provide a way to identify graphics objects. Use this property to find all objects with a specific tag within a plotting hierarchy, for example, searching for the tag using `findobj`.

Example: 'January Data'

**UserData — Data to associate with patch**

`[]` (default) | scalar, vector, or matrix | cell array | character array | table | structure

Data to associate with the patch object, specified as a scalar, vector, matrix, cell array, character array, table, or structure. MATLAB does not use this data.

To associate multiple sets of data or to attach a field name to the data, use the `getappdata` and `setappdata` functions.

Example: `1:100`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char` | `struct` | `table` | `cell`

**DisplayName — Text used by legend**

`''` (default) | string

Text used by the legend, specified as a string. The text appears next to an icon of the patch.

Example: `'Text Description'`

For multiline text, create the string using `sprintf` with the new line character `\n`.

Example: `sprintf('line one\nline two')`

Alternatively, you can specify the legend text using the `legend` function.

- If you specify the text as an input argument to the `legend` function, then the legend uses the specified text and sets the `DisplayName` property to the same value.
- If you do not specify the text as an input argument to the `legend` function, then the legend uses the text in the `DisplayName` property. If the `DisplayName` property does not contain any text, then the legend generates a string. The string has the form `'dataN'`, where `N` is the number assigned to the patch object based on its location in the list of legend entries.

If you edit interactively the string in an existing legend, then MATLAB updates the `DisplayName` property to the edited string.

**Annotation — Legend icon display style**

Annotation object

This property is read only.

Legend icon display style, returned as an `Annotation` object. Use this object to include or exclude the patch from a legend.

- 1 Query the `Annotation` property to get the `Annotation` object.
- 2 Query the `LegendInformation` property of the `Annotation` object to get the `LegendEntry` object.
- 3 Specify the `IconDisplayStyle` property of the `LegendEntry` object to one of these values:
  - 'on' — Include the patch object in the legend as one entry (default).
  - 'off' — Do not include the patch object in the legend.
  - 'children' — Include only children of the patch object as separate entries in the legend.

If a legend already exists and you change the `IconDisplayStyle` setting, then you must call `legend` to update the display.

## Parent/Child

### Parent — Parent of patch

axes object | group object | transform object

Parent of patch, specified as an axes, group, or transform object.

### Children — Children of patch

empty `GraphicsPlaceholder` array

The patch has no children. You cannot set this property.

### HandleVisibility — Visibility of object handle

'on' (default) | 'off' | 'callback'

Visibility of patch object handle in the `Children` property of the parent, specified as one of these values:

- 'on' — The patch object handle is always visible.
- 'off' — The patch object handle is invisible at all times. This option is useful for preventing unintended changes to the UI by another function. Set the `HandleVisibility` to 'off' to temporarily hide the handle during the execution of that function.

- `'callback'` — The patch object handle is visible from within callbacks or functions invoked by callbacks, but not from within functions invoked from the command line. This option blocks access to the patch at the command-line, but allows callback functions to access it.

If the patch object is not listed in the `Children` property of the parent, then functions that obtain object handles by searching the object hierarchy or querying handle properties cannot return it. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

Hidden object handles are still valid. Set the root `ShowHiddenHandles` property to `'on'` to list all object handles regardless of their `HandleVisibility` property setting.

## Interactive Control

### **ButtonDownFcn** — Mouse-click callback

`''` (default) | function handle | cell array | string

Mouse-click callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you click the patch. If you specify this property using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The patch object — You can access properties of the patch object from within the callback function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see “Callback Definition”.

---

**Note:** If the `PickableParts` property is set to `'none'` or if the `HitTest` property is set to `'off'`, then this callback does not execute.

---

Example: @myCallback

Example: {@myCallback, arg3}

## **UIContextMenu — Context menu**

uicontextmenu object

Context menu, specified as a uicontextmenu object. Use this property to display a context menu when you right-click the patch. Create the context menu using the uicontextmenu function.

---

**Note:** If the `PickableParts` property is set to 'none' or if the `HitTest` property is set to 'off', then the context menu does not appear.

---

## **Selected — Selection state**

'off' (default) | 'on'

Selection state, specified as one of these values:

- 'on' — Selected. If you click the patch when in plot edit mode, then MATLAB sets its `Selected` property to 'on'. If the `SelectionHighlight` property also is set to 'on', then MATLAB displays selection handles around the patch.
- 'off' — Not selected.

## **SelectionHighlight — Display of selection handles when selected**

'on' (default) | 'off'

Display of selection handles when selected, specified as one of these values:

- 'on' — Display selection handles when the `Selected` property is set to 'on'.
- 'off' — Never display selection handles, even when the `Selected` property is set to 'on'.

## **Callback Execution Control**

### **PickableParts — Ability to capture mouse clicks**

'visible' (default) | 'all' | 'none'

Ability to capture mouse clicks, specified as one of these values:

- `'visible'` — Can capture mouse clicks when visible. The `Visible` property must be set to `'on'` and you must click a part of the patch that has a defined color. You cannot click a part that has an associated color property set to `'none'`. If the plot contains markers, then the entire marker is clickable if either the edge or the fill has a defined color. The `HitTest` property determines if the patch responds to the click or if an ancestor does.
- `'all'` — Can capture mouse clicks regardless of visibility. The `Visible` property can be set to `'on'` or `'off'` and you can click a part of the patch that has no color. The `HitTest` property determines if the patch responds to the click or if an ancestor does.
- `'none'` — Cannot capture mouse clicks. Clicking the patch passes the click through it to the object below it in the current view of the figure window. The `HitTest` property has no effect.

### **HitTest — Response to captured mouse clicks**

`'on'` (default) | `'off'`

Response to captured mouse clicks, specified as one of these values:

- `'on'` — Trigger the `ButtonDownFcn` callback of the patch. If you have defined the `UIContextMenu` property, then invoke the context menu.
- `'off'` — Trigger the callbacks for the nearest ancestor of the patch that has a `HitTest` property set to `'on'` and a `PickableParts` property value that enables the ancestor to capture mouse clicks.

---

**Note:** The `PickableParts` property determines if the patch object can capture mouse clicks. If it cannot, then the `HitTest` property has no effect.

---

### **Interruptible — Callback interruption**

`'on'` (default) | `'off'`

Callback interruption, specified as `'on'` or `'off'`. The `Interruptible` property determines if a running callback can be interrupted.

---

**Note:** There are two callback states to consider:

- The *running* callback is the currently executing callback.
- The *interrupting* callback is a callback that tries to interrupt the running callback.

Whenever MATLAB invokes a callback, that callback attempts to interrupt a running callback. The `Interruptible` property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the `BusyAction` property of the object owning the interrupting callback determines if it is discarded or put in the queue.

---

If the `ButtonDownFcn` callback of the patch is the running callback, then the `Interruptible` property determines if it another callback can interrupt it:

- `'on'` — Interruptible. Interruption occurs at the next point where MATLAB processes the queue, such as when there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command.
  - If the running callback contains one of these commands, then MATLAB stops the execution of the callback at this point and executes the interrupting callback. MATLAB resumes executing the running callback when the interrupting callback completes. For more information, see “Interrupt Callback Execution”.
  - If the running callback does not contain one of these commands, then MATLAB finishes executing the callback without interruption.
- `'off'` — Not interruptible. MATLAB finishes executing the running callback without any interruptions.

### **BusyAction — Callback queuing**

`'queue'` (default) | `'cancel'`

Callback queuing specified as `'queue'` or `'cancel'`. The `BusyAction` property determines how MATLAB handles the execution of interrupting callbacks.

---

**Note:** There are two callback states to consider:

- The *running* callback is the currently executing callback.
- The *interrupting* callback is a callback that tries to interrupt the running callback.

Whenever MATLAB invokes a callback, that callback attempts to interrupt a running callback. The `Interruptible` property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the `BusyAction` property of the object owning the interrupting callback determines if it is discarded or put in the queue.

---

If the `ButtonDownFcn` callback of the patch tries to interrupt a running callback that cannot be interrupted, then the `BusyAction` property determines if it is discarded or put in the queue. Specify the `BusyAction` property as one of these values:

- `'queue'` — Put the interrupting callback in a queue to be processed after the running callback finishes execution. This is the default behavior.
- `'cancel'` — Discard the interrupting callback.

## Creation and Deletion Control

### `CreateFcn` — Creation callback

`''` (default) | function handle | cell array | string

Creation callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you create the patch. Setting the `CreateFcn` property on an existing patch has no effect. You must define a default value for this property, or define this property using a `Name, Value` pair during patch creation. MATLAB executes the callback after creating the patch and setting all of its properties.

If you specify this callback using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The patch object — You can access properties of the patch object from within the callback function. You also can access the patch object through the `CallbackObject` property of the root, which can be queried using the `gcbo` function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see “Callback Definition”.

Example: `@myCallback`

Example: `{@myCallback, arg3}`

**DeleteFcn — Deletion callback**`' ' (default) | function handle | cell array | string`

Deletion callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you delete the patch. MATLAB executes the callback before destroying the patch so that the callback can access its property values.

If you specify this callback using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The patch object — You can access properties of the patch object from within the callback function. You also can access the patch object through the `CallbackObject` property of the root, which can be queried using the `gcbo` function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see “Callback Definition”.

Example: `@myCallback`

Example: `{@myCallback, arg3}`

**BeingDeleted — Deletion status of patch**`'off' (default) | 'on'`

This property is read only.

Deletion status of patch, returned as `'on'` or `'off'`. MATLAB sets the `BeingDeleted` property to `'on'` when the delete function of the patch begins execution (see the `DeleteFcn` property). The `BeingDeleted` property remains set to `'on'` until the patch no longer exists.

Check the value of the `BeingDeleted` property to verify that the patch is not about to be deleted before querying or modifying it.

## path

View or change search path

### Alternatives

As an alternative to the `path` function, use the Set Path dialog box.

### Syntax

```
path
path('newpath')
path(path, 'newpath')
path('newpath', path)
p = path
```

### Description

`path` displays the MATLAB search path, which is stored in `pathdef.m`.

`path('newpath')` changes the search path to `newpath`, where `newpath` is a string array of folders.

`path(path, 'newpath')` adds the `newpath` folder to the end of the search path. If `newpath` is already on the search path, then `path(path, 'newpath')` moves `newpath` to the end of the search path.

`path('newpath', path)` adds the `newpath` folder to the top of the search path. If `newpath` is already on the search path, then `path('newpath', path)` moves `newpath` to the top of the search path. To add multiple folders in one statement, instead use `addpath`.

`p = path` returns the search path to string variable `p`.

### Examples

Display the search path:

path

MATLAB returns, for example

MATLABPATH

```
H:\My Documents\MATLAB
C:\Program Files\MATLAB\R200nn\toolbox\matlab\general
C:\Program Files\MATLAB\R200nn\toolbox\matlab\ops
C:\Program Files\MATLAB\R200nn\toolbox\matlab\lang
C:\Program Files\MATLAB\R200nn\toolbox\matlab\elmat
C:\Program Files\MATLAB\R200nn\toolbox\matlab\elfun
...
```

R200nn represents the folder for the MATLAB release, for example, R2009b.

Add a new folder to the search path on Microsoft Windows platforms:

```
path(path, 'c:/tools/goodstuff')
```

Add a new folder to the search path on UNIX<sup>3</sup> platforms:

```
path(path, '/home/tools/goodstuff')
```

Temporarily add the folder `my_files` to the search path, run `my_function` in `my_files`, then restore the previous search path:

```
p = path
path(p, 'my_files')
my_function
path(p)
```

**Introduced before R2006a**

## path2rc

Save current search path to `pathdef.m` file

### Syntax

`path2rc`

### Description

`path2rc` runs `savepath`. The `savepath` function is replacing `path2rc`. Use `savepath` instead of `path2rc` and replace instances of `path2rc` with `savepath`.

**Introduced before R2006a**

## pathsep

Search path separator for current platform

### Syntax

```
c = pathsep
```

### Description

`c = pathsep` returns the search path separator character for this platform. The search path separator is the character that separates path names in the `pathdef.m` file, as returned by the `path` function. The character is a semicolon (;). For versions of MATLAB software earlier than version 7.7 (R2008b), the character on UNIX<sup>4</sup> platforms was a colon (:). Use `pathsep` to work programmatically with the content of the search path file.

**Introduced before R2006a**

## pause

Stop MATLAB execution temporarily

### Syntax

pause

pause(n)

pause(state)

oldState = pause(state)

### Description

pause temporarily stops MATLAB execution and waits for the user to press any key. The pause function also temporarily stops the execution of Simulink models, but does not pause their repainting.

---

**Note:** If you previously disabled the pause setting, reenable it using `pause('on')` for this call to take effect.

---

`pause(n)` pauses execution for `n` seconds before continuing. Pausing must be enabled for this call to take effect.

`pause(state)` enables, disables, or displays the current pause setting.

`oldState = pause(state)` returns the current pause setting and sets the pause state as indicated by `state`. For example, if pausing is enabled, `oldState = pause('off')` returns 'on' in `oldState` and disables pausing.

### Examples

#### Pause Execution

Pause execution for 5 seconds. MATLAB blocks, or hides, the command prompt (`>>`) while it pauses execution.

```
n = 5;
pause(n)
```

## Disable Pause Setting

Disable the pause setting and query the current state.

```
pause('off')
pause('query')
```

```
ans =

off
```

Pause execution for 100 seconds. Since the pause setting is off, MATLAB ignores the request to pause execution, and immediately returns the command prompt.

```
pause(100)
```

Enable the pause setting.

```
pause('on')
```

## Save and Restore Pause State

Store the current pause setting and then disable the ability to pause execution.

```
oldState = pause('off')
```

```
oldState =

on
```

Query the current pause setting.

```
pause('query')
```

```
ans =

off
```

Restore the initial pause state.

```
pause(oldState)
```

```
pause('query')
```

```
ans =
```

```
on
```

Alternatively, you can store the queried value of the pause state and then disable the ability to pause execution.

```
oldState = pause('query');
pause('off')
```

Restore the initial pause state.

```
pause(oldState)
```

## Input Arguments

### **n** — Number of seconds

nonnegative, real number

Number of seconds to pause execution specified as a nonnegative, real number.

Typing `pause(inf)` puts you into an infinite loop. To return to the MATLAB prompt, type **Ctrl+C**.

Example: `pause(3)` pauses for 3 seconds.

Example: `pause(5/1000)` pauses for 5 milliseconds.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **state** — Pause setting

'on' | 'off' | 'query'

Pause control indicator specified as 'on', 'off', or 'query'. Use 'on' or 'off' to control whether the `pause` function is able to pause MATLAB execution. Use 'query' to query the current state of the pause setting.

To run interactive code unattended, disable the pause setting.

## More About

### Tips

- The accuracy of the `pause` function is subject to the scheduling resolution of your operating system, and to other concurrent system activity. The accuracy is not guaranteed, and finer resolution results in higher relative error.
- While MATLAB is paused, the following continue to execute:
  - Repainting of figure windows, Simulink block diagrams, and Java windows
  - HG callbacks from figure windows
  - Event handling from Java windows

**Introduced before R2006a**

# pbaspect

Control relative lengths of each axis

## Syntax

```
pbaspect(ratio)
```

```
pbaspect auto
```

```
pbaspect manual
```

```
pb = pbaspect
```

```
m = pbaspect('mode')
```

```
pbaspect(ax, ___)
```

## Description

`pbaspect(ratio)` sets the plot box aspect ratio for the current axes. The plot box aspect ratio is the relative length of the  $x$ -axis,  $y$ -axis, and  $z$ -axis. Specify `ratio` as a three-element vector of positive values that represent the ratio of the  $x$ -axis,  $y$ -axis, and  $z$ -axis lengths. For example, `[3 1 1]` specifies that the length of the  $x$ -axis is equal to three times the length of the  $y$ -axis and  $z$ -axis. For equal axis lengths in all directions, use `[1 1 1]`.

`pbaspect auto` lets the axes choose the appropriate plot box aspect ratio and sets the associated mode to automatic. The mode must be automatic to enable the stretch-to-fill feature of the axes.

`pbaspect manual` uses the ratio stored in the `PlotBoxAspectRatio` property of the axes object and sets the associated mode to manual. When the mode is manual, it disables the stretch-to-fill feature of the axes. Specifying a value for the plot box aspect ratio sets the mode to manual.

`pb = pbaspect` returns the plot box aspect ratio for the current axes.

`m = pbaspect('mode')` returns the current mode, which is either `'auto'` or `'manual'`. By default, the mode is automatic unless you specify the plot box aspect ratio or set the mode to manual.

`pbaspect(ax, ___)` uses the axes specified by `ax` instead of the current axes. Specify an axes object with any of the input argument combinations in the previous syntaxes. Use single quotes around input arguments that are character strings, for example `pbaspect(ax, 'auto')` and `pbaspect(ax, 'manual')`.

## Examples

### Use Equal Axis Lengths

Create a simple line plot. Make the *x*-axis, *y*-axis, and *z*-axis (not shown) equal lengths.

```
x = linspace(0,10);
y = sin(x);
plot(x,y)
pbaspect([1 1 1])
```

### Use Different Axis Lengths

Plot a surface and make the x-axis twice as long as the y-axis and z-axis.

```
[x,y] = meshgrid(-2:.2:2);
z = x.*exp(-x.^2 - y.^2);
surf(x,y,z)
pbaspect([2 1 1])
```

When you specify the plot box aspect ratio, the associated mode changes to manual. Query the current plot box aspect ratio mode.

```
m = pbaspect('mode')
```

```
m =
```

```
manual
```

### Query Plot Box Aspect Ratio

Create a surface plot.

```
[x,y] = meshgrid(-2:.2:2);
z = x.*exp(-x.^2 - y.^2);
surf(x,y,z)
```

Query the plot box aspect ratio. The values indicate the ratio of the  $x$ -axis length to  $y$ -axis length to  $z$ -axis length.

```
pb = pbaspect
```

```
pb =
```

```
1.0000 0.9419 0.8518
```

## **Set Plot Box Aspect Ratio for Specific Axes**

Create a figure with two subplots and return the axes objects from the `subplot` function. Set the plot box aspect ratio for lower subplot by specifying `ax2` as the first input argument to the `pbaspect` function.

```
ax1 = subplot(2,1,1);
surf(peaks)
```

```
ax2 = subplot(2,1,2);
plot(peaks)
pbaspect(ax2,[2 1 1])
```

## Input Arguments

### **ratio** — Plot box aspect ratio

three-element vector

Plot box aspect ratio, specified as a three-element vector of positive values. For example, `pbaspect([3 2 1])` specifies that the ratio of the *x*-axis length to *y*-axis length to *z*-axis length is 3 to 2 to 1. Thus, the *x*-axis is the longest and the *z*-axis is the shortest.

Specifying the ratio sets the `PlotBoxAspectRatio` property for the axes object to the specified value. The `PlotBoxAspectRatio` property interacts with the

`DataAspectAspectRatio`, `XLim`, `YLim`, and `ZLim` properties to control the length and scale of the *x*-axis, *y*-axis, and *z*-axis.

Specifying the ratio sets the `PlotBoxAspectRatioMode` property to `'manual'` and disables the “Stretch-to-fill” on page 1-1874 behavior of the axes.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **ax** — Axes object

axes object

Axes object. If you do not specify an axes object, then `pbaspect` uses the current axes (`gca`).

## Output Arguments

### **pb** — Current plot box aspect ratio values

three-element vector

Current plot box aspect ratio, returned as a three-element vector of values representing the ratio of the *x*-axis, *y*-axis, and *z*-axis lengths.

Querying the plot box aspect ratio values returns the `PlotBoxAspectRatio` property value for the axes object.

### **m** — Current plot box aspect ratio mode

`'auto'` | `'manual'`

Current plot box aspect ratio mode, returned as either `'auto'` or `'manual'`. When the mode is automatic, the axes determines the appropriate plot box aspect ratio value. If you specify a value, then the mode changes to manual.

Querying the plot box aspect ratio mode returns the `PlotBoxAspectRatioMode` property value for the axes object.

## More About

### Stretch-to-fill

When the stretch-to-fill feature is enabled, MATLAB stretches the axes to fill the available space. Some distortion can occur. Thus, the axes might not exactly match the data aspect ratio, plot box aspect ratio, and camera-view angle values stored in its `DataAspectRatio`, `PlotBoxAspectRatio`, and `CameraViewAngle` properties. When stretch-to-fill is disabled, MATLAB makes the axes as large as possible within the available space and strictly adheres to the property values so that there is no distortion. The last two elements of the `Position` property of the axes object determine the available space.

The stretch-to-fill feature is enabled when the `DataAspectRatioMode`, `PlotBoxAspectRatioMode`, and `CameraViewAngleMode` properties of the axes object are all set to `'auto'`. If one or more modes are manual, the feature is disabled. Thus, if you specify the data aspect ratio, plot box aspect ratio, or camera-view angle, then the stretch-to-fill feature is disabled.

For example, this figure shows the same plot with and without the stretch-to-fill feature enabled. The dotted line shows the available space as defined by the `Position` property. In both versions, the data aspect ratio, plot box aspect ratio, and camera-view angle values are the same. However, in the left plot, the stretching introduces some distortion.

## pcg

Preconditioned conjugate gradients method

### Syntax

```
x = pcg(A,b)
pcg(A,b,tol)
pcg(A,b,tol,maxit)
pcg(A,b,tol,maxit,M)
pcg(A,b,tol,maxit,M1,M2)
pcg(A,b,tol,maxit,M1,M2,x0)
[x,flag] = pcg(A,b,...)
[x,flag,relres] = pcg(A,b,...)
[x,flag,relres,iter] = pcg(A,b,...)
[x,flag,relres,iter,resvec] = pcg(A,b,...)
```

### Description

`x = pcg(A,b)` attempts to solve the system of linear equations  $A^*x=b$  for  $x$ . The  $n$ -by- $n$  coefficient matrix  $A$  must be symmetric and positive definite, and should also be large and sparse. The column vector  $b$  must have length  $n$ . You also can specify  $A$  to be a function handle, `aFun`, such that `aFun(x)` returns  $A^*x$ .

“Parameterizing Functions” explains how to provide additional parameters to the function `aFun`, as well as the preconditioner function `mFun` described below, if necessary.

If `pcg` converges, a message to that effect is displayed. If `pcg` fails to converge after the maximum number of iterations or halts for any reason, a warning message is printed displaying the relative residual  $\text{norm}(b-A^*x)/\text{norm}(b)$  and the iteration number at which the method stopped or failed.

`pcg(A,b,tol)` specifies the tolerance of the method. If `tol` is `[]`, then `pcg` uses the default,  $1e-6$ .

`pcg(A,b,tol,maxit)` specifies the maximum number of iterations. If `maxit` is `[]`, then `pcg` uses the default,  $\min(n,20)$ .

`pcg(A,b,tol,maxit,M)` and `pcg(A,b,tol,maxit,M1,M2)` use symmetric positive definite preconditioner `M` or `M = M1*M2` and effectively solve the system  $\text{inv}(M) * A * x = \text{inv}(M) * b$  for `x`. If `M` is `[]` then `pcg` applies no preconditioner. `M` can be a function handle `mfun` such that `mfun(x)` returns `M \ x`.

`pcg(A,b,tol,maxit,M1,M2,x0)` specifies the initial guess. If `x0` is `[]`, then `pcg` uses the default, an all-zero vector.

`[x,flag] = pcg(A,b,...)` also returns a convergence flag.

Flag	Convergence
0	<code>pcg</code> converged to the desired tolerance <code>tol</code> within <code>maxit</code> iterations.
1	<code>pcg</code> iterated <code>maxit</code> times but did not converge.
2	Preconditioner <code>M</code> was ill-conditioned.
3	<code>pcg</code> stagnated. (Two consecutive iterates were the same.)
4	One of the scalar quantities calculated during <code>pcg</code> became too small or too large to continue computing.

Whenever `flag` is not 0, the solution `x` returned is that with minimal norm residual computed over all the iterations. No messages are displayed if the `flag` output is specified.

`[x,flag,relres] = pcg(A,b,...)` also returns the relative residual  $\text{norm}(b-A*x) / \text{norm}(b)$ . If `flag` is 0, `relres <= tol`.

`[x,flag,relres,iter] = pcg(A,b,...)` also returns the iteration number at which `x` was computed, where  $0 \leq \text{iter} \leq \text{maxit}$ .

`[x,flag,relres,iter,resvec] = pcg(A,b,...)` also returns a vector of the residual norms at each iteration including  $\text{norm}(b-A*x0)$ .

## Examples

### Using `pcg` with Large Matrices

This example shows how to use `pcg` with a matrix input and with a function handle.

```

n1 = 21;
A = gallery('moler',n1);
b1 = sum(A,2);
tol = 1e-6;
maxit = 15;
M1 = spdiags((1:n1)',0,n1,n1);
[x1,flag1,rr1,iter1,rv1] = pcg(A,b1,tol,maxit,M1);

```

Alternatively, you can use the following function in place of the matrix A:

```

function y = applyMoler(x)
y = x;
y(end-1:-1:1) = y(end-1:-1:1) - cumsum(y(end:-1:2));
y(2:end) = y(2:end) - cumsum(y(1:end-1));

```

By using this function, you can solve larger systems more efficiently as there is no need to store the entire matrix A:

```

n2 = 21;
b2 = applyMoler(ones(n2,1));
tol = 1e-6;
maxit = 15;
M2 = spdiags((1:n2)',0,n2,n2);
[x2,flag2,rr2,iter2,rv2] = pcg(@applyMoler,b2,tol,maxit,M2);

```

## Using pcg with a Preconditioner

This example demonstrates how to use a preconditioner matrix with `pcg`.

Create an input matrix and try to solve the system with `pcg`.

```

A = delsq(numgrid('S',100));
b = ones(size(A,1),1);
[x0,f10,rr0,it0,rv0] = pcg(A,b,1e-8,100);

```

`f10` is 1 because `pcg` does not converge to the requested tolerance of  $1e-8$  within the requested maximum 100 iterations. A preconditioner can make the system converge more quickly.

Use `ichol` with only one input argument to construct an incomplete Cholesky factorization with zero fill.

```

L = ichol(A);

```

```
[x1,f11,rr1,it1,rv1] = pcg(A,b,1e-8,100,L,L');
```

`f11` is 0 because `pcg` drives the relative residual to  $9.8e-09$  (the value of `rr1`) which is less than the requested tolerance of  $1e-8$  at the seventy-seventh iteration (the value of `it1`) when preconditioned by the zero-fill incomplete Cholesky factorization. `rv1(1) = norm(b)` and `rv1(78) = norm(b-A*x1)`.

The previous matrix represents the discretization of the Laplacian on a 100x100 grid with Dirichlet boundary conditions. This means that a modified incomplete Cholesky preconditioner might perform even better.

Use the `michol` option to create a modified incomplete Cholesky preconditioner.

```
L = ichol(A,struct('michol','on'));
[x2,f12,rr2,it2,rv2] = pcg(A,b,1e-8,100,L,L');
```

In this case you attain convergence in only forty-seven iterations.

You can see how the preconditioners affect the rate of convergence of `pcg` by plotting each of the residual histories starting from the initial estimate (iterate number 0).

```
figure;
semilogy(0:it0,rv0/norm(b),'b. ');
hold on;
semilogy(0:it1,rv1/norm(b),'r. ');
semilogy(0:it2,rv2/norm(b),'k. ');
legend('No Preconditioner','IC(0)','MIC(0)');
xlabel('iteration number');
ylabel('relative residual');
hold off;
```

# pchip

Piecewise Cubic Hermite Interpolating Polynomial (PCHIP)

## Syntax

```
yi = pchip(x,y,xi)
pp = pchip(x,y)
```

## Description

`yi = pchip(x,y,xi)` returns vector `yi` containing elements corresponding to the elements of `xi` and determined by piecewise cubic interpolation within vectors `x` and `y`. The vector `x` specifies the points at which the data `y` is given, so `x` and `y` must have the same length. If `y` is a matrix or array, then the values in the last dimension, `y(:,...,:,j)`, are taken as the values to match with `x`. In that case, the last dimension of `y` must be the same length as `x`. If `y` has `n` dimensions, then output `yi` is of size `[size(y,1) size(y,2) ... size(y,n-1) length(xi)]`. For example, if `y` is a matrix, then `yi` is of size `[size(y,1) length(xi)]`.

`pp = pchip(x,y)` returns a piecewise polynomial structure for use by `ppval`. `x` can be a row or column vector. `y` is a row or column vector of the same length as `x`, or a matrix with `length(x)` columns.

`pchip` finds values of an underlying interpolating function  $P(x)$  at intermediate points, such that:

- On each subinterval  $x_k \leq x \leq x_{k+1}$ ,  $P(x)$  is the cubic Hermite interpolant to the given values and certain slopes at the two endpoints.
- $P(x)$  interpolates  $y$ , i.e.,  $P(x_j) = y_j$ , and the first derivative  $\frac{dP}{dx}$  is continuous. The second derivative  $\frac{d^2P}{dx^2}$  is probably not continuous; there may be jumps at the  $x_j$ .

- The slopes at the  $x_j$  are chosen in such a way that  $P(x)$  preserves the shape of the data and respects monotonicity. This means that, on intervals where the data are monotonic, so is  $P(x)$ ; at points where the data has a local extremum, so does  $P(x)$ .

---

**Note** If  $y$  is a matrix,  $P(x)$  satisfies the above for each column of  $y$ .

---

## Examples

### Data Interpolation Using `spline` and `pchip`

```
x = -3:3;
y = [-1 -1 -1 0 1 1 1];
t = -3:.01:3;
p = pchip(x,y,t);
s = spline(x,y,t);
plot(x,y,'o',t,p,'-',t,s,'-.')
legend('data','pchip','spline','Location','SouthEast')
```

## More About

### Tips

`spline` constructs  $S(x)$  in almost the same way `pchip` constructs  $P(x)$ . However, `spline` chooses the slopes at the  $x_j$  differently, namely to make even  $S''(x)$  continuous. This has the following effects:

- `spline` produces a smoother result, i.e.  $S''(x)$  is continuous.

- `spline` produces a more accurate result if the data consists of values of a smooth function.
- `pchip` has no overshoots and less oscillation if the data are not smooth.
- `pchip` is less expensive to set up.
- The two are equally expensive to evaluate.

# pcode

Create protected function file

## Syntax

```
pcode(fun)
pcode(fun1,...,funN)
pcode(fun,'-inplace')
```

## Description

`pcode(fun)` obfuscates the code in `fun.m` and produces a file called `fun.p`, known as a P-file. If `fun` is a folder, then all the script or function files in that folder are obfuscated in P-files. MATLAB creates the P-files in the current folder. The original `.m` file or folder can be anywhere on the search path.

`pcode(fun1,...,funN)` creates `N` P-files from the listed files. If any inputs are folders, then MATLAB creates a P-file for every `.m` file the folders contain.

`pcode(fun,'-inplace')` creates P-files in the same folder as the script or function files.

---

**Note:** The `pcode` function *obfuscates* your `.m` files, it does not *encrypt* them. While the content in a `.p` file is difficult to understand, it should not be considered secure. It is not recommended that you P-code files to protect your intellectual property.

---

## Input Arguments

### **fun**

MATLAB file or directory containing MATLAB files. If `fun` resides within a package and/or class folder, then `pcode` creates the same package and/or class structure to house the resulting P-files.

An input argument with no file extension and that is not a folder must be a function in the MATLAB path or in the current folder.

When using wild cards \*, pcode ignores all files with extensions other than .m.

**Default:**

## Examples

### P-Coding Multiple Files

Convert selected files from the sparfun folder into P-files.

Create a temporary folder and define an existing path to .m files.

```
tmp = tempname;
mkdir(tmp)
cd(tmp)
fun = fullfile(matlabroot, 'toolbox', 'matlab', 'sparfun', 'spr*.m');
```

Create the P-files.

```
pcode(fun)
dir(tmp)

. .. sprand.p sprandn.p sprandsym.p sprank.p
```

The temporary folder now contains encoded P-files.

### P-Coding Files That Belong to a Package and/or Class

Generate P-files from input files that are part of a package and/or class. This example uses an existing MATLAB example class.

Define funclass as an existing a class folder that contains .m files.

```
funclass = fullfile(docroot, 'techdoc', 'matlab_oop', ...
 'examples', '@BankAccount')
dir(funclass)

funclass =

C:\Program Files\MATLAB\R2013a\help\techdoc\matlab_oop\examples\@BankAccount
```

```
. .. BankAccount.m
```

Create a temporary folder. This folder has no package or class structure at this time.

```
tmp = tempname;
mkdir(tmp);
cd(tmp);
dir(tmp)
```

```
. ..
```

Create a P-file for every .m file in the path `funclass`. Because the input files are part of a package and/or class, MATLAB creates a folder structure so that the output file belongs to the same package and/or class.

```
pcode(funclass)
dir(tmp)
```

```
. .. @BankAccount
```

You see that the P-file resides in the same folder structure.

```
dir('@BankAccount')
```

```
. .. BankAccount.p
```

## P-Coding In Place

Generate P-files in the same folder as the input files using the option `inplace`

Copy several MATLAB files to a temporary folder.

```
fun = fullfile(matlabroot, 'toolbox', 'matlab', 'sparfun', 'spr*.m');
tmp = tempname;
mkdir(tmp);
copyfile(fun,tmp)
dir(tmp)
```

```
. .. sprand.m sprandn.m sprandsym.m sprank.m
```

Create P-files in the same folder as the original .m files.

```
pcode(tmp, '-inplace')
dir(tmp)
```

```
. sprand.m sprandn.m sprandsym.m sprank.m
```

.. sprand.p sprandn.p sprandsym.p sprank.p

## More About

### Tips

- The `pcode` algorithm was redesigned in MATLAB 7.5 (Release R2007b). If your P-file was generated prior to MATLAB 7.5, it will not run in MATLAB 8.6 (Release R2015b) or later. Files generated in 7.5, or later versions, cannot run in MATLAB 7.4 or earlier.
- When obfuscating all files in a folder, `pcode` does not obfuscate any files within subfolders.
- A P-file takes precedence over the corresponding `.m` file for execution, even after modifications to the `.m` file.
- MATLAB does not display any of the help comments that might be in the original `.m` file.
- “Protect Your Source Code”

# pcolor

Pseudocolor (checkerboard) plot

## Syntax

```
pcolor(C)
pcolor(X,Y,C)
pcolor(axes_handles,...)
h = pcolor(...)
```

## Description

A pseudocolor plot is a rectangular array of cells with colors determined by **C**. MATLAB creates a pseudocolor plot using each set of four adjacent points in **C** to define a surface rectangle (i.e., cell).

The default shading is **faceted**, which colors each cell with a single color. The last row and column of **C** are not used in this case. With shading **interp**, each cell is colored by bilinear interpolation of the colors at its four vertices, using all elements of **C**.

The minimum and maximum elements of **C** are assigned the first and last colors in the colormap. Colors for the remaining elements in **C** are determined by a linear mapping from value to colormap element.

`pcolor(C)` draws a pseudocolor plot. The elements of **C** are linearly mapped to an index into the current colormap. The mapping from **C** to the current colormap is defined by `colormap` and `caxis`.

`pcolor(X,Y,C)` draws a pseudocolor plot of the elements of **C** at the locations specified by **X** and **Y**. The plot is a logically rectangular, two-dimensional grid with vertices at the points  $[X(i,j), Y(i,j)]$ . **X** and **Y** are vectors or matrices that specify the spacing of the grid lines. If **X** and **Y** are vectors, **X** corresponds to the columns of **C** and **Y** corresponds to the rows. If **X** and **Y** are matrices, they must be the same size as **C**.

`pcolor(axes_handles,...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

`h = pcolor(...)` returns a handle to a `surface` graphics object.

## Examples

### Pseudocolor Plot of Hadamard Matrix

A Hadamard matrix has elements that are +1 and -1. A colormap with only two entries is appropriate when displaying a pseudocolor plot of this matrix.

```
pcolor(hadamard(20))
colormap(gray(2))
axis ij
axis square
```

### Polar Coordinate System

A simple color wheel illustrates a polar coordinate system.

```
n = 6;
r = (0:n)'/n;
theta = pi*(-n:n)/n;
X = r*cos(theta);
Y = r*sin(theta);
C = r*cos(2*theta);
pcolor(X,Y,C)
axis equal tight
```

## More About

### Tips

A pseudocolor plot is a flat surface plot viewed from above. `pcolor(X,Y,C)` is the same as viewing `surf(X,Y,zeros(size(X)),C)` using `view([0 90])`.

When you use `shading faceted` or `shading flat`, the constant color of each cell is the color associated with the corner having the smallest  $x$ - $y$  coordinates. Therefore, `C(i,j)` determines the color of the cell in the  $i$ th row and  $j$ th column. The last row and column of `C` are not used.

When you use `shading interp`, each cell's color results from a bilinear interpolation of the colors at its four vertices, and all elements of `C` are used.

### Algorithms

Use the `pcolor`, `image`, or `imagesc` function to display image data. Each function displays a rectangular array of cells and uses `C` to determine the colors.

- `pcolor(C)` uses the values in `C` to define the vertex colors by scaling the values to map to the full range of the colormap. The size of `C` determines the number of vertices. `pcolor` determines the cell colors using the colors defined at the cell vertices.
- `image(C)` uses `C` to define the cell colors by mapping the values directly into the colormap. The size of `C` determines the number of cells.
- `imagesc(C)` uses `C` to define the cell colors by scaling the values to map to the full range of the colormap. The size of `C` determines the number of cells.

`pcolor(X,Y,C)` can produce parametric grids, which is not possible with `image` or `imagesc`.

## pdepe

Solve initial-boundary value problems for parabolic-elliptic PDEs in 1-D

### Syntax

```
sol = pdepe(m,pdefun,icfun,bcfun,xmesh,tspan)
sol = pdepe(m,pdefun,icfun,bcfun,xmesh,tspan,options)
[sol,tsol,sole,te,ie] =
pdepe(m,pdefun,icfun,bcfun,xmesh,tspan,options)
```

### Arguments

<code>m</code>	A parameter corresponding to the symmetry of the problem. <code>m</code> can be slab = 0, cylindrical = 1, or spherical = 2.
<code>pdefun</code>	A handle to a function that defines the components of the PDE.
<code>icfun</code>	A handle to a function that defines the initial conditions.
<code>bcfun</code>	A handle to a function that defines the boundary conditions.
<code>xmesh</code>	A vector [ <code>x0</code> , <code>x1</code> , ..., <code>xn</code> ] specifying the points at which a numerical solution is requested for every value in <code>tspan</code> . The elements of <code>xmesh</code> must satisfy <code>x0 &lt; x1 &lt; ... &lt; xn</code> . The length of <code>xmesh</code> must be <code>&gt;= 3</code> .
<code>tspan</code>	A vector [ <code>t0</code> , <code>t1</code> , ..., <code>tf</code> ] specifying the points at which a solution is requested for every value in <code>xmesh</code> . The elements of <code>tspan</code> must satisfy <code>t0 &lt; t1 &lt; ... &lt; tf</code> . The length of <code>tspan</code> must be <code>&gt;= 3</code> .
<code>options</code>	Some options of the underlying ODE solver are available in <code>pdepe</code> : <code>RelTol</code> , <code>AbsTol</code> , <code>NormControl</code> , <code>InitialStep</code> , <code>MaxStep</code> , and <code>Events</code> . In most cases, default values for these options provide satisfactory solutions. See <code>odeset</code> for details.

### Description

`sol = pdepe(m,pdefun,icfun,bcfun,xmesh,tspan)` solves initial-boundary value problems for systems of parabolic and elliptic PDEs in the one space variable

$x$  and time  $t$ . `pdefun`, `icfun`, and `bcfun` are function handles. See “Create Function Handle” for more information. The ordinary differential equations (ODEs) resulting from discretization in space are integrated to obtain approximate solutions at times specified in `tspan`. The `pdepe` function returns values of the solution on a mesh provided in `xmesh`.

“Parameterizing Functions” explains how to provide additional parameters to the functions `pdefun`, `icfun`, or `bcfun`, if necessary.

`pdepe` solves PDEs of the form:

$$c\left(x, t, u, \frac{\partial u}{\partial x}\right) \frac{\partial u}{\partial t} = x^{-m} \frac{\partial}{\partial x} \left( x^m f\left(x, t, u, \frac{\partial u}{\partial x}\right) \right) + s\left(x, t, u, \frac{\partial u}{\partial x}\right)$$

The PDEs hold for  $t_0 \leq t \leq t_f$  and  $a \leq x \leq b$ . The interval  $[a, b]$  must be finite.  $m$  can be 0, 1, or 2, corresponding to slab, cylindrical, or spherical symmetry, respectively. If  $m > 0$ , then  $a$  must be  $\geq 0$ .

In Equation 1-4,  $f(x, t, u, \partial u/\partial x)$  is a flux term and  $s(x, t, u, \partial u/\partial x)$  is a source term. The coupling of the partial derivatives with respect to time is restricted to multiplication by a diagonal matrix  $c(x, t, u, \partial u/\partial x)$ . The diagonal elements of this matrix are either identically zero or positive. An element that is identically zero corresponds to an elliptic equation and otherwise to a parabolic equation. There must be at least one parabolic equation. An element of  $c$  that corresponds to a parabolic equation can vanish at isolated values of  $x$  if those values of  $x$  are mesh points. Discontinuities in  $c$  and/or  $s$  due to material interfaces are permitted provided that a mesh point is placed at each interface.

For  $t = t_0$  and all  $x$ , the solution components satisfy initial conditions of the form

$$u(x, t_0) = u_0(x)$$

For all  $t$  and either  $x = a$  or  $x = b$ , the solution components satisfy a boundary condition of the form

$$p(x, t, u) + q(x, t) f\left(x, t, u, \frac{\partial u}{\partial x}\right) = 0$$

Elements of  $q$  are either identically zero or never zero. Note that the boundary conditions are expressed in terms of the flux  $f$  rather than  $\partial u/\partial x$ . Also, of the two coefficients, only  $p$  can depend on  $u$ .

In the call `sol = pdepe(m,pdefun,icfun,bcfun,xmesh,tspan)`:

- `m` corresponds to  $m$ .
- `xmesh(1)` and `xmesh(end)` correspond to  $a$  and  $b$ .
- `tspan(1)` and `tspan(end)` correspond to  $t_0$  and  $t_f$ .
- `pdefun` computes the terms  $c$ ,  $f$ , and  $s$  (Equation 1-4). It has the form

$$[c,f,s] = pdefun(x,t,u,dudx)$$

The input arguments are scalars  $x$  and  $t$  and vectors  $u$  and  $dudx$  that approximate the solution  $u$  and its partial derivative with respect to  $x$ , respectively.  $c$ ,  $f$ , and  $s$  are column vectors.  $c$  stores the diagonal elements of the matrix  $c$  (Equation 1-4).

- `icfun` evaluates the initial conditions. It has the form

$$u = icfun(x)$$

When called with an argument  $x$ , `icfun` evaluates and returns the initial values of the solution components at  $x$  in the column vector  $u$ .

- `bcfun` evaluates the terms  $p$  and  $q$  of the boundary conditions (Equation 1-6). It has the form

$$[p1,q1,pr,qr] = bcfun(xl,ul,xr,ur,t)$$

$ul$  is the approximate solution at the left boundary  $xl = a$  and  $ur$  is the approximate solution at the right boundary  $xr = b$ .  $p1$  and  $q1$  are column vectors corresponding to  $p$  and  $q$  evaluated at  $xl$ , similarly  $pr$  and  $qr$  correspond to  $xr$ . When  $m > 0$  and  $a = 0$ , boundedness of the solution near  $x = 0$  requires that the flux  $f$  vanish at  $a = 0$ . `pdepe` imposes this boundary condition automatically and it ignores values returned in  $p1$  and  $q1$ .

`pdepe` returns the solution as a multidimensional array `sol`.  $u_i = ui = sol(:, :, i)$  is an approximation to the  $i$ th component of the solution vector  $u$ . The element  $ui(j,k) = sol(j,k,i)$  approximates  $u_i$  at  $(t,x) = (tspan(j),xmesh(k))$ .

$ui = sol(j, :, i)$  approximates component  $i$  of the solution at time `tspan(j)` and mesh points `xmesh(:)`. Use `pdeval` to compute the approximation and its partial derivative  $\partial u_i / \partial x$  at points not included in `xmesh`. See `pdeval` for details.

`sol = pdepe(m,pdefun,icfun,bcfun,xmesh,tspan,options)` solves as above with default integration parameters replaced by values in `options`, an argument created

with the `odeset` function. Only some of the options of the underlying ODE solver are available in `pdepe`: `RelTol`, `AbsTol`, `NormControl`, `InitialStep`, and `MaxStep`. The defaults obtained by leaving off the input argument options will generally be satisfactory. See `odeset` for details.

```
[sol,tsol,sole,te,ie] =
pdepe(m,pdefun,icfun,bcfun,xmesh,tspan,options) with the 'Events'
property in options set to a function handle Events, solves as above while
also finding where event functions g(t,u(x,t)) are zero. For each function you
specify whether the integration is to terminate at a zero and whether the direction
of the zero crossing matters. Three column vectors are returned by events:
[value,isterminal,direction] = events(m,t,xmesh,umesh). xmesh contains
the spatial mesh and umesh is the solution at the mesh points. Use pdeval to evaluate
the solution between mesh points. For the I-th event function, value(i) is the value
of the function, ISTERMINAL(I) = 1 if the integration is to terminate at a zero of this
event function and 0 otherwise. direction(i) = 0 if all zeros are to be computed
(the default), +1 if only zeros where the event function is increasing, and -1 if only zeros
where the event function is decreasing. Output tsol is a column vector of times specified
in tspan, prior to first terminal event. SOL(j,:,:) = the solution at T(j). TE is a
vector of times at which events occur. SOLE(j,:,:) = the solution at TE(j) and indices
in vector IE specify which event occurred.
```

If `UI = SOL(j,:,i)` approximates component `i` of the solution at time `TSPAN(j)` and mesh points `XMESH`, `pdeval` evaluates the approximation and its partial derivative  $\partial u_i / \partial x$  at the array of points `XOUT` and returns them in `UOUT` and `DUOUTDX`: `[UOUT,DUOUTDX] = PDEVAL(M, XMESH, UI, XOUT)`

---

**Note:** The partial derivative  $\partial u_i / \partial x$  is evaluated here rather than the flux. The flux is continuous, but at a material interface the partial derivative may have a jump.

---

## Examples

**Example 1.** This example illustrates the straightforward formulation, computation, and plotting of the solution of a single PDE.

$$\pi^2 \frac{\partial u}{\partial t} = \frac{\partial}{\partial x} \left( \frac{\partial u}{\partial x} \right)$$

This equation holds on an interval  $0 \leq x \leq 1$  for times  $t \geq 0$ .

The PDE satisfies the initial condition

$$u(x,0) = \sin \pi x$$

and boundary conditions

$$u(0,t) \equiv 0$$

$$\pi e^{-t} + \frac{\partial u}{\partial x}(1,t) = 0$$

It is convenient to use local functions to place all the functions required by `pdepe` in a single function.

```
function pdex1

m = 0;
x = linspace(0,1,20);
t = linspace(0,2,5);

sol = pdepe(m,@pdex1pde,@pdex1ic,@pdex1bc,x,t);
% Extract the first solution component as u.
u = sol(:,:,1);

% A surface plot is often a good way to study a solution.
surf(x,t,u)
title('Numerical solution computed with 20 mesh points.')
xlabel('Distance x')
ylabel('Time t')

% A solution profile can also be illuminating.
figure
plot(x,u(end,:))
title('Solution at t = 2')
xlabel('Distance x')
ylabel('u(x,2)')
% -----
function [c,f,s] = pdex1pde(x,t,u,DuDx)
c = pi^2;
f = DuDx;
```

```

s = 0;
% -----
function u0 = pdex1ic(x)
u0 = sin(pi*x);
% -----
function [pl,q1,pr,qr] = pdex1bc(xl,ul,xr,ur,t)
pl = ul;
q1 = 0;
pr = pi * exp(-t);
qr = 1;

```

In this example, the PDE, initial condition, and boundary conditions are coded in local functions `pdex1pde`, `pdex1ic`, and `pdex1bc`.

The surface plot shows the behavior of the solution.

The following plot shows the solution profile at the final value of  $t$  (i.e.,  $t = 2$ ).

**Example 2.** This example illustrates the solution of a system of PDEs. The problem has boundary layers at both ends of the interval. The solution changes rapidly for small  $t$ .

The PDEs are

$$\frac{\partial u_1}{\partial t} = 0.024 \frac{\partial^2 u_1}{\partial x^2} - F(u_1 - u_2)$$

$$\frac{\partial u_2}{\partial t} = 0.170 \frac{\partial^2 u_2}{\partial x^2} + F(u_1 - u_2)$$

where  $F(y) = \exp(5.73y) - \exp(-11.46y)$ .

This equation holds on an interval  $0 \leq x \leq 1$  for times  $t \geq 0$ .

The PDE satisfies the initial conditions

$$u_1(x, 0) \equiv 1$$

$$u_2(x, 0) \equiv 0$$

and boundary conditions

$$\begin{aligned}\frac{\partial u_1}{\partial x}(0,t) &\equiv 0 \\ u_2(0,t) &\equiv 0 \\ u_1(1,t) &\equiv 1 \\ \frac{\partial u_2}{\partial x}(1,t) &\equiv 0\end{aligned}$$

In the form expected by `pdepe`, the equations are

$$\begin{bmatrix} 1 \\ 1 \end{bmatrix} \cdot * \frac{\partial}{\partial t} \begin{bmatrix} u_1 \\ u_2 \end{bmatrix} = \frac{\partial}{\partial x} \begin{bmatrix} 0.024(\partial u_1 / \partial x) \\ 0.170(\partial u_2 / \partial x) \end{bmatrix} + \begin{bmatrix} -F(u_1 - u_2) \\ F(u_1 - u_2) \end{bmatrix}$$

The boundary conditions on the partial derivatives of  $u$  have to be written in terms of the flux. In the form expected by `pdepe`, the left boundary condition is

$$\begin{bmatrix} 0 \\ u_2 \end{bmatrix} + \begin{bmatrix} 1 \\ 0 \end{bmatrix} \cdot * \begin{bmatrix} 0.024(\partial u_1 / \partial x) \\ 0.170(\partial u_2 / \partial x) \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

and the right boundary condition is

$$\begin{bmatrix} u_1 - 1 \\ 0 \end{bmatrix} + \begin{bmatrix} 0 \\ 1 \end{bmatrix} \cdot * \begin{bmatrix} 0.024(\partial u_1 / \partial x) \\ 0.170(\partial u_2 / \partial x) \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The solution changes rapidly for small  $t$ . The program selects the step size in time to resolve this sharp change, but to see this behavior in the plots, the example must select the output times accordingly. There are boundary layers in the solution at both ends of  $[0,1]$ , so the example places mesh points near 0 and 1 to resolve these sharp changes. Often some experimentation is needed to select a mesh that reveals the behavior of the solution.

function `pdex4`

```
m = 0;
x = [0 0.005 0.01 0.05 0.1 0.2 0.5 0.7 0.9 0.95 0.99 0.995 1];
t = [0 0.005 0.01 0.05 0.1 0.5 1 1.5 2];

sol = pdepe(m,@pdex4pde,@pdex4ic,@pdex4bc,x,t);
u1 = sol(:,:,1);
u2 = sol(:,:,2);

figure
surf(x,t,u1)
title('u1(x,t)')
xlabel('Distance x')
ylabel('Time t')

figure
surf(x,t,u2)
title('u2(x,t)')
xlabel('Distance x')
ylabel('Time t')
% -----
function [c,f,s] = pdex4pde(x,t,u,DuDx)
c = [1; 1];
f = [0.024; 0.17] .* DuDx;
y = u(1) - u(2);
F = exp(5.73*y)-exp(-11.47*y);
s = [-F; F];
% -----
function u0 = pdex4ic(x);
u0 = [1; 0];
% -----
function [pl,q1,pr,qr] = pdex4bc(xl,ul,xr,ur,t)
pl = [0; ul(2)];
q1 = [1; 0];
pr = [ur(1)-1; 0];
qr = [0; 1];
```

In this example, the PDEs, initial conditions, and boundary conditions are coded in local functions `pdex4pde`, `pdex4ic`, and `pdex4bc`.

The surface plots show the behavior of the solution components.

## More About

### Tips

- The arrays `xmesh` and `tspan` play different roles in `pdepe`.

**tspan** – The `pdepe` function performs the time integration with an ODE solver that selects both the time step and formula dynamically. The elements of `tspan` merely specify where you want answers and the cost depends weakly on the length of `tspan`.

**xmesh** – Second order approximations to the solution are made on the mesh specified in `xmesh`. Generally, it is best to use closely spaced mesh points where the solution changes rapidly. `pdepe` does *not* select the mesh in  $x$  automatically. You must provide an appropriate fixed mesh in `xmesh`. The cost depends strongly on the length of `xmesh`. When  $m > 0$ , it is not necessary to use a fine mesh near  $x = 0$  to account for the coordinate singularity.

- The time integration is done with `ode15s`. `pdepe` exploits the capabilities of `ode15s` for solving the differential-algebraic equations that arise when Equation 1-4 contains elliptic equations, and for handling Jacobians with a specified sparsity pattern.
- After discretization, elliptic equations give rise to algebraic equations. If the elements of the initial conditions vector that correspond to elliptic equations are not "consistent" with the discretization, `pdepe` tries to adjust them before beginning the time integration. For this reason, the solution returned for the initial time may have a discretization error comparable to that at any other time. If the mesh is sufficiently fine, `pdepe` can find consistent initial conditions close to the given ones. If `pdepe` displays a message that it has difficulty finding consistent initial conditions, try refining the mesh.

No adjustment is necessary for elements of the initial conditions vector that correspond to parabolic equations.

## pdeval

Evaluate numerical solution of PDE using output of pdepe

### Syntax

```
[uout,duoutdx] = pdeval(m,x,ui,xout)
```

### Arguments

m	Symmetry of the problem: slab = 0, cylindrical = 1, spherical = 2. This is the first input argument used in the call to pdepe.
x	A vector [x0, x1, ..., xn] specifying the points at which the elements of ui were computed. This is the same vector with which pdepe was called.
ui	A vector sol(j, :, i) that approximates component i of the solution at time $t_f$ and mesh points xmesh, where sol is the solution returned by pdepe.
xout	A vector of points from the interval [x0,xn] at which the interpolated solution is requested.

### Description

[uout,duoutdx] = pdeval(m,x,ui,xout) approximates the solution  $u_i$  and its partial derivative  $\partial u_i / \partial x$  at points from the interval [x0,xn]. The pdeval function returns the computed values in uout and duoutdx, respectively.

---

**Note** pdeval evaluates the partial derivative  $\partial u_i / \partial x$  rather than the flux  $f$ . Although the flux is continuous, the partial derivative may have a jump at a material interface.

## peaks

Example function of two variables

### Syntax

```
Z = peaks;
Z = peaks(n);
Z = peaks(V);
Z = peaks(X,Y);
peaks(...)
[X,Y,Z] = peaks(...);
```

### Description

**peaks** is a function of two variables, obtained by translating and scaling Gaussian distributions, which is useful for demonstrating **mesh**, **surf**, **pcolor**, **contour**, and so on.

**Z = peaks**; returns a 49-by-49 matrix.

**Z = peaks(n)**; returns an n-by-n matrix.

**Z = peaks(V)**; returns an n-by-n matrix, where  $n = \text{length}(V)$ .

**Z = peaks(X,Y)**; evaluates **peaks** at the given X and Y (which must be the same size) and returns a matrix the same size.

**peaks(...)** (with no output argument) plots the peaks function with **surf**. Use any of the input argument combinations in the previous syntaxes.

**[X,Y,Z] = peaks(...)**; returns two additional matrices, X and Y, for parametric plots, for example, **surf(X,Y,Z,del2(Z))**. If not given as input, the underlying matrices X and Y are

```
[X,Y] = meshgrid(V,V)
```

where  $V$  is a given vector, or  $V$  is a vector of length  $n$  with elements equally spaced from  $-3$  to  $3$ . If no input argument is given, the default  $n$  is 49.

## Examples

### Peaks Surface

Create a 5-by-5 matrix of peaks and display the surface.

```
figure
peaks(5);
```

```
z = 3*(1-x).^2.*exp(-(x.^2) - (y+1).^2) ...
 - 10*(x/5 - x.^3 - y.^5).*exp(-x.^2-y.^2) ...
 - 1/3*exp(-(x+1).^2 - y.^2)
```

## perl

Call Perl script using appropriate operating system executable

### Syntax

```
perl('perlfile')
perl('perlfile',arg1,arg2,...)
result = perl(...)
[result, status] = perl(...)
```

### Description

`perl('perlfile')` calls the Perl script `perlfile`, using the appropriate operating system Perl executable. Perl is included with MATLAB on Microsoft Windows systems, so you can run MATLAB functions containing the `perl` function. On Linux and Macintosh systems, MATLAB calls the Perl interpreter available with the operating system.

`perl('perlfile',arg1,arg2,...)` calls the Perl script `perlfile`, using the appropriate operating system Perl executable, and passes the arguments `arg1`, `arg2`, and so on, to `perlfile`.

`result = perl(...)` returns the results of attempted Perl call to `result`.

`[result, status] = perl(...)` returns the results of attempted Perl call to `result` and its exit status to `status`.

It is sometimes beneficial to use Perl scripts instead of MATLAB code. For example:

- Perl script exists
- Perl script preprocesses data quickly, formatting it in a way more easily read by MATLAB
- Perl has features not supported by MATLAB

### Examples

Given the Perl script, `hello.pl`:

```
$input = $ARGV[0];
print "Hello $input.";
```

At the MATLAB command line, type:

```
perl('hello.pl', 'World')
```

```
ans =
Hello World.
```

## perms

All possible permutations

### Syntax

```
P = perms(v)
```

### Description

`P = perms(v)` returns a matrix containing all permutations of the elements of vector `v` in reverse lexicographic order. Each row of `P` contains a different permutation of the  $n$  elements in `v`. Matrix `P` has the same data type as `v`, and it has  $n!$  rows and  $n$  columns.

### Examples

#### All Permutations of Double Integers

```
v = [2 4 6];
P = perms(v)
```

```
P =
```

```
 6 4 2
 6 2 4
 4 6 2
 4 2 6
 2 4 6
 2 6 4
```

#### All Permutations of Unsigned Integers

```
v = uint16([1023 4095 65535]);
P = perms(v)
```

```
P =
```

```
 65535 4095 1023
 65535 1023 4095
```

```
4095 65535 1023
4095 1023 65535
1023 4095 65535
1023 65535 4095
```

## All Permutations of Complex Numbers

```
v = [1+1i 2+1i 3+1i];
```

```
P = perms(v)
```

```
P =
```

```
3.0000 + 1.0000i 2.0000 + 1.0000i 1.0000 + 1.0000i
3.0000 + 1.0000i 1.0000 + 1.0000i 2.0000 + 1.0000i
2.0000 + 1.0000i 3.0000 + 1.0000i 1.0000 + 1.0000i
2.0000 + 1.0000i 1.0000 + 1.0000i 3.0000 + 1.0000i
1.0000 + 1.0000i 2.0000 + 1.0000i 3.0000 + 1.0000i
1.0000 + 1.0000i 3.0000 + 1.0000i 2.0000 + 1.0000i
```

## Input Arguments

### **v** — Set of items

vector of numeric, logical, or char values

Set of items, specified as a vector of numeric, logical, or char values.

Example: [1 2 3 4]

Example: [1+1i 2+1i 3+1i 4+1i]

Example: int16([1 2 3 4])

Example: ['abcd']

Example: [true false true false]

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 |  
uint32 | uint64 | logical | char

Complex Number Support: Yes

## Limitations

perms(v) is practical when length(v) is less than about 10.

## **See Also**

nchoosek | permute | randperm

**Introduced before R2006a**

## permute

Rearrange dimensions of N-D array

### Syntax

```
B = permute(A,order)
```

### Description

`B = permute(A,order)` rearranges the dimensions of `A` so that they are in the order specified by the vector `order`. `B` has the same values of `A` but the order of the subscripts needed to access any particular element is rearranged as specified by `order`. All the elements of `order` must be unique, real, positive, integer values.

### Examples

Given any matrix `A`, the statement

```
permute(A,[2 1])
```

is the same as `A.'`.

For example:

```
A = [1 2; 3 4]; permute(A,[2 1])
ans =
 1 3
 2 4
```

The following code permutes a three-dimensional array:

```
X = rand(12,13,14);
Y = permute(X,[2 3 1]);
size(Y)
ans =
 13 14 12
```

---

## More About

### Tips

`permute` and `ipermute` are a generalization of transpose (.'') for multidimensional arrays.

**Introduced before R2006a**

## **persistent**

Define persistent variable

### **Syntax**

```
persistent X Y Z
```

### **Description**

`persistent X Y Z` defines X, Y, and Z as variables that are local to the function in which they are declared; yet their values are retained in memory between calls to the function. Persistent variables are similar to global variables because the MATLAB software creates permanent storage for both. They differ from global variables in that persistent variables are known only to the function in which they are declared. This prevents persistent variables from being changed by other functions or from the MATLAB command line.

Whenever you clear or modify a function that is in memory, MATLAB also clears all persistent variables declared by that function. To keep a function in memory until MATLAB quits, use `mlock`.

If the persistent variable does not exist the first time you issue the `persistent` statement, it is initialized to the empty matrix.

It is an error to declare a variable persistent if a variable with the same name exists in the current workspace. MATLAB also errors if you declare any of a function's input or output arguments as persistent within that same function. For example, the following persistent declaration is invalid:

```
function myfun(argA, argB, argC)
persistent argB
```

### **Examples**

This function writes a large array to a spreadsheet file and then reads several rows from the same file. Because you only need to write the array to the spreadsheet one time, the

program tests whether an array can be read from the file and, if so, does not waste time in repeating that task. By defining the `dblArray` variable as persistent, you can easily check whether the array has been read from the spreadsheet file.

Here is the `arrayToXLS` function:

```
function arrayToXLS(A, xlsfile, x1, x2)
persistent dblArray;

if isempty(dblArray)
 disp 'Writing spreadsheet file ...'
 xlswrite(xlsfile, A);
end

disp 'Reading array from spreadsheet ...'
dblArray = xlsread(xlsfile, 'Sheet1', [x1 ':' x2])
fprintf('\n');
```

Run the function three times and observe the time elapsed for each run. The second and third run take approximately one tenth the time of the first run in which the function must create the spreadsheet:

```
largeArray = rand(4000, 200);

tic, arrayToXLS(largeArray, 'myTest.xls', 'E254', 'J256'), toc
Writing spreadsheet file ...
Reading array from spreadsheet ...
dblArray =
 0.0982 0.3783 0.1264 0.7880 0.1902 0.5811
 0.2251 0.2704 0.5682 0.7271 0.8028 0.2834
 0.6453 0.5568 0.8254 0.4961 0.9096 0.5402
```

Elapsed time is 8.990525 seconds.

```
tic, arrayToXLS(largeArray, 'myTest.xls', 'E257', 'J258'), toc
Reading array from spreadsheet ...
dblArray =
 0.4620 0.3781 0.6386 0.5930 0.0946 0.4865
 0.1605 0.1251 0.8709 0.5188 0.6702 0.2138
```

Elapsed time is 0.912534 seconds.

```
tic, arrayToXLS(largeArray, 'myTest.xls', 'E259', 'J262'), toc
Reading array from spreadsheet ...
dblArray =
 0.7015 0.6588 0.4023 0.0359 0.4512 0.6097
 0.1308 0.6441 0.0431 0.6396 0.7481 0.8688
 0.8278 0.2686 0.5475 0.8550 0.5896 0.1080
 0.9437 0.1671 0.0505 0.1203 0.2461 0.7306
```

Elapsed time is 0.928843 seconds.

Now clear the arrayToXLS function from memory and observe that running it takes much longer again:

```
clear functions
```

```
tic, arrayToXLS(largeArray, 'myTest.xls', 'E263', 'J264'), toc
Writing spreadsheet file ...
Reading array from spreadsheet ...
dblArray =
 0.6292 0.7788 0.0732 0.6481 0.9299 0.8631
 0.7700 0.5181 0.9805 0.5092 0.8658 0.4070
```

Elapsed time is 7.603461 seconds.

## More About

### Tips

There is no function form of the `persistent` command (i.e., you cannot use parentheses and quote the variable names).

### See Also

`global` | `clear` | `mislocked` | `mlock` | `munlock` | `isempty`

**Introduced before R2006a**

## pi

Ratio of circle's circumference to its diameter

## Syntax

pi

## Description

pi returns the floating-point number nearest the value of  $\pi$ . The expressions `4*atan(1)` and `imag(log(-1))` provide the same value.

## Examples

Find the sine of  $\pi$ :

```
sin(pi)
```

returns

```
ans =
```

```
1.2246e-16
```

The expression `sin(pi)` is not exactly zero because `pi` is not exactly  $\pi$ .

**Introduced before R2006a**

## pie

Pie chart

### Syntax

```
pie(X)
pie(X,explode)
pie(X,labels)
pie(X,explode,labels)
```

```
pie(ax, ___)
```

```
p = pie(___)
```

### Description

`pie(X)` draws a pie chart using the data in `X`. Each slice of the pie chart represents an element in `X`.

- If  $\text{sum}(X) \leq 1$ , then the values in `X` directly specify the areas of the pie slices. `pie` draws only a partial pie if  $\text{sum}(X) < 1$ .
- If  $\text{sum}(X) > 1$ , then `pie` normalizes the values by  $X/\text{sum}(X)$  to determine the area of each slice of the pie.
- If `X` is of data type `categorical`, the slices correspond to categories. The area of each slice is the number of elements in the category divided by the number of elements in `X`.

`pie(X,explode)` offsets slices from the pie. `explode` is a vector or matrix of zeros and nonzeros that correspond to `X`. The `pie` function offsets slices for the nonzero elements only in `explode`.

If `X` is of data type `categorical`, then `explode` can be a vector of zeros and nonzeros corresponding to categories, or a cell array of the names of categories to offset.

`pie(X,labels)` specifies text labels for the slices. The number of labels must equal the number of slices. `X` must be numeric.

`pie(X, explode, labels)` specifies text labels for the slices. The number of labels must equal the number of slices.

`pie(ax, ___)` plots into the axes specified by `ax` instead of into the current axes (`gca`). The option `ax` can precede any of the input argument combinations in the previous syntaxes.

`p = pie(___)` returns a vector of patch and text graphics objects. The input can be any of the input argument combinations in the previous syntaxes.

## Examples

### Create Pie Chart with Offset Slices

Create a pie chart of vector `X`.

```
X = [1 3 0.5 2.5 2];
pie(X)
```

Offset the second and fourth pie slices by setting the corresponding `explode` elements to 1.

```
explode = [0 1 0 1 0];
pie(X,explode)
```

### Specify Text Labels for Pie Chart

Create a pie chart of vector  $X$  and label the slices.

```
X = 1:3;
labels = {'Taxes', 'Expenses', 'Profit'};
pie(X, labels)
```

### Modify Text Label for Pie Chart

Create a labeled pie chart, and then modify the color and font size of the text labels.

```
X = 1:3;
labels = {'Taxes', 'Expenses', 'Profit'};
p = pie(X, labels)
```

p =

1x6 graphics array:

Patch    Text    Patch    Text    Patch    Text

Get the text object for the label 'Profit'. Change its color and font size. Starting in R2014b, you can use dot notation to set properties. If you are using an earlier release, use the set function instead.

```
t = p(6);
t.BackgroundColor = 'cyan';
t.EdgeColor = 'red';
t.FontSize = 14;
```

### Plot Partial Pie Chart

Create a pie chart of vector  $X$  where the sum of the elements is less than 1.

```
X = [0.19 0.22 0.41];
pie(X)
```

pie draws a partial pie because the sum of the elements is less than 1.

### Plot Multiple Pie Charts

Create two vectors of data and plot and label each one in its own pie chart.

```
X = [0.2 0.4 0.4];
labels = {'Taxes', 'Expenses', 'Profit'};
ax1 = subplot(1,2,1);
pie(ax1,X,labels)
title(ax1, '2012');
```

```
Y = [0.24 0.46 0.3];
ax2 = subplot(1,2,2);
```

```
pie(ax2,Y,labels)
title(ax2,'2013');
```

### Plot Categorical Pie Chart with Offsets

Plot a categorical pie chart with offset slices corresponding to categories.

```
X = categorical({'North', 'South', 'North', 'East', 'South', 'West'});
explode = {'North', 'South'};
pie(X,explode)
```

Now, use a logical vector to offset the same slices.

```
explode = [0 1 1 0];
pie(X,explode)
```

### Plot Categorical Pie Chart with Labels

Plot a categorical pie chart without any offset slices and label the slices. When `X` is of data type `categorical` you must specify the input argument `explode`. To specify labels without any offset slices, specify `explode` as an empty cell array, and `labels` as the labels.

```
X = categorical({'North','South','North','East','South','West'});
explode = {};
labels = {'E','N','S','W'};
pie(X,explode,labels)
```

Now, offset a slice and label all slices.

```
X = categorical({'North', 'South', 'North', 'East', 'South', 'West'});
explode = {'West'};
labels = {'E', 'N', 'S', 'W'};
pie(X,explode,labels)
```

- “Offset Pie Slice with Greatest Contribution”
- “Label Pie Chart With Text and Percentages”

## Input Arguments

**X** — Input array  
vector or matrix

Input vector or matrix.

- If X is numeric, then all values in X must be finite. `pie` ignores nonpositive values.

- If  $X$  is categorical, then `pie` ignores undefined elements.

**Data Types:** `double` | `logical` | `categorical`

### **explode** — Offset slices

vector or matrix

Offset slices, specified as a vector or matrix.

- If  $X$  is numeric, then `explode` must be a logical or numeric vector or matrix of zeros and nonzeros that correspond to  $X$ . A true (nonzero) value offsets the corresponding slice from the center of the pie chart, so that  $X(i, j)$  is offset from the center if `explode(i, j)` is nonzero. `explode` must be the same size as  $X$ .
- If  $X$  is categorical, then `explode` can be a cell array of strings that are category names. `pie` offsets slices corresponding to categories in `explode`.
- If  $X$  is categorical, then `explode` also can be a logical or numeric vector with elements that correspond to each category in  $X$ . The `pie` function offsets slices corresponding to true (nonzero) in category order.

### **labels** — Text labels

cell array of strings

Text labels for slices, specified as a cell array of strings.

### **ax** — Axes

axes object

Axes object. Use `ax` to plot the pie chart in a specific axes instead of the current axes (`gca`).

## Output Arguments

### **p** — Patch and text objects

vector

Patch and text objects, returned as a vector.

# pie3

3-D pie chart

## Syntax

```
pie3(X)
pie3(X,explode)
pie3(...,labels)
pie3(axes_handle,...)
h = pie3(...)
```

## Description

`pie3(X)` draws a three-dimensional pie chart using the data in `X`. Each element in `X` is represented as a slice in the pie chart.

- If  $\text{sum}(X) \leq 1$ , then the values in `X` directly specify the area of the pie slices. `pie3` draws only a partial pie if  $\text{sum}(X) < 1$ .
- If the sum of the elements in `X` is greater than one, then `pie3` normalizes the values by  $X/\text{sum}(X)$  to determine the area of each slice of the pie.

`pie3(X,explode)` specifies whether to offset a slice from the center of the pie chart. `X(i,j)` is offset from the center of the pie chart if `explode(i,j)` is nonzero. `explode` must be the same size as `X`.

`pie3(...,labels)` specifies text labels for the slices. The number of labels must equal the number of elements in `X`.

`pie3(axes_handle,...)` plots into the axes with the handle `axes_handle` instead of into the current axes (`gca`).

`h = pie3(...)` returns a vector of handles to patch, surface, and text graphics objects.

## Examples

### Create 3-D Pie Chart

Create a 3-D pie chart of vector `x`.

```
x = [1,3,0.5,2.5,2];
figure
pie3(x)
```

To offset the second pie slice, set the corresponding `explode` element to 1.

```
explode = [0,1,0,0,0];
figure
pie3(x,explode)
```

### Specify Text Labels for 3-D Pie Chart

Create a 3-D pie chart and specify the text labels.

```
x = 1:3;
labels = {'Taxes', 'Expenses', 'Profit'};
figure
```

`pie3(x,labels)`

# pinv

Moore-Penrose pseudoinverse of matrix

## Syntax

```
B = pinv(A)
B = pinv(A,tol)
```

## Definitions

The Moore-Penrose pseudoinverse is a matrix **B** of the same dimensions as **A'** satisfying four conditions:

```
A*B*A = A
B*A*B = B
A*B is Hermitian
B*A is Hermitian
```

The computation is based on `svd(A)` and any singular values less than `tol` are treated as zero.

## Description

`B = pinv(A)` returns the Moore-Penrose pseudoinverse of **A**.

`B = pinv(A,tol)` returns the Moore-Penrose pseudoinverse and overrides the default tolerance, `max(size(A))*norm(A)*eps`.

## Examples

If **A** is square and not singular, then `pinv(A)` is an expensive way to compute `inv(A)`. If **A** is not square, or is square and singular, then `inv(A)` does not exist. In these cases, `pinv(A)` has some of, but not all, the properties of `inv(A)`.

If  $A$  has more rows than columns and is not of full rank, then the overdetermined least squares problem

`minimize norm(A*x-b)`

does not have a unique solution. Two of the infinitely many solutions are

`x = pinv(A)*b`

and

`y = A\b`

These two are distinguished by the facts that `norm(x)` is smaller than the norm of any other solution and that `y` has the fewest possible nonzero components.

For example, the matrix generated by

`A = magic(8); A = A(:,1:6)`

is an 8-by-6 matrix that happens to have `rank(A) = 3`.

```
A =
 64 2 3 61 60 6
 9 55 54 12 13 51
 17 47 46 20 21 43
 40 26 27 37 36 30
 32 34 35 29 28 38
 41 23 22 44 45 19
 49 15 14 52 53 11
 8 58 59 5 4 62
```

The right-hand side is `b = 260*ones(8,1)`,

```
b =
 260
 260
 260
 260
 260
 260
 260
 260
```

The scale factor 260 is the 8-by-8 magic sum. With all eight columns, one solution to  $A*x = b$  would be a vector of all 1's. With only six columns, the equations are still consistent,

so a solution exists, but it is not all 1's. Since the matrix is rank deficient, there are infinitely many solutions. Two of them are

```
x = pinv(A)*b
```

which is

```
x =
 1.1538
 1.4615
 1.3846
 1.3846
 1.4615
 1.1538
```

and

```
y = A\b
```

which produces this result.

```
Warning: Rank deficient, rank = 3 tol = 1.8829e-013.
```

```
y =
 4.0000
 5.0000
 0
 0
 0
 -1.0000
```

Both of these are exact solutions in the sense that  $\text{norm}(A*x - b)$  and  $\text{norm}(A*y - b)$  are on the order of roundoff error. The solution  $x$  is special because

```
norm(x) = 3.2817
```

is smaller than the norm of any other solution, including

```
norm(y) = 6.4807
```

On the other hand, the solution  $y$  is special because it has only three nonzero components.

# planerot

Givens plane rotation

## Syntax

```
[G,y] = planerot(x)
```

## Description

`[G,y] = planerot(x)` where  $x$  is a 2-component column vector, returns a 2-by-2 orthogonal matrix  $G$  so that  $y = G*x$  has  $y(2) = 0$ .

## Examples

```
x = [3 4];
[G,y] = planerot(x')
```

```
G =
 0.6000 0.8000
 -0.8000 0.6000
```

```
y =
 5
 0
```

# play

Play audio from `audioplayer` object

## Syntax

```
play(playerObj)
play(playerObj, start)
play(playerObj, [start, stop])
```

## Description

`play(playerObj)` plays the audio associated with `audioplayer` object `playerObj` from beginning to end.

`play(playerObj, start)` plays audio from the sample indicated by `start` to the end.

`play(playerObj, [start, stop])` plays audio from the sample indicated by `start` to the sample indicated by `stop`.

## Examples

### Play with and without Blocking

Play two audio samples with and without blocking using the `play` and `playblocking` methods.

Load data from example files `chirp.mat` and `gong.mat`.

```
chirpData = load('chirp.mat');
chirpObj = audioplayer(chirpData.y, chirpData.Fs);
```

```
gongData = load('gong.mat');
gongObj = audioplayer(gongData.y, gongData.Fs);
```

Play the samples with blocking, one after the other.

```
playblocking(chirpObj);
```

```
playblocking(gongObj);
```

Play without blocking. The audio can overlap.

```
play(chirpObj);
play(gongObj);
```

### Starting Sample

Play audio from the example file `handel.mat` starting 4 seconds from the beginning.

```
load handel.mat;
playerObj = audioplayer(y,Fs);
start = playerObj.SampleRate * 4;

play(playerObj,start);
```

### Sample Range

Play the first 3 seconds of audio from the example file `handel.mat`.

```
load handel.mat;
playerObj = audioplayer(y,Fs);
start = 1;
stop = playerObj.SampleRate * 3;

play(playerObj,[start,stop]);
```

### See Also

[audioplayer](#) | [playblocking](#)

### How To

- “Play Audio”

## play

Play audio from audiorecorder object

### Syntax

```
player = play(recObj)
player = play(recObj, start)
player = play(recObj, [start stop])
```

### Description

*player* = `play(recObj)` plays the audio associated with `audiorecorder` object *recObj* from beginning to end, and returns an `audioplayer` object.

*player* = `play(recObj, start)` plays audio from the sample indicated by *start* to the end.

*player* = `play(recObj, [start stop])` plays audio from the sample indicated by *start* to the sample indicated by *stop*.

### Examples

Record 5 seconds of your speech with a microphone, and play it back. Display the properties of the `audioplayer` object.

```
myVoice = audiorecorder;

disp('Start speaking. ');
recordblocking(myVoice, 5);
disp('End of recording. Playing back ... ');

playerObj = play(myVoice);

disp('Properties of playerObj: ');
get(playerObj)
```

Play back only the first 3 seconds of the speech recorded in the previous example:

```
play(myVoice, [1 myVoice.SampleRate*3]);
```

### **See Also**

[audioplayer](#) | [audiorecorder](#)

## playblocking

Play audio from `audioplayer` object, holding control until playback completes

### Syntax

```
playblocking(playerObj)
playblocking(playerObj, start)
playblocking(playerObj, [start, stop])
```

### Description

`playblocking(playerObj)` plays the audio associated with `audioplayer` object `playerObj` from beginning to end. `playblocking` does not return control until playback completes.

`playblocking(playerObj, start)` plays audio from the sample indicated by `start` to the end.

`playblocking(playerObj, [start, stop])` plays audio from the sample indicated by `start` to the sample indicated by `stop`.

### Examples

#### Play with and without Blocking

Play two audio samples with and without blocking using the `play` and `playblocking` methods.

Load data from example files `chirp.mat` and `gong.mat`.

```
chirpData = load('chirp.mat');
chirpObj = audioplayer(chirpData.y, chirpData.Fs);
```

```
gongData = load('gong.mat');
gongObj = audioplayer(gongData.y, gongData.Fs);
```

Play the samples with blocking, one after the other.

```
playblocking(chirpObj);
playblocking(gongObj);
```

Play without blocking. The audio can overlap.

```
play(chirpObj);
play(gongObj);
```

### Starting Sample

Play audio from the example file `handel.mat` starting 4 seconds from the beginning.

```
load handel.mat;
playerObj = audioplayer(y,Fs);
start = playerObj.SampleRate * 4;

playblocking(playerObj,start);
beep;
```

### Sample Range

Play the first 3 seconds of audio from the example file `handel.mat`.

```
load handel.mat;
playerObj = audioplayer(y,Fs);
start = 1;
stop = playerObj.SampleRate * 3;

playblocking(playerObj,[start,stop]);
beep;
```

# plot

2-D line plot

## Syntax

```
plot(X,Y)
plot(X,Y,LineStyle)
plot(X1,Y1,...,Xn,Yn)
plot(X1,Y1,LineStyle1,...,Xn,Yn,LineStylen)
```

```
plot(Y)
plot(Y,LineStyle)
```

```
plot(____,Name,Value)
plot(ax, ____)
```

```
h = plot(____)
```

## Description

`plot(X,Y)` creates a 2-D line plot of the data in `Y` versus the corresponding values in `X`.

- If `X` and `Y` are both vectors, then they must have equal length. The `plot` function plots `Y` versus `X`.
- If `X` and `Y` are both matrices, then they must have equal size. The `plot` function plots columns of `Y` versus columns of `X`.
- If one of `X` or `Y` is a vector and the other is a matrix, then the matrix must have dimensions such that one of its dimensions equals the vector length. If the number of matrix rows equals the vector length, then the `plot` function plots each matrix column versus the vector. If the number of matrix columns equals the vector length, then the function plots each matrix row versus the vector. If the matrix is square, then the function plots each column versus the vector.
- If one of `X` or `Y` is a scalar and the other is either a scalar or a vector, then the `plot` function plots discrete points. However, to see the points you must specify a marker symbol, for example, `plot(X,Y,'o')`.

`plot(X,Y,LineStyle)` sets the line style, marker symbol, and color.

`plot(X1,Y1,...,Xn,Yn)` plots multiple X, Y pairs using the same axes for all lines.

`plot(X1,Y1,LineStyle1,...,Xn,Yn,LineStylen)` sets the line style, marker type, and color for each line. You can mix X, Y, LineSpec triplets with X, Y pairs. For example, `plot(X1,Y1,X2,Y2,LineStyle2,X3,Y3)`.

`plot(Y)` creates a 2-D line plot of the data in Y versus the index of each value.

- If Y is a vector, then the x-axis scale ranges from 1 to `length(Y)`.
- If Y is a matrix, then the `plot` function plots the columns of Y versus their row number. The x-axis scale ranges from 1 to the number of rows in Y.
- If Y is complex, then the `plot` function plots the imaginary part of Y versus the real part of Y, such that `plot(Y)` is equivalent to `plot(real(Y),imag(Y))`.

`plot(Y,LineStyle)` sets the line style, marker symbol, and color.

`plot( ____,Name,Value)` specifies line properties using one or more Name, Value pair arguments. Use this option with any of the input argument combinations in the previous syntaxes. Name, Value pair settings apply to all the lines plotted. You cannot specify different Name, Value pairs for each line using this syntax.

`plot(ax, ____)` plots into the axes specified by ax instead of into the current axes (`gca`). The option, ax can precede any of the input combinations in the previous syntaxes.

`h = plot( ____)` returns a column vector of chart line objects. Use h to modify a specific chart lines after it is created.

## Examples

### Create Line Plot

Define x as a vector of linearly spaced values between 0 and  $2\pi$ . Use an increment of  $\pi/100$  between the values. Define y as sine values of x.

```
x = 0:pi/100:2*pi;
y = sin(x);
```

Create a line plot of the data.

```
figure % opens new figure window
plot(x,y)
```

## Plot Multiple Lines

Define  $x$  as 100 linearly spaced values between  $-2\pi$  and  $2\pi$ . Define  $y1$  and  $y2$  as sine and cosine values of  $x$ . Create a line plot of both sets of data.

```
x = linspace(-2*pi,2*pi);
y1 = sin(x);
y2 = cos(x);
```

```
figure
plot(x,y1,x,y2)
```

### Create Line Plot From Matrix

Define Y as the 4-by-4 matrix returned by the `magic` function.

```
Y = magic(4)
```

Y =

16	2	3	13
5	11	10	8
9	7	6	12
4	14	15	1

Create a 2-D line plot of Y. MATLAB® plots each matrix column as a separate line.

```
figure
plot(Y)
```

### Specify Line Style

Plot three sine curves with a small phase shift between each line. Use the default line style for the first line. Specify a dashed line style for the second line and a dotted line style for the third line.

```
x = 0:pi/100:2*pi;
y1 = sin(x);
y2 = sin(x-0.25);
```

```
y3 = sin(x-0.5);

figure
plot(x,y1,x,y2,'--',x,y3,':')
```

MATLAB® cycles the line color through the default color order.

### Specify Line Style, Color, and Marker

Plot three sine curves with a small phase shift between each line. Use a green line with no markers for the first sine curve. Use a blue dashed line with circle markers for the second sine curve. Use only cyan star markers for the third sine curve.

```
x = 0:pi/10:2*pi;
```

```
y1 = sin(x);
y2 = sin(x-0.25);
y3 = sin(x-0.5);

figure
plot(x,y1,'g',x,y2,'b--o',x,y3,'c*')
```

## Specify Line Width, Marker Size, and Marker Color

Create a line plot and use the `LineStyle` option to specify a dashed green line with square markers. Use `Name, Value` pairs to specify the line width, marker size, and marker colors. Set the marker edge color to blue and set the marker face color using an RGB color value.

```
x = -pi:pi/10:pi;
y = tan(sin(x)) - sin(tan(x));

figure
plot(x,y,'--gs',...
 'LineWidth',2,...
 'MarkerSize',10,...
 'MarkerEdgeColor','b',...
 'MarkerFaceColor',[0.5,0.5,0.5])
```

### Add Title and Axis Labels

Use the `linspace` function to define  $x$  as a vector of 150 values between 0 and 10. Define  $y$  as cosine values of  $x$ .

```
x = linspace(0,10,150);
y = cos(5*x);
```

Create a 2-D line plot of the cosine curve. Change the line color to a shade of blue-green using an RGB color value. Add a title and axis labels to the graph using the `title`, `xlabel`, and `ylabel` functions.

```
figure
plot(x,y, 'Color',[0,0.7,0.9])

title('2-D Line Plot')
xlabel('x')
ylabel('cos(5x)')
```

### Plot Durations and Specify Tick Format

Define `t` as seven linearly spaced duration values between 0 and 3 minutes. Plot random data and specify the format of the duration tick marks using the 'DurationTickFormat' name-value pair argument.

```
t = 0:seconds(30):minutes(3);
y = rand(1,7);
plot(t,y,'DurationTickFormat','mm:ss')
```

### Specify Axes for Line Plot

Create a figure with two subplots and return the handle to each subplot axes, `ax1` and `ax2`.

```
figure % new figure
ax1 = subplot(2,1,1); % top subplot
ax2 = subplot(2,1,2); % bottom subplot
```

Create a 2-D line plot in each axes by referring to the axes handles. Add a title and  $y$ -axis label to each axes by passing the axes handles to the `title` and `ylabel` functions.

```
x = linspace(0,3);
y1 = sin(5*x);
y2 = sin(15*x);

plot(ax1,x,y1)
title(ax1,'Top Subplot')
ylabel(ax1,'sin(5x)')

plot(ax2,x,y2)
title(ax2,'Bottom Subplot')
ylabel(ax2,'sin(15x)')
```

### Modify Lines After Creation

Define  $x$  as 100 linearly spaced values between  $-2\pi$  and  $2\pi$ . Define  $y1$  and  $y2$  as sine and cosine values of  $x$ . Create a line plot of both sets of data and return the two chart lines in  $p$ .

```
x = linspace(-2*pi,2*pi);
y1 = sin(x);
y2 = cos(x);
p = plot(x,y1,x,y2);
```

Change the line width of the first line to 2. Add star markers to the second line. Starting in R2014b, you can use dot notation to set properties. If you are using an earlier release, use the `set` function instead.

```
p(1).LineWidth = 2;
p(2).Marker = '*';
```

### Plot Circle

Plot a circle centered at the point (4,3) with a radius equal to 2. Use `axis equal` to use equal data units along each coordinate direction.

```
r = 2;
xc = 4;
yc = 3;

theta = linspace(0,2*pi);
x = r*cos(theta) + xc;
y = r*sin(theta) + yc;
plot(x,y)
axis equal
```

## Input Arguments

### **Y** — y values

scalar | vector | matrix

y values, specified as a scalar, a vector, or a matrix. Y can be a numeric array, logical array, datetime array, or duration array. To plot against specific x values you must also specify X.

### **X** — x values

scalar | vector | matrix

$x$  values, specified as a scalar, a vector, or a matrix.  $X$  can be a numeric array, logical array, datetime array, or duration array.

**LineStyleSpec** — Line style, marker symbol, and color

string

Line style, marker symbol, and color, specified as a string. The elements of the string can appear in any order, and you can omit one or more options from the string specifier. If you omit the line style and specify the marker character, then the plot shows only the marker and no line.

If  $Y$  is a matrix and you specify a color with **LineStyleSpec**, then all the lines use the specified color. If you specify a marker type or line style and do not specify a color, then the lines cycle through the color order.

Example: ' - - or ' is a red dashed line with circle markers

Specifier	Line Style
-	Solid line (default)
- -	Dashed line
:	Dotted line
- .	Dash-dot line

Specifier	Marker
o	Circle
+	Plus sign
*	Asterisk
.	Point
x	Cross
s	Square
d	Diamond
^	Upward-pointing triangle
v	Downward-pointing triangle
>	Right-pointing triangle
<	Left-pointing triangle

Specifier	Marker
p	Pentagram
h	Hexagram

Specifier	Color
y	yellow
m	magenta
c	cyan
r	red
g	green
b	blue
w	white
k	black

### **ax** — Axes object

axes object

Axes object. If you do not specify an axes, then the `plot` function uses the current axes.

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

The chart line properties listed here are only a subset. For a complete list, see [Chart Line Properties](#).

Example: `'Marker', 'o', 'MarkerFaceColor', 'red'`

### **'Color'** — Line color

[0 0.4470 0.7410] (default) | RGB triplet | color string | 'none'

Line color, specified as an RGB triplet, a color string, or 'none'. If you specify the `Color` as 'none', then the line is invisible.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0,1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[1 1 0]
'magenta'	'm'	[1 0 1]
'cyan'	'c'	[0 1 1]
'red'	'r'	[1 0 0]
'green'	'g'	[0 1 0]
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]
'black'	'k'	[0 0 0]

Example: 'blue'

Example: [0 0 1]

**'DatetimeTickFormat' — Format for datetime tick labels**

string

Format for `datetime` tick labels, specified as the comma-separated pair consisting of `'DatetimeTickFormat'` and a string. Use the letters A-Z and a-z to construct a custom string value. These letters correspond to the Unicode Locale Data Markup Language (LDML) standard for dates. You can include non-ASCII letter characters such as a hyphen, space, or colon to separate the fields.

If you do not specify a value for `'DatetimeTickFormat'`, then `plot` automatically optimizes and updates the tick labels based on the axis limits.

Example: `'DatetimeTickFormat','eeee, MMMM d, yyyy HH:mm:ss'` displays a date and time such as Saturday, April 19, 2014 21:41:06.

The following table shows several common display formats and examples of the formatted output for the date, Saturday, April 19, 2014 at 9:41:06 PM in New York City.

Value of <code>DatetimeTickFormat</code>	Example
'yyyy-MM-dd'	2014-04-19

Value of <code>DatetimeTickFormat</code>	Example
'dd/MM/yyyy'	19/04/2014
'dd.MM.yyyy'	19.04.2014
'yyyy# MM# dd#'	2014# 04# 19#
'MMMM d, yyyy'	April 19, 2014
'eeee, MMMM d, yyyy HH:mm:ss'	Saturday, April 19, 2014 21:41:06
'MMMM d, yyyy HH:mm:ss Z'	April 19, 2014 21:41:06 -0400

For a complete list of valid letter identifiers, see the `Format` property for datetime arrays.

`DatetimeTickFormat` is not a chart line property. You must set the tick format using the name-value pair argument when creating a plot.

### 'DurationTickFormat' – Format for duration tick labels

string

Format for duration tick labels, specified as the comma-separated pair consisting of 'DurationTickFormat' and a string.

If you do not specify a value for 'DurationTickFormat', then `plot` automatically optimizes and updates the tick labels based on the axis limits.

To display a duration as a single number that includes a fractional part, for example, 1.234 hours, specify one of the following strings.

Value of <code>DurationTickFormat</code>	Description
'y'	Number of exact fixed-length years. A fixed-length year is equal to 365.2425 days.
'd'	Number of exact fixed-length days. A fixed-length day is equal to 24 hours.
'h'	Number of hours
'm'	Number of minutes
's'	Number of seconds

Example: 'DurationTickFormat', 'h' displays duration values in terms of fixed-length days.

To display a duration in the form of a digital timer, specify one of the following strings.

- 'dd:hh:mm:ss'
- 'hh:mm:ss'
- 'mm:ss'
- 'hh:mm'

In addition, you can display up to nine fractional second digits by appending up to nine S characters.

Example: 'DurationTickFormat', 'hh:mm:ss.SSS' displays the milliseconds of a duration value to three digits.

DurationTickFormat is not a chart line property. You must set the tick format using the name-value pair argument when creating a plot.

**'LineStyle' — Line style**

'-' (default) | '--' | ':' | '-.' | 'none'

Line style, specified as one of the line style strings listed in this table.

String	Line Style	Resulting Line
'-'	Solid line	
'--'	Dashed line	
':'	Dotted line	
'-.'	Dash-dotted line	
'none'	No line	No line

**'LineWidth' — Line width**

0.5 (default) | positive value

Line width, specified as a positive value in point units. If the line has markers, then the line width also affects the marker edges.

Example: 0.75

**'Marker' — Marker symbol**

'none' (default) | string

Marker symbol, specified as one of the marker strings in this table. By default, a chart line does not have markers. Add markers at each data point along the line by specifying a marker symbol.

String	Marker Symbol
'o'	Circle
'+'	Plus sign
'*'	Asterisk
'.'	Point
'x'	Cross
'square' or 's'	Square
'diamond' or 'd'	Diamond
'^'	Upward-pointing triangle
'v'	Downward-pointing triangle
'>'	Right-pointing triangle
'<'	Left-pointing triangle
'pentagram' or 'p'	Five-pointed star (pentagram)
'hexagram' or 'h'	Six-pointed star (hexagram)
'none'	No markers

Example: `'Marker', '+'`

Example: `'Marker', 'diamond'`

#### **'MarkerEdgeColor' — Marker outline color**

'auto' (default) | 'none' | RGB triplet | color string

Marker outline color, specified as one of these values:

- 'auto' — Use the same color as the `Color` property.
- 'none' — Use no color, which makes unfilled markers invisible.
- RGB triplet or color string — Use the specified color.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range

[0, 1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[1 1 0]
'magenta'	'm'	[1 0 1]
'cyan'	'c'	[0 1 1]
'red'	'r'	[1 0 0]
'green'	'g'	[0 1 0]
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]
'black'	'k'	[0 0 0]

Example: [0.5 0.5 0.5]

Example: 'blue'

#### 'MarkerFaceColor' — Marker fill color

'none' (default) | 'auto' | RGB triplet | color string

Marker fill color, specified as one of these values:

- 'none' — Use no color, which makes the interior invisible.
- 'auto' — Use the same color as the Color property for the axes.
- RGB triplet or color string — Use the specified color.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0, 1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[1 1 0]
'magenta'	'm'	[1 0 1]
'cyan'	'c'	[0 1 1]
'red'	'r'	[1 0 0]

Long Name	Short Name	RGB Triplet
'green'	'g'	[0 1 0]
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]
'black'	'k'	[0 0 0]

Example: [0.3 0.2 0.1]

Example: 'green'

### 'MarkerSize' — Marker size

6 (default) | positive value

Marker size, specified as a positive value in point units.

Example: 10

## Output Arguments

### **h** — One or more chart line objects

scalar | vector

One or more chart line objects, returned as a scalar or a vector. These are unique identifiers, which you can use to query and modify properties of a specific chart line.

## More About

### Tips

- Use NaN and Inf values to create breaks in the lines. For example, this code plots the first two elements, skips the third element, and draws another line using the last two elements:

```
plot([1,2,NaN,4,5])
```

- plot uses colors and line styles based on the ColorOrder and LineStyleOrder properties of the axes. plot cycles through the colors with the first line style. Then, it cycles through the colors again with each additional line style.

You can change the default colors and line styles by setting default values for the `ColorOrder` and `LineStyleOrder` properties. For example, to set the default line styles to a solid line with asterisk markers, a dotted line, and circle markers with no line, use this command:

```
set(groot, 'defaultAxesLineStyleOrder', {'-*', ':', 'o'})
```

For more information about setting defaults, see “Default Property Values”.

### Properties

Chart Line Properties

**Introduced before R2006a**

# plot3

3-D line plot

## Syntax

```
plot3(X1,Y1,Z1,...)
plot3(X1,Y1,Z1,LineStyle,...)
plot3(...,'PropertyName',PropertyValue,...)
plot3(axes_handle,...)
h = plot3(...)
```

## Description

The `plot3` function displays a three-dimensional plot of a set of data points.

`plot3(X1,Y1,Z1,...)`, where `X1`, `Y1`, `Z1` are vectors or matrices, plots one or more lines in three-dimensional space through the points whose coordinates are the elements of `X1`, `Y1`, and `Z1`.

`plot3(X1,Y1,Z1,LineStyle,...)` creates and displays all lines defined by the `Xn,Yn,Zn,LineStyle` quads, where `LineStyle` is a line specification that determines line style, marker symbol, and color of the plotted lines.

`plot3(...,'PropertyName',PropertyValue,...)` sets line properties to the specified property values for all the charting lines created by `plot3`. See [Chart Line Properties](#) for a description of the properties you can set.

`plot3(axes_handle,...)` plots into the axes specified by `axes_handle` instead of into the current axes (`gca`). The option, `axes_handle` can precede any of the input combinations in the previous syntaxes.

`h = plot3(...)` returns a column vector of charting line handles, with one handle per object.

## Examples

### Plot 3-D Helix

Define `t` as values between 0 and  $10\pi$ . Define `st` and `ct` as vectors of sine and cosine values. Plot a 3-D helix.

```
t = 0:pi/50:10*pi;
st = sin(t);
ct = cos(t);
```

```
figure
plot3(st,ct,t)
```

## More About

### Tips

If one or more of  $X1$ ,  $Y1$ ,  $Z1$  is a vector, the vectors are plotted versus the rows or columns of the matrix, depending whether the vectors' lengths equal the number of rows or the number of columns.

You can mix  $Xn$ ,  $Yn$ ,  $Zn$  triples with  $Xn$ ,  $Yn$ ,  $Zn$ , *LineStyle* quads, for example,

```
plot3(X1,Y1,Z1,X2,Y2,Z2,LineStyle,X3,Y3,Z3)
```

See *LineStyle* and *plot* for information on line types and markers.

# plotbrowser

Show or hide figure **Plot Browser**

## Syntax

```
plotbrowser('on')
plotbrowser('off')
plotbrowser
plotbrowser(figure_handle,...)
```

## Description

`plotbrowser('on')` displays the Plot Browser on the current figure.

`plotbrowser('off')` hides the Plot Browser on the current figure.

`plotbrowser` toggles the visibility of the Plot Browser on the current figure. You can use `plotbrowser('toggle')` instead for the same functionality.

`plotbrowser(figure_handle,...)` shows or hides the Plot Browser on the figure specified by `figure_handle`.

## Examples

### Open Plot Browser

Plot a 5-by-5 matrix of random numbers. Then, open the plot browser.

```
plot(rand(5))
plotbrowser('on')
```

## Alternatives

To collectively enable the plot tools, use the larger icon  on the figure toolbar. To collectively disable the plot tools, use the smaller icon . Open or close the **Plot Browser** tool from the figure's **View** menu.

## More About

### Tips

If you call `plotbrowser` in a MATLAB program and subsequent lines depend on the Plot Browser being fully initialized, follow it by `drawnow` to ensure complete initialization.

`plottools` | `figurepalette` | `propertyeditor`

**Introduced before R2006a**

# plottedit

Interactively edit and annotate plots

## Syntax

```
plottedit on
plottedit off
plottedit
plottedit(h)
plottedit(state)
plottedit(h,state)
```

## Description

`plottedit on` starts plot edit mode for the current figure, allowing you to use a graphical interface to annotate and edit plots easily. In plot edit mode, you can label axes, change line styles, and add text, line, and arrow annotations.

`plottedit off` ends plot mode for the current figure.

`plottedit` toggles the plot edit mode for the current figure.

`plottedit(h)` toggles the plot edit mode for the figure specified by figure handle `h`.

`plottedit(state)` specifies the `plottedit` state for the current figure. Values for `state` can be as shown.

Value for state	Description
'on'	Starts plot edit mode
'off'	Ends plot edit mode
'showtoolsmenu'	Displays the <b>Tools</b> menu in the menu bar
'hidetoolsmenu'	Removes the <b>Tools</b> menu from the menu bar

---

**Note** 'hidetoolsmenu' is intended for UI developers who do not want the **Tools** menu to appear in applications that use the figure window.

---

`plottedit(h, state)` specifies the `plottedit` state for figure handle `h`.

## Examples

Start plot edit mode for figure 2.

```
plottedit(2)
```

End plot edit mode for figure 2.

```
plottedit(2, 'off')
```

Hide the **Tools** menu for the current figure:

```
plottedit('hidetoolsmenu')
```

# plotmatrix

Scatter plot matrix

## Compatibility

The behavior of `[S,AX,BigAx,H,HAX] = plotmatrix(_)` changed in R2015b. The output argument `H` now contains histogram objects instead of patch objects.

## Syntax

```
plotmatrix(X,Y)
plotmatrix(X)
plotmatrix(____,LineStyleSpec)

[S,AX,BigAx,H,HAX] = plotmatrix(____)
```

## Description

`plotmatrix(X,Y)` creates a matrix of subaxes containing scatter plots of the columns of `X` against the columns of `Y`. If `X` is  $p$ -by- $n$  and `Y` is  $p$ -by- $m$ , then `plotmatrix` produces an  $n$ -by- $m$  matrix of subaxes.

`plotmatrix(X)` is the same as `plotmatrix(X,X)` except that the subaxes along the diagonal are replaced with histogram plots of the data in the corresponding column of `X`. For example, the subaxes along the diagonal in the  $i$ th column is replaced by `histogram(X(:,i))`.

`plotmatrix( ____,LineStyleSpec)` specifies the line style, marker symbol, and color for the scatter plots. The option `LineStyleSpec` can be preceded by any of the input argument combinations in the previous syntaxes.

`[S,AX,BigAx,H,HAX] = plotmatrix( ____ )` returns the graphic objects created as follows:

- `S` – Chart line objects for the scatter plots

- `AX` – Axes objects for each subaxes
- `BigAx` – Axes object for big axes that frames the subaxes
- `H` – Histogram objects for the histogram plots
- `HAX` – Axes objects for the invisible histogram axes

`BigAx` is left as the current axes (`gca`) so that a subsequent `title`, `xlabel`, or `ylabel` command centers text with respect to the big axes.

## Examples

### Create Scatter Plot Matrix with Two Matrix Inputs

Create `X` as a matrix of random data and `Y` as a matrix of integer values. Then, create a scatter plot matrix of the columns of `X` against the columns of `Y`.

```
X = randn(50,3);
Y = reshape(1:150,50,3);
plotmatrix(X,Y)
```

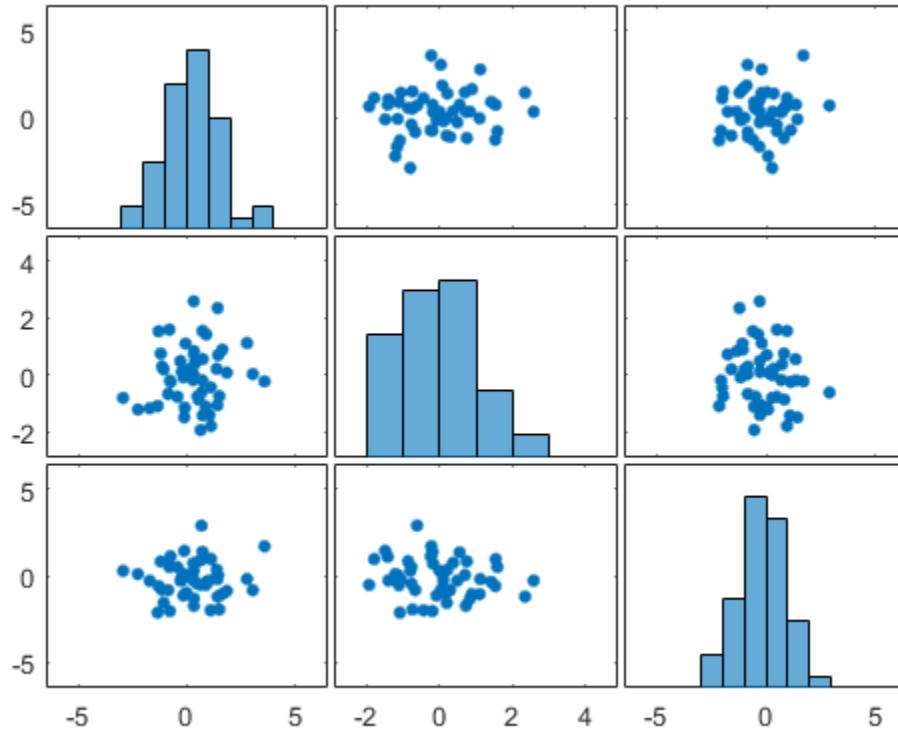

The subplot in the  $i$ th row,  $j$ th column of the figure is a scatter plot of the  $i$ th column of  $Y$  against the  $j$ th column of  $X$ .

### Create Scatter Plot Matrix with One Matrix Input

Create a scatter plot matrix of random data. The subplot in the  $i$ th row,  $j$ th column of the matrix is a scatter plot of the  $i$ th column of  $X$  against the  $j$ th column of  $X$ . Along the diagonal are histogram plots of each column of  $X$ .

```
X = randn(50,3);
plotmatrix(X)
```

### Specify Marker Type and Color

Create a scatter plot matrix of random data. Specify the marker type and the color for the scatter plots.

```
X = randn(50,3);
plotmatrix(X, '*r')
```

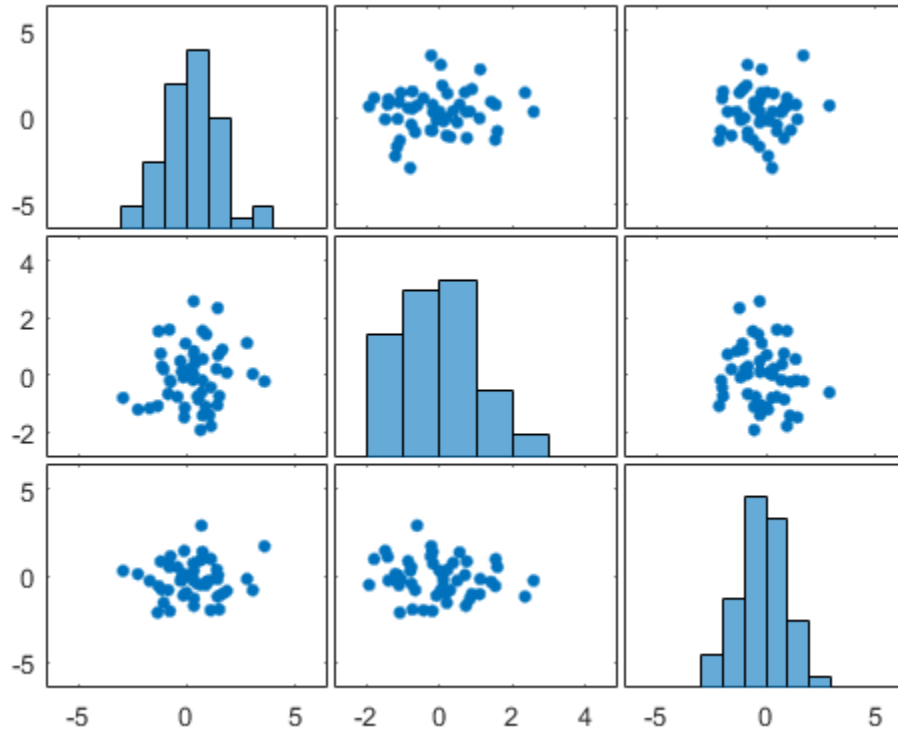

The `LineStyle` option sets properties for the scatter plots. To set properties for the histogram plots, return the histogram objects.

### Modify Scatter Plot Matrix After Creation

Create a scatter plot matrix of random data.

```
rng default
X = randn(50,3);
[S,AX,BigAx,H,HAX] = plotmatrix(X);
```

To set properties for the scatter plots, use `S`. To set properties for the histograms, use `H`. To set axes properties, use `AX`, `BigAX`, and `HAX`. Starting in R2014b, you can use dot notation to set properties. If you are using an earlier release, use the `set` function instead.

Set the color and marker type for the scatter plot in the lower left corner of the figure. Set the color for the histogram plot in the lower right corner. Use the `title` command to title the figure.

```
S(3).Color = 'g';
S(3).Marker = '*';
```

```
H(3).EdgeColor = 'k';
H(3).FaceColor = 'g';
```

```
title(BigAx, 'A Comparison of Data Sets')
```

## Input Arguments

### X — Data to display

matrix

Data to display, specified as a matrix.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical

**Y — Data to plot against X**

matrix

Data to plot against X, specified as a matrix.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

**LineStyle — Line style, marker symbol, and color for scatter plots**

string

Line style, marker symbol, and color for the scatter plots, specified as a string. For more information on line style, marker symbol, and color options see `LineStyle`.

Example: `'*r'`

## Output Arguments

**S — Chart line objects for scatter plots**

matrix

Chart line objects for the scatter plots, returned as a matrix. These are unique identifiers, which you can use to query and modify the properties of a specific scatter plot.

**AX — Axes objects for subaxes**

matrix

Axes objects for the subaxes, returned as a matrix. These are unique identifiers, which you can use to query and modify the properties of a specific subaxes.

**BigAx — Axes object for big axes**

scalar

Axes object for big axes, returned as a scalar. This is a unique identifier, which you can use to query and modify properties of the big axes.

**H — Histogram objects**

vector | []

Histogram objects, returned as a vector or `[]`. These are unique identifiers, which you can use to query and modify the properties of a specific histogram object. If no histogram plots are created, then H is returned as empty brackets.

## **HAX — Axes objects for invisible histogram axes**

vector | []

Axes objects for invisible histogram axes, returned as a vector or []. These are unique identifiers, which you can use to query and modify the properties of a specific axes. If no histogram plots are created, then HAX is returned as empty brackets.

## **See Also**

scatter | scatter3

**Introduced before R2006a**

# plottools

Show or hide plot tools

## Syntax

```
plottools('on')
plottools('off')
plottools
plottools(figure_handle,...)
plottools(...,'tool')
```

## Description

`plottools('on')` displays the Figure Palette, Plot Browser, and Property Editor on the current figure, configured as you last used them.

`plottools('off')` hides the Figure Palette, Plot Browser, and Property Editor on the current figure.

`plottools` with no arguments, is the same as `plottools('on')`

`plottools(figure_handle,...)` displays or hides the plot tools on the specified figure instead of on the current figure.

`plottools(...,'tool')` operates on the specified tool only. *tool* can be one of the following strings:

- `figurepalette`
- `plotbrowser`
- `propertyeditor`

---

**Note:** The first time you open the plotting tools, all three of them appear, grouped around the current figure as shown above. If you close, move, or undock any of the tools, MATLAB remembers the configuration you left them in and restores it when you invoke the tools for subsequent figures, both within and across MATLAB sessions.

---

## Examples

### Open Plot Tools

Create a line plot and open the plot tools.

```
plot(1:10);
plottools('on')
```

## Alternatives

To collectively enable the plot tools, use the larger icon  on the figure toolbar. To collectively disable the plot tools, use the smaller icon . Individually select the

**Figure Palette, Plot Browser, and Property Editor** tools from the figure's **View** menu. For details, see “Customize Graph Using Plot Tools”.

**See Also**

**Introduced before R2006a**

# plotyy

2-D line plots with y-axes on both left and right side

## Syntax

```
plotyy(X1,Y1,X2,Y2)
plotyy(X1,Y1,X2,Y2,function)
plotyy(X1,Y1,X2,Y2,'function1','function2')
plotyy(AX1,___)
[AX,H1,H2] = plotyy(___)
```

## Description

`plotyy(X1,Y1,X2,Y2)` plots Y1 versus X1 with y-axis labeling on the left and plots Y2 versus X2 with y-axis labeling on the right.

`plotyy(X1,Y1,X2,Y2,function)` uses the specified plotting function to produce the graph.

`function` can be either a function handle or a string specifying `plot`, `semilogx`, `semilogy`, `loglog`, `stem`, or any MATLAB function that accepts the syntax

```
h = function(x,y)
```

For example,

```
plotyy(x1,y1,x2,y2,@loglog) % function handle
plotyy(x1,y1,x2,y2,'loglog') % string
```

Function handles enable you to access user-defined local functions and can provide other advantages. For more information on using function handles, see “Create Function Handle”.

`plotyy(X1,Y1,X2,Y2,'function1','function2')` uses `function1(X1,Y1)` to plot the data for the left axis and `function2(X2,Y2)` to plot the data for the right axis.

`plotyy(AX1, ___)` plots the data using the axes specified by `AX1` for the first set of data, instead of using the current axes. Specify `AX1` as a single axes object or a vector of the two axes objects returned by a previous call to `plotyy`. If you specify a vector, then `plotyy` uses the first axes object in the vector. Use this option with any of the input argument combinations in the previous syntaxes.

`[AX,H1,H2] = plotyy(___)` returns the handles of the two axes created in `AX` and the handles of the graphics objects from each plot in `H1` and `H2`. `AX(1)` is the left axes and `AX(2)` is the right axes.

## Examples

### Plot Two Data Sets with Different y-Axes

Plot two data sets on one graph using two y-axes.

```
x = 0:0.01:20;
y1 = 200*exp(-0.05*x).*sin(x);
y2 = 0.8*exp(-0.5*x).*sin(10*x);
```

```
figure % new figure
plotyy(x,y1,x,y2)
```

### Add Title and Axis Labels

Plot two data sets using a graph with two y-axes. Add a title and axis labels.

```
x = 0:0.01:20;
y1 = 200*exp(-0.05*x).*sin(x);
y2 = 0.8*exp(-0.5*x).*sin(10*x);

figure % new figure
[hAx,hLine1,hLine2] = plotyy(x,y1,x,y2);

title('Multiple Decay Rates')
xlabel('Time (\musec)')
```

```
ylabel(hAx(1), 'Slow Decay') % left y-axis
ylabel(hAx(2), 'Fast Decay') % right y-axis
```

### Change Line Styles

Plot two data sets using a graph with two  $y$ -axes. Change the line styles. Starting in R2014b, you can use dot notation to set properties. If you are using an earlier release, use the `set` function instead.

```
x = 0:0.01:20;
y1 = 200*exp(-0.05*x).*sin(x);
y2 = 0.8*exp(-0.5*x).*sin(10*x);
```

```
[hAx,hLine1,hLine2] = plotyy(x,y1,x,y2);
hLine1.LineStyle = '--';
hLine2.LineStyle = ':';
```

### Combine Different Types of Plots

Plot two data sets using a graph with two y-axes. Use a line plot for the data associated with the left y-axes. Use a stem plot for the data associated with the right y-axes.

```
x = 0:0.1:10;
y1 = 200*exp(-0.05*x).*sin(x);
y2 = 0.8*exp(-0.5*x).*sin(10*x);
```

```
figure
```

```
plotyy(x,y1,x,y2,'plot','stem')
```

### Use Right y-Axis for Two Data Sets

Plot three data sets using a graph with two y-axes. Plot one set of data associated with the left y-axis. Plot two sets of data associated with the right y-axis by using two-column matrices.

```
x = linspace(0,10);
y1 = 200*exp(-0.05*x).*sin(x);
y2 = 0.8*exp(-0.5*x).*sin(10*x);
y3 = 0.2*exp(-0.5*x).*sin(10*x);
```

```
figure
```

```
[hAx,hLine1,hLine2] = plotyy(x,y1,[x',x'],[y2',y3']);
```

# matlab.unittest.plugins

Summary of classes in MATLAB Plugins Interface

## Description

Plugins customize a `TestRunner` object. The `matlab.unittest.plugins` package consists of the following customized MATLAB plugins.

<code>matlab.unittest.plugins.CodeCoveragePlugin</code>	Plugin that produces a code coverage report
<code>matlab.unittest.plugins.DiagnosticsValidationPlugin</code>	Plugin to help validate diagnostic code
<code>matlab.unittest.plugins.FailureDiagnosticsPlugin</code>	Plugin to show diagnostics on failure
<code>matlab.unittest.plugins.FailOnWarningsPlugin</code>	Plugin to fail tests that issue warnings
<code>matlab.unittest.plugins.LoggingPlugin</code>	Plugin to report diagnostic messages
<code>matlab.unittest.plugins.OutputStream</code>	Interface that determines where to send text output
<code>matlab.unittest.plugins.QualifyingPlugin</code>	Interface for plugins that perform system-wide qualifications
<code>matlab.unittest.plugins.StopOnFailuresPlugin</code>	Plugin to debug test failures
<code>matlab.unittest.plugins.TAPPlugin</code>	Plugin that produces Test Anything Protocol stream
<code>matlab.unittest.plugins.ToFile</code>	Output stream to write text output to file
<code>matlab.unittest.plugins.ToStandardOutput</code>	Output stream to display text information to screen

<code>matlab.unittest.plugins.TestRunnerPlugin</code>	Plugin interface for extending <code>TestRunner</code>
<code>matlab.unittest.plugins.TestRunProgressPlugin</code>	Plugin that reports test run progress
<code>matlab.unittest.plugins.XMLPlugin</code>	Plugin that writes test results in XML format

## Related Examples

- “Write Plugins to Extend `TestRunner`”
- “Create Custom Plugin”
- “Write Plugin to Save Diagnostic Details”

# matlab.unittest.plugins.CodeCoveragePlugin class

**Package:** matlab.unittest.plugins

Plugin that produces a code coverage report

## Description

To produce a line coverage report for MATLAB source code, add the `CodeCoveragePlugin` to the `TestRunner`. The testing framework runs the tests, and the resulting coverage report indicates the executed lines of code. The coverage report is based on source code located in one or more folders or packages. The source code must be on the MATLAB path and remain on the path during the test run.

The `CodeCoveragePlugin` uses the MATLAB profiler to determine which lines of code the tests execute. The tests and source code should not interact with the profiler. Before running a suite of tests, the plugin clears any data collected by the profiler.

## Construction

Instantiate a `CodeCoveragePlugin` using one of its static methods.

To report on source code within one or more folders, use the `forFolder` static method. To report on source code within one or more packages, use the `forPackage` static method.

## Methods

`forFolder`

Construct `CodeCoveragePlugin` for folders

`forPackage`

Construct `CodeCoveragePlugin` for packages

## Copy Semantics

Handle. To learn how handle classes affect copy operations, see [Copying Objects in the MATLAB documentation](#).

## Examples

### Generate Code Coverage Report

In a new file, `quadraticSolver.m`, in your working folder, create the following function.

```
function roots = quadraticSolver(a,b,c)
% quadraticSolver returns solutions to the
% quadratic equation a*x^2 + b*x + c = 0.

checkInputs

roots(1) = (-b + sqrt(b^2 - 4*a*c)) / (2*a);
roots(2) = (-b - sqrt(b^2 - 4*a*c)) / (2*a);

 function checkInputs
 if ~isa(a,'numeric') || ~isa(b,'numeric') || ~isa(c,'numeric')
 error('quadraticSolver:InputMustBeNumeric', ...
 'Coefficients must be numeric.')
 end
 end
end
```

Create a test for the quadratic solver. In a `tests` package (a `+tests` subfolder), create `SolverTest.m` containing the following test class.

```
classdef SolverTest < matlab.unittest.TestCase
% SolverTest tests solutions to the quadratic equation
% a*x^2 + b*x + c = 0

methods (Test)
 function testRealSolution(testCase)
 actSolution = quadraticSolver(1,-3,2);
 expSolution = [2,1];
 testCase.verifyEqual(actSolution,expSolution)
 end
 function testImaginarySolution(testCase)
 actSolution = quadraticSolver(1,2,10);
 expSolution = [-1+3i, -1-3i];
 testCase.verifyEqual(actSolution,expSolution)
 end
end
end
```

At the command prompt from within your original working folder, create a test suite from the `tests` package.

```
import matlab.unittest.TestSuite
import matlab.unittest.TestRunner
import matlab.unittest.plugins.CodeCoveragePlugin

suite = TestSuite.fromPackage('tests');
```

Create a test runner.

```
runner = TestRunner.withTextOutput;
```

Add `CodeCoveragePlugin` to the runner and run the tests. Specify that the source code folder is your current working folder. If you have other source code files in your current working folder, they show up in the coverage report. The folder that contains the source code (`quadraticSolver.m`) must be on your MATLAB path.

```
runner.addPlugin(CodeCoveragePlugin.forFolder(pwd))
result = runner.run(suite);
```

```
Running tests.SolverTest
..
Done tests.SolverTest
```

MATLAB opens a Profiler Coverage Report for the quadratic solver function.

## Profiler Coverage Report

Run the Coverage Report after you run the Profiler to identify how much of a file ran when it was profiled ([Learn More](#)).

Report for folder C:\myWork

<a href="#">quadraticSolver.m</a>	 Total coverage: 75.0%
<a href="#">quadraticSolver</a>	Coverage: 100.0% Total time: 0.0 seconds Total lines: 4
<a href="#">quadraticSolver&gt;checkInputs</a>	Coverage: 50.0% Total time: 0.0 seconds Total lines: 4

The `checkinputs` nested function does not have complete code coverage. Since the tests in `SolverTest.m` do not pass nonnumeric input to `quadraticSolver`, MATLAB does not exercise the code that throws an error if the inputs are not numeric. To address the missing coverage, add a test method to test the error condition.

## See Also

`matlab.unittest.plugins.TestRunnerPlugin` | [profile](#)

**Introduced in R2014b**

# matlab.unittest.plugins.CodeCoveragePlugin.forFolder

**Class:** matlab.unittest.plugins.CodeCoveragePlugin

**Package:** matlab.unittest.plugins

Construct CodeCoveragePlugin for folders

## Syntax

```
matlab.unittest.plugins.CodeCoveragePlugin.forFolder(folder)
matlab.unittest.plugins.CodeCoveragePlugin.forFolder(
folder, 'IncludingSubfolders', tf)
```

## Description

`matlab.unittest.plugins.CodeCoveragePlugin.forFolder(folder)` creates a plugin that produces a code coverage report for one or more folders. The plugin reports on the source code inside `folder`.

`matlab.unittest.plugins.CodeCoveragePlugin.forFolder(folder, 'IncludingSubfolders', tf)` indicates whether to report on source code inside all subfolders of `folder`. By default, `CodeCoveragePlugin` does not report on source code in subfolders.

## Input Arguments

**folder** — Locations of folder containing source code

string | cell array of strings

Locations of folder containing source code, specified as a string or cell array of strings. `folder` is the absolute or relative path to one or more folders. If you specify multiple folders, MATLAB opens a profile coverage report for each folder.

The source code folders must be on the MATLAB path and remain on the path during the test run.

Example: 'C:\projects\myproj'

Example: pwd

Example: {'C:\projects\myprojA', 'myprojB'}

### **tf** — Indicator to report on subfolders

false (default) | true

Indicator to report on source code in subfolders, specified as logical `false` or `true`. When this value is `false`, the plugin does not report on subfolders. The default value is `false`.

## Examples

### Generate Code Coverage Report

In a new file, `quadraticSolver.m`, in your working folder, create the following function.

```
function roots = quadraticSolver(a,b,c)
% quadraticSolver returns solutions to the
% quadratic equation a*x^2 + b*x + c = 0.

checkInputs

roots(1) = (-b + sqrt(b^2 - 4*a*c)) / (2*a);
roots(2) = (-b - sqrt(b^2 - 4*a*c)) / (2*a);

function checkInputs
 if ~isa(a,'numeric') || ~isa(b,'numeric') || ~isa(c,'numeric')
 error('quadraticSolver:InputMustBeNumeric', ...
 'Coefficients must be numeric.')
 end
end
end
```

Create a test for the quadratic solver. In a `tests` package (a `+tests` subfolder), create `SolverTest.m` containing the following test class.

```
classdef SolverTest < matlab.unittest.TestCase
 % SolverTest tests solutions to the quadratic equation
 % a*x^2 + b*x + c = 0
```

```

methods (Test)
 function testRealSolution(testCase)
 actSolution = quadraticSolver(1,-3,2);
 expSolution = [2,1];
 testCase.verifyEqual(actSolution,expSolution)
 end
 function testImaginarySolution(testCase)
 actSolution = quadraticSolver(1,2,10);
 expSolution = [-1+3i, -1-3i];
 testCase.verifyEqual(actSolution,expSolution)
 end
end
end
end

```

At the command prompt from within your original working folder, create a test suite from the `tests` package.

```

import matlab.unittest.TestSuite
import matlab.unittest.TestRunner
import matlab.unittest.plugins.CodeCoveragePlugin

suite = TestSuite.fromPackage('tests');

```

Create a test runner.

```
runner = TestRunner.withTextOutput;
```

Add `CodeCoveragePlugin` to the runner and run the tests. Specify that the source code folder is your current working folder. If you have other source code files in your current working folder, they show up in the coverage report. The folder that contains the source code (`quadraticSolver.m`) must be on your MATLAB path.

```
runner.addPlugin(CodeCoveragePlugin.forFolder(pwd))
result = runner.run(suite);

```

```

Running tests.SolverTest
..
Done tests.SolverTest

```

MATLAB opens a Profiler Coverage Report for the quadratic solver function.

## Profiler Coverage Report

Run the Coverage Report after you run the Profiler to identify how much of a file ran when it was profiled ([Learn More](#)).

Report for folder C:\myWork

<a href="#">quadraticSolver.m</a>	 Total coverage: 75.0%
<a href="#">quadraticSolver</a>	Coverage: 100.0% Total time: 0.0 seconds Total lines: 4
<a href="#">quadraticSolver&gt;checkInputs</a>	Coverage: 50.0% Total time: 0.0 seconds Total lines: 4

The `checkInputs` nested function does not have complete code coverage. Since the tests in `SolverTest.m` do not pass nonnumeric input to `quadraticSolver`, MATLAB does not exercise the code that throws an error if the inputs are not numeric. To address the missing coverage, add a test method to test the error condition.

`matlab.unittest.plugins.CodeCoveragePlugin.forPackage`

**Introduced in R2014b**

# matlab.unittest.plugins.CodeCoveragePlugin.forPackage

**Class:** matlab.unittest.plugins.CodeCoveragePlugin

**Package:** matlab.unittest.plugins

Construct CodeCoveragePlugin for packages

## Syntax

```
matlab.unittest.plugins.CodeCoveragePlugin.forPackage(package)
matlab.unittest.plugins.CodeCoveragePlugin.forPackage(
package, 'IncludingSubpackages', tf)
```

## Description

`matlab.unittest.plugins.CodeCoveragePlugin.forPackage(package)` creates a plugin that produces a code coverage report for one or more packages. The plugin reports on the source code inside `package`.

`matlab.unittest.plugins.CodeCoveragePlugin.forPackage(package, 'IncludingSubpackages', tf)` indicates whether to report on source code inside all subpackages of `package`. By default, `CodeCoveragePlugin` does not report on source code in subpackages.

## Input Arguments

**package** — Names of package containing source code

string | cell array of strings

Names of package containing source code, specified as a string or cell array of strings. If you specify multiple packages, MATLAB opens a profile coverage report for each package.

The parent folder of the top-level source code package must be on the MATLAB path and remain on the path during the test run.

Example: 'myproject.controller'

Example: {'myprojA', 'myprojB'}

## **tf** — Indicator to report on subpackages

false (default) | true

Indicator to report on source code in subpackages, specified as logical **false** or **true**. When this value is **false**, the plugin does not report on subpackages. The default value is **false**.

## **See Also**

matlab.unittest.plugins.CodeCoveragePlugin.forFolder

**Introduced in R2014b**

# matlab.unittest.plugins.DiagnosticsValidationPlugin class

**Package:** matlab.unittest.plugins

Plugin to help validate diagnostic code

## Description

The `DiagnosticsValidationPlugin` creates a plugin to help validate diagnostic code.

Add the `DiagnosticsValidationPlugin` to the `TestRunner` to confirm that user-supplied diagnostics execute correctly. This plugin is useful because typically tests do not encounter failure conditions. A failure can result in unexercised diagnostic code. If a programming error exists in this diagnostic code, the error is not evident unless the test fails. However, at this point in the testing process, the diagnostics for the failure condition are lost due to the error in the diagnostic code.

Use this plugin to unconditionally evaluate the diagnostics supplied by the test writer, regardless of whether the test results in a passing or failing condition. This approach helps you to confirm that all of the diagnostic code is free from programming errors.

The diagnostic analysis can reduce the test performance and can result in very verbose text output. Be aware of these impacts before using this plugin for routine testing.

## Construction

`matlab.unittest.plugins.DiagnosticsValidationPlugin` creates a plugin to help validate diagnostic code.

`matlab.unittest.plugins.DiagnosticsValidationPlugin(stream)` redirects all the text output to the output stream, `stream`. If you do not specify the output stream, the plugin uses the default `ToStandardOutput` stream.

## Input Arguments

### **stream**

Location where the plugin directs text output, specified as an `OutputStream`.

**Default:** `ToStandardOutput`

## Copy Semantics

Handle. To learn how handle classes affect copy operations, see [Copying Objects in the MATLAB documentation](#).

## Examples

### **Add Plugin to TestRunner**

In your working folder, create a file, `ExampleTest.m`, containing the following test class. In this example, the `testThree` method has an intentional error. The method should use a function handle to the `dir` function as a `FunctionHandleDiagnostic`, but `dir` is misspelled.

```
classdef ExampleTest < matlab.unittest.TestCase
 methods(Test)
 function testOne(testCase)
 % test code
 end
 function testTwo(testCase)
 % test code
 end
 function testThree(testCase)
 % The following should use @dir as a function handle,
 % but there is a typo
 testCase.verifyEqual('myfile','myfile', @dri)
 end
 end
end
```

All of the tests in `ExampleTest.m` result in a passing condition, but there is an error in the diagnostic.

At the command prompt, create a test suite from the `ExampleTest` class.

```
import matlab.unittest.TestRunner
import matlab.unittest.TestSuite
import matlab.unittest.plugins.DiagnosticsValidationPlugin

suite = TestSuite.fromClass(?ExampleTest);
```

Create a test runner with no plugins. This code creates a silent runner and provides you with complete control over the installed plugins.

```
runner = TestRunner.withTextOutput;
```

Run the tests.

```
result1 = runner.run(suite);
```

```
Running ExampleTest
...
Done ExampleTest
```

---

No diagnostic output is displayed because all the tests passed. The testing framework does not encounter the bug in the `FunctionHandleDiagnostic` of `testThree`.

Add `DiagnosticValidationPlugin` to the runner and run the tests.

```
runner.addPlugin(DiagnosticsValidationPlugin)
result2 = runner.run(suite);
```

```
Running ExampleTest
..

Validation of Test Diagnostic:

Error occurred while capturing diagnostics:
Error using evalc
Undefined function or variable 'dri'.

Error in ExampleTest/testThree (line 12)
 testCase.verifyEqual('myfile','myfile', @dri);

.
Done ExampleTest
```

---

The framework executes the diagnostic provided by the `FunctionHandleDiagnostic`, even though none of the tests fails. Without this plugin, the test framework only encounters the bug if the test fails.

## **See Also**

`matlab.unittest.diagnostics` | `matlab.unittest.plugins` | `OutputStream` | `ToStandardOutput`

# matlab.unittest.plugins.FailureDiagnosticsPlugin class

**Package:** matlab.unittest.plugins

Plugin to show diagnostics on failure

## Description

The `FailureDiagnosticsPlugin` creates a plugin to show diagnostics upon encountering a test failure. Add it to the `TestRunner` to output test failure diagnostics to the Command Window. This plugin is used by default when you construct a test runner using `TestRunner.withTextOutput`.

## Construction

`matlab.unittest.plugins.FailureDiagnosticsPlugin` creates a plugin to show diagnostics upon encountering a test failure.

`matlab.unittest.plugins.FailureDiagnosticsPlugin(stream)` redirects all the text output to the output stream, `stream`. If you do not specify the output stream, the plugin uses the `ToStandardOutput` stream.

## Input Arguments

### **stream**

Location where the plugin directs text output, specified as an `OutputStream`.

**Default:** `ToStandardOutput`

## Copy Semantics

Handle. To learn how handle classes affect copy operations, see [Copying Objects in the MATLAB documentation](#).

## Examples

### Add Plugin to TestRunner

In your working folder, create a file, `ExampleTest.m`, containing the following test class.

```
classdef ExampleTest < matlab.unittest.TestCase
 methods(Test)
 function testPathAdd(testCase)
 % test code
 end
 function testOne(testCase) % Test fails
 testCase.verifyEqual(5, 4, 'Testing 5==4')
 end
 function testTwo(testCase) % Test passes
 testCase.verifyEqual(5, 5, 'Testing 5==5')
 end
 end
end
end
```

The `verifyEqual` qualification in `testOne` causes a test failure. The qualifications in `testOne` and `testTwo` include an instance of a `matlab.unittest.diagnostics.StringDiagnostic`.

At the command prompt, create a test suite from the `ExampleTest` class.

```
import matlab.unittest.TestRunner
import matlab.unittest.TestSuite
import matlab.unittest.plugins.FailureDiagnosticsPlugin
```

```
suite = TestSuite.fromClass(?ExampleTest);
```

Create a test runner with no plugins. This code creates a silent runner and provides you with complete control over the installed plugins.

```
runner = TestRunner.withNoPlugins;
```

Run the tests.

```
result1 = runner.run(suite);
```

No output is displayed, but `result1` contains information about the failed test.

Add `FailureDiagnosticsPlugin` to the runner and run the tests.

```
runner.addPlugin(FailureDiagnosticsPlugin)
```

```
result2 = runner.run(suite);
```

```
=====
Verification failed in ExampleTest/testOne.
```

```

Test Diagnostic:

Testing 5==4

Framework Diagnostic:

verifyEqual failed.
--> The values are not equal using "isequaln".
--> Failure table:
 Actual Expected Error RelativeError
 ----- ----- ----- -----
 5 4 1 0.25

Actual double:

In C:\work\ExampleTest.m (ExampleTest.testOne) at 7
=====
```

```
Failure Summary:
```

Name	Failed	Incomplete	Reason(s)
ExampleTest/testOne	X		Failed by verification.

The framework displays the `DiagnosticResult` of the `StringDiagnostic` for failed tests only. It also displays additional framework diagnostics. The `TestResult` object, `result2`, is the same as `result1`.

## See Also

`matlab.unittest.diagnostics` | `matlab.unittest.plugins` | `OutputStream` | `ToStandardOutput`

**Introduced in R2013a**

# matlab.unittest.plugins.FailOnWarningsPlugin class

**Package:** matlab.unittest.plugins

Plugin to fail tests that issue warnings

## Description

The `FailOnWarningsPlugin` creates a plugin that, when added to the `TestRunner`, fails any test that issues a warning. The plugin produces a qualification failure in the test scope that issues the warning. For example, if a shared test fixture issues a warning, the plugin produces a qualification failure on the fixture and fails all tests that share the fixture.

The `FailOnWarningsPlugin` plugin does not produce a failure if:

- A test accounts for the warning through a constraint such as `IssuesWarnings` or `IssuesNoWarnings`, regardless of whether the constraint is satisfied or not.
- A warning is disabled. For example, if you disable a warning using the `SuppressedWarningsFixture`.

## Construction

`matlab.unittest.plugins.FailOnWarningsPlugin` creates a plugin that fails any test that issues a warning.

`matlab.unittest.plugins.FailOnWarningsPlugin('Ignoring', warnIDs)` creates a plugin that does not fail for the specified warning identifiers, `warnIDs`.

## Input Arguments

**warnIDs** — Identifiers for warnings to ignore

cell array of strings

Identifiers for warnings to ignore, specified as a cell array of strings. The plugin does not fail a test for the warnings with identifiers included in `warnIDs`.

Example: `FailOnWarningsPlugin('Ignoring', {'MATLAB:singularMatrix'})`

## Properties

### **Ignore** — Values to ignore

empty cell array (default) | cell array of strings

The `Ignore` property is empty by default. To specify the property as a cell array of strings, use the `'Ignoring'` syntax when you construct the plugin instance.

## Copy Semantics

Handle. To learn how handle classes affect copy operations, see [Copying Objects in the MATLAB documentation](#).

## Examples

### **Fail Tests If They Issue Warnings**

Create the `solve` function to solve a set of linear equations. There is an intentional error in the `solve` function — the `assert` call that checks whether the matrix is singular should use `rcond` instead of `det`.

```
function x = solve(A,b)

assert(abs(det(A)) > 1e-12,... % intentional bug for illustrative purposes
 'The matrix is singular or nearly singular');

x = A\b;
```

Create the following test class. In `testTwo`, the `A` matrix is singular, but since there is a bug in the `solve` function, the `assert` call does not catch it.

```
classdef TestSolve < matlab.unittest.TestCase

 methods(Test)
 function testOne(testCase)
 A = eye(3);
 b = [3; 4; 1];
 testCase.verifyEqual(solve(A b),b);
 end
 end
end
```

```

function testTwo(testCase)
 A = [1e-100 0; 0 1e100];
 b = [5; 5];
 expX = [5e100 5e-100];
 testCase.verifyEqual(solve(A,b),expX);
end
end
end

```

At the command prompt, create a test suite, and test runner.

```

import matlab.unittest.TestRunner;
import matlab.unittest.TestSuite;
import matlab.unittest.plugins.FailOnWarningsPlugin;

suite = TestSuite.fromClass(?TestSolve);
runner = TestRunner.withTextOutput;

```

Add the `FailOnWarningsPlugin` plugin, and run the tests. `testTwo` fails because the `solve` function issues a warning. Without `FailOnWarningsPlugin`, the `solve` function issues the warning, but both tests pass.

```

runner.addPlugin(FailOnWarningsPlugin);
result = runner.run(suite);

```

Running TestSolve

```

**Introduced in R2015b**

# matlab.unittest.plugins.LoggingPlugin class

**Package:** matlab.unittest.plugins

Plugin to report diagnostic messages

## Description

The `LoggingPlugin` creates a plugin to report diagnostic messages that are created by the `log` method of a `TestCase` or `Fixture`.

## Construction

Instantiate a `LoggingPlugin` using one of its static methods.

Use the `withVerbosity` static method to configure a plugin to respond to messages of a particular verbosity. Also, the `withVerbosity` method accepts a number of name/value pairs to configure the format for reporting logged messages.

## Properties

### Description — Logged diagnostic message description

'Diagnostic logged' (default) | string

Logged diagnostic message description, specified as a string. The value of this property is printed alongside each logged diagnostic message. `Description` is read only, and its value is set during construction.

### HideLevel — Indicator to display verbosity level

false (default) | true

Indicator to display the verbosity level alongside each logged diagnostic, specified as `false` (logical(0)) or `true` (logical(1)). By default, this property is `false` and the test framework displays the verbosity level. `HideLevel` is read only, and its value is set during construction.

### HideTimestamp — Indicator to display timestamp

false (default) | true

Indicator to display the timestamp from when the test framework generates the logged message alongside each logged diagnostic, specified as `false` (`logical(0)`) or `true` (`logical(1)`). By default, this property is `false` and the test framework displays the timestamp. `HideTimestamp` is read only, and its value is set during construction.

## **NumStackFrames** — Number of stack frames to display

0 (default) | integer value | `Inf`

Number of stack frames to display after each logged diagnostic message, specified as an integer value. By default, this property is 0, and the test framework does not display stack information. If `NumStackFrames` is `Inf`, the test framework displays all available stack frames. `NumStackFrames` is read only, and its value is set during construction.

## **Verbosity** — Verbosity levels supported by plugin instance

array of `matlab.unittest.Verbosity` instances

Verbosity levels supported by plugin instance, specified as an array of `matlab.unittest.Verbosity` instances. The plugin reacts to diagnostics that are logged at a verbosity level listed in this array. `Verbosity` is read only, and its value is set during construction.

## Methods

`withVerbosity`

Construct `LoggingPlugin` for messages of specified verbosity

## Copy Semantics

Handle. To learn how handle classes affect copy operations, see [Copying Objects in the MATLAB documentation](#).

## See Also

`matlab.unittest.Verbosity` | `matlab.unittest.fixtures.Fixture.log` | `matlab.unittest.TestCase.log`

**Introduced in R2014b**

# matlab.unittest.plugins.LoggingPlugin.withVerbosity

**Class:** matlab.unittest.plugins.LoggingPlugin

**Package:** matlab.unittest.plugins

Construct LoggingPlugin for messages of specified verbosity

## Syntax

```
matlab.unittest.plugins.LoggingPlugin.withVerbosity(v)
matlab.unittest.plugins.LoggingPlugin.withVerbosity(v,stream)
matlab.unittest.plugins.LoggingPlugin.withVerbosity(v,Name,Value)
```

## Description

`matlab.unittest.plugins.LoggingPlugin.withVerbosity(v)` constructs a LoggingPlugin for messages of the specified verbosity.

`matlab.unittest.plugins.LoggingPlugin.withVerbosity(v,stream)` redirects the text output to the output stream.

`matlab.unittest.plugins.LoggingPlugin.withVerbosity(v,Name,Value)` includes additional options specified by one or more Name, Value pair arguments.

## Input Arguments

**v** — Verbosity levels supported by plugin instance

1 | 2 | 3 | 4 | matlab.unittest.Verbosity enumeration

Verbosity levels supported by the plugin instance, specified as an integer value between 1 and 4 or a `matlab.unittest.Verbosity` enumeration object. The plugin reacts to diagnostics that are logged at this level and lower. Integer values correspond to the members of the `matlab.unittest.Verbosity` enumeration.

Numeric Representation	Corresponding Enumeration Object	Verbosity Description
1	matlab.unittest.Verbosity.Ter	minimal amount of information

Numeric Representation	Corresponding Enumeration Object	Verbosity Description
2	matlab.unittest.Verbosity.Con	typical amount of information
3	matlab.unittest.Verbosity.Det	supplemental amount of information
4	matlab.unittest.Verbosity.Ver	surplus of information

**stream** — Location where plugin directs text output

ToStandardOutput instance (default) | OutputStream instance

Location where the plugin directs text output, specified as an OutputStream instance. By default, the plugin uses the OutputStream subclass ToStandardOutput as the stream.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

**'Description'** — Logged diagnostic message description

'Diagnostic logged' (default) | string

Logged diagnostic message description, specified as a string. This value is printed alongside each logged diagnostic message. If the value is an empty string, the test framework does not display a description.

**'ExcludingLowerLevels'** — Indicator to display messages logged at levels lower than the verbosity level

false (default) | true

Indicator to display messages logged at levels lower than the verbosity level, v, specified as false or true (logical(0) or logical(1)). By default, the value is false and the plugin reacts to all messages logged at level v or lower. If the value is true, the plugin reacts only to messages logged at level v.

**'HideLevel1'** — Indicator to display verbosity level

false (default) | true

Indicator to display the verbosity level alongside each logged diagnostic, specified as `false` or `true` (`logical(0)` or `logical(1)`). By default, the value is `false` and the test framework displays the verbosity level.

**'HideTimestamp' — Indicator to display timestamp**

`false` (default) | `true`

Indicator to display the timestamp from when the test framework generates the logged message alongside each logged diagnostic, specified as `false` or `true` (`logical(0)` or `logical(1)`). By default, the value is `false` and the test framework displays the timestamp.

**'NumStackFrames' — Number of stack frames to display**

0 (default) | integer value | `Inf`

Number of stack frames to display after each logged diagnostic message, specified as an integer value. By default, the value is 0, and the test framework does not display stack information. If `NumStackFrames` is `Inf`, the test framework displays all available stack frames.

## Examples

### Create Logging Plugin

Create a function-based test in a file, `sampleLogTest.m`, in your working folder.

```
function tests = sampleLogTest
tests = functiontests(localfunctions);

function svdTest(testCase)
import matlab.unittest.Verbosity

log(testCase, 'Generating matrix. ');
m = rand(1000);

log(testCase, 1, 'About to call SVD. ');
[U,S,V] = svd(m);

log(testCase, Verbosity.Terse, 'SVD finished. ');

verifyEqual(testCase, U*S*V', m, 'AbsTol', 1e-6)
```

At the command prompt, run the test.

```
results = run(sampleLogTest);

Running sampleLogTest
 [Terse] Diagnostic logged (2014-04-14T14:20:59): About to call SVD.
 [Terse] Diagnostic logged (2014-04-14T14:20:59): SVD finished.
.
Done sampleLogTest
```

The default runner reports the diagnostics at level 1 (Terse).

Create a test runner to report the diagnostics at levels 1 and 2, and rerun the test.

```
import matlab.unittest.TestRunner
import matlab.unittest.plugins.LoggingPlugin

runner = TestRunner.withNoPlugins;
p = LoggingPlugin.withVerbosity(2);
runner.addPlugin(p);

results = runner.run(sampleLogTest);

[Concise] Diagnostic logged (2014-04-14T14:28:14): Generating matrix.
 [Terse] Diagnostic logged (2014-04-14T14:28:14): About to call SVD.
 [Terse] Diagnostic logged (2014-04-14T14:28:15): SVD finished.
```

## Configure Logged Message Output

Create the following class In a file in your current working folder, `ExampleLogTest.m`.

```
classdef ExampleLogTest < matlab.unittest.TestCase
 methods(Test)
 function testOne(testCase) % Test fails
 log(testCase,3,'Starting Test')
 log(testCase,'Testing 5==4')
 testCase.verifyEqual(5,4)
 log(testCase,4,'Test Complete')
 end
 function testTwo(testCase) % Test passes
 log(testCase,matlab.unittest.Verbosity.Detailed,'Starting Test')
 log(testCase,'Testing 5==5')
 testCase.verifyEqual(5,5)
 log(testCase,matlab.unittest.Verbosity.Verbose,'Test Complete')
 end
 end
end
```

```

 end
 end
end

```

The log messages in `testTwo` uses `Verbosity` enumerations instead of the corresponding integers.

At the command prompt, create the test suite and a runner at verbosity level 4, and then run the test.

```

import matlab.unittest.TestSuite
import matlab.unittest.TestRunner
import matlab.unittest.plugins.LoggingPlugin
suite = TestSuite.fromClass(?ExampleLogTest);

runner = TestRunner.withNoPlugins;
p = LoggingPlugin.withVerbosity(4);
runner.addPlugin(p);

results = runner.run(suite);

[Detailed] Diagnostic logged (2014-04-14T15:24:03): Starting Test
[Concise] Diagnostic logged (2014-04-14T15:24:03): Testing 5==4
[Verbose] Diagnostic logged (2014-04-14T15:24:03): Test Complete

# matlab.unittest.plugins.OutputStream class

**Package:** matlab.unittest.plugins

Interface that determines where to send text output

## Description

The `OutputStream` interface is an abstract interface class that you can use as a base class to specify where plugins direct their text output. To create a custom output stream, implement a `print` method that correctly handles the formatted text information the testing framework passes to it. Many text-oriented plugins accept an `OutputStream` to redirect the text they produce in a configurable manner.

## Methods

`print` Print string to output stream

## Copy Semantics

Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB documentation.

## Examples

### Create Custom Output Stream

In a file in your working directory, create a new output stream class in the file `ToFigure.m`. This class allows plugin output to be redirected to a figure.

```
classdef ToFigure < matlab.unittest.plugins.OutputStream
 properties (SetAccess=private)
 Figure
 end
 properties (Access=private)
```

```
 ListBox
 end
```

This class uses two properties. `Figure` is the figure that receives and displays the output. `ListBox` is a handle to the list box that displays the text.

In the same file, add the following `methods` block.

```
methods
function print(stream,formatSpec,varargin)
 % Create the figure
 if isempty(stream.Figure) || ~ishghandle(stream.Figure)
 stream.createFigure
 end
 newStr = sprintf(formatSpec,varargin{:});
 oldStr = strjoin(stream.ListBox.String, '\n');

 % Create the full string
 fullStr = [oldStr,newStr];
 fullStrCell = strsplit(fullStr,'\n','CollapseDelimiters',false);

 % Set the string and selection
 stream.ListBox.String = fullStrCell';
 stream.ListBox.Value = numel(fullStrCell);
 drawnow
end
end
```

You must implement the `print` method for any subclass of `OutputStream`. In this example, the method creates a new figure (if necessary), formats the incoming text, and then adds it to the output stream.

In the same file, add the following `methods` block containing a helper function to create the figure.

```
methods(Access=private)
function createFigure(stream)
 stream.Figure = figure(...
 'Name', 'Unit Test Output', ...
 'WindowStyle', 'docked');

 stream.ListBox = uicontrol(...
 'Parent', stream.Figure, ...
 'Style', 'listbox', ...
```

```

 'String', {}, ...
 'Units', 'normalized', ...
 'Position', [.05 .05 .9 .9], ...
 'Max', 2, ...
 'FontName', 'Monospaced', ...
 'FontSize', 13);
 end
end
end

```

In a new file in your working folder, create `ExampleTest.m` containing the following test class.

```

classdef ExampleTest < matlab.unittest.TestCase
 methods(Test)
 function testOne(testCase) % Test fails
 testCase.verifyEqual(5, 4, 'Testing 5==4');
 end
 function testTwo(testCase) % Test passes
 testCase.verifyEqual(5, 5, 'Testing 5==5');
 end
 function testThree(testCase)
 % test code
 end
 end
end
end

```

The `verifyEqual` qualification in `testOne` causes a test failure. The qualifications in `testOne` and `testTwo` include an instance of a `matlab.unittest.diagnostics.StringDiagnostic`.

At the command prompt, create a test suite from the `ExampleTest` class.

```

import matlab.unittest.TestSuite
import matlab.unittest.TestRunner
import matlab.unittest.plugins.DiagnosticsValidationPlugin

suite = TestSuite.fromClass(?ExampleTest);

```

Create a test runner that displays output to the command window.

```
runner = TestRunner.withTextOutput;
```

Create a `DiagnosticsValidationPlugin` that explicitly specifies that its output should go to a figure via the `ToFigure` output stream.

```
plugin = DiagnosticsValidationPlugin(ToFigure);
```

Add the plugin to the TestRunner and run the suite.

```
runner.addPlugin(plugin)
result = runner.run(suite);
```

Running ExampleTest

```

```

```

Failure Summary:

Name	Failed	Incomplete	Reason(s)
------	--------	------------	-----------

```
=====
ExampleTest/testOne X Failed by verification.
```

Only the test failures produce output to the screen. By default, `TestRunner.withTextOutput` uses a `FailureDiagnosticsPlugin` to display output on the screen.

In addition to the default text output being displayed on the screen, the `DiagnosticsValidationPlugin` output is directed to a docked figure. The figure shows the following text.

```

Validation of Test Diagnostic:

Testing 5==4

Validation of Test Diagnostic:

Testing 5==5
```

The `DiagnosticsValidationPlugin` displays the diagnostic information regardless of whether the tests encounter failure conditions.

## See Also

`matlab.unittest.plugins.OutputStream` | `fprintf` | `matlab.unittest.plugins`

**Introduced in R2014a**

## print

**Class:** matlab.unittest.plugins.OutputStream

**Package:** matlab.unittest.plugins

Print string to output stream

## Syntax

```
print(stream,formatSpec,A1,...,An)
```

## Description

`print(stream,formatSpec,A1,...,An)` formats the data in arrays `A1,...,An` according to `formatSpec`, and sends the result to the output stream, `stream`. Assign `formatSpec` and `A1,...,An` using the same interface that you use for `sprintf` and `fprintf`.

## Input Arguments

### **stream**

Output stream, specified as an instance of the `OutputStream` class

### **formatSpec**

Format of text in output stream, specified as a string. For information on the construction of `formatSpec` string, see the input argument entry on the `fprintf` or `sprint` reference pages.

### **A**

Numeric or character arrays, specified as a scalar, vector, matrix, or multidimensional array.

## Examples

### Create Custom Output Stream

In a file in your working directory, create a new output stream class in the file `ToFigure.m`. This class allows plugin output to be redirected to a figure.

```
classdef ToFigure < matlab.unittest.plugins.OutputStream

 properties(SetAccess=private)
 Figure
 end
 properties(Access=private)
 ListBox
 end
```

This class uses two properties. `Figure` is the figure that receives and displays the output. `ListBox` is a handle to the list box that displays the text.

In the same file, add the following `methods` block.

```
methods
 function print(stream,formatSpec,varargin)
 % Create the figure
 if isempty(stream.Figure) || ~ishghandle(stream.Figure)
 stream.createFigure
 end
 newStr = sprintf(formatSpec,varargin{:});
 oldStr = strjoin(stream.ListBox.String', '\n');

 % Create the full string
 fullStr = [oldStr,newStr];
 fullStrCell = strsplit(fullStr,'\n','CollapseDelimiters',false);

 % Set the string and selection
 stream.ListBox.String = fullStrCell';
 stream.ListBox.Value = numel(fullStrCell);
 drawnow
 end
end
```

You must implement the `print` method for any subclass of `OutputStream`. In this example, the method creates a new figure (if necessary), formats the incoming text, and then adds it to the output stream.

In the same file, add the following `methods` block containing a helper function to create the figure.

```
methods(Access=private)
 function createFigure(stream)
 stream.Figure = figure(...
 'Name', 'Unit Test Output', ...
 'WindowStyle', 'docked');

 stream.ListBox = uicontrol(...
 'Parent', stream.Figure, ...
 'Style', 'listbox', ...
 'String', {}, ...
 'Units', 'normalized', ...
 'Position', [.05 .05 .9 .9], ...
 'Max', 2, ...
 'FontName', 'Monospaced', ...
 'FontSize', 13);
 end
end
end
```

In an new file in your working folder, create `ExampleTest.m` containing the following test class.

```
classdef ExampleTest < matlab.unittest.TestCase
 methods(Test)
 function testOne(testCase) % Test fails
 testCase.verifyEqual(5, 4, 'Testing 5==4');
 end
 function testTwo(testCase) % Test passes
 testCase.verifyEqual(5, 5, 'Testing 5==5');
 end
 function testThree(testCase)
 % test code
 end
 end
end
```

The `verifyEqual` qualification in `testOne` causes a test failure. The qualifications in `testOne` and `testTwo` include an instance of a `matlab.unittest.diagnostics.StringDiagnostic`.

At the command prompt, create a test suite from the `ExampleTest` class.

```
import matlab.unittest.TestSuite
import matlab.unittest.TestRunner
import matlab.unittest.plugins.DiagnosticsValidationPlugin
```

```
suite = TestSuite.fromClass(?ExampleTest);
```

Create a test runner that displays output to the command window.

```
runner = TestRunner.withTextOutput;
```

Create a `DiagnosticsValidationPlugin` that explicitly specifies that its output should go to a figure via the `ToFigure` output stream.

```
plugin = DiagnosticsValidationPlugin(ToFigure);
```

Add the plugin to the `TestRunner` and run the suite.

```
runner.addPlugin(plugin)
result = runner.run(suite);
```

```
Running ExampleTest
```

```

# matlab.unittest.plugins.QualifyingPlugin class

**Package:** matlab.unittest.plugins

**Superclasses:** matlab.unittest.plugins.TestRunnerPlugin

Interface for plugins that perform system-wide qualifications

## Description

Use qualifying plugins to produce test failures apart from your test content. Qualifications at the plugin level are useful because you can avoid repeating the same qualification in every test. You can decide to apply system-wide qualifications to the test suite periodically by simply adding the plugin to the test runner for a particular test session.

The `QualifyingPlugin` interface enables test runner plugin authors to implement plugins that perform system-wide qualifications on a test suite. You can perform qualifications in these inherited methods:

- `setupSharedTestFixture`
- `teardownSharedTestFixture`
- `setupTestClass`
- `teardownTestClass`
- `setupTestMethod`
- `teardownTestMethod`

## Methods

<code>assertUsing</code>	Assert that value satisfies given constraint
<code>assumeUsing</code>	Assume that value satisfies given constraint
<code>fatalAssertUsing</code>	Fatally assert that value satisfies given constraint
<code>verifyUsing</code>	Verify that value satisfies given constraint

## Inherited Methods

<code>createSharedTestFixture</code>	Extend creation of shared test fixture instances
<code>createClassInstance</code>	Extend creation of class-level <code>TestCase</code> instances
<code>createTestMethodInstance</code>	Extend creation of method-level <code>TestCase</code> instances
<code>reportFinalizedResult</code>	Enable reporting of finalized <code>TestResults</code>
<code>runTest</code>	Extend running of single <code>TestSuite</code> element
<code>runTestClass</code>	Extend running of <code>TestSuite</code> array from same class or function
<code>runTestSuite</code>	Extend running of <code>TestSuite</code> array
<code>runTestMethod</code>	Extend running of single <code>Test</code> method
<code>setupSharedTestFixture</code>	Extend setting up shared test fixture
<code>setupTestClass</code>	Extend setting up test class
<code>setupTestMethod</code>	Extend setting up of test method
<code>teardownSharedTestFixture</code>	Extend tearing down shared test fixture
<code>teardownTestClass</code>	Extend tearing down of test class
<code>teardownTestMethod</code>	Extend tearing down of test method

## Copy Semantics

Handle. To learn how handle classes affect copy operations, see [Copying Objects](#) in the MATLAB documentation.

## Examples

### Test Using Qualification in Plugin

Create a plugin to ensure that test files leaves the MATLAB path unchanged. If the path after running the test file is different from the starting path, the test fails.

Create a class, `VerifyNoPathChangePlugin`, that inherits from the `matlab.unittest.plugins.QualifyingPlugin` class.

```
classdef VerifyNoPathChangePlugin < matlab.unittest.plugins.QualifyingPlugin
 properties (Access=private)
 OriginalPath
 end

 methods (Access=protected)
 function setupTestClass(plugin, pluginData)
 plugin.OriginalPath = path;
 setupTestClass@matlab.unittest.plugins.QualifyingPlugin(plugin,pluginData)
 end
 function teardownTestClass(plugin, pluginData)
 import matlab.unittest.constraints.IsEqualTo;
 teardownTestClass@matlab.unittest.plugins.QualifyingPlugin(plugin,pluginData)
 plugin.verifyUsing(pluginData.QualificationContext, ...
 path, IsEqualTo(plugin.OriginalPath), ...
 sprintf('%s modified the path.', pluginData.Name));
 end
 end
end
```

Create the following test class. The test modifies the path, but does not restore the original path.

```
classdef LeavesModifiesPath < matlab.unittest.TestCase
 methods (Test)
 function test1(~)
 addpath(pwd);
 end
 end
end
```

For purposes of this example, at the command prompt, remove the present working folder from the path.

```
rmpath(pwd)
```

Create a test suite, add the plugin to the test runner, and run the suite. The test fails because the path after the test is different from the starting path.

```
suite = matlab.unittest.TestSuite.fromClass(?LeavesModifiesPath);
runner = matlab.unittest.TestRunner.withTextOutput;
runner.addPlugin(VerifyNoPathChangePlugin);
```

```
runner.run(suite);
```

```
Running LeavesModifiesPath
```

```
.
=====
```

Verification failed while setting up or tearing down LeavesModifiesPath.  
As a result, all LeavesModifiesPath tests failed.

```

Test Diagnostic:

LeavesModifiesPath modified the path.
```

```

Framework Diagnostic:

IsEqualTo failed.
--> StringComparator failed.
 --> Size check failed.
 --> Sizes do not match.
```

```
 Actual size: 1 15418
 Expected size: 1 15392
```

```
--> The strings are not equal.
```

```
Actual char:
C:\work;C:\Program Files\MATLAB\R2015b\toolbox\matlab\...
Expected char:
C:\Program Files\MATLAB\R2015b\toolbox\matlab\...
```

```

## assertUsing

**Class:** matlab.unittest.plugins.QualifyingPlugin

**Package:** matlab.unittest.plugins

Assert that value satisfies given constraint

### Syntax

```
assertUsing(plugin,context,actual,constraint)
```

```
assertUsing(plugin,context,actual,constraint,diagnostic)
```

### Description

`assertUsing(plugin,context,actual,constraint)` asserts that `actual` is a value that satisfies the given constraint, `constraint`, using the qualification `context`. If the actual value does not satisfy the constraint, the testing framework reports an assertion failure.

`assertUsing(plugin,context,actual,constraint,diagnostic)` displays the diagnostic information, `diagnostic`, upon failure.

### Tips

Use the `QualifyingPlugin.assertUsing` method when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the associated test content as failed and incomplete. Alternatively,

- Use the `QualifyingPlugin.verifyUsing` method to produce and record failures without throwing an exception. Because a `QualifyingPlugin` performs additional qualifications beyond the ones defined in the unit tests, it typically uses verifications. Verifications do not cause an early exit from the test, ensuring that the test framework executes all test content. Use other qualification types to test for violation of preconditions or incorrect test setup.
- Use the `QualifyingPlugin.assumeUsing` method to ensure that the test environment meets preconditions that otherwise do not result in a test failure.

Assumption failures result in filtered tests, and the testing framework marks the associated test content as **Incomplete**.

- Use the `QualifyingPlugin fatalAssertUsing` method to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session.

## Input Arguments

### **plugin** — Qualifying plugin instance

`matlab.unittest.plugins.QualifyingPlugin`

Plugin instance, specified as an instance of the `matlab.unittest.plugins.QualifyingPlugin` class.

### **context** — Context for plugins

`matlab.unittest.plugins.plugindata.QualificationContext`

Context for plugins, specified as an instance of `matlab.unittest.plugins.plugindata.QualificationContext` class. This instance provides the context for the plugin to perform qualifications on test suites. The plugin obtains this context from the plugin data.

### **actual** — Value to test

workspace variable

Value to test, specified as a workspace variable. `actual` can be any data type. The qualification passes when `actual` satisfies the specified constraint, `constraint`.

### **constraint** — Condition test must satisfy

instance of class in `matlab.unittest.constraints` package

Condition the test must satisfy, specified as an instance of a class in the `matlab.unittest.constraints` package.

### **diagnostic** — Diagnostic information to display

string | function handle | instance of class in `matlab.unittest.diagnostics` package

Diagnostic information to display upon failure, specified as a string, a function handle, or an instance of a class in the `matlab.unittest.diagnostics` package.

## Examples

### Use Qualifications in Plugin

See examples for the `QualifyingPlugin` class and replace calls to `verifyUsing` with `assertUsing`.

### See Also

`matlab.unittest.plugins.QualifyingPlugin`

**Introduced in R2015b**

# assumeUsing

**Class:** matlab.unittest.plugins.QualifyingPlugin

**Package:** matlab.unittest.plugins

Assume that value satisfies given constraint

## Syntax

```
assumeUsing(plugin,context,actual,constraint)
```

```
assumeUsing(plugin,context,actual,constraint,diagnostic)
```

## Description

`assumeUsing(plugin,context,actual,constraint)` assumes that `actual` is a value that satisfies the given constraint, `constraint`, using the qualification `context`. If the actual value does not satisfy the constraint, the testing framework reports an assumption failure.

`assumeUsing(plugin,context,actual,constraint,diagnostic)` displays the diagnostic information, `diagnostic`, upon failure.

## Tips

Use the `QualifyingPlugin.assumeUsing` method to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the associated test content as `Incomplete`. Alternatively,

- Use the `QualifyingPlugin.verifyUsing` method to produce and record failures without throwing an exception. Because a `QualifyingPlugin` performs additional qualifications beyond the ones defined in the unit tests, it typically uses verifications. Verifications do not cause an early exit from the test, ensuring that the test framework executes all test content. Use other qualification types to test for violation of preconditions or incorrect test setup.
- Use the `QualifyingPlugin.assertUsing` method when the failure condition invalidates the remainder of the current test content, but does not prevent proper

execution of subsequent test methods. A failure at the assertion point renders the associated test content as failed and incomplete.

- Use the `QualifyingPlugin fatalAssertUsing` method to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session.

## Input Arguments

### **plugin** — Qualifying plugin instance

`matlab.unittest.plugins.QualifyingPlugin`

Plugin instance, specified as an instance of the `matlab.unittest.plugins.QualifyingPlugin` class.

### **context** — Context for plugins

`matlab.unittest.plugins.plugindata.QualificationContext`

Context for plugins, specified as an instance of `matlab.unittest.plugins.plugindata.QualificationContext` class. This instance provides the context for the plugin to perform qualifications on test suites. The plugin obtains this context from the plugin data.

### **actual** — Value to test

workspace variable

Value to test, specified as a workspace variable. `actual` can be any data type. The qualification passes when `actual` satisfies the specified constraint, `constraint`.

### **constraint** — Condition test must satisfy

instance of class in `matlab.unittest.constraints` package

Condition the test must satisfy, specified as an instance of a class in the `matlab.unittest.constraints` package.

### **diagnostic** — Diagnostic information to display

string | function handle | instance of class in `matlab.unittest.diagnostics` package

Diagnostic information to display upon failure, specified as a string, a function handle, or an instance of a class in the `matlab.unittest.diagnostics` package.

## Examples

### Use Qualifications in Plugin

See examples for the `QualifyingPlugin` class and replace calls to `verifyUsing` with `assumeUsing`.

**Package:** matlab.unittest.plugins

Fatally assert that value satisfies given constraint

## Syntax

```
fatalAssertUsing(plugin,context,actual,constraint)
fatalAssertUsing(plugin,context,actual,constraint,diagnostic)
```

## Description

`fatalAssertUsing(plugin,context,actual,constraint)` fatally asserts that `actual` is a value that satisfies the given constraint, `constraint`, using the qualification `context`. If the actual value does not satisfy the constraint, the testing framework reports a fatal assertion failure.

`fatalAssertUsing(plugin,context,actual,constraint,diagnostic)` displays the diagnostic information, `diagnostic`, upon failure.

## Tips

Use the `QualifyingPlugin.fatalAssertUsing` method to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. Alternatively,

- Use the `QualifyingPlugin.verifyUsing` method to produce and record failures without throwing an exception. Because a `QualifyingPlugin` performs additional qualifications beyond the ones defined in the unit tests, it typically uses verifications. Verifications do not cause an early exit from the test, ensuring that the test framework executes all test content. Context for plugins, specified as an instance of `matlab.unittest.plugins.plugindata.QualificationContext` class. This instance provides the context for the plugin to perform qualifications on test suites. The plugin obtains this context from the plugin data.

### **actual** — Value to test

workspace variable

Value to test, specified as a workspace variable. `actual` can be any data type. The qualification passes when `actual` satisfies the specified constraint, `constraint`.

### **constraint** — Condition test must satisfy

instance of class in `matlab.unittest.constraints` package

Condition the test must satisfy, specified as an instance of a class in the `matlab.unittest.constraints` package.

### **diagnostic** — Diagnostic information to display

string | function handle | instance of class in `matlab.unittest.diagnostics` package

Diagnostic information to display upon failure, specified as a string, a function handle, or an instance of a class in the `matlab.unittest.diagnostics` package.

## Examples

### Use Qualifications in Plugin

See examples for the `QualifyingPlugin` class.

### See Also

`matlab.unittest.plugins.QualifyingPlugin`

**Introduced in R2015b**

# matlab.unittest.plugins.StopOnFailuresPlugin class

**Package:** matlab.unittest.plugins

Plugin to debug test failures

## Description

The `StopOnFailuresPlugin` class provides a plugin to help debug test failures. Adding `StopOnFailuresPlugin` to the test runner pauses execution of a test if it encounters a qualification failure or uncaught error and puts MATLAB into debug mode.

If `StopOnFailuresPlugin` encounters a qualification failure or uncaught error in a test, you can use MATLAB debugging commands, such as `dbup`, `dbstep`, `dbcont`, and `dbquit`, to investigate the cause of the test failure.

If `StopOnFailuresPlugin` encounters an uncaught error in a test, you cannot use `dbup` to shift context to the source of the error because the error disrupts the stack.

## Construction

`matlab.unittest.plugins.StopOnFailuresPlugin` creates a plugin to debug test failures.

`matlab.unittest.plugins.StopOnFailuresPlugin('IncludingAssumptionFailures', tf)` indicates whether to react to assumption failures. By default, `StopOnFailuresPlugin` reacts to only uncaught errors and verification, assertion, and fatal assertion qualification errors. However, when `'IncludingAssumptionFailures'` is set to `true`, the plugin also reacts to assumption failures.

## Input Arguments

**tf** — Indicator to react to assumption failures

FALSE (default) | TRUE

Indicator to react to assumption failures, specified as logical `false` or `true`. When this value is `true`, the test runner reacts to assumption failures. When the value is `false`, the plugin ignores assumption failures.

## Properties

### IncludeAssumptionFailures

When this property value is `true`, the instance reacts to assumption failures. When the value is `false`, the instance ignores assumption failures. The `IncludeAssumptionFailures` property is `false` by default. To specify the property as `true`, use the `InlcudingAssumptionFailures` input when you construct the instance.

## Copy Semantics

Handle. To learn how handle classes affect copy operations, see [Copying Objects in the MATLAB documentation](#).

## Examples

### Add Plugin to TestRunner

In your working folder, create the file `ExampleTest.m` containing the following test class.

```
classdef ExampleTest < matlab.unittest.TestCase
 methods(Test)
 function testOne(testCase) % Test fails
 act = 3.1416;
 exp = pi;
 testCase.verifyEqual(act, exp)
 end
 function testTwo(testCase) % Test does not complete
 testCase.assumeEqual(5, 4)
 end
 end
end
```

At the command prompt, create a test suite from the `ExampleTest` class and a test runner.

```
import matlab.unittest.TestRunner
import matlab.unittest.TestSuite
import matlab.unittest.plugins.StopOnFailuresPlugin
```

```
suite = TestSuite.fromClass(?ExampleTest);
runner = TestRunner.withTextOutput;
```

Run the tests.

```
result = runner.run(suite);
```

Running ExampleTest

```
=====
Verification failed in ExampleTest/testOne.
```

```

Framework Diagnostic:

```

```
verifyEqual failed.
--> The values are not equal using "isequaln".
--> Failure table:
```

Actual	Expected	Error	RelativeError
3.1416	3.14159265358979	7.34641020683213e-06	2.33843499679617

```
Actual double:

**Introduced in R2013b**

# matlab.unittest.plugins.TAPPlugin class

**Package:** matlab.unittest.plugins

Plugin that produces Test Anything Protocol stream

## Description

The `TAPPlugin` creates a plugin that produces a Test Anything Protocol (TAP) stream. Using this plugin, you can integrate MATLAB Unit Test results into third-party systems that recognize the TAP protocol. For example, you can integrate test results with continuous integration systems like Jenkins™ or TeamCity®.

## Construction

`matlab.unittest.plugins.TAPPlugin.producingOriginalFormat` creates a plugin that produces output in the form of the original TAP format (version 12). By default, the plugin displays the output to the screen. In this case, other output sent to the screen can invalidate the TAP stream. To avoid this, redirect the output to a different output stream, such as the `ToFile` stream.

`matlab.unittest.plugins.TAPPlugin.producingOriginalFormat(stream)` redirects all the text output to the output stream, `stream`. If you do not specify the output stream, the plugin uses the `ToStandardOutput` stream.

## Input Arguments

**stream**

Location where the plugin directs text output, specified as an `OutputStream`.

**Default:** `ToStandardOutput`

## Copy Semantics

Handle. To learn how handle classes affect copy operations, see [Copying Objects in the MATLAB documentation](#).

## Examples

### Create TAP Plugin

In a new file in your working folder, create `ExampleTest.m` containing the following test class.

```
classdef ExampleTest < matlab.unittest.TestCase
 methods(Test)
 function testOne(testCase) % Test fails
 testCase.verifyEqual(5, 4, 'Testing 5==4')
 end
 function testTwo(testCase) % Test passes
 testCase.verifyEqual(5, 5, 'Testing 5==5')
 end
 function testThree(testCase)
 % test code
 end
 end
end
```

At the command prompt, create a test suite from the `ExampleTest` class.

```
import matlab.unittest.TestRunner
import matlab.unittest.TestSuite
import matlab.unittest.plugins.TAPPlugin
import matlab.unittest.plugins.ToFile
```

```
suite = TestSuite.fromClass(?ExampleTest);
```

Create a test runner that displays output to the command window using the default plugin.

```
runner = TestRunner.withTextOutput;
```

Create a `TAPPlugin` that explicitly specifies that its output should go to the file `MyTapOutput.tap`.

```
tapFile = 'MyTAPOutput.tap';
plugin = TAPPlugin.producingOriginalFormat(ToFile(tapFile));
```

Add the plugin to the `TestRunner` and run the suite.

```
runner.addPlugin(plugin)
```

```
result = runner.run(suite);
```

```
Running ExampleTest
```

**Introduced in R2014a**

# matlab.unittest.plugins.ToFile class

**Package:** matlab.unittest.plugins

**Superclasses:** matlab.unittest.plugins.OutputStream

Output stream to write text output to file

## Description

The `ToFile` class creates an output stream that writes text output to a UTF-8 encoded file. Whenever text prints to this stream, the output stream opens the file, appends the text, and closes the file.

## Construction

`matlab.unittest.plugins.ToFile(fname)` creates an `OutputStream` that writes text output to the file, `fname`.

## Input Arguments

### **fname**

Name of file to write the output text, specified as a string. If `fname` exists, the text from the stream is appended to the file.

## Properties

### **Filename**

Name of file to redirect text output from the plugin, specified in the input argument, `fname`.

## Copy Semantics

Handle. To learn how handle classes affect copy operations, see [Copying Objects in the MATLAB documentation](#).

## Examples

### Direct TAPPlugin Output Text to Separate File

In your working folder, create the file `ExampleTest.m` containing the following test class.

```
classdef ExampleTest < matlab.unittest.TestCase
 methods(Test)
 function testOne(testCase) % Test fails
 testCase.verifyEqual(5, 4, 'Testing 5==4')
 end
 function testTwo(testCase) % Test passes
 testCase.verifyEqual(5, 5, 'Testing 5==5')
 end
 function testThree(testCase)
 % test code
 end
 end
end
```

The `verifyEqual` qualification in `testOne` causes a test failure. The qualifications in `testOne` and `testTwo` include an instance of a `matlab.unittest.diagnostics.StringDiagnostic`.

At the command prompt, create a test suite from the `ExampleTest` class.

```
import matlab.unittest.TestRunner
import matlab.unittest.TestSuite
import matlab.unittest.plugins.TAPPlugin
import matlab.unittest.plugins.ToFile

suite = TestSuite.fromClass(?ExampleTest);
```

Create a test runner that displays output to the command window.

```
runner = TestRunner.withTextOutput;
```

Create a `TAPPlugin` that explicitly specifies that its output should go to the file, `MyTapOutput.tap`.

```
filename = 'MyTapOutput.tap';
plugin = TAPPlugin.producingOriginalFormat(ToFile(filename));
```

Add the plugin to the TestRunner and run the suite.

```
runner.addPlugin(plugin)
result = runner.run(suite);
```

matlab.unittest.plugins

**Introduced in R2014a**

# matlab.unittest.plugins.ToStandardOutput class

**Package:** matlab.unittest.plugins

**Superclasses:** matlab.unittest.plugins.OutputStream

Output stream to display text information to screen

## Description

The `ToStandardOutput` class creates an output stream to display text output to the screen. Many plugins that accept an output stream use `ToStandardOutput` as their default stream.

## Construction

`matlab.unittest.plugins.ToStandardOutput` creates an `OutputStream` that prints text output to the screen.

## Copy Semantics

Handle. To learn how handle classes affect copy operations, see [Copying Objects](#) in the MATLAB documentation.

## Examples

### Direct Plugin Output Text to Standard Output

In your working folder, create the file `ExampleTest.m` containing the following test class.

```
classdef ExampleTest < matlab.unittest.TestCase
 methods(Test)
 function testOne(testCase) % Test fails
 testCase.verifyEqual(5, 4, 'Testing 5==4')
 end
 end
end
```

```

 function testTwo(testCase) % Test passes
 testCase.verifyEqual(5, 5, 'Testing 5==5')
 end
 function testThree(testCase)
 % test code
 end
 end
end
end

```

The `verifyEqual` qualification in `testOne` causes a test failure. The qualifications in `testOne` and `testTwo` include an instance of a `matlab.unittest.diagnostics.StringDiagnostic`.

At the command prompt, create a test suite from the `ExampleTest` class.

```

import matlab.unittest.TestRunner
import matlab.unittest.TestSuite
import matlab.unittest.plugins.FailureDiagnosticsPlugin
import matlab.unittest.plugins.ToStandardOutput

```

```

suite = TestSuite.fromClass(?ExampleTest);

```

Create a test runner with no plugins. This code creates a silent runner and provides you with complete control over the installed plugins.

```

runner = TestRunner.withNoPlugins;

```

Create a `FailureDiagnosticsPlugin` that explicitly specifies that its output should go to the screen.

```

plugin = FailureDiagnosticsPlugin(ToStandardOutput);

```

Add the plugin to the `TestRunner` and run the suite.

```

runner.addPlugin(plugin)
result = runner.run(suite);

```

```

**Introduced in R2014a**

# matlab.unittest.plugins.TestRunnerPlugin class

**Package:** matlab.unittest.plugins

Plugin interface for extending TestRunner

## Description

The `TestRunnerPlugin` interface enables extension of the `matlab.unittest.TestRunner`. To customize a test run, create a subclass of `TestRunnerPlugin` and override select methods. `TestRunnerPlugin` provides you with a default implementation, so override only methods necessary to achieve your required customization. Every method you implement must invoke its corresponding superclass method, passing along the same instance of `pluginData` that it receives.

To run tests with this extension, add the custom `TestRunnerPlugin` to the `TestRunner` using the `addPlugin` method of `TestRunner`.

## Methods

<code>createSharedTestFixture</code>	Extend creation of shared test fixture instances
<code>createTestClassInstance</code>	Extend creation of class-level <code>TestCase</code> instances
<code>createTestMethodInstance</code>	Extend creation of method-level <code>TestCase</code> instances
<code>reportFinalizedResult</code>	Enable reporting of finalized <code>TestResults</code>
<code>runTest</code>	Extend running of single <code>TestSuite</code> element
<code>runTestClass</code>	Extend running of <code>TestSuite</code> array from same class or function
<code>runTestSuite</code>	Extend running of <code>TestSuite</code> array
<code>runTestMethod</code>	Extend running of single <code>Test</code> method
<code>setupSharedTestFixture</code>	Extend setting up shared test fixture
<code>setupTestClass</code>	Extend setting up test class

<code>setupTestMethod</code>	Extend setting up of test method
<code>teardownSharedTestFixture</code>	Extend tearing down shared test fixture
<code>teardownTestClass</code>	Extend tearing down of test class
<code>teardownTestMethod</code>	Extend tearing down of test method

## Copy Semantics

Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB documentation.

## Related Examples

- “Write Plugins to Extend TestRunner”
- “Create Custom Plugin”

**Introduced in R2014a**

# createSharedTestFixture

**Class:** matlab.unittest.plugins.TestRunnerPlugin

**Package:** matlab.unittest.plugins

Extend creation of shared test fixture instances

## Syntax

```
f = createSharedTestFixture(plugin,pluginData)
```

## Description

`f = createSharedTestFixture(plugin,pluginData)` extends the creation of shared test fixtures and returns the modified `Fixture` instance, `f`. The testing framework uses the fixture instance to customize running tests that use shared fixtures. The testing framework evaluates this method within the scope of the `runTestSuite` method of the `TestRunnerPlugin` for each shared test fixture it needs to set up. A typical implementation of this method is to add listeners to various events originating from the shared test fixture instance. Since the `Fixture` inherits from the `handle` class, add listeners by calling the `addlistener` method from within the `createSharedTestFixture` method.

## Input Arguments

### **plugin**

Instance of `matlab.unittest.plugins.TestRunnerPlugin`.

### **pluginData**

Shared test fixture creation information, specified as an instance of `matlab.unittest.plugins.plugindata.PluginData`. The test framework uses this information to introspect into the test content.

## Examples

### Extend Creation of Shared Test Fixture Instances

Extend the running of tests to count the number of shared test fixture assertion failures.

```
classdef ExamplePlugin < matlab.unittest.plugins.TestRunnerPlugin

 properties (SetAccess = private)
 FixtureAssertionFailureData = {};
 end

 methods (Access = protected)
 function fixture = createSharedTestFixture(plugin, pluginData)
 % Invoke the super class method
 fixture = createSharedTestFixture@...
 matlab.unittest.plugins.TestRunnerPlugin(plugin, pluginData);

 % Get the fixture name
 fixtureName = pluginData.Name;

 % Add a listener to fixture assertion failures
 % and capture the qualification failure information
 fixture.addListener('AssertionFailed', @(~,evd) ...
 plugin.captureFixtureAssertionFailureData(evd, fixtureName))
 end
 end

 methods (Access = private)
 function captureFixtureAssertionFailureData(plugin, eventData, fixtureName)
 plugin.FixtureAssertionFailureData{end+1} = struct(...
 'FixtureName', fixtureName, ...
 'ActualValue', eventData.ActualValue, ...
 'Constraint', eventData.Constraint, ...
 'Stack', eventData.Stack);
 end
 end
end
```

## createTestClassInstance

**Class:** matlab.unittest.plugins.TestRunnerPlugin

**Package:** matlab.unittest.plugins

Extend creation of class-level `TestCase` instances

### Syntax

```
tc = createTestClassInstance(plugin,pluginData)
```

### Description

`tc = createTestClassInstance(plugin,pluginData)` extends the creation of class-level `TestCase` instances, and returns the modified `TestCase` instance, `tc`. The test framework uses the `TestCase` instance to customize running tests that belong to the same test class. The test framework evaluates this method within the scope of the `runTestClass` method of the `TestRunnerPlugin`. A typical implementation of this method is to add listeners to various events originating from the class level instance. Since the `TestCase` inherits from the `handle` class, add listeners by calling the `addListener` method from within the `createTestClassInstance` method. For each class, the test framework passes the instance to any method with the `TestClassSetup` or `TestClassTeardown` attribute.

### Input Arguments

#### **plugin**

Instance of `matlab.unittest.plugins.TestRunnerPlugin`.

#### **pluginData**

Class-level `TestCase` creation information, specified as an instance of `matlab.unittest.plugins.pluginData.PluginData`. The test framework uses this information to introspect into the test content.

## Examples

### Extend Creation of Class-Level TestCase Instances

Extend the running of tests to count the number of class-level assumption failures.

```
classdef ExamplePlugin < matlab.unittest.plugins.TestRunnerPlugin

 properties (SetAccess = private)
 TestClassAssumptionFailureData = {};
 end

 methods (Access = protected)
 function testCase = createTestClassInstance(plugin,pluginData)
 % Invoke super class method
 testCase = createTestClassInstance@...
 matlab.unittest.plugins.TestRunnerPlugin(plugin,pluginData);

 % Get the test class name
 instanceName = pluginData.Name;

 % Add a listener to capture assumption failures
 testCase.addlistener('AssumptionFailed', @(~,evd) ...
 plugin.captureClassLevelAssumptionFailureData(evd,instanceName))
 end
 end

 methods (Access = private)
 function captureClassLevelAssumptionFailureData(plugin,eventData,instanceName)
 plugin.TestClassAssumptionFailureData{end+1} = struct(...
 'InstanceName', instanceName, ...
 'ActualValue' , eventData.ActualValue, ...
 'Constraint' , eventData.Constraint, ...
 'Stack' , eventData.Stack);
 end
 end
end
```

- “Write Plugins to Extend TestRunner”
- “Create Custom Plugin”

**Introduced in R2014a**

# createTestMethodInstance

**Class:** matlab.unittest.plugins.TestRunnerPlugin

**Package:** matlab.unittest.plugins

Extend creation of method-level `TestCase` instances

## Syntax

```
tc = createTestMethodInstance(plugin,pluginData)
```

## Description

`tc = createTestMethodInstance(plugin,pluginData)` extends the creation of method-level `TestCase` instances, and returns the modified `TestCase` instance, `tc`. The test framework evaluates this method within the scope of the `runTest` method of the `TestRunnerPlugin`. A typical implementation of this method is to add listeners to various events originating from the method level instance. Since the `TestCase` inherits from the `handle` class, add listeners by calling the `addlistener` method from within the `createTestMethodInstance` method. The test framework creates instances for every element of the `matlab.unittest.Test` array and passes each instance to its corresponding `Test` methods and to any method with the `TestMethodSetup` or `TestMethodTeardown` attribute.

## Input Arguments

### **plugin**

Instance of `matlab.unittest.plugins.TestRunnerPlugin`.

### **pluginData**

Method-level `TestCase` creation information, specified as an instance of `matlab.unittest.plugins.pluginData.PluginData`. The test framework uses this information to introspect into the test content.

## Examples

### Implement createMethodInstance Method

Add a listener to listen for assumption failures. Use the helper function, `captureMethodLevelAssumptionFailureData`, to populate the `TestMethodAssumptionFailureData` property.

```
classdef ExamplePlugin < matlab.unittest.plugins.TestRunnerPlugin

 properties (SetAccess = private)
 TestMethodAssumptionFailureData = {};
 end

 methods (Access = protected)
 function testCase = createTestMethodInstance(plugin, pluginData)
 testCase = createTestMethodInstance@...
 matlab.unittest.plugins.TestRunnerPlugin(plugin, pluginData);

 instanceName = pluginData.Name;
 testCase.addlistener('AssumptionFailed', @(~,evd) ...
 plugin.captureMethodLevelAssumptionFailureData(evd,instanceName))
 end
 end

 methods (Access = private)
 function captureMethodLevelAssumptionFailureData(...
 plugin, eventData, instanceName)
 plugin.TestMethodAssumptionFailureData{end+1} = struct(...
 'InstanceName', instanceName, ...
 'ActualValue' , eventData.ActualValue, ...
 'Constraint' , eventData.Constraint, ...
 'Stack' , eventData.Stack);
 end
 end
end
```

**Introduced in R2014a**

# reportFinalizedResult

**Class:** matlab.unittest.plugins.TestRunnerPlugin

**Package:** matlab.unittest.plugins

Enable reporting of finalized TestResults

A plugin that overrides the `reportFinalizedResult` method is recommended for streaming or inline reporting of test results. If you implement this method, the test runner reports the results as soon as they are finalized. The plugin can then report test results while the test runner is still running the test suite, rather than waiting until the entire test suite is complete.

## Syntax

```
reportFinalizedResult(plugin,pluginData)
```

## Description

`reportFinalizedResult(plugin,pluginData)` enables the reporting of finalized TestResults. The test runner uses this method to report finalized test results to the plugin. By overriding the method in your `TestRunnerPlugin` class, you can report information about each test result as soon as the test runner determines the test is finalized.

The test framework evaluates this method as soon as it can guarantee that the test result is finalized for a test suite element. It can evaluate this method within the scope of the `runTestSuite`, `runTestClass`, or `runTest` methods of the `TestRunnerPlugin`.

## Input Arguments

**plugin** — plugin instance

```
matlab.unittest.plugins.TestRunnerPlugin
```

Plugin instance, specified as an instance of the `matlab.unittest.plugins.TestRunnerPlugin` class.

**pluginData — Finalized test information**

`matlab.unittest.plugins.pluginData.FinalizedResultPluginData`

Finalized test information, specified as an instance of the `matlab.unittest.plugins.pluginData.FinalizedResultPluginData` class. The test framework uses this information to describe the test content to the plugin.

## Definitions

### Finalized Test Results

A test result is finalized when no remaining test content can modify the results. Examples of when the test runner might modify previously run test results include when it executes code inside of `TestClassTeardown` methods, or when it tears down shared test fixtures.

## Examples

### Display Status of Each Finalized Test Element

Use the `reportFinalizedResult` method to display the status of each test element.

Create the following plugin in a file, `ExamplePlugin.m`, in your current working folder.

```
classdef ExamplePlugin < matlab.unittest.plugins.TestRunnerPlugin
 methods (Access = protected)
 function reportFinalizedResult(plugin, pluginData)
 thisResult = pluginData.TestResult;
 if thisResult.Passed
 status = 'PASSED';
 elseif thisResult.Failed
 status = 'FAILED';
 elseif thisResult.Incomplete
 status = 'SKIPPED';
 end
 fprintf('%s: %s in %f seconds.\n',thisResult.Name,...
 status,thisResult.Duration)
 reportFinalizedResult@...
```

```
 matlab.unittest.plugins.TestRunnerPlugin(plugin,pluginData);
 end
end
end
```

Create the following test class in a file, `ExampleTest.m`, in your current working folder.

```
classdef ExampleTest < matlab.unittest.TestCase
 methods(Test)
 function testOne(testCase)
 testCase.assertGreaterThan(5,1)
 end
 function testTwo(testCase)
 wrongAnswer = 'wrong';
 testCase.verifyEmpty(wrongAnswer,'Not Empty')
 testCase.verifyClass(wrongAnswer,'double','Not double')
 end
 function testThree(testCase)
 testCase.assumeEqual(7*2,13,'Values not equal')
 end
 function testFour(testCase)
 testCase.verifyEqual(3+2,5);
 end
 end
end
```

At the command prompt, create a test suite, add the plugin to the test runner, and run the tests.

```
import matlab.unittest.TestSuite
import matlab.unittest.TestRunner

suite = TestSuite.fromClass(?ExampleTest);
runner = TestRunner.withNoPlugins;
runner.addPlugin(ExamplePlugin)
result = runner.run(suite);

ExampleTest/testOne: PASSED in 0.002216 seconds.
ExampleTest/testTwo: FAILED in 0.006105 seconds.
ExampleTest/testThree: SKIPPED in 0.007458 seconds.
ExampleTest/testFour: PASSED in 0.004865 seconds.
```

`matlab.unittest.plugins.plugindata.FinalizedResultPluginData`

**Introduced in R2015b**

## runTest

**Class:** matlab.unittest.plugins.TestRunnerPlugin

**Package:** matlab.unittest.plugins

Extend running of single TestSuite element

## Syntax

`runTest(plugin,pluginData)`

## Description

`runTest(plugin,pluginData)` extends the running of a single `TestSuite` element. This method allows the test author to override the method that runs a scalar test element in the `TestSuite` array, including the creation of the `TestCase`, and the `TestMethodSetup` and `TestMethodTeardown` routines. Provided the test framework completes all fixture setup, it invokes this method one time per test element.

## Input Arguments

### **plugin**

Instance of `matlab.unittest.plugins.TestRunnerPlugin`.

### **pluginData**

Test element information, specified as an instance of `matlab.unittest.plugins.plugindata.TestSuiteRunPluginData`. The test framework uses this information to introspect into the test content.

## Examples

### **Extend runTest method**

Print the label of the test content element at run time.

```
classdef ExamplePlugin < matlab.unittest.plugins.TestRunnerPlugin
 methods (Access = protected)
 function runTest(plugin, pluginData)
 fprintf('### Running test: %s\n', pluginData.Name)
 runTest@matlab.unittest.plugins.TestRunnerPlugin(...
 plugin, pluginData);
 end
 end
end
```

## runTestClass

**Class:** matlab.unittest.plugins.TestRunnerPlugin

**Package:** matlab.unittest.plugins

Extend running of TestSuite array from same class or function

### Syntax

```
runTestClass(plugin,pluginData)
```

### Description

`runTestClass(plugin,pluginData)` extends the running of tests that belong to the same test class, function, or script. This method applies to a subset of the full `TestSuite` being run by the `TestRunner`. The test framework evaluates this method within the scope of the `runTestSuite` method of the `TestRunnerPlugin`. It evaluates this method between setting up and tearing down the shared test fixture (`setupSharedTestFixture` and `teardownSharedTestFixture`). Provided the test framework completes shared test fixture setup, it invokes this method one time per test class.

### Input Arguments

#### **plugin**

Instance of `matlab.unittest.plugins.TestRunnerPlugin`.

#### **pluginData**

Test suite information, specified as an instance of `matlab.unittest.plugins.pluginData.TestSuiteRunPluginData`. The test framework uses this information to introspect into the test content.

## Examples

### Extend runTestClass method

Print the label of the test content element at run time.

```
classdef ExamplePlugin < matlab.unittest.plugins.TestRunnerPlugin
 methods (Access = protected)
 function runTestClass(plugin, pluginData)
 fprintf('### Running test class: %s\n', pluginData.Name)

 runTestClass@matlab.unittest.plugins.TestRunnerPlugin(...
 plugin, pluginData);
 end
 end
end
```

## runTestSuite

**Class:** matlab.unittest.plugins.TestRunnerPlugin

**Package:** matlab.unittest.plugins

Extend running of TestSuite array

## Syntax

```
runTestSuite(plugin,pluginData)
```

## Description

`runTestSuite(plugin,pluginData)` extends the running of the original `TestSuite` array that the test framework hands to the `TestRunner`.

## Input Arguments

### **plugin**

Instance of `matlab.unittest.plugins.TestRunnerPlugin`.

### **pluginData**

Test suite information, specified as an instance of `matlab.unittest.plugins.plugindata.TestSuiteRunPluginData`. The test framework uses this information to introspect into the test content.

## Examples

### Implement runTestSuite Method

```
classdef ExamplePlugin < matlab.unittest.plugins.TestRunnerPlugin
 methods (Access = protected)
 function runTestSuite(plugin, pluginData)
```

```
 % Introspect into pluginData to get TestSuite size
 suiteSize = numel(pluginData.TestSuite);
 fprintf('### Running a total of %d tests\n', suiteSize)

 % Invoke the super class method
 runTestSuite@matlab.unittest.plugins.TestRunnerPlugin(plugin, pluginData)
 end
end
end
```

## runTestMethod

**Class:** matlab.unittest.plugins.TestRunnerPlugin

**Package:** matlab.unittest.plugins

Extend running of single Test method

### Syntax

```
runTestMethod(plugin,pluginData)
```

### Description

`runTestMethod(plugin,pluginData)` extends the running of a single `Test` method. The test framework evaluates this method within the scope of the `runTest` method of the `TestRunnerPlugin`. It evaluates this method between setting up and tearing down the scalar `TestSuite` element (`setupTestMethod` and `teardownTestMethod`).

### Input Arguments

#### **plugin**

Instance of `matlab.unittest.plugins.TestRunnerPlugin`.

#### **pluginData**

Test method information, specified as an instance of `matlab.unittest.plugins.plugindata.TestSuiteRunPluginData`. The test framework uses this information to introspect into the test content.

### Examples

#### **Extend runTestMethod method**

Print the time taken to evaluate the test method.

```
classdef ExamplePlugin < matlab.unittest.plugins.TestRunnerPlugin
 methods (Access = protected)
 function runTestMethod(plugin, pluginData)
 tic

 runTestMethod@matlab.unittest.plugins.TestRunnerPlugin(...
 plugin, pluginData);

 fprintf('### %s ran in %f seconds excluding fixture time.',...
 pluginData.Name, toc)
 end
 end
end
```

# setupSharedTestFixture

**Class:** matlab.unittest.plugins.TestRunnerPlugin

**Package:** matlab.unittest.plugins

Extend setting up shared test fixture

## Syntax

setupSharedTestFixture(plugin,pluginData)

## Description

setupSharedTestFixture(plugin,pluginData) extends the setting up of a shared test fixture. This method defines how the TestRunner performs shared fixture setup. The test framework evaluates this method one time for each shared test fixture, within the scope of the runTestSuite method of the TestRunnerPlugin.

## Input Arguments

### plugin

Instance of matlab.unittest.plugins.TestRunnerPlugin.

### pluginData

Shared test fixture setup information, specified as an instance of matlab.unittest.plugins.pluginData.SharedTestFixturePluginData. The test framework uses this information to introspect into the test content.

## Examples

### Implement setupSharedTestFixture Method

Display the shared test fixture name at setup time.

```
classdef ExamplePlugin < matlab.unittest.plugins.TestRunnerPlugin

 methods (Access = protected)
 function setupSharedTestFixture(plugin, pluginData)
 fprintf('### Setting up: %s\n', pluginData.Name)
 setupSharedTestFixture@matlab.unittest.plugins.TestRunnerPlugin...
 (plugin, pluginData);
 end
 end
end
```

## setupTestClass

**Class:** matlab.unittest.plugins.TestRunnerPlugin

**Package:** matlab.unittest.plugins

Extend setting up test class

### Syntax

```
setupTestClass(plugin,pluginData)
```

### Description

`setupTestClass(plugin,pluginData)` extends the setting up of a test class. This method defines how the `TestRunner` performs test class setup. The test framework evaluates this method within the scope of the `runTestClass` method of the `TestRunnerPlugin`. If the test class contains properties with the `ClassSetupParameter` attribute, the test framework evaluates the `setupTestClass` method as many times as the class setup parameterization dictates.

### Input Arguments

#### **plugin**

Instance of `matlab.unittest.plugins.TestRunnerPlugin`.

#### **pluginData**

Test class setup information, specified as an instance of `matlab.unittest.plugins.pluginData.ImplicitFixturePluginData`. The test framework uses this information to introspect into the test content.

### Examples

#### **Implement setupTestClass Method**

Display the test class name at setup time.

```
classdef ExamplePlugin < matlab.unittest.plugins.TestRunnerPlugin

 methods (Access = protected)
 function setupTestClass(plugin, pluginData)
 fprintf('### Setting up: %s\n', pluginData.Name)
 setupTestClass@matlab.unittest.plugins.TestRunnerPlugin...
 (plugin, pluginData);
 end
 end
end
```

## setupTestMethod

**Class:** matlab.unittest.plugins.TestRunnerPlugin

**Package:** matlab.unittest.plugins

Extend setting up of test method

### Syntax

```
setupTestMethod(plugin,pluginData)
```

### Description

`setupTestMethod(plugin,pluginData)` extends the setting up of a test method. This method defines how the `TestRunner` performs test method setup for the single test suite element. The test framework evaluates this method within the scope of the `runTest` method of the `TestRunnerPlugin`.

### Input Arguments

#### **plugin**

Instance of `matlab.unittest.plugins.TestRunnerPlugin`.

#### **pluginData**

Test method setup information, specified as an instance of `matlab.unittest.plugins.pluginData.ImplicitFixturePluginData`. The test framework uses this information to introspect into the test content.

### Examples

#### Implement `setupTestMethod`

```
classdef ExamplePlugin < matlab.unittest.plugins.TestRunnerPlugin
```

```
methods (Access = protected)
 function setupTestMethod(plugin, pluginData)
 fprintf('### Setting up: %s\n', pluginData.Name)
 setupTestMethod@matlab.unittest.plugins.TestRunnerPlugin...
 (plugin, pluginData);
 end
end
end
```

# teardownSharedTestFixture

**Class:** matlab.unittest.plugins.TestRunnerPlugin

**Package:** matlab.unittest.plugins

Extend tearing down shared test fixture

## Syntax

teardownSharedTestFixture(plugin,pluginData)

## Description

teardownSharedTestFixture(plugin,pluginData) extends the tearing down of a shared test fixture. This method defines how the TestRunner performs shared fixture teardown. The test framework evaluates this method one time for each shared test fixture, within the scope of the runTestSuite method of the TestRunnerPlugin.

## Input Arguments

### plugin

Instance of matlab.unittest.plugins.TestRunnerPlugin.

### pluginData

Shared test fixture teardown information, specified as an instance of matlab.unittest.plugins.pluginData.SharedTestFixturePluginData. The test framework uses this information to introspect into the test content.

## Examples

### Implement teardownSharedTestFixture Method

Display the shared test fixture name at teardown time.

```
classdef ExamplePlugin < matlab.unittest.plugins.TestRunnerPlugin

 methods (Access = protected)
 function teardownSharedTestFixture(plugin, pluginData)
 fprintf('### Setting up: %s\n', pluginData.Name)
 teardownSharedTestFixture@matlab.unittest.plugins.TestRunnerPlugin...
 (plugin, pluginData);
 end
 end
end
```

## teardownTestClass

**Class:** matlab.unittest.plugins.TestRunnerPlugin

**Package:** matlab.unittest.plugins

Extend tearing down of test class

### Syntax

teardownTestClass(plugin,pluginData)

### Description

teardownTestClass(plugin,pluginData) extends the tearing down of a test class. This method defines how the `TestRunner` performs test class teardown. The test framework evaluates this method within the scope of the `runTestClass` method of the `TestRunnerPlugin`. If the test class contains properties with the `ClassSetupParameter` attribute, the test framework evaluates the `teardownTestClass` method as many times as the class setup parameterization dictates.

### Input Arguments

#### plugin

Instance of `matlab.unittest.plugins.TestRunnerPlugin`.

#### pluginData

Test class teardown information, specified as an instance of `matlab.unittest.plugins.pluginData.ImplicitFixturePluginData`. The test framework uses this information to introspect into the test content.

## Examples

### Implement `teardownTestClass` Method

Display the test class name at teardown time.

```
classdef ExamplePlugin < matlab.unittest.plugins.TestRunnerPlugin

 methods (Access = protected)
 function teardownTestClass(plugin, pluginData)
 fprintf('### Tearing down: %s\n', pluginData.Name)
 teardownTestClass@matlab.unittest.plugins.TestRunnerPlugin...
 (plugin, pluginData);
 end
 end
end
```

# teardownTestMethod

**Class:** matlab.unittest.plugins.TestRunnerPlugin

**Package:** matlab.unittest.plugins

Extend tearing down of test method

## Syntax

`teardownTestMethod(plugin,pluginData)`

## Description

`teardownTestMethod(plugin,pluginData)` extends the tearing down of a test method. This method defines how the `TestRunner` performs test method teardown for the single test suite element. The test framework evaluates this method within the scope of the `runTest` method of the `TestRunnerPlugin`.

## Input Arguments

### **plugin**

Instance of `matlab.unittest.plugins.TestRunnerPlugin`.

### **pluginData**

Test method teardown information, specified as an instance of `matlab.unittest.plugins.pluginData.ImplicitFixturePluginData`. The test framework uses this information to introspect into the test content.

## Examples

### **Implement teardownTestMethod Method**

Display the test method name at teardown time.

```
classdef ExamplePlugin < matlab.unittest.plugins.TestRunnerPlugin
 methods (Access = protected)
 function teardownTestMethod(plugin, pluginData)
 fprintf('### Tearing down: %s\n', pluginData.Name)
 teardownTestMethod@matlab.unittest.plugins.TestRunnerPlugin...
 (plugin, pluginData);
 end
 end
end
```

# matlab.unittest.plugins.TestRunProgressPlugin class

**Package:** matlab.unittest.plugins

Plugin that reports test run progress

## Description

The `TestRunProgressPlugin` creates a plugin that reports on test run progress.

## Construction

`matlab.unittest.plugins.TestRunProgressPlugin.withVerbosity(v)` constructs a `TestRunProgressPlugin` for the specified verbosity.

`matlab.unittest.plugins.TestRunProgressPlugin.withVerbosity(v, stream)` redirects the text output to the output stream.

## Input Arguments

**v** — Verbosity level

1 | 2 | 3 | 4 | `matlab.unittest.Verbosity` enumeration

Verbosity level, specified as an integer value between 1 and 4 or a `matlab.unittest.Verbosity` enumeration object. Integer values correspond to the members of the `matlab.unittest.Verbosity` enumeration.

Numeric Representation	Corresponding Enumeration Object	Verbosity Description
1	<code>matlab.unittest.Verbosity.Ter</code>	Minimal amount of information
2	<code>matlab.unittest.Verbosity.Con</code>	Typical amount of information
3	<code>matlab.unittest.Verbosity.Det</code>	Supplemental amount of information
4	<code>matlab.unittest.Verbosity.Ver</code>	Surplus of information

**stream — Location where plugin directs text output**

ToStandardOutput instance (default) | OutputStream instance

Location where the plugin directs text output, specified as an `OutputStream` instance. By default, the plugin uses the `OutputStream` subclass `ToStandardOutput` as the stream.

## Copy Semantics

Handle. To learn how handle classes affect copy operations, see [Copying Objects in the MATLAB documentation](#).

## Examples

### Create Test Run Progress Plugin

Create a function-based test called `cylinderPlotTest` in a file in your working folder.

```
function tests = cylinderPlotTest
tests = functiontests(localfunctions);
end

function setupOnce(testCase)
testCase.TestData.Figure = figure;
addTeardown(testCase,@close,testCase.TestData.Figure)
end

function setup(testCase)
testCase.TestData.Axes = axes('Parent',testCase.TestData.Figure);
addTeardown(testCase,@clf,testCase.TestData.Figure)
cylinder(testCase.TestData.Axes,10)
end

function testXLim(testCase)
xlim = testCase.TestData.Axes.XLim;
verifyLessThanOrEqual(testCase,xlim(1),-10,'Minimum x-limit too large')
verifyGreaterThanOrEqual(testCase,xlim(2),10,'Maximum x-limit too small')
end

function zdataTest(testCase)
```

```
s = findobj(testCase.TestData.Axes, 'Type', 'surface');
verifyEqual(testCase, min(s.ZData(:)), 0, 'Min cylinder value is incorrect')
verifyEqual(testCase, max(s.ZData(:)), 1, 'Max cylinder value is incorrect')
end
```

At the command prompt, run the test.

```
results = run(cylinderPlotTest);
```

```
Running cylinderPlotTest
..
Done cylinderPlotTest
```

---

By default, the test runner uses verbosity level 2.

Create a test runner to report the diagnostics at level 1, and rerun the test.

```
import matlab.unittest.TestRunner
import matlab.unittest.plugins.TestRunProgressPlugin

runner = TestRunner.withNoPlugins;
p = TestRunProgressPlugin.withVerbosity(1);
runner.addPlugin(p);

results = runner.run(cylinderPlotTest);

..
```

Create a test runner to report the diagnostics at level 4, and rerun the test.

```
runner = TestRunner.withNoPlugins;
p = TestRunProgressPlugin.withVerbosity(4);
runner.addPlugin(p);

results = runner.run(cylinderPlotTest);

Running cylinderPlotTest
Setting up cylinderPlotTest
Evaluating TestClassSetup: setupOnce
Done setting up cylinderPlotTest in 0.067649 seconds
Running cylinderPlotTest/testXLim
Evaluating TestMethodSetup: setup
Evaluating Test: testXLim
Evaluating TestMethodTeardown: teardown
Evaluating addTeardown function: clf
```

```

Done cylinderPlotTest/testXLim in 0.053834 seconds
Running cylinderPlotTest/zdataTest
 Evaluating TestMethodSetup: setup
 Evaluating Test: zdataTest
 Evaluating TestMethodTeardown: teardown
 Evaluating addTeardown function: clf
Done cylinderPlotTest/zdataTest in 0.037715 seconds
Tearing down cylinderPlotTest
 Evaluating TestClassTeardown: teardownOnce
 Evaluating addTeardown function: close
Done tearing down cylinderPlotTest in 0.022783 seconds
Done cylinderPlotTest in 0.18198 seconds

```

### Configure Progress Message Output

Create a class named `ExampleProgressTest` in a file in your current working folder.

```

classdef ExampleProgressTest < matlab.unittest.TestCase
 methods(Test)
 function testOne(testCase) % Test fails
 testCase.verifyEqual(5,4)
 end
 function testTwo(testCase) % Test passes
 testCase.verifyEqual(5,5)
 end
 end
end
end

```

At the command prompt, create the test suite and a runner at verbosity level 3, and then run the test.

```

import matlab.unittest.TestSuite
import matlab.unittest.TestRunner
import matlab.unittest.plugins.TestRunProgressPlugin

suite = TestSuite.fromClass(?ExampleProgressTest);

runner = TestRunner.withNoPlugins;
p = TestRunProgressPlugin.withVerbosity(3);
runner.addPlugin(p);
results = runner.run(suite);

Running ExampleProgressTest
Setting up ExampleProgressTest

```

```
Done setting up ExampleProgressTest in 0 seconds
Running ExampleProgressTest/testOne
Done ExampleProgressTest/testOne in 0.0049988 seconds
Running ExampleProgressTest/testTwo
Done ExampleProgressTest/testTwo in 0.0044541 seconds
Tearing down ExampleProgressTest
Done tearing down ExampleProgressTest in 0 seconds
Done ExampleProgressTest in 0.0094529 seconds
```

---

Create a new plugin to direct the output to a file named `myOutput.log`, and rerun the tests.

```
import matlab.unittest.plugins.ToFile
outFile = 'myOutput.log';

runner = TestRunner.withNoPlugins;
p = TestRunProgressPlugin.withVerbosity(3,ToFile(outFile));
runner.addPlugin(p);

results = runner.run(suite);
```

Observe the contents of the file created by the plugin.

```
disp(fileread(outFile))

Running ExampleProgressTest
Setting up ExampleProgressTest
Done setting up ExampleProgressTest in 0 seconds
Running ExampleProgressTest/testOne
Done ExampleProgressTest/testOne in 0.0050172 seconds
Running ExampleProgressTest/testTwo
Done ExampleProgressTest/testTwo in 0.0049449 seconds
Tearing down ExampleProgressTest
Done tearing down ExampleProgressTest in 0 seconds
Done ExampleProgressTest in 0.009962 seconds
```

---

**Introduced in R2014b**

# matlab.unittest.plugins.XMLPlugin class

**Package:** matlab.unittest.plugins

Plugin that writes test results in XML format

## Description

The XMLPlugin class creates a plugin that writes test results to a file in XML format.

## Construction

Instantiate an XMLPlugin using one of its static methods.

`matlab.unittest.plugins.XMLPlugin.producingJUnitFormat(xmlFile)` returns a plugin that produces JUnit-style XML output to the file, `xmlFile`. Using this plugin, you can integrate MATLAB Unit Test results into third-party systems that recognize the JUnit-style XML. For example, you can integrate test results with continuous integration systems like Jenkins, TeamCity, or Microsoft Team Foundation Server.

## Input Arguments

**xmlFile** — Name of test-result file

string

Name of the test-result file, specified as a string. If `xmlFile` exists, the test framework overwrites the file.

Example: `XMLPlugin.producingJUnitFormat('myTestResults.xml')`

## Copy Semantics

Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB documentation.

## Examples

### Output Results to JUnit-style XML File

Create `ExampleTest.m` containing the following test class.

```
classdef ExampleTest < matlab.unittest.TestCase
 methods(Test)
 function testOne(testCase) % Test fails
 testCase.verifyEqual(5,4,'Testing 5==4')
 end
 function testTwo(testCase) % Test passes
 testCase.verifyEqual(5,5,'Testing 5==5')
 end
 function testThree(testCase) % Test fails
 testCase.assertTrue(false)
 end
 end
end
```

Create a test suite from the `ExampleTest` class. Create a silent test runner.

```
import matlab.unittest.TestRunner
import matlab.unittest.TestSuite
import matlab.unittest.plugins.XMLPlugin

suite = TestSuite.fromClass(?ExampleTest);
runner = TestRunner.withNoPlugins;
```

Create an `XMLPlugin` that writes test results to the file `myTestResults.xml`.

```
xmlFile = 'myTestResults.xml';
p = XMLPlugin.producingJUnitFormat(xmlFile);
```

Add the plugin to the test runner and run the suite.

```
runner.addPlugin(p)
results = runner.run(suite);
table(results)
```

```
ans =
```

Name	Passed	Failed	Incomplete	Duration
------	--------	--------	------------	----------

```

'ExampleTest/testOne' false true false 0.030643
'ExampleTest/testTwo' true false false 0.004332
'ExampleTest/testThree' false false true 0.014325

```

View the contents in the file created by the plugin.

```
disp(fileread(xmlFile))
```

```

<?xml version="1.0" encoding="utf-8"?>
<testsuites>
 <testsuite errors="0" failures="1" name="" skipped="1" tests="3" time="0.0493">
 <testcase classname="ExampleTest" name="testOne" time="0.030643">
 <failure type="VerificationFailure">=====
Verification failed in ExampleTest/testOne.

Test Diagnostic:

Testing 5==4

Framework Diagnostic:

verifyEqual failed.
--> The values are not equal using "isequaln".
--> Failure table:
 Actual Expected Error RelativeError
 _____ _____ _____ _____
 5 4 1 0.25

Actual double:
 5
Expected double:
 4

Stack Information:

In C:\work\ExampleTest.m (ExampleTest.testOne) at 4
=====
</failure>
 </testcase>
<testcase classname="ExampleTest" name="testTwo" time="0.004332"/>

```

```
 <testcase classname="ExampleTest" name="testThree" time="0.014325">
 <skipped>=====
ExampleTest/testThree was filtered.
=====
 </skipped>
 </testcase>
</testsuite>
</testsuites>
```

## Tips

- If your test file is a script-based or function-based test, the value of the `classname` attribute of the `<testcase>` element is the test file name.

# matlab.unittest.plugins.plugindata

Summary of classes in MATLAB Plugin Data Interface

## Description

The `plugindata` classes store information about test content for use by the plugins and plugin methods. The `TestRunner` passes instances of these classes to various plugin methods. The `matlab.unittest.plugins.plugindata` package consists of the following MATLAB plugin data classes.

<code>matlab.unittest.plugins.plugindata.FinalizedResultPluginData</code>	Plugin data containing finalized test result information
<code>matlab.unittest.plugins.plugindata.ImplicitFixturePluginData</code>	Plugin data containing test setup and teardown information

# matlab.unittest.plugins.plugindata.FinalizedResultPluginData class

**Package:** matlab.unittest.plugins.plugindata

Plugin data containing finalized test result information

## Description

The `FinalizedResultPluginData` class defines the data the `TestRunner` passes to plugin methods related to finalized test results. The `TestRunner` creates this class, so there is no need for test plugin authors to construct the class directly.

## Properties

### **Index** — Location of result relative to entire suite

scalar numeric

Location of the finalized result relative to the entire suite, represented as a scalar numeric.

### **TestResult** — Result from finalized test suite element

matlab.unittest.TestResult scalar

Result from the finalized test suite element, represented as a `matlab.unittest.TestResult` scalar.

## See Also

# matlab.unittest.plugins.plugindata.ImplicitFixturePluginData class

**Package:** matlab.unittest.plugins.plugindata

Plugin data containing test setup and teardown information

## Description

The `ImplicitFixturePluginData` class defines the data the `TestRunner` passes to plugin methods related to setting up and tearing down tests. The `TestRunner` creates this class, so there is no need for test plugin authors to construct this class directly.

## Properties

**Name** — Label of test content test runner sets up or tears down

string

Label of test content test runner sets up or tears down, represented as a string. Use the `Name` property for informational, labeling, and display purposes. Do not use `Name` programmatically to introspect into the content.

Data Types: char

**QualificationContext** — Context for plugins to perform qualifications on test content

matlab.unittest.plugins.plugindata.QualificationContext

Context for plugins to perform qualifications on test content, represented as an instance of `matlab.unittest.plugins.plugindata.QualificationContext`. For your plugin to use qualifications it must be a subclass of `matlab.unittest.plugins.QualifyingPlugin` and provide this context in the call to one of its qualifications methods.

# matlab.unittest.plugins.plugindata.PluginData class

**Package:** matlab.unittest.plugins.plugindata

Data object passed to TestRunnerPlugin methods

## Description

The `PluginData` class defines the data the `TestRunner` passes to various plugin methods. It is created by the `TestRunner`, so there is no need for test plugin authors to construct this class directly.

## Properties

### Name

Label of test content executed by the test runner within the scope of a plugin method, represented as a string. Use the `Name` property for informational, labeling, and display purposes. Do not use `Name` programmatically to introspect into the content.

### See Also

# matlab.unittest.plugins.plugindata.SharedTestFixturePluginData class

**Package:** matlab.unittest.plugins.plugindata

Plugin data containing shared test fixture information

## Description

The `SharedTestFixturePluginData` defines the data the `TestRunner` passes to plugin methods related to shared test fixtures. The `TestRunner` creates this, so there is no need for test plugin authors to construct this class directly.

## Properties

### Name

Label of shared test fixture, represented as a string. Use the `Name` property for informational, labeling, and display purposes. Do not use `Name` programmatically to introspect into the content.

### Description

Description of action performed during setup and teardown of a shared text fixture, represented as a string

### QualificationContext

Context for plugins to perform qualifications on fixtures, represented as an instance of `matlab.unittest.plugins.plugindata.QualificationContext`. For your plugin to use qualifications it must be a subclass of `matlab.unittest.plugins.QualifyingPlugin` and provide this context in the call to one of its qualifications methods.

# matlab.unittest.plugins.plugindata.TestSuiteRunPluginData class

**Package:** matlab.unittest.plugins.plugindata

Plugin data containing selected test information

## Description

The `TestSuiteRunPluginData` defines the data the `TestRunner` passes to plugin methods related to running tests from the suite. The `TestRunner` creates this, so there is no need for test plugin authors to construct this class directly.

## Properties

### Name

Name corresponding to the portion of the test suite the runner executes within a plugin method, represented as a string. Use the `Name` property for informational, labeling, and display purposes. Do not use `Name` programmatically to introspect into the content.

### TestSuite

Select test methods, represented as a `matlab.unittest.TestSuite` instance

### TestResult

Results from running select test methods listed in `TestSuite`, represented as a `matlab.unittest.TestResult` array

## plus, +

Addition

### Syntax

```
C = A + B
C = plus(A,B)
```

### Description

`C = A + B` adds arrays `A` and `B` and returns the result in `C`.

`C = plus(A,B)` is an alternate way to execute `A + B`, but is rarely used. It enables operator overloading for classes.

### Examples

#### Add Scalar to Array

Create an array, `A`, and add a scalar value to it.

```
A = [0 1; 1 0];
C = A + 2
```

```
C =
```

```
 2 3
 3 2
```

The scalar value is added to each entry of `A`.

#### Add Two Arrays

Create two arrays, `A` and `B`, and add them together.

```
A = [1 0; 2 4];
B = [5 9; 2 1];
```

$$C = A + B$$
$$C =$$
$$\begin{array}{cc} 6 & 9 \\ 4 & 5 \end{array}$$

The elements of **A** are added to the corresponding elements of **B**.

## Input Arguments

### **A** — Input array

scalar | vector | matrix | multidimensional array

Input array, specified as a scalar, vector, matrix, or multidimensional array. **A** can be a numeric array, logical array, character array, datetime array, duration array, or calendar duration array. Inputs **A** and **B** must be the same size unless one is a scalar. You can add a scalar value to any other value.

If one input is a datetime array, duration array, or calendar duration array, then numeric values in the other input are treated as a number of 24-hour days.

Complex Number Support: Yes

### **B** — Input array

scalar | vector | matrix | multidimensional array

Input array, specified as a scalar, vector, matrix, or multidimensional array. **B** can be a numeric array, logical array, character array, datetime array, duration array, or calendar duration array. Inputs **A** and **B** must be the same size unless one is a scalar. You can add a scalar value to any other value.

If one input is a datetime array, duration array, or calendar duration array, then numeric values in the other input are treated as a number of 24-hour days.

Complex Number Support: Yes

# pointLocation

**Class:** DelaunayTri

(Not recommended) Simplex containing specified location

---

**Note:** `pointLocation(DelaunayTri)` is not recommended. Use `pointLocation(triangulation)` instead.

`DelaunayTri` is not recommended. Use `delaunayTriangulation` instead.

---

## Syntax

```
SI = pointLocation(DT,QX)
SI = pointLocation(DT,QX,QY)
SI = pointLocation(DT,QX,QY,QZ)
[SI, BC] = pointLocation(DT,...)
```

## Description

`SI = pointLocation(DT,QX)` returns the indices `SI` of the enclosing simplex (triangle/tetrahedron) for each query point location in `QX`. The enclosing simplex for `pointLocation(QX(k,:), :)` is `SI(k)`. `pointLocation` returns `NaN` for all points outside the convex hull.

`SI = pointLocation(DT,QX,QY)` and `SI = pointLocation(DT,QX,QY,QZ)` allow the query point locations to be specified in alternative column vector format when working in 2-D and 3-D.

`[SI, BC] = pointLocation(DT,...)` returns the barycentric coordinates `BC`.

## Input Arguments

`DT`                      Delaunay triangulation.

**QX** Matrix of size `mpts-by-ndim`, `mpts` being the number of query points.

## Output Arguments

**SI** Column vector of length `mpts` containing the indices of the enclosing simplex for each query point. `mpts` is the number of query points.

**BC** `BC` is a `mpts-by-ndim` matrix, each row `BC(i,:)` represents the barycentric coordinates of `QX(i,:)` with respect to the enclosing simplex `SI(i)`.

## Examples

### Example 1

Create a 2-D Delaunay triangulation:

```
X = rand(10,2);
dt = DelaunayTri(X);
```

Find the triangles that contain specified query points:

```
qrypts = [0.25 0.25; 0.5 0.5];
triids = pointLocation(dt, qrypts)
```

### Example 2

Create a 3-D Delaunay triangulation:

```
x = rand(10,1);
y = rand(10,1);
z = rand(10,1);
dt = DelaunayTri(x,y,z);
```

Find the triangles that contain specified query points and evaluate the barycentric coordinates:

```
qrypts = [0.25 0.25 0.25; 0.5 0.5 0.5];
```

```
[tetids, bcs] = pointLocation(dt, qrypts)
```

### **See Also**

## pol2cart

Transform polar or cylindrical coordinates to Cartesian

### Syntax

```
[X,Y] = pol2cart(THETA,RHO)
[X,Y,Z] = pol2cart(THETA,RHO,Z)
```

### Description

`[X,Y] = pol2cart(THETA,RHO)` transforms the polar coordinate data stored in corresponding elements of `THETA` and `RHO` to two-dimensional Cartesian, or  $xy$ , coordinates. The arrays `THETA` and `RHO` must be the same size (or either can be scalar). The values in `THETA` must be in radians.

`[X,Y,Z] = pol2cart(THETA,RHO,Z)` transforms the cylindrical coordinate data stored in corresponding elements of `THETA`, `RHO`, and `Z` to three-dimensional Cartesian, or  $xyz$  coordinates. The arrays `THETA`, `RHO`, and `Z` must be the same size (or any can be scalar). The values in `THETA` must be in radians.

### More About

#### Algorithms

The mapping from polar and cylindrical coordinates to Cartesian coordinates is:

**Polar to Cartesian Mapping**

$$x = \text{rho} * \cos(\text{theta})$$
$$y = \text{rho} * \sin(\text{theta})$$

**Polar to Cartesian Mapping**

$$x = \text{rho} * \cos(\text{theta})$$
$$y = \text{rho} * \sin(\text{theta})$$
$$z = z$$

**See Also**

cart2pol | cart2sph | sph2cart

Introduced before R2006a

## polar

Polar coordinate plot

### Syntax

```
polar(theta,rho)
polar(theta,rho,LineStyle)
polar(axes_handle,...)
h = polar(...)
```

### Description

The `polar` function accepts polar coordinates, plots them in a Cartesian plane, and draws the polar grid on the plane.

`polar(theta,rho)` creates a polar coordinate plot of the angle `theta` versus the radius `rho`. `theta` is the angle from the  $x$ -axis to the radius vector specified in radians; `rho` is the length of the radius vector specified in dataspace units.

`polar(theta,rho,LineStyle)` `LineStyle` specifies the line type, plot symbol, and color for the lines drawn in the polar plot.

`polar(axes_handle,...)` plots into the axes with the handle `axes_handle` instead of into the current axes (`gca`).

`h = polar(...)` returns the handle of a line object in `h`.

### Examples

#### Simple Polar Plot

Create a simple polar plot using a dashed red line.

```
theta = 0:0.01:2*pi;
rho = sin(2*theta).*cos(2*theta);
```

```
figure
polar(theta,rho,'--r')
```

## More About

### Tips

Negative  $r$  values reflect through the origin, rotating by  $\pi$  (since  $(\theta, r)$  transforms to  $(r \cdot \cos(\theta), r \cdot \sin(\theta))$ ). If you want different behavior, you can

manipulate `r` prior to plotting. For example, you can make `r` equal to `max(0, r)` or `abs(r)`.

**Introduced before R2006a**

# poly

Characteristic polynomial or polynomial with specified roots

## Syntax

```
p = poly(r)
p = poly(A)
```

## Description

`p = poly(r)`, where `r` is a vector, returns the coefficients of the polynomial whose roots are the elements of `r`.

`p = poly(A)`, where `A` is an  $n$ -by- $n$  matrix, returns the  $n+1$  coefficients of the characteristic polynomial of the matrix,  $\det(\lambda I - A)$ .

## Examples

### Characteristic Polynomial from Eigenvalues

Calculate the eigenvalues of a matrix, `A`.

```
A = [1 8 -10; -4 2 4; -5 2 8]
```

```
A =
```

```
 1 8 -10
 -4 2 4
 -5 2 8
```

```
e = eig(A)
```

```
e =
```

```
11.6219 + 0.0000i
-0.3110 + 2.6704i
-0.3110 - 2.6704i
```

Since the eigenvalues in `e` are the roots of the characteristic polynomial of `A`, use `poly` to determine the characteristic polynomial from the values in `e`.

```
p = poly(e)
```

```
p =
1.0000 -11.0000 -0.0000 -84.0000
```

## Characteristic Polynomial of Matrix

Use `poly` to calculate the characteristic polynomial of a matrix, `A`.

```
A = [1 2 3; 4 5 6; 7 8 0]
```

```
A =
1 2 3
4 5 6
7 8 0
```

```
p = poly(A)
```

```
p =
1.0000 -6.0000 -72.0000 -27.0000
```

Calculate the roots of `p` using `roots`. The roots of the characteristic polynomial are the eigenvalues of matrix `A`.

```
r = roots(p)
```

```
r =
```

```
12.1229
-5.7345
-0.3884
```

## Input Arguments

### **r** — Polynomial roots

vector

Polynomial roots, specified as a vector.

Example: `poly([2 -3])`

Example: `poly([2 -2 3 -3])`

Example: `poly(roots(k))`

Example: `poly(eig(A))`

Data Types: `single` | `double`

Complex Number Support: Yes

### **A** — Input matrix

matrix

Input matrix.

Example: `poly([0 -1; 1 0])`

Data Types: `single` | `double`

Complex Number Support: Yes

## Output Arguments

### **p** — Polynomial coefficients

row vector

Polynomial coefficients, returned as a row vector.

- If the input is a square  $n$ -by- $n$  matrix,  $A$ , then  $p$  contains the coefficients for the characteristic polynomial of  $A$ .

- If the input is a vector of roots,  $r$ , then  $p$  contains the coefficients for the polynomial whose roots are in  $r$ .

In each case, the  $n+1$  coefficients in  $p$  describe the polynomial

$$p_1x^n + p_2x^{n-1} + \dots + p_nx + p_{n+1}.$$

## More About

### Tips

- For vectors,  $r = \text{roots}(p)$  and  $p = \text{poly}(r)$  are inverse functions of each other, up to roundoff error, ordering, and scaling.

### Algorithms

The algorithms employed for `poly` and `roots` illustrate an interesting aspect of the modern approach to eigenvalue computation. `poly(A)` generates the characteristic polynomial of  $A$ , and `roots(poly(A))` finds the roots of that polynomial, which are the eigenvalues of  $A$ . But both `poly` and `roots` use `eig`, which is based on similarity transformations. The classical approach, which characterizes eigenvalues as roots of the characteristic polynomial, is actually reversed.

If  $A$  is an  $n$ -by- $n$  matrix, `poly(A)` produces the coefficients  $p(1)$  through  $p(n+1)$ , with  $p(1) = 1$ , in

$$\det(\lambda I - A) = p_1\lambda^n + \dots + p_n\lambda + p_{n+1}.$$

The algorithm is

```
z = eig(A);
p = zeros(n+1,1);
p(1) = 1;
for j = 1:n
 p(2:j+1) = p(2:j+1) - z(j)*p(1:j);
end
```

This recursion is derived by expanding the product,

$$(\lambda - \lambda_1)(\lambda - \lambda_2)\dots(\lambda - \lambda_n).$$

It is possible to prove that `poly(A)` produces the coefficients in the characteristic polynomial of a matrix within roundoff error of `A`. This is true even if the eigenvalues of `A` are badly conditioned. The traditional algorithms for obtaining the characteristic polynomial do not use the eigenvalues, and do not have such satisfactory numerical properties.

- “Create and Evaluate Polynomials”

**Introduced before R2006a**

## polyarea

Area of polygon

### Syntax

```
A = polyarea(X,Y)
A = polyarea(X,Y,dim)
```

### Description

`A = polyarea(X,Y)` returns the area of the polygon specified by the vertices in the vectors `X` and `Y`.

If `X` and `Y` are matrices of the same size, then `polyarea` returns the area of polygons defined by the columns `X` and `Y`.

If `X` and `Y` are multidimensional arrays, `polyarea` returns the area of the polygons in the first nonsingleton dimension of `X` and `Y`.

`A = polyarea(X,Y,dim)` operates along the dimension specified by scalar `dim`.

### Examples

#### Find Area of Polygon

```
L = linspace(0,2.*pi,9);
xv = 1.2*cos(L)';
yv = 1.2*sin(L)';

xv = [xv ; xv(1)];
yv = [yv ; yv(1)];

A = polyarea(xv,yv)
```

```
A =
```

4.0729

```
plot(xv,yv);
title(['Area = ' num2str(A)])
axis image
```

# polyder

Polynomial differentiation

## Syntax

`k = polyder(p)`  
`k = polyder(a,b)`  
`[q,d] = polyder(a,b)`

## Description

`k = polyder(p)` returns the derivative of the polynomial represented by the coefficients in `p`,

$$k(x) = \frac{d}{dx} p(x).$$

`k = polyder(a,b)` returns the derivative of the product of the polynomials `a` and `b`,

$$k(x) = \frac{d}{dx} [a(x)b(x)].$$

`[q,d] = polyder(a,b)` returns the derivative of the quotient of the polynomials `a` and `b`,

$$\frac{q(x)}{d(x)} = \frac{d}{dx} \left[ \frac{a(x)}{b(x)} \right].$$

## Examples

### Differentiate Polynomial

Create a vector to represent the polynomial  $p(x) = 3x^5 - 2x^3 + x + 5$ .

`p = [3 0 -2 0 1 5];`

Use `polyder` to differentiate the polynomial. The result is  $q(x) = 15x^4 - 6x^2 + 1$ .

`q = polyder(p)`

`q =`

15      0      -6      0      1

### Differentiate Product of Polynomials

Create two vectors to represent the polynomials  $a(x) = x^4 - 2x^3 + 11$  and  $b(x) = x^2 - 10x + 15$ .

`a = [1 -2 0 0 11];`

`b = [1 -10 15];`

Use `polyder` to calculate

$$q(x) = \frac{d}{dx} [a(x)b(x)].$$

`q = polyder(a,b)`

`q =`

6      -60      140      -90      22      -110

The result is

$$q(x) = 6x^5 - 60x^4 + 140x^3 - 90x^2 + 22x - 110.$$

### Differentiate Quotient of Polynomials

Create two vectors to represent the polynomials in the quotient,

$$\frac{x^4 - 3x^2 - 1}{x + 4}.$$

```
p = [1 0 -3 -1];
v = [1 4];
```

Use `polyder` with two output arguments to calculate

$$\frac{q(x)}{d(x)} = \frac{d}{dx} \left[ \frac{p(x)}{v(x)} \right].$$

```
[q,d] = polyder(p,v)
```

```
q =
 2 12 0 -11
```

```
d =
 1 8 16
```

The result is

$$\frac{q(x)}{d(x)} = \frac{2x^3 + 12x^2 - 11}{x^2 + 8x + 16}.$$

## Input Arguments

### **p** — Polynomial coefficients

vector

Polynomial coefficients, specified as a vector. For example, the vector `[1 0 1]` represents the polynomial  $x^2 + 1$ , and the vector `[3.13 -2.21 5.99]` represents the polynomial  $3.13x^2 - 2.21x + 5.99$ .

For more information, see “Create and Evaluate Polynomials”.

Data Types: `single` | `double`

Complex Number Support: Yes

**a, b — Polynomial coefficients (as separate arguments)**

row vectors

Polynomial coefficients, specified as two separate arguments of row vectors.

For more information, see “Create and Evaluate Polynomials”.

Example: `polyder([1 0 -1],[10 2])`

Data Types: `single` | `double`

Complex Number Support: Yes

## Output Arguments

**k — Integrated polynomial coefficients**

row vector

Integrated polynomial coefficients, returned as a row vector.

**q — Numerator polynomial**

row vector

Numerator polynomial, returned as a row vector.

**d — Denominator polynomial**

row vector

Denominator polynomial, returned as a row vector.

## polyeig

Polynomial eigenvalue problem

### Syntax

```
e = polyeig(A0,A1,...,Ap)
[X,e] = polyeig(A0,A1,...,Ap)
[X,e,s] = polyeig(A0,A1,...,Ap)
```

### Description

`e = polyeig(A0,A1,...,Ap)` returns the eigenvalues for the polynomial eigenvalue problem of degree  $p$ .

`[X,e] = polyeig(A0,A1,...,Ap)` also returns matrix  $X$ , of size  $n$ -by- $n \cdot p$ , whose columns are the eigenvectors.

`[X,e,s] = polyeig(A0,A1,...,Ap)` additionally returns vector  $s$ , of length  $p \cdot n$ , containing condition numbers for the eigenvalues. At least one of  $A_0$  and  $A_p$  must be nonsingular. Large condition numbers imply that the problem is close to a problem with repeated eigenvalues.

### Examples

#### Quadratic Eigenvalue Problem with Mass, Damping, and Stiffness Matrices

Solve a quadratic eigenvalue problem involving a mass matrix  $M$ , damping matrix  $C$ , and stiffness matrix  $K$ . This quadratic eigenvalue problem arises from the equation of motion:

$$M \frac{d^2 y}{dt^2} + C \frac{dy}{dt} + Ky = f(t)$$

This equation applies to a broad range of oscillating systems, including a dynamic mass-spring system or RLC electronic network. The fundamental solution is  $y(t) = xe^{\lambda t}$ , so both  $\lambda$  and  $x$  must solve the quadratic eigenvalue problem (QEP),

$$(M\lambda^2 + C\lambda + K)x = 0$$

Create coefficient matrices  $M$ ,  $C$ , and  $K$  to represent a mass-spring system with four-degrees-of-freedom. The coefficient matrices are all symmetric and positive semidefinite, and  $M$  is a diagonal matrix.

```
M = diag([3 1 3 1])
C = [0.4 0 -0.3 0; 0 0 0 0; -0.3 0 0.5 -0.2; 0 0 -0.2 0.2]
K = [-7 2 4 0; 2 -4 2 0; 4 2 -9 3; 0 0 3 -3]
```

M =

```
 3 0 0 0
 0 1 0 0
 0 0 3 0
 0 0 0 1
```

C =

```
 0.4000 0 -0.3000 0
 0 0 0 0
-0.3000 0 0.5000 -0.2000
 0 0 -0.2000 0.2000
```

K =

```
-7 2 4 0
 2 -4 2 0
 4 2 -9 3
 0 0 3 -3
```

Solve the QEP for the eigenvalues, eigenvectors, and condition numbers using `polyeig`.

```
[X,e,s] = polyeig(K,C,M)
```

X =

0.0933
0.0977
0.0111
```

## Input Arguments

**A0, A1, . . . , Ap** — Square coefficient matrices (as separate arguments)  
matrices

Square coefficient matrices, specified as separate arguments. The matrices must all have the same order,  $n$ .

Data Types: `single` | `double`  
Complex Number Support: Yes

## Output Arguments

**e** — Eigenvalues  
vector

Eigenvalues, returned as a vector.

**X** — Eigenvectors  
matrix

Eigenvectors, returned in the columns of a matrix. The first eigenvector is  $X(:, 1)$ , the second is  $X(:, 2)$ , and so on.

**s** — Condition numbers  
vector

Condition numbers, returned as a vector. The condition numbers in **S** correspond to similarly located eigenvalues in **e**. Large condition numbers indicate that the problem is close to having repeated eigenvalues.

## More About

### Polynomial Eigenvalue Problem

The polynomial eigenvalue problem is a variant of the standard eigenvalue problem,  $Ax = \lambda x$ , but instead involves polynomials rather than linear terms.

As with the standard eigenvalue problem, the solution involves finding the eigenvalues and eigenvectors that satisfy the equation,

$$(A_0 + \lambda A_1 + \dots + \lambda^p A_p)x = 0,$$

where the polynomial degree,  $p$ , is a nonnegative integer, and  $A_0, A_1, \dots, A_p$  are square coefficient matrices of order  $n$ .

The most common form is the *quadratic* polynomial eigenvalue problem, which is

$$(A_2 \lambda^2 + A_1 \lambda + A_0)x = 0.$$

One major difference between the quadratic eigenvalue problem and the standard (or generalized) eigenvalue problem is that there can be up to  $2n$  eigenvalues with up to  $2n$  right and left eigenvectors. In cases where there are more than  $n$  eigenvectors, the eigenvectors do not form a linearly independent set. See [1] and [2] for more detailed information about the quadratic eigenvalue problem.

### Tips

- `polyeig` handles the following simplified cases:
  - $p = 0$ , or `polyeig(A)`, is the standard eigenvalue problem, `eig(A)`.
  - $p = 1$ , or `polyeig(A,B)`, is the generalized eigenvalue problem, `eig(A,-B)`.
  - $n = 0$ , or `polyeig(a0,a1,...,ap)`, is the standard polynomial problem, `roots([ap ... a1 a0])`, where `a0,a1,...,ap` are scalars.

### Algorithms

The `polyeig` function uses the QZ factorization to find intermediate results in the computation of generalized eigenvalues. `polyeig` uses the intermediate results to

determine if the eigenvalues are well-determined. See the descriptions of `eig` and `qz` for more information.

The computed solutions might not exist or be unique, and can also be computationally inaccurate. If both `A0` and `Ap` are singular matrices, then the problem might be ill-posed. If only one of `A0` and `Ap` is singular, then some of the eigenvalues might be `0` or `Inf`.

Scaling `A0, A1, . . . , Ap` to have `norm(Ai)` roughly equal to 1 might increase the accuracy of `polyeig`. In general, however, this improved accuracy is not achievable. (See Tisseur [3] for details).

# polyfit

Polynomial curve fitting

## Syntax

```
p = polyfit(x,y,n)
[p,S] = polyfit(x,y,n)
[p,S,mu] = polyfit(x,y,n)
```

## Description

`p = polyfit(x,y,n)` returns the coefficients for a polynomial  $p(x)$  of degree  $n$  that is a best fit (in a least-squares sense) for the data in  $y$ . The coefficients in  $p$  are in descending powers, and the length of  $p$  is  $n+1$

$$p(x) = p_1x^n + p_2x^{n-1} + \dots + p_nx + p_{n+1}.$$

`[p,S] = polyfit(x,y,n)` also returns a structure  $S$  that can be used as an input to `polyval` to obtain error estimates.

`[p,S,mu] = polyfit(x,y,n)` also returns  $\mu$ , which is a two-element vector with centering and scaling values.  $\mu(1)$  is `mean(x)`, and  $\mu(2)$  is `std(x)`. Using these values, `polyfit` centers  $x$  at zero and scales it to have unit standard deviation

$$\hat{x} = \frac{x - \bar{x}}{\sigma_x}.$$

This centering and scaling transformation improves the numerical properties of both the polynomial and the fitting algorithm.

## Examples

### Fit Polynomial to Trigonometric Function

Generate 10 points equally spaced along a sine curve in the interval  $[0, 4\pi]$ .

```
x = linspace(0,4*pi,10);
y = sin(x);
```

Use `polyfit` to fit a 7th-degree polynomial to the points.

```
p = polyfit(x,y,7);
```

Evaluate the polynomial on a finer grid and plot the results.

```
x1 = linspace(0,4*pi);
y1 = polyval(p,x1);
figure
plot(x,y, 'o')
hold on
plot(x1,y1)
hold off
```

### Fit Polynomial to Set of Points

Create a vector of 5 equally spaced points in the interval  $[0, 1]$ , and evaluate  $y(x) = (1+x)^{-1}$  at those points.

```
x = linspace(0,1,5);
y = 1./(1+x);
```

Fit a polynomial of degree 4 to the 5 points. In general, for  $n$  points, you can fit a polynomial of degree  $n-1$  to exactly pass through the points.

```
p = polyfit(x,y,4);
```

Evaluate the original function and the polynomial fit on a finer grid of points between 0 and 2.

```
x1 = linspace(0,2);
y1 = 1./(1+x1);
f1 = polyval(p,x1);
```

Plot the function values and the polynomial fit in the wider interval  $[0, 2]$ , with the points used to obtain the polynomial fit highlighted as circles. The polynomial fit is good in the original  $[0, 1]$  interval, but quickly diverges from the fitted function outside of that interval.

```
figure
plot(x,y,'o')
hold on
plot(x1,y1)
plot(x1,f1,'r--')
legend('y','y1','f1')
```

### Fit Polynomial to Error Function

First generate a vector of  $x$  points, equally spaced in the interval  $[0, 2.5]$ , and then evaluate  $\text{erf}(x)$  at those points.

```
x = (0:0.1:2.5)';
y = erf(x);
```

Determine the coefficients of the approximating polynomial of degree 6.

```
p = polyfit(x,y,6)
```

```
p =
```

```
0.0084 -0.0983 0.4217 -0.7435 0.1471 1.1064 0.0004
```

To see how good the fit is, evaluate the polynomial at the data points and generate a table showing the data, fit, and error.

```
f = polyval(p,x);
T = table(x,y,f,y-f, 'VariableNames', {'X', 'Y', 'Fit', 'FitError'})
```

```
T =
```

2.5	0.99959	0.99936	0.00023151

In this interval, the interpolated values and the actual values agree fairly closely. Create a plot to show how outside this interval, the extrapolated values quickly diverge from the actual data.

```
x1 = (0:0.1:5)';
y1 = erf(x1);
f1 = polyval(p,x1);
figure
plot(x,y, 'o')
hold on
plot(x1,y1, '- ')
plot(x1,f1, 'r-- ')
axis([0 5 0 2])
hold off
```

### Use Centering and Scaling to Improve Numerical Properties

Create a table of population data for the years 1750 - 2000 and plot the data points.

```
year = (1750:25:2000)';
pop = 1e6*[791 856 978 1050 1262 1544 1650 2532 6122 8170 11560]';
T = table(year, pop)
plot(year,pop,'o')
```

T =

year	pop
1750	791000
1775	856000
1800	978000
1825	1050000
1850	1262000
1875	1544000
1900	1650000
1925	2532000
1950	6122000
1975	8170000
2000	11560000

# 1 Alphabetical List

---

1750	7.91e+08
1775	8.56e+08
1800	9.78e+08
1825	1.05e+09
1850	1.262e+09
1875	1.544e+09
1900	1.65e+09
1925	2.532e+09
1950	6.122e+09
1975	8.17e+09
2000	1.156e+10

Use `polyfit` with three outputs to fit a 5th-degree polynomial using centering and scaling, which improves the numerical properties of the problem. `polyfit` centers the data in `year` at 0 and scales it to have a standard deviation of 1, which avoids an ill-conditioned Vandermonde matrix in the fit calculation.

```
[p,~,mu] = polyfit(T.year, T.pop, 5);
```

Use `polyval` with four inputs to evaluate `p` with the scaled years,  $(\text{year} - \mu(1)) / \mu(2)$ . Plot the results against the original years.

```
f = polyval(p,year,[],mu);
hold on
plot(year,f)
hold off
```

## Input Arguments

### **x** — Query points

vector

Query points, specified as a vector. The points in **x** correspond to the fitted function values contained in **y**.

Warning messages result when **x** has repeated (or nearly repeated) points or if **x** might need centering and scaling.

Data Types: `single` | `double`

Complex Number Support: Yes

### **y** — Fitted values at query points

vector

Fitted values at query points, specified as a vector. The values in **y** correspond to the query points contained in **x**.

Data Types: `single` | `double`

Complex Number Support: Yes

### **n** — Degree of polynomial fit

positive integer scalar

Degree of polynomial fit, specified as a positive integer scalar. **n** specifies the polynomial power of the left-most coefficient in **p**.

A warning message results if **n** is greater than or equal to `length(x)`.

## Output Arguments

### **p** — Least-squares fit polynomial coefficients

vector

Least-squares fit polynomial coefficients, returned as a vector. **p** has length  $n+1$  and contains the polynomial coefficients in descending powers with the highest power being **n**.

Use `polyval` to evaluate **p** at query points.

### **S** — Error estimation structure

structure

Error estimation structure. This optional output structure is primarily used as an input to the `polyval` function to obtain error estimates. **S** contains the following fields:

Field	Description
<b>R</b>	Triangular factor from a QR decomposition of the Vandermonde matrix of <b>x</b>
<b>df</b>	Degrees of freedom

Field	Description
normr	Norm of the residuals

If the data in `y` is random, then an estimate of the covariance matrix of `p` is  $(R_{inv} * R_{inv}') * normr^2 / df$ , where `Rinv` is the inverse of `R`.

If the errors in the data in `y` are independent and normal with constant variance, then `[y,delta] = polyval(...)` produces error bounds that contain at least 50% of the predictions. That is, `y ± delta` contains at least 50% of the predictions of future observations at `x`.

### **mu — Centering and scaling values**

two element vector

Centering and scaling values, returned as a two element vector. `mu(1)` is `mean(x)`, and `mu(2)` is `std(x)`. These values center the query points in `x` at zero with unit standard deviation.

Use `mu` as the fourth input to `polyval` to evaluate `p` at the scaled points,  $(x - mu(1)) / mu(2)$ .

## **Limitations**

- In problems with many points, increasing the degree of the polynomial fit using `polyfit` does not always result in a better fit. High-order polynomials can be oscillatory between the data points, leading to a *poorer* fit to the data. In those cases, you might use a low-order polynomial fit (which tends to be smoother between points) or a different technique, depending on the problem.
- Polynomials are unbounded, oscillatory functions by nature. Therefore, they are not well-suited to extrapolating bounded data or monotonic (increasing or decreasing) data.

## **More About**

### **Algorithms**

`polyfit` uses `x` to form Vandermonde matrix `V` with `n+1` columns, resulting in the linear system

$$\begin{pmatrix} x_1^{n+1} & x_1^n & \cdots & 1 \\ x_2^{n+1} & x_2^n & \cdots & 1 \\ \vdots & \vdots & \ddots & \vdots \\ x_n^{n+1} & x_n^n & \cdots & 1 \end{pmatrix} \begin{pmatrix} p_1 \\ p_2 \\ \vdots \\ p_n \end{pmatrix} = \begin{pmatrix} y_1 \\ y_2 \\ \vdots \\ y_n \end{pmatrix},$$

which `polyfit` solves with  $\mathbf{p} = \mathbf{V} \backslash \mathbf{y}$ . Since the columns in the Vandermonde matrix are powers of the vector  $\mathbf{x}$ , the condition number of  $\mathbf{V}$  is often large for high-order fits, resulting in a singular coefficient matrix. In those cases centering and scaling can improve the numerical properties of the system to produce a more reliable fit.

## polyint

Polynomial integration

### Syntax

```
q = polyint(p,k)
q = polyint(p)
```

### Description

`q = polyint(p,k)` returns the integral of the polynomial represented by the coefficients in `p` using a constant of integration `k`.

`q = polyint(p)` assumes a constant of integration `k = 0`.

### Examples

#### Integrate Quartic Polynomial

Evaluate

$$I = \int_{-1}^3 (3x^4 - 4x^2 + 10x - 25) dx$$

Create a vector to represent the polynomial  $3x^4 - 4x^2 + 10x - 25$ .

```
p = [3 0 -4 10 -25];
```

Use `polyint` to integrate the polynomial using a constant of integration equal to 0.

```
q = polyint(p)
```

```
q =
```

```
0.6000 0 -1.3333 5.0000 -25.0000 0
```

Find the value of the integral, I, by evaluating q at the limits of integration.

```
a = -1;
b = 3;
I = diff(polyval(q,[a b]))
```

I =

49.0667

### Integrate Product of Two Polynomials

Evaluate

$$I = \int_0^2 (x^5 - x^3 + 1)(x^2 + 1) dx$$

Create vectors to represent the polynomials  $p(x) = x^5 - x^3 + 1$  and  $v(x) = x^2 + 1$ .

```
p = [1 0 -1 0 0 1];
v = [1 0 1];
```

Multiply the polynomials and integrate the resulting expression using a constant of integration  $k = 3$ .

```
k = 3;
q = polyint(conv(p,v),k)
```

q =

Columns 1 through 7

0.1250          0          0          0      -0.2500      0.3333          0

Columns 8 through 9

1.0000      3.0000

Find the value of I by evaluating q at the limits of integration.

```
a = 0;
b = 2;
I = diff(polyval(q,[a b]))
```

I =

32.6667

- “Analytic Solution to Integral of Polynomial”

## Input Arguments

### **p** — Polynomial coefficients

vector

Polynomial coefficients, specified as a vector. For example, the vector [1 0 1] represents the polynomial  $x^2 + 1$ , and the vector [3.13 -2.21 5.99] represents the polynomial  $3.13x^2 - 2.21x + 5.99$ .

For more information, see “Create and Evaluate Polynomials”.

Data Types: `single` | `double`

Complex Number Support: Yes

### **k** — Constant of integration

numeric scalar

Constant of integration, specified as a numeric scalar.

Example: `polyint([1 0 0],3)`

Data Types: `single` | `double`

Complex Number Support: Yes

## Output Arguments

### **q** — Integrated polynomial coefficients

row vector

Integrated polynomial coefficients, returned as a row vector. For more information, see “Create and Evaluate Polynomials”.

## More About

# polyval

Polynomial evaluation

## Syntax

```
y = polyval(p,x)
[y,delta] = polyval(p,x,S)
y = polyval(p,x,[],mu)
[y,delta] = polyval(p,x,S,mu)
```

## Description

`y = polyval(p,x)` returns the value of a polynomial of degree  $n$  evaluated at  $x$ . The input argument `p` is a vector of length  $n+1$  whose elements are the coefficients in descending powers of the polynomial to be evaluated.

$$y = p_1x^n + p_2x^{n-1} + \dots + p_nx + p_{n+1}$$

`x` can be a matrix or a vector. In either case, `polyval` evaluates `p` at each element of `x`.

`[y,delta] = polyval(p,x,S)` uses the optional output structure `S` generated by `polyfit` to generate error estimates `delta`. `delta` is an estimate of the standard deviation of the error in predicting a future observation at  $x$  by  $p(x)$ . If the coefficients in `p` are least squares estimates computed by `polyfit`, and the errors in the data input to `polyfit` are independent, normal, and have constant variance, then `y±delta` contains at least 50% of the predictions of future observations at  $x$ .

`y = polyval(p,x,[],mu)` or `[y,delta] = polyval(p,x,S,mu)` use  $\hat{x} = (x - \mu_1) / \mu_2$  in place of  $x$ . In this equation,  $\mu_1 = \text{mean}(x)$  and  $\mu_2 = \text{std}(x)$ . The centering and scaling parameters `mu = [mu1,mu2]` are optional output computed by `polyfit`.

## Examples

The polynomial  $p(x) = 3x^2 + 2x + 1$  is evaluated at  $x = 5, 7,$  and  $9$  with

```
p = [3 2 1];
polyval(p,[5 7 9])
```

which results in

```
ans =
```

```
86 162 262
```

For another example, see `polyfit`.

## More About

### Tips

The `polyvalm(p,x)` function, with `x` a matrix, evaluates the polynomial in a matrix sense. See `polyvalm` for more information.

### See Also

`polyfit` | `polyvalm` | `polyder` | `polyint`

**Introduced before R2006a**

# polyvalm

Matrix polynomial evaluation

## Syntax

$Y = \text{polyvalm}(p, X)$

## Description

$Y = \text{polyvalm}(p, X)$  returns the evaluation of polynomial  $p$  in a matrix sense. This evaluation is the same as substituting matrix  $X$  in the polynomial,  $p$ .

## Examples

### Matrix Evaluation of Characteristic Polynomial

Find the characteristic polynomial of a Pascal Matrix of order 4.

```
X = pascal(4)
p = poly(X)
```

X =

```
1 1 1 1
1 2 3 4
1 3 6 10
1 4 10 20
```

p =

```
1.0000 -29.0000 72.0000 -29.0000 1.0000
```

The characteristic polynomial is

$$p(x) = x^4 - 29x^3 + 72x^2 - 29x + 1$$

Pascal matrices have the property that the vector of coefficients of the characteristic polynomial is the same forward and backward (palindromic).

Substitute the matrix,  $X$ , into the characteristic equation,  $p$ . The result is very close to being a zero matrix. This example is an instance of the Cayley-Hamilton theorem, where a matrix satisfies its own characteristic equation.

$Y = \text{polyvalm}(p,X)$

$Y =$

```

# posixtime

Convert MATLAB datetime to POSIX time

## Syntax

```
p = posixtime(t)
```

## Description

`p = posixtime(t)` returns the POSIX<sup>®</sup> time equivalent to the datetime values in `t`. The POSIX time is the number of seconds (including fractional seconds) elapsed since 00:00:00 1-Jan-1970 UTC, ignoring leap seconds. `p` is a **double** array.

## Examples

### Convert Datetime Array to POSIX Time

Create a datetime array. Then, convert the dates to the equivalent POSIX<sup>®</sup> time.

```
t = datetime('now') + calmonths(1:3)
```

```
t =
```

```
 24-Sep-2015 17:44:22 24-Oct-2015 17:44:22 24-Nov-2015 17:44:22
```

```
format longG
```

```
p = posixtime(t)
```

```
p =
```

```
1443116662.23
```

```
1445708662.23
```

```
1448387062.23
```

## Input Arguments

**t** — **Input date and time**  
datetime array

Input date and time, specified as a `datetime` array.

# pow2

Base 2 power and scale floating-point numbers

## Syntax

```
X = pow2(Y)
X = pow2(F,E)
```

## Description

$X = \text{pow2}(Y)$  returns an array  $X$  whose elements are 2 raised to the power  $Y$ .

$X = \text{pow2}(F,E)$  computes  $x = f * 2^e$  for corresponding elements of  $F$  and  $E$ . The result is computed quickly by simply adding  $E$  to the floating-point exponent of  $F$ . Arguments  $F$  and  $E$  are real and integer arrays, respectively.

## Examples

For IEEE arithmetic, the statement  $X = \text{pow2}(F,E)$  yields the values:

F	E	X
1/2	1	1
pi/4	2	pi
-3/4	2	-3
1/2	-51	eps
1-eps/2	1024	realmax
1/2	-1021	realmin

## More About

### Tips

This function corresponds to the ANSI C function `ldexp()` and the IEEE floating-point standard function `scalbn()`.

**See Also**

`exp` | `hex2num` | `log2` | `mpower` | `power` | `realmax` | `realmin`

**Introduced before R2006a**

## power, .^

Element-wise power

### Syntax

```
C = A.^B
C = power(A,B)
```

### Description

$C = A.^B$  raises each element of  $A$  to the corresponding power in  $B$ .

$C = \text{power}(A,B)$  is an alternate way to execute  $A.^B$ , but is rarely used. It enables operator overloading for classes.

### Examples

#### Square Each Element of Vector

Create a vector,  $A$ , and square each element.

```
A = 1:5;
C = A.^2
```

```
C =
```

```
 1 4 9 16 25
```

#### Find Inverse of Each Matrix Element

Create a matrix,  $A$ , and take the inverse of each element.

```
A = [1 2 3; 4 5 6; 7 8 9];
C = A.^-1
```

```
C =
```

```
1.0000 0.5000 0.3333
0.2500 0.2000 0.1667
0.1429 0.1250 0.1111
```

An inversion of the elements is not equal to the inverse of the matrix, which is instead written  $A^{-1}$  or `inv(A)`.

## Find Roots of Number

Calculate the roots of -1 to the 1/3 power.

```
A = -1;
B = 1/3;
C = A.^B
```

```
C =
```

```
0.5000 + 0.8660i
```

For negative base  $A$  and noninteger  $B$ , if `abs(B)` is less than 1, the `power` function returns the complex roots of  $A$ .

Use the `nthroot` function to obtain the real roots.

```
C = nthroot(A,3)
```

```
C =
```

```
-1
```

## Input Arguments

### A — Base

scalar | vector | matrix | multidimensional array

Base, specified as a scalar, vector, matrix, or multidimensional array. Inputs  $A$  and  $B$  must be the same size unless one is a scalar. A scalar value expands into an array of the same size as the other input.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char`

Complex Number Support: Yes

**B — Exponent**

scalar | vector | matrix | multidimensional array

Exponent, specified as a scalar, vector, matrix, or multidimensional array. Inputs **A** and **B** must be the same size unless one is a scalar. A scalar value expands into an array of the same size as the other input.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical | char

Complex Number Support: Yes

**More About**

- “Operator Precedence”

**See Also**

mpower | nthroot | realpow

**Introduced before R2006a**

## ppval

Evaluate piecewise polynomial

### Syntax

```
v = ppval(pp,xx)
```

### Description

`v = ppval(pp,xx)` returns the value of the piecewise polynomial  $f$ , contained in `pp`, at the entries of `xx`. You can construct `pp` using the functions `pchip`, `spline`, or the spline utility `mkpp`.

`v` is obtained by replacing each entry of `xx` by the value of  $f$  there. If  $f$  is scalar-valued, `v` is of the same size as `xx`. `xx` may be  $N$ -dimensional.

If `pp` was constructed by `pchip`, `spline`, or `mkpp` using the orientation of non-scalar function values specified for those functions, then:

If  $f$  is  $[D1, \dots, Dr]$ -valued, and `xx` is a vector of length  $N$ , then `V` has size  $[D1, \dots, Dr, N]$ , with `V(:, ..., :, J)` the value of  $f$  at `xx(J)`.

If  $f$  is  $[D1, \dots, Dr]$ -valued, and `xx` has size  $[N1, \dots, Ns]$ , then `V` has size  $[D1, \dots, Dr, N1, \dots, Ns]$ , with `V(:, ..., :, J1, ..., Js)` the value of  $f$  at `xx(J1, ..., Js)`.

### Examples

Compare the result of integrating  $\cos(x)$  between 0 and 10 to the result of integrating a piece-wise polynomial approximation of the same function.

```
a = 0; b = 10;
int1 = integral(@cos,a,b)
```

```
int1 =
 -0.5440
```

Create a piece-wise polynomial approximation of  $\cos(x)$  and integrate over the same interval.

```
x = a:b;
y = cos(x);
pp = spline(x,y);
int2 = integral(@(x)ppval(pp,x),a,b)
```

```
int2 =
 -0.5485
```

## See Also

**Introduced before R2006a**

## prefdir

Folder containing preferences, history, and layout files

### Syntax

```
prefdir
folder = prefdir
folder = prefdir(1)
```

### Description

prefdir returns the folder that contains

- Preferences for MATLAB and related products (matlab.prf)
- Command history file (History.xml)
- MATLAB shortcuts (shortcuts\_2.xml)
- MATLAB desktop layout files (MATLABDesktop.xml and Your\_Saved\_LayoutMATLABLayout.xml)
- Other related files

folder = prefdir assigns to folder the name of the folder containing preferences and related files.

folder = prefdir(1) creates a folder for preferences and related files if one does not exist. If the folder does exist, the name is assigned to folder.

### Examples

View the location of the preferences folder:

```
prefdir
```

Make the preferences folder become the current folder:

```
cd(prefdir)
```

```
% Then, view the files for customizing MathWorks products:
dir
```

On Windows platforms, go directly to the preferences folder in Microsoft Windows Explorer

```
winopen(prefdir)
```

## More About

### Tips

- You must have write access to the preferences folder. Otherwise, MATLAB generates an error in the Command Window when you try to change preferences. This can happen if the folder is hidden, for example: `myname/.matlab/R2009a`.
- “Preferences Folder and Files MATLAB Uses When Multiple MATLAB Releases Are Installed”

### See Also

**Introduced before R2006a**

# primes

Prime numbers less than or equal to input value

## Syntax

```
p = primes(n)
```

## Description

`p = primes(n)` returns a row vector containing all the prime numbers less than or equal to `n`. The data type of `p` is the same as that of `n`.

## Examples

### Primes Less Than or Equal to 25

```
p = primes(25)
```

```
p =
```

```
 2 3 5 7 11 13 17 19 23
```

### Primes Less Than or Equal to an Unsigned Integer

```
n = uint16(12);
```

```
p = primes(n)
```

```
p =
```

```
 2 3 5 7 11
```

## Input Arguments

**n** — Input value

scalar, real integer value

Input value, specified as a scalar that is a real integer value.

Example: 10

Example: `int16(32)`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **See Also**

`factor` | `isprime`

**Introduced before R2006a**

# print

Print figure or save to specific file format

## Compatibility

Starting in R2015b, if you use `print` with the `'-r0'` option on a high-resolution system, then the size of the `cdata` output array is larger than in previous releases or on other systems. Also, the number of elements in `cdata` might not match the size of the figure in pixels based on the figure's `PaperPosition` property and the root's `ScreenPixelsPerInch` property. For more information, see “DPI-Aware Behavior in MATLAB”.

## Syntax

```
print(filename,formattype)
print(filename,formattype,formatoptions)
```

```
print
print(printer)
print(driver)
print(printer,driver)
```

```
print('-clipboard',clipboardformat)
```

```
print(resolution, ___)
print(renderer, ___)
print('-noui', ___)
print(fig, ___)
```

```
cdata = print('-RGBImage');
```

## Description

`print(filename,formattype)` saves the current figure to a file using the specified file format. If the file name does not include an extension, then `print` appends the appropriate one.

`print(filename,formattype,formatoptions)` specifies additional options that are available for some formats.

`print` prints the current figure to the default printer.

`print(printer)` specifies the printer. Specify the printer as a string containing the printer name preceded by `-P`, for example, `'-Pmy printer'`. The printer must be set up on your system.

`print(driver)` specifies the driver for the temporary file that `print` generates and sends to the printer. Specify a driver if you want to ensure that the printed output is either black and white or color.

`print(printer,driver)` specifies the printer and the driver.

`print('-clipboard',clipboardformat)` copies the current figure to the clipboard using the specified format. You can paste the copied figure into other applications.

`print(resolution, ___)` uses the specified resolution. Specify the resolution as a string containing an integer value preceded by `-r`, for example, `'-r200'`. Use this option with any of the input arguments from the previous syntaxes.

`print(renderer, ___)` uses the specified renderer. Specify the renderer as either `'-painters'` or `'-opengl'`.

`print('-noui', ___)` excludes user interface controls, such as push buttons and sliders, from the saved or printed output. It does not exclude user interface objects that can contain an axes, such as a `uitab` or `uipanel`.

`print(fig, ___)` saves or prints the figure or Simulink block diagram specified by `fig`.

`cdata = print('-RGBImage');` returns the RGB image data for the current figure. This option differs from screen captures in that all printing features apply to the output. You can also specify the `resolution`, `renderer`, `'-noui'`, and `fig` options with this syntax. However, you cannot specify a Simulink block diagram.

## Examples

### Print Paper Copy of Figure

Create a bar chart and print it to your system default printer. If you do not specify the figure to print, then `print` uses the current figure.

```
bar(1:10)
print
```

### Copy Figure to Clipboard

Create a plot and copy it to the system clipboard.

```
plot(1:10)
print('-clipboard', '-dmeta')
```

You can paste the copied plot into other applications.

### Save Figure as Image File

Create a plot and save it as a PNG image file.

```
bar(1:10)
print('BarPlot', '-dpng')
```

print saves the plot as BarPlot.png.

### Save Figure as Vector Graphics File

Create a plot and save it as an Encapsulated PostScript file.

```
bar(1:10)
print('BarPlot', '-depsc')
```

print saves the plot as BarPlot.eps.

### Add TIFF Preview to EPS File

Save the current figure as an Encapsulated PostScript File and add a TIFF preview.

```
surf(peaks)
print('SurfacePlot', '-depsc', '-tiff')
```

### Specify Figure to Save

Save a specific figure by passing its object variable to print.

```
fig = figure;
plot(1:10)
print(fig, 'MySavedPlot', '-dpng')
```

Alternatively, refer to a figure using the value of its `Number` property, which is the integer value that displays in the figure window title bar. For example, save the figure with `Figure 2` displayed in the title bar. Precede the integer value by `-f`.

```
figure(2);
plot(1:10)
print('-f2', 'MySavedPlot', '-dpng')
```

## Save Figure at Screen Size and Resolution

Save a surface plot to a PNG file. Set the `PaperPositionMode` property for the figure to `'auto'` so that it saves at the size displayed on the screen. Use `'-r0'` to save it with screen resolution.

```
surf(peaks)
set(gcf, 'PaperPositionMode', 'auto')
print('PeaksSurface', '-dpng', '-r0')
```

## Save Figure Without Saving UIControls

Create a figure with a push button that clears the axes. Save the figure to a JPEG file without saving the push button.

```
surf(peaks)
uicontrol('Style', 'pushbutton', 'String', 'Clear', ...
 'Position', [20 20 50 20], 'Callback', 'cla');
print('SurfacePlot', '-djpeg', '-noui')
```

## Return RGB Image Data for Figure

Return the RGB image data for a figure.

```
surf(peaks)
cdata = print('-RGBImage');
```

Display the image data at full resolution using `imshow`.

```
figure
imshow(cdata)
```

# Input Arguments

**filename** — File name

string

File name, specified as a string containing the desired file name and path.

Example: 'My Saved Chart'

Example: 'Folder\My Saved Chart'

The maximum file name length, including the path, is operating system and file format specific. Typically, the file name should be no more than 126 characters, or if you include the path, then no more than 128 characters.

### **formattype – File format**

'-djpeg' | '-dpng' | '-dtiff' | '-dpdf' | '-deps' | ...

File format, specified as one of the options in these tables.

## **Bitmap Image File**

Bitmap images contain a pixel-based representation of the figure. The size of the generated file depends on the figure, the format, and your system resolution. Bitmap images are widely used by Web browsers and other applications that display graphics. However, they do not scale well and you cannot modify individual graphics objects, such as lines and text, in other graphics applications.

This table lists the supported bitmap image formats.

<b>Option</b>	<b>Bitmap Image Format</b>	<b>Corresponding File Extension</b>
'jpeg'	JPEG 24-bit	.jpg
'png'	PNG 24-bit	.png
'tiff'	TIFF 24-bit (compressed)	.tif
'tiffn'	TIFF 24-bit (not compressed)	.tif
'meta'	Enhanced metafile (Windows only)	.emf
'bmpmono'	BMP Monochrome	.bmp
'bmp'	BMP 24-bit	.bmp
'bmp16m'	BMP 24-bit	.bmp

Option	Bitmap Image Format	Corresponding File Extension
'bmp256'	BMP 8-bit (256 color, uses a fixed colormap)	.bmp
'hdf'	HDF 24-bit	.hdf
'pbm'	PBM (plain format) 1-bit	.pbm
'pbmraw'	PBM (raw format) 1-bit	.pbm
'pcxmono'	PCX 1-bit	.pcx
'pcx24b'	PCX 24-bit color (three 8-bit planes)	.pcx
'pcx256'	PCX 8-bit newer color (256 color)	.pcx
'pcx16'	PCX older color (EGA/VGA 16-color)	.pcx
'pgm'	PGM (plain format)	.pgm
'pgmraw'	PGM (raw format)	.pgm
'ppm'	PPM (plain format)	.ppm
'ppmraw'	PPM (raw format)	.ppm

## Vector Graphics File

Vector graphics files store commands that redraw the figure. This type of format scales well, but can result in a large file. Also, it might not produce the correct 3-D arrangement of objects in certain cases. Some applications support extensive editing of vector graphics formats. However, some applications do not support editing beyond resizing the graphic. In general, try to make all the necessary changes while your figure is still in MATLAB.

If you set the **Renderer** property for the figure, then `print` uses that renderer when generating output. Otherwise, `print` chooses the appropriate renderer. Typically, `print` uses the Painters renderer when generating vector graphics files. For some complex figures, `print` uses the OpenGL renderer instead. If it uses the OpenGL renderer, then the vector graphics file contains an embedded image, which might limit the extent to which you can edit the image in other applications. To ensure that `print` uses the Painters renderer, set the **Renderer** property for the figure to 'painters' or specify '-painters' as an input argument to `print`.

---

**Note:** The default figure renderer is OpenGL. If the figure renderer differs from the renderer used when generating output, some details of the saved figure can differ from the figure on the display. If necessary, you can make the displayed figure and the saved figure use the same renderer. Set the `Renderer` property for the figure or specify the `renderer` input argument to the `print` function.

---

This table lists the supported vector graphics formats.

Option	Vector Graphics Format	Corresponding File Extension
'pdf'	Full page Portable Document Format (PDF) color	.pdf
'eps'	Encapsulated PostScript (EPS) Level 3 black and white	.eps
'epsc'	Encapsulated PostScript (EPS) Level 3 color	.eps
'eps2'	Encapsulated PostScript (EPS) Level 2 black and white	.eps
'epsc2'	Encapsulated PostScript (EPS) Level 2 color	.eps
'meta'	Enhanced Metafile (Windows only)	.emf
'svg'	SVG (Scalable Vector Graphics)	.svg
'ps'	Full-page PostScript (PS) Level 3 black and white	.ps
'psc'	Full-page PostScript (PS) Level 3 color	.ps
'ps2'	Full-page PostScript (PS) Level 2 black and white	.ps
'psc2'	Full-page PostScript (PS) Level 2 color	.ps

You cannot save Simulink block diagrams in PostScript or EPS formats.

---

**Note:** Only PDF and PS formats use the `PaperOrientation` property of the figure and the `left` and `bottom` elements of the `PaperPosition` property. Other formats ignore these values.

---

### **formatoptions — Additional formatting options**

'-tiff' | '-loose' | '-cmyk' | '-append'

Additional formatting options supported by some file formats, specified as one or more of these values:

- '-tiff' — Include a TIFF preview. EPS files only.
- '-loose' — Use a loose bounding box. EPS and PS files only.
- '-cmyk' — Use CMYK colors instead of RGB colors. EPS and PS files only.
- '-append' — Append the figure to an existing PS file. PS files only.

Example: `print('my file', '-deps', '-tiff', 'loose')` saves the current figure to the file `my file.eps` using a loose bounding box and includes a TIFF preview.

### **printer — Printer name**

string containing -P and printer name

Printer name, specified as a string containing -P and printer name.

Example: '-Pmy local printer'

To view a list of available printers, use this command:

```
[~,printers] = findprinters
```

If you do not specify a printer, then `print` uses the system default printer. If you want to set up a new printer or select a different default printer, use the operating system printer management utilities. Restart MATLAB if you do not see a printer that is set up already.

### **driver — Printer driver**

'-dwin' | '-dwinc' | '-dps' | '-dpsc' | '-dps2' | '-dpsc2'

Printer driver, specified as '-dwin', '-dwinc', '-dps', '-dpsc', '-dps2', or '-dpsc2'. If you do not specify a driver, then `print` relies on your operating system to choose the driver.

The option you use depends on your system, for example:

System	Driver	Output
Windows	'-dwin'	Black and white
	'-dwinc'	Color
Linux or Mac OS X	'-dps' or '-dps2'	Black and white
	'-dpvc' or '-dpvc2'	Color

### **clipboardformat** — Format copied to clipboard

-dmeta | -dbitmap | -dpdf

Format copied to clipboard, specified as one of these options:

- '-dmeta' — Enhanced metafile (Windows only)
- '-dbitmap' — Bitmap image (Windows and Mac OS X)
- '-dpdf' — PDF file (Windows and Mac OS X)

### **resolution** — Resolution

string containing -r and integer

Resolution, specified as a string containing -r and an integer value indicating the resolution in dots per inch. For example, '-r300' sets the output resolution to 300 dots per inch. To specify screen resolution, use '-r0'.

In general, using a higher resolution value yields higher-quality output, but at the cost of higher memory use and larger output files. The higher the resolution setting, the longer it takes to render your figure. By default, the resolution is 90 DPI for Simulink models and 150 DPI for figures. For typical laser-printer output, the default resolution of 150 DPI for figures is normally adequate. However, if you are preparing figures for high-quality printing, such as a textbook or color brochures, you might want to use 200 DPI or 300 DPI. The resolution can be limited by the printer's capabilities.

Specifying the resolution is useful when creating a bitmap image or when using the OpenGL renderer with a vector graphics file format (since OpenGL produces a bitmap image even with vector formats). Specifying the resolution has no effect when using the Painters renderer with a vector graphics file format, since Painters produces a true vector graphics file that contains the commands that redraw the figure.

### **renderer** — Graphics renderer

'-opengl' | '-painters'

Graphics renderer, specified as `'-opengl'` or `'-painters'`.

- `'-opengl'` — OpenGL renderer. Use this renderer when saving bitmap images. OpenGL produces a bitmap image even with vector formats, which might limit the extent to which you can edit the image in other applications.
- `'-painters'` — Painters renderer. Use this renderer when saving vector graphics files. If you save to a vector graphics file and if the figure `RendererMode` property is set to `'auto'`, then `print` automatically attempts to use the Painters renderer. If you want to ensure that your output format is a true vector graphics file, then specify the Painters renderer. For example:

```
print('-painters', '-deps', 'myVectorFile')
```

---

**Note:** Sometimes, saving a file with the `'-painters'` option can cause longer rendering times and, in rare cases, might not accurately arrange graphics objects in 3-D views. Also, the Painters renderer cannot print or save lines thinner than one pixel.

---

If you do not specify the renderer, then `print` automatically uses the appropriate renderer to produce the output format requested. However, if you set the `Renderer` property for the figure, then `print` uses that renderer when generating output.

### **fig** — Figure, Simulink block diagram

figure object | Simulink block diagram

Figure object or Simulink block diagram. You can refer to a figure using either its object variable name or using the figure number preceded by `-f`. For example, `-f2` refers to the figure with a `Number` property value of 2. When specifying a Simulink block diagram, precede the model name with `-s`. Specify the current model using `'-s'`.

You cannot save Simulink block diagrams in PostScript or EPS formats.

## **Output Arguments**

### **cdata** — Image data

n-by-m-by-3 array

Image data, returned as an n-by-m-by-3 array. The size of the image data array depends on the `PaperPosition` property of the figure and the output resolution.

---

**Note:** Starting in R2015b, if you use `print` with the `'-r0'` option on a high-resolution system, then the size of the `cdata` output array is larger than in previous releases or on other systems. Also, the number of elements in `cdata` might not match the size of the figure in pixels based on the figure's `PaperPosition` property and the root's `ScreenPixelsPerInch` property.

---

## Limitations

- `print` does not support capturing ActiveX controls.
- Starting MATLAB in no display mode on Linux or using the `-noFigureWindows` startup option on any platform has these limitations for `print`:
  - Does not print or save uicontrols.
  - Always uses the painters renderer, even if you specify the `'-opengl'` option.

## More About

### Tips

- You can set properties of the figure to control some printing and saving parameters. This table lists properties of the figure related to printing and saving.

Figure Property	Description
<code>PaperPosition</code>	Size of the printed or saved figure. If printing to a printer or a full-page output format, then this property also determines the figure location on the page.
<code>PaperPositionMode</code>	Specifies whether to use the <code>PaperPosition</code> property or the size of the figure on the screen to set the size of the printed or saved figure.
<code>InvertHardcopy</code>	Specifies whether to use the current background color of the figure or to change the background color to white when printing or saving the figure.

<b>Figure Property</b>	<b>Description</b>
PaperOrientation	Figure orientation on printed page.
PaperType	Standard printer paper size.
PaperSize	Custom width and height of printer paper.
PaperUnits	Units for the PaperSize and PaperPosition properties.

- The `print` function returns a warning message when you print a figure that has a callback defined for the `SizeChangedFcn` property. To avoid the warning, set the `PaperPositionMode` property for the figure to `'auto'`.

### **See Also**

`getframe` | `saveas` | `savefig`

**Introduced before R2006a**

# printopt

Configure printer defaults

## Syntax

```
[pcmd,dev] = printopt
```

## Description

[pcmd,dev] = printopt returns strings containing the current system-dependent printing command and output device. `printopt` is a file used by `print` to produce the hard-copy output. You can edit the file `printopt.m` to set your default printer type and destination.

`pcmd` and `dev` are platform-dependent strings. `pcmd` contains the command that `print` uses to send a file to the printer. `dev` contains the printer driver or graphics format option for the `print` command. Their defaults are platform dependent.

Platform	Print Command	Driver or Format
Mac and UNIX	<code>lpr -r</code>	<code>-dps2</code>
Windows	<code>COPY /B %s LPT1:</code>	<code>-dwin</code>

## See Also

`printdlg` | `print`

Introduced before R2006a

## printdlg

Open figure Print dialog box

---

**Note:** The `-crossplatform` and `-setup` input arguments have been removed in R2014b. They no longer have any effect.

---

## Syntax

```
printdlg
printdlg(fig)
```

## Description

`printdlg` prints the current figure.

`printdlg(fig)` creates a modal dialog box from which you can print the figure window identified by the handle `fig`. Uimenu's do not print.

## More About

### Tips

If you want to set up a new printer, use the operating system printer management utilities. Restart MATLAB if you do not see the printer which is already setup.

### See Also

`print` | `printopt` | `printpreview`

**Introduced before R2006a**

# printpreview

Open figure Print Preview dialog box

## Syntax

```
printpreview
printpreview(f)
```

## Description

`printpreview` displays a dialog box showing the figure in the currently active figure window as it will print. A scaled version of the figure displays in the right-hand pane of the dialog box.

`printpreview(f)` displays a dialog box showing the figure having the handle `f` as it will print.

Use the Print Preview dialog box, shown below, to control the layout and appearance of figures before sending them to a printer or print file. Controls are grouped into four tabbed panes: **Layout**, **Lines/Text**, **Color**, and **Advanced**.

## Right Pane Controls

You can position and scale plots on the printed page using the rulers in the right-hand pane of the Print Preview dialog. Use the outer ruler handlebars to change margins. Moving them changes plot proportions. Use the center ruler handlebars to change the position of the plot on the page. Plot proportions do not change, but you can move portions of the plot off the paper. The buttons on that pane let you refresh the plot, close the dialog (preserving all current settings), print the page immediately, or obtain context-

sensitive help. Use the **Zoom** box and scroll bars to view and position page elements more precisely.

## The Layout Tab

Use the **Layout** tab, shown above, to control the paper format and placement of the plot on printed pages. The following table summarizes the **Layout** options:

Group	Option	Description
Placement	<b>Auto</b>	Let MATLAB decide placement of plot on page <sup>*</sup>
	<b>Use manual...</b>	Specify position parameters for plot on page <sup>*</sup>
	<b>Top, Left, Width, Height</b>	Standard position parameters in current units
	<b>Use defaults</b>	Revert to default position
	<b>Fill page</b>	Expand figure to fill printable area (see note below)
	<b>Fix aspect ratio</b>	Correct height/width ratio
	<b>Center</b>	Center plot on printed page
Paper	<b>Format</b>	U.S. and ISO <sup>®</sup> sheet size selector
	<b>Width, Height</b>	Sheet size in current units
Units	<b>Inches</b>	Use inches as units for dimensions and positions
	<b>Centimeters</b>	Use centimeters as units for dimensions and positions
	<b>Points</b>	Use points as units for dimensions and positions
Orientation	<b>Portrait</b>	Upright paper orientation
	<b>Landscape</b>	Sideways paper orientation
	<b>Rotated</b>	Currently the same as <b>Landscape</b>

<sup>\*</sup> Selecting **Auto** in the Placement group sets the figure `PaperPositionMode` to 'auto' and disables the controls in that panel. Selecting **Use manual size and position** sets the figure `PaperPositionMode` to 'manual' and enables the controls. If you set

PaperPositionMode programmatically, the print preview Placement controls respond accordingly.

---

**Note:** Selecting the **Fill page** option changes the PaperPosition property to fill the page, allowing objects in normalized units to expand to fill the space. If an object within the figure has an absolute size, for example a table, it can overflow the page when objects with normalized units expand. To avoid having objects fall off the page, do not use **Fill page** under such circumstances.

---

## The Lines/Text Tab

Use the **Lines/Text** tab, shown below, to control the line weights, font characteristics, and headers for printed pages. The following table summarizes the **Lines/Text** options:

Layout Lines/Text Color Advanced

**Lines**

Line Width  Default  
 Scale By 100 %  
 Custom 0.5 points

Min Width  Default  
 Custom

**Text**

Font Name  Default  
 Custom Helvetica

Font Size  Default  
 Scale By 100 %  
 Custom 10 points

Font Weight Default

Font Angle Default

**Header**

Header Text

Font...

Date Style none

Group	Option	Description
Lines	<b>Line Width</b>	Scale all lines by a percentage from 0 upward (100 being no change), print lines at a specified point size, or default line widths used on the plot
	<b>Min Width</b>	Smallest line width (in points) to use when printing; defaults to 0.5 point
Text	<b>Font Name</b>	Select a system font for all text on plot, or default to fonts currently used on the plot

<b>Group</b>	<b>Option</b>	<b>Description</b>
	<b>Font Size</b>	Scale all text by a percentage from 0 upward (100 being no change), print text at a specified point size, or default to this used on the plot
	<b>Font Weight</b>	Select <b>Normal ... Bold</b> font styling for all text from drop-down menu or default to the font weights used on the plot
	<b>Font Angle</b>	Select <b>Normal, Italic</b> or <b>Oblique</b> font styling for all text from drop-down menu or default to the font angles used on the plot
Header	<b>Header Text</b>	Type the text to appear on the header at the upper left of printed pages, or leave blank for no header
	<b>Date Style</b>	Select a date format to have today's date appear at the upper left of printed pages, or <b>none</b> for no date

## The Color Tab

Use the **Color** tab, shown below, to control how colors are printed for lines and backgrounds. The following table summarizes the **Color** options:

Layout Lines/Text **Color** Advanced

**Color Scale**

Black and White (Lines and Text only)

Gray Scale

Color

RGB

CMYK

**Background color**

Same as figure

Custom white

Group	Option	Description
Color Scale	<b>Black and White</b>	Select to print lines and text in black and white, but use color for patches and other objects
	<b>Gray Scale</b>	Convert colors to shades of gray on printed pages
	<b>Color</b>	Print everything in color, matching colors on plot; select <b>RGB</b> (default) or <b>CMYK</b> color model for printing

Group	Option	Description
Background Color	<b>Same as figure</b>	Print the figure's background color as it is
	<b>Custom</b>	Select a color name, or type a colorspec for the background; <code>white</code> (default) implies no background color, even on colored paper.

## The Advanced Tab

Use the **Advanced** tab, shown below, to control finer details of printing, such as limits and ticks, renderer, resolution, and the printing of UIControls. The following table summarizes the **Advanced** options:

Group	Option	Description
Axes limits and ticks	<b>Recompute limits and ticks</b>	Redraw $x$ - and $y$ -axes ticks and limits based on printed plot size (default)
	<b>Keep limits and ticks</b>	Use the $x$ - and $y$ -axes ticks and limits shown on the plot when printing the previewed figure
Miscellaneous	<b>Renderer</b>	Select a rendering algorithm for printing: <code>painters</code> , <code>opengl</code> , or <code>auto</code> (default)

Group	Option	Description
	<b>Resolution</b>	Select resolution to print at in dots per inch: 150, 300, 600, or auto (default), or type in any other positive value
	<b>Print UIControls</b>	Print all visible UIControls in the figure (default), or uncheck to exclude them from being printed

## Alternatives

Use **File > Print Preview** on the figure window menu to access the Print Preview dialog box, described below. For details, see “Print Figure from File Menu”.

## More About

- “Print Figure from File Menu”

## See Also

print

Introduced before R2006a

## prod

Product of array elements

### Syntax

```
B = prod(A)
B = prod(A,dim)
B = prod(____,type)
```

### Description

`B = prod(A)` returns the product of the array elements of `A`.

- If `A` is a vector, then `prod(A)` returns the product of the elements.
- If `A` is a nonempty matrix, then `prod(A)` treats the columns of `A` as vectors and returns a row vector of the products of each column.
- If `A` is an empty 0-by-0 matrix, `prod(A)` returns 1.
- If `A` is a multidimensional array, then `prod(A)` acts along the first nonsingleton dimension and returns an array of products. The size of this dimension reduces to 1 while the sizes of all other dimensions remain the same.

`prod` computes and returns `B` as `single` when the input, `A`, is `single`. For all other numeric and logical data types, `prod` computes and returns `B` as `double`.

`B = prod(A,dim)` returns the products along dimension `dim`. For example, if `A` is a matrix, `prod(A,2)` is a column vector containing the products of each row.

`B = prod( ____,type)` returns an array in the class specified by `type`, using any of the input arguments in the previous syntaxes. `type` can be `'double'`, `'native'`, or `'default'`.

### Examples

#### Product of Elements in Each Column

Create a 3-by-3 array whose elements correspond to their linear indices.

```
A=[1:3:7;2:3:8;3:3:9]
```

```
A =
```

```
 1 4 7
 2 5 8
 3 6 9
```

Find the product of the elements in each column.

```
B = prod(A)
```

```
B =
```

```
 6 120 504
```

The length of the first dimension is 1, and the length of the second dimension matches `size(A,2)`.

### Logical Input with Double Output

Create an array of logical values.

```
A = [true false; true true]
```

```
A =
```

```
 1 0
 1 1
```

Find the product of the elements in each column.

```
B = prod(A)
```

```
B =
```

```
 1 0
```

The output is `double`.

```
class(B)
```

```
ans =
```

double

## Product of Elements in Each Row

Create a 3-by-3 array whose elements correspond to their linear indices.

```
A=[1:3:7;2:3:8;3:3:9]
```

A =

```
 1 4 7
 2 5 8
 3 6 9
```

Find the product of the elements in each row and reduce the length of the second dimension to 1.

```
dim = 2;
B = prod(A,dim)
```

B =

```
 28
 80
 162
```

The length of the first dimension matches `size(A,1)`, and the length of the second dimension is 1.

## Product of Elements in Each Plane

Create a 3-by-3-by-2 array whose elements correspond to their linear indices.

```
A=[1:3:7;2:3:8;3:3:9];
A(:,:,2)=[10:3:16;11:3:17;12:3:18]
```

A(:,:,1) =

```
 1 4 7
 2 5 8
 3 6 9
```

A(:,:,2) =

```

10 13 16
11 14 17
12 15 18

```

Find the product of each element in the first plane with its corresponding element in the second plane.

```

dim = 3;
B = prod(A,dim)

```

B =

```

10 52 112
22 70 136
36 90 162

```

The length of the first dimension matches `size(A,1)`, the length of the second dimension matches `size(A,2)`, and the length of the third dimension is 1.

### Single-Precision Input Treated as Double

Create a 3-by-3 array of single-precision values.

```

A = single([1200 1500 1800; 1300 1600 1900; 1400 1700 2000])

```

A =

```

1200 1500 1800
1300 1600 1900
1400 1700 2000

```

Find the product of the elements in each row by multiplying in double precision.

```

B = prod(A,2, 'double')

```

B =

```

1.0e+09 *
3.2400
3.9520
4.7600

```

The output is double precision.

```

class(B)

```

```
ans =
double
```

## Integer Data Type for Input and Output

Create a 3-by-3 array of 8-bit unsigned integers.

```
A = uint8([1:3:7;2:3:8;3:3:9])
```

```
A =
```

```
 1 4 7
 2 5 8
 3 6 9
```

Find the product of the elements in each column natively in `uint8`.

```
B = prod(A, 'native')
```

```
B =
```

```
 6 120 255
```

The result is an array of 8-bit unsigned integers.

```
class(B)
```

```
ans =
```

```
uint8
```

## Input Arguments

### A — Input array

vector | matrix | multidimensional array

Input array, specified as a vector, matrix, or multidimensional array.

Data Types: `double` | `single` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

Complex Number Support: Yes

**dim** – Dimension to operate along

positive integer scalar

Dimension to operate along, specified as a positive integer scalar. If no value is specified, then the default is the first array dimension whose size does not equal 1.

Dimension `dim` indicates the dimension whose length reduces to 1. The `size(B, dim)` is 1, while the sizes of all other dimensions remain the same.

Consider a two-dimensional input array, `A`.

- If `dim = 1`, then `prod(A, 1)` returns a row vector containing the product of the elements in each column.

`prod(A, 1)`

- If `dim = 2`, then `prod(A, 2)` returns a column vector containing the product of the elements in each row.

`prod(A, 2)`

`prod` returns `A` when `dim` is greater than `ndims(A)`.

Data Types: `double` | `single` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **type** — Output class

'default' (default) | 'double' | 'native'

Output class, specified as 'default', 'double', or 'native', and which defines the data type of the output, `B`.

<b>type</b>	<b>Output data type</b>
'default'	<code>double</code> , unless the input data type is <code>single</code> . In which case, the output data type is <code>single</code> .
'double'	<code>double</code>
'native'	same data type as the input array, <code>A</code>

Data Types: `char`

## Output Arguments

### **B** — Product array

`scalar` | `vector` | `matrix` | `multidimensional array`

Product array, returned as a scalar, vector, matrix, or multidimensional array.

The class of `B` is as follows:

- If the `type` argument specifies 'default' or is not used
  - and the input is not `single`, then the output is `double`.
  - and the input is `single`, then the output is `single`.
- If the `type` argument specifies 'double', then the output is `double` regardless of the input data type.
- If the `type` argument specifies 'native', then the output is the same data type as the input.

## More About

### First Nonsingleton Dimension

The first nonsingleton dimension is the first dimension of an array whose size is not equal to 1.

For example:

- If  $X$  is a 1-by- $n$  row vector, then the second dimension is the first nonsingleton dimension of  $X$ .
- If  $X$  is a 1-by-0-by- $n$  empty array, then the second dimension is the first nonsingleton dimension of  $X$ .
- If  $X$  is a 1-by-1-by-3 array, then the third dimension is the first nonsingleton dimension of  $X$ .

**Introduced before R2006a**

# profile

Profile execution time for functions

Use the Profiler to track execution time. Knowing the execution time of your MATLAB code helps you to debug and optimize it. For information on the user interface to the Profiler, see [Profiling for Improving Performance](#).

## Syntax

```
profile action
profile action option1 ... optionN
profile option1 ... optionN
```

```
p = profile('info')
```

```
s = profile('status')
```

## Description

`profile action` profiles the execution time for functions. Use `action` to start, stop, and restart the Profiler, and view or clear profile statistics. For example, `profile on` starts the Profiler.

`profile action option1 ... optionN` starts or restarts the Profiler with the specified options. For example, `profile resume -history` restarts the Profiler and records the sequence of function calls.

`profile option1 ... optionN` sets the specified Profiler options. If the Profiler is on and you specify one of the options, MATLAB throws an error. To change options, first specify `profile off`, and then specify the new options.

`p = profile('info')` stops the Profiler and displays a structure containing the results. To access the data generated by `profile`, use this syntax.

`s = profile('status')` returns a structure with the Profiler status information.

## Examples

### Profile Function and Save Results as HTML

Turn on the Profiler, and call the `magic` function.

```
profile on
n = 100;
M = magic(n);
```

View the results in the Profiler window.

```
profile viewer
```

Save the results as HTML. By default, `profsave` saves the files to the `profile_results` subfolder in your current working folder.

```
profsave
```

### Profile Function and Display Function Call History

Create the file `myFunction.m` using this main function and local function.

```
function c = myFunction(a,b)
c = sqrt(square(a)+square(b));
end
```

```
function y = square(x)
y = x.^2;
end
```

Turn on the Profiler, and enable the function call history option. Profile a call to the `myFunction` function.

```
profile on -history
a = rand(5);
b = rand(5);
c = myFunction(a,b);
```

Save the profile results.

```
p = profile('info')
p =
```

```
FunctionTable: [2x1 struct]
FunctionHistory: [2x6 double]
ClockPrecision: 3.3475e-07
ClockSpeed: 3.0600e+09
Name: 'MATLAB'
Overhead: 0
```

Display the function call history.

```
p.FunctionHistory
```

```
ans =
```

```
0 0 1 0 1 1
1 2 2 2 2 1
```

Display function entry and exit information by iterating over the function call history.

```
numEvents = size(p.FunctionHistory,2);
for n = 1:numEvents
 name = p.FunctionTable(p.FunctionHistory(2,n)).FunctionName;

 if p.FunctionHistory(1,n) == 0
 disp(['Entered ' name]);
 else
 disp(['Exited ' name]);
 end
end
```

```
Entered myFunction
Entered myFunction>square
Exited myFunction>square
Entered myFunction>square
Exited myFunction>square
Exited myFunction
```

Set the function call history to the default value.

```
profile -nohistory
```

### View Current Profiler Settings

```
s = profile('status')
```

```
s =
```

```

ProfilerStatus: 'off'
 DetailLevel: 'mmex'
 Timer: 'performance'
HistoryTracking: 'off'
 HistorySize: 1000000

```

- Profiling for Improving Performance
- “Profiling Parallel Code ”

## Input Arguments

### **action** — Control options for Profiler

on | off | resume | clear | viewer | info | status

Control options for the Profiler specified as one of these options.

Option	Result
on	Start the Profiler, clearing any previously recorded profile statistics.
off	Stop the Profiler.
resume	Restart the Profiler without clearing previously recorded statistics.
clear	Clear the recorded statistics.
viewer	Stop the Profiler and display the results in the Profiler window. For more information, see “Profile to Improve Performance”.
info	Stop the Profiler and return a structure containing the results.
status	Return a structure with the Profiler status information.

### **option1 ... optionN** — One or more profiling options

strings

One or more profiling options, specified as strings corresponding to valid settings from the history and clock option tables. You can specify one or more of these options with one of the following syntaxes:

- `profile on option1 ... optionN`
- `profile resume option1 ... optionN`

- `profile option1 ... optionN`

If you change the Profiler settings, the settings persist when you stop the Profiler or clear the statistics. To revert to default Profiler behavior, manually set the options to the default settings or start a new MATLAB session.

## History Options

Option	Result
<code>-history</code>	Record the exact sequence of function calls, including function entry and exit events. By default, the <code>-history</code> option is not enabled.
<code>-historysize</code> <i>integer</i>	Specify the number of function entry and exit events to record. By default, <code>historysize</code> is 1,000,000. If the number of function calls exceeds the specified <code>historysize</code> , the <code>profile</code> function continues to record profiling statistics other than the sequence of calls.
<code>-nohistory</code>	Default setting. Disable recording of the exact sequence of function calls. The <code>profile</code> function collects all other profiling statistics.

## Clock Options

Option	Result
<code>-timer</code> 'performance'	Default setting. Use wall-clock time from the clock that the operating system supplies to measure performance.
<code>-timer</code> 'processor'	Use the wall-clock time directly from the processor. Sometimes your power savings settings or use of multiple processors influence this measurement.
<code>-timer</code> 'real'	Use system time reported by the operating system. This option is the most computationally expensive measurement and has the most impact on the performance of profiled code. Changing the time on the operating system clock influences this measurement.

Option	Result
-timer 'cpu'	Use computer time and sums time across all threads. This measurement is different from wall-clock time. For example, the computer time for the <code>pause</code> function is typically small, but wall-clock time accounts for the actual time paused, which is larger.

## Output Arguments

### **p** — Profiler statistics

structure

Profiler statistics, returned as a structure containing these fields.

Field	Description
<code>FunctionTable</code>	<p>Function statistics, returned as a structure array. Each structure in the array contains information about one of the functions or local functions called during profiling. Each structure contains the following fields:</p> <ul style="list-style-type: none"> <li>• <code>CompleteName</code> – Full path to <code>FunctionName</code>.</li> <li>• <code>FunctionName</code> – Name of function. If the function is a local function, <code>FunctionName</code> includes the main function.</li> <li>• <code>FileName</code> – Full path to <code>FunctionName</code>, with the file extension. If the function is a local function, <code>FileName</code> is the full path to the main function.</li> <li>• <code>Type</code> – Type of function. For example, MATLAB function, MEX-function, local function, or nested function.</li> <li>• <code>NumCalls</code> – Number of times the profiled code called the function.</li> <li>• <code>TotalTime</code> – Total time spent in the function and its child functions.</li> <li>• <code>TotalRecursiveTime</code> – MATLAB no longer uses this field.</li> <li>• <code>Children</code> – Information about the child functions of <code>FunctionName</code>. Each structure in the array contains information about one of the children. The structure contains these fields: <ul style="list-style-type: none"> <li>• <code>Index</code> – Index to child function information structure within <code>FunctionTable</code>.</li> </ul> </li> </ul>

Field	Description
	<ul style="list-style-type: none"> <li>• <b>NumCalls</b> – Number of times the profiled code called the child function.</li> <li>• <b>TotalTime</b> – Total time spent in the child function.</li> <li>• <b>Parents</b> – Information about the parent functions of <b>FunctionName</b>. Each structure in the array contains information about one of the parents. The structure contains these fields:               <ul style="list-style-type: none"> <li>• <b>Index</b> – Index to parent function information structure within <b>FunctionTable</b>.</li> <li>• <b>NumCalls</b> – Number of times the profiled code called the parent function.</li> </ul> </li> <li>• <b>ExecutedLines</b> – Array containing line-by-line details for the profiled function.               <ul style="list-style-type: none"> <li>• <b>Column 1</b> – Line number for the executed line of code in <b>FileName</b>.</li> <li>• <b>Column 2</b> – Number of times the profiled code executed the line of code.</li> <li>• <b>Column 3</b> – Total time spent on the line of code. The sum of <b>Column 3</b> entries does not necessarily add up to the <b>TotalTime</b>.</li> </ul> </li> <li>• <b>IsRecursive</b> – Indicator of whether the function is recursive. If the value is 1 (<b>true</b>), the function is recursive. If the value is 0 (<b>false</b>), the function is nonrecursive.</li> <li>• <b>PartialData</b> – Indicator of whether the profile statistics are incomplete. If the value is logical 1 (<b>true</b>), the function was modified during profiling. For example, if you edited the function or cleared it from memory. In that event, the Profiler collects data only up until you modified the function.</li> </ul>
<b>FunctionHis</b>	<p>Function call history, returned as an array.</p> <ul style="list-style-type: none"> <li>• <b>Row 1</b> – Indicator of function entry or exit. The Profiler records function entry with a 0, and function exit with a 1.</li> <li>• <b>Row 2</b> – Index to function information structure within <b>FunctionTable</b>.</li> </ul>

Field	Description
<code>ClockPrecis</code>	Precision of the time measurement of the <code>profile</code> function, returned as a double.
<code>ClockSpeed</code>	Estimated CPU clock speed, returned as a double.
<code>Name</code>	Name of the profiler, returned as a character array.
<code>Overhead</code>	Reserved for future use.

### s — Profiler status

structure

Profiler status, returned as a structure containing these fields.

Field	Values	Default Value
<code>ProfilerStatus</code>	'on' or 'off'	'off'
<code>DetailLevel</code>	'mmex'	'mmex'
<code>Timer</code>	'performance', 'processor', 'cpu', or 'real'	'performance'
<code>HistoryTracking</code>	'on' or 'off'	'off'
<code>HistorySize</code>	integer	1000000

## More About

### Tips

- To open the Profiler user interface, use the `profile viewer` syntax or see Profiling for Improving Performance.
- As of MATLAB R2015b, the default timer is 'performance'. In previous versions of MATLAB, the default profiler timer was 'cpu', which measures compute time instead of wall-clock time.

### See Also

`matlab.codetools.requiredFilesAndProducts` | `mlint` | `profsave`

Introduced before R2006a

## profsave

Save profile report in HTML format

### Syntax

```
profsave
profsave(profinfo)
profsave(profinfo,dirname)
```

### Description

`profsave` executes the `profile('info')` function and saves the results in HTML format. `profsave` creates a separate HTML file for each function listed in the `FunctionTable` field of the structure returned by `profile`. By default, `profsave` stores the HTML files in a subfolder of the current folder named `profile_results`.

`profsave(profinfo)` saves the profiling results, `profinfo`, in HTML format. `profinfo` is a structure of profiling information returned by the `profile('info')` function.

`profsave(profinfo,dirname)` saves the profiling results, `profinfo`, in HTML format. `profsave` creates a separate HTML file for each function listed in the `FunctionTable` field of `profinfo` and stores them in the folder specified by `dirname`.

### Examples

Run `profile` and save the results.

```
profile on
plot(magic(5))
profile off
profsave(profile('info'),'myprofile_results')
```

## propedit

Open Property Editor

## Syntax

```
propedit
propedit(handle_list)
```

## Description

`propedit` starts the Property Editor, a graphical user interface to the properties of graphics objects. If no current figure exists, `propedit` will create one.

`propedit(handle_list)` edits the properties for the object (or objects) in `handle_list`.

Starting the Property Editor enables plot editing mode for the figure.

## See Also

`inspect` | `plottedit` | `propertyeditor`

**Introduced before R2006a**

# propedit (COM)

Open built-in property page for control

## Syntax

```
propedit(h)
```

## Description

`propedit(h)` requests the control to display its built-in property page. Note that some controls do not have a built-in property page. For those controls, this command fails.

COM functions are available on Microsoft Windows systems only.

## See Also

`get (COM)` | `inspect`

**Introduced before R2006a**

## properties

Class property names

### Syntax

```
properties('classname')
properties(obj)
p = properties(...)
```

### Description

`properties('classname')` displays the names of the public properties for the MATLAB class named by `classname`. The `properties` function also displays inherited properties.

`properties(obj)` `obj` can be either a scalar object or an array of objects. When `obj` is scalar, `properties` also returns dynamic properties. See “Dynamic Properties — Adding Properties to an Instance” for information on using dynamic properties.

`p = properties(...)` returns the property names in a cell array of strings.

### Definitions

A property is public when its `GetAccess` attribute value is `public` and its `Hidden` attribute value is `false` (default values for these attributes). See “Property Attributes” for a complete list of attributes.

`properties` is also a MATLAB class-definition keyword. See `classdef` for more information on class definition keywords.

### Examples

Retrieve the names of the public properties of class `memmapfile` and store the result in a cell array of strings:

```
p = properties('memmapfile')
p =
 'writable'
 'offset'
 'format'
 'repeat'
 'filename'
```

Construct an instance of the `MException` class and get its properties names:

```
me = MException('Msg:ID','MsgText');
properties(me)
Properties for class MException:

 identifier
 message
 cause
 stack
```

## See Also

[fieldnames](#) | [events](#) | [methods](#)

# propertyeditor

Show or hide **Property Editor**

## Syntax

```
propertyeditor('on')
propertyeditor('off')
propertyeditor
propertyeditor(figure_handle,...)
```

## Description

`propertyeditor('on')` displays the Property Editor tool on the current figure.

`propertyeditor('off')` hides the Property Editor on the current figure.

`propertyeditor` toggles the visibility of the Property Editor on the current figure. You can also use `propertyeditor('toggle')` instead for the same functionality.

`propertyeditor(figure_handle,...)` displays or hides the Property Editor on the figure specified by `figure_handle`.

## Examples

### Open Property Editor

Create a simple plot and open the property editor.

```
plot(1:10)
propertyeditor
```

## Alternatives

To collectively enable the plot tools, use the larger icon  on the figure toolbar. To collectively disable the plot tools, use the smaller icon . Open or close the **Property Editor** tool from the figure's **View** menu. For details, see “Customize Objects in Graph”.

## More About

### Tips

If you call `propertyeditor` in a MATLAB program and subsequent lines depend on the Property Editor being fully initialized, follow it by `drawnow` to ensure complete initialization.

# matlab.mixin.util.PropertyGroup class

**Package:** matlab.mixin.util

Custom property list for object display

## Description

Use the `PropertyGroup` class to create custom property display lists for class derived from `matlab.mixin.CustomDisplay`.

## Construction

`P = matlab.mixin.util.PropertyGroup(propertyList)` constructs a property group with the supplied `propertyList`.

`P = matlab.mixin.util.PropertyGroup(propertyList,title)` displays `title` above the list of properties.

## Input Arguments

### **propertyList**

The `propertyList` is either a cell array of property names, or a scalar `struct` with property name-value pairs.

### **title**

Text to display above properties.

## Properties

### **NumProperties**

The number of properties in the `PropertyList`.

**Attributes:**

Dependent	true
GetAccess	public
GetObservable	true
SetAccess	private
Transient	true

## **PropertyList**

The list of properties to display, stored as a scalar struct or a cell array of strings.

### **Attributes:**

GetAccess	public
GetObservable	true
SetAccess	public
SetObservable	true

### **Title**

An optional Title for the PropertyGroup.

### **Attributes:**

GetAccess	public
GetObservable	true
SetAccess	public
SetObservable	true

## **Copy Semantics**

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

### **See Also**

matlab.mixin.CustomDisplay

## **Related Examples**

- “Custom Display Interface”
- “Customize Property Display”

## **More About**

- Property Attributes

**Introduced in R2013b**

## psi

Psi (polygamma) function

### Syntax

```
Y = psi(X)
Y = psi(k,X)
```

### Description

`Y = psi(X)` evaluates the  $\psi$  function for each element of array `X`. `X` must be real and nonnegative. The  $\psi$  function, also known as the digamma function, is the logarithmic derivative of the gamma function

$$\begin{aligned}\psi(x) &= \text{digamma}(x) \\ &= \frac{d(\log(\Gamma(x)))}{dx} \\ &= \frac{d(\Gamma(x)) / dx}{\Gamma(x)}\end{aligned}$$

`Y = psi(k,X)` evaluates the  $k$ th derivative of  $\psi$  at the elements of `X`. `psi(0,X)` is the digamma function, `psi(1,X)` is the trigamma function, `psi(2,X)` is the tetragamma function, etc.

## Examples

### Example 1

Use the `psi` function to calculate Euler's constant,  $\gamma$ .

```
format long
-psi(1)
ans =
 0.57721566490153
```

```
-psi(0,1)
ans =
 0.57721566490153
```

## Example 2

The trigamma function of 2,  $\text{psi}(1, 2)$ , is the same as  $(\pi^2/6) - 1$ .

```
format long
psi(1,2)
ans =
 0.64493406684823
```

```
pi^2/6 - 1
ans =
 0.64493406684823
```

# publish

Generate view of MATLAB file in specified format

## Syntax

```
publish(file)
publish(file,format)

publish(file,Name,Value)
publish(file,options)

my_doc = publish(file, ___)
```

## Description

`publish(file)` generates a view of a MATLAB file in HTML format for sharing your code. For example, `publish('myfile.m')` executes the code in `myfile.m` using the base workspace and saves the formatted code and results in `/html/myfile.html`. The `html` subfolder is relative to the `file` folder.

When MATLAB publishes a file, it can delete existing files from the output folder that start with the same name as `file`.

`publish(file,format)` generates a view of a MATLAB file in the specified file format. The resulting files save to the `html` subfolder for all file formats.

`publish(file,Name,Value)` generates a view of the MATLAB file, `file`, with options specified by one or more name-value pair arguments.

`publish(file,options)` uses the `options` structure to customize the output, which is useful when you want to preconfigure and save your options for repeated use. The `options` structure fields and values correspond to names and values of name-value pair arguments, respectively.

`my_doc = publish(file, ___ )` generates a view of the MATLAB file `file`, and returns a string indicating the path of the resulting output file. It can include any of the input arguments in previous syntaxes.

## Examples

### Generate HTML View of MATLAB Script

Generate an HTML view of the code, MATLAB results, and comments in a MATLAB script.

Copy the example file, `fourier_demo2.m`, to your current folder.

```
copyfile(fullfile(matlabroot, 'help', 'techdoc', ...
'matlab_env', 'examples', 'fourier_demo2.m'), '.', 'f')
```

Generate an HTML view of the MATLAB file.

```
publish('fourier_demo2.m');
```

The `publish` command executes the code for each cell in `fourier_demo2.m`, and saves the file to `/html/fourier_demo2.html`.

View the HTML file.

```
web('html/fourier_demo2.html')
```

### Generate View of MATLAB Script in Microsoft Word Format

Generate a Microsoft Word view of the code, MATLAB results, and comments in a MATLAB script.

Copy the example file to your current folder.

```
copyfile(fullfile(matlabroot, 'help', 'techdoc', ...
'matlab_env', 'examples', 'fourier_demo2.m'), '.', 'f')
```

Publish the file in Microsoft Word format.

```
publish('fourier_demo2.m', 'doc');
```

View the published output.

```
winopen('html/fourier_demo2.doc')
```

### Publish MATLAB Script Using Name-Value Pairs to Customize Output

Generate an HTML view of the code, MATLAB results, and comments in a MATLAB script. Use name-value pair arguments to include window decorations in the published output.

Copy the example file to your current folder.

```
copyfile(fullfile(matlabroot,'help','techdoc',...
'matlab_env','examples','fourier_demo2.m'),'.','f')
```

Publish the example MATLAB file to HTML format.

```
publish('fourier_demo2.m', 'figureSnapMethod', 'entireFigureWindow')
```

The 'figureSnapMethod', 'entireFigureWindow' name-value pair argument specifies to include the window decorations in the figures, and to match the figure background color to the screen color.

View the published output.

```
web('html/fourier_demo2.html')
```

## Customize `publish` Output Using Options Structure

Generate a Microsoft Word view of the code, MATLAB results, and comments in a MATLAB script. Use a structure to customize the published output.

Specifying options as a structure is useful when you want to preconfigure and save your options for repeated use.

Copy the example file to your current folder.

```
copyfile(fullfile(matlabroot,'help','techdoc',...
'matlab_env','examples','fourier_demo2.m'),'.','f')
```

Define options to customize the published output as a structure, `options_doc_nocode`.

```
options_doc_nocode.format = 'doc';
options_doc_nocode.showCode = false;
```

Publish the file, specifying the options structure.

```
publish('fourier_demo2.m',options_doc_nocode);
```

## Save File Path of Published Script to Variable

Generate an HTML view of a MATLAB script, and save the path of the published HTML file to a variable.

This example assumes that the current folder is `C:\my_MATLAB_files`.

Copy the example file to your current folder.

```
copyfile(fullfile(matlabroot,'help','techdoc',...
 'matlab_env','examples','fourier_demo2.m'),'.','f')
```

Publish the MATLAB file, and save the path of the resulting published HTML file to an output variable.

```
mydoc = publish('fourier_demo2.m')
mydoc =
C:\my_MATLAB_files\html\fourier_demo2.html
```

## Input Arguments

### **file** — MATLAB file

string

Full or partial path of the MATLAB file for which you want to generate a presentation view, specified as a string.

Example: 'myfile.m'

### **format** — Output format of published file

'html' (default) | 'doc' | 'latex' | 'ppt' | 'xml' | 'pdf'

Output format of published MATLAB file, specified as one of the following string values.

Output Format	String Value
Hypertext Markup Language	'html' (default)
Microsoft Word	'doc'
LaTeX	'latex'
Microsoft PowerPoint	'ppt'
Extensible Markup Language	'xml'
Portable Document Format	'pdf'

Example: `publish('myfile.m','ppt');`

### **options** — Options for published output

MATLAB structure

Options for published output, specified as a structure. Use the options structure instead of name-value pair arguments when you want to reuse the same configuration for publishing multiple MATLAB code files.

The `options` structure field and values correspond to names and values of the name-value pair arguments, respectively.

For example, to specify the PDF output format and the output folder `C:`

`\myPublishedOutput`, use:

```
options = struct('format','pdf','outputDir','C:\myPublishedOutput')
```

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'format', 'latex', 'showCode', false` specifies LaTeX output file format and excludes the code from the output.

## Output Options

### 'format' — Published output file format

'html' (default) | 'doc' | 'latex' | 'ppt' | 'xml' | 'pdf'

Published output file format, specified as the comma-separated pair consisting of 'format' and one of the following string values.

Output Format	String Value
Hypertext Markup Language	'html' (default)
Microsoft Word	'doc'
LaTeX	'latex'
Microsoft PowerPoint	'ppt'
Extensible Markup Language	'xml'
Portable Document Format	'pdf'

### 'outputDir' — Output folder

' ' (default) | full path

Output folder to which the published document is saved, specified as the comma-separated pair consisting of `'outputDir'` and the full path. You must specify the full path as a string, for example `'C:\myPublishedOutput'`.

The default value, `''`, specifies the `html` subfolder of the current folder.

### **'stylesheet' — Extensible Stylesheet language (XSL) file**

`''` (default) | full path to XSL file name

Extensible Stylesheet Language (XSL) file to use when publishing MATLAB code to HTML, XML, or LaTeX format, specified as the comma-separated pair consisting of `'stylesheet'` and the full path to the XSL file. The full path must be a string, for example, `'C:\myStylesheet\stylesheet.xml'`

The default value, `''`, specifies the MATLAB default style sheet.

## Figure Options

### **'createThumbnail' — Thumbnail image creation**

`true` (default) | `false`

Thumbnail image creation for the published document, specified as the comma-separated pair consisting of `'createThumbnail'` and either `true` or `false`. You can use this thumbnail to represent your file in HTML pages.

### **'figureSnapMethod' — Published figure window appearance**

`'entireGUIWindow'` (default) | `'print'` | `'getframe'` | `'entireFigureWindow'`

Appearance of published figure windows, including window decorations and background color, specified as the comma-separated pair consisting of `'figureSnapMethod'` and one of the following string values.

String Value	Window Decorations		Background Color	
	GUIs	Figures	GUIs	Figures
<code>'entireGUIWindow'</code> (default)	Included	Excluded	Matches screen	White
<code>'print'</code>	Excluded	Excluded	White	White
<code>'getframe'</code>	Excluded	Excluded	Matches screen	Matches screen

'entireFigureWindow'	Included	Included	Matches screen	Matches screen
----------------------	----------	----------	----------------	----------------

**'imageFormat' — Published image file format**

'png' | 'eps2' | 'jpg' | ...

Published image file format, specified as the comma-separated pair consisting of 'imageFormat' and one of the following string values.

'format' Value	Valid 'imageFormat' Value	Default 'imageFormat' Value
'doc'	Any image format that your installed version of Microsoft Office can import, including 'png', 'jpg', 'bmp', and 'tiff'. If the 'figureSnapMethod' is 'print', then you can also specify 'eps', 'eps2', 'ill', 'meta', and 'pdf'.	'png'
'html'	Any format publishes successfully. Ensure that the tools you use to view and process the output files can display the output format you specify.	'png'
'latex'	Any format publishes successfully. Ensure that the tools you use to view and process the output files can display the output format you specify.	'eps2', except when 'figureSnapMethod' is any one of the following: <ul style="list-style-type: none"> <li>'getframe'</li> <li>'entireFigureWindow'</li> <li>'entireGUIWindow'</li> </ul> and the snapped window is a GUI window  In these cases the default is 'png'
'pdf'	'bmp' or 'jpg'.	'bmp'

'ppt'	Any format that your installed version of Microsoft Office can import, including 'png', 'jpg', 'bmp', and 'tiff'.	'png'
'xml'	Any format publishes successfully. Ensure that the tools you use to view and process the output files can display the output format you specify.	'png'

### 'maxHeight' — Maximum height of published images

[ ] (default) | positive integer value

Maximum height of published images that the code generates, specified as the comma-separated pair consisting of 'maxHeight' and one of the following values:

- [ ] (default)—Unrestricted height. This value is always used when the 'format' value is 'pdf'.
- Positive integer value that specifies the image height in pixels.

### 'maxWidth' — Maximum width of published images

[ ] (default) | positive integer value

Maximum width of an image that the code generates, specified as the comma-separated pair consisting of 'maxWidth' and one of the following values:

- [ ] (default)—Unrestricted width. This value is always used when the 'format' value is 'pdf'.
- Positive integer value that specifies the image width in pixels.

### 'useNewFigure' — Create new figure

true (default) | false

A logical value that determines if MATLAB creates a new Figure window for figures that the code generates, specified as the comma-separated pair consisting of 'useNewFigure' and one of the following:

- true (default)—If the code generates a figure, then MATLAB creates a Figure window with a white background, and at the default size before publishing.
- false—MATLAB does not create a figure window.

This value enables you to use a figure with different properties for publishing. For example, open a Figure window, change the size and background color, and then publish your code. Figures in your published document use the characteristics of the figure you opened before publishing.

## Code Options

### **'evalCode' — Option to run code**

true (default) | false

Option to evaluate code and include the MATLAB output in the published view, specified as a logical value.

### **'catchError' — Error handling during publishing**

true (default) | false

Error handling during publishing, specified as the comma-separated pair consisting of 'catchError' and one of the following logical values:

- **true** (default)—MATLAB continues publishing and includes the error in the published file.
- **false**—MATLAB displays the error at the command line and does not produce a published file.

### **'codeToEvaluate' — Additional code to evaluate during publishing**

string

Additional code to evaluate during publishing, specified as the comma-separated pair consisting of 'codeToEvaluate' and the string with the corresponding code. Use this option to specify code that does not appear in the MATLAB file, for example to set the value of an input argument for a function being published.

If this option is unspecified, MATLAB evaluates only the code in the MATLAB file you are publishing.

### **'maxOutputLines' — Maximum number of lines**

Inf (default) | nonnegative integer value

Maximum number of lines in MATLAB output per cell evaluated during publishing, specified as the comma-separated pair consisting of 'maxOutputLines' and one of the following values:

- `Inf` (default)—MATLAB includes all output lines in the published output.
- Nonnegative integer—MATLAB truncates the number of lines in the output at the number of lines you specify.

### 'showCode' — Option to include code in published file

`true` (default) | `false`

Option to include code in published file, specified as the comma-separated pair consisting of 'showCode' and a logical value.

## More About

### Window Decorations

Window decorations include window title bar, toolbar, menu bar, and window border.

### Syntax Highlighting

Syntax highlighting colors various elements in code to help you identify these elements while reading or editing code. By default, keywords are blue, strings are purple, and unterminated strings are maroon.

MATLAB does not preserve syntax highlighting when you set 'format' to 'latex' or 'ppt'.

### Tips

- If 'format' is 'html', MATLAB includes the code being published at the end of the published HTML file as comments, even when you set the 'showCode' option to `false`. Because MATLAB includes the code as comments, this code does not display in a Web browser. This enables you to use the `grabcode` function to extract the MATLAB code from an HTML file, even when the file does not display the code.
- “Publishing MATLAB Code”
- “Publishing Markup”

# PutCharArray

Store character array in Automation server

## Syntax

### IDL Method Signature

```
PutCharArray([in] BSTR varname, [in] BSTR workspace,
 [in] BSTR string)
```

### Microsoft Visual Basic Client

```
PutCharArray(varname As String, workspace As String,
 string As String)
```

### MATLAB Client

```
PutCharArray(h, 'varname', 'workspace', 'string')
```

## Description

`PutCharArray(h, 'varname', 'workspace', 'string')` stores the character array in `string` in the specified `workspace` of the server attached to handle `h`, assigning to it the variable `varname`. The values for `workspace` are `base` or `global`. The function name is case-sensitive.

## Examples

### Visual Basic .NET Client

This example uses the Visual Basic `MsgBox` command to control flow between MATLAB and the Visual Basic Client.

```
Dim Matlab As Object
```

```

Try
 Matlab = GetObject(, "matlab.application")
Catch e As Exception
 Matlab = CreateObject("matlab.application")
End Try
MsgBox("MATLAB window created; now open it...")

```

Open the MATLAB window, then click **Ok**.

```

Matlab.PutCharArray("str", "base", _
 "He jests at scars that never felt a wound.")
MsgBox("In MATLAB, type" & vbCrLf _
 & "str")

```

In the MATLAB window type `str`; MATLAB displays:

```

str =
He jests at scars that never felt a wound.

```

Click **Ok**.

```

MsgBox("closing MATLAB window...")

```

Click **Ok** to close and terminate MATLAB.

```

Matlab.Quit()

```

## More About

### Tips

The character array specified in the `string` argument can have any dimensions. However, `PutCharArray` changes the dimensions to a 1-by-n column-wise representation, where n is the number of characters in the array. Executing the following commands in MATLAB illustrates this behavior:

```

h = actxserver('matlab.application');
chArr = ['abc'; 'def'; 'ghk']
chArr =
abc
def
ghk

```

```
PutCharArray(h, 'Foo', 'base', chArr)
tstArr = GetCharArray(h, 'Foo', 'base')
tstArr =
adgbehcfk
```

### **See Also**

# PutFullMatrix

Matrix in Automation server workspace

## Syntax

### IDL Method Signature

```
PutFullMatrix([in] BSTR varname, [in] BSTR workspace,
[in] SAFEARRAY(double) xreal, [in] SAFEARRAY(double) ximag)
```

### Microsoft Visual Basic Client

```
PutFullMatrix([in] varname As String, [in] workspace As String,
[in] xreal As Double, [in] ximag As Double)
```

### MATLAB Client

```
PutFullMatrix(h, 'varname', 'workspace', xreal, ximag)
```

## Description

PutFullMatrix(h, 'varname', 'workspace', xreal, ximag) stores a matrix in the specified *workspace* of the server attached to handle *h* and assigns it to variable *varname*. Use *xreal* and *ximag* for the real and imaginary parts of the matrix. The matrix cannot be a scalar, an empty array, or have more than two dimensions. The values for *workspace* are *base* or *global*.

For VBScript clients, use the `GetWorkspaceData` and `PutWorkspaceData` functions to pass numeric data to and from the MATLAB workspace. These functions use the variant data type instead of `safearray`, which VBScript does not support.

## Examples

This example uses a Visual Basic .NET client to write a matrix to the base workspace of the server:

```
Dim MatLab As Object
Dim XReal(4, 4) As Double
Dim XImag(4, 4) As Double
Dim ZReal(4, 4) As Double
Dim ZImag(4, 4) As Double
Dim i, j As Integer
```

```
For i = 0 To 4
 For j = 0 To 4
 XReal(i, j) = Rnd() * 6
 XImag(i, j) = 0
 Next j
Next i
```

```
Matlab = CreateObject("matlab.application")
MatLab.PutFullMatrix("M", "base", XReal, XImag)
MatLab.GetFullMatrix("M", "base", ZReal, ZImag)
```

Use a Visual Basic .NET client to write a matrix to the global workspace of the server:

```
Dim MatLab As Object
Dim XReal(1,2) As Double
Dim XImag(1,2) As Double
Dim result As String
Dim i,j As Integer
```

```
For i = 0 To 1
 For j = 0 To 2
 XReal(i,j) = (j * 2 + 1) + i
 XImag(i,j) = 1
 Next j
Next i
```

```
Matlab = CreateObject("matlab.application")
MatLab.PutFullMatrix("X", "global", XReal, XImag)
result = Matlab.Execute("whos global")
MsgBox(result)
```

## See Also

# PutWorkspaceData

Data in Automation server workspace

## Syntax

### IDL Method Signature

```
PutWorkspaceData([in] BSTR varname, [in] BSTR workspace,
[in] VARIANT data)
```

### Microsoft Visual Basic Client

```
PutWorkspaceData(varname As String, workspace As String,
data As Object)
```

### MATLAB Client

```
PutWorkspaceData(h, 'varname', 'workspace', data)
```

## Description

`PutWorkspaceData(h, 'varname', 'workspace', data)` stores data in the *workspace* of the server attached to handle `h` and assigns it to `varname`. The values for *workspace* are `base` or `global`.

Use `PutWorkspaceData` to pass numeric and character array data respectively to the server. Do *not* use `PutWorkspaceData` on sparse arrays, structures, or function handles. Use the `Execute` method for these data types.

The `GetWorkspaceData` and `PutWorkspaceData` functions pass numeric data as a `variant` data type. These functions are especially useful for VBScript clients as VBScript does not support the `safearray` data type used by `GetFullMatrix` and `PutFullMatrix`.

## Examples

Create an array in a Visual Basic .NET client and put it in the base workspace of the MATLAB Automation server:

- 1 Create the Visual Basic application. Use the `MsgBox` command to control flow between MATLAB and the application:

```
Dim Matlab As Object
Dim data(6) As Double
Dim i As Integer
Matlab = CreateObject("matlab.application")
For i = 0 To 6
 data(i) = i * 15
Next i
Matlab.PutWorkspaceData("A","base",data)
MsgBox("In MATLAB, type" & vbCrLf & "A")
```

- 2 Open the MATLAB window and type A. MATLAB displays:

```
A =
 0 15 30 45 60 75 90
```

- 3 Click **Ok** to close and terminate MATLAB.

## **pwd**

Identify current folder

### **Syntax**

```
pwd
currentFolder = pwd
```

### **Description**

pwd displays the MATLAB current folder.

currentFolder = pwd returns the current folder as a string to currentFolder.

### **Alternatives**

- Use the Current Folder toolbar.

### **See Also**

cd | dir

**Introduced before R2006a**

## pyargs

Create keyword argument for Python function

### Syntax

```
kwa = pyargs(argKey, argValue)
```

### Description

`kwa = pyargs(argKey, argValue)` creates a `pyargs` keyword argument to pass to a Python function.

### Examples

#### Use Keyword Argument to Modify Calendar Month Display

Create a calendar.

```
cal = py.calendar.TextCalendar;
```

Display calendar for December 2014.

```
formatmonth(cal, int32(2014), int32(12))
```

```
ans =
```

```
 Python str with no properties.
```

```
 December 2014
Mo Tu We Th Fr Sa Su
 1 2 3 4 5 6 7
 8 9 10 11 12 13 14
15 16 17 18 19 20 21
22 23 24 25 26 27 28
29 30 31
```

Read the function signature from the Python documentation for the `calendar.TextCalendar.formatmonth` function.

```
py.help('calendar.TextCalendar.formatmonth')
```

```
Help on method formatmonth in calendar.TextCalendar:
```

```
calendar.TextCalendar.formatmonth = formatmonth(self, theyear, themonth, w=0, l=0) unbound method TextCalendar.formatmonth()
 Return a month's calendar string (multi-line).
```

Arguments `w` and `l` are optional, with default values of `0`.

Read the function signature in MATLAB.

```
methods(cal, '-full')
```

```
lhs formatmonth(self, theyear, themonth, w, l, pyargs)
```

Search the output for the `formatmonth` function signature. You can use the `pyargs` argument instead of the optional `w` and `l` arguments.

Change the line spacing, `l`, using a `pyargs` argument.

```
formatmonth(cal,int32(2014),int32(12),pyargs('l',int32(2)))
```

```
ans =
```

```
 Python str with no properties.
```

```
 December 2014
```

```
Mo Tu We Th Fr Sa Su
```

```
 1 2 3 4 5 6 7
```

```
 8 9 10 11 12 13 14
```

```
15 16 17 18 19 20 21
```

```
22 23 24 25 26 27 28
```

```
29 30 31
```

## Input Arguments

**argKey, argValue** — Python function arguments  
keyword and value arguments

Python function keyword arguments specified as one or more comma-separated pairs of `argKey`, `argValue` arguments. `argKey` is the Python function key name and is a string. `argValue` is the argument value, represented by any type. Use the function argument list to identify `argKey` and `argValue`. You can specify several key and value pair arguments in any order as `argKey1`, `argValue1`, ..., `argKeyN`, `argValueN`.

Example: `'length', int32(2)`

## More About

- `python.org` `calendar.TextCalendar` method

**Introduced in R2014b**

## **matlab.exception.PyException class**

**Package:** matlab.exception

Capture error information for Python exception

### **Description**

Process information from a `matlab.exception.PyException` object to handle Python errors thrown from Python methods called from MATLAB. This class is derived from `MException`.

### **Construction**

`e = matlab.exception.PyException(msgID, errMsg, excObj)` constructs instance `e` of `matlab.exception.PyException` class.

### **Input Arguments**

**msgID** — Message identifier

string

Message identifier, specified as a string.

**errMsg** — Error message

string

Error message, specified as a string.

**excObj** — Exception object

pythonclass

Exception object, specified as the `pythonclass` that caused the exception.

### **Output Arguments**

**e** — Exception object

exception object

Instance of `matlab.exception.PyException` class

## Properties

### ExceptionObject – Object

exception object

Result from Python `sys.exc_info` function. For information about what the function returns, type:

```
help('py.sys.exc_info')
```

```
exc_info() -> (type, value, traceback)
```

Return information about the most recent exception caught by an except clause in the current stack frame or in an older stack frame.

## Tips

- Typically, you do not construct a `matlab.exception.PyException` object explicitly. MATLAB automatically constructs a `PyException` object whenever Python throws an exception. The `PyException` object wraps the original Python exception.

## Examples

### Catch Python Exception

Generate a Python exception and display information.

```
try
 py.list('x','y',1)
catch e
 e.message
 if(isa(e,'matlab.exception.PyException'))
 e.ExceptionObject
 end
end
ans =
```

```
Python Error: TypeError: list() takes at most 1 argument (3 given)
```

```
ans =
```

```
Python tuple with no properties.
```

```
(<type 'exceptions.TypeError'>, TypeError('list() takes at most 1 argument (3 given)'))
```

When MATLAB displays a message containing the text `Python Error`, refer to your Python documentation for more information.

## Introduced in R2014b

# pyversion

Change default version of Python interpreter

## Syntax

```
pyversion
[version, executable, isloaded] = pyversion
```

```
___ = pyversion version
___ = pyversion executable
```

## Description

pyversion displays details about the current Python version.

[version, executable, isloaded] = pyversion returns Python version information.

\_\_\_ = pyversion version changes the default Python version on Microsoft Windows platforms. The setting is persistent across MATLAB sessions.

You cannot change the version after MATLAB loads Python. To change the version if Python is loaded already, restart MATLAB, and then call `pyversion`.

\_\_\_ = pyversion executable specifies full path to Python executable. Use on any platform or for repackaged CPython implementation downloads.

## Examples

### Display Python Version for Your System

```
pyversion

version: '2.7'
executable: 'C:\Python27\python.exe'
library: 'C:\windows\system32\python27.dll'
```

```
home: 'C:\Python27'
isloaded: 0
```

## Use Python Version 2.7

```
[v, e, isloaded] = pyversion;
if isloaded
 disp('To change the Python version, restart MATLAB, then call pyversion.')else
 pyversion 2.7
end
```

## Input Arguments

### **version** — Python version number

string

Python version number, specified as a string. Version must contain the major and minor version numbers separated by a period. Windows platform only.

`pyversion` looks for the version in the Windows registry. If you download from [www.python.org/downloads](http://www.python.org/downloads), the installation automatically adds the version to the registry. If you download the Python application from a different source, either add it to the registry, or use the `pyversion(executable)` syntax to change the version.

Example: 3.3

### **executable** — Name of existing Python executable file

string

Name of an existing Python executable file, specified as a string. This argument must contain the name of the Python executable file and it can contain the full path.

Example: C:\Python33\python.exe

Example: /usr/bin/python

## Output Arguments

### **version** — Python version number

string

Python version number, specified as a string.

**executable** — Name of Python executable file

string

Name of Python executable file, specified as a string.

**isloaded** — Indicates if specified version is loaded

logical

Indicates if specified version is loaded, specified as logical. MATLAB loads Python when you type a `py .` command.

If MATLAB cannot load Python, `isloaded` is 0 and MATLAB displays “Undefined variable “py” or function “py.command”” when you type a `py .` command.

## Limitations

- Do not use `pyversion` to set the version in a MATLAB function containing Python commands. MATLAB loads the Python interpreter when it processes a Python command in the function before it executes the `pyversion` function.

**Introduced in R2014b**

## qmr

Quasi-minimal residual method

### Syntax

```
x = qmr(A,b)
qmr(A,b,tol)
qmr(A,b,tol,maxit)
qmr(A,b,tol,maxit,M)
qmr(A,b,tol,maxit,M1,M2)
qmr(A,b,tol,maxit,M1,M2,x0)
[x,flag] = qmr(A,b,...)
[x,flag,relres] = qmr(A,b,...)
[x,flag,relres,iter] = qmr(A,b,...)
[x,flag,relres,iter,resvec] = qmr(A,b,...)
```

### Description

`x = qmr(A,b)` attempts to solve the system of linear equations  $A^*x=b$  for  $x$ . The  $n$ -by- $n$  coefficient matrix  $A$  must be square and should be large and sparse. The column vector  $b$  must have length  $n$ . You can specify  $A$  as a function handle, `afun`, such that `afun(x, 'notransp')` returns  $A^*x$  and `afun(x, 'transp')` returns  $A' * x$ .

“Parameterizing Functions” explains how to provide additional parameters to the function `afun`, as well as the preconditioner function `mfun` described below, if necessary.

If `qmr` converges, a message to that effect is displayed. If `qmr` fails to converge after the maximum number of iterations or halts for any reason, a warning message is printed displaying the relative residual  $\text{norm}(b-A^*x)/\text{norm}(b)$  and the iteration number at which the method stopped or failed.

`qmr(A,b,tol)` specifies the tolerance of the method. If `tol` is `[]`, then `qmr` uses the default,  $1e-6$ .

`qmr(A,b,tol,maxit)` specifies the maximum number of iterations. If `maxit` is `[]`, then `qmr` uses the default,  $\min(n,20)$ .

`qmr(A,b,tol,maxit,M)` and `qmr(A,b,tol,maxit,M1,M2)` use preconditioners `M` or `M = M1*M2` and effectively solve the system  $\text{inv}(M)*A*x = \text{inv}(M)*b$  for `x`. If `M` is `[]` then `qmr` applies no preconditioner. `M` can be a function handle `mfun` such that `mfun(x, 'notransp')` returns `M\x` and `mfun(x, 'transp')` returns `M'\x`.

`qmr(A,b,tol,maxit,M1,M2,x0)` specifies the initial guess. If `x0` is `[]`, then `qmr` uses the default, an all zero vector.

`[x,flag] = qmr(A,b,...)` also returns a convergence flag.

Flag	Convergence
0	qmr converged to the desired tolerance <code>tol</code> within <code>maxit</code> iterations.
1	qmr iterated <code>maxit</code> times but did not converge.
2	Preconditioner <code>M</code> was ill-conditioned.
3	The method stagnated. (Two consecutive iterates were the same.)
4	One of the scalar quantities calculated during <code>qmr</code> became too small or too large to continue computing.

Whenever `flag` is not 0, the solution `x` returned is that with minimal norm residual computed over all the iterations. No messages are displayed if the `flag` output is specified.

`[x,flag,relres] = qmr(A,b,...)` also returns the relative residual  $\text{norm}(b-A*x) / \text{norm}(b)$ . If `flag` is 0, `relres <= tol`.

`[x,flag,relres,iter] = qmr(A,b,...)` also returns the iteration number at which `x` was computed, where  $0 \leq \text{iter} \leq \text{maxit}$ .

`[x,flag,relres,iter,resvec] = qmr(A,b,...)` also returns a vector of the residual norms at each iteration, including  $\text{norm}(b-A*x_0)$ .

## Examples

### Using qmr with a Matrix Input

This example shows how to use `qmr` with a matrix input. The code:

```
n = 100;
on = ones(n,1);
A = spdiags([-2*on 4*on -on],-1:1,n,n);
b = sum(A,2);
tol = 1e-8; maxit = 15;
M1 = spdiags([on/(-2) on],-1:0,n,n);
M2 = spdiags([4*on -on],0:1,n,n);
x = qmr(A,b,tol,maxit,M1,M2);
```

displays the message:

```
qmr converged at iteration 9 to a solution...
with relative residual
5.6e-009
```

## Using qmr with a Function Handle

This example replaces the matrix *A* in the previous example with a handle to a matrix-vector product function *afun*. The example is contained in a file *run\_qmr* that

- Calls *qmr* with the function handle *@afun* as its first argument.
- Contains *afun* as a nested function, so that all variables in *run\_qmr* are available to *afun*.

The following shows the code for *run\_qmr*:

```
function x1 = run_qmr
n = 100;
on = ones(n,1);
A = spdiags([-2*on 4*on -on],-1:1,n,n);
b = sum(A,2);
tol = 1e-8;
maxit = 15;
M1 = spdiags([on/(-2) on],-1:0,n,n);
M2 = spdiags([4*on -on],0:1,n,n);
x1 = qmr(@afun,b,tol,maxit,M1,M2);

function y = afun(x,transp_flag)
 if strcmp(transp_flag,'transp') % y = A'*x
 y = 4 * x;
 y(1:n-1) = y(1:n-1) - 2 * x(2:n);
 y(2:n) = y(2:n) - x(1:n-1);
```

```

 elseif strcmp(transp_flag,'notransp') % y = A*x
 y = 4 * x;
 y(2:n) = y(2:n) - 2 * x(1:n-1);
 y(1:n-1) = y(1:n-1) - x(2:n);
 end
 end
end
end

```

When you enter

```
x1=run_qmr;
```

MATLAB software displays the message

```
qmr converged at iteration 9 to a solution with relative residual
5.6e-009
```

## Using qmr with a Preconditioner

This example demonstrates the use of a preconditioner.

Load `A = west0479`, a real 479-by-479 nonsymmetric sparse matrix.

```
load west0479;
A = west0479;
```

Define `b` so that the true solution is a vector of all ones.

```
b = full(sum(A,2));
```

Set the tolerance and maximum number of iterations.

```
tol = 1e-12;
maxit = 20;
```

Use `qmr` to find a solution at the requested tolerance and number of iterations.

```
[x0,f10,rr0,it0,rv0] = qmr(A,b,tol,maxit);
```

`f10` is 1 because `qmr` does not converge to the requested tolerance  $1e-12$  within the requested 20 iterations. The seventeenth iterate is the best approximate solution and is the one returned as indicated by `it0 = 17`. MATLAB stores the residual history in `rv0`.

Plot the behavior of qmr.

```
semilogy(0:maxit,rv0/norm(b),'-o');
xlabel('Iteration number');
ylabel('Relative residual');
```

The plot shows that the solution does not converge. You can use a preconditioner to improve the outcome.

Create the preconditioner with `ilu`, since the matrix `A` is nonsymmetric.

```
[L,U] = ilu(A,struct('type','ilutp','droptol',1e-5));
```

Error using `ilu`

There is a pivot equal to zero. Consider decreasing the drop tolerance or consider using the 'udiag' option.

MATLAB cannot construct the incomplete LU as it would result in a singular factor, which is useless as a preconditioner.

You can try again with a reduced drop tolerance, as indicated by the error message.

```
[L,U] = ilu(A,struct('type','ilutp','droptol',1e-6));
[x1,f11,rr1,it1,rv1] = qmr(A,b,tol,maxit,L,U);
```

f11 is 0 because qmr drives the relative residual to  $4.1410e-014$  (the value of rr1). The relative residual is less than the prescribed tolerance of  $1e-12$  at the sixth iteration (the value of it1) when preconditioned by the incomplete LU factorization with a drop tolerance of  $1e-6$ . The output rv1(1) is norm(b), and the output rv1(7) is norm(b-A\*x2).

You can follow the progress of qmr by plotting the relative residuals at each iteration starting from the initial estimate (iterate number 0).

```
semilogy(0:it1,rv1/norm(b),'-o');
xlabel('Iteration number');
ylabel('Relative residual');
```

## qr

Orthogonal-triangular decomposition

### Syntax

```
[Q,R] = qr(A)
[Q,R] = qr(A,0)
[Q,R,E] = qr(A)
[Q,R,E] = qr(A,'matrix')
[Q,R,e] = qr(A,'vector')
[Q,R,e] = qr(A,0)
X = qr(A)
X = qr(A,0)
R = qr(A)
R = qr(A,0)
[C,R] = qr(A,B)
[C,R,E] = qr(A,B)
[C,R,E] = qr(A,B,'matrix')
[C,R,e] = qr(A,B,'vector')
[C,R] = qr(A,B,0)
[C,R,e] = qr(A,B,0)
```

### Description

$[Q,R] = \text{qr}(A)$ , where  $A$  is  $m$ -by- $n$ , produces an  $m$ -by- $n$  upper triangular matrix  $R$  and an  $m$ -by- $m$  unitary matrix  $Q$  so that  $A = Q \cdot R$ .

$[Q,R] = \text{qr}(A,0)$  produces the economy-size decomposition. If  $m > n$ , only the first  $n$  columns of  $Q$  and the first  $n$  rows of  $R$  are computed. If  $m \leq n$ , this is the same as  $[Q,R] = \text{qr}(A)$ .

If  $A$  is full:

$[Q,R,E] = \text{qr}(A)$  or  $[Q,R,E] = \text{qr}(A, 'matrix')$  produces unitary  $Q$ , upper triangular  $R$  and a permutation matrix  $E$  so that  $A \cdot E = Q \cdot R$ . The column permutation  $E$  is chosen so that  $\text{abs}(\text{diag}(R))$  is decreasing.

$[Q,R,e] = \text{qr}(A, 'vector')$  returns the permutation information as a vector instead of a matrix. That is,  $e$  is a row vector such that  $A(:,e) = Q^*R$ .

$[Q,R,e] = \text{qr}(A,0)$  produces an economy-size decomposition in which  $e$  is a permutation vector, so that  $A(:,e) = Q^*R$ .

$X = \text{qr}(A)$  and  $X = \text{qr}(A,0)$  return a matrix  $X$  such that  $\text{triu}(X)$  is the upper triangular factor  $R$ .

If  $A$  is sparse:

$R = \text{qr}(A)$  computes a  $Q$ -less QR decomposition and returns the upper triangular factor  $R$ . Note that  $R = \text{chol}(A^*A)$ . Since  $Q$  is often nearly full, this is preferred to  $[Q,R] = \text{QR}(A)$ .

$R = \text{qr}(A,0)$  produces economy-size  $R$ . If  $m > n$ ,  $R$  has only  $n$  rows. If  $m \leq n$ , this is the same as  $R = \text{qr}(A)$ .

$[Q,R,E] = \text{qr}(A)$  or  $[Q,R,E] = \text{qr}(A, 'matrix')$  produces unitary  $Q$ , upper triangular  $R$  and a permutation matrix  $E$  so that  $A^*E = Q^*R$ . The column permutation  $E$  is chosen to reduce fill-in in  $R$ .

$[Q,R,e] = \text{qr}(A, 'vector')$  returns the permutation information as a vector instead of a matrix. That is,  $e$  is a row vector such that  $A(:,e) = Q^*R$ .

$[Q,R,e] = \text{qr}(A,0)$  produces an economy-size decomposition in which  $e$  is a permutation vector, so that  $A(:,e) = Q^*R$ .

$[C,R] = \text{qr}(A,B)$ , where  $B$  has as many rows as  $A$ , returns  $C = Q^*B$ . The least-squares solution to  $A^*X = B$  is  $X = R \setminus C$ .

$[C,R,E] = \text{qr}(A,B)$  or  $[C,R,E] = \text{qr}(A,B, 'matrix')$ , also returns a fill-reducing ordering. The least-squares solution to  $A^*X = B$  is  $X = E^*(R \setminus C)$ .

$[C,R,e] = \text{qr}(A,B, 'vector')$  returns the permutation information as a vector instead of a matrix. That is, the least-squares solution to  $A^*X = B$  is  $X(e,:) = R \setminus C$ .

$[C,R] = \text{qr}(A,B,0)$  produces economy-size results. If  $m > n$ ,  $C$  and  $R$  have only  $n$  rows. If  $m \leq n$ , this is the same as  $[C,R] = \text{qr}(A,B)$ .

$[C,R,e] = \text{qr}(A,B,0)$  additionally produces a fill-reducing permutation vector  $e$ . In this case, the least-squares solution to  $A^*X = B$  is  $X(e,:) = R \setminus C$ .

## Examples

Find the least squares approximate solution to  $A*x = b$  with the Q-less QR decomposition and one step of iterative refinement:

```
if issparse(A), R = qr(A);
else R = triu(qr(A)); end
x = R\ (R\'\'(A'*b));
r = b - A*x;
err = R\ (R\'\'(A'*r));
x = x + err;
```

# qrdelete

Remove column or row from QR factorization

## Syntax

```
[Q1,R1] = qrdelete(Q,R,j)
[Q1,R1] = qrdelete(Q,R,j,'col')
[Q1,R1] = qrdelete(Q,R,j,'row')
```

## Description

`[Q1,R1] = qrdelete(Q,R,j)` returns the QR factorization of the matrix  $A_1$ , where  $A_1$  is  $A$  with the column  $A(:,j)$  removed and  $[Q,R] = \text{qr}(A)$  is the QR factorization of  $A$ .

`[Q1,R1] = qrdelete(Q,R,j,'col')` is the same as `qrdelete(Q,R,j)`.

`[Q1,R1] = qrdelete(Q,R,j,'row')` returns the QR factorization of the matrix  $A_1$ , where  $A_1$  is  $A$  with the row  $A(j,:)$  removed and  $[Q,R] = \text{qr}(A)$  is the QR factorization of  $A$ .

## Examples

```
A = magic(5);
[Q,R] = qr(A);
j = 3;
[Q1,R1] = qrdelete(Q,R,j,'row');
```

```
Q1 =
 0.5274 -0.5197 -0.6697 -0.0578

## More About

### Algorithms

The `qrdelete` function uses a series of Givens rotations to zero out the appropriate elements of the factorization.

### See Also

`planerot` | `qr` | `qrinsert`

Introduced before R2006a

# qrinsert

Insert column or row into QR factorization

## Syntax

```
[Q1,R1] = qrinsert(Q,R,j,x)
[Q1,R1] = qrinsert(Q,R,j,x,'col')
[Q1,R1] = qrinsert(Q,R,j,x,'row')
```

## Description

`[Q1,R1] = qrinsert(Q,R,j,x)` returns the QR factorization of the matrix  $A_1$ , where  $A_1$  is  $A = Q \cdot R$  with the column  $x$  inserted before  $A(:,j)$ . If  $A$  has  $n$  columns and  $j = n + 1$ , then  $x$  is inserted after the last column of  $A$ .

`[Q1,R1] = qrinsert(Q,R,j,x,'col')` is the same as `qrinsert(Q,R,j,x)`.

`[Q1,R1] = qrinsert(Q,R,j,x,'row')` returns the QR factorization of the matrix  $A_1$ , where  $A_1$  is  $A = Q \cdot R$  with an extra row,  $x$ , inserted before  $A(j,:)$ .

## Examples

```
A = magic(5);
[Q,R] = qr(A);
j = 3;
x = 1:5;
[Q1,R1] = qrinsert(Q,R,j,x,'row')
```

```

```

## More About

### Algorithms

The `qrinsert` function inserts the values of `x` into the `j`th column (row) of `R`. It then uses a series of Givens rotations to zero out the nonzero elements of `R` on and below the diagonal in the `j`th column (row).

### See Also

`planerot` | `qr` | `qrdelete`

**Introduced before R2006a**

# qrupdate

Rank 1 update to QR factorization

## Syntax

```
[Q1,R1] = qrupdate(Q,R,u,v)
```

## Description

`[Q1,R1] = qrupdate(Q,R,u,v)` when `[Q,R] = qr(A)` is the original QR factorization of `A`, returns the QR factorization of `A + u*v'`, where `u` and `v` are column vectors of appropriate lengths.

## Examples

The matrix

```
mu = sqrt(eps)
```

```
mu =
```

```
1.4901e-08
```

```
A = [ones(1,4); mu*eye(4)];
```

is a well-known example in least squares that indicates the dangers of forming  $A' * A$ . Instead, we work with the QR factorization – orthonormal `Q` and upper triangular `R`.

```
[Q,R] = qr(A);
```

As we expect, `R` is upper triangular.

```
R =
```

```
-1.0000 -1.0000 -1.0000 -1.0000
 0 0.0000 0.0000 0.0000
 0 0 0.0000 0.0000
```

```

0 0 0 0.0000
0 0 0 0

```

In this case, the upper triangular entries of  $R$ , excluding the first row, are on the order of  $\sqrt{\text{eps}}$ .

Consider the update vectors

```
u = [-1 0 0 0 0]'; v = ones(4,1);
```

Instead of computing the rather trivial QR factorization of this rank one update to  $A$  from scratch with

```
[QT,RT] = qr(A + u*v')
```

QT =

```

0 0 0 0 1
-1 0 0 0 0
0 -1 0 0 0
0 0 -1 0 0
0 0 0 -1 0

```

RT =

```

1.0e-007 *
-0.1490 0 0 0
0 -0.1490 0 0
0 0 -0.1490 0
0 0 0 -0.1490
0 0 0 0

```

we may use `qrupdate`.

```
[Q1,R1] = qrupdate(Q,R,u,v)
```

Q1 =

```

-0.0000 -0.0000 -0.0000 -0.0000 1.0000
 1.0000 -0.0000 -0.0000 -0.0000 0.0000
 0.0000 1.0000 -0.0000 -0.0000 0.0000
 0.0000 0.0000 1.0000 -0.0000 0.0000
-0.0000 -0.0000 -0.0000 1.0000 0.0000

```

R1 =

```

1.0e-007 *
0.1490 0.0000 0.0000 0.0000
 0 0.1490 0.0000 0.0000
 0 0 0.1490 0.0000
 0 0 0 0.1490
 0 0 0 0

```

Note that both factorizations are correct, even though they are different.

## More About

### Tips

qrupdate works only for full matrices.

### Algorithms

qrupdate uses the algorithm in section 12.5.1 of the third edition of *Matrix Computations* by Golub and van Loan. qrupdate is useful since, if we take  $N = \max(m, n)$ , then computing the new QR factorization from scratch is roughly an  $O(N^3)$  algorithm, while simply updating the existing factors in this way is an  $O(N^2)$  algorithm.

## quad

Numerically evaluate integral, adaptive Simpson quadrature

## Compatibility

quad will be removed in a future release. Use `integral` instead.

## Syntax

```
q = quad(fun,a,b)
q = quad(fun,a,b,tol)
q = quad(fun,a,b,tol,trace)
[q,fcnt] = quad(...)
```

## Description

*Quadrature* is a numerical method used to find the area under the graph of a function, that is, to compute a definite integral.

$$q = \int_a^b f(x) dx$$

`q = quad(fun,a,b)` tries to approximate the integral of function `fun` from `a` to `b` to within an error of `1e-6` using recursive adaptive Simpson quadrature. `fun` is a function handle. Limits `a` and `b` must be finite. The function `y = fun(x)` should accept a vector argument `x` and return a vector result `y`, the integrand evaluated at each element of `x`.

“Parameterizing Functions” explains how to provide additional parameters to the function `fun`, if necessary.

`q = quad(fun,a,b,tol)` uses an absolute error tolerance `tol` instead of the default which is `1.0e-6`. Larger values of `tol` result in fewer function evaluations and faster computation, but less accurate results. In MATLAB version 5.3 and earlier, the `quad` function used a less reliable algorithm and a default relative tolerance of `1.0e-3`.

`q = quad(fun,a,b,tol,trace)` with non-zero `trace` shows the values of `[fcnt a b-a Q]` during the recursion.

`[q,fcnt] = quad(...)` returns the number of function evaluations.

The function `quadl` may be more efficient with high accuracies and smooth integrands.

The list below contains information to help you determine which quadrature function in MATLAB to use:

- The `quad` function may be most efficient for low accuracies with nonsmooth integrands.
- The `quadl` function may be more efficient than `quad` at higher accuracies with smooth integrands.
- The `quadgk` function may be most efficient for high accuracies and oscillatory integrands. It supports infinite intervals and can handle moderate singularities at the endpoints. It also supports contour integration along piecewise linear paths.
- The `quadv` function vectorizes `quad` for an array-valued `fun`.
- If the interval is infinite, `[a, Inf)`, then for the integral of `fun(x)` to exist, `fun(x)` must decay as `x` approaches infinity, and `quadgk` requires it to decay rapidly. Special methods should be used for oscillatory functions on infinite intervals, but `quadgk` can be used if `fun(x)` decays fast enough.
- The `quadgk` function will integrate functions that are singular at finite endpoints if the singularities are not too strong. For example, it will integrate functions that behave at an endpoint `c` like `log|x-c|` or `|x-c|^p` for `p >= -1/2`. If the function is singular at points inside `(a,b)`, write the integral as a sum of integrals over subintervals with the singular points as endpoints, compute them with `quadgk`, and add the results.

## Examples

To compute the integral

$$\int_0^2 \frac{1}{x^3 - 2x - 5} dx,$$

write a function `myfun` that computes the integrand:

```
function y = myfun(x)
y = 1./(x.^3-2*x-5);
```

Then pass `@myfun`, a function handle to `myfun`, to `quad`, along with the limits of integration, 0 to 2:

```
Q = quad(@myfun,0,2)
```

```
Q =
```

```
-0.4605
```

Alternatively, you can pass the integrand to `quad` as an anonymous function handle `F`:

```
F = @(x)1./(x.^3-2*x-5);
Q = quad(F,0,2);
```

## Diagnostics

`quad` may issue one of the following warnings:

'Minimum step size reached' indicates that the recursive interval subdivision has produced a subinterval whose length is on the order of roundoff error in the length of the original interval. A nonintegrable singularity is possible.

'Maximum function count exceeded' indicates that the integrand has been evaluated more than 10,000 times. A nonintegrable singularity is likely.

'Infinite or Not-a-Number function value encountered' indicates a floating point overflow or division by zero during the evaluation of the integrand in the interior of the interval.

## quad2d

Numerically evaluate double integral, tiled method

### Syntax

```
q = quad2d(fun,a,b,c,d)
[q,errbnd] = quad2d(...)
q = quad2d(fun,a,b,c,d,param1,val1,param2,val2,...)
```

### Description

`q = quad2d(fun,a,b,c,d)` approximates the integral of `fun(x,y)` over the planar region  $a \leq x \leq b$  and  $c(x) \leq y \leq d(x)$ . `fun` is a function handle, `c` and `d` may each be a scalar or a function handle.

All input functions must be vectorized. The function `Z=fun(X,Y)` must accept 2-D matrices `X` and `Y` of the same size and return a matrix `Z` of corresponding values. The functions `ymin=c(X)` and `ymax=d(X)` must accept matrices and return matrices of the same size with corresponding values.

`[q,errbnd] = quad2d(...)`. `errbnd` is an approximate upper bound on the absolute error,  $|Q - I|$ , where `I` denotes the exact value of the integral.

`q = quad2d(fun,a,b,c,d,param1,val1,param2,val2,...)` performs the integration as above with specified values of optional parameters:

<code>AbsTol</code>	absolute error tolerance
<code>RelTol</code>	relative error tolerance

`quad2d` attempts to satisfy `ERRBND <= max(AbsTol,RelTol*|Q|)`. This is absolute error control when  $|Q|$  is sufficiently small and relative error control when  $|Q|$  is larger. A default tolerance value is used when a tolerance is not specified. The default value of `AbsTol` is `1e-5`. The default value of `RelTol` is `100*eps(class(Q))`. This is also the minimum value of `RelTol`. Smaller `RelTol` values are automatically increased to the default value.

<b>MaxFunEvals</b>	Maximum allowed number of evaluations of <code>fun</code> reached.
--------------------	--------------------------------------------------------------------

The `MaxFunEvals` parameter limits the number of vectorized calls to `fun`. The default is 2000.

<b>FailurePlot</b>	Generate a plot if <code>MaxFunEvals</code> is reached.
--------------------	---------------------------------------------------------

Setting `FailurePlot` to `true` generates a graphical representation of the regions needing further refinement when `MaxFunEvals` is reached. No plot is generated if the integration succeeds before reaching `MaxFunEvals`. These (generally) 4-sided regions are mapped to rectangles internally. Clusters of small regions indicate the areas of difficulty. The default is `false`.

<b>Singular</b>	Problem may have boundary singularities
-----------------	-----------------------------------------

With `Singular` set to `true`, `quad2d` will employ transformations to weaken boundary singularities for better performance. The default is `true`. Setting `Singular` to `false` will turn these transformations off, which may provide a performance benefit on some smooth problems.

## Examples

### Example 1

Integrate  $y \sin(x) + x \cos(y)$  over  $\pi \leq x \leq 2\pi$ ,  $0 \leq y \leq \pi$ . The true value of the integral is  $-\pi^2$ .

```
Q = quad2d(@(x,y) y.*sin(x)+x.*cos(y),pi,2*pi,0,pi)
```

### Example 2

Integrate  $[(x+y)^{1/2}(1+x+y)^2]^{-1}$  over the triangle  $0 \leq x \leq 1$  and  $0 \leq y \leq 1-x$ . The integrand is infinite at  $(0,0)$ . The true value of the integral is  $\pi/4 - 1/2$ .

```
fun = @(x,y) 1./(sqrt(x + y) .* (1 + x + y).^2)
```

In Cartesian coordinates:

```
ymin = @(x) 1 - x;
Q = quad2d(fun,0,1,0,ymin)
```

In polar coordinates:

```
polarfun = @(theta,r) fun(r.*cos(theta),r.*sin(theta)).*r;
rmax = @(theta) 1./(sin(theta) + cos(theta));
Q = quad2d(polarfun,0,pi/2,0,rmax)
```

## Limitations

`quad2d` begins by mapping the region of integration to a rectangle. Consequently, it may have trouble integrating over a region that does not have four sides or has a side that cannot be mapped smoothly to a straight line. If the integration is unsuccessful, some helpful tactics are leaving `Singular` set to its default value of `true`, changing between Cartesian and polar coordinates, or breaking the region of integration into pieces and adding the results of integration over the pieces.

For instance:

```
fun = @(x,y)abs(x.^2 + y.^2 - 0.25);
c = @(x)-sqrt(1 - x.^2);
d = @(x)sqrt(1 - x.^2);
quad2d(fun, -1,1,c,d, 'AbsTol',1e-8,...
 'FailurePlot',true, 'Singular',false);
```

Warning: Reached the maximum number of function evaluations (2000). The result fails the global error test.

The failure plot shows two areas of difficulty, near the points  $(-1, 0)$  and  $(1, 0)$  and near the circle  $x^2 + y^2 = 0.25$ .

Changing the value of `Singular` to `true` will cope with the geometric singularities at  $(-1, 0)$  and  $(1, 0)$ . The larger shaded areas may need refinement but are probably not areas of difficulty.

```
Q = quad2d(fun, -1, 1, c, d, 'AbsTol', 1e-8, ...
 'FailurePlot', true, 'Singular', true);
```

Warning: Reached the maximum number of function evaluations (2000). The result passes the global error test.

From here you can take advantage of symmetry:

```
Q = 4*quad2d(fun,0,1,0,d,'Abstol',1e-8,...
 'Singular',true,'FailurePlot',true)
```

Q =

0.9817

However, the code is still working very hard near the singularity. It may not be able to provide higher accuracy:

```
Q = 4*quad2d(fun,0,1,0,d,'Abstol',1e-10,...
```

```
'Singular',true,'FailurePlot',true);
```

Warning: Reached the maximum number of function evaluations (2000). The result passes the global error test.

At higher accuracy, a change in coordinates may work better.

```
polarfun = @(theta,r) fun(r.*cos(theta),r.*sin(theta)).*r;
Q = 4*quad2d(polarfun,0,pi/2,0,1,'AbsTol',1e-10);
```

It is best to put the singularity on the boundary by splitting the region of integration into two parts:

```
Q1 = 4*quad2d(polarfun,0,pi/2,0,0.5,'AbsTol',5e-11);
```

```
Q2 = 4*quad2d(polarfun,0,pi/2,0.5,1,'AbsTol',5e-11);
Q = Q1 + Q2;
```

# quadgk

Numerically evaluate integral, adaptive Gauss-Kronrod quadrature

## Syntax

```
q = quadgk(fun,a,b)
[q,errbnd] = quadgk(fun,a,b)
[q,errbnd] = quadgk(fun,a,b,param1,val1,param2,val2,...)
```

## Description

`q = quadgk(fun,a,b)` attempts to approximate the integral of a scalar-valued function `fun` from `a` to `b` using high-order global adaptive quadrature and default error tolerances. The function `y = fun(x)` should accept a vector argument `x` and return a vector result `y`, where `y` is the integrand evaluated at each element of `x`. `fun` must be a function handle. Limits `a` and `b` can be `-Inf` or `Inf`. If both are finite, they can be complex. If at least one is complex, the integral is approximated over a straight line path from `a` to `b` in the complex plane.

“Parameterizing Functions” explains how to provide additional parameters to the function `fun`, if necessary.

`[q,errbnd] = quadgk(fun,a,b)` returns an approximate upper bound on the absolute error,  $|Q - I|$ , where `I` denotes the exact value of the integral.

`[q,errbnd] = quadgk(fun,a,b,param1,val1,param2,val2,...)` performs the integration with specified values of optional parameters. The available parameters are

Parameter	Description	
'AbsTol'	Absolute error tolerance.  The default value of 'AbsTol' is 1.e-10 (double), 1.e-5 (single).	quadgk attempts to satisfy $errbnd \leq \max(AbsTol, RelTol *  Q )$ . This is absolute error control when $ Q $ is sufficiently small and relative error control when $ Q $ is larger. For pure absolute error control use 'AbsTol' > 0 and 'RelTol' =
'RelTol'	Relative error tolerance.	

Parameter	Description	
	The default value of 'RelTol' is 1.e-6 (double), 1.e-4 (single).	0. For pure relative error control use 'AbsTol' = 0. Except when using pure absolute error control, the minimum relative tolerance is 'RelTol' >= 100*eps(class(Q)).
'Waypoints'	Vector of integration waypoints.	<p>If <math>\text{fun}(x)</math> has discontinuities in the interval of integration, the locations should be supplied as a <b>Waypoints</b> vector. When <b>a</b>, <b>b</b>, and the waypoints are all real, only the waypoints between <b>a</b> and <b>b</b> are used, and they are used in sorted order. Note that waypoints are not intended for singularities in <math>\text{fun}(x)</math>. Singular points should be handled by making them endpoints of separate integrations and adding the results.</p> <p>If <b>a</b>, <b>b</b>, or any entry of the waypoints vector is complex, the integration is performed over a sequence of straight line paths in the complex plane, from <b>a</b> to the first waypoint, from the first waypoint to the second, and so forth, and finally from the last waypoint to <b>b</b>.</p>

Parameter	Description	
'MaxIntervalCount'	Maximum number of intervals allowed.  The default value is 650.	The 'MaxIntervalCount' parameter limits the number of intervals that <code>quadgk</code> uses at any one time after the first iteration. A warning is issued if <code>quadgk</code> returns early because of this limit. Routinely increasing this value is not recommended, but it may be appropriate when <code>errbnd</code> is small enough that the desired accuracy has nearly been achieved.

The list below contains information to help you determine which quadrature function in MATLAB to use:

- The `quad` function may be most efficient for low accuracies with nonsmooth integrands.
- The `quadl` function may be more efficient than `quad` at higher accuracies with smooth integrands.
- The `quadgk` function may be most efficient for high accuracies and oscillatory integrands. It supports infinite intervals and can handle moderate singularities at the endpoints. It also supports contour integration along piecewise linear paths.
- The `quadv` function vectorizes `quad` for an array-valued `fun`.
- If the interval is infinite,  $[a, \text{Inf})$ , then for the integral of `fun(x)` to exist, `fun(x)` must decay as `x` approaches infinity, and `quadgk` requires it to decay rapidly. Special methods should be used for oscillatory functions on infinite intervals, but `quadgk` can be used if `fun(x)` decays fast enough.
- The `quadgk` function will integrate functions that are singular at finite endpoints if the singularities are not too strong. For example, it will integrate functions that behave at an endpoint `c` like  $\log|x-c|$  or  $|x-c|^p$  for  $p \geq -1/2$ . If the function is singular at points inside  $(a, b)$ , write the integral as a sum of integrals over subintervals with the singular points as endpoints, compute them with `quadgk`, and add the results.

## Examples

### Integrand with a singularity at an integration end point

Write a function `myfun` that computes the integrand:

```
function y = myfun(x)
y = exp(x).*log(x);
```

Then pass `@myfun`, a function handle to `myfun`, to `quadgk`, along with the limits of integration, 0 to 1:

```
q = quadgk(@myfun,0,1)

q =

 -1.3179
```

Alternatively, you can pass the integrand to `quadgk` as an anonymous function handle `F`:

```
f = @(x)exp(x).*log(x);
q = quadgk(f,0,1);
```

### Oscillatory integrand on a semi-infinite interval

Integrate over a semi-infinite interval with specified tolerances, and return the approximate error bound:

```
f = @(x)x.^5.*exp(-x).*sin(x);
[q,errbnd] = quadgk(f,0,inf,'RelTol',1e-8,'AbsTol',1e-12)

q =

 -15.0000

errbnd =

 9.4386e-009
```

### Contour integration around a pole

Use `Waypoints` to integrate around a pole using a piecewise linear contour:

```
f = @(z)1./(2*z - 1);
q = quadgk(f,-1-i,-1-i,'Waypoints',[1-i,1+i,-1+i])
```

```
q =
 0.0000 + 3.1416i
```

## Diagnostics

quadgk may issue one of the following warnings:

'Minimum step size reached' indicates that interval subdivision has produced a subinterval whose length is on the order of roundoff error in the length of the original interval. A nonintegrable singularity is possible.

'Reached the limit on the maximum number of intervals in use' indicates that the integration was terminated before meeting the tolerance requirements and that continuing the integration would require more than `MaxIntervalCount` subintervals. The integral may not exist, or it may be difficult to approximate numerically. Increasing `MaxIntervalCount` usually does not help unless the tolerance requirements were nearly met when the integration was previously terminated.

'Infinite or Not-a-Number function value encountered' indicates a floating point overflow or division by zero during the evaluation of the integrand in the interior of the interval.

## More About

# quadl

Numerically evaluate integral, adaptive Lobatto quadrature

## Compatibility

quadl will be removed in a future release. Use `integral` instead.

## Syntax

```
q = quadl(fun,a,b)
q = quadl(fun,a,b,tol)
quadl(fun,a,b,tol,trace)
[q,fcnt] = quadl(...)
```

## Description

`q = quadl(fun,a,b)` approximates the integral of function `fun` from `a` to `b`, to within an error of  $10^{-6}$  using recursive adaptive Lobatto quadrature. `fun` is a function handle. It accepts a vector `x` and returns a vector `y`, the function `fun` evaluated at each element of `x`. Limits `a` and `b` must be finite.

“Parameterizing Functions” explains how to provide additional parameters to the function `fun`, if necessary.

`q = quadl(fun,a,b,tol)` uses an absolute error tolerance of `tol` instead of the default, which is `1.0e-6`. Larger values of `tol` result in fewer function evaluations and faster computation, but less accurate results.

`quadl(fun,a,b,tol,trace)` with non-zero `trace` shows the values of [`fcnt` `a` `b` `a` `q`] during the recursion.

`[q,fcnt] = quadl(...)` returns the number of function evaluations.

Use array operators `.*`, `./` and `.^` in the definition of `fun` so that it can be evaluated with a vector argument.

The function `quad` might be more efficient with low accuracies or nonsmooth integrands.

The list below contains information to help you determine which quadrature function in MATLAB to use:

- The `quad` function might be most efficient for low accuracies with nonsmooth integrands.
- The `quadl` function might be more efficient than `quad` at higher accuracies with smooth integrands.
- The `quadgk` function might be most efficient for high accuracies and oscillatory integrands. It supports infinite intervals and can handle moderate singularities at the endpoints. It also supports contour integration along piecewise linear paths.
- The `quadv` function vectorizes `quad` for an array-valued `fun`.
- If the interval is infinite, `[a, Inf)`, then for the integral of `fun(x)` to exist, `fun(x)` must decay as `x` approaches infinity, and `quadgk` requires it to decay rapidly. Special methods should be used for oscillatory functions on infinite intervals, but `quadgk` can be used if `fun(x)` decays fast enough.
- The `quadgk` function will integrate functions that are singular at finite endpoints if the singularities are not too strong. For example, it will integrate functions that behave at an endpoint `c` like `log|x-c|` or `|x-c|^p` for `p >= -1/2`. If the function is singular at points inside `(a,b)`, write the integral as a sum of integrals over subintervals with the singular points as endpoints, compute them with `quadgk`, and add the results.

## Examples

Pass the function handle, `@myfun`, to `quadl`:

```
Q = quadl(@myfun,0,2);
```

where the function `myfun.m` is:

```
function y = myfun(x)
y = 1./(x.^3-2*x-5);
```

Pass anonymous function handle `F` to `quadl`:

```
F = @(x) 1./(x.^3-2*x-5);
Q = quadl(F,0,2);
```

## Diagnostics

quadl might issue one of the following warnings:

'Minimum step size reached' indicates that the recursive interval subdivision has produced a subinterval whose length is on the order of roundoff error in the length of the original interval. A nonintegrable singularity is possible.

'Maximum function count exceeded' indicates that the integrand has been evaluated more than 10,000 times. A nonintegrable singularity is likely.

'Infinite or Not-a-Number function value encountered' indicates a floating point overflow or division by zero during the evaluation of the integrand in the interior of the interval.

## quadv

Vectorized quadrature

### Compatibility

quadv will be removed in a future release. Use `integral` with the 'ArrayValued' option instead.

### Syntax

```
Q = quadv(fun,a,b)
Q = quadv(fun,a,b,tol)
Q = quadv(fun,a,b,tol,trace)
[Q,fcnt] = quadv(...)
```

### Description

`Q = quadv(fun,a,b)` approximates the integral of the complex array-valued function `fun` from `a` to `b` to within an error of  $1.e-6$  using recursive adaptive Simpson quadrature. `fun` is a function handle. The function `Y = fun(x)` should accept a scalar argument `x` and return an array result `Y`, whose components are the integrands evaluated at `x`. Limits `a` and `b` must be finite.

“Parameterizing Functions” explains how to provide addition parameters to the function `fun`, if necessary.

`Q = quadv(fun,a,b,tol)` uses the absolute error tolerance `tol` for all the integrals instead of the default, which is  $1.e-6$ .

---

**Note** The same tolerance is used for all components, so the results obtained with `quadv` are usually not the same as those obtained with `quad` on the individual components.

---

`Q = quadv(fun,a,b,tol,trace)` with non-zero `trace` shows the values of `[fcnt a b-a Q(1)]` during the recursion.

`[Q,fcnt] = quadv(...)` returns the number of function evaluations.

The list below contains information to help you determine which quadrature function in MATLAB to use:

- The `quad` function might be most efficient for low accuracies with nonsmooth integrands.
- The `quadl` function might be more efficient than `quad` at higher accuracies with smooth integrands.
- The `quadgk` function might be most efficient for high accuracies and oscillatory integrands. It supports infinite intervals and can handle moderate singularities at the endpoints. It also supports contour integration along piecewise linear paths.
- The `quadv` function vectorizes `quad` for an array-valued `fun`.
- If the interval is infinite, `[a, Inf)`, then for the integral of `fun(x)` to exist, `fun(x)` must decay as `x` approaches infinity, and `quadgk` requires it to decay rapidly. Special methods should be used for oscillatory functions on infinite intervals, but `quadgk` can be used if `fun(x)` decays fast enough.
- The `quadgk` function will integrate functions that are singular at finite endpoints if the singularities are not too strong. For example, it will integrate functions that behave at an endpoint `c` like `log|x-c|` or `|x-c|^p` for `p >= -1/2`. If the function is singular at points inside `(a,b)`, write the integral as a sum of integrals over subintervals with the singular points as endpoints, compute them with `quadgk`, and add the results.

## Examples

For the parameterized array-valued function `myarrayfun`, defined by

```
function Y = myarrayfun(x,n)
Y = 1./((1:n)+x);
```

the following command integrates `myarrayfun`, for the parameter value `n = 10` between `a = 0` and `b = 1`:

```
Qv = quadv(@(x)myarrayfun(x,10),0,1);
```

The resulting array `Qv` has 10 elements estimating  $Q(k) = \log((k+1)/(k))$ , for `k = 1:10`.

The entries in `Qv` are slightly different than if you compute the integrals using `quad` in a loop:

```
for k = 1:10
 Qs(k) = quadv(@(x)myscalarfun(x,k),0,1);
end
```

where `myscalarfun` is:

```
function y = myscalarfun(x,k)
y = 1./(k+x);
```

# matlab.unittest.qualifications

Summary of classes in MATLAB Qualifications Interface

## Description

Qualifications are methods for testing values and responding to failures. Qualification failures might or might not correspond to a test failure, and they might or might not continue execution in the test when one is encountered. To determine which qualification to use, see “Types of Qualifications”.

matlab.unittest.qualifications.Assertable	Qualification to validate preconditions of a test
matlab.unittest.qualifications.Assumable	Qualification to filter test content
matlab.unittest.qualifications.FatalAssertable	Qualification to abort test execution
matlab.unittest.qualifications.Verifiable	Qualification to produce soft-failure conditions

The package contains the following event data classes:

matlab.unittest.qualifications.ExceptionEventData	Event data for ExceptionThrown event listeners
matlab.unittest.qualifications.QualificationEventData	Event data for qualification event listeners

The package contains the following exception handling classes:

matlab.unittest.qualifications.AssertionFailedException	Exception used for assertion failures
---------------------------------------------------------	---------------------------------------

matlab.unittest.qualifications.AssumptionFailedException

Exception used for assumption failures

matlab.unittest.qualifications.FatalAssertionFailedException

Exception used for fatal assertion failures

# matlab.unittest.qualifications.Assertable class

**Package:** matlab.unittest.qualifications

Qualification to validate preconditions of a test

## Description

The `Assertable` class provides a qualification to validate preconditions of a test. Apart from actions performed for failures, the `Assertable` class works the same as other `matlab.unittest` qualifications.

Upon an assertion failure, the `Assertable` class throws an `AssertionFailedException` to inform the testing framework of the failure. This is most useful when a failure at the assertion point renders the rest of the current test method invalid, yet does not prevent proper execution of other test methods. Often, you use assertions to ensure that preconditions of the current test are not violated or that fixtures are set up correctly. Make sure the test content is “Exception Safe” on page 1-6821. If you cannot make the fixture teardown exception safe or if you cannot recover it after failure, use fatal assertions instead.

Use assertions to allow remaining test methods to receive coverage when preconditions are violated in a test and all fixture states are restorable. Assertions also reduce the noise level of failures by not performing later verifications that fail due the precondition failures. In the event of a failure, however, the test framework marks the full content of the test method that failed as incomplete. Therefore, if the failure does not affect the preconditions of the test or cause problems with fixture setup or teardown, use verifications, which give the added information that the full test content was run.

## Methods

<code>assertClass</code>	Assert exact class of specified value
<code>assertEmpty</code>	Assert value is empty
<code>assertEqual</code>	Assert value is equal to specified value
<code>assertError</code>	Assert function throws specified exception
<code>assertFail</code>	Produce unconditional assertion failure

<code>assertFalse</code>	Assert value is false
<code>assertGreaterThan</code>	Assert value is greater than specified value
<code>assertGreaterThanOrEqual</code>	Assert value is greater than or equal to specified value
<code>assertInstanceOf</code>	Assert value is object of specified type
<code>assertLength</code>	Assert value has specified length
<code>assertLessThan</code>	Assert value is less than specified value
<code>assertLessThanOrEqual</code>	Assert value is less than or equal to specified value
<code>assertMatches</code>	Assert string matches specified regular expression
<code>assertNotEmpty</code>	Assert value is not empty
<code>assertNotEqual</code>	Assert value is not equal to specified value
<code>assertNotSameHandle</code>	Assert value is not handle to specified instance
<code>assertNumElements</code>	Assert value has specified element count
<code>assertReturnsTrue</code>	Assert function returns true when evaluated
<code>assertSameHandle</code>	Assert two values are handles to same instance
<code>assertSize</code>	Assert value has specified size
<code>assertSubstring</code>	Assert string contains specified string
<code>assertThat</code>	Assert that value meets specified constraint
<code>assertTrue</code>	Assert value is true
<code>assertWarning</code>	Assert function issues specified warning
<code>assertWarningFree</code>	Assert function issues no warnings

## Events

<code>AssertionFailed</code>	Triggered upon failing assertion. A <code>QualificationEventData</code> object is passed to listener callback functions.
------------------------------	--------------------------------------------------------------------------------------------------------------------------

AssertionPassed

Triggered upon passing assertion. A `QualificationEventData` object is passed to listener callback functions.

## Definitions

### Exception Safe

Test content is *exception safe* when all fixture teardown is performed with `addTeardown` or through the appropriate object destructors when a failure occurs. This ensures that the failure does not affect later testing due to stale fixtures.

This code is not exception safe. After an assertion failure, the test framework does not close the figure.

```
% Not exception safe
f = figure;
testCase.assertEqual(actual, expected);
close(f);
```

This code is exception safe because the test framework closes the figure in all cases.

```
% Exception safe
f = figure;
testCase.addTeardown(@close, f);
testCase.assertEqual(actual, expected);
```

However, tearing down a fixture using `addTeardown` does not guarantee code is exception safe. This code shows a failure in `assertEqual`.

```
% Not exception safe
f = figure;
testCase.assertEqual(actual, expected);
testCase.addTeardown(@close, f);
```

## Copy Semantics

Handle. To learn how handle classes affect copy operations, see [Copying Objects in the MATLAB documentation](#).

## Examples

### Test for Preconditions Using Assertions

Use assertable qualifications to test for preconditions. This example will create a test case to write a polynomial to a MAT-file.

Create `DocPolynomSaveLoadTest` Test Case. Refer to the following `DocPolynomSaveLoadTest` test case in the subsequent steps in this example. The steps highlight specific code in the `testSaveLoad` function; the code statements are not intended to be executed outside the context of the class definition file.

### DocPolynomSaveLoadTest Class Definition File

```
classdef DocPolynomSaveLoadTest < matlab.unittest.TestCase

 methods (TestClassSetup)
 function addDocPolynomClassToPath(testCase)
 origPath = path;
 testCase.addTeardown(@path, origPath);
 addpath(fullfile(matlabroot, ...
 'help', 'techdoc', 'matlab_oop', 'examples'));
 end
 end

 methods (Test)
 function testSaveLoad(testCase)

 import matlab.unittest.diagnostics.Diagnostic;

 %% Phase 1: Setup
 % Create a temporary working folder
 tempFolder = tempname;
 [success, message] = mkdir(tempFolder);
 testCase.assertTrue(success, ...
 Diagnostic.join('Could not create temporary folder.', ...
 message));
 testCase.addTeardown(@() testCase.cleanUpTemporaryFolder(...
 tempFolder));

 % Change to the temporay folder and register the
 % teardown, which restores the original folder
 origFolder = pwd;
 testCase.addTeardown(@cd, origFolder);
 end
 end
end
```

```
cd(tempFolder);

%% Phase 2: Exercise
% Save the instance to a mat file.
p = DocPolynom([1, 0, 1]);
save('DocPolynomFile', 'p');

% Validate Precondition. Save resulted in valid .mat file
testCase.assertEqual(exist('DocPolynomFile.mat', 'file'),...
 2, Diagnostic.join(...
 'mat file was not saved correctly.',@() dir(pwd)));

loaded = load('DocPolynomFile');

%% Phase 3: Verify
testCase.verifyEqual(loaded.p, p,...
 'Loaded polynom did not equal original polynom.');
```

```
%% Phase 4: Teardown
% Done inline via calls to addTeardown at the points
% at which the state was changed.

end
end

methods(Access=private)
function cleanUpTemporaryFolder(testCase,tempFolder)
 % Clean up the temporary folder and fatally assert
 % that it was correctly cleaned up.

 import matlab.unittest.diagnostics.Diagnostic;

 [success, message] = rmdir(tempFolder, 's');
 testCase.fatalAssertTrue(success, ...
 Diagnostic.join('Could not remove temporary folder.',...
 message));
end
end

end
```

To execute the MATLAB commands in “Run DocPolynomSaveLoadTest Test Case”, add the `DocPolynomSaveLoadTest.m` file to a folder on your MATLAB path.

The `testSaveLoad` function consists of the following phases:

- Phase 1: Setup — Create and verify precondition code.
- Phase 2: Exercise — Create a `DocPolynom` object and save it to a MAT-file.
- Phase 3: Verify — Test that object was successfully saved.
- Phase 4: Teardown — Execute teardown code.

Define phase 1 precondition. For this test, use a temporary folder for creating a `DocPolynom` object. The precondition for continuing with this test is that the following commands execute successfully.

```
tempFolder = tempname;
[success, message] = mkdir(tempFolder);
```

Test the results of the `mkdir` function. Use the `assertTrue` method to test the `mkdir success` argument for errors. If an assertion occurs, the remainder of the `testSaveLoad` test method is invalid, and the test is marked `Incomplete`.

```
testCase.assertTrue(success, ...
 Diagnostic.join('Could not create the temporary folder.', ...
 message))
```

If the `mkdir` function fails, MATLAB displays the diagnostic message, `Could not create the temporary folder`, as well as the contents of the `mkdir message` argument.

Add teardown fixture code. Creating a temporary folder is setup code, which requires a corresponding call to the `rmdir` function to restore MATLAB to the original state. Use the `addTeardown` method to ensure the teardown code executes even when an exception is thrown in the middle of the test method. This makes the test `Exception Safe`.

```
testCase.addTeardown(@() testCase.cleanupTemporaryFolder(tempFolder))
```

Place teardown code in the helper function. Although the `addTeardown` statement occurs in the same code block as the `mkdir` setup statement, the `cleanupTemporaryFolder` code is executed in phase 4 of the test method.

In the `DocPolynomSaveLoadTest` test case, the helper function, `cleanupTemporaryFolder`, executes the `rmdir` function.

Define the precondition for creating valid MAT-File. A precondition for verifying that the DocPolynom object was correctly saved and loaded is that the MAT-file, DocPolynomFile.mat, was successfully created. The following code in the Phase 2: Exercise block tests this condition. If an assertion occurs, the remainder of the testSaveLoad test method is invalid, and the test is marked Failed and Incomplete.

```
testCase.assertEqual(exist('DocPolynomFile.mat','file'), 2, ...
 Diagnostic.join('The mat file was not saved correctly.', ...
 @() dir(pwd)))
```

If the file was not created, MATLAB displays the diagnostic message, The mat file was not saved correctly, as well as the contents of the temporary folder.

Run DocPolynomSaveLoadTest Test Case.

```
tc = DocPolynomSaveLoadTest;
run(tc);
```

```
Running DocPolynomSaveLoadTest
```

```
.
```

```
Done DocPolynomSaveLoadTest
```

## More About

- “Types of Qualifications”

**Introduced in R2013a**

## assertClass

**Class:** matlab.unittest.qualifications.Assertable

**Package:** matlab.unittest.qualifications

Assert exact class of specified value

## Syntax

```
assertClass(assertable,actual,className)
assertClass(assertable,actual,metaClass)
assertClass(____,diagnostic)
```

## Description

`assertClass(assertable,actual,className)` asserts that `actual` is a MATLAB value whose class is the class specified by `className`.

`assertClass(assertable,actual,metaClass)` asserts that `actual` is a MATLAB value whose class is the class specified by the `meta.class` instance `metaClass`. The instance must be an exact class match. See `assertInstanceOf` to assert inclusion in a class hierarchy.

`assertClass( ____,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- The method is functionally equivalent to:

```
import matlab.unittest.constraints.IsOfClass;
assertable.assertThat(actual, IsOfClass(className));
assertable.assertThat(actual, IsOfClass(metaClass));
```

There exists more functionality when using the `IsOfClass` constraint directly via `assertThat`.

- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. Alternatively,
  - Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.
  - Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.
  - Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. For more information, see `matlab.unittest.qualifications.Assumable`.

## Input Arguments

### **assertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assertion in conjunction with the test running framework.

### **actual**

The value to test.

### **Default:**

### **className**

Name of class, specified as a string.

**Default:**

**metaClass**

An instance of `meta.class`.

**Default:**

**diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

See examples for `verifyClass`, and replace calls to `verifyClass` with `assertClass`.

### See Also

`assertInstanceOf` | `assertThat`

### More About

- “Types of Qualifications”

**Introduced in R2013a**

# assertEmpty

**Class:** matlab.unittest.qualifications.Assertable

**Package:** matlab.unittest.qualifications

Assert value is empty

## Syntax

```
assertEmpty(assertable,actual)
assertEmpty(assertable,actual,diagnostic)
```

## Description

`assertEmpty(assertable,actual)` asserts that `actual` is an empty MATLAB value.

`assertEmpty(assertable,actual,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsEmpty;
assertable.assertThat(actual, IsEmpty());
```

This method is a convenience method. There exists more functionality when using the `IsEmpty` constraint directly via `assertThat`.

- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. Alternatively,
  - Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications

are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.

- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.
- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. For more information, see `matlab.unittest.qualifications.Assumable`.

## Input Arguments

### **assertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assertion in conjunction with the test running framework.

### **actual**

The value to test.

### **Default:**

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

See examples for `verifyEmpty`, and replace calls to `verifyEmpty` with `assertEmpty`.

## See Also

## More About

- “Types of Qualifications”

**Introduced in R2013a**

## assertEqual

**Class:** matlab.unittest.qualifications.Assertable

**Package:** matlab.unittest.qualifications

Assert value is equal to specified value

### Syntax

```
assertEqual(assertable,actual,expected)
```

```
assertEqual(____,Name,Value)
```

```
assertEqual(____,diagnostic)
```

### Description

`assertEqual(assertable,actual,expected)` asserts that `actual` is strictly equal to `expected`.

`assertEqual( ____,Name,Value)` asserts equality with additional options specified by one or more `Name,Value` pair arguments.

`assertEqual( ____,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

### Tips

- This method is functionally equivalent to any of the following:

```
import matlab.unittest.constraints.IsEqualTo;
assertable.assertThat(actual, IsEqualTo(expected));
```

```
import matlab.unittest.constraints.IsEqualTo;
import matlab.unittest.constraints.AbsoluteTolerance;
assertable.assertThat(actual, IsEqualTo(expected, ...
 'Within', AbsoluteTolerance(abstol)));
```

```
import matlab.unittest.constraints.IsEqualTo;
import matlab.unittest.constraints.RelativeTolerance;
assertable.assertThat(actual, IsEqualTo(expected, ...
```

```

 'Within', RelativeTolerance(reltol));

import matlab.unittest.constraints.IsEqualTo;
import matlab.unittest.constraints.AbsoluteTolerance;
import matlab.unittest.constraints.RelativeTolerance;
assertable.assertThat(actual, IsEqualTo(expected, ...
 'Within', AbsoluteTolerance(abstol) | RelativeTolerance(reltol)));

```

There exists more functionality when using the `IsEqualTo`, `RelativeTolerance`, and `IsEqualTo` constraints directly via `assertThat`.

- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. Alternatively,
  - Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.
  - Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.
  - Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. For more information, see `matlab.unittest.qualifications.Assumable`.

## Input Arguments

### **assertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assertion in conjunction with the test running framework.

**actual**

The value to test.

**Default:****expected**

Expected value.

**Default:****diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

**'AbsTol'**

Absolute tolerance, specified as a numeric array. The tolerance is applied only to values of the same data type. The value can be a scalar or array the same size as the actual and expected values.

For an absolute tolerance to be satisfied, `abs(expected-actual) <= absTol` must be true.

**Default:**

**'RelTol'**

Relative tolerance, specified as a numeric array. The tolerance is applied only to values of the same data type. The value can be a scalar or array the same size as the actual and expected values.

For a relative tolerance to be satisfied, `abs(expected - actual) <= relTol.*abs(expected)` must be true.

**Default:**

## Examples

See examples for `verifyEqual`, and replace calls to `verifyEqual` with `assertEqual`.

## See Also

`assertNotEqual` | `assertThat`

## More About

- “Types of Qualifications”

**Introduced in R2013a**

## assertError

**Class:** matlab.unittest.qualifications.Assertable

**Package:** matlab.unittest.qualifications

Assert function throws specified exception

## Syntax

```
assertError(assertable,actual,identifier)
assertError(assertable,actual,metaClass)
assertError(____,diagnostic)
```

## Description

`assertError(assertable,actual,identifier)` asserts that `actual` is a function handle that throws an exception with an error identifier that is equal to `identifier`.

`assertError(assertable,actual,metaClass)` asserts that `actual` is a function handle that throws an exception whose type is defined by the `meta.class` instance specified in `metaClass`. This method does not require the instance to be an exact class match, but rather it must be in the specified class hierarchy, and that hierarchy must include the `MException` class.

`assertError( ____,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.Throws;
assertable.assertThat(actual, Throws(identifier));
assertable.assertThat(actual, Throws(metaClass));
```

There exists more functionality when using the `Throws` constraint directly via `assertThat`.

- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. Alternatively,
  - Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.
  - Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.
  - Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. For more information, see `matlab.unittest.qualifications.Assumable`.

## Input Arguments

### **assertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assertion in conjunction with the test running framework.

### **actual**

The value to test.

### **Default:**

### **identifier**

Error identifier, specified as a string.

**Default:****metaClass**

An instance of `meta.class`.

**Default:****diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

See examples for `verifyError`, and replace calls to `verifyError` with `assertError`.

### See Also

`MException` | `assertThat` | `assertWarning` | `error`

### More About

- “Types of Qualifications”

**Introduced in R2013a**

# assertFail

Produce unconditional assertion failure

## Syntax

```
assertFail(assertable)
assertFail(assertable,diagnostic)
```

## Description

`assertFail(assertable)` produces an unconditional assertion failure when encountered.

`assertFail(assertable,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Input Arguments

### **assertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assertion in conjunction with the test running framework.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Tips

- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. Alternatively,
  - Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.
  - Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.
  - Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as **Incomplete**. For more information, see `matlab.unittest.qualifications.Assumable`.

## Examples

See examples for `verifyFail`, and replace calls to `verifyFail` with `assertFail`.

## More About

- “Types of Qualifications”

**Introduced in R2013a**

# assertFalse

**Class:** matlab.unittest.qualifications.Assertable

**Package:** matlab.unittest.qualifications

Assert value is false

## Syntax

```
assertFalse(assertable,actual)
assertFalse(assertable,actual,diagnostic)
```

## Description

`assertFalse(assertable,actual)` asserts that `actual` is a scalar logical with the value of false.

`assertFalse(assertable,actual,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method passes if and only if the actual value is a scalar logical with a value of false. Therefore, entities such as empty arrays, false valued arrays, and zero doubles produce failures when used in this method, despite these entities exhibiting "false-like" behavior such as bypassing the execution of code inside of "if" statements.
- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsFalse;
assertable.assertThat(actual,.IsFalse());
```

There exists more functionality when using the `IsFalse` constraint directly via `assertThat`.

- Unlike `assertTrue`, this method may create a new constraint for each call. For performance critical uses, consider using `assertTrue`.

- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. Alternatively,
  - Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.
  - Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.
  - Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. For more information, see `matlab.unittest.qualifications.Assumable`.

## Input Arguments

### **assertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assertion in conjunction with the test running framework.

### **actual**

The value to test.

### **Default:**

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

For examples, see `verifyFalse`, and replace calls to `verifyFalse` with `assertFalse`.

## See Also

`assertThat` | `assertTrue`

## More About

- “Types of Qualifications”

**Introduced in R2013a**

## assertGreaterThan

**Class:** matlab.unittest.qualifications.Assertable

**Package:** matlab.unittest.qualifications

Assert value is greater than specified value

### Syntax

```
assertGreaterThan(assertable,actual,floor)
assertGreaterThan(assertable,actual,floor,diagnostic)
```

### Description

`assertGreaterThan(assertable,actual,floor)` asserts that all elements of `actual` are greater than all the elements of `floor`.

`assertGreaterThan(assertable,actual,floor,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

### Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsGreaterThan;
assertable.assertThat(actual, IsGreaterThan(floor));
```

There exists more functionality when using the `IsGreaterThan` constraint directly via `assertThat`.

- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. Alternatively,
  - Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications

are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.

- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.
- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. For more information, see `matlab.unittest.qualifications.Assumable`.

## Input Arguments

### **assertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assertion in conjunction with the test running framework.

### **actual**

The value to test. `actual` must be the same size as `floor` unless either one is scalar, at which point scalar expansion occurs.

### **floor**

Minimum value, exclusive.

### **Default:**

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle

- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

See examples for `verifyGreaterThan`, and replace calls to `verifyGreaterThan` with `assertGreaterThan`.

## See Also

`matlab.unittest.constraints.IsGreaterThan` | `matlab.unittest.diagnostics.Diagnostic` | `assertGreaterThanOrEqual` | `assertLessThan` | `assertLessThanOrEqual` | `assertThat` | `gt`

## More About

- “Types of Qualifications”

**Introduced in R2013a**

# assertGreaterThanOrEqual

**Class:** matlab.unittest.qualifications.Assertable

**Package:** matlab.unittest.qualifications

Assert value is greater than or equal to specified value

## Syntax

```
assertGreaterThanOrEqual(assertable, actual, floor)
```

```
assertGreaterThanOrEqual(assertable, actual, floor, diagnostic)
```

## Description

`assertGreaterThanOrEqual(assertable, actual, floor)` asserts that all elements of `actual` are greater than or equal to all the elements of `floor`.

`assertGreaterThanOrEqual(assertable, actual, floor, diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsGreaterThanOrEqualTo;
assertable.assertThat(actual, IsGreaterThanOrEqualTo(floor));
```

There exists more functionality when using the `IsGreaterThanOrEqualTo` constraint directly via `assertThat`.

- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. Alternatively,
  - Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications

are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.

- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.
- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as **Incomplete**. For more information, see `matlab.unittest.qualifications.Assumable`.

## Input Arguments

### **assertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assertion in conjunction with the test running framework.

### **actual**

The value to test. **actual** must be the same size as **floor** unless either one is scalar, at which point scalar expansion occurs.

### **floor**

Minimum value.

### **Default:**

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle

- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

## More About

- “Types of Qualifications”

**Introduced in R2013a**

## assertInstanceOf

**Class:** matlab.unittest.qualifications.Assertable

**Package:** matlab.unittest.qualifications

Assert value is object of specified type

### Syntax

```
assertInstanceOf(assertable,actual,className)
assertInstanceOf(assertable,actual,metaClass)
assertInstanceOf(____,diagnostic)
```

### Description

`assertInstanceOf(assertable,actual,className)` asserts that `actual` is a MATLAB value whose class is the class specified by `className`.

`assertInstanceOf(assertable,actual,metaClass)` asserts that `actual` is a MATLAB value whose class is the class specified by the `meta.class` instance `metaClass`.

`assertInstanceOf( ____,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

### Tips

- This method is functionally equivalent to:

```
assertable.assertThat(actual, IsInstanceOf(className));
assertable.assertThat(actual, IsInstanceOf(metaClass));
```

There exists more functionality when using the `IsInstanceOf` constraint directly via `assertThat`.

- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test

methods. A failure at the assertion point renders the current test method as failed and incomplete. Alternatively,

- Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.
- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.
- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. For more information, see `matlab.unittest.qualifications.Assumable`.

## Input Arguments

### **assertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assertion in conjunction with the test running framework.

### **actual**

The value to test.

### **Default:**

### **className**

Name of class, specified as a string.

### **Default:**

## **metaClass**

An instance of `meta.class`.

### **Default:**

## **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## **Examples**

See examples for `verifyInstanceOf`, and replace calls to `verifyInstanceOf` with `assertInstanceOf`.

## **See Also**

`assertClass` | `assertThat` | `isa`

## **More About**

- “Types of Qualifications”

**Introduced in R2013a**

# assertLength

**Class:** matlab.unittest.qualifications.Assertable

**Package:** matlab.unittest.qualifications

Assert value has specified length

## Syntax

```
assertLength(assertable,actual,expectedLength)
```

```
assertLength(assertable,actual,expectedLength,diagnostic)
```

## Description

`assertLength(assertable,actual,expectedLength)` that `actual` is a MATLAB array whose length is `expectedLength`.

`assertLength(assertable,actual,expectedLength,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.HasLength;
assertable.assertThat(actual, HasLength(expectedLength));
```

There exists more functionality when using the `HasLength` constraint directly via `assertThat`.

- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. Alternatively,
  - Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications

are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.

- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.
- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. For more information, see `matlab.unittest.qualifications.Assumable`.

## Input Arguments

### **assertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assertion in conjunction with the test running framework.

### **actual**

The value to test.

### **Default:**

### **expectedLength**

The length of an array is defined as the largest dimension of that array.

### **Default:**

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string

- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

See examples for `verifyLength`, and replace calls to `verifyLength` with `assertLength`.

## See Also

`assertNumElements` | `assertSize` | `assertThat` | `length`

## More About

- “Types of Qualifications”

**Introduced in R2013a**

## assertLessThan

**Class:** matlab.unittest.qualifications.Assertable

**Package:** matlab.unittest.qualifications

Assert value is less than specified value

### Syntax

```
assertLessThan(assertable,actual,ceiling)
assertLessThan(assertable,actual,ceiling,diagnostic)
```

### Description

`assertLessThan(assertable,actual,ceiling)` asserts that all elements of `actual` are less than all the elements of `ceiling`.

`assertLessThan(assertable,actual,ceiling,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

### Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsLessThan;
assertable.assertThat(actual, IsLessThan(ceiling));
```

There exists more functionality when using the `ISLessThan` constraint directly via `assertThat`.

- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. Alternatively,
  - Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs

to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.

- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.
- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. For more information, see `matlab.unittest.qualifications.Assumable`.

## Input Arguments

### **assertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assertion in conjunction with the test running framework.

### **actual**

The value to test. `actual` must be the same size as `ceiling` unless either one is scalar, at which point scalar expansion occurs.

### **Default:**

### **ceiling**

Maximum value, exclusive.

### **Default:**

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

`assertThat` | `lt`

## More About

- “Types of Qualifications”

**Introduced in R2013a**

# assertLessThanOrEqual

**Class:** matlab.unittest.qualifications.Assertable

**Package:** matlab.unittest.qualifications

Assert value is less than or equal to specified value

## Syntax

```
assertLessThanOrEqual(assertable,actual,ceiling)
assertLessThanOrEqual(assertable,actual,ceiling,diagnostic)
```

## Description

`assertLessThanOrEqual(assertable,actual,ceiling)` asserts that all elements of `actual` are less than or equal to all the elements of `ceiling`.

`assertLessThanOrEqual(assertable,actual,ceiling,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsLessThanOrEqualTo;
assertable.assertThat(actual, IsLessThanOrEqualTo(ceiling));
```

There exists more functionality when using the `IsLessThanOrEqualTo` constraint directly via `assertThat`.

- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. Alternatively,
  - Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs

to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. ## assertMatches

**Class:** matlab.unittest.qualifications.Assertable

**Package:** matlab.unittest.qualifications

Assert string matches specified regular expression

### Syntax

```
assertMatches(assertable,actual,expression)
```

```
assertMatches(assertable,actual,expression,diagnostic)
```

### Description

`assertMatches(assertable,actual,expression)` asserts that `actual` is a string that matches the regular expression defined by `expression`.

`assertMatches(assertable,actual,expression,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

### Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.Matches;
assertable.assertThat(actual, Matches(expression));
```

There exists more functionality when using the `Matches` constraint directly via `assertThat`.

- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. Alternatively,
  - Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications

are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.

- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.
- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. For more information, see `matlab.unittest.qualifications.Assumable`.

## Input Arguments

### **assertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assertion in conjunction with the test running framework.

### **actual**

The value to test.

### **Default:**

### **expression**

The value to match, specified as a regular expression.

### **Default:**

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string

- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

See examples for `verifyMatches`, and replace calls to `verifyMatches` with `assertMatches`.

## See Also

## More About

- “Types of Qualifications”

**Introduced in R2013a**

# assertNotEmpty

**Class:** matlab.unittest.qualifications.Assertable

**Package:** matlab.unittest.qualifications

Assert value is not empty

## Syntax

```
assertNotEmpty(assertable,actual)
assertNotEmpty(assertable,actual,diagnostic)
```

## Description

`assertNotEmpty(assertable,actual)` asserts that `actual` is a non-empty MATLAB value.

`assertNotEmpty(assertable,actual,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsEmpty;
assertable.assertThat(actual, ~IsEmpty());
```

There exists more functionality when using the `IsEmpty` constraint directly via `assertThat`.

- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. Alternatively,
  - Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications

are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.

- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.

## assertNotEqual

**Class:** matlab.unittest.qualifications.Assertable

**Package:** matlab.unittest.qualifications

Assert value is not equal to specified value

### Syntax

```
assertNotEqual(assertable,actual,notExpected)
assertNotEqual(assertable,actual,notExpected,diagnostic)
```

### Description

`assertNotEqual(assertable,actual,notExpected)` asserts that `actual` is not equal to `notExpected`.

`assertNotEqual(assertable,actual,notExpected,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

### Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsEqualTo;
assertable.assertThat(actual, ~IsEqualTo(notExpected));
```

There exists more functionality when using the `IsEqualTo` constraint directly via `assertThat`.

- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. Alternatively,
  - Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications

are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.

- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.
- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. For more information, see `matlab.unittest.qualifications.Assumable`.

## Input Arguments

### **assertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assertion in conjunction with the test running framework.

### **actual**

The value to test.

### **Default:**

### **notExpected**

Value to compare.

### **Default:**

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string

- `function handle`
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

See examples for `verifyNotEqual`, and replace calls to `verifyNotEqual` with `assertNotEqual`.

## See Also

`assertEqual` | `assertThat`

## More About

- “Types of Qualifications”

**Introduced in R2013a**

# assertNotSameHandle

**Class:** matlab.unittest.TestCase

**Package:** matlab.unittest

Assert value is not handle to specified instance

## Syntax

```
assertNotSameHandle(assertable,actual,notExpectedHandle)
assertNotSameHandle(assertable,actual,notExpectedHandle,diagnostic)
```

## Description

`assertNotSameHandle(assertable,actual,notExpectedHandle)` asserts that `actual` is a different size and/or does not contain the same instances as the `notExpectedHandle` handle array.

`assertNotSameHandle(assertable,actual,notExpectedHandle,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsSameHandleAs;
assertable.assertThat(actual, ~IsSameHandleAs(notExpectedHandle));
```

There exists more functionality when using the `IsSameHandleAs` constraint directly via `assertThat`.

- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. Alternatively,
  - Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs

to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.

- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.
- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as **Incomplete**. For more information, see `matlab.unittest.qualifications.Assumable`.

## Input Arguments

### **assertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assertion in conjunction with the test running framework.

### **actual**

The value to test.

### **Default:**

### **notExpectedHandle**

The handle array to compare.

### **Default:**

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string

- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

## assertNumElements

**Class:** matlab.unittest.qualifications.Assertable

**Package:** matlab.unittest.qualifications

Assert value has specified element count

### Syntax

```
assertNumElements(assertable,actual,expectedElementCount)
assertNumElements(assertable,actual,expectedElementCount,diagnostic)
```

### Description

`assertNumElements(assertable,actual,expectedElementCount)` asserts that `actual` is a MATLAB array with `expectedElementCount` number of elements.

`assertNumElements(assertable,actual,expectedElementCount,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

### Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.HasElementCount;
assertable.assertThat(actual, HasElementCount(expectedElementCount));
```

There exists more functionality when using the `HasElementCount` constraint directly via `assertThat`.

- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. Alternatively,
  - Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications

are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.

- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.
- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. For more information, see `matlab.unittest.qualifications.Assumable`.

## Input Arguments

### **assertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assertion in conjunction with the test running framework.

### **actual**

The value to test.

### **Default:**

### **expectedElementCount**

The expected number of elements in the array.

### **Default:**

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string

- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

See examples for `verifyNumElements`, and replace calls to `verifyNumElements` with `assertNumElements`.

## See Also

`assertLength` | `assertSize` | `assertThat` | `numel`

## More About

- “Types of Qualifications”

**Introduced in R2013a**

# assertReturnsTrue

**Class:** matlab.unittest.qualifications.Assertable

**Package:** matlab.unittest.qualifications

Assert function returns true when evaluated

## Syntax

```
assertReturnsTrue(assertable,actual)
assertReturnsTrue(assertable,actual,diagnostic)
```

## Description

`assertReturnsTrue(assertable,actual)` asserts that `actual` is a function handle that returns a scalar logical whose value is true.

`assertReturnsTrue(assertable,actual,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- It is a shortcut for quick custom comparison functionality that can be defined quickly, and possibly inline. It can be preferable over simply evaluating the function directly and using `assertTrue` because the function handle will be shown in the diagnostics, thus providing more insight into the failure condition which is lost when using `assertTrue`.
- This method is functionally equivalent to:

```
import matlab.unittest.constraints.ReturnsTrue;
assertable.assertThat(actual, ReturnsTrue());
```

There exists more functionality when using the `ReturnsTrue` constraint directly via `assertThat`.

- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test

methods. A failure at the assertion point renders the current test method as failed and incomplete. Alternatively,

- Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.
- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.
- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. For more information, see `matlab.unittest.qualifications.Assumable`.

## Input Arguments

### **assertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assertion in conjunction with the test running framework.

### **actual**

The function handle to test.

### **Default:**

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string

- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

See examples for `verifyReturnsTrue`, and replace calls to `verifyReturnsTrue` with `assertReturnsTrue`.

## See Also

`assertThat` | `assertTrue`

- “Types of Qualifications”

**Introduced in R2013a**

## assertSameHandle

**Class:** matlab.unittest.qualifications.Assertable

**Package:** matlab.unittest.qualifications

Assert two values are handles to same instance

### Syntax

```
assertSameHandle(assertable,actual,expectedHandle)
assertSameHandle(assertable,actual,expectedHandle,diagnostic)
```

### Description

`assertSameHandle(assertable,actual,expectedHandle)` asserts that `actual` is the same size and contains the same instances as the `expectedHandle` handle array.

`assertSameHandle(assertable,actual,expectedHandle,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

### Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsSameHandleAs;
assertable.assertThat(actual, IsSameHandleAs(expectedHandle));
```

There exists more functionality when using the `IsSameHandleAs` constraint directly via `assertThat`.

- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. Alternatively,
  - Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs

to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.

- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.
- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. For more information, see `matlab.unittest.qualifications.Assumable`.

## Input Arguments

### **assertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assertion in conjunction with the test running framework.

### **actual**

The value to test.

### **Default:**

### **expectedHandle**

The expected handle array.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle

- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

See examples for `verifySameHandle`, and replace calls to `verifySameHandle` with `assertSameHandle`.

## See Also

`handle` | `assertNotSameHandle` | `assertThat`

## More About

- “Types of Qualifications”

**Introduced in R2013a**

# assertSize

**Class:** matlab.unittest.qualifications.Assertable

**Package:** matlab.unittest.qualifications

Assert value has specified size

## Syntax

```
assertSize(assertable,actual,expectedSize)
assertSize(assertable,actual,expectedSize,diagnostic)
```

## Description

`assertSize(assertable,actual,expectedSize)` asserts that `actual` is a MATLAB array whose size is `expectedSize`.

`assertSize(assertable,actual,expectedSize,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.HasSize;
assertable.assertThat(actual, HasSize(expectedSize));
```

There exists more functionality when using the `HasSize` constraint directly via `assertThat`.

- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. Alternatively,
  - Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications

are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.

- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.
- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. For more information, see `matlab.unittest.qualifications.Assumable`.

## Input Arguments

### **assertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assertion in conjunction with the test running framework.

### **actual**

The value to test.

### **Default:**

### **expectedSize**

The expected sizes of each dimension the array.

### **Default:**

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string

- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

See examples for `verifySize`, and replace calls to `verifySize` with `assertSize`.

## See Also

## More About

- “Types of Qualifications”

**Introduced in R2013a**

## assertSubstring

**Class:** matlab.unittest.qualifications.Assertable

**Package:** matlab.unittest.qualifications

Assert string contains specified string

### Syntax

```
assertSubstring(assertable,actual,substring)
```

```
assertSubstring(assertable,actual,substring,diagnostic)
```

### Description

`assertSubstring(assertable,actual,substring)` asserts that `actual` is a string that contains `substring`.

`assertSubstring(assertable,actual,substring,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

### Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.ContainsSubstring;
assertable.assertThat(actual, ContainsSubstring(substring));
```

There exists more functionality when using the `ContainsSubstring` constraint directly via `assertThat`.

- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. Alternatively,
  - Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications

are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.

- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.
- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. For more information, see `matlab.unittest.qualifications.Assumable`.

## Input Arguments

### **assertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assertion in conjunction with the test running framework.

### **actual**

The value to test.

### **Default:**

### **substring**

The value to match, specified as a string.

### **Default:**

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string

- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

See examples for `verifySubstring`, and replace calls to `verifySubstring` with `assertSubstring`.

## See Also

`assertMatches` | `assertThat` | `strfind`

## More About

- “Types of Qualifications”

**Introduced in R2013a**

# assertThat

**Class:** matlab.unittest.qualifications.Assertable

**Package:** matlab.unittest.qualifications

Assert that value meets specified constraint

## Syntax

```
assertThat(assertable,actual,constraint)
```

```
assertThat(assertable,actual,constraint,diagnostic)
```

## Description

`assertThat(assertable,actual,constraint)` asserts that `actual` is a value that satisfies the `constraint` provided.

If the constraint is not satisfied, an assertion failure is produced utilizing only the framework diagnostic generated by the `constraint`.

`assertThat(assertable,actual,constraint,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

When using this signature, both the diagnostic information contained within `diagnostic` is used in addition to the diagnostic information provided by the `constraint`.

## Input Arguments

### **assertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assertion in conjunction with the test running framework.

### **actual**

The value to test.

**Default:****constraint**

Constraint that the actual value must satisfy to pass the verification, specified as a `matlab.unittest.constraints` instance.

**Default:****diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

See examples for `verifyThat`, and replace calls to `verifyThat` with `assertThat`.

## Tips

- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. Alternatively,
  - Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.

- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.
- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as **Incomplete**. For more information, see `matlab.unittest.qualifications.Assumable`.

## More About

- “Types of Qualifications”

### Introduced in R2013a

## assertTrue

**Class:** matlab.unittest.qualifications.Assertable

**Package:** matlab.unittest.qualifications

Assert value is true

## Syntax

```
assertTrue(assertable,actual)
```

```
assertTrue(assertable,actual,diagnostic)
```

## Description

`assertTrue(assertable,actual)` asserts that `actual` is a scalar logical with the value of `true`.

`assertTrue(assertable,actual,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method passes if and only if the actual value is a scalar logical with a value of `true`. Therefore, entities such as true valued arrays and non-zero doubles produce qualification failures when used in this method, despite these entities exhibiting "true-like" behavior such as triggering the execution of code inside of "if" statements.
- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsTrue;
assertable.assertThat(actual, IsTrue());
```

There exists more functionality when using the `IsTrue` constraint directly via `assertThat`.

Use of this method for performance benefits can come at the expense of less diagnostic information, and may not provide the same level of strictness adhered to by other constraints such as `IsEqualTo`. A similar approach that is generally

less performant but can provide slightly better diagnostic information is the use of `assertReturnsTrue`, which at least shows the display of the function evaluated to generate the failing result.

- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. Alternatively,
  - Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.
  - Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.
  - Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. For more information, see `matlab.unittest.qualifications.Assumable`.

## Input Arguments

### **assertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assertion in conjunction with the test running framework.

### **actual**

The value to test.

### **Default:**

## **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## **Examples**

See examples for `verifyTrue`, and replace calls to `verifyTrue` with `assertTrue`.

## **See Also**

`assertFalse` | `assertReturnsTrue` | `assertThat`

## **More About**

- “Types of Qualifications”

**Introduced in R2013a**

# assertWarning

**Class:** matlab.unittest.qualifications.Assertable

**Package:** matlab.unittest.qualifications

Assert function issues specified warning

## Syntax

```
assertWarning(assertable,actual,warningID)
assertWarning(assertable,actual,warningID,diagnostic)
[output1,...,outputN] = assertWarning(___)
```

## Description

`assertWarning(assertable,actual,warningID)` asserts that `actual` issues a warning with the identifier `warningID`.

`assertWarning(assertable,actual,warningID,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

`[output1,...,outputN] = assertWarning( ___ )` also returns the output arguments `output1,...,outputN` that are produced when invoking `actual`.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IssuesWarnings;
assertable.assertThat(actual, IssuesWarnings({warningID}));
```

There exists more functionality when using the `IssuesWarnings` constraint directly via `assertThat`.

- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. Alternatively,

- Use verification qualifications to produce and record failures without throwing an exception. **Introduced in R2013a**

## assertWarningFree

**Class:** matlab.unittest.qualifications.Assertable

**Package:** matlab.unittest.qualifications

Assert function issues no warnings

### Syntax

```
assertWarningFree(assertable,actual)
assertWarningFree(assertable,actual,diagnostic)
[output1,...,outputN] = assertWarningFree(___)
```

### Description

`assertWarningFree(assertable,actual)` asserts that `actual` is a function handle that issues no warnings.

`assertWarningFree(assertable,actual,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

`[output1,...,outputN] = assertWarningFree( ___ )` also returns the output arguments `output1,...,outputN` that are produced when invoking `actual`.

### Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IssuesNoWarnings;
assertable.assertThat(actual, IssuesNoWarnings());
```

There exists more functionality when using the `IssuesNoWarnings` constraint directly via `assertThat`.

- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. Alternatively,

- Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.
- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.
- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. For more information, see `matlab.unittest.qualifications.Assumable`.

## Input Arguments

### **assertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assertion in conjunction with the test running framework.

### **actual**

The function handle to test.

### **Default:**

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle

- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Output Arguments

`output1, ..., outputN`

Output arguments, 1 through n (if any), from `actual`, returned as any type. The argument type is specified by the `actual` argument list.

**Introduced in R2013a**

# matlab.unittest.qualifications.AssertionFailedException class

**Package:** matlab.unittest.qualifications

Exception used for assertion failures

## Description

The `AssertionFailedException` class provides an exception used for assertion failures. This class is used exclusively by the `Assertable` qualification type.

## See Also

`MException` | `Assertable`

# matlab.unittest.qualifications.Assumable class

**Package:** matlab.unittest.qualifications

Qualification to filter test content

## Description

The **Assumable** class provides a qualification to filter test content. Apart from actions performed in the event of failures, the **Assumable** class works the same as other `matlab.unittest` qualifications.

Upon an assumption failure, the **Assumable** class informs the testing framework of the failure by throwing an **AssumptionFailedException**. The test framework then marks the test content as filtered and continues testing. Often, assumptions are used to ensure that the test is run only when certain preconditions are met. However, running the test without satisfying the preconditions does not produce a test failure. Ensure that the test content is “Exception Safe” on page 1-6904. If the failure condition is meant to produce a test failure, use assertions or verifications instead of assumptions.

The attributes specified in the **TestCase** method definition determine which tests are filtered. The following behavior occurs when the test framework encounters an assumption failure inside of a **TestCase** method:

- If you define the **TestCase** method using the **Test** attribute, the framework marks the entire method as filtered and runs subsequent test methods.
- If you define the **TestCase** method using the **TestMethodSetup** or **TestMethodTeardown** attributes, the test framework marks the method to run for that instance as filtered.
- If you define the **TestCase** method using the **TestClassSetup** or **TestClassTeardown** attributes, the test framework filters the entire **TestCase** class.

Filtering test content using assumptions does not produce test failures. Therefore, dead test code can result. Avoid this by monitoring filtered tests.

## Methods

<code>assumeClass</code>	Assume exact class of specified value
<code>assumeEmpty</code>	Assume value is empty
<code>assumeEqual</code>	Assume value is equal to specified value
<code>assumeError</code>	Assume function throws specified exception
<code>assumeFail</code>	Produce unconditional assumption failure
<code>assumeFalse</code>	Assume value is false
<code>assumeGreaterThan</code>	Assume value is greater than specified value
<code>assumeGreaterThanOrEqual</code>	Assume value is greater than or equal to specified value
<code>assumeInstanceOf</code>	Assume value is object of specified type
<code>assumeLength</code>	Assume value has specified length
<code>assumeLessThan</code>	Assume value is less than specified value
<code>assumeLessThanOrEqual</code>	Assume value is less than or equal to specified value
<code>assumeMatches</code>	Assume string matches specified regular expression
<code>assumeNotEmpty</code>	Assume value is not empty
<code>assumeNotEqual</code>	Assume value is not equal to specified value
<code>assumeNotSameHandle</code>	Assume value is not handle to specified instance
<code>assumeNumElements</code>	Assume value has specified element count
<code>assumeReturnsTrue</code>	Assume function returns true when evaluated
<code>assumeSameHandle</code>	Assume two values are handles to same instance
<code>assumeSize</code>	Assume value has specified size
<code>assumeSubstring</code>	Assume string contains specified string
<code>assumeThat</code>	Assume value meets specified constraint

<code>assumeTrue</code>	Assume value is true
<code>assumeWarning</code>	Assume function issues specified warning
<code>assumeWarningFree</code>	Assume function issues no warnings

## Events

<code>AssumptionFailed</code>	Triggered upon failing assumption. A <code>QualificationEventData</code> object is passed to listener callback functions.
<code>AssumptionPassed</code>	Triggered upon passing assumption. A <code>QualificationEventData</code> object is passed to listener callback functions.

## Definitions

### Exception Safe

Test content is *exception safe* when all fixture teardown is performed with `addTeardown` or through the appropriate object destructors when a failure occurs. This ensures that the failure does not affect later testing due to stale fixtures.

This code is not exception safe. After an assertion failure, the test framework does not close the figure.

```
% Not exception safe
f = figure;
testCase.assumeEqual(actual, expected)
close(f)
```

This code is exception safe because the test framework closes the figure in all cases.

```
% Exception safe
f = figure;
testCase.addTeardown(@close, f)
testCase.assumeEqual(actual, expected)
```

However, tearing down a fixture using `addTeardown` does not guarantee code is exception safe. This code shows a failure in `assumeEqual`.

```
% Not exception safe
f = figure;
testCase.assumeEqual(actual, expected)
testCase.addTeardown(@close, f)
```

## Copy Semantics

Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB documentation.

## Examples

### Write TestClassSetup Method Using Assumptions

Assumptions assure that a test runs only when certain preconditions are satisfied and when such an event should not produce a test failure. When an assumption failure occurs, the test is marked as filtered.

Create `IsSupportedTest` test case. Refer to the following `IsSupportedTest` test case in the subsequent steps in this example, which highlight specific functions in the file.

### IsSupportedTest Class Definition File

```
classdef IsSupportedTest < matlab.unittest.TestCase
 methods(TestClassSetup)
 function TestPlatform(testcase)
 testcase.assumeFalse(ispc,...
 'Do not run any of these tests on Windows.')
 end
 end
 methods(Test)
 function test1(testcase)
 % write test code here
 end
 end
end
```

To execute the MATLAB commands in this example, add the `IsSupportedTest.m` file to a folder on your MATLAB path.

Write `Test to Verify Platform`. All tests in this test case must run on UNIX platforms only. The `TestPlatform` function uses the `assumeFalse` method to test if MATLAB is running on a Windows platform. If it is, the test fails.

```
function TestPlatform(testcase)
 testcase.assumeFalse(ispc,...
 'Do not run any of these tests on Windows.')
end
```

Make `TestPlatform` a `TestClassSetup` Test. To make the `TestPlatform` test a precondition, add it inside the `methods (TestClassSetup)` block.

Run the test case. Create a test case object and run the tests on a Windows platform.

```
tc = IsSupportedTest;
res = tc.run;
```

Running `IsSupportedTest`

```
=====
All tests in IsSupportedTest were filtered.
 Test Diagnostic: Do not run any of these tests on Windows.
 Details
=====
```

Done `IsSupportedTest`

Failure Summary:

Name	Failed	Incomplete	Reason(s)
IsSupportedTest/test1		X	Filtered by assumption.

The test(s) were filtered, and did not run (marked **Incomplete**).

For more information, click the [Details](#) link.

```
=====
An assumption was not met while setting up or tearing down IsSupportedTest.
As a result, all IsSupportedTest tests were filtered.
```

```

Test Diagnostic:

```

Do not run any of these tests on Windows.

```

Framework Diagnostic:

assumeFalse failed.
--> The value must evaluate to "false".
```

```
Actual Value:
 1
```

```

Stack Information:

In C:\work\IsSupportedTest.m (IsSupportedTest.TestPlatform) at 4
=====
```

The link to `IsSupportedTest.TestPlatform` under Stack Information takes you to the failed `assumeFalse` method.

## assumeClass

**Class:** matlab.unittest.qualifications.Assumable

**Package:** matlab.unittest.qualifications

Assume exact class of specified value

### Syntax

```
assumeClass(assumable,actual,className)
assumeClass(assumable,actual,metaClass)
assumeClass(____,diagnostic)
```

### Description

`assumeClass(assumable,actual,className)` assumes that `actual` is a MATLAB value whose class is the class specified by `className`.

`assumeClass(assumable,actual,metaClass)` assumes that `actual` is a MATLAB value whose class is the class specified by the `meta.class` instance `metaClass`. The instance must be an exact class match. See `assumeInstanceOf` to assume inclusion in a class hierarchy.

`assumeClass( ____,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

### Tips

- The method is functionally equivalent to:

```
import matlab.unittest.constraints.IsOfClass;
assumable.assumeThat(actual, IsOfClass(className));
assumable.assumeThat(actual, IsOfClass(metaClass));
```

There exists more functionality when using the `IsOfClass` constraint directly via `assumeThat`.

- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures

result in filtered tests, and the testing framework marks the tests as **Incomplete**. Alternatively,

- Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.
- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.

## Input Arguments

### **assumable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assumption in conjunction with the test running framework.

### **actual**

The value to test.

### **Default:**

### **className**

Name of class, specified as a string.

**Default:****metaClass**

An instance of `meta.class`.

**Default:****diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

See examples for `verifyClass`, and replace calls to `verifyClass` with `assumeClass`.

### See Also

`assumeInstanceOf` | `assumeThat`

### More About

- “Types of Qualifications”

**Introduced in R2013a**

# assumeEmpty

**Class:** matlab.unittest.qualifications.Assumable

**Package:** matlab.unittest.qualifications

Assume value is empty

## Syntax

```
assumeEmpty(assumable,actual)
assumeEmpty(assumable,actual,diagnostic)
```

## Description

`assumeEmpty(assumable,actual)` assumes that `actual` is an empty MATLAB value.

`assumeEmpty(assumable,actual,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsEmpty;
assumable.assumeThat(actual, IsEmpty());
```

There exists more functionality when using the `IsEmpty` constraint directly via `assumeThat`.

- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as **Incomplete**. Alternatively,
  - Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not

require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.

- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.

## Input Arguments

### **assumable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assumption in conjunction with the test running framework.

### **actual**

The value to test.

### **Default:**

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

See examples for `verifyEmpty`, and replace calls to `verifyEmpty` with `assumeEmpty`.

## See Also

`assumeNotEmpty` | `assumeThat` | `isempty`

## More About

- “Types of Qualifications”

**Introduced in R2013a**

## assumeEqual

**Class:** matlab.unittest.qualifications.Assumable

**Package:** matlab.unittest.qualifications

Assume value is equal to specified value

### Syntax

```
assumeEqual(assumable,actual,expected)
assumeEqual(____,Name,Value)
assumeEqual(____,diagnostic)
```

### Description

`assumeEqual(assumable,actual,expected)` assumes that `actual` is strictly equal to `expected`.

`assumeEqual( ____,Name,Value)` assumes equality with additional options specified by one or more `Name,Value` pair arguments.

`assumeEqual( ____,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

### Tips

- This method is functionally equivalent to any of the following:

```
import matlab.unittest.constraints.IsEqualTo;
assumable.assumeThat(actual, IsEqualTo(expected));

import matlab.unittest.constraints.IsEqualTo;
import matlab.unittest.constraints.AbsoluteTolerance;
assumable.assumeThat(actual, IsEqualTo(expected, ...
 'Within', AbsoluteTolerance(abstol)));

import matlab.unittest.constraints.IsEqualTo;
```

```
import matlab.unittest.constraints.RelativeTolerance;
assumable.assumeThat(actual, IsEqualTo(expected, ...
 'Within', RelativeTolerance(reltol)));

import matlab.unittest.constraints.IsEqualTo;
import matlab.unittest.constraints.AbsoluteTolerance;
import matlab.unittest.constraints.RelativeTolerance;
assumable.assumeThat(actual, IsEqualTo(expected, ...
 'Within', AbsoluteTolerance(abstol) | RelativeTolerance(reltol)));
```

There exists more functionality when using the `IsEqualTo`, `RelativeTolerance`, and `IsEqualTo` constraints directly via `assumeThat`.

- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as **Incomplete**. Alternatively,
  - Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.
  - Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
  - Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.

## Input Arguments

### **assumable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assumption in conjunction with the test running framework.

### **actual**

The value to test.

### **Default:**

### **expected**

Expected value.

### **Default:**

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1`, `Value1`, ..., `NameN`, `ValueN`.

### **'AbsTol'**

Absolute tolerance, specified as a numeric array. The tolerance is applied only to values of the same data type. The value can be a scalar or array the same size as the actual and expected values.

For an absolute tolerance to be satisfied, `abs(expected-actual) <= absTol` must be true.

**Default:**

**'RelTol'**

Relative tolerance, specified as a numeric array. The tolerance is applied only to values of the same data type. The value can be a scalar or array the same size as the actual and expected values.

For a relative tolerance to be satisfied, `abs(expected-actual) <= relTol.*abs(expected)` must be true.

**Default:**

## Examples

See examples for `verifyEqual`, and replace calls to `verifyEqual` with `assumeEqual`.

### See Also

`assumeNotEqual` | `assumeThat`

### More About

- “Types of Qualifications”

**Introduced in R2013a**

## assumeError

**Class:** matlab.unittest.qualifications.Assumable

**Package:** matlab.unittest.qualifications

Assume function throws specified exception

### Syntax

```
assumeError(assumable,actual,identifier)
assumeError(assumable,actual,metaClass)
assumeError(____,diagnostic)
```

### Description

`assumeError(assumable,actual,identifier)` assumes that `actual` is a function handle that throws an exception with an error identifier that is equal to `identifier`.

`assumeError(assumable,actual,metaClass)` assumes that `actual` is a function handle that throws an exception whose type is defined by the `meta.class` instance specified in `metaClass`. This method does not require the instance to be an exact class match, but rather it must be in the specified class hierarchy, and that hierarchy must include the `MException` class.

`assumeError( ____,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

### Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.Throws;
assumable.assumeThat(actual, Throws(identifier));
assumable.assumeThat(actual, Throws(metaClass));
```

There exists more functionality when using the `Throws` constraint directly via `assumeThat`.

- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as **Incomplete**. Alternatively,
  - Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.
  - Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
  - Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.

## Input Arguments

### **assumable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assumption in conjunction with the test running framework.

### **actual**

The value to test.

### **Default:**

### **identifier**

Error identifier, specified as a string.

**Default:****metaClass**

An instance of `meta.class`.

**Default:****diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

See examples for `verifyError`, and replace calls to `verifyError` with `assumeError`.

### See Also

`MException` | `assumeThat` | `assumeWarning` | `error`

### More About

- “Types of Qualifications”

**Introduced in R2013a**

# assumeFail

**Class:** matlab.unittest.qualifications.Assumable

**Package:** matlab.unittest.qualifications

Produce unconditional assumption failure

## Syntax

```
assumeFail(assumable)
```

```
assumeFail(assumable,diagnostic)
```

## Description

`assumeFail(assumable)` produces an unconditional assumption failure when encountered.

`assumeFail(assumable,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Input Arguments

### **assumable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assumption in conjunction with the test running framework.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Tips

- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as **Incomplete**. Alternatively,
  - Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.
  - Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
  - Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.

## Examples

See examples for `verifyFail`, and replace calls to `verifyFail` with `assumeFail`.

## More About

- “Types of Qualifications”

**Introduced in R2013a**

# assumeFalse

**Class:** matlab.unittest.qualifications.Assumable

**Package:** matlab.unittest.qualifications

Assume value is false

## Syntax

```
assumeFalse(assumable,actual)
assumeFalse(assumable,actual,diagnostic)
```

## Description

`assumeFalse(assumable,actual)` assumes that `actual` is a scalar logical with the value of false.

`assumeFalse(assumable,actual,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method passes if and only if the actual value is a scalar logical with a value of false. Therefore, entities such as empty arrays, false valued arrays, and zero doubles produce failures when used in this method, despite these entities exhibiting "false-like" behavior such as bypassing the execution of code inside of "if" statements.
- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsFalse;
assumable.assumeThat(actual,.IsFalse());
```

There exists more functionality when using the `IsFalse` constraint directly via `assumeThat`.

- Unlike `assumeTrue`, this method may create a new constraint for each call. For performance critical uses, consider using `assumeTrue`.
- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures

result in filtered tests, and the testing framework marks the tests as **Incomplete**. Alternatively,

- Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.
- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.

## Input Arguments

### **assumable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assumption in conjunction with the test running framework.

### **actual**

The value to test.

### **Default:**

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

## More About

- “Types of Qualifications”

**Introduced in R2013a**

## assumeGreaterThan

**Class:** matlab.unittest.qualifications.Assumable

**Package:** matlab.unittest.qualifications

Assume value is greater than specified value

### Syntax

```
assumeGreaterThan(assumable,actual,floor)
assumeGreaterThan(assumable,actual,floor,diagnostic)
```

### Description

`assumeGreaterThan(assumable,actual,floor)` assumes that all elements of `actual` are greater than all the elements of `floor`.

`assumeGreaterThan(assumable,actual,floor,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure

### Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsGreaterThan;
assumable.assumeThat(actual, IsGreaterThan(floor));
```

There exists more functionality when using the `IsGreaterThan` constraint directly via `assumeThat`.

- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as **Incomplete**. Alternatively,
  - Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications

are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.

- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.

## Input Arguments

### **assumable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assumption in conjunction with the test running framework.

### **actual**

The value to test. `actual` must be the same size as `floor` unless either one is scalar, at which point scalar expansion occurs.

### **floor**

Minimum value, exclusive.

### **Default:**

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string

- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

See examples for `verifyGreaterThan`, and replace calls to `verifyGreaterThan` with `assumeGreaterThan`.

## See Also

`matlab.unittest.constraints.IsGreaterThan` | `matlab.unittest.diagnostics.Diagnostic` | `assumeGreaterThanOrEqual` | `assumeLessThan` | `assumeLessThanOrEqual` | `assumeThat` | `gt`

## More About

- “Types of Qualifications”

**Introduced in R2013a**

# assumeGreaterThanOrEqual

**Class:** matlab.unittest.qualifications.Assumable

**Package:** matlab.unittest.qualifications

Assume value is greater than or equal to specified value

## Syntax

```
assumeGreaterThanOrEqual(assumable,actual,floor)
```

```
assumeGreaterThanOrEqual(assumable,actual,floor,diagnostic)
```

## Description

`assumeGreaterThanOrEqual(assumable,actual,floor)` assumes that all elements of `actual` are greater than or equal to all the elements of `floor`.

`assumeGreaterThanOrEqual(assumable,actual,floor,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsGreaterThanOrEqualTo;
assumable.assumeThat(actual, IsGreaterThanOrEqualTo(floor));
```

There exists more functionality when using the `IsGreaterThanOrEqualTo` constraint directly via `assumeThat`.

- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as **Incomplete**. Alternatively,
  - Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications

are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.

**Introduced in R2013a**

## assumeInstanceOf

**Class:** matlab.unittest.qualifications.Assumable

**Package:** matlab.unittest.qualifications

Assume value is object of specified type

### Syntax

```
assumeInstanceOf(assumable,actual,className)
```

```
assumeInstanceOf(assumable,actual,metaClass)
```

```
assumeInstanceOf(____,diagnostic)
```

### Description

`assumeInstanceOf(assumable,actual,className)` assumes that `actual` is a MATLAB value whose class is the class specified by `className`.

`assumeInstanceOf(assumable,actual,metaClass)` assumes that `actual` is a MATLAB value whose class is the class specified by the `meta.class` instance `metaClass`.

`assumeInstanceOf( ____,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

### Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsInstanceOf;
assumable.assumeThat(actual, IsInstanceOf(className));
assumable.assumeThat(actual, IsInstanceOf(metaClass));
```

There exists more functionality when using the `IsInstanceOf` constraint directly via `assumeThat`.

- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures

result in filtered tests, and the testing framework marks the tests as **Incomplete**. Alternatively,

## More About

- “Types of Qualifications”

**Introduced in R2013a**

# assumeLength

**Class:** matlab.unittest.qualifications.Assumable

**Package:** matlab.unittest.qualifications

Assume value has specified length

## Syntax

```
assumeLength(assumable,actual,expectedLength)
assumeLength(assumable,actual,expectedLength,diagnostic)
```

## Description

`assumeLength(assumable,actual,expectedLength)` assumes that `actual` is a MATLAB array whose length is `expectedLength`.

`assumeLength(assumable,actual,expectedLength,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.HasLength;
assumable.assumeThat(actual, HasLength(expectedLength));
```

There exists more functionality when using the `HasLength` constraint directly via `assumeThat`.

- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as **Incomplete**. Alternatively,
  - Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs

to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.

- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.

## Input Arguments

### **assumable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assumption in conjunction with the test running framework.

### **actual**

The value to test.

### **Default:**

### **expectedLength**

The length of an array is defined as the largest dimension of that array.

### **Default:**

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

See examples for `verifyLength`, and replace calls to `verifyLength` with `assumeLength`.

## More About

- “Types of Qualifications”

**Introduced in R2013a**

## assumeLessThan

**Class:** matlab.unittest.qualifications.Assumable

**Package:** matlab.unittest.qualifications

Assume value is less than specified value

### Syntax

```
assumeLessThan(assumable,actual,ceiling)
assumeLessThan(assumable,actual,ceiling,diagnostic)
```

### Description

`assumeLessThan(assumable,actual,ceiling)` assumes that all elements of `actual` are less than all the elements of `ceiling`.

`assumeLessThan(assumable,actual,ceiling,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

### Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsLessThan;
assumable.assumeThat(actual, IsLessThan(ceiling));
```

There exists more functionality when using the `IsLessThan` constraint directly via `assumeThat`.

- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as **Incomplete**. Alternatively,
  - Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications

are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.

- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.

## Input Arguments

### **assumable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assumption in conjunction with the test running framework.

### **actual**

The value to test. **actual** must be the same size as **ceiling** unless either one is scalar, at which point scalar expansion occurs.

#### **Default:**

### **ceiling**

Maximum value, exclusive.

#### **Default:**

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

See examples for `verifyLessThan`, and replace calls to `LessThan` with `assumeLessThan`.

## See Also

`matlab.unittest.constraints.IsLessThan` | `matlab.unittest.diagnostics.Diagnostic` | `assumeGreaterThan` | `assumeGreaterThanOrEqual` | `assumeLessThanOrEqual` | `assumeThat` | `lt`

## More About

- “Types of Qualifications”

**Introduced in R2013a**

# assumeLessThanOrEqual

**Class:** matlab.unittest.qualifications.Assumable

**Package:** matlab.unittest.qualifications

Assume value is less than or equal to specified value

## Syntax

```
assumeLessThanOrEqual(assumable,actual,ceiling)
```

```
assumeLessThanOrEqual(assumable,actual,ceiling,diagnostic)
```

## Description

`assumeLessThanOrEqual(assumable,actual,ceiling)` assumes that all elements of `actual` are less than or equal to all the elements of `ceiling`.

`assumeLessThanOrEqual(assumable,actual,ceiling,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsLessThanOrEqualTo;
assumable.assumeThat(actual, IsLessThanOrEqualTo(ceiling));
```

There exists more functionality when using the `IsLessThanOrEqualTo` constraint directly via `assumeThat`.

- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as **Incomplete**. Alternatively,
  - Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications

are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.

- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.

## Input Arguments

### **assumable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assumption in conjunction with the test running framework.

### **actual**

The value to test. `actual` must be the same size as `ceiling` unless either one is scalar, at which point scalar expansion occurs.

### **Default:**

### **ceiling**

Maximum value.

### **Default:**

## More About

- “Types of Qualifications”

**Introduced in R2013a**

## assumeMatches

**Class:** matlab.unittest.qualifications.Assumable

**Package:** matlab.unittest.qualifications

Assume string matches specified regular expression

### Syntax

```
assumeMatches(actual, expression)
assumeMatches(actual, expression, diagnostic)
```

### Description

`assumeMatches(actual, expression)` assumes that `actual` is a string that matches the regular expression defined by `expression`.

`assumeMatches(actual, expression, diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

### Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.Matches;
assumable.assumeThat(actual, Matches(expression));
```

There exists more functionality when using the `Matches` constraint directly via `assumeThat`.

- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as **Incomplete**. Alternatively,
  - Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs

to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.

- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.

## Input Arguments

### **assumable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assumption in conjunction with the test running framework.

### **actual**

The string to test.

### **Default:**

### **expression**

The value to match, specified as a regular expression.

### **Default:**

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

See examples for `verifyMatches`, and replace calls to `verifyMatches` with `assumeMatches`.

`assumeSubstring` | `assumeThat` | `regexp`

## More About

- “Types of Qualifications”

**Introduced in R2013a**

# assumeNotEmpty

**Class:** matlab.unittest.qualifications.Assumable

**Package:** matlab.unittest.qualifications

Assume value is not empty

## Syntax

```
assumeNotEmpty(assumable,actual)
assumeNotEmpty(assumable,actual,diagnostic)
```

## Description

`assumeNotEmpty(assumable,actual)` assumes that `actual` is a non-empty MATLAB value.

`assumeNotEmpty(assumable,actual,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsEmpty;
assumable.assumeThat(actual, ~IsEmpty());
```

There exists more functionality when using the `IsEmpty` constraint directly via `assumeThat`.

- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as **Incomplete**. Alternatively,
  - Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications

are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.

- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. `assumeEmpty` | `assumeThat` | `isEmpty`

## More About

- “Types of Qualifications”

**Introduced in R2013a**

## assumeNotEqual

**Class:** matlab.unittest.qualifications.Assumable

**Package:** matlab.unittest.qualifications

Assume value is not equal to specified value

### Syntax

```
assumeNotEqual(assumable, actual, notExpected)
assumeNotEqual(assumable, actual, notExpected, diagnostic)
```

### Description

`assumeNotEqual(assumable, actual, notExpected)` assumes that `actual` is not equal to `notExpected`.

`assumeNotEqual(assumable, actual, notExpected, diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

### Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsEqualTo;
assumable.assumeThat(actual, ~IsEqualTo(notExpected));
```

There exists more functionality when using the `IsEqualTo` constraint directly via `assumeThat`.

- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as **Incomplete**. Alternatively,
  - Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs

to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.

- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.

## Input Arguments

### **assumable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assumption in conjunction with the test running framework.

### **actual**

The value to test.

### **Default:**

### **notExpected**

Value to compare.

### **Default:**

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

See examples for `verifyNotEqual`, and replace calls to `verifyNotEqual` with `assumeNotEqual`.

## See Also

`assumeEqual` | `assumeThat`

## More About

- “Types of Qualifications”

**Introduced in R2013a**

# assumeNotSameHandle

**Class:** matlab.unittest.qualifications.Assumable

**Package:** matlab.unittest.qualifications

Assume value is not handle to specified instance

## Syntax

```
assumeNotSameHandle(assumable,actual,notExpectedHandle)
assumeNotSameHandle(assumable,actual,notExpectedHandle,diagnostic)
```

## Description

`assumeNotSameHandle(assumable,actual,notExpectedHandle)` assumes that `actual` is a different size and/or does not contain the same instances as the `notExpectedHandle` handle array.

`assumeNotSameHandle(assumable,actual,notExpectedHandle,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsSameHandleAs;
assumable.assumeThat(actual, ~IsSameHandleAs(notExpectedHandle));
```

There exists more functionality when using the `IsSameHandleAs` constraint directly via `assumeThat`.

- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as **Incomplete**. Alternatively,
  - Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs

to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.

- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.

## Input Arguments

### **assumable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assumption in conjunction with the test running framework.

### **actual**

The value to test.

### **Default:**

### **notExpectedHandle**

The handle array to compare.

### **Default:**

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

See examples for `verifyNotSameHandle`, and replace calls to `verifyNotSameHandle` with `assumeNotSameHandle`.

## See Also

`assumeSameHandle` | `assumeThat`

## More About

- “Types of Qualifications”

**Introduced in R2013a**

## assumeNumElements

**Class:** matlab.unittest.qualifications.Assumable

**Package:** matlab.unittest.qualifications

Assume value has specified element count

### Syntax

```
assumeNumElements(assumable,actual,expectedElementCount)
assumeNumElements(assumable,actual,expectedElementCount,diagnostic)
```

### Description

`assumeNumElements(assumable,actual,expectedElementCount)` assumes that `actual` is a MATLAB array with `expectedElementCount` number of elements.

`assumeNumElements(assumable,actual,expectedElementCount,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

### Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.HasElementCount;
assumable.assumeThat(actual, HasElementCount(expectedElementCount));
```

There exists more functionality when using the `HasElementCount` constraint directly via `assumeThat`.

- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as **Incomplete**. Alternatively,
  - Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs

to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.

- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.

## Input Arguments

### **assumable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assumption in conjunction with the test running framework.

### **actual**

The value to test.

### **Default:**

### **expectedElementCount**

The expected number of elements in the array.

### **Default:**

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

See examples for `verifyNumElements`, and replace calls to `verifyNumElements` with `assumeNumElements`.

## See Also

`assumeLength` | `assumeSize` | `assumeThat` | `numel`

## More About

- “Types of Qualifications”

**Introduced in R2013a**

# assumeReturnsTrue

**Class:** matlab.unittest.qualifications.Assumable

**Package:** matlab.unittest.qualifications

Assume function returns true when evaluated

## Syntax

```
assumeReturnsTrue(assumable,actual)
assumeReturnsTrue(assumable,actual,diagnostic)
```

## Description

`assumeReturnsTrue(assumable,actual)` assumes that `actual` is a function handle that returns a scalar logical whose value is true.

`assumeReturnsTrue(assumable,actual,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- It is a shortcut for quick custom comparison functionality that can be defined quickly, and possibly inline. It can be preferable over simply evaluating the function directly and using `assumeTrue` because the function handle will be shown in the diagnostics, thus providing more insight into the failure condition which is lost when using `assumeTrue`.
- This method is functionally equivalent to:

```
import matlab.unittest.constraints.ReturnsTrue;
assumable.assumeThat(actual, ReturnsTrue());
```

There exists more functionality when using the `ReturnsTrue` constraint directly via `assumeThat`.

- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures

result in filtered tests, and the testing framework marks the tests as **Incomplete**. Alternatively,

- Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.
- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.

## Input Arguments

### **assumable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assumption in conjunction with the test running framework.

### **actual**

The function handle to test.

### **Default:**

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

See examples for `verifyReturnsTrue`, and replace calls to `verifyReturnsTrue` with `assumeReturnsTrue`.

## See Also

`assumeThat` | `assumeTrue`

## More About

- “Types of Qualifications”

**Introduced in R2013a**

## assumeSameHandle

**Class:** matlab.unittest.qualifications.Assumable

**Package:** matlab.unittest.qualifications

Assume two values are handles to same instance

### Syntax

```
assumeSameHandle(assumable,actual,expectedHandle)
assumeSameHandle(assumable,actual,expectedHandle,diagnostic)
```

### Description

`assumeSameHandle(assumable,actual,expectedHandle)` assumes that `actual` is the same size and contains the same instances as the `expectedHandle` handle array.

`assumeSameHandle(assumable,actual,expectedHandle,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

### Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsSameHandleAs;
assumable.assumeThat(actual, IsSameHandleAs(expectedHandle));
```

There exists more functionality when using the `IsSameHandleAs` constraint directly via `assumeThat`.

- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as **Incomplete**. Alternatively,
  - Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs

to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.

- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.

## Input Arguments

### **assumable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assumption in conjunction with the test running framework.

### **actual**

The value to test.

### **Default:**

### **expectedHandle**

The expected handle array.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string

- function `handle`
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

See examples for `verifySameHandle`, and replace calls to `verifySameHandle` with `assumeSameHandle`.

## See Also

`handle` | `assumeNotSameHandle` | `assumeThat`

## More About

- “Types of Qualifications”

**Introduced in R2013a**

# assumeSize

**Class:** matlab.unittest.qualifications.Assumable

**Package:** matlab.unittest.qualifications

Assume value has specified size

## Syntax

```
assumeSize(assumable,actual,expectedSize)
assumeSize(assumable,actual,expectedSize,diagnostic)
```

## Description

`assumeSize(assumable,actual,expectedSize)` assumes that `actual` is a MATLAB array whose size is `expectedSize`.

`assumeSize(assumable,actual,expectedSize,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.HasSize;
assumable.assumeThat(actual, HasSize(expectedSize));
```

There exists more functionality when using the `HasSize` constraint directly via `assumeThat`.

- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as **Incomplete**. Alternatively,
  - Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs

to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. ## More About

- “Types of Qualifications”

**Introduced in R2013a**

## assumeSubstring

**Class:** matlab.unittest.qualifications.Assumable

**Package:** matlab.unittest.qualifications

Assume string contains specified string

### Syntax

```
assumeSubstring(assumable,actual,substring)
assumeSubstring(assumable,actual,substring,diagnostic)
```

### Description

`assumeSubstring(assumable,actual,substring)` assumes that `actual` is a string that contains `substring`.

`assumeSubstring(assumable,actual,substring,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

### Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.ContainsSubstring;
assumable.assumeThat(actual, ContainsSubstring(substring));
```

There exists more functionality when using the `ContainsSubstring` constraint directly via `assumeThat`.

- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as **Incomplete**. Alternatively,
  - Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs

to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.

- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.

## Input Arguments

### **assumable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assumption in conjunction with the test running framework.

### **actual**

The value to test.

### **Default:**

### **substring**

The value to match, specified as a string.

### **Default:**

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

## More About

- “Types of Qualifications”

**Introduced in R2013a**

# assumeThat

**Class:** matlab.unittest.qualifications.Assumable

**Package:** matlab.unittest.qualifications

Assume value meets specified constraint

## Syntax

```
assumeThat(assumable,actual,constraint)
```

```
assumeThat(assumable,actual,constraint,diagnostic)
```

## Description

`assumeThat(assumable,actual,constraint)` assumes that `actual` is a value that satisfies the `constraint` provided.

If the constraint is not satisfied, an assumption failure is produced utilizing only the framework diagnostic generated by the `constraint`.

`assumeThat(assumable,actual,constraint,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

When using this signature, both the diagnostic information contained within `diagnostic` is used in addition to the diagnostic information provided by the `constraint`.

## Input Arguments

### **assumable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assumption in conjunction with the test running framework.

### **actual**

The value to test.

**Default:****constraint**

Constraint that the actual value must satisfy to pass the verification, specified as a `matlab.unittest.constraints` instance.

**Default:****diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Tips

- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as **Incomplete**. Alternatively,
  - Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.
  - Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.

- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.

## Examples

See examples for `verifyThat`, and replace calls to `verifyThat` with `assumeThat`.

## More About

- “Types of Qualifications”

**Introduced in R2013a**

## assumeTrue

**Class:** matlab.unittest.qualifications.Assumable

**Package:** matlab.unittest.qualifications

Assume value is true

## Syntax

```
assumeTrue(assumable,actual)
assumeTrue(assumable,actual,diagnostic)
```

## Description

`assumeTrue(assumable,actual)` assumes that `actual` is a scalar logical with the value of `true`.

`assumeTrue(assumable,actual,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method passes if and only if the actual value is a scalar logical with a value of `true`. Therefore, entities such as true valued arrays and nonzero doubles produce qualification failures when used in this method, despite these entities exhibiting "true-like" behavior such as triggering the execution of code inside of "if" statements.
- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsTrue;
assumable.assumeThat(actual, IsTrue());
```

There exists more functionality when using the `IsTrue` constraint directly via `assumeThat`.

Use of this method for performance benefits can come at the expense of less diagnostic information, and may not provide the same level of strictness adhered

to by other constraints such as `IsEqualTo`. A similar approach that is generally less performant but can provide slightly better diagnostic information is the use of `assumeReturnsTrue`, which at least shows the display of the function evaluated to generate the failing result.

- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as **Incomplete**. Alternatively,
  - Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.
  - Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
  - Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.

## Input Arguments

### **assumable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assumption in conjunction with the test running framework.

### **actual**

The value to test.

## Default:

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

See examples for `verifyTrue`, and replace calls to `verifyTrue` with `assumeTrue`.

## See Also

`assumeFalse` | `assumeReturnsTrue` | `assumeThat`

## More About

- “Types of Qualifications”

**Introduced in R2013a**

# assumeWarning

**Class:** matlab.unittest.qualifications.Assumable

**Package:** matlab.unittest.qualifications

Assume function issues specified warning

## Syntax

```
assumeWarning(assumable,actual,warningID)
assumeWarning(assumable,actual,warningID,diagnostic)
[output1,...,outputN] = assumeWarning(___)
```

## Description

`assumeWarning(assumable,actual,warningID)` assumes that `actual` issues a warning with the identifier `warningID`.

`assumeWarning(assumable,actual,warningID,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

`[output1,...,outputN] = assumeWarning( ___ )` also return the output arguments `output1,...,outputN` that are produced when invoking `actual`.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IssuesWarnings;
assumable.assumeThat(actual, IssuesWarnings({warningID}));
```

There exists more functionality when using the `IssuesWarnings` constraint directly via `assumeThat`.

- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as **Incomplete**. Alternatively,

- Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.
- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.

## Input Arguments

### **assumable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assumption in conjunction with the test running framework.

### **actual**

The function handle to test.

### **Default:**

### **warningID**

Warning ID, specified as a string.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Output Arguments

**output1, ..., outputN**

Output arguments, 1 through n (if any), from `actual`, returned as any type. The argument type is specified by the `actual` argument list.

## Examples

See examples for `verifyWarning`, and replace calls to `verifyWarning` with `assumeWarning`.

## See Also

## More About

- “Types of Qualifications”

**Introduced in R2013a**

## assumeWarningFree

**Class:** matlab.unittest.qualifications.Assumable

**Package:** matlab.unittest.qualifications

Assume function issues no warnings

### Syntax

```
assumeWarningFree(assumable,actual)
assumeWarningFree(assumable,actual,diagnostic)
[output1,...,outputN] = assumeWarningFree(___)
```

### Description

`assumeWarningFree(assumable,actual)` assumes that `actual` is a function handle that issues no warnings.

`assumeWarningFree(assumable,actual,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

`[output1,...,outputN] = assumeWarningFree( ___ )` also returns the output arguments `output1,...,outputN` that are produced when invoking `actual`.

### Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IssuesNoWarnings;
assumable.assumeThat(actual, IssuesNoWarnings());
```

There exists more functionality when using the `IssuesNoWarnings` constraint directly via `assumeThat`.

- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as **Incomplete**. Alternatively,

- Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.
- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.

## Input Arguments

### **assumable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assumption in conjunction with the test running framework.

### **actual**

The function handle to test.

### **Default:**

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle

- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Output Arguments

`output1, ..., outputN`

Output arguments, 1 through n (if any), from `actual`, returned as any type. The argument type is specified by the `actual` argument list.

**Introduced in R2013a**

# matlab.unittest.qualifications.AssumptionFailedException class

**Package:** matlab.unittest.qualifications

Exception used for assumption failures

## Description

The `AssumptionFailedException` class provides an exception used for assumption failures. This class is used exclusively by the `Assumable` qualification type.

## See Also

`MException` | `Assumable`

# matlab.unittest.qualifications.ExceptionEventData class

**Package:** matlab.unittest.qualifications

Event data for ExceptionThrown event listeners

## Description

The `ExceptionEventData` class holds event data for `ExceptionThrown` event listeners. `ExceptionThrown` event listeners are callback functions that you register with the testing framework to listen for the `TestRunner` to encounter an error during execution of test content. Typically, authors of custom plugins use this class. Only the test framework constructs this class directly.

## Properties

### Exception

Unexpected exception caught by `TestRunner` during its execution of test content

### See Also

`matlab.unittest.TestRunner` | `matlab.unittest.plugins.TestRunnerPlugin` | `MException`

**Introduced in R2014a**

# matlab.unittest.qualifications.FatalAssertable class

**Package:** matlab.unittest.qualifications

Qualification to abort test execution

## Description

The `FatalAssertable` class provides a qualification to abort test execution. Apart from actions performed for failures, the `FatalAssertable` class works the same as `matlab.unittest.qualifications`.

Upon a fatal assertion failure, the `FatalAssertable` class informs the testing framework of the failure by throwing a `FatalAssertionFailedException`. The test running framework then displays diagnostic information for the failure and aborts the entire test session. This is useful when the software under test contains so many errors that it does not make sense to continue the test session. Also, you can use fatal assertions in fixture teardown to guarantee the fixture state is restored correctly. If it is not restored, the full testing session will abort and indicates to restart MATLAB before you resume testing. This allows later tests to run in a consistent MATLAB state. If you can recover the fixture teardown and make it “Exception Safe” on page 1-6987 for failures, use assertions instead.

Fatal assertions prevent false test failures due to the failure of a fundamental test. They also prevent false test failures when a prior test failed to restore test fixtures. If the test framework cannot properly tear down fixtures, restart MATLAB to ensure testing can resume in a clean state.

## Methods

<code>fatalAssertClass</code>	Fatally assert exact class of specified value
<code>fatalAssertEmpty</code>	Fatally assert value is empty
<code>fatalAssertEqual</code>	Fatally assert value is equal to specified value
<code>fatalAssertError</code>	Fatally assert function throws specified exception

<code>fatalAssertFail</code>	Produce unconditional fatal assertion failure
<code>fatalAssertFalse</code>	Fatally assert value is false
<code>fatalAssertGreaterThanOrEqual</code>	Fatally assert value is greater than or equal to specified value
<code>fatalAssertInstanceOf</code>	Fatally assert value is object of specified type
<code>fatalAssertLength</code>	Fatally assert value has specified length
<code>fatalAssertLessThan</code>	Fatally assert value is less than specified value
<code>fatalAssertLessThanOrEqual</code>	Fatally assert value is less than or equal to specified value
<code>fatalAssertMatches</code>	Fatally assert string matches specified regular expression
<code>fatalAssertNotEmpty</code>	Fatally assert value is not empty
<code>fatalAssertNotEqual</code>	Fatally assert value is not equal to specified value
<code>fatalAssertNotSameHandle</code>	Fatally assert value is not handle to specified instance
<code>fatalAssertNumElements</code>	Fatally assert value has specified element count
<code>fatalAssertReturnsTrue</code>	Fatally assert function returns true when evaluated
<code>fatalAssertSameHandle</code>	Fatally assert two values are handles to same instance
<code>fatalAssertSize</code>	Fatally assert value has specified size
<code>fatalAssertSubstring</code>	Fatally assert string contains specified string
<code>fatalAssertThat</code>	Fatally assert value meets specified constraint
<code>fatalAssertTrue</code>	Fatally assert value is true
<code>fatalAssertWarning</code>	Fatally assert function issues specified warning

`fatalAssertWarningFree`

Fatally assert function issues no warnings

## Events

`FatalAssertionFailed`Triggered upon failing fatal assertion. A `QualificationEventData` object is passed to listener callback functions.`FatalAssertionPassed`Triggered upon passing fatal assertion. A `QualificationEventData` object is passed to listener callback functions.

## Definitions

### Exception Safe

Test content is *exception safe* when all fixture teardown is performed with `addTeardown` or through the appropriate object destructors when a failure occurs. This ensures that the failure does not affect later testing due to stale fixtures.

This code is not exception safe. After an assertion failure, the test framework does not close the figure.

```
% Not exception safe
f = figure;
testCase.fatalAssertEqual(actual, expected)
close(f)
```

This code is exception safe because the test framework closes the figure in all cases.

```
% Exception safe
f = figure;
testCase.addTeardown(@close, f)
testCase.fatalAssertEqual(actual, expected)
```

However, tearing down a fixture using `addTeardown` does not guarantee code is exception safe. This code shows a failure in `fatalAssertEqual`.

```
% Not exception safe
f = figure;
testCase.fatalAssertEqual(actual, expected);
```

```
testCase.addTeardown(@close, f)
```

## Copy Semantics

Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB documentation.

## Examples

### Write Helper Function Using Fatal Assertions

A fatal assertion renders the remainder of the current test method invalid because the state is unrecoverable. A *helper function* is a function in the `TestCase` class but not located within any of the `methods` block statement. Execution of these functions is not controlled by the `matlab.unittest` framework.

Add the `DocPolynomSaveLoadTest.m` file to a folder on your MATLAB path. Refer to the helper function, `cleanupTemporaryFolder`, in the `DocPolynomSaveLoadTest` test case.

### DocPolynomSaveLoadTest Class Definition File

```
classdef DocPolynomSaveLoadTest < matlab.unittest.TestCase

 methods (TestClassSetup)
 function addDocPolynomClassToPath(testCase)
 origPath = path;
 testCase.addTeardown(@path, origPath);
 addpath(fullfile(matlabroot, ...
 'help', 'techdoc', 'matlab_oop', 'examples'));
 end
 end

 methods (Test)
 function testSaveLoad(testCase)

 import matlab.unittest.diagnostics.Diagnostic;

 %% Phase 1: Setup
 % Create a temporary working folder
 tempFolder = tempname;
```

```
[success, message] = mkdir(tempFolder);
testCase.assertTrue(success, ...
 Diagnostic.join('Could not create temporary folder.',...
 message));
testCase.addTeardown(@() testCase.cleanupTemporaryFolder(...
 tempFolder));

% Change to the temporary folder and register the
% teardown, which restores the original folder
origFolder = pwd;
testCase.addTeardown(@cd, origFolder);
cd(tempFolder);

%% Phase 2: Exercise
% Save the instance to a mat file.
p = DocPolynom([1, 0, 1]);
save('DocPolynomFile', 'p');

% Validate Precondition. Save resulted in valid .mat file
testCase.assertEqual(exist('DocPolynomFile.mat', 'file'),...
 2, Diagnostic.join(...
 'mat file was not saved correctly.',@() dir(pwd)));

loaded = load('DocPolynomFile');

%% Phase 3: Verify
testCase.verifyEqual(loaded.p, p,...
 'Loaded polynom did not equal original polynom.');
```

```
end

end

methods(Access=private)
function cleanupTemporaryFolder(testCase,tempFolder)
 % Clean up the temporary folder and fatally assert
 % that it was correctly cleaned up.
```

```
import matlab.unittest.diagnostics.Diagnostic;

[success, message] = rmdir(tempFolder, 's');
testCase.fatalAssertTrue(success, ...
 Diagnostic.join('Could not remove temporary folder.',...
 message));
end
end
end
```

Make the `cleanUpTemporaryFolder` function a helper function by placing it inside a separate `methods` block.

```
methods(Access=private)
function cleanUpTemporaryFolder(testCase, tempFolder)
 % code
end
end
```

Use the `fatalAssertTrue` method to test the `rmdir success` argument for errors. If a fatal assertion occurs, the test run is aborted.

```
function cleanUpTemporaryFolder(testCase, tempFolder)

import matlab.unittest.diagnostics.Diagnostic

[success, message] = rmdir(tempFolder, 's');
testCase.fatalAssertTrue(success, ...
 Diagnostic.join('Could not remove the temporary folder.',...
 message))
end
```

If the `rmdir` function fails, then this test has failed to restore the state of MATLAB and the machine at initial startup. Aborting prevents subsequent tests to fail because MATLAB is left in an unexpected state by this test.

## More About

- “Types of Qualifications”

**Introduced in R2013a**

## fatalAssertClass

**Class:** matlab.unittest.qualifications.FatalAssertable

**Package:** matlab.unittest.qualifications

Fatally assert exact class of specified value

### Syntax

```
fatalAssertClass(fatalAssertable,actual,className)
```

```
fatalAssertClass(fatalAssertable,actual,metaClass)
```

```
fatalAssertClass(____,diagnostic)
```

### Description

`fatalAssertClass(fatalAssertable,actual,className)` fatally asserts that `actual` is a MATLAB value whose class is the class specified by `className`.

`fatalAssertClass(fatalAssertable,actual,metaClass)` fatally asserts that `actual` is a MATLAB value whose class is the class specified by the `meta.class` instance `metaClass`.

`fatalAssertClass( ____,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

### Tips

- The method is functionally equivalent to:

```
import matlab.unittest.constraints.IsOfClass;
fatalAssertable.fatalAssertThat(actual, IsOfClass(className));
fatalAssertable.fatalAssertThat(actual, IsOfClass(metaClass));
```

There exists more functionality when using the `IsOfClass` constraint directly via `fatalAssertThat`.

- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is

no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. Alternatively,

- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
- Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.
- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. For more information, see `matlab.unittest.qualifications.Assumable`.

## Input Arguments

### **fatalAssertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the fatal assertion in conjunction with the test running framework.

### **actual**

The value to test.

### **Default:**

### **className**

Name of class, specified as a string.

### **Default:**

## **metaClass**

An instance of `meta.class`.

### **Default:**

## **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## **Examples**

**Package:** matlab.unittest.qualifications

Fatally assert value is empty

## Syntax

```
fatalAssertEmpty(fatalAssertable,actual)
```

```
fatalAssertEmpty(fatalAssertable,actual,diagnostic)
```

## Description

`fatalAssertEmpty(fatalAssertable,actual)` fatally asserts that `actual` is an empty MATLAB value.

`fatalAssertEmpty(fatalAssertable,actual,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsEmpty;
fatalAssertable.fatalAssertThat(actual, IsEmpty());
```

There exists more functionality when using the `IsEmpty` constraint directly via `fatalAssertThat`.

- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. Alternatively,
  - Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution

of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.

- Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.
- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. For more information, see `matlab.unittest.qualifications.Assumable`.

## Input Arguments

### **`fatalAssertable`**

The `matlab.unittest.TestCase` instance which is used to pass or fail the fatal assertion in conjunction with the test running framework.

### **`actual`**

The value to test.

### **Default:**

### **`diagnostic`**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## More About

- “Types of Qualifications”

**Introduced in R2013a**

# fatalAssertEqual

**Class:** matlab.unittest.qualifications.FatalAssertable

**Package:** matlab.unittest.qualifications

Fatally assert value is equal to specified value

## Syntax

```
fatalAssertEqual(fatalAssertable,actual,expected)
```

```
fatalAssertEqual(____,Name,Value)
```

```
fatalAssertEqual(____,diagnostic)
```

## Description

`fatalAssertEqual(fatalAssertable,actual,expected)` fatally asserts that `actual` is strictly equal to `expected` .

`fatalAssertEqual( ____,Name,Value)` fatally asserts equality with additional options specified by one or more `Name,Value` pair arguments.

`fatalAssertEqual( ____,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to any of the following:

```
import matlab.unittest.constraints.IsEqualTo;
fatalAssertable.fatalAssertThat(actual, IsEqualTo(expected));
```

```
import matlab.unittest.constraints.IsEqualTo;
import matlab.unittest.constraints.AbsoluteTolerance;
fatalAssertable.fatalAssertThat(actual, IsEqualTo(expected, ...
 'Within', AbsoluteTolerance(abstol)));
```

```
import matlab.unittest.constraints.IsEqualTo;
import matlab.unittest.constraints.RelativeTolerance;
fatalAssertable.fatalAssertThat(actual, IsEqualTo(expected, ...
```

```

 'Within', RelativeTolerance(reltol)));
import matlab.unittest.constraints.IsEqualTo;
import matlab.unittest.constraints.AbsoluteTolerance;
import matlab.unittest.constraints.RelativeTolerance;
fatalAssertable.fatalAssertThat(actual, IsEqualTo(expected, ...
 'Within', AbsoluteTolerance(abstol) | RelativeTolerance(reltol)));

```

There exists more functionality when using the `IsEqualTo`, `RelativeTolerance`, and `IsEqualTo` constraints directly via `fatalAssertThat`.

- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. Alternatively,
  - Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
  - Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.
  - Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. For more information, see `matlab.unittest.qualifications.Assumable`.

## Input Arguments

### `fatalAssertable`

The `matlab.unittest.TestCase` instance which is used to pass or fail the fatal assertion in conjunction with the test running framework.

**actual**

The value to test.

**Default:****expected**

Expected value.

**Default:****diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

**'AbsTol'**

Absolute tolerance, specified as a numeric array. The tolerance is applied only to values of the same data type. The value can be a scalar or array the same size as the actual and expected values.

For an absolute tolerance to be satisfied, `abs(expected-actual) <= absTol` must be true.

**Default:**

**'RelTol'**

Relative tolerance, specified as a numeric array. The tolerance is applied only to values of the same data type. The value can be a scalar or array the same size as the actual and expected values.

For a relative tolerance to be satisfied, `abs(expected - actual) <= relTol .* abs(expected)` must be true.

**Default:**

## Examples

See examples for `verifyEqual`, and replace calls to `verifyEqual` with `fatalAssertEqual`.

## fatalAssertError

**Class:** matlab.unittest.qualifications.FatalAssertable

**Package:** matlab.unittest.qualifications

Fatally assert function throws specified exception

### Syntax

```
fatalAssertError(fatalAssertable,actual,identifier)
```

```
fatalAssertError(fatalAssertable,actual,metaClass)
```

```
fatalAssertError(____,diagnostic)
```

### Description

`fatalAssertError(fatalAssertable,actual,identifier)` fatally asserts that `actual` is a function handle that throws an exception with an error identifier that is equal to `identifier`.

`fatalAssertError(fatalAssertable,actual,metaClass)` fatally asserts that `actual` is a function handle that throws an exception whose type is defined by the `meta.class` instance specified in `metaClass`. This method does not require the instance to be an exact class match, but rather it must be in the specified class hierarchy, and that hierarchy must include the `MException` class..

`fatalAssertError( ____,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

### Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.Throws;
fatalAssertable.fatalAssertThat(actual, Throws(identifier));
fatalAssertable.fatalAssertThat(actual, Throws(metaClass));
```

There exists more functionality when using the `Throws` constraint directly via `fatalAssertThat`.

- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. Alternatively,
  - Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
  - Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.
  - Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. For more information, see `matlab.unittest.qualifications.Assumable`.

## Input Arguments

### **fatalAssertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the fatal assertion in conjunction with the test running framework.

### **identifier**

Error identifier, specified as a string.

### **Default:**

### **metaClass**

An instance of `meta.class`.

## Default:

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

See examples for `verifyError`, and replace calls to `verifyError` with `fatalAssertError`.

## See Also

## More About

- “Types of Qualifications”

**Introduced in R2013a**

# fatalAssertFail

**Class:** matlab.unittest.qualifications.FatalAssertable

**Package:** matlab.unittest.qualifications

Produce unconditional fatal assertion failure

## Syntax

```
fatalAssertFail(fatalAssertable)
fatalAssertFail(fatalAssertable,diagnostic)
```

## Description

`fatalAssertFail(fatalAssertable)` produces an unconditional fatal assertion failure when encountered.

`fatalAssertFail(fatalAssertable,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Input Arguments

### **fatalAssertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the fatal assertion in conjunction with the test running framework.

### **actual**

The value to test.

### **Default:**

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle

- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Tips

- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. Alternatively,
  - Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
  - Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.
  - Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as **Incomplete**. For more information, see `matlab.unittest.qualifications.Assumable`.

## Examples

See examples for `verifyFail`, and replace calls to `verifyFail` with `fatalAssertFail`.

## More About

- “Types of Qualifications”

**Introduced in R2013a**

# fatalAssertFalse

**Class:** matlab.unittest.qualifications.FatalAssertable

**Package:** matlab.unittest.qualifications

Fatally assert value is false

## Syntax

```
fatalAssertFalse(fatalAssertable,actual)
```

```
fatalAssertFalse(fatalAssertable,actual,diagnostic)
```

## Description

`fatalAssertFalse(fatalAssertable,actual)` fatally asserts that `actual` is a scalar logical with the value of false.

`fatalAssertFalse(fatalAssertable,actual,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method passes if and only if the actual value is a scalar logical with a value of false. Therefore, entities such as empty arrays, false valued arrays, and zero doubles produce failures when used in this method, despite these entities exhibiting "false-like" behavior such as bypassing the execution of code inside of "if" statements.
- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsFalse;
fatalAssertable.fatalAssertThat(actual, IsFalse());
```

There exists more functionality when using the `IsFalse` constraint directly via `fatalAssertThat`.

- Unlike `fatalAssertTrue`, this method may create a new constraint for each call. For performance critical uses, consider using `fatalAssertTrue`.

- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. Alternatively,
  - Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
  - Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.
  - Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. For more information, see `matlab.unittest.qualifications.Assumable`.

## Input Arguments

### **fatalAssertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the fatal assertion in conjunction with the test running framework.

### **actual**

The value to test.

### **Default:**

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

## More About

- “Types of Qualifications”

**Introduced in R2013a**

# fatalAssertGreaterThan

**Class:** matlab.unittest.qualifications.FatalAssertable

**Package:** matlab.unittest.qualifications

Fatally assert value is greater than specified value

## Syntax

```
fatalAssertGreaterThan(fatalAssertable, actual, floor)
```

```
fatalAssertGreaterThan(fatalAssertable, actual, floor, diagnostic)
```

## Description

`fatalAssertGreaterThan(fatalAssertable, actual, floor)` fatally asserts that all elements of `actual` are greater than all the elements of `floor`.

`fatalAssertGreaterThan(fatalAssertable, actual, floor, diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
matlab.unittest.constraints.IsGreaterThan;
fatalAssertable.fatalAssertThat(actual, IsGreaterThan(floor));
```

There exists more functionality when using the `IsGreaterThan` constraint directly via `fatalAssertThat`.

- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. Alternatively,
  - Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution

of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.

- Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. ## More About

- “Types of Qualifications”

**Introduced in R2013a**

# fatalAssertInstanceOf

**Class:** matlab.unittest.qualifications.FatalAssertable

**Package:** matlab.unittest.qualifications

Fatally assert value is object of specified type

## Syntax

```
fatalAssertInstanceOf(fatalAssertable, actual, className)
```

```
fatalAssertInstanceOf(fatalAssertable, actual, metaClass)
```

```
fatalAssertInstanceOf(____, diagnostic)
```

## Description

`fatalAssertInstanceOf(fatalAssertable, actual, className)` fatally asserts that `actual` is a MATLAB value whose class is the class specified by `className`.

`fatalAssertInstanceOf(fatalAssertable, actual, metaClass)` fatally asserts that `actual` is a MATLAB value whose class is the class specified by the `meta.class` instance `metaClass`.

`fatalAssertInstanceOf( ____, diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsInstanceOf;
fatalAssertable.fatalAssertThat(actual, IsInstanceOf(className));
fatalAssertable.fatalAssertThat(actual, IsInstanceOf(metaClass));
```

There exists more functionality when using the `IsInstanceOf` constraint directly via `fatalAssertThat`.

- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is

no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. Alternatively,

## More About

- “Types of Qualifications”

**Introduced in R2013a**

# fatalAssertMatches

**Class:** matlab.unittest.qualifications.FatalAssertable

**Package:** matlab.unittest.qualifications

Fatally assert string matches specified regular expression

## Syntax

```
fatalAssertMatches(fatalAssertable, actual, expression)
```

```
fatalAssertMatches(fatalAssertable, actual, expression, diagnostic)
```

## Description

`fatalAssertMatches(fatalAssertable, actual, expression)` fatally asserts that `actual` is a string that matches the regular expression defined by `expression`.

`fatalAssertMatches(fatalAssertable, actual, expression, diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.Matches;
fatalAssertable.fatalAssertThat(actual, Matches(expression));
```

There exists more functionality when using the `Matches` constraint directly via `fatalAssertThat`.

- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. Alternatively,
  - Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution

of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.

- Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.
- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. For more information, see `matlab.unittest.qualifications.Assumable`.

## Input Arguments

### **`fatalAssertable`**

The `matlab.unittest.TestCase` instance which is used to pass or fail the fatal assertion in conjunction with the test running framework.

### **`actual`**

The value to test.

### **Default:**

### **`expression`**

The value to match, specified as a regular expression.

### **Default:**

### **`diagnostic`**

Diagnostic information to display upon a failure, specified as one of the following:

- string

- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

## More About

- “Types of Qualifications”

**Introduced in R2013a**

# fatalAssertNotEmpty

**Class:** matlab.unittest.qualifications.FatalAssertable

**Package:** matlab.unittest.qualifications

Fatally assert value is not empty

## Syntax

```
fatalAssertNotEmpty(fatalAssertable, actual)
```

```
fatalAssertNotEmpty(fatalAssertable, actual, diagnostic)
```

## Description

`fatalAssertNotEmpty(fatalAssertable, actual)` fatally asserts that `actual` is a non-empty MATLAB value.

`fatalAssertNotEmpty(fatalAssertable, actual, diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsEmpty;
fatalAssertable.fatalAssertThat(actual, ~IsEmpty());
```

There exists more functionality when using the `IsEmpty` constraint directly via `fatalAssertThat`.

- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. Alternatively,
  - Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution

of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.

- Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.
- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. For more information, see `matlab.unittest.qualifications.Assumable`.

## Input Arguments

### **fatalAssertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the fatal assertion in conjunction with the test running framework.

### **actual**

The value to test.

### **Default:**

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

See examples for `verifyNotEmpty`, and replace calls to `verifyNotEmpty` with `fatalAssertNotEmpty`.

## See Also

`fatalAssertEmpty` | `fatalAssertThat` | `isempty`

## More About

- “Types of Qualifications”

**Introduced in R2013a**

# fatalAssertNotEqual

**Class:** matlab.unittest.qualifications.FatalAssertable

**Package:** matlab.unittest.qualifications

Fatally assert value is not equal to specified value

## Syntax

```
fatalAssertNotEqual(fatalAssertable, actual, notExpected)
fatalAssertNotEqual(fatalAssertable, actual, notExpected, diagnostic)
```

## Description

`fatalAssertNotEqual(fatalAssertable, actual, notExpected)` fatally asserts that `actual` is not equal to `notExpected`.

`fatalAssertNotEqual(fatalAssertable, actual, notExpected, diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsEqualTo;
fatalAssertable.fatalAssertThat(actual, ~IsEqualTo(notExpected));
```

There exists more functionality when using the `IsEqualTo` constraint directly via `fatalAssertThat`.

- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. Alternatively,
  - Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution

of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.

- Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.
- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as **Incomplete**. For more information, see `matlab.unittest.qualifications.Assumable`.

## Input Arguments

### **`fatalAssertable`**

The `matlab.unittest.TestCase` instance which is used to pass or fail the fatal assertion in conjunction with the test running framework.

### **`actual`**

The value to test.

### **Default:**

### **`notExpected`**

Value to compare.

### **Default:**

## Examples

See examples for `verifyNotEqual`, and replace calls to `verifyNotEqual` with `fatalAssertNotEqual`.

## See Also

## More About

- [“Types of Qualifications”](#)

**Introduced in R2013a**

## fatalAssertNotSameHandle

**Class:** matlab.unittest.qualifications.FatalAssertable

**Package:** matlab.unittest.qualifications

Fatally assert value is not handle to specified instance

### Syntax

```
fatalAssertNotSameHandle(fatalAssertable, actual, notExpectedHandle)
fatalAssertNotSameHandle(fatalAssertable, actual, notExpectedHandle,
diagnostic)
```

### Description

`fatalAssertNotSameHandle(fatalAssertable, actual, notExpectedHandle)` fatally asserts that `actual` is a different size and/or does not contain the same instances as the `notExpectedHandle` handle array.

`fatalAssertNotSameHandle(fatalAssertable, actual, notExpectedHandle, diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

### Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsSameHandleAs;
fatalAssertable.fatalAssertThat(actual, ~IsSameHandleAs(notExpectedHandle));
```

There exists more functionality when using the `IsSameHandleAs` constraint directly via `fatalAssertThat`.

- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. Alternatively,

- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
- Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.
- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. For more information, see `matlab.unittest.qualifications.Assumable`.

## Input Arguments

### **fatalAssertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the fatal assertion in conjunction with the test running framework.

### **actual**

The value to test.

### **Default:**

### **notExpectedHandle**

The handle array to compare.

### **Default:**

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

See examples for `verifyNotSameHandle`, and replace calls to `verifyNotSameHandle` with `fatalAssertNotSameHandle`.

**Introduced in R2013a**

# fatalAssertNumElements

**Class:** matlab.unittest.qualifications.FatalAssertable

**Package:** matlab.unittest.qualifications

Fatally assert value has specified element count

## Syntax

```
fatalAssertNumElements(fatalAssertable, actual, expectedElementCount)
fatalAssertNumElements(fatalAssertable, actual, expectedElementCount,
diagnostic)
```

## Description

`fatalAssertNumElements(fatalAssertable, actual, expectedElementCount)` fatally asserts that `actual` is a MATLAB array with `expectedElementCount` number of elements.

`fatalAssertNumElements(fatalAssertable, actual, expectedElementCount, diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.HasElementCount;
fatalAssertable.fatalAssertThat(actual, HasElementCount(expectedElementCount));
```

There exists more functionality when using the `HasElementCount` constraint directly via `fatalAssertThat`.

- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. Alternatively,

- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
- Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.
- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as **Incomplete**. For more information, see `matlab.unittest.qualifications.Assumable`.

## Input Arguments

### **fatalAssertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the fatal assertion in conjunction with the test running framework.

### **actual**

The value to test.

### **Default:**

### **expectedElementCount**

The expected number of elements in the array.

### **Default:**

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

## More About

- “Types of Qualifications”

**Introduced in R2013a**

## fatalAssertReturnsTrue

**Class:** matlab.unittest.qualifications.FatalAssertable

**Package:** matlab.unittest.qualifications

Fatally assert function returns true when evaluated

### Syntax

```
fatalAssertReturnsTrue(fatalAssertable, actual)
fatalAssertReturnsTrue(fatalAssertable, actual, diagnostic)
```

### Description

`fatalAssertReturnsTrue(fatalAssertable, actual)` fatally asserts that `actual` is a function handle that returns a scalar logical whose value is true.

`fatalAssertReturnsTrue(fatalAssertable, actual, diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

### Tips

- It is a shortcut for quick custom comparison functionality that can be defined quickly, and possibly inline. It can be preferable over simply evaluating the function directly and using `fatalAssertTrue` because the function handle will be shown in the diagnostics, thus providing more insight into the failure condition which is lost when using `fatalAssertTrue`.
- This method is functionally equivalent to:

```
import matlab.unittest.constraints.ReturnsTrue;
fatalAssertable.fatalAssertThat(actual, ReturnsTrue());
```

There exists more functionality when using the `ReturnsTrue` constraint directly via `fatalAssertThat`.

- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is

no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. Alternatively,

- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
- Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.
- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. For more information, see `matlab.unittest.qualifications.Assumable`.

## Input Arguments

### **fatalAssertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the fatal assertion in conjunction with the test running framework.

### **actual**

The function handle to test.

### **Default:**

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string

- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

**Introduced in R2013a**

# fatalAssertSameHandle

**Class:** matlab.unittest.qualifications.FatalAssertable

**Package:** matlab.unittest.qualifications

Fatally assert two values are handles to same instance

## Syntax

```
fatalAssertSameHandle(fatalAssertable, actual, expectedHandle)
fatalAssertSameHandle(fatalAssertable, actual, expectedHandle,
diagnostic)
```

## Description

`fatalAssertSameHandle(fatalAssertable, actual, expectedHandle)` fatally asserts that `actual` is the same size and contains the same instances as the `expectedHandle` handle array.

`fatalAssertSameHandle(fatalAssertable, actual, expectedHandle, diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsSameHandleAs;
fatalAssertable.fatalAssertThat(actual, IsSameHandleAs(expectedHandle));
```

There exists more functionality when using the `IsSameHandleAs` constraint directly via `fatalAssertThat`.

- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. Alternatively,

- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
- Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. - “Types of Qualifications”

**Introduced in R2013a**

## fatalAssertSize

**Class:** matlab.unittest.qualifications.FatalAssertable

**Package:** matlab.unittest.qualifications

Fatally assert value has specified size

### Syntax

```
fatalAssertSize(fatalAssertable,actual,expectedSize)
```

```
fatalAssertSize(fatalAssertable,actual,expectedSize,diagnostic)
```

### Description

`fatalAssertSize(fatalAssertable,actual,expectedSize)` fatally asserts that `actual` is a MATLAB array whose size is `expectedSize`.

`fatalAssertSize(fatalAssertable,actual,expectedSize,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

### Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.HasSize;
fatalAssertable.fatalAssertThat(actual, HasSize(expectedSize));
```

There exists more functionality when using the `HasSize` constraint directly via `fatalAssertThat`.

- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. Alternatively,
  - Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution

of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.

- Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.
- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. For more information, see `matlab.unittest.qualifications.Assumable`.

## Input Arguments

### **fatalAssertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the fatal assertion in conjunction with the test running framework.

### **actual**

The value to test.

### **Default:**

### **expectedSize**

The expected sizes of each dimension the array.

### **Default:**

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string

- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

See examples for `verifySize`, and replace calls to `verifySize` with `fatalAssertSize`.

## More About

- “Types of Qualifications”

**Introduced in R2013a**

# fatalAssertSubstring

**Class:** matlab.unittest.qualifications.FatalAssertable

**Package:** matlab.unittest.qualifications

Fatally assert string contains specified string

## Syntax

```
fatalAssertSubstring(fatalAssertable, actual, substring)
fatalAssertSubstring(fatalAssertable, actual, substring, diagnostic)
```

## Description

`fatalAssertSubstring(fatalAssertable, actual, substring)` fatally asserts that `actual` is a string that contains `substring`.

`fatalAssertSubstring(fatalAssertable, actual, substring, diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.ContainsSubstring;
fatalAssertable.fatalAssertThat(actual, ...
 ContainsSubstring(substring));
```

There exists more functionality when using the `ContainsSubstring` constraint directly via `fatalAssertThat`.

- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. Alternatively,

- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
- Use verification qualifications to produce and record failures without throwing an exception. ## More About

- “Types of Qualifications”

**Introduced in R2013a**

## **fatalAssertThat**

**Class:** matlab.unittest.qualifications.FatalAssertable

**Package:** matlab.unittest.qualifications

Fatally assert value meets specified constraint

### **Syntax**

```
fatalAssertThat(fatalAssertable,actual,constraint)
fatalAssertThat(fatalAssertable,actual,constraint,diagnostic)
```

### **Description**

`fatalAssertThat(fatalAssertable,actual,constraint)` fatally asserts that `actual` is a value that satisfies the `constraint` provided.

If the constraint is not satisfied, a fatal assertion failure is produced utilizing only the framework diagnostic generated by the `constraint`.

`fatalAssertThat(fatalAssertable,actual,constraint,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

When using this signature, both the diagnostic information contained within `diagnostic` is used in addition to the diagnostic information provided by the `constraint`.

### **Input Arguments**

#### **fatalAssertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the fatal assertion in conjunction with the test running framework.

#### **actual**

The value to test.

**Default:****constraint**

Constraint that the actual value must satisfy to pass the verification, specified as a `matlab.unittest.constraints` instance.

**Default:****diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Tips

- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. Alternatively,
  - Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
  - Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.

- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as **Incomplete**. For more information, see `matlab.unittest.qualifications.Assumable`.

## Examples

See examples for `verifyThat`, and replace calls to `verifyThat` with `fatalAssertThat`.

## More About

- “Types of Qualifications”

**Introduced in R2013a**

# fatalAssertTrue

**Class:** matlab.unittest.qualifications.FatalAssertable

**Package:** matlab.unittest.qualifications

Fatally assert value is true

## Syntax

```
fatalAssertTrue(fatalAssertable, actual)
```

```
fatalAssertTrue(fatalAssertable, actual, diagnostic)
```

## Description

`fatalAssertTrue(fatalAssertable, actual)` fatally asserts that `actual` is a scalar logical with the value of true.

`fatalAssertTrue(fatalAssertable, actual, diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method passes if and only if the actual value is a scalar logical with a value of true. Therefore, entities such as true valued arrays and nonzero doubles produce qualification failures when used in this method, despite these entities exhibiting "true-like" behavior such as triggering the execution of code inside of "if" statements.
- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsTrue;
fatalAssertable.fatalAssertThat(actual, IsTrue());
```

There exists more functionality when using the `IsTrue` constraint directly via `fatalAssertThat`.

However, this method is optimized for performance and does not construct a new `IsTrue` constraint for each call. Sometimes such use can come at the expense of less

diagnostic information. Use the `fatalAssertReturnsTrue` method for a similar approach which may provide better diagnostic information.

- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. Alternatively,
  - Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
  - Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.
  - Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. For more information, see `matlab.unittest.qualifications.Assumable`.

## Input Arguments

### **fatalAssertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the fatal assertion in conjunction with the test running framework.

### **actual**

The value to test.

### **Default:**

**diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

See examples for `verifyTrue`, and replace calls to `verifyTrue` with `fatalAssertTrue`.

## See Also

## More About

- “Types of Qualifications”

**Introduced in R2013a**

# fatalAssertWarning

**Class:** matlab.unittest.qualifications.FatalAssertable

**Package:** matlab.unittest.qualifications

Fatally assert function issues specified warning

## Syntax

```
fatalAssertWarning(fatalAssertable,actual,warningID)
fatalAssertWarning(fatalAssertable,actual,warningID,diagnostic)
[output1,...,outputN] = fatalAssertWarning(___)
```

## Description

`fatalAssertWarning(fatalAssertable,actual,warningID)` fatally asserts that `actual` issues a warning with the identifier `warningID`.

`fatalAssertWarning(fatalAssertable,actual,warningID,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

`[output1,...,outputN] = fatalAssertWarning( ___ )` also returns the output arguments `output1,...,outputN` that are produced when invoking `actual`.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IssuesWarnings;
fatalAssertable.fatalAssertThat(actual, IssuesWarnings({warningID}));
```

There exists more functionality when using the `IssuesWarnings` constraint directly via `fatalAssertThat`.

- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture

teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. Alternatively,

- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
- Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.
- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. For more information, see `matlab.unittest.qualifications.Assumable`.

## Input Arguments

### **fatalAssertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the fatal assertion in conjunction with the test running framework.

### **actual**

The function handle to test.

### **Default:**

### **warningID**

Warning ID, specified as a string.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Output Arguments

**output1, ..., outputN**

Output arguments, 1 through n (if any), from `actual`, returned as any type. The argument type is specified by the `actual` argument list.

## Examples

See examples for `verifyWarning`, and replace calls to `verifyWarning` with `fatalAssertWarning`.

## See Also

`fatalAssertError` | `fatalAssertThat` | `fatalAssertWarningFree` | `warning`

## More About

- “Types of Qualifications”

**Introduced in R2013a**

# fatalAssertWarningFree

**Class:** matlab.unittest.qualifications.FatalAssertable

**Package:** matlab.unittest.qualifications

Fatally assert function issues no warnings

## Syntax

```
fatalAssertWarningFree(fatalAssertable,actual)
fatalAssertWarningFree(fatalAssertable,actual,diagnostic)
[output1,...,outputN] = fatalAssertWarningFree(___)
```

## Description

`fatalAssertWarningFree(fatalAssertable,actual)` fatally asserts that `actual` is a function handle that issues no warnings.

`fatalAssertWarningFree(fatalAssertable,actual,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

`[output1,...,outputN] = fatalAssertWarningFree( ___ )` also returns the output arguments `output1,...,outputN` that are produced when invoking `actual`.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IssuesNoWarnings;
fatalAssertable.fatalAssertThat(actual, IssuesNoWarnings());
```

There exists more functionality when using the `IssuesNoWarnings` constraint directly via `fatalAssertThat`.

- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture

teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. Alternatively,

- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
- Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.
- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as **Incomplete**. For more information, see `matlab.unittest.qualifications.Assumable`.

## Input Arguments

### **fatalAssertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the fatal assertion in conjunction with the test running framework.

### **actual**

The function handle to test.

### **Default:**

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle

- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Output Arguments

**output1, ..., outputN**

Output arguments, 1 through n (if any), from `actual`, returned as any type. The argument type is specified by the `actual` argument list.

## Examples

See examples for `verifyWarningFree`, and replace calls to `verifyWarningFree` with `fatalAssertWarningFree`.

## More About

- “Types of Qualifications”

**Introduced in R2013a**

# **matlab.unittest.qualifications.FatalAssertionFailedException class**

**Package:** matlab.unittest.qualifications

Exception used for fatal assertion failures

## **Description**

The `FatalAssertionFailedException` class provides an exception used for fatal assertion failures. This class is used exclusively by the `FatalAssertable` qualification type.

## **See Also**

`MException` | `FatalAssertable`

# matlab.unittest.qualifications.QualificationEventData class

**Package:** matlab.unittest.qualifications

Event data for qualification event listeners

## Description

The `QualificationEventData` class holds event data for qualification event listeners. Qualification event listeners are callback functions that you register with the testing framework to listen for passing and/or failing qualifications. Qualifications can be assertions, fatal assertions, assumptions, or verifications performed on test content. The corresponding qualification classes define these events. Typically, authors of custom plugins use this class. Only the test framework constructs this class directly.

## Properties

### ActualValue

Value tested to satisfy the qualification logic of the `Constraint`

### Constraint

Instance of `matlab.unittest.constraints.Constraint` used for the qualification

When you use a qualification method on a `TestCase` or `Fixture` object, the `Constraint` property contains the underlying constraint used for the qualification. For example, if you use the `verifyEqual` method, the underlying constraint is the `IsEqualTo` constraint. Therefore, if you invoke the constraint's `getDiagnosticFor` method, the diagnostic result can appear different than what the test framework displays.

### TestDiagnostic

Diagnostic specified in the qualification, represented as a string, function handle, or instance of the `Diagnostic` class

### **TestDiagnosticResult**

Result of diagnostic specified in the qualification, represented as a cell array of strings

### **FrameworkDiagnosticResult**

Result of diagnostic from constraint used for the qualification, represented as a cell array of strings

### **Stack**

Function call stack leading up to the qualification event, represented as a structure array

# matlab.unittest.qualifications.Verifiable class

**Package:** matlab.unittest.qualifications

Qualification to produce soft-failure conditions

## Description

The `Verifiable` class provides a qualification to produce soft-failure conditions. Apart from actions performed for failures, the `Verifiable` class works the same as other `matlab.unittest` qualifications.

Upon a verification failure, the `Verifiable` class informs the testing framework of the failure, including all diagnostic information associated with the failure, but continues to execute the currently running test without throwing an `MException`. This is most useful when a failure at the verification point is not fatal to the remaining test content. Often, you use verifications as the primary verification of a Four-Phase Test. Use other qualification types, such as assertions, fatal assertions, and assumptions, to test for violation of preconditions or incorrect test setup.

Since verifications do not throw `MExceptions`, all test content runs to completion even when verification failures occur. This helps you understand how close a piece of software is to meeting the test suite requirements. Qualification types that throw exceptions do not provide this insight, since once an exception is thrown an arbitrary amount of code remains that is not reached or exercised. Verifications also provide more testing coverage in failure conditions. However, when you overuse verifications, they can produce excess noise for a single failure condition. If a failure condition will cause later qualification points to also fail, use assertions or fatal assertions instead.

## Methods

<code>verifyClass</code>	Verify exact class of specified value
<code>verifyEmpty</code>	Verify value is empty
<code>verifyEqual</code>	Verify value is equal to specified value
<code>verifyError</code>	Verify function throws specified exception
<code>verifyFail</code>	Produce unconditional verification failure

<code>verifyFalse</code>	Verify value is false
<code>verifyGreaterThan</code>	Verify value is greater than specified value
<code>verifyGreaterThanOrEqual</code>	Verify value is greater than or equal to specified value
<code>verifyInstanceOf</code>	Verify value is object of specified type
<code>verifyLength</code>	Verify value has specified length
<code>verifyLessThan</code>	Verify value is less than specified value
<code>verifyLessThanOrEqual</code>	Verify value is less than or equal to specified value
<code>verifyMatches</code>	Verify string matches specified regular expression
<code>verifyNotEmpty</code>	Verify value is not empty
<code>verifyNotEqual</code>	Verify value is not equal to specified value
<code>verifyNotSameHandle</code>	Verify value is not handle to specified instance
<code>verifyNumElements</code>	Verify value has specified element count
<code>verifyReturnsTrue</code>	Verify function returns true when evaluated
<code>verifySameHandle</code>	Verify two values are handles to same instance
<code>verifySize</code>	Verify value has specified size
<code>verifySubstring</code>	Verify string contains specified string
<code>verifyThat</code>	Verify value meets given constraint
<code>verifyTrue</code>	Verify value is true
<code>verifyWarning</code>	Verify function issues specified warning
<code>verifyWarningFree</code>	Verify function issues no warnings

## Events

<code>VerificationFailed</code>	Triggered upon failing verification. A <code>QualificationEventData</code> object is passed to listener callback functions.
---------------------------------	-----------------------------------------------------------------------------------------------------------------------------

VerificationPassed

Triggered upon passing verification. A `QualificationEventData` object is passed to listener callback functions.

## Copy Semantics

Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB documentation.

## Examples

### Write Test Methods Using Verifications

Verifications produce and record failures without throwing an exception, meaning the currently running test runs to completion. This example creates a test case to verify arithmetic operations on objects of the `DocPolynom` example class.

Create the `DocPolynomTest` Test Case. Refer to the following `DocPolynomTest` test case in the subsequent steps in this example, which highlight specific functions in the file.

### DocPolynomTest Class Definition File

```
classdef DocPolynomTest < matlab.unittest.TestCase
 % Tests the DocPolynom class.

 properties
 msgEqn = 'Equation under test: ';
 end

 methods (TestClassSetup)
 function addDocPolynomClassToPath(testCase)
 testCase.addTeardown(@path,addpath(fullfile(matlabroot,...
 'help', 'techdoc', 'matlab_oop', 'examples')))
 end
 end

 methods (Test)
 function testConstructor(testCase)
 p = DocPolynom([1, 0, 1]);
 end
 end
end
```

```
 testCase.verifyClass(p, ?DocPolynom)
 end

 function testAddition(testCase)
 p1 = DocPolynom([1, 0, 1]);
 p2 = DocPolynom([5, 2]);

 actual = p1 + p2;
 expected = DocPolynom([1, 5, 3]);

 msg = [testCase.msgEqn,...
 '(x^2 + 1) + (5*x + 2) = x^2 + 5*x + 3'];
 testCase.verifyEqual(actual, expected, msg)
 end

 function testMultiplication(testCase)
 p1 = DocPolynom([1, 0, 3]);
 p2 = DocPolynom([5, 2]);

 actual = p1 * p2;
 expected = DocPolynom([5, 2, 15, 6]);

 msg = [testCase.msgEqn,...
 '(x^2 + 3) * (5*x + 2) = 5*x^3 + 2*x^2 + 15*x + 6'];
 testCase.verifyEqual(actual, expected, msg)
 end

end
end
```

To execute the MATLAB commands in this example, add the `DocPolynomTest.m` file to a folder on your MATLAB path.

Write Test to Verify Constructor. Create a function, `testConstructor`, using the `verifyClass` method to test the `DocPolynom` class constructor.

```
function testConstructor(testCase)
 p = DocPolynom([1, 0, 1]);
 testCase.verifyClass(p, ?DocPolynom)
end
```

Write Tests to Verify Operations. In the `testAddition` function, use the `verifyEqual` method to test the equation  $(x^2 + 1) + (5x + 2) = x^2 + 5x + 3$ . The `verifyEqual` method includes this equation in the `diagnostic` argument.

```
function testAddition(testCase)
 p1 = DocPolynom([1, 0, 1]);
 p2 = DocPolynom([5, 2]);

 actual = p1 + p2;
 expected = DocPolynom([1, 5, 3]);

 msg = [testCase.msgEqn,...
 '(x^2 + 1) + (5*x + 2) = x^2 + 5*x + 3'];
 testCase.verifyEqual(actual, expected, msg)
end
```

The function, `testMultiplication`, tests multiplication operations.

Run the tests in the `DocPolynomTest` test case.

```
tc = DocPolynomTest;
ts = matlab.unittest.TestSuite.fromClass(?DocPolynomTest);
res = run(ts);
```

```
Running DocPolynomTest
...
Done DocPolynomTest
```

-----  
All tests passed.

**Introduced in R2013a**

## verifyClass

**Class:** matlab.unittest.qualifications.Verifiable

**Package:** matlab.unittest.qualifications

Verify exact class of specified value

### Syntax

```
verifyClass(verifiable,actual,className)
verifyClass(verifiable,actual,metaClass)
verifyClass(____,diagnostic)
```

### Description

`verifyClass(verifiable,actual,className)` verifies that `actual` is a MATLAB value whose class is the class specified by `className`.

`verifyClass(verifiable,actual,metaClass)` verifies that `actual` is a MATLAB value whose class is the class specified by the `meta.class` instance `metaClass`. The instance must be an exact class match. Use `verifyInstanceOf` to verify inclusion in a class hierarchy.

`verifyClass( ____,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

### Tips

- The method is functionally equivalent to the following methods:

```
import matlab.unittest.constraints.IsOfClass;
verifiable.verifyThat(actual, IsOfClass(className));
verifiable.verifyThat(actual, IsOfClass(metaClass));
```

There exists more functionality when using the `IsOfClass` constraint directly via `verifyThat`.

- Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. Alternatively,
  - Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as **Incomplete**. For more information, see `matlab.unittest.qualifications.Assumable`.
  - Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
  - Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.

## Input Arguments

### **verifiable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the verification in conjunction with the test running framework.

### **actual**

The value to test.

### **Default:**

### **className**

Name of class, specified as a string.

**Default:****metaClass**

An instance of `meta.class`.

**Default:****diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

**Test a Class**

These interactive tests verify the class of the number, 5.

Create a `TestCase` object and the value to test.

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
actvalue = 5;
```

Verify class of `actvalue` is `double`.

```
verifyClass(testCase, actvalue, 'double');
```

```
Interactive verification passed.
```

Verify class of `actvalue` is `char`.

```
verifyClass(testCase, actvalue, 'char');
```

```
Interactive verification failed.
```

```

Framework Diagnostic:

verifyClass failed.
--> The value's class is incorrect.

 Actual Class:
 double
 Expected Class:
 char

Actual Value:
 5

```

Test fails.

### Test a Function Handle

These interactive tests verify function handles, specified as a meta.class instance, ?function\_handle.

Create a TestCase object.

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
```

Create a function handle.

```
fh = @sin;
verifyClass(testCase, fh, ?function_handle);
```

```
Interactive verification passed.
```

Test the function name.

```
fh = 'sin';
verifyClass(testCase, fh, ?function_handle);
```

```
Interactive verification failed.
```

```

Framework Diagnostic:

verifyClass failed.
--> The value's class is incorrect.

```

```
Actual Class:
 char
Expected Class:
 function_handle
```

```
Actual Value:
 sin
```

Test fails.

### Test a Derived Class

Verify that a derived class is not the same class as its base class.

Create a class, `BaseExample`.

```
classdef BaseExample
end
```

Create a derived class, `DerivedExample`.

```
classdef DerivedExample < BaseExample
end
```

Verify the classes are not equal.

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
verifyClass(testCase, DerivedExample(), ?BaseExample);
```

```
Interactive verification failed.
```

```

Framework Diagnostic:

verifyClass failed.
--> The value's class is incorrect.
```

```
Actual Class:
 DerivedExample
Expected Class:
 BaseExample
```

```
Actual Value:
 DerivedExample with no properties.
```

Test fails.

### Test Class of Output Value

Use `verifyClass` to test the `add5` function returns a double value.

Function for unit testing:

```
function res = add5(x)
% ADD5 Increment input by 5.
if ~isa(x, 'numeric')
 error('add5:InputMustBeNumeric', 'Input must be numeric.')
end
res = x + 5;
end
```

TestCase class containing test methods:

```
classdef Add5Test < matlab.unittest.TestCase
 methods (Test)
 function testDoubleOut(testCase)
 actOutput = add5(1);
 testCase.verifyClass(actOutput, 'double')
 end
 function testNonNumericInput(testCase)
 testCase.verifyError(@()add5('0'), 'add5:InputMustBeNumeric')
 end
 end
end
```

Create a test suite from the `Add5Test` class file.

```
suite = matlab.unittest.TestSuite.fromFile('Add5Test.m')
result = run(suite);
```

```
Running Add5Test
..
Done Add5Test
```

## **More About**

- “Types of Qualifications”

**Introduced in R2013a**

# verifyEmpty

**Class:** matlab.unittest.qualifications.Verifiable

**Package:** matlab.unittest.qualifications

Verify value is empty

## Syntax

```
verifyEmpty(verifiable,actual)
verifyEmpty(____,diagnostic)
```

## Description

`verifyEmpty(verifiable,actual)` verifies that `actual` is an empty MATLAB value.

`verifyEmpty( ____,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsEmpty;
verifiable.verifyThat(actual, IsEmpty());
```

There exists more functionality when using the `IsEmpty` constraint directly via `verifyThat`.

- Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. Alternatively,
  - Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures

result in filtered tests, and the testing framework marks the tests as `Incomplete`. For more information, see `matlab.unittest.qualifications.Assumable`.

- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.

## Input Arguments

### **verifiable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the verification in conjunction with the test running framework.

### **actual**

The value to test.

### **Default:**

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

### Test for Empty Strings

Create a TestCase object.

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
verifyEmpty(testCase, '');
Interactive verification passed.
```

### Test for Empty Arrays

An array with any zero dimension is empty.

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
verifyEmpty(testCase, ones(2, 5, 0, 3));
Interactive verification passed.
verifyEmpty(testCase, [2 3], 'Array is not empty.');
```

Interactive verification failed.

```

Test Diagnostic:

Array is not empty.

Framework Diagnostic:

verifyEmpty failed.
--> The value must be empty.
--> The value has a size of [1 2].
```

```
Actual Value:
 2 3
```

Test failed.

### Test for Empty Cell Arrays

Test empty cell array, {}.

```
matlab.unittest.TestCase.forInteractiveUse;
```

```
verifyEmpty(testCase, {}, 'Cell array is not empty.');
```

```
Interactive verification passed.
```

A cell array of empty arrays is not empty.

```
verifyEmpty(testCase, {[[], [], []]}, 'Cell array is not empty.');
```

```
Interactive verification failed.
```

```

Test Diagnostic:

```

```
Cell array is not empty.
```

```

Framework Diagnostic:

```

```
verifyEmpty failed.
```

```
--> The value must be empty.
```

```
--> The value has a size of [1 3].
```

```
Actual Value:
```

```
 [] [] []
```

Test failed.

## Test for Empty Test Suite

Test for empty object, emptyTestSuite.

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
```

```
emptyTestSuite = matlab.unittest.TestSuite.empty;
```

```
verifyEmpty(testCase, emptyTestSuite);
```

```
Interactive verification passed.
```

## See Also

## More About

- “Types of Qualifications”

**Introduced in R2013a**

# verifyEqual

**Class:** matlab.unittest.qualifications.Verifiable

**Package:** matlab.unittest.qualifications

Verify value is equal to specified value

## Syntax

```
verifyEqual(verifiable,actual,expected)
```

```
verifyEqual(____,Name,Value)
```

```
verifyEqual(____,diagnostic)
```

## Description

`verifyEqual(verifiable,actual,expected)` verifies that `actual` is strictly equal to `expected`.

`verifyEqual( ____,Name,Value)` verifies equality with additional options specified by one or more `Name,Value` pair arguments.

`verifyEqual( ____,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure

## Tips

- This method is functionally equivalent to any of the following:

```
import matlab.unittest.constraints.IsEqualTo;
verifiable.verifyThat(actual, IsEqualTo(expected));
```

```
import matlab.unittest.constraints.IsEqualTo;
import matlab.unittest.constraints.AbsoluteTolerance;
verifiable.verifyThat(actual, IsEqualTo(expected, ...
 'Within', AbsoluteTolerance(abstol)));
```

```
import matlab.unittest.constraints.IsEqualTo;
import matlab.unittest.constraints.RelativeTolerance;
verifiable.verifyThat(actual, IsEqualTo(expected, ...
```

```
 'Within', RelativeTolerance(reltol)));

import matlab.unittest.constraints.IsEqualTo;
import matlab.unittest.constraints.AbsoluteTolerance;
import matlab.unittest.constraints.RelativeTolerance;
verifiable.verifyThat(actual, IsEqualTo(expected, ...
 'Within', AbsoluteTolerance(abstol) | RelativeTolerance(reltol)));
```

There exists more functionality when using the `IsEqualTo`, `RelativeTolerance`, and `IsEqualTo` constraints directly via `verifyThat`.

- Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. Alternatively,
  - Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as **Incomplete**. For more information, see `matlab.unittest.qualifications.Assumable`.
  - Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
  - Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.

## Input Arguments

### **verifiable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the verification in conjunction with the test running framework.

**actual**

The value to test.

**Default:****expected**

Expected value.

**Default:****diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

**'AbsTol'**

Absolute tolerance, specified as a numeric array. The tolerance is applied only to values of the same data type. The value can be a scalar or array the same size as the actual and expected values.

For an absolute tolerance to be satisfied, `abs(expected-actual) <= absTol` must be true.

**Default:**

**'RelTol'**

Relative tolerance, specified as a numeric array. The tolerance is applied only to values of the same data type. The value can be a scalar or array the same size as the actual and expected values.

For a relative tolerance to be satisfied,  $\text{abs}(\text{expected} - \text{actual}) \leq \text{relTol} \cdot \text{abs}(\text{expected})$  must be true.

**Default:**

## Examples

### Comparing Numeric Values

Numeric values are equivalent if they are of the same class with equivalent size, complexity, and sparsity.

Create a `TestCase` object for interactive testing.

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
```

A value is equal to itself.

```
verifyEqual(testCase, 5, 5);
```

```
Interactive verification passed.
```

Values must have equal sizes.

```
verifyEqual(testCase, [5 5], 5);
```

```
Interactive verification failed.
```

```

Framework Diagnostic:

verifyEqual failed.
--> Sizes do not match.
```

```
 Actual size:
 1 2
 Expected size:
```

1 1

```
Actual double:
 5 5
Expected double:
 5
```

Test failed.

## Test Classes

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
verifyEqual(testCase, int8(5), int16(5));
```

Interactive verification failed.

```

Framework Diagnostic:

verifyEqual failed.
--> Classes do not match.
```

```
Actual Class:
 int8
Expected Class:
 int16
```

```
Actual Value:
 5
Expected Value:
 5
```

Test failed.

## Test Cell Arrays

Each element of a cell array must be equal in value, class, and size.

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
verifyEqual(testCase, {'cell', struct, 5}, {'cell', struct, 5});
```

Interactive verification passed.

## Test Numeric Tolerances

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
```

```
verifyEqual(testCase, 4.95, 5);
```

```
Interactive verification failed.
```

```

Framework Diagnostic:

```

```
verifyEqual failed.
```

```
--> The values are not equal using "isequaln".
```

```
--> Failure table:
```

Actual	Expected	Error	RelativeError
-----	-----	-----	-----
4.95	5	-0.04999999999999998	-0.009999999999999996

```
Actual double:
```

```
4.9500000000000000
```

```
Expected double:
```

```
5
```

```
Test failed.
```

```
verifyEqual(testCase, 1.5, 2, 'AbsTol', 1)
```

```
Interactive verification passed.
```

```
verifyEqual(testCase, 1.5, 2, 'RelTol', 0.1, ...
```

```
'Difference between actual and expected exceeds relative tolerance')
```

```
Interactive verification failed.
```

```

Test Diagnostic:

```

```
Difference between actual and expected exceeds relative tolerance
```

```

Framework Diagnostic:

```

```
verifyEqual failed.
```

```
--> The values are not equal using "isequaln".
```

```
--> The error was not within relative tolerance.
```

```
--> Failure table:
```

Actual	Expected	Error	RelativeError	RelativeTolerance
-----	-----	-----	-----	-----

```
 1.5 2 -0.5 -0.25 0.1
Actual double:
 1.5000000000000000
Expected double:
 2
```

Test failed.

## More About

- “Types of Qualifications”

**Introduced in R2013a**

# verifyError

**Class:** matlab.unittest.qualifications.Verifiable

**Package:** matlab.unittest.qualifications

Verify function throws specified exception

## Syntax

```
verifyError(verifiable,actual,identifier)
verifyError(verifiable,actual,metaClass)
verifyError(____,diagnostic)
```

## Description

`verifyError(verifiable,actual,identifier)` verifies that `actual` is a function handle that throws an exception with an error identifier that is equal to `identifier`.

`verifyError(verifiable,actual,metaClass)` verifies that `actual` is a function handle that throws an exception whose type is defined by the `meta.class` instance specified in `metaClass`. This method does not require the instance to be an exact class match, but rather it must be in the specified class hierarchy, and that hierarchy must include the `MException` class.

`verifyError( ____,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.Throws;
verifiable.verifyThat(actual, Throws(identifier));
verifiable.verifyThat(actual, Throws(metaClass));
```

There exists more functionality when using the `Throws` constraint directly via `verifyThat`.

- Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. Alternatively,
  - Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as **Incomplete**. For more information, see `matlab.unittest.qualifications.Assumable`.
  - Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
  - Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.

## Input Arguments

### **verifiable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the verification in conjunction with the test running framework.

### **actual**

The value to test.

### **Default:**

### **identifier**

Error identifier, specified as a string.

**Default:****metaClass**

An instance of `meta.class`.

**Default:****diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

### Test for Error IDs

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
```

#### % Passing scenarios

```
%%
```

```
verifyError(testCase, @() error('SOME:error:id', 'Error!'), 'SOME:error:id');
verifyError(testCase, @testCase.assertFail, ...
 ?matlab.unittest.qualifications.AssertionFailedException);
```

#### % Failing scenarios

```
%%
```

```
verifyError(testCase, 5, 'some:id', '5 is not a function handle');
verifyError(testCase, @testCase.verifyFail, ...
 ?matlab.unittest.qualifications.AssertionFailedException, ...
 'Verifications dont throw exceptions.');
```

```
verifyError(testCase, @() error('SOME:id'), 'OTHER:id', 'Wrong id');
verifyError(testCase, @() error('whoops'), ...
 ?matlab.unittest.qualifications.AssertionFailedException, ...
```

```
'Wrong type of exception thrown');
```

## Test Error Condition

Create `testNonNumericInput` to test if function throws expected error message, `add5:InputMustBeNumeric`, for unexpected condition, input is char.

Function for unit testing:

```
function res = add5(x)
% ADD5 Increment input by 5.
if ~isa(x,'numeric')
 error('add5:InputMustBeNumeric','Input must be numeric.')
end
res = x + 5;
end
```

TestCase class containing test methods:

```
classdef Add5Test < matlab.unittest.TestCase
 methods (Test)
 function testDoubleOut(testCase)
 actOutput = add5(1);
 testCase.verifyClass(actOutput,'double')
 end
 function testNonNumericInput(testCase)
 testCase.verifyError(@()add5('0'),'add5:InputMustBeNumeric')
 end
 end
end
```

Create a test suite from the `Add5Test` class file.

```
suite = matlab.unittest.TestSuite.fromFile('Add5Test.m')
result = run(suite);
```

```
Running Add5Test
..
Done Add5Test
```

## More About

- “Types of Qualifications”

**Introduced in R2013a**

## verifyFail

**Class:** matlab.unittest.qualifications.Verifiable

**Package:** matlab.unittest.qualifications

Produce unconditional verification failure

## Syntax

```
verifyFail(verifiable)
verifyFail(verifiable,diagnostic)
```

## Description

`verifyFail(verifiable)` produces an unconditional verification failure when encountered.

`verifyFail(verifiable,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Input Arguments

### **verifiable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the verification in conjunction with the test running framework.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Tips

- Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. Alternatively,
  - Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. For more information, see `matlab.unittest.qualifications.Assumable`.
  - Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
  - Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.

## Examples

### Test for Failure Condition

An example of where this method may be used is in a callback function that should not be executed in a given scenario. A test can confirm this does not occur by unconditionally performing a failure if the code path is reached.

Create a handle class, `MyHandle`, with a `SomethingHappened` event.

```
classdef MyHandle < handle
 events
 SomethingHappened
 end
```

end

Create a file, `ListenerTest`, on your MATLAB path that contains the following `TestCase` class.

```
classdef ListenerTest < matlab.unittest.TestCase
 methods(Test)
 function testDisabledListeners(testCase)
 h = MyHandle;

 % Add a listener to a test helper method
 listener = h.addlistener('SomethingHappened', ...
 @testCase.shouldNotGetCalled);

 % Passing scenario (code path is not reached)
 %%%%%%%%%%%
 % Disabled listener should not invoke callbacks
 listener.Enabled = false;
 h.notify('SomethingHappened');

 % Failing scenario (code path is reached)
 %%%%%%%%%%%
 % Enabled listener invoke callback and fail
 listener.Enabled = true;
 h.notify('SomethingHappened');
 end
 end

 methods
 function shouldNotGetCalled(testCase, ~, ~)
 % A test helper callback method that should not execute
 testCase.verifyFail('This listener callback should not have executed');
 end
 end
end
```

From the command prompt, run the test.

```
run(ListenerTest);
```

```
Running ListenerTest
```

```
=====
Verification failed in ListenerTest/testDisabledListeners.
```

```

Test Diagnostic:

```

```
This listener callback should not have executed
```

```

Stack Information:

```

```
In C:\Desktop\ListenerTest.m (ListenerTest.shouldNotGetCalled) at 27
```

```
In C:\Desktop\ListenerTest.m (@(varargin)testCase.shouldNotGetCalled(varargin{:}))
```

```
In C:\Desktop\ListenerTest.m (ListenerTest.testDisabledListeners) at 20
```

```
=====
```

```
.
Done ListenerTest
```

```

```

```
Failure Summary:
```

Name	Failed	Incomplete	Reason(s)
ListenerTest/testDisabledListeners	X		Failed by verification.

## More About

- “Types of Qualifications”

**Introduced in R2013a**

## verifyFalse

**Class:** matlab.unittest.qualifications.Verifiable

**Package:** matlab.unittest.qualifications

Verify value is false

### Syntax

```
verifyFalse(verifiable,actual)
verifyFalse(____,diagnostic)
```

### Description

`verifyFalse(verifiable,actual)` verifies that `actual` is a scalar logical with the value of false.

`verifyFalse( ____,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

### Tips

- This method passes if and only if the actual value is a scalar logical with a value of false. Therefore, entities such as empty arrays, false valued arrays, and zero doubles produce failures when used in this method, despite these entities exhibiting "false-like" behavior such as bypassing the execution of code inside of "if" statements.
- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsFalse;
verifiable.verifyThat(actual, IsFalse());
```

There exists more functionality when using the `IsFalse` constraint directly via `verifyThat`.

- Unlike `verifyTrue`, this method may create a new constraint for each call. For performance critical uses, consider using `verifyTrue`.

- Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. Alternatively,
  - Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as **Incomplete**. For more information, see `matlab.unittest.qualifications.Assumable`.
  - Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
  - Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.

## Input Arguments

### **verifiable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the verification in conjunction with the test running framework.

### **actual**

The value to test.

### **Default:**

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

### Test MATLAB Logical Functions

Create a `TestCase` object for interactive testing.

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
```

Test true.

```
verifyFalse(testCase, true);
```

```
Interactive verification failed.
```

```

Framework Diagnostic:

```

```
verifyFalse failed.
--> The value must evaluate to "false".
```

```
Actual Value:
 1
```

Test failed.

Test false.

```
verifyFalse(testCase, false);
```

```
Interactive verification passed.
```

### Test the Value 0

The number 0 is a `double` value, not a logical value.

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
```

```
verifyFalse(testCase, 0);
```

```
Interactive verification failed.
```

```

Framework Diagnostic:

```

```
verifyFalse failed.
```

```
--> The value must be logical. It is of type "double".
```

```
Actual Value:
```

```
 0
```

```
Test failed.
```

### Test Array of Logical Values

To be false, the value must be scalar.

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
verifyFalse(testCase, [false false false]);
```

```
Interactive verification failed.
```

```

Framework Diagnostic:

```

```
verifyFalse failed.
```

```
--> The value must be scalar. It has a size of [1 3].
```

```
Actual Value:
```

```
 0 0 0
```

```
Test failed.
```

Test an array of mixed logical values.

```
verifyFalse(testCase, [false true false], ...
 'A mixed array of logicals is not the one false value');
```

```
Interactive verification failed.
```

```

Test Diagnostic:

```

A mixed array of logicals is not the one false value

```

Framework Diagnostic:

verifyFalse failed.
--> The value must be scalar. It has a size of [1 3].
```

```
Actual Value:
 0 1 0
```

Test failed.

## More About

- “Types of Qualifications”

**Introduced in R2013a**

# verifyGreaterThan

**Class:** matlab.unittest.qualifications.Verifiable

**Package:** matlab.unittest.qualifications

Verify value is greater than specified value

## Syntax

```
verifyGreaterThan(verifiable,actual,floor)
verifyGreaterThan(____,diagnostic)
```

## Description

`verifyGreaterThan(verifiable,actual,floor)` verifies that all elements of `actual` are greater than all the elements of `floor`.

`verifyGreaterThan( ____,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
matlab.unittest.constraints.IsGreaterThan;
verifiable.verifyThat(actual, IsGreaterThan(floor));
```

There exists more functionality when using the `IsGreaterThan` constraint directly via `verifyThat`.

- Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. Alternatively,

- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as **Incomplete**. For more information, see `matlab.unittest.qualifications.Assumable`.
- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.

## Input Arguments

### **verifiable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the verification in conjunction with the test running framework.

### **actual**

The value to test. **actual** must be the same size as **floor** unless either one is scalar, at which point scalar expansion occurs.

### **floor**

Minimum value, exclusive.

### **Default:**

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string

- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

### Compare Two Numbers

Create a `TestCase` object for interactive testing.

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
```

Verify 3 is greater than 2.

```
verifyGreaterThan(testCase, 3, 2);
```

```
Interactive verification passed.
```

Test if 5 is greater than 9.

```
verifyGreaterThan(testCase, 5, 9);
```

```
Interactive verification failed.
```

```

Framework Diagnostic:

verifyGreaterThan failed.
--> The value must be greater than the minimum value.
```

```
Actual Value:
```

```
 5
```

```
Minimum Value (Exclusive):
```

```
 9
```

```
Test failed.
```

### Compare an Array to a Scalar

Test if each element is greater than the FLOOR value, 2.

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
verifyGreaterThan(testCase, [5 6 7], 2);
```

Interactive verification passed.

Test if value 5 is greater than each element in the FLOOR array, [1 2 3].

```
verifyGreaterThan(testCase, 5, [1 2 3]);
```

Interactive verification passed.

Test if each element in the matrix is greater than the FLOOR value, 4.

```
verifyGreaterThan(testCase, [1 2 3; 4 5 6], 4);
```

Interactive verification failed.

```

Framework Diagnostic:

```

verifyGreaterThan failed.

--> Each element must be greater than the minimum value.

Failing Indices:

```
 1 2 3 5
```

Actual Value:

```
 1 2 3
 4 5 6
```

Minimum Value (Exclusive):

```
 4
```

Test failed.

## Compare Arrays

Test if each element is greater than each corresponding element of the FLOOR array, [4 -9 0].

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
verifyGreaterThan(testCase, [5 -3 2], [4 -9 0]);
```

Interactive verification passed.

Compare an array to itself.

```
verifyGreaterThan(testCase, eye(2), eye(2));
```

```
Interactive verification failed.
```

```

Framework Diagnostic:

```

```
verifyGreaterThan failed.
```

```
--> Each element must be greater than each corresponding element of the minimum value a
```

```
Failing Indices:
```

```
 1 2 3 4
```

```
Actual Value:
```

```
 1 0
 0 1
```

```
Minimum Value (Exclusive):
```

```
 1 0
 0 1
```

```
Test failed.
```

**Package:** matlab.unittest.qualifications

Verify value is greater than or equal to specified value

## Syntax

```
verifyGreaterThanOrEqualTo(verifiable,actual,floor)
verifyGreaterThanOrEqualTo(____,diagnostic)
```

## Description

`verifyGreaterThanOrEqualTo(verifiable,actual,floor)` that all elements of `actual` are greater than or equal to all the elements of `floor`.

`verifyGreaterThanOrEqualTo( ____,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsGreaterThanOrEqualTo;
verifiable.verifyThat(actual, IsGreaterThanOrEqualTo(floor));
```

There exists more functionality when using the `IsGreaterThanOrEqualTo` constraint directly via `verifyThat`.

- Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. Alternatively,

- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. ## Input Arguments

### **verifiable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the verification in conjunction with the test running framework.

### **actual**

The value to test. `actual` must be the same size as `floor` unless either one is scalar, at which point scalar expansion occurs.

### **floor**

Minimum value.

### **Default:**

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string

- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

### Compare Two Numbers

Create a `TestCase` object for interactive testing.

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
```

Verify 3 is greater than 2.

```
verifyGreaterThanOrEqual(testCase, 3, 2);
```

```
Interactive verification passed.
```

Verify 3 is greater than or equal to 3.

```
verifyGreaterThanOrEqual(testCase, 3, 3);
```

```
Interactive verification passed.
```

Test if 5 is greater than 9.

```
verifyGreaterThanOrEqual(testCase, 5, 9);
```

```
Interactive verification failed.
```

```

Framework Diagnostic:

```

```
verifyGreaterThanOrEqual failed.
```

```
--> The value must be greater than or equal to the minimum value.
```

```
Actual Value:
```

```
5
```

```
Minimum Value (Inclusive):
```

```
9
```

Test failed.

### Compare an Array to a Scalar

Test if each element is greater than or equal to the FLOOR value, 2.

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
verifyGreaterThanOrEqualTo(testCase, [5 2 7], 2);
```

Interactive verification passed.

Test if each element in the matrix is greater than or equal to the FLOOR value, 4.

# verifyInstanceOf

**Class:** matlab.unittest.qualifications.Verifiable

**Package:** matlab.unittest.qualifications

Verify value is object of specified type

## Syntax

```
verifyInstanceOf(verifiable,actual,className)
```

```
verifyInstanceOf(verifiable,actual,metaClass)
```

```
verifyInstanceOf(____,diagnostic)
```

## Description

`verifyInstanceOf(verifiable,actual,className)` verifies that `actual` is a MATLAB value whose class is the class specified by `className`.

`verifyInstanceOf(verifiable,actual,metaClass)` verifies that `actual` is a MATLAB value whose class is the class specified by the `meta.class` instance `metaClass`.

`verifyInstanceOf( ____,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsInstanceOf;
verifiable.verifyThat(actual, IsInstanceOf(className));
verifiable.verifyThat(actual, IsInstanceOf(metaClass));
```

There exists more functionality when using the `IsInstanceOf` constraint directly via `verifyThat`.

- Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to

completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. Alternatively,

- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as **Incomplete**. For more information, see `matlab.unittest.qualifications.Assumable`.
- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.

## Input Arguments

### **verifiable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the verification in conjunction with the test running framework.

### **actual**

The value to test.

### **Default:**

### **className**

Name of class, specified as a string.

### **Default:**

## metaClass

An instance of `meta.class`.

### Default:

## diagnostic

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

# Examples

## Test a Class

These interactive tests verify the class of the number, 5.

Create a `TestCase` object and the value to test.

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
actvalue = 5;
```

Verify `actvalue` is an instance of class `double`.

```
verifyInstanceOf(testCase, actvalue, 'double');
```

```
Interactive verification passed.
```

Verify if `actvalue` is an instance of `char`.

```
verifyInstanceOf(testCase, 5, 'char');
```

```
Interactive verification failed.
```

```

Framework Diagnostic:
```

```

verifyInstanceOf failed.
--> The value must be an instance of the expected type.
```

```
 Actual Class:
 double
 Expected Type:
 char
```

```
Actual Value:
 5
```

Test failed.

## Test a Function Handle

These tests verify function handles, specified as a meta.class instance, ?  
function\_handle.

Create a function handle.

```
fh = @sin;
testCase = matlab.unittest.TestCase.forInteractiveUse;
verifyInstanceOf(testCase, fh, ?function_handle);
```

```
Interactive verification passed.
```

Test the function name.

```
fh = 'sin';
verifyInstanceOf(testCase, fh, ?function_handle);
```

```
Interactive verification failed.
```

```

Framework Diagnostic:

verifyInstanceOf failed.
--> The value must be an instance of the expected type.
```

```
 Actual Class:
 char
 Expected Type:
 function_handle
```

```
Actual Value:
 sin
```

Test failed.

### Test a Derived Class

Verify that a derived class is not the same class as its base class.

Create a class, `BaseExample`.

```
classdef BaseExample
end
```

Create a derived class, `DerivedExample`.

```
classdef DerivedExample < BaseExample
end
```

Verify `DerivedExample` is an instance of `BaseExample`.

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
testCase.verifyInstanceOf(DerivedExample(), ?BaseExample);
```

```
Interactive verification passed.
```

Verify `BaseExample` is not an instance of `DerivedExample`.

```
testCase.verifyInstanceOf(BaseExample(), ?DerivedExample);
```

```
Interactive verification failed.
```

```

Framework Diagnostic:
```

```

verifyInstanceOf failed.
```

```
--> The value must be an instance of the expected type.
```

```
 Actual Class:
 BaseExample
 Expected Type:
 DerivedExample
```

```
Actual Value:
 BaseExample with no properties.
```

Test failed.

`matlab.unittest.diagnostics.Diagnostic` | `matlab.unittest.constraints.IsInstanceOf` | `isa` | `matlab.unittest.constraints` | `matlab.unittest.qualifications` | `verifyClass` | `verifyThat`

### **More About**

- “Types of Qualifications”

**Introduced in R2013a**

# verifyLength

**Class:** matlab.unittest.qualifications.Verifiable

**Package:** matlab.unittest.qualifications

Verify value has specified length

## Syntax

```
verifyLength(verifiable,actual,expectedLength)
verifyLength(____,diagnostic)
```

## Description

`verifyLength(verifiable,actual,expectedLength)` verifies that `actual` is a MATLAB array whose length is `expectedLength`.

`verifyLength( ____,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.HasLength;
verifiable.verifyThat(actual, HasLength(expectedLength));
```

There exists more functionality when using the `HasLength` constraint directly via `verifyThat`.

- Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. Alternatively,

- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. For more information, see `matlab.unittest.qualifications.Assumable`.
- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.

## Input Arguments

### **verifiable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the verification in conjunction with the test running framework.

### **actual**

The value to test.

### **Default:**

### **expectedLength**

The length of an array is defined as the largest dimension of that array.

### **Default:**

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

### Test Array Lengths

Create a `TestCase` object for interactive testing.

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
```

Verify length of array is the expected value, 5.

```
verifyLength(testCase, ones(2, 5, 3), 5, 'User diagnostic');
```

```
Interactive verification passed.
```

Length of array is not the expected value, 3.

```
verifyLength(testCase, [2 3], 3);
```

```
Interactive verification failed.
```

```

Framework Diagnostic:

verifyLength failed.
--> The array has an incorrect length.
```

```
 Actual Length:
 2
 Expected Length:
 3
```

```
Actual Array:
 2 3
```

Test failed.

The length of a 2x3 array is 3.

```
verifyLength(testCase, [1 2 3; 4 5 6], 3);
```

Interactive verification passed.

Verify the length of a 2x3 array is not the number of elements, 6.

```
verifyLength(testCase, [1 2 3; 4 5 6], 6);
```

Interactive verification failed.

```

Framework Diagnostic:

verifyLength failed.
--> The array has an incorrect length.
```

```
Actual Length:
 3
Expected Length:
 6
```

```
Actual Array:
 1 2 3
 4 5 6
```

Test failed.

```
verifyLength(testCase, eye(2), 4);
```

Interactive verification failed.

```

Framework Diagnostic:

verifyLength failed.
--> The array has an incorrect length.
```

```
Actual Length:
 2
Expected Length:
 4
```

```
Actual Array:
```

```
1 0
0 1
```

### Test Cell Array Lengths

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
verifyLength(testCase, {'somesstring', 'someotherstring'}, 2);
```

```
Interactive verification passed.
```

### More About

- “Types of Qualifications”

**Introduced in R2013a**

## verifyLessThan

**Class:** matlab.unittest.qualifications.Verifiable

**Package:** matlab.unittest.qualifications

Verify value is less than specified value

### Syntax

```
verifyLessThan(verifiable,actual,ceiling)
verifyLessThan(____,diagnostic)
```

### Description

`verifyLessThan(verifiable,actual,ceiling)` verifies that all elements of `actual` are less than all the elements of `ceiling`.

`verifyLessThan( ____,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

### Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsLessThan;
verifiable.verifyThat(actual, IsLessThan(ceiling));
```

There exists more functionality when using the `IsLessThan` constraint directly via `verifyThat`.

- Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. Alternatively,

- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as **Incomplete**. For more information, see `matlab.unittest.qualifications.Assumable`.
- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.

## Input Arguments

### **verifiable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the verification in conjunction with the test running framework.

### **actual**

The value to test. **actual** must be the same size as **ceiling** unless either one is scalar, at which point scalar expansion occurs.

### **Default:**

### **ceiling**

Maximum value, exclusive.

### **Default:**

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

### Compare Two Numbers

Create a `TestCase` object for interactive testing.

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
```

Verify 2 is less than 3.

```
verifyLessThan(testCase, 2, 3);
```

```
Interactive verification passed.
```

Test if 9 is less than 5.

```
verifyLessThan(testCase, 9, 5);
```

```
Interactive verification failed.
```

```

Framework Diagnostic:

verifyLessThan failed.
--> The value must be less than the maximum value.
```

```
Actual Value:
```

```
 9
```

```
Maximum Value (Exclusive):
```

```
 5
```

```
Test failed.
```

### Compare an Array to a Scalar

Test if each element is less than the `CEILING` value, 9.

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
verifyLessThan(testCase, [5 6 7], 9);
```

Interactive verification passed.

Test if each element in the matrix is less than the CEILING value, 4.

```
verifyLessThan(testCase, [1 2 3; 4 5 6], 4);
```

Interactive verification failed.

```

Framework Diagnostic:

```

verifyLessThan failed.

--> Each element must be less than the maximum value.

Failing Indices:

```
 2 4 6
```

Actual Value:

```
 1 2 3
 4 5 6
```

Maximum Value (Exclusive):

```
 4
```

Test failed.

### Compare Arrays

Test if each element is less than each corresponding element of the CEILING array, [7 -1 8].

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
verifyLessThan(testCase, [5 -3 2], [7 -1 8]);
```

Interactive verification passed.

Compare an array to itself.

```
verifyLessThan(testCase, eye(2), eye(2));
```

Interactive verification failed.

```

```

Framework Diagnostic:

-----

verifyLessThan failed.

--> Each element must be less than each corresponding element of the maximum value array.

Failing Indices:

1 2 3 4

Actual Value:

1 0

0 1

Maximum Value (Exclusive):

1 0

0 1

Test failed.

## More About

- “Types of Qualifications”

**Introduced in R2013a**

# verifyLessThanOrEqual

**Class:** matlab.unittest.qualifications.Verifiable

**Package:** matlab.unittest.qualifications

Verify value is less than or equal to specified value

## Syntax

```
verifyLessThanOrEqual(verifiable,actual,ceiling)
```

```
verifyLessThanOrEqual(____,diagnostic)
```

## Description

`verifyLessThanOrEqual(verifiable,actual,ceiling)` verifies that all elements of `actual` are less than or equal to all the elements of `ceiling`.

`verifyLessThanOrEqual( ____,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsLessThanOrEqualTo;
verifiable.verifyThat(actual, IsLessThanOrEqualTo(ceiling));
```

There exists more functionality when using the `IsLessThanOrEqualTo` constraint directly via `verifyThat`.

- Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. Alternatively,

- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. For more information, see `matlab.unittest.qualifications.Assumable`.
- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.

## Input Arguments

### **verifiable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the verification in conjunction with the test running framework.

### **actual**

The value to test.

### **Default:**

### **ceiling**

Maximum value.

### **Default:**

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string

- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

### Compare Two Numbers

Create a `TestCase` object for interactive testing.

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
```

Verify 2 is less than 3.

```
verifyLessThanOrEqualTo(testCase, 2, 3);
```

```
Interactive verification passed.
```

Verify 3 is less than or equal to 3.

```
verifyLessThanOrEqualTo(testCase, 3, 3);
```

```
Interactive verification passed.
```

Test if 9 is less than 5.

```
verifyLessThanOrEqualTo(testCase, 9, 5);
```

```
Interactive verification failed.
```

```

Framework Diagnostic:

```

```
verifyLessThanOrEqualTo failed.
```

```
--> The value must be less than or equal to the maximum value.
```

```
Actual Value:
```

```
 9
```

```
Maximum Value (Inclusive):
```

```
 5
```

Test failed.

### Compare an Array to a Scalar

Test if each element is less than or equal to the ceiling value, 7.

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
verifyLessThanOrEqualTo(testCase, [5 2 7], 7);
```

Interactive verification passed.

Test if each element in the matrix is less than or equal to the ceiling value, 4.

```
verifyLessThanOrEqualTo(testCase, [1 2 3; 4 5 6], 4);
```

Interactive verification failed.

```

Framework Diagnostic:

```

verifyLessThanOrEqualTo failed.

--> Each element must be less than or equal to the maximum value.

Failing Indices:

4 6

Actual Value:

1	2	3
4	5	6

Maximum Value (Inclusive):

4

Test failed.

### Compare Arrays

Test if each element is less than or equal to each corresponding element of the ceiling array, [5 -3 8].

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
verifyLessThanOrEqualTo(testCase, [5 -3 2], [5 -3 8]);
```

Interactive verification passed.

Compare an array to itself.

```
verifyLessThanOrEqualTo(testCase, eye(2), eye(2));
```

```
Interactive verification passed.
```

## More About

- “Types of Qualifications”

**Introduced in R2013a**

## verifyMatches

**Class:** matlab.unittest.qualifications.Verifiable

**Package:** matlab.unittest.qualifications

Verify string matches specified regular expression

### Syntax

```
verifyMatches(verifiable,actual,expression)
verifyMatches(____,diagnostic)
```

### Description

`verifyMatches(verifiable,actual,expression)` that `actual` is a string that matches the regular expression defined by `expression`.

`verifyMatches( ____,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

### Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.Matches;
verifiable.verifyThat(actual, Matches(expression));
```

There exists more functionality when using the `Matches` constraint directly via `verifyThat`.

- Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. Alternatively,

- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. For more information, see `matlab.unittest.qualifications.Assumable`.
- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.

## Input Arguments

### **verifiable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the verification in conjunction with the test running framework.

### **actual**

The string to test.

### **Default:**

### **expression**

The value to match, specified as a regular expression.

### **Default:**

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string

- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

### Test for String Matches

Create a `TestCase` object for interactive testing.

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
```

Verify that strings matches a regular expression.

```
verifyMatches(testCase, 'Some String', 'Some [Ss]tring', ...
 'My result should have matched the expression');
```

```
Interactive verification passed.
```

```
verifyMatches(testCase, 'Another string', '(Some |An)other');
```

```
Interactive verification passed.
```

```
verifyMatches(testCase, 'Another 3 strings', '^Another \d+ strings?$');
```

```
Interactive verification passed.
```

```
verifyMatches(testCase, '3 more strings', '\d+ strings?');
```

```
Interactive verification failed.
```

```

Framework Diagnostic:

verifyMatches failed.
--> The string did not match the regular expression.
```

```
Actual String:
 3 more strings
Regular Expression:
 \d+ strings?
```

Test failed.

## More About

- “Types of Qualifications”

**Introduced in R2013a**

## verifyNotEmpty

**Class:** matlab.unittest.qualifications.Verifiable

**Package:** matlab.unittest.qualifications

Verify value is not empty

### Syntax

```
verifyNotEmpty(verifiable,actual)
verifyNotEmpty(____,diagnostic)
```

### Description

`verifyNotEmpty(verifiable,actual)` verifies that `actual` is a non-empty MATLAB value.

`verifyNotEmpty( ____,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

### Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsEmpty;
verifiable.verifyThat(actual, ~IsEmpty());
```

There exists more functionality when using the `IsEmpty` constraint directly via `verifyThat`.

- Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. Alternatively,

- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. For more information, see `matlab.unittest.qualifications.Assumable`.
- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.

## Input Arguments

### **verifiable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the verification in conjunction with the test running framework.

### **actual**

The value to test.

### **Default:**

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

### Test for Non-Empty Strings

Create a TestCase object.

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
verifyNotEmpty(testCase, '');
```

```
Interactive verification failed.
```

```

Framework Diagnostic:

verifyNotEmpty failed.
--> The value must not be empty.
--> The value has a size of [0 0].
```

```
Actual Value:
 ''
```

Test failed.

### Test for Non-Empty Arrays

An array with any zero dimension is empty.

Test array [2 3].

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
verifyNotEmpty(testCase, [2 3]);
```

```
Interactive verification passed.
```

Test array with a zero dimension.

```
verifyNotEmpty(testCase, ones(2, 5, 0, 3));
```

```
Interactive verification failed.
```

```

Framework Diagnostic:

```

```
verifyNotEmpty failed.
--> The value must not be empty.
--> The value has a size of [2 5 0 3].
```

```
Actual Value:
 Empty array: 2-by-5-by-0-by-3
```

Test failed.

### Test for Non-Empty Cell Arrays

A cell array of empty arrays is not empty.

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
verifyNotEmpty(testCase, {[], [], []}, '');
```

```
Interactive verification passed.
```

### Test for Non-Empty Test Suite

Test an empty object, `emptyTestSuite`.

```
emptyTestSuite = matlab.unittest.TestSuite.empty;
testCase = matlab.unittest.TestCase.forInteractiveUse;
verifyNotEmpty(testCase, emptyTestSuite);
```

```
Interactive verification failed.
```

```

Framework Diagnostic:

```

```
verifyNotEmpty failed.
--> The value must not be empty.
--> The value has a size of [0 0].
```

```
Actual Value:
 0x0 TestCase array with no properties.
```

Test failed.

**More About**

- “Types of Qualifications”

**Introduced in R2013a**

# verifyNotEqual

**Class:** matlab.unittest.qualifications.Verifiable

**Package:** matlab.unittest.qualifications

Verify value is not equal to specified value

## Syntax

```
verifyNotEqual(verifiable,actual,notExpected)
verifyNotEqual(____,diagnostic)
```

## Description

`verifyNotEqual(verifiable,actual,notExpected)` verifies that `actual` is not equal to `notExpected`.

`verifyNotEqual( ____,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsEqualTo;
verifiable.verifyThat(actual, ~IsEqualTo(notExpected));
```

There exists more functionality when using the `IsEqualTo` constraint directly via `verifyThat`.

- Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. Alternatively,

- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as **Incomplete**. For more information, see `matlab.unittest.qualifications.Assumable`.
- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.

## Input Arguments

### **verifiable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the verification in conjunction with the test running framework.

### **actual**

The value to test.

### **Default:**

### **notExpected**

Value to compare.

### **Default:**

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string

- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

### Compare Numeric Values

Create a `TestCase` object for interactive testing.

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
```

Compare a value to itself.

```
verifyNotEqual(testCase, 5, 5);
```

```
Interactive verification failed.
```

```

Framework Diagnostic:

```

```
verifyNotEqual failed.
```

```
--> NumericComparator passed.
```

```
Actual Value:
```

```
 5
```

```
Prohibited Value:
```

```
 5
```

Test failed.

Compare different number values.

```
verifyNotEqual(testCase, 4.95, 5, '4.95 should be different from 5');
```

```
Interactive verification passed.
```

Values 4.95 and 5 are not equal.

Compare values of different sizes.

```
verifyNotEqual(testCase, [5 5], 5, '[5 5] is not equal to 5');
```

```
Interactive verification passed.
```

Values are not equal.

## Compare Classes

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
verifyNotEqual(testCase, int8(5), int16(5), 'Classes dont match');
```

```
Interactive verification passed.
```

## Compare Cell Arrays

Test a cell array by comparing each element.

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
verifyNotEqual(testCase, {'cell', struct, 5}, {'cell', struct, 5});
```

```
Interactive verification failed.
```

```

Framework Diagnostic:

```

```
verifyNotEqual failed.
--> CellComparator passed.
```

```
Actual Value:
 'cell' [1x1 struct] [5]
Prohibited Value:
 'cell' [1x1 struct] [5]
```

Test failed.

## More About

- “Types of Qualifications”

**Introduced in R2013a**

# verifyNotSameHandle

**Class:** matlab.unittest.qualifications.Verifiable

**Package:** matlab.unittest.qualifications

Verify value is not handle to specified instance

## Syntax

```
verifyNotSameHandle(verifiable,actual,notExpectedHandle)
verifyNotSameHandle(____,diagnostic)
```

## Description

`verifyNotSameHandle(verifiable,actual,notExpectedHandle)` verifies that `actual` is a different size and/or does not contain the same instances as the `notExpectedHandle` handle array.

`verifyNotSameHandle( ____,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsSameHandleAs;
verifiable.verifyThat(actual, ~IsSameHandleAs(notExpectedHandle));
```

There exists more functionality when using the `IsSameHandleAs` constraint directly via `verifyThat`.

- Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. Alternatively,

- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. For more information, see `matlab.unittest.qualifications.Assumable`.
- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.

## Input Arguments

### **verifiable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the verification in conjunction with the test running framework.

### **actual**

The value to test.

### **Default:**

### **notExpectedHandle**

The handle array to compare.

### **Default:**

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string

- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

### Test Handles from Same Class

Create a `TestCase` object for interactive testing.

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
```

Create a handle class, `ExampleHandle`.

```
classdef ExampleHandle < handle
end
```

Create two handle variables.

```
h1 = ExampleHandle;
h2 = ExampleHandle;
```

Handles point to different objects.

```
verifyNotSameHandle(testCase, h1, h2);
```

```
Interactive verification passed.
```

Show matching handle combinations.

```
verifyNotSameHandle(testCase, [h1 h2 h1], [h1 h2 h1]);
```

```
Interactive verification failed.
```

```

Framework Diagnostic:

```

```
verifyNotSameHandle failed.
```

```
--> The two handles must not refer to the same handle, or should have
different sizes.
```

```
Actual Value:
 1x3 ExampleHandle array with no properties.
Handle Object:
 1x3 ExampleHandle array with no properties.
```

Test failed.

The order of the handle arguments matters.

```
verifyNotSameHandle(testCase, [h1 h2], [h2 h1]);
```

Interactive verification passed.

Test a handle with itself.

```
verifyNotSameHandle(testCase, h1, h1);
```

Interactive verification failed.

```

Framework Diagnostic:

verifyNotSameHandle failed.
--> The two handles must not refer to the same handle, or should have
different sizes.
```

```
Actual Value:
 ExampleHandle with no properties.
Handle Object:
 ExampleHandle with no properties.
```

Test failed.

Variables are not same size.

```
verifyNotSameHandle(testCase, h2, [h2 h2]);
```

Interactive verification passed.

Variables are the same size.

```
verifyNotSameHandle(testCase, [h1 h1], [h1 h1]);
```

Interactive verification failed.

```

```

Framework Diagnostic:

-----

verifyNotSameHandle failed.

--> The two handles must not refer to the same handle, or should have different sizes.

Actual Value:

1x2 ExampleHandle array with no properties.

Handle Object:

1x2 ExampleHandle array with no properties.

Test failed.

## More About

- “Types of Qualifications”

**Introduced in R2013a**

# verifyNumElements

**Class:** matlab.unittest.qualifications.Verifiable

**Package:** matlab.unittest.qualifications

Verify value has specified element count

## Syntax

```
verifyNumElements(verifiable,actual,expectedElementCount)
```

```
verifyNumElements(____,diagnostic)
```

## Description

`verifyNumElements(verifiable,actual,expectedElementCount)` verifies that `actual` is a MATLAB array with `expectedElementCount` number of elements.

`verifyNumElements( ____,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.HasElementCount;
verifiable.verifyThat(actual, HasElementCount(expectedElementCount));
```

There exists more functionality when using the `HasElementCount` constraint directly via `verifyThat`.

- Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. Alternatively,

- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as **Incomplete**. For more information, see `matlab.unittest.qualifications.Assumable`.
- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.

## Input Arguments

### **verifiable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the verification in conjunction with the test running framework.

### **actual**

The value to test.

### **Default:**

### **expectedElementCount**

The expected number of elements in the array.

### **Default:**

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

### Test Matrices

Create a `TestCase` object for interactive testing.

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
```

```
n = 7;
verifyNumElements(testCase, eye(n), n^2);
```

Interactive verification passed.

```
verifyNumElements(testCase, 3, 1);
```

Interactive verification passed.

```
verifyNumElements(testCase, [1 2 3; 4 5 6], 5);
```

Interactive verification failed.

```

Framework Diagnostic:

verifyNumElements failed.
--> The value did not have the correct number of elements.
```

```
 Actual Number of Elements:
```

```
 6
```

```
 Expected Number of Elements:
```

```
 5
```

```
Actual Value:
```

```
 1 2 3
 4 5 6
```

Test failed.

## Test Cell Array

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
verifyNumElements(testCase, {'SomeString', 'SomeOtherString'}, 2);
```

Interactive verification passed.

## Test Structure

```
s.Field1 = 1;
s.Field2 = 2;
testCase = matlab.unittest.TestCase.forInteractiveUse;
verifyNumElements(testCase, s, 2);
```

Interactive verification failed.

```

Framework Diagnostic:

```

```
verifyNumElements failed.
--> The value did not have the correct number of elements.
```

```
Actual Number of Elements:
 1
Expected Number of Elements:
 2
```

```
Actual Value:
 Field1: 1
 Field2: 2
```

Test failed.

## More About

- “Types of Qualifications”

**Introduced in R2013a**

## verifyReturnsTrue

**Class:** matlab.unittest.qualifications.Verifiable

**Package:** matlab.unittest.qualifications

Verify function returns true when evaluated

### Syntax

```
verifyReturnsTrue(verifiable,actual)
verifyReturnsTrue(____,diagnostic)
```

### Description

`verifyReturnsTrue(verifiable,actual)` verifies that `actual` is a function handle that returns a scalar logical whose value is true.

`verifyReturnsTrue( ____,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

### Tips

- It is a shortcut for quick custom comparison functionality that can be defined quickly, and possibly inline. It can be preferable over simply evaluating the function directly and using `verifyTrue` because the function handle will be shown in the diagnostics, thus providing more insight into the failure condition which is lost when using `verifyTrue`.
- This method is functionally equivalent to:

```
import matlab.unittest.constraints.ReturnsTrue;
verifiable.verifyThat(actual, ReturnsTrue());
```

There exists more functionality when using the `ReturnsTrue` constraint directly via `verifyThat`.

- Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the

primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. Alternatively,

- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as **Incomplete**. For more information, see `matlab.unittest.qualifications.Assumable`.
- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.

## Input Arguments

### **verifiable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the verification in conjunction with the test running framework.

### **actual**

The function handle to test.

### **Default:**

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

### Test if Condition is True

Create a `TestCase` object for interactive testing.

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
verifyReturnsTrue(testCase, @true);
```

```
Interactive verification passed.
```

Verify that it is true that two numbers are equal.

```
verifyReturnsTrue(testCase, @() isequal(1,1));
```

```
Interactive verification passed.
```

Verify that it is true that two letters are not the same.

```
verifyReturnsTrue(testCase, @() ~strcmp('a','b'));
```

```
Interactive verification passed.
```

Cause verification to fail by trying to verify that “false” evaluates to “true”.

```
verifyReturnsTrue(testCase, @false);
```

```
Interactive verification failed.
```

```

Framework Diagnostic:

```

```
verifyReturnsTrue failed.
```

```
--> The function handle should have evaluated to "true".
```

```
--> Returned value:
```

```
 0
```

```
Actual Function Handle:
```

```
 @false
```

```
Test failed.
```

Cause verification to fail by having the test specified in the function handle return a vector of logical values not a scalar logical value.

```
verifyReturnsTrue(testCase, @() strcmp('a',{ 'a', 'a'}));
```

Interactive verification failed.

```

Framework Diagnostic:

```

verifyReturnsTrue failed.

```
--> The function handle should have returned a scalar. The return value had a size of
--> Returned value:
 1 1
```

Actual Function Handle:

```
@()strcmp('a',{ 'a', 'a'})
```

Test failed.

Cause verification to fail by having the test specified in the function handle return a double not a logical.

```
verifyReturnsTrue(testCase, @() exist('exist'));
```

Interactive verification failed.

```

Framework Diagnostic:

```

verifyReturnsTrue failed.

```
--> The function handle should have returned a logical value. It was of type "double".
--> Returned value:
 5
```

Actual Function Handle:

```
@()exist('exist')
```

Test failed.

# verifySameHandle

**Class:** matlab.unittest.qualifications.Verifiable

**Package:** matlab.unittest.qualifications

Verify two values are handles to same instance

## Syntax

```
verifySameHandle(verifiable,actual,expectedHandle)
verifySameHandle(____,diagnostic)
```

## Description

`verifySameHandle(verifiable,actual,expectedHandle)` verifies that `actual` is the same size and contains the same instances as the `expectedHandle` handle array.

`verifySameHandle( ____,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsSameHandleAs;
verifiable.verifyThat(actual, IsSameHandleAs(expectedHandle));
```

There exists more functionality when using the `IsSameHandleAs` constraint directly via `verifyThat`.

- Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. Alternatively,

- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as **Incomplete**. For more information, see `matlab.unittest.qualifications.Assumable`.
- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.

## Input Arguments

### **verifiable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the verification in conjunction with the test running framework.

### **actual**

The value to test.

### **Default:**

### **expectedHandle**

The expected handle array.

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle

- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

### Test Handles from Same Class

Create a `TestCase` object for interactive testing.

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
```

Create a handle class, `ExampleHandle`.

```
classdef ExampleHandle < handle
end
```

Create two handle variables.

```
h1 = ExampleHandle;
h2 = ExampleHandle;
```

Show matching handle combinations.

```
verifySameHandle(testCase, h1, h1);
```

```
Interactive verification passed.
```

```
verifySameHandle(testCase, [h1 h1], [h1 h1]);
```

```
Interactive verification passed.
```

```
verifySameHandle(testCase, [h1 h2 h1], [h1 h2 h1]);
```

```
Interactive verification passed.
```

Handles must point to same object.

```
verifySameHandle(testCase, h1, h2);
```

```
Interactive verification failed.
```

```

```

```
Framework Diagnostic:

verifySameHandle failed.
--> Values do not refer to the same handle.
```

```
Actual Value:
 ExampleHandle with no properties.
Expected Handle Object:
 ExampleHandle with no properties.
```

Test failed.

Size of handle objects must match.

```
verifySameHandle(testCase, [h1 h1], h1);
```

Interactive verification failed.

```

Framework Diagnostic:

verifySameHandle failed.
--> Sizes do not match.
 Actual Value Size : [1 2]
 Expected Handle Object Size : [1 1]
```

```
Actual Value:
 1x2 ExampleHandle array with no properties.
Expected Handle Object:
 ExampleHandle with no properties.
```

Test failed.

Order of arguments is important.

```
verifySameHandle(testCase, [h1 h2], [h2 h1]);
```

Interactive verification failed.

```

Framework Diagnostic:

verifySameHandle failed.
--> Some elements in the handle array refer to the wrong handle.
```

```
Actual Value:
 1x2 ExampleHandle array with no properties.
Expected Handle Object:
 1x2 ExampleHandle array with no properties.
```

Test failed.

These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.

## Input Arguments

### **verifiable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the verification in conjunction with the test running framework.

### **actual**

The value to test.

### **Default:**

### **expectedSize**

The expected sizes of each dimension the array.

### **Default:**

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string

- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

### Test Arrays

Create a `TestCase` object for interactive testing.

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
verifySize(testCase, ones(2, 5, 3), [2 5 3]);
```

```
Interactive verification passed.
```

```
verifySize(testCase, [1 2 3; 4 5 6], [2 3]);
```

```
Interactive verification passed.
```

```
verifySize(testCase, [2 3], [3 2]);
```

```
Interactive verification failed.
```

```

Framework Diagnostic:

```

```
verifySize failed.
```

```
--> The value had an incorrect size.
```

```
Actual Size:
```

```
 1 2
```

```
Expected Size:
```

```
 3 2
```

```
Actual Value:
```

```
 2 3
```

```
Test failed.
```

Number of elements is not the same as size.

```
verifySize(testCase, [1 2 3; 4 5 6], [6 1]);
```

```
Interactive verification failed.
```

```

Framework Diagnostic:

```

```
verifySize failed.
```

```
--> The value had an incorrect size.
```

```
Actual Size:
```

```
2 3
```

```
Expected Size:
```

```
6 1
```

```
Actual Value:
```

```
1 2 3
```

```
4 5 6
```

```
Test failed.
```

```
verifySize(testCase, eye(2), [4 1]);
```

```
Interactive verification failed.
```

```

Framework Diagnostic:

```

```
verifySize failed.
```

```
--> The value had an incorrect size.
```

```
Actual Size:
```

```
2 2
```

```
Expected Size:
```

```
4 1
```

```
Actual Value:
```

```
1 0
```

```
0 1
```

```
Test failed.
```

### Test Cell Array

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
```

```
verifySize(testCase, {'SomeString', 'SomeOtherString'}, [1 2]);
```

```
Interactive verification passed.
```

## More About

- “Types of Qualifications”

**Introduced in R2013a**

# verifySubstring

**Class:** matlab.unittest.qualifications.Verifiable

**Package:** matlab.unittest.qualifications

Verify string contains specified string

## Syntax

```
verifySubstring(verifiable,actual,substring)
verifySubstring(____,diagnostic)
```

## Description

`verifySubstring(verifiable,actual,substring)` verifies that `actual` is a string that contains `substring`.

`verifySubstring( ____,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.ContainsSubstring;
verifiable.verifyThat(actual, ContainsSubstring(substring));
```

There exists more functionality when using the `ContainsSubstring` constraint directly via `verifyThat`.

- Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. Alternatively,

- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. For more information, see `matlab.unittest.qualifications.Assumable`.
- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.

## Input Arguments

### **verifiable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the verification in conjunction with the test running framework.

### **actual**

The string to test.

### **Default:**

### **substring**

The value to match, specified as a string.

### **Default:**

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

### Test for Substrings

Create a `TestCase` object for interactive testing.

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
```

Test that a substring is contained in a string.

```
verifySubstring(testCase, 'SomeLongString', 'Long');
```

```
Interactive verification passed.
```

Show that case matters.

```
verifySubstring(testCase, 'SomeLongString', 'lonG');
```

```
Interactive verification failed.
```

```

Framework Diagnostic:

verifySubstring failed.
--> The string must contain the substring.
```

```
Actual String:
 SomeLongString
Expected Substring:
 lonG
```

Test failed.

Cause the verification to fail by testing a substring that isn't contained in the actual string.

```
verifySubstring(testCase, 'SomeLongString', 'OtherString');
```

```
Interactive verification failed.
```

```

Framework Diagnostic:

```

```
verifySubstring failed.
```

```
--> The string must contain the substring.
```

```
Actual String:
```

```
 SomeLongString
```

```
Expected Substring:
```

```
 OtherString
```

Test failed.

Show that the verification will fail if the substring is longer than the actual string.

```
verifySubstring(testCase, 'SomeLongString', 'SomeLongStringThatIsLonger');
```

```
Interactive verification failed.
```

```

Framework Diagnostic:

```

```
verifySubstring failed.
```

```
--> The string must contain the substring.
```

```
Actual String:
```

```
 SomeLongString
```

```
Expected Substring:
```

```
 SomeLongStringThatIsLonger
```

Test failed.

## More About

- “Types of Qualifications”

**Introduced in R2013a**

## verifyThat

**Class:** matlab.unittest.qualifications.Verifiable

**Package:** matlab.unittest.qualifications

Verify value meets given constraint

## Syntax

```
verifyThat(verifiable,actual,constraint)
verifyThat(____,diagnostic)
```

## Description

`verifyThat(verifiable,actual,constraint)` verifies that `actual` is a value that satisfies the `constraint` provided.

If the constraint is not satisfied, a verification failure is produced utilizing only the framework diagnostic generated by the `constraint`.

`verifyThat( ____,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

When using this signature, both the diagnostic information contained within `diagnostic` is used in addition to the diagnostic information provided by the `constraint`.

## Input Arguments

### **verifiable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the verification in conjunction with the test running framework.

### **actual**

The value to test.

**Default:****constraint**

Constraint that the actual value must satisfy to pass the verification, specified as a `matlab.unittest.constraints` instance.

**Default:****diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Tips

- Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. Alternatively,
  - Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as **Incomplete**. For more information, see `matlab.unittest.qualifications.Assumable`.
  - Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
  - Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there

is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.

## Examples

### Test Conditions Using Constraints

```
testCase = matlab.unittest.TestCase.forInteractiveUse;

% Passing scenarios
%%
import matlab.unittest.constraints.IsTrue
verifyThat(testCase, true, IsTrue)

import matlab.unittest.constraints.IsEqualTo
verifyThat(testCase, 5, IsEqualTo(5), '5 should be equal to 5')

import matlab.unittest.constraints.IsGreaterThan
import matlab.unittest.constraints.HasNaN
verifyThat(testCase, [5 NaN], IsGreaterThan(10) | HasNaN, ...
 'The value was not greater than 10 or NaN')

% Failing scenarios
%%
import matlab.unittest.constraints.AnyCellof
import matlab.unittest.constraints.ContainsSubstring
verifyThat(testCase, AnyCellof({'cell', 'of', 'strings'}), ...
 ContainsSubstring('char'), 'Test description')

import matlab.unittest.constraints.HasSize
verifyThat(testCase, zeros(10,4,2), HasSize([10,5,2]), ...
 @() disp('A function handle diagnostic.'))

import matlab.unittest.constraints.IsEmpty
verifyThat(testCase, 5, IsEmpty)
```

## **More About**

- “Types of Qualifications”

**Introduced in R2013a**

## verifyTrue

**Class:** matlab.unittest.qualifications.Verifiable

**Package:** matlab.unittest.qualifications

Verify value is true

### Syntax

```
verifyTrue(verifiable,actual)
verifyTrue(____,diagnostic)
```

### Description

`verifyTrue(verifiable,actual)` verifies that `actual` is a scalar logical with the value of `true`.

`verifyTrue( ____,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

### Tips

- This method passes if and only if the actual value is a scalar logical with a value of `true`. Therefore, entities such as `true` valued arrays and nonzero doubles produce qualification failures when used in this method, despite these entities exhibiting "true-like" behavior such as triggering the execution of code inside of "if" statements.
- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsTrue;
verifiable.verifyThat(actual, IsTrue());
```

There exists more functionality when using the `IsTrue` constraint directly via `verifyThat`.

Use of this method for performance benefits can come at the expense of less diagnostic information, and may not provide the same level of strictness adhered

to by other constraints such as `IsEqualTo`. A similar approach that is generally less performant but can provide slightly better diagnostic information is the use of `verifyReturnsTrue`, which at least shows the display of the function evaluated to generate the failing result.

- Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. Alternatively,
  - Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. For more information, see `matlab.unittest.qualifications.Assumable`.
  - Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
  - Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.

## Input Arguments

### **verifiable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the verification in conjunction with the test running framework.

### **actual**

The value to test.

### **Default:**

## **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## **Examples**

### **Test MATLAB Logical Functions**

Create a `TestCase` object for interactive testing.

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
```

Test true.

```
verifyTrue(testCase, true);
```

```
Interactive verification passed.
```

Test false.

```
verifyTrue(testCase, false);
```

```
Interactive verification failed.
```

```

Framework Diagnostic:

```

```
verifyTrue failed.
```

```
--> The value must evaluate to "true".
```

```
Actual Value:
```

```
 0
```

Test failed.

### **Test the Value 1**

The number 1 is a `double` value, not a logical value.

A double value of 1 is not true.

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
verifyTrue(testCase, 1);
```

Interactive verification failed.

```

Framework Diagnostic:

verifyTrue failed.
--> The value must be logical. It is of type "double".
```

```
Actual Value:
 1
```

Test failed.

### Test Array of Logical Values

To be true, the value must be scalar.

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
verifyTrue(testCase, [true true true]);
```

Interactive verification failed.

```

Framework Diagnostic:

verifyTrue failed.
--> The value must be scalar. It has a size of [1 3].
```

```
Actual Value:
 1 1 1
```

Test failed.

## **More About**

- “Types of Qualifications”

**Introduced in R2013a**

# verifyWarning

**Class:** matlab.unittest.qualifications.Verifiable

**Package:** matlab.unittest.qualifications

Verify function issues specified warning

## Syntax

```
verifyWarning(verifiable,actual,warningID)
verifyWarning(____,diagnostic)
[output1,...,outputN] = verifyWarning(____)
```

## Description

`verifyWarning(verifiable,actual,warningID)` verifies that `actual` issues a warning with the identifier `warningID`.

`verifyWarning( ____,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

`[output1,...,outputN] = verifyWarning( ____ )` also returns the output arguments `output1,...,outputN` that are produced when invoking `actual`.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IssuesWarnings;
verifiable.verifyThat(actual, IssuesWarnings({warningID}));
```

There exists more functionality when using the `IssuesWarnings` constraint directly via `verifyThat`.

- Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the

primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. Alternatively,

- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as **Incomplete**. For more information, see `matlab.unittest.qualifications.Assumable`.
- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.

## Input Arguments

### **verifiable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the verification in conjunction with the test running framework.

### **actual**

The function handle to test.

### **Default:**

### **warningID**

Warning ID, specified as a string.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Output Arguments

### `output1, ..., outputN`

Output arguments, 1 through n (if any), from `actual`, returned as any type. The argument type is specified by the `actual` argument list.

## Examples

### Test warning Function

Create a `TestCase` object for interactive testing.

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
```

Verify `actual` warning ID is the same as input warning ID.

```
verifyWarning(testCase, @() warning('SOME:warning:id', 'Warning!'), ...
 'SOME:warning:id');
```

Interactive verification passed.

```
verifyWarning(testCase, @() warning('SOME:other:id', 'Warning message'), ...
 'SOME:warning:id', 'Did not issue specified warning');
```

Warning: Warning message

```
> In @()warning('SOME:other:id', 'Warning message')
 In FunctionHandleConstraint>FunctionHandleConstraint.invoke at 43
 In WarningQualificationConstraint>WarningQualificationConstraint.invoke at 58
 In IssuesWarnings>IssuesWarnings.invoke at 364
 In IssuesWarnings>IssuesWarnings.issuesExpectedWarnings at 411
 In IssuesWarnings>IssuesWarnings.satisfiedBy at 240
 In QualificationDelegate>QualificationDelegate.qualifyThat at 90
```

```
In QualificationDelegate>QualificationDelegate.qualifyWarning at 196
In Verifiable>Verifiable.verifyWarning at 701
Interactive verification failed.
```

```

Test Diagnostic:

```

```
Did not issue specified warning
```

```

Framework Diagnostic:

```

```
verifyWarning failed.
--> The function handle did not issue the expected warning.
```

```
Actual Warnings:
 SOME:other:id
Expected Warning:
 SOME:warning:id
```

```
Evaluated Function:
 @()warning('SOME:other:id','Warning message')
```

## Test a Function Without Warnings

Test the `true` function, which does not issue warnings.

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
verifyWarning(testCase, @true, 'SOME:warning:id', ...
 '@true did not issue any warning');
```

```
Interactive verification failed.
```

```

Test Diagnostic:

```

```
@true did not issue any warning
```

```

Framework Diagnostic:

```

```
verifyWarning failed.
--> The function handle did not issue any warnings.
```

```
Expected Warning:
```

```
SOME:warning:id
```

```
Evaluated Function:
@true
```

Test failed.

### Test Function With Output Arguments

Create a helper function that generates a warning and returns output.

```
function varargout = helper()
 warning('SOME:warning:id', 'Warning!');
 varargout = {123, 'abc'};
end
```

Call helper.

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
[actualOut1, actualOut2] = verifyWarning(testCase, @helper, ...
 'SOME:warning:id');
```

Interactive verification passed.

Introduced in R2013a

## verifyWarningFree

**Class:** matlab.unittest.qualifications.Verifiable

**Package:** matlab.unittest.qualifications

Verify function issues no warnings

### Syntax

```
verifyWarningFree(verifiable,actual)
verifyWarningFree(____,diagnostic)
output1,...,outputN = verifyWarningFree(____)
```

### Description

`verifyWarningFree(verifiable,actual)` verifies that `actual` is a function handle that issues no warnings.

`verifyWarningFree( ____,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

`output1,...,outputN = verifyWarningFree( ____ )` also returns the output arguments `output1,...,outputN` that are produced when invoking `actual`.

### Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IssuesNoWarnings;
verifiable.verifyThat(actual, IssuesNoWarnings());
```

There exists more functionality when using the `IssuesNoWarnings` constraint directly via `verifyThat`.

- Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the

primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. Alternatively,

- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as **Incomplete**. For more information, see `matlab.unittest.qualifications.Assumable`.
- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.

## Input Arguments

### **verifiable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the verification in conjunction with the test running framework.

### **actual**

The function handle to test.

### **Default:**

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle

- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Output Arguments

**output1, ..., outputN**

Output arguments, 1 through n (if any), from `actual`, returned as any type. The argument type is specified by the `actual` argument list.

## Examples

### Test for Warnings from MATLAB Functions

Create a `TestCase` object for interactive testing.

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
```

Test the `why` function.

```
verifyWarningFree(testCase, @why);
```

```
The bald and not excessively bald and not excessively smart hamster obeyed a terrified
Interactive verification passed.
```

This is a randomly-generated message.

Test the `true` function.

```
verifyWarningFree(testCase, @true);
```

```
Interactive verification passed.
```

Test the `false` function.

```
actualOutputFromFalse = verifyWarningFree(testCase, @false);
```

```
Interactive verification passed.
```

Test a value that is not a function handle.

```
verifyWarningFree(testCase, 5, 'diagnostic');
```

## More About

- “Types of Qualifications”

**Introduced in R2013a**

## quarter

Quarter number

## Syntax

```
q = quarter(t)
```

## Description

`q = quarter(t)` returns the quarter numbers for the datetime values in `t`. The `q` output is a `double` array containing integer values from 1 to 4, and is the same size as `t`.

## Examples

### Find Quarter Number of Dates

```
t = datetime(2013,05,31):calmonths(3):datetime(2014,05,31)
```

```
t =
```

```
 31-May-2013 31-Aug-2013 30-Nov-2013 28-Feb-2014 31-May-2014
```

```
q = quarter(t)
```

```
q =
```

```
 2 3 4 1 2
```

## Input Arguments

**t** — Input date and time  
datetime array

Input date and time, specified as a `datetime` array.

**See Also**

day | month | week | year

**Introduced in R2014b**

# questdlg

Create question dialog box

## Syntax

```
button = questdlg('qstring')
button = questdlg('qstring','title')
button = questdlg('qstring','title',default)
button = questdlg('qstring','title','str1','str2',default)
button = questdlg('qstring','title','str1','str2','str3',default)
button = questdlg('qstring','title', ..., options)
```

## Description

`button = questdlg('qstring')` displays a modal dialog box presenting the question 'qstring'. The dialog has three default buttons, **Yes**, **No**, and **Cancel**. If the user presses one of these three buttons, `button` is set to the name of the button pressed. If the user presses the close button on the dialog without making a choice, `button` is set to the empty string. If the user presses the **Return** key, `button` is set to 'Yes'. 'qstring' is a cell array or a string that automatically wraps to fit within the dialog box.

---

**Note** A modal dialog box prevents the user from interacting with other windows before responding. For more information, see `WindowState` in the MATLAB Figure Properties.

---

`button = questdlg('qstring','title')` displays a question dialog with 'title' displayed in the dialog's title bar.

`button = questdlg('qstring','title',default)` specifies which push button is the default in the event that the **Return** key is pressed. '*default*' must be 'Yes', 'No', or 'Cancel'.

`button = questdlg('qstring','title','str1','str2',default)` creates a question dialog box with two push buttons labeled 'str1' and 'str2'. *default* specifies the default button selection and must be 'str1' or 'str2'.

`button = questdlg('qstring','title','str1','str2','str3',default)` creates a question dialog box with three push buttons labeled 'str1', 'str2', and 'str3'. *default* specifies the default button selection and must be 'str1', 'str2', or 'str3'.

When *default* is specified, but is not set to one of the button names, pressing the **Enter** key displays a warning and the dialog remains open.

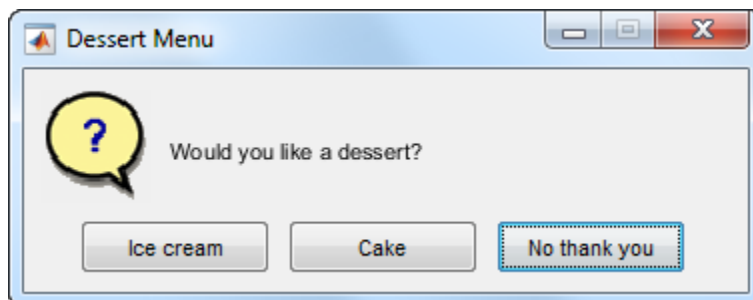

`button = questdlg('qstring','title', ..., options)` replaces the string *default* with a structure, *options*. The structure specifies which button string is the default answer, and whether to use TeX to interpret the question string, *qstring*. Button strings and dialog titles cannot use TeX interpretation. The *options* structure must include the fields `Default` and `Interpreter`, both strings. It can include other fields, but `questdlg` does not use them. You can set `Interpreter` to 'none' or 'tex'. If the `Default` field does not contain a valid button name, a command window warning is issued and the dialog box does not respond to pressing the **Enter** key.

## Examples

### Example 1

Create a dialog that requests a dessert preference and encode the resulting choice as an integer.

```
% Construct a questdlg with three options
choice = questdlg('Would you like a dessert?', ...
 'Dessert Menu', ...
 'Ice cream','Cake','No thank you','No thank you');
% Handle response
switch choice
 case 'Ice cream'
 disp([choice ' coming right up.'])
 dessert = 1;
 case 'Cake'
 disp([choice ' coming right up.'])
 dessert = 2;
 case 'No thank you'
 disp('I'll bring you your check.')
 dessert = 0;
end
```

To access the return value assigned to `dessert`, save the example as a function, for example `choosedessert`, by inserting this line on top:

```
function dessert = choosedessert
```

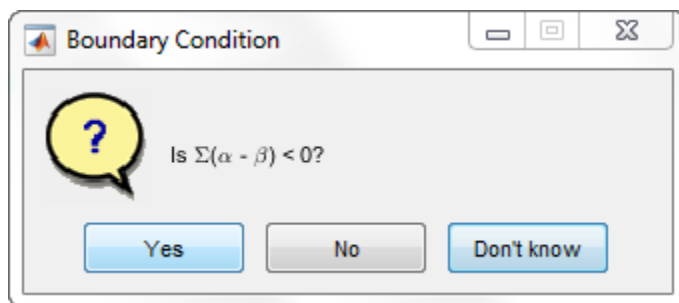

You can generalize the function by providing the cases as string or cell array calling arguments.

As the example shows, `case` statements can contain white space (but are case-sensitive).

## Example 2

Specify an options structure to use the TeX interpreter to format a question.

```
options.Interpreter = 'tex';
% Include the desired Default answer
options.Default = 'Don't know';
% Create a TeX string for the question
qstring = 'Is \Sigma(\alpha - \beta) < 0?';
choice = questdlg(qstring,'Boundary Condition',...
 'Yes','No','Don't know',options)
```

**Introduced before R2006a**

# quit

Terminate MATLAB program

## Alternatives

As an alternative to the quit function, use the Close box in the MATLAB desktop.

## Syntax

```
quit
quit cancel
quit force
```

## Description

`quit` displays a confirmation dialog box if the confirm that upon quitting preference is selected, and if confirmed or if the confirmation preference is not selected, terminates MATLAB after running `finish.m`, if `finish.m` exists. Call `quit` from the MATLAB command prompt. To interrupt a MATLAB command, see “Stop Execution”.

The `quit` function does not automatically save the workspace. To save the workspace or perform other actions when quitting, create a `finish.m` file to perform those actions. For example, you can display a custom dialog box to confirm quitting using a `finish.m` file—see the following examples for details. If an error occurs while `finish.m` is running, `quit` is canceled so that you can correct your `finish.m` file without losing your workspace.

`quit cancel` is for use in `finish.m` and cancels quitting. It has no effect anywhere else.

`quit force` bypasses `finish.m` and terminates MATLAB. Use this syntax to override `finish.m`, for example, if an errant `finish.m` does not let you quit.

## Examples

MATLAB includes two sample `finish.m` files. Use them to help you create your own `finish.m`, or rename one of the files to `finish.m` to use it.

- `finishesav.m`—Saves the workspace to a MAT-file when MATLAB quits.
- `finishdlg.m`—Displays a dialog box allowing you to cancel quitting; it uses `quit` `cancel` and contains the following code:

```
button = questdlg('Ready to quit?', 'Exit Dialog', 'Yes', 'No', 'No');
switch button
 case 'Yes',
 disp('Exiting MATLAB')
 %Save variables to matlab.mat
 save
 case 'No',
 quit cancel;
end
```

## More About

### Tips

When using Handle Graphics objects in `finish.m`, use `uiwait`, `waitfor`, or `drawnow` so that figures are visible. See the reference pages for these functions for more information.

If you want MATLAB to display the following confirmation dialog box after running `quit`, select **Preferences** in the **Environment** section on the **Home** tab. Then select the check box for Confirm before exiting MATLAB, and click **OK**.

- “Stop Execution”

exit | save | finish | startup

**Introduced before R2006a**

## Quit (COM)

Terminate MATLAB Automation server

### Syntax

#### IDL Method Signature

```
void Quit(void)
```

#### Microsoft Visual Basic Client

```
Quit
```

#### MATLAB Client

```
Quit(h)
```

### Description

`Quit(h)` terminates the MATLAB server session attached to handle `h`. The MATLAB object is active until all references have been released, such as when the variable in a function call goes out of scope, or by calling the MATLAB `clear h` command.

The function name is case-sensitive.

To release the MATLAB object, type:

```
clear h
```

**Introduced before R2006a**

# quiver

Quiver or velocity plot

## Syntax

```
quiver(x,y,u,v)
quiver(u,v)
quiver(...,scale)
quiver(...,LineStyle)
quiver(...,LineStyle,'filled')
quiver(...,'PropertyName',PropertyValue,...)
quiver(axes_handle,...)
h = quiver(...)
```

## Description

A quiver plot displays velocity vectors as arrows with components  $(u, v)$  at the points  $(x, y)$ .

For example, the first vector is defined by components  $u(1), v(1)$  and is displayed at the point  $x(1), y(1)$ .

`quiver(x, y, u, v)` plots vectors as arrows at the coordinates specified in each corresponding pair of elements in  $x$  and  $y$ . The matrices  $x$ ,  $y$ ,  $u$ , and  $v$  must all be the same size and contain corresponding position and velocity components. However,  $x$  and  $y$  can also be vectors, as explained in the next section. By default, the arrows are scaled to just not overlap, but you can scale them to be longer or shorter if you want.

`quiver(u, v)` draws vectors specified by  $u$  and  $v$  at equally spaced points in the  $x$ - $y$  plane.

`quiver(..., scale)` automatically scales the arrows to fit within the grid and then stretches them by the factor `scale`. `scale = 2` doubles their relative length, and `scale`

= 0.5 halves the length. Use `scale = 0` to plot the velocity vectors without automatic scaling. You can also tune the length of arrows after they have been drawn by choosing the Plot Edit  tool, selecting the quiver object, opening the Property Editor, and adjusting the **Length** slider.

`quiver(...,LineStyle)` specifies line style, marker symbol, and color using any valid `LineStyle`. `quiver` draws the markers at the origin of the vectors.

`quiver(...,LineStyle,'filled')` fills markers specified by `LineStyle`.

`quiver(...,'PropertyName',PropertyValue,...)` specifies property name and property value pairs for the quiver objects the function creates.

`quiver(axes_handle,...)` plots into the axes with the handle `axes_handle` instead of into the current axes (`gca`).

`h = quiver(...)` returns the handle to the quiver object.

## Expanding x- and y-Coordinates

MATLAB expands `x` and `y` if they are not matrices. This expansion is equivalent to calling `meshgrid` to generate matrices from vectors:

```
[x,y] = meshgrid(x,y);
quiver(x,y,u,v)
```

In this case, the following must be true:

`length(x) = n` and `length(y) = m`, where `[m,n] = size(u) = size(v)`.

The vector `x` corresponds to the columns of `u` and `v`, and vector `y` corresponds to the rows of `u` and `v`.

## Examples

### Plot Vector Velocities

Use `quiver` to display an arrow at each data point in `x` and `y` such that the arrow direction and length represent the corresponding values in `u` and `v`.

```
[x,y] = meshgrid(0:0.2:2,0:0.2:2);
u = cos(x).*y;
```

```
v = sin(x).*y;

figure
quiver(x,y,u,v)
```

### Show Gradient with Quiver Plot

Plot the gradient of the function  $z = xe^{-x^2-y^2}$ .

```
[X,Y] = meshgrid(-2:.2:2);
Z = X.*exp(-X.^2 - Y.^2);
[DX,DY] = gradient(Z,.2,.2);
```

```
figure
```

```
contour(X,Y,Z)
hold on

## quiver3

3-D quiver or velocity plot

### Syntax

```
quiver3(x,y,z,u,v,w)
quiver3(z,u,v,w)
quiver3(...,scale)
quiver3(...,LineStyle)
quiver3(...,LineStyle,'filled')
quiver3(...,'PropertyName',PropertyValue,...)
quiver3(axes_handle,...)
h = quiver3(...)
```

### Description

A three-dimensional quiver plot displays vectors with components  $(u, v, w)$  at the points  $(x, y, z)$ , where  $u, v, w, x, y,$  and  $z$  all have real (non-complex) values.

`quiver3(x,y,z,u,v,w)` plots vectors with directions determined by components  $(u, v, w)$  at points determined by  $(x, y, z)$ . The matrices  $x, y, z, u, v,$  and  $w$  must all be the same size and contain the corresponding position and vector components.

`quiver3(z,u,v,w)` plots vectors with directions determined by components  $(u, v, w)$  at equally spaced points along the surface  $z$ . For each vector  $(u(i, j), v(i, j), w(i, j))$ , the column index  $j$  determines the  $x$ -value of the point on the surface, the row index  $i$  determines the  $y$ -value, and  $z(i, j)$  determines the  $z$ -value. That is, `quiver3` locates the vector at the point on the surface  $(j, i, z(i, j))$ . The `quiver3` function automatically scales the vectors to prevent overlapping based on the distance between them.

`quiver3(...,scale)` automatically scales the vectors to prevent them from overlapping, and then multiplies them by `scale`. `scale = 2` doubles their relative length, and `scale = 0.5` halves them. Use `scale = 0` to plot the vectors without the automatic scaling.

`quiver3(...,LineStyle)` specifies line style, marker symbol, and color using any valid `LineStyle`. `quiver3` draws the markers at the origin of the vectors.

`quiver3(...,LineStyle,'filled')` fills markers specified by `LineStyle`.

`quiver3(...,'PropertyName',PropertyValue,...)` specifies property name and property value pairs for the quiver series that the function creates.

`quiver3(axes_handle,...)` plots into the axes with the handle `axes_handle` instead of into the current axes (`gca`).

`h = quiver3(...)` returns the quiver series handle.

## Examples

### Create 3-D Quiver Plot

Define the data.

```
x = -3:0.5:3;
y = -3:0.5:3;
[X,Y] = meshgrid(x, y);
Z = Y.^2 - X.^2;
[U,V,W] = surfnorm(Z);
```

Plot vectors with components  $(U,V,W)$  at points that are equally spaced in the  $x$ -direction and  $y$ -direction with heights determined by  $Z$ .

```
figure
quiver3(Z,U,V,W)
view(-35,45)
```

### Plot Surface Normals

Plot the surface normals of the function  $z = xe^{-x^2-y^2}$ .

```
[X,Y] = meshgrid(-2:0.25:2,-1:0.2:1);
Z = X.* exp(-X.^2 - Y.^2);
[U,V,W] = surfnorm(X,Y,Z);
```

```
figure
quiver3(X,Y,Z,U,V,W,0.5)
```

```
hold on
surf(X,Y,Z)
view(-35,45)
```

```
axis([-2 2 -1 1 -.6 .6])
hold off
```

# Quiver Series Properties

Control quiver series appearance and behavior

Quiver series properties control the appearance and behavior of a quiver series object. By changing property values, you can modify certain aspects of the quiver series.

Starting in R2014b, you can use dot notation to query and set properties.

```
q = quiver(1:10,1:10);
c = q.Color;
q.Color = 'red';
```

If you are using an earlier release, use the `get` and `set` functions instead.

## Arrows

### Color — Arrow color

[0 0 1] (default) | RGB triplet | color string | 'none'

Arrow color, specified as a three-element RGB triplet, a color string, or 'none'. If you set the color to 'none', then the arrow is invisible.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0, 1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[1 1 0]
'magenta'	'm'	[1 0 1]
'cyan'	'c'	[0 1 1]
'red'	'r'	[1 0 0]
'green'	'g'	[0 1 0]
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]

Long Name	Short Name	RGB Triplet
'black'	'k'	[0 0 0]

Example: 'blue'

Example: [0 0 1]

**LineStyle — Style of arrow stem**

'-' (default) | '--' | ':' | '-.' | 'none'

Style of arrow stem, specified as one of the strings listed in this table.

String	Line Style	Result
'-'	Solid line	
'--'	Dashed line	
':'	Dotted line	
'-.'	Dash-dotted line	
'none'	No stem	No stem

**LineWidth — Width of arrow stem**

0.5 (default) | scalar numeric value

Width of arrow stem, specified as a scalar numeric value greater than zero in point units. One point equals 1/72 inch. The default value is 0.5 point.

Example: 0.75

**ShowArrowHead — Arrowhead display**

'on' (default) | 'off'

Arrowhead display, specified as one of these values:

- 'on' — Display the vectors with arrowheads.
- 'off' — Display the vectors without arrowheads.

**MaxHeadSize — Maximum size of arrowhead**

0.2 (default) | scalar

Maximum size of arrowhead, specified as a scalar value in units relative to the length of the arrow.

Example: 0.1

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**AutoScale — Automatic scaling of arrow length**

'on' (default) | 'off'

Automatic scaling of arrow length, specified as one of these values:

- 'on' — Scale the arrow length to fit within the grid-defined coordinate data and scale arrows so that they do not overlap. The `quiver` function then applies the `AutoScaleFactor` to the arrow length.
- 'off' — Do not scale the arrow lengths.

**AutoScaleFactor — Scale factor**

0.9 (default) | scalar

Scale factor, specified as a scalar. A value of 2 doubles the length of the arrows. A value of 0.5 halves the arrow lengths.

This property has an effect only if the `AutoScale` property is set to 'on'.

Example: 2

**AlignVertexCenters — Sharp vertical and horizontal lines**

'off' (default) | 'on'

Sharp vertical and horizontal lines, specified as 'off' or 'on'.

If the associated figure has a `GraphicsSmoothing` property set to 'on' and a `Renderer` property set to 'opengl', then the figure applies a smoothing technique to plots. In some cases, this smoothing technique can cause vertical and horizontal lines to appear uneven in thickness or color. Use the `AlignVertexCenters` property to eliminate the uneven appearance.

- 'off' — Do not sharpen vertical or horizontal lines. The lines might appear uneven in thickness or color.

- 'on' — Sharpen vertical and horizontal lines to eliminate an uneven appearance.

---

**Note:** You must have a graphics card that supports this feature. To see if the feature is supported, type `opengl info`. If it is supported, then the returned fields contain the line `SupportsAlignVertexCenters: 1`.

---

## Markers

### Marker — Marker symbol

'none' (default) | marker string

Marker symbol, specified as one of the marker strings listed in this table. By default, the quiver series object does not display markers. Specifying a marker symbol adds markers at each data point or vertex.

String	Marker Symbol
'o'	Circle
'+'	Plus sign
'*'	Asterisk
'.'	Point
'x'	Cross
'square' or 's'	Square
'diamond' or 'd'	Diamond
'^'	Upward-pointing triangle
'v'	Downward-pointing triangle
'>'	Right-pointing triangle
'<'	Left-pointing triangle
'pentagram' or 'p'	Five-pointed star (pentagram)
'hexagram' or 'h'	Six-pointed star (hexagram)
'none'	No markers

Example: '+'

Example: 'diamond'

### MarkerSize — Marker size

6 (default) | positive value

Marker size, specified as a positive value in point units.

Example: 10

### MarkerEdgeColor — Marker outline color

'auto' (default) | 'none' | RGB triplet | color string

Marker outline color, specified as one of these values:

- 'auto' — Use the same color as the `Color` property.
- 'none' — Use no color, which makes unfilled markers invisible.
- RGB triplet or color string — Use the specified color.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range  $[0, 1]$ , for example,  $[0.4 \ 0.6 \ 0.7]$ . This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[1 1 0]
'magenta'	'm'	[1 0 1]
'cyan'	'c'	[0 1 1]
'red'	'r'	[1 0 0]
'green'	'g'	[0 1 0]
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]
'black'	'k'	[0 0 0]

Example:  $[0.5 \ 0.5 \ 0.5]$

Example: 'blue'

**MarkerFaceColor** — Marker fill color

'none' (default) | 'auto' | RGB triplet | color string

Marker fill color, specified as one of these values:

- 'none' — Use no color, which makes the interior invisible.
- 'auto' — Use the same color as the Color property for the axes.
- RGB triplet or color string — Use the specified color.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range  $[0, 1]$ , for example,  $[0.4 \ 0.6 \ 0.7]$ . This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[1 1 0]
'magenta'	'm'	[1 0 1]
'cyan'	'c'	[0 1 1]
'red'	'r'	[1 0 0]
'green'	'g'	[0 1 0]
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]
'black'	'k'	[0 0 0]

Example:  $[0.3 \ 0.2 \ 0.1]$ 

Example: 'green'

**Data****UData** — Vector lengths in x-direction

vector | matrix

Vector lengths in  $x$ -direction, specified as a vector or a matrix. The **UData**, **VData**, and **WData** properties together specify the components of the vectors displayed as arrows in the quiver chart.

Example: 1:10

### **VData — Vector lengths in y-direction**

vector | matrix

Vector lengths in  $y$ -direction, specified as a vector or a matrix. The `UData`, `VData`, and `WData` properties together specify the components of the vectors displayed as arrows in the quiver chart.

Example: 1:10

### **WData — Vector lengths in z-direction**

vector | matrix

Vector lengths in  $z$ -direction, specified as a vector or a matrix. The `UData`, `VData`, and `WData` properties together specify the components of the vectors displayed as arrows in the quiver chart. For 2-D quiver charts, `WData` is an empty array.

Example: 1:10

### **XData — x-coordinates**

vector | matrix

$x$ -coordinates, specified as a vector or matrix. The input argument `X` to the `quiver` function determines the  $x$ -coordinates. If you do not specify `X`, then `quiver` uses the indices of `UData` as the  $x$ -coordinates. `XData` must be equal in size to `YData`.

Setting this property sets the associated mode property to manual mode.

Example: 1:10

### **YData — y-coordinates**

vector | matrix

$y$ -coordinates, specified as a vector or matrix. The input argument `Y` to the `quiver` function determines the  $y$ -coordinates. If you do not specify `Y`, then `quiver` uses the indices of `VData` as the  $y$ -coordinates. `YData` must be equal in size to `XData`.

Setting this property sets the associated mode property to manual mode.

Example: 1:10

### **ZData — z-coordinates**

vector | matrix

$z$ -coordinates, specified as a vector or matrix. The input argument `Z` to the `quiver3` function determines the  $z$ -coordinates. For 2-D quiver charts, `ZData` is an empty array. For 3-D quiver charts, `ZData` must be equal in size to `XData` and `YData`.

Example: `1:10`

### **UDataSource — Variable linked to UData**

' ' (default) | string containing MATLAB workspace variable name

Variable linked to `UData`, specified as a string containing a MATLAB workspace variable name. MATLAB evaluates the variable in the base workspace to generate the `UData`.

By default, there is no linked variable so the value is an empty string, ' '. If you link a variable, MATLAB does not update the `UData` values immediately. To force an update of the data values, use the `refreshdata` function.

---

**Note:** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

### **VDataSource — Variable linked to VData**

' ' (default) | string containing MATLAB workspace variable name

Variable linked to `VData`, specified as a string containing a MATLAB workspace variable name. MATLAB evaluates the variable in the base workspace to generate the `VData`.

By default, there is no linked variable so the value is an empty string, ' '. If you link a variable, MATLAB does not update the `VData` values immediately. To force an update of the data values, use the `refreshdata` function.

---

**Note:** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

### **WDataSource — Variable linked to WData**

' ' (default) | string containing MATLAB workspace variable name

Variable linked to `WData`, specified as a string containing a MATLAB workspace variable name. MATLAB evaluates the variable in the base workspace to generate the `WData`.

By default, there is no linked variable so the value is an empty string, `''`. If you link a variable, MATLAB does not update the `WData` values immediately. To force an update of the data values, use the `refreshdata` function.

---

**Note:** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

### **XDataSource** — Variable linked to XData

`''` (default) | string containing MATLAB workspace variable name

Variable linked to `XData`, specified as a string containing a MATLAB workspace variable name. MATLAB evaluates the variable in the base workspace to generate the `XData`.

By default, there is no linked variable so the value is an empty string, `''`. If you link a variable, then MATLAB does not update the `XData` values immediately. To force an update of the data values, use the `refreshdata` function.

---

**Note:** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

Example: `'x'`

### **YDataSource** — Variable linked to YData

`''` (default) | string containing MATLAB workspace variable name

Variable linked to `YData`, specified as a string containing a MATLAB workspace variable name. MATLAB evaluates the variable in the base workspace to generate the `YData`.

By default, there is no linked variable so the value is an empty string, `''`. If you link a variable, then MATLAB does not update the `YData` values immediately. To force an update of the data values, use the `refreshdata` function.

---

**Note:** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

Example: 'y'

## **ZDataSource** — Variable linked to ZData

' ' (default) | string containing MATLAB workspace variable name

Variable linked to ZData, specified as a string containing a MATLAB workspace variable name. MATLAB evaluates the variable in the base workspace to generate the ZData.

By default, there is no linked variable so the value is an empty string, ' '. If you link a variable, then MATLAB does not update the ZData values immediately. To force an update of the data values, use the `refreshdata` function.

---

**Note:** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

Example: 'z'

## **XDataMode** — Selection mode for XData

'auto' | 'manual'

Selection mode for XData, specified as one of these values:

- 'auto' — Automatically select the values.
- 'manual' — Use manually specified values. To specify the values, set the XData property or use the input argument X to the function.

## **YDataMode** — Selection mode for YData

'auto' | 'manual'

Selection mode for YData, specified as one of these values:

- 'auto' — Automatically select the values.
- 'manual' — Use manually specified values. To specify the values, set the YData property or use the input argument Y to the function.

## **Visibility**

### **Visible** — State of visibility

'on' (default) | 'off'

State of visibility, specified as one of these values:

- 'on' — Display the quiver series.
- 'off' — Hide the quiver series without deleting it. You still can access the properties of an invisible quiver series object.

### **Clipping — Clipping of quiver series object to axes limits**

'on' (default) | 'off'

Clipping of the quiver series object to the axes limits, specified as one of these values:

- 'on' — Do not display parts of the quiver series object that are outside the axes limits.
- 'off' — Display the entire quiver series object, even if parts of it appear outside the axes limits. Parts of the quiver series object might appear outside the axes limits if you create a plot, set `hold on`, freeze the axis scaling, and then create the quiver series object so that it is larger than the original plot.

The `Clipping` property of the axes that contains the quiver series object must be set to 'on', otherwise this property has no effect. For more information about the clipping behavior, see the `Clipping` property of the axes.

### **EraseMode — (removed) Technique to draw and erase objects**

'normal' (default) | 'none' | 'xor' | 'background'

---

**Note:** `EraseMode` has been removed. You can delete code that accesses the `EraseMode` property with minimal impact. If you were using `EraseMode` to create line animations, use the `animatedline` function instead.

---

Technique to draw and erase objects, specified as one of these values:

- 'normal' — Redraw the affected region of the display, performing the three-dimensional analysis necessary to correctly render all objects. This mode produces the most accurate picture, but is the slowest. The other modes are faster, but do not perform a complete redraw and, therefore, are less accurate.
- 'none' — Do not erase the object when it is moved or destroyed. After you erase the object with `EraseMode`, 'none', it is still visible on the screen. However, you cannot print the object because MATLAB does not store any information on its former location.

- `'xor'` — Draw and erase the object by performing an exclusive OR (XOR) with the color of the screen beneath it. This mode does not damage the color of the objects beneath it. However, the object color depends on the color of whatever is beneath it on the display.
- `'background'` — Erase the object by redrawing it in the axes background color, or the figure background color if the axes `Color` property is `'none'`. This damages objects that are behind the erased object, but properly colors the erased object.

MATLAB always prints figures as if the `EraseMode` property of all objects is set to `'normal'`. This means graphics objects created with `EraseMode` set to `'none'`, `'xor'`, or `'background'` can look different on screen than on paper. On screen, MATLAB mathematically combines layers of colors and ignores three-dimensional sorting to obtain greater rendering speed. However, MATLAB does not apply these techniques to the printed output. Use the `getframe` command or other screen capture applications to create an image of a figure containing nonnormal mode objects.

## Identifiers

### Type — Type of graphics object

`'quiver'`

This property is read only.

Type of graphics object, returned as `'quiver'`. Use this property to find all objects of a given type within a plotting hierarchy, such as searching for the type using `findobj`.

### Tag — User-specified tag

`''` (default) | string

Tag to associate with the quiver series, specified as a string. Tags provide a way to identify graphics objects. Use this property to find all objects with a specific tag within a plotting hierarchy, for example, searching for the tag using `findobj`.

Example: `'January Data'`

### UserData — Data to associate with quiver series

`[]` (default) | scalar, vector, or matrix | cell array | character array | table | structure

Data to associate with the quiver series object, specified as a scalar, vector, matrix, cell array, character array, table, or structure. MATLAB does not use this data.

To associate multiple sets of data or to attach a field name to the data, use the `getappdata` and `setappdata` functions.

Example: `1:100`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char` | `struct` | `table` | `cell`

### **DisplayName** — Text used by legend

' ' (default) | string

Text used by the legend, specified as a string. The text appears next to an icon of the quiver series.

Example: `'Text Description'`

For multiline text, create the string using `sprintf` with the new line character `\n`.

Example: `sprintf('line one\nline two')`

Alternatively, you can specify the legend text using the `legend` function.

- If you specify the text as an input argument to the `legend` function, then the legend uses the specified text and sets the `DisplayName` property to the same value.
- If you do not specify the text as an input argument to the `legend` function, then the legend uses the text in the `DisplayName` property. If the `DisplayName` property does not contain any text, then the legend generates a string. The string has the form `'dataN'`, where N is the number assigned to the quiver series object based on its location in the list of legend entries.

If you edit interactively the string in an existing legend, then MATLAB updates the `DisplayName` property to the edited string.

### **Annotation** — Legend icon display style

Annotation object

This property is read only.

Legend icon display style, returned as an `Annotation` object. Use this object to include or exclude the quiver series from a legend.

**1** Query the `Annotation` property to get the `Annotation` object.

- 2 Query the `LegendInformation` property of the `Annotation` object to get the `LegendEntry` object.
- 3 Specify the `IconDisplayStyle` property of the `LegendEntry` object to one of these values:
  - `'on'` — Include the quiver series object in the legend as one entry (default).
  - `'off'` — Do not include the quiver series object in the legend.
  - `'children'` — Include only children of the quiver series object as separate entries in the legend.

If a legend already exists and you change the `IconDisplayStyle` setting, then you must call `legend` to update the display.

## Parent/Child

### **Parent — Parent of quiver series**

axes object | group object | transform object

Parent of quiver series, specified as an axes, group, or transform object.

### **Children — Children of quiver series**

empty `GraphicsPlaceholder` array

The quiver series has no children. You cannot set this property.

### **HandleVisibility — Visibility of object handle**

`'on'` (default) | `'off'` | `'callback'`

Visibility of quiver series object handle in the `Children` property of the parent, specified as one of these values:

- `'on'` — The quiver series object handle is always visible.
- `'off'` — The quiver series object handle is invisible at all times. This option is useful for preventing unintended changes to the UI by another function. Set the `HandleVisibility` to `'off'` to temporarily hide the handle during the execution of that function.
- `'callback'` — The quiver series object handle is visible from within callbacks or functions invoked by callbacks, but not from within functions invoked from the command line. This option blocks access to the quiver series at the command-line, but allows callback functions to access it.

If the quiver series object is not listed in the `Children` property of the parent, then functions that obtain object handles by searching the object hierarchy or querying handle properties cannot return it. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

Hidden object handles are still valid. Set the root `ShowHiddenHandles` property to `'on'` to list all object handles regardless of their `HandleVisibility` property setting.

## Interactive Control

### **ButtonDownFcn** — Mouse-click callback

`''` (default) | function handle | cell array | string

Mouse-click callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you click the quiver series. If you specify this property using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The quiver series object — You can access properties of the quiver series object from within the callback function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see “Callback Definition”.

---

**Note:** If the `PickableParts` property is set to `'none'` or if the `HitTest` property is set to `'off'`, then this callback does not execute.

---

Example: `@myCallback`

Example: `{@myCallback, arg3}`

## **UIContextMenu — Context menu**

uicontextmenu object

Context menu, specified as a uicontextmenu object. Use this property to display a context menu when you right-click the quiver series. Create the context menu using the uicontextmenu function.

---

**Note:** If the `PickableParts` property is set to 'none' or if the `HitTest` property is set to 'off', then the context menu does not appear.

---

## **Selected — Selection state**

'off' (default) | 'on'

Selection state, specified as one of these values:

- 'on' — Selected. If you click the quiver series when in plot edit mode, then MATLAB sets its `Selected` property to 'on'. If the `SelectionHighlight` property also is set to 'on', then MATLAB displays selection handles around the quiver series.
- 'off' — Not selected.

## **SelectionHighlight — Display of selection handles when selected**

'on' (default) | 'off'

Display of selection handles when selected, specified as one of these values:

- 'on' — Display selection handles when the `Selected` property is set to 'on'.
- 'off' — Never display selection handles, even when the `Selected` property is set to 'on'.

## **Callback Execution Control**

### **PickableParts — Ability to capture mouse clicks**

'visible' (default) | 'none'

Ability to capture mouse clicks, specified as one of these values:

- 'visible' — Can capture mouse clicks when visible. The `Visible` property must be set to 'on' and you must click a part of the quiver series that has a defined color.

You cannot click a part that has an associated color property set to `'none'`. If the plot contains markers, then the entire marker is clickable if either the edge or the fill has a defined color. The `HitTest` property determines if the quiver series responds to the click or if an ancestor does.

- `'none'` — Cannot capture mouse clicks. Clicking the quiver series passes the click to the object below it in the current view of the figure window. The `HitTest` property of the quiver series has no effect.

### **HitTest — Response to captured mouse clicks**

`'on'` (default) | `'off'`

Response to captured mouse clicks, specified as one of these values:

- `'on'` — Trigger the `ButtonDownFcn` callback of the quiver series. If you have defined the `UIContextMenu` property, then invoke the context menu.
- `'off'` — Trigger the callbacks for the nearest ancestor of the quiver series that has a `HitTest` property set to `'on'` and a `PickableParts` property value that enables the ancestor to capture mouse clicks.

---

**Note:** The `PickableParts` property determines if the quiver series object can capture mouse clicks. If it cannot, then the `HitTest` property has no effect.

---

### **HitTestArea — (removed) Extents of clickable area for quiver series**

`'off'` (default) | `'on'`

---

**Note:** `HitTestArea` has been removed. Use `PickableParts` instead.

---

Extents of clickable area for quiver series, specified as one of these values:

- `'off'` — Click the quiver series plot to select it. This is the default value.
- `'on'` — Click anywhere within the extent of the quiver series plot to select it, that is, anywhere within the rectangle that encloses the quiver series plot.

Example: `'off'`

### **Interruptible — Callback interruption**

`'on'` (default) | `'off'`

Callback interruption, specified as 'on' or 'off'. The `Interruptible` property determines if a running callback can be interrupted.

---

**Note:** There are two callback states to consider:

- The *running* callback is the currently executing callback.
  - The *interrupting* callback is a callback that tries to interrupt the running callback. Whenever MATLAB invokes a callback, that callback attempts to interrupt a running callback. The `Interruptible` property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the `BusyAction` property of the object owning the interrupting callback determines if it is discarded or put in the queue.
- 

If the `ButtonDownFcn` callback of the quiver series is the running callback, then the `Interruptible` property determines if it another callback can interrupt it:

- 'on' — Interruptible. Interruption occurs at the next point where MATLAB processes the queue, such as when there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command.
  - If the running callback contains one of these commands, then MATLAB stops the execution of the callback at this point and executes the interrupting callback. MATLAB resumes executing the running callback when the interrupting callback completes. For more information, see “Interrupt Callback Execution”.
  - If the running callback does not contain one of these commands, then MATLAB finishes executing the callback without interruption.
- 'off' — Not interruptible. MATLAB finishes executing the running callback without any interruptions.

### **BusyAction — Callback queuing**

'queue' (default) | 'cancel'

Callback queuing specified as 'queue' or 'cancel'. The `BusyAction` property determines how MATLAB handles the execution of interrupting callbacks.

---

**Note:** There are two callback states to consider:

- The *running* callback is the currently executing callback.

- The *interrupting* callback is a callback that tries to interrupt the running callback.

Whenever MATLAB invokes a callback, that callback attempts to interrupt a running callback. The **Interruptible** property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the **BusyAction** property of the object owning the interrupting callback determines if it is discarded or put in the queue.

---

If the **ButtonDownFcn** callback of the quiver series tries to interrupt a running callback that cannot be interrupted, then the **BusyAction** property determines if it is discarded or put in the queue. Specify the **BusyAction** property as one of these values:

- 'queue' — Put the interrupting callback in a queue to be processed after the running callback finishes execution. This is the default behavior.
- 'cancel' — Discard the interrupting callback.

## Creation and Deletion Control

### **CreateFcn** — Creation callback

' ' (default) | function handle | cell array | string

Creation callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you create the quiver series. Setting the **CreateFcn** property on an existing quiver series has no effect. You must define a default value for this property, or define this property using a **Name, Value** pair during quiver series creation. MATLAB executes the callback after creating the quiver series and setting all of its properties.

If you specify this callback using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The quiver series object — You can access properties of the quiver series object from within the callback function. You also can access the quiver series object through the **CallbackObject** property of the root, which can be queried using the **gcbo** function.

- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see “Callback Definition”.

Example: @myCallback

Example: {@myCallback, arg3}

### **DeleteFcn — Deletion callback**

' ' (default) | function handle | cell array | string

Deletion callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you delete the quiver series. MATLAB executes the callback before destroying the quiver series so that the callback can access its property values.

If you specify this callback using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The quiver series object — You can access properties of the quiver series object from within the callback function. You also can access the quiver series object through the `CallbackObject` property of the root, which can be queried using the `gcbo` function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see “Callback Definition”.

Example: @myCallback

Example: {@myCallback, arg3}

### **BeingDeleted — Deletion status of quiver series**

'off' (default) | 'on'

This property is read only.

Deletion status of quiver series, returned as 'on' or 'off'. MATLAB sets the `BeingDeleted` property to 'on' when the delete function of the quiver series begins execution (see the `DeleteFcn` property). The `BeingDeleted` property remains set to 'on' until the quiver series no longer exists.

Check the value of the `BeingDeleted` property to verify that the quiver series is not about to be deleted before querying or modifying it.

## qz

QZ factorization for generalized eigenvalues

### Syntax

```
[AA, BB, Q, Z] = qz(A, B)
[AA, BB, Q, Z, V, W] = qz(A, B)
qz(A, B, flag)
```

### Description

The `qz` function gives access to intermediate results in the computation of generalized eigenvalues.

`[AA, BB, Q, Z] = qz(A, B)` for square matrices `A` and `B`, produces upper quasitriangular matrices `AA` and `BB`, and unitary matrices `Q` and `Z` such that  $Q^*A^*Z = AA$ , and  $Q^*B^*Z = BB$ . For complex matrices, `AA` and `BB` are triangular.

`[AA, BB, Q, Z, V, W] = qz(A, B)` also produces matrices `V` and `W` whose columns are generalized eigenvectors.

`qz(A, B, flag)` for real matrices `A` and `B`, produces one of two decompositions depending on the value of `flag`:

'complex'	Produces a possibly complex decomposition with a triangular <code>AA</code> . For compatibility with earlier versions, 'complex' is the default.
'real'	Produces a real decomposition with a quasitriangular <code>AA</code> , containing 1-by-1 and 2-by-2 blocks on its diagonal.

If `AA` is triangular, then the diagonal elements  $a = \text{diag}(AA)$  and  $b = \text{diag}(BB)$  are the generalized eigenvalues that satisfy

$$\begin{aligned}A^*V^*b &= B^*V^*a \\ b^*W^*A &= a^*W^*B\end{aligned}$$

The eigenvalues produced by `lambda = eig(A,B)` are the ratios of the diagonal elements `a` and `b`, such that `lambda = a./b`.

If `AA` is not triangular, it is necessary to further reduce the 2-by-2 blocks to obtain the eigenvalues of the full system.

`eig`

**Introduced before R2006a**

## rad2deg

Convert angle from radians to degrees

### Syntax

```
D = rad2deg(R)
```

### Description

`D = rad2deg(R)` converts angle units from radians to degrees for each element of `R`.

### Examples

#### pi in Degrees

Convert `pi` into degrees.

```
D = rad2deg(pi)
```

```
D =
```

```
 180
```

#### Spherical Distance

Specify the mean radius of Earth and the distance from Munich to Bangalore measured along the Earth's surface (in kilometers). Compute the spherical distance between Munich and Bangalore in degrees.

```
dist = 7194;
radEarth = 6371;
R = dist/radEarth;
D = rad2deg(R)
```

D =

64.6972

## Input Arguments

### **R** — Angle in radians

scalar | vector | matrix | multidimensional array

Angle in radians, specified as a scalar, vector, matrix, or multidimensional array. If R contains complex elements, `rad2deg` converts the real and imaginary parts separately.

Data Types: `single` | `double`

Complex Number Support: Yes

## Output Arguments

### **D** — Angle in degrees

scalar | vector | matrix | multidimensional array

Angles in degrees, returned as a scalar, vector, matrix, or multidimensional array. D is the same size as R.

## See Also

`deg2rad`

**Introduced in R2015b**

# rand

Uniformly distributed random numbers

## Syntax

```
X = rand
X = rand(n)
X = rand(sz1,...,szN)
X = rand(sz)

X = rand(____,typename)
X = rand(____, 'like',p)
```

## Description

`X = rand` returns a single uniformly distributed random number in the interval (0,1).

`X = rand(n)` returns an  $n$ -by- $n$  matrix of random numbers.

`X = rand(sz1,...,szN)` returns an  $sz1$ -by-...-by- $szN$  array of random numbers where  $sz1, \dots, szN$  indicate the size of each dimension. For example, `rand(3,4)` returns a 3-by-4 matrix.

`X = rand(sz)` returns an array of random numbers where size vector `SZ` specifies `size(X)`. For example, `rand([3 4])` returns a 3-by-4 matrix.

`X = rand( ____, typename)` returns an array of random numbers of data type `typename`. The `typename` input can be either `'single'` or `'double'`. You can use any of the input arguments in the previous syntaxes.

`X = rand( ____, 'like', p)` returns an array of random numbers like `p`; that is, of the same object type as `p`. You can specify either `typename` or `'like'`, but not both.

The sequence of numbers produced by `rand` is determined by the internal settings of the uniform pseudorandom number generator that underlies `rand`, `randi`, and `randn`. You can control that shared random number generator using `rng`.

---

**Note:** Use the `rng` function instead of `rand` or `randn` with the `'seed'`, `'state'`, or `'twister'` inputs. For more information, see “Replace Discouraged Syntaxes of `rand` and `randn`”

---

## Examples

### Matrix of Random Numbers

Generate a 5-by-5 matrix of uniformly distributed random numbers between 0 and 1.

```
r = rand(5)
```

```
r =
```

```
 0.5468 0.6791 0.8852 0.3354 0.6538
 0.5211 0.3955 0.9133 0.6797 0.4942
 0.2316 0.3674 0.7962 0.1366 0.7791
 0.4889 0.9880 0.0987 0.7212 0.7150
 0.6241 0.0377 0.2619 0.1068 0.9037
```

### Random Numbers Within Specified Interval

Generate a 10-by-1 column vector of uniformly distributed numbers in the interval (-5,5).

```
r = -5 + (5+5)*rand(10,1)
```

```
r =
```

```
 3.1472
 4.0579
 -3.7301
 4.1338
 1.3236
 -4.0246
 -2.2150
 0.4688
 4.5751
 4.6489
```

In general, you can generate  $N$  random numbers in the interval  $(a,b)$  with the formula  $r = a + (b-a) \cdot \text{rand}(N,1)$ .

### Random Integers

Use the `randi` function (instead of `rand`) to generate 5 random integers from the uniform distribution between 10 and 50.

```
r = randi([10 50],1,5)
r =
 43 47 15 47 35
```

### Random Complex Numbers

Generate a single random complex number with real and imaginary parts in the interval  $(0,1)$ .

```
a = rand + 1i*rand
a =
 0.8147 + 0.9058i
```

### Reset Random Number Generator

Save the current state of the random number generator and create a 1-by-5 vector of random numbers.

```
s = rng;
r = rand(1,5)
r =
 0.0975 0.2785 0.5469 0.9575 0.9649
```

Restore the state of the random number generator to `s`, and then create a new 1-by-5 vector of random numbers. The values are the same as before.

```
rng(s);
r1 = rand(1,5)
r1 =
```

```
0.0975 0.2785 0.5469 0.9575 0.9649
```

Always use the `rng` function (rather than the `rand` or `randn` functions) to specify the settings of the random number generator. For more information, see “Replace Discouraged Syntaxes of `rand` and `randn`”.

### 3-D Array of Random Numbers

Create a 3-by-2-by-3 array of random numbers.

```
X = rand([3,2,3])
```

```
X(:,:,1) =
```

```
0.8909 0.1978
0.3342 0.0305
0.6987 0.7441
```

```
X(:,:,2) =
```

```
0.5000 0.6099
0.4799 0.6177
0.9047 0.8594
```

```
X(:,:,3) =
```

```
0.8055 0.2399
0.5767 0.8865
0.1829 0.0287
```

### Specify Data Type of Random Numbers

Create a 1-by-4 vector of random numbers whose elements are single precision.

```
r = rand(1,4,'single')
```

```
r =
```

```
0.1270 0.9134 0.6324 0.0975
```

```
class(r)
```

```
ans =
```

single

## Clone Size from Existing Array

Create a matrix of random numbers with the same size as an existing array.

```
A = [3 2; -2 1];
sz = size(A);
X = rand(sz)
```

X =

```
 0.4899 0.9787
 0.1679 0.7127
```

It is a common pattern to combine the previous two lines of code into a single line:

```
X = rand(size(A));
```

## Clone Size and Data Type from Existing Array

Create a 2-by-2 matrix of single precision random numbers.

```
p = single([3 2; -2 1]);
```

Create an array of random numbers that is the same size and data type as p.

```
X = rand(size(p), 'like', p)
```

X =

```
 0.5005 0.0596
 0.4711 0.6820
```

```
class(X)
```

ans =

single

## Clone Distributed Array

If you have Parallel Computing Toolbox, create a 1000-by-1000 distributed array of random numbers with underlying data type `single`. For the `distributed` data type, the `'like'` syntax clones the underlying data type in addition to the primary data type.

```
p = rand(1000, 'single', 'distributed');
```

Create an array of random numbers that is the same size, primary data type, and underlying data type as `p`.

```
X = rand(size(p), 'like', p);
```

```
class(X)
```

```
ans =
```

```
distributed
```

```
classUnderlying(X)
```

```
ans =
```

```
single
```

- “Create Arrays of Random Numbers”
- “Random Numbers Within a Specific Range”
- “Random Numbers Within a Sphere”

## Input Arguments

### **n** — Size of square matrix

integer value

Size of square matrix, specified as an integer value.

- If `n` is 0, then `X` is an empty matrix.
- If `n` is negative, then it is treated as 0.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **sz1, ..., szN** — Size of each dimension (as separate arguments)

integer values

Size of each dimension, specified as separate arguments of integer values.

- If the size of any dimension is 0, then `X` is an empty array.
- If the size of any dimension is negative, then it is treated as 0.

- Beyond the second dimension, `rand` ignores trailing dimensions with a size of 1. For example, `rand(3, 1, 1, 1)` produces a 3-by-1 vector of random numbers.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **sz** — Size of each dimension (as a row vector)

integer values

Size of each dimension, specified as a row vector of integer values. Each element of this vector indicates the size of the corresponding dimension:

- If the size of any dimension is 0, then X is an empty array.
- If the size of any dimension is negative, then it is treated as 0.
- Beyond the second dimension, `rand` ignores trailing dimensions with a size of 1. For example, `rand([3, 1, 1, 1])` produces a 3-by-1 vector of random numbers.

Example: `sz = [2, 3, 4]` creates a 2-by-3-by-4 array.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **typename** — Data type (class) to create

'double' (default) | 'single'

Data type (class) to create, specified as the string 'double', 'single', or the name of another class that provides `rand` support.

Example: `rand(5, 'single')`

### **p** — Prototype of array to create

numeric array

Prototype of array to create, specified as a numeric array.

Example: `rand(5, 'like', p)`

Data Types: `single` | `double`

Complex Number Support: Yes

## More About

**See Also**

randi | randn | randperm | RandStream | rng | sprand | sprandn

**Introduced before R2006a**

## rand (RandStream)

Uniformly distributed random numbers

### Class

RandStream

### Syntax

```
r = rand(s,n)
r = rand(s,m,n)
r = rand(s,[m,n])
r = rand(s,m,n,p,...)
r = rand(s,[m,n,p,...])
r = rand(s)
r = rand(s,size(A))
r = rand(..., 'double')
r = rand(..., 'single')
```

### Description

`r = rand(s,n)` returns an  $n$ -by- $n$  matrix containing pseudorandom values drawn from the standard uniform distribution on the open interval (0,1). The values are drawn from the random stream `s`.

`r = rand(s,m,n)` or `r = rand(s,[m,n])` returns an  $m$ -by- $n$  matrix.

`r = rand(s,m,n,p,...)` or `r = rand(s,[m,n,p,...])` returns an  $m$ -by- $n$ -by- $p$ -by-... array.

`r = rand(s)` returns a scalar.

`r = rand(s,size(A))` returns an array the same size as `A`.

`r = rand(..., 'double')` or `r = rand(..., 'single')` returns an array of uniform values of the specified class.

---

**Note:** The size inputs `m`, `n`, `p`, ... should be nonnegative integers. Negative integers are treated as 0.

---

The sequence of numbers produced by `rand` is determined by the internal state of the random number stream `s`. Resetting that stream to the same fixed state allows computations to be repeated. Setting the stream to different states leads to unique computations, however, it does not improve any statistical properties.

### See Also

`rand` | `randi` (RandStream) | `randn` (RandStream) | `@RandStream` | `randperm` (RandStream)

## randi

Uniformly distributed pseudorandom integers

### Syntax

```
X = randi(imax)
X = randi(imax,n)
X = randi(imax,sz1,...,szN)
X = randi(imax,sz)

X = randi(imax,classname)
X = randi(imax,n,classname)
X = randi(imax,sz1,...,szN,classname)
X = randi(imax,sz,classname)

X = randi(imax,'like',p)
X = randi(imax,n,'like',p)
X = randi(imax,sz1,...,szN,'like',p)
X = randi(imax,sz,'like',p)

X = randi([imin,imax], ___)
```

### Description

`X = randi(imax)` returns a pseudorandom scalar integer between 1 and `imax`.

`X = randi(imax,n)` returns an `n`-by-`n` matrix of pseudorandom integers drawn from the discrete uniform distribution on the interval `[1,imax]`.

`X = randi(imax,sz1,...,szN)` returns an `sz1`-by-...-by-`szN` array where `sz1,...,szN` indicates the size of each dimension. For example, `randi(10,3,4)` returns a 3-by-4 array of pseudorandom integers between 1 and 10.

`X = randi(imax,sz)` returns an array where size vector `sz` defines `size(X)`. For example, `randi(10,[3,4])` returns a 3-by-4 array of pseudorandom integers between 1 and 10.

`X = randi(imax,classname)` returns a pseudorandom integer where `classname` specifies the data type. `classname` can be `'single'`, `'double'`, `'int8'`, `'uint8'`, `'int16'`, `'uint16'`, `'int32'`, or `'uint32'`.

`X = randi(imax,n,classname)` returns an `n`-by-`n` array of data type `classname`.

`X = randi(imax,sz1,...,szN,classname)` returns an `sz1`-by-...-by-`szN` array of data type `classname`.

`X = randi(imax,sz,classname)` returns an array where size vector `SZ` defines `size(X)` and `classname` defines `class(X)`.

`X = randi(imax,'like',p)` returns a pseudorandom integer like `p`; that is, with the same data type (class).

`X = randi(imax,n,'like',p)` returns an `n`-by-`n` array like `p`.

`X = randi(imax,sz1,...,szN,'like',p)` returns an `sz1`-by-...-by-`szN` array like `p`.

`X = randi(imax,sz,'like',p)` returns an array like `p` where size vector `SZ` defines `size(X)`.

`X = randi([imin,imax],___)` returns an array containing integers drawn from the discrete uniform distribution on the interval `[imin,imax]`, using any of the above syntaxes.

The sequence of numbers produced by `randi` is determined by the settings of the uniform random number generator that underlies `rand`, `randn`, and `randi`. The `randi` function uses one uniform random value to create each integer random value. You can control that shared random number generator using `rng`.

## Examples

### Square Matrix of Random Integers

Generate a 5-by-5 matrix of random integers between 1 and 10. The first input to `randi` indicates the largest integer in the sampling interval (the smallest integer in the interval is 1).

```
r = randi(10,5)
```

```
r =

 4 3 2 10 5
 6 5 4 10 6
 5 1 2 1 10
 7 10 5 8 5
 7 2 4 3 10
```

## Random Integers Within Specified Interval

Generate a 10-by-1 column vector of uniformly distributed random integers from the sample interval  $[-5, 5]$ .

```
r = randi([-5,5],10,1)
```

```
r =

 3
 4
 -4
 5
 1
 -4
 -2
 1
 5
 5
```

## Control Random Number Generation

Save the current state of the random number generator and create a 1-by-5 vector of random integers.

```
s = rng;
r = randi(10,1,5)
```

```
r =

 1 6 9 7 2
```

Restore the state of the random number generator to `s`, and then create a new 1-by-5 vector of random integers. The values are the same as before.

```
rng(s);
r1 = randi(10,1,5)
```

```
r1 =
 1 6 9 7 2
```

Always use the `rng` function (rather than the `rand` or `randn` functions) to specify the settings of the random number generator. For more information, see “Replace Discouraged Syntaxes of `rand` and `randn`”.

### 3-D Array of Random Integers

Create a 3-by-2-by-3 array of uniformly distributed random integers between 1 and 500.

```
X = randi(500,[3,2,3])
```

```
X(:,:,1) =
 185 79
 231 428
 491 323
```

```
X(:,:,2) =
 189 242
 96 61
 215 295
```

```
X(:,:,3) =
 114 126
 193 146
 292 309
```

### Random Integers of Other Data Types

Create a 1-by-4 vector of random numbers whose elements are of type `int16`.

```
r = randi(100,1,4,'int16')
```

```
r =
 28 55 96 97
```

```
class(r)
```

```
ans =
```

```
int16
```

## Size Defined by Existing Array

Create a matrix of uniformly distributed random integers between 1 and 10 with the same size as an existing array.

```
A = [3 2; -2 1];
sz = size(A);
X = randi(10,sz)
```

```
X =
```

```
 3 10
 9 8
```

It is a common pattern to combine the previous two lines of code into a single line:

```
X = randi(10,size(A));
```

## Size and Numeric Data Type Defined by Existing Array

Create a 2-by-2 matrix of 8-bit signed integers.

```
p = int8([3 2; -2 1]);
```

Create an array of random integers that is the same size and data type as p.

```
X = randi(10,size(p),'like',p)
```

```
X =
```

```
 4 2
 6 10
```

```
class(X)
```

```
ans =
```

```
int8
```

- “Random Integers”
- “Create Arrays of Random Numbers”

- “Generate Random Numbers That Are Repeatable”
- “Generate Random Numbers That Are Different”

## Input Arguments

### **imax** — Largest integer in sample interval

positive integer

Largest integer in sample interval, specified as a positive integer. `randi` draws values from the uniform distribution in the sample interval `[1, imax]`.

Example: `randi(10,5)`

### **imin** — Smallest integer in sample interval

1 (default) | scalar integer

Smallest integer in sample interval, specified as a scalar integer.

Both `imin` and `imax` must be integers that satisfy  $imin \leq imax$ .

For example, `randi([50,100],5)` returns a 5-by-5 matrix of random integers between (and including) 50 and 100.

### **n** — Size of square matrix

integer value

Size of square matrix, specified as an integer value.

- If `n` is 0, then `X` is an empty matrix.
- If `n` is negative, then it is treated as 0.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **sz1, ..., szN** — Size of each dimension (as separate arguments)

two or more integer values

Size of each dimension, specified as separate arguments of integer values.

- If the size of any dimension is 0, then `X` is an empty array.

- If the size of any dimension is negative, then it is treated as 0.
- Beyond the second dimension, `randi` ignores trailing dimensions with a size of 1. For example, `randi([5,10],3,1,1,1)` produces a 3-by-1 vector of random integers between 5 and 10.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **sz** — Size of each dimension (as a row vector)

integer values

Size of each dimension, specified as a row vector of integer values. Each element of this vector indicates the size of the corresponding dimension:

- If the size of any dimension is 0, then X is an empty array.
- If the size of any dimension is negative, then it is treated as 0.
- Beyond the second dimension, `randi` ignores trailing dimensions with a size of 1. For example, `randi([5,10],[3,1,1,1])` produces a 3-by-1 vector of random integers between 5 and 10.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **classname** — Data type (class) to create

'double' (default) | 'single' | 'int8' | 'uint8' | ...

Output class, specified as the string 'double', 'single', 'int8', 'uint8', 'int16', 'uint16', 'int32', 'uint32', or the name of another class that provides `randi` support.

Example: `randi(5,5,'int8')`

Data Types: `char`

### **p** — Prototype of array to create

numeric array

Prototype of array to create, specified as a numeric array.

Example: `randi(5,5,'like',p)`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`  
Complex Number Support: Yes

## More About

### Tips

- The arrays returned by `randi` might contain repeated integer values. This behavior is sometimes referred to as sampling with replacement. Use `randperm` if you require all unique values.
- “Creating and Controlling a Random Number Stream”

**Introduced in R2008b**

## randi (RandStream)

Uniformly distributed pseudorandom integers

### Class

RandStream

### Syntax

```
r = randi(s,imax,n)
r = randi(s,imax,m,n)
r = randi(s,imax,[m,n])
r = randi(s,imax,m,n,p,...)
r = randi(s,imax,[m,n,p,...])
r = randi(s,imax)
r = randi(s,imax,size(A))
r = randi(s,[imin,imax],...)
r = randi(...,classname)
```

### Description

`r = randi(s,imax,n)` returns an  $n$ -by- $n$  matrix containing pseudorandom integer values drawn from the discrete uniform distribution on `1:imax`. `randi` draws those values from the random stream `s`.

`r = randi(s,imax,m,n)` or `r = randi(s,imax,[m,n])` returns an  $m$ -by- $n$  matrix.

`r = randi(s,imax,m,n,p,...)` or `r = randi(s,imax,[m,n,p,...])` returns an  $m$ -by- $n$ -by- $p$ -by-... array.

`r = randi(s,imax)` returns a scalar.

`r = randi(s,imax,size(A))` returns an array the same size as `A`.

`r = randi(s,[imin,imax],...)` returns an array containing integer values drawn from the discrete uniform distribution on `imin:imax`.

`r = randi(...,classname)` returns an array of integer values of class `classname`. `classname` does not support 64-bit integers.

---

**Note:** The size inputs `m`, `n`, `p`, ... should be nonnegative integers. Negative integers are treated as 0.

---

The arrays returned by `randi` might contain repeated integer values. This is sometimes referred to as sampling with replacement. To get unique integer values, sometimes referred to as sampling without replacement, use `randperm (RandStream)`.

The sequence of numbers produced by `randi` is determined by the internal state of the random stream `s`. `randi` uses one uniform value from `s` to generate each integer value. Resetting `s` to the same fixed state allows computations to be repeated. Setting the stream to different states leads to unique computations, however, it does not improve any statistical properties.

### See Also

`randi` | `RandStream` | `rand (RandStream)` | `randperm (RandStream)` | `randn (RandStream)`

## randn

Normally distributed random numbers

### Syntax

```
X = randn
X = randn(n)
X = randn(sz1, ..., szN)
X = randn(sz)

X = randn(____, typename)
X = randn(____, 'like', p)
```

### Description

`X = randn` returns a random scalar drawn from the standard normal distribution.

`X = randn(n)` returns an  $n$ -by- $n$  matrix of normally distributed random numbers.

`X = randn(sz1, ..., szN)` returns an  $sz1$ -by-...-by- $szN$  array of random numbers where  $sz1, \dots, szN$  indicate the size of each dimension. For example, `randn(3,4)` returns a 3-by-4 matrix.

`X = randn(sz)` returns an array of random numbers where size vector `sz` defines `size(X)`. For example, `randn([3 4])` returns a 3-by-4 matrix.

`X = randn( ____, typename)` returns an array of random numbers of data type `typename`. The `typename` input can be either `'single'` or `'double'`. You can use any of the input arguments in the previous syntaxes.

`X = randn( ____, 'like', p)` returns an array of random numbers like `p`; that is, of the same object type as `p`. You can specify either `typename` or `'like'`, but not both.

The sequence of numbers produced by `randn` is determined by the internal settings of the uniform pseudorandom number generator that underlies `rand`, `randi`, and `randn`. You can control that shared random number generator using `rng`.

---

**Note:** Use the `rng` function instead of `rand` or `randn` with the `'seed'`, `'state'`, or `'twister'` inputs. For more information, see “Replace Discouraged Syntaxes of `rand` and `randn`”

---

## Examples

### Matrix of Random Numbers

Generate a 5-by-5 matrix of normally distributed random numbers.

```
r = randn(5)
```

```
r =
```

```
 1.0347 0.8884 1.4384 -0.1022 -0.0301
 0.7269 -1.1471 0.3252 -0.2414 -0.1649
 -0.3034 -1.0689 -0.7549 0.3192 0.6277
 0.2939 -0.8095 1.3703 0.3129 1.0933
 -0.7873 -2.9443 -1.7115 -0.8649 1.1093
```

### Bivariate Normal Random Numbers

Generate values from a bivariate normal distribution with specified mean vector and covariance matrix.

```
mu = [1 2];
```

```
sigma = [1 0.5; 0.5 2];
```

```
R = chol(sigma);
```

```
z = repmat(mu,10,1) + randn(10,2)*R
```

```
z =
```

```
 1.3271 3.3688
 2.0826 3.3279
 2.0061 2.9663
 0.3491 3.3285
 1.2571 3.3585
 0.0556 1.8450
 -0.3218 0.4258
 1.9248 1.6005
 1.0000 3.5770
```

```
0.9451 -0.1597
```

### Random Complex Numbers

Generate a single random complex number with normally distributed real and imaginary parts.

```
a = randn + 1i*randn
```

```
a =
```

```
0.5377 + 1.8339i
```

### Reset Random Number Generator

Save the current state of the random number generator and create a 1-by-5 vector of random numbers.

```
s = rng;
```

```
r = randn(1,5)
```

```
r =
```

```
-0.0245 -1.9488 1.0205 0.8617 0.0012
```

Restore the state of the random number generator to **s**, and then create a new 1-by-5 vector of random numbers. The values are the same as before.

```
rng(s);
```

```
r1 = randn(1,5)
```

```
r1 =
```

```
-0.0245 -1.9488 1.0205 0.8617 0.0012
```

Always use the `rng` function (rather than the `rand` or `randn` functions) to specify the settings of the random number generator. For more information, see “Replace Discouraged Syntaxes of `rand` and `randn`”.

### 3-D Array of Random Numbers

Create a 3-by-2-by-3 array of random numbers.

```
X = randn([3,2,3])
```

```
X(:, :, 1) =
```

```
-0.0708 -2.1924
-2.4863 -2.3193
 0.5812 0.0799
```

```
X(:, :, 2) =
```

```
-0.9485 0.8577
 0.4115 -0.6912
 0.6770 0.4494
```

```
X(:, :, 3) =
```

```
 0.1006 0.8979
 0.8261 -0.1319
 0.5362 -0.1472
```

### Specify Data Type of Random Numbers

Create a 1-by-4 vector of random numbers whose elements are single precision.

```
r = randn(1,4,'single')
```

```
r =
```

```
 0.5377 1.8339 -2.2588 0.8622
```

```
class(r)
```

```
ans =
```

```
single
```

### Clone Size from Existing Array

Create a matrix of normally distributed random numbers with the same size as an existing array.

```
A = [3 2; -2 1];
```

```
sz = size(A);
```

```
X = randn(sz)
```

```
X =
```

```
1.0078 -0.5046
-2.1237 -1.2706
```

It is a common pattern to combine the previous two lines of code into a single line:

```
X = randn(size(A));
```

## Clone Size and Data Type from Existing Array

Create a 2-by-2 matrix of single precision random numbers.

```
p = single([3 2; -2 1]);
```

Create an array of random numbers that is the same size and data type as `p`.

```
X = randn(size(p), 'like', p)
```

```
X =
```

```
-0.3826 0.8257
 0.6487 -1.0149
```

```
class(X)
```

```
ans =
```

```
single
```

## Clone Distributed Array

If you have Parallel Computing Toolbox, create a 1000-by-1000 distributed array of random numbers with underlying data type `single`. For the `distributed` data type, the `'like'` syntax clones the underlying data type in addition to the primary data type.

```
p = randn(1000, 'single', 'distributed');
```

Create an array of random numbers that is the same size, primary data type, and underlying data type as `p`.

```
X = randn(size(p), 'like', p);
```

```
class(X)
```

```
ans =
```

```
distributed
```

```
classUnderlying(X)
```

```
ans =
```

```
single
```

- “Create Arrays of Random Numbers”
- “Random Numbers Within a Specific Range”
- “Random Numbers Within a Sphere”
- “Random Numbers from Normal Distribution with Specific Mean and Variance”

## Input Arguments

### **n** — Size of square matrix

integer value

Size of square matrix, specified as an integer value.

- If  $n$  is 0, then  $X$  is an empty matrix.
- If  $n$  is negative, then it is treated as 0.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **sz1, ..., szN** — Size of each dimension (as separate arguments)

integer values

Size of each dimension, specified as separate arguments of integer values.

- If the size of any dimension is 0, then  $X$  is an empty array.
- If the size of any dimension is negative, then it is treated as 0.
- Beyond the second dimension, `randn` ignores trailing dimensions with a size of 1. For example, `randn(3,1,1,1)` produces a 3-by-1 vector of random numbers.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **sz** — Size of each dimension (as a row vector)

integer values

Size of each dimension, specified as a row vector of integer values. Each element of this vector indicates the size of the corresponding dimension:

- If the size of any dimension is 0, then `X` is an empty array.
- If the size of any dimension is negative, then it is treated as 0.
- Beyond the second dimension, `randn` ignores trailing dimensions with a size of 1. For example, `randn([3,1,1,1])` produces a 3-by-1 vector of random numbers.

Example: `sz = [2,3,4]` creates a 2-by-3-by-4 array.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**typename** — Data type (class) to create

'double' (default) | 'single'

Data type (class) to create, specified as the string 'double', 'single', or the name of another class that provides `randn` support.

Example: `randn(5, 'single')`

**p** — Prototype of array to create

numeric array

Prototype of array to create, specified as a numeric array.

Example: `randn(5, 'like', p)`

Data Types: `single` | `double`

Complex Number Support: Yes

## See Also

`rand` | `randi` | `randperm` | `RandStream` | `rng` | `sprand` | `sprandn`

**Introduced before R2006a**

## **randn (RandStream)**

Normally distributed pseudorandom numbers

### **Class**

RandStream

### **Syntax**

```
r = randn(s,m,n)
r = randn(s,[m,n])
r = randn(s,m,n,p,...)
r = randn(s,[m,n,p,...])
r = randn(s)
r = randn(s,size(A))
r = randn(...,'double')
r = randn(...,'single')
```

### **Description**

`r = randn(s,n)` returns an  $n$ -by- $n$  matrix containing pseudorandom values drawn from the standard normal distribution. `randn` draws those values from the random stream `s`.

`r = randn(s,m,n)` or `r = randn(s,[m,n])` returns an  $m$ -by- $n$  matrix.

`r = randn(s,m,n,p,...)` or `r = randn(s,[m,n,p,...])` returns an  $m$ -by- $n$ -by- $p$ -by-... array.

`r = randn(s)` returns a scalar.

`r = randn(s,size(A))` returns an array the same size as `A`.

`r = randn(...,'double')` or `r = randn(...,'single')` returns an array of uniform values of the specified class.

---

**Note:** The size inputs `m`, `n`, `p`, ... should be nonnegative integers. Negative integers are treated as 0.

---

The sequence of numbers produced by `randn` is determined by the internal state of the random stream `s`. `randn` uses one or more uniform values from `s` to generate each normal value. Resetting that stream to the same fixed state allows computations to be repeated. Setting the stream to different states leads to unique computations, however, it does not improve any statistical properties.

### See Also

`randn` | `RandStream` | `rand` (`RandStream`) | `randi` (`RandStream`)

## randperm

Random permutation

### Syntax

```
p = randperm(n)
p = randperm(n,k)
```

### Description

`p = randperm(n)` returns a row vector containing a random permutation of the integers from 1 to `n` inclusive.

`p = randperm(n,k)` returns a row vector containing `k` unique integers selected randomly from 1 to `n` inclusive.

### Examples

```
randperm(6)
might be the vector
```

```
[3 2 6 4 1 5]
```

or it might be some other permutation of the integers from 1 to 6, depending on the state of the random number generator. Two successive calls to `randperm` would in most cases return two different vectors:

```
randperm(6)
ans =
 5 2 6 4 1 3
```

```
randperm(6)
ans =
 4 1 6 2 3 5
```

```
randperm(6,3)
might be the vector
```

[4 2 5]

or it might be some other permutation of any three integers from 1 to 6 inclusive, depending on the state of the random number generator.

## More About

### Tips

For `p = randperm(n,k)`, `p` contains `k` *unique* values. `randperm` performs `k`-permutations (sampling without replacement). To allow repeated values in the output (sampling with replacement), use `randi(n,1,k)`.

`randperm` uses the same random number generator as `rand`, `randi`, and `randn`. You control this generator with `rng`.

### See Also

`permute` | `randi` | `nchoosek` | `randperm(RandStream)` | `perms` | `rng`

**Introduced before R2006a**

## randperm (RandStream)

Random permutation

### Class

RandStream

### Syntax

```
p = randperm(s,n)
p = randperm(s,n,k)
```

### Description

`p = randperm(s,n)` returns a row vector containing a random permutation of integers from 1 to `n` inclusive. `randperm(s,n)` uses random values drawn from the random stream `s`.

`p = randperm(s,n,k)` returns a row vector containing `k` unique integers selected randomly from 1 to `n` inclusive.

### Examples

Create a random stream `s` and generate a random permutation of the integers from 1 to 6 based on `s`:

```
s = RandStream('mt19937ar','Seed',0);
randperm(s,6)
MATLAB returns the vector
```

```
[6 3 5 1 2 4]
```

Use the random stream `s` to generate three integers between 1 and 10:

```
randperm(s,10,3)
```

```
ans =
 1 8 9
```

## More About

### Tips

For `p = randperm(s,n,k)`, `p` contains `k` *unique* values. `randperm` performs `k`-permutations (sampling without replacement). To allow repeated values in the output (sampling with replacement), use `randi(s,n,1,k)`.

### See Also

# RandStream

Random number stream

## Constructor

RandStream

## Description

Pseudorandom numbers in MATLAB come from one or more random number streams. The simplest way to generate arrays of random numbers is to use `rand`, `randn`, or `randi`. These functions all rely on the same stream of uniform random numbers, known as the *global stream*. You can create other streams that act separately from the global stream, and you can use their `rand`, `randi`, or `randn` methods to generate arrays of random numbers. You can also create a random number stream and make it the global stream.

To create a single random number stream, use the `RandStream` constructor. To create multiple independent random number streams, use `RandStream.create`. The `rng` function provides a simple interface to create a new global stream.

`stream = RandStream.getGlobalStream` returns the global random number stream, that is, the one currently used by the `rand`, `randi`, and `randn` functions.

`prevstream = RandStream.setGlobalStream(stream)` designates the random number stream `stream` as the new global stream to be used by the `rand`, `randi`, and `randn` functions, and returns the previous global stream.

A random number stream `s` has properties that control its behavior. Access or assign to a property using `p = s.Property` or `s.Property = p`. The following table lists defined properties:

## Properties

Property	Description
Type	(Read-only) Generator algorithm used by the stream. The list of possible generators is given by <code>RandStream.list</code> .
Seed	(Read-only) Seed value used to create the stream.
NumStreams	(Read-only) Number of streams in the group in which the current stream was created.
StreamIndex	(Read-only) Index of the current stream from among the group of streams with which it was created.
State	<p>Internal state of the generator. You should not depend on the format of this property. The value you assign to <code>S.State</code> must be a value read from <code>S.State</code> previously. Use <code>reset</code> to return a stream to a predictable state without having previously read from the <code>State</code> property.</p> <p>The sequence of random numbers produced by a random number stream <code>s</code> is determined by the internal state of its random number generator. Saving and restoring the generator's internal state with the <code>State</code> property allows you to reproduce a sequence of random numbers.</p>
Substream	Index of the substream to which the stream is currently set. The default is 1. Multiple substreams are not supported by all generator types; the multiplicative lagged Fibonacci generator ( <code>m1fg6331_64</code> ) and combined multiple recursive generator ( <code>mrg32k3a</code> ) support substreams.
NormalTransform	Transformation algorithm used by <code>randn(s, ...)</code> to generate normal pseudorandom values. Possible values are 'Ziggurat', 'Polar', or 'Inversion'.

Property	Description
Antithetic	Logical value indicating whether <b>S</b> generates antithetic pseudorandom values, that is, the usual values subtracted from 1. The default is false.
FullPrecision	Logical value indicating whether <b>S</b> generates values using its full precision. Some generators can create pseudorandom values faster, but with fewer random bits, if <b>FullPrecision</b> is false. The default is true.

## Methods

Method	Description
<code>RandStream</code>	Create a random number stream.
<code>RandStream.create</code>	Create multiple independent random number streams.
<code>get</code>	Get the properties of a random stream object.
<code>list</code>	List available random number generator algorithms.
<code>set</code>	Set random stream property.
<code>RandStream.getGlobalStream</code>	Get the global random number stream.
<code>RandStream.setGlobalStream</code>	Set global random number stream.
<code>reset</code>	Reset a stream to its initial internal state
<code>rand</code>	Pseudorandom numbers from a uniform distribution
<code>randn</code>	Pseudorandom numbers from a standard normal distribution
<code>randi</code>	Pseudorandom integers from a uniform discrete distribution
<code>randperm</code>	Random permutation of a set of values

## Examples

### Example 1

Create a single stream and designate it as the current global stream:

```
s = RandStream('mt19937ar', 'Seed', 1);
RandStream.setGlobalStream(s);
```

### Example 2

Create three independent streams:

```
[s1,s2,s3] = RandStream.create('mrg32k3a', 'NumStreams', 3);
r1 = rand(s1, 100000, 1);
r2 = rand(s2, 100000, 1);
r3 = rand(s3, 100000, 1);
corrcoef([r1,r2,r3])
```

### Example 3

Create only one stream from a set of three independent streams, and designate it as the current global stream:

```
s2 = RandStream.create('mrg32k3a', 'NumStreams', 3, ...
 'StreamIndices', 2);
RandStream.setGlobalStream(s2);
```

### Example 4

Reset the global random number stream that underlies `rand`, `randi`, and `randn` back to its beginning, to reproduce previous results:

```
stream = RandStream.getGlobalStream;
reset(stream);
```

### Example 5

Save and restore the current global stream's state to reproduce the output of `rand`:

```
stream = RandStream.getGlobalStream;
savedState = stream.State;
u1 = rand(1,5)
u1 =
 0.8147 0.9058 0.1270 0.9134 0.6324

stream.State = savedState;
u2 = rand(1,5)
u2 =
 0.8147 0.9058 0.1270 0.9134 0.6324
u2 contains exactly the same values as u1.
```

## Example 6

Reset the global random number stream to its initial settings. This causes `rand`, `randi`, and `randn` to start over, as if in a new MATLAB session:

```
s = RandStream('mt19937ar','Seed',0);
RandStream.setGlobalStream(s);
```

## Example 7

Reinitialize the global random number stream using a seed based on the current time. This causes `rand`, `randi`, and `randn` to return different values in different MATLAB sessions. It is usually not desirable to do this more than once per MATLAB session as it may affect the statistical properties of the random numbers MATLAB produces:

```
s = RandStream('mt19937ar','Seed','shuffle');
RandStream.setGlobalStream(s);
```

## Example 8

Change the transformation algorithm that `randn` uses to create normal pseudorandom values from uniform values. This does not replace or reset the global stream.

```
stream = RandStream.getGlobalStream;
stream.NormalTransform = 'inversion'
```

## See Also

`rand` | `rng` | `randn` | `randi`

# RandStream constructor

Random number stream

## Class

RandStream

## Syntax

```
s = RandStream('gentype')
s = RandStream('gentype',Name,Value)
```

## Description

`s = RandStream('gentype')` creates a random number stream that uses the uniform pseudorandom number generator algorithm specified by `gentype`. `RandStream.list` returns all possible values for `gentype`, or see “Choosing a Random Number Generator” for details on generator algorithms.

`s = RandStream('gentype',Name,Value)` allows you to specify one or more optional `Name,Value` pairs to control creation of the stream.

Once you have created a random, you can use `RandStream.setGlobalStream` to make it the global stream, so that the functions `rand`, `randi`, and `randn` draw values from it.

Parameters for `RandStream` are:

Parameter	Description
Seed	Nonnegative scalar integer with which to initialize all streams. Seeds must be an integer between 0 and $2^{32} - 1$ or 'shuffle' to create a seed based on the current time. Default is 0.

Parameter	Description
NormalTransform	Transformation algorithm used by <code>randn(s, ...)</code> to generate normal pseudorandom values. Possible values are 'Ziggurat', 'Polar', or 'Inversion'.

## Examples

### Example 1

Create a random number stream, make it the global stream, and save and restore its state to reproduce the output of `randn`:

```
s = RandStream('mrg32k3a');
RandStream.setGlobalStream(s);
savedState = s.State;
z1 = randn(1,5)
z1 =
 -0.1894 -1.4426 -0.3592 0.8883 -0.4337
s.State = savedState;
z2 = randn(1,5)
z2 =
 -0.1894 -1.4426 -0.3592 0.8883 -0.4337
```

`z2` contains exactly the same values as `z1`.

### Example 2

Return `rand`, `randi`, and `randn` to their default startup settings:

```
s = RandStream('mt19937ar','Seed',0)
RandStream.setGlobalStream(s);
```

### Example 3

Replace the current global random number stream with a stream whose seed is based on the current time, so `rand`, `randi`, and `randn` will return different values in different MATLAB sessions. It is usually not desirable to do this more than once per MATLAB

session as it may affect the statistical properties of the random numbers MATLAB produces:

```
s = RandStream('mt19937ar','Seed','shuffle');
RandStream.setGlobalStream(s);
```

## More About

### Tips

- Streams created using `RandStream` might not be independent from each other. Use `RandStream.create` to create multiple streams that are independent.

### See Also

`RandStream` | `RandStream.rand` | `RandStream.randn` | `RandStream.randi`  
| `RandStream.getGlobalStream` | `RandStream.setGlobalStream` |  
`RandStream.list` | `rng` | `RandStream.create`

# RandStream.getGlobalStream

Current global random number stream

## Class

@RandStream

## Syntax

```
stream = RandStream.getGlobalStream
```

## Description

`stream = RandStream.getGlobalStream` returns the current global random number stream.

`rand`, `randi`, and `randn` all rely on the same stream of uniform pseudorandom numbers, known as the *global stream*. `rand` draws one value from that stream to generate each uniform value it returns. `randi` draws one uniform value from that stream to generate each integer value it returns. And `randn` draws one or more uniform values to generate each normal value it returns. Note that there are also `rand`, `randi`, and `randn` methods for which you specify a specific random stream from which to draw values.

---

**Note:** The `rng` function is a shorter alternative for many common uses of `RandStream.getGlobalStream`.

# RandStream.setGlobalStream

Set global random number stream

## Syntax

```
prevstream = RandStream.setGlobalStream(stream)
```

## Description

`prevstream = RandStream.setGlobalStream(stream)` designates the random number stream, specified as `stream`, to be the global stream that the `rand`, `randi`, and `randn` functions draw values from. It returns the previous global random number stream as `prevstream`.

`rand`, `randi`, and `randn` all rely on the same stream of uniform pseudorandom numbers, known as the *global stream*. `rand` draws one value from that stream to generate each uniform value it returns. `randi` draws one uniform value from that stream to generate each integer value it returns. And `randn` draws one or more uniform values to generate each normal value it returns. Note that there are also `rand`, `randi`, and `randn` methods for which you specify a specific random stream from which to draw values.

---

**Note:** The `rng` function is a shorter alternative for many common uses of `RandStream.setGlobalStream`.

## rank

Rank of matrix

### Syntax

```
k = rank(A)
k = rank(A,tol)
```

### Description

The rank function provides an estimate of the number of linearly independent rows or columns of a full matrix.

`k = rank(A)` returns the number of singular values of `A` that are larger than the default tolerance, `max(size(A))*eps(norm(A))`.

`k = rank(A,tol)` returns the number of singular values of `A` that are larger than `tol`.

### More About

#### Tips

Use `sprank` to determine the structural rank of a sparse matrix.

#### Algorithms

There are a number of ways to compute the rank of a matrix. MATLAB software uses the method based on the singular value decomposition, or SVD. The SVD algorithm is the most time consuming, but also the most reliable.

The rank algorithm is

```
s = svd(A);
tol = max(size(A))*eps(max(s));
r = sum(s > tol);
```

## **See Also**

sprank

**Introduced before R2006a**

## rat

Rational fraction approximation

### Syntax

```
R = rat(X)
```

```
R = rat(X,tol)
```

```
[N,D] = rat(___)
```

### Description

`R = rat(X)` returns the rational fraction approximation of `X` to within the default tolerance,  $1e-6 \cdot \text{norm}(X(:), 1)$ . The approximation is a string containing the truncated continued fractional expansion.

`R = rat(X,tol)` approximates `X` to within the tolerance, `tol`.

`[N,D] = rat( ___ )` returns two arrays, `N` and `D`, such that `N./D` approximates `X`, using any of the above syntaxes.

### Examples

#### Approximate Value of $\pi$

Approximate the value of  $\pi$  using a rational representation of the quantity `pi`.

The mathematical quantity  $\pi$  is not a rational number, but the quantity `pi` that approximates it *is* a rational number since all floating-point numbers are rational.

Find the rational representation of `pi`.

```
format rat
```

```
pi
```

```
ans =
```

355/113

The resulting expression is a string. You also can use `rats(pi)` to get the same answer.

Use `rat` to see the continued fractional expansion of `pi`.

```
R = rat(pi)
```

```
R =
```

```
3 + 1/(7 + 1/(16))
```

The resulting string is an approximation by continued fractional expansion. If you consider the first two terms of the expansion, you get the approximation  $3 + \frac{1}{7} = \frac{22}{7}$ , which only agrees with `pi` to 2 decimals.

However, if you consider all three terms printed by `rat`, you can recover the value `355/113`, which agrees with `pi` to 6 decimals.

$$3 + \frac{1}{7 + \frac{1}{16}} = \frac{355}{113}$$

Specify a tolerance for additional accuracy in the approximation.

```
R = rat(pi,1e-7)
```

```
R =
```

```
3 + 1/(7 + 1/(16 + 1/(-294)))
```

The resulting approximation, `104348/33215`, agrees with `pi` to 9 decimals.

### Express Array Elements as Ratios

Create a 4-by-4 matrix.

```
format short;
```

```
X = hilb(4)
```

```
X =
```

```
1.0000 0.5000 0.3333 0.2500
```

```
0.5000 0.3333 0.2500 0.2000
0.3333 0.2500 0.2000 0.1667
0.2500 0.2000 0.1667 0.1429
```

Express the elements of `X` as ratios of small integers using `rat`.

```
[N,D] = rat(X)
```

```
N =
```

```
1 1 1 1
1 1 1 1
1 1 1 1
1 1 1 1
```

```
D =
```

```
1 2 3 4
2 3 4 5
3 4 5 6
4 5 6 7
```

The two matrices, `N` and `D`, approximate `X` with `N./D`.

View the elements of `X` as ratios using `format rat`.

```
format rat
```

```
X
```

```
X =
```

```
1 1/2 1/3 1/4
1/2 1/3 1/4 1/5
1/3 1/4 1/5 1/6
1/4 1/5 1/6 1/7
```

In this form, it is clear that `N` contains the numerators of each fraction and `D` contains the denominators.

## Input Arguments

**X** — Input array

numeric array

Input array, specified as a numeric array of class `single` or `double`.

Data Types: `single` | `double`

Complex Number Support: Yes

### **tol** — Tolerance

scalar

Tolerance, specified as a scalar. N and D approximate X, such that  $N./D - X < \text{tol}$ . The default tolerance is  $1e-6 * \text{norm}(X(:), 1)$ .

## Output Arguments

### **R** — Continued fraction

string

Continued fraction, returned as a string. The accuracy of the rational approximation via continued fractions increases with the number of terms.

### **N** — Numerator

numeric array

Numerator, returned as a numeric array.  $N./D$  approximates X.

### **D** — Denominator

numeric array

Denominator, returned as a numeric array.  $N./D$  approximates X.

## More About

### Algorithms

Even though all floating-point numbers are rational numbers, it is sometimes desirable to approximate them by simple rational numbers, which are fractions whose numerator and denominator are small integers. Rational approximations are generated by truncating continued fraction expansions.

The `rat` function approximates each element of X by a continued fraction of the form

$$\frac{N}{D} = D_1 + \frac{1}{D_2 + \frac{1}{\left( D_3 + \dots + \frac{1}{D_k} \right)}}$$

The  $D$ s are obtained by repeatedly picking off the integer part and then taking the reciprocal of the fractional part. The accuracy of the approximation increases exponentially with the number of terms and is worst when  $X = \text{sqrt}(2)$ . For  $X = \text{sqrt}(2)$ , the error with  $k$  terms is about  $2.68 * (.173)^k$ , so each additional term increases the accuracy by less than one decimal digit. It takes 21 terms to get full floating-point accuracy.

### **See Also**

`format` | `rats`

**Introduced before R2006a**

## rats

Rational output

### Syntax

```
S = rats(X)
S = rats(X, strlen)
```

### Description

`S = rats(X)` returns a string containing the rational approximations to the elements of `X` using the default string length of 13.

`rats` returns asterisks for elements that cannot be printed in the allotted space, but which are not negligible compared to the other elements in `X`.

`S = rats(X, strlen)` returns a string of length `strlen`. The rational approximation uses a tolerance that is inversely proportional to string length.

### Examples

#### Rational Representation of Matrix

Create a 4-by-4 matrix.

```
format short
X = hilb(4)
```

X =

```
 1.0000 0.5000 0.3333 0.2500
 0.5000 0.3333 0.2500 0.2000
 0.3333 0.2500 0.2000 0.1667
 0.2500 0.2000 0.1667 0.1429
```

View the rational representation of the matrix using `rats`. The result is the same as using `format rat`.

```
R = rats(X)
```

```
R =
```

```
 1 1/2 1/3 1/4
 1/2 1/3 1/4 1/5
 1/3 1/4 1/5 1/6
 1/4 1/5 1/6 1/7
```

## Adjust Output String Length

Find the rational representation of `pi` with the default string length and approximation tolerance. The result is the same as using `format rat`.

```
rats(pi)
```

```
ans =
```

```
355/113
```

Adjust the string length of the output, which also adjusts the approximation tolerance.

```
rats(pi,20)
```

```
ans =
```

```
104348/33215
```

The resulting rational approximation has greater accuracy. As the string length increases, the tolerance decreases.

Adjust the string length again to achieve greater accuracy.

```
rats(pi,25)
```

```
ans =
```

```
1146408/364913
```

The resulting approximation agrees with `pi` to 10 decimal places.

## Input Arguments

**X** — Input array

numeric array

Input array, specified as a numeric array of class `single` or `double`.

Data Types: `single` | `double`

Complex Number Support: Yes

### **strlen** — String length

positive integer

String length, specified as a positive integer. The default string length is 13, which allows for 6 elements in 78 spaces.

## Output Arguments

### **S** — Rational output

string

Rational output, returned as a string.

## More About

### Algorithms

`rats` obtains rational approximations with  $[N,D] = \text{rat}(X, \text{tol})$ , where `tol` is  $\min(10^{-(\text{strlen}-1)/2} * \text{norm}(X(\text{isfinite}(X)), 1), .1)$ . Thus, the tolerance is inversely proportional to the string length, `strlen`.

## rbbox

Create rubberband box for area selection

### Syntax

```
rbbox
rbbox(initialRect)
rbbox(initialRect, fixedPoint)
rbbox(initialRect, fixedPoint, stepSize)
finalRect = rbbox(...)
```

### Description

`rbbox` initializes and tracks a rubberband box in the current figure. It sets the initial rectangular size of the box to 0, anchors the box at the figure's `CurrentPoint`, and begins tracking from this point.

`rbbox(initialRect)` specifies the initial location and size of the rubberband box as `[x y width height]`, where `x` and `y` define the lower left corner, and `width` and `height` define the size. `initialRect` is in the units specified by the current figure's `Units` property, and measured from the lower left corner of the figure window. The corner of the box closest to the pointer position follows the pointer until `rbbox` receives a button-up event.

`rbbox(initialRect, fixedPoint)` specifies the corner of the box that remains fixed. All arguments are in the units specified by the current figure's `Units` property, and measured from the lower left corner of the figure window. `fixedPoint` is a two-element vector, `[x y]`. The tracking point is the corner diametrically opposite the anchored corner defined by `fixedPoint`.

`rbbox(initialRect, fixedPoint, stepSize)` specifies how frequently the rubberband box is updated. When the tracking point exceeds `stepSize` figure units, `rbbox` redraws the rubberband box. The default stepsize is 1.

`finalRect = rbbox(...)` returns a four-element vector, `[x y width height]`, where `x` and `y` are the `x` and `y` components of the lower left corner of the box, and `width` and `height` are the dimensions of the box.

## Examples

Create an annotation rectangle by rubber banding the rectangle size in the figure.

```
set(gcf, 'Units', 'normalized')
k = waitforbuttonpress;
rect_pos = rbbox;
annotation('rectangle', rect_pos, 'Color', 'red')
```

Execute the code, click down and drag a rectangle within the figure. Releasing the mouse button draws a rectangle in the figure.

## More About

### Tips

`rbbox` is useful for defining and resizing a rectangular region:

- For box definition, `initialRect` is `[x y 0 0]`, where `(x,y)` is the figure's `CurrentPoint`.
- For box resizing, `initialRect` defines the rectangular region that you resize (e.g., a legend). `fixedPoint` is the corner diametrically opposite the tracking point.

`rbbox` returns immediately if a button is not currently pressed. Therefore, you use `rbbox` with `waitforbuttonpress` so that the mouse button is down when `rbbox` is called. `rbbox` returns when you release the mouse button.

### See Also

`axis` | `dragrect` | `waitforbuttonpress`

Introduced before R2006a

## rcond

Reciprocal condition number

### Syntax

```
C = rcond(A)
```

### Description

`C = rcond(A)` returns an estimate for the reciprocal condition of  $A$  in 1-norm. If  $A$  is well conditioned, `rcond(A)` is near 1.0. If  $A$  is badly conditioned, `rcond(A)` is near 0.

### Examples

#### Sensitivity of Badly Conditioned Matrix

Examine the sensitivity of a badly conditioned matrix.

A notable matrix that is symmetric and positive definite, but badly conditioned, is the Hilbert matrix. The elements of the Hilbert matrix are  $H(i,j) = 1/(i + j - 1)$ .

Create a 10-by-10 Hilbert matrix.

```
A = hilb(10);
```

Find the reciprocal condition number of the matrix.

```
C = rcond(A)
```

```
C =
```

```
2.8286e-14
```

The reciprocal condition number is small, so  $A$  is badly conditioned.

The condition of  $A$  has an effect on the solutions of similar linear systems of equations. To see this, compare the solution of  $Ax = b$  to that of the perturbed system,  $Ax = b + 0.01$ .

Create a column vector of ones and solve  $Ax = b$ .

```
b = ones(10,1);
x = A\b;
```

Now change  $b$  by  $0.01$  and solve the perturbed system.

```
b1 = b + 0.01;
x1 = A\b1;
```

Compare the solutions,  $x$  and  $x1$ .

```
norm(x-x1)
```

```
ans =
```

```
1.1250e+05
```

Since  $A$  is badly conditioned, a small change in  $b$  produces a very large change (on the order of  $1e5$ ) in the solution to  $x = A \setminus b$ . The system is sensitive to perturbations.

### Find Condition of Identity Matrix

Examine why the reciprocal condition number is a more accurate measure of singularity than the determinant.

Create a 5-by-5 multiple of the identity matrix.

```
A = eye(5)*0.01;
```

This matrix is full rank and has five equal singular values, which you can confirm by calculating `svd(A)`.

Calculate the determinant of  $A$ .

```
det(A)
```

```
ans =
```

```
1.0000e-10
```

Although the determinant of the matrix is close to zero,  $A$  is actually very well conditioned and *not* close to being singular.

Calculate the reciprocal condition number of  $A$ .

```
rcond(A)
```

```
ans =
```

```
1
```

The matrix has a reciprocal condition number of 1 and is, therefore, very well conditioned. Use `rcond(A)` or `cond(A)` rather than `det(A)` to confirm singularity of a matrix.

## Input Arguments

### **A** — Input matrix

square numeric matrix

Input matrix, specified as a square numeric matrix.

Data Types: `single` | `double`

## Output Arguments

### **C** — Reciprocal condition number

scalar

Reciprocal condition number, returned as a scalar. The data type of **C** is the same as **A**.

The reciprocal condition number is a scale-invariant measure of how close a given matrix is to the set of singular matrices.

- If **C** is near 0, the matrix is nearly singular and badly conditioned.
- If **C** is near 1.0, the matrix is well conditioned.

## More About

### Tips

- `rcond` is a more efficient but less reliable method of estimating the condition of a matrix compared to the condition number, `cond`.

## **See Also**

cond | condest | norm | normest | rank | svd

**Introduced before R2006a**

## **rdivide, ./**

Right array division

### **Syntax**

```
x = A./B
x = rdivide(A,B)
```

### **Description**

`x = A./B` divides each element of `A` by the corresponding element of `B`. Inputs `A` and `B` must have the same size unless one is a scalar value. A scalar value is expanded into an array of the same size as the other input.

`x = rdivide(A,B)` is an alternative way to divide `A` by `B`, but is rarely used. It enables operator overloading for classes.

### **Examples**

#### **Divide Two Numeric Arrays**

Create two numeric arrays, `A` and `B`, and divide the second array, `B`, into the first, `A`.

```
A = [2 4 6 8; 3 5 7 9];
B = 10*ones(2,4);
x = A./B
```

```
x =
```

```
 0.2000 0.4000 0.6000 0.8000
 0.3000 0.5000 0.7000 0.9000
```

#### **Integer Division**

Divide an `int16` scalar value by each element of an `int16` vector.

```
a = int16(10);
```

```
b = int16([3 4 6]);
x = a./b
```

```
x =
```

```
 3 3 2
```

MATLAB rounds the results when dividing integer data types.

### Divide Scalar by Array

Create an array and divide it into a scalar.

```
C = 5;
D = magic(3);
x = C./D
```

```
x =
```

```
 0.6250 5.0000 0.8333
 1.6667 1.0000 0.7143
 1.2500 0.5556 2.5000
```

When you specify a scalar value to be divided by an array, the scalar value expands into an array of the same size, then element-by-element division is performed.

## Input Arguments

### A — Numerator

scalar | vector | matrix | multidimensional array

Numerator, specified as a scalar, vector, matrix, or multidimensional array. If B is an integer data type, A must be the same integer type or a scalar double.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | duration

Complex Number Support: Yes

### B — Denominator

scalar | vector | matrix | multidimensional array

Denominator, specified as a scalar, vector, matrix, or multidimensional array. If A is an integer data type, B must be the same integer type or a scalar double.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `duration`  
Complex Number Support: Yes

## Output Arguments

### **x** — Solution

scalar | vector | matrix | multidimensional array

Solution, returned as a scalar, vector, matrix or multidimensional array. If either **A** or **B** is an integer data type, then **x** is that same integer data type.

## More About

### Tips

- When dividing integers, use `idivide` for more rounding options.
- MATLAB does not support complex integer division.
- “Array vs. Matrix Operations”
- “Operator Precedence”

`idivide` | `ldivide` | `mldivide` | `mrdivide`

**Introduced before R2006a**

---

# read

**Class:** Tiff

Read entire image

## Syntax

```
imageData = read(tiffobj)
[Y,Cb,Cr] = read(tiffobj)
```

## Description

`imageData = read(tiffobj)` reads the image data from the current image file directory (IFD) in the TIFF file associated with the Tiff object, `tiffobj`.

`[Y,Cb,Cr] = read(tiffobj)` reads the YCbCr component data from the current directory in the TIFF file. Depending upon the values of the `YCbCrSubSampling` tag, the size of the Cb and Cr channels might differ from the Y channel.

## Examples

Open a Tiff object and read data from the TIFF file:

```
t = Tiff('example.tif','r');
imageData = read(t);
close(t)
```

## See Also

Tiff.write | imread

## read

Read data from remote host over TCP/IP interface

### Syntax

```
read(t)
read(t,size)
read(t,size,datatype)
```

### Description

`read(t)` reads all available bytes of data from `tcpclient` object `t` connected to the remote host and returns the data. The number of values read is determined by the `BytesAvailable` property.

For any read or write operation, the data type is converted to `uint8` for the data transfer. It is then converted back to whatever data type you set if you specified another data type.

`read(t,size)` reads the specified number of values, `size`, from `tcpclient` object `t` connected to the remote host and returns the data. If `size` is greater than the object's `BytesAvailable` property, then the function waits until the specified amount of data is read or the `timeout` is reached.

`read(t,size,datatype)` reads the specified number of values, `size`, with the specified precision, `datatype`, from `tcpclient` object `t` connected to the remote host and returns the data. The `datatype` argument is a character string of a standard MATLAB data type.

For any read or write operation, the data type is converted to `uint8` for the data transfer. It is then converted back to whatever data type you set if you specified another data type.

## Examples

### Read All Available Data from Host

Create a TCP/IP object called `t`, using the IP address shown, and Port of 4012.

```
t = tcpclient('172.28.154.231', 4012)
```

```
t =
```

```
tcpclient with properties:
```

```
 Address: '172.28.154.231'
 Port: 4012
 Timeout: 10
 BytesAvailable: 0
```

Read all the bytes of data available.

```
read(t)
```

The `read` function used with no arguments reads all available bytes of data from `tcpclient` object `t` connected to the remote host and returns the data. The number of values read is determined by the `BytesAvailable` property, which is equal to the numbers of bytes available in the input buffer.

Close the connection between the TCP/IP client object and the remote host by clearing the object.

```
clear t
```

### Specify the Size and Data Type to Read

Create a TCP/IP object called `t`, connecting to a TCP/IP echo server, with Port of 7.

```
t = tcpclient('localhost', 7)
```

```
t =
```

```
tcpclient with properties:
```

```
 Address: 'local host'
 Port: 7
 Timeout: 10
 BytesAvailable: 0
```

Assign 10 bytes of data to the variable `data`.

```
data = (1:10)
```

Check the data.

```
whos data
```

Name	Size	Bytes	Class	Attributes
data	1x10	10	double	

Write data to the echo server.

```
write(t, data)
```

Check that the data was written using the `BytesAvailable` property.

```
t.BytesAvailable
```

```
ans =
```

```
80
```

For any read or write operation, the data type is converted to `uint8` for the data transfer. It is then converted back to whatever data type you set if you specified another data type. Since 1 `double` equals 8 `uint8` bytes, there are 80 bytes available.

Read 10 doubles from the server. The object name is always the first argument. The `size` argument must be the second argument, and `datatype` must be the third argument.

```
read(t, 10, 'double')
```

```
ans =
```

```
1 2 3 4 5 6 7 8 9 10
```

Close the connection between the TCP/IP client object and the remote host by clearing the object.

```
clear t
```

## Input Arguments

**size** — Number of bytes to read

numeric scalar

Number of bytes to read, specified as a numeric scalar. Size cannot be set to `inf`. If `size` is greater than the object's `BytesAvailable` property, the function waits until the specified amount of data is read. The first argument must be the object name, and the second argument is the size. The `size` argument is optional.

Example: `read(t, 5)`

Data Types: `double`

### **datatype** — MATLAB data type

'uint8' (default) | 'int8' | 'uint16' | 'int16' | 'uint32' | 'int32' |  
'uint64' | 'int64' | 'single' | 'double'

MATLAB data type, specified as a character string. Size cannot be set to `inf`. The `datatype` must be set to one of the 10 values shown above. The first argument must be the object name, the second argument is the size, and the third argument is the data type. The `size` and `datatype` arguments are optional.

For any read or write operation, the data type is converted to `uint8` for the data transfer. It is then converted back to whatever data type you set if you specified another data type.

Example: `read(t, 10, 'double')`

Data Types: `char`

## readasync

Read data asynchronously from device

### Syntax

```
readasync(obj)
readasync(obj,size)
```

### Description

`readasync(obj)` initiates an asynchronous read operation on the serial port object, `obj`.

`readasync(obj,size)` asynchronously reads, at most, the number of bytes given by `size`. If `size` is greater than the difference between the `InputBufferSize` property value and the `BytesAvailable` property value, an error is returned.

### Examples

This example creates the serial port object `s` on a Windows platform. It connects `s` to a Tektronix TDS 210 oscilloscope, configures `s` to read data asynchronously only if `readasync` is issued, and configures the instrument to return the peak-to-peak value of the signal on channel 1.

```
s = serial('COM1');
fopen(s)
s.ReadAsyncMode = 'manual';
fprintf(s,'Measurement:Meas1:Source CH1')
fprintf(s,'Measurement:Meas1:Type Pk2Pk')
fprintf(s,'Measurement:Meas1:Value?')
```

Begin reading data asynchronously from the instrument using `readasync`. When the read operation is complete, return the data to the MATLAB workspace using `fscanf`.

```
readasync(s)
s.BytesAvailable
```

```
ans =
 15

out = fscanf(s)

out =
2.0399999619E0

fclose(s)
```

## More About

### Tips

Before you can read data, you must connect `obj` to the device with the `fopen` function. A connected serial port object has a `Status` property value of `open`. An error is returned if you attempt to perform a read operation while `obj` is not connected to the device.

Only use `readasync` to configure the `ReadAsyncMode` property to `manual`. `readasync` is ignored if used when `ReadAsyncMode` is `continuous`.

The `TransferStatus` property indicates if an asynchronous read or write operation is in progress. You can write data while an asynchronous read is in progress because serial ports have separate read and write pins. You can stop asynchronous read and write operations with the `stopasync` function.

You can monitor the amount of data stored in the input buffer with the `BytesAvailable` property. Additionally, you can use the `BytesAvailableFcn` property to execute a callback function when the terminator or the specified amount of data is read.

## Rules for Completing an Asynchronous Read Operation

An asynchronous read operation with `readasync` completes when one of these conditions is met:

- The terminator specified by the `Terminator` property is read.
- The time specified by the `Timeout` property passes.
- The specified number of bytes is read.
- The input buffer is filled (if `size` is not specified).

Because `readasync` checks for the terminator, this function can be slow. To increase speed, you might want to configure `ReadAsyncMode` to `continuous` and continuously return data to the input buffer as soon as it is available from the device.

# readEncodedStrip

**Class:** Tiff

Read data from specified strip

## Syntax

```
stripData = readEncodedStrip(tiffobj,stripNumber)
[Y,Cb,Cr] = readEncodedStrip(tiffobj,stripNumber)
```

## Description

`stripData = readEncodedStrip(tiffobj,stripNumber)` reads data from the strip specified by `stripNumber`. Strip numbers are one-based numbers.

`[Y,Cb,Cr] = readEncodedStrip(tiffobj,stripNumber)` reads YCbCr component data from the specified strip. The size of the chrominance components `Cb` and `Cr` might differ from the size of the luminance component `Y` depending on the value of the `YCbCrSubSampling` tag.

`readEncodeStrip` clips the last strip, if the strip extends past the `ImageLength` boundary.

## Examples

### Read a Strip

Read the first strip in the second image of a TIFF file.

Create a `Tiff` object associated with the example file, `example.tif`, and make the second image the current directory.

```
t = Tiff('example.tif','r');
setDirectory(t,2)
```

Read the data in the first strip. Then, close the `Tiff` object.

```
data = readEncodedStrip(t,1);
close(t)
```

- “Reading Image Data and Metadata from TIFF Files”

## References

This method corresponds to the `TIFFReadEncodedStrip` function in the LibTIFF C API. To use this method, you must be familiar with the TIFF specification and technical notes. View this documentation at [LibTIFF - TIFF Library and Utilities](#).

## See Also

`Tiff.readEncodedTile` | `Tiff.isTiled`

# readEncodedTile

**Class:** Tiff

Read data from specified tile

## Syntax

```
tileData = readEncodedTile(tiffobj,tileNumber)
[Y,Cb,Cr] = readEncodedTile(tiffobj,tileNumber)
```

## Description

`tileData = readEncodedTile(tiffobj,tileNumber)` reads data from the tile specified by `tileNumber`. Tile numbers are one-based numbers.

`[Y,Cb,Cr] = readEncodedTile(tiffobj,tileNumber)` reads YCbCr component data from the specified tile. The size of the chrominance components `Cb` and `Cr` might differ from the size of the luminance component `Y`, depending on the value of the `YCbCrSubSampling` tag.

`readEncodedTile` clips tiles on the last row or right-most column of an image if the tile extends past the `ImageLength` and `ImageLength` boundaries.

## Examples

### Read a Tile

Create a `Tiff` object associated with the example file, `example.tif`. Then, read the first tile of data.

```
t = Tiff('example.tif','r');
data = readEncodedTile(t,1);
```

`close(t)`

## References

This method corresponds to the `TIFFReadEncodedTile` function in the LibTIFF C API. To use this method, you must be familiar with the TIFF specification and technical notes. View this documentation at [LibTIFF - TIFF Library and Utilities](#).

`Tiff.readEncodedStrip` | `Tiff.isTiled`

# readRGBAImage

**Class:** Tiff

Read image using RGBA interface

## Syntax

```
[RGB,alpha] = readRGBAImage()
```

## Description

`[RGB,alpha] = readRGBAImage()` reads an entire image using the RGBA interface. RGB consists of an  $m$ -by- $n$ -by-3 colormetric image, where  $m$  and  $n$  are the height and width of the tile, respectively. `alpha` is the associated alpha matting. If the image does not have associated alpha matting, then `alpha` is a matrix with all values set to 255 (transparent).

The pixel values may be transformed depending upon the values of the following tags:

PhotometricInterpretation

BitsPerSample

SamplesPerPixel

Orientation

ExtraSamples

ColorMap

## Examples

Return all image data as RGB, with associated alpha matting.

```
t = Tiff('example.tif','r');
t.setDirectory(2);
[RGB,A] = t.readRGBAImage();
t.close();
```

## References

This method corresponds to the `TIFFReadRGBAImage` function in the LibTIFF C API.

To use this method, you must be familiar with LibTIFF version 4.0.0, as well as the TIFF specification and technical notes. View this documentation at [LibTiff - TIFF Library and Utilities](#).

## See Also

[Tiff.readRGBAStrip](#) | [Tiff.read](#) | [Tiff.readRGBATile](#)

# readRGBAStrip

**Class:** Tiff

Read strip data using RGBA interface

## Syntax

```
[RGB,alpha] = readRGBAStrip(row)
```

## Description

`[RGB,alpha] = readRGBAStrip(row)` reads a strip using the RGBA interface. `row` is a one-based number of any row contained by the strip. `RGB` consists of an  $m$ -by- $n$ -by-3 colormetric image, where  $m$  and  $n$  are the height and width of the strip, respectively. `alpha` is the associated alpha matting. If the image does not have associated alpha matting, then `alpha` is a matrix with all values set to 255 (transparent).

The strip is clipped if the strip boundary extends past the end of the image.

The pixel values may be transformed depending upon the values of the following tags:

PhotometricInterpretation

BitsPerSample

SamplesPerPixel

Orientation

ExtraSamples

ColorMap

## Examples

Open a Tiff object and read the strip of data that contains the first row, using the RGBA interface, from the example file, `example.tif`

```
t = Tiff('example.tif','r');
```

```
t.setDirectory(2);
[RGB,A] = t.readRGBAStrip(1);
t.close();
```

## References

This method corresponds to the `TIFFReadRGBAStrip` function in the LibTIFF C API.

To use this method, you must be familiar with LibTIFF version 4.0.0, as well as the TIFF specification and technical notes. View this documentation at [LibTiff - TIFF Library and Utilities](#).

## See Also

[Tiff.readRGBATile](#) | [Tiff.readRGBAIImage](#)

# readRGBATile

**Class:** Tiff

Read tile data using RGBA interface

## Syntax

```
[RGB,alpha] = readRGBATile(row,col)
```

## Description

`[RGB,alpha] = readRGBATile(row,col)` reads a tile using the RGBA interface. `row` and `col` are the one-based row and column numbers of any pixel in the requested tile. `RGB` consists of an `m`-by-`n`-by-3 colormetric image, where `m` and `n` are the height and width of the tile, respectively. `alpha` is the associated alpha matting. If the image does not have associated alpha matting, then `alpha` is a matrix with all values set to 255 (transparent).

The tile is clipped if the tile boundaries extend past the edges of the image.

The pixel values may be transformed depending upon the values of the following tags:

PhotometricInterpretation

BitsPerSample

SamplesPerPixel

Orientation

ExtraSamples

ColorMap

## Examples

Open a Tiff object and read the first tile using the RGBA interface.

```
t = Tiff('example.tif','r');
```

```
t.setDirectory(1);
[RGB,A] = t.readRGBATile(1,1);
t.close();
```

## References

This method corresponds to the `TIFFReadRGBATile` function in the LibTIFF C API.

To use this method, you must be familiar with LibTIFF version 4.0.0, as well as the TIFF specification and technical notes. View this documentation at [LibTiff - TIFF Library and Utilities](#).

# Remove

Convenience function for static `.NET System.Delegate` Remove method

## Syntax

```
result = Remove(combinedDelegate, removedDelegate)
```

## Description

`result = Remove(combinedDelegate, removedDelegate)` removes last instance of the `removedDelegate` delegate from the `combinedDelegate` delegate.

## Input Arguments

### **combinedDelegate**

`.NET System.Delegate` object. The combined delegate from which to remove the `removedDelegate` delegate.

**Default:**

### **removedDelegate**

`.NET System.Delegate` object. The delegate to remove from the `combinedDelegate` delegate.

**Default:**

## Output Arguments

### **result**

`.NET System.Delegate` object. A new delegate which is the same as the `combinedDelegate` delegate except without the last instance of the `removedDelegate` delegate.

## **Alternatives**

Use the static `Remove` method of the `System.Delegate` class.

## **More About**

# RemoveAll

Convenience function for static .NET System.Delegate RemoveAll method

## Syntax

```
result = RemoveAll(combinedDelegate, removedDelegate)
```

## Description

`result = RemoveAll(combinedDelegate, removedDelegate)` removes all instances of `removedDelegate` from `combinedDelegate`.

## Input Arguments

### **combinedDelegate**

.NET System.Delegate object. The combined delegate from which to remove all instances of the `removedDelegate` delegate.

**Default:**

### **removedDelegate**

.NET System.Delegate object. The delegate to remove from the `combinedDelegate` delegate.

**Default:**

## Output Arguments

### **result**

.NET System.Delegate object. A new delegate which is the same as the `combinedDelegate` delegate except without all instances of the `removedDelegate` delegate.

## **Alternatives**

Use the static `RemoveAll` method of the `System.Delegate` class.

# timeseries class

Create `timeseries` object

## Description

Time series are data vectors sampled over time, in order, often at regular intervals. They are distinguished from randomly sampled data that form the basis of many other data analyses. Time series represent the time-evolution of a dynamic population or process. The linear ordering of time series gives them a distinctive place in data analysis, with a specialized set of techniques. Time series analysis is concerned with:

- Identifying patterns
- Modeling patterns
- Forecasting values

## Construction

`ts = timeseries` creates an empty time-series object.

`ts = timeseries(tsname)` creates an empty time-series object using the name, `tsname`, for the time-series object. This name can differ from the time-series variable name.

`ts = timeseries(data)` creates the time-series object using the specified `data`.

`ts = timeseries(data,time)` creates the time-series object using the specified `data` and `time`.

`ts = timeseries(data,time,quality)` specifies quality in terms of codes defined by `QualityInfo.Code`.

`ts = timeseries(data,'Name',tsname)` creates the time-series object using the specified `data` and the name, `tsname`.

`ts = timeseries(data,time,'Name',tsname)` creates the time-series object using the specified `data`, `time`, and the name, `tsname`.

`ts = timeseries(data,time,quality,'Name',tsname)` uses the specified quality and the name, `tsname`.

## Input Arguments

### **data**

The time-series data, which can be an array of samples

### **tsname**

Time-series name specified as a string

**Default:** ''

### **time**

The time vector.

When time values are date strings, you must specify `Time` as a cell array of date strings. When the time vector contains duplicate values:

- Duplicated values must occupy contiguous elements.
- Time values must not be decreasing.

Interpolating time-series data using methods like `resample` and `synchronize` can produce different results depending on whether the input `timeseries` contains duplicate times.

**Default:** A time vector that ranges from 0 to N-1 with a 1-second interval, where N is the number of samples.

### **quality**

An integer vector with values -128 to 127 that specifies the quality in terms of codes defined by `QualityInfo.Code`

When `Quality` is a vector:

- `Quality` must have the same length as the time vector.
- Each `Quality` value applies to the corresponding data sample.

When `Quality` is an array:

- `Quality` must have the same size as the data array.
- Each `Quality` value applies to the corresponding data value of the `ts.data` array.

## Properties

### Data

Time-series data, where each data sample corresponds to a specific time

The data can be a scalar, a vector, or a multidimensional array. Either the first or last dimension of the data must align with `Time`.

By default, NaNs represent missing or unspecified data. Set the `TreatNaNasMissing` property to determine how missing data is treated in calculations.

### Attributes:

`Dependent` `true`

### DataInfo

Contains fields for storing contextual information about `Data`:

- `Unit` — String that specifies data units
- `Interpolation` — A `tsdata.interpolation` object that specifies the interpolation method for this `timeseries` object.

Fields of the `tsdata.interpolation` object include:

- `Fhandle` — Function handle to a user-defined interpolation function
- `Name` — String that specifies the name of the interpolation method. Predefined methods include `'linear'` and `'zoh'` (zero-order hold). `'linear'` is the default.
- `UserData` — Any user-defined information entered as a string

### Events

An array of `tsdata.event` objects that stores event information for this `timeseries` object.

You add events by using the `addevent` method. Fields of the `tsdata.event` object include the following:

- **EventData** — Any user-defined information about the event
- **Name** — String that specifies the name of the event
- **Time** — Time value when this event occurs, specified as a real number or a date string
- **Units** — Time units
- **StartDate** — A reference date specified in MATLAB date-string format. **StartDate** is empty when you have a numerical (non-date-string) time vector.

### **IsTimeFirst**

Logical value (`true` or `false`) specifies whether the time vector is aligned with the first or last dimension of the **Data** array. The value is `false` for 3-D and higher dimensional data and `true` otherwise.

- `true` — The first dimension of the data array is aligned with the time vector. For example, `ts = timeseries(rand(3,3),1:3);`
- `false` — The last dimension of the data array is aligned with the time vector. For example: `ts = timeseries(rand(3,4,5),1:5);`

### **Attributes:**

Dependent	true
SetAccess	'protected'

### **Length**

Length of the time vector in the `timeseries` object

### **Attributes:**

Dependent	true
SetAccess	'protected'

### **Name**

The `timeseries` object name entered as a string, `tsname`.

This name can differ from the name of the `timeseries` variable in the MATLAB workspace.

### **Quality**

An integer vector or array containing values `-128` to `127` that specify the quality in terms of codes defined by `QualityInfo.Code`.

When `Quality` is a vector, it must have the same length as the time vector. In this case, each `Quality` value applies to a corresponding data sample.

When `Quality` is an array, it must have the same size as the data array. In this case, each `Quality` value applies to the corresponding value of the data array.

### **Attributes:**

<code>Dependent</code>	<code>true</code>
------------------------	-------------------

### **QualityInfo**

Provides a lookup table that converts numerical `Quality` codes to readable descriptions.

`QualityInfo` fields include the following:

- `Code` — Integer vector containing values `-128` to `127` that define the “dictionary” of quality codes. You can assign one of these integer values to each `Data` value by using the `Quality` property.
- `Description` — Cell vector of strings, where each element provides a readable description of the associated quality `Code`.
- `UserData` — Stores any additional user-defined information.

Lengths of `Code` and `Description` must match.

### **Time**

Array of time values.

When `TimeInfo.StartDate` is empty, the numerical `Time` values are measured relative to `0` in specified units. When `TimeInfo.StartDate` is defined, the time values are date strings measured relative to the `StartDate` in specified units.

The length of `Time` must be the same as either the first or the last dimension of `Data`. When the data contains three or more dimensions, the length of `Time` matches the size of the last data dimension. Otherwise, the length of `Time` matches the size of the first data dimension.

**Attributes:**

`Dependent` `true`

**TimeInfo**

Uses the following fields for storing contextual information about `Time`:

- `Units` — Time units having any of following values: 'weeks', 'days', 'hours', 'minutes', 'seconds', 'milliseconds', 'microseconds', or 'nanoseconds'
- `Start` — Start time
- `End` — End time (read only)
- `Increment` — Interval between two subsequent time values
- `Length` — Length of the time vector (read only)
- `Format` — String defining the date string display format. See the MATLAB `datestr` function reference page for more information.
- `StartDate` — Date string defining the reference date. See the MATLAB `setabstime` function reference page for more information.
- `UserData` — Stores any additional user-defined information

**TreatNaNasMissing**

Logical value that specifies how to treat NaN values in `Data`:

- `true` — (Default) Treats all NaN values as missing data except during statistical calculations.
- `false` — Includes NaN values in statistical calculations, in which case NaN values are propagated to the result.

**UserData**

Generic field for data of any class that you want to add to the object.

Default: [ ]

## Methods

### Time-Series Methods

- .
- .
- .
- .
- .

### Methods to Query and Set Object Properties and Plot the Data

get	Query <code>timeseries</code> object property values.
getdatasamplesize	Return the size of each data sample in a <code>timeseries</code> object.
getqualitydesc	Return data quality descriptions based on the <code>Quality</code> property values assigned to a <code>timeseries</code> object.
plot	Plot the <code>timeseries</code> object.
set	Set <code>timeseries</code> property values.

### Methods to Manipulate Data and Time

addsample	Add a data sample to a <code>timeseries</code> object.
append	Concatenate <code>timeseries</code> objects in the time dimension.
delsample	Delete a sample from a <code>timeseries</code> object.
detrend	Subtract the mean or best-fit line and remove all NaNs from time-series data.
filter	Shape frequency content of time-series data using a 1-D digital filter.
getabstime	Extract a date-string time vector from a <code>timeseries</code> object into a cell array.

<code>getdatasamples</code>	Extract a subset of data samples from an existing <code>timeseries</code> object into an array using a subscripted indexed array.
<code>getsamples</code>	Extract a subset of data samples from an existing <code>timeseries</code> object into a new <code>timeseries</code> object using a subscript indexed array.
<code>getinterpmethod</code>	Get the interpolation method for a <code>timeseries</code> object.
<code>getsamplingsingtime</code>	Extract data samples from an existing <code>timeseries</code> object into a new <code>timeseries</code> object based on specified start and end time values.
<code>idealfilter</code>	Apply an ideal pass or notch (noncausal) filter to a <code>timeseries</code> object.
<code>resample</code>	Select or interpolate data in a <code>timeseries</code> object using a new time vector.
<code>setabstime</code>	Set the time values in the time vector as date strings.
<code>setinterpmethod</code>	Set interpolation method for a <code>timeseries</code> object.
<code>setuniformtime</code>	Assign uniform time vector to <code>timeseries</code> object.
<code>synchronize</code>	Synchronize and resample two <code>timeseries</code> objects using a common time vector.

### **Event Methods**

To construct an event object, use the constructor `tsdata.event`. For an example of defining events for a time-series object, see “Defining Events”.

<code>addevent</code>	Add one or more events to a <code>timeseries</code> object.
<code>delevent</code>	Delete one or more events from a <code>timeseries</code> object.
<code>gettsafteratevent</code>	Create a new <code>timeseries</code> object by extracting the samples from an existing time series that occur after or at a specified event.
<code>gettsafterevent</code>	Create a new <code>timeseries</code> object by extracting the samples that occur after a specified event from an existing time series.
<code>gettsatevent</code>	Create a new <code>timeseries</code> object by extracting the samples that occur at the same time as a specified event from an existing time series.

<code>gettsbeforeevent</code>	Create a new <code>timeseries</code> object by extracting the samples that occur before or at a specified event from an existing time series.
<code>gettsbeforeevent</code>	Create a new <code>timeseries</code> object by extracting the samples that occur before a specified event from an existing time series.
<code>gettsbetweenevents</code>	Create a new <code>timeseries</code> object by extracting the samples that occur between two specified events from an existing time series.

### Methods to Arithmetically Combine `timeseries` Objects

<code>+</code>	Addition of the corresponding data values of <code>timeseries</code> objects.
<code>-</code>	Subtraction of the corresponding data values of <code>timeseries</code> objects.
<code>.*</code>	Element-by-element multiplication of <code>timeseries</code> data.
<code>*</code>	Matrix-multiply <code>timeseries</code> data.
<code>./</code>	Right element-by-element division of <code>timeseries</code> data.
<code>/</code>	Right matrix division of <code>timeseries</code> data.
<code>.\</code>	Element-by-element left-array divide of <code>timeseries</code> data.
<code>\</code>	Left matrix division of <code>timeseries</code> data.

### Methods to Calculate Descriptive Statistics for a `timeseries` Object

<code>iqr</code>	Return the interquartile range of <code>timeseries</code> data.
<code>max</code>	Return the maximum value of <code>timeseries</code> data.
<code>mean</code>	Return the mean of <code>timeseries</code> data.
<code>median</code>	Return the median of <code>timeseries</code> data.
<code>min</code>	Return the minimum of <code>timeseries</code> data.
<code>std</code>	Return the standard deviation of <code>timeseries</code> data.
<code>sum</code>	Return the sum of <code>timeseries</code> data.
<code>var</code>	Return the variance of <code>timeseries</code> data.

## Definitions

### timeseries

The time-series object, called `timeseries`, is a MATLAB variable that contains time-indexed data and properties in a single, coherent structure. For example, in addition to data and time values, you can also use the time-series object to store events, descriptive information about data and time, data quality, and the interpolation method.

### Data Sample

A time-series *data sample* consists of one or more values recorded at a specific time. The number of data samples in a time series is the same as the length of the time vector.

For example, suppose that `ts.data` has the size 3-by-4-by-5 and the time vector has the length 5. Then, the number of samples is 5 and the total number of data values is  $3 \times 4 \times 5 = 60$ .

### Time Vector

A time vector of a `timeseries` object can be either numerical (`double`) values or valid MATLAB date strings.

When the `timeseries` `TimeInfo.StartDate` property is empty, the numerical time values are measured relative to 0 (or another numerical value) in specified units. In this case, the time vector is described as *relative* (that is, it contains time values that are not associated with a specific start date).

When `TimeInfo.StartDate` is nonempty, the time values are date strings measured relative to `StartDate` in specified units. In this case, the time vector is described as *absolute* (that is, it contains time values that are associated with a specific calendar date).

MATLAB supports the following date-string formats for time-series applications.

Date-String Format	Usage Example
dd-mmm-yyyy HH:MM:SS	01-Mar-2000 15:45:17
dd-mmm-yyyy	01-Mar-2000

Date-String Format	Usage Example
mm/dd/yy	03/01/00
mm/dd	03/01
HH:MM:SS	15:45:17
HH:MM:SS PM	3:45:17 PM
HH:MM	15:45
HH:MM PM	3:45 PM
mmm.dd,yyyy HH:MM:SS	Mar.01,2000 15:45:17
mmm.dd,yyyy	Mar.01,2000
mm/dd/yyyy	03/01/2000

## Copy Semantics

Value. To learn how value classes affect copy operations, see [Copying Objects in the MATLAB documentation](#).

## Examples

Create a `timeseries` object called 'LaunchData' that contains four data sets, each stored as a column of length 5 and using the default time vector:

```
b = timeseries(rand(5, 4), 'Name', 'LaunchData')
```

Create a `timeseries` object containing a single data set of length 5 and a time vector starting at 1 and ending at 5:

```
b = timeseries(rand(5,1), [1 2 3 4 5])
```

Create a `timeseries` object called 'FinancialData' containing five data points at a single time point:

```
b = timeseries(rand(1,5), 1, 'Name', 'FinancialData')
```

## See Also

`tscollection` | `tsdata.event`

**Introduced before R2006a**

# addsample

**Class:** timeseries

Add data sample to `timeseries` object

## Syntax

```
ts1 = addsample(ts, s)
ts1 = addsample(ts, 'Data', data-value, 'Time', time-value, ...,
Name, Value)
```

## Description

`ts1 = addsample(ts, s)` adds one or more new data samples stored in a structure `s` to the `timeseries` object `ts`.

`ts1 = addsample(ts, 'Data', data-value, 'Time', time-value, ..., Name, Value)` adds one or more data samples to the `timeseries` object `ts` along with additional options specified by one or more `Name, Value` pair arguments.

## Tips

- If `N` is the number of data samples, you can get the sample size of each time with `SampleSize = getsamplesize(ts)`.

When `ts.IsTimeFirst` is `true`, the size of the data is `N-by-SampleSize`. When `ts.IsTimeFirst` is `false`, the size of the data is `SampleSize-by-N`.

## Input Arguments

**s**

A structure that you must define before passing as an argument to `addsample`. It consists of the following optional fields:

- `s.data`
- `s.time`
- `s.quality`
- `s.overwriteflag`

## **data-value**

A numeric data value.

## **time-value**

A valid time vector.

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### **'Quality'**

Array of data quality codes.

**Default:** []

### **'OverwriteFlag'**

Logical value that controls whether to overwrite a data sample at the same time with the new sample you are adding to your `timeseries` object. When set to `true`, the new sample overwrites the old sample at the same time.

**Default:** `false`

## **Output Arguments**

### **ts1**

The `timeseries` object that results when you add the specified samples to the original `timeseries` object.

## Definitions

### data sample

One or more values recorded at a specific time. The number of data samples in a time series is the same as the length of the time vector.

## Examples

Add a data value of 420 at time 3:

```
ts = ts.addsample('Time',3,'Data',420);
```

Add a data value of 420 at time 3 and specify quality code 1 for this data value. Set the `OverwriteFlag` to overwrite an existing value at time 3.

```
ts = ts.addsample('Data',3.2,'Quality',1,'OverwriteFlag',...
 true,'Time',3);
```

### See Also

[timeseries](#) | [delsample](#) | [getdatasamples](#)

**Introduced before R2006a**

## append

**Class:** timeseries

Concatenate time series objects in time dimension

### Syntax

```
ts = append(ts1,ts2, ... tsn)
```

### Description

`ts = append(ts1,ts2, ... tsn)` creates a new `timeseries` object by concatenating `timeseries` `ts1`, `ts2`, and so on, along the time dimension.

### Tips

- A single overlapping time between each input time series is valid, as long as the overlapping samples are identical.
- The time vectors must not overlap by a nonzero amount. That is, the last time in `ts1` must be earlier than or equal to the first time in `ts2`.
- The sample size of the time series must be the same.

### Input Arguments

**ts1**

The first `timeseries` object that you want to append.

**ts2**

The second `timeseries` object that you want to append.

**tsn**

The `n`th `timeseries` object that you want to append.

## Output Arguments

**ts**

The `timeseries` object that results from appending the input `timeseries` objects.

## Examples

After creating `timeseries` objects, `ts1` and `ts2`, append them:

```
ts1 = timeseries(rand(5,1),[1 2 3 4 5]);
ts2 = timeseries(rand(5,1),[6 7 8 9 10]);
ts3 = append(ts1, ts2)
```

## See Also

`timeseries`

## delsample

**Class:** timeseries

Remove sample from `timeseries` object

### Syntax

```
ts1 = delsample(ts,Name,Value)
```

### Description

`ts1 = delsample(ts,Name,Value)` deletes samples from the `timeseries` object `ts` based on the specified `Name,Value` pair arguments.

### Input Arguments

**ts**

A `timeseries` object.

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**'Index'**

The indices of the time vector that correspond to the samples you want to delete.

**'Value'**

The time values that correspond to the samples you want to delete.

## Output Arguments

**ts1**

The `timeseries` object that results from removing the specified samples.

## Examples

Create a `timeseries` object, and then remove samples:

```
ts = timeseries(rand(5,1),[10 20 30 40 50]);
```

```
% Remove data sample at time index 1
```

```
ts1 = delsample(ts,'Index', 1)
```

```
% Remove data sample at time value 20:
```

```
ts2 = delsample(ts,'Value', [20])
```

## See Also

[set](#) | [timeseries](#)

## detrend

**Class:** timeseries

Subtract mean or best-fit line and all NaNs from `timeseries` object

## Syntax

```
ts1 = detrend(ts, method)
ts1 = detrend(ts, method, index)
```

## Description

`ts1 = detrend(ts, method)` subtracts either a mean or a best-fit line from time-series data, using the specified `method`. Usually for FFT processing.

`ts1 = detrend(ts, method, index)` uses the optional `index` to specify the columns or rows to detrend.

## Tips

- You cannot apply `detrend` to `timeseries` data with more than two dimensions.

## Input Arguments

**ts**

The `timeseries` object from which you want to subtract the mean or best-fit line and all NaNs.

**Default:**

**method**

A string that specifies one of the following detrend methods:

- 'constant' — Subtracts the mean.
- 'linear' — Subtracts the best-fit line.

**index**

An integer array that specifies the columns or rows to detrrend when `ts.IsTimeFirst` is true.

## Output Arguments

**ts1**

The `timeseries` object resulting from detrrending the input `timeseries` object.

**See Also**

`timeseries`

**Introduced before R2006a**

## filter

**Class:** timeseries

Shape frequency content of time-series

## Syntax

```
ts1 = filter(ts, numerator, denominator)
ts1=filter(ts, numerator, denominator, index)
```

## Description

`ts1 = filter(ts, numerator, denominator)` applies the transfer function filter  $b(z^{-1})/a(z^{-1})$  to the data in the `timeseries` object `ts`. `b` and `a` are the coefficient arrays of the transfer function numerator and denominator, respectively.

`ts1=filter(ts, numerator, denominator, index)` uses the optional `index` integer array to specify either the columns or rows to filter, depending on the value of `ts.IsTimeFirst`.

## Tips

- The time-series data must be uniformly sampled to use this filter.
- The following function

```
y = filter(b,a,x)
```

creates filtered data `y` by processing the data in vector `x` with the filter described by vectors `a` and `b`.

- The `filter` function is a general tapped delay-line filter, described by the difference equation:  
$$a(1)y(n) = b(1)x(n) + b(2)x(n - 1) + \dots + b(nb)x(n - nb + 1) - a(2)y(n - 1) - \dots - a(N_a)y(n - N_b + 1).$$

Here,  $n$  is the index of the current sample,  $N_a$  is the order of the polynomial described by vector `a`, and  $N_b$  is the order of the polynomial described by vector `b`. The output

$y(n)$  is a linear combination of current and previous inputs,  $x(n)$   $x(n-1)$ ..., and previous outputs,  $y(n-1)$   $y(n-2)$ ... .

- You use the discrete filter to shape the data by applying a transfer function to the input signal.

Depending on your objectives, the transfer function you choose might alter both the amplitude and the phase of the variations in the data at different frequencies to produce either a smoother or a rougher output.

- In digital signal processing (DSP), it is customary to write transfer functions as rational expressions in  $z^{-1}$  and to order the numerator and denominator terms in ascending powers of  $z^{-1}$ .

Taking the z-transform of the difference equation

$$a(1)y(n) = b(1)x(n) + b(2)x(n-1) + \dots + b(nb)x(n-nb+1) - a(2)y(n-1) - \dots - a(na)y(na+1),$$

results in the transfer function

$$Y(z) = H(z^{-1})X(z) = \frac{b(1) + b(2)z^{-1} + \dots + b(nb)z^{-nb+1}}{a(1) + a(2)z^{-1} + \dots + a(na)z^{-na+1}} X(z),$$

where  $Y(z)$  is the z-transform of the filtered output  $y(n)$ . The coefficients  $b$  and  $a$  are unchanged by the z-transform.

## Input Arguments

### **ts**

The first `timeseries` object for which you want to shape the frequency content.

### **numerator**

The coefficient array of the transfer function numerator.

### **denominator**

The coefficient array of the transfer function denominator.

**index**

An integer array that specifies the columns or rows to filter when `ts.IsTimeFirst` is true.

## Output Arguments

**ts1**

The `timeseries` object that results from filtering the input `timeseries` object.

## Examples

**Apply Transfer Function to Time Series Data**

This example applies the following transfer function to the data in `count.dat`:

$$H(z^{-1}) = \frac{b(z^{-1})}{a(z^{-1})} = \frac{2 + 3z^{-1}}{1 + 0.2z^{-1}}$$

Load the matrix `count` into the workspace:

```
load count.dat
```

Create a time-series object based on this matrix:

```
count1 = timeseries(count(:,1),[1:24]);
```

Enter the coefficients of the denominator ordered in ascending powers of  $z^{-1}$  to represent  $1 + 0.2x$ :

```
a = [1 0.2];
```

Enter the coefficients of the numerator to represent  $2 - 3z^{-1}$ :

```
b = [2 3];
```

Call the filter method:

```
filter_count = filter(count1, b, a);
```

Compare the original data and the shaped data with an overlaid plot of the two curves:

```
figure
plot(count1, '-. ')
grid on
hold on
plot(filter_count, '-')
legend('Original Data', 'Shaped Data', 'Location', 'NorthWest')
```

## See Also

Introduced before R2006a

## get

**Class:** timeseries

Query `timeseries` object property values

## Syntax

```
get(ts)
value = get(ts, PropertyName)
```

## Description

`get(ts)` displays all properties and values of the `timeseries` object, `ts`.

`value = get(ts, PropertyName)` returns the property value for the specified `timeseries` object. The following syntax is equivalent:

```
value = ts.PropertyName
```

## Input Arguments

**ts**

A `timeseries` object.

**PropertyName**

String specifying the name of a `timeseries` property. For a list of `timeseries` properties, see `timeseries`.

## Output Arguments

**value**

String containing the value associated with the specified property.

## Examples

Create a `timeseries` object, and then get the name. This example gets the name three different ways:

```
ts1 = timeseries(rand(5,1),[1 2 3 4 5], 'Name', 'MyTimeseries');
get(ts1)
get(ts1, 'Name')
value = ts1.Name
```

## See Also

`timeseries` | `set`

**Introduced before R2006a**

## getabstime

**Class:** timeseries

Extract date-string time vector into cell array

### Syntax

```
getabstime(ts)
```

### Description

`getabstime(ts)` extracts the time vector from the `timeseries` object `ts` as a cell array of date strings.

### Tips

- To define the time vector relative to a calendar date, set the `TimeInfo.StartDate` property of the `timeseries` object. When the `TimeInfo.StartDate` format is a valid `datestr` format, the output strings from `getabstime` have the same format.

### Input Arguments

**ts**

The `timeseries` object from which you want to extract the time vector.

**Default:**

### Examples

The following example extracts a time vector as a cell array of date strings from a `timeseries` object.

First, create a `timeseries` object.

```
ts = timeseries([3 6 8 0 10]);
```

The default time vector for `ts` is `[0 1 2 3 4]`, which starts at 0 and increases in 1-second increments. The length of the time vector is equal to the length of the data.

Next, set the `StartDate` property.

```
ts.TimeInfo.StartDate = '10/27/2005 07:05:36';
```

Extract the time vector.

```
getabstime(ts)
```

MATLAB returns:

```
'27-Oct-2005 07:05:36'
'27-Oct-2005 07:05:37'
'27-Oct-2005 07:05:38'
'27-Oct-2005 07:05:39'
'27-Oct-2005 07:05:40'
```

Change the date-string format of the time vector, and then extract the time vector with the new date-string format:

```
ts.TimeInfo.Format = 'mm/dd/yy';
getabstime(ts)
```

MATLAB returns:

```
'10/27/05'
'10/27/05'
'10/27/05'
'10/27/05'
'10/27/05'
```

## See Also

`timeseries` | `setabstime` | `datestr`

**Introduced before R2006a**

## getdatasamples

**Class:** timeseries

Returns subset of time series samples using subscripted index array

### Syntax

```
datasamples = getdatasamples(ts, i)
```

### Description

`datasamples = getdatasamples(ts, i)` returns an array corresponding to the samples indicated by the array, `i`.

### Input Arguments

**ts**

The `timeseries` object from which you want to extract samples.

**i**

An array of linear indices or logical values that specifies the time value or values for which you want to extract the corresponding samples.

### Output Arguments

**datasamples**

The array that results from extracting the samples corresponding to the time value or values, `ts.time(i)`.

## Examples

After creating a `timeseries` object, `ts`, extract the second and third data samples into an array:

```
ts = timeseries(rand(5,1),[1 2 3 4 5]);
samples = getdatasamples(ts, [2 3])
```

## See Also

`timeseries` | `getsamples` | `resample`

# getdatasamplesize

**Class:** timeseries

Size of data sample in `timeseries` object

## Syntax

```
getdatasamplesize(ts)
```

## Description

`getdatasamplesize(ts)` returns the size of each data sample in a `timeseries` object.

## Input Arguments

**ts**

String specifying the name of a `timeseries` object.

## Definitions

### data sample

One or more scalar values recorded at a specific time. The number of data samples is the same as the length of the time vector.

## Examples

After loading data and creating a `timeseries` object, get the size of a data sample:

```
% Load a 24-by-3 data array:
load count.dat
```

```
% Create a timeseries object with 24 time values:
count_ts = timeseries(count,[1:24],'Name','VehicleCount')

% Get the size of the data sample for this timeseries object:
getdatasamplesize(count_ts)
```

MATLAB returns the following, which indicates that the size of each data sample in `count_ts` is 1-by-3. In other words, MATLAB stores each data sample as a row with three values.

```
ans =

 1 3
```

## See Also

[timeseries](#) | [set](#)

**Introduced before R2006a**

## getinterpmethod

**Class:** timeseries

Interpolation method for `timeseries` object

### Syntax

```
getinterpmethod(ts)
```

### Description

`getinterpmethod(ts)` returns the interpolation method that the `timeseries` object `ts`, uses as a string.

### Input Arguments

**ts**

The `timeseries` object from which you want to extract the interpolation method.

### Definitions

#### interpolation method

Predefined interpolation methods are zero-order hold, `zoh`, and linear interpolation, `linear`. Linear interpolation is the default.

### Examples

Create a `timeseries` object, and then get its interpolation method:

```
ts = timeseries(rand(5));
```

getinterpmethod(ts)

MATLAB returns:

linear

## See Also

timeseries | setinterpmethod

**Introduced before R2006a**

## getqualitydesc

**Class:** timeseries

Data quality descriptions

### Syntax

```
getqualitydesc(ts)
```

### Description

`getqualitydesc(ts)` returns a cell array of data quality descriptions based on the Quality values you assigned to a `timeseries` object, `ts`.

### Input Arguments

**ts**

A `timeseries` object.

### Examples

Create a `timeseries` object, and then get the data quality description strings for `ts`:

```
% Create a timeseries object, ts, with Data, Time, and Quality
% values, respectively:
```

```
ts = timeseries([3; 4.2; 5; 6.1; 8], 1:5, [1; 0; 1; 0; 1]);
```

```
% Set the QualityInfo property, including Code and Description:
```

```
ts.QualityInfo.Code = [0 1];
ts.QualityInfo.Description = {'good' 'bad'};
```

```
% Get the data quality description strings for ts:
```

```
getqualitydesc(ts)
```

MATLAB returns:

```
ans =
```

```
 'bad'
 'good'
 'bad'
 'good'
 'bad'
```

## See Also

timeseries

**Introduced before R2006a**

## getsamples

**Class:** timeseries

Subset of time series samples using subscripted index array

### Syntax

```
ts1 = getsamples(ts, i)
```

### Description

`ts1 = getsamples(ts, i)` returns a new `timeseries` object by extracting samples from `timeseries` `ts` corresponding to the time or times indicated by the subscripted index array, `i`.

### Input Arguments

**ts**

The `timeseries` object from which you want to exact samples.

**i**

A subscripted index array that specifies the time value or values for which you want to extract the corresponding samples.

### Output Arguments

**ts1**

The `timeseries` object that results from extracting the samples corresponding to the time value or values `ts.time(i)`.

## Examples

After creating a `timeseries` object, `ts`, extract the data samples at times 2 and 3 into a new `timeseries` object, `ts1`:

```
ts = timeseries(rand(5,1),[1 2 3 4 5]);
ts1 = getdatasamples(ts, ts.time([2 3]))
```

## See Also

`timeseries` | `getdatasamples` | `resample`

## getsampleusingtime

**Class:** timeseries

Extract data samples into new `timeseries` object

### Syntax

```
ts1 = getsampleusingtime(ts,time)
ts1 = getsampleusingtime(ts,time,'AllowDuplicateTimes',true)
ts1 = getsampleusingtime(ts,starttime,endtime)
```

### Description

`ts1 = getsampleusingtime(ts,time)` returns a new `timeseries` object, `ts1`, with a single sample corresponding to specified `time` in `ts`.

`ts1 = getsampleusingtime(ts,time,'AllowDuplicateTimes',true)` returns a new `timeseries` object, `ts1`, with multiple samples when the specified `time` occurs more than once in `ts`.

`ts1 = getsampleusingtime(ts,starttime,endtime)` returns a new `timeseries` object, `ts1`, with samples between the times `starttime` and `endtime` in `ts`.

### Tips

- If the time vector in `ts` is not relative to a calendar date, then `starttime` and `endtime` must be numeric.
- If the time vector in `ts` is relative to a calendar date, then `starttime` and `endtime` values must be dates—either strings or `datenum` values.

### Input Arguments

**ts**

The `timeseries` object from which you want to extract data samples.

**time**

The time corresponding to data sample you want to extract.

**starttime**

The time corresponding to the first data sample you want to extract.

**endtime**

The time corresponding to the last data sample you want to extract.

## Output Arguments

**ts1**

A `timeseries` object that contains the subset of data samples from the original `timeseries` object.

### See Also

`timeseries`

**Introduced before R2006a**

# idealfilter

**Class:** timeseries

Apply ideal (noncausal) filter to `timeseries` object

## Syntax

```
ts1 = idealfilter(ts, interval, filtertype)
ts1 = idealfilter(ts, interval, filtertype, index)
```

## Description

`ts1 = idealfilter(ts, interval, filtertype)` applies an ideal filter of `filtertype` to one or more frequency intervals that `interval` specifies for the `timeseries` object, `ts`.

`ts1 = idealfilter(ts, interval, filtertype, index)` applies an ideal filter and uses the optional `index` integer array to specify the columns or rows to filter.

## Tips

- Ideal filters require data to have a mean of zero and prepare the data by subtracting its mean. You can restore the filtered signal amplitude by adding the mean of the input data to the filter output values.
- Use the ideal *notch* filter when you want to remove variations in a specific frequency range. Alternatively, use the ideal *pass* filter to allow only the variations in a specific frequency range.
- If the time-series data is sampled nonuniformly, filtering resamples this data on a uniform time vector.
- All NaNs in the time series are interpolated before filtering, using the interpolation method you assigned to the `timeseries` object.

## Input Arguments

### **ts**

The `timeseries` object to which you want to apply an ideal filter.

### **interval**

The frequency interval (specified in cycles per time unit) at which you want the ideal filter applied. To specify several frequency intervals, use an  $n$ -by-2 array of start and end frequencies, where  $n$  represents the number of intervals.

### **filtertype**

A string specifying the type of filter you want to apply, either `pass` or `notch`.

### **index**

An integer array that specifies the columns or rows to filter when `ts.IsTimeFirst` is `true`.

## Output Arguments

### **ts1**

The `timeseries` object that results when you apply an ideal filter to the original `timeseries` object.

## Definitions

### **ideal filter**

Filters are *ideal* in the sense that they are *not realizable*. An ideal filter is noncausal and the ends of the filter amplitude are perfectly flat in the frequency domain.

## Examples

### Apply Ideal Notch and Pass Filters

This example first applies an ideal notch filter to the data in `count.dat`. Then, it applies a pass filter to the data.

Load the count matrix into the workspace:

```
load count.dat
```

Create a timeseries object from column one of this matrix. Specify a time vector that ranges from 1 to 24 s in 1-s intervals.

```
count1 = timeseries(count(:,1),1:24);
```

Obtain the mean of the data:

```
countmean = mean(count1);
```

Enter the frequency interval, in hertz, for filtering the data:

```
interval = [0.08 0.2];
```

Invoke an ideal notch filter:

```
idealfilter_countn = idealfilter(count1,interval,'notch');
```

Compare the original data and the shaped data on a line plot:

```
plot(count1,'-.')
grid on
hold on
plot(idealfilter_countn,'-')
```

Restore the mean to the filtered data and show it on the line plot, adding a legend and a title:

```
countn_restored = idealfilter_countn + countmean;
plot(countn_restored,':')
title('Notch Filter')
legend('Original Data','Shaped Data','Mean Restored',...
 'Location','NorthWest')
```

Close the Figure window:

```
close
```

Then, repeat the process using a **pass** rather than a notch filter:

```
figure
```

```
plot(count1, '-.')
```

```
grid on
```

```
hold on
```

```
idealfilter_countp = idealfilter(count1, interval, 'pass');
```

```
plot(idealfilter_countp, '-')
```

```
countp_restored = idealfilter_countp + countmean;
plot(countp_restored, ':')

title('Pass Filter')
legend('Original Data', 'Shaped Data', 'Mean Restored', ...
 'Location', 'NorthWest')
```

## See Also

[timeseries](#) | [filter](#)

# iqr

**Class:** timeseries

Interquartile range of `timeseries` data

## Syntax

```
ts_iqr = iqr(ts)
iqr(ts, Name, Value)
```

## Description

`ts_iqr = iqr(ts)` returns the interquartile range of `ts.Data`.

`iqr(ts, Name, Value)` reruns the interquartile range of `ts.Data` with the specified `Name, Value` pairs.

## Input Arguments

**ts**

The `timeseries` object for which you want the interquartile range of `timeseries` data.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

**'MissingData'**

A string specifying one of two possible values, `remove` or `interpolate`, indicating how to treat missing data during the calculation.

**Default:** `remove`

**'Quality'**

A vector of integers, indicating which quality codes represent missing samples (for vector data) or missing observations (for data arrays with two or more dimensions).

## Output Arguments

**ts\_iqr**

The interquartile range of `ts.Data`, as follows:

- When `ts.Data` is a vector, `ts_iqr` is the difference between the 75th and the 25th percentiles of the `ts.Data` values.
- When `ts.Data` is a matrix, and `IsTimeFirst` is `true`, and the first dimension of `ts` is aligned with time, then `ts_iqr` is a row vector containing the interquartile range of each column of `ts.Data`.

When `ts.Data` is an N-dimensional array, `iqr` always operates along the first nonsingleton dimension of `ts.Data`.

## Examples

Create a time series with a missing value, represented by `NaN`, and then calculate the interquartile range of `ts.Data` after removing the missing value from the calculation:

```
ts = timeseries([3.0 NaN 5 6.1 8], 1:5);
iqr(ts, 'MissingData', 'remove')
```

MATLAB returns:

```
3.0500
```

---

## max

**Class:** timeseries

Maximum value of `timeseries` data

## Syntax

```
ts_max = max(ts)
ts_max = max(ts,Name,Value)
```

## Description

`ts_max = max(ts)` returns the maximum value in the `timeseries` data.

`ts_max = max(ts,Name,Value)` returns the maximum value in the `timeseries` data with additional options specified by one or more `Name,Value` pair arguments.

## Input Arguments

**ts**

The `timeseries` object for which you want to determine the maximum data value.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**'MissingData'**

A string specifying one of two possible values, `remove` or `interpolate`, indicating how to treat missing data during the calculation.

**Default:** remove

**'Quality'**

A vector of integers, indicating which quality codes represent missing samples (for vector data) or missing observations (for data arrays with two or more dimensions).

## Output Arguments

**ts\_max**

The maximum data value in the specified `timeseries` object, as follows:

- When `ts.Data` is a vector, `ts_max` is the maximum value of `ts.Data` values.
- When `ts.Data` is a matrix, `IsTimeFirst` is `true`, and the first dimension of `ts` is aligned with time, then `ts_max` is a row vector containing the maximum value of each column of `ts.Data`.

When `ts.Data` is an N-dimensional array, `max` always operates along the first nonsingleton dimension of `ts.Data`.

## Examples

The following example illustrates how to find the maximum values in multivariate time-series data:

```
% Load a 24-by-3 data array:
load count.dat

% Create a timeseries object with 24 time values:
count_ts = timeseries(count,[1:24],'Name','CountPerSecond')

% Find the maximum in each data column for this timeseries object:

max(count_ts)

MATLAB returns:

114 145 257
```

**See Also**

## mean

**Class:** timeseries

Mean value of `timeseries` data

## Syntax

```
ts_mn = mean(ts)
ts_mn = mean(ts,Name,Value)
```

## Description

`ts_mn = mean(ts)` returns the mean value of `ts.Data`.

`ts_mn = mean(ts,Name,Value)` returns the mean value of `ts.Data` with additional options specified by one or more `Name,Value` pair arguments.

## Input Arguments

**ts**

The `timeseries` object for which you want the mean value of data.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**'MissingData'**

A string specifying one of two possible values, `remove` or `interpolate`, indicating how to treat missing data during the calculation.

**Default:** remove

### 'Quality'

A vector of integers, indicating which quality codes represent missing samples (for vector data) or missing observations (for data arrays with two or more dimensions).

### 'Weighting'

A string specifying one of two possible values, **none** or **time**.

When you specify **time**, larger time values correspond to larger weights.

## Output Arguments

### **ts\_mn**

The mean value of **ts.Data**, as follows:

- When **ts.Data** is a vector, **ts\_mn** is the mean value of **ts.Data** values.
- When **ts.Data** is a matrix, and **IsTimeFirst** is **true** and the first dimension of **ts** is aligned with time, then **ts\_mn** is a row vector containing the mean value of each column of **ts.Data**.

When **ts.Data** is an N-dimensional array, **mean** always operates along the first nonsingleton dimension of **ts.Data**.

## Examples

Find the mean values in multivariate time-series data:

```
% Load a 24-by-3 data array:
```

```
load count.dat
```

```
% Create a timeseries object with 24 time values:
```

```
count_ts = timeseries(count,[1:24],'Name','CountPerSecond')
```

```
% Find the mean of each data column for this timeseries object:
```

```
mean(count_ts)
```

MATLAB returns:

```
32.0000 46.5417 65.5833
```

## Algorithms

MATLAB determines weighting by:

- 1 Attaching a weighting to each time value, depending on its order, as follows:
  - First time point — The duration of the first time interval ( $t(2) - t(1)$ ).
  - Time point that is neither the first nor last time point — The duration between the midpoint of the previous time interval to the midpoint of the subsequent time interval ( $(t(k + 1) - t(k))/2 + (t(k) - t(k - 1))/2$ ).
  - Last time point — The duration of the last time interval ( $t(\text{end}) - t(\text{end} - 1)$ ).
- 2 Normalizing the weighting for each time by dividing each weighting by the mean of all weightings.

---

**Note:** If the `timeseries` object is uniformly sampled, then the normalized weighting for each time is 1.0. Therefore, time weighting has no effect.

---

- 3 Multiplying the data for each time by its normalized weighting.

## See Also

# median

**Class:** timeseries

Median value of `timeseries` data

## Syntax

```
ts_med = median(ts)
ts_med = method(ts,Name,Value)
```

## Description

`ts_med = median(ts)` returns the median value of `ts.Data`.

`ts_med = method(ts,Name,Value)` returns the median value of `ts.Data` with additional options specified by one or more `Name,Value` pair arguments.

## Input Arguments

**ts**

The `timeseries` object for which you want the median data value.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**'MissingData'**

A string specifying one of two possible values, `remove` or `interpolate`, indicating how to treat missing data during the calculation.

**Default:** `remove`

## 'Quality'

A vector of integers, indicating which quality codes represent missing samples (for vector data) or missing observations (for data arrays with two or more dimensions).

## 'Weighting'

A string specifying one of two possible values, `none` or `time`.

When you specify `time`, larger time values correspond to larger weights.

## Output Arguments

### `ts_med`

The median value of `ts.Data`, as follows:

- When `ts.Data` is a vector, `ts_med` is the mean value of `ts.Data` values.
- When `ts.Data` is a matrix, and `IsTimeFirst` is `true`, and the first dimension of `ts` is aligned with time, then `ts_med` is a row vector containing the median value of each column of `ts.Data`.

When `ts.Data` is an N-dimensional array, `median` always operates along the first nonsingleton dimension of `ts.Data`.

## Examples

The following example finds the median values in multivariate time-series data. MATLAB finds the median independently for each data column in the `timeseries` object:

```
% Load a 24-by-3 data array:
```

```
load count.dat
```

```
% Create a timeseries object with 24 time values:
```

```
count_ts = timeseries(count,[1:24], 'Name', 'CountPerSecond');
```

```
% Find the median of each data column for this timeseries object:
```

```
median(count_ts)
```

MATLAB returns:

```
23.5000 36.0000 39.0000
```

## Algorithms

MATLAB determines weighting by:

- 1 Attaching a weighting to each time value, depending on its order, as follows:
  - First time point — The duration of the first time interval ( $t(2) - t(1)$ ).
  - Time point that is neither the first nor last time point — The duration between the midpoint of the previous time interval to the midpoint of the subsequent time interval ( $(t(k+1) - t(k))/2 + (t(k) - t(k-1))/2$ ).
  - Last time point — The duration of the last time interval ( $t(\text{end}) - t(\text{end} - 1)$ ).
- 2 Normalizing the weighting for each time by dividing each weighting by the mean of all weightings.

---

**Note:** If the `timeseries` object is uniformly sampled, then the normalized weighting for each time is 1.0. Therefore, time weighting has no effect.

---

- 3 Multiplying the data for each time by its normalized weighting.

Introduced before R2006a

## **min**

**Class:** timeseries

Minimum value of `timeseries` data

## **Syntax**

```
ts_min = min(ts)
ts_min = method(ts,Name,Value)
```

## **Description**

`ts_min = min(ts)` returns the minimum value in the `timeseries` data.

`ts_min = method(ts,Name,Value)` uses additional options specified by one or more `Name,Value` pair arguments.

## **Input Arguments**

**ts**

The `timeseries` object for which you want the minimum data value.

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**'MissingData'**

A string specifying one of two possible values, `remove` or `interpolate`, indicating how to treat missing data during the calculation.

**Default:** `remove`

### 'Quality'

A vector of integers, indicating which quality codes represent missing samples (for vector data) or missing observations (for data arrays with two or more dimensions).

## Output Arguments

### `ts_min`

The minimum value of `ts.Data`, as follows:

- When `ts.Data` is a vector, `ts_min` is the minimum value of `ts.Data` values.
- When `ts.Data` is a matrix, and `IsTimeFirst` is `true`, and the first dimension of `ts` is aligned with time, then `ts_min` is a row vector containing the minimum value of each column of `ts.Data`.

When `ts.Data` is an N-dimensional array, `min` always operates along the first nonsingleton dimension of `ts.Data`.

## Examples

The following example finds the minimum values in multivariate time-series data. MATLAB finds the minimum independently for each data column in the `timeseries` object.

```
% Load a 24-by-3 data array:
```

```
load count.dat
```

```
% Create a timeseries object with 24 time values:
```

```
count_ts = timeseries(count,[1:24],'Name','CountPerSecond');
```

```
% Find the minimum in each data column for this timeseries object:
```

```
min(count_ts)
```

MATLAB returns:

```
7 9 7
```

# plot

**Class:** timeseries

Plot time series

## Syntax

```
plot(ts)
plot(tsc.tsname)
plot(ts,linespec)
plot(tsc.tsname,linespec)
plot(ts,Name, Value)
plot(tsc.tsname,Name, Value)
```

## Description

`plot(ts)` plots the **timeseries** data `ts` against time and interpolates values between samples by using either zero-order-hold ('zoh') or linear interpolation (the default). The plot displays in the current axes. MATLAB creates a title and axes, if none exists.

`plot(tsc.tsname)` plots the **timeseries** object, `tsname` that is part of the **tscollection**, `tsc`.

`plot(ts,linespec)` plots the **timeseries** data using a line graph and applies the specified `linespec` to lines, markers, or both.

`plot(tsc.tsname,linespec)` plots the **timeseries** object that is part of a **timeseries** collection as a line graph and applies the specified `linespec` to lines, markers, or both.

`plot(ts,Name, Value)` plots a line graph of the time series data using the values specified for Chart Line Properties.

`plot(tsc.tsname,Name, Value)` plots a line graph of the **timeseries** object that is part of the specified **timeseries** collection using the values specified for Chart Line Properties.

## Tips

- The `timeseries/plot` method generates titles and axis labels automatically. These labels are:
  - Plot Title — `'Time Series Plot: <name>'`  
where `<name>` is the string assigned to `ts.Name`, or by default, `'unnamed'`
  - X-Axis Label — `'Time (<units>)'`  
where `<units>` is the value of the `ts.TimeInfo.Units` field, which defaults to `'seconds'`
  - Y-Axis Label — `'<name>'`  
where `<name>` is the string assigned to `ts.Name`, or by default, `'unnamed'`
- You can place new time series data on a time series plot (by setting `hold` on, for example, and issuing another `timeseries/plot` command). When you add data to a plot, the title and axis labels become blank strings to avoid labeling confusion. You can add your own labels after plotting using the `title`, `xlabel`, and `ylabel` commands.
- Time series events, when defined, are marked in the plot with a circular marker with red fill. You can also specify markers for all data points using a `linespec` or `name/value` syntax in addition to any event markers your data defines. The event markers plot on top of the markers you define.
- The value assigned to `ts.DataInfo.Interpolation.Name` controls the type of interpolation the `plot` method uses when plotting and resampling time series data. Invoke the `timeseries` method `setinterpmethod` to change default linear interpolation to zero-order hold interpolation (staircase). This method creates a new `timeseries` object, with which you can overwrite the original one if you want. For example, to cause time series `ts` to use zero-order hold interpolation, type the following:

```
ts = ts.setinterpmethod('zoh');
```

## Input Arguments

### **ts**

A `timeseries` object.

### **tsc**

A `tscollection`.

### **tsname**

The name of a `timeseries` object within the `tscollection`.

## Examples

### Plot Time Series Object with Specified Start Date

Create a time series object, set the start date, and then plot the time vector relative to the start date.

```
x = [2 5 8 2 11 3 6];
ts1 = timeseries(x,1:7);

ts1.Name = 'Daily Count';
ts1.TimeInfo.Units = 'days';
ts1.TimeInfo.StartDate = '01-Jan-2011'; % Set start date.
ts1.TimeInfo.Format = 'mmm dd, yy'; % Set format for display on x-axis.

ts1.Time = ts1.Time - ts1.Time(1); % Express time relative to the start date.

plot(ts1)
```

### Plot Two Time Series Objects on the Same Axes

Create two time series objects from traffic count data, and then plot them in sequence on the same axes. Add an event to one series, which is automatically displayed with a red marker.

```
load count.dat;
count1 = timeseries(count(:,1),1:24);
count1.Name = 'Oak St. Traffic Count';
count1.TimeInfo.Units = 'hours';
plot(count1,':b')
grid on
```

Obtain time of maximum value and add it as an event:

```
[~,index] = max(count1.Data);
max_event = tsdata.event('peak',count1.Time(index));
max_event.Units = 'hours';
```

Add the event to the time series:

```
count1 = addevent(count1,max_event);
```

Replace plot with new one showing the event:

```
plot(count1, '-.b')
grid on
```

Make a new time series object from column 2 of the same data source:

```
count2 = timeseries(count(:,2),1:24);
count2.Name = 'Maple St. Traffic Count';
count2.TimeInfo.Units = 'Hours';
```

Turn hold on to add the new data to the plot:

```
hold on
```

The plot method does not add labels to a held plot. Use property/value pairs to customize markers:

```
plot(count2, 's-m', 'MarkerSize', 6),
```

Labels are erased, so generate them manually:

```
title('Time Series: Oak Street and Maple Street')
xlabel('Hour of day')
ylabel('Vehicle count')
```

Add a legend in the upper left:

```
legend('Oak St.', 'Maple St.', 'Location', 'northwest')
```

Introduced before R2006a

# resample

**Class:** timeseries

Select or interpolate `timeseries` data using new time vector

## Syntax

```
ts1 = resample(ts, time)
ts1 = resample(ts, time, interp_method)
ts1 = resample(ts, time, interp_method, code)
```

## Description

`ts1 = resample(ts, time)` resamples the `timeseries` object, `ts`, using the new time vector. The `resample` method uses the default interpolation method, which you can view by using the `getinterpmethod(ts)` syntax.

`ts1 = resample(ts, time, interp_method)` resamples the `timeseries` object `ts` using the specified interpolation method, `interp_method`.

`ts1 = resample(ts, time, interp_method, code)` resamples the `timeseries` object `ts` using the interpolation method given by the string `interp_method`. MATLAB applies the `code` to all samples.

## Input Arguments

### **ts**

The `timeseries` object that you want to resample.

### **time**

The time vector you want to use to resample the `timeseries` object.

When `ts` uses date strings and `time` is numeric, then `time` is treated as specified relative to the `ts.TimeInfo.StartDate` property and in the same units that `ts` uses.

**interp\_method**

A string specifying the interpolation method. Valid interpolation methods are `linear` and `zero-order hold, zoh`.

**Default:** `linear`

**code**

An integer value that specifies the user-defined `Quality` code for resampling. MATLAB applies this `Quality` code to all samples.

## Output Arguments

**ts1**

The `timeseries` object that results when you interpolate the original `timeseries` object with a new time vector.

## Examples

This example shows how to resample a `timeseries` object.

Create a `timeseries` object.

```
ts1 = timeseries([1.1; 2.9; 3.7; 4.0; 3.0],1:5,'Name','speed');
```

View the time, data, and interpolation method.

```
ts1.time
ts1.data
ts1.getinterpmethod
```

Resample `ts1` using its default interpolation method.

```
res_ts=resample(ts1,[1 1.5 3.5 4.5 4.9]);
```

View the time, data, and interpolation method for the resampled object.

```
res_ts.time
res_ts.data
```

`res_ts.getinterpmethod`

## **See Also**

## set

**Class:** timeseries

Set properties of `timeseries` object

## Syntax

```
set(ts, PropertyName, Value)
set(ts, PropertyName)
set(ts)
```

## Description

`set(ts, PropertyName, Value)` sets the named property, `Name`, of the `timeseries` object, `ts`, to the value, `Value`. The following syntax is equivalent:

```
ts.Property = Value
```

`set(ts, PropertyName)` displays the value of the named property for the `timeseries` object, `ts`.

`set(ts)` displays all properties and values of the `timeseries` object `ts`.

## Input Arguments

### **ts**

A `timeseries` object.

### **PropertyName**

A string specifying the name of a `timeseries` property. For a list of `timeseries` properties, see `timeseries`.

### **Value**

The value to which you want to set the named property.

## Examples

Create a `timeseries`, set its name to `mytimeseries`, and then view the `timeseries` properties:

```
ts1 = timeseries(rand(5,1),[1 2 3 4 5]);
set(ts1, 'Name', 'mytimeseries')
set(ts1)
```

## See Also

`timeseries` | `get`

**Introduced before R2006a**

## setabstime

**Class:** timeseries

Set times of `timeseries` object as date strings

### Syntax

```
ts1=setabstime(ts, times)
ts1=setabstime(ts, times, format)
```

### Description

`ts1=setabstime(ts, times)` sets the times in `ts` to the date strings specified in `times`.

`ts1=setabstime(ts, times, format)` explicitly specifies the date-string format, `format`, used in `times`.

### Input Arguments

#### **ts**

The `timeseries` object for which you want to set times as date strings.

#### **times**

A cell array of strings or a `char` array containing valid date or time values in the same date format.

#### **format**

The date-string format used for the time values.

## Output Arguments

**ts1**

The `timeseries` object that results from setting times as date strings on the original `timeseries` object.

## Examples

Create a `timeseries` object, and then set the absolute time vector:

```
ts = timeseries(rand(3,1))
ts1 = setabstime(ts,{'12-DEC-2005 12:34:56',...
 '12-DEC-2005 13:34:56','12-DEC-2005 14:34:56'})
```

% View each `timeseries` object in the Variable Editor to see the  
% differences in the time vectors for each.

## See Also

`datestr` | `getabstime` | `timeseries`

# setinterpmethod

**Class:** timeseries

Set default interpolation method for `timeseries` object

## Syntax

```
ts = setinterpmethod(ts, method)
ts = setinterpmethod(ts, fhandle)
ts = setinterpmethod(ts, interpobj)
```

## Description

`ts = setinterpmethod(ts, method)` sets the default interpolation method, `method`, for `timeseries` object, `ts`, and outputs it to `ts1`.

`ts = setinterpmethod(ts, fhandle)` sets the default interpolation method for `timeseries` object `ts`, where `fhandle` is a function handle to the interpolation method.

`ts = setinterpmethod(ts, interpobj)` sets the default interpolation method for `timeseries` object `ts`, where `interpobj` is a `tsdata.interpolation` object that directly replaces the interpolation object stored in `ts`.

## Tips

- This method is case sensitive.

## Input Arguments

**ts**

The `timeseries` object for which you want to set the default interpolation method.

**method**

A string specifying the interpolation method. Valid values are `linear` and zero-order hold, `zoh`.

**Default:** `linear`

**fhandle**

A function handle to the interpolation method. The order of input arguments defining the function handle must be `new_time`, `time`, and `data`. The single output argument must be the interpolated data only.

**interpobj**

A `tsdata.interpolation` object that directly replaces the interpolation object stored in `ts`.

## Output Arguments

**ts1**

The `timeseries` object that results when you set the interpolation method for the original `timeseries` object.

## Examples

Set the default interpolation method for `timeseries` object `ts` to zero order hold:

```
ts = timeseries(rand(100,1),1:100);
ts = setinterpmethod(ts,'zoh');
plot(ts);
```

Set the default interpolation method for `timeseries` object `ts`, where `fhandle` is a function handle to the interpolation method defined by function handle `myFuncHandle`:

```
ts = timeseries(rand(100,1),1:100);
myFuncHandle = @(new_time, time, data)...
 interp1(time, data, new_time,...
 'linear','extrap');
```

```
ts = setinterpmethod(ts, myFuncHandle);
ts = resample(ts, [-5:0.1:10]);
plot(ts);
```

Set the default interpolation method for `timeseries` object `ts` to a `tsdata.interpolation` object:

```
ts = timeseries(rand(100,1),1:100);
myFuncHandle = @(new_time, time, data)...
 interp1(time, data, new_time,...
 'linear','extrap');
myInterpObj = tsdata.interpolation(myFuncHandle);
ts = setinterpmethod(ts,myInterpObj);
plot(ts);
```

## See Also

`timeseries` | `getinterpmethod`

**Introduced before R2006a**

# setuniformtime

**Class:** timeseries

Modify uniform time vector of timeseries object

## Syntax

```
ts2 = setuniformtime(ts1, 'StartTime', StartTime)
ts2 = setuniformtime(ts1, 'Interval', Interval)
ts2 = setuniformtime(ts1, 'EndTime', EndTime)
ts2 = setuniformtime(ts1, 'StartTime', StartTime, 'Interval', Interval)
ts2 = setuniformtime(ts1, 'StartTime', StartTime, 'EndTime', EndTime)
ts2 = setuniformtime(ts1, 'Interval', Interval, 'EndTime', EndTime)
```

## Description

`ts2 = setuniformtime(ts1, 'StartTime', StartTime)` returns the time series with a modified uniform time vector, determined from the `StartTime` and `Interval`.  $EndTime = StartTime + (length(ts1) - 1) * Interval$ . The unit of time is unchanged.

`ts2 = setuniformtime(ts1, 'Interval', Interval)` sets the `StartTime` to 0, and uses  $EndTime = (length(ts1) - 1) * Interval$ .

`ts2 = setuniformtime(ts1, 'EndTime', EndTime)` sets the `StartTime` to 0, and uses  $Interval = EndTime / (length(ts1) - 1)$ .

`ts2 = setuniformtime(ts1, 'StartTime', StartTime, 'Interval', Interval)` uses  $EndTime = StartTime + (length(ts1) - 1) * Interval$ .

`ts2 = setuniformtime(ts1, 'StartTime', StartTime, 'EndTime', EndTime)` uses  $Interval = (EndTime - StartTime) / (length(ts1) - 1)$ .

`ts2 = setuniformtime(ts1, 'Interval', Interval, 'EndTime', EndTime)` uses  $StartTime = EndTime - (length(ts1) - 1) * Interval$ .

## Input Arguments

### **ts1**

timeseries object to which you want to assign a uniform time vector.

### **StartTime**

Start time of uniform time vector, specified as a numeric value.

### **Interval**

Time interval of uniform time vector, specified as a numeric scalar value.

### **EndTime**

End time of uniform time vector specified as a numeric scalar value.

## Output Arguments

### **ts2**

Time series with uniform time vector, returned as a `timeseries` object.

## Examples

### Specify New Start Time

Modify the uniform time vector of time series data by specifying a new start time.

- 1 Load the sample data.

```
load count.dat;
```

- 2 Create a `timeseries` object.

```
count_ts = timeseries(count,1:length(count),'Name','CountPerSecond');
```

- 3 Modify uniform time vector of `count_ts`.

```
count_ts = setuniformtime(count_ts,'StartTime',10);
```

The start time of the time vector is 10 seconds. `setuniformtime` uses a default time interval of 1 and computes the end time using: `EndTime = StartTime + (length(count_ts) - 1)* Interval`.

## Specify New Start and End Times

Modify the uniform time vector of time series data by specifying a new start time and end time.

- 1 Load sample data.

```
load count.dat;
```

- 2 Create `timeseries` object.

```
count_ts = timeseries(count,1:length(count),'Name','CountPerSecond');
```

- 3 Assign a uniform time vector to `count_ts`.

```
count_ts2 = setuniformtime(count_ts,'StartTime',10,'EndTime',20);
```

The start time of the time vector is now 10 seconds, and the end time is now 20 seconds. MATLAB computes the time interval using: `Interval = (EndTime - StartTime)/(length(count_ts) - 1)`

## See Also

`timeseries`

# synchronize

**Class:** timeseries

Synchronize and resample two `timeseries` objects using common time vector

## Syntax

```
[ts1 ts2] = synchronize(ts1,ts2,synchronizemethod)
[ts1 ts2] = synchronize(____,Name,Value)
```

## Description

`[ts1 ts2] = synchronize(ts1,ts2,synchronizemethod)` creates two new `timeseries` objects by synchronizing `ts1` and `ts2` using a common time vector and the specified method.

`[ts1 ts2] = synchronize( ____,Name,Value)` creates the two new `timeseries` objects with additional options specified by one or more `Name,Value` pair arguments for the previous syntax.

## Input Arguments

### `ts1`

One of the `timeseries` objects that you want to synchronize and resample.

### `ts2`

The other `timeseries` object that you want to synchronize and resample.

### `synchronizemethod`

A string that defines the method for synchronizing the `timeseries` object. It can be any one of the following:

- **Union** — Resample `timeseries` objects using a time vector that is a union of the time vectors of `ts1` and `ts2` on the time range where the two time vectors overlap.

- **Intersection** — Resample `timeseries` objects on a time vector that is the intersection of the time vectors of `ts1` and `ts2`.
- **Uniform** — Requires an additional argument as follows:

```
[ts1 ts2] = synchronize(ts1,ts2,'Uniform','Interval',value)
```

This method resamples time series on a uniform time vector, where `value` specifies the time interval between two consecutive samples. The uniform time vector is the overlap of the time vectors of `ts1` and `ts2`. The interval units are the smaller units of `ts1` and `ts2`.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### 'InterpMethod'

Forces the specified interpolation method (over the default method) for this `synchronize` operation. Can be either a string, `linear` or `zoh`, or a `tsdata.interpolation` object that contains a user-defined interpolation method.

**Default:** `linear`

### 'QualityCode'

Integer (between -128 and 127) used as the quality code for both time series after the synchronization.

### 'KeepOriginalTimes'

Logical value (`true` or `false`) indicating whether the new time series should keep the original time values.

### 'tolerance'

Real number used as the tolerance for differentiating two time values when comparing the `ts1` and `ts2` time vectors. The default tolerance is `1e-10`. For example, when the sixth time value in `ts1` is `5+(1e-12)` and the sixth time value in `ts2` is `5-(1e-13)`,

both values are treated as 5 by default. To differentiate those two times, you can set 'tolerance' to a smaller value such as `1e-15`, for example.

## Output Arguments

### **ts1**

One of the `timeseries` objects that you synchronized and resampled.

### **ts2**

The other `timeseries` object that you synchronized and resampled.

## Examples

This example illustrates how the `KeepOriginalTime` property affects synchronization.

```
% Create two timeseries, such that ts1.timeinfo.StartDate
% is one day after ts2.timeinfo.StartDate:
```

```
ts1 = timeseries([1 2],[datestr(now); datestr(now+1)]);
ts2 = timeseries([1 2],[datestr(now-1); datestr(now)]);
```

```
% If you use this code, then ts1.timeinfo.StartDate
% is changed to match ts2.TimeInfo.StartDate
% and ts1.Time changes to 1:
```

```
[ts1 ts2] = synchronize(ts1,ts2,'union');
```

```
% But if you use this code, then ts1.timeinfo.StartDate
% is unchanged and ts1.Time is still 0:
```

```
[ts1 ts2] = synchronize(ts1,ts2,'union','KeepOriginalTimes',true);
```

# std

**Class:** timeseries

Standard deviation of `timeseries` data

## Syntax

```
ts_std = std(ts)
ts_std = std(ts,Name,Value)
```

## Description

`ts_std = std(ts)` returns the standard deviation of the `timeseries` data.

`ts_std = std(ts,Name,Value)` specifies additional options specified with one or more `Name,Value` pair arguments.

## Input Arguments

### **ts**

The `timeseries` object for which you want the standard deviation of the data.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### **'MissingData'**

A string specifying one of two possible values, `remove` or `interpolate`, indicating how to treat missing data during the calculation.

**Default:** `remove`

## 'Quality'

A vector of integers, indicating which quality codes represent missing samples (for vector data) or missing observations (for data arrays with two or more dimensions).

## 'Weighting'

A string specifying one of two possible values, `none` or `time`.

When you specify `time`, larger time values correspond to larger weights.

## Output Arguments

### `ts_std`

The standard deviation of `ts.Data` values as follows:

- When `ts.Data` is a vector, `ts_std` is the standard deviation of `ts.Data` values.
- When `ts.Data` is a matrix, and `IsTimeFirst` is `true`, and the first dimension of `ts` is aligned with time, then `ts_std` is the standard deviation of each column of `ts.Data`.

When `ts.Data` is an N-dimensional array, `std` always operates along the first nonsingleton dimension of `ts.Data`.

## Examples

The following example finds the standard deviation for a `timeseries` object. MATLAB calculates the standard deviation for each data column in the `timeseries` object.

```
% Load a 24-by-3 data array:
```

```
load count.dat
```

```
% Create a timeseries object with 24 time values:
```

```
count_ts = timeseries(count,1:24,'Name','CountPerSecond');
```

```
% Calculate the standard deviation of each data column for this
% timeseries object:
```

```
std(count_ts)
```

MATLAB returns:

```
25.3703 41.4057 68.0281
```

## Algorithms

MATLAB determines weighting by:

- 1 Attaching a weighting to each time value, depending on its order, as follows:
  - First time point — The duration of the first time interval ( $t(2) - t(1)$ ).
  - Time point that is neither the first nor last time point — The duration between the midpoint of the previous time interval to the midpoint of the subsequent time interval ( $(t(k + 1) - t(k))/2 + (t(k) - t(k - 1))/2$ ).
  - Last time point — The duration of the last time interval ( $t(\text{end}) - t(\text{end} - 1)$ ).
- 2 Normalizing the weighting for each time by dividing each weighting by the mean of all weightings.

---

**Note:** If the `timeseries` object is uniformly sampled, then the normalized weighting for each time is 1.0. Therefore, time weighting has no effect.

---

- 3 Multiplying the data for each time by its normalized weighting.

## See Also

## sum

**Class:** timeseries

Sum of `timeseries` data

## Syntax

```
ts_sm = sum(ts)
ts_sm = sum(ts,Name,Value)
```

## Description

`ts_sm = sum(ts)` returns the sum of the `timeseries` data.

`ts_sm = sum(ts,Name,Value)` specifies additional options with one or more `Name,Value` pair arguments.

## Input Arguments

### **ts**

The `timeseries` object for which you want the sum of the data.

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### **'MissingData'**

A string specifying one of two possible values, `remove` or `interpolate`, indicating how to treat missing data during the calculation.

**Default:** remove

### 'Quality'

A vector of integers, indicating which quality codes represent missing samples (for vector data) or missing observations (for data arrays with two or more dimensions).

### 'Weighting'

A string specifying one of two possible values, **none** or **time**.

When you specify **time**, larger time values correspond to larger weights.

## Output Arguments

### **ts\_sm**

The sum of the `timeseries` data, as follows:

- When `ts.Data` is a vector, `ts_sm` is the sum of `ts.Data` values.
- When `ts.Data` is a matrix, and `IsTimeFirst` is `true`, and the first dimension of `ts` is aligned with time, then `ts_sm` is a row vector containing the sum of each column of `ts.Data`.

When `ts.Data` is a N-dimensional array, `sum` always operates along the first nonsingleton dimension of `ts.Data`.

## Examples

Calculate the sum of each data column for a `timeseries` object:

```
% Load a 24-by-3 data array:
```

```
load count.dat
```

```
% Create a timeseries object with 24 time values:
```

```
count_ts = timeseries(count,1:24,'Name','CountPerSecond');
```

```
% Calculate the sum of each data column for this timeseries object:
```

```
sum(count_ts)
```

MATLAB returns:

```
768 1117 1574
```

## Algorithms

MATLAB determines weighting by:

- 1 Attaching a weighting to each time value, depending on its order, as follows:
  - First time point — The duration of the first time interval ( $t(2) - t(1)$ ).
  - Time point that is neither the first nor last time point — The duration between the midpoint of the previous time interval to the midpoint of the subsequent time interval ( $(t(k + 1) - t(k))/2 + (t(k) - t(k - 1))/2$ ).
  - Last time point — The duration of the last time interval ( $t(\text{end}) - t(\text{end} - 1)$ ).
- 2 Normalizing the weighting for each time by dividing each weighting by the mean of all weightings.

---

**Note:** If the `timeseries` object is uniformly sampled, then the normalized weighting for each time is 1.0. Therefore, time weighting has no effect.

---

- 3 Multiplying the data for each time by its normalized weighting.

## var

**Class:** timeseries

Variance of `timeseries` data

## Syntax

```
ts_var = var(ts)
ts_var = var(ts,Name,Value)
```

## Description

`ts_var = var(ts)` returns the variance of `ts.data`.

`ts_var = var(ts,Name,Value)` uses additional options specified by one or more `Name,Value` pair arguments.

## Input Arguments

**ts**

The `timeseries` object for which you want the variance of the data.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**'MissingData'**

A string specifying one of two possible values, `remove` or `interpolate`, indicating how to treat missing data during the calculation.

**Default:** `remove`

**'Quality'**

A vector of integers, indicating which quality codes represent missing samples (for vector data) or missing observations (for data arrays with two or more dimensions).

**'Weighting'**

A string specifying one of two possible values, `none` or `time`.

When you specify `time`, larger time values correspond to larger weights.

## Output Arguments

**ts\_var**

The variance of `ts.data`, as follows:

- When `ts.Data` is a vector, then `ts_var` is the variance of `ts.Data` values.
- When `ts.Data` is a matrix, and `IsTimeFirst` is `true`, and the first dimension of `ts` is aligned with time, then `ts_var` is a row vector containing the variance of each column of `ts.Data`.

When `ts.Data` is an N-dimensional array, `var` always operates along the first nonsingleton dimension of `ts.Data`.

## Examples

The following example calculates the variance values of a multivariate `timeseries` object. MATLAB calculates the variance independently for each data column in the `timeseries` object.

Load a 24-by-3 data array. Then create a `timeseries` object with 24 time values.

```
load count.dat
count_ts = timeseries(count,[1:24], 'Name', 'CountPerSecond');
```

Calculate the variance of each data column.

```
var(count_ts)
```

MATLAB returns:

```
1.0e+03 *
0.6437 1.7144 4.6278
```

## Algorithms

MATLAB determines weighting by:

- 1 Attaching a weighting to each time value, depending on its order, as follows:
  - First time point — The duration of the first time interval ( $t(2) - t(1)$ ).
  - Time point that is neither the first nor last time point — The duration between the midpoint of the previous time interval to the midpoint of the subsequent time interval ( $(t(k + 1) - t(k))/2 + (t(k) - t(k - 1))/2$ ).
  - Last time point — The duration of the last time interval ( $t(\text{end}) - t(\text{end} - 1)$ ).
- 2 Normalizing the weighting for each time by dividing each weighting by the mean of all weightings.

---

**Note:** If the `timeseries` object is uniformly sampled, then the normalized weighting for each time is 1.0. Therefore, time weighting has no effect.

---

- 3 Multiplying the data for each time by its normalized weighting.

# triangulation class

Triangulation in 2-D or 3-D

## Description

Use `triangulation` to create an in-memory representation of any 2-D or 3-D triangulation data that is in matrix format, such as the matrix output from the `delaunay` function or other software tools. When your data is represented using `triangulation`, you can perform topological and geometric queries, which you can use to develop geometric algorithms. For example, you can find the triangles or tetrahedra attached to a vertex, those that share an edge, their circumcenters, and other features.

## Construction

`TR = triangulation(T,P)` creates a 2-D or 3-D triangulation representation using the triangulation connectivity list, `T`, and the points in matrix `P`.

`TR = triangulation(T,x,y)` creates a 2-D triangulation representation with the point coordinates specified as column vectors, `x` and `y`.

`TR = triangulation(T,x,y,z)` creates a 3-D triangulation representation with the point coordinates specified as column vectors, `x`, `y`, and `z`.

## Input Arguments

### **T**

Triangulation connectivity list, specified as an  $m$ -by- $n$  matrix, where  $m$  is the number of triangles or tetrahedra, and  $n$  is the number of vertices per triangle or tetrahedron. Each element in `T` is a “Vertex ID” on page 1-7428. Each row of `T` contains the vertex IDs that define a triangle or tetrahedron.

### **P**

Points, specified as a matrix whose columns are the `x`, `y`, (and possibly `z`) coordinates of the triangulation points. The row numbers of `P` are the vertex IDs in the triangulation.

**x**

$x$ -coordinates vector, specified as a column vector containing the  $x$ -coordinates of the triangulation points.

**y**

$y$ -coordinates vector, specified as a column vector containing the  $y$ -coordinates of the triangulation points.

**z**

$z$ -coordinates vector, specified as a column vector containing the  $z$ -coordinates of the triangulation points.

## Properties

### Points

Points in the triangulation, represented as a matrix containing the following information:

- Each row in `TR.Points` contains the coordinates of a vertex.
- Each row number of `TR.Points` is a vertex ID.

### ConnectivityList

Triangulation connectivity list, represented as a matrix. This matrix contains the following information:

- Each element in `TR.ConnectivityList` is a vertex ID.
- Each row represents a triangle or tetrahedron in the triangulation.
- Each row number of `TR.ConnectivityList` is a “Triangle or Tetrahedron ID” on page 1-7428.

## Methods

`barycentricToCartesian`

Converts point coordinates from barycentric to Cartesian

cartesianToBarycentric	Converts point coordinates from Cartesian to barycentric
circumcenter	Circumcenter of triangle or tetrahedron
edgeAttachments	Triangles or tetrahedra attached to specified edge
edges	Triangulation edges
faceNormal	Triangulation face normal
featureEdges	Triangulation sharp edges
freeBoundary	Triangulation facets referenced by only one triangle or tetrahedron
incenter	Incenter of triangle or tetrahedron
isConnected	Test if two vertices are connected by edge
nearestNeighbor	Vertex closest to specified location
neighbors	Neighbors to specified triangle or tetrahedron
pointLocation	Triangle or tetrahedron containing specified point
size	Size of triangulation connectivity list
vertexAttachments	Triangles or tetrahedra attached to specified vertex
vertexNormal	Triangulation vertex normal

## Definitions

### Vertex ID

A row number of the matrix, `TR.Points`. Use this ID to refer a specific vertex in the triangulation.

### Triangle or Tetrahedron ID

A row number of the matrix, `TR.ConnectivityList`. Use this ID to refer a specific triangle or tetrahedron.

## Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

## Examples

### 2-D Triangulation

Define the points in the triangulation.

```
P = [2.5 8.0
 6.5 8.0
 2.5 5.0
 6.5 5.0
 1.0 6.5
 8.0 6.5];
```

Define the triangles. This is the triangulation connectivity list.

```
T = [5 3 1;
 3 2 1;
 3 4 2;
 4 6 2];
```

Create the triangulation representation.

```
TR = triangulation(T,P)
```

```
TR =
```

```
 triangulation with properties:
 Points: [6x2 double]
 ConnectivityList: [4x3 double]
```

Examine the coordinates of the vertices of the first triangle.

```
TR.Points(TR.ConnectivityList(1,:),:)
```

```
ans =
```

```
 1.0000 6.5000
```

2.5000 5.0000  
2.5000 8.0000

**See Also**

delaunayTriangulation

# barycentricToCartesian

**Class:** triangulation

Converts point coordinates from barycentric to Cartesian

## Syntax

`PC = barycentricToCartesian(TR,ti,B)`

## Description

`PC = barycentricToCartesian(TR,ti,B)` returns the Cartesian coordinates of the points in `B`. Each row, `B(j, :)`, contains the barycentric coordinates of a point with respect to the triangle or tetrahedron, `ti(j)`. The point, `PC(j, :)`, is the `j`th point represented in Cartesian coordinates.

## Input Arguments

### **TR**

Triangulation representation, see `triangulation` or `delaunayTriangulation`.

### **ti**

Triangle or tetrahedron IDs, specified as a column vector.

### **B**

Barycentric coordinates, specified as a matrix. Each row, `B(j, :)`, contains the barycentric coordinates of a point with respect to the triangle or tetrahedron, `ti(j)`.

## Output Arguments

### **PC**

Cartesian coordinates, returned as a matrix. The point, `PC(j, :)`, is the `j`th point represented in Cartesian coordinates.

## Definitions

### Triangle or Tetrahedron ID

A row number of the matrix, `TR.ConnectivityList`. Use this ID to refer a specific triangle or tetrahedron.

## Examples

### Barycentric Coordinates Converted to Cartesian Coordinates

Create a triangulation from a set of points, `P`, and triangulation connectivity list, `T`.

```
P = [2.5 8.0
 6.5 8.0
 2.5 5.0
 6.5 5.0
 1.0 6.5
 8.0 6.5];
```

```
T = [5 3 1;
 3 2 1;
 3 4 2;
 4 6 2];
```

```
TR = triangulation(T,P);
```

Specify the first triangle.

```
ti = 1;
```

Specify the barycentric coordinates of the second point in the triangle.

```
B = [0 1 0];
```

Convert the point to Cartesian coordinates.

```
PC = barycentricToCartesian(TR,ti,B)
```

```
PC =
 2.5000 5.0000
```

### Mapped Incenters of Deformed Triangulation

Create a Delaunay triangulation from a set of points.

```
x = [0 4 8 12 0 4 8 12]';
y = [0 0 0 0 8 8 8 8]';
DT = delaunayTriangulation(x,y);
```

Calculate the Cartesian coordinates of the incenters.

```
cc = incenter(DT);
```

Plot the original triangulation and reference points.

```
figure
subplot(1,2,1);
triplot(DT);
hold on;
plot(cc(:,1),cc(:,2), '*r');
hold off;
axis equal;
```

Create a new triangulation which is a deformed version of DT .

```
ti = DT.ConnectivityList;
y = [0 0 0 0 16 16 16 16]';
TR = triangulation(ti,x,y);
```

Compute the barycentric coordinates for the incenters of DT, and use them to compute the Cartesian coordinates of the analogous points in TR.

```
b = cartesianToBarycentric(DT,[1:length(ti)]',cc);
xc = barycentricToCartesian(TR,[1:length(ti)]',b);
```

Plot the deformed triangulation and mapped locations of the reference points.

```
subplot(1,2,2);
```

```
triplot(TR);
hold on;
plot(xc(:,1),xc(:,2),'*r');
hold off;
axis equal;
```

## See Also

[cartesianToBarycentric](#) | [delaunayTriangulation](#)

## cartesianToBarycentric

**Class:** triangulation

Converts point coordinates from Cartesian to barycentric

### Syntax

$B = \text{cartesianToBarycentric}(TR, ti, PC)$

### Description

$B = \text{cartesianToBarycentric}(TR, ti, PC)$  returns the barycentric coordinates of the points in  $PC$ . Each row,  $PC(j, :)$ , contains the Cartesian coordinates of a point you want to convert.  $B(j, :)$  are the barycentric coordinates of the point,  $PC(j, :)$ , with respect to triangle or tetrahedron,  $ti(j)$ .

### Input Arguments

**TR**

Triangulation representation, see `triangulation` or `delaunayTriangulation`.

**ti**

Triangle or tetrahedron IDs, specified as a column vector.

**PC**

Cartesian coordinates, specified as a matrix. Each row,  $PC(j, :)$ , contains the Cartesian coordinates of a point with respect to triangle or tetrahedron,  $ti(j)$ .

### Output Arguments

**B**

Barycentric coordinates, returned as a matrix.  $B(j, :)$  are the barycentric coordinates of  $PC(j, :)$  with respect to  $ti(j)$ .

## Definitions

### Triangle or Tetrahedron ID

A row number of the matrix, `TR.ConnectivityList`. Use this ID to refer a specific triangle or tetrahedron.

## Examples

### Cartesian Coordinates Converted to Barycentric Coordinates

Create a triangulation from a set of points, `P`, and triangulation connectivity list, `T`.

```
P = [2.5 8.0
 6.5 8.0
 2.5 5.0
 6.5 5.0
 1.0 6.5
 8.0 6.5];
```

```
T = [5 3 1;
 3 2 1;
 3 4 2;
 4 6 2];
```

```
TR = triangulation(T,P);
```

Specify the first triangle.

```
ti = 1;
```

Get the coordinates of the third vertex in the first triangle.

```
PC = TR.Points(TR.ConnectivityList(1,3),:)
```

```
PC =
 2.5000 8.0000
```

Convert the point to barycentric coordinates.

```
B = cartesianToBarycentric(TR,ti,PC)
```

```
B =
```

```
 0 0 1
```

## Mapped Incenters of Deformed Triangulation

Create a Delaunay triangulation from a set of points.

```
x = [0 4 8 12 0 4 8 12]';
y = [0 0 0 0 8 8 8 8]';
DT = delaunayTriangulation(x,y);
```

Calculate the Cartesian coordinates of the incenters.

```
cc = incenter(DT);
```

Plot the original triangulation and reference points.

```
figure
subplot(1,2,1);
triplot(DT);
hold on;
plot(cc(:,1),cc(:,2), '*r');
hold off;
axis equal;
```

Create a new triangulation which is a deformed version of DT .

```
ti = DT.ConnectivityList;
y = [0 0 0 0 16 16 16 16]';
TR = triangulation(ti,x,y);
```

Compute the barycentric coordinates for the incenters of DT, and use them to compute the Cartesian coordinates of the analogous points in TR.

```
b = cartesianToBarycentric(DT,[1:length(ti)]',cc);
xc = barycentricToCartesian(TR,[1:length(ti)]',b);
```

Plot the deformed triangulation and mapped locations of the reference points.

```
subplot(1,2,2);
```

```
triplot(TR);
hold on;
plot(xc(:,1),xc(:,2),'*r');
hold off;
axis equal;
```

## See Also

[barycentricToCartesian](#) | [delaunayTriangulation](#)

# circumcenter

**Class:** triangulation

Circumcenter of triangle or tetrahedron

## Syntax

```
CC = circumcenter(TR,ti)
[CC,r] = circumcenter(TR,ti)
CC = circumcenter(TR)
[CC,r] = circumcenter(TR)
```

## Description

`CC = circumcenter(TR,ti)` returns the coordinates of the circumcenter of each triangle or tetrahedron specified in `ti`.

`[CC,r] = circumcenter(TR,ti)` also returns the corresponding radii of the circumscribed circles or spheres.

`CC = circumcenter(TR)` returns the circumcenters of all triangles or tetrahedra in the triangulation.

`[CC,r] = circumcenter(TR)` also returns the corresponding radii of the circumscribed circles or spheres for the entire triangulation.

## Input Arguments

**TR**

Triangulation representation, see `triangulation` or `delaunayTriangulation`.

**ti**

Triangle or tetrahedron IDs, specified as a column vector.

## Output Arguments

### **cc**

Circumcenters, returned as a matrix. Each row, `CC(j, :)`, contains the coordinates of the circumcenter of `ti(j)`.

### **r**

Radii of the circumscribed circles or spheres, returned as a vector. The radius at `r(j)` corresponds to the circle or sphere circumscribing `ti(j)`.

## Definitions

### Triangle or Tetrahedron ID

A row number of the matrix, `TR.ConnectivityList`. Use this ID to refer a specific triangle or tetrahedron.

## Examples

### Circumcenters in 2-D Triangulation

Load 2-D triangulation data and create a triangulation representation.

```
load trimesh2d
TR = triangulation(tri,x,y);
```

Compute the circumcenters.

```
CC = circumcenter(TR);
triplot(TR)
axis([-100 400 -50 350])
hold on
plot(CC(:,1),CC(:,2), '*r')
hold off
```

The circumcenters represent points on the medial axis of the polygon.

### Circumcenters in 3-D Delaunay Triangulation

Create the Delaunay triangulation using a random set of points, P.

```
P = gallery('uniformdata',10,3,0);
DT = delaunayTriangulation(P);
```

Calculate the circumcenters of the first five tetrahedra in DT.

```
CC = circumcenter(DT,[1:5]')
```

CC =

0.9626	0.3892	0.0928
6.3458	0.2377	3.1814
0.4820	0.9064	0.5176
-1.2993	1.8384	-1.2185
-0.1595	1.0852	-0.2536

# edgeAttachments

**Class:** triangulation

Triangles or tetrahedra attached to specified edge

## Syntax

```
ti = edgeAttachments(TR, vstart, vend)
ti = edgeAttachments(TR, E)
```

## Description

`ti = edgeAttachments(TR, vstart, vend)` returns the triangles or tetrahedra attached to the specified edges. To specify the edges, use the vectors, `vstart` and `vend`. These vectors contain the “Vertex ID” on page 1-7446 at the start and end of each edge.

`ti = edgeAttachments(TR, E)` specifies the starting and ending vertices of each edge in a 2-column matrix, `E`.

## Input Arguments

### **TR**

Triangulation representation, see `triangulation` or `delaunayTriangulation`.

### **vstart**

IDs of starting vertices, specified as a column vector of vertex IDs. Each ID refers to a vertex at the start of an edge.

### **vend**

IDs of ending vertices, specified as a column vector of vertex IDs. Each ID refers to a vertex at the end of an edge.

## **E**

IDs of the edge vertices, specified as a 2-column matrix of vertex IDs. Each row of **E** corresponds to an edge and contains two IDs:

- $E(j, 1)$  is the ID of the vertex at the start of an edge.
- $E(j, 2)$  is the ID of the vertex at end of the edge.

## **Output Arguments**

### **ti**

IDs of the triangles or tetrahedra attached to the edges, returned as an  $m$ -by-1 cell array. Each cell in **ti** contains the IDs of the attached triangles or tetrahedra. The attachments to the edge located between the vertices, `vstart(j)` and `vend(j)`, or  $E(j, :)$ , are returned in **ti{j}**. The attachments are returned in a cell array because the number of triangles or tetrahedra associated with each edge can vary.

## **Definitions**

### **Vertex ID**

A row number of the matrix, `TR.Points`. Use this ID to refer a specific vertex in the triangulation.

### **Triangle or Tetrahedron ID**

A row number of the matrix, `TR.ConnectivityList`. Use this ID to refer a specific triangle or tetrahedron.

## **Examples**

### **Edge Attachments in 3-D Triangulation**

Load 2-D triangulation data and create a triangulation representation.

```
load tetmesh
TR = triangulation(tet,X);
```

Define the starting and ending vertices of the edges.

```
vstart = [15; 21];
vend = [936; 716];
```

Find the edge attachments.

```
ti = edgeAttachments(TR,vstart,vend);
```

Examine the attachments to the first edge.

```
ti{1}
```

```
ans =
```

```
 927 2060 3438 3423 2583 4690
```

### Edge Attachments in 2-D Delaunay Triangulation

Create a Delaunay triangulation.

```
x = [0 1 1 0 0.5]';
y = [0 0 1 1 0.5]';
DT = delaunayTriangulation(x,y);
```

Find the triangles attached to edge (1,5).

```
ti = edgeAttachments(DT,1,5);

## edges

**Class:** triangulation

Triangulation edges

## Syntax

$E = \text{edges}(\text{TR})$

## Description

$E = \text{edges}(\text{TR})$  returns the triangulation edges as a matrix of vertex IDs. The vertices referenced in  $E$  indicate the beginning and end of each edge.

## Input Arguments

**TR**

Triangulation representation, see [triangulation](#) or [delaunayTriangulation](#).

## Output Arguments

**E**

Edge vertex IDs, returned as a 2-column matrix. Each row of  $E$  corresponds to an edge and contains two IDs:

- $E(j, 1)$  is the ID of the vertex at the start of the edge.
- $E(j, 2)$  is the ID of the vertex at end of the edge.

## Definitions

### Vertex ID

A row number of the matrix, `TR.Points`. Use this ID to refer a specific vertex in the triangulation.

## Examples

### Edges in a 2-D Triangulation

Load 2-D triangulation data and create a triangulation representation.

```
load trimesh2d
TR = triangulation(tri,x,y);
```

Find the edges in the triangulation.

```
E = edges(TR);
```

List the first five edges.

```
E(1:5, :)
```

```
ans =
```

```
 1 2
 1 118
 1 119
 1 120
 2 3
```

### Edges in a 2-D Delaunay Triangulation

Create 2-D Delaunay triangulation from a set of 10 random points.

```
X = gallery('uniformdata',[10, 2],0);
DT = delaunayTriangulation(X);
```

Find the edges in the triangulation.

```
E = edges(DT)
```

# faceNormal

**Class:** triangulation

Triangulation face normal

## Syntax

```
FN = faceNormal(TR,ti)
FN = faceNormal(TR)
```

## Description

`FN = faceNormal(TR,ti)` returns the unit normal vector to each triangle specified by `ti`. The `faceNormal` function supports only 2-D triangulations.

`FN = faceNormal(TR)` returns the unit normal vectors to all triangles.

## Input Arguments

**TR**

Triangulation representation, see `triangulation` or `delaunayTriangulation`.

**ti**

Triangle IDs, specified as a column vector.

## Output Arguments

**FN**

Face normals, returned as a matrix. Each row, `FN(j,:)`, is the unit normal vector to triangle `ti(j)`.

If you do not specify `ti`, then `faceNormal` returns the unit normal information for the entire triangulation. In this case, the normal associated with `TR.ConnectivityList(j,:)` is `FN(j,:)`.

## Definitions

### Triangle ID

A row number of the matrix, `TR.ConnectivityList`. You use this ID to refer a specific triangle.

## Examples

### Plot Unit Normals to Facets on a Spherical Surface

Create a set of random points on a spherical surface.

```
theta = gallery('uniformdata',[100,1],0)*2*pi;
phi = gallery('uniformdata',[100,1],1)*pi;
x = cos(theta).*sin(phi);
y = sin(theta).*sin(phi);
z = cos(phi);
```

Triangulate the points with `delaunayTriangulation`.

```
DT = delaunayTriangulation(x,y,z);
```

Find the free boundary facets and use them to create a triangulation representation for plotting.

```
[T,Xb] = freeBoundary(DT);
TR = triangulation(T,Xb);
```

Plot the triangulation.

```
figure
trisurf(T,Xb(:,1),Xb(:,2),Xb(:,3), ...
 'FaceColor', 'cyan', 'faceAlpha', 0.8);
axis equal;
hold on;
```

```
% Calculate the incenters and face normals.
P = incenter(TR);
fn = faceNormal(TR);

% Display the normal vectors on the surface.
quiver3(P(:,1),P(:,2),P(:,3), ...
 fn(:,1),fn(:,2),fn(:,3),0.5, 'color','r');
hold off;
```

## See Also

[delaunayTriangulation](#) | [freeBoundary](#)

## featureEdges

**Class:** triangulation

Triangulation sharp edges

### Syntax

```
FE = featureEdges(TR,filterangle)
```

### Description

`FE = featureEdges(TR,filterangle)` returns the feature edges in a 2-D triangulation.

Use this method to extract the sharp edges in the surface mesh for display purposes. A feature edge is an edge that has any of the following attributes:

- The edge is shared by only one triangle.
- The edge is shared by more than two triangles.
- The edge is shared by a pair of triangles with angular deviation greater than the `filterangle`.

### Input Arguments

**TR**

Triangulation representation, see `triangulation` or `delaunayTriangulation`.

**filterangle**

Filter angle, specified as a scalar value in the range  $[0,\pi]$ . `featureEdges` returns adjacent triangles that have a dihedral angle that deviates from  $\pi$  by an angle greater than `filterangle`.

## Output Arguments

### FE

Feature edge vertex IDs, returned as a two-column matrix. Each row of `FE` corresponds to a feature edge and contains two IDs:

- `FE(j,1)` is the ID of the vertex at the start of the edge.
- `FE(j,2)` is the ID of the vertex at end of the edge.

## Definitions

### Vertex ID

A row number of the matrix, `TR.Points`. Use this ID to refer a specific vertex in the triangulation.

## Examples

### Feature Edges Shown on a Surface

Use `featureEdges` to find the feature edges of a surface and display them on a plot.

Create a surface triangulation.

```
x = [0 0 0 0 0 3 3 3 3 3 3 6 6 6 6 6 9 9 9 9 9 9]';
y = [0 2 4 6 8 0 1 3 5 7 8 0 2 4 6 8 0 1 3 5 7 8]';
DT = delaunayTriangulation(x,y);
T = DT(:,:);
```

Elevate the 2-D mesh to create a surface.

```
z = [0 0 0 0 0 2 2 2 2 2 2 0 0 0 0 0 0 0 0 0 0 0]';
subplot(1,2,1);
trisurf(T,x,y,z, 'FaceColor', 'cyan');
axis equal;
```

Compute the feature edges using a filter angle of  $\pi/6$ .

```
TR = triangulation(T,x,y,z);
fe = featureEdges(TR,pi/6)';
subplot(1,2,2);
trisurf(TR, 'FaceColor', 'cyan', 'EdgeColor', ...
'none', 'FaceAlpha', 0.8);
axis equal;

% Add the feature edges to the plot.
hold on;
plot3(x(fe), y(fe), z(fe), 'k', 'LineWidth', 1.5);
hold off;
```

## See Also

[delaunayTriangulation](#) | [edges](#)

## freeBoundary

**Class:** triangulation

Triangulation facets referenced by only one triangle or tetrahedron

### Syntax

```
FBtri = freeBoundary(TR)
[FBtri,FBpoints] = freeBoundary(TR)
```

### Description

`FBtri = freeBoundary(TR)` returns the free boundary facets of `TR.ConnectivityList`. A facet in `TR` is on the free boundary if it is referenced by only one triangle or tetrahedron.

`[FBtri,FBpoints] = freeBoundary(TR)` also returns a matrix containing the vertices of the free boundary facets.

### Input Arguments

**TR**

Triangulation representation, see `triangulation` or `delaunayTriangulation`.

### Output Arguments

**FBtri**

Triangulation connectivity list, returned as a matrix that contains the following information:

- Each row in `FBtri` represents a facet on the free boundary.
- Each element is a “Vertex ID” on page 1-7459.

The vertex IDs in `FBtri` reference a specific matrix, depending on the syntax you choose:

- If you call `freeBoundary` with one output argument, then the elements of `FBtri` are row numbers of `TR.Points`.
- If you call `freeBoundary` with two output arguments, then the elements of `FBtri` are row numbers of `FBpoints`.

## FBpoints

Free boundary points, returned as a matrix containing the coordinates of the vertices of the free boundary facets. Each row of `FBpoints` contains coordinates of a vertex.

## Definitions

### Vertex ID

A row number of the matrix, `TR.Points` or `FBpoints`. Use this ID to refer a specific vertex in the triangulation.

## Examples

### Surface of 3-D Triangulation

Use `freeBoundary` to extract the facets of a 3-D triangulation that cover the surface of an object.

Load a 3-D triangulation.

```
load tetmesh;
TR = triangulation(tet,X);
```

Compute the boundary triangulation.

```
[FBtri,FBpoints] = freeBoundary(TR);
```

Plot the boundary triangulation.

```
trisurf(FBtri,FBpoints(:,1),FBpoints(:,2),FBpoints(:,3), ...
 'FaceColor','cyan','FaceAlpha', 0.8);
```

### Free Boundary of 2-D Delaunay Triangulation

Use `freeBoundary` when you want to highlight the outer edges of a 2-D Delaunay triangulation.

Create a triangulation from a random set of points.

```
x = gallery('uniformdata',[20,1],0);
y = gallery('uniformdata',[20,1],1);
DT = delaunayTriangulation(x,y);
```

Find the free boundary edges.

```
fe = freeBoundary(DT)';
```

Plot the mesh and highlight the free boundary edges in red.

```
triplot(DT);
hold on;
plot(x(fe),y(fe),'-r','LineWidth',2) ;
hold off;
```

## **incenter**

**Class:** triangulation

Incenter of triangle or tetrahedron

### **Syntax**

```
IC = incenter(TR,ti)
[IC,r] = incenter(TR,ti)
```

### **Description**

`IC = incenter(TR,ti)` returns the coordinates of the incenter of each triangle or tetrahedron specified by `ti`.

`[IC,r] = incenter(TR,ti)` also returns the radii of the inscribed circles or spheres.

### **Input Arguments**

**TR**

Triangulation representation, see `triangulation` or `delaunayTriangulation`.

**ti**

Triangle or tetrahedron IDs, specified as a column vector.

### **Output Arguments**

**IC**

Incenters, returned as a matrix. Each row of `IC` contains the coordinates of an incenter. For example, `IC(j,:)` is the incenter of `ti(j)`.

**r**

Radii of the inscribed circles or spheres, returned as a vector.  $r(j)$  is the radius of the inscribed circle or sphere whose center is `IC(j, :)`.

## Definitions

### Triangle or Tetrahedron ID

A row number of the matrix, `TR.ConnectivityList`. Use this ID to refer a specific triangle or tetrahedron.

## Examples

### Find Incenters in 3-D Triangulation

Load a 3-D triangulation.

```
load tetmesh
```

Calculate the incenters of the first five tetrahedra.

```
TR = triangulation(tet,X);
IC = incenter(TR,[1:5]')
```

IC =

```
-6.1083 -31.0234 8.1439
-2.1439 -31.0283 5.8742
-1.9555 -31.9463 7.4112
-4.3019 -30.8460 10.5169
-3.1596 -29.3642 6.1851
```

### Find Incenters in 2-D Delaunay Triangulation

Create the Delaunay triangulation.

```
x = [0 1 1 0 0.5]';
y = [0 0 1 1 0.5]';
DT = delaunayTriangulation(x,y);
```

Calculate incenters of the triangles

```
IC = incenter(DT)
```

```
IC =
```

```
 0.2071 0.5000
 0.5000 0.7929
 0.7929 0.5000
 0.5000 0.2071
```

Plot the triangles and incenters.

```
figure
triplot(DT)
axis equal
axis([-0.2 1.2 -0.2 1.2])
hold on
plot(IC(:,1),IC(:,2), '*r')
hold off
```

**See Also**

## isConnected

**Class:** triangulation

Test if two vertices are connected by edge

### Syntax

```
tf = isConnected(TR,vstart,vend)
tf = isConnected(TR,E)
```

### Description

`tf = isConnected(TR,vstart,vend)` returns a logical array of true or false values that indicate whether the specified pairs of vertices are connected by an edge. Element `tf(j)` is true when the vertices, `vstart(j)` and `vend(j)`, are connected by an edge.

`tf = isConnected(TR,E)` specifies the edge start and end indices in matrix `E`. Element `tf(j)` is true when the vertices, `E(j,1)` and `E(j,2)`, are connected by an edge.

### Input Arguments

#### TR

Triangulation representation, see `triangulation` or `delaunayTriangulation`.

#### vstart

IDs of start vertices, specified as a column vector. Each vertex ID refers to a vertex at the start of an edge.

#### vend

IDs of end vertices, specified as a column vector. Each vertex ID refers to a vertex at the end of an edge.

## **E**

IDs of the edge vertices, specified as a two-column matrix. Each row of **E** corresponds to a candidate edge and contains two IDs:

- $E(j,1)$  is the ID of the vertex at the start of a candidate edge.
- $E(j,2)$  is the ID of the vertex at end of the edge.

## **Output Arguments**

### **tf**

Logical values, returned as a column vector. Element  $tf(j)$  is true when either of the following are true:

- The vertices,  $vstart(j)$  and  $vend(j)$ , are connected by an edge.
- The vertices,  $E(j,1)$  and  $E(j,2)$ , are connected by an edge.

Otherwise,  $tf(j)$  is false.

## **Definitions**

### **Vertex ID**

A row number of the matrix, **TR.Points**. Use this ID to refer a specific vertex in the triangulation.

## **Examples**

### **Determine Whether Vertices are connected by an Edge in 2-D**

Load a 2-D triangulation.

```
load trimesh2d
TR = triangulation(tri,x,y);
```

Determine whether vertices 3 and 117 are connected by an edge.

```
isConnected(TR,3,117)
```

```
ans =
```

```
1
```

The vertices are connected by an edge.

Determine whether vertices 3 and 164 are connected by an edge.

```
isConnected(TR,3,164)
```

```
ans =
```

```
0
```

The vertices are not connected by an edge.

### **Determine Whether Vertices are connected by an Edge in 3-D**

```
X = gallery('uniformdata',[10,3],0);
```

```
DT = delaunayTriangulation(X);
```

Determine whether vertices 2 and 7 are connected by an edge.

```
E = [2 7];
```

```
isConnected(DT,E)
```

```
ans =
```

```
1
```

The vertices are connected by an edge.

# nearestNeighbor

**Class:** triangulation

Vertex closest to specified location

## Syntax

```
vi = nearestNeighbor(T,QP)
vi = nearestNeighbor(T,qx,qy)
vi = nearestNeighbor(T,qx,qy,qz)
[vi,d] = nearestNeighbor(___)
```

## Description

`vi = nearestNeighbor(T,QP)` returns the IDs of the vertices closest to the query points in QP. Each row in matrix QP contains the x, y, (and possibly z) coordinates of a query point.

`vi = nearestNeighbor(T,qx,qy)` specifies the x and y coordinates of the query points in 2-D as separate column vectors.

`vi = nearestNeighbor(T,qx,qy,qz)` specifies the x, y, and z coordinates of the query points in 3-D as separate column vectors.

`[vi,d] = nearestNeighbor( ___ )` also returns the Euclidean distance between each query point and its nearest neighbor. You can specify both output arguments with any of the previous syntaxes.

---

**Note:** nearestNeighbor does not support Delaunay triangulations with constrained edges.

---

## Input Arguments

**T** — Triangulation representation

triangulation object | delaunayTriangulation object

Triangulation representation, specified as a `triangulation` object or `delaunayTriangulation` object. For more information, see `triangulation` or `delaunayTriangulation`.

### **QP — Query points**

matrix with 2 columns (2-D) | matrix with 3 columns (3-D)

Query points, specified as a matrix with 2 or 3 columns. `QP` contains the x, y, (and possibly z) coordinates of the query points.

### **qx — Query point x-coordinates**

column vector

Query point x-coordinates, specified as a column vector.

### **qy — Query point y-coordinates**

column vector

Query point y-coordinates, specified as a column vector.

### **qz — Query point z-coordinates**

column vector

Query point z-coordinates, specified as a column vector.

## Output Arguments

### **vi — Vertex IDs of nearest neighbor**

column vector

Vertex IDs of the nearest neighbor, returned as a column vector. `vi(j)` is the vertex ID of the nearest neighbor to the query point `QP(j, :)`.

### **d — Distance to nearest neighbor**

column vector

Distance to the nearest neighbor, returned as a column vector of the same length as `vi`. The value at `d(j)` is the Euclidean distance between the `j`th query point `QP(j, :)` and its nearest neighbor.

## Examples

### Determine Nearest Neighbors of Query Points

Define the points and connectivity of the triangulation.

```
P = [2.5 8.0; 6.5 8.0; 2.5 5.0; 6.5 5.0; 1.0 6.5; 8.0 6.5];
T = [5 3 1; 3 2 1; 3 4 2; 4 6 2];
TR = triangulation(T,P);
```

Define two query points.

```
QP = [2 4; 6 6.5];
```

Plot the triangulation and the query points.

```
triplot(TR)
hold on
plot(QP(:,1),QP(:,2), 'r*')
ylim([1.5 8.5])
xlim([0.5 8.5])
```

Find the nearest neighbors to the query points, as well as the distances between them.

```
[vi,d] = nearestNeighbor(TR,QP);
```

Highlight the points in the triangulation that are the nearest neighbors to the query points.

```
TP = P(vi,:);
plot(TP(:,1),TP(:,2),'ks')
```

Examine the distance between each query point and its nearest neighbor.

d

d =

1.1180

1.5811

### Locate Nearest Neighbors in 3-D Delaunay Triangulation

Create a 3-D Delaunay Triangulation.

```
P = [1 1 0; -1 1 0; -1 -1 0; 1 -1 0; 0 0 2; 0 0 0];
DT = delaunayTriangulation(P);
```

Plot the triangulation and a query point.

```
tri = DT(:, :);
trisurf(tri, P(:, 1), P(:, 2), P(:, 3), 'FaceAlpha', 0.5)
hold on
QP = [0 -0.5 2];
plot3(QP(1), QP(2), QP(3), 'r*')
```

Find the coordinates for the nearest-neighbor of the query point.

```
nnVertexID = nearestNeighbor(DT, QP);
```

```
nnCoordinates = DT.Points(nnVertexID,:)
```

```
nnCoordinates =
 0 0 2
```

- “Spatial Searching”

## neighbors

**Class:** triangulation

Neighbors to specified triangle or tetrahedron

### Syntax

`N = neighbors(TR,ti)`

`N = neighbors(TR)`

### Description

`N = neighbors(TR,ti)` returns the neighbors of the triangles or tetrahedra specified in `ti`.

`N = neighbors(TR)` returns the neighbors of all the triangles or tetrahedra.

### Input Arguments

**TR**

Triangulation representation, see `triangulation` or `delaunayTriangulation`.

**ti**

Triangle or tetrahedron IDs, specified as a column vector.

### Output Arguments

**TN**

IDs of the neighboring triangles or tetrahedra, returned as a matrix. The elements in `TN(i, :)` are the neighbors associated with `ti(i)`.

By convention,  $TN(i, j)$  is the neighbor opposite the  $j$ th vertex of  $ti(i)$ . If a triangle or tetrahedron has one or more boundary facets, the nonexistent neighbors are represented as NaN values in  $TN$ .

## Definitions

### Triangle or Tetrahedron ID

A row number of the matrix, `TR.ConnectivityList`. Use this ID to refer a specific triangle or tetrahedron.

### Vertex ID

A row number of the matrix, `TR.Points`. Use this ID to refer a specific vertex in the triangulation.

## Examples

### Query Neighbors in 2-D Delaunay Triangulation

Create a Delaunay triangulation from a set of random points.

```
x = gallery('uniformdata',[10,1],0);
y = gallery('uniformdata',[10,1],1);
DT = delaunayTriangulation(x,y);
```

Find the neighbors of the first triangle.

```
TN = neighbors(DT,1)
```

```
TN =
```

```
NaN 4 5
```

The first triangle has a boundary edge and two neighbors.

Examine the vertex IDs of the first neighbor,  $TN(2)$ .

```
DT.ConnectivityList(TN(2),:)
```

```
ans =
```

```
 2 4 7
```

## Query Neighbors in 3-D Triangulation

Create the Delaunay triangulation.

```
load tetmesh
TR = triangulation(tet,X);
```

Find the neighbors to each triangle in the triangulation.

```
TN = neighbors(TR);
```

Find the neighbors of the fifth tetrahedron.

```
TN(5,:)
```

```
ans =
```

```
 2360 1539 2 1851
```

Examine the vertex IDs of the first neighbor, `TN(1)`.

```
TR.ConnectivityList(TN(1),:)
```

```
ans =
```

```
 1093 891 893 858
```

# pointLocation

**Class:** triangulation

Triangle or tetrahedron containing specified point

## Syntax

```
ti = pointLocation(T,QP)
ti = pointLocation(T,qx,qy)
ti = pointLocation(T,qx,qy,qz)
[ti,B] = pointLocation(___)
```

## Description

`ti = pointLocation(T,QP)` returns the enclosing triangles or tetrahedra for each query point in `QP`. Each row in matrix `QP` contains the `x`, `y`, (and possibly `z`) coordinates of a query point.

`ti = pointLocation(T,qx,qy)` specifies the `x` and `y` coordinates of the query points in 2-D as separate column vectors.

`ti = pointLocation(T,qx,qy,qz)` specifies the `x`, `y`, and `z` coordinates of the query points in 3-D as separate column vectors.

`[ti,B] = pointLocation( ___ )` also returns the barycentric coordinates of each query point with respect to its enclosing triangle or tetrahedron. You can specify both output arguments with any of the previous syntaxes.

## Input Arguments

### T — Triangulation representation

triangulation object | delaunayTriangulation object

Triangulation representation, specified as a `triangulation` object or `delaunayTriangulation` object. For more information, see `triangulation` or `delaunayTriangulation`.

**QP — Query points**

matrix with 2 columns (2-D) | matrix with 3 columns (3-D)

Query points, specified as a matrix with 2 or 3 columns. QP contains the x, y, (and possibly z) coordinates of the query points.

**qx — Query point x-coordinates**

column vector

Query point x-coordinates, specified as a column vector.

**qy — Query point y-coordinates**

column vector

Query point y-coordinates, specified as a column vector.

**qz — Query point z-coordinates**

column vector

Query point z-coordinates, specified as a column vector.

## Output Arguments

**ti — IDs of enclosing triangles or tetrahedra**

column vector

IDs of the enclosing triangles or tetrahedra, returned as a column vector. The values in **ti** correspond to the row numbers of the triangulation connectivity matrix **T.ConnectivityList**. For a query point **QP(k, :)**, the triangle or tetrahedron enclosing the point is **ti(k)**.

**ti** contains NaN values for points that are not located in a triangle or tetrahedron of the triangulation, **T**.

**B — Barycentric coordinates**

matrix

Barycentric coordinates, returned as a matrix. The values at **B(j, :)** are the barycentric coordinates of the **j**th query point **QP(j, :)** with respect to **ti(j)**.

## Examples

### Find Enclosing Triangles of Query Points

Define the points and connectivity of the triangulation.

```
P = [2.5 8.0; 6.5 8.0; 2.5 5.0; 6.5 5.0; 1.0 6.5; 8.0 6.5];
T = [5 3 1; 3 2 1; 3 4 2; 4 6 2];
TR = triangulation(T,P);
```

Define two query points.

```
QP = [2.25 7; 6 6.5];
```

Plot the triangulation and the query points.

```
triplot(TR)
hold on
plot(QP(:,1),QP(:,2), 'r*')
ylim([4 9])
xlim([0 9])
```

Determine which triangles in the triangulation enclose each query point.

```
ti = pointLocation(TR,QP)
```

```
ti =
```

```
 1
 3
```

Highlight the triangles that enclose each of the query points.

```
triplot(TR.ConnectivityList(ti,:),P(:,1),P(:,2),'c')
```

### Find Enclosing Tetrahedra and Barycentric Coordinates in 3-D

Create a 3-D Delaunay triangulation from a set of random points.

```
x = gallery('uniformdata',[20 1],0);
y = gallery('uniformdata',[20 1],1);
z = gallery('uniformdata',[20 1],2);
DT = delaunayTriangulation(x,y,z);
```

Find the tetrahedra that enclose the query points and calculate the barycentric coordinates of the query points.

```
QP = [0.7 0.6 0.3; 0.5 0.5 0.5];
[ti,B] = pointLocation(DT,QP)
```

ti =

## size

**Class:** triangulation

Size of triangulation connectivity list

## Syntax

```
sz = size(TR)
```

## Description

`sz = size(TR)` returns the size the triangulation connectivity list.

## Input Arguments

**TR**

Triangulation representation, see `triangulation` or `delaunayTriangulation`.

## Output Arguments

**sz**

Size of connectivity list, returned as a two-element row vector. The first element, `sz(1)` is the number of triangles or tetrahedra in the triangulation, and `sz(2)` is the number of vertices per triangle or tetrahedron.

## Examples

### Size of 2-D Triangulation

Create a triangulation.

```
P = [2.5 8.0
 6.5 8.0
 2.5 5.0
 6.5 5.0
 1.0 6.5
 8.0 6.5];
```

```
T = [5 3 1;
 3 2 1;
 3 4 2;
 4 6 2];
```

```
TR = triangulation(T,P);
```

Get the size of the connectivity list.

```
size(TR)
```

```
ans =
```

```
 4 3
```

The triangulation has 4 triangles, and each triangle has 3 vertices.

## See Also

[delaunayTriangulation](#) | [size](#)

# vertexAttachments

**Class:** triangulation

Triangles or tetrahedra attached to specified vertex

## Syntax

```
ti = vertexAttachments(TR,vi)
ti = vertexAttachments(TR)
```

## Description

`ti = vertexAttachments(TR,vi)` returns the triangles or tetrahedra attached to the specified vertices, `vi`.

`ti = vertexAttachments(TR)` returns the triangles or tetrahedra attached to every vertex in the triangulation.

## Input Arguments

**TR**

Triangulation representation, see `triangulation` or `delaunayTriangulation`.

**vi**

Query vertices, specified as a column vector of vertex IDs.

## Output Arguments

**ti**

IDs of the triangles or tetrahedra attached to the vertices, returned as an  $m$ -by-1 cell array. Each cell in `ti` contains the IDs of the attached triangles or tetrahedra. `ti{j}` contains the attachments to the vertex, `vi(j)`. The attachments are returned in a cell

array because the number of triangles or tetrahedra associated with each vertex can vary.

## Definitions

### Triangle or Tetrahedron ID

A row number of the matrix, `TR.ConnectivityList`. Use this ID to refer a specific triangle or tetrahedron.

### Vertex ID

A row number of the matrix, `TR.Points`. Use this ID to refer a specific vertex in the triangulation.

## Examples

### Attachments to Specific Vertex in 2-D Delaunay Triangulation

Locate and plot the attachments to a specific vertex.

Create a Delaunay triangulation from a set of random points.

```
x = gallery('uniformdata',[20,1],0);
y = gallery('uniformdata',[20,1],1);
DT = delaunayTriangulation(x,y);
```

Find the triangles attached to the fifth vertex.

```
ti = vertexAttachments(DT,5);
ti{:}
```

```
ans =
```

```
 18 23 21 22
```

Plot the triangulation. Plot the triangles attached to vertex 5 in red.

```
triplot(DT)
hold on

triplot(DT(ti{:},:),x,y,'Color','r') % vertex 5 (in red)
hold off
```

## See Also

[delaunayTriangulation](#) | [edgeAttachments](#)

## vertexNormal

**Class:** triangulation

Triangulation vertex normal

### Syntax

`VN = vertexNormal(TR,vi)`

`VN = vertexNormal(TR)`

### Description

`VN = vertexNormal(TR,vi)` returns the unit normal vector to each of the specified vertices in `vi`.

`VN = vertexNormal(TR)` returns the normal information for all vertices in the triangulation.

### Input Arguments

**TR**

Triangulation representation, see `triangulation` or `delaunayTriangulation`.

**vi**

IDs of vertices to query, specified as a column vector. Each element in `vi` is a “Vertex ID” on page 1-7491.

### Output Arguments

**VN**

Vertex normals, returned a matrix. Each row, `VN(j,:)`, is the unit normal vector at the vertex `vi(j)`. The vector at `VN(j,:)` is the average unit normal of the faces attached to vertex `vi(j)`.

If you do not specify `vi`, then `vertexNormal` returns the unit normal information for all vertices in the triangulation. In this case, the normal associated with `TR.Points(j, :)` is `VN(j, :)`.

## Definitions

### Vertex ID

A row number of the matrix, `TR.Points`. Use this ID to refer a specific vertex in the triangulation.

## Examples

### Unit Normal Vectors to the Surface of a Cube

Create a 3-D triangulation representing the volume of a cube.

```
[X,Y,Z] = meshgrid(1:4);
X = X(:);
Y = Y(:);
Z = Z(:);
dt = delaunayTriangulation(X,Y,Z);
```

Find the surfaces of the cube and isolate them in a 2-D triangulation.

```
[Tfb,Xfb] = freeBoundary(dt);
TR = triangulation(Tfb,Xfb);
```

Find the unit normal vectors to the triangles on the surface of the cube.

```
vn = vertexNormal(TR);
```

Plot the results.

```
trisurf(TR, 'FaceColor', [0.8 0.8 1.0]);
axis equal
hold on
quiver3(Xfb(:,1),Xfb(:,2),Xfb(:,3),...
 vn(:,1),vn(:,2),vn(:,3),0.5, 'color', 'b');
hold off
```

**See Also**

`delaunayTriangulation` | `freeBoundary`

# readtable

Create table from file

## Syntax

```
T = readtable(filename)
T = readtable(filename,Name,Value)
```

## Description

`T = readtable(filename)` creates a table by reading column oriented data from a file.

`readtable` determines the file format from the file name's extension:

- `.txt`, `.dat`, or `.csv` for delimited text files
- `.xls`, `.xlsb`, `.xlsm`, `.xlsx`, `.xltm`, `.xltx`, or `.ods` for spreadsheet files

`readtable` creates one variable in `T` for each column in the file and reads variable names from the first row of the file. By default, the variables created are **double** if the entire column is numeric, or cell arrays of strings if any element in a column is not numeric.

`T = readtable(filename,Name,Value)` creates a table from a file with additional options specified by one or more `Name,Value` pair arguments.

For example, you can specify whether `readtable` reads the first row of the file as variable names or as data.

## Examples

### Create Table from Text File

Create a file, `myCsvTable.dat`, that contains the following comma-separated column oriented data.

```
LastName,Gender,Age,Height,Weight,Smoker
Smith,M,38,71,176,1
Johnson,M,43,69,163,0
Williams,F,38,64,131,0
Jones,F,40,67,133,0
Brown,F,49,64,119,0
```

Create a table from the comma-separated text file.

```
T = readtable('myCsvTable.dat')
```

T =

LastName	Gender	Age	Height	Weight	Smoker
'Smith'	'M'	38	71	176	1
'Johnson'	'M'	43	69	163	0
'Williams'	'F'	38	64	131	0
'Jones'	'F'	40	67	133	0
'Brown'	'F'	49	64	119	0

T contains one variable for each column in the file and `readtable` treats the entries in the first line of the file as variable names.

## Create Table from Text File without Column Headings

Create a file, `mySpaceDelimTable.txt`, that contains the following space delimited, column oriented data.

```
M 45 45 NY true
F 41 32 CA false
M 40 34 MA false
```

Create a table from the space delimited text file that does not contain variable names as column headings.

```
T = readtable('mySpaceDelimTable.txt',...
 'Delimiter',' ','ReadVariableNames',false)
```

T =

Var1	Var2	Var3	Var4	Var5
------	------	------	------	------

```
'M' 45 45 'NY' 'true'
'F' 41 32 'CA' 'false'
'M' 40 34 'MA' 'false'
```

T contains default variable names.

### Create and Format Table from Text File

Create a file, `myCsvTable.dat`, that contains the following comma-separated column oriented data.

```
LastName,Gender,Age,Height,Weight,Smoker
Smith,M,38,71,176,1
Johnson,M,43,69,163,0
Williams,F,38,64,131,0
Jones,F,40,67,133,0
Brown,F,49,64,119,0
```

Create a table from the comma-separated text file. Format the first two variables as strings, the third variable as `uint32`, and the next two variables as double-precision, floating-point numbers. Format the last variable as a string.

```
T = readtable('myCsvTable.dat','Format','%s%s%u%f%f%s')
```

T =

LastName	Gender	Age	Height	Weight	Smoker
'Smith'	'M'	38	71	176	'1'
'Johnson'	'M'	43	69	163	'0'
'Williams'	'F'	38	64	131	'0'
'Jones'	'F'	40	67	133	'0'
'Brown'	'F'	49	64	119	'0'

The conversion specifiers are `%s` for a cell array of strings, `%f` for `double`, and `%u` for `uint32`.

### Read Foreign-Language Dates from Text File

Read German dates from a file and add them to a table as English dates.

Create a sample file named `myfile.txt` that contains comma-separated values. The first column of values contains dates in German and the second and third columns are numeric values.

```
fileID = fopen('myfile.txt','w','n','ISO-8859-15');
fprintf(fileID,'1 Januar 2014, 20.2, 100.5 \n');
fprintf(fileID,'1 Februar 2014, 21.6, 102.7 \n');
fprintf(fileID,'1 März 2014, 20.7, 99.8 \n');
fclose(fileID);
```

The sample file looks like this:

```
1 Januar 2014, 20.2, 100.5
1 Februar 2014, 21.6, 102.7
1 März 2014, 20.7, 99.8
```

Read the sample file using `readtable`. The conversion specifiers are `%D` for a date and `%f` for floating-point values. Specify the file encoding using the `FileEncoding` name-value pair argument. Specify the format and locale of the dates using the `DateLocale` name-value pair argument.

```
T = readtable('myfile.txt','ReadVariableNames',false,...
 'Format','{%dd MMMM yyyy}D %f %f',...
 'FileEncoding','ISO-8859-15',...
 'DateLocale','de_DE')
```

T =

Var1	Var2	Var3
01 January 2014	20.2	100.5
01 February 2014	21.6	102.7
01 March 2014	20.7	99.8

## Create Table from Spreadsheet Including Row Names

Create a table from a spreadsheet that contains variable names in the first row and row names in the first column.

```
T = readtable('patients.xls','ReadRowNames',true);
```

Display the first five rows and first four variables of the table.

```
T(1:5,1:4)
```

ans =

Gender	Age	Location	Height
--------	-----	----------	--------

Smith	'Male'	38	'County General Hospital'	71
Johnson	'Male'	43	'VA Hospital'	69
Williams	'Female'	38	'St. Mary's Medical Center'	64
Jones	'Female'	40	'VA Hospital'	67
Brown	'Female'	49	'County General Hospital'	64

View the `DimensionNames` property of the table.

```
T.Properties.DimensionNames
```

```
ans =
```

```
 'LastName' 'Variable'
```

'LastName' is the name in the first column of the first row of the spreadsheet.

### Read Specific Range of Data from Spreadsheet

Create a table from the 5-by-3 rectangular region between the two corners C2 and E6 on the spreadsheet `patients.xls`. Do not use the first row of this region as variable names.

```
T = readtable('patients.xls',...
 'Range','C2:E6',...
 'ReadVariableNames',false)
```

```
T =
```

Var1	Var2	Var3
38	'County General Hospital'	71
43	'VA Hospital'	69
38	'St. Mary's Medical Center'	64
40	'VA Hospital'	67
49	'County General Hospital'	64

T contains default variable names.

- “Access Data in a Table”

## Input Arguments

### **filename** — Name of file to read

string

Name of the file to read, specified as a string. If **filename** includes the file extension, then **readtable** determines the file format from the extension. Otherwise, you must specify the 'FileType' name-value pair arguments to indicate the type of file.

On Windows systems with Microsoft Excel software, **readtable** reads any Excel spreadsheet file format recognized by your version of Excel. If your system does not have Excel for Windows, **readtable** operates in **basic** import mode, and reads only XLS, XLSX, XLSM, XLTX, and XLTM files.

For a delimited text file, **readtable** converts empty fields in the file to either NaN (for a numeric variable) or the empty string (for a string-valued variable). All lines in the text file must have the same number of delimiters. **readtable** ignores insignificant white space in the file.

Example: 'myFile.xlsx'

## Name-Value Pair Arguments

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as **Name1**, **Value1**, . . . , **NameN**, **ValueN**.

Example: 'ReadVariableNames', **false** indicates that the first row of the file does not correspond to variable names.

## Delimited Text Files and Spreadsheet Files

### **'FileType'** — Type of file

'text' | 'spreadsheet'

Type of file, specified as the comma-separated pair consisting of 'FileType' and the string 'text' or 'spreadsheet'.

You must specify the 'FileType' name-value pair argument if the **filename** input argument does not include the file extension or if the extension is other than one of the following.

- .txt, .dat, or .csv for delimited text files
- .xls, .xlsb, .xlsm, .xlsx, .xltm, .xltx, or .ods for spreadsheet files

Example: 'FileType', 'text'

### 'ReadVariableNames' — Indicator for reading first row as variable names

true (default) | false | 1 | 0

Indicator for reading the first row as variable names, specified as the comma-separated pair consisting of 'ReadVariableNames' and either true, false, 1, or 0.

Indicator	Behavior
true	The first row of the region to read contains the variable names for the table. This is the default behavior.  If both the 'ReadVariableNames' and 'ReadRowNames' logical indicators are true, then readtable saves the name in the first column of the first row of the region to read as the first dimension name in the property, T.Properties.DimensionNames.
false	The first row of the region to read contains the first row of data in the table.  readtable creates default variable names of the form 'Var1', ..., 'VarN', where N is the number of variables.

### 'ReadRowNames' — Indicator for reading the first column as row names

false (default) | true | 0 | 1

Indicator for reading first column as row names, specified as the comma-separated pair consisting of 'ReadRowNames' and either false, true, 0, or 1.

Indicator	Behavior
false	The first column of the region to read contains the first variable in the table. It does not contain the row names for the table. This is the default behavior.
true	The first column of the region to read contains the row names for the table.

Indicator	Behavior
	If both the 'ReadVariableNames' and 'ReadRowNames' logical indicators are true, then <code>readtable</code> saves the name in the first column of the first row of the region to read as the first dimension name in the property, <code>T.Properties.DimensionNames</code> .

**'TreatAsEmpty' — Strings to treat as empty value**

string | cell array of strings

Strings to treat as empty value, specified as the comma-separated pair consisting of 'TreatAsEmpty' and a string or a cell array of strings. Table elements corresponding to these are set to NaN.

'TreatAsEmpty' only applies to numeric columns in the file, and `readtable` does not accept numeric literals, such as '-99'.

Example: 'TreatAsEmpty', 'N/A' sets N/A within numeric columns to NaN.

Example: 'TreatAsEmpty', {'.', 'NA', 'N/A'} sets ., NA and N/A within numeric columns to NaN.

**Delimited Text Files Only**

When reading delimited text files, you can specify any of the name-value pair arguments listed here. Also, if you specify the 'Format' name-value pair argument, you can specify any of the name-value pair arguments accepted by the `textscan` function.

**'Delimiter' — Field delimiter character**

string

Field delimiter character, specified as the comma-separated pair consisting of 'Delimiter' and one of the following strings:

Specifier	Field Delimiter
' , '	Comma. This is the default behavior.
' comma '	
' ' '	Space
' space '	

Specifier	Field Delimiter
'\t'	Tab
'tab'	
';'	Semicolon
'semi'	
' '	Vertical bar
'bar'	

Example: 'Delimiter', 'space'

### 'HeaderLines' — Number of lines to skip at beginning of file

0 (default) | positive integer

Number of lines to skip at beginning of file, specified as the comma-separated pair consisting of 'HeaderLines' and a positive integer.

Data Types: single | double

### 'Format' — Format of columns in file

string of one or more conversion specifiers

Format of the columns in the file, specified as the comma-separated pair consisting of 'Format' and a string of one or more conversion specifiers. The conversion specifiers are the same as those accepted by the `textscan` function.

Specifying the format can significantly improve speed for some large files. If you do not specify a value for `Format`, then `readtable` uses `%q` to interpret nonnumeric columns. The `%q` specifier reads a string and omits double quotation marks (") if appropriate.

By default, the variables created are either `double`, if the entire column is numeric, or cell arrays of strings, if any element in a column is not numeric.

### 'DateLocale' — Locale for reading dates

string

Locale for reading dates, specified as the comma-separated pair consisting of 'DateLocale' and a string. The string takes the form `xx_YY`, where `xx` is a lowercase

ISO 639-1 two-letter code indicating a language, and YY is an uppercase ISO 3166-1 alpha-2 code indicating a country. For a list of common values for the locale, see the `Locale` name-value pair argument for the `datetime` function.

When using the `%D` format specifier to read text as `datetime` values, use `DateLocale` to specify the locale in which `readtable` should interpret month and day-of-week names and abbreviations.

Example: `'DateLocale', 'ja_JP'`

### 'FileEncoding' – Character encoding scheme

`'UTF-8' | 'ISO-8859-1' | 'windows-1251' | 'windows-1252' | ...`

Character encoding scheme associated with the file, specified as the comma-separated pair consisting of `'FileEncoding'` and one of the following strings.

'Big5'	'ISO-8859-1'	'windows-847'
'Big5-HKSCS'	'ISO-8859-2'	'windows-949'
'CP949'	'ISO-8859-3'	'windows-1250'
'EUC-KR'	'ISO-8859-4'	'windows-1251'
'EUC-JP'	'ISO-8859-5'	'windows-1252'
'EUC-TW'	'ISO-8859-6'	'windows-1253'
'GB18030'	'ISO-8859-7'	'windows-1254'
'GB2312'	'ISO-8859-8'	'windows-1255'
'GBK'	'ISO-8859-9'	'windows-1256'
'IBM866'	'ISO-8859-11'	'windows-1257'
'KOI8-R'	'ISO-8859-13'	'windows-1258'
'KOI8-U'	'ISO-8859-15'	'US-ASCII'
	'Macintosh'	'UTF-8'
	'Shift_JIS'	

The default encoding is system-dependent.

Data Types: `char`

### Spreadsheet Files Only

**'Sheet' — Worksheet to read**

1 (default) | positive integer indicating worksheet index | string containing worksheet name

Worksheet to read, specified as the comma-separated pair consisting of **'Sheet'** and a positive integer indicating the worksheet index or a string containing the worksheet name. The worksheet name string cannot contain a colon (:). To determine the names of sheets in a spreadsheet file, use `[status,sheets] = xlsfinfo(filename)`.

Example: `'Sheet',2`

**'Range' — Rectangular portion of worksheet to read**

string

Rectangular portion of the worksheet to read, specified as the comma-separated pair consisting of **'Range'** and a string.

Specify the range using the syntax `'Corner1:Corner2'`, where *Corner1* and *Corner2* are two opposing corners that define the region to read. For example, `'D2:H4'` represents the 3-by-5 rectangular region between the two corners D2 and H4 on the worksheet. The **'Range'** name-value pair argument is not case sensitive, and uses Excel A1 reference style (see Excel help).

If the spreadsheet contains figures or other nontabular information, use the **'Range'** name-value pair argument to read only the tabular data. By default, `readtable` reads data from a spreadsheet contiguously out to the right-most column that contains data, including any empty columns that precede it.

Example: `'Range','D2:H4'`

**'Basic' — Indicator for reading in basic mode**

true | false | 1 | 0

Indicator for reading in **basic** mode, specified as the comma-separated pair consisting of **'Basic'** and either `true`, `false`, `1`, or `0`.

**basic** mode is the default for systems without Excel for Windows. In **basic** mode, `readtable`:

- Reads XLS, XLSX, XLSM, XLTX, and XLTM files only.
- Does not support the **'Range'** name-value pair argument when reading XLS files.

- Imports all dates as Excel serial date numbers. Excel serial date numbers use a different reference date than MATLAB date numbers.

## Output Arguments

### **T** – Output table

table

Output table, returned as a table. The table can store metadata such as descriptions, variable units, variable names, and row names. For more information, see [Table Properties](#).

**Introduced in R2013b**

# real

Real part of complex number

## Syntax

`X = real(Z)`

## Description

`X = real(Z)` returns the real part of the elements of the complex array `Z`.

## Examples

`real(2+3*i)` is 2.

## See Also

`abs` | `angle` | `conj` | `i` | `j` | `imag`

Introduced before R2006a

## reallog

Natural logarithm for nonnegative real arrays

### Syntax

```
Y = reallog(X)
```

### Description

`Y = reallog(X)` returns the natural logarithm of each element in array `X`. Array `X` must contain only nonnegative real numbers. The size of `Y` is the same as the size of `X`.

### Examples

```
M = magic(4)
```

```
M =
 16 2 3 13
 5 11 10 8
 9 7 6 12
 4 14 15 1
```

```
reallog(M)
```

```
ans =
 2.7726 0.6931 1.0986 2.5649
 1.6094 2.3979 2.3026 2.0794
 2.1972 1.9459 1.7918 2.4849
 1.3863 2.6391 2.7081 0
```

### See Also

`log` | `realpow` | `realsqrt`

**Introduced before R2006a**

# realmax

Largest positive floating-point number

## Syntax

```
n = realmax
```

## Description

`n = realmax` returns the largest finite floating-point number in IEEE double precision.

`realmax('double')` is the same as `realmax` with no arguments.

`realmax('single')` returns the largest finite floating-point number in IEEE single precision.

## Examples

Find the value of the constant `realmax`:

```
ndouble = realmax
nsingle = realmax('single')
```

```
ndouble =
 1.7977e+308
```

```
nsingle =
 3.4028e+38
```

## See Also

`eps` | `realmin` | `intmax`

**Introduced before R2006a**

## realmin

Smallest positive normalized floating-point number

### Syntax

```
n = realmin
realmin('double')
realmin('single')
```

### Description

`n = realmin` returns the smallest positive normalized floating-point number in IEEE double precision.

`realmin('double')` is the same as `realmin` with no arguments.

`realmin('single')` returns the smallest positive normalized floating-point number in IEEE single precision.

### Examples

Find the value of the constant `realmin`:

```
ndouble = realmin
nsingle = realmin('single')
```

```
ndouble =
 2.2251e-308
```

```
nsingle =
 1.1755e-38
```

### See Also

`eps` | `realmax` | `intmin`

**Introduced before R2006a**

## realpow

Array power for real-only output

### Syntax

```
Z = realpow(X,Y)
```

### Description

`Z = realpow(X,Y)` raises each element of array `X` to the power of its corresponding element in array `Y`. Arrays `X` and `Y` must be the same size. The range of `realpow` is the set of all real numbers, i.e., all elements of the output array `Z` must be real.

### Examples

```
X = -2*ones(3,3)
```

```
X =
 -2 -2 -2
 -2 -2 -2
 -2 -2 -2
```

```
Y = pascal(3)
```

```
ans =
 1 1 1
 1 2 3
 1 3 6
```

```
realpow(X,Y)
```

```
ans =
 -2 -2 -2
 -2 4 -8
 -2 -8 64
```

## **See Also**

mpower | power | realloc | realsqrt

**Introduced before R2006a**

## realsqrt

Square root for nonnegative real arrays

### Syntax

```
Y = realsqrt(X)
```

### Description

`Y = realsqrt(X)` returns the square root of each element of array `X`. Array `X` must contain only nonnegative real numbers. The size of `Y` is the same as the size of `X`.

### Examples

```
M = magic(4)
```

```
M =
 16 2 3 13
 5 11 10 8
 9 7 6 12
 4 14 15 1
```

```
realsqrt(M)
```

```
ans =
 4.0000 1.4142 1.7321 3.6056
 2.2361 3.3166 3.1623 2.8284
 3.0000 2.6458 2.4495 3.4641
 2.0000 3.7417 3.8730 1.0000
```

### See Also

# record

Record data and event information to file

## Syntax

```
record(obj)
record(obj, 'switch')
```

## Description

`record(obj)` toggles the recording state for the serial port object, `obj`.

`record(obj, 'switch')` initiates or terminates recording for `obj`. *switch* can be `on` or `off`. If *switch* is `on`, recording is initiated. If *switch* is `off`, recording is terminated.

## Examples

This example creates the serial port object `s` on a Windows platform. It connects `s` to the device, configures `s` to record information to a file, writes and reads text data, and then disconnects `s` from the device.

```
s = serial('COM1');
fopen(s)
s.RecordDetail = 'verbose';
s.RecordName = 'MySerialFile.txt';
record(s, 'on')
fprintf(s, '*IDN?')
out = fscanf(s);
record(s, 'off')
fclose(s)
```

## More About

### Tips

Before you can record information to disk, `obj` must be connected to the device with the `open` function. A connected serial port object has a `Status` property value of `open`. An

error is returned if you attempt to record information while `obj` is not connected to the device. Each serial port object must record information to a separate file. Recording is automatically terminated when `obj` is disconnected from the device with `fclose`.

The `RecordName` and `RecordMode` properties are read-only while `obj` is recording, and must be configured before using `record`.

For a detailed description of the record file format and the properties associated with recording data and event information to a file, refer to [Debugging: Recording Information to Disk](#).

# record

Record audio to `audiorecorder` object

## Syntax

```
record(recorderObj)
record(recorderObj, length)
```

## Description

`record(recorderObj)` records audio from an input device, such as a microphone connected to your system. *recorderObj* is an `audiorecorder` object that defines the sample rate, bit depth, and other properties of the recording.

`record(recorderObj, length)` records for the number of seconds specified by *length*.

## Examples

Record 5 seconds of your speech with a microphone:

```
myVoice = audiorecorder;

% Define callbacks to show when
% recording starts and completes.
myVoice.StartFcn = 'disp(''Start speaking.'')';
myVoice.StopFcn = 'disp(''End of recording.'')';

record(myVoice, 5);
```

To listen to the recording, call the `play` method:

```
play(myVoice);
```

- “Record or Play Audio within a Function”

# recordblocking

Record audio to `audiorecorder` object, holding control until recording completes

## Syntax

```
recordblocking(recorderObj, length)
```

## Description

`recordblocking(recorderObj, length)` records audio from an input device, such as a microphone connected to your system, for the number of seconds specified by *length*. The `recordblocking` method does not return control until recording completes. *recorderObj* is an `audiorecorder` object that defines the sample rate, bit depth, and other properties of the recording.

## Examples

Record 5 seconds of your speech with a microphone, and play it back:

```
myVoice = audiorecorder;

disp('Start speaking. ');
recordblocking(myVoice, 5);
disp('End of recording. Playing back ...');

play(myVoice);
```

# rectangle

Create rectangle with sharp or curved corners

## Syntax

```
rectangle('Position',pos)
rectangle('Position',pos,'Curvature',cur)
rectangle(___,Name,Value)
r = rectangle(___)
```

## Description

`rectangle('Position',pos)` creates a rectangle in 2-D coordinates. Specify `pos` as a four-element vector of the form `[x y w h]` in data units. The `x` and `y` elements determine the location and the `w` and `h` elements determine the size. The function plots into the current axes without clearing existing content from the axes.

`rectangle('Position',pos,'Curvature',cur)` adds curvature to the sides of the rectangle. For different curvatures along the horizontal and vertical sides, specify `cur` as a two-element vector of the form `[horizontal vertical]`. For the same length of curvature along all sides, specify `cur` as a scalar value. Specify values between 0 (no curvature) and 1 (maximum curvature). Use `[1 1]` to create an ellipse or circle.

`rectangle(___,Name,Value)` specifies rectangle properties using one or more name-value pair arguments. For example, `'FaceColor','red'` specifies a red fill color. You can specify rectangle properties with any of the input argument combinations in the previous syntaxes.

`r = rectangle(___)` returns the rectangle object. Use `r` to modify properties of the rectangle after it is created. For a list of properties, see [Rectangle Properties](#). You can return an output argument with any of the previous syntaxes.

## Examples

### Draw Rectangle

Draw a rectangle that has a lower left corner at the point (1,2). Make the width of the rectangle 5 units and the height 6 units. Then, change the axis limits.

```
rectangle('Position',[1 2 5 6])
axis([0 10 0 10])
```

## Draw Rectangle with Curved Edges

Draw a rectangle that has a lower left corner at (0,0) and an upper right corner at (2,4). Create the rectangle with curved corners by specifying the curvature as the scalar value 0.2. For data units of equal length along both the  $x$ -axis and  $y$ -axis, use `axis equal`.

```
figure
rectangle('Position',[0 0 2 4],'Curvature',0.2)
axis equal
```

Add a second rectangle that has the shortest side completely curved by specifying the curvature as the scalar value 1.

```
rectangle('Position',[3 0 2 4],'Curvature',1)
```

Add a third rectangle and use different curvatures along the horizontal and vertical sides. Use a horizontal curvature of 0.5 to make 50 percent of each horizontal side curved. Use a vertical curvature of 1 to make both vertical sides completely curved.

```
rectangle('Position',[6 0 2 4], 'Curvature',[0.5,1])
```

### Draw Circle

Draw a circle by setting the `Curvature` property to `[1 1]`. Draw the circle so that it fills the rectangular area between the points (2,4) and (4,6). The `Position` property defines the smallest rectangle that contains the circle.

```
pos = [2 4 2 2];
rectangle('Position',pos,'Curvature',[1 1])
axis equal
```

Draw a red rectangle using the same position values to show how the circle fills the rectangular area.

```
rectangle('Position',pos,'EdgeColor','r')
```

### Specify Rectangle Outline and Fill Color

Draw a rectangle and specify the fill color, outline color, and outline width.

```
rectangle('Position',[1,2,5,10],'FaceColor',[0 .5 .5],'EdgeColor','b',...
 'LineWidth',3)
```

### Modify Rectangle After Creation

Add a rectangle to the current axes and return the rectangle object, `r`.

```
r = rectangle('Position',[0 0 1 1])
```

```
r =
```

```
Rectangle with properties:
```

```
FaceColor: 'none'
EdgeColor: [0 0 0]
LineWidth: 0.5000
```

```
LineStyle: '-'
Curvature: [0 0]
Position: [0 0 1 1]
```

Use GET to show all properties

Modify the rectangle after creation using `r`. Change the fill color, outline color, and outline width.

```
r.FaceColor = [0 .5 .5];
r.EdgeColor = 'b';
r.LineWidth = 3;
```

## Input Arguments

### **pos** — Size and location of rectangle

four-element vector of the form [x y w h]

Size and location of the rectangle, specified as a four-element vector of the form [x y w h]. The x and y elements define the coordinate for the lower left corner of the rectangle. The w and h elements define the dimensions of the rectangle.

All values are in data units.

Example: `rectangle('Position',[0.5 0.5 0.3 0.4])`

Data Types: `double` | `single` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **cur** — Amount of horizontal and vertical curvature

[0 0] (default) | two-element vector | scalar

Amount of horizontal and vertical curvature, specified as a two-element vector or a scalar value. Use this property to vary the shape of the rectangle from rectangular to ellipsoidal.

The horizontal curvature is the fraction of the width that is curved along the top and bottom edges. The vertical curvature is the fraction of the height that is curved along the left and right edges.

- To use different horizontal and vertical curvatures, specify a two-element vector of the form [`horizontal` `vertical`]. The `horizontal` element determines the horizontal curvature and the `vertical` element determines the vertical curvature. Specify the values between 0 (no curvature) and 1 (maximum curvature). For example, a value of [0 0] creates a rectangle with square edges and value of [1 1] creates an ellipse.
- To use the same curvature for the horizontal and vertical edges, specify a scalar value between 0 and 1, inclusive. The shorter dimension determines the length of the curvature.

Example: [0.5 0.6]

Example: 0.75

Data Types: `double`

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1`, `Value1`, ..., `NameN`, `ValueN`.

Example: `rectangle('Position',[0 0 1 1],'EdgeColor','k','FaceColor',[0 .5 .5])`

### **'FaceColor'** — Fill color

'none' (default) | RGB triplet | color string

Fill color, specified as 'none', an RGB triplet, or a color string. The 'none' option makes the fill invisible.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0, 1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[1 1 0]
'magenta'	'm'	[1 0 1]
'cyan'	'c'	[0 1 1]
'red'	'r'	[1 0 0]
'green'	'g'	[0 1 0]
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]
'black'	'k'	[0 0 0]

Example: 'blue'

Example: [0 0 1]

### 'EdgeColor' — Outline color

[0 0 0] (default) | RGB triplet | color string | 'none'

Outline color, specified as an RGB triplet, a color string, or 'none'. The 'none' option makes the edge invisible. The default RGB triplet value of [0 0 0] corresponds to black.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0, 1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[1 1 0]
'magenta'	'm'	[1 0 1]
'cyan'	'c'	[0 1 1]

Long Name	Short Name	RGB Triplet
'red'	'r'	[1 0 0]
'green'	'g'	[0 1 0]
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]
'black'	'k'	[0 0 0]

Example: 'blue'

Example: [0 0 1]

### 'LineWidth' — Line width

0.5 (default) | positive value

Line width, specified as a positive value in point units.

Example: 0.75

### 'LineStyle' — Line style

'-' (default) | '--' | ':' | '-.' | 'none'

Line style, specified as one of the line style strings listed in this table.

String	Line Style	Resulting Line
'-'	Solid line	
'--'	Dashed line	
':'	Dotted line	
'-.'	Dash-dotted line	
'none'	No line	No line

# Rectangle Properties

Control rectangle appearance and behavior

Rectangle properties control the appearance and behavior of a rectangle object. By changing property values, you can modify certain aspects of the rectangle.

Starting in R2014b, you can use dot notation to query and set properties.

```
h = rectangle;
w = h.LineWidth;
h.LineWidth = 3;
```

If you are using an earlier release, use the `get` and `set` functions instead.

## Appearance

### Curvature — Amount of horizontal and vertical curvature

[0 0] (default) | two-element vector | scalar

Amount of horizontal and vertical curvature, specified as a two element vector of the form [x y] or a scalar value. Use this property to vary the shape of the rectangle from rectangular to ellipsoidal. The horizontal curvature is the fraction of the width that is curved along the top and bottom edges. The vertical curvature is the fraction of the height that is curved along the left and right edges.

- To use different horizontal and vertical curvatures, specify a two-element vector of the form [x y]. The x element determines the horizontal curvature and the y element determines the vertical curvature. Specify x and y as values between 0 (no curvature) and 1 (maximum curvature). For example, a value of [0 0] creates a rectangle with square edges and value of [1 1] creates an ellipse.
- To use the same curvature for the horizontal and vertical edges, specify a scalar value in the range [0, 1]. The shorter dimension determines the length of the curvature.

Example: [0.5 0.6]

Example: 0.75

### EdgeColor — Outline color

[0 0 0] (default) | RGB triplet | color string | 'none'

Outline color, specified as an RGB triplet, a color string, or 'none'. The 'none' option makes the edge invisible. The default RGB triplet value of [0 0 0] corresponds to black.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0, 1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[1 1 0]
'magenta'	'm'	[1 0 1]
'cyan'	'c'	[0 1 1]
'red'	'r'	[1 0 0]
'green'	'g'	[0 1 0]
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]
'black'	'k'	[0 0 0]

Example: 'blue'

Example: [0 0 1]

### **FaceColor — Fill color**

'none' (default) | RGB triplet | color string

Fill color, specified as 'none', an RGB triplet, or a color string. The 'none' option makes the fill invisible.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0, 1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[1 1 0]
'magenta'	'm'	[1 0 1]

Long Name	Short Name	RGB Triplet
'cyan'	'c'	[0 1 1]
'red'	'r'	[1 0 0]
'green'	'g'	[0 1 0]
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]
'black'	'k'	[0 0 0]

Example: 'blue'

Example: [0 0 1]

### LineStyle — Line style

'-' (default) | '--' | ':' | '- .' | 'none'

Line style, specified as one of the line style strings listed in this table.

String	Line Style	Resulting Line
'-'	Solid line	
'--'	Dashed line	
':'	Dotted line	
'- .'	Dash-dotted line	
'none'	No line	No line

### LineWidth — Line width

0.5 (default) | positive value

Line width, specified as a positive value in point units.

Example: 0.75

### AlignVertexCenters — Sharp vertical and horizontal lines

'off' (default) | 'on'

Sharp vertical and horizontal lines, specified as 'off' or 'on'.

If the associated figure has a GraphicsSmoothing property set to 'on' and a Renderer property set to 'opengl', then the figure applies a smoothing technique to plots. In some cases, this smoothing technique can cause vertical and horizontal lines to appear uneven in thickness or color. Use the `AlignVertexCenters` property to eliminate the uneven appearance.

- 'off' — Do not sharpen vertical or horizontal lines. The lines might appear uneven in thickness or color.
- 'on' — Sharpen vertical and horizontal lines to eliminate an uneven appearance.

---

**Note:** You must have a graphics card that supports this feature. To see if the feature is supported, type `opengl info`. If it is supported, then the returned fields contain the line `SupportsAlignVertexCenters: 1`.

---

## Location and Size

### Position — Size and location of rectangle

[0 0 1 1] (default) | four-element vector

Size and location of the rectangle, specified as a four-element vector of the form [x y width height]. Specify the values in data units. The x and y elements define the coordinate for the lower-left corner of the rectangle. The width and height elements define the dimensions of the rectangle.

Example: [0.5 0.5 0.3 0.4]

## Visibility

### Visible — State of visibility

'on' (default) | 'off'

State of visibility, specified as one of these values:

- 'on' — Display the rectangle.
- 'off' — Hide the rectangle without deleting it. You still can access the properties of an invisible rectangle object.

**Clipping — Clipping of rectangle object to axes limits**`'on'` (default) | `'off'`

Clipping of the rectangle object to the axes limits, specified as one of these values:

- `'on'` — Do not display parts of the rectangle object that are outside the axes limits.
- `'off'` — Display the entire rectangle object, even if parts of it appear outside the axes limits. Parts of the rectangle object might appear outside the axes limits if you create a plot, set `hold on`, freeze the axis scaling, and then create the rectangle object so that it is larger than the original plot.

The `Clipping` property of the axes that contains the rectangle object must be set to `'on'`, otherwise this property has no effect. For more information about the clipping behavior, see the `Clipping` property of the axes.

**EraseMode — (removed) Technique to draw and erase objects**`'normal'` (default) | `'none'` | `'xor'` | `'background'`

---

**Note:** `EraseMode` has been removed. You can delete code that accesses the `EraseMode` property with minimal impact. If you were using `EraseMode` to create line animations, use the `animatedline` function instead.

---

Technique to draw and erase objects, specified as one of these values:

- `'normal'` — Redraw the affected region of the display, performing the three-dimensional analysis necessary to correctly render all objects. This mode produces the most accurate picture, but is the slowest. The other modes are faster, but do not perform a complete redraw and, therefore, are less accurate.
- `'none'` — Do not erase the object when it is moved or destroyed. After you erase the object with `EraseMode`, `'none'`, it is still visible on the screen. However, you cannot print the object because MATLAB does not store any information on its former location.
- `'xor'` — Draw and erase the object by performing an exclusive OR (XOR) with the color of the screen beneath it. This mode does not damage the color of the objects beneath it. However, the object color depends on the color of whatever is beneath it on the display.
- `'background'` — Erase the object by redrawing it in the axes background color, or the figure background color if the axes `Color` property is `'none'`. This damages objects that are behind the erased object, but properly colors the erased object.

MATLAB always prints figures as if the `EraseMode` property of all objects is set to `'normal'`. This means graphics objects created with `EraseMode` set to `'none'`, `'xor'`, or `'background'` can look different on screen than on paper. On screen, MATLAB mathematically combines layers of colors and ignores three-dimensional sorting to obtain greater rendering speed. However, MATLAB does not apply these techniques to the printed output. Use the `getframe` command or other screen capture applications to create an image of a figure containing nonnormal mode objects.

## Identifiers

### **Type — Type of graphics object**

`'rectangle'`

This property is read only.

Type of graphics object, returned as `'rectangle'`. Use this property to find all objects of a given type within a plotting hierarchy, for example, searching for the type using `findobj`.

### **Tag — Tag to associate with rectangle**

`''` (default) | string

Tag to associate with the rectangle, specified as a string. Tags provide a way to identify graphics objects. Use this property to find all objects with a specific tag within a plotting hierarchy, for example, searching for the tag using `findobj`.

Example: `'January Data'`

### **UserData — Data to associate with rectangle**

`[]` (default) | scalar, vector, or matrix | cell array | character array | table | structure

Data to associate with the rectangle object, specified as a scalar, vector, matrix, cell array, character array, table, or structure. MATLAB does not use this data.

To associate multiple sets of data or to attach a field name to the data, use the `getappdata` and `setappdata` functions.

Example: `1:100`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char` | `struct` | `table` | `cell`

## Parent/Child

### Parent — Parent of rectangle

axes object | group object | transform object

Parent of rectangle, specified as an axes, group, or transform object.

### Children — Children of rectangle

empty `GraphicsPlaceholder` array

The rectangle has no children. You cannot set this property.

### HandleVisibility — Visibility of object handle

'on' (default) | 'off' | 'callback'

Visibility of rectangle object handle in the `Children` property of the parent, specified as one of these values:

- 'on' — The rectangle object handle is always visible.
- 'off' — The rectangle object handle is invisible at all times. This option is useful for preventing unintended changes to the UI by another function. Set the `HandleVisibility` to 'off' to temporarily hide the handle during the execution of that function.
- 'callback' — The rectangle object handle is visible from within callbacks or functions invoked by callbacks, but not from within functions invoked from the command line. This option blocks access to the rectangle at the command-line, but allows callback functions to access it.

If the rectangle object is not listed in the `Children` property of the parent, then functions that obtain object handles by searching the object hierarchy or querying handle properties cannot return it. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

Hidden object handles are still valid. Set the root `ShowHiddenHandles` property to 'on' to list all object handles regardless of their `HandleVisibility` property setting.

## Interactive Control

### ButtonDownFcn — Mouse-click callback

' ' (default) | function handle | cell array | string

Mouse-click callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you click the rectangle. If you specify this property using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The rectangle object — You can access properties of the rectangle object from within the callback function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see “Callback Definition”.

---

**Note:** If the `PickableParts` property is set to 'none' or if the `HitTest` property is set to 'off', then this callback does not execute.

---

Example: `@myCallback`

Example: `{@myCallback, arg3}`

## **UIContextMenu — Context menu**

`uicontextmenu` object

Context menu, specified as a `uicontextmenu` object. Use this property to display a context menu when you right-click the rectangle. Create the context menu using the `uicontextmenu` function.

---

**Note:** If the `PickableParts` property is set to 'none' or if the `HitTest` property is set to 'off', then the context menu does not appear.

---

## **Selected — Selection state**

'off' (default) | 'on'

Selection state, specified as one of these values:

- 'on' — Selected. If you click the rectangle when in plot edit mode, then MATLAB sets its **Selected** property to 'on'. If the **SelectionHighlight** property also is set to 'on', then MATLAB displays selection handles around the rectangle.
- 'off' — Not selected.

### **SelectionHighlight** — Display of selection handles when selected

'on' (default) | 'off'

Display of selection handles when selected, specified as one of these values:

- 'on' — Display selection handles when the **Selected** property is set to 'on'.
- 'off' — Never display selection handles, even when the **Selected** property is set to 'on'.

## **Callback Execution Control**

### **PickableParts** — Ability to capture mouse clicks

'visible' (default) | 'all' | 'none'

Ability to capture mouse clicks, specified as one of these values:

- 'visible' — Can capture mouse clicks when visible. The **Visible** property must be set to 'on' and you must click a part of the rectangle that has a defined color. You cannot click a part that has an associated color property set to 'none'. The **HitTest** property determines if the rectangle responds to the click or if an ancestor does.
- 'all' — Can capture mouse clicks regardless of visibility. The **Visible** property can be set to 'on' or 'off' and you can click a part of the rectangle that has no color. The **HitTest** property determines if the rectangle responds to the click or if an ancestor does.
- 'none' — Cannot capture mouse clicks. Clicking the rectangle passes the click through it to the object below it in the current view of the figure window. The **HitTest** property has no effect.

### **HitTest** — Response to captured mouse clicks

'on' (default) | 'off'

Response to captured mouse clicks, specified as one of these values:

- 'on' — Trigger the `ButtonDownFcn` callback of the rectangle. If you have defined the `UIContextMenu` property, then invoke the context menu.
- 'off' — Trigger the callbacks for the nearest ancestor of the rectangle that has a `HitTest` property set to 'on' and a `PickableParts` property value that enables the ancestor to capture mouse clicks.

---

**Note:** The `PickableParts` property determines if the rectangle object can capture mouse clicks. If it cannot, then the `HitTest` property has no effect.

---

### **Interruptible — Callback interruption**

'on' (default) | 'off'

Callback interruption, specified as 'on' or 'off'. The `Interruptible` property determines if a running callback can be interrupted.

---

**Note:** There are two callback states to consider:

- The *running* callback is the currently executing callback.
  - The *interrupting* callback is a callback that tries to interrupt the running callback. Whenever MATLAB invokes a callback, that callback attempts to interrupt a running callback. The `Interruptible` property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the `BusyAction` property of the object owning the interrupting callback determines if it is discarded or put in the queue.
- 

If the `ButtonDownFcn` callback of the rectangle is the running callback, then the `Interruptible` property determines if it another callback can interrupt it:

- 'on' — Interruptible. Interruption occurs at the next point where MATLAB processes the queue, such as when there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command.
- If the running callback contains one of these commands, then MATLAB stops the execution of the callback at this point and executes the interrupting callback. MATLAB resumes executing the running callback when the interrupting callback completes. For more information, see “Interrupt Callback Execution”.

- If the running callback does not contain one of these commands, then MATLAB finishes executing the callback without interruption.
- 'off' — Not interruptible. MATLAB finishes executing the running callback without any interruptions.

**BusyAction — Callback queuing**

'queue' (default) | 'cancel'

Callback queuing specified as 'queue' or 'cancel'. The `BusyAction` property determines how MATLAB handles the execution of interrupting callbacks.

---

**Note:** There are two callback states to consider:

- The *running* callback is the currently executing callback.
- The *interrupting* callback is a callback that tries to interrupt the running callback.

Whenever MATLAB invokes a callback, that callback attempts to interrupt a running callback. The `Interruptible` property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the `BusyAction` property of the object owning the interrupting callback determines if it is discarded or put in the queue.

---

If the `ButtonDownFcn` callback of the rectangle tries to interrupt a running callback that cannot be interrupted, then the `BusyAction` property determines if it is discarded or put in the queue. Specify the `BusyAction` property as one of these values:

- 'queue' — Put the interrupting callback in a queue to be processed after the running callback finishes execution. This is the default behavior.
- 'cancel' — Discard the interrupting callback.

## Creation and Deletion Control

**CreateFcn — Creation callback**

' ' (default) | function handle | cell array | string

Creation callback, specified as one of these values:

- Function handle

- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you create the rectangle. Setting the `CreateFcn` property on an existing rectangle has no effect. You must define a default value for this property, or define this property using a `Name, Value` pair during rectangle creation. MATLAB executes the callback after creating the rectangle and setting all of its properties.

If you specify this callback using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The rectangle object — You can access properties of the rectangle object from within the callback function. You also can access the rectangle object through the `CallbackObject` property of the root, which can be queried using the `gcbo` function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see “Callback Definition”.

Example: `@myCallback`

Example: `{@myCallback, arg3}`

### **DeleteFcn — Deletion callback**

' ' (default) | function handle | cell array | string

Deletion callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you delete the rectangle. MATLAB executes the callback before destroying the rectangle so that the callback can access its property values.

If you specify this callback using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The rectangle object — You can access properties of the rectangle object from within the callback function. You also can access the rectangle object through the `CallbackObject` property of the root, which can be queried using the `gcbo` function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see “Callback Definition”.

Example: `@myCallback`

Example: `{@myCallback, arg3}`

### **BeingDeleted — Deletion status of rectangle**

'off' (default) | 'on'

This property is read only.

Deletion status of rectangle, returned as 'on' or 'off'. MATLAB sets the `BeingDeleted` property to 'on' when the delete function of the rectangle begins execution (see the `DeleteFcn` property). The `BeingDeleted` property remains set to 'on' until the rectangle no longer exists.

Check the value of the `BeingDeleted` property to verify that the rectangle is not about to be deleted before querying or modifying it.

## rectint

Rectangle intersection area

### Syntax

```
area = rectint(A,B)
```

### Description

`area = rectint(A,B)` returns the area of intersection of the rectangles specified by position vectors `A` and `B`.

If `A` and `B` each specify one rectangle, the output `area` is a scalar.

`A` and `B` can also be matrices, where each row is a position vector. `area` is then a matrix giving the intersection of all rectangles specified by `A` with all the rectangles specified by `B`. That is, if `A` is `n`-by-4 and `B` is `m`-by-4, then `area` is an `n`-by-`m` matrix where `area(i,j)` is the intersection area of the rectangles specified by the `i`th row of `A` and the `j`th row of `B`.

---

**Note** A position vector is a four-element vector `[x,y,width,height]`, where the point defined by `x` and `y` specifies one corner of the rectangle, and `width` and `height` define the size in units along the `x` and `y` axes respectively.

---

`polyarea`

**Introduced before R2006a**

# recycle

Set option to move deleted files to recycle folder

## Syntax

```
status = recycle
oldState = recycle(state)
```

## Description

`status = recycle` returns the current state for recycling files you remove using the `delete` function. When `status` is `off`, the `delete` function permanently removes the files. When `status` is `on`, deleted files move to a different location. For details, see the [Tips](#) section.

`oldState = recycle(state)` sets the recycle option for MATLAB to the specified state, either `on` or `off`. The `previousStat` value is the recycle state before running the statement.

## Examples

### View Current Recycling State

Start from a state where file recycling is off. Verify the current recycle state.

```
state = recycle

state =

off
```

### Turn File Recycling On

Turn file recycling on. Then, delete an existing file and move it to the recycle bin or temporary folder.

```
recycle('on');
```

```
delete('myfile.txt')
```

## Input Arguments

**state** — State of recycle option

'on' | 'off'

State of the recycle option, specified as 'on' or 'off'.

## More About

### Tips

- The location for storing recycled files varies by platform, as follows:
  - Microsoft Windows systems — Recycle bin.
  - Apple Macintosh systems — Trash.
  - Linux systems — Subfolder with the prefix `MATLAB_Files_` in the system temporary folder, as returned by the `tempdir` function.
- The general preference for **Deleting files** sets the state of the `recycle` function at startup. When you change the preference, it changes the state of `recycle`. However, when you change the state of `recycle`, it does not change the preference.
- “General Preferences”

# reducepatch

Reduce number of patch faces

## Syntax

```
reducepatch(p,r)
nfv = reducepatch(p,r)
nfv = reducepatch(fv,r)
nfv = reducepatch(p)
nfv = reducepatch(fv)
reducepatch(...,'fast')
reducepatch(...,'verbose')
nfv = reducepatch(f,v,r)
[nf,nv] = reducepatch(...)
```

## Description

`reducepatch(p,r)` reduces the number of faces of the patch identified by handle `p`, while attempting to preserve the overall shape of the original object. The MATLAB software interprets the reduction factor `r` in one of two ways depending on its value:

- If `r` is less than 1, `r` is interpreted as a fraction of the original number of faces. For example, if you specify `r` as 0.2, then the number of faces is reduced to 20% of the number in the original patch.
- If `r` is greater than or equal to 1, then `r` is the target number of faces. For example, if you specify `r` as 400, then the number of faces is reduced until there are 400 faces remaining.

`nfv = reducepatch(p,r)` returns the reduced set of faces and vertices but does not set the Faces and Vertices properties of patch `p`. The struct `nfv` contains the faces and vertices after reduction.

`nfv = reducepatch(fv,r)` performs the reduction on the faces and vertices in the struct `fv`.

`nfv = reducepatch(p)` and `nfv = reducepatch(fv)` uses a reduction value of 0.5.

`reducepatch(..., 'fast')` assumes the vertices are unique and does not compute shared vertices.

`reducepatch(..., 'verbose')` prints progress messages to the command window as the computation progresses.

`nfv = reducepatch(f, v, r)` performs the reduction on the faces in `f` and the vertices in `v`.

`[nf, nv] = reducepatch(...)` returns the faces and vertices in the arrays `nf` and `nv`.

## Examples

### Reduce Number of Patch Faces

This example illustrates the effect of reducing the number of faces to only 15% of the original value.

```
figure
[x,y,z,v] = flow;
p = patch(isosurface(x,y,z,v,-3));
p.FaceColor = 'w';
p.EdgeColor = 'b';
daspect([1,1,1])
view(3)
```

Reduce the number of faces.

```
reducepatch(p,0.15)
```

## More About

### Tips

If the patch contains nonshared vertices, MATLAB computes shared vertices before reducing the number of faces. If the faces of the patch are not triangles, MATLAB triangulates the faces before reduction. The faces returned are always defined as triangles.

The number of output triangles may not be exactly the number specified with the reduction factor argument ( $r$ ), particularly if the faces of the original patch are not triangles.

### **See Also**

isosurface | isocaps | isonormals | smooth3 | subvolume | reducevolume

**Introduced before R2006a**

## reducevolume

Reduce number of elements in volume data set

### Syntax

```
[nx,ny,nz,nv] = reducevolume(X,Y,Z,V,[Rx,Ry,Rz])
[nx,ny,nz,nv] = reducevolume(V,[Rx,Ry,Rz])
nv = reducevolume(...)
```

### Description

`[nx,ny,nz,nv] = reducevolume(X,Y,Z,V,[Rx,Ry,Rz])` reduces the number of elements in the volume by retaining every  $R_x^{\text{th}}$  element in the  $x$  direction, every  $R_y^{\text{th}}$  element in the  $y$  direction, and every  $R_z^{\text{th}}$  element in the  $z$  direction. If a scalar  $R$  is used to indicate the amount or reduction instead of a three-element vector, the MATLAB software assumes the reduction to be `[R R R]`.

The arrays  $X$ ,  $Y$ , and  $Z$  define the coordinates for the volume  $V$ . The reduced volume is returned in  $nv$ , and the coordinates of the reduced volume are returned in  $nx$ ,  $ny$ , and  $nz$ .

`[nx,ny,nz,nv] = reducevolume(V,[Rx,Ry,Rz])` assumes the arrays  $X$ ,  $Y$ , and  $Z$  are defined as `[X,Y,Z] = meshgrid(1:n,1:m,1:p)`, where `[m,n,p] = size(V)`.

`nv = reducevolume(...)` returns only the reduced volume.

## Examples

### Reduce Volume Data Set

This example uses a data set that is a collection of MRI slices of a human skull. This data is processed in a variety of ways:

- The 4-D array is squeezed (`squeeze`) into three dimensions and then reduced (`reducevolume`) so that what remains is every fourth element in the  $x$  and  $y$  directions and every element in the  $z$  direction.

- The reduced data is smoothed (`smooth3`).
- The outline of the skull is an isosurface generated as a patch (`p1`) whose vertex normals are recalculated to improve the appearance when lighting is applied (`patch`, `isosurface`, `isonormals`).
- A second patch (`p2`) with an interpolated face color draws the end caps (`FaceColor` `isocaps`).
- The view of the object is set (`view`, `axis`, `daspect`).
- A 100-element grayscale colormap provides coloring for the end caps (`colormap`).
- Adding a light to the right of the camera illuminates the object (`camlight`, `lighting`).

```
load mri
D = squeeze(D);
[x,y,z,D] = reducevolume(D,[4,4,1]);
D = smooth3(D);
p1 = patch(isosurface(x,y,z,D,5),...
 'FaceColor','red','EdgeColor','none');
isonormals(x,y,z,D,p1)
p2 = patch(isocaps(x,y,z,D,5),...
 'FaceColor','interp','EdgeColor','none');
view(3)
axis tight
daspect([1,1,.4])
colormap(gray(100))
camlight
lighting gouraud
```

# refresh

Redraw current figure

## Syntax

refresh  
refresh(h)

## Description

refresh erases and redraws the current figure.

refresh(h) redraws the figure identified by h.

**Introduced before R2006a**

# refreshdata

Refresh data in graph when data source is specified

## Syntax

```
refreshdata
refreshdata(figure_handle)
refreshdata(object_handles)
refreshdata(object_handles, 'workspace')
```

## Description

`refreshdata` evaluates any data source properties (`XDataSource`, `YDataSource`, or `ZDataSource`) on all objects in graphs in the current figure. If the specified data source has changed, the MATLAB software updates the graph to reflect this change.

---

**Note:** The variable assigned to the data source property must be in the base workspace or you must specify the *workspace* option as '*caller*'.

---

`refreshdata(figure_handle)` refreshes the data of the objects in the specified figure.

`refreshdata(object_handles)` refreshes the data of the objects specified in `object_handles` or the children of those objects. Therefore, `object_handles` can contain figure, axes, or plot object handles.

`refreshdata(object_handles, 'workspace' )` enables you to specify whether the data source properties are evaluated in the base workspace or the workspace of the function in which `refreshdata` was called. *workspace* is a string that can be

- **base** — Evaluate the data source properties in the base workspace.
- **caller** — Evaluate the data source properties in the workspace of the function that called `refreshdata`.

## Examples

### Refresh Graph with Updated Data

Plot a sine wave and return the chart line handle, h.

```
x = linspace(0,8);
y = sin(x);
figure
h = plot(x,y);
```

Identify the data sources for the plot by setting the `XDataSource` and `YDataSource` properties of the line to `x` and `y`, respectively. Then, modify `y`. Call `refreshdata` so that the graph updates with the changes to `y`.

```
h.XDataSource = 'x';
h.YDataSource = 'y';

y = sin(x.^3);
refreshdata
```

## More About

### Tips

The Linked Plots feature (see documentation for `linkdata`) sets up data sources for graphs and synchronizes them with the workspace variables they display. When you use

this feature, you do not also need to call `refreshdata`, as it is essentially automatically triggered every time a data source changes.

If you are not using the Linked Plots feature, you need to set the `XDataSource`, `YDataSource`, and/or `ZDataSource` properties of a graph in order to use `refreshdata`. You can do that programmatically or use the Property Editor, one of the plotting tools. In the Property Editor, select the graph (e.g., a chart line object) and type in (or select from the drop-down choices) the name(s) of the workspace variable(s) from which you want the plot to refresh, in the fields labelled **X Data Source**, **Y Data Source**, and/or **Z Data Source**. The call to `refreshdata` causes the graph to update.

## regexp

Match regular expression (case sensitive)

### Syntax

```
startIndex = regexp(str,expression)
[startIndex,endIndex] = regexp(str,expression)
```

```
out = regexp(str,expression,outkey)
[out1,...,outN] = regexp(str,expression,outkey1,...,outkeyN)
```

```
___ = regexp(___,option1,...,optionM)
```

### Description

`startIndex = regexp(str,expression)` returns the starting index of each substring of `str` that matches the character patterns specified by the regular expression. If there are no matches, `startIndex` is an empty array.

`[startIndex,endIndex] = regexp(str,expression)` returns the starting and ending indices of all matches.

`out = regexp(str,expression,outkey)` returns the output specified by `outkey`. For example, if `outkey` is `'match'`, then `regexp` returns the substrings that match the expression rather than their starting indices.

`[out1,...,outN] = regexp(str,expression,outkey1,...,outkeyN)` returns the outputs specified by multiple output keywords, in the specified order. For example, if you specify `'match'`, `'tokens'`, then `regexp` returns substrings that match the entire expression and tokens that match parts of the expression.

`___ = regexp( ___,option1,...,optionM)` modifies the search using the specified option flags. For example, specify `'ignorecase'` to perform a case-insensitive match. You can include any of the inputs and request any of the outputs from previous syntaxes.

## Examples

### Find Patterns in Single Strings

Find words that start with `c`, end with `t`, and contain one or more vowels between them.

```
str = 'bat cat can car coat court CUT ct CAT-scan';
expression = 'c[aeiou]+t';
startIndex = regexp(str,expression)
```

```
startIndex =
 5 17
```

The regular expression `'c[aeiou]+t'` specifies this pattern:

- `c` must be the first character.
- `c` must be followed by one of the characters inside the brackets, `[aeiou]`.
- The bracketed pattern must occur one or more times, as indicated by the `+` operator.
- `t` must be the last character, with no characters between the bracketed pattern and the `t`.

Values in `startIndex` indicate the index of the first character of each word that matches the regular expression. The matching word `cat` starts at index 5, and `coat` starts at index 17. The words `CUT` and `CAT` do not match because they are uppercase.

### Find Patterns in Multiple Strings

Find the location of capital letters and spaces within strings in a cell array.

```
str = {'Madrid, Spain', 'Romeo and Juliet', 'MATLAB is great'};
capExpr = '[A-Z]';
spaceExpr = '\s';
```

```
capStartIndex = regexp(str, capExpr);
spaceStartIndex = regexp(str, spaceExpr);
```

`capStartIndex` and `spaceStartIndex` are cell arrays because the input `str` is a cell array.

View the indices for the capital letters.

```
celldisp(capStartIndex)
```

```
capStartIndex{1} =
```

```
1 9
```

```
capStartIndex{2} =
```

```
1 11
```

```
capStartIndex{3} =
```

```
1 2 3 4 5 6
```

View the indices for the spaces.

```
celldisp(spaceStartIndex)
```

```
spaceStartIndex{1} =
```

```
8
```

```
spaceStartIndex{2} =
```

```
6 10
```

```
spaceStartIndex{3} =
```

```
7 10
```

## Return Substrings Using match Keyword

Capture words within a string that contain the letter x.

```
str = 'EXTRA! The regexp function helps you relax.';
expression = '\w*x\w*';
matchStr = regexp(str,expression,'match')
```

```
matchStr =
 'regexp' 'relax'
```

The regular expression '\w\*x\w\*' specifies that the string:

- Begins with any number of alphanumeric or underscore characters, \w\*.
- Contains the lowercase letter x.
- Ends with any number of alphanumeric or underscore characters after the x, including none, as indicated by \w\*.

## Split String at Delimiter Using split Keyword

Split a string into several substrings, where each substring is delimited by a ^ character.

```
str = ['Split ^this string into ^several pieces'];
expression = '\^';
splitStr = regexp(str,expression,'split')
```

```
splitStr =
 'Split ' 'this string into ' 'several pieces'
```

Because the caret symbol has special meaning in regular expressions, precede it with the escape character, a backslash (\). To split a string at other delimiters, such as a semicolon, you do not need to include the backslash.

## Return Both Matching and Nonmatching Substrings

Capture parts of a string that match a regular expression using the 'match' keyword, and the remaining parts that do not match using the 'split' keyword.

```
str = 'She sells sea shells by the seashore.';
expression = '[Ss]h.';
[match,noMatch] = regexp(str,expression,'match','split')
```

```
match =
 'She' 'she' 'sho'

noMatch =
 '' ' sells sea ' 'lls by the sea' 're.'
```

The regular expression '[Ss]h.' specifies that:

- S or s is the first character.
- h is the second character.
- The third character can be anything, including a space, as indicated by the dot (.).

When the first (or last) character in a string matches a regular expression, the first (or last) return value from the 'split' keyword is an empty string.

Optionally, reassemble the original string from the substrings.

```
combinedStr = strjoin(noMatch,match)
```

```
combinedStr =
She sells sea shells by the seashore.
```

## Capture Substrings of Matches Using Ordinal Tokens

Find the names of HTML tags by defining a token within a regular expression. Tokens are indicated with parentheses, ().

```
str = '<title>My Title</title><p>Here is some text.</p>';
expression = '<(\w+).*>.*</\1>';
[tokens,matches] = regexp(str,expression, 'tokens', 'match');
```

The regular expression `<(\w+).*>.*</\1>` specifies this pattern:

- `<(\w+)` finds an opening angle bracket followed by one or more alphanumeric or underscore characters. Enclosing `\w+` in parentheses captures the name of the HTML tag in a token.
- `.*>` finds any number of additional characters, such as HTML attributes, and a closing angle bracket.
- `</\1>` finds the end tag corresponding to the first token (indicated by `\1`). The end tag has the form `</tagname>`.

View the tokens and matching substrings.

```
celldisp(tokens)

tokens{1}{1} =
 title

tokens{2}{1} =
 p

celldisp(matches)

matches{1} =
 <title>My Title</title>

matches{2} =
 <p>Here is some text.</p>
```

## Capture Substrings of Matches Using Named Tokens

Parse dates that can appear with either the day or the month first, in these forms: `mm/dd/yyyy` or `dd-mm-yyyy`. Use named tokens to identify each part of the date.

```
str = '01/11/2000 20-02-2020 03/30/2000 16-04-2020';
```

```
expression = ['(?<month>\d+)/(?<day>\d+)/(?<year>\d+) | '...
 '(?<day>\d+) - (?<month>\d+) - (?<year>\d+)'];
tokenNames = regexp(str,expression,'names');
```

The regular expression specifies this pattern:

- `(?<name>\d+)` finds one or more numeric digits and assigns the result to the token indicated by name.
- `|` is the logical OR operator, which indicates that there are two possible patterns for dates. In the first pattern, slashes (/) separate the tokens. In the second pattern, hyphens (-) separate the tokens.

View the named tokens.

```
for k = 1:length(tokenNames)
 disp(tokenNames(k))
end
```

```
month: '01'
day: '11'
year: '2000'

month: '02'
day: '20'
year: '2020'

month: '03'
day: '30'
year: '2000'

month: '04'
day: '16'
year: '2020'
```

## Perform Case-Insensitive Matches

Find both uppercase and lowercase instances of a word.

By default, `regexp` performs case-sensitive matching.

```
str = 'A string with UPPERCASE and lowercase text.';
expression = '\w*case';
matchStr = regexp(str,expression,'match')
```

```
matchStr =
 'lowercase'
```

The regular expression specifies that the string:

- Begins with any number of alphanumeric or underscore characters, `\w*`.
- Ends with the literal text `case`.

The `regexpi` function uses the same syntax as `regexp`, but performs case-insensitive matching.

```
matchWithRegexpi = regexp(str,expression,'match')
```

```
matchWithRegexpi =
 'UPPERCASE' 'lowercase'
```

Alternatively, disable case-sensitive matching for `regexp` using the `'ignorecase'` option.

```
matchWithIgnorecase = regexp(str,expression,'match','ignorecase')
```

```
matchWithIgnorecase =
 'UPPERCASE' 'lowercase'
```

For multiple expressions, disable case-sensitive matching for selected expressions using the `(?i)` search flag.

```
expression = {'(?-i)\w*case';...
 '(?i)\w*case'};
matchStr = regexp(str,expression,'match');
celldisp(matchStr)
```

```
matchStr{1}{1} =
lowercase
```

```
matchStr{2}{1} =
```

```
UPPERCASE
```

```
matchStr{2}{2} =
```

```
lowercase
```

## Parse Strings with Newline Characters

Create a string that contains a newline, `\n`, and parse the string using a regular expression.

```
str = sprintf('abc\n de');
expression = '.*';
matchStr = regexp(str,expression,'match')
```

```
matchStr =
```

```
 [1x7 char]
```

By default, the dot (`.`) matches every character, including the newline, and returns a single match that is equivalent to the original string.

Exclude newline characters from the match using the `'dotexceptnewline'` option. This returns separate matches for each line of text.

```
matchStrNoNewline = regexp(str,expression,'match','dotexceptnewline')
```

```
matchStrNoNewline =
```

```
 'abc' ' de'
```

Find the first or last character of each line using the `^` or `$` metacharacters and the `'lineanchors'` option.

```
expression = '.*$';
lastInLine = regexp(str,expression,'match','lineanchors')
```

```
lastInLine =
 'c' 'e'
```

## Input Arguments

### **str** — Input text

string | cell array of strings

Input text, specified as a string or a cell array of strings. Each string can be of any length and contain any characters.

If **str** and **expression** are both cell arrays, they must have the same dimensions.

Data Types: char | cell

### **expression** — Regular expression

string | cell array of strings

Regular expression, specified as a string or a cell array of strings. Each expression can contain characters, metacharacters, operators, tokens, and flags that specify patterns to match in **str**.

The following tables describe the elements of regular expressions.

### Metacharacters

Metacharacters represent letters, letter ranges, digits, and space characters. Use them to construct a generalized pattern of characters.

Metacharacter	Description	Example
.	Any single character, including white space	' <b>.ain</b> ' matches sequences of five consecutive characters that end with 'ain'.
[ <b>C<sub>1</sub>C<sub>2</sub>C<sub>3</sub></b> ]	Any character contained within the brackets. The following characters are treated literally: \$   . * + ? and - when not used to indicate a range.	' <b>[rp.]ain</b> ' matches 'rain' or 'pain' or '.ain'.

Metacharacter	Description	Example
[ <sup>^</sup> c <sub>1</sub> c <sub>2</sub> c <sub>3</sub> ]	Any character not contained within the brackets. The following characters are treated literally: \$   . * + ? and - when not used to indicate a range.	'[ <sup>^</sup> *rp]ain' matches all four-letter sequences that end in 'ain', except 'rain' and 'pain' and '*ain'. For example, it matches 'gain', 'lain', or 'vain'.
[c <sub>1</sub> -c <sub>2</sub> ]	Any character in the range of c <sub>1</sub> through c <sub>2</sub>	'[A-G]' matches a single character in the range of A through G.
\w	Any alphabetic, numeric, or underscore character. For English character sets, \w is equivalent to [a-zA-Z_0-9]	'\w*' identifies a word.
\W	Any character that is not alphabetic, numeric, or underscore. For English character sets, \W is equivalent to [ <sup>^</sup> a-zA-Z_0-9]	'\W*' identifies a substring that is not a word.
\s	Any white-space character; equivalent to [ \f\n\r\t\v]	'\w*n\s' matches words that end with the letter n, followed by a white-space character.
\S	Any non-white-space character; equivalent to [ <sup>^</sup> \f\n\r\t\v]	'\d\S' matches a numeric digit followed by any non-white-space character.
\d	Any numeric digit; equivalent to [0-9]	'\d*' matches any number of consecutive digits.
\D	Any nondigit character; equivalent to [ <sup>^</sup> 0-9]	'\w*\D\>' matches words that do not end with a numeric digit.
\oN or \o{N}	Character of octal value N	'\o{40}' matches the space character, defined by octal 40.
\xN or \x{N}	Character of hexadecimal value N	'\x2C' matches the comma character, defined by hex 2C.

### Character Representation

Operator	Description
\a	Alarm (beep)
\b	Backspace

Operator	Description
\f	Form feed
\n	New line
\r	Carriage return
\t	Horizontal tab
\v	Vertical tab
\char	Any character with special meaning in regular expressions that you want to match literally (for example, use \\ to match a single backslash)

### Quantifiers

Quantifiers specify the number of times a string pattern must occur in the matching string.

Quantifier	Matches the expression when it occurs...	Example
expr*	0 or more times consecutively.	'\w*' matches a word of any length.
expr?	0 times or 1 time.	'\w*(\..m)?' matches words that optionally end with the extension .m.
expr+	1 or more times consecutively.	'' matches an <img> HTML tag when the file name contains one or more characters.
expr{m,n}	At least m times, but no more than n times consecutively.  {0,1} is equivalent to ?.	'\S{4,8}' matches between four and eight non-white-space characters.
expr{m,}	At least m times consecutively.  {0,} and {1,} are equivalent to * and +, respectively.	'<a href="\w{1,}\..html">' matches an <a> HTML tag when the file name contains one or more characters.
expr{n}	Exactly n times consecutively.  Equivalent to {n,n}.	'\d{4}' matches four consecutive digits.

Quantifiers can appear in three modes, described in the following table. q represents any of the quantifiers in the previous table.

Mode	Description	Example
<code>exprq</code>	Greedy expression: match as many characters as possible.	Given the string ' <code>&lt;tr&gt;&lt;td&gt;&lt;p&gt;text&lt;/p&gt;&lt;/td&gt;</code> ', the expression ' <code>&lt;/?t.*&gt;</code> ' matches all characters between <code>&lt;tr</code> and <code>/td&gt;</code> :  ' <code>&lt;tr&gt;&lt;td&gt;&lt;p&gt;text&lt;/p&gt;&lt;/td&gt;</code> '
<code>exprq?</code>	Lazy expression: match as few characters as necessary.	Given the string ' <code>&lt;tr&gt;&lt;td&gt;&lt;p&gt;text&lt;/p&gt;&lt;/td&gt;</code> ', the expression ' <code>&lt;/?t.*?&gt;</code> ' ends each match at the first occurrence of the closing bracket ( <code>&gt;</code> ):  ' <code>&lt;tr&gt;</code> '    ' <code>&lt;td&gt;</code> '    ' <code>&lt;/td&gt;</code> '
<code>exprq+</code>	Possessive expression: match as much as possible, but do not rescan any portions of the string.	Given the string ' <code>&lt;tr&gt;&lt;td&gt;&lt;p&gt;text&lt;/p&gt;&lt;/td&gt;</code> ', the expression ' <code>&lt;/?t.*+&gt;</code> ' does not return any matches, because the closing bracket is captured using <code>.*</code> , and is not rescanned.

### Grouping Operators

Grouping operators allow you to capture tokens, apply one operator to multiple elements, or disable backtracking in a specific group.

Grouping Operator	Description	Example
<code>(expr)</code>	Group elements of the expression and capture tokens.	' <code>Joh?n\s(\w*)</code> ' captures a token that contains the last name of any person with the first name <code>John</code> or <code>Jon</code> .
<code>(?:expr)</code>	Group, but do not capture tokens.	' <code>(?:[aeiou][^aeiou]){2}</code> ' matches two consecutive patterns of a vowel followed by a nonvowel, such as ' <code>anon</code> '.  Without grouping, ' <code>[aeiou][^aeiou]{2}</code> ' matches a vowel followed by two nonvowels.

Grouping Operator	Description	Example
(?>expr)	Group atomically. Do not backtrack within the group to complete the match, and do not capture tokens.	'A(?>.* )Z' does not match 'AtoZ', although 'A(?:.* )Z' does. Using the atomic group, Z is captured using .* and is not rescanned.
(expr1   expr2)	Match expression expr1 or expression expr2.  If there is a match with expr1, then expr2 is ignored.  You can include ?: or ?> after the opening parenthesis to suppress tokens or group atomically.	'(let   tel)\w+' matches words in a string that start with let or tel.

### Anchors

Anchors in the expression match the beginning or end of the string or word.

Anchor	Matches the...	Example
^expr	Beginning of the input string.	'^M\w*' matches a word starting with M at the beginning of the string.
expr\$	End of the input string.	'\w*m\$' matches words ending with m at the end of the string.
\<expr	Beginning of a word.	'\<n\w*' matches any words starting with n.
expr\>	End of a word.	'\w*e\>' matches any words ending with e.

### Lookaround Assertions

Lookaround assertions look for string patterns that immediately precede or follow the intended match, but are not part of the match.

The pointer remains at the current location, and characters that correspond to the test expression are not captured or discarded. Therefore, lookahead assertions can match overlapping character groups.

Lookaround Assertion	Description	Example
<code>expr(?=test)</code>	Look ahead for characters that match <code>test</code> .	<code>'\w*(?=ing)'</code> matches strings that are followed by <code>ing</code> , such as <code>'Fly'</code> and <code>'fall'</code> in the input string <code>'Flying, not falling.'</code>
<code>expr(?!test)</code>	Look ahead for characters that do not match <code>test</code> .	<code>'i(?!ng)'</code> matches instances of the letter <code>i</code> that are not followed by <code>ng</code> .
<code>(?&lt;=test)expr</code>	Look behind for characters that match <code>test</code> .	<code>'(?&lt;=re)\w*'</code> matches strings that follow <code>'re'</code> , such as <code>'new'</code> , <code>'use'</code> , and <code>'cycle'</code> in the input string <code>'renew, reuse, recycle'</code>
<code>(?&lt;!test)expr</code>	Look behind for characters that do not match <code>test</code> .	<code>'(?&lt;!\d)(\d)(?!\d)'</code> matches single-digit numbers (digits that do not precede or follow other digits).

If you specify a lookahead assertion *before* an expression, the operation is equivalent to a logical AND.

Operation	Description	Example
<code>(?=test)expr</code>	Match both <code>test</code> and <code>expr</code> .	<code>'(?=[a-z])[^aeiou]'</code> matches consonants.
<code>(?!test)expr</code>	Match <code>expr</code> and do not match <code>test</code> .	<code>'(?![aeiou])[a-z]'</code> matches consonants.

### Logical and Conditional Operators

Logical and conditional operators allow you to test the state of a given condition, and then use the outcome to determine which string, if any, to match next. These operators support logical OR, and `if` or `if/else` conditions.

Conditions can be tokens, lookaround operators, or dynamic expressions of the form `(?@cmd)`. Dynamic expressions must return a logical or numeric value.

Conditional Operator	Description	Example
<code>expr1 expr2</code>	Match expression <code>expr1</code> or expression <code>expr2</code> .	<code>'(let tel)\w+'</code> matches words in a string that start with <code>let</code> or <code>tel</code> .

Conditional Operator	Description	Example
	If there is a match with <code>expr1</code> , then <code>expr2</code> is ignored.	
<code>(?(cond)expr)</code>	If condition <code>cond</code> is true, then match <code>expr</code> .	' <code>(?(?@ispc)[A-Z]:\\)</code> ' matches a drive name, such as <code>C:\</code> , when run on a Windows system.
<code>(?(cond)expr1 expr2)</code>	If condition <code>cond</code> is true, then match <code>expr1</code> . Otherwise, match <code>expr2</code> .	' <code>Mr(s?)\..*?(?(1)her his)\w*</code> ' matches strings that include <code>her</code> when the string begins with <code>Mrs</code> , or that include <code>his</code> when the string begins with <code>Mr</code> .

### Token Operators

Tokens are portions of the matched text that you define by enclosing part of the regular expression in parentheses. You can refer to a token by its sequence in the string (an ordinal token), or assign names to tokens for easier code maintenance and readable output.

Ordinal Token Operator	Description	Example
<code>(expr)</code>	Capture in a token the characters that match the enclosed expression.	' <code>Joh?n\s(\w*)</code> ' captures a token that contains the last name of any person with the first name <code>John</code> or <code>Jon</code> .
<code>\N</code>	Match the Nth token.	' <code>&lt;(\w+).*.*/\1&gt;</code> ' captures tokens for HTML tags, such as <code>'title'</code> from the string <code>'&lt;title&gt;Some text&lt;/title&gt;'</code> .
<code>(?(N)expr1 expr2)</code>	If the Nth token is found, then match <code>expr1</code> . Otherwise, match <code>expr2</code> .	' <code>Mr(s?)\..*?(?(1)her his)\w*</code> ' matches strings that include <code>her</code> when the string begins with <code>Mrs</code> , or that include <code>his</code> when the string begins with <code>Mr</code> .

Named Token Operator	Description	Example
<code>(?&lt;name&gt;expr)</code>	Capture in a named token the characters that match the enclosed expression.	' <code>(?&lt;month&gt;\d+) - (?&lt;day&gt;\d+) - (?&lt;yr&gt;\d+)</code> ' creates named tokens for the month, day, and year in an

Named Token Operator	Description	Example
		input date string of the form mm-dd-yy.
<code>\k&lt;name&gt;</code>	Match the token referred to by <code>name</code> .	<code>'&lt;(?(?&lt;tag&gt;\w+).*&gt;.*&lt;/\k&lt;tag&gt;&gt;'</code> captures tokens for HTML tags, such as <code>'title'</code> from the string <code>'&lt;title&gt;Some text&lt;/title&gt;'</code> .
<code>(?(name)expr1 expr2)</code>	If the named token is found, then match <code>expr1</code> . Otherwise, match <code>expr2</code> .	<code>'Mr(?(sex&gt;s?)\..*?(?(sex)her his)\w*'</code> matches strings that include <code>her</code> when the string begins with <code>Mrs</code> , or that include <code>his</code> when the string begins with <code>Mr</code> .

**Note:** If an expression has nested parentheses, MATLAB captures tokens that correspond to the outermost set of parentheses. For example, given the search pattern `'(and(y|rew))'`, MATLAB creates a token for `'andrew'` but not for `'y'` or `'rew'`.

### Dynamic Regular Expressions

Dynamic expressions allow you to execute a MATLAB command or a regular expression to determine the text to match.

The parentheses that enclose dynamic expressions do *not* create a capturing group.

Operator	Description	Example
<code>(??expr)</code>	Parse <code>expr</code> and include the resulting string in the match expression.  When parsed, <code>expr</code> must correspond to a complete, valid regular expression. Dynamic expressions that use the backslash escape character ( <code>\</code> ) require two backslashes: one for the initial parsing of <code>expr</code> , and one for the complete match.	<code>'^(\d+)((??\w{\$1}))'</code> determines how many characters to match by reading a digit at the beginning of the string. The dynamic expression is enclosed in a second set of parentheses so that the resulting match is captured in a token. For instance, matching <code>'5XXXXX'</code> captures tokens for <code>'5'</code> and <code>'XXXXX'</code> .

Operator	Description	Example
(??@cmd)	Execute the MATLAB command represented by <code>cmd</code> , and include the string returned by the command in the match expression.	'(.{2,}).?(??@fliplr(\$1))' finds palindromes that are at least four characters long, such as 'abba'.
(?@cmd)	Execute the MATLAB command represented by <code>cmd</code> , but discard any output the command returns. (Helpful for diagnosing regular expressions.)	'\w*?(\\w)(?@disp(\$1))\1\w*' matches words that include double letters (such as pp), and displays intermediate results.

Within dynamic expressions, use the following operators to define replacement strings.

Replacement String Operator	Description
\$& or \$0	Portion of the input string that is currently a match
\$`	Portion of the input string that precedes the current match
\$'	Portion of the input string that follows the current match (use '\$ ' to represent the string '\$')
\$N	Nth token
\$<name>	Named token
\${cmd}	String returned when MATLAB executes the command, <code>cmd</code>

### Comments

Characters	Description	Example
(?#comment)	Insert a comment in the regular expression. The comment text is ignored when matching the input string.	'(?# Initial digit)\<\d\w+' includes a comment, and matches words that begin with a number.

### Search Flags

Search flags modify the behavior for matching expressions. An alternative to using a search flag within an expression is to pass an `option` input argument.

Flag	Description
(?-i)	Match letter case (default for <code>regexp</code> and <code>regexprep</code> ).

Flag	Description
(?i)	Do not match letter case (default for <code>regexpi</code> ).
(?s)	Match dot (.) in the pattern string with any character (default).
(?-s)	Match dot in the pattern with any character that is not a newline character.
(?-m)	Match the ^ and \$ metacharacters at the beginning and end of a string (default).
(?m)	Match the ^ and \$ metacharacters at the beginning and end of a line.
(?-x)	Include space characters and comments when matching (default).
(?x)	Ignore space characters and comments when matching. Use '\ ' and '\#' to match space and # characters.

The expression that the flag modifies can appear either after the parentheses, such as

`(?i)\w*`

or inside the parentheses and separated from the flag with a colon (:), such as

`(?i:\w*)`

The latter syntax allows you to change the behavior for part of a larger expression.

Data Types: `char` | `cell`

**outkey** — Keyword that indicates which outputs to return

'start' (default) | 'end' | 'tokenExtents' | 'match' | 'tokens' | 'names' | 'split'

Keyword that indicates which outputs to return, specified as one of the following strings.

Output Keyword	Returns
'start' (default)	Starting indices of all matches, <code>startIndex</code>
'end'	Ending indices of all matches, <code>endIndex</code>
'tokenExtents'	Starting and ending indices of all tokens
'match'	Text of each substring that matches the pattern in <code>expression</code>
'tokens'	Text of each captured token in <code>str</code>

Output Keyword	Returns
'names'	Name and text of each named token
'split'	Text of nonmatching substrings of <code>str</code>

Data Types: char

**option — Search option**

'once' | 'warnings' | 'ignorecase' | 'emptymatch' | 'dotexceptnewline' | 'lineanchors' | ...

Search option, specified as a string. Options come in pairs: one option that corresponds to the default behavior, and one option that allows you to override the default. Specify only one option from a pair. Options can appear in any order.

Default	Override	Description
'all'	'once'	Match the expression as many times as possible (default), or only once.
'nowarnings'	'warnings'	Suppress warnings (default), or display them.
'matchcase'	'ignorecase'	Match letter case (default), or ignore case.
'noemptymatch'	'emptymatch'	Ignore zero length matches (default), or include them.
'dotall'	'dotexceptnewline'	Match dot with any character (default), or all except newline ( <code>\n</code> ).
'stringanchors'	'lineanchors'	Apply <code>^</code> and <code>\$</code> metacharacters to the beginning and end of a string (default), or to the beginning and end of a line.
'literalspacing'	'freespacing'	Include space characters and comments when matching (default), or ignore them. With <code>freespacing</code> , use <code>'\ '</code> and <code>'\#'</code> to match space and <code>#</code> characters.

Data Types: char

## Output Arguments

**startIndex — Starting index of each match**

row vector | cell array of row vectors

Starting indices of each match, returned as a row vector or cell array, as follows:

- If `str` and `expression` are both strings, the output is a row vector (or, if there are no matches, an empty array).
- If `str` or `expression` is a cell array of strings, the output is a cell array of row vectors. The output cell array has the same dimensions as the input cell array.
- If `str` and `expression` are both cell arrays, they must have the same dimensions. The output is a cell array with the same dimensions.

**endIndex** — Ending index of each match

row vector | cell array of row vectors

Ending index of each match, returned as a row vector or cell array, as follows:

- If `str` and `expression` are both strings, the output is a row vector (or, if there are no matches, an empty array).
- If `str` or `expression` is a cell array of strings, the output is a cell array of row vectors. The output cell array has the same dimensions as the input cell array.
- If `str` and `expression` are both cell arrays, they must have the same dimensions. The output is a cell array with the same dimensions.

**out** — Information about matches

numeric array | cell array | structure array

Information about matches, returned as a numeric, cell, or structure array. The information in the output depends upon the value you specify for `outkey`, as follows.

Output Keyword	Output Description	Output Type and Dimensions
'start'	Starting indices of matches	For both 'start' and 'end': <ul style="list-style-type: none"> <li>• If <code>str</code> and <code>expression</code> are both strings, the output is a row vector (or, if there are no matches, an empty array).</li> <li>• If <code>str</code> or <code>expression</code> is a cell array of strings, the output is a cell array of row vectors. The output cell array has the same dimensions as the input cell array.</li> <li>• If <code>str</code> and <code>expression</code> are both cell arrays, they must have the same dimensions. The output is a cell array with the same dimensions.</li> </ul>
'end'	Ending indices of matches	

Output Keyword	Output Description	Output Type and Dimensions
'tokenExtents'	Starting and ending indices of all tokens	<p>By default, when returning all matches:</p> <ul style="list-style-type: none"> <li>• If <code>str</code> and <code>expression</code> are both strings, the output is a 1-by-<i>n</i>-cell array, where <i>n</i> is the number of matches. Each cell contains an <i>m</i>-by-2 numeric array of indices, where <i>m</i> is the number of tokens in the match.</li> <li>• If <code>str</code> or <code>expression</code> is a cell array of strings, the output is a cell array with the same dimensions as the input cell array. Each cell contains a 1-by-<i>n</i> cell array, where each inner cell contains an <i>m</i>-by-2 numeric array.</li> <li>• If <code>str</code> and <code>expression</code> are both cell arrays, they must have the same dimensions. The output is a cell array with the same dimensions.</li> </ul> <p>When you specify the 'once' option to return only one match, the output is either an <i>m</i>-by-2 numeric array or a cell array with the same dimensions as <code>str</code> and/or <code>expression</code>.</p> <p>If a token is expected at a particular index <i>N</i>, but is not found, then MATLAB returns extents for that token of [<i>N</i>,<i>N</i>-1].</p>

Output Keyword	Output Description	Output Type and Dimensions
'match'	Text of each substring that matches the pattern in <code>expression</code>	<p>By default, when returning all matches:</p> <ul style="list-style-type: none"><li>• If <code>str</code> and <code>expression</code> are both strings, the output is a 1-by-<code>n</code>-cell array of strings, where <code>n</code> is the number of matches.</li><li>• If <code>str</code> or <code>expression</code> is a cell array of strings, the output is a cell array with the same dimensions as the input cell array. Each cell contains a 1-by-<code>n</code> cell array of strings.</li><li>• If <code>str</code> and <code>expression</code> are both cell arrays, they must have the same dimensions. The output is a cell array with the same dimensions.</li></ul> <p>When you specify the <code>'once'</code> option to return only one match, the output is either a string or a cell array of strings with the same dimensions as <code>str</code> and <code>expression</code>.</p>

Output Keyword	Output Description	Output Type and Dimensions
'tokens'	Text of each captured token in <code>str</code>	<p>By default, when returning all matches:</p> <ul style="list-style-type: none"> <li>• If <code>str</code> and <code>expression</code> are both strings, the output is a 1-by-<code>n</code>-cell array, where <code>n</code> is the number of matches. Each cell contains a 1-by-<code>m</code> cell array of strings, where <code>m</code> is the number of tokens in the match.</li> <li>• If <code>str</code> or <code>expression</code> is a cell array of strings, the output is a cell array with the same dimensions as the input cell array. Each cell contains a 1-by-<code>n</code> cell array, where each inner cell contains a 1-by-<code>m</code> cell array of strings.</li> <li>• If <code>str</code> and <code>expression</code> are both cell arrays, they must have the same dimensions. The output is a cell array with the same dimensions.</li> </ul> <p>When you specify the 'once' option to return only one match, the output is a 1-by-<code>m</code> cell array of strings or a cell array that has the same dimensions as <code>str</code> and/or <code>expression</code>.</p> <p>If a token is expected at a particular index, but is not found, then MATLAB returns an empty string for the token, ''.</p>
'names'	Name and text of each named token	<p>For all matches:</p> <ul style="list-style-type: none"> <li>• If <code>str</code> and <code>expression</code> are both strings, the output is a 1-by-<code>n</code> structure array, where <code>n</code> is the number of matches. The structure field names correspond to the token names.</li> <li>• If <code>str</code> or <code>expression</code> is a cell array of strings, the output is a cell array with the same dimensions as the input cell array. Each cell contains a 1-by-<code>n</code> structure array.</li> <li>• If <code>str</code> and <code>expression</code> are both cell arrays, they must have the same dimensions. The output is a cell array with the same dimensions.</li> </ul>

Output Keyword	Output Description	Output Type and Dimensions
'split'	Text of nonmatching substrings of <code>str</code>	<p>For all matches:</p> <ul style="list-style-type: none"> <li>• If <code>str</code> and <code>expression</code> are both strings, the output is a 1-by-<code>n</code>-cell array of strings, where <code>n</code> is the number of nonmatching strings.</li> <li>• If <code>str</code> or <code>expression</code> is a cell array of strings, the output is a cell array with the same dimensions as the input cell array. Each cell contains a 1-by-<code>n</code> cell array of strings.</li> <li>• If <code>str</code> and <code>expression</code> are both cell arrays, they must have the same dimensions. The output is a cell array with the same dimensions.</li> </ul>

## More About

### Tokens

Tokens are portions of the matched text that correspond to portions of the regular expression. To create tokens, enclose part of the regular expression in parentheses.

For example, this expression finds a date of the form `dd-mmm-yyyy`, including tokens for the day, month, and year.

```
str = 'Here is a date: 01-Apr-2020';
expression = '(\d+)-(\w+)-(\d+)';

mydate = regexp(str,expression,'tokens');
mydate{:}

ans =
 '01' 'April' '2020'
```

You can associate names with tokens so that they are more easily identifiable:

```
str = 'Here is a date: 01-Apr-2020';
expression = '(?<day>\d+)-(?<month>\w+)-(?<year>\d+)';

mydate = regexp(str,expression,'names')

mydate =
```

```
 day: '01'
 month: 'Apr'
 year: '2020'
```

For more information, see “Tokens in Regular Expressions”.

### Tips

- Use `strfind` to find an exact character match within a string. Use `regexp` to look for a pattern of characters.

### Algorithms

MATLAB parses each input string from left to right, attempting to match the text in the string with the first element of the regular expression. During this process, MATLAB skips over any text that does not match.

When MATLAB finds the first match, it continues parsing the string to match the second piece of the expression, and so on.

## regexpi

Match regular expression (case insensitive)

### Syntax

```
startIndex = regexpi(str,expression)
[startIndex,endIndex] = regexpi(str,expression)

out = regexpi(str,expression,outkey)
[out1,...,outN] = regexpi(str,expression,outkey1,...,outkeyN)

___ = regexpi(___,option1,...,optionM)
```

### Description

`startIndex = regexpi(str,expression)` returns the starting index of each substring of `str` that matches the character patterns specified by the regular expression, without regard to letter case. If there are no matches, `startIndex` is an empty array.

`[startIndex,endIndex] = regexpi(str,expression)` returns the starting and ending indices of all matches.

`out = regexpi(str,expression,outkey)` returns the output specified by `outkey`. For example, if `outkey` is `'match'`, then `regexpi` returns the substrings that match the expression rather than their starting indices.

`[out1,...,outN] = regexpi(str,expression,outkey1,...,outkeyN)` returns the outputs specified by multiple output keywords, in the specified order. For example, if you specify `'match'`, `'tokens'`, then `regexpi` returns substrings that match the entire expression and tokens that match parts of the expression.

`___ = regexpi( ___,option1,...,optionM)` modifies the search using the specified option flags. For example, specify `'matchcase'` to perform a case-sensitive match. You can include any of the inputs and request any of the outputs from previous syntaxes.

## Examples

### Pattern Matching

Find words that start with `c`, end with `t`, and contain one or more vowels between them.

```
str = 'bat cat can car COAT court cut ct CAT-scan';
expression = 'c[aeiou]+t';
startIndex = regexpi(str,expression)

startIndex =
 5 17 28 35
```

Values in `startIndex` indicate the index of the first character of each word that matches the regular expression.

The regular expression `'c[aeiou]+t'` specifies this pattern:

- `c` must be the first character.
- `c` must be followed by one of the characters inside the brackets, `[aeiou]`.
- The bracketed pattern must occur one or more times, as indicated by the `+` operator.
- `t` must be the last character, with no characters between the bracketed pattern and the `t`.

### Case-Sensitive Match

Match letter case in all or part of an expression.

By default, `regexpi` performs case-insensitive matching.

```
str = 'A string with UPPERCASE and lowercase text.';
expression = '\w*case';
matchStr = regexpi(str,expression,'match')

matchStr =
 'UPPERCASE' 'lowercase'
```

Use the `regexp` function with the same syntax as `regexpi` to perform case-sensitive matching.

```
matchWithRegexp = regexp(str,expression,'match')

matchWithRegexp =
 'lowercase'
```

To disable case-sensitive matching for `regexp`, use the `'ignorecase'` option.

```
matchWithIgnorecase = regexp(str,expression,'match','ignorecase')
matchWithIgnorecase =
 'UPPERCASE' 'lowercase'
```

For multiple expressions, enable and disable case-insensitive matching for selected expressions using the `(?i)` and `(?-i)` search flags.

```
expression = {'(?-i)\w*case';...
 '(?i)\w*case'};
matchStr = regexp(str,expression,'match');
celldisp(matchStr)

matchStr{1}{1} =
 lowercase

matchStr{2}{1} =
 UPPERCASE

matchStr{2}{2} =
 lowercase
```

## Input Arguments

### **str** — Input text

string | cell array of strings

Input text, specified as a string or a cell array of strings. Each string can be of any length and contain any characters.

If `str` and `expression` are both cell arrays, they must have the same dimensions.

Data Types: `char` | `cell`

### **expression** — Regular expression

string | cell array of strings

Regular expression, specified as a string or a cell array of strings. Each expression can contain characters, metacharacters, operators, tokens, and flags that specify patterns to match in `str`.

The following tables describe the elements of regular expressions.

## Metacharacters

Metacharacters represent letters, letter ranges, digits, and space characters. Use them to construct a generalized pattern of characters.

Metacharacter	Description	Example
.	Any single character, including white space	' <code>..ain</code> ' matches sequences of five consecutive characters that end with 'ain'.
[ <code>C<sub>1</sub>C<sub>2</sub>C<sub>3</sub></code> ]	Any character contained within the brackets. The following characters are treated literally: \$   . * + ? and - when not used to indicate a range.	' <code>[rp.]ain</code> ' matches 'rain' or 'pain' or '.ain'.
[ <code>^C<sub>1</sub>C<sub>2</sub>C<sub>3</sub></code> ]	Any character not contained within the brackets. The following characters are treated literally: \$   . * + ? and - when not used to indicate a range.	' <code>[^*rp]ain</code> ' matches all four-letter sequences that end in 'ain', except 'rain' and 'pain' and '*ain'. For example, it matches 'gain', 'lain', or 'vain'.
[ <code>C<sub>1</sub>-C<sub>2</sub></code> ]	Any character in the range of <code>C<sub>1</sub></code> through <code>C<sub>2</sub></code>	' <code>[A-G]</code> ' matches a single character in the range of A through G.
<code>\w</code>	Any alphabetic, numeric, or underscore character. For English character sets, <code>\w</code> is equivalent to [ <code>a-zA-Z_0-9</code> ]	' <code>\w*</code> ' identifies a word.
<code>\W</code>	Any character that is not alphabetic, numeric, or underscore. For English character sets, <code>\W</code> is equivalent to [ <code>^a-zA-Z_0-9</code> ]	' <code>\W*</code> ' identifies a substring that is not a word.
<code>\s</code>	Any white-space character; equivalent to [ <code>\f\n\r\t\v</code> ]	' <code>\w*n\s</code> ' matches words that end with the letter <code>n</code> , followed by a white-space character.
<code>\S</code>	Any non-white-space character; equivalent to [ <code>^\f\n\r\t\v</code> ]	' <code>\d\S</code> ' matches a numeric digit followed by any non-white-space character.
<code>\d</code>	Any numeric digit; equivalent to [ <code>0-9</code> ]	' <code>\d*</code> ' matches any number of consecutive digits.

Metacharacter	Description	Example
\D	Any nondigit character; equivalent to [^0-9]	'\w*\D\>' matches words that do not end with a numeric digit.
\oN or \o{N}	Character of octal value N	'\o{40}' matches the space character, defined by octal 40.
\xN or \x{N}	Character of hexadecimal value N	'\x2C' matches the comma character, defined by hex 2C.

### Character Representation

Operator	Description
\a	Alarm (beep)
\b	Backspace
\f	Form feed
\n	New line
\r	Carriage return
\t	Horizontal tab
\v	Vertical tab
\char	Any character with special meaning in regular expressions that you want to match literally (for example, use \\ to match a single backslash)

### Quantifiers

Quantifiers specify the number of times a string pattern must occur in the matching string.

Quantifier	Matches the expression when it occurs...	Example
expr*	0 or more times consecutively.	'\w*' matches a word of any length.
expr?	0 times or 1 time.	'\w*(\ .m)?' matches words that optionally end with the extension .m.
expr+	1 or more times consecutively.	'' matches an <img> HTML tag when the file name contains one or more characters.

Quantifier	Matches the expression when it occurs...	Example
<code>expr{m,n}</code>	At least <i>m</i> times, but no more than <i>n</i> times consecutively.  <code>{0,1}</code> is equivalent to <code>?</code> .	<code>'\S{4,8}'</code> matches between four and eight non-white-space characters.
<code>expr{m,}</code>	At least <i>m</i> times consecutively.  <code>{0,}</code> and <code>{1,}</code> are equivalent to <code>*</code> and <code>+</code> , respectively.	<code>'&lt;a href="\w{1,}\.html"&gt;'</code> matches an <code>&lt;a&gt;</code> HTML tag when the file name contains one or more characters.
<code>expr{n}</code>	Exactly <i>n</i> times consecutively.  Equivalent to <code>{n,n}</code> .	<code>'\d{4}'</code> matches four consecutive digits.

Quantifiers can appear in three modes, described in the following table. *q* represents any of the quantifiers in the previous table.

Mode	Description	Example
<code>exprq</code>	Greedy expression: match as many characters as possible.	Given the string <code>'&lt;tr&gt;&lt;td&gt;&lt;p&gt;text&lt;/p&gt;&lt;/td&gt;'</code> , the expression <code>'&lt;/?t.*&gt;'</code> matches all characters between <code>&lt;tr</code> and <code>/td&gt;</code> :  <code>'&lt;tr&gt;&lt;td&gt;&lt;p&gt;text&lt;/p&gt;&lt;/td&gt;'</code>
<code>exprq?</code>	Lazy expression: match as few characters as necessary.	Given the string <code>'&lt;tr&gt;&lt;td&gt;&lt;p&gt;text&lt;/p&gt;&lt;/td&gt;'</code> , the expression <code>'&lt;/?t.*?&gt;'</code> ends each match at the first occurrence of the closing bracket ( <code>&gt;</code> ):  <code>'&lt;tr&gt;'</code> <code>'&lt;td&gt;'</code> <code>'&lt;/td&gt;'</code>
<code>exprq+</code>	Possessive expression: match as much as possible, but do not rescan any portions of the string.	Given the string <code>'&lt;tr&gt;&lt;td&gt;&lt;p&gt;text&lt;/p&gt;&lt;/td&gt;'</code> , the expression <code>'&lt;/?t.*+&gt;'</code> does not return any matches, because the closing bracket is captured using <code>.*</code> , and is not rescanned.

## Grouping Operators

Grouping operators allow you to capture tokens, apply one operator to multiple elements, or disable backtracking in a specific group.

Grouping Operator	Description	Example
(expr)	Group elements of the expression and capture tokens.	'Joh?n\s(\w*)' captures a token that contains the last name of any person with the first name John or Jon.
(?:expr)	Group, but do not capture tokens.	'(?:[aeiou][^aeiou]){2}' matches two consecutive patterns of a vowel followed by a nonvowel, such as 'anon'.  Without grouping, '[aeiou][^aeiou]{2}' matches a vowel followed by two nonvowels.
(?>expr)	Group atomically. Do not backtrack within the group to complete the match, and do not capture tokens.	'A(?>.* )Z' does not match 'AtoZ', although 'A(?:.* )Z' does. Using the atomic group, Z is captured using .* and is not rescanned.
(expr1   expr2)	Match expression expr1 or expression expr2.  If there is a match with expr1, then expr2 is ignored.  You can include ?: or ?> after the opening parenthesis to suppress tokens or group atomically.	'(let tel)\w+' matches words in a string that start with let or tel.

### Anchors

Anchors in the expression match the beginning or end of the string or word.

Anchor	Matches the...	Example
^expr	Beginning of the input string.	'^M\w*' matches a word starting with M at the beginning of the string.
expr\$	End of the input string.	'\w*m\$' matches words ending with m at the end of the string.

Anchor	Matches the...	Example
<code>\&lt;expr</code>	Beginning of a word.	' <code>\&lt;n\w*</code> ' matches any words starting with <code>n</code> .
<code>expr\&gt;</code>	End of a word.	' <code>\w*e\&gt;</code> ' matches any words ending with <code>e</code> .

### Lookaround Assertions

Lookaround assertions look for string patterns that immediately precede or follow the intended match, but are not part of the match.

The pointer remains at the current location, and characters that correspond to the `test` expression are not captured or discarded. Therefore, lookahead assertions can match overlapping character groups.

Lookaround Assertion	Description	Example
<code>expr(?:test)</code>	Look ahead for characters that match <code>test</code> .	' <code>\w*(?=ing)</code> ' matches strings that are followed by <code>ing</code> , such as 'Fly' and 'fall' in the input string 'Flying, not falling.'
<code>expr(?:!test)</code>	Look ahead for characters that do not match <code>test</code> .	' <code>i(?:ng)</code> ' matches instances of the letter <code>i</code> that are not followed by <code>ng</code> .
<code>(?&lt;=test)expr</code>	Look behind for characters that match <code>test</code> .	' <code>(?&lt;=re)\w*</code> ' matches strings that follow 're', such as 'new', 'use', and 'cycle' in the input string 'renew, reuse, recycle'
<code>(?&lt;!test)expr</code>	Look behind for characters that do not match <code>test</code> .	' <code>(?&lt;!\d)(\d)(?!\d)</code> ' matches single-digit numbers (digits that do not precede or follow other digits).

If you specify a lookahead assertion *before* an expression, the operation is equivalent to a logical AND.

Operation	Description	Example
<code>(?=test)expr</code>	Match both <code>test</code> and <code>expr</code> .	' <code>(?=[a-z])[^aeiou]</code> ' matches consonants.

Operation	Description	Example
<code>(?!test)expr</code>	Match <code>expr</code> and do not match <code>test</code> .	<code>'(?![aeiou])[a-z]'</code> matches consonants.

### Logical and Conditional Operators

Logical and conditional operators allow you to test the state of a given condition, and then use the outcome to determine which string, if any, to match next. These operators support logical OR, and `if` or `if/else` conditions.

Conditions can be tokens, lookaround operators, or dynamic expressions of the form `(?@cmd)`. Dynamic expressions must return a logical or numeric value.

Conditional Operator	Description	Example
<code>expr1 expr2</code>	Match expression <code>expr1</code> or expression <code>expr2</code> .  If there is a match with <code>expr1</code> , then <code>expr2</code> is ignored.	<code>'(let tel)\w+'</code> matches words in a string that start with <code>let</code> or <code>tel</code> .
<code>(?(cond)expr)</code>	If condition <code>cond</code> is true, then match <code>expr</code> .	<code>'(?:?@ispc)[A-Z]:\\'</code> matches a drive name, such as <code>C:\</code> , when run on a Windows system.
<code>(?(cond)expr1 expr2)</code>	If condition <code>cond</code> is true, then match <code>expr1</code> . Otherwise, match <code>expr2</code> .	<code>'Mr(s?)\..*?(?(1)her his)\w*'</code> matches strings that include <code>her</code> when the string begins with <code>Mrs</code> , or that include <code>his</code> when the string begins with <code>Mr</code> .

### Token Operators

Tokens are portions of the matched text that you define by enclosing part of the regular expression in parentheses. You can refer to a token by its sequence in the string (an ordinal token), or assign names to tokens for easier code maintenance and readable output.

Ordinal Token Operator	Description	Example
<code>(expr)</code>	Capture in a token the characters that match the enclosed expression.	<code>'Joh?n\s(\w*)'</code> captures a token that contains the last name of any

Ordinal Token Operator	Description	Example
		person with the first name John or Jon.
\N	Match the Nth token.	'<(\w+).*>.*</\1>' captures tokens for HTML tags, such as 'title' from the string '<title>Some text</title>'.
(?(N)expr1 expr2)	If the Nth token is found, then match expr1. Otherwise, match expr2.	'Mr(s?)\..*?(?(1)her his)\w*' matches strings that include her when the string begins with Mrs, or that include his when the string begins with Mr.
Named Token Operator	Description	Example
(?<name>expr)	Capture in a named token the characters that match the enclosed expression.	'(?<month>\d+) - (?<day>\d+) - (?<yr>\d+)' creates named tokens for the month, day, and year in an input date string of the form mm-dd-yy.
\k<name>	Match the token referred to by name.	'<(?(tag)\w+).*>.*</\k<tag>>' captures tokens for HTML tags, such as 'title' from the string '<title>Some text</title>'.
(?(name)expr1 expr2)	If the named token is found, then match expr1. Otherwise, match expr2.	'Mr(?(sex)s?)\..*?(?(sex)her his)\w*' matches strings that include her when the string begins with Mrs, or that include his when the string begins with Mr.

---

**Note:** If an expression has nested parentheses, MATLAB captures tokens that correspond to the outermost set of parentheses. For example, given the search pattern '(and(y|rew))', MATLAB creates a token for 'andrew' but not for 'y' or 'rew'.

---

## Dynamic Regular Expressions

Dynamic expressions allow you to execute a MATLAB command or a regular expression to determine the text to match.

The parentheses that enclose dynamic expressions do *not* create a capturing group.

Operator	Description	Example
(??expr)	Parse <code>expr</code> and include the resulting string in the match expression.  When parsed, <code>expr</code> must correspond to a complete, valid regular expression. Dynamic expressions that use the backslash escape character (\) require two backslashes: one for the initial parsing of <code>expr</code> , and one for the complete match.	' ^ (\d+) ((? \w{ \$1} ) ) ' determines how many characters to match by reading a digit at the beginning of the string. The dynamic expression is enclosed in a second set of parentheses so that the resulting match is captured in a token. For instance, matching '5XXXXX' captures tokens for '5' and 'XXXXX'.
(??@cmd)	Execute the MATLAB command represented by <code>cmd</code> , and include the string returned by the command in the match expression.	' (. {2,} ) . ? ( ? @ flip l r ( \$1 ) ) ' finds palindromes that are at least four characters long, such as 'abba'.
(?@cmd)	Execute the MATLAB command represented by <code>cmd</code> , but discard any output the command returns. (Helpful for diagnosing regular expressions.)	' \w* ? ( \w ) ( ? @ disp ( \$1 ) ) \1 \w* ' matches words that include double letters (such as pp), and displays intermediate results.

Within dynamic expressions, use the following operators to define replacement strings.

Replacement String Operator	Description
\$& or \$0	Portion of the input string that is currently a match
\$`	Portion of the input string that precedes the current match
\$'	Portion of the input string that follows the current match (use '\$ ' ' to represent the string '\$ ')
\$N	Nth token
\$<name>	Named token
\${cmd}	String returned when MATLAB executes the command, <code>cmd</code>

## Comments

Characters	Description	Example
(?#comment)	Insert a comment in the regular expression. The comment text is ignored when matching the input string.	'(?# Initial digit)\<\d\w+' includes a comment, and matches words that begin with a number.

## Search Flags

Search flags modify the behavior for matching expressions. An alternative to using a search flag within an expression is to pass an `option` input argument.

Flag	Description
(?-i)	Match letter case (default for <code>regexp</code> and <code>regexprep</code> ).
(?i)	Do not match letter case (default for <code>regexpi</code> ).
(?s)	Match dot (.) in the pattern string with any character (default).
(?-s)	Match dot in the pattern with any character that is not a newline character.
(?-m)	Match the <code>^</code> and <code>\$</code> metacharacters at the beginning and end of a string (default).
(?m)	Match the <code>^</code> and <code>\$</code> metacharacters at the beginning and end of a line.
(?-x)	Include space characters and comments when matching (default).
(?x)	Ignore space characters and comments when matching. Use <code>'\ '</code> and <code>'\#'</code> to match space and <code>#</code> characters.

The expression that the flag modifies can appear either after the parentheses, such as

```
(?i)\w*
```

or inside the parentheses and separated from the flag with a colon (:), such as

```
(?i:\w*)
```

The latter syntax allows you to change the behavior for part of a larger expression.

Data Types: `char` | `cell`

**outkey** — Keyword that indicates which outputs to return

'start' (default) | 'end' | 'tokenExtents' | 'match' | 'tokens' | 'names' | 'split'

Keyword that indicates which outputs to return, specified as one of the following strings.

Output Keyword	Returns
'start' (default)	Starting indices of all matches, <code>startIndex</code>
'end'	Ending indices of all matches, <code>endIndex</code>
'tokenExtents'	Starting and ending indices of all tokens
'match'	Text of each substring that matches the pattern in expression
'tokens'	Text of each captured token in <code>str</code>
'names'	Name and text of each named token
'split'	Text of nonmatching substrings of <code>str</code>

Data Types: char

**option** — Search option

'once' | 'warnings' | 'matchcase' | 'emptymatch' | 'dotexceptnewline' | 'lineanchors' | ...

Search option, specified as a string. Options come in pairs: one option that corresponds to the default behavior, and one option that allows you to override the default. Specify only one option from a pair. Options can appear in any order.

Default	Override	Description
'all'	'once'	Match the expression as many times as possible (default), or only once.
'nowarnings'	'warnings'	Suppress warnings (default), or display them.
'ignorecase'	'matchcase'	Ignore letter case (default), or match case.
'noemptymatch'	'emptymatch'	Ignore zero length matches (default), or include them.
'dotall'	'dotexceptnewline'	Match dot with any character (default), or all except newline ( <code>\n</code> ).

Default	Override	Description
'stringanchors'	'lineanchors'	Apply ^ and \$ metacharacters to the beginning and end of a string (default), or to the beginning and end of a line.
'literalspacing'	'freespacing'	Include space characters and comments when matching (default), or ignore them. With <b>freespacing</b> , use '\ ' and '\#' to match space and # characters.

Data Types: char

## Output Arguments

### **startIndex** — Starting index of each match

row vector | cell array of row vectors

Starting indices of each match, returned as a row vector or cell array, as follows:

- If **str** and **expression** are both strings, the output is a row vector (or, if there are no matches, an empty array).
- If **str** or **expression** is a cell array of strings, the output is a cell array of row vectors. The output cell array has the same dimensions as the input cell array.
- If **str** and **expression** are both cell arrays, they must have the same dimensions. The output is a cell array with the same dimensions.

### **endIndex** — Ending index of each match

row vector | cell array of row vectors

Ending index of each match, returned as a row vector or cell array, as follows:

- If **str** and **expression** are both strings, the output is a row vector (or, if there are no matches, an empty array).
- If **str** or **expression** is a cell array of strings, the output is a cell array of row vectors. The output cell array has the same dimensions as the input cell array.
- If **str** and **expression** are both cell arrays, they must have the same dimensions. The output is a cell array with the same dimensions.

### **out** — Information about matches

numeric array | cell array | structure array

Information about matches, returned as a numeric, cell, or structure array. The information in the output depends upon the value you specify for `outkey`, as follows.

Output Keyword	Output Description	Output Type and Dimensions
'start'	Starting indices of matches	For both 'start' and 'end': <ul style="list-style-type: none"> <li>• If <code>str</code> and <code>expression</code> are both strings, the output is a row vector (or, if there are no matches, an empty array).</li> <li>• If <code>str</code> or <code>expression</code> is a cell array of strings, the output is a cell array of row vectors. The output cell array has the same dimensions as the input cell array.</li> <li>• If <code>str</code> and <code>expression</code> are both cell arrays, they must have the same dimensions. The output is a cell array with the same dimensions.</li> </ul>
'end'	Ending indices of matches	
'tokenExtents'	Starting and ending indices of all tokens	By default, when returning all matches: <ul style="list-style-type: none"> <li>• If <code>str</code> and <code>expression</code> are both strings, the output is a 1-by-<i>n</i>-cell array, where <i>n</i> is the number of matches. Each cell contains an <i>m</i>-by-2 numeric array of indices, where <i>m</i> is the number of tokens in the match.</li> <li>• If <code>str</code> or <code>expression</code> is a cell array of strings, the output is a cell array with the same dimensions as the input cell array. Each cell contains a 1-by-<i>n</i> cell array, where each inner cell contains an <i>m</i>-by-2 numeric array.</li> <li>• If <code>str</code> and <code>expression</code> are both cell arrays, they must have the same dimensions. The output is a cell array with the same dimensions.</li> </ul> <p>When you specify the 'once' option to return only one match, the output is either an <i>m</i>-by-2 numeric array or a cell array with the same dimensions as <code>str</code> and/or <code>expression</code>.</p>

Output Keyword	Output Description	Output Type and Dimensions
		<p>If a token is expected at a particular index <math>N</math>, but is not found, then MATLAB returns extents for that token of <math>[N, N - 1]</math>.</p>
'match'	Text of each substring that matches the pattern in <code>expression</code>	<p>By default, when returning all matches:</p> <ul style="list-style-type: none"> <li>• If <code>str</code> and <code>expression</code> are both strings, the output is a 1-by-<math>n</math>-cell array of strings, where <math>n</math> is the number of matches.</li> <li>• If <code>str</code> or <code>expression</code> is a cell array of strings, the output is a cell array with the same dimensions as the input cell array. Each cell contains a 1-by-<math>n</math> cell array of strings.</li> <li>• If <code>str</code> and <code>expression</code> are both cell arrays, they must have the same dimensions. The output is a cell array with the same dimensions.</li> </ul> <p>When you specify the 'once' option to return only one match, the output is either a string or a cell array of strings with the same dimensions as <code>str</code> and <code>expression</code>.</p>

Output Keyword	Output Description	Output Type and Dimensions
'tokens'	Text of each captured token in <code>str</code>	<p>By default, when returning all matches:</p> <ul style="list-style-type: none"> <li>• If <code>str</code> and <code>expression</code> are both strings, the output is a 1-by-<code>n</code>-cell array, where <code>n</code> is the number of matches. Each cell contains a 1-by-<code>m</code> cell array of strings, where <code>m</code> is the number of tokens in the match.</li> <li>• If <code>str</code> or <code>expression</code> is a cell array of strings, the output is a cell array with the same dimensions as the input cell array. Each cell contains a 1-by-<code>n</code> cell array, where each inner cell contains a 1-by-<code>m</code> cell array of strings.</li> <li>• If <code>str</code> and <code>expression</code> are both cell arrays, they must have the same dimensions. The output is a cell array with the same dimensions.</li> </ul> <p>When you specify the 'once' option to return only one match, the output is a 1-by-<code>m</code> cell array of strings or a cell array that has the same dimensions as <code>str</code> and/or <code>expression</code>.</p> <p>If a token is expected at a particular index, but is not found, then MATLAB returns an empty string for the token, ''.</p>
'names'	Name and text of each named token	<p>For all matches:</p> <ul style="list-style-type: none"> <li>• If <code>str</code> and <code>expression</code> are both strings, the output is a 1-by-<code>n</code> structure array, where <code>n</code> is the number of matches. The structure field names correspond to the token names.</li> <li>• If <code>str</code> or <code>expression</code> is a cell array of strings, the output is a cell array with the same dimensions as the input cell array. Each cell contains a 1-by-<code>n</code> structure array.</li> <li>• If <code>str</code> and <code>expression</code> are both cell arrays, they must have the same dimensions. The output is a cell array with the same dimensions.</li> </ul>

Output Keyword	Output Description	Output Type and Dimensions
'split'	Text of nonmatching substrings of <code>str</code>	<p>For all matches:</p> <ul style="list-style-type: none"> <li>• If <code>str</code> and <code>expression</code> are both strings, the output is a 1-by-n-cell array of strings, where n is the number of nonmatching strings.</li> <li>• If <code>str</code> or <code>expression</code> is a cell array of strings, the output is a cell array with the same dimensions as the input cell array. Each cell contains a 1-by-n cell array of strings.</li> <li>• If <code>str</code> and <code>expression</code> are both cell arrays, they must have the same dimensions. The output is a cell array with the same dimensions.</li> </ul>

## More About

### Tokens

Tokens are portions of the matched text that correspond to portions of the regular expression. To create tokens, enclose part of the regular expression in parentheses.

For example, this expression finds a date of the form `dd-mmm-yyyy`, including tokens for the day, month, and year.

```
str = 'Here is a date: 01-Apr-2020';
expression = '(\d+)-(\w+)-(\d+)';

mydate = regexp(str,expression,'tokens');
mydate{:}

ans =
 '01' 'April' '2020'
```

You can associate names with tokens so that they are more easily identifiable:

```
str = 'Here is a date: 01-Apr-2020';
expression = '(?<day>\d+)-(?<month>\w+)-(?<year>\d+)';

mydate = regexp(str,expression,'names')

mydate =
```

```
 day: '01'
 month: 'Apr'
 year: '2020'
```

For more information, see “Tokens in Regular Expressions”.

- “Lookahead Assertions in Regular Expressions”
- “Dynamic Regular Expressions”

## regexprep

Replace string using regular expression

### Syntax

```
newStr = regexprep(str,expression,replace)
newStr = regexprep(str,expression,replace,option1,...optionM)
```

### Description

`newStr = regexprep(str,expression,replace)` replaces the text in `str` that matches `expression` with the text described by `replace`. The `regexprep` function returns the updated text in `newStr`.

- If `str` is a string, then `newStr` is also a string, even when `expression` or `replace` is a cell array of strings. When `expression` is a cell array, `regexprep` applies the first expression to the string, and then applies each subsequent expression to the preceding result.
- If `str` is a cell array, then `newStr` is a cell array with the same dimensions as `str`. For each element of `str`, the `regexprep` function applies each expression in sequence.
- If there are no matches to `expression`, then `newStr` is equivalent to `str`.

`newStr = regexprep(str,expression,replace,option1,...optionM)` modifies the search using the specified options. For example, specify `'ignorecase'` to perform a case-insensitive match.

### Examples

#### Update a Single String

Replace words that begin with M, end with y, and have at least one character between them.

```
str = 'My flowers may bloom in May';
expression = 'M(\w+)y';
```

```
replace = 'April';
newStr = regexprep(str,expression,replace)
newStr =
```

My flowers may bloom in April

## Include Tokens in Replacement Text

Replace variations of the phrase 'walk up' by capturing the letters that follow 'walk' in a token.

```
str = 'I walk up, they walked up, we are walking up.';
expression = 'walk(\w*) up';
replace = 'ascend$1';
```

```
newStr = regexprep(str,expression,replace)
newStr =
```

I ascend, they ascended, we are ascending.

## Include Dynamic Expression in Replacement Text

Replace lowercase letters at the beginning of sentences with their uppercase equivalents using the `upper` function.

```
str = 'here are two sentences. neither is capitalized.';
expression = '^(|\.)\s*.';
replace = '${upper($0)}';
```

```
newStr = regexprep(str,expression,replace)
newStr =
```

Here are two sentences. Neither is capitalized.

The regular expression matches single characters (.) that follow the beginning of the string (^) or a period (\.) and any whitespace (\s\*). The `replace` expression calls the `upper` function for the currently matching character (\$0).

## Update Multiple Strings

Replace each occurrence of a double letter in a set of strings with the symbols ' - - '.

```

str = {
 'Whose woods these are I think I know.' ; ...
 'His house is in the village though;' ; ...
 'He will not see me stopping here' ; ...
 'To watch his woods fill up with snow.'};

expression = '(.)\1';
replace = '--';
newStr = regexprep(str,expression,replace)

newStr =

 'Whose w--ds these are I think I know.'
 'His house is in the vi--age though;'
 'He wi-- not s-- me sto--ing here'
 'To watch his w--ds fi-- up with snow.'

```

### Preserve Case in Original String

Ignore letter case in the regular expression when finding matches, but mimic the letter case of the original string when updating.

```

str = 'My flowers may bloom in May';
expression = 'M(\w+)y';
replace = 'April';

newStr = regexprep(str,expression,replace,'preserveCase')

newStr =

My flowers april bloom in April

```

### Replace Zero-Length Matches

Insert text at the beginning of a string using the '^' operator, which returns a zero-length match, and the 'emptymatch' keyword.

```

str = 'abc';
expression = '^';
replace = '__';

newStr = regexprep(str,expression,replace,'emptymatch')

newStr =

```

\_\_abc

## Input Arguments

### **str** — Text to update

string | cell array of strings

Text to update, specified as a string or a cell array of strings.

Data Types: char | cell

### **expression** — Regular expression

string | cell array of strings

Regular expression, specified as a string or a cell array of strings. Each expression can contain characters, metacharacters, operators, tokens, and flags that specify patterns to match in `str`.

The following tables describe the elements of regular expressions.

### Metacharacters

Metacharacters represent letters, letter ranges, digits, and space characters. Use them to construct a generalized pattern of characters.

Metacharacter	Description	Example
.	Any single character, including white space	' <code>..ain</code> ' matches sequences of five consecutive characters that end with ' <code>ain</code> '.
[ <code>C<sub>1</sub>C<sub>2</sub>C<sub>3</sub></code> ]	Any character contained within the brackets. The following characters are treated literally: <code>\$   . * + ?</code> and <code>-</code> when not used to indicate a range.	' <code>[rp.]ain</code> ' matches ' <code>rain</code> ' or ' <code>pain</code> ' or ' <code>.ain</code> '.
[ <code>^C<sub>1</sub>C<sub>2</sub>C<sub>3</sub></code> ]	Any character not contained within the brackets. The following characters are treated literally: <code>\$   . * + ?</code> and <code>-</code> when not used to indicate a range.	' <code>[^*rp]ain</code> ' matches all four-letter sequences that end in ' <code>ain</code> ', except ' <code>rain</code> ' and ' <code>pain</code> ' and ' <code>*ain</code> '. For example, it matches ' <code>gain</code> ', ' <code>lain</code> ', or ' <code>vain</code> '.

Metacharacter	Description	Example
[ C <sub>1</sub> - C <sub>2</sub> ]	Any character in the range of C <sub>1</sub> through C <sub>2</sub>	' [ A-G ] ' matches a single character in the range of A through G.
\w	Any alphabetic, numeric, or underscore character. For English character sets, \w is equivalent to [ a-zA-Z_0-9 ]	' \w* ' identifies a word.
\W	Any character that is not alphabetic, numeric, or underscore. For English character sets, \W is equivalent to [ ^a-zA-Z_0-9 ]	' \W* ' identifies a substring that is not a word.
\s	Any white-space character; equivalent to [ \f\n\r\t\v ]	' \w*n\s ' matches words that end with the letter n, followed by a white-space character.
\S	Any non-white-space character; equivalent to [ ^ \f\n\r\t\v ]	' \d\S ' matches a numeric digit followed by any non-white-space character.
\d	Any numeric digit; equivalent to [ 0-9 ]	' \d* ' matches any number of consecutive digits.
\D	Any nondigit character; equivalent to [ ^0-9 ]	' \w*\D\> ' matches words that do not end with a numeric digit.
\oN or \o{N}	Character of octal value N	' \o{40} ' matches the space character, defined by octal 40.
\xN or \x{N}	Character of hexadecimal value N	' \x2C ' matches the comma character, defined by hex 2C.

### Character Representation

Operator	Description
\a	Alarm (beep)
\b	Backspace
\f	Form feed
\n	New line
\r	Carriage return
\t	Horizontal tab

Operator	Description
<code>\v</code>	Vertical tab
<code>\char</code>	Any character with special meaning in regular expressions that you want to match literally (for example, use <code>\\</code> to match a single backslash)

## Quantifiers

Quantifiers specify the number of times a string pattern must occur in the matching string.

Quantifier	Matches the expression when it occurs...	Example
<code>expr*</code>	0 or more times consecutively.	' <code>\w*</code> ' matches a word of any length.
<code>expr?</code>	0 times or 1 time.	' <code>\w*(\.[m])?</code> ' matches words that optionally end with the extension <code>.m</code> .
<code>expr+</code>	1 or more times consecutively.	' <code>&lt;img src="\w+\.[gif]"&gt;</code> ' matches an <code>&lt;img&gt;</code> HTML tag when the file name contains one or more characters.
<code>expr{m,n}</code>	At least <code>m</code> times, but no more than <code>n</code> times consecutively.  <code>{0,1}</code> is equivalent to <code>?</code> .	' <code>\S{4,8}</code> ' matches between four and eight non-white-space characters.
<code>expr{m,}</code>	At least <code>m</code> times consecutively.  <code>{0,}</code> and <code>{1,}</code> are equivalent to <code>*</code> and <code>+</code> , respectively.	' <code>&lt;a href="\w{1,}\.html"&gt;</code> ' matches an <code>&lt;a&gt;</code> HTML tag when the file name contains one or more characters.
<code>expr{n}</code>	Exactly <code>n</code> times consecutively.  Equivalent to <code>{n,n}</code> .	' <code>\d{4}</code> ' matches four consecutive digits.

Quantifiers can appear in three modes, described in the following table. *q* represents any of the quantifiers in the previous table.

Mode	Description	Example
<code>exprq</code>	Greedy expression: match as many characters as possible.	Given the string ' <code>&lt;tr&gt;&lt;td&gt;&lt;p&gt;text&lt;/p&gt;&lt;/td&gt;</code> ', the expression ' <code>&lt;/?t.*&gt;</code> ' matches all characters between <code>&lt;tr</code> and <code>/td&gt;</code> :

Mode	Description	Example
		'<tr><td><p>text</p></td>'
exprq?	Lazy expression: match as few characters as necessary.	Given the string '<tr><td><p>text</p></td>', the expression '</?t.*?>' ends each match at the first occurrence of the closing bracket (>):  '<tr>'    '<td>'    '</td>'
exprq+	Possessive expression: match as much as possible, but do not rescan any portions of the string.	Given the string '<tr><td><p>text</p></td>', the expression '</?t.*+>' does not return any matches, because the closing bracket is captured using .*, and is not rescanned.

### Grouping Operators

Grouping operators allow you to capture tokens, apply one operator to multiple elements, or disable backtracking in a specific group.

Grouping Operator	Description	Example
(expr)	Group elements of the expression and capture tokens.	'Joh?n\s(\w*)' captures a token that contains the last name of any person with the first name JOHN or Jon.
(?:expr)	Group, but do not capture tokens.	'(?:[aeiou][^aeiou]){2}' matches two consecutive patterns of a vowel followed by a nonvowel, such as 'anon'.  Without grouping, '[aeiou][^aeiou]{2}' matches a vowel followed by two nonvowels.
(?>expr)	Group atomically. Do not backtrack within the group to complete the match, and do not capture tokens.	'A(?>.* )Z' does not match 'AtoZ', although 'A(?:.* )Z' does. Using the atomic group, Z is captured using .* and is not rescanned.

Grouping Operator	Description	Example
(expr1   expr2)	Match expression <code>expr1</code> or expression <code>expr2</code> .  If there is a match with <code>expr1</code> , then <code>expr2</code> is ignored.  You can include <code>?:</code> or <code>?&gt;</code> after the opening parenthesis to suppress tokens or group atomically.	'(let tel)\w+' matches words in a string that start with <code>let</code> or <code>tel</code> .

### Anchors

Anchors in the expression match the beginning or end of the string or word.

Anchor	Matches the...	Example
<code>^expr</code>	Beginning of the input string.	' <code>^M\w*</code> ' matches a word starting with <code>M</code> at the beginning of the string.
<code>expr\$</code>	End of the input string.	' <code>\w*m\$</code> ' matches words ending with <code>m</code> at the end of the string.
<code>\&lt;expr</code>	Beginning of a word.	' <code>\&lt;n\w*</code> ' matches any words starting with <code>n</code> .
<code>expr\&gt;</code>	End of a word.	' <code>\w*e\&gt;</code> ' matches any words ending with <code>e</code> .

### Lookaround Assertions

Lookaround assertions look for string patterns that immediately precede or follow the intended match, but are not part of the match.

The pointer remains at the current location, and characters that correspond to the `test` expression are not captured or discarded. Therefore, lookahead assertions can match overlapping character groups.

Lookaround Assertion	Description	Example
<code>expr(=?test)</code>	Look ahead for characters that match <code>test</code> .	' <code>\w*(?=ing)</code> ' matches strings that are followed by <code>ing</code> , such as 'Fly' and

Lookaround Assertion	Description	Example
		'fall' in the input string 'Flying, not falling.'
expr(?!test)	Look ahead for characters that do not match test.	'i(?!ng)' matches instances of the letter i that are not followed by ng.
(?<=test)expr	Look behind for characters that match test.	'(?<=re)\w*' matches strings that follow 're', such as 'new', 'use', and 'cycle' in the input string 'renew, reuse, recycle'
(?<!test)expr	Look behind for characters that do not match test.	'(?<!\d)(\d)(?!\d)' matches single-digit numbers (digits that do not precede or follow other digits).

If you specify a lookahead assertion *before* an expression, the operation is equivalent to a logical AND.

Operation	Description	Example
(?=test)expr	Match both test and expr.	'(?=[a-z])[^aeiou]' matches consonants.
(?!test)expr	Match expr and do not match test.	'(?![aeiou])[a-z]' matches consonants.

### Logical and Conditional Operators

Logical and conditional operators allow you to test the state of a given condition, and then use the outcome to determine which string, if any, to match next. These operators support logical OR, and if or if/else conditions.

Conditions can be tokens, lookahead operators, or dynamic expressions of the form (?@cmd). Dynamic expressions must return a logical or numeric value.

Conditional Operator	Description	Example
expr1 expr2	Match expression expr1 or expression expr2.  If there is a match with expr1, then expr2 is ignored.	'(let tel)\w+' matches words in a string that start with let or tel.

Conditional Operator	Description	Example
<code>(?(cond)expr)</code>	If condition <code>cond</code> is true, then match <code>expr</code> .	' <code>(?(?@ispc)[A-Z]:\\)</code> ' matches a drive name, such as <code>C:\</code> , when run on a Windows system.
<code>(?(cond)expr1 expr2)</code>	If condition <code>cond</code> is true, then match <code>expr1</code> . Otherwise, match <code>expr2</code> .	' <code>Mr(s?)\..*?(?(1)her his)\w*</code> ' matches strings that include <code>her</code> when the string begins with <code>Mrs</code> , or that include <code>his</code> when the string begins with <code>Mr</code> .

### Token Operators

Tokens are portions of the matched text that you define by enclosing part of the regular expression in parentheses. You can refer to a token by its sequence in the string (an ordinal token), or assign names to tokens for easier code maintenance and readable output.

Ordinal Token Operator	Description	Example
<code>(expr)</code>	Capture in a token the characters that match the enclosed expression.	' <code>Joh?n\s(\w*)</code> ' captures a token that contains the last name of any person with the first name <code>John</code> or <code>Jon</code> .
<code>\N</code>	Match the Nth token.	' <code>&lt;(\w+).*&gt;.*&lt;/\1&gt;</code> ' captures tokens for HTML tags, such as <code>'title'</code> from the string <code>'&lt;title&gt;Some text&lt;/title&gt;'</code> .
<code>(?(N)expr1 expr2)</code>	If the Nth token is found, then match <code>expr1</code> . Otherwise, match <code>expr2</code> .	' <code>Mr(s?)\..*?(?(1)her his)\w*</code> ' matches strings that include <code>her</code> when the string begins with <code>Mrs</code> , or that include <code>his</code> when the string begins with <code>Mr</code> .

Named Token Operator	Description	Example
<code>(?&lt;name&gt;expr)</code>	Capture in a named token the characters that match the enclosed expression.	' <code>(?&lt;month&gt;\d+) - (?&lt;day&gt;\d+) - (?&lt;yr&gt;\d+)</code> ' creates named tokens for the month, day, and year in an

Named Token Operator	Description	Example
		input date string of the form mm-dd-yy.
\k<name>	Match the token referred to by name.	'<(? <tag>\w+).*&gt;.*&lt;/\k&lt;tag&gt;&gt;' captures tokens for HTML tags, such as 'title' from the string '&lt;title&gt;Some text&lt;/title&gt;'.</tag>
(?(name)expr1 expr2)	If the named token is found, then match expr1. Otherwise, match expr2.	'Mr(?(sex>s?)\..*?(?(sex)her his)\w*' matches strings that include her when the string begins with Mrs, or that include his when the string begins with Mr.

---

**Note:** If an expression has nested parentheses, MATLAB captures tokens that correspond to the outermost set of parentheses. For example, given the search pattern '(and(y|rew))', MATLAB creates a token for 'andrew' but not for 'y' or 'rew'.

---

### Dynamic Regular Expressions

Dynamic expressions allow you to execute a MATLAB command or a regular expression to determine the text to match.

The parentheses that enclose dynamic expressions do *not* create a capturing group.

Operator	Description	Example
(??expr)	Parse expr and include the resulting string in the match expression.  When parsed, expr must correspond to a complete, valid regular expression. Dynamic expressions that use the backslash escape character (\) require two backslashes: one for the initial parsing of expr, and one for the complete match.	'^(\d+)((??\w{\$1}))' determines how many characters to match by reading a digit at the beginning of the string. The dynamic expression is enclosed in a second set of parentheses so that the resulting match is captured in a token. For instance, matching

Operator	Description	Example
		'5XXXXX' captures tokens for '5' and 'XXXXX'.
(??@cmd)	Execute the MATLAB command represented by <code>cmd</code> , and include the string returned by the command in the match expression.	'(.{2,}).?(??@flipr(\$1))' finds palindromes that are at least four characters long, such as 'abba'.
(?@cmd)	Execute the MATLAB command represented by <code>cmd</code> , but discard any output the command returns. (Helpful for diagnosing regular expressions.)	'\w*?(\\w)(?@disp(\$1))\1\w*' matches words that include double letters (such as <code>pp</code> ), and displays intermediate results.

Within dynamic expressions, use the following operators to define replacement strings.

Replacement String Operator	Description
\$& or \$0	Portion of the input string that is currently a match
\$`	Portion of the input string that precedes the current match
\$'	Portion of the input string that follows the current match (use '\$ ' to represent the string '\$')
\$N	Nth token
\$<name>	Named token
\${cmd}	String returned when MATLAB executes the command, <code>cmd</code>

### Comments

Characters	Description	Example
(?#comment)	Insert a comment in the regular expression. The comment text is ignored when matching the input string.	'(?# Initial digit)\<\d\w+' includes a comment, and matches words that begin with a number.

### Search Flags

Search flags modify the behavior for matching expressions. An alternative to using a search flag within an expression is to pass an `option` input argument.

Flag	Description
(? - i)	Match letter case (default for <code>regexp</code> and <code>regexprep</code> ).
(?i)	Do not match letter case (default for <code>regexp</code> ).
(?s)	Match dot (.) in the pattern string with any character (default).
(? - s)	Match dot in the pattern with any character that is not a newline character.
(? - m)	Match the ^ and \$ metacharacters at the beginning and end of a string (default).
(?m)	Match the ^ and \$ metacharacters at the beginning and end of a line.
(? - x)	Include space characters and comments when matching (default).
(?x)	Ignore space characters and comments when matching. Use '\ ' and '\#' to match space and # characters.

The expression that the flag modifies can appear either after the parentheses, such as

`(?i)\w*`

or inside the parentheses and separated from the flag with a colon (:), such as

`(?i:\w*)`

The latter syntax allows you to change the behavior for part of a larger expression.

Data Types: `char` | `cell`

### **replace** — Replacement text

`string` | `cell` array of strings

Replacement text, specified as a string or a cell array of strings, as follows:

- If `replace` is a single string and `expression` is a cell array of strings, then `regexprep` uses the same replacement text for each expression.
- If `replace` is a cell array of N strings and `expression` is a single string, then `regexprep` attempts N matches and replacements.
- If both `replace` and `expression` are cell arrays of strings, then they must contain the same number of elements. `regexprep` pairs each `replace` element with its matching element in `expression`.

The replacement text can include regular characters, special characters (such as tabs or new lines), or string operators, as shown in the following tables.

Replacement String Operator	Description
<code>\$&amp;</code> or <code>\$0</code>	Portion of the input string that is currently a match
<code>\$`</code>	Portion of the input string that precedes the current match
<code>\$'</code>	Portion of the input string that follows the current match (use <code>\$''</code> to represent the string <code>\$'</code> )
<code>\$N</code>	Nth token
<code>\$&lt;name&gt;</code>	Named token
<code>\${cmd}</code>	String returned when MATLAB executes the command, <code>cmd</code>

Operator	Description
<code>\a</code>	Alarm (beep)
<code>\b</code>	Backspace
<code>\f</code>	Form feed
<code>\n</code>	New line
<code>\r</code>	Carriage return
<code>\t</code>	Horizontal tab
<code>\v</code>	Vertical tab
<code>\char</code>	Any character with special meaning in regular expressions that you want to match literally (for example, use <code>\\</code> to match a single backslash)

Data Types: `char` | `cell`

**option — Search or replacement option**

`'once'` | `N` | `'warnings'` | `'ignorecase'` | `'preserveCase'` | `'emptyMatch'` | `'dotexceptnewline'` | `'lineanchors'` | ...

Search or replacement option, specified as a string or an integer value, as shown in the following table.

Options come in sets: one option that corresponds to the default behavior, and one or two options that allow you to override the default. Specify only one option from a set. Options can appear in any order.

Default	Override	Description
'all'	'once'	Match and replace the expression as many times as possible (default), or only once.
	N	Replace only the Nth occurrence of the match, where N is an integer value.
'nowarnings'	'warnings'	Suppress warnings (default), or display them.
'matchcase'	'ignorecase'	Match letter case (default), or ignore case while matching and replacing.
	'preserve-case'	Ignore case while matching, but preserve the case of corresponding characters in the original string while replacing.
'noemptymatch'	'emptymatch'	Ignore zero length matches (default), or include them.
'dotall'	'dotexceptnewline'	Match dot with any character (default), or all except newline (\n).
'stringanchors'	'lineanchors'	Apply ^ and \$ metacharacters to the beginning and end of a string (default), or to the beginning and end of a line.
'literal-spacing'	'free-spacing'	Include space characters and comments when matching (default), or ignore them. With <b>free-spacing</b> , use '\ ' and '\#' to match space and # characters.

Data Types: char

## Output Arguments

**newStr** — Updated text

string | cell array of strings

Updated text, returned as a string or a cell array of strings. The data type of **newStr** is the same as the data type of **str**.

# regexprtranslate

Translate string into regular expression

## Syntax

```
s2 = regexprtranslate(type, s1)
```

## Description

`s2 = regexprtranslate(type, s1)` translates string `s1` into a regular expression string `s2` that you can then use as input into one of the MATLAB regular expression functions such as `regexp`. The `type` input can be either one of the following strings that define the type of translation to be performed. See “Regular Expressions” in the MATLAB Programming Fundamentals documentation for more information.

Type	Description
'escape'	Translate all special characters (e.g., '\$', '.', '?', '[') in string <code>s1</code> so that they are treated as literal characters when used in the <code>regexp</code> and <code>regexprep</code> functions. The translation inserts an escape character ('\') before each special character in <code>s1</code> . Return the new string in <code>s2</code> .
'wildcard'	Translate all wildcard and '.' characters in string <code>s1</code> so that they are treated as literal wildcards and periods when used in the <code>regexp</code> and <code>regexprep</code> functions. The translation replaces all instances of '*' with '.*', all instances of '?' with '.', and all instances of '.' with '\.'. Return the new string in <code>s2</code> .

## Examples

### Example 1 — Using the 'escape' Option

Because `regexp` interprets the sequence `\n` as a newline character, it cannot locate the two consecutive characters `\` and `n` in this string:

```
str = 'The sequence \n generates a new line';
```

```
pat = '\n';
regexp(str, pat)
ans =
 []
```

To have `regexp` interpret the expression `expr` as the characters `'\'` and `'n'`, first translate the expression using `regexptranslate`:

```
pat2 = regexptranslate('escape', pat)
pat2 =
 \\n
regexp(str, pat2)
ans =
 14
```

## Example 2 — Using 'escape' In a Replacement String

Replace the word 'walk' with 'ascend' in this string, treating the characters '\$1' as a token designator:

```
str = 'I walk up, they walked up, we are walking up.';
pat = 'walk(\w*) up';
```

```
regexprep(str, pat, 'ascend$1')
ans =
```

I ascend, they ascended, we are ascending.

Make another replacement on the same string, this time treating the '\$1' as literal characters:

```
regexprep(str, pat, regexptranslate('escape', 'ascend$1'))
ans =
```

I ascend\$1, they ascend\$1, we are ascend\$1.

### Example 3 — Using the 'wildcard' Option

Given the following string of filenames, pick out just the MAT-files. Use `regexprtranslate` to interpret the '\*' wildcard as '\w+' instead of as a regular expression quantifier:

```
files = ['test1.mat, myfile.mat, newfile.txt, ' ...
 'jan30.mat, table3.xls'];
regexpr(files, regexprtranslate('wildcard', '*.mat'), 'match')

ans =

 'test1.mat, myfile.mat, newfile.txt, jan30.mat'
```

To see the translation, you can type

```
regexprtranslate('wildcard', '*.mat')

ans =

.*\mat
```

## registerevent

Associate event handler for COM object event at run time

### Syntax

```
registerevent(h,eventhandler)
```

### Description

`registerevent(h,eventhandler)` registers event handler routines with their corresponding events. The `eventhandler` argument can be either a string that specifies the name of the event handler function, or a function handle that maps to that function. Strings used in the `eventhandler` argument are not case-sensitive.

COM functions are available on Microsoft Windows systems only.

### Examples

Show events in the MATLAB sample control:

```
f = figure('position',[100 200 200 200]);
h = actxcontrol('mwsamp.mwsampctrl.2',[0 0 200 200],f);
events(h)

Click = void Click()
DbtClick = void DbtClick()
MouseDown = void MouseDown(int16 Button, int16 Shift,
 Variant x, Variant y)
Event_Args = void Event_Args(int16 typeshort,
 int32 typelong, double typedouble, string typestring,
 bool typebool)
```

MATLAB displays all events associated with the instance of the control.

Register all events with the same event handler routine, `sampev`:

```
registerevent(h,'sampev')
```

```

eventlisteners(h)

ans =
 'Click' 'sampev'
 'DbtClick' 'sampev'
 'MouseDown' 'sampev'
 'Event_Args' 'sampev'

```

Register individual events:

```

% Unregister existing events
unregisterallevents(h)
% Register specific events
registerevent(h,{'click' 'myclick'; 'dblclick' 'my2click'})
eventlisteners(h)

ans =
 'click' 'myclick'
 'dblclick' 'my2click'

```

Register events using a function handle (@sampev) instead of the function name:

```

h = actxcontrol('mwsamp.mwsampctrl.1.2',[0 0 200 200]);
registerevent(h,@sampev)

```

## regmatlabserver

Register current MATLAB as Automation server

### Syntax

```
regmatlabserver
[status,message] = regmatlabserver
```

### Description

regmatlabserver registers the current MATLAB executable as an Automation server.

[status,message] = regmatlabserver returns the status and error message, if any, reported by the operating system.

### Examples

#### Register MATLAB as Automation Server

Start MATLAB with the **Run as administrator** option.

At the MATLAB prompt, type:

```
[s,msg] = regmatlabserver
```

```
s =
```

```
0
```

```
msg =
```

```
''
```

MATLAB successfully registered.

## Output Arguments

**status** — MATLAB registration status

0 | nonzero

MATLAB registration status returned as 0 or nonzero. If the attempt to register MATLAB is successful, **status** is 0. Otherwise, **status** is nonzero.

**message** — System error message

string

System error message returned as a text string if registration is unsuccessful.

# rehash

Refresh function and file system path caches

## Syntax

```
rehash
rehash path
rehash toolbox
rehash pathreset
rehash toolboxreset
rehash toolboxcache
```

## Description

`rehash` with no arguments updates the MATLAB list of known files and classes for directories on the search path that are not in *matlabroot/toolbox*. It compares the timestamps for loaded functions against their timestamps on disk. It clears loaded functions if the files on disk are newer. All of this normally happens each time MATLAB displays the Command Window prompt. Use `rehash` with no arguments only when you run a program file that updates another program file, and the calling file needs to reuse the updated version of the second file before the calling file has finished running.

`rehash path` performs the same updates as `rehash`, but uses a different technique for detecting the files and directories that require updates. Run `rehash path` only if you receive a warning during MATLAB startup notifying you that MATLAB could not tell if a directory has changed, and you encounter problems with MATLAB not using the most current versions of your program files.

`rehash toolbox` performs the same updates as `rehash path`, except it updates the list of known files and classes for *all* directories on the search path, including those in *matlabroot/toolbox*. Run `rehash toolbox` when you change, add, or remove files in *matlabroot/toolbox* during a session. Typically, you should not make changes to files and directories in *matlabroot/toolbox*.

`rehash pathreset` performs the same updates as `rehash path`, and also ensures the known files and classes list follows precedence rules for shadowed functions.

rehash **toolboxreset** performs the same updates as rehash **toolbox**, and also ensures the known files and classes list follows precedence rules for shadowed functions.

rehash **toolboxcache** performs the same updates as rehash **toolbox**, and also updates the cache file. This is the equivalent of clicking the **Update Toolbox Path Cache** button in the General Preferences dialog box.

## **release**

Release COM interface

### **Syntax**

`release(h)`

### **Description**

`release(h)` releases the interface and all resources used by the interface. Other interfaces on that object might still be active.

You must release the handle when you are done with the interface. A released interface is no longer valid. MATLAB generates an error if you try to use an object that represents that interface.

To release the interface and delete the control itself, use the `delete` function.

COM functions are available on Microsoft Windows systems only.

`delete (COM)` | `actxcontrol` | `actxserver`

**Introduced before R2006a**

## rem

Remainder after division

## Syntax

```
R = rem(X,Y)
```

## Description

`R = rem(X,Y)` returns the remainder after division of `X` by `Y`. In general, if `Y` does not equal 0, `R = rem(X,Y)` returns  $X - n \cdot Y$ , where  $n = \text{fix}(X./Y)$ . If `Y` is not an integer and the quotient  $X./Y$  is within roundoff error of an integer, then `n` is that integer. Inputs `X` and `Y` must have the same dimensions unless one of them is a scalar double. If one of the inputs has an integer data type, then the other input must be of the same integer data type or be a scalar double.

The following are true by convention:

- `rem(X,0)` is NaN.
- `rem(X,X)` for `X~=0` is 0.
- `rem(X,Y)` for `X~=Y` and `Y~=0` has the same sign as `X`.

## Examples

### Remainder of Two Scalars

Compute the remainder after dividing 5 into 23.

```
X = 23;
Y = 5;
R = rem(X,Y)
```

```
R =
```

3

**Remainder of a Vector**

Create a vector, then use `rem` to find the remainder after dividing a scalar into each element of the vector.

```
X = 1:5;
Y = 3;
R = rem(X,Y)
```

```
R =
```

```
 1 2 0 1 2
```

When you specify one or more of the inputs as an array, the `rem` function acts on each array element independently.

**Remainder of Two Arrays**

Create two 3-by-3 matrices, then use `rem` to find the remainder after dividing Y into X.

```
X = [1 2 3;4 5 6;7 8 9];
Y = [9 8 7;6 5 4;3 2 1];
R = rem(X,Y)
```

```
R =
```

```
 1 2 3
 4 0 2
 1 0 0
```

Inputs X and Y must have the same dimensions unless one is a scalar double.

**Forced Rounding in rem**

If Y is not an integer and X./Y is within roundoff error of an integer, then `rem` rounds to that integer for its calculation. The size of the roundoff error is very small.

```
X = 2;
Y = 2 - eps(2)
```

```
Y =
```

```
2.0000
```

It looks like Y is trivially equal to 2, but in fact there is an infinitesimal difference.

```
2 - Y
```

```
ans =
```

```
4.4409e-16
```

This difference is forced to zero by `rem` if it is small enough.

```
R = rem(X,Y)
```

```
R =
```

```
0
```

Make the difference a little larger and the forced rounding disappears.

```
Y = 2 - eps(4);
```

```
R = rem(X,Y)
```

```
R =
```

```
8.8818e-16
```

### **Difference Between `rem` and `mod`**

Define X and Y with different signs.

```
X = 5;
```

```
Y = -2;
```

Compute the remainder after division with `rem`, then compute the modulus after division with `mod`.

```
R = rem(X,Y)
```

```
R =
```

```
1
```

```
M = mod(X,Y)
```

```
M =
```

```
-1
```

`rem(X,Y)` and `mod(X,Y)` are equal if `X` and `Y` have the same sign, but differ by `Y` if `X` and `Y` have different signs. Notice that `rem` retains the sign of `X`, while `mod` retains the sign of `Y`.

## Input Arguments

### **X — Dividend**

scalar | vector | matrix | multidimensional array

Dividend, specified as a scalar, vector, matrix, or multidimensional array. Must be a real-valued number of any numerical type.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `char` | `duration`

### **Y — Divisor**

scalar | vector | matrix | multidimensional array

Divisor, specified as a scalar, vector, matrix, or multidimensional array. Must be a real-valued number of any numerical type.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `char` | `duration`

## See Also

`mod`

**Introduced before R2006a**

## remove

**Class:** containers.Map

**Package:** containers

Remove key-value pairs from `containers.Map` object

## Syntax

```
remove(mapObj, keySet)
```

## Description

`remove(mapObj, keySet)` erases all specified keys, and the values associated with them, from `mapObj`. Input `keySet` can be a scalar key or a cell array of keys.

## Input Arguments

### **mapObj**

Object of class `containers.Map`.

### **keySet**

Scalar value, string, or cell array that specifies keys in `mapObj` to delete.

## Examples

### Remove Key-Value Pairs from a Map

Create a map and view the keys and the `Count` property:

```
myKeys = {'a', 'b', 'c', 'd'};
myValues = [1,2,3,4];
mapObj = containers.Map(myKeys,myValues);
```

```
mapKeys = keys(mapObj)
mapCount = mapObj.Count
```

The initial map contains four key-value pairs:

```
mapKeys =
 'a' 'b' 'c' 'd'
```

```
mapCount =
 4
```

Remove the pairs corresponding to keys b and d:

```
keySet = {'b', 'd'};
remove(mapObj, keySet)
```

```
mapKeys = keys(mapObj)
mapCount = mapObj.Count
```

The modified map contains two key-value pairs:

```
mapKeys =
 'a' 'c'
```

```
mapCount =
 2
```

## See Also

[keys](#) | [values](#) | [containers.Map](#) | [isKey](#)

## removecats

Remove categories from categorical array

### Syntax

```
B = removecats(A)
B = removecats(A,oldcats)
```

### Description

`B = removecats(A)` removes unused categories from the categorical array, `A`. The output categorical array, `B`, has the same size and values as `A`. However, `B` possibly has fewer categories.

`B = removecats(A,oldcats)` removes the categories specified by `oldcats`. The function `removecats` removes categories, but does not remove any elements of the array. Therefore, elements of `B`, whose values correspond to `oldcats`, are undefined.

### Examples

#### Remove All Unused Categories

Create a categorical array representing political parties of four people.

```
A = categorical({'republican' 'democrat' 'democrat' 'republican'},...
 {'democrat' 'republican' 'independent'})
```

A =

```
 republican democrat democrat republican
```

A is a 1-by-4 categorical array.

Summarize the categorical array, A.

```
summary(A)
```

```
democrat republican independent
 2 2 0
```

A has three categories. `democrat` appears twice in the array, `republican` appears twice in the array, and `independent` is unused.

Remove the unused category, `independent`.

```
B = removecats(A)
```

```
B =
```

```
republican democrat democrat republican
```

B has the same values as A.

Display the categories of B.

```
categories(B)
```

```
ans =
```

```
'democrat'
'republican'
```

B has fewer categories than A.

## Remove Categories with Corresponding Values Used in A

Create a categorical array, A, containing modes of transportation.

```
A = categorical({'plane' 'car'; 'train' 'car'; 'plane' 'car'})
```

```
A =
```

```
plane car
train car
plane car
```

A is a 3-by-2 categorical array.

Display the categories of A.

```
categories(A)
```

```
ans =
```

```
'car'
'plane'
'train'
```

A has three categories, `car`, `plane`, and `train`.

Remove the category, `train`.

```
B = removecats(A, 'train')
```

```
B =
```

```
plane car
<undefined> car
plane car
```

The element that was from the category `train` is now undefined.

Display the categories of `B`.

```
categories(B)
```

```
ans =
```

```
'car'
'plane'
```

`B` has one fewer category than `A`.

## Input Arguments

### **A** — Categorical array

vector | matrix | multidimensional array

Categorical array, specified as a vector, matrix, or multidimensional array.

### **oldcats** — Categories to remove

string | cell array of strings

Categories to remove, specified as a string or cell array of strings. The default is all the unused categories from `A`.

## More About

### Tips

- `~ismember(categories(A),unique(A))` returns logical true (1) for any unused category of A.

### See Also

`addcats` | `categories` | `iscategory` | `mergocats` | `renamecats` | `reordercats` | `setcats` | `summary`

**Introduced in R2013b**

## removets

Remove `timeseries` objects from `tscollection` object

### Syntax

```
tsc = removets(tsc,Name)
```

### Description

`tsc = removets(tsc,Name)` removes one or more `timeseries` objects with the name specified in `Name` from the `tscollection` object `tsc`. `Name` can either be a string or a cell array of strings.

### Examples

The following example shows how to remove a time series from a `tscollection`.

- 1 Create two `timeseries` objects, `ts1` and `ts2`.

```
ts1=timeseries([1.1 2.9 3.7 4.0 3.0],1:5,'name','acceleration');
ts2=timeseries([3.2 4.2 6.2 8.5 1.1],1:5,'name','speed');
```

- 2 Create a `tscollection` object `tsc`, which includes `ts1` and `ts2`.

```
tsc=tscollection({ts1 ts2});
```

- 3 To view the members of `tsc`, type the following at the MATLAB prompt:

```
tsc
```

The response is

```
Time Series Collection Object: unnamed
```

```
Time vector characteristics
```

```
Start time 1 seconds
End time 5 seconds
```

Member Time Series Objects:

```
acceleration
speed
```

The members of `tsc` are listed by name at the bottom: `acceleration` and `speed`. These are the `Name` properties of `ts1` and `ts2`, respectively.

- 4 Remove `ts2` from `tsc`.

```
tsc=removets(tsc,'speed');
```

- 5 To view the current members of `tsc`, type the following at the MATLAB prompt:

```
tsc
```

The response is

```
Time Series Collection Object: unnamed
```

```
Time vector characteristics
```

```
Start time 1 seconds
End time 5 seconds
```

```
Member Time Series Objects:
acceleration
```

The remaining member of `tsc` is `acceleration`. The timeseries `speed` has been removed.

`addts` | `tscollection`

**Introduced before R2006a**

## renamecats

Rename categories in categorical array

### Syntax

```
B = renamecats(A,newnames)
B = renamecats(A,oldnames,newnames)
```

### Description

`B = renamecats(A,newnames)` renames all the categories in the categorical array, `A`. Elements of `B` use the new category names.

`B = renamecats(A,oldnames,newnames)` renames only the categories specified by `oldnames`.

### Examples

#### Rename All Categories

Create a categorical array containing states from New England.

```
A = categorical({'MA';'ME';'CT';'VT';'ME';'NH';'VT';'MA';'NH';'CT';'RI'})
```

A =

```
MA
ME
CT
VT
ME
NH
VT
MA
NH
CT
RI
```

A is an 11-by-1 categorical array.

Display the categories of A.

```
categories(A)
```

```
ans =
```

```
'CT'
'MA'
'ME'
'NH'
'RI'
'VT'
```

A has six categories.

Rename the categories to use the full state name instead of the abbreviation.

```
B = renamecats(A,{'Connecticut', 'Massachusetts', ...
 'Maine', 'New Hampshire', 'Rhode Island', 'Vermont'})
```

```
B =
```

```
Massachusetts
Maine
Connecticut
Vermont
Maine
New Hampshire
Vermont
Massachusetts
New Hampshire
Connecticut
Rhode Island
```

Elements of B use the new category names.

Display the categories of B.

```
categories(B)
```

```
ans =
```

```
'Connecticut'
```

```
'Massachusetts'
'Maine'
'New Hampshire'
'Rhode Island'
'Vermont'
```

### Rename One Category

Create a categorical array containing colors.

```
A = categorical({'red' 'blue'; 'purple' 'white'; 'green' 'red'})
```

A =

```
 red blue
purple white
 green red
```

A is a 3-by-2 categorical array.

Display the categories of A.

```
categories(A)
```

ans =

```
'blue'
'green'
'purple'
'red'
'white'
```

A has five categories that are listed in alphabetical order.

Change the category name from purple to violet.

```
B = renamecats(A, 'purple', 'violet')
```

B =

```
 red blue
violet white
 green red
```

The element B(2,1) is violet instead of purple.

Display the categories of **B**.

```
categories(B)
```

```
ans =
```

```
 'blue'
 'green'
 'violet'
 'red'
 'white'
```

**violet** replaces **purple** and the categories are no longer in alphabetical order. Note that the category has not changed its position.

## Input Arguments

### **A** — Categorical array

vector | matrix | multidimensional array

Categorical array, specified as a vector, matrix, or multidimensional array.

### **newnames** — New category names for **B**

string | cell array of strings

New category names for **B**, specified as a string or a cell array of strings. The new category names must be unique, and must not duplicate any existing names.

### **oldnames** — Old category names from **A**

string | cell array of strings

Old category names from **A**, specified as a string or a cell array of strings.

## More About

### Tips

- Renaming categories does not change their position in `categories(B)`. Use `reordercats` to change the category ordering. For example, you can use `B = reordercats(B,sort(categories(B)))` to put the categories in alphabetical order.

**See Also**

addcats | categories | iscategory | mergecats | removecats | reordercats |  
setcats

**Introduced in R2013b**

## reordercats

Reorder categories in categorical array

### Syntax

```
B = reordercats(A)
B = reordercats(A,neworder)
```

### Description

`B = reordercats(A)` reorders the categories in the categorical array, `A`, to be in alphanumeric order.

The order of the categories is used by functions such as `summary` and `histogram`. If the categorical array is ordinal, the order of the categories defines their mathematical ordering. The first category specified is the smallest and the last category is the largest.

`B = reordercats(A,neworder)` puts the categories in the order specified by `neworder`.

### Examples

#### Alphabetize Categories of Nonordinal Categorical Array

Create two categorical arrays, `X` and `Y`.

```
X = categorical({'frog';'cat';'cat';'ant';'frog'})
```

```
Y = categorical({'deer';'bear';'eagle';'deer'})
```

```
X =
```

```
 frog
 cat
 cat
 ant
 frog
```

```
Y =

 deer
 bear
 eagle
 deer
```

X is a 5-by-1 categorical array. The categories of X are the sorted unique values from the array: {'ant'; 'cat'; 'frog'}.

Y is a 4-by-1 categorical array. The categories of Y are the sorted unique values from the array: {'bear'; 'deer'; 'eagle'}.

Concatenate X and Y into a single categorical array, A.

```
A = [X;Y]
```

```
A =

 frog
 cat
 cat
 ant
 frog
 deer
 bear
 eagle
 deer
```

`vertcat` appends the values from Y to the values from X.

List the categories of the categorical array, A.

```
acats = categories(A)
```

```
acats =

 'ant'
 'cat'
 'frog'
 'bear'
 'deer'
 'eagle'
```

`vertcat` appends the categories of `Y` to the categories from `X`. The categories of `A` are *not* in alphabetical order.

Reorder the categories of `A` into alphabetical order.

```
B = reordercats(A)
```

```
B =
```

```
 frog
 cat
 cat
 ant
 frog
 deer
 bear
 eagle
 deer
```

The output categorical array, `B`, has the same elements in the same order as the input categorical array, `A`.

List the categories of the categorical array, `B`.

```
bcats = categories(B)
```

```
bcats =
```

```
 'ant'
 'bear'
 'cat'
 'deer'
 'eagle'
 'frog'
```

The categories of `B` are in alphabetical order.

## Reorder Categories in Nonordinal Categorical Array

Create a categorical array containing the color of various items.

```
A = categorical({'red'; 'green'; 'blue'; 'red'; 'green'; 'red'; 'blue'; 'blue'})
```

```
A =
```

```
 red
```

```
green
blue
red
green
red
blue
blue
```

A is an 8-by-1 categorical array.

Display the categories of A.

```
categories(A)
```

```
ans =
```

```
'blue'
'green'
'red'
```

The categories of A are in alphabetical order and have no mathematical meaning.

Reorder the categories to match the order commonly used for colors.

```
B = reordercats(A,{'red','green','blue'})
```

```
B =
```

```
red
green
blue
red
green
red
blue
blue
```

B contains the same values as A.

Display the categories of B.

```
categories(B)
```

```
ans =
```

```
'red'
'green'
'blue'
```

B is not ordinal and the order of the categories has no mathematical meaning. Although the categories appear in the order of the color spectrum, relational operations, such as greater than and less than, have no meaning.

### Reorder Categories in Ordinal Categorical Array

Create an ordinal categorical array, A, containing modes of transportation. Order the categories based on the average price of travel.

```
A = categorical({'plane';'car'; 'train';'car';'plane';'car'},...
 {'car','train','plane'},'Ordinal',true)
```

A =

```
plane
car
train
car
plane
car
```

A is a 6-by-1 ordinal categorical array.

Display the categories of A.

```
categories(A)
```

ans =

```
'car'
'train'
'plane'
```

Since A is ordinal, `car < train < plane`.

Reorder the categories to reflect a decrease in the cost of train travel.

```
B = reordercats(A,{'train','car','plane'})
```

B =

```
plane
car
train
car
plane
car
```

**B** contains the same values as **A**.

Display the categories of **B**.

```
categories(B)
```

```
ans =
```

```
'train'
'car'
'plane'
```

The mathematical ordering of the categories is now `train < car < plane`. The results from relational operations, `min`, and `max` reflect the new category ordering.

### Reorder Categories with Numeric Vector

Create a categorical array, **A**, containing modes of transportation.

```
A = categorical({'plane'; 'car'; 'train'; 'car'; 'car'; 'plane'; 'car'})
```

```
A =
```

```
plane
car
train
car
car
plane
car
```

Display the categories of **A**.

```
categories(A)
```

```
ans =
```

```
'car'
```

```
'plane'
'train'
```

Reorder categories from least to most frequent occurrence in **A**.

```
B = countcats(A);
[C,neworder] = sort(B);
neworder

neworder =

 3
 2
 1

D = reordercats(A,neworder);
categories(D)

ans =

 'train'
 'plane'
 'car'
```

Because `countcats` counts the occurrences of each category, `neworder` describes how to reorder the categories—not the elements—of **A**.

## Input Arguments

### **A** — Categorical array

vector | matrix | multidimensional array

Categorical array, specified as a vector, matrix, or multidimensional array. If **A** is an ordinal categorical array, a reordering of the categories changes the mathematical meaning. Consequently, the relational operators, such as greater than and less than, might return different results.

### **neworder** — New category order for **B**

cell array of strings | numeric vector

New category order for **B**, specified as a cell array of strings or a numeric vector. `neworder` must be a permutation of `categories(A)`.

## More About

### Tips

- To convert the categorical array, `B`, to an ordinal categorical array, use `B = categorical(B, 'Ordinal', true)`. You can specify the order of the categories with `B = categorical(B, valueset, 'Ordinal', true)`, where the order of the values in `valueset` defines the category order.

`addcats` | `categories` | `iscategory` | `mergecats` | `removecats` | `renamecats` | `setcats`

**Introduced in R2013b**

## rename

**Class:** FTP

Rename file on FTP server

## Syntax

```
rename(ftpobj,oldname,newname)
```

## Description

`rename(ftpobj,oldname,newname)` changes the name of the file `oldname` to `newname` in the current folder on an FTP server.

## Input Arguments

### **ftpobj**

FTP object created by `ftp`.

### **oldname**

String enclosed in single quotation marks that specifies the original name of the file.

### **newname**

String enclosed in single quotation marks that specifies a new name for the file.

## Examples

Suppose that hypothetical FTP server `ftp.testsite.com` contains a file named `testfile.m`. Rename the file to `final.m`:

```
ts = ftp('ftp.testsite.com');
rename(ts,'testfile.m','final.m');
```

```
close(ts);
```

## **See Also**

dir | ftp | mput | delete | mget

**Introduced before R2006a**

## repelem

Repeat copies of array elements

### Syntax

```
u = repelem(v,n)
B = repelem(A,r1,...,rN)
```

### Description

`u = repelem(v,n)`, where `v` is a scalar or vector, returns a vector of repeated elements of `v`.

- If `n` is a scalar, then each element of `v` is repeated `n` times. The length of `u` is `length(v)*n`.
- If `n` is a vector, then it must be the same length as `v`. Each element of `n` specifies the number of times to repeat the corresponding element of `v`.

This syntax is not supported for `table` input.

`B = repelem(A,r1,...,rN)` returns an array with each element of `A` repeated according to `r1,...,rN`. Each `r1,...,rN` must either be a scalar or a vector with the same length as `A` in the corresponding dimension. For example, if `A` is a matrix, `repelem(A,2,3)` returns a matrix containing a 2-by-3 block of each element of `A`.

### Examples

#### Repeat Vector Elements

Create a vector and repeat each of its elements three times into a new vector.

```
v = [1 2 3 4];
u = repelem(v,3)
```

```
u =
```

```

1 1 1 2 2 2 3 3 3 4 4 4

```

Repeat the first two elements of  $v$  twice and the last two elements three times.

```
u = repelem(v,[2 2 3 3])
```

```
u =
```

```

1 1 2 2 3 3 3 4 4 4

```

### Repeat Matrix Elements

Create a matrix and repeat each element into a 3-by-2 block of a new matrix.

```
A = [1 2; 3 4]
```

```
A =
```

```

1 2
3 4

```

```
B = repelem(A,3,2)
```

```
B =
```

```

1 1 2 2
1 1 2 2
1 1 2 2
3 3 4 4
3 3 4 4
3 3 4 4

```

### Repeat Matrix Columns

Create a matrix and copy its columns into a new array, repeating the first column twice and second column three times.

```
A = [1 2; 3 4]
```

```
B = repelem(A,1,[2 3])
```

```
A =
```

```
 1 2
 3 4
```

```
B =
```

```
 1 1 2 2 2
 3 3 4 4 4
```

## Input Arguments

### **v** — Input element

scalar | vector

Input element, specified as a scalar or a vector.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char` | `struct` | `table` | `cell` | `datetime` | `duration`

Complex Number Support: Yes

### **n** — Number of times to repeat each element

scalar | vector

Number of times to repeat each element, specified as a scalar or a vector. If `n` is a scalar, then all elements of `v` are repeated `n` times. If `n` is a vector, then each element of `n` specifies the number of times to repeat the corresponding element of `v`. In either case, `n` must be integer-valued.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **A** — Input array

matrix | multidimensional array

Input array, specified as a matrix or multidimensional array.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char` | `struct` | `table` | `cell` | `datetime` | `duration`  
Complex Number Support: Yes

**$r_1, \dots, r_N$  — Repetition factors for each dimension (as separate arguments)**

`scalars` | `vectors`

Repetition factors for each dimension, specified as separate arguments of integer-valued scalars or vectors. If `A` is a table, each repetition factor must be a scalar.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

## Output Arguments

**`u` — Output vector**

`vector`

Output vector. If `v` is a row vector or scalar, `u` is a row vector. If `v` is a column vector, `u` is also a column vector.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char` | `struct` | `table` | `cell` | `datetime` | `duration`

**`B` — Output array**

`matrix` | `multidimensional array`

Output array, returned as a matrix or multidimensional array.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char` | `struct` | `table` | `cell` | `datetime` | `duration`

## See Also

`kron` | `repmat`

**Introduced in R2015a**

## repmat

Repeat copies of array

### Syntax

```
B = repmat(A,n)
B = repmat(A,r1,...,rN)
B = repmat(A,r)
```

### Description

`B = repmat(A,n)` returns an array containing `n` copies of `A` in the row and column dimensions. The size of `B` is `size(A)*n` when `A` is a matrix.

`B = repmat(A,r1,...,rN)` specifies a list of scalars, `r1,...,rN`, that describes how copies of `A` are arranged in each dimension. When `A` has `N` dimensions, the size of `B` is `size(A).*[r1...rN]`. For example, `repmat([1 2; 3 4],2,3)` returns a 4-by-6 matrix.

`B = repmat(A,r)` specifies the repetition scheme with row vector `r`. For example, `repmat(A,[2 3])` returns the same result as `repmat(A,2,3)`.

### Examples

#### Square Block Format

Repeat copies of a matrix into a 2-by-2 block arrangement.

```
A = diag([100 200 300])
```

```
A =
```

```
100 0 0
 0 200 0
 0 0 300
```

```
B = repmat(A,2)
```

```
B =
```

```

100 0 0 100 0 0
 0 200 0 0 200 0
 0 0 300 0 0 300
100 0 0 100 0 0
 0 200 0 0 200 0
 0 0 300 0 0 300
```

### Rectangular Block Format

Repeat copies of a matrix into a 2-by-3 block arrangement.

```
A = diag([100 200 300])
```

```
A =
```

```

100 0 0
 0 200 0
 0 0 300
```

```
B = repmat(A,2,3)
```

```
B =
```

```

100 0 0 100 0 0 100 0 0
 0 200 0 0 200 0 0 200 0
 0 0 300 0 0 300 0 0 300
100 0 0 100 0 0 100 0 0
 0 200 0 0 200 0 0 200 0
 0 0 300 0 0 300 0 0 300
```

### 3-D Block Array

Repeat copies of a matrix into a 2-by-3-by-2 block arrangement.

```
A = [1 2; 3 4]
```

A =

```
1 2
3 4
```

B = repmat(A,[2 3 2])

B(:, :, 1) =

```
1 2 1 2 1 2
3 4 3 4 3 4
1 2 1 2 1 2
3 4 3 4 3 4
```

B(:, :, 2) =

```
1 2 1 2 1 2
3 4 3 4 3 4
1 2 1 2 1 2
3 4 3 4 3 4
```

## Vertical Stack of Row Vectors

Vertically stack a row vector four times.

```
A = 1:4;
B = repmat(A,4,1)
```

B =

```
1 2 3 4
1 2 3 4
1 2 3 4
1 2 3 4
```

## Horizontal Stack of Column Vectors

Horizontally stack a column vector four times.

```
A = (1:3)';
B = repmat(A,1,4)
```

```
B =
```

```
 1 1 1 1
 2 2 2 2
 3 3 3 3
```

### Tabular Block Format

Create a table with variables `Age` and `Height`.

```
A = table([39; 26],[70; 63], 'VariableNames',{'Age' 'Height'})
```

```
A =
```

Age	Height
39	70
26	63

Repeat copies of the table into a 2-by-3 block format.

```
B = repmat(A,2,3)
```

```
B =
```

Age	Height	Age_1	Height_1	Age_2	Height_2
39	70	39	70	39	70
26	63	26	63	26	63
39	70	39	70	39	70
26	63	26	63	26	63

`repmat` repeats the entries of the table and appends a number to the new variable names.

## Input Arguments

### **A — Input array**

scalar | vector | matrix | multidimensional array

Input array, specified as a scalar, vector, matrix, or multidimensional array.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char` | `struct` | `table` | `cell`

Complex Number Support: Yes

### **n — Number of times to repeat input array in row and column dimensions**

integer value

Number of times to repeat the input array in the row and column dimensions, specified as an integer value. If `n` is 0 or negative, the result is an empty array.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **r1, ..., rN — Repetition factors for each dimension (as separate arguments)**

integer values

Repetition factors for each dimension, specified as separate arguments of integer values. If any repetition factor is 0 or negative, the result is an empty array.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **r — Vector of repetition factors for each dimension (as a row vector)**

integer values

Vector of repetition factors for each dimension, specified as a row vector of integer values. If any value in `r` is 0 or negative, the result is an empty array.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

## More About

### Tips

- To build block arrays by forming the tensor product of the input with an array of ones, use `kron`. For example, to stack the row vector `A = 1:3` four times vertically, you can use `B = kron(A, ones(4,1))`.
- To create block arrays and perform a binary operation in a single pass, use `bsxfun`. In some cases, `bsxfun` provides a simpler and more memory efficient solution. For example, to add the vectors `A = 1:5` and `B = (1:10)'` to produce a 10-by-5 array, use `bsxfun(@plus,A,B)` instead of `repmat(A,10,1) + repmat(B,1,5)`.
- When `A` is a scalar of a certain type, you can use other functions to get the same result as `repmat`.

repmat Syntax	Equivalent Alternative
<code>repmat(NaN,m,n)</code>	<code>NaN(m,n)</code>
<code>repmat(single(inf),m,n)</code>	<code>inf(m,n,'single')</code>
<code>repmat(int8(0),m,n)</code>	<code>zeros(m,n,'int8')</code>
<code>repmat(uint32(1),m,n)</code>	<code>ones(m,n,'uint32')</code>
<code>repmat(eps,m,n)</code>	<code>eps(ones(m,n))</code>

### See Also

`bsxfun` | `kron` | `meshgrid` | `ndgrid` | `repelem` | `reshape`

Introduced before R2006a

## resample (tscollection)

Select or interpolate data in `tscollection` using new time vector

### Syntax

```
tsc = resample(tsc,Time)
tsc = resample(tsc,Time,interp_method)
tsc = resample(tsc,Time,interp_method,code)
```

### Description

`tsc = resample(tsc,Time)` resamples the `tscollection` object `tsc` on the new Time vector. When `tsc` uses date strings and `Time` is numeric, `Time` is treated as numerical specified relative to the `tsc.TimeInfo.StartDate` property and in the same units that `tsc` uses. The `resample` method uses the default interpolation method for each time series member.

`tsc = resample(tsc,Time,interp_method)` resamples the `tscollection` object `tsc` using the interpolation method given by the string `interp_method`. Valid interpolation methods include 'linear' and 'zoh' (zero-order hold).

`tsc = resample(tsc,Time,interp_method,code)` resamples the `tscollection` object `tsc` using the interpolation method given by the string `interp_method`. The integer code is a user-defined quality code for resampling, applied to all samples.

### Examples

The following example shows how to resample a `tscollection` that consists of two `timeseries` members.

- 1 Create two `timeseries` objects.

```
ts1=timeseries([1.1 2.9 3.7 4.0 3.0],1:5,'name','acceleration');
ts2=timeseries([3.2 4.2 6.2 8.5 1.1],1:5,'name','speed');
```

- 2 Create a `tscollection` `tsc`.

```
tsc=tscollection({ts1 ts2});
```

The time vector of the collection `tsc` is `[1:5]`, which is the same as for `ts1` and `ts2` (individually).

- 3 Get the interpolation method for **acceleration** by typing

```
tsc.acceleration
```

MATLAB responds with

```
Time Series Object: acceleration
```

```
Time vector characteristics
```

```
Length 5
Start time 1 seconds
End time 5 seconds
```

```
Data characteristics
```

```
Interpolation method linear
Size [1 1 5]
Data type double
```

- 4 Set the interpolation method for **speed** to zero-order hold by typing

```
setinterpmethod(tsc.speed, 'zoh')
```

MATLAB responds with

```
Time Series Object: acceleration
```

```
Time vector characteristics
```

```
Length 5
Start time 1 seconds
End time 5 seconds
```

```
Data characteristics
```

```
Interpolation method zoh
Size [1 1 5]
```

Data type                      double

- 5** Resample the time-series collection `tsc` by individually resampling each time-series member of the collection and using its interpolation method.

```
res_tsc=resample(tsc,[1 1.5 3.5 4.5 4.9])
```

### **See Also**

## reset

Reset graphics object properties to their defaults

### Syntax

```
reset(h)
```

### Description

`reset(h)` resets all properties on the object identified by `h` to their default values. Properties that do not have default values are not affected.

If `h` is a figure, the MATLAB software does not reset `Position`, `Units`, `WindowStyle`, or `PaperUnits`. If `h` is an `axes`, MATLAB does not reset `Position` and `Units`.

### Examples

`reset(gca)` resets the properties of the current axes.

`reset(gcf)` resets the properties of the current figure.

### See Also

`cla` | `clf` | `gca` | `gcf` | `hold`

Introduced before R2006a

## reset (RandStream)

Reset random number stream

### Class

RandStream

### Syntax

reset(s)  
reset(s, seed)

### Description

reset(s) resets the generator for the random stream, s, to the internal state corresponding to its seed. This is similar to clearing s and recreating it using RandStream(Type, ...), except that reset does not set the stream's NormalTransform, Antithetic, and FullPrecision properties to their original values.

reset(s, seed) resets the generator for the random stream, s, to the internal state corresponding to seed (the seed value), and it updates the seed property of s. The value of seed must be an integer between 0 and  $2^{32} - 1$ . Resetting a stream's seed can invalidate independence with other streams.

---

**Note:** Resetting a stream should be used primarily for reproducing results.

---

### Examples

#### Example 1

Reset a random number stream to its initial state. This does not create a random number stream, it simply resets the stream:

```
stream = RandStream('twister','Seed',0)
stream =
 mt19937ar random stream
 Seed: 0
 NormalTransform: Ziggurat

reset(stream);
stream.Seed

ans =

 0
```

## Example 2

Reset a random number stream using a specific seed:

```
stream = RandStream('twister','Seed',0)
stream =
 mt19937ar random stream
 Seed: 0
 NormalTransform: Ziggurat

reset(stream,1);
stream.Seed

ans =

 1
```

## See Also

[RandStream](#) | [RandStream.getGlobalStream](#)

# reshape

Reshape array

## Syntax

```
B = reshape(A,sz)
B = reshape(A,sz1,...,szN)
```

## Description

`B = reshape(A,sz)` reshapes `A` using the size vector, `SZ`, to define `size(B)`. For example, `reshape(A,[2,3])` reshapes `A` into a 2-by-3 matrix. `SZ` must contain at least 2 elements, and `prod(SZ)` must be the same as `numel(A)`.

`B = reshape(A,sz1,...,szN)` reshapes `A` into a `sz1`-by-...-by-`szN` array where `sz1,...,szN` indicates the size of each dimension. You can specify a single dimension size of `[]` to have the dimension size automatically calculated, such that the number of elements in `B` matches the number of elements in `A`. For example, if `A` is a 10-by-10 matrix, then `reshape(A,2,2,[])` reshapes the 100 elements of `A` into a 2-by-2-by-25 array.

## Examples

### Reshape Vector into Matrix

Reshape a 1-by-10 vector into a 5-by-2 matrix.

```
A = 1:10;
B = reshape(A,[5,2])
```

```
B =
```

```
 1 6
 2 7
 3 8
```

```
4 9
5 10
```

### Reshape Matrix to Have Specified Number of Columns

Reshape a 6-by-6 magic square matrix into a matrix that has only 3 columns. Specify `[]` for the first dimension size to let `reshape` automatically calculate the appropriate number of rows.

```
A = magic(6);
B = reshape(A,[],3)
```

B =

```
35 6 19
 3 7 23
31 2 27
 8 33 10
30 34 14
 4 29 18
 1 26 24
32 21 25
 9 22 20
28 17 15
 5 12 16
36 13 11
```

The result is a 12-by-3 matrix, which maintains the same number of elements (36) as the original 6-by-6 matrix. The elements in `B` also maintain their columnwise order from `A`.

### Reshape Multidimensional Array into Matrix

Reshape a 3-by-2-by-3 array of zeros into a 9-by-2 matrix.

```
A = zeros(3,2,3);
B = reshape(A,9,2)
```

B =

```
0 0
0 0
0 0
0 0
0 0
```

```
0 0
0 0
0 0
0 0
```

## Input Arguments

### **A** — Input array

vector | matrix | multidimensional array

Input array, specified as a vector, matrix, or multidimensional array.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char` | `cell` | `datetime` | `duration` | `calendarDuration`

Complex Number Support: Yes

### **sz** — Output size

row vector of integers

Output size, specified as a row vector of integers. Each element of **sz** indicates the size of the corresponding dimension in **B**. You must specify **sz** so that the number of elements in **A** and **B** are the same. That is, `prod(sz)` must be the same as `numel(A)`.

Beyond the second dimension, the output, **B**, does not reflect trailing dimensions with a size of 1. For example, `reshape(A, [3,2,1,1])` produces a 3-by-2 matrix.

Example: `reshape(A, [3,2])`

Example: `reshape(A, [6,4,10])`

Example: `reshape(A, [5,5,5,5])`

### **sz1, ..., szN** — Size of each dimension

two or more integers | [] (optional)

Size of each dimension, specified as two or more integers with at most one [] (optional). You must specify at least 2 dimension sizes, and at most one dimension size can be specified as [], which automatically calculates the size of that dimension to ensure that `numel(B)` matches `numel(A)`. When you use [] to automatically calculate a dimension size, the dimensions that you *do* explicitly specify must divide evenly into the number of elements in the input matrix, `numel(A)`.

Beyond the second dimension, the output, **B**, does not reflect trailing dimensions with a size of 1. For example, `reshape(A,3,2,1,1)` produces a 3-by-2 matrix.

Example: `reshape(A,3,2)`

Example: `reshape(A,6,[],10)`

Example: `reshape(A,2,5,3,[])`

Example: `reshape(A,5,5,5,5)`

## Output Arguments

### **B** — Reshaped array

vector | matrix | multidimensional array | cell array

Reshaped array, returned as a vector, matrix, multidimensional array, or cell array. The data type and number of elements in **B** are the same as the data type and number of elements in **A**. The elements in **B** preserve their columnwise ordering from **A**.

### See Also

`colon` | `permute` | `repmat` | `shiftdim` | `squeeze`

**Introduced before R2006a**

## residue

Partial fraction expansion (partial fraction decomposition)

### Syntax

`[r,p,k] = residue(b,a)`  
`[b,a] = residue(r,p,k)`

### Description

`[r,p,k] = residue(b,a)` finds the residues, poles, and direct term of a “Partial Fraction Expansion” on page 1-7684 of the ratio of two polynomials, where the expansion is of the form

$$\frac{b(s)}{a(s)} = \frac{b_m s^m + b_{m-1} s^{m-1} + \dots + b_1 s + b_0}{a_n s^n + a_{n-1} s^{n-1} + \dots + a_1 s + a_0} = \frac{r_n}{s - p_n} + \dots + \frac{r_2}{s - p_2} + \frac{r_1}{s - p_1} + k(s).$$

The inputs to `residue` are vectors of coefficients of the polynomials  $\mathbf{b} = [b_m \dots b_1 b_0]$  and  $\mathbf{a} = [a_n \dots a_1 a_0]$ . The outputs are the residues  $\mathbf{r} = [r_n \dots r_2 r_1]$ , the poles  $\mathbf{p} = [p_n \dots p_2 p_1]$ , and the polynomial  $k$ . For most textbook problems,  $k$  is 0 or a constant.

`[b,a] = residue(r,p,k)` converts the partial fraction expansion back to the ratio of two polynomials and returns the coefficients in  $\mathbf{b}$  and  $\mathbf{a}$ .

### Examples

#### Find Partial Fraction Expansion with Real Roots

Find the partial fraction expansion of the following ratio of polynomials  $F(s)$  using `residue`

$$F(s) = \frac{b(s)}{a(s)} = \frac{-4s + 8}{s^2 + 6s + 8}.$$

$\mathbf{b} = [-4 \ 8];$   
 $\mathbf{a} = [1 \ 6 \ 8];$

```
[r,p,k] = residue(b,a)
```

```
r =
```

```
 -12
 8
```

```
p =
```

```
 -4
 -2
```

```
k =
```

```
 []
```

This represents the partial fraction expansion

$$\frac{-4s + 8}{s^2 + 6s + 8} = \frac{-12}{s + 4} + \frac{8}{s + 2}.$$

Convert the partial fraction expansion back to polynomial coefficients using `residue`.

```
[b,a] = residue(r,p,k)
```

```
b =
```

```
 -4 8
```

```
a =
```

```
 1 6 8
```

This result represents the original fraction  $F(s)$ .

### Expansion with Complex Roots and Equal Degree of Numerator and Denominator

If the degree of the numerator is equal to the degree of the denominator, the output `k` can be nonzero.

Find the partial fraction expansion of a ratio of two polynomials  $F(s)$  with complex roots and equal degree of numerator and denominator, where  $F(s)$  is

$$F(s) = \frac{b(s)}{a(s)} = \frac{2s^3 + s^2}{s^3 + s + 1}$$

```
b = [2 1 0 0];
a = [1 0 1 1];
[r,p,k] = residue(b,a)
```

r =

```
0.5354 + 1.0390i
0.5354 - 1.0390i
-0.0708 + 0.0000i
```

p =

```
0.3412 + 1.1615i
0.3412 - 1.1615i
-0.6823 + 0.0000i
```

k =

```
2
```

`residue` returns the complex roots and poles, and a constant term in `k`, representing the partial fraction expansion

$$F(s) = \frac{b(s)}{a(s)} = \frac{2s^3 + s^2}{s^3 + s^2 + 1} = \frac{0.5354 + 1.0390i}{s - (0.3412 + 1.1615i)} + \frac{0.5354 - 1.0390i}{s - (0.3412 - 1.1615i)} + \frac{-0.0708}{s + 0.6823} + 2.$$

### Expansion with Numerator Degree Greater Than Denominator Degree

When the degree of the numerator is greater than the degree of the denominator, the output `k` is a vector that represents the coefficients of a polynomial in  $s$ .

Perform the following partial fraction expansion of  $F(s)$  using `residue`.

$$F(s) = \frac{b(s)}{a(s)} = \frac{2s^4 + s}{s^2 + 1} = \frac{0.5 - 1i}{s - 1i} + \frac{0.5 + 1i}{s + 1i} + 2s^2 - 2.$$

```
b = [2 0 0 1 0];
a = [1 0 1];
[r,p,k] = residue(b,a)
```

r =

```
0.5000 - 1.0000i
0.5000 + 1.0000i
```

p =

```
0.0000 + 1.0000i
0.0000 - 1.0000i
```

k =

```
2 0 -2
```

k represents the polynomial  $2s^2 - 2$ .

## Input Arguments

### **b** — Coefficients of numerator polynomial

vector of numbers

Coefficients of the polynomial in the numerator, specified as a vector of numbers representing the coefficients of the polynomial in descending powers of  $s$ .

Data Types: `single` | `double`

Complex Number Support: Yes

### **a** — Coefficients of denominator polynomial

vector of numbers

Coefficients of the polynomial in the denominator, specified as a vector of numbers representing the coefficients of the polynomial in descending powers of  $s$ .

Data Types: `single` | `double`

Complex Number Support: Yes

## Output Arguments

### **r** — Residues of partial fraction expansion

column vector of numbers

Residues of partial fraction expansion, returned as a column vector of numbers.

### **p** — Poles of partial fraction expansion

column vector of numbers

Poles of partial fraction expansion, returned as a column vector of numbers.

### **k** — Direct term

row vector of numbers

Direct term, returned as a row vector of numbers that specify the coefficients of the polynomial in descending powers of  $s$ .

## More About

### Partial Fraction Expansion

Consider the fraction  $F(s)$  of two polynomials  $b$  and  $a$  of degree  $n$  and  $m$ , respectively

$$F(s) = \frac{b(s)}{a(s)} = \frac{b_n s^n + \dots + b_2 s^2 + b_1 s + b_0}{a_m s^m + \dots + a_2 s^2 + a_1 s + a_0}.$$

The fraction  $F(s)$  can be represented as a sum of simple fractions

$$\frac{b(s)}{a(s)} = \frac{r_m}{s - p_m} + \frac{r_{m-1}}{s - p_{m-1}} + \dots + \frac{r_0}{s - p_0} + k(s)$$

This sum is called the partial fraction expansion of  $F$ . The values  $r_m, \dots, r_1$  are the residues, the values  $p_m, \dots, p_1$  are the poles, and  $k(s)$  is a polynomial in  $s$ . For most textbook problems,  $k(s)$  is 0 or a constant.

The number of poles  $n$  is

$$n = \text{length}(a) - 1 = \text{length}(r) = \text{length}(p)$$

The direct term vector is empty if  $\text{length}(b) < \text{length}(a)$ ; otherwise

$$\text{length}(k) = \text{length}(b) - \text{length}(a) + 1$$

If  $p(j) = \dots = p(j+m-1)$  is a pole of multiplicity  $m$ , then the expansion includes terms of the form

$$\frac{r_j}{s - p_j} + \frac{r_{j+1}}{(s - p_j)^2} + \dots + \frac{r_{j+m-1}}{(s - p_j)^m}.$$

## Algorithms

`residue` first obtains the poles using `roots`. Next, if the fraction is nonproper, the direct term  $k$  is found using `deconv`, which performs polynomial long division. Finally, `residue` determines the residues by evaluating the polynomial with individual roots removed. For repeated roots, `resid2` computes the residues at the repeated root locations.

Numerically, the partial fraction expansion of a ratio of polynomials represents an ill-posed problem. If the denominator polynomial,  $a(s)$ , is near a polynomial with multiple roots, then small changes in the data, including roundoff errors, can result in arbitrarily large changes in the resulting poles and residues. Problem formulations making use of state-space or zero-pole representations are preferable.

# restoredefaultpath

Restore search path to its factory-installed state

## Alternatives

As an alternative to the `restoredefaultpath` function, use the `rmpath` function or use the `pathtool` function to open the Set Path dialog box.

## Syntax

`restoredefaultpath`

## Description

`restoredefaultpath` restores the MATLAB search path to its factory-installed state.

---

**Note:** `restoredefaultpath` is intended only for situations where MATLAB is experiencing startup problems due to a corrupt search path. For general search-path cleanup, use the `rmpath` function or the Set Path dialog box.

---

If MATLAB fails to initialize properly on startup, then call both `restoredefaultpath` and `matlabrc`. For more details, see “Path Unsuccessfully Set at Startup”.

MATLAB does not support issuing `restoredefaultpath` from a UNC path name. Doing so might result in MATLAB being unable to find files on the search path. If you do use `restoredefaultpath` from a UNC path name, restore the expected behavior by changing the current folder to an absolute path, and then reissuing the `restoredefaultpath` command.

## More About

- “Path Unsuccessfully Set at Startup”

**Introduced before R2006a**

# rethrow

Reissue error

---

**Note:** As of version 7.5, MATLAB supports error handling that is based on the `MException` class. Calling `rethrow` with a structure argument, as described on this page, is now replaced by calling `rethrow` with an `MException` object, as described on the reference page for `MException.rethrow`. `rethrow` called with a structure input will be removed in a future version.

---

## Syntax

```
rethrow(errorStruct)
```

## Description

`rethrow(errorStruct)` reissues the error specified by `errorStruct`. The currently running function terminates and control returns to the keyboard (or to any enclosing catch block). The `errorStruct` argument must be a MATLAB structure containing at least the `message` and `identifier` fields:

Fieldname	Description
<code>message</code>	Text of the error message
<code>identifier</code>	Message identifier of the error message
<code>stack</code>	Information about the error from the program stack

See "Message Identifiers" in the MATLAB documentation for more information on the syntax and usage of message identifiers.

## Examples

`rethrow` is usually used in conjunction with `try`, `catch` statements to reissue an error from a `catch` block after performing `catch`-related operations. For example,

```
try
 do_something
catch
 do_cleanup
 rethrow(previous_error)
end
```

## More About

### Tips

The `errorStruct` input can contain the field `stack`, identical in format to the output of the `dbstack` command. If the `stack` field is present, the stack of the rethrown error will be set to that value. Otherwise, the stack will be set to the line at which the rethrow occurs.

**Introduced before R2006a**

## return

Return control to invoking function

## Syntax

return

## Description

return forces MATLAB to return control to the invoking function before it reaches the end of the function. The invoking function is the function that calls the script or function containing the call to `return`. If you call the function or script that contains `return` directly, there is no invoking function and MATLAB returns control to the command prompt.

---

**Note:** Be careful when you use `return` within conditional blocks, such as `if` or `switch`, or within loop control statements, such as `for` or `while`. When MATLAB reaches a `return` statement, it does not just exit the loop; it exits the script or function and returns control to the invoking function or command prompt.

---

## Examples

### Return Control to Keyboard

In your current working folder, create a function, `findSqrRootIndex`, to find the index of the first occurrence of the square root of a value within an array. If the square root isn't found, the function returns `NaN`.

```
function idx = findSqrRootIndex(target,arrayToSearch)

idx = NaN;
if target < 0
 return
```

```
end

for idx = 1:length(arrayToSearch)
 if arrayToSearch(idx) == sqrt(target)
 return
 end
end
```

At the command prompt, call the function.

```
A = [3 7 28 14 42 9 0];
b = 81;
findSqrRootIndex(b,A)
```

```
ans =
```

```
6
```

When MATLAB encounters the `return` statement, it returns control to the keyboard because there is no invoking function.

## Return Control to Invoking Function

In a file, `myFunction.m`, in your current working folder, create the following function to find the index of the first occurrence of the square root of a value within an array. This function calls the `findSqrRootIndex` function you created in the previous example.

```
function myFunction(target)

arrayToSearch = [3 7 28 14 42 9 0];
idx = findSqrRootIndex(target,arrayToSearch);

if isnan(idx)
 disp('Square root not found.')
else
 disp(['Square root found at index ' num2str(idx)])
end
```

At the command prompt, call the function.

```
myFunction(49)
```

```
Square root found at index 2
```

When MATLAB encounters the `return` statement within `findSqrRootIndex`, it returns control to the invoking function, `myFunction`, and displays the relevant message.

**Introduced before R2006a**

## rewriteDirectory

**Class:** Tiff

Write modified metadata to existing IFD

### Syntax

```
rewriteDirectory(tiffobj)
```

### Description

`rewriteDirectory(tiffobj)` writes modified metadata (tag) data to an existing directory. Use this tag when you want to change the value of a tag in an existing image file directory.

### Examples

#### Modify Value of Tag

Write a sample TIFF file, `mytif.tif`. Create a TIFF object associated with this file.

```
imdata = peaks(256);
imwrite(imdata, 'mytif.tif');
t = Tiff('mytif.tif', 'r');
```

Modify the value of a tag.

```
setTag(t, 'Software', 'MATLAB')
rewriteDirectory(t)
close(t);
```

### References

This method corresponds to the `TIFFRewriteDirectory` function in the LibTIFF C API. To use this method, you must be familiar with the TIFF specification and technical notes. View this documentation at [LibTIFF - TIFF Library and Utilities](#).

## **See Also**

Tiff.writeDirectory

## rgb2gray

Convert RGB image or colormap to grayscale

### Syntax

```
I = rgb2gray(RGB)
newmap = rgb2gray(map)
```

### Description

`I = rgb2gray( RGB )` converts the truecolor image `RGB` to the grayscale intensity image `I`. The `rgb2gray` function converts RGB images to grayscale by eliminating the hue and saturation information while retaining the luminance. If you have Parallel Computing Toolbox installed, `rgb2gray` can perform this conversion on a GPU.

`newmap = rgb2gray( map )` returns a grayscale colormap equivalent to `map`.

### Examples

#### Convert RGB Image to Grayscale Image

Read and display an RGB image, and then convert it to grayscale.

Read the sample file, `peppers.png`, and display the RGB image.

```
RGB = imread('peppers.png');
imshow(RGB)
```

Convert the RGB image to a grayscale image and display it.

```
I = rgb2gray(RGB);
figure
imshow(I)
```

### Convert RGB Colormap to Grayscale Colormap

Read an indexed image with an RGB colormap. Then, convert the colormap to grayscale.

Read the sample file, `corn.tif`, which is an indexed image with an RGB colormap.

```
[X,map] = imread('corn.tif');
```

Display the image.

```
imshow(X,map)
```

Convert the RGB colormap to a grayscale colormap and redisplay the image.

```
newmap = rgb2gray(map);
imshow(X, newmap)
```

## **Input Arguments**

**RGB** — Truecolor image  
3-D numeric array

Truecolor image, specified as 3-D numeric array.

If you have Parallel Computing Toolbox installed, RGB can also be a `gpuArray`.

Data Types: `single` | `double` | `uint8` | `uint16`

### **map** — Colormap

*m*-by-3 numeric array

Colormap, specified as an *m*-by-3 numeric array.

If you have Parallel Computing Toolbox installed, `map` can also be a `gpuArray`.

Data Types: `double`

## Output Arguments

### **I** — grayscale image

numeric array

Grayscale image, returned as a numeric array.

If you have Parallel Computing Toolbox installed, then `I` can also be a `gpuArray`.

### **newmap** — grayscale color map

*m*-by-3 numeric array

Grayscale colormap, returned as an *m*-by-3 numeric array.

If you have Parallel Computing Toolbox installed, then `newmap` can also be a `gpuArray`.

## More About

### Tips

- `rgb2gray` supports the generation of C code using MATLAB Coder.

### Algorithms

`rgb2gray` converts RGB values to grayscale values by forming a weighted sum of the *R*, *G*, and *B* components:

$$0.2989 * R + 0.5870 * G + 0.1140 * B$$

These are the same weights used by the `rgb2ntsc` function to compute the *Y* component.

# rgb2hsv

Convert RGB colormap to HSV colormap

## Syntax

```
cmap = rgb2hsv(M)
hsv_image = rgb2hsv(rgb_image)
```

## Description

`cmap = rgb2hsv(M)` converts an RGB colormap `M` to an HSV colormap `cmap`. Both colormaps are  $m$ -by-3 matrices. The elements of both colormaps are in the range 0 to 1.

The columns of the input matrix `M` represent intensities of red, green, and blue, respectively. The columns of the output matrix `cmap` represent hue, saturation, and value, respectively.

`hsv_image = rgb2hsv(rgb_image)` converts the RGB image to the equivalent HSV image. RGB is an  $m$ -by- $n$ -by-3 image array whose three planes contain the red, green, and blue components for the image. HSV is returned as an  $m$ -by- $n$ -by-3 image array whose three planes contain the hue, saturation, and value components for the image.

## See Also

[brighten](#) | [colormap](#) | [hsv2rgb](#) | [rgbplot](#)

**Introduced before R2006a**

## rgb2ind

Convert RGB image to indexed image

### Syntax

```
[X,map] = rgb2ind(RGB,n)
X = rgb2ind(RGB, map)
[X,map] = rgb2ind(RGB, tol)
[___] = rgb2ind(___ ,dither_option)
```

### Description

`[X,map] = rgb2ind( RGB,n)` converts the RGB image to an indexed image `X` using minimum variance quantization and dithering. `map` contains at most `n` colors. `n` must be less than or equal to 65,536.

`X = rgb2ind( RGB, map)` converts the RGB image to an indexed image `X` with colormap `map` using the inverse colormap algorithm and dithering. `size( map,1)` must be less than or equal to 65,536.

`[X,map] = rgb2ind( RGB, tol)` converts the RGB image to an indexed image `X` using uniform quantization and dithering. `map` contains at most  $(\text{floor}(1/\text{tol})+1)^3$  colors. `tol` must be between 0.0 and 1.0.

`[ ___ ] = rgb2ind( ___ ,dither_option)` enables or disables dithering. `dither_option` is a string that can have one of these values.

'dither' (default)	Dithers, if necessary, to achieve better color resolution at the expense of spatial resolution
'nodither'	Maps each color in the original image to the closest color in the new map. No dithering is performed.

---

**Note** The values in the resultant image `X` are indexes into the colormap `map` and should not be used in mathematical processing, such as filtering operations.

---

## Class Support

The input image can be of class `uint8`, `uint16`, `single`, or `double`. If the length of `map` is less than or equal to 256, the output image is of class `uint8`. Otherwise, the output image is of class `uint16`.

The value 0 in the output array `X` corresponds to the first color in the colormap.

## Examples

Read and display a truecolor `uint8` JPEG image of a nebula.

```
RGB = imread('ngc6543a.jpg');
figure('Name','RGB Image')
imagesc(RGB)
axis image
zoom(4)
```

Convert RGB to an indexed image with 32 colors

```
[IND,map] = rgb2ind(RGB,32);
figure('Name','Indexed image with 32 Colors')
imagesc(IND)
colormap(map)
axis image
zoom(4)
```

## More About

### Tips

- If you specify `tol`, `rgb2ind` uses uniform quantization to convert the image. This method involves cutting the RGB color cube into smaller cubes of length `tol`.
- If you specify `n`, `rgb2ind` uses minimum variance quantization. This method involves cutting the RGB color cube into smaller boxes (not necessarily cubes) of different sizes, depending on how the colors are distributed in the image. If the input image actually uses fewer colors than the number you specify, the output colormap is also smaller.

- If you specify `map`, `rgb2ind` uses colormap mapping, which involves finding the colors in `map` that best match the colors in the RGB image.

## Algorithms

- **Uniform Quantization** — Uniform quantization cuts the RGB color cube into smaller cubes of length `tol`. For example, if you specify a `tol` of 0.1, the edges of the cubes are one-tenth the length of the RGB cube. The total number of small cubes is:

$$n = (\text{floor}(1/\text{tol})+1)^3$$

Each cube represents a single color in the output image. Therefore, the maximum length of the colormap is `n`. `rgb2ind` removes any colors that don't appear in the input image, so the actual colormap can be much smaller than `n`.

- **Minimum Variance Quantization** — Minimum variance quantization cuts the RGB color cube into smaller boxes (not necessarily cubes) of different sizes, depending on how the colors are distributed in the image. If the input image actually uses fewer colors than the number specified, the output colormap is also smaller.
- **Inverse Colormap** — The inverse colormap algorithm quantizes the specified colormap into 32 distinct levels per color component. Then, for each pixel in the input image, the closest color in the quantized colormap is found.

# rgbplot

Plot colormap

## Syntax

```
rgbplot(cmap)
```

## Description

`rgbplot(cmap)` plots the three columns of `cmap`, where `cmap` is an  $m$ -by-3 colormap matrix. `rgbplot` draws the first column in red, the second in green, and the third in blue.

## Examples

### Copper Colormap

Plot the RGB values of the `copper` colormap.

```
rgbplot(copper)
```

### Summer Colormap

Plot the RGB values of the `summer` colormap.

```
rgbplot(summer)
```

### See Also

`colormap`

Introduced before R2006a

# ribbon

Ribbon plot

## Syntax

```
ribbon(Y)
ribbon(X,Y)
ribbon(X,Y,width)
ribbon(axes_handle,...)
h = ribbon(...)
```

## Description

`ribbon(Y)` plots the columns of `Y` as three-dimensional ribbons of uniform width using `X = 1:size(Y,1)`. Ribbons advance along the *x*-axis centered on tick marks at unit intervals, three-quarters of a unit in width. Ribbon maps values in `X` to colors in `colormap` linearly. To change ribbon colors in the graph, change the `colormap`.

`ribbon(X,Y)` plots three dimensional ribbons for data in `Y`, centered at locations specified in `X`. `X` and `Y` are vectors or matrices of the same size. Additionally, `X` can be a row or a column vector, and `Y` a matrix with `length(X)` rows. When `Y` is a matrix, `ribbon` plots each column in `Y` as a ribbon at the corresponding `X` location.

`ribbon(X,Y,width)` specifies the width of the ribbons. The default is `0.75`. If `width = 1`, the ribbons touch, leaving no space between them when viewed down the *z*-axis. If `width > 1`, ribbons overlap and can intersect.

`ribbon(axes_handle,...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

`h = ribbon(...)` returns a vector of handles to surface graphics objects. `ribbon` returns one handle per strip.

## Examples

### Ribbon Plot

Create a ribbon plot of the `peaks` function.

```
[x,y] = meshgrid(-3:.5:3,-3:.1:3);
z = peaks(x,y);

figure
ribbon(y,z)
```

# rmappdata

Remove application-defined data

## Syntax

```
rmappdata(h,name)
```

## Description

`rmappdata(h,name)` removes the application-defined data, `name`, from its association with the UI component, `h`.

## See Also

`getappdata` | `isappdata` | `setappdata`

**Introduced before R2006a**

## rmdir

Remove folder

### Syntax

```
rmdir(folderName)
rmdir(folderName, 's')
[status, message, messageid] = rmdir(folderName, 's')
```

### Description

`rmdir(folderName)` removes the folder `folderName` from the current folder if `folderName` is empty. If `folderName` is not in the current folder, then specify the relative path or the full path for `folderName`.

`rmdir(folderName, 's')` removes the folder `folderName` and its contents from the current folder. With the 's' option, `rmdir` attempts to remove all subfolders and files in `folderName` regardless of their write permissions.

`[status, message, messageid] = rmdir(folderName, 's')` removes the folder `folderName` and its contents from the current folder, returning the status, a message, and the MATLAB message ID.

### Input Arguments

#### **folderName**

String specifying the absolute or relative path name of the folder you want to remove.

**Default:** None

#### **'s'**

Literal string that directs `rmdir` to remove all subfolders and files in the specified folder, regardless of their write permissions. The result for read-only files follows the practices of the operating system.

**Default:** `rmdir` does not remove subfolders and files in the specified folder.

## Output Arguments

### **status**

Logical scalar indicating the outcome of the `rmdir` operation. The status value is 1 if the operation was successful and 0 if it returned an error.

### **message**

String containing the warning or error message text if the operation is unsuccessful. An empty string, if the operation is successful.

### **messageid**

String containing the warning or error message ID, if the operation is unsuccessful. MATLAB returns an empty string if the operation is successful.

## Examples

These examples remove an empty folder, `myfiles`, assuming it is in the current folder:

```
% Remove myfiles from the current folder:
```

```
rmdir('myfiles')
```

```
% Use the relative path to remove myfiles. Assuming
% the current folder is matlab/work and myfiles is in
% d:/matlab/work/project, type this:
```

```
rmdir('project/myfiles')
```

```
% Use the full path to remove myfiles, assuming
% the current folder is matlab/work and myfiles is in
% d:/matlab/work/project:
```

```
rmdir('d:/matlab/work/project/myfiles')
```

This example removes the `myfiles` folder and its contents, assuming `myfiles` is in the current folder:

```
rmdir('myfiles','s')
```

This example unsuccessfully attempts to remove the `myfiles` folder and its contents. It directs MATLAB to display the results.

```
[stat, mess, id]=rmdir('myfiles')
```

MATLAB returns:

```
stat =
 0
```

```
mess =
```

```
No directories were removed.
```

```
id =
```

```
MATLAB:RMDIR:NoDirectoriesRemoved
```

This example successfully removes the `myfiles` folder and its contents. It directs MATLAB to display the results.

```
[stat, mess]=rmdir('myfiles','s')
```

MATLAB returns:

```
stat =
 1
```

```
mess =
```

```
''
```

## Alternatives

Open the Current Folder browser by running `filebrowser`. Then, in the Current Folder browser, right-click the folder name and select **Delete** from the context menu.

## More About

### Tips

- If you specify the 's' flag or include a wildcard in the folder name, MATLAB produces an error if it is unable to remove all folders. The error message lists the folder and files that MATLAB could not remove.

### See Also

| cd | copyfile | delete | dir | fileattrib | filebrowser | mkdir | movefile

**Introduced before R2006a**

## **rmdir**

**Class:** FTP

Remove folder on FTP server

## **Syntax**

```
rmdir(ftpobj, folder)
```

## **Description**

`rmdir(ftpobj, folder)` removes the specified folder from the current folder on an FTP server.

## **Input Arguments**

### **ftpobj**

FTP object created by `ftp`.

### **folder**

String enclosed in single quotation marks that specifies the name of the folder to delete.

## **Examples**

Remove the folder `temp` from the hypothetical FTP server `ftp.testsite.com`:

```
ts = ftp('ftp.testsite.com');
rmdir(ts, 'temp');
```

## **See Also**

`delete` | `dir` | `mkdir` | `cd` | `ftp`

**Introduced before R2006a**

## rmfield

Remove fields from structure

### Syntax

```
s = rmfield(s,field)
```

### Description

`s = rmfield(s,field)` removes the specified field or fields from structure array **S**. Specify multiple fields using a cell array of strings. The dimensions of **S** remain the same.

### Examples

#### Remove Single Field

Define a scalar structure with fields named **a**, **b**, and **c**.

```
s.a = 1;
s.b = 2;
s.c = 3;
```

Remove field **b**.

```
field = 'b';
s = rmfield(s,field)
```

```
s =
 a: 1
 c: 3
```

#### Remove Multiple Fields

Define a scalar structure with fields **first**, **second**, **third**, and **fourth**.

```
S.first = 1;
S.second = 2;
```

```
S.third = 3;
S.fourth = 4;
```

Remove fields `first` and `fourth`.

```
fields = {'first', 'fourth'};
S = rmfield(S, fields)
```

```
S =
 second: 2
 third: 3
```

## Input Arguments

### **s** — Input structure

structure array

Input structure, specified as a structure array.

Data Types: `struct`

### **field** — Field name or names

character array | cell array of strings

Field name or names, specified as a character array or a cell array of strings.

Example: `'f1'`

Example: `{'f1'; 'f2'}`

Data Types: `char` | `cell`

## More About

- “Generate Field Names from Variables”

## See Also

`fieldnames` | `isfield` | `orderfields`

## rmpath

Remove folders from search path

### Syntax

```
rmpath(folderName)
```

### Description

`rmpath(folderName)` removes the specified folder from the search path.

### Examples

#### Remove Folder from Search Path

Remove `/usr/local/matlab/mytools` from the search path.

```
rmpath('/usr/local/matlab/mytools')
```

### Input Arguments

**folderName** — Name of folder

string

Name of folder to remove from the search path, specified as a string. Use the full path name for `folderName`.

Example: `'c:\matlab\work'`

Example: `'/home/user/matlab'`

### More About

- “What Is the MATLAB Search Path?”

## **See Also**

addpath | path | savepath

**Introduced before R2006a**

## rmpref

Remove preference

### Syntax

```
rmpref('group','pref')
rmpref('group',{'pref1','pref2',... 'prefn'})
rmpref('group')
```

### Description

`rmpref('group','pref')` removes the preference specified by `group` and `pref`. It is an error to remove a preference that does not exist.

`rmpref('group',{'pref1','pref2',... 'prefn'})` removes each preference specified in the cell array of preference names. It is an error if any of the preferences do not exist.

`rmpref('group')` removes all the preferences for the specified `group`. It is an error to remove a group that does not exist.

### Examples

```
addpref('mytoolbox','version','1.0')
rmpref('mytoolbox')
```

### See Also

`addpref` | `ispref` | `getpref` | `setpref` | `uigetpref` | `uisetpref`

**Introduced before R2006a**

## rng

Control random number generation

### Syntax

```
rng(seed)
rng('shuffle')
rng(seed, generator)
rng('shuffle', generator)
rng('default')
scurr = rng
rng(s)
sprev = rng(...)
```

### Description

---

**Note:** To use the `rng` function instead of `rand` or `randn` with the `'seed'`, `'state'`, or `'twister'` inputs, see the documentation on “Replace Discouraged Syntaxes of `rand` and `randn`”.

---

`rng(seed)` seeds the random number generator using the nonnegative integer `seed` so that `rand`, `randi`, and `randn` produce a predictable sequence of numbers.

`rng('shuffle')` seeds the random number generator based on the current time. Thus, `rand`, `randi`, and `randn` produce a different sequence of numbers after each time you call `rng`.

`rng(seed, generator)` and `rng('shuffle', generator)` additionally specify the type of the random number generator used by `rand`, `randi`, and `randn`. The `generator` input is one of:

- `'twister'`: Mersenne Twister
- `'simdTwister'`: SIMD-oriented Fast Mersenne Twister
- `'combRecursive'`: Combined Multiple Recursive

- 'multFibonacci': Multiplicative Lagged Fibonacci
- 'v5uniform': Legacy MATLAB 5.0 uniform generator
- 'v5normal': Legacy MATLAB 5.0 normal generator
- 'v4': Legacy MATLAB 4.0 generator

`rng('default')` puts the settings of the random number generator used by `rand`, `randi`, and `randn` to their default values. This way, the same random numbers are produced as if you restarted MATLAB. The default settings are the Mersenne Twister with seed 0.

`scurr = rng` returns the current settings of the random number generator used by `rand`, `randi`, and `randn`. The settings are returned in a structure `scurr` with fields 'Type', 'Seed', and 'State'.

`rng(s)` restores the settings of the random number generator used by `rand`, `randi`, and `randn` back to the values captured previously with a command such as `s = rng`.

`sprev = rng(...)` returns the previous settings of the random number generator used by `rand`, `randi`, and `randn` before changing the settings.

## Examples

### Example 1 — Retrieve and Restore Generator Settings

Save the current generator settings in `s`:

```
s = rng;
```

Call `rand` to generate a vector of random values:

```
x = rand(1,5)
```

```
x =
```

```
 0.8147 0.9058 0.1270 0.9134 0.6324
```

Restore the original generator settings by calling `rng`. Generate a new set of random values and verify that `x` and `y` are equal:

```
rng(s);
```

```
y = rand(1,5)
```

```
y =
```

```
 0.8147 0.9058 0.1270 0.9134 0.6324
```

## Example 2 — Restore Settings for Legacy Generator

Use the legacy generator.

```
sprev = rng(0,'v5uniform')
```

```
sprev =
```

```
 Type: 'twister'
 Seed: 0
 State: [625x1 uint32]
```

```
x = rand
```

```
x =
```

```
 0.9501
```

Restore the previous settings by calling `rng`:

```
rng(sprev)
```

## More About

- “Creating and Controlling a Random Number Stream”
- “Why Do Random Numbers Repeat After Startup?”

## See Also

`rand` | `randi` | `randn` | `RandStream` | `now`

## Root Properties

Graphics environment and state information

The root object is the root of the graphics object tree. Root properties contain information about the graphics environment and the current state of the graphics system. Starting in R2014b, you can use dot notation to refer to a particular object and property:

```
r = groot;
fig = r.Children;
```

If you are using an earlier release, use the `get` function to query property values.

## Display Information

### **MonitorPositions** — Width and height of displays

n-by-4 matrix

This property is read only.

Width and height of displays, returned as an n-by-4 matrix, where n is the number of displays. Each row corresponds to one display and is a four-element vector of the form `[x y width height]`. For example, if there are two displays, then the matrix has this form:

```
[x1 y1 width1 height1
 x2 y2 width2 height2]
```

The first two elements in each row indicate the display location with respect to the origin point. The last two elements in each row indicate the display size. The origin point is the lower-left corner of the primary display. If the units are pixels, then the origin point is `(1, 1)`. For all other units, the origin point is `(0, 0)`. The `Units` property determines the units of this measurement.

---

**Note:** MATLAB sets the display information values for this property at startup. The values are static. If your system display settings change, the values do not update. To refresh the values, restart MATLAB.

---

### **PointerLocation** — Current location of pointer

two-element vector

Current location of pointer, specified as a two-element vector of the form `[x y]`. The `x` and `y` values are the coordinates of the pointer position measured from the origin point. The origin point is the lower-left corner of the primary display. If the units are pixels, then the origin point is `(1,1)`. For all other units, the origin point is `(0,0)`. The `Units` property determines the units of this measurement.

This property contains the current pointer location, even if the pointer is outside a MATLAB window. Move the pointer by changing the values of this property. On Macintosh systems, you cannot change the pointer location by setting this property.

Querying the `PointerLocation` property in a callback routine might return a value that is different from the location of the pointer when the callback was triggered. This difference results from delays in callback execution caused by competition for system resources.

Example: `[500 400]`

### **ScreenDepth — Number of bits that define each pixel color**

scalar

Number of bits that define each pixel color, specified as a scalar. The default value depends on the computer. The maximum number of simultaneously displayed colors on the current graphics device equals 2 raised to the value of this property.

### **ScreenPixelsPerInch — Display resolution**

scalar

This property is read only.

Display resolution, returned as a scalar in pixels per inch. The value depends on the system.

- On Windows systems, the value is 96 DPI.
- On Macintosh systems, the value is 72 DPI.
- On Linux system, the value is determined by your system resolution.

---

**Note:** The `ScreenPixelsPerInch` property became a read-only property in R2015b. To change the size of text and other elements on the screen, adjust the display scaling for your operating system.

---

### **ScreenSize** — Size of primary display

four-element vector

This property is read only.

Size of primary display, returned as a four-element vector of the form [`left` `bottom` `width` `height`].

- The `left` and `bottom` values are both 1 when the units are pixels, and 0 for all other units.
- The `width` and `height` values are the width and height of the display, respectively.

---

**Note:** Starting in R2015b on Windows systems, if the `Units` property is set to `'pixels'`, then the width and height values might differ from the screen size reported by the operating system. The values MATLAB reports are based on a pixel size of 1/96th of an inch. On Macintosh and Linux systems, the values match the size reported by the operating system.

---

Some important information to consider when using this property:

- The values might not represent the usable display size due to the presence of UIs, such as the Microsoft Windows task bar.
- MATLAB sets the display size values for this property at startup. The values are static. If your system display settings change, the display size values do not update. To refresh the values, restart MATLAB.

### **FixedWidthFontName** — Font name for fixed-width font

string

Font name for fixed-width font, specified as a string giving the name of a system supported font. This property determines the font for axes, text, and uicontrols that have a `FontName` property set to `'FixedWidth'`. The default value depends on the system. `'Courier New'` is the default in systems that use Latin-based characters.

Specifying the `FixedWidthFontName` property eliminates the need to hardcode font names in MATLAB applications. MATLAB attempts to set `FixedWidthFontName` property to the correct value for the system.

If you are a MATLAB application developer and want to use a fixed-width font, set the `FontName` property for axes, text, and uicontrol objects to `'FixedWidth'` instead of

setting this root property. Users of the application can set the root property if they do not want to use the preselected value.

Example: 'Courier New'

### Units — Units for MonitorPositions, ScreenSize, and PointerLocation

'pixels' (default) | 'inches' | 'centimeters' | 'points' | 'characters' | 'normalized'

Units for the MonitorPositions, ScreenSize, and PointerLocation properties, specified as one of the values shown in this table.

Units	Description
'pixels' (default)	<p>Pixels.</p> <p>Starting in R2015b, distances in pixels are independent of your system resolution on Windows and Macintosh systems:</p> <ul style="list-style-type: none"> <li>• On Windows systems, a pixel is 1/96th of an inch.</li> <li>• On Macintosh systems, a pixel is 1/72nd of an inch.</li> </ul> <p>On Linux systems, the size of a pixel is determined by your system resolution.</p>
'inches'	Inches.
'centimeters'	Centimeters.
'points'	Points. One point equals 1/72 inch.
'normalized'	Normalized with respect to the display. The lower left corner of the display maps to (0,0) and the upper right corner maps to (1,1).
'characters'	<p>Based on the default system font character size.</p> <ul style="list-style-type: none"> <li>• Character width = width of letter x.</li> <li>• Character height = distance between the baselines of two lines of text.</li> </ul>

All units are measured from the lower-left corner of the primary display. If the units are pixels, then the lower-left corner maps to (1, 1). For all other units, the lower-left corner maps to (0, 0).

If you change the units, it is good practice to return it to its default value after completing your operation to prevent affecting other functions that assume the `Units` property is set to the default value.

## Identifiers

### **CallbackObject** — Object whose callback is executing

[ ] (default) | graphics object

This property is read only.

Object whose callback is executing, returned as a graphics object. For more information, see the `gcbo` command.

### **CurrentFigure** — Current figure

empty `GraphicsPlaceholder` (default) | figure object

Current figure, specified as a figure object. The current figure is typically the one most recently created, clicked on, or made current by calling the `figure` function. Setting this property makes a figure the current figure without sorting it to the front of other figures on the display. However, using the `figure` function to make a figure the current figure sorts that figure to the front of the display. To become the current figure, the `HandleVisibility` property of the figure must be set to 'on'.

This property returns an empty `GraphicsPlaceholder` array if there are no figures. However, the `gcf` command always returns a figure object. If there are no figure objects, then `gcf` creates one.

### **Type** — Type of graphics object

'root'

This property is read only.

Type of graphics object, returned as the string 'root'. The root object handle is always visible using the `groot` function.

### **Tag** — Tag to associate with root

' ' (default)

Tag to associate with root, specified as a string. There is only one root object, which you can always access using the `groot` function.

### **UserData** — Data to associate with root

`[]` (default) | scalar, vector, or matrix | cell array | character array | table | structure

Data to associate with the root object, specified as a scalar, vector, matrix, cell array, character array, table, or structure. MATLAB does not use this data.

To associate multiple sets of data or to attach a field name to the data, use the `getappdata` and `setappdata` functions.

Example: `1:100`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char` | `struct` | `table` | `cell`

## **Parent/Child**

### **Parent** — Parent

empty `GraphicsPlaceholder`

The root object has no parent. This property is always an empty `GraphicsPlaceholder`.

### **Children** — Children

empty `GraphicsPlaceholder` | array of figure objects

Children, specified as an array of figure objects that have visible handles. The `HandleVisibility` property of the figure determines if the handle is visible or hidden. This property does not contain figures with hidden handles.

Change the order of the children to change the sorting order of the figures on the display.

### **HandleVisibility** — Visibility of root object handle

`'on'` (default) | `'callback'` | `'off'`

This property has no effect. The root object handle is always visible using the `groot` function.

### **ShowHiddenHandles** — Hidden handle display

`'off'` (default) | `'on'`

Hidden handle display, specified as one of these values:

- 'off' — Do not display hidden object handles. The `HandleVisibility` property of the object determines if the handle is visible or hidden.
- 'on' — Expose all object handles regardless of the `HandleVisibility` property.

## roots

Polynomial roots

### Syntax

`r = roots(p)`

### Description

`r = roots(p)` returns the roots of the polynomial represented by `p` as a column vector. Input `p` is a vector containing  $n+1$  polynomial coefficients, starting with the coefficient of  $x^n$ . A coefficient of 0 indicates an intermediate power that is not present in the equation.

For example, `p = [3 2 -2]` represents the polynomial  $3x^2 + 2x - 2$ .

The `roots` function solves polynomial equations of the form  $p_1x^n + \dots + p_nx + p_{n+1} = 0$ . Polynomial equations contain a single variable with nonnegative exponents.

### Examples

#### Roots of Quadratic Polynomial

Solve the equation  $3x^2 - 2x - 4 = 0$ .

Create a vector to represent the polynomial, then find the roots.

```
p = [3 -2 -4];
r = roots(p)
```

```
r =
```

```
 1.5352
 -0.8685
```

## Roots of Quartic Polynomial

Solve the equation  $x^4 - 1 = 0$ .

Create a vector to represent the polynomial, then find the roots.

```
p = [1 0 0 0 -1];
r = roots(p)
```

```
r =

-1.0000 + 0.0000i
 0.0000 + 1.0000i
 0.0000 - 1.0000i
 1.0000 + 0.0000i
```

## Input Arguments

### **p** — Polynomial coefficients

vector

Polynomial coefficients, specified as a vector. For example, the vector [1 0 1] represents the polynomial  $x^2 + 1$ , and the vector [3.13 -2.21 5.99] represents the polynomial  $3.13x^2 - 2.21x + 5.99$ .

For more information, see “Create and Evaluate Polynomials”.

Data Types: `single` | `double`

Complex Number Support: Yes

## More About

### Tips

- Use the `poly` function to obtain a polynomial from its roots: `p = poly(r)`. The `poly` function is the inverse of the `roots` function.

- Use the `fzero` function to find the roots of nonlinear equations. While the `roots` function works only with polynomials, the `fzero` function is more broadly applicable to different types of equations.

### Algorithms

The `roots` function considers `p` to be a vector with `n+1` elements representing the `n`th degree characteristic polynomial of an `n`-by-`n` matrix, `A`. The roots of the polynomial are calculated by computing the eigenvalues of the companion matrix, `A`.

```
A = diag(ones(n-1,1), -1);
A(1,:) = -p(2:n+1) ./ p(1);
r = eig(A)
```

The results produced are the exact eigenvalues of a matrix within roundoff error of the companion matrix, `A`. However, this does not mean that they are the exact roots of a polynomial whose coefficients are within roundoff error of those in `p`.

- “Roots of Polynomials”
- “Create and Evaluate Polynomials”

## rose

Angle histogram plot

## Syntax

```
rose(theta)
rose(theta,x)
rose(theta,nbins)
rose(axes_handle,...)
h = rose(...)
[tout,rout] = rose(...)
```

## Description

`rose(theta)` creates an angle histogram, which is a polar plot showing the distribution of values grouped according to their numeric range, showing the distribution of `theta` in 20 angle bins or less. The vector `theta`, expressed in radians, determines the angle of each bin from the origin. The length of each bin reflects the number of elements in `theta` that fall within a group, which ranges from 0 to the greatest number of elements deposited in any one bin.

`rose(theta,x)` uses the vector `x` to specify the number and the locations of bins. `length(x)` is the number of bins and the values of `x` specify the center angle of each bin. For example, if `x` is a five-element vector, `rose` distributes the elements of `theta` in five bins centered at the specified `x` values.

`rose(theta,nbins)` plots `nbins` equally spaced bins in the range `[0,2*pi]`. The default is 20.

`rose(axes_handle,...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

`h = rose(...)` returns the handle of the line object used to create the graph.

`[tout,rout] = rose(...)` returns the vectors `tout` and `rout` so `polar(tout,rout)` generates the histogram for the data. This syntax does not generate a plot.

## Examples

### Create Rose Histogram

Load the `sunspot.dat` data set which contains the 2-column matrix `sunspot`. Store the second column of the data set as `theta`.

```
load sunspot.dat
theta = sunspot(:,2);
```

Create a rose histogram of `theta` using 12 bins.

```
figure
rose(theta,12)
```

## rosser

Classic symmetric eigenvalue test problem

### Syntax

```
A = rosser
A = rosser(classname)
```

### Description

A = rosser returns the Rosser matrix in double precision.

A = rosser(classname) returns the Rosser matrix with a class specified by classname. Specify classname as 'single' to return the Rosser matrix in single precision.

### Examples

#### Generate the Rosser matrix

rosser returns the Rosser matrix.

```
rosser
```

```
ans =
 611 196 -192 407 -8 -52 -49 29
 196 899 113 -192 -71 -43 -8 -44
 -192 113 899 196 61 49 8 52
 407 -192 196 611 8 44 59 -23
 -8 -71 61 8 411 -599 208 208
 -52 -43 49 44 -599 411 208 208
 -49 -8 8 59 208 208 99 -911
 29 -44 52 -23 208 208 -911 99
```

#### Generate matrix of class 'single'

Specify classname as single to return a Rosser matrix of that class.

```
Y = rosser('single')
whos('Y')
```

```
Y =
```

```
 611 196 -192 407 -8 -52 -49 29
 196 899 113 -192 -71 -43 -8 -44
 -192 113 899 196 61 49 8 52
 407 -192 196 611 8 44 59 -23
 -8 -71 61 8 411 -599 208 208
 -52 -43 49 44 -599 411 208 208
 -49 -8 8 59 208 208 99 -911
 29 -44 52 -23 208 208 -911 99
```

Name	Size	Bytes	Class	Attributes
Y	8x8	256	single	

## Input Arguments

### **classname** — Input class

'double' (default) | 'single'

Input class, specified as 'double' (default) or 'single'. `rosser(C)` produces a matrix of the specified class.

## More About

### **Rosser Matrix**

The Rosser matrix is a well known matrix used, for example, to evaluate eigenvalue algorithms. The matrix is 8-by-8 with integer elements. It has:

- A double eigenvalue
- Three nearly equal eigenvalues
- Dominant eigenvalues of the opposite sign
- A zero eigenvalue
- A small, nonzero eigenvalue

## **See Also**

eig

**Introduced before R2006a**

## rot90

Rotate array 90 degrees

### Syntax

```
B = rot90(A)
B = rot90(A,k)
```

### Description

`B = rot90(A)` rotates array `A` counterclockwise by 90 degrees. For multidimensional arrays, `rot90` rotates in the plane formed by the first and second dimensions.

`B = rot90(A,k)` rotates array `A` counterclockwise by `k*90` degrees, where `k` is an integer.

### Examples

#### Rotate Column Vector

Create a column vector of sequential elements.

```
A = (1:5)'
```

```
A =
```

```
1
2
3
4
5
```

Rotate `A` counterclockwise by 90 degrees using `rot90`.

```
B = rot90(A)
```

B =

```

 1 2 3 4 5

```

The result, B, has the same elements as A but a different orientation.

### Rotate Multidimensional Array

Create a 3-by-3-by-2 cell array of strings.

```
A = cat(3,{'a' 'b' 'c';'d' 'e' 'f';'g' 'h' 'i'},{'j' 'k' 'l';'m' 'n' 'o';'p' 'q' 'r'})
```

A(:, :, 1) =

```

 'a' 'b' 'c'
 'd' 'e' 'f'
 'g' 'h' 'i'

```

A(:, :, 2) =

```

 'j' 'k' 'l'
 'm' 'n' 'o'
 'p' 'q' 'r'

```

Rotate the cell array by 270 degrees.

```
B = rot90(A,3)
```

B(:, :, 1) =

```

 'g' 'd' 'a'
 'h' 'e' 'b'
 'i' 'f' 'c'

```

B(:, :, 2) =

```

 'p' 'm' 'j'
 'q' 'n' 'k'
 'r' 'o' 'l'

```

The function rotates each page of the array independently. Since a full 360 degree rotation ( $k = 4$ ) leaves the array unchanged, `rot90(A,3)` is equivalent to `rot90(A,-1)`.

## Input Arguments

### **A** — Input array

vector | matrix | array | cell array | categorical array

Input array, specified as a vector, matrix, array, cell array, or categorical array of any data type.

Complex Number Support: Yes

### **k** — Rotation constant

integer

Rotation constant, specified as an integer. Specify  $k$  to rotate by  $k*90$  degrees rather than nesting calls to `rot90`.

Example: `rot90(A,-2)` rotates  $A$  by -180 degrees and is equivalent to `rot90(A,2)`, which rotates by 180 degrees.

## More About

### Tips

- Use the `flip` function to flip arrays in any dimension.

### See Also

`flip` | `fliplr` | `flipud`

Introduced before R2006a

## rotate

Rotate object about specified origin and direction

### Syntax

```
rotate(h,direction,alpha)
rotate(...,origin)
```

### Description

The `rotate` function rotates a graphics object in three-dimensional space.

`rotate(h,direction,alpha)` rotates the graphics object `h` by `alpha` degrees. `direction` is a two- or three-element vector that describes the axis of rotation in conjunction with the origin of the axis of rotation. The default origin of the axis of rotation is the center of the plot box. This point is not necessarily the origin of the axes.

Positive `alpha` is defined as the righthand-rule angle about the direction vector as it extends from the origin of rotation.

If `h` is an array of handles, all objects must be children of the same axes.

`rotate(...,origin)` specifies the origin of the axis of rotation as a three-element vector  $[x_0, y_0, z_0]$ .

### Examples

#### Rotate Plot Around x-Axis

Create a surface plot of the `peaks` function and return the surface handle.

```
hSurface = surf(peaks(20));
```

Rotate the surface plot 25 degrees around its  $x$ -axis.

```
direction = [1 0 0];
rotate(hSurface,direction,25)
```

### Rotate Plot Around $y$ -Axis

Create a surface plot of the peaks function and return the surface handle.

```
hSurface = surf(peaks(20));
```

Rotate the surface plot 25 degrees around its  $y$ -axis.

```
direction = [0 1 0];
rotate(hSurface,direction,25)
```

### Rotate Plot Around x-Axis and y-Axis

Create a surface plot of the peaks function and return the surface handle.

```
hSurface = surf(peaks(20));
```

Rotate the surface plot 25 degrees around its  $x$ -axis and  $y$ -axis.

```
direction = [1 1 0];
rotate(hSurface,direction,25)
```

## More About

### Tips

The rotation transformation modifies the object's data. This technique is different from that used by `view` and `rotate3d`, which modify only the viewpoint.

The axis of rotation is defined by an origin of rotation and a point P. Specify P as the spherical coordinates `[theta phi]` or as the Cartesian coordinates `[xp yp zp]`.

In the two-element form for **direction**, **theta** is the angle in the *x-y* plane counterclockwise from the positive *x*-axis. **phi** is the elevation of the direction vector from the *x-y* plane.

The three-element form for **direction** specifies the axis direction using Cartesian coordinates. The direction vector is the vector from the origin of rotation to P.

**Tips**

`rotate` changes the values of the `Xdata`, `Ydata`, and `Zdata` properties to rotate graphics objects.

## **See Also**

`rotate3d` | `sph2cart` | `view`

## rotate3d

Rotate 3-D view using mouse

### Syntax

```
rotate3d on
rotate3d off
rotate3d
rotate3d(figure_handle,...)
rotate3d(axes_handle,...)
h = rotate3d(figure_handle)
```

### Description

`rotate3d on` enables mouse-base rotation on all axes within the current figure.

`rotate3d off` disables interactive axes rotation in the current figure.

`rotate3d` toggles interactive axes rotation in the current figure.

`rotate3d(figure_handle, ...)` enables rotation within the specified figure instead of the current figure.

`rotate3d(axes_handle, ...)` enables rotation only in the specified axes.

`h = rotate3d(figure_handle)` returns a `rotate3d mode object` for figure `figure_handle` for you to customize the mode's behavior.

### Using Rotate Mode Objects

You access the following properties of rotate mode objects.

- `FigureHandle` `<handle>` — The associated figure handle, a read-only property that cannot be set
- `Enable` `'on' | 'off'` — Specifies whether this figure mode is currently enabled on the figure

- `RotateStyle` 'orbit' | 'box' — Sets the method of rotation  
'orbit' rotates the entire axes; 'box' rotates a plot-box outline of the axes.

## Rotate3D Mode Callbacks

You can program the following callbacks for rotate3d mode operations.

- `ButtonDownFilter` <function\_handle> — Function to intercept `ButtonDown` events

The application can inhibit the rotate operation under circumstances the programmer defines, depending on what the callback returns. The input function handle should reference a function with two implicit arguments (similar to handle callbacks):

```
function [res] = myfunction(obj,event_obj)
% obj handle to the object that has been clicked on
% event_obj handle to event data object (empty in this release)
% res [output] logical flag to determine whether the rotate
% operation should take place or the 'ButtonDownFcn'
% property of the object should take precedence
```

- `ActionPreCallback` <function\_handle> — Function to execute before rotating

Set this callback to listen to when a rotate operation will start. The input function handle should reference a function with two implicit arguments (similar to Handle Graphics object callbacks):

```
function myfunction(obj,event_obj)
% obj handle to the figure that has been clicked on
% event_obj object containing struct of event data
```

The event data has the following field:

Axes	The handle of the axes that is being panned
------	---------------------------------------------

- `ActionPostCallback` <function\_handle> — Function to execute after rotating

Set this callback to listen to when a rotate operation has finished. The input function handle should reference a function with two implicit arguments (similar to Handle Graphics object callbacks):

```
function myfunction(obj,event_obj)
% obj handle to the figure that has been clicked on
```

```
% event_obj object containing struct of event data (same as the
% event data of the 'ActionPreCallback' callback)
```

## Rotate3D Mode Utility Functions

The following functions in pan mode query and set certain of its properties.

- `flags = isAllowAxesRotate(h, axes)` — Function querying permission to rotate axes

Calling the function `isAllowAxesRotate` on the `rotate3d` object, `h`, with a vector of axes handles, `axes`, as input will return a logical array of the same dimension as the axes handle vector which indicate whether a rotate operation is permitted on the axes objects.

- `setAllowAxesRotate(h, axes, flag)` — Function to set permission to pan axes

Calling the function `setAllowAxesRotate` on the `rotate3d` object, `h`, with a vector of axes handles, `axes`, and a logical scalar, `flag`, will either allow or disallow a rotate operation on the axes objects.

## Examples

### Example 1

Rotate the plot using the mouse:

```
surf(peaks);
rotate3d on;
```

### Example 2

Rotate the plot using the "Plot Box" rotate style:

```
surf(peaks);
h = rotate3d;
h.RotateStyle = 'box';
h.Enable = 'on';
```

### Example 3

Create two axes as subplots and then prevent one from rotating:

```
ax1 = subplot(1,2,1);
surf(peaks);
h = rotate3d;
h.Enable = 'on';
ax2 = subplot(1,2,2);
surf(membrane);
setAllowAxesRotate(h,ax2,false); % disable rotating for second plot
```

### Example 4

Create a buttonDown callback for rotate mode objects to trigger. Copy the following code to a new file, execute it, and observe rotation behavior:

```
function demo_mbd
% Allow a line to have its own 'ButtonDownFcn' callback
hLine = plot(rand(1,10),'ButtonDownFcn','disp(''This executes''));
hLine.Tag = 'DoNotIgnore';
h = rotate3d;
h.ButtonDownFilter = @mycallback;
h.Enable = 'on';
% mouse-click on the line
function [flag] = mycallback(obj,event_obj)
% If the tag of the object is 'DoNotIgnore', then return true
objTag = obj.Tag;
if strcmpi(objTag,'DoNotIgnore')
 flag = true;
else
 flag = false;
end
```

### Example 5

Create callbacks for pre- and post-buttonDown events for rotate3D mode objects to trigger. Copy the following code to a new file, execute it, and observe rotation behavior:

```
function demo_mbd2
% Listen to rotate events
surf(peaks);
h = rotate3d;
```

```
h.ActionPreCallback = @myprecallback;
h.ActionPostCallback = @mypostcallback;
h.Enable = 'on';

function myprecallback(obj, evd)
disp('A rotation is about to occur.');
```

```
function mypostcallback(obj, evd)
newView = round(evd.Axes.View);
msgbox(sprintf('The new view is [%d %d].', newView));
```

## Alternatives

Use the Rotate3D tool  on the figure toolbar to enable and disable rotate3D mode on a plot, or select **Rotate 3D** from the figure's **Tools** menu. For details, see “Rotate in 3-D”.

## More About

### Tips

When enabled, `rotate3d` provides continuous rotation of axes and the objects it contains through mouse movement. A numeric readout appears in the lower left corner of the figure during rotation, showing the current azimuth and elevation of the axes. Releasing the mouse button removes the animated box and the readout. This differs from the `camorbit` function in that while the `rotate3d` tool modifies the `View` property of the axes, the `camorbit` function fixes the aspect ratio and modifies the `CameraTarget`, `CameraPosition` and `CameraUpVector` properties of the axes. See [Axes Properties](#) for more information.

You can also enable 3-D rotation from the figure **Tools** menu or the figure toolbar.

You can create a `rotate3d` mode object once and use it to customize the behavior of different axes, as example 3 illustrates. You can also change its callback functions on the fly.

---

**Note:** Do not change figure callbacks within an interactive mode. While a mode is active (when panning, zooming, etc.), you will receive a warning if you attempt to change

any of the figure's callbacks and the operation will not succeed. The one exception to this rule is the figure `WindowButtonMotionFcn` callback, which can be changed from within a mode. Therefore, if you are creating a UI that updates a figure's callbacks, the UI should some keep track of which interactive mode is active, if any, before attempting to do this.

---

When you assign different 3-D rotation behaviors to different `subplot` axes via a mode object and then link them using the `linkaxes` function, the behavior of the axes you manipulate with the mouse will carry over to the linked axes, regardless of the behavior you previously set for the other axes.

### **See Also**

`camorbit` | `pan` | `rotate` | `view` | `zoom`

**Introduced before R2006a**

## round

Round to nearest decimal or integer

### Syntax

$Y = \text{round}(X)$   
 $Y = \text{round}(X,N)$   
 $Y = \text{round}(X,N,\text{type})$   
 $Y = \text{round}(t)$   
 $Y = \text{round}(t,\text{unit})$

### Description

$Y = \text{round}(X)$  rounds each element of  $X$  to the nearest integer. In the case of a tie, where an element has a fractional part of exactly 0.5, the `round` function rounds away from zero to the integer with larger magnitude.

$Y = \text{round}(X,N)$  rounds to  $N$  digits:

- $N > 0$ : round to  $N$  digits to the *right* of the decimal point.
- $N = 0$ : round to the nearest integer.
- $N < 0$ : round to  $N$  digits to the *left* of the decimal point.

$Y = \text{round}(X,N,\text{type})$  specifies the type of rounding. Specify 'significant' to round to  $N$  significant digits (counted from the leftmost digit). In this case,  $N$  must be a positive integer.

$Y = \text{round}(t)$  rounds each element of the `duration` array  $t$  to the nearest number of seconds.

$Y = \text{round}(t,\text{unit})$  rounds each element of  $t$  to the nearest number of the specified unit of time.

## Examples

### Round Matrix Elements

Round the elements of a 2-by-2 matrix to the nearest integer.

```
X = [2.11 3.5; -3.5 0.78];
Y = round(X)
```

Y =

```
 2 4
 -4 1
```

### Round to Specified Number of Decimal Digits

Round pi to the nearest 3 decimal digits.

```
Y = round(pi,3)
```

Y =

```
 3.1420
```

### Round to Nearest Multiple of 100

Round the number 863178137 to the nearest multiple of 100.

```
round(863178137, -2)
```

ans =

```
 863178100
```

### Round Elements to Specified Number of Significant Digits

Round the elements of a vector to retain 2 significant digits.

```
format shortg
x = [1253 1.345 120.44]
y = round(x,2,'significant')
```

x =

```
 1253 1.345 120.44
```

```
y =
 1300 1.3 120
```

## Controlling Number Display While Rounding

The `format` command controls how MATLAB displays numbers at the command line. If a number has extra digits that cannot be displayed in the current format, then MATLAB automatically rounds the number for display purposes. This can lead to unexpected results when combined with the `round` function.

Consider the result of the following subtraction operation, which displays 5 digits.

```
format short
x = 112.05 - 110

x =
 2.0500
```

Based on the displayed value of `x`, rounding `x` to 1 decimal should return `2.1`.

```
round(x,1)

ans =
 2
```

In fact, the problem here is that MATLAB is rounding `x` to 5 digits for display purposes. The `round` function returns the correct answer. Confirm the answer by viewing `x` with `format long`, which displays `x` rounded to 15 digits.

```
format long
x

x =
 2.049999999999997
```

## Round Duration Values

Round each value in a duration array to the nearest number of seconds.

```
t = hours(8) + minutes(29:31) + seconds(1.3:0.5:2.3);
```

```
t.Format = 'hh:mm:ss.SS'
```

```
t =
```

```
 08:29:01.30 08:30:01.80 08:31:02.30
```

```
Y1 = round(t)
```

```
Y1 =
```

```
 08:29:01.00 08:30:02.00 08:31:02.00
```

Round each value in `t` to the nearest number of hours.

```
Y2 = round(t, 'hours')
```

```
Y2 =
```

```
 08:00:00.00 09:00:00.00 09:00:00.00
```

## Input Arguments

### **X** — Input array

scalar | vector | matrix | multidimensional array

Input array, specified as a scalar, vector, matrix, or multidimensional array. For complex `X`, `round` treats the real and imaginary parts independently.

`X` must be `single` or `double` when you use `round` with more than one input.

`round` converts logical and `char` elements of `X` into `double` values.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `char` | `logical`

Complex Number Support: Yes

### **N** — Number of digits

scalar integer

Number of digits, specified as a scalar integer. When you specify  $N$ , the `round` function rounds  $X$  to the nearest multiple of  $10^{-N}$ .

If you specify the `'significant'` rounding type, then  $N$  must be a positive integer.

### **type** — Rounding type

`'decimals'` (default) | `'significant'`

Rounding type, specified as `'decimals'` or `'significant'`. The rounding type determines whether `round` considers digits in relation to the decimal point or the overall number of significant digits.  $N$  must be a positive integer when you specify `'significant'`. In that case, the `round` function rounds to the nearest number with  $N$  significant digits.

The default value is `'decimals'`, so that `round(X,N,'decimals')` is equivalent to `round(X,N)`.

Example: `round(3132,2,'significant')` returns 3100, which is the closest number to 3132 that has 2 significant digits.

Data Types: char

### **t** — Input duration

duration array

Input duration, specified as a `duration` array.

### **unit** — Unit of time

`'seconds'` (default) | `'minutes'` | `'hours'` | `'days'` | `'years'`

Unit of time, specified as `'seconds'`, `'minutes'`, `'hours'`, `'days'`, or `'years'`. A duration of 1 year is equal to exactly 365.2425 24-hour days.

## More About

### Compatibility Considerations

In R2014b, these syntaxes were added to `round` to any number of decimal or significant digits and to round duration values:

```
Y = round(X,N)
```

```
Y = round(X,N,type)
Y = round(t)
Y = round(t,unit)
```

Older versions support only this syntax, which rounds to the nearest integer:

```
Y = round(X)
```

### Tips

- `format short` and `format long` both display rounded numbers. This can cause unexpected results when combined with the `round` function.
- For display purposes, use `sprintf` to control the exact display of a number as a string. For example, to display exactly 2 decimal digits of `pi` (and no trailing zeros), use `sprintf('%.2f',pi)`.
- “Integers”
- “Floating-Point Numbers”

### See Also

`ceil` | `fix` | `floor`

**Introduced before R2006a**

## rowfun

Apply function to table rows

### Syntax

```
B = rowfun(func,A)
B = rowfun(func,A,Name,Value)
```

### Description

`B = rowfun(func,A)` applies the function `func` to each row of the table `A` and returns the results in the table `B`.

`func` accepts `size(A,2)` inputs.

`B = rowfun(func,A,Name,Value)` applies the function `func` to each row of the table `A` with additional options specified by one or more `Name,Value` pair arguments.

For example, you can specify which variables to pass to the function `func` and how to call `func`.

### Examples

#### Apply Function with Single Output to Rows

Apply the function `hypot` to each row of the 5-by-2 table `A` to find the shortest distance between the variables `x` and `y`.

Create a table, `A`, with two variables of numeric data.

```
x = gallery('integerdata',10,[5,1],2);
y = gallery('integerdata',10,[5,1],8);
```

```
A = table(x,y)
```

```
A =
```

```
 x y
 — —
```

```

9 1
4 5
3 2
7 3
1 10

```

Apply the function, `hypot` to each row of `A`. The function `hypot` takes two inputs and returns one output.

```
B = rowfun(@hypot,A,'OutputVariableNames','z')
```

```
B =
```

```

 z

9.0554
6.4031
3.6056
7.6158
10.05

```

`B` is a table.

Append the function output, `B`, to the input table, `A`.

```
[A B]
```

```
ans =
```

```

x y z
-- -- ---
9 1 9.0554
4 5 6.4031
3 2 3.6056
7 3 7.6158
1 10 10.05

```

### Apply Function with Multiple Outputs to Rows

Define and apply a geometric Brownian motion model to a range of parameters.

Create a function in a file named `gbmSim.m` that contains the following code.

```
function [m,mtrue,s,strue] = gbmSim(mu,sigma)
```

```
% Discrete approximation to geometric Brownian motion
%
% [m,mtrue,s,strue] = gbmSim(mu,sigma) computes the
% simulated mean, true mean, simulated standard deviation,
% and true standard deviation based on the parameters mu and sigma.
```

```
numReplicates = 1000; numSteps = 100;
y0 = 1;
t1 = 1;
dt = t1 / numSteps;
y1 = y0*prod(1 + mu*dt + sigma*sqrt(dt)*randn(numSteps,numReplicates));
m = mean(y1); s = std(y1);
% Theoretical values
mtrue = y0 * exp(mu*t1); strue = mtrue * sqrt(exp(sigma^2*t1) - 1);
```

`gbmSim` accepts two inputs, `mu` and `sigma`, and returns four outputs, `m`, `mtrue`, `s`, and `strue`.

Define the table, `params`, containing the parameters to input to the Brownian Motion Model.

```
mu = [-.5; -.25; 0; .25; .5];
sigma = [.1; .2; .3; .2; .1];
```

```
params = table(mu,sigma)
```

```
params =
```

mu	sigma
-----	-----
-0.5	0.1
-0.25	0.2
0	0.3
0.25	0.2
0.5	0.1

Apply the function, `gbmSim` to the rows of the table, `params`.

```
stats = rowfun(@gbmSim,params,...
 'OutputVariableNames',...
 {'simulatedMean' 'trueMean' 'simulatedStd' 'trueStd'})
```

```
stats =
```

simulatedMean	trueMean	simulatedStd	trueStd
-----	-----	-----	-----

```

0.60501 0.60653 0.05808 0.060805
0.77916 0.7788 0.161 0.15733
1.0024 1 0.3048 0.30688
1.2795 1.284 0.25851 0.25939
1.6498 1.6487 0.16285 0.16529

```

The 4 strings specified by the 'OutputVariableNames' name-value pair argument indicate that `rowfun` should obtain 4 outputs from `gbmSim`. You can specify fewer output variable names to return fewer outputs from `gbmSim`.

Append the function output, `stats`, to the input, `params`.

```
[params stats]
```

```
ans =
```

mu	sigma	simulatedMean	trueMean	simulatedStd	trueStd
-0.5	0.1	0.60501	0.60653	0.05808	0.060805
-0.25	0.2	0.77916	0.7788	0.161	0.15733
0	0.3	1.0024	1	0.3048	0.30688
0.25	0.2	1.2795	1.284	0.25851	0.25939
0.5	0.1	1.6498	1.6487	0.16285	0.16529

### Apply Function to Groups of Rows

Create a table, `A`, where `g` is a grouping variable.

```

g = gallery('integerdata',3,[15,1],1);
x = gallery('uniformdata',[15,1],9);
y = gallery('uniformdata',[15,1],2);

```

```
A = table(g,x,y)
```

```
A =
```

g	x	y
3	0.24756	0.87516
3	0.4358	0.3179
3	0.97755	0.27323
2	0.85995	0.6765
3	0.30063	0.071171

```

2 0.26589 0.19659
3 0.13338 0.52908
2 0.7425 0.17176
1 0.85692 0.86996
2 0.24286 0.24369
3 0.19492 0.84291
2 0.39076 0.55766
1 0.29683 0.35681
1 0.39031 0.2324
2 0.18726 0.6476

```

Define the anonymous function, `func`, to compute the average difference between `x` and `y`.

```
func = @(x,y) mean(x-y);
```

Find the average difference between variables in groups 1, 2, and 3 defined by the grouping variable, `g`.

```
B = rowfun(func,A,...
 'GroupingVariable','g',...
 'OutputVariableName','MeanDiff')
```

B =

	g	GroupCount	MeanDiff
1	1	3	0.028298
2	2	6	0.032569
3	3	6	-0.10327

The variable `GroupCount` indicates the number of rows in `A` for each group.

- “Calculations on Tables”
- “Split Table Data Variables and Apply Functions”

## Input Arguments

### **func** — Function

function handle

Function, specified as a function handle. You can define the function in a file or as an anonymous function. If `func` corresponds to more than one function file (that is, if `func`

represents a set of overloaded functions), MATLAB determines which function to call based on the class of the input arguments.

`func` can accept no more than `size(A,2)` inputs. By default, `rowfun` returns the first output of `func`. To return more than one output from `func`, use the `'NumOutputs'` or `'OutputVariableNames'` name-value pair arguments.

Example: `func = @(x,y) x.^2+y.^2;` takes two inputs and finds the sum of the squares.

### **A** — Input table

table

Input table, specified as a table.

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'InputVariables',2` uses only the second variable in `A` as an input to `func`.

### **'InputVariables'** — Variables of `A` to pass to `func`

positive integer | vector of positive integers | variable name | cell array of variable names | logical vector | ...

Variables of `A` to pass to `func`, specified as the comma-separated pair consisting of `'InputVariables'` and a positive integer, vector of positive integers, variable name, cell array of variable names, logical vector, or an anonymous function that returns a logical scalar. If you specify `'InputVariables'` as an anonymous function that returns a logical scalar, `rowfun` only passes the variables in `A` where the specified function returns 1 (true).

### **'GroupingVariables'** — One or more variables in `A` that define groups of rows

positive integer | vector of positive integers | variable name | cell array of variable names | logical vector

One or more variables in `A` that define groups of rows, specified as the comma-separated pair consisting of `'GroupingVariables'` and a positive integer, vector of positive integers, variable name, cell array of variable names, or logical vector.

A grouping variable can be a numeric vector, logical vector, string (or character array), cell array of strings, or a categorical vector. Rows in *A* that have the same grouping variable values belong to the same group. `rowfun` applies `func` to each group of rows, rather than separately to each row of *A*. The output, *B*, contains one row for each group.

**'SeparateInputs' — Indicator for calling func with separate inputs**

true (default) | false | 1 | 0

Indicator for calling `func` with separate inputs, specified as the comma-separated pair consisting of `'SeparateInputs'` and either `true`, `false`, `1`, or `0`.

true	<p><code>func</code> expects separate inputs. <code>rowfun</code> calls <code>func</code> with <code>size(A,2)</code> inputs, one argument for each data variable.</p> <p>This is the default behavior.</p>
false	<p><code>func</code> expects one vector containing all inputs. <code>rowfun</code> creates the input vector to <code>func</code> by concatenating the values in each row of <i>A</i>.</p>

**'ExtractCellContents' — Indicator to pass values from cell variables to func**

false (default) | true | 0 | 1

Indicator to pass values from cell variables to `func`, specified as the comma-separated pair consisting of `'ExtractCellContents'` and either `false`, `true`, `0`, or `1`.

true	<p><code>rowfun</code> extracts the contents of a variable in <i>A</i> whose data type is <code>cell</code> and passes the values, rather than the cells, to <code>func</code></p> <p>For grouped computation, the values within each group in a cell variable must allow vertical concatenation.</p>
false	<p><code>rowfun</code> passes the cells of a variable in <i>A</i> whose data type is <code>cell</code> to <code>func</code>.</p> <p>This is the default behavior.</p>

**'OutputVariableNames' — Variable names for outputs of func**

string | cell array of nonempty, distinct strings

Variable names for outputs of `func`, specified as the comma-separated pair consisting of `'OutputVariableNames'` and a string or a cell array of nonempty, distinct strings. The number of strings must equal the number of outputs desired from `func`.

Furthermore, the strings must be valid MATLAB identifiers. If valid MATLAB identifiers are not available for use as variable names, MATLAB uses a cell array of  $N$  strings of the form `{'Var1' ... 'VarN'}` where  $N$  is the number of variables. You can determine valid MATLAB variable names using the function `isvarname`.

### 'NumOutputs' — Number of outputs from func

0 | positive integer

Number of outputs from `func`, specified as the comma-separated pair consisting of `'NumOutputs'` and 0 or a positive integer. The integer must be less than or equal to the possible number of outputs from `func`.

Example: `'NumOutputs',2` causes `rowfun` to call `func` with two outputs.

### 'OutputFormat' — Format of B

'table' (default) | 'uniform' | 'cell'

Format of `B`, specified as the comma-separated pair consisting of `'OutputFormat'` and either the string `'table'`, `'uniform'`, or `'cell'`.

'table'	<p><code>rowfun</code> returns a table with one variable for each output of <code>func</code>. For grouped computation, <code>B</code>, also contains the grouping variables.</p> <p>'table' allows you to use a function that returns values of different sizes or data types. However, for ungrouped computation, all of the outputs from <code>func</code> must have one row each time it is called. For grouped computation, all of the outputs from <code>func</code> must have the same number of rows.</p> <p>This is the default output format.</p>
'uniform'	<p><code>rowfun</code> concatenates the values returned by <code>func</code> into a vector. All of the outputs from <code>func</code> must be scalars with the same data type.</p>
'cell'	<p><code>rowfun</code> returns <code>B</code> as a cell array. 'cell' allows you to use a function that returns values of different sizes or data types.</p>

### 'ErrorHandler' — Function to call if func fails

function handle

Function to call if `func` fails, specified as the comma-separated pair consisting of `'ErrorHandler'` and a function handle. Define this function so that it rethrows the error or returns valid outputs for function `func`.

MATLAB calls the specified error-handling function with two input arguments:

- A structure with these fields:

<code>identifier</code>	Error identifier.
<code>message</code>	Error message text.
<code>index</code>	Row or group index at which the error occurred.

- The set of input arguments to function `func` at the time of the error.

For example,

```
function [A, B] = errorFunc(S, varargin)
warning(S.identifier, S.message);
A = NaN; B = NaN;
```

## Output Arguments

### **B** — Output table

table

Output table, returned as a table. The table can store metadata such as descriptions, variable units, variable names, and row names. For more information, see [Table Properties](#).

## More About

- “Anonymous Functions”

**Introduced in R2013b**

# rref

Reduced row echelon form (Gauss-Jordan elimination)

## Syntax

```
R = rref(A)
[R, jb] = rref(A)
[R, jb] = rref(A, tol)
```

## Description

`R = rref(A)` produces the reduced row echelon form of `A` using Gauss Jordan elimination with partial pivoting. A default tolerance of  $(\max(\text{size}(A)) * \text{eps} * \text{norm}(A, \text{inf}))$  tests for negligible column elements.

`[R, jb] = rref(A)` also returns a vector `jb` such that:

- `r = length(jb)` is this algorithm's idea of the rank of `A`.
- `x(jb)` are the pivot variables in a linear system  $Ax = b$ .
- `A(:, jb)` is a basis for the range of `A`.
- `R(1:r, jb)` is the `r`-by-`r` identity matrix.

`[R, jb] = rref(A, tol)` uses the given tolerance in the rank tests.

Roundoff errors may cause this algorithm to compute a different value for the rank than `rank`, `orth` and `null`. Additionally, use `mldivide` to solve linear systems when high precision is required.

## Examples

Use `rref` on a rank-deficient magic square:

```
A = magic(4), R = rref(A)
```

```
A =
```

16	2	3	13
5	11	10	8
9	7	6	12
4	14	15	1

R =

1	0	0	1
0	1	0	3
0	0	1	-3
0	0	0	0

Introduced before R2006a

## rsf2csf

Convert real Schur form to complex Schur form

### Syntax

`[U,T] = rsf2csf(U,T)`

### Description

The *complex Schur form* of a matrix is upper triangular with the eigenvalues of the matrix on the diagonal. The *real Schur form* has the real eigenvalues on the diagonal and the complex eigenvalues in 2-by-2 blocks on the diagonal.

`[U,T] = rsf2csf(U,T)` converts the real Schur form to the complex form.

Arguments `U` and `T` represent the unitary and Schur forms of a matrix `A`, respectively, that satisfy the relationships:  $A = U^*T^*U'$  and  $U' * U = \text{eye}(\text{size}(A))$ . See `schur` for details.

### Examples

Given matrix `A`,

```

1 1 1 3
1 2 1 1
1 1 3 1
-2 1 1 4

```

with the eigenvalues

```

4.8121 1.9202 + 1.4742i 1.9202 + 1.4742i 1.3474

```

Generating the Schur form of `A` and converting to the complex Schur form

```

[u,t] = schur(A);
[U,T] = rsf2csf(u,t)

```

yields a triangular matrix  $T$  whose diagonal (underlined here for readability) consists of the eigenvalues of  $A$ .

$U =$

-0.4916	-0.2756 - 0.4411i	0.2133 + 0.5699i	-0.3428

## run

Run MATLAB script

## Syntax

```
run(scriptname)
```

## Description

`run(scriptname)` runs the MATLAB script specified by `scriptname`.

## Examples

### Run Script Not on Current Path

Create a temporary folder and copy an example MATLAB script to it.

```
tmp = tempname;
mkdir(tmp);
runtmp = fullfile(tmp, 'buckyball.m');
demodir = fullfile(matlabroot, 'toolbox', 'matlab', ...
 'demos', 'buckydem.m');
copyfile(demodir, runtmp);
```

Run the new script.

```
run(runtmp)
```

## Input Arguments

**scriptname** — Full or relative script path

string

Full or relative script path to a MATLAB script, specified as a string. **scriptname** can specify any file type that MATLAB can execute, such as MATLAB script files, Simulink models, or MEX-files.

---

## More About

### Tips

- `run` executes scripts not currently on the MATLAB path. However, you should use `cd` or `addpath` to navigate to or to add the appropriate folder, making a script executable by entering its name alone.
- `scriptname` can access any variables in the current workspace.
- `run` changes to the folder that contains the script, executes it, and resets back to the original folder. If the script itself changes folders, then `run` does not revert to the original folder, unless `scriptname` changes to the folder in which this script resides.
- If `scriptname` corresponds to both a `.m` file and a P-file residing in the same folder, then `run` executes the P-file. This occurs even if you specify `scriptname` with a `.m` extension.
- If a script is not on the MATLAB path, executing the `run` command caches the script. In the same session and after calling `run`, you can edit the script using an external editor. Call `clear scriptname` before calling `run` again to use the changed version of the script rather than the cached version. If you edit the script with the MATLAB editor, `run` executes the changed version and there is no need to call `clear scriptname`.

Introduced before R2006a

## runtests

Run set of tests

### Syntax

```
results = runtests
results = runtests(tests)
results = runtests(tests,Name,Value)
```

### Description

`results = runtests` runs all the tests in your current folder, and returns the results as a `TestResult` object.

`results = runtests(tests)` runs a specified set of tests.

`results = runtests(tests,Name,Value)` runs a set of tests with additional options specified by one or more `Name,Value` pair arguments.

### Examples

#### Run Tests in Working Folder

Create a folder `myExample` in your current working folder, and change into that folder.

In the `myExample` folder, create a test script, `typeTest.m`.

```
%% Test double class
exp = 'double';
act = ones;
assert(isa(act,exp))

%% Test single class
exp = 'single';
act = ones('single');
assert(isa(act,exp))
```

```
%% Test uint16 class
exp = 'uint16';
act = ones('uint16');
assert(isa(act,exp))
```

In the `myExample` folder, create a test script, `sizeValueTest.m`.

```
%% Test size
exp = [7 13];
act = ones([7 13]);
assert(isequal(size(act),exp))
```

```
%% Test values
act = ones(42);
assert(unique(act) == 1)
```

Run all tests in the current folder.

```
runtests
```

```
Running sizeValueTest
```

```
..
```

```
Done sizeValueTest
```

```

```

```
Running typeTest
```

```
...
```

```
Done typeTest
```

```

```

```
ans =
```

```
1x5 TestResult array with properties:
```

```
 Name
```

```
 Passed
```

```
 Failed
```

```
 Incomplete
```

```
 Duration
```

```
Totals:
```

```
5 Passed, 0 Failed, 0 Incomplete.
```

```
0.013069 seconds testing time.
```

MATLAB ran 5 tests. There are 2 passing tests from `sizeValueTest` and 3 passing tests from `typeTest`.

## Run Tests Using File Name

Create the test file shown below, and save it as `runtestsExampleTest.m` on your MATLAB path.

```
function tests = runtestsExampleTest
tests = functiontests(localfunctions);

function testFunctionOne(testCase)
```

Run the tests.

```
results = runtests('runtestsExampleTest.m');
```

```
Running runtestsExampleTest
.
Done runtestsExampleTest
```

---

## Run Tests in Subdirectory

If it doesn't already exist, create the test file, `runtestsExampleTest.m`, in the example above.

Create a subdirectory, `tmpTest`, and, in that directory, create the following `runtestsExampleSubFolderTest.m` file.

```
function tests = runtestsExampleSubFolderTest
tests = functiontests(localfunctions);

function testFunctionTwo(testCase)
```

Run the tests from the directory above `tmpTest` by setting `'Recursively'` to true.

```
results = runtests(pwd, 'Recursively', true);
```

```
Running runtestsExampleTest
.
Done runtestsExampleTest
```

---

```
Running runtestsExampleSubFolderTest
.
Done runtestsExampleSubFolderTest
```

---

`runtests` ran the tests in both the current directory and the subdirectory.

If you do not specify the `'Recursively'` property for the `runtests` function, it does not run the test in the subdirectory.

```
results = runtests(pwd);

Running runtestsExampleTest
.
Done runtestsExampleTest
```

---

### Run Tests in Parallel

Create the following test file, and save it as `runInParallelTest.m` on your MATLAB path.

```
function tests = runInParallelTest
tests = functiontests(localfunctions);

function testA(testCase)
verifyEqual(testCase,5,5);

function testB(testCase)
verifyTrue(testCase,logical(1));

function testC(testCase)
verifySubstring(testCase,'SomeLongString','Long');

function testD(testCase)
verifySize(testCase,ones(2,5,3),[2 5 3]);

function testE(testCase)
verifyGreaterThan(testCase,3,2);

function testF(testCase)
verifyEmpty(testCase,{'},'Cell array is not empty.');
```

```
function testG(testCase)
verifyMatches(testCase,'Some String','Some [Ss]tring');
```

Run the tests in parallel. Running tests in parallel requires the Parallel Computing Toolbox. The testing framework might vary the order and number of groups or which tests it includes in each group.

```
results = runtests('runInParallelTest','UseParallel',true);
```

```
Split tests into 7 groups and running them on 4 workers.
```

```

Finished Group 2

Running runInParallelTest
.
Done runInParallelTest

```

```

Finished Group 3

Running runInParallelTest
.
Done runInParallelTest

```

```

Finished Group 1

Running runInParallelTest
.
Done runInParallelTest

### Run Select Parameterized Tests

In your working folder, create `testZeros.m`. This class contains four test methods.

```

classdef testZeros < matlab.unittest.TestCase
 properties (TestParameter)
 type = {'single','double','uint16'};
 outSize = struct('s2d',[3 3], 's3d',[2 5 4]);
 end

 methods (Test)
 function testClass(testCase, type, outSize)
 testCase.verifyClass(zeros(outSize,type), type);
 end

 function testSize(testCase, outSize)
 testCase.verifySize(zeros(outSize), outSize);
 end

 function testDefaultClass(testCase)
 testCase.verifyClass(zeros, 'double');
 end
 end
end

```

```
 end
 function testDefaultSize(testCase)
 testCase.verifySize(zeros, [1 1]);
 end

 function testDefaultValue(testCase)
 testCase.verifyEqual(zeros,0);
 end
end
end
```

The full test suite has 11 test elements: 6 from the `testClass` method, 2 from the `testSize` method, and 1 each from the `testDefaultClass`, `testDefaultSize`, and `testDefaultValue` methods.

At the command prompt, run the test elements that use the `outSize` parameter property.

```
runtests('testZeros','ParameterProperty','outSize')
```

```
Running testZeros
.....
Done testZeros
```

```
ans =
```

```
1x8 TestResult array with properties:
```

```
 Name
 Passed
 Failed
 Incomplete
 Duration
```

```
Totals:
```

```
 8 Passed, 0 Failed, 0 Incomplete.
 0.013499 seconds testing time.
```

`runtests` executed eight tests that use the `outSize` parameter property: six from the `testClass` method and two from the `testSize` method.

At the command prompt, run the test elements that use the `single` parameter name.

```
runtests('testZeros', 'ParameterName', 'single')
```

```
Running testZeros
```

```
..
```

```
Done testZeros
```

```

```

```
c =
```

```
1x2 TestResult array with properties:
```

```
 Name
 Passed
 Failed
 Incomplete
 Duration
```

```
Totals:
```

```
2 Passed, 0 Failed, 0 Incomplete.
```

```
0.0034442 seconds testing time.
```

`runtests` executed the two tests from the `testClass` method that use the `outSize` parameter name.

- “Write Function-Based Unit Tests”
- “Write Simple Test Case Using Functions”
- “Write Test Using Setup and Teardown Functions”

## Input Arguments

### **tests** — Array of tests

string | cell array of strings

Suite of tests specified as a string or cell array of strings. Each string in the cell array can contain the name of a test file, a test class, a test suite element name, a package that containing your test classes, or a folder containing your test files.

Example: `runtests('ATestFile.m')`

Example: `runtests('ATestFile/aTest')`

Example: `runtests('mypackage.MyTestClass')`

Example: `runtests(pwd)`

Example:

```
runtests({'mypackage.MyTestClass', 'ATestFile.m', pwd, 'mypackage.subpackage'})
```

## Name-Value Pair Arguments

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as **Name1**, **Value1**, ..., **NameN**, **ValueN**.

Example:

### '**Recursively**' — Indicator to run tests in subfolders and subpackages

false (default) | true | 0 | 1

Indicator to run tests in subfolders and subpackages, specified as **false** or **true** (0 or 1). By default `runtests` runs tests in the specified folder or package and not in their subfolders or subpackages.

Data Types: logical

### '**UseParallel**' — Indicator to run tests in parallel

false (default) | true | 0 | 1

Indicator to run tests in parallel, specified as **false** or **true** (0 or 1). By default `runtests` runs tests in serial. If you set **UseParallel** to **true**, the `runtests` function divides the test suite into separate groups and runs the groups in parallel provided that:

- The Parallel Computing Toolbox is installed.
- An open parallel pool exists or automatic pool creation is enabled in the Parallel Preferences.

Otherwise, `runtests` runs tests in serial regardless of the value for **UseParallel**.

---

**Note:** Running tests in parallel requires the Parallel Computing Toolbox. The testing framework might vary the order and number of groups or which tests it includes in each group.

---

Data Types: logical

**'Name' — Name of suite element**`string`

String indicating the name of the suite element. For the testing framework to run a test, the `Name` property of the test element must match the specified name. Use the wildcard character, `*`, to match any number of characters. Use the question mark character, `?`, to match to exactly one character.

**'ParameterProperty' — Name of parameterization property**`string`

String indicating the name of a property that defines a parameter used by the test suite element. Use the wildcard character, `*`, to match any number of characters. Use the question mark character, `?`, to match to exactly one character.

**'ParameterName' — Name of parameter**`string`

String indicating the name of a parameter used by the test suite element. Use the wildcard character, `*`, to match any number of characters. Use the question mark character, `?`, to match to exactly one character.

**'BaseFolder' — Name of base folder**`string`

String indicating the name of the folder that contains the file defining the test class, function, or script. For a test element to be included in the suite, the test element must be contained in the specified base folder. Use the wildcard character, `*`, to match any number of characters. Use the question mark character, `?`, to match exactly one character. For test files defined in packages, the base folder is the parent of the top-level package folder.

**'Tag' — Name of test element tag**`string`

Name of test element tag, specified as a string. Use the wildcard character, `*`, to match any number of characters. Use the question mark character, `?`, to match to exactly one character.

**Introduced in R2013b**

# Chart Surface Properties

Control chart surface appearance and behavior

Chart surface properties control the appearance and behavior of chart surface objects. By changing property values, you can modify certain aspects of the surface.

Starting in R2014b, you can use dot notation to query and set properties.

```
h = surf(...);
c = h.CData;
h.CDataMapping = 'direct';
```

If you are using an earlier release, use the `get` and `set` functions instead.

## Faces

### FaceColor — Face color

'flat' (default) | 'interp' | 'none' | 'texturemap' | RGB triplet or color string

Face color, specified as one of these values:

- 'flat' — Use uniform face colors. Use the `CData` values. The color data at the first vertex determines the color for the entire face. You cannot use this value when the `FaceAlpha` property is set to 'interp'.
- 'interp' — Interpolate the face colors. Bilinear interpolation of the `CData` values at each vertex determines the colors. You cannot use this value when the `FaceAlpha` property is set to 'flat'.
- 'none' — Do not draw the faces.
- 'texturemap' — Transform the color data in `CData` so that it conforms to the surface.
- RGB triplet or color string — Use the same color for all of the faces.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0, 1]`, for example, `[0.4 0.6 0.7]`. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[ 1 1 0 ]

Long Name	Short Name	RGB Triplet
'magenta'	'm'	[ 1 0 1 ]
'cyan'	'c'	[ 0 1 1 ]
'red'	'r'	[ 1 0 0 ]
'green'	'g'	[ 0 1 0 ]
'blue'	'b'	[ 0 0 1 ]
'white'	'w'	[ 1 1 1 ]
'black'	'k'	[ 0 0 0 ]

**FaceAlpha — Face transparency**

1 (default) | scalar in range [0,1] | 'flat' | 'interp' | 'texturemap'

Face transparency, specified as one of these values:

- Scalar in range [0,1] — Use uniform transparency across all of the faces. A value of 1 is fully opaque and 0 is completely transparent. Values between 0 and 1 are semitransparent. This option does not use the transparency values in the AlphaData property.
- 'flat' — Use a different transparency for each face based on the values in the AlphaData property. First you must specify the AlphaData property as a matrix the same size as the ZData property. The transparency value at the first vertex determines the transparency for the entire face. The FaceColor property also must be set to 'flat'.
- 'interp' — Use interpolated transparency for each face based on the values in AlphaData property. First you must specify the AlphaData property as a matrix the same size as the ZData property. The transparency varies across each face by interpolating the values at the vertices. The FaceColor property also must be set to 'interp'.
- 'texturemap' — Transform the data in AlphaData so that it conforms to the surface.

**FaceLighting — Effect of light objects on faces**

'flat' (default) | 'gouraud' | 'none'

Effect of light objects on faces, specified as one of these values:

- 'flat' — Apply light uniformly across the faces. Use this value to view faceted objects.

- `'gouraud'` — Vary the light across the faces. Calculate the light at the vertices and then linearly interpolate the light across the faces. Use this value to view curved surfaces.
- `'none'` — Do not apply light from light objects to the faces.

---

**Note:** The `'phong'` value has been removed. Use `'gouraud'` instead.

---

### BackFaceLighting — Face lighting when normals point away from camera

`'reverselit'` (default) | `'unlit'` | `'lit'`

Face lighting when the vertex normals point away from camera, specified as one of these values:

- `'reverselit'` — Light the face as if the vertex normal pointed towards the camera.
- `'unlit'` — Do not light the face.
- `'lit'` — Light the face according to the vertex normal.

Use this property to discriminate between the internal and external surfaces of an object. For an example, see “Back Face Lighting”.

## Edges

### MeshStyle — Edges to display

`'both'` (default) | `'row'` | `'column'`

Edges to display, specified as `'both'`, `'row'`, or `'column'`.

### LineStyle — Line style

`'-'` (default) | `'--'` | `':'` | `'-.'` | `'none'`

Line style, specified as one of the line style strings listed in this table.

String	Line Style	Resulting Line
<code>'-'</code>	Solid line	
<code>'--'</code>	Dashed line	

String	Line Style	Resulting Line
' : '	Dotted line	.....
' - . '	Dash-dotted line	- . - . - .
' none '	No line	No line

**LineWidth** — Line width

0.5 (default) | positive value

Line width, specified as a positive value in point units. If the line has markers, then the line width also affects the marker edges.

Example: 0.75

**EdgeColor** — Edge line color

[0 0 0] (default) | 'none' | 'flat' | 'interp' | RGB triplet or color string

Surface edge line color, specified as one of these values:

- 'none' — Do not draw edges.
- 'flat' — Draw uniform edge colors. Use the CData value of the first vertex of the face to determine the color for each edge. You cannot use this value when the EdgeAlpha property is set to 'interp'.

- 'interp' — Interpolate the edge colors. Use a linear interpolation of the CData values at the face vertices to determine the edge color. You cannot use this value when the EdgeAlpha property is set to 'flat'.
- RGB triplet or color string — Use the same color for all edges.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range  $[0, 1]$ , for example,  $[0.4 \ 0.6 \ 0.7]$ . This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[ 1 1 0 ]
'magenta'	'm'	[ 1 0 1 ]
'cyan'	'c'	[ 0 1 1 ]
'red'	'r'	[ 1 0 0 ]
'green'	'g'	[ 0 1 0 ]
'blue'	'b'	[ 0 0 1 ]
'white'	'w'	[ 1 1 1 ]
'black'	'k'	[ 0 0 0 ]

### EdgeAlpha — Edge transparency

1 (default) | scalar value in range $[0, 1]$  | 'flat' | 'interp'

Edge transparency, specified as one of these values:

- Scalar in range  $[0, 1]$  — Use uniform transparency across all of the edges. A value of 1 is fully opaque and 0 is completely transparent. Values between 0 and 1 are semitransparent. This option does not use the transparency values in the `AlphaData` property.
- 'flat' — Use a different transparency for each edge based on the values in the `AlphaData` property. First you must specify the `AlphaData` property as a matrix the same size as the `ZData` property. The transparency value at the first vertex determines the transparency for the entire edge. The `EdgeColor` property also must be set to 'flat'.
- 'interp' — Use interpolated transparency for each edge based on the values in `AlphaData` property. First you must specify the `AlphaData` property as a matrix the same size as the `ZData` property. The transparency varies across each edge by interpolating the values at the vertices. The `EdgeColor` property also must be set to 'interp'.

### EdgeLighting — Effect of light objects on edges

'none' (default) | 'flat' | 'gouraud'

Effect of light objects on edges, specified as one of these values:

- 'flat' — Apply light uniformly across the each edges.
- 'none' — Do not apply lights from light objects to the edges.
- 'gouraud' — Calculate the light at the vertices, and then linearly interpolate across the edges.

---

**Note:** The 'phong' value has been removed. Use 'gouraud' instead.

---

## **AlignVertexCenters — Sharp vertical and horizontal lines**

'off' (default) | 'on'

Sharp vertical and horizontal lines, specified as 'off' or 'on'.

If the associated figure has a GraphicsSmoothing property set to 'on' and a Renderer property set to 'opengl', then the figure applies a smoothing technique to plots. In some cases, this smoothing technique can cause vertical and horizontal lines to appear uneven in thickness or color. Use the `AlignVertexCenters` property to eliminate the uneven appearance.

- 'off' — Do not sharpen vertical or horizontal lines. The lines might appear uneven in thickness or color.
- 'on' — Sharpen vertical and horizontal lines to eliminate an uneven appearance.

---

**Note:** You must have a graphics card that supports this feature. To see if the feature is supported, type `opengl info`. If it is supported, then the returned fields contain the line `SupportsAlignVertexCenters: 1`.

---

## **Markers**

### **Marker — Marker symbol**

'none' (default) | marker string

Marker symbol, specified as one of the marker strings listed in this table. By default, the chart surface object does not display markers. Specifying a marker symbol adds markers at each data point or vertex.

String	Marker Symbol
'o'	Circle
'+'	Plus sign
'*'	Asterisk
'.'	Point
'x'	Cross
'square' or 's'	Square
'diamond' or 'd'	Diamond
'^'	Upward-pointing triangle
'v'	Downward-pointing triangle
'>'	Right-pointing triangle
'<'	Left-pointing triangle
'pentagram' or 'p'	Five-pointed star (pentagram)
'hexagram' or 'h'	Six-pointed star (hexagram)
'none'	No markers

Example: '+'

Example: 'diamond'

### MarkerSize — Marker size

6 (default) | positive value

Marker size, specified as a positive value in point units.

Example: 10

### MarkerEdgeColor — Marker outline color

'auto' (default) | 'none' | 'flat' | RGB triplet or color string

Marker outline color, specified as specified as one of these values:

- 'auto' — Use the same color as the `EdgeColor` property.
- 'none' — Use no color, which makes unfilled markers invisible.
- 'flat' — Use the `CData` value at the vertex to set the color.
- RGB triplet or color string — Use the specified color.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range  $[0, 1]$ , for example,  $[0.4 \ 0.6 \ 0.7]$ . This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[ 1 1 0 ]
'magenta'	'm'	[ 1 0 1 ]
'cyan'	'c'	[ 0 1 1 ]
'red'	'r'	[ 1 0 0 ]
'green'	'g'	[ 0 1 0 ]
'blue'	'b'	[ 0 0 1 ]
'white'	'w'	[ 1 1 1 ]
'black'	'k'	[ 0 0 0 ]

Example:  $[0.5 \ 0.5 \ 0.5]$

Example: 'blue'

**MarkerFaceColor — Marker fill color**

'none' (default) | 'auto' | 'flat' | RGB triplet or color string

Marker fill color, specified as one of these values:

- 'none' — Use no color, which allows the background to show through.
- 'auto' — Use the same color as the Color property for the axes.
- 'flat' — Use the CData value of the vertex to set the color.
- RGB triplet or color string — Use the specified color.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range  $[0, 1]$ , for example,  $[0.4 \ 0.6 \ 0.7]$ . This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[ 1 1 0 ]

Long Name	Short Name	RGB Triplet
'magenta'	'm'	[ 1 0 1 ]
'cyan'	'c'	[ 0 1 1 ]
'red'	'r'	[ 1 0 0 ]
'green'	'g'	[ 0 1 0 ]
'blue'	'b'	[ 0 0 1 ]
'white'	'w'	[ 1 1 1 ]
'black'	'k'	[ 0 0 0 ]

This property affects only the circle, square, diamond, pentagram, hexagram, and the four triangle marker types.

Example: [0.3 0.2 0.1]

Example: 'green'

Example:

## Face and Vertex Normals

### FaceNormals — Normal vectors for each surface face

[ ] (default) | (m-1)-by-(n-1)-by-3 array

Normal vectors for each surface face, specified as a (m-1)-by-(n-1)-by-3 array, where  $[m, n] = \text{size}(ZData)$ . Specify one normal vector per face.

Specifying values for this property sets the associated mode to manual. If you do not specify normal vectors, then the surface generates this data for lighting calculations.

Data Types: single | double

### FaceNormalsMode — Selection mode for FaceNormals

'auto' (default) | 'manual'

Selection mode for FaceNormals, specified as one of these values:

- 'auto' — Calculate the normal vectors based on the coordinate data.
- 'manual' — Use manually specified values. To specify the values, set the FaceNormals property.

**VertexNormals** — Normal vectors for each surface vertex

[] (default) | m-by-n-by-3 array

Normal vectors for each surface vertex, specified as a m-by-n-by-3 array, where `[m,n] = size(ZData)`. Specify one normal vector per vertex.

Specifying values for this property sets the associated mode to manual. If you do not specify normal vectors, then the surface generates this data for lighting calculations.

Data Types: `single` | `double`

**VertexNormalsMode** — Selection mode for VertexNormals

'auto' (default) | 'manual'

Selection mode for `VertexNormals`, specified as one of these values:

- 'auto' — Calculate the normal vectors based on the coordinate data.
- 'manual' — Use manually specified values. To specify the values, set the `VertexNormals` property.

**NormalMode** — (removed) Selection mode for VertexNormals

'auto' (default) | 'manual'

The `NormalMode` property will be removed in a future release. Use `VertexNormalsMode` instead.

## Color and Transparency Mapping

**CData** — Vertex colors

2-D or 3-D array

Vertex colors, specified in one of these forms:

- 2-D array — Use colormap colors. Specify a color for each vertex by setting `CData` to an array the same size as `ZData`. The `CDataMapping` property determines how these values map into the current colormap. If the `FaceColor` property is set to 'texturemap', then `CData` does not need to be the same size as `ZData`. However, it must be of type `double` or `uint8`. The `CData` values map to conform to the surface defined by `ZData`.
- 3-D array — Use true colors. Specify an RGB triplet color for each vertex by setting `CData` to an m-by-n-by-3 array where `[m,n] = size(ZData)`. An RGB triplet

is a three-element vector that specifies the intensities of the red, green, and blue components of a color. The first page of the array contains the red components, the second the green components, and the third the blue components of the colors. Since the surface uses true colors instead of colormap colors, the `CDataMapping` property has no effect.

- If `CData` is of type `double` or `single`, then an RGB triplet value of `[0 0 0]` corresponds to black and `[1 1 1]` corresponds to white.
- If `CData` is an integer type, then the surface uses the full range of data to determine the color. For example, if `CData` is of type `uint8`, then `[0 0 0]` corresponds to black and `[255 255 255]` corresponds to white. If `CData` is of type `int8`, then `[-128 -128 -128]` corresponds to black and `[127 127 127]` corresponds to white.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **CDataMode — Selection mode for CData**

`'auto'` (default) | `'manual'`

Selection mode for `CData`, specified as one of these values:

- `'auto'` — Use the `ZData` values to set the colors.
- `'manual'` — Use manually specified values. To specify the values, set the `CData` property.

### **CDataSource — Variable linked to CData**

`''` | string containing MATLAB workspace variable name

Variable linked to `CData`, specified as a string containing a MATLAB workspace variable name. MATLAB evaluates the variable in the base workspace to generate the `CData`.

By default, there is no linked variable, so the value is an empty string, `''`. If you link a variable, then MATLAB does not update the `CData` values immediately. To force an update of the values, use the `refreshdata` function.

---

**Note:** If you change one data source property to a variable that contains data of a different dimension, then you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

## **CDataMapping — Color mapping method**

'scaled' (default) | 'direct'

Color mapping method, specified as 'scaled' or 'direct'. Use this property to control the mapping of color data values in **CData** into the colormap.

The methods have these effects:

- 'direct' — Interpret the values as indices into the current colormap. Values with a decimal portion are fixed to the nearest lower integer.
  - If the values are of type **double** or **single**, then values of 1 or less map to the first color in the colormap. Values equal to or greater than the length of the colormap map to the last color in the colormap.
  - If the values are of type **uint8**, **uint16**, **uint32**, **uint64**, **int8**, **int16**, **int32**, or **int64**, then values of 0 or less map to the first color in the colormap. Values equal to or greater than the length of the colormap map to the last color in the colormap (or up to the range limits of the type).
  - If the values are of type **logical**, then values of 0 map to the first color in the colormap and values of 1 map to the second color in the colormap.
- 'scaled' — Scale the values to range between the minimum and maximum color limits. The **CLim** property of the axes contains the color limits.

## **AlphaData — Transparency data**

1 (default) | array same size as **ZData**

Transparency data for each vertex, specified as an array the same size as the **ZData** property. After specifying the values, set the **FaceAlpha** and **EdegAlpha** properties to control the type of transparency. If the **FaceAlpha** and **EdgeAlpha** properties are both set to scalar values, then the chart surface does not use the **AlphaData** values.

The **AlphaDataMapping** property determines how the chart surface interprets the **AlphaData** property values.

Data Types: **single** | **double** | **int8** | **int16** | **int32** | **int64** | **uint8** | **uint16** | **uint32** | **uint64** | **logical**

## **AlphaDataMapping — Interpretation of AlphaData values**

'scaled' (default) | 'direct' | 'none'

Interpretation of **AlphaData** values, specified as one of these values:

- 'none' — Interpret the values as transparency values. A value of 1 or greater is completely opaque, a value of 0 or less is completely transparent, and a value between 0 and 1 is semitransparent.
- 'scaled' — Map the values into the figure's alphamap. The minimum and maximum alpha limits of the axes determine the AlphaData values that map to the first and last elements in the alphamap, respectively. For example, if the alpha limits are [3 5], then values of 3 or less map to the first element in the alphamap. Values of 5 or greater map to the last element in the alphamap. The ALim property of the axes contains the alpha limits. The Alphamap property of the figure contains the alphamap.
- 'direct' — Interpret the values as indices into the figure's alphamap. Values with a decimal portion are fixed to the nearest lower integer.
  - If the values are of type double or single, then values of 1 or less map to the first element in the alphamap. Values equal to or greater than the length of the alphamap map to the last element in the alphamap.
  - If the values are of integer type, then values of 0 or less map to the first element in the alphamap. Values equal to or greater than the length of the alphamap map to the last element in the alphamap (or up to the range limits of the type). The integer types are uint8, uint16, uint32, uint64, int8, int16, int32, and int64.
  - If the values are of type logical, then values of 0 map to the first element in the alphamap and values of 1 map to the second element in the alphamap.

## Ambient Lighting

### AmbientStrength — Strength of ambient light

0.3 (default) | scalar in range [0, 1]

Strength of ambient light, specified as a scalar value in the range [0, 1]. Ambient light is a nondirectional light that illuminates the entire scene. There must be at least one visible light object in the axes for the ambient light to be visible.

The AmbientLightColor property for the axes sets the color of the ambient light. The color is the same for all objects in the axes.

Example: 0.5

Data Types: double

## **DiffuseStrength — Strength of diffuse light**

0.6 (default) | scalar in range [0, 1]

Strength of diffuse light, specified as a scalar value in the range [0, 1]. Diffuse light is the nonspecular reflectance from light objects in the axes.

Example: 0.3

Data Types: double

## **SpecularColorReflectance — Color of specular reflections**

1 (default) | scalar in range [0, 1]

Color of specular reflections, specified as a scalar value in the range [0, 1]. A value of 1 sets the color using only the color of the light source. A value of 0 sets the color using both the color of the object from which it reflects and the color of the light source. The Color property of the light contains the color of the light source. The proportions vary linearly for values in between.

Example: 0.5

Data Types: double

## **SpecularExponent — Size of specular spot**

10 (default) | scalar greater than or equal to 1

Size of specular spot, specified as a scalar value greater than or equal to 1. Most materials have exponents in the range [5 20].

Example: 7

Data Types: double

## **SpecularStrength — Strength of specular reflection**

0.9 (default) | scalar in range [0, 1]

Strength of specular reflection, specified as a scalar value in the range [0, 1]. Specular reflections are the bright spots on the surface from light objects in the axes.

Example: 0.3

Data Types: double

## Data

### **XData** — x-coordinate data

matrix | vector

x-coordinate data specified as a matrix that is the same size as **ZData** or as a vector of length  $n$ , where  $[m,n] = \text{size}(\text{ZData})$ .

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **YData** — y-coordinate data

matrix | vector

y-coordinate data, specified as a matrix that is the same size as **ZData** or a vector of length  $m$ , where  $[m,n] = \text{size}(\text{ZData})$ .

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **ZData** — z-coordinate data

matrix

z-coordinate data, specified as a matrix of numeric values.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **XDataSource** — Variable linked to XData

`''` (default) | string containing MATLAB workspace variable name

Variable linked to **XData**, specified as a string containing a MATLAB workspace variable name. MATLAB evaluates the variable in the base workspace to generate the **XData**.

By default, there is no linked variable so the value is an empty string, `''`. If you link a variable, then MATLAB does not update the **XData** values immediately. To force an update of the data values, use the `refreshdata` function.

---

**Note:** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

Example: 'x'

## **YDataSource — Variable linked to YData**

' ' (default) | string containing MATLAB workspace variable name

Variable linked to **YData**, specified as a string containing a MATLAB workspace variable name. MATLAB evaluates the variable in the base workspace to generate the **YData**.

By default, there is no linked variable so the value is an empty string, ' '. If you link a variable, then MATLAB does not update the **YData** values immediately. To force an update of the data values, use the **refreshdata** function.

---

**Note:** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

Example: 'y'

## **ZDataSource — Variable linked to ZData**

' ' (default) | string containing MATLAB workspace variable name

Variable linked to **ZData**, specified as a string containing a MATLAB workspace variable name. MATLAB evaluates the variable in the base workspace to generate the **ZData**.

By default, there is no linked variable so the value is an empty string, ' '. If you link a variable, then MATLAB does not update the **ZData** values immediately. To force an update of the data values, use the **refreshdata** function.

---

**Note:** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

Example: 'z'

## **XDataMode — Selection mode for XData**

'auto' | 'manual'

Selection mode for **XData**, specified as one of these values:

- 'auto' — Use the column indices of `ZData`.
- 'manual' — Use manually specified values. To specify the values, use an input argument to the plotting function or directly set the `XData` property.

### **YDataMode — Selection mode for YData**

'auto' | 'manual'

Selection mode for `YData`, specified as one of these values:

- 'auto' — Use the row indices of `ZData`.
- 'manual' — Use manually specified values. To specify the values, use an input argument to the plotting function or directly set the `YData` property.

## **Visibility**

### **Visible — State of visibility**

'on' (default) | 'off'

State of visibility, specified as one of these values:

- 'on' — Display the chart surface.
- 'off' — Hide the chart surface without deleting it. You still can access the properties of an invisible chart surface object.

### **Clipping — Clipping of chart surface object to axes limits**

'on' (default) | 'off'

Clipping of the chart surface object to the axes limits, specified as one of these values:

- 'on' — Do not display parts of the chart surface object that are outside the axes limits.
- 'off' — Display the entire chart surface object, even if parts of it appear outside the axes limits. Parts of the chart surface object might appear outside the axes limits if you create a plot, set `hold on`, freeze the axis scaling, and then create the chart surface object so that it is larger than the original plot.

The `Clipping` property of the axes that contains the chart surface object must be set to 'on', otherwise this property has no effect. For more information about the clipping behavior, see the `Clipping` property of the axes.

**EraseMode — (removed) Technique to draw and erase objects**

'normal' (default) | 'none' | 'xor' | 'background'

---

**Note:** EraseMode has been removed. You can delete code that accesses the EraseMode property with minimal impact. If you were using EraseMode to create line animations, use the `animatedline` function instead.

---

Technique to draw and erase objects, specified as one of these values:

- 'normal' — Redraw the affected region of the display, performing the three-dimensional analysis necessary to correctly render all objects. This mode produces the most accurate picture, but is the slowest. The other modes are faster, but do not perform a complete redraw and, therefore, are less accurate.
- 'none' — Do not erase the object when it is moved or destroyed. After you erase the object with EraseMode, 'none', it is still visible on the screen. However, you cannot print the object because MATLAB does not store any information on its former location.
- 'xor' — Draw and erase the object by performing an exclusive OR (XOR) with the color of the screen beneath it. This mode does not damage the color of the objects beneath it. However, the object color depends on the color of whatever is beneath it on the display.
- 'background' — Erase the object by redrawing it in the axes background color, or the figure background color if the axes Color property is 'none'. This damages objects that are behind the erased object, but properly colors the erased object.

MATLAB always prints figures as if the EraseMode property of all objects is set to 'normal'. This means graphics objects created with EraseMode set to 'none', 'xor', or 'background' can look different on screen than on paper. On screen, MATLAB mathematically combines layers of colors and ignores three-dimensional sorting to obtain greater rendering speed. However, MATLAB does not apply these techniques to the printed output. Use the `getframe` command or other screen capture applications to create an image of a figure containing nonnormal mode objects.

## Identifiers

**Type — Type of graphics object**

'surface'

This property is read only.

Type of graphics object, returned as the string 'surface'.

### **Tag — User-specified tag**

' ' (default) | any string

Tag to associate with the chart surface, specified as a string. Tags provide a way to identify graphics objects. Use this property to find all objects with a specific tag within a plotting hierarchy, for example, searching for the tag using `findobj`.

Example: 'January Data'

### **UserData — Data to associate with chart surface**

[] (default) | scalar, vector, or matrix | cell array | character array | table | structure

Data to associate with the chart surface object, specified as a scalar, vector, matrix, cell array, character array, table, or structure. MATLAB does not use this data.

To associate multiple sets of data or to attach a field name to the data, use the `getappdata` and `setappdata` functions.

Example: 1:100

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical | char | struct | table | cell

### **DisplayName — Text used by legend**

' ' (default) | string

Text used by the legend, specified as a string. The text appears next to an icon of the chart surface.

Example: 'Text Description'

For multiline text, create the string using `sprintf` with the new line character `\n`.

Example: `sprintf('line one\nline two')`

Alternatively, you can specify the legend text using the `legend` function.

- If you specify the text as an input argument to the `legend` function, then the legend uses the specified text and sets the `DisplayName` property to the same value.
- If you do not specify the text as an input argument to the `legend` function, then the legend uses the text in the `DisplayName` property. If the `DisplayName` property

does not contain any text, then the legend generates a string. The string has the form 'dataN', where N is the number assigned to the chart surface object based on its location in the list of legend entries.

If you edit interactively the string in an existing legend, then MATLAB updates the `DisplayName` property to the edited string.

## **Annotation — Legend icon display style**

Annotation object

This property is read only.

Legend icon display style, returned as an `Annotation` object. Use this object to include or exclude the chart surface from a legend.

- 1 Query the `Annotation` property to get the `Annotation` object.
- 2 Query the `LegendInformation` property of the `Annotation` object to get the `LegendEntry` object.
- 3 Specify the `IconDisplayStyle` property of the `LegendEntry` object to one of these values:
  - 'on' — Include the chart surface object in the legend as one entry (default).
  - 'off' — Do not include the chart surface object in the legend.
  - 'children' — Include only children of the chart surface object as separate entries in the legend.

If a legend already exists and you change the `IconDisplayStyle` setting, then you must call `legend` to update the display.

## **Parent/Child**

### **Parent — Parent of chart surface**

axes object | group object | transform object

Parent of chart surface, specified as an axes, group, or transform object.

### **Children — Children of chart surface**

empty `GraphicsPlaceholder` array

The chart surface has no children. You cannot set this property.

### **HandleVisibility** — Visibility of object handle

'on' (default) | 'off' | 'callback'

Visibility of chart surface object handle in the **Children** property of the parent, specified as one of these values:

- 'on' — The chart surface object handle is always visible.
- 'off' — The chart surface object handle is invisible at all times. This option is useful for preventing unintended changes to the UI by another function. Set the **HandleVisibility** to 'off' to temporarily hide the handle during the execution of that function.
- 'callback' — The chart surface object handle is visible from within callbacks or functions invoked by callbacks, but not from within functions invoked from the command line. This option blocks access to the chart surface at the command-line, but allows callback functions to access it.

If the chart surface object is not listed in the **Children** property of the parent, then functions that obtain object handles by searching the object hierarchy or querying handle properties cannot return it. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

Hidden object handles are still valid. Set the root **ShowHiddenHandles** property to 'on' to list all object handles regardless of their **HandleVisibility** property setting.

## **Interactive Control**

### **ButtonDownFcn** — Mouse-click callback

' ' (default) | function handle | cell array | string

Mouse-click callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you click the chart surface. If you specify this property using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The chart surface object — You can access properties of the chart surface object from within the callback function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see “Callback Definition”.

---

**Note:** If the `PickableParts` property is set to 'none' or if the `HitTest` property is set to 'off', then this callback does not execute.

---

Example: `@myCallback`

Example: `{@myCallback, arg3}`

## **UIContextMenu — Context menu**

`uicontextmenu` object

Context menu, specified as a `uicontextmenu` object. Use this property to display a context menu when you right-click the chart surface. Create the context menu using the `uicontextmenu` function.

---

**Note:** If the `PickableParts` property is set to 'none' or if the `HitTest` property is set to 'off', then the context menu does not appear.

---

## **Selected — Selection state**

'off' (default) | 'on'

Selection state, specified as one of these values:

- 'on' — Selected. If you click the chart surface when in plot edit mode, then MATLAB sets its `Selected` property to 'on'. If the `SelectionHighlight` property also is set to 'on', then MATLAB displays selection handles around the chart surface.
- 'off' — Not selected.

## **SelectionHighlight — Display of selection handles when selected**

'on' (default) | 'off'

Display of selection handles when selected, specified as one of these values:

- 'on' — Display selection handles when the **Selected** property is set to 'on'.
- 'off' — Never display selection handles, even when the **Selected** property is set to 'on'.

## Callback Execution Control

### **PickableParts** — Ability to capture mouse clicks

'visible' (default) | 'all' | 'none'

Ability to capture mouse clicks, specified as one of these values:

- 'visible' — Can capture mouse clicks when visible. The **Visible** property must be set to 'on' and you must click a part of the chart surface that has a defined color. You cannot click a part that has an associated color property set to 'none'. If the plot contains markers, then the entire marker is clickable if either the edge or the fill has a defined color. The **HitTest** property determines if the chart surface responds to the click or if an ancestor does.
- 'all' — Can capture mouse clicks regardless of visibility. The **Visible** property can be set to 'on' or 'off' and you can click a part of the chart surface that has no color. The **HitTest** property determines if the chart surface responds to the click or if an ancestor does.
- 'none' — Cannot capture mouse clicks. Clicking the chart surface passes the click through it to the object below it in the current view of the figure window. The **HitTest** property has no effect.

### **HitTest** — Response to captured mouse clicks

'on' (default) | 'off'

Response to captured mouse clicks, specified as one of these values:

- 'on' — Trigger the **ButtonDownFcn** callback of the chart surface. If you have defined the **UIContextMenu** property, then invoke the context menu.
- 'off' — Trigger the callbacks for the nearest ancestor of the chart surface that has a **HitTest** property set to 'on' and a **PickableParts** property value that enables the ancestor to capture mouse clicks.

---

**Note:** The **PickableParts** property determines if the chart surface object can capture mouse clicks. If it cannot, then the **HitTest** property has no effect.

---

### **Interruptible — Callback interruption**

'on' (default) | 'off'

Callback interruption, specified as 'on' or 'off'. The `Interruptible` property determines if a running callback can be interrupted.

---

**Note:** There are two callback states to consider:

- The *running* callback is the currently executing callback.
  - The *interrupting* callback is a callback that tries to interrupt the running callback. Whenever MATLAB invokes a callback, that callback attempts to interrupt a running callback. The `Interruptible` property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the `BusyAction` property of the object owning the interrupting callback determines if it is discarded or put in the queue.
- 

If the `ButtonDownFcn` callback of the chart surface is the running callback, then the `Interruptible` property determines if it another callback can interrupt it:

- 'on' — Interruptible. Interruption occurs at the next point where MATLAB processes the queue, such as when there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command.
  - If the running callback contains one of these commands, then MATLAB stops the execution of the callback at this point and executes the interrupting callback. MATLAB resumes executing the running callback when the interrupting callback completes. For more information, see “Interrupt Callback Execution”.
  - If the running callback does not contain one of these commands, then MATLAB finishes executing the callback without interruption.
- 'off' — Not interruptible. MATLAB finishes executing the running callback without any interruptions.

### **BusyAction — Callback queuing**

'queue' (default) | 'cancel'

Callback queuing specified as 'queue' or 'cancel'. The `BusyAction` property determines how MATLAB handles the execution of interrupting callbacks.

**Note:** There are two callback states to consider:

- The *running* callback is the currently executing callback.
- The *interrupting* callback is a callback that tries to interrupt the running callback.

Whenever MATLAB invokes a callback, that callback attempts to interrupt a running callback. The **Interruptible** property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the **BusyAction** property of the object owning the interrupting callback determines if it is discarded or put in the queue.

---

If the **ButtonDownFcn** callback of the chart surface tries to interrupt a running callback that cannot be interrupted, then the **BusyAction** property determines if it is discarded or put in the queue. Specify the **BusyAction** property as one of these values:

- 'queue' — Put the interrupting callback in a queue to be processed after the running callback finishes execution. This is the default behavior.
- 'cancel' — Discard the interrupting callback.

## Creation and Deletion Control

### **CreateFcn** — Creation callback

' ' (default) | function handle | cell array | string

Creation callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you create the chart surface. Setting the **CreateFcn** property on an existing chart surface has no effect. You must define a default value for this property, or define this property using a **Name, Value** pair during chart surface creation. MATLAB executes the callback after creating the chart surface and setting all of its properties.

If you specify this callback using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The chart surface object — You can access properties of the chart surface object from within the callback function. You also can access the chart surface object through the `CallbackObject` property of the root, which can be queried using the `gcbo` function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see “Callback Definition”.

Example: `@myCallback`

Example: `{@myCallback, arg3}`

### **DeleteFcn — Deletion callback**

' ' (default) | function handle | cell array | string

Deletion callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you delete the chart surface. MATLAB executes the callback before destroying the chart surface so that the callback can access its property values.

If you specify this callback using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The chart surface object — You can access properties of the chart surface object from within the callback function. You also can access the chart surface object through the `CallbackObject` property of the root, which can be queried using the `gcbo` function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see “Callback Definition”.

Example: `@myCallback`

Example: `{@myCallback, arg3}`

**BeingDeleted** — Deletion status of chart surface`'off'` (default) | `'on'`

This property is read only.

Deletion status of chart surface, returned as `'on'` or `'off'`. MATLAB sets the **BeingDeleted** property to `'on'` when the delete function of the chart surface begins execution (see the **DeleteFcn** property). The **BeingDeleted** property remains set to `'on'` until the chart surface no longer exists.

Check the value of the **BeingDeleted** property to verify that the chart surface is not about to be deleted before querying or modifying it.

## Primitive Surface Properties

Control primitive surface appearance and behavior

Primitive surface properties control the appearance and behavior of primitive surface objects. By changing property values, you can modify certain aspects of the primitive surface.

Starting in R2014b, you can use dot notation to query and set properties.

```
s = surface;
c = s.CData;
s.CDataMapping = 'direct';
```

If you are using an earlier release, use the `get` and `set` functions instead.

### Faces

#### FaceColor — Face color

'flat' (default) | 'interp' | 'none' | 'texturemap' | RGB triplet or color string

Face color, specified as one of these values:

- 'flat' — Use uniform face colors. Use the `CData` values. The color data at the first vertex determines the color for the entire face. You cannot use this value when the `FaceAlpha` property is set to 'interp'.
- 'interp' — Interpolate the face colors. Bilinear interpolation of the `CData` values at each vertex determines the colors. You cannot use this value when the `FaceAlpha` property is set to 'flat'.
- 'none' — Do not draw the faces.
- 'texturemap' — Transform the color data in `CData` so that it conforms to the surface.
- RGB triplet or color string — Use the same color for all of the faces.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0, 1]`, for example, `[0.4 0.6 0.7]`. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[ 1 1 0 ]
'magenta'	'm'	[ 1 0 1 ]
'cyan'	'c'	[ 0 1 1 ]
'red'	'r'	[ 1 0 0 ]
'green'	'g'	[ 0 1 0 ]
'blue'	'b'	[ 0 0 1 ]
'white'	'w'	[ 1 1 1 ]
'black'	'k'	[ 0 0 0 ]

### FaceAlpha — Face transparency

1 (default) | scalar in range [0,1] | 'flat' | 'interp' | 'texturemap'

Face transparency, specified as one of these values:

- Scalar in range [0, 1] — Use uniform transparency across all of the faces. A value of 1 is fully opaque and 0 is completely transparent. Values between 0 and 1 are semitransparent. This option does not use the transparency values in the `AlphaData` property.
- 'flat' — Use a different transparency for each face based on the values in the `AlphaData` property. First you must specify the `AlphaData` property as a matrix the same size as the `ZData` property. The transparency value at the first vertex determines the transparency for the entire face. The `FaceColor` property also must be set to 'flat'.
- 'interp' — Use interpolated transparency for each face based on the values in `AlphaData` property. First you must specify the `AlphaData` property as a matrix the same size as the `ZData` property. The transparency varies across each face by interpolating the values at the vertices. The `FaceColor` property also must be set to 'interp'.
- 'texturemap' — Transform the data in `AlphaData` so that it conforms to the surface.

### FaceLighting — Effect of light objects on faces

'flat' (default) | 'gouraud' | 'none'

Effect of light objects on faces, specified as one of these values:

- 'flat' — Apply light uniformly across the faces. Use this value to view faceted objects.
- 'gouraud' — Vary the light across the faces. Calculate the light at the vertices and then linearly interpolate the light across the faces. Use this value to view curved surfaces.
- 'none' — Do not apply light from light objects to the faces.

---

**Note:** The 'phong' value has been removed. Use 'gouraud' instead.

---

## **BackFaceLighting** — Face lighting when normals point away from camera

'reverselit' (default) | 'unlit' | 'lit'

Face lighting when the vertex normals point away from camera, specified as one of these values:

- 'reverselit' — Light the face as if the vertex normal pointed towards the camera.
- 'unlit' — Do not light the face.
- 'lit' — Light the face according to the vertex normal.

Use this property to discriminate between the internal and external surfaces of an object. For an example, see “Back Face Lighting”.

## **Edges**

### **EdgeColor** — Edge line color

[0 0 0] (default) | 'none' | 'flat' | 'interp' | RGB triplet or color string

Surface edge line color, specified as one of these values:

- 'none' — Do not draw edges.
- 'flat' — Draw uniform edge colors. Use the `CData` value of the first vertex of the face to determine the color for each edge. You cannot use this value when the `EdgeAlpha` property is set to 'interp'.

- 'interp' — Interpolate the edge colors. Use a linear interpolation of the CData values at the face vertices to determine the edge color. You cannot use this value when the EdgeAlpha property is set to 'flat'.
- RGB triplet or color string — Use the same color for all edges.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range  $[0, 1]$ , for example,  $[0.4 \ 0.6 \ 0.7]$ . This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[ 1 1 0 ]
'magenta'	'm'	[ 1 0 1 ]
'cyan'	'c'	[ 0 1 1 ]
'red'	'r'	[ 1 0 0 ]
'green'	'g'	[ 0 1 0 ]
'blue'	'b'	[ 0 0 1 ]
'white'	'w'	[ 1 1 1 ]
'black'	'k'	[ 0 0 0 ]

### EdgeAlpha — Edge transparency

1 (default) | scalar value in range  $[0, 1]$  | 'flat' | 'interp'

Edge transparency, specified as one of these values:

- Scalar in range [0, 1] — Use uniform transparency across all of the edges. A value of 1 is fully opaque and 0 is completely transparent. Values between 0 and 1 are semitransparent. This option does not use the transparency values in the `AlphaData` property.
- 'flat' — Use a different transparency for each edge based on the values in the `AlphaData` property. First you must specify the `AlphaData` property as a matrix the same size as the `ZData` property. The transparency value at the first vertex determines the transparency for the entire edge. The `EdgeColor` property also must be set to 'flat'.
- 'interp' — Use interpolated transparency for each edge based on the values in `AlphaData` property. First you must specify the `AlphaData` property as a matrix the same size as the `ZData` property. The transparency varies across each edge by interpolating the values at the vertices. The `EdgeColor` property also must be set to 'interp'.

**EdgeLighting — Effect of light objects on edges**

'none' (default) | 'flat' | 'gouraud'

Effect of light objects on edges, specified as one of these values:

- 'flat' — Apply light uniformly across the each edges.
- 'none' — Do not apply lights from light objects to the edges.
- 'gouraud' — Calculate the light at the vertices, and then linearly interpolate across the edges.

---

**Note:** The 'phong' value has been removed. Use 'gouraud' instead.

---

**LineStyle — Line style**

'-' (default) | '--' | ':' | '-.' | 'none'

Line style, specified as one of the line style strings listed in this table.

String	Line Style	Resulting Line
'-'	Solid line	
'--'	Dashed line	

String	Line Style	Resulting Line
' : '	Dotted line	.....
' - . '	Dash-dotted line	- . - . - .
' none '	No line	No line

**LineWidth — Line width**

0.5 (default) | positive value

Line width, specified as a positive value in point units. If the line has markers, then the line width also affects the marker edges.

Example: 0.75

**AlignVertexCenters — Sharp vertical and horizontal lines**

'off' (default) | 'on'

Sharp vertical and horizontal lines, specified as 'off' or 'on'.

If the associated figure has a GraphicsSmoothing property set to 'on' and a Renderer property set to 'opengl', then the figure applies a smoothing technique to plots. In some cases, this smoothing technique can cause vertical and horizontal lines to appear uneven in thickness or color. Use the `AlignVertexCenters` property to eliminate the uneven appearance.

- 'off' — Do not sharpen vertical or horizontal lines. The lines might appear uneven in thickness or color.
- 'on' — Sharpen vertical and horizontal lines to eliminate an uneven appearance.

---

**Note:** You must have a graphics card that supports this feature. To see if the feature is supported, type `opengl info`. If it is supported, then the returned fields contain the line `SupportsAlignVertexCenters: 1`.

---

**MeshStyle — Edges to display**

'both' (default) | 'row' | 'column'

Edges to display, specified as 'both', 'row', or 'column'.

## Markers

### Marker — Marker symbol

'none' (default) | marker string

Marker symbol, specified as one of the marker strings listed in this table. By default, the primitive surface object does not display markers. Specifying a marker symbol adds markers at each data point or vertex.

String	Marker Symbol
'o'	Circle
'+'	Plus sign
'*'	Asterisk
'.'	Point
'x'	Cross
'square' or 's'	Square
'diamond' or 'd'	Diamond
'^'	Upward-pointing triangle
'v'	Downward-pointing triangle
'>'	Right-pointing triangle
'<'	Left-pointing triangle
'pentagram' or 'p'	Five-pointed star (pentagram)
'hexagram' or 'h'	Six-pointed star (hexagram)
'none'	No markers

Example: '+'

Example: 'diamond'

### MarkerSize — Marker size

6 (default) | positive value

Marker size, specified as a positive value in point units.

Example: 10

**MarkerEdgeColor — Marker outline color**

'auto' (default) | 'none' | 'flat' | RGB triplet or color string

Marker outline color, specified as specified as one of these values:

- 'auto' — Use the same color as the `EdgeColor` property.
- 'none' — Use no color, which makes unfilled markers invisible.
- 'flat' — Use the `CData` value at the vertex to set the color.
- RGB triplet or color string — Use the specified color.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range  $[0, 1]$ , for example,  $[0.4 \ 0.6 \ 0.7]$ . This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[1 1 0]
'magenta'	'm'	[1 0 1]
'cyan'	'c'	[0 1 1]
'red'	'r'	[1 0 0]
'green'	'g'	[0 1 0]
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]
'black'	'k'	[0 0 0]

Example:  $[0.5 \ 0.5 \ 0.5]$

Example: 'blue'

**MarkerFaceColor — Marker fill color**

'none' (default) | 'auto' | 'flat' | RGB triplet or color string

Marker fill color, specified as one of these values:

- 'none' — Use no color, which allows the background to show through.
- 'auto' — Use the same color as the `Color` property for the axes.
- 'flat' — Use the `CData` value of the vertex to set the color.
- RGB triplet or color string — Use the specified color.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range  $[0, 1]$ , for example,  $[0.4 \ 0.6 \ 0.7]$ . This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[ 1 1 0 ]
'magenta'	'm'	[ 1 0 1 ]
'cyan'	'c'	[ 0 1 1 ]
'red'	'r'	[ 1 0 0 ]
'green'	'g'	[ 0 1 0 ]
'blue'	'b'	[ 0 0 1 ]
'white'	'w'	[ 1 1 1 ]
'black'	'k'	[ 0 0 0 ]

This property affects only the circle, square, diamond, pentagram, hexagram, and the four triangle marker types.

Example: `[0.3 0.2 0.1]`

Example: `'green'`

Example:

## Face and Vertex Normals

### FaceNormals — Normal vectors for each surface face

`[]` (default) | (m-1)-by-(n-1)-by-3 array

Normal vectors for each surface face, specified as a (m-1)-by-(n-1)-by-3 array, where `[m,n] = size(ZData)`. Specify one normal vector per face.

Specifying values for this property sets the associated mode to manual. If you do not specify normal vectors, then the surface generates this data for lighting calculations.

Data Types: `single` | `double`

### FaceNormalsMode — Selection mode for FaceNormals

`'auto'` (default) | `'manual'`

Selection mode for `FaceNormals`, specified as one of these values:

- `'auto'` — Calculate the normal vectors based on the coordinate data.
- `'manual'` — Use manually specified values. To specify the values, set the `FaceNormals` property.

### **VertexNormals** — Normal vectors for each surface vertex

`[]` (default) | `m-by-n-by-3` array

Normal vectors for each surface vertex, specified as a `m-by-n-by-3` array, where `[m, n] = size(ZData)`. Specify one normal vector per vertex.

Specifying values for this property sets the associated mode to manual. If you do not specify normal vectors, then the surface generates this data for lighting calculations.

Data Types: `single` | `double`

### **VertexNormalsMode** — Selection mode for VertexNormals

`'auto'` (default) | `'manual'`

Selection mode for `VertexNormals`, specified as one of these values:

- `'auto'` — Calculate the normal vectors based on the coordinate data.
- `'manual'` — Use manually specified values. To specify the values, set the `VertexNormals` property.

## **Color and Transparency Mapping**

### **AlphaData** — Transparency data

`1` (default) | array same size as `ZData`

Transparency data for each vertex, specified as an array the same size as the `ZData` property. After specifying the values, set the `FaceAlpha` and `EdegAlpha` properties to control the type of transparency. If the `FaceAlpha` and `EdgeAlpha` properties are both set to scalar values, then the primitive surface does not use the `AlphaData` values.

The `AlphaDataMapping` property determines how the primitive surface interprets the `AlphaData` property values.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

**AlphaDataMapping — Interpretation of AlphaData values**

'scaled' (default) | 'direct' | 'none'

Interpretation of `AlphaData` values, specified as one of these values:

- 'none' — Interpret the values as transparency values. A value of 1 or greater is completely opaque, a value of 0 or less is completely transparent, and a value between 0 and 1 is semitransparent.
- 'scaled' — Map the values into the figure's alphamap. The minimum and maximum alpha limits of the axes determine the `AlphaData` values that map to the first and last elements in the alphamap, respectively. For example, if the alpha limits are [3 5], then values of 3 or less map to the first element in the alphamap. Values of 5 or greater map to the last element in the alphamap. The `ALim` property of the axes contains the alpha limits. The `Alphamap` property of the figure contains the alphamap.
- 'direct' — Interpret the values as indices into the figure's alphamap. Values with a decimal portion are fixed to the nearest lower integer.
  - If the values are of type `double` or `single`, then values of 1 or less map to the first element in the alphamap. Values equal to or greater than the length of the alphamap map to the last element in the alphamap.
  - If the values are of integer type, then values of 0 or less map to the first element in the alphamap. Values equal to or greater than the length of the alphamap map to the last element in the alphamap (or up to the range limits of the type). The integer types are `uint8`, `uint16`, `uint32`, `uint64`, `int8`, `int16`, `int32`, and `int64`.
  - If the values are of type `logical`, then values of 0 map to the first element in the alphamap and values of 1 map to the second element in the alphamap.

**CData — Vertex colors**

2-D or 3-D array

Vertex colors, specified in one of these forms:

- 2-D array — Use colormap colors. Specify a color for each vertex by setting `CData` to an array the same size as `ZData`. The `CDataMapping` property determines how these values map into the current colormap. If the `FaceColor` property is set to 'texturemap', then `CData` does not need to be the same size as `ZData`. However, it must be of type `double` or `uint8`. The `CData` values map to conform to the surface defined by `ZData`.

- 3-D array — Use true colors. Specify an RGB triplet color for each vertex by setting `CData` to an `m-by-n-by-3` array where `[m,n] = size(ZData)`. An RGB triplet is a three-element vector that specifies the intensities of the red, green, and blue components of a color. The first page of the array contains the red components, the second the green components, and the third the blue components of the colors. Since the surface uses true colors instead of colormap colors, the `CDataMapping` property has no effect.
  - If `CData` is of type `double` or `single`, then an RGB triplet value of `[0 0 0]` corresponds to black and `[1 1 1]` corresponds to white.
  - If `CData` is an integer type, then the surface uses the full range of data to determine the color. For example, if `CData` is of type `uint8`, then `[0 0 0]` corresponds to black and `[255 255 255]` corresponds to white. If `CData` is of type `int8`, then `[-128 -128 -128]` corresponds to black and `[127 127 127]` corresponds to white.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **`CDataMapping` — Direct or scaled colormapping**

`'scaled'` (default) | `'direct'`

Direct or scaled colormapping, specified as one of these values:

- `scaled` — Transform the color data to span the portion of the colormap indicated by the axes `CLim` property, linearly mapping data values to colors. See the `caxis` reference page for more information on this mapping.
- `direct` — Use the color data as indices directly into the colormap. The color data should then be integer values ranging from 1 to `length(colormap)`. MATLAB maps values less than 1 to the first color in the colormap, and values greater than `length(colormap)` to the last color in the colormap. Values with a decimal portion are fixed to the nearest lower integer.

### **`CDataMode` — Selection mode for `CData`**

`'auto'` (default) | `'manual'`

Selection mode for `CData`, specified as one of these values:

- `'auto'` — Use the `ZData` values to set the colors.
- `'manual'` — Use manually specified values. To specify the values, set the `CData` property.

## Lighting

### **AmbientStrength — Strength of ambient light**

0.3 (default) | scalar in range [0, 1]

Strength of ambient light, specified as a scalar value in the range [0, 1]. Ambient light is a nondirectional light that illuminates the entire scene. There must be at least one visible light object in the axes for the ambient light to be visible.

The AmbientLightColor property for the axes sets the color of the ambient light. The color is the same for all objects in the axes.

Example: 0.5

Data Types: double

### **DiffuseStrength — Strength of diffuse light**

0.6 (default) | scalar in range [0, 1]

Strength of diffuse light, specified as a scalar value in the range [0, 1]. Diffuse light is the nonspecular reflectance from light objects in the axes.

Example: 0.3

Data Types: double

### **SpecularColorReflectance — Color of specular reflections**

1 (default) | scalar in range [0, 1]

Color of specular reflections, specified as a scalar value in the range [0, 1]. A value of 1 sets the color using only the color of the light source. A value of 0 sets the color using both the color of the object from which it reflects and the color of the light source. The Color property of the light contains the color of the light source. The proportions vary linearly for values in between.

Example: 0.5

Data Types: double

### **SpecularExponent — Size of specular spot**

10 (default) | scalar greater than or equal to 1

Size of specular spot, specified as a scalar value greater than or equal to 1. Most materials have exponents in the range [5 20].

Example: 7

Data Types: double

### **SpecularStrength** — Strength of specular reflection

0.9 (default) | scalar in range [0, 1]

Strength of specular reflection, specified as a scalar value in the range [0, 1]. Specular reflections are the bright spots on the surface from light objects in the axes.

Example: 0.3

Data Types: double

## **Data**

### **XData** — x-coordinate data

[3x3 double] (default) | vector or matrix

x-coordinate data specified as a matrix that is the same size as ZData or a vector of length(n), where  $[m,n] = \text{size}(ZData)$ .

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

### **YData** — y-coordinate data

[3x3 double] (default) | vector or matrix

y-coordinate data specified as a matrix that is the same size as ZData or a vector of length(m), where  $[m,n] = \text{size}(ZData)$ .

Example:

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

### **ZData** — z-coordinate data

[3x3 double] (default) | 2-D array

z-coordinate data specified as a 2-D array of numeric values.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

### **XDataMode** — Selection mode for XData

'auto' | 'manual'

Selection mode for `XData`, specified as one of these values:

- `'auto'` — Use the column indices of `ZData`.
- `'manual'` — Use manually specified value. To specify the value, pass an input argument to the plotting function or directly set the `XData` property.

### **YDataMode — Selection mode for YData**

`'auto' | 'manual'`

Selection mode for `YData`, specified as one of these values:

- `'auto'` — Use the row indices of `ZData`.
- `'manual'` — Use manually specified value. To specify the value, pass an input argument to the plotting function or directly set the `YData` property.

## **Visibility**

### **Visible — State of visibility**

`'on' (default) | 'off'`

State of visibility, specified as one of these values:

- `'on'` — Display the primitive surface.
- `'off'` — Hide the primitive surface without deleting it. You still can access the properties of an invisible primitive surface object.

### **Clipping — Clipping of primitive surface object to axes limits**

`'on' (default) | 'off'`

Clipping of the primitive surface object to the axes limits, specified as one of these values:

- `'on'` — Do not display parts of the primitive surface object that are outside the axes limits.
- `'off'` — Display the entire primitive surface object, even if parts of it appear outside the axes limits. Parts of the primitive surface object might appear outside the axes limits if you create a plot, set `hold on`, freeze the axis scaling, and then create the primitive surface object so that it is larger than the original plot.

The `Clipping` property of the axes that contains the primitive surface object must be set to `'on'`, otherwise this property has no effect. For more information about the clipping behavior, see the `Clipping` property of the axes.

**EraseMode — (removed) Technique to draw and erase objects**`'normal'` (default) | `'none'` | `'xor'` | `'background'`

---

**Note:** `EraseMode` has been removed. You can delete code that accesses the `EraseMode` property with minimal impact. If you were using `EraseMode` to create line animations, use the `animatedline` function instead.

---

Technique to draw and erase objects, specified as one of these values:

- `'normal'` — Redraw the affected region of the display, performing the three-dimensional analysis necessary to correctly render all objects. This mode produces the most accurate picture, but is the slowest. The other modes are faster, but do not perform a complete redraw and, therefore, are less accurate.
- `'none'` — Do not erase the object when it is moved or destroyed. After you erase the object with `EraseMode`, `'none'`, it is still visible on the screen. However, you cannot print the object because MATLAB does not store any information on its former location.
- `'xor'` — Draw and erase the object by performing an exclusive OR (XOR) with the color of the screen beneath it. This mode does not damage the color of the objects beneath it. However, the object color depends on the color of whatever is beneath it on the display.
- `'background'` — Erase the object by redrawing it in the axes background color, or the figure background color if the axes `Color` property is `'none'`. This damages objects that are behind the erased object, but properly colors the erased object.

MATLAB always prints figures as if the `EraseMode` property of all objects is set to `'normal'`. This means graphics objects created with `EraseMode` set to `'none'`, `'xor'`, or `'background'` can look different on screen than on paper. On screen, MATLAB mathematically combines layers of colors and ignores three-dimensional sorting to obtain greater rendering speed. However, MATLAB does not apply these techniques to the printed output. Use the `getframe` command or other screen capture applications to create an image of a figure containing nonnormal mode objects.

## Identifiers

**Tag — User-specified tag**`''` (default) | any string

Tag to associate with the primitive surface, specified as a string. Tags provide a way to identify graphics objects. Use this property to find all objects with a specific tag within a plotting hierarchy, for example, searching for the tag using `findobj`.

Example: 'January Data'

**Type — Type of graphics object**

'surface'

This property is read only.

Type of graphics object, returned as the string 'surface'

**UserData — Data to associate with primitive surface**

[] (default) | scalar, vector, or matrix | cell array | character array | table | structure

Data to associate with the primitive surface object, specified as a scalar, vector, matrix, cell array, character array, table, or structure. MATLAB does not use this data.

To associate multiple sets of data or to attach a field name to the data, use the `getappdata` and `setappdata` functions.

Example: 1:100

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical | char | struct | table | cell

**DisplayName — Text used by legend**

'' (default) | string

Text used by the legend, specified as a string. The text appears next to an icon of the primitive surface.

Example: 'Text Description'

For multiline text, create the string using `sprintf` with the new line character `\n`.

Example: `sprintf('line one\nline two')`

Alternatively, you can specify the legend text using the `legend` function.

- If you specify the text as an input argument to the `legend` function, then the legend uses the specified text and sets the `DisplayName` property to the same value.
- If you do not specify the text as an input argument to the `legend` function, then the legend uses the text in the `DisplayName` property. If the `DisplayName` property

does not contain any text, then the legend generates a string. The string has the form 'dataN', where N is the number assigned to the primitive surface object based on its location in the list of legend entries.

If you edit interactively the string in an existing legend, then MATLAB updates the `DisplayName` property to the edited string.

### **Annotation — Legend icon display style**

Annotation object

This property is read only.

Legend icon display style, returned as an `Annotation` object. Use this object to include or exclude the primitive surface from a legend.

- 1 Query the `Annotation` property to get the `Annotation` object.
- 2 Query the `LegendInformation` property of the `Annotation` object to get the `LegendEntry` object.
- 3 Specify the `IconDisplayStyle` property of the `LegendEntry` object to one of these values:
  - 'on' — Include the primitive surface object in the legend as one entry (default).
  - 'off' — Do not include the primitive surface object in the legend.
  - 'children' — Include only children of the primitive surface object as separate entries in the legend.

If a legend already exists and you change the `IconDisplayStyle` setting, then you must call `legend` to update the display.

## **Parent/Child**

### **Parent — Parent of primitive surface**

axes object | group object | transform object

Parent of primitive surface, specified as an axes, group, or transform object.

### **HandleVisibility — Visibility of object handle**

'on' (default) | 'off' | 'callback'

Visibility of primitive surface object handle in the `Children` property of the parent, specified as one of these values:

- 'on' — The primitive surface object handle is always visible.
- 'off' — The primitive surface object handle is invisible at all times. This option is useful for preventing unintended changes to the UI by another function. Set the `HandleVisibility` to 'off' to temporarily hide the handle during the execution of that function.
- 'callback' — The primitive surface object handle is visible from within callbacks or functions invoked by callbacks, but not from within functions invoked from the command line. This option blocks access to the primitive surface at the command-line, but allows callback functions to access it.

If the primitive surface object is not listed in the `Children` property of the parent, then functions that obtain object handles by searching the object hierarchy or querying handle properties cannot return it. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

Hidden object handles are still valid. Set the root `ShowHiddenHandles` property to 'on' to list all object handles regardless of their `HandleVisibility` property setting.

### **Children — Children of primitive surface**

empty `GraphicsPlaceholder` array

The primitive surface has no children. You cannot set this property.

## **Interactive Control**

### **ButtonDownFcn — Mouse-click callback**

' ' (default) | function handle | cell array | string

Mouse-click callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you click the primitive surface. If you specify this property using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The primitive surface object — You can access properties of the primitive surface object from within the callback function.

- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see “Callback Definition”.

---

**Note:** If the `PickableParts` property is set to 'none' or if the `HitTest` property is set to 'off', then this callback does not execute.

---

Example: `@myCallback`

Example: `{@myCallback, arg3}`

### **UIContextMenu — Context menu**

`uicontextmenu` object

Context menu, specified as a `uicontextmenu` object. Use this property to display a context menu when you right-click the primitive surface. Create the context menu using the `uicontextmenu` function.

---

**Note:** If the `PickableParts` property is set to 'none' or if the `HitTest` property is set to 'off', then the context menu does not appear.

---

### **Selected — Selection state**

'off' (default) | 'on'

Selection state, specified as one of these values:

- 'on' — Selected. If you click the primitive surface when in plot edit mode, then MATLAB sets its `Selected` property to 'on'. If the `SelectionHighlight` property also is set to 'on', then MATLAB displays selection handles around the primitive surface.
- 'off' — Not selected.

### **SelectionHighlight — Display of selection handles when selected**

'on' (default) | 'off'

Display of selection handles when selected, specified as one of these values:

- 'on' — Display selection handles when the **Selected** property is set to 'on'.
- 'off' — Never display selection handles, even when the **Selected** property is set to 'on'.

## Callback Execution Control

### **PickableParts** — Ability to capture mouse clicks

'visible' (default) | 'all' | 'none'

Ability to capture mouse clicks, specified as one of these values:

- 'visible' — Can capture mouse clicks when visible. The **Visible** property must be set to 'on' and you must click a part of the primitive surface that has a defined color. You cannot click a part that has an associated color property set to 'none'. If the plot contains markers, then the entire marker is clickable if either the edge or the fill has a defined color. The **HitTest** property determines if the primitive surface responds to the click or if an ancestor does.
- 'all' — Can capture mouse clicks regardless of visibility. The **Visible** property can be set to 'on' or 'off' and you can click a part of the primitive surface that has no color. The **HitTest** property determines if the primitive surface responds to the click or if an ancestor does.
- 'none' — Cannot capture mouse clicks. Clicking the primitive surface passes the click through it to the object below it in the current view of the figure window. The **HitTest** property has no effect.

### **HitTest** — Response to captured mouse clicks

'on' (default) | 'off'

Response to captured mouse clicks, specified as one of these values:

- 'on' — Trigger the **ButtonDownFcn** callback of the primitive surface. If you have defined the **UIContextMenu** property, then invoke the context menu.
- 'off' — Trigger the callbacks for the nearest ancestor of the primitive surface that has a **HitTest** property set to 'on' and a **PickableParts** property value that enables the ancestor to capture mouse clicks.

---

**Note:** The **PickableParts** property determines if the primitive surface object can capture mouse clicks. If it cannot, then the **HitTest** property has no effect.

---

**BusyAction — Callback queuing**

'queue' (default) | 'cancel'

Callback queuing specified as 'queue' or 'cancel'. The `BusyAction` property determines how MATLAB handles the execution of interrupting callbacks.

---

**Note:** There are two callback states to consider:

- The *running* callback is the currently executing callback.
- The *interrupting* callback is a callback that tries to interrupt the running callback.

Whenever MATLAB invokes a callback, that callback attempts to interrupt a running callback. The `Interruptible` property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the `BusyAction` property of the object owning the interrupting callback determines if it is discarded or put in the queue.

---

If the `ButtonDownFcn` callback of the primitive surface tries to interrupt a running callback that cannot be interrupted, then the `BusyAction` property determines if it is discarded or put in the queue. Specify the `BusyAction` property as one of these values:

- 'queue' — Put the interrupting callback in a queue to be processed after the running callback finishes execution. This is the default behavior.
- 'cancel' — Discard the interrupting callback.

**Interruptible — Callback interruption**

'on' (default) | 'off'

Callback interruption, specified as 'on' or 'off'. The `Interruptible` property determines if a running callback can be interrupted.

---

**Note:** There are two callback states to consider:

- The *running* callback is the currently executing callback.
- The *interrupting* callback is a callback that tries to interrupt the running callback.

Whenever MATLAB invokes a callback, that callback attempts to interrupt a running callback. The `Interruptible` property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the

**BusyAction** property of the object owning the interrupting callback determines if it is discarded or put in the queue.

---

If the **ButtonDownFcn** callback of the primitive surface is the running callback, then the **Interruptible** property determines if it another callback can interrupt it:

- 'on' — Interruptible. Interruption occurs at the next point where MATLAB processes the queue, such as when there is a **drawnow**, **figure**, **getframe**, **waitfor**, or **pause** command.
  - If the running callback contains one of these commands, then MATLAB stops the execution of the callback at this point and executes the interrupting callback. MATLAB resumes executing the running callback when the interrupting callback completes. For more information, see “Interrupt Callback Execution”.
  - If the running callback does not contain one of these commands, then MATLAB finishes executing the callback without interruption.
- 'off' — Not interruptible. MATLAB finishes executing the running callback without any interruptions.

## Creation and Deletion Control

### **CreateFcn** — Creation callback

' ' (default) | function handle | cell array | string

Creation callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you create the primitive surface. Setting the **CreateFcn** property on an existing primitive surface has no effect. You must define a default value for this property, or define this property using a **Name, Value** pair during primitive surface creation. MATLAB executes the callback after creating the primitive surface and setting all of its properties.

If you specify this callback using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The primitive surface object — You can access properties of the primitive surface object from within the callback function. You also can access the primitive surface object through the `CallbackObject` property of the root, which can be queried using the `gcbo` function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see “Callback Definition”.

Example: `@myCallback`

Example: `{@myCallback, arg3}`

### **DeleteFcn — Deletion callback**

' ' (default) | function handle | cell array | string

Deletion callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you delete the primitive surface. MATLAB executes the callback before destroying the primitive surface so that the callback can access its property values.

If you specify this callback using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The primitive surface object — You can access properties of the primitive surface object from within the callback function. You also can access the primitive surface object through the `CallbackObject` property of the root, which can be queried using the `gcbo` function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see “Callback Definition”.

Example: `@myCallback`

Example: {@myCallback, arg3}

## **BeingDeleted** — Deletion status of primitive surface

'off' (default) | 'on'

This property is read only.

Deletion status of primitive surface, returned as 'on' or 'off'. MATLAB sets the **BeingDeleted** property to 'on' when the delete function of the primitive surface begins execution (see the **DeleteFcn** property). The **BeingDeleted** property remains set to 'on' until the primitive surface no longer exists.

Check the value of the **BeingDeleted** property to verify that the primitive surface is not about to be deleted before querying or modifying it.

- “Graphics Object Properties”

## save

Save workspace variables to file

### Syntax

```
save(filename)
save(filename,variables)
save(filename,variables,fmt)
save(filename,variables,version)
save(filename,variables,'-append')
```

```
save filename
```

### Description

`save(filename)` saves all variables from the current workspace in a MATLAB formatted binary file (MAT-file) called `filename`. If `filename` exists, `save` overwrites the file.

`save(filename,variables)` saves only the variables or fields of a structure array specified by `variables`.

`save(filename,variables,fmt)` saves in the file format specified by `fmt`. The `variables` argument is optional. If you do not specify `variables`, the `save` function saves all variables in the workspace.

`save(filename,variables,version)` saves to the MAT-file version specified by `version`. The `variables` argument is optional.

`save(filename,variables,'-append')` adds new variables to an existing file. If a variable already exists in a MAT-file, then `save` overwrites it. The `variables` argument is optional.

To append to a Version 6 MAT-file, you must also include `'-v6'` as an input argument.

`save filename` is the command form of the syntax. Command form requires fewer special characters. You do not need to type parentheses or enclose input strings in single quotes. Separate inputs with spaces instead of commas.

For example, to save a file named `test.mat`, these statements are equivalent:

```
save test.mat % command form
save('test.mat') % function form
```

You can include any of the inputs described in previous syntaxes. For example, to save the variable named `X`:

```
save test.mat X % command form
save('test.mat','X') % function form
```

Do not use command form when any of the inputs, such as `filename`, are variables.

## Examples

### Save All Workspace Variables to MAT-File

Save all variables from the workspace in a binary MAT-file, `test.mat`. If `filename` is a variable, use function syntax.

```
filename = 'test.mat';
save(filename)
```

Otherwise, you also can use command syntax.

```
save test.mat
```

Remove the variables from the workspace, and then retrieve the data with the `load` function.

```
clear
load('test.mat')
```

### Save Specific Variables to MAT-File

Create and save two variables, `p` and `q`, to a file called `pqfile.mat`.

```
p = rand(1,10);
q = ones(10);
save('pqfile.mat','p','q')
```

MATLAB® saves the variables to the file, `pqfile.mat`, in the current folder.

You also can use command syntax to save the variables, `p` and `q`.

```
save pqfile.mat p q
```

### Save Data to ASCII File

Create two variables, save them to an ASCII file, and then view the contents of the file.

```
p = rand(1,10);
q = ones(10);
save('pqfile.txt','p','q','-ascii')
type('pqfile.txt')
```

The `type` function displays the contents of the file.

Alternatively, use command syntax for the `save` operation.

```
save pqfile.txt p q -ascii
```

### Save Structure Fields as Individual Variables

Create a structure, `s1`, that contains three fields, `a`, `b`, and `c`.

```
s1.a = 12.7;
s1.b = {'abc',[4 5; 6 7]};
s1.c = 'Hello!';
```

Save the fields of structure `s1` as individual variables in a file called `newstruct.mat`.

```
save('newstruct.mat','-struct','s1');
```

Check the contents of the file using the `whos` function.

```
disp('Contents of newstruct.mat:')
whos('-file','newstruct.mat')
```

```
Contents of newstruct.mat:
 Name Size Bytes Class Attributes

 a 1x1 8 double

 b 1x2 262 cell

 c 1x6 12 char
```

### Save Variables to Version 7.3 MAT-File

Create two variables and save them to a version 7.3 MAT-file called `example.mat`.

```
A = rand(5);
B = magic(10);
save('example.mat', 'A', 'B', '-v7.3')
```

You also can use command syntax for the `save` operation.

```
save example.mat A B -v7.3
```

### Append Variable to MAT-File

Save two variables to a MAT-file. Then, append a third variable to the same file.

```
p = rand(1,10);
q = ones(10);
save('test.mat', 'p', 'q')
```

View the contents of the MAT-file.

```
whos('-file', 'test.mat')
```

Name	Size	Bytes	Class	Attributes
p	1x10	80	double	
q	10x10	800	double	

Create a new variable, `a`, and append it to the MAT-file.

```
a = 50;
save('test.mat', 'a', '-append')
```

View the contents of the MAT-file.

```
whos('-file', 'test.mat')
```

Name	Size	Bytes	Class	Attributes
a	1x1	8	double	
p	1x10	80	double	
q	10x10	800	double	

The variable, `a`, is appended to `test.mat`, without overwriting the previous variables, `p` and `q`.

---

**Note:** To append to a Version 6 MAT-file, specify both `'-v6'` and `'-append'`. For example, to save variable `a` to the file, `test.mat`, call:

---

```
save('test.mat','a','-v6','-append')
```

---

## Input Arguments

### filename — Name of file

'matlab.mat' (default) | string

Name of file, specified as a string. If you do not specify `filename`, the `save` function saves to a file named `matlab.mat`.

If `filename` has no extension (that is, no period followed by text), and the value of `format` is `-mat` (the default), then MATLAB appends `.mat`. If `filename` does not include a full path, MATLAB saves to the current folder. You must have permission to write to the file.

When using the command form of `save`, it is unnecessary to enclose input strings in single quotes. However, if `filename` contains a space, you must enclose the argument in single quotes. For example, `save 'filename withspace.mat'`.

Example: `'myFile.mat'`

Data Types: char

### variables — Names of variables to save

string

Names of variables to save, specified as one or more strings. When using the command form of `save`, you do not need to enclose input strings in single quotes. `variables` can be in one of the following forms.

Form of variables Input	Variables to Save
<code>var1, ..., varN</code>	Save the listed variables, specified as individual strings. Use the '*' wildcard to match patterns. For example, <code>save('filename.mat','A*')</code> saves all variables in the file that start with A.
<code>'-regex', expr1, ..., exprN</code>	Save only the variables whose names match the regular expressions, specified as strings. For example, <code>save('filename.mat','-regex','^Mon','^Tues')</code> saves only the

Form of variables Input	Variables to Save
	variables in the file whose names begin with <code>MON</code> or <code>Tues</code> .
<code>'-struct', structName</code>	Store the fields of the scalar structure specified by <i>structName</i> as individual variables in the file. For example, <code>save('filename.mat', '-struct', 'S')</code> saves the scalar structure, <code>S</code> .
<code>'-struct', structName, field1, ...,</code>	Store the specified fields of the specified scalar structure as individual variables in the file. For example, <code>save('filename.mat', '-struct', 'S', 'a', 'b')</code> saves the fields <code>S.a</code> and <code>S.b</code> .
<code>'-struct', structName, '-regexp', expr1, ..., exprN</code>	Store only the fields whose names match the regular expressions, specified as strings.

Data Types: char

**fmt — File format**

`'-mat'` (default) | `'-ascii'` | `'-ascii', '-tabs'` | `'-ascii', '-double'` | `'-ascii', '-double', '-tabs'`

File format, specified as one of the following strings. When using the command form of `save`, you do not need to enclose input strings in single quotes, for example, `save myFile.txt -ascii -tabs`.

Value of <code>fmt</code>	File Format
<code>'-mat'</code>	Binary MAT-file format.
<code>'-ascii'</code>	Text format with 8 digits of precision.
<code>'-ascii', '-tabs'</code>	Tab-delimited text format with 8 digits of precision.
<code>'-ascii', '-double'</code>	Text format with 16 digits of precision.
<code>'-ascii', '-double', '-tabs'</code>	Tab-delimited text format with 16 digits of precision.

For MAT-files, data saved on one machine and loaded on another machine retains as much accuracy and range as the different machine floating-point formats allow.

Use one of the text formats to save MATLAB numeric values to text files. In this case:

- Each variable must be a two-dimensional **double** array.
- The output includes only the real component of complex numbers.
- MATLAB writes data from each variable sequentially to the file. If you plan to use the `load` function to read the file, all variables must have the same number of columns. The `load` function creates a single variable from the file.

If you specify a text format and any variable is a two-dimensional character array, then MATLAB translates characters to their corresponding internal ASCII codes. For example, 'abc' appears in a text file as:

```
9.7000000e+001 9.8000000e+001 9.9000000e+001
```

#### version — MAT-file version

```
'-v7.3' | '-v7' | '-v6' | '-v4'
```

MAT-file version, specified as one of the following strings. When using the command form of `save`, you do not need to enclose input strings in single quotes.

Value of version	Loads in MATLAB Versions	Supported Features	Compression	Maximum Size of Each Variable
'-v7.3'	7.3 (R2006b) or later	Saving and loading parts of variables, and all Version 7 features	Yes	≥ 2 GB on 64-bit computers
'-v7'	7.0 (R14) or later	Unicode character encoding, which enables file sharing between systems that use different default character encoding schemes, and all Version 6 features.	Yes	2 <sup>31</sup> bytes per variable
'-v6'	5 (R8) or later	N-dimensional arrays, cell arrays, structure arrays, variable names longer than 19 characters, and all Version 4 features.	No	2 <sup>31</sup> bytes per variable

Value of version	Loads in MATLAB Versions	Supported Features	Compression	Maximum Size of Each Variable
'-v4'	All	Two-dimensional double, character, and sparse arrays	No	100,000,000 elements per array, and $2^{31}$ bytes per variable

If any data items require features that the specified version does not support, MATLAB does not save those items and issues a warning. You cannot specify a version later than your current version of MATLAB software.

---

**Note:** Version 7.3 MAT-files use an HDF5 based format that requires some overhead storage to describe the contents of the file. For cell arrays, structure arrays, or other containers that can store heterogeneous data types, Version 7.3 MAT-files are sometimes larger than Version 7 MAT-files.

---

To view or set the default version for MAT-files, select a **MAT-file save format** option in the General Preferences.

## More About

### Tips

- For more flexibility in creating ASCII files, use `dlmwrite` or `fprintf`.
- Saving graphics objects with the `save` function can result in a large file since the file contains all the information required to regenerate the object.
- Avoid saving figures with the `save` function. Use the `savefig` function instead. Using `save` to save a figure in R2014b or later makes MAT-file inaccessible in earlier versions of MATLAB. If you use `save` to save a figure, then the function displays a warning message. Delete any figures before using `save`. Keep in mind that the figures might not be directly in your workspace. For example, they might be stored in a structure or in the workspace of a callback function.

**Introduced before R2006a**

## save (COM)

Serialize control object to file

### Syntax

```
save(h, 'filename')
```

### Description

`save(h, 'filename')` saves the COM control object, `h`, to the file specified in the string, `filename`.

---

**Note** The COM save function is only supported for controls.

---

### Examples

Create an `mwsamp` control and save its original state to the file `mwsample`.

```
f = figure('position',[100 200 200 200]);
h = actxcontrol('mwsamp.mwsampctrl1.2',[0 0 200 200],f);
save(h, 'mwsample')
```

Alter the figure by changing its label and the radius of the circle.

```
h.Label = 'Circle';
h.Radius = 50;
Redraw(h)
```

Restore the control to its original state using the `load` function.

```
load(h, 'mwsample')
get(h)
```

```
ans =
 Label: 'Label'
 Radius: 20
```

## More About

### Tips

COM functions are available on Microsoft Windows systems only.

**Introduced before R2006a**

## save (serial)

Save serial port objects and variables to file

### Syntax

```
save filename
save filename obj1 obj2...
```

### Description

`save filename` saves all MATLAB variables to the file `filename`. If an extension is not specified for `filename`, then the `.mat` extension is used.

`save filename obj1 obj2...` saves the serial port objects `obj1 obj2...` to the file `filename`.

### Examples

This example illustrates how to use the command and functional form of `save` on a Windows platform.

```
s = serial('COM1');
set(s,'BaudRate',2400,'StopBits',1)
save MySerial1 s
set(s,'BytesAvailableFcn',@mycallback)
save('MySerial2','s')
```

### More About

#### Tips

You can use `save` in the functional form as well as the command form shown above. When using the functional form, you must specify the filename and serial port objects as strings. For example, to save the serial port object `s` to the file `MySerial.mat` on a Windows platform

```
s = serial('COM1');
save('MySerial','s')
```

Any data that is associated with the serial port object is not automatically stored in the file. For example, suppose there is data in the input buffer for `obj`. To save that data to a file, you must bring it into the MATLAB workspace using one of the synchronous read functions, and then save to the file using a separate variable name. You can also save data to a text file with the `record` function.

You return objects and variables to the MATLAB workspace with the `load` command. Values for read-only properties are restored to their default values upon loading. For example, the `Status` property is restored to `closed`. To determine if a property is read-only, examine its reference pages.

## See Also

`load` | `record` | `Status`

**Introduced before R2006a**

## saveas

Save figure to specific file format

### Syntax

```
saveas(fig,filename)
saveas(fig,filename,formattype)
```

### Description

`saveas(fig,filename)` saves the figure or Simulink block diagram specified by `fig` to file `filename`. Specify the file name as a string that includes a file extension, for example, `'myplot.jpg'`. The file extension defines the file format. If you do not specify an extension, then `saveas` saves the figure to a FIG-file. To save the current figure, specify `fig` as `gcf`.

`saveas(fig,filename,formattype)` creates the file using the specified file format, `formattype`. If you do not specify a file extension in the file name, for example, `'myplot'`, then the standard extension corresponding to the specified format automatically appends to the file name. If you specify a file extension, it does not have to match the format. `saveas` uses `formattype` for the format, but saves the file with the specified extension. Thus, the file extension might not match the actual format used.

### Examples

#### Save Figure as PNG File

Create a bar chart and save it as a PNG file.

```
x = [2 4 7 2 4 5 2 5 1 4];
bar(x);
saveas(gcf, 'Barchart.png')
```

#### Save Figure as EPS File

Create a bar chart and save it as an EPS file. Specify the `'epsc'` driver to save it in color.

```
x = [2 4 7 2 4 5 2 5 1 4];
bar(x);
saveas(gcf, 'Barchart', 'eps')
```

saveas saves the bar chart as Barchart.eps.

### Save Simulink Block Diagram as BMP File

Save a Simulink block diagram named 'sldemo\_tank' as a BMP file. Use `get_param` to get the handle of the diagram. You must have Simulink installed to run this code.

```
sldemo_tank
fig = get_param('sldemo_tank', 'Handle');
saveas(fig, 'MySimulinkDiagram.bmp');
```

- “Save Figure for Document or Presentation”

## Input Arguments

### **fig** — Figure to save

figure object | Simulink block diagram

Figure to save, specified as a figure object or a Simulink block diagram. If you specify other types of graphics objects, such as an axes, then `saveas` saves the parent figure to the object. This means that `saveas` cannot save a subplot without also saving all subplots in the parent figure.

Example: `saveas(gcf, 'MyFigure.png')`

To save a Simulink block diagram, use `get_param` to get the handle of the diagram. For example, save a block diagram named 'sldemo\_tank'.

```
sldemo_tank
saveas(get_param('sldemo_tank', 'Handle'), 'MySimulinkDiagram.bmp');
```

### **filename** — File name

string

File name, specified as a string with or without a file extension.

Example: 'Bar Chart'

Example: 'Bar Chart.png'

If you specify a file extension, then `saveas` uses the associated format. If you specify a file extension and additionally specify the `formattype` input argument, then `saveas` uses `formattype` for the format and saves the file with the specified file name. Thus, the file extension might not match the actual format used.

You can specify any extension corresponding to a file format. This table lists some common file extensions.

Extension	Resulting Format
.fig	MATLAB FIG-file (invalid for Simulink block diagrams)
.m	MATLAB FIG-file and MATLAB code that opens figure (invalid for Simulink block diagrams)
.jpg	JPEG image
.png	Portable Network Graphics
.eps	EPS Level 3 Black and White
.pdf	Portable Document Format
.bmp	Windows bitmap
.emf	Enhanced metafile
.pbm	Portable bitmap
.pcx	Paintbrush 24-bit
.pgm	Portable Graymap
.ppm	Portable Pixmap
.tif	TIFF image, compressed

**formattype — File format**

'fig' | 'm' | 'mfig' | bitmap image file format | vector graphics file format

File format, specified as one of these options:

- 'fig' — Save the figure as a MATLAB figure file with the .fig extension. To open figures saved with the .fig extension, use the `openfig` function. This format is not value for Simulink block diagrams.

- 'm' or 'mfig' — Save the figure as a MATLAB figure file and additionally create a MATLAB file that opens the figure. To open the figure, run the MATLAB file. This option is not valid for Simulink block diagrams.
- Bitmap image file format — Specify the format as one of the bitmap image options in the table, Bitmap Image Formats.
- Vector graphics file format — Specify the format as one of the vector graphics options in the table, Vector Graphics Formats.

## Bitmap Image File

Bitmap images contain a pixel-based representation of the figure. The size of the generated file depends on the figure, the format, and your system resolution. Bitmap images are widely used by web browsers and other applications that display graphics. However, they do not scale well and you cannot modify individual graphics objects (such as lines and text) in other graphics applications.

### Bitmap Image Formats

Option	Format	Default File Extension
'jpeg'	JPEG 24-bit	.jpg
'png'	PNG 24-bit	.png
'tiff'	TIFF 24-bit (compressed)	.tif
'tiffn'	TIFF 24-bit (not compressed)	.tif
'meta'	Enhanced metafile (Windows only)	.emf
'bpmmono'	BMP Monochrome	.bmp
'bmp'	BMP 24-bit	.bmp
'bmp16m'	BMP 24-bit	.bmp
'bmp256'	BMP 8-bit (256 color, uses a fixed colormap)	.bmp
'hdf'	HDF 24-bit	.hdf
'pbm'	PBM (plain format) 1-bit	.pbm
'pbmraw'	PBM (raw format) 1-bit	.pbm

Option	Format	Default File Extension
'pcxmono'	PCX 1-bit	.pcx
'pcx24b'	PCX 24-bit color (three 8-bit planes)	.pcx
'pcx256'	PCX 8-bit newer color (256 color)	.pcx
'pcx16'	PCX older color (EGA/VGA 16-color)	.pcx
'pgm'	PGM (plain format)	.pgm
'pgmraw'	PGM (raw format)	.pgm
'ppm'	PPM (plain format)	.ppm
'ppmraw'	PPM (raw format)	.ppm

## Vector Graphics File

Vector graphics files store commands that redraw the figure. This type of format scales well, but can result in a large file. In some cases, a vector graphics format might not produce the correct 3-D arrangement of objects. Some applications support extensive editing of vector graphics formats, but others do not support editing beyond resizing the graphic. The best practice is to make all the necessary changes while your figure is still in MATLAB.

Typically, `saveas` uses the Painters renderer when generating vector graphics files. For some complex figures, `saveas` uses the OpenGL renderer instead. If it uses the OpenGL renderer, then the vector graphics file contains an embedded image, which might limit the extent to which you can edit the image in other applications. To ensure that `saveas` uses the Painters renderer, set the `Renderer` property for the figure to `'painters'`.

If you set the `Renderer` property for the figure, then `saveas` uses that renderer. Otherwise, it chooses the appropriate renderer. However, if `saveas` chooses a renderer that differs from the renderer used for the figure on the display, then some details of the saved figure can differ from the displayed figure. If necessary, you can make the displayed figure and the saved figure use the same renderer by setting the `Renderer` property for the figure.

### Vector Graphics Formats

Option	Format	Default File Extension
'pdf'	Full page Portable Document Format (PDF) color	.pdf
'eps'	Encapsulated PostScript (EPS) Level 3 black and white	.eps
'epsc'	Encapsulated PostScript (EPS) Level 3 color	.eps
'eps2'	Encapsulated PostScript (EPS) Level 2 black and white	.eps
'epsc2'	Encapsulated PostScript (EPS) Level 2 color	.eps
'meta'	Enhanced Metafile (Windows only)	.emf
'svg'	SVG (scalable vector graphics)	.svg
'ps'	Full-page PostScript (PS) Level 3 black and white	.ps
'psc'	Full-page PostScript (PS) Level 3 color	.ps
'ps2'	Full-page PostScript (PS) Level 2 black and white	.ps
'psc2'	Full-page PostScript (PS) Level 2 color	.ps

---

**Note:** Only PDF and PS formats use the PaperOrientation property of the figure and the left and bottom elements of the PaperPosition property. Other formats ignore these values.

---

## More About

### Tips

- To control the size or resolution when you save a figure, use the `print` function instead.
- The `saveas` function and the **Save As** dialog box (accessed from the **File** menu) do not produce identical results. The **Save As** dialog box produces images at screen resolution and at screen size. The `saveas` function uses a resolution of 150 DPI and uses the `PaperPosition` and `PaperPositionMode` properties of the figure to determine the size of the image.
- Details of saved and printed figures can differ from the figure on the display. To get output that is more consistent with the display, see “Save Figure Preserving Background Color” and “Save Figure at Specific Size and Resolution”.

### See Also

`open` | `print` | `savefig`

**Introduced before R2006a**

# savefig

Save figure and contents to FIG-file

## Syntax

```
savefig(filename)
savefig(H,filename)
savefig(H,filename,'compact')
```

## Description

`savefig(filename)` saves the current figure to a FIG-file named *filename.fig*.

`savefig(H,filename)` saves the figures identified by the graphics array `H` to a FIG-file named *filename.fig*.

`savefig(H,filename,'compact')` saves the specified figures in a FIG-file that can be opened only in MATLAB R2014b or later releases. The `'compact'` option reduces the size of the `.fig` file and the time required to create the file.

## Examples

### Save Current Figure to FIG-File

Create a surface plot of the `peaks` function. Save the figure to the file `PeaksFile.fig`.

```
figure
surf(peaks)
savefig('PeaksFile.fig')
```

To open the saved figure, use the command:

```
openfig('PeaksFile.fig');
```

MATLAB creates a new figure using the saved `.fig` file.

### Save Multiple Figures to FIG-File

Create two plots and store the figure handles in array `h`. Save the figures to the file `TwoFiguresFile.fig`. Close the figures after saving them.

```
h(1) = figure;
z = peaks;
surf(z)

h(2) = figure;
plot(z)

savefig(h, 'TwoFiguresFile.fig')
close(h)
```

To open the two figures, use the command:

```
figs = openfig('TwoFiguresFile.fig');
```

`figs` contains the handles of the two figures created.

### Save Figure Using 'compact' Option

Save a figure using the compact option:

```
h = figure
surf(peaks)
savefig(h, 'PeaksFile.fig', 'compact')
```

To open the figure, use the command:

```
openfig('PeaksFile.fig');
```

- “Save Figure for Document or Presentation”

## Input Arguments

### **H** — One or more figures

single figure | array of figures

One or more figures, specified as a single figure or an array of figures.

**filename** — File name`'Untitled.fig'` (default) | string

File name, specified as a string. If you do not specify a file name, then MATLAB saves the file as `Untitled.fig`, which is the default.

If the specified string does not include a `.fig` file extension, then MATLAB appends the extension. `savefig` does not accept other file extensions.

Example: `'ExampleFile.fig'`

**'compact'** — File format for R2014b or later releases`'compact'`

File format for R2014b or later releases of MATLAB, specified as the string `'compact'`. This option results in smaller `.fig` files. However, do not use the `'compact'` option if you want to open the `.fig` file in versions of MATLAB before R2014b.

## More About

### Tips

- You must use MATLAB to open files saved using `savefig`. To open the file, pass the file name to the function `openfig` or `open`. For example,  

```
openfig('ExampleFile.fig')
```

opens the file, `ExampleFile.fig`, in MATLAB.
- `savefig` saves the full MATLAB figure. To save only part of a figure, such as an axes, or to save handles in addition to the data, use the `save` function to create a MAT-file.

### See Also

`findobj` | `load` | `open` | `openfig` | `save`**Introduced in R2013b**

## saveobj

Modify save process for object

### Syntax

```
b = saveobj(a)
```

### Description

`b = saveobj(a)` is called by the `save` function if the class of `a` defines a `saveobj` method. `save` writes the returned value, `b`, to the MAT-file.

Define a `loadobj` method to take the appropriate action when loading the object.

If `A` is an array of objects, MATLAB invokes `saveobj` separately for each object saved.

### Examples

Call the superclass `saveobj` method from the subclass implementation of `saveobj` with the following syntax:

```
classdef mySub < super
 methods
 function sobj = saveobj(obj)
 % Call superclass saveobj method
 sobj = saveobj@super(obj);
 % Perform subclass save operations
 ...
 end
 end
 ...
end
...
end
```

Update object when saved:

```
function b = saveobj(a)
```

```
% If the object does not have an account number,
% Add account number to AccountNumber property
if isempty(a.AccountNumber)
 a.AccountNumber = getAccountNumber(a);
end
b = a;
end
```

## See Also

save | load | loadobj

**Introduced before R2006a**

## savepath

Save current search path

### Syntax

```
savepath
savepath folderName/pathdef.m

status = savepath(___)
```

### Description

`savepath` saves the current MATLAB search path to an existing `pathdef.m` file in the current folder. If there is no `pathdef.m` file in the current folder, then `savepath` saves the search path to the first `pathdef.m` file on the current path. If there is no such file on the current path, then `savepath` saves the search path to the `pathdef.m` file that MATLAB located at startup.

On a Windows system with User Account Control (UAC) enabled, you might be prompted to allow the update operation because it requires administrator-level permission.

`savepath folderName/pathdef.m` saves the current search path to `pathdef.m` located in the folder specified by `folderName`. If you do not specify `folderName`, then `savepath` saves `pathdef.m` in the current folder.

Use this syntax if you do not have write access to the current `pathdef.m` file.

`status = savepath( ___ )` additionally indicates if the operation is successful, using any of the input arguments in the previous syntaxes. The `status` output is 0 when `savepath` is successful, and 1 otherwise.

### Examples

#### Save Search Path to Specific Folder

Save the current search path to `pathdef.m` located in the folder, `I:/my_matlab_files`.

```
savepath I:/my_matlab_files/pathdef.m
```

## Input Arguments

**folderName** — Folder name

string

Folder name, specified as a string. `folderName` can be a relative or absolute path.

Example: `C:\myFolder`

## More About

### Tips

- To display the paths to all `pathdef.m` files in the current folder and on the current search path, use `which`.  

```
which pathdef.m -all
```

The `savepath` command updates the first `pathdef.m` file in this list.
- To save the search path programmatically each time you exit MATLAB, use `savepath` in a `finish.m` file.
- To save a search path and automatically use it in a future session, use the `savepath folderName/pathdef.m` syntax and set the folder specified by `folderName` as the MATLAB startup folder.
- “What Is the MATLAB Search Path?”
- “Running a Script When Exiting”

Introduced before R2006a

## **scatter**

Scatter plot

### **Syntax**

```
scatter(x,y)
scatter(x,y,a)
scatter(x,y,a,c)
scatter(____, 'filled')
scatter(____, markertype)
scatter(____, Name, Value)
```

```
scatter(ax, ____)
```

```
s = scatter(____)
```

### **Description**

`scatter(x,y)` creates a scatter plot with circles at the locations specified by the vectors `x` and `y`. This type of graph is also known as a bubble plot.

`scatter(x,y,a)` specifies the circle areas. To plot each circle with equal area, specify `a` as a scalar. To plot each circle with a different area, specify `a` as a vector with length equal to the length of `x` and `y`.

`scatter(x,y,a,c)` specifies the circle colors. To plot all circles with the same color, specify `c` as a single color string or an RGB triplet. To use varying color, specify `c` as a vector or a three-column matrix of RGB triplets.

`scatter( ____, 'filled' )` fills in the circles. Use the `'filled'` option with any of the input argument combinations in the previous syntaxes.

`scatter( ____, markertype )` specifies the marker type.

`scatter( ____, Name, Value )` specifies scatter series properties using one or more `Name, Value` pair arguments. For example, `'LineWidth', 2` sets the marker outline width to 2 points.

`scatter(ax, ___)` plots into the axes specified by `ax` instead of into the current axes. The option `ax` can precede any of the input argument combinations in the previous syntaxes.

`s = scatter( ___)` returns the scatter series object. Use `s` to make future modifications to the scatter series after it is created.

## Examples

### Create Scatter Plot

Create `x` as 200 equally spaced values between 0 and  $3\pi$ . Create `y` as cosine values with random noise. Then, create a scatter plot.

```
x = linspace(0,3*pi,200);
y = cos(x) + rand(1,200);
scatter(x,y)
```

## Vary Circle Size

Create a scatter plot using circles with different areas.

```
x = linspace(0,3*pi,200);
y = cos(x) + rand(1,200);
a = linspace(1,100,200);
scatter(x,y,a)
```

Corresponding elements in  $x$ ,  $y$ , and  $a$  determine the location and area of each circle. To plot all circles with the equal area, specify  $a$  as a numeric scalar.

### Vary Circle Color

Create a scatter plot and vary the circle color.

```
x = linspace(0,3*pi,200);
y = cos(x) + rand(1,200);
c = linspace(1,10,length(x));
scatter(x,y,[],c)
```

Corresponding elements in `x`, `y`, and `c` determine the location and color of each circle. The `scatter` function maps the elements in `c` to colors in the current colormap.

### Fill the Markers

Create a scatter plot and fill in the markers. `scatter` fills each marker using the color of the marker edge.

```
x = linspace(0,3*pi,200);
y = cos(x) + rand(1,200);
a = 25;
c = linspace(1,10,length(x));
scatter(x,y,a,c,'filled')
```

### Specify Marker Symbol

Create vectors  $x$  and  $y$  as sine and cosine values with random noise. Then, create a scatter plot and use diamond markers with an area of 140 points squared.

```
theta = linspace(0,2*pi,150);
x = sin(theta) + 0.75*rand(1,150);
y = cos(theta) + 0.75*rand(1,150);
a = 140;
scatter(x,y,a,'d')
```

### Change Marker Color and Line Width

Create vectors  $x$  and  $y$  as sine and cosine values with random noise. Create a scatter plot and set the marker edge color, marker face color, and line width.

```
theta = linspace(0,2*pi,300);
x = sin(theta) + 0.75*rand(1,300);
y = cos(theta) + 0.75*rand(1,300);
a = 40;
scatter(x,y,a,'MarkerEdgeColor',[0 .5 .5],...
 'MarkerFaceColor',[0 .7 .7],...
 'LineWidth',1.5)
```

### Specify Subplot for Scatter Plot

Create a figure with two subplots and add a scatter plot to each subplot. Use filled diamond markers for the scatter plot in the lower subplot.

```
x = linspace(0,3*pi,200);
y = cos(x) + rand(1,200);
ax1 = subplot(2,1,1);
scatter(ax1,x,y)

ax2 = subplot(2,1,2);
scatter(ax2,x,y,'filled','d')
```

## Modify Scatter Series After Creation

Create a scatter plot and return the scatter series object, `s`.

```
theta = linspace(0,1,500);
x = exp(theta).*sin(100*theta);
y = exp(theta).*cos(100*theta);
s = scatter(x,y);
```

Use `s` to query and set properties of the scatter series after it has been created. Set the line width to `0.6` point. Set the marker edge color to blue. Set the marker face color using an RGB triplet color. Starting in R2014b, you can use dot notation to set properties. If you are using an earlier release, use the `set` function instead.

```
s.LineWidth = 0.6;
s.MarkerEdgeColor = 'b';
s.MarkerFaceColor = [0 0.5 0.5];
```

## Input Arguments

### **x — x values**

vector

x values, specified as a vector. x and y must be vectors of equal length.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical

### **y — y values**

vector

$y$  values, specified as a vector.  $x$  and  $y$  must be vectors of equal length.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

### **a** — Marker area

36 (default) | numeric scalar | row or column vector | []

Marker area, specified in one of these forms:

- Numeric scalar — Plot all markers with equal area.
- Row or column vector — Use different areas for each marker. Corresponding elements in  $x$ ,  $y$ , and  $a$  determine the location and area of each marker. The length of  $a$  must equal the length of  $x$  and  $y$ .
- [] — Use the default area of 36 points squared.

The units for the marker area is points squared.

Example: 50

Example: [36 25 25 17 46]

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

### **c** — Marker color

[0 0 1] (default) | color string | RGB triplet | three-column matrix of RGB triplets | vector

Marker color, specified in one of these forms:

- Color string or RGB triplet — Plot all markers with the same color.
- Three column matrix of RGB triplets — Use different colors for each marker. Each row of the matrix specifies an RGB triplet color for the corresponding marker. The number of rows must equal the length of  $x$  and  $y$ .
- Vector — Use different colors for each marker and linearly map values in  $c$  to the colors in the current colormap. The length of  $c$  must equal the length of  $x$  and  $y$ . To change the colormap for the axes, use the `colormap` function.

If you have three points in the scatter plot and want the colors to be indices into the colormap, specify  $c$  as a three-element column vector.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range  $[0, 1]$ , for example,  $[0.4 \ 0.6 \ 0.7]$ . This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[1 1 0]
'magenta'	'm'	[1 0 1]
'cyan'	'c'	[0 1 1]
'red'	'r'	[1 0 0]
'green'	'g'	[0 1 0]
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]
'black'	'k'	[0 0 0]

Example: 'k'

Example: [1 2 3 4]

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical | char

**markertype — Marker type**

'o' (default) | '+' | '\*' | '.' | ...

Marker type, specified as one of the strings listed in this table.

String	Marker Symbol
'o'	Circle
'+'	Plus sign
'*'	Asterisk
'.'	Point
'x'	Cross
'square' or 's'	Square
'diamond' or 'd'	Diamond
'^'	Upward-pointing triangle

String	Marker Symbol
'v'	Downward-pointing triangle
'>'	Right-pointing triangle
'<'	Left-pointing triangle
'pentagram' or 'p'	Five-pointed star (pentagram)
'hexagram' or 'h'	Six-pointed star (hexagram)
'none'	No markers

### 'filled' — Option to fill interior of markers

'filled'

Option to fill the interior of the markers, specified as 'filled'. Use this option with markers that have a face, for example, 'o' or 'square'. Markers that do not have a face and contain only edges do not draw ('+', '\*', '.', and 'x').

The 'filled' option sets the MarkerFaceColor property of the scatter series to 'flat' and the MarkerEdgeColor property to 'none', so the marker faces draw, but the edges do not.

### ax — Axes object

axes object

Axes object. If you do not specify an axes, then the scatter function uses the current axes.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Example: 'MarkerFaceColor', 'red' sets the marker face color to red.

The scatter series properties listed here are only a subset. For a complete list, see Scatter Series Properties.

### 'MarkerEdgeColor' — Marker outline color

'flat' (default) | 'none' | RGB triplet | color string

Marker outline color, specified as one of these values:

- 'flat' — Colors defined by the CData property.
- 'none' — No color, which makes unfilled markers invisible.
- RGB triplet or color string — Specify a custom color.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0, 1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[1 1 0]
'magenta'	'm'	[1 0 1]
'cyan'	'c'	[0 1 1]
'red'	'r'	[1 0 0]
'green'	'g'	[0 1 0]
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]
'black'	'k'	[0 0 0]

Example: [0.5 0.5 0.5]

Example: 'blue'

**'MarkerFaceColor' — Marker fill color**

'none' (default) | 'flat' | 'auto' | RGB triplet | color string

Marker fill color, specified as one of these values:

- 'none' — No color, which makes the interior invisible.
- 'flat' — Colors defined by the CData property.
- 'auto' — Same color as the Color property for the axes.
- RGB triplet or color string — Specify a custom color.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range

[0, 1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[1 1 0]
'magenta'	'm'	[1 0 1]
'cyan'	'c'	[0 1 1]
'red'	'r'	[1 0 0]
'green'	'g'	[0 1 0]
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]
'black'	'k'	[0 0 0]

Example: [0.3 0.2 0.1]

Example: 'green'

### 'LineWidth' — Width of marker edge

0.5 (default) | positive value

Width of marker edge, specified as a positive value in point units.

Example: 0.75

## Output Arguments

### s — Scatter series object

scatter series object

Scatter series object. Use **s** to access and modify properties of the scatter series after it has been created.

## scatter3

3-D scatter plot

### Syntax

```
scatter3(X,Y,Z)
scatter3(X,Y,Z,S)
scatter3(X,Y,Z,S,C)
scatter3(____, 'filled')
scatter3(____, markertype)
scatter3(____, Name, Value)
```

```
scatter3(ax, ____)
```

```
h = scatter3(____)
```

### Description

`scatter3(X,Y,Z)` displays circles at the locations specified by the vectors `X`, `Y`, and `Z`.

`scatter3(X,Y,Z,S)` draws each circle with the size specified by `S`. To plot each circle with equal size, specify `S` as a scalar. To plot each circle with a specific size, specify `S` as a vector.

`scatter3(X,Y,Z,S,C)` draws each circle with the color specified by `C`.

- If `C` is a color string or an RGB row vector, then all circles are plotted with the specified color.
- If `C` is a three column matrix with the number of rows in `C` equal to the length of `X`, `Y`, and `Z`, then each row of `C` specifies an RGB color value for the corresponding circle.
- If `C` is a vector with length equal to the length of `X`, `Y`, and `Z`, then the values in `C` are linearly mapped to the colors in the current colormap.

`scatter3( ____, 'filled' )` fills in the circles, using any of the input argument combinations in the previous syntaxes.

`scatter3( ____, markerType)` specifies the marker type.

`scatter3( ____, Name, Value)` specifies scatter series properties using one or more `Name, Value` pair arguments.

`scatter3(ax, ____,)` plots into the axes specified by `ax` instead of into the current axes (`gca`). The `ax` option can precede any of the input argument combinations in the previous syntaxes.

`h = scatter3( ____,)` returns the scatter series object. Use `h` to modify properties of the scatter series after it is created.

## Examples

### Create 3-D Scatter Plot

Create a 3-D scatter plot. Use `sphere` to define vectors `x`, `y`, and `z`.

```
figure
[X,Y,Z] = sphere(16);
x = [0.5*X(:); 0.75*X(:); X(:)];
y = [0.5*Y(:); 0.75*Y(:); Y(:)];
z = [0.5*Z(:); 0.75*Z(:); Z(:)];
scatter3(x,y,z)
```

### Vary Marker Size

Use `sphere` to define vectors `x`, `y`, and `z`.

```
[X,Y,Z] = sphere(16);
x = [0.5*X(:); 0.75*X(:); X(:)];
y = [0.5*Y(:); 0.75*Y(:); Y(:)];
z = [0.5*Z(:); 0.75*Z(:); Z(:)];
```

Define vector `s` to specify the marker sizes.

```
S = repmat([100,50,5],numel(X),1);
s = S(:);
```

Create a 3-D scatter plot and use `view` to change the angle of the axes in the figure.

```
figure
scatter3(x,y,z,s)
view(40,35)
```

Corresponding entries in  $x$ ,  $y$ ,  $z$ , and  $s$  determine the location and size of each marker.

### **Vary Marker Color**

Use `sphere` to define vectors  $x$ ,  $y$ , and  $z$ .

```
[X,Y,Z] = sphere(16);
x = [0.5*X(:); 0.75*X(:); X(:)];
y = [0.5*Y(:); 0.75*Y(:); Y(:)];
```

```
z = [0.5*Z(:); 0.75*Z(:); Z(:)];
```

Define vectors `s` and `c` to specify the size and color of each marker.

```
S = repmat([50,25,10],numel(X),1);
C = repmat([1,2,3],numel(X),1);
s = S(:);
c = C(:);
```

Create a 3-D scatter plot and use `view` to change the angle of the axes in the figure.

```
figure
scatter3(x,y,z,s,c)
view(40,35)
```

Corresponding entries in **x**, **y**, **z**, and **c** determine the location and color of each marker.

**Fill in Markers**

Create vectors **x** and **y** as cosine and sine values with random noise.

```
z = linspace(0,4*pi,250);
x = 2*cos(z) + rand(1,250);
y = 2*sin(z) + rand(1,250);
```

Create a 3-D scatter plot and fill in the markers. Use **view** to change the angle of the axes in the figure.

```
scatter3(x,y,z,'filled')
view(-30,10)
```

### Set Marker Type

Initialize the random-number generator to make the output of `rand` repeatable. Define vectors `x` and `y` as cosine and sine values with random noise.

```
rng default
z = linspace(0,4*pi,250);
x = 2*cos(z) + rand(1,250);
y = 2*sin(z) + rand(1,250);
```

Create a 3-D scatter plot and set the marker type. Use `view` to change the angle of the axes in the figure.

```
figure
```

```
scatter3(x,y,z,'*')
view(-30,10)
```

## Set Marker Properties

Initialize the random-number generator to make the output of `rand` repeatable. Define vectors `x` and `y` as cosine and sine values with random noise.

```
rng default
z = linspace(0,4*pi,250);
x = 2*cos(z) + rand(1,250);
y = 2*sin(z) + rand(1,250);
```

Create a 3-D scatter plot and set the marker edge color and the marker face color. Use `view` to change the angle of the axes in the figure.

```
figure
scatter3(x,y,z,...
 'MarkerEdgeColor','k',...
 'MarkerFaceColor',[0 .75 .75])
view(-30,10)
```

### Specify Axes for 3-D Scatter Plot

Load the seamount data set to get vectors  $x$ ,  $y$ , and  $z$ .

```
load seamount
```

Create a figure with two subplots and return the handles to the two axes in array  $hS$ . In each subplot, create a 3-D scatter plot. Specify the marker properties for each scatter plot.

```
figure
hs(1) = subplot(2,1,1);
hs(2) = subplot(2,1,2);
scatter3(hs(1),x,y,z,'MarkerFaceColor',[0 .75 .75])
scatter3(hs(2),x,y,z,'*')
```

## Set Scatter Series Properties Using Handle

Use the `sphere` function to create vectors `x`, `y`, and `z`.

```
[X,Y,Z] = sphere(16);
x = [0.5*X(:); 0.75*X(:); X(:)];
y = [0.5*Y(:); 0.75*Y(:); Y(:)];
z = [0.5*Z(:); 0.75*Z(:); Z(:)];
```

Create vectors `s` and `c` to specify the size and color for each marker.

```
S = repmat([70,50,20], numel(X), 1);
C = repmat([1,2,3], numel(X), 1);
s = S(:);
c = C(:);
```

Create a 3-D scatter plot and return the scatter series object.

```
h = scatter3(x,y,z,s,c);
```

Use an RGB triplet color value to set the marker face color. Starting in R2014b, you can use dot notation to set properties. If you are using an earlier release, use the `set` function instead.

```
h.MarkerFaceColor = [0 0.5 0.5];
```

## Input Arguments

### **X** — x values

vector

x values, specified as a vector. X, Y, and Z must be vectors of equal length.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical

**Y — y values**

(default) | vector

y values, specified as a vector. X, Y, and Z must be vectors of equal length.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical

**Z — z values**

(default) | vector

z values, specified as a vector. X, Y, and Z must be vectors of equal length.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical

**S — Marker area**

36 (default) | scalar | vector | []

Marker area, specified as a scalar, a vector, or []. The values in S must be positive. The units for area are points squared.

- If S is a scalar, then `scatter3` plots all markers with the specified area.
- If S is a row or column vector, then each entry in S specifies the area for the corresponding marker. The length of S must equal the length of X, Y and Z. Corresponding entries in X, Y, Z and S determine the location and area of each marker.
- If S is empty, then the default size of 36 points squared is used.

Example: 50

Example: [36, 25, 25, 17, 46]

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical

**C — Marker color**

[0 0 1] (blue) (default) | color string | RGB row vector | three-column matrix of RGB values | vector

Marker color, specified as a color string, an RGB row vector, a three-column matrix of RGB values, or a vector. For an RGB row vector, use a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The

intensities must be in the range [0 1]. If you have three points in the scatter plot and want the colors to be indices into the colormap, specify **C** as a three-element column vector.

This table lists the predefined colors and their RGB equivalents.

RGB Vector	Short Name	Long Name
[1 1 0]	'y'	'yellow'
[1 0 1]	'm'	'magenta'
[0 1 1]	'c'	'cyan'
[1 0 0]	'r'	'red'
[0 1 0]	'g'	'green'
[0 0 1]	'b'	'blue'
[1 1 1]	'w'	'white'
[0 0 0]	'k'	'black'

Example: 'y'

Example: [1,2,3,4]

Example: `reshape([0,1,0,0,0,1,0.5,1,0.2],3,3)`

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical

**markertype — Marker type**

'o' (default) | string

Marker type, specified as a string. The table below lists the supported marker types.

Specifier	Marker Type
'o'	Circle
'+'	Plus sign
'*'	Asterisk
'.'	Point
'x'	Cross
'square' or 's'	Square

Specifier	Marker Type
'diamond' or 'd'	Diamond
'^'	Upward-pointing triangle
'v'	Downward-pointing triangle
'>'	Right-pointing triangle
'<'	Left-pointing triangle
'pentagram' or 'p'	Five-pointed star (pentagram)
'hexagram' or 'h'	Six-pointed star (hexagram)
'none'	No marker

### **ax — Axes object**

axes object

Axes object. If you do not specify an axes, then `scatter3` plots into the current axes.

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'MarkerFaceColor', 'red'` sets the marker face color to red.

The properties listed here are only a subset. For a complete list, see Scatter Series Properties.

### **'LineWidth' — Width of marker edge**

0.5 (default) | positive value

Width of marker edge, specified as a positive value in point units.

Example: 0.75

### **'MarkerEdgeColor' — Marker outline color**

'flat' (default) | 'none' | RGB triplet | color string

Marker outline color, specified as one of these values:

- 'flat' — Colors defined by the CData property.
- 'none' — No color, which makes unfilled markers invisible.
- RGB triplet or color string — Specify a custom color.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0, 1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[1 1 0]
'magenta'	'm'	[1 0 1]
'cyan'	'c'	[0 1 1]
'red'	'r'	[1 0 0]
'green'	'g'	[0 1 0]
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]
'black'	'k'	[0 0 0]

Example: [0.5 0.5 0.5]

Example: 'blue'

**'MarkerFaceColor' — Marker fill color**

'none' (default) | 'flat' | 'auto' | RGB triplet | color string

Marker fill color, specified as one of these values:

- 'none' — No color, which makes the interior invisible.
- 'flat' — Colors defined by the CData property.
- 'auto' — Same color as the Color property for the axes.
- RGB triplet or color string — Specify a custom color.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0, 1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[ 1 1 0 ]
'magenta'	'm'	[ 1 0 1 ]
'cyan'	'c'	[ 0 1 1 ]
'red'	'r'	[ 1 0 0 ]
'green'	'g'	[ 0 1 0 ]
'blue'	'b'	[ 0 0 1 ]
'white'	'w'	[ 1 1 1 ]
'black'	'k'	[ 0 0 0 ]

Example: [0.3 0.2 0.1]

Example: 'green'

## Output Arguments

### **h** — Scatter series object

scalar

Scatter series object, returned as a scalar. This is a unique identifier, which you can use to query and modify the properties of the scatter object after it is created.

## See Also

### Functions

LineStyle | plot3 | scatter

### Properties

Scatter Series Properties

Introduced before R2006a

## Scatter Series Properties

Control scatter series appearance and behavior

Scatter series properties control the appearance and behavior of scatter series object. By changing property values, you can modify certain aspects of the scatter series.

Starting in R2014b, you can use dot notation to query and set properties.

```
s = scatter(1:10,1:10);
m = s.Marker;
s.Marker = '*';
```

If you are using an earlier release, use the `get` and `set` functions instead.

### Markers

#### Marker — Marker symbol

'o' (default) | '+' | '\*' | '.' | 'x' | ...

Marker symbol, specified as one of the strings listed in this table:

String	Marker Symbol
'o'	Circle
'+'	Plus sign
'*'	Asterisk
'.'	Point
'x'	Cross
'square' or 's'	Square
'diamond' or 'd'	Diamond
'^'	Upward-pointing triangle
'v'	Downward-pointing triangle
'>'	Right-pointing triangle
'<'	Left-pointing triangle
'pentagram' or 'p'	Five-pointed star (pentagram)

String	Marker Symbol
'hexagram' or 'h'	Six-pointed star (hexagram)
'none'	No markers

**MarkerEdgeColor — Marker outline color**

'flat' (default) | 'none' | RGB triplet | color string

Marker outline color, specified as one of these values:

- 'flat' — Colors defined by the CData property.
- 'none' — No color, which makes unfilled markers invisible.
- RGB triplet or color string — Specify a custom color.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0, 1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[1 1 0]
'magenta'	'm'	[1 0 1]
'cyan'	'c'	[0 1 1]
'red'	'r'	[1 0 0]
'green'	'g'	[0 1 0]
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]
'black'	'k'	[0 0 0]

Example: [0.5 0.5 0.5]

Example: 'blue'

**MarkerFaceColor — Marker fill color**

'none' (default) | 'flat' | 'auto' | RGB triplet | color string

Marker fill color, specified as one of these values:

- 'none' — No color, which makes the interior invisible.
- 'flat' — Colors defined by the `CData` property.
- 'auto' — Same color as the `Color` property for the axes.
- RGB triplet or color string — Specify a custom color.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range  $[0, 1]$ , for example,  $[0.4 \ 0.6 \ 0.7]$ . This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[1 1 0]
'magenta'	'm'	[1 0 1]
'cyan'	'c'	[0 1 1]
'red'	'r'	[1 0 0]
'green'	'g'	[0 1 0]
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]
'black'	'k'	[0 0 0]

Example: `[0.3 0.2 0.1]`

Example: `'green'`

### **MarkerEdgeAlpha — Edge transparency**

1 (default) | scalar in range  $[0, 1]$

Marker edge transparency, specified as a scalar in the range  $[0, 1]$ . A value of 1 is opaque and 0 is completely transparent. Values between 0 and 1 are semitransparent.

Example: `s.EdgeAlpha = 0.5;`

### **MarkerFaceAlpha — Marker face transparency**

1 (default) | scalar in range  $[0, 1]$

Marker face transparency, specified as a scalar in the range  $[0, 1]$ . A value of 1 is opaque and 0 is completely transparent. Values between 0 and 1 are semitransparent.

Example: `s.FaceAlpha = 0.5;`

### **LineWidth** — Width of marker edge

0.5 (default) | positive value

Width of marker edge, specified as a positive value in point units.

Example: 0.75

## **Data**

### **XData** — x values

[] (default) | scalar | vector

x values, specified as a scalar or a vector. The scatter plot displays an individual marker for each value in **XData**.

The input argument **X** to the `scatter` and `scatter3` functions set the x values. **XData** and **YData** must have equal lengths.

Example: [1 2 4 2 6]

### **YData** — y values

[] (default) | scalar | vector

y values, specified as a scalar or a vector. The scatter plot displays an individual marker for each value in **YData**.

The input argument **Y** to the `scatter` and `scatter3` functions set the y values. **XData** and **YData** must have equal lengths.

Example: [1 3 3 4 6]

### **ZData** — z values

[] (default) | scalar | vector

z values, specified as a scalar or a vector.

- For 2-D scatter plots, **ZData** is empty by default.
- For 3-D scatter plots, the input argument **Z** to the `scatter3` function sets the z values. **XData**, **YData**, and **ZData** must have equal lengths.

Example: [1 2 2 1 0]

**CData — Marker colors**

[] (default) | RGB triplet | matrix of RGB triplets | vector

Marker colors, specified as one of these values:

- RGB triplet — Use the same color for all the markers in the plot. An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0, 1], for example, [0.5 0.6 0.7].
- Three-column matrix of RGB triplets — Use a different color for each marker in the plot. Each row of the matrix defines one color. The number of rows must equal the number of markers.
- Vector — Use a different color for each marker in the plot. Specify **CData** as a vector the same length as **XData**. Linearly map the values in the vector to the colors in the current colormap.

Example: [1 0 0; 0 1 0; 0 0 1]

**SizeData — Marker sizes**

[] (default) | scalar | vector

Marker sizes, specified in one of these forms:

- Scalar — Use the same size for all of the markers.
- Vector — Use a different size for each marker. Specify **SizeData** as a vector the same length as **XData**.

Specify the values in point units, where one point equals 1/72 inch. To specify a marker that has an area of one square inch, use a value of 72<sup>2</sup>.

Example: 50

**XDataSource — Variable linked to XData**

' ' (default) | string containing MATLAB workspace variable name

Variable linked to **XData**, specified as a string containing a MATLAB workspace variable name. MATLAB evaluates the variable in the base workspace to generate the **XData**.

By default, there is no linked variable so the value is an empty string, ' '. If you link a variable, then MATLAB does not update the **XData** values immediately. To force an update of the data values, use the **refreshdata** function.

---

**Note:** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

Example: 'x'

### **YDataSource — Variable linked to YData**

' ' (default) | string containing MATLAB workspace variable name

Variable linked to **YData**, specified as a string containing a MATLAB workspace variable name. MATLAB evaluates the variable in the base workspace to generate the **YData**.

By default, there is no linked variable so the value is an empty string, ' '. If you link a variable, then MATLAB does not update the **YData** values immediately. To force an update of the data values, use the **refreshdata** function.

---

**Note:** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

Example: 'y'

### **ZDataSource — Variable linked to ZData**

' ' (default) | string containing MATLAB workspace variable name

Variable linked to **ZData**, specified as a string containing a MATLAB workspace variable name. MATLAB evaluates the variable in the base workspace to generate the **ZData**.

By default, there is no linked variable so the value is an empty string, ' '. If you link a variable, then MATLAB does not update the **ZData** values immediately. To force an update of the data values, use the **refreshdata** function.

---

**Note:** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

Example: 'z'

## **CDataSource** — Variable linked to CData

' ' | string containing MATLAB workspace variable

Variable linked to **CData**, specified as a string containing a MATLAB workspace variable. MATLAB evaluates the variable in the base workspace to generate the **CData**.

By default, there is no linked variable so the value is an empty string. If you link a variable, then MATLAB does not update the **CData** values immediately. To force an update of the data values, use the **refreshdata** function.

---

**Note:** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

## **SizeDataSource** — Variable linked to SizeData

' ' | string containing MATLAB workspace variable

Variable linked to **SizeData**, specified as a string containing a MATLAB workspace variable. MATLAB evaluates the variable in the base workspace to generate the **SizeData**.

By default, there is no linked variable so the value is an empty string. If you link a variable, then MATLAB does not update the **SizeData** values. To force an update of the data values, use the **refreshdata** function.

---

**Note:** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

## **Visibility**

### **Visible** — State of visibility

'on' (default) | 'off'

State of visibility, specified as one of these values:

- 'on' — Display the scatter series.

- 'off' — Hide the scatter series without deleting it. You still can access the properties of an invisible scatter series object.

### Clipping — Clipping of scatter series object to axes limits

'on' (default) | 'off'

Clipping of the scatter series object to the axes limits, specified as one of these values:

- 'on' — Do not display parts of the scatter series object that are outside the axes limits.
- 'off' — Display the entire scatter series object, even if parts of it appear outside the axes limits. Parts of the scatter series object might appear outside the axes limits if you create a plot, set `hold on`, freeze the axis scaling, and then create the scatter series object so that it is larger than the original plot.

The **Clipping** property of the axes that contains the scatter series object must be set to 'on', otherwise this property has no effect. For more information about the clipping behavior, see the **Clipping** property of the axes.

### EraseMode — (removed) Technique to draw and erase objects

'normal' (default) | 'none' | 'xor' | 'background'

---

**Note:** **EraseMode** has been removed. You can delete code that accesses the **EraseMode** property with minimal impact. If you were using **EraseMode** to create line animations, use the `animatedline` function instead.

---

Technique to draw and erase objects, specified as one of these values:

- 'normal' — Redraw the affected region of the display, performing the three-dimensional analysis necessary to correctly render all objects. This mode produces the most accurate picture, but is the slowest. The other modes are faster, but do not perform a complete redraw and, therefore, are less accurate.
- 'none' — Do not erase the object when it is moved or destroyed. After you erase the object with **EraseMode**, 'none', it is still visible on the screen. However, you cannot print the object because MATLAB does not store any information on its former location.
- 'xor' — Draw and erase the object by performing an exclusive OR (XOR) with the color of the screen beneath it. This mode does not damage the color of the objects

beneath it. However, the object color depends on the color of whatever is beneath it on the display.

- **'background'** — Erase the object by redrawing it in the axes background color, or the figure background color if the axes **Color** property is **'none'**. This damages objects that are behind the erased object, but properly colors the erased object.

MATLAB always prints figures as if the **EraseMode** property of all objects is set to **'normal'**. This means graphics objects created with **EraseMode** set to **'none'**, **'xor'**, or **'background'** can look different on screen than on paper. On screen, MATLAB mathematically combines layers of colors and ignores three-dimensional sorting to obtain greater rendering speed. However, MATLAB does not apply these techniques to the printed output. Use the **getframe** command or other screen capture applications to create an image of a figure containing nonnormal mode objects.

## Identifiers

### **Type — Type of graphics object**

**'scatter'**

This property is read only.

Type of graphics object, returned as **'scatter'**. Use this property to find all objects of a given type within a plotting hierarchy, for example, searching for the type using **findobj**.

### **Tag — Tag to associate with scatter series**

**''** (default) | string

Tag to associate with the scatter series, specified as a string. Tags provide a way to identify graphics objects. Use this property to find all objects with a specific tag within a plotting hierarchy, for example, searching for the tag using **findobj**.

Example: **'January Data'**

### **UserData — Data to associate with scatter series**

**[]** (default) | scalar, vector, or matrix | cell array | character array | table | structure

Data to associate with the scatter series object, specified as a scalar, vector, matrix, cell array, character array, table, or structure. MATLAB does not use this data.

To associate multiple sets of data or to attach a field name to the data, use the **getappdata** and **setappdata** functions.

Example: 1:100

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char` | `struct` | `table` | `cell`

### **DisplayName** — Text used by legend

' ' (default) | string

Text used by the legend, specified as a string. The text appears next to an icon of the scatter series.

Example: `'Text Description'`

For multiline text, create the string using `sprintf` with the new line character `\n`.

Example: `sprintf('line one\nline two')`

Alternatively, you can specify the legend text using the `legend` function.

- If you specify the text as an input argument to the `legend` function, then the legend uses the specified text and sets the `DisplayName` property to the same value.
- If you do not specify the text as an input argument to the `legend` function, then the legend uses the text in the `DisplayName` property. If the `DisplayName` property does not contain any text, then the legend generates a string. The string has the form `'dataN'`, where N is the number assigned to the scatter series object based on its location in the list of legend entries.

If you edit interactively the string in an existing legend, then MATLAB updates the `DisplayName` property to the edited string.

### **Annotation** — Legend icon display style

Annotation object

This property is read only.

Legend icon display style, returned as an `Annotation` object. Use this object to include or exclude the scatter series from a legend.

- 1 Query the `Annotation` property to get the `Annotation` object.
- 2 Query the `LegendInformation` property of the `Annotation` object to get the `LegendEntry` object.
- 3 Specify the `IconDisplayStyle` property of the `LegendEntry` object to one of these values:

- 'on' — Include the scatter series object in the legend as one entry (default).
- 'off' — Do not include the scatter series object in the legend.
- 'children' — Include only children of the scatter series object as separate entries in the legend.

If a legend already exists and you change the `IconDisplayStyle` setting, then you must call `legend` to update the display.

## Parent/Child

### Parent — Parent of scatter series

axes object | group object | transform object

Parent of scatter series, specified as an axes, group, or transform object.

### Children — Children of scatter series

empty `GraphicsPlaceholder` array

The scatter series has no children. You cannot set this property.

### HandleVisibility — Visibility of object handle

'on' (default) | 'off' | 'callback'

Visibility of scatter series object handle in the `Children` property of the parent, specified as one of these values:

- 'on' — The scatter series object handle is always visible.
- 'off' — The scatter series object handle is invisible at all times. This option is useful for preventing unintended changes to the UI by another function. Set the `HandleVisibility` to 'off' to temporarily hide the handle during the execution of that function.
- 'callback' — The scatter series object handle is visible from within callbacks or functions invoked by callbacks, but not from within functions invoked from the command line. This option blocks access to the scatter series at the command-line, but allows callback functions to access it.

If the scatter series object is not listed in the `Children` property of the parent, then functions that obtain object handles by searching the object hierarchy or querying handle properties cannot return it. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

Hidden object handles are still valid. Set the root `ShowHiddenHandles` property to 'on' to list all object handles regardless of their `HandleVisibility` property setting.

## Interactive Control

### **ButtonDownFcn** — Mouse-click callback

' ' (default) | function handle | cell array | string

Mouse-click callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you click the scatter series. If you specify this property using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The scatter series object — You can access properties of the scatter series object from within the callback function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see “Callback Definition”.

---

**Note:** If the `PickableParts` property is set to 'none' or if the `HitTest` property is set to 'off', then this callback does not execute.

---

Example: `@myCallback`

Example: `{@myCallback, arg3}`

### **UIContextMenu** — Context menu

uicontextmenu object

Context menu, specified as a `uicontextmenu` object. Use this property to display a context menu when you right-click the scatter series. Create the context menu using the `uicontextmenu` function.

---

**Note:** If the `PickableParts` property is set to `'none'` or if the `HitTest` property is set to `'off'`, then the context menu does not appear.

---

## **Selected** — Selection state

`'off'` (default) | `'on'`

Selection state, specified as one of these values:

- `'on'` — Selected. If you click the scatter series when in plot edit mode, then MATLAB sets its `Selected` property to `'on'`. If the `SelectionHighlight` property also is set to `'on'`, then MATLAB displays selection handles around the scatter series.
- `'off'` — Not selected.

## **SelectionHighlight** — Display of selection handles when selected

`'on'` (default) | `'off'`

Display of selection handles when selected, specified as one of these values:

- `'on'` — Display selection handles when the `Selected` property is set to `'on'`.
- `'off'` — Never display selection handles, even when the `Selected` property is set to `'on'`.

## **Callback Execution Control**

### **PickableParts** — Ability to capture mouse clicks

`'visible'` (default) | `'none'`

Ability to capture mouse clicks, specified as one of these values:

- `'visible'` — Can capture mouse clicks when visible. The `Visible` property must be set to `'on'` and you must click a part of the scatter series that has a defined color. You cannot click a part that has an associated color property set to `'none'`. If the plot contains markers, then the entire marker is clickable if either the edge or the fill has a defined color. The `HitTest` property determines if the scatter series responds to the click or if an ancestor does.
- `'none'` — Cannot capture mouse clicks. Clicking the scatter series passes the click to the object below it in the current view of the figure window. The `HitTest` property of the scatter series has no effect.

**HitTest — Response to captured mouse clicks**

'on' (default) | 'off'

Response to captured mouse clicks, specified as one of these values:

- 'on' — Trigger the `ButtonDownFcn` callback of the scatter series. If you have defined the `UIContextMenu` property, then invoke the context menu.
- 'off' — Trigger the callbacks for the nearest ancestor of the scatter series that has a `HitTest` property set to 'on' and a `PickableParts` property value that enables the ancestor to capture mouse clicks.

---

**Note:** The `PickableParts` property determines if the scatter series object can capture mouse clicks. If it cannot, then the `HitTest` property has no effect.

---

**HitTestArea — (removed) Extents of clickable area for scatter series**

'off' (default) | 'on'

---

**Note:** `HitTestArea` has been removed. Use `PickableParts` instead.

---

Extents of clickable area for scatter series, specified as one of these values:

- 'off' — Click the scatter series plot to select it. This is the default value.
- 'on' — Click anywhere within the extent of the scatter series plot to select it, that is, anywhere within the rectangle that encloses the scatter series plot.

Example: 'off'

**Interruptible — Callback interruption**

'on' (default) | 'off'

Callback interruption, specified as 'on' or 'off'. The `Interruptible` property determines if a running callback can be interrupted.

---

**Note:** There are two callback states to consider:

- The *running* callback is the currently executing callback.
- The *interrupting* callback is a callback that tries to interrupt the running callback.

Whenever MATLAB invokes a callback, that callback attempts to interrupt a running callback. The `Interruptible` property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the `BusyAction` property of the object owning the interrupting callback determines if it is discarded or put in the queue.

---

If the `ButtonDownFcn` callback of the scatter series is the running callback, then the `Interruptible` property determines if it another callback can interrupt it:

- 'on' — Interruptible. Interruption occurs at the next point where MATLAB processes the queue, such as when there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command.
  - If the running callback contains one of these commands, then MATLAB stops the execution of the callback at this point and executes the interrupting callback. MATLAB resumes executing the running callback when the interrupting callback completes. For more information, see “Interrupt Callback Execution”.
  - If the running callback does not contain one of these commands, then MATLAB finishes executing the callback without interruption.
- 'off' — Not interruptible. MATLAB finishes executing the running callback without any interruptions.

### **BusyAction — Callback queuing**

'queue' (default) | 'cancel'

Callback queuing specified as 'queue' or 'cancel'. The `BusyAction` property determines how MATLAB handles the execution of interrupting callbacks.

---

**Note:** There are two callback states to consider:

- The *running* callback is the currently executing callback.
- The *interrupting* callback is a callback that tries to interrupt the running callback.

Whenever MATLAB invokes a callback, that callback attempts to interrupt a running callback. The `Interruptible` property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the `BusyAction` property of the object owning the interrupting callback determines if it is discarded or put in the queue.

---

If the `ButtonDownFcn` callback of the scatter series tries to interrupt a running callback that cannot be interrupted, then the `BusyAction` property determines if it is discarded or put in the queue. Specify the `BusyAction` property as one of these values:

- `'queue'` — Put the interrupting callback in a queue to be processed after the running callback finishes execution. This is the default behavior.
- `'cancel'` — Discard the interrupting callback.

## Creation and Deletion Control

### CreateFcn — Creation callback

`''` (default) | function handle | cell array | string

Creation callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you create the scatter series. Setting the `CreateFcn` property on an existing scatter series has no effect. You must define a default value for this property, or define this property using a `Name, Value` pair during scatter series creation. MATLAB executes the callback after creating the scatter series and setting all of its properties.

If you specify this callback using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The scatter series object — You can access properties of the scatter series object from within the callback function. You also can access the scatter series object through the `CallbackObject` property of the root, which can be queried using the `gcbo` function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see “Callback Definition”.

Example: `@myCallback`

Example: `{@myCallback, arg3}`

**DeleteFcn — Deletion callback**

' ' (default) | function handle | cell array | string

Deletion callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you delete the scatter series. MATLAB executes the callback before destroying the scatter series so that the callback can access its property values.

If you specify this callback using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The scatter series object — You can access properties of the scatter series object from within the callback function. You also can access the scatter series object through the `CallbackObject` property of the root, which can be queried using the `gcbo` function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see “Callback Definition”.

Example: `@myCallback`

Example: `{@myCallback, arg3}`

**BeingDeleted — Deletion status of scatter series**

'off' (default) | 'on'

This property is read only.

Deletion status of scatter series, returned as 'on' or 'off'. MATLAB sets the `BeingDeleted` property to 'on' when the delete function of the scatter series begins execution (see the `DeleteFcn` property). The `BeingDeleted` property remains set to 'on' until the scatter series no longer exists.

Check the value of the `BeingDeleted` property to verify that the scatter series is not about to be deleted before querying or modifying it.

## schur

Schur decomposition

### Syntax

```
T = schur(A)
T = schur(A,flag)
[U,T] = schur(A,...)
```

### Description

The `schur` command computes the Schur form of a matrix.

`T = schur(A)` returns the Schur matrix `T`.

`T = schur(A,flag)` for real matrix `A`, returns a Schur matrix `T` in one of two forms depending on the value of `flag`:

'complex'	<code>T</code> is triangular and is complex if <code>A</code> is real and has complex eigenvalues.
'real'	<code>T</code> has the real eigenvalues on the diagonal and the complex eigenvalues in 2-by-2 blocks on the diagonal. 'real' is the default when <code>A</code> is real.

If `A` is complex, `schur` returns the complex Schur form in matrix `T` and `flag` is ignored. The complex Schur form is upper triangular with the eigenvalues of `A` on the diagonal.

The function `rsf2csf` converts the real Schur form to the complex Schur form.

`[U,T] = schur(A,...)` also returns a unitary matrix `U` so that  $A = U^*T^*U'$  and  $U^*U = \text{eye}(\text{size}(A))$ .

### Examples

`H` is a 3-by-3 eigenvalue test matrix:

```
H = [-149 -50 -154
 537 180 546
 -27 -9 -25]
```

Its Schur form is

```
schur(H)
```

```
ans =
 1.0000 -7.1119 -815.8706
 0 2.0000 -55.0236
 0 0 3.0000
```

The eigenvalues, which in this case are 1, 2, and 3, are on the diagonal. The fact that the off-diagonal elements are so large indicates that this matrix has poorly conditioned eigenvalues; small changes in the matrix elements produce relatively large changes in its eigenvalues.

## scatteredInterpolant class

Scattered data interpolation

### Description

Use `scatteredInterpolant` to perform interpolation on a 2-D or 3-D “Scattered Data” on page 1-7933 set. For example, you can pass a set of  $(x, y)$  points and values,  $v$ , to `scatteredInterpolant`, and it returns a surface of the form  $v = F(x, y)$ . This surface always passes through the sample values at the point locations. You can evaluate this surface at any query point,  $(xq, yq)$ , to produce an interpolated value,  $vq$ .

Use `scatteredInterpolant` to create the “Interpolant” on page 1-7933, F. Then, you can evaluate F at specific points using any of the following syntaxes:

- $Vq = F(Pq)$  specifies the query points in the matrix  $Pq$ . Each row in  $Pq$  contains the coordinates of a query point.
- $Vq = F(Xq, Yq)$  and  $Vq = F(Xq, Yq, Zq)$  specify the query points as two or three matrices of equal size.
- $Vq = F(\{xq, yq\})$  and  $Vq = F(\{xq, yq, zq\})$  specify the query points as “Grid Vectors” on page 1-7933. The interpolated values are returned in  $Vq$ . Use this syntax to conserve memory when you want to query a large grid of points.

### Construction

$F = \text{scatteredInterpolant}(x, y, v)$  creates an interpolant that fits a surface of the form  $v = F(x, y)$ . Vectors  $x$  and  $y$  specify the  $(x, y)$  coordinates of the sample points.  $v$  is a vector that contains the sample values associated with the points,  $(x, y)$ .

$F = \text{scatteredInterpolant}(x, y, z, v)$  creates a 3-D interpolant of the form  $v = F(x, y, z)$ .

$F = \text{scatteredInterpolant}(P, v)$  specifies the coordinates of the sample points as an array. The rows of  $P$  contain the  $(x, y)$  or  $(x, y, z)$  coordinates for the values in  $v$ .

$F = \text{scatteredInterpolant}(\text{___}, \text{Method})$  specifies a string that describes an interpolation method: 'nearest', 'linear', or 'natural'. Specify `Method` as the last input argument in any of the first three syntaxes.

`F = scatteredInterpolant( ____, Method, ExtrapolationMethod)` specifies both the interpolation and extrapolation methods as strings. `Method` can be one of three strings: 'nearest', 'linear', or 'natural'. Specify `ExtrapolationMethod` as one of the following strings: 'nearest', 'linear', or 'none'. Pass `Method` and `ExtrapolationMethod` together as the last two input arguments in any of the first three syntaxes.

`F = scatteredInterpolant()` creates an empty scattered data interpolant. Use `F.Points = P` to initialize `F` with the points in matrix `P`. Use `F.Values = v` to initialize `F` with the values in `v`.

## Input Arguments

### **x**

Sample points  $x$ -coordinates, specified as a vector of the same size as `v`.

### **y**

Sample points  $y$ -coordinates, specified as a vector of the same size as `v`.

### **z**

Sample points  $z$ -coordinates, specified as a vector of the same size as `v`.

### **P**

Sample points array, specified as an  $m$ -by- $n$  matrix, where  $m$  is the number of points and  $n$  is the dimension of the space where the points reside. Each row of `P` contains the  $(x, y)$  or  $(x, y, z)$  coordinates of a sample point.

### **v**

Sample values, specified as a vector that defines the function values,  $v = F(x,y)$ , at the sample points.

## Method

Interpolation method, specified as one of the following options.

Method String	Description	Continuity
'linear' (default)	Linear interpolation.	$C^0$

Method String	Description	Continuity
'nearest'	Nearest neighbor interpolation.	Discontinuous
'natural'	Natural neighbor interpolation.	C <sup>1</sup> except at sample points

### ExtrapolationMethod

Extrapolation method, specified as one of these strings.

ExtrapolationMethod String	Description
'linear'	Linear extrapolation based on boundary gradients. Default when Method is 'linear' or 'natural'.
'nearest'	Nearest neighbor extrapolation. This method evaluates to the value of the nearest neighbor on the boundary. Default when Method = 'nearest'.
'none'	No extrapolation. Any queries outside the convex hull of F.Points return NaN.

## Properties

### Points

Array of sample points (locations) for the values in F.Values. Each row of F.Points contains the  $(x, y)$  or  $(x, y, z)$  coordinates of a sample point.

### Values

Vector of values associated with each point in F.Points.

### Method

A string specifying the method used to interpolate the data: 'nearest', 'linear', or 'natural'.

### ExtrapolationMethod

A string specifying the method used to extrapolate the data: 'nearest', 'linear', or 'none'. A value of 'none' indicates that extrapolation is disabled.

## Definitions

### Interpolant

Interpolating function that you can evaluate at query locations.

### Scattered Data

A set of points that have no structure among their relative locations.

### Full Grid

A grid represented as a set of arrays. For example, you can create a full grid using `ndgrid`.

### Grid Vectors

A set of vectors that serve as a compact representation of a grid in `ndgrid` format. For example, `[X,Y] = ndgrid(xg,yg)` returns a full grid in the matrices `X` and `Y`. You can represent the same grid using the grid vectors, `xg` and `yg`.

## Copy Semantics

Value. To learn how value classes affect copy operations, see [Copying Objects in the MATLAB documentation](#).

## Indexing

`scatteredInterpolant` supports index-based editing of the properties of `F`. You can add or remove points in `F.Points` and update the corresponding values in `F.Values`.

For example, `F.Points(5,:) = []` removes the fifth point, and `F.Values(5) = []` removes the corresponding value.

## Examples

### 2-D Interpolation

Define 200 random points.

```
xy = -2.5 + 5*gallery('uniformdata',[200 2],0);
x = xy(:,1);
y = xy(:,2);
```

Sample an exponential function. These are the sample values for the interpolant.

```
v = x.*exp(-x.^2-y.^2);
```

Create the interpolant.

```
F = scatteredInterpolant(x,y,v);
```

Evaluate the interpolant at query locations (*xq*, *yq*).

```
ti = -2:.25:2;
[xq,yq] = meshgrid(ti,ti);
vq = F(xq,yq);
```

Plot the result.

```
figure
mesh(xq,yq,vq);
hold on;
plot3(x,y,v,'o');
hold off;
```

## 2-D Extrapolation

Query the interpolant at a single point outside the convex hull using nearest neighbor extrapolation.

Define a matrix of 200 random points.

```
P = -2.5 + 5*gallery('uniformdata',[200 2],0);
```

Sample an exponential function. These are the sample values for the interpolant.

```
x = P(:,1);
y = P(:,2);
v = x.*exp(-x.^2-y.^2);
```

Create the interpolant, specifying linear interpolation and nearest neighbor extrapolation.

```
F = scatteredInterpolant(P,v,'linear','nearest')
```

```
F =
```

```
scatteredInterpolant with properties:
```

```
 Points: [200x2 double]
 Values: [200x1 double]
 Method: 'linear'
 ExtrapolationMethod: 'nearest'
```

Evaluate the interpolant outside the convex hull.

```
vq = F(3.0,-1.5)
```

```
vq =
```

```
 0.0031
```

Disable extrapolation and evaluate F at the same point.

```
F.ExtrapolationMethod = 'none';
vq = F(3.0,-1.5)
```

```
vq =
```

```
 NaN
```

## Replacement of Sample Values

Replace the elements in the `Values` property when you want to change the values at the sample points. You get immediate results when you evaluate the new interpolant because the original triangulation has not changed.

Create 50 random points.

```
x = -2.5 + 5*gallery('uniformdata',[50 1],0);
y = -2.5 + 5*gallery('uniformdata',[50 1],1);
```

Sample an exponential function. These are the sample values for the interpolant.

```
v = x.*exp(-x.^2-y.^2);
```

Create the interpolant.

```
F = scatteredInterpolant(x,y,v)
```

```
F =
```

```
scatteredInterpolant with properties:
```

```
 Points: [50x2 double]
 Values: [50x1 double]
 Method: 'linear'
 ExtrapolationMethod: 'linear'
```

Evaluate the interpolant at (1.40,1.90).

```
F(1.40,1.90)
```

```
ans =
```

```
0.0029
```

Change the interpolant sample values.

```
vnew = x.^2 + y.^2;
F.Values = vnew;
```

Evaluate the interpolant at (1.40,1.90).

```
F(1.40,1.90)
```

```
ans =
```

```
6.1109
```

- “Interpolating Gridded Data”

## sec

Secant of angle in radians

## Syntax

$Y = \sec(X)$

## Description

$Y = \sec(X)$  returns the secant of the elements of  $X$ . The `sec` function operates element-wise on arrays. The function accepts both real and complex inputs. For real values of  $X$  in the interval  $[-\text{Inf}, \text{Inf}]$ , `sec` returns real values in the interval  $[-\text{Inf}, -1]$  and  $[1, \text{Inf}]$ . For complex values of  $X$ , `sec` returns complex values. All angles are in radians.

## Examples

### Plot Secant Function

Plot the secant over the domain  $-\pi/2 < x < \pi/2$  and  $\pi/2 < x < 3\pi/2$ .

```
x1 = -pi/2+0.01:0.01:pi/2-0.01;
x2 = pi/2+0.01:0.01:(3*pi/2)-0.01;
plot(x1,sec(x1),x2,sec(x2)), grid on
```

### Secant of Vector of Complex Angles

Calculate the secant of the complex angles in vector  $x$ .

```
x = [-i pi+i*pi/2 -1+i*4];
y = sec(x)
```

y =

```
0.6481 + 0.0000i -0.3985 + 0.0000i 0.0198 - 0.0308i
```

## Input Arguments

### X — Input angle in radians

number | vector | matrix | multidimensional array

Input angle in radians, specified as a number, vector, matrix, or multidimensional array.

Data Types: `single` | `double`

Complex Number Support: Yes

## Output Arguments

### Y — Secant of input angle

scalar value | vector | matrix | N-D array

Secant of input angle, returned as real-valued or complex-valued scalar value, vector, matrix or N-D array.

## More About

### Secant Function

The secant of an angle,  $\alpha$ , defined with reference to a right angled triangle is

$$\sec(\alpha) = \frac{1}{\cos(\alpha)} = \frac{\text{hypotenuse}}{\text{adjacent side}} = \frac{h}{b}.$$

The secant of a complex angle,  $\alpha$ , is

$$\sec(\alpha) = \frac{2}{e^{i\alpha} + e^{-i\alpha}}.$$

### See Also

asec | asecd | asech | secd | sech

Introduced before R2006a

## secd

Secant of argument in degrees

## Syntax

$Y = \text{secd}(X)$

## Description

$Y = \text{secd}(X)$  returns the secant of the elements of  $X$ , which are expressed in degrees.

## Examples

### Secant of 90 degrees compared to secant of $\pi/2$ radians

```
secd(90)
```

```
ans =
```

```
 Inf
```

```
sec(pi/2)
```

```
ans =
```

```
 1.6331e+16
```

$\text{secd}(90)$  is infinite, whereas  $\text{sec}(\pi/2)$  is large but finite.

### Secant of vector of complex angles, specified in degrees

```
z = [35+i 15+2i 10+3i];
```

```
y = secd(z)
```

```
y =
```

1.2204 + 0.0149i    1.0346 + 0.0097i    1.0140 + 0.0094i

## Input Arguments

### **X — Angle in degrees**

scalar value | vector | matrix | N-D array

Angle in degrees, specified as a real-valued or complex-valued scalar, vector, matrix, or N-D array. The `secd` operation is element-wise when  $X$  is nonscalar.

Example:

Data Types: `single` | `double`

Complex Number Support: Yes

## Output Arguments

### **Y — Secant of angle**

scalar value | vector | matrix | N-D array

Secant of angle, returned as a real-valued or complex-valued scalar, vector, matrix, or N-D array of the same size as  $X$ .

## See Also

`asec` | `asecd` | `sec`

**Introduced before R2006a**

# sech

Hyperbolic secant

## Syntax

$Y = \operatorname{sech}(X)$

## Description

The `sech` function operates element-wise on arrays. The function's domains and ranges include complex values. All angles are in radians.

$Y = \operatorname{sech}(X)$  returns an array the same size as  $X$  containing the hyperbolic secant of the elements of  $X$ .

## Examples

### Graph of Hyperbolic Secant Function

Graph the hyperbolic secant over the domain  $-2\pi \leq x \leq 2\pi$ .

```
x = -2*pi:0.01:2*pi;
plot(x,sech(x)), grid on
```

## More About

### Hyperbolic Secant

The hyperbolic secant of  $z$  is

$$\text{sech}(z) = \frac{1}{\cosh(z)}.$$

### See Also

**Introduced before R2006a**

## second

Second number

### Syntax

```
s = second(t)
s = second(t,secondType)
```

### Description

`s = second(t)` returns the second values, including a fractional part, for the datetime values in `t`. The `s` output is a `double` array the same size as `t` and contains values from 0 to less than 60.

For datetime values whose time zone is `UTCLeapSeconds`, the `s` output can contain a value between 60 and 61 for times that fall during a leap second occurrence.

`s = second(t,secondType)` returns the type of second number specified by `secondType`.

The `second` function returns the second numbers of datetime values. To assign second values to datetime array `t`, use `t.Second` and modify the `Second` property.

### Examples

#### Find Second Number of Datetime Values

```
t1 = datetime('now','Format','dd-MMM-yyyy HH:mm:ss.SSS');
t = t1 + seconds(30:15:60)
```

```
t =
```

```
Columns 1 through 2
```

```
24-Aug-2015 17:45:42.701 24-Aug-2015 17:45:57.701
```

```
Column 3
```

```
24-Aug-2015 17:46:12.701
```

```
s = second(t)
```

```
s =
```

```
42.7010 57.7010 12.7010
```

## Input Arguments

**t** — Input date and time

datetime array

Input date and time, specified as a `datetime` array.

**secondType** — Type of second values

'secondofminute' (default) | 'secondofday'

Type of second values, specified as either 'secondofminute' or 'secondofday'.

- If `secondType` is 'secondofminute', then `second` returns the second of the minute.
- If `secondType` is 'secondofday', then `second` returns the second of the day, which (except for leap seconds) is in the range [0, 86400).

## See Also

`datetime` Properties | `hms` | `hour` | `minute` | `timeofday`

**Introduced in R2014b**

## seconds

Duration in seconds

### Syntax

`S = seconds(X)`

### Description

`S = seconds(X)` returns an array of seconds equivalent to the values in `X`.

- If `X` is a numeric array, then `S` is a duration array in units of seconds.
- If `X` is a duration array, then `S` is a double array with each element equal to the number of seconds in the corresponding element of `X`.

The `seconds` function converts between duration and double values. To display a duration in units of seconds, set its `Format` property to `'s'`.

### Examples

#### Create Duration Array of Seconds

```
X = magic(4);
S = seconds(X)
```

S =

```
16 secs 2 secs 3 secs 13 secs
5 secs 11 secs 10 secs 8 secs
9 secs 7 secs 6 secs 12 secs
4 secs 14 secs 15 secs 1 sec
```

#### Convert Durations to Numeric Array of Seconds

Create a duration array.

```
X = hours(1) + minutes(1:4)
```

```
X =
```

```
 1.0167 hrs 1.0333 hrs 1.05 hrs 1.0667 hrs
```

Convert each duration in X to a number of seconds.

```
S = seconds(X)
```

```
S =
```

```
 3660 3720 3780 3840
```

S is a double array.

Find the natural logarithm of S. The `log` function accepts inputs of type **double**.

```
Y = log(S)
```

```
Y =
```

```
 8.2052 8.2215 8.2375 8.2532
```

## Input Arguments

### **X** — Input array

numeric array | duration array | logical array

Input array, specified as a numeric array, duration array, or logical array.

### **See Also**

duration

**Introduced in R2014b**

## selectmoveresize

Select, move, resize, or copy axes and uicontrol graphics objects

---

**Note:** The `selectmoveresize` was removed in R2014b. Use the `plottedit` function to copy, move, resize, and edit objects instead.

---

### Syntax

```
A = selectmoveresize
set(gca, 'ButtonDownFcn', 'selectmoveresize')
```

### Description

In releases before R2014b, `selectmoveresize` was useful as the callback routine for axes and uicontrol button down functions. It allowed users to move, resize, and copy axes and uicontrol objects.

`A = selectmoveresize` returns a structure array containing

- **A.Type:** a string containing the action type, which can be `Select`, `Move`, `Resize`, or `Copy`
- **A.Handles:** a list of the selected handles, or, for a `Copy`, an m-by-2 matrix containing the original handles in the first column and the new handles in the second column

`set(gca, 'ButtonDownFcn', 'selectmoveresize')` sets the `ButtonDownFcn` property of the current axes to `'selectmoveresize'`.

**Introduced before R2006a**

# matlab.unittest.selectors

Summary of classes in MATLAB Selectors Interface

## Description

Use selectors to filter or select elements of a test suite based on their attributes. The `matlab.unittest.selectors` package consists of the following selectors.

<code>matlab.unittest.selectors.HasParameter</code>	Selector for TestSuite elements determined by parameterization
<code>matlab.unittest.selectors.HasSharedTestFixture</code>	Selector for TestSuite elements that use shared test fixture
<code>matlab.unittest.selectors.HasBaseFolder</code>	Selector for TestSuite elements determined by folder
<code>matlab.unittest.selectors.HasName</code>	Selector for TestSuite elements determined by name
<code>matlab.unittest.selectors.HasTag</code>	Selector for TestSuite elements determined by tag

## See Also

`matlab.unittest.TestSuite.selectIf`

# matlab.unittest.selectors.HasParameter class

**Package:** matlab.unittest.selectors

Selector for TestSuite elements determined by parameterization

## Description

The `HasParameter` selector filters `TestSuite` array elements determined by parameterization.

## Construction

`matlab.unittest.selectors.HasParameter` constructs a selector for `TestSuite` elements determined by their parameterization. When you instantiate `HasParameter` without input arguments, the resulting `TestSuite` array only contains elements that have parameterized test methods.

`matlab.unittest.selectors.HasParameter(Name, Value)` constructs a selector with additional options specified by one or more `Name, Value` pair arguments. The selector filters based on the name of the property that defines a parameter, the name of the parameter, and the value of the parameter. For an element to be selected for the `TestSuite` array, it must have at least one parameter that satisfies all the conditions.

## Input Arguments

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

### 'Property'

Name of the property that defines the parameter specified as a string or as an instance of the `matlab.unittest.constraints.Constraint` class. If the specified property

name is a string, the testing framework creates an `IsEqualTo` constraint with the input string, `Property`, as the expected value.

### **'Name'**

Name of the parameter specified as a string or as an instance of the `matlab.unittest.constraints.Constraint` class. If the specified name is a string, the testing framework creates an `IsEqualTo` constraint with the input string, `Name`, as the expected value.

### **'Value'**

Value of the parameter specified as any MATLAB data type or as an instance of the `matlab.unittest.constraints.Constraint` class. If the specified property name is not a constraint, the testing framework creates an `IsEqualTo` constraint with the input data, `Value`, as the expected value.

## **Properties**

### **PropertyConstraint**

Condition that the test element's parameter property name must satisfy to be included in the test suite, specified as an instance of the `Constraint` in the `Property` input argument.

### **NameConstraint**

Condition that the test element's parameter name must satisfy to be included in the test suite, specified as an instance of the `Constraint` in the `Name` input argument.

### **ValueConstraint**

Condition that the test element's parameter property value must satisfy to be included in the test suite, specified as an instance of the `Constraint` in the `Value` input argument.

## **Copy Semantics**

Value. To learn how value classes affect copy operations, see [Copying Objects in the MATLAB documentation](#).

## Examples

### Filter Test Suite by Parameterization

In your working folder, create `testZeros.m`. This class contains four test methods.

```
classdef testZeros < matlab.unittest.TestCase
 properties (TestParameter)
 type = {'single', 'double', 'uint16'};
 outSize = struct('s2d',3, 's3d',[2 5 4]);
 end

 methods (Test)
 function testClass(testCase, type, outSize)
 testCase.verifyClass(zeros(outSize,type), type);
 end

 function testSize(testCase, outSize)
 testCase.verifySize(zeros(outSize), outSize);
 end

 function testDefaultClass(testCase)
 testCase.verifyClass(zeros, 'double');
 end

 function testDefaultSize(testCase)
 testCase.verifySize(zeros, [1 1]);
 end

 function testDefaultValue(testCase)
 testCase.verifyEqual(zeros,0);
 end
 end
end
```

The test class contains two parameterized test methods, `testClass` and `testSize`.

At the command prompt, create a test suite from the file.

```
s = matlab.unittest.TestSuite.fromFile('testZeros.m');
{s.Name}'

ans =

 'testZeros/testClass(type=single,outSize=s2d)'
```

```

'testZeros/testClass(type=single,outSize=s3d) '
'testZeros/testClass(type=double,outSize=s2d) '
'testZeros/testClass(type=double,outSize=s3d) '
'testZeros/testClass(type=uint16,outSize=s2d) '
'testZeros/testClass(type=uint16,outSize=s3d) '
'testZeros/testSize(outSize=s2d) '
'testZeros/testSize(outSize=s3d) '
'testZeros/testDefaultClass '
'testZeros/testDefaultSize '
'testZeros/testDefaultValue '

```

The suite contains 11 test elements: 6 from the parameterized `testClass` method, 2 from the parameterized `testSize` method, and 1 from each of the `testDefaultClass`, `testDefaultSize`, and `testDefaultValue` methods.

Select all of the test elements from parameterized test methods.

```
import matlab.unittest.selectors.HasParameter;
```

```
s1 = s.selectIf(HasParameter);
{s1.Name} '

```

ans =

```

'testZeros/testClass(type=single,outSize=s2d) '
'testZeros/testClass(type=single,outSize=s3d) '
'testZeros/testClass(type=double,outSize=s2d) '
'testZeros/testClass(type=double,outSize=s3d) '
'testZeros/testClass(type=uint16,outSize=s2d) '
'testZeros/testClass(type=uint16,outSize=s3d) '
'testZeros/testSize(outSize=s2d) '
'testZeros/testSize(outSize=s3d) '

```

The suite contains the eight test elements from the two parameterized test methods.

Select all of the test elements from nonparameterized test methods.

```
s2 = s.selectIf(~HasParameter);
{s2.Name} '

```

ans =

```

'testZeros/testDefaultClass '
'testZeros/testDefaultSize '
'testZeros/testDefaultValue '

```

Select all test elements that are parameterized and have a property named 'type' with a parameter name 'double'.

```
s3 = s.selectIf(HasParameter('Property', 'type', 'Name', 'double'));
{s3.Name}'
```

```
ans =
```

```
'testZeros/testClass(type=double,outSize=s2d)'
'testZeros/testClass(type=double,outSize=s3d)'
```

The resulting suite contains two elements. The `testClass` method is the only method in `testZeros` that uses the 'type' property. Selecting only 'double' from the parameters results in two test elements — one for each value of 'outSize'.

Select all test elements that have a parameter defined by a property starting with 't'.

```
import matlab.unittest.constraints.StartsWithSubstring;
```

```
s4 = s.selectIf(HasParameter('Property', StartsWithSubstring('t')));
{s4.Name}'
```

```
ans =
```

```
'testZeros/testClass(type=single,outSize=s2d)'
'testZeros/testClass(type=single,outSize=s3d)'
'testZeros/testClass(type=double,outSize=s2d)'
'testZeros/testClass(type=double,outSize=s3d)'
'testZeros/testClass(type=uint16,outSize=s2d)'
'testZeros/testClass(type=uint16,outSize=s3d)'
```

The resulting suite contains the six parameterized test elements from the `testClass` method. The `testSize` method is parameterized, but the elements from the method are not included in the suite because the method does not use a property that starts with 't'.

Select all test elements that are parameterized and test the `zeros` function with a 2-D array. A parameter value representing a 2-D array has a length of 1 (for example `zeros(3)`) or 2 (for example `zeros(2,3)`).

```
import matlab.unittest.constraints.HasLength;
```

```
s5 = s.selectIf(HasParameter('Property', 'outSize', ...
 'Value', HasLength(1)|HasLength(2)));
```

```
{s5.Name}'
ans =
 'testZeros/testClass(type=single,outSize=s2d)'
 'testZeros/testClass(type=double,outSize=s2d)'
 'testZeros/testClass(type=uint16,outSize=s2d)'
 'testZeros/testSize(outSize=s2d)'
```

Select only the test element that tests that the output is a `double` data type and that it has the correct size for a 2-D array.

```
s6 = s.selectIf(HasParameter('Property','type','Name','double')...
 & HasParameter('Property','outSize','Name','s2d'))
```

```
s6 =
```

```
Test with properties:
```

```
 Name: 'testZeros/testClass(type=double,outSize=s2d)'
 Parameterization: [1x2 matlab.unittest.parameters.TestParameter]
 SharedTestFixtures: []
 Tags: {0x1 cell}
```

```
Tests Include:
```

```
2 Unique Parameterizations, 0 Shared Test Fixture Classes, 0 Tags.
```

# matlab.unittest.selectors.HasSharedTestFixture class

**Package:** matlab.unittest.selectors

Selector for TestSuite elements that use shared test fixture

## Description

The `HasSharedTestFixture` selector filters `TestSuite` array elements based on shared test fixtures.

## Construction

`matlab.unittest.selectors.HasSharedTestFixture(f)` constructs a selector for `TestSuite` elements based on their required shared test fixtures. For an element to be selected for the `TestSuite` array, it must use a fixture that is compatible with the specified fixture, `f`.

## Input Arguments

**f** — Shared test fixture  
Fixture

Shared test fixture specified as a `matlab.unittest.fixtures.Fixture` instance. The `TestSuite` array element must use the shared text fixture, `f`, to be selected for the `TestSuite`.

## Properties

### ExpectedFixture

The shared test fixture that a `TestSuite` array element must use to be selected for the `TestSuite`. The `ExpectedFixture` property is specified as a `matlab.unittest.fixtures.Fixture` in the input argument, `f`.

## Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

## Examples

### Filter Test Suite by Shared Test Fixtures

Create a package folder, `+mytestpackage`, in your current working folder. This package contains two test classes.

In the `+mytestpackage` folder, create `AExampleTest.m`. This class contains two tests that use a suppressed warnings fixture.

```
classdef (SharedTestFixtures={ ...
 matlab.unittest.fixtures.SuppresseWarningsFixture(...
 'MATLAB:rmpath:DirNotFound'}) ...
 AExampleTest < matlab.unittest.TestCase
 methods (Test)
 function testOne(testCase)
 % test code
 end
 function testTwo(testCase)
 % test code
 end
 end
end
```

In the `+mytestpackage` folder, create `BExampleTest.m`. This class contains one test that uses a shared path fixture and a suppressed warnings fixture.

```
classdef (SharedTestFixtures={ ...
 matlab.unittest.fixtures.PathFixture(...
 fullfile(matlabroot, 'help', 'techdoc', 'matlab_oop', 'examples')), ...
 matlab.unittest.fixtures.SuppresseWarningsFixture(...
 'MATLAB:rmpath:DirNotFound'}) ...
 BExampleTest < matlab.unittest.TestCase
 methods (Test)
 function testPathAdd(testCase)
 % test code
 end
 end
end
```

```
 end
 end
end
```

At the command prompt, define the following fixtures.

```
pf = matlab.unittest.fixtures.PathFixture(...
 fullfile(matlabroot, 'help', 'techdoc', 'matlab_oop', 'examples'));
swf = matlab.unittest.fixtures.SuppressedWarningsFixture(...
 'MATLAB:rmpath:DirNotFound');
```

Create a test suite from the package.

```
import matlab.unittest.TestSuite;
import matlab.unittest.selectors.HasSharedTestFixture;

suite = TestSuite.fromPackage('mytestpackage')
```

```
suite =
```

```
 1x3 Test array with properties:
```

```
 Name
 Parameterization
 SharedTestFixtures
 Tags
```

```
Tests Include:
```

```
 0 Parameterizations, 2 Unique Shared Test Fixture Classes, 0 Tags.
```

The test suite has three test elements.

Create a filtered suite that only contains tests that use the path fixture, `pf`.

```
s1 = suite.selectIf(HasSharedTestFixture(pf));
```

The resulting suite, `s1`, contains the test element from `BExampleTest.m`, since the test in that class uses the shared test fixture, `pf`.

Alternatively, pass the selector to the `TestSuite.fromPackage` method instead of generating a full test suite, and then using the `TestSuite.selectIf` method to filter the suite.

```
s1 = TestSuite.fromPackage('mytestpackage', HasSharedTestFixture(pf));
```

Create a filtered test suite that contains tests that use the suppressed warnings fixture, `swf`, but not the path fixture, `pf`.

```
s2 = suite.selectIf(~HasSharedTestFixture(pf) & HasSharedTestFixture(swf));
```

The test suite, `s2`, only contains the two test elements from `AExampleTest.m`. Tests in `BExampleTest.m` are excluded because, in addition to the suppressed warnings fixture, they use the path fixture.

Create a filtered suite that only contains tests that use the path fixture to a different location.

```
pf2 = matlab.unittest.fixtures.PathFixture(fullfile(matlabroot));
s3 = TestSuite.fromPackage('mytestpackage', HasSharedTestFixture(pf2))
```

```
s3 =
```

```
1x0 Test array with properties:
```

```
 Name
Parameterization
SharedTestFixtures
 Tags
```

```
Tests Include:
```

```
 0 Parameterizations, 0 Shared Test Fixture Classes, 0 Tags.
```

The test suite does not contain any test elements. The tests in `BExampleTest.m` use a shared path fixture, but the selected path fixture, `pf2`, adds a different folder to the path so its tests are not included in the suite.

**Introduced in R2014a**

# matlab.unittest.selectors.HasBaseFolder class

**Package:** matlab.unittest.selectors

Selector for TestSuite elements determined by folder

## Description

The `HasBaseFolder` selector filters `TestSuite` array elements determined by the name of the folder that contains the file that defines the test class or function.

## Construction

`matlab.unittest.selectors.HasBaseFolder(f)` constructs a selector for `TestSuite` elements determined by the folder, `f`, which contains the file that defines the test class or function. You can specify the base folder as a string or as an instance of the `matlab.unittest.constraints.Constraint` class. If the specified base folder, `f`, is a string instead of a `Constraint`, the testing framework creates an `ISEQUALTO` constraint with the input string, `f`, as the expected value.

For a test element to be included in the suite, the file that defines it must be contained in the specified base folder. For test classes defined in packages, the base folder is the parent of the top-level package folder. The base folder never contains any folders that start with '+' or '@'.

## Input Arguments

**f** — Base folder

string | `Constraint`

Base folder specified as a string or a `matlab.unittest.constraints.Constraint` instance. The following conditions must be satisfied for the test element to be selected for the `TestSuite`:

- If `f` is a string, the test element's base folder must exactly match the specified folder.
- If `f` is a constraint, the test element's base folder must satisfy the specified constraint.

## Properties

### Constraint

Condition the base folder must satisfy to be included in the test suite, specified as an instance of the `matlab.unittest.constraints.Constraints` class.

## Copy Semantics

Value. To learn how value classes affect copy operations, see [Copying Objects in the MATLAB documentation](#).

## Examples

### Filter Test Suite by Base Folder

Create a folder, `MyTests`, in your current working folder. In this folder, create two subfolders, `Feature1` and `Feature2`.

In a new file, `Feature1_Test.m`, in the `Feature1` subfolder, create the following test class.

```
classdef Feature1_Test < matlab.unittest.TestCase
 methods (Test)
 function testA1(testCase)
 % test code
 end
 function testB1(testCase)
 % test code
 end
 end
end
```

In a new file, `Feature2_Test.m`, in the `Feature2` subfolder, create the following test class.

```
classdef Feature2_Test < matlab.unittest.TestCase
 methods (Test)
 function testA2(testCase)
```

```
 % test code
 end
 function testB2(testCase)
 % test code
 end
end
end
```

If necessary, set your current working folder to the folder above `MyTests`. At the command prompt, create a test suite from the `MyTests` folder and examine the contents.

```
import matlab.unittest.TestSuite
import matlab.unittest.selectors.HasBaseFolder;
import matlab.unittest.constraints.ContainsSubstring;

suite = TestSuite.fromFolder('MyTests', 'IncludingSubfolders', true);
{suite.Name}

ans =

 'Feature1_Test/testA1' 'Feature1_Test/testB1' 'Feature2_Test/testA2' 'Feat
```

The suite contains the four tests from the two test files.

Select all test suite elements for classes that are defined in the `'Feature1'` folder.

```
s1 = suite.selectIf(HasBaseFolder(fullfile(pwd, 'MyTests', 'Feature1')));
{s1.Name}

ans =

 'Feature1_Test/testA1' 'Feature1_Test/testB1'
```

The filtered test suite contains only test elements from the `Feature1` folder.

Select all the test suite elements for classes that are defined in folders that do not contain the string `'Feature1'`, and then examine the contents.

```
s1 = suite.selectIf(HasBaseFolder(...
 fullfile(pwd, 'MyTests', 'Feature1')));
{s1.Name}

ans =

 'Feature2_Test/testA2' 'Feature2_Test/testB2'
```

The filtered test suite only contains test elements from the `Feature2` folder.

Alternatively, to generate a filtered suite directly, pass the selector to the `TestSuite.fromFolder` method.

```
s1 = TestSuite.fromFolder('MyTests',...
 ~HasBaseFolder(ContainsSubstring('Feature1')),...
 'IncludingSubfolders',true);
```

**Introduced in R2014a**

# matlab.unittest.selectors.HasName class

**Package:** matlab.unittest.selectors

Selector for TestSuite elements determined by name

## Description

The `HasName` selector filters `TestSuite` array elements determined by the test element name.

## Construction

`matlab.unittest.selectors.HasName(n)` constructs a selector for `TestSuite` elements determined by the test element name, `n`. You can specify the name as a string or as an instance of the `matlab.unittest.constraints.Constraint` class. If the specified name, `n`, is a string, the testing framework creates an `ISEQUALTO` constraint with the input string, `n`, as the expected value.

For a test element to be included in the suite, the test element must have the same name as the specified name.

## Input Arguments

**n — Test element name**

string | `Constraint`

Test element name specified as a string or `matlab.unittest.constraints.Constraint` instance. The following conditions must be satisfied for the test element to be selected for the `TestSuite`:

- If `n` is a string, the test element's name must exactly match the specified name.
- If `n` is a constraint, the test element's name must satisfy the specified constraint.

## Properties

### Constraint

Condition the test element name must satisfy to be included in the test suite, specified as an instance of the `matlab.unittest.constraints.Constraints` class.

## Copy Semantics

Value. To learn how value classes affect copy operations, see [Copying Objects in the MATLAB documentation](#).

## Examples

### Filter Test Suite by Name

Create the following test class in a file, `ExampleTest.m`, in your current working folder.

```
classdef ExampleTest < matlab.unittest.TestCase
 methods(Test)
 function testPathAdd(testCase)
 % test code
 end
 function testOne(testCase)
 % test code
 end
 function testTwo(testCase)
 % test code
 end
 end
end
```

At the command prompt, create a test suite from the `ExampleTest.m` file and examine the contents.

```
import matlab.unittest.TestSuite;
import matlab.unittest.selectors.HasName;
import matlab.unittest.constraints.EndsWithSubstring;

suite = TestSuite.fromFile('ExampleTest.m');
```

```
{suite.Name}
```

```
ans =
```

```
 'ExampleTest/testPathAdd' 'ExampleTest/testOne' 'ExampleTest/testTwo'
```

The suite contains three tests.

Select all the test suite elements that have the name 'ExampleTest/testPathAdd', and examine the contents.

```
s1 = suite.selectIf(HasName('ExampleTest/testPathAdd'));
{s1.Name}
```

```
ans =
```

```
 'ExampleTest/testPathAdd'
```

The filtered test suite only contains one test element.

Select all the test suite elements that end in either 'One' or 'Two', and examine the contents.

```
s1 = suite.selectIf(HasName(EndsWithSubstring('One')) | ...
 HasName(EndsWithSubstring('Two')));
{s1.Name}
```

```
ans =
```

```
 'ExampleTest/testOne' 'ExampleTest/testTwo'
```

At the time of the test suite construction, create a test suite that only contains tests with the substring 'One'.

```
import matlab.unittest.constraints.ContainsSubstring;
s2 = TestSuite.fromFile('ExampleTest.m', ...
 HasName(ContainsSubstring('One')))
```

```
s2 =
```

```
Test with properties:
```

```
 Name: 'ExampleTest/testOne'
 Parameterization: []
 SharedTestFixtures: []
```

Tags: {0x1 cell}

Tests Include:

0 Parameterizations, 0 Shared Test Fixture Classes, 0 Tags.

**Introduced in R2014a**

# matlab.unittest.selectors.HasTag class

**Package:** matlab.unittest.selectors

Selector for TestSuite elements determined by tag

## Description

The `HasTag` selector filters `TestSuite` array elements determined by the test element tag.

## Construction

`matlab.unittest.selectors.HasTag` constructs a selector for `TestSuite` elements determined by the test element tag. When you instantiate `HasTag` without input arguments, the resulting `TestSuite` array contains only elements with one or more tags.

`matlab.unittest.selectors.HasTag(t)` constructs a selector for `TestSuite` elements determined by the test element tag, `t`. You can specify the name as a string or as an instance of the `matlab.unittest.constraints.Constraint` class. If the specified name, `t`, is a string, the testing framework creates an `ISEQUALTO` constraint with the input string, `t`, as the expected value.

For a test element to be included in the suite, the test element must be tagged with the specified string or with a value that satisfies the specified constraint.

## Input Arguments

**t** — Test element tag  
`string` | `Constraint`

Test element tag, specified as a string or `matlab.unittest.constraints.Constraint` instance. If a test element tag meets the following conditions, the `TestSuite` contains the test:

- If `t` is a string, the test element tag is the specified value.

- If `t` is a constraint, the test element tag is a value that satisfies the specified constraint.

## Properties

### **Constraint** — Condition test element tag must satisfy

instance of `matlab.unittest.constraints.Constraints` class

Condition the test element tag must satisfy to be included in the test suite, specified as an instance of the `matlab.unittest.constraints.Constraints` class.

## Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

## Examples

### Filter Test Suite by Tag

Create the following test class in a file, `ExampleTest.m`, in your current working folder.

```
classdef ExampleTest < matlab.unittest.TestCase
 methods (Test)
 function testA (testCase)
 % test code
 end
 end
 methods (Test, TestTags = {'Unit'})
 function testB (testCase)
 % test code
 end
 function testC (testCase)
 % test code
 end
 end
 methods (Test, TestTags = {'Unit', 'FeatureA'})
 function testD (testCase)
```

```
 % test code
 end
end
methods (Test, TestTags = {'System', 'FeatureA'})
 function testE (testCase)
 % test code
 end
end
end
```

At the command prompt, create a test suite from the `ExampleTest` class and examine the contents.

```
import matlab.unittest.TestSuite
import matlab.unittest.selectors.HasTag

suite = TestSuite.fromClass(?ExampleTest)
```

```
suite =
```

```
1x5 Test array with properties:
```

```
 Name
Parameterization
SharedTestFixtures
Tags
```

```
Tests Include:
```

```
0 Parameterizations, 0 Shared Test Fixture Classes, 3 Unique Tags.
```

Click the hyperlink for **3 Unique Tags** to display all the tags in the suite.

```
Tag

'FeatureA'
'System'
'Unit'
```

Select all the test suite elements that have the tag `'Unit'`.

```
s1 = suite.selectIf(HasTag('Unit'))
```

```
s1 =
```

1x3 Test array with properties:

```
Name
Parameterization
SharedTestFixtures
Tags
```

Tests Include:

0 Parameterizations, 0 Shared Test Fixture Classes, 2 Unique Tags.

Select all the test suite elements that do not contain the tag 'FeatureA'.

```
s2 = suite.selectIf(~HasTag('FeatureA'));
{s2.Name}
```

ans =

```
'ExampleTest/testB' 'ExampleTest/testC' 'ExampleTest/testA'
```

Select all the test suite elements that have no tags.

```
s3 = suite.selectIf(~HasTag)
```

s3 =

Test with properties:

```
Name: 'ExampleTest/testA'
Parameterization: []
SharedTestFixtures: []
Tags: {0x1 cell}
```

Tests Include:

0 Parameterizations, 0 Shared Test Fixture Classes, 0 Tags.

- “Tag Unit Tests”

## Alternatives

Use the `HasTag` selector for maximum flexibility to create test suites from tags. Alternatively, at the time of test suite construction, you can filter the test suite Using the 'Tag' name-value pair. For example,

```
s = TestSuite.fromClass(?ExampleTest, 'Tag', 'Unit');
```

You can also select and run tagged tests using the 'Tag' name-value pair with the `runtests` function. For example,

```
runtests('ExampleTest.m', 'Tag', 'Unit')
```

**Introduced in R2015a**

# semilogx

Semilogarithmic plot

## Syntax

```
semilogx(Y)
semilogx(X1,Y1,...)
semilogx(X1,Y1,LineStyle,...)
semilogx(...,'PropertyName',PropertyValue,...)
h = semilogx(...)
```

## Description

`semilogx` plot data as logarithmic scales for the  $x$ -axis.

`semilogx(Y)` creates a plot using a base 10 logarithmic scale for the  $x$ -axis and a linear scale for the  $y$ -axis. It plots the columns of  $Y$  versus their index if  $Y$  contains real numbers. `semilogx(Y)` is equivalent to `semilogx(real(Y),imag(Y))` if  $Y$  contains complex numbers. `semilogx` ignores the imaginary component in all other uses of this function.

`semilogx(X1,Y1,...)` plots all  $Y_n$  versus  $X_n$  pairs. If only one of  $X_n$  or  $Y_n$  is a matrix, `semilogx` plots the vector argument versus the rows or columns of the matrix, along the dimension of the matrix whose length matches the length of the vector. If the matrix is square, its columns plot against the vector if their lengths match.

`semilogx(X1,Y1,LineStyle,...)` plots all lines defined by the  $X_n, Y_n, LineSpec$  triples. `LineStyle` determines line style, marker symbol, and color of the plotted lines.

`semilogx(..., 'PropertyName', PropertyValue, ...)` sets property values for all charting lines created by `semilogx`. For a list of properties, see [Chart Line Properties](#).

`h = semilogx(...)` return a vector of chart line handles, one handle per line.

## Examples

### Logarithmic Scale for x-Axis

Create a plot with a logarithmic scale for the x-axis and a linear scale for the y-axis.

```
x = 0:1000;
y = log(x);

figure
semilogx(x,y)
```

## More About

### Tips

If you do not specify a color when plotting more than one line, `semilogx` automatically cycle through the colors and line styles in the order specified by the current axes `ColorOrder` and `LineStyleOrder` properties.

You can mix  $X_n, Y_n$  pairs with  $X_n, Y_n, LineSpec$  triples; for example,

```
semilogx(X1, Y1, X2, Y2, LineSpec, X3, Y3)
```

If you attempt to add a `loglog`, `semilogx`, or `semilogy` plot to a linear axis mode graph with `hold on`, the axis mode remains as it is and the new data plots as linear.

# semilogy

Semilogarithmic plot

## Syntax

```
semilogy(Y)
semilogy(X1,Y1,...)
semilogy(X1,Y1,LineStyle,...)
semilogy(...,'PropertyName',PropertyValue,...)
h = semilogy(...)
```

## Description

`semilogy` plots data with logarithmic scale for the  $y$ -axis.

`semilogy(Y)` creates a plot using a base 10 logarithmic scale for the  $y$ -axis and a linear scale for the  $x$ -axis. It plots the columns of  $Y$  versus their index if  $Y$  contains real numbers. `semilogy(Y)` is equivalent to `semilogy(real(Y), imag(Y))` if  $Y$  contains complex numbers. `semilogy` ignores the imaginary component in all other uses of this function.

`semilogy(X1, Y1, ...)` plots all  $Y_n$  versus  $X_n$  pairs. If only one of  $X_n$  or  $Y_n$  is a matrix, `semilogy` plots the vector argument versus the rows or columns of the matrix, along the dimension of the matrix whose length matches the length of the vector. If the matrix is square, its columns plot against the vector if their lengths match.

`semilogy(X1, Y1, LineSpec, ...)` plots all lines defined by the  $X_n, Y_n, LineSpec$  triples. `LineSpec` determines line style, marker symbol, and color of the plotted lines.

`semilogy(..., 'PropertyName', PropertyValue, ...)` sets property values for all the charting lines created by `semilogy`. For a list of properties, see [Chart Line Properties](#).

`h = semilogy(...)` returns a vector of chart line handles, one handle per line.

## Examples

### Logarithmic Scale for y-Axis

Create a plot with a logarithmic scale for the y-axis and a linear scale for the x-axis.

```
x = 0:0.1:10;
y = exp(x);

figure
semilogy(x,y)
```

## More About

### Tips

If you do not specify a color when plotting more than one line, `semilogy` automatically cycle through the colors and line styles in the order specified by the current axes `ColorOrder` and `LineStyleOrder` properties.

You can mix  $X_n, Y_n$  pairs with  $X_n, Y_n, LineSpec$  triples; for example,

```
semilogy(X1, Y1, X2, Y2, LineSpec, X3, Y3)
```

If you attempt to add a `loglog`, `semilogx`, or `semilogy` plot to a linear axis mode graph with `hold on`, the axis mode remains as it is and the new data plots as linear.

# sendmail

Send email message to address list

## Syntax

```
sendmail(recipients,subject)
sendmail(recipients,subject,message)
sendmail(recipients,subject,message,attachments)
```

## Description

`sendmail(recipients,subject)` sends email to `recipients` with the specified `subject`. The `recipients` input is a string for a single address, or a cell array of strings for multiple addresses.

`sendmail(recipients,subject,message)` includes the specified `message`. If `message` is a string, `sendmail` automatically wraps text at 75 characters. To force a line break in the message text, use `10`, as shown in the Examples. If `message` is a cell array of strings, each cell represents a new line of text.

`sendmail(recipients,subject,message,attachments)` attaches the files listed in the string or cell array `attachments`.

## Examples

Send a message with two attachments to a hypothetical email address:

```
sendmail('user@otherdomain.com',...
 'Test subject','Test message',...
 {'folder/attach1.html','attach2.doc'});
```

Send a message with forced line breaks (using `10`) to a hypothetical email address:

```
sendmail('user@otherdomain.com','New subject', ...
 ['Line1 of message' 10 'Line2 of message' 10 ...
 'Line3 of message' 10 'Line4 of message']);
```

The resulting message is:

```
Line1 of message
Line2 of message
Line3 of message
Line4 of message
```

## Alternatives

On Windows systems with Microsoft Outlook<sup>®</sup>, you can send email directly through Outlook by accessing the COM server with `actxserver`. For an example, see Solution 1-RTY6J.

## More About

### Tips

- The `sendmail` function does not support HTML-formatted messages. However, you can send HTML files as attachments.
- If `sendmail` cannot determine your email address or outgoing SMTP mail server from your system registry, specify those settings using the `setpref` function. For example:

```
setpref('Internet', 'SMTP_Server', 'my_server.example.com');
setpref('Internet', 'E_mail', 'my_email@example.com');
```

To identify the SMTP server for the call to `setpref`, check the preferences for your electronic mail application, or consult your email system administrator. If you cannot easily determine the server name, try `'mail'`, which is a common default, such as:

```
setpref('Internet', 'SMTP_Server', 'mail');
```

- By default, the `sendmail` function does not support email servers that require authentication. To support these servers, change your system settings and set preferences for the SMTP user name and password, with commands in the following form:

```
props = java.lang.System.getProperties();
props.setProperty('mail.smtp.auth', 'true');
```

```
setpref('Internet','SMTP_Username','myaddress@example.com');
setpref('Internet','SMTP_Password','mypassword');
```

- To override the default character encoding, set the preference for email character encoding as follows:

```
setpref('Internet','E_mail_Charset',encoding);
where encoding is a string specifying the character encoding, such as 'SJIS'.
```

- “Specify Proxy Server Settings for Connecting to the Internet”

## See Also

getpref | setpref

## serial

Create serial port object

### Syntax

```
obj = serial('port')
obj = serial('port', 'PropertyName', PropertyValue, ...)
```

### Description

`obj = serial('port')` creates a serial port object associated with the serial port specified by *port*. If *port* does not exist, or if it is in use, you will not be able to connect the serial port object to the device.

*Port* object name will depend upon the platform that the serial port is on. `instrhwinfo` ('serial') provides a list of available serial ports. This list is an example of serial constructors on different platforms:

Platform	Serial Port Constructor
Linux and Linux 64	<code>serial('/dev/ttyS0');</code>
Mac OS X 64	<code>serial('/dev/tty.KeySerial1');</code>
Windows 32 and Windows 64	<code>serial('com1');</code>

`obj = serial('port', 'PropertyName', PropertyValue, ...)` creates a serial port object with the specified property names and property values. If an invalid property name or property value is specified, an error is returned and the serial port object is not created.

### Examples

This example creates the serial port object `s1` associated with the serial port `COM1` on a Windows platform.

```
s1 = serial('COM1');
```

The `Type`, `Name`, and `Port` properties are automatically configured.

```
get(s1,{'Type','Name','Port'})
ans =
 'serial' 'Serial-COM1' 'COM1'
```

To specify properties during object creation

```
s2 = serial('COM2','BaudRate',1200,'DataBits',7);
```

## More About

### Tips

When you create a serial port object, these property values are automatically configured:

- The `Type` property is given by `serial`.
- The `Name` property is given by concatenating `Serial` with the port specified in the `serial` function.
- The `Port` property is given by the port specified in the `serial` function.

You can specify the property names and property values using any format supported by the `set` function. For example, you can use property name/property value cell array pairs. Additionally, you can specify property names without regard to case, and you can make use of property name completion. For example, the following commands are all valid on a Windows platform.

```
s = serial('COM1','BaudRate',4800);
s = serial('COM1','baudrate',4800);
s = serial('COM1','BAUD',4800);
```

Refer to [Configuring Property Values](#) for a list of serial port object properties that you can use with `serial`.

Before you can communicate with the device, it must be connected to `obj` with the `fopen` function. A connected serial port object has a `Status` property value of `open`. An error is returned if you attempt a read or write operation while the object is not connected to the device. You can connect only one serial port object to a given serial port.

**See Also**

fclose | fopen | Name | Port | Status | Type

**Introduced before R2006a**

# serialbreak

Send break to device connected to serial port

## Syntax

```
serialbreak(obj)
serialbreak(obj,time)
```

## Description

`serialbreak(obj)` sends a break of 10 milliseconds to the device connected to the serial port object, `obj`.

`serialbreak(obj,time)` sends a break to the device with a duration, in milliseconds, specified by `time`. Note that the duration of the break might be inaccurate under some operating systems.

## More About

### Tips

For some devices, the break signal provides a way to clear the hardware buffer.

Before you can send a break to the device, it must be connected to `obj` with the `fopen` function. A connected serial port object has a `Status` property value of `open`. An error is returned if you attempt to send a break while `obj` is not connected to the device.

`serialbreak` is a synchronous function, and blocks the command line until execution is complete.

If you issue `serialbreak` while data is being asynchronously written, an error is returned. In this case, you must call the `stopasync` function or wait for the write operation to complete.

## set

Set graphics object properties

### Syntax

```
set(H,Name,Value)
set(H,NameArray,ValueArray)
set(H,S)
s = set(H)
values = set(H,Name)
```

### Description

---

**Note:** Do not use the `set` function on Java objects as it will cause a memory leak. For more information, see “Accessing Private and Public Data”

---

`set(H,Name,Value)` specifies a value for the property `Name` on the object identified by `H`. Use single quotes around the property name, for example, `set(H,'Color','red')`. If `H` is a vector of objects, then `set` sets the property for all the objects. If `H` is empty (that is, `[]`), `set` does nothing, but does not return an error or warning.

`set(H,NameArray,ValueArray)` specifies multiple property values using the cell arrays `NameArray` and `ValueArray`. To set `n` property values on each of `m` graphics objects, specify `ValueArray` as an `m`-by-`n` cell array, where `m` = `length(H)` and `n` is equal to the number of property names contained in `NameArray`.

`set(H,S)` specifies multiple property values using `S`, where `S` is a structure whose field names are the object property names and whose field values are the corresponding property values. MATLAB ignores empty structures.

`s = set(H)` returns the user-settable properties and possible values for the object identified by `H`. `s` is a structure array whose field names are the object's property names and whose field values are the possible values of the corresponding properties. If you do not specify an output argument, the MATLAB software displays the information on the screen. `H` must be a single object.

`values = set(H,Name)` returns the possible values for the specified property. If the possible values are strings, `set` returns each in a cell of the cell array `values`. For other properties, `set` returns a statement indicating that `Name` does not have a fixed set of property values. If you do not specify an output argument, MATLAB displays the information on the screen. `H` must be a single object.

---

**Note:** For more information about properties you can set, see the property pages for each object, for example, Figure Properties, Axes Properties, Chart Line Properties, Text Properties, and so on.

---

## Examples

### Change Color of Specific Line

Plot a line and return the chart line object as `p`. Set the `Color` property of the line to `'red'`.

```
p = plot(1:10);
set(p, 'Color', 'red')
```

### Change Color for Multiple Lines

Create a plot with four lines using random data and return the four chart line objects as `P`. Set the `Color` property for all of the lines to `'red'`.

```
P = plot(rand(4));
set(P, 'Color', 'red')
```

### Set Line Style to Different Value for Multiple Lines

Set the value of the `LineStyle` property for four chart line objects each to a different value. Transpose the value of the cell array so that it has the proper shape.

```
P = plot(rand(4));
NameArray = {'LineStyle'};
ValueArray = {'-', '--', ':', '-.'}'';
set(P, NameArray, ValueArray)
```

## Set Different Values for Multiple Properties on Multiple Objects

Set the values of the `Marker` and `Tag` properties on three different stem series objects to different values. Each row of the value cell array corresponds to an object in `h` and contains two values, one for the `Marker` property and one for the `Tag` property.

```
x = 0:30;
y = [1.5*cos(x); 4*exp(-.1*x).*cos(x); exp(.05*x).*cos(x)]';
S = stem(x,y);
NameArray = {'Marker', 'Tag'};
ValueArray = {'o', 'Decaying Exponential';...
 'square', 'Growing Exponential';...
 '*', 'Steady State'};
set(S,NameArray,ValueArray)
```

## More About

### Tips

You can use any combination of property name/property value pairs, structure arrays, and cell arrays in one call to `set`.

## Setting Property Units

Note that if you are setting both the `FontSize` and the `FontUnits` properties in one function call, you must set the `FontUnits` property first so that the MATLAB software can correctly interpret the specified `FontSize`. The same applies to figure and axes units — always set the `Units` property before setting properties whose values you want to be interpreted in those units. For example,

```
f = figure('Units', 'characters', 'Position', [30 30 120 35]);
```

- “Graphics Object Properties”

## See Also

`findobj` | `gca` | `gcf` | `gco` | `gcbo` | `get`

Introduced before R2006a

## set

Set property values for `audioplayer` object

## Syntax

```
set(obj,Name,Value)
set(obj,cellOfNames,cellOfValues)
set(obj,structOfProperties)
settableProperties = set(obj)
```

## Description

`set(obj,Name,Value)` sets the named property to the specified value for the object `obj`.

`set(obj,cellOfNames,cellOfValues)` sets the properties listed in the cell array `cellOfNames` to the corresponding values in the cell array `cellOfValues`. Each cell array must contain the same number of elements.

`set(obj,structOfProperties)` sets the properties identified by each field of the structure array `structOfProperties` to the values of the associated fields.

`settableProperties = set(obj)` returns the names of the properties that you can set in a structure array. The field names of `settableProperties` are the property names.

## Tips

The `set` function allows combinations of property name/value pairs, cell array pairs, and structure arrays in the same function call.

## Examples

View the list of properties that you can set for an `audioplayer` object:

```
load handel.mat;
handelObj = audioplayer(y, Fs);
set(handelObj)
```

Set the `Tag` and `UserData` properties of an `audioplayer` object using a structure array:

```
newValues.Tag = 'My Tag';
newValues.UserData = {'My User Data', pi, [1 2 3 4]};
```

```
load handel.mat;
handelObj = audioplayer(y, Fs);
set(handelObj, newValues)
```

```
% View the values all properties.
get(handelObj)
```

## Alternatives

To set the value of a single property, you can use dot notation. Reference each property as though it is a field of a structure array. For example, set the `Tag` property for an object called `handelObj` (as created in the Examples):

```
handelObj.Tag = 'This is my tag.';
```

This command is exactly equivalent to:

```
set(handelObj, 'Tag', 'This is my tag.');
```

## See Also

`audioplayer` | `get`

## set

Set property values for `audiorecorder` object

## Syntax

```
set(obj,Name,Value)
set(obj,cellOfNames,cellOfValues)
set(obj,structOfProperties)
settableProperties = set(obj)
```

## Description

`set(obj,Name,Value)` sets the named property to the specified value for the object `obj`.

`set(obj,cellOfNames,cellOfValues)` sets the properties listed in the cell array `cellOfNames` to the corresponding values in the cell array `cellOfValues`. Each cell array must contain the same number of elements.

`set(obj,structOfProperties)` sets the properties identified by each field of the structure array `structOfProperties` to the values of the associated fields.

`settableProperties = set(obj)` returns the names of the properties that you can set in a structure array. The field names of `settableProperties` are the property names.

## Tips

The `set` function allows combinations of property name/value pairs, cell array pairs, and structure arrays in the same function call.

## Examples

View the list of properties that you can set for an `audiorecorder` object:

```
recorderObj = audiorecorder;
set(recorderObj)
```

Set the `Tag` and `UserData` properties of an `audiorecorder` object using a structure array:

```
newValues.Tag = 'My Tag';
newValues.UserData = {'My User Data', pi, [1 2 3 4]};
```

```
recorderObj = audiorecorder;
set(recorderObj, newValues)
```

```
% View the values all properties.
get(recorderObj)
```

## Alternatives

To set the value of a single property, you can use dot notation. Reference each property as though it is a field of a structure array. For example, set the `Tag` property for an object called `recorderObj` (as created in the Examples):

```
recorderObj.Tag = 'This is my tag.';
```

This command is exactly equivalent to:

```
set(recorderObj, 'Tag', 'This is my tag.');
```

## See Also

`audiorecorder` | `get`

## set (COM)

Set object or interface property to specified value

### Syntax

```
set(h, 'pname', value)
set(h, 'pname1', value1, 'pname2', value2, ...)
```

### Description

`set(h, 'pname', value)` sets the property specified in the string `pname` to the given value.

`set(h, 'pname1', value1, 'pname2', value2, ...)` sets each property specified in the `pname` strings to the given value.

For information on how MATLAB converts workspace matrices to COM data types, see “Handle COM Data in MATLAB”.

COM functions are available on Microsoft Windows systems only.

### Examples

Create an `mwsamp` control and use `set` to change the `Label` and `Radius` properties with a single statement.

```
f = figure('position',[100 200 200 200]);
h = actxcontrol('mwsamp.mwsampctrl.1',[0 0 200 200],f);

set(h,'Label','Click to fire event','Radius',40);
Redraw(h)
```

Alternatively:

```
h.Label = 'Click to fire event';
h.Radius = 40;
```

Redraw(h)

## matlab.mixin.SetGet class

**Package:** matlab.mixin

Abstract class used to derive handle classes with set and get methods

---

**Note:** hgsetget will be removed in a future release. Use `matlab.mixin.SetGet` instead.

---

### Description

`classdef MySubClass < matlab.mixin.SetGet` makes *MySubClass* a subclass of the `matlab.mixin.SetGet` class, which is itself a subclass of the `handle` class

Use the `matlab.mixin.SetGet` class to derive classes that inherit `set` and `get` methods that behave like MATLAB graphics `set` and `get` functions.

### Methods

The `matlab.mixin.SetGet` class defines these method:

Method	Purpose
<code>set</code>	Assigns values to the specified properties or returns a cell array of possible values for writable properties.
<code>get</code>	Returns value of specified property or a <code>struct</code> with all property values.
<code>setdisp</code>	Implicitly called when <code>set</code> is called with no output arguments and a handle array, but no property name. Override this method to change what set displays.
<code>getdisp</code>	Implicitly called when <code>get</code> is called with no output arguments and handle array, but no property name. Override this method to change what get displays.

## Attributes

Abstract	true
ConstructOnLoad	true
HandleCompatible	true

## set

**Class:** matlab.mixin.SetGet

**Package:** matlab.mixin

Assign specified property name/property value pairs

## Syntax

```
set(H, 'Name', Value, ...)
set(H, pn, pv)
set(H, S)
S = set(h)
```

## Description

`set(H, 'Name', Value, ...)` sets the named property to the specified value for the objects in the handle array `H`.

`set(H, pn, pv)` sets the named properties specified in the cell array of strings `pn` to the corresponding values in the cell array `pv` for all objects specified in `H`. The cell array `pn` must be 1-by-`n` (where `n` is the number of property names), but the cell array `pv` can be `m`-by-`n` where `m` is equal to `length(H)`. `set` updates each object with the associated set of values for the list of property names contained in.

`set(H, S)` sets the properties identified by each field name of `struct` `S` with the values contained in `S`. `S` is a `struct` whose field names are object property names.

`S = set(h)` returns the user-settable properties of scalar `h`. `S` is a `struct` whose field names are the object's property names and values that are either empty cell arrays or cell arrays of possible values for properties that have a finite set of predefined possible values.

## Tips

- Override the `matlab.mixin.SetGet` class `setdisp` method to change how MATLAB displays information returned by `set`.

## Input Arguments

### **H** — Input handle array

handle array

Input handle array, specified as a single handle or an array of handles

### **'Name'** — Property name

string

Property name, specified as a quoted string

### **Value** — Property value to assign to the named property

property value

Property value to assign to the named property, specified as appropriate for that property.

### **pn** — Property names

cell array of strings

Property names, specified as a cell array of strings. The cell array **pn** must be 1-by-*n* (where *n* is the number of property names).

Data Types: `cell`

### **pv** — Property values

cell array

Property values, specified as a cell array. The cell array **pv** can be *m*-by-*n* where *m* is equal to `length(H)` and *n* is the number of property names in **pn**.

Data Types: `cell`

### **S** — Property name and value structure

struct

Property name and value structure. The fields of **S** correspond to property names and the values of the fields are the property values to set.

Data Types: `struct`

### **h** — Scalar object handle

handle

Scalar object handle. To obtain user-settable properties, input argument must be a scalar object handle.

## Output Arguments

### **S** — Settable properties

struct

Settable properties, returned as a structure with fields corresponding to property names and values that are either empty cell arrays or cell arrays of possible values for properties that have a finite set of predefined possible values.

## Attributes

Access

public

To learn about attributes of methods, see Method Attributes in the MATLAB Object-Oriented Programming documentation.

### **More About**

- “Implement Set/Get Interface for Properties”

# setdisp

**Class:** matlab.mixin.SetGet

**Package:** matlab.mixin

Customize set method display

## Syntax

setdisp(h)

## Description

setdisp(h) called by `set` when `set` is called with no output arguments and a single input argument that is a scalar handle. Override this `matlab.mixin.SetGet` class method in a subclass to change how property information is displayed in the command window.

## Input Arguments

**h** — Object handle

handle

Object handle whose settable properties and their possible values are to be displayed.

## Attributes

Access

public

To learn about attributes of methods, see Method Attributes in the MATLAB Object-Oriented Programming documentation.

## See Also

## **More About**

- “Implement Set/Get Interface for Properties”

# get

**Class:** matlab.mixin.SetGet

**Package:** matlab.mixin

Query specified property values

## Syntax

```
CV = get(H, 'Name ')
SV = get(h)
get(h)
```

## Description

`CV = get(H, 'Name ' )` returns the value of the named property from the objects in the handle array `H`. If `H` is scalar, `get` returns a single value; if `H` is an array, `get` returns a cell array of property values.

If you specify a cell array of property names as the second argument, then `get` returns a cell array of values, where each row in the cell corresponds to an element in `H` and each column in the cell corresponds to an element in the property name cell array.

If `H` is nonscalar and `'Name '` is the name of a dynamic property, `get` returns a value only if the property exists in all objects referenced in `H`.

`SV = get(h)` returns a structure array in which the field names are the object's property names and the values are the current values of the corresponding properties. If `h` is nonscalar, then `SV` is a `numel(h)`-by-1 array of structures.

`get(h)` displays all property names and their current values for the MATLAB objects with handle `h`.

Your subclass can override the `matlab.mixin.SetGet` `getdisp` method to control how MATLAB displays this information.

## Tips

- Override the `matlab.mixin.SetGet` class `matlab.mixin.SetGet.getdisp` method to change how MATLAB displays information returned by `get`.

## Input Arguments

### **H** — Input handle array

object array

Input handle array, specified as a single handle or an array of handles

### **'Name'** — Property to query

string

Property to query, specified as a case-sensitive string.

## Output Arguments

### **CV** — Value of queried property

property value

Value of queried property, returned as a single value or a cell array of values.

### **SV** — Structure array of property names and values

struct

Structure array of property names and values, in which the field names are the object's property names and the values are the current values of the corresponding properties.

Data Types: `struct`

## set (RandStream)

Set random number stream property

### Class

RandStream

### Syntax

```
set(stream, 'PropertyName', Value)
set(stream, 'Property1', Value1, 'Property2', Value2, ...)
set(stream, A)
A = set(stream, 'Property')
set(stream, 'Property')
A = set(stream)
set(stream)
```

### Description

`set(stream, 'PropertyName', Value)` sets the property 'PropertyName' of the random stream `stream` to the value `Value`.

`set(stream, 'Property1', Value1, 'Property2', Value2, ...)` sets multiple random stream property values with a single statement.

`set(stream, A)` where `A` is a structure whose field names are property names of the random stream `stream` sets the properties of `stream` named by each field with the values contained in those fields.

`A = set(stream, 'Property')` or `set(stream, 'Property')` displays possible values for the specified property of `stream`.

`A = set(stream)` or `set(stream)` displays or returns all writable properties of `stream` and their possible values.

## See Also

RandStream | get (RandStream) | rand | randn | randi

## set (serial)

Configure or display serial port object properties

### Syntax

```
set(obj)
props = set(obj)
set(obj, 'PropertyName')
props = set(obj, 'PropertyName')
set(obj, 'PropertyName', PropertyValue, ...)
set(obj, PN, PV)
set(obj, S)
```

### Description

`set(obj)` displays all configurable properties values for the serial port object, `obj`. If a property has a finite list of possible string values, then these values are also displayed.

`props = set(obj)` returns all configurable properties and their possible values for `obj` to `props`. `props` is a structure whose field names are the property names of `obj`, and whose values are cell arrays of possible property values. If the property does not have a finite set of possible values, then the cell array is empty.

`set(obj, 'PropertyName')` displays the valid values for *PropertyName* if it possesses a finite list of string values.

`props = set(obj, 'PropertyName')` returns the valid values for *PropertyName* to `props`. If *PropertyName* does not have a finite list of possible values, `props` is a cell array of possible string values or an empty cell array.

`set(obj, 'PropertyName', PropertyValue, ...)` configures multiple property values with a single command.

`set(obj, PN, PV)` configures the properties specified in the cell array of strings `PN` to the corresponding values in the cell array `PV`. `PN` must be a vector. `PV` can be m-by-n where `m` is equal to the number of serial port objects in `obj` and `n` is equal to the length of `PN`.

`set(obj, S)` configures the named properties to the specified values for `obj`. `S` is a structure whose field names are serial port object properties, and whose field values are the values of the corresponding properties.

## Examples

This example illustrates shows how to use the `set` function to configure or return property values, on a Windows platform.

```
s = serial('COM1');
set(s, 'BaudRate', 9600, 'Parity', 'even')
set(s, {'StopBits', 'RecordName'}, {2, 'sydney.txt'})
set(s, 'Parity')
[{none} | odd | even | mark | space]
```

## More About

### Tips

Refer to [Configuring Property Values](#) for a list of serial port object properties that you can configure with `set`.
