© COPYRIGHT 1984–2015 by The MathWorks, Inc.

The software described in this document is furnished under a license agreement. The software may be used or copied only under the terms of the license agreement. No part of this manual may be photocopied or reproduced in any form without prior written consent from The MathWorks, Inc.

FEDERAL ACQUISITION: This provision applies to all acquisitions of the Program and Documentation by, for, or through the federal government of the United States. By accepting delivery of the Program or Documentation, the government hereby agrees that this software or documentation qualifies as commercial computer software or commercial computer software documentation as such terms are used or defined in FAR 12.212, DFARS Part 227.72, and DFARS 252.227-7014. Accordingly, the terms and conditions of this Agreement and only those rights specified in this Agreement, shall pertain to and govern the use, modification, reproduction, release, performance, display, and disclosure of the Program and Documentation by the federal government (or other entity acquiring for or through the federal government) and shall supersede any conflicting contractual terms or conditions. If this License fails to meet the government's needs or is inconsistent in any respect with federal procurement law, the government agrees to return the Program and Documentation, unused, to The MathWorks, Inc.

Trademarks

MATLAB and Simulink are registered trademarks of The MathWorks, Inc. See www.mathworks.com/trademarks for a list of additional trademarks. Other product or brand names may be trademarks or registered trademarks of their respective holders.

Patents

MathWorks products are protected by one or more U.S. patents. Please see www.mathworks.com/patents for more information.

Revision History

December 1996	First printing	For MATLAB 5.0 (Release 8)
June 1997	Online only	Revised for MATLAB 5.1 (Release 9)
October 1997	Online only	Revised for MATLAB 5.2 (Release 10)
January 1999	Online only	Revised for MATLAB 5.3 (Release 11)
June 1999	Second printing	For MATLAB 5.3 (Release 11)
June 2001	Online only	Revised for MATLAB 6.1 (Release 12.1)
July 2002	Online only	Revised for 6.5 (Release 13)
June 2004	Online only	Revised for 7.0 (Release 14)
September 2006	Online only	Revised for 7.3 (Release 2006b)
March 2007	Online only	Revised for 7.4 (Release 2007a)
September 2007	Online only	Revised for Version 7.5 (Release 2007b)
March 2008	Online only	Revised for Version 7.6 (Release 2008a)
October 2008	Online only	Revised for Version 7.7 (Release 2008b)
March 2009	Online only	Revised for Version 7.8 (Release 2009a)
September 2009	Online only	Revised for Version 7.9 (Release 2009b)
March 2010	Online only	Revised for Version 7.10 (Release 2010a)
September 2010	Online only	Revised for Version 7.11 (Release 2010b)
April 2011	Online only	Revised for Version 7.12 (Release 2011a)
September 2011	Online only	Revised for Version 7.13 (Release 2011b)
March 2012	Online only	Revised for Version 7.14 (Release 2012a)
September 2012	Online only	Revised for Version 8.0 (Release 2012b)
March 2013	Online only	Revised for Version 8.1 (Release 2013a)
September 2013	Online only	Revised for Version 8.2 (Release 2013b)
March 2014	Online only	Revised for Version 8.3 (Release 2014a)
October 2014	Online only	Revised for Version 8.4 (Release 2014b)
March 2015	Online only	Revised for Version 8.5 (Release 2015a)
September 2015	Online only	Revised for Version 8.6 (Release 2015b)

Relational Operators < > <= >= == ~=

Relational operations

Syntax

A < B

A > B

A <= B

A >= B

A == B

A ~= B

Description

The relational operators are <, >, <=, >=, ==, and ~=. Relational operators perform element-by-element comparisons between two arrays. They return a **logical** array of the same size, with elements set to logical 1 (**true**) where the relation is true, and elements set to logical 0 (**false**) where it is not.

The operators <, >, <=, and >= use only the real part of their operands for the comparison. The operators == and ~= test real and imaginary parts.

To test if two strings are equivalent, use `strcmp`, which allows vectors of dissimilar length to be compared.

Note For some toolboxes, the relational operators are overloaded, that is, they perform differently in the context of that toolbox. To see the toolboxes that overload a given operator, type `help` followed by the operator name. For example, type `help lt`. The toolboxes that overload `lt` (<) are listed. For information about using the operator in that toolbox, see the documentation for the toolbox.

Examples

If one of the operands is a scalar and the other a matrix, the scalar expands to the size of the matrix. For example, the two pairs of statements

```
X = 5; X >= [1 2 3; 4 5 6; 7 8 10]
X = 5*ones(3,3); X >= [1 2 3; 4 5 6; 7 8 10]
```

produce the same result:

```
ans =
```

```
    1    1    1
    1    1    0
    0    0    0
```

Logical Operators: Short-Circuit && ||

Logical operations with short-circuiting

Syntax

```
expr1 && expr2  
expr1 || expr2
```

Description

`expr1 && expr2` represents a logical AND operation that employs short-circuiting behavior. That is, `expr2` is not evaluated if `expr1` is logical 0 (false). Each expression must evaluate to a scalar logical result.

`expr1 || expr2` represents a logical OR operation that employs short-circuiting behavior. That is, `expr2` is not evaluated if `expr1` is logical 1 (true). Each expression must evaluate to a scalar logical result.

Examples

Use Scalar Logical Conditions

Create two vectors.

```
X = [1 0 0 1 1];  
Y = [0 0 0 0 0];
```

Use the short-circuit OR operator with `X` and `Y`.

```
X || Y
```

Operands to the `||` and `&&` operators must be convertible to logical scalar values.

The short-circuit operators operate only with scalar logical conditions.

Use the `any` and `all` functions to reduce each vector to a single logical condition.

```
any(X) || any(Y)
```

```
ans =
```

```
1
```

The expression is equivalent to `1 || 0`, so it evaluates to logical 1 (**true**) after computing only the first condition, `any(X)`.

Specify Dependent Logical Conditions

Specify a logical statement where the second condition depends on the first. In the following statement, it doesn't make sense to evaluate the relation on the right if the divisor, `b`, is zero.

```
b = 1;  
a = 20;  
x = (b ~= 0) && (a/b > 18.5)
```

```
x =
```

```
1
```

The result is logical 1 (**true**). However, if `(b ~= 0)` evaluates to **false**, MATLAB[®] assumes the entire expression to be **false** and terminates its evaluation of the expression early.

Specify `b = 0` and evaluate the same expression.

```
b = 0;  
x = (b ~= 0) && (a/b > 18.5)
```

```
x =
```

```
0
```

The result is logical 0 (**false**). The first statement evaluates to logical 0 (**false**), so the expression short-circuits.

Change Structure Field Value

Create a structure with fields named 'File' and 'Format'.

```
S = struct('File', {'myGraph'}, 'Format', [])
```

```
S =
    File: 'myGraph'
    Format: []
```

Short-circuit expressions are useful in *if* statements when you want multiple conditions to be true. The conditions can build on one another in such a way that it only makes sense to evaluate the second expression if the first expression is true.

Specify an *if* statement that executes only when **S** contains an empty field named 'Format'.

```
if isfield(S,'Format') && isempty(S.Format)
    S.Format = '.png';
end
S
```

S =

```
    File: 'myGraph'
    Format: '.png'
```

The first condition tests if the string 'Format' is the name of a field in structure **S**. The second statement then tests whether the **Format** field is empty. The truth of the second condition depends on the first. The second condition can never be true if the first condition is not true. Since **S** has an empty field named 'Format', the body statement executes and assigns **S.Format** the value '.png'.

More About

Logical Short-Circuiting

With logical short-circuiting, the second operand, **expr2**, is evaluated only when the result is not fully determined by the first operand, **expr1**.

Due to the properties of logical AND and OR, the result of a logical expression is sometimes fully determined before evaluating all of the conditions. The logical **and** operator returns logical 0 (**false**) if even a single condition in the expression is false. The logical **or** operator returns logical 1 (**true**) if even a single condition in the expression is true. When the evaluation of a logical expression terminates early by encountering one of these values, the expression is said to have *short-circuited*.

For example, in the expression `A && B`, MATLAB does not evaluate condition `B` at all if condition `A` is false. If `A` is false, then the value of `B` does not change the outcome of the operation.

When you use the element-wise `&` and `|` operators in the context of an `if` or `while` loop expression (and *only* in that context), they use short-circuiting to evaluate expressions.

Note: Always use the `&&` and `||` operators to enable short-circuit evaluation. Using the `&` and `|` operators for short-circuiting can yield unexpected results when the expressions do not evaluate to logical scalars.

Description

[]	<p>Brackets are used to form vectors and matrices. <code>[6.9 9.64 sqrt(-1)]</code> is a vector with three elements separated by blanks. <code>[6.9, 9.64, i]</code> is the same thing. <code>[1+j 2-j 3]</code> and <code>[1 +j 2 -j 3]</code> are not the same. The first has three elements, the second has five.</p> <p><code>[11 12 13; 21 22 23]</code> is a 2-by-3 matrix. The semicolon ends the first row.</p> <p>Vectors and matrices can be used inside [] brackets. <code>[A B;C]</code> is allowed if the number of rows of A equals the number of rows of B and the number of columns of A plus the number of columns of B equals the number of columns of C. This rule generalizes to allow fairly complicated constructions.</p>
-----	---

	<p>$A = []$ stores an empty matrix in A. $A(m, :) = []$ deletes row m of A. $A(:, n) = []$ deletes column n of A. $A(n) = []$ reshapes A into a column vector and deletes the nth element.</p> <p>$[A1, A2, A3 \dots] = \text{function}$ assigns function output to multiple variables.</p> <p>For the use of $[$ and $]$ on the left of an “=” in multiple assignment statements, see <code>lu</code>, <code>eig</code>, <code>svd</code>, and so on.</p>
{ }	<p>Curly braces are used in cell array assignment statements. For example, $A(2,1) = \{[1\ 2\ 3; 4\ 5\ 6]\}$, or $A\{2,2\} = ('str')$. See <code>help paren</code> for more information about $\{ \}$.</p>
()	<p>Parentheses are used to indicate precedence in arithmetic expressions in the usual way. They are used to enclose arguments of functions in the usual way. They are also used to enclose subscripts of vectors and matrices in a manner somewhat more general than usual. If X and V are vectors, then $X(V)$ is $[X(V(1)), X(V(2)), \dots, X(V(n))]$. The components of V must be integers to be used as subscripts. An error occurs if any such subscript is less than 1 or greater than the size of X. Some examples are</p> <ul style="list-style-type: none"> • $X(3)$ is the third element of X. • $X([1\ 2\ 3])$ is the first three elements of X. <p>See <code>help paren</code> for more information about $()$.</p> <p>If X has n components, $X(n:-1:1)$ reverses them. The same indirect subscripting works in matrices. If V has m components and W has n components, then $A(V,W)$ is the m-by-n matrix formed from the elements of A whose subscripts are the elements of V and W. For example, $A([1,5], :) = A([5,1], :)$ interchanges rows 1 and 5 of A.</p>
=	<p>Used in assignment statements. $B = A$ stores the elements of A in B. $==$ is the relational equals operator. See the Relational Operators page.</p>
'	<p>Matrix transpose. X' is the complex conjugate transpose of X. $X \cdot '$ is the nonconjugate transpose.</p> <p>Quotation mark. <code>'any text'</code> is a vector whose components are the ASCII codes for the characters. A quotation mark within the text is indicated by two quotation marks.</p>

.	Decimal point. <code>314/100</code> , <code>3.14</code> , and <code>.314e1</code> are all the same. Element-by-element operations. These are obtained using <code>.*</code> , <code>.^</code> , <code>./</code> , or <code>.\</code> . See the Arithmetic Operators page.
.	Field access. <code>S(m).f</code> when <code>S</code> is a structure, accesses the contents of field <code>f</code> of that structure.
. ()	Dynamic Field access. <code>S.(df)</code> when <code>S</code> is a structure, accesses the contents of dynamic field <code>df</code> of that structure. Dynamic field names are defined at runtime.
..	Parent folder. See <code>cd</code> .
...	Continuation. Three or more periods at the end of a line continue the current function on the next line. Three or more periods before the end of a line cause the MATLAB software to ignore the remaining text on the current line and continue the function on the next line. This effectively makes a comment out of anything on the current line that follows the three periods. For an example, see “Continue Long Statements on Multiple Lines”.
,	Comma. Used to separate matrix subscripts and function arguments. Used to separate statements in multistatement lines. For multistatement lines, the comma can be replaced by a semicolon to suppress printing.
;	Semicolon. Used inside brackets to end rows. Used after an expression or statement to suppress printing or to separate statements.
:	Colon. Create vectors, array subscripting, and <code>for</code> loop iterations. See <code>colon</code> for details.
%	Percent. The percent symbol denotes a comment; it indicates a logical end of line. Any following text is ignored. MATLAB displays the first contiguous comment lines in a function or script file in response to a <code>help</code> command.
%{ %}	Percent-brace. The text enclosed within the <code>%{</code> and <code>%}</code> symbols is a comment block. Use these symbols to insert comments that take up more than a single line in your script of function code. Any text between these two symbols is ignored by MATLAB. With the exception of whitespace characters, the <code>%{</code> and <code>%}</code> operators must appear alone on the lines that immediately precede and follow the block of help text. Do not include any other text on these lines.
!	Exclamation point. Indicates that the rest of the input line is issued as a command to the operating system. See “Run External Commands, Scripts, and Programs” for more information.

@	Function handle. MATLAB data type that is a handle to a function. See “Create Function Handle” for details.
---	---

More About

Tips

Some uses of special characters have function equivalents, as shown:

Horizontal concatenation	[A,B,C...]	horzcat(A,B,C...)
Vertical concatenation	[A;B;C...]	vertcat(A,B,C...)
Subscript reference	A(i,j,k...)	subsref(A,S). See help subsref.
Subscript assignment	A(i,j,k...)= B	subsasgn(A,S,B). See help subsasgn.

Note For some toolboxes, the special characters are overloaded, that is, they perform differently in the context of that toolbox. To see the toolboxes that overload a given character, type `help` followed by the character name. For example, type `help transpose`. The toolboxes that overload `transpose` (.'') are listed. For information about using the character in that toolbox, see the documentation for the toolbox.

- “Logical Operations”
- “Relational Operations”

“Array vs. Matrix Operations”

colon, :

Create vectors, array subscripting, and for-loop iterators

Description

The colon is one of the most useful operators in MATLAB. It can create vectors, subscript arrays, and specify for iterations.

The colon operator uses the following rules to create regularly spaced vectors for scalar values i , j , and k :

$j:k$	is the same as $[j, j+1, j+2, \dots, j+m]$, where $m = \text{fix}(k-j)$. In the case where both j and k are integers, this is simply $[j, j+1, \dots, k]$. This syntax returns an empty matrix when $j > k$.
$j:i:k$	is the same as $[j, j+i, j+2i, \dots, j+m*i]$, where $m = \text{fix}((k-j)/i)$. This syntax returns an empty matrix when $i == 0, i > 0$ and $j > k$, or $i < 0$ and $j < k$.

If i , j , or k is an empty input, then the colon operator returns an empty 1-by-0 matrix. If you specify nonscalar arrays, MATLAB interprets $j:i:k$ as $j(1):i(1):k(1)$.

You can use the colon to create a vector of indices to select rows, columns, or elements of arrays, where:

$A(:, j)$	is the j th column of A .
$A(i, :)$	is the i th row of A .
$A(:, :)$	is the equivalent two-dimensional array. For matrices this is the same as A .
$A(j:k)$	is $A(j), A(j+1), \dots, A(k)$.
$A(:, j:k)$	is $A(:, j), A(:, j+1), \dots, A(:, k)$.
$A(:, :, k)$	is the k th page of three-dimensional array A .
$A(i, j, k, :)$	is a vector in four-dimensional array A . The vector includes $A(i, j, k, 1), A(i, j, k, 2), A(i, j, k, 3)$, and so on.

<code>A(:)</code>	is all the elements of <code>A</code> , regarded as a single column. On the left side of an assignment statement, <code>A(:)</code> fills <code>A</code> , preserving its shape from before. In this case, the right side must contain the same number of elements as <code>A</code> .
-------------------	--

When you create a vector to index into a cell array or structure array (such as `cellName{:}` or `structName(:).fieldName`), MATLAB returns multiple outputs in a comma-separated list. For more information, see “How to Use the Comma-Separated Lists” in the MATLAB Programming Fundamentals documentation.

Examples

Using the colon with integers,

```
D = 1:4
```

results in

```
D =  
    1    2    3    4
```

Using two colons to create a vector with arbitrary real increments between the elements,

```
E = 0:.1:.5
```

results in

```
E =  
    0    0.1000    0.2000    0.3000    0.4000    0.5000
```

The command

```
A(:,:,2) = pascal(3)
```

generates a three-dimensional array whose first page is all zeros.

```
A(:,:,1) =  
    0    0    0  
    0    0    0  
    0    0    0
```

```
A(:,:,2) =  
    1    1    1
```

```
1     2     3
1     3     6
```

Using a colon with characters to iterate a for-loop,

```
for x='a':'d',x,end
```

results in

```
x =
  a
x =
  b
x =
  c
x =
  d
```

See Also

for | linspace | logspace | reshape | varargin

abs

Absolute value and complex magnitude

Syntax

```
Y = abs(X)
```

Description

`Y = abs(X)` returns the absolute value of each element in array `X`.

If `X` is complex, `abs(X)` returns the complex magnitude.

Examples

Absolute Value of Scalar

```
y = abs(-5)
```

```
y =
```

```
    5
```

Absolute Value of Vector

Create a numeric vector of real values.

```
x = [1.3 -3.56 8.23 -5 -0.01]'
```

```
x =
```

```
    1.3000  
   -3.5600  
    8.2300  
   -5.0000  
   -0.0100
```

Find the absolute value of the elements of the vector.

```
y = abs(x)
```

```
y =
```

```
1.3000  
3.5600  
8.2300  
5.0000  
0.0100
```

Magnitude of Complex Number

```
y = abs(3+4i)
```

```
y =
```

```
5
```

Input Arguments

X — Input array

scalar | vector | matrix | multidimensional array

Input array, specified as a scalar, vector, matrix, or multidimensional array. X can be a **single** array, **double** array, signed integer array, or **duration** array. The size and data type of the output array is the same as the input array.

Complex Number Support: Yes

More About

Absolute Value

The absolute value (or modulus) of a real number is the corresponding nonnegative value that disregards the sign.

For a real value, **a**, the absolute value is:

- **a**, if **a** is greater than or equal to zero
- **-a**, if **a** is less than zero

`abs(-0)` returns 0.

Complex Magnitude

The complex magnitude (or modulus) is the length of a vector from the origin to a complex value plotted in the complex plane.

For a complex value, $|a + bi|$ is defined as $\sqrt{a^2 + b^2}$.

See Also

angle | hypot | sign | unwrap

Introduced before R2006a

accumarray

Construct array with accumulation

Syntax

```
A = accumarray(subs, val)
A = accumarray(subs, val, sz)
A = accumarray(subs, val, sz, fun)
A = accumarray(subs, val, sz, fun, fillval)
A = accumarray(subs, val, sz, fun, fillval, issparse)
```

Description

`A = accumarray(subs, val)` returns array `A` by accumulating elements of vector `val` using the subscripts `subs`. If `subs` is a column vector, then each element defines a corresponding subscript in the output, which is also a column vector. The `accumarray` function collects all elements of `val` that have identical subscripts in `subs` and stores their sum in the location of `A` corresponding to that subscript (for index `i`, `A(i)=sum(val(subs(:)==i))`). Elements of `A` whose subscripts do not appear in `subs` are equal to 0.

For an m -by- n matrix `subs`, each row represents an n -dimensional subscript into output `A`. The i th row of `subs` corresponds to the i th element in the vector `val`.

`A = accumarray(subs, val, sz)` returns an array, `A`, with size `sz`. Specify `sz` as a vector of positive integers to define the size of the output, or as `[]` to let the subscripts in `subs` determine the size of the output. Use `sz` when `subs` does not reference trailing rows, columns, or dimensions that you would like to be present in the output.

`A = accumarray(subs, val, sz, fun)` applies the function `fun` to each subset of elements in `val` that have identical subscripts in `subs`. Specify `fun` using the `@` symbol (e.g., `@mean`), or as `[]` to use the default function, `@sum`.

`A = accumarray(subs, val, sz, fun, fillval)` fills all elements of `A` that are not referred to by any subscript in `subs` with the scalar value, `fillval`. The `fillval` input must have the same class as the values returned by `fun`. Specify `fillval` as `[]` to use the default value, 0.

`A = accumarray(subs, val, sz, fun, fillval, issparse)` returns an array, `A`, that is sparse if the scalar `issparse` is `true` or `1`, and full if `issparse` is `false` or `0`. The output, `A`, is full by default.

Examples

Find Bin Counts

Create a vector of subscripts, `subs`.

```
subs = [1; 2; 4; 2; 4]
```

```
subs =  
     1  
     2  
     4  
     2  
     4
```

Use `accumarray` with `val = 1` to count the number of identical subscripts in `subs`.

```
A = accumarray(subs, 1)
```

```
A =  
     1  
     2  
     0  
     2
```

The result is a vector of bin counts. You can obtain the same answer with `histcounts(subs, 'BinMethod', 'integers')`. However, `accumarray` also can compute bin counts over higher dimensional grids.

Accumulate Data

Create a vector of data, `val`, and a vector of subscript values with the same length, `subs`.

```
val = 101:105';  
subs = [1; 3; 4; 3; 4]  
  
subs =
```

```

1
3
4
3
4

```

Use `accumarray` to sum the values in `val` that have identical subscripts in `subs`.

```
A = accumarray(subs, val)
```

```
A =
    101
     0
    206
    208

```

The result is a vector of accumulated values. Since the second and fourth elements of `subs` are equal to 3, `A(3)` is the sum of the second and fourth elements of `val`, that is, `A(3) = 102 + 104 = 206`. Also, `A(2) = 0` because `subs` does not contain the value 2. Since `subs` is a vector, the output, `A`, is also a vector. The length of `A` is `max(subs, [], 1)`.

Specify Output Size

Create a vector of data, `val`, and a matrix of subscripts, `subs`.

```
val = 101:106';
subs = [1 1; 2 2; 3 2; 1 1; 2 2; 4 1]
```

```
subs =
```

```

1     1
2     2
3     2
1     1
2     2
4     1

```

The subscripts in `subs` define a 4-by-2 matrix for the output.

Use `accumarray` to sum the values in `val` that have identical subscripts in `subs`.

```
A = accumarray(subs, val)
```

```
A =
```

```
205    0
    0 207
    0 103
106    0
```

The result is a 4-by-2 matrix of accumulated values.

Use the `sz` input of `accumarray` to return a 4-by-4 matrix. You can specify a size with each dimension equal to or greater than the default size, in this case 4-by-2, but not smaller.

```
A = accumarray(subs, val, [4 4])
```

```
A =
```

```
205    0    0    0
    0 207    0    0
    0 103    0    0
106    0    0    0
```

The result is a 4-by-4 matrix of accumulated values.

Use Custom Functions

Create a vector of data, `val`, and a matrix of subscripts, `subs`.

```
val = [100.1 101.2 103.4 102.8 100.9 101.5]';
subs = [1 1; 1 1; 2 2; 3 2; 2 2; 3 2]
```

```
subs =
```

```
1    1
1    1
2    2
3    2
2    2
3    2
```

The subscripts in `subs` define a 3-by-2 matrix for the output.

Use the `fun` input of `accumarray` to calculate the within-group variances of data in `val` that have identical subscripts in `subs`. Specify `fun` as `@var`.

```
A1 = accumarray(subs, val, [], @var)
```

```
A1 =
    0.6050         0
         0    3.1250
         0    0.8450
```

The result is a 3-by-2 matrix of variance values.

Alternatively, you can specify `fun` as an anonymous function so long as it accepts vector inputs and returns a scalar. A common situation where this is useful is when you want to pass additional parameters to a function. In this case, use the `var` function with a normalization parameter.

```
A2 = accumarray(subs, val, [], @(x) var(x, 1))
```

```
A2 =
    0.3025         0
         0    1.5625
         0    0.4225
```

The result is a 3-by-2 matrix of normalized variance values.

Sum Values Natively

Create a vector of data, `val`, and a matrix of subscripts, `subs`.

```
val = int8(10:15);
subs = [1 1 1; 1 1 1; 1 1 2; 1 1 2; 2 3 1; 2 3 2]
```

```
subs =
     1     1     1
     1     1     1
     1     1     2
     1     1     2
     2     3     1
     2     3     2
```

The subscripts in `subs` define a 2-by-3-by-2 multidimensional array for the output.

Use `accumarray` to sum the data values in `val` that have identical subscripts in `subs`. You can use a function handle to sum the values in their native, `int8`, integer class by using the `'native'` option of the `sum` function.

```
A = accumarray(subs, val, [], @(x) sum(x, 'native'))
```

```
A(:, :, 1) =
```

```
    21     0     0
     0     0    14
```

```
A(:, :, 2) =
```

```
    25     0     0
     0     0    15
```

The result is a 2-by-3-by-2 multidimensional array of class `int8`.

Group Values in Cell Array

Create a vector of data, `val`, and a matrix of subscripts, `subs`.

```
val = 1:10;
```

```
subs = [1 1; 1 1; 1 1; 1 1; 2 1; 2 1; 2 1; 2 1; 2 1; 2 2]
```

```
subs =
```

```
     1     1
     1     1
     1     1
     1     1
     2     1
     2     1
     2     1
     2     1
     2     1
     2     2
```

The subscripts in `subs` define a 2-by-2 matrix for the output.

Use `accumarray` to group the elements of `val` into a cell array.

```
A = accumarray(subs, val, [], @(x) {x})
```

```
A =
```

```
    [4x1 double]    []
```

```
[5x1 double]    [10]
```

The result is a 2-by-2 cell array.

Verify that the vector elements are in the same order as they appear in `val`.

```
A{2,1}
```

```
ans =
```

```
5
6
7
8
9
```

Since the subscripts in `subs` are sorted, the elements of the numeric vectors in the cell array are in the same order as they appear in `val`.

Using Functions That Depend on Data Order

Create a vector of data, `val`, and a matrix of subscripts, `subs`.

```
val = 1:5;
subs = [1 2; 1 1; 1 2; 1 1; 2 3]
```

```
subs =
```

```
1    2
1    1
1    2
1    1
2    3
```

The subscripts in `subs` define a 2-by-3 matrix for the output, but are unsorted with respect to the linear indices in the output, `A`.

Group the values in `val` into a cell array by specifying `fun = @(x) {x}`.

```
A = accumarray(subs, val, [], @(x) {x})
```

```
A =
```

```
[2x1 double]    [2x1 double]    []
```

```
        []          []    [5]
```

The result is a 2-by-3 cell array.

Examine the vector in `A{1,2}`.

```
A{1,2}
```

```
ans =
```

```
    3  
    1
```

The elements of the `A{1,2}` vector are in a different order than in `val`. The first element of the vector is 3 instead of 1. If the subscripts in `subs` are not sorted with respect to their linear indices, then `accumarray` might not always preserve the order of the data in `val` when it passes them to `fun`. In the unusual case that `fun` requires that its input values be in the same order as they appear in `val`, sort the indices in `subs` with respect to the linear indices of the output.

In this case, use the `sortrows` function with two inputs and two outputs to reorder `subs` and `val` concurrently with respect to the linear indices of the output.

```
[S,I] = sortrows(subs,[2,1]);  
A = accumarray(S,val(I),[],@(x) {x});  
A{1,2}
```

```
ans =
```

```
    1  
    3
```

The elements of the `A{1,2}` vector are now in sorted order.

Fill Output with NaN Values

Create a vector of data, `val`, and a matrix of subscripts, `subs`.

```
val = 101:106';  
subs = [1 1; 2 2; 3 3; 1 1; 2 2; 4 4]
```

```
subs =
```

```

1     1
2     2
3     3
1     1
2     2
4     4

```

The subscripts in `subs` define a 4-by-4 matrix for the output, but only reference 4 out of the 16 elements. By default, the other 12 elements are `0` in the output.

Use the `fillval` input of `accumarray` to fill in the extra output elements with NaN values.

```
A = accumarray(subs, val, [], [], NaN)
```

```
A =
```

```

205   NaN   NaN   NaN
NaN   207   NaN   NaN
NaN   NaN   103   NaN
NaN   NaN   NaN   106

```

The result is a 4-by-4 matrix padded with NaN values.

Change Output Sparsity

Create a vector of data, `val`, and a matrix of subscripts, `subs`.

```
val = [34 22 19 85 53 77 99 6];
subs = [1 1; 400 400; 80 80; 1 1; 400 400; 400 400; 80 80; 1 1]
```

```
subs =
```

```

1     1
400  400
80    80
1     1
400  400
400  400
80    80
1     1

```

The subscripts in `subs` define a 400-by-400 matrix for the output, but only reference 3 out of the 160,000 elements. When the result of an operation with `accumarray` leads to

a large output array with low density of nonzero elements, you can save storage space by storing the output as a sparse matrix.

Use the `issparse` input of `accumarray` to return a sparse matrix.

```
A = accumarray(subs, val, [], [], [], true)
```

A =

```
      (1,1)      125
      (80,80)    118
      (400,400)  152
```

The result is a sparse matrix. You can obtain the same answer with `sparse(subs(:,1), subs(:,2), val)`.

Input Arguments

subs — Subscript matrix

vector of indices | matrix of indices | cell array of index vectors

Subscript matrix, specified as a vector of indices, matrix of indices, or cell array of index vectors. The indices must be positive integers:

- The value in each row of the m -by- n matrix, **subs**, specifies an n -dimensional index into the output, **A**. For example, if **subs** is a 3-by-2 matrix, it contains three 2-D subscripts. **subs** also can be a column vector of indices, in which case the output, **A**, is also a column vector.
- The i th row in **subs** corresponds to the i th data value in **val**.
- If **subs** is empty, then the `accumarray` function errors.

Thus, **subs** determines which data in **val** to group, as well as its final destination in the output. If **subs** is a cell array of index vectors, each vector must have the same length, and the function treats the vectors as columns of a subscript matrix.

val — Data

vector | scalar

Data, specified as a vector or scalar:

- If `val` is a vector, it must have the same length as the number of rows in `subs`.
- If `val` is a scalar, it is scalar expanded.

In both cases, a one-to-one pairing is present between the subscripts in each row of `subs` and the data values in `val`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char`

Complex Number Support: Yes

sz — Size of output array

`[]` (default) | vector of positive integers

Size of output array, specified as a vector of positive integers or `[]` (default). When you specify `[]` for the default size, the values in `subs` determine the size of the output array, `A`.

When you specify `sz` as a vector of positive integers, it must satisfy these properties:

- If `subs` is a nonempty m -by- n matrix with $n > 1$ columns, then `sz` must have n elements and pass the logical test `all(sz >= max(subs, [], 1))`.
- If `subs` is a nonempty column vector, then `sz` must be `[m 1]` where $m \geq \max(\text{subs})$.

Example: `sz = [3 3]`

fun — Function

`[]` (default) | function handle

Function, specified as a function handle or `[]` (default). The default function is `@sum`. The `fun` function must accept a column vector and return a numeric, `logical`, or `char` scalar, or a scalar `cell`. If the subscripts in `subs` are not sorted with respect to their linear indices, `fun` should not depend on the order of the values in its input data. For more information on function handles, see “Create Function Handle”.

Example: `fun = @max`

Data Types: `function_handle`

fillval — Fill value

`[]` (default) | scalar

Fill value, specified as a scalar or `[]` (default). The default value of `fillval` is `0`. If `subs` does not reference each element in the output, `accumarray` fills in the output with the value specified by `fillval`. The class of `fillval` must be the same as the values returned by `fun`.

issparse — Output sparsity

`false` (default) | `true` | `1` | `0`

Output sparsity, specified as `true`, `1`, `0`, or `false` (default). Specify `true` or `1` when you want the output array to be sparse. If `issparse` is `true` or `1`:

- `fillval` must be `0` or `[]`.
- The values in `val` and the output values of `fun` must both have type `double`.

Output Arguments

A — Output array

vector | matrix | multidimensional array

Output array, returned as a vector, matrix, or multidimensional array. `A` has the same class as the values returned by `fun`.

When `sz` is not specified, the size of `A` depends on the input `subs`:

- If `subs` is a nonempty matrix with $n > 1$ columns, then `A` is an n -dimensional array of size `max(subs, [], 1)`.
- If `subs` is an empty matrix with $n > 1$ columns, then `A` is an n -dimensional empty array with size `0-by-0-by-...-by-0`.
- If `subs` is a nonempty column vector, then `A` is a column vector of length `max(subs, [], 1)`. The length of `A` is `0` when `subs` is empty.

More About

Accumulating Elements

The following graphic illustrates the behavior of `accumarray` on a vector of temperature data taken over a 12-month period. To find the maximum temperature reading for each

month, `accumarray` applies the `max` function to each group of values in `temperature` that have identical subscripts in `month`.

```
maxTemp = accumarray(subs, val, [], @max)
```

No values in `month` point to the 5, 6, 7, or 10 positions of the output. These elements are 0 in the output by default, but you can specify a value to fill in using `fillval`.

Tips

- The behavior of `accumarray` is similar to that of the `histcounts` function. Both functions group data into bins.
 - `histcounts` groups continuous values into a 1-D range using bin edges. `accumarray` groups data using n -dimensional subscripts.
 - `histcounts` returns the bin counts and/or bin placement. However, `accumarray` can apply any function to the binned data.

You can mimic the behavior of `histcounts` using `accumarray` with `val = 1`.

- The `sparse` function also has accumulation behavior similar to that of `accumarray`.
 - `sparse` groups data into bins using 2-D subscripts, whereas `accumarray` groups data into bins using n -dimensional subscripts.
 - For elements with identical subscripts, `sparse` assigns the sum of those elements to the output. `accumarray` does the same by default, but optionally can apply any function to the bins.

Introduced before R2006a

acos

Inverse cosine in radians

Syntax

```
y = acos(x)
```

Description

`y = acos(x)` returns the “Inverse Cosine” on page 1-103 (\cos^{-1}) of the elements of `x`. The `acos` function operates element-wise on arrays. For real elements of `x` in the interval $[-1, 1]$, `acos(x)` returns real values in the interval $[0, \pi]$. For real values of `x` outside the interval $[-1, 1]$ and for complex values of `x`, `acos(x)` returns complex values. All angles are in radians.

Examples

Inverse Cosine of a Value

```
acos(0.3)
```

```
ans =  
    1.2661
```

Inverse Cosine of a Vector of Complex Values

Find the inverse cosine of the elements of vector `x`. The `acos` function acts on `x` element-wise.

```
x = [0.5i 1+3i -2.2+i];  
y = acos(x)
```

```
y =  
    1.5708 - 0.4812i    1.2632 - 1.8642i    2.6799 - 1.5480i
```

Plot the Inverse Cosine Function

Plot the inverse cosine function over the domain $-1 \leq x \leq 1$.

```
x = -1:.05:1;  
plot(x,acos(x))  
grid on
```

Input Arguments

x — Numeric input

number | vector | matrix | multidimensional array

Numeric input, specified as a number, vector, matrix, or multidimensional array.

Data Types: single | double

Complex Number Support: Yes

More About

Inverse Cosine

The inverse cosine is defined as

$$\cos^{-1}(z) = -i \log \left[z + i(1 - z^2)^{1/2} \right].$$

acosd | acosh | cos

Introduced before R2006a

acosd

Inverse cosine in degrees

Syntax

$Y = \text{acosd}(X)$

Description

$Y = \text{acosd}(X)$ returns the inverse cosine (\cos^{-1}) of the elements of X in degrees. The function's domain and range include complex values. For real elements of X in the domain $[-1,1]$, **acosd** returns values in the range $[0, 180]$. For values of X outside this range, **acosd** returns complex values.

Examples

Inverse Cosine of 0

Verify that inverse cosine of 0 is exactly 90.

```
acosd(0)
```

```
ans =
```

```
90
```

Round-Trip Calculation for Complex Angles

Show that the inverse cosine, followed by cosine, returns the original values of X .

```
cosd(acosd([2 3]))
```

```
ans =
```

```
2.0000    3.0000
```

`acosd([2 3])` returns two complex angles, which are then passed to the `cosd` function. `cosd` returns the original values, 2 and 3.

Input Arguments

X — Cosine of angle

scalar value | vector | matrix | N-D array

Cosine of angle, specified as a real-valued or complex-valued scalar, vector, matrix, or N-D array. The `acosd` operation is element-wise when `X` is non-scalar.

Data Types: `single` | `double`

Complex Number Support: Yes

Output Arguments

Y — Angle in degrees

scalar value | vector | matrix | N-D array

Angle in degrees, returned as a real-valued or complex-valued scalar, vector, matrix, or N-D array of the same size as `X`.

`acos` | `cos` | `cosd`

Introduced before R2006a

acosh

Inverse hyperbolic cosine

Syntax

`Y = acosh(X)`

Description

`Y = acosh(X)` returns the inverse hyperbolic cosine for each element of `X`.

The `acosh` function operates element-wise on arrays. The function's domains and ranges include complex values. All angles are in radians.

Examples

Graph of Inverse Hyperbolic Cosine Function

Graph the inverse hyperbolic cosine function over the domain $-1 \leq x \leq \pi$.

```
x = 1:pi/40:pi;  
plot(x,acosh(x)), grid on
```

More About

Inverse Hyperbolic Cosine

The inverse hyperbolic cosine can be defined as

$$\cosh^{-1}(z) = \log\left[z + (z^2 - 1)^{1/2}\right].$$

Introduced before R2006a

acot

Inverse cotangent in radians

Syntax

$Y = \text{acot}(X)$

Description

$Y = \text{acot}(X)$ returns the “Inverse Cotangent” on page 1-111 (\cot^{-1}) of the elements of X . The `acot` function operates element-wise on arrays. For real elements of X , `acot(X)` returns values in the interval $[-\pi/2, \pi/2]$. For complex values of X , `acot(X)` returns complex values. All angles are in radians.

Examples

Inverse Cotangent of a Value

```
acot(2.6)
```

```
ans =  
    0.3672
```

Inverse Cotangent of a Vector of Complex Values

Find the inverse cotangent of the elements of vector x . The `acot` function acts on x element-wise.

```
x = [0.5i 1+3i -2.2+i];  
Y = acot(x)
```

```
Y =  
    1.5708 - 0.5493i    0.1093 - 0.3059i   -0.3689 - 0.1506i
```

Plot the Inverse Cotangent Function

Plot the inverse cotangent function over the intervals $-2\pi \leq x < 0$ and $0 < x \leq 2\pi$.

```
x1 = -2*pi:pi/30:-0.1;
```

```
x2 = 0.1:pi/30:2*pi;  
plot(x1,acot(x1),'b')  
hold on  
plot(x2,acot(x2),'b')  
grid on
```

Input Arguments

X — Numeric input

number | vector | matrix | multidimensional array

Numeric input, specified as a number, vector, matrix, or multidimensional array.

Data Types: `single` | `double`
Complex Number Support: Yes

More About

Inverse Cotangent

The inverse cotangent is defined as

$$\cot^{-1}(z) = \tan^{-1}\left(\frac{1}{z}\right).$$

`acotd` | `acoth` | `cot`

Introduced before R2006a

acotd

Inverse cotangent in degrees

Syntax

`Y = acotd(X)`

Description

`Y = acotd(X)` returns the inverse cotangent (\cot^{-1}) of the elements of `X` in degrees. The function's domain and range include complex values. For real elements of `X` in the range `[-Inf,Inf]`, `acotd` returns values in the range `[-90,90]`. For complex values of `X`, `acotd` returns complex values.

Examples

Inverse Cotangent of Vector

```
x = [0 20 Inf];  
y = acotd(x)
```

```
y =
```

```
90.0000    2.8624         0
```

The `acotd` operation is element-wise when you pass a vector, matrix, or N-D array.

Inverse Cotangent of Complex Value

```
acotd(1+i)
```

```
ans =
```

31.7175 -23.0535i

Input Arguments

X — Cotangent of angle

scalar value | vector | matrix | N-D array

Cotangent of angle, specified as a real-valued or complex-valued scalar, vector, matrix, or N-D array. The `acotd` operation is element-wise when X is non-scalar.

Data Types: `single` | `double`

Complex Number Support: Yes

Output Arguments

Y — Angle in degrees

scalar value | vector | matrix | N-D array

Angle in degrees, returned as a real-valued or complex-valued scalar, vector, matrix, or N-D array of the same size as X .

`acot` | `cot` | `cotd`

Introduced before R2006a

acoth

Inverse hyperbolic cotangent

Syntax

$Y = \operatorname{acoth}(X)$

Description

$Y = \operatorname{acoth}(X)$ returns the inverse hyperbolic cotangent for each element of X .

The `acoth` function operates element-wise on arrays. The function's domains and ranges include complex values. All angles are in radians.

Examples

Graph of Inverse Hyperbolic Cotangent Function

Graph the inverse hyperbolic cotangent function over the domains $-30 \leq x < -1$ and $1 < x \leq 30$.

```
x1 = -30:0.1:-1.1;  
x2 = 1.1:0.1:30;  
plot(x1,acoth(x1),x2,acoth(x2)), grid on
```

More About

Inverse Hyperbolic Cotangent

The inverse hyperbolic cotangent can be defined as

$$\operatorname{coth}^{-1}(z) = \tanh^{-1}\left(\frac{1}{z}\right).$$

acsc

Inverse cosecant in radians

Syntax

$Y = \text{acsc}(X)$

Description

$Y = \text{acsc}(X)$ returns the “Inverse Cosecant” on page 1-119 (csc^{-1}) of the elements of X . The **acsc** function operates element-wise on arrays. For real elements of X in intervals $[-\text{Inf}, -1]$ and $[1, \text{Inf}]$, **acsc** returns real values in the interval $[-\pi/2, \pi/2]$. For real values of X in the interval $[-1, 1]$ and for complex values of X , **acsc** returns complex values. All angles are in radians.

Examples

Inverse Cosecant of a Value

```
acsc(3)
ans =
    0.3398
```

Inverse Cosecant of a Vector of Complex Angles

Find the inverse cosecant of the elements of vector x . The **acsc** function acts on x element-wise.

```
x = [0.5i 1+3i -2.2+i];
Y = acsc(x)
Y =
    0.0000 - 1.4436i    0.0959 - 0.2970i   -0.3795 - 0.1833i
```

Plot the Inverse Cosecant Function

Plot the inverse cosecant function over the intervals $-10 \leq x < -1$ and $1 < x \leq 10$.

```
x1 = -10:0.01:-1.01;  
x2 = 1.01:0.01:10;  
plot(x1,acsc(x1),'b')  
hold on  
plot(x2,acsc(x2),'b')  
grid on
```

Input Arguments

X — Numeric input

number | vector | matrix | multidimensional array

Numeric input, specified as a number, vector, matrix, or multidimensional array.

Data Types: `single` | `double`
Complex Number Support: Yes

More About

Inverse Cosecant

The inverse cosecant is defined as

$$\operatorname{csc}^{-1}(z) = \sin^{-1}\left(\frac{1}{z}\right).$$

acscd

Inverse cosecant in degrees

Syntax

$Y = \text{acscd}(X)$

Description

$Y = \text{acscd}(X)$ returns the inverse cosecant (cosec^{-1}) of the elements of X in degrees. The function's domain and range include complex values. For real elements of X in the domain $[-\text{Inf}, 1]$ and $[1, \text{Inf}]$, **acscd** returns values in the range $[-90, 90]$. For values of X outside this range, **acscd** returns complex values.

Examples

Inverse Cosecant of Vector

```
x = [20 10 Inf];  
y = acscd(x)
```

```
y =
```

```
    2.8660    5.7392         0
```

The **acscd** operation is element-wise when you pass a vector, matrix, or N-D array.

Inverse Cosecant of Complex Value

```
acscd(1+i)
```

```
ans =
```

25.9136 -30.4033i

Input Arguments

X — Cosecant of angle

scalar value | vector | matrix | N-D array

Cosecant of angle, specified as a real-valued or complex-valued scalar, vector, matrix, or N-D array. The `acscd` operation is element-wise when X is non-scalar.

Data Types: `single` | `double`

Complex Number Support: Yes

Output Arguments

Y — Angle in degrees

scalar value | vector | matrix | N-D array

Angle in degrees, returned as a real-valued or complex-valued scalar, vector, matrix, or N-D array of the same size as X .

See Also

`acsc` | `csc` | `cscd`

Introduced before R2006a

acsch

Inverse hyperbolic cosecant

Syntax

$Y = \operatorname{acsch}(X)$

Description

$Y = \operatorname{acsch}(X)$ returns the inverse hyperbolic cosecant for each element of X .

The `acsch` function operates element-wise on arrays. The function's domains and ranges include complex values. All angles are in radians.

Examples

Graph of Inverse Hyperbolic Cosecant Function

Graph the inverse hyperbolic cosecant function over the domains $-20 \leq x \leq -1$ and $1 \leq x \leq 20$.

```
x1 = -20:0.01:-1;  
x2 = 1:0.01:20;  
plot(x1,acsch(x1),x2,acsch(x2)), grid on
```

More About

Inverse Hyperbolic Cosecant

The inverse hyperbolic cosecant can be defined as

$$\operatorname{csch}^{-1}(z) = \sinh^{-1}\left(\frac{1}{z}\right).$$

[acsc](#) | [csch](#) | [asinh](#) | [acosh](#)

Introduced before R2006a

actxcontrol

Create Microsoft ActiveX control in figure window

Syntax

```
h = actxcontrol('progid')
h = actxcontrol('progid','param1',value1,...)
h = actxcontrol('progid',position)
h = actxcontrol('progid', position, fig_handle)
h = actxcontrol('progid',position,fig_handle,event_handler)
h =
actxcontrol('progid',position,fig_handle,event_handler,'filename')
```

Description

`h = actxcontrol('progid')` creates an ActiveX[®] control in a figure window. The programmatic identifier (**progid**) for the control determines the type of control created. (See the documentation provided by the control vendor to get this string.) The returned object, **h**, represents the default interface for the control.

You cannot use an ActiveX server for the **progid** because MATLAB cannot insert ActiveX servers in a figure. See `actxserver` for use with ActiveX servers.

`h = actxcontrol('progid','param1',value1,...)` creates an ActiveX control using the optional parameter name/value pairs. Parameter names include:

- **position** — MATLAB position vector specifying the position of the control. The format is [left, bottom, width, height] using pixel units.
- **parent** — Handle to parent figure, model, or Command Window.
- **callback** — Name of event handler. To use the same handler for all events, specify a single name. To handle specific events, specify a cell array of event name/event handler pairs.
- **filename** — Sets the initial conditions to the previously saved control.
- **licensekey** — License key to create licensed ActiveX controls that require design-time licenses. See “Deploy ActiveX Controls Requiring Run-Time Licenses” for information on how to use controls that require run-time licenses.

One possible format is:

```
h = actxcontrol('myProgid','newPosition',[0 0 200 200],...
    'myFigHandle',gcf,...
    'myCallback',{ 'Click' 'myClickHandler';...
    'DbClick' 'myDbClickHandler';...
    'MouseDown' 'myMouseDownHandler'});
```

Note: The following syntaxes are not recommended. Use the previous syntaxes instead.

`h = actxcontrol('progid',position)` creates an ActiveX control having the location and size specified in the vector, `position`. The format of this vector is:

```
[x y width height]
```

The first two elements of the vector determine where the control is placed in the figure window. `x` and `y` are offsets, in pixels, from the bottom left corner of the figure window to the same corner of the control. `width` and `height` determine the size of the control itself.

The default `position` vector is `[20 20 60 60]`.

`h = actxcontrol('progid', position, fig_handle)` creates an ActiveX control at the specified `position` in an existing figure window. The Handle Graphics® handle, `fig_handle`, identifies this window.

The `gcf` command returns the current figure handle.

Note If the figure window designated by `fig_handle` is invisible, the control is invisible. If you want the control you are creating to be invisible, use the handle of an invisible figure window.

`h = actxcontrol('progid',position,fig_handle,event_handler)` creates an ActiveX control that responds to events. Controls respond to events by invoking a MATLAB function whenever an event (such as clicking a mouse button) is fired. The `event_handler` argument identifies one or more functions to be used in handling events. For more information, see “Specifying Event Handlers” on page 1-127.

```
h =
actxcontrol('progid',position,fig_handle,event_handler,'filename')
```

creates an ActiveX control with the first four arguments, and sets its initial state to that of a previously saved control. MATLAB loads the initial state from the file specified in the string `filename`.

If you do not want to specify an `event_handler`, you can use an empty string (`' '`) as the fourth argument.

The `progid` argument must match the `progid` of the saved control.

Specifying Event Handlers

There is more than one valid format for the `event_handler` argument. Use this argument to specify one of the following:

- A different event handler routine for each event supported by the control
- One common routine to handle selected events
- One common routine to handle all events

In the first case, use a cell array for the `event_handler` argument, with each row of the array specifying an event and handler pair:

```
{'event' 'eventhandler'; 'event2' 'eventhandler2'; ...}
```

`event` is either a string containing the event name or a numeric event identifier (see “Handling Events” on page 1-128). `eventhandler` is a string identifying the function you want the control to use in handling the event. Include only those events that you want enabled.

In the second case, use the same cell array syntax described, but specify the same `eventhandler` for each event. Again, include only those events that you want enabled.

In the third case, make `event_handler` a string (instead of a cell array) that contains the name of the one function that is to handle all events for the control.

There is no limit to the number of event and handler pairs you can specify in the `event_handler` cell array. However, if you register the same event name to the same callback handler multiple times, MATLAB executes the event only once.

Event handler functions accept a variable number of arguments.

Strings used in the `event_handler` argument are not case-sensitive.

Note Although using a single handler for all events might be easier sometimes, specifying an individual handler for each event creates more efficient code, resulting in better performance.

Examples

Handling Events

The `event_handler` argument specifies how you want the control to handle any events that occur. The control can handle all events with one common handler function, selected events with a common handler function, or each type of event can be handled by a separate function.

Create an `mwsamp` control with one event handler, `sampev`, to respond to all events:

```
h = actxcontrol('mwsamp.mwsampctrl1.2',[0 0 200 200],gcf,'sampev');
```

Invoke event handler when events `Click` and `Db1Click` are fired.

```
h = actxcontrol('mwsamp.mwsampctrl1.2',[0 0 200 200],gcf,{'Click' 'sampev'; 'Db1Click' 'sampev'});
```

Assign a different handler routine to each event.

```
h = actxcontrol('mwsamp.mwsampctrl1.2',[0 0 200 200],...gcf,{'Click', 'myclick'; 'Db1Click' 'my2click'; ...'MouseDown' 'mymoused'});
```

Specify the events using numeric event identifiers.

```
h = actxcontrol('mwsamp.mwsampctrl1.2',[0 0 200 200],...gcf,{-600, 'myclick'; -601 'my2click'; -605 'mymoused'});
```

More About

Tips

If the control implements any custom interfaces, use the `interfaces` function to list them, and the `invoke` function to get a handle to a selected interface.

When you no longer need the control, call **release** to release the interface and free memory and other resources used by the interface. Releasing the interface does not delete the control itself. To release the interface, use the **delete** function.

For more information on handling control events, see [Writing Event Handlers](#).

For an example event handler, see the file `sampev.m` in the `toolbox\matlab\winfun\comcli` folder.

COM functions are available on Microsoft® Windows® systems only.

Note If you encounter problems creating Microsoft Forms 2.0 controls in MATLAB or other non-VBA container applications, see “Microsoft Forms 2.0 Controls”.

- [Writing Event Handlers](#)

Introduced before R2006a

actxcontrollist

List currently installed Microsoft ActiveX controls

Syntax

```
info = actxcontrollist
```

Description

`info = actxcontrollist` returns a list of controls in `info`, a 1-by-3 cell array containing the name, programmatic identifier (ProgID), and file name for the control. Each control has one row, which MATLAB software sorts by file name.

COM functions are available on Microsoft Windows systems only.

Examples

Show information for two controls:

```
list = actxcontrollist;  
for k = 1:2  
    sprintf(' Name = %s\n ProgID = %s\n File = %s\n', list{k,:})  
end
```

```
ans =  
    Name = Calendar Control 11.0  
    ProgID = MSCAL.Calendar.7  
    File = C:\Program Files\MSOffice\OFFICE11\MSCAL.OCX
```

```
ans =  
    Name = CTreeView Control  
    ProgID = CTREEVIEW.CTreeViewCtrl.1  
    File = C:\WINNT\system32\dmocx.dll
```

MATLAB displays controls specific to your system.

See Also

`actxcontrolselect` | `actxcontrol`

Introduced before R2006a

actxcontrolselect

Create Microsoft ActiveX control from UI

Syntax

```
h = actxcontrolselect  
[h, info] = actxcontrolselect
```

Description

`h = actxcontrolselect` displays a UI listing all ActiveX controls installed on the system and creates the one you select from the list. Returns handle `h` for the object. Use the handle to identify this control when calling MATLAB COM functions.

`[h, info] = actxcontrolselect` returns a 1-by-3 cell array `info` containing the name, programmatic identifier (ProgID), and file name for the control.

COM functions are available on Microsoft Windows systems only.

More About

- “Creating Control Objects Using a UI”

See Also

`actxcontrollist` | `actxcontrol`

Introduced before R2006a

actxGetRunningServer

Handle to running instance of Automation server

Syntax

```
h = actxGetRunningServer('progid')
```

Description

`h = actxGetRunningServer('progid')` gets a reference to a running instance of the OLE Automation server. `progid` is the programmatic identifier of the Automation server object and `h` is the handle to the default interface of the server object.

The function returns an error if the server specified by `progid` is not currently running or if the server object is not registered. When multiple instances of the Automation server are running, the operating system controls the behavior of this function.

COM functions are available on Microsoft Windows systems only.

Examples

Get a handle to the Microsoft Excel[®] program:

```
h = actxGetRunningServer('Excel.Application')
```

More About

- “MATLAB COM Automation Server Interface”

See Also

`actxcontrol` | `actxserver`

Introduced in R2007a

actxserver

Create COM server

Syntax

```
h = actxserver('progid')
h = actxserver('progid','machine','machineName')
h = actxserver('progid','interface','interfaceName')
h =
actxserver('progid','machine','machineName','interface','interfaceName')
h = actxserver('progid',machine)
```

Description

`h = actxserver('progid')` creates a local OLE Automation server, where `progid` is the programmatic identifier of an OLE-compliant COM server. Returns `h`, a handle to the default interface of the server.

Get `progid` from the control or server vendor documentation. To see the `progid` values for MATLAB software, refer to “Programmatic Identifiers”.

`h = actxserver('progid','machine','machineName')` creates an OLE Automation server on a remote machine, where `machineName` is a string specifying the name of the machine on which to start the server.

`h = actxserver('progid','interface','interfaceName')` creates a Custom interface server, where `interfaceName` is a string specifying the interface name of the COM object. Values for `interfaceName` are

- `IUnknown` — Use the `IUnknown` interface. MATLAB does not support the `IUnknown` interface with 64-bit MATLAB.
- The Custom interface name

To use the `interfaceName` value, you must know the name of the interface and have the server vendor documentation. For information about custom COM servers and interfaces, see “COM Server Types”.

Note: The MATLAB COM Interface does not support invoking functions with optional parameters.

```
h =  
actxserver('progid','machine','machineName','interface','interfaceName')  
creates a Custom interface server on a remote machine.
```

Note: The following syntax is not recommended. Use the previous syntaxes instead.

`h = actxserver('progid',machine)` creates a COM server running on the remote system named by the `machine` argument. `machine` can be an IP address or a DNS name. Use this syntax only in environments that support Distributed Component Object Model (for more information, see “MATLAB Application as DCOM Server”).

COM functions are available on Microsoft Windows systems only.

Examples

Create Microsoft Excel Workbook

Create a COM server running Microsoft Excel.

```
e = actxserver('Excel.Application');
```

Make the Excel frame window visible.

```
e.Visible = 1;
```

List the properties of the Excel application.

```
get(e)
```

MATLAB displays the properties for your Excel version.

Create an interface `eWorkBooks`.

```
eWorkbooks = e.Workbooks;
```

List all methods for the workbooks interface.

```
invoke(eWorkbooks)
```

MATLAB displays the methods for your Excel version.

Add a workbook *w*.

```
w = Add(eWorkbooks);
```

Open the Excel frame window. You can manipulate the spreadsheet in the Excel application.

When you are finished with the Excel application, close Excel in MATLAB and delete the server object.

```
Quit(e)  
delete(e)
```

More About

Tips

For components implemented in a dynamic link library (DLL), `actxserver` creates an in-process server. For components implemented as an executable (EXE), `actxserver` creates an out-of-process server. Out-of-process servers can be created either on the client system or on any other system on a network that supports DCOM.

If the control implements any Custom interfaces, use the `interfaces` function to list them, and the `invoke` function to get a handle to a selected interface.

You can register events for COM servers.

Introduced before R2006a

add

Add single key-value pair to `KeyValueStore`

Syntax

```
add(KVStore, key, value)
```

Description

`add(KVStore, key, value)` adds a single key-value pair to `KVStore`, which is a `KeyValueStore` created during `mapreduce` execution. Use `add` in a map or reduce function written for use with `mapreduce` to store intermediate or final key-value pair information.

Input Arguments

KVStore — Key-value pair storage object

`KeyValueStore` object

Key-value pair storage object, specified as a `KeyValueStore` object. The `mapreduce` function automatically creates the `KeyValueStore` object during execution:

- In the map function, the name of the intermediate `KeyValueStore` object is the third input argument to the map function, `myMapper(data, info, intermKVStore)`. Use that same variable name to add intermediate key-value pairs with `add` or `addmulti` in the map function.
- In the reduce function, the name of the final `KeyValueStore` object is the third input argument to the reduce function, `myReducer(intermKey, intermValIter, outKVStore)`. Use that same variable name to add final key-value pairs with `add` or `addmulti` in the reduce function.

For more information, see [Using KeyValueStore Objects](#).

key — Key

numeric scalar | string

Key, specified as a numeric scalar or string.

All of the keys added by the map function must have the same class. The keys added by the reduce function also must have the same class, but that class can differ from the class of the keys added by the map function.

Numeric keys cannot be NaN, complex, logical, or sparse.

Example: `add(intermediateKVStore, 'Sum', sum(X))` adds a key-value pair to an intermediate `KeyValueStore` object (named `intermediateKVStore`) in a map function.

Example: `add(outKVStore, 'Stats', [mean(X) max(X) min(X) var(X) std(X)])` adds a key-value pair to a final `KeyValueStore` object (named `outKVStore`) in a reduce function.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `char`

value — Value

any MATLAB object

Value, specified as any MATLAB object. This includes all valid MATLAB data types.

The `OutputType` argument of `mapreduce` affects the type of values that the reduce function can add:

- If the `OutputType` is `'Binary'` (the default), then a value added by the reduce function can be any MATLAB object.
- If the `OutputType` is `'TabularText'`, then a value added by the reduce function can be a numeric scalar or string when using the `add` function. Additionally, you can use the `addmulti` function to add multiple values with a numeric vector, cell vector of strings, or cell vector of numeric scalars. In each case, the numeric values cannot be NaN, complex, logical, or sparse.

Note: The above key-value pair requirements may differ when using other products with `mapreduce`. See the documentation for the appropriate product to get product-specific key-value pair requirements.

Example: `add(intermediateKVStore, 'Sum', sum(X))` specifies a single scalar value to pair with a key.

Example: `add(outKVStore, 'Stats', [mean(X) max(X) min(X) var(X) std(X)])`
specifies a numeric array as the value to pair with a key.

More About

Tips

- Avoid using `add` in a loop, as it can negatively affect `mapreduce` execution time. Instead, use cell arrays to collect multiple values (using vectorized operations if possible) and use a single call to `addmulti`.
- Using KeyValueStore Objects
- “Build Effective Algorithms with MapReduce”

`addmulti`

Introduced in R2014b

matlab.apputil.create

Create or modify app project file for packaging app into `.mlappinstall` file using interactive dialog box

Syntax

```
matlab.apputil.create  
matlab.apputil.create(prjfile)
```

Description

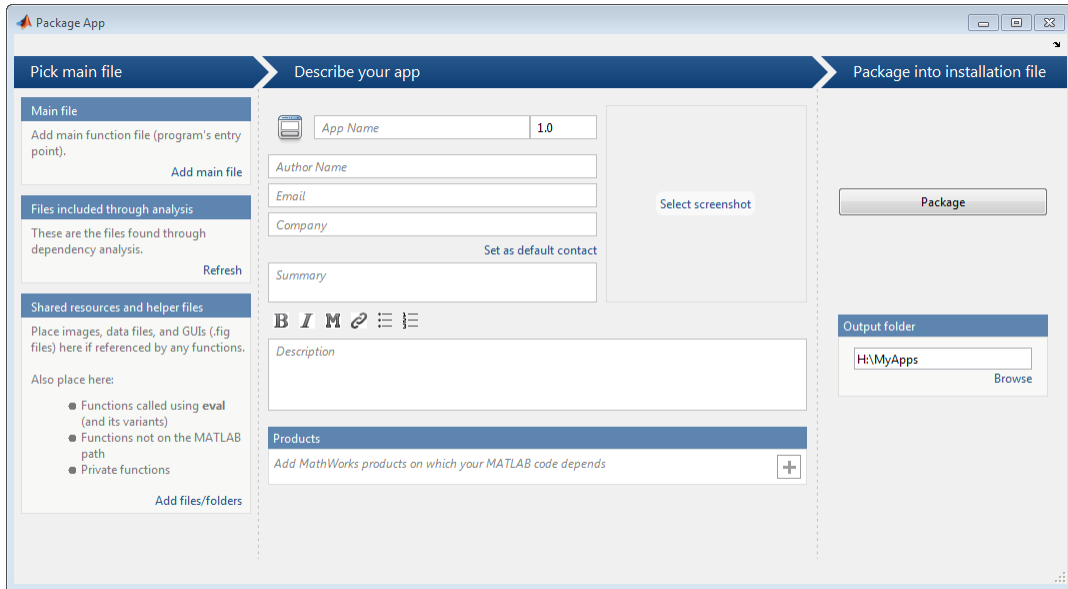

`matlab.apputil.create` opens the Package App dialog box that steps you through the process of creating an `.mlappinstall` file.

`matlab.apputil.create(prjfile)` loads the specified `.prj` file and populates the Package App dialog box with the information from the specified project file. Use this option if you need to update an existing app.

Examples

Open Dialog Box for Creating an App Package

```
matlab.apputil.create
```

Minimally, add a main file, specify an app name, and indicate the required products. MATLAB creates and continuously saves a `.prj` file, regardless of whether you click **Package**. However, MATLAB does not create a `.mlappinstall` file if you do not click **Package**.

Update Existing App Package

Assume you have an existing project file, `myapp.prj`. You want to add a file and update the description.

Open the Package App dialog box, specifying the previously created `.prj` file:

```
matlab.apputil.create('myapp.prj')
```

The dialog box opens populated with the data you previously specified for `myapp`. Adjust the information in the dialog box, as needed.

Input Arguments

prjfile — Full or partial path to the `.prj` file
string

Full or partial path to the `.prj` file you created previously with the Package App dialog box, specified as a string

Example: `'C:\myapp.prj'`

`matlab.apputil.package`

Introduced in R2012b

matlab.apputil.getInstalledAppInfo

List installed app information

Syntax

```
matlab.apputil.getInstalledAppInfo
```

```
appinfo = matlab.apputil.getInstalledAppInfo
```

Description

`matlab.apputil.getInstalledAppInfo` displays the ID and name of all installed custom apps. It does not display this information for apps packaged with MathWorks® products.

`appinfo = matlab.apputil.getInstalledAppInfo` returns structure to `appinfo`, which includes the status, ID, location, and name of all installed custom apps. It does not return this information for apps packaged with MathWorks products.

Examples

Display Installed Apps Information in the Command Window

Assume you installed two apps, `LinePlotter` and `PlotRandNumbers`. Display the app information in the Command Window.

```
matlab.apputil.getInstalledAppInfo
```

```
ID                Name
-----
LinePlotterAPP    LinePlotter
PlotRandNumbersAPP PlotRandNumbers
```

Store Installed App Information in a Variable

Assume you installed an app, `ColorPalette`. Get the app information and store it in a variable, `myappinfo`.

```
myappinfo = matlab.apputil.getInstalledAppInfo;
```

Store Installed App Information in a Variable and Display IDs

Assume you installed two apps, `LinePlotter` and `PlotRandNumbers`. Get and store the app information for both installed apps in a variable, `myappinfo`. Then, get the `id` for each app.

```
myappinfo = matlab.apputil.getInstalledAppInfo
```

```
myappinfo =
```

```
1x2 struct array with fields:
    id
    name
    status
    location
```

Get the `id` of each installed app:

```
appids={myappinfo.id}
```

```
appids =
```

```
    'LinePlotterAPP'    'PlotRandNumbersAPP'
```

Output Arguments

appinfo — Information about installed apps

structure array

Information about the installed app, returned as a structure array, with one element for each installed app. Each element of the structure array has the following fields:

status — Installation status

```
'installed'
```

Status of the installation, returned as the string `'installed'`.

id — Unique identifier for the installed app

string

Unique identifier for the installed app, returned as a string

The ID is for use when running or uninstalling the app programmatically.

location — Folder where the app is installed

string

Folder where the app is installed, returned as a string

name — Name of the installed app

string

Name of the installed app as it appears in the apps gallery, returned as a string

See Also

`matlab.apputil.install` | `matlab.apputil.run` | `matlab.apputil.uninstall`

Introduced in R2012b

matlab.apputil.install

Install app from a `.mlappinstall` file

Syntax

```
appinfo = matlab.apputil.install(appfile)
```

Description

`appinfo = matlab.apputil.install(appfile)` installs the specified app file and returns information about the app.

Examples

Install App and Display Information About the Installation

Assume you have downloaded an app from File Exchange named `EmployeeData`. Install it and return information about the installation to the variable `appinfo`. Later, if you decide to uninstall the app programmatically, you have the app id required to do so.

```
appinfo = matlab.apputil.install...  
    ('C:\myguis\myapps\EmployeeData.mlappinstall')  
  
appinfo =  
  
    id: 'EmployeeDataApp'  
    name: 'EmployeeData'  
    status: 'installed'  
    location: 'C:\myguis\myapps\EmployeeData.mlappinstall'
```

Input Arguments

appfile — Full or partial path to `.mlappinstall` file
string

Full or partial path of the app file you want to install, specified as a string.

Example: 'C:\myguis\myapps\myapp.mlappinstall'

Output Arguments

appinfo — Information about installed app

structure

Information about the installed app, returned as a structure with the fields:

status — Installation status

'installed' | 'updated'

Installation status, returned as a string:

- 'installed' — New app is installed.
- 'updated' — Previously installed app is updated.

id — Unique identifier

string

Unique identifier for the installed app, returned as a string

The ID is for use when running or uninstalling the app programmatically.

location — Folder where app is installed

string

Folder where app is installed, returned as a string

name — Name of installed app

string

Name of installed app as it appears in the apps gallery, returned as a string

`matlab.apputil.getInstalledAppInfo` | `matlab.apputil.package` |
`matlab.apputil.uninstall`

Introduced in R2012b

matlab.apputil.package

Package app files into .mlappinstall file

Syntax

```
matlab.apputil.package(prjfile)
```

Description

`matlab.apputil.package(prjfile)` creates a .mlappinstall file based on the information in the specified `prjfile`.

Examples

Create mlappinstall File for Previously Created Project File

Assume you previously created `myprjfile.prj` using `matlab.apputil.create`. The following command creates the corresponding .mlappinstall file.

```
matlab.apputil.package('myprjfile.prj')
```

Input Arguments

prjfile — Full or partial path to app project (.prj) file

string

Full or partial path to app project (.prj) file, specified as a string.

Example: 'plotdata.prj'

More About

Tips

- To create a .prj file, use `matlab.apputil.create`.

See Also

`matlab.apputil.create` | `matlab.apputil.install` | `matlab.apputil.run`

Introduced in R2012b

matlab.apputil.run

Run app programmatically

Syntax

```
matlab.apputil.run(appid)
```

Description

`matlab.apputil.run(appid)` runs the custom app specified by the unique identifier, `appid`.

Examples

Run Previously Installed App

Assume you installed two apps, `PlotData` and `setslider`. Run `PlotData` programmatically, using its ID.

Get IDs of all installed apps.

```
matlab.apputil.getInstalledAppInfo
```

ID	Name
-----	-----
setsliderAPP	setslider
PlotDataAPP	PlotData

Run `PlotData`.

```
matlab.apputil.run('PlotDataAPP')
```

Input Arguments

appid — ID of custom app
string

ID of custom app you want to run, specified as a string.

Example: 'DataExplorationAPP'

More About

Tips

- The ID of a custom app is returned when you install it. You can use `matlab.apputil.getInstalledAppInfo` to get the ID after you have installed an app.
- When a custom app runs, MATLAB adds any folders it needs to have added to the path, as identified when the app was packaged. When the app exits, MATLAB removes those folders from the path.
- You can run multiple, different custom apps concurrently. However, you cannot run two instances of the same app concurrently.

`matlab.apputil.install`

Introduced in R2012b

matlab.apputil.uninstall

Uninstall app

Syntax

```
matlab.apputil.uninstall(appid)
```

Description

`matlab.apputil.uninstall(appid)` removes the app specified by the unique identifier, `appid`. MATLAB removes all files corresponding to the app and removes the app from the app gallery.

Examples

Uninstall App

Assume you previously installed two apps, `setslider` and `simplegui`. Get the IDs of all installed apps, and then use the ID for `simplegui` to uninstall it.

View the IDs of all apps

```
matlab.apputil.getInstalledAppInfo
```

ID	Name
-----	-----
setsliderAPP	setslider
simpleguiAPP	simplegui

Uninstall the `simplegui` app.

```
matlab.apputil.uninstall('simpleguiAPP')
```

Confirm the app was removed, by running `matlab.apputil.getInstalledAppInfo` again.

```
matlab.apputil.getInstalledAppInfo
```

ID	Name
-----	-----
setsliderAPP	setslider

Input Arguments

appid — ID of app

string

ID of app to be uninstalled, specified as a string.

Example: 'DataExplorationAPP'

More About

Tips

- To determine the appid of an installed app, preserve the value returned when you install the app programmatically with `matlab.apputil.install`, or use `matlab.apputil.getInstalledAppInfo`.

See Also

`matlab.apputil.getInstalledAppInfo` | `matlab.apputil.install`

Introduced in R2012b

addevent

Add event to `timeseries` object

Syntax

```
ts = addevent(ts,e)
ts = addevent(ts,Name,Time)
```

Description

`ts = addevent(ts,e)` adds one or more `tsdata.event` objects, `e`, to the `timeseries` object `ts`. `e` is either a single `tsdata.event` object or an array of `tsdata.event` objects.

`ts = addevent(ts,Name,Time)` constructs one or more `tsdata.event` objects and adds them to the `Events` property of `ts`. `Name` is a cell array of event name strings. `Time` is a cell array of event times.

Examples

Create a time-series object and add an event to this object.

```
%% Import the sample data
load count.dat

%% Create time-series object
count1=timeseries(count(:,1),1:24,'name', 'data');

%% Modify the time units to be 'hours' ('seconds' is default)
count1.TimeInfo.Units = 'hours';

%% Construct and add the first event at 8 AM
e1 = tsdata.event('AMCommute',8);

%% Specify the time units of the time
e1.Units = 'hours';
```

View the properties (EventData, Name, Time, Units, and StartDate) of the event object.

```
get(e1)
```

MATLAB software responds with

```
EventData: []
          Name: 'AMCommute'
          Time: 8
          Units: 'hours'
          StartDate: ''
%% Add the event to count1
count1 = addevent(count1,e1);
```

An alternative syntax for adding two events to the time series `count1` is as follows:

```
count1 = addevent(count1,{'AMCommute' 'PMCommute'},{8 18})
```

See Also

[timeseries](#) | [tsdata.event](#)

Introduced before R2006a

addmulti

Add multiple key-value pairs to `KeyValueStore`

Syntax

```
addmulti(KVStore, keys, values)
```

Description

`addmulti(KVStore, keys, values)` adds multiple key-value pairs to `KVStore`, which is a `KeyValueStore` created during `mapreduce` execution. Use `addmulti` in a map or reduce function written for use with `mapreduce` to store intermediate or final key-value pair information.

Input Arguments

KeyValueStore — Key-value pair storage object

`KeyValueStore` object

Key-value pair storage object, specified as a `KeyValueStore` object. The `mapreduce` function automatically creates the `KeyValueStore` object during execution:

- In the map function, the name of the intermediate `KeyValueStore` object is the third input argument to the map function, `myMapper(data, info, intermKVStore)`. Use that same variable name to add intermediate key-value pairs with `add` or `addmulti` in the map function.
- In the reduce function, the name of the final `KeyValueStore` object is the third input argument to the reduce function, `myReducer(intermKey, intermValIter, outKVStore)`. Use that same variable name to add final key-value pairs with `add` or `addmulti` in the reduce function.

For more information, see [Using KeyValueStore Objects](#).

keys — Keys

numeric scalar | numeric vector | string | cell vector of strings | cell vector of numeric scalars

Keys, specified as a numeric scalar, numeric vector, string, cell vector of strings, or cell vector of numeric scalars. If the keys are a numeric vector or cell vector, then each entry specifies a different key.

All of the keys added by the map function must have the same class. The keys added by the reduce function must also have the same class, but that class can differ from the class of the keys added by the map function.

Numeric keys cannot be NaN, complex, logical, or sparse.

Example: `addmulti(intermKVStore,{'Sum'; 'Count'; 'Variance'},{sum(X); numel(X); var(X)})` adds three key-value pairs to an intermediate `KeyValueStore` object (named `intermKVStore`) using a cell vector of strings to specify the keys.

Example: `addmulti(intermKVStore,[1 2 3 4],{sum(X); mean(X); max(X); min(X)})` adds four key-value pairs to an intermediate `KeyValueStore` object using a numeric vector to specify the keys.

Example: `addmulti(outKVStore,'Stats',{[mean(X) max(X) min(X) var(X) std(X)]})` adds a single key-value pair to a final `KeyValueStore` object (named `outKVStore`) using a string as the key.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `char`

values — Values

cell array

Values, specified as a cell array. Each entry in the cell array specifies the value in a key-value pair, so `numel(values)` must be equal to the number of keys. The entries in the cell array can be any MATLAB object, including all valid MATLAB data types.

The `OutputType` argument of `mapreduce` affects the type of values that the reduce function can add:

- If the `OutputType` is `'Binary'` (the default), then a value added by the reduce function can be any MATLAB object.
- If the `OutputType` is `'TabularText'`, then a value added by the reduce function can be a numeric scalar or string when using the `add` function. Additionally, you can use the `addmulti` function to add multiple values with a numeric vector, cell vector of strings, or cell vector of numeric scalars. In each case, the numeric values cannot be NaN, complex, logical, or sparse.

Note: The above key-value pair requirements may differ when using other products with `mapreduce`. See the documentation for the appropriate product to get product-specific key-value pair requirements.

Example: `addmulti(intermKVStore,{'Sum'; 'Count'; 'Variance'},{sum(X); numel(X); var(X)})` adds three key-value pairs to an intermediate `KeyValueStore` object named `intermKVStore`.

Example: `addmulti(intermKVStore,[1 2 3 4],{sum(X); mean(X); max(X); min(X)})` adds four key-value pairs to an intermediate `KeyValueStore` object using a cell vector.

Example: `addmulti(outKVStore,'Stats',{[mean(X) max(X) min(X) var(X) std(X)]})` adds a single key-value pair to a final `KeyValueStore` object named `outKVStore`.

Example: `addmulti(outKVStore,{'Distance' 'Time'},{table.Distance table.Time})` adds two key-value pairs using variables in a table to specify the values.

More About

Tips

- Avoid using `add` in a loop, as it can negatively affect `mapreduce` execution time. Instead, use cell arrays to collect multiple values (using vectorized operations if possible) and use a single call to `addmulti`.
- Using `KeyValueStore` Objects
- “Build Effective Algorithms with MapReduce”

See Also

`add`

Introduced in R2014b

audioinfo

Information about audio file

Syntax

```
info = audioinfo(filename)
```

Description

`info = audioinfo(filename)` returns information about the contents of the audio file specified by `filename`.

Examples

Get Information About Audio File

Create a WAVE file from the example file `handel.mat`, and get information about the file.

Create a WAVE (.wav) file in the current folder.

```
load handel.mat
filename = 'handel.wav';
audiowrite(filename,y,Fs);
clear y Fs
```

Use `audioinfo` to return information about the WAVE file.

```
info = audioinfo(filename)

info =
    Filename: 'S:\handel.wav'
    CompressionMethod: 'Uncompressed'
    NumChannels: 1
    SampleRate: 8192
    TotalSamples: 73113
    Duration: 8.9249
    Title: []
```

```
Comment: []  
Artist: []  
BitsPerSample: 16
```

Input Arguments

filename — Name of file

string

Name of file, specified as a string. If a path is specified, it can be absolute, relative, or partial.

Example: 'myFile.mp3'

Example: '../myFile.mp3'

Example: 'C:\temp\myFile.mp3'

`audioinfo` supports the following file formats.

Platform Support	File Format
All platforms	WAVE (.wav)
	OGG (.ogg)
	FLAC (.flac)
	AU (.au)
	AIFF (.aiff, .aif)
	AIFC (.aifc)
Windows 7 (or later), Macintosh, and Linux [®]	MP3 (.mp3)
	MPEG-4 AAC (.m4a, .mp4)

On Windows 7 platforms (or later), `audioinfo` might also return information about the contents of any files supported by Windows Media[®] Foundation.

On Linux platforms, `audioinfo` might also return information about the contents of any files supported by GStreamer.

`audioinfo` can extract audio metadata from MPEG-4 (.mp4, .m4v) video files on Windows 7 or later, Mac OS X 10.7 Lion or higher, and Linux, and from Windows Media Video (.wmv) and AVI (.avi) files on Windows 7 (or later) and Linux platforms.

Output Arguments

info — Information about audio file

structure

Information about audio file, returned as a structure. `info` can contain the following fields.

Field Name	Description	Data Type
Filename	Filename including the absolute path to the file and the file extension.	string
CompressionMethod	Compression method used.	string
NumChannels	Number of audio channels encoded in the audio file.	double
SampleRate	Sample rate of the audio data in the file, in hertz.	double
TotalSamples	Total number of audio samples in the file.	double
Duration	Duration of the file, in seconds.	double
BitsPerSample	Number of bits per sample encoded in the audio file. Only valid for WAVE (.wav) and FLAC (.flac) files.	double
BitRate	Number of kilobits per second (kbit/s) used for compressed audio files. Only valid for MP3 (.mp3) and MPEG-4 Audio (.m4a, .mp4) files.	double
Title	Value of 'Title', if any.	string
Artist	Value of 'Artist', if any.	string
Comment	Value of 'Comment', if any.	string

Note: The `BitRate` property returns the actual bit rate on Mac platforms, and not the encoded bit rate. This means that bit rate values might be lower than specified at the time of the encoding, depending on the source data.

Note: On Mac platforms, `audioinfo` returns metadata from `.m4a` and `.mp4` files only on Mac OS X 10.7 Lion or higher. Previous versions of Mac OS X will not read the `'Title'`, `'Author'`, or `'Comment'` fields.

Limitations

- For MP3 and MPEG-4 AAC audio files on Windows 7 or later and Linux platforms, `audioinfo` might report fewer samples than expected. On Linux platforms, this is due to a limitation in the underlying GStreamer framework.
- On Linux platforms, `audioinfo` interprets single channel data in MPEG-4 AAC files as stereo data.

See Also

`audioread` | `audiowrite`

Introduced in R2012b

audioread

Read audio file

Syntax

```
[y,Fs] = audioread(filename)
[y,Fs] = audioread(filename,samples)

[y,Fs] = audioread( ____,dataType)
```

Description

`[y,Fs] = audioread(filename)` reads data from the file named `filename`, and returns sampled data, `y`, and a sample rate for that data, `Fs`.

`[y,Fs] = audioread(filename,samples)` reads the selected range of audio samples in the file, where `samples` is a vector of the form `[start,finish]`.

`[y,Fs] = audioread(____,dataType)` returns sampled data in the data range corresponding to the `dataType` of 'native' or 'double', and can include any of the input arguments in previous syntaxes.

Examples

Read Complete Audio File

Create a WAVE file from the example file `handel.mat`, and read the file back into MATLAB.

Create a WAVE (`.wav`) file in the current folder.

```
load handel.mat

filename = 'handel.wav';
audiowrite(filename,y,Fs);
clear y Fs
```

Read the data back into MATLAB using `audioread`.

```
[y,Fs] = audioread('handel.wav');
```

Play the audio.

```
sound(y,Fs);
```

Read Portion of Audio File

Create a FLAC file from the example file `handel.mat`, and then read only the first 2 seconds.

Create a FLAC (`.flac`) file in the current folder.

```
load handel.mat
```

```
filename = 'handel.flac';  
audiowrite(filename,y,Fs);
```

Read only the first 2 seconds.

```
samples = [1,2*Fs];  
clear y Fs  
[y,Fs] = audioread(filename,samples);
```

Play the samples.

```
sound(y,Fs);
```

Return Audio in Native Integer Format

Create a FLAC file and read the first 2 seconds according to the previous Example. Then, view the data type of the sampled data `y`.

```
whos y
```

Name	Size	Bytes	Class	Attributes
y	16384x1	131072	double	

The data type of `y` is `double`.

Request audio data in the native format of the file, and then view the data type of the sampled data `y`.

```
[y,Fs] = audioread(filename,'native');
whos y
```

```

Name          Size          Bytes  Class  Attributes
y             16384x1         32768  int16

```

The data type of `y` is now `int16`.

Input Arguments

filename — Name of file to read

string

Name of file to read, specified as a string that includes the file extension. If a path is specified, it can be absolute, relative or partial.

Example: 'myFile.mp3'

Example: './myFile.mp3'

Example: 'C:\temp\myFile.mp3'

`audioread` supports the following file formats.

Platform Support	File Format
All platforms	WAVE (.wav)
	OGG (.ogg)
	FLAC (.flac)
	AU (.au)
	AIFF (.aiff, .aif)
	AIFC (.aifc)
Windows 7 (or later), Macintosh, and Linux	MP3 (.mp3)
	MPEG-4 AAC (.m4a, .mp4)

On Windows platforms prior to Windows 7, `audioread` does not read WAVE files with MP3 encoded data.

On Windows 7 (or later) platforms, `audioread` might also read any files supported by Windows Media Foundation.

On Linux platforms, `audioread` might also read any files supported by GStreamer.

`audioread` can extract audio from MPEG-4 (`.mp4`, `.m4v`) video files on Windows 7 or later, Macintosh, and Linux, and from Windows Media Video (`.wmv`) and AVI (`.avi`) files on Windows 7 (or later) and Linux platforms.

samples — Audio samples to read

[1, inf] (default) | two-element vector of positive scalar integers

Audio samples to read, specified as a two-element vector of the form [`start`, `finish`], where `start` and `finish` are the first and last samples to read, and are positive scalar integers.

- `start` must be less than or equal to `finish`.
- `start` and `finish` must be less than the number of audio samples in the file,
- You can use `inf` to indicate the last sample in the file.

Note: When reading a portion of some MP3 files on Windows 7 platforms, `audioread` might read a shifted range of samples. This is due to a limitation in the underlying Windows Media Foundation framework.

When reading a portion of MP3 and M4A files on Linux platforms, `audioread` might read a shifted range of samples. This is due to a limitation in the underlying GStreamer framework.

Example: [1, 100]

Data Types: `double`

dataType — Data format of audio data, `y`

'double' (default) | 'native'

Data format of audio data, `y`, specified as one of the following strings:

'double' Double-precision normalized samples.

'native' Samples in the native format found in the file.

For compressed audio formats, such as MP3 and MPEG-4 AAC that do not store data in integer form, 'native' defaults to 'single'.

Output Arguments

y — Audio data

matrix

Audio data in the file, returned as an m -by- n matrix, where m is the number of audio samples read and n is the number of audio channels in the file.

- If you do not specify `dataType`, or `dataType` is 'double', then `y` is of type `double`, and matrix elements are normalized values between -1.0 and 1.0 .
- If `dataType` is 'native', then `y` can be one of several MATLAB data types, depending on the file format and the `BitsPerSample` value of the input file. Call `audioinfo` to determine the `BitsPerSample` value of the file.

File Format	BitsPerSample	Data Type of y	Data Range of y
WAVE (.wav)	8	uint8	$0 \leq y \leq 255$
	16	int16	$-32768 \leq y \leq +32767$
	24	int32	$-2^{32} \leq y \leq 2^{32}-1$
	32	int32	$-2^{32} \leq y \leq 2^{32}-1$
	32	single	$-1.0 \leq y \leq +1.0$
	64	double	$-1.0 \leq y \leq +1.0$
FLAC (.flac)	8	uint8	$0 \leq y \leq 255$
	16	int16	$-32768 \leq y \leq +32767$
	24	int32	$-2^{32} \leq y \leq 2^{32}-1$
MP3 (.mp3), MPEG-4 AAC (.m4a, .mp4), OGG (.ogg), and certain compressed WAVE files	N/A	single	$-1.0 \leq y \leq +1.0$

Note: Where `y` is `single` or `double` and the `BitsPerSample` is 32 or 64, values in `y` might exceed `-1.0` or `+1.0`.

Fs — Sample rate

positive scalar

Sample rate, in hertz, of audio data `y`, returned as a positive scalar.

Limitations

- For MP3, MPEG-4 AAC, and AVI audio files on Windows 7 or later and Linux platforms, `audioread` might read fewer samples than expected. On Windows 7 platforms, this is due to a limitation in the underlying Media Foundation framework. On Linux platforms, this is due to a limitation in the underlying GStreamer framework. If you require sample-accurate reading, work with WAV or FLAC files.
- On Linux platforms, `audioread` reads MPEG-4 AAC files that contain single-channel data as stereo data.

See Also

`audioinfo` | `audiowrite`

Introduced in R2012b

audiowrite

Write audio file

Syntax

```
audiowrite(filename,y,Fs)
audiowrite(filename,y,Fs,Name,Value)
```

Description

`audiowrite(filename,y,Fs)` writes a matrix of audio data, `y`, with sample rate `Fs` to a file called `filename`. The `filename` input also specifies the output file format. The output data type depends on the output file format and the data type of the audio data, `y`.

`audiowrite(filename,y,Fs,Name,Value)` uses additional options specified by one or more `Name,Value` pair arguments.

Examples

Write an Audio File

Create a WAVE file from the example file `handel.mat`, and read the file back into MATLAB.

Write a WAVE (.wav) file in the current folder.

```
load handel.mat

filename = 'handel.wav';
audiowrite(filename,y,Fs);
clear y Fs
```

Read the data back into MATLAB using `audioread`.

```
[y,Fs] = audioread(filename);
```

Listen to the audio.

```
sound(y,Fs);
```

Specify Bits Per Sample and Metadata

Create a FLAC file from the example file `handel.mat` and specify the number of output bits per sample and a comment.

```
load handel.mat

filename = 'handel.flac';
audiowrite(filename,y,Fs,'BitsPerSample',24,...
'Comment','This is my new audio file.');
```

View information about the new FLAC file.

```
info = audioinfo(filename)

info =

    Filename: 'S:\handel.flac'
  CompressionMethod: 'FLAC'
    NumChannels: 1
    SampleRate: 8192
   TotalSamples: 73113
    Duration: 8.9249
         Title: []
    Comment: 'This is my new audio file.'
         Artist: []
   BitsPerSample: 24
```

Input Arguments

filename — Name of file to write

string

Name of file to write, or the full path to the file, specified as a string that includes the file extension. If a path is specified, it can be absolute or relative. If you do not specify the path, then the destination directory is the current working directory.

`audiowrite` supports the following file formats.

Platform Support	File Format
All platforms	WAVE (.wav)
	OGG (.ogg)
	FLAC (.flac)
Windows and Mac	MPEG-4 AAC (.m4a, .mp4)

Example: 'myFile.m4a'

Example: '../myFile.m4a'

Example: 'C:\temp\myFile.m4a'

When writing AAC files on Windows, `audiowrite` pads the front and back of the output signal with extra samples of silence. The Windows AAC encoder also places a very sharp fade-in and fade-out on the audio. This results in audio with an increased number of samples after being written to disk.

y — Audio data to write

matrix

Audio data to write, specified as an m -by- n matrix, where m is the number of audio samples to write and n is the number of audio channels to write.

If either m or n is 1, then `audiowrite` assumes that this dimension specifies the number of audio channels, and the other dimension specifies the number of audio samples.

The maximum number of channels depends on the file format.

File Format	Maximum Number of Channels
WAVE (.wav)	256
OGG (.ogg)	255
FLAC (.flac)	8
MPEG-4 AAC (.m4a, .mp4)	2

The valid range for the data in y depends on the data type of y .

Data Type of y	Valid Range for y
uint8	$0 \leq y \leq 255$

Data Type of <i>y</i>	Valid Range for <i>y</i>
int16	$-32768 \leq y \leq +32767$
int32	$-2^{32} \leq y \leq 2^{32}-1$
single	$-1.0 \leq y \leq +1.0$
double	$-1.0 \leq y \leq +1.0$

Data beyond the valid range is clipped.

If *y* is `single` or `double`, then audio data in *y* should be normalized to values in the range -1.0 and 1.0 , inclusive.

Data Types: `single` | `double` | `int16` | `int32` | `uint8`

Fs — Sample rate

positive scalar

Sample rate, in hertz, of audio data *y*, specified as a positive scalar greater than 0. Values of *Fs* are truncated to integer boundaries. When writing to `.m4a` or `.mp4` files on Windows platforms, `audiowrite` supports only samples rates of 44100 and 48000.

Example: 44100

Data Types: `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of *Name*, *Value* arguments. *Name* is the argument name and *Value* is the corresponding value. *Name* must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as *Name1*, *Value1*, ..., *NameN*, *ValueN*.

Example: 'Title', 'Symphony No. 9', 'Artist', 'My Orchestra' instructs `audiowrite` to write an audio file with the title “Symphony No. 9” and the artist information “My Orchestra.”

'BitsPerSample' — Number of output bits per sample

16 (default) | 8 | 24 | 32 | 64

Number of output bits per sample, specified as the comma-separated pair consisting of 'BitsPerSample' and a number.

Only available for WAVE (.wav) and FLAC (.flac) files. For FLAC files, only 8, 16, or 24 bits per sample are supported.

Example: 'BitsPerSample',32

'BitRate' — Kilobits per second (kbit/s)

128 (default) | 64 | 96 | 160 | 192 | 256 | 320

Number of kilobits per second (kbit/s) used for compressed audio files, specified as the comma-separated pair consisting of 'BitRate' and an integer. Noninteger values are truncated. On Windows 7 or later, the only valid values are 96, 128, 160, and 192.

In general, a larger BitRate value results in higher compression quality.

Only available for MPEG-4 (.m4a, .mp4) files.

Example: 'BitRate',96

'Quality' — Quality setting for the Ogg Vorbis Compressor

75 (default) | value in the range [0 100]

Quality setting for the Ogg Vorbis Compressor, specified as the comma-separated pair consisting of 'Quality' and a number in the range [0 100], where 0 is lower quality and higher compression, and 100 is higher quality and lower compression.

Only available for OGG (.ogg) files.

Example: 'Quality',25

'Title' — Title information

[] (default) | string

Title information, specified as the comma-separated pair consisting of 'Title' and a string.

'Artist' — Artist information

[] (default) | string

Artist information, specified as the comma-separated pair consisting of 'Artist' and a string.

'Comment' — Additional information

[] (default) | string

Additional information, specified as the comma-separated pair consisting of 'Comment' and a string.

Note: On Mac platforms, `audiowrite` writes metadata to WAVE, OGG, and FLAC files only, and will not write the 'Title', 'Author', or 'Comment' fields to MPEG-4 AAC files.

More About

Algorithms

The output data type is determined by the file format, the data type of `y`, and the specified output `BitsPerSample`.

File Formats	Data Type of <code>y</code>	Output <code>BitsPerSample</code>	Output Data Type
WAVE (.wav),	uint8, int16, int32, single, double	8	uint8
		16	int16
		24	int32
	uint8, int16, int32	32	int32
	single, double	32	single
	single, double	64	double
FLAC (.flac)	uint8, int16, int32, single, double	8	int8
		16	int16
		24	int32
MPEG-4 (.m4a, .mp4), OGG (.ogg)	uint8, int16, int32, single, double	N/A	single

See Also

`audioinfo` | `audioread`

Introduced in R2012b

addOptional

Class: inputParser

Add optional positional argument to input parser scheme

Syntax

```
addOptional(p, argName, default)
addOptional(p, argName, default, validationFcn)
```

Description

`addOptional(p, argName, default)` adds optional input, `argName`, to the input parser scheme of `inputParser` object, `p`. When the inputs that you are checking do not include a value for this optional input, the input parser assigns the `default` value to the input.

`addOptional(p, argName, default, validationFcn)` specifies a validation function for the input argument.

Tips

- For optional string inputs, specify a validation function. Without a validation function, the input parser interprets valid string inputs as invalid parameter names and throws an error.
- Use `addOptional` to add an individual argument into the input parser scheme. If you want to parse an optional name-value pair, use `addParameter`.

Input Arguments

p

Object of class `inputParser`.

argName

String that specifies the internal name for the input argument.

Arguments added with `addOptional` are positional. When you call a function with positional inputs:

- Specify inputs in the same order that they are added into the input parser scheme.
- Specify a value for the k th argument by assigning values for the first $(k-1)$ arguments in the input scheme.

default

Default value for the input. This value can be of any data type.

validationFcn

Handle to a function that checks if the input argument is valid.

`inputParser` accepts two types of validation functions: functions that return `true` or `false`, and functions that pass or throw an error. Both types of validation functions must accept a single input argument.

Examples

Add Optional Input

Create an `inputParser` object and add an optional input named `myinput` with a default value of 0 to the input scheme.

```
p = inputParser;  
argName = 'myinput';  
default = 0;  
addOptional(p,argName,default);
```

Validate Optional Input

Check whether an optional input named `num` with a default value of 1 is a numeric scalar greater than zero.

```
p = inputParser;  
argName = 'num';
```

```
default = 1;
validationFcn = @(x) isnumeric(x) && isscalar(x) && (x > 0);
addOptional(p, argName, default, validationFcn)
```

The syntax `@(x)` creates a handle to an anonymous function with one input.

Attempt to parse an invalid input, such as `-1`:

```
parse(p, -1)
```

The value of 'num' is invalid. It must satisfy the function: `@(x)isnumeric(x)&&isscalar(x)&&(x>0)`.

Validate Optional Input with `validateattributes`

Create an `inputParser` object and define a validation function using `validateattributes` to test that optional input is numeric, positive, and even. Add the required input to the scheme.

```
p = inputParser;
argName = 'evenPosNum';
default = 1;
validationFcn = @(x) validateattributes(x, {'numeric'}, ...
    {'even', 'positive'});
addOptional(p, argName, default, validationFcn)
```

Parse an input string. Parse will fail.

```
parse(p, 'hello')
```

The value of 'evenPosNum' is invalid. Expected input to be one of these types:

```
double, single, uint8, uint16, uint32, uint64, int8, int16, int32, int64
```

Instead its type was char.

Parse an odd number. Parse will fail.

```
parse(p, 13)
```

The value of 'evenPosNum' is invalid. Expected input to be even.

Parse an even, positive number. Parse will pass.

```
parse(p, 42)
```

More About

- “Create Function Handle”
- “Anonymous Functions”

Introduced in R2007a

addParameter

Class: inputParser

Add optional parameter name-value pair argument to input parser scheme

Syntax

```
addParameter(p,paramName,default)
addParameter(p,paramName,default,validationFcn)
addParameter( ____, 'PartialMatchPriority', matchPriorityValue)
```

Description

`addParameter(p,paramName,default)` adds parameter name and value argument `paramName` to the input parser scheme of `inputParser` object, `p`. When the inputs that you are checking do not include a value for this optional parameter, the input parser assigns the `default` value.

`addParameter(p,paramName,default,validationFcn)` specifies a validation function for the input argument.

`addParameter(____, 'PartialMatchPriority', matchPriorityValue)` allows specification of `matchPriorityValue` to indicate priority for matching of conflicting partial parameter names and can include any of the input arguments in the previous syntaxes.

Input Arguments

p

Object of class `inputParser`.

paramName

String that specifies the internal name for the input parameter.

Parameter names and values are optional inputs. When calling the function, name and value pairs can appear in any order, with the general form `Name1, Value1, . . . , NameN, ValueN`.

default

Default value for the input. This value can be of any data type.

matchPriorityValue

Positive integer value indicating the priority for matching of conflicting partial parameter names. The input parser selects lower priority values over higher ones. If, within an input parser scheme, partial parameter names are ambiguous and have the same priority, `inputParser` will throw an error. If the names are ambiguous, but have different `PartialMatchPriority` values, `inputParser` issues a warning indicating the matched name.

Default: 1

validationFcn

Handle to a function that checks if the input argument is valid.

`inputParser` accepts two types of validation functions: functions that return `true` or `false`, and functions that pass or throw an error. Both types of validation functions must accept a single input argument.

Examples

Add Optional Parameter Value Input

Create an `inputParser` object and add an optional input named `myparam` with a default value of 0 to the input scheme.

```
p = inputParser;  
paramName = 'myparam';  
default = 0;  
addParameter(p,paramName,default);
```

Unlike the positional inputs added with the `addRequired` and `addOptional` methods, each parameter added with `addParameter` corresponds to two input arguments: one for the name and one for the value of the parameter.

Pass both the parameter name and value to the `parse` method.

```
parse(p, 'myparam', 100);
p.Results
```

```
ans =
```

```
    myparam: 100
```

Validate Parameter Value

Check whether the value corresponding to `myparam` is a numeric scalar greater than zero.

```
p = inputParser;
paramName = 'myparam';
default = 1;
errorStr = 'Value must be positive, scalar, and numeric.';
validationFcn = @(x) assert(isnumeric(x) && isscalar(x) ...
    && (x > 0), errorStr);
addParameter(p, paramName, default, validationFcn)
```

The syntax `@(x)` creates a handle to an anonymous function with one input.

Attempt to parse an invalid value, such as `-1`:

```
parse(p, 'myparam', -1)
```

```
The value of 'myparam' is invalid. Value must be positive, scalar, and numeric.
```

Validate Parameter Value Input with `validateattributes`

Create an `inputParser` object and define a validation function using `validateattributes` to test that input parameter `myName` is a nonempty string.

```
p = inputParser;
paramName = 'myName';
default = 'John Doe';
validationFcn = @(x) validateattributes(x, {'char'}, {'nonempty'});
addParameter(p, paramName, default, validationFcn)
```

Define `myName` as a number. The attempt to parse fails.

```
parse(p, 'myName', 1138)
```

The value of 'myName' is invalid. Expected input to be one of these types:

char

Instead its type was double.

Parse a string. The attempt to parse passes.

```
parse(p, 'myName', 'George')
```

More About

- “Create Function Handle”
- “Anonymous Functions”

Introduced in R2013b

addParamValue

Class: inputParser

(Not recommended) Add parameter name and value argument to Input Parser scheme

Compatibility

addParamValue is not recommended. Use addParameter instead.

Syntax

```
addParamValue(p,paramName,default)
addParamValue(p,paramName,default,validationFcn)
```

Description

addParamValue(p,paramName,default) adds parameter name and value argument paramName to the input scheme of inputParser object p. When the inputs that you are checking do not include a value for this optional parameter, the parser assigns the default value.

addParamValue(p,paramName,default,validationFcn) specifies a validation function for the input argument.

Tips

- If your parameter values do not require validation, you do not have to include them in the input scheme with addParamValue. As an alternative, set the KeepUnmatched property of the inputParser object to true. The parser stores extra parameter names and values in the Unmatched property rather than in the Results property of the object. For an example, see the inputParser reference page.

Input Arguments

p

Object of class `inputParser`.

paramName

String that specifies the internal name for the input parameter.

Parameter names and values are optional inputs. When calling the function, name and value pairs can appear in any order, with the general form `Name1, Value1, . . . , NameN, ValueN`.

default

Default value for the input. This value can be of any data type.

validationFcn

Handle to a function that checks if the input argument is valid.

`inputParser` accepts two types of validation functions: functions that return `true` or `false`, and functions that pass or throw an error. Both types of validation functions must accept a single input argument.

Examples

Add Optional Parameter Value Input

Create an `inputParser` object and add an optional input named `myparam` with a default value of 0 to the input scheme.

```
p = inputParser;  
paramName = 'myparam';  
default = 0;  
addParameter(p,paramName,default);
```

Unlike the positional inputs added with the `addRequired` and `addOptional` methods, each parameter added with `addParameter` corresponds to two input arguments: one for the name and one for the value of the parameter.

Pass both the parameter name and value to the `parse` method.

```
parse(p, 'myparam', 100);  
p.Results
```

```
ans =
```

```
    myparam: 100
```

Validate Parameter Value

Check whether the value corresponding to `myparam` is a numeric scalar greater than zero.

```
p = inputParser;  
paramName = 'myparam';  
default = 1;  
validationFcn = @(x) isnumeric(x) && isscalar(x) && (x > 0);  
addParamValue(p,paramName,default,validationFcn)
```

The syntax `@(x)` creates a handle to an anonymous function with one input.

Attempt to parse an invalid value, such as -1:

```
parse(p, 'myparam', -1)
```

```
Argument 'myparam' failed validation @(x)isnumeric(x)&&isscalar(x)&&(x>0).
```

Introduced in R2007a

addcats

Add categories to categorical array

Syntax

```
B = addcats(A,newcats)
B = addcats(A,newcats,'Before',beforewhere)
B = addcats(A,newcats,'After',afterwhere)
```

Description

`B = addcats(A,newcats)` adds categories to the end of the category list for the input categorical array, `A`. The output categorical array, `B`, contains the same values as `A`. The output, `B`, does not contain any elements equal to the new categories until you assign values from `newcats` to elements in `B`.

If `A` is an ordinal categorical array, you must specify the `'Before'`, `beforewhere` or `'After'`, `afterwhere` input arguments.

`B = addcats(A,newcats,'Before',beforewhere)` adds categories before the category specified by `beforewhere`.

`B = addcats(A,newcats,'After',afterwhere)` adds categories after the category specified by `afterwhere`.

Examples

Add Categories at End

Create a nonordinal categorical array.

```
A = categorical({'republican' 'democrat' 'republican';...
               'democrat' 'republican' 'democrat'})
```

A =

```

    republican    democrat    republican
    democrat     republican    democrat

```

Display the categories of A.

```
categories(A)
```

```
ans =
```

```

    'democrat'
    'republican'

```

A is a 2-by-3 categorical array with two categories.

Add the categories, `independent` and `undeclared`, to the end of the category list

```
B = addcats(A,{'independent' 'undeclared'})
```

```
B =
```

```

    republican    democrat    republican
    democrat     republican    democrat

```

B contains the same values as A.

Display the categories of B.

```
categories(B)
```

```
ans =
```

```

    'democrat'
    'republican'
    'independent'
    'undeclared'

```

B is a 2-by-3 categorical array with four categories.

Add Categories and Specify Category to Precede

Create an ordinal categorical array.

```
A = categorical({'medium' 'large'; 'small' 'xlarge'; 'large' 'medium'},...
```

```
{'small' 'medium' 'large' 'xlarge'}, 'Ordinal', true)
```

A =

```
medium    large
small     xlarge
large     medium
```

Display the categories of A.

```
categories(A)
```

ans =

```
'small'
'medium'
'large'
'xlarge'
```

Since A is ordinal, the categories have the mathematical ordering `small < medium < large < xlarge`.

Add the category `xsmall` before `small`.

```
B = addcats(A, 'xsmall', 'Before', 'small')
```

B =

```
medium    large
small     xlarge
large     medium
```

B contains the same values as A.

Display the categories of B.

```
categories(B)
```

ans =

```
'xsmall'
'small'
'medium'
'large'
'xlarge'
```

The categories have the mathematical ordering `xsmall < small < medium < large < xlarge`.

Input Arguments

A — Categorical array

vector | matrix | multidimensional array

Categorical array, specified as a vector, matrix, or multidimensional array.

newcats — New categories

string | cell array of strings

New categories, specified as a string or a cell array of strings.

beforewhere — Category to precede

string

Category to precede, specified as a string.

afterwhere — Category to follow

string

Category to follow, specified as a string.

See Also

Introduced in R2013b

addpath

Add folders to search path

Syntax

```
addpath(folderName1,...,folderNameN)  
addpath(folderName1,...,folderNameN,position)
```

```
addpath( ____, '-frozen')
```

```
oldpath = addpath( ____)
```

Description

`addpath(folderName1,...,folderNameN)` adds the specified folders to the top of the search path for the current MATLAB session.

`addpath(folderName1,...,folderNameN,position)` adds the specified folders to the top or bottom of the search path, as specified by `position`.

`addpath(____, '-frozen')` additionally disables folder change detection for folders being added in Windows. Use this syntax with any of the arguments in previous syntaxes. You can specify `'-frozen'` and `position` in either order. Use this syntax to conserve Windows change notification resources (Windows only). For more information, type `help changenotification` in the Command Window.

`oldpath = addpath(____)` additionally returns the path prior to adding the specified folders.

Examples

Add Folder to Top of Search Path

Create a folder, add it to the top of your search path, and then save the search path for future MATLAB sessions.

```
mkdir('c:/matlab/myfiles')
addpath('c:/matlab/myfiles')
savepath c:/matlab/myfiles/pathdef.m
```

Add Folder to End of Search Path

Add `c:/matlab/myfiles` to the end of the search path.

```
addpath('c:/matlab/myfiles', '-end')
```

Add Folder and Its Subfolders to Search Path

Add `c:/matlab/myfiles` and its subfolders to the search path.

Call `genpath` inside of `addpath` to add all subfolders of `c:/matlab/myfiles` to the search path.

```
addpath(genpath('c:/matlab/myfiles'))
```

Add Folder to Search Path and Disable Folder Change Notification

On Windows, add the folder `c:/matlab/myfiles` to the top of the search path, disable folder change notification, and return the search path before adding the folder.

```
oldpath = addpath('c:/matlab/myfiles', '-frozen');
```

Input Arguments

folderName1, ..., folderNameN — Folder names to add to search path

string

Folder names to add to the search path, specified as strings. Use the full path name for each folder. Use `genpath` with `addpath` to add all subfolders of `folderName`.

Example: `'c:\matlab\work'`

Example: `'/home/user/matlab'`

Example: `'/home/user/matlab', '/home/user/matlab/test'`

position — Position on search path

'-begin' (default) | '-end'

Position on the search path, specified as one of these strings.

Value of position	Description
'-begin'	Add specified folders to the top of the search path.
'-end'	Add specified folders to the bottom of the search path.

Output Arguments

oldpath — Path prior to addition of folders

string

Path prior to the addition of folders, returned as a string.

More About

Tips

- To save the newly modified search path for future MATLAB sessions, use the `savepath` function. Alternatively, use `addpath` statements in a `startup.m` file to modify the search path programmatically at startup.
- If you use `addpath` within a local function, the path change persists after program control returns from the function. That is, the scope of the path change is global.
 - “What Is the MATLAB Search Path?”
 - “Files and Folders that MATLAB Accesses”
 - “Specify File Names”
 - “Startup Options in MATLAB Startup File”

`genpath` | `path` | `pathsep` | `rmpath` | `savepath`

Introduced before R2006a

addpref

Add preference

Syntax

```
addpref('group','pref',val)
addpref('group',{'pref1','pref2',... 'prefn'},{val1,val2,...valn})
```

Description

`addpref('group','pref',val)` creates the preference specified by `group` and `pref` and sets its value to `val`. It is an error to add a preference that already exists. Individual preference values can be any MATLAB data type, including numeric types, strings, cell arrays, structures, and objects.

`group` labels a related collection of preferences. You can choose any name that is a legal variable name, and is descriptive enough to be unique, e.g. `'ApplicationOnePrefs'`. The input argument `pref` identifies an individual preference in that group, and must be a legal variable name.

`addpref('group',{'pref1','pref2',... 'prefn'},{val1,val2,...valn})` creates the preferences specified by the cell array of names `'pref1'`, `'pref2'`, ..., `'prefn'`, setting each to the corresponding value.

Note Preference values are persistent and maintain their values between MATLAB sessions. Where they are stored is system dependent.

Examples

Add a preference called `version` to the `mytoolbox` group of preferences, setting its value to the cell array `{'1.0','beta'}`.

```
addpref('mytoolbox','version',{'1.0','beta'})
```

Add a preference called `documentation` to the `mytoolbox` group of preferences, setting its value to a struct you define as having four fields:

```
mydoc.docexists = 1;
mydoc.docpath = fullfile(docroot,'techdoc',...
    'matlab_env','examples');
mydoc.demoexists = 1;
mydoc.demopath = fullfile(docroot,'techdoc',...
    'matlab_env','examples','demo_examples');
addpref('mytoolbox','documentation',mydoc)
% Retrieve the preference with GETPREF
p = getpref('mytoolbox','documentation')
```

```
p =
    docexists: 1
      docpath: [1x109 char]
    demoexists: 1
      demopath: [1x123 char]
```

See Also

Introduced before R2006a

addpoints

Add points to animated line

Syntax

```
addpoints(h,x,y)  
addpoints(h,x,y,z)
```

Description

`addpoints(h,x,y)` adds points defined by `x` and `y` to the animated line specified by `h`. Create an animated line with the `animatedline` function. To display the updates on the screen, use `drawnow` or `drawnow limitrate`. New points automatically connect to previous points. For more information on line animations, see [Using Animated Line Objects](#).

`addpoints(h,x,y,z)` adds points defined by `x`, `y`, and `z` to the 3-D animated line specified by `h`.

Examples

Add Five Points to Animated Line

Create an animated line object with no data. Then, add five points to the line. Use a circle to mark each point.

```
h = animatedline('Marker','o');  
x = 1:5;  
y = 1:5;  
addpoints(h,x,y)
```

Add Points Within Loop to Animated Line

Create an animated line using the `animatedline` function. Then, add points to the line within a loop to create an animation. Set the axis limits before the loop to prevent the limits from changing.

```
figure
h = animatedline;
axis([0 4*pi -1 1])

for x = linspace(0,4*pi,10000)
    y = sin(x);
    addpoints(h,x,y)
    drawnow limitrate
```

end

Input Arguments

h — **Animated line object**

animated line object

Animated line object. Create an animated line using the `animatedline` function.

x — **x values**

scalar | vector

x values, specified as a scalar or a vector. The length of x must equal the length of y .

Example: 11:20

Data Types: double

y – y values

scalar | vector

y values, specified as a scalar or a vector. The length of y must equal the length of x .

Example: 11:20

Data Types: double

z – z values

scalar | vector

z values, specified as a scalar or a vector. The length of z must equal the length of x and y .

Example: 11:20

Data Types: double

animatedline | clearpoints | getpoints

Using Objects

Using Animated Line Objects

Introduced in R2014b

dynamicprops.addprop

Add dynamic property

Syntax

```
P = addprop(Hobj, 'PropName')
```

Description

`P = addprop(Hobj, 'PropName')` adds a property named `PropName` to each object in array `Hobj`. The class definition is not affected by the addition of dynamic properties. Note that you can add dynamic properties only to objects derived from the `dynamicprops` class. You can set and retrieve the data in dynamic properties as you would any property.

The output argument `P` is an array the same size as `Hobj` of `meta.DynamicProperty` objects, which you can use to assign `SetMethod` and `GetMethod` functions to the property. These functions operate just like property set and get access methods.

See “Dynamic Properties — Adding Properties to an Instance” for more information and examples.

See Also

`handle` | `dynamicprops`

addproperty

Add custom property to COM object

Syntax

```
addproperty(h, 'name')
```

Description

`addproperty(h, 'name')` adds custom property specified in string, `name`, to object or interface, `h`.

COM functions are available on Microsoft Windows systems only.

Examples

This example adds a custom property to the MATLAB sample control.

- 1 Create an instance of the control.

```
f = figure('position',[100 200 200 200]);  
h = actxcontrol('mwsamp.mwsampctrl.2',[0 0 200 200],f);  
get(h)
```

```
Label: 'Label'  
Radius: 20
```

- 2 Add a custom property named `Position` and assign a value:

```
addproperty(h,'Position')  
h.Position = [200 120];  
get(h)
```

```
Label: 'Label'  
Radius: 20  
Position: [200 120]
```

- 3 Delete the custom property `Position`. MATLAB displays the original list of properties.

```
deleteproperty(h, 'Position')  
get(h)
```

```
Label: 'Label'  
Radius: 20
```

More About

- “COM Object Properties”

`deleteproperty` | `set` (COM) | `inspect` | `get` (COM)

Introduced before R2006a

addRequired

Class: inputParser

Add required positional argument to input parser scheme

Syntax

```
addRequired(p, argName)  
addRequired(p, argName, validationFcn)
```

Description

`addRequired(p, argName)` adds required argument, `argName`, to the input parser scheme of `inputParser` object, `p`.

`addRequired(p, argName, validationFcn)` includes a validation function for the input argument.

Input Arguments

p

Object of class `inputParser`.

argName

String that specifies the internal name for the input argument.

Arguments added with `addRequired` are positional. When you call a function with positional inputs, you must specify inputs in the order that they are added to the input parser scheme.

validationFcn

Handle to a function that checks if the input argument is valid.

`inputParser` accepts two types of validation functions: functions that return `true` or `false`, and functions that pass or throw an error. Both types of validation functions must accept a single input argument.

Examples

Add Required Input

Create an `inputParser` object and add a required input named `myinput` to the input scheme.

```
p = inputParser;  
argName = 'myinput';  
addRequired(p,argName);
```

Validate Required Input

Check whether a required input named `num` is a numeric scalar greater than zero.

```
p = inputParser;  
argName = 'num';  
validationFcn = @(x) isnumeric(x) && isscalar(x) && (x > 0);  
addRequired(p,argName,validationFcn)
```

The syntax `@(x)` creates a handle to an anonymous function with one input.

Attempt to parse an invalid input, such as `-1`:

```
parse(p,-1)
```

The value of 'num' is invalid. It must satisfy the function: `@(x)isnumeric(x)&&isscalar(x)&&(x>0)`.

Validate Required Input with `validateattributes`

Create an `inputParser` object and define a validation function using `validateattributes` to test that required input is numeric, positive, and even. Add the required input to the scheme.

```
p = inputParser;  
argName = 'evenPosNum';  
validationFcn = @(x) validateattributes(x,{'numeric'},...  
    {'even','positive'});  
addRequired(p,argName,validationFcn)
```

Parse an input string. Parse will fail.

```
parse(p, 'hello')
```

The value of 'evenPosNum' is invalid. Expected input to be one of these types:

double, single, uint8, uint16, uint32, uint64, int8, int16, int32, int64

Instead its type was char.

Parse an odd number. Parse will fail.

```
parse(p, 13)
```

The value of 'evenPosNum' is invalid. Expected input to be even.

Parse an even, positive number. Parse will pass.

```
parse(p, 42)
```

- “Create Function Handle”
- “Anonymous Functions”

Introduced in R2007a

addsampletocollection

Add sample to `tscollection` object

Syntax

```
tsc = addsampletocollection(tsc, 'time', Time, TS1Name, TS1Data,  
TSnName, TSnData)
```

Description

`tsc = addsampletocollection(tsc, 'time', Time, TS1Name, TS1Data, TSnName, TSnData)` adds data samples `TSnData` to the collection member `TSnName` in the `tscollection` object `tsc` at one or more `Time` values. Here, `TSnName` is the string that represents the name of a time series in `tsc`, and `TSnData` is an array containing data samples.

Examples

The following example shows how to create a `tscollection` that consists of two `timeseries` objects, where one `timeseries` does not have quality codes and the other does. The final step of the example adds a sample to the `tscollection`.

- 1 Create two `timeseries` objects, `ts1` and `ts2`.

```
ts1 = timeseries([1.1 2.9 3.7 4.0 3.0],1:5,...  
                'name','acceleration');  
ts2 = timeseries([3.2 4.2 6.2 8.5 1.1],1:5,...  
                'name','speed');
```

- 2 Define a dictionary of quality codes and descriptions for `ts2`.

```
ts2.QualityInfo.Code = [0 1];  
ts2.QualityInfo.Description = {'bad','good'};
```

- 3 Assign a quality of code of 1, which is equivalent to 'good', to each data value in `ts2`.

```
ts2.Quality = ones(5,1);
```

- 4 Create a time-series collection `tsc`, which includes time series `ts1` and `ts2`.

```
tsc = tscollection({ts1,ts2});
```

- 5 Add a data sample to the collection `tsc` at 3.5 seconds.

```
tsc = addsampletocollection(tsc,'time',3.5,'acceleration',10,'speed',{5 1});
```

The cell array for the `timeseries` object `'speed'` specifies both the data value 5 and the quality code 1.

Note If you do not specify a quality code when adding a data sample to a time series that has quality codes, then the lowest quality code is assigned to the new sample by default.

More About

Tips

If you do not specify data samples for a time-series member in `tsc`, that time-series member will contain missing data at the times given by `Time` (for numerical time-series data), NaN values, or (for logical time-series data) `false` values.

When a time-series member requires `Quality` values, you can specify data quality codes together with the data samples by using the following syntax:

```
tsc = addsampletocollection(tsc,'time',time,TS1Name,...  
    ts1cellarray,TS2Name,ts2cellarray,...)
```

Specify data in the first cell array element and `Quality` in the second cell array element.

Note If a time-series member already has `Quality` values but you only provide data samples, 0s are added to the existing `Quality` array at the times given by `Time`.

`delsamplefromcollection` | `timeseries` | `tscollection`

Introduced before R2006a

addtodate

Modify date number by field

Syntax

```
R = addtodate(D, Q, F)
```

Description

`R = addtodate(D, Q, F)` adds quantity `Q` to the indicated date field `F` of a scalar serial date number `D`, returning the updated date number `R`.

The quantity `Q` to be added can be a positive or negative integer. The absolute value of `Q` must be less than or equal to `1e16`. The date field `F` must be a 1-by-`N` character array equal to one of the following: `'year'`, `'month'`, `'day'`, `'hour'`, `'minute'`, `'second'`, or `'millisecond'`.

If the addition to the date field causes the field to roll over, the MATLAB software adjusts the next more significant fields accordingly. Adding a negative quantity to the indicated date field rolls back the calendar on the indicated field. If the addition causes the field to roll back, MATLAB adjusts the next less significant fields accordingly.

Examples

Modify the hours, days, and minutes of a given date:

```
t = datenum('07-Apr-2008 23:00:00');
datestr(t)
ans =
    07-Apr-2008 23:00:00

t= addtodate(t, 2, 'hour');
datestr(t)
ans =
    08-Apr-2008 01:00:00
```

```
t= addtodate(t, -7, 'day');
datestr(t)
ans =
    01-Apr-2008 01:00:00
```

```
t= addtodate(t, 59, 'minute');
datestr(t)
ans =
    01-Apr-2008 01:59:00
```

Adding 20 days to the given date in late December causes the calendar to roll over to January of the next year:

```
R = addtodate(datetime('12/24/2007 12:45'), 20, 'day');

datestr(R)
ans =
    13-Jan-2008 12:45:00
```

Introduced before R2006a

addts

Add `timeseries` object to `tscollection` object

Syntax

```
tsc = addts(tsc,ts)
tsc = addts(tsc,ts)
tsc = addts(tsc,ts,Name)
tsc = addts(tsc,Data,Name)
```

Description

`tsc = addts(tsc,ts)` adds the `timeseries` object `ts` to `tscollection` object `tsc`.

`tsc = addts(tsc,ts)` adds a cell array of `timeseries` objects `ts` to the `tscollection` `tsc`.

`tsc = addts(tsc,ts,Name)` adds a cell array of `timeseries` objects `ts` to `tscollection` `tsc`. `Name` is a cell array of strings that gives the names of the `timeseries` objects in `ts`.

`tsc = addts(tsc,Data,Name)` creates a new `timeseries` object from `Data` with the name `Name` and adds it to the `tscollection` object `tsc`. `Data` is a numerical array and `Name` is a string.

Examples

The following example shows how to add a time series to a time-series collection:

- 1 Create two `timeseries` objects, `ts1` and `ts2`.

```
ts1 = timeseries([1.1 2.9 3.7 4.0 3.0],1:5,...
                 'name','acceleration');
ts2 = timeseries([3.2 4.2 6.2 8.5 1.1],1:5,...
```

- ```
'name', 'speed');
```
- 2** Create a time-series collection `tsc`, which includes `ts1`.

```
tsc = tscollection(ts1);
```

- 3** Add `ts2` to the `tsc` collection.

```
tsc = addts(tsc, ts2);
```

- 4** To view the members of `tsc`, type

```
tsc
```

at the MATLAB prompt. the response is

```
Time Series Collection Object: unnamed
```

```
Time vector characteristics
```

```
Start time 1 seconds
End time 5 seconds
```

```
Member Time Series Objects:
```

```
acceleration
speed
```

The members of `tsc` are listed by name at the bottom: `acceleration` and `speed`. These are the `Name` properties of the `timeseries` objects `ts1` and `ts2`, respectively.

## More About

### Tips

The `timeseries` objects you add to the collection must have the same time vector as the collection. That is, the time vectors must have the same time values and units.

Suppose that the time vector of a `timeseries` object is associated with calendar dates. When you add this `timeseries` to a collection with a time vector without calendar dates, the time vectors are compared based on the units and the values relative to the `StartDate` property. For more information about properties, see the `timeseries` reference page.

# airy

Airy Functions

## Syntax

```
W = airy(Z)
W = airy(k,Z)
W = airy(k,Z,scale)
```

## Description

`W = airy(Z)` returns the Airy function,  $Ai(Z)$ , for each element of  $Z$ .

`W = airy(k,Z)` returns any of four different Airy functions, depending on the value of  $k$ , such as the Airy function of the second kind or the first derivative of an Airy function.

`W = airy(k,Z,scale)` scales the resulting Airy function. `airy` applies a specific scaling function to  $W$  depending on your choice of  $k$  and `scale`.

## Examples

### Airy Function of Real-Valued $x$

Define  $x$ .

```
x = -10:0.01:1;
```

Calculate  $Ai(x)$

```
ai = airy(x);
```

Calculate  $Bi(x)$  using  $k = 2$ .

```
bi = airy(2,x);
```

Plot both results together on the same axes.

```
figure
plot(x,ai,'-b',x,bi,'-r')
axis([-10 1 -0.6 1.4])
```

```

xlabel('x')
legend('Ai(x)', 'Bi(x)', 'Location', 'NorthWest')

```

### Airy Function of Complex-Valued $x$

Compute the Airy function at a slice through the complex plane at  $x + i$ .

Take a slice through the complex plane.

```

x = -4:0.1:4;
z = x+1i;

```

Calculate  $Ai(z)$ .

```

w = airy(z);

```

Plot the real part of the result.

```
figure
plot(x, real(w))
axis([-4 4 -1.5 1])
xlabel('real(z)')
```

### Scaled Airy Function

Define x.

```
x = -10:0.01:1;
```

Calculate the scaled and unscaled Airy function.

```
scaledAi = airy(0,x,1);
noscaleAi = airy(0,x,0);
```

Plot the real part of each result.

```
rscaled = real(scaledAi);
rnoscale = real(noscaleAi);
figure
plot(x,rscaled,'-b',x,rnoscale,'-r')
axis([-10 1 -0.60 0.60])
xlabel('x')
legend('scaled','not scaled','Location','SouthEast')
```

## Input Arguments

### **Z** — System variable

vector | matrix | N-D Array

System variable, specified as a real or complex vector, matrix, or N-D array.

Data Types: `single` | `double`

Complex Number Support: Yes

### **k** — Type of Airy function

0 (default) | 1 | 2 | 3

Type of Airy function, specified as one of four values.

| <b>k</b> | <b>Returns</b>                                                       |
|----------|----------------------------------------------------------------------|
| 0        | Airy function, $Ai(Z)$ , which is the same as <code>airy(Z)</code> . |
| 1        | First derivative of Airy function, $Ai'(Z)$ .                        |
| 2        | Airy function of the second kind, $Bi(Z)$                            |
| 3        | First derivative of Airy function of the second kind, $Bi'(Z)$       |

Data Types: `single` | `double`

### **scale** — Scaling option

0 (default) | 1

Scaling option, specified as 0 or 1. Use `scale = 1` to enable the scaling of Z. The values you specify for `k` and `scale` determine the scaling function `airy` applies to Z.

| <b>scale</b> | <b>k</b> | <b>Scaling applied to output</b>        |
|--------------|----------|-----------------------------------------|
| 0            | Any      | None                                    |
| 1            | 0 or 1   | $\frac{2}{e^3} Z^{(3/2)}$               |
| 1            | 2 or 3   | $e^{-\frac{2}{3} \text{Re}(Z^{(3/2)})}$ |

Data Types: `single` | `double`

## Output Arguments

### **W** — Airy function of Z

vector | matrix | N-D Array

Airy function of Z, returned as an array the same size as Z.

## More About

### Airy Functions

The Airy functions form a pair of linearly independent solutions to

$$\frac{d^2W}{dZ^2} - ZW = 0.$$

The relationship between the Airy and modified Bessel functions is

$$Ai(Z) = \left[ \frac{1}{\pi} \sqrt{\frac{Z}{3}} \right] K_{1/3}(\zeta)$$
$$Bi(Z) = \sqrt{\frac{Z}{3}} [I_{-1/3}(\zeta) + I_{1/3}(\zeta)],$$

where

$$\zeta = \frac{2}{3} Z^{3/2}.$$

# align

Align user interface controls (uicontrols) and axes

## Syntax

```
align(HandleList, 'HorizontalAlignment', 'VerticalAlignment')
Positions = align(HandleList, 'HorizontalAlignment',
'VerticalAlignment')
Positions = align(CurPositions, 'HorizontalAlignment',
'VerticalAlignment')
```

## Description

`align(HandleList, 'HorizontalAlignment', 'VerticalAlignment')` aligns the `uicontrol` and `axes` objects in `HandleList`, a vector of handles, according to the options `HorizontalAlignment` and `VerticalAlignment`. The following tables show the possible values for `HorizontalAlignment` and `VerticalAlignment`.

| <b>HorizontalAlignment</b> | <b>Definition</b>                                                                                    |
|----------------------------|------------------------------------------------------------------------------------------------------|
| None                       | No horizontal alignment                                                                              |
| Left                       | Shifts the objects' left edges to that of the first object selected                                  |
| Center                     | Shifts objects to center their positions to the average of the extreme <i>x</i> -values of the group |
| Right                      | Shifts the objects' right edges to that of the first object selected                                 |
| Distribute                 | Equalizes <i>x</i> -distances between all objects within the span of the extreme <i>x</i> -values    |
| Fixed                      | Spaces objects to have a specified number of points between them in the <i>y</i> -direction          |

| <b>VerticalAlignment</b> | <b>Definition</b>     |
|--------------------------|-----------------------|
| None                     | No vertical alignment |

| VerticalAlignment | Definition                                                                                           |
|-------------------|------------------------------------------------------------------------------------------------------|
| Top               | Shifts the objects' top edges to that of the first object selected                                   |
| Middle            | Shifts objects to center their positions to the average of the extreme <i>y</i> -values of the group |
| Bottom            | Shifts the objects' bottom edges to that of the first object selected                                |
| Distribute        | Equalizes <i>y</i> -distances between all objects within the span of the extreme <i>y</i> -values    |
| Fixed             | Spaces objects to have a specified number of points between them in the <i>x</i> -direction          |

Aligning objects does not change their absolute sizes. All alignment options align the objects within the bounding box that encloses the objects. **Distribute** and **Fixed** align objects to the bottom left of the bounding box. **Distribute** evenly distributes the objects while **Fixed** distributes the objects with a fixed distance (in points) between them. When you specify both horizontal and vertical distance together, the keywords 'HorizontalAlignment' and 'VerticalAlignment' are not necessary.

If you use **Fixed** for **HorizontalAlignment** or **VerticalAlignment**, you must also specify the distance, in points, where 72 points equals 1 inch. For example:

```
align(HandleList, 'Fixed', Distance, 'VerticalAlignment')
```

distributes the specified components **Distance** points horizontally and aligns them vertically as specified.

```
align(HandleList, 'HorizontalAlignment', 'Fixed', Distance)
```

aligns the specified components horizontally as specified and distributes them **Distance** points vertically.

```
align(HandleList, 'Fixed', HorizontalDistance, ...
 'Fixed', VerticalDistance)
```

distributes the specified components **HorizontalDistance** points horizontally and distributes them **VerticalDistance** points vertically.

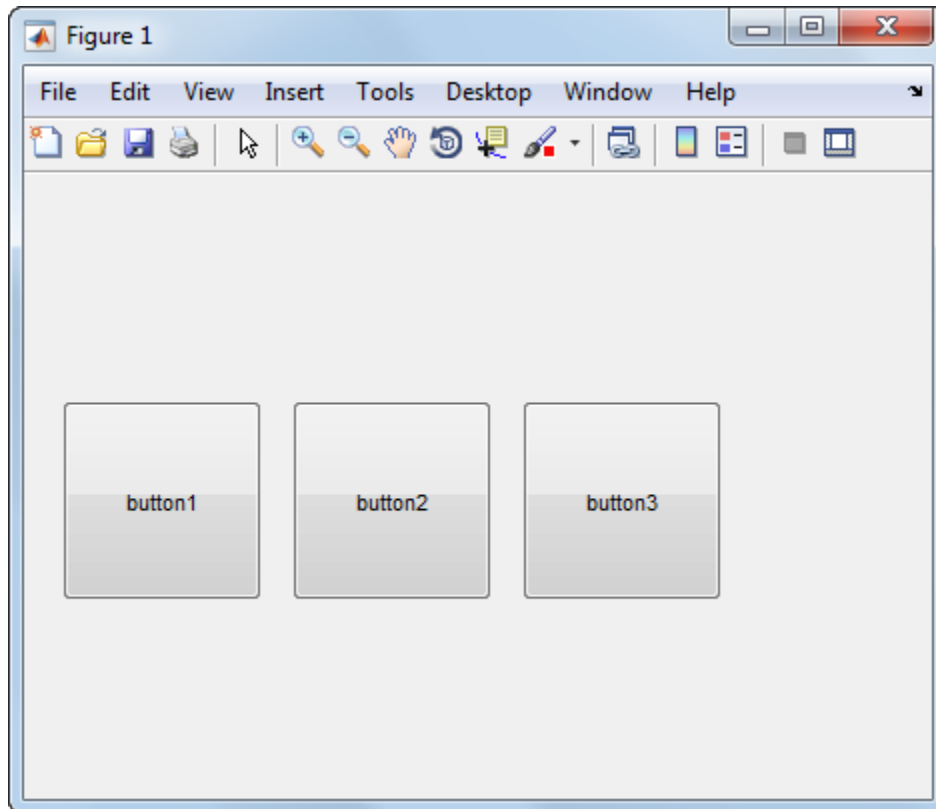

`Positions = align(HandleList, 'HorizontalAlignment', 'VerticalAlignment')` returns updated positions for the specified objects as a vector of **Position** vectors. The position of the objects on the figure does not change.

`Positions = align(CurPositions, 'HorizontalAlignment', 'VerticalAlignment')` returns updated positions for the objects whose positions are contained in `CurPositions`, where `CurPositions` is a vector of `Position` vectors. The position of the objects on the figure does not change.

## Examples

Create a UI containing three buttons, and use the `align` function to line up the buttons.

```
% Create a figure window and one button object:
f=figure;
u1 = uicontrol('Style','push', 'parent', f,'pos',...
[20 100 100 100],'string','button1');
% Create two more button objects, not aligned with
% each other or any part of the figure window:
u2 = uicontrol('Style','push', 'parent', f,'pos',...
[150 250 100 100],'string','button2');
u3 = uicontrol('Style','push', 'parent', f,'pos',...
[250 100 100 100],'string','button3');
% Align the button objects with the bottom of the first
% button object, equalizing the distance between the
% objects within the span of the extreme x-values:
align([u1 u2 u3],'distribute','bottom');
```

## More About

- “Align Objects in Graph Using Alignment Tools”

## See Also

`uicontrol` | `uistack`

# alim

Set or query axes alpha limits

## Syntax

```
alpha_limits = alim
alim([amin amax])
alim_mode = alim('mode')
alim('alim_mode')
alim(axes_handle,...)
```

## Description

`alpha_limits = alim` returns the alpha limits (ALim property) of the current axes.

`alim([amin amax])` sets the alpha limits to the specified values. `amin` is the value of the data mapped to the first alpha value in the alphamap, and `amax` is the value of the data mapped to the last alpha value in the alphamap. Data values in between are linearly interpolated across the alphamap, while data values outside are clamped to either the first or last alphamap value, whichever is closest.

`alim_mode = alim('mode')` returns the alpha limits mode (ALimMode property) of the current axes.

`alim('alim_mode')` sets the alpha limits mode on the current axes. `alim_mode` can be

- `auto` — MATLAB automatically sets the alpha limits based on the alpha data of the objects in the axes.
- `manual` — MATLAB does not change the alpha limits.

`alim(axes_handle,...)` operates on the specified axes.

## Examples

Map transparency to a surface plot of z-data and change the `alim` property to make all values below zero transparent:

```
[x,y] = meshgrid([-2:.2:2]);
z = x.*exp(-x.^2-y.^2);
% Plot the data, using the gradient of z as
% the alphasmap:
surf(x,y,z+.001,'FaceAlpha','flat',...
 'AlphaDataMapping','scaled',...
 'AlphaData',gradient(z),...
 'FaceColor','blue');
axis tight
% Adjust the alim property to see only where
% the gradient is between 0 and 0.15:
alim([0 .15])
```

## See Also

### Functions

alpha | alphamap | caxis

### Properties

Axes Properties

**Introduced before R2006a**

## **all**

Determine if all array elements are nonzero or `true`

### **Syntax**

```
B = all(A)
B = all(A,dim)
```

### **Description**

`B = all(A)` tests along the first array dimension of `A` whose size does not equal 1, and determines if the elements are all nonzero or logical 1 (`true`). In practice, `all` is a natural extension of the logical AND operator.

- If `A` is a vector, then `all(A)` returns logical 1 (`true`) if all the elements are nonzero and returns logical 0 (`false`) if one or more elements are zero.
- If `A` is a nonempty, nonvector matrix, then `all(A)` treats the columns of `A` as vectors and returns a row vector of logical 1s and 0s.
- If `A` is an empty 0-by-0 matrix, then `all(A)` returns logical 1 (`true`).
- If `A` is a multidimensional array, then `all(A)` acts along the first array dimension whose size does not equal 1 and returns an array of logical values. The size of this dimension becomes 1, while the sizes of all other dimensions remain the same.

`B = all(A,dim)` tests elements along dimension `dim`. The `dim` input is a positive integer scalar.

### **Examples**

#### **Test Matrix Columns**

Create a 3-by-3 matrix.

```
A = [0 0 3;0 0 3;0 0 3]
```

```
A =
```

```

0 0 3
0 0 3
0 0 3

```

Test each column for all nonzero elements.

```
B = all(A)
```

```
B =
```

```

0 0 1

```

### Reduce a Logical Vector to a Single Condition

Create a vector of decimal values and test which values are less than 0.5.

```
A = [0.53 0.67 0.01 0.38 0.07 0.42 0.69];
```

```
B = (A < 0.5)
```

```
B =
```

```

0 0 1 1 1 1 0

```

The output is a vector of logical values. The `all` function reduces such a vector of logical values to a single condition. In this case, `B = all(A < 0.5)` yields logical 0.

This makes `all` particularly useful in `if` statements.

```

if all(A < 0.5)
 %do something
else
 %do something else
end

```

The code is executed depending on a single condition, rather than a vector of possibly conflicting conditions.

### Test Arrays of Any Dimension

Create a 3-by-7-by-5 multidimensional array and test to see if all of its elements are less than 3.

```
A = rand(3,7,5) * 5;
```

```
B = all(A(:) < 3)
```

```
B =
```

```
0
```

You can also test the array for elements that are greater than zero.

```
B = all(A(:) > 0)
```

```
B =
```

```
1
```

The syntax `A(:)` turns the elements of `A` into a single column vector, so you can use this type of statement on an array of any size.

## Test Matrix Rows

Create a 3-by-3 matrix.

```
A = [0 0 3;0 0 3;0 0 3]
```

```
A =
```

```
0 0 3
0 0 3
0 0 3
```

Test the rows of `A` for all nonzero elements by specifying `dim = 2`.

```
B = all(A,2)
```

```
B =
```

```
0
0
0
```

## Input Arguments

### **A** — Input Array

scalar | vector | matrix | multidimensional array

Input array, specified as a scalar, vector, matrix, or multidimensional array.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char`

Complex Number Support: Yes

### **dim** – Dimension to operate along

positive integer scalar

Dimension to operate along, specified as a positive integer scalar. If no value is specified, then the default is the first array dimension whose size does not equal 1.

Consider a two-dimensional input array, A:

- `all(A,1)` works on successive elements in the columns of A and returns a row vector of logical values.
- `all(A,2)` works on successive elements in the rows of A and returns a column vector of logical values.

Data Types: `double` | `single` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

## Output Arguments

### **B** – Logical array

scalar | vector | matrix | multidimensional array

Logical array, returned as a scalar, vector, matrix, or multidimensional array. The dimension of A acted on by `all` has size 1 in B.

## **More About**

- “Reduce Logical Arrays to Single Value”

## **See Also**

and | any | colon | prod | sum

**Introduced before R2006a**

# allchild

Find all children of specified objects

## Syntax

```
child_handles = allchild(handle_list)
```

## Description

`child_handles = allchild(handle_list)` returns the list of all children (including ones with hidden handles) for each handle. If `handle_list` is a single element, `allchild` returns the output in a vector. If `handle_list` is a vector of handles, the output is a cell array.

## Examples

Compare the results these two statements return:

```
axes
get(gca, 'Children')
allchild(gca)
```

## See Also

`findall` | `findobj`

**Introduced before R2006a**

# alpha

Add transparency to objects in axes

## Syntax

```
alpha value
alpha alphadata
alpha facealpha
alpha alphadatamapping
```

```
alpha(obj, ___)
```

## Description

`alpha value` sets the face transparency for graphics objects in the current axes that support transparency. Specify **value** as a scalar value between 0 (transparent) and 1 (no transparency), 'clear', or 'opaque'.

`alpha alphadata` varies the transparency across all image, patch, chart surface, and primitive surface objects in the axes. This option sets the corresponding alpha data properties for the objects.

`alpha facealpha` specifies whether to use flat or interpolated transparency across the faces of all patch, chart surface, and primitive surface objects in the axes. This option sets the `FaceAlpha` property for the objects.

`alpha alphadatamapping` controls the interpretation of the alpha data values for all image, patch, chart surface, and primitive surface objects in the axes. This option sets the `AlphaDataMapping` property for the objects.

`alpha(obj, ___ )` sets the face transparency for the objects specified by `obj`. The option, `obj`, can precede any of the input arguments in the previous syntaxes. Use single quotes around input arguments that are character arrays, for example, `alpha(obj, 'opaque')`.

## Examples

### Set Transparency for All Graphics Objects in Axes

Create a bar chart and a scatter chart. Set the face transparency for both the bar series and scatter series object to 0.5.

```
bar(1:10)
hold on
scatter(10*rand(10,1),10*rand(10,1),'filled','SizeData',200)
hold off
alpha(.5)
```

## Set Transparency for Specific Graphics Object

Create a bar chart and a scatter chart. Set the transparency for the scatter series object to 0.5 without affecting the bar series object.

```
b = bar(1:10);
hold on
s = scatter(10*rand(10,1),10*rand(10,1), 'filled', 'SizeData',200);
hold off
alpha(s,.5)
```

### Set Surface Transparency Using z Values

Create a surface chart. Vary the transparency across the surface based on the z values.

```
s = surf(peaks);
alpha(s, 'z')
```

### Set Mapping of Alpha Data into Alphamap

Create an image. Vary the transparency across the image based on the color values. By default, the image clamps the transparency values between 0 and 1. Values less than 0 are completely transparency and values greater than 1 are completely opaque. Instead, transform the transparency values to span the alphamap using the `alpha_scaled` command.

```
imagesc(peaks)
alpha color
alpha scaled
```

- “Add Transparency to Graphics Objects”

## Input Arguments

### **value** — Face transparency value

scalar from 0 through 1 | 'clear' | 'opaque'

Face transparency value, specified as one of these values:

- Scalar from 0 through 1 — Set the face transparency to the specified value. A value of 0 means transparent. A value of 1 means opaque. Values between 0 and 1 are semitransparent.

- 'clear' — Set the face transparency to 0 (transparent).
- 'opaque' — Set the face transparency to 1 (opaque).

If the object does not have a face or if the face has no color, then the `alpha` function does not have a visual effect on the object. For example, `alpha` does not have a visual effect on scatter charts that use unfilled markers or that use markers without a face ('\*', '+', '.', and 'x').

This table lists the graphics objects that support transparency and the associated face transparency property that updates to the value specified.

| Graphics Object                     | Face Transparency Property |
|-------------------------------------|----------------------------|
| Area objects                        | FaceAlpha                  |
| Bar series objects                  | FaceAlpha                  |
| Scatter series objects              | MarkerFaceAlpha            |
| Histogram and histogram2 objects    | FaceAlpha                  |
| Image objects                       | AlphaData                  |
| Chart and primitive surface objects | FaceAlpha                  |
| Patch objects                       | FaceAlpha                  |

**alphadata — Option to vary transparency across object**

'x' | 'y' | 'z' | 'color' | 'rand' | matrix

Option to vary the transparency across the object, specified as one of the values in this table. The table columns indicate how each option affects the different types of objects, depending on what objects are contained in the axes.

| Option | Chart or Primitive Surface Objects                                                                        | Patch Objects                                                                                                       | Image Objects |
|--------|-----------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------|---------------|
| 'x'    | Set the AlphaData property to be the same as the XData property and set the FaceAlpha property to 'flat'. | Set the FaceVertexAlphaData property to be the same as the XData property and set the FaceAlpha property to 'flat'. | No effect.    |

| Option  | Chart or Primitive Surface Objects                                                                                                     | Patch Objects                                                                                                                                    | Image Objects                                                                                      |
|---------|----------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------|
| 'y'     | Set the AlphaData property to be the same as the YData property and set the FaceAlpha property to 'flat'.                              | Set the FaceVertexAlphaData property to be the same as the YData property and set the FaceAlpha property to 'flat'.                              | No effect.                                                                                         |
| 'z'     | Set the AlphaData property to be the same as the ZData property and set the FaceAlpha property to 'flat'.                              | Set the FaceVertexAlphaData property to be the same as the ZData property and set the FaceAlpha property to 'flat'.                              | No effect.                                                                                         |
| 'color' | Set the AlphaData property to be the same as the CData property and set the FaceAlpha property to 'flat'.                              | Set the FaceVertexAlphaData property to be the same as the FaceVertexCData property and set the FaceAlpha property to 'flat'.                    | Set the AlphaData data property to be the same as the CData property.                              |
| 'rand'  | Set the AlphaData property to a matrix of random numbers the same size as the ZData property and set the FaceAlpha property to 'flat'. | Set the FaceVertexAlphaData property to a matrix of random numbers the same size as the ZData property and set the FaceAlpha property to 'flat'. | Set the AlphaData data property to a matrix of random numbers the same size as the CData property. |

| Option                                                                                     | Chart or Primitive Surface Objects                                                                                                                        | Patch Objects                                                                                                                                                               | Image Objects                                                                                                       |
|--------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------|
| Matrix<br>Use the function form of the command, for example, <code>alpha([.1 .2; .3</code> | Set the AlphaData property to the matrix and set the FaceAlpha property to 'flat'. The matrix must be the same size as the CData property of the surface. | Set the FaceVertexAlphaData property to the matrix and set the FaceAlpha property to 'flat'. The matrix must be the same size as the FaceVertexCData property of the patch. | Set the AlphaData data property to the matrix. The matrix must be the same size as the CData property of the image. |

**faceAlpha — Option for flat or interpolated face transparency**

'flat' | 'interp' | 'texture'

Option for flat or interpolated face transparency, specified as one of the values in this table. The table columns indicate how each option affects the different types of objects, depending on what objects are contained in the axes.

| Option    | Chart or Primitive Surface Objects                                                                                                                                   | Patch Objects                                                                                                                                                          |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'flat'    | Set the FaceAlpha property to 'flat'. The AlphaData property must be an array the same size as the CData property. The FaceColor property must be set to 'flat'.     | Set the FaceAlpha property to 'flat'. The FaceVertexAlphaData property must be a column vector with length equal to the number of faces in the Faces property.         |
| 'interp'  | Set the FaceAlpha property to 'interp'. The AlphaData property must be an array the same size as the CData property. The FaceColor property must be set to 'interp'. | Set the FaceAlpha property to 'interp'. The FaceVertexAlphaData property must be a column vector with length equal to the number of vertices in the Vertices property. |
| 'texture' | Set the FaceAlpha property to 'texturemap'.                                                                                                                          | No effect.                                                                                                                                                             |

| Option | Chart or Primitive Surface Objects                                             | Patch Objects |
|--------|--------------------------------------------------------------------------------|---------------|
|        | The <code>FaceColor</code> property must be set to <code>'texturemap'</code> . |               |

### **alphaDataMapping** — Interpretation of alpha data values

`'none'` | `'direct'` | `'scaled'`

Interpretation of alpha data values, specified as `'none'`, `'direct'`, or `'scaled'`. This option sets the `AlphaDataMapping` property for image, patch, and surface objects in the axes.

- `'none'` — Interpret alpha data values as transparency values. A value of 0 or less is completely transparent. A value of 1 or greater is opaque. Values between 0 and 1 are semitransparent.
- `'direct'` — Interpret the values as indices into the figure's `alphamap`. Fix values with a decimal portion to the nearest lower integer. The `Alphamap` property of the figure contains the `alphamap`.
- `'scaled'` — Transform the alpha data values to span the portion of the figure's `alphamap` indicated by the `ALim` property of the axes. Linearly map the data values to alpha values.

### **obj** — Graphics objects that support transparency

scalar | vector

Graphics objects that support transparency, specified as a scalar or vector. Use this option if you want to control which objects `alpha` affects. Otherwise, `alpha` affects all objects in the axes that support transparency.

Specify one or more of these types of objects:

- Area object
- Bar series object
- Scatter series object
- Histogram or `histogram2` object
- Image object
- Patch object

- Chart or primitive surface object

---

**Note:** Not all objects support the `alphadata`, `facealpha`, and `alphadatamapping` input arguments. See the syntax descriptions for a list of objects that each option supports.

---

# alphamap

Specify figure alphamap (transparency)

## Syntax

```
alphamap(alpha_map)
alphamap('parameter')
alphamap('parameter',length)
alphamap('parameter',delta)
alphamap(figure_handle,...)
alphamap(axes_handle,...)
alpha_map = alphamap
alpha_map = alphamap(figure_handle)
alpha_map = alphamap(axes_handle)
alpha_map = alphamap('parameter')
```

## Description

`alphamap(alpha_map)` sets the `AlphaMap` of the current figure to the specified `m`-by-1 array of alpha values, `alpha_map`.

`alphamap('parameter')` creates a new alphamap or modifies the current alphamap. You can specify the following parameters:

- `'default'` — Set the `AlphaMap` property to the figure's default alphamap.
- `'rampup'` — Create a linear alphamap with increasing opacity (default `length` equals the current alphamap length).
- `'rampdown'` — Create a linear alphamap with decreasing opacity (default `length` equals the current alphamap length).
- `'vup'` — Create an alphamap that is opaque in the center and becomes more transparent linearly towards the beginning and end (default `length` equals the current alphamap length).
- `'vdown'` — Create an alphamap that is transparent in the center and becomes more opaque linearly towards the beginning and end (default `length` equals the current alphamap length).

- `'increase'` — Modify the alphamap making it more opaque (default `delta` is `.1`, added to the current values).
- `'decrease'` — Modify the alphamap making it more transparent (default `delta` is `.1`, subtracted from the current values).
- `'spin'` — Rotate the current alphamap (default `delta` is `1`; `delta` must be an integer).

`alphamap('parameter', length)` creates a new alphamap with the length specified by the integer `length` (used with parameters `'rampup'`, `'rampdown'`, `'vup'`, `'vdown'`).

`alphamap('parameter', delta)` modifies the existing alphamap using the value specified by the integer `delta` (used with parameters `'increase'`, `'decrease'`, `'spin'`).

`alphamap(figure_handle, ...)` performs the operation on the alphamap of the figure identified by `figure_handle`.

`alphamap(axes_handle, ...)` performs the operation on the alphamap of the axes identified by `axes_handle`.

`alpha_map = alphamap` returns the current alphamap.

`alpha_map = alphamap(figure_handle)` returns the current alphamap from the figure identified by `figure_handle`.

`alpha_map = alphamap(axes_handle)` returns the current alphamap from the axes identified by `axes_handle`.

`alpha_map = alphamap('parameter')` returns the alphamap modified by the `parameter`, but does not set the `AlphaMap` property.

## Examples

### Change Alphamap for Surface Plot

Create a surface plot and change the alphamap.

```
[x,y] = meshgrid([-2:.2:2]);
```

```
z = x.*exp(-x.^2-y.^2);
```

Plot the data, using the gradient of z as the alphamap.

```
figure
surf(x,y,z+.001,'FaceAlpha','flat',...
 'AlphaDataMapping','scaled',...
 'AlphaData',gradient(z),...
 'FaceColor','blue')
```

Change the alphamap to be opaque at the middle and transparent towards the ends.

```
alphamap('vup')
```

**See Also**

**Introduced before R2006a**

# alphaShape

Polygons and polyhedra from points in 2-D and 3-D

## Syntax

```
shp = alphaShape(x,y)
shp = alphaShape(x,y,z)
shp = alphaShape(P)
shp = alphaShape(____,a)
shp = alphaShape(____,Name,Value)
```

## Description

`shp = alphaShape(x,y)` creates a 2-D alpha shape of the points  $(x,y)$  using the default alpha radius. The default alpha radius produces the tightest fitting alpha shape, which encloses all of the points.

`shp = alphaShape(x,y,z)` creates a 3-D alpha shape of the points  $(x,y,z)$  using the default alpha radius.

`shp = alphaShape(P)` specifies points  $(x,y)$  or  $(x,y,z)$  in the columns of matrix `P`.

`shp = alphaShape( ____,a)` creates an alpha shape with alpha radius `a` using any of the arguments in the previous syntaxes.

`shp = alphaShape( ____,Name,Value)` uses additional options specified by one or more `Name,Value` pair arguments. For example, you can suppress interior holes or voids using `'HoleThreshold'`.

## Examples

### Alpha Shape from 2-D Point Cloud

Create and plot a set of 2-D points.

```
th = (pi/12:pi/12:2*pi)';
x1 = [reshape(cos(th)*(1:5), numel(cos(th))*(1:5)),1); 0];
y1 = [reshape(sin(th)*(1:5), numel(sin(th))*(1:5)),1); 0];
x = [x1; x1+15];
y = [y1; y1];
plot(x,y, '.')
axis equal
```

Compute an alpha shape for the point set using the default alpha radius.

```
shp = alphaShape(x,y);
plot(shp)
```

Check the value of the default alpha radius.

```
shp.Alpha
```

```
ans =
```

```
0.7752
```

The default alpha radius results in an alpha shape with a jagged boundary. To better capture the boundary of the point set, try a larger alpha radius.

Compute an alpha shape using an alpha value of 2.5.

```
shp.Alpha = 2.5;
plot(shp)
```

## Alpha Shape from 3-D Point Cloud

Create and plot a set of 3-D points.

```
[x1, y1, z1] = sphere(24);
x1 = x1(:);
y1 = y1(:);
z1 = z1(:);
x2 = x1+5;
P = [x1 y1 z1; x2 y1 z1];
```

```
P = unique(P,'rows');
plot3(P(:,1),P(:,2),P(:,3),'.')
axis equal
grid on
```

Compute a 3-D alpha shape using an alpha radius of 1.

```
shp = alphaShape(P(:,1),P(:,2),P(:,3),1);
plot(shp)
axis equal
```

## Fill Holes in 2-D Alpha Shape

Create and plot a 2-D set of points.

```
th = (pi/12:pi/12:2*pi)';
x1 = [reshape(cos(th)*(2:5), numel(cos(th)*(2:5)),1)];;
y1 = [reshape(sin(th)*(2:5), numel(sin(th)*(2:5)),1)];;
x = [x1; x1+15;];
y = [y1; y1];
plot(x,y, '.')
axis equal
```

Compute an alpha shape for the point set using an alpha radius of 1.

```
shp = alphaShape(x,y,1);
plot(shp)
```

An alpha radius of 1 results in an alpha shape with two regions containing holes. To suppress the small holes in the alpha shape, you can specify a `HoleThreshold` by estimating the area of the largest hole to fill. To fill all holes in the shape, you can assign an arbitrarily large value to `HoleThreshold`.

Create a new alpha shape that suppresses the holes by specifying a `HoleThreshold` of 15.

```
shp = alphaShape(x,y,1, 'HoleThreshold',15);
plot(shp)
```

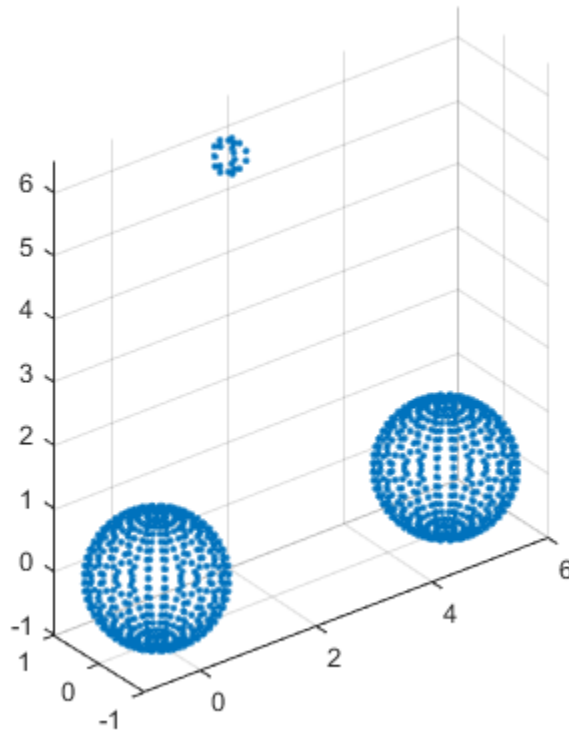

### Discard Small Regions of 3-D Alpha Shape

Create and plot a set of 3-D points.

```
[x1, y1, z1] = sphere(24);
x1 = x1(:);
y1 = y1(:);
z1 = z1(:);
x2 = x1+5;
[x3, y3, z3] = sphere(5);
x3 = x3(:)+5;
y3 = y3(:);
z3 = z3(:)+25;
P = [x1 y1 z1; x2 y1 z1; 0.25*x3 0.25*y3 0.25*z3];
```

```
P = unique(P,'rows');
plot3(P(:,1),P(:,2),P(:,3),'.')
axis equal
grid on
```

Compute an alpha shape for the point set using an alpha radius of 1.

```
shp = alphaShape(P,1);
plot(shp)
axis equal
```

In this case, the alpha shape produces a small region above the two equal-sized spheres. To suppress this region, you can specify a `RegionThreshold` by estimating its volume.

Specify a `RegionThreshold` of 2. The resulting shape contains only the two larger regions.

```
shp.RegionThreshold = 2;
plot(shp)
axis equal
```

### Modify Points of 2-D Alpha Shape

Create and plot a 2-D set of points.

```
th = (pi/12:pi/12:2*pi)';
x1 = [reshape(cos(th)*(1:5), numel(cos(th))*(1:5)),1); 0];
y1 = [reshape(sin(th)*(1:5), numel(sin(th))*(1:5)),1); 0];
x = [x1; x1+15;];
y = [y1; y1];
plot(x,y, '.')
axis equal
```

Compute an alpha shape for the point set using an alpha radius of 1. The resulting alpha shape has two regions.

```
shp = alphaShape(x,y,1);
plot(shp)
```

Now add a third region to the alpha shape by adding new points directly to the `shp.Points` matrix.

```
x3 = x1+8;
y3 = y1+10;
shp.Points(end+1,:) = [x3 y3];
plot(shp)
```

## Input Arguments

**x** — **x-coordinates of points**  
column vector

x-coordinates of points, specified as a column vector.

Data Types: double

**y** — **y-coordinates of points**  
column vector

y-coordinates of points, specified as a column vector.

Data Types: double

**z — z-coordinates of points**

column vector

z-coordinates of points, specified as a column vector.

Data Types: double

**P — Point coordinates**

matrix with two columns | matrix with three columns

Point coordinates, specified as a matrix with two columns (for a 2-D alpha shape) or a matrix with three columns (for a 3-D alpha shape).

- For 2-D, the columns of **P** represent *x* and *y* coordinates, respectively.
- For 3-D, the columns of **P** represent *x*, *y*, and *z* coordinates, respectively.

Data Types: double

**a — Alpha radius**

nonnegative scalar

Alpha radius, specified as a nonnegative scalar. The default alpha radius is `a = criticalAlpha(shp, 'all-points')`, which is the smallest alpha radius that produces an alpha shape that encloses all points.

Specify `a = criticalAlpha(shp, 'one-region')` to use the smallest alpha radius that produces an alpha shape with only one region.

The extreme values of **a** are

- `Inf`, where `alphaShape` produces the convex hull.
- `0`, where `alphaShape` produces an empty alpha shape.

Data Types: double

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `shp = alphaShape(..., 'HoleThreshold', 10)`

**'HoleThreshold'** — Maximum area or volume of interior holes or voids to fill in  
0 (default) | finite, nonnegative scalar

Maximum area or volume of interior holes or voids to fill in, specified as a finite, nonnegative scalar.

- For 2-D, `HoleThreshold` specifies the maximum area of interior holes to fill in.
- For 3-D, `HoleThreshold` specifies the maximum volume of interior voids to fill in. Holes extending completely through the alpha shape cannot be filled in.

When you specify both a `'HoleThreshold'` and a `'RegionThreshold'`, the application of the thresholds is order dependent. `alphaShape` fills in holes before suppressing regions.

Data Types: `double`

**'RegionThreshold'** — Maximum area or volume of regions to suppress  
0 (default) | finite, nonnegative scalar

Maximum area (2-D) or volume (3-D) of regions to suppress, specified as a finite, nonnegative scalar.

When you specify a `'HoleThreshold'` and a `'RegionThreshold'`, the application of the thresholds is order dependent. `alphaShape` fills in holes before suppressing regions.

Data Types: `double`

## Output Arguments

**shp** — 2-D or 3-D alpha shape  
alphaShape object

2-D or 3-D alpha shape. For more information, see [Using alphaShape Objects](#).

The `alphaShape` function returns regularized alpha shapes:

- In 2-D, `shp` represents a polygon. The polygon has no isolated points or edges, nor does it have dangling edges.
- In 3-D, `shp` represents a polyhedron. The polyhedron has the previously stated polygon traits, but it additionally does not have isolated faces or dangling faces.

**Introduced in R2014b**

# alphaSpectrum

Alpha values giving distinct alpha shapes

## Syntax

```
a = alphaSpectrum(shp)
```

## Description

`a = alphaSpectrum(shp)` returns the values of the alpha radius that produce distinct alpha shapes. `a` is in descending sorted order. Each element in `a` represents a value of the alpha radius that results in a distinct shape. The length of `a` is equal to the number of unique shapes. Values of alpha that lie between the values in `a` do not produce unique alpha shapes.

## Examples

### Find Alpha Spectrum for 2-D Point Cloud

Create and plot a set of 2-D points.

```
th = (pi/12:pi/12:2*pi)';
x1 = [reshape(cos(th)*(1:5), numel(cos(th)*(1:5)),1); 0];
y1 = [reshape(sin(th)*(1:5), numel(sin(th)*(1:5)),1); 0];
x = [x1; x1+15;];
y = [y1; y1];
plot(x,y, '. ')
axis equal
```

Create an alpha shape for the point cloud using the default alpha radius.

```
shp = alphaShape(x,y);
```

Find the spectrum of critical alpha values that produces unique alpha shapes for the point cloud.

```
alphaspec = alphaSpectrum(shp);
```

Plot the alpha shape corresponding to the smallest alpha value in the spectrum.

```
shp.Alpha = alphaspec(length(alphaspec));
plot(shp)
```

Compare this alpha shape to the one produced by the next smallest critical alpha value. The alpha shapes are unique.

```
shp.Alpha = alphaspec(length(alphaspec) - 1);
plot(shp)
```

## Input Arguments

**shp** — Alpha shape  
alphaShape object

Alpha shape, specified as an alphaShape object. For more information, see alphaShape.

Example: `shp = alphaShape(x,y)` creates a 2-D alphaShape object from the (x,y) point coordinates.

## Output Arguments

### **a** — Alpha values for distinct alpha shapes

column vector

Alpha values for distinct alpha shapes, returned as a column vector in descending sorted order.

## alphaTriangulation

Triangulation that fills alpha shape

### Syntax

```
tri = alphaTriangulation(shp)
tri = alphaTriangulation(shp,RegionID)

[tri,P] = alphaTriangulation(___)
```

### Description

`tri = alphaTriangulation(shp)` returns a triangulation that defines the domain of the alpha shape. Each row in `tri` specifies a triangle or tetrahedron defined by vertex IDs (the row numbers of the `shp.Points` matrix).

`tri = alphaTriangulation(shp,RegionID)` returns a triangulation for a region of the alpha shape. `RegionID` is the ID for the region and  $1 \leq \text{RegionID} \leq \text{numRegions}(\text{shp})$ .

`[tri,P] = alphaTriangulation( ___ )` also returns a matrix of vertex coordinates, `P`, using any of the previous syntaxes.

### Examples

#### Compute Triangulation for 3-D Point Cloud

Create a set of 3-D points.

```
[x1, y1, z1] = sphere(24);
x1 = x1(:);
y1 = y1(:);
z1 = z1(:);
x2 = x1+5;
P = [x1 y1 z1; x2 y1 z1];
P = unique(P, 'rows');
```

Create and plot an alpha shape for the point cloud using an alpha radius of 1.

```
shp = alphaShape(P,1);
plot(shp)
```

Use `alphaTriangulation` to recover the triangulation that defines the domain of the alpha shape.

```
tri = alphaTriangulation(shp);
```

Find the total number of tetrahedra that make up the alpha shape.

```
numtetrahedra = size(tri,1)
```

```
numtetrahedra =
 3729
```

## Input Arguments

**shp** — Alpha shape  
alphaShape object

Alpha shape, specified as an alphaShape object. For more information, see alphaShape.

Example: `shp = alphaShape(x,y)` creates a 2-D alphaShape object from the (x,y) point coordinates.

**RegionID** — ID number for a region in the alpha shape  
positive integer scalar

ID number for region in alpha shape, specified as a positive integer scalar between 1 and `numRegions(shp)`.

An alpha shape can contain several smaller regions, depending on the point set and parameters. Each of these smaller regions is assigned a unique **RegionID**, which numbers the regions from the largest area or volume to the smallest. For example, consider a 3-D alpha shape with two regions. The region with the largest volume has a **RegionID** of 1, and the smaller region has a **RegionID** of 2.

Example: `shp.RegionThreshold = area(shp,numRegions(shp)-2);` suppresses the two smallest regions in 2-D alpha shape `shp`.

Data Types: double

## Output Arguments

**tri** — Triangulation  
matrix

Triangulation, returned as a matrix. `tri` is of size `mtri`-by-`nv`, where `mtri` is the number of triangles or tetrahedra in the alpha shape and `nv` is the number of vertices. The value of `nv` is 3 for 2-D alpha shapes and 4 for 3-D alpha shapes.

**P — Vertex coordinates**`matrix`

Vertex coordinates, returned as a matrix. `P` is of size `N-by-dim`, where `N` is the number of points in the alpha shape and `dim` is either `2` or `3` (for either a 2-D or 3-D alpha shape).

## area

Area of 2-D alpha shape

## Syntax

```
A = area(shp)
A = area(shp,RegionID)
```

## Description

`A = area(shp)` returns the area of 2-D alpha shape `shp`.

`A = area(shp,RegionID)` returns the area of a region of the alpha shape. `RegionID` is the ID for the region and  $1 \leq \text{RegionID} \leq \text{numRegions}(\text{shp})$ .

## Examples

### Find Area of 2-D Alpha Shape

Create a set of 2-D points.

```
th = (pi/12:pi/12:2*pi)';
x1 = [reshape(cos(th)*(1:5), numel(cos(th)*(1:5)),1); 0];
y1 = [reshape(sin(th)*(1:5), numel(sin(th)*(1:5)),1); 0];
x = [x1; x1+15;];
y = [y1; y1];
```

Create and plot an alpha shape using an alpha radius of 2.5.

```
shp = alphaShape(x,y,2.5);
plot(shp)
```

Compute the area of the alpha shape.

```
totalarea = area(shp)
```

```
totalarea =
```

```
155.2914
```

Compute the areas of each of the two regions separately.

```
regionareas = area(shp, 1:numRegions(shp))
```

```
regionareas =
 77.6457 77.6457
```

## Input Arguments

**shp** — Alpha shape  
alphaShape object

Alpha shape, specified as an alphaShape object. For more information, see alphaShape.

Example: `shp = alphaShape(x,y)` creates a 2-D alphaShape object from the (x,y) point coordinates.

**RegionID** — ID number for a region in the alpha shape  
positive integer scalar

ID number for region in alpha shape, specified as a positive integer scalar between 1 and `numRegions(shp)`.

An alpha shape can contain several smaller regions, depending on the point set and parameters. Each of these smaller regions is assigned a unique **RegionID**, which numbers the regions from the largest area or volume to the smallest. For example, consider a 3-D alpha shape with two regions. The region with the largest volume has a **RegionID** of 1, and the smaller region has a **RegionID** of 2.

Example: `shp.RegionThreshold = area(shp,numRegions(shp)-2)`; suppresses the two smallest regions in 2-D alpha shape `shp`.

Data Types: double

## boundaryFacets

Boundary facets of alpha shape

### Syntax

```
bf = boundaryFacets(shp)
bf = boundaryFacets(shp,RegionID)

[bf,P] = boundaryFacets(___)
```

### Description

`bf = boundaryFacets(shp)` returns a matrix representing the facets that make up the boundary of the alpha shape. The facets represent edge segments in 2-D and triangles in 3-D. The vertices of the facets index into the `shp.Points` matrix.

`bf = boundaryFacets(shp,RegionID)` returns the boundary facets for a region of the alpha shape. `RegionID` is the ID for the region and  $1 \leq \text{RegionID} \leq \text{numRegions}(\text{shp})$ .

`[bf,P] = boundaryFacets( ___ )` also returns a matrix of vertex coordinates, `P`, using any of the previous syntaxes.

### Examples

#### Find Boundary of 3-D Alpha Shape

Create a set of 3-D points.

```
[x1, y1, z1] = sphere(24);
x1 = x1(:);
y1 = y1(:);
z1 = z1(:);
x2 = x1+5;
```

```
P = [x1 y1 z1; x2 y1 z1];
P = unique(P, 'rows');
```

Create and plot an alpha shape using an alpha radius of 1.5.

```
shp = alphaShape(P,1.5);
plot(shp)
axis equal
```

Compute and plot only the boundary of the alpha shape.

```
[tri, xyz] = boundaryFacets(shp);
trisurf(tri, xyz(:,1), xyz(:,2), xyz(:,3), ...
 'FaceColor', 'cyan', 'FaceAlpha', 0.3)
```

axis equal

## Input Arguments

**shp** — Alpha shape  
alphaShape object

Alpha shape, specified as an alphaShape object. For more information, see alphaShape.

Example: `shp = alphaShape(x,y)` creates a 2-D alphaShape object from the (x,y) point coordinates.

**RegionID — ID number for a region in the alpha shape**

positive integer scalar

ID number for region in alpha shape, specified as a positive integer scalar between 1 and `numRegions(shp)`.

An alpha shape can contain several smaller regions, depending on the point set and parameters. Each of these smaller regions is assigned a unique **RegionID**, which numbers the regions from the largest area or volume to the smallest. For example, consider a 3-D alpha shape with two regions. The region with the largest volume has a **RegionID** of 1, and the smaller region has a **RegionID** of 2.

Example: `shp.RegionThreshold = area(shp,numRegions(shp)-2)`; suppresses the two smallest regions in 2-D alpha shape `shp`.

Data Types: `double`

## Output Arguments

**bf — Boundary facets**

matrix

Boundary facets, returned as a matrix. **bf** is of size `m-by-n`, where `m` is the number of boundary facets and `n` is the number of vertices per facet.

**P — Vertex coordinates**

matrix

Vertex coordinates, returned as a matrix. **P** is of size `N-by-dim`, where `N` is the number of points on the boundary of the the alpha shape and `dim` is either 2 or 3 (for either a 2-D or 3-D alpha shape).

## criticalAlpha

Alpha radius defining a critical transition in the shape

### Syntax

```
a = criticalAlpha(shp,type)
```

### Description

`a = criticalAlpha(shp,type)` returns the critical alpha radius that produces a notable transition in the alpha shape. Specifying `type` as 'all-points' returns the smallest alpha radius producing an alpha shape that encloses all points. Specifying `type` as 'one-region' returns the smallest alpha radius producing an alpha shape that encloses all points *and* has only one region.

### Examples

#### Find Critical Alpha Values of 2-D Point Cloud

Create and plot a set of 2-D points.

```
th = (pi/12:pi/12:2*pi)';
x1 = [reshape(cos(th)*(1:5), numel(cos(th)*(1:5)),1); 0];
y1 = [reshape(sin(th)*(1:5), numel(sin(th)*(1:5)),1); 0];
x = [x1; x1+15;];
y = [y1; y1];
plot(x,y, '.')
axis equal
```

Create an alpha shape using the default alpha radius.

```
shp = alphaShape(x,y);
```

Compute the smallest alpha radius that produces an alpha shape enclosing all of the points and plot the corresponding alpha shape.

```
pc = criticalAlpha(shp, 'all-points');
shp.Alpha = pc;
plot(shp)
```

Compute the smallest alpha radius that produces an alpha shape enclosing all of the points and having only one region.

```
shp = alphaShape(x,y);
pc = criticalAlpha(shp, 'one-region');
shp.Alpha = pc;
plot(shp)
```

## Input Arguments

**shp** — Alpha shape  
alphaShape object

Alpha shape, specified as an alphaShape object. For more information, see alphaShape.

Example: `shp = alphaShape(x,y)` creates a 2-D alphaShape object from the  $(x,y)$  point coordinates.

## **type** — Type of critical transition

'all-points' | 'one-region'

Type of critical transition, specified as either 'all-points' or 'one-region'.

- 'all-points' corresponds to the smallest alpha radius producing an alpha shape that encloses all points.
- 'one-region' corresponds to the smallest alpha radius producing an alpha shape that encloses all points *and* has only one region.

Data Types: char

## **Output Arguments**

### **a** — Critical alpha radius

scalar

Critical alpha radius, returned as a scalar. **a** is the value of the alpha radius that produces an alpha shape, which either encloses all points (if **type** is 'all-points'), or encloses all points within a single region (if **type** is 'one-region').

After using `criticalAlpha` to find **a**, you can make the alpha radius of **shp** equal to **a** by typing `shp.Alpha = a`.

## **More About**

## **See Also**

alphaShape | alphaSpectrum

**Introduced in R2014b**

# inShape

Determine if point is inside alpha shape

## Syntax

```
tf = inShape(shp,qx,qy)
tf = inShape(shp,qx,qy,qz)
tf = inShape(shp,QP)
tf = inShape(____,RegionID)
[tf,ID] = inShape(____)
```

## Description

`tf = inShape(shp,qx,qy)` returns logical 1 (`true`) values for the 2-D query points  $(qx,qy)$  that are within 2-D alpha shape `shp`. Otherwise, `inShape` returns values of logical 0 (`false`). The `qx` and `qy` arguments are numeric arrays whose corresponding elements specify the  $(x,y)$  query point coordinates.

`tf = inShape(shp,qx,qy,qz)` tests whether the 3-D query points  $(qx,qy,qz)$  are within 3-D alpha shape `shp`.

`tf = inShape(shp,QP)` specifies the 2-D or 3-D query point coordinates in a matrix with 2 or 3 columns.

`tf = inShape( ____,RegionID)` tests whether the query points are within a specific region of the alpha shape, using any of the previous syntaxes. `RegionID` is the ID for the region and  $1 \leq \text{RegionID} \leq \text{numRegions}(\text{shp})$ .

`[tf,ID] = inShape( ____)` also returns the IDs for the regions in the alpha shape that contain the query points. `ID` is `NaN` for query points that are not in the alpha shape.

## Examples

### Query Points Inside and Outside of 2-D Alpha Shape

Create a set of 2-D points.

```
th = (pi/12:pi/12:2*pi)';
x1 = [reshape(cos(th)*(1:5), numel(cos(th))*(1:5)),1); 0];
y1 = [reshape(sin(th)*(1:5), numel(sin(th))*(1:5)),1); 0];
x = [x1; x1+15;];
y = [y1; y1];
```

Create and plot an alpha shape using an alpha radius of 2.5.

```
shp = alphaShape(x,y,2.5);
plot(shp)
```

Create a Cartesian grid of query points near the alpha shape.

```
[qx, qy] = meshgrid(-10:2:25, -10:2:10);
```

Check if the query points are inside of the alpha shape, and if so, plot them red. Plot the query points that lie outside of the alpha shape in blue.

```
in = inShape(shp,qx,qy);
plot(shp)
hold on
plot(qx(in),qy(in),'r.')
plot(qx(~in),qy(~in),'b.')
```

## Input Arguments

**shp** — Alpha shape  
alphaShape object

Alpha shape, specified as an `alphaShape` object. For more information, see `alphaShape`.

Example: `shp = alphaShape(x,y)` creates a 2-D `alphaShape` object from the `(x,y)` point coordinates.

**qx — Query point x-coordinates**

numeric array

Query point x-coordinates, specified as a numeric array.

Data Types: `double`

**qy — Query point y-coordinates**

numeric array

Query point y-coordinates, specified as a numeric array.

Data Types: `double`

**qz — Query point z-coordinates**

numeric array

Query point z-coordinates, specified as a numeric array.

Data Types: `double`

**QP — Query point coordinates**

matrix with two columns | matrix with three columns

Query point coordinates, specified as a matrix with two columns (2-D) or a matrix with three columns (3-D).

- For 2-D, the columns of `QP` represent `x` and `y` coordinates, respectively.
- For 3-D, the columns of `QP` represent `x`, `y`, and `z` coordinates, respectively.

Data Types: `double`

**RegionID — ID number for a region in the alpha shape**

positive integer scalar

ID number for region in alpha shape, specified as a positive integer scalar between 1 and `numRegions(shp)`.

An alpha shape can contain several smaller regions, depending on the point set and parameters. Each of these smaller regions is assigned a unique **RegionID**, which numbers the regions from the largest area or volume to the smallest. For example, consider a 3-D alpha shape with two regions. The region with the largest volume has a **RegionID** of 1, and the smaller region has a **RegionID** of 2.

Example: `shp.RegionThreshold = area(shp,numRegions(shp)-2)`; suppresses the two smallest regions in 2-D alpha shape `shp`.

Data Types: `double`

## Output Arguments

### **tf** — Containment status of query points

logical array

Status of the query points, returned as a logical array. The size of `tf` is equal to the size of the inputs that specify the query points (`qx`, `qy`, `qz`, or `QP`).

`inShape` returns logical 1 (`true`) values for points that are within the alpha shape or exactly on the boundary.

### **ID** — IDs of the regions containing the query points

numeric array

IDs of regions containing query points, returned as a numeric array. `ID` is the same size as `tf`.

## More About

- Using alphaShape Objects

### See Also

`alphaShape` | `plot`

## nearestNeighbor

Determine nearest alpha shape boundary point

### Syntax

```
I = nearestNeighbor(shp,qx,qy)
I = nearestNeighbor(shp,qx,qy,qz)
I = nearestNeighbor(shp,QP)
```

```
I = nearestNeighbor(____,RegionID)
```

```
[I,D] = nearestNeighbor(____)
```

### Description

`I = nearestNeighbor(shp,qx,qy)`, for a 2-D alpha shape `shp`, returns the indices of points on the boundary of `shp` closest to the query points. `I` is the array of nearest neighbor indices where each index corresponds to the row index in `shp.Points`. The `qx` and `qy` query coordinates must be the same size.

`I = nearestNeighbor(shp,qx,qy,qz)`, for a 3-D alpha shape, returns the indices of the boundary points of `shp` closest to `(qx,qy,qz)` and corresponds to the row indices in `shp.Points`. The `qx`, `qy`, and `qz` query coordinates must be the same size.

`I = nearestNeighbor(shp,QP)` specifies the query points as a matrix `QP`. For a 2-D alpha shape, `QP` is a matrix with two columns representing the `qx` and `qy` coordinates. For a 3-D alpha shape, `QP` has three columns representing the `qx`, `qy`, and `qz` coordinates.

`I = nearestNeighbor( ____,RegionID)` returns the index of the nearest point that lies on the boundary of the region specified by `RegionID`, where  $1 \leq \text{RegionID} \leq \text{numRegions}(\text{shp})$ . You can include any of the input arguments in the previous syntaxes.

`[I,D] = nearestNeighbor( ____)` additionally returns the Euclidean distance between the query point and its nearest neighbor. `D` has the same size as `I`.

## Examples

### Nearest Alpha Shape Boundary Point

Create a set of 2-D points.

```
th = (pi/12:pi/12:2*pi)';
x1 = [reshape(cos(th)*(1:5), numel(cos(th)*(1:5)),1); 0];
y1 = [reshape(sin(th)*(1:5), numel(sin(th)*(1:5)),1); 0];
x = [x1; x1+15];
y = [y1; y1];
```

Create and plot an alpha shape with alpha radius equal to 1.

```
shp = alphaShape(x,y,1);
plot(shp)
hold on
```

Compute the nearest `shp` boundary point to the query point `QP`. Plot the query point in blue and the nearest boundary neighbor in red.

```
QP = [6 3];
plot(QP(1),QP(2), 'b.', 'MarkerSize', 10)
hold on
I = nearestNeighbor(shp, QP);
plot(shp.Points(I,1),shp.Points(I,2), 'r.', 'MarkerSize', 10)
```

## Input Arguments

**shp** — Alpha shape  
alphaShape object

Alpha shape, specified as an alphaShape object. For more information, see alphaShape.

Example: `shp = alphaShape(x,y)` creates a 2-D alphaShape object from the (x,y) point coordinates.

**qx — Query point x-coordinates**

numeric array

Query point x-coordinates, specified as a numeric array.

Data Types: double

**qy — Query point y-coordinates**

numeric array

Query point y-coordinates, specified as a numeric array.

Data Types: double

**qz — Query point z-coordinates**

numeric array

Query point z-coordinates, specified as a numeric array.

Data Types: double

**QP — Query point coordinates**

two-column matrix | three-column matrix

Query point coordinates, specified as a two-column matrix or a three-column matrix.

- For 2-D, the columns of P represent qx and qy coordinates, respectively.
- For 3-D, the columns of P represent qx, qy, and qz coordinates, respectively.

Data Types: double

**RegionID — ID number for a region in the alpha shape**

positive integer scalar

ID number for region in alpha shape, specified as a positive integer scalar between 1 and numRegions(shp).

An alpha shape can contain several smaller regions, depending on the point set and parameters. Each of these smaller regions is assigned a unique RegionID, which numbers the regions from the largest area or volume to the smallest. For example, consider a 3-D alpha shape with two regions. The region with the largest volume has a RegionID of 1, and the smaller region has a RegionID of 2.

Example: shp.RegionThreshold = area(shp,numRegions(shp)-2); suppresses the two smallest regions in 2-D alpha shape shp.

Data Types: double

## Output Arguments

### **I** — Nearest neighbor indices

integer-valued array

Nearest neighbor indices, returned as an integer-valued array. The indices correspond to the row index of `shp.Points` and indicate the points on the boundary of `shp` that are closest to the given query points.

### **D** — Distance from query points to nearest neighbors

numeric array

Distance from query points to nearest neighbors, returned as a numeric array. `D` is the 2-D or 3-D Euclidean distance and is the same size as `I`.

## More About

- Using alphaShape Objects

### See Also

alphaShape

Introduced in R2015a

## numRegions

Number of regions in alpha shape

### Syntax

```
N = numRegions(shp)
```

### Description

`N = numRegions(shp)` returns the number of distinct regions that make up the alpha shape. For an alpha radius of `Inf`, the alpha shape is the convex hull, and the number of regions is one. As the value of the alpha radius decreases the shape can break into separate regions, depending on the point set.

### Examples

#### Find Number of Regions in 2-D Alpha Shape

Create and plot a set of 2-D points.

```
th = (pi/12:pi/12:2*pi)';
x1 = [reshape(cos(th)*(1:5), numel(cos(th)*(1:5)),1); 0];
y1 = [reshape(sin(th)*(1:5), numel(sin(th)*(1:5)),1); 0];
x = [x1; x1+15;];
y = [y1; y1];
plot(x,y, '. ')
axis equal
```

Create an alpha shape using an alpha radius of 7 and query the number of distinct regions in the shape.

```
shp = alphaShape(x,y,7);
nregions = numRegions(shp)
```

```
nregions =
```

```
1
```

Use a smaller alpha radius of 2.5 to better capture the boundary and then retrieve the new number of distinct regions.

```
shp.Alpha = 2.5;
nregions = numRegions(shp)
```

```
nregions =
```

```
2
```

Plot the alpha shape to check the boundary quality.

```
plot(shp)
```

## Input Arguments

**shp** — Alpha shape  
alphaShape object

Alpha shape, specified as an alphaShape object. For more information, see alphaShape.

Example: `shp = alphaShape(x,y)` creates a 2-D alphaShape object from the  $(x,y)$  point coordinates.

## **More About**

- Using alphaShape Objects

## **See Also**

alphaShape

**Introduced in R2014b**

# perimeter

Perimeter of 2-D alpha shape

## Syntax

```
L = perimeter(shp)
L = perimeter(shp,RegionID)
```

## Description

`L = perimeter(shp)` returns the total perimeter of 2-D alpha shape `shp`, including the perimeter of any interior holes in the alpha shape.

`L = perimeter(shp,RegionID)` returns the perimeter of a region within the alpha shape. `RegionID` is the ID for the region and  $1 \leq \text{RegionID} \leq \text{numRegions}(\text{shp})$ .

## Examples

### Find Perimeter of 2-D Alpha Shape

Create a set of 2-D points.

```
th = (pi/12:pi/12:2*pi)';
x1 = [reshape(cos(th)*(1:5), numel(cos(th)*(1:5)),1); 0];
y1 = [reshape(sin(th)*(1:5), numel(sin(th)*(1:5)),1); 0];
x = [x1; x1+15;];
y = [y1; y1];
```

Create and plot an alpha shape using an alpha radius of 2.5.

```
shp = alphaShape(x,y,2.5);
plot(shp)
```

Compute the perimeter of the alpha shape.

```
totalperim = perimeter(shp)
```

```
totalperim =
```

```
62.6526
```

Compute the perimeters of each of the two regions separately.

```
regionperims = perimeter(shp, 1:numRegions(shp))
```

```
regionperims =
 31.3263 31.3263
```

## Input Arguments

### **shp** — 2-D alpha shape

alphaShape object

2-D alpha shape, specified as an alphaShape object. For more information, see alphaShape.

Example: `shp = alphaShape(x,y)` creates a 2-D alphaShape object from the (x,y) point coordinates.

### **RegionID** — ID number for a region in the alpha shape

positive integer scalar

ID number for region in alpha shape, specified as a positive integer scalar between 1 and `numRegions(shp)`.

An alpha shape can contain several smaller regions, depending on the point set and parameters. Each of these smaller regions is assigned a unique **RegionID**, which numbers the regions from the largest area or volume to the smallest. For example, consider a 3-D alpha shape with two regions. The region with the largest volume has a **RegionID** of 1, and the smaller region has a **RegionID** of 2.

Example: `shp.RegionThreshold = area(shp,numRegions(shp)-2)`; suppresses the two smallest regions in 2-D alpha shape `shp`.

Data Types: double

## More About

**Introduced in R2014b**

# plot (alphashape)

Plot alpha shape

## Syntax

```
plot(shp)
plot(shp,Name,Value)
h = plot(___)
```

## Description

`plot(shp)` plots alpha shape `shp` in a figure window.

`plot(shp,Name,Value)` uses additional options specified by one or more `Name,Value` pair arguments. For a complete list of allowed `Name,Value` pairs, see [Patch Properties](#).

`h = plot( ___ )` returns a handle to a `Patch` object using any of the previous syntaxes.

## Examples

### Plot 3-D Alpha Shape and Modify Patch Properties

Create a set of 3-D points.

```
[x1, y1, z1] = sphere(24);
x1 = x1(:);
y1 = y1(:);
z1 = z1(:);
x2 = x1+5;
P = [x1 y1 z1; x2 y1 z1];
P = unique(P, 'rows');
```

Create and plot an alpha shape using an alpha radius of 1.5.

```
shp = alphaShape(P,1.5);
plot(shp)
```

Plot the alpha shape with a specified color and transparency factor.

```
plot(shp, 'FaceColor', 'red', 'FaceAlpha', 0.1)
```

## Input Arguments

**shp** — Alpha shape  
alphaShape object

Alpha shape, specified as an alphaShape object. For more information, see alphaShape.

Example: `shp = alphaShape(x,y)` creates a 2-D alphaShape object from the  $(x,y)$  point coordinates.

## Output Arguments

**h** — Handle to Patch object

handle

Handle to Patch object, returned as a handle. For more information, see “Introduction to Patch Objects”.

## More About

- Using alphaShape Objects

## See Also

alphaShape | patch

# surfaceArea

Surface area of 3-D alpha shape

## Syntax

```
A = surfaceArea(shp)
A = surfaceArea(shp,RegionID)
```

## Description

`A = surfaceArea(shp)` returns the total surface area of 3-D alpha shape `shp`, including the surface area of any interior voids in the alpha shape.

`A = surfaceArea(shp,RegionID)` returns the surface area of a region of the alpha shape. `RegionID` is the ID for the region and  $1 \leq \text{RegionID} \leq \text{numRegions}(\text{shp})$ .

## Examples

### Find Surface Area of 3-D Alpha Shape

Create a set of 3-D points.

```
[x1, y1, z1] = sphere(24);
x1 = x1(:);
y1 = y1(:);
z1 = z1(:);
x2 = x1+5;
P = [x1 y1 z1; x2 y1 z1];
P = unique(P, 'rows');
```

Create and plot an alpha shape using an alpha radius of 1.5.

```
shp = alphaShape(P,1.5);
plot(shp)
```

Compute the surface area of the alpha shape.

```
totalsurfarea = surfaceArea(shp)
```

```
totalsurfarea =
```

```
24.9361
```

Compute the surface area of each region separately.

```
regionsurfareas = surfaceArea(shp, 1:numRegions(shp))
```

```
regionsurfareas =
 12.4680 12.4680
```

## Input Arguments

### **shp** — 3-D alpha shape

alphaShape object

3-D alpha shape, specified as an alphaShape object. For more information, see alphaShape

Example: `shp = alphaShape(x,y,z)` creates a 3-D alphaShape object from the (x,y,z) point coordinates.

### **RegionID** — ID number for a region in the alpha shape

positive integer scalar

ID number for region in alpha shape, specified as a positive integer scalar between 1 and `numRegions(shp)`.

An alpha shape can contain several smaller regions, depending on the point set and parameters. Each of these smaller regions is assigned a unique **RegionID**, which numbers the regions from the largest area or volume to the smallest. For example, consider a 3-D alpha shape with two regions. The region with the largest volume has a **RegionID** of 1, and the smaller region has a **RegionID** of 2.

Example: `shp.RegionThreshold = area(shp,numRegions(shp)-2)`; suppresses the two smallest regions in 2-D alpha shape shp.

Data Types: double

# volume

Volume of 3-D alpha shape

## Syntax

```
V = volume(shp)
V = volume(shp,RegionID)
```

## Description

`V = volume(shp)` returns the volume of 3-D alpha shape `shp`.

`V = volume(shp,RegionID)` returns the volume of a region of the alpha shape. `RegionID` is the ID for the region and  $1 \leq \text{RegionID} \leq \text{numRegions}(\text{shp})$ .

## Examples

### Find Volume of 3-D Alpha Shape

Create a set of 3-D points.

```
[x1, y1, z1] = sphere(24);
x1 = x1(:);
y1 = y1(:);
z1 = z1(:);
x2 = x1+5;
P = [x1 y1 z1; x2 y1 z1];
P = unique(P, 'rows');
```

Create and plot an alpha shape using an alpha radius of 1.5.

```
shp = alphaShape(P,1.5);
plot(shp)
```

Compute the volume of the alpha shape.

```
totalvol = volume(shp)
```

```
totalvol =
```

```
8.2468
```

Compute the volumes of each of the two regions separately.

```
regionvols = volume(shp, 1:numRegions(shp))
```

```
regionvols =
 4.1234 4.1234
```

## Input Arguments

### **shp** — 3-D alpha shape

alphaShape object

3-D alpha shape, specified as an alphaShape object. For more information, see alphaShape

Example: `shp = alphaShape(x,y,z)` creates a 3-D alphaShape object from the  $(x,y,z)$  point coordinates.

### **RegionID** — ID number for a region in the alpha shape

positive integer scalar

ID number for region in alpha shape, specified as a positive integer scalar between 1 and `numRegions(shp)`.

An alpha shape can contain several smaller regions, depending on the point set and parameters. Each of these smaller regions is assigned a unique **RegionID**, which numbers the regions from the largest area or volume to the smallest. For example, consider a 3-D alpha shape with two regions. The region with the largest volume has a **RegionID** of 1, and the smaller region has a **RegionID** of 2.

Example: `shp.RegionThreshold = area(shp,numRegions(shp)-2)`; suppresses the two smallest regions in 2-D alpha shape `shp`.

Data Types: double

## amd

Approximate minimum degree permutation

### Syntax

```
P = amd(A)
P = amd(A,opts)
```

### Description

`P = amd(A)` returns the approximate minimum degree permutation vector for the sparse matrix  $C = A + A'$ . The Cholesky factorization of  $C(P,P)$  or  $A(P,P)$  tends to be sparser than that of  $C$  or  $A$ . The `amd` function tends to be faster than `symamd`, and also tends to return better orderings than `symamd`. Matrix  $A$  must be square. If  $A$  is a full matrix, then `amd(A)` is equivalent to `amd(sparse(A))`.

`P = amd(A,opts)` allows additional options for the reordering. The `opts` input is a structure with the two fields shown below. You only need to set the fields of interest:

- **dense** — A nonnegative scalar value that indicates what is considered to be dense. If  $A$  is  $n$ -by- $n$ , then rows and columns with more than  $\max(16, (\text{dense} * \sqrt{n}))$  entries in  $A + A'$  are considered to be "dense" and are ignored during the ordering. MATLAB software places these rows and columns last in the output permutation. The default value for this field is 10.0 if this option is not present.
- **aggressive** — A scalar value controlling aggressive absorption. If this field is set to a nonzero value, then aggressive absorption is performed. This is the default if this option is not present.

MATLAB software performs an assembly tree post-ordering, which is typically the same as an elimination tree post-ordering. It is not always identical because of the approximate degree update used, and because "dense" rows and columns do not take part in the post-order. It well-suited for a subsequent `chol` operation, however, If you require a precise elimination tree post-ordering, you can use the following code:

```
P = amd(S);
C = spones(S)+spones(S');
[ignore, Q] = etree(C(P,P));
```

```
P = P(Q);
```

If **S** is already symmetric, omit the second line, `C = spones(S)+spones(S')`.

## Examples

This example constructs a sparse matrix and computes a two Cholesky factors: one of the original matrix and one of the original matrix preordered by `amd`. Note how much sparser the Cholesky factor of the preordered matrix is compared to the factor of the matrix in its natural ordering:

```
A = gallery('wathen',50,50);
p = amd(A);
L = chol(A,'lower');
Lp = chol(A(p,p),'lower');

figure;
subplot(2,2,1); spy(A);
title('Sparsity structure of A');

subplot(2,2,2); spy(A(p,p));
title('Sparsity structure of AMD ordered A');

subplot(2,2,3); spy(L);
title('Sparsity structure of Cholesky factor of A');

subplot(2,2,4); spy(Lp);
title('Sparsity structure of Cholesky factor of AMD ordered A');

set(gcf,'Position',[100 100 800 700]);
```

## ancestor

Ancestor of graphics object

### Syntax

```
p = ancestor(h,type)
p = ancestor(h,type,'toplevel')
```

### Description

`p = ancestor(h,type)` returns the handle of the closest ancestor of `h`, if the ancestor is one of the types of graphics objects specified by `type`. `type` can be:

- a string that is the name of a single type of object. For example, `'figure'`
- a cell array containing the names of multiple objects. For example, `{'hgtransform','hgroup','axes'}`

If MATLAB cannot find an ancestor of `h` that is one of the specified types, then `ancestor` returns `p` as empty. When `ancestor` searches the hierarchy, it includes the object itself in the search. Therefore, if the object with handle `h` is of one of the types listed in `type`, `ancestor` will return object `h`.

`ancestor` returns `p` as empty but does not issue an error if `h` is not the handle of a Handle Graphics object.

`p = ancestor(h,type,'toplevel')` returns the highest-level ancestor of `h`, if this type appears in the `type` argument.

### Examples

Find the ancestors of a line object:

```
% Create some line objects and parent them
% to an hgroup object.
hgg = hgroup;
hgl = line(randn(5),randn(5),'Parent',hgg);
```

```
% Now get the ancestor of the lines:
p = ancestor(hgg,{'figure','axes','hgroup'});
get(p,'Type')
% Now get the top-level ancestor:
ptop=ancestor(hgg,{'figure','axes','hgroup'},'toplevel');
get(ptop,'type')
```

## **See Also**

## and, &

Find logical AND

### Syntax

```
A & B & ...
and(A, B)
```

### Description

`A & B & ...` performs a logical AND of all input arrays `A`, `B`, etc., and returns an array containing elements set to either logical 1 (`true`) or logical 0 (`false`). An element of the output array is set to 1 if all input arrays contain a nonzero element at that same array location. Otherwise, that element is set to 0.

Each input of the expression can be an array or can be a scalar value. All nonscalar input arrays must have equal dimensions. If one or more inputs are an array, then the output is an array of the same dimensions. If all inputs are scalar, then the output is scalar.

If the expression contains both scalar and nonscalar inputs, then each scalar input is treated as if it were an array having the same dimensions as the other input arrays. In other words, if input `A` is a 3-by-5 matrix and input `B` is the number 1, then `B` is treated as if it were a 3-by-5 matrix of ones.

`and(A, B)` is called for the syntax `A & B` when either `A` or `B` is an object.

---

**Note** The symbols `&` and `&&` perform different operations in the MATLAB software. The element-wise AND operator described here is `&`. The short-circuit AND operator is `&&`.

---

### Examples

If matrix `A` is

```
0.4235 0.5798 0 0.7942 0
0.5155 0 0.7833 0.0592 0.8744
```

```
0.3340 0 0 0 0.0150
0.4329 0.6405 0.6808 0.0503 0
```

and matrix B is

```
0 1 0 1 0
1 1 1 0 1
0 1 1 1 0
0 1 0 0 1
```

then

A & B

ans =

```
0 1 0 1 0
1 0 1 0 1
0 0 0 0 0
0 1 0 0 0
```

# angle

Phase angle

## Syntax

`P = angle(Z)`

## Description

`P = angle(Z)` returns the phase angles, in radians, for each element of complex array `Z`. The angles lie between  $\pm\pi$ .

For complex `Z`, the magnitude `R` and phase angle `theta` are given by

```
R = abs(Z)
theta = angle(Z)
```

and the statement

```
Z = R.*exp(i*theta)
```

converts back to the original complex `Z`.

## Examples

```
Z = [1 - 1i 2 + 1i 3 - 1i 4 + 1i
 1 + 2i 2 - 2i 3 + 2i 4 - 2i
 1 - 3i 2 + 3i 3 - 3i 4 + 3i
 1 + 4i 2 - 4i 3 + 4i 4 - 4i]
```

```
P = angle(Z)
```

```
P =
-0.7854 0.4636 -0.3218 0.2450
 1.1071 -0.7854 0.5880 -0.4636
-1.2490 0.9828 -0.7854 0.6435
 1.3258 -1.1071 0.9273 -0.7854
```

## More About

### Algorithms

The `angle` function can be expressed as  $\text{angle}(z) = \text{imag}(\log(z)) = \text{atan2}(\text{imag}(z), \text{real}(z))$ .

# Using Animated Line Objects

Line animations

## Description

Animated line objects optimize line animations by accumulating data from a streaming data source. After you create the initial animated line using the `animatedline` function, you can add new points to the line without having to redefine the existing points. Modify the appearance of the animated line by setting its properties.

## Examples

### Display Line Animation

Create the initial animated line object. Then, use a loop to add 1,000 points to the line. After adding each new point, use `drawnow` to display the new point on the screen.

```
h = animatedline;
axis([0,4*pi,-1,1])

x = linspace(0,4*pi,1000);
y = sin(x);
for k = 1:length(x)
 addpoints(h,x(k),y(k));
 drawnow
end
```

For faster rendering, add more than one point to the line each time through the loop or use `drawnow limitrate`.

Query the points of the line.

```
[xdata,ydata] = getpoints(h);
```

Clear the points from the line.

```
clearpoints(h)
drawnow
```

### Set Maximum Number of Points

Limit the number of points in the animated line to 100. Use a loop to add one point to the line at a time. When the line contains 100 points, adding a new point to the line deletes the oldest point.

```
h = animatedline('MaximumNumPoints',100);
axis([0,4*pi,-1,1])

x = linspace(0,4*pi,1000);
y = sin(x);
for k = 1:length(x)
 addpoints(h,x(k),y(k));
 drawnow
```

end

### Add Points in Sets for Fast Animation

Use a loop to add 100,000 points to an animated line. Since the number of points is large, adding one point to the line each time through the loop might be slow. Instead, add 100 points to the line each time through the loop for a faster animation.

```
h = animatedline;
axis([0,4*pi,-1,1])

numpoints = 100000;
x = linspace(0,4*pi,numpoints);
y = sin(x);
for k = 1:100:numpoints-100
```

```
xvec = x(k:k+99);
yvec = y(k:k+99);
addpoints(h,xvec,yvec)
drawnow
end
```

Another technique for creating faster animations is to use `drawnow limitrate` instead of `drawnow`.

### Use `drawnow limitrate` for Fast Animation

Use a loop to add 100,000 points to an animated line. Since the number of points is large, using `drawnow` to display the changes might be slow. Instead, use `drawnow limitrate` for a faster animation.

```
h = animatedline;
axis([0,4*pi,-1,1])

numpoints = 100000;
x = linspace(0,4*pi,numpoints);
y = sin(x);
for k = 1:numpoints
 addpoints(h,x(k),y(k))
 drawnow limitrate
end
```

### Control Animation Speed

Control the animation speed by running through several iterations of the animation loop before drawing the updates on the screen. Use this technique when `drawnow` is too slow and `drawnow limitrate` is too fast.

For example, update the screen every 1/30 seconds. Use the `tic` and `toc` commands to keep track of how much time passes between screen updates.

```
h = animatedline;
axis([0,4*pi,-1,1])
numpoints = 10000;
x = linspace(0,4*pi,numpoints);
y = sin(x);
```

```
a = tic; % start timer
for k = 1:numpoints
 addpoints(h,x(k),y(k))
 b = toc(a); % check timer
 if b > (1/30)
 drawnow % update screen every 1/30 seconds
 a = tic; % reset timer after updating
 end
end
drawnow % draw final frame
```

A smaller interval updates the screen more often and results in a slower animation. For example, use `b > (1/1000)` to slow down the animation.

## Properties

Animated Line Properties

`drawnow` | `movie`

**Introduced in R2014b**

## animatedline

Create animated line

### Syntax

```
h = animatedline
h = animatedline(x,y)
h = animatedline(x,y,z)

h = animatedline(____,Name,Value)
```

### Description

`h = animatedline` creates an animated line that has no data and adds it to the current axes. Add points to the line in a loop to create a line animation. For more information, see [Using Animated Line Objects](#).

`h = animatedline(x,y)` creates an animated line with initial data points defined by `x` and `y`.

`h = animatedline(x,y,z)` creates an animated line with initial data points defined by `x`, `y`, and `z`.

`h = animatedline( ____,Name,Value)` specifies animated line properties using one or more `Name,Value` pair arguments. For example, `'Color','r'` sets the line color to red. Use this option with any of the input argument combinations in the previous syntaxes.

### Examples

#### Display Line Animation

Create the initial animated line object. Then, use a loop to add 1,000 points to the line. After adding each new point, use `drawnow` to display the new point on the screen.

```
h = animatedline;
axis([0,4*pi,-1,1])

x = linspace(0,4*pi,1000);
y = sin(x);
for k = 1:length(x)
 addpoints(h,x(k),y(k));
 drawnow
end
```

For faster rendering, add more than one point to the line each time through the loop or use `drawnow limitrate`.

Query the points of the line.

```
[xdata,ydata] = getpoints(h);
```

Clear the points from the line.

```
clearpoints(h)
drawnow
```

### **Specify Animated Line Color**

Set the color of the animated line to red and set its line width to 3 points.

```
x = [1 2];
y = [1 2];
```

```
h = animatedline(x,y,'Color','r','LineWidth',3);
```

## Input Arguments

### **x** — Initial x values

[ ] (default) | scalar or vector

Initial  $x$  values for the animated line, specified as a scalar or vector. The input  $x$  must be equal in size to  $y$ .

Example: 1:10

Data Types: double

**y** — Initial y values

[ ] (default) | scalar or vector

Initial *y* values for the animated line, specified as a scalar or vector. The input *y* must be equal in size to *x*.

Example: 1:10

Data Types: double

**z** — Initial z values

[ ] (default) | scalar or vector

Initial *z* values for the animated line, specified as a scalar or vector. The input *z* must be equal in size to *x* and *y*.

Example: 1:10

Data Types: double

## Name-Value Pair Arguments

Specify optional comma-separated pairs of *Name*, *Value* arguments. *Name* is the argument name and *Value* is the corresponding value. *Name* must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as *Name*<sub>1</sub>, *Value*<sub>1</sub>, . . . , *Name*<sub>N</sub>, *Value*<sub>N</sub>.

The animated line properties listed here are only a subset. For a complete list, see [Animated Line Properties](#).

Example: 'Color', 'red', 'Marker', 'o'

**'Color'** — Line color

[0 0 0] (default) | RGB triplet | color string | 'none'

Line color, specified as an RGB triplet, a color string, or 'none'. The default RGB triplet value of [0 0 0] corresponds to black. If you specify the *Color* as 'none', then the line is invisible.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range

[0, 1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

| Long Name | Short Name | RGB Triplet |
|-----------|------------|-------------|
| 'yellow'  | 'y'        | [1 1 0]     |
| 'magenta' | 'm'        | [1 0 1]     |
| 'cyan'    | 'c'        | [0 1 1]     |
| 'red'     | 'r'        | [1 0 0]     |
| 'green'   | 'g'        | [0 1 0]     |
| 'blue'    | 'b'        | [0 0 1]     |
| 'white'   | 'w'        | [1 1 1]     |
| 'black'   | 'k'        | [0 0 0]     |

Example: 'blue'

Example: [0 0 1]

**'LineStyle' – Line style**

'-' (default) | '--' | ':' | '-.' | 'none'

Line style, specified as one of the line style strings listed in this table.

| String | Line Style       | Resulting Line                                                                       |
|--------|------------------|--------------------------------------------------------------------------------------|
| '-'    | Solid line       |  |
| '--'   | Dashed line      |  |
| ':'    | Dotted line      |  |
| '-.'   | Dash-dotted line |  |
| 'none' | No line          | No line                                                                              |

**'LineWidth' – Line width**

0.5 (default) | positive value

Line width, specified as a positive value in point units. If the line has markers, then the line width also affects the marker edges.

Example: 0.75

**'Marker' — Marker symbol**

'none' (default) | 'o' | '+' | '\*' | '.' | ...

Marker symbol, specified as one of the marker symbol strings listed in this table. By default, the animated line object does not have markers. Specifying a marker symbol adds markers at each data point or vertex.

| String             | Marker Symbol                 |
|--------------------|-------------------------------|
| 'o'                | Circle                        |
| '+'                | Plus sign                     |
| '*'                | Asterisk                      |
| '.'                | Point                         |
| 'x'                | Cross                         |
| 'square' or 's'    | Square                        |
| 'diamond' or 'd'   | Diamond                       |
| '^'                | Upward-pointing triangle      |
| 'v'                | Downward-pointing triangle    |
| '>'                | Right-pointing triangle       |
| '<'                | Left-pointing triangle        |
| 'pentagram' or 'p' | Five-pointed star (pentagram) |
| 'hexagram' or 'h'  | Six-pointed star (hexagram)   |
| 'none'             | No markers                    |

**'MarkerSize' — Marker size**

6 (default) | positive value

Marker size, specified as a positive value in point units.

Example: 10

**'MarkerEdgeColor' — Color of marker edge**

'auto' (default) | 'none' | RGB triplet | color string

Marker outline color, specified as one of these values:

- 'auto' — Use the same color as the `Color` property.
- 'none' — Use no color, which makes unfilled markers invisible.
- RGB triplet or color string — Use the specified color.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range  $[0, 1]$ , for example,  $[0.4 \ 0.6 \ 0.7]$ . This table lists RGB triplet values that have equivalent color strings.

| Long Name | Short Name | RGB Triplet |
|-----------|------------|-------------|
| 'yellow'  | 'y'        | [1 1 0]     |
| 'magenta' | 'm'        | [1 0 1]     |
| 'cyan'    | 'c'        | [0 1 1]     |
| 'red'     | 'r'        | [1 0 0]     |
| 'green'   | 'g'        | [0 1 0]     |
| 'blue'    | 'b'        | [0 0 1]     |
| 'white'   | 'w'        | [1 1 1]     |
| 'black'   | 'k'        | [0 0 0]     |

Example:  $[0.5 \ 0.5 \ 0.5]$

Example: 'blue'

### 'MarkerFaceColor' — Color of marker interior

'none' (default) | 'auto' | RGB triplet | color string

Marker fill color, specified as one of these values:

- 'none' — Use no color, which makes the interior invisible.
- 'auto' — Use the same color as the `Color` property for the axes.
- RGB triplet or color string — Use the specified color.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range  $[0, 1]$ , for example,  $[0.4 \ 0.6 \ 0.7]$ . This table lists RGB triplet values that have equivalent color strings.

| Long Name | Short Name | RGB Triplet |
|-----------|------------|-------------|
| 'yellow'  | 'y'        | [ 1 1 0 ]   |
| 'magenta' | 'm'        | [ 1 0 1 ]   |
| 'cyan'    | 'c'        | [ 0 1 1 ]   |
| 'red'     | 'r'        | [ 1 0 0 ]   |
| 'green'   | 'g'        | [ 0 1 0 ]   |
| 'blue'    | 'b'        | [ 0 0 1 ]   |
| 'white'   | 'w'        | [ 1 1 1 ]   |
| 'black'   | 'k'        | [ 0 0 0 ]   |

Example: [0.3 0.2 0.1]

Example: 'green'

**'MaximumNumPoints' — Maximum number of points stored and displayed**

1000000 (default) | positive value | Inf

Maximum number of points stored and displayed as part of the line, specified as a positive value or `Inf`. By default, the value is one million points. If the number of points exceeds the maximum value permitted, then the animated line keeps the most recently added points and drops points from the beginning of the line. These dropped points no longer display on the screen and are not returned when using `getpoints`.

Use this property to limit the number of points appearing on the screen at any given time or to limit the amount of memory used. If you specify the value as `Inf`, then the animated line does not drop any points, but the number of points stored is limited by the amount of memory available.

Example: 10

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

## Output Arguments

**h — Animated line object**

animated line object

Animated line object. Use `h` to modify the animated line object after its been created, such as changing property values or adding points to the line. For more information, see [Using Animated Line Objects](#).

## More About

### Tips

- Animated lines do not support data tips.

### Properties

[Animated Line Properties](#)

**Introduced in R2014b**

## Animated Line Properties

Control animated line appearance and behavior

Animated line properties control the appearance and behavior of an animated line object. By changing property values, you can modify certain aspects of the line. Use dot notation to refer to a particular object and property:

```
h = animatedline;
c = h.Color;
h.Color = 'red';
```

### Line

#### Color — Line color

[0 0 0] (default) | RGB triplet | color string | 'none'

Line color, specified as an RGB triplet, a color string, or 'none'. The default RGB triplet value of [0 0 0] corresponds to black. If you specify the `Color` as 'none', then the line is invisible.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0, 1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

| Long Name | Short Name | RGB Triplet |
|-----------|------------|-------------|
| 'yellow'  | 'y'        | [1 1 0]     |
| 'magenta' | 'm'        | [1 0 1]     |
| 'cyan'    | 'c'        | [0 1 1]     |
| 'red'     | 'r'        | [1 0 0]     |
| 'green'   | 'g'        | [0 1 0]     |
| 'blue'    | 'b'        | [0 0 1]     |
| 'white'   | 'w'        | [1 1 1]     |
| 'black'   | 'k'        | [0 0 0]     |

Example: 'blue'

Example: [0 0 1]

### LineStyle — Line style

'-' (default) | '--' | ':' | '-.' | 'none'

Line style, specified as one of the line style strings listed in this table.

| String | Line Style       | Resulting Line                                                                     |
|--------|------------------|------------------------------------------------------------------------------------|
| '-'    | Solid line       |  |
| '--'   | Dashed line      |  |
| ':'    | Dotted line      |  |
| '-.'   | Dash-dotted line |  |
| 'none' | No line          | No line                                                                            |

### LineWidth — Line width

0.5 (default) | positive value

Line width, specified as a positive value in point units. If the line has markers, then the line width also affects the marker edges.

Example: 0.75

### MaximumNumPoints — Maximum number of points stored and displayed

1000000 (default) | positive value | Inf

Maximum number of points stored and displayed as part of the line, specified as a positive value or `Inf`. By default, the value is one million points. If the number of points exceeds the maximum value permitted, then the animated line keeps the most recently added points and drops points from the beginning of the line. These dropped points no longer display on the screen and are not returned when using `getpoints`.

Use this property to limit the number of points appearing on the screen at any given time or to limit the amount of memory used. If you specify the value as `Inf`, then the animated line does not drop any points, but the number of points stored is limited by the amount of memory available.

Example: 10

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **AlignVertexCenters** — Sharp vertical and horizontal lines

'off' (default) | 'on'

Sharp vertical and horizontal lines, specified as 'off' or 'on'.

If the associated figure has a `GraphicsSmoothing` property set to 'on' and a `Renderer` property set to 'opengl', then the figure applies a smoothing technique to plots. In some cases, this smoothing technique can cause vertical and horizontal lines to appear uneven in thickness or color. Use the `AlignVertexCenters` property to eliminate the uneven appearance.

- 'off' — Do not sharpen vertical or horizontal lines. The lines might appear uneven in thickness or color.
- 'on' — Sharpen vertical and horizontal lines to eliminate an uneven appearance.

---

**Note:** You must have a graphics card that supports this feature. To see if the feature is supported, type `opengl info`. If it is supported, then the returned fields contain the line `SupportsAlignVertexCenters: 1`.

---

## **Markers**

### **Marker** — Marker symbol

'none' (default) | marker string

Marker symbol, specified as one of the marker strings listed in this table. By default, the animated line object does not display markers. Specifying a marker symbol adds markers at each data point or vertex.

| <b>String</b> | <b>Marker Symbol</b> |
|---------------|----------------------|
| 'o'           | Circle               |
| '+'           | Plus sign            |
| '*'           | Asterisk             |
| '.'           | Point                |
| 'x'           | Cross                |

| String             | Marker Symbol                 |
|--------------------|-------------------------------|
| 'square' or 's'    | Square                        |
| 'diamond' or 'd'   | Diamond                       |
| '^'                | Upward-pointing triangle      |
| 'v'                | Downward-pointing triangle    |
| '>'                | Right-pointing triangle       |
| '<'                | Left-pointing triangle        |
| 'pentagram' or 'p' | Five-pointed star (pentagram) |
| 'hexagram' or 'h'  | Six-pointed star (hexagram)   |
| 'none'             | No markers                    |

Example: '+'

Example: 'diamond'

**MarkerSize — Marker size**

6 (default) | positive value

Marker size, specified as a positive value in point units.

Example: 10

**MarkerEdgeColor — Marker outline color**

'auto' (default) | 'none' | RGB triplet | color string

Marker outline color, specified as one of these values:

- 'auto' — Use the same color as the **Color** property.
- 'none' — Use no color, which makes unfilled markers invisible.
- RGB triplet or color string — Use the specified color.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0, 1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

| Long Name | Short Name | RGB Triplet |
|-----------|------------|-------------|
| 'yellow'  | 'y'        | [ 1 1 0 ]   |

| Long Name | Short Name | RGB Triplet |
|-----------|------------|-------------|
| 'magenta' | 'm'        | [1 0 1]     |
| 'cyan'    | 'c'        | [0 1 1]     |
| 'red'     | 'r'        | [1 0 0]     |
| 'green'   | 'g'        | [0 1 0]     |
| 'blue'    | 'b'        | [0 0 1]     |
| 'white'   | 'w'        | [1 1 1]     |
| 'black'   | 'k'        | [0 0 0]     |

Example: [0.5 0.5 0.5]

Example: 'blue'

### **MarkerFaceColor** — Marker fill color

'none' (default) | 'auto' | RGB triplet | color string

Marker fill color, specified as one of these values:

- 'none' — Use no color, which makes the interior invisible.
- 'auto' — Use the same color as the Color property for the axes.
- RGB triplet or color string — Use the specified color.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0, 1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

| Long Name | Short Name | RGB Triplet |
|-----------|------------|-------------|
| 'yellow'  | 'y'        | [1 1 0]     |
| 'magenta' | 'm'        | [1 0 1]     |
| 'cyan'    | 'c'        | [0 1 1]     |
| 'red'     | 'r'        | [1 0 0]     |
| 'green'   | 'g'        | [0 1 0]     |
| 'blue'    | 'b'        | [0 0 1]     |
| 'white'   | 'w'        | [1 1 1]     |

| Long Name | Short Name | RGB Triplet |
|-----------|------------|-------------|
| 'black'   | 'k'        | [0 0 0]     |

Example: [0.3 0.2 0.1]

Example: 'green'

## Visibility

### Visible — State of visibility

'on' (default) | 'off'

State of visibility, specified as one of these values:

- 'on' — Display the animated line.
- 'off' — Hide the animated line without deleting it. You still can access the properties of an invisible animated line object.

### Clipping — Clipping of animated line object to axes limits

'on' (default) | 'off'

Clipping of the animated line object to the axes limits, specified as one of these values:

- 'on' — Do not display parts of the animated line object that are outside the axes limits.
- 'off' — Display the entire animated line object, even if parts of it appear outside the axes limits. Parts of the animated line object might appear outside the axes limits if you create a plot, set `hold on`, freeze the axis scaling, and then create the animated line object so that it is larger than the original plot.

The **Clipping** property of the axes that contains the animated line object must be set to 'on', otherwise this property has no effect. For more information about the clipping behavior, see the Clipping property of the axes.

## Identifiers

### Type — Type of graphics object

'animatedline'

This property is read only.

Type of graphics object, returned as `'animatedline'`. Use this property to find all objects of a given type within a plotting hierarchy, for example, searching for the type using `findobj`.

**Tag — User-specified tag**

`''` (default) | string

Tag to associate with the animated line, specified as a string. Tags provide a way to identify graphics objects. Use this property to find all objects with a specific tag within a plotting hierarchy, for example, searching for the tag using `findobj`.

Example: `'January Data'`

**UserData — Data to associate with animated line**

`[]` (default) | scalar, vector, or matrix | cell array | character array | table | structure

Data to associate with the animated line object, specified as a scalar, vector, matrix, cell array, character array, table, or structure. MATLAB does not use this data.

To associate multiple sets of data or to attach a field name to the data, use the `getappdata` and `setappdata` functions.

Example: `1:100`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char` | `struct` | `table` | `cell`

**DisplayName — Text used by legend**

`''` (default) | string

Text used by the legend, specified as a string. The text appears next to an icon of the animated line.

Example: `'Text Description'`

For multiline text, create the string using `sprintf` with the new line character `\n`.

Example: `sprintf('line one\nline two')`

Alternatively, you can specify the legend text using the `legend` function.

- If you specify the text as an input argument to the `legend` function, then the legend uses the specified text and sets the `DisplayName` property to the same value.
- If you do not specify the text as an input argument to the `legend` function, then the legend uses the text in the `DisplayName` property. If the `DisplayName` property

does not contain any text, then the legend generates a string. The string has the form 'dataN', where N is the number assigned to the animated line object based on its location in the list of legend entries.

If you edit interactively the string in an existing legend, then MATLAB updates the `DisplayName` property to the edited string.

### **Annotation — Legend icon display style**

Annotation object

This property is read only.

Legend icon display style, returned as an `Annotation` object. Use this object to include or exclude the animated line from a legend.

- 1 Query the `Annotation` property to get the `Annotation` object.
- 2 Query the `LegendInformation` property of the `Annotation` object to get the `LegendEntry` object.
- 3 Specify the `IconDisplayStyle` property of the `LegendEntry` object to one of these values:
  - 'on' — Include the animated line object in the legend as one entry (default).
  - 'off' — Do not include the animated line object in the legend.
  - 'children' — Include only children of the animated line object as separate entries in the legend.

If a legend already exists and you change the `IconDisplayStyle` setting, then you must call `legend` to update the display.

## **Parent/Child**

### **Parent — Parent of animated line**

axes object | group object | transform object

Parent of animated line, specified as an axes, group, or transform object.

### **Children — Children of animated line**

empty `GraphicsPlaceholder` array

The animated line has no children. You cannot set this property.

**HandleVisibility — Visibility of object handle**`'on' (default) | 'off' | 'callback'`

Visibility of animated line object handle in the `Children` property of the parent, specified as one of these values:

- `'on'` — The animated line object handle is always visible.
- `'off'` — The animated line object handle is invisible at all times. This option is useful for preventing unintended changes to the UI by another function. Set the `HandleVisibility` to `'off'` to temporarily hide the handle during the execution of that function.
- `'callback'` — The animated line object handle is visible from within callbacks or functions invoked by callbacks, but not from within functions invoked from the command line. This option blocks access to the animated line at the command-line, but allows callback functions to access it.

If the animated line object is not listed in the `Children` property of the parent, then functions that obtain object handles by searching the object hierarchy or querying handle properties cannot return it. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

Hidden object handles are still valid. Set the root `ShowHiddenHandles` property to `'on'` to list all object handles regardless of their `HandleVisibility` property setting.

**Interactive Control****ButtonDownFcn — Mouse-click callback**`' ' (default) | function handle | cell array | string`

Mouse-click callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you click the animated line. If you specify this property using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The animated line object — You can access properties of the animated line object from within the callback function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see “Callback Definition”.

---

**Note:** If the `PickableParts` property is set to 'none' or if the `HitTest` property is set to 'off', then this callback does not execute.

---

Example: `@myCallback`

Example: `{@myCallback, arg3}`

### **UIContextMenu — Context menu**

`uicontextmenu` object

Context menu, specified as a `uicontextmenu` object. Use this property to display a context menu when you right-click the animated line. Create the context menu using the `uicontextmenu` function.

---

**Note:** If the `PickableParts` property is set to 'none' or if the `HitTest` property is set to 'off', then the context menu does not appear.

---

### **Selected — Selection state**

'off' (default) | 'on'

Selection state, specified as one of these values:

- 'on' — Selected. If you click the animated line when in plot edit mode, then MATLAB sets its `Selected` property to 'on'. If the `SelectionHighlight` property also is set to 'on', then MATLAB displays selection handles around the animated line.
- 'off' — Not selected.

### **SelectionHighlight — Display of selection handles when selected**

'on' (default) | 'off'

Display of selection handles when selected, specified as one of these values:

- 'on' — Display selection handles when the `Selected` property is set to 'on'.
- 'off' — Never display selection handles, even when the `Selected` property is set to 'on'.

## Callback Execution Control

### **PickableParts** — Ability to capture mouse clicks

'visible' (default) | 'none'

Ability to capture mouse clicks, specified as one of these values:

- 'visible' — Can capture mouse clicks when visible. The `Visible` property must be set to 'on' and you must click a part of the animated line that has a defined color. You cannot click a part that has an associated color property set to 'none'. If the plot contains markers, then the entire marker is clickable if either the edge or the fill has a defined color. The `HitTest` property determines if the animated line responds to the click or if an ancestor does.
- 'none' — Cannot capture mouse clicks. Clicking the animated line passes the click to the object below it in the current view of the figure window. The `HitTest` property of the animated line has no effect.

### **HitTest** — Response to captured mouse clicks

'on' (default) | 'off'

Response to captured mouse clicks, specified as one of these values:

- 'on' — Trigger the `ButtonDownFcn` callback of the animated line. If you have defined the `UIContextMenu` property, then invoke the context menu.
- 'off' — Trigger the callbacks for the nearest ancestor of the animated line that has a `HitTest` property set to 'on' and a `PickableParts` property value that enables the ancestor to capture mouse clicks.

---

**Note:** The `PickableParts` property determines if the animated line object can capture mouse clicks. If it cannot, then the `HitTest` property has no effect.

---

### **Interruptible** — Callback interruption

'on' (default) | 'off'

Callback interruption, specified as 'on' or 'off'. The `Interruptible` property determines if a running callback can be interrupted.

---

**Note:** There are two callback states to consider:

- The *running* callback is the currently executing callback.
  - The *interrupting* callback is a callback that tries to interrupt the running callback. Whenever MATLAB invokes a callback, that callback attempts to interrupt a running callback. The `Interruptible` property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the `BusyAction` property of the object owning the interrupting callback determines if it is discarded or put in the queue.
- 

If the `ButtonDownFcn` callback of the animated line is the running callback, then the `Interruptible` property determines if it another callback can interrupt it:

- 'on' — Interruptible. Interruption occurs at the next point where MATLAB processes the queue, such as when there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command.
  - If the running callback contains one of these commands, then MATLAB stops the execution of the callback at this point and executes the interrupting callback. MATLAB resumes executing the running callback when the interrupting callback completes. For more information, see “Interrupt Callback Execution”.
  - If the running callback does not contain one of these commands, then MATLAB finishes executing the callback without interruption.
- 'off' — Not interruptible. MATLAB finishes executing the running callback without any interruptions.

### **BusyAction — Callback queuing**

'queue' (default) | 'cancel'

Callback queuing specified as 'queue' or 'cancel'. The `BusyAction` property determines how MATLAB handles the execution of interrupting callbacks.

---

**Note:** There are two callback states to consider:

- The *running* callback is the currently executing callback.

- The *interrupting* callback is a callback that tries to interrupt the running callback.

Whenever MATLAB invokes a callback, that callback attempts to interrupt a running callback. The **Interruptible** property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the **BusyAction** property of the object owning the interrupting callback determines if it is discarded or put in the queue.

---

If the **ButtonDownFcn** callback of the animated line tries to interrupt a running callback that cannot be interrupted, then the **BusyAction** property determines if it is discarded or put in the queue. Specify the **BusyAction** property as one of these values:

- 'queue' — Put the interrupting callback in a queue to be processed after the running callback finishes execution. This is the default behavior.
- 'cancel' — Discard the interrupting callback.

## Creation and Deletion Control

### **CreateFcn** — Creation callback

' ' (default) | function handle | cell array | string

Creation callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you create the animated line. Setting the **CreateFcn** property on an existing animated line has no effect. You must define a default value for this property, or define this property using a **Name, Value** pair during animated line creation. MATLAB executes the callback after creating the animated line and setting all of its properties.

If you specify this callback using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The animated line object — You can access properties of the animated line object from within the callback function. You also can access the animated line object through the **CallbackObject** property of the root, which can be queried using the **gcb0** function.

- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see “Callback Definition”.

Example: @myCallback

Example: {@myCallback, arg3}

### DeleteFcn — Deletion callback

' ' (default) | function handle | cell array | string

Deletion callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you delete the animated line. MATLAB executes the callback before destroying the animated line so that the callback can access its property values.

If you specify this callback using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The animated line object — You can access properties of the animated line object from within the callback function. You also can access the animated line object through the `CallbackObject` property of the root, which can be queried using the `gcbo` function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see “Callback Definition”.

Example: @myCallback

Example: {@myCallback, arg3}

### BeingDeleted — Deletion status of animated line

'off' (default) | 'on'

This property is read only.

Deletion status of animated line, returned as 'on' or 'off'. MATLAB sets the `BeingDeleted` property to 'on' when the delete function of the animated line begins execution (see the `DeleteFcn` property). The `BeingDeleted` property remains set to 'on' until the animated line no longer exists.

Check the value of the `BeingDeleted` property to verify that the animated line is not about to be deleted before querying or modifying it.

# annotation

Create annotations

## Syntax

```
annotation(lineType,x,y)
annotation(lineType)
```

```
annotation(shapeType,dim)
annotation(shapeType)
```

```
annotation(____,Name,Value)
annotation(container, ____)
```

```
a = annotation(____)
```

## Description

`annotation(lineType,x,y)` creates a line or arrow annotation extending between two points in the current figure. Specify `lineType` as 'line', 'arrow', 'doublearrow', or 'textarrow'. Specify `x` and `y` as two-element vectors of the form `[x_begin x_end]` and `[y_begin y_end]`, respectively.

`annotation(lineType)` creates the annotation in the default position between the points `(0.3,0.3)` and `(0.4,0.4)`.

`annotation(shapeType,dim)` creates a rectangle, ellipse, or text box annotation with a particular size and location in the current figure. Specify `shapeType` as 'rectangle', 'ellipse', or 'textbox'. Specify `dim` as a four-element vector of the form `[x y w h]`. The `x` and `y` elements determine the position and the `w` and `h` elements determine the size.

`annotation(shapeType)` creates the annotation in the default position so that the lower left corner is at `(0.3,0.3)` and the width and height are both `0.1`.

`annotation( ____,Name,Value)` creates the annotation and specifies properties as name-value pair arguments. Different types of annotations support different properties.

You can specify properties with any of the input argument combinations in the previous syntaxes.

`annotation(container, ___)` creates the annotation in the figure, uipanel, or uitab specified by `container`, instead of in the current figure.

`a = annotation(___)` returns the annotation object. The type of object returned depends on first input argument. Use `a` to modify properties of the annotation object after it is created. You can specify an output argument with any of the previous syntaxes.

## Examples

### Create Text Arrow Annotation

Create a simple line plot and add a text arrow to the figure. Specify the text arrow location in normalized figure coordinates, starting at the point (0.3,0.6) and ending at (0.5,0.5). Specify the text description by setting the `String` property.

```
figure
plot(1:10)
x = [0.3 0.5];
y = [0.6 0.5];
annotation('textarrow',x,y,'String','y = x')
```

### Create Text Box Annotation

Create a simple line plot and add a text box annotation to the figure. Specify the text description by setting the `String` property. Force the box to fit tightly around the text by setting the `FitBoxToText` property to `'on'`.

```
figure
plot(1:10)
dim = [.2 .5 .3 .3];
str = 'Straight Line Plot from 1 to 10';
annotation('textbox',dim,'String',str,'FitBoxToText','on');
```

Create a text box annotation without setting the `FitBoxToText` property. The text box uses the specified width and height and wraps text as needed.

```
figure
plot(1:10)
dim = [.2 .5 .3 .3];
str = 'Straight Line Plot from 1 to 10';
annotation('textbox',dim,'String',str)
```

### Create Text Box Annotation with Multiline Text

Create a text box annotation with multiline text by setting the `String` property to a cell array. Each element of the cell array displays on a separate line. Force the box to fit tightly around the text by setting the `FitBoxToText` property to `'on'`.

```
figure
plot(1:10)
dim = [0.2 0.5 0.3 0.3];
str = {'Straight Line Plot','from 1 to 10'};
annotation('textbox',dim,'String',str,'FitBoxToText','on');
```

## Create Rectangle Annotation

Create a stem plot and add a rectangle annotation to the figure. Change the color of the rectangle outline by specifying the `Color` property.

```
figure
data = [2 4 6 7 8 7 5 2];
stem(data)
dim = [.3 .68 .2 .2];
annotation('rectangle',dim,'Color','red')
```

Add a second rectangle annotation to the figure. Specify the fill color by setting the `FaceColor` property. Add transparency by setting the `FaceAlpha` property to a value between 0 (completely transparent) and 1 (completely opaque).

```
dim2 = [.74 .56 .1 .1];
annotation('rectangle',dim2,'FaceColor','blue','FaceAlpha',.2)
```

### Create Ellipse Annotation

Create a simple line plot and add an ellipse annotation to the figure. Specify `dim` as the size and location of the smallest rectangle that encloses the ellipse.

```
figure
x = linspace(-4,4);
y = x.^3 - 12*x;
plot(x,y)

dim = [.2 .74 .25 .15];
annotation('ellipse',dim)
```

Draw a red rectangle using the same dimensions to show how the ellipse fills the rectangular area.

```
annotation('rectangle',dim,'Color','red')
```

## Combine Two Types of Annotations

Create a simple line plot. Then, add a bent arrow to the graph by combining a line and an arrow annotation.

```
figure
plot(1:10)

x1 = [.3 .3];
y1 = [.3 .4];
annotation('line',x1,y1)

xa = [.3 .4];
ya = [.4 .4];
```

```
annotation('arrow',xa,ya)
```

### Modify Annotation After Creation

Add a text arrow to a figure and return the annotation text arrow object, `a`.

```
figure
plot(1:10)
x = [0.3,0.5];
y = [0.6,0.5];
a = annotation('textarrow',x,y,'String','y = x');
```

Modify properties of the annotation text arrow using `a`. For example, change the color to red and the font size to 14 points.

```
a.Color = 'red';
a.FontSize = 14;
```

See the annotation property pages for a list of properties for each type of annotation.

- “Add Annotations to Graph Interactively”

## Input Arguments

**lineType** — Type of line annotation

'line' | 'arrow' | 'doublearrow' | 'textarrow'

Type of line annotation, specified as one of these values.

| Value         | Type of Object                                                                                    | Example                                                       |
|---------------|---------------------------------------------------------------------------------------------------|---------------------------------------------------------------|
| 'line'        | Annotation line                                                                                   | annotation('line', [.1 .2],[.1 .2])                           |
| 'arrow'       | Annotation arrow                                                                                  | annotation('arrow', [.1 .2],[.1 .2])                          |
| 'doublearrow' | Annotation double arrow                                                                           | annotation('doublearrow', [.1 .2],[.1 .2])                    |
| 'textarrow'   | Annotation text arrow.<br>To add text to the tail end of the text arrow, use the String property. | annotation('textarrow', [.1 .2],[.1 .2], 'String', 'my text') |

**shapeType — Type of shape annotation**

'rectangle' | 'ellipse' | 'textbox'

Type of shape annotation, specified as one of these values.

| Value       | Type of Object                                                                                                                                                                                 | Example                                                                         |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------|
| 'rectangle' | Annotation rectangle                                                                                                                                                                           | annotation('rectangle', [.2 .3 .4 .5])                                          |
| 'ellipse'   | Annotation ellipse                                                                                                                                                                             | annotation('ellipse', [.2 .3 .4 .5])                                            |
| 'textbox'   | Annotation text box.<br>To specify the text, set the String property. To automatically adjust the dimensions of the box to fit closely around the text, set the FitBoxToText property to 'on'. | annotation('textbox', [.2 .3 .4 .5], 'String', 'my text', 'FitBoxToText', 'on') |

**x — Beginning and ending x-coordinates**

two-element vector of the form [x\_begin x\_end]

Beginning and ending *x*-coordinates, specified as a two-element vector of the form [x\_begin x\_end]. Together the *x* and *y* input arguments determine the endpoints of the line, arrow, double arrow, or text arrow annotation. The annotation extends from the point (x\_begin, y\_begin) to (x\_end, y\_end).

By default, the units are normalized to the figure. The lower left corner of the figure maps to  $(0,0)$  and the upper right corner maps to  $(1,1)$ . To change the units, use the `Units` property.

Example: `x = [.3 .5]`

### **y** — Beginning and ending y-coordinates

two-element vector of the form `[x_begin x_end]`

Beginning and ending *y*-coordinates, specified as a two-element vector of the form `[y_begin y_end]`. Together the *x* and *y* input arguments determine the endpoints of the line, arrow, double arrow, or text arrow annotation. The annotation extends from the point  $(x\_begin, y\_begin)$  to  $(x\_end, y\_end)$ .

By default, the units are normalized to the figure. The lower left corner of the figure maps to  $(0,0)$  and the upper right corner maps to  $(1,1)$ . To change the units, use the `Units` property.

Example: `y = [.3 .5]`

### **dim** — Size and location

four-element vector of the form `[x y w h]`

Size and location, specified as a four-element vector of the form `[x y w h]`. The first two elements specify the coordinates of the lower left corner of the text box, rectangle, or ellipse with respect to the lower left corner of the figure. The second two elements specify the width and height of the annotation, respectively.

If you are creating an ellipse, then `dim` is the size and location of the smallest rectangle that encloses the ellipse.

By default, the units are normalized to the figure. The lower left corner of the figure maps to  $(0,0)$  and the upper right corner maps to  $(1,1)$ . To change the units, use the `Units` property

Example: `dim = [.3 .4 .5 .6]`

### **container** — Target for annotation

figure object | uipanel object | uitab object

Target for annotation, specified as a figure, uipanel, or uitab object. For example, to add an annotation to a specific figure, specify the figure object as the first input argument to the function.

```
f = figure;
annotation(f, 'line', [.1 .2], [.2 .3])
```

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `annotation('rectangle', [.5 .5 .1 .1], 'EdgeColor', 'r')` creates a rectangle annotation with a red outline.

Each type of annotation object supports a different set of properties. For a full list of properties and descriptions for each type, see the associated property page.

- [Annotation Double Arrow Properties](#)
- [Annotation Text Arrow Properties](#)
- [Annotation Text Box Properties](#)
- [Annotation Rectangle Properties](#)
- [Annotation Ellipse Properties](#)

## Output Arguments

### **a** — Annotation object

scalar

Annotation object, returned as a scalar. The type of annotation object returned depends on the first input argument.

| First Input Argument | Type of Object Returned | Property Page                                      |
|----------------------|-------------------------|----------------------------------------------------|
| 'line'               | Annotation line         | <a href="#">Annotation Line Properties</a>         |
| 'arrow'              | Annotation arrow        | <a href="#">Annotation Arrow Properties</a>        |
| 'doublearrow'        | Annotation double arrow | <a href="#">Annotation Double Arrow Properties</a> |

| First Input Argument | Type of Object Returned | Property Page                    |
|----------------------|-------------------------|----------------------------------|
| 'textarrow'          | Annotation text arrow   | Annotation Text Arrow Properties |
| 'textbox'            | Annotation text box     | Annotation Text Box Properties   |
| 'rectangle'          | Annotation rectangle    | Annotation Rectangle Properties  |
| 'ellipse'            | Annotation ellipse      | Annotation Ellipse Properties    |

## More About

### Compatibility Considerations

Starting in R2014b, annotations cannot cross uipanel boundaries. Instead, they clip at the boundaries. Previous versions of MATLAB allow annotations to extend into (or out of) the boundaries. To display an annotation within a specific figure, uipanel, or uitab, use the `container` input argument.

Introduced before R2006a

# Annotation Arrow Properties

Control annotation arrow appearance and behavior

Annotation arrow properties control the appearance and behavior of an annotation arrow object. By changing property values, you can modify certain aspects of the arrow.

Starting in R2014b, you can use dot notation to query and set properties.

```
a = annotation('arrow');
c = a.Color;
a.Color = 'red';
```

If you are using an earlier release, use the `get` and `set` functions instead.

## Appearance

### Color — Arrow color

[0 0 0] (default) | RGB triplet | color string | 'none'

Arrow color, specified as a three-element RGB triplet, a color string, or 'none'. The default RGB triplet value of [0 0 0] corresponds to black. If you set the color to 'none', then the arrow is invisible.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0, 1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

| Long Name | Short Name | RGB Triplet |
|-----------|------------|-------------|
| 'yellow'  | 'y'        | [1 1 0]     |
| 'magenta' | 'm'        | [1 0 1]     |
| 'cyan'    | 'c'        | [0 1 1]     |
| 'red'     | 'r'        | [1 0 0]     |
| 'green'   | 'g'        | [0 1 0]     |
| 'blue'    | 'b'        | [0 0 1]     |

| Long Name | Short Name | RGB Triplet |
|-----------|------------|-------------|
| 'white'   | 'w'        | [ 1 1 1 ]   |
| 'black'   | 'k'        | [ 0 0 0 ]   |

Example: 'blue'

Example: [ 0 0 1 ]

### LineStyle — Style of arrow stem

'-' (default) | '--' | ':' | '-.' | 'none'

Style of arrow stem, specified as one of the strings listed in this table.

| String | Line Style       | Result                                                                              |
|--------|------------------|-------------------------------------------------------------------------------------|
| '-'    | Solid line       |   |
| '--'   | Dashed line      |   |
| ':'    | Dotted line      |   |
| '-.'   | Dash-dotted line |  |
| 'none' | No stem          | No stem                                                                             |

### LineWidth — Width of arrow stem

0.5 (default) | positive value

Width of arrow stem, specified as a positive value in point units. One point equals 1/72 inch.

Example: 0.75

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

### HeadStyle — Style of arrowhead

'vback2' (default) | string

Style of the arrowhead, specified as one of the strings in this table.

| String             | Result                                                                            | String        | Result                                                                              |
|--------------------|-----------------------------------------------------------------------------------|---------------|-------------------------------------------------------------------------------------|
| 'plain'            |  | 'fourstar'    |  |
| 'ellipse'          |  | 'rectangle'   |  |
| 'vback1'           |  | 'diamond'     |  |
| 'vback2' (default) |  | 'rose'        |  |
| 'vback3'           |  | 'hypocycloid' |  |
| 'cback1'           |  | 'astroid'     |  |
| 'cback2'           |  | 'deltoid'     |  |
| 'cback3'           |  | 'none'        | No arrowhead                                                                        |

**HeadLength — Length of arrowhead**

10 (default) | scalar numeric value

Length of the arrowhead, specified as a scalar numeric value in point units. One point equals 1/72 inch. The arrowhead extends backwards from the point (x\_end,y\_end) determined by the X and Y properties.

Example: 15

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**HeadWidth — Width of arrowhead**

10 (default) | scalar numeric value

Width of the arrowhead, specified as a scalar numeric value in point units. One point equals 1/72 inch.

Example: 15

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

## Location and Size

### X — Beginning and ending x-coordinates

[0.3 0.4] (default) | two-element vector

Beginning and ending  $x$ -coordinates, specified as a two-element vector of the form `[x_begin x_end]`.

By default, the units are normalized to the figure. The lower-left corner of the figure maps to  $(0,0)$ , and the upper-right corner maps to  $(1,1)$ . To change the units, use the `Units` property.

Example: `[0.2 0.5]`

### Y — Beginning and ending y-coordinates

[0.3 0.4] (default) | two-element vector

Beginning and ending  $y$ -coordinates, specified as a two-element vector of the form `[y_begin y_end]`.

By default, the units are normalized to the figure. The lower-left corner of the figure maps to  $(0,0)$ , and the upper-right corner maps to  $(1,1)$ . To change the units, use the `Units` property.

Example: `[0.2 0.5]`

### Position — Size and location

[0.3 0.3 0.1 0.1] (default) | four-element vector

Size and location, specified as a four-element vector of the form `[x_begin y_begin dx dy]`. The first two elements specify the coordinates for the beginning of the arrow. The second two elements specify the slope of the arrow.

By default, the units are normalized to the figure. The lower-left corner of the figure maps to  $(0,0)$ , and the upper-right corner maps to  $(1,1)$ . To change the units, use the `Units` property.

Example: `[0.5 0.5 0.2 0.3]`

### Units — Position units

'normalized' (default) | 'inches' | 'centimeters' | 'characters' | 'points'  
| 'pixels'

Position units, specified as one of the values in this table.

| Units                  | Description                                                                                                                                                                                                                                                                                                                                                                                   |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'normalized' (default) | Normalized with respect to the figure, uipanel, or uitab that contains the annotation. The lower-left corner of the container maps to (0,0) and the upper-right corner maps to (1,1).                                                                                                                                                                                                         |
| 'inches'               | Inches.                                                                                                                                                                                                                                                                                                                                                                                       |
| 'centimeters'          | Centimeters.                                                                                                                                                                                                                                                                                                                                                                                  |
| 'characters'           | Based on the default system font character size. <ul style="list-style-type: none"> <li>• Character width = width of letter x.</li> <li>• Character height = distance between the baselines of two lines of text.</li> </ul>                                                                                                                                                                  |
| 'points'               | Points. One point equals 1/72 inch.                                                                                                                                                                                                                                                                                                                                                           |
| 'pixels'               | Pixels. <p>Starting in R2015b, distances in pixels are independent of your system resolution on Windows and Macintosh systems:</p> <ul style="list-style-type: none"> <li>• On Windows systems, a pixel is 1/96th of an inch.</li> <li>• On Macintosh systems, a pixel is 1/72nd of an inch.</li> </ul> <p>On Linux systems, the size of a pixel is determined by your system resolution.</p> |

All units are measured from the lower-left corner of the figure window.

This property affects the **Position** property. If you change the units, then it is good practice to return it to the default value after completing your computation to prevent affecting other functions that assume **Units** is set to the default value.

If you specify the **Position** and **Units** properties as **Name, Value** pairs when creating the annotation arrow, then the order of specification matters. If you want to define

the position with particular units, then you must set the `Units` property before the `Position` property.

# Annotation Double Arrow Properties

Control annotation double arrow appearance and behavior

Annotation double arrow properties control the appearance and behavior of an annotation double arrow object. By changing property values, you can modify certain aspects of the double arrow.

Starting in R2014b, you can use dot notation to query and set properties.

```
h = annotation('doublearrow');
c = h.Color;
h.Color = 'red';
```

If you are using an earlier release, use the `get` and `set` functions instead.

## Appearance

### Color — Arrow color

[0 0 0] (default) | RGB triplet | color string | 'none'

Arrow color, specified as a three-element RGB triplet, a color string, or 'none'. The default RGB triplet value of [0 0 0] corresponds to black. If you set the color to 'none', then the arrow is invisible.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0, 1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

| Long Name | Short Name | RGB Triplet |
|-----------|------------|-------------|
| 'yellow'  | 'y'        | [1 1 0]     |
| 'magenta' | 'm'        | [1 0 1]     |
| 'cyan'    | 'c'        | [0 1 1]     |
| 'red'     | 'r'        | [1 0 0]     |
| 'green'   | 'g'        | [0 1 0]     |

| Long Name | Short Name | RGB Triplet |
|-----------|------------|-------------|
| 'blue'    | 'b'        | [0 0 1]     |
| 'white'   | 'w'        | [1 1 1]     |
| 'black'   | 'k'        | [0 0 0]     |

Example: 'blue'

Example: [0 0 1]

### LineStyle — Style of arrow stem

'-' (default) | '--' | ':' | '-.' | 'none'

Style of arrow stem, specified as one of the strings listed in this table.

| String | Line Style       | Result                                                                               |
|--------|------------------|--------------------------------------------------------------------------------------|
| '-'    | Solid line       |    |
| '--'   | Dashed line      |    |
| ':'    | Dotted line      |    |
| '-.'   | Dash-dotted line |  |
| 'none' | No stem          | No stem                                                                              |

### LineWidth — Width of arrow stem

0.5 (default) | positive value

Width of arrow stem, specified as a positive value in point units. One point equals 1/72 inch.

Example: 0.75

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

### Head1Style — Style of first arrowhead

'vback2' (default) | string

Style of the first arrowhead, specified as one of the head style strings in this table. The first arrowhead is located at the point (x\_begin, y\_begin) determined by the X and Y properties.

| String             | Result                                                                            | String        | Result                                                                              |
|--------------------|-----------------------------------------------------------------------------------|---------------|-------------------------------------------------------------------------------------|
| 'plain'            |  | 'fourstar'    |  |
| 'ellipse'          |  | 'rectangle'   |  |
| 'vback1'           |  | 'diamond'     |  |
| 'vback2' (default) |  | 'rose'        |  |
| 'vback3'           |  | 'hypocycloid' |  |
| 'cback1'           |  | 'astroid'     |  |
| 'cback2'           |  | 'deltoid'     |  |
| 'cback3'           |  | 'none'        | No arrowhead                                                                        |

**Head2Style** — Style of second arrowhead

'vback2' (default) | string

Style of the second arrowhead, specified as one of the head style strings in this table. The second arrowhead is located at the point (x\_end, y\_end) determined by the X and Y properties.

| String    | Result                                                                              | String      | Result                                                                                |
|-----------|-------------------------------------------------------------------------------------|-------------|---------------------------------------------------------------------------------------|
| 'plain'   |  | 'fourstar'  |  |
| 'ellipse' |  | 'rectangle' |  |
| 'vback1'  |  | 'diamond'   |  |

| String             | Result                                                                            | String        | Result                                                                              |
|--------------------|-----------------------------------------------------------------------------------|---------------|-------------------------------------------------------------------------------------|
| 'vback2' (default) |  | 'rose'        |  |
| 'vback3'           |  | 'hypocycloid' |  |
| 'cback1'           |  | 'astroid'     |  |
| 'cback2'           |  | 'deltoid'     |  |
| 'cback3'           |  | 'none'        | No arrowhead                                                                        |

### Head1Length — Length of first arrowhead

10 (default) | scalar numeric value

Length of the first arrowhead, specified as a scalar numeric value in point units. One point equals 1/72 inch. The first arrowhead extends backwards from the point (x\_begin, y\_begin) determined by the X and Y properties.

Example: 15

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

### Head2Length — Length of second arrowhead

10 (default) | scalar numeric value

Length of the second arrowhead, specified as a scalar numeric value in point units. One point equals 1/72 inch. The second arrowhead extends backwards from the point (x\_end, y\_end) determined by the X and Y properties.

Example: 15

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

### Head1Width — Width of first arrowhead

10 (default) | scalar numeric value

Width of the first arrowhead, specified as a scalar numeric value in point units. One point equals 1/72 inch. The first arrowhead is located at the point (x\_begin, y\_begin) determined by the X and Y properties.

Example: 15

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **Head2Width — Width of second arrowhead**

10 (default) | scalar numeric value

Width of the second arrowhead, specified as a scalar numeric value in point units. One point equals 1/72 inch. The second arrowhead is located at the point (`x_end`, `y_end`) determined by the X and Y properties.

Example: 15

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

## **Location and Size**

### **X — Beginning and ending x-coordinates**

[0.3 0.4] (default) | two-element vector

Beginning and ending *x*-coordinates, specified as a two-element vector of the form [`x_begin` `x_end`].

By default, the units are normalized to the figure. The lower-left corner of the figure maps to (0,0) and the upper-right corner maps to (1,1). To change the units, use the `Units` property.

Example: [0.2 0.3]

### **Y — Beginning and ending y-coordinates**

[0.3 0.4] (default) | two-element vector

Beginning and ending *y*-coordinates, specified as a two-element vector of the form [`y_begin` `y_end`].

By default, the units are normalized to the figure. The lower-left corner of the figure maps to (0,0) and the upper-right corner maps to (1,1). To change the units, use the `Units` property.

Example: [0.2 0.3]

**Position — Size and location**

[0.3 0.3 0.1 0.1] (default) | four-element vector

Size and location, specified as a four-element vector of the form [x\_begin y\_begin dx dy]. The first two elements specify the coordinates for the beginning of the arrow. The second two elements specify the slope of the arrow.

By default, the units are normalized to the figure. The lower-left corner of the figure maps to (0,0) and the upper-right corner maps to (1,1). To change the units, use the `Units` property.

Example: [0.5 0.5 0.2 0.3]

**Units — Position units**

'normalized' (default) | 'inches' | 'centimeters' | 'characters' | 'points'  
| 'pixels'

Position units, specified as one of the values in this table.

| Units                  | Description                                                                                                                                                                                                                  |
|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'normalized' (default) | Normalized with respect to the figure, uipanel, or uitab that contains the annotation. The lower-left corner of the container maps to (0,0) and the upper-right corner maps to (1,1).                                        |
| 'inches'               | Inches.                                                                                                                                                                                                                      |
| 'centimeters'          | Centimeters.                                                                                                                                                                                                                 |
| 'characters'           | Based on the default system font character size. <ul style="list-style-type: none"> <li>• Character width = width of letter x.</li> <li>• Character height = distance between the baselines of two lines of text.</li> </ul> |
| 'points'               | Points. One point equals 1/72 inch.                                                                                                                                                                                          |
| 'pixels'               | Pixels.<br><br>Starting in R2015b, distances in pixels are independent of your system resolution on Windows and Macintosh systems:                                                                                           |

| <b>Units</b> | <b>Description</b>                                                                                                                                                                                                                                      |
|--------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|              | <ul style="list-style-type: none"><li>• On Windows systems, a pixel is 1/96th of an inch.</li><li>• On Macintosh systems, a pixel is 1/72nd of an inch.</li></ul> <p>On Linux systems, the size of a pixel is determined by your system resolution.</p> |

All units are measured from the lower-left corner of the figure window.

This property affects the **Position** property. If you change the units, then it is good practice to return it to the default value after completing your computation to prevent affecting other functions that assume **Units** is set to the default value.

If you specify the **Position** and **Units** properties as **Name, Value** pairs when creating the annotation double arrow, then the order of specification matters. If you want to define the position with particular units, then you must set the **Units** property before the **Position** property.

# Annotation Ellipse Properties

Control annotation ellipse appearance and behavior

Annotation ellipse properties control the appearance and behavior of an annotation ellipse object. By changing property values, you can modify certain aspects of the ellipse.

Starting in R2014b, you can use dot notation to query and set properties.

```
h = annotation('ellipse');
c = h.Color;
h.Color = 'red';
```

If you are using an earlier release, use the `get` and `set` functions instead.

## Appearance

### Color — Outline color

[0 0 0] (default) | RGB triplet | color string | 'none'

Outline color, specified as an RGB triplet, a color string, or 'none'. The default RGB triplet value of [0 0 0] corresponds to black. If you specify the `Color` as 'none', then the annotation ellipse outline is invisible.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0, 1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

| Long Name | Short Name | RGB Triplet |
|-----------|------------|-------------|
| 'yellow'  | 'y'        | [1 1 0]     |
| 'magenta' | 'm'        | [1 0 1]     |
| 'cyan'    | 'c'        | [0 1 1]     |
| 'red'     | 'r'        | [1 0 0]     |
| 'green'   | 'g'        | [0 1 0]     |
| 'blue'    | 'b'        | [0 0 1]     |
| 'white'   | 'w'        | [1 1 1]     |

| Long Name | Short Name | RGB Triplet |
|-----------|------------|-------------|
| 'black'   | 'k'        | [0 0 0]     |

Example: 'blue'

Example: [0 0 1]

**FaceColor — Fill color**

'none' (default) | RGB triplet | color string

Fill color, specified as 'none', an RGB triplet, or a color string. The 'none' option makes the fill invisible.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0, 1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

| Long Name | Short Name | RGB Triplet |
|-----------|------------|-------------|
| 'yellow'  | 'y'        | [1 1 0]     |
| 'magenta' | 'm'        | [1 0 1]     |
| 'cyan'    | 'c'        | [0 1 1]     |
| 'red'     | 'r'        | [1 0 0]     |
| 'green'   | 'g'        | [0 1 0]     |
| 'blue'    | 'b'        | [0 0 1]     |
| 'white'   | 'w'        | [1 1 1]     |
| 'black'   | 'k'        | [0 0 0]     |

Example: 'blue'

Example: [0 0 1]

**LineStyle — Line style**

'-' (default) | '--' | ':' | '-.' | 'none'

Line style, specified as one of the line style strings listed in this table.

| String | Line Style       | Resulting Line                                                                     |
|--------|------------------|------------------------------------------------------------------------------------|
| '_'    | Solid line       |  |
| '--'   | Dashed line      |  |
| '...'  | Dotted line      |  |
| '-.''  | Dash-dotted line |  |
| 'none' | No line          | No line                                                                            |

**LineWidth — Line width**

0.5 (default) | positive value

Line width of ellipse outline, specified as a positive value in point units. One point equals 1/72 inch.

Example: 0.75

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**Location and Size****Position — Size and location**

[0.3 0.3 0.1 0.1] (default) | four-element vector

Size and location, specified as a four-element vector of the form [x y length height]. The first two elements specify the coordinates of the lower-left corner of the smallest rectangle that enclose the ellipse. The second two elements specify length and height of the rectangle.

By default, the units are normalized to the figure. The lower-left corner of the figure maps to (0,0) and the upper-right corner maps to (1,1). To change the units, use the `Units` property.

Example: [0.2 0.3 0.4 0.5]

**Units — Position units**

'normalized' (default) | 'inches' | 'centimeters' | 'characters' | 'points' | 'pixels'

Position units, specified as one of the values in this table.

| Units                  | Description                                                                                                                                                                                                                                                                                                                                                                            |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'normalized' (default) | Normalized with respect to the figure, uipanel, or uitab that contains the annotation. The lower-left corner of the container maps to (0,0) and the upper-right corner maps to (1,1).                                                                                                                                                                                                  |
| 'inches'               | Inches.                                                                                                                                                                                                                                                                                                                                                                                |
| 'centimeters'          | Centimeters.                                                                                                                                                                                                                                                                                                                                                                           |
| 'characters'           | Based on the default system font character size. <ul style="list-style-type: none"> <li>• Character width = width of letter x.</li> <li>• Character height = distance between the baselines of two lines of text.</li> </ul>                                                                                                                                                           |
| 'points'               | Points. One point equals 1/72 inch.                                                                                                                                                                                                                                                                                                                                                    |
| 'pixels'               | Pixels.<br><br>Starting in R2015b, distances in pixels are independent of your system resolution on Windows and Macintosh systems: <ul style="list-style-type: none"> <li>• On Windows systems, a pixel is 1/96th of an inch.</li> <li>• On Macintosh systems, a pixel is 1/72nd of an inch.</li> </ul> On Linux systems, the size of a pixel is determined by your system resolution. |

All units are measured from the lower-left corner of the figure window.

This property affects the **Position** property. If you change the units, then it is good practice to return it to the default value after completing your computation to prevent affecting other functions that assume **Units** is set to the default value.

If you specify the **Position** and **Units** properties as **Name, Value** pairs when creating the annotation ellipse, then the order of specification matters. If you want to define

the position with particular units, then you must set the `Units` property before the `Position` property.

## Annotation Line Properties

Control annotation line appearance and behavior

Annotation line properties control the appearance and behavior of an annotation line object. By changing property values, you can modify certain aspects of the line.

Starting in R2014b, you can use dot notation to query and set properties.

```
h = annotation('line');
c = h.Color;
h.Color = 'red';
```

If you are using an earlier release, use the `get` and `set` functions instead.

### Appearance

#### LineStyle — Line style

'-' (default) | '--' | ':' | '-.' | 'none'

Line style, specified as one of the line style strings listed in this table.

| String | Line Style       | Resulting Line                                                                       |
|--------|------------------|--------------------------------------------------------------------------------------|
| '-'    | Solid line       |   |
| '--'   | Dashed line      |  |
| ':'    | Dotted line      |  |
| '-.'   | Dash-dotted line |  |
| 'none' | No line          | No line                                                                              |

#### LineWidth — Line width

0.5 (default) | positive value

Line width, specified as a positive value in point units. One point equals 1/72 inch.

Example: 0.75

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**Color — Line color**

[0 0 0] (default) | RGB triplet | color string

Line color, specified as an RGB triplet or a color string. The default RGB triplet value of [0 0 0] corresponds to black.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0, 1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

| Long Name | Short Name | RGB Triplet |
|-----------|------------|-------------|
| 'yellow'  | 'y'        | [1 1 0]     |
| 'magenta' | 'm'        | [1 0 1]     |
| 'cyan'    | 'c'        | [0 1 1]     |
| 'red'     | 'r'        | [1 0 0]     |
| 'green'   | 'g'        | [0 1 0]     |
| 'blue'    | 'b'        | [0 0 1]     |
| 'white'   | 'w'        | [1 1 1]     |
| 'black'   | 'k'        | [0 0 0]     |

Example: 'blue'

Example: [0 0 1]

**Location and Size****X — Beginning and ending x-coordinates**

[0.3 0.4] (default) | two-element vector

Beginning and ending  $x$ -coordinates, specified as a two-element vector of the form [x\_begin x\_end].

By default, the units are normalized to the figure. The lower-left corner of the figure maps to (0,0) and the upper-right corner maps to (1,1). To change the units, use the Units property.

Example: [0.2 0.3]

**Y — Beginning and ending y-coordinates**

[0.3 0.4] (default) | two-element vector

Beginning and ending *y*-coordinates, specified as a two-element vector of the form [y\_begin y\_end].

By default, the units are normalized to the figure. The lower-left corner of the figure maps to (0,0) and the upper-right corner maps to (1,1). To change the units, use the `Units` property.

Example: [0.2 0.3]

**Position — Size and location**

[0.3 0.3 0.1 0.1] (default) | four-element vector

Size and location, specified as a four-element vector of the form [x\_begin y\_begin dx dy]. The first two elements specify the coordinates of the starting point of the line. The second two elements specify the slope of the line.

By default, the units are normalized to the figure. The lower-left corner of the figure maps to (0,0) and the upper-right corner maps to (1,1). To change the units, use the `Units` property. To change the units, use the `Units` property.

Example: [0.2 0.2 0.3 0.3]

**Units — Position units**

'normalized' (default) | 'inches' | 'centimeters' | 'characters' | 'points' | 'pixels'

Position units, specified as one of the values in this table.

| Units                  | Description                                                                                                                                                                           |
|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'normalized' (default) | Normalized with respect to the figure, uipanel, or uitab that contains the annotation. The lower-left corner of the container maps to (0,0) and the upper-right corner maps to (1,1). |
| 'inches'               | Inches.                                                                                                                                                                               |
| 'centimeters'          | Centimeters.                                                                                                                                                                          |

| Units        | Description                                                                                                                                                                                                                                                                                                                                                                                   |
|--------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'characters' | Based on the default system font character size. <ul style="list-style-type: none"> <li>• Character width = width of letter x.</li> <li>• Character height = distance between the baselines of two lines of text.</li> </ul>                                                                                                                                                                  |
| 'points'     | Points. One point equals 1/72 inch.                                                                                                                                                                                                                                                                                                                                                           |
| 'pixels'     | Pixels. <p>Starting in R2015b, distances in pixels are independent of your system resolution on Windows and Macintosh systems:</p> <ul style="list-style-type: none"> <li>• On Windows systems, a pixel is 1/96th of an inch.</li> <li>• On Macintosh systems, a pixel is 1/72nd of an inch.</li> </ul> <p>On Linux systems, the size of a pixel is determined by your system resolution.</p> |

All units are measured from the lower-left corner of the figure window.

This property affects the **Position** property. If you change the units, then it is good practice to return it to the default value after completing your computation to prevent affecting other functions that assume **Units** is set to the default value.

If you specify the **Position** and **Units** properties as **Name, Value** pairs when creating the annotation line, then the order of specification matters. If you want to define the position with particular units, then you must set the **Units** property before the **Position** property.

# Annotation Rectangle Properties

Control annotation rectangle appearance and behavior

Annotation rectangle properties control the appearance and behavior of an annotation rectangle object. By changing property values, you can modify certain aspects of the rectangle.

Starting in R2014b, you can use dot notation to query and set properties.

```
h = annotation('rectangle');
c = h.Color;
h.Color = 'red';
```

If you are using an earlier release, use the `get` and `set` functions instead.

## Appearance

### Color — Outline color

[0 0 0] (default) | RGB triplet | color string | 'none'

Outline color, specified as an RGB triplet, a color string, or 'none'. The default RGB triplet value of [0 0 0] corresponds to black. If you specify the Color as 'none', then the annotation rectangle outline is invisible.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0, 1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

| Long Name | Short Name | RGB Triplet |
|-----------|------------|-------------|
| 'yellow'  | 'y'        | [1 1 0]     |
| 'magenta' | 'm'        | [1 0 1]     |
| 'cyan'    | 'c'        | [0 1 1]     |
| 'red'     | 'r'        | [1 0 0]     |
| 'green'   | 'g'        | [0 1 0]     |
| 'blue'    | 'b'        | [0 0 1]     |
| 'white'   | 'w'        | [1 1 1]     |

| Long Name | Short Name | RGB Triplet |
|-----------|------------|-------------|
| 'black'   | 'k'        | [0 0 0]     |

Example: 'blue'

Example: [0 0 1]

### **FaceColor — Fill color**

'none' (default) | RGB triplet | color string

Fill color, specified as 'none', an RGB triplet, or a color string. The 'none' option makes the fill invisible.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0, 1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

| Long Name | Short Name | RGB Triplet |
|-----------|------------|-------------|
| 'yellow'  | 'y'        | [1 1 0]     |
| 'magenta' | 'm'        | [1 0 1]     |
| 'cyan'    | 'c'        | [0 1 1]     |
| 'red'     | 'r'        | [1 0 0]     |
| 'green'   | 'g'        | [0 1 0]     |
| 'blue'    | 'b'        | [0 0 1]     |
| 'white'   | 'w'        | [1 1 1]     |
| 'black'   | 'k'        | [0 0 0]     |

Example: 'blue'

Example: [0 0 1]

### **FaceAlpha — Fill transparency**

1 (default) | value in range [0, 1]

Fill transparency, specified as a scalar value in the range [0, 1]. A value of 1 is opaque and 0 is completely transparent. Values between 0 and 1 are semitransparent.

Example: 0.5

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### LineStyle — Line style

'-' (default) | '--' | ':' | '-.' | 'none'

Line style, specified as one of the line style strings listed in this table.

| String | Line Style       | Resulting Line                                                                     |
|--------|------------------|------------------------------------------------------------------------------------|
| '-'    | Solid line       |  |
| '--'   | Dashed line      |  |
| ':'    | Dotted line      |  |
| '-.'   | Dash-dotted line |  |
| 'none' | No line          | No line                                                                            |

### LineWidth — Line width

0.5 (default) | positive value

Line width of rectangle outline, specified as a positive value in point units. One point equals 1/72 inch.

Example: 0.75

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

## Location and Size

### Position — Size and location

[0.3 0.3 0.1 0.1] (default) | four-element vector

Size and location, specified as a four-element vector of the form `[x y length height]`. The first two elements specify the coordinates of the lower left corner of the rectangle. The second two elements specify the length and height of the rectangle.

By default, the units are normalized to the figure. The lower-left corner of the figure maps to (0,0) and the upper-right corner maps to (1,1). To change the units, use the `Units` property.

Example: [0.2 0.3 0.4 0.5]

**Units — Position units**

'normalized' (default) | 'inches' | 'centimeters' | 'characters' | 'points' | 'pixels'

Position units, specified as one of the values in this table.

| Units                  | Description                                                                                                                                                                                                                                                                                                                                                                                          |
|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'normalized' (default) | Normalized with respect to the figure, uipanel, or uitab that contains the annotation. The lower-left corner of the container maps to (0,0) and the upper-right corner maps to (1,1).                                                                                                                                                                                                                |
| 'inches'               | Inches.                                                                                                                                                                                                                                                                                                                                                                                              |
| 'centimeters'          | Centimeters.                                                                                                                                                                                                                                                                                                                                                                                         |
| 'characters'           | Based on the default system font character size. <ul style="list-style-type: none"> <li>• Character width = width of letter x.</li> <li>• Character height = distance between the baselines of two lines of text.</li> </ul>                                                                                                                                                                         |
| 'points'               | Points. One point equals 1/72 inch.                                                                                                                                                                                                                                                                                                                                                                  |
| 'pixels'               | <p>Pixels.</p> <p>Starting in R2015b, distances in pixels are independent of your system resolution on Windows and Macintosh systems:</p> <ul style="list-style-type: none"> <li>• On Windows systems, a pixel is 1/96th of an inch.</li> <li>• On Macintosh systems, a pixel is 1/72nd of an inch.</li> </ul> <p>On Linux systems, the size of a pixel is determined by your system resolution.</p> |

All units are measured from the lower-left corner of the figure window.

This property affects the **Position** property. If you change the units, then it is good practice to return it to the default value after completing your computation to prevent affecting other functions that assume **Units** is set to the default value.

If you specify the **Position** and **Units** properties as **Name, Value** pairs when creating the annotation rectangle, then the order of specification matters. If you want to define the position with particular units, then you must set the **Units** property before the **Position** property.

## Annotation Text Arrow Properties

Control annotation text arrow appearance and behavior

Annotation text arrow properties control the appearance and behavior of an annotation text arrow object. By changing property values, you can modify certain aspects of the text arrow.

Starting in R2014b, you can use dot notation to query and set properties.

```
h = annotation('textarrow');
s = h.FontSize;
h.FontSize = 12;
```

If you are using an earlier release, use the `get` and `set` functions instead.

### Text

#### String — Text to display

' ' (default) | character array | cell array | numeric value

Text to display, specified as a character array, cell array, or numeric value.

Example: 'my label'

Example: {'first line', 'second line'}

Example: 123

To include numeric variables with text, use the `num2str` function. For example:

```
x = 42;
str = ['The value is ', num2str(x)];
```

To include special characters, such as superscripts, subscripts, Greek letters, or mathematical symbols use TeX markup. For a list of supported markup, see the `Interpreter` property.

To create multiline text:

- Use a cell array, where each cell contains a line of text, such as {'first line', 'second line'}.
- Use a character array, where each row contains the same number of characters, such as ['abc'; 'ab '].

- Use `sprintf` to create a string with a new line character, such as `sprintf('first line \n second line')`. This property converts strings with new line characters to cell arrays.

Text that contains only a numeric value is converted to a string using `sprintf('%g', value)`. For example, `12345678` displays as `1.23457e+07`.

---

**Note:** The words `default`, `factory`, and `remove` are reserved words that will not appear in text when quoted as a normal string. To display any of these words individually, precede them with a backslash, such as `'\default'` or `'\remove'`.

---

### Interpreter — Interpretation of text characters

'tex' (default) | 'latex' | 'none'

Interpretation of text characters, specified as one of these values:

- 'tex' — Interpret text strings using a subset of TeX markup.
- 'latex' — Interpret text strings using LaTeX markup.
- 'none' — Display literal characters.

## TeX Markup

By default, MATLAB supports a subset of TeX markup. Use TeX markup to add superscripts and subscripts, modify the text type and color, and include special characters in the text string.

This table lists the supported modifiers with the `Interpreter` property set to `'tex'`. Modifiers remain in effect until the end of the string. Superscripts and subscripts are an exception because they only modify the next character or the text within the curly braces `{}`.

| Modifier          | Description | Example of String                 |
|-------------------|-------------|-----------------------------------|
| <code>^{ }</code> | Superscript | <code>'text^{superscript}'</code> |
| <code>_{ }</code> | Subscript   | <code>'text_{subscript}'</code>   |
| <code>\bf</code>  | Bold font   | <code>'\bf text'</code>           |
| <code>\it</code>  | Italic font | <code>'\it text'</code>           |

| Modifier                            | Description                                                                                                                                       | Example of String                            |
|-------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------|
| <code>\sl</code>                    | Oblique font (usually the same as italic font)                                                                                                    | ' <code>\sl text</code> '                    |
| <code>\rm</code>                    | Normal font                                                                                                                                       | ' <code>\rm text</code> '                    |
| <code>\fontname{specifier}</code>   | Font name — Set <b>specifier</b> as the name of a font family. You can use this in combination with other modifiers.                              | ' <code>\fontname{Courier} text</code> '     |
| <code>\fontsize{specifier}</code>   | Font size — Set <b>specifier</b> as a numeric scalar value in point units to change the font size.                                                | ' <code>\fontsize{15} text</code> '          |
| <code>\color{specifier}</code>      | Font color — Set <b>specifier</b> as one of these colors: red, green, yellow, magenta, blue, black, white, gray, darkGreen, orange, or lightBlue. | ' <code>\color{magenta} text</code> '        |
| <code>\color[rgb]{specifier}</code> | Custom font color — Set <b>specifier</b> as a three-element RGB triplet.                                                                          | ' <code>\color[rgb]{0,0.5,0.5} text</code> ' |

This table lists the supported special characters with the `Interpreter` property set to `'tex'`.

| Character Sequence    | Symbol | Character Sequence    | Symbol | Character Sequence        | Symbol |
|-----------------------|--------|-----------------------|--------|---------------------------|--------|
| <code>\alpha</code>   | α      | <code>\upsilon</code> | υ      | <code>\sim</code>         | ~      |
| <code>\angle</code>   | ∠      | <code>\phi</code>     | Φ      | <code>\leq</code>         | ≤      |
| <code>\ast</code>     | *      | <code>\chi</code>     | χ      | <code>\infty</code>       | ∞      |
| <code>\beta</code>    | β      | <code>\psi</code>     | ψ      | <code>\clubsuit</code>    | ♣      |
| <code>\gamma</code>   | γ      | <code>\omega</code>   | ω      | <code>\diamondsuit</code> | ♦      |
| <code>\delta</code>   | δ      | <code>\Gamma</code>   | Γ      | <code>\heartsuit</code>   | ♥      |
| <code>\epsilon</code> | ε      | <code>\Delta</code>   | Δ      | <code>\spadesuit</code>   | ♠      |

| Character Sequence     | Symbol      | Character Sequence     | Symbol      | Character Sequence                | Symbol            |
|------------------------|-------------|------------------------|-------------|-----------------------------------|-------------------|
| <code>\zeta</code>     | $\zeta$     | <code>\Theta</code>    | $\Theta$    | <code>\leftrightsquigarrow</code> | $\leftrightarrow$ |
| <code>\eta</code>      | $\eta$      | <code>\Lambda</code>   | $\Lambda$   | <code>\leftarrow</code>           | $\leftarrow$      |
| <code>\theta</code>    | $\theta$    | <code>\Xi</code>       | $\Xi$       | <code>\Leftarrow</code>           | $\Leftarrow$      |
| <code>\vartheta</code> | $\vartheta$ | <code>\Pi</code>       | $\Pi$       | <code>\uparrow</code>             | $\uparrow$        |
| <code>\iota</code>     | $\iota$     | <code>\Sigma</code>    | $\Sigma$    | <code>\rightarrow</code>          | $\rightarrow$     |
| <code>\kappa</code>    | $\kappa$    | <code>\Upsilon</code>  | $\Upsilon$  | <code>\Rightarrow</code>          | $\Rightarrow$     |
| <code>\lambda</code>   | $\lambda$   | <code>\Phi</code>      | $\Phi$      | <code>\downarrow</code>           | $\downarrow$      |
| <code>\mu</code>       | $\mu$       | <code>\Psi</code>      | $\Psi$      | <code>\circ</code>                | $\circ$           |
| <code>\nu</code>       | $\nu$       | <code>\Omega</code>    | $\Omega$    | <code>\pm</code>                  | $\pm$             |
| <code>\xi</code>       | $\xi$       | <code>\forall</code>   | $\forall$   | <code>\geq</code>                 | $\geq$            |
| <code>\pi</code>       | $\pi$       | <code>\exists</code>   | $\exists$   | <code>\propto</code>              | $\propto$         |
| <code>\rho</code>      | $\rho$      | <code>\ni</code>       | $\ni$       | <code>\partial</code>             | $\partial$        |
| <code>\sigma</code>    | $\sigma$    | <code>\cong</code>     | $\cong$     | <code>\bullet</code>              | $\bullet$         |
| <code>\varsigma</code> | $\varsigma$ | <code>\approx</code>   | $\approx$   | <code>\div</code>                 | $\div$            |
| <code>\tau</code>      | $\tau$      | <code>\Re</code>       | $\Re$       | <code>\neq</code>                 | $\neq$            |
| <code>\equiv</code>    | $\equiv$    | <code>\oplus</code>    | $\oplus$    | <code>\aleph</code>               | $\aleph$          |
| <code>\Im</code>       | $\Im$       | <code>\cup</code>      | $\cup$      | <code>\wp</code>                  | $\wp$             |
| <code>\otimes</code>   | $\otimes$   | <code>\subseteq</code> | $\subseteq$ | <code>\oslash</code>              | $\oslash$         |
| <code>\cap</code>      | $\cap$      | <code>\in</code>       | $\in$       | <code>\supseteq</code>            | $\supseteq$       |
| <code>\supset</code>   | $\supset$   | <code>\lceil</code>    | $\lceil$    | <code>\subset</code>              | $\subset$         |
| <code>\int</code>      | $\int$      | <code>\cdot</code>     | $\cdot$     | <code>\o</code>                   | $\circ$           |
| <code>\rfloor</code>   | $\rfloor$   | <code>\neg</code>      | $\neg$      | <code>\nabla</code>               | $\nabla$          |
| <code>\lfloor</code>   | $\lfloor$   | <code>\times</code>    | $\times$    | <code>\ldots</code>               | $\dots$           |
| <code>\perp</code>     | $\perp$     | <code>\surd</code>     | $\surd$     | <code>\prime</code>               | $\prime$          |
| <code>\wedge</code>    | $\wedge$    | <code>\varpi</code>    | $\varpi$    | <code>\emptyset</code>            | $\emptyset$       |
| <code>\rceil</code>    | $\rceil$    | <code>\rangle</code>   | $\rangle$   | <code>\mid</code>                 | $ $               |
| <code>\vee</code>      | $\vee$      | <code>\langle</code>   | $\langle$   | <code>\copyright</code>           | $\copyright$      |

## LaTeX Markup

To use LaTeX markup, set the `Interpreter` property to `'latex'`. The displayed text uses the default LaTeX font style. The `FontName`, `FontWeight`, and `FontAngle` properties do not have an effect. To change the font style, use LaTeX markup within the text string.

The maximum size of the string that you can use with the LaTeX interpreter is 1200 characters. For multiline strings, this reduces by about 10 characters per line.

For more information about the LaTeX system, see The LaTeX Project Web site at <http://www.latex-project.org/>.

### **TextColor** — Text color

[0 0 0] (default) | RGB triplet | color string | 'none'

Text color, specified as a three-element RGB triplet, a color string, or `'none'`. The default RGB triplet value of [0 0 0] corresponds to black. If you set the color to `'none'`, then the text is invisible.

---

**Note:** Setting the `Color` property changes the `TextColor` property to the same value, unless you explicitly set the `TextColor` property.

---

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0, 1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

| Long Name | Short Name | RGB Triplet |
|-----------|------------|-------------|
| 'yellow'  | 'y'        | [1 1 0]     |
| 'magenta' | 'm'        | [1 0 1]     |
| 'cyan'    | 'c'        | [0 1 1]     |
| 'red'     | 'r'        | [1 0 0]     |
| 'green'   | 'g'        | [0 1 0]     |
| 'blue'    | 'b'        | [0 0 1]     |
| 'white'   | 'w'        | [1 1 1]     |

| Long Name | Short Name | RGB Triplet |
|-----------|------------|-------------|
| 'black'   | 'k'        | [0 0 0]     |

Example: 'blue'

Example: [0 0 1]

### **TextRotation** — Text rotation angle in degrees

0 (default) | scalar numeric value

Text rotation angle in degrees, specified as a scalar numeric value. Set this property to a positive value to rotate the text counterclockwise. Angles are absolute and not relative to previous rotations. A rotation of 0 degrees is always horizontal.

Example: 90

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical

## **Font Style**

### **FontAngle** — Character slant

'normal' (default) | 'italic'

Character slant, specified as 'normal' or 'italic'. Not all fonts have both font styles. Therefore, the italic font might look the same as the normal font.

---

**Note:** The 'oblique' value has been removed. Use 'italic' instead.

---

### **FontName** — Font name

'Helvetica' (default) | 'FixedWidth' | system supported font name

Font name, specified as the name of the font to use or the string 'FixedWidth'. To display and print properly, the font name must be a font that your system supports.

To use a fixed-width font that looks good in any locale, use the case-sensitive string 'FixedWidth'. The 'FixedWidth' value relies on the root FixedWidthFontName property. Setting the root FixedWidthFontName property causes an immediate update of the display to use the new font.

Example: 'Cambria'

**FontSize** — **Font size**

10 (default) | scalar value greater than 0

Font size, specified as a scalar value greater than 0 in point units. One point equals 1/72 inch. To change the font units, use the **FontUnits** property.

Example: 12

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical

**FontUnits** — **Font size units**

'points' (default) | 'inches' | 'centimeters' | 'characters' | 'normalized' | 'pixels'

Font size units, specified as one of the values in this table.

| <b>Units</b>  | <b>Description</b>                                                                                                                                                                                                          |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'points'      | Points. One point equals 1/72 inch.                                                                                                                                                                                         |
| 'inches'      | Inches.                                                                                                                                                                                                                     |
| 'centimeters' | Centimeters.                                                                                                                                                                                                                |
| 'characters'  | Based on the default system font character size. <ul style="list-style-type: none"><li>• Character width = width of letter x.</li><li>• Character height = distance between the baselines of two lines of text.</li></ul>   |
| 'normalized'  | Interpret font size as a fraction of the axes height. If you resize the axes, the font size modifies accordingly. For example, if the <b>FontSize</b> is 0.1 in normalized units, then the text is 1/10 of the axes height. |
| 'pixels'      | Pixels.<br><br>Starting in R2015b, distances in pixels are independent of your system resolution on Windows and Macintosh systems:                                                                                          |

| Units | Description                                                                                                                                                                                                                                                |
|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|       | <ul style="list-style-type: none"> <li>• On Windows systems, a pixel is 1/96th of an inch.</li> <li>• On Macintosh systems, a pixel is 1/72nd of an inch.</li> </ul> <p>On Linux systems, the size of a pixel is determined by your system resolution.</p> |

If you set both the font size and the font units in one function call, you must set the `FontUnits` property first so that the axes correctly interprets the specified font size.

### FontWeight — Thickness of text characters

'normal' (default) | 'bold'

Thickness of the text characters, specified as one of these values:

- 'normal' — Default weight as defined by the particular font
- 'bold' — Thicker character outlines than normal

MATLAB uses the `FontWeight` property to select a font from those available on your system. Not all fonts have a bold font weight. Therefore, specifying a bold font weight still can result in the normal font weight.

---

**Note:** The 'light' and 'demi' font weight values have been removed. Use 'normal' instead.

---

## Text Box

### TextLineWidth — Width of text box outline

0.5 (default) | scalar numeric value

Width of text box outline, specified as a scalar numeric value in point units. One point equals 1/72 inch.

Example: 1.5

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**TextEdgeColor — Color of text box outline**

'none' (default) | RGB triplet | color string

Color of text box outline, specified as 'none', a three-element RGB triplet, or a color string. If the color is 'none', the box outline is invisible.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0, 1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

| Long Name | Short Name | RGB Triplet |
|-----------|------------|-------------|
| 'yellow'  | 'y'        | [1 1 0]     |
| 'magenta' | 'm'        | [1 0 1]     |
| 'cyan'    | 'c'        | [0 1 1]     |
| 'red'     | 'r'        | [1 0 0]     |
| 'green'   | 'g'        | [0 1 0]     |
| 'blue'    | 'b'        | [0 0 1]     |
| 'white'   | 'w'        | [1 1 1]     |
| 'black'   | 'k'        | [0 0 0]     |

Example: 'blue'

Example: [0 0 1]

**TextBackgroundColor — Color of text box background**

'none' (default) | RGB triplet | color string

Color of text box background, specified as 'none', a three-element RGB triplet, or a color string. If the color is 'none', the background color is invisible.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0, 1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

| Long Name | Short Name | RGB Triplet |
|-----------|------------|-------------|
| 'yellow'  | 'y'        | [1 1 0]     |

| Long Name | Short Name | RGB Triplet |
|-----------|------------|-------------|
| 'magenta' | 'm'        | [ 1 0 1 ]   |
| 'cyan'    | 'c'        | [ 0 1 1 ]   |
| 'red'     | 'r'        | [ 1 0 0 ]   |
| 'green'   | 'g'        | [ 0 1 0 ]   |
| 'blue'    | 'b'        | [ 0 0 1 ]   |
| 'white'   | 'w'        | [ 1 1 1 ]   |
| 'black'   | 'k'        | [ 0 0 0 ]   |

Example: 'blue'

Example: [ 0 0 1 ]

### **TextMargin** — Space around text within text box

2 (default) | scalar numeric value

Space around the text within the text box, specified as a scalar numeric value in pixel units.

Example: 10

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical

## **Arrow**

### **Color** — Arrow color

[ 0 0 0 ] (default) | RGB triplet | color string | 'none'

Arrow color, specified as a three-element RGB triplet, a color string, or 'none'. The default RGB triplet value of [ 0 0 0 ] corresponds to black. If you set the color to 'none', then the arrow is invisible.

---

**Note:** Setting this property also changes the text color if you have not explicitly set the text color using the `TextColor` property.

---

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range

[0, 1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

| Long Name | Short Name | RGB Triplet |
|-----------|------------|-------------|
| 'yellow'  | 'y'        | [1 1 0]     |
| 'magenta' | 'm'        | [1 0 1]     |
| 'cyan'    | 'c'        | [0 1 1]     |
| 'red'     | 'r'        | [1 0 0]     |
| 'green'   | 'g'        | [0 1 0]     |
| 'blue'    | 'b'        | [0 0 1]     |
| 'white'   | 'w'        | [1 1 1]     |
| 'black'   | 'k'        | [0 0 0]     |

Example: 'blue'

Example: [0 0 1]

**LineStyle — Line style**

'-' (default) | '--' | ':' | '-.' | 'none'

Line style, specified as one of the line style strings listed in this table.

| String | Line Style       | Resulting Line                                                                       |
|--------|------------------|--------------------------------------------------------------------------------------|
| '-'    | Solid line       |  |
| '--'   | Dashed line      |  |
| ':'    | Dotted line      |  |
| '-.'   | Dash-dotted line |  |
| 'none' | No line          | No line                                                                              |

**LineWidth — Width of arrow stem**

0.5 (default) | scalar numeric value

Width of arrow stem, specified as a scalar numeric value greater than zero in point units. One point equals 1/72 inch. The default value is 0.5 points.

Example: 0.75

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**HeadStyle – Style of arrowhead**

'vback2' (default) | head style string

Style of the arrowhead, specified as one of the head style strings in this table.

| String             | Result                                                                              | String        | Result                                                                                |
|--------------------|-------------------------------------------------------------------------------------|---------------|---------------------------------------------------------------------------------------|
| 'plain'            |    | 'fourstar'    |    |
| 'ellipse'          |    | 'rectangle'   |    |
| 'vback1'           |    | 'diamond'     |    |
| 'vback2' (default) |    | 'rose'        |    |
| 'vback3'           |    | 'hypocycloid' |    |
| 'cback1'           |   | 'astroid'     |   |
| 'cback2'           |  | 'deltoid'     |  |
| 'cback3'           |  | 'none'        | No arrowhead                                                                          |

**HeadLength – Length of arrowhead**

10 (default) | scalar numeric value

Length of the arrowhead, specified as a scalar numeric value in point units. One point equals 1/72 inch.

Example: 15

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical

**HeadWidth — Width of arrowhead**

10 (default) | scalar numeric value

Width of the arrowhead, specified as a scalar numeric value in point units. One point equals 1/72 inch.

Example: 15

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

**Location and Size****X — Beginning and ending x-coordinates**

[0.3 0.4] (default) | two-element vector

Beginning and ending *x*-coordinates for the arrow, specified as a two-element vector of the form [`x_begin` `x_end`].

By default, the units are normalized to the figure. The lower-left corner of the figure maps to (0,0), and the upper-right corner maps to (1,1). To change the units, use the `Units` property.

Example: [0.2 0.3]

**Y — Beginning and ending y-coordinates**

[0.3 0.4] (default) | two-element vector

Beginning and ending *y*-coordinates for the arrow, specified as a two-element vector of the form [`y_begin` `y_end`].

By default, the units are normalized to the figure. The lower-left corner of the figure maps to (0,0), and the upper-right corner maps to (1,1). To change the units, use the `Units` property.

Example: [0.2 0.3]

**Position — Size and location**

[0.3 0.3 0.1 0.1] (default) | four-element vector

Size and location, specified as a four-element vector of the form [`x_begin` `y_begin` `length` `height`]. The first two elements specify the coordinates of the beginning of the

arrow. The second two elements specify the length and height of the arrow. The text box extends from the beginning of the arrow.

By default, the units are normalized to the figure. The lower-left corner of the figure maps to  $(0,0)$ , and the upper-right corner maps to  $(1,1)$ . To change the units, use the `Units` property.

Example: `[0.2 0.2 0.3 0.1]`

### Units — Position units

'normalized' (default) | 'inches' | 'centimeters' | 'characters' | 'points' | 'pixels'

Position units, specified as one of the values in this table.

| Units                  | Description                                                                                                                                                                                                                          |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'normalized' (default) | Normalized with respect to the figure, uipanel, or uitab that contains the annotation. The lower-left corner of the container maps to $(0,0)$ and the upper-right corner maps to $(1,1)$ .                                           |
| 'inches'               | Inches.                                                                                                                                                                                                                              |
| 'centimeters'          | Centimeters.                                                                                                                                                                                                                         |
| 'characters'           | Based on the default system font character size. <ul style="list-style-type: none"> <li>• Character width = width of letter x.</li> <li>• Character height = distance between the baselines of two lines of text.</li> </ul>         |
| 'points'               | Points. One point equals 1/72 inch.                                                                                                                                                                                                  |
| 'pixels'               | Pixels.<br>Starting in R2015b, distances in pixels are independent of your system resolution on Windows and Macintosh systems: <ul style="list-style-type: none"> <li>• On Windows systems, a pixel is 1/96th of an inch.</li> </ul> |

| Units | Description                                                                                                                                                                                 |
|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|       | <ul style="list-style-type: none"> <li>On Macintosh systems, a pixel is 1/72nd of an inch.</li> </ul> <p>On Linux systems, the size of a pixel is determined by your system resolution.</p> |

All units are measured from the lower-left corner of the figure window.

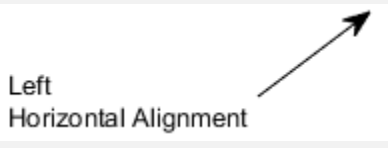

This property affects the **Position** property. If you change the units, then it is good practice to return it to the default value after completing your computation to prevent affecting other functions that assume **Units** is set to the default value.

If you specify the **Position** and **Units** properties as **Name, Value** pairs when creating the annotation text arrow, then the order of specification matters. If you want to define the position with particular units, then you must set the **Units** property before the **Position** property.

**HorizontalAlignment** — Horizontal alignment of text

'left' (default) | 'center' | 'right'

Horizontal alignment of the text, specified as one of the values in this table. This property is useful when aligning multiple lines of text.

| Value    | Result                                                                               |
|----------|--------------------------------------------------------------------------------------|
| 'left'   |  |
| 'center' |  |
| 'right'  |  |

**VerticalAlignment** — Vertical alignment of text with respect to arrow`'top'` (default) | `'cap'` | `'middle'` | `'baseline'` | `'bottom'`

Vertical alignment of the text with respect to the end of the arrow, specified as `'top'`, `'cap'`, `'middle'`, `'baseline'`, or `'bottom'`.

## Annotation Text Box Properties

Control annotation text box appearance and behavior

Annotation text box properties control the appearance and behavior of an annotation text box object. By changing property values, you can modify certain aspects of the text box.

Starting in R2014b, you can use dot notation to query and set properties.

```
t = annotation('textbox');
s = t.FontSize;
t.FontSize = 12;
```

If you are using an earlier release, use the `get` and `set` functions instead.

### Text

#### **String** – Text to display

' ' (default) | character array | cell array | numeric value

Text to display, specified as a character array, cell array, or numeric value.

Example: 'my label'

Example: {'first line', 'second line'}

Example: 123

To include numeric variables with text, use the `num2str` function. For example:

```
x = 42;
str = ['The value is ', num2str(x)];
```

To include special characters, such as superscripts, subscripts, Greek letters, or mathematical symbols use TeX markup. For a list of supported markup, see the `Interpreter` property.

To create multiline text:

- Use a cell array, where each cell contains a line of text, such as {'first line', 'second line'}.
- Use a character array, where each row contains the same number of characters, such as ['abc'; 'ab '].

- Use `sprintf` to create a string with a new line character, such as `sprintf('first line \n second line')`. This property converts strings with new line characters to cell arrays.

Text that contains only a numeric value is converted to a string using `sprintf('%g', value)`. For example, `12345678` displays as `1.23457e+07`.

---

**Note:** The words `default`, `factory`, and `remove` are reserved words that will not appear in text when quoted as a normal string. To display any of these words individually, precede them with a backslash, such as `'\default'` or `'\remove'`.

---

### Interpreter — Interpretation of text characters

'tex' (default) | 'latex' | 'none'

Interpretation of text characters, specified as one of these values:

- 'tex' — Interpret text strings using a subset of TeX markup.
- 'latex' — Interpret text strings using LaTeX markup.
- 'none' — Display literal characters.

## TeX Markup

By default, MATLAB supports a subset of TeX markup. Use TeX markup to add superscripts and subscripts, modify the text type and color, and include special characters in the text string.

This table lists the supported modifiers with the `Interpreter` property set to `'tex'`. Modifiers remain in effect until the end of the string. Superscripts and subscripts are an exception because they only modify the next character or the text within the curly braces `{}`.

| Modifier          | Description | Example of String                 |
|-------------------|-------------|-----------------------------------|
| <code>^{ }</code> | Superscript | <code>'text^{superscript}'</code> |
| <code>_{ }</code> | Subscript   | <code>'text_{subscript}'</code>   |
| <code>\bf</code>  | Bold font   | <code>'\bf text'</code>           |
| <code>\it</code>  | Italic font | <code>'\it text'</code>           |

| Modifier                            | Description                                                                                                                                       | Example of String                          |
|-------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------|
| <code>\sl</code>                    | Oblique font (usually the same as italic font)                                                                                                    | <code>'\sl text'</code>                    |
| <code>\rm</code>                    | Normal font                                                                                                                                       | <code>'\rm text'</code>                    |
| <code>\fontname{specifier}</code>   | Font name — Set <b>specifier</b> as the name of a font family. You can use this in combination with other modifiers.                              | <code>'\fontname{Courier} text'</code>     |
| <code>\fontsize{specifier}</code>   | Font size — Set <b>specifier</b> as a numeric scalar value in point units to change the font size.                                                | <code>'\fontsize{15} text'</code>          |
| <code>\color{specifier}</code>      | Font color — Set <b>specifier</b> as one of these colors: red, green, yellow, magenta, blue, black, white, gray, darkGreen, orange, or lightBlue. | <code>'\color{magenta} text'</code>        |
| <code>\color[rgb]{specifier}</code> | Custom font color — Set <b>specifier</b> as a three-element RGB triplet.                                                                          | <code>'\color[rgb]{0,0.5,0.5} text'</code> |

This table lists the supported special characters with the `Interpreter` property set to `'tex'`.

| Character Sequence    | Symbol     | Character Sequence    | Symbol     | Character Sequence        | Symbol         |
|-----------------------|------------|-----------------------|------------|---------------------------|----------------|
| <code>\alpha</code>   | $\alpha$   | <code>\upsilon</code> | $\upsilon$ | <code>\sim</code>         | $\sim$         |
| <code>\angle</code>   | $\angle$   | <code>\phi</code>     | $\Phi$     | <code>\leq</code>         | $\leq$         |
| <code>\ast</code>     | $*$        | <code>\chi</code>     | $\chi$     | <code>\infty</code>       | $\infty$       |
| <code>\beta</code>    | $\beta$    | <code>\psi</code>     | $\psi$     | <code>\clubsuit</code>    | $\clubsuit$    |
| <code>\gamma</code>   | $\gamma$   | <code>\omega</code>   | $\omega$   | <code>\diamondsuit</code> | $\diamondsuit$ |
| <code>\delta</code>   | $\delta$   | <code>\Gamma</code>   | $\Gamma$   | <code>\heartsuit</code>   | $\heartsuit$   |
| <code>\epsilon</code> | $\epsilon$ | <code>\Delta</code>   | $\Delta$   | <code>\spadesuit</code>   | $\spadesuit$   |

| Character Sequence     | Symbol      | Character Sequence     | Symbol      | Character Sequence                | Symbol            |
|------------------------|-------------|------------------------|-------------|-----------------------------------|-------------------|
| <code>\zeta</code>     | $\zeta$     | <code>\Theta</code>    | $\Theta$    | <code>\leftrightsquigarrow</code> | $\leftrightarrow$ |
| <code>\eta</code>      | $\eta$      | <code>\Lambda</code>   | $\Lambda$   | <code>\leftarrow</code>           | $\leftarrow$      |
| <code>\theta</code>    | $\theta$    | <code>\Xi</code>       | $\Xi$       | <code>\Leftarrow</code>           | $\Leftarrow$      |
| <code>\vartheta</code> | $\vartheta$ | <code>\Pi</code>       | $\Pi$       | <code>\uparrow</code>             | $\uparrow$        |
| <code>\iota</code>     | $\iota$     | <code>\Sigma</code>    | $\Sigma$    | <code>\rightarrow</code>          | $\rightarrow$     |
| <code>\kappa</code>    | $\kappa$    | <code>\Upsilon</code>  | $\Upsilon$  | <code>\Rightarrow</code>          | $\Rightarrow$     |
| <code>\lambda</code>   | $\lambda$   | <code>\Phi</code>      | $\Phi$      | <code>\downarrow</code>           | $\downarrow$      |
| <code>\mu</code>       | $\mu$       | <code>\Psi</code>      | $\Psi$      | <code>\circ</code>                | $\circ$           |
| <code>\nu</code>       | $\nu$       | <code>\Omega</code>    | $\Omega$    | <code>\pm</code>                  | $\pm$             |
| <code>\xi</code>       | $\xi$       | <code>\forall</code>   | $\forall$   | <code>\geq</code>                 | $\geq$            |
| <code>\pi</code>       | $\pi$       | <code>\exists</code>   | $\exists$   | <code>\propto</code>              | $\propto$         |
| <code>\rho</code>      | $\rho$      | <code>\ni</code>       | $\ni$       | <code>\partial</code>             | $\partial$        |
| <code>\sigma</code>    | $\sigma$    | <code>\cong</code>     | $\cong$     | <code>\bullet</code>              | $\bullet$         |
| <code>\varsigma</code> | $\varsigma$ | <code>\approx</code>   | $\approx$   | <code>\div</code>                 | $\div$            |
| <code>\tau</code>      | $\tau$      | <code>\Re</code>       | $\Re$       | <code>\neq</code>                 | $\neq$            |
| <code>\equiv</code>    | $\equiv$    | <code>\oplus</code>    | $\oplus$    | <code>\aleph</code>               | $\aleph$          |
| <code>\Im</code>       | $\Im$       | <code>\cup</code>      | $\cup$      | <code>\wp</code>                  | $\wp$             |
| <code>\otimes</code>   | $\otimes$   | <code>\subseteq</code> | $\subseteq$ | <code>\oslash</code>              | $\oslash$         |
| <code>\cap</code>      | $\cap$      | <code>\in</code>       | $\in$       | <code>\supseteq</code>            | $\supseteq$       |
| <code>\supset</code>   | $\supset$   | <code>\lceil</code>    | $\lceil$    | <code>\subset</code>              | $\subset$         |
| <code>\int</code>      | $\int$      | <code>\cdot</code>     | $\cdot$     | <code>\o</code>                   | $\o$              |
| <code>\rfloor</code>   | $\rfloor$   | <code>\neg</code>      | $\neg$      | <code>\nabla</code>               | $\nabla$          |
| <code>\lfloor</code>   | $\lfloor$   | <code>\times</code>    | $\times$    | <code>\ldots</code>               | $\dots$           |
| <code>\perp</code>     | $\perp$     | <code>\surd</code>     | $\surd$     | <code>\prime</code>               | $\prime$          |
| <code>\wedge</code>    | $\wedge$    | <code>\varpi</code>    | $\varpi$    | <code>\emptyset</code>            | $\emptyset$       |
| <code>\rceil</code>    | $\rceil$    | <code>\rangle</code>   | $\rangle$   | <code>\mid</code>                 | $\mid$            |
| <code>\vee</code>      | $\vee$      | <code>\langle</code>   | $\langle$   | <code>\copyright</code>           | $\copyright$      |

## LaTeX Markup

To use LaTeX markup, set the `Interpreter` property to `'latex'`. The displayed text uses the default LaTeX font style. The `FontName`, `FontWeight`, and `FontAngle` properties do not have an effect. To change the font style, use LaTeX markup within the text string.

The maximum size of the string that you can use with the LaTeX interpreter is 1200 characters. For multiline strings, this reduces by about 10 characters per line.

For more information about the LaTeX system, see The LaTeX Project Web site at <http://www.latex-project.org/>.

## Font Style

### Color — Text color

[0 0 0] (default) | RGB triplet | color string | 'none'

Text color, specified as a three-element RGB triplet, a color string, or `'none'`. The default RGB triplet value of [0 0 0] corresponds to black. If you set the color to `'none'`, then the text is invisible.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0, 1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

| Long Name | Short Name | RGB Triplet |
|-----------|------------|-------------|
| 'yellow'  | 'y'        | [1 1 0]     |
| 'magenta' | 'm'        | [1 0 1]     |
| 'cyan'    | 'c'        | [0 1 1]     |
| 'red'     | 'r'        | [1 0 0]     |
| 'green'   | 'g'        | [0 1 0]     |
| 'blue'    | 'b'        | [0 0 1]     |
| 'white'   | 'w'        | [1 1 1]     |
| 'black'   | 'k'        | [0 0 0]     |

Example: `'blue'`

Example: [0 0 1]

### FontAngle — Character slant

'normal' (default) | 'italic'

Character slant, specified as 'normal' or 'italic'. Not all fonts have both font styles. Therefore, the italic font might look the same as the normal font.

---

**Note:** The 'oblique' value has been removed. Use 'italic' instead.

---

### FontName — Font name

'Helvetica' (default) | 'FixedWidth' | system supported font name

Font name, specified as the name of the font to use or the string 'FixedWidth'. To display and print properly, the font name must be a font that your system supports.

To use a fixed-width font that looks good in any locale, use the case-sensitive string 'FixedWidth'. The 'FixedWidth' value relies on the root FixedWidthFontName property. Setting the root FixedWidthFontName property causes an immediate update of the display to use the new font.

Example: 'Cambria'

### FontSize — Font size

10 (default) | scalar value greater than 0

Font size, specified as a scalar value greater than 0 in point units. One point equals 1/72 inch. To change the font units, use the FontUnits property.

Example: 12

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical

### FontUnits — Font size units

'points' (default) | 'inches' | 'centimeters' | 'characters' | 'normalized' | 'pixels'

Font size units, specified as one of the values in this table.

| Units    | Description                         |
|----------|-------------------------------------|
| 'points' | Points. One point equals 1/72 inch. |

| <b>Units</b>  | <b>Description</b>                                                                                                                                                                                                                                                                                                                                                                     |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'inches'      | Inches.                                                                                                                                                                                                                                                                                                                                                                                |
| 'centimeters' | Centimeters.                                                                                                                                                                                                                                                                                                                                                                           |
| 'characters'  | Based on the default system font character size. <ul style="list-style-type: none"><li>• Character width = width of letter x.</li><li>• Character height = distance between the baselines of two lines of text.</li></ul>                                                                                                                                                              |
| 'normalized'  | Interpret font size as a fraction of the axes height. If you resize the axes, the font size modifies accordingly. For example, if the <code>FontSize</code> is 0.1 in normalized units, then the text is 1/10 of the axes height.                                                                                                                                                      |
| 'pixels'      | Pixels.<br><br>Starting in R2015b, distances in pixels are independent of your system resolution on Windows and Macintosh systems: <ul style="list-style-type: none"><li>• On Windows systems, a pixel is 1/96th of an inch.</li><li>• On Macintosh systems, a pixel is 1/72nd of an inch.</li></ul><br>On Linux systems, the size of a pixel is determined by your system resolution. |

If you set both the font size and the font units in one function call, you must set the `FontUnits` property first so that the axes correctly interprets the specified font size.

### **FontWeight** — Thickness of text characters

'normal' (default) | 'bold'

Thickness of the text characters, specified as one of these values:

- 'normal' — Default weight as defined by the particular font
- 'bold' — Thicker character outlines than normal

MATLAB uses the `FontWeight` property to select a font from those available on your system. Not all fonts have a bold font weight. Therefore, specifying a bold font weight still can result in the normal font weight.

---

**Note:** The `'light'` and `'demi'` font weight values have been removed. Use `'normal'` instead.

---

## Text Box

### LineStyle — Line style of box outline

`'-'` (default) | `'--'` | `':'` | `'-.'` | `'none'`

Line style of box outline, specified as one of the strings listed in this table.

| String              | Line Style               |
|---------------------|--------------------------|
| <code>'-'</code>    | Solid line               |
| <code>'--'</code>   | Dashed line              |
| <code>':'</code>    | Dotted line              |
| <code>'-.'</code>   | Dash-dotted line         |
| <code>'none'</code> | Box outline is invisible |

### LineWidth — Width of box outline

0.5 (default) | scalar numeric value

Width of box outline, specified as a scalar numeric value in point units. One point equals 1/72 inch.

Example: 1.5

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### EdgeColor — Color of box outline

`[0 0 0]` (default) | RGB triplet | color string | `'none'`

Color of box outline, specified as a three-element RGB triplet, a color string, or `'none'`. The default RGB triplet value of `[0 0 0]` corresponds to black. If you set the color to `'none'`, then the box outline is invisible.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range  $[0, 1]$ , for example,  $[0.4 \ 0.6 \ 0.7]$ . This table lists RGB triplet values that have equivalent color strings.

| Long Name | Short Name | RGB Triplet |
|-----------|------------|-------------|
| 'yellow'  | 'y'        | [ 1 1 0 ]   |
| 'magenta' | 'm'        | [ 1 0 1 ]   |
| 'cyan'    | 'c'        | [ 0 1 1 ]   |
| 'red'     | 'r'        | [ 1 0 0 ]   |
| 'green'   | 'g'        | [ 0 1 0 ]   |
| 'blue'    | 'b'        | [ 0 0 1 ]   |
| 'white'   | 'w'        | [ 1 1 1 ]   |
| 'black'   | 'k'        | [ 0 0 0 ]   |

Example: 'blue'

Example: [ 0 0 1 ]

### **BackgroundColor** — Color of text box background

'none' (default) | RGB triplet | color string

Color of text box background, specified as 'none', a three-element RGB triplet, or a color string. If you set the background color to 'none', then the background is invisible.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range  $[0, 1]$ , for example,  $[0.4 \ 0.6 \ 0.7]$ . This table lists RGB triplet values that have equivalent color strings.

| Long Name | Short Name | RGB Triplet |
|-----------|------------|-------------|
| 'yellow'  | 'y'        | [ 1 1 0 ]   |
| 'magenta' | 'm'        | [ 1 0 1 ]   |
| 'cyan'    | 'c'        | [ 0 1 1 ]   |
| 'red'     | 'r'        | [ 1 0 0 ]   |
| 'green'   | 'g'        | [ 0 1 0 ]   |

| Long Name | Short Name | RGB Triplet |
|-----------|------------|-------------|
| 'blue'    | 'b'        | [ 0 0 1 ]   |
| 'white'   | 'w'        | [ 1 1 1 ]   |
| 'black'   | 'k'        | [ 0 0 0 ]   |

Example: 'blue'

Example: [ 0 0 1 ]

### FaceAlpha — Transparency of background color

1 (default) | scalar value between 0 and 1 inclusive

Transparency of the background color, specified as a scalar value between 0 and 1. If the value is 1, then the color is opaque. To add transparency, set the property to a value closer to 0, where 0 is completely transparent.

### FitBoxToText — Option to fit box width and height to text

'on' (default) | 'off'

Option to fit the box width and height to the text, specified as one of these values:

- 'on' — Resize the text box to fit the text.
- 'off' — Wrap the text strings to fit the width of the text box. Wrapping can cause some of the text string to extend below the text box.

If you resize a text box when in plot edit mode, or if you change the `Position` property, then the `FitBoxToText` property changes to 'off'.

### Margin — Space around text within the text box

5 (default) | scalar numeric value

The space around the text within the text box, specified as a scalar numeric value in pixel units.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical

## Location and Size

### Position — Size and location

[ 0.3 0.3 0.1 0.1 ] (default) | four-element vector

Size and location, specified as a four-element vector of the form `[x_begin y_begin length height]`. The first two elements specify the coordinates for the lower-left corner of the text box. The second two elements specify the length and height of the text box.

By default, the units are normalized to the figure. The lower-left corner of the figure maps to `(0,0)`, and the upper-right corner maps to `(1,1)`. To change the units, use the `Units` property.

---

**Note:** If the `FitBoxToText` property is set to `'on'` and you change the `String` property, then the `Position` property might not reflect the latest changes until the next time the screen refreshes. To ensure that the position value reflects the latest changes, call `drawnow` before querying the position when working in a script or function.

---

Example: `[0.2 0.3 0.4 0.5]`

**Units — Position units**

`'normalized'` (default) | `'inches'` | `'centimeters'` | `'characters'` | `'points'` | `'pixels'`

Position units, specified as one of the values in this table.

| Units                               | Description                                                                                                                                                                                                                  |
|-------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>'normalized'</code> (default) | Normalized with respect to the figure, uipanel, or uitab that contains the annotation. The lower-left corner of the container maps to <code>(0,0)</code> and the upper-right corner maps to <code>(1,1)</code> .             |
| <code>'inches'</code>               | Inches.                                                                                                                                                                                                                      |
| <code>'centimeters'</code>          | Centimeters.                                                                                                                                                                                                                 |
| <code>'characters'</code>           | Based on the default system font character size. <ul style="list-style-type: none"> <li>• Character width = width of letter x.</li> <li>• Character height = distance between the baselines of two lines of text.</li> </ul> |
| <code>'points'</code>               | Points. One point equals 1/72 inch.                                                                                                                                                                                          |

| Units    | Description                                                                                                                                                                                                                                                                                                                                                                                          |
|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'pixels' | <p>Pixels.</p> <p>Starting in R2015b, distances in pixels are independent of your system resolution on Windows and Macintosh systems:</p> <ul style="list-style-type: none"> <li>• On Windows systems, a pixel is 1/96th of an inch.</li> <li>• On Macintosh systems, a pixel is 1/72nd of an inch.</li> </ul> <p>On Linux systems, the size of a pixel is determined by your system resolution.</p> |

All units are measured from the lower-left corner of the figure window.

This property affects the **Position** property. If you change the units, then it is good practice to return it to the default value after completing your computation to prevent affecting other functions that assume **Units** is set to the default value.

If you specify the **Position** and **Units** properties as **Name, Value** pairs when creating the annotation text box, then the order of specification matters. If you want to define the position with particular units, then you must set the **Units** property before the **Position** property.

#### **HorizontalAlignment** — Horizontal alignment of text within text box

'left' (default) | 'center' | 'right'

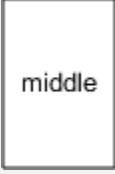

Horizontal alignment of the text within the text box, specified as one of the values in this table.

| Value    | Result                                                                               |
|----------|--------------------------------------------------------------------------------------|
| 'left'   |  |
| 'center' |  |
| 'right'  |  |

**VerticalAlignment** — Vertical alignment of text within text box

'top' (default) | 'middle' | 'bottom'

Vertical alignment of the text within the text box, specified as one of the values in this table.

| Value    | Result                                                                             |
|----------|------------------------------------------------------------------------------------|
| 'top'    |   |
| 'middle' |   |
| 'bottom' |  |

---

**Note:** The 'cap' and 'baseline' values are not recommended. Use the 'top' and 'bottom' values, respectively, instead.

## ans

Most recent answer

## Syntax

ans

## Description

The MATLAB software creates the `ans` variable automatically when you specify no output argument.

## Examples

The statement

```
2+2
```

is the same as

```
ans = 2+2
```

## See Also

`display`

**Introduced before R2006a**

## any

Determine if any array elements are nonzero

## Syntax

$B = \text{any}(A)$   
 $B = \text{any}(A, \text{dim})$

## Description

$B = \text{any}(A)$  tests along the first array dimension of  $A$  whose size does not equal 1, and determines if any element is a nonzero number or logical 1 (**true**). In practice, **any** is a natural extension of the logical OR operator.

- If  $A$  is a vector, then  $B = \text{any}(A)$  returns logical 1 (**true**) if any of the elements of  $A$  is a nonzero number or is logical 1, and returns logical 0 (**false**) if all the elements are zero.
- If  $A$  is a nonempty, nonvector matrix, then  $B = \text{any}(A)$  treats the columns of  $A$  as vectors, returning a row vector of logical 1s and 0s.
- If  $A$  is an empty 0-by-0 matrix,  $\text{any}(A)$  returns logical 0 (**false**).
- If  $A$  is a multidimensional array,  $\text{any}(A)$  acts along the first array dimension whose size does not equal 1 and returns an array of logical values. The size of this dimension becomes 1, while the sizes of all other dimensions remain the same.

$B = \text{any}(A, \text{dim})$  tests elements along dimension  $\text{dim}$ . The  $\text{dim}$  input is a positive integer scalar.

## Examples

### Test Matrix Columns

Create a 3-by-3 matrix.

```
A = [0 0 3;0 0 3;0 0 3]
```

```
A =
 0 0 3
 0 0 3
 0 0 3
```

Test each column for nonzero elements.

```
B = any(A)
```

```
B =
 0 0 1
```

### Reduce a Logical Vector to a Single Condition

Create a vector of decimal values and test which values are less than 0.5.

```
A = [0.53 0.67 0.01 0.38 0.07 0.42 0.69];
B = (A < 0.5)
```

```
B =
 0 0 1 1 1 1 0
```

The output is a vector of logical values. The `any` function reduces such a vector of logical values to a single condition. In this case, `B = any(A < 0.5)` yields logical 1.

This makes `any` particularly useful in `if` statements.

```
if any(A < 0.5)
 %do something
else
 %do something else
end
```

The code is executed depending on a single condition, rather than a vector of possibly conflicting conditions.

### Test Arrays of Any Dimension

Create a 3-by-7-by-5 multidimensional array and test to see if any of its elements are greater than 3.

```
A = rand(3,7,5) * 5;
```

```
B = any(A(:) > 3)
```

```
B =
```

```
1
```

You can also test the array for elements that are less than zero.

```
B = any(A(:) < 0)
```

```
B =
```

```
0
```

The syntax `A(:)` turns the elements of `A` into a single column vector, so you can use this type of statement on an array of any size.

## Test Matrix Rows

Create a 3-by-3 matrix.

```
A = [0 0 3;0 0 3;0 0 3]
```

```
A =
```

```
0 0 3
0 0 3
0 0 3
```

Test the rows of `A` for nonzero elements by specifying `dim = 2`.

```
B = any(A,2)
```

```
B =
```

```
1
```

```
1
```

```
1
```

## Input Arguments

### **A** — Input array

scalar | vector | matrix | multidimensional array

Input array, specified as a scalar, vector, matrix, or multidimensional array. The `any` function ignores elements of `A` that are NaN (Not a Number).

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char`

Complex Number Support: Yes

### **dim** – Dimension to operate along

positive integer scalar

Dimension to operate along, specified as a positive integer scalar. If no value is specified, then the default is the first array dimension whose size does not equal 1.

Consider a two-dimensional input array, `A`:

- `any(A,1)` works on successive elements in the columns of `A` and returns a row vector of logical values.
- `any(A,2)` works on successive elements in the rows of `A` and returns a column vector of logical values.

Data Types: `double` | `single` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

## Output Arguments

### **B** – Logical array

scalar | vector | matrix | multidimensional array

Logical array, returned as a scalar, vector, matrix, or multidimensional array. The dimension of `A` acted on by `any` has size 1 in `B`.

## area

Filled area 2-D plot

## Syntax

```
area(Y)
area(X,Y)
area(...,basevalue)
area(...,'PropertyName',PropertyValue,...)
area(axes_handle,...)
h = area(...)
```

## Description

An area graph displays elements in  $Y$  as one or more curves and fills the area beneath each curve. When  $Y$  is a matrix, the curves are stacked showing the relative contribution of each row element to the total height of the curve at each  $x$  interval.

`area(Y)` plots the vector  $Y$  or plots each column in matrix  $Y$  as a separate curve and stacks the curves. The  $x$ -axis automatically scales to `1:size(Y,1)`.

`area(X,Y)` For vectors  $X$  and  $Y$ , `area(X,Y)` is the same as `plot(X,Y)` except that the area between 0 and  $Y$  is filled. When  $Y$  is a matrix, `area(X,Y)` plots the columns of  $Y$  as filled areas. For each  $X$ , the net result is the sum of corresponding values from the rows of  $Y$ .

If  $X$  is a vector, `length(X)` must equal `length(Y)`. If  $X$  is a matrix, `size(X)` must equal `size(Y)`.

`area(...,basevalue)` specifies the base value for the area fill. The default `basevalue` is 0.

`area(..., 'PropertyName', PropertyValue, ...)` specifies property name and property value pairs for the patch graphics object created by `area`.

`area(axes_handle, ...)` plots into the axes with the handle `axes_handle` instead of into the current axes (`gca`).

`h = area(...)` returns handles of `area` graphics objects.

Creating an area graph of an  $m$ -by- $n$  matrix creates  $n$  area objects (that is, one per column), whereas a 1-by- $n$  vector creates one area object.

Some area object properties that you set on an individual area object set the values for all area objects in the graph. See Area Properties for information on specific properties.

## Examples

### Create Area Graph

Plot the data in matrix `Y` as an area graph.

```
Y = [1, 5, 3;
 3, 2, 7;
 1, 5, 3;
 2, 6, 1];
figure
area(Y)
```

### Adjust Base Value of Area Graph

By default, `area` uses the  $y$ -axis as the base value. Change the base value by setting the `basevalue` input argument to `-4`.

```
Y = [1, 5, 3;
 3, 2, 7;
 1, 5, 3;
 2, 6, 1];
figure
basevalue = -4;
area(Y,basevalue)
```

### Specify Color and Line Style for Area Plot

Create an area plot of Y and use a dotted line style. Return the three area objects in array h. The area function creates one area object for each column in Y.

```
Y = [1, 5, 3;
 3, 2, 7;
 1, 5, 3;
 2, 6, 1];
h = area(Y, 'LineStyle', ':');
```

Change the area colors using RGB triplet color values. Starting in R2014b, you can use dot notation to set properties. If you are using an earlier release, use the set function instead.

```
h(1).FaceColor = [0 0.25 0.25];
h(2).FaceColor = [0 0.5 0.5];
h(3).FaceColor = [0 0.75 0.75];
```

### Properties

[Area Properties](#)

**Introduced before R2006a**

## Area Properties

Control area appearance and behavior

Area properties control the appearance and behavior of an area object. By changing property values, you can modify certain aspects of the area.

Starting in R2014b, you can use dot notation to query and set properties.

```
a = area(1:10);
ec = a.EdgeColor;
a.EdgeColor = 'red';
```

If you are using an earlier release, use the `get` and `set` functions instead.

### Appearance

#### EdgeColor — Area outline color

[0 0 0] (default) | RGB triplet | color string | 'none' | 'flat'

Area outline color, specified as one of these values:

- 'none' — Do not draw the outline.
- 'flat' — Use colors from the axes colormap.
- RGB triplet or a color string — Specify a custom color. The default RGB triplet value of [0 0 0] corresponds to black.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0, 1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

| Long Name | Short Name | RGB Triplet |
|-----------|------------|-------------|
| 'yellow'  | 'y'        | [1 1 0]     |
| 'magenta' | 'm'        | [1 0 1]     |
| 'cyan'    | 'c'        | [0 1 1]     |
| 'red'     | 'r'        | [1 0 0]     |
| 'green'   | 'g'        | [0 1 0]     |

| Long Name | Short Name | RGB Triplet |
|-----------|------------|-------------|
| 'blue'    | 'b'        | [0 0 1]     |
| 'white'   | 'w'        | [1 1 1]     |
| 'black'   | 'k'        | [0 0 0]     |

Example: 'blue'

Example: [0 0 1]

### FaceColor — Area fill color

'flat' (default) | 'none' | RGB triplet | color string

Area fill color, specified as one of these values:

- 'flat' — Use colors from the axes colormap.
- 'none' — Do not use any color for the fill, which allows the background to show through.
- RGB triplet or a color string — Specify a custom color.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0, 1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

| Long Name | Short Name | RGB Triplet |
|-----------|------------|-------------|
| 'yellow'  | 'y'        | [1 1 0]     |
| 'magenta' | 'm'        | [1 0 1]     |
| 'cyan'    | 'c'        | [0 1 1]     |
| 'red'     | 'r'        | [1 0 0]     |
| 'green'   | 'g'        | [0 1 0]     |
| 'blue'    | 'b'        | [0 0 1]     |
| 'white'   | 'w'        | [1 1 1]     |
| 'black'   | 'k'        | [0 0 0]     |

### EdgeAlpha — Edge transparency

1 (default) | scalar in range [0, 1]

Edge transparency, specified as a scalar in the range [0, 1]. A value of 1 is opaque and 0 is completely transparent. Values between 0 and 1 are semitransparent.

Example: `a.EdgeAlpha = 0.5;`

**FaceAlpha — Face transparency**

1 (default) | scalar in range [0, 1]

Face transparency, specified as a scalar in the range [0, 1]. A value of 1 is opaque and 0 is completely transparent. Values between 0 and 1 are semitransparent.

Example: `a.FaceAlpha = 0.5;`

**LineStyle — Line style**

'-' (default) | '--' | ':' | '-.' | 'none'

Line style, specified as one of the line style strings listed in this table.

| String | Line Style       | Resulting Line                                                                       |
|--------|------------------|--------------------------------------------------------------------------------------|
| '-'    | Solid line       |    |
| '--'   | Dashed line      |    |
| ':'    | Dotted line      |    |
| '-.'   | Dash-dotted line |  |
| 'none' | No line          | No line                                                                              |

**LineWidth — Area outline width**

0.5 (default) | scalar numeric value

Area outline width, specified as a scalar numeric value in point units. One point equals 1/72 inch.

Example: `1.5`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**AlignVertexCenters — Sharp vertical and horizontal lines**

'off' (default) | 'on'

Sharp vertical and horizontal lines, specified as 'off' or 'on'.

If the associated figure has a `GraphicsSmoothing` property set to `'on'` and a `Renderer` property set to `'opengl'`, then the figure applies a smoothing technique to plots. In some cases, this smoothing technique can cause vertical and horizontal lines to appear uneven in thickness or color. Use the `AlignVertexCenters` property to eliminate the uneven appearance.

- `'off'` — Do not sharpen vertical or horizontal lines. The lines might appear uneven in thickness or color.
- `'on'` — Sharpen vertical and horizontal lines to eliminate an uneven appearance.

---

**Note:** You must have a graphics card that supports this feature. To see if the feature is supported, type `opengl info`. If it is supported, then the returned fields contain the line `SupportsAlignVertexCenters: 1`.

---

## Baseline

### **BaseLine** — Baseline

baseline object

This property is read only.

Baseline object. For a list of baseline properties, see [Baseline Properties](#).

### **BaseValue** — Baseline location

0 (default) | numeric scalar value

Baseline location, specified as a numeric scalar value.

### **ShowBaseLine** — Baseline visibility

'on' (default) | 'off'

Baseline visibility, specified as one of these values:

- `'on'` — Show the baseline.
- `'off'` — Hide the baseline.

## Data

### **XData** — Values along x-axis

[] (default) | vector

Values along *x*-axis, specified as a vector. The input argument `X` to the `area` function determines the *x*-values. If you do not specify `X`, then `area` uses the indices of the values in `YData` to set the *x*-values. `XData` and `YData` must have equal lengths.

Setting this property sets the associate mode property `XDataMode` to manual.

Example: `1:10`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **YData — Values along *y*-axis**

`[]` (default) | vector

Values along *y*-axis, specified as a vector. The input argument `Y` to the `area` function determines the *y*-values. `XData` and `YData` must have equal lengths.

Example: `1:10`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **XDataSource — Variable linked to XData**

`''` (default) | string containing MATLAB workspace variable name

Variable linked to `XData`, specified as a string containing a MATLAB workspace variable name. MATLAB evaluates the variable in the base workspace to generate the `XData`.

By default, there is no linked variable so the value is an empty string, `''`. If you link a variable, then MATLAB does not update the `XData` values immediately. To force an update of the data values, use the `refreshdata` function.

---

**Note:** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

Example: `'x'`

### **YDataSource — Variable linked to YData**

`''` (default) | string containing MATLAB workspace variable name

Variable linked to `YData`, specified as a string containing a MATLAB workspace variable name. MATLAB evaluates the variable in the base workspace to generate the `YData`.

By default, there is no linked variable so the value is an empty string, ''. If you link a variable, then MATLAB does not update the `YData` values immediately. To force an update of the data values, use the `refreshdata` function.

---

**Note:** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

Example: 'y'

### **XDataMode — Selection mode for XData**

'auto' (default) | 'manual'

Selection mode for `XData`, specified as one of these values:

- 'auto' — Use the indices of the values in `YData`.
- 'manual' — Use manually specified values. To specify the values, set the `XData` property or pass the input argument `X` to the `area` function.

## **Visibility**

### **Visible — State of visibility**

'on' (default) | 'off'

State of visibility, specified as one of these values:

- 'on' — Display the area.
- 'off' — Hide the area without deleting it. You still can access the properties of an invisible area object.

### **Clipping — Clipping of area object to axes limits**

'on' (default) | 'off'

Clipping of the area object to the axes limits, specified as one of these values:

- 'on' — Do not display parts of the area object that are outside the axes limits.
- 'off' — Display the entire area object, even if parts of it appear outside the axes limits. Parts of the area object might appear outside the axes limits if you create a

plot, set `hold` on, freeze the axis scaling, and then create the area object so that it is larger than the original plot.

The `Clipping` property of the axes that contains the area object must be set to `'on'`, otherwise this property has no effect. For more information about the clipping behavior, see the `Clipping` property of the axes.

**EraseMode — (removed) Technique to draw and erase objects**

`'normal'` (default) | `'none'` | `'xor'` | `'background'`

---

**Note:** `EraseMode` has been removed. You can delete code that accesses the `EraseMode` property with minimal impact. If you were using `EraseMode` to create line animations, use the `animatedline` function instead.

---

Technique to draw and erase objects, specified as one of these values:

- `'normal'` — Redraw the affected region of the display, performing the three-dimensional analysis necessary to correctly render all objects. This mode produces the most accurate picture, but is the slowest. The other modes are faster, but do not perform a complete redraw and, therefore, are less accurate.
- `'none'` — Do not erase the object when it is moved or destroyed. After you erase the object with `EraseMode`, `'none'`, it is still visible on the screen. However, you cannot print the object because MATLAB does not store any information on its former location.
- `'xor'` — Draw and erase the object by performing an exclusive OR (XOR) with the color of the screen beneath it. This mode does not damage the color of the objects beneath it. However, the object color depends on the color of whatever is beneath it on the display.
- `'background'` — Erase the object by redrawing it in the axes background color, or the figure background color if the axes `COLOR` property is `'none'`. This damages objects that are behind the erased object, but properly colors the erased object.

MATLAB always prints figures as if the `EraseMode` property of all objects is set to `'normal'`. This means graphics objects created with `EraseMode` set to `'none'`, `'xor'`, or `'background'` can look different on screen than on paper. On screen, MATLAB mathematically combines layers of colors and ignores three-dimensional sorting to obtain greater rendering speed. However, MATLAB does not apply these techniques to the printed output. Use the `getframe` command or other screen capture applications to create an image of a figure containing nonnormal mode objects.

## Identifiers

### Type — Type of graphics object

'area'

This property is read only.

Type of graphics object, returned as 'area'. Use this property to find all objects of a given type within a plotting hierarchy, for example, searching for the type using `findobj`.

### Tag — Tag to associate with area

'' (default) | string

Tag to associate with the area, specified as a string. Tags provide a way to identify graphics objects. Use this property to find all objects with a specific tag within a plotting hierarchy, for example, searching for the tag using `findobj`.

Example: 'January Data'

Data Types: char

### UserData — Data to associate with area

[] (default) | scalar, vector, or matrix | cell array | character array | table | structure

Data to associate with the area object, specified as a scalar, vector, matrix, cell array, character array, table, or structure. MATLAB does not use this data.

To associate multiple sets of data or to attach a field name to the data, use the `getappdata` and `setappdata` functions.

Example: 1:100

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical | char | struct | table | cell

### DisplayName — Text used by legend

'' (default) | string

Text used by the legend, specified as a string. The text appears next to an icon of the area.

Example: 'Text Description'

For multiline text, create the string using `sprintf` with the new line character `\n`.

Example: `fprintf('line one\nline two')`

Alternatively, you can specify the legend text using the `legend` function.

- If you specify the text as an input argument to the `legend` function, then the legend uses the specified text and sets the `DisplayName` property to the same value.
- If you do not specify the text as an input argument to the `legend` function, then the legend uses the text in the `DisplayName` property. If the `DisplayName` property does not contain any text, then the legend generates a string. The string has the form `'dataN'`, where N is the number assigned to the area object based on its location in the list of legend entries.

If you edit interactively the string in an existing legend, then MATLAB updates the `DisplayName` property to the edited string.

### **Annotation — Legend icon display style**

Annotation object

This property is read only.

Legend icon display style, returned as an `Annotation` object. Use this object to include or exclude the area from a legend.

- 1 Query the `Annotation` property to get the `Annotation` object.
- 2 Query the `LegendInformation` property of the `Annotation` object to get the `LegendEntry` object.
- 3 Specify the `IconDisplayStyle` property of the `LegendEntry` object to one of these values:
  - `'on'` — Include the area object in the legend as one entry (default).
  - `'off'` — Do not include the area object in the legend.
  - `'children'` — Include only children of the area object as separate entries in the legend.

If a legend already exists and you change the `IconDisplayStyle` setting, then you must call `legend` to update the display.

## **Parent/Child**

### **Parent — Parent of area**

axes object | group object | transform object

Parent of area, specified as an axes, group, or transform object.

### **Children — Children of area**

empty `GraphicsPlaceholder` array

The area has no children. You cannot set this property.

### **HandleVisibility — Visibility of object handle**

'on' (default) | 'off' | 'callback'

Visibility of area object handle in the `Children` property of the parent, specified as one of these values:

- 'on' — The area object handle is always visible.
- 'off' — The area object handle is invisible at all times. This option is useful for preventing unintended changes to the UI by another function. Set the `HandleVisibility` to 'off' to temporarily hide the handle during the execution of that function.
- 'callback' — The area object handle is visible from within callbacks or functions invoked by callbacks, but not from within functions invoked from the command line. This option blocks access to the area at the command-line, but allows callback functions to access it.

If the area object is not listed in the `Children` property of the parent, then functions that obtain object handles by searching the object hierarchy or querying handle properties cannot return it. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

Hidden object handles are still valid. Set the root `ShowHiddenHandles` property to 'on' to list all object handles regardless of their `HandleVisibility` property setting.

## **Interactive Control**

### **ButtonDownFcn — Mouse-click callback**

' ' (default) | function handle | cell array | string

Mouse-click callback, specified as one of these values:

- Function handle

- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you click the area. If you specify this property using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The area object — You can access properties of the area object from within the callback function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see “Callback Definition”.

---

**Note:** If the `PickableParts` property is set to 'none' or if the `HitTest` property is set to 'off', then this callback does not execute.

---

Example: `@myCallback`

Example: `{@myCallback, arg3}`

## **UIContextMenu — Context menu**

`uicontextmenu` object

Context menu, specified as a `uicontextmenu` object. Use this property to display a context menu when you right-click the area. Create the context menu using the `uicontextmenu` function.

---

**Note:** If the `PickableParts` property is set to 'none' or if the `HitTest` property is set to 'off', then the context menu does not appear.

---

## **Selected — Selection state**

'off' (default) | 'on'

Selection state, specified as one of these values:

- 'on' — Selected. If you click the area when in plot edit mode, then MATLAB sets its **Selected** property to 'on'. If the **SelectionHighlight** property also is set to 'on', then MATLAB displays selection handles around the area.
- 'off' — Not selected.

### **SelectionHighlight** — Display of selection handles when selected

'on' (default) | 'off'

Display of selection handles when selected, specified as one of these values:

- 'on' — Display selection handles when the **Selected** property is set to 'on'.
- 'off' — Never display selection handles, even when the **Selected** property is set to 'on'.

## **Callback Execution Control**

### **PickableParts** — Ability to capture mouse clicks

'visible' (default) | 'none'

Ability to capture mouse clicks, specified as one of these values:

- 'visible' — Can capture mouse clicks only when visible. The **Visible** property must be set to 'on'. The **HitTest** property determines if the area responds to the click or if an ancestor does.
- 'none' — Cannot capture mouse clicks. Clicking the area passes the click to the object below it in the current view of the figure window. The **HitTest** property of the area has no effect.

### **HitTest** — Response to captured mouse clicks

'on' (default) | 'off'

Response to captured mouse clicks, specified as one of these values:

- 'on' — Trigger the **ButtonDownFcn** callback of the area. If you have defined the **UIContextMenu** property, then invoke the context menu.
- 'off' — Trigger the callbacks for the nearest ancestor of the area that has a **HitTest** property set to 'on' and a **PickableParts** property value that enables the ancestor to capture mouse clicks.

---

**Note:** The `PickableParts` property determines if the area object can capture mouse clicks. If it cannot, then the `HitTest` property has no effect.

---

**HitTestArea** — (removed) Extents of clickable area for area  
'off' (default) | 'on'

---

**Note:** `HitTestArea` has been removed. Use `PickableParts` instead.

---

Extents of clickable area for area, specified as one of these values:

- 'off' — Click the area plot to select it. This is the default value.
- 'on' — Click anywhere within the extent of the area plot to select it, that is, anywhere within the rectangle that encloses the area plot.

Example: 'off'

**Interruptible** — Callback interruption  
'on' (default) | 'off'

Callback interruption, specified as 'on' or 'off'. The `Interruptible` property determines if a running callback can be interrupted.

---

**Note:** There are two callback states to consider:

- The *running* callback is the currently executing callback.
  - The *interrupting* callback is a callback that tries to interrupt the running callback. Whenever MATLAB invokes a callback, that callback attempts to interrupt a running callback. The `Interruptible` property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the `BusyAction` property of the object owning the interrupting callback determines if it is discarded or put in the queue.
- 

If the `ButtonDownFcn` callback of the area is the running callback, then the `Interruptible` property determines if it another callback can interrupt it:

- 'on' — Interruptible. Interruption occurs at the next point where MATLAB processes the queue, such as when there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command.
  - If the running callback contains one of these commands, then MATLAB stops the execution of the callback at this point and executes the interrupting callback. MATLAB resumes executing the running callback when the interrupting callback completes. For more information, see “Interrupt Callback Execution”.
  - If the running callback does not contain one of these commands, then MATLAB finishes executing the callback without interruption.
- 'off' — Not interruptible. MATLAB finishes executing the running callback without any interruptions.

**BusyAction — Callback queuing**`'queue'` (default) | `'cancel'`

Callback queuing specified as `'queue'` or `'cancel'`. The `BusyAction` property determines how MATLAB handles the execution of interrupting callbacks.

---

**Note:** There are two callback states to consider:

- The *running* callback is the currently executing callback.
- The *interrupting* callback is a callback that tries to interrupt the running callback.

Whenever MATLAB invokes a callback, that callback attempts to interrupt a running callback. The `Interruptible` property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the `BusyAction` property of the object owning the interrupting callback determines if it is discarded or put in the queue.

---

If the `ButtonDownFcn` callback of the area tries to interrupt a running callback that cannot be interrupted, then the `BusyAction` property determines if it is discarded or put in the queue. Specify the `BusyAction` property as one of these values:

- 'queue' — Put the interrupting callback in a queue to be processed after the running callback finishes execution. This is the default behavior.
- 'cancel' — Discard the interrupting callback.

## Creation and Deletion Control

### **CreateFcn** — Creation callback

' ' (default) | function handle | cell array | string

Creation callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you create the area. Setting the `CreateFcn` property on an existing area has no effect. You must define a default value for this property, or define this property using a `Name, Value` pair during area creation. MATLAB executes the callback after creating the area and setting all of its properties.

If you specify this callback using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The area object — You can access properties of the area object from within the callback function. You also can access the area object through the `CallbackObject` property of the root, which can be queried using the `gcbo` function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see “Callback Definition”.

Example: `@myCallback`

Example: `{@myCallback, arg3}`

### **DeleteFcn** — Deletion callback

' ' (default) | function handle | cell array | string

Deletion callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you delete the area. MATLAB executes the callback before destroying the area so that the callback can access its property values.

If you specify this callback using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The area object — You can access properties of the area object from within the callback function. You also can access the area object through the `CallbackObject` property of the root, which can be queried using the `gcb0` function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see “Callback Definition”.

Example: `@myCallback`

Example: `{@myCallback, arg3}`

### **BeingDeleted** — Deletion status of area

'off' (default) | 'on'

This property is read only.

Deletion status of area, returned as 'on' or 'off'. MATLAB sets the `BeingDeleted` property to 'on' when the delete function of the area begins execution (see the `DeleteFcn` property). The `BeingDeleted` property remains set to 'on' until the area no longer exists.

Check the value of the `BeingDeleted` property to verify that the area is not about to be deleted before querying or modifying it.

## array2table

Convert homogeneous array to table

### Syntax

```
T = array2table(A)
T = array2table(A,Name,Value)
```

### Description

`T = array2table(A)` converts the  $m$ -by- $n$  array, `A`, to an  $m$ -by- $n$  table, `T`. Each column of `A` becomes a variable in `T`.

`array2table` uses the input array name appended with the column number for the variable names in the table. If these names are not valid MATLAB identifiers, `array2table` uses strings of the form `'Var1'`, ..., `'VarN'`, where  $N$  is the number of columns in `A`.

`T = array2table(A,Name,Value)` creates a table from an array, `A`, with additional options specified by one or more `Name,Value` pair arguments.

For example, you can specify row names or variable names to include in the table.

### Examples

#### Convert Numeric Array to Table

Create an array of numeric data.

```
A = [1 4 7; 2 5 8; 3 6 9]
```

```
A =
```

```
 1 4 7
 2 5 8
```

```

3 6 9

```

Convert the array, A, to a table.

```
T = array2table(A)
```

```
T =
```

```

A1 A2 A3
— — —
1 4 7
2 5 8
3 6 9

```

The table has variable names that append the column number to the input array name, A.

### Convert Array to Table Including Variable Names

Create an array of numeric data.

```
A = [1 12 30.48; 2 24 60.96; 3 36 91.44]
```

```
A =
```

```

1.0000 12.0000 30.4800
2.0000 24.0000 60.9600
3.0000 36.0000 91.4400

```

Convert the array, A, to a table and include variable names.

```
T = array2table(A, ...
 'VariableNames', {'Feet' 'Inches' 'Centimeters'})
```

```
T =
```

```

Feet Inches Centimeters
— — —
1 12 30.48
2 24 60.96
3 36 91.44

```

- “Access Data in a Table”

## Input Arguments

### **A** — Input array

matrix

Input array, specified as a matrix.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char` | `struct` | `cell`

Complex Number Support: Yes

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1`, `Value1`, ..., `NameN`, `ValueN`.

Example: `'RowNames', {'row1', 'row2', 'row3'}` uses the row names, `row1`, `row2`, and `row3` for the table, `T`.

### **'RowNames'** — Row names for `T`

`{}` (default) | cell array of nonempty, distinct strings

Row names for `T`, specified as the comma-separated pair consisting of `'RowNames'` and a cell array of nonempty, distinct strings. The number of strings must equal the number of rows, `size(A,1)`.

### **'VariableNames'** — Variable names for `T`

cell array of nonempty, distinct strings

Variable names for `T`, specified as the comma-separated pair consisting of `'VariableNames'` and a cell array of nonempty, distinct strings. The number of strings must equal the number of variables, `size(A,2)`.

Furthermore, the strings must be valid MATLAB identifiers. If valid MATLAB identifiers are not available for use as variable names, MATLAB uses a cell array of  $N$  strings of the form `{'Var1' ... 'VarN'}` where  $N$  is the number of variables. You can determine valid MATLAB variable names using the function `isvarname`.

## Output Arguments

### **T** — Output table

table

Output table, returned as a table. The table can store metadata such as descriptions, variable units, variable names, and row names. For more information, see [Table Properties](#).

## More About

### Tips

- If **A** is a cell array, use `cell2table(A)` to create a table from the contents of the cells in **A**. Each variable in the table is numeric or a cell array of strings. `array2table(A)` creates a table where each variable is a column of cells.

**Introduced in R2013b**

# arrayfun

Apply function to each element of array

## Syntax

```
[B1,...,Bm] = arrayfun(func,A1,...,An)
[B1,...,Bm] = arrayfun(func,A1,...,An,Name,Value)
```

## Description

`[B1,...,Bm] = arrayfun(func,A1,...,An)` calls the function specified by function handle `func` and passes elements from arrays `A1,...,An`, where `n` is the number of inputs to function `func`. Output arrays `B1,...,Bm`, where `m` is the number of outputs from function `func`, contain the combined outputs from the function calls. The *i*th iteration corresponds to the syntax `[B1(i),...,Bm(i)] = func(A1(i),...,An(i))`. The `arrayfun` function does not perform the calls to function `func` in a specific order.

`[B1,...,Bm] = arrayfun(func,A1,...,An,Name,Value)` calls function `func` with additional options specified by one or more `Name,Value` pair arguments. Possible values for `Name` are 'UniformOutput' or 'ErrorHandler'.

## Input Arguments

### **func**

Handle to a function that accepts `n` input arguments and returns `m` output arguments.

If function `func` corresponds to more than one function file (that is, if `func` represents a set of overloaded functions), MATLAB determines which function to call based on the class of the input arguments.

### **A1,...,An**

Arrays that contain the `n` inputs required for function `func`. Each array must have the same dimensions. Arrays can be numeric, character, logical, cell, structure, or user-defined object arrays.

If any input **A** is a user-defined object array, and you overloaded the **subsref** or **size** methods, **arrayfun** requires that:

- The **size** method returns an array of type **double**.
- The object array supports linear indexing.
- The product of the sizes returned by the **size** method does not exceed the limit of the array, as defined by linear indexing into the array.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as **Name1**, **Value1**, ..., **NameN**, **ValueN**.

### 'UniformOutput'

Logical value, as follows:

|                  |                                                                                                                                                                                                                                                                                                                                                                                               |
|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>true</b> (1)  | Indicates that for all inputs, each output from function <b>func</b> is a scalar cell array, scalar structure, or scalar value that is always of the same type and size. The <b>arrayfun</b> function combines the outputs in arrays <b>B1</b> , ..., <b>Bm</b> , where <b>m</b> is the number of function outputs. Each output array is of the same type as the individual function outputs. |
| <b>false</b> (0) | Requests that the <b>arrayfun</b> function combine the outputs into cell arrays <b>B1</b> , ..., <b>Bm</b> . The outputs of function <b>func</b> can be of any size or type.                                                                                                                                                                                                                  |

**Default:** true

### 'ErrorHandler'

Handle to a function that catches any errors that occur when MATLAB attempts to execute function **func**. Define this function so that it rethrows the error or returns valid outputs for function **func**.

MATLAB calls the specified error-handling function with two input arguments:

- A structure with these fields:

|                   |                   |
|-------------------|-------------------|
| <b>identifier</b> | Error identifier. |
|-------------------|-------------------|

|         |                                                                                             |
|---------|---------------------------------------------------------------------------------------------|
| message | Error message text.                                                                         |
| index   | Linear index corresponding to the element of the input cell array at the time of the error. |

- The set of input arguments to function `func` at the time of the error.

## Output Arguments

**B<sub>1</sub>, . . . , B<sub>m</sub>**

Arrays that collect the  $m$  outputs from function `func`. Each array `B` is the same size as each of the inputs `A1, . . . , An`.

Function `func` can return output arguments of different classes. However, if `UniformOutput` is `true` (the default):

- The individual outputs from function `func` must be scalar values (numeric, logical, or character), scalar structures, or scalar cell arrays.
- The class of a particular output argument must be the same for each set of inputs. The class of the corresponding output array is the same as the class of the outputs from function `func`.

## Examples

To run the examples in this section, create a nonscalar structure array with arrays of different sizes in field `f1`.

```
s(1).f1 = rand(3, 6);
s(2).f1 = magic(12);
s(3).f1 = ones(5, 10);
```

Count the number of elements in each `f1` field.

```
counts = arrayfun(@(x) numel(x.f1), s)
```

The syntax `@(x)` creates an anonymous function. This code returns

```
counts =
 18 144 50
```

Compute the size of each array in the `f1` fields.

```
[nrows, ncols] = arrayfun(@(x) size(x.f1), s)
```

This code returns

```
nrows =
 3 12 5
ncols =
 6 12 10
```

Compute the mean of each column in the `f1` fields of `s`. Because the output is nonscalar, set `UniformOutput` to `false`.

```
averages = arrayfun(@(x) mean(x.f1), s, 'UniformOutput', false)
```

This code returns

```
averages =
 [1x6 double] [1x12 double] [1x10 double]
```

Create additional nonscalar structures `t` and `u`, and test for equality between the arrays in fields `f1` across structures `s`, `t`, and `u`.

```
t = s; t(1).f1(:)=0;
u = s; u(2).f1(:)=0;
```

```
same = arrayfun(@(x,y,z) isequal(x.f1, y.f1, z.f1), s, t, u)
```

This code returns

```
same =
 0 0 1
```

## See Also

`structfun` | `cellfun` | `spfun` | `cell2mat`

**Introduced before R2006a**

## **ascii**

**Class:** FTP

Set FTP transfer type to ASCII

## **Syntax**

```
ascii(ftpobj)
```

## **Description**

`ascii(ftpobj)` sets the download and upload FTP mode to ASCII, which converts new line characters. Use this method only for text files, including HTML pages and Rich Text Format (RTF) files.

## **Input Arguments**

**ftpobj**

FTP object created by `ftp`.

## **Examples**

Connect to the National Geophysical Data Center (NGDC) FTP server, and switch from binary (default) to ASCII mode:

```
ngdc = ftp('ftp.ngdc.noaa.gov');
ascii(ngdc)
```

FTP service courtesy of the NGDC. See NGDC Privacy Policy, Disclaimer, and Copyright for NGDC terms of service.

## **See Also**

binary | ftp

**Introduced before R2006a**

## **asec**

Inverse secant in radians

## **Syntax**

$Y = \text{asec}(X)$

## **Description**

$Y = \text{asec}(X)$  returns the “Inverse Secant” on page 1-478 ( $\text{sec}^{-1}$ ) of the elements of  $X$ . The **asec** function operates element-wise on arrays. For real elements of  $X$  in the interval  $[-\text{Inf}, -1]$  and  $[1, \text{Inf}]$ , **asec** returns values in the interval  $[0, \pi]$ . For real values of  $X$  in the interval  $[-1, 1]$  and for complex values of  $X$ , **asec** returns complex values. All angles are in radians.

## **Examples**

### **Inverse Secant of a Value**

```
asec(-2.8)
```

```
ans =
 1.9360
```

### **Inverse Secant of a Vector of Complex Values**

Find the inverse secant of the elements of vector  $x$ . The **asec** function acts on  $x$  element-wise.

```
x = [0.5i 1+3i -2.2+i];
Y = asec(x)
```

```
Y =
 1.5708 + 1.4436i 1.4749 + 0.2970i 1.9503 + 0.1833i
```

### **Plot the Inverse Secant Function**

Plot the inverse secant function over the intervals  $-5 \leq x \leq -1$  and  $1 \leq x \leq 5$ .

```
x1 = -5:0.01:-1;
x2 = 1:0.01:5;
plot(x1,asec(x1),'b')
hold on
plot(x2,asec(x2),'b')
grid on
```

## Input Arguments

### **X** — Numeric input

number | vector | matrix | multidimensional array

Numeric input, specified as a number, vector, matrix, or multidimensional array.

Data Types: `single` | `double`  
Complex Number Support: Yes

## More About

### Inverse Secant

The inverse secant is defined as

$$\sec^{-1}(z) = \cos^{-1}\left(\frac{1}{z}\right).$$

### See Also

`asecd` | `asech` | `sec`

Introduced before R2006a

# asecd

Inverse secant in degrees

## Syntax

```
Y = asecd(X)
```

## Description

`Y = asecd(X)` returns the inverse secant ( $\sec^{-1}$ ) of the elements of `X` in degrees. The function's domain and range include complex values. For real elements of `X` in the domain `[-Inf,1]` and `[1,Inf]`, `asecd` returns values in the range `[0, 180]`. For values of `X` outside this range, `asecd` returns complex values.

## Examples

### Inverse Secant of Vector

```
x = [10 1 Inf];
y = asecd(x)
```

```
y =
```

```
84.2608 0 90.0000
```

The `asecd` operation is element-wise when you pass a vector, matrix, or N-D array.

### Inverse Secant of Complex Value

```
asecd(1+i)
```

```
ans =
```

64.0864 +30.4033i

## Input Arguments

### **X — Secant of angle**

scalar value | vector | matrix | N-D array

Secant of angle, specified as a real-valued or complex-valued scalar, vector, matrix, or N-D array. The `asecd` operation is element-wise when `X` is non-scalar.

Data Types: `single` | `double`

Complex Number Support: Yes

## Output Arguments

### **Y — Angle in degrees**

scalar value | vector | matrix | N-D array

Angle in degrees, returned as a real-valued or complex-valued scalar, vector, matrix, or N-D array of the same size as `X`.

## See Also

`asec` | `sec` | `secd`

**Introduced before R2006a**

# asech

Inverse hyperbolic secant

## Syntax

$Y = \text{asech}(X)$

## Description

$Y = \text{asech}(X)$  returns the inverse hyperbolic secant for each element of  $X$ .

The `asech` function operates element-wise on arrays. The function's domains and ranges include complex values. All angles are in radians.

## Examples

### Graph of Inverse Hyperbolic Secant Function

Graph the inverse hyperbolic secant over the domain  $0.01 \leq x \leq 1$ .

```
x = 0.01:0.001:1;
plot(x,asech(x)), grid on
```

## More About

### Inverse Hyperbolic Secant

The inverse hyperbolic secant can be defined as

$$\operatorname{sech}^{-1}(z) = \cosh^{-1}\left(\frac{1}{z}\right).$$

### See Also

[asec](#) | [sech](#) | [asinh](#) | [acosh](#)

**Introduced before R2006a**

## **asin**

Inverse sine in radians

### **Syntax**

```
y = asin(x)
```

### **Description**

`y = asin(x)` returns the “Inverse Sine” on page 1-485 ( $\sin^{-1}$ ) of the elements of `x`. The `asin` function operates element-wise on arrays. For real elements of `x` in the interval  $[-1, 1]$ , `asin(x)` returns values in the interval  $[-\pi/2, \pi/2]$ . For real elements of `x` outside the interval  $[-1, 1]$  and for complex values of `x`, `asin(x)` returns complex values. All angles are in radians.

### **Examples**

#### **Inverse Sine of a Value**

```
asin(0.5)
```

```
ans =
 0.5236
```

#### **Inverse Sine of a Vector of Complex Values**

Find the inverse sine of the elements of vector `x`. The `asin` function acts on `x` element-wise.

```
x = [0.5i 1+3i -2.2+i];
y = asin(x)
```

```
y =
 0.0000 + 0.4812i 0.3076 + 1.8642i -1.1091 + 1.5480i
```

#### **Graph of the Inverse Sine Function**

Graph the inverse sine over the domain  $-1 \leq x \leq 1$ .

```
x = -1:.01:1;
plot(x,asin(x))
grid on
```

## More About

### Inverse Sine

The inverse sine is defined as

$$\sin^{-1}(z) = -i \log \left[ iz + (1 - z^2)^{1/2} \right].$$

**See Also**

asind | sin | sind

**Introduced before R2006a**

# asind

Inverse sine in degrees

## Syntax

$Y = \text{asind}(X)$

## Description

$Y = \text{asind}(X)$  returns the inverse sine ( $\sin^{-1}$ ) of the elements of  $X$  in degrees. The function's domain and range include complex values. For real elements of  $X$  in the domain  $[-1,1]$ , `asind` returns values in the range  $[-90,90]$ . For values of  $X$  outside this range, `asind` returns complex values.

## Examples

### Inverse Sine of Scalar

Show that the inverse sine of 1 is exactly  $90^\circ$ .

```
asind(1)
```

```
ans =
```

```
90
```

### Round-Trip Calculation for Complex Angles

Show that the inverse sine, followed by sine, returns the original values of  $X$ .

```
sind(asind([2 3]))
```

```
ans =
```

```
2.0000 3.0000
```

### Graph of Inverse Sine Function

Plot the inverse sine function over the domain  $-1 \leq x \leq 1$ .

```
x = -1:.01:1;
plot(x,asind(x))
grid on
```

## Input Arguments

### **X** — Sine of angle

scalar value | vector | matrix | N-D array

Sine of angle, specified as a real-valued or complex-valued scalar, vector, matrix, or N-D array. The `asind` operation is element-wise when `X` is nonscalar.

Data Types: `single` | `double`

Complex Number Support: Yes

## Output Arguments

### **Y — Angle in degrees**

scalar value | vector | matrix | N-D array

Angle in degrees, returned as a real-valued or complex-valued scalar, vector, matrix, or N-D array of the same size as  $X$ .

### **See Also**

asin | sin | sind

**Introduced before R2006a**

## **asinh**

Inverse hyperbolic sine

### **Syntax**

`Y = asinh(X)`

### **Description**

`Y = asinh(X)` returns the inverse hyperbolic sine for each element of `X`.

The `asinh` function operates element-wise on arrays. The function's domains and ranges include complex values. All angles are in radians.

### **Examples**

#### **Graph of Inverse Hyperbolic Sine Function**

Graph the inverse hyperbolic sine over the domain  $-5 \leq x \leq 5$ .

```
x = -5:.01:5;
plot(x,asinh(x)), grid on
```

## More About

### Inverse Hyperbolic Sine

The inverse hyperbolic sine can be defined as

$$\sinh^{-1}(z) = \log \left[ z + (z^2 + 1)^{1/2} \right].$$

### See Also

asin | sinh | acosh

**Introduced before R2006a**

## assert

Throw error if condition false

### Syntax

```
assert(cond)
```

```
assert(cond,msg)
assert(cond,msg,A1,...,An)
```

```
assert(cond,msgID,msg)
assert(cond,msgID,msg,A1,...,An)
```

### Description

`assert(cond)` throws an error if `cond` is false.

`assert(cond,msg)` throws an error and displays the error message, `msg`, if `cond` is false.

`assert(cond,msg,A1,...,An)` displays an error message that contains formatting conversion characters, such as those used with the MATLAB `sprintf` function, if `cond` is false. Each conversion character in `msg` is converted to one of the values `A1,...,An`.

`assert(cond,msgID,msg)` throws an error, displays the error message, `msg`, and includes an error identifier on the exception, if `cond` is false. The identifier enables you to distinguish errors and to control what happens when MATLAB encounters the errors.

`assert(cond,msgID,msg,A1,...,An)` includes an error identifier on the exception and displays a formatted error message.

### Examples

#### Value in Expected Range

Assert that the value, `x`, is greater than a specified minimum value.

```
minVal = 7;
x = 26;

assert(minVal < x)
```

The expression evaluates as true, and the assertion passes.

Assert that the value of `x` is between the specified minimum and maximum values.

```
maxVal = 13;

assert((minVal < x) && (x < maxVal))

Assertion failed.
```

The expression evaluates as false. The assertion fails and MATLAB throws an error.

### Expected Data Type

Assert that the product of two numbers is a double-precision number.

```
a = 13;
b = single(42);
c = a*b;

assert(isa(c, 'double'), 'Product is not type double.')
```

Product is not type double.

Enhance the error message to display the data type of `c`.

```
assert(isa(c, 'double'), 'Product is type %s, not double.', class(c))

Product is type single, not double.
```

### Expected Code Conditions

Use the `assert` function to test for conditions that should not happen in normal code execution. If the coefficients are numeric, the computed roots should be numeric. A quadratic equation using the specified coefficients and computed roots should be zero.

```
function x = quadraticSolver(C)

validateattributes(C, {'numeric'}, {'size', [1 3]})
```

```

a = C(1);
b = C(2);
c = C(3);

x(1) = (-b+sqrt(b^2-4*a*c))/(2*a);
x(2) = (-b-sqrt(b^2-4*a*c))/(2*a);
assert(isnumeric(x), 'quadraticSolver:nonnumericRoots',...
 'Computed roots are not numeric')

y1 = a*x(1)^2+b*x(1)+c;
y2 = a*x(2)^2+b*x(2)+c;
assert(y1 == 0, 'quadraticSolver:root1Error', 'Error in first root')
assert(isequal(y2,0), 'quadraticSolver:root2Error', 'Error in second root')

end

```

- “Capture Information About Exceptions”

## Input Arguments

### **cond** — Condition to assert

MATLAB expression

Condition to assert, specified as a valid MATLAB expression. If **cond** is false, the **assert** function throws an error. **cond** can include relational operators (such as `<` or `==`) and logical operators (such as `&&`, `|`, or `~`). Use the logical operators **and** and **or** to create compound expressions. MATLAB evaluates compound expressions from left to right, adhering to operator precedence rules.

Example: `a<0`

Example: `exist('myfunction.m','file')`

### **msg** — Information about assertion failure

string

Information about the assertion failure, specified as a string. This message displays as the error message. To format the string, use escape sequences, such as `\t` or `\n`. You also can use any format specifiers supported by the **sprintf** function, such as `%s` or `%d`. Specify values for the conversion specifiers via the `A1, . . . ,An` input arguments. For more information, see “Formatting Strings”.

---

**Note:** You must specify more than one input argument with `assert` if you want MATLAB to convert special characters (such as `\t`, `\n`, `%s`, and `%d`) in the error message string.

---

Example: `'Assertion condition failed.'`

## **A1, . . . , An — Numeric or character arrays**

scalar | vector | matrix | multidimensional array

Numeric or character arrays, specified as a scalar, vector, matrix, or multidimensional array. This input argument provides the values that correspond to and replace the conversion specifiers in `msg`.

## **msgID — Identifier for assertion failure**

string

Identifier for the assertion failure, specified as a string. Use the message identifier to help identify the source of the error or to control a selected subset of the errors in your program.

The message identifier includes a `component` and `mnemonic`. The identifier must always contain a colon and follows this simple format: `component:mnemonic`. The `component` and `mnemonic` fields must each begin with a letter. The remaining characters can be alphanumeric (A–Z, a–z, 0–9) and underscores. No whitespace characters can appear anywhere in `msgID`. For more information, see “Message Identifiers”.

Example: `'MATLAB:singularMatrix'`

Example: `'MATLAB:narginchk:notEnoughInputs'`

## **More About**

### **Tips**

- When you issue an error, MATLAB captures information about it and stores it in a data structure that is an object of the `MException` class. You can access information in the exception object by using `try/catch`. Or, if your program terminates because of an exception and returns control to the Command Prompt, you can use `MException.last`.

- If an assertion failure occurs within a `try` block, MATLAB does not cease execution of the program. In this case, MATLAB passes control to the `catch` block.

## See Also

`MException` | `error`

**Introduced in R2007a**

## assignin

Assign value to variable in specified workspace

### Syntax

```
assignin(ws, 'var', val)
```

### Description

`assignin(ws, 'var', val)` assigns the value `val` to the variable `var` in the workspace `ws`. The `var` input must be the array name only; it cannot contain array indices. If `var` does not exist in the specified workspace, `assignin` creates it. `ws` can have a value of `'base'` or `'caller'` to denote the MATLAB base workspace or the workspace of the caller function.

The `assignin` function is particularly useful for these tasks:

- Exporting data from a function to the MATLAB workspace
- Within a function, changing the value of a variable that is defined in the workspace of the caller function (such as a variable in the function argument list)

## Examples

### Example 1

This example creates a dialog box for the image display function, prompting a user for an image name and a colormap name. The `assignin` function is used to export the user-entered values to the MATLAB workspace variables `imfile` and `cmap`.

```
prompt = {'Enter image name:', 'Enter colormap name:'};
title = 'Image display - assignin example';
lines = 1;
def = {'my_image', 'hsv'};
answer = inputdlg(prompt, title, lines, def);
assignin('base', 'imfile', answer{1});
```

```
assignin('base', 'cmap', answer{2});
```

## Example 2

`assignin` does not assign to specific elements of an array. The following statement generates an error:

```
X = 1:8;
assignin('base', 'X(3:5)', -1);
```

However, you can use the `evalin` function to do this:

```
evalin('base', 'X(3:5) = -1')
X =
 1 2 -1 -1 -1 6 7 8
```

## More About

### Tips

The MATLAB base workspace is the workspace that is seen from the MATLAB command line (when not in the debugger). The caller workspace is the workspace of the function that called the currently running function. Note that the base and caller workspaces are equivalent in the context of a function that is invoked from the MATLAB command line. For more information, see “Base and Function Workspaces”.

### See Also

`evalin`

**Introduced before R2006a**

## atan

Inverse tangent in radians

### Syntax

$Y = \text{atan}(X)$

### Description

$Y = \text{atan}(X)$  returns the “Inverse Tangent” on page 1-502 ( $\tan^{-1}$ ) of the elements of  $X$ . The `atan` function operates element-wise on arrays. For real elements of  $X$ , `atan(X)` returns values in the interval  $[-\pi/2, \pi/2]$ . For complex values of  $X$ , `atan(X)` returns complex values. All angles are in radians.

### Examples

#### Inverse Tangent of a Value

```
atan(0.8)
```

```
ans =
 0.6747
```

#### Inverse Tangent of a Vector of Complex Values

Find the inverse tangent of the elements of vector  $x$ . The `atan` function acts on  $x$  element-wise.

```
x = [0.5i 1+3i -2.2+i];
Y = atan(x)
```

```
Y =
 0.0000 + 0.5493i 1.4615 + 0.3059i -1.2019 + 0.1506i
```

#### Plot the Inverse Tangent Function

Plot the inverse tangent function over the interval  $-20 \leq x \leq 20$ .

```
x = -20:0.01:20;
plot(x,atan(x))
grid on
```

## Input Arguments

### **X** — Numeric input

number | vector | matrix | multidimensional array

Numeric input, specified as a number, vector, matrix, or multidimensional array.

Data Types: single | double

Complex Number Support: Yes

## More About

### Inverse Tangent

The inverse tangent is defined as

$$\tan^{-1}(z) = \frac{i}{2} \log\left(\frac{i+z}{i-z}\right).$$

### See Also

atan2 | atand | atanh | tan

Introduced before R2006a

## atan2

Four-quadrant inverse tangent

### Syntax

$P = \text{atan2}(Y, X)$

### Description

$P = \text{atan2}(Y, X)$  returns the “Four-Quadrant Inverse Tangent” on page 1-506 ( $\tan^{-1}$ ) of  $Y$  and  $X$ , which must be real. The `atan2` function acts on  $Y$  and  $X$  element-wise to return  $P$ , which is the same size as  $Y$  and  $X$ .

### Examples

#### Find Four-Quadrant Inverse Tangent of a Point

Find the four-quadrant inverse tangent of the point  $y = 4, x = -3$ .

```
atan2(4, -3)
```

```
ans =
 2.2143
```

#### Convert Complex Number to Polar Coordinates

Convert  $4 + 3i$  into polar coordinates.

```
z = 4 + 3i;
r = abs(z)
theta = atan2(imag(z), real(z))
```

```
r =
 5
theta =
```

```
0.6435
```

The radius `r` and the angle `theta` are the polar coordinate representation of  $4 + 3i$ .

Alternatively, use `angle` to calculate `theta`.

```
theta = angle(z)
```

```
theta =
 0.6435
```

Convert `r` and `theta` back into the original complex number.

```
z = r*exp(i*theta)
```

```
z =
 4.0000 + 3.0000i
```

### **Plot Four-Quadrant Inverse Tangent**

Plot `atan2(Y,X)` for  $-4 < Y < 4$  and  $-4 < X < 4$ .

Define the interval to plot over.

```
[X,Y] = meshgrid(-4:0.1:4, -4:0.1:4);
```

Find `atan2(Y,X)` over the interval.

```
P = atan2(Y,X);
```

Use `surf` to generate a surface plot of the function. Note that `plot` plots the discontinuity that exists at  $Y=0$  for all  $X < 0$ .

```
surf(X,Y,P);
view(45,45);
```

## Input Arguments

### **Y** — Real valued input

number | vector | matrix | multidimensional array

Real valued input, specified as a number, vector, matrix, or multidimensional array.

Data Types: `single` | `double`

### **X** — Real valued input

number | vector | matrix | multidimensional array

Real valued input, specified as a number, vector, matrix, or multidimensional array.

Data Types: `single` | `double`

## More About

### Four-Quadrant Inverse Tangent

The four-quadrant tangent inverse, `atan2(Y,X)`, returns values in the closed interval  $[-\pi, \pi]$  based on the values of  $Y$  and  $X$  as shown in the graphic.

In contrast, `atan(Y/X)` returns results which are limited to the interval  $[-\pi/2, \pi/2]$ , which is the right side of this diagram.

### See Also

`angle` | `atan` | `atan2d` | `atanh` | `tan`

Introduced before R2006a

## atan2d

Four-quadrant inverse tangent in degrees

### Syntax

$D = \text{atan2d}(Y,X)$

### Description

$D = \text{atan2d}(Y,X)$  returns the four-quadrant inverse tangent of points specified in the  $x$ - $y$  plane. The result,  $D$ , is expressed in degrees.

## Examples

### Inverse Tangent of Four Points on the Unit Circle

```
x = [1 0 -1 0];
y = [0 1 0 -1];
d = atan2d(y,x)
```

```
d =
```

```
0 90 180 -90
```

## Input Arguments

### **Y** — **y-coordinates**

scalar value | vector | matrix | N-D array

y-coordinates, specified as a real-valued scalar, vector, matrix, or N-D array.

Data Types: `single` | `double`

### **X** — **x-coordinates**

scalar value | vector | matrix | N-D array

x-coordinates, specified as a real-valued scalar, vector, matrix, or N-D array.

Data Types: `single` | `double`

## Output Arguments

### **D** — **Angles in degrees**

scalar value | vector | matrix | N-D array

Angles in degrees, returned as a scalar, vector, matrix, or N-D array. These angles correspond to the points defined by **X** and **Y**, and they lie in the closed interval  $[-180,180]$ .

## More About

### Tips

- Use `atan`( $Y/X$ ) for the inverse tangent with results on the interval  $[-90, 90]$ .

**See Also**

atan | atan2 | atand | tan | tand

**Introduced in R2012b**

## atand

Inverse tangent in degrees

### Syntax

```
Y = atand(X)
```

### Description

`Y = atand(X)` returns the inverse tangent ( $\tan^{-1}$ ) of the elements of `X` in degrees. The function's domain and range include complex values. For real elements of `X` in the domain `[-Inf, Inf]`, `atand` returns values in the range `[-90, 90]`. For complex values of `X`, `atand` returns complex values.

### Examples

#### Inverse Tangent of Vector

```
x = [-50 -20 0 20 50];
y = atand(x)
```

```
y =
```

```
 -88.8542 -87.1376 0 87.1376 88.8542
```

The `atand` operation is element-wise when you pass a vector, matrix, or N-D array.

#### Inverse Tangent of Complex Value

```
atand(10+i)
```

```
ans =
```

84.3450 + 0.5618i

## Input Arguments

### **X — Tangent of angle**

scalar value | vector | matrix | N-D array

Tangent of angle, specified as a real-valued or complex-valued scalar, vector, matrix, or N-D array. The `atand` operation is element-wise when `X` is non-scalar.

Data Types: `single` | `double`

Complex Number Support: Yes

## Output Arguments

### **Y — Angle in degrees**

scalar value | vector | matrix | N-D array

Angle in degrees, returned as a real-valued or complex-valued scalar, vector, matrix, or N-D array of the same size as `X`.

## See Also

`atan` | `atan2d` | `tan` | `tand`

**Introduced before R2006a**

## atanh

Inverse hyperbolic tangent

### Syntax

$Y = \operatorname{atanh}(X)$

### Description

The `atanh` function operates element-wise on arrays. The function's domains and ranges include complex values. All angles are in radians.

$Y = \operatorname{atanh}(X)$  returns the inverse hyperbolic tangent for each element of  $X$ .

### Examples

#### Graph of Inverse Hyperbolic Tangent Function

Graph the inverse hyperbolic tangent over the domain  $-1 < x < 1$ .

```
x = -0.99:0.01:0.99;
plot(x,atanh(x)), grid on
```

## More About

### Inverse Hyperbolic Tangent

The inverse hyperbolic tangent can be defined as

$$\operatorname{tanh}^{-1}(z) = \frac{1}{2} \log\left(\frac{1+z}{1-z}\right).$$

### See Also

# audiodevinfo

Information about audio device

## Syntax

```
info = audiodevinfo
nDevices = audiodevinfo(IO)
name = audiodevinfo(IO, ID)
DriverVersion = audiodevinfo(IO, ID, 'DriverVersion')
support = audiodevinfo(IO, ID, Fs, nBits, nChannels)

ID = audiodevinfo(IO, name)
ID = audiodevinfo(IO, Fs, nBits, nChannels)
```

## Description

`info = audiodevinfo` returns information about the input and output audio devices on the system.

`nDevices = audiodevinfo(IO)` returns the number of input devices on the system if `IO` is 1, and returns the number of output devices on the system if `IO` is 0.

`name = audiodevinfo(IO, ID)` returns the name of the audio device specified by the device identifier, `ID`.

`DriverVersion = audiodevinfo(IO, ID, 'DriverVersion')` returns the name of the driver for the audio device specified by `ID`.

`support = audiodevinfo(IO, ID, Fs, nBits, nChannels)` returns 1 if the input or output audio device specified by `ID` supports the sample rate, number of bits, and number of channels specified by the values of `Fs`, `nBits`, and `nChannels`, respectively. Otherwise, `support` is 0.

`ID = audiodevinfo(IO, name)` returns the device identifier of the input or output audio device identified by the device name, `name`. If no device is found with the specified name, then `audiodevinfo` returns an error.

ID = `audiodevinfo(IO, Fs, nBits, nChannels)` returns the device identifier of the first input or output device that supports the sample rate, number of bits, and the number of channels specified by the values of `Fs`, `nBits`, and `nChannels`, respectively. If no supporting device is found, then ID is -1.

## Examples

### View Information About Audio Devices

Call `audiodevinfo` with no inputs to view information about the input and output audio devices on a system.

```
info = audiodevinfo

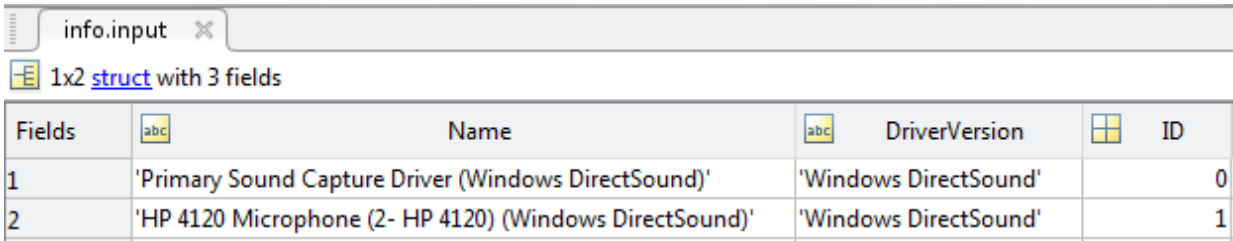

info =

 input: [1x2 struct]
 output: [1x3 struct]
```

`audiodevinfo` returns a structure containing two fields, `input` and `output`.

View the contents of the `input` field in the Variables editor.

```
openvar info.input
```

| Fields | Name                                                    | DriverVersion         | ID |
|--------|---------------------------------------------------------|-----------------------|----|
| 1      | 'Primary Sound Capture Driver (Windows DirectSound)'    | 'Windows DirectSound' | 0  |
| 2      | 'HP 4120 Microphone (2- HP 4120) (Windows DirectSound)' | 'Windows DirectSound' | 1  |

The Variables editor displays the input audio device names, driver used, and device identifiers. The values on your system might differ from this example.

### View Number of Output Devices

View the number of output audio devices on the system, using an `IO` value of 0 to indicate output.

```
nDevices = audiodevinfo(0)
nDevices =
 3
```

This example shows three output devices, but your system might vary.

### Check Support for Input Device

Check if the input audio device identified by the ID value, 0, supports a sample rate of 44100 hertz, with 16 bits per sample, and two channels.

```
support = audiodevinfo(1,0,44100,16,2)
support =
 1
```

The input device supports the specified sample rate, number of bits and number of channels.

## Input Arguments

### **I0** — Input or output device

1 | 0

Input or output device, specified as 1 to indicate input, or 0 to indicate output.

### **ID** — Audio device identifier

integer

Audio device identifier, specified as an integer. The device can be an input or output audio device.

### **Fs** — Sample rate

scalar

Sample rate, in hertz, specified as a positive scalar.

Example: 44100

Data Types: single | double

## **nBits** — Number of bits per sample

scalar

Number of bits per sample, specified as a scalar.

Example: 16

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

## **nChannels** — Number of audio channels

1 | 2

Number of audio channels, specified as 1 (mono) or 2 (stereo).

## **name** — Name of input or output device

string

Name of the input or output audio device, specified as a string.

Data Types: `char`

# Output Arguments

## **info** — Information about audio devices

structure array

Information about audio devices, returned as a structure array containing two fields, `input` and `output`. Each field is an array of structures, with each structure containing information about one of the audio input or output devices on the system. The individual device structure fields are:

- `Name` — Name of the device, returned as a string.
- `DriverVersion` — Name of the driver used to communicate with the device, returned as a string.
- `ID` — Device identifier, returned as a scalar.

## See Also

`audioplayer` | `audiorecorder`

# audioplayer

Create object for playing audio

## Syntax

```
player = audioplayer(Y,Fs)
player = audioplayer(Y,Fs,nBits)
player = audioplayer(Y,Fs,nBits,ID)
player = audioplayer(recorder)
player = audioplayer(recorder,ID)
```

## Description

`player = audioplayer(Y,Fs)` creates an `audioplayer` object for signal `Y`, using sample rate `Fs`. The function returns a handle to the `audioplayer` object, `player`.

`player = audioplayer(Y,Fs,nBits)` uses `nBits` bits per sample for signal `Y`.

`player = audioplayer(Y,Fs,nBits,ID)` uses the audio device identified by `ID` for output.

`player = audioplayer(recorder)` creates an `audioplayer` object using audio recorder object `recorder`.

`player = audioplayer(recorder,ID)` creates an object from `recorder` that uses the audio device identified by `ID` for output.

## Input Arguments

**Y**

Audio signal represented by a vector or two-dimensional array containing `single`, `double`, `int8`, `uint8`, or `int16` values.

The value range of the input sample depends on the data type. The following table lists these ranges.

|                           |                                                                                          |
|---------------------------|------------------------------------------------------------------------------------------|
| <code>isplaying</code>    | Query whether playback is in progress: returns <code>true</code> or <code>false</code> . |
| <code>pause</code>        | Pause playback.                                                                          |
| <code>play</code>         | Play audio from beginning to end.                                                        |
| <code>playblocking</code> | Play, and do not return control until playback completes.                                |
| <code>resume</code>       | Restart playback from paused position.                                                   |
| <code>set</code>          | Set properties of <code>audioplayer</code> object.                                       |
| <code>stop</code>         | Stop playback.                                                                           |

See the reference pages for `get`, `play`, `playblocking`, and `set` for additional syntax options.

## Properties

|                               |                                                                                                                                                                                                         |
|-------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>BitsPerSample</code>    | Number of bits per sample. (Read-only)                                                                                                                                                                  |
| <code>CurrentSample</code>    | Current sample that the audio output device is playing. If the device is not playing, <code>CurrentSample</code> is the next sample to play with <code>play</code> or <code>resume</code> . (Read-only) |
| <code>DeviceID</code>         | Identifier for audio device. (Read-only)                                                                                                                                                                |
| <code>NumberOfChannels</code> | Number of audio channels. (Read-only)                                                                                                                                                                   |
| <code>Running</code>          | Status of the audio player: <code>'on'</code> or <code>'off'</code> . (Read-only)                                                                                                                       |
| <code>SampleRate</code>       | Sampling frequency in Hz.                                                                                                                                                                               |
| <code>TotalSamples</code>     | Total length of the audio data in samples. (Read-only)                                                                                                                                                  |
| <code>Tag</code>              | String that labels the object.                                                                                                                                                                          |
| <code>Type</code>             | Name of the class: <code>'audioplayer'</code> . (Read-only)                                                                                                                                             |
| <code>UserData</code>         | Any type of additional data to store with the object.                                                                                                                                                   |

The following four properties apply to callback functions. The first two inputs to your callback function must be the `audioplayer` object and an *event* structure.

|                       |                                                    |
|-----------------------|----------------------------------------------------|
| <code>StartFcn</code> | Function to execute one time when playback starts. |
| <code>StopFcn</code>  | Function to execute one time when playback stops.  |

|             |                                                                                                                                           |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------|
| TimerFcn    | Function to execute repeatedly during playback. To specify time intervals for the repetitions, use the <code>TimerPeriod</code> property. |
| TimerPeriod | Time in seconds between <code>TimerFcn</code> callbacks. Default: <code>.05</code>                                                        |

## Examples

Load and play a sample audio file of Handel's "Hallelujah Chorus:"

```
load handel;
player = audioplayer(y, Fs);
play(player);
```

**Introduced before R2006a**

# audiorecorder

Create object for recording audio

## Syntax

```
recorder = audiorecorder
recorder = audiorecorder(Fs,nBits,nChannels)
recorder = audiorecorder(Fs,nBits,nChannels, ID)
```

## Description

`recorder = audiorecorder` creates an 8000 Hz, 8-bit, 1-channel audiorecorder object.

`recorder = audiorecorder(Fs,nBits,nChannels)` sets the sample rate `Fs` (in Hz), the sample size `nBits`, and the number of channels `nChannels`.

`recorder = audiorecorder(Fs,nBits,nChannels, ID)` sets the audio input device to the device specified by `ID`.

## Input Arguments

### **Fs**

Sampling rate in Hz. Valid values depend on the specific audio hardware installed. Typical values supported by most sound cards are 8000, 11025, 22050, 44100, 48000, and 96000 Hz.

**Default:** 8000

### **nBits**

Bits per sample. Valid values depend on the audio hardware installed: 8, 16, or 24.

**Default:** 8

## nChannels

The number of channels: 1 (mono) or 2 (stereo).

**Default:** 1

## ID

Device identifier. To obtain the ID of a device, use the `audiodevinfo` function.

**Default:** -1 (default device)

## Methods

---

**Note:** When calling any method, include the `audiorecorder` object name using function syntax, such as `stop(recorder)`.

---

|                             |                                                                                                                                                                                               |
|-----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>get</code>            | Query properties of <code>audiorecorder</code> object.                                                                                                                                        |
| <code>getaudiodata</code>   | Create an array that stores the recorded signal values.                                                                                                                                       |
| <code>getplayer</code>      | Create an <code>audioplayer</code> object.                                                                                                                                                    |
| <code>isrecording</code>    | Query whether recording is in progress: returns <code>true</code> or <code>false</code> .                                                                                                     |
| <code>pause</code>          | Pause recording.                                                                                                                                                                              |
| <code>play</code>           | Play recorded audio. This method returns an <code>audioplayer</code> object.                                                                                                                  |
| <code>record</code>         | Start recording.                                                                                                                                                                              |
| <code>recordblocking</code> | Record, and do not return control until recording completes. This method requires a second input for the length of the recording in seconds:<br><code>recordblocking(recorder, length)</code> |
| <code>resume</code>         | Restart recording from paused position.                                                                                                                                                       |
| <code>set</code>            | Set properties of <code>audiorecorder</code> object.                                                                                                                                          |
| <code>stop</code>           | Stop recording.                                                                                                                                                                               |

See the reference pages for `get`, `getaudiodata`, `play`, `record`, `recordblocking`, and `set` for additional syntax options.

## Properties

|                               |                                                                                                                                                                                                                |
|-------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>BitsPerSample</code>    | Number of bits per sample. (Read-only)                                                                                                                                                                         |
| <code>CurrentSample</code>    | Current sample that the audio input device is recording. If the device is not recording, <code>CurrentSample</code> is the next sample to record with <code>record</code> or <code>resume</code> . (Read-only) |
| <code>DeviceID</code>         | Identifier for audio device. (Read-only)                                                                                                                                                                       |
| <code>NumberOfChannels</code> | Number of audio channels. (Read-only)                                                                                                                                                                          |
| <code>Running</code>          | Status of the audio recorder: 'on' or 'off'. (Read-only)                                                                                                                                                       |
| <code>SampleRate</code>       | Sampling frequency in Hz. (Read-only)                                                                                                                                                                          |
| <code>TotalSamples</code>     | Total length of the audio data in samples. (Read-only)                                                                                                                                                         |
| <code>Tag</code>              | String that labels the object.                                                                                                                                                                                 |
| <code>Type</code>             | Name of the class: 'audiorecorder'. (Read-only)                                                                                                                                                                |
| <code>UserData</code>         | Any type of additional data to store with the object.                                                                                                                                                          |

The following four properties apply to callback functions. The first two inputs to your callback function must be the `audiorecorder` object and an `event` structure.

|                          |                                                                                                                                            |
|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| <code>StartFcn</code>    | Function to execute one time when recording starts.                                                                                        |
| <code>StopFcn</code>     | Function to execute one time when recording stops.                                                                                         |
| <code>TimerFcn</code>    | Function to execute repeatedly during recording. To specify time intervals for the repetitions, use the <code>TimerPeriod</code> property. |
| <code>TimerPeriod</code> | Time in seconds between <code>TimerFcn</code> callbacks. Default: .05                                                                      |

`audiorecorder` ignores any specified values for these properties, which will be removed in a future release.

|                              |                              |
|------------------------------|------------------------------|
| <code>BufferLength</code>    | Length of buffer in seconds. |
| <code>NumberOfBuffers</code> | Number of buffers.           |

## Examples

Create an `audiorecorder` object for CD-quality audio in stereo, and view its properties:

```
recObj = audiorecorder(44100, 16, 2);
get(recObj)
```

Collect a sample of your speech with a microphone, and plot the signal data:

```
% Record your voice for 5 seconds.
recObj = audiorecorder;
disp('Start speaking.')
```

```
recordblocking(recObj, 5);
disp('End of Recording.');
```

```
% Play back the recording.
play(recObj);
```

```
% Store data in double-precision array.
myRecording = getaudiodata(recObj);
```

```
% Plot the waveform.
plot(myRecording);
```

## More About

### Tips

- To use an `audiorecorder` object, your system must have a properly installed and configured sound card.
- `audiorecorder` is not intended for long, high-sample-rate recording. `audiorecorder` uses system memory for storage and does not use disk buffering. When you attempt a large recording, your MATLAB performance sometimes degrades over time.

`audiodevinfo` | `sound` | `audioplayer`

**Introduced before R2006a**

## **aufinfo**

Information about NeXT/SUN (.au) sound file

---

**Note:** `aufinfo` has been removed. Use `audioinfo` instead.

---

### **Syntax**

```
[m d] = aufinfo(aufile)
```

### **Description**

`[m d] = aufinfo(aufile)` returns information about the contents of the AU sound file specified by the string `aufile`.

`m` is the string 'Sound (AU) file', if `filename` is an AU file. Otherwise, it contains an empty string ('').

`d` is a string that reports the number of samples in the file and the number of channels of audio data. If `filename` is not an AU file, it contains the string 'Not an AU file'.

# auread

Read NeXT/SUN (.au) sound file

---

**Note:** auread has been removed. Use audioread instead.

---

## Syntax

```
y = auread(afile)
[y,Fs] = auread(afile)
[y,Fs,nbits] = auread(afile)
[___] = auread(afile,N)
[___] = auread(afile,[N1 N2])
siz = auread(afile, 'size')
```

## Description

*y* = auread(*afile*) loads a sound file specified by the string *afile*, returning the sampled data in *y*. The .au extension is appended if no extension is given. Amplitude values are in the range [-1, +1]. auread supports multichannel data in the following formats:

- 8-bit mu-law
- 8-, 16-, and 32-bit linear
- Floating-point

[*y*,*Fs*] = auread(*afile*) returns the sample rate (*Fs*) in Hertz used to encode the data in the file.

[*y*,*Fs*,*nbits*] = auread(*afile*) returns the number of bits per sample (*nbits*).

[ \_\_\_ ] = auread(*afile*,*N*) returns only the first *N* samples from each channel in the file.

[ \_\_\_ ] = auread(*afile*,[*N1* *N2*]) returns only samples *N1* through *N2* from each channel in the file.

`size = auread(aufile, 'size')` returns the size of the audio data contained in the file in place of the actual audio data, returning the vector `size = [samples channels]`.

## Examples

Create a sound file from the example file `handel.mat`, and read portions of the file back into MATLAB:

```
% Create .au file in current folder.
load handel.mat

hfile = 'handel.au';
auwrite(y, Fs, hfile)
clear y Fs

% Read the data back into MATLAB, and listen to audio.
[y, Fs, nbits] = auread(hfile);
sound(y, Fs);

% Pause before next read and playback operation.
duration = numel(y) / Fs;
pause(duration + 2)

% Read and play only the first 2 seconds.
nsamples = 2 * Fs;
[y2, Fs] = auread(hfile, nsamples);
sound(y2, Fs);
pause(4)

% Read and play the middle third of the file.
sizeinfo = auread(hfile, 'size');

tot_samples = sizeinfo(1);
startpos = tot_samples / 3;
endpos = 2 * startpos;

[y3, Fs] = auread(hfile, [startpos endpos]);
sound(y3, Fs);
```

## auwrite

Write NeXT/SUN (.au) sound file

---

**Note:** `auwrite` has been removed.

---

## Syntax

```
auwrite(y, aufile)
auwrite(y, Fs, aufile)
auwrite(y, Fs, N, aufile)
auwrite(y, Fs, N, method, aufile)
```

## Description

`auwrite(y, aufile)` writes a sound file specified by the string *aufile*. The data should be arranged with one channel per column. Amplitude values outside the range  $[-1, +1]$  are clipped prior to writing. `auwrite` supports multichannel data for 8-bit mu-law and 8- and 16-bit linear formats.

`auwrite(y, Fs, aufile)` specifies the sample rate of the data in Hertz.

`auwrite(y, Fs, N, aufile)` selects the number of bits in the encoder. Allowable settings are  $N = 8$  and  $N = 16$ .

`auwrite(y, Fs, N, method, aufile)` allows selection of the encoding method, which can be either 'mu' or 'linear'. Note that mu-law files must be 8-bit. By default, *method* = 'mu'.

# aviinfo

Information about Audio/Video Interleaved (AVI) file

---

**Note:** `aviinfo` will be removed in a future release. Use `VideoReader` instead.

---

## Syntax

```
fileinfo = aviinfo(filename)
```

## Description

`fileinfo = aviinfo(filename)` returns a structure whose fields contain information about the AVI file specified in the string `filename`. If `filename` does not include an extension, then `.avi` is used. The file must be in the current working directory or in a directory on the MATLAB path.

The set of fields in the `fileinfo` structure is shown below.

| Field Name      | Description                                                                                                             |
|-----------------|-------------------------------------------------------------------------------------------------------------------------|
| AudioFormat     | String containing the name of the format used to store the audio data, if audio data is present                         |
| AudioRate       | Integer indicating the sample rate in Hertz of the audio stream, if audio data is present                               |
| Filename        | String specifying the name of the file                                                                                  |
| FileModDate     | String containing the modification date of the file                                                                     |
| FileSize        | Integer indicating the size of the file in bytes                                                                        |
| FramesPerSecond | Integer indicating the desired frames per second                                                                        |
| Height          | Integer indicating the height of the AVI movie in pixels                                                                |
| ImageType       | String indicating the type of image. Either 'truecolor' for a truecolor (RGB) image, or 'indexed' for an indexed image. |

| <b>Field Name</b>               | <b>Description</b>                                                                                                                                                                                                                                                |
|---------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>NumAudioChannels</code>   | Integer indicating the number of channels in the audio stream, if audio data is present                                                                                                                                                                           |
| <code>NumFrames</code>          | Integer indicating the total number of frames in the movie                                                                                                                                                                                                        |
| <code>NumColormapEntries</code> | Integer specifying the number of colormap entries. For a truecolor image, this value is 0 (zero).                                                                                                                                                                 |
| <code>Quality</code>            | Number between 0 and 100 indicating the video quality in the AVI file. Higher quality numbers indicate higher video quality; lower quality numbers indicate lower video quality. This value is not always set in AVI files and therefore can be inaccurate.       |
| <code>VideoCompression</code>   | String containing the compressor used to compress the AVI file. If the compressor is not Microsoft Video 1, Run Length Encoding (RLE), Cinepak, or Intel <sup>®</sup> Indeo, <code>aviinfo</code> returns the four-character code that identifies the compressor. |
| <code>Width</code>              | Integer indicating the width of the AVI movie in pixels                                                                                                                                                                                                           |

## axes

Create axes graphics object

### Syntax

```
axes
axes('PropertyName',propertyvalue,...)
axes(h)
h = axes(...)
```

### Properties

For a list of properties, see Axes Properties.

### Description

`axes` creates an axes graphics object in the current figure using default property values. `axes` is the low-level function for creating axes graphics objects. MATLAB automatically creates an axes, if one does not already exist, when you issue a command that creates a graph.

`axes('PropertyName',propertyvalue,...)` creates an axes object having the specified property values. For a description of the properties, see Axes Properties. MATLAB uses default values for any properties that you do not explicitly define as arguments. The `axes` function accepts property name/property value pairs, structure arrays, and cell arrays as input arguments (see the `set` and `get` commands for examples of how to specify these data types). While the basic purpose of an axes object is to provide a coordinate system for plotted data, axes properties provide considerable control over the way MATLAB displays data.

`axes(h)` makes existing axes `h` the current axes and brings the figure containing it into focus. It also makes `h` the first axes listed in the figure's `Children` property and sets the figure's `CurrentAxes` property to `h`. The current axes is the target for functions that draw image, line, patch, rectangle, surface, and text graphics objects.

If you want to make an axes the current axes without changing the state of the parent figure, set the `CurrentAxes` property of the figure containing the axes:

```
set(figure_handle, 'CurrentAxes', axes_handle)
```

This command is useful if you want a figure to remain minimized or stacked below other figures, but want to specify the current axes.

`h = axes(...)` returns the handle of the created axes object.

Use the `set` function to modify the properties of an existing axes or the `get` function to query the current values of axes properties. Use the `gca` command to obtain the handle of the current axes.

The `axis` (not `axes`) function provides simplified access to commonly used properties that control the scaling and appearance of axes.

Set default axes properties on the figure and root levels:

```
set(groot, 'DefaultAxesPropertyName', PropertyValue, ...)
set(gcf, 'DefaultAxesPropertyName', PropertyValue, ...)
```

*PropertyName* is the name of the axes property and *PropertyValue* is the value you are specifying. Use `set` and `get` to access axes properties.

## Stretch-to-Fill

By default, MATLAB stretches the axes to fill the axes position rectangle (the rectangle defined by the last two elements in the `Position` property). This results in graphs that use the available space in the rectangle. However, some 3-D graphs (such as a sphere) appear distorted because of this stretching, and are better viewed with a specific three-dimensional aspect ratio.

Stretch-to-fill is active when the `DataAspectRatioMode`, `PlotBoxAspectRatioMode`, and `CameraViewAngleMode` are all auto (the default). However, stretch-to-fill is turned off when the `DataAspectRatio`, `PlotBoxAspectRatio`, or `CameraViewAngle` is user-specified, or when one or more of the corresponding modes is set to manual (which happens automatically when you set the corresponding property value).

This picture shows the same sphere displayed both with and without the stretch-to-fill. The dotted lines show the axes rectangle.

When stretch-to-fill is disabled, MATLAB sets the size of the axes to be as large as possible within the constraints imposed by the `Position` rectangle without introducing distortion. In the picture above, the height of the rectangle constrains the axes size.

## Examples

### Position Multiple Axes in Figure Window

Create multiple axes in a single figure window and specify their positions.

```
axes('Position',[0.1,0.1,0.7,0.7])
contour(peaks(20))
```

```
axes('Position',[0.65,0.7,0.28,0.28])
surf(peaks(20))
```

## Alternatives

To create a figure select **New > Figure** from the figure window **File** menu. To add an axes to a figure, click one of the *New Subplots* icons in the Figure Palette, and slide right to select an arrangement of new axes. For details, see “Customize Graph Using Plot Tools”.

## See Also

### Functions

`axis` | `cla` | `clf` | `figure` | `gca` | `grid` | `subplot` | `title` | `view` | `xlabel` | `ylabel` | `zlabel`

### Properties

Axes Properties

**Introduced before R2006a**

## Axes Properties

Control axes appearance and behavior

Axes properties control the appearance and behavior of an axes object. By changing property values, you can modify certain aspects of the axes.

Starting in R2014b, you can use dot notation to query and set properties.

```
ax = gca;
c = ax.Color;
ax.Color = 'blue';
```

If you are using an earlier release, use the `get` and `set` functions instead.

### Appearance

#### Color — Color of axes back planes

[1 1 1] (default) | RGB triplet | color string | 'none'

Color of axes back planes, specified as an RGB triplet, a color string, or 'none'. If you set the color to 'none', then the axes is invisible and the figure color shows through.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0, 1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

| Long Name | Short Name | RGB Triplet |
|-----------|------------|-------------|
| 'yellow'  | 'y'        | [1 1 0]     |
| 'magenta' | 'm'        | [1 0 1]     |
| 'cyan'    | 'c'        | [0 1 1]     |
| 'red'     | 'r'        | [1 0 0]     |
| 'green'   | 'g'        | [0 1 0]     |
| 'blue'    | 'b'        | [0 0 1]     |
| 'white'   | 'w'        | [1 1 1]     |

| Long Name | Short Name | RGB Triplet |
|-----------|------------|-------------|
| 'black'   | 'k'        | [0 0 0]     |

Example: `ax.Color = [0 0 1]`

Example: `ax.Color = 'b'`

Example: `ax.Color = 'blue'`

### Box — Axes box outline

'off' (default) | 'on'

Axes box outline, specified as one of these values:

- 'off' — Do not display the box outline around the axes.
- 'on' — Display the box outline around the axes. In a 3-D view, the outline appears around the axes back planes. Use the `BoxStyle` property to change the extent of the outline.

The `XColor`, `YColor`, and `ZColor` properties control the color of the outline.

Example: `ax.Box = 'on'`

### BoxStyle — Style of axes box outline

'back' (default) | 'full'

Style of axes box outline, specified as one of these values:

- 'back' — Outline the back planes of the 3-D box.
- 'full' — Outline the entire 3-D box.

The `BoxStyle` property affects only 3-D views.

Example: `ax.BoxStyle = 'full'`

### LineWidth — Width of axes outline, tick marks, and grid lines

0.5 (default) | scalar value

Width of axes outline, tick marks, and grid lines, specified as a scalar value in point units. One point equals 1/72 inch.

Example: `ax.LineWidth = 1.5`

## Individual Axis Appearance and Scale

**XAxis, YAxis, ZAxis** — Component that controls appearance and behavior of each axis  
numeric ruler object (default)

Component that controls the appearance and behavior of the  $x$ -axis,  $y$ -axis, or  $z$ -axis, returned as a numeric ruler object. When MATLAB creates an axes, it automatically creates a numeric ruler for each axis. Modify the appearance and behavior of a particular axis by accessing the associated ruler and setting ruler properties. For a list of options, see Numeric Ruler Properties.

For example, access the ruler for the  $x$ -axis through the `XAxis` property. Then, change the `Color` property of the ruler, and thus the color of the  $x$ -axis, to red. Similarly, change the color of the  $y$ -axis to green.

```
ax = gca;
ax.XAxis.Color = 'r';
ax.YAxis.Color = 'g';
```

Use the `XAxis`, `YAxis`, and `ZAxis` properties to access the ruler objects and set ruler properties. If you want to set axes properties, set them directly on the axes object. For example, `ax.XAxisLocation = 'top'` sets the `XAxisLocation` property of the axes.

**XAxisLocation** — Location of  $x$ -axis  
'bottom' (default) | 'top' | 'origin'

Location of the  $x$ -axis, specified as one of these values:

- 'bottom' — Display the  $x$ -axis at the bottom of the axes.
- 'top' — Display the  $x$ -axis at the top of the axes.
- 'origin' — Display the  $x$ -axis so that it passes through the origin point (0,0).

This property applies only to 2-D views.

Example: `ax.XAxisLocation = 'origin'`

**YAxisLocation** — Location of  $y$ -axis  
'left' (default) | 'right' | 'origin'

Location of the  $y$ -axis, specified as one of these values:

- 'left' — Display the  $y$ -axis on the left side of the axes.

- 'right' — Display the *y*-axis on the right side of the axes.
- 'origin' — Display the *y*-axis so that it passes through the origin point (0,0).

This property applies only to 2-D views.

Example: `ax.YAxisLocation = 'origin'`

**XColor, YColor, ZColor — Color of axis lines and tick marks**

[0.15 0.15 0.15] (default) | RGB triplet | color string | 'none'

Color of the axis lines in the *x*, *y*, or *z* direction and the associated tick marks, specified as an RGB triplet, a color string, or 'none'. If you set the color to 'none', then the axes outline is invisible.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0, 1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

| Long Name | Short Name | RGB Triplet |
|-----------|------------|-------------|
| 'yellow'  | 'y'        | [1 1 0]     |
| 'magenta' | 'm'        | [1 0 1]     |
| 'cyan'    | 'c'        | [0 1 1]     |
| 'red'     | 'r'        | [1 0 0]     |
| 'green'   | 'g'        | [0 1 0]     |
| 'blue'    | 'b'        | [0 0 1]     |
| 'white'   | 'w'        | [1 1 1]     |
| 'black'   | 'k'        | [0 0 0]     |

Setting this property sets the associated mode property to manual.

Example: `ax.XColor = [1 1 0]`

Example: `ax.YColor = 'y'`

Example: `ax.ZColor = 'yellow'`

**XColorMode, YColorMode, ZColorMode — Selection mode for axis line color**

'auto' (default) | 'manual'

Selection mode for the axis line color, specified as one of these values:

- 'auto' — Use the default color. For related information about grid-line selection, see the `GridColorMode` property.
- 'manual' — Use the manually specified color. To specify the color, set the `XColor`, `YColor`, or `ZColor` property.

Example: `ax.XColorMode = 'auto'`

### **XDir, YDir, ZDir — Direction of increasing values along axis**

'normal' (default) | 'reverse'

Direction of increasing values along axis, specified as one of these values:

- 'normal' — Normal direction of increasing values:
  - *x*-axis values increase from left to right.
  - *y*-axis values increase from bottom to top (2-D view) or front to back (3-D view).
  - *z*-axis values increase pointing out of the screen (2-D view) or from bottom to top (3-D view).
- 'reverse' — Reverse direction of increasing values:
  - *x*-axis values decrease from left to right.
  - *y*-axis values decrease from bottom to top (2-D view) or front to back (3-D view).
  - *z*-axis values decrease pointing out of the screen (2-D view) or from bottom to top (3-D view).

Example: `ax.XDir = 'normal'`

Example: `ax.YDir = 'reverse'`

### **XScale, YScale, ZScale — Scale of values along axis**

'linear' (default) | 'log'

Scale of values along axis, specified as 'linear' or 'log'.

Example: `ax.XScale = 'linear'`

Example: `ax.YScale = 'log'`

### **XLim, YLim, ZLim — Minimum and maximum axis limits**

[0 1] (default) | two-element vector of the form [min max]

Minimum and maximum  $x$ -axis,  $y$ -axis, or  $z$ -axis limits, specified as a two-element vector of the form `[min max]`.

If the associated mode property is set to `'auto'`, then MATLAB chooses the axis limits. If you assign a value to this property, then MATLAB sets the mode to `'manual'` and does not automatically compute the limits.

Example: `ax.XLim = [0 10]`

### **XLimMode, YLimMode, ZLimMode — Selection mode for axis limits**

`'auto'` (default) | `'manual'`

Selection mode for the axis limits, specified as one of these values:

- `'auto'` — Select axis limits based on the data plotted, that is, the total span of the `XData`, `YData`, or `ZData` of all the objects displayed in the axes.
- `'manual'` — Use manually specified axis limits. To specify the axis limits, set the `XLim`, `YLim`, or `ZLim` property.

Example: `ax.XLimMode = 'auto'`

## **Tick Values and Labels**

### **XTick, YTick, ZTick — Tick mark locations**

`[]` (default) | vector of increasing values

Tick mark locations, specified as a vector of increasing values.

If the associated mode property is set to `'auto'`, then MATLAB chooses the tick values. If you assign a value to this property, then MATLAB sets the mode to `'manual'` and does not automatically recompute the tick values.

Example: `ax.XTick = [2 4 6 8 10]`

Example: `ax.YTick = 0:10:100`

Data Types: `single` | `double`

### **XTickMode, YTickMode, ZTickMode — Selection mode for tick mark locations**

`'auto'` (default) | `'manual'`

Selection mode for the tick mark locations, specified as one of these values:

- 'auto' — Select the tick mark locations based on the range of data for the axis.
- 'manual' — Use manually specified tick mark locations. To specify the values, set the XTick, YTick, or ZTick property.

Example: `ax.XTickMode = 'auto'`

### **XTickLabel, YTickLabel, ZTickLabel — Tick mark labels**

' ' (default) | cell array of strings

Tick mark labels, specified as a cell array of strings. If you do not specify enough strings for all the ticks marks, then the axes cycles through the specified strings. Tick mark labels support TeX and LaTeX markup. See the TickLabelInterpreter property for more information.

If the associated mode property is set to 'auto', then MATLAB chooses the labels. If you assign a value to this property, then MATLAB sets the mode to 'manual' and does not automatically choose the labels.

Example: `ax.XTickLabel = {'Jan', 'Feb', 'Mar', 'Apr'}`

### **XTickLabelMode, YTickLabelMode, ZTickLabelMode — Selection mode for tick mark labels**

'auto' (default) | 'manual'

Selection mode for the tick mark labels, specified as one of these values:

- 'auto' — Label tick marks with numeric values that span the range of the plotted data.
- 'manual' — Use manually specified tick mark labels. To specify the labels, set the XTickLabel, YTickLabel, or ZTickLabel property.

Example: `ax.XTickLabelMode = 'auto'`

### **TickLabelInterpreter — Interpretation of characters in tick labels**

'tex' (default) | 'latex' | 'none'

Interpretation of tick label characters, specified as one of these values:

- 'tex' — Interpret strings using a subset of TeX markup.
- 'latex' — Interpret strings using LaTeX markup.
- 'none' — Display literal characters

## TeX Markup

By default, MATLAB supports a subset of TeX markup. Use TeX markup to add superscripts and subscripts, modify the text type and color, and include special characters in the text string.

This table lists the supported modifiers when the `TickLabelInterpreter` property is set to `'tex'`, which is the default value. Modifiers remain in effect until the end of the string, except for superscripts and subscripts which only modify the next character or the text within the curly braces `{}`.

| Modifier                            | Description                                                                                                                                | Example of String                          |
|-------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------|
| <code>^{ }</code>                   | Superscript                                                                                                                                | <code>'text^{superscript}'</code>          |
| <code>_{ }</code>                   | Subscript                                                                                                                                  | <code>'text_{subscript}'</code>            |
| <code>\bf</code>                    | Bold font                                                                                                                                  | <code>'\bf text'</code>                    |
| <code>\it</code>                    | Italic font                                                                                                                                | <code>'\it text'</code>                    |
| <code>\sl</code>                    | Oblique font (rarely available)                                                                                                            | <code>'\sl text'</code>                    |
| <code>\rm</code>                    | Normal font                                                                                                                                | <code>'\rm text'</code>                    |
| <code>\fontname{specifier}</code>   | Set <code>specifier</code> as the name of a font family to change the font style. You can use this in combination with other modifiers.    | <code>'\fontname{Courier} text'</code>     |
| <code>\fontsize{specifier}</code>   | Set <code>specifier</code> as a scalar numeric value to change the font size.                                                              | <code>'\fontsize{15} text'</code>          |
| <code>\color{specifier}</code>      | Set <code>specifier</code> as one of these colors: red, green, yellow, magenta, blue, black, white, gray, darkGreen, orange, or lightBlue. | <code>'\color{magenta} text'</code>        |
| <code>\color[rgb]{specifier}</code> | Set <code>specifier</code> as a three-element RGB triplet to change the font color.                                                        | <code>'\color[rgb]{0,0.5,0.5} text'</code> |

This table lists the supported special characters with the `Interpreter` property set to 'tex'.

| Character Sequence     | Symbol      | Character Sequence     | Symbol      | Character Sequence                | Symbol                 |
|------------------------|-------------|------------------------|-------------|-----------------------------------|------------------------|
| <code>\alpha</code>    | $\alpha$    | <code>\upsilon</code>  | $\upsilon$  | <code>\sim</code>                 | $\sim$                 |
| <code>\angle</code>    | $\angle$    | <code>\phi</code>      | $\Phi$      | <code>\leq</code>                 | $\leq$                 |
| <code>\ast</code>      | $*$         | <code>\chi</code>      | $\chi$      | <code>\infty</code>               | $\infty$               |
| <code>\beta</code>     | $\beta$     | <code>\psi</code>      | $\psi$      | <code>\clubsuit</code>            | $\clubsuit$            |
| <code>\gamma</code>    | $\gamma$    | <code>\omega</code>    | $\omega$    | <code>\diamondsuit</code>         | $\diamondsuit$         |
| <code>\delta</code>    | $\delta$    | <code>\Gamma</code>    | $\Gamma$    | <code>\heartsuit</code>           | $\heartsuit$           |
| <code>\epsilon</code>  | $\epsilon$  | <code>\Delta</code>    | $\Delta$    | <code>\spadesuit</code>           | $\spadesuit$           |
| <code>\zeta</code>     | $\zeta$     | <code>\Theta</code>    | $\Theta$    | <code>\leftrightsquigarrow</code> | $\leftrightsquigarrow$ |
| <code>\eta</code>      | $\eta$      | <code>\Lambda</code>   | $\Lambda$   | <code>\leftarrow</code>           | $\leftarrow$           |
| <code>\theta</code>    | $\Theta$    | <code>\Xi</code>       | $\Xi$       | <code>\Leftarrow</code>           | $\Leftarrow$           |
| <code>\vartheta</code> | $\vartheta$ | <code>\Pi</code>       | $\Pi$       | <code>\uparrow</code>             | $\uparrow$             |
| <code>\iota</code>     | $\iota$     | <code>\Sigma</code>    | $\Sigma$    | <code>\rightarrow</code>          | $\rightarrow$          |
| <code>\kappa</code>    | $\kappa$    | <code>\Upsilon</code>  | $\Upsilon$  | <code>\Rightarrow</code>          | $\Rightarrow$          |
| <code>\lambda</code>   | $\lambda$   | <code>\Phi</code>      | $\Phi$      | <code>\downarrow</code>           | $\downarrow$           |
| <code>\mu</code>       | $\mu$       | <code>\Psi</code>      | $\Psi$      | <code>\circ</code>                | $\circ$                |
| <code>\nu</code>       | $\nu$       | <code>\Omega</code>    | $\Omega$    | <code>\pm</code>                  | $\pm$                  |
| <code>\xi</code>       | $\xi$       | <code>\forall</code>   | $\forall$   | <code>\geq</code>                 | $\geq$                 |
| <code>\pi</code>       | $\pi$       | <code>\exists</code>   | $\exists$   | <code>\propto</code>              | $\propto$              |
| <code>\rho</code>      | $\rho$      | <code>\ni</code>       | $\ni$       | <code>\partial</code>             | $\partial$             |
| <code>\sigma</code>    | $\sigma$    | <code>\equiv</code>    | $\equiv$    | <code>\bullet</code>              | $\bullet$              |
| <code>\varsigma</code> | $\varsigma$ | <code>\approx</code>   | $\approx$   | <code>\div</code>                 | $\div$                 |
| <code>\tau</code>      | $\tau$      | <code>\Re</code>       | $\Re$       | <code>\neq</code>                 | $\neq$                 |
| <code>\equiv</code>    | $\equiv$    | <code>\oplus</code>    | $\oplus$    | <code>\aleph</code>               | $\aleph$               |
| <code>\Im</code>       | $\Im$       | <code>\cup</code>      | $\cup$      | <code>\wp</code>                  | $\wp$                  |
| <code>\otimes</code>   | $\otimes$   | <code>\subseteq</code> | $\subseteq$ | <code>\oslash</code>              | $\oslash$              |

| Character Sequence   | Symbol    | Character Sequence   | Symbol    | Character Sequence      | Symbol       |
|----------------------|-----------|----------------------|-----------|-------------------------|--------------|
| <code>\cap</code>    | $\cap$    | <code>\in</code>     | $\in$     | <code>\supseteq</code>  | $\supseteq$  |
| <code>\supset</code> | $\supset$ | <code>\lceil</code>  | $\lceil$  | <code>\subset</code>    | $\subset$    |
| <code>\int</code>    | $\int$    | <code>\cdot</code>   | $\cdot$   | <code>\o</code>         | $\circ$      |
| <code>\rfloor</code> | $\rfloor$ | <code>\neg</code>    | $\neg$    | <code>\nabla</code>     | $\nabla$     |
| <code>\lfloor</code> | $\lfloor$ | <code>\times</code>  | $\times$  | <code>\ldots</code>     | $\dots$      |
| <code>\perp</code>   | $\perp$   | <code>\sqrt</code>   | $\sqrt$   | <code>\prime</code>     | $'$          |
| <code>\wedge</code>  | $\wedge$  | <code>\varpi</code>  | $\varpi$  | <code>\o</code>         | $\emptyset$  |
| <code>\rceil</code>  | $\rceil$  | <code>\rangle</code> | $\rangle$ | <code>\mid</code>       | $ $          |
| <code>\vee</code>    | $\vee$    | <code>\langle</code> | $\langle$ | <code>\copyright</code> | $\copyright$ |

## LaTeX Markup

To use LaTeX markup, set the `TickLabelInterpreter` property to `'latex'`. The displayed text uses the default LaTeX font style. The `FontName`, `FontWeight`, and `FontAngle` properties do not have an effect. To change the font style, use LaTeX markup within the text string.

The maximum size of the string that you can use with the LaTeX interpreter is 1200 characters. For multiline strings, this reduces by about 10 characters per line.

For more information about the LaTeX system, see The LaTeX Project website at <http://www.latex-project.org/>.

### **XTickLabelRotation, YTickLabelRotation, ZTickLabelRotation** — Rotation of tick labels

0 (default) | scalar value in degrees

Rotation of tick labels, specified as a scalar value in degrees. Negative values give clockwise rotation.

Example: `ax.XTickLabelRotation = 45`

Example: `ax.YTickLabelRotation = 90`

### **XMinorTick, YMinorTick, ZMinorTick** — Display of minor tick marks

'off' (default) | 'on'

Display of minor tick marks, specified as one of these values:

- 'off' — Do not display minor tick marks.
- 'on' — Display minor tick marks between the major tick marks on the axis. The space between the major tick marks determines the number of minor tick marks.

Example: `ax.XMinorTick = 'on'`

### **TickLength — Tick mark length**

[0.01 0.025] (default) | two-element vector

Tick mark length, specified as a two-element vector of the form [2Dlength 3Dlength]. The first element is the tick mark length in 2-D views and the second element is the tick mark length in 3-D views. Specify the values in units normalized relative to the longest of the visible *x*-axis, *y*-axis, or *z*-axis lines.

Example: `ax.TickLength = [0.02 0.035]`

### **TickDir — Tick mark direction**

'in' (default) | 'out' | 'both'

Tick mark direction, specified as one of these values:

- 'in' — Direct the tick marks inward from the axis lines. This is the default for 2-D views.
- 'out' — Direct the tick marks outward from the axis lines. This is the default for 3-D views.
- 'both' — Center the tick marks over the axis lines.

If the associated mode property is set to 'auto', then MATLAB chooses the tick label direction. If you set this property, then MATLAB sets the mode to 'manual' and does not automatically choose the tick label direction.

Example: `ax.TickDir = 'out'`

### **TickDirMode — Selection mode for TickDir**

'auto' (default) | 'manual'

Selection mode for the `TickDir` property, specified as one of these values:

- 'auto' — Use default tick direction.
- 'manual' — Use manually specified tick mark direction. To specify the tick mark direction, set the `TickDir` property.

Example: `ax.TickDirMode = 'auto'`

## Grid Lines

### XGrid, YGrid, ZGrid — Display of grid lines

'off' (default) | 'on'

Display of grid lines, specified as one of these values:

- 'off' — Do not display the grid lines.
- 'on' — Display grid lines perpendicular to the axis, for example, along lines of constant  $x$ ,  $y$ , or  $z$  values. Use the `grid` command to set all three properties 'on' or 'off'.

Example: `ax.XGrid = 'on'`

### XMinorGrid, YMinorGrid, ZMinorGrid — Display of minor grid lines

'off' (default) | 'on'

Display of minor grid lines, specified as one of these values:

- 'off' — Do not display grid lines.
- 'on' — Display grid lines aligned with the minor tick marks of the axis. You do not need to enable minor ticks to display minor grid lines.

Example: `ax.XMinorGrid = 'on'`

### GridLineStyle — Line style for grid lines

'-' (default) | '--' | ':' | '-.' | 'none'

Line style used for grid lines, specified as one of the strings shown in this table.

| String | Line Style       |
|--------|------------------|
| '-'    | Solid line       |
| '--'   | Dashed line      |
| ':'    | Dotted line      |
| '-.'   | Dash-dotted line |
| 'none' | No line          |

To display the grid lines, use the `grid on` command or set the `XGrid`, `YGrid`, or `ZGrid` property to 'on'.

Example: `ax.GridLineStyle = '--'`

**MinorGridLineStyle — Line style for minor grid lines**

' :' (default) | '- ' | '-- ' | '- .' | 'none'

Line style used for minor grid lines, specified as one of the strings shown in this table.

| String   | Line Style       |
|----------|------------------|
| ' - '    | Solid line       |
| ' - - '  | Dashed line      |
| ' : '    | Dotted line      |
| ' - . '  | Dash-dotted line |
| ' none ' | No line          |

To display minor grid lines, use the `grid minor` command or set the `XGridMinor`, `YGridMinor`, or `ZGridMinor` property to 'on'.

Example: `ax.MinorGridLineStyle = '-.'`

**GridColor — Color of grid lines**

[0.15 0.15 0.15] (default) | RGB triplet | color string | 'none'

Color of grid lines, specified as an RGB triplet, a color string, or 'none'.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0,1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

| Long Name | Short Name | RGB Triplet |
|-----------|------------|-------------|
| 'yellow'  | 'y'        | [1 1 0]     |
| 'magenta' | 'm'        | [1 0 1]     |
| 'cyan'    | 'c'        | [0 1 1]     |
| 'red'     | 'r'        | [1 0 0]     |
| 'green'   | 'g'        | [0 1 0]     |
| 'blue'    | 'b'        | [0 0 1]     |
| 'white'   | 'w'        | [1 1 1]     |

| Long Name | Short Name | RGB Triplet |
|-----------|------------|-------------|
| 'black'   | 'k'        | [0 0 0]     |

To set the colors for the axes box outline, use the XColor, YColor, and ZColor properties.

Setting this property sets the associated mode property to manual.

Example: `ax.GridColor = [0 0 1]`

Example: `ax.GridColor = 'b'`

Example: `ax.GridColor = 'blue'`

### GridColorMode — Selection mode for GridColor

'auto' (default) | 'manual'

Selection mode for the GridColor property, specified as 'auto' or 'manual'. The color is based on the values of the GridColorMode, XColorMode, YColorMode, and ZColorMode properties.

These tables list the grid line colors for different combinations of color modes.

| GridColorMode Property | XColorMode Property | x-Axis Grid-Line Color   |
|------------------------|---------------------|--------------------------|
| 'auto'                 | 'auto'              | Use GridColor property.  |
| 'auto'                 | 'manual'            | Use XGridColor property. |
| 'manual'               | 'auto'              | Use GridColor property.  |
| 'manual'               | 'manual'            | Use GridColor property.  |

| GridColorMode Property | YColorMode Property | y-Axis Grid-Line Color   |
|------------------------|---------------------|--------------------------|
| 'auto'                 | 'auto'              | Use GridColor property.  |
| 'auto'                 | 'manual'            | Use YGridColor property. |
| 'manual'               | 'auto'              | Use GridColor property.  |
| 'manual'               | 'manual'            | Use GridColor property.  |

| GridColorMode Property | ZColorMode Property | z-Axis Grid-Line Color   |
|------------------------|---------------------|--------------------------|
| 'auto'                 | 'auto'              | Use GridColor property.  |
| 'auto'                 | 'manual'            | Use ZGridColor property. |

| GridColorMode Property | ZColorMode Property | z-Axis Grid-Line Color  |
|------------------------|---------------------|-------------------------|
| 'manual'               | 'auto'              | Use GridColor property. |
| 'manual'               | 'manual'            | Use GridColor property. |

Example: `ax.GridColorMode = 'auto'`

**MinorGridColor — Color of minor grid lines**

[0.1 0.1 0.1] (default) | RGB triplet | color string

Color of minor grid lines, specified as an RGB triplet, a color string, or 'none'.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0,1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

| Long Name | Short Name | RGB Triplet |
|-----------|------------|-------------|
| 'yellow'  | 'y'        | [1 1 0]     |
| 'magenta' | 'm'        | [1 0 1]     |
| 'cyan'    | 'c'        | [0 1 1]     |
| 'red'     | 'r'        | [1 0 0]     |
| 'green'   | 'g'        | [0 1 0]     |
| 'blue'    | 'b'        | [0 0 1]     |
| 'white'   | 'w'        | [1 1 1]     |
| 'black'   | 'k'        | [0 0 0]     |

Example: `ax.MinorGridColor = [0 0 1]`

Example: `ax.MinorGridColor = 'b'`

Example: `ax.MinorGridColor = 'blue'`

**MinorGridColorMode — Selection mode for MinorGridColor**

'auto' (default) | 'manual'

Selection mode for the MinorGridColor property, specified as 'auto' or 'manual'. The minor grid line color is based on the values of the MinorGridColorMode, XColorMode, YColorMode, and ZColorMode properties.

These tables list the minor grid line colors for different combinations of color modes.

| MinorGridColorMode Property | XColorMode Property | x-Axis Minor Grid-Line Color |
|-----------------------------|---------------------|------------------------------|
| 'auto'                      | 'auto'              | Use MinorGridColor property. |
| 'auto'                      | 'manual'            | Use XGridColor property.     |
| 'manual'                    | 'auto'              | Use MinorGridColor property. |
| 'manual'                    | 'manual'            | Use MinorGridColor property. |

| MinorGridColorMode Property | YColorMode Property | y-Axis Minor Grid-Line Color |
|-----------------------------|---------------------|------------------------------|
| 'auto'                      | 'auto'              | Use MinorGridColor property. |
| 'auto'                      | 'manual'            | Use YGridColor property.     |
| 'manual'                    | 'auto'              | Use MinorGridColor property. |
| 'manual'                    | 'manual'            | Use MinorGridColor property. |

| MinorGridColorMode Property | ZColorMode Property | z-Axis Minor Grid-Line Color |
|-----------------------------|---------------------|------------------------------|
| 'auto'                      | 'auto'              | Use MinorGridColor property. |
| 'auto'                      | 'manual'            | Use ZGridColor property.     |
| 'manual'                    | 'auto'              | Use MinorGridColor property. |
| 'manual'                    | 'manual'            | Use MinorGridColor property. |

Example: `ax.MinorGridColorMode = 'auto'`

### GridAlpha — Grid-line transparency

0.15 (default) | value in the range [0,1]

Grid-line transparency, specified as a value in the range [0, 1]. A value of 1 means opaque and a value of 0 means completely transparent.

Setting this property sets the associated mode property to manual.

Example: `ax.GridAlpha = 0.5`

### **GridAlphaMode — Selection mode for GridAlpha**

'auto' (default) | 'manual'

Selection mode for the `GridAlpha` property, specified as one of these values:

- 'auto' — Use default transparency value of 0.15.
- 'manual' — Use the manually specified transparency value. To specify the value, set the `GridAlpha` property.

Example: `ax.GridAlphaMode = 'auto'`

### **MinorGridAlpha — Minor grid-line transparency**

0.25 (default) | value in the range [0, 1]

Minor grid-line transparency, specified as a value in the range [0, 1]. A value of 1 means opaque and a value of 0 means completely transparent.

Setting this property sets the associated mode property to manual.

Example: `ax.MinorGridAlpha = 0.5`

### **MinorGridAlphaMode — Selection mode for MinorGridAlpha**

'auto' (default) | 'manual'

Selection mode for the `MinorGridAlpha` property, specified as one of these values:

- 'auto' — Use the default transparency value of 0.15.
- 'manual' — Use the manually specified transparency value. To specify the value, set the `MinorGridAlpha` property.

Example: `ax.MinorGridAlphaMode = 'auto'`

### **Layer — Placement of grid lines and tick marks in relation to graphic objects**

'bottom' (default) | 'top'

Placement of grid lines and tick marks in relation to graphic objects, specified as one of these values:

- 'bottom' — Display tick marks and grid lines under graphics objects.
- 'top' — Display tick marks and grid lines over graphics objects.

This property affects only 2-D views.

Example: `ax.Layer = 'top'`

## Font Style

### FontName — Font name

'Helvetica' (default) | 'FixedWidth' | system supported font name

Font name, specified as the name of the font to use or the string 'FixedWidth'. To display and print properly, the font name must be a font that your system supports.

To use a fixed-width font that looks good in any locale, use the case-sensitive string 'FixedWidth'. The 'FixedWidth' value relies on the root `FixedWidthFontName` property. Setting the root `FixedWidthFontName` property causes an immediate update of the display to use the new font.

Example: `'Cambria'`

### FontSize — Font size

10 (default) | scalar numeric value

Font size, specified as a scalar numeric value. The `FontSize`, `LabelFontSizeMultiplier`, and `TitleFontSizeMultiplier` properties determine the size of the text used for the axis labels and the title. The `FontUnits` property determines the units used to interpret the font size.

Example: `ax.FontSize = 12`

### TitleFontSizeMultiplier — Scale factor for title font size

1.1 (default) | numeric value greater than 0

Scale factor for title font size, specified as a numeric value greater than 0. The axes applies this scale factor to the value of the `FontSize` property to determine the font size for the title.

Example: `ax.TitleFontSizeMultiplier = 1.75`

### LabelFontSizeMultiplier — Scale factor for label font size

1.1 (default) | numeric value greater than 0

Scale factor for label font size, specified as a numeric value greater than 0. The axes applies this scale factor to the value of the `FontSize` property to determine the font size for the *x*-axis, *y*-axis, and *z*-axis labels.

Example: `ax.LabelFontSizeMultiplier = 1.5`

**FontUnits — Font size units**

'points' (default) | 'inches' | 'centimeters' | 'normalized' | 'pixels'

Font size units, specified as one of the values in this table.

| Units         | Description                                                                                                                                                                                                                                                                                                                                                                                          |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'points'      | Points. One point equals 1/72 inch.                                                                                                                                                                                                                                                                                                                                                                  |
| 'inches'      | Inches.                                                                                                                                                                                                                                                                                                                                                                                              |
| 'centimeters' | Centimeters.                                                                                                                                                                                                                                                                                                                                                                                         |
| 'normalized'  | Interpret font size as a fraction of the axes height. If you resize the axes, the font size modifies accordingly. For example, if the <code>FontSize</code> is 0.1 in normalized units, then the text is 1/10 of the axes height.                                                                                                                                                                    |
| 'pixels'      | <p>Pixels.</p> <p>Starting in R2015b, distances in pixels are independent of your system resolution on Windows and Macintosh systems:</p> <ul style="list-style-type: none"> <li>• On Windows systems, a pixel is 1/96th of an inch.</li> <li>• On Macintosh systems, a pixel is 1/72nd of an inch.</li> </ul> <p>On Linux systems, the size of a pixel is determined by your system resolution.</p> |

If you set both the font size and the font units in one function call, you must set the `FontUnits` property first so that the axes correctly interprets the specified font size.

**FontAngle — Character slant**

'normal' (default) | 'italic'

Character slant, specified as 'normal' or 'italic'. Not all fonts have both font styles. Therefore, the italic font might look the same as the normal font.

---

**Note:** The 'oblique' value has been removed. Use 'italic' instead.

---

### **FontWeight** — Thickness of text characters

'normal' (default) | 'bold'

Thickness of the text characters, specified as one of these values:

- 'normal' — Default weight as defined by the particular font
- 'bold' — Thicker character outlines than normal

MATLAB uses the `FontWeight` property to select a font from those available on your system. Not all fonts have a bold font weight. Therefore, specifying a bold font weight still can result in the normal font weight.

---

**Note:** The 'light' and 'demi' font weight values have been removed. Use 'normal' instead.

---

### **TitleFontWeight** — Thickness of title text

'bold' (default) | 'normal'

Thickness of the title text, specified as one of these values:

- 'bold' — Thicker characters outlines than normal.
- 'normal' — Default weight as defined by the particular font.

Example: `ax.TitleFontWeight = 'normal'`

### **FontSmoothing** — Text smoothing

'on' (default) | 'off'

Text smoothing, specified as one of these values:

- 'on' — Use antialiasing to make text appear smoother on the screen.
- 'off' — Do not use antialiasing. Use this setting if the text seems blurry. In certain cases, smoothed text blends against the background color and results in a blurring effect.

Example: `ax.FontSmoothing = 'off'`

## Title and Axis Labels

### **Title** — Text object for axes title

text object (default)

Text object for axes title. Refer to this text object to change properties of the title.

```
ax = gca;
ax.Title.String = 'My Graph Title';
ax.Title.FontWeight = 'normal';
```

---

**Note:** To access the axes title text object, use the `Title` property or the `title` function. This text object is not contained in the axes `Children` property, it cannot be returned by `findobj`, and it does not use default values defined for text objects.

---

### **XLabel, YLabel, ZLabel** — Text object for axis label

text object (default)

Text object for *x*-axis, *y*-axis, or *z*-axis label. Refer to this text object to change properties of the axis label.

```
ax = gca;
ax.YLabel.String = 'Y Axis';
ax.YLabel.FontSize = 12;
```

---

**Note:** To access the axis label text objects, use the `XLabel`, `YLabel`, and `ZLabel` properties or the `xlabel`, `ylabel`, and `zlabel` functions. These text objects are not contained in the axes `Children` property, they cannot be returned by `findobj`, and they do not use default values defined for text objects.

---

## Line Colors and Line Styles

### **ColorOrder** — Colors for multiline plots

seven predefined colors (default) | three-column matrix of RGB triplets

Colors for multiline plots, specified as a three-column matrix of RGB triplets. Each row of the matrix defines one color in the color order. The default color order has seven colors.

| Default Color Order                                                               | Associated RGB Triplets                                                                                                                                            |
|-----------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|  | [ 0 0.4470 0.7410<br>0.8500 0.3250 0.0980<br>0.9290 0.6940 0.1250<br>0.4940 0.1840 0.5560<br>0.4660 0.6740 0.1880<br>0.3010 0.7450 0.9330<br>0.6350 0.0780 0.1840] |

The functions that create line plots cycle through the colors to color each line. The hold state for the axes affects the colors used.

- If the hold state is off (when the `NextPlot` property is set to `'replace'`), then high-level plotting functions such as `plot` reset the color order to the default colors before plotting. If you want to specify new colors for the color order and do not want high-level plotting functions to reset them, then set the `NextPlot` property to `'replacechildren'`. Alternatively, you can specify a new default value for the `ColorOrder` property on the root using the `set` function. For example, use `set(groot,'defaultAxesColorOrder',[0 1 0; 0 0 1])`.
- If the hold state for the axes is on (when the `NextPlot` property is set to `'add'`), then plotting functions cycle through the colors starting from the place in the color order where the last plot ended.

Data Types: `single` | `double`

### **LineStyleOrder** — Line styles and markers for multiline plots

' - ' solid line (default) | cell array of specifiers

Line styles and markers for multiline plots, specified as a cell array of one or more specifiers in this table, for example, `{ '- * ', ': ', 'o' }`.

| Specifier       | Line Style        |
|-----------------|-------------------|
| ' - ' (default) | Solid line        |
| ' _ _ '         | Dashed line       |
| ' : '           | Dotted line       |
| ' - . '         | Dash-dotted line  |
| ' + '           | Plus sign markers |

| Specifier | Line Style                            |
|-----------|---------------------------------------|
| 'o'       | Circle markers                        |
| '*'       | Star markers                          |
| '.'       | Point markers                         |
| 'x'       | Cross markers                         |
| 's'       | Square markers                        |
| 'd'       | Diamond markers                       |
| '^'       | Upward-pointing triangle markers      |
| 'v'       | Downward-pointing triangle markers    |
| '>'       | Right-pointing triangle markers       |
| '<'       | Left-pointing triangle markers        |
| 'p'       | Five-pointed star (pentagram) markers |
| 'h'       | Six-pointed star (hexagram) markers   |

Combine strings to specify lines with markers, such as `'-*'`. The plot cycles through the line styles only after using all the colors contained in the `ColorOrder` property. If the hold state for the axes is off (when the `NextPlot` property of the axes is set to `'replace'`), then high-level plotting functions such as `plot` reset the line style order to the default line styles before plotting. If you want to specify a set of line styles that is different from the default and do not want high-level plotting functions to reset the `LineStyleOrder` property, then set `NextPlot` to `'replacechildren'`. Alternatively, you can specify a new default value for the `LineStyleOrder` property on the root using the `set` function. For example, use `set(groot, 'defaultAxesLineStyleOrder', {'-*', ':', 'o'})`.

Example: `{'-*', ':', 'o'}`

**ColorOrderIndex — Next color to use in color order**

1 (default) | positive integer

Next color to use in the color order, specified as a positive integer. New plots added to the axes use colors based on the current value of the color order index. To use the first color for the next plot added to the axes, set the property to 1.

After a `hold on` command, subsequently called plotting functions continue to cycle through the color-order, beginning with the current value of the color order index. Reset the color-order by setting the index to 1.

If the specified index exceeds the number of colors defined by the current `ColorOrder` property, then plotting functions use the `mod` function to determine the index value as:

```
mod(ColorOrderIndex value, number of colors in ColorOrder)
```

Example: `ax.ColorOrderIndex = 5`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

### **LineStyleOrderIndex** — Next line style to use in line style order

1 (default) | positive integer

Next line style to use in line style order, specified as a positive integer. New plots added to the axes use line styles based on the current value of the line style order index. To use the first line style, set this property to 1.

After a `hold on` command, subsequently called plotting functions continue to cycle through the line-style order, beginning with the current value of the line style order index.

If the specified index exceeds the number of line styles defined by the current `LineStyleOrder` property, plotting functions use the `mod` function to determine the index value as:

```
mod(LineStyleOrderIndex value, number of line styles in LineStyleOrder)
```

---

**Note:** The default `LineStyleOrder` has only one line style.

---

Example: `ax.LineStyleOrderIndex = 1`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

## **Color and Transparency Mapping**

### **CLim** — Color limits for objects using colormap

[0 1] (default) | two-element vector of the form [cmin cmax]

Color limits for objects in axes that use the colormap, specified as a two-element vector of the form [cmin cmax]. This property determines how data values map to the colors in the colormap where:

- `cmin` specifies the data value that maps to the first color in the colormap.
- `cmax` specifies the data value that maps to the last color in the colormap.

The axes linearly interpolates data values between `cmin` and `cmax` across the colormap. Values outside this range use either the first or last color, whichever is closest.

For information on changing the colormap, see the `colormap` function. For information on color mapping, see the `caxis` function.

If the associated mode property is set to `'auto'`, then MATLAB chooses the color limits. If you assign a value to this property, then MATLAB sets the mode to `'manual'` and does not automatically choose the color limits.

#### **CLimMode** — Selection mode for **CLim**

`'auto'` (default) | `'manual'`

Selection mode for the **CLim** property, specified as one of these values:

- `'auto'` — Set the **CLim** property to span the **CData** limits of the graphics objects displayed in the axes.
- `'manual'` — Use the manually specified values. To specify the values, set the **CLim** property. The axes does not change the values when the limits of the axes children change.

#### **ALim** — Alpha limits for images, patches, and surfaces with transparency

`[0 1]` (default) | two-element vector of the form `[amin amax]`

Alpha limits for images, patches, and surfaces with transparency, specified as a two-element vector of the form `[amin amax]`. This property determines how values in the **AlphaData** properties of image, patch, and surface objects map to the figure alpha map, where:

- `amin` specifies the data value mapped to the first alpha value in the figure alpha map.
- `amax` specifies the data value mapped to the last alpha value in the figure alpha map.

The axes linearly interpolates data values between `amin` and `amax` across the figure alpha map. Values outside this range use either the first or last alpha map value, whichever is closest.

The **Alphamap** property of the figure contains the alpha map. For more information, see the `alpha` function.

If the associated mode property is set to 'auto', then MATLAB chooses the alpha limits. If you set this property, then MATLAB sets the mode to 'manual' and does not automatically choose the alpha limits.

#### **ALimMode — Selection mode for ALim**

'auto' (default) | 'manual'

Selection mode for the ALim property, specified as one of these values:

- 'auto' — Use values that span the AlphaData of the axes children contained in the Children property.
- 'manual' — Use the manually specified values. To specify the values, set the ALim property.

#### **AmbientLightColor — Background light color**

[1 1 1] (default) | RGB triplet | color string | 'none'

Background light color, specified as an RGB triplet, a color string, or 'none'. The light is a directionless light that shines uniformly on all objects in the axes when there is a visible light object in the axes.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0, 1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

| Long Name | Short Name | RGB Triplet |
|-----------|------------|-------------|
| 'yellow'  | 'y'        | [1 1 0]     |
| 'magenta' | 'm'        | [1 0 1]     |
| 'cyan'    | 'c'        | [0 1 1]     |
| 'red'     | 'r'        | [1 0 0]     |
| 'green'   | 'g'        | [0 1 0]     |
| 'blue'    | 'b'        | [0 0 1]     |
| 'white'   | 'w'        | [1 1 1]     |
| 'black'   | 'k'        | [0 0 0]     |

The 'none' option is equivalent to using an RGB triplet value of [0 0 0].

Example: `ax.AmbientLightColor = [1 0 1]`

Example: `ax.AmbientLightColor = 'm'`

Example: `ax.AmbientLightColor = 'magenta'`

## Multiple Plots

### **NextPlot** — Properties to reset when adding new plot

`'replace'` (default) | `'add'` | `'replacechildren'`

Properties to reset when adding a new plot to the axes, specified as one of these values:

- `'replace'` — Reset all axes properties, except **Position** and **Units**, to their default values and delete all axes children before displaying the new plot. Using this value is similar to using `cla reset`.
- `'add'` — Use the existing axes to add more plots to the axes and do not reset properties.
- `'replacechildren'` — Remove all child objects before adding new plots, but do not reset axes properties. This is similar to using `cla`.

The `newplot` function simplifies the use of the `NextPlot` property and is useful for writing custom graphing functions. Figures also have a `NextPlot` property.

### **SortMethod** — Order for rendering objects

`'depth'` (default) | `'childorder'`

Order for rendering objects, specified as one of these values:

- `'depth'` — Draw objects in back-to-front order based on the current view. Use this value to ensure that objects in front of other objects are drawn correctly.
- `'childorder'` — Draw objects in the order in which they are created by graphics functions, without considering the relationship of the objects in three dimensions. This value can result in faster rendering, particularly if the figure is very large, but can also result in improper depth sorting of the objects displayed

## Visibility

### **Visible** — State of visibility

`'on'` (default) | `'off'`

State of visibility, specified as one of these values:

- 'on' — Display the axes.
- 'off' — Hide the axes without deleting it. You still can access the properties of an invisible axes object.

### Clipping — Clipping of objects to axes limits

'on' (default) | 'off'

Clipping of objects to the axes limits, specified as either 'on' or 'off'. The clipping behavior of an object within the axes object depends on both the `Clipping` property of the axes object and the `Clipping` property of the individual object. The property value of the axes has these effects:

- 'on' — Allow each individual object within the axes to control its own clipping behavior based on the `Clipping` property value for the object.
- 'off' — Disable clipping for all objects within the axes, regardless of the `Clipping` property value for the individual objects. Parts of objects can appear outside of the axes limits. For example, parts can appear outside the limits if you create a plot, use the `hold on` command, freeze the axis scaling, and then add a plot that is larger than the original plot.

This table lists the results for different combinations of `Clipping` property values.

| Clipping Property for Axes Object | Clipping Property for Individual Object | Result                                 |
|-----------------------------------|-----------------------------------------|----------------------------------------|
| 'on'                              | 'on'                                    | Individual object is clipped (default) |
| 'on'                              | 'off'                                   | Individual object is not clipped       |
| 'off'                             | 'on'                                    | Axes contains no clipped objects       |
| 'off'                             | 'off'                                   | Axes contains no clipped objects       |

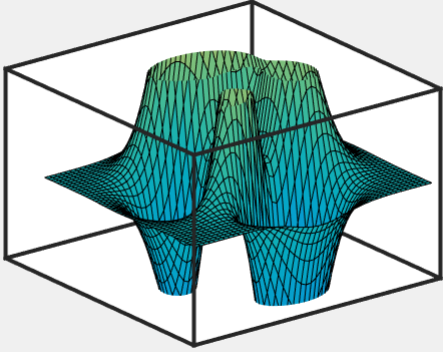

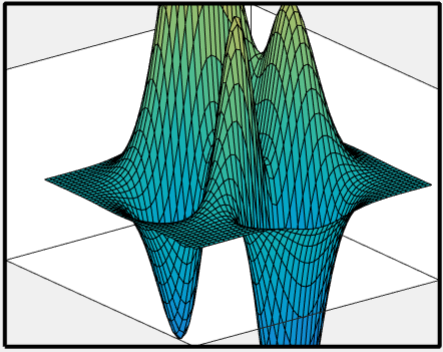

Thick lines and markers might display outside the axes limits, even if clipping is enabled. If a plot contains markers, then as long as the data point lies within the axes, MATLAB draws the entire marker. If a plot uses thick lines, then part of the line might appear outside the limits depending on the value of the `ClippingStyle` property of the axes object.

- When the `ClippingStyle` property is set to `'3dbox'` (the default), MATLAB draws the line using the full line width even if part of the line width is outside the axes.
- When the `ClippingStyle` property is set to `'rectangle'`, MATLAB clips the line width at the limits.

**ClippingStyle — Boundaries used for clipping**

`'3dbox'` (default) | `'rectangle'`

Boundaries used for clipping, specified as one of the values in this table.

| Value       | Descriptions                                                                         | Illustration of Boundary Region                                                       |
|-------------|--------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------|
| '3dbox'     | Clip plotted objects to the six sides of the axes box defined by the axis limits.    |   |
| 'rectangle' | Clip plotted objects to a rectangular boundary enclosing the axes in any given view. |  |

The `ClippingStyle` property has no effect if the `Clipping` property is set to `'off'`.

## Location and Size

### **Position** — Size and position of axes within figure or uipanel

`[0.1300 0.1100 0.7750 0.8150]` (default) | four-element vector

Size and position of the axes within the figure or uipanel that contains the axes, specified as a four-element vector of the form `[left bottom width height]`. The `left` and `bottom` elements define the distance from the lower-left corner of the container to the lower-left corner of the axes. The `width` and `height` elements are the axes dimensions.

By default, the values are measured in units normalized to the container. To change the units, set the `Units` property.

The axes dimensions are the largest possible values that conform to all other properties and do not extend outside the `Position` rectangle. Other axes properties that affect the axes size and shape include `DataAspectRatio`, `PlotBoxAspectRatio`, and `CameraViewAngle`.

Example: `ax.Position = [0 0 1 1]`

### **TightInset** — Margins for text labels

four-element vector of the form `[left bottom right top]`

This property is read only.

Margins for the text labels, specified as a four-element vector of the form `[left bottom right top]`. The elements define the distances between the bounds of the `Position` property and the extent of the axes text labels and title. By default, the values are measured in units normalized to the figure or uipanel that contains the axes. To change the units, set the `Units` property.

The `Position` property and the `TightInset` property define the tightest bounding box that encloses the axes and its labels and title. The figure shows the region defined by combining the `TightInset` values and the `Position` values.

For more information, see “Axes Resize to Accommodate Titles and Labels”.

**OuterPosition** — Size and location of axes, including labels and margins

[0 0 1 1] (default) | four-element vector

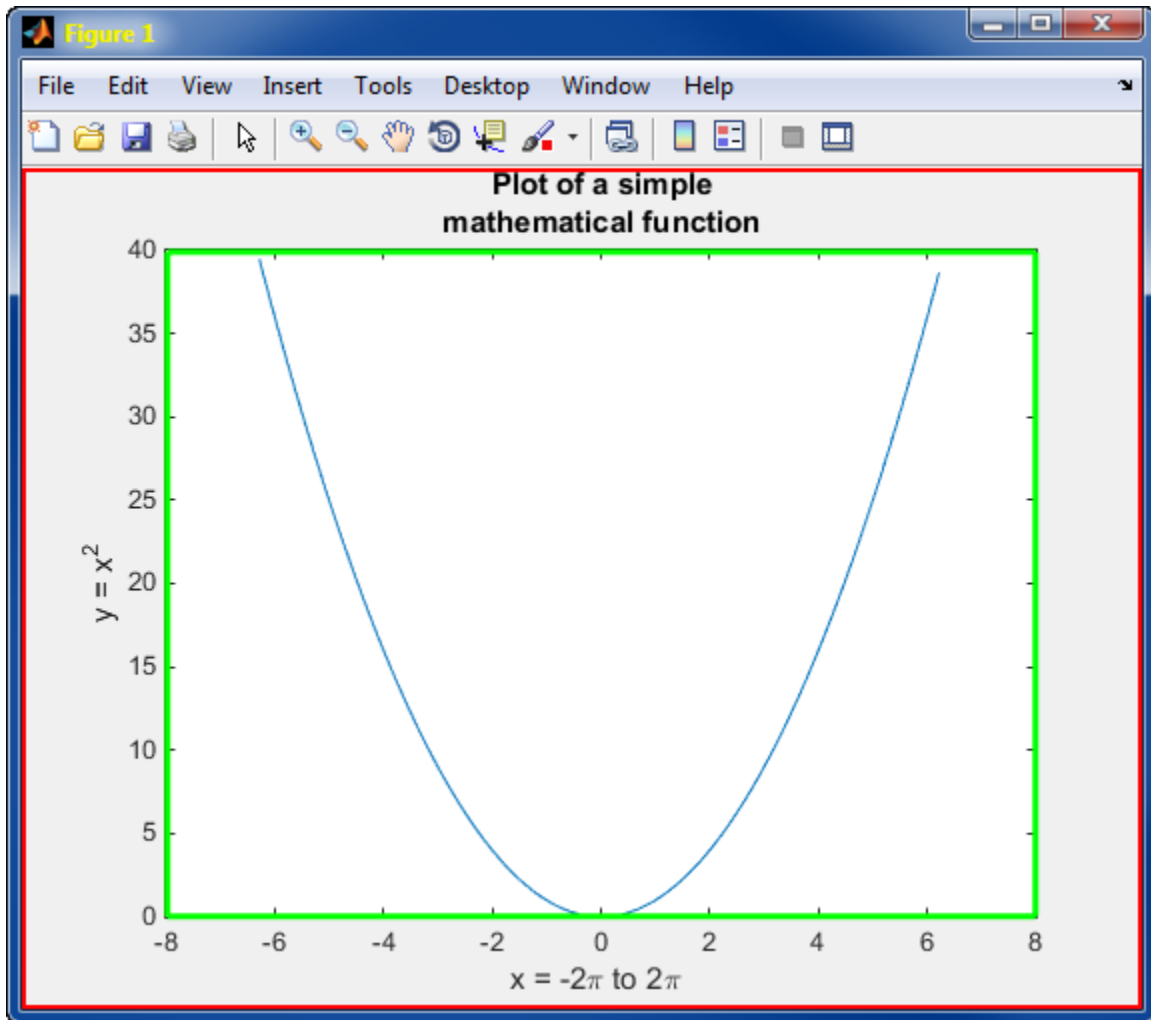

Size and location of axes, including the labels and margins, specified as a four-element vector of the form [left bottom width height]. This vector defines the extents of

the rectangle that encloses the outer bounds of the axes. The `left` and `bottom` elements define the distance from the lower-left corner of the figure or uipanel that contains the axes to the lower-left corner of the rectangle. The `width` and `height` elements are the rectangle dimensions.

By default, the values are measured in units normalized to the container. To change the units, set the `Units` property. The default value of `[0 0 1 1]` includes the whole interior of the container.

The figure shows the region defined by the `OuterPosition` enclosed in the red rectangle. The green rectangle is the region defined by the `Position` property.

For more information, see “Axes Resize to Accommodate Titles and Labels”.

**ActivePositionProperty** — Position property to hold constant during resize operation  
'outerposition' (default) | 'position'

Position property to hold constant during resize operation, specified as one of these values:

- 'outerposition' — Hold the OuterPosition property constant. Resizing the figure does not clip any of the text.
- 'position' — Hold the Position property constant.

A figure can change size if you interactively change resize it or during a printing or exporting operation.

**Units — Position units**

'normalized' (default) | 'inches' | 'centimeters' | 'points' | 'pixels' | 'characters'

Position units, specified as one of the values in this table.

| Units                  | Description                                                                                                                                                                                                                              |
|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'normalized' (default) | Normalized with respect to the container, which is typically the figure or a uipanel. The lower left corner of the container maps to (0,0) and the upper right corner maps to (1,1).                                                     |
| 'inches'               | Inches.                                                                                                                                                                                                                                  |
| 'centimeters'          | Centimeters.                                                                                                                                                                                                                             |
| 'characters'           | Based on the default system font character size. <ul style="list-style-type: none"> <li>• Character width = width of letter x.</li> <li>• Character height = distance between the baselines of two lines of text.</li> </ul>             |
| 'points'               | Typography points. One point equals 1/72 inch.                                                                                                                                                                                           |
| 'pixels'               | Pixels.<br><br>Starting in R2015b, distances in pixels are independent of your system resolution on Windows and Macintosh systems: <ul style="list-style-type: none"> <li>• On Windows systems, a pixel is 1/96th of an inch.</li> </ul> |

| Units | Description                                                                                                                                                                                 |
|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|       | <ul style="list-style-type: none"> <li>On Macintosh systems, a pixel is 1/72nd of an inch.</li> </ul> <p>On Linux systems, the size of a pixel is determined by your system resolution.</p> |

When specifying the units as a Name , Value pair during object creation, you must set the Units property before specifying the properties that you want to use these units, such as Position.

## Aspect Ratio

### Projection — Type of projection onto 2-D screen

'orthographic' (default) | 'perspective'

Type of projection onto 2-D screen, specified as one of these values:

- 'orthographic' — Maintain the correct relative dimensions of graphics objects regarding the distance of a given point from the viewer, and draw lines that are parallel in the data on the screen.
- 'perspective' — Incorporate foreshortening, which allows you to perceive depth in 2-D representations of 3-D objects. Perspective projection does not preserve the relative dimensions of objects. Instead, it displays a distant line segment smaller than a nearer line segment of the same length. Lines that are parallel in the data might not appear parallel on screen.

### DataAspectRatio — Relative length of data units along each axis

[1 1 1] (default) | three-element vector of the form [dx dy dz]

Relative length of data units along each axis, specified as a three-element vector of the form [dx dy dz]. This vector defines the relative  $x$ ,  $y$ , and  $z$  data scale factors. For example, specifying this property as [1 2 1] sets the length of one unit of data in the  $x$ -direction to be the same length as two units of data in the  $y$ -direction and one unit of data in the  $z$ -direction.

The DataAspectRatio property interacts with the PlotBoxAspectRatio, XLimMode, YLimMode, and ZLimMode properties to control how MATLAB scales the  $x$ -axis,  $y$ -axis, and  $z$ -axis.

Setting a value for the `DataAspectRatio` disables the “stretch-to-fill figure shape” behavior if `DataAspectRatioMode`, `PlotBoxAspectRatioMode`, and `CameraViewAngleMode` are all set to 'auto'.

If the associated mode property is set to 'auto', then MATLAB chooses the ratio values. If you set this property, then MATLAB sets the mode to 'manual'.

Example: [1 1 1]

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**DataAspectRatioMode — Selection mode for DataAspectRatio**

'auto' (default) | 'manual'

Selection mode for the `DataAspectRatio` property, specified as one of these values:

- 'auto' — Use values that make best use of the area provided by the figure.
- 'manual' — Use the manually specified values. To specify the values, set the `DataAspectRatio` property. Changing `DataAspectRatioMode` to 'manual' disables the “stretch-to-fill figure shape” behavior if `DataAspectRatioMode`, `PlotBoxAspectRatioMode`, and `CameraViewAngleMode` are all 'auto'.

This table describes the behavior for various combinations of properties when you disable the stretch-to-fill behavior.

| <b>XLimitMode, YLimitMode, and ZLimitMode</b> | <b>DataAspectRatioMode</b> | <b>PlotBoxAspectRatioMode</b> | <b>Behavior</b>                                                                                                                                                                          |
|-----------------------------------------------|----------------------------|-------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'auto'                                        | 'auto'                     | 'auto'                        | The axes chooses limits that span the data range in all dimensions.                                                                                                                      |
| 'auto'                                        | 'auto'                     | 'manual'                      | The axes chooses limits that span the data range in all dimensions and modifies <code>DataAspectRatio</code> to achieve the specified <code>PlotBoxAspectRatio</code> within the limits. |
| 'auto'                                        | 'manual'                   | 'auto'                        | The axes chooses limits that span the data                                                                                                                                               |

| XLimitMode, YLimitMode, and ZLimitMode | DataAspectRatioMode | PlotBoxAspectRatioMode | Behavior                                                                                                                                                                                                                             |
|----------------------------------------|---------------------|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                        |                     |                        | range in all dimensions and modifies <code>PlotBoxAspectRatio</code> to achieve the specified <code>DataAspectRatio</code> within the limits.                                                                                        |
| 'auto'                                 | 'manual'            | 'manual'               | The axes chooses limits that completely fit and center the plot within the specified <code>PlotBoxAspectRatio</code> given the specified <code>DataAspectRatio</code> (this might produce empty space around 2 of the 3 dimensions). |
| 'manual'                               | 'auto'              | 'auto'                 | The axes honors the specified limits and modifies the <code>DataAspectRatio</code> and <code>PlotBoxAspectRatio</code> as necessary.                                                                                                 |
| 'manual'                               | 'auto'              | 'manual'               | The axes honors the specified limits and <code>PlotBoxAspectRatio</code> values and modifies the <code>DataAspectRatio</code> values as necessary.                                                                                   |
| 'manual'                               | 'manual'            | 'auto'                 | The axes honors the specified limits and <code>DataAspectRatio</code> values and modifies the <code>PlotBoxAspectRatio</code> values as necessary.                                                                                   |

| <b>XLimitMode, YLimitMode, and ZLimitMode</b>                           | <b>DataAspectRatioMode</b> | <b>PlotBoxAspectRatioMode</b> | <b>Behavior</b>                                                                                                           |
|-------------------------------------------------------------------------|----------------------------|-------------------------------|---------------------------------------------------------------------------------------------------------------------------|
| One set to 'manual' and two set to 'auto'                               | 'manual'                   | 'manual'                      | The axes selects the remaining limits to honor the specified aspect ratios and limit.                                     |
| Two set to 'manual' and one set to 'auto', or all three set to 'manual' | 'manual'                   | 'manual'                      | The axes ignores the <code>PlotBoxAspectRatio</code> value and uses the specified limits and <code>DataAspectRatio</code> |

### **PlotBoxAspectRatio — Relative length of each axis**

[1 1 1] (default) | three-element vector of the form [px py pz]

Relative length of each axis, specified as a three-element vector of the form [px py pz] defining the relative x-axis, y-axis, and z-axis scale factors. The plot box is a box enclosing the axes data region as defined by the axis limits.

The `PlotBoxAspectRatio` property interacts with the `DataAspectRatio`, `XLimMode`, `YLimMode`, and `ZLimMode` properties. Setting the `PlotBoxAspectRatio` disables the “stretch-to-fill figure shape” behavior, if `DataAspectRatioMode`, `PlotBoxAspectRatioMode`, and `CameraViewAngleMode` are all 'auto'.

If the associated mode property is set to 'auto', then MATLAB chooses the ratio values. If you set this property, then MATLAB sets the mode to 'manual'.

Example: [1,0.75,0.75]

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

### **PlotBoxAspectRatioMode — Selection mode for PlotBoxAspectRatio**

'auto' (default) | 'manual'

Selection mode for the `PlotBoxAspectRatio` property, specified as one of these values:

- 'auto' — Use values that make best use of the area provided by the figure.
- 'manual' — Use the manually specified values. To specify the values, set the `PlotBoxAspectRatio` property. Changing `PlotBoxAspectRatioMode`

to 'manual' disables the “stretch-to-fill figure shape” behavior if `PlotBoxAspectRatioMode`, `DataAspectRatioMode`, and `CameraViewAngleMode` are all 'auto'.

This table describes the behavior for various combinations of properties when you disable the stretch-to-fill behavior.

| <b>XLimitMode, YLimitMode, and ZLimitMode</b> | <b>DataAspectRatioMode</b> | <b>PlotBoxAspectRatioMode</b> | <b>Behavior</b>                                                                                                                                                                                                                      |
|-----------------------------------------------|----------------------------|-------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'auto'                                        | 'auto'                     | 'auto'                        | The axes chooses limits that span the data range in all dimensions.                                                                                                                                                                  |
| 'auto'                                        | 'auto'                     | 'manual'                      | The axes chooses limits that span the data range in all dimensions and modifies <code>DataAspectRatio</code> to achieve the specified <code>PlotBoxAspectRatio</code> within the limits.                                             |
| 'auto'                                        | 'manual'                   | 'auto'                        | The axes chooses limits that span the data range in all dimensions and modifies <code>PlotBoxAspectRatio</code> to achieve the specified <code>DataAspectRatio</code> within the limits.                                             |
| 'auto'                                        | 'manual'                   | 'manual'                      | The axes chooses limits that completely fit and center the plot within the specified <code>PlotBoxAspectRatio</code> given the specified <code>DataAspectRatio</code> (this might produce empty space around 2 of the 3 dimensions). |

| <b>XLimitMode, YLimitMode, and ZLimitMode</b>                           | <b>DataAspectRatioMode</b> | <b>PlotBoxAspectRatioMode</b> | <b>Behavior</b>                                                                                                                                    |
|-------------------------------------------------------------------------|----------------------------|-------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| 'manual'                                                                | 'auto'                     | 'auto'                        | The axes honors the specified limits and modifies the <code>DataAspectRatio</code> and <code>PlotBoxAspectRatio</code> as necessary.               |
| 'manual'                                                                | 'auto'                     | 'manual'                      | The axes honors the specified limits and <code>PlotBoxAspectRatio</code> values and modifies the <code>DataAspectRatio</code> values as necessary. |
| 'manual'                                                                | 'manual'                   | 'auto'                        | The axes honors the specified limits and <code>DataAspectRatio</code> values and modifies the <code>PlotBoxAspectRatio</code> values as necessary. |
| One set to 'manual' and two set to 'auto'                               | 'manual'                   | 'manual'                      | The axes selects the remaining limits to honor the specified aspect ratios and limit.                                                              |
| Two set to 'manual' and one set to 'auto', or all three set to 'manual' | 'manual'                   | 'manual'                      | The axes ignores the <code>PlotBoxAspectRatio</code> value and uses the specified limits and <code>DataAspectRatio</code>                          |

## View

### **CameraPosition** — Location of camera

three-element vector of the form `[x y z]`

Location of camera, or the viewpoint, specified as a three-element vector of the form `[x y z]`. This vector defines the axes coordinates of the location. Changing the `CameraPosition` property changes the point from which you view the axes.

The camera is oriented along the view axis, which is a straight line that connects the camera position and the camera target. For an illustration, see “Camera Graphics Terminology”.

If the Projection is 'perspective', then as you change the CameraPosition, the amount of perspective also changes.

If the associated mode property is set to 'auto', then MATLAB chooses the camera location. If you set this property, then MATLAB sets the mode to 'manual'.

Data Types: single | double

**CameraPositionMode — Selection mode for CameraPosition**

'auto' (default) | 'manual'

Selection mode for the CameraPosition property, specified as one of these values:

- 'auto' — Calculate the CameraPosition value such that the camera lies a fixed distance from the target along the azimuth and elevation specified by the current view, as returned by the view function. Functions like rotate3d, zoom, and pan, change this mode to 'auto' to perform their actions.
- 'manual' — Use the manually specified value. To specify the value, set the CameraPosition property.

This table summarizes the camera behavior for various combinations of CameraViewAngleMode, CameraTargetMode, and CameraPositionMode property values.

| CameraViewAngleMode | CameraTargetMode | CameraPositionMode | Behavior                                                                                                                       |
|---------------------|------------------|--------------------|--------------------------------------------------------------------------------------------------------------------------------|
| 'auto'              | 'auto'           | 'auto'             | Sets CameraTarget to plot box centroid, sets CameraViewAngle to capture entire scene, sets CameraPosition along the view axis. |
| 'auto'              | 'auto'           | 'manual'           | Sets CameraTarget to plot box centroid, sets CameraViewAngle to capture entire scene.                                          |
| 'auto'              | 'manual'         | 'auto'             | Sets CameraViewAngle to                                                                                                        |

| CameraViewAngleMode | CameraTargetMode | CameraPositionMode | Behavior                                                                         |
|---------------------|------------------|--------------------|----------------------------------------------------------------------------------|
|                     |                  |                    | capture entire scene, sets CameraPosition along the view axis.                   |
| 'auto'              | 'manual'         | 'manual'           | Sets CameraViewAngle to capture entire scene.                                    |
| 'manual'            | 'auto'           | 'auto'             | Sets CameraTarget to plot box centroid, sets CameraPosition along the view axis. |
| 'manual'            | 'auto'           | 'manual'           | Sets CameraTarget to plot box centroid.                                          |
| 'manual'            | 'manual'         | 'auto'             | Sets CameraPosition along the view axis.                                         |
| 'manual'            | 'manual'         | 'manual'           | Uses specified camera values                                                     |

### CameraTarget — Point used as camera target

three-element vector of the form  $[x \ y \ z]$

Point used as camera target, specified as a three-element vector of the form  $[x \ y \ z]$ . This vector defines the axes coordinates of the point. The camera is oriented along the view axis, which is a straight line that connects the camera position and the camera target. For an illustration, see “Camera Graphics Terminology”.

If the associated mode property is set to 'auto', then MATLAB chooses the camera target point. If you set this property, then MATLAB sets the mode to 'manual'.

Data Types: single | double

### CameraTargetMode — Selection mode for CameraTarget

'auto' (default) | 'manual'

Selection mode for the CameraTarget property, specified as one of these values:

- 'auto' — Position the camera target at the centroid of the axes plot box.
- 'manual' — Use the manually specified camera target value. To specify a value, set the CameraTarget property.

This table summarizes the camera behavior for various combinations of `CameraViewAngleMode`, `CameraTargetMode`, and `CameraPositionMode` property values.

| <code>CameraViewAngleMode</code> | <code>CameraTargetMode</code> | <code>CameraPositionMode</code> | Behavior                                                                                                                                                              |
|----------------------------------|-------------------------------|---------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'auto'                           | 'auto'                        | 'auto'                          | Sets <code>CameraTarget</code> to plot box centroid, sets <code>CameraViewAngle</code> to capture entire scene, sets <code>CameraPosition</code> along the view axis. |
| 'auto'                           | 'auto'                        | 'manual'                        | Sets <code>CameraTarget</code> to plot box centroid, sets <code>CameraViewAngle</code> to capture entire scene.                                                       |
| 'auto'                           | 'manual'                      | 'auto'                          | Sets <code>CameraViewAngle</code> to capture entire scene, sets <code>CameraPosition</code> along the view axis.                                                      |
| 'auto'                           | 'manual'                      | 'manual'                        | Sets <code>CameraViewAngle</code> to capture entire scene.                                                                                                            |
| 'manual'                         | 'auto'                        | 'auto'                          | Sets <code>CameraTarget</code> to plot box centroid, sets <code>CameraPosition</code> along the view axis.                                                            |
| 'manual'                         | 'auto'                        | 'manual'                        | Sets <code>CameraTarget</code> to plot box centroid.                                                                                                                  |
| 'manual'                         | 'manual'                      | 'auto'                          | Sets <code>CameraPosition</code> along the view axis.                                                                                                                 |
| 'manual'                         | 'manual'                      | 'manual'                        | Uses specified camera values                                                                                                                                          |

**CameraUpVector — Vector defining upwards direction**

[0 1 0] (default for 2-D view) | [0 0 1] (default for 3-D view) | three-element direction vector of the form [x y z]

Vector defining upwards direction, specified as a three-element direction vector of the form  $[x \ y \ z]$ . For an illustration, see “Camera Graphics Terminology”.

If the associated mode property is set to 'auto', then MATLAB chooses the vector values. If you set this property, then MATLAB sets the mode to 'manual'.

Example: `[sin(45) cos(45) 1]`

### **CameraUpVectorMode — Selection mode for CameraUpVector**

'auto' (default) | 'manual'

Selection mode for the `CameraUpVector` property, specified as one of these values:

- 'auto' — Use `[0 0 1]` for 3-D views so that the positive  $z$ -direction is up. Use `[0 1 0]` for 2-D views so that the positive  $y$ -direction is up.
- 'manual' — Use the manually specified vector defining the upwards direction. To specify a value, set the `CameraUpVector` property.

### **CameraViewAngle — Field of view**

6.6086 (default) | scalar angle in range [0,180)

Field of view, specified as a scalar angle greater than 0 and less than or equal to 180. Changing the camera view angle affects the size of graphics objects displayed in the axes, but does not affect the degree of perspective distortion. The greater the angle, the larger the field of view and the smaller objects appear in the scene. For an illustration, see “Camera Graphics Terminology”.

If the associated mode property is set to 'auto', then MATLAB chooses the field of view value. If you set this property, then MATLAB sets the mode to 'manual'.

Example: 15

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

### **CameraViewAngleMode — Selection mode for CameraViewAngle**

'auto' (default) | 'manual'

Selection mode for the `CameraViewAngle` property, specified as one of these values:

- 'auto' — Select the field of view as the minimum angle that captures the entire scene, up to 180 degrees.
- 'manual' — Use the manually specified field of view. To specify a value, set the `CameraViewAngle` property.

This table summarizes the camera behavior for various combinations of `CameraViewAngleMode`, `CameraTargetMode`, and `CameraPositionMode` property values.

| CameraViewAngleMode | CameraTargetMode | CameraPositionMode | Behavior                                                                                                                                                              |
|---------------------|------------------|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'auto'              | 'auto'           | 'auto'             | Sets <code>CameraTarget</code> to plot box centroid, sets <code>CameraViewAngle</code> to capture entire scene, sets <code>CameraPosition</code> along the view axis. |
| 'auto'              | 'auto'           | 'manual'           | Sets <code>CameraTarget</code> to plot box centroid, sets <code>CameraViewAngle</code> to capture entire scene.                                                       |
| 'auto'              | 'manual'         | 'auto'             | Sets <code>CameraViewAngle</code> to capture entire scene, sets <code>CameraPosition</code> along the view axis.                                                      |
| 'auto'              | 'manual'         | 'manual'           | Sets <code>CameraViewAngle</code> to capture entire scene.                                                                                                            |
| 'manual'            | 'auto'           | 'auto'             | Sets <code>CameraTarget</code> to plot box centroid, sets <code>CameraPosition</code> along the view axis.                                                            |
| 'manual'            | 'auto'           | 'manual'           | Sets <code>CameraTarget</code> to plot box centroid.                                                                                                                  |
| 'manual'            | 'manual'         | 'auto'             | Sets <code>CameraPosition</code> along the view axis.                                                                                                                 |
| 'manual'            | 'manual'         | 'manual'           | Uses specified camera values                                                                                                                                          |

**View — Azimuth and elevation of view**

[0 90] (default) | two-element vector of the form [azimuth elevation]

Azimuth and elevation of view, specified as a two-element vector of the form [azimuth elevation] defined in degree units.

Example: `ax.View = [45 45];`

## Identifiers

### Type — Type of graphics object

'axes'

This property is read only.

Type of graphics object returned as the string 'axes'.

### Tag — Tag to associate with axes

' ' (default) | any string

Tag to associate with the axes, specified as a string. Tags provide a way to identify graphics objects. Use this property to find all objects with a specific tag within a plotting hierarchy, for example, searching for the tag using `findobj`.

Example: 'January Data'

### UserData — Data to associate with axes

[] (default) | scalar, vector, or matrix | cell array | character array | table | structure

Data to associate with the axes object, specified as a scalar, vector, matrix, cell array, character array, table, or structure. MATLAB does not use this data.

To associate multiple sets of data or to attach a field name to the data, use the `getappdata` and `setappdata` functions.

Example: `1:100`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char` | `struct` | `table` | `cell`

## Parent/Child

### Parent — Parent of axes

figure object | uipanel object | uitab object

Parent of axes, specified as figure object, uipanel object, or uitab object.

### **Children — Children of axes**

empty GraphicsPlaceholder array | array of graphics objects

Children of axes, returned as an array of graphics objects. Use this property to view a list of the children or to reorder the children by setting the property to a permutation of itself.

You cannot add or remove children using the `Children` property of the axes. To add a child to this list, set the `Parent` property of the child graphics object to the axes object.

### **HandleVisibility — Visibility of object handle**

'on' (default) | 'off' | 'callback'

Visibility of axes object handle in the `Children` property of the parent, specified as one of these values:

- 'on' — The axes object handle is always visible.
- 'off' — The axes object handle is invisible at all times. This option is useful for preventing unintended changes to the UI by another function. Set the `HandleVisibility` to 'off' to temporarily hide the handle during the execution of that function.
- 'callback' — The axes object handle is visible from within callbacks or functions invoked by callbacks, but not from within functions invoked from the command line. This option blocks access to the axes at the command-line, but allows callback functions to access it.

If the axes object is not listed in the `Children` property of the parent, then functions that obtain object handles by searching the object hierarchy or querying handle properties cannot return it. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

Hidden object handles are still valid. Set the root `ShowHiddenHandles` property to 'on' to list all object handles regardless of their `HandleVisibility` property setting.

## **Interactive Control**

### **CurrentPoint — Location of mouse pointer**

2-by-3 array

Location of mouse pointer, specified as a 2-by-3 array. The `CurrentPoint` property contains the coordinates of two points defined by the location of the mouse pointer with respect to the requested axes.

The two points indicate the location of the last mouse click, unless there is a `WindowButtonMotionFcn` callback defined for the figure. If the `WindowButtonMotionFcn` callback is defined, then the points indicate the last location of the mouse pointer.

If the click is within the axes in orthogonal projection, then the two points lie on the line that is perpendicular to the plane of the screen and that passes through the pointer. This is true for both 2-D and 3-D views.

The 3-D coordinates are the points, in the axes coordinate system, where this line intersects the front and back surfaces of the axes volume (which is defined by the axes `x`, `y`, and `z` limits).

The returned matrix is of the form:

```
[xfront yfront zfront
 xback yback zback]
```

The first row defines the point nearest to the camera position. The second row specified the point furthest from the camera position.

If the click is outside the axes in orthogonal projection, but within the figure, the returned values are:

- Back point — Point in the plane of the camera target (which is perpendicular to the viewing axis).
- Front point — Point in the camera position plane (which is perpendicular to the viewing axis).

These points lie on a line that passes through the pointer and is perpendicular to the camera target and camera position planes.

The values of the current point when using perspective projection can be different from the same point in orthographic projection because the shape of the axes volume can be different.

Clicking outside of the axes volume in perspective projection returns the front point as the current camera position at all times. Only the back point updates with the coordinates of a point that lies on a line extending from the camera position through the pointer and intersecting the camera target at that point.

For related information, see the axes `Projection`, `CameraPosition`, and `CameraTarget` properties. Also, see the figure `CurrentPoint` properties.

### **ButtonDownFcn — Mouse-click callback**

' ' (default) | function handle | cell array | string

Mouse-click callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you click the axes. If you specify this property using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The axes object — You can access properties of the axes object from within the callback function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see “Callback Definition”.

---

**Note:** If the `PickableParts` property is set to 'none' or if the `HitTest` property is set to 'off', then this callback does not execute.

---

Example: `@myCallback`

Example: `{@myCallback, arg3}`

### **UIContextMenu — Context menu**

`uicontextmenu` object

Context menu, specified as a `uicontextmenu` object. Use this property to display a context menu when you right-click the axes. Create the context menu using the `uicontextmenu` function.

---

**Note:** If the `PickableParts` property is set to 'none' or if the `HitTest` property is set to 'off', then the context menu does not appear.

---

**Selected** — Selection state`'off'` (default) | `'on'`

Selection state, specified as one of these values:

- `'on'` — Selected. If you click the axes when in plot edit mode, then MATLAB sets its `Selected` property to `'on'`. If the `SelectionHighlight` property also is set to `'on'`, then MATLAB displays selection handles around the axes.
- `'off'` — Not selected.

**SelectionHighlight** — Display of selection handles when selected`'on'` (default) | `'off'`

Display of selection handles when selected, specified as one of these values:

- `'on'` — Display selection handles when the `Selected` property is set to `'on'`.
- `'off'` — Never display selection handles, even when the `Selected` property is set to `'on'`.

## Callback Execution Control

**PickableParts** — Ability to capture mouse clicks`'visible'` (default) | `'all'` | `'none'`

Ability to capture mouse clicks, specified as one of these values:

- `'visible'` — Can capture mouse clicks only when visible. The `Visible` property must be set to `'on'`. The `HitTest` property determines if the axes responds to the click or if an ancestor does.
- `'all'` — Can capture mouse clicks regardless of visibility. The `Visible` property can be set to `'on'` or `'off'`. The `HitTest` property determines if the axes responds to the click or if an ancestor does.
- `'none'` — Cannot capture mouse clicks. Clicking the axes passes the click to the object below it in the current view of the figure window, which is typically the axes or the figure. The `HitTest` property has no effect.

If you want an object to be clickable when it is underneath other objects that you do not want to be clickable, then set the `PickableParts` property of the other objects to `'none'` so that the click passes through them.

### **HitTest — Response to captured mouse clicks**

'on' (default) | 'off'

Response to captured mouse clicks, specified as one of these values:

- 'on' — Trigger the `ButtonDownFcn` callback of the axes. If you have defined the `UIContextMenu` property, then invoke the context menu.
- 'off' — Trigger the callbacks for the nearest ancestor of the axes that has a `HitTest` property set to 'on' and a `PickableParts` property value that enables the ancestor to capture mouse clicks.

---

**Note:** The `PickableParts` property determines if the axes object can capture mouse clicks. If it cannot, then the `HitTest` property has no effect.

---

### **Interruptible — Callback interruption**

'on' (default) | 'off'

Callback interruption, specified as 'on' or 'off'. The `Interruptible` property determines if a running callback can be interrupted.

---

**Note:** There are two callback states to consider:

- The *running* callback is the currently executing callback.
  - The *interrupting* callback is a callback that tries to interrupt the running callback. Whenever MATLAB invokes a callback, that callback attempts to interrupt a running callback. The `Interruptible` property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the `BusyAction` property of the object owning the interrupting callback determines if it is discarded or put in the queue.
- 

If the `ButtonDownFcn` callback of the axes is the running callback, then the `Interruptible` property determines if it another callback can interrupt it:

- 'on' — Interruptible. Interruption occurs at the next point where MATLAB processes the queue, such as when there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command.

- If the running callback contains one of these commands, then MATLAB stops the execution of the callback at this point and executes the interrupting callback. MATLAB resumes executing the running callback when the interrupting callback completes. For more information, see “Interrupt Callback Execution”.
- If the running callback does not contain one of these commands, then MATLAB finishes executing the callback without interruption.
- 'off' — Not interruptible. MATLAB finishes executing the running callback without any interruptions.

### **BusyAction — Callback queuing**

'queue' (default) | 'cancel'

Callback queuing specified as 'queue' or 'cancel'. The `BusyAction` property determines how MATLAB handles the execution of interrupting callbacks.

---

**Note:** There are two callback states to consider:

- The *running* callback is the currently executing callback.
- The *interrupting* callback is a callback that tries to interrupt the running callback.

Whenever MATLAB invokes a callback, that callback attempts to interrupt a running callback. The `Interruptible` property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the `BusyAction` property of the object owning the interrupting callback determines if it is discarded or put in the queue.

---

If the `ButtonDownFcn` callback of the axes tries to interrupt a running callback that cannot be interrupted, then the `BusyAction` property determines if it is discarded or put in the queue. Specify the `BusyAction` property as one of these values:

- 'queue' — Put the interrupting callback in a queue to be processed after the running callback finishes execution. This is the default behavior.
- 'cancel' — Discard the interrupting callback.

## **Creation and Deletion Control**

### **CreateFcn — Creation callback**

' ' (default) | function handle | cell array | string

Creation callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you create the axes. Setting the `CreateFcn` property on an existing axes has no effect. You must define a default value for this property, or define this property using a `Name, Value` pair during axes creation. MATLAB executes the callback after creating the axes and setting all of its properties.

If you specify this callback using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The axes object — You can access properties of the axes object from within the callback function. You also can access the axes object through the `CallbackObject` property of the root, which can be queried using the `gcb0` function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see “Callback Definition”.

Example: `@myCallback`

Example: `{@myCallback, arg3}`

### **DeleteFcn — Deletion callback**

' ' (default) | function handle | cell array | string

Deletion callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you delete the axes. MATLAB executes the callback before destroying the axes so that the callback can access its property values.

If you specify this callback using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The axes object — You can access properties of the axes object from within the callback function. You also can access the axes object through the `CallbackObject` property of the root, which can be queried using the `gcb0` function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see “Callback Definition”.

Example: `@myCallback`

Example: `{@myCallback, arg3}`

### **BeingDeleted** — Deletion status of axes

'off' (default) | 'on'

This property is read only.

Deletion status of axes, returned as 'on' or 'off'. MATLAB sets the `BeingDeleted` property to 'on' when the delete function of the axes begins execution (see the `DeleteFcn` property). The `BeingDeleted` property remains set to 'on' until the axes no longer exists.

Check the value of the `BeingDeleted` property to verify that the axes is not about to be deleted before querying or modifying it.

## **axis**

Set axis limits and appearance

### **Syntax**

```
axis(limits)
```

```
axis style
```

```
axis mode
```

```
axis ydirection
```

```
axis visibility
```

```
lim = axis
```

```
[m,v,d] = axis('state')
```

```
___ = axis(ax, ___)
```

### **Description**

`axis(limits)` sets the *x*-axis and *y*-axis limits for the current axes. Specify `limits` as a four-element vector of the form `[xmin xmax ymin ymax]`. To additionally set the *z*-axis limits, specify a six-element vector. To additionally set the color limits, specify an eight-element vector.

`axis style` uses a predefined style to set the limits and scaling. For example, specify the style as `equal` to use equal data unit lengths along each axis.

`axis mode` sets whether the axes automatically chooses the limits or not. Specify the mode as `manual`, `auto`, or one of the semiautomatic options, for example, `'auto x'`.

`axis ydirection` controls the placement of the coordinate system origin and the direction of increasing *y* values. Set `ydirection` to `ij` to place the origin at the upper left corner of the axes. The *y* values increase from top to bottom. Set `ydirection` to `xy` to place the origin at the lower left corner. The *y* values increase from bottom to top. This is the default value.

`axis visibility` controls the visibility of the axes background. Set `visibility` to `off` to turn off the display of the axes background. Plots in the axes still display. Set `visibility` to `on` to display the axes background. This is the default value.

`lim = axis` returns the  $x$ -axis and  $y$ -axis limits for the current axes. For 3-D axes, it additionally returns the  $z$ -axis limits.

`[m,v,d] = axis('state')` returns the current settings for the axis limit selection, the axes visibility, and the  $y$ -axis direction.

---

**Note:** This syntax will be removed in a future release. Use the `XLimMode`, `YLimMode`, `ZLimMode`, `Visible`, and `YDir` properties of the axes to the get values instead.

---

`___ = axis(ax, ___)` uses the axes specified by `ax` instead of the current axes. The `ax` input argument can precede any of the input arguments in the previous syntaxes. Use single quotes around input arguments that are character strings, for example, `axis(ax, 'equal')`. You can include any of the output arguments in the preceding syntaxes if the original syntax supports an output argument.

## Examples

### Set Axis Limits

Plot the sine function.

```
x = linspace(0,2*pi);
y = sin(x);
plot(x,y, '-o')
```

Change the axis limits so that the  $x$ -axis ranges from  $0$  to  $2\pi$  and the  $y$ -axis ranges from  $-1.5$  to  $1.5$ .

```
axis([0 2*pi -1.5 1.5])
```

### Use Semiautomatic Axis Limits

Create a plot. Set the limits for the  $x$ -axis and set the minimum  $y$ -axis limit. Use an automatically calculated value for the maximum  $y$ -axis limit.

```
x = linspace(-10,10,200);
y = sin(4*x)./exp(.1*x);
plot(x,y)
axis([-10 10 0 inf])
```

### Set Axis Limits for Multiple Axes

Create a figure with two subplots. Plot a sine wave in each subplot. Then, set the axis limits for the subplots to the same values.

```
x1 = linspace(0,10,100);
y1 = sin(x1);
ax1 = subplot(2,1,1);
plot(ax1,x1,y1)
```

```
x2 = linspace(0,5,100);
y2 = sin(x2);
ax2 = subplot(2,1,2);
plot(ax2,x2,y2)
```

```
axis([ax1 ax2],[0 10 -1 1])
```

### Display Plot Without Axes Background

Plot a surface without displaying the axes lines and background.

```
surf(peaks)
axis off
```

### Use Tight Axis Limits and Return Values

Plot a surface. Set the axis limits to equal the range of the data so that the plot extends to the edges of the axes.

```
surf(peaks)
axis tight
```

Return the values of the current axis limits.

```
l = axis
```

```
l =
```

```
1.0000 49.0000 1.0000 49.0000 -6.5466 8.0752
```

### Change Direction of Coordinate System

Create a checkerboard plot and change the direction of the coordinate system.

First, create the plot using the `summer` colormap. By default, the  $x$  values increase from left to right and the  $y$  values increase from bottom to top.

```
C = eye(10);
pcolor(C)
colormap summer
```

Reverse the coordinate system so that the  $y$  values increase from top to bottom.

```
axis ij
```

### Retain Current Axis Limits When Adding New Plots

Plot a sine wave.

```
x = linspace(0,10);
y = sin(x);
plot(x,y)
```

Add another sine wave to the axes using `hold on`. Keep the current axis limits by setting the limits mode to manual.

```
y2 = 2*sin(x);
hold on
axis manual
plot(x,y2)
hold off
```

If you want the axes to choose the appropriate limits, set the limits mode back to automatic.

axis auto

## Input Arguments

### **limits** — Axis limits

four-element vector | six-element vector | eight-element vector

Axis limits, specified as a vector of four, six, or eight elements in one of these forms:

- `[xmin xmax ymin ymax]` — Set the *x*-axis limits to range from `xmin` to `xmax`. Set the *y*-axis limits to range from `ymin` to `ymax`.
- `[xmin xmax ymin ymax zmin zmax]` — Additionally set the *z*-axis limits to range from `zmin` to `zmax`.

- `[xmin xmax ymin ymax zmin zmax cmin cmax]` — Additionally set the color limits. `cmin` is the data value that maps to the first color in the colormap. `cmax` is the data value that maps to the last color in the colormap.

---

**Note:** For partially automatic limits, use `inf` or `-inf` for the limits you want the axes to choose automatically. For example, `axis([-inf 10 0 inf])` lets the axes choose the appropriate minimum *x*-axis limit and maximum *y*-axis limit. It uses the specified values for the maximum *x*-axis limit and minimum *y*-axis limit.

---

If you specify the limits, then the `XLim`, `YLim`, `ZLim`, and `CLim` properties for the axes change to the specified values. Additionally, the associated mode properties change to `'manual'`.

Example: `[0 1 0 1]`

Example: `[0 1 0 1 0 1]`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**mode** — Manual, automatic, or semiautomatic selection of axis limits

`manual` | `auto` | `'auto x'` | `'auto y'` | `'auto z'` | `'auto xy'` | `'auto xz'` | `'auto yz'`

Manual, automatic, or semiautomatic selection of axis limits, specified as one of the values in this table.

| Value                 | Description                                               | Axes Properties That Change                                                                               |
|-----------------------|-----------------------------------------------------------|-----------------------------------------------------------------------------------------------------------|
| <code>manual</code>   | Freeze all axis limits at their current values.           | Sets <code>XLimMode</code> , <code>YLimMode</code> , and <code>ZLimMode</code> to <code>'manual'</code> . |
| <code>auto</code>     | The axes automatically chooses all axis limits.           | Sets <code>XLimMode</code> , <code>YLimMode</code> , and <code>ZLimMode</code> to <code>'auto'</code> .   |
| <code>'auto x'</code> | The axes automatically chooses the <i>x</i> -axis limits. | Sets <code>XLimMode</code> to <code>'auto'</code> .                                                       |
| <code>'auto y'</code> | The axes automatically chooses the <i>y</i> -axis limits. | Sets <code>YLimMode</code> to <code>'auto'</code> .                                                       |
| <code>'auto z'</code> | The axes automatically chooses the <i>z</i> -axis limits. | Sets <code>ZLimMode</code> to <code>'auto'</code> .                                                       |

| Value     | Description                                                                  | Axes Properties That Change           |
|-----------|------------------------------------------------------------------------------|---------------------------------------|
| 'auto xy' | The axes automatically chooses the <i>x</i> -axis and <i>y</i> -axis limits. | Sets XLimMode and YLimMode to 'auto'. |
| 'auto xz' | The axes automatically chooses the <i>x</i> -axis and <i>z</i> -axis limits. | Sets XLimMode and ZLimMode to 'auto'. |
| 'auto yz' | The axes automatically chooses the <i>y</i> -axis and <i>z</i> -axis limits. | Sets YLimMode and ZLimMode to 'auto'. |

**style — Axis limits and scaling**

tight | fill | equal | image | square | vis3d | normal

Axis limits and scaling, specified as one of these values.

| Value | Description                                                                                          | Axes Properties That Change                                                                                                                                                                               |
|-------|------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| tight | Fit the axes box tightly around the data by setting the axis limits equal to the range of the data.  | XLimMode, YLimMode, and ZLimMode change to 'auto'. The limits automatically update to incorporate new data added to the axes. To keep the limits from changing when using hold on, use axis tight manual. |
| equal | Use the same length for the data units along each axis.                                              | Sets DataAspectRatio to [1 1 1], sets PlotBoxAspectRatio to [3 4 4], and sets the associated mode properties to manual. Disables the “stretch-to-fill” behavior.                                          |
| image | Use the same length for the data units along each axis and fit the axes box tightly around the data. | Sets DataAspectRatio to [1 1 1] and sets the associated mode property to manual. Disables the “stretch-to-fill” behavior.                                                                                 |

| Value  | Description                                                                                                                                                  | Axes Properties That Change                                                                                                               |
|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------|
| square | Use axis lines with equal lengths. Adjust the increments between data units accordingly.                                                                     | Sets <code>PlotBoxAspectRatio</code> to [1 1 1] and sets the associated mode property to manual. Disables the “stretch-to-fill” behavior. |
| fill   | Enable the “stretch-to-fill” behavior (the default). The lengths of each axis line fill the position rectangle defined in the Position property of the axes. | Sets the plot box aspect ratio mode and data aspect ratio mode properties to auto.                                                        |
| vis3d  | Freeze the aspect ratio properties.                                                                                                                          | Sets the plot box aspect ratio mode and data aspect ratio mode properties to manual.                                                      |
| normal | Restore the default behavior.                                                                                                                                | Sets the plot box aspect ratio mode and data aspect ratio mode properties to auto.                                                        |

For more information on the plot box aspect ratio and the data aspect ratio, see the `PlotBoxAspectRatio` and `DataAspectRatio` properties for the axes.

You can combine style options. The options are evaluated from left to right, so subsequent options can overwrite properties set by prior ones.

### **ydirection — y-axis direction**

`xy` (default) | `ij`

y-axis direction, specified as one of these values:

- `xy` — Default direction. For axes with a 2-D view, the y-axis is vertical with values increasing from bottom to top.
- `ij` — Reverse direction. For axes with a 2-D view, the y-axis is vertical with values increasing from top to bottom.

### **visibility — Axes lines and background visibility**

`on` (default) | `off`

Axes lines and background visibility, specified as either `on` or `off`. Specifying the visibility sets the `Visible` property of the axes to the same value.

**ax — Axes objects**

scalar | vector

Axes objects, specified as a scalar or a vector. If you do not specify an axes, then `axis` sets the limits for the current axes (`gca`).

When you specify an axes, use single quotes around other input arguments that are character strings.

Example: `axis(ax, 'tight')`

Example: `axis(ax, limits)`

Example: `axis(ax, 'manual')`

## Output Arguments

**lim — Current limit values**

four-element vector | six-element vector

Current limit values, returned as a four-element or six-element vector. For axes with a 2-D view, `lim` is of the form `[xmin xmax ymin ymax]`. For axes with a 3-D view, `lim` is of the form `[xmin xmax ymin ymax zmin zmax]`.

The `XLim`, `YLim`, and `ZLim` properties for the axes contain the limit values.

## More About

**Tips**

- If an axes does not exist, the `axis` function creates one.
- Use `hold on` to keep plotting functions from overriding preset axis limits.

# Using alphaShape Objects

Polygons and polyhedra from points in 2-D and 3-D

## Description

An `alphaShape` creates a bounding area or volume that envelops a set of 2-D or 3-D points. You can manipulate the `alphaShape` object to tighten or loosen the fit around the points to create a nonconvex region. You can also add or remove points or suppress holes or regions.

After you create an `alphaShape` object, you can perform geometric queries. For example, you can determine if a point is inside the shape or find the number of regions that make up the shape. You can also calculate useful quantities like area, perimeter, surface area, or volume and plot the shape for visual inspection.

## Examples

### Using alphaShape Objects

This example shows how to change an alpha shape object and compute useful quantities that describe the alpha shape.

Create and plot a set of 2-D points.

```
x = gallery('normaldata',50,1,1);
y = gallery('normaldata',50,1,2);
plot(x,y, '.')
```

Create and plot an alpha shape using an alpha radius of 0.7.

```
shp = alphaShape(x,y,0.7);
plot(shp)
```

Change the alpha radius to 0.5 to tighten the boundary around the set of points.

```
shp.Alpha = 0.5;
plot(shp)
```

Query the number of regions that make up the new alpha shape.

```
numRegions(shp)
```

```
ans =
```

```
2
```

Suppress the smaller of the two regions.

```
shp.RegionThreshold = 1;
plot(shp)
```

Compute the perimeter and area of the remaining region.

```
regionperims = perimeter(shp)
regionareas = area(shp)
```

```
regionperims =
```

```
11.8543
```

```
regionareas =
```

```
4.5407
```

## Properties

### Points — Coordinates of points

matrix

Coordinates of points, specified as a matrix with two or three columns (for 2-D or 3-D point sets). These points are initially used to create the alpha shape, excluding duplicates.

Data Types: double

### Alpha — Alpha radius

nonnegative scalar

Alpha radius, specified as a nonnegative scalar. The alpha radius is the radius of the alpha disk or sphere which sweeps over the points to create the alpha shape.

The default alpha radius is `a = criticalAlpha(shp, 'all-points')`, which is the smallest alpha radius that produces an alpha shape enclosing all points. Specify `a = criticalAlpha(shp, 'one-region')` to use the smallest alpha radius that produces an alpha shape with only one region.

The extreme values of Alpha:

- If Alpha is `Inf`, then `alphaShape` produces the convex hull.
- If Alpha is `0`, then the resulting `alphaShape` is empty.

Data Types: double

### HoleThreshold — Maximum area (2-D) or volume (3-D) of interior holes or voids to fill in

0 (default) | finite nonnegative scalar

Maximum area or volume of interior holes or voids to fill in, specified as a finite nonnegative scalar.

- For 2-D, `HoleThreshold` specifies the maximum area of interior holes to fill in.
- For 3-D, `HoleThreshold` specifies the maximum volume of interior voids to fill in. Holes extending completely through the 3-D alpha shape cannot be filled in.

The default value is 0, so that `alphaShape` does not suppress any holes or voids. The application of the `HoleThreshold` and `RegionThreshold` properties is order-dependent. `alphaShape` fills in holes before suppressing regions.

Data Types: `double`

### **RegionThreshold** — Maximum area (2-D) or volume (3-D) of regions to suppress

0 (default) | finite nonnegative scalar

Maximum area (2-D) or volume (3-D) of regions to suppress, specified as a finite nonnegative scalar.

The default value is 0, so that `alphaShape` does not suppress any regions. The application of the `HoleThreshold` and `RegionThreshold` properties is order-dependent. `alphaShape` fills in holes before suppressing regions.

Data Types: `double`

## balance

Diagonal scaling to improve eigenvalue accuracy

### Syntax

```
[T,B] = balance(A)
[S,P,B] = balance(A)
B = balance(A)
B = balance(A, 'noperm')
```

### Description

`[T,B] = balance(A)` returns a similarity transformation  $T$  such that  $B = T \backslash A * T$ , and  $B$  has, as nearly as possible, approximately equal row and column norms.  $T$  is a permutation of a diagonal matrix whose elements are integer powers of two to prevent the introduction of roundoff error. If  $A$  is symmetric, then  $B == A$  and  $T$  is the identity matrix.

`[S,P,B] = balance(A)` returns the scaling vector  $S$  and the permutation vector  $P$  separately. The transformation  $T$  and balanced matrix  $B$  are obtained from  $A$ ,  $S$ , and  $P$  by  $T(:,P) = \text{diag}(S)$  and  $B(P,P) = \text{diag}(1./S) * A * \text{diag}(S)$ .

`B = balance(A)` returns just the balanced matrix  $B$ .

`B = balance(A, 'noperm')` scales  $A$  without permuting its rows and columns.

### Examples

This example shows the basic idea. The matrix  $A$  has large elements in the upper right and small elements in the lower left. It is far from being symmetric.

```
A = [1 100 10000; .01 1 100; .0001 .01 1]
A =
 1.0e+04 *
 0.0001 0.0100 1.0000
 0.0000 0.0001 0.0100
 0.0000 0.0000 0.0001
```

Balancing produces a diagonal matrix  $T$  with elements that are powers of two and a balanced matrix  $B$  that is closer to symmetric than  $A$ .

```
[T,B] = balance(A)
T =
 1.0e+03 *
 2.0480 0 0
 0 0.0320 0
 0 0 0.0003
B =
 1.0000 1.5625 1.2207
 0.6400 1.0000 0.7813
 0.8192 1.2800 1.0000
```

To see the effect on eigenvectors, first compute the eigenvectors of  $A$ , shown here as the columns of  $V$ .

```
[V,E] = eig(A); V
V =
 0.9999 -0.9999 -0.9999
 0.0100 0.0059 + 0.0085i 0.0059 - 0.0085i
 0.0001 0.0000 - 0.0001i 0.0000 + 0.0001i
```

Note that all three vectors have the first component the largest. This indicates  $V$  is badly conditioned; in fact  $\text{cond}(V)$  is  $8.7766\text{e}+003$ . Next, look at the eigenvectors of  $B$ .

```
[V,E] = eig(B); V
V =
 0.6933 -0.6993 -0.6993
 0.4437 0.2619 + 0.3825i 0.2619 - 0.3825i
 0.5679 0.2376 - 0.4896i 0.2376 + 0.4896i
```

Now the eigenvectors are well behaved and  $\text{cond}(V)$  is  $1.4421$ . The ill conditioning is concentrated in the scaling matrix;  $\text{cond}(T)$  is  $8192$ .

This example is small and not really badly scaled, so the computed eigenvalues of  $A$  and  $B$  agree within roundoff error; balancing has little effect on the computed results.

## Limitations

Balancing can destroy the properties of certain matrices; use it with some care. If a matrix contains small elements that are due to roundoff error, balancing might scale them up to make them as significant as the other elements of the original matrix.

## More About

### Tips

•

Nonsymmetric matrices can have poorly conditioned eigenvalues. Small perturbations in the matrix, such as roundoff errors, can lead to large perturbations in the eigenvalues. The condition number of the eigenvector matrix,

$$\text{cond}(V) = \text{norm}(V) * \text{norm}(\text{inv}(V))$$

where

$$[V,T] = \text{eig}(A)$$

relates the size of the matrix perturbation to the size of the eigenvalue perturbation. Note that the condition number of  $A$  itself is irrelevant to the eigenvalue problem.

Balancing is an attempt to concentrate any ill conditioning of the eigenvector matrix into a diagonal scaling. Balancing usually cannot turn a nonsymmetric matrix into a symmetric matrix; it only attempts to make the norm of each row equal to the norm of the corresponding column.

---

**Note** The MATLAB eigenvalue function, `eig(A)`, automatically balances  $A$  before computing its eigenvalues. Turn off the balancing with `eig(A, 'nobalance')`.

---

`eig`

# bandwidth

Lower and upper matrix bandwidth

## Syntax

```
B = bandwidth(A,type)
```

```
[lower,upper] = bandwidth(A)
```

## Description

`B = bandwidth(A,type)` returns the bandwidth of matrix `A` specified by `type`. Specify `type` as `'lower'` for the lower bandwidth, or `'upper'` for the upper bandwidth.

`[lower,upper] = bandwidth(A)` returns the lower bandwidth, `lower`, and upper bandwidth, `upper`, of matrix `A`.

## Examples

### Find Bandwidth of Triangular Matrix

Create a 6-by-6 lower triangular matrix.

```
A = tril(magic(6))
```

```
A =
```

```
 35 0 0 0 0 0
 3 32 0 0 0 0
 31 9 2 0 0 0
 8 28 33 17 0 0
 30 5 34 12 14 0
 4 36 29 13 18 11
```

Find the lower bandwidth of `A` by specifying `type` as `'lower'`.

```
B = bandwidth(A,'lower')
```

```
B =
```

```
5
```

The result is 5 because every diagonal below the main diagonal has nonzero elements.

Find the upper bandwidth of A by specifying `type` as `'upper'`.

```
B = bandwidth(A, 'upper')
```

```
B =
```

```
0
```

The result is 0 because there are no nonzero elements above the main diagonal.

### Find Bandwidth of Sparse Block Matrix

Create a 100-by-100 sparse block matrix.

```
B = kron(speye(25), ones(4));
```

View a 10-by-10 section of elements from the top left of B.

```
full(B(1:10, 1:10))
```

```
ans =
```

```
1 1 1 1 0 0 0 0 0 0
1 1 1 1 0 0 0 0 0 0
1 1 1 1 0 0 0 0 0 0
1 1 1 1 0 0 0 0 0 0
0 0 0 0 1 1 1 1 0 0
0 0 0 0 1 1 1 1 0 0
0 0 0 0 1 1 1 1 0 0
0 0 0 0 1 1 1 1 0 0
0 0 0 0 0 0 0 0 1 1
0 0 0 0 0 0 0 0 1 1
```

B has 4-by-4 blocks of ones centered on the main diagonal.

Find both the lower and upper bandwidths of B by specifying two output arguments.

```
[lower, upper] = bandwidth(B)
```

```
lower =
```

```
 3

upper =
 3
```

The lower and upper bandwidths are both 3.

## Input Arguments

### **A** — Input matrix

2-D numeric matrix

Input matrix, specified as a 2-D numeric matrix. A can be either full or sparse.

Data Types: `single` | `double`

Complex Number Support: Yes

### **type** — Bandwidth type

'lower' | 'upper'

Bandwidth type, specified as 'lower' or 'upper'.

- Specify 'lower' for the lower bandwidth (below the main diagonal).
- Specify 'upper' for the upper bandwidth (above the main diagonal).

Data Types: `char`

## Output Arguments

### **B** — Lower or upper bandwidth

nonnegative integer scalar

Lower or upper bandwidth, returned as a nonnegative integer scalar.

- If `type` is 'lower', then  $0 \leq B \leq \text{size}(A, 1) - 1$ .
- If `type` is 'upper', then  $0 \leq B \leq \text{size}(A, 2) - 1$ .

**lower — Lower bandwidth**

nonnegative integer scalar

Lower bandwidth, returned as a nonnegative integer scalar. `lower` is in the range  $0 \leq \text{lower} \leq \text{size}(A, 1) - 1$ .

**upper — Upper bandwidth**

nonnegative integer scalar

Upper bandwidth, returned as a nonnegative integer scalar. `upper` is in the range  $0 \leq \text{upper} \leq \text{size}(A, 2) - 1$ .

## More About

### Upper and Lower Bandwidth

The upper and lower bandwidths of a matrix are measured by finding the last diagonal (above or below the main diagonal, respectively) that contains nonzero values.

That is, for a matrix  $A$  with elements  $A_{ij}$ :

- The upper bandwidth  $B_1$  is the smallest number such that  $A_{ij} = 0$  whenever  $j - i > B_1$ .
- The lower bandwidth  $B_2$  is the smallest number such that  $A_{ij} = 0$  whenever  $i - j > B_2$ .

Note that this measurement does not disallow intermediate diagonals in a band from being all zero, but instead focuses on the location of the last diagonal containing nonzeros. By convention, the upper and lower bandwidths of an empty matrix are both zero.

### Tips

- Use the `isbanded` function to test if a matrix is within a specific lower and upper bandwidth.

**Introduced in R2014a**

## bar

Bar graph

### Syntax

```
bar(y)
bar(x,y)
```

```
bar(____,width)
bar(____,style)
bar(____,color)
bar(____,Name,Value)
```

```
bar(ax, ____)
```

```
b = bar(____)
```

### Description

`bar(y)` creates a bar graph with one bar for each element in `y`. If `y` is a matrix, then `bar` groups the bars according to the rows in `y`.

`bar(x,y)` draws the bars at the locations specified by `x`.

`bar( ____,width)` sets the relative bar width, which controls the separation of bars within a group. Specify `width` as a scalar value. Use this option with any of the input argument combinations in the previous syntaxes.

`bar( ____,style)` specifies the style of the bar groups. For example, use `'stacked'` to display each group as one multicolored bar.

`bar( ____,color)` sets the color for all the bars. For example, use `'r'` for red bars.

`bar( ____,Name,Value)` sets bar series properties using one or more `Name,Value` pair arguments. The settings apply to all bars plotted. For example, use `'EdgeColor','black'` to outline all the bars in black.

---

`bar(ax, ___)` plots into the axes specified by `ax` instead of into the current axes (`gca`). The option `ax` can precede any of the input argument combinations in the previous syntaxes.

`b = bar(___)` returns one or more bar series objects. If `y` is a vector, then `bar` creates one bar series object. If `y` is a matrix, then `bar` creates a bar series object for each column. Use `b` to make future modifications to the bars after they are created.

## Examples

### Create Bar Graph

```
y = [75 91 105 123.5 131 150 179 203 226 249 281.5];
bar(y)
```

### Specify Bar Locations

Specify the bar locations along the *x*-axis.

```
x = 1900:10:2000;
y = [75 91 105 123.5 131 150 179 203 226 249 281.5];
bar(x,y)
```

### Specify Bar Width

Set the width of each bar to 40 percent of the total space available for each bar.

```
y = [75 91 105 123.5 131 150 179 203 226 249 281.5];
bar(y,0.4)
```

### Display Groups of Bars

Display four groups of three bars.

```
y = [2 2 3; 2 5 6; 2 8 9; 2 11 12];
bar(y)
```

### Display Stacked Bars

Display one bar for each row of the matrix. The height of each bar is the sum of the elements in the row.

```
y = [2 2 3; 2 5 6; 2 8 9; 2 11 12];
bar(y, 'stacked')
```

### Specify Subplot for Bar Graph

Create a figure with two subplots. In the upper subplot, plot a bar graph. In the lower subplot, plot a stacked bar graph of the same data.

```
y = [1 2 3; 4 5 6];
ax1 = subplot(2,1,1);
bar(ax1,y)

ax2 = subplot(2,1,2);
bar(ax2,y, 'stacked')
```

### Specify Bar Color

Create a bar graph using red bars.

```
y = [75 91 105 123.5 131 150 179 203 226 249 281.5];
bar(y, 'r')
```

### Specify Bar and Outline Colors

Set the bar interior color and outline color using RGB triplets. Set the width of the bar outline.

```
y = [75 91 105 123.5 131 150 179 203 226 249 281.5];
bar(y, 'FaceColor',[0 .5 .5], 'EdgeColor',[0 .9 .9], 'LineWidth',1.5)
```

### Change Properties for Specific Bar Series

Create a bar graph with a three-column matrix input and return the three bar series objects. `bar` creates one bar series for each column in the matrix.

```
y = [2 4 6; 3 4 5];
b = bar(y);
```

Change properties for a specific bar series by indexing into the object array. For example, change properties of the bars representing the second column of `y` using `b(2)`. Starting in R2014b, you can use dot notation to set properties. If you are using an earlier release, use the `set` function instead.

```
b(2).LineWidth = 2;
b(2).EdgeColor = 'red';
```

- “Modify Baseline of Bar Graph”
- “Overlay Bar Graphs”
- “Overlay Line Plot on Bar Graph Using Different y-Axes”

## Input Arguments

### **x** — x values

vector | matrix

x values, specified as a vector or a matrix. If x and y are both vectors, then they must be equal length. If x and y are both matrices, then they must be equal size. If x is a vector and y is a matrix, then the length of x must equal the number of rows in y.

The  $x$  values do not have to be in order, but they cannot contain duplicate values. If  $x$  is a matrix, then it cannot contain duplicate values across columns.

Example: `1:10`

Data Types: `single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64`

### **y — y values**

vector | matrix

$y$  values, specified as a vector or a matrix.

- If  $y$  is a vector, then `bar` draws one bar for each element. The `bar` function treats all vectors as column vectors.
- If  $y$  is a matrix, then `bar` groups the bars according to the rows in  $y$ .

Example: `[10 8 5 7 3 9 1]`

Data Types: `single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64`

### **width — Bar width**

0.8 (default) | scalar

Bar width, specified as a fraction of the total space available for each bar. The default of 0.8 means the bar width is 80% of the space from the previous bar to the next bar, with 10% of that space on each side.

If the width is 1, then the bars within a group touch one another.

Example: `0.5`

Data Types: `single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64`

### **style — Bar group style**

'grouped' (default) | 'stacked' | 'hist' | 'histc'

Bar group style, specified by one of these values.

| Style     | Purpose                                 |
|-----------|-----------------------------------------|
| 'grouped' | Display one group for each row in $y$ . |

| Style     | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|           | <ul style="list-style-type: none"> <li>If <math>y</math> is an <math>m</math>-by-<math>n</math> matrix, then <code>bar</code> displays <math>m</math> groups of <math>n</math> vertical bars, where <math>m</math> is the number of rows and <math>n</math> is the number of columns in <math>y</math>.</li> <li>If <math>y</math> is a vector of length <math>n</math>, then <code>bar</code> displays one group of <math>n</math> bars. Colors correspond to distinct elements and show the relative contribution each row element makes to the total sum.</li> <li>If <math>y</math> is a vector of length <math>n</math>, then <code>bar</code> displays <math>n</math> bars. The <code>bar</code> function treats all vectors as column vectors.</li> </ul> |
| 'histc'   | Display the graph in histogram format, in which bars touch one another.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| 'hist'    | Display the graph in histogram format, but center each bar over the $x$ -ticks, rather than making bars span $x$ -ticks as the <code>histc</code> option does.                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

### color — Bar color

'b' | 'r' | 'g' | 'c' | 'm' | 'y' | 'k' | 'w'

Bar color, specified as one of the strings in this table.

| String | Color |
|--------|-------|
| 'b'    | Blue  |
| 'r'    | Red   |
| 'g'    | Green |

| String | Color   |
|--------|---------|
| 'c'    | Cyan    |
| 'm'    | Magenta |
| 'y'    | Yellow  |
| 'k'    | Black   |
| 'w'    | White   |

**ax — Axes object**

axes object

Axes object. If you do not specify an axes, then `bar` uses the current axes for the bar graph.

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

The bar series properties listed here are only a subset. For a complete list, see Bar Series Properties.

---

**Note:** You cannot specify `Name`, `Value` pairs when using the `'hist'` or `'histc'` bar group style options.

---

Example: `'EdgeColor', 'g'` specifies a green outline around the bars.

**'EdgeColor' — Bar outline color**

[0 0 0] (default) | 'flat' | 'none' | RGB triplet | color string

Bar outline color, specified as one of these values:

- `'flat'` — Colors based on axes colormap. To change the colormap, use the `colormap` function.
- `'none'` — No color, which makes the outlines invisible.

- RGB triplet or color string — Specify a custom color. The default RGB triplet value of `[0 0 0]` corresponds to black.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0, 1]`, for example, `[0.4 0.6 0.7]`. This table lists RGB triplet values that have equivalent color strings.

| Long Name | Short Name | RGB Triplet |
|-----------|------------|-------------|
| 'yellow'  | 'y'        | [1 1 0]     |
| 'magenta' | 'm'        | [1 0 1]     |
| 'cyan'    | 'c'        | [0 1 1]     |
| 'red'     | 'r'        | [1 0 0]     |
| 'green'   | 'g'        | [0 1 0]     |
| 'blue'    | 'b'        | [0 0 1]     |
| 'white'   | 'w'        | [1 1 1]     |
| 'black'   | 'k'        | [0 0 0]     |

Example: 'blue'

Example: [0 0 1]

### 'FaceColor' — Bar fill color

'flat' (default) | 'none' | RGB triplet | color string

Bar fill color, specified as one of these values:

- 'flat' — Colors based on the axes colormap.
- 'none' — No color, which makes the fill invisible.
- RGB triplet or color string — Specify a custom color.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0, 1]`, for example, `[0.4 0.6 0.7]`. This table lists RGB triplet values that have equivalent color strings.

| Long Name | Short Name | RGB Triplet |
|-----------|------------|-------------|
| 'yellow'  | 'y'        | [1 1 0]     |

| Long Name | Short Name | RGB Triplet |
|-----------|------------|-------------|
| 'magenta' | 'm'        | [ 1 0 1 ]   |
| 'cyan'    | 'c'        | [ 0 1 1 ]   |
| 'red'     | 'r'        | [ 1 0 0 ]   |
| 'green'   | 'g'        | [ 0 1 0 ]   |
| 'blue'    | 'b'        | [ 0 0 1 ]   |
| 'white'   | 'w'        | [ 1 1 1 ]   |
| 'black'   | 'k'        | [ 0 0 0 ]   |

**'BaseValue' — Baseline location**

0 (default) | numeric scalar value

Baseline location, specified as a numeric scalar value.

**'LineStyle' — Line style of bar outlines**

'-' (default) | '--' | ':' | '-.' | 'none'

Line style of bar outlines, specified as one of the strings in this table.

| String | Line Style       | Resulting Line                                                                       |
|--------|------------------|--------------------------------------------------------------------------------------|
| '-'    | Solid line       |  |
| '--'   | Dashed line      |  |
| ':'    | Dotted line      |  |
| '-.'   | Dash-dotted line |  |
| 'none' | No line          | No line                                                                              |

**'LineWidth' — Width of bar outlines**

0.5 (default) | positive value

Width of bar outlines, specified as a positive value in point units. One point equals 1/72 inch.

Example: 1.5

---

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

## Output Arguments

### **b** — Bar series objects

single object | array of objects

Bar series objects, returned as a single object or an array of objects. Each bar series object comprises a set of bars that have the same color. Use the elements in **b** to access and modify properties of a specific bar series object after it has been created.

## More About

### Tips

- The default bar colors are based on the axes colormap. You can change the axes colormap using the `colormap` function.

### Properties

Bar Series Properties

Introduced before R2006a

## barh

Plot bar graph horizontally

## Syntax

```
barh(y)
barh(x,y)
barh(...,width)
barh(...,style)
barh(...,'bar_color')
barh(...,'PropertyName',PropertyValue,...)
barh(ax,...)
b = barh(...)
```

## Description

A `barh` graph displays the values in a vector or matrix as horizontal bars.

`barh(y)` draws one horizontal bar for each element in `y`. If `y` is a matrix, `barh` groups the bars produced by the elements in each row. The `y`-axis scale ranges from 1 up to `length(y)` when `y` is a vector, and 1 to `size(y,1)`, which is the number of rows, when `y` is a matrix.

`barh(x,y)` draws a bar for each element in `y` at locations specified in `x`, where `x` is a vector defining locations along the `y`-axis. The location values can be nonmonotonic, but cannot contain duplicate values. If `y` is a matrix, `barh` groups the elements of each row in `y` at corresponding locations in `x`.

`barh(...,width)` sets the relative bar width and controls the separation of bars within a group. The default `width` is 0.8, so if you do not specify `x`, the bars within a group have a slight separation. If `width` is 1, the bars within a group touch one another. The value of `width` must be a scalar.

`barh(..., style)` specifies the style of the bars. Specify `style` as one of these values:

- `'grouped'` displays  $m$  groups of  $n$  bars, where  $m$  is the number of rows and  $n$  is the number of columns in `y`. Each group contains one bar per column in `y`. This is the default value.
- `'stacked'` displays one bar for each row in `y`. The bar length is the sum of the elements in the row. Each bar is multicolored, with colors corresponding to distinct elements and showing the relative contribution each row element makes to the total sum. The `barh` function treats all vectors as column vectors. If `y` is a vector of length  $n$ , then `barh` displays  $n$  bars.
- `'histc'` displays the graph in histogram format, in which bars touch one another.
- `'hist'` also displays the graph in histogram format, but centers each bar over the tick value, rather than making bars span the tick values as the `histc` option does.

---

**Note:** When you use either the `hist` or `histc` option, you cannot also use parameter/value syntax. These two options create patch objects rather than bar series.

---

`barh(..., 'bar_color')` displays all bars using the color specified by the single-letter abbreviation `'r'`, `'g'`, `'b'`, `'c'`, `'m'`, `'y'`, `'k'`, or `'w'`.

`barh(..., 'PropertyName', PropertyValue, ...)` sets the named property or properties to the specified values. You cannot specify properties when `hist` or `histc` options are used. See Bar Series Properties for more information.

`barh(ax, ...)` plots into the axes `ax` instead of into the current axes (`gca`).

`b = barh(...)` returns a vector of bar series objects. When `y` is a matrix, `barh` creates one bar series per column in `y`. Each bar series comprises a set of bars that have the same color. Use the bar series object to change properties for all bars in a series.

## Examples

### Horizontal Bar Graph of Single Data Series

Create a horizontal bar graph of vector data.

```
y = [57,91,105,123,131,150,...
 170,203,226.5,249,281.4];
```

```
figure
barh(y)
```

barh draws one horizontal bar for each element in y.

### Specify Width for Horizontal Bar Graph

Specify the bar width to 0.4.

```
y = [57,91,105,123,131,150,...
 170,203,226.5,249,281.4];
```

```
figure;
width = 0.4;
barh(y,width);
```

### Specify Style for Horizontal Bar Graph

Create a figure with four subplots. In each subplot, create a horizontal bar graph using a different style option for each graph.

```
x = [2,4];
y = [1,2,3,4;...
 5,6,7,8];

figure;
subplot(2,2,1);
barh(x,y,'grouped'); % groups by row
title('Grouped Style')
```

```
subplot(2,2,2);
barh(x,y,'stacked'); % stacks values in each row together
title('Stacked Style')
```

```
subplot(2,2,3);
barh(x,y,'hist'); % centers bars over x values
title('hist Style')
```

```
subplot(2,2,4);
barh(x,y,'histc'); % spans bars over x values
title('histc Style')
```

### Specify Color for Horizontal Bar Graph

Create a horizontal bar graph and change the color of the bars to red.

```
y = [57,91,105,123,131,150,...
 170,203,226.5,249,281.4];
figure
barh(y, 'r')
```

## Specify Bar Properties Using Name-Value Pairs

Create a horizontal bar graph and set the line width to 2. Use RGB triplets to set the face color and edge color for the bars.

```
y = [57,91,105,123,131,150,...
 170,203,226.5,249,281.4];

figure
barh(y, 'FaceColor', [0,0.5,0.5], ...
 'EdgeColor', [0,0,0.9], ...
 'LineWidth', 2)
```

### Specify Horizontal Bar Locations

Define `x` and `y` as vectors of data.

```
x = 1900:10:2000;
y = [57,91,105,123,131,150,...
 170,203,226.5,249,281.4];
```

Create a horizontal bar graph of the data in `y`. Use `x` to specify the bar locations along the `y`-axis.

```
figure
barh(x,y)
```

### Horizontal Bar Graph of Matrix Data

Load the data set `count.dat`, which returns a three-column matrix, `count`. Store `y` as the first six rows of `count`.

```
load count.dat
y = count(1:6,:);
```

Create a horizontal bar graph of matrix `y`.

```
figure
barh(y)
```

By default, `barh` groups the bars by row.

### Specify Different Properties For Each Bar Series

Load the data set, `count.dat`, that returns a three-column matrix, `count`. Define `y` as the first four rows of `count`.

```
load count.dat
y = count(1:4,:);
```

Create a horizontal bar graph of `y` using a dotted line style. Return the three bar series handles. `barh` creates a bar series for each column in `y`.

```
h = barh(y, 'LineStyle', ':');
```

Use the handles in `h` to set different property values for each bar series. Change the face color of the first bar series to cyan by setting the `FaceColor` property to `cyan`. Set the face color for the third bar series using an RGB triplet.

Starting in R2014b, you can use dot notation to set properties. If you are using an earlier release, use the `set` function instead.

```
h(1).FaceColor = 'cyan';
h(3).FaceColor = [0,0.5,0.5];
```

### Change Baseline Value for Horizontal Bar Graph

Load the data set `count.dat`, which returns a three-column matrix, `count`. Store `y` as the first six rows of `count`.

```
load count.dat
y = count(1:6,:);
```

Create a horizontal bar graph of `y` and set the basevalue to 25.

```
figure
barh(y, 'BaseValue', 25)
```

**Properties**

Bar Series Properties

**Introduced before R2006a**

## bar3

Plot 3-D bar graph

## Syntax

```
bar3(Y)
bar3(x,Y)
bar3(...,width)
bar3(...,'style')
bar3(...,LineStyle)
bar3(axes_handle,...)
h = bar3(...)
```

## Description

`bar3` draws a three-dimensional bar graph.

`bar3(Y)` draws a three-dimensional bar chart, where each element in `Y` corresponds to one bar. When `Y` is a vector, the  $x$ -axis scale ranges from 1 to `length(Y)`. When `Y` is a matrix, the  $x$ -axis scale ranges from 1 to `size(Y,1)` and the elements in each row are grouped together.

`bar3(x,Y)` draws a bar chart of the elements in `Y` at the locations specified in `x`, where `x` is a vector defining the  $y$ -axis intervals for vertical bars. The  $x$ -values can be nonmonotonic, but cannot contain duplicate values. If `Y` is a matrix, `bar3` clusters elements from the same row in `Y` at locations corresponding to an element in `x`. Values of elements in each row are grouped together.

`bar3(...,width)` sets the width of the bars and controls the separation of bars within a group. The default `width` is 0.8, so if you do not specify `x`, bars within a group have a slight separation. If `width` is 1, the bars within a group touch one another.

`bar3(..., 'style')` specifies the style of the bars. `'style'` is `'detached'`, `'grouped'`, or `'stacked'`. Default mode of display is `'detached'`.

- `'detached'` displays the elements of each row in `Y` as separate blocks behind one another in the  $x$  direction.
- `'grouped'` displays  $n$  groups of  $m$  vertical bars, where  $n$  is the number of rows and  $m$  is the number of columns in `Y`. The group contains one bar per column in `Y`.
- `'stacked'` displays one bar for each row in `Y`. The bar height is the sum of the elements in the row. Each bar is multicolored, with colors corresponding to distinct elements and showing the relative contribution each row element makes to the total sum.

`bar3(..., LineSpec)` displays all bars using the color specified by `LineSpec`.

`bar3(axes_handle, ...)` plots into the axes with the handle `axes_handle` instead of into the current axes (`gca`).

`h = bar3(...)` returns a vector of handles to surface objects, one for each created. When `Y` is a matrix, `bar3` creates one surface object per column in `Y`.

## Examples

### Create 3-D Bar Graph

Load the data set `count.dat`, which returns a three-column matrix, `count`. Store `Y` as the first 10 rows of `count`.

```
load count.dat
Y = count(1:10,:);
```

Create a 3-D bar graph of `Y`. By default, the style is `detached`.

```
figure
bar3(Y)
title('Detached Style')
```

### Specify Bar Width for 3-D Bar Graph

Load the data set `count.dat`, which returns a three-column matrix, `count`. Store `Y` as the first 10 rows of `count`.

```
load count.dat
Y = count(1:10, :);
```

Create a 3-D bar graph of `Y` and set the bar width to 0.5.

```
width = 0.5;
```

```
figure
bar3(Y,width)
```

```
title('Bar Width of 0.5')
```

### 3-D Bar Graph with Grouped Style

Load the data set `count.dat`, which returns a three-column matrix, `count`. Store `Y` as the first 10 rows of `count`.

```
load count.dat
Y = count(1:10,:);
```

Create a 3-D bar graph of `Y`. Group the elements in each row of `Y` by specifying the style option as `grouped`.

```
figure
```

```
bar3(Y,'grouped')
title('Grouped Style')
```

### 3-D Bar Graph with Stacked Style

Load the data set `count.dat`, which returns a three-column matrix, `count`. Store `Y` as the first 10 rows of `count`.

```
load count.dat
Y = count(1:10,:);
```

Create a 3-D bar graph of `Y`. Stack the elements in each row of `Y` by specifying the style option as `stacked`.

```
figure
```

```
bar3(Y,'stacked')
title('Stacked Style')
```

bar | barh | bar3h | LineSpec

Introduced before R2006a

## bar3h

Plot horizontal 3-D bar graph

## Syntax

```
bar3h(Y)
bar3h(x,Y)
bar3h(...,width)
bar3h(...,'style')
bar3h(...,LineStyle)
bar3h(axes_handle,...)
h = bar3h(...)
```

## Description

`bar3h` draws three-dimensional horizontal bar charts.

`bar3h(Y)` draws a three-dimensional bar chart, where each element in `Y` corresponds to one bar. When `Y` is a vector, the  $y$ -axis scale ranges from 1 to `length(Y)`. When `Y` is a matrix, the  $y$ -axis scale ranges from 1 to `size(Y,1)` and the elements in each row are grouped together.

`bar3h(x,Y)` draws a bar chart of the elements in `Y` at the locations specified in `x`, where `x` is a vector defining the  $y$ -axis intervals for horizontal bars. The  $x$ -values can be nonmonotonic, but cannot contain duplicate values. If `Y` is a matrix, `bar3` clusters elements from the same row in `Y` at locations corresponding to an element in `x`. Values of elements in each row are grouped together.

`bar3h(...,width)` sets the width of the bars and controls the separation of bars within a group. The default `width` is 0.8, so if you do not specify `x`, bars within a group have a slight separation. If `width` is 1, the bars within a group touch one another.

`bar3h(..., 'style')` specifies the style of the bars. *style* is 'detached', 'grouped', or 'stacked'. Default mode of display is 'detached'.

- 'detached' displays the elements of each row in *Y* as separate blocks behind one another in the *y* direction.
- 'grouped' displays *n* groups of *m* vertical bars, where *n* is the number of rows and *m* is the number of columns in *Y*. The group contains one bar per column in *Y*.
- 'stacked' displays one bar for each row in *Y*. The bar length is the sum of the elements in the row. Each bar is multicolored, with colors corresponding to distinct elements and showing the relative contribution each row element makes to the total sum.

`bar3h(..., LineSpec)` displays all bars using the color specified by `LineSpec`.

`bar3h(axes_handle, ...)` plots into the axes with the handle `axes_handle` instead of into the current axes (`gca`).

`h = bar3h(...)` returns a vector of handles to surface objects, one for each created. When *Y* is a matrix, `bar3h` creates one surface object per column in *Y*.

## Examples

### Create 3-D Horizontal Bar Graph

Load the data set `count.dat`, which returns a three-column matrix, `count`. Store *Y* as the first ten rows of `count`.

```
load count.dat
Y = count(1:10, :);
```

Create a 3-D horizontal bar graph of *Y*. By default, the style is `detached`.

```
figure
bar3h(Y)
```

### Specify Bar Width for 3-D Horizontal Bar Graph

Load the data set `count.dat`, which returns a three-column matrix, `count`. Store `Y` as the first ten rows of `count`.

```
load count.dat;
Y = count(1:10, :);
```

Create a 3-D horizontal bar graph of `Y` and set the bar width to 0.5.

```
width = 0.5;

figure
bar3h(Y,width)
```

```
title('Width of 0.5')
```

### 3-D Horizontal Bar Graph with Grouped Style

Load the data set `count.dat`, which returns a three-column matrix, `count`. Store `Y` as the first ten rows of `count`.

```
load count.dat
Y = count(1:10,:);
```

Create a 3-D horizontal bar graph of `Y` and specify the style option as `grouped`.

```
figure
bar3h(Y, 'grouped')
```

```
title('Grouped Style Option')
```

### 3-D Horizontal Bar Graph with Stacked Option

Load the data set `count.dat`, which returns a three-column matrix, `count`. Store `Y` as the first ten rows of `count`.

```
load count.dat
Y = count(1:10,:);
```

Create a 3-D horizontal bar graph of `Y` and specify the style option as `stacked`.

```
figure
bar3h(Y, 'stacked')
```

```
title('Stacked Style Option')
```

## Bar Series Properties

Control bar series appearance and behavior

Bar series properties control the appearance and behavior of a bar series object. By changing property values, you can modify certain aspects of the bar series.

Starting in R2014b, you can use dot notation to query and set properties.

```
b = bar(1:10);
w = b.BarWidth;
b.BarWidth = 1;
```

If you are using an earlier release, use the `get` and `set` functions instead.

### Bars

#### **BarWidth** — Relative width of individual bars

0.8 (default) | scalar in range [0,1]

Relative width of individual bars, specified as a scalar value in the range [0,1]. Use this property to control the separation of bars within a group. The default value is 0.8, which means that MATLAB separates the bars slightly. If you set this property to 1, then adjacent bars touch.

Example: 0.5

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

#### **EdgeColor** — Bar outline color

[0 0 0] (default) | 'flat' | 'none' | RGB triplet | color string

Bar outline color, specified as one of these values:

- 'flat' — Colors based on axes colormap. To change the colormap, use the `colormap` function.
- 'none' — No color, which makes the outlines invisible.
- RGB triplet or color string — Specify a custom color. The default RGB triplet value of [0 0 0] corresponds to black.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range

[0, 1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

| Long Name | Short Name | RGB Triplet |
|-----------|------------|-------------|
| 'yellow'  | 'y'        | [1 1 0]     |
| 'magenta' | 'm'        | [1 0 1]     |
| 'cyan'    | 'c'        | [0 1 1]     |
| 'red'     | 'r'        | [1 0 0]     |
| 'green'   | 'g'        | [0 1 0]     |
| 'blue'    | 'b'        | [0 0 1]     |
| 'white'   | 'w'        | [1 1 1]     |
| 'black'   | 'k'        | [0 0 0]     |

Example: 'blue'

Example: [0 0 1]

### FaceColor — Bar fill color

'flat' (default) | 'none' | RGB triplet | color string

Bar fill color, specified as one of these values:

- 'flat' — Colors based on the axes colormap.
- 'none' — No color, which makes the fill invisible.
- RGB triplet or color string — Specify a custom color.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0, 1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

| Long Name | Short Name | RGB Triplet |
|-----------|------------|-------------|
| 'yellow'  | 'y'        | [1 1 0]     |
| 'magenta' | 'm'        | [1 0 1]     |
| 'cyan'    | 'c'        | [0 1 1]     |
| 'red'     | 'r'        | [1 0 0]     |

| Long Name | Short Name | RGB Triplet |
|-----------|------------|-------------|
| 'green'   | 'g'        | [0 1 0]     |
| 'blue'    | 'b'        | [0 0 1]     |
| 'white'   | 'w'        | [1 1 1]     |
| 'black'   | 'k'        | [0 0 0]     |

**EdgeAlpha — Edge transparency**

1 (default) | scalar in range [0, 1]

Edge transparency, specified as a scalar in the range [0, 1]. A value of 1 is opaque and 0 is completely transparent. Values between 0 and 1 are semitransparent.

Example: `b.EdgeAlpha = 0.5;`

**FaceAlpha — Face transparency**

1 (default) | scalar in range [0, 1]

Face transparency, specified as a scalar in the range [0, 1]. A value of 1 is opaque and 0 is completely transparent. Values between 0 and 1 are semitransparent.

Example: `b.FaceAlpha = 0.5;`

**LineStyle — Line style**

'-' (default) | '--' | ':' | '-.' | 'none'

Line style, specified as one of the line style strings listed in this table.

| String | Line Style       | Resulting Line                                                                       |
|--------|------------------|--------------------------------------------------------------------------------------|
| '-'    | Solid line       |  |
| '--'   | Dashed line      |  |
| ':'    | Dotted line      |  |
| '-.'   | Dash-dotted line |  |
| 'none' | No line          | No line                                                                              |

**LineWidth — Width of bar outlines**

0.5 (default) | positive value

Width of bar outlines, specified as a positive value in point units. One point equals 1/72 inch.

Example: 1.5

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

## Bar Graph Type

### BarLayout — Arrangement of bars

`'grouped'` (default) | `'stacked'`

Arrangement of bars, specified as one of these values:

- `'grouped'` — Group bars by rows in `Y`, where `Y` is the input argument to the `bar` or `barh` function that created the bar chart.
- `'stacked'` — Display one bar for each row in `Y`. The bar height is the sum of the elements in the row. Each bar is multicolored. Colors correspond to distinct elements and show the relative contribution each row element makes to the total sum.

### Horizontal — Horizontal bar chart

`'off'` (default) | `'on'`

Horizontal bar chart, specified as one of these values:

- `'on'` — Display bars horizontally. If you create a graph with `barh`, then the `Horizontal` property is set to `'on'`.
- `'off'` — Display bars vertically. If you create the chart with `bar`, then the `Horizontal` property is set to `'off'`.

## Baseline

### BaseLine — Baseline

baseline object

This property is read only.

Baseline object. For a list of baseline properties, see Baseline Properties.

### BaseValue — Baseline location

0 (default) | numeric scalar value

Baseline location, specified as a numeric scalar value.

### **ShowBaseLine — Baseline visibility**

'on' (default) | 'off'

Baseline visibility, specified as one of these values:

- 'on' — Show the baseline.
- 'off' — Hide the baseline.

## **Data**

### **XData — Bar locations**

vector of real values

Bar locations, specified as a vector. For vertical bar charts, the values in **XData** are the bar locations along the *x*-axis. For horizontal bar charts, the values are the bar locations along the *y*-axis. You cannot specify the same value twice.

The input argument **X** to the **bar** and **barh** functions determines the bar locations. If you do not specify **X**, then the indices of the values in **YData** determine the bar locations. **XData** and **YData** must have equal lengths.

Setting this property sets the associated mode property to manual.

Example: 1:10

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

### **YData — Bar lengths**

vector

Bar lengths, specified as a vector. The input argument **Y** to the **bar** and **barh** functions determines the bar lengths.

**XData** and **YData** must have equal lengths.

Example: 1:10

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**XDataSource — Variable linked to XData**

' ' (default) | string containing MATLAB workspace variable name

Variable linked to **XData**, specified as a string containing a MATLAB workspace variable name. MATLAB evaluates the variable in the base workspace to generate the **XData**.

By default, there is no linked variable so the value is an empty string, ' '. If you link a variable, then MATLAB does not update the **XData** values immediately. To force an update of the data values, use the **refreshdata** function.

---

**Note:** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

Example: 'x'

**YDataSource — Variable linked to YData**

' ' (default) | string containing MATLAB workspace variable name

Variable linked to **YData**, specified as a string containing a MATLAB workspace variable name. MATLAB evaluates the variable in the base workspace to generate the **YData**.

By default, there is no linked variable so the value is an empty string, ' '. If you link a variable, then MATLAB does not update the **YData** values immediately. To force an update of the data values, use the **refreshdata** function.

---

**Note:** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

Example: 'y'

**XDataMode — Selection mode for XData**

'auto' (default) | 'manual'

Selection mode for **XData**, specified as one of these values:

- 'auto' — Use the indices of the values in **YData** (or **ZData** for 3-D plots).

- `'manual'` — Use manually specified values. To specify the values, set the `XData` property or specify the input argument `X` to the plotting function.

## Visibility

### **Visible** — State of visibility

`'on'` (default) | `'off'`

State of visibility, specified as one of these values:

- `'on'` — Display the bar series.
- `'off'` — Hide the bar series without deleting it. You still can access the properties of an invisible bar series object.

### **Clipping** — Clipping of bar series object to axes limits

`'on'` (default) | `'off'`

Clipping of the bar series object to the axes limits, specified as one of these values:

- `'on'` — Do not display parts of the bar series object that are outside the axes limits.
- `'off'` — Display the entire bar series object, even if parts of it appear outside the axes limits. Parts of the bar series object might appear outside the axes limits if you create a plot, set `hold on`, freeze the axis scaling, and then create the bar series object so that it is larger than the original plot.

The `Clipping` property of the axes that contains the bar series object must be set to `'on'`, otherwise this property has no effect. For more information about the clipping behavior, see the `Clipping` property of the axes.

### **EraseMode** — (removed) Technique to draw and erase objects

`'normal'` (default) | `'none'` | `'xor'` | `'background'`

---

**Note:** `EraseMode` has been removed. You can delete code that accesses the `EraseMode` property with minimal impact. If you were using `EraseMode` to create line animations, use the `animatedline` function instead.

---

Technique to draw and erase objects, specified as one of these values:

- `'normal'` — Redraw the affected region of the display, performing the three-dimensional analysis necessary to correctly render all objects. This mode produces

the most accurate picture, but is the slowest. The other modes are faster, but do not perform a complete redraw and, therefore, are less accurate.

- `'none'` — Do not erase the object when it is moved or destroyed. After you erase the object with `EraseMode`, `'none'`, it is still visible on the screen. However, you cannot print the object because MATLAB does not store any information on its former location.
- `'xor'` — Draw and erase the object by performing an exclusive OR (XOR) with the color of the screen beneath it. This mode does not damage the color of the objects beneath it. However, the object color depends on the color of whatever is beneath it on the display.
- `'background'` — Erase the object by redrawing it in the axes background color, or the figure background color if the axes `Color` property is `'none'`. This damages objects that are behind the erased object, but properly colors the erased object.

MATLAB always prints figures as if the `EraseMode` property of all objects is set to `'normal'`. This means graphics objects created with `EraseMode` set to `'none'`, `'xor'`, or `'background'` can look different on screen than on paper. On screen, MATLAB mathematically combines layers of colors and ignores three-dimensional sorting to obtain greater rendering speed. However, MATLAB does not apply these techniques to the printed output. Use the `getframe` command or other screen capture applications to create an image of a figure containing nonnormal mode objects.

## Identifiers

### Type — Type of graphics object

`'bar'` (default)

This property is read only.

Type of graphics object, returned as `'bar'`. Use this property to find all objects of a given type within a plotting hierarchy, such as searching for the type using `findobj`.

### Tag — Tag to associate with bar series

`''` (default) | string

Tag to associate with the bar series, specified as a string. Tags provide a way to identify graphics objects. Use this property to find all objects with a specific tag within a plotting hierarchy, for example, searching for the tag using `findobj`.

Example: `'January Data'`

Data Types: char

**UserData — Data to associate with bar series**

[] (default) | scalar, vector, or matrix | cell array | character array | table | structure

Data to associate with the bar series object, specified as a scalar, vector, matrix, cell array, character array, table, or structure. MATLAB does not use this data.

To associate multiple sets of data or to attach a field name to the data, use the `getappdata` and `setappdata` functions.

Example: `1:100`

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical | char | struct | table | cell

**DisplayName — Text used by legend**

'' (default) | string

Text used by the legend, specified as a string. The text appears next to an icon of the bar series.

Example: `'Text Description'`

For multiline text, create the string using `sprintf` with the new line character `\n`.

Example: `sprintf('line one\nline two')`

Alternatively, you can specify the legend text using the `legend` function.

- If you specify the text as an input argument to the `legend` function, then the legend uses the specified text and sets the `DisplayName` property to the same value.
- If you do not specify the text as an input argument to the `legend` function, then the legend uses the text in the `DisplayName` property. If the `DisplayName` property does not contain any text, then the legend generates a string. The string has the form `'dataN'`, where N is the number assigned to the bar series object based on its location in the list of legend entries.

If you edit interactively the string in an existing legend, then MATLAB updates the `DisplayName` property to the edited string.

**Annotation — Legend icon display style**

Annotation object

This property is read only.

Legend icon display style, returned as an `Annotation` object. Use this object to include or exclude the bar series from a legend.

- 1 Query the `Annotation` property to get the `Annotation` object.
- 2 Query the `LegendInformation` property of the `Annotation` object to get the `LegendEntry` object.
- 3 Specify the `IconDisplayStyle` property of the `LegendEntry` object to one of these values:
  - `'on'` — Include the bar series object in the legend as one entry (default).
  - `'off'` — Do not include the bar series object in the legend.
  - `'children'` — Include only children of the bar series object as separate entries in the legend.

If a legend already exists and you change the `IconDisplayStyle` setting, then you must call `legend` to update the display.

## Parent/Child

### Parent — Parent of bar series

axes object | group object | transform object

Parent of bar series, specified as an axes, group, or transform object.

### Children — Children of bar series

empty `GraphicsPlaceholder` array

The bar series has no children. You cannot set this property.

### HandleVisibility — Visibility of object handle

`'on'` (default) | `'off'` | `'callback'`

Visibility of bar series object handle in the `Children` property of the parent, specified as one of these values:

- `'on'` — The bar series object handle is always visible.
- `'off'` — The bar series object handle is invisible at all times. This option is useful for preventing unintended changes to the UI by another function. Set the `HandleVisibility` to `'off'` to temporarily hide the handle during the execution of that function.

- 'callback' — The bar series object handle is visible from within callbacks or functions invoked by callbacks, but not from within functions invoked from the command line. This option blocks access to the bar series at the command-line, but allows callback functions to access it.

If the bar series object is not listed in the `Children` property of the parent, then functions that obtain object handles by searching the object hierarchy or querying handle properties cannot return it. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

Hidden object handles are still valid. Set the root `ShowHiddenHandles` property to 'on' to list all object handles regardless of their `HandleVisibility` property setting.

## Interactive Control

### **ButtonDownFcn — Mouse-click callback**

' ' (default) | function handle | cell array | string

Mouse-click callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you click the bar series. If you specify this property using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The bar series object — You can access properties of the bar series object from within the callback function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see “Callback Definition”.

---

**Note:** If the `PickableParts` property is set to 'none' or if the `HitTest` property is set to 'off', then this callback does not execute.

---

Example: @myCallback

Example: {@myCallback, arg3}

### **UIContextMenu — Context menu**

uicontextmenu object

Context menu, specified as a uicontextmenu object. Use this property to display a context menu when you right-click the bar series. Create the context menu using the uicontextmenu function.

---

**Note:** If the PickableParts property is set to 'none' or if the HitTest property is set to 'off', then the context menu does not appear.

---

### **Selected — Selection state**

'off' (default) | 'on'

Selection state, specified as one of these values:

- 'on' — Selected. If you click the bar series when in plot edit mode, then MATLAB sets its Selected property to 'on'. If the SelectionHighlight property also is set to 'on', then MATLAB displays selection handles around the bar series.
- 'off' — Not selected.

### **SelectionHighlight — Display of selection handles when selected**

'on' (default) | 'off'

Display of selection handles when selected, specified as one of these values:

- 'on' — Display selection handles when the Selected property is set to 'on'.
- 'off' — Never display selection handles, even when the Selected property is set to 'on'.

## **Callback Execution Control**

### **PickableParts — Ability to capture mouse clicks**

'visible' (default) | 'none'

Ability to capture mouse clicks, specified as one of these values:

- `'visible'` — Can capture mouse clicks when visible. The `Visible` property must be set to `'on'` and you must click a part of the bar series that has a defined color. You cannot click a part that has an associated color property set to `'none'`. The `HitTest` property determines if the bar series responds to the click or if an ancestor does.
- `'none'` — Cannot capture mouse clicks. Clicking the bar series passes the click to the object below it in the current view of the figure window. The `HitTest` property of the bar series has no effect.

### **HitTest — Response to captured mouse clicks**

`'on'` (default) | `'off'`

Response to captured mouse clicks, specified as one of these values:

- `'on'` — Trigger the `ButtonDownFcn` callback of the bar series. If you have defined the `UIContextMenu` property, then invoke the context menu.
- `'off'` — Trigger the callbacks for the nearest ancestor of the bar series that has a `HitTest` property set to `'on'` and a `PickableParts` property value that enables the ancestor to capture mouse clicks.

---

**Note:** The `PickableParts` property determines if the bar series object can capture mouse clicks. If it cannot, then the `HitTest` property has no effect.

---

### **HitTestArea — (removed) Extents of clickable area for bar series**

`'off'` (default) | `'on'`

---

**Note:** `HitTestArea` has been removed. Use `PickableParts` instead.

---

Extents of clickable area for bar series, specified as one of these values:

- `'off'` — Click the bar series plot to select it. This is the default value.
- `'on'` — Click anywhere within the extent of the bar series plot to select it, that is, anywhere within the rectangle that encloses the bar series plot.

Example: `'off'`

### **Interruptible — Callback interruption**

`'on'` (default) | `'off'`

Callback interruption, specified as 'on' or 'off'. The `Interruptible` property determines if a running callback can be interrupted.

---

**Note:** There are two callback states to consider:

- The *running* callback is the currently executing callback.
  - The *interrupting* callback is a callback that tries to interrupt the running callback. Whenever MATLAB invokes a callback, that callback attempts to interrupt a running callback. The `Interruptible` property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the `BusyAction` property of the object owning the interrupting callback determines if it is discarded or put in the queue.
- 

If the `ButtonDownFcn` callback of the bar series is the running callback, then the `Interruptible` property determines if it another callback can interrupt it:

- 'on' — Interruptible. Interruption occurs at the next point where MATLAB processes the queue, such as when there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command.
  - If the running callback contains one of these commands, then MATLAB stops the execution of the callback at this point and executes the interrupting callback. MATLAB resumes executing the running callback when the interrupting callback completes. For more information, see “Interrupt Callback Execution”.
  - If the running callback does not contain one of these commands, then MATLAB finishes executing the callback without interruption.
- 'off' — Not interruptible. MATLAB finishes executing the running callback without any interruptions.

### **BusyAction — Callback queuing**

'queue' (default) | 'cancel'

Callback queuing specified as 'queue' or 'cancel'. The `BusyAction` property determines how MATLAB handles the execution of interrupting callbacks.

---

**Note:** There are two callback states to consider:

- The *running* callback is the currently executing callback.

- The *interrupting* callback is a callback that tries to interrupt the running callback.

Whenever MATLAB invokes a callback, that callback attempts to interrupt a running callback. The **Interruptible** property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the **BusyAction** property of the object owning the interrupting callback determines if it is discarded or put in the queue.

---

If the **ButtonDownFcn** callback of the bar series tries to interrupt a running callback that cannot be interrupted, then the **BusyAction** property determines if it is discarded or put in the queue. Specify the **BusyAction** property as one of these values:

- 'queue' — Put the interrupting callback in a queue to be processed after the running callback finishes execution. This is the default behavior.
- 'cancel' — Discard the interrupting callback.

## Creation and Deletion Control

### **CreateFcn** — Creation callback

' ' (default) | function handle | cell array | string

Creation callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you create the bar series. Setting the **CreateFcn** property on an existing bar series has no effect. You must define a default value for this property, or define this property using a **Name, Value** pair during bar series creation. MATLAB executes the callback after creating the bar series and setting all of its properties.

If you specify this callback using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The bar series object — You can access properties of the bar series object from within the callback function. You also can access the bar series object through the **CallbackObject** property of the root, which can be queried using the **gcb0** function.

- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see “Callback Definition”.

Example: @myCallback

Example: {@myCallback, arg3}

### DeleteFcn — Deletion callback

' ' (default) | function handle | cell array | string

Deletion callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you delete the bar series. MATLAB executes the callback before destroying the bar series so that the callback can access its property values.

If you specify this callback using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The bar series object — You can access properties of the bar series object from within the callback function. You also can access the bar series object through the `CallbackObject` property of the root, which can be queried using the `gcbo` function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see “Callback Definition”.

Example: @myCallback

Example: {@myCallback, arg3}

### BeingDeleted — Deletion status of bar series

'off' (default) | 'on'

This property is read only.

Deletion status of bar series, returned as 'on' or 'off'. MATLAB sets the `BeingDeleted` property to 'on' when the delete function of the bar series begins execution (see the `DeleteFcn` property). The `BeingDeleted` property remains set to 'on' until the bar series no longer exists.

Check the value of the `BeingDeleted` property to verify that the bar series is not about to be deleted before querying or modifying it.

# baryToCart

**Class:** TriRep

(Not recommended) Convert point coordinates from barycentric to Cartesian

---

**Note:** `baryToCart(TriRep)` is not recommended. Use `barycentricToCartesian(triangulation)` instead.

`TriRep` is not recommended. Use `triangulation` instead.

---

## Syntax

`XC = baryToCart(TR, SI, B)`

## Description

`XC = baryToCart(TR, SI, B)` returns the Cartesian coordinates `XC` of each point in `B` that represents the barycentric coordinates with respect to its associated simplex `SI`.

## Input Arguments

|                 |                                                                                                                                                                                                                                                                                                                                |
|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>TR</code> | Triangulation representation.                                                                                                                                                                                                                                                                                                  |
| <code>SI</code> | Column vector of simplex indices that index into the triangulation matrix <code>TR.Triangulation</code>                                                                                                                                                                                                                        |
| <code>B</code>  | <code>B</code> is a matrix that represents the barycentric coordinates of the points to convert with respect to the simplices <code>SI</code> . <code>B</code> is of size <code>m-by-k</code> , where <code>m = length(SI)</code> , the number of points to convert, and <code>k</code> is the number of vertices per simplex. |

## Output Arguments

**XC** Matrix of cartesian coordinates of the converted points. **XC** is of size  $m$ -by- $n$ , where  $n$  is the dimension of the space where the triangulation resides. That is, the Cartesian coordinates of the point  $B(j)$  with respect to simplex  $SI(j)$  is  $XC(j)$ .

## Definitions

A simplex is a triangle/tetrahedron or higher-dimensional equivalent.

## Examples

Compute the Delaunay triangulation of a set of points.

```
x = [0 4 8 12 0 4 8 12]';
y = [0 0 0 0 8 8 8 8]';
dt = DelaunayTri(x,y)
```

Compute the barycentric coordinates of the incenters.

```
cc = incenters(dt);
tri = dt(:,:);
```

Plot the original triangulation and reference points.

```
figure
subplot(1,2,1);
triplot(dt); hold on;
plot(cc(:,1), cc(:,2), '*r'); hold off;
axis equal;
```

Stretch the triangulation and compute the mapped locations of the incenters on the deformed triangulation.

```
b = cartToBary(dt,[1:length(tri)]',cc);
y = [0 0 0 0 16 16 16 16]';
tr = TriRep(tri,x,y)
xc = baryToCart(tr, [1:length(tri)]', b);
```

Plot the deformed triangulation and mapped locations of the reference points.

```
subplot(1,2,2);
triplot(tr); hold on;
plot(xc(:,1), xc(:,2), '*r'); hold off;
axis equal;
```

## base2dec

Convert base N number string to decimal number

### Syntax

```
d = base2dec('strn', base)
```

### Description

`d = base2dec('strn', base)` converts the string number *strn* of the specified *base* into its decimal (base 10) equivalent. *base* must be an integer between 2 and 36. *strn* must represent a nonnegative integer value. If *strn* represents an integer value greater than  $2^{52}$ , `base2dec` might not return an exact conversion.

If *strn* is a character array, each row is interpreted as a string in the specified *base*.

### Examples

The expression `base2dec('212',3)` converts  $212_3$  to decimal, returning 23.

### See Also

`dec2base`

# Baseline Properties

Control baseline appearance and behavior

Baseline objects are created as part of bar charts, area charts, and stem charts. Baseline properties control the appearance and behavior of a baseline object. By changing property values, you can modify certain aspects of the baseline. Use dot notation to refer to a particular object and property:

```
b = bar(1:10);
bl = b.BaseLine;
c = bl.Color;
bl.Color = 'red';
```

## Appearance

### Color — Line color

RGB triplet | color string | 'none'

Line color, specified as an RGB triplet, a color string, or 'none'. If you specify the color as 'none', then the baseline is invisible.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0, 1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

| Long Name | Short Name | RGB Triplet |
|-----------|------------|-------------|
| 'yellow'  | 'y'        | [1 1 0]     |
| 'magenta' | 'm'        | [1 0 1]     |
| 'cyan'    | 'c'        | [0 1 1]     |
| 'red'     | 'r'        | [1 0 0]     |
| 'green'   | 'g'        | [0 1 0]     |
| 'blue'    | 'b'        | [0 0 1]     |
| 'white'   | 'w'        | [1 1 1]     |
| 'black'   | 'k'        | [0 0 0]     |

Example: 'blue'

Example: [0 0 1]

**LineStyle** — Line style

'-' | '--' | ':' | '-.' | 'none'

Line style, specified as one of the line style strings listed in this table.

| String | Line Style       | Resulting Line                                                                     |
|--------|------------------|------------------------------------------------------------------------------------|
| '-'    | Solid line       |  |
| '--'   | Dashed line      |  |
| ':'    | Dotted line      |  |
| '-.'   | Dash-dotted line |  |
| 'none' | No line          | No line                                                                            |

**LineWidth** — Line width

positive value

Line width, specified as a positive value in point units.

Example: 0.75

**Location and Visibility**

**BaseValue** — Value of baseline

scalar

Value of the baseline, specified as a scalar.

Typically, baselines are associated with bar series, stem series, or area objects. The **BaseValue** property for the associated object and the **BaseValue** property for the baseline object always have the same value. Setting one property also sets the other property. The **BaseLine** property for the associated object contains the baseline object.

Example: 0.75

**Visible** — Baseline visibility

'on' | 'off'

Baseline visibility, specified as one of these values:

- 'on' — Display the baseline.
- 'off' — Hide the baseline without deleting it. You can access the properties of an invisible baseline.

Typically, baselines are associated with bar series, stem series, or area objects. The `ShowBaseline` property for the associated object and the `Visible` property for the baseline object always have the same value. Setting one property also sets the other property. The `Baseline` property for the associated object contains the baseline object.

## Parent/Child

### **Parent** — Parent of baseline

axes object

Parent of baseline, returned as an axes object. However, baseline objects are not listed as children of the axes.

### **Children** — Children of baseline

empty `GraphicsPlaceholder` array

The baseline has no children. You cannot set this property.

## **beep**

Produce operating system beep sound

### **Syntax**

```
beep
beep on
beep off
```

```
status = beep
```

### **Description**

`beep` produces your computer's default beep sound, if it is enabled.

`beep on` enables the beep sound.

`beep off` disables the beep sound.

`status = beep` returns the current beep mode (on or off).

### **Examples**

#### **Produce Beep Sound**

Produce your system's default beep sound after a period of silence.

Pause for 5 seconds of silence, and then produce your system's default beep sound.

```
pause(5)
beep
```

### **More About**

#### **Tips**

- If you have configured your system not to produce any sound, then `beep` is silent.

- `beep` produces the operating system's default beep sound. To produce a sound and specify its pitch and duration in MATLAB, use the `sound` function.

## **See Also**

`sound`

## BeginInvoke

Initiate asynchronous .NET delegate call

### Syntax

```
result = BeginInvoke(arg1, ..., argN, callback, object)
```

### Description

`result = BeginInvoke(arg1, ..., argN, callback, object)` initiates asynchronous call to a .NET delegate. You must call `EndInvoke` to complete the asynchronous call.

### Input Arguments

#### **arg1, ..., argN**

Input arguments for delegate. The type and number of arguments must agree with the delegate signature.

#### **callback**

.NET `System.AsyncCallback` delegate, or [ ] null value.

#### **object**

User-defined object, or [ ] null value.

### Output Arguments

#### **result**

.NET `System.IAsyncResult` object. Used to monitor the progress of the asynchronous call. Input argument to `EndInvoke`.

# bench

MATLAB benchmark

## Syntax

```
bench
bench(N)
bench(0)
t = bench(N)
```

## Description

`bench` measures the execution speed of six different MATLAB tasks and compares it to the speed of several other computers. The six tasks are:

| Test   | Description                                            | Performance Factors                       |
|--------|--------------------------------------------------------|-------------------------------------------|
| LU     | Perform LU of a full matrix                            | Floating-point, regular memory access     |
| FFT    | Perform FFT of a full vector                           | Floating-point, irregular memory access   |
| ODE    | Solve van der Pol equation with ODE45                  | Data structures and MATLAB function files |
| Sparse | Solve a symmetric sparse linear system                 | Mixed integer and floating-point          |
| 2-D    | Plot Lissajous curves                                  | 2-D line drawing graphics                 |
| 3-D    | Display colormapped peaks with clipping and transforms | 3-D animated OpenGL graphics              |

A final bar chart shows speed, which is inversely proportional to time. The longer bars represent faster machines, and the shorter bars represent the slower ones.

`bench(N)` runs each of the six tasks N times.

`bench(0)` just displays the results from other machines.

`t = bench(N)` returns an N-by-6 array with the execution times.

## More About

### Tips

---

**Note:** A benchmark is intended to compare performance of one particular version of MATLAB on different machines. It does not offer direct comparisons between different versions of MATLAB because tasks and problem sizes change from version to version.

---

The LU and FFT tasks involve large matrices and long vectors. The 2-D and 3-D tasks measure graphics performance, including software or hardware support for OpenGL<sup>®</sup>. The command

```
opengl info
```

describes the OpenGL support available on a particular machine.

Fluctuations of five or ten percent in the measured times of repeated runs on a single machine are normal.

## besselh

Bessel function of third kind (Hankel function)

### Syntax

H = besselh(nu, K, Z)

H = besselh(nu, Z)

H = besselh(nu, K, Z, 1)

### Definitions

The differential equation

$$z^2 \frac{d^2 y}{dz^2} + z \frac{dy}{dz} + (z^2 - \nu^2)y = 0,$$

where  $\nu$  is a real constant, is called *Bessel's equation*, and its solutions are known as *Bessel functions*.  $J_\nu(z)$  and  $J_{-\nu}(z)$  form a fundamental set of solutions of Bessel's equation for noninteger  $\nu$ .  $Y_\nu(z)$  is a second solution of Bessel's equation—linearly independent of  $J_\nu(z)$ —defined by

$$Y_\nu(z) = \frac{J_\nu(z) \cos(\nu\pi) - J_{-\nu}(z)}{\sin(\nu\pi)}.$$

The relationship between the Hankel and Bessel functions is

$$H_\nu^{(1)}(z) = J_\nu(z) + iY_\nu(z)$$

$$H_\nu^{(2)}(z) = J_\nu(z) - iY_\nu(z),$$

where  $J_\nu(z)$  is `besselj`, and  $Y_\nu(z)$  is `bessely`.

## Description

`H = besselh(nu, K, Z)` computes the Hankel function  $H_v^{(K)}(z)$  where  $K = 1$  or  $2$ , for each element of the complex array `Z`. If `nu` and `Z` are arrays of the same size, the result is also that size. If either input is a scalar, `besselh` expands it to the other input's size.

`H = besselh(nu, Z)` uses  $K = 1$ .

`H = besselh(nu, K, Z, 1)` scales  $H_v^{(K)}(z)$  by  $\exp(-i*Z)$  if  $K = 1$ , and by  $\exp(+i*Z)$  if  $K = 2$ .

## Examples

### Modulus and Phase of Hankel Function

This example generates the contour plots of the modulus and phase of the Hankel function  $H_0^{(1)}(z)$  shown on page 359 of Abramowitz and Stegun, *Handbook of Mathematical Functions* [1].

Create a grid of values for the domain.

```
[X,Y] = meshgrid(-4:0.025:2, -1.5:0.025:1.5);
```

Calculate the Hankel function over this domain and generate the modulus contour plot.

```
H = besselh(0,1,X+1i*Y);
contour(X,Y,abs(H),0:0.2:3.2)
hold on
```

In the same figure, add the contour plot of the phase.

```
contour(X,Y, (180/pi)*angle(H), -180:10:180)
hold off
```

## besseli

Modified Bessel function of first kind

### Syntax

```
I = besseli(nu,Z)
I = besseli(nu,Z,1)
```

### Definitions

The differential equation

$$z^2 \frac{d^2 y}{dz^2} + z \frac{dy}{dz} - (z^2 + \nu^2) y = 0,$$

where  $\nu$  is a real constant, is called the *modified Bessel's equation*, and its solutions are known as *modified Bessel functions*.

$I_\nu(z)$  and  $L_\nu(z)$  form a fundamental set of solutions of the modified Bessel's equation.  $I_\nu(z)$  is defined by

$$I_\nu(z) = \left(\frac{z}{2}\right)^\nu \sum_{(k=0)}^{\infty} \frac{\left(\frac{z^2}{4}\right)^k}{k! \Gamma(\nu + k + 1)},$$

where  $\Gamma(a)$  is the gamma function.

$K_\nu(z)$  is a second solution, independent of  $I_\nu(z)$ . It can be computed using `besselk`.

### Description

`I = besseli(nu,Z)` computes the modified Bessel function of the first kind,  $I_\nu(z)$ , for each element of the array `Z`. The order `nu` need not be an integer, but must be real. The argument `Z` can be complex. The result is real where `Z` is positive.

If `nu` and `Z` are arrays of the same size, the result is also that size. If either input is a scalar, it is expanded to the other input's size.

`I = besseli(nu,Z,1)` computes `besseli(nu,Z).*exp(-abs(real(Z)))`.

## Examples

### Vector of Function Values

Create a column vector of domain values.

```
z = (0:0.2:1)';

title('Bessel Functions of the First Kind for v = 0,1,2,3,4')
xlabel('X')
ylabel('J_v(X)')
```

## More About

### Tips

The Bessel functions are related to the Hankel functions, also called Bessel functions of the third kind, by the formula

$$H_{\nu}^{(1)}(z) = J_{\nu}(z) + iY_{\nu}(z)$$

$$H_{\nu}^{(2)}(z) = J_{\nu}(z) - iY_{\nu}(z)$$

where  $H_{\nu}^{(K)}(z)$  is **besselh**,  $J_{\nu}(z)$  is **besselj**, and  $Y_{\nu}(z)$  is **bessely**. The Hankel functions also form a fundamental set of solutions to Bessel's equation (see **besselh**).

**See Also**

# besselk

Modified Bessel function of second kind

## Syntax

$K = \text{besselk}(\text{nu}, Z)$

$K = \text{besselk}(\text{nu}, Z, 1)$

## Definitions

The differential equation

$$z^2 \frac{d^2 y}{dz^2} + z \frac{dy}{dz} - (z^2 + \nu^2) y = 0,$$

where  $\nu$  is a real constant, is called the *modified Bessel's equation*, and its solutions are known as *modified Bessel functions*.

A solution  $K_\nu(z)$  of the second kind can be expressed as:

$$K_\nu(z) = \left(\frac{\pi}{2}\right) \frac{I_{-\nu}(z) - I_\nu(z)}{\sin(\nu\pi)},$$

where  $I_\nu(z)$  and  $I_{-\nu}(z)$  form a fundamental set of solutions of the modified Bessel's equation,

$$I_\nu(z) = \left(\frac{z}{2}\right)^\nu \sum_{k=0}^{\infty} \frac{\left(\frac{z^2}{4}\right)^k}{k! \Gamma(\nu + k + 1)}$$

and  $\Gamma(a)$  is the gamma function.  $K_\nu(z)$  is independent of  $I_\nu(z)$ .

$I_\nu(z)$  can be computed using `besseli`.

## Description

`K = bessellk(nu,Z)` computes the modified Bessel function of the second kind,  $K_\nu(z)$ , for each element of the array `Z`. The order `nu` need not be an integer, but must be real. The argument `Z` can be complex. The result is real where `Z` is positive.

If `nu` and `Z` are arrays of the same size, the result is also that size. If either input is a scalar, it is expanded to the other input's size.

`K = bessellk(nu,Z,1)` computes `bessellk(nu,Z) .* exp(Z)`.

## Examples

### Column Vector of Function Values

Create a column vector of domain values.

# bessely

Bessel function of second kind

## Syntax

$Y = \text{bessely}(nu, Z)$

$Y = \text{bessely}(nu, Z, 1)$

## Definitions

The differential equation

$$z^2 \frac{d^2 y}{dz^2} + z \frac{dy}{dz} + (z^2 - \nu^2) y = 0,$$

where  $\nu$  is a real constant, is called *Bessel's equation*, and its solutions are known as *Bessel functions*.

A solution  $Y_\nu(z)$  of the second kind can be expressed as

$$Y_\nu(z) = \frac{J_\nu(z) \cos(\nu\pi) - J_{-\nu}(z)}{\sin(\nu\pi)}$$

where  $J_\nu(z)$  and  $J_{-\nu}(z)$  form a fundamental set of solutions of Bessel's equation for noninteger  $\nu$

$$J_\nu(z) = \left(\frac{z}{2}\right)^\nu \sum_{k=0}^{\infty} \frac{\left(-\frac{z^2}{4}\right)^k}{k! \Gamma(\nu + k + 1)},$$

and  $\Gamma(a)$  is the gamma function.  $Y_\nu(z)$  is linearly independent of  $J_\nu(z)$ .

$J_\nu(z)$  can be computed using `besselj`.

## Description

`Y = bessely(nu,Z)` computes Bessel functions of the second kind,  $Y_\nu(z)$ , for each element of the array `Z`. The order `nu` need not be an integer, but must be real. The argument `Z` can be complex. The result is real where `Z` is positive.

If `nu` and `Z` are arrays of the same size, the result is also that size. If either input is a scalar, it is expanded to the other input's size.

`Y = bessely(nu,Z,1)` computes `bessely(nu,Z).*exp(-abs(imag(Z)))`.

## Examples

### Vector of Function Values

Create a column vector of domain values.

```
z = (0:0.2:1)';
```

Calculate the function values using `bessely` with `nu = 1`.

```
format long
bessely(1,z)
```

```
ans =
```

```
 -Inf
-3.323824988111848
-1.780872044270052
-1.260391347177388
-0.978144176683359
-0.781212821300289
```

### Plot Bessel Functions of Second Kind

Define the domain.

```
X = 0:0.1:20;
```

Calculate the first five Bessel functions of the second kind.

```
Y = zeros(5,201);
for i = 0:4
 Y(i+1,:) = bessely(i,X);
end
```

Plot the results.

```
plot(X,Y, 'LineWidth',1.5)
axis([-0.1 20.2 -2 0.6])
grid on
legend('Y_0', 'Y_1', 'Y_2', 'Y_3', 'Y_4', 'Location', 'Best')
title('Bessel Functions of the Second Kind for $\nu = 0,1,2,3,4$ ')
xlabel('X')
ylabel('Y_v(X)')
```

## More About

### Tips

The Bessel functions are related to the Hankel functions, also called Bessel functions of the third kind,

$$H_\nu^{(1)}(z) = J_\nu(z) + iY_\nu(z)$$

$$H_\nu^{(2)}(z) = J_\nu(z) - iY_\nu(z),$$

where  $H_\nu^{(K)}(z)$  is `besselh`,  $J_\nu(z)$  is `besselj`, and  $Y_\nu(z)$  is `bessely`. The Hankel functions also form a fundamental set of solutions to Bessel's equation (see `besselh`).

**See Also**

`besselh` | `besseli` | `besselj` | `besselk`

## beta

Beta function

## Syntax

B = beta(Z,W)

## Definitions

The beta function is

$$B(z,w) = \int_0^1 t^{z-1}(1-t)^{w-1} dt = \frac{\Gamma(z)\Gamma(w)}{\Gamma(z+w)}$$

where  $\Gamma(z)$  is the gamma function.

## Description

B = beta(Z,W) computes the beta function for corresponding elements of arrays Z and W. The arrays must be real and nonnegative. They must be the same size, or either can be scalar.

## Examples

In this example, which uses integer arguments,

```
beta(n,3)
= (n-1)!*2!/(n+2)!
= 2/(n*(n+1)*(n+2))
```

is the ratio of fairly small integers, and the rational format is able to recover the exact result.

```
format rat
```

```
beta((0:10)',3)
```

```
ans =
```

```
1/0
1/3
1/12
1/30
1/60
1/105
1/168
1/252
1/360
1/495
1/660
```

## More About

### Algorithms

$\text{beta}(z,w) = \exp(\text{gamma}\ln(z)+\text{gamma}\ln(w)-\text{gamma}\ln(z+w))$

### See Also

## betainc

Incomplete beta function

### Syntax

```
I = betainc(X,Z,W)
I = betainc(X,Z,W,tail)
```

### Definitions

The incomplete beta function is

$$I_x(z,w) = \frac{1}{B(z,w)} \int_0^x t^{z-1} (1-t)^{w-1} dt$$

where  $B(z,w)$ , the beta function, is defined as

$$B(z,w) = \int_0^1 t^{z-1} (1-t)^{w-1} dt = \frac{\Gamma(z)\Gamma(w)}{\Gamma(z+w)}$$

and  $\Gamma(z)$  is the gamma function.

### Description

`I = betainc(X,Z,W)` computes the incomplete beta function for corresponding elements of the arrays `X`, `Z`, and `W`. The elements of `X` must be in the closed interval  $[0,1]$ . The arrays `Z` and `W` must be nonnegative and real. All arrays must be the same size, or any of them can be scalar.

`I = betainc(X,Z,W,tail)` specifies the tail of the incomplete beta function. Choices are:

|                       |                                   |
|-----------------------|-----------------------------------|
| 'lower' (the default) | Computes the integral from 0 to x |
|-----------------------|-----------------------------------|

|         |                                   |
|---------|-----------------------------------|
| 'upper' | Computes the integral from x to 1 |
|---------|-----------------------------------|

These functions are related as follows:

$$1 - \text{betainc}(X, Z, W) = \text{betainc}(X, Z, W, 'upper')$$

Note that especially when the upper tail value is close to 0, it is more accurate to use the 'upper' option than to subtract the 'lower' value from 1.

## Examples

```
format long
betainc(.5, (0:10)', 3)
```

```
ans =
 1.000000000000000
 0.875000000000000
 0.687500000000000
 0.500000000000000
 0.343750000000000
 0.226562500000000
 0.144531250000000
 0.089843750000000
 0.054687500000000
 0.032714843750000
 0.019287109375000
```

## See Also

beta | betaIn

## betaincinv

Beta inverse cumulative distribution function

### Syntax

```
x = betaincinv(y,z,w)
x = betaincinv(y,z,w,tail)
```

### Description

`x = betaincinv(y,z,w)` computes the inverse incomplete beta function for corresponding elements of `y`, `z`, and `w`, such that `y = betainc(x,z,w)`. The elements of `y` must be in the closed interval  $[0,1]$ , and those of `z` and `w` must be nonnegative. `y`, `z`, and `w` must all be real and the same size (or any of them can be scalar).

`x = betaincinv(y,z,w,tail)` specifies the tail of the incomplete beta function. Choices are 'lower' (the default) to use the integral from 0 to `x`, or 'upper' to use the integral from `x` to 1. These two choices are related as follows: `betaincinv(y,z,w,'upper') = betaincinv(1-y,z,w,'lower')`. When `y` is close to 0, the 'upper' option provides a way to compute `x` more accurately than by subtracting `y` from 1.

### Definitions

The incomplete beta function is defined as

$$I_x(z,w) = \frac{1}{\beta(z,w)} \int_0^x t^{(z-1)}(1-t)^{(w-1)} dt$$

`betaincinv` computes the inverse of the incomplete beta function with respect to the integration limit `x` using Newton's method.

### See Also

`betainc` | `beta` | `betaln`

# betaIn

Logarithm of beta function

## Syntax

```
L = betaIn(Z,W)
```

## Description

`L = betaIn(Z,W)` computes the natural logarithm of the `beta` function  $\log(\text{beta}(Z,W))$ , for corresponding elements of arrays `Z` and `W`, without computing `beta(Z,W)`. Since the beta function can range over very large or very small values, its logarithm is sometimes more useful.

`Z` and `W` must be real and nonnegative. They must be the same size, or either can be scalar.

## Examples

```
x = 510
betaIn(x,x)
```

```
ans =
 -708.8616
```

-708.8616 is slightly less than `log(realmin)`. Computing `beta(x,x)` directly would underflow (or be denormal).

## More About

### Algorithms

```
betaIn(z,w) = gammaIn(z)+gammaIn(w)-gammaIn(z+w)
```

---

# between

Calendar math differences

## Syntax

```
dt = between(t1,t2)
dt = between(t1,t2,components)
```

## Description

`dt = between(t1,t2)` returns the differences between the datetime values in `t1` and `t2`. The `dt` output is a `calendarDuration` array in terms of the calendar components years, months, days, and time, such that `t2 = t1+dt`.

`dt = between(t1,t2,components)` returns the differences between datetime values in terms of the specified calendar or time components.

## Examples

### Differences Between Two Datetime Arrays

Create two datetime arrays.

```
t1 = datetime('now')
```

```
t1 =
```

```
24-Aug-2015 17:46:17
```

```
t2 = datetime('tomorrow','Format','dd-MMM-yyyy HH:mm:ss') + caldays(0:2)
```

```
t2 =
```

```
25-Aug-2015 00:00:00 26-Aug-2015 00:00:00 27-Aug-2015 00:00:00
```

Find the difference between the two arrays.

```
dt = between(t1,t2)
```

```
dt =
```

```
 6h 13m 42.722s 1d 6h 13m 42.722s 2d 6h 13m 42.722s
```

`between` returns a `calendarDuration` array containing differences in terms of days, hours, minutes, and seconds.

## Difference Between Datetime Values in Calendar Days

Create a sequence of datetimes over a 6-month period. Then, find the number of days between the first date and each of the dates in the sequence.

```
t1 = datetime(2013,1,1);
t2 = dateshift(t1,'end','month',0:4)
```

```
t2 =
```

```
 31-Jan-2013 28-Feb-2013 31-Mar-2013 30-Apr-2013 31-May-2013
```

```
dt = between(t1,t2,'Days')
```

```
dt =
```

```
 30d 58d 89d 119d 150d
```

## Input Arguments

### **t1** — Input date and time

`datetime` array | `datetime` string | cell array of `datetime` strings

Input date and time, specified as a `datetime` array, `datetime` string, or cell array of `datetime` strings. At least one of inputs `t1` and `t2` must be a `datetime` array. `t1` and `t2` must be the same size unless one is a scalar.

**t2 — Input date and time**

datetime array | datetime string | cell array of datetime strings

Input date and time, specified as a `datetime` array, datetime string, or cell array of datetime strings. At least one of inputs `t1` and `t2` must be a `datetime` array. `t1` and `t2` must be the same size unless one is a scalar.

**components — Calendar or time components**

'years' | 'quarters' | 'months' | 'weeks' | 'days' | 'time' | cell array of strings

Calendar or time components, specified as one of the following strings, or a cell array containing one or more of these strings:

- 'years'
- 'quarters'
- 'months'
- 'weeks'
- 'days'
- 'time'

Except for 'time', the above components are flexible lengths of time. For example, 1 month represents a different length of time when added to a datetime in January than when added to a datetime in February.

`between` operates on the calendar or time components in decreasing order, starting with the largest component.

In general, `t2` is not equal to `t1 + dt`, unless you include 'time' in components.

Example: {'years', 'quarters'}

Data Types: char | cell

## Output Arguments

**dt — Difference array**

calendarDuration array

Difference array, returned as a `calendarDuration` array.

## More About

### Tips

- To compute differences between datetime values in `t1` and `t2` as exact, fixed-length durations, use `t2 - t1`.

### See Also

`caldiff` | `calendarDuration` | `diff` | `minus`

**Introduced in R2014b**

# bicg

Biconjugate gradients method

## Syntax

```
x = bicg(A,b)
bicg(A,b,tol)
bicg(A,b,tol,maxit)
bicg(A,b,tol,maxit,M)
bicg(A,b,tol,maxit,M1,M2)
bicg(A,b,tol,maxit,M1,M2,x0)
[x,flag] = bicg(A,b,...)
[x,flag,relres] = bicg(A,b,...)
[x,flag,relres,iter] = bicg(A,b,...)
[x,flag,relres,iter,resvec] = bicg(A,b,...)
```

## Description

`x = bicg(A,b)` attempts to solve the system of linear equations  $A*x = b$  for  $x$ . The  $n$ -by- $n$  coefficient matrix  $A$  must be square and should be large and sparse. The column vector  $b$  must have length  $n$ .  $A$  can be a function handle, `afun`, such that `afun(x, 'notransp')` returns  $A*x$  and `afun(x, 'transp')` returns  $A' * x$ .

“Parameterizing Functions” explains how to provide additional parameters to the function `afun`, as well as the preconditioner function `mfun` described below, if necessary.

If `bicg` converges, it displays a message to that effect. If `bicg` fails to converge after the maximum number of iterations or halts for any reason, it prints a warning message that includes the relative residual  $\text{norm}(b - A*x) / \text{norm}(b)$  and the iteration number at which the method stopped or failed.

`bicg(A,b,tol)` specifies the tolerance of the method. If `tol` is `[]`, then `bicg` uses the default,  $1e-6$ .

`bicg(A,b,tol,maxit)` specifies the maximum number of iterations. If `maxit` is `[]`, then `bicg` uses the default,  $\min(n, 20)$ .

`bicg(A,b,tol,maxit,M)` and `bicg(A,b,tol,maxit,M1,M2)` use the preconditioner `M` or `M = M1*M2` and effectively solve the system  $\text{inv}(M)*A*x = \text{inv}(M)*b$  for `x`. If `M` is `[]` then `bicg` applies no preconditioner. `M` can be a function handle `mfun`, such that `mfun(x,'notransp')` returns `M\x` and `mfun(x,'transp')` returns `M'\x`.

`bicg(A,b,tol,maxit,M1,M2,x0)` specifies the initial guess. If `x0` is `[]`, then `bicg` uses the default, an all-zero vector.

`[x,flag] = bicg(A,b,...)` also returns a convergence flag.

| Flag | Convergence                                                                                                           |
|------|-----------------------------------------------------------------------------------------------------------------------|
| 0    | <code>bicg</code> converged to the desired tolerance <code>tol</code> within <code>maxit</code> iterations.           |
| 1    | <code>bicg</code> iterated <code>maxit</code> times but did not converge.                                             |
| 2    | Preconditioner <code>M</code> was ill-conditioned.                                                                    |
| 3    | <code>bicg</code> stagnated. (Two consecutive iterates were the same.)                                                |
| 4    | One of the scalar quantities calculated during <code>bicg</code> became too small or too large to continue computing. |

Whenever `flag` is not 0, the solution `x` returned is that with minimal norm residual computed over all the iterations. No messages are displayed if the `flag` output is specified.

`[x,flag,relres] = bicg(A,b,...)` also returns the relative residual  $\text{norm}(b-A*x)/\text{norm}(b)$ . If `flag` is 0, `relres`  $\leq$  `tol`.

`[x,flag,relres,iter] = bicg(A,b,...)` also returns the iteration number at which `x` was computed, where  $0 \leq \text{iter} \leq \text{maxit}$ .

`[x,flag,relres,iter,resvec] = bicg(A,b,...)` also returns a vector of the residual norms at each iteration including  $\text{norm}(b-A*x0)$ .

## Examples

### Using `bicg` with a Matrix Input

This example shows how to use `bicg` with a matrix input. `bicg`. The following code:

```

n = 100;
on = ones(n,1);
A = spdiags([-2*on 4*on -on],-1:1,n,n);
b = sum(A,2);
tol = 1e-8;
maxit = 15;
M1 = spdiags([on/(-2) on],-1:0,n,n);
M2 = spdiags([4*on -on],0:1,n,n);

x = bicg(A,b,tol,maxit,M1,M2);

```

displays this message:

```

bicg converged at iteration 9 to a solution with relative
residual 5.3e-009

```

## Using bicg with a Function Handle

This example replaces the matrix `A` in the previous example with a handle to a matrix-vector product function `afun`. The example is contained in a file `run_bicg` that

- Calls `bicg` with the `@afun` function handle as its first argument.
- Contains `afun` as a nested function, so that all variables in `run_bicg` are available to `afun`.

Place the following into a file called `run_bicg`:

```

function x1 = run_bicg
n = 100;
on = ones(n,1);
b = afun(on,'notransp');
tol = 1e-8;
maxit = 15;
M1 = spdiags([on/(-2) on],-1:0,n,n);
M2 = spdiags([4*on -on],0:1,n,n);
x1 = bicg(@afun,b,tol,maxit,M1,M2);

function y = afun(x,transp_flag)
 if strcmp(transp_flag,'transp') % y = A'*x
 y = 4 * x;
 y(1:n-1) = y(1:n-1) - 2 * x(2:n);
 y(2:n) = y(2:n) - x(1:n-1);
 end

```

```
elseif strcmp(transp_flag,'notransp') % y = A*x
 y = 4 * x;
 y(2:n) = y(2:n) - 2 * x(1:n-1);
 y(1:n-1) = y(1:n-1) - x(2:n);
end
end
end
```

When you enter

```
x1 = run_bicg;
```

MATLAB software displays the message

```
bicg converged at iteration 9 to a solution with ...
relative residual
5.3e-009
```

## Using bicg with a Preconditioner

This example demonstrates the use of a preconditioner.

Load `A = west0479`, a real 479-by-479 nonsymmetric sparse matrix.

```
load west0479;
A = west0479;
```

Define `b` so that the true solution is a vector of all ones.

```
b = full(sum(A,2));
```

Set the tolerance and maximum number of iterations.

```
tol = 1e-12;
maxit = 20;
```

Use `bicg` to find a solution at the requested tolerance and number of iterations.

```
[x0,f10,rr0,it0,rv0] = bicg(A,b,tol,maxit);
```

`f10` is 1 because `bicg` does not converge to the requested tolerance `1e-12` within the requested 20 iterations. In fact, the behavior of `bicg` is so poor that the initial guess (`x0`

`= zeros(size(A,2),1)` is the best solution and is returned as indicated by `it0 = 0`. MATLAB® stores the residual history in `rv0`.

Plot the behavior of `bicg`.

```
semilogy(0:maxit,rv0/norm(b),'-o');
xlabel('Iteration number');
ylabel('Relative residual');
```

The plot shows that the solution does not converge. You can use a preconditioner to improve the outcome.

Create the preconditioner with `ilu`, since the matrix  $A$  is nonsymmetric.

```
[L,U] = ilu(A,struct('type','ilutp','droptol',1e-5));
```

Error using ilu

There is a pivot equal to zero. Consider decreasing the drop tolerance or consider using the 'udiag' option.

MATLAB cannot construct the incomplete LU as it would result in a singular factor, which is useless as a preconditioner.

You can try again with a reduced drop tolerance, as indicated by the error message.

```
[L,U] = ilu(A,struct('type','ilutp','droptol',1e-6));
[x1,f11,rr1,it1,rv1] = bicg(A,b,tol,maxit,L,U);
```

f11 is 0 because `bicg` drives the relative residual to  $4.1410e-014$  (the value of `rr1`). The relative residual is less than the prescribed tolerance of  $1e-12$  at the sixth iteration (the value of `it1`) when preconditioned by the incomplete LU factorization with a drop tolerance of  $1e-6$ . The output `rv1(1)` is `norm(b)`, and the output `rv1(7)` is `norm(b-A*x2)`.

You can follow the progress of `bicg` by plotting the relative residuals at each iteration starting from the initial estimate (iterate number 0).

```
semilogy(0:it1,rv1/norm(b),'-o');
xlabel('Iteration number');
ylabel('Relative residual');
```

# bicgstab

Biconjugate gradients stabilized method

## Syntax

```
x = bicgstab(A,b)
bicgstab(A,b,tol)
bicgstab(A,b,tol,maxit)
bicgstab(A,b,tol,maxit,M)
bicgstab(A,b,tol,maxit,M1,M2)
bicgstab(A,b,tol,maxit,M1,M2,x0)
[x,flag] = bicgstab(A,b,...)
[x,flag,relres] = bicgstab(A,b,...)
[x,flag,relres,iter] = bicgstab(A,b,...)
[x,flag,relres,iter,resvec] = bicgstab(A,b,...)
```

## Description

`x = bicgstab(A,b)` attempts to solve the system of linear equations  $A*x=b$  for  $x$ . The  $n$ -by- $n$  coefficient matrix  $A$  must be square and should be large and sparse. The column vector  $b$  must have length  $n$ .  $A$  can be a function handle, `afun`, such that `afun(x)` returns  $A*x$ .

“Parameterizing Functions” explains how to provide additional parameters to the function `afun`, as well as the preconditioner function `mfun` described below, if necessary.

If `bicgstab` converges, a message to that effect is displayed. If `bicgstab` fails to converge after the maximum number of iterations or halts for any reason, a warning message is printed displaying the relative residual  $\text{norm}(b-A*x) / \text{norm}(b)$  and the iteration number at which the method stopped or failed.

`bicgstab(A,b,tol)` specifies the tolerance of the method. If `tol` is `[]`, then `bicgstab` uses the default,  $1e-6$ .

`bicgstab(A,b,tol,maxit)` specifies the maximum number of iterations. If `maxit` is `[]`, then `bicgstab` uses the default,  $\min(n,20)$ .

`bicgstab(A,b,tol,maxit,M)` and `bicgstab(A,b,tol,maxit,M1,M2)` use preconditioner `M` or `M = M1*M2` and effectively solve the system  $\text{inv}(M)*A*x = \text{inv}(M)*b$  for `x`. If `M` is `[]` then `bicgstab` applies no preconditioner. `M` can be a function handle `mfun`, such that `mfun(x)` returns `M\x`.

`bicgstab(A,b,tol,maxit,M1,M2,x0)` specifies the initial guess. If `x0` is `[]`, then `bicgstab` uses the default, an all zero vector.

`[x,flag] = bicgstab(A,b,...)` also returns a convergence flag.

| Flag | Convergence                                                                                                               |
|------|---------------------------------------------------------------------------------------------------------------------------|
| 0    | <code>bicgstab</code> converged to the desired tolerance <code>tol</code> within <code>maxit</code> iterations.           |
| 1    | <code>bicgstab</code> iterated <code>maxit</code> times but did not converge.                                             |
| 2    | Preconditioner <code>M</code> was ill-conditioned.                                                                        |
| 3    | <code>bicgstab</code> stagnated. (Two consecutive iterates were the same.)                                                |
| 4    | One of the scalar quantities calculated during <code>bicgstab</code> became too small or too large to continue computing. |

Whenever `flag` is not 0, the solution `x` returned is that with minimal norm residual computed over all the iterations. No messages are displayed if the `flag` output is specified.

`[x,flag,relres] = bicgstab(A,b,...)` also returns the relative residual  $\text{norm}(b-A*x)/\text{norm}(b)$ . If `flag` is 0, `relres`  $\leq$  `tol`.

`[x,flag,relres,iter] = bicgstab(A,b,...)` also returns the iteration number at which `x` was computed, where  $0 \leq \text{iter} \leq \text{maxit}$ . `iter` can be an integer + 0.5, indicating convergence halfway through an iteration.

`[x,flag,relres,iter,resvec] = bicgstab(A,b,...)` also returns a vector of the residual norms at each half iteration, including  $\text{norm}(b-A*x0)$ .

## Examples

### Using `bicgstab` with a Matrix Input

This example first solves  $Ax = b$  by providing `A` and the preconditioner `M1` directly as arguments.

The code:

```
A = gallery('wilk',21);
b = sum(A,2);
tol = 1e-12;
maxit = 15;
M1 = diag([10:-1:1 1 1:10]);

x = bicgstab(A,b,tol,maxit,M1);
```

displays the message:

```
bicgstab converged at iteration 12.5 to a solution with relative
residual 2e-014.
```

## Using bicgstab with a Function Handle

This example replaces the matrix *A* in the previous example with a handle to a matrix-vector product function *afun*, and the preconditioner *M1* with a handle to a backsolve function *mfun*. The example is contained in a file `run_bicgstab` that

- Calls `bicgstab` with the function handle `@afun` as its first argument.
- Contains `afun` and `mfun` as nested functions, so that all variables in `run_bicgstab` are available to `afun` and `mfun`.

The following shows the code for `run_bicgstab`:

```
function x1 = run_bicgstab
n = 21;
b = afun(ones(n,1));
tol = 1e-12;
maxit = 15;
x1 = bicgstab(@afun,b,tol,maxit,@mfun);

 function y = afun(x)
 y = [0; x(1:n-1)] + ...
 [((n-1)/2:-1:0)'; (1:(n-1)/2)'].*x + ...
 [x(2:n); 0];
 end

 function y = mfun(r)
 y = r ./ [((n-1)/2:-1:1)'; 1; (1:(n-1)/2)'];
```

```
 end
end
```

When you enter

```
x1 = run_bicgstab;
```

MATLAB software displays the message

```
bicgstab converged at iteration 12.5 to a solution with relative
residual 2e-014.
```

## Using `bicgstab` with a Preconditioner

This example demonstrates the use of a preconditioner.

Load `west0479`, a real 479-by-479 nonsymmetric sparse matrix.

```
load west0479;
A = west0479;
```

Define `b` so that the true solution is a vector of all ones.

```
b = full(sum(A,2));
```

Set the tolerance and maximum number of iterations.

```
tol = 1e-12;
maxit = 20;
```

Use `bicgstab` to find a solution at the requested tolerance and number of iterations.

```
[x0,f10,rr0,it0,rv0] = bicgstab(A,b,tol,maxit);
```

`f10` is 1 because `bicgstab` does not converge to the requested tolerance  $1e-12$  within the requested 20 iterations. In fact, the behavior of `bicgstab` is so bad that the initial guess (`x0 = zeros(size(A,2),1)`) is the best solution and is returned as indicated by `it0 = 0`. MATLAB® stores the residual history in `rv0`.

Plot the behavior of `bicgstab`.

```
semilogy(0:0.5:maxit,rv0/norm(b),'-o');
```

```
xlabel('Iteration number');
ylabel('Relative residual');
```

The plot shows that the solution does not converge. You can use a preconditioner to improve the outcome.

Create a preconditioner with `ilu`, since  $A$  is nonsymmetric.

```
[L,U] = ilu(A,struct('type','ilutp','droptol',1e-5));
```

Error using `ilu`

There is a pivot equal to zero. Consider decreasing the drop tolerance or consider using the `'udiag'` option.

MATLAB cannot construct the incomplete LU as it would result in a singular factor, which is useless as a preconditioner.

You can try again with a reduced drop tolerance, as indicated by the error message.

```
[L,U] = ilu(A,struct('type','ilutp','droptol',1e-6));
[x1,f11,rr1,it1,rv1] = bicgstab(A,b,tol,maxit,L,U);
```

f11 is 0 because `bicgstab` drives the relative residual to `5.9829e-014` (the value of `rr1`). The relative residual is less than the prescribed tolerance of `1e-12` at the third iteration (the value of `it1`) when preconditioned by the incomplete LU factorization with a drop tolerance of `1e-6`. The output `rv1(1)` is `norm(b)` and the output `rv1(7)` is `norm(b-A*x2)` since `bicgstab` uses half iterations.

You can follow the progress of `bicgstab` by plotting the relative residuals at each iteration starting from the initial estimate (iterate number 0).

```
semilogy(0:0.5:it1,rv1/norm(b),'-o');
xlabel('Iteration Number');
ylabel('Relative Residual');
```

# bicgstabl

Biconjugate gradients stabilized (l) method

## Syntax

```
x = bicgstabl(A,b)
x = bicgstabl(afun,b)
x = bicgstabl(A,b,tol)
x = bicgstabl(A,b,tol,maxit)
x = bicgstabl(A,b,tol,maxit,M)
x = bicgstabl(A,b,tol,maxit,M1,M2)
x = bicgstabl(A,b,tol,maxit,M1,M2,x0)
[x,flag] = bicgstabl(A,b,...)
[x,flag,relres] = bicgstabl(A,b,...)
[x,flag,relres,iter] = bicgstabl(A,b,...)
[x,flag,relres,iter,resvec] = bicgstabl(A,b,...)
```

## Description

`x = bicgstabl(A,b)` attempts to solve the system of linear equations  $A*x=b$  for  $x$ . The  $n$ -by- $n$  coefficient matrix  $A$  must be square and the right-hand side column vector  $b$  must have length  $n$ .

`x = bicgstabl(afun,b)` accepts a function handle `afun` instead of the matrix  $A$ . `afun(x)` accepts a vector input  $x$  and returns the matrix-vector product  $A*x$ . In all of the following syntaxes, you can replace  $A$  by `afun`.

`x = bicgstabl(A,b,tol)` specifies the tolerance of the method. If `tol` is `[]` then `bicgstabl` uses the default,  $1e-6$ .

`x = bicgstabl(A,b,tol,maxit)` specifies the maximum number of iterations. If `maxit` is `[]` then `bicgstabl` uses the default,  $\min(N,20)$ .

`x = bicgstabl(A,b,tol,maxit,M)` and `x = bicgstabl(A,b,tol,maxit,M1,M2)` use preconditioner  $M$  or  $M=M1*M2$  and effectively solve the system  $A*inv(M)*x = b$  for

x. If M is [] then a preconditioner is not applied. M may be a function handle returning  $M \setminus x$ .

`x = bicgstabl(A,b,tol,maxit,M1,M2,x0)` specifies the initial guess. If x0 is [] then `bicgstabl` uses the default, an all zero vector.

`[x,flag] = bicgstabl(A,b,...)` also returns a convergence flag:

| Flag | Convergence                                                                                                                |
|------|----------------------------------------------------------------------------------------------------------------------------|
| 0    | <code>bicgstabl</code> converged to the desired tolerance <code>tol</code> within <code>maxit</code> iterations.           |
| 1    | <code>bicgstabl</code> iterated <code>maxit</code> times but did not converge.                                             |
| 2    | Preconditioner M was ill-conditioned.                                                                                      |
| 3    | <code>bicgstabl</code> stagnated. (Two consecutive iterates were the same.)                                                |
| 4    | One of the scalar quantities calculated during <code>bicgstabl</code> became too small or too large to continue computing. |

`[x,flag,relres] = bicgstabl(A,b,...)` also returns the relative residual  $\text{norm}(b-A*x)/\text{norm}(b)$ . If flag is 0,  $\text{relres} \leq \text{tol}$ .

`[x,flag,relres,iter] = bicgstabl(A,b,...)` also returns the iteration number at which x was computed, where  $0 \leq \text{iter} \leq \text{maxit}$ . `iter` can be  $k/4$  where k is some integer, indicating convergence at a given quarter iteration.

`[x,flag,relres,iter,resvec] = bicgstabl(A,b,...)` also returns a vector of the residual norms at each quarter iteration, including  $\text{norm}(b-A*x_0)$ .

## Examples

### Using `bicgstabl` with Inputs or with a Function

You can pass inputs directly to `bicgstabl`:

```
n = 21;
A = gallery('wilk',n);
b = sum(A,2);
```

```

tol = 1e-12;
maxit = 15;
M = diag([10:-1:1 1 1:10]);
x = bicgstbl(A,b,tol,maxit,M);

```

You can also use a matrix-vector product function:

```

function y = afun(x,n)
y = [0; x(1:n-1)] + [((n-1)/2:-1:0)';
(1:(n-1)/2)'] .*x+[x(2:n); 0];

```

and a preconditioner backsolve function:

```

function y = mfun(r,n)
y = r ./ [((n-1)/2:-1:1)';
1;
(1:(n-1)/2)'];

```

as inputs to `bicgstbl`:

```

x1 = bicgstbl(@(x)afun(x,n),b,tol,maxit,@(x)mfun(x,n));

```

## Using `bicgstbl` with a Preconditioner

This example demonstrates the use of a preconditioner.

Load `west0479`, a real 479-by-479 nonsymmetric sparse matrix.

```

load west0479;
A = west0479;

```

Define `b` so that the true solution is a vector of all ones.

```

b = full(sum(A,2));

```

Set the tolerance and maximum number of iterations.

```

tol = 1e-12;
maxit = 20;

```

Use `bicgstbl` to find a solution at the requested tolerance and number of iterations.

```

[x0,f10,rr0,it0,rv0] = bicgstbl(A,b,tol,maxit);

```

`f10` is 1 because `bicgstabl` does not converge to the requested tolerance  $1e-12$  within the requested 20 iterations. In fact, the behavior of `bicgstabl` is so poor that the initial guess (`x0 = zeros(size(A,2),1)`) is the best solution and is returned as indicated by `it0 = 0`. MATLAB® stores the residual history in `rv0`.

Plot the behavior of `bicgstabl`.

```
semilogy(0:0.25:maxit,rv0/norm(b),'-o');
xlabel('Iteration number');
ylabel('Relative residual');
```

The plot shows that the solution does not converge. You can use a preconditioner to improve the outcome.

Create a preconditioner with `ilu`, since `A` is nonsymmetric.

```
[L,U] = ilu(A,struct('type','ilutp','droptol',1e-5));
```

Error using `ilu`

There is a pivot equal to zero. Consider decreasing the drop tolerance or consider using the `'udiag'` option.

MATLAB cannot construct the incomplete LU as it would result in a singular factor, which is useless as a preconditioner.

You can try again with a reduced drop tolerance, as indicated by the error message.

```
[L,U] = ilu(A,struct('type','ilutp','droptol',1e-6));
[x1,f11,rr1,it1,rv1] = bicgstabl(A,b,tol,maxit,L,U);
```

`f11` is 0 because `bicgstabl` drives the relative residual to  $1.0257e-015$  (the value of `rr1`). The relative residual is less than the prescribed tolerance of  $1e-12$  at the sixth iteration (the value of `it1`) when preconditioned by the incomplete LU factorization with a drop tolerance of  $1e-6$ . The output `rv1(1)` is `norm(b)`, and the output `rv1(9)` is `norm(b-A*x2)` since `bicgstabl` uses quarter iterations.

You can follow the progress of `bicgstabl` by plotting the relative residuals at each iteration starting from the initial estimate (iterate number 0).

```
semilogy(0:0.25:it1,rv1/norm(b),'-o');
```

```
h = gca;
h.XTick = 0:0.25:it1;
```

```
xlabel('Iteration number');
ylabel('Relative residual');
```

# bin2dec

Convert binary number string to decimal number

## Syntax

```
bin2dec(binarystr)
```

## Description

`bin2dec(binarystr)` interprets the binary string *binarystr* and returns the equivalent decimal number. *binarystr* must represent a nonnegative integer value smaller than or equal to  $2^{52}$ .

`bin2dec` ignores any space (' ') characters in the input string.

## Examples

Binary 010111 converts to decimal 23:

```
bin2dec('010111')
ans =
 23
```

Because space characters are ignored, this string yields the same result:

```
bin2dec(' 010 111 ')
ans =
 23
```

## See Also

`dec2bin`

## binary

**Class:** FTP

Set FTP transfer type to binary

## Syntax

```
binary(ftpobj)
```

## Description

`binary(ftpobj)` sets the FTP download and upload mode to binary, which does not convert new line characters. Binary mode is the default for FTP objects. If you previously called the `ascii` method, use this method before transferring a nontext file, such as an executable or ZIP archive.

## Input Arguments

**ftpobj**

FTP object created by `ftp`.

## Examples

Connect to the National Geophysical Data Center (NGDC) FTP server, and set the transfer mode to binary:

```
ngdc = ftp('ftp.ngdc.noaa.gov');
binary(ngdc)
```

FTP service courtesy of the NGDC. See NGDC Privacy Policy, Disclaimer, and Copyright for NGDC terms of service.

## bitand

Bit-wise AND

### Syntax

```
intout = bitand(integ1,integ2)
intout = bitand(integ1,integ2,assumedtype)

objout = bitand(netobj1,netobj2)
```

### Description

`intout = bitand(integ1,integ2)` returns the bit-wise AND of values `integ1` and `integ2`.

`intout = bitand(integ1,integ2,assumedtype)` assumes that `integ1` and `integ2` are of `assumedtype`.

`objout = bitand(netobj1,netobj2)` returns the bit-wise AND of the .NET enumeration objects `netobj1` and `netobj2`.

### Examples

#### Truth Table

Create a truth table for the logical AND operation.

```
A = uint8([0 1; 0 1]);
B = uint8([0 0; 1 1]);
TTable = bitand(A, B)
```

```
TTable =
```

```
 0 0
 0 1
```

bitand returns 1 only if both bit-wise inputs are 1.

### Negative Values

Explore how bitand handles negative values

MATLAB encodes signed integers using two's complement. Thus, the bit-wise AND of  $-5$  (11111011) and 6 (00000110) is 2 (00000010).

```
C = -5;
D = 6;
bitand(C,D, 'int8')
```

```
ans =
```

```
2
```

- “Creating .NET Enumeration Bit Flags”

## Input Arguments

### integ1, integ2 — Input values

signed integer arrays | unsigned integer arrays | double arrays

Input values, specified as signed integer arrays, unsigned integer arrays, or double arrays. `integ1` and `integ2` must be the same data type, or one must be a scalar double value.

- If `integ1` and `integ2` are double arrays, and `assumedtype` is not specified, then MATLAB treats `integ1` and `integ2` as unsigned 64-bit integers.
- If `assumedtype` is specified, then all elements in `integ1` and `integ2` must have integer values within the range of `assumedtype`.

Data Types: double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

### assumedtype — Assumed data type of integ1 and integ2

'uint64' | 'uint32' | 'uint16' | 'uint8' | 'int64' | 'int32' | 'int16' | 'int8'

Assumed data type of `integ1` and `integ2`, specified as 'uint64', 'uint32', 'uint16', 'uint8', 'int64', 'int32', 'int16', or 'int8'.

- If `integ1` and `integ2` are double arrays, then `assumedtype` can specify any valid integer type, but defaults to `'uint64'`.
- If `integ1` and `integ2` are integer type arrays, then `assumedtype` must specify that same integer type.

Data Types: char

### **netobj1, netobj2 — Input values**

.NET enumeration objects

Input values, specified as .NET enumeration objects. You must be running a version of Windows to use .NET enumeration objects as input arguments.

`bitand` is an instance method for MATLAB enumeration objects created from a .NET enumeration.

## Output Arguments

### **intout — Bit-wise AND result**

signed integer array | unsigned integer array | double array

Bit-wise AND result, returned as a signed integer array, unsigned integer array, or double array. `intout` is the same data type and size as `integ1` and `integ2`.

- If either `integ1` or `integ2` is a scalar double, and the other is a non-double integer type, `intout` is the non-double integer type.

### **objout — Bit-wise AND result**

.NET enumeration object

Bit-wise AND result, returned as a .NET enumeration objects.

## See Also

**Introduced before R2006a**

# bitcmp

Bit-wise complement

## Syntax

```
cmp = bitcmp(A)
cmp = bitcmp(A,assumedtype)
```

## Description

`cmp = bitcmp(A)` returns the bit-wise complement of `A`.

`cmp = bitcmp(A,assumedtype)` assumes that `A` is of `assumedtype`.

## Examples

### Complement of a Negative Integer

```
A = int8(-11);
cmp = bitcmp(A)
```

```
cmp =
 10
```

You can see the complement operation when the numbers are shown in binary.

```
original = bitget(A,8:-1:1)
complement = bitget(bitcmp(A),8:-1:1)
```

```
original =
 1 1 1 1 0 1 0 1
```

```
complement =
```

```
0 0 0 0 1 0 1 0
```

## Complement of Unsigned Integers

```
cmp = bitcmp(64,'uint8')
maxint = intmax('uint8') - 64
```

```
cmp =
 191
```

```
maxint =
 191
```

The complement of an unsigned integer is equal to itself subtracted from the maximum integer of its data type.

## Input Arguments

### A — Input value

signed integer array | unsigned integer array | double array

Input value, specified as a signed integer array, unsigned integer array, or double array.

- If **A** is a double array, and **assumedtype** is not specified, then MATLAB treats **A** as an unsigned 64-bit integer.
- If **assumedtype** is specified, then all elements in **A** must have integer values within the range of **assumedtype**.

Data Types: double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

### assumedtype — Assumed data type of A

```
'uint64' | 'uint32' | 'uint16' | 'uint8' | 'int64' | 'int32' | 'int16' | 'int8'
```

Assumed data type of **A**, specified as 'uint64', 'uint32', 'uint16', 'uint8', 'int64', 'int32', 'int16', or 'int8'.

- If `A` is a double array, then `assumedtype` can specify any valid integer type, but defaults to `'uint64'`.
- If `A` is an integer type array, then `assumedtype` must specify that same integer type.

Data Types: char

## Output Arguments

### **cmp** — Bit-wise complement

signed integer array | unsigned integer array | double array

Bit-wise complement, returned as a signed integer array, unsigned integer array, or double array. `cmp` is the same size and type as `A`.

### **See Also**

`bitand` | `bitget` | `bitor` | `bitset` | `bitshift` | `bitxor` | `intmax`

**Introduced before R2006a**

## bitget

Get bit at specified position

### Syntax

```
b = bitget(A,bit)
b = bitget(A,bit,assumedtype)
```

### Description

`b = bitget(A,bit)` returns the bit value at position `bit` in integer array `A`.

`b = bitget(A,bit,assumedtype)` assumes that `A` is of `assumedtype`.

### Examples

#### Maximum Integer

Find the difference in the binary representation between the maximum integer of signed and unsigned integers.

```
a1 = intmax('int8');
a2 = intmax('uint8');
b1 = bitget(a1,8:-1:1)
b2 = bitget(a2,8:-1:1)
```

b1 =

```
0 1 1 1 1 1 1 1
```

b2 =

```
1 1 1 1 1 1 1 1
```

The signed integers require a bit to accommodate negative integers.

### Negative Numbers Using Two's Complement

Find the 8-bit representation of a negative number.

```
A = -29;
b = bitget(A,8:-1:1,'int8')
```

b =

```
 1 1 1 0 0 0 1 1
```

## Input Arguments

### A — Input values

array

Input values, specified as an array. A can be a scalar or an array of the same size as `bit`.

- If A is a double array, and `assumedtype` is not specified, then MATLAB treats A as an unsigned 64-bit integer.
- If `assumedtype` is specified, then all elements in A must have integer values within the range of `assumedtype`.

Data Types: double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

### bit — Bit position

integer | integer array

Bit position, specified as an integer or integer array. `bit` can be a scalar or an array of the same size as A. `bit` must be between 1 (the least-significant bit) and the number of bits in the integer class of A.

Data Types: double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

### assumedtype — Assumed data type of A

'uint64' | 'uint32' | 'uint16' | 'uint8' | 'int64' | 'int32' | 'int16' | 'int8'

Assumed data type of `A`, specified as `'uint64'`, `'uint32'`, `'uint16'`, `'uint8'`, `'int64'`, `'int32'`, `'int16'`, or `'int8'`.

- If `A` is a double array, then `assumedtype` can specify any valid integer type, but defaults to `'uint64'`.
- If `A` is an integer type array, then `assumedtype` must specify that same integer type.

Data Types: `char`

## Output Arguments

### **b** — Bit value at `bit`

array

Bit value at `bit`, returned as an array of 0s and 1s. `b` is the same data type as `A`.

- If `A` and `bit` are scalars, then `b` is also a scalar.
- If either `A` or `bit` is an array, then `b` is the same size as that array.

### See Also

`bitand` | `bitcmp` | `bitor` | `bitset` | `bitshift` | `bitxor` | `intmax`

Introduced before R2006a

# bitmax

Maximum double-precision floating-point integer

## Compatibility

bitmax has been removed. Use `flintmax` instead.

## Syntax

```
bitmax
```

## Description

bitmax returns the maximum unsigned double-precision floating-point integer for your computer. It is the value when all bits are set, namely the value  $2^{53} - 1$ .

---

**Note** Instead of integer-valued double-precision variables, use unsigned integers for bit manipulations and replace `bitmax` with `intmax`.

---

## Examples

Display in different formats the largest floating point integer and the largest 32 bit unsigned integer:

```
format long e
bitmax
ans =
 9.007199254740991e+015
```

```
intmax('uint32')
ans =
 4294967295
```

```
format hex
bitmax
ans =
 433fffffffffffffff

intmax('uint32')
ans =
 ffffffff
```

In the second `bitmax` statement, the last 13 hex digits of `bitmax` are `f`, corresponding to 52 1's (all 1's) in the mantissa of the binary representation. The first 3 hex digits correspond to the sign bit 0 and the 11 bit biased exponent 10000110011 in binary (1075 in decimal), and the actual exponent is  $(1075 - 1023) = 52$ . Thus the binary value of `bitmax` is  $1.111\dots111 \times 2^{52}$  with 52 trailing 1's, or  $2^{53} - 1$ .

# bitnot

.NET enumeration object bit-wise NOT instance method

## Syntax

```
objout = bitnot(netobj)
```

## Description

`objout = bitnot(netobj)` reverses all bits of the .NET enumeration objects `netobj`.

## Examples

- “Creating .NET Enumeration Bit Flags”

## Input Arguments

**netobj** — Input value

.NET enumeration objects

Input value, specified as .NET enumeration object. You must be running a version of Windows to use .NET enumeration objects as input arguments.

## Output Arguments

**objout** — Bit-wise NOT result

.NET enumeration object

Bit-wise NOT result, returned as a .NET enumeration object.

## Limitations

- The method is an instance method for MATLAB enumeration objects created from a .NET enumeration. This method does not have an equivalent MATLAB function.

**See Also**

bitand | bitor | bitxor

**Introduced in R2011a**

# bitor

Bit-wise OR

## Syntax

```
intout = bitor(integ1,integ2)
intout = bitor(integ1,integ2,assumedtype)

objout = bitor(netobj1,netobj2)
```

## Description

`intout = bitor(integ1,integ2)` returns the bit-wise OR of `integ1` and `integ2`.

`intout = bitor(integ1,integ2,assumedtype)` assumes that `integ1` and `integ2` are of `assumedtype`.

`objout = bitor(netobj1,netobj2)` returns the bit-wise OR of the .NET enumeration objects `netobj1` and `netobj2`.

## Examples

### Truth Table

Create a truth table for the logical OR operation.

```
A = uint8([0 1; 0 1]);
B = uint8([0 0; 1 1]);
TTable = bitor(A, B)
```

TTable =

|   |   |
|---|---|
| 0 | 1 |
| 1 | 1 |

`bitor` returns 1 if either bit-wise input is 1.

## Negative Values

Explore how `bitor` handles negative values.

MATLAB encodes negative integers using two's complement. Thus, the bit-wise OR of -5 (11111010) and 6 (00000110) is -1 (11111110).

```
C = -5;
D = 6;
bitor(C,D, 'int8')
```

```
ans =
```

```
-1
```

- “Creating .NET Enumeration Bit Flags”

## Input Arguments

### `integ1`, `integ2` — Input values

signed integer arrays | unsigned integer arrays | double arrays

Input values, specified as signed integer arrays, unsigned integer arrays, or double arrays. `integ1` and `integ2` must be the same data type, or one must be a scalar double value.

- If `integ1` and `integ2` are double arrays, and `assumedtype` is not specified, then MATLAB treats `integ1` and `integ2` as unsigned 64-bit integers.
- If `assumedtype` is specified, then all elements in `integ1` and `integ2` must have integer values within the range of `assumedtype`.

Data Types: `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### `assumedtype` — Assumed data type of `integ1` and `integ2`

'uint64' | 'uint32' | 'uint16' | 'uint8' | 'int64' | 'int32' | 'int16' | 'int8'

Assumed data type of `integ1` and `integ2`, specified as 'uint64', 'uint32', 'uint16', 'uint8', 'int64', 'int32', 'int16', or 'int8'.

- If `integ1` and `integ2` are double arrays, then `assumedtype` can specify any valid integer type, but defaults to `'uint64'`.
- If `integ1` and `integ2` are integer type arrays, then `assumedtype` must specify that same integer type.

Data Types: char

### **netobj1, netobj2 — Input values**

.NET enumeration objects

Input values, specified as .NET enumeration objects. You must be running a version of Windows to use .NET enumeration objects as input arguments.

`bitor` is an instance method for MATLAB enumeration objects created from a .NET enumeration.

## **Output Arguments**

### **intout — Bit-wise OR result**

signed integer array | unsigned integer array | double array

Bit-wise OR result, returned as a signed integer array, unsigned integer array, or double array. `intout` is the same data type and size as `integ1` and `integ2`.

- If either `integ1` or `integ2` is a scalar double, and the other is a non-double integer type, `intout` is the non-double integer type.

### **objout — Bit-wise OR result**

.NET enumeration object

Bit-wise OR result, returned as a .NET enumeration objects.

## **See Also**

`bitand` | `bitcmp` | `bitget` | `bitnot` | `bitset` | `bitshift` | `bitxor` | `intmax`

**Introduced before R2006a**

## bitset

Set bit at specific location

### Syntax

```
intout = bitset(A,bit)
intout = bitset(A,bit,assumedtype)

intout = bitset(A,bit,V)
intout = bitset(A,bit,V,assumedtype)
```

### Description

`intout = bitset(A,bit)` returns the value of `A` with position `bit` set to 1 (on).

`intout = bitset(A,bit,assumedtype)` assumes `A` is of type `assumedtype`.

`intout = bitset(A,bit,V)` returns `A` with position `bit` set to the value of `V`.

- If `V` is zero, then the bit position `bit` is set to 0 (off).
- If `V` is nonzero, then the bit position `bit` is set to 1 (on).

`intout = bitset(A,bit,V,assumedtype)` assumes `A` is of type `assumedtype`.

### Examples

#### Set Bits to On

Add powers of 2 onto a number.

```
A = 4;
intout = bitset(A,4:6)
```

```
intout =
```

```
 12 20 36
```

You can see that `bitset` sequentially turns on bits 4 through 6.

```
c = dec2bin(intout)
c =
001100
010100
100100
```

### Out of Range of Integer Type

MATLAB throws an error if you specify an integer outside the range of `assumedtype`.

```
intout = bitset(300,5,'int8')
```

```
Error using bitset
Double inputs must have integer values in the range of ASSUMEDTYPE.
```

You can avoid this error by limiting your input to the range of the specified datatype.

### Set Bits to Off

Repeatedly subtract powers of 2 from a number.

```
a = intmax('uint8')
for k = 0:7
 a = bitset(a, 8-k, 0);
 b(1,k+1) = a;
end
b
a =
255
b =
127 63 31 15 7 3 1 0
```

### Set Multiple Bits

Set multiple bits to different values

```
bits = 2:6;
```

```
val = [1 0 0 1 1];
intout = bitset(0,bits,val,'int8')

intout =

 2 0 0 16 32
```

## Input Arguments

### **A** — Input values

array

Input values, specified as an array. **A**, **bit**, and **V** can each be scalars or arrays of the same size.

- If **A** is a double array, and **assumedtype** is not specified, then MATLAB treats **A** as an unsigned 64-bit integer.
- If **assumedtype** is specified, then all elements in **A** must have integer values within the range of **assumedtype**.

Data Types: double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

### **bit** — Bit position

integer | integer array

Bit position, specified as an integer or integer array. **A**, **bit**, and **V** can each be scalars or arrays of the same size. The values of **bit** must be between 1 (the least significant bit) and the number of bits in the integer class of **A**.

Data Types: double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

### **assumedtype** — Assumed data type of **A**

'uint64' | 'uint32' | 'uint16' | 'uint8' | 'int64' | 'int32' | 'int16' | 'int8'

Assumed data type of **A**, specified as 'uint64', 'uint32', 'uint16', 'uint8', 'int64', 'int32', 'int16', or 'int8'.

- If **A** is a double array, then **assumedtype** can specify any valid integer type, but defaults to 'uint64'.

- If `A` is an integer type array, then `assumedtype` must specify that same integer type.

Data Types: `char`

### **V — bit value**

scalar | numeric array

Bit value, specified as a scalar or a numeric array. `A`, `bit`, and `V` can each be scalars or arrays of the same size.

Data Types: `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

## Output Arguments

### **intout — Adjusted integers**

array

Adjusted integers, returned as an array. `intout` is the same data type as `A`.

- If `A`, `bit`, and `V` are all scalars, then `intout` is also a scalar.
- If any of `A`, `bit`, or `V` is an array, then `intout` is the same size as that array.

### **See Also**

`bitand` | `bitcmp` | `bitget` | `bitor` | `bitshift` | `bitxor` | `intmax`

**Introduced before R2006a**

## bitshift

Shift bits specified number of places

### Syntax

```
intout = bitshift(A,k)
intout = bitshift(A,k,assumedtype)
```

### Description

`intout = bitshift(A,k)` returns `A` shifted to the left by `k` bits, equivalent to multiplying by  $2^k$ . Negative values of `k` correspond to shifting bits right or dividing by  $2^{|k|}$  and rounding to the nearest integer towards negative infinity. Any overflow bits are truncated.

- If `A` is an array of signed integers, then `bitshift` returns the arithmetic shift results, preserving the signed bit when `k` is negative, and not preserving the signed bit when `k` is positive.
- If `k` is positive, MATLAB shifts the bits to the left and inserts `k` 0-bits on the right.
- If `k` is negative and `A` is nonnegative, then MATLAB shifts the bits to the right and inserts  $|k|$  0-bits on the left.
- If `k` is negative and `A` is negative, then MATLAB shifts the bits to the right and inserts  $|k|$  1-bits on the left.

`intout = bitshift(A,k,assumedtype)` assumes `A` is of type `assumedtype`.

### Examples

#### Shifted 8-bit Integer

Repeatedly shift the bits of an unsigned 8-bit value to the left until all the nonzero bits overflow.

```
a = intmax('uint8');
```

```

s1 = 'Initial uint8 value %5d is %08s in binary\n';
s2 = 'Shifted uint8 value %5d is %08s in binary\n';
fprintf(s1,a,dec2bin(a))
for i = 1:8
 a = bitshift(a,1);
 fprintf(s2,a,dec2bin(a))
end

```

```

Initial uint8 value 255 is 11111111 in binary
Shifted uint8 value 254 is 11111110 in binary
Shifted uint8 value 252 is 11111100 in binary
Shifted uint8 value 248 is 11111000 in binary
Shifted uint8 value 240 is 11110000 in binary
Shifted uint8 value 224 is 11100000 in binary
Shifted uint8 value 192 is 11000000 in binary
Shifted uint8 value 128 is 10000000 in binary
Shifted uint8 value 0 is 00000000 in binary

```

### Different Results for Different Integer Types

Find the shift for a number using different assumed integer types.

```

uintout = bitshift(6,5:7,'uint8')
intout = bitshift(6,5:7,'int8')

```

```
uintout =
```

```
 192 128 0
```

```
intout =
```

```
 -64 -128 0
```

## Input Arguments

### A — Input values

array

Input values, specified as an array. A can be a scalar or an array of the same size as k.

- If A is a double array, and `assumedtype` is not specified, then MATLAB treats A as an unsigned 64-bit integer.

- If `assumedtype` is specified, then all elements in `A` must have integer values within the range of `assumedtype`.

Data Types: `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **k** — Number of switched bits

`integer` | `integer array`

Number of switched bits, specified as an integer or integer array. `k` can be a scalar or an array of the same size as `A`.

Data Types: `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **assumedtype** — Assumed data type of `A`

`'uint64'` | `'uint32'` | `'uint16'` | `'uint8'` | `'int64'` | `'int32'` | `'int16'` | `'int8'`

Assumed data type of `A`, specified as `'uint64'`, `'uint32'`, `'uint16'`, `'uint8'`, `'int64'`, `'int32'`, `'int16'`, or `'int8'`.

- If `A` is an integer type array, then `assumedtype` must specify that same integer type.
- If `A` is a double array, then `assumedtype` can specify any valid integer type.

Data Types: `char`

## Output Arguments

### **intout** — Shifted values

`array`

Shifted values, returned as an array. `intout` is the same data type as `A`.

- If `A` and `k` are scalars, then `intout` is also a scalar.
- If either `A` or `k` is an array, then `intout` is the same size as that array.

### See Also

`bitand` | `bitcmp` | `bitget` | `bitor` | `bitset` | `bitxor` | `intmax`

**Introduced before R2006a**

## bitxor

Bit-wise XOR

### Syntax

```
intout = bitxor(integ1,integ2)
intout = bitxor(integ1,integ2,assumedtype)

objout = bitxor(netobj1,netobj2)
```

### Description

`intout = bitxor(integ1,integ2)` returns the bit-wise XOR of `integ1` and `integ2`.

`intout = bitxor(integ1,integ2,assumedtype)` assumes that `integ1` and `integ2` are of `assumedtype`.

`objout = bitxor(netobj1,netobj2)` returns the bit-wise XOR of the .NET enumeration objects `netobj1` and `netobj2`.

### Examples

#### Truth Table

Create a truth table for the logical XOR operation.

```
A = uint8([0 1; 0 1]);
B = uint8([0 0; 1 1]);
TTable = bitxor(A, B)
```

```
TTable =
```

```
 0 1
 1 0
```

bitxor returns 0 if both bit-wise inputs are equal.

## Negative Values

Explore how bitxor handles negative values.

MATLAB encodes negative integers using two's complement. Thus, the bit-wise XOR of -5 (11111010) and 6 (00000110) is -3 (11111100).

```
C = -5;
D = 6;
bitxor(C,D, 'int8')
```

```
ans =
```

```
-3
```

- “Creating .NET Enumeration Bit Flags”

## Input Arguments

### integ1, integ2 — Input values

signed integer arrays | unsigned integer arrays | double arrays

Input values, specified as signed integer arrays, unsigned integer arrays, or double arrays. `integ1` and `integ2` must be the same data type, or one must be a scalar double value.

- If `integ1` and `integ2` are double arrays, and `assumedtype` is not specified, then MATLAB treats `integ1` and `integ2` as unsigned 64-bit integers.
- If `assumedtype` is specified, then all elements in `integ1` and `integ2` must have integer values within the range of `assumedtype`.

Data Types: double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

### assumedtype — Assumed data type of integ1 and integ2

'uint64' | 'uint32' | 'uint16' | 'uint8' | 'int64' | 'int32' | 'int16' | 'int8'

Assumed data type of `integ1` and `integ2`, specified as 'uint64', 'uint32', 'uint16', 'uint8', 'int64', 'int32', 'int16', or 'int8'.

- If `integ1` and `integ2` are double arrays, then `assumedtype` can specify any valid integer type, but defaults to `'uint64'`.
- If `integ1` and `integ2` are integer type arrays, then `assumedtype` must specify that same integer type.

Data Types: char

### **netobj1, netobj2 — Input values**

.NET enumeration objects

Input values, specified as .NET enumeration objects. You must be running a version of Windows to use .NET enumeration objects as input arguments.

`bitxor` is an instance method for MATLAB enumeration objects created from a .NET enumeration.

## Output Arguments

### **intout — Bit-wise XOR result**

signed integer array | unsigned integer array | double array

Bit-wise XOR result, returned as a signed integer array, unsigned integer array, or double array. `intout` is the same data type and size as `integ1` and `integ2`.

- If either `integ1` or `integ2` is a scalar double, and the other is a non-double integer type, `intout` is the non-double integer type.

### **objout — Bit-wise XOR result**

.NET enumeration object

Bit-wise XOR result, returned as a .NET enumeration objects.

# blanks

Create character array of blanks

## Syntax

```
blanks(n)
```

## Description

`blanks(n)` returns an array of `n` space characters.

## Examples

`blanks` is useful with the `display` function. For example,

```
disp(['xxx' blanks(20) 'yyy'])
```

displays twenty spaces between the character arrays `'xxx'` and `'yyy'`.

```
disp(blanks(n) ')
```

 moves the cursor down `n` lines.

**Introduced before R2006a**

## blkdiag

Construct block diagonal matrix from input arguments

### Syntax

```
out = blkdiag(a,b,c,d,...)
```

### Description

`out = blkdiag(a,b,c,d,...)`, where `a`, `b`, `c`, `d`, ... are matrices, outputs a block diagonal matrix of the form

$$\begin{bmatrix} a & 0 & 0 & 0 & 0 \\ 0 & b & 0 & 0 & 0 \\ 0 & 0 & c & 0 & 0 \\ 0 & 0 & 0 & d & 0 \\ 0 & 0 & 0 & 0 & \dots \end{bmatrix}$$

The input matrices do not have to be square, nor do they have to be of equal size.

# boundary

Boundary of a set of points in 2-D or 3-D

## Syntax

```
k = boundary(x,y)
k = boundary(x,y,z)
k = boundary(P)
k = boundary(____,s)
[k,v] = boundary(____)
```

## Description

`k = boundary(x,y)` returns a vector of point indices representing a single conforming 2-D boundary around the points  $(x,y)$ . The points  $(x(k),y(k))$  form the boundary. Unlike the convex hull, the boundary can shrink towards the interior of the hull to envelop the points.

`k = boundary(x,y,z)` returns a triangulation representing a single conforming 3-D boundary around the points  $(x,y,z)$ . Each row of `k` is a triangle defined in terms of the point indices.

`k = boundary(P)` specifies points  $(x,y)$  or  $(x,y,z)$  in the columns of matrix `P`.

`k = boundary( ____,s)` specifies shrink factor `s` using any of the previous syntaxes. `s` is a scalar between 0 and 1. Setting `s` to 0 gives the convex hull, and setting `s` to 1 gives a compact boundary that envelops the points. The default shrink factor is 0.5.

`[k,v] = boundary( ____ )` also returns a scalar `v`, which is the area (2-D) or volume (3-D) which boundary `k` encloses.

## Examples

### Boundary of 2-D Point Cloud

Create and plot a set of random 2-D points.

```
x = gallery('uniformdata',30,1,1);
y = gallery('uniformdata',30,1,10);
plot(x,y, '.')
xlim([-0.2 1.2])
ylim([-0.2 1.2])
```

Compute a boundary around the points using the default shrink factor.

```
k = boundary(x,y);
hold on;
plot(x(k),y(k));
```

Create a new boundary around the points using a shrink factor of 0.1. The result is a less compact boundary enveloping the points.

```
j = boundary(x,y,0.1);
hold on;
plot(x(j),y(j));
```

### Boundary of 3-D Point Cloud

Create and plot a set of random 3-D points.

```
P = gallery('uniformdata',30,3,5);
plot3(P(:,1),P(:,2),P(:,3),'.','MarkerSize',10)
grid on
```

Plot the boundary using the default shrink factor.

```
k = boundary(P);
hold on
trisurf(k,P(:,1),P(:,2),P(:,3), 'Facecolor', 'red', 'FaceAlpha', 0.1)
```

### Shrink Factor Effect on 3-D Boundary

Create and plot a set of random 3-D points.

```
P = gallery('uniformdata',30,3,8);
plot3(P(:,1),P(:,2),P(:,3),'.')
grid on
```

Compute two boundaries: one with a shrink factor of 0 and the other with a shrink factor of 1.

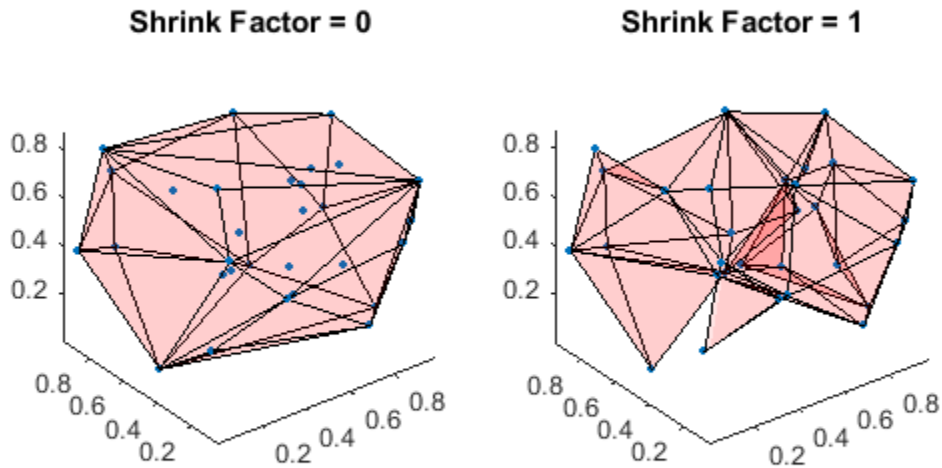

```
k = boundary(P,0);
j = boundary(P,1);
```

Compare the shrink factors by plotting the original points and the two boundaries side-by-side.

```
subplot(1,2,1);
plot3(P(:,1),P(:,2),P(:,3),'.','MarkerSize',10)
hold on
trisurf(k,P(:,1),P(:,2),P(:,3),'Facecolor','red','FaceAlpha',0.1)
axis equal
```

```
title('Shrink Factor = 0')

subplot(1,2,2);
plot3(P(:,1),P(:,2),P(:,3),'.','MarkerSize',10)
hold on
trisurf(j,P(:,1),P(:,2),P(:,3),'Facecolor','red','FaceAlpha',0.1)
axis equal
title('Shrink Factor = 1')
```

### Volume of 3-D Boundary

Create and plot a set of random 3-D points.

```
P = gallery('uniformdata',30,3,1);
```

```
plot3(P(:,1),P(:,2),P(:,3),'.')
grid on
```

Use the `boundary` function to compute a boundary around the points, and find the volume of the resulting shape.

```
[~, vol] = boundary(P);
vol
```

```
vol =
```

```
0.3012
```

## Input Arguments

### **x** — x-coordinates of points

column vector

x-coordinates of points, specified as a column vector.

Data Types: double

### **y** — y-coordinates of points

column vector

y-coordinates of points, specified as a column vector.

Data Types: double

### **z** — z-coordinates of points

column vector

z-coordinates of points, specified as a column vector.

Data Types: double

### **P** — Point coordinates

matrix with two columns | matrix with three columns

Point coordinates, specified as a matrix with two columns (for a 2-D alpha shape) or a matrix with three columns (for a 3-D alpha shape).

- For 2-D, the columns of **P** represent **x** and **y** coordinates, respectively.
- For 3-D, the columns of **P** represent **x**, **y**, and **z** coordinates, respectively.

Data Types: double

### **s** — Shrink factor

0.5 (default) | scalar in range [0, 1]

Shrink factor, specified as a scalar in the range of [0, 1].

- **s** = 0 corresponds to the convex hull of the points.

- $s = 1$  corresponds to the tightest single-region boundary around the points.

The default shrink factor is `0.5`. Specify a larger or smaller shrink factor to tighten or loosen the boundary around the points, respectively.

Example: `k = boundary(x, y, 0.76)` specifies a shrink factor of `0.76`, producing a tighter boundary than the default.

## Output Arguments

### **k** — Boundary point indices

vector | matrix

Boundary point indices, returned as a vector or matrix. `k` contains the indices of the input points that lie on the boundary.

- For 2-D problems, `k` is a column vector of point indices representing the sequence of points around the boundary, which is a polygon.
- For 3-D problems, `k` is a triangulation matrix of size `mtri-by-3`, where `mtri` is the number of triangular facets on the boundary. Each row of `k` defines a triangle in terms of the point indices, and the triangles collectively form a bounding polyhedron.

### **v** — Area or volume enclosed by boundary

scalar

Area or volume enclosed by boundary, returned as a scalar.

- For 2-D problems, `v` is the area enclosed by boundary `k`.
- For 3-D problems, `v` is the volume enclosed by boundary `k`.

## See Also

`alphaShape` | `convhull` | `delaunayTriangulation` | `triangulation` | `trisurf`

Introduced in R2014b

## box

Display axes outline

### Syntax

```
box on
box off
box
```

```
box(ax, ___)
```

### Description

`box on` displays the box outline around the current axes. This option sets the `Box` property of the current axes to `'on'`.

`box off` does not the display the box outline around the current axes. This option sets the `Box` property of the current axes to `'off'`.

`box` toggles the display of the box outline.

`box(ax, ___)` uses the axes specified by `ax` instead of the current axes (`gca`). Specify `ax` as a scalar axes object. You can specify an axes with any of the input arguments in the previous syntaxes. Use single quotes around input arguments that are character strings, for example, `box(ax, 'on')` and `box(ax, 'off')`.

### Examples

#### Display Box Outline Around Axes

Plot a surface and display the box outline around the axes.

```
[X,Y,Z] = peaks;
surf(X,Y,Z)
box on
```

Turn off the display of the box outline.

box `off`

### Change Style of Box Outline

First, plot a surface and display the box outline around the axes. By default, the outline appears around the back planes of the axes because the `BoxStyle` property of the axes is set to 'back'.

```
[X,Y,Z] = peaks;
surf(X,Y,Z)
box on
```

Next, display the outline around the entire axes by setting the `BoxStyle` property to `'full'`. Starting in R2014b, you can use dot notation to set properties. If you are using an earlier release, use the `set` function instead.

```
ax = gca;
ax.BoxStyle = 'full';
```

### Change Color of Box Outline

Create a scatter plot and display the box outline around the axes.

```
x = rand(10,1);
y = rand(10,1);
scatter(x,y)
box on
```

Change the color of the box outline in the  $x$ -axis direction by setting the `XColor` property of the axes. Starting in R2014b, you can use dot notation to set properties. If you are using an earlier release, use the `set` function instead.

```
ax = gca;
ax.XColor = 'red';
```

### Turn Off Box Outline for Specific Axes

Create a figure with two subplots and return the axes objects. Plot a line in each subplot. Turn off the display of the box outline around the axes for the lower subplot.

```
ax1 = subplot(2,1,1);
plot(1:10)

ax2 = subplot(2,1,2);
plot(1:10)
box(ax2, 'off')
```

## More About

### Tips

- Some axes properties affect the appearance of the box outline. This table lists a subset of axes properties related to the box outline.

| Axes Property | Description            |
|---------------|------------------------|
| Box           | Display of box outline |
| BoxStyle      | Style of box outline   |

| <b>Axes Property</b>   | <b>Description</b>                                                         |
|------------------------|----------------------------------------------------------------------------|
| XColor, YColor, ZColor | Color of box outline in the $x$ -axis, $y$ -axis, and $z$ -axis directions |
| LineWidth              | Width of box outline, tick marks, and grid lines                           |

# break

Terminate execution of for or while loop

## Syntax

```
break
```

## Description

`break` terminates the execution of a `for` or `while` loop. Statements in the loop after the `break` statement do not execute.

In nested loops, `break` exits only from the loop in which it occurs. Control passes to the statement that follows the end of that loop.

## Examples

### Exit Loop Before Expression Is False

Sum a sequence of random numbers until the next random number is greater than an upper limit. Then, exit the loop using a `break` statement.

```
limit = 0.8;
s = 0;

while 1
 tmp = rand;
 if tmp > limit
 break
 end
 s = s + tmp;
```

end

## More About

### Tips

- The `break` statement exits a `for` or `while` loop completely. To skip the rest of the instructions in the loop and begin the next iteration, use a `continue` statement.
- `break` is not defined outside a `for` or `while` loop. To exit a function, use `return`.

# brighten

Brighten or darken colormap

## Syntax

```
brighten(beta)
brighten(h,beta)
newmap = brighten(beta)
newmap = brighten(cmap,beta)
```

## Description

`brighten(beta)` increases or decreases the color intensities in a colormap by replacing the current colormap with a brighter or darker colormap of essentially the same colors. The modified colormap is brighter if  $0 < \text{beta} < 1$  and darker if  $-1 < \text{beta} < 0$ . `brighten(beta)`, followed by `brighten(-beta)`, where  $\text{beta} < 1$ , restores the original map.

`brighten(h,beta)` brightens all objects that are children of the figure having the handle `h`.

`newmap = brighten(beta)` returns a brighter or darker version of the current colormap without changing the display.

`newmap = brighten(cmap,beta)` returns a brighter or darker version of the colormap `cmap` without changing the display.

## Examples

### Brighten Colormap

Display a surface plot of membrane.

```
surf(membrane)
```

Brighten the colormap.

```
beta = .7;
brighten(beta)
```

## More About

### Algorithms

`brighten` raises values in the colormap to the power of gamma, where gamma is

$$\gamma = \begin{cases} 1 - \beta, & \beta > 0 \\ \frac{1}{1 + \beta}, & \beta \leq 0 \end{cases}$$

`brighten` has no effect on graphics objects defined with true color.

# brush

Interactively mark, delete, modify, and save observations in graphs

## Syntax

```
brush on
brush off
brush
brush color
brush(figure_handle,...)
brushobj = brush(figure_handle)
```

## Description

Data brushing is a mode for interacting with graphs in figure windows in which you can click data points or drag a selection rectangle around data points to highlight observations in a color of your choice. Highlighting takes different forms for different types of graphs, and brushing marks persist—even in other interactive modes—until removed by deselecting them.

`brush on` turns on interactive data brushing mode.

`brush off` turns brushing mode off, leaving any brushed observations still highlighted.

`brush` by itself toggles the state of the data brushing tool.

`brush color` sets the current color used for brushing graphics to the specified `ColorSpec`. Changing brush color affects subsequent brushing, but does not change the color of observations already brushed or the brush tool's state.

`brush(figure_handle, ...)` applies the function to the specified figure handle.

`brushobj = brush(figure_handle)` returns a *brush mode object* for that figure, useful for controlling and customizing the figure's brushing state. The following properties of such objects can be modified using `get` and `set`:

|              |                |                                                                             |
|--------------|----------------|-----------------------------------------------------------------------------|
| Enable       | 'on'   {'off'} | Specifies whether this figure mode is currently enabled on the figure.      |
| FigureHandle |                | The associated figure handle. This property supports <code>get</code> only. |
| Color        |                | Specifies the color to be used for brushing.                                |

`brush` cannot return a brush mode object at the same time you are calling it to set a brushing option.

## Examples

### Example 1

On a scatter plot, drag out a rectangle to brush the graph:

```
x = rand(20,1);
y = rand(20,1);
scatter(x,y,80,'s')
brush on
```

## Example 2

Brush observations from  $-.2$  to  $.2$  on a line plot in dark red:

```
x = [-2*pi:.1:2*pi];
y = sin(x);
plot(x,y);
h = brush;
set(h, 'Color', [.6 .2 .1], 'Enable', 'on');
```

## Types of Plots You Can Brush

Data brushing places lines and patches on plots to create highlighting, marking different types of graphs as follows (brushing marks are shown in red):

| Graph Type | Brushing Annotation                                                                                                                                                                                                             | Overlays? | Example                                                                               |
|------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------|---------------------------------------------------------------------------------------|
| line       | Colored lines slightly wider than those in the line with a marker distinct from those on the line (filled circles if none) to identify brushed vertices. Only those line segments that connect brushed vertices are highlighted | Y         |    |
| scatter    | Line with <code>LineStyle 'none'</code> and a marker with a color distinct from and slightly larger than the base scatter marker.                                                                                               | Y         |    |
| stem       | The brushed stems and stem heads are shaded in the brushing color.                                                                                                                                                              | Y         |   |
| bar        | The interior of selected bars is filled in the brushing color.                                                                                                                                                                  | N         |  |

| Graph Type | Brushing Annotation                                                                                                                                                                                                                                                                                                   | Overlays? | Example                                                                             |
|------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------|-------------------------------------------------------------------------------------|
| area       | Patches filling the region between selected points and the $x$ -axis in the brushing color.                                                                                                                                                                                                                           | N         |  |
| surface    | Faces with edges slightly wider than the surface line width and with a marker distinct from that of the surface ( <b>X</b> if none) to identify brushed vertices. Faces are plotted only when all four vertices that define them are brushed. The brushed observations are the set of marked vertices, not the faces. | N         |  |

When using the linked plots feature, a graph can become brushed when you brush another graph that displays some of the same data, potentially brushing the same observations more than once. The overlaid brushing marks (whether lines or markers) are slightly wider than the brushing marks that they overlay; this makes multiply brushed observations visually distinct. The wider brushing marks are placed under the narrower ones, so that if they happen to have different colors, you can see all the colors. See the subsection “How Data Linking Affects Data Brushing” on page 1-819 for more information about brushing linked figures.

As the above table indicates, only line, scatter, and stem brushing marks can be overlaid in this manner. Although you can brush them, you cannot overlay brushing marks on area, bar, or surface.

## Plot Types You Cannot Brush

Currently, not all plot types enable data brushing. Graph functions that *do not* support brushing are:

- Line plots created with `line`
- Scatter plots created with `spy`
- Contour plots created with `contour`, `contourf`, or `contour3`

- Pie charts created with `pie` or `pie3`
- Radial graphs created with `polar`, `compass`, or `rose`
- Direction graphs created with `feather`, `quiver`, or `comet`
- Area and image plots created with `fill`, `image`, `imagesc`, or `pcolor`
- Bar graphs created with `pareto` or `errorbar`
- Functional plots created with `ezcontour` or `ezcontourf`
- 3-D plot types *other than* `plot3`, `stem3`, `scatter3`, `mesh`, `meshc`, `surf`, `surf1`, and `surfc`

You can use some of these functions to display base data that do not need to be brushable. For example, use `line` to plot mean  $y$ -values as horizontal lines that you do not need or want to brush.

## Mode Exclusivity and Persistence

Data brushing mode is *exclusive*, like zoom, pan, data cursor, or plot edit mode. However, brush marks created in data brushing mode *persist* through all changes in mode. Brush marks that appear in other graphs while they are linked via `linkdata` also persist even when data linking is subsequently turned off. That is, severing connections to a graph's data sources does not remove brushing marks from it. The only ways to remove brushing marks are (in brushing mode):

- Brush an empty area in a brushed graph.
- Right-click and select **Clear all brushing** from the context menu.

Changing the brushing color for a figure does not recolor existing brush marks. If you change the brushing color and hold down the **Shift** key when brushing new data, all existing brush marks change to the new color. All brush marks that appear on linked plots in the same or different figure also change to the new color if the brushing action affects them. The behavior is the same whether you select a brushing color from the Brush Tool dropdown palette, set it by calling `brush(colorspec)`, or by setting the `Color` property of a brush mode object (e.g., `set(brushobj, 'Color', colorspec)`).

## How Data Linking Affects Data Brushing

When you use the Data Linking tool or call the `linkdata` function, brushing marks that you make on one plot appear on other plots that depict the same variable you are

brushing—if those plots are also linked. This happens even if the affected plot is not in Brushing mode. That is, brushing marks appear on a linked plot *in any mode* when you brush another plot linked to it via a common variable or brush that variable in the Variables editor. Be aware that the following conditions apply, however:

- The graph type must support data brushing (see “Types of Plots You Can Brush” on page 1-817 and “Plot Types You Cannot Brush” on page 1-818)
- The graphed variable must not be complex; if you can plot a complex variable you can brush it, but such graphs do not respond when you brush the complex variable in another linked plot. For more information about linking complex variables, see Example 3 in the `linkdata` reference page.
- Observations that you brush display in the same color in all linked graphs. The color is the brush color you have selected in the window you are interacting with, and can differ from the brushing colors selected in the other affected figures. When you brush linked plots, the brushing color is associated with the variable(s) you brush

The last bullet implies that brush marks on an unlinked graph can change color when data linking is turned on for that figure. Brushing marks can, in fact, vanish and be replaced by marks in the same or different color when the plot enters a linked state. In the linked state, brushing is tied to variables (data sources), not just the graphics. If different observations for the same variable on a linked figure are brushed, those variables override the brushed graphics on the newly linked plot. In other words, the newly linked graph loses all its previous brush marks when it “joins the club” of common data sources.

## Mouse Gestures for Data Brushing

You can brush graphs in several ways. The basic operation is to drag the mouse to highlight all observations within the rectangle you define. The following table lists data brushing gestures and their effects.

| Action                                 | Gesture        | Result                                                                                                                                                                                                                                                                                   |
|----------------------------------------|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Select data using a Region Of Interest | ROI mouse drag | Region of interest (ROI) rectangle (or rectangular prism for 3-D axes) appears during the gesture and all brushable observations within the rectangle are highlighted. All other brushing marks in the axes are removed. The ROI rectangle disappears when the mouse button is released. |

| Action                                                                              | Gesture                                                                                           | Result                                                                                                                                                                                                               |
|-------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Select a single point                                                               | Single left-click on a graphic object that supports data brushing                                 | Produces an equivalent result to ROI rectangle, brushing where the rectangle encloses only the single vertex on the graphical object closest to the mouse. All other brushing annotations in the figure are removed. |
| Add a point to the selection or remove a highlighted one                            | Single left-click on a graphic object that supports data brushing, with the <b>Shift</b> key down | Equivalent brushing by dragging an ROI rectangle that encloses only the single vertex on the graphic object closest to the mouse. All other brushed regions in the figure remain brushed.                            |
| Select all data associated with a graphic object                                    | Double left-click on a graphic object that supports data brushing                                 | All vertices for the graphic object are brushed.                                                                                                                                                                     |
| Add to or subtract from region of interest                                          | Click or ROI drag with the <b>Shift</b> or <b>Ctrl</b> keys down                                  | Region of interest grows; all unbrushed vertices within the rectangle become brushed and all brushed observations in it become unbrushed. All brushed vertices outside the ROI remain brushed.                       |
| Copy brushed data to Editor, Command Window, Variables editor, or Workspace Browser | Drag brushed data to another window or to a program/icon on the system desktop                    | Equivalent to copying brushed data and pasting into other window or an existing/new variable.                                                                                                                        |

## Brush Mode Callbacks

You can program the following callbacks for brush mode operations.

- `ActionPreCallback` `<function_handle>` — Function to execute before brushing

Use this callback to execute code when a brush operation begins. The function handle should reference a function with two implicit arguments:

```
function myfunction(src,event_data)
```

```
% src handle to the figure that has been clicked
% event_data object containing event data
end
```

The event data has the following property:

| Axes | The handle of the axes that is being brushed |
|------|----------------------------------------------|
|------|----------------------------------------------|

- **ActionPostCallback** <function\_handle> — Function to execute after brushing

Use this callback to execute code when a brush operation ends. The function handle should reference a function with two implicit arguments:

```
function myfunction(src,event_data)
% src handle to the figure that has been clicked
% event_data object containing event data
% (same as the event data of the
% 'ActionPreCallback' callback)
end
```

- “Marking Up Graphs with Data Brushing”

# bsxfun

Apply element-by-element binary operation to two arrays with singleton expansion enabled

## Syntax

`C = bsxfun(fun,A,B)`

## Description

`C = bsxfun(fun,A,B)` applies the element-by-element binary operation specified by the function handle `fun` to arrays `A` and `B`, with singleton expansion enabled. `fun` can be one of the following built-in functions:

|          |                                                  |
|----------|--------------------------------------------------|
| @plus    | Plus                                             |
| @minus   | Minus                                            |
| @times   | Array multiply                                   |
| @rdivide | Right array divide                               |
| @ldivide | Left array divide                                |
| @power   | Array power                                      |
| @max     | Binary maximum                                   |
| @min     | Binary minimum                                   |

`fun` can also be a handle to any binary element-wise function not listed above. A binary element-wise function of the form  $C = \text{fun}(A, B)$  accepts arrays **A** and **B** of arbitrary, but equal size and returns output of the same size. Each element in the output array **C** is the result of an operation on the corresponding elements of **A** and **B** only. `fun` must also support scalar expansion, such that if **A** or **B** is a scalar, **C** is the result of applying the scalar to every element in the other input array.

The corresponding dimensions of **A** and **B** must be equal to each other or equal to one. Whenever a dimension of **A** or **B** is singleton (equal to one), `bsxfun` virtually replicates the array along that dimension to match the other array. In the case where a dimension of **A** or **B** is singleton, and the corresponding dimension in the other array is zero, `bsxfun` virtually diminishes the singleton dimension to zero.

The size of the output array **C** is equal to:  
`max(size(A), size(B)).*(size(A)>0 & size(B)>0).`

## Examples

### Deviations from Mean

Use `bsxfun` to subtract the column mean from the corresponding column elements of a matrix, **A**.

```
A = [1 2 10; 1 4 20; 1 6 15] ;
C = bsxfun(@minus, A, mean(A))
```

```
C =
```

```

0 -2 -5
0 0 5
0 2 0

```

### Singleton Expansion with Custom Function

Call a custom-defined binary function with `bsxfun` by specifying a handle to the function.

```

fun = @(A,B) A.*sin(B);
A = 1:7;
B = pi*[0 1/4 1/3 1/2 2/3 3/4 1].';
C = bsxfun(fun,A,B)

```

C =

```

 0 0 0 0 0 0 0
0.7071 1.4142 2.1213 2.8284 3.5355 4.2426 4.9497
0.8660 1.7321 2.5981 3.4641 4.3301 5.1962 6.0622
1.0000 2.0000 3.0000 4.0000 5.0000 6.0000 7.0000
0.8660 1.7321 2.5981 3.4641 4.3301 5.1962 6.0622
0.7071 1.4142 2.1213 2.8284 3.5355 4.2426 4.9497
0.0000 0.0000 0.0000 0.0000 0.0000 0.0000 0.0000

```

Singleton expansion allows `bsxfun` to expand the input vectors into a full matrix.

# builddocsearchdb

Build searchable documentation database

## Syntax

```
builddocsearchdb(folder)
```

## Description

`builddocsearchdb(folder)` builds a searchable database, also referred to as a search index, from HTML files in the specified folder.

The `builddocsearchdb` function creates a subfolder, `helpsearch-v3`, to contain the database files. The database enables MATLAB to search for content within the HTML files assuming the MATLAB version is the same version used to create the database.

Beginning with MATLAB R2014b, you can maintain search indexes side by side. For instance, if you already have a search index for MATLAB R2014a or earlier, run `builddocsearchdb` against your help files using MATLAB R2014b or later. Then, when you run any MATLAB release, the help browser automatically uses the appropriate index for searching your documentation database.

## Examples

### Search Custom Help Files

Build a search database for custom help files.

MATLAB includes a set of sample files to demonstrate how to create a custom toolbox and supporting documentation. This sample toolbox is called the *Upslope Area Toolbox*. The `upslope` folder includes a file named `info.xml`, which is required to display custom documentation, and a subfolder named `html`, which contains HTML documentation and supporting files.

Copy the sample files to a temporary folder, and add the copied files to the path.

```

sample = fullfile(...
 matlabroot, 'help', 'techdoc', 'matlab_env', ...
 'examples', 'upslope');
tmp = tempname;
mkdir(tmp);
copyfile(sample,tmp);
addpath(tmp);

```

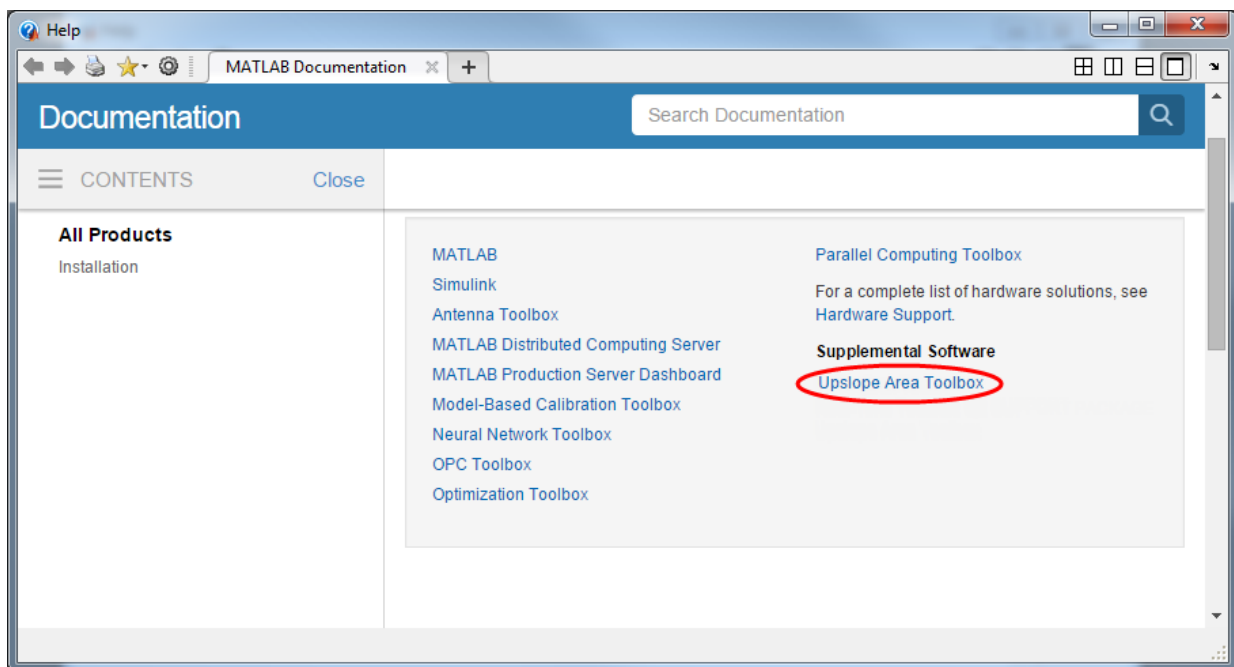

Create a search database.

```

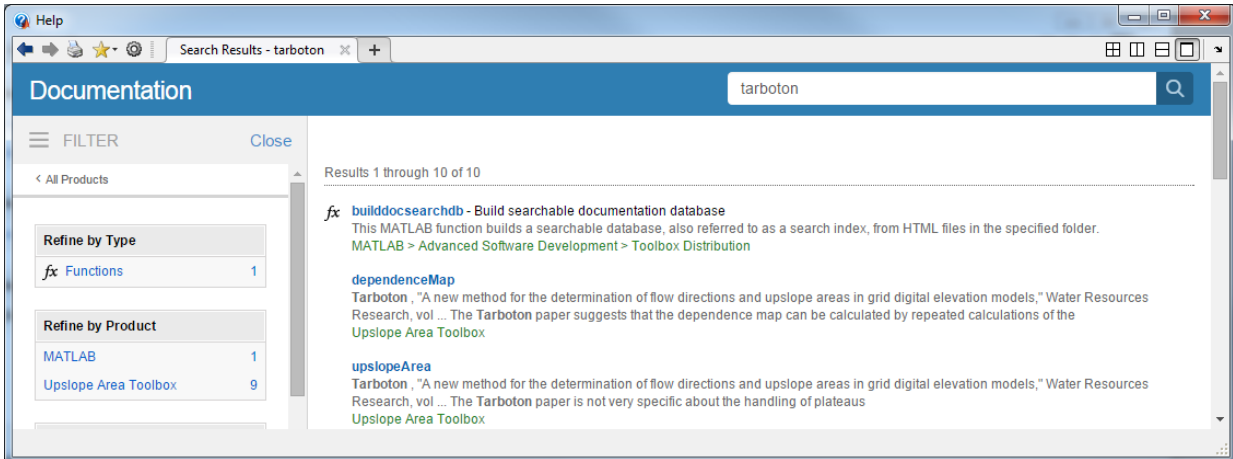

folder = fullfile(tmp, 'html');
builddocsearchdb(folder)

```

Under the Supplemental Software heading, click **Upslope Area Toolbox**.

Search the supplemental documentation for the term *tarboton*, which appears in several of the example help files. The search returns several results from the Upslope Area Toolbox.

Remove the temporary example files.

```
rmpath(tmp)
rmdir(tmp, 's')
```

---

**Note:** Your help appears alongside the MathWorks documentation only when you are viewing installed documentation. If you are viewing documentation on the web, your documentation displays in a help browser separate from the MathWorks documentation.

---

## Input Arguments

**folder** — Full path to folder with HTML files

string

Full path to a folder with HTML files, specified as a string. The folder must be:

- On the MATLAB search path
- Outside the *matlabroot* folder
- Outside any installed Hardware Support Package help folder

To include a particular HTML document in the search database, the `builddocsearchdb` function requires that:

- The document has a title.
- The content is different from the title.

Example: `builddocsearchdb('c:\myfiles\html')`

## More About

- “Display Custom Documentation”

## See Also

`doc` | `help`

**Introduced in R2007a**

## **builtin**

Execute built-in function from overloaded method

### **Syntax**

```
builtin(function,x1,...,xn)
[y1,...,yn] = builtin(function,x1,...,xn)
```

### **Description**

`builtin(function,x1,...,xn)` executes the built-in function with the input arguments `x1` through `xn`. Use `builtin` to execute the original built-in from within a method that overloads the function. To work properly, you must never overload `builtin`.

`[y1,...,yn] = builtin(function,x1,...,xn)` stores any output from function in `y1` through `yn`.

## **Examples**

### **Run an Overloaded Function within a Class Definition**

Execute the built-in functionality from within an overloaded method.

Create a simple class describing the speed of a particle and providing a `disp` method by pasting the following code into a file called `MyParticle.m`.

```
classdef MyParticle
 properties
 velocity;
 end
 methods
 function p = MyParticle(x,y,z)
 p.velocity.x = x;
 p.velocity.y = y;
 p.velocity.z = z;
 end
 end
end
```

```

function disp(p)
 builtin('disp',p) %call builtin
 if isscalar(p)
 disp(' Velocity')
 disp([' x: ',num2str(p.velocity.x)])
 disp([' y: ',num2str(p.velocity.y)])
 disp([' z: ',num2str(p.velocity.z)])
 end
end
end
end
end

```

Create an instance MyParticle.

```

p = MyParticle(1,2,4)

p =

 MyParticle

 Properties:
 velocity: [1x1 struct]

 Methods

 Velocity
 x: 1
 y: 2
 z: 4

```

## Input Arguments

**function** — Built-in function name

string

Valid built-in function name in the MATLAB path, specified as a string. **function** cannot be a function handle.

**x1, ..., xn** — Valid input arguments for function

supported data types

Valid input arguments for **function**, specified by supported data types.

## More About

### built-in function

A built-in function is part of the MATLAB executable. MATLAB does not implement these functions in the MATLAB language. Although most built-in functions have a `.m` file associated with them, this file only supplies documentation for the function.

You can use the syntax `which function` to check whether a function is built-in.

## bvp4c

Solve boundary value problems for ordinary differential equations

### Syntax

```
sol = bvp4c(odefun,bcfun,solinit)
sol = bvp4c(odefun,bcfun,solinit,options)
solinit = bvpinit(x, yinit, params)
```

### Arguments

|         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

|                      | <code>parameters</code> | Optional. A vector that provides an initial guess for unknown parameters.                                                                                                                                                                             |
|                      |                         | The structure can have any name, but the fields must be named <code>x</code> , <code>y</code> , and <code>parameters</code> . You can form <code>solinit</code> with the helper function <code>bvpinit</code> . See <code>bvpinit</code> for details. |
| <code>options</code> |                         | Optional integration argument. A structure you create using the <code>bvpset</code> function. See <code>bvpset</code> for details.                                                                                                                    |

## Description

`sol = bvp4c(odefun,bcfun,solinit)` integrates a system of ordinary differential equations of the form

$$y' = f(x,y)$$

on the interval  $[a,b]$  subject to two-point boundary value conditions  $bc(y(a),y(b)) = 0$ .

`odefun` and `bcfun` are function handles. See “Create Function Handle” for more information.

“Parameterizing Functions” explains how to provide additional parameters to the function `odefun`, as well as the boundary condition function `bcfun`, if necessary.

`bvp4c` can also solve multipoint boundary value problems. See “Multipoint Boundary Value Problems” on page 1-836. You can use the function `bvpinit` to specify the boundary points, which are stored in the input argument `solinit`. See the reference page for `bvpinit` for more information.

The `bvp4c` solver can also find unknown parameters  $p$  for problems of the form

$$y' = f(x,y, p)$$

$$0 = bc(y(a),y(b),p)$$

where  $p$  corresponds to parameters. You provide `bvp4c` an initial guess for any unknown parameters in `solinit.parameters`. The `bvp4c` solver returns the final values of these unknown parameters in `sol.parameters`.

`bvp4c` produces a solution that is continuous on  $[a, b]$  and has a continuous first derivative there. Use the function `deval` and the output `sol` of `bvp4c` to evaluate the solution at specific points `xint` in the interval  $[a, b]$ .

```
sxint = deval(sol,xint)
```

The structure `sol` returned by `bvp4c` has the following fields:

|                             |                                                                                                                     |
|-----------------------------|---------------------------------------------------------------------------------------------------------------------|
| <code>sol.x</code>          | Mesh selected by <code>bvp4c</code>                                                                                 |
| <code>sol.y</code>          | Approximation to $y(x)$ at the mesh points of <code>sol.x</code>                                                    |
| <code>sol.yp</code>         | Approximation to $y'(x)$ at the mesh points of <code>sol.x</code>                                                   |
| <code>sol.parameters</code> | Values returned by <code>bvp4c</code> for the unknown parameters, if any                                            |
| <code>sol.solver</code>     | ' <code>bvp4c</code> '                                                                                              |
| <code>sol.stats</code>      | Computational cost statistics (also displayed when the <code>stats</code> option is set with <code>bvpset</code> ). |

The structure `sol` can have any name, and `bvp4c` creates the fields `x`, `y`, `yp`, `parameters`, and `solver`.

`sol = bvp4c(odefun,bcfun,solinit,options)` solves as above with default integration properties replaced by the values in `options`, a structure created with the `bvpset` function. See `bvpset` for details.

`solinit = bvpinit(x, yinit, params)` forms the initial guess `solinit` with the vector `params` of guesses for the unknown parameters.

## Singular Boundary Value Problems

`bvp4c` solves a class of singular boundary value problems, including problems with unknown parameters  $p$ , of the form

$$y' = S \cdot y/x + F(x,y,p)$$
$$0 = bc(y(0),y(b),p)$$

The interval is required to be  $[0, b]$  with  $b > 0$ . Often such problems arise when computing a smooth solution of ODEs that result from partial differential equations (PDEs) due to cylindrical or spherical symmetry. For singular problems, you specify the (constant) matrix **S** as the value of the 'SingularTerm' option of `bvpset`, and `odefun` evaluates only  $f(x,y,p)$ . The boundary conditions must be consistent with the necessary condition  $S \cdot y(0) = 0$  and the initial guess should satisfy this condition.

## Multipoint Boundary Value Problems

`bvp4c` can solve multipoint boundary value problems where  $a = a_0 < a_1 < a_2 < \dots < a_n = b$  are boundary points in the interval  $[a,b]$ . The points  $a_1, a_2, \dots, a_{n-1}$  represent interfaces that divide  $[a,b]$  into regions. `bvp4c` enumerates the regions from left to right (from  $a$  to  $b$ ), with indices starting from 1. In region  $k$ ,  $[a_{k-1}, a_k]$ , `bvp4c` evaluates the derivative as

$$yp = \text{odefun}(x,y,k)$$

In the boundary conditions function

$$\text{bcfun}(y_{\text{left}}, y_{\text{right}})$$

`yleft(:,k)` is the solution at the left boundary of  $[a_{k-1}, a_k]$ . Similarly, `yright(:,k)` is the solution at the right boundary of region  $k$ . In particular,

$$y_{\text{left}}(:,1) = y(a)$$

and

$$y_{\text{right}}(:,\text{end}) = y(b)$$

When you create an initial guess with

$$\text{solinit} = \text{bvpinit}(x_{\text{init}}, y_{\text{init}}),$$

use double entries in `xinit` for each interface point. See the reference page for `bvpinit` for more information.

If `yinit` is a function, `bvpinit` calls `y = yinit(x,k)` to get an initial guess for the solution at `x` in region `k`. In the solution structure `sol` returned by `bvp4c`, `sol.x` has

double entries for each interface point. The corresponding columns of `sol.y` contain the left and right solution at the interface, respectively.

To see an example that solves a three-point boundary value problem, type `threebvp` at the MATLAB command prompt.

---

**Note:** The `bvp5c` function is used exactly like `bvp4c`, with the exception of the meaning of error tolerances between the two solvers. If  $S(x)$  approximates the solution  $y(x)$ , `bvp4c` controls the residual  $|S'(x) - f(x, S(x))|$ . This controls indirectly the true error  $|y(x) - S(x)|$ . `bvp5c` controls the true error directly.

---

## Examples

### Using Initial Guess to Indicate Desired Solution

Boundary value problems can have multiple solutions. One purpose of the initial guess is to indicate which solution, among several, that you want.

The second-order differential equation

$$y'' + |y| = 0$$

has exactly two solutions that satisfy the boundary conditions

$$y(0) = 0,$$

$$y(4) = -2.$$

Before using `bvp4c` to solve the problem, you need to rewrite the differential equation as a system of two first-order ODEs,

$$y_1' = y_2,$$

$$y_2' = -|y_1|,$$

where  $y_1 = y$  and  $y_2 = y'$ . This system has the required form

$$y' = f(x, y),$$

$$bc(y(a), y(b)) = 0.$$

The function,  $f$ , and the boundary conditions,  $bc$ , are coded in MATLAB as the functions `twoode` and `twobc`.

```
function dydx = twoode(x,y)
dydx = [y(2); -abs(y(1))];
```

```
function res = twobc(ya,yb)
res = [ya(1); yb(1) + 2];
```

Form a guess structure consisting of an initial mesh of five equally spaced points in  $[0,4]$  and a guess of the constant values

$$y_1(x) = 1,$$

$$y_2(x) = 0.$$

```
solinit = bvpinit(linspace(0,4,5),[1 0]);
```

Solve the problem using `bvp4c`.

```
sol = bvp4c(@twoode,@twobc,solinit);
```

Evaluate the numerical solution at 100 equally spaced points and plot  $y(x)$ .

```
x = linspace(0,4);
y = deval(sol,x);
plot(x,y(1,:))
```

To obtain the other solution of this problem, use the initial guess

$$y_1(x) = -1,$$

$$y_2(x) = 0.$$

```
solinit = bvpinit(linspace(0,4,5),[-1 0]);
sol = bvp4c(@twoode,@twobc,solinit);
x = linspace(0,4);
y = deval(sol,x);
plot(x,y(1,:))
```

### Compute Fourth Eigenvalue of Mathieu's Equation

This boundary value problem involves an unknown parameter. The task is to compute the fourth ( $q = 5$ ) eigenvalue  $\lambda$  of Mathieu's equation

$$y'' + (\lambda - 2q \cos 2x)y = 0.$$

Because the unknown parameter  $\lambda$  is present, this second-order differential equation is subject to *three* boundary conditions:

$$y'(0) = 0$$

$$y'(\pi) = 0$$

$$y(0) = 1$$

It is convenient to use local functions to place all the functions required by `bvp4c` in a single file.

```
function mat4bvp

lambda = 15;
solinit = bvpinit(linspace(0,pi,10),@mat4init,lambda);
sol = bvp4c(@mat4ode,@mat4bc,solinit);

fprintf('The fourth eigenvalue is approximately %7.3f.\n',...
 sol.parameters)

xint = linspace(0,pi);
Sxint = deval(sol,xint);
plot(xint,Sxint(1,:))
axis([0 pi -1 1.1])
title('Eigenfunction of Mathieu''s equation.')
xlabel('x')
ylabel('solution y')
% -----
function dydx = mat4ode(x,y,lambda)
q = 5;
dydx = [y(2)
 -(lambda - 2*q*cos(2*x))*y(1)];
% -----
function res = mat4bc(ya,yb,lambda)
res = [ya(2)
 yb(2)
 ya(1)-1];
% -----
function yinit = mat4init(x)
yinit = [cos(4*x)
 -4*sin(4*x)];
```

The differential equation (converted to a first-order system) and the boundary conditions are coded as local functions `mat4ode` and `mat4bc`, respectively. Because unknown parameters are present, these functions must accept three input arguments, even though some of the arguments are not used.

The guess structure `solinit` is formed with `bvpinit`. An initial guess for the solution is supplied in the form of a function `mat4init`. We chose  $y = \cos 4x$  because it satisfies the boundary conditions and has the correct qualitative behavior (the correct number of sign changes). In the call to `bvpinit`, the third argument (`lambda = 15`) provides an initial guess for the unknown parameter  $\lambda$ .

After the problem is solved with `bvp4c`, the field `sol.parameters` returns the value  $\lambda = 17.097$ , and the plot shows the eigenfunction associated with this eigenvalue.

## More About

### Algorithms

`bvp4c` is a finite difference code that implements the three-stage Lobatto IIIa formula. This is a collocation formula and the collocation polynomial provides a  $C^1$ -continuous solution that is fourth-order accurate uniformly in  $[a, b]$ . Mesh selection and error control are based on the residual of the continuous solution.

## Description

`sol = bvp5c(odefun,bcfun,solinit)` integrates a system of ordinary differential equations of the form

$$y' = f(x,y)$$

on the interval  $[a,b]$  subject to two-point boundary value conditions

$$bc(y(a),y(b)) = 0$$

`odefun` and `bcfun` are function handles. See “Create Function Handle” for more information.

“Parameterizing Functions” explains how to provide additional parameters to the function `odefun`, as well as the boundary condition function `bcfun`, if necessary. You can use the function `bvpinit` to specify the boundary points, which are stored in the input argument `solinit`.

The `bvp5c` solver can also find unknown parameters  $p$  for problems of the form

$$y' = f(x,y,p)$$

$$0 = bc(y(a),y(b),p)$$

where  $p$  corresponds to `parameters`. You provide `bvp5c` an initial guess for any unknown parameters in `solinit.parameters`. The `bvp5c` solver returns the final values of these unknown parameters in `sol.parameters`.

`bvp5c` produces a solution that is continuous on  $[a,b]$  and has a continuous first derivative there. Use the function `deval` and the output `sol` of `bvp5c` to evaluate the solution at specific points `xint` in the interval  $[a,b]$ .

```
sxint = deval(sol,xint)
```

The structure `sol` returned by `bvp5c` has the following fields:

|                             |                                                                                                                     |
|-----------------------------|---------------------------------------------------------------------------------------------------------------------|
| <code>sol.x</code>          | Mesh selected by <code>bvp5c</code>                                                                                 |
| <code>sol.y</code>          | Approximation to $y(x)$ at the mesh points of <code>sol.x</code>                                                    |
| <code>sol.parameters</code> | Values returned by <code>bvp5c</code> for the unknown parameters, if any                                            |
| <code>sol.solver</code>     | ' <code>bvp5c</code> '                                                                                              |
| <code>sol.stats</code>      | Computational cost statistics (also displayed when the <code>stats</code> option is set with <code>bvpset</code> ). |

The structure `sol` can have any name, and `bvp5c` creates the fields `x`, `y`, `parameters`, and `solver`.

`sol = bvp5c(odefun,bcfun,solinit,options)` solves as above with default integration properties replaced by the values in `options`, a structure created with the `bvpset` function. See `bvpset` for details.

`solinit = bvpinit(x, yinit, params)` forms the initial guess `solinit` with the vector `params` of guesses for the unknown parameters.

## Singular Boundary Value Problems

`bvp5c` solves a class of singular boundary value problems, including problems with unknown parameters  $p$ , of the form

$$y' = S \cdot y/x + f(x,y,p)$$

$$0 = bc(y(0),y(b),p)$$

The interval is required to be  $[0, b]$  with  $b > 0$ . Often such problems arise when computing a smooth solution of ODEs that result from partial differential equations (PDEs) due to cylindrical or spherical symmetry. For singular problems, you specify the (constant) matrix  $S$  as the value of the 'SingularTerm' option of `bvpset`, and `odefun` evaluates only  $f(x,y,p)$ . The boundary conditions must be consistent with the necessary condition  $S \cdot y(0) = 0$  and the initial guess should satisfy this condition.

## Multipoint Boundary Value Problems

`bvp5c` can solve multipoint boundary value problems where  $a = a_0 < a_1 < a_2 < \dots < a_n = b$  are boundary points in the interval  $[a,b]$ . The points  $a_1, a_2, \dots, a_{n-1}$  represent interfaces

that divide  $[a,b]$  into regions. `bvp5c` enumerates the regions from left to right (from  $a$  to  $b$ ), with indices starting from 1. In region  $k$ ,  $[a_{k-1}, a_k]$ , `bvp5c` evaluates the derivative as

```
yp = odefun(x,y,k)
```

In the boundary conditions function

```
bcfun(yleft,yright)
```

`yleft(:, k)` is the solution at the left boundary of  $[a_{k-1}, a_k]$ . Similarly, `yright(:, k)` is the solution at the right boundary of region  $k$ . In particular,

```
yleft(:,1) = y(a)
```

and

```
yright(:,end) = y(b)
```

When you create an initial guess with

```
solinit = bvpinit(xinit,yinit),
```

use double entries in `xinit` for each interface point. See the reference page for `bvpinit` for more information.

If `yinit` is a function, `bvpinit` calls `y = yinit(x, k)` to get an initial guess for the solution at `x` in region `k`. In the solution structure `sol` returned by `bvp5c`, `sol.x` has double entries for each interface point. The corresponding columns of `sol.y` contain the left and right solution at the interface, respectively.

To see an example of that solves a three-point boundary value problem, type `threebvp` at the MATLAB command prompt.

---

**Note:** The `bvp5c` function is used exactly like `bvp4c`, with the exception of the meaning of error tolerances between the two solvers. If  $S(x)$  approximates the solution  $y(x)$ , `bvp4c` controls the residual  $|S'(x) - f(x, S(x))|$ . This controls indirectly the true error  $|y(x) - S(x)|$ . `bvp5c` controls the true error directly.

---

## More About

### Algorithms

`bvp5c` is a finite difference code that implements the four-stage Lobatto IIIa formula. This is a collocation formula and the collocation polynomial provides a  $C^1$ -continuous solution that is fifth-order accurate uniformly in  $[a, b]$ . The formula is implemented as an implicit Runge-Kutta formula. `bvp5c` solves the algebraic equations directly; `bvp4c` uses analytical condensation. `bvp4c` handles unknown parameters directly; while `bvp5c` augments the system with trivial differential equations for unknown parameters.

# bvpget

Extract properties from options structure created with bvpset

## Syntax

```
val = bvpget(options,'name')
val = bvpget(options,'name',default)
```

## Description

`val = bvpget(options,'name')` extracts the value of the named property from the structure `options`, returning an empty matrix if the property value is not specified in `options`. It is sufficient to type only the leading characters that uniquely identify the property. Case is ignored for property names. `[]` is a valid `options` argument.

`val = bvpget(options,'name',default)` extracts the named property as above, but returns `val = default` if the named property is not specified in `options`. For example,

```
val = bvpget(options,'RelTol',1e-4);
```

returns `val = 1e-4` if the `RelTol` is not specified in `options`.

**Introduced before R2006a**

## **bvpinit**

Form initial guess for BVP solvers

### **Syntax**

```
solinit = bvpinit(x,yinit)
solinit = bvpinit(x,yinit,parameters)
solinit = bvpinit(sol,[anew bnew])
solinit = bvpinit(sol,[anew bnew],parameters)
```

### **Description**

`solinit = bvpinit(x,yinit)` forms the initial guess for a boundary value problem solver.

`x` is a vector that specifies an initial mesh. If you want to solve the BVP on  $[a,b]$ , then specify `x(1)` as  $a$  and `x(end)` as  $b$ . The solver adapts this mesh to the solution, so a guess like `xb=nlinspace(a,b,10)` often suffices. However, in difficult cases, you should place mesh points where the solution changes rapidly. The entries of `x` must be in

- Increasing order if  $a < b$
- Decreasing order if  $a > b$

For two-point boundary value problems, the entries of `x` must be distinct. That is, if  $a < b$ , the entries must satisfy `x(1) < x(2) < ... < x(end)`. If  $a > b$ , the entries must satisfy `x(1) > x(2) > ... > x(end)`

For multipoint boundary value problem, you can specify the points in  $[a,b]$  at which the boundary conditions apply, other than the endpoints  $a$  and  $b$ , by repeating their entries in `x`. For example, if you set

```
x = [0, 0.5, 1, 1, 1.5, 2];
```

the boundary conditions apply at three points: the endpoints 0 and 2, and the repeated entry 1. In general, repeated entries represent boundary points between regions in  $[a,b]$ . In the preceding example, the repeated entry 1 divides the interval  $[0,2]$  into two regions:  $[0,1]$  and  $[1,2]$ .

`yinit` is a guess for the solution. It can be either a vector, or a function:

- Vector – For each component of the solution, `bvpinit` replicates the corresponding element of the vector as a constant guess across all mesh points. That is, `yinit(i)` is a constant guess for the *i*th component `yinit(i,:)` of the solution at all the mesh points in `x`.
- Function – For a given mesh point, the guess function must return a vector whose elements are guesses for the corresponding components of the solution. The function must be of the form

```
y = guess(x)
```

where `x` is a mesh point and `y` is a vector whose length is the same as the number of components in the solution. For example, if the guess function is a function, `bvpinit` calls

```
y(:,j) = guess(x(j))
```

at each mesh point.

For multipoint boundary value problems, the guess function must be of the form

```
y = guess(x, k)
```

where `y` an initial guess for the solution at `x` in region `k`. The function must accept the input argument `k`, which is provided for flexibility in writing the guess function. However, the function is not required to use `k`.

`solinit = bvpinit(x,yinit,parameters)` indicates that the boundary value problem involves unknown parameters. Use the vector `parameters` to provide a guess for all unknown parameters.

`solinit` is a structure with the following fields. The structure can have any name, but the fields must be named `x`, `y`, and `parameters`.

|                         |                                                                                                                                  |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>          | Ordered nodes of the initial mesh.                                                                                               |
| <code>y</code>          | Initial guess for the solution with <code>solinit.y(:,i)</code> a guess for the solution at the node <code>solinit.x(i)</code> . |
| <code>parameters</code> | Optional. A vector that provides an initial guess for unknown parameters.                                                        |

`solinit = bvpinit(sol,[anew bnew])` forms an initial guess on the interval `[anew bnew]` from a solution `sol` on an interval `[a,b]`. The new interval must be larger than the previous one, so either `anew <= a < b <= bnew` or `anew >= a > b >= bnew`. The solution `sol` is extrapolated to the new interval. If `sol` contains `parameters`, they are copied to `solinit`.

`solinit = bvpinit(sol,[anew bnew],parameters)` forms `solinit` as described above, but uses `parameters` as a guess for unknown parameters in `solinit`.

# bvpset

Create or alter options structure of boundary value problem

## Syntax

```
options = bvpset('name1',value1,'name2',value2,...)
options = bvpset(oldopts,'name1',value1,...)
options = bvpset(oldopts,newopts)
bvpset
```

## Description

`options = bvpset('name1',value1,'name2',value2,...)` creates a structure `options` that you can supply to the boundary value problem solver `bvp4c`, in which the named properties have the specified values. Any unspecified properties retain their default values. For all properties, it is sufficient to type only the leading characters that uniquely identify the property. `bvpset` ignores case for property names.

`options = bvpset(oldopts,'name1',value1,...)` alters an existing options structure `oldopts`. This overwrites any values in `oldopts` that are specified using name/value pairs and returns the modified structure as the output argument.

`options = bvpset(oldopts,newopts)` combines an existing options structure `oldopts` with a new options structure `newopts`. Any values set in `newopts` overwrite the corresponding values in `oldopts`.

`bvpset` with no input arguments displays all property names and their possible values, indicating defaults with braces `{}`.

You can use the function `bvpget` to query the `options` structure for the value of a specific property.

## BVP Properties

`bvpset` enables you to specify properties for the boundary value problem solver `bvp4c`. There are several categories of properties that you can set:

- “Error Tolerance Properties” on page 1-854
- “Vectorization” on page 1-855
- “Analytical Partial Derivatives” on page 1-856
- “Singular BVPs” on page 1-857
- “Mesh Size Property” on page 1-857
- “Solution Statistic Property” on page 1-858

## Error Tolerance Properties

Because `bvp4c` uses a collocation formula, the numerical solution is based on a mesh of points at which the collocation equations are satisfied. Mesh selection and error control are based on the residual of this solution, such that the computed solution  $S(x)$  is the exact solution of a perturbed problem  $S'(x) = f(x, S(x)) + res(x)$ . On each subinterval of the mesh, a norm of the residual in the  $i$ th component of the solution, `res(i)`, is estimated and is required to be less than or equal to a tolerance. This tolerance is a function of the relative and absolute tolerances, `RelTol` and `AbsTol`, defined by the user.

$$\| (res(i) / \max(abs(f(i)), AbsTol(i) / RelTol)) \| \leq RelTol$$

The following table describes the error tolerance properties.

### BVP Error Tolerance Properties

| Property            | Value                               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|---------------------|-------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>RelTol</code> | Positive scalar<br>{1e-3}           | <p>A relative error tolerance that applies to all components of the residual vector. It is a measure of the residual relative to the size of <math>f(x,y)</math>. The default, 1e-3, corresponds to 0.1% accuracy.</p> <p>The computed solution <math>S(x)</math> is the exact solution of <math>S'(x) = F(x, S(x)) + res(x)</math>. On each subinterval of the mesh, the residual <math>res(x)</math> satisfies</p> $\  (res(i) / \max(abs(F(i)), AbsTol(i) / RelTol)) \  \leq RelTol$ |
| <code>AbsTol</code> | Positive scalar<br>or vector {1e-6} | Absolute error tolerances that apply to the corresponding components of the residual vector. <code>AbsTol(i)</code> is a threshold below which the values of the corresponding components are                                                                                                                                                                                                                                                                                           |

| Property | Value | Description                                                                |
|----------|-------|----------------------------------------------------------------------------|
|          |       | unimportant. If a scalar value is specified, it applies to all components. |

## Vectorization

The following table describes the BVP vectorization property. Vectorization of the ODE function used by `bvp4c` differs from the vectorization used by the ODE solvers:

- For `bvp4c`, the ODE function must be vectorized with respect to the first argument as well as the second one, so that `F([x1 x2 ...],[y1 y2 ...])` returns `[F(x1,y1) F(x2,y2) ...]`.
- `bvp4c` benefits from vectorization even when analytical Jacobians are provided. For stiff ODE solvers, vectorization is ignored when analytical Jacobians are used.

### Vectorization Properties

| Property   | Value      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|------------|------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Vectorized | on   {off} | <p>Set on to inform <code>bvp4c</code> that you have coded the ODE function <code>F</code> so that <code>F([x1 x2 ...],[y1 y2 ...])</code> returns <code>[F(x1,y1) F(x2,y2) ...]</code>. That is, your ODE function can pass to the solver a whole array of column vectors at once. This enables the solver to reduce the number of function evaluations and may significantly reduce solution time.</p> <p>With the MATLAB array notation, it is typically an easy matter to vectorize an ODE function. In the <code>shockbvp</code> example shown previously, the <code>shockODE</code> function has been vectorized using colon notation into the subscripts and by using the array multiplication (<code>.*</code>) operator.</p> <pre>function dydx = shockODE(x,y,e) pix = pi*x; dydx = [ y(2,:)... -x/e.*y(2,)-pi^2*cos(pix)- pix/e.*sin(pix)];</pre> |

## Analytical Partial Derivatives

By default, the `bvp4c` solver approximates all partial derivatives with finite differences. `bvp4c` can be more efficient if you provide analytical partial derivatives  $\partial f/\partial y$  of the differential equations, and analytical partial derivatives,  $\partial bc/\partial ya$  and  $\partial bc/\partial yb$ , of the boundary conditions. If the problem involves unknown parameters, you must also provide partial derivatives,  $\partial f/\partial p$  and  $\partial bc/\partial p$ , with respect to the parameters.

The following table describes the analytical partial derivatives properties.

### BVP Analytical Partial Derivative Properties

| Property   | Value           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|------------|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| FJacobian  | Function handle | A function handle that computes the analytical partial derivatives of $f(x,y)$ . When solving $y' = f(x,y)$ , set this property to <code>@fjac</code> if <code>dfdy = fjac(x,y)</code> evaluates the Jacobian $\partial f/\partial y$ . If the problem involves unknown parameters $p$ , <code>[dfdy,dfdp] = fjac(x,y,p)</code> must also return the partial derivative $\partial f/\partial p$ . For problems with constant partial derivatives, set this property to the value of <code>dfdy</code> or to a cell array <code>{dfdy,dfdp}</code> .                                                                                              |
| BCJacobian | Function handle | A function handle that computes the analytical partial derivatives of $bc(ya,yb)$ . For boundary conditions $bc(ya,yb)$ , set this property to <code>@bcjac</code> if <code>[dbclya,dbclyb] = bcjac(ya,yb)</code> evaluates the partial derivatives $\partial bc/\partial ya$ , and $\partial bc/\partial yb$ . If the problem involves unknown parameters $p$ , <code>[dbclya,dbclyb,dbclyp] = bcjac(ya,yb,p)</code> must also return the partial derivative $\partial bc/\partial p$ . For problems with constant partial derivatives, set this property to a cell array <code>{dbclya,dbclyb}</code> or <code>{dbclya,dbclyb,dbclyp}</code> . |

## Singular BVPs

`bvp4c` can solve singular problems of the form

$$y' = S \frac{y}{x} + f(x, y, p)$$

posed on the interval  $[0, b]$  where  $b > 0$ . For such problems, specify the constant matrix  $S$  as the value of `SingularTerm`. For equations of this form, `odefun` evaluates only the  $f(x, y, p)$  term, where  $p$  represents unknown parameters, if any.

### Singular BVP Property

| Property                  | Value           | Description                                                                                                                                                                                                                |
|---------------------------|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>SingularTerm</code> | Constant matrix | <p>Singular term of singular BVPs. Set to the constant matrix <math>S</math> for equations of the form</p> $y' = S \frac{y}{x} + f(x, y, p)$ <p>posed on the interval <math>[0, b]</math> where <math>b &gt; 0</math>.</p> |

## Mesh Size Property

`bvp4c` solves a system of algebraic equations to determine the numerical solution to a BVP at each of the mesh points. The size of the algebraic system depends on the number of differential equations ( $n$ ) and the number of mesh points in the current mesh ( $N$ ). When the allowed number of mesh points is exhausted, the computation stops, `bvp4c` displays a warning message and returns the solution it found so far. This solution does not satisfy the error tolerance, but it may provide an excellent initial guess for computations restarted with relaxed error tolerances or an increased value of `NMax`.

The following table describes the mesh size property.

### BVP Mesh Size Property

| Property          | Value                                          | Description                                                                  |
|-------------------|------------------------------------------------|------------------------------------------------------------------------------|
| <code>NMax</code> | positive integer<br>$\{\text{floor}(1000/n)\}$ | Maximum number of mesh points allowed when solving the BVP, where $n$ is the |

| Property | Value | Description                                                                                                                                                                                                                                                                                       |
|----------|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|          |       | number of differential equations in the problem. The default value of <code>NMax</code> limits the size of the algebraic system to about 1000 equations. For systems of a few differential equations, the default value of <code>NMax</code> should be sufficient to obtain an accurate solution. |

## Solution Statistic Property

The `Stats` property lets you view solution statistics.

The following table describes the solution statistics property.

### BVP Solution Statistic Property

| Property           | Value                                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|--------------------|--------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>Stats</code> | <code>on</code>   <code>{off}</code> | Specifies whether statistics about the computations are displayed. If the <code>stats</code> property is <code>on</code> , after solving the problem, <code>bvp4c</code> displays: <ul style="list-style-type: none"> <li>• The number of points in the mesh</li> <li>• The maximum residual of the solution</li> <li>• The number of times it called the differential equation function <code>odefun</code> to evaluate <math>f(x,y)</math></li> <li>• The number of times it called the boundary condition function <code>bcfun</code> to evaluate <math>bc(y(a),y(b))</math></li> </ul> |

## Examples

To create an options structure that changes the relative error tolerance of `bvp4c` from the default value of `1e-3` to `1e-4`, enter

```
options = bvpset('RelTol',1e-4);
```

To recover the value of 'RelTol' from options, enter

```
bvpget(options, 'RelTol')
```

```
ans =
```

```
1.0000e-004
```

**Introduced before R2006a**

## **bvpxtend**

Form guess structure for extending boundary value solutions

### **Syntax**

```
solinit = bvpxtend(sol,xnew,ynew)
solinit = bvpxtend(sol,xnew,extrap)
solinit = bvpxtend(sol,xnew)
solinit = bvpxtend(sol,xnew,ynew,pnew)
solinit = bvpxtend(sol,xnew,extrap,pnew)
```

### **Description**

`solinit = bvpxtend(sol,xnew,ynew)` uses solution `sol` computed on `[a,b]` to form a solution guess for the interval extended to `xnew`. The extension point `xnew` must be outside the interval `[a,b]`, but on either side. The vector `ynew` provides an initial guess for the solution at `xnew`.

`solinit = bvpxtend(sol,xnew,extrap)` forms the guess at `xnew` by extrapolating the solution `sol`. `extrap` is a string that determines the extrapolation method. `extrap` has three possible values:

- 'constant' — `ynew` is a value nearer to end point of solution in `sol`.
- 'linear' — `ynew` is a value at `xnew` of linear interpolant to the value and slope at the nearer end point of solution in `sol`.
- 'solution' — `ynew` is the value of (cubic) solution in `sol` at `xnew`.

The value of `extrap` is case-insensitive and only the leading, unique portion needs to be specified.

`solinit = bvpxtend(sol,xnew)` uses the extrapolating solution where `extrap` is 'constant'. If there are unknown parameters, values present in `sol` are used as the initial guess for parameters in `solinit`.

`solinit = bvpxtend(sol,xnew,ynew,pnew)` specifies a different guess `pnew`. `pnew` can be used with extrapolation, using the syntax `solinit =`

`bvpxtend(sol, xnew, extrap, pnew)`. To modify parameters without changing the interval, use `[]` as place holder for `xnew` and `ynew`.

**See Also**

`bvp4c` | `bvp5c` | `bvpinit`

## caldays

Calendar duration in days

### Syntax

`D = caldays(X)`

### Description

`D = caldays(X)` returns an array representing calendar days equivalent to the values in array `X`.

- If `X` is a numeric array, then `D` is a `calendarDuration` array with each element equal to the number of calendar days in the corresponding element of `X`. Calendar days account for Daylight Saving Time shifts when used in calendar calculations.
- If `X` is a `calendarDuration` array, then `D` is a `double` array with each element equal to the number of whole calendar days in the corresponding element of `X`.

### Examples

#### Create Array of Calendar Days

```
X = magic(5);
D = caldays(X)
```

D =

```
 17d 24d 1d 8d 15d
 23d 5d 7d 14d 16d
 4d 6d 13d 20d 22d
 10d 12d 19d 21d 3d
 11d 18d 25d 2d 9d
```

### Convert Calendar Durations to Calendar Days

Create an array of calendar durations. Then, convert each value to the equivalent number of whole calendar days.

```
X = caldays(8:10) + hours(1.2345)
```

```
X =
```

```
 8d 1h 14m 4.2s 9d 1h 14m 4.2s 10d 1h 14m 4.2s
```

```
D = caldays(X)
```

```
D =
```

```
 8 9 10
```

`caldays` returns a numeric array.

### Current Time at Future Date

Add two calendar days to the current date and time.

```
t = datetime('now') + caldays(2)
```

```
t =
```

```
26-Aug-2015 17:56:26
```

### Create Sequence of Dates

Create a sequence of consecutive dates beginning on March 18, 2014.

```
T = datetime([2014,03,18]) + caldays(0:4)
```

```
T =
```

```
18-Mar-2014 19-Mar-2014 20-Mar-2014 21-Mar-2014 22-Mar-2014
```

Create a sequence of dates beginning on March 18, 2014, spaced 2 days apart.

```
T = datetime([2014,03,18]) + caldays(0:2:8)
```

```
T =
```

```
18-Mar-2014 20-Mar-2014 22-Mar-2014 24-Mar-2014 26-Mar-2014
```

## Input Arguments

### **X** — Input array

numeric array | calendar duration array | logical array

Input array, specified as a numeric array, calendar duration array, or logical array. If **X** is a numeric array, it must contain only integer values. That is, you cannot create fractional calendar units.

## More About

### Tips

- `caldays` creates days that account for Daylight Saving Time shifts when used in calendar calculations. To create exact fixed-length (24 hour) days, use the `days` function.

### See Also

`calendarDuration` | `days` | `hours`

**Introduced in R2014b**

# caldiff

Calendar math successive differences

## Syntax

```
dt = caldiff(t)
dt = caldiff(t,components)
dt = caldiff(t,components,dim)
```

## Description

`dt = caldiff(t)` calculates time differences between adjacent datetime values in `t` in terms of the calendar components years, months, days, and time. `caldiff` calculates differences along the first array dimension whose size does not equal 1.

- If `t` is a vector of length `m`, then `dt = caldiff(t)` returns a vector of length `m-1`. The elements of `dt` are the differences between adjacent elements of `t`.

```
dt = [between(t(1),t(2)), between(t(2),t(3)), ..., between(t(m-1),t(m))]
```

- If `t` is a nonvector `p`-by-`m` matrix, then `dt = caldiff(t)` returns a matrix of size `(p-1)`-by-`m`, whose elements are the differences between the rows of `t`.

```
dt(:,I) = [between(t(1,I),t(2,I), between(t(2,I),t(3,I)), ...,
 between(t(p-1,I),t(p,I))]
```

`dt = caldiff(t,components)` finds the differences between successive datetimes in `t` in terms of the specified calendar or time components.

`dt = caldiff(t,components,dim)` finds the differences between successive datetimes along the dimension specified by `dim`.

## Examples

### Calendar Differences Between Datetime Values

Create a `datetime` array and then compute the differences between the values in terms of calendar components.

```
t = [datetime('yesterday');datetime('today');datetime('tomorrow')]
```

```
t =
```

```
23-Aug-2015
24-Aug-2015
25-Aug-2015
```

```
D = caldiff(t)
```

```
D =
```

```
1d
1d
```

## Differences Using Specific Calendar Components

Create a `datetime` array and then compute the differences between the values in terms of days.

```
t = datetime('now') + calmonths(0:3)
```

```
t =
```

```
Columns 1 through 3
```

```
24-Aug-2015 17:42:53 24-Sep-2015 17:42:53 24-Oct-2015 17:42:53
```

```
Column 4
```

```
24-Nov-2015 17:42:53
```

```
D = caldiff(t, 'days')
```

```
D =
```

```
31d 30d 31d
```

Computer the differences between the datetime values in terms of weeks and days.

```
D = caldiff(t,{'weeks','days'})
```

D =

```
 4w 3d 4w 2d 4w 3d
```

## Input Arguments

### **t** — Input date and time

datetime array

Input date and time, specified as a `datetime` array.

### **components** — Calendar or time components

'years' | 'quarters' | 'months' | 'weeks' | 'days' | 'time' | cell array of strings

Calendar or time components, specified as one of the following strings, or a cell array containing one or more of these strings.

- 'years'
- 'quarters'
- 'months'
- 'weeks'
- 'days'
- 'time'

Except for 'time', the above components are flexible lengths of time. For example, one month represents a different length of time when added to a datetime in January than when added to a datetime in February.

`caldiff` operates on the calendar or time components in decreasing order, starting with the largest component.

In general, `t(2:m)` is not equal to `t(1:m-1) + dt`, unless you include 'time' in components.

Example: {'years', 'quarters'}

Data Types: char | cell

**dim** — Dimension to operate along

positive integer

Dimension to operate along, specified as a positive integer. If no value is specified, the default is the first array dimension whose size does not equal 1.

## Output Arguments

**dt** — Difference array

scalar | vector | matrix | multidimensional array

Difference array, returned as a scalar, vector, matrix, or multidimensional `calendarDuration` array.

## More About

### Tips

- To compute successive differences between datetimes in `t1` and `t2` as exact, fixed-length units of hours, minutes, and seconds, use `diff(t)`.

### See Also

`between` | `calendarDuration` | `diff` | `minus`

Introduced in R2014b

# calendar

Calendar for specified month

## Syntax

```
c = calendar
c = calendar(d)
c = calendar(y, m)
```

## Description

`c = calendar` returns a 6-by-7 matrix containing a calendar for the current month. The calendar runs Sunday (first column) to Saturday.

`c = calendar(d)`, where `d` is a serial date number or a date string, returns a calendar for the specified month.

`c = calendar(y, m)`, where `y` and `m` are integers, returns a calendar for the specified month of the specified year.

If you do not specify an output argument, then `calendar` displays a calendar in the Command Window but does not return a value.

## Examples

The command

```
calendar(1957,10)
```

reveals that the Space Age began on a Friday (on October 4, 1957, when Sputnik 1 was launched).

```

 Oct 1957
 S M Tu W Th F S
 0 0 1 2 3 4 5
 6 7 8 9 10 11 12
```

|    |    |    |    |    |    |    |
|----|----|----|----|----|----|----|
| 13 | 14 | 15 | 16 | 17 | 18 | 19 |
| 20 | 21 | 22 | 23 | 24 | 25 | 26 |
| 27 | 28 | 29 | 30 | 31 | 0  | 0  |
| 0  | 0  | 0  | 0  | 0  | 0  | 0  |

**Introduced before R2006a**

# calendarDuration

Create calendar duration array from numeric values

The `calendarDuration` function creates an array that represents elapsed time in calendar units of variable length. For example, the number of days in 1 month depend on the particular month of the year. Calculations with calendar durations account for daylight saving time changes and leap years.

## Syntax

`L = calendarDuration(Y,M,D)`

`L = calendarDuration(Y,M,D,H,MI,S)`

`L = calendarDuration(Y,M,D,T)`

`L = calendarDuration( ____, 'Format', displayFormat)`

## Description

`L = calendarDuration(Y,M,D)` creates an array of calendar durations from numeric arrays containing the number of years, months, and days specified by `Y`, `M`, and `D`, respectively. Alternatively, you can specify the input arguments as a matrix with three columns, `[Y,M,D]`.

`L = calendarDuration(Y,M,D,H,MI,S)` also includes the hours, minutes, and seconds specified by `H`, `MI`, and `S`, respectively. Alternatively, you can specify the input arguments as a matrix with six columns, `[Y,M,D,H,MI,S]`.

`L = calendarDuration(Y,M,D,T)` creates an array of calendar durations from numeric arrays containing the number of years, months, and days, and a duration array `T` containing elapsed times.

`L = calendarDuration( ____, 'Format', displayFormat)` additionally specifies the format in which `L` displays, using any of the input arguments from the previous syntaxes.

## Examples

### Create Calendar Duration from Numeric Scalars

```
L = calendarDuration(1,3,15)
```

```
L =
```

```
 1y 3mo 15d
```

### Create Calendar Duration from Year, Month, Day, and Duration Arrays

Create a 2-by-2 array representing numbers of days.

```
D = magic(2)
```

```
D =
```

```
 1 3
 4 2
```

Create a 2-by-2 duration array of hours.

```
T = hours([1 2; 25 12])
```

```
T =
```

```
 1 hr 2 hrs
 25 hrs 12 hrs
```

Create a `calendarDuration` array using scalar values for the year and month inputs.

```
L = calendarDuration(1,13,D,T)
```

```
L =
```

```
 2y 1mo 1d 1h 0m 0s 2y 1mo 3d 2h 0m 0s
 2y 1mo 4d 25h 0m 0s 2y 1mo 2d 12h 0m 0s
```

Month values greater than 12 carry over to years in the display. Hour values greater than 24 do not carry over to days in the display, because the number of hours in a calendar day is not necessarily 24 hours.

### Specify Display Format of Calendar Duration

Create a `calendarDuration` array and specify a format that displays the values in terms of months, weeks, days, and time.

```
L = calendarDuration(1,1,5:9,12,0,0, 'Format', 'mwdt')
```

```
L =
```

```
Columns 1 through 3
```

```
 13mo 5d 12h 0m 0s 13mo 6d 12h 0m 0s 13mo 1w 12h 0m 0s
```

```
Columns 4 through 5
```

```
 13mo 1w 1d 12h 0m 0s 13mo 1w 2d 12h 0m 0s
```

## Input Arguments

### Y, M, D — Year, month, and day values

scalar | vector | matrix | multidimensional array

Year, month, and day values, specified as scalars, vectors, matrices, or multidimensional arrays. These values must be the same size, or any can be a scalar. `Y, M, D` should contain only integer values.

If `Y, M, D` are all scalars or all column vectors, you can specify the input arguments as a matrix with three columns, `[Y, M, D]`.

Specifying month values greater than 12 is equivalent to a number of years plus a number of months. For example, 25 months are equal to 2 years and 1 month. However, day values are not equivalent to a number of months, because the number of days in a month is not fixed, and cannot be determined until you add the calendar duration to a specific datetime.

Example: 2, 10, 24

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **Y, M, D, H, MI, S — Year, month, day, hour, minute, and second values**

scalar | vector | matrix | multidimensional array

Year, month, day, hour, minute and second values, specified as scalars, vectors, matrices, or multidimensional arrays. These values must be the same size, or any can be a scalar. Specify fractional seconds as part of the seconds input, `S`. The `Y, M, D, H, MI` inputs should contain only integer values.

If `Y, M, D, H, MI, S` are all scalars or all column vectors, you can specify the input arguments as a matrix with six columns, `[Y, M, D, H, MI, S]`.

Specifying month values greater than 12 is equivalent to a number of years plus a number of months. For example, 25 months are equal to 2 years and 1 month. Minute values greater than 60 carry over to a number of hours, and second values greater than 60 carry over to a number of minutes. However, day values are not equivalent to a number of months because the number of days in a month is not fixed and cannot be determined until you add the calendar duration to a specific datetime. Similarly, hour values are not equivalent to a number of calendar days.

Example: `2, 10, 24, 12, 45, 07.451`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **Y, M, D, T — Year, month, day, and duration values**

scalar | vector | matrix | multidimensional array

Year, month, day and duration values, specified as scalars, vectors, matrices, or multidimensional arrays. These values must be the same size, or any can be a scalar. `Y, M, and D` are numeric arrays, and `T` is a `duration` array containing elapsed times.

Specifying month values greater than 12 is equivalent to a number of years plus a number of months. For example, 25 months are equal to 2 years and 1 month. However, day values are not equivalent to a number of months and duration values are not equivalent to a number of days. The number of days in a month and the number of hours in a day are not fixed and cannot be determined until you add the calendar duration to a specific datetime.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**displayFormat** — Display format

'ymdt' (default) | string

Display format of the values in `L`, specified as a string that can include the characters `y`, `q`, `m`, `w`, `d`, and `t`, in this order. The string must include `m` to display the number of months, `d` to display the number of days, and `t` to display the number of hours, minutes, and seconds. The `y` (year), `q` (quarter), and `w` (week) characters are optional.

This table describes the date and time components that the characters represent.

| Character      | Date or Time Unit                  | Details                                               |
|----------------|------------------------------------|-------------------------------------------------------|
| <code>y</code> | Years                              | Multiples of 12 months display as a number of years   |
| <code>q</code> | Quarters                           | Multiples of 3 months display as a number of quarters |
| <code>m</code> | Months                             | Must be included in <code>displayFormat</code>        |
| <code>w</code> | Weeks                              | Multiples of 7 days display as a number of weeks      |
| <code>d</code> | Days                               | Must be included in <code>displayFormat</code>        |
| <code>t</code> | Time (hours, minutes, and seconds) | Must be included in <code>displayFormat</code>        |

If the value of a date or time component is zero, it is not displayed.

Changing the display format of a `calendarDuration` array does not change the values in the array.

Example: 'yqmdt'

## Output Arguments

**L** — Calendar duration`calendarDuration` array

Calendar duration, returned as a `calendarDuration` array.

You can change the display format of a calendar duration by modifying the `Format` property. For example, to display the calendar duration, `L`, as a number of months, type:

```
L.Format = 'm'
```

## More About

### Tips

- When you add a `calendarDuration` array that contains more than one unit to a `datetime`, MATLAB always adds the larger units first. If `t` is a `datetime`, then this command:

```
t + calendarDuration(1,2,3)
```

is the same as:

```
t + calyears(1) + calmonths(2) + caldays(3)
```

- “Represent Dates and Times in MATLAB”

### See Also

`duration`

**Introduced in R2014b**

# calllib

Call function in shared library

## Syntax

```
[x1,...,xN] = calllib(libname,funcname,arg1,...,argN)
```

## Description

`[x1,...,xN] = calllib(libname,funcname,arg1,...,argN)` calls function, `funcname`, in library, `libname`, passing input arguments, `arg1,...,argN`, and returns output values obtained from `funcname` in `x1,...,xN`.

## Examples

### Call `addStructByRef` Function

Load the library.

```
if ~libisloaded('shrlibsample')
 addpath(fullfile(matlabroot,'extern','examples','shrlib'))
 loadlibrary('shrlibsample')
end
```

Display function signature.

```
libfunctionsview shrlibsample

[double, c_structPtr] addStructByRef(c_structPtr)
```

The input argument is a pointer to a `c_struct` data type.

Create a MATLAB structure, `struct`:

```
struct.p1 = 4; struct.p2 = 7.3; struct.p3 = -290;
```

Call the function.

```
[res,st] = calllib('shrlibsample','addStructByRef',struct);
```

Display the results.

```
res
```

```
res =
 -279
```

Cleanup.

```
unloadlibrary shrllibsample
```

## Input Arguments

### **libname** — Name of shared library

string

Name of shared library, specified as a string. Do not include the path or file extension in `libname`.

If you call `loadlibrary` using the `alias` option, then you must use the alias name for the `libname` argument.

Data Types: char

### **funcname** — Name of function in library

string

Name of function in library, specified as a string.

Data Types: char

### **arg1, ..., argN** — Input arguments

any type

Input arguments, 1 through N, required by `funcname` (if any), specified by any type. The `funcname` argument list specifies the argument type.

## Output Arguments

### **x1, ..., xN** — Output arguments

any type

Output arguments, 1 through N, from `funcname` (if any), returned as any type. The `funcname` argument list specifies the argument type.

## Limitations

- Use with libraries that are loaded using the `loadlibrary` function.

## More About

- [Passing Arguments](#)
- [“MATLAB Terminates Unexpectedly When Calling Function in Shared Library”](#)

## See Also

**Introduced before R2006a**

## callSoapService

Send SOAP (Simple Object Access Protocol) message to endpoint

### Compatibility

`callSoapService` will be removed in a future release. Use `matlab.wsd1.createWSDLCient` instead.

### Syntax

```
response = callSoapService(endpoint,soapAction,message)
```

### Description

`response = callSoapService(endpoint,soapAction,message)` sends message to the `soapAction` service at endpoint.

### Examples

#### Retrieve Book Information from Library Database

This example assumes the library is on a local intranet and does not use an actual endpoint; therefore, you cannot run it.

Retrieve the name of the author of a book titled “In the Fall.” The relative path of the library service is `urn:LibraryCatalog`. To get the author's name, use the `getAuthor` function, which takes the book name as the input value. The `getAuthor` parameter is `nameToLookUp`. The XML data type for title is `{http://www.w3.org/2001/XMLSchema}string`. The SOAP message style is `rpc` by default.

Create the SOAP message.

```
message = createSoapMessage(...
```

```
'urn:LibraryCatalog',...
'getAuthor',...
{'In the Fall'},...
{'nameToLookUp'},...
{'{http://www.w3.org/2001/XMLSchema}string'})
```

```
message =
```

```
[#document: null]
```

This response does not necessarily indicate that the message is valid, although certain input problems produce error messages.

Send the message to the server for processing, and get the author's name back. The server endpoint is `http://test/soap/services/LibraryCatalog`. The server method is `urn:LibraryCatalog#getAuthor`.

```
response = callSoapService(...
 'http://test/soap/services/LibraryCatalog',...
 'urn:LibraryCatalog#getAuthor',...
 message)
```

```
<?xml version="1.0" encoding="utf-8"?>
<soapenv:Envelope
xmlns:soapenv="http://schemas.xmlsoap.org/soap/envelope/"
xmlns:xsd="http://www.w3.org/2001/XMLSchema"
xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
<soapenv:Body>
<getAuthorResponse xmlns="urn:LibraryCatalog">
<ns1:getAuthorReturn xmlns:ns1="http://latestversion.soap.test">
Kate Alvin
</ns1:getAuthorReturn>
</getAuthorResponse>
</soapenv:Body>
</soapenv:Envelope>
```

MATLAB returns the message in a single line, displayed here on separate lines for legibility.

Extract the author's name.

```
author = parseSoapResponse(response)
```

```
author = Kate Alvin
```

MATLAB automatically converted the XML string data type to `char`.

## Input Arguments

### **endpoint** — URL identifying a built-in HTTP service

string

URL identifying a built-in HTTP service, specified as a string.

Example: `'http://test/soap/services/LibraryCatalog'`

### **soapAction** — Name of service

string

Name of service, specified as a string.

Example: `'urn:LibraryCatalog#getAuthor'`

### **message** — Java<sup>®</sup> document object model (DOM)

string

Java document object model (DOM), specified as a string. Use `createSoapMessage` to create message.

## Output Arguments

### **response** — Result of `soapAction`

string

Result of `soapAction`, returned as a string. To read information in response, use the `parseSoapResponse` function.

## See Also

`createSoapMessage` | `matlab.wsd1.createWSDLCClient` | `parseSoapResponse` | `urlread` | `xmlread`

**Introduced before R2006a**

# calmonths

Calendar duration in months

## Syntax

`M = calmonths(X)`

## Description

`M = calmonths(X)` returns an array representing calendar months equivalent to the values in `X`.

- If `X` is a numeric array, then `M` is a `calendarDuration` array with each element equal to the number of calendar months in the corresponding element of `X`.
- If `X` is a `calendarDuration` array, then `M` is a `double` array with each element equal to the number of whole calendar months in the corresponding element of `X`.

## Examples

### Create Array of Calendar Months

```
X = magic(4);
M = calmonths(X)
```

M =

```
 1y 4mo 2mo 3mo 1y 1mo
 5mo 11mo 10mo 8mo
 9mo 7mo 6mo 1y
 4mo 1y 2mo 1y 3mo 1mo
```

### Convert Calendar Durations to Calendar Months

Create an array of calendar durations. Then, convert each value to the equivalent number of whole calendar months.

```
X = calmonths(15:17) + caldays(8) + hours(1.2345)
```

```
X =
```

```
1y 3mo 8d 1h 14m 4.2s 1y 4mo 8d 1h 14m 4.2s 1y 5mo 8d 1h 14m 4.2s
```

```
M = calmonths(X)
```

```
M =
```

```
15 16 17
```

## Input Arguments

### **X** — Input array

numeric array | calendar duration array | logical array

Input array, specified as a numeric array, calendar duration array, or logical array. If *X* is a numeric array, it must contain only integer values. That is, you cannot create fractional calendar units.

### See Also

`calendarDuration` | `calweeks`

**Introduced in R2014b**

# calquarters

Calendar duration in quarters

## Syntax

```
Q = calquarters(X)
```

## Description

`Q = calquarters(X)` returns an array representing calendar quarters equivalent to the values in array `X`.

- If `X` is a numeric array, then `Q` is a `calendarDuration` array with each element equal to the number of calendar quarters in the corresponding element of `X`.
- If `X` is a `calendarDuration` array, then `Q` is a `double` array with each element equal to the number of whole calendar quarters in the corresponding element of `X`.

```
Q = fix(calmonths(t)/3)
```

## Examples

### Create Array of Calendar Quarters

```
X = magic(4);
Q = calquarters(X)
```

```
Q =
```

```
16q 2q 3q 13q
 5q 11q 10q 8q
 9q 7q 6q 12q
 4q 14q 15q 1q
```

### Convert Calendar Durations to Quarters

Create an array of calendar durations. Then, convert each value to the equivalent number of whole calendar quarters.

```
X = calmonths(2:2:6) + caldays(8)
```

```
X =
```

```
 2mo 8d 4mo 8d 6mo 8d
```

```
Q = calquarters(X)
```

```
Q =
```

```
 0 1 2
```

## Input Arguments

### **X** — Input array

numeric array | calendar duration array | logical array

Input array, specified as a numeric array, calendar duration array, or logical array. If **X** is a numeric array, it must contain only integer values. That is, you cannot create fractional calendar units.

### See Also

calendarDuration | calmonths

**Introduced in R2014b**

# calweeks

Calendar duration in weeks

## Syntax

```
W = calweeks(X)
```

## Description

`W = calweeks(X)` returns an array representing calendar weeks equivalent to the values in `X`.

- If `X` is a numeric array, then `W` is a `calendarDuration` array with each element equal to the number of calendar weeks in the corresponding element of `X`.
- If `X` is a `calendarDuration` array, then `calweeks` returns the number of whole weeks equivalent to each calendar duration in `X`.

## Examples

### Create Array of Calendar Weeks

```
X = magic(4);
W = calweeks(X)
```

W =

```
 16w 2w 3w 13w
 5w 11w 10w 8w
 9w 7w 6w 12w
 4w 14w 15w 1w
```

### Convert Calendar Durations to Calendar Weeks

Create an array of calendar durations. Then, convert each value to the equivalent number of whole calendar weeks.

```
X = caldays(15:17) + hours(1.2345)
```

```
X =
```

```
 15d 1h 14m 4.2s 16d 1h 14m 4.2s 17d 1h 14m 4.2s
```

```
W = calweeks(X)
```

```
W =
```

```
 2 2 2
```

## Input Arguments

### **X** — Input array

numeric array | calendar duration array | logical array

Input array, specified as a numeric array, calendar duration array, or logical array. If *X* is a numeric array, it must contain only integer values. That is, you cannot create fractional calendar units.

## Output Arguments

### **W** — Calendar weeks

scalar | vector | matrix | multidimensional array

Calendar weeks, returned as a scalar, vector, matrix, or multidimensional array. *W* is the same size as *X*. The data type of *W* depends on *X*.

- If *X* is a numeric array, then *W* is an array of calendar durations in units of equivalent flexible-length calendar weeks.
- If *X* is a `calendarDuration` array, then *W* is a `double` array of integer values representing whole calendar weeks.

## See Also

`caldays` | `calendarDuration`

**Introduced in R2014b**

## calyears

Calendar duration in years

### Syntax

```
Y = calyears(X)
```

### Description

`Y = calyears(X)` returns an array representing calendar years equivalent to the values in `X`. Calendar years account for leap days when used in calendar calculations.

- If `X` is a numeric array, then `Y` is a `calendarDuration` array with each element equal to the number of calendar years in the corresponding element of `X`.
- If `X` is a `calendarDuration` array, then `calyears` returns the number of whole years equivalent to each calendar duration in `X`.

### Examples

#### Create Array of Calendar Years

```
X = magic(4);
Y = calyears(X)
```

`Y =`

```
 16y 2y 3y 13y
 5y 11y 10y 8y
 9y 7y 6y 12y
 4y 14y 15y 1y
```

#### Convert Calendar Durations to Calendar Years

Create an array of calendar durations. Then, convert each value to the equivalent number of whole calendar years.

```
X = calmonths(21:25) + caldays(8)
```

```
X =
```

```
 1y 9mo 8d 1y 10mo 8d 1y 11mo 8d 2y 8d 2y 1mo 8d
```

```
Y = calyears(X)
```

```
Y =
```

```
 1 1 1 2 2
```

## Input Arguments

### X — Input array

numeric array | calendar duration array | logical array

Input array, specified as a numeric array, calendar duration array, or logical array. If X is a numeric array, it must contain only integer values. That is, you cannot create fractional calendar units.

## Output Arguments

### Y — Calendar years

scalar | vector | matrix | multidimensional array

Calendar years, returned as a scalar, vector, matrix, or multidimensional array. Y is the same size as X. The data type of Y depends on X.

- If X is a numeric array, then Y is an array of calendar durations in units of equivalent flexible-length calendar years.
- If X is a `calendarDuration` array, then Y is a `double` array of integer values representing whole calendar years.

## More About

### Tips

- `calyears` creates years that account for leap days when used in calendar calculations. To create exact fixed-length (365.2425 day) years, use the `years` function.

### See Also

# camdolly

Move camera position and target

## Syntax

```
camdolly(dx,dy,dz)
camdolly(dx,dy,dz,'targetmode')
camdolly(dx,dy,dz,targetmode,coordsys)
camdolly(ax,...)
```

## Description

`camdolly(dx,dy,dz)` moves the camera position and the camera target by the specified amounts `dx`, `dy`, and `dz`.

`camdolly(dx,dy,dz,'targetmode')` uses the `targetmode` argument to determine how the camera moves:

- `'movetarget'` (default) — Move both the camera and the target.
- `'fixtarget'` — Move only the camera.

`camdolly(dx,dy,dz,targetmode,coordsys)` uses the `coordsys` argument to determine how MATLAB interprets `dx`, `dy`, and `dz`:

- `'camera'` (default) — Move in the coordinate system of the camera. `dx` moves left/right, `dy` moves down/up, and `dz` moves along the viewing axis. MATLAB normalizes the units to the scene.

For example, setting `dx` to 1 moves the camera to the right, which pushes the scene to the left edge of the box formed by the axes position rectangle. A negative value moves the scene in the other direction. Setting `dz` to 0.5 moves the camera to a position halfway between the camera position and the camera target.

- `'pixels'` — Interpret `dx` and `dy` as pixel offsets. This option ignores `dz`.
- `'data'` — Interpret `dx`, `dy`, and `dz` as offsets in axes data coordinates.

`camdolly(ax,...)` operates on the axes identified by the first argument, `ax`. When you do not specify an axes object, `camdolly` operates on the current axes.

`camdolly` sets the axes `CameraPosition` and `CameraTarget` properties, which in turn sets the `CameraPositionMode` and `CameraTargetMode` properties to `manual`.

## Examples

Move the camera along the  $x$ - and  $y$ -axes in a series of steps:

```
surf(peaks)
axis vis3d
t = 0:pi/20:4*pi;
dx = sin(t)/40;
dy = cos(t)/40;
for i = 1:length(t);
 camdolly(dx(i),dy(i),0)
 drawnow
end
```

# cameratoolbar

Control camera toolbar programmatically

## Syntax

```
cameratoolbar
cameratoolbar('NoReset')
cameratoolbar('SetMode',mode)
cameratoolbar('SetCoordSys',coordsys)
cameratoolbar('Show')
cameratoolbar('Hide')
cameratoolbar('Toggle')
cameratoolbar('ResetCameraAndSceneLight')
cameratoolbar('ResetCamera')
cameratoolbar('ResetSceneLight')
cameratoolbar('ResetTarget')
h = cameratoolbar(...)
mode = cameratoolbar('GetMode')
paxis = cameratoolbar('GetCoordSys')
tf = cameratoolbar('GetVisible')
cameratoolbar('Close')
cameratoolbar(fig,...)
```

## Description

`cameratoolbar` creates a toolbar that enables interactive manipulation of the axes camera and light when you drag the mouse on the figure window. Several axes camera properties are set when the toolbar is initialized.

`cameratoolbar('NoReset')` creates the toolbar without setting any camera properties.

`cameratoolbar('SetMode',mode)` sets the toolbar mode (depressed button). `mode` can be 'orbit', 'orbitscenelight', 'pan', 'dollyhv', 'dollyfb', 'zoom', 'roll', 'nomode'. For descriptions of the various modes, see “Camera Toolbar”. You can also set these modes using the toolbar, by clicking the respective buttons.

`cameratoolbar('SetCoordSys', coordsys)` sets the principal axis of the camera motion. `coordsys` can be: 'x', 'y', 'z', 'none'.

`cameratoolbar('Show')` shows the toolbar on the current figure.

`cameratoolbar('Hide')` hides the toolbar on the current figure.

`cameratoolbar('Toggle')` toggles the visibility of the toolbar.

`cameratoolbar('ResetCameraAndSceneLight')` resets the current camera and scenelight.

`cameratoolbar('ResetCamera')` resets the current camera.

`cameratoolbar('ResetSceneLight')` resets the current scenelight.

`cameratoolbar('ResetTarget')` resets the current camera target.

`h = cameratoolbar(...)` returns the handle to the toolbar.

`mode = cameratoolbar('GetMode')` returns the current mode.

`paxis = cameratoolbar('GetCoordSys')` returns the current principal axis.

`tf = cameratoolbar('GetVisible')` returns the visibility of the toolbar (1 if visible, 0 if not visible).

`cameratoolbar('Close')` removes the toolbar from the current figure.

`cameratoolbar(fig, ...)` specifies the figure to operate on by passing the figure handle as the first argument.

In general, the use of OpenGL hardware improves rendering performance.

## Alternatives

Display the toolbar by selecting **Camera Toolbar** from the figure window's **View** menu.

## More About

- “Camera Toolbar”

## **See Also**

rotate3d | zoom

**Introduced before R2006a**

## **camlight**

Create or move light object in camera coordinates

### **Syntax**

```
camlight('headlight')
camlight('right')
camlight('left')
camlight
camlight(az,e1)
camlight(...,'style')
camlight(light_handle,...)
light_handle = camlight(...)
```

### **Description**

`camlight('headlight')` creates a light at the camera position.

`camlight('right')` creates a light right and up from camera.

`camlight('left')` creates a light left and up from camera.

`camlight` with no arguments is the same as `camlight('right')`.

`camlight(az,e1)` creates a light at the specified azimuth (`az`) and elevation (`e1`) with respect to the camera position. The camera target is the center of rotation and `az` and `e1` are in degrees.

`camlight(...,'style')` defines the style argument using one of two values:

- `local` (default) — The light is a point source that radiates from the location in all directions.
- `infinite` — The light shines in parallel rays.

`camlight(light_handle,...)` uses the light specified in `light_handle`.

`light_handle = camlight(...)` returns the light object handle.

`camlight` sets the light object `Position` and `Style` properties. A light created with `camlight` does not track the camera. In order for the light to stay in a constant position relative to the camera, call `camlight` whenever you move the camera.

## Examples

Create a light positioned to the left of the camera and then reposition the light each time the camera moves:

```
surf(peaks)
axis vis3d
h = camlight('left');
for i = 1:20;
 camorbit(10,0)
 camlight(h,'left')
 pause(.1)
end
```

## More About

- [“Lighting Overview”](#)

## camlookat

Position camera to view object or group of objects

### Syntax

```
camlookat(object_handles)
camlookat(axes_handle)
camlookat
```

### Description

`camlookat(object_handles)` views the objects identified in the vector `object_handles`. The vector can contain the handles of axes Children.

`camlookat(axes_handle)` views the objects that are children of the axes identified by `axes_handle`.

`camlookat` views the objects that are in the current axes by moving the camera position and camera target while preserving the relative view direction and camera view angle. The viewed object (or objects) roughly fill the axes position rectangle. To change the view, `camlookat` sets the axes `CameraPosition` and `CameraTarget` properties.

### Examples

Create three spheres at different locations and then progressively position the camera so that the scene composes around each sphere individually:

```
% Create three spheres using the sphere function:
[x y z] = sphere;
s1 = surf(x,y,z);
hold on
s2 = surf(x+3,y,z+3);
s3 = surf(x,y,z+6);
% Set the data aspect ratio using daspect:
daspect([1 1 1])
% Set the view:
```

```
view(30,10)
% Set the projection type using camproj:
camproj perspective
% Compose the scene around the current axes
camlookat(gca)
pause(2)
% Compose the scene around sphere s1
camlookat(s1)
pause(2)
% Compose the scene around sphere s2
camlookat(s2)
pause(2)
% Compose the scene around sphere s3
camlookat(s3)
pause(2)
camlookat(gca)
```

## More About

campos | camtarget

**Introduced before R2006a**

## camorbit

Rotate camera position around camera target

### Syntax

```
camorbit(dtheta,dphi)
camorbit(dtheta,dphi,'coordsys')
camorbit(dtheta,dphi,'coordsys','direction')
camorbit(axes_handle,...)
```

### Description

`camorbit(dtheta,dphi)` rotates the camera position around the camera target by the amounts specified in `dtheta` and `dphi` (both in degrees). `dtheta` is the horizontal rotation and `dphi` is the vertical rotation.

`camorbit(dtheta,dphi,'coordsys')` rotates the camera position around the camera target, using the `coordsys` argument to determine the center of rotation. `coordsys` can take on two values:

- `data` (default) — Rotate the camera around an axis defined by the camera target and the `direction` (default is the positive  $z$  direction).
- `camera` — Rotate the camera about the point defined by the camera target.

`camorbit(dtheta,dphi,'coordsys','direction')` defines the axis of rotation for the data coordinate system using the `direction` argument in conjunction with the camera target. Specify `direction` as a three-element vector containing the  $x$ -,  $y$ -, and  $z$ -components of the direction or one of the characters, `x`, `y`, or `z`, to indicate  $[1\ 0\ 0]$ ,  $[0\ 1\ 0]$ , or  $[0\ 0\ 1]$  respectively.

`camorbit(axes_handle,...)` operates on the axes identified by the first argument, `axes_handle`. When you do not specify an axes handle, `camorbit` operates on the current axes.

The behavior of `camorbit` differs from the `rotate3d` function in that while the `rotate3d` tool modifies the `View` property of the axes, the `camorbit` function fixes the

aspect ratio and modifies the `CameraTarget`, `CameraPosition`, and `CameraUpVector` properties of the axes. See [Axes Properties](#) for more information on all axes properties.

## Examples

Rotate the camera horizontally about a line defined by the camera target point and a direction that is parallel to the *y*-axis. Visualize this rotation as a cone formed with the camera target at the apex and the camera position forming the base:

```
surf(peaks)
axis vis3d
for i=1:36
 camorbit(10,0,'data',[0 1 0])
 drawnow
end
```

Rotate in the `camera` coordinate system to orbit the camera around the axes along a circle while keeping the center of a circle at the camera target:

```
surf(peaks)
axis vis3d
for i=1:36
 camorbit(10,0,'camera')
 drawnow
end
```

## Alternatives

Enable 3-D rotation from the figure **Tools** menu or the figure toolbar.

## More About

- “Camera Graphics Terminology”

## See Also

`axes` | `axis` | `camdolly` | `campan` | `camzoom` | `camroll`

**Introduced before R2006a**

## campan

Rotate camera target around camera position

### Syntax

```
campan(dtheta,dphi)
campan(dtheta,dphi,coordsys)
campan(dtheta,dphi,coordsys,direction)
campan(axes_handle,...)
```

### Description

`campan(dtheta,dphi)` rotates the camera target of the current axes around the camera position by the amounts specified in `dtheta` and `dphi` (both in degrees). `dtheta` is the horizontal rotation and `dphi` is the vertical rotation.

`campan(dtheta,dphi,coordsys)` determine the center of rotation using the `coordsys` argument. It can take on two values:

- 'data' (default) — Rotate the camera target around an axis defined by the camera position and the `direction` (default is the positive  $z$  direction)
- 'camera' — Rotate the camera about the point defined by the camera target.

`campan(dtheta,dphi,coordsys,direction)` defines the axis of rotation for the data coordinate system using the `direction` argument with the camera position. Specify `direction` as a three-element vector containing the  $x$ -,  $y$ -, and  $z$ -components of the direction or one of the characters, 'x', 'y', or 'z', to indicate  $[1\ 0\ 0]$ ,  $[0\ 1\ 0]$ , or  $[0\ 0\ 1]$  respectively.

`campan(axes_handle,...)` operates on the axes identified by the first argument, `axes_handle`. When you do not specify an axes handle, `campan` operates on the current axes.

### Examples

Move the camera target to pan the object in a circular motion.

```
sphere;
axis vis3d
hPan = sin(-pi:1:pi);
vPan = cos(-pi:1:pi);
for k=1:length(hPan)
 campan(hPan(k),vPan(k))
 pause(.1)
end
```

## More About

## campos

Set or query camera position

### Syntax

```
campos
campos([camera_position])
campos('mode')
campos('auto')
campos('manual')
campos(axes_handle, ...)
```

### Description

`campos` returns the camera position in the current axes.

`campos([camera_position])` sets the position of the camera in the current axes to the specified value. Specify the position as a three-element vector containing the  $x$ -,  $y$ -, and  $z$ -coordinates of the desired location in the data units of the axes.

`campos('mode')` returns the value of the camera position mode, which can be either `auto` (the default) or `manual`.

`campos('auto')` sets the camera position mode to `auto`.

`campos('manual')` sets the camera position mode to `manual`.

`campos(axes_handle, ...)` performs the set or query on the axes identified by the first argument, `axes_handle`. When you do not specify an axes handle, `campos` operates on the current axes.

`campos` sets or queries values of the axes `CameraPosition` and `CameraPositionMode` properties. The camera position is the point in the Cartesian coordinate system of the axes from which you view the scene.

## Examples

Move the camera along the  $x$ -axis in a series of steps:

```
surf(peaks)
axis vis3d off
for x = -200:5:200
 campos([x,5,10])
 drawnow
end
```

## More About

- “Camera Graphics Terminology”

## See Also

[axis](#) | [camproj](#) | [camup](#) | [camva](#) | [camtarget](#)

**Introduced before R2006a**

## camproj

Set or query projection type

### Syntax

```
camproj
camproj('projection_type')
camproj(axes_handle,...)
```

### Description

`camproj` returns the projection type setting in the current axes. The projection type determines whether MATLAB 3-D views use a perspective or orthographic projection.

`camproj('projection_type')` sets the projection type in the current axes to the specified value. Possible values for *projection\_type* are *orthographic* and *perspective*.

`camproj(axes_handle,...)` performs the set or query on the axes identified by the first argument, `axes_handle`. When you do not specify an axes handle, `camproj` operates on the current axes.

`camproj` sets or queries values of the axes object `Projection` property.

### Examples

Compare the different `camproj` settings using `subplot`:

```
subplot(1,2,1); surf(membrane); camproj('perspective')
subplot(1,2,2); surf(membrane); camproj('orthographic')
```

## More About

- “Camera Graphics Terminology”

## See Also

axis | campos | camtarget | camup | camva

Introduced before R2006a

## camroll

Rotate camera about view axis

### Syntax

```
camroll(dtheta)
camroll(axes_handle,dtheta)
```

### Description

`camroll(dtheta)` rotates the camera around the camera viewing axis by the amounts specified in `dtheta` (in degrees). The viewing axis is the line passing through the camera position and the camera target.

`camroll(axes_handle,dtheta)` operates on the axes identified by the first argument, `axes_handle`. When you do not specify an axes handle, `camroll` operates on the current axes.

`camroll` sets the axes `CameraUpVector` property and also sets the `CameraUpVectorMode` property to `manual`.

### Examples

Rotate the camera around the viewing axis:

```
surf(peaks)
axis vis3d
for i=1:36
 camroll(10)
 drawnow
end
```

### More About

- “Camera Graphics Terminology”

## **See Also**

axes | axis | camdolly | camorbit | camzoom | campan

**Introduced before R2006a**

## **camtarget**

Set or query location of camera target

### **Syntax**

```
camtarget
camtarget([camera_target])
camtarget('mode')
camtarget('auto')
camtarget('manual')
camtarget(axes_handle,...)
```

### **Description**

`camtarget` returns the location of the camera target in the current axes. The camera target is the location in the axes that the camera points to. The camera remains oriented toward this point regardless of its position.

`camtarget([camera_target])` sets the camera target in the current axes to the specified value. Specify the target as a three-element vector containing the *x*-, *y*-, and *z*-coordinates of the desired location in the data units of the axes.

`camtarget('mode')` returns the value of the camera target mode, which can be either `auto` (default) or `manual`.

`camtarget('auto')` sets the camera target mode to `auto`. When the camera target mode is `auto`, the camera target is the center of the axes plot box.

`camtarget('manual')` sets the camera target mode to `manual`.

`camtarget(axes_handle,...)` performs the set or query on the axes identified by `axes_handle`. When you do not specify an axes handle, `camtarget` operates on the current axes.

`camtarget` sets or queries values of the axes object `CameraTarget` and `CameraTargetMode` properties.

## Examples

Move the camera position and the camera target along the  $x$ -axis in a series of steps:

```
surf(peaks);
axis vis3d
xp = linspace(-150,40,50);
xt = linspace(25,50,50);
for i=1:50
 campos([xp(i),25,5]);
 camtarget([xt(i),30,0])
 drawnow
end
```

## More About

- “Camera Graphics Terminology”

## See Also

[axis](#) | [campos](#) | [camup](#) | [camva](#)

**Introduced before R2006a**

## camup

Set or query camera up vector

### Syntax

```
camup
camup([up_vector])
camup('mode')
camup('auto')
camup('manual')
camup(axes_handle,...)
```

### Description

`camup` returns the camera up vector setting in the current axes. The camera up vector specifies the direction that is oriented up in the scene.

`camup([up_vector])` sets the up vector in the current axes to the specified value. Specify the up vector as  $x$ ,  $y$ , and  $z$  components.

`camup('mode')` returns the current value of the camera up vector mode, which can be either `auto` (default) or `manual`.

`camup('auto')` sets the camera up vector mode to `auto`. In `auto` mode, `[0 1 0]` is the up vector of for 2-D views. This means the  $y$ -axis points up. For 3-D views, the up vector is `[0 0 1]`, meaning the  $z$ -axis points up.

`camup('manual')` sets the camera up vector mode to `manual`. In `manual` mode, the value of the camera up vector does not change unless you set it.

`camup(axes_handle,...)` performs the set or query on the axes identified by the first argument, `axes_handle`. When you do not specify an axes handle, `camup` operates on the current axes.

### Examples

Set the  $x$ -axis to be the up axis:

```
surf(peaks)
camup([1 0 0]);
```

## More About

- “Camera Graphics Terminology”

## See Also

axis | campos | camup | camtarget

Introduced before R2006a

## camva

Set or query camera view angle

### Syntax

```
camva
camva(view_angle)
camva('mode')
camva('auto')
camva('manual')
camva(axes_handle, ...)
```

### Description

`camva` returns the camera view angle setting in the current axes. The camera view angle determines the field of view of the camera. Larger angles produce a smaller view of the scene. Implement zooming by changing the camera view angle.

`camva(view_angle)` sets the view angle in the current axes to the specified value. Specify the view angle in degrees.

`camva('mode')` returns the current value of the camera view angle mode, which can be either `auto` (the default) or `manual`.

`camva('auto')` sets the camera view angle mode to `auto`.

`camva('manual')` sets the camera view angle mode to `manual`.

`camva(axes_handle, ...)` performs the set or query on the axes identified by the first argument, `axes_handle`. When you do not specify an axes handle, `camva` operates on the current axes.

### Tips

The `camva` function sets or queries values of the axes object `CameraViewAngle` and `CameraViewAngleMode` properties.

When the camera view angle mode is `auto`, the camera view angle adjusts so that the scene fills the available space in the window. If you move the camera to a different position, the camera view angle changes to maintain a view of the scene that fills the available area in the window.

Setting a camera view angle or setting the camera view angle to `manual` disables the MATLAB stretch-to-fill feature (stretching of the axes to fit the window). This means setting the camera view angle to its current value,

```
camva(camva)
```

can cause a change in the way the graph looks. See `axes` for more information.

## Examples

Create two pushbuttons, one that zooms in and another that zooms out:

```
% Set the range checking in the callback statements to keep
% the values for the camera view angle in the range greater
% than zero and less than 180.
uicontrol('Style','pushbutton',...
 'String','Zoom In',...
 'Position',[20 20 60 20],...
 'Callback','if camva <= 1;return;else;camva(camva-1);end');
uicontrol('Style','pushbutton',...
 'String','Zoom Out',...
 'Position',[100 20 60 20],...
 'Callback',...
 'if camva >= 179;return;else;camva(camva+1);end');
% Now create a graph to zoom in and out on:
surf(peaks);
```

## More About

- “Camera Graphics Terminology”

## See Also

`axis` | `campos` | `camup` | `camtarget`

**Introduced before R2006a**

## **camzoom**

Zoom in and out on scene

### **Syntax**

```
camzoom(zoom_factor)
camzoom(axes_handle,...)
```

### **Description**

`camzoom(zoom_factor)` zooms in or out on the scene depending on the value specified by `zoom_factor`. If `zoom_factor` is greater than 1, the scene appears larger; if `zoom_factor` is greater than zero and less than 1, the scene appears smaller.

`camzoom(axes_handle,...)` operates on the axes identified by the first argument, `axes_handle`. When you do not specify an axes handle, `camzoom` operates on the current axes.

### **More About**

#### **Tips**

`camzoom` sets the axes `CameraViewAngle` property, which in turn causes the `CameraViewAngleMode` property to be set to `manual`. Note that setting the `CameraViewAngle` property disables the MATLAB stretch-to-fill feature (stretching of the axes to fit the window). This may result in a change to the aspect ratio of your graph. See the `axes` function for more information on this behavior.

# cartToBary

**Class:** TriRep

(Not recommended) Convert point coordinates from cartesian to barycentric

---

**Note:** `cartToBary(TriRep)` is not recommended. Use `cartesianToBarycentric(triangulation)` instead.

`TriRep` is not recommended. Use `triangulation` instead.

---

## Syntax

`B = cartToBary(TR, SI, XC)`

## Description

`B = cartToBary(TR, SI, XC)` returns the barycentric coordinates of each point in `XC` with respect to its associated simplex `SI`.

## Input Arguments

|    |                                                                                                                                                                                                                                                                                                          |
|----|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TR | Triangulation representation.                                                                                                                                                                                                                                                                            |
| SI | Column vector of simplex indices that index into the triangulation matrix <code>TR.Triangulation</code> .                                                                                                                                                                                                |
| XC | Matrix that represents the Cartesian coordinates of the points to be converted. <code>XC</code> is of size <code>m-by-n</code> , where <code>m</code> is of <code>length(SI)</code> , the number of points to convert, and <code>n</code> is the dimension of the space where the triangulation resides. |

## Output Arguments

|   |                                                                                                     |
|---|-----------------------------------------------------------------------------------------------------|
| B | Matrix of dimension <code>m-by-k</code> where <code>k</code> is the number of vertices per simplex. |
|---|-----------------------------------------------------------------------------------------------------|

## Definitions

A simplex is a triangle/tetrahedron or higher dimensional equivalent.

## Examples

Compute the Delaunay triangulation of a set of points.

```
x = [0 4 8 12 0 4 8 12]';
y = [0 0 0 0 8 8 8 8]';
dt = DelaunayTri(x,y)
```

Compute the barycentric coordinates of the incenters.

```
cc = incenters(dt);
tri = dt(:,:);
```

Plot the original triangulation and reference points.

```
figure
subplot(1,2,1);
triplot(dt); hold on;
plot(cc(:,1), cc(:,2), '*r');
hold off;
axis equal;
```

Stretch the triangulation and compute the mapped locations of the incenters on the deformed triangulation.

```
b = cartToBary(dt,[1:length(tri)]',cc);
y = [0 0 0 0 16 16 16 16]';
tr = TriRep(tri,x,y)
xc = baryToCart(tr, [1:length(tri)]', b);
```

Plot the deformed triangulation and mapped locations of the reference points.

```
subplot(1,2,2);
triplot(tr);
hold on;
plot(xc(:,1), xc(:,2), '*r');
hold off;
axis equal;
```

## **cart2pol**

Transform Cartesian coordinates to polar or cylindrical

### **Syntax**

```
[THETA,RHO,Z] = cart2pol(X,Y,Z)
[THETA,RHO] = cart2pol(X,Y)
```

### **Description**

`[THETA,RHO,Z] = cart2pol(X,Y,Z)` transforms three-dimensional Cartesian coordinates stored in corresponding elements of arrays `X`, `Y`, and `Z`, into cylindrical coordinates. `THETA` is a counterclockwise angular displacement in radians from the positive  $x$ -axis, `RHO` is the distance from the origin to a point in the  $x$ - $y$  plane, and `Z` is the height above the  $x$ - $y$  plane. Arrays `X`, `Y`, and `Z` must be the same size (or any can be scalar).

`[THETA,RHO] = cart2pol(X,Y)` transforms two-dimensional Cartesian coordinates stored in corresponding elements of arrays `X` and `Y` into polar coordinates.

### **More About**

#### **Algorithms**

The mapping from two-dimensional Cartesian coordinates to polar coordinates, and from three-dimensional Cartesian coordinates to cylindrical coordinates is

#### Two-Dimensional Mapping

$$\theta = \text{atan2}(y, x)$$

$$\rho = \sqrt{x.^2 + y.^2}$$

#### Three-Dimensional Mapping

$$\theta = \text{atan2}(y, x)$$

$$\rho = \sqrt{x.^2 + y.^2}$$

$$z = z$$

### See Also

cart2sph | pol2cart | sph2cart

Introduced before R2006a

## cart2sph

Transform Cartesian coordinates to spherical

### Syntax

```
[azimuth,elevation,r] = cart2sph(X,Y,Z)
```

### Description

`[azimuth,elevation,r] = cart2sph(X,Y,Z)` transforms Cartesian coordinates stored in corresponding elements of arrays `X`, `Y`, and `Z` into spherical coordinates. `azimuth` and `elevation` are angular displacements in radians. `azimuth` is the counterclockwise angle in the  $x$ - $y$  plane measured from the positive  $x$ -axis. `elevation` is the elevation angle from the  $x$ - $y$  plane. `r` is the distance from the origin to a point.

Arrays `X`, `Y`, and `Z` must be the same size (or any of them can be scalar).

### More About

#### Algorithms

The mapping from three-dimensional Cartesian coordinates to spherical coordinates is

```
azimuth = atan2(y,x)
elevation = atan2(z,sqrt(x.^2 + y.^2))
r = sqrt(x.^2 + y.^2 + z.^2)
```

The notation for spherical coordinates is not standard. For the `cart2sph` function, `elevation` is measured from the  $x$ - $y$  plane. Notice that if `elevation` = 0, the point is in the  $x$ - $y$  plane. If `elevation` =  $\pi/2$ , then the point is on the positive  $z$ -axis.

`cart2pol` | `pol2cart` | `sph2cart`

Introduced before R2006a

## cast

Cast variable to different data type

### Syntax

```
B = cast(A,newclass)
B = cast(A,'like',p)
```

### Description

`B = cast(A,newclass)` converts `A` to class `newclass`, where `newclass` is the name of a built-in data type compatible with `A`. The `cast` function truncates any values in `A` that are too large to map into `newclass`.

`B = cast(A,'like',p)` converts `A` to the same data type and sparsity as the variable `p`. If `A` and `p` are both real, then `B` is also real. Otherwise, `B` is complex.

### Examples

#### Convert Numeric Data Type

Convert an `int8` value to `uint8`.

Define a scalar 8-bit integer.

```
a = int8(5);
```

Convert `a` to an unsigned 8-bit integer.

```
b = cast(a,'uint8');
class(b)
```

```
ans =
uint8
```

#### Match Data Type and Complex Nature of `p`

Define a single precision vector `p` that is complex valued.

```
p = single([1+i 2]);
```

Define a 2-by-3 matrix of ones.

```
A = ones(2,3);
```

Convert *A* to the same data type and complexity (real or complex) as *p*.

```
B = cast(A, 'like', p)
```

```
B =
```

```
 1.0000 + 0.0000i 1.0000 + 0.0000i 1.0000 + 0.0000i
 1.0000 + 0.0000i 1.0000 + 0.0000i 1.0000 + 0.0000i
```

Check the class of *B*.

```
class(B)
```

```
ans =
```

```
single
```

## cat

Concatenate arrays along specified dimension

### Syntax

```
C = cat(dim, A, B)
C = cat(dim, A1, A2, A3, A4, ...)
```

### Description

`C = cat(dim, A, B)` concatenates the arrays `A` and `B` along array the dimension specified by `dim`. The `dim` argument must be a real, positive, integer value.

`C = cat(dim, A1, A2, A3, A4, ...)` concatenates all the input arrays (`A1`, `A2`, `A3`, `A4`, and so on) along array dimension `dim`.

For nonempty arrays, `cat(2, A, B)` is the same as `[A, B]`, and `cat(1, A, B)` is the same as `[A; B]`.

If your input arrays are tables, `dim` must be either 1 or 2. `cat` then concatenates by calling `horzcat` or `vertcat` respectively.

### Examples

Given

```
A = B =
 1 5 6
 2 7 8
 3 4
```

concatenating along different dimensions produces

|   |   |
|---|---|
| 1 | 2 |
| 3 | 4 |
| 5 | 6 |
| 7 | 8 |

**C = cat(1,A,B)**

|   |   |   |   |
|---|---|---|---|
| 1 | 2 | 5 | 6 |
| 3 | 4 | 7 | 8 |

**C = cat(2,A,B)**

|   |   |
|---|---|
| 1 | 2 |
| 3 | 4 |

|   |   |
|---|---|
| 5 | 6 |
| 7 | 8 |

**C = cat(3,A,B)**

The commands

```
A = magic(3); B = pascal(3);
C = cat(4, A, B);
```

produce a 3-by-3-by-1-by-2 array.

## More About

### Tips

When used with comma-separated list syntax, `cat(dim, C{:})` or `cat(dim, C.field)` is a convenient way to concatenate a cell or structure array containing numeric matrices into a single matrix.

You can concatenate categorical arrays with cell arrays of strings. For more information, see “Combine Categorical Arrays”.

If all the input arrays are ordinal categorical arrays, they must have the same sets of categories including their order. For more information, see “Ordinal Categorical Arrays”.

You can concatenate datetime arrays with cell arrays of strings.

You can concatenate duration arrays and calendar duration arrays. The result is a calendar duration array.

You can concatenate duration or calendar duration arrays with numeric arrays. Prior to concatenation, MATLAB converts the numeric array to an array of equivalent days using the `days` function.

For information on combining unlike integer types, integers with nonintegers, cell arrays with non-cell arrays, or empty matrices with other elements, see “Valid Combinations of Unlike Classes”

**Introduced before R2006a**

# categorical

Create categorical array

Use `categorical` to create a categorical array from data with values from a finite set of discrete categories. To group numeric data into categories, use `discretize`.

## Syntax

```
B = categorical(A)
B = categorical(A,valueset)
B = categorical(A,valueset,catnames)
B = categorical(A, ___,Name,Value)
```

## Description

`B = categorical(A)` creates a categorical array from the array, `A`. The categories of `B` are the sorted unique values from `A`.

For more information on creating and using categorical arrays, see “Categorical Arrays”.

`B = categorical(A,valueset)` creates one category for each value in `valueset`. The categories of `B` are in the same order as the values of `valueset`.

You can use `valueset` to include categories for values not present in `A`. Conversely, if `A` contains any values not present in `valueset`, the corresponding elements of `B` are undefined.

`B = categorical(A,valueset,catnames)` names the categories in `B` by matching the category values in `valueset` with the names in `catnames`.

`B = categorical(A, ___,Name,Value)` creates a categorical array with additional options specified by one or more `Name,Value` pair arguments. You can include any of the input arguments in previous syntaxes.

For example, you can specify that the categories have a mathematical ordering.

## Examples

### Create Categorical Array from Strings

Convert a cell array of strings to a categorical array.

Create a cell array of strings.

```
A = {'r' 'b' 'g'; 'g' 'r' 'b'; 'b' 'r' 'g'}
```

```
A =
```

```
 'r' 'b' 'g'
 'g' 'r' 'b'
 'b' 'r' 'g'
```

A is a 3-by-3 cell array containing three unique values.

Convert the cell array of strings, A, to a categorical array, B.

```
B = categorical(A)
```

```
B =
```

```
 r b g
 g r b
 b r g
```

The contents of B match the contents of A.

Display the categories of B.

```
categories(B)
```

```
ans =
```

```
 'b'
 'g'
 'r'
```

The categories of B are the unique values from A in alphabetical order.

### Create Categorical Array and Specify Possible Unique Values

Convert a cell array of strings, A, to a categorical array. Specify a list of categories that includes values that are not present in A.

Create a cell array of strings.

```
A = {'republican' 'democrat'; 'democrat' 'democrat'; 'democrat' 'republican'}
```

```
A =
```

```
 'republican' 'democrat'
 'democrat' 'democrat'
 'democrat' 'republican'
```

A is a 3-by-2 cell array containing two unique values.

Convert the cell array of strings, A, to a categorical array, B and include a category for independent.

```
valueset = {'democrat' 'republican' 'independent'}
```

```
B = categorical(A,valueset)
```

```
B =
```

```
 republican democrat
 democrat democrat
 democrat republican
```

The contents of B match the contents of A.

Display the categories of B.

```
categories(B)
```

```
ans =
```

```
 'democrat'
 'republican'
 'independent'
```

The categories of B are in the same order as the values specified in valueset.

### Create Categorical Array and Specify Category Names

Create a cell array of strings.

```
A = {'r' 'b' 'g'; 'g' 'r' 'b'; 'b' 'r' 'g'}
```

```
A =
```

```
'r' 'b' 'g'
'g' 'r' 'b'
'b' 'r' 'g'
```

A is a 3-by-3 cell array containing three unique values.

Convert the cell array of strings, A, to a categorical array, B, and specify category names.

```
B = categorical(A,{'r' 'g' 'b'},{'red' 'green' 'blue'})
```

B =

```
 red blue green
 green red blue
 blue red green
```

B uses the specified category names for the contents from A.

Display the categories of B.

```
categories(B)
```

ans =

```
'red'
'green'
'blue'
```

The categories of B are in the order they were specified.

## Create Categorical Array from Integers

Create a 2-by-3 numeric array.

```
A = gallery('integerdata',3,[2,3],3)
```

A =

```
 2 1 2
 1 1 3
```

A contains the values 1, 2, and 3.

Convert the numeric array, A, to a categorical array. Use the values 1, 2, and 3 to define the categories `car`, `bus`, and `bike`, respectively.

```

valueset = 1:3;
catnames = {'car' 'bus' 'bike'};

B = categorical(A,valueset,catnames)

B =

 bus car bus
 car car bike

```

`categorical` maps the numeric values in `valueset` to the category names in `catnames`.

The 2-by-3 categorical array, `B`, is not ordinal. Therefore, you can only compare the values in `B` for equality. To compare the values in `B` using relational operators, such as less than and greater than, you must include the `'Ordinal'`, `true` name-value pair argument.

### Create Ordinal Categorical Array from Integers

Create a 5-by-2 numeric array.

```

A = gallery('integerdata',3,[5,2],1)

A =

 3 2
 3 3
 3 2
 2 1
 3 2

```

`A` contains the values 1, 2, and 3.

Convert the numeric array, `A`, to an ordinal categorical array where 1, 2, and 3 represent child, adult, and senior respectively.

```

valueset = [1:3];
catnames = {'child' 'adult' 'senior'};

B = categorical(A,valueset,catnames,'Ordinal',true)

B =

```

```
senior adult
senior senior
senior adult
adult child
senior adult
```

Since **B** is ordinal, the categories of **B** have a mathematical ordering, `child < adult < senior`.

### Create Categorical Array by Binning Numeric Data

Use the `discretize` function (instead of `categorical`) to bin 100 random numbers into three categories.

```
x = rand(100,1);
y = discretize(x,[0 .25 .75 1], 'categorical', {'small', 'medium', 'large'});
summary(y)
```

```
small 22
medium 46
large 32
```

## Input Arguments

### A — Input array

numeric array | logical array | categorical array | cell array of strings | ...

Input array, specified as a numeric array, logical array, categorical array, or cell array of strings.

If **A** contains missing values, the corresponding element of **B** is `<undefined>`. Missing values are `NaN` for numeric arrays, the empty string ( `' '` ) for cell arrays of strings, and `<undefined>` for categorical arrays. **B** does not have a category for undefined values. To create an explicit category for missing or undefined values, you must include the desired category name in `catnames`, and `NaN`, the empty string, or `<undefined>` in `valueset`.

In addition to an array, **A** can be an object with the following class methods:

- `unique`
- `eq`

**valueset — Values to define categories**

unique(A) (default) | vector of unique values

Values to define categories, specified as a vector of unique values. The data type of `valueset` and the data type of `A` must be the same.

**catnames — Category names**

cell array of strings

Category names, specified as a cell array of strings. If you do not specify the `catnames` input argument, `categorical` uses the values in `valueset` as category names.

To merge multiple distinct values in `A` into a single category in `B`, include duplicate names corresponding to those values.

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1`, `Value1`, ..., `NameN`, `ValueN`.

Example: `'Ordinal'`, `true` specifies that the categories have a mathematical ordering

**'Ordinal' — Mathematical ordering indicator**

false (default) | true | 0 | 1

Mathematical ordering indicator, specified as the comma-separated pair consisting of `'Ordinal'` and either `false`, `true`, `0`, or `1`.

|                    |                                                                                                                                                                                                                                                                                                                                                                                                         |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>false</code> | <p><code>categorical</code> creates a categorical array that is not ordinal. This is the default behavior.</p> <p>The categories of <code>B</code> have no mathematical ordering. Therefore, you can only compare the values in <code>B</code> for equality.</p>                                                                                                                                        |
| <code>true</code>  | <p><code>categorical</code> creates an ordinal categorical array.</p> <p>The categories of <code>B</code> have a mathematical ordering, such that the first category specified is the smallest and the last category is the largest. You can compare the values in <code>B</code> using relational operators, such as less than and greater than, in addition to comparing the values for equality.</p> |

**'Protected' — Category protection indicator**`false | true | 0 | 1`

Category protection indicator specified as the comma-separated pair consisting of `'Protected'` and either `false`, `true`, `0`, or `1`. The categories of ordinal categorical arrays are always protected. The default value is `true` when you specify `'Ordinal'`, `true` and `false` otherwise.

|                    |                                                                                                                                                                                                                                                                           |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>false</code> | When you assign new values to <code>B</code> , the categories update automatically. Therefore, you can combine (nonordinal) categorical arrays that have different categories. The categories can update accordingly to include the categories from both arrays.          |
| <code>true</code>  | When you assign new values to <code>B</code> , the values must belong to one of the existing categories. Therefore, you can only combine arrays that have the same categories. To add new categories to <code>B</code> , you must use the function <code>addcats</code> . |

## More About

- “Advantages of Using Categorical Arrays”

## See Also

`categories | discretize`**Introduced in R2013b**

# categories

Categories of categorical array

## Syntax

```
C = categories(A)
```

## Description

`C = categories(A)` returns a cell array of strings containing the categories of the categorical array, `A`.

## Examples

### List Categories in Categorical Array

Create a categorical array, `A`.

```
A = categorical({'plane' 'car' 'train' 'car' 'plane'})
```

```
A =
```

```
 plane car train car plane
```

`A` is a 1-by-5 categorical array.

Display the categories of `A`.

```
C = categories(A)
```

```
C =
```

```
 'car'
 'plane'
 'train'
```

Since you created `A` by specifying only an input array, the categories appear in alphabetical order.

## List Categories in Ordinal Categorical Array

Create an ordinal categorical array.

```
A = categorical({'medium' 'large'; 'small' 'xlarge'; 'large' 'medium'},...
 {'small' 'medium' 'large' 'xlarge'},'Ordinal',true)
```

A =

```
 medium large
 small xlarge
 large medium
```

A is a 3-by-2 ordinal categorical array.

Display the categories of A.

```
C = categories(A)
```

C =

```
'small'
'medium'
'large'
'xlarge'
```

The categories appear in the order in which you specified them. Since `A` is ordinal, the categories have the mathematical ordering `small < medium < large < xlarge`.

## Input Arguments

### A — Categorical array

vector | matrix | multidimensional array

Categorical array, specified as a vector, matrix, or multidimensional array.

## More About

### Tips

- `C` includes all categories in `A`, even if `A` does not contain any data from a category. To see the unique values in `A`, use `unique(A)`.
- The order of the categories listed in `C` is the same order used by functions, such as `summary` and `histogram`. To change the order of the categories, use `reordercats`.

## **caxis**

Color axis scaling

### **Syntax**

```
caxis([cmin cmax])
caxis auto
caxis manual
caxis(caxis)
v = caxis
caxis(axes_handle,...)
```

### **Description**

`caxis` controls the mapping of data values to the colormap. It affects any `surface`, `patch`, or `image` with indexed `CData` and `CDataMapping` set to `scaled`. It does not affect surfaces, patches, or images with true color `CData` or with `CDataMapping` set to `direct`.

`caxis([cmin cmax])` sets the color limits to specified minimum and maximum values. Data values less than `cmin` or greater than `cmax` map to `cmin` and `cmax`, respectively. Values between `cmin` and `cmax` linearly map to the current colormap.

`caxis auto` computes the color limits automatically using the minimum and maximum data values. This is the default behavior. Color values set to `Inf` map to the maximum color, and values set to `-Inf` map to the minimum color. Faces or edges with color values set to `NaN` are not drawn.

`caxis manual` and `caxis(caxis)` freeze the color axis scaling at the current limits. This enables subsequent plots to use the same limits when `hold` is `on`.

`v = caxis` returns a two-element row vector containing the `[cmin cmax]` currently in use.

`caxis(axes_handle,...)` uses the axes specified by `axes_handle` instead of the current axes.

`caxis` changes the `CLim` and `CLimMode` properties of axes graphics objects.

## Examples

### Change Color Axis Scaling

Define  $X$ ,  $Y$ , and  $Z$  as data for a sphere and view the data as a surface. Define the colors for the surface,  $C$ .

```
[X,Y,Z] = sphere;
C = Z;
surf(X,Y,Z,C)
```

Values of  $C$  are in the range  $[-1, 1]$ . Values of  $C$  near  $-1$  are assigned the lowest values in the colormap. Values of  $C$  near  $1$  are assigned the highest values in the colormap.

Map the top half of the surface to the highest value in the color table by setting the maximum color limit to 0.

```
caxis([-1,0])
```

Reset the axis scaling back to its default range.

```
caxis auto
```

Return the values of the current color limits.

```
v = caxis
```

```
v =
```

```
 -1 1
```

### Set Color Axis Scaling for Image Data

Load the `cape` file which contains the image data, `X`, and the colormap, `map`, for Cape Cod, Massachusetts.

```
load cape
```

Display the image with `CDataMapping` set to `scaled`, and use the `map` colormap.

```
figure
image(X, 'CDataMapping', 'scaled')
colormap(map)
```

The color limits span the range of the image data, which is 1 to 192. The blue color of the ocean is the first color in the colormap and is mapped to the lowest data value, 1. You can effectively move sea level by changing the lower color limit value using `caxis`.

Display the image data using four different color limit values.

```
load cape
```

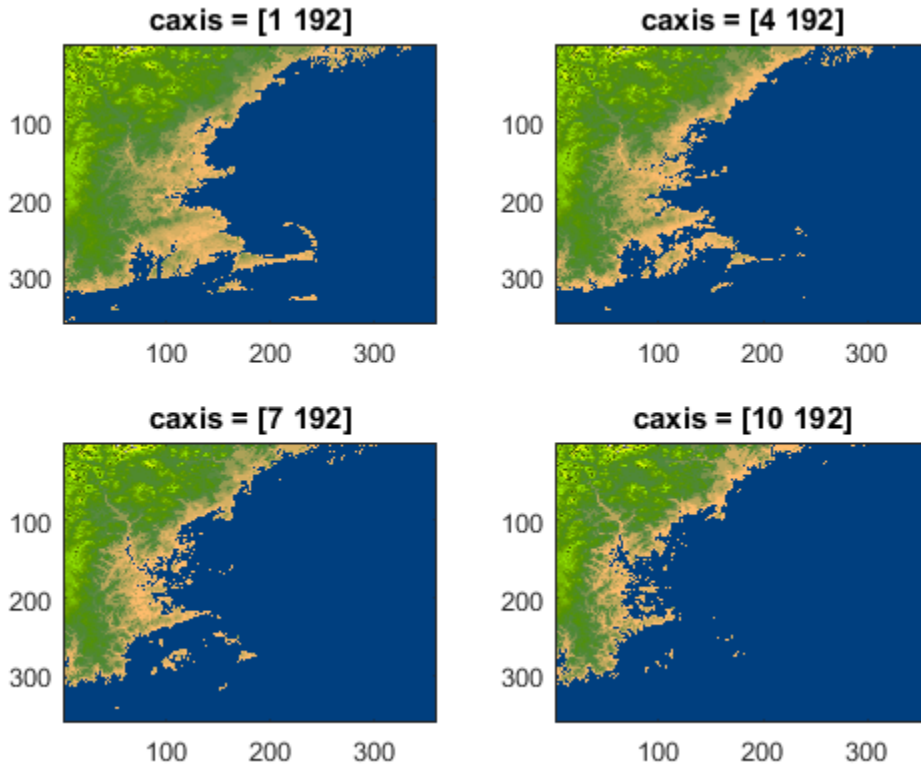

```
figure
colormap(map)

subplot(2,2,1)
image(X,'CDataMapping','scaled')
title('caxis = [1 192]')

subplot(2,2,2)
image(X,'CDataMapping','scaled')
caxis([4,192]) % change caxis
title('caxis = [4 192]')

subplot(2,2,3)
image(X,'CDataMapping','scaled')
caxis([7,192]) % change caxis
title('caxis = [7 192]')

subplot(2,2,4)
image(X,'CDataMapping','scaled')
caxis([10,192]) % change caxis
title('caxis = [10 192]')
```

## More About

### Tips

### How Color Axis Scaling Works

Surface, patch, and image graphics objects having indexed `CData` and `CDataMapping` set to scaled map `CData` values to colors in the figure colormap each time they render. `CData` values equal to or less than `cmin` map to the first color value in the colormap, and `CData` values equal to or greater than `cmax` map to the last color value in the colormap. The following linear transformation is performed on the intermediate values (referred to

as `C` below) to map them to an entry in the colormap (whose length is `m`, and whose row index is referred to as `index` below).

```
index = fix((C-cmin)/(cmax-cmin)*m)+1;
%Clamp values outside the range [1 m]
index(index<1) = 1;
index(index>m) = m;
```

## cd

Change current folder

### Syntax

```
cd(newFolder)
oldFolder = cd(newFolder)
cd
```

### Description

`cd(newFolder)` changes the current folder to `newFolder`.

`oldFolder = cd(newFolder)` returns the existing current folder as a string to `oldFolder`, and then changes the current folder to `newFolder`.

`cd` displays the current folder.

### Input Arguments

#### **newFolder**

A string specifying the folder to which you want to change the current folder. Valid values can be any one of the following:

- A full or relative path.
- `../`, which indicates one level up from the current folder.
- Multiple strings of `../`, which indicates multiple levels up from the current folder.
- `./`, which indicates a path relative to the current folder, although without the `./`, `cd` assumes that the path is relative to the current folder.

## Output Arguments

### **oldFolder**

A string specifying the current folder that was in place when you issued the `cd` command.

## Definitions

The current folder is a reference location that MATLAB uses to find files. This folder is sometimes referred to as the *current directory*, *current working folder*, or *present working directory*.

## Examples

Use `cd` with the `matlabroot` function to change the current folder to the examples directory for the currently running version of MATLAB:

```
cd(fullfile(matlabroot, '/help/techdoc/matlab_env/examples'))
```

On a Microsoft Windows platform, specify the full path to change the current folder from any location to the examples directory for MATLAB Version 7.11 (R2010b), assuming that version is installed on your `C:` drive:

```
cd('C:/Program Files/MATLAB/R2010b/help/techdoc/matlab_env/examples')
```

```
% Change the current folder from
% C:/Program Files/MATLAB/R2010b/help/techdoc/matlab_env/examples to
% C:/Program Files/MATLAB/R2010b/help/techdoc:
```

```
cd ../../
```

```
% Use a relative path to change the current folder from
% C:/Program Files/MATLAB/R2010b/help/techdoc back to
% C:/Program Files/MATLAB/R2010b/help/techdoc/matlab_env/examples:
```

```
cd matlab_env/examples
```

```
% Change the current folder from its current location to a new
% location, but save its previous location. Later, change the
```

```
% current folder to the previous location.

% This returns
% C:/Program Files/MATLAB/R2010b/help/techdoc/matlab_env/examples
% to oldFolder, and then changes the current folder to
% C:/Program Files:

oldFolder = cd('C:/Program Files')

% Display current folder:

pwd

% Change the current folder to the previous location:
cd(oldFolder)

pwd
```

On a UNIX platform, change the current folder to the examples directory for the currently running version of MATLAB, assuming it is installed in your home location:

```
cd('~ /help/techdoc/matlab_env/examples')
```

## More About

### Tips

- When using the command syntax (`cd newFolder`), if the `newFolder` string contains spaces, enclose the string in single quotation marks.
- On UNIX<sup>®</sup> platforms, use the `~` (tilde) character to represent the user home directory.
- If you use `cd` within a local function, the folder change persists after program control returns from the function. That is, the scope of the folder change is global.
- “Specify File Names”
- “Files and Folders that MATLAB Accesses”

# convexHull

**Class:** DelaunayTri

(Not recommended) Convex hull

---

**Note:** `convexHull(DelaunayTri)` is not recommended. Use `convexHull(delaunayTriangulation)` instead.

`DelaunayTri` is not recommended. Use `delaunayTriangulation` instead.

---

## Syntax

`K = convexHull(DT)`  
`[K AV] = convexHull(DT)`

## Description

`K = convexHull(DT)` returns the indices into the array of points `DT.X` that correspond to the vertices of the convex hull.

`[K AV] = convexHull(DT)` returns the convex hull and the area or volume bounded by the convex hull.

## Input Arguments

`DT`            Delaunay triangulation.

## Output Arguments

`K`            If the points lie in 2-D space, `K` is a column vector of length `numf`.  
Otherwise `K` is a matrix of size `numf-by-ndim`, `numf` being the number of

facets in the convex hull, and `ndim` the dimension of the space where the points reside.

AV            The area or volume of the convex hull.

## Definitions

The convex hull of a set of points  $X$  is the smallest convex region containing all of the points of  $X$ .

## Examples

### Example 1

Compute the convex hull of a set of random points located within a unit square in 2-D space.

```
x = rand(10,1)
y = rand(10,1)
dt = DelaunayTri(x,y)
k = convexHull(dt)
plot(dt.X(:,1),dt.X(:,2), '.', 'markersize',10); hold on;
plot(dt.X(k,1),dt.X(k,2), 'r'); hold off;
```

## Example 2

Compute the convex hull of a set of random points located within a unit cube in 3-D space, and the volume bounded by the convex hull.

```
X = rand(25,3)
dt = DelaunayTri(X)
[ch v] = convexHull(dt)
trisurf(ch, dt.X(:,1),dt.X(:,2),dt.X(:,3), 'FaceColor', 'cyan')
```

# cd

**Class:** FTP

Change or view current folder on FTP server

## Syntax

```
cd(ftpobj, folder)
cd(ftpobj)
```

## Description

`cd(ftpobj, folder)` changes the current folder on the FTP server.

`cd(ftpobj)` displays the current folder on the server.

## Input Arguments

### **ftpobj**

FTP object created by `ftp`.

### **folder**

String enclosed in single quotation marks that specifies the target folder. To specify the folder above the current one, use `'..'`.

## Examples

Connect to the National Geophysical Data Center (NGDC) FTP server, change to the `pub` folder, and view its contents:

```
ngdc = ftp('ftp.ngdc.noaa.gov');
cd(ngdc, 'pub');
dir(ngdc)
```

FTP service courtesy of the NGDC. See NGDC Privacy Policy, Disclaimer, and Copyright for NGDC terms of service.

## cdf2rdf

Convert complex diagonal form to real block diagonal form

### Syntax

$[V,D] = \text{cdf2rdf}(V,D)$

### Description

If the eigensystem  $[V,D] = \text{eig}(X)$  has complex eigenvalues appearing in complex-conjugate pairs, `cdf2rdf` transforms the system so  $D$  is in real diagonal form, with 2-by-2 real blocks along the diagonal replacing the complex pairs originally there. The eigenvectors are transformed so that

$$X = V*D/V$$

continues to hold. The individual columns of  $V$  are no longer eigenvectors, but each pair of vectors associated with a 2-by-2 block in  $D$  spans the corresponding invariant vectors.

### Examples

The matrix

$$X = \begin{bmatrix} 1 & 2 & 3 \\ 0 & 4 & 5 \\ 0 & -5 & 4 \end{bmatrix}$$

has a pair of complex eigenvalues.

$$[V,D] = \text{eig}(X)$$

$V =$

$$\begin{bmatrix} 1.0000 & -0.0191 - 0.4002i & -0.0191 + 0.4002i \\ 0 & 0 - 0.6479i & 0 + 0.6479i \\ 0 & 0.6479 & 0.6479 \end{bmatrix}$$

D =

$$\begin{array}{ccc} 1.0000 & 0 & 0 \\ 0 & 4.0000 + 5.0000i & 0 \\ 0 & 0 & 4.0000 - 5.0000i \end{array}$$

Converting this to real block diagonal form produces

[V,D] = cdf2rdf(V,D)

V =

$$\begin{array}{ccc} 1.0000 & -0.0191 & -0.4002 \\ 0 & 0 & -0.6479 \\ 0 & 0.6479 & 0 \end{array}$$

D =

$$\begin{array}{ccc} 1.0000 & 0 & 0 \\ 0 & 4.0000 & 5.0000 \\ 0 & -5.0000 & 4.0000 \end{array}$$

## More About

### Algorithms

The real diagonal form for the eigenvalues is obtained from the complex form using a specially constructed similarity transformation.

## **cdfepoch**

Convert date string or serial date number to CDF formatted dates

### **Syntax**

```
E = cdfepoch(date)
```

### **Description**

`E = cdfepoch(date)` converts the date, specified by `date`, into a `cdfepoch` object. `date` must be a valid date string, returned by `datestr`, or a serial date number, returned by `datenum`. `date` can also be a `cdfepoch` object.

When writing data to a CDF file using `cdfwrite`, use `cdfepoch` to convert MATLAB date strings or serial date numbers to CDF formatted dates. The MATLAB `cdfepoch` object simulates the `CDFEPOCH` data type in CDF files.

To convert a `cdfepoch` object into a MATLAB serial date number, use the `todatenum` function.

### **Definitions**

The MATLAB serial date number calculates dates differently than CDF epochs.

A MATLAB serial date number represents the whole and fractional number of days from 0-Jan-0000 to a specific date. The year 0000 is merely a reference point and is not intended to be interpreted as a real year in time.

A CDF epoch is the number of milliseconds since 1-Jan-0000.

### **Examples**

Convert the current time in serial date number format into a CDF epoch object.

```
% NOW function returns current time as serial date number
```

```
dateobj = cdfepoch(now)
```

```
dateobj =
```

```
 cdfepoch object:
 11-Mar-2009 15:09:25
```

Convert the current time in date string format into a CDF epoch object.

```
% DATESTR function returns date as string
dateobj2 = cdfepoch(datestr(now))
```

```
dateobj2 =
```

```
 cdfepoch object:
 11-Mar-2009 15:09:25
```

Convert the CDF epoch object into a serial date number.

```
dateobj = cdfepoch(now);
mydatenum = todatenum(dateobj)
```

```
mydatenum =
```

```
 7.3384e+005
```

# cdfinfo

Information about Common Data Format (CDF) file

## Syntax

```
info = cdfinfo(filename)
```

## Description

`info = cdfinfo(filename)` returns information about the Common Data Format (CDF) file specified in the string `filename`.

---

**Note** Because `cdfinfo` creates temporary files, the current working directory must be writeable.

---

The following table lists the fields returned in the structure, `info`. The table lists the fields in the order that they appear in the structure.

| Field         | Description                                                                                                                                                   |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Filename      | Text string specifying the name of the file                                                                                                                   |
| FileModDate   | Text string indicating the date the file was last modified                                                                                                    |
| FileSize      | Double scalar specifying the size of the file, in bytes                                                                                                       |
| Format        | Text string specifying the file format                                                                                                                        |
| FormatVersion | Text string specifying the version of the CDF library used to create the file                                                                                 |
| FileSettings  | Structure array containing library settings used to create the file                                                                                           |
| Subfiles      | Filenames containing the CDF file's data, if it is a multi-file format CDF                                                                                    |
| Variables     | N-by-6 cell array, where N is the number of variables, containing information about the variables in the file. The columns present the following information: |

| Field              | Description                                                                                                                                                                                                                                                                                                                                                                         |                                                                                                                                                                                                                                                                                                                                                                                                                            |

|                    | Column 3                                                                                                                                                                                                                                                                                                                                                                            | Double scalar specifying the number of records assigned for the variable                                                                                                                                                                                                                                                                                                                                                   |
|                    | Column 4                                                                                                                                                                                                                                                                                                                                                                            | Text string specifying the data type of the variable, as stored in the CDF file                                                                                                                                                                                                                                                                                                                                            |
|                    | Column 5                                                                                                                                                                                                                                                                                                                                                                            | <p>Text string specifying the record and dimension variance settings for the variable. The single T or F to the left of the slash designates whether values vary by record. The zero or more T or F letters to the right of the slash designate whether values vary at each dimension. Here are some examples.</p> <p>T/ (scalar variable)<br/> F/T (one-dimensional variable)<br/> T/TFF (three-dimensional variable)</p> |
| GlobalAttributes   | Structure array that contains one field for each global attribute. The name of each field corresponds to the name of an attribute. The data in each field, contained in a cell array, represents the entry values for that attribute.                                                                                                                                               |                                                                                                                                                                                                                                                                                                                                                                                                                            |
| VariableAttributes | Structure array that contains one field for each variable attribute. The name of each field corresponds to the name of an attribute. The data in each field is contained in a $n$ -by-2 cell array, where $n$ is the number of variables. The first column of this cell array contains the variable names associated with the entries. The second column contains the entry values. |                                                                                                                                                                                                                                                                                                                                                                                                                            |

**Note** Attribute names returned by `cdfinfo` might not match the names of the attributes in the CDF file exactly. Attribute names can contain characters that are illegal in MATLAB field names. `cdfinfo` removes illegal characters that appear at the beginning of attributes and replaces other illegal characters with underscores ('\_'). When `cdfinfo` modifies an attribute name, it appends the attribute's internal number to the end

of the field name. For example, the attribute name `Variable%Attribute` becomes `Variable_Attribute_013`.

---

**Note:** To improve performance, turn off the file validation which the CDF library does by default when opening files. For more information, see `cdflib.setValidate`.

---

## Examples

### Get Information About CDF File

Get information about the sample file, `example.cdf`.

```
info = cdfinfo('example.cdf')
```

```
info =
```

```

 Filename: 'example.cdf'
 FileModDate: '10-May-2010 21:35:00'
 FileSize: 1310
 Format: 'CDF'
 FormatVersion: '2.7.0'
 FileSettings: [1x1 struct]
 Subfiles: {}
 Variables: {6x6 cell}
 GlobalAttributes: [1x1 struct]
 VariableAttributes: [1x1 struct]
```

View information about the variables in the file.

```
info.Variables
```

```
ans =
```

```

**Introduced before R2006a**

# cdflib

Interact directly with CDF library

## Description

MATLAB provides direct access to dozens of functions in the CDF library. Using these functions, you can read and write data, create variables, attributes, and entries, and take advantage of other features of the CDF library. To use these functions, you must be familiar with the CDF C interface. Documentation about CDF is available at the CDF website.

The MATLAB functions correspond to functions in the CDF library new Standard Interface. In most cases, the syntax of a MATLAB function is similar to the syntax of the corresponding CDF library function. To use these functions, you must prefix the function name with the package name, `cdflib`. For example, to use the CDF library function to open an existing CDF file, use this syntax:

```
cdfid = cdflib.open('example.cdf');
```

MATLAB supports CDF version 3.3.0. For copyright information, see the `cdfcopyright.txt` file.

The following tables list all of the functions in the MATLAB CDF library package, grouped by category.

---

**Note:** For information about MATLAB support for the Network Common Data Form (netCDF), which is a completely separate, incompatible format, see `netcdf`.

## Library Information

|                                      |                                                                          |
|--------------------------------------|--------------------------------------------------------------------------|
| <code>cdflib.getConstantNames</code> | Names of Common Data Format (CDF) library constants                      |
| <code>cdflib.getConstantValue</code> | Numeric value corresponding to Common Data Format (CDF) library constant |
| <code>cdflib.getFileBackward</code>  | Return current backward compatibility mode setting                       |

|                                         |                                                      |
|-----------------------------------------|------------------------------------------------------|
| <code>cdflib.getLibraryCopyright</code> | Copyright notice of Common Data Format (CDF) library |
| <code>cdflib.getLibraryVersion</code>   | Library version and release information              |
| <code>cdflib.getValidate</code>         | Library validation mode                              |
| <code>cdflib.setFileBackward</code>     | Set backward compatibility mode                      |
| <code>cdflib.setValidate</code>         | Specify library validation mode                      |

## **File Operations**

|                                             |                                                                  |
|---------------------------------------------|------------------------------------------------------------------|
| <code>cdflib.close</code>                   | Close Common Data Format (CDF) file                              |
| <code>cdflib.create</code>                  | Create Common Data Format (CDF) file                             |
| <code>cdflib.delete</code>                  | Delete existing Common Data Format (CDF) file                    |
| <code>cdflib.getCacheSize</code>            | Number of cache buffers used                                     |
| <code>cdflib.getChecksum</code>             | Checksum mode                                                    |
| <code>cdflib.getCompression</code>          | Compression settings                                             |
| <code>cdflib.getCompressionCacheSize</code> | Number of compression cache buffers                              |
| <code>cdflib.getCopyright</code>            | Copyright notice in Common Data Format (CDF) file                |
| <code>cdflib.getFormat</code>               | Format of Common Data Format (CDF) file                          |
| <code>cdflib.getMajority</code>             | Majority of variables                                            |
| <code>cdflib.getName</code>                 | Name of Common Data Format (CDF) file                            |
| <code>cdflib.getReadOnlyMode</code>         | Read-only mode                                                   |
| <code>cdflib.getStageCacheSize</code>       | Number of cache buffers for staging                              |
| <code>cdflib.getVersion</code>              | Common Data Format (CDF) library version and release information |
| <code>cdflib.inquire</code>                 | Basic characteristics of Common Data Format (CDF) file           |
| <code>cdflib.open</code>                    | Open existing Common Data Format (CDF) file                      |
| <code>cdflib.setCacheSize</code>            | Specify number of dotCDF cache buffers                           |
| <code>cdflib.setChecksum</code>             | Specify checksum mode                                            |

|                                             |                                                                           |
|---------------------------------------------|---------------------------------------------------------------------------|
| <code>cdflib.setCompression</code>          | Specify compression settings                                              |
| <code>cdflib.setCompressionCacheSize</code> | Specify number of compression cache buffers                               |
| <code>cdflib.setFormat</code>               | Specify format of Common Data Format (CDF) file                           |
| <code>cdflib.setMajority</code>             | Specify majority of variables                                             |
| <code>cdflib.setReadOnlyMode</code>         | Specify read-only mode                                                    |
| <code>cdflib.setStageCacheSize</code>       | Specify number of staging cache buffers for Common Data Format (CDF) file |

|                                             |                                                                              |
|---------------------------------------------|------------------------------------------------------------------------------|
| <code>cdflib.closeVar</code>                | Close specified variable from multifile format Common Data Format (CDF) file |
| <code>cdflib.createVar</code>               | Create new variable                                                          |
| <code>cdflib.deleteVar</code>               | Delete variable                                                              |
| <code>cdflib.deleteVarRecords</code>        | Delete range of records from variable                                        |
| <code>cdflib.getVarAllocRecords</code>      | Number of records allocated for variable                                     |
| <code>cdflib.getVarBlockingFactor</code>    | Blocking factor for variable                                                 |
| <code>cdflib.getVarCacheSize</code>         | Number of multifile cache buffers                                            |
| <code>cdflib.getVarCompression</code>       | Information about compression used by variable                               |
| <code>cdflib.getVarData</code>              | Single value from record in variable                                         |
| <code>cdflib.getVarMaxAllocRecNum</code>    | Maximum allocated record number for variable                                 |
| <code>cdflib.getVarMaxWrittenRecNum</code>  | Maximum written record number for variable                                   |
| <code>cdflib.getVarsMaxWrittenRecNum</code> | Maximum written record number for CDF file                                   |
| <code>cdflib.getVarName</code>              | Variable name, given variable number                                         |
| <code>cdflib.getVarNum</code>               | Variable number, given variable name                                         |
| <code>cdflib.getVarNumRecsWritten</code>    | Number of records written to variable                                        |

|                                             |                                                         |
|---------------------------------------------|---------------------------------------------------------|
| <code>cdflib.getVarPadValue</code>          | Pad value for variable                                  |
| <code>cdflib.getVarRecordData</code>        | Entire record for variable                              |
| <code>cdflib.getVarReservePercent</code>    | Compression reserve percentage for variable             |
| <code>cdflib.getVarSparseRecords</code>     | Information about how variable handles sparse records   |
| <code>cdflib.hyperGetVarData</code>         | Read hyperslab of data from variable                    |
| <code>cdflib.hyperPutVarData</code>         | Write hyperslab of data to variable                     |
| <code>cdflib.inquireVar</code>              | Information about variable                              |
| <code>cdflib.putVarData</code>              | Write single value to variable                          |
| <code>cdflib.putVarRecordData</code>        | Write entire record to variable                         |
| <code>cdflib.renameVar</code>               | Rename existing variable                                |
| <code>cdflib.setVarAllocBlockRecords</code> | Specify range of records to be allocated for variable   |
| <code>cdflib.setVarBlockingFactor</code>    | Specify blocking factor for variable                    |
| <code>cdflib.setVarCacheSize</code>         | Specify number of multi-file cache buffers for variable |
| <code>cdflib.setVarCompression</code>       | Specify compression settings used with variable         |
| <code>cdflib.setVarInitialRecs</code>       | Specify initial number of records written to variable   |
| <code>cdflib.setVarPadValue</code>          | Specify pad value used with variable                    |
| <code>cdflib.SetVarReservePercent</code>    | Specify reserve percentage for variable                 |
| <code>cdflib.setVarsCacheSize</code>        | Specify number of cache buffers used for all variables  |
| <code>cdflib.setVarSparseRecords</code>     | Specify how variable handles sparse records             |

## Attributes

|                                |                  |
|--------------------------------|------------------|
| <code>cdflib.createAttr</code> | Create attribute |
| <code>cdflib.deleteAttr</code> | Delete attribute |

|                                        |                                                          |
|----------------------------------------|----------------------------------------------------------|
| <code>cdflib.deleteAttrEntry</code>    | Delete attribute entry                                   |
| <code>cdflib.deleteAttrgEntry</code>   | Delete entry in global attribute                         |
| <code>cdflib.getAttrEntry</code>       | Value of entry in attribute with variable scope          |
| <code>cdflib.getAttrgEntry</code>      | Value of entry in global attribute                       |
| <code>cdflib.getAttrMaxEntry</code>    | Number of last entry for variable attribute              |
| <code>cdflib.getAttrMaxgEntry</code>   | Number of last entry for global attribute                |
| <code>cdflib.getAttrName</code>        | Name of attribute, given attribute number                |
| <code>cdflib.getAttrNum</code>         | Attribute number, given attribute name                   |
| <code>cdflib.getAttrScope</code>       | Scope of attribute                                       |
| <code>cdflib.getNumAttrEntries</code>  | Number of entries for attribute with variable scope      |
| <code>cdflib.getNumAttrgEntries</code> | Number of entries for attribute with global scope        |
| <code>cdflib.getNumAttributes</code>   | Number of attributes with variable scope                 |
| <code>cdflib.getNumgAttributes</code>  | Number of attributes with global scope                   |
| <code>cdflib.inquireAttr</code>        | Information about attribute                              |
| <code>cdflib.inquireAttrEntry</code>   | Information about entry in attribute with variable scope |
| <code>cdflib.inquireAttrgEntry</code>  | Information about entry in attribute with global scope   |
| <code>cdflib.putAttrEntry</code>       | Write value to entry in attribute with variable scope    |
| <code>cdflib.putAttrgEntry</code>      | Write value to entry in attribute with global scope      |
| <code>cdflib.renameAttr</code>         | Rename existing attribute                                |

## Utility Functions

|                                      |                                         |
|--------------------------------------|-----------------------------------------|
| <code>cdflib.computeEpoch</code>     | Convert time value to CDF_EPOCH value   |
| <code>cdflib.computeEpoch16</code>   | Convert time value to CDF_EPOCH16 value |
| <code>cdflib.epoch16Breakdown</code> | Convert CDF_EPOCH16 value to time value |

`cdflib.epochBreakdown`

Convert CDF\_EPOCH value into time value

## **cdflib.close**

Close Common Data Format (CDF) file

### **Syntax**

```
cdflib.close(cdfId)
```

### **Description**

`cdflib.close(cdfId)` closes the specified CDF file. `cdfId` identifies the CDF file.

You must close a CDF to guarantee that all modifications you made since opening the CDF are actually written to the file.

### **Examples**

Open the example CDF file and then close it.

```
cdfid = cdflib.open('example.cdf');
cdflib.close(cdfid)
```

### **References**

This function corresponds to the CDF library C API routine `CDFcloseCDF`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

### **See Also**

`cdflib.open` | `cdflib.create`

## **cdflib.closeVar**

Close specified variable from multifile format Common Data Format (CDF) file

### **Syntax**

```
cdflib.closeVar(cdfId, varNum)
```

### **Description**

`cdflib.closeVar(cdfId, varNum)` closes a variable in a multifile format CDF.

`cdfId` identifies the CDF file and `varNum` is a numeric value that specifies the variable. Variable identifiers (variable numbers) are zero-based.

For multifile CDFs, you must close all open variable files to guarantee that all modifications you have made are actually written to the CDF file(s). You do not need to call this function for variables in a single-file format CDF.

### **Examples**

Create a multifile CDF, create a variable, and then close the variable. To run this example, you must be in a writable folder.

```
cdfid = cdflib.create('your_multifile.cdf');

% Make it a multifile format CDF
cdflib.setFormat(cdfid, 'MULTI_FILE')

% Create a variable in the CDF.
varNum = cdflib.createVar(cdfid, 'Time', 'cdf_int1', 1, [], true, []);

% Close the variable.
cdflib.closeVar(cdfid, varnum)

% Clean up
cdflib.delete(cdfid)
clear cdfid
```

## References

This function corresponds to the CDF library C API routine `CDFclosezVar`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

## **cdflib.computeEpoch**

Convert time value to CDF\_EPOCH value

### **Syntax**

```
epoch = cdflib.computeEpoch(timeval)
```

### **Description**

`epoch = cdflib.computeEpoch(timeval)` converts the time value specified by `timeval` into a CDF\_EPOCH value.

### **Input Arguments**

#### **timeval**

7-by-1 time vector. The following table describes the time components.

| <b>Component</b> | <b>Description</b> |
|------------------|--------------------|
| year             | AD e.g. 1994       |
| month            | 1–12               |
| day              | 1–31               |
| hour             | 0–23               |
| minute           | 0–59               |
| second           | 0–59               |
| millisecond      | 0–999              |

### **Output Arguments**

#### **epoch**

MATLAB double representing a CDF\_EPOCH time value.

## Examples

Convert a time value into a CDF\_EPOCH value.

```
timeval = [1999 12 31 23 59 59 0];
epoch = cdflib.computeEpoch(timeval);
```

## References

This function corresponds to the CDF library C API routine `computeEPOCH`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

## See Also

`cdflib.epoch16Breakdown`

## **cdflib.computeEpoch16**

Convert time value to CDF\_EPOCH16 value

### **Syntax**

```
epoch16 = cdflib.computeEpoch16(timeval)
```

### **Description**

`epoch16 = cdflib.computeEpoch16(timeval)` converts the time value specified by `timeval` into a CDF\_EPOCH16 value.

### **Input Arguments**

#### **timeval**

10-by-1 time vector. The following table describes the time components. To specify multiple time values, use additional columns.

| <b>Component</b> | <b>Description</b> |
|------------------|--------------------|
| year             | AD e.g. 1994       |
| month            | 1–12               |
| day              | 1–31               |
| hour             | 0–23               |
| minute           | 0–59               |
| second           | 0–59               |
| millisecond      | 0–999              |
| microsecond      | 0–999              |
| nanosecond       | 0–999              |
| picosecond       | 0–999              |

## Output Arguments

### **epoch16**

CDF Epoch16 time value. If the input argument `timeval` has `m-by-10` elements, the return value `epoch16` will have size `2-by-m`

## Examples

Convert the time value into an `CDF_EPOCH16` value:

```
timeval = [1999; 12; 31; 23; 59; 59; 50; 100; 500; 999];
epoch16 = cdflib.computeEpoch16(timeval);
```

## References

This function corresponds to the CDF library C API routine `computeEPOCH16`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

## See Also

`cdflib.computeEpoch` | `cdflib.epochBreakdown` | `cdflib.epoch16Breakdown`

## cdflib.create

Create Common Data Format (CDF) file

### Syntax

```
cdfId = cdflib.create(filename)
```

### Description

`cdfId = cdflib.create(filename)` creates a new CDF file with the name specified by the text string *filename*. Returns the CDF file identifier `cdfId`.

### Examples

Create a CDF file. To run this example, you must have write permission in your current directory.

```
cdfId = cdflib.create('myfile.cdf');

% Clean up
cdflib.delete(cdfId);

clear cdfId
```

### References

This function corresponds to the CDF library C API routine `CDFcreateCDF`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

### See Also

`cdflib.open` | `cdflib.close`

# **cdflib.createAttr**

Create attribute

## **Syntax**

```
attrnum = cdflib.createAttr(cdfId,attrName,scope)
```

## **Description**

`attrnum = cdflib.createAttr(cdfId,attrName,scope)` creates an attribute in a CDF file with the specified scope.

## **Input Arguments**

### **cdfId**

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

### **attrName**

Text string that specifies the name you want to assign to the attribute.

### **scope**

One of the following text strings, or its numeric equivalent, that specifies the scope of the attribute.

| <b>Text String</b> | <b>Description</b>                       |
|--------------------|------------------------------------------|
| 'global_scope'     | Attribute applies to the CDF as a whole. |
| 'variable_scope'   | Attribute applies only to the variable   |

To get the numeric equivalent of these text string constants, use the `cdflib.getConstantValue` function.

## Output Arguments

### **attrNum**

Numeric value identifying the attribute. Attribute numbers are zero-based.

## Examples

Create a CDF, and then create an attribute in the CDF. To run this example, you must be in a writable folder.

```
cdfid = cdflib.create('your_file.cdf');

% Create attribute
attrNum = cdflib.createAttr(cdfid, 'Purpose', 'global_scope');

% Clean up
cdflib.delete(cdfid);

clear cdfid
```

## References

This function corresponds to the CDF library C API routine `CDFcreateAttr`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

### **See Also**

`cdflib.getAttrNum` | `cdflib.deleteAttr` | `cdflib.getConstantValue` | `cdflib.getConstantNames`

## **cdflib.createVar**

Create new variable

### **Syntax**

```
varnum = cdflib.createVar(cdfId, varname, datatype, numElements,
dims, recVariance, dimVariance)
```

### **Description**

`varnum = cdflib.createVar(cdfId, varname, datatype, numElements, dims, recVariance, dimVariance)` creates a new variable in the Common Data Format (CDF) file with the specified characteristics.

### **Input Arguments**

#### **cdfId**

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

#### **varname**

Text string that specifies the name you want to assign to the variable.

#### **datatype**

Data type of the variable. One of the following text strings, or its numeric equivalent, that specifies a valid CDF data type.

| <b>CDF Data Type</b> | <b>Description</b>                                                                    |
|----------------------|---------------------------------------------------------------------------------------|
| CDF_BYTE             | 1-byte, signed integer                                                                |
| CDF_CHAR             | 1 byte, signed character data type that maps to the MATLAB <code>char</code> class    |
| CDF_INT1             | 1-byte, signed integer                                                                |
| CDF_UCHAR            | 1 byte, unsigned character data type that maps to the MATLAB <code>uint8</code> class |

| <b>CDF Data Type</b> | <b>Description</b>         |
|----------------------|----------------------------|
| CDF_UINT1            | 1-byte, unsigned integer   |
| CDF_INT2             | 2-byte, signed integer     |
| CDF_UINT2            | 2-byte, unsigned integer   |
| CDF_INT4             | 4-byte, signed integer     |
| CDF_UINT4            | 4-byte, unsigned integer   |
| CDF_FLOAT            | 4-byte, floating point     |
| CDF_REAL4            | 4-byte, floating point     |
| CDF_REAL8            | 8-byte, floating point.    |
| CDF_DOUBLE           | 8-byte, floating point     |
| CDF_EPOCH            | 8-byte, floating point     |
| CDF_EPOCH16          | two 8-byte, floating point |

**numElements**

Number of elements per datum. Value should be 1 for all data types, except CDF\_CHAR and CDF\_UCHAR.

**dims**

A vector of the dimensions extents; empty if there are no dimension extents.

**recVariance**

Specifies record variance: `true` or `false`.

**dimVariance**

A vector of logicals; empty if there are no dimensions.

## Output Arguments

**varNum**

The numeric identifier for the variable. Variable numbers are zero-based.

## Examples

Create a CDF file and then create a variable named 'Time' in the CDF. The variable has no dimensions and varies across records. To run this example, you must be in a writable folder.

```
cdfid = cdfplib.create('your_file.cdf');

% Initially the file contains no variables.
info = cdfplib.inquire(cdfid)

info =

 encoding: 'IBMPC_ENCODING'
 majority: 'ROW_MAJOR'
 maxRec: -1
 numVars: 0
 numvAttrs: 0
 numgAttrs: 0

% Create a variable in the file.
varNum = cdfplib.createVar(cdfid, 'Time', 'cdf_int1', 1, [], true, []);

% Retrieve info about the file again to verify variable was created.
% Note value of numVars field is now 1.
info = cdfplib.inquire(cdfid)

info =

 encoding: 'IBMPC_ENCODING'
 majority: 'ROW_MAJOR'
 maxRec: -1
 numVars: 1
 numvAttrs: 0
 numgAttrs: 0

% Clean up
cdfplib.delete(cdfid);

clear cdfid
```

## References

This function corresponds to the CDF library C API routine `CDFcreatezVar`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

## See Also

`cdflib.deleteVar` | `cdflib.closeVar`

## **cdflib.delete**

Delete existing Common Data Format (CDF) file

### **Syntax**

```
cdflib.delete(cdfId)
```

### **Description**

`cdflib.delete(cdfId)` deletes the existing CDF file specified by the identifier `cdfId`. If the CDF file is a multi-file format CDF, the `cdflib.delete` function also deletes the variable files (having file extensions of `.z0`, `.z1`, etc.).

### **Examples**

Create a CDF file, and then delete it. To run this example, you must be in a writable folder.

```
cdfId = cdflib.create('mytempfile.cdf');
```

```
% Verify that the file was created.
ls *.cdf
```

```
mytempfile.cdf
```

```
% Delete the file.
cdflib.delete(cdfId)
```

```
% Verify that the file no longer exists.
ls *.cdf
```

### **References**

This function corresponds to the CDF library C API routine `CDFdeleteCDF`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

## **See Also**

`cdflib.create` | `cdflib.setFormat`

# **cdflib.deleteAttr**

Delete attribute

## **Syntax**

```
cdflib.deleteAttr(cdfId,attrNum)
```

## **Description**

`cdflib.deleteAttr(cdfId,attrNum)` deletes the specified attribute from the CDF file.

`cdfId` identifies the Common Data Format (CDF) file.`attrNum` is a numeric identifier that specifies the attribute. Attribute numbers are zero-based.

## **Examples**

Create a CDF file, and then create an attribute in the file. Then delete the attribute. To run this example, you must be in a writable folder.

```
cdfid = cdflib.create('your_file.cdf');

% Create attribute.
attrNum = cdflib.createAttr(cdfid,'Purpose','global_scope');

% Prove it exists.
anum = cdflib.getAttrNum(cdfid,'Purpose')

anum =

 0

% Delete the attribute.
cdflib.deleteAttr(cdfid,attrNum);

% Clean up
```

```
cdflib.delete(cdfid);
clear cdfid
```

## References

# **cdflib.deleteAttrEntry**

Delete attribute entry

## **Syntax**

```
cdflib.deleteAttrEntry(cdfId, attrNum, entryNum)
```

## **Description**

`cdflib.deleteAttrEntry(cdfId, attrNum, entryNum)` deletes an entry from an attribute in a Common Data Format (CDF) file.

## **Input Arguments**

### **`cdfId`**

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

### **`attrNum`**

Numeric value that identifies the attribute. Attribute numbers are zero-based. The attribute must have variable scope.

### **`entryNum`**

Numeric value that specifies the entry in the attribute. Entry numbers are zero-based.

## **Examples**

Create a CDF, and then create an attribute in the file. Write a value to an entry for the attribute, and then delete the entry. To run this example, you must be in a writable folder.

```
cdfid = cdflib.create('your_file.cdf');
```

```
% Initially the file contains no attributes, global or variable.
info = cdfplib.inquire(cdfid)

info =

 encoding: 'IBMPC_ENCODING'
 majority: 'ROW_MAJOR'
 maxRec: -1
 numVars: 0
 numVAttrs: 0
 numGAttrs: 0

% Create an attribute with variable scope in the file.
attrNum = cdfplib.createAttr(cdfid,'my_var_scope_attr','variable_scope');

% Write a value to an entry for the attribute
cdfplib.putAttrEntry(cdfid,attrNum,0,'CDF_CHAR','My attr value');

% Get the value of the attribute entry
value = cdfplib.getAttrEntry(cdfid,attrNum,0)

value =

My attr value

% Delete the entry
cdfplib.deleteAttrEntry(cdfid,attrNum,0);

% Now try to view the value of the entry
% Should return NO_SUCH_ENTRY failure.
value = cdfplib.getAttrEntry(cdfid,attrNum,0) % Should fail

% Clean up
cdfplib.delete(cdfid);

clear cdfid
```

## References

# **cdflib.deleteAttrgEntry**

Delete entry in global attribute

## **Syntax**

```
cdflib.deleteAttrgEntry(cdfId, attrNum, entryNum)
```

## **Description**

`cdflib.deleteAttrgEntry(cdfId, attrNum, entryNum)` deletes an entry from a global attribute in a Common Data Format (CDF) file.

## **Input Arguments**

### **cdfId**

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

### **attrNum**

Numeric value that identifies the attribute. Attribute numbers are zero-based. The attribute must have global scope.

### **entryNum**

Numeric value that specifies the entry in the attribute. Entry numbers are zero-based.

## **Examples**

Create a CDF and create a global attribute in the file. Write a value to an entry for the attribute and then delete the entry. To run this example, you must be in a writable folder.

```
cdfid = cdflib.create('your_file.cdf');
```

```
% Initially the file contains no attributes, global or variable.
info = cdfplib.inquire(cdfid)

info =

 encoding: 'IBMPC_ENCODING'
 majority: 'ROW_MAJOR'
 maxRec: -1
 numVars: 0
 numVAttrs: 0
 numGAttrs: 0

% Create an attribute with global scope in the file.
attrNum = cdfplib.createAttr(cdfid,'my_global_attr','global_scope');

% Write a value to an entry for the attribute
cdfplib.putAttrgEntry(cdfid,attrNum,0,'CDF_CHAR','My global attr');

% Get the value of the global attribute entry
value = cdfplib.getAttrgEntry(cdfid,attrNum,0)

value =

My global attr

% Delete the entry
cdfplib.deleteAttrgEntry(cdfid,attrNum,0);

% Now try to view the value of the entry
% Should return NO_SUCH_ENTRY failure.
value = cdfplib.getAttrgEntry(cdfid,attrNum,0) % Should fail

% Clean up
cdfplib.delete(cdfid);

clear cdfid
```

# **cdflib.deleteVar**

Delete variable

## **Syntax**

```
cdflib.deleteVar(cdfId,varNum)
```

## **Description**

`cdflib.deleteVar(cdfId,varNum)` deletes a variable from a Common Data Format (CDF) file.

`cdfId` identifies the CDF file. `varNum` is a numeric value that specifies the variable. Variable numbers are zero-based.

## **Examples**

Create a CDF, create a variable in the CDF, and then delete it.

```
cdfid = cdflib.create('mycdf.cdf');

% Initially the file contains no variables.
info = cdflib.inquire(cdfid)

info =

 encoding: 'IBMPC_ENCODING'
 majority: 'ROW_MAJOR'
 maxRec: -1
 numVars: 0
 numvAttrs: 0
 numgAttrs: 0

% Create a variable in the CDF.
varNum = cdflib.createVar(cdfid,'Time','cdf_int1',1,[],true,[]);
```

```
% Retrieve info about the variable in the CDF.

info = cdfplib.inquireVar(cdfid, 0)

info =

 name: 'Time'
 datatype: 'cdf_int1'
 numElements: 1
 dims: []
 recVariance: 1
 dimVariance: []

% Delete the variable from the CDF

cdfplib.deleteVar(cdfid,0);

% Check to see if the variable was deleted from the CDF.
info = cdfplib.inquire(cdfid)

info =

 encoding: 'IBMPC_ENCODING'
 majority: 'ROW_MAJOR'
 maxRec: -1
 numVars: 0
 numvAttrs: 0
 numgAttrs: 0

% Clean up
cdfplib.delete(cdfid);

clear cdfid
```

cdflib.createVar

## **cdflib.deleteVarRecords**

Delete range of records from variable

### **Syntax**

```
cdflib.deleteVarRecords(cdfId, varNum, startRec, endRec)
```

### **Description**

`cdflib.deleteVarRecords(cdfId, varNum, startRec, endRec)` deletes a range of records from a variable in a Common Data Format (CDF) file.

### **Input Arguments**

#### **cdfId**

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

#### **varNum**

Numeric value that identifies the variable. Variable numbers are zero-based.

#### **startRec**

Numeric value that specifies the record at which to start deleting records. Record numbers are zero-based.

#### **endRec**

Numeric value that specifies the record at which to stop deleting records. Record numbers are zero-based.

### **Examples**

Make a writable copy of the example CDF, get the number of a variable in the CDF, and delete specific records in the variable. To run this example, you must be in a writable folder.

```
srcFile = fullfile(matlabroot,'toolbox','matlab','demos','example.cdf');
copyfile(srcFile,'myfile.cdf');
fileattrib('myfile.cdf','+w');
cdfid = cdflib.open('myfile.cdf');
varnum = cdflib.getVarNum(cdfid,'Temperature');
cdflib.deleteVarRecords(cdfid,varnum,1,2);
cdflib.close(cdfid);
```

## References

## cdflib.epoch16Breakdown

Convert CDF\_EPOCH16 value to time value

### Syntax

```
timeVec = cdflib.epoch16Breakdown(epoch16Time)
```

### Description

`timeVec = cdflib.epoch16Breakdown(epoch16Time)` convert a CDF\_EPOCH16 value into a time vector. `timeVec` will have 10-by-*n* elements, where *n* is the number of CDF\_EPOCH16 values.

The following table describes the time value components.

| <b>timeVec Element</b>     | <b>Description</b> | <b>Valid Values</b> |
|----------------------------|--------------------|---------------------|
| <code>timeVec(1,:)</code>  | Year AD            | e.g. 1994           |
| <code>timeVec(2,:)</code>  | Month              | 1–12                |
| <code>timeVec(3,:)</code>  | Day                | 1–31                |
| <code>timeVec(4,:)</code>  | Hour               | 0–23                |
| <code>timeVec(5,:)</code>  | Minute             | 0–59                |
| <code>timeVec(6,:)</code>  | Second             | 0–59                |
| <code>timeVec(7,:)</code>  | Millisecond        | 0–999               |
| <code>timeVec(8,:)</code>  | Microsecond        | 0–999               |
| <code>timeVec(9,:)</code>  | Nanosecond         | 0–999               |
| <code>timeVec(10,:)</code> | Picosecond         | 0–999               |

### Examples

Convert CDF\_EPOCH16 value into time value.

```
timeval = [1999; 12; 31; 23; 59; 59; 50; 100; 500; 999];
epoch16 = cdflib.computeEpoch16(timeval);

timevec = cdflib.epoch16Breakdown(epoch16)

timevec =

 1999
 12
 31
 23
 59
 59
 50
 100
 500
 999
```

## References

This function corresponds to the CDF library C API routine `EPOCH16breakdown`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

## See Also

`cdflib.computeEpoch16`

## cdflib.epochBreakdown

Convert CDF\_EPOCH value into time value

### Syntax

```
timeVec = cdflib.epochBreakdown(epochTime)
```

### Description

`timeVec = cdflib.epochBreakdown(epochTime)` decomposes the CDF\_EPOCH value, `epochTime` value into individual time components. `timeVec` will have 7-by-*n* elements, where *n* is the number of CDF\_EPOCH values in `epochTime`.

The return value `timeVec` has the following elements:

| timeVec Element           | Description | Valid Values |
|---------------------------|-------------|--------------|
| <code>timeVec(1,:)</code> | Year AD     | e.g. 1994    |
| <code>timeVec(2,:)</code> | Month       | 1–12         |
| <code>timeVec(3,:)</code> | Day         | 1–31         |
| <code>timeVec(4,:)</code> | Hour        | 0–23         |
| <code>timeVec(5,:)</code> | Minute      | 0–59         |
| <code>timeVec(6,:)</code> | Second      | 0–59         |
| <code>timeVec(7,:)</code> | Millisecond | 0–999        |

### Examples

Convert a CDF\_EPOCH value into a time vector.

```
% First convert a time vector into a CDF_EPOCH value
timeval = [1999 12 31 23 59 59 0];
epoch = cdflib.computeEpoch(timeval);
```

```
% Convert the CDF_EPOCH value into a time vector
timevec = cdflib.epochBreakdown(epoch)
```

```
timevec =
```

```
 1999
 12
 31
 23
 59
 59
 0
```

## References

## **cdflib.getAttrEntry**

Value of entry in attribute with variable scope

### **Syntax**

```
value = cdflib.getAttrEntry(cdfId,attrNum,entryNum)
```

### **Description**

`value = cdflib.getAttrEntry(cdfId,attrNum,entryNum)` returns the value of an attribute entry in a Common Data Format (CDF) file.

### **Input Arguments**

#### **cdfId**

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

#### **attrNum**

Numeric value that identifies the attribute. Attribute numbers are zero-based. The attribute must have variable scope.

#### **entryNum**

Numeric value that specifies the entry in the attribute. Entry numbers are zero-based.

### **Output Arguments**

#### **Value**

Value of the entry.

## Examples

Open the example CDF and get the value of an entry associated with an attribute with variable scope in the file.

```
cdfid = cdflib.open('example.cdf');

% The fourth attribute is of variable scope.
attrscope = cdflib.getAttrScope(cdfid,3)

attrscope =

VARIABLE_SCOPE

% Get information about the first entry for this attribute
[dtype numel] = cdflib.inquireAttrEntry(cdfid,3,0)

dtype =

cdf_char

numel =

 10

% Get the value of the entry for this attribute.
% Note that it's a character string, 10 characters in length
value = cdflib.getAttrEntry(cdfid,3,0)

value =

Time value

% Clean up
cdflib.close(cdfid);

clear cdfid
```

## References

This function corresponds to the CDF library C API routine `CDFgetAttrzEntry`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

## **See Also**

`cdflib.putAttrEntry` | `cdflib.getAttrEntry` | `cdflib.putAttrEntry`

## **cdflib.getAttrgEntry**

Value of entry in global attribute

### **Syntax**

```
value = cdflib.getAttrgEntry(cdfId,attrNum,entryNum)
```

### **Description**

`value = cdflib.getAttrgEntry(cdfId,attrNum,entryNum)` returns the value of a global attribute entry in a Common Data Format (CDF) file.

### **Input Arguments**

#### **cdfId**

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

#### **attrNum**

Numeric value that identifies the attribute. Attribute numbers are zero-based. The attribute must have global scope.

#### **entryNum**

Numeric value that specifies the entry in the attribute. Entry numbers are zero-based.

### **Output Arguments**

#### **Value**

Value of the entry.

## Examples

Open the example CDF, and then get the value of an entry associated with a global attribute in the file:

```
cdfid = cdflib.open('example.cdf');

% Any of the first three attributes have global scope.
attrscope = cdflib.getAttrScope(cdfid,0)

attrscope =

GLOBAL_SCOPE

% Get information about the first entry for global attribute
[dtype numel] = cdflib.inquireAttrgEntry(cdfid,0,0)

dtype =

cdf_char

numel =

 23

% Get the value of the first entry for this global attribute.
value = cdflib.getAttrgEntry(cdfid,0,0)

value =

This is a sample entry.

% Clean up
cdflib.close(cdfid);

clear cdfid
```

## References

This function corresponds to the CDF library C API routine `CDFgetAttrgEntry`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

## **cdflib.getAttrMaxEntry**

Number of last entry for variable attribute

### **Syntax**

```
maxEntry = cdflib.getAttrMaxEntry(cdfId, attrNum)
```

### **Description**

`maxEntry = cdflib.getAttrMaxEntry(cdfId, attrNum)` returns the number of the last entry for an attribute in a Common Data Format (CDF) file.

`cdfId` identifies the CDF file.

`attrNum` is a numeric value that specifies the attribute. Attribute numbers are zero-based. The attribute must have variable scope.

### **Input Arguments**

#### **cdfId**

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

#### **attrNum**

Numeric value that identifies the attribute. Attribute numbers are zero-based. The attribute must have variable scope.

### **Output Arguments**

#### **maxEntry**

Entry number of the last entry in the attribute. Entry numbers are zero-based.

## Examples

Open the example CDF and get the number of the last entry associated with an attribute with variable scope in the file:

```
cdfid = cdflib.open('example.cdf');

% The fourth attribute is of variable scope.
attrscope = cdflib.getAttrScope(cdfid,3)

attrscope =

VARIABLE_SCOPE

% Get the number of the last entry for this attribute.
entrynum = cdflib.getAttrMaxEntry(cdfid,3)

entrynum =

 3

% Clean up
cdflib.close(cdfid);

clear cdfid
```

## References

This function corresponds to the CDF library C API routine `CDFgetAttrMaxEntry`.

## **cdflib.getAttrMaxgEntry**

Number of last entry for global attribute

### **Syntax**

```
maxEntry = cdflib.getAttrMaxgEntry(cdfId, attrNum)
```

### **Description**

`maxEntry = cdflib.getAttrMaxgEntry(cdfId, attrNum)` returns the last entry number of a global attribute in a Common Data Format (CDF) file.

### **Input Arguments**

#### **cdfId**

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

#### **attrNum**

Numeric value that identifies the attribute. Attribute numbers are zero-based. The attribute must have global scope.

### **Output Arguments**

#### **maxEntry**

Entry number of the last entry in the attribute. Entry numbers are zero-based.

### **Examples**

Open the example CDF and get the number of the last entry associated with a global attribute in the file:

```
cdfid = cdflib.open('example.cdf');

% Any of the first three attribute are of global scope.
attrscope = cdflib.getAttrScope(cdfid,0)

attrscope =

GLOBAL_SCOPE

% Get the number of the last entry for this attribute.
entrynum = cdflib.getAttrMaxgEntry(cdfid,0)

entrynum =

 4

% Clean up
cdflib.close(cdfid);

clear cdfid
```

## References

## **cdflib.getAttrName**

Name of attribute, given attribute number

### **Syntax**

```
name = cdflib.getAttrName(cdfId, attrNum)
```

### **Description**

`name = cdflib.getAttrName(cdfId, attrNum)` returns the name of an attribute in a Common Data Format (CDF) file.

### **Input Arguments**

#### **`cdfId`**

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

#### **`attrNum`**

Numeric value that identifies the attribute. Attribute numbers are zero-based.

### **Output Arguments**

#### **`name`**

Text string specifying the name of the attribute.

### **Examples**

Open the example CDF and get name of an attribute.

```
cdfid = cdflib.open('example.cdf');
```

```
% Get name of the first attribute in the file.
attrName = cdflib.getAttrName(cdfId,0)

attrName =

SampleAttribute

% Clean up
cdflib.close(cdfid);

clear cdfid
```

## References

This function corresponds to the CDF library C API routine `CDFgetAttrName`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

## See Also

`cdflib.createAttr`

## **cdflib.getAttrNum**

Attribute number, given attribute name

### **Syntax**

```
attrNum = cdflib.getAttrNum(cdfId, attrName)
```

### **Description**

`attrNum = cdflib.getAttrNum(cdfId, attrName)` returns the number of an attribute in a Common Data Format (CDF) file.

### **Input Arguments**

#### **`cdfId`**

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

#### **`attrName`**

Text string specifying the name of an attribute.

### **Output Arguments**

#### **`attrNum`**

Numeric value that identifies the attribute. Attribute numbers are zero-based.

### **Examples**

Open the example CDF and get the attribute number associated with the `SampleAttribute` attribute.

```
cdfid = cdflib.open('example.cdf');
attrNum = cdflib.getAttrNum(cdfid,'SampleAttribute')
attrNum =
 0

% Clean up
cdflib.close(cdfid);

clear cdfid
```

## References

This function corresponds to the CDF library C API routine `CDFgetAttrNum`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

`cdflib.createAttr` | `cdflib.getAttrName`

## **cdflib.getAttrScope**

Scope of attribute

### **Syntax**

```
scope = cdflib.getAttrScope(cdfId,attrNum)
```

### **Description**

`scope = cdflib.getAttrScope(cdfId,attrNum)` returns the scope of an attribute in a Common Data Format (CDF) file.

### **Input Arguments**

#### **cdfId**

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

#### **attrNum**

Numeric value that specifies the attribute. Attribute numbers are zero-based.

### **Output Arguments**

#### **scope**

Either of the following text strings, or its numeric equivalent.

| <b>Text String</b> | <b>Description</b>                       |
|--------------------|------------------------------------------|
| 'GLOBAL_SCOPE '    | Attribute applies to the CDF as a whole. |
| 'VARIABLE_SCOPE '  | Attribute applies only to the variable.  |

To get the numeric equivalent of these text string constants, use the `cdflib.getConstantValue` function.

## Examples

Open example CDF and get the scope of the first attribute in the file:

```
cdfid = cdflib.open('example.cdf');

attrScope = cdflib.getAttrScope(cdfid,0)

attrScope =

GLOBAL_SCOPE

% Clean up
cdflib.close(cdfid);

clear cdfid
```

## References

This function corresponds to the CDF library C API routine `CDFgetAttrScope`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

## See Also

`cdflib.createAttr` | `cdflib.getAttrName` | `cdflib.getConstantValue`

## **cdflib.getCacheSize**

Number of cache buffers used

### **Syntax**

```
numBuffers = cdflib.getCacheSize(cdfId)
```

### **Description**

`numBuffers = cdflib.getCacheSize(cdfId)` returns the number of cache buffers used for the Common Data Format (CDF) file identified by `cdfId`. For a discussion of cache schemes, see the *CDF User's Guide*.

### **Examples**

Open the example CDF file and get the cache size:

```
cdfid = cdflib.open('example.cdf');

numBuf = cdflib.getCacheSize(cdfid)

numBuf =

 300

% Clean up
cdflib.close(cdfid)
clear cdfid
```

### **References**

This function corresponds to the CDF library C API routine `CDFgetCacheSize`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

**See Also**

`cdflib.setCacheSize`

## **cdflib.getChecksum**

Checksum mode

### **Syntax**

```
mode = cdflib.getChecksum(cdfId)
```

### **Description**

`mode = cdflib.getChecksum(cdfId)` returns the checksum mode of the Common Data Format (CDF) file.

### **Input Arguments**

#### **`cdfId`**

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

### **Output Arguments**

#### **`mode`**

Either of the following text strings or its numeric equivalent.

|                |                               |
|----------------|-------------------------------|
| 'MD5_CHECKSUM' | File uses MD5 checksum.       |
| 'NO_CHECKSUM'  | File does not use a checksum. |

To get the numeric equivalent of these text strings, use `cdflib.getConstantValue`.

### **Examples**

Open the example CDF file, and then get the checksum mode of the file:

```
cdfid = cdflib.open('example.cdf');
checksummode = cdflib.getChecksum(cdfid)

checksummode =
NO_CHECKSUM

% Clean up
cdflib.close(cdfid);
clear cdfid;
```

## References

This function corresponds to the CDF library C API routine `CDFgetChecksum`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

## See Also

`cdflib.setChecksum` | `cdflib.getConstantValue`

## **cdflib.getCompression**

Compression settings

### **Syntax**

```
[ctype, cparms, cpercentage] = cdflib.getCompression(cdfId)
```

### **Description**

[ctype, cparms, cpercentage] = cdflib.getCompression(cdfId) returns information about the compression settings of a Common Data Format (CDF) file.

### **Input Arguments**

#### **cdfId**

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

### **Output Arguments**

#### **ctype**

Text string specifying compression type, such as 'HUFF\_COMPRESSION'. If the CDF does not use compression, the function returns the string 'NO\_COMPRESSION'. For a list of supported compression types, see `cdflib.setCompression`.

#### **cparms**

The value of the parameter associated with the type of compression. For example, for the 'RLE\_COMPRESSION' compression type, the parameter specifies the style of run-length encoding. For a list of parameters supported by each compression type, see `cdflib.setCompression`.

#### **cpercentage**

The rate of compression, expressed as a percentage.

## Examples

Open the example CDF file and check the compression settings in the file.

```
cdfId = cdflib.open('example.cdf');

[ctype, cparms, cpercentage] = cdflib.getCompression(cdfId)

ctype =

 GZIP_COMPRESSION

cparms =

 7

cper =

 26

% Clean up
cdflib.close(cdfId)
clear cdfId
```

## References

This function corresponds to the CDF library C API routine `CDFgetCompression`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

## See Also

```

## **cdflib.getCompressionCacheSize**

Number of compression cache buffers

### **Syntax**

```
numBuffers = cdflib.getCompressionCacheSize(cdfId)
```

### **Description**

`numBuffers = cdflib.getCompressionCacheSize(cdfId)` returns the number of cache buffers used for the compression scratch Common Data Format (CDF) file. `cdfId` identifies the CDF file. For a discussion of cache schemes, see the *CDF User's Guide*.

### **Examples**

Open the example CDF file and check the compression cache size of the file:

```
cdfId = cdflib.open('example.cdf');

numBuf = cdflib.getCompressionCacheSize(cdfId)

numBuf =

 80

% Clean up
cdflib.close(cdfId)
clear cdfId
```

### **References**

This function corresponds to the CDF library C API routine `CDFgetCompressionCacheSize`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

**See Also**

`cdflib.setCompressionCacheSize`

## cdflib.getConstantNames

Names of Common Data Format (CDF) library constants

### Syntax

```
names = cdflib.getConstantNames()
```

### Description

`names = cdflib.getConstantNames()` returns a cell array of text strings, where each text string is the name of a constant known to the Common Data Format (CDF) library.

### Examples

Get a list of the names of CDF library constants.

```
names = cdflib.getConstantNames()
```

```
names =
```

```
 'AHUFF_COMPRESSION'
 'ALPHAMVSD_ENCODING'
 'ALPHAMVSG_ENCODING'
 'ALPHAMVSI_ENCODING'
 'ALPHAOSF1_ENCODING'
 'CDF_BYTE'
 'CDF_CHAR'
 .
 .
 .
```

### References

For copyright information, see the `cdfcopyright.txt` file.

**See Also**

`cdflib.getConstantValue`

## cdflib.getConstantValue

Numeric value corresponding to Common Data Format (CDF) library constant

### Syntax

```
value = cdflib.getConstantValue(constantName)
```

### Description

`value = cdflib.getConstantValue(constantName)` returns the numeric value of the CDF library constant specified by the text string *constantName*. To see a list of constant names, use `cdflib.getConstantNames`.

### Examples

View the list of CDF library constants and get the numeric value corresponding to one of the constants.

```
% Retrieve a list of library constants
names = cdflib.getConstantNames();

value = cdflib.getConstantValue(names{1})

value =

 3
```

### References

For copyright information, see the `cdfcopyright.txt` file.

### See Also

`cdflib.getConstantNames`

# **cdflib.getCopyright**

Copyright notice in Common Data Format (CDF) file

## **Syntax**

```
copyright = cdflib.getCopyright(cdfId)
```

## **Description**

`copyright = cdflib.getCopyright(cdfId)` returns the copyright notice in the CDF file identified by `cdfId`.

## **Examples**

Create a CDF file, and then get the copyright notice in the file. To run this example, you must be in a writable folder.

```
cdfId = cdflib.create('your_file.cdf');
copyright = cdflib.getCopyright(cdfId)
copyright =

Common Data Format (CDF)
(C) Copyright 1990-2009 NASA/GSFC
Space Physics Data Facility
NASA/Goddard Space Flight Center
Greenbelt, Maryland 20771 USA
(Internet -- CDFSUPPORT@LISTSERV.GSFC.NASA.GOV)

% Clean up.
cdflib.delete(cdfId)
clear cdfId
```

## **References**

This function corresponds to the CDF library C API routine `CDFgetCopyright`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

**See Also**

`cdflib.getLibraryCopyright`

# **cdflib.getFileBackward**

Return current backward compatibility mode setting

## **Syntax**

```
mode = cdflib.getFileBackward()
```

## **Description**

`mode = cdflib.getFileBackward()` returns the backward compatibility mode.

## **Output Arguments**

### **mode**

One of the following text strings:

|                 |                                     |
|-----------------|-------------------------------------|
| BACKWARDFILEon  | Backward compatibility mode is on.  |
| BACKWARDFILEoff | Backward compatibility mode is off. |

For more information about backward compatibility mode, see `cdflib.setFileBackward`.

## **Examples**

```
mode = cdflib.getFileBackward
```

```
mode =
```

```
BACKWARDFILEoff
```

## **References**

This function corresponds to the CDF library C API routine `CDFgetFileBackward`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

**See Also**

`cdflib.setFileBackward` | `cdflib.getConstantValue`

## **cdflib.getFormat**

Format of Common Data Format (CDF) file

### **Syntax**

```
format = cdflib.setFormat(cdfId)
```

### **Description**

*format* = cdflib.setFormat(*cdfId*) returns the format of the CDF file.

### **Input Arguments**

#### ***cdfId***

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

### **Output Arguments**

#### ***format***

Either of the following text strings, or its numeric equivalent.

|               |                                       |
|---------------|---------------------------------------|
| 'SINGLE_FILE' | The CDF is stored in a single file.   |
| 'MULTI_FILE'  | The CDF is made up of multiple files. |

To get the numeric equivalent of these text strings, use `cdflib.getConstantValue`.

### **Examples**

Open the example CDF file and determine its file format:

```
cdfId = cdflib.open('example.cdf');
```

```
format = cdflib.getFormat(cdfId)

format =

 'SINGLE_FILE'

% Clean up.
cdflib.close(cdfId)
clear cdfId
```

## References

This function corresponds to the CDF library C API routine `CDFgetFormat`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

## See Also

`cdflib.setFormat` | `cdflib.getConstantValue`

# **cdflib.getLibraryCopyright**

Copyright notice of Common Data Format (CDF) library

## **Syntax**

```
copyright = cdflib.getLibraryCopyright()
```

## **Description**

`copyright = cdflib.getLibraryCopyright()` returns a text string containing the copyright notice of the CDF library.

## **Examples**

Get the copyright of the CDF library.

```
copyright = cdflib.getLibraryCopyright()
```

```
copyright =
```

```
Common Data Format (CDF)
(C) Copyright 1990-2008 NASA/GSFC
Space Physics Data Facility
NASA/Goddard Space Flight Center
Greenbelt, Maryland 20771 USA
(Internet -- CDFSUPPORT@LISTSERV.GSFC.NASA.GOV)
```

## **References**

This function corresponds to the CDF library C API routine `CDFgetLibraryCopyright`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

**See Also**

`cdflib.getCopyright`

# **cdflib.getLibraryVersion**

Library version and release information

## **Syntax**

```
[version,release,increment] = cdflib.getLibraryVersion()
```

## **Description**

[version,release,increment] = cdflib.getLibraryVersion() returns information about the Common Data Format (CDF) library.

## **Output Arguments**

### **version**

Numeric value indicating the version number of the CDF library.

### **release**

Numeric value indicating the release number of the CDF library.

### **increment**

Numeric value indicating the increment number of the CDF library.

## **Examples**

Get the version information of the CDF library:

```
[version, release, increment] = cdflib.getLibraryVersion()
```

```
version =
```

```
3
```

```
release =
 3
increment =
 0
```

## References

This function corresponds to the CDF library C API routine `CDFgetLibraryVersion`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

## See Also

`cdflib.getVersion`

# **cdflib.getMajority**

Majority of variables

## **Syntax**

```
majority = cdflib.getMajority(cdfId)
```

## **Description**

*majority* = cdflib.getMajority(cdfId) returns the majority of variables in a Common Data Format (CDF) file.

## **Input Arguments**

### ***cdfId***

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

## **Output Arguments**

### ***majority***

Either of the following text strings, or its numeric equivalent.

|                 |                                                                                                                                 |
|-----------------|---------------------------------------------------------------------------------------------------------------------------------|
| 'ROW_MAJOR '    | C-like array ordering for variable storage. The first dimension in each variable array varies the slowest. This is the default. |
| 'COLUMN_MAJOR ' | Fortran-like array ordering for variable storage. The first dimension in each variable array varies the fastest.                |

To get the numeric equivalent of these values, use `cdflib.getConstantValue`.

## Examples

Open the example CDF file, and then determine the majority of variables in the file:

```
cdfId = cdflib.open('example.cdf');

majority = cdflib.getMajority(cdfId)

majority =

ROW_MAJOR

% Clean up
cdflib.close(cdfId)

clear cdfId
```

## References

This function corresponds to the CDF library C API routine `CDFgetMajority`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

`cdflib.setMajority` | `cdflib.getConstantValue`

## **cdflib.getName**

Name of Common Data Format (CDF) file

### **Syntax**

```
name = cdflib.getName(cdfId)
```

### **Description**

`name = cdflib.getName(cdfId)` returns the name of the CDF file identified by `cdfId`.

### **Examples**

Open the example CDF file and get the name of the file. The path name returned for your installation will be different.

```
cdfId = cdflib.open('example.cdf');
name = cdflib.getName(cdfId)

name =

yourinstallation\matlab\toolbox\matlab\demos\example

% Clean up
cdflib.close(cdfId)

clear cdfId
```

### **References**

This function corresponds to the CDF library C API routine `CDFgetName`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

**See Also**

## **cdflib.getNumAttrEntries**

Number of entries for attribute with variable scope

### **Syntax**

```
nentries = cdflib.getNumAttrEntries(cdfId,attrNum)
```

### **Description**

`nentries = cdflib.getNumAttrEntries(cdfId,attrNum)` returns the number of entries for the specified attribute in the Common Data Format (CDF) file.

`cdfId` identifies the CDF file.

`attrNum` is a numeric value that specifies the attribute. Attribute numbers are zero-based. The attribute must have variable scope.

### **Examples**

Open the example CDF, find an attribute with variable scope, and determine how many entries are associated with the attribute:

```
cdfid = cdflib.open('example.cdf');

% Get the number of an attribute
% with variable scope
attrNum = cdflib.getAttrNum(cdfid,'Description');

% Check that scope of attribute is variable
attrScope = cdflib.getAttrScope(cdfid,attrNum)

VARIABLE_SCOPE

% Determine the number of entries for the attribute
attrEntries = cdflib.getNumAttrEntries(cdfid,attrNum)

attrEntries =
```

4

```
% Clean up
cdflib.close(cdfid);
```

## References

This function corresponds to the CDF library C API routine `CDFgetNumAttrzEntries`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

## See Also

`cdflib.getAttrScope`

## **cdflib.getNumAttrgEntries**

Number of entries for attribute with global scope

### **Syntax**

```
nentries = cdflib.getNumAttrgEntries(cdfId,attrNum)
```

### **Description**

`nentries = cdflib.getNumAttrgEntries(cdfId,attrNum)` returns the number of entries written for the specified global attribute in the Common Data Format (CDF) file.

`cdfId` identifies the CDF file. `attrNum` is a numeric value that identifies the attribute. Attribute numbers are zero-based. The attribute must have global scope.

### **Examples**

Open the example CDF and find out how many entries are associated with a global attribute in the file.

```
cdfid = cdflib.open('example.cdf');

% The first attribute is a global attribute.
attrgEntries = cdflib.getNumAttrgEntries(cdfid,0)

attrgEntries =

 3

% Clean up
cdflib.close(cdfid);

clear cdfid
```

### **References**

This function corresponds to the CDF library C API routine `CDFgetNumAttrgEntries`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

## **See Also**

`cdflib.getNumAttrEntries`

# **cdflib.getNumAttributes**

Number of attributes with variable scope

## **Syntax**

```
numAtts = cdflib.getNumAttributes(cdfId)
```

## **Description**

`numAtts = cdflib.getNumAttributes(cdfId)` returns the total number of attributes with variable scope in a Common Data Format (CDF) file. `cdfId` identifies the CDF file.

## **Examples**

Open the example CDF and find out how many attributes in the file have variable scope:

```
cdfid = cdflib.open('example.cdf');

% Determine the number of attributes with variable scope
numAttrs = cdflib.getNumAttributes(cdfid)

numAttrs =

 1

% Clean up
cdflib.close(cdfid);

clear cdfid
```

## **References**

This function corresponds to the CDF library C API routine `CDFgetNumvAttributes`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

## **See Also**

`cdflib.getNumAttributes`

# **cdflib.getNumgAttributes**

Number of attributes with global scope

## **Syntax**

```
ngatts = cdflib.getNumgAttributes(cdfId)
```

## **Description**

`ngatts = cdflib.getNumgAttributes(cdfId)` returns the total number of global attributes in a Common Data Format (CDF) file. `cdfId` identifies the CDF file.

## **Examples**

Open the example CDF and find out how many global attributes are in the file:

```
cdfid = cdflib.open('example.cdf');

% Determine the number of global attributes in the file.
numgAttrs = cdflib.getNumgAttributes(cdfid)

numgAttrs =

 3

% Clean up
cdflib.close(cdfid);
```

## **References**

This function corresponds to the CDF library C API routine `CDFgetNumgAttributes`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

`cdflib.getNumAttributes`

# **`cdflib.getReadOnlyMode`**

Read-only mode

## **Syntax**

```
mode = cdflib.getReadOnlyMode(cdfId)
```

## **Description**

*mode* = `cdflib.getReadOnlyMode(cdfId)` returns the read-only mode of a Common Data Format (CDF) file.

## **Input Arguments**

### **`cdfId`**

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

## **Output Arguments**

### **`mode`**

Either of the following text strings or its numeric equivalent.

|                |                          |
|----------------|--------------------------|
| 'READONLYon '  | CDF is in read-only mode |
| 'READONLYoff ' | CDF can be modified.     |

To get the numeric equivalent of these text strings, use `cdflib.getConstantValue`.

## **Examples**

Open the example CDF file and determine its current read-only status:

```
cdfId = cdflib.open('example.cdf');
mode = cdflib.getReadOnlyMode(cdfId)
mode =
READONLYoff

% Clean up.
cdflib.close(cdfId);
clear cdfId
```

## References

This function corresponds to the CDF library C API routine `CDFgetReadOnlyMode`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

## See Also

`cdflib.setReadOnlyMode` | `cdflib.getConstantValue`

# **cdflib.getStageCacheSize**

Number of cache buffers for staging

## **Syntax**

```
numBuffers = cdflib.getStageCacheSize(cdfId)
```

## **Description**

`numBuffers = cdflib.getStageCacheSize(cdfId)` returns the number of cache buffers used for the staging scratch file of the Common Data Format (CDF) file. For more information about cache buffers, see the *CDF User's Guide*.

`cdfId` identifies the CDF file.

## **Examples**

Open the example CDF file and determine the number of cache buffers used for staging:

```
cdfId = cdflib.open('example.cdf');
numBuf = cdflib.getStageCacheSize(cdfId)
numBuf =
 125

% Clean up
cdflib.close(cdfId)
clear cdfId
```

## **References**

This function corresponds to the CDF library C API routine `CDFgetStageCacheSize`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

## **See Also**

`cdflib.setStageCacheSize`

# **cdfplib.getValidate**

Library validation mode

## **Syntax**

```
mode = cdfplib.getValidate()
```

## **Description**

`mode = cdfplib.getValidate()` returns the validation mode of the Common Data Format (CDF) library.

## **Output Arguments**

### **mode**

Either of the following text strings or its numeric equivalent.

|                   |                                                                                                      |
|-------------------|------------------------------------------------------------------------------------------------------|
| 'VALIDATEFILEon'  | Validation mode is on. For information about validation mode, see <code>cdfplib.setValidate</code> . |
| 'VALIDATEFILEoff' | Validation mode is off.                                                                              |

To get the numeric equivalent of these text strings, use `cdfplib.getConstantValue`.

## **Examples**

Determine the current validation mode of the CDF library.

```
mode = cdfplib.getValidate()
```

```
mode =
```

```
'VALIDATEFILEon'
```

## References

This function corresponds to the CDF library C API routine `CDFgetValidate`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

## See Also

`cdflib.setValidate` | `cdflib.getConstantValue`

# **cdflib.getVarAllocRecords**

Number of records allocated for variable

## **Syntax**

```
numrecs = cdflib.getVarAllocRecords(cdfId, varNum)
```

## **Description**

`numrecs = cdflib.getVarAllocRecords(cdfId, varNum)` returns the number of records allocated for a variable in a Common Data Format (CDF) file.

`cdfId` identifies the CDF file. `varNum` is a numeric value that identifies the variable. Variable numbers are zero-based.

## **Examples**

Open example CDF and get the number of records allocated for a variable:

```
cdfid = cdflib.open('example.cdf');

% Determine the number of records allocated for the
% first variable in the file.
numrecs = cdflib.getVarAllocRecords(cdfid,0)

numrecs =

 64

% Clean up
cdflib.close(cdfid)

clear cdfid
```

## References

This function corresponds to the CDF library C API routine `CDFgetzVarAllocRecords`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

## See Also

`cdflib.setVarAllocBlockRecords`

## **cdflib.getVarBlockingFactor**

Blocking factor for variable

### **Syntax**

```
blockingFactor = cdflib.getVarBlockingFactor(cdfId,varNum)
```

### **Description**

`blockingFactor = cdflib.getVarBlockingFactor(cdfId,varNum)` returns the blocking factor for a variable in a Common Data Format (CDF) file. A variable's *blocking factor* specifies the minimum number of records the library allocates when you write to an unallocated record.

`cdfId` identifies the CDF file. `varNum` is a numeric value that identifies the variable. Variable numbers are zero-based.

### **Examples**

Open the example CDF and determine the blocking factor of a variable.

```
cdfid = cdflib.open('example.cdf');

cdflib.getVarBlockingFactor(cdfid,0)

ans =

 0

% Clean up
cdflib.close(cdfid)
clear cdfid
```

### **References**

This function corresponds to the CDF library C API routine `CDFgetzVarBlockingFactor`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

## **See Also**

`cdflib.setVarBlockingFactor`

## **cdflib.getVarCacheSize**

Number of multifile cache buffers

### **Syntax**

```
numBuffers = cdflib.getVarCacheSize(cdfId,varNum)
```

### **Description**

`numBuffers = cdflib.getVarCacheSize(cdfId,varNum)` returns the number of cache buffers used for a variable in a Common Data Format (CDF) file.

`cdfId` identifies the CDF file. `varNum` is a numeric value that identifies the variable. Variable identifiers are zero-based.

This function applies only to multifile format CDFs. For more information about caching, see the *CDF User's Guide*.

### **Examples**

Create a multifile CDF and retrieve the number of buffers being used for a variable. To run this example, you must be in a writable folder.

```
cdfid = cdflib.create('your_file.cdf')

% Set the format of the file to be multi-file
cdflib.setFormat(cdfid,'MULTI_FILE');

% Create a variable in the file
varNum = cdflib.createVar(cdfid,'Time','cdf_int1',1,[],true,[]);

% Note how the library creates a separate file for the variable
ls your_file.*

your_file.cdf your_file.z0

% Determine the number of cache buffers used with the variable
```

```
numBuf = cdfplib.getVarCacheSize(cdfid,varNum)

numBuf =

 1

% Clean up
cdfplib.delete(cdfid);

clear cdfid
```

## References

This function corresponds to the CDF library C API routine `CDFgetzVarCacheSize`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

## See Also

`cdfplib.setVarCacheSize`

# **cdflib.getVarCompression**

Information about compression used by variable

## **Syntax**

```
[ctype,cparams,percent] = cdflib.getVarCompression(cdfId, varNum)
```

## **Description**

```
[ctype,cparams,percent] = cdflib.getVarCompression(cdfId, varNum)
```

returns information about the compression used for a variable in a Common Data Format (CDF) File.

## **Input Arguments**

### **cdfId**

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

## **Output Arguments**

### **ctype**

Text string identifying the type of compression. For a list of compression types, see `cdflib.setCompression`.

### **cparams**

Any additional parameter required by the compression type.

### **percent**

Numeric value indicating the level of compression, expressed as a percentage.

## Examples

Open the example CDF file and check the compression settings of any variable.

```
cdfid = cdflib.open('example.cdf');

% Check the compression setting of any variable in the file
% The example checks the first variable (variable numbers are zero-based).
[ctype params percent] = cdflib.getVarCompression(cdfid,0)

ctype =

NO_COMPRESSION

params =

[]

percent =

100

% Clean up
cdflib.close(cdfid);
clear cdfid
```

## References

This function corresponds to the CDF library C API routine `CDFgetzVarCompression`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

## See Also

`cdflib.setCompression` | `cdflib.setVarCompression`

## **cdflib.getVarData**

Single value from record in variable

### **Syntax**

```
datum = cdflib.getVarData(cdfId, varNum, recNum, indices)
datum = cdflib.getVarData(cdfId, varNum, recNum)
```

### **Description**

`datum = cdflib.getVarData(cdfId, varNum, recNum, indices)` returns a single value from a variable in a Common Data Format (CDF) file.

`datum = cdflib.getVarData(cdfId, varNum, recNum)` returns a single value from a variable with no dimensions in a Common Data Format (CDF) file.

### **Input Arguments**

#### **cdfId**

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

#### **varNum**

Numeric value identifying the variable containing the datum. Variable numbers are zero-based.

#### **recNum**

Numeric value identifying the location of the datum in the variable. In CDF terminology, this is called the *record number*. Record numbers are zero-based.

#### **indices**

Array of dimension indices within the record. Dimension indices are zero-based. If the variable has no dimensions, you can omit this parameter.

## Output Arguments

### **datum**

Value of the specified record.

## Examples

Open the example CDF file and retrieve data associated with a variable:

```
cdfid = cdflib.open('example.cdf');

% Determine how many variables are in the file.
info = cdflib.inquire(cdfid);

info.numVars

ans =

 5

% Determine if the first variable has dimensions.
varinfo = cdflib.inquireVar(cdfid,0);
vardims = varinfo.dims
vardims =

 []

% Get data from variable, without specifying dimensions.
datum = cdflib.getVarData(cdfid, varnum, recnum)

datum =

 6.3146e+013

% Get dimensions of another variable in file.
varinfo = cdflib.inquireVar(cdfid,3);
vardims = varinfo.dims
vardims =

 [4 2 2]
```

```
% Retrieve the first datum in the record. Indices are zero-based.
datum = cdflib.getVarData(cdfId,3,0,[0 0 0])

info =

 30

% Clean up.
cdflib.close(cdfid);
clear cdfid
```

## References

## **cdflib.getVarMaxAllocRecNum**

Maximum allocated record number for variable

### **Syntax**

```
maxrec = cdflib.getVarMaxAllocRecNum(cdfId,varNum)
```

### **Description**

`maxrec = cdflib.getVarMaxAllocRecNum(cdfId,varNum)` returns the record number of the maximum allocated record for a variable in a Common Data Format (CDF) file.

`cdfId` identifies the CDF file. `varNum` is a numeric value that identifies the variable. Variable numbers and record numbers are zero-based.

### **Examples**

Open example CDF and get the maximum allocated record number for a variable:

```
cdfid = cdflib.open('example.cdf');

% Determine maximum record number for variable in file.
maxRecNum = cdflib.getVarMaxAllocRecNum(cdfid,0)

maxRecNum =

 63

% Clean up
cdflib.close(cdfid)

clear cdfid
```

## References

This function corresponds to the CDF library C API routine `CDFgetzVarMaxAllocRecNum`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

## See Also

`cdflib.getVarMaxWrittenRecNum`

## **cdflib.getVarMaxWrittenRecNum**

Maximum written record number for variable

### **Syntax**

```
maxrec = cdflib.getVarMaxwrittenRecNum(cdfId,varNum)
```

### **Description**

`maxrec = cdflib.getVarMaxwrittenRecNum(cdfId,varNum)` returns the record number of the maximum record written for a variable in a Common Data Format (CDF) file.

`cdfId` identifies the CDF file. `varNum` is a numeric value that identifies the variable. Variable numbers and record numbers are zero-based.

### **Examples**

Open the example CDF, and then determine the maximum number of records written to a variable:

```
cdfid = cdflib.open('example.cdf');
```

```
% Determine the number records written to variable.
numRecs = cdflib.getVarNumRecsWritten(cdfid,0)
```

```
numRecs =
```

```
 24
```

```
% Determine the maximum record number of the records written
maxRecNum = cdflib.getVarMaxWrittenRecNum(cdfid,0)
```

```
maxRecNum =
```

```
 23
```

```
% Clean up
cdflib.close(cdfid)

clear cdfid
```

## References

This function corresponds to the CDF library C API routine `CDFgetzVarMaxWrittenRecNum`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

## **cdflib.getVarsMaxWrittenRecNum**

Maximum written record number for CDF file

### **Syntax**

```
maxrec = cdflib.getVarsMaxwrittenRecNum(cdfId)
```

### **Description**

`maxrec = cdflib.getVarsMaxwrittenRecNum(cdfId)` returns the maximum record number written for all variables in a Common Data Format (CDF) file.

`cdfId` identifies the CDF file. Record numbers are zero-based.

### **Examples**

Open the example CDF, and then determine the maximum number of records written to the file:

```
cdfid = cdflib.open('example.cdf');

% Determine the maximum record number of the records written
maxRecNum = cdflib.getVarsMaxWrittenRecNum(cdfid)

maxRecNum =

 23

% Clean up
cdflib.close(cdfid)
```

### **References**

This function corresponds to the CDF library C API routine `CDFgetzVarsMaxWrittenRecNum`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

### **See Also**

`cdflib.getVarMaxWrittenRecNum`

## **cdflib.getVarName**

Variable name, given variable number

### **Syntax**

```
name = cdflib.getVarName(cdfId,varNum)
```

### **Description**

`name = cdflib.getVarName(cdfId,varNum)` returns the name of the variable in a Common Data Format (CDF) file.

`cdfId` identifies the CDF file. `varNum` is a numeric value that identifies the variable. Variable numbers are zero-based. `name` is a text string specifying the name.

### **Examples**

Open the example CDF, and then get the name of a variable in the file:

```
cdfid = cdflib.open('example.cdf');
name = cdflib.getVarName(cdfid,1)
name =
Longitude

% Clean up
cdflib.close(cdfid)

clear cdfid
```

### **References**

This function corresponds to the CDF library C API routine `CDFgetzVarName`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

**See Also**

`cdflib.inquireVar`

## cdflib.getVarNum

Variable number, given variable name

### Syntax

```
varNum = cdflib.getVarNum(cdfId, varname)
```

### Description

`varNum = cdflib.getVarNum(cdfId, varname)` returns the identifier (variable number) for a variable in a Common Data Format (CDF) file.

`cdfId` identifies the CDF file. *varname* is a text string that identifies the variable. Variable names are case-sensitive.

### Examples

Open example CDF, and then get the number of a variable named `Longitude`:

```
cdfid = cdflib.open('example.cdf');

varNum = cdflib.getVarNum(cdfid, 'Longitude')

varNum =

 1

% Clean up
cdflib.close(cdfid);

clear cdfid
```

### References

This function corresponds to the CDF library C API routine `CDFgetzVarNum`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

**See Also**

`cdflib.getVarName`

## **cdflib.getVarNumRecsWritten**

Number of records written to variable

### **Syntax**

```
numrecs = cdflib.getVarNumRecsWritten(cdfId,varNum)
```

### **Description**

`numrecs = cdflib.getVarNumRecsWritten(cdfId,varNum)` returns the total number of records written to a variable in a Common Data Format (CDF) file.

`cdfId` identifies the CDF file. `varNum` is a numeric value that identifies the variable. Variable numbers are zero-based.

### **Examples**

Open the example CDF, and then determine the number of records written to a variable:

```
cdfid = cdflib.open('example.cdf');

% Determine the number of records written to the variable.
numRecs = cdflib.getVarNumRecsWritten(cdfid,0)

numRecs =

 24

% Clean up
cdflib.close(cdfid)

clear cdfid
```

### **References**

This function corresponds to the CDF library C API routine `CDFgetzVarNumRecsWritten`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

### **See Also**

`cdflib.getVarMaxWrittenRecNum`

## **cdflib.getVarPadValue**

Pad value for variable

### **Syntax**

```
padvalue = cdflib.getVarPadValue(cdfId,varNum)
```

### **Description**

`padvalue = cdflib.getVarPadValue(cdfId,varNum)` returns the pad value used with a variable in a Common Data Format (CDF) file.

`cdfId` identifies the CDF file. `varNum` is a numeric value that identifies the variable. Variable numbers are zero-based.

### **Examples**

Open the example CDF, and then determine the pad value for a variable:

```
cdfid = cdflib.open('example.cdf');

% Check pad value of variable in the file.
padval = cdflib.getVarPadValue(cdfid,0)

padval =

 0

% Clean up.
cdflib.close(cdfid);

clear cdfid
```

### **References**

This function corresponds to the CDF library C API routine `CDFgetzVarPadValue`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

**See Also**

`cdflib.setVarPadValue`

## **cdflib.getVarRecordData**

Entire record for variable

### **Syntax**

```
data = cdflib.getVarRecordData(cdfId, varNum, recNum)
```

### **Description**

`data = cdflib.getVarRecordData(cdfId, varNum, recNum)` returns the data in a record associated with a variable in a Common Data Format (CDF) file.

### **Input Arguments**

#### **cdfId**

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

#### **varNum**

Numeric value that identifies the variable in the CDF file. Variable numbers are zero-based.

#### **recNum**

Numeric value that identifies the record in the variable. Record numbers are zero-based.

### **Output Arguments**

#### **data**

Data in the record.

## Examples

Open the example CDF, and then get the data associated with a record in a variable:

```
cdfid = cdflib.open('example.cdf');

% Get data in first record in first variable in file.
recData = cdflib.getVarRecordData(cdfid,0,0)

recData =

 6.3146e+013

% Clean up
cdflib.close(cdfid)

clear cdfid
```

## References

This function corresponds to the CDF library C API routine `CDFgetzVarRecordData`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

## See Also

## **cdflib.getVarReservePercent**

Compression reserve percentage for variable

### **Syntax**

```
percent = cdflib.getVarReservePercent(cdfId,varNum)
```

### **Description**

`percent = cdflib.getVarReservePercent(cdfId,varNum)` returns the compression reserve percentage for a variable in a Common Data Format (CDF) file. This operation only applies to compressed variables.

`cdfId` identifies the CDF file. `varNum` is a numeric value that identifies the variable. Variable numbers are zero-based.

### **Examples**

Open the example CDF file, get the number of a compressed variable, and then determine the reserve percent for the variable.

```
cdfid = cdflib.open('example.cdf');
varnum = cdflib.getVarNum(cdfid,'Temperature');
percent = cdflib.getVarReservePercent(cdfid,varnum);
cdflib.close(cdfid);
```

### **More About**

#### **reserve percentage**

Specifies how much extra space to allocate for a compressed variable. This extra space allows the variable to expand when you write additional records to the variable. If you do not specify this room for growth, the library has to move the variable to the end of the file when the size expands and the space at the original location of the variable becomes wasted space.

By default, the reserve percent is 0 (no extra space is reserved). You can specify any percentage between 1 and 100 and values greater than 100. The value specifies the percentage of the uncompressed size of the variable.

## References

This function corresponds to the CDF library C API routine `CDFgetzVarReservePercent`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

## See Also

`cdflib.setVarReservePercent`

## **cdflib.getVarSparseRecords**

Information about how variable handles sparse records

### **Syntax**

```
stype = cdflib.getVarSparseRecords(cdfId,varNum)
```

### **Description**

*stype* = `cdflib.getVarSparseRecords(cdfId,varNum)` returns information about how a variable in the Common Data Format (CDF) file handles sparse records.

### **Input Arguments**

#### ***cdfId***

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

#### ***varNum***

Numeric value that identifies the variable. Variable numbers are zero-based.

### **Output Arguments**

#### ***stype***

One of the following text strings, or its numeric equivalent, that specifies how the variable handles sparse records.

| <b>Text String</b>  | <b>Description</b>                                                                                       |
|---------------------|----------------------------------------------------------------------------------------------------------|
| 'NO_SPARSERECORDS'  | No sparse records.                                                                                       |
| 'PAD_SPARSERECORDS' | For sparse records, the library uses the variable's pad value when reading values from a missing record. |

| Text String          | Description                                                                                                                                                                                                  |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'PREV_SPARSERECORDS' | For sparse records, the library uses values from the previous existing record when reading values from a missing record. If there is no previous existing record, the library uses the variable's pad value. |

To get the numeric equivalent of these text strings, use `cdflib.getConstantValue`.

## Examples

Open the example CDF, and then get the sparse record type of a variable in the file:

```

cdfid = cdflib.open('example.cdf');
stype = cdflib.getVarSparseRecords(cdfid,0)

stype =

NO_SPARSERECORDS

%Clean up
cdflib.close(cdfid);

clear cdfid

```

## References

This function corresponds to the CDF library C API routine `CDFgetzVarSparseRecords`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

## See Also

`cdflib.setVarSparseRecords`

## **cdflib.getVersion**

Common Data Format (CDF) library version and release information

### **Syntax**

```
[version,release,increment] = cdflib.getVersion(cdfId)
```

### **Description**

[version,release,increment] = cdflib.getVersion(cdfId) returns information about the version of the Common Data Format (CDF) library used to create a CDF file.

### **Input Arguments**

#### **cdfId**

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

### **Output Arguments**

#### **version**

Numeric value indicating the version number of the CDF library.

#### **release**

Numeric value indicating the release number of the CDF library.

#### **increment**

Numeric value indicating the increment number of the CDF library.

## Examples

Open the example CDF file, and then find out the version of the CDF library used to create it:

```
cdfId = cdflib.open('example.cdf');

[version, release, increment] = cdflib.getVersion(cdfId)

version =

 2

release =

 7

increment =

 8

% Clean up
cdflib.close(cdfId)
clear cdfId
```

## References

This function corresponds to the CDF library C API routine `CDFgetVersion`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

## See Also

`cdflib.getLibraryVersion`

## **cdflib.hyperGetVarData**

Read hyperslab of data from variable

### **Syntax**

```
data = cdflib.hyperGetVarData(cdfId,varNum,recSpec,dimSpec)
data = cdflib.hyperGetVarData(cdfId,varNum,recSpec)
```

### **Description**

`data = cdflib.hyperGetVarData(cdfId,varNum,recSpec,dimSpec)` reads a hyperslab of data from a variable in the Common Data Format (CDF) file. Hyper access allows more than one value to be read from or written to a variable with a single call to the CDF library.

`data = cdflib.hyperGetVarData(cdfId,varNum,recSpec)` reads a hyperslab of data for a zero-dimensional variable in the Common Data Format (CDF) file.

### **Input Arguments**

#### **cdfId**

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

#### **varNum**

Number identifying the variable containing the datum.

#### **recSpec**

Three-element array, `[RSTART RCOUNT RSTRIDE]`, where `RSTART`, `RCOUNT`, and `RSTRIDE` are scalar values specifying the starting record, number of records to read, and the sampling interval or stride between records. Record numbers are zero-based.

#### **dimSpec**

Three-element cell array, `{DSTART DCOUNT DSTRIDE}`, where `DSTART`, `DCOUNT`, and `DSTRIDE` are  $n$ -element vectors that describe the start, number of values along each

dimension, and sampling interval along each dimension. If the hyperslab has zero dimensions, you can omit this parameter. Dimension indices are zero-based.

## Examples

Open the example CDF file, and then get all the data associated with a variable:

```
cdfid = cdflib.open('example.cdf');

% Determine the number of records allocated for the first variable in the file.
maxRecNum = cdflib.getVarMaxWrittenRecNum(cdfid,0);

% Retrieve all data in records for variable.
data = cdflib.hyperGetVarData(cdfid,0,[0 maxRecNum 1]);

% Clean up
cdflib.close(cdfid)

clear cdfid
```

## References

This function corresponds to the CDF library C API routine `CDFhyperGetzVarData`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

## See Also

`cdflib.hyperPutVarData`

## **cdflib.hyperPutVarData**

Write hyperslab of data to variable

### **Syntax**

```
cdflib.hyperPutVarData(cdfId, varNum, recSpec, dimSpec, data)
```

### **Description**

`cdflib.hyperPutVarData(cdfId, varNum, recSpec, dimSpec, data)` writes a hyperslab of data to a variable in a Common Data Format (CDF) file. Hyper access allows more than one value to be read from or written to a variable with a single call to the CDF library.

### **Input Arguments**

#### **cdfId**

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

#### **varNum**

Specifies the variable containing the datum.

#### **recSpec**

Three-element array described by `[RSTART RCOUNT RSTRIDE]`, where `RSTART`, `RCOUNT`, and `RSTRIDE` are scalar values giving the start, number of records, and sampling interval (or stride) between records. Record indices are zero-based.

#### **dimSpec**

Three-element cell array described by `{DSTART DCOUNT DSTRIDE}`, where `DSTART`, `DCOUNT`, and `DSTRIDE` are n-element vectors that describe the start, number of values along each dimension, and sampling interval along each dimension. If the hyperslab has zero dimensions, you can omit this parameter. Dimension indices are zero-based.

**data**

Data to write to the variable.

## Examples

Create a CDF, create a variable, and then write a slab of data to the variable. To run this example, you must be in a writable folder.

```
cdfid = cdflib.create('your_file.cdf');

% Create a variable in the file.
varNum = cdflib.createVar(cdfid, 'Grades', 'cdf_int1', 1, [], true, []);

% Write data to the variable
cdflib.hyperPutVarData(cdfid, varNum, 0, [], int8(98))

%Clean up
cdflib.delete(cdfid);
clear cdfid
```

## References

This function corresponds to the CDF library C API routine `CDFhyperzPutVarData`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

## See Also

`cdflib.hyperGetVarData`

## **cdflib.inquire**

Basic characteristics of Common Data Format (CDF) file

### **Syntax**

```
info = cdflib.inquire(cdfId)
```

### **Description**

`info = cdflib.inquire(cdfId)` returns basic information about a Common Data Format (CDF) file.

### **Input Arguments**

#### **cdfId**

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

### **Output Arguments**

#### **info**

A structure containing the following fields:

| <b>Field</b> | <b>Description</b>                                     |
|--------------|--------------------------------------------------------|
| encoding     | Encoding of the variable data and attribute entry data |
| majority     | Majority of the variable data                          |
| maxRec       | Maximum record number written to a CDF variable        |
| numVars      | Number of CDF variables                                |
| numVAttrs    | Number of attributes with variable scope               |
| numGAttrs    | Number of attributes with global scope                 |

## Examples

Open the example CDF file, and then get basic information about the file:

```
cdfId = cdflib.open('example.cdf');

info = cdflib.inquire(cdfId)

info =

 encoding: 'IBMPC_ENCODING'
 majority: 'ROW_MAJOR'
 maxRec: 23
 numVars: 5
 numvAttrs: 1
 numgAttrs: 3
```

## References

This function corresponds to the CDF library C API routines `CDFinquireCDF` and `CDFgetNumgAttributes`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

## See Also

`cdflib.inquireVar`

## **cdflib.inquireAttr**

Information about attribute

### **Syntax**

```
info = cdflib.inquireAttr(cdfId,attrNum)
```

### **Description**

`info = cdflib.inquireAttr(cdfId,attrNum)` returns information about an attribute in a Common Data Format (CDF) file.

### **Input Arguments**

#### **cdfId**

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

#### **attrNum**

Numeric value that identifies the attribute in the file. Attribute numbers are zero-based.

### **Output Arguments**

#### **info**

Structure containing the following fields.

| <b>Field</b> | <b>Description</b>                                   |
|--------------|------------------------------------------------------|
| name         | Attribute's name                                     |
| scope        | Either 'GLOBAL_SCOPE' or 'VARIABLE_SCOPE'            |
| maxgEntry    | The maximum entry number used for global attributes. |

| Field    | Description                                                       |
|----------|-------------------------------------------------------------------|
| maxEntry | The maximum entry number used for attributes with variable scope. |

## Examples

Open the example CDF, and then get information about the first attribute in the file.

```
cdfid = cdflib.open('example.cdf');

% Get information about an attribute
info = cdflib.inquireAttr(cdfid,0)

info =

 name: 'SampleAttribute'
 scope: 'GLOBAL_SCOPE'
maxgEntry: 4
maxEntry: -1

% Clean up
cdflib.close(cdfid);

clear cdfid
```

## References

This function corresponds to the CDF library C API routine `CDFinquireAttr`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

## See Also

`cdflib.inquireAttrEntry` | `cdflib.inquireAttrEntry`

## **cdflib.inquireAttrEntry**

Information about entry in attribute with variable scope

### **Syntax**

```
[datatype, numElements] =
cdflib.inquireAttrEntry(cdfId, attrNum, entryNum)
```

### **Description**

[datatype, numElements] =  
cdflib.inquireAttrEntry(cdfId, attrNum, entryNum) returns the data type and the number of elements for an attribute entry in a Common Data Format (CDF) file.

### **Input Arguments**

#### **cdfId**

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

#### **attrNum**

Numeric value identifying an attribute in the file. Attribute numbers are zero-based. The attribute must have variable scope.

#### **entryNum**

Numeric value identifying the entry in the attribute. Entry number are zero-based.

### **Output Arguments**

#### **datatype**

Text string identifying a CDF data type. For a list of CDF data types, see `cdflib.putAttrEntry`

**numElements**

Numeric value indicating the number of elements in the entry.

**Examples**

Open example CDF, and then get information about entries associated with an attribute in the file:

```
cdfid = cdflib.open('example.cdf');

% The fourth attribute is of variable scope.
attrscope = cdflib.getAttrScope(cdfid,3)

attrscope =

VARIABLE_SCOPE

% Get information about the first entry for this attribute
[dtype numel] = cdflib.inquireAttrEntry(cdfid,3,0)

dtype =

cdf_char

numel =

 10

% Clean up
cdflib.close(cdfid);

clear cdfid
```

**References**

This function corresponds to the CDF library C API routine `CDFinquireAttrzEntry`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

**See Also**

`cdflib.inquireAttr` | `cdflib.getAttrScope`

# **cdflib.inquireAttrgEntry**

Information about entry in attribute with global scope

## **Syntax**

```
[datatype, numElements] =
cdflib.inquireAttrgEntry(cdfId, attrNum, entryNum)
```

## **Description**

[datatype, numElements] =  
cdflib.inquireAttrgEntry(cdfId, attrNum, entryNum) returns the data type and the number of elements for a global attribute entry in a Common Data Format (CDF) file.

## **Input Arguments**

### **cdfId**

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

### **attrNum**

Numeric value identifying an attribute in the file. Attribute numbers are zero-based. The attribute must have global scope.

### **entryNum**

Numeric value identifying the entry in the attribute. Entry number are zero-based.

## **Output Arguments**

### **datatype**

Text string identifying a CDF data type. For a list of CDF data types, see `cdflib.putAttrgEntry`

**numElements**

Numeric value indicating the number of elements in the entry.

**Examples**

Open the example CDF, and then get information about entries associated with a global attribute in the file.

```
cdfid = cdflib.open('example.cdf');

% Any of the first three attributes have global scope.
attrscope = cdflib.getAttrScope(cdfid,0)

attrscope =

GLOBAL_SCOPE

% Get information about the first entry for this attribute
[dtype numel] = cdflib.inquireAttrEntry(cdfid,0,0)

dtype =

cdf_char

numel =

 23

% Clean up
cdflib.close(cdfid);

clear cdfid
```

**References**

This function corresponds to the CDF library C API routine `CDFinquireAttrEntry`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

**See Also**

`cdflib.inquireAttr` | `cdflib.inquireAttrEntry`

## **cdflib.inquireVar**

Information about variable

### **Syntax**

```
info = cdflib.inquireVar(cdfId,varNum)
```

### **Description**

`info = cdflib.inquireVar(cdfId,varNum)` returns information about a variable in a Common Data Format (CDF) file.

### **Input Arguments**

#### **`cdfId`**

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

#### **`varNum`**

Numeric value that identifies the variable. Variable numbers are zero-based.

### **Output Arguments**

#### **`info`**

Structure containing the following fields.

| <b>Field</b>             | <b>Description</b>                 |
|--------------------------|------------------------------------|
| <code>name</code>        | Name of the variable               |
| <code>datatype</code>    | Data type                          |
| <code>numElements</code> | Number of elements of the datatype |
| <code>dims</code>        | Sizes of the dimensions            |

| Field       | Description         |
|-------------|---------------------|
| recVariance | Record variance     |
| dimVariance | Dimension variances |

Record and dimension variances affect how the library physically stores variable data. For example, if a variable has a record variance of `VARY`, the library physically stores each record. If the record variance is `NOVARY`, the library only stores one record.

## Examples

Open the example CDF file and get information about a variable.

```

cdfid = cdflib.open('example.cdf');

% Determine if the file contains variables
info = cdflib.inquireVar(cdfid,1)

info =
 name: 'Longitude'
 datatype: 'cdf_int1'
numElements: 1
 dims: [2 2]
recVariance: 0
dimVariance: [1 0]

```

## References

This function corresponds to the CDF library C API routine `CDFinquirezVar`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

## See Also

`cdflib.inquire`

## cdflib.open

Open existing Common Data Format (CDF) file

### Syntax

```
cdfId = cdflib.open(filename)
```

### Description

`cdfId = cdflib.open(filename)` opens an existing Common Data Format (CDF) file. *filename* is a text string that identifies the file.

This function returns a CDF file identifier, `cdfId`.

All CDF files opened this way have the `zMode` set to `zModeon2`. Refer to the *CDF User's Guide* for information about `zModes`.

### Examples

Open the example CDF file:

```
cdfId = cdflib.open('example.cdf');

% Clean up
cdflib.close(cdfId)

clear cdfId
```

### References

This function corresponds to the CDF library C API routine `CDFopenCDF`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

### **See Also**

`cdflib.close` | `cdflib.create`

## **cdflib.putAttrEntry**

Write value to entry in attribute with variable scope

### **Syntax**

```
cdflib.putAttrEntry(cdfId,attrNum,entryNum,CDFDataType,entryVal)
```

### **Description**

`cdflib.putAttrEntry(cdfId,attrNum,entryNum,CDFDataType,entryVal)` writes a value to an attribute entry in a Common Data Format (CDF) file.

### **Input Arguments**

#### **cdfId**

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

#### **attrNum**

Number identifying attribute. The attribute must have variable scope. Attribute numbers are zero-based.

#### **entryNum**

Number identifying entry. Entry numbers are zero-based.

#### **CDFdatatype**

One of the following text strings, or its numeric equivalent, that specify the data type of the attribute entry.

| <b>CDF Data Type</b> | <b>MATLAB Equivalent</b>                                              |
|----------------------|-----------------------------------------------------------------------|
| CDF_BYTE             | 1-byte, signed integer                                                |
| CDF_CHAR             | 1 byte, signed character data type that maps to the MATLAB char class |

| CDF Data Type | MATLAB Equivalent                                                        |
|---------------|--------------------------------------------------------------------------|
| CDF_INT1      | 1-byte, signed integer.                                                  |
| CDF_UCHAR     | 1 byte, unsigned character data type that maps to the MATLAB uint8 class |
| CDF_UINT1     | 1-byte, unsigned integer                                                 |
| CDF_INT2      | 2-byte, signed integer                                                   |
| CDF_UINT2     | 2-byte, unsigned integer.                                                |
| CDF_INT4      | 4-byte, signed integer                                                   |
| CDF_UINT4     | 4-byte, unsigned integer                                                 |
| CDF_FLOAT     | 4-byte, floating point                                                   |
| CDF_REAL4     | 4-byte, floating point                                                   |
| CDF_REAL8     | 8-byte, floating point.                                                  |
| CDF_DOUBLE    | 8-byte, floating point                                                   |
| CDF_EPOCH     | 8-byte, floating point                                                   |
| CDF_EPOCH16   | two 8-byte, floating point                                               |

### entryVal

Data to be written to attribute entry.

## Examples

Create a CDF and create an attribute with variable scope in the file. Write a value to an entry in the attribute. To run this example, you must be in a writable folder.

```

cdfid = cdflib.create('your_file.cdf');

% Initially the file contains no attributes, global or variable.
info = cdflib.inquire(cdfid)

info =

 encoding: 'IBMPC_ENCODING'
 majority: 'ROW_MAJOR'
 maxRec: -1

```

```
 numVars: 0
 numvAttrs: 0
 numgAttrs: 0

% Create an attribute of variable scope in the file.
attrNum = cdfplib.createAttr(cdfid,'Another Attribute','variable_scope');

% Write a value to an entry for the attribute
cdfplib.putAttrEntry(cdfid,attrNum,0,'CDF_CHAR','My Variable Attribute Test');

% Get the value of the global attribute entry
value = cdfplib.getAttrEntry(cdfid,attrNum,0)

value =

My Variable Attribute Test

% Clean up
cdfplib.delete(cdfid);

clear cdfid
```

## References

# **cdflib.putAttrgEntry**

Write value to entry in attribute with global scope

## **Syntax**

```
cdflib.putAttrgEntry(cdfId,attrNum,entryNum,cdfDataType,entryVal)
```

## **Description**

`cdflib.putAttrgEntry(cdfId,attrNum,entryNum,cdfDataType,entryVal)` writes a value to a global attribute entry in a Common Data Format (CDF) file.

## **Input Arguments**

### **cdfId**

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

### **attrNum**

Number identifying attribute. Attribute numbers are zero-based. The attribute must have global scope.

### **entryNum**

Number identifying entry. Entry numbers are zero-based.

### **CDFdatatype**

One of the following text strings that specify the data type of the attribute entry, or its numeric equivalent.

| <b>CDF Data Type</b> | <b>MATLAB Equivalent</b>                                              |
|----------------------|-----------------------------------------------------------------------|
| CDF_BYTE             | 1-byte, signed integer                                                |
| CDF_CHAR             | 1 byte, signed character data type that maps to the MATLAB char class |

| <b>CDF Data Type</b> | <b>MATLAB Equivalent</b>                                                 |
|----------------------|--------------------------------------------------------------------------|
| CDF_INT1             | 1-byte, signed integer.                                                  |
| CDF_UCHAR            | 1 byte, unsigned character data type that maps to the MATLAB uint8 class |
| CDF_UINT1            | 1-byte, unsigned integer                                                 |
| CDF_INT2             | 2-byte, signed integer                                                   |
| CDF_UINT2            | 2-byte, unsigned integer.                                                |
| CDF_INT4             | 4-byte, signed integer                                                   |
| CDF_UINT4            | 4-byte, unsigned integer                                                 |
| CDF_FLOAT            | 4-byte, floating point                                                   |
| CDF_REAL4            | 4-byte, floating point                                                   |
| CDF_REAL8            | 8-byte, floating point.                                                  |
| CDF_DOUBLE           | 8-byte, floating point                                                   |
| CDF_EPOCH            | 8-byte, floating point                                                   |
| CDF_EPOCH16          | two 8-byte, floating point                                               |

**entryVal**

Data to be written to global attribute entry.

**Examples**

Create a CDF and create a global attribute in the file. Write a value to an entry in the attribute. To run this example, you must be in a writable folder.

```
cdfid = cdflib.create('your_file.cdf');
```

```
% Initially the file contains no attributes, global or variable.
info = cdflib.inquire(cdfid)
```

```
info =
```

```
 encoding: 'IBMPC_ENCODING'
 majority: 'ROW_MAJOR'
 maxRec: -1
```

```
 numVars: 0
 numvAttrs: 0
 numgAttrs: 0

% Create a global attribute in the file.
attrNum = cdfplib.createAttr(cdfid,'Purpose','global_scope');

% Write a value to an entry for the global attribute
cdfplib.putAttrEntry(cdfid,attrNum,0,'CDF_CHAR','My Test');

% Get the value of the global attribute entry
value = cdfplib.getAttrEntry(cdfid,attrNum,0)

value =

My Test

% Clean up
cdfplib.delete(cdfid);

clear cdfid
```

## References

This function corresponds to the CDF library C API routine `CDFputAttrEntry`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

## **cdflib.putVarData**

Write single value to variable

### **Syntax**

```
cdflib.putVarData(cdfId, varNum, recNum, indices, datum)
```

### **Description**

`cdflib.putVarData(cdfId, varNum, recNum, indices, datum)` writes a single value to a variable in a Common Data File (CDF) file.

### **Input Arguments**

#### **cdfId**

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

#### **varNum**

Numeric value that identifies the variable to which you want to write the datum. Variable numbers are zero-based.

#### **recNum**

Numeric value that identifies the record to which you want to write the datum. Record numbers are zero-based.

#### **dims**

Dimension indices within the record. Dimension indices are zero-based.

#### **datum**

Data to be written to the variable.

## Examples

Create a CDF, create a variable in the CDF and write data to the variable. To run this example, you must have write permission in the current folder.

```
cdfid = cdflib.create('your_file.cdf');

% Create a variable in the file.
varNum = cdflib.createVar(cdfid, 'Grades', 'cdf_int1', 1, [], true, []);

% Write some data to the variable
cdflib.putVarData(cdfid, varNum, 0, [], int8(98))

% Read the value from the variable.
datum = cdflib.getVarData(cdfid, varNum, 0)

datum =

 98

%Clean up
cdflib.delete(cdfid);
clear cdfid
```

## References

This function corresponds to the CDF library C API routine `CDFputzVarData`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

## See Also

`cdflib.getVarData` | `cdflib.getVarRecordData` | `cdflib.hyperGetVarData`

## **cdflib.putVarRecordData**

Write entire record to variable

### **Syntax**

```
cdflib.putVarRecordData(cdfId, varNum, recNum, recordData)
```

### **Description**

`cdflib.putVarRecordData(cdfId, varNum, recNum, recordData)` writes data to a record in a variable in a Common Data Format (CDF) file.

### **Input Arguments**

#### **cdfId**

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

#### **varNum**

Numeric value that identifies the variable to which you want to write the datum. Variable numbers are zero-based.

#### **recNum**

Numeric value identifying the location of the datum in the variable. Record numbers are zero-based.

#### **recordData**

Data to be written to the variable.

### **Examples**

Create a CDF, create a variable, and write an entire record of data to the variable. To run this example, you must be in a writable folder.

```
cdfid = cdfplib.create('your_file.cdf');

% Create a variable in the file.
varNum = cdfplib.createVar(cdfid, 'Grades', 'cdf_int1', 1, [], true, []);

% Write some data to the variable
cdfplib.putVarRecordData(cdfid, varNum, 0, int8(98))

% Read the value from the variable.
datum = cdfplib.getVarData(cdfid, varNum, 0)

datum =

 98

%Clean up
cdfplib.delete(cdfid);
clear cdfid
```

## References

This function corresponds to the CDF library C API routine `CDFputzVarRecordData`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

## **cdflib.renameAttr**

Rename existing attribute

### **Syntax**

```
cdflib.renameAttr(cdfId, attrNum, newName)
```

### **Description**

`cdflib.renameAttr(cdfId, attrNum, newName)` renames an attribute in a Common Data Format (CDF) file.

`cdfId` identifies the CDF file. `attrNum` is a numeric value that identifies the attribute. Attribute numbers are zero-based. `newName` is a text string that specifies the name you want to assign to the attribute.

### **Examples**

Create a CDF, create an attribute in the CDF, and then rename the attribute. To run this example, you must be in a writable folder.

```
cdfid = cdflib.create('your_file.cdf');

% Create an attribute
attrNum = cdflib.createAttr(cdfid, 'Purpose', 'global_scope');

% Rename the attribute
cdflib.renameAttr(cdfid, attrNum, 'NewPurpose');

% Check the name of the attribute
attrName = cdflib.getAttrName(cdfid, anum)

attrName =

NewPurpose

% Clean up
```

```
cdflib.delete(cdfid);
clear cdfid
```

## References

This function corresponds to the CDF library C API routine `CDFrenameAttr`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

## See Also

`cdflib.createAttr`

## **cdflib.renameVar**

Rename existing variable

### **Syntax**

```
cdflib.renameVar(cdfId, varNum, newName)
```

### **Description**

`cdflib.renameVar(cdfId, varNum, newName)` renames a variable in a Common Data Format (CDF) file.

`cdfId` identifies the CDF file. `varNum` is a numeric value that identifies the variable. Variable numbers are zero-based. `newName` is a text string that specifies the name you want to assign to the variable.

### **Examples**

Create a CDF, create a variable in the CDF, and then rename the variable. To run this example, you must be in a writable folder.

```
cdfid = cdflib.create('your_file.cdf');

% Create a variable in the file.
varNum = cdflib.createVar(cdfid, 'Time', 'cdf_int1', 1, [], true, []);

% Get the name of the variable.
name = cdflib.getVarName(cdfid, varNum)

name =

Time

% Rename the variable
cdflib.renameVar(cdfid, varNum, 'NewName');

% Check the new name.
```

```
name = cdflib.getVarName(cdfid, varNum)

name =
NewName

% Clean up
cdflib.delete(cdfid)

clear cdfid
```

## References

This function corresponds to the CDF library C API routine `CDFrenamezVar`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

## See Also

`cdflib.createVar`

## **cdflib.setCacheSize**

Specify number of dotCDF cache buffers

### **Syntax**

```
cdflib.setCacheSize(cdfId,numBuffers)
```

### **Description**

`cdflib.setCacheSize(cdfId,numBuffers)` specifies the number of cache buffers the CDF library uses for an open dotCDF file. A *dotCDF* file is a file with the `.cdf` file extension.

`cdfId` identifies an open CDF file. `numBuffers` is a numeric value that specifies the number of buffers.

For information about cache schemes, see the *CDF User's Guide*.

### **Examples**

Create a CDF file and set the cache size. To run this example, you must have write permission in your current folder.

```
cdfId = cdflib.create('your_file.cdf');

% Get the default cache size
numBuf = cdflib.getCacheSize(cdfid)

numBuf =

 300

% Specify a cache size
cdflib.setCacheSize(cdfid,150)

% Check the cache size again
numBuf = cdflib.getCacheSize(cdfid)
```

```
numBuf =
 150

% Clean up
cdflib.delete(cdfId)
clear cdfId
```

## References

This function corresponds to the CDF library C API routine `CDFsetCacheSize`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

## See Also

`cdflib.getCacheSize`

## cdflib.setChecksum

Specify checksum mode

### Syntax

```
cdflib.setChecksum(cdfId,mode)
```

### Description

`cdflib.setChecksum(cdfId,mode)` specifies the checksum mode of a Common Data Format (CDF) file.

### Input Arguments

#### **cdfId**

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

#### **mode**

Either of the following text strings, or its numeric equivalent. To get the numeric equivalent of these values, use `cdflib.getConstantValue`.

|                |                                     |
|----------------|-------------------------------------|
| 'MD5_CHECKSUM' | Sets file checksum to MD5 checksum. |
| 'NO_CHECKSUM'  | File does not use a checksum.       |

### Examples

Create a CDF file and set the checksum mode. To run this example, you must be in a writable folder.

```
cdfid = cdflib.create('mycdf.cdf');

% Check initial value of checksum.
```

```
mode = cdflib.getChecksum(cdfid)

NO_CHECKSUM

cdflib.setChecksum(cdfid, 'MD5_CHECKSUM')

% Verify the setting
mode = cdflib.getChecksum(cdfid)

MD5_CHECKSUM
```

## References

This function corresponds to the CDF library C API routine `CDFsetChecksum`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

## See Also

`cdflib.getChecksum` | `cdflib.getConstantValue`

## **cdflib.setCompression**

Specify compression settings

### **Syntax**

```
cdflib.setCompression(cdfId, ctype, cparms)
```

### **Description**

`cdflib.setCompression(cdfId, ctype, cparms)` specifies compression settings of a Common Data Format (CDF) file.

This function sets the compression for the CDF file itself, not that of any variables in the file.

### **Input Arguments**

#### **cdfId**

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

#### **ctype**

One of the following text strings, or its numeric equivalent, specifying compression type.

| <b>Text String</b>  | <b>Compression Type</b>         |
|---------------------|---------------------------------|
| 'NO_COMPRESSION'    | No compression                  |
| 'RLE_COMPRESSION'   | Run-length encoding compression |
| 'HUFF_COMPRESSION'  | Huffman compression             |
| 'AHUFF_COMPRESSION' | Adaptive Huffman compression    |
| 'GZIP_COMPRESSION'  | GNU's zip compression           |

To get the numeric equivalent, use `cdflib.getConstantValue`.

## **cparms**

Optional parameter specifying any additional parameters required by the compression type. Currently, the only compression type that uses this parameter is 'GZIP\_COMPRESSION'. For this compression type, use `cparms` to specify the level of compression as a numeric value between 1 and 9.

## **Examples**

Create a CDF file and set the compression setting of the file. To run this example, your current folder must be writable.

```
cdfId = cdflib.create('your_file.cdf');

% Determine the file's default compression setting
[ctype, cparms, cpercent] = cdflib.getCompression(cdfId)

ctype =

NO_COMPRESSION

cparms =

[]

cpercent =

100

% Specify new compression setting
cdflib.setCompression(cdfId, 'HUFF_COMPRESSION');

% Check the file's compression setting.
[ctype, cparms, cpercent] = cdflib.getCompression(cdfId)

ctype =

HUFF_COMPRESSION

cparms =

OPTIMAL_ENCODING_TREES
```

```
cpercent =

 0

% Clean up
cdflib.delete(cdfId)
clear cdfId
```

## References

# **cdflib.setCompressionCacheSize**

Specify number of compression cache buffers

## **Syntax**

```
cdflib.setCompressionCacheSize(cdfId,numBuffers)
```

## **Description**

`cdflib.setCompressionCacheSize(cdfId,numBuffers)` specifies the number of cache buffers used for the compression scratch CDF file. For more information about CDF cache schemes, see the *CDF User's Guide*.

`cdfId` identifies the CDF file. `numBuffers` specifies the number of buffers.

## **Examples**

Create a CDF file and specify the number of compression cache buffers used. To run this example you must be in a writable folder.

```
cdfId = cdflib.create('your_file.cdf');

% Get the current number of compression cache buffers
numBuf = cdflib.getCompressionCacheSize(cdfId)

numBuf =

 80

% Set a new value
cdflib.setCompressionCacheSize(cdfId,100)

% Check the new value
numBuf = cdflib.getCompressionCacheSize(cdfId)

numBuf =
```

100

```
% Clean up
cdflib.delete(cdfId)
clear cdfId
```

## References

This function corresponds to the CDF library C API routine `CDFsetCompressionCacheSize`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

`cdflib.getCompressionCacheSize`

# **cdflib.setFileBackward**

Set backward compatibility mode

## **Syntax**

```
cdflib.setFileBackward(mode)
```

## **Description**

`cdflib.setFileBackward(mode)` sets the backward compatibility mode to the value specified by `mode`.

## **Input Arguments**

### **mode**

One of the following text strings:

|                 |                                      |
|-----------------|--------------------------------------|
| BACKWARDFILEon  | Set backward compatibility mode on.  |
| BACKWARDFILEoff | Set backward compatibility mode off. |

**Default:** BACKWARDFILEoff

## **Examples**

Set backward compatibility mode and then check the value.

```
cdflib.setFileBackward('BACKWARDFILEon');
```

```
mode = cdflib.getFileBackward
```

```
mode =
```

```
BACKWARDFILEon
```

## More About

### backward compatibility mode

When specified, ensures that any new CDF file created using CDF V3.0 (or later) will be readable by clients using version 2.7 of the CDF library. CDF 3.0 and later releases use a 64-bit file offset to allow for files greater than 2G bytes in size. CDF library versions released before CDF 3.0 use a 32-bit file offset.

### Tips

- Setting backward compatibility mode affects only your current MATLAB session, or until you call `cdflib.setFileBackward` again.

## References

This function corresponds to the CDF library C API routine `CDFsetFileBackward`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

## **cdflib.setFormat**

Specify format of Common Data Format (CDF) file

### **Syntax**

```
cdflib.setFormat(cdfId, format)
```

### **Description**

`cdflib.setFormat(cdfId, format)` specifies the format of a Common Data Format (CDF) file.

### **Input Arguments**

#### **cdfId**

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

#### **format**

Either of the following text strings, or its numeric equivalent.

|               |                                                                                                                          |
|---------------|--------------------------------------------------------------------------------------------------------------------------|
| 'SINGLE_FILE' | The CDF consists of only one file. This is the default file format                                                       |
| 'MULTI_FILE'  | The CDF consists of one header file for control and attribute data and one additional file for each variable in the CDF. |

To get the numeric equivalent of these values, use `cdflib.getConstantValue`.

### **Examples**

Create a CDF file and specify its format. To run this example, you must have write permission in your current folder.

```
cdfId = cdflib.create('mycdffile.cdf');
```

```
% Specify multifile format.
cdflib.setFormat(cdfId, 'MULTI_FILE');

% Check format.
format = cdflib.getFormat(cdfId)

format =

MULTI_FILE

% Clean up
cdflib.delete(cdfId)
clear cdfId
```

## References

This function corresponds to the CDF library C API routine `CDFsetFormat`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

## See Also

## **cdflib.setMajority**

Specify majority of variables

### **Syntax**

```
cdflib.setMajority(cdfId, majority)
```

### **Description**

`cdflib.setMajority(cdfId, majority)` specifies the majority of variables in a Common Data Format (CDF) file.

### **Input Arguments**

#### **cdfId**

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

#### **majority**

Either of the following text strings, or its numeric equivalent.

|                 |                                                                                                                                 |
|-----------------|---------------------------------------------------------------------------------------------------------------------------------|
| 'ROW_MAJOR '    | C-like array ordering for variable storage. The first dimension in each variable array varies the slowest. This is the default. |
| 'COLUMN_MAJOR ' | Fortran-like array ordering for variable storage. The first dimension in each variable array varies the fastest.                |

To get the numeric equivalent of these values, use `cdflib.getConstantValue`.

### **Examples**

Create a CDF file and specify the majority used by variables in the file. To run this example, you must have write permission in your current folder.

```
cdfId = cdflib.create('your_file.cdf')

% Specify the majority used by variables in the file
cdflib.setMajority(cdfId,'COLUMN_MAJOR');

% Check the majority value
majority = cdflib.getMajority(cdfId)

majority =

COLUMN_MAJOR

% Clean up
cdflib.delete(cdfId)
clear cdfId
```

## References

This function corresponds to the CDF library C API routine `CDFsetMajority`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

## See Also

`cdflib.getMajority`

# **`cdflib.setReadOnlyMode`**

Specify read-only mode

## **Syntax**

```
cdflib.setReadOnlyMode(cdfId,mode)
```

## **Description**

`cdflib.setReadOnlyMode(cdfId,mode)` specifies the read-only mode of a Common Data Format (CDF) file.

After you open a CDF file, you can put the file into read-only mode to prevent accidental modification.

## **Input Arguments**

### **`cdfId`**

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

### **`mode`**

Either of the following text strings or its numeric equivalent.

|                            |                         |
|----------------------------|-------------------------|
| <code>'READONLYon'</code>  | CDF file is read-only   |
| <code>'READONLYoff'</code> | CDF file is modifiable. |

To get the numeric equivalent of these mode values, use `cdflib.getConstantValue`.

## **Examples**

Open the example CDF file and set the file to read-only mode.

```
cdfId = cdflib.open('example.cdf');

% Set the file to READONLY mode
cdflib.setReadOnlyMode(cdfId, 'READONLYon')

% Check read-only status of file again.
mode = cdflib.getReadOnlyMode(cdfId)

mode =

READONLYon

% Clean up
cdflib.close(cdfId)
clear cdfId
```

## References

This function corresponds to the CDF library C API routine `CDFsetReadOnlyMode`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

## **cdflib.setStageCacheSize**

Specify number of staging cache buffers for Common Data Format (CDF) file

### **Syntax**

```
cdflib.setStageCacheSize(cdfId,numBuffers)
```

### **Description**

`cdflib.setStageCacheSize(cdfId,numBuffers)` specifies the number of staging cache buffers for a Common Data Format (CDF) file. For information about CDF cache schemes, see the *CDF User's Guide*.

`cdfId` identifies the CDF file. `numBuffers` is a numeric value that specifies the number of buffers.

### **Examples**

Open the example CDF file and specify the number of cache buffers used.

```
cdfId = cdflib.open('example.cdf');

% Get current number of staging cache buffers
size = cdflib.getStageCacheSize(cdfId)

size =

 125

% Specify new cache size value.
cdflib.setStageCacheSize(cdfId, 200)

% Get size again.
size = cdflib.getStageCacheSize(cdfId)

size =
```

200

```
% Clean up
cdflib.close(cdfId)

clear cdfId
```

## References

This function corresponds to the CDF library C API routine `CDFsetStageCacheSize`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

## See Also

`cdflib.getStageCacheSize`

## **cdflib.setValidate**

Specify library validation mode

### **Syntax**

```
cdflib.setValidate(mode)
```

### **Description**

`cdflib.setValidate(mode)` specifies the validation mode of the Common Data Format (CDF) library. Specify the validation mode before opening any files.

### **Input Arguments**

#### **mode**

Either of the following text strings, or its numeric equivalent:

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'VALIDATEFILEon'  | Turns validation mode on. With validation mode on, the library performs sanity checks on the data fields in the CDF' file's internal data structures to make sure that the values are within valid ranges and consistent with the defined values/types/entries. This mode also ensures that variable and attribute associations within the file are valid. Note, however, that enabling this mode will, in most cases, slow down the file opening process, especially for large or very fragmented files. |
| 'VALIDATEFILEoff' | Turns validation mode off.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

To get the numeric equivalent of these values, use `cdflib.getConstantValue`.

### **Examples**

Set the validation mode of the CDF library.

```
cdflib.setValidate('VALIDATEFILEon');
```

## References

This function corresponds to the CDF library C API routine `CDFsetValidate`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

`cdflib.getValidate` | `cdflib.getConstantValue`

# **`cdflib.setVarAllocBlockRecords`**

Specify range of records to be allocated for variable

## **Syntax**

```
cdflib.setVarAllocBlockRecords(cdfId, varNum, firstrec, lastrec)
```

## **Description**

`cdflib.setVarAllocBlockRecords(cdfId, varNum, firstrec, lastrec)` specifies a range of records you want to allocate (but not write) for a variable in a Common Data Format (CDF) file.

## **Input Arguments**

### **`cdfId`**

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

### **`varNum`**

Numeric value identifying a variable in the file. Variable identifiers (variable numbers) are zero-based.

### **`firstRec`**

Numeric value identifying the record at which to start allocating. Record numbers are zero-based.

### **`lastRec`**

Numeric value identifying the record at which to stop allocating. Record numbers are zero-based.

## Examples

Create a CDF, create a variable in the CDF, and then specify the number of records to allocate for the variable. To run this example, you must be in a writable folder.

```
cdfid = cdfplib.create('your_file.cdf');

% Create a variable in the file.
varNum = cdfplib.createVar(cdfid, 'Grades', 'cdf_int1', 1, [], true, []);

% Specify the number of records to allocate.
cdfplib.setVarAllocBlockRecords(cdfid, varNum, 1, 10);

% Clean up
cdfplib.delete(cdfid)

clear cdfid
```

## References

This function corresponds to the CDF library C API routine `CDFsetzVarAllocBlockRecords`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

## See Also

`cdfplib.getVarAllocRecords`

# **cdflib.setVarBlockingFactor**

Specify blocking factor for variable

## **Syntax**

```
cdflib.setVarBlockingFactor(cdfId,varNum,blockingFactor)
```

## **Description**

`cdflib.setVarBlockingFactor(cdfId,varNum,blockingFactor)` specifies the blocking factor for a variable in a Common Data Format (CDF) file.

## **Input Arguments**

### **cdfId**

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

### **varNum**

Numeric value identifying a variable in the file. Variable numbers are zero-based.

### **blockingFactor**

Numeric value that specifies the number of records to allocate when writing to an unallocated record.

## **Examples**

Create a CDF, create a variable in the CDF, and then set the blocking factor used with the variable. To run this example, you must be in a writable folder.

```
cdfid = cdflib.create('your_file.cdf');
```

```
% Create a variable in the file.
varNum = cdfplib.createVar(cdfid, 'Time', 'cdf_int1', 1, [], true, []);

% Get the current blocking factor used with the variable
bFactor = cdfplib.getVarBlockingFactor(cdfid, varNum)

bFactor =

 0

% Change the blocking factor for the variable
cdfplib.setVarBlockingFactor(cdfid, varNum, 10);

% Check the new blocking factor .
bFactor = cdfplib.getVarBlockingFactor(cdfid, varNum)

bFactor =

 10

% Clean up
cdfplib.delete(cdfid)

clear cdfid
```

## More About

### blocking factor

A variable's *blocking factor* specifies the minimum number of records the library allocates when you write to an unallocated record. If you specify a fractional blocking factor, the library rounds the value down.

## References

This function corresponds to the CDF library C API routine `CDFsetzVarBlockingFactor`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

**See Also**

`cdflib.getVarBlockingFactor`

## **cdflib.setVarCacheSize**

Specify number of multi-file cache buffers for variable

### **Syntax**

```
cdflib.setVarCacheSize(cdfId, varNum, numBuffers)
```

### **Description**

`cdflib.setVarCacheSize(cdfId, varNum, numBuffers)` specifies the number of cache buffers the CDF library uses for a variable in a Common Data Format (CDF) file.

This function is only used with multifile format CDF files. It does not apply to single-file format CDFs. For more information about caching, see the *CDF User's Guide*.

### **Input Arguments**

#### **`cdfId`**

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

#### **`varNum`**

Numeric value identifying a variable in the file. Variable identifiers (variable numbers) are zero-based.

#### **`numBuffers`**

Numeric value identifying the number of cache buffers to use.

### **Examples**

Create a multifile CDF, and then retrieve the number of buffers being used for a variable:

```
cdfid = cdfplib.create('your_file.cdf')

% Set the format of the file to be multi-file
cdfplib.setFormat(cdfid,'MULTI_FILE');

% Create a variable in the file
varNum = cdfplib.createVar(cdfid,'Time','cdf_int1',1,[],true,[]);

% Note how the library creates a separate file for the variable
ls your_file.*

your_file.cdf your_file.z0

% Determine the number of cache buffers used with the variable
numBuf = cdfplib.getVarCacheSize(cdfid,varNum)

numBuf =

 1

% Increase the number of cache buffers used.
cdfplib.setVarCacheSize(cdfid,varNum,5)

% Check the number of cache buffers used with the variable.
numBuf = cdfplib.getVarCacheSize(cdfid,varNum)

numBuf =

 5

% Clean up
cdfplib.delete(cdfid);

clear cdfid
```

## References

This function corresponds to the CDF library C API routine `CDFsetzVarCacheSize`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

**See Also**

`cdflib.getVarCacheSize` | `cdflib.setVarsCacheSize`

# **cdflib.setVarCompression**

Specify compression settings used with variable

## **Syntax**

```
cdflib.setVarCompression(cdfId, varNum, ctype, cparams)
```

## **Description**

**cdflib.setVarCompression(cdfId, varNum, ctype, cparams)** configures the compression setting for a variable in a Common Data Format (CDF) file.

## **Input Arguments**

### **cdfId**

Identifier of a CDF file, returned by a call to **cdflib.create** or **cdflib.open**.

### **varNum**

Numeric value identifying a variable in the file. Variable identifiers (variable numbers) are zero-based.

### **ctype**

One of the following text strings, or its numeric equivalent, specifying the compression type.

| <b>Text String</b>  | <b>Compression Type</b>         |
|---------------------|---------------------------------|
| 'NO_COMPRESSION'    | No compression.                 |
| 'RLE_COMPRESSION'   | Run-length encoding compression |
| 'HUFF_COMPRESSION'  | Huffman compression             |
| 'AHUFF_COMPRESSION' | Adaptive Huffman compression    |

| Text String        | Compression Type      |
|--------------------|-----------------------|
| 'GZIP_COMPRESSION' | GNU's zip compression |

### **cparams**

Optional parameter specifying any additional parameters required by the compression type. Currently, the only compression type that uses this parameter is 'GZIP\_COMPRESSION'. For this compression type, you use `cparams` to specify the level of compression as a numeric value between 1 and 9.

## **Examples**

Create a CDF, create a variable, and then set the compression used by the variable. To run this example, you must be in a folder with execute permission.

```
cdfid = cdflib.create('mycdf.cdf');

% Create a variable in the file.
varNum = cdflib.createVar(cdfid, 'Time', 'cdf_int1', 1, [], true, []);

% Specify the compression used by the variable.
cdflib.setVarCompression(cdfid, 0, 'GZIP_COMPRESSION', 8)

% Check the compression setting of the variable
[ctype params percent] = cdflib.getVarCompression(cdfid, 0)

ctype =

GZIP_COMPRESSION

params =

 8

percent =

 0

% Clean up
cdflib.delete(cdfid);
clear cdfid
```

## References

This function corresponds to the CDF library C API routine `CDFsetzVarCompression`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

`cdflib.setCompression` | `cdflib.getVarCompression`

## **cdflib.setVarInitialRecs**

Specify initial number of records written to variable

### **Syntax**

```
cdflib.setVarInitialRecs(cdfId,varNum,numrecs)
```

### **Description**

`cdflib.setVarInitialRecs(cdfId,varNum,numrecs)` specifies the initial number of records to write to a variable in a Common Data Format (CDF) file.

### **Input Arguments**

#### **cdfId**

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

#### **varNum**

Numeric value identifying a variable in the file. Variable numbers are zero-based.

#### **numRecs**

Numeric value specifying the number of records to write.

### **Examples**

Create a CDF, create a variable, and then specify the number of records to write for the variable. To run this example, you must be in a writable folder.

```
cdfid = cdflib.create('your_file.cdf');

% Create a variable in the file.
varNum = cdflib.createVar(cdfid,'Grades','cdf_int1',1,[],true,[]);
```

```
% Specify the number of records to write for the variable
cdflib.setVarInitialRecs(cdfid,varNum,100);

recsWritten = cdflib.getVarNumRecsWritten(cdfid,varNum)

recsWritten =

 100

% Clean up
cdflib.delete(cdfid)

clear cdfid
```

## References

This function corresponds to the CDF library C API routine `CDFsetzVarInitialRecs`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

`cdflib.createVar`

## **cdflib.setVarPadValue**

Specify pad value used with variable

### **Syntax**

```
cdflib.setVarPadValue(cdfId, varNum, padvalue)
```

### **Description**

`cdflib.setVarPadValue(cdfId, varNum, padvalue)` specifies the pad value used with a variable in a Common Data Format (CDF) file.

### **Input Arguments**

#### **cdfId**

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

#### **varNum**

Numeric value identifying a variable in the file. Variable numbers are zero-based.

#### **padValue**

Value to use a pad value for the variable. The data type of the pad value must match the data type of the variable.

### **Examples**

Create a CDF, create a variable in the CDF, and then set the pad value used with the variable. To run this example, you must be in a writable folder.

```
cdfid = cdflib.create('your_file.cdf');
```

```
% Create a variable in the file.
```

```
varNum = cdflib.createVar(cdfid, 'Time', 'cdf_int1', 1, [], true, []);

% Get the current pad value used with the variable
padval = cdflib.getVarPadValue(cdfid, varNum)

padval =

 0

% Change the pad value for the variable
cdflib.setVarPadValue(cdfid, varNum, int8(1));

% Check the new pad value.
padval = cdflib.getVarPadValue(cdfid, varNum)

padval =

 1

% Clean up
cdflib.delete(cdfid)

clear cdfid
```

## References

## **cdflib.SetVarReservePercent**

Specify reserve percentage for variable

### **Syntax**

```
cdflib.setVarReservePercent(cdfId, varNum, percent)
```

### **Description**

`cdflib.setVarReservePercent(cdfId, varNum, percent)` specifies the compression reserve percentage for a variable in a Common Data Format (CDF) file.

### **Input Arguments**

#### **cdfId**

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

#### **varNum**

Numeric value identifying a variable in the file. Variable identifiers (variable numbers) are zero-based.

#### **percent**

Numeric value specifying the amount of extra space to allocate for a compressed variable, expressed as a percentage. You can specify values between 0 (no extra space is reserved) and 100, or values greater than 100. The value specifies the percentage of the uncompressed size of the variable. If you specify a fractional reserve percentages, the library rounds the value down.

### **Examples**

Create a CDF, create a variable, set the compression of the variable, and then set the reserve percent for the variable. To run this example, you must be in a writable folder.

```
cdfid = cdflib.create('your_file.cdf');

% Create a variable in the file.
varNum = cdflib.createVar(cdfid, 'Time', 'cdf_int1', 1, [], true, []);

% Set the compression of the variable.
cdflib.setVarCompression(cdfid, varNum, 'GZIP_COMPRESSION', 8);

% Set the compression reserver percentage
cdflib.setVarReservePercent(cdfid, varNum, 80);

cdflib.close(cdfid);
```

## More About

### **reserve percentage**

Specifies how much extra space to allocate for a compressed variable. This extra space allows the variable to expand when you write additional records to the variable. If you do not specify this room for growth, the library has to move the variable to the end of the file when the size expands and the space at the original location of the variable becomes wasted space.

## References

This function corresponds to the CDF library C API routine `CDFsetzVarReservePercent`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

## **cdflib.setVarsCacheSize**

Specify number of cache buffers used for all variables

### **Syntax**

```
cdflib.setVarsCacheSize(cdfId, varNum, numBuffers)
```

### **Description**

`cdflib.setVarsCacheSize(cdfId, varNum, numBuffers)` specifies the number of cache buffers the CDF library uses for all the variables in the multifile format Common Data Format (CDF) file.

This function is not applicable to single-file CDFs. For more information about caching, see the *CDF User's Guide*.

### **Input Arguments**

#### **`cdfId`**

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

#### **`varNum`**

Numeric value identifying a variable in the file. Variable identifiers (variable numbers) are zero-based.

#### **`numBuffers`**

Numeric value specifying the cache buffers.

### **Examples**

Create a multifile CDF and specify the number of buffers used for all variables. To run this example, you must be in a writable folder.

```
cdfid = cdfplib.create('your_file.cdf')

% Set the format of the file to be multi-file
cdfplib.setFormat(cdfid,'MULTI_FILE');

% Create a variable in the file
varNum = cdfplib.createVar(cdfid,'Time','cdf_int1',1,[],true,[]);

% Note how the library creates a separate file for the variable
ls your_file.*

your_file.cdf your_file.z0

% Determine the number of cache buffers used with the variable
numBuf = cdfplib.getVarCacheSize(cdfid,varNum)

numBuf =

 1

% Specify the number of cache buffers used by all variables in CDF.
cdfplib.setVarsCacheSize(cdfid,6)

% Check the number of cache buffers used with the variable.
numBuf = cdfplib.getVarCacheSize(cdfid,varNum)

numBuf =

 6

% Clean up
cdfplib.delete(cdfid);

clear cdfid
```

# **cdflib.setVarSparseRecords**

Specify how variable handles sparse records

## **Syntax**

```
cdflib.getVarSparseRecords(cdfId, varNum, stype)
```

## **Description**

**cdflib.getVarSparseRecords(cdfId, varNum, stype)** specifies the sparse records type of a variable in a Common Data Format (CDF) file.

## **Input Arguments**

### **cdfId**

Identifier of a CDF file, returned by a call to **cdflib.create** or **cdflib.open**.

### **varNum**

Number that identifies the variable to be set. Variable numbers are zero-based.

### **stype**

One of the following text strings, or its numeric equivalent, that specifies how the variable handles sparse records.

| <b>Text String</b>    | <b>Description</b>                                                                                                                                                                                           |
|-----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'NO_SPARSERECORDS '   | No sparse records                                                                                                                                                                                            |
| 'PAD_SPARSERECORDS '  | For sparse records, the library uses the variable's pad value when reading values from a missing record.                                                                                                     |
| 'PREV_SPARSERECORDS ' | For sparse records, the library uses values from the previous existing record when reading values from a missing record. If there is no previous existing record, the library uses the variable's pad value. |

To get the numeric equivalent of these text string constants, use the `cdflib.getConstantValue` function.

## Examples

Open a multifile CDF and close a variable.

Create a CDF, create a variable, and set the sparse records type of the variable. To run this example you must be in a writable folder.

```
cdfid = cdflib.create('your_file.cdf');

% Create a variable in the file.
varNum = cdflib.createVar(cdfid, 'Time', 'cdf_int1', 1, [], true, []);

% Set the sparse records type of the variable
cdflib.setVarSparseRecords(cdfid, varNum, 'PAD_SPARSERECORDS');

% Check the sparse records type of the variable
stype = cdflib.getVarSparseRecords(cdfid, varNum)

stype =

PAD_SPARSERECORDS

%Clean up
cdflib.delete(cdfid);

clear cdfid
```

## References

## **cdfread**

Read data from Common Data Format (CDF) file

### **Syntax**

```
data = cdfread(filename)
data = cdfread(filename, param1, val1, param2, val2, ...)
[data, info] = cdfread(filename, ...)
```

### **Description**

`data = cdfread(filename)` reads all the data from the Common Data Format (CDF) file specified in the string `filename`. CDF data sets typically contain a set of variables, of a specific data type, each with an associated set of records. The variable might represent time values with each record representing a specific time that an observation was recorded. `cdfread` returns all the data in a cell array where each column represents a variable and each row represents a record associated with a variable. If the variables have varying numbers of associated records, `cdfread` pads the rows to create a rectangular cell array, using pad values defined in the CDF file.

---

**Note** Because `cdfread` creates temporary files, the current working directory must be writable.

---

`data = cdfread(filename, param1, val1, param2, val2, ...)` reads data from the file, where `param1`, `param2`, and so on, can be any of the parameters listed in the following table.

`[data, info] = cdfread(filename, ...)` returns details about the CDF file in the `info` structure.

| <b>Parameter</b> | <b>Value</b>                                                                                                                                                                                                               |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'Records'        | A vector specifying which records to read. Record numbers are zero-based. <code>cdfread</code> returns a cell array with the same number of rows as the number of records read and as many columns as there are variables. |

| Parameter               | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'Variables'             | A 1-by- $n$ or $n$ -by-1 cell array specifying the names of the variables to read from the file. $n$ must be less than or equal to the total number of variables in the file. <code>cdfread</code> returns a cell array with the same number of columns as the number of variables read, and a row for each record read.                                                                                                                                                                                                                                                                                                                                                                           |
| 'Slices'                | An $m$ -by-3 array, where each row specifies where to start reading along a particular dimension of a variable, the skip interval to use on that dimension (every item, every other item, etc.), and the total number of values to read on that dimension. $m$ must be less than or equal to the number of dimensions of the variable. If $m$ is less than the total number of dimensions, <code>cdfread</code> reads every value from the unspecified dimensions ( $[0 \ 1 \ n]$ , where $n$ is the total number of elements in the dimension.<br>Note: Because the 'Slices' parameter describes how to process a single variable, it must be used in conjunction with the 'Variables' parameter. |
| 'ConvertEpochToDatenum' | A Boolean value that determines whether <code>cdfread</code> automatically converts CDF epoch data types to MATLAB serial date numbers. If set to <code>false</code> (the default), <code>cdfread</code> wraps epoch values in MATLAB <code>cdfepoch</code> objects.<br>Note: For better performance when reading large data sets, set this parameter to <code>true</code> .                                                                                                                                                                                                                                                                                                                       |

| Parameter        | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'CombineRecords' | <p>A Boolean value that determines how <code>cdfread</code> returns the CDF data sets read from the file. If set to <code>false</code> (the default), <code>cdfread</code> stores the data in an <math>m</math>-by-<math>n</math> cell array, where <math>m</math> is the number of records and <math>n</math> is the number of variables requested. If set to <code>true</code>, <code>cdfread</code> combines all records for a particular variable into one cell in the output cell array. In this cell, <code>cdfread</code> stores scalar data as a column array. <code>cdfread</code> extends the dimensionality of nonscalar and string data. For example, instead of creating 1000 elements containing 20-by-30 arrays for each record, <code>cdfread</code> stores all the records in one cell as a 1000-by-20-by-30 array</p> <p>Note: If you use the 'Records' parameter to specify which records to read, you cannot use the 'CombineRecords' parameter.</p> <p>Note: When using the 'Variable' parameter to read one variable, if the 'CombineRecords' parameter is <code>true</code>, <code>cdfread</code> returns the data as an M-by-N numeric or character array; it does not put the data into a cell array.</p> |

---

**Note:** To improve performance when working with large data files, use the 'ConvertEpochToDatenum' and 'CombineRecords' options.

---

---

**Note:** To improve performance, turn off the file validation which the CDF library does by default when opening files. For more information, see `cdflib.setValidate`.

---

## Examples

Read all the data from a CDF file.

```
data = cdfread('example.cdf');
```

Read the data from the variable 'Time'.

```
data = cdfread('example.cdf', 'Variable', {'Time'});
```

Read the first value in the first dimension, the second value in the second dimension, the first and third values in the third dimension, and all values in the remaining dimension of the variable 'multidimensional'.

```
data = cdfread('example.cdf', ...
 'Variable', {'multidimensional'}, ...
 'Slices', [0 1 1; 1 1 1; 0 2 2]);
```

This is similar to reading the whole variable into `data` and then using matrix indexing, as in the following.

```
data{1}(1, 2, [1 3], :)
```

Collapse the records from a data set and convert CDF epoch data types to MATLAB serial date numbers.

```
data = cdfread('example.cdf', ...
 'CombineRecords', true, ...
 'ConvertEpochToDatenum', true);
```

## More About

- “Import CDF Files Using Low-Level Functions”

## See Also

`cdfepoch` | `cdfinfo` | `cdflib.setValidate`

**Introduced before R2006a**

## **cdfwrite**

Write data to Common Data Format (CDF) file

---

**Note:** `cdfwrite` is not recommended. Use the `cdflib` low-level functions instead.

---

### **Syntax**

```
cdfwrite(filename,variablelist)
cdfwrite(...,'PadValues',padvals)
cdfwrite(...,'GlobalAttributes',gattrib)
cdfwrite(...,'VariableAttributes',vattrib)
cdfwrite(...,'WriteMode',mode)
cdfwrite(...,'Format',format)
```

### **Description**

`cdfwrite(filename,variablelist)` writes out a Common Data Format (CDF) file, specified in `filename`. The `filename` input is a string enclosed in single quotes. The `variablelist` argument is a cell array of ordered pairs, each of which comprises a CDF variable name (a string) and the corresponding CDF variable value. To write out multiple records for a variable, put the values in a cell array where each element in the cell array represents a record.

---

**Note** Because `cdfwrite` creates temporary files, both the destination directory for the file and the current working directory must be writeable.

---

`cdfwrite(...,'PadValues',padvals)` writes out pad values for given variable names. `padvals` is a cell array of ordered pairs, each of which comprises a variable name (a string) and a corresponding pad value. Pad values are the default values associated with the variable when an out-of-bounds record is accessed. Variable names that appear in `padvals` must appear in `variablelist`.

`cdfwrite(..., 'GlobalAttributes', gattrib)` writes the structure `gattrib` as global metadata for the CDF file. Each field of the structure is the name of a global attribute. The value of each field contains the value of the attribute. To write out multiple values for an attribute, put the values in a cell array where each element in the cell array represents a record.

---

**Note** To specify a global attribute name that is invalid in your MATLAB application, create a field called 'CDFAttributeRename' in the attribute structure. The value of this field must have a value that is a cell array of ordered pairs. The ordered pair consists of the name of the original attribute, as listed in the `GlobalAttributes` structure, and the corresponding name of the attribute to be written to the CDF file.

---

`cdfwrite(..., 'VariableAttributes', vattrib)` writes the structure `vattrib` as variable metadata for the CDF. Each field of the struct is the name of a variable attribute. The value of each field should be an M-by-2 cell array where M is the number of variables with attributes. The first element in the cell array should be the name of the variable and the second element should be the value of the attribute for that variable.

---

**Note** To specify a variable attribute name that is illegal in MATLAB, create a field called 'CDFAttributeRename' in the attribute structure. The value of this field must have a value that is a cell array of ordered pairs. The ordered pair consists of the name of the original attribute, as listed in the `VariableAttributes` struct, and the corresponding name of the attribute to be written to the CDF file. If you are specifying a variable attribute of a CDF variable that you are renaming, the name of the variable in the `VariableAttributes` structure must be the same as the renamed variable.

---

`cdfwrite(..., 'WriteMode', mode)`, where *mode* is either 'overwrite' or 'append', indicates whether or not the specified variables should be appended to the CDF file if the file already exists. By default, `cdfwrite` overwrites existing variables and attributes.

`cdfwrite(..., 'Format', format)`, where *format* is either 'multifile' or 'singlefile', indicates whether or not the data is written out as a multifile CDF. In a multifile CDF, each variable is stored in a separate file with the name \*.vN, where N is the number of the variable that is written out to the CDF. By default, `cdfwrite` writes out a single file CDF. When 'WriteMode' is set to 'Append', the 'Format' option is ignored, and the format of the preexisting CDF is used.

## Examples

Write out a file 'example.cdf' containing a variable 'Longitude' with the value [0:360].

```
cdfwrite('example', {'Longitude', 0:360});
```

Write out a file 'example.cdf' containing variables 'Longitude' and 'Latitude' with the variable 'Latitude' having a pad value of 10 for all out-of-bounds records that are accessed.

```
cdfwrite('example', {'Longitude', 0:360, 'Latitude', 10:20}, ...
 'PadValues', {'Latitude', 10});
```

Write out a file 'example.cdf', containing a variable 'Longitude' with the value [0:360], and with a variable attribute of 'validmin' with the value 10.

```
varAttribStruct.validmin = {'Longitude' [10]};
cdfwrite('example', {'Longitude' 0:360}, 'VariableAttributes', ...
 varAttribStruct);
```

# ceil

Round toward positive infinity

## Syntax

`Y = ceil(X)`

`Y = ceil(t)`

`Y = ceil(t,unit)`

## Description

`Y = ceil(X)` rounds each element of `X` to the nearest integer greater than or equal to that element.

`Y = ceil(t)` rounds each element of the duration array `t` to the nearest number of seconds greater than or equal to that element.

`Y = ceil(t,unit)` rounds each element of `t` to the nearest number of the specified unit of time greater than or equal to that element.

## Examples

### Round Matrix Elements Toward Positive Infinity

`X = [-1.9 -0.2 3.4; 5.6 7 2.4+3.6i];`

`Y = ceil(X)`

`Y =`

```
-1.0000 + 0.0000i 0.0000 + 0.0000i 4.0000 + 0.0000i
 6.0000 + 0.0000i 7.0000 + 0.0000i 3.0000 + 4.0000i
```

### Round Duration Values Toward Positive Infinity

Round each value in a duration array to the nearest number of seconds greater than or equal to that value.

```
t = hours(8) + minutes(29:31) + seconds(1.23);
t.Format = 'hh:mm:ss.SS'
```

```
t =
```

```
08:29:01.23 08:30:01.23 08:31:01.23
```

```
Y1 = ceil(t)
```

```
Y1 =
```

```
08:29:02.00 08:30:02.00 08:31:02.00
```

Round each value in `t` to the nearest number of hours greater than or equal to that value.

```
Y2 = ceil(t, 'hours')
```

```
Y2 =
```

```
09:00:00.00 09:00:00.00 09:00:00.00
```

## Input Arguments

### **X** — Input array

scalar | vector | matrix | multidimensional array

Input array, specified as a scalar, vector, matrix, or multidimensional array. For complex `X`, `ceil` treats the real and imaginary parts independently.

`ceil` converts logical and `char` elements of `X` into `double` values.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `char` | `logical`

Complex Number Support: Yes

### **t** — Input duration

duration array

Input duration, specified as a `duration` array.

**unit** – Unit of time

'seconds' (default) | 'minutes' | 'hours' | 'days' | 'years'

Unit of time, specified as 'seconds', 'minutes', 'hours', 'days', or 'years'. A duration of 1 year is equal to exactly 365.2425 24-hour days.

## cell

Create cell array

### Syntax

```
C = cell(n)
C = cell(sz1, ..., szN)
C = cell(sz)

D = cell(obj)
```

### Description

`C = cell(n)` returns an  $n$ -by- $n$  cell array of empty matrices.

`C = cell(sz1, ..., szN)` returns a  $sz1$ -by-...-by- $szN$  cell array of empty matrices where  $sz1, \dots, szN$  indicate the size of each dimension. For example, `cell(2,3)` returns a 2-by-3 cell array.

`C = cell(sz)` returns a cell array of empty matrices where size vector `SZ` defines `size(C)`. For example, `cell([2 3])` returns a 2-by-3 cell array.

`D = cell(obj)` converts a Java array or .NET `System.String` or `System.Object` array into a MATLAB cell array.

### Examples

#### Square Cell Array

Create a 3-by-3 cell array of empty matrices.

```
C = cell(3)
```

```
C =
```

```
 [] [] []
```

```

[] [] []
[] [] []

```

### 3-D Cell Array

Create a 3-by-4-by-2 cell array of empty matrices.

```

C = cell(3,4,2);
size(C)

```

ans =

```

 3 4 2

```

### Clone Size from Existing Array

Create a cell array of empty matrices that is the same size as an existing array.

```

A = [7 9; 2 1; 8 3];
sz = size(A);
C = cell(sz)

```

C =

```

[] []
[] []
[] []

```

It is a common pattern to combine the previous two lines of code into a single line.

```

C = cell(size(A));

```

### Cell Array from Java Array

Convert an array of `java.lang.String` objects into a cell array.

```

X = java_array('java.lang.String', 3);
X(1) = java.lang.String('one');
X(2) = java.lang.String('two');
X(3) = java.lang.String('three');

```

```
D = cell(X)
```

```
D =
```

```
 'one'
 'two'
 'three'
```

## Cell Array from .NET Array

Convert a .NET array of `System.Double` objects into a cell array.

```
N = NET.createArray('System.Double[]',2);
```

```
N(1) = [13 7 30];
```

```
N(2) = 42;
```

```
D = cell(N)
```

```
D =
```

```
 [1x3 double] [42]
```

- “Create a Cell Array”
- “Access Data in a Cell Array”
- “Use Python list Type in MATLAB”

## Input Arguments

### **n** — Size of square cell array

integer value

Size of a square cell array, specified as an integer value.

- If `n` is 0, then `C` is an empty cell array.
- If `n` is negative, then it is treated as 0.

Data Types: `double` | `single` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **sz1, ..., szN** — Size of each dimension (as separate arguments)

integer values

Size of each dimension, specified as separate arguments of integer values.

- If the size of any dimension is 0, then **C** is an empty cell array.
- If the size of any dimension is negative, then it is treated as 0.
- Beyond the second dimension, `cell` ignores trailing dimensions with a size of 1. For example, `cell([3,1,1,1])` produces a 3-by-1 cell array of empty matrices.

Data Types: `double` | `single` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **sz** — Size of each dimension (as a row vector)

integer values

Size of each dimension, specified as a row vector of integer values. Each element of this vector indicates the size of the corresponding dimension.

- If the size of any dimension is 0, then **C** is an empty cell array.
- If the size of any dimension is negative, then it is treated as 0.
- Beyond the second dimension, `cell` ignores trailing dimensions with a size of 1. For example, `cell([3,1,1,1])` produces a 3-by-1 cell array of empty matrices.

Example: `sz = [2, 3, 4]` creates a 2-by-3-by-4 cell array of empty matrices.

Data Types: `double` | `single` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **obj** — Input array

Java array or object | .NET array of type `System.String` or `System.Object` | Python<sup>®</sup> sequence type

Input array, specified as:

- Java array or object
- .NET array of type `System.String` or `System.Object`
- Python sequence type

## Output Arguments

### **C** — Output array

cell array

Output array, returned as a cell array. Each cell contains an empty, 0-by-0 array of type `double`.

## **D — Converted array**

cell array

Converted array, returned as a cell array.

Each cell contains a MATLAB type closest to the Java or .NET type. For more information, see:

- “Conversion of Java Return Types”
- “.NET Type to MATLAB Type Mapping”

## **More About**

### **Tips**

- Creating an empty array with the `cell` function, such as

```
C = cell(3,4,2);
```

is equivalent to assigning an empty array to the last index of a new cell array:

```
C{3,4,2} = [];
```

- “cell Function Syntax for System.Object[,] Arrays”

### **See Also**

`num2cell` | `table2cell`

**Introduced before R2006a**

## cell2mat

Convert cell array to ordinary array of the underlying data type

### Syntax

```
A = cell2mat(C)
```

### Description

`A = cell2mat(C)` converts a cell array into an ordinary array. The elements of the cell array must all contain the same data type, and the resulting array is of that data type.

The contents of `C` must support concatenation into an N-dimensional rectangle. Otherwise, the results are undefined. For example, the contents of cells in the same column must have the same number of columns, although they need not have the same number of rows (see figure).

### Examples

#### Convert Cell Array to Numeric Array

Convert numeric arrays in four cells of a cell array into one numeric array.

```
C = {[1], [2 3 4];
 [5; 9], [6 7 8; 10 11 12]}
```

```
C =
```

```
 [1] [1x3 double]
 [2x1 double] [2x3 double]
```

```
A = cell2mat(C)
```

```
A =
```

```
 1 2 3 4
 5 6 7 8
 9 10 11 12
```

## Convert Cell Array of Structures to Array

Convert structures in a cell array into one structure array. The structures must have the same fields.

```
s1.a = [1 2 3 4];
s1.b = 'Good';
s2.a = [5 6; 7 8];
s2.b = 'Morning';
c = {s1,s2};
d = cell2mat(c)
```

```
d =
```

```
1x2 struct array with fields:
```

```
 a
 b
```

Display the first field of structure `d(1)`.

```
d(1).a
```

```
ans =
```

```
 1 2 3 4
```

Display the second field of `d(2)`.

```
d(2).b
```

```
ans =
```

```
Morning
```

## Input Arguments

### **C** — Input cell array

cell array

Input cell array, in which all cells contain the same data type. `cell2mat` accepts numeric or character data within cells of `C`, or structures with the same field names and data types. `cell2mat` does not accept objects or nested cells within `C`.

### See Also

`cell` | `cell2struct` | `cell2table` | `iscell` | `mat2cell` | `num2cell` | `struct2cell` | `table2cell`

**Introduced before R2006a**

## cell2struct

Convert cell array to structure array

### Syntax

```
structArray = cell2struct(cellArray, fields, dim)
```

### Description

*structArray* = cell2struct(*cellArray*, *fields*, *dim*) creates a structure array, *structArray*, from the information contained within cell array *cellArray*.

The *fields* argument specifies field names for the structure array. This argument is an array of strings or a cell array of strings.

The *dim* argument tells MATLAB which axis of the cell array to use in creating the structure array. Use a numeric **double** to specify *dim*.

To create a structure array with fields derived from N rows of a cell array, specify N field names in the *fields* argument, and the number 1 in the *dim* argument. To create a structure array with fields derived from M columns of a cell array, specify M field names in the *fields* argument and the number 2 in the *dim* argument.

The *structArray* output is a structure array with N fields, where N is equal to the number of fields in the *fields* input argument. The number of fields in the resulting structure must equal the number of cells along dimension *dim* that you want to convert.

### Examples

Create the following table for use with the examples in this section. The table lists information about the employees of a small Engineering company. Reading the table by rows shows the names of employees by department. Reading the table by columns shows the number of years each employee has worked at the company.

|             | 5 Years         | 10 Years   | 15 Years        |
|-------------|-----------------|------------|-----------------|
| Development | Lee, Reed, Hill | Dean, Frye | Lane, Fox, King |

|                      | 5 Years      | 10 Years        | 15 Years   |
|----------------------|--------------|-----------------|------------|
| <b>Sales</b>         | Howe, Burns  | Kirby, Ford     | Hall       |
| <b>Management</b>    | Price        | Clark, Shea     | Sims       |
| <b>Quality</b>       | Bates, Gray  | Nash            | Kay, Chase |
| <b>Documentation</b> | Lloyd, Young | Ryan, Hart, Roy | Marsh      |

Enter the following commands to create the initial cell array `employees`:

```
devel = {'Lee', 'Reed', 'Hill'}, {'Dean', 'Frye'}, ...
 {'Lane', 'Fox', 'King'};
sales = {'Howe', 'Burns'}, {'Kirby', 'Ford'}, {'Hall'};
mgmt = {'Price'}, {'Clark', 'Shea'}, {'Sims'};
qual = {'Bates', 'Gray'}, {'Nash'}, {'Kay', 'Chase'};
docu = {'Lloyd', 'Young'}, {'Ryan', 'Hart', 'Roy'}, {'Marsh'};
```

```
employees = [devel; sales; mgmt; qual; docu]
employees =
```

```

 {1x3 cell} {1x2 cell} {1x3 cell}
 {1x2 cell} {1x2 cell} {1x1 cell}
 {1x1 cell} {1x2 cell} {1x1 cell}
 {1x2 cell} {1x1 cell} {1x2 cell}
 {1x2 cell} {1x3 cell} {1x1 cell}
```

This is the resulting cell array:

|               | fiveYears           | tenYears            | fifteenYears        |
|---------------|---------------------|---------------------|---------------------|
| development   | Lee<br>Reed<br>Hill | Dean<br>Frye        | Lane<br>Fox<br>King |
| sales         | Howe<br>Burns       | Kirby<br>Ford       | Hall                |
| management    | Price               | Clark<br>Shea       | Sims                |
| quality       | Bates<br>Gray       | Nash                | Kay<br>Chase        |
| documentation | Young<br>Lloyd      | Ryan<br>Hart<br>Roy | Marsh               |

**5 x 3 cell array**

Convert the cell array to a struct along dimension 1:

- 1 Convert the 5-by-3 cell array along its first dimension to construct a 3-by-1 struct array with 5 fields. Each of the rows along dimension 1 of the cell array becomes a field in the struct array:

Traversing the first (i.e., vertical) dimension, there are 5 rows with row headings that read as follows:

```
rowHeadings = {'development', 'sales', 'management', ...
 'quality', 'documentation'};
```

- Convert the cell array to a struct array, `depts`, in reference to this dimension:

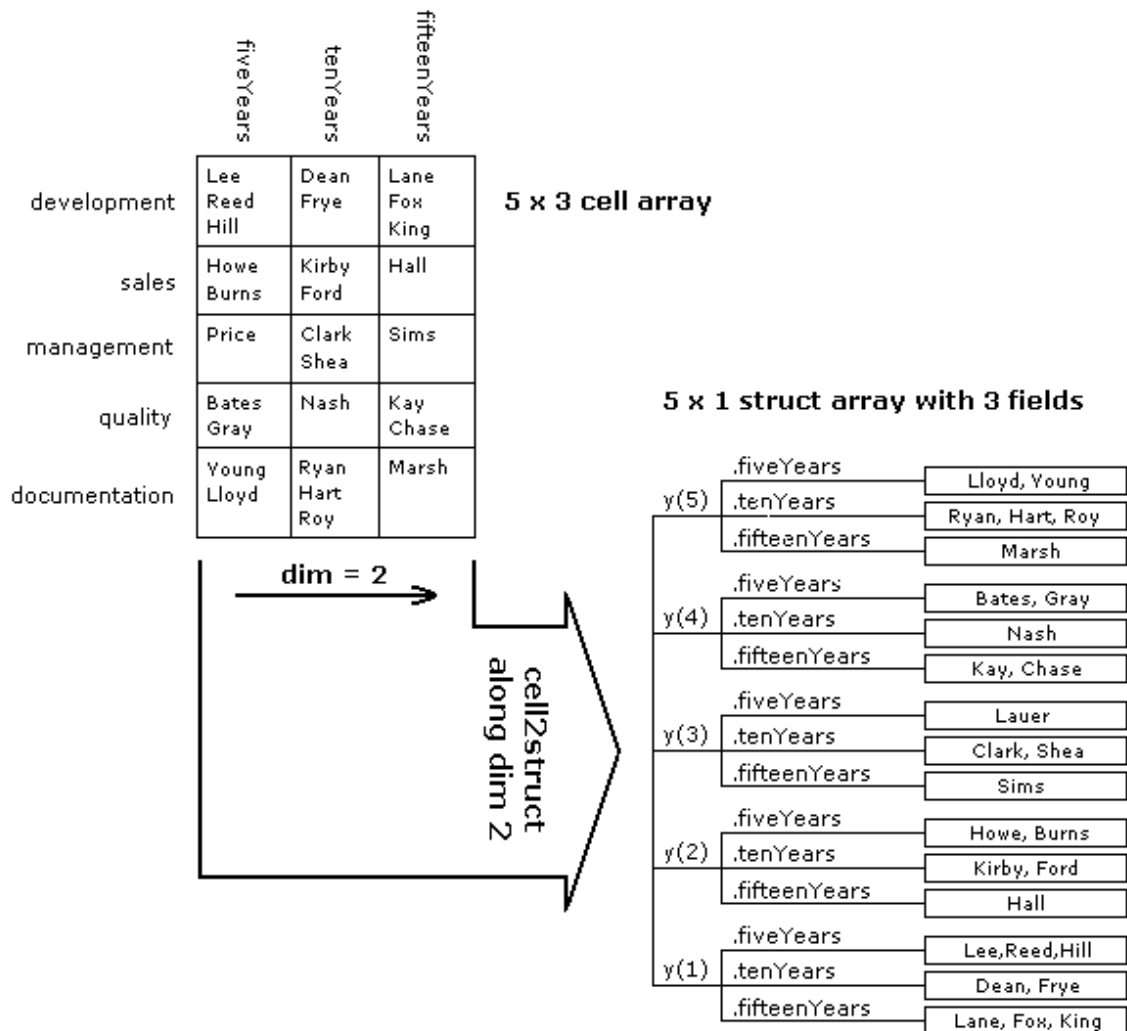

```
depts = cell2struct(employees, rowHeadings, 1)
depts =
3x1 struct array with fields:
 development
 sales
 management
 quality
 documentation
```

- Use this row-oriented structure to find the names of the Development staff who have been with the company for up to 10 years:

```
depts(1:2).development
ans =
 'Lee' 'Reed' 'Hill'
ans =
 'Dean' 'Frye'
```

Convert the same cell array to a struct along dimension 2:

- 1 Convert the 5-by-3 cell array along its second dimension to construct a 5-by-1 struct array with 3 fields. Each of the columns along dimension 2 of the cell array becomes a field in the struct array:

- 2 Traverse the cell array along the second (or horizontal) dimension. The column headings become fields of the resulting structure:

```
colHeadings = {'fiveYears' 'tenYears' 'fifteenYears'};
```

```
years = cell2struct(employees, colHeadings, 2)
years =
5x1 struct array with fields:
 fiveYears
 tenYears
 fifteenYears
```

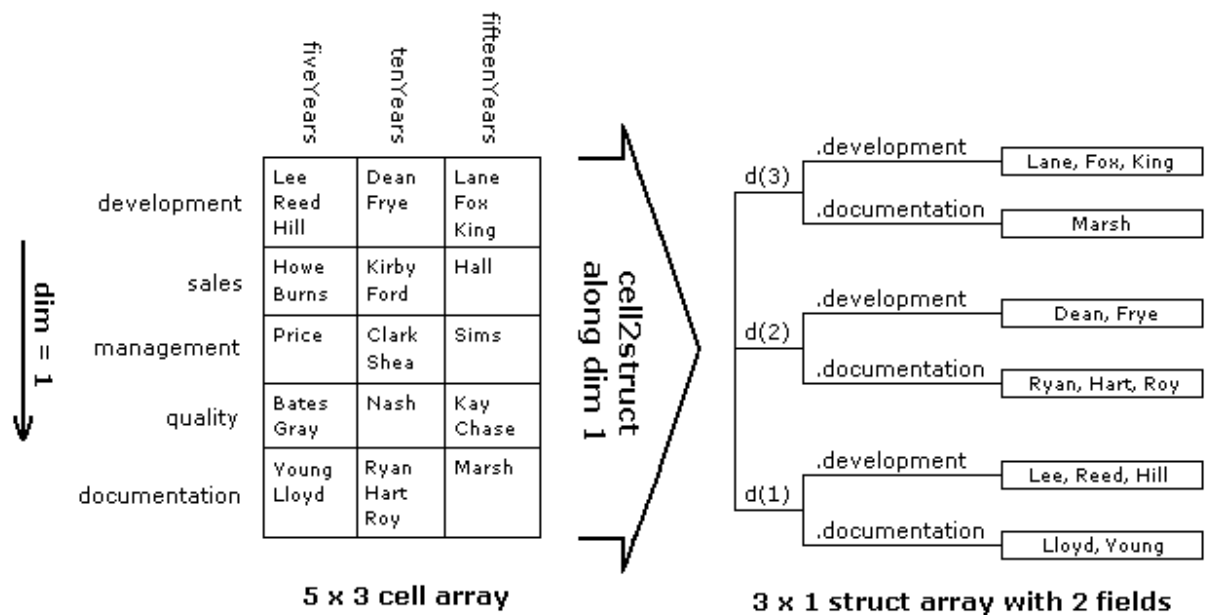

- 3 Using the column-oriented structure, show how many employees from the Sales and Documentation departments have worked for the company for at least 5 years:

```
[~, sales_5years, ~, ~, docu_5years] = years.fiveYears
sales_5years =
 'Howe' 'Burns'
docu_5years =
 'Lloyd' 'Young'
```

Convert only part of the cell array to a struct:

- 1 Convert only the first and last rows of the cell array. This results in a 3-by-1 struct array with 2 fields:

```
rowHeadings = {'development', 'documentation'};
depts = cell2struct(employees([1,5],:), rowHeadings, 1)
depts =
3x1 struct array with fields:
 development
 documentation
```

- 2 Display those employees who belong to these departments for all three periods of time:

```

for k=1:3
 depts(k,:)
end

ans =
 development: {'Lee' 'Reed' 'Hill'}
 documentation: {'Lloyd' 'Young'}

ans =
 development: {'Dean' 'Frye'}
 documentation: {'Ryan' 'Hart' 'Roy'}

ans =
 development: {'Lane' 'Fox' 'King'}
 documentation: {'Marsh'}

```

## **More About**

- dynamic field names

| `fieldnames`

**Introduced before R2006a**

# cell2table

Convert cell array to table

## Syntax

```
T = cell2table(C)
T = cell2table(C,Name,Value)
```

## Description

`T = cell2table(C)` converts the contents of an  $m$ -by- $n$  cell array, `C`, to an  $m$ -by- $n$  table, `T`. Each variable in the table, `T`, is numeric, with a data type `double`, or a cell array of strings.

`cell2table` uses the input array name appended with the column number for the variable names in the table. If these names are not valid MATLAB identifiers, `cell2table` uses strings of the form `'Var1'`, ..., `'VarN'` where  $N$  is the number of columns in `C`.

`T = cell2table(C,Name,Value)` creates a table from a cell array, `C`, with additional options specified by one or more `Name,Value` pair arguments.

For example, you can specify row names or variable names to include in the table.

## Examples

### Convert Cell Array to Table

Create a cell array containing strings and numeric data.

```
C = {5 'cereal' 110 'C+'; 12 'pizza' 140 'B';...
 23 'salmon' 367 'A'; 2 'cookies' 160 'D'}
```

`C =`

```
[5] 'cereal' [110] 'C+'
```

```
[12] 'pizza' [140] 'B'
[23] 'salmon' [367] 'A'
[2] 'cookies' [160] 'D'
```

Convert the cell array, C, to a table and specify variable names.

```
T = cell2table(C,...
 'VariableNames',{ 'Age' 'FavoriteFood' 'Calories' 'NutritionGrade'})
```

T =

| Age | FavoriteFood | Calories | NutritionGrade |
|-----|--------------|----------|----------------|
| 5   | 'cereal'     | 110      | 'C+'           |
| 12  | 'pizza'      | 140      | 'B'            |
| 23  | 'salmon'     | 367      | 'A'            |
| 2   | 'cookies'    | 160      | 'D'            |

The variables T.Age and T.Calories are numeric while the variables T.FavoriteFood and T.NutritionGrade are cell arrays of strings.

## Convert Column Headings to Variable Names

Convert a cell array to a table, and then include the first row from the cell array as variable names for the table.

Create a cell array where the first row contains strings to identify column headings.

```
Patients = {'Gender' 'Age' 'Height' 'Weight' 'Smoker';...
 'M' 38 71 176 true;...
 'M' 43 69 163 false;...
 'M' 38 64 131 false;...
 'F' 38 64 131 false;...
 'F' 40 67 133 false;...
 'F' 49 64 119 false}
```

Patients =

| 'Gender' | 'Age' | 'Height' | 'Weight' | 'Smoker' |
|----------|-------|----------|----------|----------|
| 'M'      | [ 38] | [ 71]    | [ 176]   | [ 1]     |
| 'M'      | [ 43] | [ 69]    | [ 163]   | [ 0]     |
| 'M'      | [ 38] | [ 64]    | [ 131]   | [ 0]     |
| 'F'      | [ 38] | [ 64]    | [ 131]   | [ 0]     |
| 'F'      | [ 40] | [ 67]    | [ 133]   | [ 0]     |

```
'F' [49] [64] [119] [0]
```

Exclude the columns headings and convert the contents of the cell array to a table.

```
C = Patients(2:end,:);
T = cell2table(C)
```

```
T =
```

| C1  | C2 | C3 | C4  | C5    |
|-----|----|----|-----|-------|
| 'M' | 38 | 71 | 176 | true  |
| 'M' | 43 | 69 | 163 | false |
| 'M' | 38 | 64 | 131 | false |
| 'F' | 38 | 64 | 131 | false |
| 'F' | 40 | 67 | 133 | false |
| 'F' | 49 | 64 | 119 | false |

The table, T, has variable names C1, . . . , C5.

Change the variable names by setting the table property, T.Properties.VariableNames, to the first row of the cell array.

```
T.Properties.VariableNames = Patients(1,:)
```

```
T =
```

| Gender | Age | Height | Weight | Smoker |
|--------|-----|--------|--------|--------|
| 'M'    | 38  | 71     | 176    | true   |
| 'M'    | 43  | 69     | 163    | false  |
| 'M'    | 38  | 64     | 131    | false  |
| 'F'    | 38  | 64     | 131    | false  |
| 'F'    | 40  | 67     | 133    | false  |
| 'F'    | 49  | 64     | 119    | false  |

- “Access Data in a Table”

## Input Arguments

### **C** — Input cell array

2-D cell array

Input cell array, specified as a 2-D cell array.

If the cell contents have compatible sizes and types, then `cell2table` vertically concatenates the contents of the cells in each column of `C` to create each variable in `T`. If the cell contents have different sizes or incompatible types, then the corresponding variable in the table, `T`, is a column of cells.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( `' '`). You can specify several name and value pair arguments in any order as `Name1`, `Value1`, ..., `NameN`, `ValueN`.

Example: `RowNames` `'`, { `' row1 '`, `' row2 '`, `' row3 '` } uses the row names, `row1`, `row2`, and `row3` for the table, `T`.

### **'RowNames'** — Row names for `T`

{ } (default) | cell array of nonempty, distinct strings

Row names for `T`, specified as the comma-separated pair consisting of `'RowNames'` and a cell array of nonempty, distinct strings. The number of strings must equal the number of rows, `size(C,1)`.

### **'VariableNames'** — Variable names for `T`

cell array of nonempty, distinct strings

Variable names for `T`, specified as the comma-separated pair consisting of `'VariableNames'` and a cell array of nonempty, distinct strings. The number of strings must equal the number of variables, `size(C,2)`.

Furthermore, the strings must be valid MATLAB identifiers. If valid MATLAB identifiers are not available for use as variable names, MATLAB uses a cell array of `N` strings of the form { `'Var1'` ... `'VarN'` }, where `N` is the number of variables. You can determine valid MATLAB variable names using the function `isvarname`.

## Output Arguments

### **T** — Output table

table

Output table, returned as a table. The table can store metadata such as descriptions, variable units, variable names, and row names. For more information, see [Table Properties](#).

### **See Also**

`array2table` | `isvarname` | `struct2table` | `table` | `table2cell`

**Introduced in R2013b**

## celldisp

Display cell array contents

### Syntax

```
celldisp(C)
celldisp(C, name)
```

### Description

`celldisp(C)` recursively displays the contents of a cell array.

`celldisp(C, name)` uses the string *name* for the display instead of the name of the first input (or `ans`).

### Examples

Use `celldisp` to display the contents of a 2-by-3 cell array:

```
C = {[1 2] 'Tony' 3+4i; [1 2;3 4] -5 'abc'};
celldisp(C)
```

```
C{1,1} =
 1 2
```

```
C{2,1} =
 1 2
 3 4
```

```
C{1,2} =
Tony
```

```
C{2,2} =
-5
```

```
C{1,3} =
3.0000+ 4.0000i
```

```
C{2,3} =
abc
```

## More About

- “Export Cell Array to Text File”

## See Also

cellplot

Introduced before R2006a

## cellfun

Apply function to each cell in cell array

### Syntax

```
[A1,...,Am] = cellfun(func,C1,...,Cn)
[A1,...,Am] = cellfun(func,C1,...,Cn,Name,Value)
```

### Description

`[A1,...,Am] = cellfun(func,C1,...,Cn)` calls the function specified by function handle `func` and passes elements from cell arrays `C1,...,Cn`, where `n` is the number of inputs to function `func`. Output arrays `A1,...,Am`, where `m` is the number of outputs from function `func`, contain the combined outputs from the function calls. The *i*th iteration corresponds to the syntax `[A1(i),...,Am(i)] = func(C1{i},...,Cn{i})`. The `cellfun` function does not perform the calls to function `func` in a specific order.

`[A1,...,Am] = cellfun(func,C1,...,Cn,Name,Value)` calls function `func` with additional options specified by one or more `Name,Value` pair arguments. Possible values for `Name` are 'UniformOutput' or 'ErrorHandler'.

### Input Arguments

#### **func**

Handle to a function that accepts `n` input arguments and returns `m` output arguments.

If function `func` corresponds to more than one function file (that is, if `func` represents a set of overloaded functions), MATLAB determines which function to call based on the class of the input arguments.

#### **Backward Compatibility**

`cellfun` accepts function name strings for function `func`, rather than a function handle, for these function names: `isempty`, `islogical`, `isreal`, `length`, `ndims`, `prodofsize`, `size`, `isclass`. Enclose the function name in single quotes.

If you specify a function name string rather than a function handle:

- `cellfun` does not call any overloaded versions of the function.
- The `size` and `isclass` functions require additional inputs to the `cellfun` function:

`A = cellfun('size', C, k)` returns the size along the `k`th dimension of each element of `C`.

`A = cellfun('isclass', C, classname)` returns logical 1 (`true`) for each element of `C` that matches the `classname` string. This syntax returns logical 0 (`false`) for objects that are a subclass of `classname`.

### **C1, ..., Cn**

Cell arrays that contain the `n` inputs required for function `func`. Each cell array must have the same dimensions.

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

### **'UniformOutput'**

Logical value, as follows:

|                        |                                                                                                                                                                                                                                                                                                                                                                                                                |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>true (1)</code>  | Indicates that for all inputs, each output from function <code>func</code> is a scalar cell array, scalar structure, or a scalar value that is always of the same type and size. The <code>cellfun</code> function combines the outputs in arrays <code>A1, ..., Am</code> , where <code>m</code> is the number of function outputs. Each output array is of the same type as the individual function outputs. |
| <code>false (0)</code> | Requests that the <code>cellfun</code> function combine the outputs into cell arrays <code>A1, ..., Am</code> . The outputs of function <code>func</code> can be of any size or type.                                                                                                                                                                                                                          |

**Default:** `true`

**'ErrorHandler'**

Handle to a function that catches any errors that occur when MATLAB attempts to execute function `func`. Define this function so that it rethrows the error or returns valid outputs for function `func`.

MATLAB calls the specified error-handling function with two input arguments:

- A structure with these fields:

|                         |                                                                                             |
|-------------------------|---------------------------------------------------------------------------------------------|
| <code>identifier</code> | Error identifier.                                                                           |
| <code>message</code>    | Error message text.                                                                         |
| <code>index</code>      | Linear index corresponding to the element of the input cell array at the time of the error. |

- The set of input arguments to function `func` at the time of the error.

## Output Arguments

**A1, ..., Am**

Arrays that collect the  $m$  outputs from function `func`. Each array `A` is the same size as each of the inputs `C1, ..., Cn`.

Function `func` can return output arguments of different classes. However, if `UniformOutput` is `true` (the default):

- The individual outputs from function `func` must be scalar values (numeric, logical, or character), scalar structures, or scalar cell arrays.
- The class of a particular output argument must be the same for each set of inputs. The class of the corresponding output array is the same as the class of the outputs from function `func`.

## Examples

Compute the mean of each vector in cell array `C`.

```
C = {1:10, [2; 4; 6], []};
```

```
averages = cellfun(@mean, C)
```

This code returns

```
averages =
 5.5000 4.0000 NaN
```

Compute the size of each array in `C`, created in the previous example.

```
[nrows, ncols] = cellfun(@size, C)
```

This code returns

```
nrows =
 1 3 0
ncols =
 10 1 0
```

Create a cell array that contains strings, and abbreviate those strings to the first three characters. Because the output strings are nonscalar, set `UniformOutput` to `false`.

```
days = {'Monday', 'Tuesday', 'Wednesday', 'Thursday', 'Friday'};
abbrev = cellfun(@(x) x(1:3), days, 'UniformOutput', false)
```

The syntax `@(x)` creates an anonymous function. This code returns

```
abbrev =
 'Mon' 'Tue' 'Wed' 'Thu' 'Fri'
```

Compute the covariance between arrays in two cell arrays `C` and `D`. Because the covariance output is nonscalar, set `UniformOutput` to `false`.

```
c1 = rand(5,1); c2 = rand(10,1); c3 = rand(15,1);
d1 = rand(5,1); d2 = rand(10,1); d3 = rand(15,1);
C = {c1, c2, c3};
D = {d1, d2, d3};

covCD = cellfun(@cov, C, D, 'UniformOutput', false)
```

This code returns

```
covCD =
 [2x2 double] [2x2 double] [2x2 double]
```

Define and call a custom error handling function.

```
function result = errorfun(S, varargin)
 warning(S.identifier, S.message);
 result = NaN;
end

A = {rand(3)};
B = {rand(5)};
AgtB = cellfun(@(x,y) x > y, A, B, 'ErrorHandler', @errorfun, ...
 'UniformOutput', false)
```

# cellplot

Graphically display structure of cell array

## Syntax

```
cellplot(c)
cellplot(c, 'legend')
handles = cellplot(c)
```

## Description

`cellplot(c)` displays a figure window that graphically represents the contents of `c`. Filled rectangles represent elements of vectors and arrays, while scalars and short text strings are displayed as text.

`cellplot(c, 'legend')` places a colorbar next to the plot labelled to identify the data types in `c`.

`handles = cellplot(c)` displays a figure window and returns a vector of surface handles.

## Limitations

The `cellplot` function can display only two-dimensional cell arrays.

## Examples

Consider a 2-by-2 cell array containing a matrix, a vector, and two text strings:

```
c{1,1} = '2-by-2';
c{1,2} = 'eigenvalues of eye(2)';
c{2,1} = eye(2);
c{2,2} = eig(eye(2));
```

The command `cellplot(c)` produces

# cellstr

Convert to cell array of strings

## Syntax

`C = cellstr(S)`

`S = cellstr(D)`

`S = cellstr(D,fmt)`

`S = cellstr(D,fmt,locale)`

## Description

`C = cellstr(S)` converts array `S` to a cell array.

- If `S` is a character array, then each row of `S` is a cell of `C`. Any trailing spaces in the rows of `S` are removed. Use the `char` function to convert back into a character array.
- If `S` is a cell array of strings, then `cellstr` returns `S` unaltered.
- If `S` is a categorical array, then `cellstr` returns a cell array of the same size.

`S = cellstr(D)` converts a datetime, duration, or calendar duration array into a cell array of strings in the format specified by the `Format` property of `D`. The output has the same dimensions as `D`.

`S = cellstr(D,fmt)` represents dates or durations in the specified format, such as `'HH:mm:ss'`.

`S = cellstr(D,fmt,locale)` represents dates or durations in the specified locale, such as `'en_US'`. The locale affects the language used to represent character strings such as month and day names.

## Examples

### Convert Character Array to Cell Array of Strings

Create a character array. Include trailing spaces so that each row has the same length, resulting in a 3-by-4 array.

```
S = ['abc '; 'defg'; 'hi ']
```

```
S =
```

```
abc
defg
hi
```

```
whos S
```

| Name | Size | Bytes | Class | Attributes |
|------|------|-------|-------|------------|
| S    | 3x4  | 24    | char  |            |

Convert the character array to a 3-by-1 cell array of strings.

```
C = cellstr(S)
```

```
C =
```

```
'abc'
'defg'
'hi'
```

```
whos C
```

| Name | Size | Bytes | Class | Attributes |
|------|------|-------|-------|------------|
| C    | 3x1  | 354   | cell  |            |

## Convert Calendar Duration Array to Cell Array of Strings

Create a `calendarDuration` array.

```
D = calmonths(15:17) + caldays(8) + hours(1.2345)
```

```
D =
```

```
1y 3mo 8d 1h 14m 4.2s 1y 4mo 8d 1h 14m 4.2s 1y 5mo 8d 1h 14m 4.2s
```

Convert the array to a cell array of strings.

```
C = cellstr(D)
```

```
C =
 '1y 3mo 8d 1h 14m ...' '1y 4mo 8d 1h 14m ...' '1y 5mo 8d 1h 14m ...'
```

```
whos C
```

| Name | Size | Bytes | Class | Attributes |
|------|------|-------|-------|------------|
| C    | 1x3  | 462   | cell  |            |

## Input Arguments

### **S** — Input array

character array | cell array of strings | categorical array

Input array, specified as a character array, a cell array of strings, or a categorical array.

If **S** is a character array, then each row of **S** becomes a separate cell of **C**, with trailing spaces removed.

If **S** is a cell array of strings, then `cellstr` returns **S** unaltered.

Data Types: `char` | `cell`

### **D** — Input date and time

date or duration array

Input date and time, specified as a date or duration array.

Data Types: `datetime` | `duration` | `calendarDuration`

### **fmt** — Date format

string

Date format, specified as a string. The supported formats depend on the data type of input **D**.

- `datetime` formats can include combinations of units and delimiters, such as `'yyyy-MMM-dd HH:mm:ss.SSS'`. For details, see the `Format` property for `datetime` arrays.
- `duration` formats are either single characters (`'y'`, `'d'`, `'h'`, `'m'`, or `'s'`) or one of these combinations:

- `'dd:hh:mm:ss'`
- `'hh:mm:ss'`
- `'mm:ss'`
- `'hh:mm'`
- Any of the above, with up to nine `S` characters to indicate fractional second digits, such as `'hh:mm:ss.SSSS'`
- `calendarDuration` formats can include combinations of the characters `'y'`, `'q'`, `'m'`, `'w'`, `'d'`, and `'t'` in order from largest to smallest unit of time, such as `'ym'`.

For more information on the `duration` and `calendarDuration` formats, see “Set Date and Time Display Format”.

## **locale** — Locale of the character strings to create

`string`

Locale of the character strings to create, specified as a string.

`locale` can be:

- `'system'`, to specify your system locale.
- a string in the form `xx_YY`, where `xx` is a lowercase ISO 639-1 two-letter code that specifies a language, and `YY` is an uppercase ISO 3166-1 alpha-2 code that specifies a country.

These are the same strings accepted by the `'Locale'` name-value pair argument for the `datetime` function. The locale affects the language used in the output array.

Example: `'en_US'`

Example: `'ja_JP'`

## cgs

Conjugate gradients squared method

### Syntax

```
x = cgs(A,b)
cgs(A,b,tol)
cgs(A,b,tol,maxit)
cgs(A,b,tol,maxit,M)
cgs(A,b,tol,maxit,M1,M2)
cgs(A,b,tol,maxit,M1,M2,x0)
[x,flag] = cgs(A,b,...)
[x,flag,relres] = cgs(A,b,...)
[x,flag,relres,iter] = cgs(A,b,...)
[x,flag,relres,iter,resvec] = cgs(A,b,...)
```

### Description

`x = cgs(A,b)` attempts to solve the system of linear equations  $A*x = b$  for  $x$ . The  $n$ -by- $n$  coefficient matrix  $A$  must be square and should be large and sparse. The column vector  $b$  must have length  $n$ . You can specify  $A$  as a function handle, `afun`, such that `afun(x)` returns  $A*x$ .

“Parameterizing Functions” explains how to provide additional parameters to the function `afun`, as well as the preconditioner function `mfun` described below, if necessary.

If `cgs` converges, a message to that effect is displayed. If `cgs` fails to converge after the maximum number of iterations or halts for any reason, a warning message is printed displaying the relative residual  $\text{norm}(b-A*x)/\text{norm}(b)$  and the iteration number at which the method stopped or failed.

`cgs(A,b,tol)` specifies the tolerance of the method, `tol`. If `tol` is `[]`, then `cgs` uses the default, `1e-6`.

`cgs(A,b,tol,maxit)` specifies the maximum number of iterations, `maxit`. If `maxit` is `[]` then `cgs` uses the default, `min(n,20)`.

`cgs(A,b,tol,maxit,M)` and `cgs(A,b,tol,maxit,M1,M2)` use the preconditioner `M` or `M = M1*M2` and effectively solve the system  $\text{inv}(M) * A * x = \text{inv}(M) * b$  for `x`. If `M` is `[]` then `cgs` applies no preconditioner. `M` can be a function handle `mfun` such that `mfun(x)` returns `M \ x`.

`cgs(A,b,tol,maxit,M1,M2,x0)` specifies the initial guess `x0`. If `x0` is `[]`, then `cgs` uses the default, an all-zero vector.

`[x,flag] = cgs(A,b,...)` returns a solution `x` and a flag that describes the convergence of `cgs`.

| Flag | Convergence                                                                                                          |
|------|----------------------------------------------------------------------------------------------------------------------|
| 0    | <code>cgs</code> converged to the desired tolerance <code>tol</code> within <code>maxit</code> iterations.           |
| 1    | <code>cgs</code> iterated <code>maxit</code> times but did not converge.                                             |
| 2    | Preconditioner <code>M</code> was ill-conditioned.                                                                   |
| 3    | <code>cgs</code> stagnated. (Two consecutive iterates were the same.)                                                |
| 4    | One of the scalar quantities calculated during <code>cgs</code> became too small or too large to continue computing. |

Whenever `flag` is not 0, the solution `x` returned is that with minimal norm residual computed over all the iterations. No messages are displayed if the `flag` output is specified.

`[x,flag,relres] = cgs(A,b,...)` also returns the relative residual  $\text{norm}(b - A * x) / \text{norm}(b)$ . If `flag` is 0, then `relres <= tol`.

`[x,flag,relres,iter] = cgs(A,b,...)` also returns the iteration number at which `x` was computed, where  $0 \leq \text{iter} \leq \text{maxit}$ .

`[x,flag,relres,iter,resvec] = cgs(A,b,...)` also returns a vector of the residual norms at each iteration, including  $\text{norm}(b - A * x_0)$ .

## Examples

### Using `cgs` with a Matrix Input

```
A = gallery('wilk',21);
```

```

b = sum(A,2);
tol = 1e-12; maxit = 15;
M1 = diag([10:-1:1 1 1:10]);
x = cgs(A,b,tol,maxit,M1);

```

displays the message

```

cgs converged at iteration 13 to a solution with
relative residual 2.4e-016.

```

## Using cgs with a Function Handle

This example replaces the matrix *A* in the previous example with a handle to a matrix-vector product function *afun*, and the preconditioner *M1* with a handle to a backsolve function *mfun*. The example is contained in the file *run\_cgs* that

- Calls *cgs* with the function handle *@afun* as its first argument.
- Contains *afun* as a nested function, so that all variables in *run\_cgs* are available to *afun* and *mfun*.

The following shows the code for *run\_cgs*:

```

function x1 = run_cgs
n = 21;
b = afun(ones(n,1));
tol = 1e-12; maxit = 15;
x1 = cgs(@afun,b,tol,maxit,@mfun);

 function y = afun(x)
 y = [0; x(1:n-1)] + ...
 [((n-1)/2:-1:0)'; (1:(n-1)/2)'] .* x + ...
 [x(2:n); 0];
 end

 function y = mfun(r)
 y = r ./ [((n-1)/2:-1:1)'; 1; (1:(n-1)/2)'];
 end
end

```

When you enter

```
x1 = run_cgs
```

MATLAB software returns

```
cgs converged at iteration 13 to a solution with
relative residual 2.4e-016.
```

## Using cgs with a Preconditioner.

This example demonstrates the use of a preconditioner.

Load `west0479`, a real 479-by-479 nonsymmetric sparse matrix.

```
load west0479;
A = west0479;
```

Define `b` so that the true solution is a vector of all ones.

```
b = full(sum(A,2));
```

Set the tolerance and maximum number of iterations.

```
tol = 1e-12;
maxit = 20;
```

Use `cgs` to find a solution at the requested tolerance and number of iterations.

```
[x0,f10,rr0,it0,rv0] = cgs(A,b,tol,maxit);
```

`f10` is 1 because `cgs` does not converge to the requested tolerance  $1e-12$  within the requested 20 iterations. In fact, the behavior of `cgs` is so poor that the initial guess (`x0 = zeros(size(A,2),1)`) is the best solution and is returned as indicated by `it0 = 0`. MATLAB stores the residual history in `rv0`.

Plot the behavior of `cgs`.

```
semilogy(0:maxit,rv0/norm(b),'-o');
xlabel('Iteration number');
ylabel('Relative residual');
```

The plot shows that the solution does not converge. You can use a preconditioner to improve the outcome.

Create a preconditioner with `ilu`, since  $A$  is nonsymmetric.

```
[L,U] = ilu(A,struct('type','ilutp','droptol',1e-5));
```

Error using `ilu`

There is a pivot equal to zero. Consider decreasing the drop tolerance or consider using the `'udiag'` option.

MATLAB cannot construct the incomplete LU as it would result in a singular factor, which is useless as a preconditioner.

You can try again with a reduced drop tolerance, as indicated by the error message.

```
[L,U] = ilu(A,struct('type','ilutp','droptol',1e-6));
[x1,f11,rr1,it1,rv1] = cgs(A,b,tol,maxit,L,U);
```

f11 is 0 because cgs drives the relative residual to  $4.3851e-014$  (the value of rr1). The relative residual is less than the prescribed tolerance of  $1e-12$  at the third iteration (the value of it1) when preconditioned by the incomplete LU factorization with a drop tolerance of  $1e-6$ . The output rv1(1) is norm(b) and the output rv1(14) is norm(b-A\*x2).

You can follow the progress of cgs by plotting the relative residuals at each iteration starting from the initial estimate (iterate number 0).

```
semilogy(0:it1,rv1/norm(b),'-o');
xlabel('Iteration number');
ylabel('Relative residual');
```

# char

Convert to character array (string)

## Syntax

```
S = char(A)
S = char(A1, ..., AN)

S = char(D)
S = char(D, fmt)
S = char(D, fmt, locale)
```

## Description

**S** = **char**(**A**) converts array **A** into a character array.

- If **A** is a numeric array, then **char** converts numbers into characters. Valid numeric values range from 0 to 65535, with 0 to 127 corresponding to 7-bit ASCII characters. Values from 128 to 65535 produce characters that depend upon your locale setting.
- If **A** is a character array, then **char** returns **A** unaltered.

To convert characters into a numeric array, use a function that converts to a numeric type (for example, **double**, **int32**, or **cast**).

- If **A** is a cell array of strings, then **char** converts the cell array into a character array. The strings from the cell array become rows in **S** (automatically padded with blanks as needed).

To convert **S** back into a cell array, use the **cellstr** function.

- If **A** is a categorical array, then **char** converts each element of **A** into a row of a character array, in column order.

**S** = **char**(**A1**, ..., **AN**) converts the arrays **A1**, ..., **AN** into a single character array. After conversion to characters, the input arrays become rows in **S**. Each row is automatically padded with blanks as needed. An empty string becomes a row of blanks.

The input arrays **A1**, ..., **AN** cannot be cell arrays or categorical arrays.

$A_1, \dots, A_N$  can be of different sizes and shapes.

`S = char(D)` converts a datetime, duration, or calendar duration array into a character array in the format specified by the `Format` property of `D`. The output contains one date or duration in each row.

`S = char(D, fmt)` represents dates or durations in the specified format, such as `'HH:mm:ss'`.

`S = char(D, fmt, locale)` represents dates or durations in the specified locale, such as `'en_US'`. The locale affects the language used to represent character strings such as month and day names.

## Examples

### Convert Integers to Printable ASCII Character Array

Convert the integers 32–127 into a 3-by-32 array of the printable ASCII characters.

```
A = (32:127);
S = char(A);
S = reshape(S,32,3)

S =

! "#$%&'()*+,-./0123456789:;<=>?
@ABCDEFGHIJKLMNopqrstuvwxyz[\]^_
`abcdefghijklmnopqrstuvwxyz{|}~#
```

### Convert Multiple Arrays to Character Array

Convert multiple arrays into a single character array. The input arrays need not have the same shape.

```
A1 = [65 66; 67 68];
A2 = 'abcd';
S = char(A1,A2)

S =

AB
CD
```

```
abcd
```

Because the input arrays do not have the same number of columns, `char` pads the rows from A1 with blanks.

```
whos S
```

| Name | Size | Bytes | Class | Attributes |
|------|------|-------|-------|------------|
| S    | 3x4  | 24    | char  |            |

### Convert Cell Array of Strings to Character Array

Convert a cell array of strings into a character array.

```
A = {'ABCD', 'efghijk', '', 'LM'};
S = char(A)
```

```
S =
```

```
ABCD
efghijk
```

```
LM
```

Because the input strings from cell array A have different lengths, `char` pads the strings with blanks. `char` pads the third row with seven blanks, because the third cell of A contains an empty string.

```
whos S
```

| Name | Size | Bytes | Class | Attributes |
|------|------|-------|-------|------------|
| S    | 4x7  | 56    | char  |            |

### Convert Duration Array to Character Array

Create a duration array.

```
D = hours(23:25) + minutes(8) + seconds(1.2345)
```

```
D =
```

```
23.134 hrs 24.134 hrs 25.134 hrs
```

Convert D to a character array.

```
S = char(D)
```

```
S =
```

```
23.134 hrs
24.134 hrs
25.134 hrs
```

S is a character array with one duration value per row.

Specify the format of the duration values in S.

```
S = char(D, 'hh:mm')
```

```
S =
```

```
23:08
24:08
25:08
```

## Input Arguments

### A — Input array

numeric array | character array | cell array of strings | categorical array

Input array, specified as an array of real numbers or characters, a cell array of strings, or a categorical array.

If A is a numeric array, then:

- Nonintegers are rounded towards zero.
- Values less than 0 are treated as 0.
- Values greater than 65535 are treated as 65535.

Example: `char(65)` converts the integer 65 into the character A.

### **D** — Input date and time

date or duration array

Input date and time, specified as a date or duration array.

Data Types: `datetime` | `duration` | `calendarDuration`

### **fmt** — Date format

string

Date format, specified as a string. The supported formats depend on the data type of input D.

- `datetime` formats can include combinations of units and delimiters, such as `'yyyy-MM-dd HH:mm:ss.SSS'`. For details, see the `Format` property for `datetime` arrays.
- `duration` formats are either single characters (`'y'`, `'d'`, `'h'`, `'m'`, or `'s'`) or one of these combinations:
  - `'dd:hh:mm:ss'`
  - `'hh:mm:ss'`
  - `'mm:ss'`
  - `'hh:mm'`
  - Any of the above, with up to nine `S` characters to indicate fractional second digits, such as `'hh:mm:ss.SSSS'`
- `calendarDuration` formats can include combinations of the characters `'y'`, `'q'`, `'m'`, `'w'`, `'d'`, and `'t'` in order from largest to smallest unit of time, such as `'ym'`.

For more information on the `duration` and `calendarDuration` formats, see “Set Date and Time Display Format”.

### **locale** — Locale of the character strings to create

string

Locale of the character strings to create, specified as a string.

`locale` can be:

- `'system'`, to specify your system locale.

- a string in the form `xx_YY`, where `xx` is a lowercase ISO 639-1 two-letter code that specifies a language, and `YY` is an uppercase ISO 3166-1 alpha-2 code that specifies a country.

These are the same strings accepted by the `'Locale'` name-value pair argument for the `datetime` function. The locale affects the language used in the output array.

Example: `'en_US'`

Example: `'ja_JP'`

# checkcode

Check MATLAB code files for possible problems

## Alternatives

For information on using the graphical user interface for checking code, see “Check Code for Errors and Warnings”.

## Syntax

```
checkcode('filename')
checkcode('filename', '-config=settings.txt')
checkcode('filename', '-config=factory')
inform=checkcode('filename', '-struct')
msg=checkcode('filename', '-string')
[inform, filepaths]=checkcode('filename')
inform=checkcode('filename', '-id')
inform=checkcode('filename', '-fullpath')
inform=checkcode('filename', '-notok')
checkcode('filename', '-cyc')
checkcode('filename', '-codegen')
checkcode('filename', '-eml')
```

## Description

`checkcode('filename')` displays messages, sometimes referred to as Code Analyzer messages, about `filename`, where the message reports potential problems and opportunities for code improvement. The line number in the message is a hyperlink that opens the file in the Editor, scrolled to that line. If `filename` is a cell array, information is displayed for each file. For `checkcode(F1, F2, F3, ...)`, where each input is a character array, MATLAB software displays information about each input file name. You cannot combine cell arrays and character arrays of file names. Note that the exact text of the `checkcode` messages is subject to some change between versions.

`checkcode('filename', '-config=settings.txt')` overrides the default active settings file with the settings that enable or suppress messages as indicated in the specified `settings.txt` file.

---

**Note:** If used, you must specify the full path to the `settings.txt` file specified with the `-config` option.

---

For information about creating a `settings.txt` file, see “Save and Reuse Code Analyzer Message Settings”. If you specify an invalid file, `checkcode` returns a message indicating that it cannot open or read the file you specified. In that case, `checkcode` uses the factory default settings.

`checkcode('filename', '-config=factory')` ignores all settings files and uses the factory default preference settings.

`inform=checkcode('filename', '-struct')` returns the information in a structure array whose length is the number of messages found. The structure has the fields that follow.

| Field                | Description                                                                                                                                                                                                                                                                                                                                     |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>message</code> | Message describing the suspicious construct that code analysis caught.                                                                                                                                                                                                                                                                          |
| <code>line</code>    | Vector of file line numbers to which the message refers.                                                                                                                                                                                                                                                                                        |
| <code>column</code>  | Two-column array of file columns (column extents) to which the message applies. The first column of the array specifies the column in the Editor where the message begins. The second column of the array specifies the column in the Editor where the message ends. There is one row in the two-column array for each occurrence of a message. |

If you specify multiple file names as input, or if you specify a cell array as input, `inform` contains a cell array of structures.

`msg=checkcode('filename', '-string')` returns the information as a string to the variable `msg`. If you specify multiple file names as input, or if you specify a cell array as input, `msg` contains a string where each file's information is separated by 10 equal sign characters (=), a space, the file name, a space, and 10 equal sign characters.

If you omit the **-struct** or **-string** argument and you specify an output argument, the default behavior is **-struct**. If you omit the argument and there are no output arguments, the default behavior is to display the information to the command line.

`[inform, filepaths]=checkcode('filename')` additionally returns `filepaths`, the absolute paths to the file names, in the same order as you specified them.

`inform=checkcode('filename', '-id')` requests the message ID, where ID is a string of the form ABC... When returned to a structure, the output also has the `id` field, which is the ID associated with the message.

`inform=checkcode('filename', '-fullpath')` assumes that the input file names are absolute paths, so that `checkcode` does not try to locate them.

`inform=checkcode('filename', '-notok')` runs `checkcode` for all lines in `filename`, even those lines that end with the `checkcode` suppression directive, `%#OK`.

`checkcode('filename', '-cyc')` displays the McCabe complexity (also referred to as cyclomatic complexity) of each function in the file. Higher McCabe complexity values indicate higher complexity, and there is some evidence to suggest that programs with higher complexity values are more likely to contain errors. Frequently, you can lower the complexity of a function by dividing it into smaller, simpler functions. In general, smaller complexity values indicate programs that are easier to understand and modify. Some people advocate splitting up programs that have a complexity rating over 10.

`checkcode('filename', '-codegen')` enables code generation messages for display in the Command Window.

`checkcode('filename', '-eml')` `-eml` is not recommended. Use `-codegen` instead.

## Examples

The following examples use `lengthofline.m`, which is a sample file with MATLAB code that can be improved. You can find it in `matlabroot/help/techdoc/matlab_env/examples`. If you want to run the examples, save a copy of `lengthofline.m` to a location on your MATLAB path.

### Running checkcode on a File with No Options

To run `checkcode` on the example file, `lengthofline.m`, run

```
checkcode('lengthofline')
```

MATLAB displays the Code Analyzer messages for `lengthofline.m` in the Command Window:

```
L 21 (C 1-9): The value assigned to variable 'nohandle' might be unused.
L 22 (C 12-15): NUMEL(x) is usually faster than PROD(SIZE(x)).
L 23 (C 5-11): The variable 'notline' appears to change size on every loop iteration. Consider preallocating for speed.
L 23 (C 44-49): Use STRCMP1(str1,str2) instead of using UPPER/LOWER in a call to STRCMP.
L 27 (C 12-15): NUMEL(x) is usually faster than PROD(SIZE(x)).
L 33 (C 13-16): The variable 'data' appears to change size on every loop iteration. Consider preallocating for speed.
L 33 (C 24-31): Use dynamic fieldnames with structures instead of GETFIELD.
L 37 (C 29): Use || instead of | as the OR operator in (scalar) conditional statements.
L 38 (C 47): Use || instead of | as the OR operator in (scalar) conditional statements.
L 39 (C 47): Use || instead of | as the OR operator in (scalar) conditional statements.
L 42 (C 13-15): The variable 'dim' appears to change size on every loop iteration. Consider preallocating for speed.
L 44 (C 13-15): The variable 'dim' appears to change size on every loop iteration. Consider preallocating for speed.
L 47 (C 52): Invalid syntax at ';'. Possibly, a), }, or] is missing.
L 47 (C 53): Invalid syntax at ')'. Possibly, a), }, or] is missing.
L 47 (C 54): Parse error at ']': usage might be invalid MATLAB syntax.
L 48 (C 17): Terminate statement with semicolon to suppress output (in functions).
L 48 (C 23): Use of brackets [] is unnecessary. Use parentheses to group, if needed.
```

For details about these messages and how to improve the code, see “Changing Code Based on Code Analyzer Messages” in the MATLAB Desktop Tools and Development Environment documentation.

## Running checkcode with Options to Show IDs and Return Results to a Structure

To store the results to a structure and include message IDs, run

```
inform=checkcode('lengthofline','-id')
```

MATLAB returns

```
inform =
```

17x1 struct array with fields:

```
 id
 message
 fix
 line
 column
```

To see values for the first message, run

```
inform(1)
```

## MATLAB displays

```
ans =

 id: 'NASGU'
 message: 'The value assigned to variable 'nohandle' might be unused.'
 fix: 0
 line: 21
 column: [1 9]
```

Here, the message is for the value that appears on line 21 that extends from column 1–9 in the file.NASGU is the ID for the message 'The value assigned to variable 'nohandle' might be unused.'.

## Displaying McCabe Complexity with checkcode

To display the McCabe complexity of a MATLAB code file, run `checkcode` with the `-cyc` option, as shown in the following example (assuming you have saved `lengthofline.m` to a local folder).

```
checkcode lengthofline.m -cyc
```

Results displayed in the Command Window show the McCabe complexity of the file, followed by the Code Analyzer messages, as shown here:

```
L 1 (C 23-34): The McCabe complexity of 'lengthofline' is 12.
L 21 (C 1-9): The value assigned to variable 'nohandle' might be unused.
L 22 (C 12-15): NUMEL(x) is usually faster than PROD(SIZE(x)).
L 23 (C 5-11): The variable 'notline' appears to change size on every loop iteration. Consider preallocating for speed.
L 23 (C 44-49): Use STRCMP1(str1,str2) instead of using UPPER/LOWER in a call to STRCMP.
L 27 (C 12-15): NUMEL(x) is usually faster than PROD(SIZE(x)).
L 33 (C 13-16): The variable 'data' appears to change size on every loop iteration. Consider preallocating for speed.
L 33 (C 24-31): Use dynamic fieldnames with structures instead of GETFIELD.
L 37 (C 29): Use || instead of | as the OR operator in (scalar) conditional statements.
L 38 (C 47): Use || instead of | as the OR operator in (scalar) conditional statements.
L 39 (C 47): Use || instead of | as the OR operator in (scalar) conditional statements.
L 42 (C 13-15): The variable 'dim' appears to change size on every loop iteration. Consider preallocating for speed.
L 44 (C 13-15): The variable 'dim' appears to change size on every loop iteration. Consider preallocating for speed.
L 47 (C 52): Invalid syntax at ';'. Possibly, a), }, or] is missing.
L 47 (C 53): Invalid syntax at ')'. Possibly, a), }, or] is missing.
L 47 (C 54): Parse error at ']': usage might be invalid MATLAB syntax.
L 48 (C 17): Terminate statement with semicolon to suppress output (in functions).
L 48 (C 23): Use of brackets [] is unnecessary. Use parentheses to group, if needed.
```

## **How To**

- For information on the suppression directive, `##0k`, and suppressing messages from within your program, see “Adjust Code Analyzer Message Indicators and Messages”.

**Introduced in R2011b**

# checkin

(To be removed) Check files into source control system (UNIX platforms)

---

**Note:** checkin will be removed in a future release.

---

## Syntax

```
checkin('filename', 'comments', 'comment_text')
checkin({'filename1', 'filename2'}, 'comments', 'comment_text')
checkin('filename', 'comments', 'comment_text', 'option', 'value')
```

## Description

checkin('filename', 'comments', 'comment\_text') checks in the file named filename to the source control system. Use the full path for filename and include the file extension. You must save the file before checking it in, but the file can be open or closed. The comment\_text is a MATLAB string containing checkin comments for the source control system. You must supply comments and comment\_text.

checkin({'filename1', 'filename2'}, 'comments', 'comment\_text') checks in the files filename1 through filename2 to the source control system. Use the full paths for the files and include file extensions. Comments apply to all files checked in.

checkin('filename', 'comments', 'comment\_text', 'option', 'value') provides additional checkin options. For multiple file names, use an array of strings instead of filename, that is, {'filename1', 'filename2', ...}. Options apply to all file names. The option and value arguments are shown in the following table.

| option Argument | value Argument  | Purpose                                                                           |
|-----------------|-----------------|-----------------------------------------------------------------------------------|
| 'force'         | 'on'            | filename is checked in even if the file has not changed since it was checked out. |
| 'force'         | 'off' (default) | filename is not checked in if there were no changes since checkout.               |

| option Argument | value Argument  | Purpose                                                                 |
|-----------------|-----------------|-------------------------------------------------------------------------|
| 'lock'          | 'on'            | filename is checked in with comments, and is automatically checked out. |
| 'lock'          | 'off' (default) | filename is checked in with comments but does not remain checked out.   |

## Examples

### Check In a File

Check the file `/myserver/myfiles/clock.m` into the source control system, with the comment `Adjustment for leapyear`:

```
checkin('/myserver/myfiles/clock.m', 'comments', ...
'Adjustment for leapyear')
```

### Check In Multiple Files

Check two files into the source control system, using the same comment for each:

```
checkin({'/myserver/myfiles/clock.m', ...
'/myserver/myfiles/calendar.m'}, 'comments', ...
'Adjustment for leapyear')
```

### Check In a File and Keep It Checked Out

Check the file `/myserver/myfiles/clock.m` into the source control system and keep the file checked out:

```
checkin('/myserver/myfiles/clock.m', 'comments', ...
'Adjustment for leapyear', 'lock', 'on')
```

**Introduced before R2006a**

# checkout

(To be removed) Check files out of source control system (UNIX platforms)

---

**Note:** checkout will be removed in a future release.

---

## Syntax

```
checkout('filename')
checkout({'filename1','filename2',...})
checkout('filename','option','value',...)
```

## Description

`checkout('filename')` checks out the file named `filename` from the source control system. Use the full path for `filename` and include the file extension. The file can be open or closed when you use `checkout`.

`checkout({'filename1','filename2',...})` checks out the files named `filename1` through `filename` from the source control system. Use the full paths for the files and include the file extensions.

`checkout('filename','option','value',...)` provides additional `checkout` options. For multiple file names, use an array of strings instead of `filename`, that is, `{'filename1','filename2',...}`. Options apply to all file names. The *option* and *value* arguments are shown in the following table.

| option Argument | value Argument | Purpose                                                                                                                                                    |
|-----------------|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'force'         | 'on'           | The checkout is forced, even if you already have the file checked out. This is effectively an <code>undockout</code> followed by a <code>checkout</code> . |

| <b>option Argument</b> | <b>value Argument</b> | <b>Purpose</b>                                                                                                                                                                            |
|------------------------|-----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'force'                | 'off' (default)       | Prevents you from checking out the file if you already have it checked out.                                                                                                               |
| 'lock'                 | 'on' (default)        | The checkout gets the file, allows you to write to it, and locks the file so that access to the file for others is read only.                                                             |
| 'lock'                 | 'off'                 | The checkout gets a read-only version of the file, allowing another user to check out the file for updating. You do not have to check the file in after checking it out with this option. |
| 'revision'             | 'version_num'         | Checks out the specified revision of the file.                                                                                                                                            |

If you end the MATLAB session, the file remains checked out. You can check in the file from within the MATLAB desktop during a later session, or directly from your source control system.

## Examples

### Check Out a File

Check out the file `/myserver/myfiles/clock.m` from the source control system:

```
checkout('/myserver/myfiles/clock.m')
```

### Check Out Multiple Files

Check out `/matlab/myfiles/clock.m` and `/matlab/myfiles/calendar.m` from the source control system:

```
checkout({'/myserver/myfiles/clock.m',...
'/myserver/myfiles/calendar.m'})
```

## **Force a Checkout, Even If File Is Already Checked Out**

Check out `/matlab/myfiles/clock.m` even if `clock.m` is already checked out to you:

```
checkout('/myserver/myfiles/clock.m','force','on')
```

## **Check Out Specified Revision of File**

Check out revision 1.1 of `clock.m`:

```
checkout('/matlab/myfiles/clock.m','revision','1.1')
```

**Introduced before R2006a**

# chol

Cholesky factorization

## Syntax

```
R = chol(A)
L = chol(A, 'lower')
R = chol(A, 'upper')
[R,p] = chol(A)
[L,p] = chol(A, 'lower')
[R,p] = chol(A, 'upper')
[R,p,S] = chol(A)
[R,p,s] = chol(A, 'vector')
[L,p,s] = chol(A, 'lower', 'vector')
[R,p,s] = chol(A, 'upper', 'vector')
```

## Description

`R = chol(A)` produces an upper triangular matrix  $R$  from the diagonal and upper triangle of matrix  $A$ , satisfying the equation  $R' * R = A$ . The `chol` function assumes that  $A$  is (complex Hermitian) symmetric. If it is not, `chol` uses the (complex conjugate) transpose of the upper triangle as the lower triangle. Matrix  $A$  must be positive definite.

`L = chol(A, 'lower')` produces a lower triangular matrix  $L$  from the diagonal and lower triangle of matrix  $A$ , satisfying the equation  $L * L' = A$ . The `chol` function assumes that  $A$  is (complex Hermitian) symmetric. If it is not, `chol` uses the (complex conjugate) transpose of the lower triangle as the upper triangle. When  $A$  is sparse, this syntax of `chol` is typically faster. Matrix  $A$  must be positive definite. `R = chol(A, 'upper')` is the same as `R = chol(A)`.

`[R,p] = chol(A)` for positive definite  $A$ , produces an upper triangular matrix  $R$  from the diagonal and upper triangle of matrix  $A$ , satisfying the equation  $R' * R = A$  and  $p$  is zero. If  $A$  is not positive definite, then  $p$  is a positive integer and MATLAB does not generate an error. When  $A$  is full,  $R$  is an upper triangular matrix of order  $q = p - 1$  such that  $R' * R = A(1 : q, 1 : q)$ . When  $A$  is sparse,  $R$  is an upper triangular matrix of size  $q$ -by- $n$ .

so that the L-shaped region of the first  $q$  rows and first  $q$  columns of  $R' * R$  agree with those of  $A$ .

$[L, p] = \text{chol}(A, 'lower')$  for positive definite  $A$ , produces a lower triangular matrix  $L$  from the diagonal and lower triangle of matrix  $A$ , satisfying the equation  $L * L' = A$  and  $p$  is zero. If  $A$  is not positive definite, then  $p$  is a positive integer and MATLAB does not generate an error. When  $A$  is full,  $L$  is a lower triangular matrix of order  $q = p - 1$  such that  $L * L' = A(1:q, 1:q)$ . When  $A$  is sparse,  $L$  is a lower triangular matrix of size  $q$ -by- $n$  so that the L-shaped region of the first  $q$  rows and first  $q$  columns of  $L * L'$  agree with those of  $A$ .  $[R, p] = \text{chol}(A, 'upper')$  is the same as  $[R, p] = \text{chol}(A)$ .

The following three-output syntaxes require sparse input  $A$ .

$[R, p, S] = \text{chol}(A)$ , when  $A$  is sparse, returns a permutation matrix  $S$ . Note that the preordering  $S$  may differ from that obtained from `amd` since `chol` will slightly change the ordering for increased performance. When  $p=0$ ,  $R$  is an upper triangular matrix such that  $R' * R = S' * A * S$ . When  $p$  is not zero,  $R$  is an upper triangular matrix of size  $q$ -by- $n$  so that the L-shaped region of the first  $q$  rows and first  $q$  columns of  $R' * R$  agree with those of  $S' * A * S$ . The factor of  $S' * A * S$  tends to be sparser than the factor of  $A$ .

$[R, p, s] = \text{chol}(A, 'vector')$ , when  $A$  is sparse, returns the permutation information as a vector  $s$  such that  $A(s, s) = R' * R$ , when  $p=0$ . You can use the `'matrix'` option in place of `'vector'` to obtain the default behavior.

$[L, p, s] = \text{chol}(A, 'lower', 'vector')$ , when  $A$  is sparse, uses only the diagonal and the lower triangle of  $A$  and returns a lower triangular matrix  $L$  and a permutation vector  $s$  such that  $A(s, s) = L * L'$ , when  $p=0$ . As above, you can use the `'matrix'` option in place of `'vector'` to obtain a permutation matrix.  $[R, p, s] = \text{chol}(A, 'upper', 'vector')$  is the same as  $[R, p, s] = \text{chol}(A, 'vector')$ .

---

**Note** Using `chol` is preferable to using `eig` for determining positive definiteness.

---

## Examples

### Example 1

The `gallery` function provides several symmetric, positive, definite matrices.

```
A=gallery('moler',5)
```

```
A =
 1 -1 -1 -1 -1
 -1 2 0 0 0
 -1 0 3 1 1
 -1 0 1 4 2
 -1 0 1 2 5
```

```
C=chol(A)
```

```
ans =
 1 -1 -1 -1 -1
 0 1 -1 -1 -1
 0 0 1 -1 -1
 0 0 0 1 -1
 0 0 0 0 1
```

```
isequal(C'*C,A)
```

```
ans =
```

```
 1
```

For sparse input matrices, `chol` returns the Cholesky factor.

```
N = 100;
A = gallery('poisson', N);
```

$N$  represents the number of grid points in one direction of a square  $N$ -by- $N$  grid. Therefore,  $A$  is  $N^2$  by  $N^2$ .

```
L = chol(A, 'lower');
D = norm(A - L*L', 'fro');
```

The value of  $D$  will vary somewhat among different versions of MATLAB but will be on order of  $10^{-14}$ .

## Example 2

The binomial coefficients arranged in a symmetric array create a positive definite matrix.

```
n = 5;
```

```
X = pascal(n)
X =
 1 1 1 1 1
 1 2 3 4 5
 1 3 6 10 15
 1 4 10 20 35
 1 5 15 35 70
```

This matrix is interesting because its Cholesky factor consists of the same coefficients, arranged in an upper triangular matrix.

```
R = chol(X)
R =
 1 1 1 1 1
 0 1 2 3 4
 0 0 1 3 6
 0 0 0 1 4
 0 0 0 0 1
```

Destroy the positive definiteness (and actually make the matrix singular) by subtracting 1 from the last element.

```
X(n,n) = X(n,n) - 1
```

```
X =
 1 1 1 1 1
 1 2 3 4 5
 1 3 6 10 15
 1 4 10 20 35
 1 5 15 35 69
```

Now an attempt to find the Cholesky factorization of X fails.

```
chol(X)
Error using chol
Matrix must be positive definite.
```

## See Also

[ichol](#) | [cholupdate](#)

**Introduced before R2006a**

## cholupdate

Rank 1 update to Cholesky factorization

### Syntax

```
R1 = cholupdate(R,x)
R1 = cholupdate(R,x,'+')
R1 = cholupdate(R,x,'-')
[R1,p] = cholupdate(R,x,'-')
```

### Description

`R1 = cholupdate(R,x)` where `R = chol(A)` is the original Cholesky factorization of `A`, returns the upper triangular Cholesky factor of  $A + x*x'$ , where `x` is a column vector of appropriate length. `cholupdate` uses only the diagonal and upper triangle of `R`. The lower triangle of `R` is ignored.

`R1 = cholupdate(R,x,'+')` is the same as `R1 = cholupdate(R,x)`.

`R1 = cholupdate(R,x,'-')` returns the Cholesky factor of  $A - x*x'$ . An error message reports when `R` is not a valid Cholesky factor or when the downdated matrix is not positive definite and so does not have a Cholesky factorization.

`[R1,p] = cholupdate(R,x,'-')` will not return an error message. If `p` is 0, `R1` is the Cholesky factor of  $A - x*x'$ . If `p` is greater than 0, `R1` is the Cholesky factor of the original `A`. If `p` is 1, `cholupdate` failed because the downdated matrix is not positive definite. If `p` is 2, `cholupdate` failed because the upper triangle of `R` was not a valid Cholesky factor.

### Examples

```
A = pascal(4)
A =
```

```
 1 1 1 1
 1 2 3 4
```

```

1 3 6 10
1 4 10 20

```

```

R = chol(A)
R =

```

```

1 1 1 1
0 1 2 3
0 0 1 3
0 0 0 1

```

```

x = [0 0 0 1]';

```

This is called a rank one update to  $A$  since  $\text{rank}(x*x')$  is 1:

```

A + x*x'
ans =

```

```

1 1 1 1
1 2 3 4
1 3 6 10
1 4 10 21

```

Instead of computing the Cholesky factor with  $R1 = \text{chol}(A + x*x')$ , we can use `cholupdate`:

```

R1 = cholupdate(R,x)
R1 =

```

```

1.0000 1.0000 1.0000 1.0000
0 1.0000 2.0000 3.0000
0 0 1.0000 3.0000
0 0 0 1.4142

```

Next destroy the positive definiteness (and actually make the matrix singular) by subtracting 1 from the last element of  $A$ . The downdated matrix is:

```

A - x*x'
ans =

```

```

1 1 1 1
1 2 3 4
1 3 6 10
1 4 10 19

```

Compare `chol` with `cholupdate`:

```
R1 = chol(A-x*x')
Error using chol
Matrix must be positive definite.
R1 = cholupdate(R,x,'-')
Error using cholupdate
Downdated matrix must be positive definite.
```

However, subtracting 0.5 from the last element of **A** produces a positive definite matrix, and we can use `cholupdate` to compute its Cholesky factor:

```
x = [0 0 0 1/sqrt(2)]';
R1 = cholupdate(R,x,'-')
R1 =
 1.0000 1.0000 1.0000 1.0000
 0 1.0000 2.0000 3.0000
 0 0 1.0000 3.0000
 0 0 0 0.7071
```

## More About

### Tips

`cholupdate` works only for full matrices.

### Algorithms

`cholupdate` uses the algorithms from the LINPACK subroutines `ZCHUD` and `ZCHDD`. `cholupdate` is useful since computing the new Cholesky factor from scratch is an  $O(N^3)$  algorithm, while simply updating the existing factor in this way is an  $O(N^2)$  algorithm.

## **circshift**

Shift array circularly

### **Compatibility**

The default behavior of `circshift(A,K)`, where `K` is a scalar, will change in a future release. The new default behavior will be to operate along the first array dimension of `A` whose size does not equal 1. Use `circshift(A,[K 0])` to retain current behavior.

### **Syntax**

```
Y = circshift(A,K)
Y = circshift(A,K,dim)
```

### **Description**

`Y = circshift(A,K)` circularly shifts the elements in array `A` by `K` positions. Specify `K` as an integer to shift the rows of `A`, or as a vector of integers to specify the shift amount in each dimension.

`Y = circshift(A,K,dim)` circularly shifts the values in array `A` by `K` positions along dimension `dim`. Inputs `K` and `dim` must be scalars.

### **Examples**

#### **Shift Column Vector Elements**

Create a numeric column vector.

```
A = (1:10)'
```

```
A =
```

```
 1
 2
```

```
3
4
5
6
7
8
9
10
```

Use `circshift` to shift the elements by three positions.

```
Y = circshift(A,3)
```

```
Y =
```

```
8
9
10
1
2
3
4
5
6
7
```

The result, `Y`, has the same elements as `A` but they are in a different order.

### Move Characters in Array

Create an array of characters.

```
A = 'racecar'
```

```
A =
```

```
racecar
```

Use `circshift` to shift the characters by three positions in the second dimension.

```
Y = circshift(A,3,2)
```

```
Y =
```

```
carrace
```

The characters are in a different order in Y.

### **Move Matrix Elements**

Create a numeric array with a cluster of ones in the top left.

```
A = [1 1 0 0; 1 1 0 0; 0 0 0 0; 0 0 0 0]
```

A =

```
1 1 0 0
1 1 0 0
0 0 0 0
0 0 0 0
```

Use `circshift` to shift the elements of A by one position in each dimension.

```
Y = circshift(A,[1 1])
```

Y =

```
0 0 0 0
0 1 1 0
0 1 1 0
0 0 0 0
```

The cluster of ones is now in the center of the matrix.

To move the cluster back to its original position, use `circshift` on Y with negative shift values.

```
X = circshift(Y,[-1 -1])
```

X =

```
1 1 0 0
1 1 0 0
0 0 0 0
0 0 0 0
```

The matrix  $X$  is equivalent to  $A$ .

## Input Arguments

### **A** — Input array

vector | matrix | multidimensional array

Input array, specified as a vector, matrix, or multidimensional array.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char` | `struct` | `table` | `cell`

Complex Number Support: Yes

### **K** — Shift amount

integer scalar | vector of integers

Shift amount, specified as an integer scalar or vector of integers. If the shift amount is larger than the length of the corresponding dimension in  $A$ , then the shift circularly wraps to the beginning of that dimension. For example, shifting a 3-element vector by +3 positions will bring its elements back to their original positions.

- If you specify  $K$  as an integer and do not specify  $\text{dim}$ , then `circshift` shifts the rows of  $A$  down (positive integer) or up (negative integer).
- If you specify  $K$  as a vector of integers, each element specifies the shift amount for the  $N$ th dimension in  $A$ . If the  $N$ th element in  $K$  is positive, then the values of  $A$  are shifted towards the end (positive integer) or beginning (negative integer) of the  $N$ th dimension.

### **dim** — Dimension to operate along

positive integer scalar

Dimension to operate along, specified as a positive integer scalar. If no value is specified, the default is  $\text{dim} = 1$ . If you specify  $\text{dim}$ , then  $K$  must be an integer scalar. Specify  $\text{dim} = 1$  to exchange rows,  $\text{dim} = 2$  to exchange columns, and so on.

## circumcenters

**Class:** TriRep

(Not recommended) Circumcenters of specified simplices

---

**Note:** `circumcenters(TriRep)` is not recommended. Use `circumcenter(triangulation)` instead.

`TriRep` is not recommended. Use `triangulation` instead.

---

## Syntax

```
CC = circumcenters(TR, SI)
[CC RCC] = circumcenters(TR, SI)
```

## Description

`CC = circumcenters(TR, SI)` returns the coordinates of the circumcenter of each specified simplex `SI`. `CC` is an `m`-by-`n` matrix, where `m` is of length `length(SI)`, the number of specified simplices, and `n` is the dimension of the space where the triangulation resides.

`[CC RCC] = circumcenters(TR, SI)` returns the circumcenters and the corresponding radii of the circumscribed circles or spheres.

## Input Arguments

|    |                                                                                                                                                                            |
|----|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TR | Triangulation object.                                                                                                                                                      |
| SI | Column vector of simplex indices that index into the triangulation matrix <code>TR.Triangulation</code> . If <code>SI</code> is not specified the circumcenter information |

for the entire triangulation is returned, where the circumcenter associated with simplex  $i$  is the  $i$ 'th row of  $CC$ .

## Output Arguments

- CC**             $m$ -by- $n$  matrix.  $m$  is the number of specified simplices and  $n$  is the dimension of the space where the triangulation resides. Each row  $CC(i, :)$  represents the coordinates of the circumcenter of simplex  $SI(i)$ .
- RCC**            Vector of length  $length(SI)$ , the number of specified simplices containing radii of the circumscribed circles or spheres.

## Definitions

A simplex is a triangle/tetrahedron or higher-dimensional equivalent.

## Examples

### Example 1

Load a 2-D triangulation.

```
load trimesh2d
trep = TriRep(tri, x,y)
```

Compute the circumcenters.

```
cc = circumcenters(trep);
triplot(trep);
axis([-50 350 -50 350]);
axis equal;
hold on;
plot(cc(:,1),cc(:,2), '*r');
hold off;
```

The circumcenters represent points on the medial axis of the polygon.

## Example 2

Query a 3-D triangulation created with `DelaunayTri`. Compute the circumcenters of the first five tetrahedra.

```
X = rand(10,3);
dt = DelaunayTri(X);
cc = circumcenters(dt, [1:5]')
```

## See Also

[delaunayTriangulation](#) | [incenter](#) | [triangulation](#)

# cla

Clear axes

## Syntax

```
cla
cla reset

cla(ax)
cla(ax, 'reset')
```

## Description

`cla` deletes all graphics objects that have visible handles from the current axes. The handle is visible if the `HandleVisibility` property of the object is set to `'on'`. The next plot added to the axes uses the first color and line style based on the `ColorOrder` and `LineStyleOrder` properties of the axes.

`cla reset` deletes graphics objects from the current axes regardless of their handle visibility. It also resets axes properties to their default values, with the exception of the `Position` and `Units` properties.

`cla(ax)` deletes graphics objects from the axes specified by `ax` instead of the current axes.

`cla(ax, 'reset')` resets properties for the specified axes.

## Examples

### Clear Current Axes

Plot two sine waves. Then, clear the line plots from the axes.

```
x = linspace(0,2*pi);
```

```
y1 = sin(x);
y2 = sin(2*x);

plot(x,y1)
hold on
plot(x,y2)
```

```
cla
```

`cla` clears the line plots and resets the `ColorIndex` and `LineStyleIndex` properties of the axes to 1. Subsequent plots start from the beginning of the color order and line style order. For example, plot another sine wave.

```
y3 = sin(3*x);
plot(x,y3)
hold off
```

## Clear Objects from Specific Axes

Create a figure with two subplots and add plots to both axes.

```
ax1 = subplot(2,1,1);
surf(peaks)
```

```
ax2 = subplot(2,1,2);
contour(peaks)
```

Clear the surface plot from the upper subplot.

```
cla(ax1)
```

Now, reset all axes properties for the upper subplot, including the camera properties that control the view, by using the optional input argument 'reset'.

```
cla(ax1, 'reset')
```

### Clear Axes and Reset All Axes Properties

Create a line plot and set the axis limits.

```
x = linspace(0,2*pi);
y = sin(x);

plot(x,y)
axis([0,5,-2,2])
```

Clear the line plot from the axes and reset all the axes properties to their default values. `cla reset` resets all properties of the current axes, except for the **Position** and **Units** properties.

```
cla reset
```

## Input Arguments

### **ax** — Axes object

axes object

Axes object. Use `ax` to clear a specific axes, instead of the current axes.

## More About

### Tips

- If an axes does not exist, then `cla` creates one.
- The `cla` command resets the `ColorOrderIndex` and `LineStyleOrderIndex` properties of the current axes to 1.
- `cla` only deletes objects with a `HandleVisibility` property set to `'on'`. Therefore, if the `HandleVisibility` of an object is set to `'callback'` and you are in a callback, then `cla` does not delete it.

# clabel

Label contour plot elevation

## Syntax

```
clabel(C,h)
clabel(C,h,v)
clabel(C,h,'manual')
t = clabel(C,h,'manual')
```

```
clabel(C)
clabel(C,v)
clabel(C,'manual')
t1 = clabel(____)
```

```
clabel(____,Name,Value)
```

## Description

`clabel(C,h)` labels the current contour plot with rotated text inserted into each contour line. The contour lines must be long enough to fit the label, otherwise `clabel` does not insert a label. If you do not have the contour matrix `C`, then replace `C` with `[]`.

`clabel(C,h,v)` labels the contour levels specified by vector `v`.

`clabel(C,h,'manual')` labels the locations you select with the mouse. Click the mouse or press the space bar to label the contour closest to the center of the crosshair. Press the **Return** key while the cursor is within the figure window to terminate labeling.

`t = clabel(C,h,'manual')` returns the text objects created.

`clabel(C)` labels contours with '+' symbols and upright text.

`clabel(C,v)` adds upright labels to the contour levels specified by the vector, `v`.

`clabel(C,'manual')` adds upright labels at the locations you select with the mouse. Click the mouse or press the space bar to label the contour closest to the center of

the crosshair. Press the **Return** key while the cursor is within the figure window to terminate labeling.

`tl = clabel( ___ )` returns the text and line objects created. Use any of the input argument combinations in the previous syntaxes that do not include the contour object `h`.

`clabel( ___, Name, Value )` modifies the label appearance using one or more `Name, Value` pair arguments. Use any of the input argument combinations in the previous syntaxes. For example, `'FontSize', 14` sets the font size to 14 points.

## Examples

### Label Contour Plot Levels

Create a contour plot and obtain the contour matrix, `C`, and the contour object, `h`. Then, label the contour plot.

```
[x,y,z] = peaks;
[C,h] = contour(x,y,z);
clabel(C,h)
```

### Label Specific Contour Levels

Label only the contours with contour levels 2 or 6.

```
[x,y,z] = peaks;
[C,h] = contour(x,y,z);
v = [2,6];
clabel(C,h,v)
```

### Set Contour Label Properties

Set the font size of the labels to 15 points and set the color to red using Name, Value pair arguments.

```
[x,y,z] = peaks;
[C,h] = contour(x,y,z);
clabel(C,h, 'FontSize',15, 'Color', 'red')
```

Set additional properties by reissuing the `clabel` command. For example, set the font weight to bold and change the color to blue.

```
clabel(C,h, 'FontWeight', 'bold', 'Color', 'blue')
```

Set the font size back to the default size using the 'default' keyword.

```
clabel(C,h, 'FontSize', 'default')
```

### Label Contour Plot with Vertical Text

Create a contour plot and return the contour matrix, `C`. Then, label the contours.

```
[x,y,z] = peaks;
C = contour(x,y,z);
clabel(C)
```

## Input Arguments

**C** — Contour matrix

two-row matrix

Contour matrix returned by the `contour`, `contour3`, or `contourf` function. **C** contains the data that defines the contour lines. For more information on the contour matrix, see `ContourMatrix`.

---

**Note:** If you pass the contour object `h` to the `clabel` function, then you can replace **C** with `[]`. For example, use `clabel([],h)`.

---

**h — Contour object**

contour object

Contour object returned by the `contour`, `contour3`, or `contourf` function.

**v — Contour level values**

vector

Contour level values, specified as a row or column vector of individual values.

Example: `[0 10 20]`

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( `' '`). You can specify several name and value pair arguments in any order as `Name1`, `Value1`, `...`, `NameN`, `ValueN`.

`clabel` supports the `LabelSpacing` property plus a subset of text properties.

Example: `clabel(C,h,'Color','red','FontSize',12)` specifies red, 12-point labels.

**'LabelSpacing' — Space between labels**

scalar

Space between labels, specified as a scalar value in point units.

---

**Note:** Use this option with either the `clabel(C,h)` or `clabel(C,h,v)` syntax. Other syntaxes do not support this option.

---

Example: `clabel(C,h,'LabelSpacing',100)`

**'Color' — Text color**`[0 0 0]` (default) | RGB triplet | color string | `'none'`

Text color, specified as a three-element RGB triplet, a color string, or `'none'`. The default color is black with an RGB triplet value of `[0 0 0]`. If you set the color to `'none'`, then the text is invisible.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range  $[0, 1]$ , for example,  $[0.4 \ 0.6 \ 0.7]$ . This table lists RGB triplet values that have equivalent color strings.

| Long Name | Short Name | RGB Triplet |
|-----------|------------|-------------|
| 'yellow'  | 'y'        | [1 1 0]     |
| 'magenta' | 'm'        | [1 0 1]     |
| 'cyan'    | 'c'        | [0 1 1]     |
| 'red'     | 'r'        | [1 0 0]     |
| 'green'   | 'g'        | [0 1 0]     |
| 'blue'    | 'b'        | [0 0 1]     |
| 'white'   | 'w'        | [1 1 1]     |
| 'black'   | 'k'        | [0 0 0]     |

Example: 'blue'

Example: [0 0 1]

### 'EdgeColor' — Color of text box outline

'none' (default) | RGB triplet | color string

Color of text box outline, specified as 'none', a three-element RGB triplet, or a color string. The default edge color of 'none' makes the box outline invisible.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range  $[0, 1]$ , for example,  $[0.4 \ 0.6 \ 0.7]$ . This table lists RGB triplet values that have equivalent color strings.

| Long Name | Short Name | RGB Triplet |
|-----------|------------|-------------|
| 'yellow'  | 'y'        | [1 1 0]     |
| 'magenta' | 'm'        | [1 0 1]     |
| 'cyan'    | 'c'        | [0 1 1]     |
| 'red'     | 'r'        | [1 0 0]     |
| 'green'   | 'g'        | [0 1 0]     |
| 'blue'    | 'b'        | [0 0 1]     |

| Long Name | Short Name | RGB Triplet |
|-----------|------------|-------------|
| 'white'   | 'w'        | [ 1 1 1 ]   |
| 'black'   | 'k'        | [ 0 0 0 ]   |

Example: `clabel(C,h,'EdgeColor','k')`

### 'BackgroundColor' — Color of text box background

'none' (default) | RGB triplet | color string

Color of text box background, specified as 'none', a three-element RGB triplet, or a color string. The default background color of 'none' makes the text box background transparent.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0, 1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

| Long Name | Short Name | RGB Triplet |
|-----------|------------|-------------|
| 'yellow'  | 'y'        | [ 1 1 0 ]   |
| 'magenta' | 'm'        | [ 1 0 1 ]   |
| 'cyan'    | 'c'        | [ 0 1 1 ]   |
| 'red'     | 'r'        | [ 1 0 0 ]   |
| 'green'   | 'g'        | [ 0 1 0 ]   |
| 'blue'    | 'b'        | [ 0 0 1 ]   |
| 'white'   | 'w'        | [ 1 1 1 ]   |
| 'black'   | 'k'        | [ 0 0 0 ]   |

Example: `clabel(C,h,'BackgroundColor','g')`

### 'FontSize' — Font size

10 (default) | scalar value greater than 0

Font size, specified as a scalar value greater than 0. By default, the font size uses point units. One point equals 1/72 inch. However, some syntaxes allow you to change the font units using the `FontUnits` property.

Example: `clabel(C,h,'FontSize',15)`

## 'FontName' — Font name

'Helvetica' (default) | 'FixedWidth' | system supported font name

Font name, specified as the name of the font to use or the string 'FixedWidth'. To display and print properly, the font name must be a font that your system supports.

To use a fixed-width font that looks good in any locale, use the case-sensitive string 'FixedWidth'. The 'FixedWidth' value relies on the root FixedWidthFontName property. Setting the root FixedWidthFontName property causes an immediate update of the display to use the new font.

Example: 'Cambria'

## 'FontAngle' — Character slant

'normal' (default) | 'italic'

Character slant, specified as 'normal' or 'italic'. Not all fonts have both font styles. Therefore, the italic font might look the same as the normal font.

---

**Note:** The 'oblique' value has been removed. Use 'italic' instead.

---

## 'FontWeight' — Thickness of text characters

'normal' (default) | 'bold'

Thickness of the text characters, specified as one of these values:

- 'normal' — Default weight as defined by the particular font
- 'bold' — Thicker character outlines than normal

MATLAB uses the FontWeight property to select a font from those available on your system. Not all fonts have a bold font weight. Therefore, specifying a bold font weight still can result in the normal font weight.

---

**Note:** The 'light' and 'demi' font weight values have been removed. Use 'normal' instead.

---

## 'FontSmoothing' — Smooth font character appearance

'on' (default) | 'off'

Smooth font character appearance, specified as one of these values:

- 'on' — Apply font smoothing. Reduce the appearance of jaggedness in the text characters to make the text easier to read.
- 'off' — Do not apply font smoothing.

Example: `clabel(C,h,'FontSmoothing','on')`

#### 'FontUnits' — Font size units

'points' (default) | 'inches' | 'centimeters' | 'characters' | 'normalized' | 'pixels'

Font size units, specified as one of the values in this table.

| Units         | Description                                                                                                                                                                                                                                                                                             |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'points'      | Points. One point equals 1/72 inch.                                                                                                                                                                                                                                                                     |
| 'inches'      | Inches.                                                                                                                                                                                                                                                                                                 |
| 'centimeters' | Centimeters.                                                                                                                                                                                                                                                                                            |
| 'characters'  | Based on the default system font character size. <ul style="list-style-type: none"> <li>• Character width = width of letter x.</li> <li>• Character height = distance between the baselines of two lines of text.</li> </ul>                                                                            |
| 'normalized'  | Interpret font size as a fraction of the axes height. If you resize the axes, the font size modifies accordingly. For example, if the <code>FontSize</code> is 0.1 in normalized units, then the text is 1/10 of the axes height.                                                                       |
| 'pixels'      | Pixels. <p>Starting in R2015b, distances in pixels are independent of your system resolution on Windows and Macintosh systems:</p> <ul style="list-style-type: none"> <li>• On Windows systems, a pixel is 1/96th of an inch.</li> <li>• On Macintosh systems, a pixel is 1/72nd of an inch.</li> </ul> |

| Units | Description                                                                    |
|-------|--------------------------------------------------------------------------------|
|       | On Linux systems, the size of a pixel is determined by your system resolution. |

If you set both the font size and the font units in one function call, you must set the `FontUnits` property first so that the axes correctly interprets the specified font size.

---

**Note:** The `clabel(C,h)` and `clabel(C,h,v)` syntaxes do not support this option. They always use the default value of points.

---

Example: `clabel(C, 'FontUnits', 'normalized')`

### 'Rotation' — Text orientation

0 (default) | scalar

Text orientation, specified as a scalar value in degrees. The default rotation of 0 degrees makes the text horizontal. For vertical text, set this property to **90** or **-90**. Positive values rotate the text counterclockwise. Negative values rotate the text clockwise.

---

**Note:** The `clabel(C,h)` and `clabel(C,h,v)` syntaxes do not support this option. Instead, they insert rotated text into the contour lines, with each label rotated to match the local orientation of the corresponding line.

---

Example: `clabel(C, 'Rotation', 90)`

### 'Interpreter' — Interpretation of text characters

'tex' (default) | 'latex' | 'none'

Interpretation of text characters, specified as one of these values:

- 'tex' — Display text using TeX markup.
- 'latex' — Display text using LaTeX markup.
- 'none' — Display literal characters.

Since the labels are numeric text strings, the effect of this property is limited to subtle changes in the font style and weight.

Example: `clabel(C,h, 'Interpreter', 'latex')`

**'LineStyle' — Line style of text box outline**

'-' (default) | '--' | ':' | '-.' | 'none'

Line style of text box outline, specified as one of the strings in this table.

| String | Line Style        | Resulting Line                                                                     |
|--------|-------------------|------------------------------------------------------------------------------------|
| '-'    | Solid line        |  |
| '--'   | Dashed line       |  |
| ':'    | Dotted line       |  |
| '-.'   | Dash-dotted line  |  |
| 'none' | Line is invisible |                                                                                    |

Example: `clabel(C,h,'LineStyle','--')`

**'LineWidth' — Width of text box outline**

0.5 (default) | scalar

Width of text box outline, specified as a scalar value in point units. One point equals 1/72 inch.

Example: `clabel(C,h,'LineWidth',1)`

**'Margin' — Space around text within the text box**

3 (default) | scalar

The space around the text within the text box, specified as scalar value in point units.

MATLAB uses the `Extent` property value plus the `Margin` property value to determine the size of the text box.

Example: `clabel(C,h,'Margin',4)`

## Output Arguments

**t — Text objects**

vector

Text objects, returned as a vector. The `String` properties of the text objects contain the contour values displayed.

## **t1 — Text and line objects**

vector

Text and line objects, returned as a vector. The `String` properties of the text objects contain the contour values displayed. The line objects correspond to the '+' symbols.

# class

Determine class of object

## Syntax

```
ClassName = class(object)
obj = class(s, 'class_name')
obj = class(s, 'class_name', parent1, parent2, ...)
obj = class(struct([]), 'class_name', parent1, parent2, ...)
obj_struct = class(struct_array, 'class_name', parent_array)
```

## Description

*ClassName* = `class(object)` returns a string specifying the class of `object`. See “Fundamental MATLAB Classes” for more information on MATLAB classes.

---

**Note:** Before MATLAB 7.6 (classes defined without a `classdef` statement), `class` constructors called the `class` function to create the object. The following `class` function syntaxes apply only within classes defined before Version 7.6.

---

`obj = class(s, 'class_name')` creates an array of class *class\_name* objects using the `struct` `s` as a pattern to determine the size of `obj`.

`obj = class(s, 'class_name', parent1, parent2, ...)` inherits the methods and fields of the parent objects `parent1`, `parent2`, and so on. The size of the parent objects must match the size of `s` or be a scalar (1-by-1), in which case, MATLAB performs scalar expansion.

`obj = class(struct([]), 'class_name', parent1, parent2, ...)` constructs object containing only fields that it inherits from the parent objects. All parents must have the same, nonzero size, which determines the size of the returned object `obj`.

`obj_struct = class(struct_array, 'class_name', parent_array)` maps every element of the `parent_array` to a corresponding element in the `struct_array` to produce the output array of objects, `obj_struct`.

All arrays must be of the same size. If either the `struct_array` or the `parent_array` is of size 1-by-1, then MATLAB performs scalar expansion to match the array sizes.

To create an object array of size 0-by-0, set the size of the `struct_array` and `parent_array` to 0-by-0.

## Examples

Return the class of Java object `obj`:

```
import java.lang.*;
obj = String('mystring');
class(obj)
```

```
ans =
```

```
java.lang.String
```

Return class of any MATLAB variable:

```
h = @sin;
class(h)
```

```
ans =
```

```
function_handle
```

# classdef

Class definition keywords

## Syntax

```
classdef classname
 properties
 PropName
 end
 methods
 methodName
 end
 events
 EventName
 end
 enumeration
 EnumName
 end
end
```

## Description

`classdef classname` begins the class definition and an `end` keyword terminates the `classdef` block. Only blank lines and comments can precede `classdef`. Enter a class definition in a file having the same name as the class, with a filename extension of `.m`.

Class definition files can be in folders on the MATLAB path or in class folders whose parent folder is on the MATLAB path. Class folder names begin with the '@' character followed by the class name (for example, `@MyClass`). For more information on class folders, see “Class Files and Folders”.

For more information on classes, see “Classdef Block” and “Class Definition”.

`properties` begins a property definition block, an `end` keyword terminates the `properties` block. Class definitions can contain multiple property definition blocks, each specifying different attribute settings that apply to the properties in that particular block.

For more information on properties, see “Defining Properties”.

---

**Note:** Properties cannot have the same name as the class.

---

`methods` begins a methods definition block, an `end` keyword terminates the `methods` block. This block contains functions that implement class methods. Class definitions can contain multiple method blocks, each specifying different attribute settings that apply to the methods in that particular block. It is possible to define method functions in separate files.

For more information on methods, see “How to Use Methods”.

`events` begins an events definition block, an `end` keyword terminates the `events` block. This block contains event names defined by the class. Class definitions can contain multiple event blocks, each specifying different attribute settings that apply to the events in that particular block.

For more information on events, see “Events and Listeners — Syntax and Techniques”.

`enumeration` begins an enumeration definition block, an `end` keyword terminates the `enumeration` block.

For more information on enumerations, see “Enumerations”.

`properties`, `methods`, `events`, and `enumeration` are also the names of MATLAB functions used to query the respective class members for a given object or class name.

To see the attributes of all class components in a popup window, click this link: [Attribute Tables](#)

## Examples

Use these keywords to define classes.

```
classdef (Attributes) ClassName
 properties (Attributes)
 PropertyName
 end
 methods (Attributes)
```

```
 function obj = methodName(obj, arg2, ...)
 ...
 end
 end
 events (Attributes)
 EventName
 end
 enumeration
 EnumName
 end
end
```

## **clc**

Clear Command Window

## **Syntax**

```
clc
```

## **Description**

`clc` clears all input and output from the Command Window display, giving you a “clean screen.”

After using `clc`, you cannot use the scroll bar to see the history of functions, but you still can use the up arrow key, `↑`, to recall statements from the command history.

## **Examples**

Use `clc` in a MATLAB code file to always display output in the same starting position on the screen.

`clear` | `clf` | `close` | `home`

**Introduced before R2006a**

## clear

Remove items from workspace, freeing up system memory

### Syntax

```
clear
clear name1 ... nameN
clear -regex expr1 ... exprN
clear ItemType
```

### Description

`clear` removes all variables from the current workspace, releasing them from system memory.

`clear name1 ... nameN` removes the variables, scripts, functions, or MEX-functions, `name1 ... nameN`, from memory.

If `name` is

- A function, then `clear name` reinitializes any persistent variables in the function
- A script or function that is currently executing, then it is not cleared
- A function locked by `mlock`, then it remains in memory
- A variable that is global, then `clear` removes it from the current workspace, but it remains in the global workspace

`clear -regex expr1 ... exprN` removes all variables that match any of the regular expressions listed. This option only clears variables.

`clear ItemType` removed the types of items indicated by `ItemType`, such as `all`, `functions`, or `classes`.

### Examples

#### Clear a Single Variable

Define two variables `a` and `b`, and then clear `a`.

```
a = 1;
b = 2;
clear a
whos
```

| Name | Size | Bytes | Class  | Attributes |
|------|------|-------|--------|------------|
| b    | 1x1  | 8     | double |            |

Only variable **b** remains in the workspace.

## Clear Specific Variables by Name

Using regular expressions, clear those variables with names that begin with **Mon**, **Tue**, or **Wed**.

```
clear -regexp ^Mon ^Tue ^Wed;
```

## Clear List of Variables

Create a cell array, **varlist**, that contains the names of variables to clear. Then, clear those variables.

```
varlist = {'v1', 'v2', 'time'};
clear(varlist{:})
```

## Clear All Compiled Scripts, Functions, and MEX-functions

```
clear functions
```

If a function is locked or currently running, it is not cleared from memory.

# Input Arguments

**name1 ... nameN** — Names of variables, scripts, functions, or MEX-functions to clear  
string

Names of variables, scripts, functions, or MEX-functions to clear, specified as strings.

Use a partial path to distinguish between different overloaded versions of a function. For example, `clear polynom/display` clears only the `display` method for `polynom` objects, leaving any other implementations in memory.

**expr1 ... exprN — Regular expressions matching names of variables to clear**

string

Regular expressions matching names of variables to clear, specified as strings.

**ItemType — Type of items to clear**

all | classes | functions | global | import | java | mex | variables

Type of items to clear, specified as one of the following strings. Click the linked strings below for additional information.

| Value of ItemType | Items Cleared      |                       |                   |                      |               |                  |                          |                                  |
|-------------------|--------------------|-----------------------|-------------------|----------------------|---------------|------------------|--------------------------|----------------------------------|

| mex               |                    |                       |                   |                      | ✓             |                  |                          |                                  |
| variables         | ✓                  |                       |                   |                      |               |                  |                          |                                  |

The following applies to clearing types of items.

**all:**

- Calling `clear all` decreases code performance and is usually unnecessary.
- To clear one or more specific variables from the current workspace, use `clear name1 ... nameN`.

- To clear all variables from the current workspace, use `clear` or `clearvars`.
- To clear all global variables, use `clear global` or `clearvars -global`.
- To clear a particular function or script, use `clear myFun`.

## **classes:**

- Calling `clear classes` decreases code performance and is usually unnecessary. If you modify a class definition, MATLAB automatically updates it.
  - To instantiate an object with an updated class definition, it is not necessary to clear classes.
  - To clear a particular class, use `clear myClass`.

For more information, see “Automatic Updates for Modified Classes”.

- `clear classes` issues a warning and does not clear a class of objects if any of those objects still exists after the workspace is cleared. For example, objects can still exist in persistent variables of functions or figure windows.
- `clear classes` does not clear a class if its file is locked using the `mlock` command. No warning is issued in this case.

## **functions:**

- Calling `clear functions` decreases code performance and is usually unnecessary.
  - Use `clear functionName` to clear individual functions that need to be refreshed.
  - Use `clear mex` to clear all MEX functions.

## **global:**

- `clear global` removes all global variables in the current and global workspaces. For example, when called from a function, `clear global` removes all global variables in the function and global workspaces, but not in the base workspace.
- Use `clear global name1 ... nameN` to clear the global variables with the specified names.
- Use `clear global -regexp expr1 ... exprN` to clear all global variables that match any of the regular expressions listed.

## **import:**

- Call `clear import` only from the command prompt. Calling `clear import` in a function returns an error.

**java:**

- `clear java` issues a warning and does not remove the Java class definition if any Java objects exist outside the workspace (for example, in user data or persistent variables in a locked code file).
- Issue a `clear java` command after modifying any files on the dynamic Java path.

**mex:**

- `clear mex` does not clear locked MEX functions or functions that are currently in use.

If the name of a variable is a value of `ItemType`, then calling `clear` followed by that name deletes the variable with that name. `clear` does not interpret the name as a keyword in this context. For example, if the workspace contains variables `a`, `all`, `b`, and `ball`, `clear all` removes the variable `all` only.

## More About

**Tips**

- The `clear` function can remove variables that you specify. To remove all but some specified variables, use `clearvars` instead.
- You can clear the handle of a figure or graphics object, but the object itself is not removed. Use `delete` to remove objects. Deleting an object does not delete the variable (if any) used for storing its handle.
- The `clear` function does not clear Simulink<sup>®</sup> models. Use `bdclose` instead.
- On UNIX systems, `clear` does not affect the amount of memory allocated to the MATLAB process.
- “Base and Function Workspaces”
- “Strategies for Efficient Use of Memory”

# clearpoints

Clear points from animated line

## Syntax

```
clearpoints(h)
```

## Description

`clearpoints(h)` clears all points from the animated line specified by `h`. Create an animated line with the `animatedline` function. If you want to display the update on the screen, use `drawnow` after using `clearpoints`. For more information on line animations, see [Using Animated Line Objects](#).

## Examples

### Clear Points from Animated Line

Create an animated line with 10 points. Then, clear the points stored in the animated line.

```
h = animatedline(1:10,1:10);
clearpoints(h)
```

The animated line still exists, but has no data.

## Input Arguments

### **h** — Animated line object

animated line object

Animated line object. Create an animated line object using the `animatedline` function.

## **See Also**

### **Functions**

addpoints | animatedline | getpoints

### **Using Objects**

Using Animated Line Objects

### **Introduced in R2014b**

# clearvars

Clear variables from memory

## Syntax

```
clearvars
clearvars variables
clearvars -except keepVariables
clearvars variables -except keepVariables

clearvars -global ____
```

## Description

`clearvars` removes all variables from the currently active workspace.

`clearvars variables` removes the variables specified by `variables`. If any of the variables are global, `clearvars` removes these variables from the current workspace only, leaving them accessible to any functions that declare them as global.

`clearvars -except keepVariables` removes all variables, except for those specified by `keepVariables`. Use this syntax to keep specific variables and remove all others.

`clearvars variables -except keepVariables` removes the variables specified by `variables`, and does not remove the variables specified by `keepVariables`. This syntax allows you to use a combination of variable names, wild card characters, or regular expressions to specify variables to remove or keep.

`clearvars -global ____` removes the specified global variables from the workspace, including those made `global` within functions, using any of the input arguments in the preceding syntaxes. The `-global` flag must be first in the argument list.

## Examples

### Clear Named Variables

Define three variables, `a`, `b`, and `c`. Then, clear `a` and `c`.

```
a = 1;
b = 2;
c = 3;
clearvars a c
whos
```

| Name | Size | Bytes | Class  | Attributes |
|------|------|-------|--------|------------|
| b    | 1x1  | 8     | double |            |

Only variable **b** remains in the workspace.

### Clear All Variables Except Specified

Remove all variables from the workspace except for the variables **C** and **D**.

```
clearvars -except C D
```

### Clear Variables Using Regular Expressions and Name Variables to Exclude

Clear variables with names that start with **b** and are followed by 3 digits, except for the variable **b106**.

```
clearvars -regexp ^b\d{3}$ -except b106
```

### Name Variables to Clear and Preserve Variables Using Regular Expressions

Clear variables with names that start with **a** and do not end with **a**.

```
clearvars a* -except -regexp a$
```

### Clear Global Variables Except Specified

Clear all global variables, except those with names that start with **x**.

```
clearvars -global -except x*
```

### Clear List of Variables

Clear a list of variables used for intermediate calculations.

Create two variables in the workspace.

```
cashOnHand = 20;
cost = 12.99;
```

Store a list of the names of all the variables currently in the workspace.

```
initialVars = who;
```

Specify or calculate additional variables, `taxRate` and `tax`.

```
taxRate = 0.0625;
tax = round(100*cost*taxRate)/100;
```

Update the initial variables, `cost` and `cashOnHand`.

```
cost = cost + tax;
cashOnHand = cashOnHand - cost;
```

Clear all variables except the initial variables, using the function form of `clearvars`. When using the function form of a syntax, enclose input strings in single quotes, and separate them with commas.

```
clearvars('-except',initialVars{:})
```

`clearvars` clears the variables, `initialVars`, `taxRate`, and `tax`.

## Input Arguments

### **variables** — Names of variables to remove

strings

Names of variables to remove, specified as one or more strings in one of the following forms.

| Form of Variables Input              | Variables to Remove                                                                                                                                                                                                      |
|--------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>var1 ... varN</i>                 | Named variables, specified as individual strings. Use the '*' wildcard to match patterns. For example, <code>clearvars A*</code> clears all variables in the workspace with names that start with A.                     |
| <code>-regexp expr1 ... exprN</code> | Variables with names that match the regular expressions, specified as strings. For example, <code>clearvars -regexp ^Mon ^Tues</code> clears only the variables in the workspace with names that begin with Mon or Tues. |

**keepVariables** — Names of variables to keep

strings

Names of variables to keep, specified as one or more strings in one of the following forms.

| Form of Variables Input              | Variables to Keep                                                                                                                                                                                                                             |
|--------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>var1 ... varN</i>                 | Named variables, specified as individual strings. Use the ' * ' wildcard to match patterns. For example, <code>clearvars -except A*</code> clears all variables in the workspace, except those with names that start with A.                  |
| <code>-regexp expr1 ... exprN</code> | Variables with names that match the regular expressions, specified as strings. For example, <code>clearvars -except -regexp ^Mon ^Tues</code> clears all the variables in the workspace, except those with names that begin with Mon or Tues. |

## clear (serial)

Remove serial port object from MATLAB workspace

### Syntax

```
clear obj
```

### Description

`clear obj` removes `obj` from the MATLAB workspace, where `obj` is a serial port object or an array of serial port objects.

### Examples

This example creates the serial port object `s` on a Windows platform, copies `s` to a new variable `scopy`, and clears `s` from the MATLAB workspace. `s` is then restored to the workspace with `instrfind` and is shown to be identical to `scopy`.

```
s = serial('COM1');
scopy = s;
clear s
s = instrfind;
isequal(scopy,s)
ans =
 1
```

### More About

#### Tips

If `obj` is connected to the device and it is cleared from the workspace, then `obj` remains connected to the device. You can restore `obj` to the workspace with the `instrfind` function. A serial port object connected to the device has a `Status` property value of `open`.

To disconnect `obj` from the device, use the `fclose` function. To remove `obj` from memory, use the `delete` function. You should remove invalid serial port objects from the workspace with `clear`.

## **See Also**

`delete` | `isvalid` | `fclose` | `instrfind` | `Status`

**Introduced before R2006a**

# clf

Clear current figure window

## Syntax

```
clf
clf('reset')
clf(fig)
clf(fig, 'reset')
figure_handle = clf(...)
```

## Description

`clf` deletes from the current figure all graphics objects whose handles are not hidden (i.e., their `HandleVisibility` property is set to `on`).

`clf('reset')` deletes from the current figure all graphics objects regardless of the setting of their `HandleVisibility` property and resets all figure properties except `Position`, `Units`, `PaperPosition`, and `PaperUnits` to their default values.

`clf(fig)` or `clf(fig, 'reset')` clears the single figure with handle `fig`.

`figure_handle = clf(...)` returns the handle of the figure. This is useful when the figure `IntegerHandle` property is `off` because the noninteger handle becomes invalid when the reset option is used (i.e., `IntegerHandle` is reset to `on`, which is the default).

## Alternatives

Use **Clear Figure** from the figure window's **Edit** menu to clear the contents of a figure. You can also create a *desktop shortcut* to clear the current figure with one mouse click. See “Create Shortcuts to Rerun Commands”.

## More About

### Tips

The `clf` command behaves the same way when issued on the command line as it does in callback routines — it does not recognize the `HandleVisibility` setting of `callback`. This means that when issued from within a callback routine, `clf` deletes only those objects whose `HandleVisibility` property is set to `on`.

### See Also

`cla` | `clc` | `hold` | `reset`

**Introduced before R2006a**

# clipboard

Copy and paste strings to and from system clipboard

## Syntax

```
clipboard('copy', data)
str = clipboard('paste')
data = clipboard('pastespecial')
```

## Description

`clipboard('copy', data)` sets the clipboard contents to *data*. If *data* is not a character array, the clipboard uses `mat2str` to convert *data* to a string.

`str = clipboard('paste')` returns the current contents of the clipboard as a string or, if MATLAB cannot convert the current clipboard contents to a string, as an empty string (' ').

`data = clipboard('pastespecial')` returns the current contents of the clipboard as an array by using `uiimport`.

## Definitions

The `clipboard` function requires Oracle® Java software.

## See Also

`load` | `mat2str` | `uiimport`

**Introduced before R2006a**

## clock

Current date and time as date vector

### Syntax

```
c = clock
```

### Description

`c = clock` returns a six-element date vector containing the current date and time in decimal form:

```
[year month day hour minute seconds]
```

### Examples

#### Round clock Output to Integer Display

Use `clock` to return the current date and time.

```
format shortg
```

```
c = clock
```

```
c =
```

```
 2015 8 24 17 41 1.142
```

The sixth element of the date vector output (seconds) is accurate to several digits beyond the decimal point.

Use the `fix` function to round to integer display format.

```
fix(c)
```

```
ans =
 2015 8 24 17 41 1
```

## More About

### Tips

- To time the duration of an event, use the `timeit` or `tic` and `toc` functions instead of `clock` and `etime`. The `clock` function is based on the system time, which can be adjusted periodically by the operating system, and thus might not be reliable in time comparison operations.
- To return a datetime scalar representing the current date and time, type:

```
t = datetime('now')
```

### See Also

**Introduced before R2006a**

## close

Remove specified figure

### Syntax

```
close
close(h)
close name
close all
close all hidden
close all force
status = close(...)
```

### Description

`close` deletes the current figure or the specified figure(s). It optionally returns the status of the close operation.

`close` deletes the current figure (equivalent to `close(gcf)`).

`close(h)` deletes the figure identified by `h`. If `h` is an array, `close` deletes all figures identified by `h`. `h` can also be the figure Number.

`close name` deletes the figure with the specified name.

`close all` deletes all figures whose handles are not hidden.

`close all hidden` deletes all figures including those with hidden handles.

`close all force` deletes all figures, including GUIs for which `CloseRequestFcn` has been altered to not close the window.

`status = close(...)` returns 1 if the specified windows have been deleted and 0 otherwise.

## More About

### Algorithms

The `close` function works by evaluating the specified figure's `CloseRequestFcn` property with the statement

```
eval(get(h, 'CloseRequestFcn'))
```

The default `CloseRequestFcn`, `closereq`, deletes the current figure using `delete(get(groot, 'CurrentFigure'))`. If you specify an array of figure handles, `close` executes each figure's `CloseRequestFcn` in turn. If an error that terminates the execution of a `CloseRequestFcn` occurs, the figure is not deleted. Note that using your computer's window manager (i.e., the **Close** menu item) also calls the figure's `CloseRequestFcn`.

If a figure's handle is hidden (i.e., the figure's `HandleVisibility` property is set to `callback` or `off` and the root `ShowHiddenHandles` property is set to `on`), you must specify the `hidden` option when trying to access a figure using the `all` option.

To delete all figures unconditionally, use the statements

```
set(groot, 'ShowHiddenHandles', 'on')
c = get(groot, 'Children');
delete(c)
```

The figure `CloseRequestFcn` allows you to either delay or abort the closing of a figure once the `close` function has been issued. For example, you can display a dialog box to see if the user really wants to delete the figure or save and clean up before closing.

When coding a `CloseRequestFcn` callback, make sure that it does not call `close`, because this sets up a recursion that results in a MATLAB warning. Instead, the callback should destroy the figure with `delete`. The `delete` function does not execute the figure's `CloseRequestFcn`; it deletes the specified figure.

### See Also

`delete` | `figure` | `gcf`

Introduced before R2006a

## close

**Class:** Tiff

Close Tiff object

## Syntax

```
close(tiffobj)
```

## Description

`close(tiffobj)` closes a Tiff object.

## Examples

### Close Tiff Object

Open a Tiff object and then close it.

```
t = Tiff('example.tif', 'r');
close(t)
```

- “Exporting Image Data and Metadata to TIFF Files”
- “Reading Image Data and Metadata from TIFF Files”

## References

This method corresponds to the `TIFFClose` function in the LibTIFF C API. To use this method, you must be familiar with the TIFF specification and technical notes. View this documentation at [LibTiff - TIFF Library and Utilities](#).

## close

**Class:** FTP

Close connection to FTP server

## Syntax

```
close(ftpobj)
```

## Description

`close(ftpobj)` closes the connection to the FTP server.

## Tips

- If you do not run `close` at the end of your session, the connection either times out automatically or terminates when you exit MATLAB.
- After calling `close`, calling any other FTP method on the same object automatically reopens the connection.
- `close` does not return any output to indicate success or failure.

## Input Arguments

**ftpobj**

FTP object created by `ftp`.

## Examples

Connect to the National Geophysical Data Center (NGDC) FTP server, and then disconnect:

```
ngdc = ftp('ftp.ngdc.noaa.gov');
close(ngdc)
```

FTP service courtesy of the NGDC. See NGDC Privacy Policy, Disclaimer, and Copyright for NGDC terms of service.

## cmpermute

Rearrange colors in colormap

### Syntax

```
[Y,newmap] = cmpermute(X,map)
[Y,newmap] = cmpermute(X,map,index)
```

### Description

`[Y,newmap] = cmpermute(X,map)` randomly reorders the colors in `map` to produce a new colormap, `newmap`. The `cmpermute` function also modifies the values in `X` to maintain correspondence between the indices and the colormap, and returns the result in `Y`. The image `Y` and associated colormap, `newmap`, produce the same image as `X` and `map`.

`[Y,newmap] = cmpermute(X,map,index)` uses an ordering matrix (such as the second output of `sort`) to define the order of colors in the new colormap.

### Class Support

The input image `X` can be of class `uint8` or `double`. `Y` is returned as an array of the same class as `X`.

### Examples

#### Randomly Reorder Colormap and Display Image

Load the `clown` data set to get image `X` and its associated colormap, `map`. Display the image.

```
load clown
figure
image(X)
colormap(map)
```

Randomly reorder the colormap to get the new colormap, `newmap`. Display image `X` with the new colormap.

```
[Y, newmap] = cmpermute(X,map);
colormap(newmap)
```

**See Also**

randperm | sort

## cmunique

Eliminate duplicate colors in colormap; convert grayscale or truecolor image to indexed image

### Syntax

```
[Y,newmap] = cmunique(X,map)
[Y,newmap] = cmunique(RGB)
[Y,newmap] = cmunique(I)
```

### Description

`[Y,newmap] = cmunique(X,map)` returns the indexed image `Y` and associated colormap, `newmap`, that produce the same image as `(X,map)` but with the smallest possible colormap. The `cmunique` function removes duplicate rows from the colormap and adjusts the indices in the image matrix accordingly.

`[Y,newmap] = cmunique(RGB)` converts the truecolor image `RGB` to the indexed image `Y` and its associated colormap, `newmap`. The return value `newmap` is the smallest possible colormap for the image, containing one entry for each unique color in `RGB`.

---

**Note:** `newmap` might be very large, because the number of entries can be as many as the number of pixels in `RGB`.

---

`[Y,newmap] = cmunique(I)` converts the grayscale image `I` to an indexed image `Y` and its associated colormap, `newmap`. The return value, `newmap`, is the smallest possible colormap for the image, containing one entry for each unique intensity level in `I`.

### Class Support

The input image can be of class `uint8`, `uint16`, or `double`. The class of the output image `Y` is `uint8` if the length of `newmap` is less than or equal to 256. If the length of `newmap` is greater than 256, `Y` is of class `double`.

## Examples

### Eliminate Duplicate Entries in Colormap

Use the `magic` function to define `X` as a 4-by-4 array that uses every value in the range between 1 and 16.

```
X = magic(4);
```

Use the `gray` function to create an eight-entry colormap. Then, concatenate the two eight-entry colormaps to create a colormap with 16 entries, `map`. In `map`, entries 9 through 16 are duplicates of entries 1 through 8.

```
map = [gray(8); gray(8)];
size(map)
```

```
ans =
 16 3
```

Use `cmunique` to eliminate duplicate entries in the colormap.

```
[Y, newmap] = cmunique(X, map);
size(newmap)
```

```
ans =
 8 3
```

`cmunique` adjusts the values in the original image `X` so that `Y` and `newmap` produce the same image as `X` and `map`.

```
figure
image(X)
colormap(map)
title('X and map')
```

```
figure
image(Y)
```

```
colormap(newmap)
title('Y and newmap')
```

**See Also**  
rgb2ind

## colamd

Column approximate minimum degree permutation

### Syntax

`p = colamd(S)`

### Description

`p = colamd(S)` returns the column approximate minimum degree permutation vector for the sparse matrix `S`. For a non-symmetric matrix `S`, `S(:,p)` tends to have sparser LU factors than `S`. The Cholesky factorization of `S(:,p)' * S(:,p)` also tends to be sparser than that of `S' * S`.

`knobs` is a two-element vector. If `S` is `m`-by-`n`, then rows with more than `(knobs(1)) * n` entries are ignored. Columns with more than `(knobs(2)) * m` entries are removed prior to ordering, and ordered last in the output permutation `p`. If the `knobs` parameter is not present, then `knobs(1) = knobs(2) = spparms('wh_frac')`.

`stats` is an optional vector that provides data about the ordering and the validity of the matrix `S`.

|                       |                                                                                                                                                                     |
|-----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>stats(1)</code> | Number of dense or empty rows ignored by <code>colamd</code>                                                                                                        |
| <code>stats(2)</code> | Number of dense or empty columns ignored by <code>colamd</code>                                                                                                     |
| <code>stats(3)</code> | Number of garbage collections performed on the internal data structure used by <code>colamd</code> (roughly of size $2.2 * \text{nnz}(S) + 4 * m + 7 * n$ integers) |
| <code>stats(4)</code> | 0 if the matrix is valid, or 1 if invalid                                                                                                                           |
| <code>stats(5)</code> | Rightmost column index that is unsorted or contains duplicate entries, or 0 if no such column exists                                                                |
| <code>stats(6)</code> | Last seen duplicate or out-of-order row index in the column index given by <code>stats(5)</code> , or 0 if no such row index exists                                 |
| <code>stats(7)</code> | Number of duplicate and out-of-order row indices                                                                                                                    |

Although MATLAB built-in functions generate valid sparse matrices, a user may construct an invalid sparse matrix using the MATLAB C or Fortran APIs and pass it to `colamd`. For this reason, `colamd` verifies that `S` is valid:

- If a row index appears two or more times in the same column, `colamd` ignores the duplicate entries, continues processing, and provides information about the duplicate entries in `stats(4:7)`.
- If row indices in a column are out of order, `colamd` sorts each column of its internal copy of the matrix `S` (but does not repair the input matrix `S`), continues processing, and provides information about the out-of-order entries in `stats(4:7)`.
- If `S` is invalid in any other way, `colamd` cannot continue. It prints an error message, and returns no output arguments (`p` or `stats`).

The ordering is followed by a column elimination tree post-ordering.

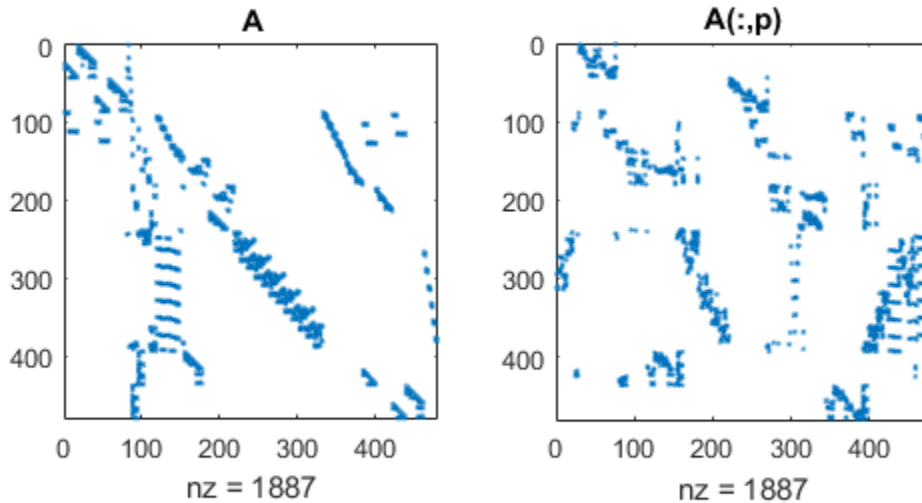

## Examples

### Compare Sparse Matrix and LU Factorization

The Harwell-Boeing collection of sparse matrices and the MATLAB® demos directory include a test matrix `west0479`. It is a matrix of order 479 resulting from a model due to Westerberg of an eight-stage chemical distillation column. The spy plot shows evidence of the eight stages. The `colamd` ordering scrambles this structure.

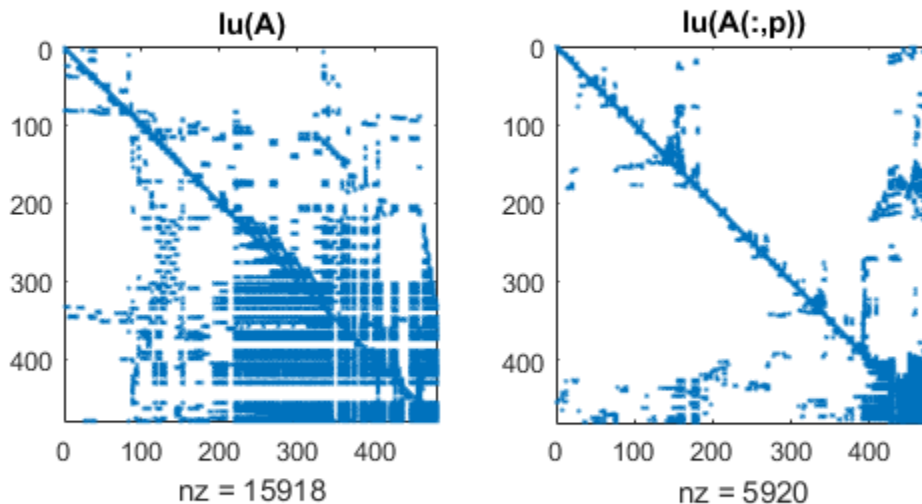

```
load west0479
A = west0479;
p = colamd(A);

figure()
subplot(1,2,1), spy(A,4), title('A')
subplot(1,2,2), spy(A(:,p),4), title('A(:,p)')
```

Comparing the spy plot of the LU factorization of the original matrix with that of the reordered matrix shows that minimum degree reduces the time and storage requirements by better than a factor of 2.8. The nonzero counts are 15918 and 5920, respectively.

```
figure()
subplot(1,2,1), spy(lu(A),4), title('lu(A)')
subplot(1,2,2), spy(lu(A(:,p)),4), title('lu(A(:,p))')
```

## References

- [1] The authors of the code for “colamd” are Stefan I. Larimore and Timothy A. Davis (davis@cise.ufl.edu), University of Florida. The algorithm was developed in collaboration with John Gilbert, Xerox PARC, and Esmond Ng, Oak Ridge National Laboratory. ## colorbar

Colorbar showing color scale

### Syntax

```
colorbar
colorbar(placement)
colorbar(Name,Value)
colorbar(placement,Name,Value)
```

```
colorbar(ax, ___)
colorbar('peer',ax ___)
h = colorbar(___)
```

```
colorbar('off')
colorbar(h,'off')
colorbar(ax,'off')
```

### Description

`colorbar` displays a vertical colorbar to the right of the current axes. Colorbars display the current colormap and indicate the mapping of data values into the colormap.

`colorbar(placement)` displays a colorbar in the location specified by `placement`, which is a location string such as `'northoutside'`.

`colorbar(Name,Value)` specifies colorbar properties using one or more `Name,Value` pair arguments. For example, `'Direction','reverse'` reverses the color scale.

`colorbar(placement,Name,Value)` specifies both the colorbar location and other colorbar properties.

`colorbar(ax, ___ )` adds a colorbar to the axes specified by `ax` instead of the current axes (`gca`). The option, `ax`, can precede any of the input argument combinations in the previous syntaxes.

`colorbar('peer',ax,___)` adds a colorbar to the axes specified by `ax` instead of the current axes. This syntax is not recommended and might be removed in a future release. Use `colorbar(ax,___)` instead.

`h = colorbar( ___ )` returns the colorbar object. Use `h` to set properties of the colorbar after it is created.

---

**Note:** Starting in R2014b, the `colorbar` function returns a colorbar object. In previous releases it returns an axes object.

---

`colorbar('off')` deletes all colorbars associated with the current axes.

`colorbar(h,'off')` deletes the colorbar specified by `h`.

`colorbar(ax,'off')` deletes all colorbars associated with the axes specified by `ax` instead of the current axes (`gca`).

## Examples

### Add Colorbar to Graph

Add a colorbar to a surface plot indicating the color scale.

```
figure
surf(peaks)
colorbar
```

By default, the `colorbar` function adds a vertical colorbar to the right side of the graph.

### Add Horizontal Colorbar to Graph

Add a horizontal colorbar below a plot by specifying the colorbar location as `'southoutside'`.

```
figure
contourf(peaks)
colorbar('southoutside')
```

### Reverse Colorbar Direction

Reverse the direction of values in a colorbar on a graph by setting the 'Direction' property of the colorbar to 'reverse'.

```
figure
surf(peaks)
colorbar('Direction','reverse')
```

The colorbar values ascend from top to bottom instead of ascending from bottom to top.

### Display Colorbar Ticks on Opposite Side

Display the colorbar tick marks and tick labels on the side of a colorbar facing the surface plot.

```
surf(peaks)
colorbar('AxisLocation','in')
```

### Add Colorbars to Subplots

Create a figure with two subplots. Add colorbars to both subplots.

```
figure
subplot(2,1,1) % upper subplot
surf(peaks)
colorbar

subplot(2,1,2) % lower subplot
contourf(peaks)
colorbar
```

### Specify Colorbar Ticks and Tick Labels

Add a colorbar to a plot and specify the colorbar tick marks and tick labels. Specify the same number of tick labels as tick marks. If you do not specify enough tick labels, then the colorbar function repeats the labels.

```
contourf(peaks)
colorbar('Ticks',[-5,-2,1,4,7],...
 'TickLabels',{'Cold','Cool','Neutral','Warm','Hot'})
```

### Label Colorbar

Add a text label along a colorbar. Starting in R2014b, you can use dot notation to set properties. If you are using an earlier release, use the set function instead.

```
surf(peaks)
c = colorbar;
c.Label.String = 'Elevation (ft in 1000s)';
```

### Delete Colorbar

Add a colorbar to a surface plot.

```
figure
surf(peaks)
colorbar
```

Delete the colorbar from the surface plot.

```
colorbar('off')
```

- “Change Colorbar Width”
- “Change Mapping of Data Values into Colormap”

## Input Arguments

### **placement** — Colorbar location and orientation

'eastoutside' (default) | location string

Colorbar location and orientation with respect to the axes, specified as a location string. This table lists the location strings.

| String         | Resulting Location                 | Resulting Orientation |
|----------------|------------------------------------|-----------------------|
| 'north'        | Top of axes                        | Horizontal            |
| 'south'        | Bottom of axes                     | Horizontal            |
| 'east'         | Right side of axes                 | Vertical              |
| 'west'         | Left side of axes                  | Vertical              |
| 'northoutside' | Top outside of axes                | Horizontal            |
| 'southoutside' | Bottom outside of axes             | Horizontal            |
| 'eastoutside'  | Right outside of axes<br>(default) | Vertical              |
| 'westoutside'  | Left outside of axes               | Vertical              |

If a colorbar already exists in the specified location, then an updated colorbar replaces the existing one. To ensure that the colorbar does not overlap the graph, specify a location with the suffix, `outside`.

You also can set the colorbar location using its `Location` property. For example, `colorbar('Location','northoutside')` is the same as `colorbar('northoutside')`. If you use the shorthand syntax, `colorbar('northoutside')`, then MATLAB sets the colorbar `Location` property value to `'northoutside'`.

Example: `colorbar('westoutside')`

### **ax** — Axes object

axes object

Axes object. If you do not specify an axes, then the `colorbar` function adds a colorbar for the current axes.

## **Name-Value Pair Arguments**

The colorbar properties listed here are only a subset. For a complete list see [Colorbar Properties](#).

Example: `colorbar('FontSize',12,'Direction','reverse')` sets the font size of the colorbar to 12 points and reverses the orientation of the colorbar.

### **'Location'** — Location with respect to the axes

'eastoutside' (default) | `tring`

Location with respect to the axes, specified as one of the strings listed in this table.

| String         | Resulting Location                              | Resulting Orientation |
|----------------|-------------------------------------------------|-----------------------|
| 'north'        | Top of axes                                     | Horizontal            |
| 'south'        | Bottom of axes                                  | Horizontal            |
| 'east'         | Right side of axes                              | Vertical              |
| 'west'         | Left side of axes                               | Vertical              |
| 'northoutside' | Top outside of axes                             | Horizontal            |
| 'southoutside' | Bottom outside of axes                          | Horizontal            |
| 'eastoutside'  | Right outside of axes<br>(default)              | Vertical              |
| 'westoutside'  | Left outside of axes                            | Vertical              |
| 'manual'       | Determined by <code>Position</code><br>property | Vertical              |

To display the colorbar in a location that does not appear in the table, use the `Position` property to specify a custom location. If you set the `Position` property, then MATLAB sets the `Location` property to 'manual'. The associated axes does not resize to accommodate the colorbar when the `Location` property is set to 'manual'.

**'TickLabels' — Tick mark labels**

cell array of strings | numeric array | string

Tick mark labels, specified as a cell array of strings, a numeric array, or a string. By default, the colorbar labels the tick marks with numeric values. If you specify labels and do not specify enough labels for all the tick marks, then MATLAB cycles through the labels.

Example: {'cold', 'warm', 'hot'}

**'TickLabelInterpreter' — Interpretation of characters in tick labels**

'tex' (default) | 'latex' | 'none'

Interpretation of tick label characters, specified as one of these values:

- 'tex' — Interpret strings using a subset of the TeX markup.
- 'latex' — Interpret strings using a subset of LaTeX markup.

- 'none' — Display literal characters

## TeX Markup

By default, MATLAB supports a subset of TeX markup. Use TeX markup to add superscripts and subscripts, modify the text type and color, and include special characters in the text string.

This table lists the supported modifiers when the `TickLabelInterpreter` property is set to 'tex', which is the default value. Modifiers remain in effect until the end of the string, except for superscripts and subscripts which only modify the next character or the text within the curly braces {}.

| Modifier                          | Description                                                                                                                                | Example of String                |
|-----------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------|
| <code>^{ }</code>                 | Superscript                                                                                                                                | 'text <sup>{superscript}</sup> ' |
| <code>_{ }</code>                 | Subscript                                                                                                                                  | 'text <sub>{subscript}</sub> '   |
| <code>\bf</code>                  | Bold font                                                                                                                                  | '\bf text'                       |
| <code>\it</code>                  | Italic font                                                                                                                                | '\it text'                       |
| <code>\sl</code>                  | Oblique font (rarely available)                                                                                                            | '\sl text'                       |
| <code>\rm</code>                  | Normal font                                                                                                                                | '\rm text'                       |
| <code>\fontname{specifier}</code> | Set <code>specifier</code> as the name of a font family to change the font style. You can use this in combination with other modifiers.    | '\fontname{Courier} text'        |
| <code>\fontsize{specifier}</code> | Set <code>specifier</code> as a scalar numeric value to change the font size.                                                              | '\fontsize{15} text'             |
| <code>\color{specifier}</code>    | Set <code>specifier</code> as one of these colors: red, green, yellow, magenta, blue, black, white, gray, darkGreen, orange, or lightBlue. | '\color{magenta} text'           |

| Modifier                            | Description                                                            | Example of String                          |
|-------------------------------------|------------------------------------------------------------------------|--------------------------------------------|
| <code>\color[rgb]{specifier}</code> | Set specifier as a three-element RGB triplet to change the font color. | <code>'\color[rgb]{0,0.5,0.5} text'</code> |

This table lists the supported special characters with the Interpreter property set to 'tex'.

| <code>\rceil</code>  | $\rceil$  | <code>\rangle</code>   | $\rangle$   | <code>\mid</code>       | $\mid$       |
| <code>\vee</code>    | $\vee$    | <code>\langle</code>   | $\langle$   | <code>\copyright</code> | $\copyright$ |

## LaTeX Markup

To use LaTeX markup, set the `TickLabelInterpreter` property to `'latex'`. The displayed text uses the default LaTeX font style. The `FontName`, `FontWeight`, and `FontAngle` properties do not have an effect. To change the font style, use LaTeX markup within the text string.

The maximum size of the string that you can use with the LaTeX interpreter is 1200 characters. For multiline strings, this reduces by about 10 characters per line.

For more information about the LaTeX system, see The LaTeX Project Web site at <http://www.latex-project.org/>.

### 'Ticks' — Tick mark locations

vector of monotonically increasing numeric values

Tick mark locations, specified as a vector of monotonically increasing numeric values. The values do not need to be equally spaced. If you do not want tick marks displayed, then set the property to the empty vector, `[]`.

Example: [-1,0,1,2,3,4,5]

Data Types: `single` | `double`

**'Direction' — Direction of color scale**

`'normal'` (default) | `'reverse'`

Direction of color scale, specified as one of these values:

- `'normal'` — Display the colormap and labels ascending from bottom to top for a vertical colorbar, and ascending from left to right for a horizontal colorbar. This is the default value.
- `'reverse'` — Display the colormap and labels descending from bottom to top for a vertical colorbar, and descending from left to right for a horizontal colorbar.

**'FontSize' — Font size**

9 (default) | scalar value greater than zero

Font size, specified as a scalar value greater than zero in point units. The default value is 9 points. If you change the axes font size, then MATLAB automatically sets the colorbar font size to 90% of the axes font size. If you manually set the colorbar font size, then changing the axes font size does not affect the colorbar.

Example: 12

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

## Output Arguments

**h — Colorbar object**

colorbar object

Colorbar object. Use `h` to set properties of the colorbar after it is created.

## More About

### Tips

- To add a text description along the colorbar, access the underlying text object using the `Label` property of the colorbar.

```
c.Label.String = 'My Colorbar Label';
```

To change the label appearance, such as the font style or color, set other text properties. For a list of properties, see [Text Properties](#). For example, this code changes the font size.

```
c.Label.FontSize = 12;
```

- Adding a colorbar might resize the axes to accommodate the colorbar.
- If an axes does not exist, then the `colorbar` function creates a blank axes and displays a colorbar with the default colormap.
- You can use `colorbar('delete')` or `colorbar('hide')` instead of `colorbar('off')` to delete all colorbars in the current axes.

**Introduced before R2006a**

# Colorbar Properties

Control colorbar appearance and behavior

Colorbar properties control the appearance and behavior of a colorbar object. By changing property values, you can modify certain aspects of the colorbar. Use dot notation to refer to a particular object and property:

```
c = colorbar;
w = c.LineWidth;
c.LineWidth = 1.5;
```

## Appearance

### Color — Color of tick marks, text, and box outline

[0 0 0] (default) | RGB triplet | color string

Color of the tick marks, text, and box outline, specified as an RGB triplet or a color string.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0, 1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

| Long Name | Short Name | RGB Triplet |
|-----------|------------|-------------|
| 'yellow'  | 'y'        | [1 1 0]     |
| 'magenta' | 'm'        | [1 0 1]     |
| 'cyan'    | 'c'        | [0 1 1]     |
| 'red'     | 'r'        | [1 0 0]     |
| 'green'   | 'g'        | [0 1 0]     |
| 'blue'    | 'b'        | [0 0 1]     |
| 'white'   | 'w'        | [1 1 1]     |
| 'black'   | 'k'        | [0 0 0]     |

Example: [0 1 0]

Example: 'green'

### **Box — Box outline**

'on' (default) | 'off'

Box outline, specified as one of these values:

- 'on' — Display the box outline around the colorbar.
- 'off' — Do not display the box outline around the colorbar.

### **LineWidth — Width of box outline**

0.5 (default) | positive value

Width of box outline, specified as a positive value in point units. One point equals 1/72 inches.

Example: 1.5

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

### **Label — Label that displays along colorbar**

text object (default)

Label that displays along the colorbar, returned as a text object. This text object contains properties that control the label appearance and the text that displays. Use the `Label` property to access the text object, for example:

```
c = colorbar;
c.Label
```

```
ans =
```

```
Text with properties:
```

```
String: ''
FontSize: 10
FontWeight: 'normal'
FontName: 'Helvetica'
Color: [0.1500 0.1500 0.1500]
HorizontalAlignment: 'left'
Position: [0 0 0]
Units: 'data'
```

Show all properties

By default, there is no text displayed. To display text or change existing text, set the `String` property for the text object, for example:

```
c.Label.String = 'Label Text Goes Here';
```

To change the label appearance, such as the font style or color, set other text properties. For example, this code changes the font size.

```
c.Label.FontSize = 12;
```

For a full list of options, see [Text Properties](#).

## Location and Size

### Location — Location with respect to the axes

'eastoutside' (default) | tring

Location with respect to the axes, specified as one of the strings listed in this table.

| String         | Resulting Location                              | Resulting Orientation |
|----------------|-------------------------------------------------|-----------------------|
| 'north'        | Top of axes                                     | Horizontal            |
| 'south'        | Bottom of axes                                  | Horizontal            |
| 'east'         | Right side of axes                              | Vertical              |
| 'west'         | Left side of axes                               | Vertical              |
| 'northoutside' | Top outside of axes                             | Horizontal            |
| 'southoutside' | Bottom outside of axes                          | Horizontal            |
| 'eastoutside'  | Right outside of axes<br>(default)              | Vertical              |
| 'westoutside'  | Left outside of axes                            | Vertical              |
| 'manual'       | Determined by <code>Position</code><br>property | Vertical              |

To display the colorbar in a location that does not appear in the table, use the `Position` property to specify a custom location. If you set the `Position` property, then MATLAB sets the `Location` property to 'manual'. The associated axes does not resize to accommodate the colorbar when the `Location` property is set to 'manual'.

**Position — Custom location and size**

four-element vector

Custom location and size, specified as a four-element vector of the form [`left`, `bottom`, `width`, `height`]. The `left` and `bottom` elements specify the distance from the lower-left corner of the figure or to the lower-left corner of the colorbar. The `width` and `height` elements specify the dimensions of the colorbar. The `Units` property determines the position units.

If you specify the `Position` property, then MATLAB changes the `Location` property to `'manual'`. The associated axes does not resize to accommodate the colorbar when the `Location` property is `'manual'`.

Example: `[0.1 0.1 0.3 0.7]`

**Units — Position units**

`'normalized'` (default) | `'inches'` | `'centimeters'` | `'characters'` | `'points'` | `'pixels'`

Position units, specified as one of the values in this table.

| Units                               | Description                                                                                                                                                                                                                  |
|-------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>'normalized'</code> (default) | Normalized with respect to the container, which is usually the figure. The lower left corner of the figure maps to (0,0) and the upper right corner maps to (1,1).                                                           |
| <code>'inches'</code>               | Inches.                                                                                                                                                                                                                      |
| <code>'centimeters'</code>          | Centimeters.                                                                                                                                                                                                                 |
| <code>'characters'</code>           | Based on the default system font character size. <ul style="list-style-type: none"> <li>• Character width = width of letter x.</li> <li>• Character height = distance between the baselines of two lines of text.</li> </ul> |
| <code>'points'</code>               | Points. One point equals 1/72 inch.                                                                                                                                                                                          |
| <code>'pixels'</code>               | Pixels. <p>Starting in R2015b, distances in pixels are independent of your system resolution on Windows and Macintosh systems:</p>                                                                                           |

| <b>Units</b> | <b>Description</b>                                                                                                                                                                                                                                      |
|--------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|              | <ul style="list-style-type: none"><li>• On Windows systems, a pixel is 1/96th of an inch.</li><li>• On Macintosh systems, a pixel is 1/72nd of an inch.</li></ul> <p>On Linux systems, the size of a pixel is determined by your system resolution.</p> |

All units are measured from the lower-left corner of the container window.

This property affects the **Position** property. If you change the units, then it is good practice to return it to its default value after completing your computation to prevent affecting other functions that assume **Units** is the default value.

If you specify the **Position** and **Units** properties as **Name, Value** pairs when creating the colorbar, then the order of specification matters. If you want to define the position with particular units, then you must set the **Units** property before the **Position** property.

## Tick Marks and Tick Labels

### **Ticks** — Tick mark locations

vector of monotonically increasing numeric values

Tick mark locations, specified as a vector of monotonically increasing numeric values. The values do not need to be equally spaced. If you do not want tick marks displayed, then set the property to the empty vector, `[]`.

Example: `[-1,0,1,2,3,4,5]`

Data Types: `single` | `double`

### **TicksMode** — Selection mode for Ticks

'auto' (default) | 'manual'

Selection mode for **Ticks**, specified as one of these values:

- 'auto' — Automatically choose the values.
- 'manual' — Use manually specified values. To specify the values, set the **Ticks** property.

**TickLabels — Tick mark labels**

cell array of strings | numeric array | string

Tick mark labels, specified as a cell array of strings, a numeric array, or a string. By default, the colorbar labels the tick marks with numeric values. If you specify labels and do not specify enough labels for all the tick marks, then MATLAB cycles through the labels.

Example: {'cold', 'warm', 'hot'}

**TickLabelsMode — Selection mode for TickLabels**

'auto' (default) | 'manual'

Selection mode for `TickLabels`, specified as one of these values:

- 'auto' — Automatically choose the tick mark labels.
- 'manual' — Use manually specified values. To specify the values, set the `TickLabels` property.

**TickLabelInterpreter — Interpretation of characters in tick labels**

'tex' (default) | 'latex' | 'none'

Interpretation of tick label characters, specified as one of these values:

- 'tex' — Interpret strings using a subset of the TeX markup.
- 'latex' — Interpret strings using a subset of LaTeX markup.
- 'none' — Display literal characters

## TeX Markup

By default, MATLAB supports a subset of TeX markup. Use TeX markup to add superscripts and subscripts, modify the text type and color, and include special characters in the text string.

This table lists the supported modifiers when the `TickLabelInterpreter` property is set to 'tex', which is the default value. Modifiers remain in effect until the end of the string, except for superscripts and subscripts which only modify the next character or the text within the curly braces {}.

| Modifier           | Description | Example of String                |
|--------------------|-------------|----------------------------------|
| <code>^ { }</code> | Superscript | 'text <sup>{superscript}</sup> ' |

| Modifier                            | Description                                                                                                                                | Example of String             |
|-------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------|
| <code>_{} </code>                   | Subscript                                                                                                                                  | 'text_{subscript}'            |
| <code>\bf</code>                    | Bold font                                                                                                                                  | '\bf text'                    |
| <code>\it</code>                    | Italic font                                                                                                                                | '\it text'                    |
| <code>\sl</code>                    | Oblique font (rarely available)                                                                                                            | '\sl text'                    |
| <code>\rm</code>                    | Normal font                                                                                                                                | '\rm text'                    |
| <code>\fontname{specifier}</code>   | Set <code>specifier</code> as the name of a font family to change the font style. You can use this in combination with other modifiers.    | '\fontname{Courier} text'     |
| <code>\fontsize{specifier}</code>   | Set <code>specifier</code> as a scalar numeric value to change the font size.                                                              | '\fontsize{15} text'          |
| <code>\color{specifier}</code>      | Set <code>specifier</code> as one of these colors: red, green, yellow, magenta, blue, black, white, gray, darkGreen, orange, or lightBlue. | '\color{magenta} text'        |
| <code>\color[rgb]{specifier}</code> | Set <code>specifier</code> as a three-element RGB triplet to change the font color.                                                        | '\color[rgb]{0,0.5,0.5} text' |

This table lists the supported special characters with the `Interpreter` property set to 'tex'.

| Character Sequence  | Symbol   | Character Sequence    | Symbol     | Character Sequence     | Symbol      |
|---------------------|----------|-----------------------|------------|------------------------|-------------|
| <code>\alpha</code> | $\alpha$ | <code>\upsilon</code> | $\upsilon$ | <code>\sim</code>      | $\sim$      |
| <code>\angle</code> | $\angle$ | <code>\phi</code>     | $\Phi$     | <code>\leq</code>      | $\leq$      |
| <code>\ast</code>   | $*$      | <code>\chi</code>     | $\chi$     | <code>\infty</code>    | $\infty$    |
| <code>\beta</code>  | $\beta$  | <code>\psi</code>     | $\psi$     | <code>\clubsuit</code> | $\clubsuit$ |

| Character Sequence     | Symbol      | Character Sequence     | Symbol      | Character Sequence                | Symbol            |
|------------------------|-------------|------------------------|-------------|-----------------------------------|-------------------|
| <code>\gamma</code>    | $\gamma$    | <code>\omega</code>    | $\omega$    | <code>\diamondsuit</code>         | $\blacklozenge$   |
| <code>\delta</code>    | $\delta$    | <code>\Gamma</code>    | $\Gamma$    | <code>\heartsuit</code>           | $\heartsuit$      |
| <code>\epsilon</code>  | $\epsilon$  | <code>\Delta</code>    | $\Delta$    | <code>\spadesuit</code>           | $\spadesuit$      |
| <code>\zeta</code>     | $\zeta$     | <code>\Theta</code>    | $\Theta$    | <code>\leftrightsquigarrow</code> | $\Leftrightarrow$ |
| <code>\eta</code>      | $\eta$      | <code>\Lambda</code>   | $\Lambda$   | <code>\leftarrow</code>           | $\leftarrow$      |
| <code>\theta</code>    | $\theta$    | <code>\Xi</code>       | $\Xi$       | <code>\Leftarrow</code>           | $\Leftarrow$      |
| <code>\vartheta</code> | $\vartheta$ | <code>\Pi</code>       | $\Pi$       | <code>\uparrow</code>             | $\uparrow$        |
| <code>\iota</code>     | $\iota$     | <code>\Sigma</code>    | $\Sigma$    | <code>\rightarrow</code>          | $\rightarrow$     |
| <code>\kappa</code>    | $\kappa$    | <code>\Upsilon</code>  | $\Upsilon$  | <code>\Rightarrow</code>          | $\Rightarrow$     |
| <code>\lambda</code>   | $\lambda$   | <code>\Phi</code>      | $\Phi$      | <code>\downarrow</code>           | $\downarrow$      |
| <code>\mu</code>       | $\mu$       | <code>\Psi</code>      | $\Psi$      | <code>\circ</code>                | $\circ$           |
| <code>\nu</code>       | $\nu$       | <code>\Omega</code>    | $\Omega$    | <code>\pm</code>                  | $\pm$             |
| <code>\xi</code>       | $\xi$       | <code>\forall</code>   | $\forall$   | <code>\geq</code>                 | $\geq$            |
| <code>\pi</code>       | $\pi$       | <code>\exists</code>   | $\exists$   | <code>\propto</code>              | $\propto$         |
| <code>\rho</code>      | $\rho$      | <code>\ni</code>       | $\ni$       | <code>\partial</code>             | $\partial$        |
| <code>\sigma</code>    | $\sigma$    | <code>\equiv</code>    | $\equiv$    | <code>\bullet</code>              | $\bullet$         |
| <code>\varsigma</code> | $\varsigma$ | <code>\approx</code>   | $\approx$   | <code>\div</code>                 | $\div$            |
| <code>\tau</code>      | $\tau$      | <code>\Re</code>       | $\Re$       | <code>\neq</code>                 | $\neq$            |

## LaTeX Markup

To use LaTeX markup, set the `TickLabelInterpreter` property to `'latex'`. The displayed text uses the default LaTeX font style. The `FontName`, `FontWeight`, and `FontAngle` properties do not have an effect. To change the font style, use LaTeX markup within the text string.

The maximum size of the string that you can use with the LaTeX interpreter is 1200 characters. For multiline strings, this reduces by about 10 characters per line.

For more information about the LaTeX system, see The LaTeX Project Web site at <http://www.latex-project.org/>.

### Direction — Direction of color scale

`'normal'` (default) | `'reverse'`

Direction of color scale, specified as one of these values:

- `'normal'` — Display the colormap and labels ascending from bottom to top for a vertical colorbar, and ascending from left to right for a horizontal colorbar. This is the default value.
- `'reverse'` — Display the colormap and labels descending from bottom to top for a vertical colorbar, and descending from left to right for a horizontal colorbar.

### AxisLocation — Location of tick marks, tick labels, and colorbar label

`'out'` (default) | `'in'`

Location of tick marks, tick labels, and colorbar label, specified as one of these values:

- `'out'` — Display the tick marks and labels on the side of the colorbar towards the outside of the figure. This is the default value.
- `'in'` — Display the tick marks and labels on the side of the colorbar towards the inside of the figure.

**AxisLocationMode — Selection mode for AxisLocation**`'auto' (default) | 'manual'`

Selection mode for `AxisLocation`, specified as one of these values:

- `'auto'` — Automatically choose the location.
- `'manual'` — Use a manually specified location. To specify the location, set the `AxisLocation` property.

**TickDirection — Tick mark direction**`'in' (default) | 'out'`

Tick mark direction, specified as one of these values:

- `'in'` — Display the tick marks facing inward from the colorbar box.
- `'out'` — Display the tick marks facing outward from the colorbar box.

**TickLength — Tick mark length**`0.01 (default) | scalar`

Tick mark length, specified as a scalar. Specify the tick length in units normalized to the length of the colorbar axis.

Example: `0.05`

Data Types: `single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64`

**Limits — Minimum and maximum tick mark values**`two-element vector`

The minimum and maximum tick mark values, specified as a two-element vector. The second vector element must be greater than the first element.

Example: `[0 1]`

Data Types: `single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64`

**LimitsMode — Selection mode for limits**`'auto' (default) | 'manual'`

Selection mode for limits, specified as one of these values:

- `'auto'` — Automatically chooses the limits.

- `'manual'` — Use manually specified limits. To specify the limits, set the `Limits` property.

## Font Style

### FontAngle — Character slant

`'normal'` (default) | `'italic'`

Character slant, specified as `'normal'` or `'italic'`. Not all fonts have both font styles. Therefore, the italic font might look the same as the normal font.

---

**Note:** The `'oblique'` value has been removed. Use `'italic'` instead.

---

### FontName — Font name

`'Helvetica'` (default) | `'FixedWidth'` | system supported font name

Font name, specified as the name of the font to use or the string `'FixedWidth'`. To display and print properly, the font name must be a font that your system supports.

To use a fixed-width font that looks good in any locale, use the case-sensitive string `'FixedWidth'`. The `'FixedWidth'` value relies on the root `FixedWidthFontName` property. Setting the root `FixedWidthFontName` property causes an immediate update of the display to use the new font.

Example: `'Cambria'`

### FontSize — Font size

9 (default) | scalar value greater than zero

Font size, specified as a scalar value greater than zero in point units. The default value is 9 points. If you change the axes font size, then MATLAB automatically sets the colorbar font size to 90% of the axes font size. If you manually set the colorbar font size, then changing the axes font size does not affect the colorbar.

Example: 12

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

### FontWeight — Thickness of text characters

`'normal'` (default) | `'bold'`

Thickness of the text characters, specified as one of these values:

- `'normal'` — Default weight as defined by the particular font
- `'bold'` — Thicker character outlines than normal

MATLAB uses the `FontWeight` property to select a font from those available on your system. Not all fonts have a bold font weight. Therefore, specifying a bold font weight still can result in the normal font weight.

---

**Note:** The `'light'` and `'demi'` font weight values have been removed. Use `'normal'` instead.

---

## Visibility

### Visible — State of visibility

`'on'` (default) | `'off'`

State of visibility, specified as one of these values:

- `'on'` — Display the colorbar.
- `'off'` — Hide the colorbar without deleting it. You still can access the properties of an invisible colorbar object.

## Identifiers

### Type — Type of graphics object

`'colorbar'`

This property is read only.

Type of graphics object, returned as `'colorbar'`. Use this property to find all objects of a given type within a plotting hierarchy, such as searching for the type using `findobj`.

### Tag — Tag to associate with colorbar

`'colorbar'` (default) | string

Tag to associate with the colorbar, specified as a string. Tags provide a way to identify graphics objects. Use this property to find all objects with a specific tag within a plotting hierarchy, for example, searching for the tag using `findobj`.

Example: 'January Data'

**UserData — Data to associate with colorbar**

[ ] (default) | scalar, vector, or matrix | cell array | character array | table | structure

Data to associate with the colorbar object, specified as a scalar, vector, matrix, cell array, character array, table, or structure. MATLAB does not use this data.

To associate multiple sets of data or to attach a field name to the data, use the `getappdata` and `setappdata` functions.

Example: `1:100`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char` | `struct` | `table` | `cell`

**Parent/Child****Parent — Parent of colorbar**

figure object | uipanel object | uitab object

Parent of the colorbar, specified as a figure object, uipanel object, or a uitab object.

The colorbar must have the same parent as the associated axes. If you change the parent of the associated axes, then the colorbar automatically updates to use the same parent.

**Children — Children of colorbar**

empty `GraphicsPlaceholder` array

The colorbar has no children. You cannot set this property.

**HandleVisibility — Visibility of object handle**

'on' (default) | 'off' | 'callback'

Visibility of colorbar object handle in the `Children` property of the parent, specified as one of these values:

- 'on' — The colorbar object handle is always visible.
- 'off' — The colorbar object handle is invisible at all times. This option is useful for preventing unintended changes to the UI by another function. Set the `HandleVisibility` to 'off' to temporarily hide the handle during the execution of that function.

- `'callback'` — The colorbar object handle is visible from within callbacks or functions invoked by callbacks, but not from within functions invoked from the command line. This option blocks access to the colorbar at the command-line, but allows callback functions to access it.

If the colorbar object is not listed in the `Children` property of the parent, then functions that obtain object handles by searching the object hierarchy or querying handle properties cannot return it. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

Hidden object handles are still valid. Set the root `ShowHiddenHandles` property to `'on'` to list all object handles regardless of their `HandleVisibility` property setting.

## Interactive Control

### **ButtonDownFcn** — Mouse-click callback

`''` (default) | function handle | cell array | string

Mouse-click callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you click the colorbar. If you specify this property using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The colorbar object — You can access properties of the colorbar object from within the callback function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see “Callback Definition”.

---

**Note:** If the `PickableParts` property is set to `'none'` or if the `HitTest` property is set to `'off'`, then this callback does not execute.

---

Example: @myCallback

Example: {@myCallback, arg3}

## **UIContextMenu — Context menu**

uicontextmenu object

Context menu, specified as a uicontextmenu object. Use this property to display a context menu when you right-click the colorbar. Create the context menu using the uicontextmenu function.

---

**Note:** If the `PickableParts` property is set to 'none' or if the `HitTest` property is set to 'off', then the context menu does not appear.

---

## **Selected — Selection state**

'off' (default) | 'on'

Selection state, specified as one of these values:

- 'on' — Selected. If you click the colorbar when in plot edit mode, then MATLAB sets its `Selected` property to 'on'. If the `SelectionHighlight` property also is set to 'on', then MATLAB displays selection handles around the colorbar.
- 'off' — Not selected.

## **SelectionHighlight — Display of selection handles when selected**

'on' (default) | 'off'

Display of selection handles when selected, specified as one of these values:

- 'on' — Display selection handles when the `Selected` property is set to 'on'.
- 'off' — Never display selection handles, even when the `Selected` property is set to 'on'.

## **Callback Execution Control**

### **PickableParts — Ability to capture mouse clicks**

'visible' (default) | 'none'

Ability to capture mouse clicks, specified as one of these values:

- `'visible'` — Can capture mouse clicks only when visible. The `Visible` property must be set to `'on'`. The `HitTest` property determines if the colorbar responds to the click or if an ancestor does.
- `'none'` — Cannot capture mouse clicks. Clicking the colorbar passes the click to the object below it in the current view of the figure window. The `HitTest` property of the colorbar has no effect.

### **HitTest — Response to captured mouse clicks**

`'on'` (default) | `'off'`

Response to captured mouse clicks, specified as one of these values:

- `'on'` — Trigger the `ButtonDownFcn` callback of the colorbar. If you have defined the `UIContextMenu` property, then invoke the context menu.
- `'off'` — Trigger the callbacks for the nearest ancestor of the colorbar that has a `HitTest` property set to `'on'` and a `PickableParts` property value that enables the ancestor to capture mouse clicks.

---

**Note:** The `PickableParts` property determines if the colorbar object can capture mouse clicks. If it cannot, then the `HitTest` property has no effect.

---

### **Interruptible — Callback interruption**

`'off'` (default) | `'on'`

Callback interruption, specified as `'off'` or `'on'`. The `Interruptible` property determines if a running callback can be interrupted.

If the `ButtonDownFcn` callback of the colorbar is the running callback, then the `Interruptible` property determines if it can be interrupted by another callback. The `Interruptible` property has two possible values:

- `'off'` — The running callback cannot be interrupted. MATLAB finishes executing the running callback without any interruptions. This is the default behavior.
- `'on'` — The running callback can be interrupted. Interruption occurs at the next point where MATLAB processes the queue, such as when there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command.
- If the running callback contains one of these commands, then MATLAB stops the execution of the callback at this point and executes the interrupting callback.

MATLAB resumes executing the running callback when the interrupting callback completes. For more information, see “Interrupt Callback Execution”.

- If the running callback does not contain one of these commands, then MATLAB finishes executing the callback without interruption.

---

**Note:** There are two callback states to consider:

- The *running* callback is the currently executing callback.
  - The *interrupting* callback is a callback that tries to interrupt the running callback. Whenever MATLAB invokes a callback, that callback attempts to interrupt a running callback. The `Interruptible` property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the `BusyAction` property of the object owning the interrupting callback determines if it is discarded or put in the queue.
- 

Example: `'off'`

### **BusyAction — Callback queuing**

`'queue'` (default) | `'cancel'`

Callback queuing specified as `'queue'` or `'cancel'`. The `BusyAction` property determines how MATLAB handles the execution of interrupting callbacks.

---

**Note:** There are two callback states to consider:

- The *running* callback is the currently executing callback.
- The *interrupting* callback is a callback that tries to interrupt the running callback.

Whenever MATLAB invokes a callback, that callback attempts to interrupt a running callback. The `Interruptible` property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the `BusyAction` property of the object owning the interrupting callback determines if it is discarded or put in the queue.

---

If the `ButtonDownFcn` callback of the colorbar tries to interrupt a running callback that cannot be interrupted, then the `BusyAction` property determines if it is discarded or put in the queue. Specify the `BusyAction` property as one of these values:

- 'queue' — Put the interrupting callback in a queue to be processed after the running callback finishes execution. This is the default behavior.
- 'cancel' — Discard the interrupting callback.

## Creation and Deletion Control

### CreateFcn — Creation callback

' ' (default) | function handle | cell array | string

Creation callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you create the colorbar. Setting the `CreateFcn` property on an existing colorbar has no effect. You must define a default value for this property, or define this property using a `Name, Value` pair during colorbar creation. MATLAB executes the callback after creating the colorbar and setting all of its properties.

If you specify this callback using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The colorbar object — You can access properties of the colorbar object from within the callback function. You also can access the colorbar object through the `CallbackObject` property of the root, which can be queried using the `gcbo` function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see “Callback Definition”.

Example: `@myCallback`

Example: `{@myCallback, arg3}`

### DeleteFcn — Deletion callback

' ' (default) | function handle | cell array | string

Deletion callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you delete the colorbar. MATLAB executes the callback before destroying the colorbar so that the callback can access its property values.

If you specify this callback using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The colorbar object — You can access properties of the colorbar object from within the callback function. You also can access the colorbar object through the `CallbackObject` property of the root, which can be queried using the `gcb0` function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see “Callback Definition”.

Example: `@myCallback`

Example: `{@myCallback, arg3}`

## **BeingDeleted** — Deletion status of colorbar

'off' (default) | 'on'

This property is read only.

Deletion status of colorbar, returned as 'on' or 'off'. MATLAB sets the `BeingDeleted` property to 'on' when the delete function of the colorbar begins execution (see the `DeleteFcn` property). The `BeingDeleted` property remains set to 'on' until the colorbar no longer exists.

Check the value of the `BeingDeleted` property to verify that the colorbar is not about to be deleted before querying or modifying it.

## colordef

Set default property values to display different color schemes

### Syntax

```
colordef white
colordef black
colordef none
colordef(fig,color_option)
h = colordef('new',color_option)
```

### Description

`colordef` enables you to select either a white or black background for graphics display. It sets axis lines and labels so that they contrast with the background color.

`colordef white` sets the axis background, axis lines and labels, and the figure background to the default system colors.

`colordef black` sets the axis background color to black, the axis lines and labels to white, and the figure background color to dark gray.

`colordef none` sets the figure coloring to that used by MATLAB Version 4. The most noticeable difference is that the axis background is set to 'none', making the axis background and figure background colors the same. The figure background color is set to black.

`colordef(fig,color_option)` sets the color scheme of the figure identified by the handle `fig` to one of the color options 'white', 'black', or 'none'. When you use this syntax to apply `colordef` to an existing figure, the figure must have no graphic content. If it does, you should first clear it (via `clf`) before using this form of the command.

`h = colordef('new',color_option)` returns the handle to a new figure created with the specified color options (i.e., 'white', 'black', or 'none'). This form of the command is useful for creating GUIs when you may want to control the default environment. The figure is created with 'visible', 'off' to prevent flashing.

## More About

### Tips

`colordef` affects only subsequently drawn figures, not those currently on the display. This is because `colordef` works by setting default property values (on the root or figure level). You can list the currently set default values on the root level with the statement

```
get(groot, 'Default')
```

You can remove all default values using the `reset` command:

```
reset(groot)
```

See the `get` and `reset` references pages for more information.

# colormap

View and set current colormap

## Syntax

```
colormap name
colormap default
```

```
colormap(map)
colormap(fig,map)
colormap(ax,map)
```

```
colormap(fig,'default')
colormap(ax,'default')
```

```
cmap = colormap
cmap = colormap(fig)
cmap = colormap(ax)
```

## Description

`colormap name` sets the colormap for the current figure to the built-in colormap specified by `name`. The new colormap uses the same number of colors as the current colormap. The figure colormap affects all axes in the figure, unless you set an axes colormap separately. For more information, see “What Is a Colormap?” on page 1-1380.

`colormap default` uses the default colormap, which is the `parula` colormap with 64 colors. Versions of MATLAB prior to R2014b use `jet` as the default.

`colormap(map)` sets the colormap for the current figure to the colormap specified by `map`. The figure colormap affects all axes in the figure, unless you set an axes colormap separately. Use this syntax if you want to use a built-in colormap with a specific number of colors or if you want to use a custom colormap.

- For a built-in colormap with a specific number of colors, specify `map` as one of the built-in colormap functions and pass it an integer value as an input argument. For

example, `colormap(summer(10))` uses 10 colors from the `summer` colormap. If you do not specify the number of colors, such as `colormap(summer)`, then the colormap contains the same number of colors as the current colormap.

- For a custom colormap, specify `map` as a three-column matrix of values in the range `[0, 1]` where each row is an RGB triplet that defines one color of the colormap. An RGB triplet is a three-element row vector specifying the red, green, and blue intensities for a color.

`colormap(fig, map)` sets the colormap for the figure specified by `fig`.

`colormap(ax, map)` sets the colormap for the axes specified by `ax`. Each axes within a figure can have a unique colormap. After you set an axes colormap, changing the figure colormap does not affect the axes.

`colormap(fig, 'default')` sets the colormap for the figure specified by `fig` to the default colormap.

`colormap(ax, 'default')` sets the colormap for the axes specified by `ax` to the default colormap.

`cmap = colormap` returns the three-column matrix of RGB triplets defining the colormap for the current figure.

`cmap = colormap(fig)` returns the colormap for the figure specified by `fig`.

`cmap = colormap(ax)` returns the colormap for the axes specified by `ax`.

## Examples

### Change Colormap for Figure

Create a surface plot and set the colormap to `winter`.

```
figure
surf(peaks)
colormap winter
```

### Set Colormap Back to Default

First, change the colormap for the current figure to `summer`.

```
figure
surf(peaks)
colormap summer
```

Now set the colormap back to your system's default value. If you have not specified a different default value, then the default colormap is `parula`.

```
colormap default
```

### Use Different Colormaps for Each Axes in Figure

Create a figure with two subplots and store the axes handles, `ax1` and `ax2`. Use a different colormap for each axes by passing the axes handles to the `colormap` function. In the upper subplot, create a surface plot using the `spring` colormap. In the lower subplot, create a surface plot using the `winter` colormap.

```
figure
ax1 = subplot(2,1,1);
surf(peaks)
colormap(ax1, spring)

ax2 = subplot(2,1,2);
surf(peaks)
```

```
colormap(ax2,winter)
```

### Specify Number of Colors for Colormap

Specify the number of colors used in a colormap by passing an integer as an input argument to the built-in colormap. Use five colors from the parula colormap.

```
figure
mesh(peaks)
colormap(parula(5))
```

### Create Custom Colormap

Create a custom colormap by defining a three-column matrix of values between 0.0 and 1.0. Each row defines a three-element RGB triplet. The first column specifies the red intensities. The second column specifies the green intensities. The third column specifies the blue intensities.

Use a colormap of blue values by setting the first two columns to zeros.

```
map = [0, 0, 0.3
 0, 0, 0.4
 0, 0, 0.5
 0, 0, 0.6
 0, 0, 0.8
```

```
0, 0, 1.0];

figure
surf(peaks)
colormap(map)
```

### Return Colormap Values Used in Plot

Create a surface plot of the peaks function and specify a colormap.

```
figure
mesh(peaks)
colormap(autumn(5))
```

Return the three-column matrix of values that define the colors used in the plot. Each row is an RGB triplet color value that specifies one color of the colormap.

```
cmap = colormap
```

```
cmap =
```

```
1.0000 0 0
1.0000 0.2500 0
1.0000 0.5000 0
1.0000 0.7500 0
1.0000 1.0000 0
```

### Return Colormap Values for Specific Axes

Return the colormap values for a specific axes by passing its axes handle to the `colormap` function.

Create a figure with two subplots and return the axes handles, `ax1` and `ax2`. Add a filled contour plot to each axes and use a different colormap for each axes.

```
figure
ax1 = subplot(2,1,1);
contourf(peaks)
colormap(ax1,hot(8))

ax2 = subplot(2,1,2);
contourf(peaks)
colormap(ax2,pink)
```

Return the colormap values used in the upper subplot by passing its axes handle, `ax1`, to the `colormap` function. Each row is an RGB triplet color value that specifies one color of the colormap.

```
cmap = colormap(ax1)
```

```
cmap =
```

```

### Change Colormap for Figure with Image

Load the `spine` data set that returns the image `X` and its associated colormap `map`. Display `X` using the `image` function and set the colormap to `map`.

```
load spine
figure
image(X)
colormap(map)
```

- “Change Mapping of Data Values into Colormap”

## Input Arguments

**name** — Built-in colormap

parula (default) | built-in colormap

Built-in colormap, specified as a one of the colormaps listed in the table. The default colormap is `parula`. Versions of MATLAB prior to R2014b use `jet` as the default.

The `colormap` function applies the new colormap with the same number of colors as the current colormap. To change the number of colors, use the `map` input argument.

This table lists the built-in colormaps.

| Colormap Name | Color Scale |
|---------------|-------------|
| parula        |             |
| jet           |             |
| hsv           |             |
| hot           |             |
| cool          |             |
| spring        |             |
| summer        |             |
| autumn        |             |
| winter        |             |
| gray          |             |
| bone          |             |
| copper        |             |
| pink          |             |
| lines         |             |
| colorcube     |             |
| prism         |             |
| flag          |             |
| white         |             |

### map — Built-in or custom colormap

parula (default) | built-in colormap function | three-column matrix of RGB triplets

Built-in or custom colormap, specified as one of the built-in colormap functions or a three-column matrix of RGB triplets. The default colormap is `parula`. Versions of MATLAB prior to R2014b use `jet` as the default.

## Built-In Colormap Functions

To use a built-in colormap with a specific number of colors, specify `map` as one of the built-in colormaps functions and pass it an integer value as an input argument. For example, `colormap(parula(12))` uses a map with 12 colors from the `parula` colormap. If you do not specify the number of colors, such as `colormap(parula)`, then MATLAB uses the same number of colors as the current colormap.

---

**Note:** Both the `name` and the `map` input arguments provide the same built-in colormap options. However, if you use the input argument `name`, then the `colormap` function processes `name` as a string and you cannot control the number of colors. If you use the input argument `map`, then the `colormap` function processes `map` as a function, which means that you can pass the built-in colormap an integer value to control the number of colors.

---

This table lists the built-in colormaps functions.

| Colormap Name | Color Scale                                                                          |
|---------------|--------------------------------------------------------------------------------------|
| parula        |    |
| jet           |   |
| hsv           |  |
| hot           |  |
| cool          |  |
| spring        |  |
| summer        |  |
| autumn        |  |
| winter        |  |
| gray          |  |
| bone          |  |
| copper        |  |

| Colormap Name | Color Scale                                                                        |
|---------------|------------------------------------------------------------------------------------|
| pink          |  |
| lines         |  |
| colorcube     |  |
| prism         |  |
| flag          |  |
| white         |  |

## Custom Colormap

To create a custom colormap, specify `map` as a three-column matrix of RGB triplets where each row defines one color. An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range  $[0, 1]$ . For example, this matrix defines a colormap containing five colors.

```
map = [0.2, 0.1, 0.5
 0.1, 0.5, 0.8
 0.2, 0.7, 0.6
 0.8, 0.7, 0.3
 0.9, 1, 0];
```

This table lists the RGB triplet values for common colors.

| Color   | RGB Triplet |
|---------|-------------|
| yellow  | [1, 1, 0]   |
| magenta | [1, 0, 1]   |
| cyan    | [0, 1, 1]   |
| red     | [1, 0, 0]   |
| green   | [0, 1, 0]   |
| blue    | [0, 0, 1]   |
| white   | [1, 1, 1]   |
| black   | [0, 0, 0]   |

**fig** — Figure object

figure object

Figure object. The figure colormap affects plots for all axes within the figure, unless you specify an axes colormap separately.

Each figure has a `Colormap` property. When you change the figure colormap using the `colormap` function, MATLAB updates the `Colormap` property of the figure.

**ax** — Axes object

axes object

Axes object. You can define a unique colormap for each axes. After you set an axes colormap, changing the figure colormap does not affect the axes.

## Output Arguments

**cmap** — Colormap values

three-column matrix of RGB triplets

Colormap values, returned as a three-column matrix of RGB triplets. Each row of the matrix defines one RGB triplet that specifies one color of the colormap. The values are in the range `[0, 1]`.

## More About

**What Is a Colormap?**

A colormap is matrix of values between 0 and 1 that define the colors for graphics objects such as surface, image, and patch objects. MATLAB draws the objects by mapping data values to colors in the colormap.

Colormaps can be any length, but must be three columns wide. Each row in the matrix defines one color using an RGB triplet. An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0, 1]`. A value of 0 indicates no color and a value of 1 indicates full intensity. For example, this is a colormap with five colors: black, red, green, blue, and white.

```
mymap = [0 0 0
 1 0 0
```

```
0 1 0
0 0 1
1 1 1];
```

Colormaps are associated with axes and figures. Use the `colormap` function to change the colormap for a particular axes or figure. For example, create a surface plot and use `mymap` as the colormap for the figure.

```
surf(peaks)
colormap(mymap)
```

### Tips

- To control the mapping of data values into the colormap, use the `caxis` function.

rgbplot

**Introduced before R2006a**

# colormapeditor

Open colormap editor

## Syntax

colormapeditor

## Description

colormapeditor displays the colormap for the current axes as a strip of rectangular cells in the colormap editor. Node pointers are colored cells below the colormap strip that indicate points in the colormap where the rate of the variation of R, G, and B values changes. You can also work in the HSV colorspace by setting the **Interpolating Colorspace** selector to HSV.

You can also start the colormap editor by selecting **Colormap** from the **Edit** menu.

## Node Pointer Operations

You can select and move node pointers to change a range of colors in the colormap. The color of a node pointer remains constant as you move it, but the colormap changes by linearly interpolating the RGB values between nodes.

Change the color at a node by double-clicking the node pointer. A color picker box appears, from which you can select a new color. After you select a new color at a node, the colors between nodes are reinterpolated.

You can select a different color map using the **Standard Colormaps** submenu of the **Tools** menu. The Plotting Tools Property Editor has a dropdown menu that also lets you select from standard colormaps, but does not help you to modify a colormap.

| Operation                  | How to Perform                       |
|----------------------------|--------------------------------------|
| Select a built-in colormap | <b>Tools &gt; Standard Colormaps</b> |

| Operation                       | How to Perform                                                                                                                                                              |
|---------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Add a node                      | Click below the corresponding cell in the colormap strip.                                                                                                                   |
| Select a node                   | Left-click the node.                                                                                                                                                        |
| Select multiple nodes           | Adjacent: left-click first node, <b>Shift+click</b> the last node.<br><br>Nonadjacent: left-click first node, <b>Ctrl+click</b> subsequent nodes.                           |
| Move a node                     | Select and drag with the mouse or select and use the left and right arrow keys.                                                                                             |
| Move multiple nodes             | Select multiple nodes and use the left and right arrow keys to move nodes as a group. Movement stops when one of the selected nodes hits an unselected node or an end node. |
| Delete a node                   | Select the node and then press the <b>Delete</b> key, or select <b>Delete</b> from the <b>Edit</b> menu, or type <b>Ctrl+x</b> .                                            |
| Delete multiple nodes           | Select the nodes and then press the <b>Delete</b> key, or select <b>Delete</b> from the <b>Edit</b> menu, or type <b>Ctrl+x</b> .                                           |
| Display color picker for a node | Double-click the node pointer.                                                                                                                                              |

## Current Color Info

When you put the mouse over a color cell or node pointer, the colormap editor displays the following information about that colormap element:

- The element's index in the colormap
- The value from the graphics object color data that is mapped to the node's color (i.e., data from the **CData** property of any image, patch, or surface objects in the figure)
- The color's RGB and HSV color value

## Interpolating Colorspace

The colorspace determines what values are used to calculate the colors of cells between nodes. For example, in the RGB colorspace, internode colors are calculated by linearly interpolating the red, green, and blue intensity values from one node to the next. Switching to the HSV colorspace causes the colormap editor to recalculate the colors between nodes using the hue, saturation, and value components of the color definition.

Note that when you switch from one colorspace to another, the color editor preserves the number, color, and location of the node pointers, which can cause the colormap to change.

**Interpolating in HSV.** Since hue is conceptually mapped about a color circle, the interpolation between hue values can be ambiguous. To minimize this ambiguity, the interpolation uses the shortest distance around the circle. For example, interpolating between two nodes, one with hue of 2 (slightly orange red) and another with a hue of 356 (slightly magenta red), does not result in hues 3,4,5...353,354,355 (orange/red-yellow-green-cyan-blue-magenta/red). Taking the shortest distance around the circle gives 357,358,1,2 (orange/red-red-magenta/red).

## Color Data Min and Max

The **Color Data Min** and **Color Data Max** text fields enable you to specify values for the axes CLim property. These values change the mapping of object color data (the CData property of images, patches, and surfaces) to the colormap.

## Examples

This example modifies a default MATLAB colormap so that ranges of data values are displayed in specific ranges of color. The graph is a slice plane illustrating a cross section of fluid flow through a jet nozzle. See the `slice` reference page for more information on this type of graph.

### Enhance Colormap

This example modifies a default MATLAB colormap so that ranges of data values are displayed more prominently.

Create a slice plane for the flow dataset:

```
[x,y,z,v] = flow;
hz = slice(x,y,z,v,[],[],0);
hz.EdgeColor = 'none';
hz.FaceColor = 'interp';
view(2)
```

Start the colormap editor:

```
colormapeditor
```

To reveal more information about the flow data, create more color variation in the region of interest. Add the color red for the largest color data value and blend it with the yellow and orange colors:

The new colormap reveals more of the flow data variation in the higher data values:

## Saving the Modified Colormap

You can save the modified colormap using the `colormap` function.

After you have applied your changes, save the current axes colormap in a variable:

```
mycmap = colormap(ax);
```

To use this colormap in another axes, set the colormap for the axes to `mycmap`:

```
colormap(ax_new,mycmap)
```

To save your modified colormap in a MAT-file, use the `save` command to save the `mycmap` workspace variable:

```
save('MyColormaps','mycmap')
```

To use your saved colormap in another MATLAB session, load the variable into the workspace and assign the colormap to the axes:

```
load('MyColormaps','mycmap')
colormap(ax,mycmap)
```

**Introduced before R2006a**

## ColorSpec (Color Specification)

Color specification

### Description

`ColorSpec` is not a function; it refers to the three ways in which you specify color for MATLAB graphics:

- RGB triplet
- Short name
- Long name

The short names and long names are MATLAB strings that specify one of eight predefined colors. The RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color; the intensities must be in the range [0 1]. The following table lists the predefined colors and their RGB triplet equivalents.

| RGB Triplet | Short Name | Long Name |
|-------------|------------|-----------|
| [1 1 0]     | y          | yellow    |
| [1 0 1]     | m          | magenta   |
| [0 1 1]     | c          | cyan      |
| [1 0 0]     | r          | red       |
| [0 1 0]     | g          | green     |
| [0 0 1]     | b          | blue      |
| [1 1 1]     | w          | white     |
| [0 0 0]     | k          | black     |

### Examples

To change the background color of a figure to green, specify the color with a short name, a long name, or an RGB triplet. These statements generate equivalent results:

```
whitebg('g')
whitebg('green')
whitebg([0 1 0]);
```

You can use `ColorSpec` anywhere you need to define a color. For example, this statement changes the figure background color to pink:

```
set(gcf, 'Color', [1,0.4,0.6])
```

## More About

### Tips

The eight predefined colors and any colors you specify as RGB triplets are not part of a figure's colormap, nor are they affected by changes to the figure's colormap. They are referred to as *fixed* colors, as opposed to *colormap* colors.

Some high-level functions (for example, `scatter`) accept a colorspec as an input argument and use it to set the `CData` of graphic objects they create. When using such functions, take care not to specify a colorspec in a property/value pair that sets `CData`; values for `CData` are always n-length vectors or n-by-3 matrices, where n is the length of `XData` and `YData`, never strings.

## colperm

Sparse column permutation based on nonzero count

### Syntax

```
j = colperm(S)
```

### Description

`j = colperm(S)` generates a permutation vector `j` such that the columns of `S(:, j)` are ordered according to increasing count of nonzero entries. This is sometimes useful as a reordering for LU factorization; in this case use `lu(S(:, j))`.

If `S` is symmetric, then `j = colperm(S)` generates a permutation `j` so that both the rows and columns of `S(j, j)` are ordered according to increasing count of nonzero entries. If `S` is positive definite, this is sometimes useful as a reordering for Cholesky factorization; in this case use `chol(S(j, j))`.

### Examples

The  $n$ -by- $n$  *arrowhead* matrix

```
A = [ones(1,n); ones(n-1,1) speye(n-1,n-1)]
```

has a full first row and column. Its LU factorization, `lu(A)`, is almost completely full. The statement

```
j = colperm(A)
```

returns `j = [2:n 1]`. So `A(j, j)` sends the full row and column to the bottom and the rear, and `lu(A(j, j))` has the same nonzero structure as `A` itself.

On the other hand, the Bucky ball example,

```
B = bucky
```

has exactly three nonzero elements in each row and column, so  $j = \text{colperm}(B)$  is the identity permutation and is no help at all for reducing fill-in with subsequent factorizations.

## More About

### Algorithms

The algorithm involves a sort on the counts of nonzeros in each column.

## Combine

Convenience function for static `.NET System.Delegate` Combine method

### Syntax

```
result = Combine(delegateA,delegateB)
```

### Description

`result = Combine(delegateA,delegateB)` combines two delegates into a new delegate.

### Input Arguments

#### **delegateA**

`.NET System.Delegate` object. The first delegate in the new delegate.

**Default:**

#### **delegateB**

`.NET System.Delegate` object. The last delegate in the new delegate.

**Default:**

### Output Arguments

#### **result**

`.NET System.Delegate` object. A new delegate that delegates to the input delegate `delegateA`, then `delegateB`

## Alternatives

Use the static `Combine` method of the `System.Delegate` class.

## More About

- “Combine and Remove .NET Delegates”
- MSDN `System.Delegate.Combine` Method reference page

## comet

2-D comet plot

### Syntax

```
comet(y)
comet(x,y)
comet(x,y,p)
comet(axes_handle,...)
```

### Description

`comet(y)` displays a comet graph of the vector `y`. A comet graph is an animated graph in which a circle (the comet *head*) traces the data points on the screen. The comet *body* is a trailing segment that follows the head. The *tail* is a solid line that traces the entire function.

`comet(x,y)` displays a comet graph of vector `y` versus vector `x`.

`comet(x,y,p)` specifies a comet body of length `p*length(y)`. `p` defaults to `0.1`.

`comet(axes_handle,...)` plots into the axes with the handle `axes_handle` instead of into the current axes (`gca`).

### Create Comet Graph

```
t = 0:.01:2*pi;
x = cos(2*t).*(cos(t).^2);
y = sin(2*t).*(sin(t).^2);
comet(x,y);
```

## More About

### Tips

- Comet graphs do not support data tips.

### See Also

comet3 | animatedline

Introduced before R2006a

## comet3

3-D comet plot

### Syntax

```
comet3(z)
comet3(x,y,z)
comet3(x,y,z,p)
comet3(axes_handle,...)
```

### Description

A comet plot is an animated graph in which a circle (the comet *head*) traces the data points on the screen. The comet *body* is a trailing segment that follows the head. The *tail* is a solid line that traces the entire function.

`comet3(z)` displays a 3-D comet graph of the vector `z`.

`comet3(x,y,z)` displays a comet graph of the curve through the points `[x(i),y(i),z(i)]`.

`comet3(x,y,z,p)` specifies a comet body of length `p*length(y)`. `p` must be between 0 and 1.

`comet3(axes_handle,...)` plots into the axes with the handle `axes_handle` instead of into the current axes (`gca`).

### Create 3-D Comet Graph

```
t = -10*pi:pi/250:10*pi;
x = (cos(2*t).^2).*sin(t);
y = (sin(2*t).^2).*cos(t);
comet3(x,y,t);
```

## See Also

comet | animatedline

Introduced before R2006a

## **commandhistory**

Open Command History window, or select it if already open

### **Syntax**

`commandhistory`

### **Description**

`commandhistory` opens the MATLAB Command History window when it is closed, and selects the Command History window when it is open. The Command History window presents a log of the statements most recently run in the Command Window.

### **More About**

- “Command History”

### **See Also**

`diary` | `prefdir` | `startup` | `filebrowser` | `workspace` | `commandwindow`

**Introduced before R2006a**

# commandwindow

Open Command Window, or select it if already open

## Syntax

```
commandwindow
```

## Description

`commandwindow` opens the MATLAB Command Window when it is closed, and selects the Command Window when it is open.

## More About

### Tips

To determine the number of columns and rows that display in the Command Window, given its current size, use

```
matlab.desktop.commandwindow.size
```

The number of columns is based on the width of the Command Window. With the matrix display width preference set to 80 columns, the number of columns is always 80.

- “Optimize Desktop Layout for Limited Screen Space”
- “Set Command Window Preferences”

### See Also

`commandhistory` | `input` | `inputdlg` | `filebrowser` | `workspace`

Introduced before R2006a

## companion

Companion matrix

### Syntax

```
A = companion(u)
```

### Description

`A = companion(u)` returns the corresponding companion matrix whose first row is  $-u(2:n)/u(1)$ , where  $u$  is a vector of polynomial coefficients. The eigenvalues of `companion(u)` are the roots of the polynomial.

### Examples

The polynomial  $(x - 1)(x - 2)(x + 3) = x^3 - 7x + 6$  has a companion matrix given by

```
u = [1 0 -7 6]
```

```
A = companion(u)
```

```
A =
```

```
 0 7 -6
 1 0 0
 0 1 0
```

The eigenvalues are the polynomial roots:

```
eig(companion(u))
```

```
ans =
```

```
 -3.0000
 2.0000
 1.0000
```

This is also `roots(u)`.

**Introduced before R2006a**

## compass

Plot arrows emanating from origin

### Syntax

```
compass(U,V)
compass(Z)
compass(...,LineStyle)
compass(axes_handle,...)
h = compass(...)
```

### Description

A compass graph displays the vectors with components  $(U,V)$  as arrows emanating from the origin.  $U$ ,  $V$ , and  $Z$  are in Cartesian coordinates and plotted on a circular grid.

`compass(U,V)` displays a compass graph having  $n$  arrows, where  $n$  is the number of elements in  $U$  or  $V$ . The location of the base of each arrow is the origin. The location of the tip of each arrow is a point relative to the base and determined by  $[U(i),V(i)]$ .

`compass(Z)` displays a compass graph having  $n$  arrows, where  $n$  is the number of elements in  $Z$ . The location of the base of each arrow is the origin. The location of the tip of each arrow is relative to the base as determined by the real and imaginary components of  $Z$ . This syntax is equivalent to `compass(real(Z),imag(Z))`.

`compass(...,LineStyle)` draws a compass graph using the line type, marker symbol, and color specified by `LineStyle`.

`compass(axes_handle,...)` plots into the axes with the handle `axes_handle` instead of into the current axes (`gca`).

`h = compass(...)` returns handles to line objects.

## Examples

### Create Compass Graph

Create a compass graph of the eigenvalues of a random matrix.

```
rng(0,'twister') % initialize random number generator
M = randn(20,20);
Z = eig(M);

figure
compass(Z)
```

### See Also

feather | quiver | rose | polar | LineSpec

Introduced before R2006a

# complex

Create complex array

## Syntax

```
z = complex(a,b)
z = complex(x)
```

## Description

`z = complex(a,b)` creates a complex output, `z`, from two real inputs, such that  $z = a + bi$ .

The `complex` function provides a useful substitute for expressions, such as  $a + 1i*b$  or  $a + 1j*b$ , when

- `a` and `b` are not `double` or `single`
- `b` is all zeros

`z = complex(x)` returns the complex equivalent of `x`, such that `isreal(z)` returns logical `0` (`false`).

- If `x` is real, then `z` is  $x + 0i$ .
- If `x` is complex, then `z` is identical to `x`.

## Examples

### Complex Scalar from Two Real Scalars

Use the `complex` function to create the complex scalar,  $3 + 4i$ .

```
z = complex(3,4)
```

```
z =
```

```
3.0000 + 4.0000i
```

## Complex Vector from Two Complex Vectors

Create a complex `uint8` vector from two real `uint8` vectors.

```
a = uint8([1;2;3;4]);
b = uint8([2;2;7;7]);
```

```
z = complex(a,b)
```

```
z =
```

```
1 + 2i
2 + 2i
3 + 7i
4 + 7i
```

The size of `z`, 4-by-1, is the same as the size of the input arguments.

## Complex Scalar from One Real Scalar

Create a complex scalar with zero imaginary part.

```
z = complex(12)
```

```
z =
```

```
12.0000 + 0.0000i
```

Verify that `z` is complex.

```
isreal(z)
```

```
ans =
```

```
0
```

## Input Arguments

### **a** — Real component

scalar | vector | matrix | multidimensional array

Real component, specified as a scalar, vector, matrix, or multidimensional array.

The size of **a** must match the size of **b**, unless one is a scalar. If either **a** or **b** is a scalar, MATLAB expands the scalar to match the size of the other input.

**a** and **b** must be the same data type with the following exceptions:

- **single** can combine with **double**.
- scalar **double** can combine with an integer data type.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **b** — Imaginary component

scalar | vector | matrix | multidimensional array

Imaginary component, specified as a scalar, vector, matrix, or multidimensional array.

The size of **b** must match the size of **a**, unless one is a scalar. If either **a** or **b** is a scalar, MATLAB expands the scalar to match the size of the other input.

**a** and **b** must be the same data type with the following exceptions:

- **single** can combine with **double**.
- scalar **double** can combine with an integer data type.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **x** — Input array

scalar | vector | matrix | multidimensional array

Input array, specified as a scalar, vector, matrix, or multidimensional array.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Complex Number Support: Yes

## Output Arguments

### **z** — Complex array

scalar | vector | matrix | multidimensional array

Complex array, returned as a scalar, vector, matrix, or multidimensional array.

The size of `z` is the same as the input arguments.

The following describes the data type of `z`, when `a` and `b` have different data types.

- If either `a` or `b` is `single`, then `z` is `single`.
- If either `a` or `b` is an integer data type, then `z` is the same integer data type.

## More About

### Tips

- If `b` contains only zeros, then `z` is complex and the value of all its imaginary components is `0`. In contrast, the addition `a + 0i` returns a strictly real result.

# computeStrip

**Class:** Tiff

Index number of strip containing specified coordinate

## Syntax

```
stripNumber = computeStrip(tiffobj,row)
stripNumber = computeStrip(tiffobj,row,plane)
```

## Description

`stripNumber = computeStrip(tiffobj,row)` returns the index number of the strip containing the given row. The value of `row` must be one-based.

`stripNumber = computeStrip(tiffobj,row,plane)` returns the index number of the strip containing the given row in the specified plane, if the value of the `PlanarConfiguration` tag is `Tiff.PlanarConfiguration.Separate`. The values of `row` and `plane` must be one-based.

`computeStrip` clamps out-of-range coordinate values to the bounds of the image.

## Examples

### Determine Index Number of Strip

Determine the index number of the strip containing a row in the second image of a file.

Create a `Tiff` object associated with the example file, `example.tif`, and make the second image the current directory.

```
t = Tiff('example.tif','r');
setDirectory(t,2)
```

Get the number of rows in the image. Then, get the index of the strip containing the middle row.

```
numRows = getTag(t, 'ImageLength');
stripNumber = computeStrip(t, numRows/2)
```

```
stripNumber =
```

```
4
```

Close the `Tiff` object.

```
close(t)
```

- “Exporting Image Data and Metadata to TIFF Files”
- “Reading Image Data and Metadata from TIFF Files”

## References

This method corresponds to the `TIFFComputeStrip` function in the LibTIFF C API. To use this method, you must be familiar with the TIFF specification and technical notes. View this documentation at [LibTIFF - TIFF Library and Utilities](#).

## See Also

`Tiff.computeTile`

# computeTile

**Class:** Tiff

Index number of tile containing specified coordinates

## Syntax

```
tileNumber = computeTile(tiffobj,[row col])
tileNumber = computeTile(tiffobj,[row col],plane)
```

## Description

`tileNumber = computeTile(tiffobj,[row col])` returns the index number of the tile containing the pixel specified by the one-based indices, `row` and `col`.

`tileNumber = computeTile(tiffobj,[row col],plane)` returns the index number of the tile containing the pixel specified by the indices in the specified plane, if the value of the `PlanarConfiguration` tag is `Tiff.PlanarConfiguration.Separate`. The row, column, and plane coordinate values are one-based.

`computeTile` clamps out-of-range coordinate values to the bounds of the image.

## Examples

### Get Index Number of Tile Containing Last Pixel

Open a Tiff object and get the dimensions of the image to calculate coordinates.

```
t = Tiff('example.tif','r');
numRows = getTag(t,'ImageLength');
numCols = getTag(t,'ImageWidth');
```

Get the ID number of the tile containing the coordinates.

```
tileNum = computeTile(t,[numRows numCols])
```

```
tileNum =
```

```
 110
```

Close the `Tiff` object.

```
close(t)
```

- “Exporting Image Data and Metadata to TIFF Files”
- “Reading Image Data and Metadata from TIFF Files”

`Tiff.computeStrip`

# computer

Information about computer on which MATLAB software is running

## Syntax

```
str = computer
archstr = computer('arch')
[str,maxsize] = computer
[str,maxsize,endianness] = computer
```

## Description

`str = computer` returns the string `str` with the computer type on which MATLAB is running.

`archstr = computer('arch')` returns the string `archstr` which is used by the `mex` command and standalone applications to locate MATLAB library files.

`[str,maxsize] = computer` returns the integer `maxsize`, the maximum number of elements allowed in an array with this version of MATLAB.

`[str,maxsize,endianness] = computer` returns either 'L' for little-endian byte ordering or 'B' for big-endian byte ordering.

| Platform          | Word Size | str     | archstr | maxsize      | endianness | ispc | isunix | ismac |
|-------------------|-----------|---------|---------|--------------|------------|------|--------|-------|
| Microsoft Windows | 32-bit    | PCWIN   | win32   | $2^{31} - 1$ | L          | 1    | 0      | 0     |
|                   | 64-bit    | PCWIN64 | win64   | $2^{48} - 1$ | L          | 1    | 0      | 0     |
| Linux             | 64-bit    | GLNXA64 | glnxa64 | $2^{48} - 1$ | L          | 0    | 1      | 0     |
| Apple Mac         | 64-bit    | MACI64  | maci64  | $2^{48} - 1$ | L          | 0    | 1      | 1     |

## More About

### Tips

Sometimes, both 32-bit and 64-bit versions of MATLAB can run on the same platform. In this case, the value returned by `computer` reflects which version is running. For example, if you run a 32-bit version of MATLAB on a Windows x64 platform, `computer` returns `PCWIN`, indicating that the 32-bit version is running. You can get this information and the value of `archstr` from the **Help** menu, as described in “Information About Your Installation”.

# cond

Condition number with respect to inversion

## Syntax

`c = cond(X)`

`c = cond(X,p)`

## Description

The *condition number* of a matrix measures the sensitivity of the solution of a system of linear equations to errors in the data. It gives an indication of the accuracy of the results from matrix inversion and the linear equation solution. Values of `cond(X)` and `cond(X,p)` near 1 indicate a well-conditioned matrix.

`c = cond(X)` returns the 2-norm condition number, the ratio of the largest singular value of X to the smallest.

`c = cond(X,p)` returns the matrix condition number in p-norm:

`norm(X,p) * norm(inv(X),p)`

| If p is... | Then cond(X,p) returns the...   |
|------------|---------------------------------|
| 1          | 1-norm condition number         |
| 2          | 2-norm condition number         |
| 'fro'      | Frobenius norm condition number |
| inf        | Infinity norm condition number  |

## More About

### Algorithms

The algorithm for `cond` (when `p = 2`) uses the singular value decomposition, `svd`. When the input matrix is sparse, `cond` ignores any specified `p` value and calls `condest`.

**See Also**

condeig | norm | condest | normest | rank | rcond | svd

**Introduced before R2006a**

# condeig

Condition number with respect to eigenvalues

## Syntax

```
c = condeig(A)
[V,D,s] = condeig(A)
```

## Description

`c = condeig(A)` returns a vector of condition numbers for the eigenvalues of **A**. These condition numbers are the reciprocals of the cosines of the angles between the left and right eigenvectors.

`[V,D,s] = condeig(A)` is equivalent to

```
[V,D] = eig(A);
s = condeig(A);
```

Large condition numbers imply that **A** is near a matrix with multiple eigenvalues.

## See Also

`balance` | `cond` | `eig`

**Introduced before R2006a**

## condest

1-norm condition number estimate

### Syntax

```
c = condest(A)
c = condest(A,t)
[c,v] = condest(A)
```

### Description

`c = condest(A)` computes a lower bound `c` for the 1-norm condition number of a square matrix `A`.

`c = condest(A,t)` changes `t`, a positive integer parameter equal to the number of columns in an underlying iteration matrix. Increasing the number of columns usually gives a better condition estimate but increases the cost. The default is `t = 2`, which almost always gives an estimate correct to within a factor 2.

`[c,v] = condest(A)` also computes a vector `v` which is an approximate null vector if `c` is large. `v` satisfies  $\text{norm}(A*v, 1) = \text{norm}(A, 1) * \text{norm}(v, 1) / c$ .

---

**Note:** `condest` invokes `rand`. If repeatable results are required then use `rng` to set the random number generator to its startup settings before using `condest`.

```
rng('default')
```

---

## More About

### Tips

This function is particularly useful for sparse matrices.

### Algorithms

`condest` is based on the 1-norm condition estimator of Hager [1] and a block-oriented generalization of Hager's estimator given by Higham and Tisseur [2]. The heart of the

algorithm involves an iterative search to estimate  $\|A^{-1}\|_1$  without computing  $A^{-1}$ . This is posed as the convex but nondifferentiable optimization problem  $\max \|A^{-1}\mathbf{x}\|_1$  subject to  $\|\mathbf{x}\|_1 = 1$

Introduced before R2006a

## coneplot

Plot velocity vectors as cones in 3-D vector field

### Syntax

```
coneplot(X,Y,Z,U,V,W,Cx,Cy,Cz)
coneplot(U,V,W,Cx,Cy,Cz)
coneplot(...,s)
coneplot(...,color)
coneplot(...,'quiver')
coneplot(...,'method')
coneplot(X,Y,Z,U,V,W,'nointerp')
coneplot(axes_handle,...)
h = coneplot(...)
```

### Description

`coneplot(X,Y,Z,U,V,W,Cx,Cy,Cz)` plots velocity vectors as cones pointing in the direction of the velocity vector and having a length proportional to the magnitude of the velocity vector. `X`, `Y`, `Z` define the coordinates for the vector field. `U`, `V`, `W` define the vector field. These arrays must be the same size, monotonic, and represent a Cartesian, axis-aligned grid (such as the data produced by `meshgrid`). `Cx`, `Cy`, `Cz` define the location of the cones in the vector field. The section “Specifying Starting Points for Stream Plots” in Visualization Techniques provides more information on defining starting points.

`coneplot(U,V,W,Cx,Cy,Cz)` (omitting the `X`, `Y`, and `Z` arguments) assumes `[X,Y,Z] = meshgrid(1:n,1:m,1:p)`, where `[m,n,p] = size(U)`.

`coneplot(...,s)` automatically scales the cones to fit the graph and then stretches them by the scale factor `s`. If you do not specify a value for `s`, `coneplot` uses a value of 1. Use `s = 0` to plot the cones without automatic scaling.

`coneplot(...,color)` interpolates the array `color` onto the vector field and then colors the cones according to the interpolated values. The size of the `color` array must be the same size as the `U`, `V`, `W` arrays. This option works only with cones (that is, not with the `quiver` option).

`coneplot(..., 'quiver')` draws arrows instead of cones (see `quiver3` for an illustration of a quiver plot).

`coneplot(..., 'method')` specifies the interpolation method to use. *method* can be `linear`, `cubic`, or `nearest`. `linear` is the default. (See `interp3` for a discussion of these interpolation methods.)

`coneplot(X,Y,Z,U,V,W, 'nointerp')` does not interpolate the positions of the cones into the volume. The cones are drawn at positions defined by `X`, `Y`, `Z` and are oriented according to `U`, `V`, `W`. Arrays `X`, `Y`, `Z`, `U`, `V`, `W` must all be the same size.

`coneplot(axes_handle, ...)` plots into the axes with the handle `axes_handle` instead of into the current axes (`gca`).

`h = coneplot(...)` returns the handle to the `patch` object used to draw the cones.

`coneplot` automatically scales the cones to fit the graph, while keeping them in proportion to the respective velocity vectors.

## Examples

### 3-D Cone Plot

Plot velocity vector cones for vector volume data representing motion of air through a rectangular region of space.

Load the data. The `wind` data set contains the arrays `u`, `v`, and `w` that specify the vector components and the arrays `x`, `y`, and `z` that specify the coordinates.

```
load wind
```

Establish the range of the data to place the slice planes and to specify where you want the cone plots.

```
xmin = min(x(:));
xmax = max(x(:));
ymin = min(y(:));
ymax = max(y(:));
zmin = min(z(:));
```

Define where to plot the cones. Select the full range in `x` and `y` and select the range 3 to 15 in `z`.

```
xrange = linspace(xmin,xmax,8);
yrange = linspace(ymin,ymax,8);
zrange = 3:4:15;
[cx,cy,cz] = meshgrid(xrange,yrange,zrange);
```

Plot the cones and set the scale factor to 5 to make the cones larger than the default size.

```
figure
hcone = coneplot(x,y,z,u,v,w,cx,cy,cz,5);
```

Set the cone colors.

```
hcone.FaceColor = 'red';
hcone.EdgeColor = 'none';
```

Calculate the magnitude of the vector field (which represents wind speed) to generate scalar data for the `slice` command.

```
hold on
wind_speed = sqrt(u.^2 + v.^2 + w.^2);
```

Create slice planes along the  $x$ -axis at  $xmin$  and  $xmax$ , along the  $y$ -axis at  $ymin$ , and along the  $z$ -axis at  $zmin$ . Specify interpolated face color so the slice coloring indicates wind speed, and do not draw edges.

```
hsurfaces = slice(x,y,z,wind_speed,[xmin,xmax],ymin,zmin);
set(hsurfaces,'FaceColor','interp','EdgeColor','none')
hold off
```

Change the axes view and set the data aspect ratio.

```
view(30,40)
daspect([2,2,1])
```

Add a light source to the right of the camera and use Gouraud lighting to give the cones and slice planes a smooth, three-dimensional appearance.

```
camlight right
lighting gouraud
set(hsurfaces,'AmbientStrength',0.6)
hcone.DiffuseStrength = 0.8;
```

- “Overview of Volume Visualization”

# conj

Complex conjugate

## Syntax

`ZC = conj(Z)`

## Description

`ZC = conj(Z)` returns the complex conjugate of the elements of `Z`.

## More About

### Algorithms

If `Z` is a complex array:

$\text{conj}(Z) = \text{real}(Z) - i \cdot \text{imag}(Z)$

### See Also

`i` | `j` | `imag` | `real`

Introduced before R2006a

## **continue**

Pass control to next iteration of `for` or `while` loop

### **Syntax**

```
continue
```

### **Description**

`continue` passes control to the next iteration of a `for` or `while` loop. It skips any remaining statements in the body of the loop for the current iteration. The program continues execution from the next iteration.

`continue` applies only to the body of the loop where it is called. In nested loops, `continue` skips remaining statements only in the body of the loop in which it occurs.

### **Examples**

#### **Selectively Display Values in Loop**

Display the multiples of 7 from 1 through 50. If a number is not divisible by 7, use `continue` to skip the `disp` statement and pass control to the next iteration of the `for` loop.

```
for n = 1:50
 if mod(n,7)
 continue
 end
 disp(['Divisible by 7: ' num2str(n)])
end
```

```
Divisible by 7: 7
Divisible by 7: 14
Divisible by 7: 21
Divisible by 7: 28
Divisible by 7: 35
Divisible by 7: 42
```

Divisible by 7: 49

### Skip to Next Loop Iteration

Count the number of lines of code in the file `magic.m`. Skip blank lines and comments using a `continue` statement. `continue` skips the remaining instructions in the `while` loop and begins the next iteration.

```
fid = fopen('magic.m','r');
count = 0;
while ~feof(fid)
 line = fgetl(fid);
 if isempty(line) || strcmp(line,'% ',1) || ~ischar(line)
 continue
 end
 count = count + 1;
end
count
fclose(fid);
```

```
count =
```

```
 31
```

## More About

### Tips

- The `continue` statement skips the rest of the instructions in a `for` or `while` loop and begins the next iteration. To exit the loop completely, use a `break` statement.
- `continue` is not defined outside a `for` or `while` loop. To exit a function, use `return`.

### See Also

`break` | `for` | `while`

Introduced before R2006a

## contour

Contour plot of matrix

### Syntax

```
contour(Z)
contour(Z,n)
contour(Z,v)
contour(X,Y,Z)
contour(X,Y,Z,n)
contour(X,Y,Z,v)
contour(...,LineStyle)
contour(...,Name,Value)
contour(ax,...)
[C,h] = contour(...)
```

### Description

A contour plot displays isolines of matrix **Z**. Label the contour lines using `clabel`.

`contour(Z)` draws a contour plot of matrix **Z**, where **Z** is interpreted as heights with respect to the *x-y* plane. **Z** must be at least a 2-by-2 matrix that contains at least two different values. The *x* values correspond to the column indices of **Z** and the *y* values correspond to the row indices of **Z**. The contour levels are chosen automatically.

`contour(Z,n)` draws a contour plot of matrix **Z** with *n* contour levels where *n* is a scalar. The contour levels are chosen automatically.

`contour(Z,v)` draws a contour plot of matrix **Z** with contour lines at the data values specified in the monotonically increasing vector **v**. To display a single contour line at a particular value, define **v** as a two-element vector with both elements equal to the desired contour level. For example, to draw contour lines at level *k*, use `contour(Z,[k k])`. Specifying the vector **v** sets the `LevelListMode` property to `manual`.

`contour(X,Y,Z)`, `contour(X,Y,Z,n)`, and `contour(X,Y,Z,v)` draw contour plots of **Z** using **X** and **Y** to determine the *x* and *y* values.

- If  $X$  and  $Y$  are vectors, then `length(X)` must equal `size(Z,2)` and `length(Y)` must equal `size(Z,1)`. The vectors must be strictly increasing or strictly decreasing and cannot contain any repeated values.
- If  $X$  and  $Y$  are matrices, then their sizes must equal the size of  $Z$ . Typically, you should set  $X$  and  $Y$  so that the columns are strictly increasing or strictly decreasing and the rows are uniform (or the rows are strictly increasing or strictly decreasing and the columns are uniform).

If  $X$  or  $Y$  is irregularly spaced, then `contour` calculates contours using a regularly spaced contour grid, and then transforms the data to  $X$  or  $Y$ .

`contour(...,LineStyle)` draws the contours using the line type and color specified by `LineStyle`. `contour` ignores marker symbols.

`contour(...,Name,Value)` specifies contour properties using one or more property name, property value pairs. `Name` is the property name and must appear inside single quotes (' '). `Value` is the corresponding value. For example, `'LineWidth',2` sets the contour line width to 2. For a list of contour property names and values, see [Contour Properties](#).

`contour(ax,...)` plots into the axes specified by `ax` instead of the current axes (`gca`).

`[C,h] = contour(...)` returns the contour matrix `C` containing the data that defines the contour lines, and the contour object `h`. The `ContourMatrix` property for the contour object also contains the contour matrix. The `clabel` function uses the contour matrix to label the contour lines.

Use contour object properties to control the contour plot appearance. For a list, see [Contour Properties](#).

## Examples

### Create Contour Plot

Use the `meshgrid` function to generate matrices  $X$  and  $Y$ . Create a third matrix,  $Z$ , and plot its contours.

```
x = linspace(-2*pi,2*pi);
y = linspace(0,4*pi);
```

```
[X,Y] = meshgrid(x,y);
Z = sin(X)+cos(Y);
```

```
figure
contour(X,Y,Z)
```

### Specify Number of Contour Lines

Store the data from the `peaks` function in matrices `X`, `Y`, and `Z`. Plot 20 contours of the data in `Z`.

```
[X,Y,Z] = peaks;
figure
```

```
contour(X,Y,Z,20)
```

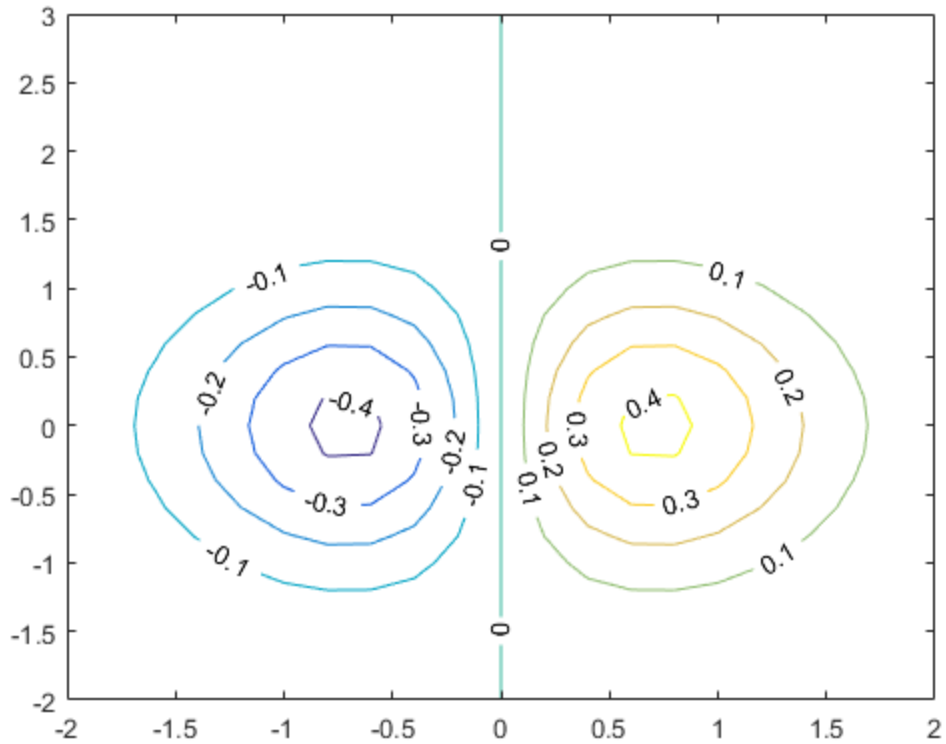

### Display Contour Labels

Set up matrices X, Y, and Z. Create a contour plot and display the contour labels by setting the ShowText property to on.

```
x = -2:0.2:2;
y = -2:0.2:3;
[X,Y] = meshgrid(x,y);
Z = X.*exp(-X.^2-Y.^2);
```

```
figure
```

```
contour(X,Y,Z, 'ShowText', 'on')
```

### Display Single Contour Line

Create a contour plot of the `peaks` function and display only one contour level at  $Z = 1$ .

```
x = -3:0.125:3;
y = -3:0.125:3;
[X,Y] = meshgrid(x,y);
Z = peaks(X,Y);
v = [1,1];
```

```
figure
```

```
contour(X,Y,Z,v)
```

## More About

### Tips

- The `contour` function cannot determine if there are discontinuities in the input data. Add NaN values to the data to prevent drawing the contour lines in those regions.
- “Label Contour Plot Levels”
- “Highlight Specific Contour Levels”

## contour3

3-D contour plot

### Syntax

```
contour3(Z)
contour3(Z,n)
contour3(Z,v)
contour3(X,Y,Z)
contour3(X,Y,Z,n)
contour3(X,Y,Z,v)
contour3(...,LineStyle)
contour3(...,Name,Value)
contour3(ax,...)
[C,h] = contour3(...)
```

### Description

`contour3` creates a 3-D contour plot of a surface defined on a rectangular grid.

`contour3(Z)` draws a contour plot of matrix `Z` in a 3-D view. `Z` is interpreted as heights with respect to the  $x$ - $y$  plane. `Z` must be at least a 2-by-2 matrix that contains at least two different values. The  $x$  values correspond to the column indices of `Z` and the  $y$  values correspond to the row indices of `Z`. The contour levels are chosen automatically.

`contour3(Z,n)` draws a contour plot of matrix `Z` with `n` contour levels in a 3-D view.

`contour3(Z,v)` draws a contour plot of matrix `Z` with contour lines at the values specified in vector `v`. The number of contour levels is equal to `length(v)`. Specifying the vector `v` sets the `LevelListMode` property to manual. To display a single contour line at a particular value, define `v` as a two-element vector with both elements equal to the desired contour level. For example, to draw a single contour of level `k`, use `contour3(Z,[k k])`.

`contour3(X,Y,Z)`, `contour3(X,Y,Z,n)`, and `contour3(X,Y,Z,v)` draw contour plots of `Z` using `X` and `Y` to determine the  $x$  and  $y$  values.

- If  $X$  and  $Y$  are vectors, then `length(X)` must equal `size(Z,2)` and `length(Y)` must equal `size(Z,1)`. The vectors must be strictly increasing or strictly decreasing and cannot contain any repeated values.
- If  $X$  and  $Y$  are matrices, then their sizes must equal the size of  $Z$ . Typically, you should set  $X$  and  $Y$  so that the columns are strictly increasing or strictly decreasing and the rows are uniform (or the rows are strictly increasing or strictly decreasing and the columns are uniform).

If  $X$  or  $Y$  is irregularly spaced, then `contour3` calculates contours using a regularly spaced contour grid, and then transforms the data to  $X$  or  $Y$ .

`contour3(...,LineStyle)` draws the contour lines using the line type and color specified by `LineStyle`. `contour3` ignores marker symbols.

`contour3(...,Name,Value)` specifies contour properties using one or more property name, property value pairs. `Name` is the property name and must appear inside single quotes (' '). `Value` is the corresponding value. For example, `'LineWidth',2` sets the contour line width to 2. For a list of contour property names and values, see [Contour Properties](#).

`contour3(ax,...)` plots into the axes specified by `ax` instead of into the current axes (`gca`).

`[C,h] = contour3(...)` returns the contour matrix `C` containing the data that defines the contour lines and the contour object `h`. The `clabel` function uses the contour matrix to label the contour lines.

## Examples

### Create 3-D Contour Plot

Set up matrices  $X$  and  $Y$  using the `meshgrid` function. Plot 30 contours of matrix  $Z$ .

```
x = -2:0.25:2;
[X,Y] = meshgrid(x);
Z = X.*exp(-X.^2-Y.^2);
contour3(X,Y,Z,30)
```

## More About

### Tips

If you do not specify `LineStyle`, the functions `colormap` and `caxis` control the color.

Label the contour lines using `clabel`.

`contour3(...)` works the same as `contour(...)` except that the contours are drawn at their corresponding  $z$  values.

## **See Also**

### **Functions**

`contour` | `contourc` | `contourf` | `meshc` | `meshgrid` | `surf`

### **Properties**

Contour Properties

**Introduced before R2006a**

## contourc

Low-level contour plot computation

### Syntax

```
C = contourc(Z)
C = contourc(Z,n)
C = contourc(Z,v)
C = contourc(x,y,Z)
C = contourc(x,y,Z,n)
C = contourc(x,y,Z,v)
```

### Description

`contourc` calculates the contour matrix **C** used by `contour`, `contour3`, and `contourf`. The values in **Z** determine the heights of the contour lines with respect to a plane. The contour calculations use a regularly spaced grid determined by the dimensions of **Z**.

**C** = `contourc(Z)` computes the contour matrix from data in matrix **Z**, where **Z** must be at least a 2-by-2 matrix. The contours are isolines in the units of **Z**. The number of contour lines and the corresponding values of the contour lines are chosen automatically.

**C** = `contourc(Z,n)` computes contours of matrix **Z** with *n* contour levels.

**C** = `contourc(Z,v)` computes contours of matrix **Z** with contour lines at the values specified in vector **v**. The length of **v** determines the number of contour levels. To compute a single contour of level *k*, use `contourc(Z,[k k])`.

**C** = `contourc(x,y,Z)`, **C** = `contourc(x,y,Z,n)`, and **C** = `contourc(x,y,Z,v)` compute contours of **Z** using vectors **x** and **y** to determine the *x* and *y* values. **x** and **y** must be monotonically increasing.

## More About

### Tips

For more information on the contour matrix, see the `ContourMatrix` property for contour objects.

Specifying irregularly spaced `x` and `y` vectors is not the same as contouring irregularly spaced data. If `x` or `y` is irregularly spaced, `contourc` calculates contours using a regularly spaced contour grid, then transforms the data to `x` or `y`.

# contourf

Filled 2-D contour plot

## Syntax

```
contourf(Z)
contourf(Z,n)
contourf(Z,v)
contourf(X,Y,Z)
contourf(X,Y,Z,n)
contourf(X,Y,Z,v)
contourf(...,LineStyle)
contourf(...,Name,Value)
contourf(ax,...)
[C,h] = contourf(...)
```

## Description

A filled contour plot displays isolines calculated from matrix  $Z$  and fills the areas between the isolines using constant colors corresponding to the current figure's colormap.

`contourf(Z)` draws a filled contour plot of matrix  $Z$ , where  $Z$  is interpreted as heights with respect to the  $x$ - $y$  plane.  $Z$  must be at least a 2-by-2 matrix that contains at least two different values. The  $x$  values correspond to the column indices of  $Z$  and the  $y$  values correspond to the row indices of  $Z$ . The contour levels are chosen automatically.

`contourf(Z,n)` draws a filled contour plot of matrix  $Z$  with  $n$  contour levels.

`contourf(Z,v)` draws a filled contour plot of matrix  $Z$  with contour lines at the data values specified in the monotonically increasing vector  $v$ . To display a single contour line at a particular value, define  $v$  as a two-element vector with both elements equal to the desired contour level. For example, to draw a single contour of level  $k$ , use `contourf(Z,[k k])`. Specifying the vector  $v$  sets the `LevelListMode` property to manual.

`contourf(X,Y,Z)`, `contourf(X,Y,Z,n)`, and `contourf(X,Y,Z,v)` draw filled contour plots of  $Z$  using  $X$  and  $Y$  to determine the  $x$  and  $y$  values.

- If `X` and `Y` are vectors, then `length(X)` must equal `size(Z,2)` and `length(Y)` must equal the number of rows in `size(Z,1)`. The vectors must be strictly increasing or strictly decreasing and cannot contain any repeated values.
- If `X` and `Y` are matrices, then their sizes must equal the size of `Z`. Typically, you should set `X` and `Y` so that the columns are strictly increasing or strictly decreasing and the rows are uniform (or the rows are strictly increasing or strictly decreasing and the columns are uniform).

If `X` or `Y` is irregularly spaced, then `contourf` calculates contours using a regularly spaced contour grid, and then transforms the data to `X` or `Y`.

`contourf(...,LineStyle)` draws the contour lines using the line type and color specified by `LineStyle`. `contourf` ignores marker symbols.

`contourf(...,Name,Value)` specifies contour properties using one or more property name, property value pairs. `Name` is the property name and must appear inside single quotes (' '). `Value` is the corresponding value. For example, `'LineWidth',2` sets the contour line width to 2. For a list of contour property names and values, see [Contour Properties](#).

`contourf(ax,...)` plots into the axes specified by `ax` instead of into the current axes (`gca`).

`[C,h] = contourf(...)` returns the contour matrix `C` containing the data that defines the contour lines and a contour object `h`. The `ContourMatrix` property for the contour object also contains the contour matrix. The `clabel` function uses the contour matrix to label the contour lines.

## Examples

### Create Filled Contour Plot

Use the `peaks` function to define `z` as a 20-by-20 matrix. Create a filled contour plot of `z` with 10 contour lines.

```
Z = peaks(20);
contourf(Z,10)
```

## More About

### Tips

NaN values in Z leave white holes with black borders in the contour plot.

- “Change Fill Colors for Contour Plot”

#### Functions

`clabel` | `contour` | `contour3` | `contourc` | `quiver`

**Properties**

Contour Properties

**Introduced before R2006a**

# Contour Properties

Control contour appearance and behavior

Contour properties control the appearance and behavior of contour objects. By changing property values, you can modify certain aspects of the contour.

Starting in R2014b, you can use dot notation to query and set properties.

```
[C,h] = contour(...);
w = h.LineWidth;
h.LineWidth = 2;
```

If you are using an earlier release, use the `get` and `set` functions instead.

## Lines

### LineColor — Color of contour lines

'flat' (default) | 'none' | RGB triplet | color string

Color of contour lines, specified as one of these values:

- 'flat' — Use a different color for each contour line, determined by its contour value, the colormap, and the scaling of data values into the colormap. For more information on color scaling, see `caxis`.
- 'none' — Do not draw the contour lines.
- RGB triplet or color string — Use the same color for all contour lines. Specify the color using an RGB triplet or a color string.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range  $[0, 1]$ , for example,  $[0.4 \ 0.6 \ 0.7]$ . This table lists RGB triplet values that have equivalent color strings.

| Long Name | Short Name | RGB Triplet |
|-----------|------------|-------------|
| 'yellow'  | 'y'        | [ 1 1 0 ]   |
| 'magenta' | 'm'        | [ 1 0 1 ]   |
| 'cyan'    | 'c'        | [ 0 1 1 ]   |

| Long Name | Short Name | RGB Triplet |
|-----------|------------|-------------|
| 'red'     | 'r'        | [ 1 0 0 ]   |
| 'green'   | 'g'        | [ 0 1 0 ]   |
| 'blue'    | 'b'        | [ 0 0 1 ]   |
| 'white'   | 'w'        | [ 1 1 1 ]   |
| 'black'   | 'k'        | [ 0 0 0 ]   |

**LineStyle — Line style**

'-' (default) | '--' | ':' | '-.' | 'none'

Line style, specified as one of the line style strings listed in this table.

| String | Line Style       | Resulting Line                                                                      |
|--------|------------------|-------------------------------------------------------------------------------------|
| '-'    | Solid line       |   |
| '--'   | Dashed line      |   |
| ':'    | Dotted line      |   |
| '-.'   | Dash-dotted line |  |
| 'none' | No line          | No line                                                                             |

**LineWidth — Width of contour lines**

0.5 (default) | positive value

Width of contour lines, specified as a positive value in points. One point equals 1/72 inch.

Example: 2

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**Contour Levels**

**LevelList — Contour levels**

empty matrix (default) | vector of z values

Contour levels, specified as a vector of z values. By default, the `contour` function chooses values that span the range of values in the `ZData` property.

Setting this property sets the associated mode property to manual.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **LevelListMode** — Selection mode for LevelList

'auto' (default) | 'manual'

Selection mode for the `LevelList`, specified as one of these values:

- 'auto' — Determine the values based on the `ZData` values.
- 'manual' — Use manually specified values. To specify the values, set the `LevelList` property. When the mode is manual, the `contour` function does not change the values as you change `ZData`.

### **LevelStep** — Spacing between contour lines

0 (default) | scalar numeric value

Spacing between contour lines, specified as a scalar numeric value. For example, specify a value of 2 to draw contour lines at increments of 2. The `contour` function determines the contour interval based on the `ZData` values.

Setting this property sets the associated mode property to manual.

Example: 3.4

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **LevelStepMode** — Selection mode for LevelStep

'auto' (default) | 'manual'

Selection mode for the `LevelStep`, specified as one of these values:

- 'auto' — Determine the value based on the `ZData` values.
- 'manual' — Use a manually specified value. To specify the value, set the `LevelStep` property. When the mode is manual, the `contour` function does not change the value as you change `ZData`.

## Contour Labels

### ShowText — Contour line labels

'off' (default) | 'on'

Contour line labels, specified as one of these values:

- 'off' — Do not label the contour lines.
- 'on' — Display text labels on each contour line indicating the contour value.

### LabelSpacing — Spacing between contour line labels

144 (default) | numeric scalar

Spacing between contour line labels, specified as a numeric scalar in point units. One point equals 1/72 inch. You must set the ShowText property to 'on' for the LabelSpacing property to have an effect.

If you use the `cLabel` function to display the labels, then the LabelSpacing property has no effect. The contour plot contains a single label per line instead.

Example: 36

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### TextList — Contour lines to label

empty matrix (default) | vector of real values

Contour lines to label, specified as a vector of real values.

Setting this property sets the associated mode property to manual.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### TextListMode — Selection mode for TextList

'auto' (default) | 'manual'

Selection mode for the TextList, specified as one of these values:

- 'auto' — Use values equal to the values of the LevelList property. The contour plot includes a text label for each line.

- `'manual'` — Use manually specified values. Specify the values by setting the `TextList` property.

### **TextStep** — Interval between labeled contour lines

0 (default) | scalar numeric value

Interval between labeled contour lines, specified as a scalar numeric value. By default, the contour plot includes a label for every contour line when the `ShowText` property is set to `'on'`.

Setting this property sets the associated mode property to manual.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **TextStepMode** — Selection mode for TextStep

`'auto'` (default) | `'manual'`

Selection mode for the `TextStep`, specified as one of these values:

- `'auto'` — Determine value based on the `ZData` values. If the `ShowText` property is set to `'on'`, then the `contour` function labels every contour line.
- `'manual'` — Use a manually specified value. To specify the value, set the `TextStep` property.

## **Filled Contours**

### **Fill** — Fill between contour lines

`'off'` (default) | `'on'`

Fill between contour lines, specified as one of these values:

- `'off'` — Do not fill the spaces between contour lines with a color. This is the default value when you create the contour chart using the `contour` or `contour3` functions.
- `'on'` — Fill the spaces between contour lines with color. This is the default value when you create the contour chart using the `contourf` function.

## **Contour Matrix**

### **ContourMatrix** — Contour line definitions

`[]` (default) | two-row matrix

This property is read only.

Contour line definitions, returned as a two-row matrix. Each contour line in the plot has an associated definition. If there are a total of N contour lines in the plot, then the contour matrix consists of N definitions:

$C = [C(1) \ C(2) \ \dots \ C(k) \ \dots \ C(N)]$

Each contour line definition follows this pattern:

$C(k) = [level \quad x(1) \ x(2) \ \dots$   
 $\quad \quad \quad numxy \quad y(1) \ y(2) \ \dots ]$

The first entry, `level`, indicates the contour level where the contour line is drawn. Beneath the contour level is the number of  $(x,y)$  vertices that define the contour line. The remaining columns contain the data for each of the vertices. If the first and last vertices are the same, then the contour line is a closed loop. If a particular contour level has multiple contour lines in the graph, then the matrix contains a separate definition for each line.

## Example

Create a contour plot of values from the `peaks` function.

```
[X,Y,Z] = peaks(3);
[C,h] = contour(X,Y,Z);
```

Access the contour matrix using either the output argument `C` or the `ContourMatrix` property of the contour object (`h.ContourMatrix`). The contour matrix contains definitions for each of the seven contour lines. The circles in this matrix show the beginnings of the contour line definitions.

C =

Columns 1 through 8

|         |         |         |         |        |         |         |         |
|---------|---------|---------|---------|--------|---------|---------|---------|
| -0.2000 | -0.5504 | 0       | 0.5506  | 0      | -2.9992 | 0       | 3.0000  |
| 3.0000  | -3.0000 | -2.8900 | -3.0000 | 3.0000 | -3.0000 | -2.4006 | -2.9995 |

Columns 9 through 16

|        |         |         |         |        |         |         |         |
|--------|---------|---------|---------|--------|---------|---------|---------|
| 0      | -3.0000 | -2.8924 | -3.0000 | 0.2000 | -0.9992 | -2.3027 | 0       |
| 3.0000 | 2.9974  | 0       | -2.9945 | 5.0000 | 3.0000  | 0       | -1.9112 |

Columns 17 through 24

|        |        |        |         |         |        |        |         |
|--------|--------|--------|---------|---------|--------|--------|---------|
| 2.4719 | 0.9993 | 0.4000 | -1.7130 | 0       | 1.8389 | 0      | -1.7130 |
| 0      | 3.0000 | 5.0000 | 0       | -1.4218 | 0      | 2.5590 | 0       |

Columns 25 through 32

|        |         |         |        |        |         |        |         |
|--------|---------|---------|--------|--------|---------|--------|---------|
| 0.6000 | -1.1234 | 0       | 1.2059 | 0      | -1.1234 | 0.8000 | -0.5337 |
| 5.0000 | 0       | -0.9324 | 0      | 1.6781 | 0       | 5.0000 | 0       |

Columns 33 through 36

|         |        |        |         |
|---------|--------|--------|---------|
| 0       | 0.5729 | 0      | -0.5337 |
| -0.4429 | 0      | 0.7972 | 0       |

The first definition in the matrix indicates that there is a contour line drawn at the -0.2 level, consisting of the three vertices (-0.5504, -3), (0, -2.89), and (0.5506, -3). Since the first and last vertices are not the same, the contour line is not a closed loop. The last definition indicates that there is a closed loop at the 0.8 level.

## Data

### XData — x values

[ ] (default) | vector or matrix

x values, specified as a vector or matrix.

- If XData is a vector, then `length(XData)` must equal `size(ZData,2)` and YData must also be a vector. The XData values must be strictly increasing or strictly decreasing and cannot contain any duplicates.

- If `XData` is a matrix, then `size(XData)` and `size(YData)` must equal `size(ZData)`. Typically, you should set the `XData` values so that the columns are strictly increasing or strictly decreasing and the rows are uniform (or the rows are strictly increasing or strictly decreasing and the columns are uniform).

Setting this property sets the associated mode property to manual.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

### **YData — y values**

`[]` (default) | vector or matrix

`y` values, specified as a vector or matrix.

- If `YData` is a vector, then `length(YData)` must equal `size(ZData,1)` and `XData` must also be a vector. The `XData` values must be strictly increasing or strictly decreasing and cannot contain any duplicates.
- If `YData` is a matrix, then `size(XData)` and `size(YData)` must equal `size(ZData)`. Typically, you should set the `YData` values so that the columns are strictly increasing or strictly decreasing and the rows are uniform (or the rows are strictly increasing or strictly decreasing and the columns are uniform).

Setting this property sets the associated mode property to manual.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

### **ZData — Data that defines surface to contour**

`[]` (default) | matrix

Data that defines the surface to contour, specified as a matrix. `ZData` must be at least a 2-by-2 matrix.

Setting this property sets the associated mode property to manual.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **XDataSource — Variable linked to XData**

`''` (default) | string containing MATLAB workspace variable name

Variable linked to `XData`, specified as a string containing a MATLAB workspace variable name. MATLAB evaluates the variable in the base workspace to generate the `XData`.

By default, there is no linked variable so the value is an empty string, `''`. If you link a variable, then MATLAB does not update the `XData` values immediately. To force an update of the data values, use the `refreshdata` function.

---

**Note:** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

Example: `'x'`

### **YDataSource — Variable linked to YData**

`''` (default) | string containing MATLAB workspace variable name

Variable linked to `YData`, specified as a string containing a MATLAB workspace variable name. MATLAB evaluates the variable in the base workspace to generate the `YData`.

By default, there is no linked variable so the value is an empty string, `''`. If you link a variable, then MATLAB does not update the `YData` values immediately. To force an update of the data values, use the `refreshdata` function.

---

**Note:** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

Example: `'y'`

### **ZDataSource — Variable linked to ZData**

`''` (default) | string containing MATLAB workspace variable name

Variable linked to `ZData`, specified as a string containing a MATLAB workspace variable name. MATLAB evaluates the variable in the base workspace to generate the `ZData`.

By default, there is no linked variable so the value is an empty string, `''`. If you link a variable, then MATLAB does not update the `ZData` values immediately. To force an update of the data values, use the `refreshdata` function.

---

**Note:** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

Example: 'z'

### **XDataMode — Selection mode for XData**

'auto' (default) | 'manual'

Selection mode for the XData, specified as one of these values:

- 'auto' — Set the XData using the column indices of ZData.
- 'manual' — Use manually specified values. To specify the values, set the XData property directly, or specify the input argument X to the `contour`, `contourf`, or `contour3` function.

### **YDataMode — Selection mode for YData**

'auto' (default) | 'manual'

Selection mode for the YData, specified as one of these values:

- 'auto' — Set the YData using the row indices of ZData.
- 'manual' — Use manually specified values. To specify the values, set the YData property directly, or specify the input argument Y to the `contour`, `contourf`, or `contour3` function.

## **Visibility**

### **Visible — State of visibility**

'on' (default) | 'off'

State of visibility, specified as one of these values:

- 'on' — Display the contour.
- 'off' — Hide the contour without deleting it. You still can access the properties of an invisible contour object.

### **Clipping — Clipping of contour object to axes limits**

'on' (default) | 'off'

Clipping of the contour object to the axes limits, specified as one of these values:

- 'on' — Do not display parts of the contour object that are outside the axes limits.
- 'off' — Display the entire contour object, even if parts of it appear outside the axes limits. Parts of the contour object might appear outside the axes limits if you create a plot, set `hold on`, freeze the axis scaling, and then create the contour object so that it is larger than the original plot.

The `Clipping` property of the axes that contains the contour object must be set to 'on', otherwise this property has no effect. For more information about the clipping behavior, see the `Clipping` property of the axes.

### **EraseMode — (removed) Technique to draw and erase objects**

'normal' (default) | 'none' | 'xor' | 'background'

---

**Note:** `EraseMode` has been removed. You can delete code that accesses the `EraseMode` property with minimal impact. If you were using `EraseMode` to create line animations, use the `animatedline` function instead.

---

Technique to draw and erase objects, specified as one of these values:

- 'normal' — Redraw the affected region of the display, performing the three-dimensional analysis necessary to correctly render all objects. This mode produces the most accurate picture, but is the slowest. The other modes are faster, but do not perform a complete redraw and, therefore, are less accurate.
- 'none' — Do not erase the object when it is moved or destroyed. After you erase the object with `EraseMode`, 'none', it is still visible on the screen. However, you cannot print the object because MATLAB does not store any information on its former location.
- 'xor' — Draw and erase the object by performing an exclusive OR (XOR) with the color of the screen beneath it. This mode does not damage the color of the objects beneath it. However, the object color depends on the color of whatever is beneath it on the display.
- 'background' — Erase the object by redrawing it in the axes background color, or the figure background color if the axes `Color` property is 'none'. This damages objects that are behind the erased object, but properly colors the erased object.

MATLAB always prints figures as if the `EraseMode` property of all objects is set to 'normal'. This means graphics objects created with `EraseMode` set to 'none', 'xor', or 'background' can look different on screen than on paper. On screen, MATLAB

mathematically combines layers of colors and ignores three-dimensional sorting to obtain greater rendering speed. However, MATLAB does not apply these techniques to the printed output. Use the `getframe` command or other screen capture applications to create an image of a figure containing nonnormal mode objects.

## Identifiers

### Type — Type of graphics object

'contour'

This property is read only.

Type of graphics object, returned as the string 'contour'.

### Tag — User-specified tag

'' (default) | any string

Tag to associate with the contour, specified as a string. Tags provide a way to identify graphics objects. Use this property to find all objects with a specific tag within a plotting hierarchy, for example, searching for the tag using `findobj`.

Example: 'January Data'

### UserData — Data to associate with contour

[] (default) | scalar, vector, or matrix | cell array | character array | table | structure

Data to associate with the contour object, specified as a scalar, vector, matrix, cell array, character array, table, or structure. MATLAB does not use this data.

To associate multiple sets of data or to attach a field name to the data, use the `getappdata` and `setappdata` functions.

Example: `1:100`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char` | `struct` | `table` | `cell`

### DisplayName — Text used by legend

'' (default) | string

Text used by the legend, specified as a string. The text appears next to an icon of the contour.

Example: `'Text Description'`

For multiline text, create the string using `sprintf` with the new line character `\n`.

Example: `sprintf('line one\nline two')`

Alternatively, you can specify the legend text using the `legend` function.

- If you specify the text as an input argument to the `legend` function, then the legend uses the specified text and sets the `DisplayName` property to the same value.
- If you do not specify the text as an input argument to the `legend` function, then the legend uses the text in the `DisplayName` property. If the `DisplayName` property does not contain any text, then the legend generates a string. The string has the form `'dataN'`, where N is the number assigned to the contour object based on its location in the list of legend entries.

If you edit interactively the string in an existing legend, then MATLAB updates the `DisplayName` property to the edited string.

## **Annotation — Legend icon display style**

Annotation object

This property is read only.

Legend icon display style, returned as an `Annotation` object. Use this object to include or exclude the contour from a legend.

- 1 Query the `Annotation` property to get the `Annotation` object.
- 2 Query the `LegendInformation` property of the `Annotation` object to get the `LegendEntry` object.
- 3 Specify the `IconDisplayStyle` property of the `LegendEntry` object to one of these values:
  - `'on'` — Include the contour object in the legend as one entry (default).
  - `'off'` — Do not include the contour object in the legend.
  - `'children'` — Include only children of the contour object as separate entries in the legend.

If a legend already exists and you change the `IconDisplayStyle` setting, then you must call `legend` to update the display.

## Parent/Child

### Parent — Parent of contour

axes object | group object | transform object

Parent of contour, specified as an axes, group, or transform object.

### Children — Children of contour

empty `GraphicsPlaceholder` array

The contour has no children. You cannot set this property.

### HandleVisibility — Visibility of object handle

'on' (default) | 'off' | 'callback'

Visibility of contour object handle in the `Children` property of the parent, specified as one of these values:

- 'on' — The contour object handle is always visible.
- 'off' — The contour object handle is invisible at all times. This option is useful for preventing unintended changes to the UI by another function. Set the `HandleVisibility` to 'off' to temporarily hide the handle during the execution of that function.
- 'callback' — The contour object handle is visible from within callbacks or functions invoked by callbacks, but not from within functions invoked from the command line. This option blocks access to the contour at the command-line, but allows callback functions to access it.

If the contour object is not listed in the `Children` property of the parent, then functions that obtain object handles by searching the object hierarchy or querying handle properties cannot return it. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

Hidden object handles are still valid. Set the root `ShowHiddenHandles` property to 'on' to list all object handles regardless of their `HandleVisibility` property setting.

## Interactive Control

### ButtonDownFcn — Mouse-click callback

' ' (default) | function handle | cell array | string

Mouse-click callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you click the contour. If you specify this property using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The contour object — You can access properties of the contour object from within the callback function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see “Callback Definition”.

---

**Note:** If the `PickableParts` property is set to 'none' or if the `HitTest` property is set to 'off', then this callback does not execute.

---

Example: `@myCallback`

Example: `{@myCallback, arg3}`

## **UIContextMenu — Context menu**

`uicontextmenu` object

Context menu, specified as a `uicontextmenu` object. Use this property to display a context menu when you right-click the contour. Create the context menu using the `uicontextmenu` function.

---

**Note:** If the `PickableParts` property is set to 'none' or if the `HitTest` property is set to 'off', then the context menu does not appear.

---

## **Selected — Selection state**

'off' (default) | 'on'

Selection state, specified as one of these values:

- 'on' — Selected. If you click the contour when in plot edit mode, then MATLAB sets its `Selected` property to 'on'. If the `SelectionHighlight` property also is set to 'on', then MATLAB displays selection handles around the contour.
- 'off' — Not selected.

### **SelectionHighlight — Display of selection handles when selected**

'on' (default) | 'off'

Display of selection handles when selected, specified as one of these values:

- 'on' — Display selection handles when the `Selected` property is set to 'on'.
- 'off' — Never display selection handles, even when the `Selected` property is set to 'on'.

## **Callback Execution Control**

### **PickableParts — Ability to capture mouse clicks**

'visible' (default) | 'none'

Ability to capture mouse clicks, specified as one of these values:

- 'visible' — Can capture mouse clicks only when visible. The `Visible` property must be set to 'on'. The `HitTest` property determines if the contour responds to the click or if an ancestor does.
- 'none' — Cannot capture mouse clicks. Clicking the contour passes the click to the object below it in the current view of the figure window. The `HitTest` property of the contour has no effect.

### **HitTest — Response to captured mouse clicks**

'on' (default) | 'off'

Response to captured mouse clicks, specified as one of these values:

- 'on' — Trigger the `ButtonDownFcn` callback of the contour. If you have defined the `UIContextMenu` property, then invoke the context menu.
- 'off' — Trigger the callbacks for the nearest ancestor of the contour that has a `HitTest` property set to 'on' and a `PickableParts` property value that enables the ancestor to capture mouse clicks.

---

**Note:** The `PickableParts` property determines if the contour object can capture mouse clicks. If it cannot, then the `HitTest` property has no effect.

---

**HitTestArea — (removed) Extents of clickable area for contour**

'off' (default) | 'on'

---

**Note:** `HitTestArea` has been removed. Use `PickableParts` instead.

---

Extents of clickable area for contour, specified as one of these values:

- 'off' — Click the contour plot to select it. This is the default value.
- 'on' — Click anywhere within the extent of the contour plot to select it, that is, anywhere within the rectangle that encloses the contour plot.

Example: 'off'

**Interruptible — Callback interruption**

'on' (default) | 'off'

Callback interruption, specified as 'on' or 'off'. The `Interruptible` property determines if a running callback can be interrupted.

---

**Note:** There are two callback states to consider:

- The *running* callback is the currently executing callback.
  - The *interrupting* callback is a callback that tries to interrupt the running callback. Whenever MATLAB invokes a callback, that callback attempts to interrupt a running callback. The `Interruptible` property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the `BusyAction` property of the object owning the interrupting callback determines if it is discarded or put in the queue.
- 

If the `ButtonDownFcn` callback of the contour is the running callback, then the `Interruptible` property determines if it another callback can interrupt it:

- 'on' — Interruptible. Interruption occurs at the next point where MATLAB processes the queue, such as when there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command.
  - If the running callback contains one of these commands, then MATLAB stops the execution of the callback at this point and executes the interrupting callback. MATLAB resumes executing the running callback when the interrupting callback completes. For more information, see “Interrupt Callback Execution”.
  - If the running callback does not contain one of these commands, then MATLAB finishes executing the callback without interruption.
- 'off' — Not interruptible. MATLAB finishes executing the running callback without any interruptions.

**BusyAction — Callback queuing**

'queue' (default) | 'cancel'

Callback queuing specified as 'queue' or 'cancel'. The `BusyAction` property determines how MATLAB handles the execution of interrupting callbacks.

---

**Note:** There are two callback states to consider:

- The *running* callback is the currently executing callback.
- The *interrupting* callback is a callback that tries to interrupt the running callback.

Whenever MATLAB invokes a callback, that callback attempts to interrupt a running callback. The `Interruptible` property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the `BusyAction` property of the object owning the interrupting callback determines if it is discarded or put in the queue.

---

If the `ButtonDownFcn` callback of the contour tries to interrupt a running callback that cannot be interrupted, then the `BusyAction` property determines if it is discarded or put in the queue. Specify the `BusyAction` property as one of these values:

- 'queue' — Put the interrupting callback in a queue to be processed after the running callback finishes execution. This is the default behavior.
- 'cancel' — Discard the interrupting callback.

## Creation and Deletion Control

### **CreateFcn** — Creation callback

' ' (default) | function handle | cell array | string

Creation callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you create the contour. Setting the **CreateFcn** property on an existing contour has no effect. You must define a default value for this property, or define this property using a **Name, Value** pair during contour creation. MATLAB executes the callback after creating the contour and setting all of its properties.

If you specify this callback using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The contour object — You can access properties of the contour object from within the callback function. You also can access the contour object through the **CallbackObject** property of the root, which can be queried using the **gcbo** function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see “Callback Definition”.

Example: @myCallback

Example: {@myCallback, arg3}

### **DeleteFcn** — Deletion callback

' ' (default) | function handle | cell array | string

Deletion callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you delete the contour. MATLAB executes the callback before destroying the contour so that the callback can access its property values.

If you specify this callback using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The contour object — You can access properties of the contour object from within the callback function. You also can access the contour object through the `CallbackObject` property of the root, which can be queried using the `gcbo` function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see “Callback Definition”.

Example: `@myCallback`

Example: `{@myCallback, arg3}`

### **BeingDeleted** — Deletion status of contour

'off' (default) | 'on'

This property is read only.

Deletion status of contour, returned as 'on' or 'off'. MATLAB sets the `BeingDeleted` property to 'on' when the delete function of the contour begins execution (see the `DeleteFcn` property). The `BeingDeleted` property remains set to 'on' until the contour no longer exists.

Check the value of the `BeingDeleted` property to verify that the contour is not about to be deleted before querying or modifying it.

## contourslice

Draw contours in volume slice planes

### Syntax

```
contourslice(X,Y,Z,V,Sx,Sy,Sz)
contourslice(X,Y,Z,V,Xi,Yi,Zi)
contourslice(V,Sx,Sy,Sz)
contourslice(V,Xi,Yi,Zi)
contourslice(...,n)
contourslice(...,cvals)
contourslice(...,[cv cv])
contourslice(...,'method')
contourslice(axes_handle,...)
h = contourslice(...)
```

### Description

`contourslice(X,Y,Z,V,Sx,Sy,Sz)` draws contours in the  $x$ -,  $y$ -, and  $z$ -axis aligned planes at the points in the vectors  $Sx$ ,  $Sy$ ,  $Sz$ . The arrays  $X$ ,  $Y$ , and  $Z$  define the coordinates for the volume  $V$  and must be monotonic and represent a Cartesian, axis-aligned grid (such as the data produced by `meshgrid`). The color at each contour is determined by the volume  $V$ , which must be an  $m$ -by- $n$ -by- $p$  volume array.

`contourslice(X,Y,Z,V,Xi,Yi,Zi)` draws contours through the volume  $V$  along the surface defined by the 2-D arrays  $Xi$ ,  $Yi$ ,  $Zi$ . The surface should lie within the bounds of the volume.

`contourslice(V,Sx,Sy,Sz)` and `contourslice(V,Xi,Yi,Zi)` (omitting the  $X$ ,  $Y$ , and  $Z$  arguments) assume `[X,Y,Z] = meshgrid(1:n,1:m,1:p)`, where `[m,n,p] = size(v)`.

`contourslice(...,n)` draws  $n$  contour lines per plane, overriding the automatic value.

`contourslice(...,cvals)` draws `length(cval)` contour lines per plane at the values specified in vector `cvals`.

`contourslice(...,[cv cv])` computes a single contour per plane at the level `cv`.

`contourslice(...,'method')` specifies the interpolation method to use. *method* can be `linear`, `cubic`, or `nearest`. `nearest` is the default except when the contours are being drawn along the surface defined by `Xi`, `Yi`, `Zi`, in which case `linear` is the default. (See `interp3` for a discussion of these interpolation methods.)

`contourslice(axes_handle,...)` plots into the axes with the handle `axes_handle` instead of into the current axes (`gca`).

`h = contourslice(...)` returns a vector of handles to `patch` objects that are used to implement the contour lines.

## Examples

### Contour Slices of Fluid Flow

Store the matrices `X`, `Y`, `Z`, and `V` from the `flow` data set.

```
[X,Y,Z,V] = flow;
```

Create nine contour plots in the `y-z` plane, no plots in the `x-z` plane, and one plot in the `x-y` plane by specifying `Sx` as a vector of nine elements, `Sy` as an empty vector, and `Sz` as a scalar.

```
Sx = 1:9;
Sy = [];
Sz = 0;
```

Draw 10 contour lines between -8 and 2 by specifying `cvals` as a 10-element vector of linearly spaced values between -8 and 2.

```
cvals = linspace(-8,2,10);
```

Create the contour slice plots and set the axis limits. Set the data aspect ratio, change the camera position, and display the black box outline.

```
figure
contourslice(X,Y,Z,V,Sx,Sy,Sz,cvals)
```

```
axis([0,10,-3,3,-3,3])
daspect([1,1,1])
campos([0,-20,7])
box on
```

## Contour Slices Along Spherical Surface

Set up matrices X, Y, and Z using the `meshgrid` function.

```
x = -2:0.2:2;
y = -2:0.25:2;
z = -2:0.16:2;
[X,Y,Z] = meshgrid(x,y,z);
```

Use X, Y, and Z to define V as a matrix of volume data.

```
V = X.*exp(-X.^2-Y.^2-Z.^2);
```

Return matrices `Xi`, `Yi`, and `Zi` from the `sphere` function.

```
[Xi,Yi,Zi] = sphere;
```

Draw contours through the volume `V` along the surface defined by `Xi`, `Yi`, and `Zi`. Change the plot view to a 3-D view.

```
contourslice(X,Y,Z,V,Xi,Yi,Zi)
view(3)
```

# matlab.unittest.constraints

Summary of classes in MATLAB Constraints Interface

## Description

Constraints specify business rules against which to qualify a calculated value. Use constraints in conjunction with the `matlab.unittest.qualifications` qualification methods `assertThat`, `assumeThat`, `fatalAssertThat`, or `verifyThat`. Constraints determine whether or not a calculated (actual) value satisfies the constraint. Constraints also provide diagnostics. The `matlab.unittest.constraints` package consists of the following classes.

- “Constraint Implementations” on page 1-1477
- “Actual Value Proxies” on page 1-1480
- “Tolerances” on page 1-1481
- “Comparators” on page 1-1481

## Constraint Implementations

### Fundamental Constraint-Related Interfaces

|                                                            |                                                         |
|------------------------------------------------------------|---------------------------------------------------------|
| <code>matlab.unittest.constraints.BooleanConstraint</code> | Interface class for boolean combinations of constraints |
| <code>matlab.unittest.constraints.Constraint</code>        | Fundamental interface class for comparisons             |

### General Purpose

|                                                     |                                                             |
|-----------------------------------------------------|-------------------------------------------------------------|
| <code>matlab.unittest.constraints.Eventually</code> | Poll for value to asynchronously satisfy constraint         |
| <code>matlab.unittest.constraints.HasField</code>   | Constraint specifying structure containing particular field |

|                                                         |                                                         |
|---------------------------------------------------------|---------------------------------------------------------|
| <code>matlab.unittest.constraints.IsAnything</code>     | Constraint specifying any value                         |
| <code>matlab.unittest.constraints.IsFalse</code>        | Constraint specifying false value                       |
| <code>matlab.unittest.constraints.IsEqualTo</code>      | General constraint to compare for equality              |
| <code>matlab.unittest.constraints.IsSameHandleAs</code> | Constraint specifying handle instance same as another   |
| <code>matlab.unittest.constraints.IsTrue</code>         | Constraint specifying true value                        |
| <code>matlab.unittest.constraints.ReturnsTrue</code>    | Constraint specifying function handle that returns true |

### **Errors and Warnings**

|                                                           |                                                                           |
|-----------------------------------------------------------|---------------------------------------------------------------------------|
| <code>matlab.unittest.constraints.IssuesNoWarnings</code> | Constraint specifying function that issues no warnings                    |
| <code>matlab.unittest.constraints.IssuesWarnings</code>   | Constraint specifying function that issues expected warning profile       |
| <code>matlab.unittest.constraints.Throws</code>           | Constraint specifying function handle that throws <code>MException</code> |

### **Inequalities**

|                                                                 |                                                                    |
|-----------------------------------------------------------------|--------------------------------------------------------------------|
| <code>matlab.unittest.constraints.IsGreaterThan</code>          | Constraint specifying value greater than another value             |
| <code>matlab.unittest.constraints.IsGreaterThanOrEqualTo</code> | Constraint specifying value greater than or equal to another value |

matlab.unittest.constraints.IsLessThan  
Constraint specifying value less than another value

matlab.unittest.constraints.IsLessThanOrEqualTo  
Constraint specifying value less than or equal to another value

### **Array Size**

matlab.unittest.constraints.HasElementCount  
Constraint specifying expected number of elements

matlab.unittest.constraints.HasLength  
Constraint specifying expected length of array

matlab.unittest.constraints.HasSize  
Constraint specifying expected size of array

matlab.unittest.constraints.IsEmpty  
Constraint specifying empty value

matlab.unittest.constraints.IsScalar  
Constraint specifying scalar value

### **Type**

matlab.unittest.constraints.IsInstanceOf  
Constraint specifying inclusion in given class hierarchy

matlab.unittest.constraints.IsOfClass  
Constraint specifying class type

### **Strings**

matlab.unittest.constraints.ContainsSubstring  
Constraint specifying string containing substring

|                                                              |                                                         |
|--------------------------------------------------------------|---------------------------------------------------------|
| <code>matlab.unittest.constraints.EndsWithSubstring</code>   | Constraint specifying string ending with substring      |
| <code>matlab.unittest.constraints.IsSubstringOf</code>       | Constraint specifying substring of another string       |
| <code>matlab.unittest.constraints.Matches</code>             | Constraint specifying string matches regular expression |
| <code>matlab.unittest.constraints.StartsWithSubstring</code> | Constraint specifying string starting with substring    |

### **Finiteness**

|                                                   |                                                           |
|---------------------------------------------------|-----------------------------------------------------------|
| <code>matlab.unittest.constraints.HasInf</code>   | Constraint specifying array containing any infinite value |
| <code>matlab.unittest.constraints.HasNaN</code>   | Constraint specifying array containing NaN value          |
| <code>matlab.unittest.constraints.IsFinite</code> | Constraint specifying finite value                        |

### **Numeric Attributes**

|                                                   |                                         |
|---------------------------------------------------|-----------------------------------------|
| <code>matlab.unittest.constraints.IsReal</code>   | Constraint specifying real valued array |
| <code>matlab.unittest.constraints.IsSparse</code> | Constraint specifying sparse array      |

### **Actual Value Proxies**

|                                                    |                                                    |
|----------------------------------------------------|----------------------------------------------------|
| <code>matlab.unittest.constraints.AnyCellOf</code> | Test if any element of cell array meets constraint |
|----------------------------------------------------|----------------------------------------------------|

matlab.unittest.constraints.StructComparator

Comparator for MATLAB structure arrays

# matlab.unittest.constraints.AbsoluteTolerance class

**Package:** matlab.unittest.constraints

**Superclasses:** matlab.unittest.constraints.Tolerance

Absolute numeric tolerance

## Description

This numeric `Tolerance` assesses the magnitude of the difference between actual and expected values. For the tolerance to be satisfied, `abs(expVal - actVal) <= absTol` must be true.

## Construction

`AbsoluteTolerance(tolVals)` creates an absolute tolerance object that assesses the magnitude of the difference between the actual and expected values.

The data types of the inputs to the `AbsoluteTolerance` constructor determines which data types the tolerance supports. For example, `AbsoluteTolerance(10*eps)` constructs an `AbsoluteTolerance` for comparing double-precision numeric arrays, while `AbsoluteTolerance(int8(2))` constructs an `AbsoluteTolerance` for comparing numeric arrays of type `int8`. If the actual and expected values being compared contain more than one numeric data type, the tolerance only applies to the data types specified by the values passed into the constructor.

To specify different tolerance values for different data types, you can pass multiple tolerance values to the constructor. For example, `AbsoluteTolerance(10*eps, 10*eps('single'), int8(1))` constructs an `AbsoluteTolerance` object applies the following absolute tolerances:

- `10*eps` applies an absolute tolerance of `10*eps` for double-precision numeric arrays.
- `10*eps('single')` applies an absolute tolerance of `10*eps` for single-precision numeric arrays.
- `int8(1)` applies an absolute tolerance of `1` for numeric arrays of type `int8`.

You can specify more than one tolerance for a particular data type by combining tolerances with the & and | operators. To combine two tolerances, the sizes of the tolerance values for each data type must be compatible.

## Input Arguments

### **tolVals**

Numeric tolerances, specified as a comma-separated list of numeric arrays. Each input argument contains the tolerance specification for a particular data type. Each numeric array can be a scalar or array the same size as the actual and expected values.

**Default:**

## Properties

### **Values**

Numeric tolerances, specified by the `tolVals` input argument

## Copy Semantics

Value. To learn how value classes affect copy operations, see [Copying Objects in the MATLAB documentation](#).

## Examples

### **Test with Absolute Tolerance**

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.IsEqualTo
import matlab.unittest.constraints.AbsoluteTolerance

testCase = TestCase.forInteractiveUse;
```

Assert that the difference between an actual value, 4.1, and an expected value, 4.5, is less than 0.5.

```
testCase.assertThat(4.1, IsEqualTo(4.5, ...
 'Within', AbsoluteTolerance(0.5)))
```

Interactive assertion passed.

### Specify Absolute Tolerance for Different Data Types

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.IsEqualTo
import matlab.unittest.constraints.AbsoluteTolerance
```

```
testCase = TestCase.forInteractiveUse;
```

Create the following actual and expected cell arrays.

```
act = {'abc', 123, single(106), int8([1, 2, 3])};
exp = {'abc', 122, single(105), int8([2, 4, 6])};
```

Test whether the arrays satisfy the `AbsoluteTolerance` constraint within a value of 2.

```
testCase.verifyThat(act, IsEqualTo(exp, ...
 'Within', AbsoluteTolerance(2)))
```

Interactive verification failed.

```

Framework Diagnostic:

```

```
IsEqualTo failed.
```

```
--> NumericComparator failed.
```

```
Path to failure: <Value>{3}
```

```
--> The values are not equal using "isequaln".
```

```
--> The tolerance does not support single values so it was not used.
```

```
--> Failure table:
```

| Actual | Expected | Error | RelativeError |
|--------|----------|-------|---------------|
| -----  | -----    | ----- | -----         |
| 106    | 105      | 1     | 0.00952381    |

```
Actual single:
```

```
 106
Expected single:
 105

Actual cell:
'abc' [123] [106] [1x3 int8]
Expected cell:
'abc' [122] [105] [1x3 int8]
```

The test fails because the tolerance is only applied to the `double` data type.

Create a tolerance object that specifies different tolerances for different data types.

```
tolObj = AbsoluteTolerance(2, single(3), int8([2, 3, 5]));
```

A tolerance of 2 is applied to `double` valued data. A tolerance of 3 is applied to `single` valued data. A tolerance of [2 3 5] is applied to corresponding array elements of `int8` valued data.

Verify that the expected and actual values satisfy the `AbsoluteTolerance` constraint.

```
testCase.verifyThat(act, IsEqualTo(exp, 'Within', tolObj))
```

```
Interactive verification passed.
```

## Combine Absolute and Relative Tolerances

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.IsEqualTo
import matlab.unittest.constraints.AbsoluteTolerance
import matlab.unittest.constraints.RelativeTolerance
```

```
testCase = TestCase.forInteractiveUse;
```

Define an actual value approximation for `pi`.

```
act = 3.14;
```

Construct a tolerance object to test that the difference between the actual and expected values is within 0.001 and within 0.25%.

```
tolObj = AbsoluteTolerance(0.001) & RelativeTolerance(0.0025);
```

Verify that the actual value is within the tolerance of the expected value of `pi`.

```
testCase.verifyThat(act, IsEqualTo(pi, 'Within', tolObj))
```

Interactive verification failed.

```

Framework Diagnostic:

```

IsEqualTo failed.

```
--> NumericComparator failed.
```

```
 --> The values are not equal using "isequaln".
```

```
 --> AndTolerance failed.
```

```
 --> AbsoluteTolerance failed.
```

```
 --> The error was not within absolute tolerance.
```

```
 --> RelativeTolerance passed.
```

```
 --> Failure table:
```

|  | Actual | Expected         | Error                | Relative     |
|--|--------|------------------|----------------------|--------------|
|  | 3.14   | 3.14159265358979 | -0.00159265358979299 | -0.000506957 |

Actual double:

```
3.1400000000000000
```

Expected double:

```
3.141592653589793
```

The actual value does not satisfy the `AbsoluteTolerance` constraint.

Construct a constraint that is satisfied if the values are within 0.001 or 0.25%, and then retest the actual value.

```
tolObj = AbsoluteTolerance(0.001) | RelativeTolerance(0.0025);
```

```
testCase.verifyThat(act, IsEqualTo(pi, 'Within', tolObj))
```

Interactive verification passed.

### Combine Absolute and Relative Tolerances to Test Small and Large Values

Combine tolerances so when you test the equality of values, an absolute (floor) tolerance dominates when the values are near zero, and a relative tolerance dominates for larger values.

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.IsEqualTo
```

```
import matlab.unittest.constraints.AbsoluteTolerance
import matlab.unittest.constraints.RelativeTolerance
```

```
testCase = TestCase.forInteractiveUse;
```

Define two structures containing electromagnetic properties of a vacuum. One structure, `approxVacuumProps`, contains approximate values for the permeability and speed of light in a vacuum.

```
approxVacuumProps.Permeability = 1.2566e-06; % Approximate
approxVacuumProps.Permittivity = 8.854187817*10^-12;
approxVacuumProps.LightSpeed = 2.9979e+08; % Approximate
```

```
baselineVacuumProps.Permeability = 4*pi*10^-7;
baselineVacuumProps.Permittivity = 8.854187817*10^-12;
baselineVacuumProps.LightSpeed = 1/sqrt(...
 baselineVacuumProps.Permeability*baselineVacuumProps.Permittivity);
```

Test that the relative difference between the approximate and baseline values is within `eps*1e11`.

```
testCase.verifyThat(approxVacuumProps, IsEqualTo(baselineVacuumProps, ...
 'Within', RelativeTolerance(eps*1e11)))
```

```
Interactive verification failed.
```

```

Framework Diagnostic:

```

```
IsEqualTo failed.
```

```
--> NumericComparator failed.
```

```
Path to failure: <Value>.Permeability
```

```
--> The values are not equal using "isequaln".
```

```
--> RelativeTolerance failed.
```

```
--> The error was not within relative tolerance.
```

```
--> Failure table:
```

| Actual     | Expected             | Error                 |      |
|------------|----------------------|-----------------------|------|
| 1.2566e-06 | 1.25663706143592e-06 | -3.70614359173257e-11 | -2.9 |

```
Actual double:
```

```
1.2566000000000000e-06
```

```
Expected double:
```

```
1.256637061435917e-06
```

```

Actual struct:
 Permeability: 1.2566000000000000e-06
 Permittivity: 8.854187816999999e-12
 LightSpeed: 299790000
Expected struct:
 Permeability: 1.256637061435917e-06
 Permittivity: 8.854187816999999e-12
 LightSpeed: 2.997924580105029e+08

```

The test fails because the relative difference in the permeabilities is not within the tolerance. The difference between the two values is small, but the numbers are close to zero, so the difference relative to their size is not small enough to satisfy the tolerance.

Construct a tolerance object to test that the absolute difference between the approximate and baseline values is within  $1e-4$ .

```

testCase.verifyThat(approxVacuumProps, IsEqualTo(baselineVacuumProps, ...
 'Within', AbsoluteTolerance(1e-4)))

```

Interactive verification failed.

```

Framework Diagnostic:

```

IsEqualTo failed.

--> NumericComparator failed.

Path to failure: <Value>.LightSpeed

--> The values are not equal using "isequaln".

--> AbsoluteTolerance failed.

--> The error was not within absolute tolerance.

--> Failure table:

| Actual    | Expected         | Error             | RelativeE    |
|-----------|------------------|-------------------|--------------|
| 299790000 | 299792458.010503 | -2458.01050287485 | -8.199040493 |

Actual double:

299790000

Expected double:

2.997924580105029e+08

```

Actual struct:
 Permeability: 1.2566000000000000e-06
 Permittivity: 8.854187816999999e-12

```

```
LightSpeed: 299790000
Expected struct:
 Permeability: 1.256637061435917e-06
 Permittivity: 8.854187816999999e-12
 LightSpeed: 2.997924580105029e+08
```

The test fails because the absolute difference in the speed of light is not within the tolerance. The difference between the two values is small relative to their size, but too large to satisfy the tolerance.

Construct a logical disjunction of tolerance objects to test that the absolute difference between the approximate and baseline values is within  $1e-4$  or the relative difference is within  $\text{eps} \times 1e11$ . The test uses this tolerance so permeability values that are close to zero satisfy the absolute (floor) tolerance, and speed of light values that are large, satisfy the relative tolerance.

```
testCase.verifyThat(approxVacuumProps, IsEqualTo(baselineVacuumProps, ...
 'Within', RelativeTolerance(eps*1e11) | AbsoluteTolerance(1e-4)))
```

Interactive verification passed.

**Introduced in R2013a**

# matlab.unittest.constraints.AnyCellOf class

**Package:** matlab.unittest.constraints

Test if any element of cell array meets constraint

## Description

The `AnyCellOf` class creates a proxy of the actual value to the framework. The proxy enables a test writer to apply a constraint against each element of a cell array, which ensures that a passing result occurs if at least one element of the cell array satisfies the constraint.

It is intended that you use this class through `matlab.unittest` qualifications as shown in the examples. The class does not modify the provided actual value, but serves as a wrapper to perform the constraint analysis. The testing framework analyzes the constraint on an element-by-element basis.

## Construction

`AnyCellOf(actVal)` creates a proxy instance that tests if any element of a provided cell array, `actVal`, meets a constraint. The test passes if at least one element individually satisfies the constraint.

## Input Arguments

**actVal**

Actual value to test against constraint

## Properties

**ActualValue**

Actual value to test against constraint. Set this property through the constructor via the `actVal` input argument.

## Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

## Examples

### Test That Any Cell Satisfies Constraint

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.AnyCellOf
```

```
testCase = TestCase.forInteractiveUse;
```

Test that at least one cell of `actVal` is finite.

```
import matlab.unittest.constraints.IsFinite
actVal = {NaN, Inf, 5};
testCase.verifyThat(AnyCellOf(actVal), IsFinite)
```

```
Interactive verification passed.
```

Test that at least one cell of the actual value contains five elements.

```
import matlab.unittest.constraints.HasElementCount
testCase.verifyThat(AnyCellOf({42, [11 38], 1:5}), HasElementCount(5))
```

```
Interactive verification passed.
```

Test that at least one cell of the actual value matches the string 'tea' regardless of case.

```
import matlab.unittest.constraints.Matches
testCase.verifyThat(AnyCellOf({'Coffee', 'Tea', 'Water'}), ...
 Matches('tea', 'IgnoringCase', true))
```

```
Interactive verification passed.
```

Test that at least one cell of the actual value is less than zero.

```
import matlab.unittest.constraints.IsLessThan
```

```
testCase.verifyThat(AnyCellOf({1, 5}), IsLessThan(0))
```

Interactive verification failed.

```

Framework Diagnostic:

```

All cells failed. The first cell failed because:

```
--> IsLessThan failed.
```

```
 --> The value must be less than the maximum value.
```

```
Actual Value:
```

```
 1
```

```
Maximum Value (Exclusive):
```

```
 0
```

```
Actual Value Cell Array:
```

```
 [1] [5]
```

Neither actual value element is less than zero.

Test that neither cell of the actual value is empty.

```
import matlab.unittest.constraints.IsEmpty
```

```
testCase.verifyThat(AnyCellOf({inputParser.empty, ''}), ~IsEmpty)
```

Interactive verification failed.

```

Framework Diagnostic:

```

All cells failed. The first cell failed because:

```
--> Negated IsEmpty failed.
```

```
 --> The value must not be empty.
```

```
 --> The value has a size of [0 0].
```

```
Actual Value:
```

```
 0x0 inputParser array with properties:
```

```
 FunctionName
 CaseSensitive
 KeepUnmatched
 PartialMatching
 StructExpand
 Parameters
```

```
Results
Unmatched
UsingDefaults
```

```
Actual Value Cell Array:
[] ''
```

Both actual value elements are empty.

# matlab.unittest.constraints.AnyElementOf class

**Package:** matlab.unittest.constraints

Test if any element of array meets constraint

## Description

The `AnyElementOf` class creates a proxy of the actual value to the framework. The proxy enables a test writer to apply a constraint against each element of an array, which ensures that a passing result occurs when at least one element of the array satisfies the constraint.

It is intended that you use this class through `matlab.unittest` qualifications as shown in the examples. The class does not modify the provided actual value, but serves as a wrapper to perform the constraint analysis. The testing framework analyzes the constraint on an element-by-element basis.

## Construction

`AnyElementOf(actVal)` creates a proxy instance that tests if any element of a provided array, `actVal`, meets a constraint. The test passes if at least one element individually satisfies the constraint.

## Tips

- `AnyElementOf` checks if any element in the provided array satisfies an associated constraint. However, there are some constraints, such as `HasNaN` and `HasInf`, that natively validate if any of the elements satisfy a condition. In these situations, use of `AnyElementOf` is unnecessary and impedes qualification performance.

## Input Arguments

**actVal**

Actual value to test against constraint

## Properties

### ActualValue

Actual value to test against constraint. Set this property through the constructor via the `actVal` input argument.

## Copy Semantics

Value. To learn how value classes affect copy operations, see [Copying Objects in the MATLAB documentation](#).

## Examples

### Test That Any Element Satisfies Constraint

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.AnyElementOf
```

```
testCase = TestCase.forInteractiveUse;
```

Test that at least one element of `actVal` is finite.

```
import matlab.unittest.constraints.IsFinite
actVal = [NaN, Inf, 5];
testCase.verifyThat(AnyElementOf(actVal), IsFinite)
```

```
Interactive verification passed.
```

Test that at least one element of the actual value is complex.

```
import matlab.unittest.constraints.IsReal
testCase.verifyThat(AnyElementOf([1+0i 4i]), ~IsReal)
```

```
Interactive verification passed.
```

Test that at least one element of the actual value array is less than zero.

```
import matlab.unittest.constraints.IsLessThan
```

```
testCase.verifyThat(AnyElementOf([1 5]), IsLessThan(0))
```

```
Interactive verification failed.
```

```

Framework Diagnostic:

```

```
All elements failed. The first element failed because:
```

```
--> IsLessThan failed.
```

```
 --> The value must be less than the maximum value.
```

```
Actual Value:
```

```
 1
```

```
Maximum Value (Exclusive):
```

```
 0
```

```
Actual Value Array:
```

```
 1 5
```

```
Neither actual value element is less than zero.
```

## matlab.unittest.constraints.BooleanConstraint class

**Package:** matlab.unittest.constraints

**Superclasses:** matlab.unittest.constraints.Constraint

Interface class for boolean combinations of constraints

### Description

The `BooleanConstraint` interface class provides an interface for boolean combinations of `Constraints`. Any constraint that derives from `BooleanConstraint` can be combined and negated using the `and (&)`, `or (|)`, and `not (~)` operators.

Classes that derive from the `BooleanConstraint` interface class must implement everything required by the standard `Constraint` interface. When a given constraint is negated, the diagnostics must be written in a different form than for a standard (non-negated) failure. Therefore, classes deriving from the `BooleanConstraint` class must implement a method to provide a `Diagnostic` object for the negated case, in addition to the non-negated case.

In exchange for meeting these requirements, all `BooleanConstraint` implementations inherit the appropriate MATLAB overloads for `and`, `or`, and `not` so that they can be combined with other `BooleanConstraint` objects or negated.

### Methods

`getNegativeDiagnosticFor`

Produce negated diagnostic for value

### Copy Semantics

Value. To learn how value classes affect copy operations, see `Copying Objects in the MATLAB documentation`.

## Examples

### Boolean Combinations of Constraints

At the command prompt, create a test case for interactive testing and import several classes that subclass `BooleanConstraint`.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.HasElementCount
import matlab.unittest.constraints.HasLength
import matlab.unittest.constraints.HasInf
import matlab.unittest.constraints.HasNaN
import matlab.unittest.constraints.IsEmpty
import matlab.unittest.constraints.IsEqualTo
import matlab.unittest.constraints.IsGreaterThanOrEqualTo
import matlab.unittest.constraints.IsOfClass
import matlab.unittest.constraints.IsReal
```

```
testCase = TestCase.forInteractiveUse;
```

Test these passing cases.

```
testCase.verifyThat(3, IsReal & IsGreaterThanOrEqualTo(3))
testCase.verifyThat([1 2 3; 4 5 6], HasLength(3) & HasElementCount(6))
testCase.verifyThat([3 NaN 5], HasNaN | HasInf)
testCase.verifyThat(3, ~IsEqualTo(4))
testCase.verifyThat('Some char', IsOfClass(?char) & ~IsEmpty)
```

- “Create Custom Boolean Constraint”

### See Also

Diagnostic | `matlab.unittest.constraints`

## getNegativeDiagnosticFor

Produce negated diagnostic for value

### Syntax

```
diag = getNegativeDiagnosticFor(constObj, actVal)
```

### Description

`diag = getNegativeDiagnosticFor(constObj, actVal)` produces a negated diagnostic for a value. The `getNegativeDiagnosticFor` method analyzes the provided value, `actVal`, against the constraint, `constObj`, and produces a `matlab.unittest.diagnostics.Diagnostic` object, `diag`, which corresponds to the negation of the constraint, `constObj`. This method is a protected method.

The diagnostics that this method produces are expressed in the negative sense of the constraint. For example, a hypothetical `IsTasty` constraint, when negated, should express that the actual value was "tasty", when it should not have been, and it should describe the details on why it was found to be tasty.

Like the `getDiagnosticFor` method of `Constraint`, the `getNegativeDiagnosticFor` is only called upon failures, and thus can afford a more detailed analysis than the `satisfiedBy` method.

### Input Arguments

#### **constObj**

BooleanConstraint instance

#### **actVal**

Value for comparison

## Examples

### Implement getNegativeDiagnosticFor method

```
function diag = getNegativeDiagnosticFor(constraint, actual)
% getNegativeDiagnosticFor - produce a diagnostic when the constraint is
% incorrectly met
%
% This method is called by the testing framework when the constraint has
% been met but should not have been met because it was negated in a
% boolean expression. It should produce a Diagnostic result that
% describes the failure in the correct terms which express the
% requirement that the constraint actually should not have been met.

import matlab.unittest.diagnostics.StringDiagnostic

if constraint.satisfiedBy(actual)
 % Create the negative diagnostic. This will show information such as the
 % constraint class name and display the raw actual and expected values.
 % Using the DiagnosticSense.NegativeDiagnostic enumeration also
 % produces language more appropriate for the negated case.
 diag = StringDiagnostic(sprintf(...
 ['Negated HasSameSizeAs failed.\nSize [%s] of ' ...
 'Actual Value and Expected Value were the same ' ...
 'but should not have been.', int2str(size(actual))));
else
 % Produce a passing diagnostic, with language appropriate for
 % the negated case.
 diag = StringDiagnostic('Negated HasSameSizeAs passed. ');
end % if

end % function
```

# matlab.unittest.constraints.CellComparator class

**Package:** matlab.unittest.constraints

Comparator for cell arrays

## Description

The `CellComparator` compares cell arrays.

## Construction

`CellComparator` creates a comparator for cell arrays.

`CellComparator(compObj)` indicates a comparator, `compObj`, that defines the comparator used to compare values contained in the cell array. By default, a cell comparator supports only empty cell arrays.

`CellComparator(compObj, Name, Value)` provides a comparator with additional options specified by one or more `Name, Value` pair arguments.

`CellComparator(Name, Value)` provides a comparator for empty cell arrays with additional options specified by one or more `Name, Value` pair arguments.

## Input Arguments

**compObj**

Comparator object

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

**'IgnoringCase'**

Indicator whether the comparator is insensitive to case, specified as `false` or `true` (logical 0 or 1). When it is `false`, the comparator is sensitive to case. The comparator uses this name-value pair only if the contents being compared are strings.

**Default:** `false`

**'IgnoringWhitespace'**

Indicator whether the comparator is insensitive to whitespace characters, specified as `false` or `true` (logical 0 or 1). When it is `false`, the comparator is sensitive to whitespace characters. Whitespace characters consist of space, form feed, new line, carriage return, horizontal tab, and vertical tab. The comparator uses this name-value pair only if the contents being compared are strings.

**Default:** `false`

**'Recursively'**

Indicator of whether comparator operates recursively, specified as `false` or `true` (logical 0 or 1). When this value is `false`, the comparator does not operate recursively on its data.

When the value is `true`, the data types the cell comparator supports are fully supported in recursion. For example:

```
comp1 = CellComparator(StringComparator)
```

```
comp2 = CellComparator(StringComparator, 'Recursively', true)
```

Both `comp1` and `comp2` support cell arrays of strings. However, only `comp2` supports cell arrays that recursively contain either cell arrays or strings as their elements.

**Default:** `false`

**'Within'**

Tolerance to use for numerical comparison, specified as a `matlab.unittest.constraints.Tolerance` object. The comparator uses this name-value pair only if the contents being compared are numeric types.

**Default:** (empty)

## Properties

### **IgnoreCase**

Indicator whether the comparator is insensitive to case, specified in the name-value pair argument, 'IgnoringCase'

### **IgnoreWhitespace**

Indicator whether the comparator is insensitive to whitespace characters, specified in the name-value pair argument, 'IgnoringWhitespace'

### **Recursive**

Indicator of whether comparator operates recursively, specified in the name-value pair argument, 'Recursively'

### **Tolerance**

Specific tolerance used in construction of the comparator, specified as a `matlab.unittest.constraints.Tolerance` object in the name-value pair argument, 'Within'

## Copy Semantics

Value. To learn how value classes affect copy operations, see [Copying Objects in the MATLAB documentation](#).

## Examples

### **Compare Cell Arrays**

Create a test case for interactive testing.

```
import matlab.unittest.constraints.CellComparator
import matlab.unittest.constraints.StringComparator
import matlab.unittest.constraints.IsEqualTo
```

```
testCase = matlab.unittest.TestCase;
```

Use a `CellComparator` to test that two cell arrays are equal to each other.

```
actual = {'abc','def'};
expected = {'abc','def'};
testCase.verifyThat(actual, IsEqualTo(expected, ...
 'Using', CellComparator(StringComparator)))
```

Interactive verification passed.

By default, the `CellComparator` supports only comparison of empty cell arrays. Therefore, it is necessary to pass it a `StringComparator`.

Change the actual value and compare it to the expected value. To satisfy the constraint, construct it to ignore case and whitespace characters.

```
actual = {'ABC','D E F'};
testCase.verifyThat(actual, IsEqualTo(expected, 'Using', ...
 CellComparator(StringComparator, ...
 'IgnoringWhitespace', true, 'IgnoringCase',true)))
```

Interactive verification passed.

Test nested cell arrays of strings by constructing the comparator to operate recursively.

```
actual = {'abc',{'def','ghi'}};
expected = {'abc',{'def','ghi'}};

testCase.verifyThat(actual, IsEqualTo(expected, 'Using', ...
 CellComparator(StringComparator, 'Recursively', true)))
```

Interactive verification passed.

**Introduced in R2013a**

# matlab.unittest.constraints.Constraint class

**Package:** matlab.unittest.constraints

Fundamental interface class for comparisons

## Description

The `Constraint` interface class is the means by which `matlab.unittest` constraints encode comparison logic and the corresponding diagnostic information. Every comparison that conditionally can produce a failure inherits from the `Constraint` interface class.

Classes deriving from the `Constraint` interface class must provide a means to determine if a given value satisfies the constraint. To do this, implement the `satisfiedBy` method, which includes the definition of the underlying comparison logic. Classes deriving from the `Constraint` class also must provide a diagnostic for any given actual value. The testing framework uses the diagnostic when it encounters a qualification failure. To do this, implement the `getDiagnosticFor` method.

In exchange for meeting these requirements, all `Constraint` implementations are easily used with all qualification types through the `verifyThat`, `assertThat`, `assumeThat`, or `fatalAssertThat` methods. The qualifications use the comparison and diagnostic knowledge contained within the constraints. Also, the constraints can be used in situations where a test failure is not wanted, but the testing framework needs to reuse the comparison logic. For example, a constraint implementation may want to use the logic defined inside of another constraint. Since the constraint can interact with the other constraint directly, it can use the logic without the potential of causing a qualification failure.

## Methods

`getDiagnosticFor`  
`satisfiedBy`

Produce diagnostic for compared value  
Determine whether value satisfies constraint

## Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

### Related Examples

- “Create Custom Constraint”

## getDiagnosticFor

**Class:** matlab.unittest.constraints.Constraint

**Package:** matlab.unittest.constraints

Produce diagnostic for compared value

### Syntax

```
diag = getDiagnosticFor(constObj,actVal)
```

### Description

`diag = getDiagnosticFor(constObj,actVal)` produces a diagnostic, `diag`, for a compared value, `actVal`. When creating a custom constraint, the class author must implement the `getDiagnosticFor` method so that it analyzes the value, `actVal`, against the constraint, `constObj`, and instantiates and returns a `matlab.unittest.diagnostics.Diagnostic` object.

Typically, the testing framework calls this method when it encounters a qualification failure. Therefore, the constraint author can afford to undertake a more detailed analysis in the `getDiagnosticFor` method than the `satisfiedBy` method.

### Input Arguments

**actVal**

Value for comparison

**constObj**

Constraint instance

### Output Arguments

**diag**

Diagnostic instance

## See Also

ConstraintDiagnostic | Diagnostic | satisfiedBy

## Related Examples

- “Create Custom Constraint”

## satisfiedBy

**Class:** matlab.unittest.constraints.Constraint

**Package:** matlab.unittest.constraints

Determine whether value satisfies constraint

## Syntax

```
TF = satisfiedBy(constObj,actVal)
```

## Description

`TF = satisfiedBy(constObj,actVal)` determines whether a value, `actVal`, satisfies a constraint, `constObj`. The `satisfiedBy` method is used to determine qualification success or failure. It returns `true` or `false` (logical 0 or 1). When creating a custom constraint, a class author must place comparison logic in this method.

Since the most common usage is for the passing case, the constraint author should optimize for speed in that case. It is only in the failing case that more expensive detailed analysis is helpful.

## Input Arguments

### **actVal**

Value to evaluate against the constraint

### **constObj**

Constraint instance

## See Also

`getDiagnosticFor`

## **Related Examples**

- “Create Custom Constraint”

## matlab.unittest.constraints.ContainsSubstring class

**Package:** matlab.unittest.constraints

**Superclasses:** matlab.unittest.constraints.BooleanConstraint

Constraint specifying string containing substring

### Construction

`ContainsSubstring(substring)` creates a constraint that specifies a string containing a substring, `substring`. The constraint is satisfied only if the actual value contains an expected string.

`ContainsSubstring(substring,Name,Value)` provides a constraint with additional options specified by one or more `Name,Value` pair arguments. `Name` must appear inside single quotes (' '). You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### Input Arguments

#### **substring**

Text that must be contained within the actual value, specified as a string. `substring` can include newline characters.

#### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

#### **'IgnoringCase'**

Indicator if the constraint is insensitive to case, specified as `false` or `true` (logical 0 or 1)

**Default:** `false`

### **'IgnoringWhitespace'**

Indicator if the constraint is insensitive to whitespace, specified as `false` or `true` (logical 0 or 1)

**Default:** `false`

## **Properties**

### **IgnoreCase**

Indicator if the constraint is insensitive to case, specified in the name-value pair argument, `'IgnoreCase'`. This property applies at all levels of recursion, such as nested structures.

### **IgnoreWhitespace**

Indicator if the constraint is insensitive to whitespace, specified in the name-value pair argument, `'IgnoringWhitespace'`. This property applies at all levels of recursion, such as nested structures.

### **Substring**

String that must be included in the actual value, specified in the input argument, `substring`.

## **Copy Semantics**

Value. To learn how value classes affect copy operations, see [Copying Objects in the MATLAB documentation](#).

## **Examples**

### **Test That Actual Value Contains Specified Substring**

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
```

```
import matlab.unittest.constraints.ContainsSubstring
```

```
testCase = TestCase.forInteractiveUse;
```

Define the actual value string.

```
actVal = 'This Is One Long String';
```

Test the actVal contains the substring 'One'.

```
testCase.verifyThat(actVal, ContainsSubstring('One'))
```

```
Interactive verification passed.
```

Test the actVal contains the substring 'long'.

```
testCase.verifyThat(actVal, ContainsSubstring('long'))
```

```
Interactive verification failed.
```

```

Framework Diagnostic:

```

```
ContainsSubstring failed.
```

```
--> The string must contain the substring.
```

```
Actual String:
```

```
 This Is One Long String
```

```
Expected Substring:
```

```
 long
```

By default, the `ContainsSubstring` constraint is case sensitive.

Repeat the test ignoring case.

```
testCase.verifyThat(actVal, ContainsSubstring('long', ...
 'IgnoringCase', true))
```

```
Interactive verification passed.
```

Test actVal contains the substring 'thisisone'. For the test to pass, configure the constraint to ignore whitespace and case.

```
testCase.verifyThat(actVal, ContainsSubstring('thisisone', ...
 'IgnoringCase', true, 'IgnoringWhitespace', true))
```

Interactive verification passed.

Assert that `actVal` does not contain the substring 'longer'.

```
testCase.assertThat(actVal, ~ContainsSubstring('longer',...
 'IgnoringCase', true))
```

Interactive verification passed.

[EndsWithSubstring](#) | [IsSubstringOf](#) | [Matches](#) | [StartsWithSubstring](#)

# matlab.unittest.constraints.EndsWithSubstring class

**Package:** matlab.unittest.constraints

**Superclasses:** matlab.unittest.constraints.BooleanConstraint

Constraint specifying string ending with substring

## Construction

`EndsWithSubstring(suffix)` creates a constraint specifying a string ending with a substring. The constraint is satisfied only if the actual value ends with an expected string, `suffix`.

`EndsWithSubstring(suffix,Name,Value)` provides a constraint with additional options specified by one or more `Name,Value` pair arguments. `Name` must appear inside single quotes (' '). You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

## Input Arguments

### **suffix**

Text that occurs at the end of the actual value, specified as a string. `suffix` can include newline characters.

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### **'IgnoringCase'**

Indicator if the constraint is insensitive to case, specified as `false` or `true` (logical 0 or 1)

**Default:** `false`

### 'IgnoringWhitespace'

Indicator if the constraint is insensitive to whitespace, specified as `false` or `true` (logical 0 or 1)

**Default:** `false`

## Properties

### IgnoreCase

Indicator if the constraint is insensitive to case, specified in the name-value pair argument, `'IgnoringCase'`. This property applies at all levels of recursion, such as nested structures.

### IgnoreWhitespace

Indicator if the constraint is insensitive to whitespace, specified in the name-value pair argument, `'IgnoringWhitespace'`. This property applies at all levels of recursion, such as nested structures.

### Suffix

Text that occurs at the end of the actual value, specified in the input argument, `suffix`.

## Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

## Examples

### Test That Actual Value Ends with Specified Substring

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.EndsWithSubstring
```

```
testCase = TestCase.forInteractiveUse;
```

Define the actual value string.

```
actVal = 'This Is One Long String';
```

Test the `actVal` ends with the substring `'String'`.

```
testCase.verifyThat(actVal, EndsWithSubstring('String'))
```

Interactive verification passed.

Test the `actVal` ends with the substring `'InG'`.

```
testCase.verifyThat(actVal, EndsWithSubstring('InG'))
```

Interactive verification failed.

```

Framework Diagnostic:

```

```
EndsWithSubstring failed.
```

```
--> The string has an incorrect suffix.
```

```
Actual String:
```

```
 This Is One Long String
```

```
Expected Suffix:
```

```
 InG
```

By default, the `EndsWithSubstring` constraint is case sensitive.

Repeat the test ignoring case.

```
testCase.verifyThat(actVal, EndsWithSubstring('InG', ...
 'IgnoringCase', true))
```

Interactive verification passed

Test the `actVal` ends with the substring `'longstring'`. For the test to pass, configure the constraint to ignore whitespace and case.

```
testCase.verifyThat(actVal, EndsWithSubstring('longstring', ...
 'IgnoringCase', true, 'IgnoringWhitespace', true))
```

Interactive verification passed.

Assert that `actVal` does not end with the substring 'long'.

```
testCase.assertThat(actVal, ~EndsWithSubstring('long'))
```

Interactive verification passed.

[ContainsSubstring](#) | [IsSubstringOf](#) | [Matches](#) | [StartsWithSubstring](#)

# matlab.unittest.constraints.Eventually class

**Package:** matlab.unittest.constraints

**Superclasses:** matlab.unittest.constraints.Constraint

Poll for value to asynchronously satisfy constraint

## Construction

`outConstObj = Eventually(constObj)` creates a constraint, `outConstObj`, that polls for an actual value function handle to asynchronously satisfy the constraint specified in the `constObj` constraint. It is not satisfied if evaluation of the function handle does not produce a value that satisfies the constraint within 20 seconds. The testing framework invokes the `drawnow` function while the `Eventually` constraint waits for specified function to satisfy the constraint.

`outConstObj = Eventually(constObj, 'WithTimeoutOf', timeOutVal)` creates a constraint that polls for the constraint to be satisfied within the timer period specified in `timeOutVal`.

## Input Arguments

### `constObj`

Constraint instance

### `timeOutVal`

Maximum time to wait for passing behavior, specified in seconds

**Default:** 20 seconds

## Properties

### `TimeOut`

Maximum time to wait for passing behavior, specified by the `timeOutVal` input argument

## Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

## Examples

### Verify Test Passes Eventually

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.Eventually
import matlab.unittest.constraints.IsGreaterThan
import matlab.unittest.constraints.IsLessThan
```

```
testCase = TestCase.forInteractiveUse;
```

Verify that, within the timeout period, a call to `toc` results in a value greater than 10 (seconds). The `Eventually` constraint repeatedly calls `toc` until either the constraint is satisfied or the elapsed time exceeds the timeout period. Repeated calls to `toc` result in the elapsed time since the last call to `tic`.

```
tic
testCase.verifyThat(@toc, Eventually(IsGreaterThan(10)))
```

```
Interactive verification passed.
```

The verification may take as long as 10 seconds for `toc` to reach a passing value. If you issue the call to `tic` and wait more than 10 seconds before issuing the `verifyThat` command, the verification returns immediately since `toc` already returns a value greater than 10.

Verify that, within the timeout period, `toc` does not return a negative value.

```
testCase.verifyThat(@toc, Eventually(IsLessThan(0)))
```

```
Interactive verification failed.
```

```

Framework Diagnostic:

```

```
Eventually failed.
```

```
--> The function did not pass after 20 seconds.
```

```
--> IsLessThan failed.
--> The value must be less than the maximum value.
```

```
Actual Value:
 20.286452356691139
Maximum Value (Exclusive):
 0
```

```
Evaluated Function:
 @toc
```

This failure is expected since elapsed time is not going to be less than zero. However, `Eventually` polls `toc` for the duration of the timeout period.

Adjust the timeout period so `Eventually` polls for 5 seconds.

```
tic
testCase.verifyThat(@toc, Eventually(IsGreaterThan(10), ...
 'WithTimeoutOf', 5))
```

```
Interactive verification failed.
```

```

Framework Diagnostic:

```

```
Eventually failed.
--> The function did not pass after 5 seconds.
--> IsGreaterThan failed.
--> The value must be greater than the minimum value.
```

```
Actual Value:
 5.076293030150061
Minimum Value (Exclusive):
 10
```

```
Evaluated Function:
 @toc
```

If you didn't wait more than 5 seconds between calls to `tic` and `verifyThat`, the test fails because the elapsed time is not greater than 10 seconds within the modified timeout period.

## See Also

`matlab.unittest.constraints.Constraint` | `drawnow`

# matlab.unittest.constraints.EveryCellOf class

**Package:** matlab.unittest.constraints

Test if all elements of cell array meet constraint

## Description

The `EveryCellOf` class creates a proxy of the actual value to the framework. The proxy enables a test writer to apply a constraint against each element of a cell array, which ensures that a passing result occurs when every element of the cell array satisfies the constraint.

It is intended that you use this class through `matlab.unittest` qualifications as shown in the examples. The class does not modify the provided actual value, but serves as a wrapper to perform the constraint analysis. The testing framework analyzes the constraint on an element-by-element basis.

## Construction

`EveryCellOf(actVal)` creates a proxy instance that tests if every element of a provided cell array, `actVal`, meets a constraint. The test passes if all elements satisfy the constraint.

## Tips

- `EveryCellOf` checks if every element in the provided cell array satisfies an associated constraint. However, there are some constraints, a prominent one being `IsEqualTo`, that natively validate if all elements in cell arrays satisfy a condition. In these situations, use of `EveryCellOf` is unnecessary and impedes qualification performance.

## Input Arguments

### `actVal`

Actual value to test against constraint

## Properties

### ActualValue

Actual value to test against constraint. Set this property through the constructor via the `actVal` input argument.

## Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

## Examples

### Test That Every Cell Satisfies Constraint

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.EveryCellOf
```

```
testCase = TestCase.forInteractiveUse;
```

Test that every cell of `actVal` contains the substring 'ain'.

```
import matlab.unittest.constraints.ContainsSubstring
actVal = {'Rain', 'Main', 'Plain'};
testCase.verifyThat(EveryCellOf(actVal), ContainsSubstring('ain'))
```

```
Interactive verification passed.
```

Test that every cell of the actual value array has two elements.

```
import matlab.unittest.constraints.HasElementCount
testCase.verifyThat(EveryCellOf({'hello', 'world'}, {11 38}), HasElementCount(2))
```

```
Interactive verification passed.
```

Test that every cell of the actual value array is empty.

```
import matlab.unittest.constraints.IsEmpty
```

```
testCase.verifyThat(EveryCellOf({inputParser.empty, ''}), IsEmpty)
```

Interactive verification passed.

Test that every cell of the actual value array is finite.

```
import matlab.unittest.constraints.IsFinite
testCase.verifyThat(EveryCellOf({NaN, Inf, 5}), IsFinite)
```

Interactive verification failed.

```

Framework Diagnostic:

At least one cell failed.
```

```
Failing indices:
 1 2
The first failing cell failed because:
--> IsFinite failed.
 --> The value must be finite.
```

```
Actual Value:
 NaN
```

```
Actual Value Cell Array:
 [NaN] [Inf] [5]
```

Only the third element has a finite value.

Test that every cell of the actual value array is real.

```
import matlab.unittest.constraints.IsReal
testCase.verifyThat(EveryCellOf({1 4i}), IsReal)
```

Interactive verification failed.

```

Framework Diagnostic:

At least one cell failed.
```

```
Failing indices:
 2
The first failing cell failed because:
```

```
--> IsReal failed.
--> The value must be real.
```

```
Actual Value:
0.0000000000000000 + 4.0000000000000000i
```

```
Actual Value Cell Array:
[1] [0.0000000000000000 + 4.0000000000000000i]
```

The second element has an imaginary value.

# matlab.unittest.constraints.EveryElementOf class

**Package:** matlab.unittest.constraints

Test if all elements of array meet constraint

## Description

The `EveryElementOf` class creates a proxy of the actual value to the framework. The proxy enables a test writer to apply a constraint against each element of an array, which ensures that a passing result occurs when every element of the array that satisfies the constraint.

It is intended that you use this class through `matlab.unittest` qualifications as shown in the examples. The class does not modify the provided actual value, but serves as a wrapper to perform the constraint analysis. The testing framework analyzes the constraint on an element-by-element basis.

## Construction

`EveryElementOf(actVal)` creates a proxy instance that tests if every element of a provided array, `actVal`, meets a constraint. The test passes if all elements satisfy the constraint.

## Tips

- `EveryElementOf` checks if every element in the provided array satisfies an associated constraint. However, there are some constraints, such as `IsEqualTo` and `IsGreaterThan`, `IsLessThan`, that natively validate if all elements in the array satisfy a condition. In these situations, use of `EveryElementOf` is unnecessary and impedes qualification performance.

## Input Arguments

### `actVal`

Actual value to test against constraint

## Properties

### ActualValue

Actual value to test against constraint. Set this property through the constructor via the `actVal` input argument.

## Copy Semantics

Value. To learn how value classes affect copy operations, see [Copying Objects in the MATLAB documentation](#).

## Examples

### Test That Every Element Satisfies Constraint

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.EveryElementOf
```

```
testCase = TestCase.forInteractiveUse;
```

Test that every element of `actVal` is less than 55.

```
import matlab.unittest.constraints.IsLessThan
actVal = [1 1 2 3 5 8 13 21 34];
testCase.verifyThat(EveryElementOf(actVal), IsLessThan(55))
```

```
Interactive verification passed.
```

Test that every element of the actual value array is complex.

```
import matlab.unittest.constraints.IsReal
testCase.verifyThat(EveryElementOf([1+2i 4i]), ~IsReal)
```

```
Interactive verification passed.
```

Test that every element of the actual value array is less than zero.

```
import matlab.unittest.constraints.IsLessThan
```

```
testCase.verifyThat(EveryElementOf([1 -5]), IsLessThan(0))
```

```
Interactive verification failed.
```

```

Framework Diagnostic:

```

```
At least one element failed.
```

```
Failing indices:
```

```
1
```

```
The first failing element failed because:
```

```
--> IsLessThan failed.
```

```
--> The value must be less than the maximum value.
```

```
Actual Value:
```

```
1
```

```
Maximum Value (Exclusive):
```

```
0
```

```
Actual Value Array:
```

```
1 -5
```

Only the second element is less than zero.

Test that every element of the actual value array has a NaN value.

```
import matlab.unittest.constraints.HasNaN
```

```
testCase.verifyThat(EveryElementOf([NaN 0/0 5]), HasNaN)
```

```
Interactive verification failed.
```

```

Framework Diagnostic:

```

```
At least one element failed.
```

```
Failing indices:
```

```
3
```

```
The first failing element failed because:
```

```
--> HasNaN failed.
```

```
--> The value must be NaN.
```

```
Actual Value:
```

```
5
```

```
Actual Value Array:
 NaN NaN 5
```

Only the third element has a NaN value.

# matlab.unittest.constraints.HasElementCount class

**Package:** matlab.unittest.constraints

**Superclasses:** matlab.unittest.constraints.BooleanConstraint

Constraint specifying expected number of elements

## Construction

`HasElementCount(countVal)` provides a constraint that specifies an expected number of elements. The constraint is satisfied if the actual value array has the same number of elements specified as by `countVal`.

## Input Arguments

**countVal**

Number of elements a value must have to satisfy the constraint.

## Properties

**Count**

Number of elements a value must have to satisfy the constraint. Set this property through the constructor via the `countVal` input argument.

## Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

## Examples

### Test for Expected Number of Elements

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.HasElementCount
```

```
testCase = TestCase.forInteractiveUse;
```

Verify a scalar has an element count of one.

```
testCase.verifyThat(3, HasElementCount(1))
```

```
Interactive verification passed.
```

Test the element count of the vector.

```
testCase.assertThat([42 7 13], HasElementCount(3))
```

```
Interactive assertion passed.
```

Test the element count of the matrix.

```
testCase.assertThat([1 2 3; 4 5 6], HasElementCount(5))
```

```
Interactive assertion failed.
```

```

Framework Diagnostic:

```

```
HasElementCount failed.
```

```
--> The value did not have the correct number of elements.
```

```
 Actual Number of Elements:
```

```
 6
```

```
 Expected Number of Elements:
```

```
 5
```

```
Actual Value:
```

```
 1 2 3
```

```
 4 5 6
```

```
Assertion failed.
```

The matrix has six elements.

Test that a square identity matrix has the correct number of elements.

```
n = 7;
```

```
testCase.assumeThat(eye(n), HasElementCount(n^2))
```

Interactive assumption passed.

Verify the element count of a cell array of strings.

```
testCase.verifyThat({'aString', 'anotherString'}, HasElementCount(2))
```

Interactive verification passed.

Test the element count of a structure.

```
s.Field1 = 1;
s.Field2 = 2;
testCase.verifyThat(s, HasElementCount(2))
```

Interactive verification failed.

```

Framework Diagnostic:

```

HasElementCount failed.

--> The value did not have the correct number of elements.

Actual Number of Elements:

1

Expected Number of Elements:

2

Actual Value:

Field1: 1

Field2: 2

The structure has two fields, but it only has one element.

```
testCase.verifyThat(s, HasElementCount(1))
```

Interactive verification passed.

HasLength | HasSize | IsEmpty | numel

## matlab.unittest.constraints.HasField class

**Package:** matlab.unittest.constraints

**Superclasses:** matlab.unittest.constraints.BooleanConstraint

Constraint specifying structure containing particular field

### Construction

`HasField(fieldname)` provides a constraint specifying structure containing particular field, `fieldname`. The constraint is satisfied if the actual value is a structure and that structure contains a field named `fieldname`.

### Input Arguments

**fieldname**

Name of the field that a structure must contain to satisfy the constraint, specified as a string.

### Properties

**Field**

Name of the field that a structure must contain to satisfy the constraint. Set this property through the constructor via the `fieldname` input argument.

### Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

### Examples

#### Test That Structure Has Particular Field

Create a `TestCase` for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.HasField

testCase = TestCase.forInteractiveUse;

Define the following structure, S, with two fields.
S = struct('Tag', 123, 'Serial', 345);

Verify that the structure has a 'Tag' field.
testCase.verifyThat(S, HasField('Tag'))
Interactive verification passed.

Verify that the structure has a 'tag' field.
testCase.verifyThat(S, HasField('tag'))
Interactive verification failed.

Framework Diagnostic:

HasField failed.
--> The value did not have the expected field.

 Actual Fieldnames:
 'Tag'
 'Serial'
 Expected Fieldname:
 'tag'

Actual Value:
 Tag: 123
 Serial: 345
```

The verification fails because the field name comparison is case sensitive.

Verify that the structure has a 'Tag' field.

```
testCase.verifyThat(S, HasField('Tag'))
```

Interactive verification passed.

Verify that the structure has both a 'Tag' and a 'Serial' field.

```
testCase.verifyThat(S, HasField('Tag') & HasField('Serial'))
```

Interactive verification passed.

Verify that the structure does not have a 'Name' field.

```
testCase.verifyThat(S, ~HasField('Name'))
```

Interactive verification passed.

# matlab.unittest.constraints.HasInf class

**Package:** matlab.unittest.constraints

**Superclasses:** matlab.unittest.constraints.BooleanConstraint

Constraint specifying array containing any infinite value

## Construction

HasInf creates a constraint that is able to determine if any value of an actual value array is an infinite value. This constraint is satisfied only if the actual value array contains at least one infinite value.

## Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

## Examples

### Test That Actual Value Array Contains Infinite Value

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.HasInf
```

```
testCase = TestCase.forInteractiveUse;
```

Test that the value Inf satisfies the constraint.

```
testCase.verifyThat(Inf, HasInf)
```

```
Interactive verification passed.
```

Assert that an array contains an infinite value.

```
testCase.assertThat([0 1 1 2 3 5 8 13], HasInf)
```

Interactive assertion failed.

```

Framework Diagnostic:

```

HasInf failed.

--> At least one element must be Inf or -Inf.

Actual Value:

```
 0 1 1 2 3 5 8 13
```

Assertion failed.

The array does not contain any infinite values.

Verify that an array contains an infinite value.

```
testCase.verifyThat([-Inf 5 NaN], HasInf)
```

Interactive verification passed.

Assert that a complex number that is infinite in the imaginary part satisfies the constraint.

```
testCase.assertThat(42+Inf*1i, HasInf)
```

Interactive verification passed.

Verify that an array does not contain any infinite values.

```
testCase.verifyThat([NaN -7+NaN*1i], ~HasInf)
```

Interactive verification passed.

Negating the `HasInf` constraint does not ensure the value is finite, only that it does not contain any infinite values.

`HasNaN` | `IsFinite` | `isinf`

# matlab.unittest.constraints.HasLength class

**Package:** matlab.unittest.constraints

**Superclasses:** matlab.unittest.constraints.BooleanConstraint

Constraint specifying expected length of array

## Construction

`HasLength(lengthVal)` provides a constraint that specifies an expected length of an array. The constraint is satisfied if the largest dimension length of the actual value array has the same number of elements specified as by `lengthVal`.

## Input Arguments

**lengthVal**

Length a value must have to satisfy the constraint.

## Properties

**Count**

Length a value must have to satisfy the constraint. Set this property through the constructor via the `lengthVal` input argument.

## Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

## Examples

### Test for Expected Array Length

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.HasLength
```

```
testCase = TestCase.forInteractiveUse;
```

Assert that a 2x5x3 array has an expected length.

```
testCase.assertThat(rand(2, 5, 3), HasLength(5))
```

```
Interactive assertion passed.
```

Verify that a cell array of strings has an expected length.

```
testCase.verifyThat({'SomeString', 'SomeOtherString'}, HasLength(2))
```

```
Interactive verification passed.
```

Verify that an identity matrix has an expected length.

```
testCase.verifyThat(eye(2), HasLength(4))
```

```
Interactive verification failed.
```

```

Framework Diagnostic:

```

```
HasLength failed.
```

```
--> The array has an incorrect length.
```

```
Actual Length:
```

```
2
```

```
Expected Length:
```

```
4
```

```
Actual Array:
```

```
1 0
```

```
0 1
```

The matrix has a length of 2.

# matlab.unittest.constraints.HasNaN class

**Package:** matlab.unittest.constraints

**Superclasses:** matlab.unittest.constraints.BooleanConstraint

Constraint specifying array containing NaN value

## Construction

HasNaN creates a constraint that is able to determine if any value of an actual value array is NaN. This constraint is satisfied only if the actual value array contains at least one NaN value.

## Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

## Examples

### Test That Actual Value Array Contains NaN Value

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.HasNaN
```

```
testCase = TestCase.forInteractiveUse;
```

Test that the value NaN satisfies the constraint.

```
testCase.verifyThat(NaN, HasNaN)
```

```
Interactive verification passed.
```

Assert that an array contains a NaN value.

```
testCase.assertThat([0 1 1 2 3 5 8 13], HasNaN)
```

Interactive assertion failed.

```

Framework Diagnostic:

```

HasNaN failed.

--> At least one element must be NaN.

Actual Value:

0 1 1 2 3 5 8 13

Assertion failed.

The array does not contain a NaN value.

Verify that an array contains a NaN value.

```
testCase.verifyThat([-Inf 5 NaN], HasNaN)
```

Interactive verification passed.

Assert that a complex number satisfies the constraint.

```
testCase.assertThat(42+NaN*1i, HasNaN)
```

Interactive assertion passed.

Verify that an array does not contain any NaN values.

```
testCase.verifyThat([Inf -7+Inf*1i], ~HasNaN)
```

Interactive verification passed.

Negating the `HasNaN` constraint does not ensure the value is finite, only that it does not contain any NaN values.

# matlab.unittest.constraints.HasSize class

**Package:** matlab.unittest.constraints

**Superclasses:** matlab.unittest.constraints.BooleanConstraint

Constraint specifying expected size of array

## Construction

`HasSize(sizeVal)` provides a constraint that specifies an expected size of an array. The constraint is satisfied if the actual value array size is equal to the size specified by `sizeVal`.

## Input Arguments

**sizeVal**

Size a value must have to satisfy the constraint.

## Properties

**Count**

Size a value must have to satisfy the constraint. Set this property through the constructor via the `sizeVal` input argument.

## Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

## Examples

### Test for Expected Array Size

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.HasSize

testCase = TestCase.forInteractiveUse;

Assert that a 2x5x3 array has an expected size.
testCase.assertThat(rand(2, 5, 3), HasSize([2 5 3]))
Interactive assertion passed.

Verify that a cell array of strings has an expected size.
testCase.verifyThat({'SomeString', 'SomeOtherString'}, HasSize([1 2]))
Interactive verification passed.

Verify that an identity matrix has an expected size.
testCase.verifyThat(eye(2), HasSize([4 1]))
Interactive verification failed.

Framework Diagnostic:

HasSize failed.
--> The value had an incorrect size.

 Actual Size:
 2 2
 Expected Size:
 4 1

Actual Value:
 1 0
 0 1
```

The matrix has a size of 2x2.

# matlab.unittest.constraints.IsAnything class

**Package:** matlab.unittest.constraints

**Superclasses:** matlab.unittest.constraints.Constraint

Constraint specifying any value

## Construction

IsAnything provides a constraint specifying any value. The constraint is satisfied by any value. It is the default constraint for selectors that do not require an input argument.

## Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

## Examples

### Instantiate IsAnything Object

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.IsAnything
```

```
testCase = TestCase.forInteractiveUse;
```

Verify that the following values satisfy the IsAnything constraint: NaN, an inputParser object, a numeric array, and a complex number.

```
testCase.verifyThat(NaN, IsAnything)
testCase.verifyThat(inputParser, IsAnything)
testCase.verifyThat(1:10, IsAnything)
testCase.verifyThat(-Inf+5j, IsAnything)
```

```
Interactive verification passed.
Interactive verification passed.
```

```
Interactive verification passed.
Interactive verification passed.
```

Test that empty cells, arrays, and strings satisfy the `IsAnything` constraint.

```
testCase.verifyThat({}, IsAnything)
testCase.verifyThat([], IsAnything)
testCase.verifyThat(' ', IsAnything)
```

```
Interactive verification passed.
Interactive verification passed.
Interactive verification passed.
```

The constraint is satisfied even though the data are empty.

## See Also

# matlab.unittest.constraints.IsEmpty class

**Package:** matlab.unittest.constraints

**Superclasses:** matlab.unittest.constraints.BooleanConstraint

Constraint specifying empty value

## Construction

IsEmpty provides a constraint that specifies an empty value. The constraint is satisfied if the actual value array is empty.

## Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

## Examples

### Test That Actual Value Is Empty

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.IsEmpty
```

```
testCase = TestCase.forInteractiveUse;
```

Verify that an empty string satisfies the IsEmpty constraint.

```
testCase.verifyThat('', IsEmpty)
```

```
Interactive verification passed.
```

Assert that a vector is not empty.

```
testCase.assertThat([13 42], ~IsEmpty)
```

```
Interactive verification passed.
```

Verify that a matrix with a dimension of length zero is empty.

```
testCase.verifyThat(rand(2, 5, 0, 3), IsEmpty)
```

```
Interactive verification passed.
```

Assert that an empty object satisfies the `IsEmpty` constraint.

```
testCase.assertThat(MException.empty, IsEmpty)
```

```
Interactive assertion passed.
```

Verify that a cell array containing an empty numeric array is empty.

```
testCase.verifyThat({[]}, IsEmpty)
```

```
Interactive verification failed.
```

```

Framework Diagnostic:

IsEmpty failed.
--> The value must be empty.
--> The value has a size of [1 1].
```

```
Actual Value:
 {[]}
```

The cell array is not empty, even though the only thing it contains is an empty array.

# matlab.unittest.constraints.IsFalse class

**Package:** matlab.unittest.constraints

**Superclasses:** matlab.unittest.constraints.Constraint

Constraint specifying false value

## Construction

`IsFalse` provides a constraint specifying a false value. This constraint is satisfied only by a scalar logical with a value of `false`.

## Copy Semantics

Value. To learn how value classes affect copy operations, see [Copying Objects in the MATLAB documentation](#).

## Examples

### Test Actual Value Is False

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.IsFalse
```

```
testCase = TestCase.forInteractiveUse;
```

Test that `false` satisfies the `IsFalse` constraint.

```
testCase.verifyThat(false, IsFalse)
```

```
Interactive verification passed.
```

Test that the `IsFalse` constraint is not satisfied by `true`.

```
testCase.verifyThat(true, IsFalse)
```

Interactive verification failed.

-----  
Framework Diagnostic:  
-----

IsFalse failed.  
--> The value must evaluate to "false".

Actual Value:  
          1

The test fails because `true` returns `logical(1)`.

Test that the `IsFalse` constraint is not satisfied by the double `0`.

`testCase.verifyThat(0, IsFalse)`

Interactive verification failed.

-----  
Framework Diagnostic:  
-----

IsFalse failed.  
--> The value must be logical. It is of type "double".

Actual Value:  
          0

The `IsFalse` constraint is satisfied only by `logical(0)`.

Test that the `IsFalse` constraint is not satisfied by a logical array of zeros.

`testCase.verifyThat([false false false], IsFalse)`

Interactive verification failed.

-----  
Framework Diagnostic:  
-----

IsFalse failed.  
--> The value must be scalar. It has a size of [1 3].

Actual Value:  
          0    0    0

The `IsFalse` constraint is only satisfied if the value is scalar and `logical(0)`.

## matlab.unittest.constraints.IsFinite class

**Package:** matlab.unittest.constraints

**Superclasses:** matlab.unittest.constraints.BooleanConstraint

Constraint specifying finite value

### Construction

`IsFinite` creates a constraint that is able to determine if all values of an actual value array are finite. This constraint is satisfied only if the actual value array does not contain any infinite or NaN values.

### Copy Semantics

Value. To learn how value classes affect copy operations, see [Copying Objects in the MATLAB documentation](#).

### Examples

#### Test That Actual Value Array Contains Only Finite Values

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.IsFinite
```

```
testCase = TestCase.forInteractiveUse;
```

Test that the value 17 satisfies the constraint.

```
testCase.verifyThat(17, IsFinite)
```

```
Interactive verification passed.
```

Assert that an array is completely finite.

```
testCase.assertThat([0 1 1 2 3 5 8 13], IsFinite)
```

Interactive assertion passed.

Verify that an array is completely finite.

```
testCase.verifyThat([-Inf 5 NaN], IsFinite)
```

Interactive verification failed.

```

Framework Diagnostic:

```

IsFinite failed.

--> All elements must be finite-valued.

Failing indices:

```
 1 3
```

Actual Value:

```
 -Inf 5 NaN
```

The array contains an infinite value.

Test if a complex number that is infinite in the imaginary part satisfies the constraint.

```
testCase.assertThat(42+Inf*1i, IsFinite)
```

Interactive assertion failed.

```

Framework Diagnostic:

```

IsFinite failed.

--> The value must be finite.

Actual Value:

```
 42.000000000000000 + Infi
```

Assertion failed.

Verify that an array does not contain all finite values.

```
testCase.verifyThat([NaN -7+NaN*1i], ~IsFinite)
```

Interactive verification passed.

## matlab.unittest.constraints.IsGreaterThan class

**Package:** matlab.unittest.constraints

**Superclasses:** matlab.unittest.constraints.Constraint

Constraint specifying value greater than another value

### Construction

`IsGreaterThan(floorVal)` creates a constraint specifying that an actual value is greater than another value. The constraint is satisfied if the actual value array is greater than the specified floor value, `floorVal`. The actual value is greater than `floorVal` only if the result of the expression `actual > floorVal` is nonempty and all values are true.

### Input Arguments

**floorVal**

Largest value that fails the constraint.

### Properties

**FloorValue**

Largest value that fails the constraint. Set this property through the constructor via the `floorVal` input argument.

### Methods

### Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

## Examples

### Test That Actual Value Is Greater Than Provided Floor Value

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.IsGreaterThan
```

```
testCase = TestCase.forInteractiveUse;
```

Test that the actual value is greater than two.

```
actVal = 3;
testCase.verifyThat(actVal, IsGreaterThan(2))
```

```
Interactive verification passed.
```

Test that the actual value is greater than three.

```
testCase.verifyThat(actVal, IsGreaterThan(3))
```

```
Interactive verification failed.
```

```

Framework Diagnostic:

IsGreaterThan failed.
--> The value must be greater than the minimum value.
```

```
Actual Value:
 3
Minimum Value (Exclusive):
 3
```

The actual value is equal to, not greater than, three.

Test that each element in the actual value array is greater than four.

```
actVal = [5 6 7];
testCase.verifyThat(actVal, IsGreaterThan(4))
```

```
Interactive verification passed.
```

Test that each element in the actual value matrix is greater than four.

```
actVal = [1 2 3; 4 5 6];
testCase.verifyThat(actVal, IsGreaterThan(4))
```

Interactive verification failed.

```

Framework Diagnostic:

```

IsGreaterThan failed.

--> Each element must be greater than the minimum value.

Failing Indices:

```
 1 2 3 5
```

Actual Value:

```
 1 2 3
```

```
 4 5 6
```

Minimum Value (Exclusive):

```
 4
```

The matrix contains four elements with a value less than or equal to four.

Test that the actual value, 5, is greater than every element in an array.

```
testCase.verifyThat(5, IsGreaterThan([1 2 3]))
```

Interactive verification passed.

Test that elements in the actual value array are greater than the corresponding floor values.

```
testCase.verifyThat([5 -3 2], IsGreaterThan([4 -9 0]))
```

Interactive verification passed.

Repeat the test, this time negating the first actual value element.

```
testCase.verifyThat([-5 -3 2], IsGreaterThan([4 -9 0]))
```

Interactive verification failed.

```

Framework Diagnostic:

```

IsGreaterThan failed.

--> Each element must be greater than each corresponding element of the minimum value a

Failing Indices:

1

Actual Value:

-5 -3 2

Minimum Value (Exclusive):

4 -9 0

The negated element is less than four.

**Package:** matlab.unittest.constraints

**Superclasses:** matlab.unittest.constraints.Constraint

Constraint specifying value greater than or equal to another value

## Construction

`IsGreaterThanOrEqualTo(floorVal)` creates a constraint specifying that an actual value is greater than or equal to another value. The constraint is satisfied if the actual value array is greater than or equal to the specified floor value, `floorVal`. The actual value is greater than or equal to `floorVal` only if the result of the expression `actual >= floorVal` is nonempty and all values are true.

## Input Arguments

**floorVal**

Minimum value to satisfy the constraint.

## Properties

**FloorValue**

Minimum value to satisfy the constraint. Set this property through the constructor via the `floorVal` input argument.

## Methods

## Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

## Examples

### Test That Actual Value Is Greater Than or Equal to Provided Floor Value

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.IsGreaterThanOrEqualTo
```

```
testCase = TestCase.forInteractiveUse;
```

Test that the actual value is greater than or equal to two.

```
actVal = 3;
testCase.verifyThat(actVal, IsGreaterThanOrEqualTo(2))
```

Test that the actual value is greater than or equal to three.

```
testCase.verifyThat(actVal, IsGreaterThanOrEqualTo(3))
```

```
Interactive verification passed.
```

Test that each element in the actual value array is greater than or equal to four.

```
actVal = [5 6 7];
testCase.verifyThat(actVal, IsGreaterThanOrEqualTo(4))
```

```
Interactive verification passed.
```

Test that each element in the actual value matrix is greater than or equal to four.

```
actVal = [1 2 3; 4 5 6];
testCase.verifyThat(actVal, IsGreaterThanOrEqualTo(4))
```

```
Interactive verification failed.
```

```

Framework Diagnostic:

```

```
IsGreaterThanOrEqualTo failed.
```

```
--> Each element must be greater than or equal to the minimum value.
```

```
Failing Indices:
```

```
 1 3 5
```

```
Actual Value:
 1 2 3
 4 5 6
Minimum Value (Inclusive):
 4
```

The matrix contains three elements that are greater than or equal to four.

Test that the actual value, 5, is greater than or equal to every element in an array.

```
testCase.verifyThat(5, IsGreaterThanOrEqualTo([1 2 3 5]))
```

Interactive verification passed.

Test that elements in the actual value array are greater than or equal to the corresponding floor values.

```
testCase.verifyThat([5 -3 0], IsGreaterThanOrEqualTo([4 -9 0]))
```

Interactive verification passed.

Repeat the test, this time negating the first actual value element.

```
testCase.verifyThat([-5 -3 0], IsGreaterThanOrEqualTo([4 -9 0]))
```

Interactive verification failed.

```

Framework Diagnostic:

```

IsGreaterThanOrEqualTo failed.

--> Each element must be greater than or equal to each corresponding element of the mi

```
Failing Indices:
 1
```

```
Actual Value:
 -5 -3 0
Minimum Value (Inclusive):
 4 -9 0
```

The negated element is less than or equal to four.

# matlab.unittest.constraints.IsEqualTo class

**Package:** matlab.unittest.constraints

**Superclasses:** matlab.unittest.constraints.BooleanConstraint

General constraint to compare for equality

## Description

The `IsEqualTo` class creates a constraint that compares data for equality. The type of comparison it uses is governed by the data type of the expected value. First, the testing framework checks if the expected value is an object. This check is performed first because it is possible for the object to have overridden methods that are used in subsequent checks (e.g. `islogical`). The following list categorizes and describes the various tests.

| Data Type             | Equality Comparison Method                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| MATLAB & Java Objects | If the expected value is a MATLAB or Java object, the <code>IsEqualTo</code> constraint calls the <code>isequaln</code> method if it is defined on the expected value object, otherwise it calls <code>isequal</code> . If the check returns false and a supported tolerance is specified, the <code>IsEqualTo</code> constraint checks the actual and expected values for equivalent class, size, and sparsity before determining if the values are within the tolerance.                                                                                      |
| Logicals              | If the expected value is a <code>logical</code> , the constraint checks the actual and expected values for equivalent sparsity. If the sparsity matches, the constraint compares the values with the <code>isequal</code> method. Otherwise, the constraint is not satisfied.                                                                                                                                                                                                                                                                                   |
| Numerics              | If the expected value is <code>numeric</code> , the constraint checks the actual and expected values for equivalent class, size, and sparsity. If all these checks match, the constraint uses the <code>isequaln</code> method for comparison. If <code>isequaln</code> returns <code>true</code> , the constraint is satisfied. If the complexity does not match or <code>isequaln</code> returns <code>false</code> , and a supported tolerance is supplied, the constraint uses the tolerance in the comparison. Otherwise, the constraint is not satisfied. |
| Strings               | If the expected value is a <code>string</code> , the constraint uses the <code>strcmp</code> function to check the actual and expected values for equality. However, if the <code>IgnoreCase</code> property is true, the strings are compared using <code>strcmpi</code> . If the <code>IgnoreWhitespace</code> is true, all whitespace characters                                                                                                                                                                                                             |

| Data Type   | Equality Comparison Method                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|             | are removed from the actual and expected strings before passing them to <code>strcmp</code> or <code>strcmpi</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Structures  | If the expected value is a <code>struct</code> , the constraint compares the field count of the actual and expected values. If not equal, the constraint is not satisfied. Otherwise, each field of the expected value <code>struct</code> must exist on the actual value <code>struct</code> . If any field names are different, the constraint is not satisfied. Then, the constraint recursively compares the fields in a depth first examination. The recursion continues until a fundamental data type is encountered (i.e. logical, numeric, string, or object), and then the values are compared as described above. |
| Cell Arrays | If the expected value is a cell array, the constraint checks the actual and expected values for size equality. If they are not equal in size, the constraint is not satisfied. Otherwise, each element of the array is recursively compared in a manner identical to fields in a structure, described above.                                                                                                                                                                                                                                                                                                                |

## Construction

`IsEqualTo(expVal)` provides a general constraint to compare for equality.

`IsEqualTo(expVal, Name, Value)` provides a constraint with additional options specified by one or more `Name, Value` pair arguments. `Name` must appear inside single quotes ( ' '). You can specify several name-value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

## Input Arguments

### `expVal`

The expected value that will be compared to the actual value.

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

**'IgnoringCase'**

Indicator if the constraint is insensitive to case, specified as `false` or `true` (logical 0 or 1)

**Default:** `false`

**'IgnoringWhitespace'**

Indicator if the constraint is insensitive to whitespace, specified as `false` or `true` (logical 0 or 1)

**Default:** `false`

**'Using'**

Particular comparator to use for constraint construction, specified as a `matlab.unittest.constraints.Comparator` object

**Default:** (empty)

**'Within'**

Tolerance to use in constraint construction, specified as a `matlab.unittest.constraints.Tolerance` object

**Default:** (empty)

## Properties

**Comparator**

Specific comparator used in construction of the constraint, specified as a `matlab.unittest.constraints.Comparator` object in the name-value pair argument, `'Using'`.

**Expected**

The expected value that will be compared to the actual value specified in the `expVal` input argument.

## IgnoreCase

Indicator if the constraint is insensitive to case, specified in the name-value pair argument, 'IgnoringCase'. This property applies at all levels of recursion, such as nested structures.

## IgnoreWhitespace

Indicator if the constraint is insensitive to whitespace, specified in the name-value pair argument, 'IgnoringWhitespace'. This property applies at all levels of recursion, such as nested structures.

## Tolerance

Specific tolerance used in construction of the constraint, specified as a `matlab.unittest.constraints.Tolerance` object in the name-value pair argument, 'Within'. This property applies at all levels of recursion, such as nested structures.

## Copy Semantics

Value. To learn how value classes affect copy operations, see [Copying Objects in the MATLAB documentation](#).

## Examples

### Test Numerics for Equality

Create a `TestCase` for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.IsEqualTo
import matlab.unittest.constraints.AbsoluteTolerance
import matlab.unittest.constraints.RelativeTolerance
```

```
testCase = TestCase.forInteractiveUse;
```

Verify that an actual value of 5 is equal to the expected value.

```
expVal = 5;
testCase.verifyThat(expVal, IsEqualTo(5))
```

Interactive verification passed.

Assume that the actual value is 4.95. Verify that the difference between the actual value and expected value is less than 0.09.

```
testCase.verifyThat(expVal, IsEqualTo(4.95, 'Within', AbsoluteTolerance(0.09)))
```

Interactive verification passed.

Assume that the actual value is 4.9. Verify that the difference between the actual and expected value is less than 1%.

```
testCase.verifyThat(expVal, IsEqualTo(4.9, 'Within', RelativeTolerance(0.01)))
```

Interactive verification failed.

```

Framework Diagnostic:

```

IsEqualTo failed.

--> NumericComparator failed.

--> The values are not equal using "isequaln".

--> RelativeTolerance failed.

--> The error was not within relative tolerance.

--> Failure table:

|  | Actual | Expected | Error               | RelativeError     | Re |
|--|--------|----------|---------------------|-------------------|----|
|  | 5      | 4.9      | 0.09999999999999996 | 0.020408163265306 | 0  |

Actual double:

5

Expected double:

4.9000000000000000

The two values differ by more than 1%.

## Test Floating Point Calculation with Tolerance

Create a TestCase for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.IsEqualTo
import matlab.unittest.constraints.RelativeTolerance
```

```
testCase = TestCase.forInteractiveUse;
```

Test that  $0.1 \times 3 = 0.3$ .

```
act = 0.1*3;
exp = 0.3;
testCase.verifyThat(act, IsEqualTo(exp))
```

Interactive verification failed.

```

Framework Diagnostic:

```

IsEqualTo failed.

--> NumericComparator failed.

--> The values are not equal using "isequaln".

--> Failure table:

| Actual | Expected | Error                | RelativeError        |
|--------|----------|----------------------|----------------------|
| 0.3    | 0.3      | 5.55111512312578e-17 | 1.85037170770859e-16 |

Actual double:

0.3000000000000000

Expected double:

0.3000000000000000

This test fails due to round off error in floating point arithmetic.

Perform the comparison of floating point numbers using a tolerance. Test that  $0.1 \times 3 = 0.3$  within a relative tolerance of  $2 \times \text{eps}$ .

```
testCase.verifyThat(act, IsEqualTo(exp, ...
 'Within', RelativeTolerance(2*eps)))
```

Interactive verification passed.

## Test Strings for Equality

Create a TestCase for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.IsEqualTo
```

```
testCase = TestCase.forInteractiveUse;
```

Verify that two strings are equal.

```
expVal = 'Hello';
testCase.verifyThat(expVal, IsEqualTo('Hello'))
```

Interactive verification passed.

Change the case of the actual string and test for equality.

```
testCase.verifyThat(expVal, IsEqualTo('hello'))
```

Interactive verification failed.

```

Framework Diagnostic:

IsEqualTo failed.
--> StringComparator failed.
 --> The strings are not equal
```

```
Actual String:
 Hello
Expected String:
 hello
```

Ignore case and test again.

```
testCase.verifyThat(expVal, IsEqualTo('hello', 'IgnoringCase', true))
```

Interactive verification passed.

Ignore whitespace and test two strings.

```
expVal = 'a bc';
testCase.verifyThat(expVal, IsEqualTo('abc', 'IgnoringWhitespace', true))
testCase.verifyThat(expVal, IsEqualTo('ab c', 'IgnoringWhitespace', true))
```

Interactive verification passed.  
Interactive verification passed.

### Test Objects for Equality Using Comparator

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.IsEqualTo
```

```
import matlab.unittest.constraints.RelativeTolerance
import matlab.unittest.constraints.PublicPropertyComparator
```

```
testCase = TestCase.forInteractiveUse;
```

Define actual and expected timeseries objects. Perturb one of the actual data points by 1%.

```
expected = timeseries(1:10);
actual = expected;
actual.Data(7) = 1.01*actual.Data(7);
```

Test that the actual and expected values are equal within a relative tolerance of 2%.

```
testCase.verifyThat(actual, IsEqualTo(expected,...
 'Within', RelativeTolerance(.02)))
```

```
Interactive verification failed.
```

```

Framework Diagnostic:

```

```
IsEqualTo failed.
```

```
--> ObjectComparator failed.
```

```
 --> The objects are not equal using "isequal".
```

```
 --> The tolerance does not support timeseries values so it was not used.
```

```
Actual Object:
```

```
 timeseries
```

```
 Common Properties:
```

```
 Name: 'unnamed'
```

```
 Time: [10x1 double]
```

```
 TimeInfo: [1x1 tsdata.timemetadata]
```

```
 Data: [1x1x10 double]
```

```
 DataInfo: [1x1 tsdata.datametadata]
```

```
 More properties, Methods
```

```
Expected Object:
```

```
 timeseries
```

```
 Common Properties:
```

```
 Name: 'unnamed'
```

```
 Time: [10x1 double]
```

```
 TimeInfo: [1x1 tsdata.timemetadata]
```

```
Data: [1x1x10 double]
DataInfo: [1x1 tsdata.datametadate]
```

More properties, Methods

Use the `PublicPropertyComparator` in the construction of the constraint.

```
testCase.verifyThat(actual, IsEqualTo(expected,...
 'Within', RelativeTolerance(.02),...
 'Using', PublicPropertyComparator.supportingAllValues))
```

Interactive verification passed.

The test passes because the `PublicPropertyComparator` compares each public property individually instead of comparing the object all at once. In the former test, the `ObjectComparator` compares `timeseries` objects, and therefore relies on the `isequal` method of the `timeseries` class. Due to the perturbation in the actual `timeseries`, `isequal` returns `false`. The comparator does not apply the tolerance because the double-valued tolerance cannot apply directly to the `timeseries` object. In the latter test, the comparator applies the tolerance to each public property that contains double-valued data.

**Introduced in R2013a**

## **matlab.unittest.constraints.IsInstanceOf class**

**Package:** matlab.unittest.constraints

**Superclasses:** matlab.unittest.constraints.BooleanConstraint

Constraint specifying inclusion in given class hierarchy

### **Construction**

`IsInstanceOf(class)` provides a constraint specifying inclusion in a given class hierarchy. The constraint is satisfied if the actual value instance passes the “isa” relationship with `class`.

### **Input Arguments**

#### **class**

Class name that the actual value must derive from or be an instance of to satisfy the constraint, specified as a fully qualified class name string or a `meta.class` instance.

### **Properties**

#### **Class**

Class name that the actual value must derive from or be an instance of to satisfy the constraint. Set this property through the constructor via the `class` input argument.

### **Copy Semantics**

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

### **Examples**

#### **Test That Actual Value Is Instance of Specified Class**

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.IsInstanceOf

testCase = TestCase.forInteractiveUse;

Verify that the actual value, 5, is an instance of the double class.
testCase.verifyThat(5, IsInstanceOf('double'))
Interactive verification passed.

Repeat the test using an instance of meta.class instead of a string.
testCase.verifyThat(5, IsInstanceOf(?double))
Interactive verification passed.

Assert that zero is an instance of the logical class.
testCase.assertThat(0, IsInstanceOf('logical'))
Interactive assertion failed.

Framework Diagnostic:

IsInstanceOf failed.
--> The value must be an instance of the expected type.

 Actual Class:
 double
 Expected Type:
 logical

Actual Value:
 0
Assertion failed.

Verify that @sin is a function handle.
testCase.verifyThat(@sin, IsInstanceOf(?function_handle))
Interactive verification passed.

Verify that name is an instance of the char class.
name = 42;
```

```
testCase.verifyThat(name, IsInstanceOf('char'))
Interactive verification failed.

Framework Diagnostic:

IsInstanceOf failed.
--> The value must be an instance of the expected type.

 Actual Class:
 double
 Expected Type:
 char

Actual Value:
 42
```

## Test That Derived Class Is Instance of Specified Class

In a file in your working folder, create a class, `DerivedExample`, that inherits from the `handle` class.

```
classdef DerivedExample < handle
end
```

At the command prompt, create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.IsInstanceOf

testCase = TestCase.forInteractiveUse;
```

Verify that an instance of the `DerivedExample` class is an instance of a `handle`.

```
exObj = DerivedExample;
testCase.verifyThat(exObj, IsInstanceOf(?handle))
```

```
Interactive verification passed.
```

Even though `exObj` is not an instance of the `handle` class, the verification passes because it derives from the `handle` class.

# matlab.unittest.constraints.IsLessThan class

**Package:** matlab.unittest.constraints

**Superclasses:** matlab.unittest.constraints.Constraint

Constraint specifying value less than another value

## Construction

`IsLessThan(ceilVal)` creates a constraint specifying that an actual value is less than another value. The constraint is satisfied if the actual value array is less than the specified ceiling value, `ceilVal`. The actual value is less than `ceilVal` only if the result of the expression `actual < ceilVal` is nonempty and all values are true.

## Input Arguments

**ceilVal**

Smallest value that fails the constraint.

## Properties

**CeilingValue**

Smallest value that fails the constraint. Set this property through the constructor via the `ceilVal` input argument.

## Methods

## Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

## Examples

### Test That Actual Value Is Less Than Provided Ceiling Value

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.IsLessThan
```

```
testCase = TestCase.forInteractiveUse;
```

Test that the actual value is less than four.

```
actVal = 3;
testCase.verifyThat(actVal, IsLessThan(4))
```

```
Interactive verification passed.
```

Test that the actual value is less than three.

```
testCase.verifyThat(actVal, IsLessThan(3))
```

```
Interactive verification failed.
```

```

Framework Diagnostic:

IsLessThan failed.
--> The value must be less than the maximum value.
```

```
Actual Value:
 3
Maximum Value (Exclusive):
 3
```

The actual value is equal to, not less than, three.

Test that each element in the actual value array is less than four.

```
actVal = [1 2 3];
testCase.verifyThat(actVal, IsLessThan(4))
```

```
Interactive verification passed.
```

Test that each element in the actual value matrix is less than four.

```
actVal = [1 2 3; 4 5 6];
testCase.verifyThat(actVal, IsLessThan(4))
```

Interactive verification failed.

```

Framework Diagnostic:

```

IsLessThan failed.

--> Each element must be less than the maximum value.

Failing Indices:

```
 2 4 6
```

Actual Value:

```
 1 2 3
```

```
 4 5 6
```

Maximum Value (Exclusive):

```
 4
```

The matrix contains three elements that are greater than or equal to four.

Test that the actual value, 0, is less than every element in an array.

```
testCase.verifyThat(0, IsLessThan([1 2 3]))
```

Interactive verification passed.

Test that elements in the actual value array are less than the corresponding ceiling values.

```
testCase.verifyThat([4 -9 0], IsLessThan([5 -3 2]))
```

Interactive verification passed.

Repeat the test, this time negating the second actual value element.

```
testCase.verifyThat([4 9 0], IsLessThan([5 -3 2]))
```

Interactive verification failed.

```

Framework Diagnostic:

```

IsLessThan failed.

--> Each element must be less than each corresponding element of the maximum value array.

Failing Indices:  
2

Actual Value:

4 9 0

Maximum Value (Exclusive):

5 -3 2

The negated element is greater than -3.

# matlab.unittest.constraints.IsLessThanOrEqualTo class

**Package:** matlab.unittest.constraints

**Superclasses:** matlab.unittest.constraints.Constraint

Constraint specifying value less than or equal to another value

## Construction

`IsLessThanOrEqualTo(ceilVal)` creates a constraint specifying that an actual value is less than or equal to another value. The constraint is satisfied if the actual value array is less than or equal to the specified ceiling value, `ceilVal`. The actual value is less than or equal to `ceilVal` only if the result of the expression `actual <= ceilVal` is nonempty and all values are true.

## Input Arguments

**ceilVal**

Maximum value to satisfy the constraint.

## Properties

**CeilingValue**

Maximum value to satisfy the constraint. Set this property through the constructor via the `ceilVal` input argument.

## Methods

## Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

## Examples

### Test That Actual Value Is Less Than or Equal to Provided Ceiling Value

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.IsLessThanOrEqualTo
```

```
testCase = TestCase.forInteractiveUse;
```

Test that the actual value is less than or equal to four.

```
actVal = 3;
testCase.verifyThat(actVal, IsLessThanOrEqualTo(4))
```

```
Interactive verification passed.
```

Test that the actual value is less than or equal to three.

```
testCase.verifyThat(actVal, IsLessThanOrEqualTo(3))
```

```
Interactive verification passed.
```

Test that each element in the actual value array is less than or equal to four.

```
actVal = [1 2 3 4];
testCase.verifyThat(actVal, IsLessThanOrEqualTo(4))
```

```
Interactive verification passed.
```

Test that each element in the actual value matrix is less than or equal to four.

```
actVal = [1 2 3; 4 5 6];
testCase.verifyThat(actVal, IsLessThanOrEqualTo(4))
```

```
Interactive verification failed.
```

```

Framework Diagnostic:

```

```
IsLessThanOrEqualTo failed.
```

```
--> Each element must be less than or equal to the maximum value.
```

```
Failing Indices:
```

```
 4 6
```

```

Actual Value:
 1 2 3
 4 5 6
Maximum Value (Inclusive):
 4

```

The matrix contains two elements that are greater than four.

Test that the actual value, 1, is less than or equal to every element in an array.

```
testCase.verifyThat(1, IsLessThanOrEqualTo([1 2 3]))
```

```
Interactive verification passed.
```

Test that elements in the actual value array are less than the corresponding ceiling values.

```
testCase.verifyThat([4 -9 2], IsLessThanOrEqualTo([5 -3 2]))
```

```
Interactive verification passed.
```

Repeat the test, this time negating the second actual value element.

```
testCase.verifyThat([4 9 2], IsLessThanOrEqualTo([5 -3 2]))
```

```
Interactive verification failed.
```

```

Framework Diagnostic:

```

```
IsLessThanOrEqualTo failed.
```

```
--> Each element must be less than or equal to each corresponding element of the maximum
```

```

Failing Indices:
 2

```

```

Actual Value:
 4 9 2
Maximum Value (Inclusive):
 5 -3 2

```

The negated element is greater than -3.

## **matlab.unittest.constraints.IsOfClass class**

**Package:** matlab.unittest.constraints

**Superclasses:** matlab.unittest.constraints.BooleanConstraint

Constraint specifying class type

### **Construction**

`IsOfClass(class)` provides a constraint specifying the class type. The constraint is satisfied if the actual value is the same class as `class`. The constraint is not satisfied if the actual value derives from `class`.

### **Input Arguments**

#### **class**

Class name that must be matched by the actual value to satisfy the constraint, specified as a fully qualified class name string or a `meta.class` instance.

### **Properties**

#### **Class**

Class name that must be matched by the actual value to satisfy the constraint. Set this property through the constructor via the `class` input argument.

### **Copy Semantics**

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

### **Examples**

#### **Test That Actual Value Class Is Specified Class**

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.IsOfClass
```

```
testCase = TestCase.forInteractiveUse;
```

Verify that the actual value, 5, is a double.

```
testCase.verifyThat(5, IsOfClass('double'))
```

```
Interactive verification passed.
```

Repeat the test using an instance of `meta.class` instead of a string.

```
testCase.verifyThat(5, IsOfClass(?double))
```

```
Interactive verification passed.
```

Assert that zero is an instance of the logical class.

```
testCase.assertThat(0, IsOfClass('logical'))
```

```
Interactive assertion failed.
```

```

Framework Diagnostic:

```

```
IsOfClass failed.
```

```
--> The value's class is incorrect.
```

```
 Actual Class:
```

```
 double
```

```
 Expected Class:
```

```
 logical
```

```
Actual Value:
```

```
 0
```

```
Assertion failed.
```

Verify that `@sin` is a function handle.

```
testCase.verifyThat(@sin, IsOfClass(?function_handle))
```

```
Interactive verification passed.
```

Verify that `name` is an instance of the `char` class.

```
name = 42;
testCase.verifyThat(name, IsOfClass('char'))
```

```
Interactive verification failed.
```

```

Framework Diagnostic:

```

```
IsOfClass failed.
--> The value's class is incorrect.
```

```
 Actual Class:
 double
 Expected Class:
 char
```

```
Actual Value:
 42
```

## Test That Derived Class Is Instance of Specified Class

In a file in your working folder, create a class, `DerivedExample`, that inherits from the `handle` class.

```
classdef DerivedExample < handle
end
```

At the command prompt, create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.IsOfClass
```

```
testCase = TestCase.forInteractiveUse
```

Verify that an instance of the `DerivedExample` class is an instance of a `handle`.

```
exObj = DerivedExample;
testCase.verifyThat(exObj, IsOfClass(?handle))
```

```
Interactive verification failed.
```

```

Framework Diagnostic:

```

```
IsOfClass failed.
```

--> The value's class is incorrect.

```
Actual Class:
 DerivedExample
Expected Class:
 handle
```

```
Actual Value:
 DerivedExample with no properties.
```

Even though `exObj` derives from the `handle` class, it is not an instance of the `handle` class.

Verify that an instance of the `DerivedExample` class is an instance of a `DerivedExample`.

```
testCase.verifyThat(exObj, IsOfClass(?DerivedExample))
```

```
Interactive verification passed.
```

## **matlab.unittest.constraints.IsReal class**

**Package:** matlab.unittest.constraints

**Superclasses:** matlab.unittest.constraints.BooleanConstraint

Constraint specifying real valued array

### **Construction**

`IsReal` provides a constraint specifying a real valued array. This constraint is satisfied only if the actual value contains only real values.

### **Copy Semantics**

Value. To learn how value classes affect copy operations, see [Copying Objects in the MATLAB documentation](#).

### **Examples**

#### **Test That Actual Value Array Is Real Valued**

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.IsReal
```

```
testCase = TestCase.forInteractiveUse;
```

Verify that the values 5 and 5+0i are real.

```
testCase.verifyThat(5, IsReal)
testCase.verifyThat(5+0i, IsReal)
```

```
Interactive verification passed.
Interactive verification passed.
```

Test if the imaginary number is real.

```
testCase.verifyThat(sqrt(-1), IsReal)
```

Interactive verification failed.

```

Framework Diagnostic:

```

IsReal failed.

--> The value must be real.

Actual Value:

```
0.0000000000000000 + 1.0000000000000000i
```

The actual value is imaginary.

Assert that an array contains only real values.

```
testCase.assertThat([0 1 1 2 3 5 8 13], IsReal)
```

Interactive assertion passed.

Test that the array, `arr`, is real.

```
arr = [NaN -Inf];
```

```
testCase.verifyThat(arr, IsReal)
```

Interactive verification passed.

Multiply the array by a complex number and test that the values are not real.

```
testCase.verifyThat(42i*arr, ~IsReal)
```

Interactive verification passed.

## matlab.unittest.constraints.IsSameHandleAs class

**Package:** matlab.unittest.constraints

**Superclasses:** matlab.unittest.constraints.BooleanConstraint

Constraint specifying handle instance same as another

### Construction

`IsSameHandle(h)` provides a constraint specifying a handle instance or group of instances is same as another.

The constraint is satisfied only if each element of the actual value is the same instance as each corresponding element of `h`.

### Input Arguments

**h**

handle object or array of handle objects. The actual value array passed to the qualification must be the same size as `h`.

### Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

### Examples

#### Test Handles for Equality

In a file in your working folder, create the following handle class for interactive testing.

```
classdef ExampleHandle < handle
end
```

At the command prompt, create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.IsSameHandleAs

testCase = TestCase.forInteractiveUse;
```

Instantiate two handles.

```
h1 = ExampleHandle;
h2 = ExampleHandle;
```

Verify that the handle, h1, is the same as h1.

```
testCase.verifyThat(h1, IsSameHandleAs(h1))
```

```
Interactive verification passed.
```

Test that h1 is the same handle instance as h2.

```
testCase.verifyThat(h1, IsSameHandleAs(h2))
```

```
Interactive verification failed.
```

```

Framework Diagnostic:

IsSameHandleAs failed.
--> Values do not refer to the same handle.
```

```
Actual Value:
 ExampleHandle with no properties.
Expected Handle Object:
 ExampleHandle with no properties.
```

Test that two arrays of handles are the same instances.

```
expArr = [h1 h2 h1];
actArr = [h1 h2 h1];
```

```
testCase.verifyThat(expArr, IsSameHandleAs(actArr))
```

```
Interactive verification passed.
```

The arrays satisfy the constraint even though the elements within a particular array are not the same instance as each other.

Verify that the constraint is not satisfied if it expects a single handle and the actual value is an array of the same instances.

```
testCase.verifyThat([h1 h1], IsSameHandleAs(h1))
```

```
Interactive verification failed.
```

```

Framework Diagnostic:

```

```
IsSameHandleAs failed.
```

```
--> Sizes do not match.
```

```
Actual Value Size : [1 2]
Expected Handle Object Size : [1 1]
```

```
Actual Value:
```

```
1x2 ExampleHandle array with no properties.
```

```
Expected Handle Object:
```

```
ExampleHandle with no properties.
```

Similarly, the constraint is not satisfied a single handle instance if it expects an array of handles.

```
testCase.verifyThat(h2, IsSameHandleAs([h2 h2]))
```

```
Interactive verification failed.
```

```

Framework Diagnostic:

```

```
IsSameHandleAs failed.
```

```
--> Sizes do not match.
```

```
Actual Value Size : [1 1]
Expected Handle Object Size : [1 2]
```

```
Actual Value:
```

```
ExampleHandle with no properties.
```

```
Expected Handle Object:
```

```
1x2 ExampleHandle array with no properties.
```

# matlab.unittest.constraints.IsScalar class

**Package:** matlab.unittest.constraints

**Superclasses:** matlab.unittest.constraints.BooleanConstraint

Constraint specifying scalar value

## Construction

IsScalar provides a constraint that specifies a scalar value. The constraint is satisfied if the actual value is a scalar.

## Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

## Examples

### Test That Actual Value Is Scalar

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.IsScalar
```

```
testCase = TestCase.forInteractiveUse;
```

Verify that a value of zero satisfies the IsScalar constraint.

```
testCase.verifyThat(0, IsScalar)
```

```
Interactive verification passed.
```

Assert that a single object is scalar.

```
testCase.assertThat(timeseries(1), IsScalar)
```

```
Interactive verification passed.
```

Verify that a vector is not scalar.

```
testCase.verifyThat([2 3], IsScalar)
```

Interactive verification failed.

```

Framework Diagnostic:

```

IsScalar failed.

--> The value must be a scalar.

--> The value has a size of [1 2].

Actual Value:

```
 2 3
```

Assert that an empty structure does not satisfy the `IsScalar` constraint.

```
testCase.assertThat(struct([]), IsScalar)
```

Interactive assertion failed.

```

Framework Diagnostic:

```

IsScalar failed.

--> The value must be a scalar.

--> The value has a size of [0 0].

Actual Value:

```
 0x0 struct array with no fields.
```

Assertion failed.

**Introduced in R2014b**

# matlab.unittest.constraints.IsSparse class

**Package:** matlab.unittest.constraints

**Superclasses:** matlab.unittest.constraints.BooleanConstraint

Constraint specifying sparse array

## Construction

`IsSparse` creates a constraint specifying a sparse array. This constraint is satisfied only when the actual value is sparse.

## Copy Semantics

Value. To learn how value classes affect copy operations, see [Copying Objects in the MATLAB documentation](#).

## Examples

### Test That Actual Value Array Is Sparse

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.IsSparse
```

```
testCase = TestCase.forInteractiveUse;
```

Create an identity matrix, and test if it is sparse.

```
F = eye(7);
testCase.verifyThat(F, IsSparse)
```

```
Interactive verification failed.
```

```

Framework Diagnostic:

```

```
IsSparse failed.
--> The value must be sparse.
```

```
Actual Value:
```

```
 1 0 0 0 0 0 0
 0 1 0 0 0 0 0
 0 0 1 0 0 0 0
 0 0 0 1 0 0 0
 0 0 0 0 1 0 0
 0 0 0 0 0 1 0
 0 0 0 0 0 0 1
```

The matrix, F, is a full matrix.

Convert F to a sparse matrix and retest for sparsity.

```
S = sparse(F);
testCase.verifyThat(S, IsSparse)
```

```
Interactive verification passed.
```

# matlab.unittest.constraints.IsSubstringOf class

**Package:** matlab.unittest.constraints

**Superclasses:** matlab.unittest.constraints.BooleanConstraint

Constraint specifying substring of another string

## Construction

`IsSubstringOf(superstring)` creates a constraint specifying a substring of another string. The constraint is satisfied only if the actual value is contained within an expected string, `superstring`.

`IsSubstringOf(superstring,Name,Value)` provides a constraint with additional options specified by one or more `Name,Value` pair arguments. `Name` must appear inside single quotes (' '). You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

## Input Arguments

### **superstring**

Text that contains the actual value, specified as a string. `superstring` can include newline characters.

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### **'IgnoringCase'**

Indicator if the constraint is insensitive to case, specified as `false` or `true` (logical 0 or 1)

**Default:** `false`

## 'IgnoringWhitespace'

Indicator if the constraint is insensitive to whitespace, specified as `false` or `true` (logical 0 or 1)

**Default:** `false`

## Properties

### IgnoreCase

Indicator if the constraint is insensitive to case, specified in the name-value pair argument, `'IgnoreCase'`. This property applies at all levels of recursion, such as nested structures.

### IgnoreWhitespace

Indicator if the constraint is insensitive to whitespace, specified in the name-value pair argument, `'IgnoringWhitespace'`. This property applies at all levels of recursion, such as nested structures.

### Superstring

String that includes the actual value, specified in the input argument, `superstring`.

## Copy Semantics

Value. To learn how value classes affect copy operations, see [Copying Objects](#) in the MATLAB documentation.

## Examples

### Test That Actual Value Is Substring of Specified String

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.IsSubstringOf
```

```
testCase = TestCase.forInteractiveUse;
```

Define the actual value string.

```
S = 'This Is One Long String';
```

Test that the actual value string, 'One ', is contained in S.

```
testCase.verifyThat('One', IsSubstringOf(S))
```

```
Interactive verification passed.
```

Test that the actual value string, 'long ', is contained in S.

```
testCase.verifyThat('long', IsSubstringOf(S))
```

```
Interactive verification failed.
```

```

Framework Diagnostic:

IsSubstringOf failed.
--> The string must be found within the superstring.
```

```
Actual String:
 long
Expected Superstring:
 This Is One Long String
```

By default, the `IsSubstringOf` constraint is case sensitive.

Repeat the test ignoring case.

```
testCase.verifyThat('long', IsSubstringOf(S, ...
 'IgnoringCase', true))
```

```
Interactive verification passed.
```

Test that the actual value string, 'thisisone ', is contained in S. For the test to pass, configure the constraint to ignore whitespace and case.

```
testCase.verifyThat('thisisone', IsSubstringOf(S, ...
 'IgnoringCase', true, 'IgnoringWhitespace', true))
```

```
Interactive verification passed.
```

Assert that the actual value string, 'longer', is not contained in S.

```
testCase.assertThat('Longer', -IsSubstringOf(S))
```

Interactive assertion passed.

# matlab.unittest.constraints.IssuesNoWarnings class

**Package:** matlab.unittest.constraints

**Superclasses:** matlab.unittest.constraints.Constraint

Constraint specifying function that issues no warnings

## Construction

`outConstObj = IssuesNoWarnings` creates a constraint, `outConstObj`, specifying a function that issues no warnings when the testing framework invokes it. The constraint is satisfied if no warnings are issued when the testing framework invokes the function.

`outConstObj = IssuesNoWarnings('WhenNargoutIs', numOutputs)` creates a constraint that can determine if the actual value is a function handle that issues no warnings when the testing framework invokes it with a particular number of output arguments, `numOutputs`.

## Input Arguments

### **numOutputs**

Number of outputs the constraint requests when invoking the function handle, specified as a non-negative, real, scalar integer.

**Default:** 0

## Properties

### **FunctionOutputs**

Output arguments produced at invocation of the supplied function handle, specified as a cell array. This property provides access to output arguments. It is read only and the testing framework sets it when it invokes the function handle. The number of outputs is determined by the `Nargout` property.

### **Nargout**

Number of output arguments the instance uses when executing functions. Set this property through the constructor via the `numOutputs` input argument.

## Copy Semantics

Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB documentation.

## Examples

### Instantiate IssuesNoWarnings Constraint

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.IssuesNoWarnings
```

```
testCase = TestCase.forInteractiveUse;
```

Verify that a call to `true` does not result in any warning.

```
testCase.verifyThat(@true, IssuesNoWarnings)
```

```
Interactive verification passed.
```

Verify that a call to `size` with an empty array does not result in any warning. Examine the output arguments.

```
issuesNoWarningsConstraint = IssuesNoWarnings('WhenNargoutIs', 2);
testCase.verifyThat(@() size([]), issuesNoWarningsConstraint)
[actualOut1, actualOut2] = issuesNoWarningsConstraint.FunctionOutputs{:};
```

```
Interactive verification passed.
```

Verify that the constraint is not satisfied if the actual value is not a function handle.

```
testCase.verifyThat(5, IssuesNoWarnings)
```

```
Interactive verification failed.
```

```

Framework Diagnostic:

```

```
IssuesNoWarnings failed.
```

```
--> The value must be an instance of the expected type.
```

```
Actual Class:
 double
Expected Type:
 function_handle
```

```
Actual Value:
 5
```

Verify that the constraint is not satisfied if the actual value results in a warning.

```
testCase.verifyThat(@() warning('some:id', 'Message'), IssuesNoWarnings)
```

```
Warning: Message
```

```
> In @()warning('some:id','Message')
 In FunctionHandleConstraint>FunctionHandleConstraint.invoke at 39

# matlab.unittest.constraints.IssuesWarnings class

**Package:** matlab.unittest.constraints

**Superclasses:** matlab.unittest.constraints.Constraint

Constraint specifying function that issues expected warning profile

## Description

The `IssuesWarnings` class creates a constraint that issues an expected warning profile. The constraint is satisfied only if the actual value is a function handle that issues a specific set of warnings. You specify warnings using warning identifiers.

By default, the constraint only confirms that when the testing framework invokes the function handle, MATLAB issues the specified set of warnings. It ignores the number of times the warnings are issued, in what order they are issued, and whether or not any unspecified warnings are issued. However, you can set parameters to respect the order, the count, and the warning set. Alternatively, you can specify the exact warning profile for comparison.

## Construction

`outConstObj = IssuesWarnings(warnArr)` creates a constraint, `outConstObj`, specifying a function that issues expected warnings, `warnArr`.

`outConstObj = IssuesWarnings(expVal, Name, Value)` creates a constraint with additional options specified by one or more `Name, Value` pair arguments. `Name` must appear inside single quotes ( `' '` ). You can specify several name-value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

## Input Arguments

### **warnArr**

Warning identifiers expected when the testing framework invokes the function handle, specified as a cell array of warning identifiers. If `warnArr` is empty, the constructor throws an `MException`.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### 'Exactly'

Indicator if the value is a function handle that must issue a warning profile that is an exact match, specified as `false` or `true` (logical 0 or 1). When this value is `false`, the instance relies on specification of other parameters and default instance behavior to determine the strictness of its comparison. When set to `true`, the instance requires the warning profile to be exactly the same as the specified warning profile.

**Default:** `false`

### 'RespectingCount'

Indicator whether to respect element counts, specified as `false` or `true` (logical 0 or 1). When this value is `false`, the instance is insensitive to the number of occurrences of members and ignores their frequency. When set to `true`, the instance is sensitive to the total number of set members. This means that, in addition to ensuring that all of the specified warnings are issued, this instance is not satisfied if the number of times that a particular warning issues differs from the number of times that warning is specified in `warnArr`.

**Default:** `false`

### 'RespectingOrder'

Indicator whether to respect the order of elements, specified as `false` or `true` (logical 0 or 1). When this value is `false`, the instance is insensitive to the order of the set members. When set to `true`, the instance is sensitive to the order of the set members. This means that this instance is not satisfied if the order of the issued warnings differs from the order the warnings are specified in `warnArr`.

The order of a given set of warnings is determined by trimming the warning profiles to a profile with no repeated adjacent warnings. For example, the warning profile `{id:A, id:A, id:B, id:C, id:C, id:C, id:A, id:A, id:A}` is trimmed to `{id:A, id:B, id:C, id:A}`.

When this constraint respects order, the order of the warnings that are issued and expected must match the order of the expected warning profile. Warnings issued that are not listed in `warnArr` are ignored when determining order.

**Default:** `false`

### **'RespectingSet'**

Indicator whether to respect set elements, specified as `false` or `true` (logical 0 or 1). When this value is `false`, the instance ignores additional set members. When set to `true`, the instance is sensitive to additional set members. This means that, in addition to ensuring that all of the specified warnings are issued, this instance is not satisfied if any extra, unspecified warnings are issued.

**Default:** `false`

### **'WhenNargoutIs'**

Number of outputs the constraint should request when invoking the function handle, specified as a non-negative, real, scalar integer.

**Default:** `0`

## **Properties**

### **Exact**

Indicator of whether the constraint performs exact comparisons. Set this property through the constructor via the name-value pair argument, `'Exactly'`.

### **ExpectedWarnings**

Expected warning identifiers. Set this read-only property through the constructor via the `warnArr` input argument.

### **FunctionOutputs**

Output arguments produced at invocation of the supplied function handle, specified as a cell array. This property provides access to output arguments. It is read only and the testing framework sets it when it invokes the function handle. The number of outputs is determined by the `Nargout` property.

### **Nargout**

Number of output arguments the instance uses when it executes functions. Set this property through the constructor via the name-value pair argument, 'WhenNargoutIs'.

### **RespectCount**

Indicator if the constraint respects the element counts, specified through the constructor via the name-value pair argument, 'RespectingCount'.

### **RespectOrder**

Indicator if the constraint respects the order of elements, specified through the constructor via the name-value pair argument, 'RespectingOrder'.

### **RespectSet**

Indicator if the constraint respects set elements, specified through the constructor via the name-value pair argument, 'RespectingSet'.

## **Copy Semantics**

Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB documentation.

## **Examples**

### **Instantiate IssuesWarnings Constraint**

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.IssuesWarnings
```

```
testCase = TestCase.forInteractiveUse;
```

Create a helper anonymous function for use in this example. Create several warning identifiers.

```
issueWarnings = @(idCell) cellfun(@(id) warning(id, 'Message'), idCell);
```

```
firstID = 'first:id';
secondID = 'second:id';
thirdID = 'third:id';
```

Verify that the helper function issues a particular warning.

```
testCase.verifyThat(@() issueWarnings({firstID}), ...
 IssuesWarnings({firstID}))
```

Interactive verification passed.

Verify the function issues a warning ignoring count, warning set, and order.

```
testCase.verifyThat(@() issueWarnings({firstID, thirdID, secondID, ...
 firstID}), IssuesWarnings({secondID, firstID}))
```

Interactive verification passed.

Verify the function issues a warning while respecting the warning set.

```
testCase.verifyThat(@() issueWarnings({firstID, thirdID, secondID, ...
 firstID}), IssuesWarnings({firstID, secondID, thirdID}, ...
 'RespectingSet', true))
```

Interactive verification passed.

Verify the function issues a warning while respecting the warning count.

```
testCase.verifyThat(@() issueWarnings({secondID, firstID, thirdID, ...
 secondID}), IssuesWarnings({firstID, secondID, secondID}, ...
 'RespectingCount', true))
```

Interactive verification passed.

Verify the function issues a warning while respecting the warning order.

```
testCase.verifyThat(@() issueWarnings({firstID, secondID, secondID, ...
 thirdID}), IssuesWarnings({firstID, secondID}, 'RespectingOrder', true))
```

Interactive verification passed.

Verify the function issues an exact match to the expected warning profile.

```
testCase.verifyThat(@() issueWarnings({firstID, secondID, secondID, ...
 thirdID}), IssuesWarnings({firstID, secondID, secondID, thirdID}, ...
```

```
'Exactly', true))
```

```
Interactive verification passed.
```

Verify that the constraint is not satisfied if the actual value is not a function handle.

```
testCase.verifyThat(5, IssuesWarnings({firstID}))
```

```
Interactive verification failed.
```

```

Framework Diagnostic:

```

```
IssuesWarnings failed.
```

```
--> The value must be an instance of the expected type.
```

```
Actual Class:
 double
Expected Type:
 function_handle
```

```
Actual Value:
 5
```

Verify that the constraint is not satisfied if the function does not issue a warning.

```
testCase.verifyThat(@rand, IssuesWarnings({firstID}))
```

```
Interactive verification failed.
```

```

Framework Diagnostic:

```

```
IssuesWarnings failed.
```

```
--> The function handle did not issue a correct warning profile.
The expected warning profile ignores:
```

```
Set
Count
Order
```

```
--> The function handle did not issue any warnings.
```

```
Expected Warning Profile:
 first:id
```

```
Evaluated Function:
```

@rand

Verify that the constraint is not satisfied if the function issues a non-specified warning identifier.

```
testCase.verifyThat(@() issueWarnings({firstID}), IssuesWarnings({secondID}))
```

Warning: Message

order and count.

testCase.verifyThat(actVal, IssuesWarnings(warnArr,...
 'RespectingSet',true,'RespectingOrder',true,'RespectingCount',true))

Interactive verification passed.
```

In this example, a constraint that specifies a warning profile that respects set, order and count is not the same as one that specifies an exact warning profile.

## More About

- “Message Identifiers”

## matlab.unittest.constraints.IsTrue class

**Package:** matlab.unittest.constraints

**Superclasses:** matlab.unittest.constraints.Constraint

Constraint specifying true value

### Construction

IsTrue provides a constraint specifying a true value. This constraint is satisfied only by a scalar logical with a value of `true`.

### Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

### Tips

- For faster test execution, use `verifyTrue`, `assertTrue`, `assumeTrue`, or `fatalAssertTrue` instead of `IsTrue`.
- To display custom comparisons in the form of a function handle, use `ReturnsTrue` instead of `IsTrue`.

### Examples

#### Test Actual Value Is True

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.IsTrue
```

```
testCase = TestCase.forInteractiveUse;
```

Test that `true` satisfies the `IsTrue` constraint.

```
testCase.verifyThat(true, IsTrue)
```

```
Interactive verification passed.
```

Test that the `IsTrue` constraint is not satisfied by `false`.

```
testCase.verifyThat(false, IsTrue)
```

```
Interactive verification failed.
```

```

Framework Diagnostic:

```

```
IsTrue failed.
```

```
--> The value must evaluate to "true".
```

```
Actual Value:
```

```
 0
```

The test fails because `false` returns `logical(0)`.

Test that the `IsTrue` constraint is not satisfied by the double `1`.

```
testCase.verifyThat(1, IsTrue)
```

```
Interactive verification failed.
```

```

Framework Diagnostic:

```

```
IsTrue failed.
```

```
--> The value must be logical. It is of type "double".
```

```
Actual Value:
```

```
 1
```

The `IsTrue` constraint is satisfied only by `logical(1)`.

Test that the `IsTrue` constraint is not satisfied by a logical array of ones.

```
testCase.verifyThat([true true true], IsTrue)
```

```
Interactive verification failed.
```

```

Framework Diagnostic:

```

```

IsTrue failed.
--> The value must be scalar. It has a size of [1 3].

Actual Value:
 1 1 1
```

The `IsTrue` constraint is satisfied only if the value is scalar and `logical(1)`.

**See Also**

`IsFalse` | `ReturnsTrue`

# matlab.unittest.constraints.LogicalComparator class

**Package:** matlab.unittest.constraints

Comparator for two logical values

## Construction

`LogicalComparator` creates a comparator for two logical values. The comparator is satisfied if the actual and expected values have the same sparsity and the logical values are equivalent.

## Copy Semantics

Value. To learn how value classes affect copy operations, see [Copying Objects in the MATLAB documentation](#).

## Examples

### Compare Logical Values

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.LogicalComparator
import matlab.unittest.constraints.IsEqualTo
```

```
testCase = TestCase.forInteractiveUse;
```

Test the value of `true`.

```
testCase.assertThat(true, IsEqualTo(true, ...
 'Using', LogicalComparator))
```

Interactive assertion passed.

Test an array of `true` values.

```
testCase.assertThat([true true true], IsEqualTo(true, ...
```

```
 'Using', LogicalComparator))
Interactive assertion failed.

Framework Diagnostic:

IsEqualTo failed.
--> LogicalComparator failed.
 --> The logical values are not equal

Actual Logical Value:
 1 1 1
Expected Logical Value:
 1
Assertion failed.
```

The actual value must be a scalar logical to satisfy the constraint.

Compare the value of 1 to true.

```
testCase.verifyThat(1, IsEqualTo(true, 'Using', LogicalComparator))
```

```
Interactive verification failed.

Framework Diagnostic:

IsEqualTo failed.
--> LogicalComparator failed.
 --> The logical values are not equal

Actual Logical Value:
 1
Expected Logical Value:
 1
```

Compare the value of false to true.

```
testCase.assertThat(false, IsEqualTo(true, 'Using', LogicalComparator))
```

```
Interactive assertion failed.

Framework Diagnostic:
```

```

IsEqualTo failed.
--> LogicalComparator failed.
 --> The logical values are not equal

Actual Logical Value:
 0
Expected Logical Value:
 1
Assertion failed.
```

matlab.unittest.constraints.IsEqualTo

**Introduced in R2013a**

## matlab.unittest.constraints.Matches class

**Package:** matlab.unittest.constraints

**Superclasses:** matlab.unittest.constraints.BooleanConstraint

Constraint specifying string matches regular expression

### Construction

`Matches(expr)` creates a constraint that specifies that a string matches a regular expression. The constraint is satisfied only if the actual value matches the given regular expression, `expr`.

`Matches(expr, 'IgnoringCase', caseInsensitive)` creates a constraint indicating whether to ignore case difference.

### Input Arguments

**expr**

Regular expression that the actual value must match to satisfy the constraint, specified as a string. `expr` can include newline characters.

**caseInsensitive**

Indicator if the constraint is insensitive to case, specified as `false` or `true` (logical 0 or 1)

**Default:** `false`

### Properties

**Expression**

Regular expression that the actual value must match, specified in the input argument, `expr`.

## IgnoreCase

Indicator if the constraint is insensitive to case, specified in the input argument, `ignoreCase`. This property applies at all levels of recursion, such as nested structures.

## Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

## Examples

### Test That Actual Value Matches Regular Expression

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.Matches
```

```
testCase = TestCase.forInteractiveUse;
```

Test that the actual value string, 'Epsilon Eridani', matches 'eps'.

```
testCase.verifyThat('Epsilon Eridani', Matches('^eps'))
```

```
Interactive verification failed.
```

```

Framework Diagnostic:

```

```
Matches failed.
```

```
--> The string did not match the regular expression.
```

```
Actual String:
```

```
 Epsilon Eridani
```

```
Regular Expression:
```

```
 ^eps
```

To satisfy the constraint, configure it to be case insensitive.

```
testCase.verifyThat('Epsilon Eridani', Matches('^eps', ...
```

```
 'IgnoringCase', true))
```

Interactive verification passed.

Define the regular expression that the actual value must match.

```
expr = 'Some[Ss]?tring';
```

The [Ss]? contained in the regular expression indicates that either 'S' or 's' matches at that location 0 or 1 times.

Test that the actual values, 'SomeString' and 'Somestring', satisfy the constraint.

```
testCase.verifyThat('SomeString', Matches(expr))
testCase.verifyThat('Somestring', Matches(expr))
```

Interactive verification passed.

Interactive verification passed.

Test that the actual value 'Sometring' satisfies the constraint.

```
testCase.verifyThat('Sometring', Matches(expr))
```

Interactive verification passed.

Test that the actual value 'somestring' satisfies the constraint.

```
testCase.verifyThat('somestring', Matches(expr))
```

Interactive verification failed.

```

Framework Diagnostic:

```

Matches failed.

--> The string did not match the regular expression.

Actual String:

```
 somestring
```

Regular Expression:

```
 Some[Ss]?tring
```

# matlab.unittest.constraints.NumericComparator class

**Package:** matlab.unittest.constraints

Comparator for numeric data types

## Construction

`NumericComparator` creates a comparator for numeric data types. The comparator is satisfied if inputs are of the same class with equivalent size, complexity, and sparsity, and the built-in `isequaln` function returns `true`.

`NumericComparator('Within',tolObj)` creates a comparator using a specified tolerance. In this case, `NumericComparator` first checks for equivalent class, size, and sparsity of the actual and expected values. If these checks fail, the comparator is not satisfied. If these checks pass and the `isequaln` or complexity check fails, `NumericComparator` delegates comparison to the supplied tolerance, `tolObj`.

## Input Arguments

**tolObj**

matlab.unittest.constraints.Tolerance instance

## Properties

**Tolerance**

Specific tolerance used in construction of the comparator, specified as a `Tolerance` object in the `tolObj` input argument

## Copy Semantics

Value. To learn how value classes affect copy operations, see [Copying Objects](#) in the MATLAB documentation.

## Examples

### Compare Numeric Values

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.NumericComparator
import matlab.unittest.constraints.IsEqualTo
```

```
testCase = TestCase.forInteractiveUse;
```

Use a numeric comparator to test that 1.618 is equal to 1.618.

```
testCase.verifyThat(1.618, IsEqualTo(1.618, ...
 'Using', NumericComparator))
```

Interactive verification passed.

Verify that  $(1+\sqrt{5})/2$  is equal to 1.618.

```
testCase.verifyThat((1+sqrt(5))/2, IsEqualTo(1.618, ...
 'Using', NumericComparator))
```

Interactive verification failed.

```

Framework Diagnostic:

```

IsEqualTo failed.

--> NumericComparator failed.

--> The values are not equal using "isequaln".

--> Failure table:

| Actual           | Expected | Error                | RelativeError  |
|------------------|----------|----------------------|----------------|
| 1.61803398874989 | 1.618    | 3.39887498947977e-05 | 2.100664393992 |

Actual double:

```
1.618033988749895
```

Expected double:

```
1.618000000000000
```

Retest using a relative tolerance of 0.25%.

```
import matlab.unittest.constraints.RelativeTolerance

testCase.verifyThat((1+sqrt(5))/2, IsEqualTo(1.618, ...
 'Using', NumericComparator('Within', RelativeTolerance(0.0025))))

Interactive verification passed.
```

## See Also

[matlab.unittest.constraints.IsEqualTo](#) | [matlab.unittest.constraints.Tolerance](#) | [isequaln](#)

**Introduced in R2013a**

# matlab.unittest.constraints.ObjectComparator class

**Package:** matlab.unittest.constraints

Comparator for MATLAB or Java objects

## Construction

`ObjectComparator` creates a comparator for MATLAB or Java objects. The comparator is satisfied if the built-in `isequal` function returns `true`. However, if the class of the expected value defines an `isequaln` method, the `ObjectComparator` uses that method for comparison instead of `isequal`.

`ObjectComparator('Within',tolObj)` creates a comparator using a specified tolerance. `ObjectComparator` first checks that a call to `isequal` or `isequaln` returns `true`. If the check fails, the `ObjectComparator` checks for equivalent class, size, and sparsity of the actual and expected values. If these checks pass, `ObjectComparator` delegates comparison to the supplied tolerance, `tolObj`. The value of this tolerance must be of the same class as the actual and expected values.

## Input Arguments

**tolObj**

Tolerance instance

## Properties

**Tolerance**

Specific tolerance used in construction of the comparator, specified as a `matlab.unittest.constraints.Tolerance` object in the `tolObj` input argument

## Copy Semantics

Value. To learn how value classes affect copy operations, see [Copying Objects in the MATLAB documentation](#).

## Examples

### Compare MATLAB Objects

In a file, `MyInt.m`, in your working folder, create a subclass of `int8`.

```
classdef MyInt < int8
 methods
 function i = MyInt(value)
 i@int8(value);
 end
 end
end
```

At the command prompt, create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.ObjectComparator
import matlab.unittest.constraints.IsEqualTo
```

```
testCase = TestCase.forInteractiveUse;
```

Use an `ObjectComparator` to test that two instances of `MyInt` are equal to each other.

```
testCase.verifyThat(MyInt(10), ...
 IsEqualTo(MyInt(10), 'Using', ObjectComparator))
```

```
Interactive verification passed.
```

Test the equality of two instances of `MyInt` that are constructed with different input values.

```
testCase.verifyThat(MyInt(11), ...
 IsEqualTo(MyInt(10), 'Using', ObjectComparator))
```

```
Interactive verification failed.
```

```

Framework Diagnostic:

```

```
IsEqualTo failed.
```

```
--> ObjectComparator failed.
```

```
 --> The objects are not equal using "isequal".
```

```
Actual Object:
```

```
MyInt:
 int8 data:
 11
Expected Object:
MyInt:
 int8 data:
 10
```

One instance of `MyInt` has a value of 11, and the other has a value of 10.

Repeat the test and specify that values must be equal within an absolute tolerance of 1.

```
import matlab.unittest.constraints.AbsoluteTolerance
testCase.verifyThat(MyInt(11), IsEqualTo(MyInt(10), ...
 'Using', ObjectComparator('Within', AbsoluteTolerance(MyInt(1)))))
```

Interactive verification passed.

## See Also

**Introduced in R2013a**

# matlab.unittest.constraints.PublicPropertyComparator class

**Package:** matlab.unittest.constraints

Comparator for public properties of MATLAB objects

## Description

The `PublicPropertyComparator` compares public properties of MATLAB objects.

The `PublicPropertyComparator` supports MATLAB objects or arrays of objects and recursively compares data structures contained in the public properties. The `PublicPropertyComparator` is different from the `isequal` function because it examines only the public properties of the objects.

## Construction

`PublicPropertyComparator` creates a comparator for public properties of MATLAB objects. This comparator supports only objects with no public properties.

`PublicPropertyComparator(compObj)` indicates a comparator, `compObj`, that defines the comparator used to compare public properties. This comparator supports recursion only in the data types supported by `compObj`.

`PublicPropertyComparator(compObj, Name, Value)` provides a comparator with additional options specified by one or more `Name, Value` pair arguments.

`PublicPropertyComparator(Name, Value)` provides a comparator for MATLAB objects with no public properties with additional options specified by one or more `Name, Value` pair arguments.

`PublicPropertyComparator.supportingAllValues` creates a comparator for public properties of MATLAB objects. This comparator supports any value in recursion. `supportingAllValues` is a `Static` method of the `PublicPropertyComparator` class.

You typically pass this comparator to another constraint, such as `IsEqualTo`. You can use the `Name, Value` pairs of the `IsEqualTo`

constraint in combination with a comparator constructed with the `PublicPropertyComparator.supportingAllValues` syntax.

## Input Arguments

### **compObj**

Comparator object

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

### **'IgnoringCase'**

Indicator if the comparator is insensitive to case, specified as `false` or `true` (logical 0 or 1). When it is `false`, the comparator is sensitive to case. The comparator uses this name-value pair only if the contents being compared consist of strings.

**Default:** `false`

### **'IgnoringWhitespace'**

Indicator if the comparator is insensitive to whitespace characters, specified as `false` or `true` (logical 0 or 1). When it is `false`, the comparator is sensitive to whitespace characters. Whitespace characters consist of space, form feed, new line, carriage return, horizontal tab, and vertical tab. The comparator uses this name-value pair only if the contents being compared consist of strings.

**Default:** `false`

### **'Recursively'**

Indicator of whether comparator operates recursively, specified as `false` or `true` (logical 0 or 1). When this value is `false`, the comparator does not operate recursively on its data.

When the value is `true`, the data types that the public property comparator supports are fully supported in recursion.

**Default:** `false`

**'Within'**

Tolerance to use for numerical comparison, specified as a `matlab.unittest.constraints.Tolerance` object. The comparator uses this name-value pair only if the contents being compared consist of numeric types.

**Default:** (empty)

## Properties

### IgnoreCase

Indicator if the comparator is insensitive to case, specified in the name-value pair argument, `'IgnoringCase'`

### IgnoreWhitespace

Indicator if the comparator is insensitive to whitespace characters, specified in the name-value pair argument, `'IgnoringWhitespace'`

### Recursive

Indicator of whether comparator operates recursively, specified in the name-value pair argument, `'Recursively'`

### Tolerance

Specific tolerance used in construction of the comparator, specified as a `matlab.unittest.constraints.Tolerance` object in the name-value pair argument, `'Within'`

## Copy Semantics

Value. To learn how value classes affect copy operations, see [Copying Objects](#) in the MATLAB documentation.

## Examples

### Instantiate PublicPropertyComparator Object

In a file in your working folder, construct this `Employee` class.

```
classdef Employee
 properties (SetAccess=immutable)
 Name
 end
 properties (Access=private)
 Location
 end
 methods
 function obj = Employee(name,location)
 obj.Name = name;
 obj.Location = location;
 end
 end
end
```

At the command prompt, create two instances of the `Employee` class.

```
e1 = Employee('sam', 'Building A');
e2 = Employee('Sam', 'Building B');
```

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.IsEqualTo
import matlab.unittest.constraints.PublicPropertyComparator
import matlab.unittest.constraints.StringComparator
```

```
testCase = TestCase.forInteractiveUse;
```

Construct a comparator and verify that `e1` and `e2` are equal.

```
compObj = PublicPropertyComparator;
testCase.verifyThat(e1, IsEqualTo(e2, 'Using', compObj))
```

```
Error using matlab.unittest.constraints.ComparatorList/throwUnsupportedType (line 148)
No comparator in list supports the char below:
 Sam
List contains the following comparators:
 <empty>
```

```
Error in matlab.unittest.constraints.ComparatorList/getAndPrepareComparatorFor (line 19)
 list.throwUnsupportedType(expVal);

Error in matlab.unittest.constraints.ComparatorList/satisfiedBy (line 129)
 comp = list.getAndPrepareComparatorFor(expVal);

Error in matlab.unittest.internal.constraints.FieldComparator/findFirstDifferingField (line 10)
 bool = comp.satisfiedBy(actField, expField);

Error in matlab.unittest.internal.constraints.FieldComparator/fieldsHaveSameContents (line 11)
 bool = comparator.findFirstDifferingField(actVal, expVal);

Error in matlab.unittest.internal.constraints.FieldComparator/satisfiedBy (line 22)
 bool = haveSameClass(actVal, expVal) && ...

Error in matlab.unittest.constraints.IsEqualTo/satisfiedBy (line 165)
 bool = comp.supports(actual) && comp.satisfiedBy(actual, constraint.ExpectedValue);

Error in matlab.unittest.internal.qualifications.QualificationDelegate/qualifyThat (line 10)
 result = constraint.satisfiedBy(actual);

Error in matlab.unittest.qualifications.Verifiable/verifyThat (line 206)
 qualifyThat(verifiable.VerificationDelegate, actual, constraint, varargin{1:nargin-1});
```

The test fails because, by default, the `PublicPropertyComparator` does not support strings.

Construct a comparator that supports strings. Specify that the comparison is not case-sensitive.

```
compObj = PublicPropertyComparator(StringComparator, 'IgnoringCase', true);
testCase.verifyThat(e1, IsEqualTo(e2, 'Using', compObj))
```

Interactive verification passed.

Note that the test passes even though `e1.Location` and `e2.Location` are not the same. Since `Location` is a private property, the comparator does not compare its contents.

## Instantiate `PublicPropertyComparator` Object to Support All Values

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
```

```
import matlab.unittest.constraints.IsEqualTo
import matlab.unittest.constraints.PublicPropertyComparator
```

```
testCase = TestCase.forInteractiveUse;
```

Test a passing case.

```
m1 = MException('Msg:ID', 'MsgText');
m2 = MException('Msg:ID', 'MsgText');
testCase.verifyThat(m1, IsEqualTo(m2, 'Using', ...
 PublicPropertyComparator.supportingAllValues))
```

Interactive verification passed.

Test a failing case.

```
m1 = MException('Msg:ID', 'MsgText');
m2 = MException('Msg:ID', 'msgtext');
testCase.verifyThat(m1, IsEqualTo(m2, 'Using', ...
 PublicPropertyComparator.supportingAllValues))
```

Interactive verification failed.

```

Framework Diagnostic:

```

IsEqualTo failed.

```
--> StringComparator failed.
 Path to failure: <Value>.message
--> The strings are not equal
```

Actual String:

MsgText

Expected String:

msgtext

Actual MException:

MException with properties:

```
 identifier: 'Msg:ID'
 message: 'MsgText'
 cause: {}
 stack: [0x1 struct]
```

Expected MException:

MException with properties:

```
 identifier: 'Msg:ID'
 message: 'msgtext'
 cause: {}
 stack: [0x1 struct]
```

Test a case that passes when the comparator ignores differences in case.

```
m1 = MException('Msg:ID', 'MsgText');
m2 = MException('Msg:ID', 'msgtext');
testCase.verifyThat(m1, IsEqualTo(m2, 'IgnoringCase', true, ...
 'Using', PublicPropertyComparator.supportingAllValues))
```

Interactive verification passed.

## Instantiate `PublicPropertyComparator` Object with Tolerance

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.IsEqualTo
import matlab.unittest.constraints.RelativeTolerance
import matlab.unittest.constraints.PublicPropertyComparator
```

```
testCase = TestCase.forInteractiveUse;
```

Define actual and expected `timeseries` objects. Perturb one of the actual data points by 1%.

```
expected = timeseries(1:10);
actual = expected;
actual.Data(7) = 1.01*actual.Data(7);
```

Test that the actual and expected values are equal within a relative tolerance of 2%.

```
testCase.verifyThat(actual, IsEqualTo(expected, ...
 'Within', RelativeTolerance(.02)))
```

Interactive verification failed.

```

Framework Diagnostic:

```

```
IsEqualTo failed.
```

```
--> ObjectComparator failed.
```

```
--> The objects are not equal using "isequal".
```

```
--> The tolerance does not support timeseries values so it was not used.
```

```

Actual Object:
 timeseries

 Common Properties:
 Name: 'unnamed'
 Time: [10x1 double]
 TimeInfo: [1x1 tsdata.timemetadata]
 Data: [1x1x10 double]
 DataInfo: [1x1 tsdata.datametadata]

 More properties, Methods
Expected Object:
 timeseries

 Common Properties:
 Name: 'unnamed'
 Time: [10x1 double]
 TimeInfo: [1x1 tsdata.timemetadata]
 Data: [1x1x10 double]
 DataInfo: [1x1 tsdata.datametadata]

 More properties, Methods

```

Use the `PublicPropertyComparator` in the construction of the constraint.

```

testCase.verifyThat(actual, IsEqualTo(expected, ...
 'Within', RelativeTolerance(.02), ...
 'Using', PublicPropertyComparator.supportingAllValues))

```

Interactive verification passed.

The test passes because the `PublicPropertyComparator` compares each public property individually instead of comparing the object all at once. In the former test, the `ObjectComparator` compares `timeseries` objects, and therefore relies on the `isequal` method of the `timeseries` class. Due to the perturbation in the actual `timeseries`, `isequal` returns `false`. The comparator does not apply the tolerance because the double-valued tolerance cannot apply directly to the `timeseries` object. In the latter test, the comparator applies the tolerance to each public property that contains double-valued data.

**Introduced in R2014a**

# matlab.unittest.constraints.RelativeTolerance class

**Package:** matlab.unittest.constraints

**Superclasses:** matlab.unittest.constraints.Tolerance

Relative numeric tolerance

## Description

This numeric `Tolerance` assesses the magnitude of the difference between actual and expected values, relative to the expected value. For the tolerance to be satisfied, `abs(expVal - actVal) <= relTol.*abs(expVal)` must be true.

## Construction

`RelativeTolerance(tolVals)` creates a relative tolerance object that assesses the magnitude of the difference between actual and expected values, relative to the expected value.

The data types of the inputs to the `RelativeTolerance` constructor determine which data types the tolerance supports. For example, `RelativeTolerance(10*eps)` constructs a `RelativeTolerance` for comparing double-precision numeric arrays while `RelativeTolerance(int8(2))` constructs a `RelativeTolerance` for comparing numeric arrays of type `int8`. If the actual and expected values being compared contain more than one numeric data type, the tolerance only applies to the data types specified by the values passed into the constructor.

To specify different tolerance values for different data types, you can pass multiple tolerance values to the constructor. For example, `RelativeTolerance(10*eps, 10*eps('single'), int8(1))` constructs an `RelativeTolerance` that applies the following absolute tolerances:

- `10*eps` applies a relative tolerance of `10*eps` for double-precision numeric arrays.
- `10*eps('single')` applies a relative tolerance of `10*eps` for single-precision numeric arrays.
- `int8(1)` applies a relative tolerance of 1 for numeric arrays of type `int8`.

You can specify more than one tolerance for a particular data type by combining tolerances with the & and | operators. To combine two tolerances, the sizes of the tolerance values for each data type must be compatible.

## Input Arguments

### **tolVals**

Numeric tolerances, specified as a comma-separated list of numeric arrays. Each input argument contains the tolerance specification for a particular data type. Each numeric array can be a scalar or array the same size as the actual and expected values.

**Default:**

## Properties

### **Values**

Numeric tolerances, specified by the `tolVals` input argument

## Copy Semantics

Value. To learn how value classes affect copy operations, see [Copying Objects in the MATLAB documentation](#).

## Examples

### **Test with Relative Tolerance**

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.IsEqualTo
import matlab.unittest.constraints.RelativeTolerance

testCase = TestCase.forInteractiveUse;
```

Assert that the difference between an actual value, 4.1, and an expected value, 4.5, is less than 10%.

```
testCase.assertThat(4.1, IsEqualTo(4.5, ...
 'Within', RelativeTolerance(0.1)))
```

Interactive assertion passed.

### Specify Relative Tolerance for Different Data Types

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.IsEqualTo
import matlab.unittest.constraints.RelativeTolerance
```

```
testCase = TestCase.forInteractiveUse;
```

Create the following actual and expected cell arrays.

```
act = {'abc', 123, single(106)};
exp = {'abc', 122, single(105)};
```

Test that the arrays satisfy the `RelativeTolerance` constraint within 2%.

```
testCase.verifyThat(act, IsEqualTo(exp, ...
 'Within', RelativeTolerance(0.02)))
```

Interactive verification failed.

```

Framework Diagnostic:

```

```
IsEqualTo failed.
```

```
--> NumericComparator failed.
```

```
Path to failure: <Value>{3}
```

```
--> The values are not equal using "isequaln".
```

```
--> The tolerance does not support single values so it was not used.
```

```
--> Failure table:
```

| Actual | Expected | Error | RelativeError |
|--------|----------|-------|---------------|
| -----  | -----    | ----- | -----         |
| 106    | 105      | 1     | 0.00952381    |

```
Actual single:
```

```
 106
Expected single:
 105

Actual cell:
 'abc' [123] [106]
Expected cell:
 'abc' [122] [105]
```

The test fails because the tolerance is only applied to the `double` data type.

Create a tolerance object that specifies different tolerances for different data types.

```
tolObj = RelativeTolerance(0.02, single(0.02));
```

A tolerance of 2% is applied to `double` and `single` valued data.

Verify that the expected and actual values satisfy the `RelativeTolerance` constraint.

```
testCase.verifyThat(act, IsEqualTo(exp, 'Within', tolObj))
```

```
Interactive verification passed.
```

## Combine Relative and Absolute Tolerances

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.IsEqualTo
import matlab.unittest.constraints.AbsoluteTolerance
import matlab.unittest.constraints.RelativeTolerance
```

```
testCase = TestCase.forInteractiveUse;
```

Define an actual value approximation for `pi`.

```
act = 3.14;
```

Construct a tolerance object to test that the difference between the actual and expected values is within 0.001 and within 0.25%.

```
tolObj = AbsoluteTolerance(0.001) & RelativeTolerance(0.0025);
```

Verify that the actual value is within the tolerance of the expected value of `pi`.

```
testCase.verifyThat(act, IsEqualTo(pi, 'Within', tolObj))
```

Interactive verification failed.

-----  
 Framework Diagnostic:  
 -----

IsEqualTo failed.

--> NumericComparator failed.

--> The values are not equal using "isequaln".

--> AndTolerance failed.

--> AbsoluteTolerance failed.

--> The error was not within absolute tolerance.

--> RelativeTolerance passed.

--> Failure table:

| Actual | Expected         | Error                | Relative      |
|--------|------------------|----------------------|---------------|
| 3.14   | 3.14159265358979 | -0.00159265358979299 | -0.0005069573 |

Actual double:

3.1400000000000000

Expected double:

3.141592653589793

The actual value does not satisfy the `AbsoluteTolerance` constraint.

Construct a constraint that is satisfied if the values are within 0.001 or 0.25%, and then retest the actual value.

```
tolObj = AbsoluteTolerance(0.001) | RelativeTolerance(0.0025);
testCase.verifyThat(act, IsEqualTo(pi, 'Within', tolObj))
```

Interactive verification passed.

### Combine Absolute and Relative Tolerances to Test Small and Large Values

Combine tolerances so when you test the equality of values, an absolute (floor) tolerance dominates when the values are near zero, and a relative tolerance dominates for larger values.

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.IsEqualTo
import matlab.unittest.constraints.AbsoluteTolerance
import matlab.unittest.constraints.RelativeTolerance
```

```
testCase = TestCase.forInteractiveUse;
```

Define two structures containing electromagnetic properties of a vacuum. One structure, `approxVacuumProps`, contains approximate values for the permeability and speed of light in a vacuum.

```
approxVacuumProps.Permeability = 1.2566e-06; % Approximate
approxVacuumProps.Permittivity = 8.854187817*10^-12;
approxVacuumProps.LightSpeed = 2.9979e+08; % Approximate
```

```
baselineVacuumProps.Permeability = 4*pi*10^-7;
baselineVacuumProps.Permittivity = 8.854187817*10^-12;
baselineVacuumProps.LightSpeed = 1/sqrt(...
 baselineVacuumProps.Permeability*baselineVacuumProps.Permittivity);
```

Test that the relative difference between the approximate and baseline values is within `eps*1e11`.

```
testCase.verifyThat(approxVacuumProps, IsEqualTo(baselineVacuumProps, ...
 'Within', RelativeTolerance(eps*1e11)))
```

```
Interactive verification failed.
```

```

Framework Diagnostic:

```

```
IsEqualTo failed.
```

```
--> NumericComparator failed.
```

```
Path to failure: <Value>.Permeability
```

```
--> The values are not equal using "isequaln".
```

```
--> RelativeTolerance failed.
```

```
--> The error was not within relative tolerance.
```

```
--> Failure table:
```

|  | Actual     | Expected             | Error                 |      |
|--|------------|----------------------|-----------------------|------|
|  | 1.2566e-06 | 1.25663706143592e-06 | -3.70614359173257e-11 | -2.9 |

```
Actual double:
```

```
1.2566000000000000e-06
```

```
Expected double:
```

```
1.256637061435917e-06
```

```
Actual struct:
```

```

 Permeability: 1.2566000000000000e-06
 Permittivity: 8.854187816999999e-12
 LightSpeed: 299790000
Expected struct:
 Permeability: 1.256637061435917e-06
 Permittivity: 8.854187816999999e-12
 LightSpeed: 2.997924580105029e+08

```

The test fails because the relative difference in the permeabilities is not within the tolerance. The difference between the two values is small, but the numbers are close to zero, so the difference relative to their size is not small enough to satisfy the tolerance.

Construct a tolerance object to test that the absolute difference between the approximate and baseline values is within  $1e-4$ .

```
testCase.verifyThat(approxVacuumProps, IsEqualTo(baselineVacuumProps, ...
 'Within', AbsoluteTolerance(1e-4)))
```

Interactive verification failed.

```

Framework Diagnostic:

```

IsEqualTo failed.

--> NumericComparator failed.

Path to failure: <Value>.LightSpeed

--> The values are not equal using "isequaln".

--> AbsoluteTolerance failed.

--> The error was not within absolute tolerance.

--> Failure table:

|  | Actual    | Expected         | Error             | RelativeError    |
|--|-----------|------------------|-------------------|------------------|
|  | 299790000 | 299792458.010503 | -2458.01050287485 | -8.199040493e-06 |

Actual double:

299790000

Expected double:

2.997924580105029e+08

Actual struct:

Permeability: 1.2566000000000000e-06

Permittivity: 8.854187816999999e-12

LightSpeed: 299790000

Expected struct:

```
Permeability: 1.256637061435917e-06
Permittivity: 8.854187816999999e-12
LightSpeed: 2.997924580105029e+08
```

The test fails because the absolute difference in the speed of light is not within the tolerance. The difference between the two values is small relative to their size, but too large to satisfy the tolerance.

Construct a logical disjunction of tolerance objects to test that the absolute difference between the approximate and baseline values is within  $1e-4$  or the relative difference is within  $\text{eps} \times 1e11$ . The test uses this tolerance so permeability values that are close to zero satisfy the absolute (floor) tolerance, and speed of light values that are large, satisfy the relative tolerance.

```
testCase.verifyThat(approxVacuumProps, IsEqualTo(baselineVacuumProps, ...
 'Within', RelativeTolerance(eps*1e11) | AbsoluteTolerance(1e-4)))
```

```
Interactive verification passed.
```

**Introduced in R2013a**

# matlab.unittest.constraints.ReturnsTrue class

**Package:** matlab.unittest.constraints

**Superclasses:** matlab.unittest.constraints.BooleanConstraint

Constraint specifying function handle that returns true

## Construction

ReturnsTrue provides a constraint specifying that a function handle that returns true. The constraint is satisfied only by a function handle that returns a scalar logical with a value of `true`.

When negated using the tilde operator, `~`, this constraint not only passes when the function handle returns `false`, but also when the function handle returns any non-scalar value (such as `[true true]`) or any non-logical (such as `integer valued1`).

## Copy Semantics

Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB documentation.

## Tips

- To display custom comparisons in the form of a function handle, use `ReturnsTrue` instead of `IsTrue`.

## Examples

### Test Actual Value Specified by Function Handle Returns True

These comparisons are shown for example only. There are other constraints that might better handle the particular comparisons.

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.ReturnsTrue
```

```
testCase = TestCase.forInteractiveUse;
```

Verify that the ReturnsTrue constraint is satisfied by the value returned by a handle to true.

```
testCase.verifyThat(@true, ReturnsTrue)
```

```
Interactive verification passed.
```

Verify that the ReturnsTrue constraint is not satisfied by a handle to false.

```
testCase.verifyThat(@false, ReturnsTrue)
```

```
Interactive verification failed.
```

```

Framework Diagnostic:

```

```
ReturnsTrue failed.
```

```
--> The function handle should have evaluated to "true".
```

```
--> Returned value:
```

```
 0
```

```
Actual Function Handle:
```

```
 @false
```

Verify that a call to `isequal` returns true.

```
testCase.verifyThat(@() isequal(1,1), ReturnsTrue)
```

```
Interactive verification passed.
```

Verify that a function that returns a double-valued 1 does not satisfy the ReturnsTrue constraint.

```
testCase.verifyThat(@() double(true), ReturnsTrue)
```

```
Interactive verification failed.
```

```

Framework Diagnostic:

```

```
ReturnsTrue failed.
```

```
--> The function handle should have returned a logical value. It was of type "double".
--> Returned value:
 1
```

```
Actual Function Handle:
 @()double(true)
```

Verify that the negation of a string comparison of 'a' and 'b' returns true.

```
testCase.verifyThat(@() ~strcmp('a','b'), ReturnsTrue)
```

```
Interactive verification passed.
```

Test if a comparison of 'a' to the cell array {'a','a'} returns true.

```
testCase.verifyThat(@() strcmp('a',{'a','a'}), ReturnsTrue)
```

```
Interactive verification failed.
```

```

Framework Diagnostic:

```

```
ReturnsTrue failed.
```

```
--> The function handle should have returned a scalar. The return value had a size of
--> Returned value:
 1 1
```

```
Actual Function Handle:
 @()strcmp('a',{'a','a'})
```

The constraint is not satisfied because the call to `strcmp` results a logical array, not a logical scalar.

Constraint | IsTrue

## matlab.unittest.constraints.StartsWithSubstring class

**Package:** matlab.unittest.constraints

**Superclasses:** matlab.unittest.constraints.BooleanConstraint

Constraint specifying string starting with substring

### Construction

`StartsWithSubstring(prefix)` creates a constraint specifying a string starting with a substring. The constraint is satisfied only if the actual value starts with an expected string, `prefix`.

`StartsWithSubstring(prefix,Name,Value)` provides a constraint with additional options specified by one or more `Name,Value` pair arguments. `Name` must appear inside single quotes ( ' '). You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### Input Arguments

#### **prefix**

Text at the start of the actual value, specified as a string. `prefix` can include newline characters.

#### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

#### **'IgnoringCase'**

Indicator if the constraint is insensitive to case, specified as `false` or `true` (logical 0 or 1)

**Default:** `false`

### 'IgnoringWhitespace'

Indicator if the constraint is insensitive to whitespace, specified as `false` or `true` (logical 0 or 1)

**Default:** `false`

## Properties

### IgnoreCase

Indicator if the constraint is insensitive to case, specified in the name-value pair argument, `'IgnoringCase'`. This property applies at all levels of recursion, such as nested structures.

### IgnoreWhitespace

Indicator if the constraint is insensitive to whitespace, specified in the name-value pair argument, `'IgnoringWhitespace'`. This property applies at all levels of recursion, such as nested structures.

### Prefix

Text at the start of the actual value, specified in the input argument, `prefix`.

## Copy Semantics

Value. To learn how value classes affect copy operations, see [Copying Objects](#) in the MATLAB documentation.

## Examples

### Test That Actual Value Starts with Specified Substring

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.StartsWithSubstring
```

```
testCase = TestCase.forInteractiveUse;
```

Define the actual value string.

```
actVal = 'This Is One Long String';
```

Test that `actVal` starts with the substring `'This'`.

```
testCase.verifyThat(actVal, StartsWithSubstring('This'))
```

```
Interactive verification passed.
```

Test that `actVal` starts with the substring `'this is'`.

```
testCase.verifyThat(actVal, StartsWithSubstring('this is'))
```

```
Interactive verification failed.
```

```

Framework Diagnostic:

```

```
StartsWithSubstring failed.
```

```
--> The string has an incorrect prefix.
```

```
Actual String:
```

```
 This Is One Long String
```

```
Expected Prefix:
```

```
 this is
```

By default, the `StartsWithSubstring` constraint is case sensitive.

Repeat the test, this time ignoring case.

```
testCase.verifyThat(actVal, StartsWithSubstring('this is', ...
 'IgnoringCase', true))
```

```
Interactive verification passed.
```

Test that `actVal` starts with the substring `'thisisone'`. For the test to pass, configure the constraint to ignore whitespace and case.

```
testCase.verifyThat(actVal, StartsWithSubstring('thisisone', ...
 'IgnoringCase', true, 'IgnoringWhitespace', true))
```

```
Interactive verification passed.
```

Assert that `actVal` does not start with the substring 'long'.

```
testCase.assertThat(actVal, ~StartsWithSubstring('Long'))
```

Interactive assertion passed.

## matlab.unittest.constraints.StringComparator class

**Package:** matlab.unittest.constraints

Comparator for two strings

### Construction

`StringComparator` creates a comparator for two strings. The comparator is satisfied if the two strings are equal.

`StringComparator(Name, Value)` creates a comparator with additional options specified by one or more `Name, Value` pair arguments.

### Input Arguments

#### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

#### 'IgnoringCase'

Indicator if the comparator is insensitive to case, specified as `false` or `true` (logical 0 or 1). When it is `false`, the comparator is sensitive to case.

**Default:** `false`

#### 'IgnoringWhitespace'

Indicator if the comparator is insensitive to whitespace characters, specified as `false` or `true` (logical 0 or 1). When it is `false`, the comparator is sensitive to whitespace characters. Whitespace characters consist of space, form feed, new line, carriage return, horizontal tab, and vertical tab.

**Default:** `false`

## Properties

### IgnoreCase

Indicator if the comparator is insensitive to case, specified in the name-value pair argument, 'IgnoringCase'

### IgnoreWhitespace

Indicator if the comparator is insensitive to whitespace characters, specified in the name-value pair argument, 'IgnoringWhitespace'

## Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

## Examples

### Compare Cell Arrays

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.StringComparator
import matlab.unittest.constraints.IsEqualTo
```

```
testCase = TestCase.forInteractiveUse;
```

Verify that the actual and expected strings are equal using a string comparator.

```
expected = 'coffee';
actual = 'coffee';
testCase.verifyThat(actual, IsEqualTo(expected, ...
 'Using', StringComparator))
```

```
Interactive verification passed.
```

Change the actual string and repeat the comparison.

```
expected = 'coF Fee';
```

```
testCase.verifyThat(actual, IsEqualTo(expected, ...
 'Using', StringComparator))
```

Interactive verification failed.

```

Framework Diagnostic:

```

```
IsEqualTo failed.
--> StringComparator failed.
 --> Size check failed.
 --> Sizes do not match.

 Actual size:
 1 6
 Expected size:
 1 7
 --> The strings are not equal.
```

```
Actual char:
 coffee
Expected char:
 coF Fee
```

For the test to pass, construct a comparator that ignores case and whitespace characters.

```
testCase.verifyThat(actual, IsEqualTo(expected, ...
 'Using', StringComparator('IgnoringCase', true, ...
 'IgnoringWhitespace', true)))
```

Interactive verification passed.

## See Also

matlab.unittest.constraints.IsEqualTo | strcmp

**Introduced in R2013a**

# matlab.unittest.constraints.StructComparator class

**Package:** matlab.unittest.constraints

Comparator for MATLAB structure arrays

## Construction

`StructComparator` creates a comparator for MATLAB structure arrays.

`StructComparator(compObj)` indicates a comparator, `compObj`, that defines the comparator used to compare values contained in the structure. By default, a `StructComparator` supports only empty structure arrays.

`StructComparator(compObj, Name, Value)` provides a comparator with additional options specified by one or more `Name, Value` pair arguments.

`StructComparator(Name, Value)` provides a comparator for empty structure arrays with additional options specified by one or more `Name, Value` pair arguments.

## Input Arguments

### `compObj`

Comparator object

A comparator is passed into the `StructComparator` to provide support for data types during recursion. By default, the `StructComparator` supports only empty structure arrays.

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

**'IgnoringCase'**

Indicator if the comparator is insensitive to case, specified as `false` or `true` (logical 0 or 1). When it is `false`, the comparator is sensitive to case. The comparator uses this name-value pair only if the contents being compared are strings.

**Default:** `false`

**'IgnoringWhitespace'**

Indicator if the comparator is insensitive to whitespace characters, specified as `false` or `true` (logical 0 or 1). When it is `false`, the comparator is sensitive to whitespace characters. Whitespace characters consist of space, form feed, new line, carriage return, horizontal tab, and vertical tab. The comparator uses this name-value pair only if the contents being compared are strings.

**Default:** `false`

**'Recursively'**

Indicator of whether comparator operates recursively, specified as `false` or `true` (logical 0 or 1). When this value is `false`, the comparator does not operate recursively on its data.

When the value is `true`, the data types the `StructComparator` supports are fully supported in recursion. For example:

```
comp1 = StructComparator(NumericComparator);
comp2 = StructComparator(NumericComparator, 'Recursively', true);
```

Both `comp1` and `comp2` support structures that contain numeric values as their fields. However, only `comp2` supports structures that recursively contain either structures or numeric values as their fields.

**Default:** `false`

**'Within'**

Tolerance to use for numerical comparison, specified as a `matlab.unittest.constraints.Tolerance` object. This name-value pair is applicable to contents that are numeric types.

**Default:** (empty)

## Properties

### IgnoreCase

Indicator if the comparator is insensitive to case, specified in the name-value pair argument, 'IgnoringCase'

### IgnoreWhitespace

Indicator if the comparator is insensitive to whitespace characters, specified in the name-value pair argument, 'IgnoringWhitespace'

### Recursive

Indicator of whether comparator operates recursively, specified in the name-value pair argument, 'Recursively'

### Tolerance

Specific tolerance used in construction of the comparator, specified as a `matlab.unittest.constraints.Tolerance` object in the name-value pair argument, 'Within'

## Copy Semantics

Value. To learn how value classes affect copy operations, see [Copying Objects in the MATLAB documentation](#).

## Examples

### Compare Numeric Structures

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.IsEqualTo
import matlab.unittest.constraints.AbsoluteTolerance
import matlab.unittest.constraints.StructComparator
import matlab.unittest.constraints.NumericComparator
```

```
testCase = TestCase.forInteractiveUse;
```

Create two equal structures.

```
s1 = struct('id',7,'score',7.3);
s2 = s1;
```

Test that the structures are equal. By default, the `StructComparator` supports only empty structures, so you need to configure the comparator with a `NumericComparator`.

```
testCase.verifyThat(s1, IsEqualTo(s2, 'Using', ...
 StructComparator(NumericComparator)))
```

Interactive verification passed.

Change the score of `s2` and compare the structures again.

```
s2.score = 7.6;
testCase.verifyThat(s1, IsEqualTo(s2, 'Using', ...
 StructComparator(NumericComparator)))
```

Interactive verification failed.

```

Framework Diagnostic:

```

IsEqualTo failed.

```
--> NumericComparator failed.
```

```
 Path to failure: <Value>.score
```

```
 --> The values are not equal using "isequaln".
```

```
 --> Failure table:
```

| Actual | Expected | Error | RelativeError       |
|--------|----------|-------|---------------------|
| 7.3    | 7.6      | -0.3  | -0.0394736842105263 |

```
Actual double:
```

```
 7.3000000000000000
```

```
Expected double:
```

```
 7.6000000000000000
```

```
Actual struct:
```

```
 id: 7
```

```
 score: 7.3000000000000000
```

```
Expected struct:
 id: 7
 score: 7.600000000000000
```

Specify an absolute tolerance for the comparison.

```
testCase.verifyThat(s1, IsEqualTo(s2, 'Using', ...
 StructComparator(NumericComparator, 'Within', ...
 AbsoluteTolerance(0.5)))
```

Interactive verification passed.

### Compare Character Structures

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.IsEqualTo
import matlab.unittest.constraints.StructComparator
import matlab.unittest.constraints.StringComparator
```

```
testCase = TestCase.forInteractiveUse;
```

Create two structures. Make one of the fields a nested structure.

```
e1 = struct('name', struct('first','sam','last','smith'), ...
 'location','Building A');
e2 = e1;
```

Verify that the two structures are equal. Since the struct contains a nested structure, configure the constraint to operate recursively.

```
testCase.verifyThat(e1, IsEqualTo(e2, 'Using', ...
 StructComparator(StringComparator, 'Recursively', true)))
```

Interactive verification passed.

Change the first name field of the e2 structure and repeat the comparison.

```
e2.name.first = ' SAM';
testCase.verifyThat(e1, IsEqualTo(e2, 'Using', ...
 StructComparator(StringComparator, 'Recursively', true)))
```

Interactive verification failed.

```

```

```
Framework Diagnostic:

IsEqualTo failed.
--> StringComparator failed.
 Path to failure: <Value>.name.first
--> Size check failed.
 --> Sizes do not match.
```

```
 Actual size:
 1 3
 Expected size:
 1 4
```

```
--> The strings are not equal.
```

```
Actual char:
 sam
Expected char:
 SAM
```

```
Actual struct:
 name: [1x1 struct]
 location: 'Building A'
Expected struct:
 name: [1x1 struct]
 location: 'Building A'
```

Configure the comparator to ignore case and whitespace characters.

```
testCase.verifyThat(e1, IsEqualTo(e2, 'Using', ...
 StructComparator(StringComparator, 'Recursively', true, ...
 'IgnoringCase', true, 'IgnoringWhitespace', true)))
```

Interactive verification passed.

**Introduced in R2013a**

# matlab.unittest.constraints.Throws class

**Package:** matlab.unittest.constraints

**Superclasses:** matlab.unittest.constraints.Constraint

Constraint specifying function handle that throws MException

## Description

The Throws class creates a constraint that is satisfied only if the actual value is a function handle that throws a specific exception.

If the function throws an MException and the ExpectedException property of the constraint is an error identifier, a qualification failure occurs if the actual MException thrown has a different identifier. Alternately, if the ExpectedException property is a meta.class, the constraint is not satisfied if the actual MException thrown does not derive from the ExpectedException.

## Construction

outConstObj = Throws(excep) provides a constraint, outConstObj, specifying a function handle that throws a particular MException, excep.

outConstObj = Throws(excep,Name,Value) provides a constraint with additional options specified by one or more Name,Value pair arguments.

## Input Arguments

### excep

Error identifier or meta.class representing the specific type of expected exception. If excep is a meta.class but does not derive from MException, the Throws constructor throws an MException.

### Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single

quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

## 'CausedBy'

Expected causes, specified as a cell array of strings or an array of `meta.class` instances.

The testing results in a qualification failure if any causes specified in `CausedBy` are not found within the cause tree.

**Default:** {}

## 'WhenNargoutIs'

Number of outputs the constraint should request when invoking the function handle, specified as a non-negative, real, scalar integer.

**Default:** 0

## 'RespectingSet'

Indicator whether to respect the set of expected causes, specified as `false` or `true` (logical 0 or 1). When this value is `false`, the instance ignores additional causes. When set to `true`, the instance is sensitive to additional causes. A `true` value means that the constraint is not satisfied if the expected exceptions contain causes that are not specified in the 'CausedBy' name-value pair.

**Default:** 0

## Properties

### ExpectedException

Expected `MException` identifier or class. Set this read-only property through the constructor via the `except` input argument.

### Nargout

Number of output arguments the instance uses when executing functions. Set this property through the constructor via the name-value pair argument, 'WhenNargoutIs'.

## RequiredCauses

Expected causes for the function handle throwing an `MException`. Set this property through the constructor via the name-value pair argument, `'CausedBy'`.

## RespectSet

Indicator if the constraint respects set elements, specified through the constructor via the name-value pair argument, `'RespectingSet'`.

# Copy Semantics

Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB documentation.

# Examples

## Instantiate Throws Constraint

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.Throws
```

```
testCase = TestCase.forInteractiveUse;
```

Verify that a function throws a specified error id.

```
testCase.verifyThat(@() error('SOME:error:id','Error!'), ...
 Throws('SOME:error:id'))
```

```
Interactive verification passed.
```

Verify that a function throws a specified exception class.

```
testCase.verifyThat(@() error('SOME:error:id','Error!'), ...
 Throws(?MException))
```

```
Interactive verification passed.
```

Verify that a function, when called with a specified number of outputs, throws a specified error.

```
testCase.verifyThat(@() disp('hi'), Throws('MATLAB:maxlhs', ...
 'WhenNargoutIs', 1))
```

Interactive verification passed.

Check causes by identifier.

```
me = MException('TOP:error:id', 'TopLevelError!');
causeBy1 = MException('causedBy:someOtherError:id', 'CausedByError!');
causeBy2 = MException('causedBy:yetAnotherError:id', 'AnotherCausedByError!');
me = me.addCause(causeBy1);
me = me.addCause(causeBy2);
```

```
testCase.verifyThat(@() me.throw, Throws('TOP:error:id', 'CausedBy', ...
 {'causedBy:someOtherError:id'}))
```

Interactive verification passed.

Check that the exception does not include any additional causes then the ones specified by 'CausedBy'.

```
testCase.verifyThat(@() me.throw, Throws('TOP:error:id', 'CausedBy', ...
 {'causedBy:someOtherError:id'}, 'RespectingSet', true))
```

Interactive verification failed.

```

## matlab.unittest.constraints.Tolerance class

**Package:** matlab.unittest.constraints

Abstract interface class for tolerances

### Description

Tolerances define a notion of fuzzy equality for a set of data types and can be plugged in to the `IsEqualTo` constraint through the ‘`Within`’ name-value pair argument.

Classes that derive from the `Tolerance` interface class must provide a tolerance definition. Use the `satisfiedBy` method to implement the tolerance definition. Classes that derive from the `Tolerance` class also must provide a diagnostic for two compared values. The testing framework uses the diagnostic when the compared values are outside of the allowable tolerance. Use the `getDiagnosticFor` method to implement this condition. Finally, classes that derive from the `Tolerance` class must provide a means to determine which data types the tolerance supports. Define the supported data types by implementing the `supports` method.

### Methods

|                               |                                                                    |
|-------------------------------|--------------------------------------------------------------------|
| <code>getDiagnosticFor</code> | Produce diagnostic for two values specified to be within tolerance |
| <code>satisfiedBy</code>      | Determine whether two values are within tolerance                  |
| <code>supports</code>         | Determine whether tolerance supports specified data type           |

### Copy Semantics

Value. To learn how value classes affect copy operations, see [Copying Objects in the MATLAB documentation](#).

## Related Examples

- [“Create Custom Tolerance”](#)

## getDiagnosticFor

**Class:** matlab.unittest.constraints.Tolerance

**Package:** matlab.unittest.constraints

Produce diagnostic for two values specified to be within tolerance

### Syntax

```
diag = getDiagnosticFor(tolObj,actVal,expVal)
```

### Description

`diag = getDiagnosticFor(tolObj,actVal,expVal)` produces a diagnostic, `diag`, for a value, `actVal`, evaluated against another value, `expVal`, within the tolerance defined by `tolObj`. When creating a custom tolerance, the class author must implement the `getDiagnosticFor` method so that it analyzes the two values, `actVal` and `expVal`, against the tolerance, `tolObj`, and instantiates and returns a `matlab.unittest.diagnostics.Diagnostic` object.

Typically, this diagnostic is used when the `getDiagnosticFor` method of `IsEqualTo` is invoked, and the result is incorporated into the diagnostic output of the `IsEqualTo` constraint.

### Input Arguments

**actVal**

Value to determine if is within tolerance of `expVal`

**tolObj**

Tolerance instance

**expVal**

Expected value

## See Also

ConstraintDiagnostic | Diagnostic | satisfiedBy | supports

## Related Examples

- “Create Custom Tolerance”

## satisfiedBy

**Class:** matlab.unittest.constraints.Tolerance

**Package:** matlab.unittest.constraints

Determine whether two values are within tolerance

## Syntax

TF = satisfiedBy(tolObj,actVal,expVal)

## Description

TF = satisfiedBy(tolObj,actVal,expVal) determines whether two values, actVal and expVal, are within the tolerance defined by tolObj. The satisfiedBy method is used to determine whether the tolerance is met. It returns true or false (logical 0 or 1). When creating a custom tolerance, a class author uses this method to contain the tolerance definition.

## Input Arguments

### actVal

Value to determine if is within tolerance of expVal

### tolObj

Tolerance instance

### expVal

Expected value

## See Also

getDiagnosticFor | supports

## **Related Examples**

- “Create Custom Tolerance”

## supports

**Class:** matlab.unittest.constraints.Tolerance

**Package:** matlab.unittest.constraints

Determine whether tolerance supports specified data type

## Syntax

TF = supports(tolObj, typeVal)

## Description

TF = supports(tolObj, typeVal) determines whether the tolerance supports a specific data type. It returns true or false (logical 0 or 1).

The `supports` method provides the ability for a tolerance author to specify support for data types. Generally, the method operates by examining the type of `typeVal` to determine whether it is supported.

## Input Arguments

### tolObj

Tolerance instance

### typeVal

Value used to determine tolerance support

## See Also

getDiagnosticFor | satisfiedBy

## Related Examples

- “Create Custom Tolerance”

## contrast

Grayscale colormap for contrast enhancement

### Syntax

```
cmap = contrast(X)
cmap = contrast(X,m)
```

### Description

The `contrast` function enhances the contrast of an `image`. It creates a new gray colormap, `cmap`, that has an approximately equal intensity distribution. All three elements in each row are identical.

`cmap = contrast(X)` returns a gray colormap that is the same length as the current colormap. If there are `NaN` or `Inf` elements in `X` the length of the colormap increases.

`cmap = contrast(X,m)` returns an `m`-by-3 gray colormap.

### Examples

#### Display Image with Gray Colormap

Load `clown` to get image `X` and its associated colormap, `map`. Display the image produced by `X` and `map`.

```
load clown
figure
image(X)
colormap(map)
```

Use `contrast` to return a gray colormap that is the same length as the current colormap, `map`. Display the image with the new colormap, `cmap`.

```
cmap = contrast(X);
colormap(cmap)
```

**See Also**

brighten | image | colormap

**Introduced before R2006a**

## conv

Convolution and polynomial multiplication

### Syntax

```
w = conv(u,v)
w = conv(u,v,shape)
```

### Description

`w = conv(u,v)` returns the convolution of vectors `u` and `v`. If `u` and `v` are vectors of polynomial coefficients, convolving them is equivalent to multiplying the two polynomials.

`w = conv(u,v,shape)` returns a subsection of the convolution, as specified by `shape`. For example, `conv(u,v,'same')` returns only the central part of the convolution, the same size as `u`, and `conv(u,v,'valid')` returns only the part of the convolution computed without the zero-padded edges.

### Examples

#### Polynomial Multiplication via Convolution

Create vectors `u` and `v` containing the coefficients of the polynomials  $x^2 + 1$  and  $2x + 7$ .

```
u = [1 0 1];
v = [2 7];
```

Use convolution to multiply the polynomials.

```
w = conv(u,v)
```

```
w =
```

```
 2 7 2 7
```

w contains the polynomial coefficients for  $2x^3 + 7x^2 + 2x + 7$ .

### Vector Convolution

Create two vectors and convolve them.

```
u = [1 1 1];
v = [1 1 0 0 0 1 1];
w = conv(u,v)
```

w =

```
1 2 2 1 0 1 2 2 1
```

The length of w is `length(u)+length(v)-1`, which in this example is 9.

### Central Part of Convolution

Create two vectors. Find the central part of the convolution of u and v that is the same size as u.

```
u = [-1 2 3 -2 0 1 2];
v = [2 4 -1 1];
w = conv(u,v, 'same')
```

w =

```
15 5 -9 7 6 7 -1
```

w has a length of 7. The full convolution would be of length `length(u)+length(v)-1`, which in this example would be 10.

## Input Arguments

**u, v** — Input vectors  
vectors

Input vectors, specified as either row or column vectors. The output vector is the same orientation as the first input argument, `u`. The vectors `u` and `v` can be different lengths or data types.

Data Types: `double` | `single`

Complex Number Support: Yes

### **shape** — Subsection of convolution

`'full'` (default) | `'same'` | `'valid'`

Subsection of the convolution, specified as `'full'`, `'same'`, or `'valid'`.

|                      |                                                                                                                                                                                                                                                                                                     |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>'full'</code>  | Full convolution (default).                                                                                                                                                                                                                                                                         |
| <code>'same'</code>  | Central part of the convolution of the same size as <code>u</code> .                                                                                                                                                                                                                                |
| <code>'valid'</code> | Only those parts of the convolution that are computed without the zero-padded edges. Using this option, <code>length(w)</code> is <code>max(length(u)-length(v)+1,0)</code> , except when <code>length(v)</code> is zero. If <code>length(v) = 0</code> , then <code>length(w) = length(u)</code> . |

## **More About**

### **Convolution**

The convolution of two vectors, `u` and `v`, represents the area of overlap under the points as `v` slides across `u`. Algebraically, convolution is the same operation as multiplying polynomials whose coefficients are the elements of `u` and `v`.

Let `m = length(u)` and `n = length(v)`. Then `w` is the vector of length `m+n-1` whose `k`th element is

$$w(k) = \sum_j u(j)v(k-j+1).$$

The sum is over all the values of `j` that lead to legal subscripts for `u(j)` and `v(k-j+1)`, specifically `j = max(1, k+1-n) : min(k, m)`. When `m = n`, this gives

$$\begin{aligned}w(1) &= u(1)*v(1) \\w(2) &= u(1)*v(2)+u(2)*v(1) \\w(3) &= u(1)*v(3)+u(2)*v(2)+u(3)*v(1)\end{aligned}$$

$$\begin{aligned} \dots \\ \dot{w}(n) &= u(1)*v(n)+u(2)*v(n-1)+ \dots +u(n)*v(1) \\ \dots \\ \dot{w}(2*n-1) &= u(n)*v(n) \end{aligned}$$

**See Also**

**Introduced before R2006a**

## conv2

2-D convolution

### Syntax

```
C = conv2(A,B)
C = conv2(h1,h2,A)
C = conv2(...,shape)
```

### Description

`C = conv2(A,B)` computes the two-dimensional convolution of matrices `A` and `B`. If one of these matrices describes a two-dimensional finite impulse response (FIR) filter, the other matrix is filtered in two dimensions. The size of `C` is determined as follows: if `[ma,na] = size(A)`, `[mb,nb] = size(B)`, and `[mc,nc] = size(C)`, then `mc = max([ma+mb-1,ma,mb])` and `nc = max([na+nb-1,na,nb])`.

`C = conv2(h1,h2,A)` first convolves each column of `A` with the vector `h1` and then convolves each row of the result with the vector `h2`. The size of `C` is determined as follows: if `n1 = length(h1)` and `n2 = length(h2)`, then `mc = max([ma+n1-1,ma,n1])` and `nc = max([na+n2-1,na,n2])`.

`C = conv2(...,shape)` returns a subsection of the two-dimensional convolution, as specified by the `shape` parameter:

|         |                                                                                                                                                                                 |
|---------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'full'  | Returns the full two-dimensional convolution (default).                                                                                                                         |
| 'same'  | Returns the central part of the convolution of the same size as <code>A</code> .                                                                                                |
| 'valid' | Returns only those parts of the convolution that are computed without the zero-padded edges. Using this option, <code>size(C) = max([ma-max(0,mb-1),na-max(0,nb-1)],0)</code> . |

---

**Note:** All numeric inputs to `conv2` must be of type `double` or `single`.

---

## Examples

### Shape for Subsection of 2-D Convolution

For the 'same' case, `conv2` returns the central part of the convolution. If there are an odd number of rows or columns, the “center” leaves one more at the beginning than the end.

This example first computes the convolution of A using the default ('full') shape, then computes the convolution using the 'same' shape. Note that the array returned using 'same' corresponds to the red highlighted elements of the array returned using the default shape.

```
A = rand(3);
B = rand(4);
C = conv2(A,B) % C is 6-by-6

C =
 0.1838 0.2374 0.9727 1.2644 0.7890 0.3750
 0.6929 1.2019 1.5499 2.1733 1.3325 0.3096
 0.5627 1.5150 2.3576 3.1553 2.5373 1.0602
 0.9986 2.3811 3.4302 3.5128 2.4489 0.8462
 0.3089 1.1419 1.8229 2.1561 1.6364 0.6841
 0.3287 0.9347 1.6464 1.7928 1.2422 0.5423

Cs = conv2(A,B,'same') % Cs is the same size as A: 3-by-3
Cs =
 2.3576 3.1553 2.5373
 3.4302 3.5128 2.4489
 1.8229 2.1561 1.6364
```

### Extract Edges from Raised Pedestal

In image processing, the Sobel edge finding operation is a two-dimensional convolution of an input array with the special matrix:

```
s = [1 2 1; 0 0 0; -1 -2 -1];
```

These commands extract the horizontal edges from a raised pedestal.

```
A = zeros(10);
```

```
A(3:7,3:7) = ones(5);
H = conv2(A,s);
figure, mesh(H)
```

Transposing the filter  $s$  extracts the vertical edges of  $A$ .

```
V = conv2(A,s');
figure, mesh(V)
```

This figure combines both horizontal and vertical edges.

```
figure
mesh(sqrt(H.^2 + V.^2))
```

## More About

### Algorithms

`conv2` uses a straightforward formal implementation of the two-dimensional convolution equation in spatial form. If  $a$  and  $b$  are functions of two discrete variables,  $n_1$  and  $n_2$ , then the formula for the two-dimensional convolution of  $a$  and  $b$  is

$$c(n_1, n_2) = \sum_{k_1=-\infty}^{\infty} \sum_{k_2=-\infty}^{\infty} a(k_1, k_2) b(n_1 - k_1, n_2 - k_2)$$

In practice however, `conv2` computes the convolution for finite intervals.

Note that matrix indices in MATLAB software always start at 1 rather than 0. Therefore, matrix elements `A(1,1)`, `B(1,1)`, and `C(1,1)` correspond to mathematical quantities  $a(0,0)$ ,  $b(0,0)$ , and  $c(0,0)$ .

# convhull

Convex hull

---

**Note:** Qhull-specific options are no longer supported. Remove the `OPTIONS` argument from all instances in your code that pass it to `convhull`.

---

## Syntax

```
K = convhull(X,Y)
K = convhull(X,Y,Z)
K = convhull(X)
K = convhull(...,'simplify', logicalvar)
[K,V] = convhull(...)
```

## Definitions

`convhull` returns the convex hull of a set of points in 2-D or 3-D space.

## Description

`K = convhull(X,Y)` returns the 2-D convex hull of the points  $(X,Y)$ , where  $X$  and  $Y$  are column vectors. The convex hull  $K$  is expressed in terms of a vector of point indices arranged in a counterclockwise cycle around the hull.

`K = convhull(X,Y,Z)` returns the 3-D convex hull of the points  $(X,Y,Z)$ , where  $X$ ,  $Y$ , and  $Z$  are column vectors.  $K$  is a triangulation representing the boundary of the convex hull.  $K$  is of size `mtri`-by-3, where `mtri` is the number of triangular facets. That is, each row of  $K$  is a triangle defined in terms of the point indices.

`K = convhull(X)` returns the 2-D or 3-D convex hull of the points  $X$ . This variant supports the definition of points in matrix format.  $X$  is of size `mpts`-by-`ndim`, where `mpts`

is the number of points and `ndim` is the dimension of the space where the points reside,  $2 \leq \text{ndim} \leq 3$ . The output facets are equivalent to those generated by the 2-input or 3-input calling syntax.

`K = convhull(..., 'simplify', logicalvar)` provides the option of removing vertices that do not contribute to the area/volume of the convex hull, the default is false. Setting 'simplify' to true returns the topology in a more concise form.

`[K,V] = convhull(...)` returns the convex hull `K` and the corresponding area/volume `V` bounded by `K`.

## Visualization

Use `plot` to plot the output of `convhull` in 2-D. Use `trisurf` or `trimesh` to plot the output of `convhull` in 3-D.

## Examples

### Plot 2-D Convex Hull

```
xx = -1:.05:1;
yy = abs(sqrt(xx));
[x,y] = pol2cart(xx,yy);
k = convhull(x,y);
plot(x(k),y(k), 'r-', x,y, 'b*')
```

**See Also**

**Introduced before R2006a**

# convhulln

N-D convex hull

## Syntax

```
K = convhulln(X)
K = convhulln(X, options)
[K, v] = convhulln(...)
```

## Description

`K = convhulln(X)` returns the indices `K` of the points in `X` that comprise the facets of the convex hull of `X`. `X` is an `m`-by-`n` array representing `m` points in `N`-dimensional space. If the convex hull has `p` facets then `K` is `p`-by-`n`.

`convhulln` uses `Qhull`.

`K = convhulln(X, options)` specifies a cell array of strings `options` to be used as options in `Qhull`. The default options are:

- `{ 'Qt' }` for 2-, 3-, and 4-dimensional input
- `{ 'Qt', 'Qx' }` for 5-dimensional input and higher.

If `options` is `[]`, the default options are used. If `options` is `{ '' }`, no options are used, not even the default. For more information on `Qhull` and its options, see <http://www.qhull.org/>.

`[K, v] = convhulln(...)` also returns the volume `v` of the convex hull.

## Visualization

Plotting the output of `convhulln` depends on the value of `n`:

- For `n = 2`, use `plot` as you would for `convhull`.
- For `n = 3`, you can use `trisurf` to plot the output. The calling sequence is

```
K = convhulln(X);
trisurf(K,X(:,1),X(:,2),X(:,3))
```

- You cannot plot `convhulln` output for  $n > 3$ .

## Examples

The following example illustrates the options input for `convhulln`. The following commands

```
X = [0 0; 0 1e-10; 0 0; 1 1];
K = convhulln(X)
```

return a warning.

```
Warning: qhull precision warning:
The initial hull is narrow
(cosine of min. angle is 0.9999999999999998).
A coplanar point may lead to a wide facet.
Options 'QbB' (scale to unit box) or 'Qbb'
(scale last coordinate) may remove this warning.
Use 'Pp' to skip this warning.
```

To suppress the warning, use the option `'Pp'`. The following command passes the option `'Pp'`, along with the default `'Qt'`, to `convhulln`.

```
K = convhulln(X,{'Qt','Pp'})
```

```
K =
```

```
1 4
1 2
4 2
```

## More About

### Algorithms

`convhulln` is based on Qhull [1]. For information about Qhull, see <http://www.qhull.org/>. For copyright information, see <http://www.qhull.org/COPYING.txt>.

## **convn**

N-D convolution

### **Syntax**

```
C = convn(A,B)
C = convn(A,B, 'shape')
```

### **Description**

`C = convn(A,B)` computes the N-dimensional convolution of the arrays `A` and `B`. The size of the result is `size(A)+size(B)-1`.

`C = convn(A,B, 'shape')` returns a subsection of the N-dimensional convolution, as specified by the `shape` parameter:

|                      |                                                                                                                                                                                                           |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>'full'</code>  | Returns the full N-dimensional convolution (default).                                                                                                                                                     |
| <code>'same'</code>  | Returns the central part of the result that is the same size as <code>A</code> .                                                                                                                          |
| <code>'valid'</code> | Returns only those parts of the convolution that can be computed without assuming that the array <code>A</code> is zero-padded. The size of the result is<br><br><code>max(size(A)-size(B) + 1, 0)</code> |

# matlab.mixin.CustomDisplay class

**Package:** matlab.mixin

Display customization interface class

## Description

This class provides an interface for customizing the MATLAB display of objects. Derive your class from `matlab.mixin.CustomDisplay` to add the custom display functionality to your class.

`matlab.mixin.CustomDisplay` implements three public sealed methods. `disp` and `display` provide a simple object display. The `details` method provides a standard formal display of object information.

For customizing object display, `matlab.mixin.CustomDisplay` defines a number of protected methods that you can override in your subclass. By overriding specific methods, you can customize specific aspects of the object display.

---

**Note:** You cannot use `matlab.mixin.CustomDisplay` to derive a custom display for enumeration classes. For an alternative approach, see “Overload the disp Function”

---

## Methods

|                                        |                                               |
|----------------------------------------|-----------------------------------------------|
| <code>convertDimensionsToString</code> | Return array dimensions as string             |
| <code>details</code>                   | Fully detailed formal object display          |
| <code>disp</code>                      | Simple informal object display                |
| <code>display</code>                   | Print variable name and display object        |
| <code>displayEmptyObject</code>        | Display for empty object arrays               |
| <code>displayNonScalarObject</code>    | Display format for non-scalar objects         |
| <code>displayPropertyGroups</code>     | Display titles and property groups as defined |

|                                                 |                                                    |
|-------------------------------------------------|----------------------------------------------------|
| <code>displayScalarHandleToDeletedObject</code> | Display format for deleted scalar handles          |
| <code>displayScalarObject</code>                | Display format for scalar objects                  |
| <code>getClassNameForHeader</code>              | Return class name for display                      |
| <code>getDeletedHandleText</code>               | Returns text for handle to deleted object display  |
| <code>getDetailedFooter</code>                  | Returns default detailed footer for object display |
| <code>getDetailedHeader</code>                  | Returns default detailed header for object display |
| <code>getFooter</code>                          | Build and return display footer text               |
| <code>getHandleText</code>                      | Return string 'handle' with link to documentation  |
| <code>getHeader</code>                          | Build and return display header text               |
| <code>getPropertyGroups</code>                  | Construct array of property groups                 |
| <code>getSimpleHeader</code>                    | Return simple header for object display            |

## Attributes

|                               |                                                                                             |
|-------------------------------|---------------------------------------------------------------------------------------------|
| <code>Abstract</code>         | This class defines an interface that subclasses inherit. You cannot instantiate this class. |
| <code>HandleCompatible</code> | You can use this class to derive both handle and value classes.                             |

**Introduced in R2013b**

# matlab.mixin.CustomDisplay.convertDimensionsToString

**Class:** matlab.mixin.CustomDisplay

**Package:** matlab.mixin

Return array dimensions as string

## Syntax

```
dimstr = matlab.mixin.CustomDisplay.convertDimensionsToString(obj)
```

## Description

`dimstr = matlab.mixin.CustomDisplay.convertDimensionsToString(obj)` converts a size vector into a properly formatted string of dimensions for the nonscalar header.

## Input Arguments

**obj**

MATLAB object

**Default:**

## Output Arguments

**dimstr**

String representing the object's dimensions as determined by calling `size`.

## Attributes

Static

true

|        |           |
|--------|-----------|
| Access | Protected |
| Sealed | true      |
| Hidden | true      |

## details

**Class:** matlab.mixin.CustomDisplay

**Package:** matlab.mixin

Fully detailed formal object display

## Syntax

details(obj)

## Description

details(obj) displays the detailed state of obj. The detailed display is not affected by customizations made to classes derived from matlab.mixin.CustomDisplay.

## Attributes

|                 |                                                                                             |
|-----------------|---------------------------------------------------------------------------------------------|
| Access = public | You can call details on any object that is a class derived from matlab.mixin.CustomDisplay. |
| Sealed          | You cannot override the details method in your subclass of matlab.mixin.CustomDisplay       |

## Input Arguments

**obj**

Instance of a class derived from matlab.mixin.CustomDisplay.

**Default:** none

## Examples

Suppose EmployeeInfo is a subclass of matlab.mixin.CustomDisplay

details(e1)

EmployeeInfo handle with properties:

    Name: 'Bill Tork'  
    JobTitle: 'Software Engineer'  
    Department: 'Product Development'  
    Salary: 1000  
    Password: 'bill123'

Methods, Events, Superclasses

# display

**Class:** matlab.mixin.CustomDisplay

**Package:** matlab.mixin

Print variable name and display object

## Syntax

```
display(obj)
```

## Description

`display(obj)` prints the name of input argument `obj` as it appears in the workspace of the caller. If there is no assignment to a variable, `display` uses, `ans`. `display` then calls the `disp` method to print the object.

## Input Arguments

**obj**

Object array of a class derived from `matlab.mixin.CustomDisplay`

## Attributes

|        |        |
|--------|--------|
| Access | public |
| Sealed | true   |

To learn about attributes of methods, see [Method Attributes](#) in the MATLAB Object-Oriented Programming documentation.

## **Related Examples**

- “Custom Display Interface”

# displayEmptyObject

**Class:** matlab.mixin.CustomDisplay

**Package:** matlab.mixin

Display for empty object arrays

## Syntax

```
displayEmptyObject(obj)
```

## Description

`displayEmptyObject(obj)` is called by `disp` when the object, `obj`, is empty. An object array is empty if one or more of its dimensions are zero. An empty object array is never scalar.

The default display of an empty object consists of a header and a list of property names. The header consists of the object's dimensions and the properties are shown in the order defined in the class definition. `displayEmptyObject` shows only those properties with `public GetAccess` and `Hidden` set to `false`.

Override this method to customize the appearance of an empty object array.

## Input Arguments

**obj**

Object of a class derived from `matlab.mixin.CustomDisplay`

**Default:**

## Attributes

Access

protected

## Related Examples

- [“Custom Display Interface”](#)

# displayNonScalarObject

**Class:** matlab.mixin.CustomDisplay

**Package:** matlab.mixin

Display format for non-scalar objects

## Syntax

```
displayNonScalarObject(obj)
```

## Description

`displayNonScalarObject(obj)` is called by the `disp` method when the object, `obj`, is nonscalar (`prod(size(obj)) > 1`)

The default display of a nonscalar object array consists of a header and a list of property names. The header consists of the object's dimensions and the properties are shown in the order defined in the class definition. `displayNonScalarObject` shows only those properties with public `GetAccess` and `Hidden` set to `false`.

Override this method to customize the display a nonscalar object array.

## Input Arguments

**obj**

Object array of a class derived from `matlab.mixin.CustomDisplay`

**Default:**

## Attributes

Access

protected

To learn about attributes of methods, see [Method Attributes](#) in the MATLAB Object-Oriented Programming documentation.

**Class:** matlab.mixin.CustomDisplay

**Package:** matlab.mixin

Display titles and property groups as defined

## Syntax

```
matlab.mixin.CustomDisplay.displayPropertyGroups(obj,
propertyGroupArray)
```

## Description

`matlab.mixin.CustomDisplay.displayPropertyGroups(obj, propertyGroupArray)` displays titles and custom property lists as defined by the property groups.

## Input Arguments

**obj**

MATLAB object

**Default:**

**propertyGroupArray**

Array of `matlab.mixin.util.PropertyGroup` objects.

**Default:**

## Attributes

Static

true

|        |           |
|--------|-----------|

# displayScalarHandleToDeletedObject

**Class:** matlab.mixin.CustomDisplay

**Package:** matlab.mixin

Display format for deleted scalar handles

## Syntax

```
displayScalarHandleToDeletedObject(obj)
```

## Description

`displayScalarHandleToDeletedObject(obj)` is called by the `disp` method when `obj` is:

- An instance of a handle class
- Scalar
- A handle to a deleted object

That is, the following expression is `true`.

```
isa(obj, 'handle') && isscalar(obj) && ~isvalid(obj)
```

Override this method to customize the appearance of your object's display when it is deleted.

## Input Arguments

**obj**

Object of a class derived from `matlab.mixin.CustomDisplay`

**Default:**

## Attributes

Access

protected

To learn about attributes of methods, see [Method Attributes](#) in the MATLAB Object-Oriented Programming documentation.

- [“Custom Display Interface”](#)

# displayScalarObject

**Class:** matlab.mixin.CustomDisplay

**Package:** matlab.mixin

Display format for scalar objects

## Syntax

```
displayScalarObject(obj)
```

## Description

`displayScalarObject(obj)` is called by the `disp` method when the object, `obj`, is scalar (`prod(size(obj)) == 1`).

The default display of a scalar object consists of a header and a list of properties and their values. Properties are shown in the order they are defined in the class definition. `displayScalarObject` shows only those properties with public `GetAccess` and `Hidden` set to `false`.

Override this method to customize the display of a scalar object.

## Input Arguments

**obj**

Object of a class derived from `matlab.mixin.CustomDisplay`

**Default:**

## Attributes

Access

protected

# matlab.mixin.CustomDisplay.getClassNameForHeader

**Class:** matlab.mixin.CustomDisplay

**Package:** matlab.mixin

Return class name for display

## Syntax

```
name = matlab.mixin.CustomDisplay.getClassNameForHeader(obj)
```

## Description

`name = matlab.mixin.CustomDisplay.getClassNameForHeader(obj)` returns the class name of `obj`. If the display supports hypertext links, the text is linked to the help for the class of `obj`.

Use this method when building a custom display that includes the class name, but differs from the default header.

## Input Arguments

**obj**

MATLAB object

**Default:**

## Output Arguments

**name**

The simple class name, linked to the help for the class if the display supports hypertext links

## Attributes

## getFooter

**Class:** matlab.mixin.CustomDisplay

**Package:** matlab.mixin

Build and return display footer text

## Syntax

```
s = getFooter(obj)
```

## Description

`s = getFooter(obj)` returns the text used as the footer when displaying `obj`. This method is called once for the entire object array.

Override this method to create a custom footer. The overriding implementation must support all states of the object, including scalar, nonscalar, empty, and deleted (if `obj` is an instance of a handle class).

## Input Arguments

**obj**

Object array of a class derived from `matlab.mixin.CustomDisplay`

**Default:**

## Output Arguments

**s**

Footer text, returned as a string.

The default implementation returns an empty string

## Attributes

Access

protected

## **See Also**

getHeader

## **Related Examples**

- “Custom Display Interface”

# getHeader

**Class:** matlab.mixin.CustomDisplay

**Package:** matlab.mixin

Build and return display header text

## Syntax

```
s = getHeader(obj)
```

## Description

`s = getHeader(obj)` returns the text used as the header when displaying `obj`. This method is called once for the entire object array.

Override this method to create a custom header. The overriding implementation must support all states of the object, including scalar, nonscalar, empty, and deleted (if `obj` is an instance of a handle class).

## Input Arguments

**obj**

Object array of a class derived from `matlab.mixin.CustomDisplay`

## Output Arguments

**s**

Header string, returned as a `char` array

The default implementation returns the following:

- If `obj` is scalar, returns *classname*, which is the simple name of the class (the nonpackage-qualified name).
- If `obj` is nonscalar, returns *classname* and dimensions.

- If `obj` is empty, returns an empty string.
- If `obj` is a deleted handle, returns the string `deleted classname handle`

`classname` is linked to MATLAB documentation for the class. Selecting the link displays the `helpPopup` window.

If you override this method, you might need to terminate `s` with a newline (`\n`) character.

## Examples

### Append Text to Default Header

Append the string, 'with Customized Display', to the header text.

Write a `getHeader` method.

```
methods (Access = protected)
 function header = getHeader(obj)
 if ~isscalar(obj)
 header = getHeader@matlab.mixin.CustomDisplay(obj);
 else
 headerStr = matlab.mixin.CustomDisplay.getClassNameForHeader(obj);
 headerStr = [headerStr, ' with Customized Display'];
 header = sprintf('%s\n',headerStr);
 end
 end
end
```

Add `getHeader` method to class definition.

- “Custom Display Interface”

## Attributes

Access

`protected`

To learn about attributes of methods, see [Method Attributes](#) in the MATLAB Object-Oriented Programming documentation.

## See Also

`matlab.mixin.CustomDisplay.getFooter` |

`matlab.mixin.CustomDisplay.getPropertyGroups`

# getPropertyGroups

**Class:** matlab.mixin.CustomDisplay

**Package:** matlab.mixin

Construct array of property groups

## Syntax

```
groups = getPropertyGroups(obj)
```

## Description

`groups = getPropertyGroups(obj)` returns an array of `matlab.mixin.util.PropertyGroup` objects. MATLAB displays property groups separated by blank spaces.

Each default display state handler method calls this method once. The default implementation returns the properties in one group. These properties must have public `GetAccess` and not be defined as `Hidden`. If the object is scalar, MATLAB includes dynamic properties.

Override this method to construct one or more customized groups of properties to display.

Each group object array has the following fields:

- **Title** — String used as the header for the property group or an empty string if no title is used.
- **PropertyList** — The property list can be either:
  - A 1-by-1 `struct` of property name-property value pairs
  - A cell array of string property names.

Use the `struct` of name-value pairs if the object is scalar and you want to assign custom property values. Otherwise, use a cell array of string property names. If the object is scalar MATLAB adds the property values retrieved from the object.

## Input Arguments

### obj

Object array of a class derived from `matlab.mixin.CustomDisplay`

**Default:**

## Output Arguments

### groups

1xN array of `matlab.mixin.util.PropertyGroup` objects, where N is the number of groups

## Examples

### Custom Property Group

Customize the values returned by some properties.

Write a `getPropertyGroups` method.

```
methods (Access = protected)
 function propgrp = getPropertyGroups(obj)
 if ~isscalar(obj)
 propgrp = getPropertyGroups@matlab.mixin.CustomDisplay(obj);
 else
 pd(1:length(obj.Password)) = '*';
 propList = struct('Department',obj.Department,...
 'JobTitle',obj.JobTitle,...
 'Name',obj.Name,...
 'Salary','Not available',...
 'Password',pd);
 propgrp = matlab.mixin.util.PropertyGroup(propList);
 end
 end
end
```

Add function to class definition.

Superclass providing copy functionality for handle objects

### Description

The `matlab.mixin.Copyable` class is an abstract handle class that provides a `copy` method for copying handle objects. The `copy` method makes a shallow copy of the object (that is, it shallow copies all non-dependent properties from the source to the destination object). In making a shallow copy, MATLAB does not call `copy` recursively on any handles contained in property values.

Subclass `matlab.mixin.Copyable` when you want to define handles classes that inherit a `copy` method. The `copy` method:

- Copies data without calling class constructors or property set functions and therefore produces no side effects.
- Enables subclasses to customize the copy behavior

### Customizing Subclass Copy Behavior

The `copy` method provides the public, non-overrideable interface to copy behavior. `copy` takes an array of objects as input and returns an array of the same dimensions.

`copyElement` is a protected method that the `copy` method uses to perform the copy operation on each object in the input array. `copyElement` is not `Sealed` so you can override it in your subclass to customize the behavior of the inherited `copy` method.

Use the property `NonCopyable` attribute to control if the copy operation copies specific property values.

### Implementing a Selective Deep Copy

This example overrides the `copyElement` method in a subclass of `matlab.mixin.Copyable` to implement a deep copy of a specific class of handle objects.

Consider the following classes:

- `ContainsHandles` — subclass of `matlab.mixin.Copyable` that contains handle objects in two properties
- `DeepCp` — subclass of `matlab.mixin.Copyable`
- `ShallowCp` — subclass of `handle`

Here are the simplified class definitions:

```
classdef ContainsHandles < matlab.mixin.Copyable
 properties
 Prop1
 Prop2
 DeepObj % Contains a DeepCp object
 ShallowObj % Contains a ShallowCp object
 end
 methods
 function obj = ContainsHandles(val1,val2,deepobj,shallowobj)
 if nargin > 0
 obj.Prop1 = val1;
 obj.Prop2 = val2;
 obj.DeepObj = deepobj;
 obj.ShallowObj = shallowobj;
 end
 end
 end
end
methods(Access = protected)
 % Override copyElement method:
 function cpObj = copyElement(obj)
 % Make a shallow copy of all four properties
 cpObj = copyElement@matlab.mixin.Copyable(obj);
 % Make a deep copy of the DeepCp object
 cpObj.DeepObj = copy(obj.DeepObj);
 end
end
end
```

The `DeepCp` class derives from `matlab.mixin.Copyable`:

```
classdef DeepCp < matlab.mixin.Copyable
 properties
 DpProp
 end
 methods
 function obj = DeepCp(val)
 ...
 end
 end
end
```

```
 end
 end
end
```

The `handle` class `ShallowCp` does not derive from `matlab.mixin.Copyable` and, therefore, has no copy method:

```
classdef ShallowCp < handle
 properties
 ShProp
 end
 methods
 function obj = ShallowCp(val)
 ...
 end
 end
end
```

Create a `ContainsHandles` object, which contains the two handle objects in its `DpProp` and `ShProp` properties:

```
>> sc = ShallowCp(7);
>> dc = DeepCp(7);
>> a = ContainsHandles(4,5,dc,sc);
>> a.DeepObj
ans =
```

DeepCp with properties:

```
 DpProp: 7
>> a.ShallowObj.ShProp
ans =
```

ShallowCp with properties:

```
 ShProp: 7
```

Make a copy of the `ContainsHandles` object:

```
>> b = copy(a);
```

The returned copy `b` contains a shallow copy of object `sc`, and a deep copy of object `dc`. That is, the `dc` object passed to `ContainsHandles` constructor is now a new, independent objects as a result of the copy operation. You can now change the `dc` object without affecting the copy. This is not the case for the shallow copied object, `sc`:

```

% Change the property values of the handle objects:
>> sc.ShProp = 5;
>> dc.DpProp = 5;
% Note that the deep copied object is not affected:
>> b.DeepObj

ans =

 DeepCp with properties:

 DpProp: 7
% The shallow copied object is still referencing the same data:
>> b.ShallowObj

ans =

 ShallowCp with properties:

 ShProp: 5

```

### Overriding Copy Behavior in Hierarchies

The `copyElement` method in a superclass cannot access the private data in a subclass.

If you override `copyElement` in a subclass of `matlab.mixin.Copyable`, and then use this subclass as a superclass, you need to override `copyElement` in all subclasses that contain private properties. The override of `copyElement` in subclasses should call the `copyElement` in the respective superclass, as in the previous example.

The following simplified code demonstrates this approach:

```

classdef SuperClass < matlab.mixin.Copyable
 properties(Access = private)
 super_prop
 end
 methods
 ...

 function cpObj = copyElement(obj)
 ...
 cpObj = copyElement@matlab.mixin.Copyable(obj);
 ...
 end
 end
end

```

```
end

classdef SubClass1 < SuperClass
 properties(Access=private)
 sub_prop1
 end
 methods
 function cpObj = copyElement(obj)
 % Copy super_prop
 cpObj = copyElement@SuperClass(obj);
 % Copy sub_prop1 in subclass
 % Assignment can introduce side effects
 cpObj.sub_prop1 = obj.sub_prop1;
 end
 end
end
```

The override of `copyElement` in `SubClass1` copies the private subclass property because the superclass cannot access private data in the subclass.

---

**Note:** The assignment of `sub_prop1` in the override of `copyElement` in `SubClass1` calls the property set method, if one exists, possibly introducing side effects to the copy operation.

---

## Copy Behaviors for Specific Inputs

Given a call to the `matlab.mixin.Copyable` `copy` method of the form:

```
B = copy(A);
```

Under the following conditions, produces the described results:

- A has dynamic properties — `copy` does not copy dynamic properties. You can implement dynamic-property copying in the subclass if needed.
- A has no non-Dependent properties — `copy` creates a new object with no property values without calling the class constructor to avoid introducing side effects.
- A contains deleted handles — `copy` creates deleted handles of the same class in the output array.
- A has attached listeners — `copy` does not copy listeners.

- A contains objects of enumeration classes — Enumeration classes cannot subclass `matlab.mixin.Copyable`.
- A `delete` method calls `copy` — `copy` creates a legitimate copy, obeying all the behaviors that apply in any other usage.

---

**Note:** You cannot derive an enumeration class from `matlab.mixin.Copyable` because the number of instances you can create are limited to the ones defined inside the enumeration block. See “How to Use Enumerations” for more information about enumeration classes.

---

## Methods

`copy` Copy array of handle objects

## Definitions

### Deep Copy

Copy each property value and assign it to the new (copied) property. Recursively copy property values that reference handle objects to copy all of the underlying data.

### Shallow Copy

Copy each property value and assign it to the new (copied) property. If a property value is a handle, copy the handle but not the underlying data.

## Attributes

`ConstructOnLoad` true

handle

**How To**

- “Customize Copy”

**Introduced in R2011a**

## copy

**Class:** matlab.mixin.Copyable

**Package:** matlab.mixin

Copy array of handle objects

## Syntax

`B = copy(A)`

## Description

`B = copy(A)` copies each element in the array of handles `A` to the new array of handles `B`.

The `copy` method performs a copy according to the following rules:

- The `copy` method does not copy `Dependent` properties
- MATLAB does not call the `copy` method recursively on any handles contained in property values
- MATLAB does not call the class constructor or property set methods during the copy operation.
- `B` has the same number of elements and same size as `A`.
- `B` is the same class as `A`.
- If `A` is empty, `B` is also empty.
- If `A` is heterogeneous, `B` is also heterogeneous.
- If `A` contains deleted handle objects, `copy` creates deleted handles of the same class in `B`.
- Dynamic properties and listeners associated with objects in `A` are not copied to objects in `B`.
- You can call `copy` inside your class `delete` method.

## Input Arguments

### A

Handle object array

Default:

## Output Arguments

### B

Handle object array containing copies of the objects in A.

## Attributes

Sealed true

**Introduced in R2011a**

# copyfile

Copy file or folder

## Syntax

```
copyfile('source', 'destination')
copyfile('source', 'destination', 'f')
status = copyfile(____)
[status, message] = copyfile(____)
[status, message, messageId] = copyfile(____)
```

## Description

`copyfile('source', 'destination')` copies the file or folder named `source` to the file or folder `destination`. The values for `source` and `destination` are 1 x n strings. Use full path names or path names relative to the current folder. To copy multiple files or folders, use one or more wildcard characters (\*) after the last file separator in `source`. You cannot use a wildcard character in `destination`.

`copyfile('source', 'destination', 'f')` copies `source` to `destination`, even when `destination` is not writable. The state of the read-write attribute for `destination` does not change. You can use `f` with any syntax for `copyfile`.

`status = copyfile(____)` reports the outcome as a logical scalar, `status`. The value is 1 for success and 0 for failure.

`[status, message] = copyfile(____)` returns any warning or error message as a string to `message`. When `copyfile` succeeds, `message` is an empty string.

`[status, message, messageId] = copyfile(____)` returns any warning or error identifier as a string to `messageId`. When `copyfile` succeeds, `messageId` is an empty string.

## Examples

### Copy File to Another Folder

Copy `myFun.m` from the current folder to `d:/work/Projects/`.

```
copyfile('myFun.m', 'd:/work/Projects/')
```

### Copy File to Its Current Folder

Copy `myFun.m` in the current folder, assigning it the name `myFun2.m`.

```
copyfile('myFun.m', 'myFun2.m')
```

### Copy Files and Folders to a New Folder Using Wildcards

Copy files and subfolders whose names begin with `my`, from the `Projects` subfolder within the current folder to the folder `newProjects`, which is at the same level as the current folder:

```
copyfile('Projects/my*', '../newProjects/')
```

### Copy Files to a New, Nonexistent Folder

Copy the contents of the `Projects` subfolder within the current folder to the `I:/work/newProjects` folder, where `newProjects` does not exist.

```
copyfile('Projects', 'I:/work/newProjects')
```

### Copy File that Overwrites a Read-Only File

Copy the contents of `myFun.m` from the current folder to `d:/work/restricted/myFun2.m`, where `myFun2.m` is read-only.

```
[status,message,messageId] = copyfile('myFun.m', ...
'd:/work/restricted/myFun2.m', 'f')
```

```
status =
 1
```

```
message =
 ''
```

```
messageId =
```

The `status` of 1 and empty `message` and `messageId` strings confirm the copy was successful.

## More About

### Tips

- The timestamp for `destination` is the same as the timestamp for `source`.
- When `source` is a folder, `destination` must be a folder.
  - When `source` is a folder and `destination` does not exist, `copyfile` creates `destination` and copies the contents of `source` into `destination`.
  - When `source` is a folder and `destination` is an existing folder, `copyfile` copies the contents of `source` into `destination`.
  - When `source` is multiple files and `destination` does not exist, `copyfile` creates `destination`.
- “Specify File Names”
- “Manage Files and Folders”

## copyobj

Copy graphics objects and their descendants

### Syntax

```
new_handle = copyobj(h,p)
copyobj(____, 'legacy')
```

### Description

`copyobj` creates copies of graphics objects and assigns the objects to the new parent.

The new parent must be appropriate for the copied object (for example, you can copy an axes only to figure or uipanel). `copyobj` copies children as well.

`new_handle = copyobj(h,p)` copies one or more graphics objects identified by `h` and returns the handle of the new object or an array of new objects. The new graphics objects are children of the graphics objects specified by `p`.

`copyobj( ____, 'legacy' )` copies object callback properties and object application data. This behavior is consistent with versions of `copyobj` before MATLAB release R2014b.

### What is Not Copied

`copyobj` does not copy properties or objects that depend on their original context to operate properly. Objects with default context menus (such as legends and colorbars) create new context menus for the new object. Figures create new toolbars and menus for the new figure.

`copyobj` does *not* copy:

- Callback properties (except when using the `legacy` option)
- Application data associated with the object (except when using the `legacy` option)
- Context menu of legends, colorbars, or other objects that define default context menus.

- Default Figure toolbar and menus
- You cannot copy the same object more than once to the same parent in a single call to `copyobj`.

MATLAB changes the `Parent` property to the new parent and assigns the new objects a new handle.

## Examples

Copy a surface to a new axes that is in a different figure.

```
h = surf(peaks);
colormap hsv
```

Create the destination figure and axes:

```
fig = figure;
ax = axes;
```

Copy the surface to the new axes and set properties that are not surface properties:

```
new_handle = copyobj(h,ax);
colormap(fig,hsv)
view(ax,3)
grid(ax,'on')
```

Note that while the surface is copied, the `colormap`, `view`, and `grid` are not copied.

## More About

### Tips

`h` and `p` can be scalars or vectors. When both are vectors, they must be the same length, and the output argument, `new_handle`, is a vector of the same length. In this case, `new_handle(i)` is a copy of `h(i)` with its `Parent` property set to `p(i)`.

When `h` is a scalar and `p` is a vector, `h` is copied once to each of the parents in `p`. Each `new_handle(i)` is a copy of `h` with its `Parent` property set to `p(i)`, and `length(new_handle)` equals `length(p)`.

When `h` is a vector and `p` is a scalar, each `new_handle(i)` is a copy of `h(i)` with its `Parent` property set to `p`. The length of `new_handle` equals `length(h)`.

---

**Note:** You must copy the associated axes when copying a legend or a colorbar.

---

When programming a UI, do not call `copyobj` or `textwrap` (which calls `copyobj`) inside a `CreateFcn`. The act of copying the uicontrol object fires the `CreateFcn` repeatedly, which raises a series of error messages after exceeding the recursion limit.

**Introduced before R2006a**

# corrcoef

Correlation coefficients

## Syntax

`R = corrcoef(A)`

`R = corrcoef(A,B)`

`[R,P] = corrcoef( ___ )`

`[R,P,RL,RU] = corrcoef( ___ )`

`___ = corrcoef( ___ ,Name,Value)`

## Description

`R = corrcoef(A)` returns the matrix of correlation coefficients for `A`, where the columns of `A` represent random variables and the rows represent observations.

`R = corrcoef(A,B)` returns coefficients between two random variables `A` and `B`.

`[R,P] = corrcoef( ___ )` returns the matrix of correlation coefficients and the matrix of `p`-values for testing the hypothesis that there is no relationship between the observed phenomena (null hypothesis). Use this syntax with any of the arguments from the previous syntaxes. If an off-diagonal element of `P` is smaller than the significance level (default is `0.05`), then the corresponding correlation in `R` is considered significant. This syntax is invalid if `R` contains complex elements.

`[R,P,RL,RU] = corrcoef( ___ )` includes matrices containing lower and upper bounds for a 95% confidence interval for each coefficient. This syntax is invalid if `R` contains complex elements.

`___ = corrcoef( ___ ,Name,Value)` returns any of the output arguments from the previous syntaxes with additional options specified by one or more `Name,Value` pair arguments. For example, `corrcoef(A, 'alpha', 0.1)` specifies a 90% confidence interval, and `corrcoef(A, 'rows', 'complete')` omits all rows of `A` containing one or more NaN values.

## Examples

### Random Columns of Matrix

Compute the correlation coefficients for a matrix with two normally distributed, random columns and one column that is defined in terms of another. Since the third column of  $A$  is a multiple of the second, these two variables are directly correlated, thus the correlation coefficient in the  $(2,3)$  and  $(3,2)$  entries of  $R$  is 1.

```
x = randn(6,1);
y = randn(6,1);
A = [x y 2*y+3];
R = corrcoef(A)
```

R =

```
1.0000 -0.6237 -0.6237
-0.6237 1.0000 1.0000
-0.6237 1.0000 1.0000
```

### Two Random Variables

Compute the correlation coefficient matrix between two normally distributed, random vectors of 10 observations each.

```
A = randn(10,1);
B = randn(10,1);
R = corrcoef(A,B)
```

R =

```
1.0000 0.4518
0.4518 1.0000
```

### P-Values of Matrix

Compute the correlation coefficients and p-values of a normally distributed, random matrix, with an added fourth column equal to the sum of the other three columns. Since the last column of  $A$  is a linear combination of the others, a correlation is introduced between the fourth variable and each of the other three variables. Therefore, the fourth

row and fourth column of P contain very small p-values, identifying them as significant correlations.

```
A = randn(50,3);
A(:,4) = sum(A,2);
[R,P] = corrcoef(A)
```

R =

|        |         |         |        |
|--------|---------|---------|--------|
| 1.0000 | 0.1135  | 0.0879  | 0.7314 |
| 0.1135 | 1.0000  | -0.1451 | 0.5082 |
| 0.0879 | -0.1451 | 1.0000  | 0.5199 |
| 0.7314 | 0.5082  | 0.5199  | 1.0000 |

P =

|        |        |        |        |
|--------|--------|--------|--------|
| 1.0000 | 0.4325 | 0.5438 | 0.0000 |
| 0.4325 | 1.0000 | 0.3146 | 0.0002 |
| 0.5438 | 0.3146 | 1.0000 | 0.0001 |
| 0.0000 | 0.0002 | 0.0001 | 1.0000 |

### Correlation Bounds

Create a normally distributed, random matrix, with an added fourth column equal to the sum of the other three columns, and compute the correlation coefficients, p-values, and lower and upper bounds on the coefficients.

```
A = randn(50,3);
A(:,4) = sum(A,2);
[R,P,RL,RU] = corrcoef(A)
```

R =

|        |         |         |        |
|--------|---------|---------|--------|
| 1.0000 | 0.1135  | 0.0879  | 0.7314 |
| 0.1135 | 1.0000  | -0.1451 | 0.5082 |
| 0.0879 | -0.1451 | 1.0000  | 0.5199 |
| 0.7314 | 0.5082  | 0.5199  | 1.0000 |

P =

|        |        |        |        |
|--------|--------|--------|--------|
| 1.0000 | 0.4325 | 0.5438 | 0.0000 |
| 0.4325 | 1.0000 | 0.3146 | 0.0002 |
| 0.5438 | 0.3146 | 1.0000 | 0.0001 |
| 0.0000 | 0.0002 | 0.0001 | 1.0000 |

RL =

|         |         |         |        |
|---------|---------|---------|--------|
| 1.0000  | -0.1702 | -0.1952 | 0.5688 |
| -0.1702 | 1.0000  | -0.4070 | 0.2677 |
| -0.1952 | -0.4070 | 1.0000  | 0.2825 |
| 0.5688  | 0.2677  | 0.2825  | 1.0000 |

RU =

|        |        |        |        |
|--------|--------|--------|--------|
| 1.0000 | 0.3799 | 0.3575 | 0.8389 |
| 0.3799 | 1.0000 | 0.1388 | 0.6890 |
| 0.3575 | 0.1388 | 1.0000 | 0.6974 |
| 0.8389 | 0.6890 | 0.6974 | 1.0000 |

The matrices RL and RU give lower and upper bounds, respectively, on each correlation coefficient according to a 95% confidence interval by default. You can change the confidence level by specifying the value of `alpha`, which defines the percent confidence,  $100 * (1 - \alpha)\%$ . For example, use `alpha` equal to 0.01 to compute a 99% confidence interval, which is reflected in the bounds RL and RU. The intervals defined by the coefficient bounds in RL and RU are bigger for 99% confidence compared to 95%, since higher confidence requires a more inclusive range of potential correlation values.

```
[R,P,RL,RU] = corrcoef(A, 'alpha', 0.01)
```

R =

|        |         |         |        |
|--------|---------|---------|--------|
| 1.0000 | 0.1135  | 0.0879  | 0.7314 |
| 0.1135 | 1.0000  | -0.1451 | 0.5082 |
| 0.0879 | -0.1451 | 1.0000  | 0.5199 |
| 0.7314 | 0.5082  | 0.5199  | 1.0000 |

P =

|        |        |        |        |
|--------|--------|--------|--------|
| 1.0000 | 0.4325 | 0.5438 | 0.0000 |
|--------|--------|--------|--------|

```

0.4325 1.0000 0.3146 0.0002
0.5438 0.3146 1.0000 0.0001
0.0000 0.0002 0.0001 1.0000

```

RL =

```

1.0000 -0.2559 -0.2799 0.5049
-0.2559 1.0000 -0.4792 0.1825
-0.2799 -0.4792 1.0000 0.1979
0.5049 0.1825 0.1979 1.0000

```

RU =

```

1.0000 0.4540 0.4332 0.8636
0.4540 1.0000 0.2256 0.7334
0.4332 0.2256 1.0000 0.7407
0.8636 0.7334 0.7407 1.0000

```

## NaN Values

Create a normally distributed matrix involving NaN values, and compute the correlation coefficient matrix, excluding any rows that contain NaN.

```

A = randn(5,3);
A(1,3) = NaN;
A(3,2) = NaN;
A

```

A =

```

0.5377 -1.3077 NaN
1.8339 -0.4336 3.0349
-2.2588 NaN 0.7254
0.8622 3.5784 -0.0631
0.3188 2.7694 0.7147

```

```

R = corrcoef(A, 'rows', 'complete')

```

R =

```
1.0000 -0.8506 0.8222
-0.8506 1.0000 -0.9987
0.8222 -0.9987 1.0000
```

Use 'all' to include all NaN values in the calculation.

```
R = corrcoef(A, 'rows', 'all')
```

R =

```
1 NaN NaN
NaN NaN NaN
NaN NaN NaN
```

Use 'pairwise' to compute each two-column correlation coefficient on a pairwise basis. If one of the two columns contains a NaN, that row is omitted.

```
R = corrcoef(A, 'rows', 'pairwise')
```

R =

```
1.0000 -0.3388 0.4649
-0.3388 1.0000 -0.9987
0.4649 -0.9987 1.0000
```

## Input Arguments

### A — Input array

matrix

Input array, specified as a matrix.

- If A is a scalar, `corrcoef(A)` returns NaN.
- If A is a vector, `corrcoef(A)` returns 1.

Data Types: `single` | `double`

Complex Number Support: Yes

### **B** — Additional input array

vector | matrix | multidimensional array

Additional input array, specified as a vector, matrix, or multidimensional array.

- A and B must be the same size.
- If A and B are scalars, then `corrcoef(A,B)` returns 1. If A and B are equal, however, `corrcoef(A,B)` returns NaN.
- If A and B are matrices or multidimensional arrays, then `corrcoef(A,B)` converts each input into its vector representation and is equivalent to `corrcoef(A(:),B(:))` or `corrcoef([A(:) B(:)])`.
- If A and B are 0-by-0 empty arrays, `corrcoef(A,B)` returns a 2-by-2 matrix of NaN values.

Data Types: `single` | `double`

Complex Number Support: Yes

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `R = corrcoef(A,'alpha',0.03)`

### **'alpha'** — Significance level

0.05 (default) | number between 0 and 1

Significance level, specified as a number between 0 and 1. `alpha` defines the percent confidence level,  $100*(1-\text{alpha})\%$ , for the correlation coefficients, which determines the bounds in RL and RU.

Data Types: `single` | `double`

### **'rows'** — Use of NaN option

'all' (default) | 'complete' | 'pairwise'

Use of NaN option, specified as one of these values:

- 'all' — Include all NaN values in the input before computing the correlation coefficients.
- 'complete' — Omit any rows of the input containing NaN values before computing the correlation coefficients. This option always returns a positive definite matrix.
- 'pairwise' — Omit any rows containing NaN only on a pairwise basis for each two-column correlation coefficient calculation. This option can return a matrix that is not positive definite.

Data Types: char

## Output Arguments

### **R — Correlation coefficients**

matrix

Correlation coefficients, returned as a matrix.

- For one matrix input, **R** has size `[size(A,2) size(A,2)]` based on the number of random variables (columns) represented by **A**. The diagonal entries are set to one by convention, while the off-diagonal entries are correlation coefficients of variable pairs. The values of the coefficients can range from -1 to 1, with -1 representing a direct, negative correlation, 0 representing no correlation, and 1 representing a direct, positive correlation. **R** is symmetric.
- For two input arguments, **R** is a 2-by-2 matrix with ones along the diagonal and the correlation coefficients along the off-diagonal.
- If any random variable is constant, its correlation with all other variables is undefined, and the respective row and column value is NaN.

### **P — P-values**

matrix

P-values, returned as a matrix. **P** is symmetric and is the same size as **R**. The diagonal entries are all ones and the off-diagonal entries are the p-values for each variable pair. P-values range from 0 to 1, where values close to 0 correspond to a significant correlation in **R** and a low probability of observing the null hypothesis.

### **RL — Lower bound for correlation coefficient**

matrix

Lower bound for correlation coefficient, returned as a matrix. **RL** is symmetric and is the same size as **R**. The diagonal entries are all ones and the off-diagonal entries are the 95% confidence interval lower bound for the corresponding coefficient in **R**. The syntax returning **RL** is invalid if **R** contains complex values.

### **RU** — Upper bound for correlation coefficient

matrix

Upper bound for correlation coefficient, returned as a matrix. **RU** is symmetric and is the same size as **R**. The diagonal entries are all ones and the off-diagonal entries are the 95% confidence interval upper bound for the corresponding coefficient in **R**. The syntax returning **RL** is invalid if **R** contains complex values.

## More About

### Correlation Coefficient

The correlation coefficient of two random variables is a measure of their linear dependence. If each variable has  $N$  scalar observations, then the Pearson correlation coefficient is defined as

$$\rho(A, B) = \frac{1}{N-1} \sum_{i=1}^N \left( \frac{A_i - \mu_A}{\sigma_A} \right) \left( \frac{B_i - \mu_B}{\sigma_B} \right)$$

where  $\mu_A$  and  $\sigma_A$  are the mean and standard deviation of  $A$ , respectively, and  $\mu_B$  and  $\sigma_B$  are the mean and standard deviation of  $B$ . Alternatively, you can define the correlation coefficient in terms of the covariance of  $A$  and  $B$ :

$$\rho(A, B) = \frac{\text{cov}(A, B)}{\sigma_A \sigma_B}.$$

The correlation coefficient *matrix* of two random variables is the matrix of correlation coefficients for each pairwise variable combination,

$$R = \begin{pmatrix} \rho(A, A) & \rho(A, B) \\ \rho(B, A) & \rho(B, B) \end{pmatrix}.$$

Since  $A$  and  $B$  are always directly correlated to themselves, the diagonal entries are just 1, that is,

$$R = \begin{pmatrix} 1 & \rho(A,B) \\ \rho(B,A) & 1 \end{pmatrix}.$$

## COS

Cosine of argument in radians

## Syntax

`Y = cos(X)`

## Description

`Y = cos(X)` returns the cosine for each element of `X`. The `COS` function operates element-wise on arrays. The function accepts both real and complex inputs. For purely real values or imaginary values of `X`, `COS` returns real values in the interval  $[-1, 1]$ . For complex values of `X`, `COS` returns complex values. All angles are in radians.

## Examples

### Plot Cosine Function

Plot the cosine function over the domain  $-\pi \leq x \leq \pi$ .

```
x = -pi:0.01:pi;
plot(x,cos(x))
grid on
```

### Cosine of Vector of Complex Angles

Calculate the cosine of the complex angles in vector  $x$ .

```
x = [-i pi+i*pi/2 -1+i*4];
y = cos(x)
```

y =

```
1.5431 + 0.0000i -2.5092 - 0.0000i 14.7547 +22.9637i
```

## Input Arguments

### **X — Input angle in radians**

number | vector | matrix | multidimensional array

Input angle in radians, specified as a number, vector, matrix, or multidimensional array.

Data Types: `single` | `double`

Complex Number Support: Yes

## Output Arguments

### **Y — Cosine of input angle**

scalar value | vector | matrix | N-D array

Cosine of input angle, returned as a real-valued or complex-valued scalar, vector, matrix or N-D array.

## More About

### **Cosine Function**

The cosine of an angle,  $\alpha$ , defined with reference to a right angled triangle is

$$\cos(\alpha) = \frac{\text{adjacent side}}{\text{hypotenuse}} = \frac{b}{h}.$$

The cosine of a complex angle,  $\alpha$ , is

$$\cos(\alpha) = \frac{e^{j\alpha} + e^{-j\alpha}}{2}.$$

### See Also

[acos](#) | [acosd](#) | [cosd](#) | [cosh](#)

## cosd

Cosine of argument in degrees

### Syntax

$Y = \text{cosd}(X)$

### Description

$Y = \text{cosd}(X)$  returns the cosine of the elements of  $X$ , which are expressed in degrees.

### Examples

#### Cosine of 90 degrees compared to cosine of $\pi/2$ radians

```
cosd(90)
```

```
ans =
```

```
0
```

```
cos(pi/2)
```

```
ans =
```

```
6.1232e-17
```

#### Cosine of complex angles specified in degrees

Create an array of three complex angles and compute the cosine.

```
z = [180+i 45+2i 10+3i];
```

```
y = cosd(z)
```

```
y =
```

-1.0002      0.7075 - 0.0247i      0.9862 - 0.0091i

## Input Arguments

### **X — Angle in degrees**

scalar value | vector | matrix | N-D array

Angle in degrees, specified as a real-valued or complex-valued scalar, vector, matrix, or N-D array. The `cosd` operation is element-wise when `X` is nonscalar.

Data Types: `single` | `double`

Complex Number Support: Yes

## Output Arguments

### **Y — Cosine of angle**

scalar value | vector | matrix | N-D array

Cosine of angle, returned as a real-valued or complex-valued scalar, vector, matrix, or N-D array of the same size as `X`.

## See Also

# cosh

Hyperbolic cosine

## Syntax

$Y = \cosh(X)$

## Description

The `cosh` function operates element-wise on arrays. The function's domains and ranges include complex values. All angles are in radians.

$Y = \cosh(X)$  returns the hyperbolic cosine for each element of  $X$ .

## Examples

### Graph of Hyperbolic Cosine

Graph the hyperbolic cosine function over the domain  $-5 \leq x \leq 5$ .

```
x = -5:0.01:5;
plot(x,cosh(x)), grid on
```

## Hyperbolic Cosine

The hyperbolic cosine of  $z$  is

$$\cosh(z) = \frac{e^z + e^{-z}}{2}.$$

### See Also

[acosh](#) | [cos](#) | [sinh](#) | [tanh](#)

**Introduced before R2006a**

## **cot**

Cotangent of angle in radians

### **Syntax**

`Y = cot(X)`

### **Description**

`Y = cot(X)` returns the cotangent of elements of `X`. The `cot` function operates element-wise on arrays. The function accepts both real and complex inputs. For real values of `X` in the interval `[-Inf,Inf]`, `cot` returns real values in the interval `[-Inf,Inf]`. For complex values of `X`, `cot` returns complex values. All angles are in radians.

### **Examples**

#### **Plot Cotangent Function**

Plot the cotangent function over the domain  $-\pi < x < 0$  and  $0 < x < \pi$ .

```
x1 = -pi+0.01:0.01:-0.01;
x2 = 0.01:0.01:pi-0.01;
plot(x1,cot(x1),x2,cot(x2)), grid on
```

### Cotangent of Vector of Complex Angles

Calculate the cotangent of the complex angles in vector  $x$ .

```
x = [-i pi+i*pi/2 -1+i*4];
y = cot(x)
```

y =

```
0.0000 + 1.3130i -0.0000 - 1.0903i -0.0006 - 0.9997i
```

## Input Arguments

### **X** — Input angle in radians

number | vector | matrix | multidimensional array

Input angle in radians, specified as a number, vector, matrix, or multidimensional array.

Data Types: `single` | `double`

Complex Number Support: Yes

## Output Arguments

### **Y** — Cotangent of input angle

scalar value | vector | matrix | N-D array

Cotangent of input angle, returned as a real-valued or complex-valued scalar, vector, matrix or N-D array.

## More About

### Cotangent Function

The cotangent of an angle,  $\alpha$ , defined with reference to a right angled triangle is

$$\cot(\alpha) = \frac{1}{\tan(\alpha)} = \frac{\text{adjacent side}}{\text{opposite side}} = \frac{b}{a}.$$

The cotangent of a complex angle  $\alpha$  is

$$\cot(\alpha) = \frac{i(e^{i\alpha} + e^{-i\alpha})}{(e^{i\alpha} - e^{-i\alpha})}.$$

### See Also

acot | acotd | acoth | cotd | coth

Introduced before R2006a

## **cotd**

Cotangent of argument in degrees

### **Syntax**

$Y = \text{cotd}(X)$

### **Description**

$Y = \text{cotd}(X)$  returns the cotangent of the elements of  $X$ , which are expressed in degrees.

### **Examples**

#### **Cotangent of angles approaching 90 and 180 degrees**

Create a vector of input angles consisting of 90° and the next smaller and larger double precision numbers. Then compute the cotangent.

```
x1 = [90-eps(90) 90 90+eps(90)];
y1 = cotd(x1)
```

```
y1 =
```

```
1.0e-15 *
```

```
0.2480 0 -0.2480
```

`cotd` returns zero when the input angle is exactly 90°. Evaluation at the next smaller double-precision angle returns a slightly positive result. Likewise, the cotangent is slightly negative when the input angle is the next double-precision number larger than 90.

The behavior is similar for input angles near 180°.

```
x2 = [180-eps(180) 180 180+eps(180)];
y2 = cotd(x2)
```

```

y2 =
 1.0e+15 *
 -2.0159 Inf 2.0159

```

### Cotangent of complex angle, specified in degrees

```

x = 35+5i;
y = cotd(x)

```

```

y =
 1.3958 - 0.2606i

```

## Input Arguments

### X — Angle in degrees

scalar value | vector | matrix | N-D array

Angle in degrees, specified as a real-valued or complex-valued scalar, vector, matrix, or N-D array. The `cotd` operation is element-wise when X is nonscalar.

Data Types: `single` | `double`

Complex Number Support: Yes

## Output Arguments

### Y — Cotangent of angle

scalar value | vector | matrix | N-D array

Cotangent of angle, returned as a real-valued or complex-valued scalar, vector, matrix, or N-D array of the same size as X.

### See Also

`acot` | `acotd` | `cot`

Introduced before R2006a

## **coth**

Hyperbolic cotangent

### **Syntax**

$Y = \text{coth}(X)$

### **Description**

The `coth` function operates element-wise on arrays. The function's domains and ranges include complex values. All angles are in radians.

$Y = \text{coth}(X)$  returns the hyperbolic cotangent for each element of  $X$ .

### **Examples**

#### **Graph of Hyperbolic Cotangent**

Plot the hyperbolic cotangent over the domain  $-\pi < x < 0$  and  $0 < x < \pi$ .

```
x1 = -pi+0.01:0.01:-0.01;
x2 = 0.01:0.01:pi-0.01;
plot(x1,coth(x1),x2,coth(x2))
grid on
```

## More About

### Hyperbolic Cotangent

The hyperbolic cotangent of  $z$  is

$$\coth(z) = \frac{1}{\tanh(z)}.$$

### See Also

[acoth](#) | [cot](#) | [sinh](#) | [cosh](#) | [tanh](#)

## countcats

Count occurrences of categorical array elements by category

### Syntax

```
B = countcats(A)
B = countcats(A,dim)
```

### Description

`B = countcats(A)` returns the number of elements in each category of the categorical array, `A`.

- If `A` is a vector, then `countcats` returns the number of elements in each category.
- If `A` is a matrix, then `countcats` treats the columns of `A` as vectors and returns the category counts for each column of `A`.
- If `A` is a multidimensional array, then `countcats` acts along the first array dimension whose size does not equal 1.

`B = countcats(A,dim)` returns the category counts along dimension `dim`.

For example, you can return the category counts of each row in a categorical array using `countcats(A,2)`.

### Examples

#### Category Counts of Categorical Vector

Create a 1-by-5 categorical vector.

```
A = categorical({'plane' 'car' 'train' 'car' 'plane'})
```

```
A =
```

```
 plane car train car plane
```

`A` has three categories, `car`, `plane`, and `train`.

Find the number of elements in each category of **A**.

```
B = countcats(A)
```

```
B =
```

```
 2 2 1
```

The first element in **B** corresponds to the first category of **A**, which is **car**. The second element in **B** corresponds to the second category of **A**, which is **plane**. The third element of **B** corresponds to the third category of **A**, which is **train**.

Since **A** is a row vector, `countcats` returns a row vector.

### Category Counts of Each Column in Array

Create a 3-by-2 categorical array, **A**, from a numeric array.

```
valueset = 1:3;
```

```
catnames = {'red' 'green' 'blue'};
```

```
A = categorical([1 3; 2 1; 3 1],valueset,catnames)
```

```
A =
```

```
 red blue
 green red
 blue red
```

**A** has three categories, **red**, **green**, and **blue**.

Find the category counts of each column in **A**.

```
B = countcats(A)
```

```
B =
```

```
 1 2
 1 0
 1 1
```

The first row of **B** corresponds to the first category of **A**. The value, **red**, occurs once in the first column of **A** and twice in the second column.

The second row of **B** corresponds to the second category of **A**. The value, **green**, occurs once in the first column of **A**, and it does not occur in the second column.

The third row of **B** corresponds to the third category of **A**. The value, **blue**, occurs once in the first column of **A** and once in the second column.

### Category Counts of Each Row in Array

Create a 3-by-2 categorical array, **A**, from a numeric array.

```
valueset = 1:3;
catnames = {'red' 'green' 'blue'};

A = categorical([1 3; 2 1; 3 1],valueset,catnames)
```

A =

|       |      |
|-------|------|
| red   | blue |
| green | red  |
| blue  | red  |

**A** has three categories, **red**, **green**, and **blue**.

Find the category counts of **A** along the second dimension.

```
B = countcats(A,2)
```

B =

|   |   |   |
|---|---|---|
| 1 | 0 | 1 |
| 1 | 1 | 0 |
| 1 | 0 | 1 |

The first column of **B** corresponds to the first category of **A**. The value, **red**, occurs once in the first row of **A**, once in the second row, and once in the third row.

The second column of **B** corresponds to the second category of **A**. The value, **green**, occurs in only one element. It occurs in the second row of **A**.

The third column of **B** corresponds to the third category of **A**. The value, **blue**, occurs once in the first row of **A** and once in the third row.

### Category Counts of Array Containing Undefined Elements

Create a 6-by-1 categorical array, **A**, from a numeric array.

```
valueset = 1:3;
catnames = {'red' 'green' 'blue'};
```

```
A = categorical([1;3;2;1;3;1],valueset,catnames)
```

```
A =
```

```
 red
 blue
 green
 red
 blue
 red
```

Remove the **blue** category.

```
A = removecats(A, 'blue')
```

```
A =
```

```
 red
 <undefined>
 green
 red
 <undefined>
 red
```

A has two categories, **red** and **green**. Elements of A that were from the **blue** category are now undefined.

Find the number of elements in each category of A.

```
B = countcats(A)
```

```
B =
```

```
 3
 1
```

The first element in B corresponds to the first category of A. The value, **red**, occurs three times in A.

The second element in B corresponds to the second category of A. The value, **green**, occurs once in A.

`countcats` does not return any information on undefined elements.

Use the `summary` function to view the number of undefined elements in addition to the number of elements in each category of A.

```
summary(A)
```

```
red 3
green 1
<undefined> 2
```

## Input Arguments

### A — Categorical array

vector | matrix | multidimensional array

Categorical array, specified as a vector, matrix, or multidimensional array.

### dim — Dimension to operate along

positive integer scalar

Dimension to operate along, specified as a positive integer scalar. If no value is specified, then the default is the first array dimension whose size does not equal 1.

Consider a two-dimensional categorical array, A.

If `dim = 1`, then `countcats(A,1)` returns the category counts for each column of A.

If `dim = 2`, then `countcats(A,2)` returns the category counts of each row of A.

If `dim` is greater than `ndims(A)`, then `countcats(A)` returns an array the same size as `A` for each category. `countcats` returns 1 for elements in the corresponding category and 0 otherwise.

## More About

### Tips

- To find the number of undefined elements in a categorical array, `A`, you must use `summary` or `isundefined`.

### See Also

`categories` | `iscategory` | `ismember` | `isundefined` | `summary`

Introduced in R2013b

## COV

Covariance

### Syntax

```
C = cov(A)
C = cov(A,B)
C = cov(____,w)
C = cov(____,nanflag)
```

### Description

`C = cov(A)` returns the covariance.

- If `A` is a vector of observations, `C` is the scalar-valued variance.
- If `A` is a matrix whose columns represent random variables and whose rows represent observations, `C` is the covariance matrix with the corresponding column variances along the diagonal.
- `C` is normalized by the number of observations - 1. If there is only one observation, it is normalized by 1.
- If `A` is a scalar, `cov(A)` returns 0. If `A` is an empty array, `cov(A)` returns NaN.

`C = cov(A,B)` returns the covariance between two random variables `A` and `B`.

- If `A` and `B` are vectors of observations with equal length, `cov(A,B)` is the 2-by-2 covariance matrix.
- If `A` and `B` are matrices of observations, `cov(A,B)` treats `A` and `B` as vectors and is equivalent to `cov(A(:),B(:))`. `A` and `B` must have equal size.
- If `A` and `B` are scalars, `cov(A,B)` returns a 2-by-2 block of zeros. If `A` and `B` are empty arrays, `cov(A,B)` returns a 2-by-2 block of NaN.

`C = cov( ____,w)` specifies the normalization weight for any of the previous syntaxes. When `w = 0` (default), `C` is normalized by the number of observations - 1. When `w = 1`, it is normalized by the number of observations.

`C = cov( ____, nanflag)` specifies a condition for omitting NaN values from the calculation for any of the previous syntaxes. For example, `cov(A, 'omitrows')` will omit any rows of `A` with one or more NaN elements.

## Examples

### Covariance of Matrix

Create a 3-by-4 matrix and compute its covariance.

```
A = [5 0 3 7; 1 -5 7 3; 4 9 8 10];
C = cov(A)
```

```
C =
```

```
 4.3333 8.8333 -3.0000 5.6667
 8.8333 50.3333 6.5000 24.1667
 -3.0000 6.5000 7.0000 1.0000
 5.6667 24.1667 1.0000 12.3333
```

Since the number of columns of `A` is 4, the result is a 4-by-4 matrix.

### Covariance of Two Vectors

Create two vectors and compute their 2-by-2 covariance matrix.

```
A = [3 6 4];
B = [7 12 -9];
cov(A,B)
```

```
ans =
```

```
 2.3333 6.8333
 6.8333 120.3333
```

### Covariance of Two Matrices

Create two matrices of the same size and compute their 2-by-2 covariance.

```
A = [2 0 -9; 3 4 1];
```

```
B = [5 2 6; -4 4 9];
cov(A,B)
```

```
ans =
```

```
22.1667 -6.9333
 -6.9333 19.4667
```

### Specify Normalization Weight

Create a matrix and compute the covariance normalized by the number of rows.

```
A = [1 3 -7; 3 9 2; -5 4 6];
C = cov(A,1)
```

```
C =
```

```
11.5556 5.1111 -10.2222
 5.1111 6.8889 5.2222
-10.2222 5.2222 29.5556
```

### Covariance Excluding NaN

Create a matrix and compute its covariance, excluding any rows containing NaN values.

```
A = [1.77 -0.005 3.98; NaN -2.95 NaN; 2.54 0.19 1.01]
```

```
A =
```

```
1.7700 -0.0050 3.9800
 NaN -2.9500 NaN
2.5400 0.1900 1.0100
```

```
C = cov(A, 'omitrows')
```

```
C =
```

```
0.2964 0.0751 -1.1435
0.0751 0.0190 -0.2896
```

-1.1435   -0.2896   4.4105

## Input Arguments

### **A — Input array**

vector | matrix

Input array, specified as a vector or matrix.

Data Types: single | double

### **B — Additional input array**

vector | matrix

Additional input matrix, specified as a vector or matrix. **B** must be the same size as **A**.

Data Types: single | double

### **w — Normalization weight**

0 (default) | 1

Normalization weight, specified as one of these values:

- **0** — The output is normalized by the number of observations - 1. If there is only one observation, it is normalized by 1.
- **1** — The output is normalized by the number of observations.

Data Types: single | double

### **nanflag — NaN condition**

'includenan' (default) | 'omitrows' | 'partialrows'

NaN condition, specified as one of these values:

- **'includenan'** — include all NaN values in the input prior to computing the covariance.
- **'omitrows'** — omit any row of input containing one or more NaN values prior to computing the covariance.
- **'partialrows'** — omit rows containing NaN only on a pair-wise basis for each two-column covariance calculation.

Data Types: char

## Output Arguments

### **C** — Covariance

scalar | matrix

Covariance, specified as a scalar or matrix.

- For single matrix input, **C** has size `[ size(A,2) size(A,2) ]` based on the number of random variables (columns) represented by **A**. The variances of the columns are along the diagonal. If **A** is a row or column vector, **C** is the scalar-valued variance.
- For two-vector or two-matrix input, **C** is the 2-by-2 covariance matrix between the two random variables. The variances are along the diagonal of **C**.

## More About

### Covariance

For two random variable vectors *A* and *B*, the covariance is defined as

$$\text{cov}(A, B) = \frac{1}{N-1} \sum_{i=1}^N (A_i - \mu_A)^* (B_i - \mu_B)$$

where  $\mu_A$  is the mean of *A*,  $\mu_B$  is the mean of *B*, and  $*$  denotes the complex conjugate.

The *covariance matrix* of two random variables is the matrix of pair-wise covariance calculations between each variable,

$$C = \begin{pmatrix} \text{cov}(A, A) & \text{cov}(A, B) \\ \text{cov}(B, A) & \text{cov}(B, B) \end{pmatrix}.$$

For a matrix **A** whose columns are each a random variable made up of observations, the covariance matrix is the pair-wise covariance calculation between each column combination. In other words,  $C(i, j) = \text{cov}(A(:, i), A(:, j))$ .

**Variance**

For a random variable vector  $A$  made up of  $N$  scalar observations, the variance is defined as

$$V = \frac{1}{N-1} \sum_{i=1}^N |A_i - \mu|^2$$

where  $\mu$  is the mean of  $A$ ,

$$\mu = \frac{1}{N} \sum_{i=1}^N A_i.$$

Some definitions of variance use a normalization factor of  $N$  instead of  $N-1$ , which can be specified by setting `w` to `1`. In either case, the mean is assumed to have the usual normalization factor  $N$ .

**Introduced before R2006a**

# cplxpair

Sort complex numbers into complex conjugate pairs

## Syntax

```
B = cplxpair(A)
B = cplxpair(A,tol)
B = cplxpair(A,[],dim)
B = cplxpair(A,tol,dim)
```

## Description

`B = cplxpair(A)` sorts the elements along different dimensions of a complex array, grouping together complex conjugate pairs.

The conjugate pairs are ordered by increasing real part. Within a pair, the element with negative imaginary part comes first. The purely real values are returned following all the complex pairs. The complex conjugate pairs are forced to be exact complex conjugates. A default tolerance of  $100 \times \text{eps}$  relative to  $\text{abs}(A(i))$  determines which numbers are real and which elements are paired complex conjugates.

If `A` is a vector, `cplxpair(A)` returns `A` with complex conjugate pairs grouped together.

If `A` is a matrix, `cplxpair(A)` returns `A` with its columns sorted and complex conjugates paired.

If `A` is a multidimensional array, `cplxpair(A)` treats the values along the first non-singleton dimension as vectors, returning an array of sorted elements.

`B = cplxpair(A,tol)` overrides the default tolerance.

`B = cplxpair(A,[],dim)` sorts `A` along the dimension specified by scalar `dim`.

`B = cplxpair(A,tol,dim)` sorts `A` along the specified dimension and overrides the default tolerance.

## **Diagnostics**

If there are an odd number of complex numbers, or if the complex numbers cannot be grouped into complex conjugate pairs within the tolerance, `cxpair` generates the error message

Complex numbers can't be paired.

**Introduced before R2006a**

# cputime

Elapsed CPU time

## Syntax

```
cputime
```

## Description

`cputime` returns the total CPU time (in seconds) used by your MATLAB application from the time it was started. This number can overflow the internal representation and wrap around.

## Examples

The following code returns the CPU time used to run `surf(peaks(40))`.

```
t = cputime;
surf(peaks(40));
e = cputime-t

e =
 0.4667
```

## More About

### Tips

Although it is possible to measure performance using the `cputime` function, it is recommended that you use the `timeit` or `tic` and `toc` functions for this purpose exclusively. See [Using tic and toc Versus the cputime Function in the MATLAB Programming Fundamentals documentation](#) for more information.

### See Also

`clock` | `etime` | `tic` | `timeit` | `toc`

**Introduced before R2006a**

# RandStream.create

Create random number streams

## Class

RandStream

## Syntax

```
[s1,s2,...] = RandStream.create('gentype','NumStreams',n)
s = RandStream.create('gentype')
[...] = RandStream.create('gentype', Name, Value,...)
```

## Description

[s1,s2,...] = RandStream.create('gentype','NumStreams',n) creates n random number streams that use the uniform pseudorandom number generator algorithm specified by **gentype**. The streams are independent in a pseudorandom sense. The streams are not necessarily independent from streams created at other times. `RandStream.list` returns all possible values for **gentype** or see “Choosing a Random Number Generator” in the MATLAB Mathematics documentation for details on generator algorithms.

---

**Note:** Multiple streams are not supported by all generator types. Use either the multiplicative lagged Fibonacci generator (`m1fg6331_64`) or the combined multiple recursive generator (`mrg32k3a`) to create multiple streams.

---

`s = RandStream.create('gentype')` creates a single random stream. The `RandStream` constructor is a more concise alternative when you need to create a single stream.

`[ ... ] = RandStream.create('gentype', Name, Value,...)` allows you to specify optional Name, Value pairs to control creation of the stream. The parameters are:

|                 |                                                                                                                                                                                             |
|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NumStreams      | Total number of streams of this type that will be created across sessions or labs. Default is 1.                                                                                            |
| StreamIndices   | Stream indices that should be created in this call. Default is 1:N, where N is the value given with the 'NumStreams' parameter.                                                             |
| Seed            | Nonnegative scalar integer with which to initialize all streams. Default is 0. Seeds must be an integer between 0 and $2^{32} - 1$ or 'shuffle' to create a seed based on the current time. |
| NormalTransform | Transformation algorithm used by <code>randn(S, ...)</code> to generate normal pseudorandom values. Options are 'Ziggurat', 'Polar', or 'Inversion'.                                        |
| CellOutput      | Logical flag indicating whether or not to return the stream objects as elements of a cell array. Default is false.                                                                          |

Typically, you call `RandStream.create` once to create multiple independent streams in a single pass. Alternatively, you can create each stream from separate calls to `RandStream.create`, but you must specify the appropriate values for `gentype`, 'NumStreams', 'Seed', and 'StreamIndices' to ensure their independence:

- Specify the same set of values for `gentype`, 'NumStreams', and 'Seed' in each case.
- Specify a different value for 'StreamIndices' that is between 1 and the 'NumStreams' value in each case.

## Examples

Create three independent streams.

```
[s1,s2,s3] = RandStream.create('mrg32k3a', 'NumStreams', 3);
r1 = rand(s1, 100000, 1);
r2 = rand(s2, 100000, 1);
r3 = rand(s3, 100000, 1);
```

```
corrcoef([r1,r2,r3])
```

Create one stream from a set of three independent streams and designate it as the global stream.

```
s2 = RandStream.create('mrg32k3a','NumStreams',3,'StreamIndices',2);
RandStream.setGlobalStream(s2);
```

## See Also

## createClassFromWsd1

Create MATLAB class based on WSDL document

### Compatibility

`createClassFromWsd1` will be removed in a future release. Use `matlab.wsd1.createWSDIClient` instead.

### Syntax

```
createClassFromWsd1(source)
```

### Description

`createClassFromWsd1(source)` creates a MATLAB class based on the service name defined in `source`.

`createClassFromWsd1` creates a class folder, `@servicename`, in the current folder. The class folder contains:

- A method file for each Web service operation.
- A display method, `display.m`.
- A constructor, `servicename.m`.

### Examples

#### Display Standardized Test Scores

This example illustrates how to use the function. It does not use an actual WSDL document; therefore, you cannot run it. Retrieve information from a database that provides standardized test scores. Assume the WSDL document is located at `http://examplestandardtests.com/scoreswebservice?WSDL`.

Create the MATLAB class, `@TestScoreWebService`, in the current folder.

```
createClassFromWsd1('http://examplestandardtests.com/scoreswebservice?WSDL')
Retrieving document at 'http://examplestandardtests.com/scoreswebservice?WSDL'
```

Create the service.

```
svc = TestScoreWebService
endpoint: 'http://examplestandardtests.com/scoreswebservice'
wsdl: 'http://examplestandardtests.com/scoreswebservice?WSDL'
```

Display the class methods.

```
dir @TestScoreWebService

display.m
StudentNames.m
Tests.m
TestScoreWebService.m
```

Display the calling syntax for the `StudentNames` function.

```
help StudentNames

StudentNames(obj)

 Get names of students who took tests

 Output:
 Names = (string)
```

Get the names. MATLAB creates a structure with the names of the test takers.

```
students = StudentNames(svc)

students =

 StudentInfo: [125x1 struct]
```

View the data for the first student.

```
students.StudentInfo(1)

StudentNameLast: 'Benjamin'
StudentNameFirst: 'Ali'
```

- “Specify Proxy Server Settings for Connecting to the Internet”

## Input Arguments

**source** — Web Services Description Language (WSDL) document

string

Web Services Description Language (WSDL) document, specified as a string. The name must include the location of the document, using one of the following:

- URL
- Full path
- Relative path

Example: 'http://examplestandardtests.com/scoreswebservice?WSDL'

### See Also

`createSoapMessage` | `matlab.wsd1.createWSDLClient` | `xmlread`

**Introduced before R2006a**

# createSoapMessage

Create SOAP (Simple Object Access Protocol) message to send to server

## Compatibility

createSoapMessage will be removed in a future release. Use `matlab.wsd1.createWSDLClient` instead.

## Syntax

```
message = createSoapMessage(namespace,method,values, names, types)
message = createSoapMessage(namespace,method,values, names, types,
style)
```

## Description

`message = createSoapMessage(namespace,method,values, names, types)` creates a SOAP message.

`message = createSoapMessage(namespace,method,values, names, types, style)` creates message with specified style.

## Examples

### Retrieve Book Information from Library Database

This example assumes the library is on a local intranet and does not use an actual endpoint; therefore, you cannot run it.

Retrieve the name of the author of a book titled “In the Fall.” The relative path of the library service is `urn:LibraryCatalog`. To get the author's name, use the `getAuthor` function, which takes the book name as the input value. The `getAuthor` parameter is `nameToLookUp`. The XML data type for title is `{http://www.w3.org/2001/XMLSchema}string`. The SOAP message style is `rpc` by default.

Create the SOAP message.

```
message = createSoapMessage(...
 'urn:LibraryCatalog',...
 'getAuthor',...
 {'In the Fall'},...
 {'nameToLookUp'},...
 {'{http://www.w3.org/2001/XMLSchema}string'})
```

```
message =
```

```
[#document: null]
```

This response does not necessarily indicate that the message is valid, although certain input problems produce error messages.

Send the message to the server for processing, and get the author's name back. The server endpoint is `http://test/soap/services/LibraryCatalog`. The server method is `urn:LibraryCatalog#getAuthor`.

```
response = callSoapService(...
 'http://test/soap/services/LibraryCatalog',...
 'urn:LibraryCatalog#getAuthor',...
 message)
```

```
<?xml version="1.0" encoding="utf-8"?>
<soapenv:Envelope
 xmlns:soapenv="http://schemas.xmlsoap.org/soap/envelope/"
 xmlns:xsd="http://www.w3.org/2001/XMLSchema"
 xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
 <soapenv:Body>
 <getAuthorResponse xmlns="urn:LibraryCatalog">
 <ns1:getAuthorReturn xmlns:ns1="http://latestversion.soap.test">
 Kate Alvin
 </ns1:getAuthorReturn>
 </getAuthorResponse>
 </soapenv:Body>
</soapenv:Envelope>
```

MATLAB returns the message in a single line, displayed here on separate lines for legibility.

Extract the author's name.

```
author = parseSoapResponse(response)
```

```
author = Kate Alvin
```

MATLAB automatically converted the XML string data type to char.

## Input Arguments

### **namespace** — Location of Web service

string

Location of Web service, specified as a string in the form of a valid Uniform Resource Identifier (URI).

Example: 'urn:LibraryCatalog'

### **method** — Name of Web service operation

string

Name of Web service operation, specified as a string.

Example: 'getAuthor'

### **values** — Input arguments for method

cell array

Input arguments for method, specified as a cell array.

Example: {'In the Fall'}

### **names** — Parameter for method

cell array

Parameter for method, specified as a cell array.

Example: {'nameToLookUp'}

### **types** — XML data types for values

cell array

XML data types for values, specified as a cell array.

Example: {'{http://www.w3.org/2001/XMLSchema}string'}

### **style** — Style for structuring SOAP message

'rpc' (default) | 'document'

Style for structuring the SOAP message, specified as one of these values. Use a style supported by the service specified in namespace.

|            |                                      |
|------------|--------------------------------------|
| 'rpc'      | Remote Procedure Call (RPC) encoding |
| 'document' | Document-style encoding              |

## Output Arguments

**message** — Java document object model (DOM)

*string*

Java document object model (DOM), returned as a string. Use **message** as input to `callSoapService` function.

### See Also

`callSoapService` | `matlab.wsd1.createWSDLClient` | `parseSoapResponse` | `urlread` | `xmlread`

**Introduced before R2006a**

## cross

Cross product

### Syntax

```
C = cross(A,B)
C = cross(A,B,dim)
```

### Description

`C = cross(A,B)` returns the cross product of `A` and `B`.

- If `A` and `B` are vectors, then they must have a length of 3.
- If `A` and `B` are matrices or multidimensional arrays, then they must have the same size. In this case, the `CROSS` function treats `A` and `B` as collections of three-element vectors. The function calculates the cross product of corresponding vectors along the first array dimension whose size equals 3.

`C = cross(A,B,dim)` evaluates the cross product of arrays `A` and `B` along dimension, `dim`. `A` and `B` must have the same size, and both `size(A,dim)` and `size(B,dim)` must be 3. The `dim` input is a positive integer scalar.

### Examples

#### Cross Product of Vectors

Create two 3-D vectors.

```
A = [4 -2 1];
B = [1 -1 3];
```

Find the cross product of `A` and `B`.

```
C = cross(A,B)
C =
```

```
-5 -11 -2
```

The result, **C**, is a vector that is perpendicular to both **A** and **B**.

Use dot products to verify that **C** is perpendicular to **A** and **B**.

```
dot(C,A)==0 & dot(C,B)==0
```

```
ans =
```

```
1
```

The result is logical 1 (**true**).

### **Cross Product of Matrices**

Create two matrices containing random integers.

```
rng(0)
```

```
A = randi(15,3,5)
```

```
B = randi(25,3,5)
```

```
A =
```

```
13 14 5 15 15
14 10 9 3 8
2 2 15 15 13
```

```
B =
```

```
4 20 1 17 10
11 24 22 19 17
23 17 24 19 5
```

Find the cross product of **A** and **B**.

```
C = cross(A,B)
```

```
C =
```

```
300 122 -114 -228 -181
-291 -198 -105 -30 55
87 136 101 234 175
```

The result, **C**, contains five independent cross products between the columns of **A** and **B**. For example,  $C(:,1)$  is equal to the cross product of  $A(:,1)$  with  $B(:,1)$ .

### Cross Product of Multidimensional Arrays

Create two 3-by-3-by-3 multidimensional arrays of random integers.

```
rng(0)
A = randi(10,3,3,3);
B = randi(25,3,3,3);
```

Find the cross product of **A** and **B**, treating the rows as vectors.

```
C = cross(A,B,2)
```

```
C(:,:,1) =
```

```
 -34 12 62
 15 72 -109
 -49 8 9
```

```
C(:,:,2) =
```

```
 198 -164 -170
 45 0 -18
 -55 190 -116
```

```
C(:,:,3) =
```

```
 -109 -45 131
 1 -74 82
 -6 101 -121
```

The result is a collection of row vectors. For example,  $C(1, :, 1)$  is equal to the cross product of  $A(1, :, 1)$  with  $B(1, :, 1)$ .

Find the cross product of **A** and **B** along the third dimension (`dim = 3`).

```
D = cross(A,B,3)
```

```
D(:,:,1) =
```

```
 -14 179 -106
 -56 -4 -75
```

```
2 -37 10
```

```
D(:, :, 2) =
```

```
-37 -162 -37
50 -124 -78
1 63 118
```

```
D(:, :, 3) =
```

```
62 -170 56
46 72 105
-2 -53 -160
```

The result is a collection of vectors oriented in the third dimension. For example,  $C(1, 1, :)$  is equal to the cross product of  $A(1, 1, :)$  with  $B(1, 1, :)$ .

## Input Arguments

### **A, B** — Input arrays

numeric arrays

Input arrays, specified as numeric arrays.

Data Types: `single` | `double`

Complex Number Support: Yes

### **dim** — Dimension to operate along

positive integer scalar

Dimension to operate along, specified as a positive integer scalar. The size of dimension `dim` must be 3. If no value is specified, the default is the first array dimension whose size equals 3.

Consider two 2-D input arrays, *A* and *B*:

- `cross(A,B,1)` treats the columns of *A* and *B* as vectors and returns the cross products of corresponding columns.
- `cross(A,B,2)` treats the rows of *A* and *B* as vectors and returns the cross products of corresponding rows.

A

cross(A,B,1)

cross(A,B,2)

cross returns an error if dim is greater than ndims(A).

## More About

### Cross Product

The cross product between two 3-D vectors produces a new vector that is perpendicular to both.

Consider the two vectors

$$A = a_1\hat{i} + a_2\hat{j} + a_3\hat{k},$$

$$B = b_1\hat{i} + b_2\hat{j} + b_3\hat{k}.$$

In terms of a matrix determinant involving the basis vectors  $\hat{i}$ ,  $\hat{j}$ , and  $\hat{k}$ , the cross product of  $A$  and  $B$  is

$$C = A \times B = \begin{vmatrix} \hat{i} & \hat{j} & \hat{k} \\ a_1 & a_2 & a_3 \\ b_1 & b_2 & b_3 \end{vmatrix}$$

$$= (a_2b_3 - a_3b_2)\hat{i} + (a_3b_1 - a_1b_3)\hat{j} + (a_1b_2 - a_2b_1)\hat{k}.$$

Geometrically,  $A \times B$  is perpendicular to both  $A$  and  $B$ . The magnitude of the cross product,  $\|A \times B\|$ , is equal to the area of the parallelogram formed using  $A$  and  $B$  as sides. This area is related to the magnitudes of  $A$  and  $B$  as well as the angle between the vectors by

$$\|A \times B\| = \|A\| \|B\| \sin \alpha .$$

Thus, if  $A$  and  $B$  are parallel, then the cross product is zero.

## CSC

Cosecant of input angle in radians

## Syntax

$Y = \text{csc}(X)$

## Description

$Y = \text{csc}(X)$  returns the cosecant of the elements of  $X$ . The `csc` function operates element-wise on arrays. The function accepts both real and complex inputs. For real values of  $X$  in the interval  $[-\text{Inf}, \text{Inf}]$ , `csc` returns real values in the interval  $[-\text{Inf}, -1]$  and  $[1, \text{Inf}]$ . For complex values of  $X$ , `csc` returns complex values. All angles are in radians.

## Examples

### Plot Cosecant Function

Plot the cosecant function over the domain  $-\pi < x < 0$  and  $0 < x < \pi$  as shown.

```
x1 = -pi+0.01:0.01:-0.01;
x2 = 0.01:0.01:pi-0.01;
plot(x1,csc(x1),x2,csc(x2)), grid on
```

### Cosecant of Vector of Complex Angles

Calculate the cosecant of the complex angles in vector  $x$ .

```
x = [-i pi+i*pi/2 -1+i*4];
y = csc(x)
```

y =

```
0.0000 + 0.8509i 0.0000 + 0.4345i -0.0308 - 0.0198i
```

## Input Arguments

### X — Input angle in radians

number | vector | matrix | multidimensional array

Input angle in radians, specified as a number, vector, matrix, or multidimensional array.

Data Types: `single` | `double`

Complex Number Support: Yes

## Output Arguments

### Y — Cosecant of input angle

scalar value | vector | matrix | N-D array

Cosecant of input angle, returned as a real-valued or complex-valued scalar, vector, matrix or N-D array.

## More About

### Cosecant Function

The cosecant of an angle,  $\alpha$ , defined with reference to a right angled triangle is

$$\csc(\alpha) = \frac{1}{\sin(\alpha)} = \frac{\text{hypotenuse}}{\text{opposite side}} = \frac{h}{a}.$$

The cosecant of a complex angle,  $\alpha$ , is

$$\operatorname{csc}(\alpha) = \frac{2i}{e^{i\alpha} - e^{-i\alpha}}.$$

### See Also

Introduced before R2006a

## cscd

Cosecant of argument in degrees

### Syntax

$Y = \text{cscd}(X)$

### Description

$Y = \text{cscd}(X)$  returns the cosecant of the elements of  $X$ , which are expressed in degrees.

### Examples

#### Cosecant of 180 degrees compared to cosecant of $\pi$ radians

$\text{cscd}(180)$  is infinite, whereas  $\text{csc}(\pi)$  is large but finite.

```
cscd(180)
```

```
ans =
```

```
 Inf
```

```
csc(pi)
```

```
ans =
```

```
 8.1656e+15
```

#### Cosecant of vector of complex angles, specified in degrees

```
z = [35+i 15+2i 10+3i];
```

```
y = cscd(z)
```

```
y =
```

1.7421 - 0.0434i    3.7970 - 0.4944i    5.2857 - 1.5681i

## Input Arguments

### **X — Angle in degrees**

scalar value | vector | matrix | N-D array

Angle in degrees, specified as a real-valued or complex-valued scalar, vector, matrix, or N-D array. The `cscd` operation is element-wise when `X` is nonscalar.

Data Types: `single` | `double`

Complex Number Support: Yes

## Output Arguments

### **Y — Cosecant of angle**

scalar value | vector | matrix | N-D array

Cosecant of angle, returned as a real-valued or complex-valued scalar, vector, matrix, or N-D array of the same size as `X`.

## See Also

`acsc` | `acscd` | `csc`

**Introduced before R2006a**

# csch

Hyperbolic cosecant

## Syntax

$Y = \operatorname{csch}(x)$

## Description

The `csch` function operates element-wise on arrays. The function's domains and ranges include complex values. All angles are in radians.

$Y = \operatorname{csch}(x)$  returns the hyperbolic cosecant for each element of  $x$ .

## Examples

### Graph of Hyperbolic Cosecant

Plot the hyperbolic cosecant over the domain  $-\pi < x < 0$  and  $0 < x < \pi$ .

```
x1 = -pi+0.01:0.01:-0.01;
x2 = 0.01:0.01:pi-0.01;
plot(x1,csch(x1),x2,csch(x2)), grid on
```

## More About

### Hyperbolic Cosecant

The hyperbolic cosecant of  $z$  is

$$\operatorname{csch}(z) = \frac{1}{\sinh(z)}.$$

### See Also

## csvread

Read comma-separated value (CSV) file

### Syntax

```
M = csvread(filename)
M = csvread(filename,R1,C1)
M = csvread(filename,R1,C1,[R1 C1 R2 C2])
```

### Description

`M = csvread(filename)` reads a comma-separated value (CSV) formatted file into array `M`. The file must contain only numeric values.

`M = csvread(filename,R1,C1)` reads data from the file starting at row offset `R1` and column offset `C1`. For example, the offsets `R1=0`, `C1=0` specify the first value in the file.

`M = csvread(filename,R1,C1,[R1 C1 R2 C2])` reads only the range bounded by row offsets `R1` and `R2` and column offsets `C1` and `C2`. Another way to define the range is to use spreadsheet notation, such as `'A1..B7'` instead of `[0 0 6 1]`.

### Examples

#### Read Entire CSV File

Create a file named `csvlist.dat` that contains comma-separated values.

```
02, 04, 06, 08
03, 06, 09, 12
05, 10, 15, 20
07, 14, 21, 28
```

Read the numeric values in the file.

```
filename = 'csvlist.dat';
M = csvread(filename)
```

```
M =
 2 4 6 8
 3 6 9 12
 5 10 15 20
 7 14 21 28
```

### Read CSV File Starting at Specific Row and Column Offset

Read the matrix starting two rows below the first row from the file described in the previous example.

```
M = csvread('csvlist.dat',2,0)
```

```
M =
 5 10 15 20
 7 14 21 28
```

### Read Specific Range from CSV File

Read the matrix bounded by row offsets 1 and 2 and column offsets 0 and 2 from the file described in the first example.

```
M = csvread('csvlist.dat',1,0,[1,0,2,2])
```

```
M =
 3 6 9
 5 10 15
```

## Input Arguments

### **filename** — File name

string

File name, specified as a string.

Example: 'myFile.dat'

Data Types: char

### **R1** — Starting row offset

0 (default) | nonnegative integer

Starting row offset, specified as a nonnegative integer. The first row has an offset of 0.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

## **C1 — Starting column offset**

0 (default) | nonnegative integer

Starting column offset, specified as a nonnegative integer. The first column has an offset of 0.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

## **R2 — Ending row offset**

nonnegative integer

Ending row offset, specified as a nonnegative integer. The first row has an offset of 0.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

## **C2 — Ending column offset**

nonnegative integer

Ending column offset, specified as a nonnegative integer. The first column has an offset of 0.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

## **More About**

### **Tips**

- Skip header rows or columns by specifying row and column offsets. All values in the file other than headers must be numeric.

### **Algorithms**

`csvread` fills empty delimited fields with zero. When the `csvread` function reads data files with lines that end with a nonspace delimiter, such as a semicolon, it returns a matrix, `M`, that has an additional last column of zeros.

csvread imports any complex number as a whole into a complex numeric field, converting the real and imaginary parts to the specified numeric type. The table shows valid forms for a complex number.

| Form                                                             | Example  |
|------------------------------------------------------------------|----------|
| $\pm\langle\text{real}\rangle\pm\langle\text{imag}\rangle i   j$ | 5.7-3.1i |
| $\pm\langle\text{imag}\rangle i   j$                             | -7j      |

Embedded white space in a complex number is invalid and is regarded as a field delimiter.

## **ctranspose, '**

Complex conjugate transpose

### **Syntax**

$B = A'$

$B = \text{ctranspose}(A)$

### **Description**

$B = A'$  computes the complex conjugate transpose of  $A$ .

$B = \text{ctranspose}(A)$  is an alternate way to execute  $A'$ , but is rarely used. It enables operator overloading for classes.

### **Examples**

#### **Conjugate Transpose of Real Matrix**

Create a 4-by-2 matrix.

$A = [2 \ 1; \ 9 \ 7; \ 2 \ 8; \ 3 \ 5]$

$A =$

|   |   |
|---|---|
| 2 | 1 |
| 9 | 7 |
| 2 | 8 |
| 3 | 5 |

Find the conjugate transpose of  $A$ .

$B = A'$

$B =$

```

2 9 2 3
1 7 8 5

```

The result is a 2-by-4 matrix. **B** has the same elements as **A**, but the row and column index for each element are interchanged. When no complex elements are present, **A'** produces the same result as **A.'**

### Conjugate Transpose of Complex Matrix

Create a 2-by-2 matrix with complex elements.

```
A = [0-1i 2+1i;4+2i 0-2i]
```

```
A =
```

```

0.0000 - 1.0000i 2.0000 + 1.0000i
4.0000 + 2.0000i 0.0000 - 2.0000i

```

Find the conjugate transpose of **A**.

```
B = A'
```

```
B =
```

```

0.0000 + 1.0000i 4.0000 - 2.0000i
2.0000 - 1.0000i 0.0000 + 2.0000i

```

The result, **B**, contains the elements of **A** with the row and column indices interchanged. The sign of the imaginary part of each number is also switched.

## Input Arguments

### A — Input array

vector | matrix | cell array | categorical array | datetime array | duration array | calendarDuration array | structure field

Input array, specified as a vector or matrix of any numeric, logical, or **char** data type, or as a cell array, categorical array, datetime array, duration array, calendarDuration array, or structure field.

Complex Number Support: Yes

## More About

### Complex Conjugate Transpose

The complex conjugate transpose of a matrix interchanges the row and column index for each element, reflecting the elements across the main diagonal. The operation also negates the imaginary part of any complex numbers.

For example, if  $B = A'$  and  $A(1,2)$  is  $1+1i$ , then the element  $B(2,1)$  is  $1-1i$ .

### Tips

- The nonconjugate transpose operator,  $A.'$ , performs a transpose without conjugation. That is, it does not change the sign of the imaginary parts of the elements.
- For logical or non-numeric inputs, `ctranspose` and `transpose` produce the same result.
- “Array vs. Matrix Operations”
- “Operator Precedence”

## csvwrite

Write comma-separated value file

### Syntax

```
csvwrite(filename,M)
csvwrite(filename,M,row,col)
```

### Description

`csvwrite(filename,M)` writes matrix `M` into `filename` as comma-separated values. The `filename` input is a string enclosed in single quotes.

`csvwrite(filename,M,row,col)` writes matrix `M` into `filename` starting at the specified row and column offset. The row and column arguments are zero based, so that `row=0` and `C=0` specify the first value in the file.

### Examples

The following example creates a comma-separated value file from the matrix `m`.

```
m = [3 6 9 12 15; 5 10 15 20 25; ...
 7 14 21 28 35; 11 22 33 44 55];
```

```
csvwrite('csvlist.dat',m)
type csvlist.dat
```

```
3,6,9,12,15
5,10,15,20,25
7,14,21,28,35
11,22,33,44,55
```

The next example writes the matrix to the file, starting at a column offset of 2.

```
csvwrite('csvlist.dat',m,0,2)
type csvlist.dat
```

,,3,6,9,12,15  
,,5,10,15,20,25  
,,7,14,21,28,35  
,,11,22,33,44,55

## More About

### Tips

- `csvwrite` terminates each line with a line feed character and no carriage return.
- `csvwrite` writes a maximum of five significant digits. If you need greater precision, use `dlmwrite` with a precision argument.
- `csvwrite` does not accept cell arrays for the input matrix `M`. To export a cell array that contains only numeric data, use `cell2mat` to convert the cell array to a numeric matrix before calling `csvwrite`. To export cell arrays with mixed alphabetic and numeric data, where each cell contains a single element, you can create an Excel spreadsheet (if your system has Excel installed) using `xlswrite`. For all other cases, you must use low-level export functions to write your data. For more information, see “Export Cell Array to Text File” in the MATLAB Data Import and Export documentation.

## cummax

Cumulative maximum

### Syntax

```
M = cummax(A)
M = cummax(A,dim)
M = cummax(____,direction)
```

### Description

`M = cummax(A)` returns the cumulative maximum elements of `A`. By default, `cummax(A)` operates along the first array dimension whose size does not equal 1.

- If `A` is a vector, then `cummax(A)` returns a vector of the same size containing the cumulative maxima of `A`.
- If `A` is a matrix, then `cummax(A)` returns a matrix of the same size containing the cumulative maxima in each column of `A`.
- If `A` is a multidimensional array, then `cummax(A)` returns an array of the same size containing the cumulative maxima along the first array dimension of `A` whose size does not equal 1.

`M = cummax(A,dim)` returns the cumulative maxima along the dimension `dim`. For example, if `A` is a matrix, then `cummax(A,2)` returns the cumulative maxima along the rows of `A`.

`M = cummax( ____,direction)` optionally specifies the direction using any of the previous syntaxes. You must specify `A` and, optionally, can specify `dim`. For instance, `cummax(A,2, 'reverse')` returns the cumulative maxima of `A` by working from end to beginning of the second dimension of `A`.

### Examples

#### Cumulative Maximum Values in Vector

Find the cumulative maxima of a 1-by-10 vector of random integers.

```
v = randi(10,1,10)
```

```
v =
```

```
 8 3 6 7 9 10 6 2 2 3
```

```
M = cummax(v)
```

```
M =
```

```
 8 8 8 8 9 10 10 10 10 10
```

## Cumulative Maximum Values in Matrix Columns

Find the cumulative maxima of the columns of a 3-by-3 matrix.

```
A = [3 5 2; 1 6 3; 7 8 1]
```

```
A =
```

```
 3 5 2
 1 6 3
 7 8 1
```

```
M = cummax(A)
```

```
M =
```

```
 3 5 2
 3 6 3
 7 8 3
```

## Cumulative Maximum Values in Matrix Rows

Find the cumulative maxima of the rows of a 3-by-3 matrix.

```
A = [3 5 2; 1 6 3; 7 8 1]
```

```
A =
```

```
 3 5 2
 1 6 3
 7 8 1
```

```
M = cummax(A,2)
```

```
M =
```

```
3 5 5
1 6 6
7 8 8
```

### Cumulative Maximum Array Values in Reverse Direction

Calculate the cumulative maxima in the third dimension of a 2-by-2-by-3 array. Specify direction as 'reverse' to work from the end of the third dimension to the beginning.

```
A = cat(3,[1 2; 3 4],[9 10; 11 12],[5 6; 7 8])
```

```
A(:,:,1) =
```

```
1 2
3 4
```

```
A(:,:,2) =
```

```
9 10
11 12
```

```
A(:,:,3) =
```

```
5 6
7 8
```

```
M = cummax(A,3,'reverse')
```

```
M(:,:,1) =
```

```
9 10
11 12
```

```
M(:,:,2) =
```

```
9 10
11 12
```

```
M(:,:,3) =
```

```
5 6
```

## Input Arguments

### **A** — Input array

vector | matrix | multidimensional array

Input array, specified as a vector, matrix, or multidimensional array. For complex elements, `cummax` compares the magnitude of the elements. If magnitudes are equal, `cummax` also compares the phase angles.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `duration`

Complex Number Support: Yes

### **dim** — Dimension to operate along

positive integer scalar

Dimension to operate along, specified as a positive integer scalar. If no value is specified, then the default is the first array dimension whose size does not equal 1.

Consider a two-dimensional input array, **A**:

- `cummax(A,1)` works on successive elements in the columns of **A** and returns an array of the same size as **A** with the cumulative maxima in each column.

`cummax(A,1)`

- `cummax(A,2)` works on successive elements in the rows of **A** and returns an array of the same size as **A** with the cumulative maxima in each row.

`cummax(A,2)`

`cummax` returns `A` if `dim` is greater than `ndims(A)`.

### **direction** — Direction of cumulation

'forward' (default) | 'reverse'

Direction of cumulation, specified as the string 'forward' (default) or 'reverse'.

- 'forward' works from 1 to end of the active dimension.
- 'reverse' works from end to 1 of the active dimension.

Data Types: char

## Output Arguments

### **M** — Cumulative maxima

vector | matrix | multidimensional array

Cumulative maxima, returned as a vector, matrix, or multidimensional array. The size and data type of `M` are the same as those of `A`.

## More About

### Tips

- The `cummax` function does not return NaN values unless the first element in the active dimension is a NaN. In that case, the corresponding first element in the output is a NaN. If the input has further consecutive NaN values, so that `cummax` must compare NaNs to determine the cumulative maximum, the output also has consecutive NaNs.

- The 'reverse' option in many cumulative functions allows quick directional calculations without requiring a flip or reflection of the input array.

## **See Also**

`cummin` | `cumprod` | `cumsum` | `max` | `min`

**Introduced in R2014b**

## cummin

Cumulative minimum

### Syntax

```
M = cummin(A)
M = cummin(A,dim)
M = cummin(____,direction)
```

### Description

`M = cummin(A)` returns the cumulative minimum elements of `A`. By default, `cummin(A)` operates along the first array dimension whose size does not equal 1.

- If `A` is a vector, then `cummin(A)` returns a vector of the same size containing the cumulative minima of `A`.
- If `A` is a matrix, then `cummin(A)` returns a matrix of the same size containing the cumulative minima in each column of `A`.
- If `A` is a multidimensional array, then `cummin(A)` returns an array of the same size containing the cumulative minima along the first array dimension of `A` whose size does not equal 1.

`M = cummin(A,dim)` returns the cumulative minima along the dimension `dim`. For example, if `A` is a matrix, then `cummin(A,2)` returns the cumulative minima along the rows of `A`.

`M = cummin( ____,direction)` optionally specifies the direction using any of the previous syntaxes. You must specify `A` and, optionally, can specify `dim`. For instance, `cummin(A,2, 'reverse')` returns the cumulative minima of `A` by working from end to beginning of the second dimension of `A`.

### Examples

#### Cumulative Minimum Values in Vector

Find the cumulative minima of a 1-by-10 vector of random integers.

```
v = randi([0,10],1,10)
```

```
v =
```

```
8 9 1 10 6 1 3 6 10 10
```

```
M = cummin(v)
```

```
M =
```

```
8 8 1 1 1 1 1 1 1 1
```

## Cumulative Minimum Values in Matrix Columns

Find the cumulative minima of the columns of a 3-by-3 matrix.

```
A = [3 5 2; 1 6 3; 7 8 1]
```

```
A =
```

```
3 5 2
1 6 3
7 8 1
```

```
M = cummin(A)
```

```
M =
```

```
3 5 2
1 5 2
1 5 1
```

## Cumulative Minimum Values in Matrix Rows

Find the cumulative minima of the rows of a 3-by-3 matrix.

```
A = [3 5 2; 1 6 3; 7 8 1]
```

```
A =
```

```
3 5 2
1 6 3
7 8 1
```

```
M = cummin(A,2)
```

```
M =
```

```

3 3 2
1 1 1
7 7 1

```

### Cumulative Minimum Array Values in Reverse Direction

Calculate the cumulative minima in the third dimension of a 2-by-2-by-3 array. Specify direction as 'reverse' to work from the end of the third dimension to the beginning.

```
A = cat(3,[1 2; 3 4],[9 10; 11 12],[5 6; 7 8])
```

```
A(:,:,1) =
```

```

1 2
3 4

```

```
A(:,:,2) =
```

```

9 10
11 12

```

```
A(:,:,3) =
```

```

5 6
7 8

```

```
M = cummin(A,3,'reverse')
```

```
M(:,:,1) =
```

```

1 2
3 4

```

```
M(:,:,2) =
```

```

5 6
7 8

```

```
M(:,:,3) =
```

```

5 6

```

## Input Arguments

### **A** — Input array

vector | matrix | multidimensional array

Input array, specified as a vector, matrix, or multidimensional array. For complex elements, `cummin` compares the magnitude of the elements. If magnitudes are equal, `cummin` also compares the phase angles.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `duration`

Complex Number Support: Yes

### **dim** — Dimension to operate along

positive integer scalar

Dimension to operate along, specified as a positive integer scalar. If no value is specified, then the default is the first array dimension whose size does not equal 1.

Consider a two-dimensional input array, **A**:

- `cummin(A,1)` works on successive elements in the columns of **A** and returns an array of the same size as **A** with the cumulative minima in each column.

`cummin(A,1)`

- `cummin(A,2)` works on successive elements in the rows of **A** and returns an array of the same size as **A** with the cumulative minima in each row.

`cummin(A,2)`

`cummin` returns `A` if `dim` is greater than `ndims(A)`.

#### **direction** — Direction of cumulation

'forward' (default) | 'reverse'

Direction of cumulation, specified as the string 'forward' (default) or 'reverse'.

- 'forward' works from 1 to end of the active dimension.
- 'reverse' works from end to 1 of the active dimension.

Data Types: char

## Output Arguments

### **M** — Cumulative minima

vector | matrix | multidimensional array

Cumulative minima, returned as a vector, matrix, or multidimensional array. The size and data type of `M` are the same as those of `A`.

## More About

### Tips

- The `cummin` function does not return NaN values unless the first element in the active dimension is a NaN. In that case, the corresponding first element in the output is a NaN. If the input has further consecutive NaN values, so that `cummin` must compare NaNs to determine the cumulative minimum, the output also has consecutive NaNs.

- The 'reverse' option in many cumulative functions allows quick directional calculations without requiring a flip or reflection of the input array.

# cumprod

Cumulative product

## Syntax

```
B = cumprod(A)
B = cumprod(A,dim)
B = cumprod(____,direction)
```

## Description

`B = cumprod(A)` returns the cumulative product of `A` starting at the beginning of the first array dimension in `A` whose size does not equal 1.

- If `A` is a vector, then `cumprod(A)` returns a vector containing the cumulative product of the elements of `A`.
- If `A` is a matrix, then `cumprod(A)` returns a matrix containing the cumulative products for each column of `A`.
- If `A` is a multidimensional array, then `cumprod(A)` acts along the first nonsingleton dimension.

`B = cumprod(A,dim)` returns the cumulative product along dimension `dim`. For example, if `A` is a matrix, then `cumprod(A,2)` returns the cumulative product of each row.

`B = cumprod( ____,direction)` optionally specifies the direction using any of the previous syntaxes. You must specify `A`, and optionally can specify `dim`. For instance, `cumprod(A,2, 'reverse')` returns the cumulative product within the rows of `A` by working from end to beginning of the second dimension.

## Examples

### Cumulative Product of Vector

Find the cumulative product of the integers from 1 to 5.

```
A = 1:5;
B = cumprod(A)
```

```
B =

 1 2 6 24 120
```

B(2) is the product of A(1) and A(2), while B(5) is the product of elements A(1) through A(5).

### Cumulative Product of Each Column in Matrix

Define a 3-by-3 matrix whose elements correspond to their linear indices.

```
A = [1 4 7; 2 5 8; 3 6 9]
```

```
A =

 1 4 7
 2 5 8
 3 6 9
```

Find the cumulative product of the columns of A.

```
B = cumprod(A)
```

```
B =

 1 4 7
 2 20 56
 6 120 504
```

B(5) is the product of A(4) and A(5), while B(9) is the product of A(7), A(8), and A(9).

### Cumulative Product of Each Row in Matrix

Define a 2-by-3 matrix whose elements correspond to their linear indices.

```
A = [1 3 5; 2 4 6]
```

```
A =

 1 3 5
 2 4 6
```

Find the cumulative product of the rows of A.

```
B = cumprod(A,2)
```

```
B =
```

```
 1 3 15
 2 8 48
```

B(3) is the product of A(1) and A(3), while B(5) is the product of A(1), A(3), and A(5) .

### Logical Input with Double Output

Create an array of logical values.

```
A = [true false true; true true false]
```

```
A =
```

```
 1 0 1
 1 1 0
```

Find the cumulative product of the rows of A.

```
B = cumprod(A,2)
```

```
B =
```

```
 1 0 0
 1 1 0
```

The output is double.

```
class(B)
```

```
ans =
```

```
double
```

### Reverse Cumulative Product

Create a 3-by-3 matrix of random integers between 1 and 10.

```
rng default;
```

```
A = randi([1,10],3)
```

A =

```
 9 10 3
 10 7 6
 2 1 10
```

Calculate the cumulative product along the columns. Specify the 'reverse' option to work from bottom to top in each column.

```
B = cumprod(A, 'reverse')
```

B =

```
 180 70 180
 20 7 60
 2 1 10
```

The result is the same size as A.

## Input Arguments

### A — Input array

vector | matrix | multidimensional array

Input array, specified as a vector, matrix, or multidimensional array.

Data Types: double | single | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical

Complex Number Support: Yes

### dim — Dimension to operate along

positive integer scalar

Dimension to operate along, specified as a positive integer scalar. If no value is specified, then the default is the first array dimension whose size does not equal 1.

Consider a two-dimensional input array, A.

- `cumprod(A,1)` works on successive elements in the columns of A and returns the cumulative products of each column.
- `cumprod(A,2)` works on successive elements in the rows of A and returns the cumulative products of each row.

cumprod returns A if `dim` is greater than `ndims(A)`.

#### **direction** — Direction of cumulation

'forward' (default) | 'reverse'

Direction of cumulation, specified as the string 'forward' (default) or 'reverse'.

- 'forward' works from 1 to end of the active dimension.
- 'reverse' works from end to 1 of the active dimension.

Data Types: char

## Output Arguments

### **B** — Cumulative product array

vector | matrix | multidimensional array

Cumulative product array, returned as a vector, matrix, or multidimensional array of the same size as the input array A.

The class of B is the same as the class of A except if A is `logical`, in which case B is `double`.

## More About

### **First Nonsingleton Dimension**

The first nonsingleton dimension is the first dimension of an array whose size is not equal to 1.

For example:

- If  $X$  is a 1-by- $n$  row vector, then the second dimension is the first nonsingleton dimension of  $X$ .
- If  $X$  is a 1-by-0-by- $n$  empty array, then the second dimension is the first nonsingleton dimension of  $X$ .
- If  $X$  is a 1-by-1-by-3 array, then the third dimension is the first nonsingleton dimension of  $X$ .

### Tips

- Many cumulative functions in MATLAB support the 'reverse' option. This option allows quick directional calculations without needing a flip or reflection of the input array.

**Introduced before R2006a**

## cumsum

Cumulative sum

### Syntax

```
B = cumsum(A)
B = cumsum(A,dim)
B = cumsum(____,direction)
```

### Description

`B = cumsum(A)` returns the cumulative sum of `A` starting at the beginning of the first array dimension in `A` whose size does not equal 1.

- If `A` is a vector, then `cumsum(A)` returns a vector containing the cumulative sum of the elements of `A`.
- If `A` is a matrix, then `cumsum(A)` returns a matrix containing the cumulative sums for each column of `A`.
- If `A` is a multidimensional array, then `cumsum(A)` acts along the first nonsingleton dimension.

`B = cumsum(A,dim)` returns the cumulative sum of the elements along dimension `dim`. For example, if `A` is a matrix, then `cumsum(A,2)` returns the cumulative sum of each row.

`B = cumsum( ____,direction)` optionally specifies the direction using any of the previous syntaxes. You must specify `A`, and optionally can specify `dim`. For instance, `cumsum(A,2, 'reverse')` returns the cumulative sum within the rows of `A` by working from end to beginning of the second dimension.

### Examples

#### Cumulative Sum of Vector

Find the cumulative sum of the integers from 1 to 5.

```
A = 1:5;
B = cumsum(A)
```

```
B =
```

```
 1 3 6 10 15
```

B(2) is the sum of A(1) and A(2), while B(5) is the sum of elements A(1) through A(5).

### Cumulative Sum of Each Column in Matrix

Define a 3-by-3 matrix whose elements correspond to their linear indices.

```
A = [1 4 7; 2 5 8; 3 6 9]
```

```
A =
```

```
 1 4 7
 2 5 8
 3 6 9
```

Find the cumulative sum of the columns of A.

```
B = cumsum(A)
```

```
B =
```

```
 1 4 7
 3 9 15
 6 15 24
```

B(5) is the sum of A(4) and A(5), while B(9) is the sum of A(7) , A(8) , and A(9).

### Cumulative Sum of Each Row in Matrix

Define a 2-by-3 matrix whose elements correspond to their linear indices.

```
A = [1 3 5; 2 4 6]
```

```
A =
```

```
 1 3 5
 2 4 6
```

Find the cumulative sum of the rows of A.

```
B = cumsum(A,2)
```

```
B =
```

```
 1 4 9
 2 6 12
```

B(3) is the sum of A(1) and A(3), while B(5) is the sum of A(1), A(3), and A(5) .

### Logical Input with Double Output

Create an array of logical values.

```
A = [true false true; true true false]
```

```
A =
```

```
 1 0 1
 1 1 0
```

Find the cumulative sum of the rows of A.

```
B = cumsum(A,2)
```

```
B =
```

```
 1 1 2
 1 2 2
```

The output is double.

```
class(B)
```

```
ans =
```

```
double
```

### Reverse Cumulative Sum

Create a 3-by-3 matrix of random integers between 1 and 10.

```
rng default;
```

```
A = randi([1,10],3)
```

```
A =
```

```
9 10 3
10 7 6
2 1 10
```

Calculate the cumulative sum along the rows. Specify the 'reverse' option to work from right to left in each row.

```
B = cumsum(A,2,'reverse')
```

B =

```
22 13 3
23 13 6
13 11 10
```

The result is the same size as A.

## Input Arguments

### A — Input array

vector | matrix | multidimensional array

Input array, specified as a vector, matrix, or multidimensional array.

Data Types: double | single | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical | duration

Complex Number Support: Yes

### dim — Dimension to operate along

positive integer scalar

Dimension to operate along, specified as a positive integer scalar. If no value is specified, then the default is the first array dimension whose size does not equal 1.

Consider a two-dimensional input array, A:

- `cumsum(A,1)` works on successive elements in the columns of A and returns the cumulative sums of each column.
- `cumsum(A,2)` works on successive elements in the rows of A and returns the cumulative sums of each row.

cumsum returns A if `dim` is greater than `ndims(A)`.

### **direction** — Direction of cumulation

'forward' (default) | 'reverse'

Direction of cumulation, specified as the string 'forward' (default) or 'reverse'.

- 'forward' works from 1 to end of the active dimension.
- 'reverse' works from end to 1 of the active dimension.

Data Types: char

## Output Arguments

### **B** — Cumulative sum array

vector | matrix | multidimensional array

Cumulative sum array, returned as a vector, matrix, or multidimensional array of the same size as the input array A.

The class of B is the same as the class of A except if A is `logical`, in which case B is `double`.

## More About

### **First Nonsingleton Dimension**

The first nonsingleton dimension is the first dimension of an array whose size is not equal to 1.

For example:

- If  $X$  is a 1-by- $n$  row vector, then the second dimension is the first nonsingleton dimension of  $X$ .
- If  $X$  is a 1-by-0-by- $n$  empty array, then the second dimension is the first nonsingleton dimension of  $X$ .
- If  $X$  is a 1-by-1-by-3 array, then the third dimension is the first nonsingleton dimension of  $X$ .

### Tips

- Many cumulative functions in MATLAB support the 'reverse' option. This option allows quick directional calculations without needing a flip or reflection of the input array.

## cumtrapz

Cumulative trapezoidal numerical integration

### Syntax

```
Z = cumtrapz(Y)
Z = cumtrapz(X,Y)
Z = cumtrapz(____,dim)
```

### Description

`Z = cumtrapz(Y)` computes an approximation of the cumulative integral of `Y` via the trapezoidal method with unit spacing. To compute the integral with other than unit spacing, multiply `Z` by the spacing increment. Input `Y` can be complex.

For vectors, `cumtrapz(Y)` is a vector containing the cumulative integral of `Y`.

For matrices, `cumtrapz(Y)` is a matrix the same size as `Y` with the cumulative integral over each column.

For multidimensional arrays, `cumtrapz(Y)` works across the first nonsingleton dimension.

`Z = cumtrapz(X,Y)` computes the cumulative integral of `Y` with respect to `X` using trapezoidal integration. `X` and `Y` must be vectors of the same length, or `X` must be a column vector and `Y` an array whose first nonsingleton dimension is `length(X)`. `cumtrapz` operates across this dimension. Inputs `X` and `Y` can be complex.

If `X` is a column vector and `Y` an array whose first nonsingleton dimension is `length(X)`, `cumtrapz(X,Y)` operates across this dimension.

`Z = cumtrapz( ____,dim)` integrates across the dimension of `Y` specified by scalar `dim`, using any of the input arguments in the previous syntaxes. The length of `X` must be the same as `size(Y,dim)`.

## Examples

### Example 1

```
Y = [0 1 2; 3 4 5];

cumtrapz(Y,1)
ans =
0 0 0
 1.5000 2.5000 3.5000

cumtrapz(Y,2)
ans =
0 0.5000 2.0000
 0 3.5000 8.0000
```

### Example 2

This example uses two complex inputs:

```
z = exp(1i*pi*(0:100)/100);

ct = cumtrapz(z,1./z);
ct(end)
ans =
 0.0000 + 3.1411i
```

# curl

Compute curl and angular velocity of vector field

## Syntax

```
[curlx,curly,curlz,cav] = curl(X,Y,Z,U,V,W)
[curlx,curly,curlz,cav] = curl(U,V,W)
[curlz,cav]= curl(X,Y,U,V)
[curlz,cav]= curl(U,V)
[curlx,curly,curlz] = curl(...)
[curlx,curly] = curl(...)
cav = curl(...)
```

## Description

`[curlx,curly,curlz,cav] = curl(X,Y,Z,U,V,W)` computes the curl (`curlx`, `curly`, `curlz`) and angular velocity (`cav`) perpendicular to the flow (in radians per time unit) of a 3-D vector field `U`, `V`, `W`.

The arrays `X`, `Y`, and `Z`, which define the coordinates for `U`, `V`, and `W`, must be monotonic, but do not need to be uniformly spaced. `X`, `Y`, and `Z` must have the same number of elements, as if produced by `meshgrid`.

`[curlx,curly,curlz,cav] = curl(U,V,W)` assumes `X`, `Y`, and `Z` are determined by the expression

```
[X Y Z] = meshgrid(1:n,1:m,1:p)
```

where `[m,n,p] = size(U)`.

`[curlz,cav]= curl(X,Y,U,V)` computes the curl z-component and the angular velocity perpendicular to `Z` (in radians per time unit) of a 2-D vector field `U`, and `V`.

The arrays `X` and `Y`, which define the coordinates for `U` and `V`, must be monotonic, but do not need to be uniformly spaced. `X` and `Y` must have the same number of elements, as if produced by `meshgrid`.

`[curlz,cav]= curl(U,V)` assumes `X` and `Y` are determined by the expression

```
[X Y] = meshgrid(1:n,1:m)
```

where `[m,n] = size(U)`.

`[curlx,curly,curlz] = curl(...)`, `[curlx,curly] = curl(...)` returns only the curl.

`cav = curl(...)` returns only the curl angular velocity.

## Examples

This example uses colored slice planes to display the curl angular velocity at specified locations in the vector field.

```
figure
load wind
cav = curl(x,y,z,u,v,w);
h = slice(x,y,z,cav,[90 134],59,0);
shading interp
daspect([1 1 1]);
axis tight
colormap hot(16)
camlight
set([h(1),h(2)], 'ambientstrength', .6)
```

This example views the curl angular velocity in one plane of the volume and plots the velocity vectors (`quiver`) in the same plane.

```
load wind
k = 4;
x = x(:,:,k); y = y(:,:,k); u = u(:,:,k); v = v(:,:,k);
cav = curl(x,y,u,v);
pcolor(x,y,cav); shading interp
hold on;
quiver(x,y,u,v,'y')
```

```
hold off
colormap copper
```

## currentDirectory

**Class:** Tiff

Index of current IFD

### Syntax

```
dirNum = currentDirectory(tiffobj)
```

### Description

`dirNum = currentDirectory(tiffobj)` returns the index of the current image file directory (IFD). Index values are one-based. Use this index value with the `setDirectory` member function.

### Examples

#### Determine Current IFD

Open a Tiff object and determine which IFD is the current IFD.

```
t = Tiff('example.tif', 'r');
dnum = currentDirectory(t)
```

```
dnum =
```

```
1
```

Close the Tiff object.

```
close(t)
```

- “Exporting Image Data and Metadata to TIFF Files”
- “Reading Image Data and Metadata from TIFF Files”

## References

This method corresponds to the `TIFFCurrentDirectory` function in the LibTIFF C API. To use this method, you must be familiar with the TIFF specification and technical notes. View this documentation at [LibTiff - TIFF Library and Utilities](#).

`Tiff.setDirectory`

## customverctrl

(To be removed) Allow custom source control system (UNIX platforms)

---

**Note:** `customverctrl` will be removed in a future release.

---

### Syntax

`customverctrl`

### Description

`customverctrl` function is for customers who want to integrate a source control system that is not supported for use with MATLAB software. When using this function, conform to the structure of one of the supported version control systems, for example, RCS. For examples, see the files `clearcase.m`, `cvs.m`, `pvcs.m`, and `rcs.m` in `matlabroot\toolbox\matlab\verctrl`.

**Introduced before R2006a**

# cylinder

Generate cylinder

## Syntax

```
[X,Y,Z] = cylinder
[X,Y,Z] = cylinder(r)
[X,Y,Z] = cylinder(r,n)
cylinder(axes_handle,...)
cylinder(...)
```

## Description

`cylinder` generates  $x$ -,  $y$ -, and  $z$ -coordinates of a unit cylinder. You can draw the cylindrical object using `surf` or `mesh`, or draw it immediately by not providing output arguments.

`[X,Y,Z] = cylinder` returns the  $x$ -,  $y$ -, and  $z$ -coordinates of a cylinder with a radius equal to 1. The cylinder has 20 equally spaced points around its circumference.

`[X,Y,Z] = cylinder(r)` returns the  $x$ -,  $y$ -, and  $z$ -coordinates of a cylinder using `r` to define a profile curve. `cylinder` treats each element in `r` as a radius at equally spaced heights along the unit height of the cylinder. The cylinder has 20 equally spaced points around its circumference.

`[X,Y,Z] = cylinder(r,n)` returns the  $x$ -,  $y$ -, and  $z$ -coordinates of a cylinder based on the profile curve defined by vector `r`. The cylinder has `n` equally spaced points around its circumference.

`cylinder(axes_handle, ...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

`cylinder(...)`, with no output arguments, plots the cylinder using `surf`.

## Examples

### Display Unit Cylinder

```
figure
cylinder
```

### Generate Coordinates of Cylinder and Display Surface

Generate a cylinder defined by the profile function  $2+\sin(t)$ .

```
t = 0:pi/10:2*pi;
figure
[X,Y,Z] = cylinder(2+cos(t));
surf(X,Y,Z)
axis square
```

## More About

### Tips

`cylinder` treats its first argument as a profile curve. The resulting surface graphics object is generated by rotating the curve about the  $x$ -axis, and then aligning it with the  $z$ -axis.

### See Also

`sphere` | `surf`

**Introduced before R2006a**

# daqread

Read Data Acquisition Toolbox (.daq) file

## Syntax

```
data = daqread('filename')
[data,time] = daqread(...)
[data,time,abstime] = daqread(...)
[data,time,abstime,events] = daqread(...)
[data,time,abstime,events,daqinfo] = daqread(...)
data = daqread(...,'Param1',Val1,...)
daqinfo = daqread('filename','info')
```

## Description

`data = daqread('filename')` reads all the data from the Data Acquisition Toolbox™ (.daq) file specified by `filename`. `daqread` returns `data`, an  $m$ -by- $n$  data matrix, where  $m$  is the number of samples and  $n$  is the number of channels. If `data` includes data from multiple triggers, the data from each trigger is separated by a NaN. If you set the `OutputFormat` property to `tscollection`, `daqread` returns a time series collection object. See below for more information.

`[data,time] = daqread(...)` returns time/value pairs. `time` is an  $m$ -by-1 vector, the same length as `data`, that contains the relative time for each sample. Relative time is measured with respect to the first trigger that occurs.

`[data,time,abstime] = daqread(...)` returns the absolute time of the first trigger. `abstime` is returned as a `clock` vector.

`[data,time,abstime,events] = daqread(...)` returns a log of events. `events` is a structure containing event information. If you specify either the `Samples`, `Time`, or `Triggers` parameters (see below), the events structure contains only the specified events.

`[data,time,abstime,events,daqinfo] = daqread(...)` returns a structure, `daqinfo`, that contains two fields: `ObjInfo` and `HwInfo`. `ObjInfo` is a structure containing property name/property value pairs and `HwInfo` is a

structure containing hardware information. The entire event log is returned to `daqinfo.ObjInfo.EventLog`.

`data = daqread(..., 'Param1', Val1, ...)` specifies the amount of data returned and the format of the data, using the following parameters.

| Parameter    | Description                                                                                                                                                                                      |
|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Samples      | Specify the sample range.                                                                                                                                                                        |
| Time         | Specify the relative time range.                                                                                                                                                                 |
| Triggers     | Specify the trigger range.                                                                                                                                                                       |
| Channels     | Specify the channel range. Channel names can be specified as a cell array.                                                                                                                       |
| DataFormat   | Specify the data format as <code>doubles</code> (default) or <code>native</code> .                                                                                                               |
| TimeFormat   | Specify the time format as <code>vector</code> (default) or <code>matrix</code> .                                                                                                                |
| OutputFormat | Specify the output format as <code>matrix</code> (the default) or <code>tscollection</code> . When you specify <code>tscollection</code> , <code>daqread</code> only returns <code>data</code> . |

The `Samples`, `Time`, and `Triggers` properties are mutually exclusive; that is, either `Samples`, `Triggers` or `Time` can be defined at once.

`daqinfo = daqread('filename', 'info')` returns metadata from the file in the `daqinfo` structure, without incurring the overhead of reading the data from the file as well. The `daqinfo` structure contains two fields:

`daqinfo.ObjInfo`

a structure containing parameter/value pairs for the data acquisition object used to create the file, `filename`. Note: The `UserData` property value is not restored.

`daqinfo.HwInfo`

a structure containing hardware information. The entire event log is returned to `daqinfo.ObjInfo.EventLog`.

## Examples

Use Data Acquisition Toolbox to acquire data. The analog input object, `ai`, acquires one second of data for four channels, and saves the data to the output file `data.daq`.

```
ai = analoginput('nidaq','Dev1');
chans = addchannel(ai,0:3);
set(ai,'SampleRate',1000)
ActualRate = get(ai,'SampleRate');
set(ai,'SamplesPerTrigger', ActualRate)
set(ai,'LoggingMode','Disk&Memory')
set(ai,'LogFileName','data.daq')
start(ai)
```

After the data has been collected and saved to a disk file, you can retrieve the data and other acquisition-related information using `daqread`. To read all the sample-time pairs from `data.daq`:

```
[data,time] = daqread('data.daq');
```

To read samples 500 to 1000 for all channels from `data.daq`:

```
data = daqread('data.daq','Samples',[500 1000]);
```

To read only samples 1000 to 2000 of channel indices 2, 4 and 7 in native format from the file, `data.daq`:

```
data = daqread('data.daq', 'Samples', [1000 2000],...
 'Channels', [2 4 7], 'DataFormat', 'native');
```

To read only the data which represents the first and second triggers on all channels from the file, `data.daq`:

```
[data,time] = daqread('data.daq', 'Triggers', [1 2]);
```

To obtain the channel property information from `data.daq`:

```
daqinfo = daqread('data.daq','info');
chaninfo = daqinfo.ObjInfo.Channel;
```

To obtain a list of event types and event data contained by `data.daq`:

```
daqinfo = daqread('data.daq','info');
events = daqinfo.ObjInfo.EventLog;
event_type = {events.Type};
event_data = {events.Data};
```

To read all the data from the file `data.daq` and return it as a time series collection object:

```
data = daqread('data.daq','OutputFormat','tscollection');
```

## More About

### Tips

### More About .daq Files

- The format used by `daqread` to return data, relative time, absolute time, and event information is identical to the format used by the `getdata` function that is part of Data Acquisition Toolbox. For more information, see the Data Acquisition Toolbox documentation.
- If data from multiple triggers is read, then the size of the resulting data array is increased by the number of triggers issued because each trigger is separated by a `NaN`.
- `ObjInfo.EventLog` always contains the entire event log regardless of the value specified by `Samples`, `Time`, or `Triggers`.
- The `UserData` property value is not restored when you return device object (`ObjInfo`) information.
- When reading a `.daq` file, the `daqread` function does not return property values that were specified as a cell array.
- Data Acquisition Toolbox (`.daq`) files are created by specifying a value for the `LogFileName` property (or accepting the default value), and configuring the `LoggingMode` property to `Disk` or `Disk&Memory`.

### More About Time Series Collection Object Returned

When `OutputFormat` is set to `tscollection`, `daqread` returns a time series collection object. This times series collection object contains an absolute time series object for each channel in the file. The following describes how `daqread` sets some of the properties of the times series collection object and the time series objects.

- The `time` property of the time series collection object is set to the value of the `InitialTriggerTime` property specified in the file.
- The `name` property of each time series object is set to the value of the `Name` property of a channel in the file. If this name cannot be used as a time series object name, `daqread` sets the name to `'Channel '` with the `HwChannel` property of the channel appended.
- The value of the `Units` property of the time series object depends on the value of the `DataFormat` parameter. If the `DataFormat` parameter is set to `'double'`, `daqread`

sets the `DataInfo` property of each time series object in the collection to the value of the `Units` property of the corresponding channel in the file. If the `DataFormat` parameter is set to `'native'`, `daqread` sets the `Units` property to `'native'`. See the Data Acquisition Toolbox documentation for more information on these properties.

- Each time series object will have `tsdata.event` objects attached corresponding to the log of events associated with the channel.

If `daqread` returns data from multiple triggers, the data from each trigger is separated by a `NaN` in the time series data. This increases the length of data and time vectors in the time series object by the number of triggers.

`timeseries` | `tscollection`

# daspect

Control data unit length along each axis

## Syntax

```
daspect(ratio)
```

```
daspect auto
```

```
daspect manual
```

```
d = daspect
```

```
m = daspect('mode')
```

```
daspect(ax, ___)
```

## Description

`daspect(ratio)` sets the data aspect ratio for the current axes. The data aspect ratio is the relative length of the data units along the  $x$ -axis,  $y$ -axis, and  $z$ -axis. Specify `ratio` as a three-element vector of positive values that represent the relative lengths of data units along each axis. For example, `[1 2 3]` indicates that the length from 0 to 1 along the  $x$ -axis is equal to the length from 0 to 2 along the  $y$ -axis and 0 to 3 along the  $z$ -axis. For equal data unit lengths in all directions, use `[1 1 1]`.

`daspect auto` lets the axes choose the data aspect ratio and sets the associated mode to automatic. The mode must be automatic to enable the “Stretch-to-fill” on page 1-1874 feature of the axes.

`daspect manual` uses the ratio stored in the `DataAspectRatio` property for the axes object and sets the associated mode to manual. When the mode is manual, it disables the stretch-to-fill behavior of the axes. Specifying a value for the data aspect ratio sets the mode to manual.

`d = daspect` returns the data aspect ratio for the current axes.

`m = daspect('mode')` returns the current mode, which is either `'auto'` or `'manual'`. By default, the mode is automatic unless you specify the data aspect ratio or set the mode to manual.

`daspect(ax, ___)` uses the axes specified by `ax` instead of the current axes. Specify an axes object with any of the input argument combinations in the previous syntaxes. Use single quotes around input arguments that are character strings, for example `daspect(ax, 'auto')` and `daspect(ax, 'manual')`.

## Examples

### Use Equal Data Unit Lengths Along Each Axis

Plot a set of data. Use data units of equal lengths in all directions by setting the data aspect ratio to `[1 1 1]`.

```
t = linspace(0,2*pi);
x = cos(t);
y = sin(t);
plot(x,y)
daspect([1 1 1])
```

### Use Different Data Unit Lengths Along Each Axis

Plot a set of data. Set the data aspect ratio so that the length of one data unit in the  $x$ -axis direction equals the length of two data units in the  $y$ -axis direction and  $z$ -axis direction (not shown).

```
t = linspace(0,2*pi);
x = cos(t);
y = sin(t);
plot(x,y)
daspect([1 2 2])
```

When you set the data aspect ratio, the associated mode changes to manual. Query the current data aspect ratio mode.

```
d = daspect('mode')
```

```
d =
```

```
manual
```

### **Query Data Aspect Ratio**

Create a surface plot and query.

```
[x,y] = meshgrid(-2:.2:2);
z = x.*exp(-x.^2 - y.^2);
surf(x,y,z)
```

Query the data aspect ratio. The ratio indicates that the length of four units in the  $x$ -axis direction equals four units in the  $y$ -axis direction and one unit in the  $z$ -axis direction. For example, the length from 0 to 1 on the  $x$ -axis equals the length from 0 to 1 on the  $y$ -axis and 0 to 0.25 on the  $z$ -axis.

```
d = daspect
```

```
d =
```

4 4 1

## Set Data Aspect Ratio for Specific Axes Object

Create a figure with two subplots and return the axes objects from the `subplot` function. Set the data aspect ratio for the lower subplot by specifying `ax2` as the first input argument to the `daspect` function.

```
ax1 = subplot(2,1,1);
plot(1:10)

ax2 = subplot(2,1,2);
plot(1:10)
daspect(ax2,[1 2 1])
```

## Input Arguments

### **ratio** — Data aspect ratio

three-element vector

Data aspect ratio, specified as a three-element vector of positive values. For example, `daspect([1 2 3])` specifies that the length of one unit along the  $x$ -axis equals the length of two units along the  $y$ -axis and three units along the  $z$ -axis.

Specifying the data aspect ratio sets the `DataAspectRatio` property for the axes object. The `DataAspectRatio` property interacts with the `PlotBoxAspectRatio`, `XLim`, `YLim`, and `ZLim` properties to control the length and scale of the  $x$ -axis,  $y$ -axis, and  $z$ -axis.

Specifying the ratio sets the `DataAspectRatioMode` property to `'manual'` and disables the “Stretch-to-fill” on page 1-1874 behavior of the axes.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **ax** — Axes object

axes object

Axes object. If you do not specify an axes object, then `daspect` uses the current axes (`gca`).

## Output Arguments

### **d** — Current data aspect ratio values

three-element vector

Current data aspect ratio, returned as a three-element vector of values representing the ratio of the *x*-axis, *y*-axis, and *z* data unit lengths.

Querying the data aspect ratio values returns the `DataAspectRatio` property value for the corresponding axes object.

### **m** — Current data aspect ratio mode

`'auto'` | `'manual'`

Current data aspect ratio mode, returned as either `'auto'` or `'manual'`. When the mode is automatic, the axes determines the appropriate data aspect ratio value. If you specify a value, then the mode changes to manual.

Querying the data aspect ratio mode returns the `DataAspectRatioMode` property value for the corresponding axes object.

## More About

### **Stretch-to-fill**

When the stretch-to-fill feature is enabled, MATLAB stretches the axes to fill the available space. Some distortion can occur. Thus, the axes might not exactly match the data aspect ratio, plot box aspect ratio, and camera-view angle values stored in

its `DataAspectRatio`, `PlotBoxAspectRatio`, and `CameraViewAngle` properties. When stretch-to-fill is disabled, MATLAB makes the axes as large as possible within the available space and strictly adheres to the property values so that there is no distortion. The last two elements of the `Position` property of the axes object determine the available space.

The stretch-to-fill feature is enabled when the `DataAspectRatioMode`, `PlotBoxAspectRatioMode`, and `CameraViewAngleMode` properties of the axes object are all set to `'auto'`. If one or more modes are manual, the feature is disabled. Thus, if you specify the data aspect ratio, plot box aspect ratio, or camera-view angle, then the stretch-to-fill feature is disabled.

For example, this figure shows the same plot with and without the stretch-to-fill feature enabled. The dotted line shows the available space as defined by the `Position` property. In both versions, the data aspect ratio, plot box aspect ratio, and camera-view angle values are the same. However, in the left plot, the stretching introduces some distortion.

**Introduced before R2006a**

# datacursormode

Enable, disable, and manage interactive data cursor mode

## Syntax

```
datacursormode on
datacursormode off
datacursormode
datacursormode toggle
datacursormode(figure_handle)
dcm_obj = datacursormode(figure_handle)
```

## Description

`datacursormode on` enables data cursor mode on the current figure.

`datacursormode off` disables data cursor mode on the current figure.

`datacursormode` or `datacursormode toggle` toggles data cursor mode in the current figure.

`datacursormode(figure_handle)` enables or disables data cursor mode on the specified figure.

`dcm_obj = datacursormode(figure_handle)` returns the data cursor mode object for the figure. The object enables you to customize the data cursor. For more information on data cursor mode objects, see “Output Arguments” on page 1-1878. You cannot change the state of data cursor mode in a call to `datacursormode` that returns a mode object.

A *data cursor* is a small black square with a white border that you interactively position on a graph in data cursor mode. When you click a graphic object such as a line on a graph, a *data tip* appears. Data tips are small text boxes or windows that float within an axes that display data values at data cursor locations. The default style is a text box. Data tips list *x*-, *y*- and (where appropriate) *z*-values for one data point at a time. See “Examples” on page 1-1881 for an illustration of these two styles.

## Input Arguments

### **figure\_handle**

Optional handle of figure window

**Default:** The current figure

### **state**

'', 'toggle', 'on', or 'off'

**Default:** 'toggle'

## Output Arguments

### **dcm\_obj**

Use the object returned by `datacursormode` to control aspects of data cursor behavior. You can use the `set` and `get` commands to set and query object property values. You can customize how data cursor mode presents information by coding callback functions for these objects.

## Parameter Name/Value Pairs for Data Cursor Mode Objects

The following parameters apply to objects returned by calls to `datacursormode`, not to the function itself.

### **'DisplayStyle'**

`datatip` | `window`

Determines how the data cursor displays.

- `datatip` displays data cursor information in a small yellow text box attached to a black square marker at a data point you interactively select.
- `window` displays data cursor information for the data point you interactively select in a floating window within the figure.

**Default:** `datatip`

**'Enable'**

`on` | `off`

Specifies whether data cursor mode is currently enabled for the figure.

**Default:** `off`

**'Figure'**

handle

Handle of the figure associated with the data cursor mode object.

**'SnapToDataVertex'**

`on` | `off`

Specifies whether the data cursor snaps to the nearest data value or is located at the actual pointer position.

**Default:** `on`

**'UpdateFcn'**

function handle

Reference to a function that formats the text appearing in the data cursor. You can supply your own function to customize data tip display. Your function must include at least two arguments. The first argument is unused, and can be a variable name or tilde (~). The second argument passes the data cursor event object to your update function. The event object encapsulates the state of the data cursor. The following function definition illustrates the update function:

```
function output_txt = myfunction(~,event_obj)
% ~ Currently not used (empty)
% event_obj Object containing event data structure
% output_txt Data cursor text (string or cell array
% of strings)
```

`event_obj` is an object that has the following properties.

|                 |                                                                                                                              |
|-----------------|------------------------------------------------------------------------------------------------------------------------------|
| <b>Target</b>   | Handle of the object the data cursor is referencing (the object which you click, for example, a line or a bar from a series) |
| <b>Position</b> | An array specifying the $x$ , $y$ (and $z$ for 3-D graphs) coordinates of the cursor                                         |

You can query these properties within your function. For example,

```
pos = get(event_obj, 'Position');
```

returns the coordinates of the cursor. Another way of accessing that data is to obtain the struct and query its `Position` field:

```
eventdata = get(event_obj);
pos = eventdata.Position;
```

You can also obtain the position directly from the object:

```
pos = event_obj.Position;
```

You can redefine the data cursor `UpdateFcn` at run time. For example:

```
set(dcm_obj, 'UpdateFcn', @myupdatefcn)
```

applies the function `myupdatefcn` to the current data tip or tips. When you set an update function in this way, the function must be on the MATLAB path. If instead you select the data cursor mode context menu item **Select text update function**, you can interactively select a function that is not on the path.

*Do not redefine figure window callbacks*, such as `ButtonDownFcn`, `KeyPressFcn`, or `CloseRequestFcn` *while in data cursor mode*. If you attempt to change any *figure* callbacks when you are in an interactive mode, you receive a warning and the attempt fails. MATLAB interactive modes are:

- `brush`
- `datacursormode`
- `pan`
- `rotate3d`
- `zoom`

This restriction does not apply to changing the figure `WindowButtonMotionFcn` callback or `uicontrol` callbacks.

## Querying Data Cursor Mode

Use the `getCursorInfo` function to query the data cursor mode object (`dcm_obj` in the update function syntax) to obtain information about the data cursor. For example,

```
info_struct = getCursorInfo(dcm_obj);
```

returns a vector of structures, one for each data cursor on the graph. Each structure has the following fields.

|                 |                                                                          |
|-----------------|--------------------------------------------------------------------------|
| <b>Target</b>   | The handle of the graphics object containing the data point              |
| <b>Position</b> | An array specifying the $x$ , $y$ , (and $z$ ) coordinates of the cursor |

Line and lineseries objects have an additional field.

|                  |                                                                                                                      |
|------------------|----------------------------------------------------------------------------------------------------------------------|
| <b>DataIndex</b> | A scalar index into the data arrays that correspond to the nearest data point. The value is the same for each array. |
|------------------|----------------------------------------------------------------------------------------------------------------------|

See “Output Arguments” on page 1-1878 for more details on data cursor mode objects.

## Examples

This example creates a plot and enables data cursor mode from the command line.

```
surf(peaks)
datacursormode on
% Click mouse on surface to display data cursor
```

Selecting a point on the surface opens a data tip displaying its  $x$ -,  $y$ -, and  $z$ -coordinates.

You change the data tip display style to be a window instead of a text box using the **Tools > Options > Display cursor in window** , or use the context menu **Display Style > Window inside figure** to view the data tip in a floating window that you can move around inside the axes.

You can position multiple text box data tips on the same graph, the window style of data tip displays only one value at a time. For more information on interacting with data cursors, including point selection options and exporting data tips to the workspace, see “Display Data Values Interactively”.

This example enables data cursor mode on the current figure and sets data cursor mode options. The following statements

- Create a graph
- Toggle data cursor mode to on
- Obtain the data cursor mode object, specify data tip options, and get the handle of the line the data tip occupies:

```
fig = figure;
z = peaks;
plot(z(:,30:35))
dcm_obj = datacursormode(fig);
set(dcm_obj, 'DisplayStyle', 'datatip', ...
 'SnapToDataVertex', 'off', 'Enable', 'on')

disp('Click line to display a data tip, then press Return.')
% Wait while the user does this.
pause

c_info = getCursorInfo(dcm_obj);
% Make selected line wider
set(c_info.Target, 'LineWidth', 2)
```

This example shows you how to customize the text that the data cursor displays. For example, you can replace the text displayed in the data tip and data window (x: and y:) with `Time:` and `Amplitude:` by creating a simple update function.

Save the following functions in your current directory or any writable directory on the MATLAB path before running them. As they are functions, you cannot highlight them and then evaluate the selection to make them work.

Save this code as `doc_datacursormode.m`:

```
function doc_datacursormode
% Plots graph and sets up a custom data tip update function
fig = figure;
```

```

a = -16; t = 0:60;
plot(t,sin(a*t))
dcm_obj = datacursormode(fig);
set(dcm_obj, 'UpdateFcn', @myupdatefcn)

```

Save the following code as `myupdatefcn.m` on the MATLAB path:

```

function txt = myupdatefcn(empty,event_obj)
% Customizes text of data tips

pos = get(event_obj, 'Position');
txt = {'Time: ', num2str(pos(1))}, ...
 ['Amplitude: ', num2str(pos(2))]];

```

To set up and use the update function, type:

```
doc_datacursormode
```

When you place a data tip using this update function, it looks like the one in the following figure.

## Alternatives

Use the Data Cursor tool  to label  $x$ ,  $y$ , and  $z$  values on graphs and surfaces. You can control how data tips display by right-clicking and selecting items from the context menu.

## More About

### Tips

- Most types of graphs and 3-D plots support data cursor mode, but several do not (pareto, for example).

- Polar plots support data tips, but display Cartesian rather than polar coordinates on them.
- Histograms created with `histogram` display specialized data tips that itemize the observation counts and bin edges.
- You place data tips only by clicking data objects on graphs. You cannot place them programmatically (by executing code to position a data cursor).
- When `DisplayStyle` is `datatip`, you can place multiple data tips on a graph. When `DisplayStyle` is `window`, it reports only the most recent data tip.
- `datacursormode off` exits data cursor mode but does not remove displayed data tips. However, if the `DisplayStyle` is `window`, the data tip window goes away.
- “Example — Visually Exploring Demographic Statistics”
- “Data Cursors with Histograms”

`brush` | `pan` | `rotate3d` | `zoom`

**Introduced before R2006a**

# datastore

Create datastore to access collection of data

## Syntax

```
ds = datastore(location)
ds = datastore(location,Name,Value)
```

## Description

`ds = datastore(location)` creates a datastore from the collection of data specified by `location`. A datastore is a repository for collections of data that are too large to fit in memory. After creating `ds`, you can read the data.

`ds = datastore(location,Name,Value)` specifies the properties of `ds` using one or more name-value pair arguments. For example, you can specify the type of datastore to create as a `TabularTextDatastore`, an `ImageDatastore`, or a `KeyValueDatastore` object.

## Examples

### Create Datastore for Text Data

Create a datastore associated with the sample file, `airlinesmall.csv`. This file contains airline data from the years 1987 through 2008.

Use the `'TreatAsMissing'` name-value pair argument to specify the strings in the file to treat as missing data.

```
ds = datastore('airlinesmall.csv',...
 'TreatAsMissing','NA')
```

```
ds =
```

TabularTextDatastore with properties:

```
Files: {
 '...\matlab\toolbox\matlab\demos\airlinesmall.csv'
}
FileEncoding: 'UTF-8'
ReadVariableNames: true
VariableNames: {'Year', 'Month', 'DayofMonth' ... and 26 more}
```

Text Format Properties:

```
NumHeaderLines: 0
Delimiter: ','
RowDelimiter: '\r\n'
TreatAsMissing: 'NA'
MissingValue: NaN
```

Advanced Text Format Properties:

```
TextscanFormats: {'%f', '%f', '%f' ... and 26 more}
ExponentCharacters: 'eEdD'
CommentStyle: ''
Whitespace: ' \b\t'
MultipleDelimitersAsOne: false
```

Properties that control the table returned by preview, read, readall:

```
SelectedVariableNames: {'Year', 'Month', 'DayofMonth' ... and 26 more}
SelectedFormats: {'%f', '%f', '%f' ... and 26 more}
ReadSize: 20000 rows
```

datastore creates a TabularTextDatastore.

## Create Datastore for Image Data

Create a datastore associated with all .tif files in the MATLAB path and its subfolders.

```
ds = datastore(fullfile(matlabroot, 'toolbox', 'matlab'),...
'IncludeSubfolders', true, 'FileExtensions', '.tif', 'Type', 'image')
```

ds =

ImageDatastore with properties:

```
Files: {
 'C:\matlab\toolbox\matlab\demos\example.tif';
 'C:\matlab\toolbox\matlab\imagesci\corn.tif'
}
```

---

ReadFcn: @readDatastoreImage

## Input Arguments

### **location** — Files or folders to include in the datastore

string | cell array of strings

Files or folders to include in the datastore, specified as a string or cell array of strings. If the files are not in the current folder, then **files** must include full or relative paths. Files within subfolders of the specified folder are not automatically included in the datastore. You must indicate the paths to these subfolders in **location**.

If the files are not available locally, then the full path of the files or folders must be an internationalized resource identifier (IRI) of the form `hdfs://hostname:portnumber/path_to_file`.

Before reading from HDFS™, you must set the `HADOOP_HOME`, `HADOOP_PREFIX`, or `MATLAB_HADOOP_INSTALL` environment variable to the folder where Hadoop® is installed. For more information, see “Read from HDFS”.

---

**Note:** When reading from HDFS or when reading Sequence files locally, the `datastore` function calls the `javaaddpath` command. This command clears the definitions of all Java classes defined by files on the dynamic class path, removes all global variables and variables from the base workspace, and removes all compiled scripts, functions, and MEX-functions from memory. To prevent persistent variables, code files or MEX-files from being cleared, use the `mlock` function.

---

For `TabularTextDatastore`, `ImageDatastore`, and `KeyValueDatastore`, you can use the wildcard character (\*) to indicate that all matching files or all files in the matching folders are included in the datastore.

For `KeyValueDatastore`, the files must be MAT-files or Sequence files generated by the `mapreduce` function, and they must be in a local file system or in a network file system.

Example: `'file1.csv'`

Example: `'../dir/data/file1.csv'`

Example: `{'C:\dir\data\file1.csv','C:\dir\data\file2.csv'}`

Example: 'C:\dir\data\\*.mat'

Example: 'hdfs://myserver:7867/data/file1.txt'

## Name-Value Pair Arguments

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as **Name1**, **Value1**, . . . , **NameN**, **ValueN**.

Example: 'Delimiter', ',', ' specifies a comma delimiter for a `TabularTextDatastore` object.

## All Datastore Types

### 'Type' — Type of datastore

'tabulartext' | 'image' | 'keyvalue'

Type of datastore, specified as the comma-separated pair consisting of 'Type' and one of the following strings.

| Value of 'Type' | Description                                                                                                                                                                             |
|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'tabulartext'   | Interpret the data set specified by <b>location</b> as text files containing tabular data. The encoding of the data must be ASCII or UTF-8.                                             |
| 'image'         | Interpret the data set specified by <b>location</b> as image files in a format such as JPEG or PNG. Acceptable formats include those supported by <code>imread</code> .                 |
| 'keyvalue'      | Interpret the data set specified by <b>location</b> as key-value pair data. The files can be MAT-files or sequence files with key-value pair data generated by <code>mapreduce</code> . |

- If you have other MathWorks products installed, then you might have access to other datastore types. In this case, other values for 'Type' are valid.

- If there are multiple types that support the format of the files, then use the `'Type'` argument to specify a datastore type.
- If you do not specify a value for `'Type'`, then `datastore` automatically determines the appropriate type of datastore to create, based on the extension of the files specified by the `location` argument.

### TabularTextDatastore Only

In addition to the properties described here, you can specify the `TabularTextDatastore` properties using name-value pair arguments. The only exception is `Files`. See `TabularTextDatastore Properties` for the full property list.

#### **'VariableNames' — Names of variables**

cell array of strings

Names of variables in the datastore, specified as the comma-separated pair consisting of `'VariableNames'` and a cell array of strings. Specify the variable names in the order in which they appear in the files. If you do not specify the variable names, they are detected from the first nonheader line in the first file in the datastore. You can rename the variables after creating the datastore, by modifying its `VariableNames` property.

When `ReadVariableNames` is `false`, then `VariableNames` defaults to `{'Var1', 'Var2', ...}`.

Example: `'VariableNames', {'Time', 'Name', 'Quantity'}`

#### **'TextscanFormats' — Format of the data fields**

string | cell array of strings

Format of the data fields, specified as the comma-separated pair consisting of `'TextscanFormats'` and a string or a cell array of strings. If the value of `TextscanFormats` is a string, then it can contain one or more conversion specifiers. If the value of `TextscanFormats` is a cell array of strings, then each string must contain only one conversion specifier.

You can use the same conversion specifiers that the `textscan` function accepts for the `formatSpec` argument.

If the value of `TextscanFormats` includes conversion specifiers that skip fields using asterisk characters (\*), then the value of the `SelectedVariableNames` property automatically updates.

If you do not specify a value for `TextscanFormats`, then `datastore` determines the format of the data fields by scanning text from first nonheader, nonvariable name line in the first file.

Example: `'TextscanFormats', '%s%s%f'`

Example: `'TextscanFormats', {'%s', '%s', '%f'}`

### **'SelectedVariableNames' — Variables to read**

cell array of strings

Variables to read, specified as the comma-separated pair consisting of `'SelectedVariableNames'` and a cell array of strings, where each string contains the name of one variable. You can specify the variable names in any order.

Example: `'SelectedVariableNames', {'Var3', 'Var7', 'Var4'}`

### **'SelectedFormats' — Formats for selected variables**

cell array of strings

Formats for the selected variables, specified as the comma-separated pair consisting of `'SelectedFormats'` and a cell array of strings, where each string contains one conversion specifier. Use the `SelectedVariableNames` property to indicate the variables to read. The number of strings in `SelectedFormats` must match the number of variables to read.

You can use the same conversion specifiers that the `textscan` function accepts. However, you cannot use a conversion specifier that skips a field. For example, the conversion specifier cannot include an asterisk character (\*).

Example: `'SelectedFormats', {'%d', '%d'}`

### **ImageDatastore Only**

#### **'IncludeSubfolders' — Include subfolders within folder**

logical `true` or `false`

Include subfolders within a folder, specified as the comma-separated pair consisting of `'IncludeSubfolders'` and a logical `true` or `false`. Specify `true` to include all files and subfolders within each folder or `false` to include only the files within each folder.

When you do not specify `'IncludeSubfolders'`, then the default value is `false`.

Example: `'IncludeSubfolders', true`

**'FileExtensions' — Extensions of image files**

string | cell array of strings

Extensions of image files, specified as the comma-separated pair consisting of `'FileExtensions'` and a string or a cell array of strings. You must combine this name-value pair with the `'Type'` name-value pair. The specified extensions do not require an `imformats` format, and you can use the empty string `''` to represent files without extensions. If `'FileExtensions'` is not specified, then `datastore` will automatically include all images with `imformats` extensions in the specified path. If you want to include extensions that are not recognized by `imformats`, then you must specify all extensions.

Example: `'FileExtensions', '.jpg'`

Example: `'FileExtensions', {' .jpg', '.png' }`

**'ReadFcn' — Name of the function that reads image data**

function handle

Name of function that reads image data, specified as the comma-separated pair consisting of `'ReadFcn'` and a function handle. The function handle takes the form, `@customreader`, where `customreader` is a function with this signature:

```
function data = customreader(filename)
 ..
end
```

After you create the `ImageDatastore` object, you can modify `ReadFcn` using the `ReadFcn` property.

**KeyValueDatastore Only**

For `KeyValueDatastore` objects, you can specify the `FileType` and `ReadSize` properties using name-value pair arguments. See `KeyValueDatastore` for more information.

## Output Arguments

**ds — Datastore for collection of files**

TabularTextDatastore | ImageDatastore | KeyValueDatastore

Datastore for a collection of files, returned as a `TabularTextDatastore`, an `ImageDatastore`, or a `KeyValueDatastore`. The type of datastore depends on the type of files in the datastore. For more information, click the output datastore name.

| Type of Files               | Output                            |
|-----------------------------|-----------------------------------|
| Text files                  | <code>TabularTextDatastore</code> |
| Image files                 | <code>ImageDatastore</code>       |
| MAT-files or Sequence files | <code>KeyValueDatastore</code>    |

For each of the datastore types in the table, the `Files` property is a cell array of strings, where each string is an absolute path to a file resolved from the `location` argument.

# hasdata

Determine if data is available to read

## Syntax

```
tf = hasdata(ds)
```

## Description

`tf = hasdata(ds)` returns logical 1 (**true**) if there is data available to read from the datastore specified by `ds`. Otherwise, it returns logical 0 (**false**).

## Examples

### Determine if Data is Available to Read

Create a datastore from the sample file, `mapredout.mat`, which is the output file of the `mapreduce` function.

```
ds = datastore('mapredout.mat');
```

While there is data available in the datastore, read the data.

```
while hasdata(ds)
 T = read(ds);
end
```

## Input Arguments

### **ds** — Input datastore

datastore

Input datastore. Use the `datastore` function to create a datastore object from your data.

**See Also**  
datastore

**Introduced in R2014b**

# Using ImageDatastore Objects

Datastore for image data

## Description

An `ImageDatastore` object manages a collection of image files, where each individual image can fit in memory, but the collection might not. After you create an `ImageDatastore` object, you can use functions with the object and modify the properties associated with it. To create an `ImageDatastore` object, use the `datastore` function. When you use the `datastore` function, you must specify the image file locations. Optionally, you also can include name-value pair arguments. For example, use this syntax to specify the file extensions in the `ImageDatastore`.

```
ds = datastore({'peppers.png', 'corn.tif'}, ...
 'Type', 'image', 'FileExtensions', {' .png', '.tif'});
```

To see all options for creating an `ImageDatastore` object, see `datastore`.

After you create the `ImageDatastore` object, use dot notation to view or modify the properties, for example:

```
ds = datastore('peppers.png');
ds.ReadFcn = @customreader;
```

When you create the `ImageDatastore` object, you also can use a name-value pair to specify the value of the `ReadFcn` property.

```
ds = datastore('peppers.png', 'ReadFcn', @customreader);
```

## Examples

### Specify Images to Read

Create a `datastore` object containing four images and preview the first image.

```
ds = datastore({'street1.jpg', 'street2.jpg', 'peppers.png', 'corn.tif'}, ...
 'Type', 'image', 'FileExtensions', {' .jpg', '.png', '.tif'})
```

```
ds =
```

```
 ImageDatastore with properties:
```

```
Files: {
 'C:\matlab\examples\matlab\street1.jpg';
 'C:\matlab\examples\matlab\street2.jpg';
 'C:\matlab\toolbox\matlab\imagesci\peppers.png'
 ... and 1 more
}
ReadFcn: @readDatastoreImage

imshow(preview(ds));
```

Read only the second and third images, one at a time.

```
for i = 2:3
 img = readimage(ds,i);
end
```

Read all four images and view the third image.

```
imgs = readall(ds);
imshow(imgs{3})
```

- “Read and Analyze Image Files”
- “Compute Maximum Average HSV of Images with MapReduce”

## Properties

**Files** — Files included in datastore

string | cell array of strings

Files included in the datastore object, specified as a cell array of strings, where each string is a full path to a file. These are the files defined by the `location` argument in the `datastore` function.

Example: `{'C:\dir\data\file1.jpg'; 'C:\dir\data\file2.jpg'}`

## **ReadFcn — Name of function that reads image data**

@readDatastoreImage (default) | function handle

Name of the function that reads image data, specified as a function handle that names the function to read the images. The function must take an image file name as input, and then output the corresponding image data. For example, if `customreader` is the specified function to read the image data, then it must have the following signature:

```
function data = customreader(filename)
..
end
```

Example: @customreader

Data Types: function\_handle

## **Object Functions**

|               |                                        |
|---------------|----------------------------------------|
| hasdata       | Determine if data is available to read |
| numpartitions | Number of partitions                   |
| partition     | Partition a datastore                  |
| preview       | Return subset of data from datastore   |
| read          | Read data in datastore                 |
| readall       | Read all data in datastore             |
| readimage     | Read specified image from datastore    |
| reset         | Reset datastore to initial state       |

## **Create Object**

Create `ImageDatastore` objects using the `datastore` function.

## **See Also**

`datastore` | `mapreduce`

## **More About**

- “Getting Started with Datastore”

**Introduced in R2015b**

# Using KeyValueDatastore Objects

Datastore for key-value pair data

## Description

KeyValueDatastore objects are associated with files containing key-value pair data that are outputs of or inputs to `mapreduce`. Use the `KeyValueDatastore` properties to specify how you want to access the data. Use dot notation to view or modify a particular property of a `KeyValueDatastore` object:

```
ds = datastore('mapredout.mat');
ds.ReadSize = 20;
```

You also can specify the value of `KeyValueDatastore` properties using name-value pair arguments when you create a datastore using the `datastore` function:

```
ds = datastore('mapredout.mat', 'ReadSize', 20);
```

## Examples

### Set Number of Key-Value Pairs to Read

Create a datastore from the sample file, `mapredout.mat`, which is an output file of the `mapreduce` function.

```
ds = datastore('mapredout.mat')

ds =
 KeyValueDatastore with properties:

 Files: {
 ' ...\matlab\toolbox\matlab\demos\mapredout.mat'
 }
 ReadSize: 1 key-value pairs
 FileType: 'mat'
```

Set the `ReadSize` property to 8 so that each call to `read` reads at most 8 key-value pairs.

```
ds.ReadSize = 8
```

```

ds =
 KeyValueDatastore with properties:

 Files: {
 ' ...\matlab\toolbox\matlab\demos\mapredout.mat'
 }
 ReadSize: 8 key-value pairs
 FileType: 'mat'

```

Read 8 key-value pairs at a time using the `read` function in a `while` loop. The loop executes until there is no more data available to read and `hasdata(ds)` returns `false`.

```

while hasdata(ds)
 T = read(ds);
end

```

Show the last set of key-value pairs read.

```
T
```

```
T =
```

| Key  | Value  |
|------|--------|
| '00' | [3090] |
| 'TZ' | [ 216] |
| 'XE' | [2357] |
| '9E' | [ 521] |
| 'YV' | [ 849] |

- “Read and Analyze MAT-File with Key-Value Data”
- “Read and Analyze Hadoop Sequence File”

## Properties

### Files — Files included in datastore

cell array of strings

Files included in the datastore, specified as an  $n$ -by-1 cell array of strings, where each string is a full path to a file. These are the files defined by the `location` argument to the `datastore` function.

The files must be either MAT-files or Sequence files generated by the `mapreduce` function. The files must be in a local file system or in a network file system. Sequence files also can be in HDFS.

Example: `{'C:\dir\data\file1.mat';'C:\dir\data\file2.mat'}`

### **FileType** — File type

'mat' (default) | 'seq'

File type, specified as either 'mat' for MAT-files or 'seq' for sequence files. By default, the output of `mapreduce` running against Hadoop is a datastore containing sequence files. By default, the output of all other `mapreduce` operations is a datastore containing MAT-files.

### **ReadSize** — Maximum number of key-value pairs to read

1 (default) | positive integer

Maximum number of key-value pairs to read in a call to the `read` or `preview` functions, specified as a positive integer.

### **KeyValueLimit** — Maximum number of key-value pairs to read

1 (default) | positive integer

---

**Note:** `KeyValueLimit` will be removed in a future release. Use `ReadSize` instead.

---

Maximum number of key-value pairs to read in a call to the `read` or `preview` functions, specified as a positive integer.

## **Object Functions**

|                            |                                        |
|----------------------------|----------------------------------------|
| <code>hasdata</code>       | Determine if data is available to read |
| <code>numpartitions</code> | Number of partitions                   |
| <code>partition</code>     | Partition a datastore                  |
| <code>preview</code>       | Return subset of data from datastore   |
| <code>read</code>          | Read data in datastore                 |
| <code>readall</code>       | Read all data in datastore             |
| <code>reset</code>         | Reset datastore to initial state       |

## Create Object

Create `KeyValueDatastore` objects using the `datastore` function.

### See Also

`datastore` | `mapreduce`

**Introduced in R2014b**

## numpartitions

Number of partitions

### Syntax

```
N = numpartitions(ds)
N = numpartitions(ds,pool)
```

### Description

`N = numpartitions(ds)` returns the default number of partitions for datastore `ds`.

`N = numpartitions(ds,pool)` returns a number of partitions to parallelize datastore access over the parallel pool specified by `pool`. To parallelize datastore access, you must have Parallel Computing Toolbox™ installed.

### Examples

#### Number of Partitions

Create a datastore from the sample file, `mapredout.mat`, which is the output file of the `mapreduce` function.

```
ds = datastore('mapredout.mat');
```

Get the default number of partitions.

```
N = numpartitions(ds)
```

```
N =
 1
```

By default, there is only one partition in `ds` because it contains only one small file.

Partition the datastore and return the datastore corresponding to the first part.

```
subds = partition(ds,N,1);
```

Read the data in subds.

```
while hasdata(subds)
 data = read(subds);
end
```

### Number of Partitions for Parallel Datastore Access

Get a number of partitions to parallelize datastore access over the current parallel pool. You must have Parallel Computing Toolbox installed.

Create a datastore from the sample file, `mapredout.mat`, which is the output file of the `mapreduce` function.

```
ds = datastore('mapredout.mat');
```

Get a number of partitions to parallelize datastore access over the current parallel pool.

```
N = numpartitions(ds, gcp);
```

Partition the datastore and read the data in each part.

```
parfor ii=1:N
 subds = partition(ds,N,ii);
 while hasdata(subds)
 data = read(subds);
 end
end
```

- “Partition a Datastore in Parallel”

## Input Arguments

### **ds** — Input datastore

datastore

Input datastore. Use the `datastore` function to create a datastore object from your data.

### **pool1** — Parallel pool

parallel pool object

Parallel pool object.

Example: `gcp`

**See Also**

`datastore` | `partition`

**Introduced in R2015a**

# partition

Partition a datastore

## Syntax

```
subds = partition(ds,N,index)
```

```
subds = partition(ds,'Files',index)
```

```
subds = partition(ds,'Files',filename)
```

## Description

`subds = partition(ds,N,index)` partitions datastore `ds` into the number of parts specified by `N` and returns the partition corresponding to the index `index`.

`subds = partition(ds,'Files',index)` partitions the datastore by files and returns the partition corresponding to the file of index `index` in the `Files` property.

`subds = partition(ds,'Files',filename)` partitions the datastore by files and returns the partition corresponding to the file specified by `filename`.

## Examples

### Partition Datastore into Specific Number of Parts

Create a datastore from the sample file, `airlinesmall.csv`, which contains tabular data.

```
ds = datastore('airlinesmall.csv');
```

Partition the datastore into three parts.

```
subds = partition(ds,3,1)
```

```
subds =
 TabularTextDatastore with properties:
```

```
Files: {
 '...\matlab\toolbox\matlab\demos\airlinesmall.csv'
}
ReadVariableNames: true
VariableNames: {'Year', 'Month', 'DayofMonth' ... and 26 more}

Text Format Properties:
 NumHeaderLines: 0
 Delimiter: ','
 RowDelimiter: '\r\n'
 TreatAsMissing: ''
 MissingValue: NaN

Advanced Text Format Properties:
 TextscanFormats: {'%f', '%f', '%f' ... and 26 more}
 ExponentCharacters: 'eEdD'
 CommentStyle: ''
 Whitespace: ' \b\t'
 MultipleDelimitersAsOne: false

Properties that control the table returned by preview, read, readall:
 SelectedVariableNames: {'Year', 'Month', 'DayofMonth' ... and 26 more}
 SelectedFormats: {'%f', '%f', '%f' ... and 26 more}
 ReadSize: 20000 rows
```

## Partition Datastore into Default Number of Parts

Create a datastore from the sample file, `mapredout.mat`, which is the output file of the `mapreduce` function.

```
ds = datastore('mapredout.mat');
```

Get the default number of partitions for `ds`.

```
N = numpartitions(ds);
```

Partition the datastore into the default number of partitions and return the datastore corresponding to the first partition.

```
subds = partition(ds,N,1);
```

Read the data in `subds`.

```
while hasdata(subds)
 data = read(subds);
```

end

### Partition Datastore by Files

Create a datastore that contains three image files.

```
ds = datastore({'street1.jpg', 'peppers.png', 'corn.tif'}, ...
 'Type', 'image', 'FileExtensions', {'.jpg', '.png', '.tif'})

ds =

 ImageDatastore with properties:

 Files: {
 '...\matlab\toolbox\matlab\demos\street1.jpg';
 '...\matlab\toolbox\matlab\imagesci\peppers.png';
 '...\matlab\toolbox\matlab\imagesci\corn.tif'
 }
 ReadFcn: @readDatastoreImage
```

Partition the datastore by files and return the part corresponding to the second file.

```
subds = partition(ds, 'Files', 2)

subds =

 ImageDatastore with properties:

 Files: {
 '...\matlab\toolbox\matlab\imagesci\peppers.png'
 }
 ReadFcn: @readDatastoreImage
```

subds contains one file.

### Partition Data in Parallel

Create a datastore from the sample file, `mapredout.mat`, which is the output file of the `mapreduce` function.

```
ds = datastore('mapredout.mat');
```

Partition the datastore into three parts on three workers in a parallel pool.

```
N = 3;
```

```
p = parpool('local',N);

parfor ii=1:N
 subds = partition(ds,N,ii);
 while hasdata(subds)
 data = read(subds);
 end
end
```

- “Partition a Datastore in Parallel”

## Input Arguments

### **ds** — Input datastore

datastore

Input datastore. To create a datastore object from your data, use the `datastore` function.

### **N** — Number of partitions

positive integer

Number of partitions, specified as a positive integer.

Example: 3

Data Types: double

### **index** — Index

positive integer

Index, specified as a positive integer.

Example: 1

Data Types: double

### **filename** — file name

string

File name, specified as a string.

Example: 'file1.csv'

Example: `'../dir/data/file1.csv'`

Example: `'hdfs://myserver:7867/data/file1.txt'`

## Output Arguments

### **subds** — Output datastore

datastore

Output datastore. The output datastore is of the same type as the input datastore `ds`.

### **See Also**

`datastore` | `numpartitions`

**Introduced in R2015a**

## preview

Return subset of data from datastore

## Syntax

```
data = preview(ds)
```

## Description

`data = preview(ds)` returns a subset of data from datastore `ds` without changing its current position.

## Examples

### Preview Data in TabularTextDatastore

Create a datastore from the sample file, `airlinesmall.csv`, which contains tabular data.

```
ds = datastore('airlinesmall.csv', 'TreatAsMissing', 'NA');
```

Modify the `SelectedVariableNames` property to specify the variables of interest.

```
ds.SelectedVariableNames = {'DepTime', 'ArrTime', 'ActualElapsedTime'};
```

Preview the data for the selected variables.

```
data = preview(ds)
```

```
data =
```

| DepTime | ArrTime | ActualElapsedTime |
|---------|---------|-------------------|
| 642     | 735     | 53                |
| 1021    | 1124    | 63                |

|      |      |     |
|------|------|-----|
| 2055 | 2218 | 83  |
| 1332 | 1431 | 59  |
| 629  | 746  | 77  |
| 1446 | 1547 | 61  |
| 928  | 1052 | 84  |
| 859  | 1134 | 155 |

### Preview Data in KeyValueDatastore

Create a datastore from the sample file, `mapredout.mat`, which is the output file of the `mapreduce` function.

```
ds = datastore('mapredout.mat');
```

Preview the data in the datastore.

```
data = preview(ds)
```

```
data =
```

| Key  | Value   |
|------|---------|
| 'AA' | [14930] |

## Input Arguments

### **ds** — Input datastore

datastore

Input datastore. Use the `datastore` function to create a datastore object from your data.

## Output Arguments

### **data** — Subset of data

table | array of integers

Subset of data, returned as a table or an array of integers.

| Type of datastore    | Description                                                                                                           |
|----------------------|-----------------------------------------------------------------------------------------------------------------------|
| TabularTextDatastore | Table with variables specified by the <code>SelectedVariableNames</code> property. The table contains at most 8 rows. |
| ImageDatastore       | Array of integers corresponding to the first image.                                                                   |
| KeyValueDatastore    | Table with the variables <code>Key</code> and <code>Value</code> .                                                    |

## See Also

`datastore` | `hasdata`

Introduced in R2014b

# read

Read data in datastore

## Syntax

```
data = read(ds)
[data,info] = read(ds)
```

## Description

`data = read(ds)` returns data from a datastore. Subsequent calls to `read` continue reading from the endpoint of the previous call.

`[data,info] = read(ds)` additionally returns information about the extracted data in `info`, including metadata.

## Examples

### Read Data in TabularTextDatastore

Create a datastore from the sample file, `airlinesmall.csv`, which contains tabular data.

```
ds = datastore('airlinesmall.csv','TreatAsMissing','NA','MissingValue',0);
```

Modify the `SelectedVariableNames` property to specify the variables of interest.

```
ds.SelectedVariableNames = {'DepTime','ArrTime','ActualElapsedTime'};
```

While there is data available to be read from the datastore, read one block of data at a time and analyze the data. In this example, sum the actual elapsed time.

```
sumElapsedTime = 0;
while hasdata(ds)
 T = read(ds);
 sumElapsedTime = sumElapsedTime + sum(T.ActualElapsedTime);
end
```

View the sum of the actual elapsed time.

```
sumElapsedTime
```

```
sumElapsedTime =
```

```
14531797
```

### **Read Data in KeyValueDatastore**

Create a datastore from the sample file, `mapredout.mat`, which is the output file of the `mapreduce` function.

```
ds = datastore('mapredout.mat');
```

Read a subset of data in the datastore.

```
T = read(ds)
```

```
T =
```

| Key  | Value   |
|------|---------|
| 'AA' | [14930] |

Change the number of key-value pairs to read at a time, by changing the `ReadSize` property of the datastore.

```
ds.ReadSize = 5;
```

Read the next five key-value pairs in the datastore.

```
T = read(ds)
```

```
T =
```

| Key  | Value   |
|------|---------|
| 'AS' | [ 2910] |

```
'CO' [8138]
'DL' [16578]
'EA' [920]
'HP' [3660]
```

## Input Arguments

### **ds** — Input datastore

datastore

Input datastore. Use the `datastore` function to create a datastore object from your data.

## Output Arguments

### **data** — Output data

table

Output data, returned as a table or an array depending on the type of `ds`.

| Type of Datastore    | Data type of data | Description                                                                                                                                                                                                                                |
|----------------------|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TabularTextDatastore | Table             | The table variables are determined by the <code>SelectedVariableNames</code> property.                                                                                                                                                     |
| ImageDatastore       | Integer array     | For grayscale images, <code>data</code> is m-by-n. For truecolor images, <code>data</code> is m-by-n-by-3. For CMYK Tiff images, <code>data</code> is m-by-n-by-4. <code>read</code> is implemented with the <code>imread</code> function. |
| KeyValueDatastore    | Table             | The table variable names are <code>Key</code> and <code>Value</code> .                                                                                                                                                                     |

### **info** — Information about read data

structure array

Information about read data, returned as a structure array. The structure array can contain the following fields.

| <b>Field Name</b>        | <b>Description</b>                                                                                                                                       |
|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Filename</b>          | File name.                                                                                                                                               |
| <b>FileSize</b>          | Total file size, in bytes. For MAT-files, <b>FileSize</b> is the total number of key-value pairs in the file.                                            |
| <b>FileType</b>          | The type of file from which data is read, either 'mat' for MAT-files or 'seq' for sequence files.<br><br>Applies to <code>KeyValueDatastore</code> only. |
| <b>Offset</b>            | Starting position of the read operation, in bytes. For MAT-files, <b>Offset</b> is the index of the first key and value read.                            |
| <b>NumCharactersRead</b> | Number of characters read.<br><br>Applies to <code>TabularTextDatastore</code> only.                                                                     |

### **See Also**

`datastore` | `hasdata` | `imread` | `readall`

**Introduced in R2014b**

# readall

Read all data in datastore

## Syntax

```
data = readall(ds)
```

## Description

`data = readall(ds)` returns all the data in the datastore specified by `ds`, and resets the datastore to the point where no data has been read from it.

If all of the data in the datastore does not fit in memory, then `readall` returns an error.

## Examples

### Read All Data in TabularTextDatastore

Create a datastore from the sample file `airlinesmall.csv`, which contains tabular data.

```
ds = datastore('airlinesmall.csv', 'TreatAsMissing', 'NA');
```

Modify the `SelectedVariableNames` property to specify the variables of interest.

```
ds.SelectedVariableNames = {'DepTime', 'ArrTime', 'ActualElapsedTime'};
```

Read all the data in the datastore.

```
T = readall(ds);
```

`readall` returns all the data in a table.

View information about the table.

```
T.Properties
```

```
ans =
```

```
 Description: ''
VariableDescriptions: {}
VariableUnits: {}
DimensionNames: {'Row' 'Variable'}
 UserData: []
 RowNames: {}
VariableNames: {'DepTime' 'ArrTime' 'ActualElapsedTime'}
```

View a summary of the output table.

```
summary(T)
```

Variables:

```
DepTime: 123523x1 double
Values:
```

|        |      |
|--------|------|
| min    | 1    |
| median | 1335 |
| max    | 2505 |
| NaNs   | 2351 |

```
ArrTime: 123523x1 double
Values:
```

|        |      |
|--------|------|
| min    | 1    |
| median | 1522 |
| max    | 2608 |
| NaNs   | 2656 |

```
ActualElapsedTime: 123523x1 double
Values:
```

|        |      |
|--------|------|
| min    | 11   |
| median | 102  |
| max    | 1650 |
| NaNs   | 2657 |

## Read All Data in KeyValueDatastore

Create a datastore from the sample file, `mapredout.mat`, which is the output file of the `mapreduce` function.

```
ds = datastore('mapredout.mat');
```

Read all the data in the datastore.

```
T = readall(ds);
```

View a summary of the output table.

```
summary(T)
```

Variables:

```
 Key: 29x1 cell string
```

```
 Value: 29x1 cell
```

## Input Arguments

### **ds** — Input datastore

datastore

Input datastore. Use the `datastore` function to create a datastore object from your data.

## Output Arguments

### **data** — All data in the datastore

table | cell array

All data in the datastore, returned as a table or cell array.

- For `TabularTextDatastore` objects, `data` is a table whose variables are determined by the `SelectedVariableNames` property.
- For `ImageDatastore` objects, `data` is a cell array where each element displays the size and data type of the corresponding image data. For example, `[480x640x3 uint8]` describes the size of `uint8` data corresponding to a color image.
- For `KeyValueDatastore` objects, `data` is a table whose variable names are `Key` and `Value`.

datastore | hasdata | read

**Introduced in R2014b**

# readimage

Read specified image from datastore

## Syntax

```
img = readimage(ds,I)
[img,fileinfo] = readimage(ds,I)
```

## Description

`img = readimage(ds,I)` reads the *I*th image file from the datastore `ds` and returns the image data `img`. The `readimage` function is implemented with the `imread` function.

`[img,fileinfo] = readimage(ds,I)` also returns a struct `fileinfo` that contains two file information fields:

- `Filename` — Name of the file from which the image is read.
- `FileSize` — Size of the file in bytes.

## Examples

### Read Specified Image

Create a datastore object containing two images, and then read and view the second image.

```
ds = datastore({'street1.jpg','street2.jpg'});
img = readimage(ds,2);
imshow(img)
```

## File Information

Create a datastore object containing two images. Read the second image and display the corresponding file name and size (bytes).

```
ds = datastore({'street1.jpg', 'street2.jpg'});
[img,info] = readimage(ds,2);
info.FileName

ans =

C:\matlab\examples\matlab\street2.jpg
info.FileSize
```

```
ans =

 39920
```

## Input Arguments

### **ds** — Input datastore

datastore

Input datastore. To create a datastore object from your data, use the `datastore` function.

### **I** — Image file index

positive integer

Image file index, specified as a positive integer.

## Output Arguments

### **img** — Image data

multidimensional array of integers

Image data, returned as a multidimensional array of integers. The size of `img` depends on the image type:

- `m-by-n` array for grayscale images
- `m-by-n-by-3` array for truecolor images
- `m-by-n-by-4` array for CMYK Tiff images

### **fileinfo** — File information

structure array

File information, returned as a structure array containing two fields:

- `Filename` — Name of the file from which the image is read.
- `FileSize` — Size of the file in bytes.

## See Also

| `datastore` | `imread` | `read` | `readall`

**Introduced in R2015b**

## reset

Reset datastore to initial state

## Syntax

```
reset(ds)
```

## Description

`reset(ds)` resets the datastore specified by `ds` to the state where no data has been read from it. This allows re-reading from the same datastore.

## Examples

### Reset Datastore to Initial State

Create a datastore from the sample file, `mapredout.mat`, which is the output file of the `mapreduce` function.

```
ds = datastore('mapredout.mat');
```

Read the first key-value pair.

```
T = read(ds);
```

Reset the datastore to the state where no data has been read from it.

```
reset(ds)
```

## Input Arguments

### **ds** — Input datastore

datastore

Input datastore. Use the `datastore` function to create a datastore object from your data.

**See Also**  
datastore

**Introduced in R2014b**

# Using TabularTextDatastore Objects

Datastore for tabular text files

## Description

TabularTextDatastore objects are associated with collections of text files containing column-oriented or tabular data. Tabular data is data that is arranged in a rectangular fashion with each row having the same number of entries. TabularTextDatastore properties specify how data is formatted in the files, and how you want to access the data.

## Examples

### Select Variables to Read

Create a datastore from the sample file `airlinesmall.csv`, which contains tabular data.

```
ds = datastore('airlinesmall.csv', 'TreatAsMissing', 'NA');
```

View the variables in the datastore.

```
ds.VariableNames
```

```
ans =
```

```
Columns 1 through 5
```

```
'Year' 'Month' 'DayofMonth' 'DayOfWeek' 'DepTime'
```

```
Columns 6 through 10
```

```
'CRSDepTime' 'ArrTime' 'CRSArrTime' 'UniqueCarrier' 'FlightNum'
```

```
Columns 11 through 14
```

```
'TailNum' 'ActualElapsedTime' 'CRSElapsedTime' 'AirTime'
```

Columns 15 through 20

```
'ArrDelay' 'DepDelay' 'Origin' 'Dest' 'Distance' 'TaxiIn'
```

Columns 21 through 24

```
'TaxiOut' 'Cancelled' 'CancellationCode' 'Diverted'
```

Columns 25 through 28

```
'CarrierDelay' 'WeatherDelay' 'NASDelay' 'SecurityDelay'
```

Column 29

```
'LateAircraftDelay'
```

Modify the `SelectedVariableNames` property to specify the variables of interest.

```
ds.SelectedVariableNames = {'Year', 'Month', 'Cancelled'};
```

Alternatively, you can specify the variables of interest when you create the datastore.

```
ds = datastore('airlinesmall.csv', 'TreatAsMissing', 'NA', 'SelectedVariableNames', {'Year
```

## Specify Format of Data to Read

Create a datastore from the sample file `airlinesmall.csv`, which contains tabular data.

```
ds = datastore('airlinesmall.csv', 'TreatAsMissing', 'NA');
```

Specify the variables of interest.

```
ds.SelectedVariableNames = {'Year', 'Month', 'UniqueCarrier'};
```

View the `SelectedFormats` property.

```
ds.SelectedFormats
```

```
ans =
```

```
'%f' '%f' '%q'
```

The `SelectedFormats` property indicates that the `Year` and `Month` variables will be interpreted as columns of floating-point values, and the `UniqueCarrier` variable will be interpreted as a column of text strings.

Specify that the first two variables should be read as signed integers, and the third variable should be read as a categorical value by modifying the `SelectedFormats` property.

```
ds.SelectedFormats = {'%d', '%d', '%C'};
```

Preview the data.

```
T = preview(ds)
```

T =

| Year | Month | UniqueCarrier |
|------|-------|---------------|
| 1987 | 10    | PS            |
| 1987 | 10    | PS            |
| 1987 | 10    | PS            |
| 1987 | 10    | PS            |
| 1987 | 10    | PS            |
| 1987 | 10    | PS            |
| 1987 | 10    | PS            |
| 1987 | 10    | PS            |

- “Read and Analyze Large Tabular Text File”

**Introduced in R2014b**

# datatipinfo

Produce short description of input variable

## Syntax

```
datatipinfo(var)
```

## Description

`datatipinfo(var)` displays a short description of a variable, similar to what is displayed in a data tip when debugging a MATLAB program. See “View Variable Value” for an example of a data tip.

## Examples

Get datatip information for a 5-by-5 matrix:

```
A = rand(5);
```

```
datatipinfo(A)
```

```
A: 5x5 double =
 0.4445 0.3567 0.7458 0.0767 0.4400
 0.7962 0.6575 0.3918 0.8289 0.9746
 0.5641 0.9808 0.0265 0.4838 0.6722
 0.9099 0.9653 0.2508 0.4859 0.4054
 0.2857 0.5198 0.7383 0.9301 0.9604
```

Get datatip information for a 50-by-50 matrix. For this larger matrix, `datatipinfo` displays just the size and data type:

```
A = rand(50);
```

```
datatipinfo(A)
```

```
A: 50x50 double
```

Also for multidimensional matrices, `datatipinfo` displays just the size and data type:

```
A = rand(5);
A(:, :, 2) = A(:, :, 1);
```

```
datatipinfo(A)
A: 5x5x2 double
```

# date

Current date string

## Syntax

```
str = date
```

## Description

`str = date` returns a string containing the date in the format, day-month-year, for example, 01-Jan-2014.

## More About

### Tips

- To return a datetime scalar representing the current date, type:

```
d = datetime('today')
```

### See Also

`clock` | `datestr` | `datetime` | `datenum` | `now`

**Introduced before R2006a**

## **datenum**

Convert date and time to serial date number

The `datenum` function creates a numeric array that represents each point in time as the number of days from January 0, 0000. The numeric values also can represent elapsed time in units of days. However, the best way to represent points in time is by using the `datetime` data type. The best way to represent elapsed time is by using the `duration` or `calendarDuration` data types.

### **Syntax**

`DateNumber` = `datenum(t)`

`DateNumber` = `datenum(DateString)`

`DateNumber` = `datenum(DateString,formatIn)`

`DateNumber` = `datenum(DateString,PivotYear)`

`DateNumber` = `datenum(DateString,formatIn,PivotYear)`

`DateNumber` = `datenum(DateVector)`

`DateNumber` = `datenum(Y,M,D)`

`DateNumber` = `datenum(Y,M,D,H,MN,S)`

### **Description**

`DateNumber` = `datenum(t)` converts the `datetime` values in `datetime` array `t` to serial date numbers.

A serial date number represents the whole and fractional number of days from a fixed, preset date (January 0, 0000) in the proleptic ISO calendar.

`DateNumber` = `datenum(DateString)` converts date strings to serial date numbers. If the date string format is known, use `formatIn`. Syntaxes without `formatIn` are significantly slower than syntaxes that include it.

`DateNumber` = `datenum(DateString,formatIn)` uses `formatIn` to interpret each date string.

`DateNumber` = `datenum(DateString,PivotYear)` uses `PivotYear` to interpret date strings that specify the year as two characters. If the date string format is known,

use `formatIn`. Syntaxes without `formatIn` are significantly slower than syntaxes that include it.

`DateNumber = datenum(DateString,formatIn,PivotYear)` uses `formatIn` to interpret each date string, and `PivotYear` to interpret date strings that specify the year as two characters. You can specify `formatIn` and `PivotYear` in either order.

`DateNumber = datenum(DateVector)` converts date vectors to serial date numbers, and returns a column vector of `m` date numbers, where `m` is the total number of date vectors in `DateVector`.

`DateNumber = datenum(Y,M,D)` returns the serial date numbers for corresponding elements of the `Y`, `M`, and `D` (year, month, day) arrays. The arrays must be of the same size (or any can be a scalar). You also can specify the input arguments as a date vector, `[Y,M,D]`.

`DateNumber = datenum(Y,M,D,H,MN,S)` additionally returns the serial date numbers for corresponding elements of the `H`, `MN`, and `S` (hour, minute, and second) arrays. The arrays must be of the same size (or any can be a scalar). You also can specify the input arguments as a date vector, `[Y,M,D,H,MN,S]`.

## Examples

### Convert datetime Array to Date Numbers

```
format long
```

```
t = [datetime('now');datetime('tomorrow')]
DateNumber = datenum(t)
```

```
t =
```

```
 24-Aug-2015 17:42:35
 25-Aug-2015 00:00:00
```

```
DateNumber =
```

```
 1.0e+05 *
 7.362007379117476
```

```
7.3620100000000000
```

## Convert Date String to Date Number

```
DateString = '19-May-2001';
formatIn = 'dd-mmm-yyyy';
datenum(DateString,formatIn)
```

```
ans =
```

```
730990
```

datenum returns a date number for the date string with the format 'dd-mmm-yyyy' .

## Convert Multiple Date Strings to Date Numbers

Pass multiple date strings in a cell array. All input date strings must use the same format.

```
DateString = {'09/16/2007';'05/14/1996';'11/29/2010'};
formatIn = 'mm/dd/yyyy';
datenum(DateString,formatIn)
```

```
ans =
```

```
733301
729159
734471
```

## Convert Date String to Date Number Using Pivot Year

Convert a date string to a serial date number using the default pivot year.

```
n = datenum('12-jun-17','dd-mmm-yy')
```

```
n =
```

```
736858
```

The corresponding date string to this date number is 12-Jun-2017.

Convert the same date string to a serial date number using 1400 as the pivot year.

```
n = datenum('12-jun-17','dd-mmm-yy',1400)
```

```
n =
```

```
517712
```

The corresponding date string to this date number is 12-Jun-1417.

### Convert Date Vector to Date Number

```
datenum([2009,4,2,11,7,18])
```

```
ans =
```

```
7.3387e+05
```

### Convert Year, Month, and Day to Date Number

Convert a date specified by year, month and day values to a serial date number.

```
n = datenum(2001,12,19)
```

```
n =
```

```
731204
```

## Input Arguments

### **t** — datetime values

scalar | vector | matrix | multidimensional array

**datetime** values, specified as a scalar, vector, matrix, or multidimensional **datetime** array. **datenum** does not account for time zone information in **t** and does not adjust **datetime** values that occur during Daylight Saving Time. That is, **datenum** treats the **TimeZone** property of **t** as empty and converts the remaining date and time information to a serial date number.

**DateVector — Date vectors**

matrix

Date vectors, specified as an *m*-by-6 or *m*-by-3 matrix containing *m* full or partial date vectors, respectively. A full date vector has six elements, specifying year, month, day, hour, minute, and second, in that order. A partial date vector has three elements, specifying year, month, and day, in that order. Each element of **DateVector** should be a positive or negative integer value except for the seconds element, which can be fractional. If an element falls outside the conventional range, **datenum** adjusts both that date vector element and the previous element. For example, if the minutes element is 70, **datenum** adjusts the hours element by 1 and sets the minutes element to 10. If the minutes element is -15, then **datevec** decreases the hours element by 1 and sets the minutes element to 45. Month values are an exception. **datenum** sets month values less than 1 to 1.

Example: [ 2003, 10, 24, 12, 45, 07 ]

Data Types: double

**DateString — Date strings**

string | character array | 1-D cell array of strings

Date strings, specified as a character array where each row corresponds to one date string, or as a one dimensional cell array of strings. All of the date strings must have the same format.

Example: ' 24-Oct-2003 12:45:07 '

Example: [ ' 19-Sep-2013 ' ; ' 20-Sep-2013 ' ; ' 21-Sep-2013 ' ]

Example: { ' 15-Oct-2010 ' ' 20-Nov-2012 ' }

If the date string format is known, you should also specify **formatIn**. If you do not specify **formatIn**, **DateString** must be in one of the following formats.

| Date String Format               | Example                      |
|----------------------------------|------------------------------|
| ' dd - mmm - yyyy HH : MM : SS ' | 01 - Mar - 2000 15 : 45 : 17 |
| ' dd - mmm - yyyy '              | 01 - Mar - 2000              |
| ' mm / dd / yyyy '               | 03 / 01 / 2000               |
| ' mm / dd / yy '                 | 03 / 01 / 00                 |

| Date String Format     | Example              |
|------------------------|----------------------|
| 'mm/dd'                | 03/01                |
| 'mmm.dd,yyyy HH:MM:SS' | Mar.01,2000 15:45:17 |
| 'mmm.dd,yyyy'          | Mar.01,2000          |
| 'yyyy-mm-dd HH:MM:SS'  | 2000-03-01 15:45:17  |
| 'yyyy-mm-dd'           | 2000-03-01           |
| 'yyyy/mm/dd'           | 2000/03/01           |
| 'HH:MM:SS'             | 15:45:17             |
| 'HH:MM:SS PM'          | 3:45:17 PM           |
| 'HH:MM'                | 15:45                |
| 'HH:MM PM'             | 3:45 PM              |

---

**Note:** The symbolic identifiers describing date string formats are different from those that describe the display formats of `datetime` arrays.

---

Certain date string formats might not contain enough information to convert the date string. In those cases, hours, minutes, and seconds default to 0, days default to 1, months default to January, and years default to the current year. `datevec` and `datenum` consider two-character date string years (e.g., '79') to fall within the 100-year range centered around the current year.

When you do not specify `formatIn`, note the following:

- For the formats that specify the month as two digits (mm), the month value must not be greater than 12.
- However, for the format 'mm/dd/yy', if the first entry in the date string is greater than 12 and the second entry is less than or equal to 12, then `datenum` considers the date string to be in 'yy/mm/dd' format.

### **formatIn** — Format of the input date string

string

Format of the input date string, specified as a string of symbolic identifiers.

Example: 'dddd, mmm dd, yyyy'

The following table shows symbolic identifiers that you can use to construct the `formatIn` string. You can include characters such as a hyphen, space, or colon to separate the fields.

---

**Note:** The symbolic identifiers describing date string formats are different from the identifiers that describe the display formats of `datetime` arrays.

---

| Symbolic Identifier | Description                                                                        | Example         |
|---------------------|------------------------------------------------------------------------------------|-----------------|
| yyyy                | Year in full                                                                       | 1990, 2002      |
| yy                  | Year in two digits                                                                 | 90, 02          |
| QQ                  | Quarter year using letter Q and one digit                                          | Q1              |
| mmmm                | Month using full name                                                              | March, December |
| mmm                 | Month using first three letters                                                    | Mar, Dec        |
| mm                  | Month in two digits                                                                | 03, 12          |
| m                   | Month using capitalized first letter                                               | M, D            |
| dddd                | Day using full name                                                                | Monday, Tuesday |
| ddd                 | Day using first three letters                                                      | Mon, Tue        |
| dd                  | Day in two digits                                                                  | 05, 20          |
| d                   | Day using capitalized first letter                                                 | M, T            |
| HH                  | Hour in two digits<br>(no leading zeros when symbolic identifier AM or PM is used) | 05, 5 AM        |
| MM                  | Minute in two digits                                                               | 12, 02          |
| SS                  | Second in two digits                                                               | 07, 59          |
| FFF                 | Millisecond in three digits                                                        | 057             |
| AM or PM            | AM or PM inserted in date string                                                   | 3:45:02 PM      |

The `formatIn` string must follow these guidelines:

- You cannot specify any field more than once. For example, you cannot use 'yy-mmm-dd-m' because it has two month identifiers. The one exception to this is that you can combine one instance of dd with one instance of any of the other day identifiers. For example, 'dddd mmm dd yyyy' is a valid input.
- When you use AM or PM, the HH field is also required.
- You only can use QQ alone or with a year specifier.

**PivotYear — Start year of 100-year date range**

present minus 50 years (default) | integer

Start year of the 100-year date range in which a two-character year resides, specified as an integer. Use a pivot year to interpret date strings that specify the year as two characters.

If `formatIn` contains the time of day, the pivot year is computed from the current time of the current day, month, and year. Otherwise it is computed from midnight of the current day, month, and year.

Example: 2000

Data Types: double

**Y,M,D — Year, month, and day arrays**

scalar | vector | matrix | array

Year, month, and day arrays specified as a scalar, vector, matrix, or array. These must be the same size, or any one can be a scalar. Y,M,D should be integer values.

If Y,M,D are all scalars or all column vectors, you can specify the input arguments as a date vector, [Y,M,D].

Example: 2003,10,24

Data Types: double

**Y,M,D,H,MN,S — Year, month, day, hour, minute, and second arrays**

scalar | vector | matrix | array

Year, month, day, hour, minute, and second arrays specified as a scalar, vector, matrix, or array. These must be the same size, or any one can be a scalar. `datenum` does not accept milliseconds as a separate input, but as a fractional part of the seconds input, S. Y,M,D,H,MN should be integer values.

If  $Y, M, D, H, MN, S$  are all scalars or all column vectors, you can specify the input arguments as a date vector  $[Y, M, D, H, MN, S]$ .

Example: 2003, 10, 24, 12, 45, 07.451

Data Types: double

## Output Arguments

### **DateNumber** — Serial date numbers

scalar | vector

Serial date numbers, returned as a column vector of length  $m$ , where  $m$  is the total number of input date vectors or date strings.

## More About

### Tips

- To create arbitrarily shaped output, use the `datenum(Y,M,D)` and `datenum(Y,M,D,H,MN,S)` syntaxes. The `datenum(DateVector)` syntax creates only a column vector of date numbers.

```
datenum(2013,[1 3; 2 4],ones(2,2))
```

```
ans =
```

```
 735235 735294
 735266 735325
```

**Introduced before R2006a**

# dateshift

Shift date or generate sequence of dates and time

## Syntax

```
t2 = dateshift(t, 'start', unit)
t2 = dateshift(t, 'end', unit)
t2 = dateshift(t, 'dayofweek', dow)

t2 = dateshift(____, rule)
```

## Description

`t2 = dateshift(t, 'start', unit)` shifts each value in the `datetime` array `t` back to the beginning of the unit of time specified by `unit`. The output `t2` is the same size as `t`.

`t2 = dateshift(t, 'end', unit)` shifts the values ahead to the end of the unit of time specified by `unit`. The end of a day, hour, minute, or second is also the beginning of the next one. For example, the end of a day occurs at midnight at the beginning of the next day. The end of a year, quarter, month, or week is midnight at the beginning of the last day of that time period.

`t2 = dateshift(t, 'dayofweek', dow)` returns the next occurrence of the specified day of the week on or after each `datetime` in array `t`. If the date in `t` falls on the specified day of the week, then `dateshift` returns the same date.

`t2 = dateshift( ____, rule)` shifts each value in array `t` according to the pattern specified by `rule`. You can use this syntax with any of the arguments in the previous syntaxes.

## Examples

### Shift Current Date to End of Current Month

Define the current date.

```
t = datetime('today')
```

```
t =
```

```
24-Aug-2015
```

Shift the date to the end of the same month.

```
t2 = dateshift(t,'end','month')
```

```
t2 =
```

```
31-Aug-2015
```

## Shift Current Date to Next Month

Define the current date.

```
t = datetime('today')
```

```
t =
```

```
24-Aug-2015
```

Shift the date to the start of the next month.

```
t2 = dateshift(t,'start','month','next')
```

```
t2 =
```

```
01-Sep-2015
```

Shift the date to the end of the next month.

```
t2 = dateshift(t,'end','month','next')
```

```
t2 =
```

```
30-Sep-2015
```

### Shift Dates to Specific Day of Week

Shift an array of dates forward to the next Friday.

```
t = datetime([2014,08,03;2014,04,15])
```

```
t =
```

```
03-Aug-2014
15-Apr-2014
```

```
t2 = dateshift(t, 'dayofweek', 'Friday')
```

```
t2 =
```

```
08-Aug-2014
18-Apr-2014
```

Shift the array of dates backward to the previous Monday.

```
t2 = dateshift(t, 'dayofweek', 'Monday', 'previous')
```

```
t2 =
```

```
28-Jul-2014
14-Apr-2014
```

### Determine Future Date

Find the date that falls at the end of the fifth week from today.

```
t = datetime('today')
```

```
t =
```

```
24-Aug-2015
```

```
t2 = dateshift(t, 'end', 'week', 5)
```

```
t2 =
```

```
03-Oct-2015
```

## Create Sequence of Dates Falling on Specific Day of Week

Generate a sequence of dates consisting of the next three occurrences of Friday.

```
t = datetime('today')
```

```
t =
```

```
24-Aug-2015
```

```
t2 = dateshift(t, 'dayofweek', 'Friday', 1:3)
```

```
t2 =
```

```
28-Aug-2015 04-Sep-2015 11-Sep-2015
```

## Input Arguments

### **t** — Input date and time

`datetime` array

Input date and time, specified as a `datetime` array.

### **unit** — Unit of time

'year' | 'quarter' | 'month' | 'week' | 'day' | 'hour' | 'minute' | 'second'

Unit of time, specified as one of the following strings:

- 'year'

- 'quarter'
- 'month'
- 'week'
- 'day'
- 'hour'
- 'minute'
- 'second'

**dow — Day of Week**

scalar integer | string

Day of the week, specified as a scalar integer indicating the day of week number, or a string containing a localized day name.

Example: 'Sunday'

Example: 1

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | char

**rule — Rule for shifting datetime values**

string | scalar integer | array of integer values

Rule for shifting datetime values, specified as a string, scalar integer, or an array of integer values. If **rule** is a string, it must be one of the following.

| Value of rule | Description                                                                                  |
|---------------|----------------------------------------------------------------------------------------------|
| 'next'        | Shift datetime to next unit of time or specified day.                                        |
| 'previous'    | Shift datetime to previous unit of time or specified day.                                    |
| 'nearest'     | Shift datetime to nearest occurrence of unit of time or specified day.                       |
| 'current'     | Shift datetime within the current unit of time, or to the specified day in the current week. |

If **rule** is an integer or an array of integers, then:

- When used with `unit`, 0 corresponds to the start or end of the current unit for each datetime, 1 corresponds to the next unit, and -1 corresponds to the previous unit, and so on.
- When used with `dow`, 0 corresponds to the specified day in the current week for each datetime, 1 corresponds to the next occurrence of the specified day, and -1 corresponds to the previous occurrence, and so on.
- `t` and `rule` must be the same size, or one must be a scalar.

**Introduced in R2014b**

# datestr

Convert date and time to string format

The `datestr` function creates a string or character array that display one or more points in time. However, the best way to represent points in time is by using the `datetime` data type.

## Syntax

```
DateString = datestr(t)
```

```
DateString = datestr(DateVector)
```

```
DateString = datestr(DateNumber)
```

```
DateString = datestr(____, formatOut)
```

```
DateString = datestr(DateStringIn)
```

```
DateString = datestr(DateStringIn, formatOut, PivotYear)
```

```
DateString = datestr(____, 'local')
```

## Description

`DateString = datestr(t)` converts the `datetime` values in `datetime` array `t` to date strings. `datestr` returns a column vector of `m` date strings, where `m` is the total number of `datetime` values in `t`.

By default, `datestr` returns date strings in the format, day-month-year hour:minute:second. If `hour:minute:second = 00:00:00`, then the date string returned has the format, day-month-year.

`DateString = datestr(DateVector)` converts date vectors to date strings. `datestr` returns a column vector of `m` date strings, where `m` is the total number of date vectors in `DateVector`.

`DateString = datestr(DateNumber)` converts serial date numbers to date strings. `datestr` returns a column vector of `m` date strings, where `m` is the total number of date numbers in `DateNumber`.

`DateString = datestr( ____, formatOut)` specifies the format of the output date strings using `formatOut`. You can use `formatOut` with any of the input arguments in the above syntaxes.

`DateString = datestr(DateStringIn)` converts `DateStringIn` to date strings in the format, day-month-year hour:minute:second. All date strings in `DateStringIn` must have the same format.

`DateString = datestr(DateStringIn, formatOut, PivotYear)` converts `DateStringIn` to `DateString`, in the format specified by `formatOut`, and using optional `PivotYear` to interpret date strings that specify the year as two characters.

`DateString = datestr( ____, 'local')` returns the date string in the language of the current locale. This is the language you select by means of your computer's operating system. If you leave `local` out of the argument list, `datestr` returns the date string in the default language, which is US English. Use `local` with any of the previous syntaxes. The `local` argument must be last in the argument sequence.

## Examples

### Convert datetime Array to Date Strings

```
t = [datetime('now');datetime('tomorrow')]
DateString = datestr(t)
```

```
t =
```

```
 24-Aug-2015 18:06:56
 25-Aug-2015 00:00:00
```

```
DateString =
```

```
 24-Aug-2015 18:06:56
 25-Aug-2015 00:00:00
```

`datestr` returns date strings in the format, day-month-year hour:minute:second.

### Convert Date Vector to Date String

```
DateVector = [2009,4,2,11,7,18];
```

```
datestr(DateVector)
```

```
ans =
```

```
02-Apr-2009 11:07:18
```

`datestr` returns a date string in the default date string format.

### **Convert Date and Time to Specific Format**

Format the current date in the mm/dd/yy format.

You can specify this format using a string of symbolic identifiers.

```
formatOut = 'mm/dd/yy';
datestr(now,formatOut)
```

```
ans =
```

```
08/24/15
```

Alternatively, you can specify this format using a numeric identifier.

```
formatOut = 2;
datestr(now,formatOut)
```

```
ans =
```

```
08/24/15
```

You can reformat the date and time, and also show milliseconds.

```
dt = datestr(now, 'mmm dd, yyyy HH:MM:SS.FFF AM')
```

```
dt =
```

```
August 24, 2015 5:41:52.149 PM
```

## Convert 12-Hour Time String to 24-Hour Equivalent

Convert the 12-hour time 05:32 p.m. to its 24-hour equivalent.

```
datestr('05:32 PM', 'HH:MM')
```

```
ans =
```

```
17:32
```

Convert the 24-hour time 05:32 to its 12-hour equivalent.

```
datestr('05:32', 'HH:MM PM')
```

```
ans =
```

```
5:32 AM
```

The use of AM or PM in the `formatOut` string does not influence which characters actually become part of the date string; they only determine whether or not to include them in the date string. MATLAB® selects AM or PM based on the time entered.

## Convert Date String from Custom Format

Call `datenum` inside of `datestr` to specify the format of the input date string.

```
formatOut = 'dd mmm yyyy';
datestr(datenum('16-04-55', 'dd-mm-yy', 1900), formatOut)
```

```
ans =
```

```
16 Apr 1955
```

## Convert Multiple Date Strings

Convert more than one date string input by passing the multiple date strings in a cell array.

All input date strings must use the same format. For example, the following command passes three dates that all use the mm/dd/yyyy format.

```
datestr(datetime({'09/16/2007';'05/14/1996';'11/29/2010'}, ...
 'mm/dd/yyyy'))
```

```
ans =
```

```
16-Sep-2007
14-May-1996
29-Nov-2010
```

`datestr` returns a character array of converted date strings in the format, day-month-year.

### Convert Date String with Values Outside Normal Range

Call `datetime` inside of `datestr` to return the expected value, because the date below uses a value outside its normal range (month=13).

```
datestr(datetime('13/24/88', 'mm/dd/yy'))
```

```
ans =
```

```
24-Jan-1989
```

### Use a Pivot Year

Change the pivot year to change the year range.

Use a pivot year of 1900.

```
DateStringIn = '4/16/55';
formatOut = 1;
PivotYear = 1900;
datestr(DateStringIn,formatOut,PivotYear)
```

```
ans =
```

```
16-Apr-1955
```

For the same date string, use a pivot year of 2000.

```
PivotYear = 2000;
datestr(DateStringIn,formatOut,PivotYear)
```

```
ans =
```

```
16-Apr-2055
```

## Return Date String in Local Language

Convert a date number to a date string in the language of the current locale.

Use the `local` argument in a French locale.

```
DateNumber = 725935;
formatOut = 'mmm-dd-yyyy';
str = datestr(DateNumber,formatOut,'local')
```

```
str =
```

```
Juillet-17-1987
```

You can make the same call without specifying `'local'`.

```
str = datestr(DateNumber,formatOut)
```

```
str =
```

```
July-17-1987
```

In this case, the output defaults to the English language.

## Input Arguments

### **t** — **datetime values**

scalar | vector | matrix | multidimensional array

`datetime` values, specified as a scalar, vector, matrix, or multidimensional `datetime` array.

### **DateVector** — **Date vectors**

matrix

Date vectors, specified as an  $m$ -by-6 matrix, where  $m$  is the number of full (six-element) date vectors. Each element of `DateVector` should be a positive or negative integer value with the exception of the seconds element, which can be fractional. If an element falls outside the conventional range, `datestr` adjusts both that date vector element and the previous element. For example, if the minutes element is 70, `datestr` adjusts the hours element by 1 and sets the minutes element to 10. If the minutes element is -15, then `datestr` decreases the hours element by 1 and sets the minutes element to 45. Month values are an exception. `datestr` sets month values less than 1 to 1.

Example: [2003,10,24,12,45,07]

Data Types: double

### **DateNumber** — Serial date numbers

scalar | vector | matrix | array

Serial date numbers, specified as a scalar, vector, matrix, or array of positive double-precision numbers.

Example: 731878

Data Types: double

### **formatOut** — Format of the date string output

-1 (default) | string | integer

Format of the date string output, specified as a string of symbolic identifiers or an integer that corresponds to a predefined format. If you do not specify `formatOut`, then `datestr` returns a date string in the default date string format `dd-mmm-yyyy HH:MM:SS` (day-month-year hour:minute:second). By default, if `HH:MM:SS = 00:00:00` then the date string returned has the format `dd-mmm-yyyy`.

The following table shows symbolic identifiers you can use to construct the `formatOut` string. You can include characters such as a hyphen, space, or colon to separate the fields.

---

**Note:** The symbolic identifiers describing date string formats are different from those that describe the display formats of `datetime` arrays.

---

| Symbolic Identifier | Description  | Example    |
|---------------------|--------------|------------|
| yyyy                | Year in full | 1990, 2002 |

| Symbolic Identifier | Description                                                                        | Example         |
|---------------------|------------------------------------------------------------------------------------|-----------------|
| yy                  | Year in two digits                                                                 | 90, 02          |
| QQ                  | Quarter year using letter Q and one digit                                          | Q1              |
| mmmm                | Month using full name                                                              | March, December |
| mmm                 | Month using first three letters                                                    | Mar, Dec        |
| mm                  | Month in two digits                                                                | 03, 12          |
| m                   | Month using capitalized first letter                                               | M, D            |
| dddd                | Day using full name                                                                | Monday, Tuesday |
| ddd                 | Day using first three letters                                                      | Mon, Tue        |
| dd                  | Day in two digits                                                                  | 05, 20          |
| d                   | Day using capitalized first letter                                                 | M, T            |
| HH                  | Hour in two digits<br>(no leading zeros when symbolic identifier AM or PM is used) | 05, 5 AM        |
| MM                  | Minute in two digits                                                               | 12, 02          |
| SS                  | Second in two digits                                                               | 07, 59          |
| FFF                 | Millisecond in three digits                                                        | 057             |
| AM or PM            | AM or PM inserted in date string                                                   | 3:45:02 PM      |

The `formatOut` string must follow these guidelines:

- You cannot specify any field more than once. For example, you cannot use `'yy-mmm-dd-m'` because it has two month identifiers. The one exception to this is that you can combine one instance of `dd` with one instance of any of the other day identifiers. For example, `'dddd mmm dd yyyy'` is a valid input.
- When you use `AM` or `PM`, the `HH` field is also required.
- You only can use `QQ` alone or with a year specifier.

This table lists predefined date formats that you can use with `datestr`.

| Numeric Identifier | Date String Format                                                     | Example                                |
|--------------------|------------------------------------------------------------------------|----------------------------------------|
| - 1 (default)      | 'dd-mmm-yyyy HH:MM:SS'<br>or 'dd-mmm-yyyy' if<br>'HH:MM:SS' = 00:00:00 | 01-Mar-2000 15:45:17 or<br>01-Mar-2000 |

| 17                 | 'QQ-YY'                                                                | Q1-01                                  |
| 18                 | 'QQ'                                                                   | Q1                                     |
| 19                 | 'dd/mm'                                                                | 01/03                                  |
| 20                 | 'dd/mm/yy'                                                             | 01/03/00                               |
| 21                 | 'mmm.dd,yyyy HH:MM:SS'                                                 | Mar.01,2000 15:45:17                   |
| 22                 | 'mmm.dd,yyyy'                                                          | Mar.01,2000                            |
| 23                 | 'mm/dd/yyyy'                                                           | 03/01/2000                             |
| 24                 | 'dd/mm/yyyy'                                                           | 01/03/2000                             |

| Numeric Identifier | Date String Format             | Example             |
|--------------------|--------------------------------|---------------------|
| 25                 | 'yy/mm/dd'                     | 00/03/01            |
| 26                 | 'yyyy/mm/dd'                   | 2000/03/01          |
| 27                 | 'QQ-YYYY'                      | Q1-2001             |
| 28                 | 'mmyyyy'                       | Mar2000             |
| 29                 | 'yyyy-mm-dd'<br>(ISO 8601)     | 2000-03-01          |
| 30                 | 'yyyymmddTHMMSS'<br>(ISO 8601) | 20000301T154517     |
| 31                 | 'yyyy-mm-dd HH:MM:SS'          | 2000-03-01 15:45:17 |

**DateStringIn — Date strings to convert**

string | cell array

Date strings to convert, specified as a single string or a cell array of strings, where each row corresponds to one date string.

`datestr` considers two-character date string years (for example, '79') to fall within the 100-year range centered around the current year.

All date strings must have the same date format, and they must be in one of the following date formats.

| Date String Format     | Example              |
|------------------------|----------------------|
| 'dd-mmm-yyyy HH:MM:SS' | 01-Mar-2000 15:45:17 |
| 'dd-mmm-yyyy'          | 01-Mar-2000          |
| 'mm/dd/yyyy'           | 03/01/2000           |
| 'mm/dd/yy'             | 03/01/00             |
| 'mm/dd'                | 03/01                |
| 'mmm.dd,yyyy HH:MM:SS' | Mar.01,2000 15:45:17 |
| 'mmm.dd,yyyy'          | Mar.01,2000          |
| 'yyyy-mm-dd HH:MM:SS'  | 2000-03-01 15:45:17  |
| 'yyyy-mm-dd'           | 2000-03-01           |

| Date String Format | Example    |
|--------------------|------------|
| 'yyyy/mm/dd'       | 2000/03/01 |
| 'HH:MM:SS'         | 15:45:17   |
| 'HH:MM:SS PM'      | 3:45:17 PM |
| 'HH:MM'            | 15:45      |
| 'HH:MM PM'         | 3:45 PM    |

---

**Note:** When converting from one date string format to another, you should first pass the strings to the `datenum` function, so that you can specify the format of the input date strings. This ensures that the format of the input date strings is correctly interpreted. For example, see “Convert Date String from Custom Format” on page 1-1956.

---

### **PivotYear** — Start year of 100-year date range

present minus 50 years (default) | integer

Start year of the 100-year date range in which a two-character year resides, specified as an integer. Use a pivot year to interpret date strings that specify the year as two characters.

If `formatIn` contains the time of day, the pivot year is computed from the current time of the current day, month, and year. Otherwise it is computed from midnight of the current day, month, and year.

Example: 2000

Data Types: double

## **Output Arguments**

### **DateString** — Date strings

string | two-dimensional character array

Date strings, returned as a character array with `m` rows, where `m` is the total number of input date vectors, serial date numbers, or date strings. The default output date string format is `dd-mmm-yyyy HH:MM:SS` (day-month-year hour:minute:second) unless the hours, minutes and seconds are all 0 in which case `HH:MM:SS` is suppressed.

## More About

### Tips

- To convert a date string not in a predefined MATLAB date format, first convert the date string to a date number, using either `datenum` or `datevec`.
- “Represent Dates and Times in MATLAB”
- “Converting Date Vector Returns Unexpected Output”

**Introduced before R2006a**

# datetick

Date formatted tick labels

The `datetick` function labels the tick lines of an axis using dates, replacing the default labels. `datetick` is useful when plotting numeric values that are serial date numbers.

For 2-D line and scatter plots, it is more convenient to plot datetime values using the `plot` function. Specify the format of the tick labels using the `DatetimeTickFormat` name-value pair argument. You do not need to use `datetick` to label such plots of datetime values.

## Syntax

```
datetick(tickaxis)
datetick(tickaxis,dateFormat)
```

```
datetick(____, 'keeplimits')
```

```
datetick(____, 'keepticks')
```

```
datetick(axes_handle, ____)
```

## Description

`datetick(tickaxis)` labels the tick lines of the axis specified by `tickaxis` using dates, replacing the default numeric labels. `datetick` selects a label format based on the minimum and maximum limits of the specified axis. The axis data values should be serial date numbers, as returned by the `datenum` function.

`datetick(tickaxis,dateFormat)` formats the labels according to the string `dateFormat`.

`datetick( ____, 'keeplimits')` changes the tick labels to date-based labels while preserving the axis limits. Append `'keeplimits'` to any of the previous syntaxes.

`datetick( ____, 'keepticks')` changes the tick labels to date-based labels while preserving their locations. Append `'keepticks'` to any of the previous syntaxes.

`datetick(axes_handle, ___)` labels the tick lines of an axis on the axes specified by `axes_handle`. The `axes_handle` argument can precede any of the input argument combinations in the previous syntaxes.

## Examples

### Label x-Axis Ticks with 2-digit Years

Graph population data for the 20th Century taken from the 1990 US census and label x-axis ticks with 2-digit years.

Create time data by decade.

```
t = (1900:10:1990)';
```

Enter total population counts for the USA.

```
p = [75.995 91.972 105.711 123.203 131.669 ...
 150.697 179.323 203.212 226.505 249.633]';
```

Convert years to serial date numbers using the `datenum` function, and then create a bar graph of the data.

```
figure
bar(datenum(t,1,1),p)
```

Replace *x*-axis ticks with 2-digit years. The numeric identifier 11 corresponds to the predefined MATLAB® date format 'yy'.

```
dateFormat = 11;
datetick('x',dateFormat)
```

## Label x-Axis Ticks with Hours of the Day

Plot traffic count data against date ticks for hours of the day showing AM and PM.

Get traffic count data.

```
load count.dat
```

Create arrays for an arbitrary date, for example, April 18, 1995.

```
n = length(count);
year = repmat(1995,1,n);
month = repmat(4,1,n);
day = repmat(18,1,n);
```

Create arrays for each of 24 hours.

```
hour = 1:n;
minutes = zeros(1,n);
```

Get the serial date numbers for the date arrays.

```
sdate = datenum(year,month,day,hour,minutes,minutes);
```

Plot a 3-D bar graph of the traffic data against the serial date numbers.

```
bar3(sdate,count)
```

Label the tick lines of the graph's y-axis with the hours of the day.

```
datetick('y','HHPM')
```

## Label x-Axis and Preserve Axis Limits

Select a starting date.

```
startDate = datenum('02-01-1962');
```

Select an ending date.

```
endDate = datenum('11-15-2012');
```

Create a variable, `xdata`, that corresponds to the number of years between the start and end dates.

```
xData = linspace(startDate, endDate, 50);
```

Plot random data.

```
figure
stem(xData,rand(1,50))
```

Label the  $x$ -axis with 4-digit years, preserving the  $x$ -axis limits by using the 'keeplimits' option.

```
datetick('x','yyyy','keeplimits')
```

## Add Month Labels to Plot and Preserve Number of Ticks

Select a starting date.

```
startDate = datenum('01-01-2009');
```

Select an ending date.

```
endDate = datenum('12-31-2009');
```

Create a variable, `xData`, that corresponds to the number of months between the start and end dates.

```
xData = linspace(startDate, endDate, 12);
```

Plot random data.

```
figure
stairs(xData,rand(1,12))
```

Set the number of XTicks to the number of points in xData.

```
ax = gca;
ax.XTick = xData;
```

Label the x-axis with month names, preserving the total number of ticks by using the 'kepticks' option.

```
datetick('x', 'mmm', 'kepticks')
```

### Create Multiple Plots Within Figure and Label Axis with Month Names

Select a starting date and an ending date.

```
startDate = datenum('01-01-2009');
endDate = datenum('12-31-2009');
```

Create a variable, `xdata`, that corresponds to the number of months between the start and end dates.

```
xData = linspace(startDate, endDate, 12);
```

Plot random data.

```
ax1 = subplot(2,1,1);
```

```
bar(xData,rand(1,12))
ax2 = subplot(2,1,2);
bar(xData,rand(1,12))
```

Set the number of `XTicks` to the number of points in `xData`. Label the *x*-axis of each subplot with month names, referring to each subplot using its axes handle. Preserve the total number of ticks by using the `'keepticks'` option. Starting in R2014b, you can use dot notation to set properties. If you are using an earlier release, use the `set` function instead.

```
ax1.XTick = xData;
datetick(ax1,'x','mm','keepticks')

ax2.XTick = xData;
```

```
datetick(ax2,'x','mmm','kepticks')
```

## Input Arguments

### **tickaxis** — Axis to label

'x' (default) | 'y' | 'z'

Axis to label with dates, specified as 'x', 'y', or 'z'.

### **dateFormat** — Format of tick line labels

string | integer

Format of the tick line labels, specified as a string of symbolic identifiers or an integer that corresponds to a predefined format.

The following table shows symbolic identifiers that you can use to construct the `dateFormat` string. You can include characters such as a hyphen, space, or colon to separate the fields. For example, to display the day of the month followed by the three-letter abbreviation of the day of the week in parentheses, use `dateFormat = 'dd (ddd)'`.

---

**Note:** The letter identifiers that `datetick` accepts are different from the identifiers used by the `datetime` function.

---

| Symbolic Identifier | Description                                                                        | Example         |
|---------------------|------------------------------------------------------------------------------------|-----------------|
| yyyy                | Year in full                                                                       | 1990, 2002      |
| yy                  | Year in two digits                                                                 | 90, 02          |
| QQ                  | Quarter year using letter Q and one digit                                          | Q1              |
| mmmm                | Month using full name                                                              | March, December |
| mmm                 | Month using first three letters                                                    | Mar, Dec        |
| mm                  | Month in two digits                                                                | 03, 12          |
| m                   | Month using capitalized first letter                                               | M, D            |
| dddd                | Day using full name                                                                | Monday, Tuesday |
| ddd                 | Day using first three letters                                                      | Mon, Tue        |
| dd                  | Day in two digits                                                                  | 05, 20          |
| d                   | Day using capitalized first letter                                                 | M, T            |
| HH                  | Hour in two digits<br>(no leading zeros when symbolic identifier AM or PM is used) | 05, 5 AM        |
| MM                  | Minute in two digits                                                               | 12, 02          |
| SS                  | Second in two digits                                                               | 07, 59          |
| FFF                 | Millisecond in three digits                                                        | 057             |

| Symbolic Identifier | Description                      | Example    |
|---------------------|----------------------------------|------------|
| AM or PM            | AM or PM inserted in date string | 3:45:02 PM |

The following table lists predefined MATLAB date formats.

| Numeric Identifier | Date String Format                                                     | Example                                |
|--------------------|------------------------------------------------------------------------|----------------------------------------|
| -1 (default)       | 'dd-mmm-yyyy HH:MM:SS'<br>or 'dd-mmm-yyyy' if<br>'HH:MM:SS' = 00:00:00 | 01-Mar-2000 15:45:17 or<br>01-Mar-2000 |
| 0                  | 'dd-mmm-yyyy HH:MM:SS'                                                 | 01-Mar-2000 15:45:17                   |
| 1                  | 'dd-mmm-yyyy'                                                          | 01-Mar-2000                            |
| 2                  | 'mm/dd/yy'                                                             | 03/01/00                               |
| 3                  | 'mmm'                                                                  | Mar                                    |
| 4                  | 'm'                                                                    | M                                      |
| 5                  | 'mm'                                                                   | 03                                     |
| 6                  | 'mm/dd'                                                                | 03/01                                  |
| 7                  | 'dd'                                                                   | 01                                     |
| 8                  | 'ddd'                                                                  | Wed                                    |
| 9                  | 'd'                                                                    | W                                      |
| 10                 | 'yyyy'                                                                 | 2000                                   |
| 11                 | 'yy'                                                                   | 00                                     |
| 12                 | 'mmyy'                                                                 | Mar00                                  |
| 13                 | 'HH:MM:SS'                                                             | 15:45:17                               |
| 14                 | 'HH:MM:SS PM'                                                          | 3:45:17 PM                             |
| 15                 | 'HH:MM'                                                                | 15:45                                  |
| 16                 | 'HH:MM PM'                                                             | 3:45 PM                                |
| 17                 | 'QQ-YY'                                                                | Q1-01                                  |
| 18                 | 'QQ'                                                                   | Q1                                     |
| 19                 | 'dd/mm'                                                                | 01/03                                  |
| 20                 | 'dd/mm/yy'                                                             | 01/03/00                               |

| Numeric Identifier | Date String Format              | Example              |
|--------------------|---------------------------------|----------------------|
| 21                 | 'mmm.dd,yyyy HH:MM:SS'          | Mar.01,2000 15:45:17 |
| 22                 | 'mmm.dd,yyyy'                   | Mar.01,2000          |
| 23                 | 'mm/dd/yyyy'                    | 03/01/2000           |
| 24                 | 'dd/mm/yyyy'                    | 01/03/2000           |
| 25                 | 'yy/mm/dd'                      | 00/03/01             |
| 26                 | 'yyyy/mm/dd'                    | 2000/03/01           |
| 27                 | 'QQ-YYYY'                       | Q1-2001              |
| 28                 | 'mmmyyyy'                       | Mar2000              |
| 29                 | 'yyyy-mm-dd'<br>(ISO 8601)      | 2000-03-01           |
| 30                 | 'yyyymmddTHHMMSS'<br>(ISO 8601) | 20000301T154517      |
| 31                 | 'yyyy-mm-dd HH:MM:SS'           | 2000-03-01 15:45:17  |

## More About

### Tips

- To change the tick spacing and locations, set the appropriate axes property (that is, `XTick`, `YTick`, or `ZTick`) before calling `datetick`.
- Calling `datetick` sets the `TickMode` of the specified axis to `'manual'`. This means that after zooming, panning or otherwise changing axis limits, you should call `datetick` again to update the ticks and labels.
- The best way to work with dates and times in MATLAB is to use `datetime` values, which offer more features than serial date numbers. Plot `datetime` values using the `plot` function. Use the `DatetimeTickFormat` name-value pair argument to modify the format of the axis tick labels.

### Algorithms

`datetick` calls the `datestr` function to convert date numbers to date strings.

## datetime

Create array based on current date, or convert from date strings or numbers

The `datetime` function creates an array that represents points in time using the proleptic ISO calendar. `datetime` values have flexible display formats up to nanosecond precision and can account for time zones, daylight saving time, and leap seconds.

### Syntax

```
t = datetime
t = datetime(relativeDay)

t = datetime(DateStrings)
t = datetime(DateStrings, 'InputFormat', infmt)

t = datetime(DateVectors)
t = datetime(Y,M,D)
t = datetime(Y,M,D,H,MI,S)
t = datetime(Y,M,D,H,MI,S,MS)

t = datetime(X, 'ConvertFrom', dateType)

t = datetime(____, Name, Value)
```

### Description

`t = datetime` returns a scalar `datetime` array corresponding to the current date and time.

`t = datetime(relativeDay)` uses the date specified by `relativeDay`. The `relativeDay` input can be `'today'`, `'tomorrow'`, `'yesterday'`, or `'now'`.

`t = datetime(DateStrings)` creates an array of `datetime` values representing points in time from the strings in `DateStrings`.

`t = datetime(DateStrings, 'InputFormat', infmt)` interprets the strings in `DateStrings` using the format specified by `infmt`. All strings in `DateStrings` must have the same format.

To avoid ambiguities between similar formats, specify `'InputFormat'` and its corresponding value, `infmt`.

`t = datetime(DateVectors)` creates a column vector of datetime values from the date vectors in `DateVectors`.

`t = datetime(Y,M,D)` creates an array of datetime values for corresponding elements of the `Y`, `M`, and `D` (year, month, day) arrays. The arrays must be of the same size (or any can be a scalar). You also can specify the input arguments as a date vector, `[Y,M,D]`.

`t = datetime(Y,M,D,H,MI,S)` creates an array of `datetime` values for corresponding elements of the `Y`, `M`, `D`, `H`, `MI`, and `S` (year, month, day, hour, minute, and second) arrays. The arrays must be of the same size (or any can be a scalar). You also can specify the input arguments as a date vector, `[Y,M,D,H,MI,S]`.

`t = datetime(Y,M,D,H,MI,S,MS)` creates an array of `datetime` values for corresponding elements of the `Y`, `M`, `D`, `H`, `MI`, `S`, and `MS` (year, month, day, hour, minute, second, and millisecond) arrays. The arrays must be of the same size (or any can be a scalar).

`t = datetime(X,'ConvertFrom',dateType)` converts the numeric values in `X` to a `datetime` array, `t`. The `dateType` argument specifies the type of values in `X`.

`t = datetime(___,Name,Value)` specifies additional options using one or more name-value pair arguments, in addition to any of the input arguments in the previous syntaxes. For example, you can specify the display format of `t` using the `'Format'` name-value pair argument.

For best performance when creating datetime values from strings, specify either `'Format'` or `'InputFormat'` and its corresponding value, `infmt`.

## Examples

### Current Date and Time in Specific Time Zone

Specify the current date and time in the local system time zone.

```
t = datetime('now','TimeZone','local','Format','d-MMM-y HH:mm:ss Z')
```

```
t =
 24-Aug-2015 18:08:41 -0400
```

Specify the current date and time in the time zone represented by Seoul, Korea

```
t = datetime('now','TimeZone','Asia/Seoul','Format','d-MMM-y HH:mm:ss Z')
```

```
t =
 25-Aug-2015 07:08:41 +0900
```

## Date and Time from Strings

Create a `datetime` array from a cell array of two strings.

```
DateStrings = {'2014-05-26';'2014-08-03'};
t = datetime(DateStrings,'InputFormat','yyyy-MM-dd')
```

```
t =
 26-May-2014
 03-Aug-2014
```

The `datetime` values in `t` display using the default format, and not the format of the input date strings.

## Date and Time from Strings with Literal Characters

Convert date strings in ISO 8601 format to `datetime` values.

Create a cell array of strings containing dates in ISO 8601 format. In this format, the letter `T` is used as a delimiter that separates a date and a time. Each string includes a time zone offset. The letter `Z` indicates no offset from UTC.

```
DateStrings = {'2014-05-26T13:30-05:00';'2014-08-26T13:30-04:00';'2014-09-26T13:30Z'}
```

```
DateStrings =
```

```
'2014-05-26T13:30-05:00'
'2014-08-26T13:30-04:00'
'2014-09-26T13:30Z'
```

Convert the strings to datetime values. When specifying the input format, enclose the letter T in single quotes to indicate that it is a literal character. Specify the time zone of the output datetime array using the `TimeZone` name-value pair argument.

```
t = datetime(DateStrings, 'InputFormat', 'uuuu-MM-dd' 'T' 'HH:mmXXX', 'TimeZone', 'UTC')
```

```
t =
```

```
26-May-2014 18:30:00
26-Aug-2014 17:30:00
26-Sep-2014 13:30:00
```

The datetime values in `t` display in the default format.

### Date and Time from Strings in Foreign Language

Create a cell array of strings containing dates in French.

```
C = {'8 avril 2013', '9 mai 2013'; '10 juin 2014', '11 juillet 2014'}
```

```
C =
```

```
'8 avril 2013' '9 mai 2013'
'10 juin 2014' '11 juillet 2014'
```

Convert the strings in `C` to datetime values. If your computer is set to a locale that uses English, you must specify the `Locale` name-value pair argument to indicate that the strings are in French.

```
t = datetime(C, 'InputFormat', 'd MMMM yyyy', 'Locale', 'fr_FR')
```

```
t =
```

```
08-Apr-2013 09-May-2013
10-Jun-2014 11-Jul-2014
```

The datetime values in `t` display in the default format, and in the language MATLAB uses depending on your system locale.

## Date and Time from Vectors

Create a `datetime` array from individual arrays of year, month, and day values.

Create sample numeric arrays of year values `Y` and day values `D`. In this case, the month value `M` is a scalar.

```
Y = [2014;2013;2012];
M = 01;
D = [31;30;31];
```

Create the `datetime` array.

```
t = datetime(Y,M,D)
```

```
t =

 31-Jan-2014
 30-Jan-2013
 31-Jan-2012
```

Specify a custom display format for the output, using the `Format` name-value pair argument.

```
t = datetime(Y,M,D,'Format','eeee, MMMM d, y')
```

```
t =

 Friday, January 31, 2014
 Wednesday, January 30, 2013
 Tuesday, January 31, 2012
```

## Convert Excel Date Number to Datetime

Create a sample array of Excel® date numbers that represent a number of days since January 0, 1900.

```
X = [39558, 39600; 39700, 39800]
```

```
X =
```

```
 39558 39600
 39700 39800
```

Convert the values in X to datetime values.

```
t = datetime(X, 'ConvertFrom', 'excel')
```

```
t =
```

```
 20-Apr-2008 00:00:00 01-Jun-2008 00:00:00
 09-Sep-2008 00:00:00 18-Dec-2008 00:00:00
```

## Input Arguments

### **relativeDay** — Day relative to current date

'yesterday' | 'today' | 'tomorrow' | 'now'

Day relative to the current date, specified as one of the following strings.

| Value of <b>relativeDay</b> | Description                            |
|-----------------------------|----------------------------------------|
| 'yesterday'                 | Date of the previous day, at midnight  |
| 'today'                     | Current date, at midnight              |
| 'tomorrow'                  | Date of the following day, at midnight |
| 'now'                       | Current date and time                  |

### **DateStrings** — Date strings

string | character array | cell array of strings

Date strings, specified as a string, character array, or a cell array of strings. The `datetime` function first attempts to match the format of the strings to some common formats. If you know the format of the date strings, specify `'InputFormat'` and its corresponding value, `infmt`, or the `'Format'` name-value pair argument.

Example: '24-Oct-2014 12:45:07'

Example: {'15-Oct-2013' '20-Nov-2014'}

Data Types: char | cell

### **infmt** — Format of input date strings

string

Format of the input date strings, specified as a string of letter identifiers:

- If `infmt` does not include a date specifier, then `datetime` assumes that the values in `DateStrings` occur during the current day.
- If `infmt` does not include a time specifier, then `datetime` assumes that the values in `DateStrings` occur at midnight.
- If `infmt` includes a time-zone specifier and you do not specify a time zone, then `datetime` creates unzoned datetimes and ignores any time-zone information in `DateStrings`.

This table shows several common input formats and examples of the formatted input for the date, Saturday, April 19, 2014 at 9:41:06 PM in New York City.

| <b>Value of Format</b>      | <b>Example</b>                   |
|-----------------------------|----------------------------------|
| 'yyyy-MM-dd'                | 2014-04-19                       |
| 'dd/MM/yyyy'                | 19/04/2014                       |
| 'dd.MM.yyyy'                | 19.04.2014                       |
| 'yyyy# MM# dd#'             | 2014# 04# 19#                    |
| 'MMMM d, yyyy'              | April 19, 2014                   |
| 'eeee, MMMM d, yyyy h:mm a' | Saturday, April 19, 2014 9:41 PM |
| 'MMMM d, yyyy HH:mm:ss Z'   | April 19, 2014 21:41:06 -0400    |
| 'yyyy-MM-dd' 'T' 'HH:mmXXX' | 2014-04-19T21:41-04:00           |

For a complete list of valid letter identifiers, see the `Format` property for `datetime` arrays.

---

**Note:** The letter identifiers that `datetime` accepts are different from the identifiers used by the `datestr`, `datenum`, and `datevec` functions.

---

Data Types: char

### **DateVectors — Date vectors**

matrix

Date vectors, specified as an  $m$ -by-6 or  $m$ -by-3 matrix containing  $m$  full or partial date vectors, respectively. A full date vector has six elements, specifying year, month, day, hour, minute, and second, in that order. A partial date vector has three elements, specifying year, month, and day, in that order. Each element of `DateVector` should be a positive or negative integer value except for the seconds element, which can be fractional. If an element falls outside the conventional range, `datetime` adjusts both that date vector element and the previous element. For example, if the minutes element is 70, then `datetime` adjusts the hours element by 1 and sets the minutes element to 10. If the minutes element is -15, then `datetime` decreases the hours element by 1 and sets the minutes element to 45.

Example: [2014, 10, 24, 12, 45, 07]

Example: [2014, 10, 24]

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

### **Y, M, D — Year, month, and day arrays**

scalar | vector | matrix | array

Year, month, and day arrays specified as a scalar, vector, matrix, or array. These must be the same size, or any one can be a scalar. `Y, M, D` should be integer values.

If `Y, M, D` are all scalars or all column vectors, you can specify the input arguments as a date vector, [`Y, M, D`].

If an element of the `Y, M, or D` inputs falls outside the conventional range, then `datetime` adjusts both that element and the same element of the previous input. For details, see the description for the `DateVectors` input argument.

Example: 2003, 10, 24

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

### **Y, M, D, H, MI, S — Year, month, day, hour, minute, and second arrays**

scalar | vector | matrix | array

Year, month, day, hour, minute, and second arrays specified as a scalar, vector, matrix, or array. These must be the same size, or any one can be a scalar. Specify fractional seconds as part of the seconds input, `S`. The `Y, M, D, H, MI` arrays must contain integer values.

If `Y, M, D, H, MI, S` are all scalars or all column vectors, you can specify the input arguments as a date vector [`Y, M, D, H, MI, S`].

If an element of the `Y, M, D, H, MI, S` inputs falls outside the conventional range, then `datetime` adjusts both that element and the same element of the previous input. For details, see the description for the `DateVectors` input argument.

Example: `2003,10,24,12,45,07.451`

Data Types: `single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64`

**`Y, M, D, H, MI, S, MS` — Year, month, day, hour, minute, second, and millisecond arrays**  
`scalar | vector | matrix | array`

Year, month, day, hour, minute, second, and millisecond arrays, specified as a scalar, vector, matrix, or array. These must be the same size, or any one can be a scalar. The `Y, M, D, H, MI, S` arrays must contain integer values. `MS` can contain fractional milliseconds.

If an element of the `Y, M, D, H, MI, S, MS` inputs falls outside the conventional range, then `datetime` adjusts both that element and the same element of the previous input. For details, see the description for the `DateVectors` input argument.

Example: `2003,10,24,12,45,07,10.52`

Data Types: `single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64`

**`X` — Numeric values**  
`scalar | matrix | multidimensional array`

Numeric values, specified as a scalar, matrix, or multidimensional array.

Data Types: `single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64`

**`dateType` — Type of values in `X`**  
`'datenum' | 'excel' | 'juliandate' | 'posixtime' | 'yyyymmdd' | ...`

Type of values in X, specified as one of the following strings.

| Value of dateType                       | Type of values in X                                                                                                                                                                                                                                                                                                                        |
|-----------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'datetime'                              | Number of days since 0-Jan-0000 (proleptic ISO calendar)                                                                                                                                                                                                                                                                                   |
| 'excel'                                 | Number of days since 0-Jan-1900<br><br>Excel date numbers are rounded to the nearest microsecond.                                                                                                                                                                                                                                          |
| 'excel1904'                             | Number of days since 0-Jan-1904<br><br>Excel date numbers are rounded to the nearest microsecond.                                                                                                                                                                                                                                          |
| 'juliandate'                            | Number of days since noon UTC 24-Nov-4712 BCE (Gregorian calendar)                                                                                                                                                                                                                                                                         |
| 'modifiedjuliandate'                    | Number of days since midnight UTC 17-Nov-1858                                                                                                                                                                                                                                                                                              |
| 'posixtime'                             | Number of seconds since 1-Jan-1970 00:00:00 UTC                                                                                                                                                                                                                                                                                            |
| 'yyyymmdd'                              | Dates as YYYYMMDD numeric values. For example, 20140402 represents April 2, 2014.                                                                                                                                                                                                                                                          |
| 'epochtime', 'Epoch', <i>epochValue</i> | Number of seconds since an epoch.<br><br>You must additionally specify <i>epochValue</i> , which is a scalar <code>datetime</code> or a date string representing the epoch time. This example returns the number of days since January 1, 2000:<br><br><code>T = datetime(X, 'ConvertFrom', ... 'epochtime', 'Epoch', '2000-01-01')</code> |

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single

quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'Format','eeee MMMM d, y','TimeZone','local'` applies a display format to datetime values and specifies the local time zone.

**'Format' – Display format**

`'default' | 'defaultdate' | 'preserveinput' | string`

Display format of the values in the output array, `y`, specified as the comma-separated pair consisting of `'Format'` and one of the following strings.

| Value of Format              | Description                                                                                                                                                                   |
|------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>'default'</code>       | Use the default display format.                                                                                                                                               |
| <code>'defaultdate'</code>   | Use the default display format for datetime values created without time components.                                                                                           |
| <code>'preserveinput'</code> | Use the format specified by the input format, <code>infmt</code> . If you do not specify <code>infmt</code> , then <code>datetime</code> determines the format automatically. |

The factory default format depends on your system locale. To change the default display format, see “Default datetime Format”.

Alternatively, use the letters `A-Z` and `a-z` to construct a custom value for `Format`. These letters correspond to the Unicode® Locale Data Markup Language (LDML) standard for dates. You can include non-ASCII or nonletter characters such as a hyphen, space, or colon to separate the fields. To include the letters `A-Z` and `a-z` as literal characters in the format, enclose them with single quotes.

Example: `'Format','eeee, MMMM d, yyyy HH:mm:ss'` displays a date and time such as `Saturday, April 19, 2014 21:41:06`.

This table shows several common display formats and examples of the formatted output for the date, Saturday, April 19, 2014 at 9:41:06 PM in New York City. For a complete list of valid letter identifiers, see the `Format` property for datetime arrays.

| Value of Format           | Example                 |
|---------------------------|-------------------------|
| <code>'yyyy-MM-dd'</code> | <code>2014-04-19</code> |
| <code>'dd/MM/yyyy'</code> | <code>19/04/2014</code> |

| Value of Format             | Example                          |
|-----------------------------|----------------------------------|
| 'dd.MM.yyyy'                | 19.04.2014                       |
| 'yyyy# MM# dd#'             | 2014# 04# 19#                    |
| 'MMMM d, yyyy'              | April 19, 2014                   |
| 'eeee, MMMM d, yyyy h:mm a' | Saturday, April 19, 2014 9:41 PM |
| 'MMMM d, yyyy HH:mm:ss Z'   | April 19, 2014 21:41:06 -0400    |
| 'yyyy-MM-dd 'T' 'HH:mmXXX'  | 2014-04-19T21:41-04:00           |

**Note:** The letter identifiers that `datetime` accepts are different from the identifiers used by the `datestr`, `datenum`, and `datevec` functions.

If you specify a `DateStrings` input but do not specify the `'InputFormat'` parameter, then `datetime` tries to use the `Format` value to interpret the strings.

Data Types: `char`

### 'Locale' — Locale of DateStrings

`string`

Locale of the date strings in `DateStrings`, specified as the comma-separated pair consisting of `'Locale'` and a string. The `Locale` value determines how `datetime` interprets the strings in `DateStrings`. However, the output `datetime` values always display in the system locale.

The `Locale` value can be:

- `'system'`, to specify your system locale.
- a string in the form `xx_YY`, where `xx` is a lowercase ISO 639-1 two-letter code that specifies a language, and `YY` is an uppercase ISO 3166-1 alpha-2 code that specifies a country.

This table lists some common values for the locale.

| Locale  | Language | Country        |
|---------|----------|----------------|
| 'de_DE' | German   | Germany        |
| 'en_GB' | English  | United Kingdom |

| <b>Locale</b> | <b>Language</b>      | <b>Country</b> |
|---------------|----------------------|----------------|
| 'en_US'       | English              | United States  |
| 'es_ES'       | Spanish              | Spain          |
| 'fr_FR'       | French               | France         |
| 'it_IT'       | Italian              | Italy          |
| 'ja_JP'       | Japanese             | Japan          |
| 'ko_KR'       | Korean               | Korea          |
| 'nl_NL'       | Dutch                | Netherlands    |
| 'zh_CN'       | Chinese (simplified) | China          |

You can use the 'Locale' name-value pair only when you use the `DateStrings` input argument.

Example: 'Locale', 'de\_DE'

Data Types: char

#### **'PivotYear' — Start year of 100-year date range**

`year(datetime('now')) - 50 (default) | integer`

Start year of the 100-year date range in which a two-character year resides, specified as the comma-separated pair consisting of 'PivotYear' and an integer. Use a pivot year to interpret date strings that specify the year as two characters. That is, the pivot year has an effect only when the `infmt` argument includes `y` or `yy`.

You can use the 'PivotYear' name-value pair only when you use the `DateStrings` input argument.

Example: 'PivotYear', 1900

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

#### **'TimeZone' — Time zone region**

`'' (default) | string`

Time zone region, specified as the comma-separated pair consisting of 'TimeZone' and a string. The value of `TimeZone` specifies the time zone that the `datetime` function uses to interpret the input data. `TimeZone` also specifies the time zone of the output array,

T. If the input data are strings that include a time zone, then the `datetime` function converts all values to the specified time zone.

The value of `TimeZone` can be:

- `''`, to create an “unzoned” `datetime` array that does not belong to a specific time zone.
- The name of a time zone region from the IANA Time Zone Database, for example, `'America/Los_Angeles'`. The name of a time zone region accounts for the current and historical rules for standard and daylight offsets from UTC that are observed in a geographic region.
- An ISO 8601 string of the form `+HH:mm` or `-HH:mm`, for example, `'+01:00'`, to specify a time zone that is a fixed offset from UTC.
- `'UTC'`, to create a `datetime` array in Universal Coordinated Time.
- `'UTCLeapSeconds'`, to create a `datetime` array in Universal Coordinated Time that accounts for leap seconds.
- `'local'`, to create a `datetime` array in the system time zone.

This table lists some common names of time zone regions from the IANA Time Zone Database.

| Value of <code>TimeZone</code>     | UTC Offset | UTC DST Offset |
|------------------------------------|------------|----------------|
| <code>'Africa/Johannesburg'</code> | +02:00     | +02:00         |
| <code>'America/Chicago'</code>     | -06:00     | -05:00         |
| <code>'America/Denver'</code>      | -07:00     | -06:00         |
| <code>'America/Los_Angeles'</code> | -08:00     | -07:00         |
| <code>'America/New_York'</code>    | -05:00     | -04:00         |
| <code>'America/Sao_Paulo'</code>   | -03:00     | -02:00         |
| <code>'Asia/Hong_Kong'</code>      | +08:00     | +08:00         |
| <code>'Asia/Kolkata'</code>        | +05:30     | +05:30         |
| <code>'Asia/Tokyo'</code>          | +09:00     | +09:00         |
| <code>'Australia/Sydney'</code>    | +10:00     | +11:00         |
| <code>'Europe/London'</code>       | +00:00     | +01:00         |
| <code>'Europe/Zurich'</code>       | +01:00     | +02:00         |

Data Types: char

## Output Arguments

### **t** — Dates and time

`datetime` array
